Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune connective tissue disease that can affect multiple organs including the heart. Primary heart involvement in SSc refers to the presence of cardiac fibrosis, inflammation, and dysfunction in the absence of pulmonary hypertension (PH). Although PH is usually considered one of the major risk factors for death in SSc patients, diastolic dysfunction (DD) has been proposed as an independent predictor of mortality, which may

Table 1: Difference in variables between patients with left ventricle diastolic dysfunction and not. Bold indicates p-value<0.05. LVDD: left ventricle diastolic dysfunction; TAPSE: tricuspid annular plane systolic excursion, LVEF: left ventricle ejection fraction; RV: right ventricle; LA: left atrium; RA: right atrium; CVRF: cardiovascular risk factors; AGEs: advanced glycation end products; ATA: anti-topoisomerase antibodies; ACA: anticentromere antibodies; NT-proBNP: aminoterminal pro B-type natriuretic peptide.

Number of CVRF	1.00 [0.00;2.00]	2.00 [1.00;2.00]	**0.020**
AGEs	2.59 (0.50)	3.02 (0.53)	**0.001**
ATA	8 (17.0%)	1 (3.70%)	0.144
ACA	29 (61.7%)	21 (77.8%)	0.244
NT-ProBNP	78.4 [42.9;156]	138 [73.3;310]	**0.012**

be more robust than PH. Early identification and management of heart complications in SSc patients are crucial to prevent further deterioration and improve treatment outcomes. However, myocardial damage caused by SSc is often poorly understood, and the long-term effects and prognosis remain unknown.

Our purpose is to study the prevalence and factors associated with left ventricular DD (LVDD) in a cohort of patients with SSc.

Methods: Cross-sectional study of 75 patients with SSc evaluated between Feb/2022 and Feb/2023. We classified patients as having LVDD as recommended by the 2016 American Society of Echocardiography/European Association of Cardiovascular Imaging (ASE/EACVI) guidelines. We compared the presence of factors associated with LVDD by performing first a bivariate analysis and lately a logistic regression adjusting by confounders (age, arterial hypertension (AH) and body mass index (BMI)).

Results: Of the 75 patients, 27 (36%) had LVDD and 48 (64%) had normal diastolic function. Table 1 shows compared characteristics of both groups. Older age, AH, BMI, the total number of cardiovascular risk factors (CVRF), advanced glycation end products (AGEs), NT-proBNP levels, impairment of the right ventricular (RV) free wall strain, and lower left atrial (LA) strain reservoir function were significantly associated with having LVDD (Table 1), while classical parameters of ventricular function, such as left ventricular ejection fraction or tricuspid annular plane systolic excursion were not. After adjusting for confounding factors in the logistic regression, the presence of anticentromere antibodies (ACA) conferred a risk 32 times higher (OR 32.15 95%CI [1.3;775.86], p=0.03) for presenting LVDD than having anti-topoisomerase antibodies. An increase in 1 unit of AGEs also augmented the risk of LVDD almost 5 times (OR 4.9 95%CI [1.3;18.43], p=0.018).

Conclusion: LVDD is highly prevalent in SSc, particularly in elderly patients with a higher BMI, AH and more CVRF. LVDD is associated with higher levels of NT-proBNP and findings in less classical echocardiographic parameters like the RV free wall strain impairment and lower LA strain function. ACA and higher level of AGEs were associated with a significant increased risk of LVDD after adjusting for confounders. These findings highlight the importance of regular cardiovascular monitoring in SSc patients and the potential value of using new echocardiographic parameters to identify those at risk for LVDD.

Race, n (%)	
Chinese	257 (74.5)
Malay	41 (11.9)
Indian	20 (5.8)
Mean disease duration*, years	6.3 (12.4)
SSc subtype, n (%)	
Diffuse	108 (31.3)
Limited	138 (40.0)
SSc-overlap	78 (22.6)
Anti-centromere positive	66 (19.1)
Anti-Scl70 positive	130 (37.7)
Mean (SD) body mass index	22.5 (4.4)
Fulfil GLIM phenotype criterion, n (%)	78 (22.6)
Fulfil GLIM etiologic criterion, n(%)	179 (51.9)
Fulfil GLIM malnourished criteria, n(%)	50 (14.5)

GLIM = Global Leadership Initiative on Malnutrition;
*disease duration from onset of first non-Raynaud's symptom or SSc diagnosis

Background/Purpose: Gastrointestinal (GI) involvement is common in patients with systemic sclerosis (SSc), and may lead to malnutrition that adversely affects quality of life, morbidity and mortality. The Global Leadership Initiative on Malnutrition (GLIM) criteria is a new criterion reported to have better sensitivity in detecting malnutrition than the Malnutrition Universal Screening Tool.

Aim: To determine 1) the incidence and prevalence of malnutrition using GLIM criteria 2) the impact of malnutrition on mortality.

Methods: From 1st of January 2008 to 31st of December 2020, patients fulfilling the SSc ACR/EULAR 2013 criteria were recruited from 3 tertiary rheumatology centres into the Systemic Sclerosis Cohort Singapore (SCORE) cohort. Baseline demographics, disease characteristics, medications and mortality were recorded. Patients with < 6 months followup were excluded from analysis. To fulfil malnutrition with GLIM criteria, at least 1 phenotypic and 1 etiologic criteria are required. For phenotypic criterion, we used BMI < 18.5 (< 70 years old) or BMI < 20 (>70 years old); for etiologic criterion, we used presence of any one of severe vasculopathy, modified Rodnan skin score > 15, pulmonary hypertension, forced vital capacity < 70%, cardiac involvement, renal crisis, total gastrointestinal tract score > 1.00. Univariate analysis using chi-square test was performed, with p-values < 0.05 considered statistically significant.

Results: Of 345 SSc patients, mean age at baseline visit was 51.8 years, with mean disease duration of 6.3 years. More patients were positive for anti-Scl70 (37.7%) than anti-centromere antibody (19.1%). Mean body mass index was 22.5 (Table 1). Prevalence of malnutrition at baseline visit was 14.5%. Cumulative incidence of malnutrition was 2% at 2 years and 6.4% across the follow-up period (median 47 months). Presence of malnutrition at baseline visit was not associated with mortality, although ever presence of malnutrition during the follow up period was associated with an increased risk of mortality [OR 4.47 (95%CI 3.67-5.26), p-value 0.0008].

Conclusion: This study highlights the burden of malnutrition in SSc patients. Among patients with malnutrition, majority fulfilled GLIM criteria for malnutrition at first visit. The persistence or development of malnutrition throughout the follow-up period was significantly associated with mortality.

Early Systemic Sclerosis Definitions: Time to Rethink 'Early' in SSc Disease?

Francesco Del Galdo[1], Matthew Woods[2], Mario Ehlers[3] and Stefano Di Donato[1], [1]University of Leeds - Leeds Institute of Rheumatic and Muskuloskeletal Medicine, Leeds, United Kingdom, [2]Lumanity, Manchester, United Kingdom, [3]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune fibrotic disease with highly variable type and severity of organ involvement. Pathological changes in the skin, lungs, gastrointestinal tract, kidneys and heart determine clinical outcomes, with cardiopulmonary complications being the main cause of mortality, and musculokeletal changes and loss of hand function driving morbidity and disability. Early identification of the disease has been targeted in clinical trials in order to identify windows of opportunities for intervention, before organ damage becomes irreversible. Here we review how early SSc is defined in the literature and propose a paradigm shift in definition.

Table 1: Clinical diagnosis criteria for early SSc

Table 1: Clinical diagnosis criteria for early SSc

Reference	Country of origin	Summary of classification criteria
VEDOSS criteria	Europe	(1) Raynaud's phenomenon (2) puffy fingers (3) antinuclear antibodies and (4) capillaroscopy or (5) SSc-specific antibodies
ACR EULAR 2013	International (US and Europe)	Nine items including skin thickening of the fingers of both hands extending proximal to the metacarpophalangeal joints, skin thickening of the fingers, fingertip lesions, and abnormal nailfold capillaries
LeRoy and Medsger, 2001	US	• Limited SSc (lSSc) (1) Raynaud's phenomenon and (2) abnormal wide-field nailfold capillaroscopy or (3) SSc selective autoantibodies • Limited cutaneous (lcSSc): criteria for lSSc and cutaneous changes distal to the elbow, knees and clavicles • Diffuse cutaneous (dcSSc): criteria for lSSc and cutaneous involvement of the arms, chest, abdomen, back, or thighs
ARA criteria, 1980	US	• One major criterion: proximal scleroderma defined as tightening, thickening and non-pitting induration proximal to the metacarpophalangeal or metatarsophalangeal joints; • or ≥2 minor criteria: (1) sclerodactyly (2) digital pitting scars of the fingertips or loss of the substance of the distal pad (3) bilateral basilar pulmonary fibrosis
Koening et al., 2008	Canada	Raynaud's phenomenon plus either SSc marker autoantibodies and/or megacapillaries or avascular areas and no manifestation other than puffy fingers and/or arthritis

Table 2: Definitions of early SSc in the literature

Table 2: Definitions of early SSc in the literature

Definition	Early SSc classification criteria	Additional criteria	Number of publications
Very early SSc	VEDOSS	–	22
	Independent classification	–	1
Early SSc	ACR/EULAR 2013	–	20
		Additional clinical criteria	2
		Disease duration criteria (range 2 – 5 years)	11
	LeRoy and Medsger	–	8
		And ACR/EULAR 2013	1
		Disease duration criteria (range 0 – 3 years)	3
	ARA 1980	–	1
		And LeRoy and Medsger	1
		Additional clinical criteria	2
		Disease duration criteria (range 2 – 5 years)	13
	Koening, 2008	–	1
		And LeRoy and Medsger	5
	Independent classification	–	14

Methods: Structured, targeted searches were conducted by two reviewers in PubMed, Google Scholar, Google, and ClinicalTrials.gov in November 2021 and updated in March 2023. Search terms included 'early systemic sclerosis', 'early systemic sclerosis criteria', 'patients with early systemic sclerosis', 'opportunities in early systemic sclerosis', 'early scleroderma criteria' and 'early systemic sclerosis definition' to identify publications, treatment guidelines and clinical trial records.

Results: Published evidence defining early SSc included 103 publications, three clinical guidelines and 16 clinical trial records. Early SSc is commonly defined by one of four classification criteria (ARA, 1980; LeRoy and Medsger; Koening, 2008; or ACR/EULAR, 2013) (Table 1), often alongside a time from first non-Raynaud's symptom (Table 2). However, there was no universal consensus on what this duration should be (generally ranging from 2 to 5 years). The key finding was the significant heterogeneity in definitions used across the literature (Table 2); however, there was consensus that Raynaud's phenomenon is usually the first sign. Some publications even used their own variations of the classification criteria. The aim of each of the main definitions was to improve the early identification of patients, with studies adding additional criteria to provide further clarity and/or to aid treatment decisions to avoid early disease damage and burden.

Conclusion: There is no clear consensus on the optimal clinical classification criteria or disease onset duration that should be used to define early SSc. This is likely due to the differing rationale behind existing research. A common drive for a definition of 'early', aligned with 'potentially reversible', may be true at different times across different organs. Since the goal to treat early SSc patients is to prevent irreversible organ damage, we would suggest that early is not considered as a factor of time, but of severity of organ involvement, and would recommend a consensus statement exercise to align on an appropriate definition.

Understanding the Employment Landscape in People with Systemic Sclerosis

Hila Jazayeri[1], Zareen Ahmad[1], Monique Gignac[2] and Sindhu Johnson[3], [1]University of Toronto, Toronto, ON, Canada, [2]Institute for Work & Health, Toronto, ON, Canada, [3]Division of Rheumatology, Department of Medicine, Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western and Mount Sinai Hospitals; Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a systemic rheumatic disease that restricts participation in various life roles, including in the workplace. Our objectives were to identify the job sectors where people with SSc work, and comparatively evaluate health factors, work factors and workplace accommodations between those who are employed and not employed.

Methods: A cross-sectional survey was conducted of employed and unemployed individuals with SSc. Demographics, sector of employment, health factors, non-disease related variables, frequency of disease flares, and the need, availability and use of various workplace supports were collected.

Results: We report 140 participants (108 (77.1%) women, 32 (22.9%) men) where 110 (78.6%) were employed and 30 (21.4%) not employed. Sectors in which the participants worked were Education/Health/Sciences/Arts (n=51 (36.4%), Sales/Retail (n=23, 16.5%), Banking/Insurance/Business/Technology (n=22, 15.7%), Government (n=15, 10.7%), Construction/Utilities (n=10, 7.1%), and Manufacturing/Agriculture/Mining/ Logging (n=10, 7.1%), with no difference in employment across job sectors (p=0.69). The employed have a significantly lower mean age (48.4 versus 54.3 years), higher level of education (77.3% post-secondary education versus 22.7% without post-secondary education), and higher income (44.8% income >$100,000, 32.3% income $60,000-$100,000, 22.9% income of $10,000-$59,999). Those who had no flares had the highest employment rate (41.7%), compared to those who had 1-2 flares (35.2%) and ≥3 flares (23.1%). The *availability* of workplace accommodations differed significantly between the employed and unemployed: flexible hours (75.2% versus 41.4%, p=0.005), more rest periods (81.8% versus 46.7%, p=0.0001), special equipment (87.5% versus 50%, p< 0.0001), and alternative work-schedule flexibility (70.2% versus 38.8%, p=0.003).

Conclusion: Health factors alone do not differentiate those who are employed and not employed. This study lays the groundwork for where SSc-specific efforts in workplace policies and practices should be directed.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study is to describe the nailfold video-capillaroscopy (NVC) findings in patients with interstitial lung disease associated to connective tissue diseases (CTD-ILD), interstitial pneumonia with autoimmune features (IPAF) or undifferentiated autoimmune interstitial pneumonia (uAIP), and to assess the association of ILD features with abnormal NVC findings.

Methods: This is a cross-sectional study from a multicenter prospective registry (NEREA) of patients with a clinical diagnosis of ILD in the context of an autoimmune disease including CTD-ILD, IPAF or uAIP, from 10 hospitals in Madrid. All patients with available data on NVC were included. NVC studies were performed according to standardized definitions from the EULAR study group on capillaroscopy. Main outcome: abnormal NVC pattern (including systemic sclerosis [SSc] pattern and non-SSc pattern).Independent variables: radiographic patterns grouped as UIP (usual interstitial pneumonia), NSIP (non-specific interstitial pneumonia) and others. Covariates: demographics, clinical diagnosis. Statistics: For bivariate associations, Student's t-test, Mann-Whitney test or Kruskal-Wallis test were used for the analysis of continuous variables while categorical variables were analyzed with Chi-square or the Fisher test. A logistic regression multivariate model was also run (Odds ratio (OR) and 95% Confidence Interval [CI]).

Results: Seventy six patients with a mean age of 61.4 ± 13.3 years (66% women) were included (Table 1). Main clinical groups were IPAF (33 patients, 43.4%) and SSc (16 patients, 21.1%). NVC was classified as normal/minimal changes in 36 (47.4%), SSc-pattern in 19 (15%) and non-SSc pattern in 21 (27.6%) patients, respectively. Abnormal NVC was associated with younger age (p=0.016), Raynaud's phenomenon (p=0.003), and a non-UIP pattern on CT (p=0.001). There were statistically significant differences among clinical subgroups (p< 0.001), with a higher number of abnormal NVC in SSc and IIM groups. With regards to antibody status, an abnormal NVC pattern was associated with positive ANA (p=0.002) and SSc-specific antibodies (p=0.002). Although abnormal NVC was associated with Raynaud's phenomenon, in our cohort we also found abnormal NVC in 14 out of 40 patients (35%) without this manifestation. NVC features are detailed in table 2.

In the multivariate analysis, non-UIP patterns (NSIP and others), CTD and Raynaud's phenomenon were independently associated with abnormal NVC (table 3).

Conclusion: NVC may be a useful tool in the assessment of patients with autoimmune ILD. Besides the acknowledged association of NVC lesions with SSc and IIM, our findings support that performance of NVC may help identify an underlying autoimmune disease in patients with ILD and a non-UIP radiographic pattern.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem fibrosing autoimmune disease with a high mortality rate. Ethnicity can influence prevalence and disease characteristics in SSc. Less is known about SSc-associated interstitial lung disease (SSc-ILD), an important subgroup with even higher mortality rate. We investigate whether there are ethnic variations in people with SSc-ILD.

Methods: We conducted a retrospective cohort study of the Toronto Scleroderma Program – a network of academic and community clinics (1970-2023). Ethnicity was self-reported and categorized as Caucasian, Black, East-Asian, South Asian, or First Nations. We evaluated differences in demographics, disease manifestations, comorbidities, and survival in people with SSc-ILD. Kaplan-Meier survival curves were used to determine median survival and survival at 1-5, 10, 15, and 20 years. A Cox proportional hazards model estimated survival, adjusting for age, age of diagnosis, disease duration, and comorbidities.

Results: 405 people with SSc-ILD were included with n=234 (58%) Caucasian, n=57 (14%) South-Asian, n=49 (12%) East-Asian, n=28 (7%) Black, n=16 (4%) First Nation and n=22 (5%) Other. The median age at SSc diagnosis was significantly younger for First Nations ethnicity compared to Caucasian (38.4 years versus 52.0 years, $p< 0.01$). More Caucasians, South-Asians, and East-Asians had limited disease (53.2%, 51.8%, 53.1%), while more Black and First Nation had diffuse disease (57.1%, 62.5% respectively). Esophageal dysmotility was more common in Black and First Nations (96.4%, 93.8% respectively) than Caucasians, South Asians, and East Asians (88.5%, 80.7%, 71.4% respectively, p=0.01). Coronary artery disease occurred more frequently in First Nations (18.8%) than Caucasians, South Asians and East Asians (11.5%, 3.5%, 6.1%, p=0.04). East Asians had significantly better 10-year survival 93.2% (95%CI 85%, 100%) than Caucasians 78.3% (95%CI 72.1%, 85.1%). People of First Nations ethnicity appeared to have worse 10-year survival of 65.9% (95%CI 42.9%, 100%) but this was not statistically significant. In the adjusted survival analysis, age at diagnosis ($p< 0.001$) was an independent risk factor mortality, whereas ethnicity was not associated with mortality.

Conclusion: Ethnic variations in demographics, disease manifestations and comorbidities exist in SSc-ILD yet this does not result in significant differences in survival across ethnicities.

Abstract Number: 0653

Association Between Systemic Sclerosis and Increased Risk of Ischemic Stroke: A Meta-Analysis

Christina Flourou[1], Andreas Liampas[1] and Konstantinos Parperis[2], [1]Nicosia General Hospital, Nicosia, Cyprus, [2]University of Cyprus Medical School, Nicosia, Cyprus

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune rheumatic disease characterized by significant vascular abnormalities due to microvascular damage and intimal proliferation in the small arterioles. Additionally, SSc has been associated with macrovascular complications, including cardiovascular disease (CVDs) and peripheral vascular disease. Cerebrovascular accident, also known as stroke, is a macrovascular condition that can occur among patients with SSc. In this study, we conducted a meta-analysis to corroborate previous studies on the risk of ischemic stroke in SSc patients.

Methods: Two investigators searched published articles on Medline database using two subject heading (MeSH) terms. Term A was "SSc OR Systemic Sclerosis OR Scleroderma OR CREST syndrome". Term B was "Stroke OR cerebrovascular accident OR cerebrovascular event". Inclusion criteria were studies describing the association between SSc and ischemic and/or hemorrhagic stroke. Statistical calculation of pooled proportions was conducted in R language. The outcome of interest was the proportion of patients with SSc that developed stroke. The heterogeneity between studies was assessed by the I2 test.

Results: Four studies (4 cohort studies) were met our criteria with 7871 patients with SSc. Our analysis demonstrated a statistically significant higher risk of ischemic stroke in patients with SSc compared with controls yielding a pooled risk estimate of 1.36 (95% CI, 1.16 to 1.61). The level of statistical heterogeneity was moderately low with an I2 of 39.9%. As shown in the respective forest plot, no significant asymmetry was observed between the included studies (Figure).

Conclusion: To our knowledge, this meta-analysis includes the largest number of SSc patients and provides robust evidence supporting an increased risk of ischemic stroke in SSc patients. These results underscore the importance of recognizing SSc as a potential risk factor for cerebrovascular complications and highlight the need for prevention and close monitoring in this patient population.

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic sclerosis (SSc) may be burdened by increased cardiovascular (CV) risk due to accelerated atherosclerosis (ATS) due to systemic inflammation, and vascular impairment. This study aimed to evaluate CV risk in SSc patients SSc compared to healthy controls (HC) and to assess its association with disease-specific features.

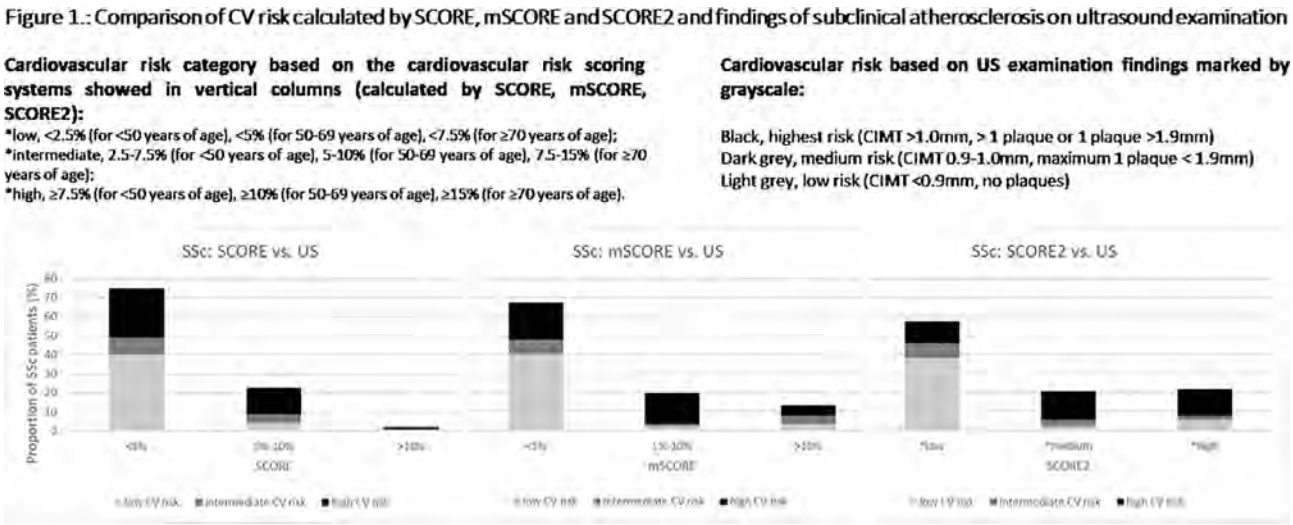

Figure 1.: Comparison of CV risk calculated by SCORE, mSCORE and SCORE2 and findings of subclinical atherosclerosis on ultrasound examination

Methods: 92 patients with SSc (81 females; mean age 52; mean disease duration 6.8 years; diffuse cutaneous (dc)SSc: n=28, limited cutaneous (lc)SSc: n=64) and 197 HC (147 females, mean age 56.7) were included, all with no history of CV disease (angina pectoris, myocardial infarction, cerebrovascular, and peripheral arterial vascular events). Comorbidities and current treatment were recorded. Disease activity and organ involvement were evaluated in SSc, including lung function tests and skin involvement (by mRSS). All participants underwent examinations of carotid intima-media thickness (CIMT), pulse wave velocity (PWV), ankle-brachial index (ABI), and body composition (by densitometry (DXA) and bioelectrical impedance analysis (BIA)). The risk of fatal CV events was evaluated by the Systematic COronary Risk Evaluation (SCORE, charts for the European population) and its modifications: SCORE multiplied by the coefficient 1.5 (mSCORE), and SCORE2.

Results: SSc patients had a trend to higher prevalence of dyslipidemia (p=0.063) and significantly more often prediabetes (p< 0.001) than HC, but a comparable prevalence of arterial hypertension, diabetes mellitus, and current smoking to HC. Nevertheless, SSc had significantly more frequent use of antihypertensive treatment compared to HC (p< 0.001), including calcium channel blockers (indicated for Raynaud's phenomenon).

The prevalence of carotid artery disease was significantly increased in SSc compared to HC. SSc had significantly more unfavorable CIMT and ABI (p< 0.05 for both). There was only a trend to lower SCORE and overall CV risk based on SCORE in SSc compared to HC, but no significant difference in SCORE2. On the contrary, the overall CV risk based on US examination showed significantly higher CV risk in SSc. A comparison of CV risk with the findings of subclinical ATS on US examination showed that none of the CV risk scoring systems in SSc was exact in estimating the CV risk (Figure 1). Nevertheless, SCORE2 underestimated the real CV risk significantly less than SCORE (p=0.043), while SCORE2 vs. mSCORE and SCORE vs. mSCORE were comparable. In SSc, the CV risk and markers of subclinical ATS were associated especially with age, HbA1c, disease duration, and mean arterial pressure (p< 0.05 for all).

Conclusion: This cross-sectional case-control study in SSc patients demonstrated a significantly increased risk of subclinical ATS in SSc compared to HC, although there was an opposite trend in CV risk estimated by calculated SCORE. The CV risk in SSc was associated especially with age, disease duration, and HbA1c levels, among others. Scoring systems underestimated the CV risk (when compared to ultrasound findings), while SCORE2 was significantly more accurate than SCORE.

Supported by MHCR (023728; NV18-01-00161A; NU21-01-00146).

A Novel Association Between Lipodermatosclerosis and Key Vascular Outcomes in Systemic Sclerosis

Srijana Davuluri[1], Puneet Kapoor[2], Swarna Nandyala[2], David Fiorentino[3], Julia Simard[4] and Lorinda Chung[5], [1]Stanford University- School of Medicine, Sunnyvale, CA, [2]Stanford University- School of Medicine, Palo Alto, CA, [3]Department of Dermatology, Stanford University, Redwood City, CA, [4]Department of Epidemiology & Population Health, Stanford University School of Medicine, Stanford, CA, [5]Department of Medicine, Division of Immunology and Rheumatology, Stanford University School of Medicine, Woodside, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lipodermatosclerosis (LDS) is a progressive manifestation of chronic venous insufficiency characterized by distinctive lower extremity changes, including an "inverted champagne bottle" appearance, skin hyperpigmentation, and occasionally, non-healing ulcers. (see Figure 1) While LDS is not extensively studied in the context of connective tissue diseases, it shares similar pathogenic pathways with systemic sclerosis (SSc), where vasculopathy leads to tissue hypoxia, inflammation, and subsequent fibrosis of the skin and subcutaneous tissues. This study estimated the prevalence of LDS in SSc, examined the demographic and SSc-related characteristics of patients with LDS, and estimated the association between LDS and major vascular outcomes in patients with SSc.

Methods: We performed a retrospective cohort analysis of adult patients who had prospectively enrolled in our Autoimmune Skin Disease Registry between 2004-2023 and met ACR/EULAR 2013 classification criteria for SSc. Descriptive statistics were used to summarize data, and chi-square/Fisher's exact test and t-test/Mann-Whitney U test were employed to compare categorical and continuous variables, respectively. Logistic regression estimated prevalence odds ratios (pOR) and 95% confidence intervals of the association between LDS and a composite macrovascular outcome measure, including digital gangrene and/or renal crisis and/or pulmonary hypertension, adjusted for age and follow-up time. A. sensitivity analysis was conducted for the outcome of pulmonary hypertension (PH).

Results: Among 586 SSc patients, 4% (N=25) had LDS. Baseline demographic and disease features were similar between patients with and without LDS (Tables 1 and 2) with the exception that patients with LDS had higher frequencies of cardiac arrhythmias, heart failure, and PH. Among patients with LDS, 36% were either discharged to hospice or died during a median follow-up time of 7.5 (IQR- 3.9, 11.4) years, compared to 20.5% of patients without LDS followed for 5.6 (IQR- 1.5, 9.8) years. LDS was associated with the composite vascular outcome in adjusted analysis with pOR=2.36 [1.02-5.45], but this was primarily driven by the association with PH. Sensitivity analysis confirmed an elevated pOR between LDS and pulmonary hypertension, with an adjusted pOR of 3.20 [1.37-7.49].

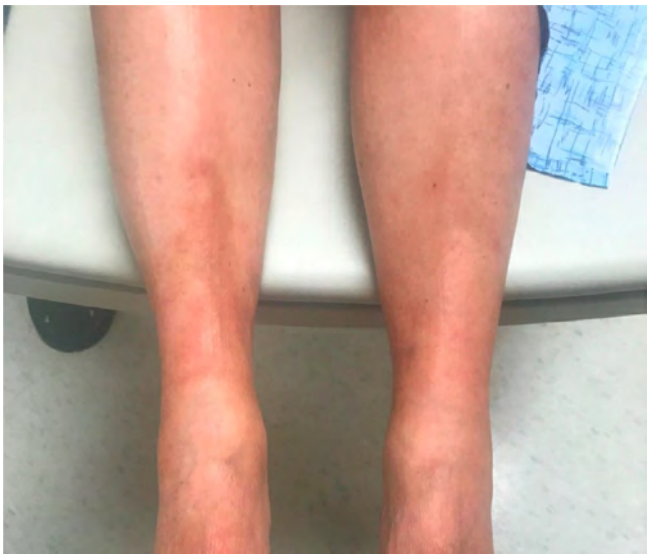

Figure 1 A 66-year-old female with SSc having lipodermatosclerosis of bilateral lower extremities

Conclusion: LDS was diagnosed in 4% of SSc patients evaluated at a multi-disciplinary Rheumatologic Dermatology Clinic. Patients with LDS have more than two-fold higher prevalence of a composite macrovascular outcome and more than three-fold higher prevalence of pulmonary hypertension. We conclude that LDS could portend severe vasculopathic manifestations in SSc, however, temporality could not be determined by our analyses. Clinicians should recognize the clinical features of LDS in SSc patients and closely monitor these patients for PH and other macrovascular complications.

SESSION INFORMATION

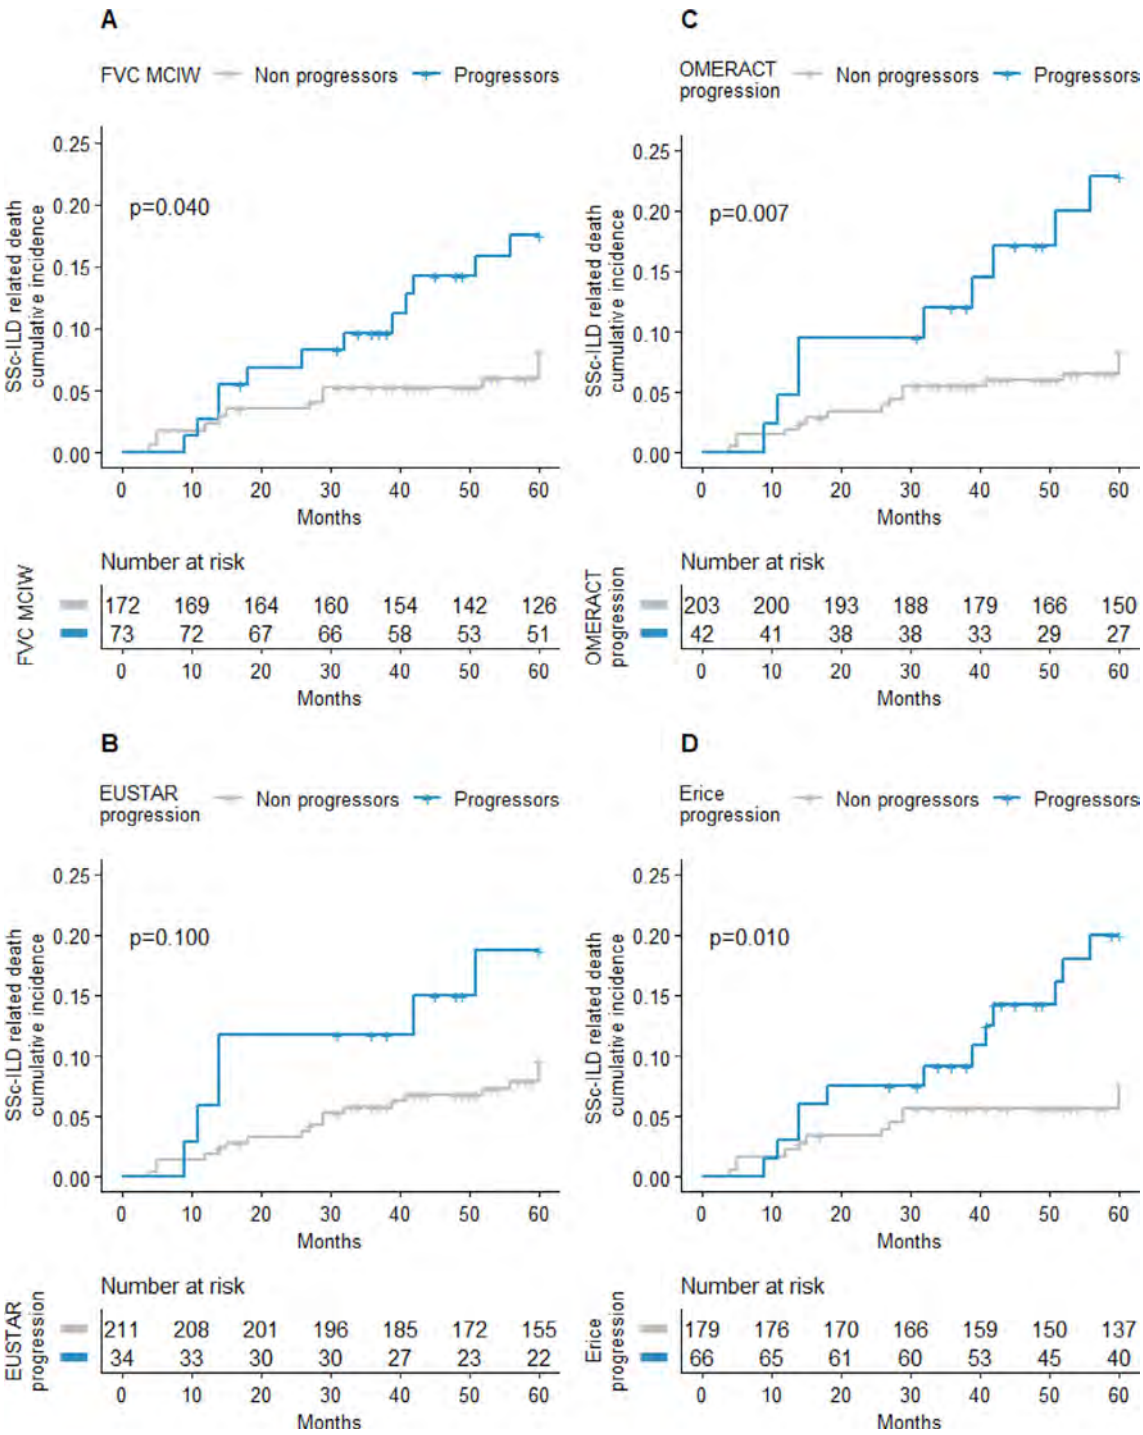
Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial Lung Disease (ILD) in systemic sclerosis (SSc) is a common complication that has varied progression rate and prognosis. Different progression definitions include minimal clinically important worsening of forced vital capacity (FVC MCIW), EUropean Scleroderma Trials and Research group (EUSTAR) progression, Outcome Measures



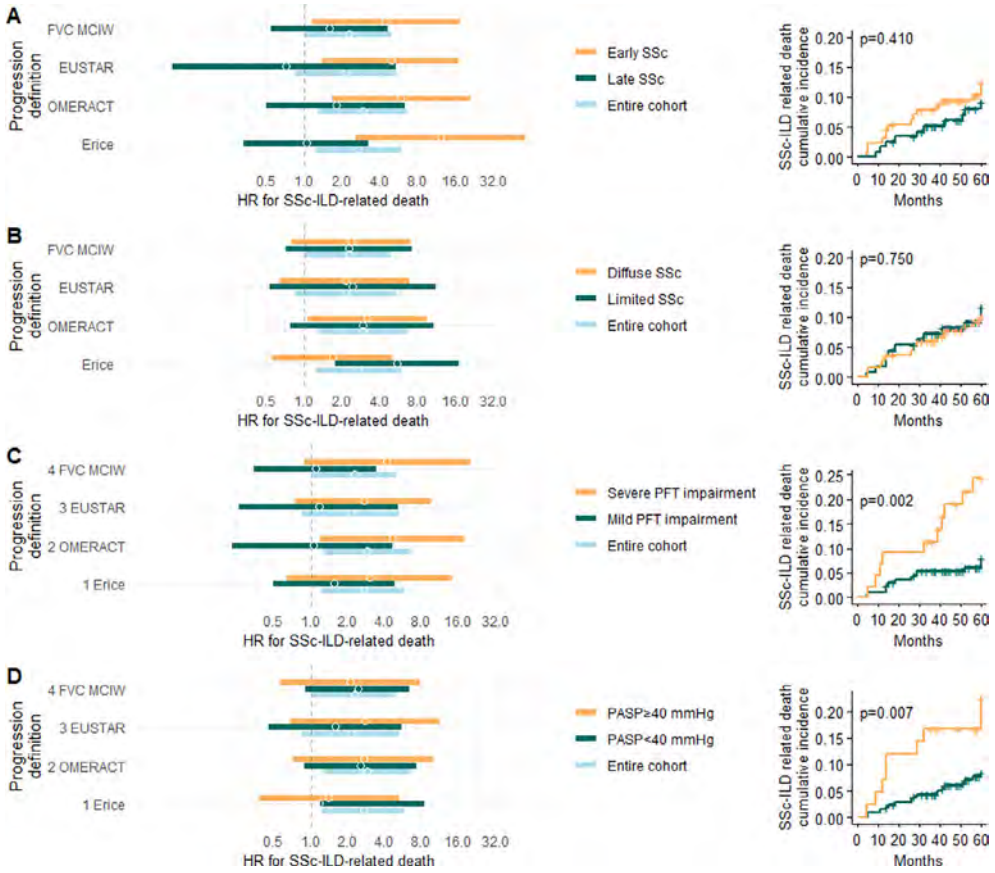
Comparisons of SSc-ILD survival of progressors and non-progressors according to different definitions. Four main definitions are compared: A) FVC MCIW, B) OMERACT definition, C) EUSTAR definition D) Erice definition. Abbreviations: EUSTAR EUropean Scleroderma Trials and Research group; FVC MCIW minimal clinical important worsening of forced vital capacity, OMERACT Outcome Measures in Rheumatology Clinical Trials, SSc-ILD scleroderma-related interstitial lung disease.

in Rheumatology Clinical Trials (OMERACT) progression, and INBUILD/ Erice ILD working group progression. The aim of the study was to assess the concordance and prognostic value of these different definitions in SSc-ILD patients overall and specific clinical subsets.

Methods: Progression status in consecutive SSc-ILD patients was assessed over 24 months, comparing SSc-ILD-related mortality between progressors and non-progressors according to different definitions over the following 60 months. The prediction performances of different progression definitions were investigated with Cox Regression analysis and compared using Akaike information criterion (AIC) with a difference greater than 2 considered as evidence in favor of the model with the smaller AIC.

Results: The 245 SSc-ILD patients enrolled had a mean age of 54.6± 3.2 years and a median disease duration of 4 (IQR 2-8) years from the first non-Raynaud symptoms. Among these patients, 18.8% were males, and 54.7% had the diffuse LeRoy cutaneous variant, 59.2% had anti-Scl70 positivity, and 14.3% anti-centromere antibody positivity.

Twenty-six deaths were reported, and mortality was linked to progression per FVC MCIW (HR 2.27, 95% CI 1.03 - 4.97, p=0.041), OMERACT (HR 2.90, 95% CI 1.28 - 6.57, p=0.011), and INBUILD/Erice trial definitions (HR 11.02, 95% CI 2.38 - 51.08, p=0.002). Prognostic prediction using these four definitions was challenging in patients with longer disease duration, mild pulmonary function impairment, and pulmonary artery systolic pressure (PASP)≥40 mmHg. Erice criteria were



Risk of SSc-ILD-related death in progressor patients across key clinical subsets The patients were divided according to A) disease duration, B) LeRoy cutaneous variant, C) severity of baseline functional lung impairment and D) PASP values on echocardiography. The average risks of the whole population are also reported as comparators. The corresponding survival curves of the considered subgroup are displayed and compared on the right. Abbreviations: EUSTAR EUropean Scleroderma Trials and Research group; FVC MCIW minimal clinical important worsening of forced vital capacity, HR hazard ratio, OMERACT Outcome Measures in Rheumatology Clinical Trials, PASP pulmonary artery systolic pressure, PFT pulmonary function test, SSc-ILD scleroderma-related interstitial lung disease.

superior in patients with disease duration >3 years, limited cutaneous variant, and PASP< 40 mmHg (ΔAIC >2). OMERACT criteria performed better in diffuse cutaneous variant patients with severe baseline functional impairment (ΔAIC >2).

Conclusion: The proposed SSc-ILD progression definitions are not interchangeable, risking potential misdiagnosis in up to a third of progressors. Regardless of criteria, progressors frequently showed diffuse skin disease variant, shorter disease duration, and worse functional impairment.

Abstract Number: 0657

The Value of the Six-Minute Walk Test in Detecting Cardiopulmonary Involvement in Patients with Systemic Sclerosis

Saad Ahmed, Sophie Liem, Jeska de Vries-Bouwstra and Thomas Huizinga, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiopulmonary involvement (CPI) in systemic sclerosis (SSc) is associated with significant morbidity and mortality. Early detection and timely treatment is warranted. The Six-minute walk test (6-MWT) is a non-invasive exercise test that evaluates the distance a patient can walk in 6 minutes (6-MWD), pre- and post-test heart rate and oxygen saturation. There is ongoing debate about the sensitivity and specificity of the 6-MWT as a screening tool for CPI in SSc. Therefore, this study aimed to assess the course of the 6-MWT parameters over time, its main determinants and the diagnostic value to detect new onset CPI in a large cohort of SSc patients.

Table 1: Disease characteristics impacting the 6MWT at baseline.

	6-MWD				Desaturation at 6 minutes		
	Univariable β (95% CI)	Adjusted for BMI, sex and age β (95% CI)	Multivariable model β (95% CI)	VIF	Univariable OR [95% CI]	Adjusted for BMI, sex and age OR [95% CI]	Multivariable model OR [95% CI]
CPI	-47,5 [-68,5, -26,6]	-40 [-59, -21]	-25,8 [-46,1, -5,5]	1,08	6,5 [3,8, 10,9]	5,8 [3,4, 9,9]	6,7 [3,6, 12,4]
DcSSc	-36,3 [-61.8, -10.8]	-61 [-84,5, -37,8]	-39,7 [-64,7, -14,8]	1,15	1,6 [0,9, 2,7]	1,5 [0.8, 2,6]	1,3 [0,7, 2,4]
Myositis	-52,2 [-134,5, 30]	-67,7 [-142,2, 6,7]	-42 [-114,2, 30,2]	1,05	1,6 [0,3, 7,7]	1,1 [0,2, 5,7]	1 [0,2, 5,7]
Renal crisis	-78,1 [-145,4, -10,8]	-81,5 [-141,6, -21]	-62,9 [-123,9, -2]	1,04	0,5 [0,06, 3,7]	0,4 [0,05, 3,4]	0,5 [0,06, 4]
Arthritis	-56 [-86.7, -25.2]	-55,9 [-84,2, -27]	-47,8 [-76,1, -19,5]	1,01	0,7 [0,3, 1,6]	0,7 [0,3, 1,6]	0,6 [0,3, 1,5]
Hemoglobin	36,1 [24,6, 47,6]	30,8 [19,6, 42]	19,6 [7,6, 31,6]	1,19	1,2 [0,9, 1,6]	1,2 [0,9, 1,6]	1,4 [0,99, 2]

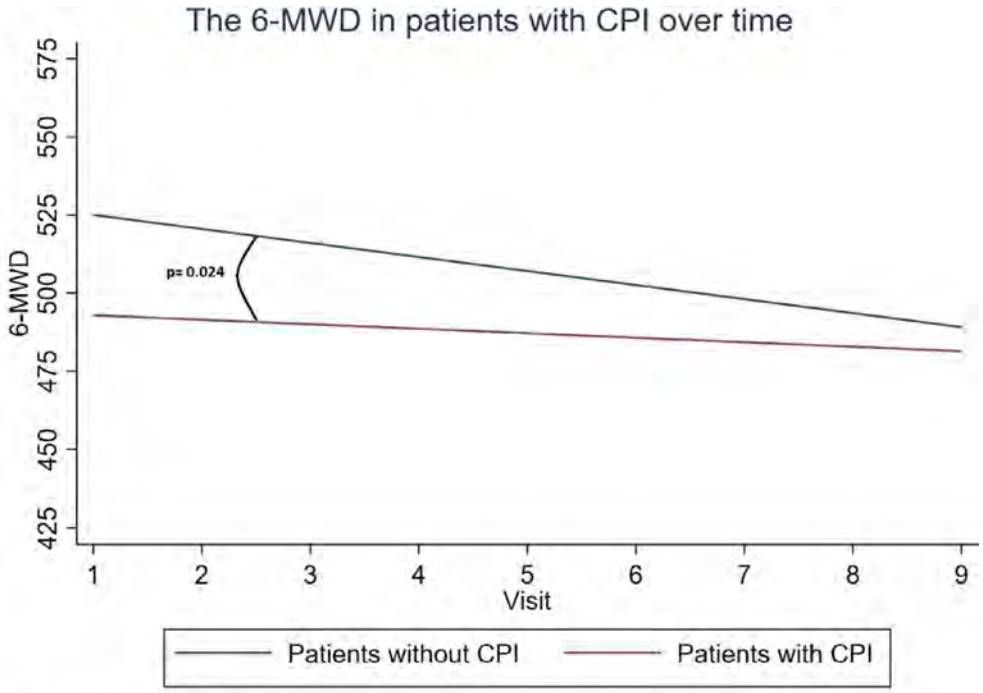
6-MWD: Six-minute walk distance; **CPI:** Cardiopulmonary involvement; **DcSSc:** Diffuse cutaneous systemic sclerosis.

Example: Presence of CPI results in an Odds ratio of 6.5, when correcting for Age, sex and BMI this becomes 5.8, when taking into account the other disease characteristics we find an odds ratio of 6.7. This is also statistically significant and informs us that patients with CPI have higher odds at having a desaturation after the test than patients without, corrected for BMI, sex, age, hemoglobin level and the presence of DcSSc, myositis, renal crisis, arthritis.

Methods: All SSc-patients from the Leiden Combined Care in SSc (CCISS)-cohort, who fulfilled ACR/EULAR 2013 criteria and performed ≥1 6-MWT, were included. CPI included presence of interstitial lung disease (ILD), pulmonary arterial hypertension (PAH) and/or myocardial involvement. Differences in 6-MWT parameters were assessed cross-sectionally at baseline between patients with and without CPI using multivariable linear regression. Course of 6-MWT parameters over time and its main associates were assessed using linear mixed models. Sensitivity and specificity of a decline in 6-MWD distance using a decline of ≥ 33 as cut-off to detect newly developed CPI was determined.

Results: 685 patients were included, with median follow-up duration of 5.4 years and in total 2769 6MWTs available (median 6 [IQR 4-8] 6MWTs per patient). 267 (39%) patients had CPI at baseline, 75 (11%) patients developed CPI during follow-up, 343 (50%) patients did not develop CPI at all. At baseline, 6 Minute walking distance (6-MWD) was significantly associated with sex, age, BMI, CPI, diffuse skin involvement, hemoglobin level, renal crisis and arthritis (see table 1). Patients with CPI also were more likely to develop a desaturation at 6 minutes (OR [95% CI]: 6,7 [3,6, 12,4]) at baseline (see table 1). Over time, CPI was independently associated with a lower 6-MWD (β [95% CI]: 27 [-42, -12]) and a higher occurrence of desaturation at 6 minutes (OR [95% CI]: 8.9 [1.1, 13]). Strikingly, over time, patients without CPI experienced a steeper decline in their 6-MWD in comparison to patients with CPI (See figure 1). A decline in 6-MWD did not accurately identify patients with new CPI (sensitivity 22%, specificity 80%).

Conclusion: This study shows that functional capability of SSc patients as evaluated by 6-MWT is importantly and strongly impacted by cardiopulmonary involvement at baseline and over time. Patients without CPI experienced a faster decline of the 6-WMD, which may be due to a survivor bias. Unfortunately change in 6-MWT parameters over time are not sensitive nor specific enough to identify SSc patients at risk for newly developed CPI. Based on these observations we conclude that



Dropout rates and death rates by presence of CPI

Visit		1	2	3	4	5	6	7	8	9
No CPI	Patients (N)	343	263	203	147	112	87	60	39	22
	Dropout (N)	31	20	13	4	1	2	1	0	0
	Death (N)	7	3	1	0	0	0	0	0	0
CPI	Patients (N)	342	274	225	178	137	115	86	59	41
	Dropout (N)	40	21	16	16	3	5	4	2	3
	Death (N)	22	11	11	10	3	2	3	1	2

we can apply 6-MWT to capture a general idea of functional capability of SSc patients but that for diagnostic screening of new CPI this test should be used in combination with other tests like PFT and laboratory testing.

Abstract Number: 0658

Evaluating the Associations Between Autonomic Dysfunction, Clinical Phenotype and Gastrointestinal Transit in Patients with Systemic Sclerosis

Maria Paula Alvarez Hernandez[1], Brittany Adler[2], Jamie Perin[3], Michael Hughes[4] and Zsuzsanna McMahan[5], [1]Hospital Clinico San Carlos, Madrid, Spain, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Northern Care Alliance NHS Foundation Trust, Salford Care Organisation, Salford, United Kingdom, [5]Johns Hopkins Rheumatology, Lutherville, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The gastrointestinal (GI) tract is the second most commonly impacted organ in systemic sclerosis (SSc). However, the pathogenesis and clinical expression of GI involvement in SSc are heterogeneous. Although it is well-established that a subset of patients with SSc have co-existing dysautonomia, the type(s) of GI dysmotility seen among these patients, and the clinical and serologic features that distinguish such patients from the rest of the SSc population are unknown. Therefore, we sought to determine whether patients with SSc have a high burden of autonomic symptoms, a distinct clinical and serologic phenotype, and specific GI transit abnormalities.

Methods: Patients were part of a prospectively enrolled cohort of SSc patients with GI disease who were evaluated at the Johns Hopkins Scleroderma Center, and demographic and clinical data for all study participants were obtained every 6 months at routine clinic visits. Autonomic symptoms were identified using the maximum obtained values of the validated Composite Autonomic Symptom Score (COMPASS)-31 questionnaire. GI transit was measured by Whole-gut transit (WGT) scintigraphy, which captures the percent emptying of the esophagus, stomach, small bowel, and colon at defined time points. The presence and severity of organ involvement were assessed using the maximum Medsger severity scores. We then sought to define the clinical and demographic features associated with significant dysautonomia in SSc. Clinical and demographic variables were compared between patients with global autonomic dysfunction [(GAD); ≥5 positive

Table 1. Total scores of each 6 subdomains of the COMPASS-31 questionnaire in our GAP cohort.

COMPASS-31 Subdomain	SSc GAP cohort, mean score (SD)
Orthostatic	3.6 (2.4)
Vasomotor	3.5 (1.6)
Secretomotor	3.2 (1.8)
Gastrointestinal	9.7 (4.1)
Urinary	1.1 (1.4)

PMSCI	1 (6)	3 (7)	1.000
Clinical features			
Modified Rodnan skin score, median (IQR)	4 (1, 6)	4 (2, 12)	0.120
Significant GI disease, n (%) (Medsger score ≥2)	24 (89)	48 (83)	0.538
Significant cardiac disease, n (%) (Medsger score ≥2)	0 (0)	12 (26)	**0.014**
Significant lung disease, n (%) (Medsger score ≥2)	7 (37)	27 (63)	*0.058*
Significant Raynaud's phenomenon (Medsger score ≥2)	11 (41)	23 (40)	1.000
Significant Muscle weakness (Medsger score ≥2)	11 (44)	15 (27)	0.139
Myopathy	6 (22)	11 (19)	0.755
Arthralgia	25 (93)	50 (91)	1.000
Sicca	27 (100)	48 (83)	**0.027**

COMPASS-31 subdomains] and those with limited autonomic dysfunction [(LAD); < 5 positive subdomains] as previously defined. Differences in GI transit in across different regions of the gut were also compared between the GAD and LAD groups.

Results: The study included 99 patients with SSc and GI involvement. The mean age was 58 years (IQR 49-67), 90% were female, 74% had limited cutaneous disease, and 49% had anticentromere proteins antibodies. 83% had significant GI disease (Medsger score ≥2), and 88% had Sicca syndrome. The mean COMPASS-31 score across the cohort was 36.7 ± 14.2 (SD), which was higher overall than COMPASS-31 scores in another SSc cohort and healthy control cohorts in the published literature. We found that 31% of patients had GAD, and 69% had LAD. Patients with GAD were significantly more likely to have Sicca symptoms (100% vs. 83%; p=0.027) and less likely to have severe heart disease (0% vs. 23%; p=0.014). Patients with more severe upper GI involvement (Medsger scores 1 or 2) had higher autonomic symptom scores. All patients with Raynaud´s phenomenon (RP) and patients with severe myopathy were more likely to have higher autonomic symptoms. Patients with GAD had a higher percentage of gastric emptying of solids at 4 hours than LAD patients (97% vs 94%, respectively, p =0.023).

Conclusion: Global dysautonomia is common among patients with SSc and GI dysmotility and associated with a distinct clinical features. Identifying these clinical characteristics may help support patient risk stratification and aid in choosing the right patient population who may benefit from the evolving array of autonomic nervous system modulating therapies.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis, cigarette smoking confers a risk for anti-CCP positive disease and the risk further increases in smokers carrying specific HLA DRB1-variants. These observations have fuelled the hypothesis that, in susceptible individuals, chronic exposure to specific antigens, (for example in the lungs) can trigger a targeted chronic autoimmune response. With this in mind, the lower frequency of anti-topoisomerase antibodies (ATA) observed among never-

smokers in systemic sclerosis (SSc) is intriguing. We evaluated in the EUSTAR database the effect of smoking on ATA expression, both for the total cohort and also for males and females separately. We evaluated how sex, smoking and ATA/anticentromere (ACA) expression interact and impact on disease progression.

Methods: All SSc patients with complete information about smoking status available were included and categorised as "never-smokers" or "ever-smokers". Chi-square test and logistic regression were used to evaluate differences in ATA and ACA expression between ever-smokers and never-smokers. A possible dose-response effect was evaluated using logistic regression with pack/years or smoking duration as predictors. We evaluated the association between disease progression,

Table 1. Baseline characteristics of USTAR cohort patients included in the analysis. Legend: DLCO: diffusing capacity of the lungs for carbon monoxide; FVC: forced vital capacity; IQR: interquartile range; SD: standard deviation. Disease duration was defined since the date of onset of Raynaud's phenomenon.

Demographic and clinical variables		Number of patients with data
Male sex, n (%)	1921 (16)	12314
Ever-smokers, n (%)	4271 (35)	12314
Pack/years, median (IQR)	15 (6 - 30)	2112
Smoking duration, mean ± SD	23.7 ± 13.2	1686
Age, mean ± SD, years	55.5 ± 13.8	12314
Disease duration, median (IQR)	7.6 (3.0 - 16.0)	8773
Extent of skin involvement		8649
no skin involvement, n (%)	584 (7)	
only sclerodactyly, n (%)	831 (10)	
limited cutaneous involvement, n (%)	4751(56)	
diffuse cutaneous involvement, n (%)	2483 (29)

ACA, n (%)	1400 (46%)	2875 (39%)	**<0.001**

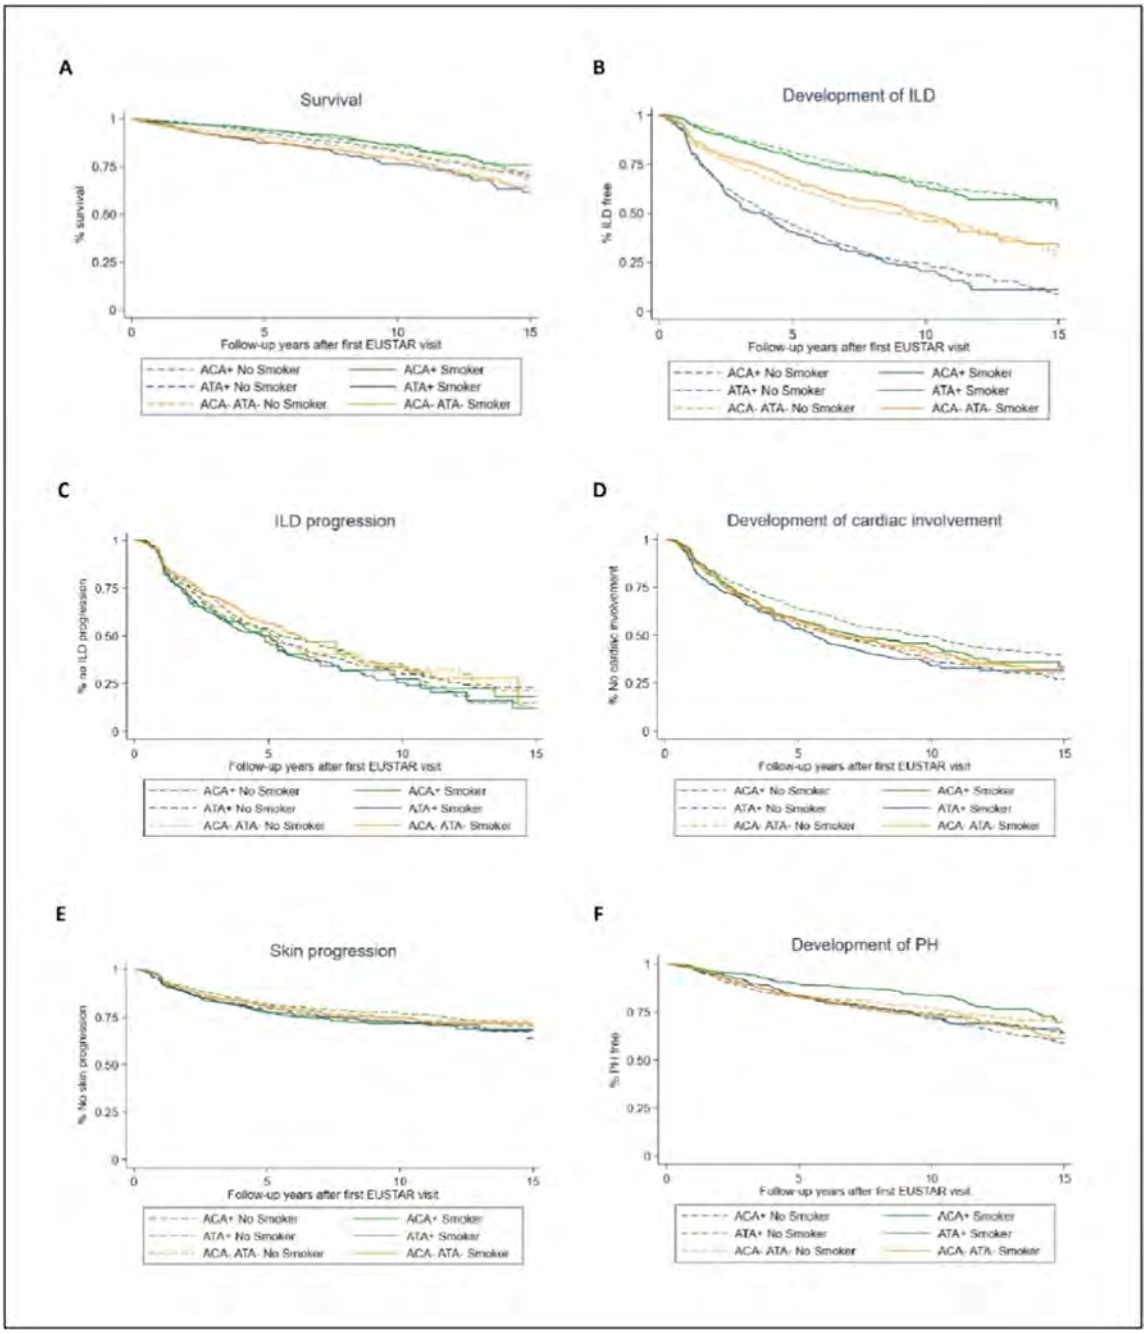

Figure 1: Kaplan–Meier curves of ever-smokers and never-smokers showing survival rate (panel A), development of interstitial lung disease (ILD) (panel B), ILD progression (panel C), development of cardiac involvement (panel D), skin progression (panel E) and development of pulmonary hypertension (panel F) in the EUSTAR patients stratified by positivity of anti-centromere antibodies (ACA+), positivity of anti-topoisomerase I antibodies (ATA+), or negativity for both antibodies (ACA- ATA-).

smoking and antibody expression using Kaplan-Meier curves and multivariate Cox regression models corrected for age and sex and with stratification for ACA/ATA status.

Results: In total 12314 patients were included (Table 1). In women 34% of never-smokers were ATA+ compared to 21% of ever-smokers ($p < 0.001$; Table 2).Ever-smoking females had lower risk of ATA+ [OR 0.523 (95% CI 0.473 – 0.578), $p < 0.001$] and higher exposure further decreased the risk of being ATA+ [OR number of pack/years 0.988 (95% CI 0.978 – 0.997), $p= 0.009$; OR years smoking duration 0.963 (95% CI 0.952 – 0.975), $p < 0.001$]. Ever-smoking females had

increased risk to be ACA+ [OR 1.320 (95% CI 1.212 – 1.437),p< 0.001] and a higher number of pack/years further increased risk of ACA expression [OR 1.012(95% CI 1.002 – 1.021), p= 0.014].In men, the proportion of ATA+ was comparable between non-smokers and ever-smokers, but higher exposure decreased the risk of ATA expression (OR 0.989 (95% CI 0.979 – 0.999), p= 0.032]. We observed different associations with disease progression depending on antibody status: in ACA+ patients, smoking was associated with mortality (HR 1.3, 95%CI 1.0–1.6), cardiac involvement (HR 1.2, 95%CI 1.1–1.4) and lower risk of pulmonary hypertension (HR 0.8, 95%CI 0.6–1.0), while in ATA+ patients, smoking was a risk factor for mortality (HR 1.4, 95%CI 1.1–1.8) and digital ulcers (HR 1.2, 95%CI 1.0–1.3) (Figure 1).

Conclusion: In this large EUSTAR cohort we observe a clear association between smoking exposure and ATA expression in SSc, particularly in females. For the first time, we describe a negative dose-response relationship between cumulative cigarette exposure and ATA expression, pointing at a possible etiopathogenetic link between smoking and ATA expression. Intruigingly, smoking exposure had different impact on disease manifestations depending on ATA/ ACA status.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Cigarette smoking is an established risk factor for mortality in the general population but, in systemic sclerosis (SSc), evidence about the role of smoking in the evolution of the disease is lacking. In this study, we aim to determine whether smoking is a risk factor for reduced survival in SSc and whether smoking can contribute to the excess mortality observed in male patients compared with females.

Methods: The multinational EUSTAR database was analysed. Individuals with missing or inconsistent information about smoking status were excluded. The included patients were categorised as "never-smokers" or "ever-smokers" at the baseline visit. After stratification for sex, Kaplan–Meier estimates of time until death in ever-smokers and never-smokers were compared using a log-rank test. Follow-up time was censored at 15 years. Cox proportional hazards models adjusted for age were used to assess the risk of mortality in men and women, expressed as hazard ratios (HR) and 95% confidence

Table 1. Baseline characteristics of EUSTAR cohort patients included in the analysis. Legend: DLCO: diffusing capacity of the lungs for carbon monoxide; FVC: forced vital capacity; IQR: interquartile range; SD: standard deviation. Disease duration was defined since the date of onset of Raynaud's phenomenon.

Demographic and clinical variables		**Number of patients with data**
Male sex, n (%)	1921 (16)	12314
Ever-smokers, n (%)	4271 (35)	12314
Pack/years, median (IQR)	15 (6 - 30)	2112
Smoking duration, mean ± SD	23.7 ± 13.2	1686
Age, mean ± SD, years	55.5 ± 13.8	12314
Disease duration, median (IQR)	7.6 (3.0 - 16.0)	8773
Extent of skin involvement		8649
no skin involvement, n (%)	584 (7)	
only sclerodactyly, n (%)	831 (10)	
limited cutaneous involvement, n (%)	4751(56)	
diffuse cutaneous involvement, n (%)	2483 (29)	
Modified Rodnan Skin Score, median (IQR)	7 (4 -13)	1822
Digital ulcers, n (%)	3266 (40)	8266
Pulmonary hypertension, n (%)	644 (21)	3039
Anti-centromere antibodies, n (%)	4637 (38)	12314
Anti-topoisomerase I antibodies, n (%)	3919 (32)	12314
Interstitial lung disease, n (%)	4472 (44)	10173
DLCO % predicted, mean ± SD	69.9 ± 20.8	9012
FVC % predicted, mean ± SD	94.9 ± 22.0	8677
Gastrointestinal symptoms, n (%)	8189 (67)	12198

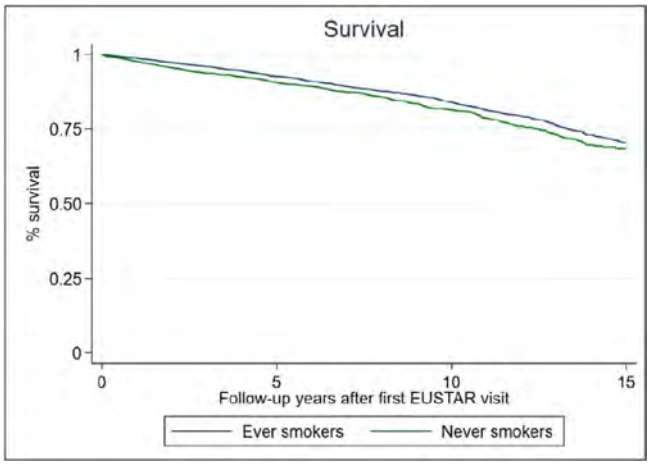

Figure 2. Kaplan–Meier curves showing survival rate of ever-smokers and never-smokers in the whole EUSTAR cohort.

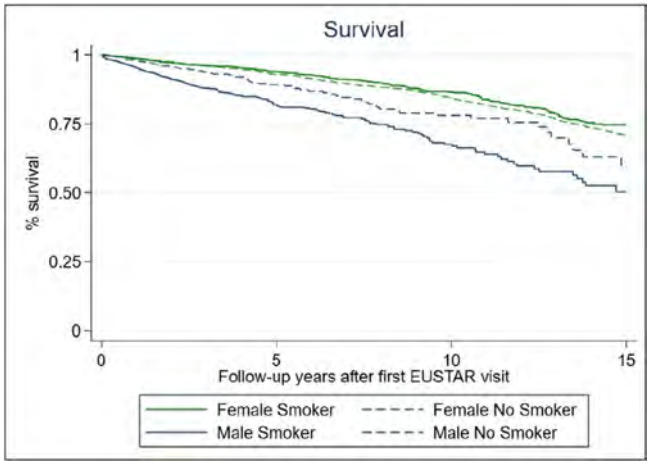

Figure 2. Kaplan–Meier curves of ever-smokers and never-smokers showing survival rate in male and female SSc patients.

intervals (95% CI). Incidence rates of mortality and 95% CI were calculated in men and women according to their smoking habit, considering never-smoking women as the reference category to determine the relative risk (RR) of death.

Results: Of the 12314 included patients (Table 1), 10393 were females (84%) and 1921 were males (16%). Overall, 807 deaths were observed during 47162 patient-years of follow-up in females and 241 deaths were observed in males over 6878 patient-years of follow-up, accounting for a mortality rate of, respectively, 28% and 46%. Survival was significantly lower in ever-smokers compared to never-smokers (68% vs 70%, p= 0.001, Figure 1). This difference was accounted for by the males: survival was 50% in ever-smoking males compared to 60% in never-smoking males ($p < 0.001$) (Figure 2). No difference was found in ever-smoking and never-smoking female patients (survival rate 75% vs 71%, p= 0.207). In Cox regression analysis adjusted for age, smoking was associated with increased risk of mortality (HR 1.63, 95% CI 1.23 – 2.16, p= 0.001) in male patients and no association emerged in women (HR 1.13, 95% CI 0.96 – 1.32, p= 0.148). Incidence rate for mortality was 1.77/100 patient-years in never-smoking women (reference category), 1.56/100 patient-years in ever-smoking women (RR= 0.88), 2.53/100 person-years in never-smoking men (RR= 1.43), 4.10/100 person-years in ever-smoking men (RR= 2.32).

Conclusion: Using he largest available real-life registry of longitudinally collected data on SSc, we demonstrated for the first time that smoking increases the risk for mortality in male SSc patients, but not in female SSc patients. Our results indicate that smoking partially explains the excess mortality observed in male SSc patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Myocardial involvement is a significant contributor to mortality in patients with Systemic Sclerosis (SSc). The objective of this study was to analyze the clinical characteristics of SSc patients with myocardial involvement (MI) and assess their outcomes after treatment modifications.

Methods: We conducted a retrospective study involving patients who met the ACR/EULAR 2013 Scleroderma criteria and were diagnosed with non-ischemic myocarditis. The study period spanned from July 2010 to May 2023. Cardiac MRI (CMR) scans were primarily conducted to evaluate cardiovascular symptoms, as well as to investigate abnormal findings in echocardiography and/or Holter monitoring.

Results: Our study included a total of 18 female SSc patients, diagnosed with non-ischemic myocarditis following CMR. The mean age at diagnosis was 50.6 years (SD 14.3), with a mean disease duration of 9.7 years (SD 7.3). The follow-up period since MI diagnosis was 3.6 years (SD 3). Notably, half of the patients (9/18) had early-stage disease, diagnosed within three years from the onset of SSc. No significant differences were found in the clinical characteristics between the two MI groups (early vs. established SSc), except for a slightly higher occurrence of gastrointestinal involvement noted in the early SSc group (p=0.058).Echocardiography performed at the time of MI diagnosis, revealed a slightly lower ejection fraction in patients with established SSc compared to those with early SSc (EF=55.6, SD 9.7 vs EF=60.6, SD 5.3), but this difference did not reach statistical significance. Diastolic dysfunction was identified in only three patients. Conversely, abnormal findings on 24-hour Holter monitoring were observed in 9 out of 18 patients (5/9 patients with early SSc). Regarding treatment modifications, 5 patients received cyclophosphamide as the initial treatment regimen for SSc myocarditis, while 10 patients were treated with rituximab. Concomitant use of corticosteroids was observed in 11 patients. In 6 out of the 18 patients, a second CMR was performed. The interval between the initial and second MRI varied, with a one-year interval in 4 patients, a 5-year interval in 1 patient, and a 10-year interval in 1 patient. Among these patients, myocarditis had resolved in 2 cases, both of whom were receiving a combination of Rituximab and corticosteroids. Improvement in T2-weighted parameters (T2 ratio), reflecting decrease of myocardial oedema, was observed in other 2 cases, undergoing combination therapy with rituximab and mycophenolate mofetil. Surprisingly, the remaining 2 patients who had initially received cyclophosphamide as the treatment for myocardial involvement showed no change in the cardiac MRI parameters.

Conclusion: The results of our study align with the theory that myocardial involvement in SSc can occur in both early and long-standing disease. The findings highlight the significance of early detection of SSc patients with myocarditis, as there is evidence suggesting that some patients may experience resolution of myocardial lesions. However, further studies are needed to determine the most appropriate treatment regimen and to investigate the potential use of cardiac MRI as a monitoring tool for treatment response.

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

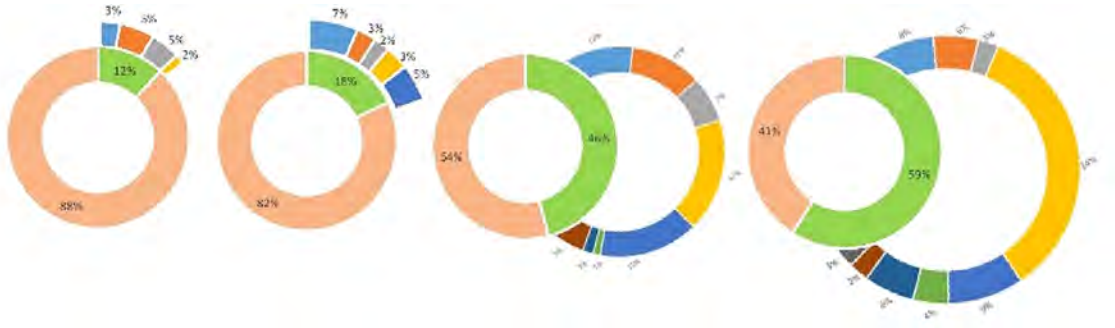
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment armamentarium with immunosuppressive treatments (ISTs) for interstitial lung disease (ILD) in systemic sclerosis (SSc) has greatly expanded. It is to date unclear to which degree and its impact on ILD progression, which is of importance for the management of patients and clinical trials. Here, we assess treatment regimens and its impact on ILD progression and mortality in SSc-ILD.

Methods: SSc patients registered in the EUSTAR database with presence of ILD on imaging, available FVC%, DLCO% predicted and treatments at baseline and at 12 ± 3 months were included. ILD progression was defined as absolute FVC≥5% or DLCO≥10% decline. We segregated treatment regimens into four periods based on patients first assessment: 1) ≤ 2006; 2) 2007-2011; 3) 2012-2016; 4) ≥ 2017 and assessed clinical characteristics and type of IST. Next, we evaluated the impact of ISTs across the periods on ILD progression and a combined morbidity-mortality endpoint (progression and 3-year death). Lastly, we assessed the impact of ISTs on these endpoints in patients with positive anti-topoisomerase I (ATA) and short disease duration (≤60 months since first non-Raynaud's symptom) in a subgroup analysis. Non-parametric tests were used for multiple group comparisons.

Results: We included 1408 SSc–ILD patients with 122 (8.7%) in period 1; 376 (26.7%) in period 2; 459 (32.6%) in period 3 and 451 (32.0%) in period 4. We did not identify major differences in clinical characteristics across the periods (Table 1); whereas the ISTs changed significantly from 12 % treated with IST in period 1 to 59% in period 4 (Figure 1). When assessing the impact of ISTs across the periods on our endpoints, we did not identify significant impact on ILD progression or the morbidity-mortality (Figure 2). In the subgroup analysis, enriching for progressive patients with short disease duration and ATA, we included 324 (23%) SSc-ILD patients across the 4 periods (4, 32, 120 and 168 in period 1-4). In this analysis, excluding those from period 1 due to low numbers, we identified significantly less ILD progression with 59.4%, 37.5% and



Treatment	≤2006	2007-2011	2012-2016	≥2017	P-value
IST, n(%)	15 (12.3)	67 (17.8)	213 (46.4)	265 (58.8)	<0.001

Figure 1. Immunosuppressive therapies across the four periods

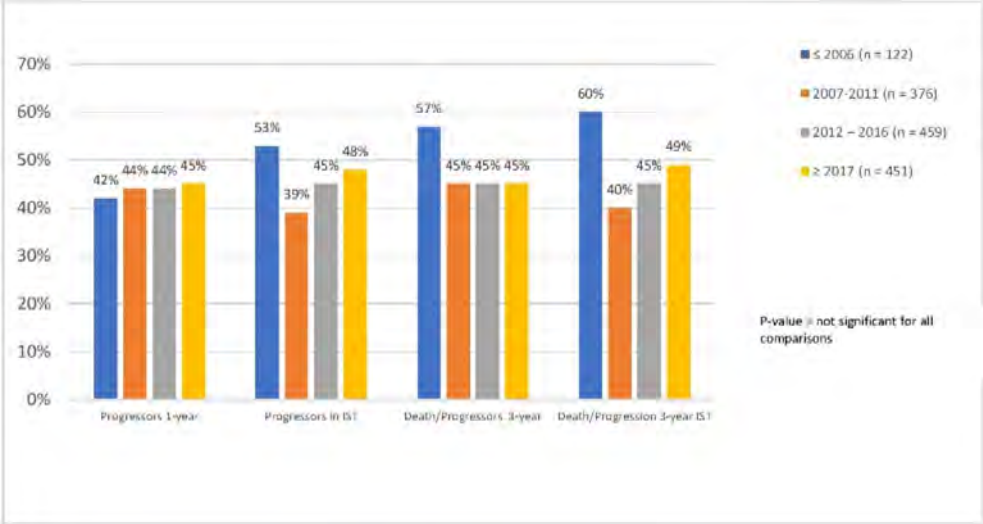

Figure 2. Outcomes of SSc-ILD patients at first-time assessment across the four periods.

Table 1. Clinical and treatment features of SSc-ILD patients at first-time assessment across the four periods

Time Period	≤ 2006 (n = 122)	2007-2011 (n = 376)	2012 – 2016 (n = 459)	≥ 2017 (n = 451)	p-value
Age (SD)	54.8 (13.3)	55.7 (11.0)	55.0 (12.8)	55.5 (13.4)	0.670
Male (%)	26 (21.3)	77 (20.5)	91 (19.8)	91 (20.2)	0.981
Disease Duration (months)	100.4 (88.0)	97.8 (99.1)	98.0 (98.2)	95.8 (89.7)	0.876
%pDLCO (SD)	61.4 (18.7)	61.3 (21.7)	60.3 (20.2)	59.9 (19.3)	0.825
%pFVC (SD)	86.3 (19.9)	85.2 (22.3)	85.6 (20.0)	83.9 (21.2)	0.599
Skin involvement, n	120	354	453	443	
Sine, n(%)	3 (2.4)	14 (4.0)	16 (3.5)	10 (2.3)	0.637
Limited cutaneous, n(%)	66 (53.2)	183 (51.7)	235 (51.9)	211 (47.6)	0.794
Diffuse cutaneous, n(%)	55 (44.4)	157 (44.4)	202 (44.6)	222 (50.1)	0.885
Antibodies, n	116	350	432	421	
Anti-centromere, n(%)	25 (18.4)	61 (15.6)	85 (16.9)	75 (15.3)	0.780
Anti-topoisomerase, n(%)	66 (47.8)	222 (55.4)	268 (52.0)	282 (56.3)	0.235
Anti-RNA-polymeraseIII, n(%)	7 (9.7)	11 (5.2)	16 (5.8)	15 (5.7)	0.537

35.1%, respectively (p =0.037) and morbidity-mortality endpoint with 62.5%, 38.3% and 38.7%, respectively (p=0.036).

Conclusion: We show that treatment with immunosuppressives has increased significantly over the past decade, with currently 60% of SSc-ILD patients on IST. This is important knowledge for the design and inclusion of patients into clinical trials. We do not identify an impact on ILD progression in the total cohort but in an enriched population, showing the importance of treatment, specifically of patients at risk for progression.

Abstract Number: 0663

Vaccine-Preventable Diseases in Hospitalized Patients with Systemic Sclerosis: A Nationwide Cohort Analysis

Saman Tanveer, Chun Pan and Faria Sami, John H. Stroger Jr. Hospital of Cook County, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Connective tissue disorders, including systemic sclerosis (SSc), are associated with an increased risk of infections. Infections are the most common diagnosis during hospitalizations and the leading cause of in-hospital deaths for SSc patients. A significant number of these infections are preventable through vaccination. In our study, we have measured the frequency and demographics of patients with SSc who were hospitalized with a vaccine-preventable disease (VPD) compared to patients without SSc.

Methods: We conducted a population-based descriptive cohort study using the US National Inpatient Sample (NIS) from 2016 to 2020. International classification disease (ICD-10) was used to identify cohorts. We measured the frequency of patients with SSc who were admitted to the hospital with a vaccine-preventable disease (VPD). Frequencies and demographics were determined and compared between patients with SSc and patients without SSc.

Table 1 - Adjusted Odds Ratio for incidence of vaccine preventable diseases in hospitalized patients with SSc as compared to hospitalized patients without SSc

VPD	Adjusted Odds Ratio (95% CI)	P value
Herpes Zoster Virus	1.65 (1.39-1.97)	<0.001
Meningococcal meningitis	2.77 (0.68-11.20)	0.15
Influenza	0.75 (0.64-0.89)	<0.001
Pneumococcal pneumonia	0.92 (0.69-1.22)	0.55
Hepatitis A	0.59 (0.32-1.08)	0.18

Table 2 - Hospitalization characteristics of SSc patients admitted with vaccine preventable diseases (LOS: Length of stay)

	Herpes zoster	Meningococcal Meningitis	Influenza	Pneumococcal Pneumonia	Hepatitis A
Total Hospitalizations (n)	1,065	10	1,785	305	55
Mean Age (years)	63.38±1.06	52.50±5.30	62.52±0.74	61.19±1.80	57.00±3.53
Mortality %	2.35%	0%	5.32%	9.84%	0%
Mean LOS (days)	6.82±0.46	9	6.82±0.47	11.85±1.42	5.99±0.98
Mean total charge ($)	72293.22±7189	110949.3±7513	78411.86±7544	173183.6±48903	67013.28±15746.69
Total hospitalization charge ($)	75900000±9471316	1109467± 788102	138000000±1.53e+07	52000000±1.61e+07	3685726±1408948

Results: We identified 1,834,149 hospitalizations with a principal diagnosis of a VPD (including influenza, Herpes Zoster Virus (HZV), pneumococcal pneumonia, hepatitis A virus, and meningococcal meningitis). Among these, 3,179 had concomitant secondary diagnosis of SSc. The most common VPDs among patients with SSc were influenza (56.1%), herpes zoster virus (HZV) (33.5%) and pneumococcal pneumonia (9.5%). Hepatitis A virus (1.7%) and meningococcal meningitis (0.3%) were less common. Patients with SSc were more likely to have HZV when compared to non-SSc patients (odds ratios [OR] = 1.65, 95% Confidence Interval [CI] = 1.39–1.97, $P < 0.001$). Interestingly, patients with SSc were less likely to develop influenza infection when compared to non-SSc patients (OR = 0.75, 95% CI = 0.64–0.89], $P < 0.001$). There was no significant difference in frequency of other VPDs between the two groups.

Conclusion: There was a significantly higher frequency of HZV infections in SSc hospitalizations compared to non-SSc admissions. This finding is pertinent as it could signify a possible low rate of vaccination versus vaccination failure in a potentially immunocompromised population, increasing the risk of infection. Most common infection in SSc patients was influenza, but observed to be less frequent than in the non-SSc group. These findings can help clinicians introduce and improve HZV vaccination programs for SSc patients.

Quantitative Hand Held Dynamometry to Assess Muscle Strength in Scleroderma Associated Myopathy

Julie Paik[1], Christopher Mecoli[2], Anshula Nallapati[1], Ami Shah[3], Fred Wigley[4], Zsuzsanna McMahan[5] and Laura Hummers[1], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Ellicott City, MD, [4]Department of Rheumatology, Johns Hopkins Medicine, Baltimore, MD, [5]Johns Hopkins Rheumatology, Lutherville, MD

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Manual muscle strength testing can be challenging in SSc associated myopathy (SSc-AM) due to contractures or skin tightening. Since there is currently no validated strength assessment in SSc, the purpose of this study is to investigate the reliability and validity of hand held dynamometry (HHD) in SSc-AM.

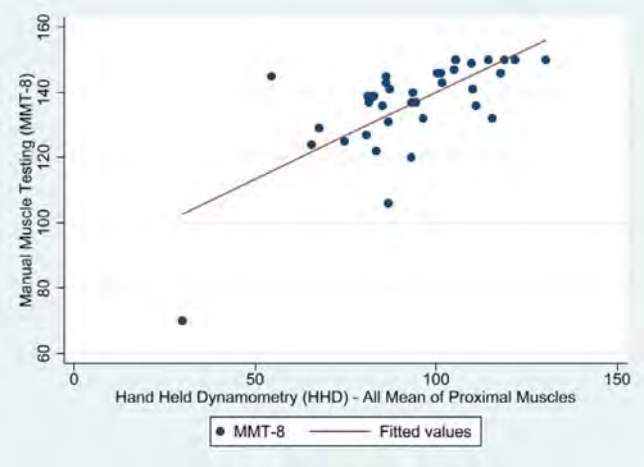
Methods: This was a prospective, cross-sectional study of 36 patients with SSc-AM enrolled at a single-center from August 2021 to May 2022. Inclusion criteria required patients to fulfill the 2013 ACR/EULAR criteria for SSc, and have skeletal myopathy as defined by a history of proximal weakness and/or elevated creatine kinase (CK) with at least one abnormal objective test result such as myopathic findings on EMG, muscle edema on muscle MRI, or inflammation, necrosis, or fibrosis on muscle biopsy.

Quantitative muscle strength testing of 3 proximal muscle groups [neck flexors, iliopsoas (bilateral hip flexors), and deltoid (bilateral arm abductors)], was assessed using a Micro-FET2 HHD and compared to the validated Manual Muscle Testing of 8 muscles (MMT-8). Each patient underwent 3 serial measurements for each of the three proximal muscle groups. A second blinded investigator performed the same assessments on 7 patients to assess inter-rater reliability. Both investigators had prior training using HHD and MMT-8.

The final HHD score was an average of each proximal muscle group (with or without neck flexors). Intra-rater reliability was assessed with a Pearson correlation and the intraclass correlation coefficient (ICC). Inter-rater reliability was also assessed with ICC. To determine how well the HHD score correlated with MMT-8, Pearson correlation was used to quantify the magnitude of correlation.

Results: Thirty-six patients with SSc-AM were enrolled. The average age at enrollment was 52.5 ± 11.1 years and at SSc diagnosis was 44.2 ± 11.9 years. 75% (27 of 36) were female and 44% (16 of 36) were Black while 37% (17 of 36) were Caucasian. 63.8% had diffuse SSc with a maximum modified Rodnan skin score (mRSS) of 13.7 ± 10.1. Maximum CK was 311 ± 425 U/L and aldolase was 12.6 ± 8.9 U/L . Closest CK at time of enrollment was 165 ± 166 U/L. Available commercial autoantibody testing and Euroimmun SSc profile demonstrated that 15% were anti-Scl-70 positive, 15% anti-PM-Scl positive, 6.25% anti-centromere B positive, 15% anti-RNA Poly III positive, 22% anti-U3RNP positive, 5.5% positive for U1RNP.

HHD strongly correlated with MMT-8 with neck flexors ($r=0.70$, $p< 0.00001$) and without neck flexors ($r=0.68$, $p< 0.00001$) (See Figure 1). Intra-rater reliability of HHD for the three consecutive assessments was also strong for the neck flexors and arm abductors with ICC of 0.96 (CI 0.94, 0.98) and hip flexors was ICC of 0.87 (CI 0.79,0.93), $p=0.001$. The inter-rater



reliability of HHD between two examiners was good for the neck flexors [ICC of 0.87 (CI 0.23-0.97), p=0.01], arm abductors [ICC of 0.88 (CI 0.39-0.98), p=0.006] and hip flexors with [ICC of 0.73 (CI -0.56-0.95, p=0.07)].

Conclusion: HHD highly correlates with the validated MMT-8 in SSc-AM and demonstrates good intra-rater and inter-rater reliability, thereby making it a feasible alternative to quantify and measure muscle strength in scleroderma.

A Descriptive Study of Disease Characterisics of SSc Patients with the U2RNP Autoantibody

Mridula Dilip[1], Maureen Laffoon[2], Yongseok Park[3], Robert Lafyatis[4], Thomas Medsger[5], Virginia Steen[6], Leigh Freno[2] and Robyn Domsic[4], [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]University of Pittsburgh School of Public Health, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Pittsburgh School of Medicine, Verona, PA, [6]Georgetown University School of Medicine, Washington, DC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: U2RNP is a spliceosome-associated autoantibody that has in prior case reports presented with scleroderma with myositis (SSc/PM)and SLE overlap. Autoantibodies are growing in prognostic importance in rheumatology and our center has performed immunoprecipitation for decades. There are few existing publications on U2RNP-associated disease features. This study aims to characterize disease phenotypes of U2RNP-positive patients.

We hypothesized based on limited available literature that patients positive for the anti-U2RNP autoantibody would display SSc features along with SLE or myositis characteristics compared to controls such as oral ulcers, thrombotic events, or cutaneous features.

Methods: This case-control study used our longstanding, prospectively followed SSc dataset. U2RNP patients initially seen in clinic between 1982 and 2015 were captured. Controls were the next two individuals seen without U2RNP (U2RNP-) Two-sided t-tests for continuous and Chi-squared tests for categorical variables were performed at a 95% confidence level.

Results: 79 U2RNP+ and 158 U2RNP- patients were identified. There was no significant difference in proportion of non-white patients between groups. Mean age of symptom onset was earlier for U2RNP+ patients (mean 40.9, SD 14.7) than controls (mean 45, SD 14.9) with a p-value of 0.05 (Table 1).

Amongst U2RNP+ patients, 43% had diffuse skin thickening, similar to U2RNP- patients. We did not find a difference in rates of myositis between groups. Surprisingly, U2RNP- controls had a higher incidence of SLE-like features such as oral ulcers, thrombi, and pleurisy (Table 2). Only unspecified rashes differed significantly between groups (15.2% in U2RNP+ vs. 4.43% in U2RNP-, $p = 0.0087$). There was no difference in vascular comorbidities other than higher rate of MI in the U2RNP- group.

For SSc features, less U2RNP+ patients (26.92%) had telangiectasias than U2RNP- (70.9%; $p < 0.0001$). A larger percentage of individuals in the U2RNP+ group developed pulmonary fibrosis (57% vs. 44%, $p = 0.12$) in follow-up, and had pulmonary fibrosis at their first visit (54.4% vs. 39.9%, $p = 0.06$), though both findings related to fibrosis were not statistically significant. There was no difference in development and subtypes of pulmonary hypertension (Table 2).

Conclusion: This is the first large case-control study of patients with the anti-U2RNP antibody. Unlike U1RNP, U2RNP+ did not present with typical SLE or myositis features, aside from unspecified rash. Approximately 43% of U2RNP+ patients had diffuse skin thickening, but with less telangiectasias (27%). Though not statistically significant, there is a greater percentage of pulmonary fibrosis over the long-term and at initial visit in the U2RNP+ group. This finding may be further elucidated in further studies that match for age, biological sex, and other environmental factors that may influence fibrosis and perhaps guide screening recommendations for individuals who test positive for the autoantibody through serologies. The primary weakness is that this is a single-center study.

Troponin I Levels in Systemic Sclerosis Patients with Myocardial Involvement

Eva Hoekstra[1], Sophie Liem[1], Nivine Levarht[1], Cynthia Fehres[1], Saad Ahmed[1], Nina Ajmone Marsan[2], Thomas Huizinga[1] and Jeska de Vries-Bouwstra[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Department of Cardiology, Heart Lung Centre, Leiden University Medical Centre, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: As primary myocardial involvement in systemic sclerosis (SSc) is associated with worse prognosis, research on diagnostic tools for recognition is essential. Troponin I was suggested as a more specific biomarker for myocardial involvement in SSc than the frequently used troponin T. The aim of this study is to evaluate the association between troponin I levels and primary myocardial involvement in SSc patients, and to evaluate the presence of subclinical myocardial involvement by comparing troponin I levels between SSc patients and healthy controls.

Methods: A cross-sectional observational study was performed, including four groups of each 20 SSc patients, fulfilling ACR/EULAR 2013 criteria, selected from the Leiden Combined Care in Systemic Sclerosis cohort: (1) patients with primary myocardial involvement, (2) patients with myositis, (3) patients with elevated troponin T and CK levels but without organ involvement, and (4) patients without any suggestions of organ involvement. Primary myocardial involvement was assessed independently by an experienced rheumatologist and an experienced cardiologist. Troponin I levels were measured in patient sera and 20 additional healthy donors using ELISA. Troponin I levels were compared between the different groups using Mann-Whitney U and Kruskal-Wallis tests.

Results: The mean age of the 80 included patients was 56.2 ± 12.7 years, 61% of the study population was female. Troponin I levels were comparable between patients with and without myocardial involvement (2.7 [0.5 – 15.3] vs. 1.2 [0.1 – 6.6] ng/L; p = 0.117). Within the group of patients without myocardial involvement, SSc patients with myositis, SSc patients with elevated troponin T levels without organ involvement and SSc patients with normal troponin T levels without organ involvement, had median troponin I levels of 0.4 (0.0 – 4.7) ng/L, 2.2 (0.0 – 9.9) ng/L, and 1.2 (0.2 – 7.2) ng/L, respectively. No significant differences were found in median troponin I levels between the four different subgroups (p=0.131) (Figure 1). SSc patients (without myocardial involvement) were more often positive for troponin I than healthy controls (30.0% vs. 65.0%, p = 0.006) (Figure 2).

Conclusion: Elevated troponin T and I levels were identified in SSc patients without myocardial involvement possibly indicating subclinical myocardial involvement in the majority of patients. However, these elevated levels were not of additive value to identify SSc patients with clinical myocardial involvement.

The Risk of Stroke and Myocardial Infarction in Systemic Sclerosis: A Population-based Study

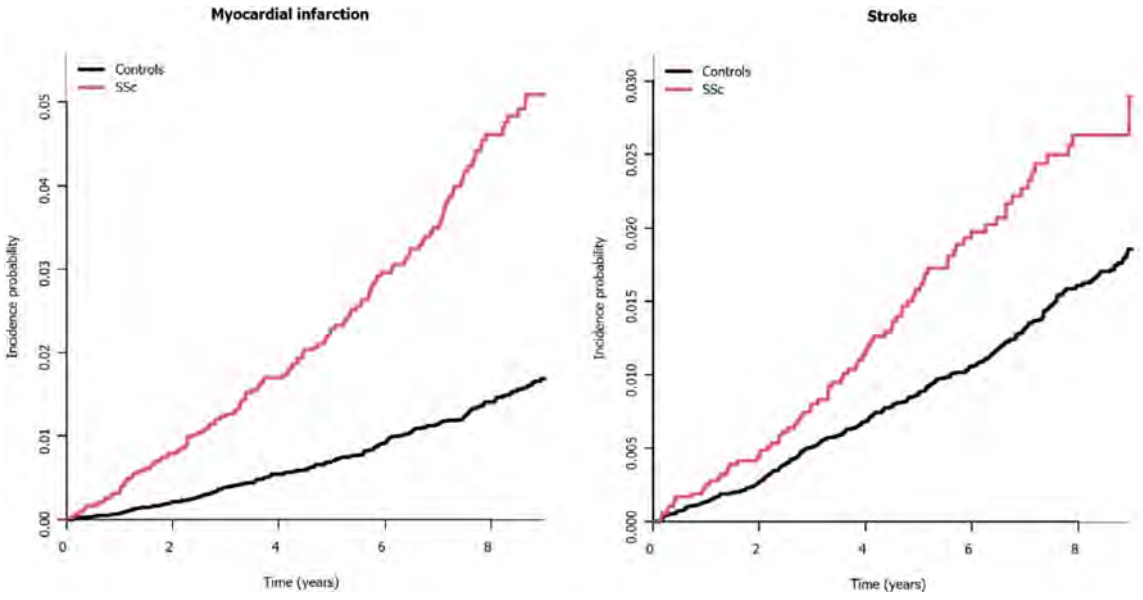
Jiwon Hwang[1], Yeonghee Eun[2], Kyungdo Han[3] and Joong Kyong Ahn[2], [1]Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon, South Korea, [2]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Department of Statistics and Actuarial Science, Soongsil University, Seoul, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have suggested a link between systemic sclerosis (SSc) and cardiovascular disease, but large-scale data are still lacking due to the nature of rare autoimmune diseases. We aimed to compare the incidence of myocardial infarction (MI) and stroke in patients with SSc and age- and sex-matched controls in a nationwide population-based cohort in Korea.

Methods: We included patients with SSc defined by the ICD-10 code (M34) and rare and intractable disease code (V138) and 1:5 age- and sex-matched controls using the Korean National Health Insurance Database. The outcomes of the study were MI and stroke. Cox proportional hazard analysis and Kaplan-Meier curve were used to compare the incidence of outcomes between patients with SSc and controls.

Results: A total of 4700 patients with SSc and 23500 controls were included in the study. The mean follow-up period was 5.6 ± 2.8 years. At baseline, patients with SSc had higher prevalent rates of comorbidities such as hypertension, hyperlipidemia, and congestive heart failure than controls. Patients with SSc had a 3-fold higher risk of MI (adjusted hazard ratio [aHR] 3.01, 95% confidence interval [CI] 2.41–3.76) and a 1.7-fold higher risk of stroke (aHR 1.65, 95% CI 1.28–2.14) compared to controls. There were no differences in the association between SSc and MI or stroke by age, sex, or comorbidities.



Cumulative incidence of myocardial infarction and stroke

Conclusion: This nationwide population-based cohort study revealed an association between SSc and increased risk of MI and stroke. Therefore, careful monitoring and preventive measure for the cardiovascular diseases in patients with SSc are required.

Increased Risk of Cancer in Patients with Systemic Sclerosis: A Population-based Study

Jiwon Hwang[1], Yeonghee Eun[2], Kyungdo Han[3] and Joong Kyong Ahn[2], [1]Division of Rheumatology, Department of Internal Medicine, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon-si, South Korea, [2]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Department of Statistics and Actuarial Science, Soongsil University, Seoul, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have shown an association between systemic sclerosis and cancer. However, because the disease is rare, large-scale studies are lacking, especially in Asians. We aimed to compare the incidence of cancer in patients with SSc and age- and sex-matched controls in a nationwide population-based cohort in Korea.

Methods: We included patients with SSc defined by the ICD-10 code (M34) and rare and intractable disease code (V138) and 1:5 age- and sex-matched controls using the Korean National Health Insurance Database. The outcomes of the study were incidence of cancer. Cox proportional hazard analysis and Kaplan-Meier curve were used to compare the incidence of cancer between patients with SSc and controls.

Results: A total of 5,145 patients with systemic sclerosis and 25,725 controls were included in the study. During the study period, the overall cancer incidence rate was 11.07 per 1,000 person-years in patients with systemic sclerosis and 7.59 per 1,000 person-years in controls. Overall cancer risk was 1.5 times higher in patients with systemic sclerosis (adjusted hazard ratio 1.46, 95% confidence interval 1.28–1.67). Lung cancer and lymphoma had a high risk in both male and female patients with systemic sclerosis, and colorectal cancer had a high risk only in male patients with systemic sclerosis. The risk of biliary cancer, skin cancer, and cervical cancer was high in female systemic sclerosis patients.

Conclusion: This nationwide cohort study showed that patients with systemic sclerosis were associated with increased cancer risk. Clinicians should be aware of cancers that may increase the risk in patients with systemic sclerosis and apply appropriate screening measures.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare and complex autoimmune disease featured by a progressive microvascular damage. The involvement of the ocular microvasculature has been reported in SSc but correlations with nail-fold capillaroscopy (NVC) and laser speckle contrast analysis (LASCA) have been scarcely investigated [1].

We aimed to compare Optical Coherence Tomography Angiography (OCTA) variables in SSc patients vs age- and sex-matched healthy controls (HCs). The morphological peripheral microvascular status, assessed by NVC, and the functional perfusion, analysed by LASCA, were correlated with the OCTA data among the SSc cohort.

Methods: The enrolment included 35 SSc patients (mean age 61.1 ± 13.4 years, mean disease duration 9.5 ± 6 years) and 28 HCs in a single centre from March to October 2022.

Table 1. Comparisons of ocular features and OCTA data between SSc and HCs. Abbreviations. SSc: systemic sclerosis; HCs: healthy controls; lcSSc: localized cutaneous systemic sclerosis; dcSSc: diffuse cutaneous systemic sclerosis; RNFL= retinal nerve fiber layer.

Variable	SSc (n=32)			HCs (n=27)	p-value
Intraocular pressure, (mmHg)	13.6 ± 2.3			11.9 ± 2.2	**0.006**
Scan quality	61±6			63±5	0.315
Superficial capillary plexus, (% of perfusion)	39.4±2.4			40.8±2.7	**0.040**
Deep capillary plexus, (% of perfusion)	39.6±2.7			41.3±3.0	**0.026**
Choriocapillaris, (% of perfusion)	51.1±2.7			52.9±1.5	**0.003**
	lcSSc (n = 22)	**dcSSc (n = 10)**	**p- value**		
	51.8±1.5	49.8±3.6	**0.03**		
Choroidal thickness, (µm)	212±90			220±68	0.725
	lcSSc (n = 22)	**dcSSc (n = 10)**	**p- value**		
	176±79	304±57	**p < 0.0001**		
Retinal thickness, (µm)	267±28			275±15	0.181
RNFL, (µm)	101 ± 11			102 ± 10	0.707

The patients were classified according to the ACR/EULAR 2013 criteria, and multiple assessments were performed, at the same day, including ophthalmological examinations, OCTA, NVC and LASCA.

The clinical, laboratory and instrumental data of SSc patients were analysed and correlated with the OCTA data.

Patients were under standard treatment for SSc and those requiring endovenous prostanoids were evaluated for the study assessment at least one month after the last infusion.

Results: Among the ocular features, the intraocular pressure (IOP) was significantly higher in SSc than in HCs (p=0.006).

Despite the structural features in OCTA being similar, a significant difference was detected in all the perfusion variables, including the superficial vascular plexus (SVP), deep vascular plexus (DVP), and choriocapillaris (CC) **(Table 1**).

When patients were stratified according to the clinical extension of skin involvement, diffuse cutaneous SSc (dcSSc) patients showed a significantly reduced CC perfusion compared to limited cutaneous SSc (lcSSc) patients. Interestingly, the choroidal thickness (CT) in dcSSc was nearly twice that of lcSSc ($p < 0.0001$). The age and disease duration did not significantly differ among the two subgroups (respectively, $p = 0.18$ and $p = 0.37$).

In addition, the mean number of capillaries per linear mm at NVC and the mean peripheral perfusion assessed by LASCA at the level of 2^{nd} to 5^{th} fingertip were negatively correlated with the IOP ($r = -0.30$ and $r = -0.36$, both $p < 0.01$).

Finally, the mean capillary number at NVC was also positively correlated with the perfusion values of the SVP and DVP at OCTA ($r = 0.3$, $p = 0.01$ and $r = 0.28$, $p = 0.01$) and the mean peripheral perfusion detected by LASCA positively correlated with the DVP and CC perfusion ($r = 0.29$ and $r = 0.28$, both $p = 0.01$).

Conclusion: The higher IOP in all SSc patients might be in line with reported vascular abnormalities occurring in the optic nerve head [2].

The reduced capillary density and perfusion of the retina and choriocapillaris suggest an ocular microvascular impairment similarly to what is observed at the nailfold and fingertips in SSc patients.

The increased CT limited to dcSSc might be related to attempts of ocular microvascular reactivity and deposition of subendothelial extracellular matrix in agreement with the fibrotic process observed in other tissues in such patients.

Title: Patient Characteristics and Outcomes of Scleroderma Renal Crisis versus Hypertensive Emergencies: A Nationwide Comparative Study

Husam el Sharu[1], Sukhvir Singh[1], Omar Alwahadneh[2] and Mohammad Alqaisieh[3], [1]East Carolina University, Greenville, NC, [2]Carle Foundation Hospital, Urbana, IL, [3]Hamilton Medical Center, Dalton, GA

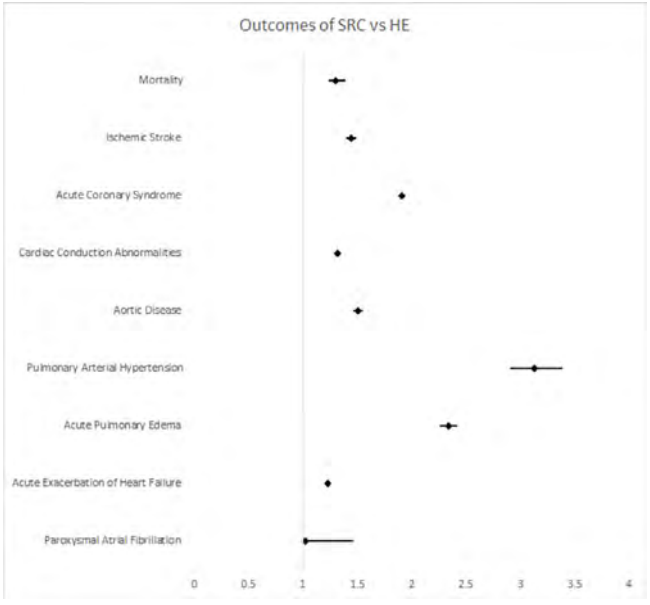
SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleroderma renal crisis (SRC) is a life-threatening complication of systemic sclerosis. It presents with sudden onset of severe hypertension, a rise in serum creatinine levels with oliguria, and/or thrombotic microangiopathy. We aimed to identify the differences in outcomes and comorbidities in patients with this SRC in comparison to patients presenting with hypertensive emergency without SRC (HE).

Methods: The 2016-2020 National Inpatient Sample database (NIS) was analyzed to identify adult hospitalizations with SRC, using International Classification of Diseases – 10 Clinical Modification (ICD-10-CM) codes. The studied primary outcome was to assess SRC versus HE inpatient mortality and inpatient morbidities. A multivariate logistic regression, and linear regression analyses were used to adjust for possible confounders.

Results: Logistic and linear regression analyses showed that patients with SRC had a higher odds of mortality (adjusted Odds Ratio [aOR] of 1.3, 95% Confidence Interval [CI] 1.24-1.39), ischemic stroke (aOR: 1.44, CI: 1.40-1.49), acute coronary syndrome (aOR: 1.91, CI: 1.87-1.95), cardiac conduction abnormalities (aOR: 1.32, CI: 1.30-1.35), aortic disease (aOR: 1.51, CI: 1.46-1.55), pulmonary arterial hypertension (aOR: 3.13, CI: 2.9-3.39), acute pulmonary edema (aOR: 2.34, CI: 2.26-2.42), acute exacerbation of heart failure (aOR: 1.23, CI: 1.21-1.25), and paroxysmal atrial fibrillation (aOR: 1.02,



Outcomes in patients with SRC versus patients with Hypertensive disease only

CI: 1.008-1.046) in comparison to HE. Figure 1 shows the Forrest plot for multivariate analysis of in hospital morbidities when adjusted for patient demographics, comorbidities, and hospital characteristics.

Conclusion: In conclusion, our study underscores the notable distinctions between patients with scleroderma renal crisis and those presenting with hypertensive emergencies without scleroderma. Our findings demonstrate that patients with scleroderma renal crisis face significantly elevated risks of mortality, ischemic stroke, acute coronary syndrome, cardiac conduction abnormalities, aortic disease, pulmonary arterial hypertension, acute pulmonary edema, and acute exacerbation of heart disease. These results highlight the imperative for healthcare providers to exercise heightened caution and tailored management strategies when dealing with scleroderma renal crisis patients due to their heightened susceptibility to complications.

Decreased Odds of Malignancy with Mycophenolate Use in a Single-Center Scleroderma Cohort

Jin Feng[1], Chrisanna Dobrowolski[2], Celestine He[2], Hannah Verma[3], Roshan Vasoya[3], Daniel Qian[3], Ezequiel olumuyide[3], Alicia Leong[3], Joseph Menand[1], Murilo Roberto Bastos Silva[1], Vincent Courant[1] and Sophia Lutgen[1], [1]Icahn School of Medicine at Mount Sinai Morningside and West, New York, NY, [2]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [3]Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Prior studies have shown an increased risk of malignancy in patients with systemic sclerosis (SSc). The reasons for this increased risk may be multifactorial, including effects of chronic inflammation, genetics, shared environmental risk factors, use of immunosuppressive medications, among others. The aim of this study is to identify and characterize malignancy risk factors in a diverse SSc cohort.

Methods: A retrospective cohort was assembled of all patients with SSc followed within a large, urban, tertiary care center. Validated ICD codes were used to identify cases. Descriptive statistics were used to study the cross-sectional distribution of patient characteristics, including age, sex, ethnicity, health insurance status, smoking status, scleroderma subtype, mycophenolate (MMF) use and other immunosuppressant use. Student t-test was performed to compare variations in age. Chi-square test and Fisher exact test were used to examine the difference in other categorical characteristics of patients with and without malignancy. The prevalence of specific types of cancers was calculated. Odds ratios (OR) of cancer diagnosis with respect to patient characteristics were calculated with multivariable logistic regression.

Results: A total of 625 patients met inclusion criteria. The distribution of participant characteristics was calculated and stratified by cancer diagnosis (Table 1). 93 (14.9%) patients were found to have a history of cancer. Breast cancer (N=32, 5.1%) was the most prevalent cancer in our cohort; distribution of each specific malignancy is outlined in Figure 1. Patients with a malignancy history were older than those without malignancy (median age 69 vs 61 $P < 0.01$). Lack of medical insurance was associated with increased odds of malignancy (OR 2.13, 95% CI 1.07-4.24, $P = 0.03$). Participants taking MMF were significantly less likely to be diagnosed with malignancy (OR 0.58, 95% CI 0.36-0.94, $P = 0.03$), whereas other

Table 1. Characteristics of patients with systemic sclerosis with and without history of malignancy (N = 625)

		History of malignancy (N=93)	No history of malignancy (N=532)	P-value
Median age, years		69	61	<0.01
		N (%)	*N (%)*	
Female Sex		79 (85.0%)	438 (82.3%)	0.54
Ethnicity	White	47 (50.5%)	225 (42.5%)	0.31
	Black	18 (19.4%)	86 (16.2%)	
	Asian	1 (1.1%)	18 (3.4%)	
	Hispanic	5 (5.4%)	48 (9.0%)	
	Other	22 (23.7%)	155 (29.1%)	
Health Insurance	Private	25 (26.9%)	203 (38.2%)	0.07
	Public	52 (55.9%)	268 (50.4%)	
	None	16 (17.2%)	61 (11.5%)	
Scleroderma Subtype	Limited	59 (63.4%)	349 (65.6%)	0.69
	Diffuse	34 (36.6%)	183 (34.4%)	
Smoking history		4 (4.3%)	29 (5.5%)	0.80
Mycophenolate use		28 (30.1%)	226 (42.5%)	0.03
Other Immunosuppressant Use		62 (66.7%)	256 (48.1%)	<0.01

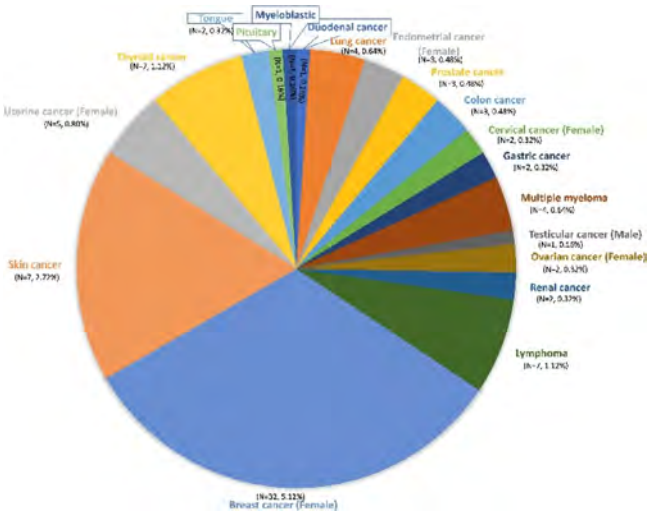

Figure 1. Prevalence of specific malignancies in patients with scleroderma, distributed in a pie chart

immunosuppressant use was associated with higher prevalence of malignancy (OR 2.16, 95% CI 1.36-3.43, P = 0.001) (Figure 2). The multivariable logistic regression showed cancer had statistically significant associations with public insurance (P = 0.01), lack of insurance(P = 0.01), MMF (P< 0.01), and other immunosuppressants (P< 0.01), but not with SSc's time of diagnosis, SSc subtypes, or smoking.

Conclusion: While MMF has been associated with increased malignancy risk in prior studies, this analysis showed a reduced odds of malignancy in participants with SSc treated with mycophenolate. The reason for this unexpected finding is unclear and further studies are warranted to determine if a relationship exists beyond correlation. Lack of health insurance, increasing age and non-MMF immunosuppressant use are associated with increased malignancy risk in this urban, single-center multiethnic SSc cohort. The cancer prevalence in our cohort is similar to prior SSc studies, and higher than the general population.

Abstract Number: 0672

Risk of New-onset Depression in Patients with Systemic Sclerosis : A Nationwide Population-based Study

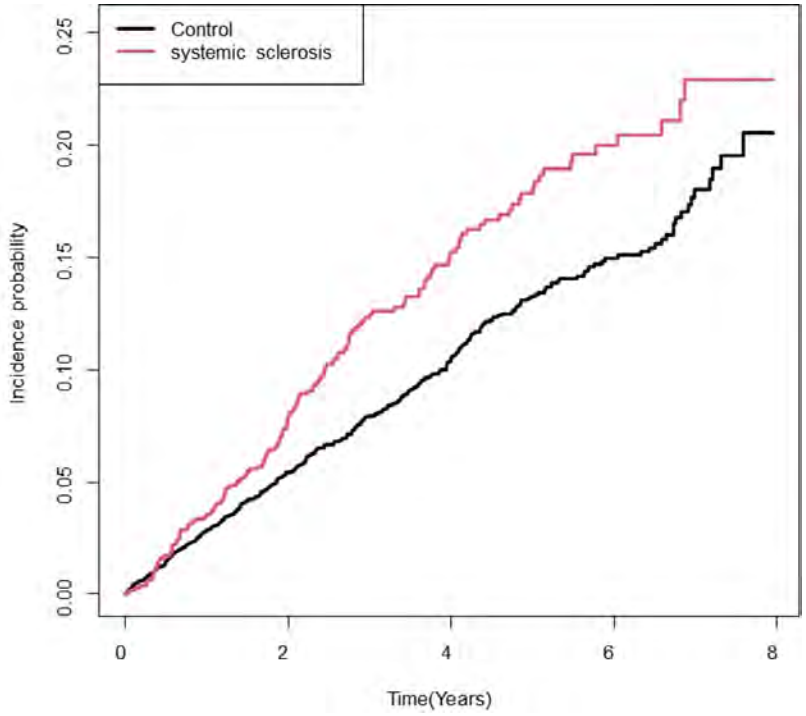
Hahee Son and Su-Jin Moon, Yeouido St. Mary's Hospital, Catholic University of Korea, Seoul, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I: Research
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare chronic inflammatory disease characterized by vasculopathy, autoimmunity and progressive fibrosis in various organs. The patients with SSc are suffered from dyspnea, cough, and gradual skin and joint contracture, resulting in significant physical and psychological burden. Psychological symptoms in SSc patients include pain, depression, and concerns about appearance disfigurement. Previous studies have reported that depression is common in SSc patients, ranging from 36% to 65%. However, no study has unveiled the risk of new-onset depression in SSc patients.

The present study was conducted to determine whether SSc is an indeed risk factor for the development of new-onset depression. To determine whether the incidence rate (IR) of new- onset depression in SSc patients is higher than in normal subjects, we used data from a nationwide health care database.

Methods: We selected subjects from National Health Insurance System database who were diagnosed with SSc between 2010 and 2016. Subjects who did not get a general health checkup in the previous 2 years, who were diagnosed with depression before their SSc diagnosis, who were less than 20 years old, or who had missing data were excluded. To minimize the possibility of reverse causality, an analysis with a 1-year lag was performed. Kaplan-Meier analysis was conducted



Incidence of new-onset depression in SSc patients.

to assess the incidence of new-onset depression, and Cox proportional hazards regression was used to calculate adjusted and unadjusted hazard ratio (HR) and 95% CIs. HR for new-onset depression was adjusted for age, sex, smoking, drinking, physical activity, body mass index (BMI), income, diabetes, hypertension, and dyslipidemia.

Results: A total of 1,063 SSc patients (female 82.4 %) and 3,189 age-, sex-matched non-SSc controls with mean (SD) age of 53.1 (10.6) years were included in the analysis. During follow-up periods after 1 year of lag time, the cumulative incidence of new-onset depression was significantly higher in patients with SSc vs controls (38.7 vs. 27.7 IR per 1000 person-years). After adjusting for covariates (age, sex, smoking, drinking, physical activity, BMI, income, diabetes, hypertension, and dyslipidemia), the presence of SSc was associated with 38.1 % increased risk of new-onset depression (HR 1.381; 95% CI, 1.128-1.691), compared with controls. SSc disease itself was determined as an independent risk factor for new-onset depression in subjects with younger age (age < 65 years; HR 1.41; 95% CI 1.122-1.773), female gender (HR 1.415; 95% CI 1.139-1.759), and absence of regular exercise (HR 1.433; 95% CI 1.143-1.795), after adjusting for covariates. Interestingly, the risk of new-onset depression after SSc diagnosis was found to be relatively higher in the low-income group (HR 1.667; 95% CI 1.121-2.479 vs HR 1.303; 95% CI 1.028-1.650).

Conclusion: The present study suggests that the SSc diagnosis is associated with a significantly increased cumulative incidence and risk of new-onset depression. This association is more pronounced in female gender, younger age group, and those who do not exercise regularly. Regular assessment of the occurrence of depressive symptoms should be more emphasized in the patients with SSc after diagnosis.

Reporting of Race, Ethnicity, Sex, Gender, Socioeconomic Status and Representativeness of Race and Ethnicity in ANCA-associated Vasculitis Randomized Trials

Michele Iudici[1], Juan C. Rueda[2] and Xavier Puéchal[3], [1]Division of Rheumatology, Department of Internal Medicine Specialties, Geneva University Hospitals, Geneva, Switzerland, [2]Universidad de La Sabana, Chía, Colombia, Chia, Colombia, [3]National Referral Center for Rare Systemic Autoimmune Diseases, Paris, France

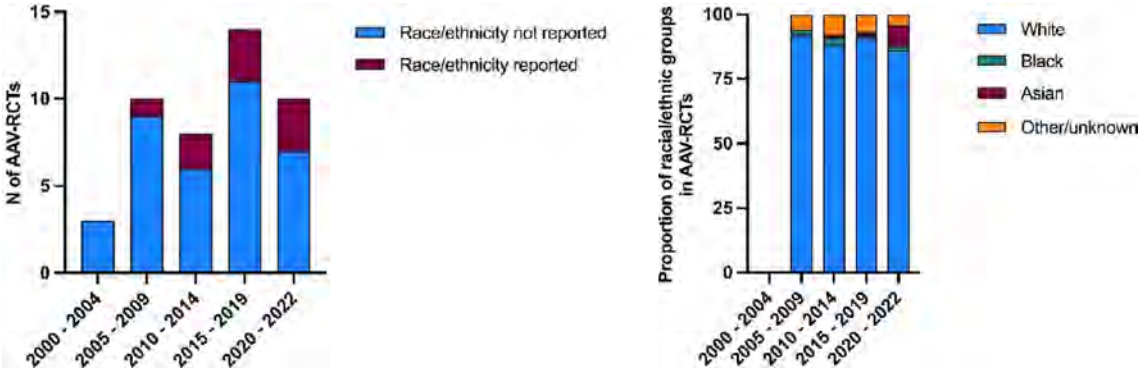
SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess how and to what extent race, ethnicity, sex, gender and socioeconomic status of participants are reported in ANCA-associated vasculitis (AAV) randomized controlled trials (RCTs), and to estimate the representativeness of different ethnic/racial groups in AAV-RCTs.

Methods: We searched all published AAV-RCTs indexed in PubMed and Embase since 2000. We retrieved information on main features of RCTs published from 2000 to 2022 and recorded for each study whether participant race/ethnicity, socioeconomic status (SES) and sex/gender were reported; how ethnicity/race was defined and assigned; the number of patients included for each racial/ethnic group. Descriptive statistics was used to summarize the main study results.

Results: We included 45 studies enrolling a total of 5053 patients (42% recruiting in more than one country), mostly published between 2011 - 2022 (62%), including patients with mainly granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) (68%), and mainly investigating pharmacologic interventions (98%). Information on race/ethnicity was available in 9 (20%) studies, 7 of which published ≥ 2011, including a total of 1445 (28%) patients. Figure 1 (left panel) shows the number of studies reporting race/ethnicity over time. Sex and/or gender of participants was reported in all but one study, but in 33 (73%) studies the authors clearly specified whether they reported the sex or the gender. In univariate analysis, we found a better reporting of race/ethnicity for larger studies including patients from different continents, funded by industry, and being published in higher impact factor journals. In studies where race/ethnicity was reported, White patients were the most represented (90%), followed by Asian (3%) and African American (2%). Figure 1 (right panel)presents temporal trends in the proportion of included participants across racial/ethnic groups in the overall sample of studies. Studies never reported



the reasons for collecting race/ethnicity or subgroup analyses focusing on race/ethnicity. Only one study provided the definitions used to identify different patient's origin. Only one paper reported patient SES.

Conclusion: Reporting of race/ethnicity and socioeconomic status deserves to be improved in AAV-RCTs. The non-White patients are underrepresented in AAV-RCTs reporting race/ethnicity of participants.

Efficacy and Safety of Mepolizumab During Maintenance Therapy in Patients with Eosinophilic Granulomatosis with Polyangiitis

Daiki Sakai[1], Kaichi Kaneko[1], Karin Furukawa[2], Mai Kawazoe[2], Yasuo Matsuzawa[3] and Toshihiro Nanki[2], [1]Division of Rheumatology, Department of Internal Medicine, Toho University Sakura Medical Center, Sakura, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Toho University School of Medicine, Ota-ku, Japan, [3]Division of Respiratory Medicine, Department of Internal Medicine, Toho University Sakura Medical Center, Sakura, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a small-vessel vasculitis characterized by asthma, hyper-eosinophilia, and progressive multiorgan organ involvement. Mepolizumab (MPZ) is a humanized monoclonal anti-interleukin-5 antibody that can reduce peripheral blood eosinophil. Previous studies demonstrated the efficacy and safety of MPZ for induction of remission in patients with relapsing or refractory EGPA, but the efficacy of MPZ during maintenance therapy in patients with EGPA remains unclear. This study is to clarify the efficacy and safety of MPZ during maintenance therapy compared with standard therapy for improving disease activity, preventing relapse, and reducing glucocorticoid (GC) dose.

Methods: This was a retrospective observational study. This study was approved by the Ethics Committees at Toho University School of Medicine (approval number; A22065). Patients, diagnosed with EGPA and treated at Toho University Sakura or Omori Medical Center between January 2016 and June 2022, were included if they met all of the following criteria:

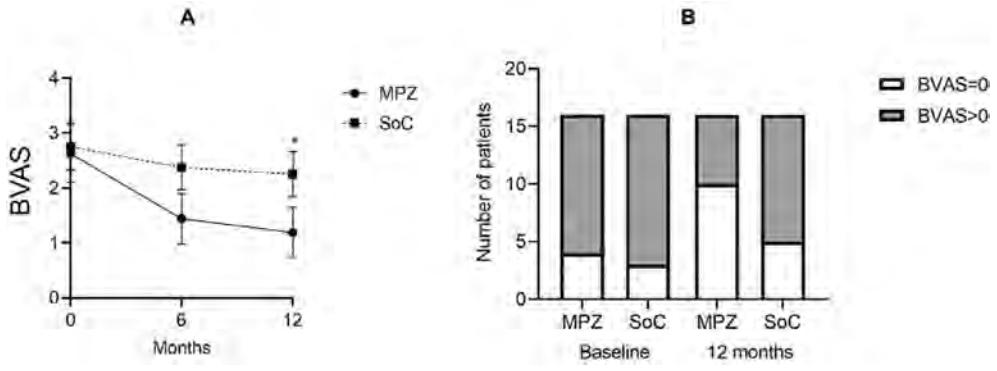

Figure1. Comparison of changes of BVAS between 12 months period in MPZ and SoC groups. A Changes in BVAS over 12 months, B Percentage of patients achieving BVAS = 0 at baseline and 12 months. BVAS; Birmingham Vasculitis Activity Score, MPZ; Mepolizumab, SoC; standard-of-care

prednisolone ≤ 20 mg/day, Birmingham Vasculitis Activity Score (BVAS) < 10 and administration of MPZ or immunosuppressants after 6 months or more from the onset of EGPA. Participants comprised patients with EGPA on MPZ (MPZ group: n = 16) and those on immunosuppressants (standard-of-care [SoC] group: n= 16). Disease activity was evaluated by BVAS as an index of disease activity and a predictor of the prognosis and outcome in patients with EGPA. GC toxicity was evaluated by GC toxicity index (GTI). We investigated BVAS, MPZ retention rate, absolute eosinophil count, cumulative GC dose and GTI after 12 months of MPZ or other immunosuppressant treatment in patients with EGPA.

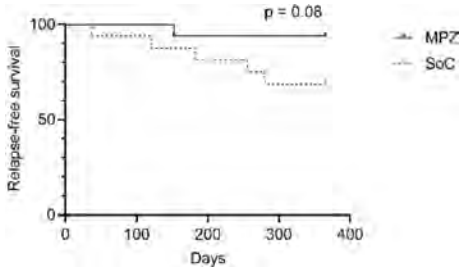

Figure 2. Relapse-free survival in MPZ and SoC groups. MPZ; Mepolizumab, SoC; standard-of-care

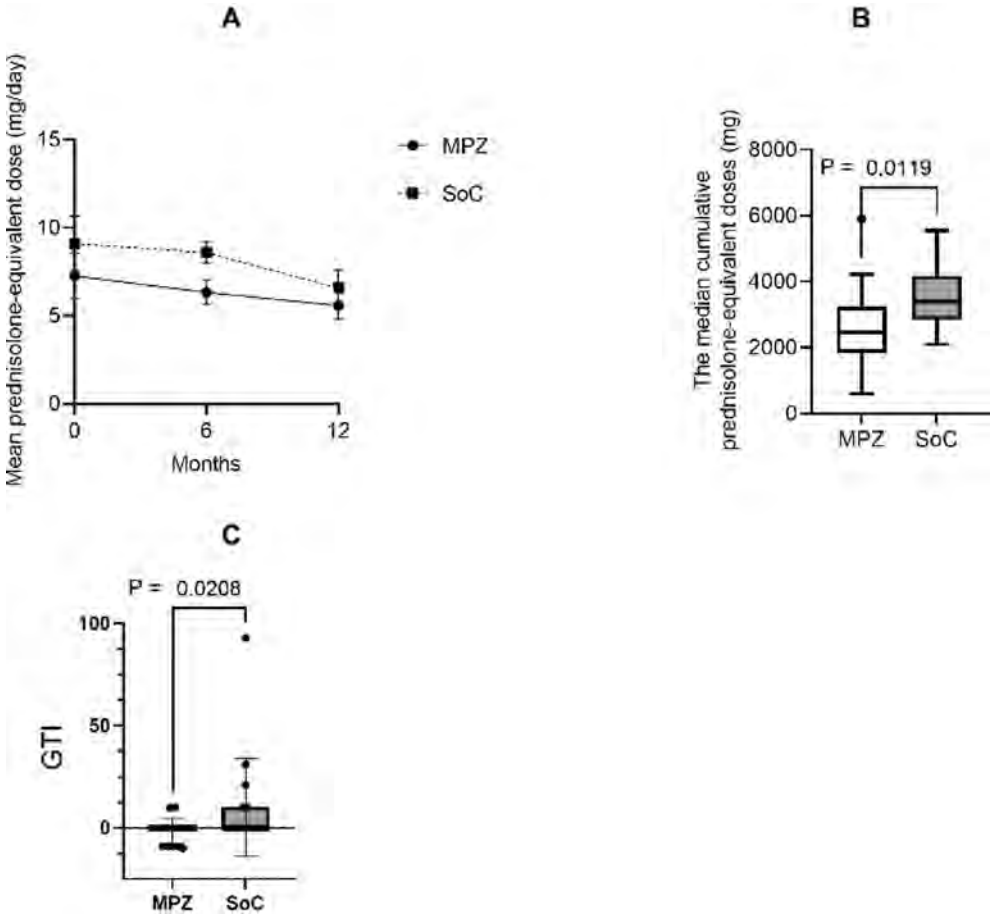

Figure3. Comparison of changes in glucocorticoid dose and GTI over 12 months period in MPZ and SoC groups. A. Changes in glucocorticoid dose over 12 months, B. Cumulative glucocorticoid dose at 12 months, C. GTI at 12 months. GTI; Glucocorticoid toxicity index, MPZ; Mepolizumab, SoC; standard-of-care

Results: There were no statistically significant differences in age, BMI, CRP, MPO-ANCA, IgE and CRP and BVAS between two groups at baseline. The median disease duration of MPZ group was significantly longer than that of SoC group [46.5 (22.5-122.8) months, 11.0 (3.2-29.0) months, P = 0.001]. The median absolute eosinophil count in MPZ group was significantly higher than that in SoC group [596.0 (114.5-784.2) /μL, 134.6 (2.0-262.1) /μL, P = 0.0034]. No significant differences were observed in the concomitant GC dose or the rate of concomitant immunosuppressant use between the groups. The BVAS at 12 months after treatment was significantly lower in MPZ group than in SoC group (P = 0.0367) (Figure 1). Percentage of patients achieving BVAS = 0 at 12 months tended to be higher in MPZ group than in SoC group. Relapse rates tended to be lower in the MPZ group (1 patient) than in the SoC group (6 patients) (P = 0.08) (Figure 2). Cumulative GC dose at 12 months were significantly decreased in the MPZ group than in the SoC group [2452 (1825-3256) mg, 3384 (2840-4179) mg, P = 0.0356] (Figure 3). The GTI at 52 weeks was significantly lower in the MPZ group than in the SoC group [0.0 (-9.0-0.0), 0.0 (0.0-10.0), P = 0.0208].

Conclusion: Our study demonstrated that administration of MPZ to EGPA during maintenance therapy reduced disease activity and relapse rates. MPZ in EGPA maintenance therapy may also have the potential to reduce cumulative GC dosage and GC toxicity.

Investigating the Impact of anti-IL5 Therapy in the Management of Relapsing and Refractory Eosinophilic Granulomatosis with Polyangiitis (EGPA); A Three Year Longitudinal Perspective and Beyond

allyson egan[1], Pasupathy Sivasothy[2] and David Jayne[3], [1]Trinity Health Kidney Centre, Tallaght University Hospital, Ireland, Dublin, Ireland, [2]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom, [3]University of Cambridge, Cambridge, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In the randomized, placebo-controlled MIRRA trial for relapsing and refractory eosinophilic granulomatosis with polyangiitis (EGPA), adjuvant therapy with 300mg anti-IL5 mAB Mepolizumab [MEPO] for 12 months (M), accrued longer times in remission, reduced steroid exposure and reduced relapse rates[2]. The aim of this study is to analyze

the outcome of 100mg MEPO monthly s/c for a minimum of 36 months. Changes to adjuvant immunosuppression and indications for anti-IL5 class switch from MEPO 100mg s/c to Benralizumab (BRZ) or Reslizumab (Res) were assessed.

Methods: In this observational study, 20 EGPA patients received anti-IL5 therapy for a minimum of 36M (range 49-68M). All commenced on 100mg s/c MEPO every four weeks. Anti-IL5 therapy switched to BRZ or Res due to partial response or intolerance. Assessment time points included MEPO commencement, 6, 12, 18, 24 and 36 months.

Results: Overall, there was a 50% reduction in steroid usage by 12 months. This continued to reduce to 24M, by which time 2 were off steroids and further 10 on weaning dose ≤ 5mg. Mean steroid dosage continued to decreased to 36 months. The number on adjuvant conventional immunosuppressants (ACIS), reduced over time from 10 at M0 to 4 by M24. Clinical benefits included ANCA serology normalized in all four positive patients by 12 months. Mean eosinophil count reduced from 0.42mg ±0.33 $X10^9$/L at M0 to 0.04±0.03 $X10^9$/L at 12 and 24M. BVAS reduced from median 5 [3-7], to 0 [0-1] by 24M. The change in mean FEV1 over 12 months was from (M0) 2.11±0.66 to (M12) 2.39±0.62 and FVC (M0) 3.42±0.87 to (M12) 3.67±0.93/105.60±20.47 respectively.

All 20 EGPA patients receiving anti -IL5 therapy, ranging from 49-68M remain on therapy. At 36M, 9 have remained on 100mg s/c MEPO. 10 (50%) have switched to an altenative anti-IL5 agent - 10 switched to benralizumab, 1 initially on benralizumab to reslizumab. 9/10 had achieved partial response prior to switch (reduction in steroids / relapse rate), 1/10 had no response. During the duration of the study,3 patients had a break of therapy, but all resumed anti-IL5 treatment with good response. Hence, all 20 remain on anti-IL5 beyond 24M. After 36M, one patient required cyclophosphamide along with anti-IL5 therapy for myocarditis. A further patient had Rituximab for EGPA/ Rheumatoid arthritis overlap between anti-IL5 agents.

Conclusion: In this study, there was a 50% reduction in steroid dosage by 12 months and steroid requirements continue to decrease to 36M. By 24 months 2 are steroid free and a further 10 on weaning dose ≤ 5mg. Furthermore, the number on adjuvant conventional immunosuppression reduced over the 24M (n=4 at 24M). This study demonstrates that anti-IL5 therapy serves as a favorable model for steroid and conventional immunosuppressant minimization in EGPA. Clinical benefits of reduction in BVAS, improved pulmonary function tests and reduced serum eosinophilia were recorded. The relapsing nature of EGPA places a dependency of therapy on steroids and this study demonstrated sustained and ongoing improvement annually with continued anti-IL5 therapy. Some participants required a switch in anti-IL5 agent.

Mepolizumab Can Achieve Glucocorticoid Discontinuation in Eosinophilic Granulomatosis with Polyangiitis Patients Regardless of IgE Levels: A Retrospective Study at a Single Center

Takashi Yamane[1] and Akira Hashiramoto[2], [1]Kakogawa Central City Hospital, Kakogawa, Japan, [2]Kobe University Graduate School of Health Sciences, Kobe, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a systemic vasculitis associated with eosinophil infiltration and Anti-neutrophil cytoplasmic antibody (ANCA) production. Mepolizumab (MPZ), an anti-IL-5 monoclonal antibody, facilitates good disease control, but the evidence for glucocorticoid (GC) discontinuation is still insufficient. In daily clinical practice, IgE levels along with peripheral blood eosinophil counts, ESR and CRP levels are used to evaluate disease activity, but they are limited in their ability to predict disease recurrence. In this study, we investigated the significance of IgE levels in the process of reducing or discontinuing GC in patients with EGPA.

Methods: Patients with EGPA at Kakogawa Central City Hospital as of January 2023 were classified into two groups: IgE high (>232IU/ml) and IgE low (≤232IU/ml) at the start of MPZ. The diagnosis of EGPA was based on the 1990 American College of Rheumatology criteria. The differences in patient backgrounds were examined by IgE, eosinophil count, Birmingham Vasculitis Activity Score (BVAS), daily prednisolone (PSL) dose and Vascular Damage Index (VDI). The rate of GC discontinuation and disease relapse were also examined. Statistical analysis was performed using SPSS version 26 (IBM Corp, Armonk, NY, USA), and P< 0.05 was considered significant.

Results: 27 patients had received MPZ for median 34 months. Patient background at the initiation of MPZ was median 59 years and 11 female (41%), disease duration was median 3 years (Table1). The eosinophil count was median 432/μl, CRP 0.06mg/dl, IgE 128 IU/mL, and 11 patients (41%) were in IgE high group. When compared the IgE levels at the initiation of MPZ, patients with high IgE were significantly younger. In addition, eosinophil counts were significantly higher in patients

without concomitant immunosuppressive drugs (Table 2). After MPZ initiation, eosinophil counts, BVAS and the daily PSL dose were significantly reduced in both groups while IgE levels did not change at all (Figure 1). Significant improvement in VDI was observed in patients with low IgE. GC discontinuation was achieved in 7 patients (64%) in the high IgE group and 6 (38%) in the low IgE group (p=0.182), and patients who achieved GC discontinuation had no disease relapse during a median follow-up of 19 months.1 patient with low IgE experienced a disease flare-up, which subsequently went into remission with continued administration of MPZ.

Conclusion: Although there is a limitation of single center retrospective data, more than half of the EGPA patients were able to discontinue GCs after approximately 3 years of treatment with MPZ. Notably, IgE levels did not appear to affect the reduction in GC or the achievement of GC discontinuation.

Analysis of Clinical Outcomes in Eosinophilic Granulomatosis with Polyangiitis (EGPA) Treated with Mepolizumab over 2 Years for Remission Induction or Maintenance: A Single Center Experience in Japan

SOKO KAWASHIMA[1], Yoshinori Komagata[1], Mitsumasa Kishimoto[2] and Shinya Kaname[1], [1]Kyorin University School of Medicine, Tokyo, Japan, [2]Kyorin University School of Medicine, Yokohoma, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Contrary to Western countries, MPO-ANCA-associated vasculitis (MPO-AAV) is dominant in Japan or Asian countries. It is possible that therapeutic responses to EGPA with mepolizumab (MPZ) are different in Asian countries. In addition, there have been few reports on the course of long-term treatment of EGPA with MPZ. We conducted a

retrospective analysis of the clinical database of the 25 patients of EGPA treated with MPZ in our hospital for remission induction or remission maintenance.

Methods: Twenty-five EGPA patients [19 females and 6 males. 11 MPO-ANCA positive and 14 MPO-negative.] have been treated with MPZ and followed for at least two years since 2018 in the department of Nephrology and Rheumatology in Kyorin University Hospital. They were analysed for clinical courses, including dose of administered corticosteroids (GC) and rates of flare-up. Remission was defined as Birmingham Vasculitis Activity Score (BVAS) was 0. Disease flare-up was defined as a state the disease activity increased and required intensification of immunosuppressive therapy.

They were divided into patients who were administered MPZ within 3 months of onset (early administration group) and who were started administration of MPZ during maintenance therapy at least 3 months after onset (during maintenance group).

Results: Of the 25 patients administered MPZ, 6 patients were categorized as the early administration group (1 male and 5 females; 4 patients were ANCA-positive and 2 patients were ANCA-negative) and the other 19 patients were categorized as the during maintenance group (5 males and 14 females; 7 patients were ANCA-positive and 12 patients were ANCA-negative). Mean ages at onset of groups of the early administration and the during maintenance were 52.2 and 55.0 years old, respectively.

In addition to GC and MPZ, cyclophosphamide (CY) was used in 17% (1/6) of the early group and in 53% (10/19) of the maintenance group.

After two years of therapy, mean doses of GC of each group were 1.7±2.1mg/day and 3.6±2.7mg/day, respectively. The achievement rates of GC dose below 5mg/day after two years treatment of the early group and the maintenance group were 100% and 47% (9/19), respectively. While no flare-up was observed in the early group, 26% (5/19) of the maintenance group developed flare-up after the start of MPZ therapy. These results were similar regardless of ANCA positivity. The incidence of serious infections requiring hospitalization and death after starting MPZ were 0 in both groups.

Conclusion: These results showed that long-term use of MPZ was effective and had an acceptable safety profile in EGPA patients. The use of MPZ from early stage might be recommended because the start of MPZ within 3 months of onset might reduce the dose of GCs after two years of therapy and the flare-up rate.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

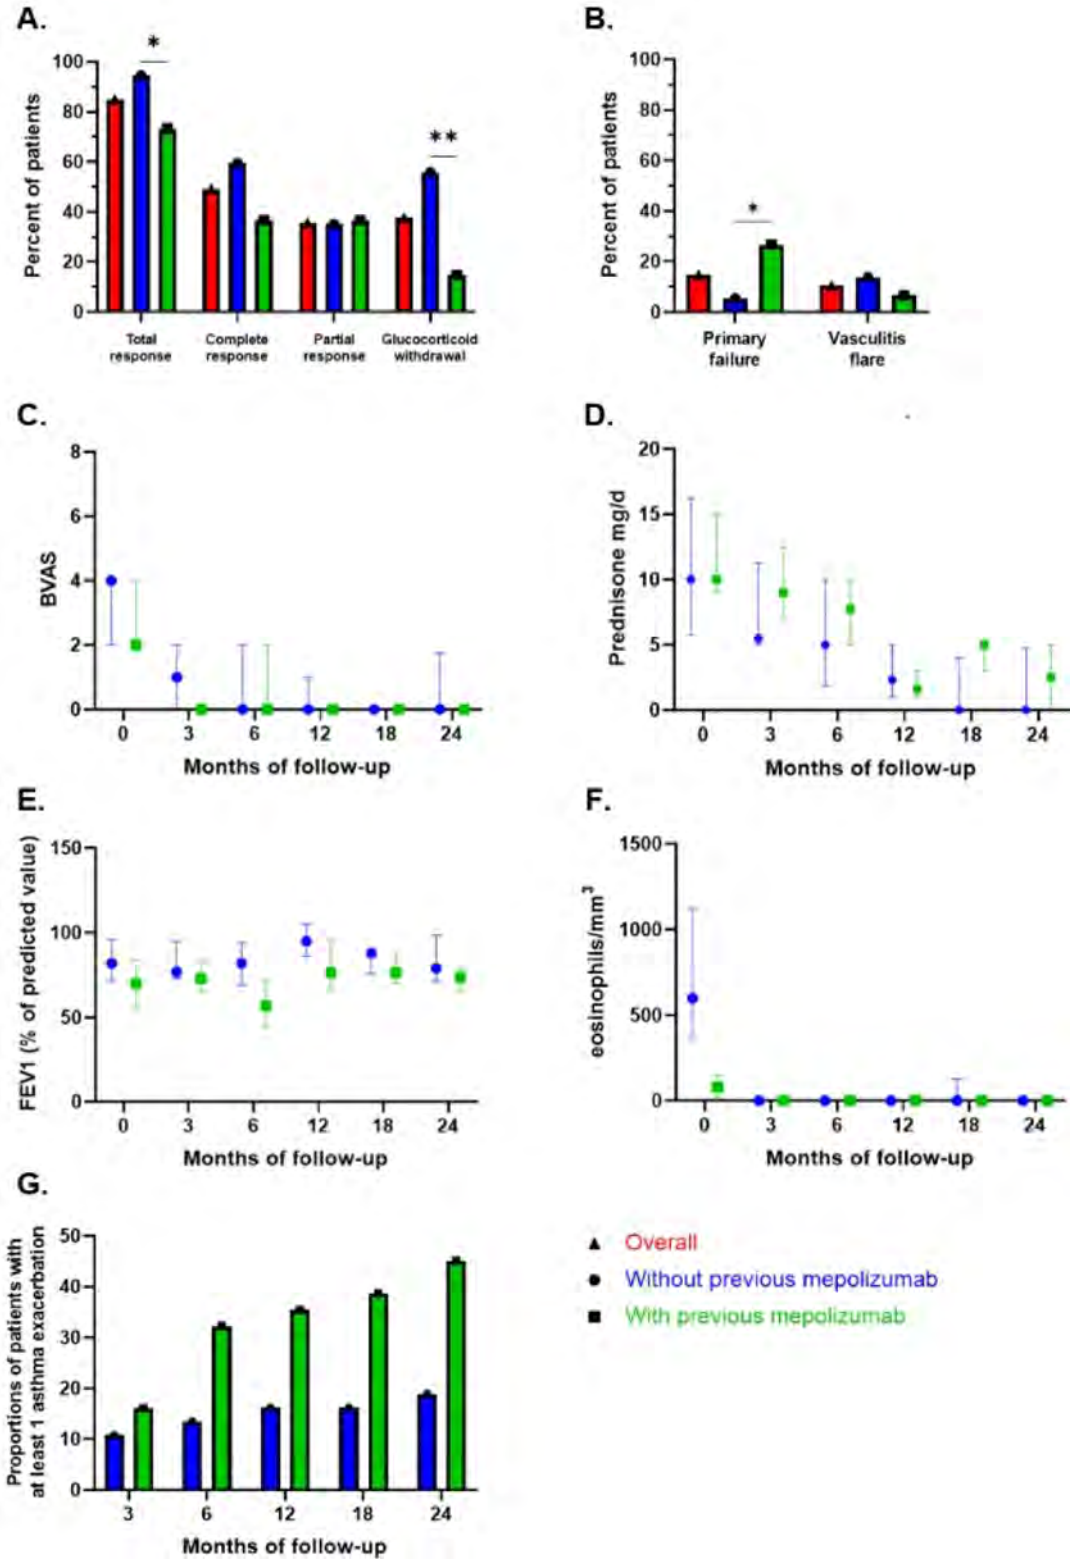
Background/Purpose: Gucocorticoid (GC)-dependant asthma and ENT exacerbations may persist in more than 80% of eosinophilic granulomatosis with polyangiitis (EGPA). The MIRRA trial demonstrated the efficacy of mepolizumab, a monoclonal antibody targeting interleukin-5 (IL-5), in treating these manifestations. However, roughly 70% of patients still required more than 4 mg per day of prednisone at the end of follow-up or relapsed. Benralizumab, a monoclonal-antibody targeting IL-5 receptor, causes profound eosinophil depletion in plasma, sputum, and tissues. However, its efficacy in GC-dependent manifestations remains to be determined in EGPA. We aimed to describe the use and efficacy of benralizumab in patients with refractory manifestations of EGPA.

Methods: We conducted a multicentre, retrospective study of patients with EGPA according to ACR/EULAR 2022 criteria and treated with benralizumab between February 2019 and February 2023. Complete response was defined as no disease activity (BVAS=0) and a prednisone dose ≤4 mg/day. Partial response was defined as no disease activity and a prednisone dose ≥4 mg/day. Total response was defined by either complete or partial response. Comparisons between patients with and without prior mepolizumab therapy were made using the Fisher exact test and the Mann Whitney test. Comparisons of responses or time to vasculitis flares were made with log-rank test.

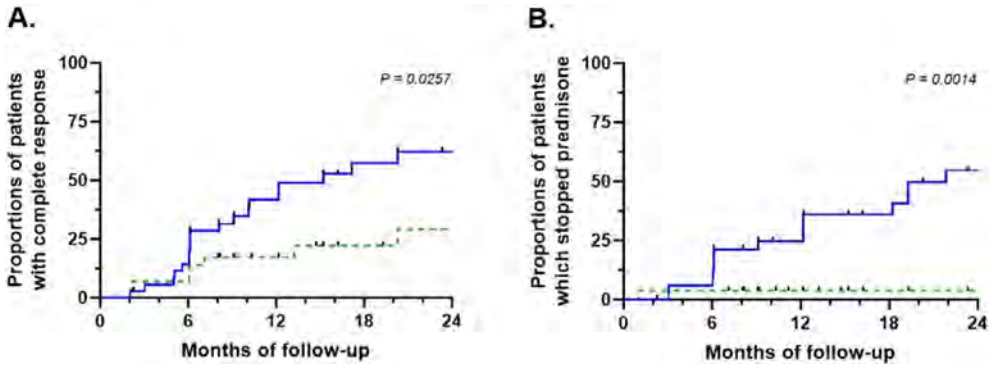
Results: Sixty-eight patients were included. The median age was 50 (IQR 39-63) years. ANCA were positive in 20 (29%) patients at EGPA diagnosis. Thirty-one patients (46%) had previously received mepolizumab, at a dose of 100 mg/month in 18/26 (69%) and 300 mg/month in 8/26 (31%). Primary or secondary failure of mepolizumab accounted for 16 patients (52%) and 15 patients (48%). The use of benralizumab was justified by uncontrolled asthma in 54 (81%), uncontrolled ENT manifestations in 27 (40%) and persistent glucocorticoid use in 48 (74%) patients. The asthma regimen (30 mg/month 3 times then every 2 months) was used in 63/66 patients (95%). Sixteen patients (24%) were concomitantly treated with another immunosuppressant.

Median follow-up after initiation of benralizumab was 23 months (IQR 9-34). Thirty-three patients (49%) had a complete response, 24 (36%) had a partial response and 10 (15%) failed to respond (response assessed in 67 patients). Of 57 patients with at least a partial initial response, 10 (18%) experienced secondary failure. GCs were discontinued in 23 patients (38%). Prior mepolizumab use was associated with more primary failure (p=0.034) and less GC discontinuation (p=0.001).

Vasculitis flares occurred in 7 patients (11%) and were associated with histological evidence of vasculitis and/or ANCA positivity at benralizumab initiation (p=0.010). Six infections requiring specific treatments were reported during follow-up.



Response to benralizumab (A) and failure to benralizumab (B) among patients with eosinophilic granulomatosis with polyangiitis, according to previous treatment by mepolizumab. Variation in disease activity using the Birmingham Vasculitis Activity Score (BVAS) (C), daily dose of prednisone (D), variation in the forced expiratory volume in 1 second (FEV1) (E) and eosinophils count (F) among patients with eosinophilic granulomatosis with polyangiitis treated with benralizumab, according to previous treatment by mepolizumab. Accumulated proportions of patient with at least one asthma exacerbations during follow-up (G). Values in C, D, E, and F are the median and interquartile range. IS = immunosuppressant; * = $P < 0.05$; ** = $P < 0.01$ (Fisher exact test).



Kaplan-Meier survival curve of complete response (A) and withdrawal of glucocorticoids (B) among patients with eosinophilic granulomatosis with polyangiitis treated with benralizumab, according to previous treatment by mepolizumab. Blue full line = without previous mepolizumab; green dotted line = with previous mepolizumab. (Logrank test)

Conclusion: Benralizumab appears to be an effective treatment for refractory asthma or ENT manifestations in EGPA and allows glucocorticoid withdrawal. However, its efficacy was lower after prior mepolizumab failure.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab is a first-line treatment for remission induction and the prevention of relapse in ANCA-associated vasculitis (AAV). There is a paucity of real-world data on the long-term safety of rituximab in patients with AAV. This study aimed to estimate the incidence of safety events and to compare time to first SAE between a rituximab cohort and a cohort treated with non-rituximab therapy up to 15 years from first exposure.

Methods: RIVAS was a single-center, retrospective observational study including patients with GPA/MPA who had received rituximab (MabThera) or other treatments between 2003 and 2017 at Addenbrooke's hospital, Cambridge, UK followed up until 30 September 2018. Time 0 was defined as either initiation of MabThera treatment for the rituximab cohort or time of first disease flare/diagnosis for the control cohort. The primary endpoint was time to first SAE. Key secondary endpoints were time to first pre-categorized SAE including serious infection and cardiovascular disorder. Time to second SAE was an exploratory endpoint.

Results: 392 GPA/MPA patients were enrolled: 247 in the rituximab and 145 in the control cohort with a total of 2,217 person-years (mean study duration 5.7 years). Mean age was 61 years (SD 16.3), 52% were female, 77% had GPA and 23% MPA. The median disease duration at baseline was 25.0 months (range: 0-393.7) in the rituximab and 1.6 months (range: 0-272.6) in the control arm. There were differences in the baseline characteristics between groups reflecting the predominant use of rituximab for relapsing or refractory disease. Three hundred and eighty-six SAEs occurred in 134 patients (54%) in the rituximab and 114 in 58 patients (40%) in the control groups (Table 1). Sixty-five patients (26%) in the rituximab group and 18 (12%) in the control group experienced serious infections. Twenty-one patients (9%) in the rituximab group developed severe hypogammaglobulinemia (IgG < 3 g/L) requiring change of treatment and 19 (8%) received immunoglobulin replacement for hypogammaglobulinemia compared to 3 (2%) and 1 (0.7%) of patients in the control group. There were no differences in incidence rates for malignancy, cardiovascular events or renal insufficiency between groups. Time to first SAE was shorter in the rituximab group than in the control group (HR 1.55, 95%CI 1.07-2.26, p=0.022) (Figure 1). Time to first serious infection was shorter in the rituximab group (HR 2.34, 95%CI 1.079-5.07, p=0.031), while no between-group differences were found for other SAE categories. Also, a shorter time to second SAE was observed in the rituximab group. Predictors of first SAE were higher vasculitis damage scores and chronic pulmonary or kidney disease. The relative risk of serious infection and additional safety events was higher in the rituximab group (unadjusted relative risk (RR) 2.12, 95%CI 1.31-3.43; RR 1.86, 95%CI 1.30-2.65, respectively).

Conclusion: Over 40% of patients with GPA/MPA experienced at least one SAE in their disease course. Although the risk of first and second SAE was higher in the rituximab group, baseline imbalances, particularly in disease duration and prior immunosuppressive use, due to the study design were a cause of bias and results should be interpreted with caution.

Table 1. Serious adverse events (SAEs) by event category for rituximab and control groups

Event type	Events (n)/ Patients (n (%)) Rituximab	Events (n)/ Patients (n (%)) Control
All SAEs	386/ 134 (54%)	114/ 58 (40%)
Serious infection	121/ 65 (26%)	28/ 18 (12%)
Cardiovascular disorder	28/ 23 (9%)	17/ 15 (10%)
Hematological events	9/ 8 (3%)	2/ 2 (1%)
Malignant events	11/ 11 (4%)	8/ 8 (6%)
Renal Insufficiency	19/ 14 (6%)	19/ 15 (10%)
PML	1/ 1 (0.4%)	0/ 0 (0%)
Additional safety events*	197/ 95 (38%)	40/ 30 (21%)

*This category includes 'Any other SAEs of unclear categorization (most common)', 'Hypogammaglobulinemia (IgG<3g/L) requiring change of treatment', 'Hypogammaglobulinemia requiring immunoglobulin replacement', 'Serious disease flares', 'Serious infusion-related reaction' and 'Vaccination failure'.
n, number; PML, progressive multifocal leukoencephalopathy.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: B-cell depletion induced by rituximab (RTX) in ANCA-associated vasculitis (AAV) is a risk factor for hypogammaglobulinemia. Aggregating data on the kinetics of gammaglobulin levels during RTX and its association with the risk of relapse and serious infection is of interest.

Methods: We conducted a retrospective single-centre cohort study including patients with granulomatosis with polyangiitis and microscopic polyangiitis who received RTX maintenance therapy between January 2010 and November 2022. Gammaglobulin levels were measured before induction therapy (month -6), at initiation of RTX maintenance therapy (month 0) and every 6 months during maintenance therapy. Patients were categorized into several groups: (1) patients with gammaglobulin levels < 6 g/L at initiation month 0; (2) patients with gammaglobulin decline between induction and initiation of maintenance therapy >25%; and finally (3) patients responding to both criteria simultaneously. Our primary objective was to assess the impact of gammaglobulin decline on the risk of vasculitis relapse and serious infections.

Results: We included 98 patients, all of whom fulfilled the ACR/EULAR classification criteria of AAV. The median gammaglobulin level at initiation of induction therapy was 10.4 g/L (IQR 8.4–12.9) and it significantly decreased to 7.5 g/L (5.9-8.8) at initiation of maintenance therapy with a median decrease of -25% (IQR -13.8 – -42.4). Gammaglobulin levels remained stable throughout follow-up **(Figure 1).** Factors associated with gammaglobulin level decline >25% and gammaglobulin level < 6 g/L after induction were age > 60 years (OR 4.1; 95%CI 1.2–14.7), baseline gammaglobulin levels < 10 g/L (OR 5.9; 95%CI 1.7–25.4) and use of pulses of methylprednisolone at induction (OR 4.7; 95%CI 1.4–2). Gammaglobulin decline was not associated with the risk of relapse. In contrast, serious infection-free survival was significantly poorer in patients with both gammaglobulin < 6 g/L and gammaglobulin decline >25% (adjusted HR 2.3; 95%CI 1.0–5.1) **(Figure 2)** and in those who received pulses of methylprednisolone (HR 5.6; 95%CI 2.3–13.4) **(Table 1).**

Table 1. Odds ratios (95% CI) for the risk of severe infection (N=98)

			Risk of severe infection	
	Overall (N=98)	**N events (%)**	**Univariate OR (95%CI)**	**Multivariate OR (95%CI)**
Gammaglobulin <6 g/L at month 0	26 (26.5)	4 (15.4)	2.6 (1.2-5.6)	
Gammaglobulin decline >25% between induction and month 0	49 (50)	6 (12.2)	4.4 (1.8-10.9)	
Gammaglobulin <6 g/L AND decline >25%	19 (19.4)	4 (21.1)	3.2 (1.5-7.0)	2.3 (1.0-5.1)
Pulses of methylprednisolone at induction	31 (31.6)	31 (31.6)	6.8 (2.9-15.9)	5.6 (2.3-13.4)

HR=Hazard ratios; 95% CI = 95% confidence interval.

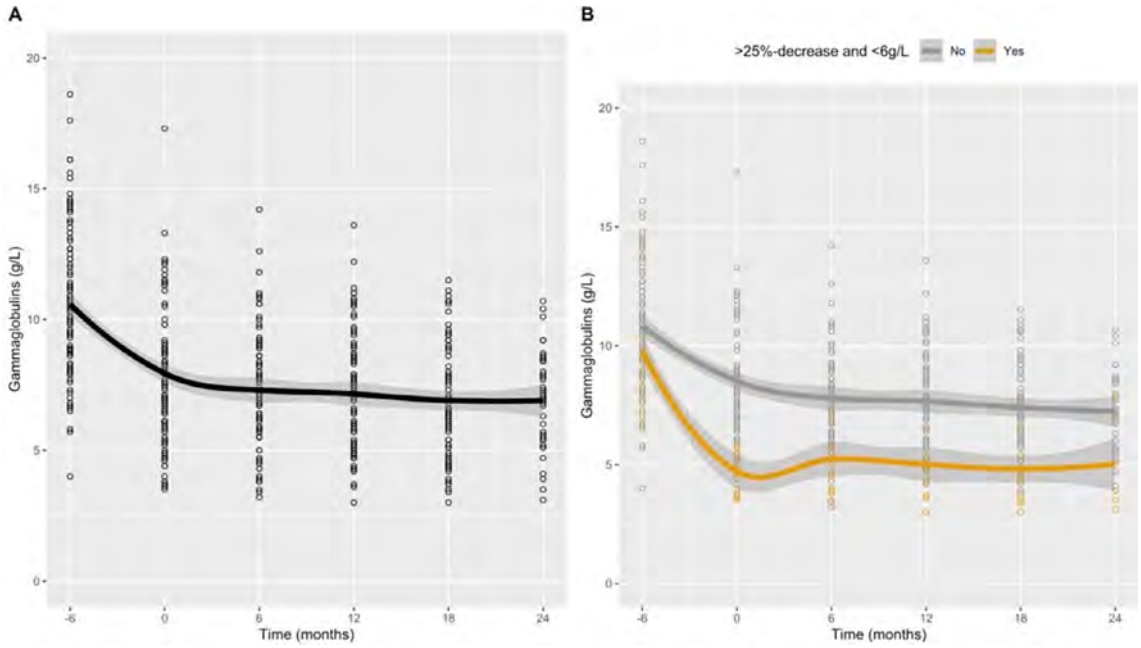

Figure 1. Evolution of gammaglobulin levels after induction and maintenance therapy with RTX. Panel A shows the evolution of gammaglobulin levels after induction and maintenance therapy for the whole population (N=98). Panel B shows the evolution of gammaglobulin levels after induction and maintenance therapy comparing the group with or without both gammaglobulin decrease >25% and gammaglobulin level <6 g/L.

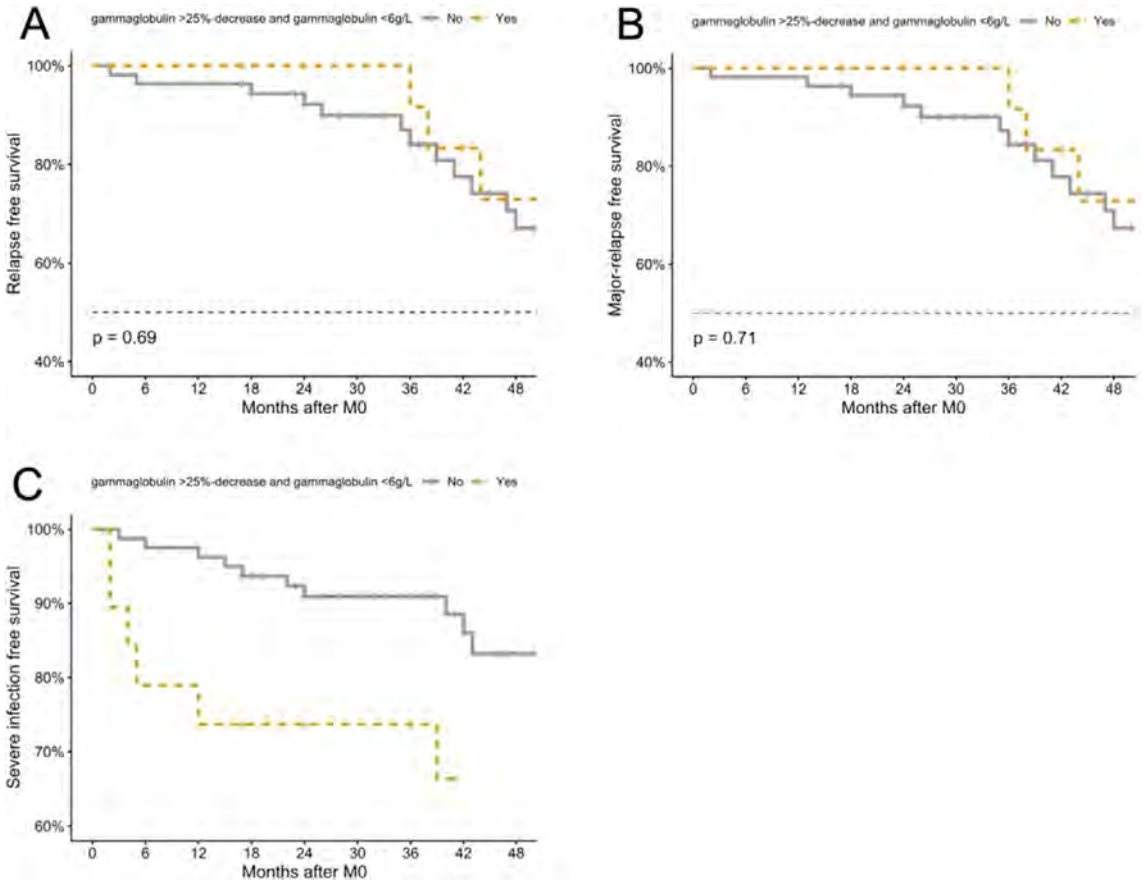

Figure 2. Kaplan–Meier plots of the risk of vasculitis relapse, major relapse and severe infections. Panel A shows the time to the first relapse according to gammaglobulin decline and gammaglobulin level at month 0. Panel B shows the time to the first major relapse according to gammaglobulin decline and gammaglobulin level at month 0. Panel C shows the time to the first severe infection according to gammaglobulins decline and gammaglobulin level at month 0.

Conclusion: Older age, low gammaglobulin levels and pulses of methylprednisolone at induction are associated with greater gammaglobulin decline after induction. Although it is not associated with a lower risk of vasculitis relapse, gammaglobulin decline is associated with an increased risk of serious infections.

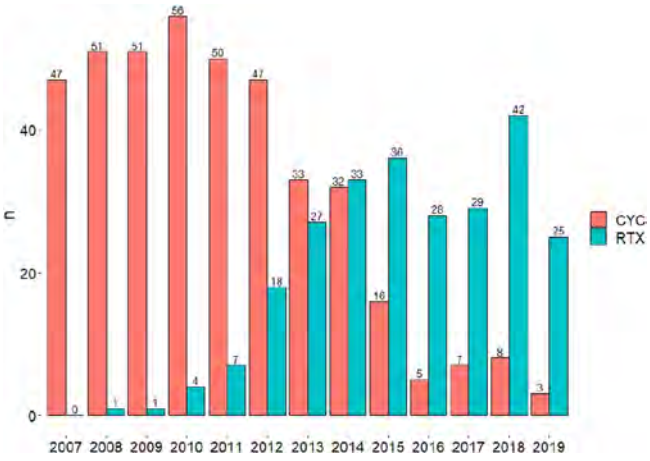
SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

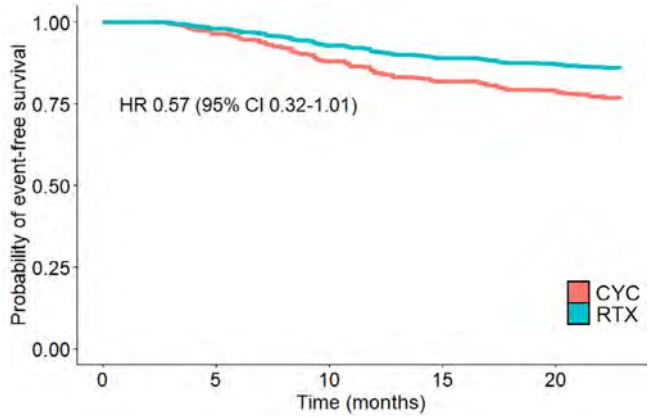
Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), including Granulomatosis with Polyangiitis (GPA) and Microscopic Polyangiitis (MPA), often manifests with life-threatening complications. Cyclophosphamide (CYC) and rituximab (RTX) are the mainstay of remission induction treatment in severe AAV, but their safety and efficacy have not been comprehensively compared in "real-world" settings.

Methods: We conducted a retrospective cohort study using administrative data from the

2006–2019 IBM® MarketScan® Commercial Database. We identified working-age adults (age 18-64 years) with a new diagnosis of GPA/MPA, using the International Classification of Diseases (ICD) version 9 or 10 codes, who received induction treatment with CYC or RTX. We used propensity score matching and a Cox proportional hazard model to estimate hazard ratios (HRs) for the first major disease relapse and severe infection.



Absolute number of patients treated with each induction medication, by year. The data clearly shows a shift in practice over time, with RTX gradually becoming the medication of choice. CYC, cyclophosphamide; RTX, rituximab



Adjusted event-free survival for the primary outcomes, in the first 24 months following induction, by induction medication. 3A: Major relapse; 3B: Severe infection. Curves were plotted using multivariate Cox proportional hazards model, conducted following propensity score matching. CYC, cyclophosphamide; RTX, rituximab; HR, hazard ratio; CI, confidence interval

Variable	First Major Relapse HR (95% CI)	p [a]	First Severe Infection HR (95% CI)	p [a]
Full cohort (N = 657)				
Induction with RTX	0.63 (0.38-1.04)	0.073	0.63 (0.40-0.99)	**0.044**
Age	1.00 (0.98-1.02)	0.842	1.01 (0.98-1.03)	0.575
Female sex	1.13 (0.78-1.64)	0.521	1.07 (0.72-1.57)	0.74
Elixhauser comorbidity score	1.02 (0.97-1.06)	0.45	1.07 (1.02-1.12)	**0.004**
GPA diagnosis	1.05 (0.67-1.64)	0.835	1.02 (0.63-1.65)	0.93
Major BVAS score at baseline	1.04 (1.02-1.06)	**<0.001**	1.04 (1.02-1.06)	**<0.001**
Additional exposure to CYC [b]	0.59 (0.27-1.32)	0.2	1.65 (0.70-3.89)	0.25
Additional exposure to RTX [b]	0.75 (0.38-1.47)	0.4	0.78 (0.33-1.86)	0.57
Exposure to DMARDs [b]	0.63 (0.38-1.02)	0.063	1.38 (0.81-2.36)	0.23
Propensity score matching cohort (N = 454)				
Induction with RTX	0.57 (0.32-1.01)	0.052	0.63 (0.39-1.02)	0.059
Age	1.00 (0.98-1.03)	0.69	1.01 (0.98-1.03)	0.61
Female sex	1.06 (0.67-1.68)	0.81	0.97 (0.59-1.60)	0.92
Elixhauser comorbidity score	1.02 (0.97-1.08)	0.48	1.02 (0.95-1.08)	0.62
GPA diagnosis	0.97 (0.55-1.73)	0.92	0.74 (0.42-1.33)	0.32
Major BVAS score at baseline	1.05 (1.03-1.08)	**<0.001**	1.06 (1.03-1.08)	**<0.001**
Additional exposure to CYC [b]	0.80 (0.28-2.30)	0.68	1.68 (0.54-5.22)	0.37
Additional exposure to RTX [b]	0.80 (0.36-1.78)	0.59	0.66 (0.22-1.99)	0.46
Exposure to DMARDs [b]	0.66 (0.34-1.26)	0.2	1.75 (0.93-3.29)	0.081

[a] Using Cox proportional hazard model, $\alpha < 0.05$

[b] Time-dependent covariates: exposure to medication at the time of the event
For CYC/RTX: exposure more than 180 days after the induction date
For DMARDs: exposure at any time

HR, hazard ratio; CI, confidence interval; RTX, rituximab; GPA, granulomatosis with polyangiitis; BVAS, Birmingham Vasculitis Activity Score; DMARDs, disease ,modifying anti-rheumatic drugs

Multivariable-adjusted risk factors a for the primary outcomes in the first 24 months following induction

Results: We identified 657 patients, 406 (61.8%) of whom were treated with CYC and 251 (38.2%) with RTX. Patients in the CYC group had worse disease severity scores at baseline.

In the 24 months after induction, 146 (22.2%) patients experienced a major disease relapse and 129 patients (19.6%) had severe infection. Multivariate analysis with propensity score matching showed no significant differences between RTX and CYC in the likelihood of experiencing major relapse (HR 0.57, 95% CI 0.32-1.01) or severe infection (HR 0.63, 95% CI 0.30-1.02).

Conclusion: In a nationally representative sample of working-age adults, RTX was found to be comparable to CYC for remission induction treatment in severe AAV.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The orally administered C5a receptor inhibitor avacopan is approved for the therapy of ANCA-associated vasculitis (AAV) in combination with rituximab or cyclophosphamide and shows significant steroid sparing effect as recently published [1]. In severe disease manifestations, preferentially with multiple organ involvement, combined immunochemotherapy of cyclophosphamide plus rituximab can be considered using protocols analogous to the RITUXIVAS

Table 1. Characteristics of ANCA-associated vasculitis patients (n=12)

AAV patients	
Diagnosis GPA/MPA (n)	10/12
ANCA status PR3/MPO (n)	11/1

ANCA=anti-neutrophile cytoplasm antibody; GIT=gastrointestinal tract

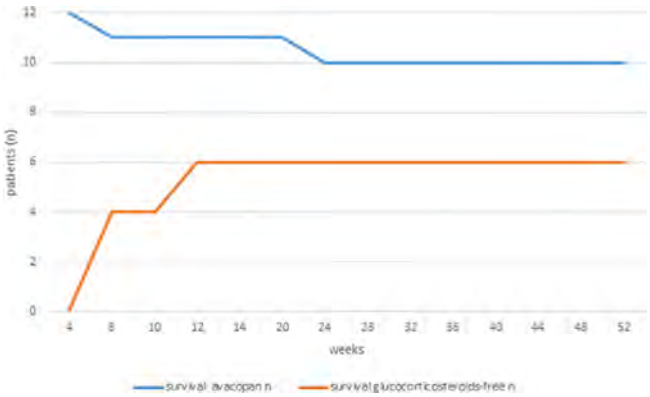

Figure 1: Survival of avacopan treatment and corresponding glucocorticosteroid free in ANCA-associated vasculitis patients (n=12) over 52 weeks

study [2] as well as to CycLowVas study [3]. However, there is no experience with the implementation of avacopan in this therapeutic setting.

Methods: Here we present the case serial of 12 patients with AAV, all of whom had severe renal and pulmonary involvement and received induction therapy with high-dose glucocorticoids and cyclophosphamide in combination with rituximab. In addition, patients received avacopan for rapid steroid reduction/slowing down later in the course (from week 2-6), following the above mentioned study [1] in which up to 20mg prednisolone equivalent was given in addition to avacopan as needed. Patients` characteristics are shown in Table 1.All patients were suffering from kidney and lung manifestations and additionally at least one more organ involvement of nervous system, HNO tract, eye, joints or gastrointestinal tract. Three of them had previous courses of cyclophosphamide due to relapsing disease. All patients were treated between February 2022 and June 2023 in the University Hospital Minden (n=10), University Clinic department of Goettingen (n=1), and the Hospital of Holstein-University in Luebeck; the mean observation time was 44.1 weeks (8-72); supportive treatment including anti-infective prophylaxis were administered according to standard treatment regimes.

Results: Avacopan were stopped in 2 patients, one due to relapsing disease in week 24, and one due to infectious complication in week 4; the remaining 10 patients on avacopan achieved stable remission of AVV, in 6 cases even with successful discontinuation of glucocorticosteroids on average after 11.8 weeks (from 6 to 20; figure 1). 4-6 months after induction therapy, patients received rituximab maintenance therapy in accordance with guidelines (n=8).

Conclusion: Avacopan appears to favor steroid tapering in severe courses of AAV on combined therapy with cyclophosphamide plus rituximab. However, due to the small number of cases and the retrospective evaluation, the results have to be confirmed by studies with larger number of cases.

Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: In the Phase 3 ADVOCATE trial comparing avacopan to a prednisone taper, 81% of patients with ANCA-associated vasculitis (AAV) had renal involvement based on the Birmingham Vasculitis Activity Score. This renal subgroup had a baseline mean estimated glomerular filtration rate of 45.1 mL/min/1.73 m^2.

Methods: This post hoc analysis evaluated remission, glucocorticoid (GC) use, GC toxicity index (GTI), health-related quality of life (HRQoL by SF-36), and safety in patients with baseline renal involvement for those treated with avacopan (N=134) versus a prednisone taper (N=134).

Sustained disease remission week 52, n (%)	91 (67.9%)	76 (56.7%)
Total all-source glucocorticoid dose during 52-week period, mg (mean / median)	1589 / 575	3801 / 3028
GTI-CWS at weeks 13 / 26, LSM ± SEM	24.1 ± 3.9 / 38.9 ± 3.9	37.7 ± 4.0 / 58.5 ± 4.0
GTI-AIS at weeks 13 / 26, LSM ± SEM	8.5 ± 3.9 / 11.2 ± 4.0	24.3 ± 4.0 / 24.3 ± 4.0
SF-36 PCS Score, Change from baseline at weeks 26 / 52, LSM ± SEM	4.8 ± 0.8 / 4.9 ± 0.8	1.9 ± 0.8 / 3.1 ± 0.8
SF-36 MCS Score, Change from baseline at weeks 26 / 52, LSM ± SEM	5.2 ± 0.9 / 6.6 ± 1.0	3.5 ± 1.0 / 5.1 ± 1.0
Serious Adverse Events, n patients (%), n events	61 (45.5%) 104 events	65 (48.5%) 148 events
Deaths, n (%)	2 (1.5%)	3 (2.2%)

AIS, aggregate improvement score; CWS, cumulative worsening score; eGFR, estimated glomerular filtration rate; GTI, glucocorticoid toxicity index; GPA, granulomatosis with polyangiitis; LSM, least squares mean; MCS, mental component summary; MPA, microscopic polyangiitis; PCS, physical component summary; SEM, standard error of the mean; SF-36, Short Form-36.

Results: Compared to the overall study population, for this subgroup the mean age was similar (62 vs 61 years), but there was a slightly higher proportion of patients with newly diagnosed AAV (74% vs 69%), myeloperoxidase+ ANCA (63% vs 57%), microscopic polyangiitis (52% vs 45%), and use of cyclophosphamide (39% vs 35%). The avacopan group achieved a higher sustained remission rate at week 52 (67.9% vs 56.7%) while receiving a (mean/median) 2.4-/5.3-fold less total GC dose than the prednisone taper group (**Table 1**). The GTI cumulative worsening and aggregate improvement scores were lower at weeks 13 and 26 in the avacopan group compared to the prednisone group. At weeks 26 and 52 the avacopan group reported a greater improvement in SF-36 physical and mental component summary scores. Serious adverse events occurred in 46% (2 deaths) and 49% (3 deaths) of patients in the avacopan and prednisone groups, respectively.

Conclusion: In the ADVOCATE trial, patients with AAV with baseline renal involvement treated with avacopan achieved higher sustained remission rates while receiving less GCs, experiencing less GC-related toxicity, and reporting greater improvements in HRQoL versus those treated with a prednisone taper.

Report on Twelve Patients with Diffuse Alveolar Hemorrhage in the Phase 3 Trial of Avacopan for the Treatment of ANCA-Associated Vasculitis

Ulrich Specks[1], David Jayne[2] and **Peter Merkel**[3], [1]Mayo Clinic, Rochester, MN, [2]University of Cambridge, Cambridge, United Kingdom, [3]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Although respiratory tract involvement in ANCA-associated vasculitis (AAV) is frequent and associated with increased mortality, studies focusing on diffuse alveolar hemorrhage (DAH) in AAV are uncommon. DAH can progress rapidly and is often life-threatening. The 330-patient ADVOCATE trial was an active-controlled, randomized, Phase 3 study that compared avacopan to a prednisone-tapering regimen and enrolled 12 patients with DAH.

Methods: This post hoc analysis focuses on outcomes of the 12 patients with DAH at baseline on the basis of BVAS. Patients requiring invasive pulmonary ventilation support at screening were excluded from enrollment. Remission at Week 4 was defined as BVAS=0. Remission at Week 26 was defined as BVAS=0 and no glucocorticoid (GC) use in the previous 4 weeks. Sustained remission at Week 52 was defined as BVAS=0 and no GC use in the previous 4 weeks, remission at

Table 1: Baseline Characteristics, Glucocorticoid Dose, Pulmonary Manifestations, Remission, and Relapses for Patients with Diffuse Alveolar Hemorrhage at Baseline in the ADVOCATE trial of Avacopan for ANCA-Associated Vasculitis

Case	Study Treatment/ Background Therapy	Age, Sex, Type of AAV, Race, ANCA status, AAV disease status	Cumulative GC Dose (mg)		Pulmonary Manifestations of AAV			Remission (weeks 4 and 26) Sustained remission (week 52)			Relapse

10	Prednisone/ Rituximab	55, M, White, GPA, PR3+, Relapsed	0	1558	DAH, Infiltrate	None	None	No	Yes	No	Yes
11	Prednisone/IV Cyclophosphamide	57, M, White, GPA, PR3+, Newly diagnosed	1945	1368	DAH, Infiltrate	None	None	Yes	Yes	Yes	No
12	Prednisone/IV Cyclophosphamide	48, M, White, GPA, PR3+, Relapsed	2225	1597	DAH, Infiltrate, Endobronchial disease	Infiltrate, Endobronchial disease	None	No	No	No	Yes

AAV, ANCA-associated vasculitis; DAH, diffuse alveolar hemorrhage; GPA, granulomatosis with polyangiitis; IV, intravenous; MPA, microscopic polyangiitis; MPO, myeloperoxidase; PR3, proteinase 3

Week 26, and no relapse between Week 26 and Week 52. Relapse was defined as a return of vasculitis activity on BVAS with ≥1 major item, ≥3 minor items, or 1 or 2 minor items for at least two consecutive trial visits.

Results: Five patients in the avacopan group and 7 in the prednisone taper group had DAH at baseline. Of the 12 patients, 11 (92%) had granulomatosis with polyangiitis, 10 (83%) received rituximab background therapy, 8 (67%) were male, 8 (67%) had PR3-ANCA, and 6 (50%) were newly diagnosed (**Table 1**). BVAS was 19.5±5.4 (mean±SD) at baseline. The total dose of GCs (median / mean) from all sources for the avacopan and prednisone taper groups, respectively, were 300 / 585 mg vs 1945 / 1616 mg during the screening period (day -14 to -1) and 625 / 508 mg vs 1627 / 1866 mg during day 1 to 29. DAH was no longer active by Week 4 for all patients (**Table 1**). Remission rates in the avacopan and prednisone taper groups, respectively, were 80.0% (4/5) and 71.4% (5/7) at Week 4, 80.0% (4/5) and 71.4% (5/7) at Week 26, and 80.0% (4/5) and 57.1% (4/7) at Week 52. No patients in the avacopan group and 2 in the prednisone taper group relapsed during the treatment period. One patient in the avacopan group (case 3) was hospitalized twice for pneumonia. Two in the prednisone taper group had hospitalizations, twice for one patient (case 9) due to hepatocellular injury andherpes keratitis and once for the other patient (case 12) for worsening of AAV. Prednisone taper treatment was not completed in case 9 due to a serious adverse event of lymphopenia (day 33). None of the patients required mechanical ventilation during the study.

Conclusion: In the ADVOCATE trial of patients with AAV, the outcomes of patients with DAH were similar for those treated with avacopan versus with a prednisone taper. None of the patients with DAH in the avacopan group progressed to respiratory failure, despite receiving a minimal dose of GCs. In this report on a small number of patients, overall remission rates were higher in the avacopan group than the prednisone taper group at Weeks 4, 26, and 52, although all pulmonary manifestations of AAV were resolved in all patients by Week 26. These data provide support for the treatment of DAH in AAV using avacopan with a lower dose of GCs.

Efficacy and Safety of Avacopan in Patients with ANCA-Associated Vasculitis Receiving Rituximab in a Phase 3 Trial

Duvuru Geetha[1], **Anisha Dua**[2], Huibin Yue[3], Carlo Salvarani[4], David Jayne[5] and Peter Merkel[6], [1]Johns Hopkins University, Baltimore, MD, [2]Northwestern University, Chicago, IL, [3]Amgen, Inc., Thousand Oaks, CA, [4]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [5]University of Cambridge, Cambridge, United Kingdom, [6]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The randomized, double-blind, double-dummy, controlled Phase 3 ADVOCATE trial tested whether avacopan, an oral selective C5a receptor inhibitor approved for the treatment of ANCA-associated vasculitis (AAV), could replace a glucocorticoid (GC)-tapering regimen. Randomization was stratified according to vasculitis disease status (newly diagnosed or relapsing), ANCA status (anti-proteinase 3 (PR3) positive or anti-myeloperoxidase positive), and immunosuppressive treatment (cyclophosphamide (CYC) or rituximab (RTX)). American College of Rheumatology/Vasculitis Foundation guidelines recommend induction treatment with RTX over CYC (Chung SA et al, *Arthritis Care Res* (*Hoboken)* 2021). For relapsing disease, EULAR guidelines recommend RTX (Hellmich B et al,*Ann Rheum Dis* 2023). The objective of this study was to evaluate the efficacy and safety of avacopan in patients in the RTX stratum of the ADVOCATE trial.

Methods: Primary efficacy endpoints were the proportion of patients achieving disease remission at week 26 and sustained remission at week 52 (Birmingham Vasculitis Activity Score (BVAS) of 0 and no GC use for AAV 4 weeks before measurement). RTX was administered intravenously 375 mg/m^2 once weekly for 4 weeks beginning on Day 1. The protocol did not include repeat dosing of RTX, according to its approved labeled regimen at the time.

Results: A total 214 of 330 patients (64.8%) comprised the RTX stratum. At baseline, patients were 60 years old (mean), ~76% had renal vasculitis (based on BVAS), ~46% were PR3-ANCA positive, and ~58% were newly diagnosed. Men constituted 57.0% of the avacopan group and 48.6% of the prednisone group. Baseline estimated glomerular filtration rate

Table 1: Efficacy and Safety for Patients with ANCA-Associated Vasculitis in the Rituximab Stratum in the ADVOCATE Trial

	Avacopan Group (N=107)	Prednisone Group (N=107)
Remission at Week 26, n (%)	83 (77.6%)	81 (75.7%)
Sustained remission at Week 52, n (%)	76 (71.0%)	60 (56.1%)
Relapse rate, n (%)	9 (8.7%)	21 (20.2%)
eGFR change at Week 52, mL/min/1.73 m^2, mean ± SEM	5.9 ± 1.56	3.2 ± 1.56
UACR percent change at Week 4, geometric mean	-43.4%	8.3%
GTI-CWS at Week 26, mean ± SEM	36.8 ± 3.62	52.9 ± 4.92
GTI-AIS at Week 26, mean ± SEM	11.7 ± 3.42	19.8 ± 4.31
Any Serious Treatment Emergent Adverse Event; patient experiencing events, n (%), number of events (n)	37 (34.6%), 62 events	42 (39.3%), 91 events

eGFR=estimated glomerular filtration rate; UACR=urinary albumin:creatinine ratio; GTI-CWS=Glucocorticoid Toxicity Index Cumulative Worsening Score; GTI-AIS=Glucocorticoid Toxicity Index Aggregate Improvement Score

(eGFR) was 57.1±32.2 and 56.0±33.4 mL/min/1.73 m^2 (mean±SD), for the avacopan and prednisone groups, respectively. Remission at week 26 was 77.6% in the avacopan group and 75.7% in the prednisone group (**Table 1**). Sustained remission at week 52 was 71.0% in the avacopan group and 56.1% in the prednisone group (**Table 1**), estimated common difference, 16.5 percentage points; 95% confidence interval, 4.3 to 28.6. Additionally, there were numerical improvements in relapse rate, albuminuria, and lower GC-associated toxicity in the avacopan group versus the prednisone group. The proportion of patients experiencing a serious treatment emergent adverse event (TEAE) was 34.6% (n = 37) with 62 events in the avacopan group compared to 39.3% (n = 42) with 91 events in the prednisone group (**Table 1**).

Conclusion: This analysis from the ADVOCATE trial of patients with AAV receiving RTX showed a significantly increased sustained remission rate at week 52 in the avacopan group compared to the prednisone group. Compared to the prednisone group, patients in the avacopan group had numerical improvements in remission at week 26, relapse rate, eGFR, albuminuria, and less GC toxicity. There was no increase in serious TEAEs in patients treated with avacopan. These results demonstrate the efficacy of avacopan for achieving and sustaining remission in patients with AAV treated with RTX.

Safety and Efficacy of Avacopan in Patients 65 Years and Older with ANCA-Associated Vasculitis

David Jayne[1], Duvuru Geetha[2], Christian Pagnoux[3], Sebastian Sattui[4] and Peter Merkel[5], [1]University of Cambridge, Cambridge, United Kingdom, [2]Johns Hopkins University, Baltimore, MD, [3]Mount Sinai Hospital, Toronto, ON, Canada, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Older adults are at increased risk of glucocorticoid (GC)-related toxicity; minimization of GCs is a major focus for treatment of patients with ANCA-associated vasculitis (AAV). Although AAV especially affects older adults, many studies have excluded patients >75 years (y). In the Phase 3 ADVOCATE trial of avacopan, there was no exclusion criterion for maximum participant age.

Methods: This post hoc analysis reports safety and efficacy of avacopan compared to a prednisone taper in the subgroups of patients 65-74y (N=109) and ≥75y (N=51).

Results: In both studied age and treatment groups, a similar proportion of patients (69.4-73.1%) achieved remission at week 26 (**Table 1**). In the 65-74y age group, sustained remission rates at week 52 were 55.1% in the prednisone arm and 65.0% in the avacopan arm. Relapse rates were 18.8% in the prednisone arm and 12.3% in the avacopan arm. The total

Table 1: Safety and Efficacy Outcomes in Patients with ANCA-Associated Vasculitis Aged 65 to 74 Years and 75 Years and Older in the ADVOCATE Trial of Avacopan

SAEs possibly related to GCs, n patients, %	4 (8.2)	7 (11.7)	7 (28.0)	5 (19.2)
Deaths, n (%)	2 (4.1)	2 (3.3)	0 (0.0)	0 (0.0)

[§] Relapse rates are based on the number of patients who achieved a Birmingham Vasculitis Activity Score (BVAS) of 0 during the 52-week treatment period

[†] eGFR assessed only in patients with renal involvement (based on BVAS) at baseline

[‡] UACR assessed only in patients with renal involvement (based on BVAS) at baseline and baseline UACR≥10 mg/g creatinine

AE, adverse events; AIS, aggregate improvement score; CWS, cumulative worsening score; eGFR, estimated glomerular filtration rate; GC, glucocorticoid; GTI, glucocorticoid toxicity index; LSM, least squares mean; MCS, mental component summary; PCS, physical component summary; SAE, serious adverse event; SEM, standard error of the mean; SF-36, Short Form-36; UACR, urine albumin:creatinine ratio; VAS, visual analogue scale.

all-source median GC dose was 5.3x higher in the prednisone vs avacopan arm. Serious adverse events (SAEs) occurred in 22/49 patients (45%) in the prednisone arm (2 deaths) and 25/60 patients (42%) in the avacopan arm (2 deaths). In the ≥75y age group, sustained remission rates at week 52 were 56.0% in the prednisone arm and 65.4% in the avacopan arm. Relapse rates were 20.8% in the prednisone arm and 3.8% in the avacopan arm. Median GC dose was 4.8x higher in the prednisone vs avacopan arm. SAEs occurred in 14/25 patients (56%) in the prednisone arm and 17/26 patients (65%) in the avacopan arm. Other results including renal and quality of life outcomes are in **Table 1**.

Conclusion: A subgroup analysis of patients ≥65y demonstrated similar trends of efficacy and safety of avacopan as in the overall ADVOCATE trial, including reductions in GC-related toxicities, supporting a role for avacopan in the treatment of older adults with AAV.

Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis are chronic and relapsing diseases. Relapses are frequently associated with organ damage accrual as a consequence of disease activity or treatment-related side effects. Avacopan, a selective antagonist of C5a receptor, has been approved for the treatment of adult patients with severe and active granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) in combination with rituximab (RTX) or cyclophosphamide (CF). We describe our initial experience with avacopan as part of an Early Access program in Spain.

Methods: The study population consisted of all patients diagnosed with GPA/PAM who initiated treatment with avacopan between June 2022 and March 2023 as part of the program. Patients (newly diagnosed or relapsing) were locally selected by participating investigators based on impaired renal function or long glucocorticoid exposure and toxicities. Descriptive statistics (mean and SD or median and IQR for continuous variables, and percentages for categorical variables) are presented.

Results: 24 patients were included: age 58,5±15 years, 60% women, 50% newly diagnosed and 71% ANCA- MPO+. 88% (21/24) had kidney involvement with an eGFR of 26±15 ml/min/1.73m^2 (n=17). Extrarenal manifestations were present in 42% (10/24), the most common was pulmonary involvement (6/24).

In 75% of patients avacopan was initiated because of presence/risk of glucocorticoid (GC)-related adverse events (AEs) (diabetes, hypertension, osteoporosis, previous infection, frailty, cardiovascular risk and previous GC exposure). 30% had previous GC-derived AEs and 8% were on chronic GC use. In 30% of patients, avacopan was added for refractory disease and in 46% of patients for potential recovery of kidney function.

RTX was used for induction in 100% of patients and was combined with CF in 54% of cases. Moreover, 67% received methyl-prednisolone pulses, 96% oral prednisone and 25% plasma exchange. Median follow-up under avacopan treatment was 5,4 months (IQR 2,55-9,25). Remission was achieved by 79% of patients with no relapses during follow. eGFR increased 6.1±12.5 ml/min/1.73m2

Prednisone was completely discontinued in 33% of patients (after 11,3±5,9 weeks). At the time of this analysis, 40% were tapering GC. Three AEs were reported (diarrhea, urinary tract infection and neutropenia). Avacopan was discontinued in 1 patient.

Conclusion: Combination of avacopan and standard remission induction therapy had a good safety profile in real world clinical practice. Although in the presence of efficient induction therapy, short follow up and lack of comparator no conclusions can be drawn about efficacy, our patients tolerated lower GC exposure than previously adviced.

Efficacy and Safety Experience with Avacopan Beyond 52 Weeks in the Early Access Program (EAP)

Federico Alberici[1], **Carlo Salvarani**[2], Christine Chan[3], Achim Obergfell[4] and Tamara Popov[4], [1]Universita degli Studi di Brescia, Brescia, Italy, [2]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [3]CSL Vifor, Redwood City, CA, [4]CSL Vifor, Glattbrugg, Switzerland

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Avacopan, a selective C5aR1 inhibitor, has demonstrated efficacy and safety over 52 weeks in patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis. However, efficacy and safety data on avacopan beyond 52 weeks are limited. Here, we describe the experience with avacopan beyond 52 weeks from the EAP.

Methods: Safety data in patients with severe, active granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) within the EAP were recorded in a global safety database from Feb 2019 – Apr 2023. Adverse events (AE) included a lack of effect and other events (i.e., relapse or worsening of disease).

Results: A total of 19 patients were treated with avacopan beyond 52 weeks within the EAP. Average age was 47 years, with 13 patients (68%) diagnosed with GPA and 6 (32%) with MPA. The median duration of therapy was 17 months (range 12–45). A total of 9 AEs were recorded in 2 patients (10.6%) (Table 1). One vasculitis flare was recorded 6 months after avacopan initiation and coincided with an unintended dose reduction to 20 mg BID, due to a product supply issue during COVID. The event was well-managed with rituximab, with no additional use of glucocorticoids, and avacopan 30 mg BID was reinstated. No further cases of a lack of effect, worsening of disease, or disease relapse were reported. Data regarding concomitant medications did not indicate a decline in the patients' status during treatment. No treatment discontinuations due to AEs were recorded.

Conclusion: These results suggest that continuation of avacopan beyond 52 weeks is generally well-tolerated in patients with GPA and MPA and may be effective in terms of disease control. Limitations of this program include low patient number, potential underreporting, and incomplete data.

Table 1. Overview of Safety Events Reported in 2 of 19 Patients Receiving Avacopan Beyond 52 Weeks in the Early Access Program

System Organ Class (*Preferred term*)	No. of events
Patient 1	
General disorders and administration site conditions *Malaise*	1
Infections and infestations *COVID-19*	1
Injury, poisoning, and procedural complications *Product dose omission issue*	1
Product issues *Product supply issue*	1
Patient 2

Use of Avacopan in Patients with ANCA-associated Vasculitis and Estimated Glomerular Filtration Rate < 15 mL/min/1.73m^2

Bryce Barr, Kim Cheema, Aurore Fifi-Mah, **Stephanie Garner**, Louis Girard and Jeffrey Ma, University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Glomerulonephritis represents a severe manifestation of anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) and is associated with substantial morbidity and mortality. Therefore, maximal recovery of kidney function is imperative to improve long-term survival and quality of life. Patients who require kidney replacement therapy (KRT) have the worst long-term outcomes with kidney function following six months of therapy being predictive of future requirement of KRT. Despite advances in induction therapy, there remains a substantial reliance on glucocorticoids, resulting in significant treatment-associated morbidity. Avacopan, a small molecule C5a receptor antagonist, was recently demonstrated to be superior to prednisone with respect to sustained remission at 52 weeks and reduced glucocorticoid toxicity. Avacopan has also been shown to improve estimated glomerular filtration rate (eGFR) compared to prednisone, particularly in the subset of patients with eGFR < 20 mL/min/1.73m^2. However, patients with eGFR < 15 mL/min/1.73m^2 were excluded from the clinical trials. Our objective was to describe the experience of patients at our centre with AAV who presented with eGFR < 15 mL/min/1.73m^2.

[3]units are mg/mmol

Methods: This was a retrospective case series of four patients with AAV and an eGFR < 15 mL/min/1.73m^2, treated with avacopan at the University of Calgary, Calgary, Canada between November 2022 and May 2023.

Results: Four patients with AAV presenting with an eGFR < 15 mL/min/1.73m^2 were treated at our centre. Their clinical characteristics, management and outcomes are detailed in Table 1. The patients ranged in age from 59-80. Two patients had GPA and one was PR3 positive. All four had an eGFR < 15 (range 5-10 mL/min/1.73m^2) at presentation and a renal biopsy documenting glomerulonephritis. Two received cyclophosphamide as induction, one a combination of rituximab and cyclophosphamide and one rituximab. All four patients were in remission at last follow-up with one patient dialysis dependent. For the patient dialysis dependent, avacopan was stopped at three months. Cumulative steroid exposure ranged from 1 to 1.7 grams of prednisone or prednisone equivalent. There were no treatment related adverse events or serious infections.

Conclusion: In conclusion, we present four cases describing the use of avacopan in individuals with AAV and eGFR < 15 mL/min/1.73m^2 at presentation. Avacopan appeared to be safe, with reduced glucocorticoid exposure in all patients, and resulted in substantial eGFR recovery in three individuals. More study is required to understand the short- and long-term impacts of avacopan on kidney function in this subgroup of AAV patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – ANCA-Associated Poster I: Treatment Outcomes

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX), an anti-CD20 monoclonal antibody, has shown to be an effective induction treatment for small-vessel vasculitides associated with antineutrophil cytoplasm antibodies (AAV) in both newly diagnosed and relapsing patients. However, the role of RTX in the management of the most severe cases of AAV remains to be fully elucidated. Objective of the study

to assess both safety and efficacy of an intensified B-cell depletion therapy (IBCDT) protocol, including RTX, cyclophosphamide (CYC), and methylprednisolone pulses without additional maintenance immunosuppressive therapy compared to conventional therapy regimen based on oral CYC and steroids and prolonged maintenance therapy with azathioprine (AZA) in patients with AAV and severe renal injury.

Methods: A cohort of 15 AAV patients with the most severe features of AVV renal involvement (as < 15 ml/min GFR and histological findings of paucimmune necrotizing glomerulonephritis with more than 50% crescents of non-sclerotic glomeruli at the renal biopsy) was treated IBCDT and compared to compared toa control group of 10 patients with AAV treated with a conventional therapy regimen based on oral CYC and steroids and prolonged maintenance therapy with azathioprine (AZA). Independently on the pharmacologic regimen, plasma exchange (7 procedures with 1-1.5 plasma volume replacement) was performed in the presence of 1. alveolar haemorrhage, and 2.more than 50% florid crescents in the nonsclerotic glomeruli, or 3. dialysis dependence.

Results: Complete clinical remission (BVAS 0) was observed at 6 months in 14 of 15 patients (93%). All cases treated with IBCDT who achieved a complete clinical remission experienced a depletion of peripheral blood B cells at the end of therapy. Of the 10 dialysis dependent patients at onset, 6 subjects (60%) experienced a functional recovery allowing the suspension of dialysis treatment. When compared to the control group, no statistically significant difference was observed in patients treated with IBCDT in terms of overall survival, 6-month therapeutic response rate, and 6-, and 12-month functional renal recovery. The cumulative total dose of CYC in the case group was on average 1 g/patient while in the control group on average 8.5 g / patient ($p = 0.00008$). Plasmapheresis sessions were performed at part of the induction therapy among 13 patients (87%) in the case group and 8 (80%) in the control group.

Conclusion: The results of this study showed that IBCDT appeared to be safe and has the same efficacy profile when compared to conventional therapy with CYC plus AZA in the management of the most severe patients with AAV. Additionally, this avoids the need of prolonged maintenance therapy for long, and limits the exposure to CYC with consequent reduced toxicity and drug-related side effect rates.

Recognizing the New Disorder "Idiopathic Hypocryoglobulinaemia" in Patients with Previously Unidentified Clinical Conditions

Dario Roccatello[1], Savino Sciascia[2], carla naretto[3], ANTONELLA BARRECA[4], MASSIMO RADIN[5], IRENE CECCHI[5], ALICE BARINOTTI[5], ELENA RUBINI[5], SILVIA GRAZIETTA FODDAI[5], laura solfietti[3], laura battaglia[3], lucia vizziello[3], ROBERTA FENOGLIO[3] and DANIELA ROSSI[3], [1]University of Torino, Torino, Italy, [2]University of Turin, Torino, Italy, [3]University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases (ERK-net, ERN-Reconnect and RITA-ERN Member) with Nephrology and Dialysis Unit and Center of Immuno-Rheumatology and Rare Diseases (CMID), Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, Turin, Italy, [4]Pathology Unit, Città della Salute e della Scienza, Turin, Italy, [5]University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases (ERK-Net, ERN-Reconnect and RITA-ERN Member) with Nephrology and Dialysis Unit and Center of Immuno-Rheumatology and Rare Diseases (CMID), Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, Department of Clinical and Biological Sciences, University of Turin, Turin, Italy

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: A considerable number of patients with high clinical suspicion for cryoglobulinaemic vasculitis either show negative results for the detection of cryoglobulins or show only trace amounts which cannot be characterized for composition.We aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulin with conventional methods either identifies a peculiar subset of low level cryoglobulinaemia (from now on *hypocryoglobulinaemia*) or represents a separate entity.

Methods: The present cohort includes 237 patients, median age 60.8, range 22–97 years, 100 males and 137 females, having trace amounts of cryoglobulins (< 0.5% cryocrit) detected in the Laboratory of CMID, San Giovanni Bosco Hub Hospital and University of Turin between 2008 and 2021. Patients presenting with high clinical suspicion of autoimmune systemic conditions yet negative for the detection of cryoglobulinemia with the standard technique were tested for hypocryoglobulins.All patients with urinary abnormalities underwent kidney biopsy.

Results: Using a modified precipitation technique in hypo-ionic medium, we prospectively identified between 2008 and 2021 237 patients (median age 60.8 years [22–97], 137 females) having < 0.5% cryocrit and clinical suspicion of autoimmune disorder. Of these 237 patients, only 54 (22.7%) had a history of HCV infection. One hundred and sixty-nine out of 237 patients (71%) had an established underlying disease, while 68 patients (28.6%) (median age 62.9 years [29–93], 35 females) did not show either laboratory markers or clinical symptoms consonant with an underlying aetiology. These 68 cases with only trace amounts of cryoglobulins were defined as having a *putatively idiopathic* hypocryoglobulinaemia. Nineteen of these 68 patients (27.9%) had a history of HCV infection. Twenty-four patients out of 68 (35.3%) were positive for rheumatoid factor (RF), while 25 (36.7%) patients had signs of complement consumption (i.e., C4 < 15 mg/dl and/or C3 < 80 mg/dl), and 36 (52.9%) had increased inflammatory indexes. Seven patients only had arthralgia and constitutional symptoms while 61 out of 68 (89.7%) presented with at least one of the three cardinal signs of cryoglobulinaemic vasculitis including skin lesions, peripheral nerve involvement, and glomerulonephritis. Seventy-five percent of the subjects had type III hypocryoglobulins. In patients with hypocryoglobulinaemia the histologic features of glomerulonephritis (also examined by electron microscopy) resembled those of mixed cryoglobulinaemia-associated glomerulonephritis.

Conclusion: In conclusion, hypocryoglobulins are often polyclonal and are mainly unrelated to HCV infection. Patients who present high clinical suspicion for vasculitis, especially glomerulonephritis and yet test negative for cryoglobulinaemia detected by standard techniques, could require deeper investigation even in the absence of HCV infection, RF activity or signs of complement consumption.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD) is an HLA class I-associated disorder, given its strong link to *HLA-B*51*. However, evidence of HLA class I restriction is lacking, and candidate antigens are elusive. Here, we hypothesized that clonal CD8 T cell expansions are present in BD at tissue sites during active disease aiming to provide evidence of HLA class I restriction by identifying their disease-related CD8 TCR.

Methods: We performed scRNAseq with TCR V(D)J analyses in PBMC from a Turkish cohort of 37 untreated subjects (14 HD, 23 BD) with ocular and vascular BD. In a separate set of experiments, we obtained anterior chamber fluid cells from two additional *HLA-B*51*$^+$ Behçet's uveitis (BU) subjects from an independent cohort, as well as time-matched autologous peripheral blood, assessed TCR sequences, clonotype- and T cell phenotype distribution between peripheral blood and the eye, and clonotype sharing across study subjects in both cohorts.

Results: Anterior chamber fluid cells in BU showed substantial oligoclonal CD8 T cell expansions. Highly expanded ocular clonotypes overlapped with autologous peripheral blood exhibiting an intraclonotype shift towards a more cytotoxic (Granzyme B$^+$) phenotype in the eye over peripheral blood. An identical disease-related CD8 a/bTCR, determined in the eye-blood paired sample experiments, was re-identified in *HLA-B*51*$^+$ active uveitis peripheral blood in the Turkish cohort but not in HDs or BD subjects without uveitis. We identified additional clonotypes which showed high CDR3 sequence similarity to our experimentally determined TCR computationally, using TCRdist. Again, we re-located those in *HLA-B*51*$^+$ subjects with active uveitis but not in HD, BD without uveitis, or *HLA-B*51*$^-$ subjects.

Conclusion: We demonstrate the presence of highly expanded CD8 T cells in BU eyes and autologous peripheral blood and identify disease-associated TCR across independent cohorts of affected *HLA-B*51*-carrying subjects but not HDs. Our findings suggest that an HLA class I-restricted process drives BD in a subset of clinically distinct patients and will facilitate antigen discovery by enabling the identification of cognate peptides in an *HLA-B*51* restriction context.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) has been reported as the most common cause of death in ANCA-associated vasculitis (AAV)[1,2]. Systemic inflammation, in addition to traditional risk factors such as diabetes mellitus (DM), has been suggested as the main contributor to cardiovascular (CV) events in vasculitis, as there is a well-known association between chronic inflammation and atherosclerosis[3].

The aim of this study is to assess the CV risk in patients with vasculitis and DM, and understand whether the risk of CVD in patients with vasculitis is as high as in those with DM.

Methods: In this retrospective cohort study, we identified patients with different types of vasculitis without DM based on ICD-10 codes, including large vessel vasculitis (LVV), ANCA-associated vasculitis (AAV), and other vasculitis such as Bechet disease (BD), polyarteritis nodosa (PAN) and cryoglobulinemia. We used the Nationwide Inpatient Sample database (NIS) from 2016 to 2019. We included all-cause mortality, acute coronary syndrome (ACS), cerebrovascular accident (CVA), transient ischemic attack (TIA), and deep venous thrombosis (DVT) or pulmonary embolism (PE) as our primary outcomes. Atrial

PVD	2.56	2.4	2.73	<0.001

fibrillation (Afib), atrial flutter (AF), peripheral vascular disease (PVD), and metabolic syndrome were our secondary outcomes. We implemented logistic regression analysis in the univariable and multivariable models. In the multivariable model, we adjusted all outcomes for potential confounders, including age, sex, ethnicity, obesity, anemia, hypertension, renal failure, history of smoking or alcohol abuse, prior history of MI, primary coronary intervention, or coronary artery bypass grafting, coagulopathy, ischemic cardiomyopathy, Elixhauser comorbidity index, hypothyroidism, history of defibrillator or pacemaker, and long-term use of steroids, insurance status and income quartiles. The analysis was done using the STATA software, version 17.0 (MP).

Results: We identified 32,491,290 patients with DM and 109,410 patients with vasculitis without DM, of whom 50,265 (46%) had LVV, 41,220 (37.7%) had AAV, and 13,635 had other vasculitides (12.5%). Our results showed that patients with vasculitis had a higher mortality (OR: 1.38; 95%-CI 1.28-1.49; p-value < 0.001), and increased risk of developing ACS (OR: 1.64; 95%-CI 1.48-1.82; p-value < 0.001), CVA (OR: 1.62; 95%-CI 1.07-1.27; p-value < 0.001), DVT/PE (OR: 2.33; 95%-CI 2.02-2.69; p-value < 0.001), Afib/AF (OR: 1.73; 95%-CI 1.66-1.80; p-value < 0.001), and PVD (OR: 2.56; 95%-CI 2.4-2.73; p-value < 0.001) when compared to patients with DM even after adjusting for potential confounders.

Conclusion: Patients with vasculitis had a higher risk of cardiovascular disease and venous thromboembolism. Our study confirms the high CV risk in patients with vasculitis as highlighted in previous studies, and suggests an even higher risk when compared to patients with DM.

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Urticarial vasculitis (UV) is characterized by atypical urticarial lesions and leukocytoclastic vasculitis, sometimes with extra-cutaneous manifestations. First-line treatment is often based on colchicine, hydroxychloroquine, dapsone or low-dose glucocorticoids. In refractory forms, the use of biologics has been anecdotally described as potentially effective. We aimed to describe the efficacy and safety of biologics in patients with UV.

Methods: We conducted a retrospective European multicentre study including patients with hypocomplementemic (HUV) or normocomplementemic (NUV) UV who received at least one biologic, including anti-CD20, anti-IgE and/or anti-IL-1. We analyzed the clinical and biological characteristics as well as the efficacy and safety of the biologics.

Results: Forty-one patients were analyzed, including 24 patients with HUV and 17 with NUV.Fifty-two therapeutic sequences were recorded, including rituximab in 23, anti-IL1 in 16 and anti-IgE in 13 cases. Extra-cutaneous manifestations were present in 90%. The most common manifestations were arthralgia in 66%, arthritis in 27%, ocular inflammation in 24%, gastrointestinal involvement in 15%, renal involvement in 15% and pulmonary involvement in 12%.

The median number of treatments before biologic was 4 (IQR 3-6). A higher proportion of HUV was observed in patients treated with anti-CD20 (83%), while a higher proportion of NUV was observed in patients treated with anti-IL-1 (62%) and omalizumab (77%). All patients with renal involvement were treated with anti-CD20.

Biologics were used in combination with glucocorticoids in 75% of patients, with a median prednisone dose of 18 mg/day (IQR 10-39), hydroxychloroquine in 25%, dapsone in 6% and azathioprine in 8%.

After a median follow-up of 25 (IQR 12-43) months, the cutaneous response was complete in 40%, partial in 37% and considered inadequate in 23%. Extracutaneous response was similar to cutaneous response in 84%. Prednisone dose reduction to < 10 mg/day was achieved in 72% of patients, including discontinuation of glucocorticoids in 34%. Despite different disease profiles for each biologic, cutaneous and global clinical response rates were broadly comparable across all biologics.

Severe adverse events, mainly serious infectious, were observed in 7 patients (17%), including 4 patients treated with rituximab and 3 patients treated with anakinra.

Conclusion: Rituximab, anti-IL-1 and omalizumab are an effective and well-tolerated treatment option for UV that are refractory to conventional therapies. Rituximab was mainly used for HUV while anakinra and omalizumab were mainly used for NUV.

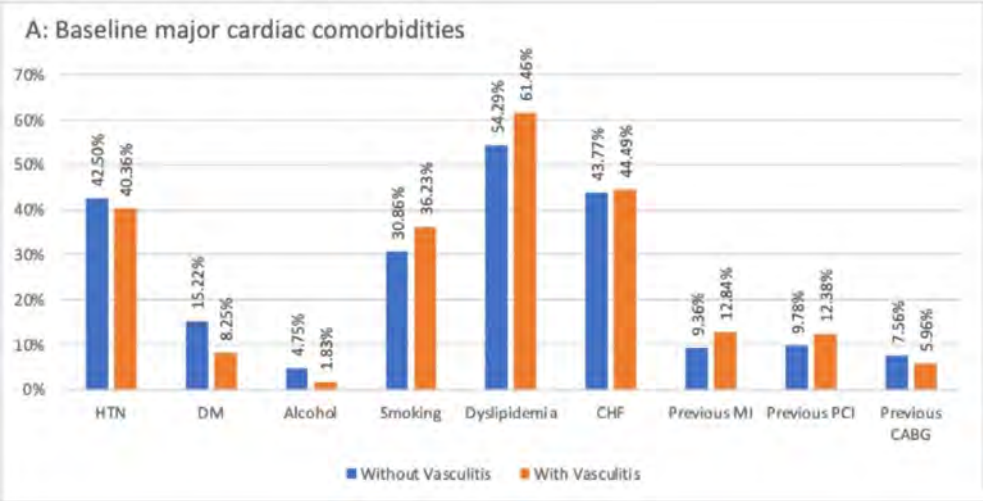
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Atrial fibrillation is the most commonly treated cardiac arrhythmia, associated with significant morbidity and mortality. Recent research is suggestive that autoimmunity and inflammation might have a role in the pathophysiology of atrial fibrillation (AF). While several autoimmune conditions are associated with AF, autoimmune vasculitis confers a worse survival in patients with AF. Current literature is limited in determining the impact of large vessel vasculitis (LVV) in AF patients. We present a study discussing the cardiovascular outcomes in patients with LVV and atrial fibrillation.



Baseline major co-morbidities

			Unadjusted		Adjusted	
	Without vasculitis, (%)	With vasculitis, (%)	OR(95% CI)	P-value	aOR(95% CI)	P-value

In-hospital outcomes and resource utilization in patients with Atrial Fibrillation with and without vasculitis

Methods: We queried the National Inpatient Sample database in the period between 2016 - 2019. Primary AF hospitalizations were identified and subsequently we stratified the cohort based on the presence of LVV. The adjusted odds ratios (aOR) of in-hospital outcomes and resource utilization were calculated using chi-square statistics in software STATA v.17.

Results: Of 1,041,670 AF hospitalizations between 2016-2019; 1,090 had LVV (Giant cell arteritis: 1050 and Takayasu arteritis: 40). Afib with LVV patients were older (78.33 vs. 71.04, p< 0.001) and predominantly female (71.55 vs. 51.39, p< 0.001). On adjusted analysis, compared to non-LVV patients, LVV patients had significantly higher MACCE (aOR 1.72, 95% CI 1.02-2.89), AMI (aOR 1.99, 95% CI 1.13-3.51), AKI (aOR 9.73, 95% CI 2.33-40.68) with longer length of stay (3.38±3.73 vs. 4.44±4.23). Interestingly, there seemed to be a reduced risk of heart failure in AF patients with vs without vasculitis (aOR 0.60, 95% CI 0.42-0.78). On the contrary, there was no difference in in-hospital mortality, stroke, bleeding, need for PCI and total charge of hospitalization between the two groups.

Conclusion: The clinical outcomes in patients with concurrent LVV and AF are significantly worse, as evidenced by increased risk of MACCE, AMI and AKI compared to patients with only AF but not LVV. This study provides evidence that patients with large vessel vasculitis and AF need to be managed more aggressively as clinical outcomes are notably worse. However, we do not have enough data to suggest whether patients with LVV need to be screened for AF. Further prospective trials are needed to answer these queries.

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The association of large vessel vasculitis (LVV), whether Takayasu arteritis (TA) or giant cell arteritis (GCA), with inflammatory bowel disease (IBD) is a rare and challenging condition. The prevalence of LVV in IBD cohorts is less than 1%, but the prevalence of IBD can be as high as 15.4% in TA cohorts, and population-based studies confirmed this association. We aimed to describe the characteristics and outcome of LVV-IBD patients, with a focus on the therapeutic management.

Methods: We performed an observational, multicenter, retrospective case-control study in Western Europe countries (France, Italy, Spain, Germany, Belgium). Cases were adults or children with both LVV and IBD (LVV-IBD), whereas controls had isolated TA (iTA) or GCA (iGCA).

Results: Fifty-one LVV-IBD patients were included, including 39 TA-IBD and 12 GCA-IBD patients, and compared with 93 iTA and 52 iGCA. LVV-IBD patients were mostly females (75% in TA-IBD and 72% in GCA-IBD). Crohn's disease was more common in TA-IBD (67%), while ulcerative colitis was more common in GCA-IBD (58%). LVV occurred after IBD in most cases (56% in TA-IBD and 75% in GCA-IBD), with a median interval of 1 year in TA-IBD and 8.6 years in GCA-IBD, and were diagnosed concomitantly in 16%. Location, behaviour and complications of IBD were similar to previously reported IBD cohorts.

Compared to iTA patients, TA-IBD patients were significantly younger at TA diagnosis (27 vs. 37 years, $p < 0.001$) and had more upper limb claudication (36 vs 12%, p=0.006). The number of affected arterial segments was lower in TA-IBD (3 vs. 4 segments, p=0.015) and carotid artery involvement was less common in TA-IBD patients than in iTA patients (50 vs. 75% respectively, p=0.005).

Compared to iGCA patients, GCA-IBD patients had more arthralgia (50 vs 15%, p=0.017) and vascular murmur (25 vs 0%, p=0.016). GCA-IBD patients had more arterial thickening or stenosis than controls (75 vs. 30% respectively, p=0.044).

Table 1. Comparisons between GCA and TA patients with and without IBD (N=196)

Feature	N	Overall (N = 196)	GCA-IBD (N = 12)	iGCA (N = 52)	p	TA-IBD (N = 39)	iTA (N = 93)	p

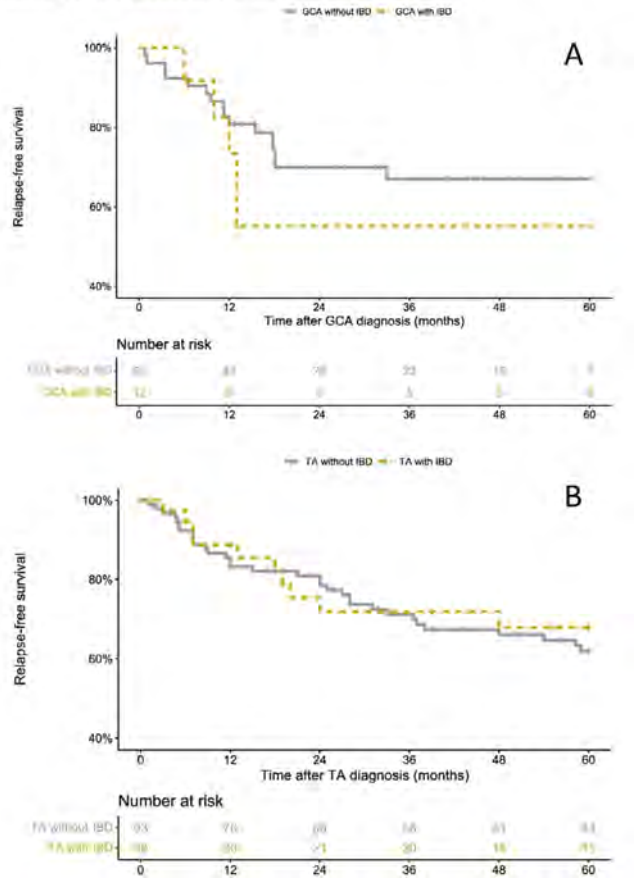
Figure 1. Kaplan Meier curves for the risk of (A) GCA and (B) Takayasu Arteritis relapses depending on the association with IBD



LVV occurred in IBD patients while on therapy in 77% (86% for TA-IBD and 56% for GCA-IBD), including oral glucocorticoids (GCs) in 36%, azathioprine (AZA) in 25%, or TNF-a blockers in 33% of TA-IBD.

LVV-IBD were treated with GCs in 91%, methotrexate in 43%, AZA in 17% or cyclophosphamide in 3.2%. Biologics were used in 24%, including mainly TNF-a blockers in TA-IBD patients (33%). AZA was used more frequently in TA-IBD patients than in iTA, with the latter mainly receiving methotrexate.

The presence of IBD did not influence the vasculitis relapse rate (OR 1.40 [0.39-5.10] for GCA and OR 0.72 [0.34-1.51] for TA). Aortic insufficiency in GCA patients (OR 8.36, 95% CI 1.35-51.66), and ascendent aorta involvement (OR 2.35, 95% CI 1.20-4.60) and the presence of general symptoms (HR 2.02, 95% CI 1.01-4.03) in TA patients were identified as independent vasculitis relapse risk factors.

Conclusion: This large case-control study identifies new clinical, imaging and outcome features in LVV-IBD. Vascular involvement seems to be less severe in TA-IBD than in iTA, while it seems to be the opposite in GCA-IBD. LVV-IBD occurred despite ongoing treatment in 77%, including AZA and/or TNF-a blockers in almost half of the cases.

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The gut microbiome has a critical role in immune homeostasis and there is growing interest in understanding the relationship between the microbiome and autoimmunity. There are epidemiologic and genetic associations between large-vessel vasculitis (LVV) and inflammatory bowel disease, an autoimmune disease where intestinal dysbiosis is common. This study evaluated the relationship between composition and function of gut microbiota and disease activity in patients with LVV.

Methods: In this longitudinal, prospective cohort study, stool samples and clinical data were collected from patients with giant cell arteritis (GCA) and Takayasu arteritis (TAK) every 6 months at a single center. Diagnosis and disease activity of LVV were determined by the investigator and informed by the 1990 ACR classification criteria and BVAS, respectively. Healthy control patients without autoimmune disease were also recruited and supplemented by existing healthy control stool microbiome data from a separate convenience cohort. The fecal microbiome was profiled using shotgun metagenomic sequencing. Comparisons to healthy controls were conducted using samples from the first visit at which: 1) LVV was inactive, and 2) LVV was active. The relative abundance of microbial taxa in the stool was estimated using Kraken2, and the relative abundance of microbial gene orthologs was determined by alignment to the Kyoto Encyclopedia of Genes and Genomes (KEGG). Community-level differences in taxonomic (beta diversity) and gene function composition in the microbiome were assessed using Bray-Curtis distances between samples in principle coordinate analysis (PCoA) plots. The relative abundance of the 10 most common functional pathways, determined by the abundance of constituent genes, was

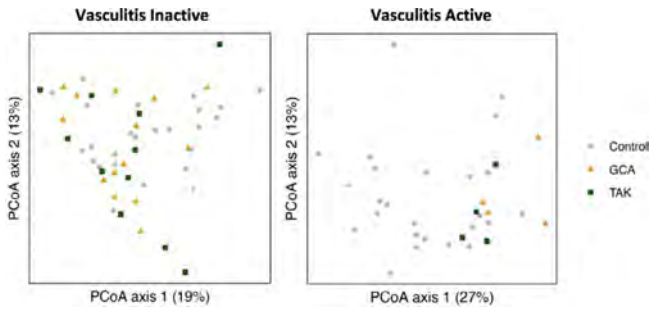

Figure 1. Bacterial composition in large-vessel vasculitis (inactive and active) vs controls. Principal coordinate analysis (PCoA) plots compare beta diversity between controls vs inactive vasculitis (left panel) and active vasculitis (right panel) using Bray-Curtis distances. Beta diversity did not significantly differ when comparing inactive LVV to controls ($p=0.21$) but did between active vasculitis and controls ($p<0.01$).

compared using heatmaps and linear models. P-values were adjusted to control for a false discovery rate of 5% when multiple comparisons were made.

Results: 27 patients with LVV, which included 16 with GCA and 11 with TAK, and 23 healthy controls were included in the study with a total of 76 stool samples obtained. GCA patients were 75% female with mean age 70.4 years (SD 6.5) while TAK patients were all female with mean age 37.2 years (SD 13.8). Eight patients with LVV experienced a flare with the most common symptoms in GCA being constitutional symptoms (75%) and headache (50%) and in TAK chest pain/dyspnea (50%) and lower limb claudication (25%). Composition of fecal microbiota, measured by beta diversity, was significantly different in active LVV samples but not inactive LVV when compared to controls (**Figure 1**). In our analysis of microbial gene ortholog abundance, functional genes of bacteria were significantly different in both active and inactive LVV patients

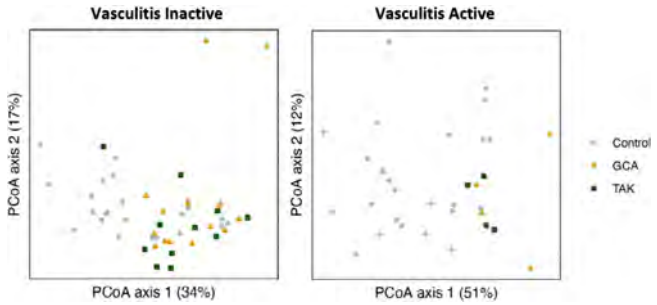

Figure 2. Bacterial functional analysis in large-vessel vasculitis (inactive and active) vs controls. PCoA plots compare microbial metagenomic functional composition in inactive vasculitis (left panel) and active vasculitis (right panel) compared to controls using Bray-Curtis distances. These distributions significantly differed between controls and vasculitis subgroups both during inactive disease ($p<0.01$) and active disease ($p<0.01$).

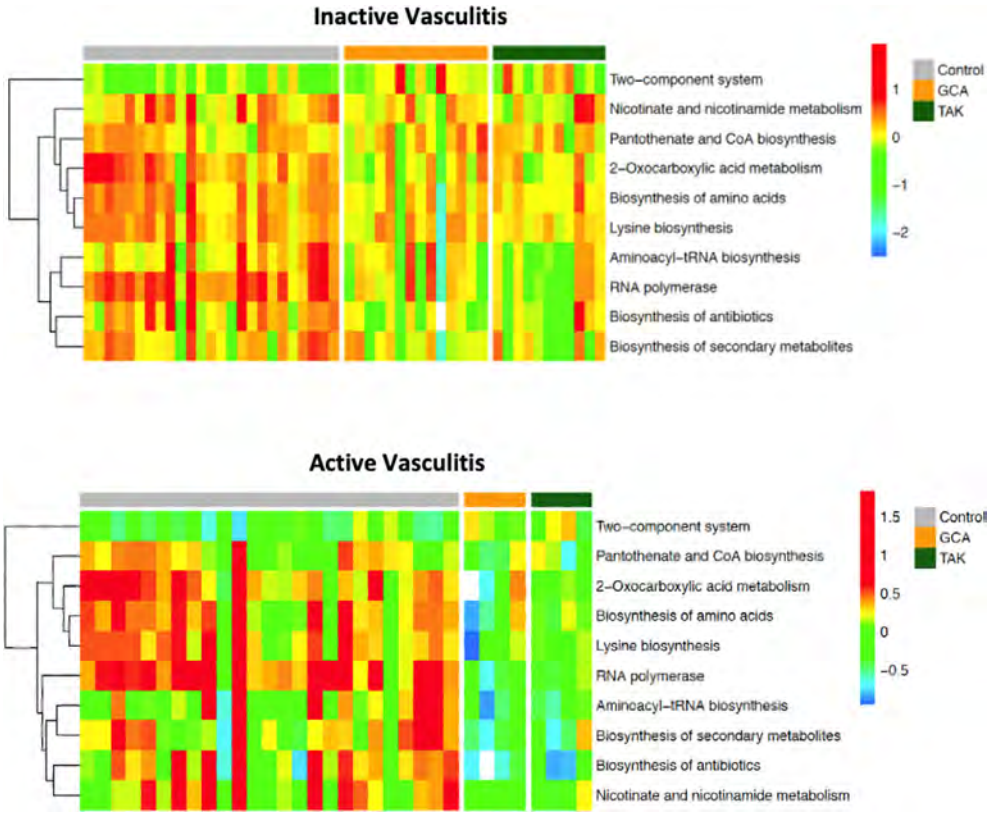

Figure 3. Functional pathways of gut microbiota in large-vessel vasculitis vs controls. Heatmaps representing relative abundance of functional pathways between control patients, patients with giant cell arteritis, and patients with Takayasu arteritis. While few pathways significantly differed between groups during inactive vasculitis (top), more significant differences were observed from samples during active vasculitis (bottom).

compared to controls (**Figure 2**). Several microbial gene pathways were identified to distinguish patients with active LVV from controls, but few emerged in our comparison of inactive LVV and controls (**Figure 3**).

Conclusion: Patients with LVV, particularly those with active disease, have altered composition, functional genes and pathways of gut microbiota compared to healthy controls. The possibility of shared mechanisms driving the altered microbiome in GCA and TAK warrants further investigation.

Differentiating Large Vessel Vasculitis from Vasculitis Mimickers in a Real World Setting: Clinical Presentation, Laboratory Tests and Radiographic Findings

James haigney[1], Laura Fandino[1] and Vasileios Kyttaris[2], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]BIDMC, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: As the resolution of Computed Tomography Angiography (CTA) has improved, rheumatologists have faced an increased volume of consults to evaluate patients for the presence of radiographic abdominal vasculitis (RAV). Biopsy is often not possible due to the nature of the lesion. In our experience, a large portion of these patients are ultimately not found to have vasculitis after a thorough evaluation. In this study we sought to identify the most predictive symptoms, laboratory, and imaging findings of having RAV at the first point of contact with the rheumatology consult service.

Methods: Patients with billing codes for vasculitis or non-inflammatory arteriopathies (NIA) evaluated by the rheumatology service between January 1, 2016 and December 31, 2021 were considered for inclusion in this study. Of these, only patients with question of vasculitis by imaging of the renal arteries, abdominal aorta, or mesenteric arteries and their branches (celiac, inferior and superior mesenteric arteries) with >1 year of follow up were included in the final analysis. Biographic data, presenting symptoms, laboratory data, and imaging reports were extracted. Patients were classified by their final diagnosis at the 1-year time point as either having vasculitis or NIA as determined by the treating physician based on their clinical course and response to treatment. Statistical analysis was conducted using STATA software.

Results: Of 683 candidate patients, 63 were seen by rheumatology for the question of RAV. 27 were excluded for insufficient data, 1 was excluded for question of vasculitis surrounding a stent, and 35 were included in the final analysis. Of these, 17 were ultimately determined to have vasculitis, and 18 were determined to not have vasculitis. Baseline patient characteristics are available in table 1. Notably 2 patients ultimately found to not have vasculitis received treatment for vasculitis in the follow up period, and 1 patient ultimately found to have vasculitis was managed as non-vasculitis with observation before

Table 1: Demographics and clinical characteristics of patients at baseline diagnosed with vasculitis vs non-vasculitis after consultation for question of RAV. AID denotes autoimmune disease, HTN smoking, HLD hyperlipidemia, and CAD coronary artery disease.

Characteristics	*Vasculitis (N=17)*	*Non-vasculitis (N=18)*	*Total (N=35)*
Age			
Mean years *(SD)*	53.3+/- 14.1	59.2+/-16.2	59.2+/-15.1

History of CAD - no. (%)	2 (12)	2 (11)	4 (11.4)

Table 2: Sensitivity, specificity, and positive/negative likelihood ratios (+LR/-LR) of presenting symptoms and CTA findings of patients with and without vasculitis.

Variable	*Sensitivity*	*Specificity*	*+LR*	*-LR*
Imaging Findings (%)				
Wall Thickening	59%	83%	3.53	0.49
Fat Stranding	41%	67%	1.24	0.88
Stenosis	29%	44%	0.53	1.59
Aneurysm	6%	89%	0.53	1.06
Pseudoaneurysm	6%	83%	0.35	1.13
Enhancement	18%	94%	3.18	0.87
Soft tissue encasement	18%	83%	1.06	0.99
Presenting Symptoms (%)				
Fatigue	29%	83%	1.76	0.84
Weight loss	29%	78%	1.32	0.91
Headache	24%	89%	2.11	0.86
Abdominal Pain	41%	17%	0.49	3.52
Nausea/vomiting	18%	44%	0.31	1.85
Diarrhea	12%	78%	0.52	1.13
Numbness/weakness	12%	94%	2.11	0.93
Fevers	29%	89%	2.65	0.79

treatment was initiated. Analysis of the predictive value of imaging findings and presenting symptoms are reported in table 2. Notably, wall thickening of the relevant vessels was found to be the most helpful finding with a specificity of 83% and positive likelihood ratio (+LR) of 3.53. Interestingly fat stranding was found to be less helpful with a specificity of 67% and +LR of 1.2. Wall enhancement was rarely seen but was highly specific for vasculitis with a specificity of 94% and +LR of 3.18. None of the presenting symptoms were found to be especially predictive of vasculitis. Analysis of laboratory findings on presentation revealed initial white blood cell count (WBC) and platelet count (Plt) were significantly higher in patients with vasculitis (Table 3).

Conclusion: Our study identified wall thickening, wall enhancement, and elevations in WBC and Plt as being predictive of having abdominal vasculitis. While commonly reported, fat stranding was non-specific. Interestingly the tested presenting symptoms were not successful in delineating which patients were ultimately determined to have vasculitis. Confirmation of these findings with larger prospective studies is warranted.

Table 3: Comparison of baseline laboratory values ($P < 0.05$ is statistically significant). CRP denotes C-reactive protein, WBC white blood cell count, Plt platelets, AST aspartate aminotransferase, ALT alanine aminotransferase, ALP alkaline phosphatase, and IQR interquartile range. CRP is in mg/L. AST, ALT, and ALP are in mg/dL. WBC and Plt are in K/μL.

Baseline Labs	*Vasculitis (N=17)*	*Non-vasculitis (N=18)*	*p Value*
CRP – median (IQR)	43.6 (11, 112.8)	16.95 (4.8, 37.3)	0.24
WBC – median (IQR)	9.7 (7.6, 13)	7.15 (6.1, 8.3)	0.006
Plt – median (IQR)	375 (266, 398)	218.5 (176, 272)	<0.001
AST – median (IQR)	20 (18, 24)	19 (13, 41)	0.88
ALT – median (IQR)	21 (14, 27.5)	20 (18, 39)	0.79
ALP – median (IQR)	100 (77, 116)	82 (67, 104)	0.070

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Large-vessel vasculitis (LVV) is characterized by granulomatous inflammation of the aorta and its major branches. The two major forms are giant cell arteritis (GCA) and Takayasu's arteritis (TAK). Clinical manifestations and angiographic patterns of diseases can be similar between these diseases; however, GCA exclusively affects older people while TAK is frequently a disease of the young. Few studies directly compare circulating immune cell subsets between TAK and GCA. Some studies have independently shown involvement of Treg, Th1, and Th17 subsets in GCA and TAK. The study objectives were to profile human peripheral blood mononuclear cells (PBMCs) using spectral flow cytometry and directly compare $CD4^+$ T helper (Th) and $CD8^+$ cytotoxic T cell (Tc) subsets between patients with GCA and TAK.

Methods: Cryopreserved PBMCs, collected during active disease from patients with LVV enrolled in an observational cohort study and from healthy controls (HC), were profiled. A 30-color panel for spectral flow cytometry was designed. Each antibody was titrated to determine its optimal volume and then adjusted until the staining pattern was comparable between multicolor and single-color staining. The two conditions tested involved 4-6 h PBMC incubation with PMA, ionomycin, and Brefeldin A (stimulated) and in media alone (unstimulated). Treg, Th1, Th2, Th9, Th17, Tc1, Tc2, Tc9, and Tc17 subsets were defined as the proportion of CD4 or CD8 T cells expressing a key transcription factor or cytokine. Kruskal-Wallis tests were conducted to compare between groups. Spearman correlation was reported for comparisons of subset abundance and age within HC.

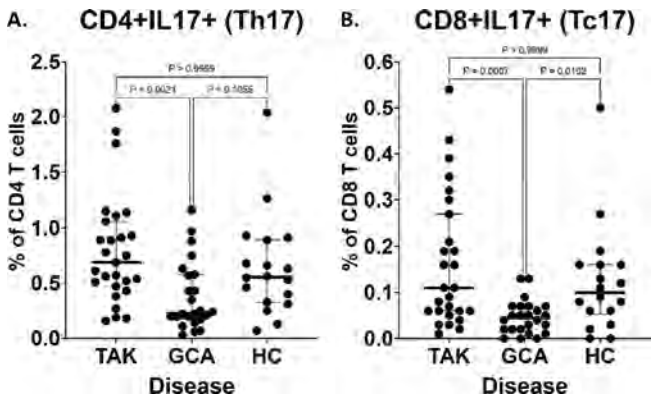

Figure 1: Expression of (A) Th17 and (B) Tc17 subsets in PBMCs from patients with Takayasu's arteritis (TAK), patients with giant cell arteritis (GCA), and healthy controls (HC)

Results: Patients with active GCA (N=24, ages 54-88), patients with active TAK (N=27, ages 15-54), and HC (N=18, ages 14-74) were included. Statistically significant differences between TAK and GCA were only observed in Th17 and Tc17 subsets. TAK patients (median 0.69%) showed significantly higher Th17 (CD4+IL17+) compared to GCA patients (0.23%, p=0.002) but not HC (0.56%, p >0.999) (Figure 1). GCA patients (0.05%) had significantly lower Tc17 (CD8+IL17+) levels than TAK (0.11%, p=0.001) and HC (0.10%, p=0.033) (Figure 1). Neither of Th17 nor Tc17 correlated with age within the HC group (r=-0.194 and r=-0.1741 respectively). There were no significant differences between TAK and GCA for Th1 and Tc1 populations. TAK patients (31.7%) did have lower Tc1 (CD8+IFNg+) than HC (56.1%, p=0.028). The only significantly difference observed in Tregs (CD4+FOXP3+) was lower expression in GCA patients (4.99%) than HC (7.06%, p=0.004).

Conclusion: Abundance of Th17 and Tc17 subsets were greater in TAK compared to GCA with no differences in Treg, Th1, or Tc1 subsets. Differences in IL17-producing T lymphocytes may be a fundamental immunologic difference between GCA and TAK and may inform novel therapeutic strategies in these conditions. A lack of strong differences in circulating immune cell populations between TAK, GCA, and HC suggests that profiling peripheral blood may not be as informative as direct study of affected arterial tissue in these conditions.

Abstract Number: 0700

A Population-Based Study of Vasculitis Among Farmers and Urban Residents in Alberta

Elaine Yacyshyn, Simran Gulati, Whitney Hung, Don Voaklander and Allyson Jones, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic vasculitis encompasses a group of autoimmune diseases involving inflammation of blood vessels. Although a rare disease, vasculitis can present with life-threatening symptoms which pose a significant burden on patients as well as the health care system. Newer studies have demonstrated some association with environmental factors and geographic location. In this study, we compare the epidemiology of vasculitis of farmers to other populations in Alberta in a province-wide study.

Type of Vasculitis	Urban (n =103,112)		Rural (non-farm) (n= 96,667)		Rural (farm) (n= 102,310)	
PMR	678	44.20%	687	43.05%	1220	51.74%
Large vessel	142	9.26%	151	9.46%	219	9.29%
Medium vessel	37	2.41%	46	2.88%	69	2.93%
Small vessel	289	18.84%	272	17.04%	393	16.67%
Arteritis unspecified	253	16.49%	277	17.36%	307	13.02%
Single organ	122	7.95%	153	9.59%	144	6.11%
Variable vessel	13	0.85%	10	0.63%	6	0.25%

Methods: An Alberta intergovernmental data linkage identified all farm families in 1999.Two comparison groups were chosen: a random sample of rural residents and a random sample of urban residents. Vasculitis cases across these groups were determined using linked administrative health data from physician claims and hospital episodes. Data was retrieved from Alberta Health Services, a unifying healthcare provider for all residents of Alberta. This data includes all residents covered under the Canadian universal healthcare system. Descriptive statistics were generated comparing incident cases of vasculitis. Data were collected between April 1, 2000, and March 31, 2021.

Results: A total of 5488 vasculitis cases were found across all populations. Incidence rates varied across the 3 populations with farmers having the highest at 110.6/100,000 person-years followed by rural non-farmers (94.3) and urbanites (71.7).Age adjustment narrowed the variation between the incidence rates, but they remained in the same order: 90.1 farmers, 83.8 rural non-farmers, and 70.7 urbanites. In most cases, ∼60% were initially identified by physician claims. Polymyalgia rheumatica accounted for 47% of cases followed by Arteritis Unspecified (15%) and small-vessel vasculitis (14%) with the remainder being distributed among 9 other sub-categories. More males were observed having vasculitis in the farm population (50%) versus rural non-farmers and urbanites (41% and 40% respectively). Age at diagnosis was also higher in the farmer population (66.2 years) compared to rural non-farmers (64.5 years) and urbanites (63.9 years). Urban dwellers with vasculitis used fewer hospital-based health services than farmers and other rural residents.

Conclusion: In this large data set, the farm population in Alberta faces a greater burden of vasculitis compared to others in terms of rates of diagnosis and number of hospital admissions. This study lays the cornerstone for subsequent studies on assessing environmental exposures and the distribution of healthcare resources. Understanding the incidence of disease and relating to health care service intervention is important for access to care and management with vasculitis patients.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's Disease (BD) incidence varies widely worldwide. Neurobehcet's disease (NBD) is one of the most severe manifestations of BD**.** Data on NBD incidence is scarce and contradictory.

Our Objective was to estimate NBD incidence in Northern Spain.

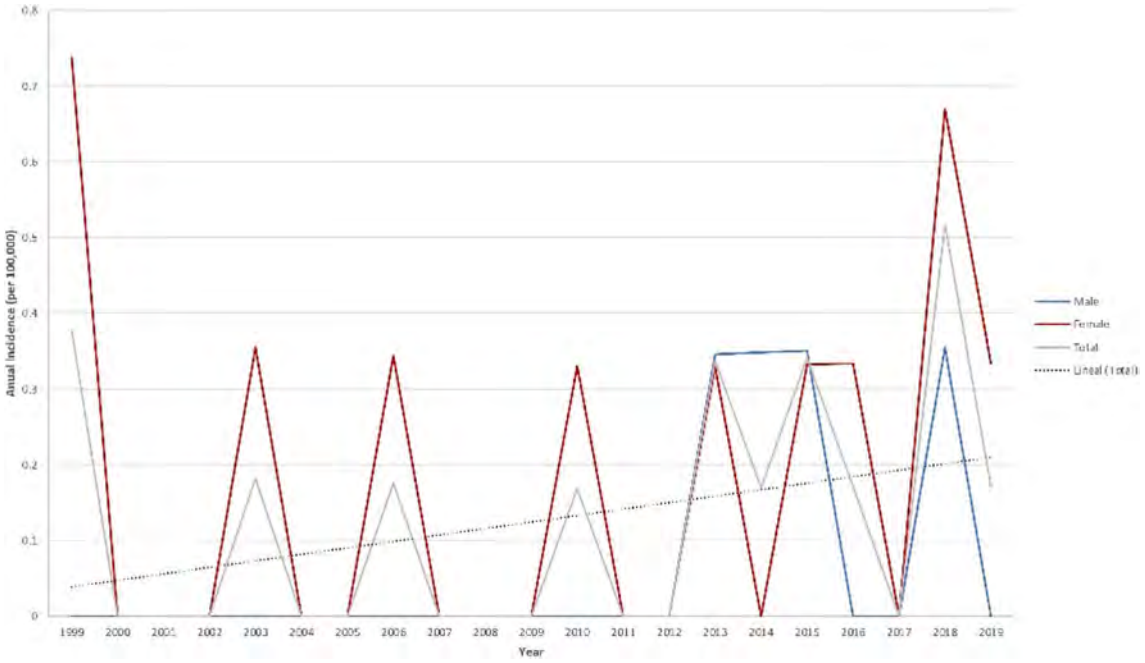

FIGURE. Incidence of neurobehçet's disease in residents in Northern Spain, in 1999-2019 according to gender.

Table. Main clinical features of neurobehçet's disease in different geographical areas. Abbreviations: BD: Behçet's disease, NBD: Neurobehçet's disease, ND: Non data

Methods: Population-based cohort study of 120 patients diagnosed with BD in Northern Spain, between January 1, 1999, to December 31, 2019. Finally, 92 were included according to the 2013 International Criteria for BD**(2).** NBD was diagnosed according to the International Consensus Recommendation criteria **(3).** The incidence of NBD between 1999-2019 was estimated by gender, age, and year of diagnosis. Annual incidence is expressed as cases per 100,000 people.

Results: NBD was diagnosed in 23 of 92 (25%) patients (15 women/8 men) (mean±SD age: 44±13.9 years). Ten (43.5%) patients had parenchymatous NBD, 10 (43.5%) had non-parenchymatous NBD and 3 (13%) cases had mixed NBD. Annual incidence of NBD in Northern Spain in the 1999-2019 period was 0.13 per 100,000 people [95% CI: 0.11-0.26] (0.14 [0.04-0.23] in men, 0.24 [0.12-0.37] in women). There were variations in annual incidences, with a minimum value of 0.08 in 2009-2010 and a maximum of 0.26 in 2017-2018 (**Figure**).

The highest incidence rate was observed in men in the 20-29 years group (0.03 per 100,000 people) and in women in the 30-39 years group (0.07per 100,000 people). On the other hand, the lowest incidence rate was observed in the 10-19 years group and 80-89 years group (0.008per 100,000 people). When analyzed the incidence rate stratified by age, there were no statistical differences according to gender. The annual incidence studied by year showed an annual peak incidence over the last 20 years. A comparison between different geographical areas was made (**Table**). NBD frequency ranges from 5.6 to 38%. It is usually more frequent in male young adults.

Conclusion: NBD frequency varies widely. The epidemiological characteristics of NBD in our series are similar to other except for gender predominance. Like in other immune mediated diseases this cyclic pattern in annual incidence could possibly be related to infectious environmental factors.

Large Vessel Vasculitis Increases Risk of Acute Myocardial Infarction in Patients Admitted for Congestive Heart Failure : A Nationwide Inpatient Database Study

Yanint Raksadawan, Sabahat Usmani, Harigopal Sandhyavenu, Thatiana Schulze Goni, Jalpan Patel, Hafiz Muhammad Waqar Younas and Amro Taha, Weiss Memorial Hospital, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac disease has been known to be a major morbidity and mortality cause in vasculitis. Large vessel vasculitis is mostly associated with pericarditis, myocarditis and valvular disease. The impact of association between LVV and CHF is less studied. 15-50% of Takayasu arteritis patients have aortic insufficiency and cases have been reported where patients present with acute congestive heart failure secondary to aortic insufficiency as their presenting symptom. On the other hand, the incidence of cardiac involvement in Giant Cell arteritis is less compared to Takayasu. Generally, there is a

paucity of data due to the rarity of cases. Our study attempted to determine the association of CHF and LVV in one of the largest datasets available in the country.

Methods: National inpatient sample database from 2016-2019 was queried to identify patients with a primary diagnosis of CHF and stratified based on the presence of LVV. The adjusted odds ratios (aOR) of in-hospital outcomes were calculated using chi-square statistics in software STATA v.17.

Results: Of 1,276,429 patients with CHF, 669 had LVV (Giant cell arteritis: 619 and Takayasu arteritis: 50). CHF with LVV patients were older (78.32 vs 70.72, p-value 0.00) and predominantly female (71.6% vs 48%, p-value 0.00). On adjusted analysis, compared to non-LVV patients, LVV patients had significantly higher acute myocardial infarction (AMI) (aOR 2.2,

Abstract Number: 0703

Cardiovascular Disease-Related Mortality in Primary Systemic Vasculitis

Alicia Rodriguez-Pla, Sierra Pacific Arthritis and Rheumatology Centers, Fresno, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the leading cause of death in patients with the most common subtypes of primary systemic vasculitides. We aimed to estimate the scope of cardiovascular-related death in patients with primary systemic vasculitis in the United States in recent years.

Methods: We used the CDC Wonder Multiple Causes of Death database and its query system. All deaths related to cardiovascular disease (CVD) as the UCD, and primary systemic vasculitides as CCDs were included from January 1, 1999, to December 31, 2020. We used the ICD-10 code I00-I99 (Diseases of the circulatory system) as the UCD, and the ICD-10 codes of the different subtypes of the primary systemic vasculitides were grouped as CCDs. Diseases of the circulatory system and all grouped vasculitides were initially queried separately, and the 2 disorders were also queried together to find out the mortality rates of CVD as UCD and vasculitis as CCD. We also performed the analysis by vasculitis subtypes. We obtained mortality rates by year, gender, race, and state. To obtain age-adjusted mortality rates we used the year 2000 U.S. standard population. We show mortality rates as the number of deaths per 100,000 for CVD, and per million for vasculitis. We applied a linear regression model to evaluate trends over time.

Results: During the 22-year period, CVD was the UCD of death of 18,783,791 patients. The age-adjusted mortality rate was 254.38 per 100,000 (95% CI: 254.27-254.50). For vasculitis as CCD, there were 29,229 deaths, and the age-adjusted mortality rate was 4.02 per 1,000,000 (95% CI: 3.97-4.07). When CVD as UCD and vasculitis as CCD were combined, there were 6,042 deaths, with an age-adjusted rate of 0.82 per 1,000,000 (95% CI: 0.80-0.84). Since 1999, there has been a significant trend to the decrease ($p < 0.0001$) (Figure 1). The age-adjusted mortality rate was higher in females than in males (0.88 vs. 0.71 per million). The percentage of females was 64.5%. The age-adjusted mortality rate was higher in Whites (0.90, 0.87-0.92) than in Blacks (0.39, 0.34-0.44) (Table 1). The percentage of Whites was 93.4%. M31.6 (Other giant cell arteritis) accounted for 58% of all vasculitis deaths. There was differential geographic distribution in the mortality rates by state. The states with the highest age-adjusted mortality rates were Maine, Vermont, Oregon, Iowa, and Minnesota (Table 2). The states with the lowest rates were Louisiana, Nevada, Mississippi, Florida, and Georgia.

Conclusion: There has been a progressive decrease in mortality rates in recent years. Contrary to what is found in the general population, in our study, the age-adjusted mortality rates were higher in females and in Whites. This can be explained, at least in part, by the fact that vasculitides are more frequent in Whites, and GCA, which is the subtype of vasculitis associated with the highest mortality rate in our study, is more frequent in white females. Mortality rates of vasculitis are more frequent in northern states. Investigation of the reasons for the geographic disparities is warranted. Our findings should be taken with caution until quality studies to determine the reliability of the data about these rare diseases available in national databases are performed.

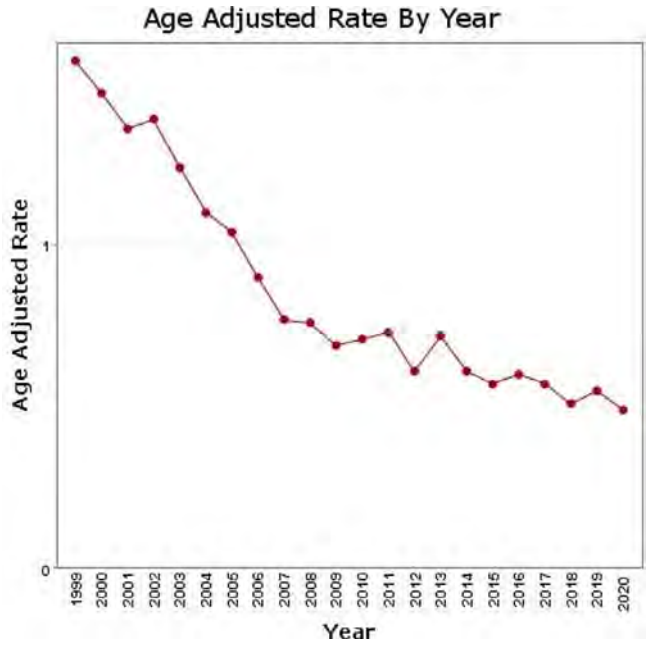

Figure 1. Age-adjusted mortality rate for cardiovascular as the underlying cause of death and with vasculitis as contributing cause of death, by year.

Table 1. Age-adjusted mortality rate per million for cardiovascular disease as underlying cause of death and vasculitis as contributing cause of death, by race and gender.

Clinical Characteristics and Outcomes in Patients Found to Have Clinically Isolated Aortitis After Aortic Aneurysm Repair: A Single-Center Experience

Ora Gewurz-Singer[1], **Julia Ford**[2], Thu Thu Aung[2] and Lauren Humphrey-Stark[2], [1]University of Michigan, Huntington Woods, MI, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinically isolated aortitis (CIA), or aortitis in the absence of identifiable systemic vasculitis, is typically discovered histopathologically after aortic aneurysm repair. The approach to caring for CIA patients as a rheumatologist remains uncertain, including the role of immunosuppression (IS) and the risk of developing systemic rheumatologic disease. To add to the limited literature on this topic[1,2],we conducted a study using the Cardiovascular Health Improvement Project (CHIP) database at Michigan Medicine, which is enriched for patients with surgical aortic disease. Our aim was to identify and describe CIA patients in CHIP and provide insights into the clinical characteristics and outcomes.

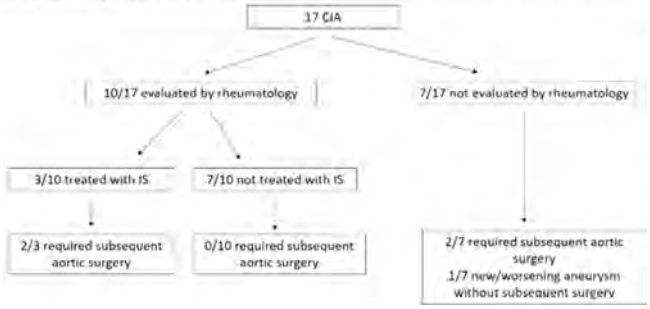
Methods: We queried CHIP to identify patients with diagnosis codes or keywords in the electronic medical record (EMR) related to aortitis from 8/1/2013-3/31/2022. CIA cases were independently verified with chart review by two physicians. Patients without any follow-up in the EMR after diagnosis of aortitis were excluded. Clinical data was recorded at time of CIA diagnosis until date of last follow-up in EMR, including subsequent aortic events (subsequent aortic surgery, new or worsening aneurysm, new stenosis, or dissection).

Table 1. Characteristics at time of CIA diagnosis (N=17).

Age, median (IQR) years	69 (63, 74)
Female	8 (47)
Caucasian	16 (94)
BMI, median (IQR) kg/m^2	27.8 (26.4, 32)
Comorbidities	
Hypertension	12 (71)
Hyperlipidemia	6 (35)
Type 2 diabetes mellitus	3 (18)
Coronary artery disease	0 (0)
Ever-smoker	14 (82)
Smoking, median (IQR) pack-years	15 (1, 30)
Histopathologic pattern of aortitis	
Lymphoplasmacytic	8 (47)
Giant cell/granulomatous aortitis	6 (35)
Nonspecific aortitis	3 (18)
ESR Post-operative, median (IQR) mm/hr*	15 (12.5, 26.5)
CRP Post-operative, median (IQR) mg/dl*	0.5 (0.15, 0.55)

Values are number (%) unless indicated otherwise. CIA=clinically isolated aortitis, BMI=body mass index, ESR= erythrocyte sedimentation rate, CRP= C-reactive protein.
*ESR and CRP checked 2-6 months post-operatively were available for n=7. No pre-operative ESR/CRP were available.

Figure 1. Flow diagram of outcomes among patients found to have clinically isolated aortitis (CIA) after aortic aneurysm repair. IS= immunosuppression.



Results: 17 patients with CIA were identified with 7.1 (IQR 2.9, 10.0) years of follow-up, all of whom had undergone ascending aortic aneurysm repair. Clinical characteristics at CIA diagnosis are presented in **Table 1**. Rheumatology was engaged post-operatively in 10 cases (59%); only 3 patients (18%) were treated with IS (steroids ± tocilizumab) at any point during follow-up. One patient was diagnosed with systemic rheumatologic disease (rheumatoid arthritis) 6.6 years after CIA diagnosis. Subsequent aortic events occurred in 5 patients (29%) at median 3.7 (IQR 1.5, 6.2) years of follow-up (**Figure 1**). One patient passed due to unrelated reasons 16.4 years after CIA diagnosis.

Conclusion: In this single-center cohort of 17 patients with CIA aortic aneurysm repair, there was a high prevalence of hypertension and ever-smoking, and post-operative inflammatory markers (when available) tended to be normal. Interestingly, evolution into systemic rheumatologic disease was uncommon. A third of patients had subsequent aortic events after CIA diagnosis, highlighting the need for continued clinical surveillance of patients with CIA; no conclusions could be drawn regarding the impact of IS on preventing subsequent aortic events.

Sleep Disturbances in Patients with Vasculitis: Results of the Vasculitis Patient-Powered Research Network Sleep Study (SleepVasc)

Misa Tanaka[1], Saverio Stranges[1], Kathy Speechley[1], Osvaldo Espin Garcia[1], Molly Mason[2], Renee Borchin[3], Cristina Burroughs[3], Christine Yeung[4], Indira Gurubhagavatula[4], Christian Pagnoux[5], Peter Merkel[4] and **Lillian Barra**[1], [1]Western University, London, ON, Canada, [2]Vasculitis Patient Powered Research Network, Philadelphia, PA, [3]University of South Florida, Tampa, FL, [4]University of Pennsylvania, Philadelphia, PA, [5]Mount Sinai Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Sleep deprivation and sleep disorders can impair health-related quality of life and increase the risk of chronic diseases, such as cardiovascular disease, and mental illness. In patients with vasculitis, several factors could contribute to a higher risk of disordered sleep, including glucocorticoid use and upper airway involvement. This study aimed to describe sleep disturbances in patients with vasculitis.

Methods: In this cross-sectional study, we conducted an online survey of patients registered with the Vasculitis Patient-Powered Research Network (VPPRN). The questionnaire included these validated measures: Epworth Sleepiness Scale (ESS, range 0-24, < 10 normal), Functional Outcomes of Sleep Questionnaire-10 (FOSQ-10, range 5-20, higher scores indicate better function), and the Multivariable Apnea Prediction Index (MVAP, range 0-1, 1 indicates highest risk for obstructive sleep apnea (OSA)). Patients were also asked about previously diagnosed sleep disorders, characteristics of their vasculitis, medication use, and demographics. Responses were collected from February 1 to April 1, 2023.

Table 1: Characteristics of the study population

	Total	Female	Male
Sample size, n (%)	1104	821 (74.4)	280 (25.4)
Type of vasculitis, n (%)			
Giant cell arteritis	60 (5.4)	60 (7.3)	0 (0.0)
Takayasu's arteritis	72 (6.5)	61 (7.4)	11 (3.9)
Microscopic polyangiitis	111 (10.1)	85 (10.4)	26 (9.3)
Granulomatosis with polyangiitis	479 (43.4)	334 (40.7)	144 (51.4)
Eosinophilic granulomatosis with polyangiitis	147 (13.3)	92 (11.2)	10 (3.6)
Other types of vasculitis[a]	235 (21.3)	189 (23.0)	89 (31.8)
Body mass index, kg/m^2, mean (SD)	28.2 (7.9)	28.5 (8.4)	27.2 (6.3)
Age, mean (SD)	59.5 (13.6)	58.5 (13.8)	62.7 (12.5)
Race, White, n (%)	1005 (91.0)	756 (92.1)	249 (88.9)
Treatments received at survey completion, n (%)			
Glucocorticoids	386 (35.0)	281(34.2)	102(36.4)
Prednisone-equivalent glucocorticoid dose			
0- 10 mg/day	316 (28.6)	225(27.4)	88 (31.4)
11-39 mg/day	57 (5.2)	43 (5.2)	14 (5.0)
≥ 40 mg/day	10 (0.9)	10 (1.2)	0 (0.0)
Rituximab	200 (18.1)	145(17.1)	53 (18.9)
Azathioprine	92 (8.3)	71 (8.6)	21 (7.5)
Methotrexate	86 (7.8)	64 (7.8)	22 (7.9)
Mycophenolate	79 (7.1)	58 (7.1)	20 (7.1)
Other immunosuppressive drugs[b]	120 (10.9)	98 (11.9)	22 (7.9)
Pain at time of survey, 0=no pain, 10=worst pain; median VAS (IQR)	3.0 (4.0)	3.0 (4.0)	2.0 (3.0)
Symptoms of vasculitis at the time of survey, 0=no symptoms, 10=severe symptoms; median VAS (IQR)	4.0 (4.0)	4.0 (4.0)	2.0 (5.0)

SD: standard deviation; IQR: inter-quartile range

[a]Includes polyarteritis nodosa, IgA vasculitis, cryoglobulinemic vasculitis, hypocomplementemic urticarial vasculitis, Behçet's disease, central nervous system vasculitis

[b]Includes biologic therapies other than rituximab and Janus kinase inhibitors

Results: Of the 1,104 patients with vasculitis recruited, 1,037 completed the questionnaire in full. Participants included 479 with granulomatosis with polyangiitis, 147 with eosinophilic granulomatosis with polyangiitis, 111 with microscopic polyangiitis, 60 with Takayasu arteritis, 72 with giant cell arteritis, and 235 with other types of vasculitis. The study population was 74.4% female. The mean (SD) age and disease duration were 59.5 (13.6) and 9.7 (8.4) years, respectively. Use of glucocorticoids and immunosuppressants were common at the time of the survey (**Table 1**). At least 1 sleep disturbance was reported by 82% of patients with vasculitis. Excessive daytime sleepiness occurred in 26%, impaired daily function in 77%, and 19% were at high risk for obstructive sleep apnea (OSA). Previously diagnosed OSA, insomnia, and restless legs syndrome were reported by 20%, 14%, and 11% of patients, respectively (**Table 2**). Prevalence of OSA among this sample was higher than what is reported for the general population (6-17%). Similar to the general population, the risk of OSA was higher in males. Other sleep disorders, excessive daytime sleepiness, and daily functional impairment were more common in females (**Table 2**). Sleep disturbances were more prevalent in those taking higher doses of glucocorticoids (**Table 3**).

Table 2: Sleep disturbances among patients with systemic vasculitis

	Total	Female	Male	p-value
Epworth sleep scale				
Median (IQR)	7.0 (7.0)	7.0 (7.0)	6.0 (6.0)	0.007
≥ 11, n (%); Excessive daytime sleepiness	274 (24.8)	215 (26.2)	57 (20.4)	0.032
Functional outcomes of sleep questionnaire				
Median (IQR)	14.7 (6.3)	14.3 (6.0)	16.2 (6.0)	<.001
< 18, n (%); Significant impairment in daily function	841 (76.2)	655 (79.8)	183 (65.4)	<.001
Multivariable apnea prediction index				
Median (IQR)	0.29 (0.4)	0.20 (0.3)	0.51 (0.3)	<.001
≥ 0.6, n (%); High risk for obstructive sleep apnea	183 (16.6)	82 (10.0)	101 (36.1)	<.001
Previously diagnosed sleep disorders[a], n (%)				
Obstructive sleep apnea	218 (19.7)	144 (17.5)	73 (26.1)	0.004
Insomnia	158 (14.3)	132 (16.1)	26 (9.3)	0.004
Restless leg syndrome	124 (11.2)	95 (11.6)	29 (10.4)	0.500
Narcolepsy	9 (0.8)	7 (0.9)	2 (0.7)	0.802
Any sleep disturbance[b], n (%)	908 (82.2)	688 (83.8)	217(77.5)	<.001
Use of a sleep aid in the past month[c], n (%)	1046 (94.7)	772 (94.0)	271 (96.8)	0.404
Sleep satisfaction, n (%)				
Dissatisfaction	521 (47.2)	400 (48.7)	118 (42.1)	0.022
Neutral	272 (24.6)	200 (24.4)	72 (25.7)	
Satisfaction	252 (22.8)	172 (21.0)	80 (28.6)	
Sleep satisfaction at time of survey compared to prior to the diagnosis of vasculitis, n (%)				
Worse	623 (56.4)	481 (58.6)	140 (50.0)	0.003
Same	297 (26.9)	199 (24.2)	98 (35.0)	
Better	125 (11.3)	92 (11.2)	32 (11.4)	

[a]based on self-report of a sleep disorder diagnosed by a health professional
[b]defined as having ESS ≥ 11 or FOSQ-10 < 18 or MVAP ≥ 0.6 or a prior diagnosis of any sleep disorder by a health professional
[c]includes prescription medications, over the counter medications, and non-pharmacologic interventions (exercise, meditation, etc.)

Table 3:Sleep disturbances among patients with systemic vasculitis by prednisone-equivalent glucocorticoid doses

	Prednisone-equivalent glucocorticoid dose in mg/day, n (%)				
	0	0 to 10	11 to 39	≥ 40	p-value
	658 (59.6)	316 (28.6)	57 (5.2)	10 (0.9)	
Epworth sleep scale[a]					
median (IQR)	7 (6.0)	7 (7.0)	9 (6.0)	13.5 (7.0)	<.001
≥ 11, n (%)	153 (23.3)	82 (25.9)	23 (40.4)	7 (70.0)	0.001
Functional outcomes of sleep questionnaire[b]					
median (IQR)	15.2 (6.0)	14.3 (6.3)	10.5 (6.8)	10.3 (5.3)	<.001
< 18, n (%)	490 (74.5)	256 (81.0)	51 (89.5)	10 (100)	0.007
Multivariable apnea prediction index[c]					
median (IQR)	0.26 (0.37)	0.33 (0.45)	0.32 (0.49)	0.26 (0.18)	0.163
≥ 0.6, n (%)	97 (14.7)	70 (22.2)	15 (26.3)	1 (10.0)	0.011
Previously diagnosed sleep disorder, n (%)					
Obstructive sleep apnea	134 (20.4)	67 (21.2)	14 (24.6)	1 (10.0)	0.811
Insomnia	92 (14.0)	48 (15.2)	14 (24.6)	4 (40.0)	0.025
Restless leg syndrome	70 (10.6)	40 (12.7)	11 (19.3)	2 (20.0)	0.267
Narcolepsy	6 (0.9)	2 (0.6)	1 (1.8)	0 (0.0)	0.931

[a] ≥ 11 on the Epworth sleep scale indicates excessive daytime sleepiness.
[b] <18 on the Functional outcomes of sleep questionnaire indicates significant impairment in daily function
[c] ≥ 0.6 on the Multivariable apnea prediction index indicates high risk for OSA

Conclusion: Sleep disturbances are common in patients with vasculitis and significantly impact daily function. Use and dose of glucocorticoids may increase the risk of sleep disturbances in patients with vasculitis.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Aortitis is the inflammation of the aortic wall, and can be idiopathic or associated with a cluster of infectious and non-infectious diseases **(1-3)**. Periaortitis, is an inflammatory process arising from the adventicia of the aortic wall and extending into the surrounding periaortic space. The aim of this study is to assess the causes and the main features of patients with aortitis and/or periaortitis.

Methods: Observational study of patients with aortitis or periaortitis from a large-vessel vasculitis monographic consultation at a referral hospital from June 2022 to April 2023. Aortitis and periaortitis were diagnosed by imaging techniques.

Results: We include 135 patients (87 female/ 48 male) (mean±SD age; 57.3±7.6 years). The different subtypes of aortitis/ periaortitis were: Giant-cell arteritis (GCA) (n=102), Takayasu arteritis (n=6), other immune mediated diseases (n=13), IgG4-related disease (IgG4-RD) (n=6), infectious (n=3), retroperitoneal idiopathic fibrosis (n=2), malignancy (n=1), drugs (n=1), and isolated aortitis (n=1). The imaging techniques used for the diagnosis of aortitis were: PET/TAC (n=134), TAC (n=44), and RMN (n=33). The main features of the patients with non-infectious aortitis/periaortitis are summarized in **Table**. Aortitis was most frequent in women. High blood pressure and dyslipidaemia was present in 52% and 48% respectively. Polymyalgia rheumatica and general symptoms were the more frequent manifestations. The underlying diseases in the group of aortitis related to other immune mediated diseases were: Sjögren syndrome (n=2), sarcoidosis (n=2), rheumatoid arthritis (n=2), axial spondyloarthritis (n=2), inflammatory bowel disease (n=1), primary biliary cirrhosis (n=1), lung fibrosis (n=1), recurrent pericarditis (n=1), and polyarteritis nodosa (n=1). The ascending thoracic aorta was the most frequently involved segment **(Figure)**.

TABLE. Main features of the patients with non-infectious aortitis/periaortitis.

FEATURES	OVERALL (n=132)	GCA (n=102)	TA (n=6)	OTHER INFLAMMATORY DISEASES (n=13)	IgG4-RD (n=6)	Idiopathic retroperitoneal fibrosis (n=2)	Malignancy (n=1)	Drugs (n=1)	Isolated aortitis (n=1)

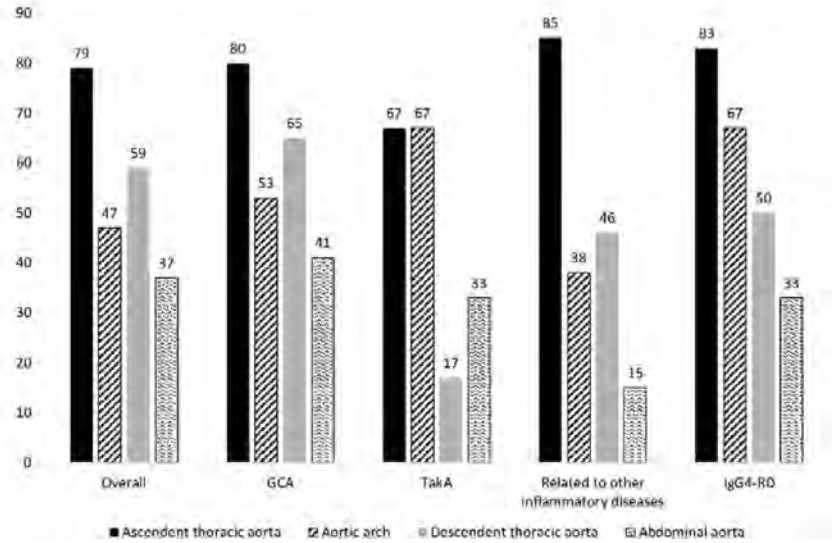
ESR (mm/1h), median [IQR]	43.5 [6-50]	26.5 [7-54]	16.5 [3.5-32.5]	36 [6-47]	9 [7.5-59]	-	50	29	12.5 [10-15]

Abbreviations: CRP: C-reactive protein, ESR: erythrocyte sedimentation rate, GCA: giant cell arteritis, IgG4-RD: IgG4-related disease, PmR: polymyalgia rheumatica, TA: Takayasu arteritis

Main features of the patients with non-infectious aortitis/periaortitis.

Figure. Segments of the aorta affected. All data are in %.



Segments of the aorta affected. All data are in %.

Conclusion: Aortitis can be isolated or secondary to infectious and more frequently to non-infectious processes. GCA is the most frequent cause, being common the presence of PmR and constitutional symptoms. The thoracic aorta, specially ascending, seems to be the most frequently involved segment.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Arterial wall calcifications are a hallmark of atherosclerosis and represent an important cardiovascular risk factor. Accelerated atherosclerosis and vascular calcifications have been reported in large vessel vasculitis (LVV), but data are scarce about the amount and localizations. The aim of this study was to compare the prevalence, entity, and local distribution of arterial wall calcifications evaluated on CT scans in patients with LVV and lymphoma.

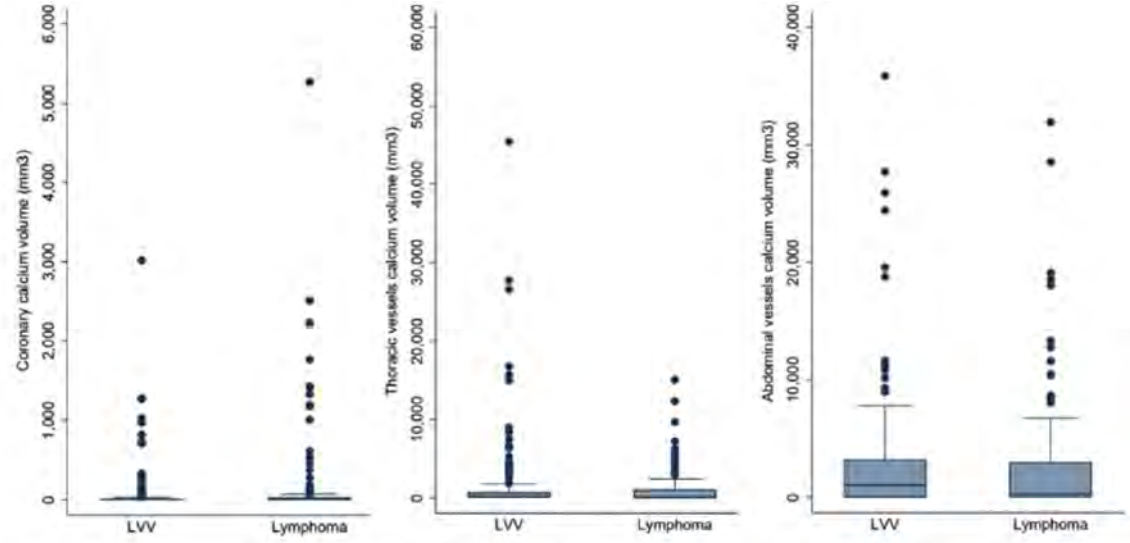

Figure: Distribution of the volume of calcifications in coronary, thoracic, and abdominal vessels in the LVV group (including non-matched patients) and lymphoma group.

Distribution of the volume of calcifications in coronary, thoracic, and abdominal vessels in the LVV group (including non-matched patients) and lymphoma group.

Table: Association of LVV group with the presence of calcification in different locations

	LVV Group Prevalence of calcification	Lymphoma Group Prevalence of calcification	*OR (95%CI) of calcification in LVV vs. Lymphoma group*	*P value*
Coronary Calcification	35/129 (27.1%)	38/129 (29.5%)	0.79 [0.35 – 1.78]	0.575
Thoracic Calcification	93/129 (72.1%)	71/129 (55.0%)	4.13 [1.35 – 12.66]	0.013
Abdominal Calcification	93/129 (72.1%)	86/129 (66.7%)	2.05 [0.48 – 8.71]	0.328

*Conditional logistic regression analyses on matched patients (n=129 for each group). OR, Odds Ratio; CI, confidence interval.

Association of LVV group with the presence of calcification in different locations

Methods: All consecutive patients diagnosed with LVVs with available baseline PET-CT scan performed between 2007 and 2019 were included; lymphoma patients were matched by age (+/-5 years), sex, and year of baseline PET-CT (≤2013; >2013). CT images derived from baseline PET-CT scans of both patient groups were retrospectively reviewed by a single radiologist who, after setting a threshold of minimum 130 HU, semi-automatically computed vascular calcifications in three separate locations (coronaries, thoracic and abdominal arteries), quantified as Agatston and volume scores.

Results: A total of 266 patients were included (129 for each group and 8 non-matched LVV patients). Thoracic artery calcifications were more represented in LVV patients, when compared with lymphoma patients (mean volume 2026 in LVVs vs 1014 in lymphomas, p=0.054), coronary calcifications were higher in lymphoma patients (mean volume 104 in LVVs and 198 in lymphomas, p=0.13), whereas abdominal artery calcifications were equally distributed (mean volume 3220 in LVVs and 2712 in lymphomas) (Figure). Being in the LVVs group was associated with the presence of thoracic calcifications after adjusting by age and year of diagnosis (OR=4.13, 95%CI=1.35-12.66; p=0.013). Similarly, LVVs group was significantly associated with the volume score in the thoracic arteries (p=0.048) (Table).In patients >50 years old, calcifications in the coronaries were more extended in lymphoma patients (p=0.027 for volume).

Conclusion: When compared with lymphoma patients, LVVs patients have higher volumes of calcifications in the thoracic arteries, but not in coronary and abdominal arteries.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunoglobulin A Vasculitis (IgAV) is a B-cell-mediated inflammatory disease. NF-kappa B (NF-kB) plays a key role in autoimmunity and inflammation[1]. In this regard, the development of B-cells is described as dependent on the activation of NF-kB[2]. In addition, *NFKB1* (gene encoding NF-kB) is described as a shared risk *locus* for several immune-mediated diseases[3]. Specifically, *NFKB1* is crucial in the pathogenesis of IgA nephropathy[4,5], a disease that shares molecular mechanisms with IgAV. Accordingly, we aimed to determine whether *NFKB1* and *NFKBIA* (gene encoding the NF-kB Inhibitor Alpha) represent novel genetic risk factors for IgAV.

Methods: 410 patients with IgAV, the largest series of Caucasian patients with IgAV ever assessed for genetic studies, and 764 healthy ethnically matched controls, were recruited for this study. Six tag single nucleotide polymorphisms (SNPs) within *NFKB1* (rs77830930, rs1598856, rs7340881, rs4648055, rs4648090 and rs230547) and 7 *NFKBIA* tag SNPs (rs3138055, rs696, rs1022714, rs2233419, rs2233415, rs1050851 and rs1957106) were genotyped using TaqMan Probes. P-values were corrected with the FDR method for multiple testing.

Results: A statistically significant decrease of *NFKB1* rs4648055 A allele was disclosed in patients with IgAV when compared to controls (p=0.013 OR=0.78 [0.64 - 0.95], Tables 1 and 2). Additionally, a statistically significant decrease in the *NFKB1* GGCAGC haplotype was observed in IgAV patients compared to controls (p=0.007, Table 3). These results were

Table 1: *NFKB1* and *NFKBIA* genotype and allele frequencies in IgAV patients and healthy controls.

	GGAGACC	18.5	16.6	1.33	0.25
	GAGAGCT	16.1	15.5	0.15	0.69
	GGAGGTT	10.6	11.0	0.08	0.78
	GGGGGCT	7.3	8.6	1.21	0.27
	GGGGGTT	6.1	5.5	0.37	0.54
	AGGGGCT	4.3	6.0	3.07	0.08

IgAV: IgA Vasculitis. The table shows the *NFKB1* and *NFKBIA* haplotypes with a frequency greater than 5%. [1]Haplotypes are arranged in the following order: *NFKB1* (rs77830930, rs1598856, rs7340881, rs4648055, rs4648090, and rs230547) and *NFKBIA* (rs1957106, rs1050851, rs2233415, rs2233419, rs1022714, rs696, rs3138055).

not significant after FDR correction. No other statistically significant results were found in *NFKB1* and *NFKBIA* genotype, allele, or haplotype frequencies between patients with IgAV and controls (Tables 1-3), nor when IgAV patients were stratified according to the age at disease onset or the presence/absence of gastrointestinal or renal manifestations (data not shown).

Conclusion: Our results suggest that *NFKB1* and *NFKBIA* do not seem to be involved in the pathogenesis of IgAV.

Abstract Number: 0709

Survival of Adults with IgA Vasculitis

Alojzija Hocevar[1], JAKA OSTROVRŠNIK[2], vESNA JURČIĆ[3], Matija Tomšič[4] and Ziga Rotar[5], [1]Department of Rheumatology, Universitiy Medical Centre Ljubljana, Ljubljana, Slovenia, [2]UKC Ljubljana, Ljubljana, Slovenia, [3]University of Ljubljana, Medical Faculty, Institute of Pathology, Ljubljana, Slovenia, [4]Department of Rheumatology, University Medical Centre LJubljana, Ljubljana, Slovenia, [5]University Medical Centre Ljubljana, Ljubljana, Slovenia

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Data on survival of adults with IgA vasculitis (IgAV) are scarce. The aim of our study was to estimate for the first time the survival of IgAV patients in our country.

Methods: Our cohort consisted of adult patients diagnosed with IgAV between January 2010 and July 2022 and followed at our secondary/tertiary rheumatology center. To study the survival/mortality the censor date of 22, December 2022 was set, and time until death or the censor date, whichever came first, was recorded. Kaplan–Meier analysis and standardized mortality ratio (SMR) were plotted using survival data from age and sex matched Slovenian population as a reference. Cox proportional hazards regression analysis was used to study prognostic factors for mortality in IgAV.

Results: Of 265 IgAV patients (156 (58.9%) males, median (IQR) age at diagnosis 61 (44; 74) years; median (IQR) follow up time 62 (27; 93) months), 48 (18.1%) patients died. Five-year survival in our cohort was 78% (95% CI 74%; 83%); in adults < 51 years 100% survival, and in adults aged ≥51 years 68% survival (the difference was significant, p=0.01). Ten-year survival in our patients was 65% (95%CI 59%; 72%). We found no sex related differences in the survival (p=0.37). The comparison of mortality between the IgAV cohort and age and sex matched general Slovenian population showed a significantly higher overall mortality in IgAV cohort, with an overall SMR of 1.4 (95%CI 1.14-1.71). The Kaplan-Meier survival curves of IgAV patients and matched general population as a comparator are shown in Figure 1. Excess deaths occurred mainly during the first two years of follow-up (Table 1). As risk factors associated with increased mortality in IgAV emerged patient age (HR 1.09 (95%CI 1.06; 1.13)), purpura above waistline (HR 2.14 (95% CI 1.13; 4.06)) and pre-existent heart failure (HR 7.37 (95%CI 3.74; 14.54)).

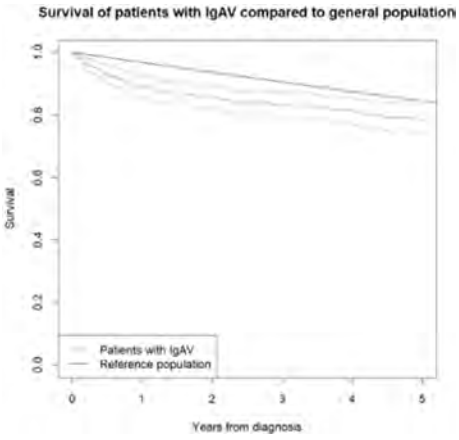

Figure 1. Survival curve of IgAV patients according to Kaplan–Meier analysis compared to sex and age matched general Slovenian population

Table 1. The standardized mortality ratio of adults with IgAV . Legend: SMR standardized mortality ratio

Follow-up	SMR (95% CI)	P value
1 year	3.79 (2.68 – 5.20)	<0.001
2 years	2.75 (2.05 – 3.62)	<0.001
3 years	2.18 (1.66 – 2.82)	<0.001
4 years	1.84 (1.41 – 2.35)	<0.001
5 years	1.70 (1.33 – 2.15)	<0.001
6 years	1.60 (1.26 – 1.99)	<0.001
7 years	1.53 (1.22 – 1.90)	<0.001
8 years	1.46 (1.17 – 1.80)	<0.001
9 years	1.42 (1.14 – 1.75)	0.001
10 years	1.39 (1.12 – 1.70)	0.002

Cardiovascular diseases, cancer and infections represented the most frequent causes of death in our patients, recorded in 16 (33.3%), 6 (12.5%) and 6 (12.5%) patients, respectively, followed by hepatobiliary disease (3 cases), respiratory failure (2 cases), trauma/bleeding (3 cases) and dementia (3 cases). In one patient death was related to IgAV relapse, and in 8 (16.7%) patients the cause of death was unknown.

Conclusion: Survival of adults with IgAV was worse compared to matched general population in our country. Nevetheless, IgAV per se was an infrequent cause of death during follow up in our population.

The Association of IgA Vasculitis and Malignancy in Adults: A Systematic Review

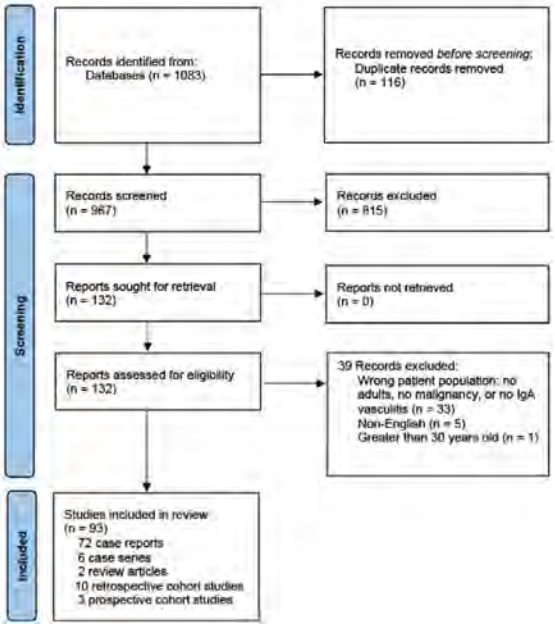
Hila Ghersin[1], Michelle Toker[2], Urmi Khanna[2], Rachel Schwartz[1], Benedict Wu[3] and Anand Kumthekar[2], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY, [3]Montefiore Medical Center, Bronx, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IgA vasculitis (IgAV) is associated with malignancy in adult patients [1,2]. The clinical characteristics, temporal relationship, and underlying mechanisms of malignancy-associated IgAV are not well understood. Currently, there are no evidence-based screening guidelines for occult malignancies in adults presenting with IgAV.

Methods: We performed a systematic literature review of five major databases: Cochrane Library, Embase.com, PubMed.gov, Google Scholar, and Web of Science Core Collection using the Preferred Reporting Items for Systematic Reviews and MetaAnalyses (PRISMA) guidelines. A combination of multiple synonyms, controlled vocabulary search terms (MeSH in PubMed and Emtree in Embase), and exhaustive text words were used to search the databases. Two independent reviewers selected studies, extracted data, and determined study quality. A third reviewer adjudicated the article if there was a discrepancy between the 2 reviewers. The articles met inclusion criteria if they contained information regarding IgAV and malignancy in adults older than 18 years-old. Non-English articles and articles older than 30 years-old were excluded.

Figure 1. PRISMA Flowchart illustrating article selection and inclusion process



Flowchart illustrating article selection and inclusion process.

Table 1. Demographic and clinical information by malignancy type

		Solid Malignancy	Hematologic Malignancy	Total

Summary of sample demographic information, including age, sex, and race/ethnicity, and clinical information, including relative timing, systemic involvement, pathology, serology , and outcomes, by malignancy type.

Results: We screened 967 studies and 93 articles were included, comprising of 108 individual patient cases (Figure 1). The mean age of patients was 60.3±12.9 years, and the majority (n=71, 65.7%) were male (Table 1). Solid malignancy was more commonly associated with IgAV than hematologic malignancy (67.7% vs 32.4%). Malignancy preceded IgAV for most patients with solid cancer, whereas for most with hematological cancer, IgAV preceded malignancy or was diagnosed synchronously. Patients with IgAV and solid malignancies had a significantly higher mortality rate compared to patients with IgAV and hematological malignancies (38.6% vs. 16.7%, $p \leq 0.05$). Patients with solid malignancies were also more likely to exhibit systemic involvement of IgAV, including renal, gastrointestinal, joint, and cutaneous symptoms, although the differences were not significant. The majority of patients with skin biopsy had IgA on DIF (71.2%), and of the patients that reported serum IgA levels, 26 (68.2%) had elevated serum IgA.

Conclusion: To our knowledge, this is the largest systematic review of IgAV associated with malignancy. Based on our findings, screening older patients with new-onset or recurring IgAV for malignancy, particularly solid organ cancer, should be considered. Serum IgA levels might serve as a useful, non-invasive screening test since elevated IgA may correlate with underlying malignancy, though further studies are needed to validate these findings.

IgA Vasculitis in a Diverse Adult Patient Population

Michelle Toker[1], Urmi Khanna[1], Roya Nazarian[1], Adhya Mehta[2], Bibi Ayesha[1], Anand Kumthekar[1] and Benedict Wu[1], [1]Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY, [2]Jacobi Medical Center, Bronx, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunoglobulin-A (IgA) Vasculitis (IgAV) is a small-vessel vasculitis that is primarily diagnosed based on the European League Against Rheumatism (EULAR) criteria. There is limited knowledge about the IgAV phenotype in a racially and ethnically diverse population. We aimed to describe the clinicopathologic characteristics of IgAV in our adult skin of color (SOC) patients.

Methods: We retrospectively reviewed adult patients (>18 years) from the dermatopathology database with leukocytoclastic vasculitis (LCV) at Montefiore Medical Center between January 2012–December 2022 (Figure 1). We collected demographic, clinical, laboratory, and histopathological data from the electronic medical record to identify individuals with SOC who met EULAR criteria. We defined SOC as any non-White race/ethnicity. Descriptive statistics and Fisher's exact test were used to analyze the SOC cohort.

Results: We identified 65 patients with LCV, 52 patients met EULAR criteria for IgAV, of which 42 (81%) were SOC. In our SOC cohort of 42 patients, 32 (76%) identified themselves as Spanish/Hispanic/Latino, 7 (17%) identified themselves as Black, and 3 (7%) identified themselves as Asian. The mean (±SD) age was 56 (±16) years and 29 (69%) were females. The median (IQR) number of affected body sites was 3 (2-5). Renal involvement was present in 36 (86%) patients (Table 1). Gastrointestinal (GI) involvement was present in 16 (38%) and joint involvement was present in 5 (12%). Elevated neutrophil/lymphocyte ratio (NLR) was present in 22 (52%). Elevated serum IgA levels were present in 13 (62%) of the 21 patients with measured serum IgA. Skin biopsy direct immunofluorescence (DIF) was performed in 28 (67%) patients and showed IgA and C3 in 11 (39%) and 19 (64%), respectively. Remission was achieved in 34 (81%) patients and 8 (19%) experienced relapse.

	Topical tx	33 (78.6%)
	Systemic tx	16 (38.1%)
	Remission	34 (81.0%)
	Relapse	8 (19.0%)
	Death (all-cause)	4 (9.5%)

Footnote: SD = standard deviation, IQR = interquartile range, NLR = neutrophil-to-lymphocyte ratio, Cr = creatinine, dx = diagnosis, f/u = follow-up, DIF = direct immunofluorescence, tx = treatment, [*]N = 21, [#]N = 36, [^]N = 37, [v]N = 12, [+]N = 37, [•]N = 31, [•]N = 16

We further analyzed the 28 patients who had skin biopsy with DIF and compared those with and without IgA deposition (Figure 1). The IgA^+ group had significantly lower prevalence of renal involvement (p=0.0161), higher prevalence of GI involvement (p=0.0204), high NLR (p=0.0238), and C3 deposition on DIF (p=0.0039), and greater number of affected body sites (p=0.0206). Lesions above waistline and elevated serum IgA were not associated with systemic symptoms, including renal involvement, or positive DIF. Elevated NLR was associated with IgA deposition (p=0.0209).

Conclusion: In contrast to previous studies, the majority of our adult SOC patients had renal or GI involvement with IgA^+ DIF being associated with lower prevalence of renal involvement. Additionally, our SOC patients with IgA^+ DIF had more widely distributed lesions. Cutaneous involvement above the waist was not associated with renal complications. Prior studies showing the predictive value of skin biopsy and lesion location in predominantly White populations may not apply to SOC patients.

Abstract Number: 0712

Clinical and Histologic Prognostic Factors of Renal Progression in Adults with IgA Vasculitis

Meenakshi Vanka[1] and Taesoo Kim[2], [1]Oregon Health & Science University/Emory, Atlanta, GA, [2]Oregon Health & Science University, Portland, OR

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IgA Vasculitis (IgAV) is a systemic small vessel vasculitis that affects the skin, joints, gastrointestinal tract, and kidneys. While most common in children, it is rare in adults and associated with worse prognosis. IgAV has a variable course with many patients spontaneously entering remission, making it difficult to know which patients need treatment.

A few retrospective trials have shown that adult IgAV patients with greater proteinuria, kidney insufficiency at time of biopsy, and hypertension have worse overall prognosis, often developing progressive kidney disease. Retrospective studies in European and Asian populations have also considered the MEST-C renal biopsy score components as predictive tools in IgAV.

The goal of this study is to expand on existing studies and identify clinical factors that predict poor outcome in IgAV adults. We also aim to identify histologic prognostic factors using the MEST-C score components. Identifying prognostic factors will improve patient treatment plans while informing future therapeutic studies.

Methods: We conducted a retrospective analysis of 31 IgAV adult patients. A Cohort Discovery Tool was built to identify eligible patients. The primary outcome was progressive kidney disease, defined as nephrotic range proteinuria (> 3.5g/d) or > 30% creatinine elevation within 1 year of kidney biopsy.

We included patients age > 18, with at least one symptom of IgA Vasculitis (cutaneous palpable purpura, arthritis, bowel angina), and kidney biopsy consistent with IgAV.

We collected data on patient's kidney function at time of diagnosis, and at 3, 6, and 12 month intervals. For preliminary analyses, we assessed Pearson correlation of clinical factors and MEST-C components with the primary outcome.

Results: Baseline creatinine was shown to have significant correlation with renal progression at 1 year**,** yielding a Pearson coefficient of .887 (2-tailed significance < .001, n = 21). Age, systolic blood pressure, and degree of proteinuria did not have significant Pearson coefficients at 3, 6, or 12 month intervals.

The "E" component in MEST-C, which stands for Endocapillary Hypercellularity, also showed significant correlation with renal progression at 1 year, with a Pearson coefficient of .776 (2-tailed significance < .001, n = 26). Other components of the MEST-C score did not yield significant correlations

Conclusion: Similar to existing studies, renal insufficiency at baseline is a prognostic indicator of poor outcomes in IgA Vasculitis patients. Age, initial proteinuria, and hypertension were not correlated with kidney progression in our study, which diverges from prior literature. Regarding histologic predictive factors, the "E" in MEST-C (Endocapillary Hypercellularity) is predictive of renal progression in prior studies, and we were able to validate this finding. Next steps in our study include expanding our cohort, as well as correlating treatment regimens with renal progression at 1 year.

IgG4-Related Disease as a Potencial Etiology of Idiopathic Constrictive Pericarditis

Edwin Ulises Cortez-Domínguez[1], Gabriela Hernandez-Molina[1], Norma Ofelia Uribe-Uribe[2], María J Lizardo-Thiebaud[2] and Eduardo Martin-Nares[1], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Department of Pathology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Constrictive pericarditis (CP) is a type of diastolic heart failure characterized by impaired cardiac filling due to the presence of an inelastic pericardium. Histologically, the pericardium exhibits fibrotic and thickened features. While tuberculosis remains the primary cause of CP in developing countries, idiopathic CP predominates in North America and Europe. The extent to which idiopathic CP patients may belong to the spectrum of IgG4-related disease remains unknown. Therefore, our objective was to determine the number of idiopathic CP patients meeting histopathological criteria for IgG4-RD.

Methods: Clinical records of patients with CP attended between 1987-2020 were reviewed. Those without a biopsy or with a known etiology of CP were excluded. Pericardial biopsies were analyzed in search of dense lymphoplasmacytic infiltrate, storiform fibrosis, and obliterative phlebitis. Immunohistochemistry for IgG and IgG4 was performed. The number of IgG+ and IgG4+ plasma cells and the IgG4/IgG ratio were determined according to the International Consensus on Pathology (ICP) of IgG4-RD. According to the ICP, cases were classified as highly suggestive, probable histopathological

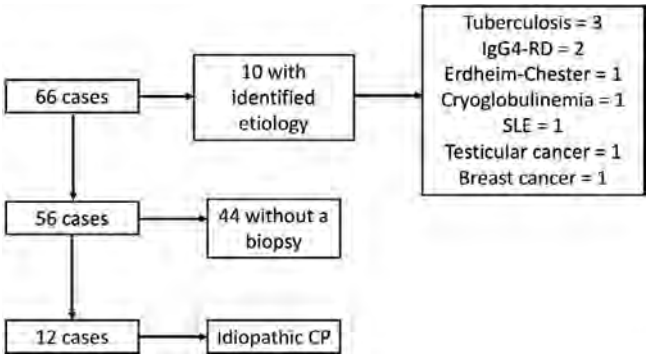

Figure 1. Flowchart illustrating the inclusion criteria.

Table 1. Electrocardiographic and cardiac imaging findings.

Table 1.	N=12 n (%)
Electrocardiogram	
Low QRS voltage	3 (25)
Increased heart rate	3 (25)
Echocardiogram	
Pericardial thickening	5 (41.7)
Pericardial effusion	4 (33)
Atrial enlargement	4 (33)
Hypokinesia	3 (25)
Cardiac magnetic resonance imaging	
Pericardial thickening	5/9 (55.5)
Pleural effusion	2/9 (22.2)
Pericardial effusion	1/9 (11.1)
Cardiac computed tomography	
Pleural effusion	4/6 (66.6)
Pericardial effusion	3/6 (50)
Pericardial thickening	2/6 (33.3)

characteristics, or insufficient histopathological evidence. The Comprehensive Diagnostic Criteria for IgG4-RD (CDCI) and the 2019 ACR/EULAR classification criteria (AECC) were also applied. Clinical characteristics were extracted from the patients' medical records.

Results: Sixty-six cases were reviewed, of which 10 had an identified etiology. Of the remaining 56, only 12 had a pericardial biopsy. All had been classified as idiopathic (Figure 1). Mean age of 43.5 ± 14.4 years; 9 were men. Regarding clinical behavior, all patients presented with signs and symptoms of heart failure. Six (50%) patients presented with effusive CP and 10 (83.3%) with chronic CP (non-mutually exclusive). Findings on electrocardiogram, echocardiogram, cardiac magnetic resonance imaging and cardiac computed tomography are summarized in Table 1. All patients underwent pericardiectomy, with glucocorticoid treatment administered to only one patient. At last follow-up, 3 (25%) patients had died.

Lymphoplasmacytic infiltrate was found in all, fibrosis in eight, and storiform fibrosis in only one case. Obliterative phlebitis was not found. In 2 cases the IgG stains were not assessable, so the IgG4/IgG ratio was calculated in 10 cases. The median number of IgG4+ plasma cells/HPF was 30.5 (IQR 16.5-41). The median IgG4/IgG ratio was 59.5% (IQR 27-66). All cases had >10 IgG4+ plasma cells/HPF while 7/10 (70%) had an IgG4/IgG ratio >40%. According to the ICP, 1 (8.3%) case was highly suggestive, 6 (50%) had probable histological characteristics, and 5 (41.6%) showed insufficient histopathological evidence. Seven (58.3%) were diagnosed as probable IgG4-RD according to the CDCI, but only one patient met 2019 AECC for atypical IgG4-RD.

Conclusion: A significant proportion of pericardial biopsies from patients with idiopathic CP display findings indicative of IgG4-RD and meet at least one set of diagnostic or classification criteria. Considering the implications for treatment, IgG4-RD should be considered when evaluating patients with CP.

Abstract Number: 0714

Single Center Experience of Rituximab Treatment for IgG4-RD Disease in a Large Multi-ethnic Cohort

Matthew Colquhoun[1], Taryn Youngstein[2] and James Tomlinson[3], [1]Department of Rheumatology, Imperial College Healthcare Trust, London, United Kingdom, [2]National Heart & Lung Institute, Imperial College London, London, United Kingdom, [3]Department of nephrology, Imperial College Healthcare Trust, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic fibro-inflammatory disorder that can affect almost any organ system. Response to corticosteroids(CS) is typically prompt although adverse effects are commonplace and relapses frequently occur during withdrawal. There is evidence to suggest that rituximab (RTX) may be an effective alternative however as yet, the optimal RTX treatment regimen for IgG4RDremains unclear. In this retrospective study, we report the use of a RTX treatment protocol for multi-system IgG4RD in a large single tertiary center cohort.

Methods: Patients were selected from an IgG4RD multi-disciplinary service receiving referrals from the catchment of North West London. Patients diagnosed with IgG4-RD received RTX according to local protocol guided by B cell repopulation (to a level of > 10 cells/uL) for a target period of two years. The electronic patient records were reviewed to record presentation and outcome data over the course of their RTX therapy.

Results: In total, 45 patients received treatment with RTX. 1 patient was excluded from analysis due to insufficient follow up data. The median age was 62 and 66% were male. Multiple ethnic backgrounds were represented; 20% black, 20% white and 60% Asian. The average number of organs affected was 2.9 (range 1-7) and the average IgG4-RD Responder Index (RI) prior to treatment was 10.02. 8/44 (18%) were on another conventional immunosuppressant at the time of RTX induction and 27/44 (61%) had concurrent treatment with CS. The proportions of the 27 patients remaining on CS at 9, 12 and 24 months were 66%, 54% and 19% (average dose at 2 years 3.8mg). All patients demonstrated reduced disease activity post RTX with an average IgG4-RI of 2.4 at most recent review (76% reduction). 34 patients had follow-up imaging and all had a degree (100%) of disease response; 2/34 (6%) stable; 21/34 (62%) partial response; 11/34 (33%) had a complete response. Intercurrent flares did occur in 9 patients, 7 of whom had concurrent B cell repopulation (78%). All 7/7 (100%) patients treated with further RTX responded positively. 15 patients completed two years of consistent RTX-induced B cell depletion with no subsequent flares (average follow up 15 months, median 10 months, range 1-51 months). The only 2 patients requiring >2 years maintenance RTX therapy had isolated pituitary disease. 12/45 (27%) of the entire cohort experienced an adverse event including infection requiring admission (4), hypogammaglobinaemia (2), infusion reaction (1) and death (5; 11%; average age 81).

Conclusion: In this cohort of patients treated with RTX for IgG4-RD, all patients demonstrated improved disease activity according to IgG4-RD RI and available imaging. Flares did occur but most often in the presence of measurable B cell repletion and all patients re-treated with further RTX responded. In those who discontinued treatment after >2 years of B cell depletion therapy, there were no further flares over an average follow-up duration of almost 15 months. This retrospective study indicates that protocolled management of IgG4RD with RTX is an effective treatment option for IgG4-RD. Patient selection is important to minimize the risk of complications.

Glucocorticoid Toxicity in Patients with IgG4-Related Disease Within the First Year of Treatment

Ana Mora-Rosas, Gabriela Hernandez-Molina, Edwin Ulises Cortez-Domínguez and Eduardo Martin-Nares, Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with IgG4-related disease (IgG4-RD) often require long-term glucocorticoid therapy. The prevalence, types, and underlying factors of glucocorticoid toxicity in IgG4-RD patients remain unknown. We aimed to describe the prevalence, types, and associated factors of glucocorticoid toxicity in our IgG4-RD cohort.

Methods: We retrospectively included patients diagnosed with IgG4-related disease (IgG4-RD) based on the Comprehensive Diagnostic Criteria and/or the 2019 ACR/EULAR classification criteria who had received glucocorticoid treatment for a minimum of one month and were followed up for at least one year. We categorized them into clinical phenotypes: pancreatobiliary (group 1), retroperitoneal/aortic (group 2), head and neck limited (group 3), Mikulicz/systemic (group 4), and undefined (group 5). From the medical records, we collected demographic, clinical, and treatment variables. We focused on prednisone usa during the first year of treatment, including the mean daily dose of prednisone, accumulated prednisone

Table 1. Frequency of glucocorticoid-related toxicity in IgG4-related disease patients.

Table 1.	Glucocorticoid-induced toxicity N (%)
Endocrinologic/metabolic	36 (63.3)

dose, maximum prednisone dose, and duration of prednisone treatment. To assess glucocorticoid toxicity, we employed the definitions proposed in the Glucocorticoid Toxicity Index, along with its domains and appendixes.

Results: Fifty-seven patients were included with a mean age of 53±15.8 years, of whom 34 (59.6%) were male. Fifteen (26.3%) belong to group 1, six (10.5%) to group 2, 13 (22.8%) to group 3, 19 (33.3%) to group 4 and 4 (7%) to group 5. The mean prednisone daily dose was 15.9±6.9 grm the median accumulated prednisone dose was 4,967.5 (IQR 3,195-6,670) gm, the mean maximum dose of prednisone was 39.3±14.2 gm, while the median number of days under prednisone treatment was 303.2 ± 103.9 days.

Forty-two (73.7%) patients developed one or more toxicities. The first toxicity was documented at a median of 64 (IQR 34.5-132) days. The median number of toxicities was 3 (IQR 1-4). The frequency and types of toxicities reported during the study period (non-mutually exclusive) are summarized in Figure and Table 1.

There were no differences in daily, accumulated, and maximum prednisone dose, or days with prednisone treatment, development of toxicities, days to first toxicity or number of toxicities according to sex or clinical phenotypes. Patients in group 3 and 4 presented more endocrinologic/metabolic toxicities compared to the other groups.

Patients who experienced toxicities had a higher accumulated prednisone dose (5,605 [IQR 4.215-7,015] vs. 3,400 gm [IQR 2,025-5,638], p=0.03), maximum prednisone dose (42.5±12.8 vs. 30.2±14.5 gm, p=0.003) and days of prednisone treatment (321.3±96.7 vs. 252.6±110, p=0.02) than patients without toxicities (Figure 2). Patients that used immunosuppressors did not present lower accumulated prednisone doses (5,335 [IQR 4,132-6,314] vs. 4,272.5 gm [IQR 2,100-7,427], p=0.41) or a lower incidence of toxicities (29 [74.4%] vs. 13 [72.2%], p=0.23).

Conclusion: Our findings highlight the high prevalence of glucocorticoid toxicity in patients with IgG4-RD undergoing glucocorticoid therapy, even within a relatively brief timeframe of one year. The presence of glucocorticoid toxicity was associated with higher doses and a longer use of prednisone.

Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Most patients with IgG4-related disease (IgG4-RD) have a good response to glucocorticoid (GC) therapy, however, disease relapses sometimes occur during GC tapering. Therefore, the immunosuppressants are considered in these cases. On the other hand, the predictors of disease relapse and the efficacy of immunosuppressants have not been fully clarified.

Therefore, we retrospectively analyzed the current treatment status of patients with IgG4-RD to identify the efficacy of immunosuppressants for disease relapse.

Methods: We used the data of patients with IgG4-RD diagnosed by May 2023 based on the 2020 revised comprehensive diagnostic criteria for IgG4-RD, and extracted those who had undergone therapeutic intervention. We retrospectively evaluated the organ involved, immunological findings including serum IgG4 levels, treatment agents, especially in GC dose and concomitant use of immunosuppressants, and the presence of relapse within 2 years after the start of treatment.

Results: 95 patients were diagnosed according to the 2020 revised comprehensive diagnostic criteria for IgG4-RD. Of these, 59 patients underwent therapeutic intervention, and all cases were initially treated with GC at a mean dose of 0.54 mg/kg body weight. Immunosuppressants were used concomitantly in 30 patients (50.8%), mostly azathioprine. In 17 of these cases, immunosuppressants were started either at the time of initial therapy or GC dose reduction. There was no significant difference between the 17 patients who received these immunosuppressants and the other patients (Table 1), however, the rate of definite cases tended to be higher in the cases who received immunosuppressants (P=0.06). 15 patients (25.4%) relapsed during GC reduction, and the mean time to disease relapse from the start of treatment was 33.2

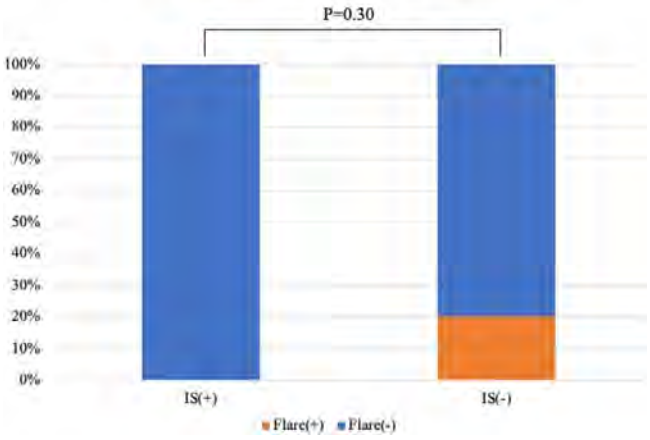
Figure. The rate of flare within 2 years after initial treatment with and without immunosuppressants



±32.0 months. Most of the disease relapsed cases were treated with GC monotherapy, and after relapse, immunosuppressants were administered in addition to increased doses of GC. Additionally, 39 patients who continued treatment for 2 years were analyzed separately according to whether they relapsed or not (Table 2). There were no significant differences in age at diagnosis, gender, number of lesions, immunological findings including serum IgG4 levels, or GC dose at the start of treatment. However, all patients who had received immunosuppressants either at the time of initial treatment or GC dose reduction did not relapse during the 2-year period (Figure). Their GC dose at 2 years after the start of treatment was 4.1 ± 2.1 mg/day. In contrast, the GC dose at relapse in the 6 patients relapsing within 2 years was 7.8 ± 1.4 mg/day.

Conclusion: No relapses were observed in patients treated with immunosuppressants during the first 2 years of treatment. Early concomitant use of immunosuppressants is a useful therapeutic strategy for IgG4-RD, but further studies are needed to determine which patients should be considered for concomitant use.

López[3], Solbritt Rantapää-Dahlqvist[4] and Christian Lood[1], [1]University of Washington, Seattle, WA, [2]Umea University, Umea, Sweden, [3]Bloodworks Research Institute, Seattle, WA, [4]Department of Public Health and Clinical Medicine/ Rheumatology, Umeå University, Umeå, Sweden

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Platelets have been suggested to be involved in polymyalgia rheumatica (PMR) pathogenesis with elevated platelet activation observed in early stages of the disease. Upon platelet activation, mitochondria are expelled into the extracellular space. Extracellular mitochondria, due to their prokaryotic origin, are immunogenic and promote inflammation, as well as serve as a source of autoantigens leading to formation of anti-mitochondrial antibodies (AMAs). The purpose of this study was to explore whether patients with PMR have elevated plasma levels of thrombospondin-1 (TSP-1)—an alpha granule protein of human platelets, presence of the extracellular mitochondrial component N-formyl methionine peptide (fMET) in plasma, and autoantibodies directed towards specific mitochondrial antigens. We also sought to explore whether extracellular mitochondria could be mediators of platelet activation in patients with PMR.

Methods: Levels of TSP-1, fMET, and anti-mitofusin 1 IgG (anti-MFN1) were measured by ELISA in the plasma of healthy controls (HC, n=30) and PMR patients before (n=54) and after (n=60) treatment with glucocorticoids. Ultrapure mitochondria isolated from HepG2 cells were opsonized with patient (n=56) or healthy control (n=10) plasma and, upon washing, incubated with platelets isolated from a healthy donor in the presence of the fibrin polymerization inhibitor, GPRP. Mitochondria-mediated platelet activation was assessed by measurement of the platelet cell surface marker P-selectin via flow cytometry.

Results: Plasma levels of anti-MFN1 IgG, fMET, and TSP-1 were elevated in patients with PMR before glucocorticoid therapy compared to HC ($p< 0.001$, Table 1). Levels of anti-MFN1 IgG, fMET, and TSP-1 significantly decreased after treatment with glucocorticoids ($p< 0.001$, $p< 0.001$, and $p=0.016$ respectively, Table 2). Mitochondria opsonized with plasma factors

Table 1. Median concentration of mitochondrial biomarkers and thrombospondin-1 (TSP-1) in patients with active PMR before glucocorticoid therapy compared to healthy controls.

Biomarker	Patients with PMR Median (Q1-Q3)	Healthy Control Median (Q1-Q3)	MW P-value
Before cortisone	N=54	N=30	
Anti-MFN1	0.46 (0.28-0.83)	0.22 (0.15-0.25)	p<0.001
fMET	18.32 (16.59-19.81)	11.31 (7.14-16.26)	p<0.001
TSP-1	26.9 (17.9-33.15)	8.93 (4.8-11.6)	p<0.001

P-values calculated with Mann Whitney (MW) U test. Anti-MFN1: anti-mitofusin 1, fMET: N-formyl methionine peptide

Table 2. Median concentration of mitochondrial biomarkers and thrombospondin-1 (TSP-1) before and after glucocorticoid therapy in patients with PMR.

Biomarker	Before glucocorticoids Median (Q1-Q3)	After glucocorticoids Median (Q1-Q3)	Wilcoxon P-value
	N=54	N=60	
Anti-MFN1	0.46 (0.29-0.83)	0.35 (0.23-0.51)	p<0.001
fMET	18.32 (16.59-19.81)	13.85 (8.76-16.47)	p<0.001
TSP-1	26.9 (17.9-33.15)	23.7 (16.5-29.5)	p=0.016

P-values calculated with Wilcoxon signed rank test. Anti-MFN1: anti-mitofusin 1, fMET: N-formyl methionine peptide

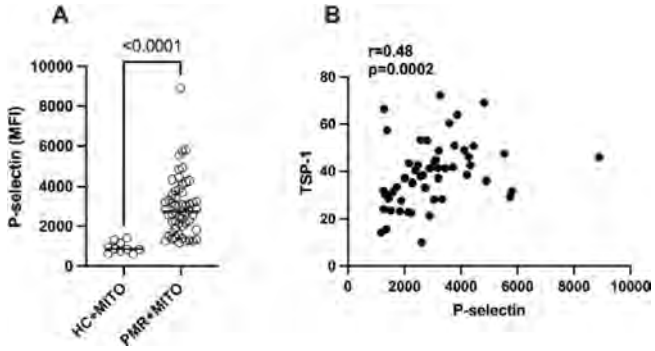

Figure 1. Mitochondrial-induced platelet activation in patients with PMR. A. Platelet rich plasma (PRP) from a healthy individual was exposed to mitochondria (mito) opsonized with plasma of patients with PMR (n=56) or HC (n=10. B. Plasma levels of TSP-1 were related to levels of mitochondrial-induced P-selectin in patients with PMR. Results are shown as the mean fluorescence intensity (MFI). Statistical analyses were done using the Mann-Whitney U-test and Spearman's correlation test. Each circle represents an individual sample, with the bar representing the median of the group.

from PMR patients showed markedly higher platelet activation than mitochondria opsonized with plasma factors from healthy individuals ($p< 0.0001$) (Figure 1A). Further, the extent of platelet activation (P-selectin level) by opsonized mitochondria correlated with plasma levels of TSP-1 in patients with PMR ($r=0.48$, $p=0.0002$, Figure 1B). TSP-1 levels were also associated with levels of immune complexes (IC) before glucocorticoid therapy. ($r=0.32$, $p< 0.05$).

Conclusion: Our results indicate increased platelet activation, the presence of mitochondrial damage-associated molecular patterns (DAMPs), and AMAs in the circulation of patients with PMR, associated with active disease. These results suggest a pathogenic involvement of mitochondrial antigens and autoantibodies in PMR. Blocking mitochondrial-mediated platelet activation may reduce inflammation in patients with PMR, with potential therapeutic implications.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The burden of continuing glucocorticoids (GCs) in patients with polymyalgia rheumatica (PMR) who have an inadequate response (IR)to GCs has not been evaluated.

Methods: An inception cohort of adult patients with a new diagnosis of PMR was created using fee-for-service Medicare claims data from 2016 to 2020. Patients with PMR were included if they were aged≥50 and had 1)≥1 inpatient or ≥2 outpatient claims with ICD-10-CM M35.3 ≥30 days apart, 2) a prescription for GC 7.5–25 mg/day <30 days from the 1stinpatient code or between 1stoutpatient code to 30 days after the 2ndcodewith cumulative use of≥200 mg over ≥120 days, and 3) continuous enrollment ≥1 year prior (baseline) to index date, with no evidence for PMR. The index date was the later of the 2nd outpatient PMR diagnosis, or the inpatient PMR diagnosis; and the date that GC dose/use criteria was met; and had to fall between 10/1/2016 to 12/31/2019. Exclusion criteria included baseline diagnosis of seropositive rheumatoid arthritis, other systemic rheumatic disease (including giant cell arteritis),organ transplant, multiple sclerosis, or active treatment of malignancy or who had any prescription for conventional immunomodulatory therapy or an interleukin-6 receptor inhibition

Steroid myopathy	4.28 (3.35–5.39)	2.23 (0.96–4.40)	3.99 (2.28–6.48)	2.73 (1.41–4.76)	7.45 (5.22–10.32)
Glaucoma	2.22 (1.69–2.86)	1.83 (0.88–3.37)	2.31 (1.26–3.87)	2.63 (1.56–4.16)	2.06 (1.20–3.30)
Heart failure	6.56 (5.52–7.73)	4.57 (2.79–7.05)	5.73 (3.84–8.23)	5.91 (4.09–8.26)	9.14 (6.95–11.78)
Total all-cause HCRU cost**, $	13,181.11 (29622.82)	12902.25 (30757.37)	12677.44 (35306.56)	11271.88 (23684.90)	15600.14 (27896.09)

*Events/100 patient-years (95% CI).
**Sum of cost associated with inpatient hospitalization, outpatient visits, ER visits and prescriptions; data shown as mean (SD).
AE, adverse event; CI, confidence interval; Dx, diagnosis; ER, emergency room; GC-IR, glucocorticoid inadequate responder; HCRU, healthcare resource utilization; MACE, major adverse cardiac event; SD, standard deviation; Tx, treatment.

at baseline. Patients were classified as GC inadequate responders (GC–IRs), defined as use of ≥7.5 mg/day at 6 months (i.e., presumed flare), continued use of GCs >12 months, or relapse (re-initiation of GC after >60-day gap discontinuation) or non-GC–IR.

All-cause healthcare resource utilization cost and event rate of pre-specified, GC-associated adverse events (GC-AEs) that were defined by ICD-10-CM diagnosis codes, medication use, and/or Healthcare Common Procedure Coding System medical procedures beginning 6 months after the index date and updated in 6-month intervals were reported. Adverse events (AEs) were identified using claims-based algorithms that have been previously used or reported in the literature. For GC-AEs, with the exception of hospitalized infections and fractures, only the 1stevent was counted. Event rates and 95% confidence intervals were estimated using Exact Poisson methods. A subgroup analysis of the GC–IR cohort was performed, estimating outcomes by cumulative steroid dose quartiles received; dose quartiles were updated at 6 months.

Results: A total of 6,054 patients with PMR met eligibility criteria:mean age 77.0 years, 65.4% women, 96.1% White, and 3.0% Hispanic. The rate of GC-AEs and medical cost were consistently higher in the GC–IR versus non-GC–IR through 18 months, except for osteoporosis (Table 1). In the GC–IR cohort, cost and most GC-AEs suggested a decrease over time, likely due to GC discontinuation or lower doses of GC, and/or for AE-related censoring (i.e., depletion of at-risk patients). Further, most outcomes showed a dose-response relationship between cumulative GC dose and outcomes (Table 2).

Conclusion: There is a substantial clinical and economic burden of continuing GCs in PMR patients with IR. Some GC-AEs and associated costs may be enduring. These data provide insight into the potential benefit of minimizing long-term GCuse and need for more effective GC-sparing therapies.

Polymyalgia Rheumatica Following SarsCOV-2 Vaccination: A Single Center Cohort Study

Lindsay Lally[1], Aliza Bloostein[1], Deanna Jannat-Khan[1] and Robert Spiera[2], [1]Hospital for Special Surgery, New York, NY, [2]Hosptial for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) incidence peaks in individuals between 70 and 80 years of age; this same group is also at increased risk of complications and mortality related to COVID-19 infection. Vaccination against SARS-CoV2 is an essential tool in combatting COVID-19. There have been several case reports of PMR following vaccination with mRNA SARS-CoV2 vaccines.

The aim of this study was to identify patients with temporal association between mRNA SARS-CoV2 vaccination and PMR onset and to compare characteristics and disease course to those with new onset PMR without temporal association with SARS CoV2 vaccine exposure.

TABLE 1

	Entire Cohort	PMR without temporal association to vaccine	PMR within 6 weeks of vaccine	p-value
N	80	60	20	
Age , median (IQR)	74.5 (71, 80)	75.5 (71, 80)	73.5 (69, 79.5)	0.43
Sex				0.80
Male	40 (50%)	29 (48%)	11 (55%)	
Female	40 (50%)	31 (52%)	9 (45%)	
Vaccine Type				1.00
Moderna	38 (48%)	29 (48%)	9 (45%)

ESR at 12 months (mm/hr), median (IQR)	14 (4, 29)	14 (4, 34)	13.5 (3, 24)	0.81
CRP at 12 months (mg/L), median (IQR)	7 (4, 7.5)	7 (5, 9)	7 (3, 7)	0.51
Steroid dose at 12 months (mg), median (IQR)	3 (0, 6)	3 (1.25, 6)	0 (0, 4)	0.11
Relapse at 12 months				0.65
No	27 (34%)	22 (37%)	5 (25%)	
Yes	8 (10%)	6 (10%)	2 (10%)	

Methods: We conducted a retrospective chart review of all newly diagnosed PMR patients in a single center. Using ICD-10 codes, our EMR was queried to identify patients with newly diagnosed PMR beginning in December 2020, when the first SARS-CoV-2 vaccines were available in the US. Charts were reviewed for demographic information, disease characteristics and vaccination details. Patients who developed onset of PMR symptoms within 6 weeks after vaccination were compared to those whose PMR symptoms occurred without temporal association to vaccination. When available data at 6 and 12 months following diagnosis was collected.

Results: Eighty patients with newly diagnosed PMR between 12/1/2020 and 12/31/2021 were identified. There were 60 patients with new PMR without a temporal association to vaccination who were compared to 20 patients who developed PMR symptoms within 6 weeks of vaccination. Baseline demographics did not differ between the two groups. In the 20 cases with PMR onset after vaccination, symptoms developed a mean 38 days (IQR 19.5-48) after first dose of vaccine and 11.5 days (IQR 1-22) after second dose. There were no differences in baseline demographics, glucocorticoid dosages or relapse rates at 6 and 12 months following diagnosis. There was no association between vaccine manufacturer and PMR onset after vaccination (TABLE 1)

Conclusion: In this cohort, patients with onset of PMR within 6 weeks following mRNA vaccination against SARSCoV2 were similar to patients with de novo PMR at diagnosis, with no significant differences in disease course over the first 12 months. This does not support the notion that PMR following vaccination is a unique disease entity. The recognition of new PMR onset following SARS CoV2 vaccine may be coincidental in this common inflammatory disorder in a population with high rates of vaccine exposure.

Cognitive Function and Its Associated Factors in Polymyalgia Rheumatica

Patricia Harkins[1], Sharon Cowley[2], David Kane[3] and Richard Conway[4], [1]St James's Hospital, Dublin, Ireland, [2]Tallaght University Hospital, Dublin, Dublin, Ireland, [3]Tallaght University Hospital & Trinity College Dublin, Dublin, Ireland, [4]Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Over the past decade our understanding of the prevalence, and indeed impact of cognitive impairment in rheumatic diseases has increased. Intact cognitive function is imperative not only for quality of life and maintenance of one's functional capacity, but also for the successful therapeutic management of disease, namely the adherence to treatment regimens. The prevalence of cognitive impairment in community dwelling older adults has been estimated at 13%.[1]To date the prevalence of cognitive impairment in Polymyalgia Rheumatica (PMR) has not been studied. The aim of this research is therefore to explore the prevalence and potential associated factors of cognitive impairment in those with PMR.

Methods: Patients with a diagnosis of PMR (fulfilling the 2012 EULAR/ACR Classification Criteria) who were in clinical remission and on active treatment with glucocorticoids were recruited from two centres. Patients were ≥3 months and ≤12 months from diagnosis. Cognitive function was evaluated using the Montreal Cognitive Assessment (MoCA) test which

was conducted by two trained interviewers. Cognitive impairment was defined by the previously validated MoCA cut-off score of < 26.Demographics, clinical and laboratory data, in addition to patient reported outcomes (PRO's) were collected. PRO's including anxiety, using the Generalised Anxiety Disorder Assessment (GAD-7), mood using the Patient Health Questionnaire (PHQ-9), fatigue using the Functional Assessment of Chronic Illness Therapy - Fatigue Scale (FACIT-F), pain using the visual analogue scale (VAS) and overall health related quality of life using the Health Assessment Questionnaire-Disability Index (HAQ-DI).The associations between categorical variables were compared using the chi-squared or Fishers exact test as appropriate. The association between continuous variables and categorical variables were assessed using the Kruskal-Wallis test. Correlations were calculated using Pearson's r. All analyses were conducted using R (R Core Team, 2022). A p-value of < 0.05 was considered as statistically significant.

Results: 51 consecutive patients with PMR were recruited, of which 56.9% (n=29) were female. 70.6% (n=36) of patients were cognitively impaired, with visual-spatial, delayed recall and abstraction the most commonly affected cognitive domains. Interestingly, those with cognitive impairment had a younger age, versus those without (p=0.514). Although not statistically significant, median BMI, anxiety, depression and pain scores were all higher in those who were cognitively impaired. Moreover, median fatigue scores were also worse in the cognitively impaired group. No statistically significant difference in serum markers was observed.

Characteristic	Impaired cognitive function (n=33)	Normal Cognitive function (n=14)	p-value
Sex, female, n(%)	23 (63.9)	6 (40)	0.135
Age, median (IQR)	70 (65-74)	72 (68-74.5)	0.514
Body Mass Index, median (IQR)	27.2 (24.5- 31.9)	25.4 (23.5-29)	0.169
Rheumatic disease comorbidity index (RDCI), median (IQR)	2.0 (0.8-3)	2.0 (1.0-2.5)	0.916
GAD-7 score, median (IQR)	1.5 (0-4.2)	0 (0-1.5)	0.209
PHQ-9 score, median (IQR)	2.5 (0-7.2)	2 (0-3)	0.168
HAQ-DI score, median (IQR)	0 (0-0)	0 (0-0.1)	0.282
VAS pain score, median (IQR)	2 (0-4)	0 (0-1)	0.082
FACIT-F score, median (IQR)	44.5 (38-50)	47 (42.5-49.5)	0.443
C-reactive protein (mg/L), median (IQR)	3.8 (1.2-6.1)	3.4 (1.1-5.5)	0.835
Erythrocyte sedimentation rate (mm/hr), median (IQR)	10 (4-25)	8 (5.5-21)	0.915
Serum interleukin-6 levels (pg/ml) median (IQR)	6.8 (3.1-10.1)	6.7 (4.6-13.2)	0.539
Haptoglobin level (g/L), median (IQR)	1.7 (1.3-2.6)	1.7 (1-2.1)	0.414
Hemoglobin (g/dL), median (IQR)	13.2 (12.6-13.7)	13.7 (13.4-14.1)	0.234

Baseline Characteristics stratified by cognition status.

Conclusion: This study demonstrates the burden of cognitive impairment in PMR is significant and is markedly higher than that observed usually at population level. This has a potential profound impact on disease management, including treatment compliance, and thus disease outcomes. Future studies exploring this, in addition to specific etiologic contributors of cognitive impairment are needed.

Characterization of Numeric Rating Scales for Symptom Assessment in Polymyalgia Rheumatica

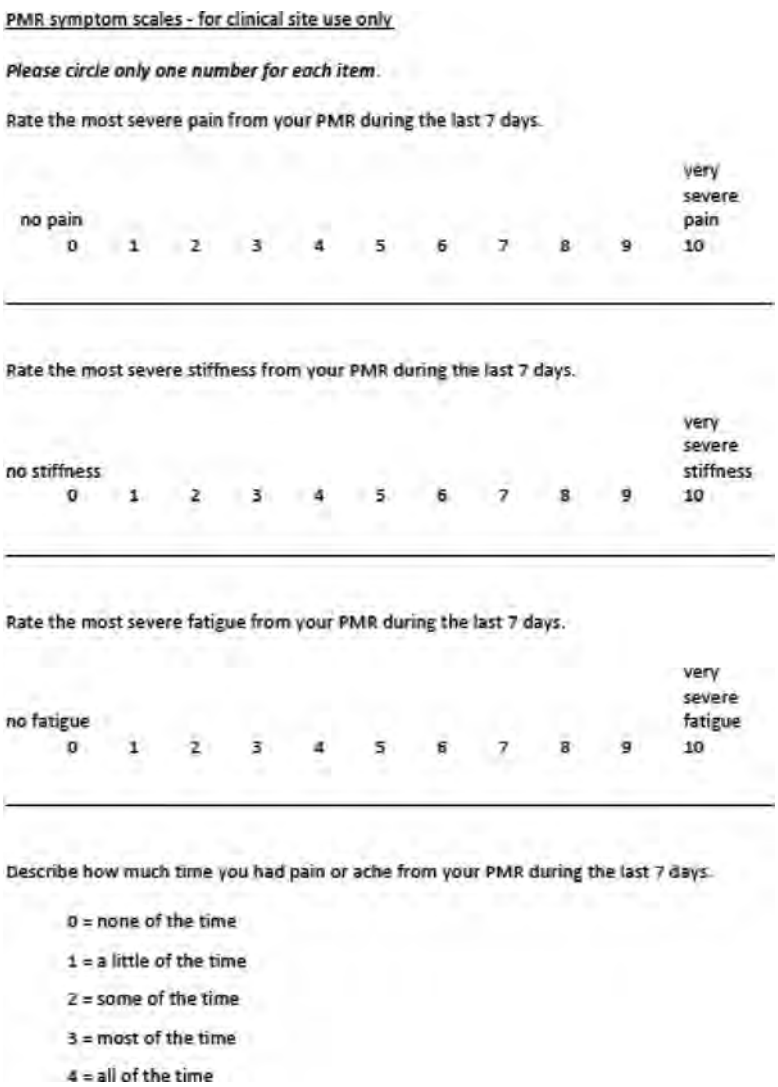
Tonya K Marmon[1], Jason C Cole[2], Claire Owen[3], Sarah Mackie[4] and **David Katz**[5], [1]Marmon Biostatistics, Seattle, WA, [2]P3 Research Consulting, Torrance, CA, [3]Austin Health, Malvern East, Australia, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom, [5]Sparrow Pharmaceuticals, Portland, OR

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain, stiffness, and fatigue have been defined as core assessment domains in polymyalgia rheumatica (PMR) by the OMERACT PMR Working Group (PMRWG). Patient partners have expressed a preference for numeric rating scales (NRS) over visual analogue scales to measure these symptoms. Numerous NRS forms have been used in different PMR clinical trials, yet evidence to support their use is lacking. We propose a standardized NRS form and provide initial results of some measurement properties.

Methods: PMRWG clinicians, methodologists, and patient partners rated two different NRS stems and anchors and provided free-text feedback. The preferred set was modified according to patient partner input. Clinical trial participants with PMR, no or low disease activity, and who received prednisolone 10 mg for ≥ 1 week prior to entry were treated with prednisolone 10 mg for 4 weeks and received each of SPI-62 and matching placebo as adjunctive therapy for 2 weeks. They completed individual NRS for pain, stiffness, and fatigue intensity, and pain chronicity, each at fortnightly trial visits with a 7-day look-back and daily at home with a 1-day look-back. Compliance at home, test-retest reliability, and correlation between the on-site and at-home versions were assessed using placebo period data from the inception trial cohort (N=12).

Results: The standardized items are shown (Figure). At-home compliance was 97%; 7/12 had 100% compliance. There were no missing items, only occasional days that participants did not respond at all. Weighted k comparing responses 2 weeks apart for on-site pain, stiffness, and fatigue intensity were 0.52, 0.45, and 0.67, and for pain chronicity was 0.54. Intraclass correlation coefficients, with intra-individual as the variance of interest, for at-home pain, stiffness, and fatigue intensity were 0.62, 0.70, and 0.84, and for pain chronicity was 0.72. Weighted k between the on-site response for 7-day look-back and the maximum at-home response for 1-day look back during any of the 7 prior days were 0.53, 0.82, and 0.80 for the intensity items and 0.55 for pain chronicity. When the on-site response was compared instead to the at-home response on the same day, weighted k were 0.51, 0.68, 0.76, and 0.64. Confidence intervals for all statistics were wide due to the limited number of participants.



PMR symptom scales - for clinical site use only

Please circle only one number for each item.

Rate the most severe pain from your PMR during the last 7 days.

no pain 0 1 2 3 4 5 6 7 8 9 very severe pain 10

Rate the most severe stiffness from your PMR during the last 7 days.

no stiffness 0 1 2 3 4 5 6 7 8 9 very severe stiffness 10

Rate the most severe fatigue from your PMR during the last 7 days.

no fatigue 0 1 2 3 4 5 6 7 8 9 very severe fatigue 10

Describe how much time you had pain or ache from your PMR during the last 7 days.

0 = none of the time

1 = a little of the time

2 = some of the time

3 = most of the time

4 = all of the time

Standardized clinical site items. Patient diary items replace '7 days' with '24 hours'.

Conclusion: The results provide necessary initial evidence to encourage further examination of these NRS' psychometrics. They suggest high patient compliance for daily symptom report and moderate test-retest reliability. Patient ability to recall accurately their most severe symptoms during 7 days prior to a trial visit was strong for stiffness and fatigue, whilst moderate for pain. Symptom recall did not appear to be particularly biased by symptoms of the most recent 24 hours. The reported measurement properties point favorably toward validated symptom assessment for PMR clinical trials, lack of which currently limits conduct of patient-centric research. More data are needed to confirm these results on reliability, and to support other measurement properties such as thresholds of meaning.

Acute Cardiovascular Events in Autoimmune Rheumatic Disease Pregnancies

Rashmi Dhital[1], Rebecca Baer[2], Monica Guma[2], Kenneth Kalunian[2], Accelerating Medicines Partnership Program RA SLE Network[3] and Christina Chambers[2], [1]UC San Diego, San Diego, CA, [2]University of California San Diego, La Jolla, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Plenary I
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Cardiovascular diseases (CVDs) complicate 1-4% of pregnancies. Autoimmune rheumatic diseases (ARDs) are associated with a 1.5 to 3-fold higher CVD risk. Similarly, antiphospholipid syndrome (APS) is associated with increased risks of thromboembolism, pregnancy loss, and CVDs. However, research on the impact of ARDs and APS on maternal cardiovascular health is limited. In this study, we aim to compare the rates of acute CVEs in pregnant women with ARDs and primary APS as compared to a general population of pregnant women with neither condition, using a large population-based birth cohort in California.

Methods: We retrospectively analyzed pregnant individuals who delivered singleton liveborn infants in California between 2005-2020. Birth certificates were linked by the California Study of Outcomes in Mothers and Infants (SOMI) to maternal hospital discharge, emergency department and ambulatory surgery records. We identified ARDs, APS, and acute CVEs during pregnancy and up to 6 weeks postpartum using ICD codes. We used logistic regression to calculate adjusted relative risks (RRs) and 95% confidence intervals (CI) of association between acute CVEs and ARDs and APS, for each specific category of ARDs, and for CVEs by timing in relation to delivery. We performed mediation analysis to investigate if pregnancy complications such as gestational diabetes mellitus (GDM) and pre-eclampsia mediated the association between ARDs and CVEs.

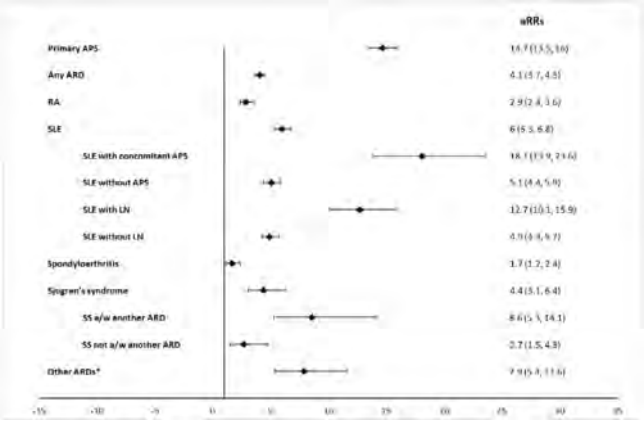

Figure 1. Comparison of risks of acute cardiovascular events during pregnancy or within 6 weeks post-partum for autoimmune rheumatic diseases (ARDs) and primary antiphospholipid syndrome (APS) as compared to the comparison group with neither condition, 2005 – 2020 #Adjusted relative risks (aRRs) adjusted for baseline covariates that occurred before pregnancy (maternal age at delivery, race/ethnicity, payer for delivery, maternal education, maternal pre-pregnancy body mass index, preexisting hypertension, preexisting diabetes, hyperlipidemia, smoking, alcohol use, drug use, and depression). * APS: antiphospholipid syndrome, ARD: autoimmune rheumatic disease, RA: rheumatoid arthritis, SLE: systemic lupus erythematosus, LN: lupus nephritis, SS: Sjogren's syndrome, * Other ARDs (Systemic sclerosis, myositis, vasculitis)

Table 2. Rates of acute cardiovascular events by timing in relation to delivery for autoimmune rheumatic diseases (ARDs) and primary antiphospholipid syndrome (APS) as compared to the comparison group with neither condition, 2005 – 2020 *ARD: autoimmune rheumatic disease, APS: antiphospholipid syndrome, CVE: cardiovascular event, ED: emergency department

	Ref	**4.5 (3.8, 5.5)**	**12.7 (10.7, 15.1)**
Postpartum CVE on ED records	3,567 (0.1)	38 (0.2)	40 (0.5)
	Ref	4.3 (3.1, 5.8)	13.4 (8.4, 15.6)
	Ref	**3.1 (2.2, 4.2)**	**7.9 (5.8, 10.8)**
Postpartum CVE on readmission record	3,484 (0.1)	85 (0.4)	105 (1.4)
	Ref	8.9 (7.2, 11.1)	28.7 (23.7, 34.9)
	Ref	**5.8 (4.6, 7.2)**	**18.6 (15.3, 22.6)**

Results: CVEs occurred in 2.0% of 19,340 pregnant women with ARDs, 6.9% of 7,758 women with primary APS, and 0.4% of 7,004,334 women with neither. The risks of acute CVEs were significantly higher for pregnant women with ARDs (aRR 4.1, 95% CI 3.7, 4.5) and primary APS (aRR 14.7, 95% CI 13.5,16.0) than for the comparison group. Systemic lupus erythematosus (SLE) was associated with a 6-fold increased risk for CVE, which was further elevated with concomitant APS or nephritis (aRRs 18.1 and 12.7, respectively). (**Figure 1**). Only 12% of the excess association of acute CVEs with an ARD was mediated by preeclampsia and < 1% by GDM. About 25-30% of the CVEs occurred postpartum as documented in readmission records. This represented a 6-fold greater risk than in the comparison group (**Table 2).**

Conclusion: Pregnant women with ARDs and primary APS have significantly higher risks for acute CVEs compared to pregnant women without these conditions, with the highest risks among those with SLE with concomitant APS, followed by primary APS and SLE with nephritis. Furthermore, about 25-30% of CVEs occurred during the postpartum period, highlighting the importance of close monitoring of cardiovascular risks and events in women with ARDs or APS both during pregnancy and postpartum.

Investigating the Effects and Molecular Mechanisms of TRAF5 on the Pathogenesis of SLE Associated Pulmonary Arterial Hypertension

Xiaoyue Deng[1], Junyan Qian[1], Ranran Wang[2], JIULIANG ZHAO[3], Qian Wang[4], Tianyi Yuan[2], MENGTAO LI[1] and Xiaofeng Zeng[5], [1]Peking Union Medical College Hospital, Beijing, China, [2]Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [3]Beijing Union Medical College Hospital, Beijing, China, [4]Peking Union Medical College, Beijing, China, [5]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Plenary I
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a serious complication in SLE patients, with rapid progression and poor prognosis. In China, approximately 3% of the over one million SLE patients suffer from PAH. PAH is believed to result from inflammation and genetic abnormalities leading to dysfunction of pulmonary arterial endothelial cells (PAEC), followed by cellular proliferation and progressive pulmonary vascular remodeling. Considering the high morbidity and mortality rates, our research aims to investigate the pathogenesis of SLE-PAH and identify new biomarkers.

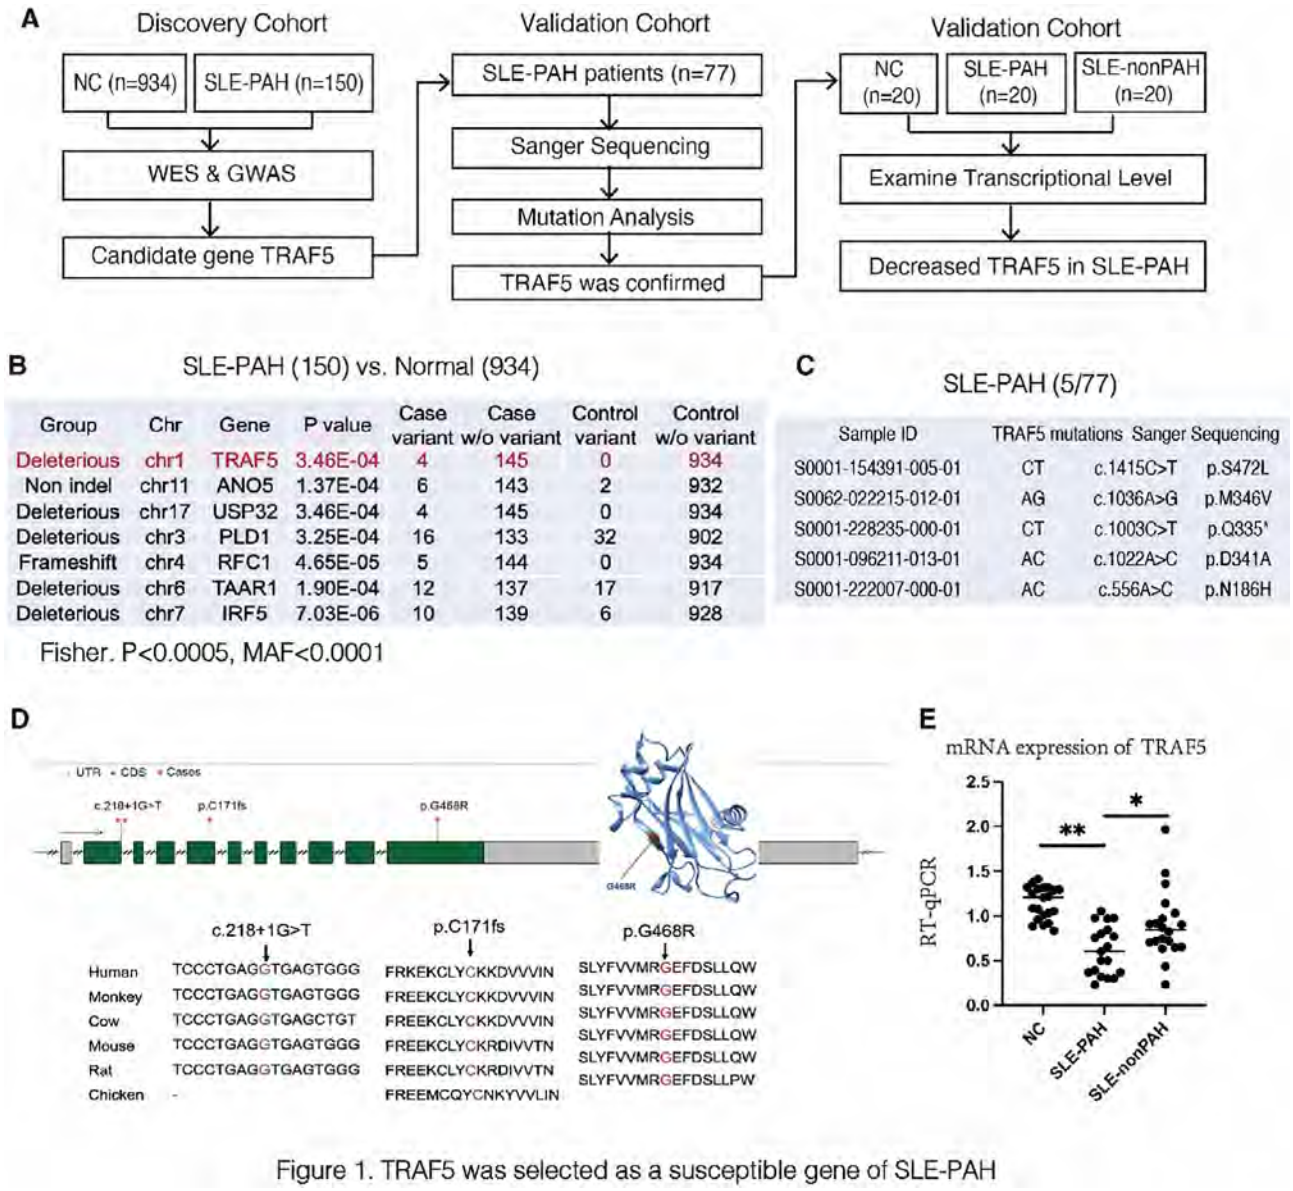

Figure 1. TRAF5 was selected as a susceptible gene of SLE-PAH

Figure1 Identification of TRAF5 as a Susceptible Gene in SLE-PAH. A) Workflow of selecting susceptible genes of SLE-PAH; B) and C) Results of GWAS and Sanger sequencing; D) Genomic and protein structure of TRAF5. p.G468R mutation causes dysfunction of protein. E) TRAF5 mRNA expression levels in peripheral blood .

Methods: To investigate the pathogenesis of SLE-PAH, we employed various approaches. First, we performed whole-exome sequencing (WES) on peripheral blood samples from 150 SLE-PAH patients and conducted a genome-wide association study (GWAS) by comparing them with samples from 934 healthy controls. Subsequently, we validated mutations of candidate gene in 77 patients using Sanger sequencing. Additionally, we assessed the transcriptional expression levels of the identified genes in peripheral blood using RT-qPCR. In vitro intervention experiments were performed on human PAEC to elucidate the potential pathogenesis. RNA-seq and gene ontology analysis were employed to identify downstream pathways. Furthermore, we established SLE-PAH mouse models through pristane injection and hypoxia induction and measured pulmonary arterial pressure (PAP) using right heart catheterization. We also examined the effects of tail-intravenous injection of therapeutic vectors based on candidate gene. Lastly, we examined expression of candidate genes on monocrotaline (MCT) induced rat model of PAH.

Results: 1. Based on WES and GWAS, we identified the tumor necrosis factor receptor-associated factor 5 (TRAF5) as a susceptible gene in SLE-PAH. Transcriptional analysis revealed a significant reduction in TRAF5 expression in the peripheral blood of SLE-PAH patients, indicating its potential clinical diagnostic value. 2. Knockdown of TRAF5 in PAEC demonstrated notable effects on early apoptosis and the pathogenesis of PAH through distinct pathways. Flow cytometry analysis showed

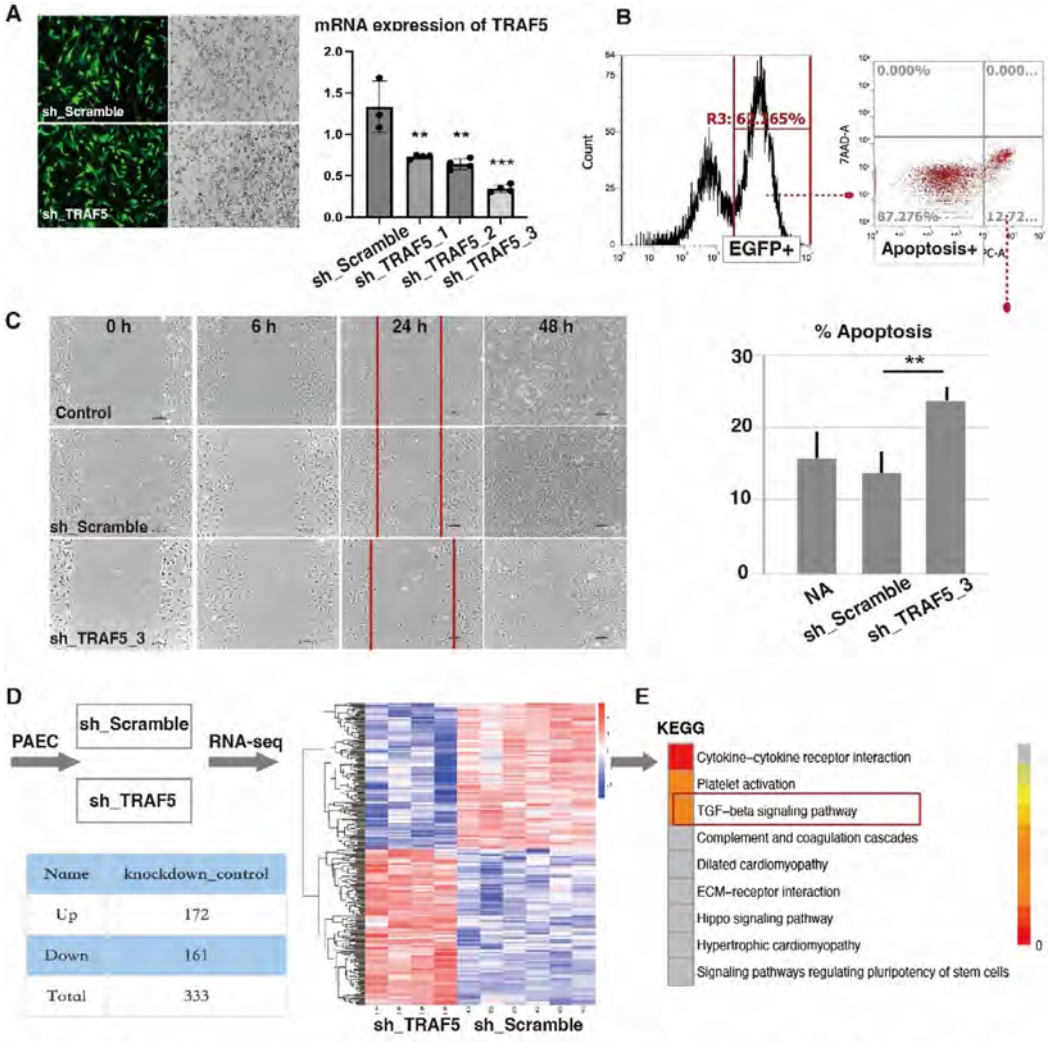

Figure 2. Knockdown of TRAF5 significantly increased early apoptosis of PAEC through distinct pathway.

Figure2 Knockdown of TRAF5 Affected the Functions of PAEC. A) shTRAF5 transfected human PAEC (EGFP positive); B) FACS was performed to detect early apoptotic cells labeled with Annexin V-APC (Apoptosis Detection Kit); C) Wound healing experiments were performed in different groups; D) and E) TGF-β pathway was identified as downstream targets of TRAF5 using RNA-seq and KEGG analysis.

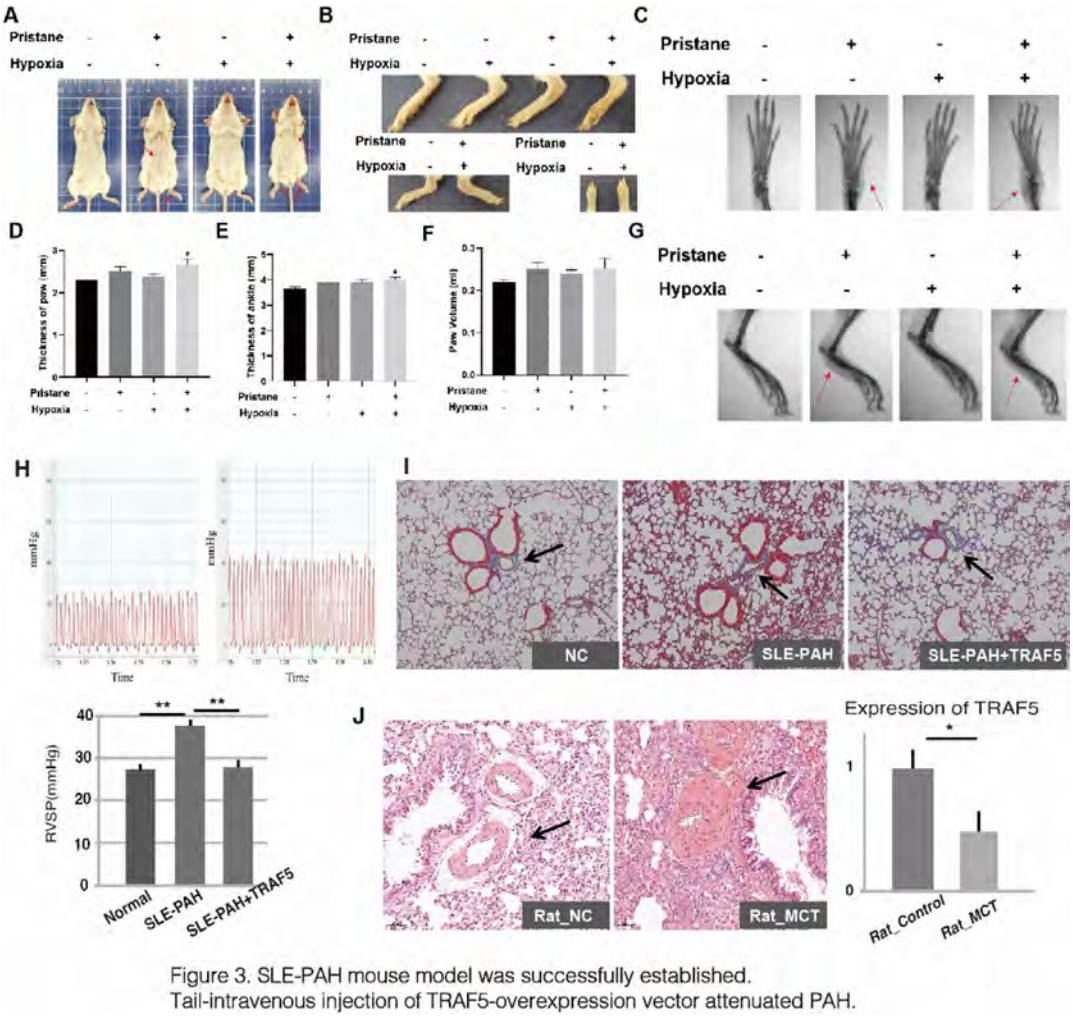

Figure 3. SLE-PAH mouse model was successfully established.
Tail-intravenous injection of TRAF5-overexpression vector attenuated PAH.

Figure 3 SLE-PAH Mouse Model was Successfully Established. A-G) SLE phenotypes were observed after pristane induction; H-I) mPAP was elevated in model mouse, and tail-intravenous infection of TRAF5-overexpression vector attenuated PAH; J) Expression of TRAF5 was decreased significantly in MCT induced rats.

a significant increase in early apoptotic cells, and wound healing experiments demonstrated the loss of migratory ability in PAEC following TRAF5 knockdown. RNA-seq and KEGG pathway analysis identified TRAF5's regulatory role in the TGF-beta pathway. 3. Our SLE-PAH mouse model successfully exhibited lupus phenotypes and increased mean PAP levels. Tail-intravenous injection of a TRAF5-overexpression vector attenuated PAH symptoms. Additionally, TRAF5 expression was significantly decreased in lung tissue of the MCT-induced PAH model rats.

Conclusion: In conclusion, lack of TRAF5 triggers the pathogenesis of PAH in SLE patients by inducing dysfunction of PAEC, which highlights the significance of TRAF5 as a susceptible gene in SLE-PAH and underscores its potential as a candidate biomarker for the diagnosis and therapy of SLE-PAH. Therefore, further research on TRAF5 and its involvement in the pathogenesis of SLE-PAH may provide valuable insights for the identification of novel therapeutic targets and improved management strategies for this condition.

Synovial Macrophage Subsets Defined by ScRNAseq Demonstrate Sexually Dimorphic Gene Expression in RA and a Mouse Inflammatory Arthritis Model

Richard Bell, Ewurama Cann, Chao Yang, Accelerating Medicine Partnership Rheumatoid Arthritis, Amit Lakhanpal, Laura Donlin and Lionel Ivashkiv, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Plenary I
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Macrophages (MΦ) play a key pathogenic role in Rheumatoid Arthritis (RA), a disease that exhibits female sex bias. Recent work using scRNAseq has defined putative pathogenic synovial MΦ subtypes in RA. It is not known whether these MΦ subtypes exhibit sexually dimorphic gene expression that can contribute to female sex bias. Additionally,

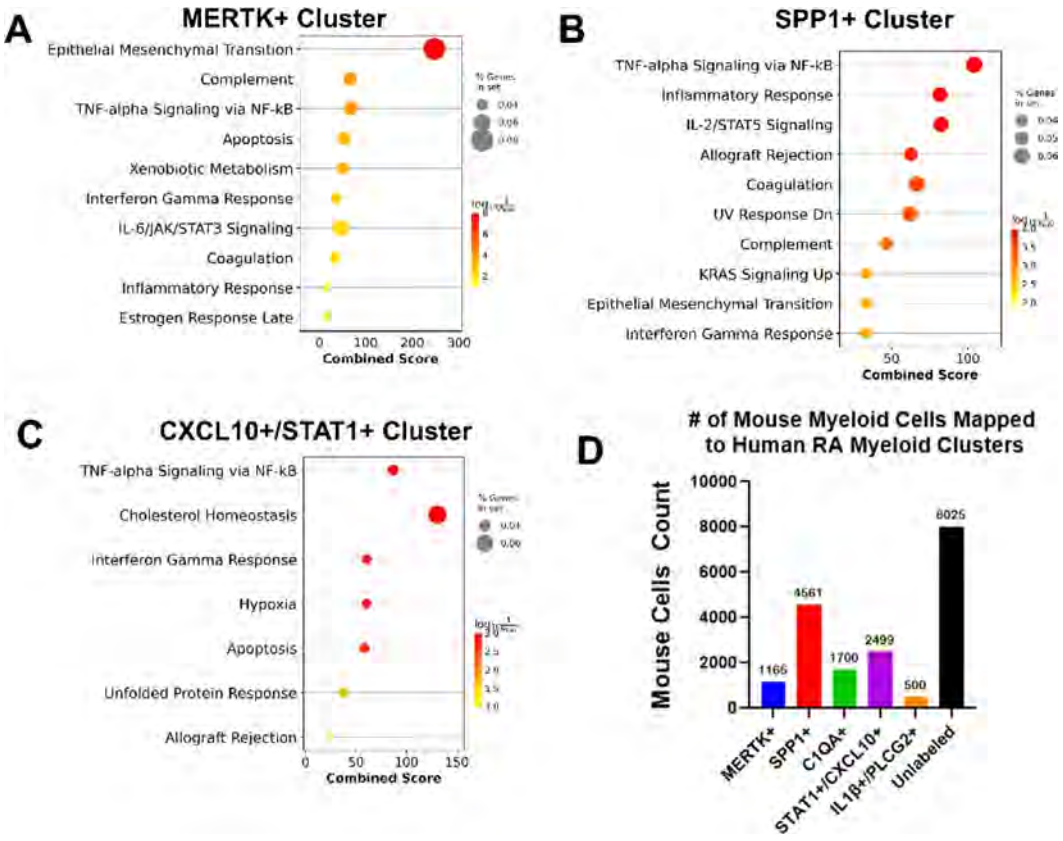

Figure 1. Human RA Female macrophages subsets are enriched with inflammatory and IFN gene signature. We performed DEG and GSEA analysis between male and female subjects within each putative pathogenic MΦ cluster. In 3 clusters (SPP1+, CXCL10+/STAT1+, and MERTK+ clusters), female cells were enriched with IFN related pathways (IFN-γ Response, EMT, Allograft Rejection) and other inflammatory pathways (TNF signaling, Inflammatory Response, A-C). To validate our mouse model, we built a mouse-to-human transfer learning model (a five-fold cross validated gradient boosted decision tree) to classify the human cell types (MERTK+; SPP1+, C1QA; STAT1+/CXCL10; IL1β/PLCG2). The model produced high quality predictions with an overall F1 score of 0.76 ± 0.1. This model was then transferred to the mouse dataset via mouse-to-human gene mapping and used to predict which human cluster each mouse cell is in. This analysis reveals that mouse ZIA synovium map to relevant sexually dimorphic human cell clusters (D).

the causal role of RA MΦ subsets in inflammatory arthritis is difficult to ascertain in the absence of a disease model that recapitulates these cells' phenotype and gene expression. We tested the hypothesis that pathogenic MΦ subsets express higher levels of inflammatory genes in females, and developed a mouse model that recapitulates select RA MΦ subsets and the sexually dimorphic gene expression pattern.

Methods: We analyzed the myeloid scRNAseq data from the Accelerating Medicines Partnership-RA (AMP-RA) consortium[1] comprised of ~76K cells from human synovial biopsies with RA clustered into 5 MΦ subsets (MERTK+, SPP1+, C1QA+, CXCL10+/STAT1+ and IL1β+/PLCG2+). We performed differential gene expression (DEG) and GSEA between female (n=55) and male (n=20) RA subjects. Zymosan induced arthritis (ZIA) was induced via intra-articular injection of 180 ug of zymosan in female and male, WT and Tg8 (transgenic for human TLR8) mice.scRNAseq of synovial tissue CD45+ cells depleted of neutrophils at peak ZIA disease, D7 and DEG with GSEA between female and male mice was performed. We also performed qPCR analysis of FACS-sorted immune cells at D2 of disease and histologic analysis at D28. To assess the similarity between human RA and ZIA, we performed scRNAseq mouse-to-human (M2H) transfer learning to map mouse cells to human defined clusters. Appropriate t-test and two-ANOVA's with Tukey's post-hoc tests were used for all statistical analysis.

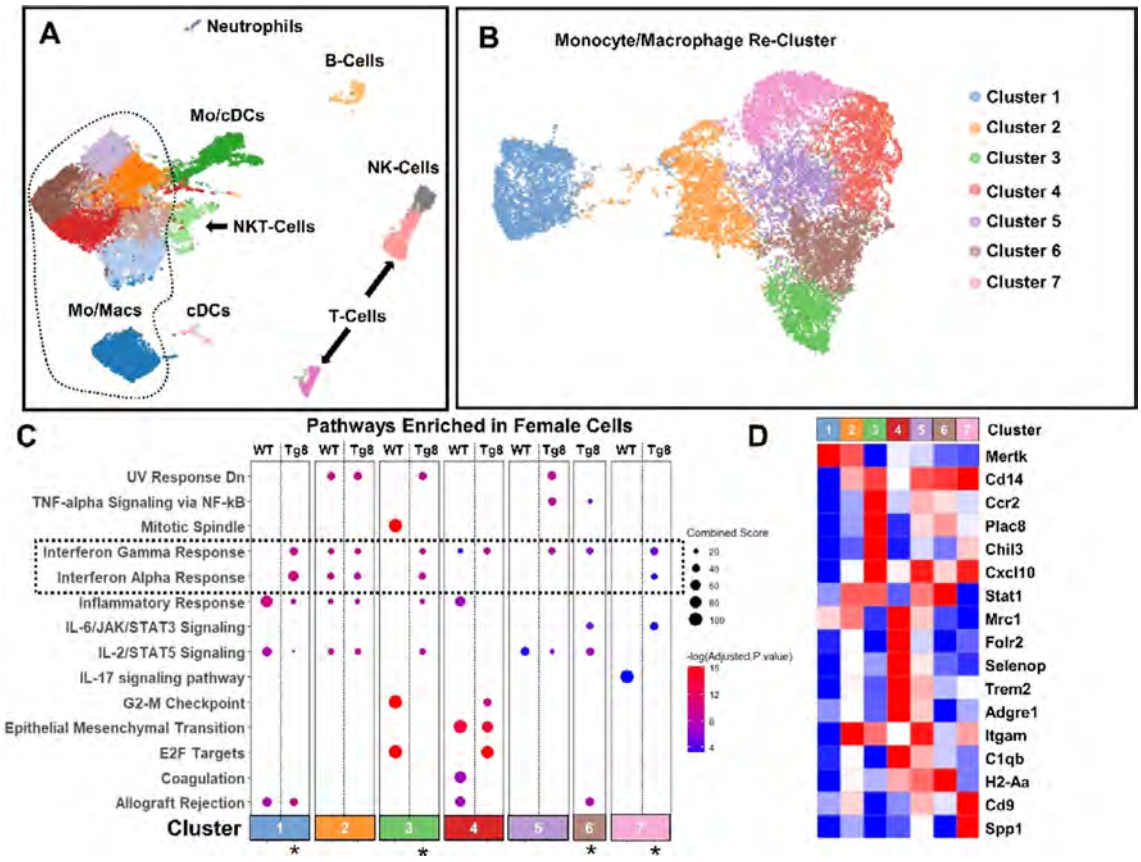

Figure 2. scRNAseq reveals Tg8 Female specific monocyte/macrophage sub-clusters that are enriched with IFN genes. scRNAseq of synovial CD45+ cells depleted of neutrophils on day 7 of ZIA show distinct clusters of immune cells, and sub clusters of monocyte/macrophages in UMAP space (A&B). Differential gene expression comparing male WT to female WT and male Tg8 to female Tg8 with subsequent gene set enrichment shows clusters 1, 3, 6 & 7 (Asterisks) are enriched in IFN related genes (Dotted Box) in female Tg8 cells (D). Mean expression of marker genes per cluster demonstrate that cluster 1 and 2 are proliferating tissue resident macrophages (Ccr2-, Cd14-, Mrc1+, MerTK+), Cluster 3, 5, and 6 are inflammatory monocytes (CD14+, Ccr2+ Chil3+, Plac8+, and Ly6c2+) with cluster 6 being MHCII+, cluster 4 are other tissue resident M2-like macrophages (Mrc+, Trem2+, Adgre1+) and cluster 7 is a monocyte derived inflammatory macrophages (CD14+, CD9+, Spp1+). Analysis: R, Orchestrating Single Cell Experiments, deSeq2, EnrichR, Two-way ANOVA with Tukey's post-hoc tests. scRNAseq: 4 mice pooled per group; Mo/cDC: Monocyte Derived or Conventional Dendritic Cells; Mo/Macs: Monocyte or Macrophages; NK: Natural Killer.

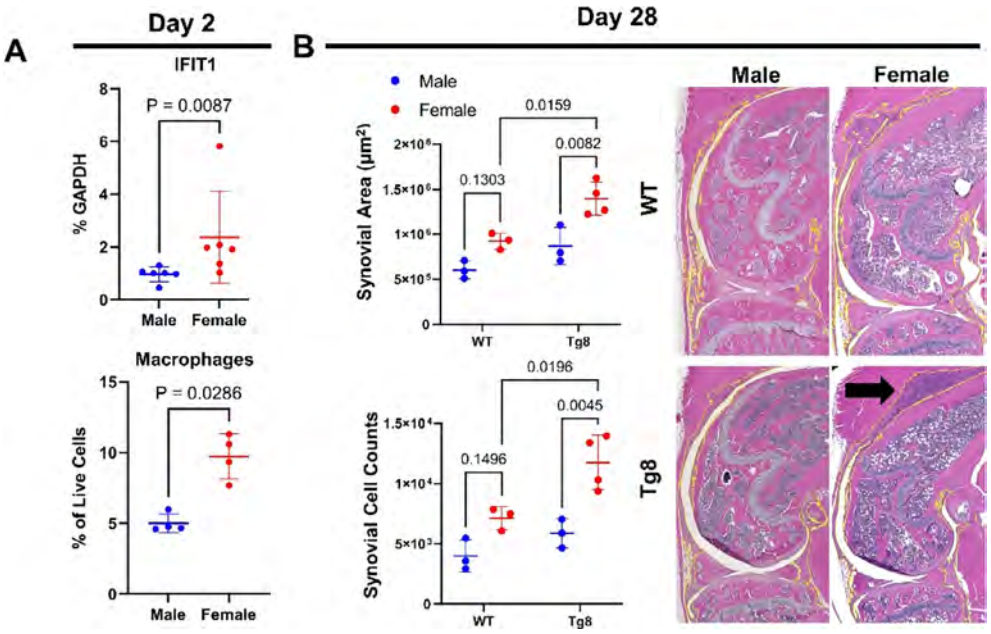

Figure 3. Early increase in IFIT1 in female macrophages with a concomitant increase macrophage abundance in female synovium that leads to increased synovitis at Day 28. On Day 2 after ZIA, FACS sorted F4-80+, CD11b+ macrophages show an increase of ISG expression, one example shown here IFIT1, in female cells. Macrophage numbers are also increased in female mice (A). Histologic analysis at Day 28 indicates that Female Tg8 mice develop increased synovial area and cell counts (B). H&E representative images are presented in the right panel with the synovium outlined in Yellow, note the large synovial reaction still present in the Tg8 female only (Arrow).

Results: GSEA demonstrated that the MERTK+, SPP1+ and CXCL10+/STAT1+ RA myeloid synovial cell clusters showed significant female bias in IFN and other inflammatory pathways (**Fig 1A-C,** FDR < 0.05, LFC >1). The M2H model produced high quality predictions with an overall F1 score of 0.76 ± 0.1 and revealed that ~60% of cells in the mouse ZIA synovium map to human RA synovial myeloid cell subsets (**Fig 1D**) validating our approach. After sub-setting the myeloid cells in ZIA synovium (**Fig 2A**) and re-clustering (**Fig 2B**), 4 of 7 clusters (C1, C3, C6 and C7) were enriched in IFN pathways in Tg8 female cells (FDR< 0.05, logFC > 1, **Fig 2C,** marked with *). These cell clusters represent tissue resident MΦ (C1: *Ccr2*-, *MerTK*+); inflammatory monocytes (C3 & C6: *Ccr2*+, *Chil3*+); and inflammatory MΦ (C7: *Cd14*+, *Cd9*+, *Spp1*+, **Fig 2D**). In addition, qPCR confirmed female specific increase of ISGs in MΦ with concomitant increase in CD11b+ cell abundance by flow cytometry on D2 (**Fig 3A**). This Tg8 female specific gene signature translates into histologic differences at D28 (**Fig 3B**).

Conclusion: This is the first demostration of sexually dimporhic myeloid gene signatures in human RA. We also validate the ZIA mouse model by mapping to human RA and demostrate that it is sexually dimorphic. We are currently exploring mechanistics studies to determine the roles of sex dependent factors, like steroid hormone signaling and X-inactivation, and their specific interactions with the IFN signaling axis.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Plenary I

Session Type: Plenary Session

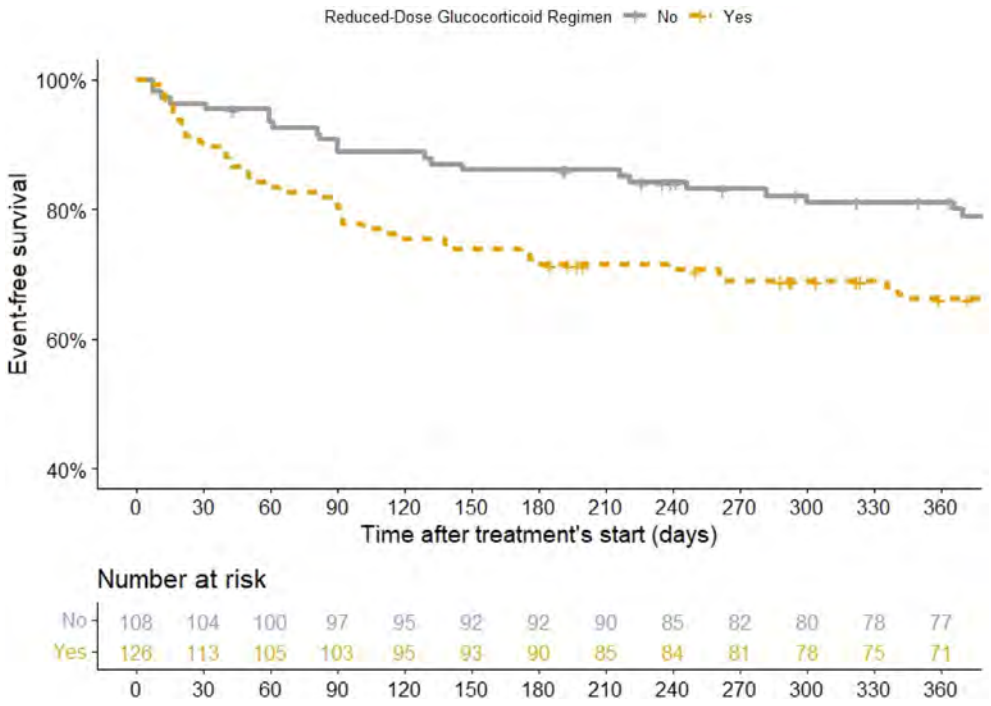
Session Time: 11:00AM–12:30PM

Background/Purpose: Glucocorticoids (GCs) in combination with rituximab (RTX) or cyclophosphamide are the cornerstone of treatment for patients with severe granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA). GCs are associated with adverse effects, including serious infections. The PEXIVAS trial demonstrated non-inferiority of reduced-dose GC regimen compared to standard dose for the incidence of death or end-stage kidney disease (ESKD), with a significant reduction in serious infections at one year. However, the primary endpoint did not include disease progression or relapse, the majority of patients received cyclophosphamide as induction therapy, and subgroup analysis showed a trend towards an increased risk of death or ESKD in RTX-treated patients. We aimed to evaluate the efficacy and safety of the reduced-dose GC regimen in a real-world setting.

Methods: We conducted a retrospective, multicentre study comparing the PEXIVAS reduced-dose GC regimen with a standard regimen in patients with severe GPA or PAM flare between January 2018 and April 2022. The primary composite endpoint included the occurrence of death, ESKD, progression before remission requiring treatment modification or relapse, whichever occurred first. Factors associated with the occurrence of the primary endpoint and of death or ESKD (i.e. the PEXIVAS endpoint) were estimated using univariate and multivariate Cox models. In a sensitivity analysis, patients treated with reduced-dose and standard-dose GCs were compared after matching on a propensity score.

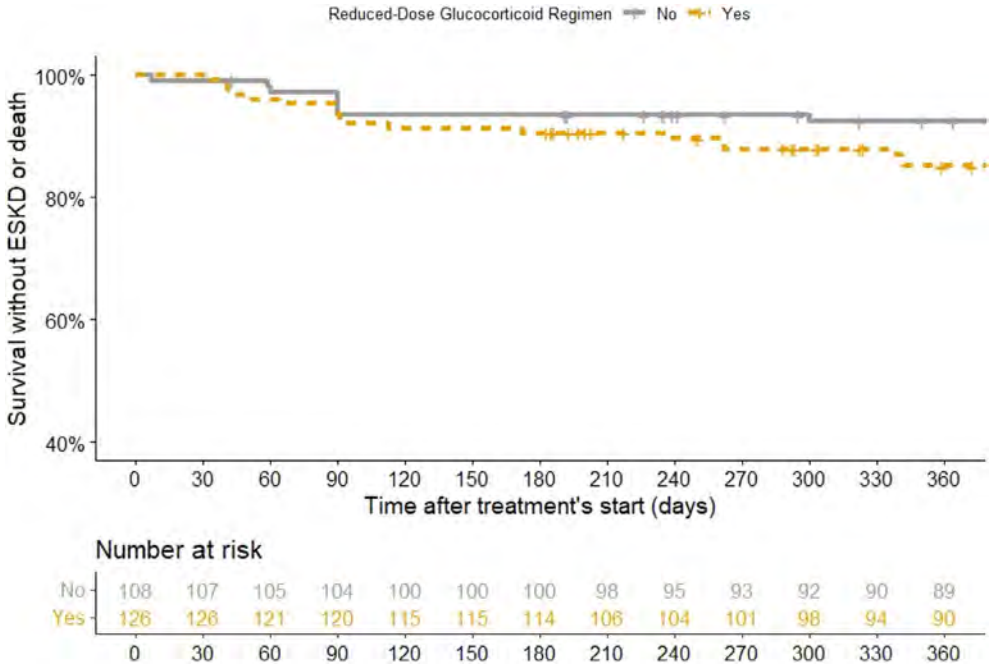
Results: Of the 234 patients enrolled (93 MPA and 148 GPA), 126 (53.8%) received a reduced GC regimen and 108 (46.2%) received a standard regimen. The primary endpoint occurred in 62/234 (26.5%) of patients during the first year of follow-up: 33.3% of patients on the reduced dose versus 18.5% on the standard dose (p=0.016).

In multivariate analysis, a reduced GC regimen was significantly associated with the occurrence of the endpoint compared to a standard regimen (HR 1.72; 95%CI 1.08-2.74) (Figure 1), but was not associated with an increased risk of death or ESKD (HR 1.62; 95%CI 0.82-3.19) (Figure 2). There was no significant difference in serious infections at 1 year (20.6% vs 15.7%, p=0.427).

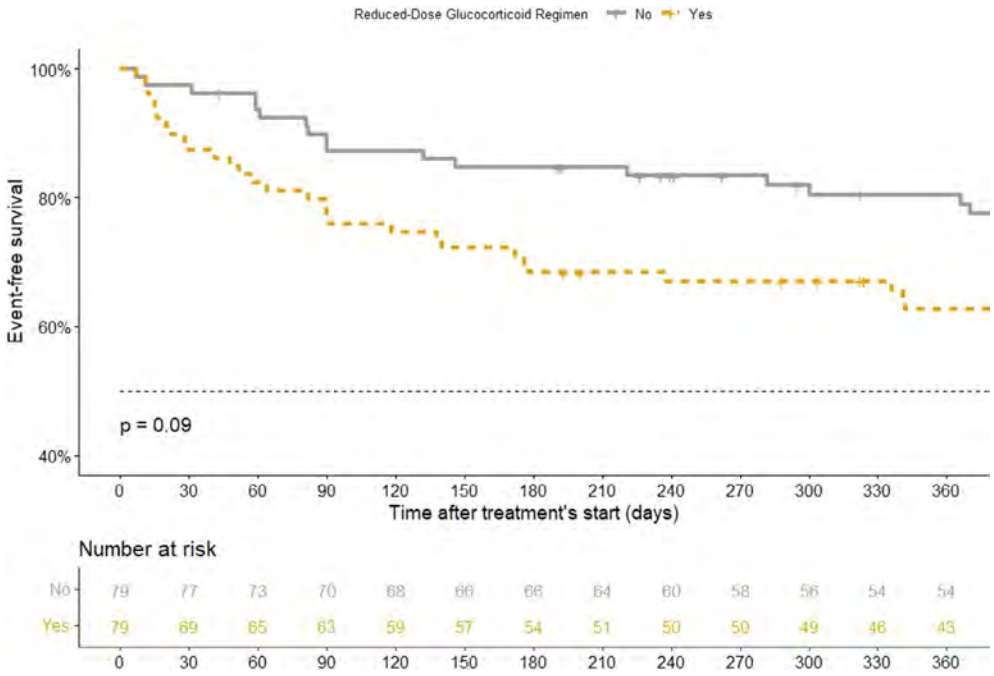


Kaplan-Meier survival curve comparing occurence of primary endpoint at 12 months between patients treated with reduced-dose GC regimen (Yes: orange) and patients treated with standard-dose regimen (No: grey) during the first year of follow-up

After propensity score matching, the reduced-dose GC regimen tended to be more likely to meet the primary endpoint than the standard regimen (HR 1.57; 95%CI 0.93-2.64) (Figure 3). In the subgroup of patients treated with the reduced-dose GC regimen, patients with creatinine levels above 300 µmol/L were more likely to meet the primary endpoint (RR 2.14; 95% CI 1.14-4.03). Similarly, in the subgroup of patients treated with RTX, the reduced-dose GC regimen tended to be more likely



Kaplan-Meier survival curve comparing occurence of death or ESKD at 12 months between patients treated with reduced-dose GC regimen (Yes: orange) and patients treated with standard-dose regimen (No: grey) during the first year of follow-up



Kaplan-Meier survival curve comparing occurence of primary endpoint at 12 months between patients treated with reduced-dose GC regimen (Yes: orange) and patients treated with standard-dose regimen (No: grey) during the first year of follow-up, after matching with a propensity score

to achieve the primary endpoint (HR 1.61; 95% CI 0.94-2.77) and was more likely to meet death or ESKD (HR 2.42; 95%CI 1.04-5.66).

Conclusion: In patients with severe GPA or MPA, the reduced-dose GC regimen was associated with an increased risk of death, ESKD, progression before remission requiring treatment modification or relapse. This risk was even greater in patients with creatinine levels above 300 μmol/L and in those treated with RTX as induction therapy.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Plenary I
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: The Royal College of Physicians and Surgeons of Canada has recently incorporated musculoskeletal ultrasound (MSUS) education into Canadian rheumatology residency programs as an optional training experience. Many Canadian rheumatology programs offer MSUS training for residents, but there is currently no national ultrasound curriculum in Canada outside of externally available courses. The objective of this study was to establish expert consensus on the MSUS competencies that can be incorporated into Canadian rheumatology residency training programs.

Methods: We used a 3-stage consensus design to identify MSUS competencies for Canadian rheumatology residents. We defined consensus a priori as agreement of 70% or higher. We identified all study participants using non-probability sampling and snowball technique. In stage 1, we invited 13 MSUS experts to participate in an online meeting using a modified nominal group technique (NGT) to identify a prioritized list of MSUS competencies. In stage 2, we invited 18 individuals including MSUS experts, rheumatology residents with MSUS experience, and rheumatology program directors with exposure to MSUS in their residency program to participate in a MSUS working group. We invited members of the MSUS working group to complete 3 rounds of online surveys using a modified Delphi technique to establish consensus on the items that should be included for each of the prioritized MSUS competencies identified during the modified NGT. Items not reaching consensus were re-addressed in a maximum of two subsequent rounds. In Stage 3, we invited MSUS experts to attend a structured online focus group to review the final list of competencies.

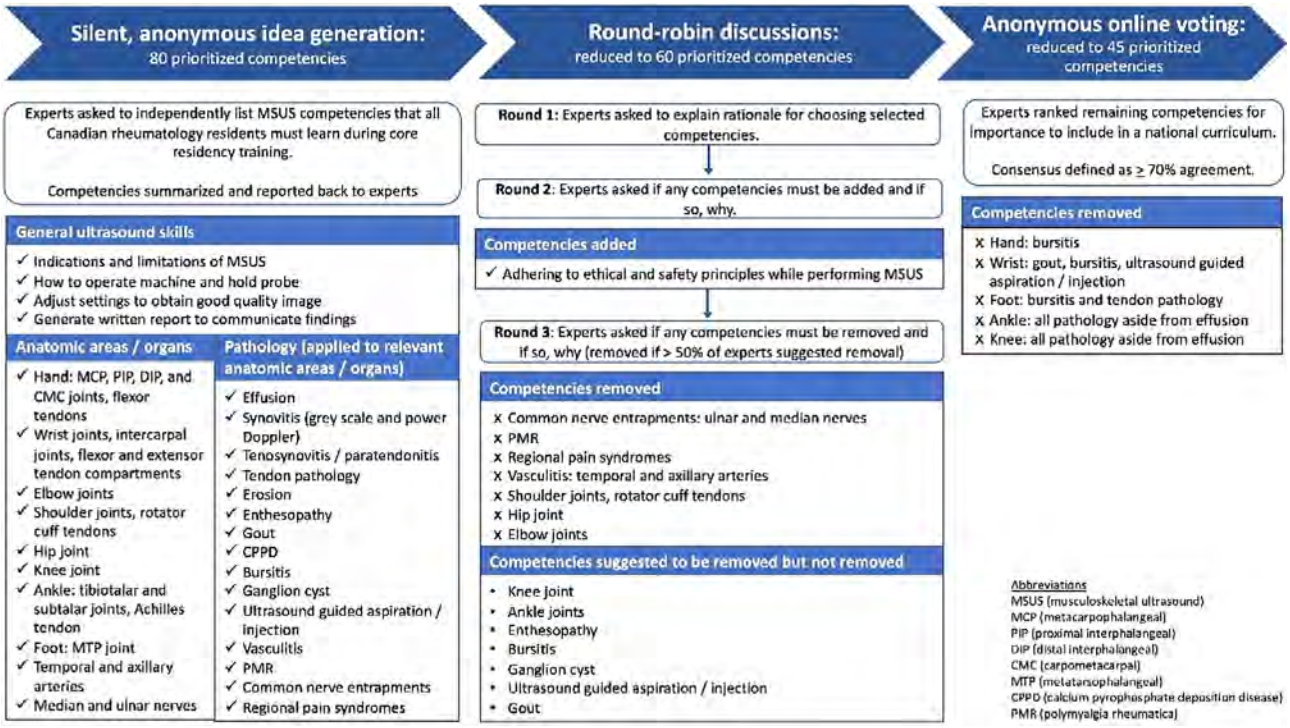

Figure 1: Summary of the modified nominal group technique (NGT) process used to identify prioritized musculoskeletal ultrasound (MSUS) competencies for Canadian rheumatology residents.

Results: Ten of the 13 invited MSUS experts attended the online meeting using a modified NGT, in which experts reached consensus on a prioritized list of 45 competencies (Figure 1). In stage 2, members of the MSUS working group included individuals from 7/12 (58%) Canadian rheumatology programs (English stream) and two MSUS experts from the United States. There was a 100% response rate for all 3 rounds of surveys in the modified Delphi technique. The first round of surveys addressed 86 items derived from the prioritized competencies identified during the modified NGT. The second round of surveys addressed 51 items, and the third round addressed 10 items. After 3 rounds of surveys, the MSUS working group reached consensus on all but 5 items, recommending 42 items be mandatory and 39 be optional. Members of the MSUS working group recommended that it is mandatory for all Canadian rheumatology residents to learn basic ultrasound skills;

Table 1: Summary of final recommended musculoskeletal ultrasound (MSUS) competencies for Canadian rheumatology residents after 3 rounds of surveys using a modified Delphi technique.

Consensus: Mandatory Competencies

Basic ultrasound Skills

Prior to the scan

1. Understand the basic physics of ultrasound including frequency, wavelength, amplitude, etc.
2. Know the indications and limitations of the MSUS exam being performed.
3. Select appropriate probe based on structure being imaged, recognizing how frequency relates to resolution and penetration.

During the scan

1. Maneuver the probe appropriately to define structural characteristics (sufficient gel and pressure).
2. Ensure proper patient positioning for image optimization.
3. Adjust gain and depth to obtain the best image possible.
4. Adjust focal zone to area of interest.
5. Understand basic sonographic characteristics of tissues including bone, tendon, nerve, blood vessel, fat, fluid, etc.
6. Recognize relevant MSUS artifacts such as anisotropy, acoustic shadow, reverberation, and mirror image.
7. Obtain an acceptable image in at least two views (orthogonal planes).
8. Observe the As Low As Reasonable Achievable (ALARA) principle when possible.
9. Perform a MSUS exam in an ergonomic fashion.
10. Save and archive image if desired.

After the scan

1. Properly clean / sanitize the machine and transducers after the exam.
2. Ensure all MSUS exams adhere to ethical principles and patient safety guidelines.
3. Document MSUS findings in the medical record.
4. Integrate relevant MSUS findings into patient management.

Hand: focused ultrasound exam for features of inflammatory arthritis

1. Effusion: MCP and PIP joints
2. Synovitis (grey scale): MCP and PIP joints
3. Synovitis (power Doppler): MCP and PIP joints
4. Bone erosion vs osteophyte: MCP and PIP joints
5. Tenosynovitis: flexor tendon (finger level)

Wrist: focused ultrasound exam for features of inflammatory arthritis

1. Effusion: radio-carpal joint
2. Synovitis (grey scale): radio-carpal joint
3. Synovitis (power Doppler): radio-carpal joint
4. Tenosynovitis: 6th extensor compartment
5. Select carpal bones: lunate, capitate

Foot: focused ultrasound exam for features of inflammatory arthritis

1. Effusion: MTP joint
2. Synovitis (grey scale): MTP joint
3. Synovitis (power Doppler): MTP joint
4. Bone erosion vs osteophyte: MTP joint
5. Double contour sign: MTP joint

Knee: limited ultrasound exam to identify a joint effusion

1. Effusion: suprapatellar and parapatellar recesses of the knee joint

Ankle: limited ultrasound exam to identify a joint effusion

1. Effusion: anterior recess of the tibiotalar joint

Consensus: Optional Competencies

Hand

1. Pathology: gouty tophi, crystal deposition, tendon tear, calcific tendinopathy, ganglion cyst, cartilage degradation
2. Anatomic areas: DIP joint, CMC joint, extensor tendon (finger level)

Wrist

1. Pathology: bone erosion, tendon tear, calcific tendinopathy, ganglion cyst
2. Anatomic areas: radio-ulnar joint, ulno-carpal joint, flexor tendons at the level of the carpal tunnel

Foot

1. Pathology: tenosynovitis, crystal deposition
2. Anatomic areas: IP joint, Lisfranc joint

Knee: limited ultrasound exam to identify a joint effusion

1. Infrapatellar, medial, lateral, and posterior views of the knee

Ankle: limited ultrasound exam to identify a joint effusion

1. Posterior view of ankle
2. Subtalar joint
3. Talonavicular joint

No Consensus

Hand

1. Double contour sign: MCP and PIP joints

Wrist

1. Tenosynovitis: 1st extensor tendon compartment
2. Tenosynovitis: 2-5th extensor tendon compartment
3. Synovitis: lunate-capitate joint (only addressed in 2 rounds)

Foot

1. Gouty tophi: MTP joint

Abbreviations
MSUS (musculoskeletal ultrasound)
MCP (metacarpophalangeal)
PIP (proximal interphalangeal)
DIP (distal interphalangeal)
MTP (metatarsophalangeal)
IP (interphalangeal joint)
CMC (carpometacarpal)

how to perform a focused MSUS exam of the hands, wrists, and feet for features of inflammatory arthritis including effusion, synovitis (grey scale and power Doppler), bone erosion versus osteophyte, and tenosynovitis; and a limited MSUS exam of the knee and ankle to identify a joint effusion (Table 1).

Conclusion: This study reports the expert consensus recommendations for MSUS in Canadian rheumatology residency training programs. These recommendations can be used to help guide programs as they develop MSUS curricula.

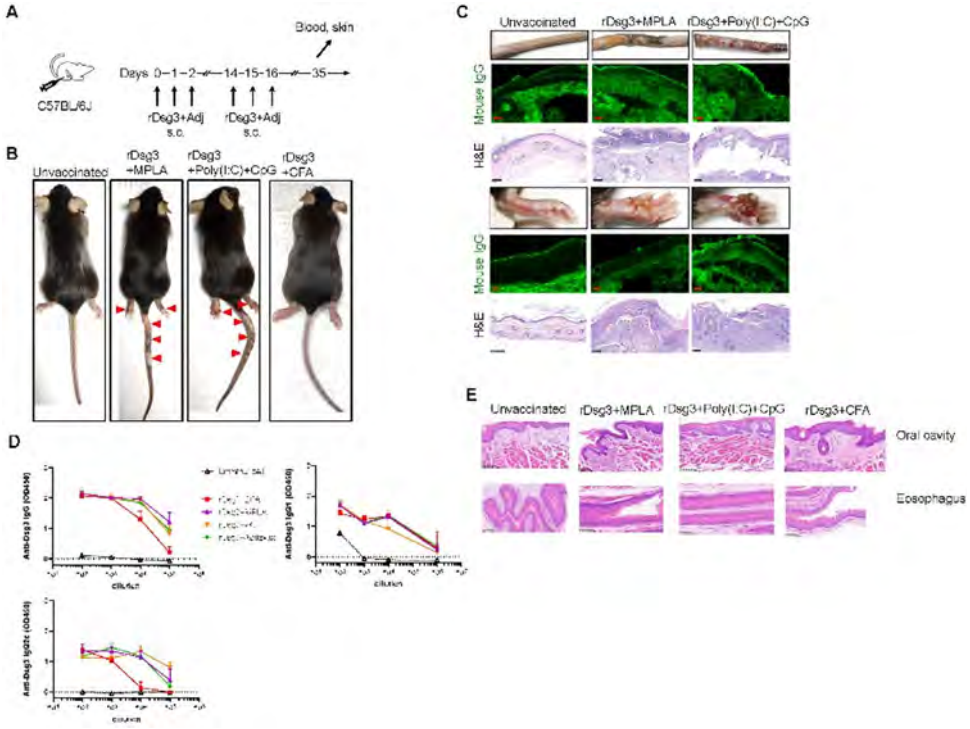
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Pemphigus vulgaris (PV) is an autoimmune bullous skin disease mediated by desmoglein-3 (Dsg3) specific auto-antibody present in skin and mucosae. The binding of pathogenic antibody to Dsg3, which are cell-cell adhesion molecules found in desmosome, induces loss of adhesion between keratinocyte in epidermis and blister formation, resulting in painful erosion in PV patient and are even fatal when severe. Animal model plays vital role in developing safe and effective therapies for PV. However, the PV adult animal model is quite limited, with the adoptive transfer mouse model being the most widely-used, which requires both *Dsg3* knock-out mice and immune-deficient mice as donor and recipient mice, respectively. In this study, we aimed to develop a novel active adult PV model to overcome some of the limitations of current animal models.

Methods: The recombinant Dsg3 (rDsg3) protein vaccines were prepared by mixing rDsg3 and different candidate immune adjuvants for induction of active PV model. Wild-type C57BL/6J mouse was immunized by subcutaneous injection in the footpad through a prime/boost regime. The gross phenotype was monitored and plasma was prepared periodically post immunization. Enzyme-linked immunosorbent assay (ELISA) was conducted for measurement of anti-Dsg3 antibody levels. Passive neonatal mouse model was used to determine the pathogenicity of plasma from PV model mouse. Skin tissues were harvest and formalin-fixed, paraffin-embedded for histological examination, or snap-frozen in liquid nitrogen and embedded in OCT for direct immunofluorescence (IF) to detect the deposition of auto-antibodies.



Direct immunization induced PV symptoms in wild-type mice. (A) A scheme showing the treatment of mice. Mice were vaccinated with rDsg3 and different adjuvants as indicated by a prime-boost regime. 35 days after first vaccination, plasma or serum was prepared from peripheral blood and skin or mucosal tissues were harvested for histological analysis. (B) Gross phenotype of mice. Red arrowhead indicated the sites with skin erosion. (C) Skin tissues from tail and footpad were harvested for H&E staining or direct IF. (D) Dsg3 specific IgG, IgG1 and IgG2c were measured by ELISA. OD values at serial dilution read at 450nm was shown. (E) Histological examination of mucosal tissues from oral cavity and esophagus. Scale bar: 100μm. Results represented are from three-four independent experiments with similar results and shown as mean ± SD.

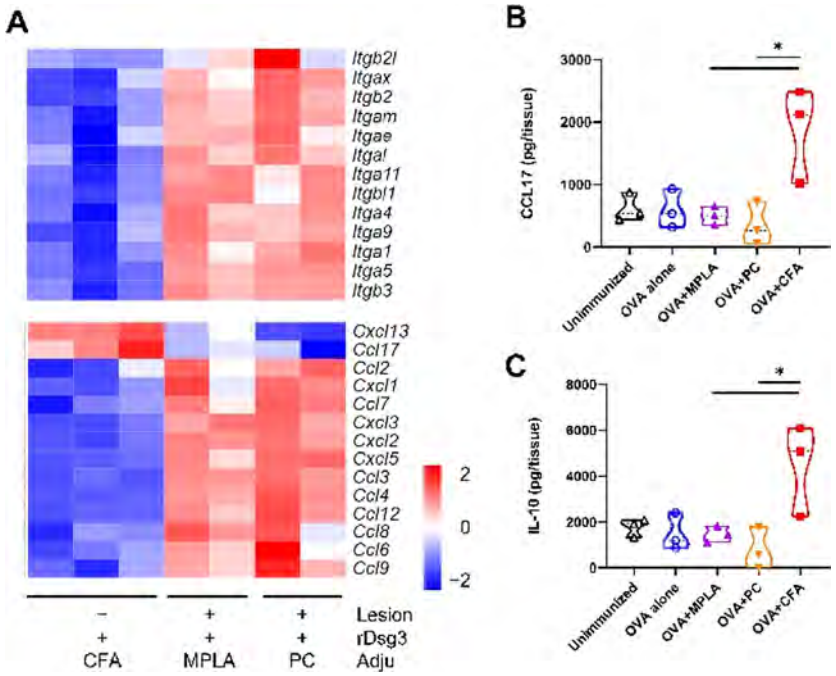


Fig. 2. CCL17 was down-regulated by TLR ligands. (A) Skin lesion of PV model mice was harvested and homogenized for RNA-seq. Transcriptome was analyzed. (B) Mice were vaccinated with OVA and different adjuvants as indicated. 7 days after immunization, draining lymph node was harvested and homogenized for quantification of cytokines by ELISA. Results are representative of three independent experiments and shown as mean ± SD. *p<0.05 indicate a significant difference between.

Results: We found that immunization with rDsg3 adjuvanted with single or a combination of TLR ligands could induce blister formation, skin erosion and hemorrhage in the footpad and tail. H&E staining indicated suprabasilar blister with acantholysis in skin tissues. Direct IF showed deposition of IgG between keratinocyte in the epidermis of PV model mice. A significant elevation of anti-Dsg3 level was observed in plasma of PV model mice as compared with unvaccinated mice measured by ELISA. We also found that completeFreund's adjuvant could not facilitate the breach of tolerance against self-desmoglein 3, as indicated by gross phenotype and histological examination. Bulk RNA-seq suggested Treg-attractant chemokine *Ccl17* was down-regulated by TLR ligand, which was confirmed by ELISA at the protein level, indicating the reduced recruitment of regulatory T cell into the skin lesion and uncontrolled autoimmunity against Dsg3 when TLR ligands was applied.

Conclusion: A novel active pemphigus vulgaris mouse model was established by immunization wild-type C57BL/6J mouse with adjuvanted recombinant desmoglein 3 protein vaccine, which closely mimic clinical symptoms of mucocutaneous type of PV patients. This model could compensate for current PV models with no need of either *Dsg3* knock-out mice or immune-deficient mice, and greatly promote the development of antigen-specific therapies for PV.

Systemic Lupus Erythematosus B Lymphocyte Responsiveness to Type I and Type III Interferon Is Determined by Donor IFN Status and B Cell Phenotype

Diana Alzamareh, Mary O'Connell, Jennifer Anolik and **Jennifer Barnas**, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic lupus erythematous (SLE) is a heterogenous autoimmune disorder characterized by pathogenic antinuclear antibodies. An interferon (IFN) gene signature and B cell aberrations are found in subsets of SLE patients. Type I IFN is involved in immune cell activation, correlates with disease activity, and promotes plasma cell (PC) development. Anifrolumab is a monoclonal type I IFN receptor neutralizing antibody approved for SLE treatment. Anifrolumab reduces PC numbers differentiated from B cells *in vitro*.CD11c+ T-Bet+ autoimmune-associated B cells (ABC) are expanded in SLE and thought to be precursors to autoreactive antibody-producing PCs. We hypothesized that B cell IFN responsiveness is determined by phenotype and past *in vivo* IFN exposure. Here, we characterized the IFN response of IgD- CD27- double negative (DN) B cells, a subset enriched in CD11c+ T-Bet+ ABCs in SLE.

Methods: We screened our biorepository of SLE peripheral blood mononuclear cells (PBMC) for IFI27 expression, an IFN stimulated gene, by quantitative RT-qPCR. Serum IFN-α levels were measured by ELISA. Age, sex, and race matched IFI27-low and high SLE PBMCs were stimulated with IFN-α2 or IFN-λ1 then immunostained for flow cytometry (n=9 pairs plus n=5 matched healthy donor, HD). STAT1 phosphorylation after IFN stimulation was measured by median fluorescent intensity. We measured IFNLR1 expression (type III IFN receptor subunit) in HD B cells by RT-qPCR after TLR and IFN stimulation. Flow cytometry immunophenotyping of PBMC from SLE patients starting anifrolumab prior to first infusion and after second infusion was used to identify DN1 (CD11c- T-Bet- IgD- CD27-) and DN2 (CD11c+ T-Bet+ IgD- CD27-) B cells.

Results: SLE PBMC with high IFI27 had significantly higher level serum IFN-α compared to PBMC from SLE with low IFI27 or HD. Baseline pSTAT1 was not statistically different between low versus high SLE IFI27 donors for ABC/DN2 or DN1.However, ABC/DN2 had higher baseline pSTAT1 when compared to DN1 from the same donor in all groups (HD p=0.02, IFI27 low 0.0001, IFI27 high,0.0008; Wilcoxon matched pairs signed rank test with FDR). DN1 responsiveness to IFN-α was markedly reduced when cells were derived from a high IFI27 patient (p=0.001 for Δstim-unstim pSTAT1) while ABC/DN2 response was unchanged. Despite higher baseline pSTAT1, Δstim-unstim pSTAT1 was higher (p=0.001) after IFN-λ1 stimulation when ABC/DN2 came from a high IFI27 donor. IFN-α2, IFN-λ1, and IFN-γ did not change total B cell IFNLR1 expression. However, TLR7 agonist R848 was able to increase IFNLR1. One month of anifrolumab therapy did not alter percentages of ABC/DN2 in our preliminary phenotyping analyses for ABC/DN2.

Conclusion: Our data demonstrate that type I and type III IFN have differential effects on B cells subsets in both SLE and HD. When cells are derived high IFN environments in SLE, responsiveness of ABC/DN2 to type III IFN is increased while DN1 remain minimally responsive to type III IFN and have reduced type I responses as compared to DN B cells derived from low IFN patients. The role of type III IFN in the setting of type I IFN blockade such as anifrolumab requires further exploration given its potential to stimulate ABC/DN2, a B cell subset target of interest.

ROCK1 Orchestrates B-cell Differentiation Under Stress

Juan Rivera-Correa[1], Sanjay Gupta[1], Edd Ricker[2], Danny Flores-Castro[1], Daniel Jenkins[1], Stephen Vulcano[1], Tania Pannellini[1], Matthew Miele[3], Zhuoning Li[3], Nahuel Zamponi[4], Young-Bum Kim[5], Evgenia Giannopoulou[1], Leandro Cerchietti[4] and **Alessandra Pernis**[1], [1]Hospital for Special Surgery, New York, NY, [2]Columbia University, New York, NY, [3]Memorial Sloan Kettering Cancer Center, New York, NY, [4]Weill Cornell Medicine, New York, NY, [5]Beth Israel Deaconess Medical Center, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The mechanisms utilized by B cells to execute their differentiation programs when exposed to damaging and stressful environments, which often accompany severe infections and inflammatory disorders, are poorly understood. RhoA GTPases are molecular switches, which signal by binding to key downstream effectors. In particular, RhoA signaling activates two crucial serine-threonine kinases, ROCK1 and ROCK2. In B cells, ROCK2 is known to regulate the positioning and cholesterol biosynthesis of germinal center B cells and to control plasma cell (PC) differentiation. Although ROCK1 and ROCK2 share a highly homologous kinase domain, they exhibit a lower degree of similarity in the remainder of the molecule suggesting the existence of isoform-specific functions. The precise role of ROCK1 in B cells has, however, not been studied. Here, we have investigated the contribution of ROCK1 to B cell differentiation in complex inflammatory settings by employing a malaria infection model and *in vitro* studies.

Methods: Mice with B cell-specific deletion of ROCK1 (CD23-Cre.Rock1$^{flox/flox}$) were subjected to *Plasmodium yoelii 17XNL (P. yoelii),* a non-lethal malaria infection model characterized by severe transient anemia. Rock1$^{flox/flox}$ mice were employed as controls. Immune responses were monitored by FACS at various timepoints and histopathological analyses. Antibody responses and cytokine production were assessed by ELISA. The molecular mechanisms employed by ROCK1 to regulate

B cell differentiation were examined by FACS-sorting B cell populations from spleens followed by RNA-sequencing analyses and *in vitro* experiments coupled with transcriptomic, phospho-proteomic, and biochemical strategies.

Results: *In vivo* and *in vitro* studies demonstrate that the serine-threonine kinase ROCK1 helps B cells execute their differentiation programs upon exposure to pathogen-associated stressors, like TLR9 ligands and high levels of heme. ROCK1 restrains premature plasma cell differentiation by phosphorylating the heme-regulated transcription factor Bach2. As B cells differentiate, furthermore, ROCK1 limits the proinflammatory potential of B cells, and fine-tunes mTORC1 activity and stress responses. ROCK1 orchestrates these processes by regulating the assembly of p62 complexes containing mTORC1, TBK1, RhIM-domain proteins, and molecules involved in RNA metabolism and proteostasis.

Conclusion: These studies indicate that ROCK1 is a critical "stress" sensor, which helps B cells execute their differentiation programs upon exposure to potentially damaging conditions by coordinating the activity and localization of a key core of molecules that mediate cell-fate decisions, proinflammatory functions, and RNA and protein homeostasis. These ROCK1-dependent mechanisms may be widely employed by B cells to cope with intense environmental stresses and these findings may be relevant not only for infections, but also for vaccinations, and autoimmune diseases.

NF-κB Signaling Is Critically Important for Functional Responses of ACPA-producing B Cell Clones from Patients with Rheumatoid Arthritis

Giulia Frazzei[1], Jan Piet van Hamburg[2], Ronald van Vollenhoven[2] and **Sander Tas**[3], [1]Amsterdam University Medical Center, location AMC, Amsterdam, Netherlands, [2]Amsterdam University Medical Centers, Amsterdam, Netherlands, [3]Amsterdam UMC, locatie AMC, Utrecht, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) play a role in rheumatoid arthritis (RA) pathogenesis, and their presence is associated with disease severity. Consequently, detailed analysis of ACPA^{pos} B cells is required to disentangle the role of these cells in RA. Multiple intracellular signaling pathways are involved in functional B cell responses. NF-κB signaling is one of the prime regulators of B cell proliferation, differentiation and (auto)antibody production. Moreover, NF-κB activation leads to pro-inflammatory cytokine and chemokine production. JAK-STAT signaling is induced after activation of the B cell receptor (BCR) and is also involved in B cell proliferation and maturation. Targeting NF-κB or JAK-STAT signaling may advance our understanding of the mechanisms involved in the activation of ACPA-producing B cells. We make use of ACPA^{pos} B cell clones, since peripheral ACPA^{pos} cells are present at low frequencies in the peripheral blood.

We aimed to identify whether NF-κB or JAK-STAT signaling inhibition using small molecule inhibitors (SMIs) is effective in targeting functional responses of ACPA^{pos} B cell clones from RA patients.

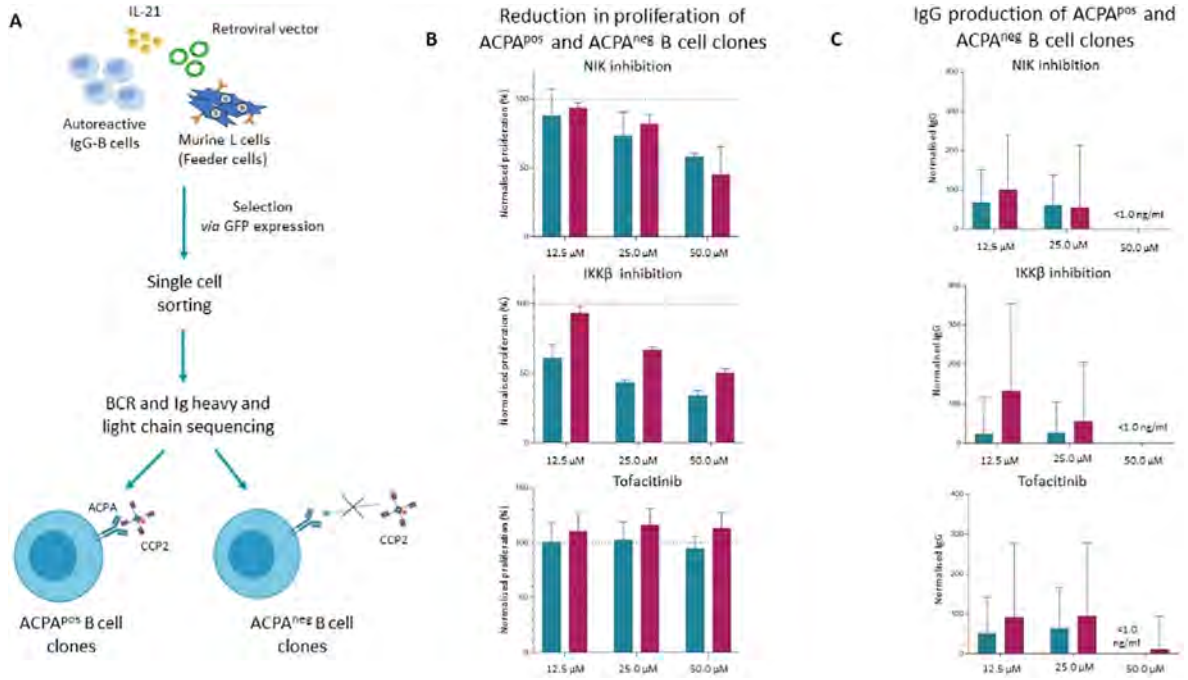

Fig. 1 - ACPApos and ACPAneg B cell clone generation (A). Effects of small molecule inhibition of intracellular signaling pathways on B cell proliferation (B, data normalized on DMSO) and IgG production (C). Legend: ACPApos B cell clones in blue, ACPAneg B cell clones in red.

Methods: Previously generated ACPA^{pos} and ACPA^{neg} B cell clones (Fig. 1A) were expanded and cultured with anti-CD40 and IL-21. Canonical and non-canonical NF-κB signaling were targeted by validated SMIs of Inhibitor of κB kinase β (IKKβi, canonical NF-κB signaling) and NF-κB inducing kinase (NIKi, non-canonical NF-κB signaling), respectively. Tofacitinib (a JAK1/JAK3 specific SMI) was used to target JAK-STAT signaling. Cell viability, proliferation and differentiation were evaluated by flow cytometry. Antibody production was measured by ELISA.

Results: We observed a dose-dependent reduction in proliferation in ACPA^{pos} B cell clones treated with either IKKβi (12.5 μM IKKβi: 39.12±9.86% decrease, 25 μM IKKβi: 56.55±1.84% decrease, 50 μM IKKβi: 65.65±3.1% decrease) or NIKi (12.5 μM NIKi: 12.13±19.42% decrease, 25 μM NIKi: 26.63±17.37% decrease, 50 μM NIKi: 41.69±2.00% decrease) upon stimulation with 2.25 μg/ml anti-CD40 and 1.0 ng/ml IL-21 (Fig. 1B). Similarly, we observed a dose-dependent reduction in IgG production (Fig. 1C). IKKβi treatment seemed to have a stronger effect than NIKi treatment on ACPA^{pos} B cell clones.

We did not observe a clear difference between IKKβi and NIKi in ACPA^{neg} B cells (12.5 μM IKKβi: 6.90±5.38% decrease, 25 μM IKKβi: 33.32±2.15% decrease, 50 μM IKKβi: 50.11±3.15% decrease; 12.5 μM NIKi: 6.09±3.61% decrease, 25 μM NIKi: 17.83±6.53% decrease, 50 μM NIKi: 54.67±20.37% decrease). Cell viability was not affected by IKKβi or NIKi treatment. In contrast to IKKβi and NIKi treatment, tofacitinib only had limited effects on ACPA^{pos} and ACPA^{neg} B cell proliferation and IgG production. At present these results are being corroborated in freshly isolated ACPA^{pos} B lineage cells of RA patients.

Conclusion: Our data point towards a critical role of the NF-κB signaling pathways in the functional responses of ACPA-producing B cells, whereas a limited role of JAK-STAT signaling was observed. Consequently, targeting NF-κB signaling may have beneficial effects in limiting (autoreactive) B cell responses in RA.

ZEB2 Acts as a Crucial Transcriptional Regulator Governing Age-Associated B Cell Formation and Pathogenicity in Systemic Lupus Erythematosus

Dai Dai[1], Shuangshuang Gu[1], Xiaxia Han[1], Huihua Ding[2], Yang Jiang[1], Sheng Chen[1] and **Nan Shen**[2], [1]Shanghai Institute of Rheumatology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University (SJTUSM), Shanghai, China, [2]Shanghai Jiao Tong University School of Medicine, Shanghai, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Age-associated B cells (ABCs) accumulate and contribute to the pathogenesis of systemic autoimmune diseases like lupus. Despite recent insights into the ontogeny and function of ABCs, the key transcriptional regulators of ABCs differentiation remain ill-defined. Addressing this gap in knowledge will reveal targets to enable the prevention or reduction of ABCs in disease therapy.

Methods: We employed single-cell RNA sequencing to identify transcription factors (TFs) that were differentially expressed in age-associated B cells (ABCs) from both lupus patients and lupus-prone mice. An arrayed CRISPR screen of these regulatory TFs was conducted under in-vitro conditions that induce ABC formation. In our cohort, we included patients diagnosed with Mowat-Wilson Syndrome (MWS), a condition attributed to ZEB2 haploinsufficiency. We constructed B-cell-specific Zeb2 knockout mice and subjected them to TLR7-driving and Bm12-transfer lupus models, enabling us to study Zeb2's regulatory role in ABC formation and associated autoimmunity. The detection of autoantibodies was achieved using an autoantigen microarray. To investigate Zeb2's direct targets, we performed ATAC-seq, Cut & Tag, and Cut & Run sequencing, and integrated these regulome findings with transcriptome data obtained from RNA sequencing. We employed trans-well and PHrodo staining techniques to study the distinct migratory and phagocytic features of ABCs. The induced lupus models were used to evaluate the potential of the JAK1/3 inhibitor tofacitinib in intervening with ABC formation and associated autoimmunity.

Results: We carried out a screening process and identified that Zeb2 is required for in-vitro differentiation of ABCs in both humans and mice. We observed a reduction in ABCs in individuals with ZEB2 haploinsufficiency and in mice devoid of Zeb2 in B-cells. By utilizing mice that selectively lack Zeb2 in B cells, we demonstrated the essential role of Zeb2 in facilitating autoimmune pathology relevant to ABCs, including autoantibody formation, production of proinflammatory cytokines and chemokines, migration to end-organ tissues, and induction of tissue damage in a lupus model. Zeb2 binds to the +20kb intronic enhancer of Mef2b, thereby repressing Mef2b-mediated germinal center B-cell differentiation and instead promoting ABC formation. Zeb2 also targets genes crucial for ABC specification and function, including Itgax. Furthermore, Zeb2 regulates the distinct cellular characteristics of ABCs, including their migration and phagocytic abilities. The differentiation of ABCs driven by Zeb2 necessitates Jak-Stat signaling. Notably, we found that the use of tofacitinib, an approved JAK1/3 inhibitor, effectively reduces the accumulation of ABCs in autoimmune mice and patients.

Conclusion: Our study reveals that ABCs, a unique B cell subset, rely on Zeb2 expression and regulation. Zeb2 affects germinal center B cell development and dictates ABC identity. Modulating Zeb2-mediated Jak-Stat signaling could effectively curb ABC accumulation and related autoimmunity, presenting a potential therapy for autoimmune diseases.

Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Complete peripheral B cell depletion has been considered as a relevant indicator of short-term response to rituximab (RTX) in rheumatoid arthritis (RA). The purpose of our study was to determine whether sustained complete B cell (BC) depletion is associated with a better clinical response in RA patients long-term treated with RTX.

Methods: Retrospective routine care study conducted in the Rheumatology department of Cochin hospital. We included consecutive patients fulfilling the ACR/EULAR 2010 classification criteria for RA hospitalized in 2021 for a new RTX infusion. All recruited patients had received at least 3 prior RTX infusions and had disease activity assessment (DAS28 and DAS28-CRP) and CD19 counts (Aquios, Beckman Coulter) available during each of the 4 last infusion visits. The primary endpoint was the evaluation of the disease activity (mean DAS28 and DAS28-CRP) calculated the day of the last 4 infusion

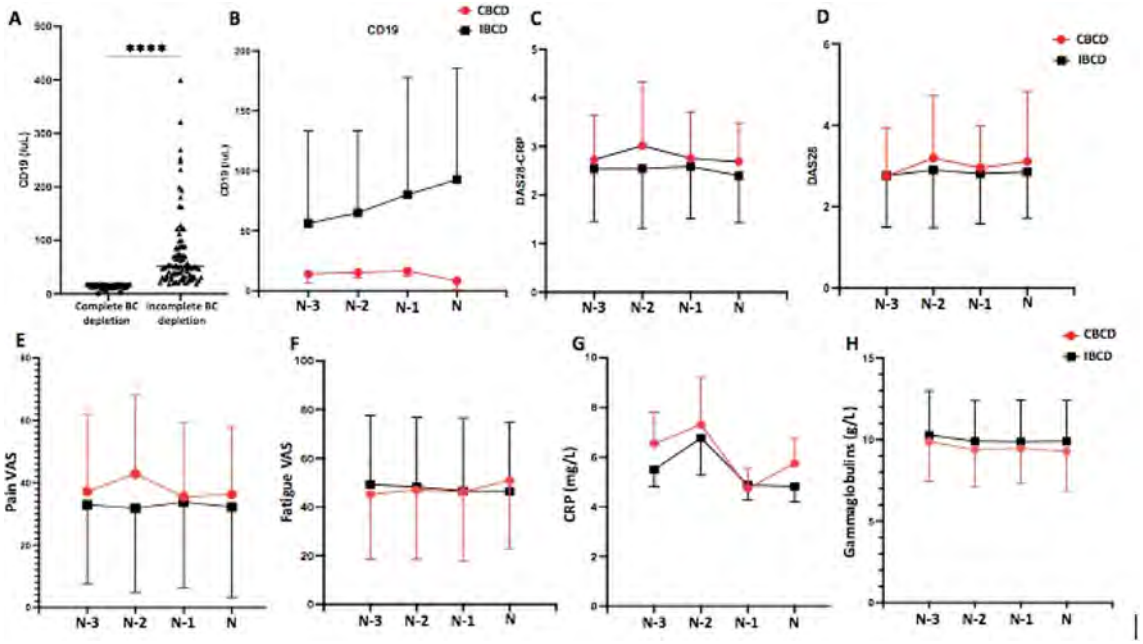

Figure 1: Course of mean (SD) CD19, DAS28, DAS28-CRP, pain and fatigue VAS, CRP and gammaglobulins at the last 4 RTX infusion visits according to sustained complete or incomplete B cell depletion (CBCD and IBCD respectively).

Table 1: Patient and disease characteristics at inclusion according to sustained complete or incomplete B cell depletion.

1	33 (26)	8 (19)	25 (30)	0.19
2	37 (29)	16 (37)	21 (25)	0.16
>2	18 (14)	10 (23)	8 (10)	0.049
Median duration of RTX exposure (months), mean±SD	76±52	69±47	99±57	0.003
Number of infusions, mean±SD	14±7	12±6	14±7	0.037
Cumulative RTX dose (g), mean±SD	9±6	8±5	10±6	0.010
Median retreatment interval (months), mean±SD	7.5±2	6±1	8±3	0.001

visits, according to the persistence of complete BC depletion (mean CD19 counts of the last 4 visits < 18/mL) or incomplete BC depletion (mean CD19 counts of the last 4 visits ≥18/mL). Secondary endpoints were the frequency of end-of-dose effect and patient self-reported RA flares at each infusion visit, the course of pain/fatigue VAS, CRP and gammaglobulin levels

Results: We included 126 patients with a mean age of 64±12 years and a mean disease duration of 22± 5 years. Only 43 patients (34%) had maintained complete BC depletion during the last 4 infusions (mean CD19 counts 13±4/mL) (Figure 1A-B). Patients with incomplete BC depletion (n=83, mean CD19 counts: 77±73/mL, p< 0.001) did not differ from those who maintained complete BC depletion in terms of age, gender, disease duration, structural damages and concomitant treatment. Patients with incomplete BC depletion had received RTX for a longer period (99±57 months vs. 69 ±47 months, p=0.003), with significantly higher number of infusions (14±7 vs. 12±6 infusions, p=0.037) and increased cumulative dose (10±6 g vs. 8±5 g, p=0.10) compared to patients with sustained complete BC depletion. On the other hand, their interval between 2 infusions was significantly longer (8±3 months vs. 6±1 months, p< 0.001). The course of DAS28 and DAS28-CRP during the last 4 infusions was not different between the 2 groups (Figures 1C-D). The mean DAS28 and DAS28-CRP calculated at the time of last 4 infusion visits did not differ between patients with incomplete or sustained complete BC depletion (DAS28: 2.71±1.06 vs. 3.01±1.10, p=0.33 and DAS28-CRP: 2.53±0.88 vs. 2.88±0.84, p=0.095). Secondary outcomes were similar between the 2 groups (Figures 1E-H).

Conclusion: While it is associated with a better response to RTX at the start of treatment, the persistence of complete BC depletion is not associated with better efficacy of RTX in RA patients receiving this treatment over the long term. There is a limited benefit of monitoring CD19 in RA patients long term treated with RTX and having achieved low disease activity/remission. During the COVID-19 pandemic, this data is all the more important as the humoral anti-SARS-CoV-2 vaccine response is preferentially obtained in patients with incomplete BC depletion.

Global Identification of Lupus Genetic Risk Variants Facilitating the Type I Interferon Pathway Through CRISPR-based Genomic Screening

Guojun Hou[1], Xinyi Zhu[1], Yutong Zhang[1], Zhaorui Cheng[1] and **Nan Shen**[2], [1]Shanghai Institute of Rheumatology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University (SJTUSM), Shanghai, China, [2]Shanghai Jiao Tong University School of Medicine, Shanghai, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Genetics, Genomics & Proteomics
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Genome-Wide Association Studies (GWAS) have unveiled over 1000 risk variants for lupus, predominantly situated in non-coding genomic regions. Their functional roles, especially their potential impacts on the dysregulated type I interferon pathway inherent in lupus, remain largely uncharted. To bridge this knowledge gap, our study employs CRISPR/Cas9 technology, enabling a deeper exploration into the functional implications of these risk loci.

Methods: Our novel strategy entailed CRISPR-based screening for functional variants that regulate the type I interferon pathway. We collected all known SLE-associated SNPs and expanded them through linkage disequilibrium in the population where the SNP was reported. We designed an sgRNA library covering these SLE-associated SNPs and developed a

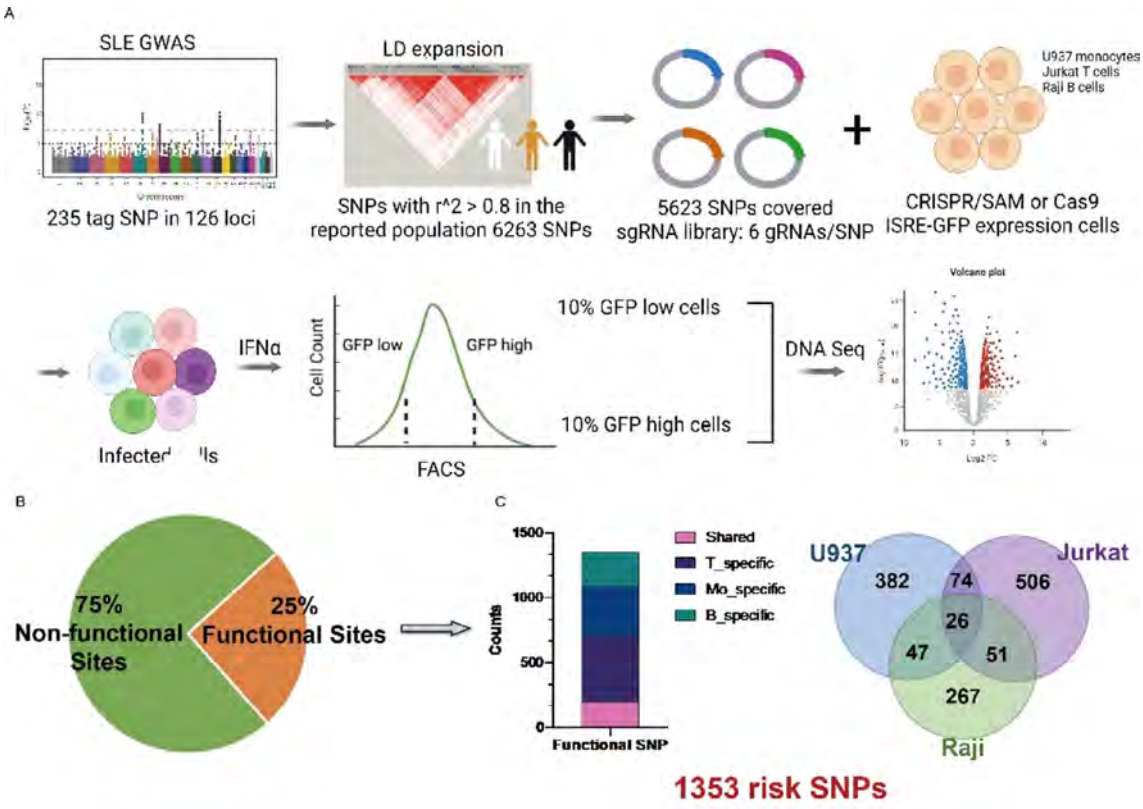

Figure 1. Functional Variant Screening for Regulation of Type I Interferon Pathway Activation Using CRISPR/SAM and CRISPR/Cas9 Across Various Immune Cells. (A) A depiction of the CRISPR screening workflow. (B) Representation of the proportion of functional regions implicated in the modulation of the type I interferon pathway. (C) Evaluation of functional variant regions that are common or specific to individual cell types.

cellular model using U-937, Jurkat, and Raji cells that stably express the CRISPR/Cas9-ISRE-GFP and CRISPR/SAM-ISRE-GFP systems. Post-transduction with the sgRNA lentiviral library, we sorted cells based on GFP intensity and extracted and sequenced DNA from these sorted cells. The functional variants were identified and characterized using multi-omics analysis (eQTL data, HiC data, RNA-sequencing data). We validated the function of the rs11152966-located region and identified PRDM1 as the target gene of rs11152966 through integration of advanced technologies like capture-HiC, CRISPR-SAM, and prime editing technology.

Results: We've characterized the comprehensive landscape of functional SNPs related to lupus that regulate the Type I interferon pathway. Notably, we discovered that the majority of these functional variant regions are cell type-specific .Utilizing the CRISPR/Cas9 and CRISPR/SAM systems effectively, we found these tools to have complementary benefits in the identification of these functional variants. Furthermore, these functional variant regions were found to be associated with the expression of critical regulators within the JAK-STAT pathway and interferon-stimulated genes (ISGs). Importantly, we observed a correlation between the expression of transcription factors disrupted by these functional variants and the expression of ISGs in SLE patients. One standout finding was the negative regulatory effect on the Type I interferon pathway upon activation of the region

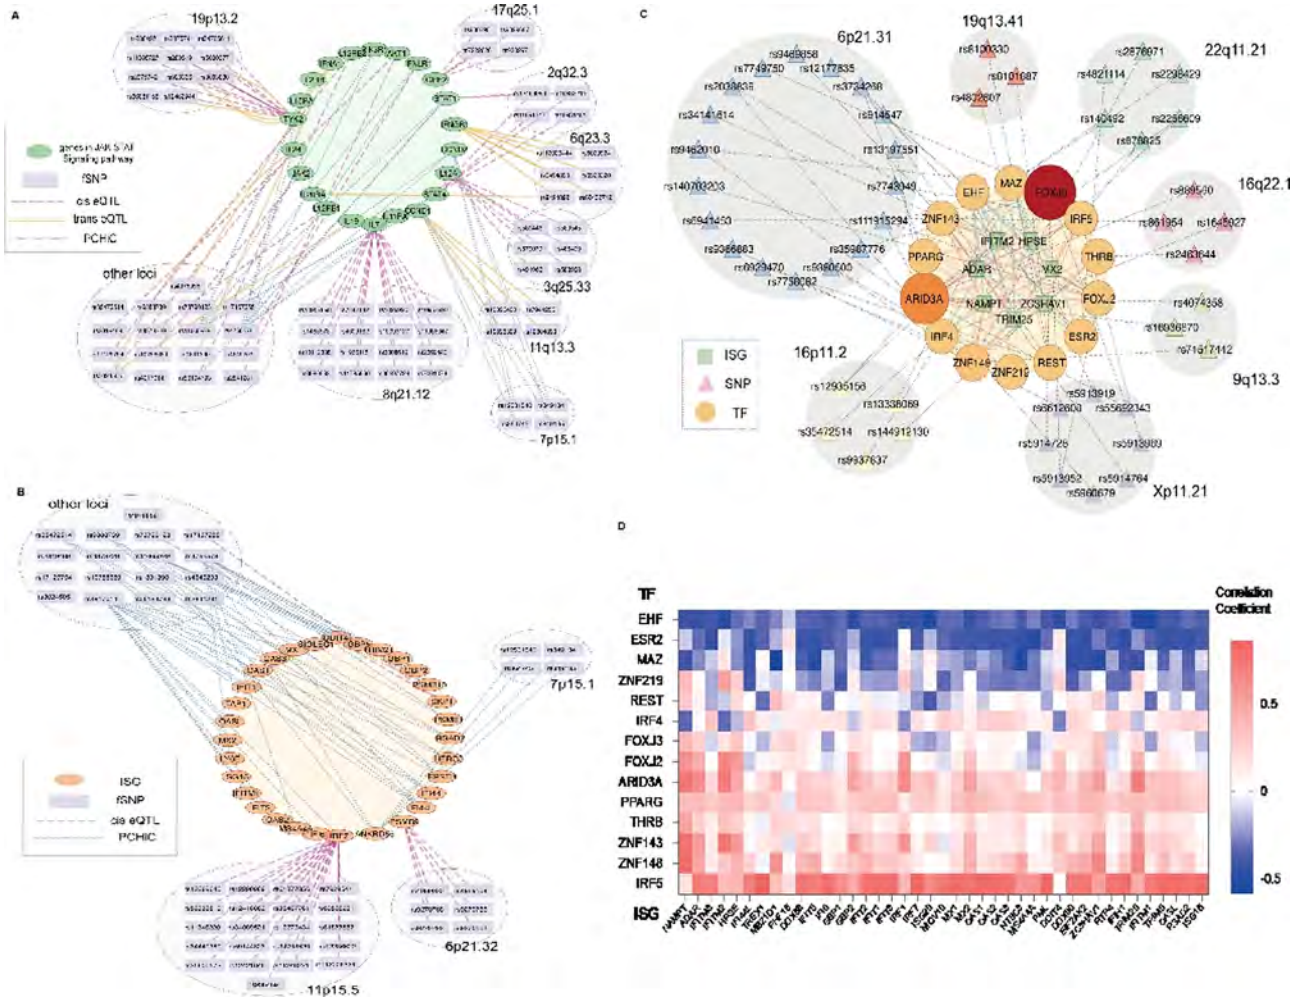

Figure 2. Annotation of SNP-Target Gene-TF Interaction Network and Their Role in the Interferon (IFN) Pathway (A-B) Illustrates the interconnection of functional SNPs and associated genes in the JAK-STAT signaling pathway and ISGs, with lines denoting eQTL signals or 3D genomic interactions. Gene size and color correspond to differential expression results in SLE patients. (C) Shows a network of functional SNPs, disrupted TFs due to SNP, and ISGs with significant correlation to these TFs. Gray lines suggest disruption of TF binding motifs by SNPs. Blue and red lines indicate negative and positive correlations between ISGs and TFs, respectively. TF size and color display its degree or interaction count, as determined by Cytoscape. (D) Demonstrates Spearman correlation analysis between transcription factors and ISGs expression levels (RPKMs) in whole blood samples from SLE patients.

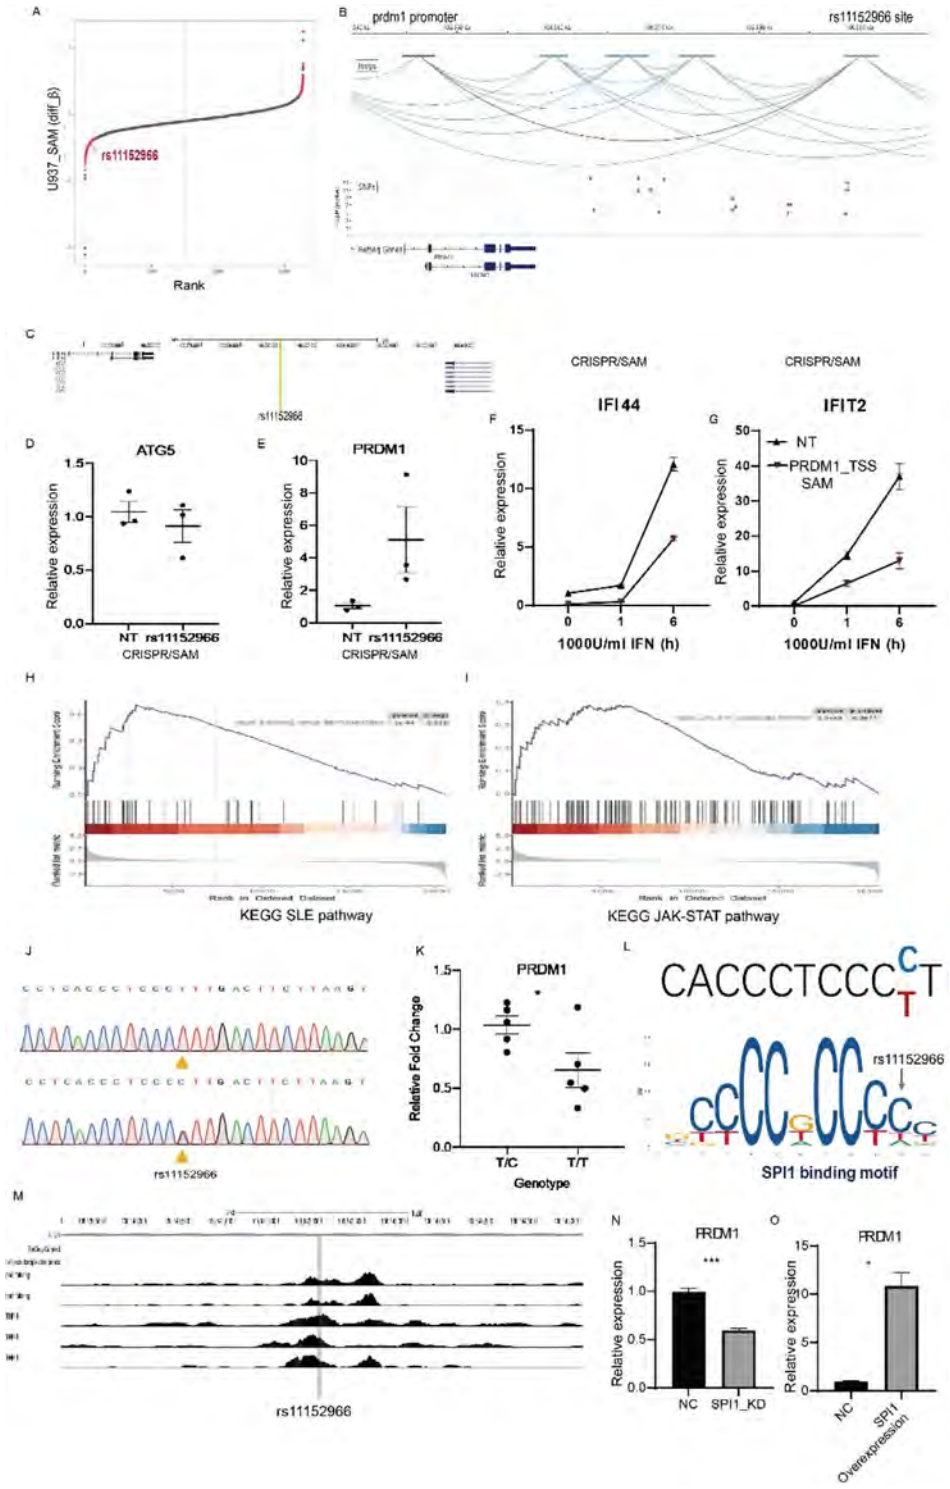

Figure 3. PRDM1 expression is regulated by rs11152966, contributing to the modulation of the type I interferon pathway. (A) A region containing rs11152966, revealed by CRISPR screening, inhibits the activation of the type I interferon pathway. (B) Gene loop between the rs11152966 location and PRDM1 promoter, as evidenced by HiC data. (C-E) CRISPR/SAM targeting the area containing rs11152966 boosts PRDM1 expression, but not the adjacent gene ATG5. (F-G) Targeting of the PRDM1 TSS region by CRISPR/SAM results in reduced ISGs expression. (H-I) Analysis by GSEA of JAK-STAT and SLE pathways in PRDM1 KO U-937 cells post-IFNα stimulation for 1 hour. (J) Genotype of rs11152966 in cell clones established by prime editing technology. (K) The T risk allele of rs11152966 results in diminished PRDM1 expression compared to the C non-risk allele. (L) SPI1 has a preference for binding to the non-risk C allele of rs11152966. (M) ChIP-seq data indicate SPI1 binding within the rs11152966 region. (N-O) PRDM1 expression following SPI1 overexpression or knockdown.

containing the SNP rs11152966. This region, inclusive of the SNP, forms a gene loop with the PRDM1 promoter, thereby managing PRDM1 expression. Additionally, we provided evidence that PRDM1 acts as a novel negative regulator of the Type I interferon pathway. Lastly, our research revealed a link between the presence of the risk allele T and a reduction in PRDM1 expression. This reduced expression appears to be due to the allele T's effect on the binding of the transcription factor SPI1.

Conclusion: Our study leveraged advanced gene-editing tools to elucidate the landscape of functional SNPs in lupus, revealing their cell type-specific regulation of the Type I interferon pathway and their influence on key genes in the JAK-STAT pathway. Notably, we highlighted the significant role of SNP rs11152966 and its target gene PRDM1 in regulating the interferon pathway in lupus.

Immune Isoform Atlas: Landscape of Alternative Splicing in Human Immune Cells and Involvement of Dysregulated Alternative Splicing in Autoimmune Diseases

Jun Inamo[1], Akari Suzuki[2], Mahoko Takahashi Ueda[1], Kensuke Yamaguchi[1], Hiroshi Nishida[3], Katsuya Suzuki[4], Yuko Kaneko[5], Tsutomu Takeuchi[6], Hiroaki Hatano[7], Kazuyoshi Ishigaki[8], Yasushi Ishihama[3], Kazuhiko Yamamoto[9] and Yuta Kochi[1], [1]Tokyo Medical and Dental University, Tokyo, Japan, [2]RIKEN Center for Integrative Medical Science, Kanagawa, Japan, [3]Kyoto University, Kyoto, Japan, [4]Keio University, Shinjuku, Japan, [5]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, [6]Keio University School of Medicine and Saitama Medical University, Tokyo, Japan, [7]Laboratory for Human Immunogenetics, RIKEN Center for Integrative Medical Sciences, Tokyo, Japan, [8]RIKEN, Tokyo, Japan, [9]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo and Laboratory for Autoimmune Diseases, Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Genetics, Genomics & Proteomics
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Alternative splicing events play a critical role in the immune system[1,2] and one of major causal mechanisms for complex traits including immune-mediated diseases (IMDs), but they have been understudied due to the limitation of the short-read sequencing technology[3,4]. With the emergence of long-read sequencing, large-scale projects have aimed to reconstruct full-length transcripts; however, existing studies focusing on whole blood cells or lymphoblastoid cell lines[5,6]. The profiling of isoforms by cell types will help elucidate complicated immune system networks and unknown pathogenesis of IMDs.

Methods: We isolated 29 immune cell subsets from the peripheral blood cells of a healthy donor (42 years-old female) (Figure 1A). cDNA libraries were made from the poly(A) mRNA, PCR amplified, and subjected to long-read sequencing using the MinION. After mapping raw reads and quality control steps, we generated the atlas containing the full-length of isoforms.

Results: Our atlas (Immune Isoform Atlas) contained a total of 159,369 isoforms transcribed from 17,496 genomic loci. We discovered novel isoforms such as a read-through transcript from the TOMM40-APOE locus, known as the Alzheimer's disease locus (Figure 1B). Further, we identified disease-associated isoforms by remapping short-read RNA-seq datasets from

SLE[7], RA[8] individuals and relevant controls to the Immune Isoform Atlas (isoform switch analysis). For SLE, we identified 84 genes whose isoform fractions were significantly switched between SLE and healthy individuals (false discovery rate < 0.05). For example, the expression of the known isoform of IRAK1 (ENST 00000393687.6) with a protein kinase domain

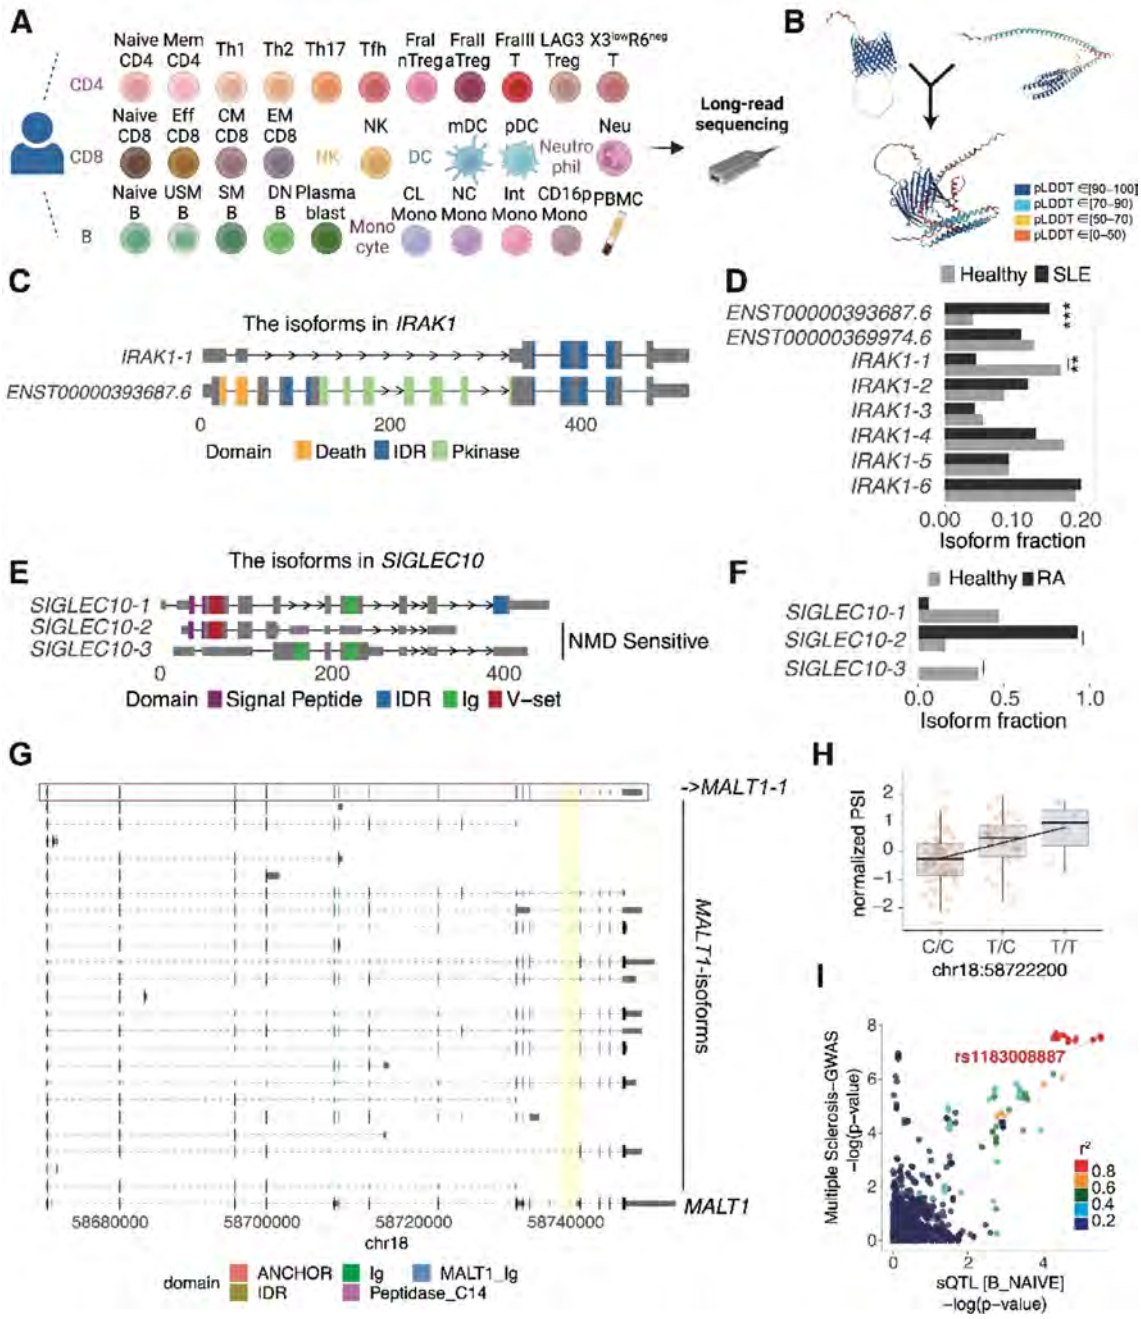

Figure 1. Overview of the Immune Isoform Atlas. (A) Summary of the cell subsets included in long-read RNA sequencing in our study. (B) Protein 3D structures of TOMM40 (left), APOE (right), and the read-though isoform (bottom) predicted using AlphaFold2. pLDDT is a per-residue estimate of its confidence on a scale from 0 - 100. Regions with pLDDT > 90, between 70 and 90, between 50 and 70, and < 50 are expected to be high accuracy, well (a generally good backbone prediction), low confidence, and a reasonably strong predictor of disorder, respectively. (C) Structures of isoforms transcribed from the IRAK1 locus. The x-axis shows distance from the TSS. (D) Isoform fractions in IRAK1 in SLE and healthy individuals. The significance of comparison is as follows: ***, p<0.001; **, p<0.01; *, p<0.05. (E) Structures of isoforms transcribed from the SIGLEC10 locus. (F) Isoform fractions in SIGLEC10 in RA and healthy individuals. (G) Structures of isoforms transcribed from MALT1. The collapsed gene structure registered in GENCODE is shown at the bottom. (H) sQTL plot of normalized PSI of the unique junction (chr18:58739121-58741865, highlighted in yellow in Figure 1G) in the related isoform (MALT1-1, highlighted in red in Figure 1G) in naïve B cells. (I) Colocalization plot of sQTL and GWAS of multiple sclerosis.

increased in SLE individuals compared to controls, while the novel IRAK1-1 without this domain decreased (Figure 1C-D). As to RA, we found that one of the novel isoforms in SIGLEC10 being sensitive to nonsense-mediated mRNA decay was more highly expressed in RA compared to controls (Figure 1E-F). Finally, to investigate disease-causal isoforms, we evaluated the colocalization between loci identified by Genome-Wide Association Studies (GWAS) for autoimmune diseases and splicing quantitative trait loci (sQTL) signals using coloc[9]. Among them, an SNP in MALT1 (rs11873030), which was associated with multiple sclerosis[10], had an sQTL effect for a junction read unique to MALT1-1; this isoform decreased with the risk allele for the disease (Figure 1G-I).

Conclusion: Our atlas, obtained by long-read RNA sequencing of 29 immune cell subsets, provided a comprehensive full-length isoform profiling in the human primary immune cells. Our atlas will help reveal unknown pathogenic mechanisms via alternative splicing.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Genetics, Genomics & Proteomics

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease with currently no effective prevention strategies. Single-cell technologies have been used to investigate established RA heterogeneity (1), but it is unknown if the immune populations identified from RA tissues play important roles in blood during the preclinical phase of disease. Thus, identifying pathogenic immune phenotypes in individuals who are at risk for future RA, designated "At-Risk RA", is crucial to establishing prevention strategies.

Methods: We applied mass cytometry to deeply characterize immunophenotypes in PBMCs (peripheral blood mononuclear cells) from At-Risk individuals based on the presence of antibodies to citrullinated protein antigens (ACPA) and/or first-degree relative (FDR) status (n=52), established RA (n=67), and healthy controls (n=48) (Figure 1). We performed co-varying neighborhood analysis to characterize immunophenotypes in At-Risk individuals and identify phenotypical changes between At-Risk subpopulations accounting for batch effect, age, sex, and inter-individual variation. We further developed an "RA immunophenotype score" for cross-phenotype classification using mixed-effect modeling and logistic regression.

Results: We quantified the immune populations and uncovered significant cell expansions in At-Risk individuals compared with controls (p = 6e-3), including CCR2+CD4+ effector memory T cells (TEM) (OR = 1.47), T peripheral helper cells (Tph) (OR = 1.30), type 1 T helper cells (OR = 1.31), and CXCR5+CD8+ T cells (OR = 3.33) (Figure 2A-B). We further confirmed the expansions of these T cell phenotypes in the At-Risk individuals using our validation cohort with 57 At-Risk and 23 healthy individuals. In addition, we found that CD15+ classical monocytes were especially expanded in ACPA-negative At-Risk individuals who had FDR (p = 1e-3, OR = 1.30), and an activated PAX5low naïve B cell population expanded in ACPA-positive individuals who also had an FDR with RA (p = 9e-3, OR = 1.35). Further, we demonstrated that our "RA immunophenotype score" classification method built based on the degree of enrichment and the abundance of cell states relative to established RA (adjusted p < 0.05) (Figure 3A) is able to significantly distinguish At-Risk individuals from the control (p = 0.039, AUC >0.6) (Figure 3B-C).

Conclusion: We systematically characterized altered circulating immune phenotypes in At-Risk individuals, along with immunophenotypical differences among ACPA+ and FDR At-Risk subpopulations. Our classification model may provide a promising approach for understanding the pathogenesis of preclinical RA with the goal to develop preventive strategies and novel therapeutic targets.

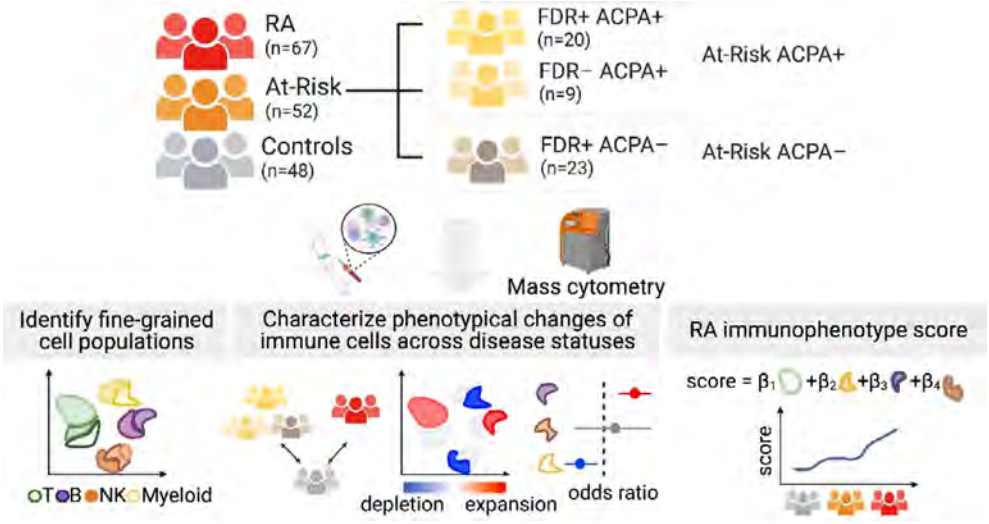

Fig.1: Overview of mass cytometry analytical strategy, clustering, and classifications for At-Risk RA and established RA individuals.

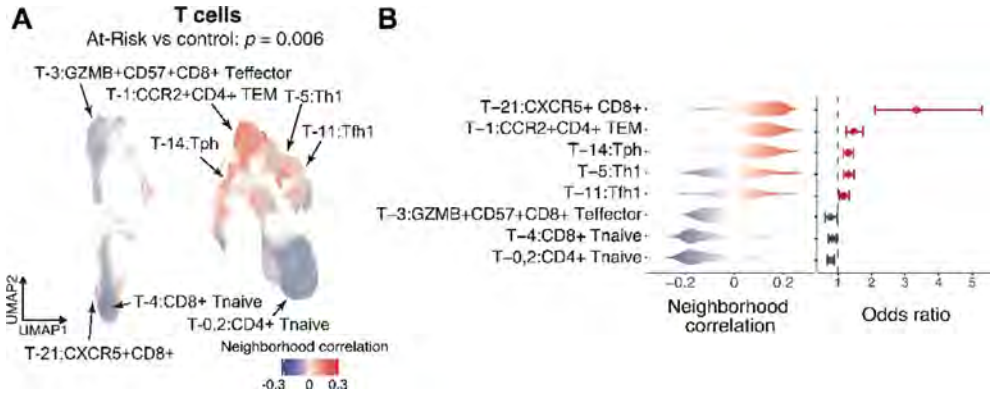

Fig.2: Identifications of specific T cell populations that were associated with At-Risk. A. Cells in UMAP are colored in red (expansion) or blue (depletion) and p-value is shown as well. B. Distributions of cell neighborhood correlations and odds ratio. Error bars represent 95% confidence intervals.

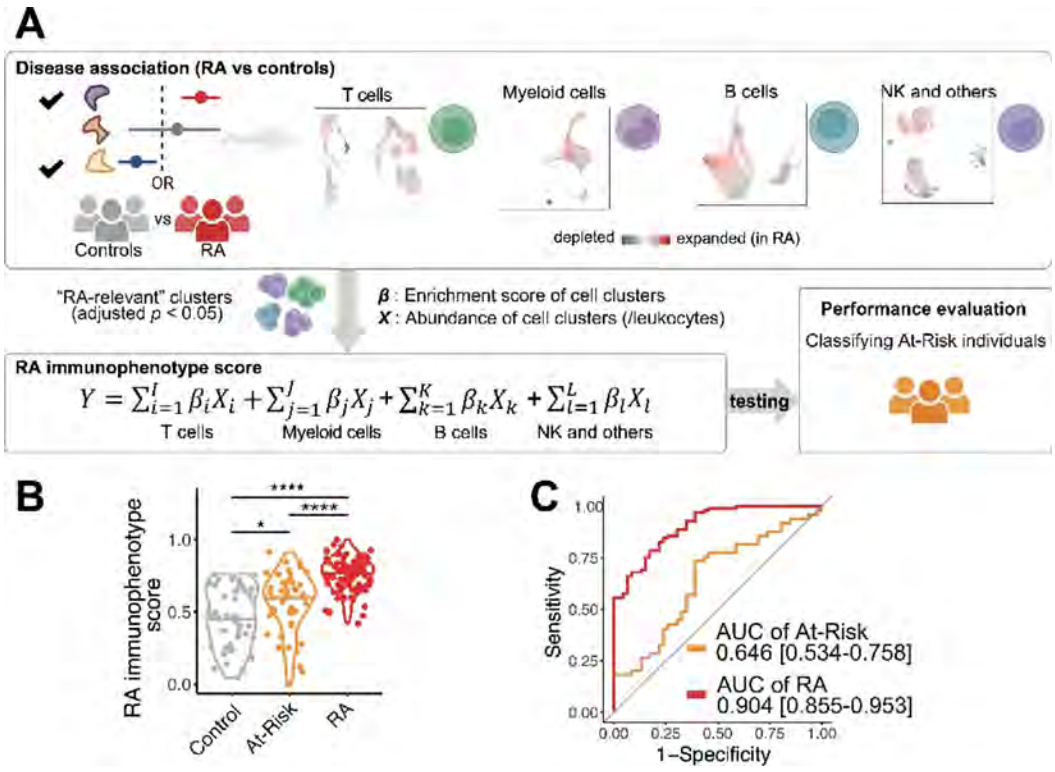

Fig.3: Classifications for At-Risk individuals and established RA individuals. A. RA immunophenotype score utilizing RA-specific cell type abundances to quantify and distinguish At-Risk individuals from control. For each cell type, all p-values from the covarying neighborhood analysis test were p = 1e-3. We incorporated clusters that are significantly associated with RA (adjusted $p < 0.05$) to model the RA immunophenotype score. We calculated RA immunophenotype score based on cell type abundances multiplied by corresponding major cell type proportions and enrichment scores for each cell type, B. Distribution of RA immunophenotype score across individual samples from RA, At-Risk, and controls; **** $p < 0.0001$, * $p < 0.05$, C. Receiver operating characteristic (ROC) analysis to evaluate the classification performance of RA immunophenotype score in distinguishing At-Risk from control. Areas under the curve (AUC) with 95% confidence intervals were described. All the analyses are adjusted for age and sex.

Deciphering Complement System-dependent Cellular Pathways in Human Rheumatoid Arthritis Synovial Tissue Using Large Single-cell Computational Omics

Juan Vargas[1], Ian Mantel[2], Nirmal Banda[1], Anna Helena Jonsson[3], Kevin Wei[4], Deepak Rao[3], Susan Goodman[5], kevin Deane[1], Jennifer Seifert[1], Jennifer Anolik[6], Michael Brenner[4], Soumya Raychaudhuri[3], Accelerating Medicines Partnership (AMP) RA/SLE Network[7], Michael Holer[1], Laura Donlin[5] and **Fan Zhang**[8], [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]Weill Cornell Medicine, New York, NY, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [5]Hospital for Special Surgery, New York, NY, [6]University of Rochester Medical Center, Rochester, NY, [7]the Accelerating Medicines Partnership (AMP) RA/SLE Network, Boston, MA, [8]University of Colorado, Aurora, CO

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Genetics, Genomics & Proteomics

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: The complement system is a major component of innate immunity and plays a vital role in autoimmune disease pathogenesis. In patients with rheumatoid arthritis (RA), complement activation proteins generated in the synovium can interact with macrophages and other cell types. However, it remains to be determined how complement components directly modulate cell-type functions in the RA synovium to influence phagocytosis and inflammation resolution.

Methods: We have classified the spectrum of RA biopsies into six tissue phenotypes called CTAPs (Cell Type Abundance Phenotypes) using a comprehensive synovial single-cell multimodal atlas (>314,000 cells, 28 treatment naïve, 27 Methotrexate and 15 TNF inadequate responders) generated from the AMP RA/SLE (1). In this current study, we linked single-cell transcriptomics of complement activation pathway components and receptors with cell-type heterogeneity and tested significant associations with different tissue phenotypes using unsupervised clustering and network analysis. Next, we characterized myeloid cell differentiation using single-cell trajectory analysis and aligned complement gene expression to myeloid functional states. Furthermore, we utilized cell-type interactome analysis to explore whether complement-dependent receptor-ligand pairs are likely to contribute to tissue pathology.

Results: We generated a complement cellular graph characterizing interactions between complement components and cell-type patterns in RA synovium. The complement components present unexpected distinct transcriptomic expression across cell types (**Figure 1A**). We next systematically captured the relationship between tissue phenotypes with specific complement gene expression (**Figure 1B**). Within myeloid cells, we identified a myeloid cell differentiation axis revealing that functional macrophage modules align with complement pathways; in particular, complement *FCN1* and *CFP* co-vary with the *IL1B*+ pro-inflammatory macrophages (p < 2e-16; R=0.48), while complement *C1QA-C* and *C3AR1* co-vary with the *MERTK*+ phagocytic macrophages (p < 2e-16; R=0.7) (**Figure 2**). Intriguingly, we revealed that the abundance of complement-dependent receptor-ligand (C3AR1-C3 and C5AR2-C5) are correlated across patients (**Figure 3A**), and interactome analysis further suggests a potential interaction between the *C3AR1* highly expressed *MERTK*+ macrophages and *C3* highly expressed sublining fibroblasts in a particular RA synovial phenotype that relatively lacks lymphocytes (**Figure 3B**).

Conclusion: Through systematically aligning complement pathways with synovial heterogeneity, we generated a graph describing how complement components can modulate functional cells, especially macrophage phenotypes, in stratified RA patients. This approach of analyzing high-resolution single-cell data in human synovium brings insights into complement pathway-based targets and mechanisms to evaluate in patients with RA, and provides a roadmap for other complex pathways in tissues.

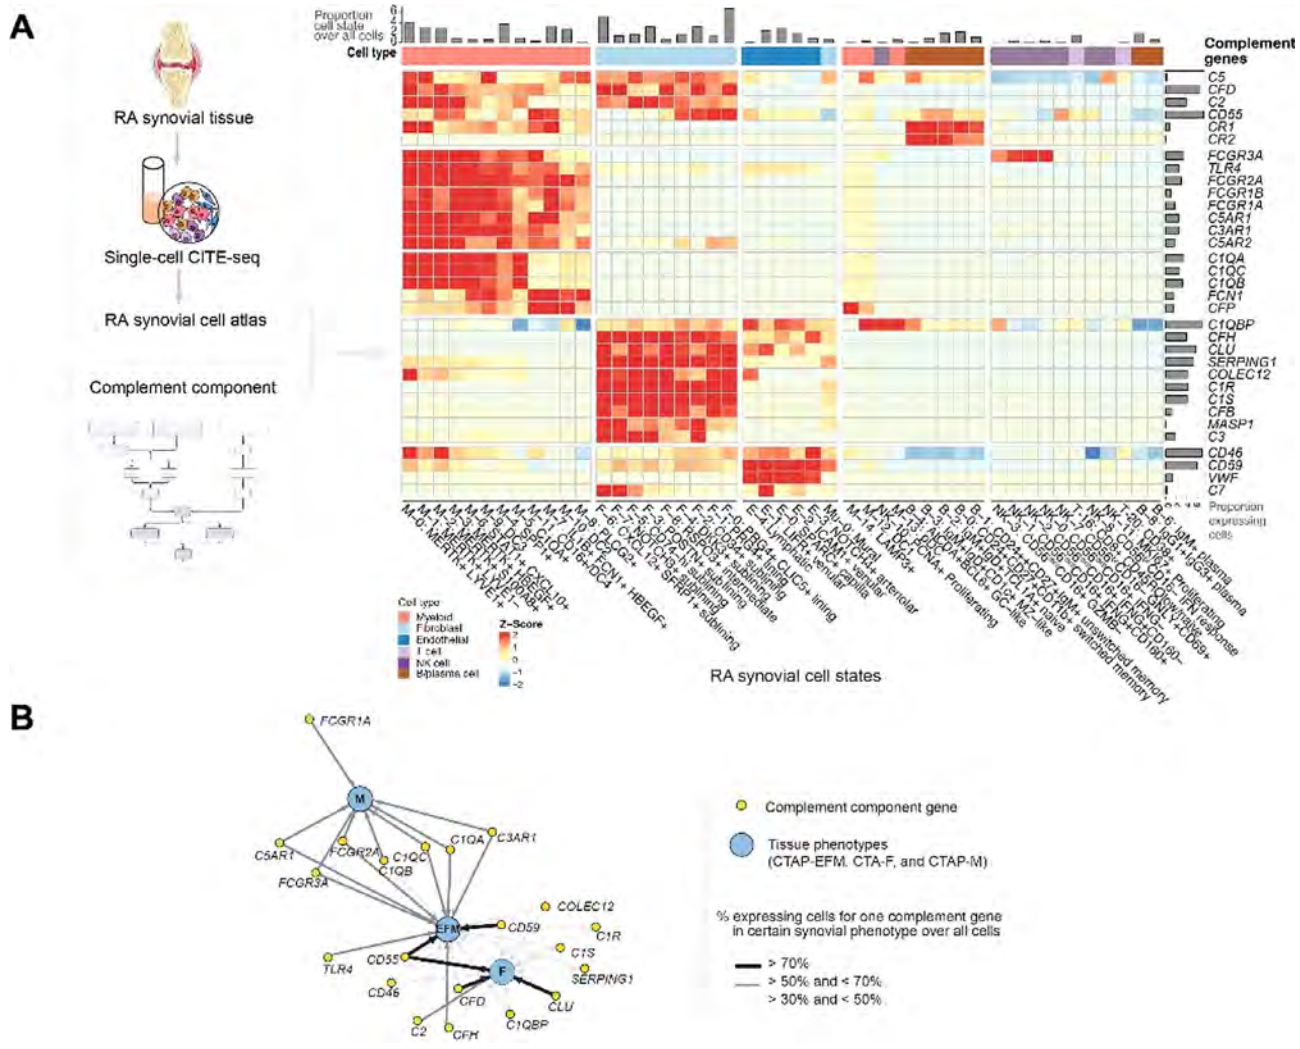

Fig. 1. Single-cell expression distributions of complement components across cell types in rheumatoid arthritis synovial tissues (A). Different myeloid, fibroblast and endothelial cell states express different complement components. Relationship between complement components and RA synovial tissue phenotypes (B).

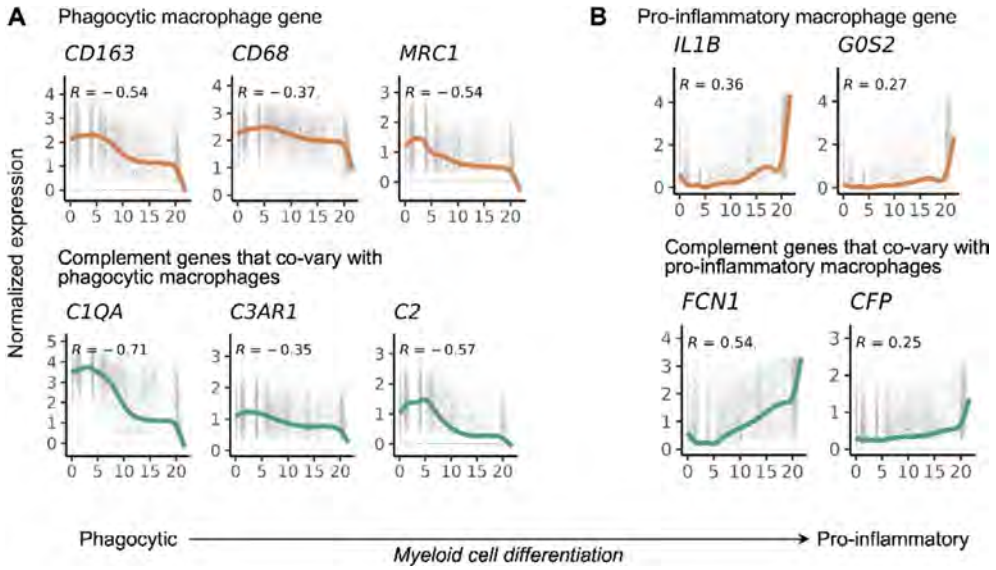

Fig. 2. Myeloid-specific single-cell trajectory analysis revealed a myeloid cell differentiation trajectory from phagocytic to pro-inflammatory lineage. Complement components C1QA-B, C3AR1, and C2 expressions correlated with anti-inflammatory/phagocytic functions (A); complement components FCN1 and CFP expressions correlated with pro-inflammatory function (B). Spearman correlation R and p-value are shown.

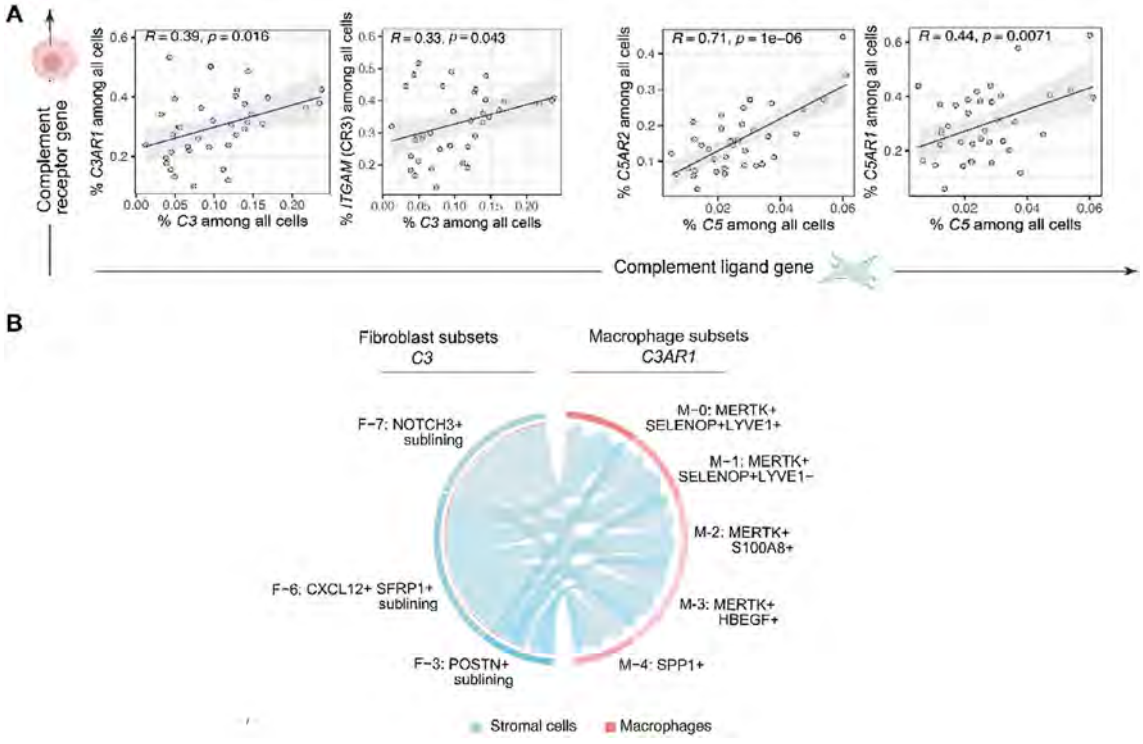

Fig. 3. Across cell type analyses revealed complement-development receptor-ligand correlations (A) and potential complement pathway-dependent C3+ sublininig fibroblasts and MERTK+ tissue macrophages interacting patterns in stratified RA tissues (B). Spearman correlation and p-value are shown.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Genetics, Genomics & Proteomics

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: VEXAS syndrome is an adult-onset, X-linked, life-threatening, autoinflammatory and hematological disease caused by somatic mutation in *UBA1* gene. To understand its pathophysiology, we aimed to achieve a molecular and phenotypic characterization of hematopoiesis of VEXAS patients and to develop cellular and humanized mouse models by gene editing.

Methods: Six VEXAS patients (p.Met41 >Thr; p.Met41 >Val; p.Met41 >Leu; c.118-1 G >C) were recruited from our Unit. Variant allele frequency (VAF) of *UBA1* mutant cells was quantified by targeted sequencing in isolated hematopoietic lineages and hematopoietic stem/progenitor cells (HSPCs). Multiparametric immunophenotypic analysis was performed on peripheral blood and bone marrow (BM), focusing on HSPCs. Circulating monocytes were analyzed by whole RNA-seq and metabolome analysis. Healthy age and sex-matched controls were included. To introduce UBA1 mutations and develop VEXAS models, cutting-edge gene editing technologies were adopted in healthy human HSPCs.

Results: Targeted sequencing in VEXAS patients showed >0.8 VAF in HSPCs. Conversely, VAF largely differed across mature cells, averaging 0.81 in neutrophils, 0.64 in monocytes, 0.42 in NK, 0.07 in T cells, and 0.09 in B cells, supporting a myeloid skewing of mutant HSPCs. Multiparametric immunophenotypic analyses showed unbalanced composition of HSPCs in the BM, with 2-to-3-fold reduction of primitive stem cells, multipotent and lymphoid progenitors, and 2-fold increase of myeloid progenitors, compared to matched healthy individuals. HSPCs, myeloid-biased HSPCs and immature myeloid cells were increased by 3-to-4 fold in the circulation ($p< 0.03$). Gene expression analysis of circulating monocytes

displayed upregulation of inflammatory pathways and metabolic rewiring (Fig. 1, panels A-B). Metabolomic analyses confirmed hyperactivation of the glycolytic pathway and specific lipid metabolism (Fig. 1, C-D). Models of VEXAS generated by gene editing recapitulated patients' hematopoiesis and pathophysiology *in vitro* and *in vivo*. UBA1 mutations were installed at VAF >0.9 in HSPCs and generated a myeloid bias *in vitro*. Transplantation of edited HSPCs in immunodeficient mice resulted in a 100-fold reduction in circulating B cells, while NK and myeloid compartments were preserved. Human BM HSPCs were 5-fold lower than control mice, largely myeloid-biased and presented abnormal vacuolar morphology. Concordantly, VAF was >0.8 in myeloid cells and HSPCs and < 0.3 in B cells.

Figure 1

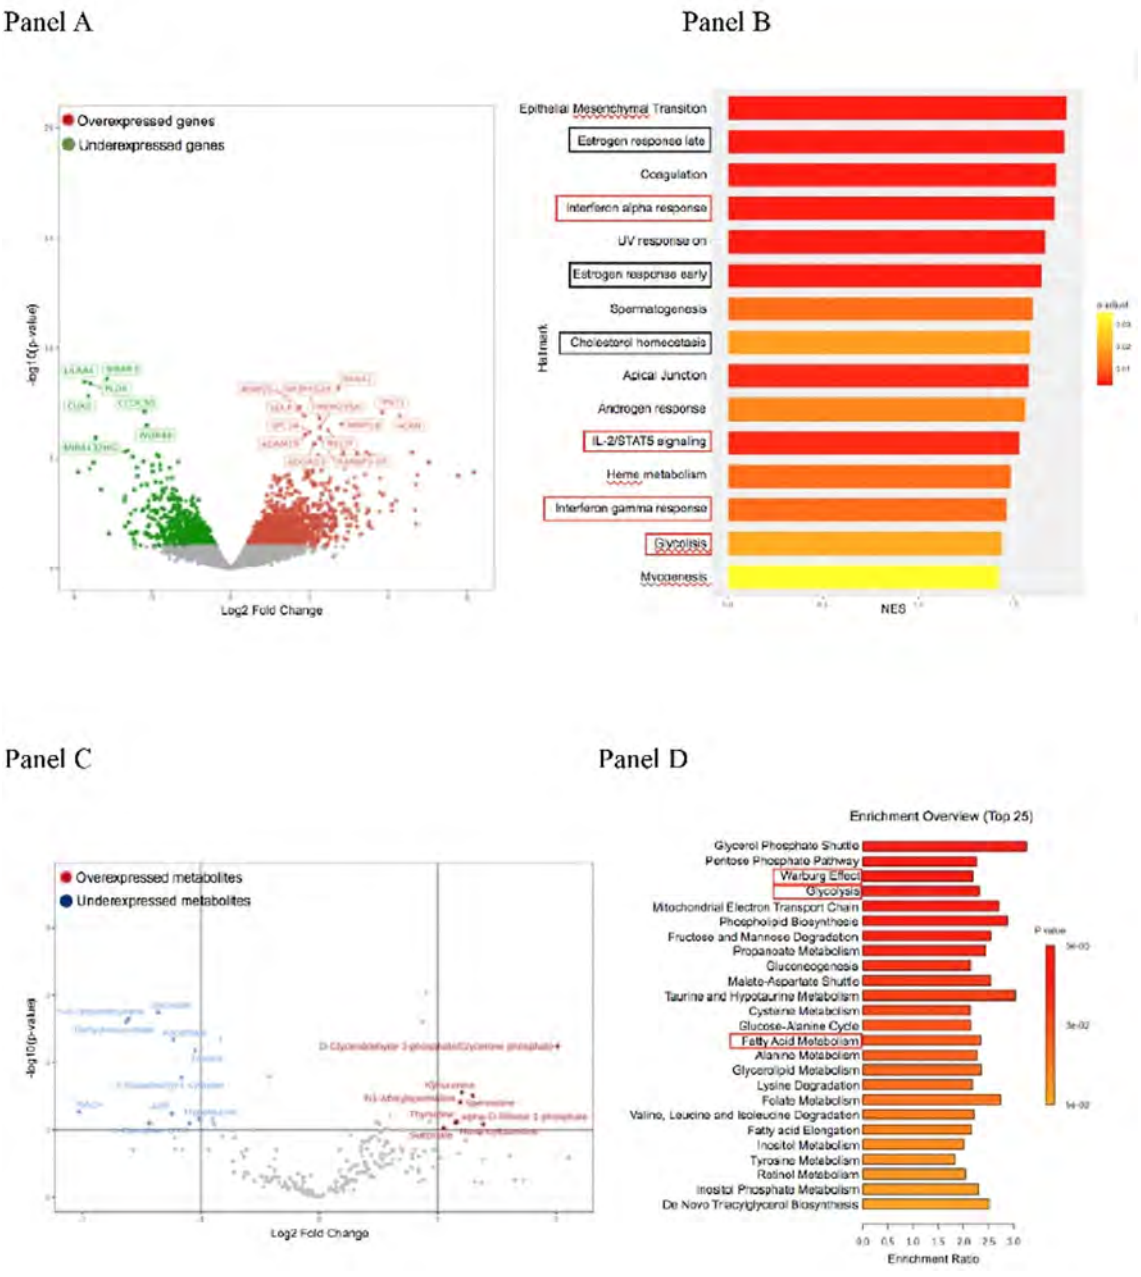

Figure 1. Panel A. Gene expression analysis of peripheral monocytes in VEXAS patients compared to controls. Panel B. Gene-enrichmed pathway analysis in VEXAS patients compared to controls. Panel C. Metabolic analysis in VEXAS patients compared to controls. Panel D. Metabolic-enriched pathway analysis in VEXAS patients compared to controls.

Conclusion: Mutations in UBA1 drive expansion of HSPCs and enhance myelopoiesis-guided accumulation of myeloid precursors. Mutant lymphoid cells are negatively selected and their myeloid counterpart in peripheral blood displays upregulation of transcriptomic signatures and metabolic pathways indicative of inflammatory activation. Gene editing-based models hold promise to enable preclinical testing and validation of novel therapeutics to treat VEXAS syndrome.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Genetics, Genomics & Proteomics

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Primary antiphospholipid syndrome (PAPS) is a rare autoimmune disease characterized by the presence of antiphospholipid antibodies and the occurrence of thrombotic events and pregnancy complications. Although the etiology of PAPS is incompletely understood, previous studies have suggested a role for genetic susceptibility in this disease. The goal of our study was to identify novel susceptibility loci associated with PAPS by performing a large genome-wide association study across five different populations of European ancestry.

Methods: A total of 482 patients with PAPS and 5,006 controls from five independent populations were included. Genotyping was performed using the Illumina Infinium ImmunoArray, Global Screening Array, and the Infinium Human Core platforms. PLINK software was used for quality control and association analyses adjusting for population structure. Genotype imputation was performed in each independent cohort using the TOPMed Imputation Server and the TOPMed version R2

as reference panel. Summary statistics from each population were meta-analyzed and further *in silico* functional analyses were performed. A weighted polygenic risk score was calculated and compared between populations. Hierarchical clustering and Mahalanobis distance analyses were used to assess genetic similarities between PAPS and other immune-mediated diseases.

Results: The meta-analysis of 7 million variants revealed two significant loci (p-value< $5x10^{-8}$) and 43 suggestive loci (p-value< $1x10^{-5}$) associated with PAPS. Significant signals are located near *STAT4* (rs11889341, OR [95% CI]=0.61 [0.52-0.71], p-value=$1.39x10^{-9}$) and *HLA-DRA* (rs9269041, OR [95% CI]=0.63 [0.54-0.74], p-value=$2.07x10^{-8}$). Biological process enrichment analysis revealed association of PAPS susceptibility loci with pathways related to the nervous system (p-value=$1.91x10^{-5}$) and the immune response (p-value=$3.39x10^{-3}$). Our data suggest a higher genetic risk for PAPS in East Asian compared to European populations. Genetic similarity analysis showed that PAPS is genetically most closely related to neuromyelitis optica, systemic sclerosis, and Sjögren's syndrome.

Conclusion: Our results provide new insights into the genetic basis of PAPS across multiple populations. Genetic similarities of PAPS with other immune-mediated diseases characterized by neurological and vascular involvement might provide additional insights into the etiology and pathogenesis of antiphospholipid syndrome.

Major Adverse Cardiovascular Event and Venous Thromboembolism Risk Comparing Advanced Therapies Among Individuals with Axial Spondylarthritis and Psoriatic Arthritis

Sali Merjanah[1], Devin Driscoll[2], Christine Peloquin[3], Jean liew[3] and Maureen Dubreuil[4], [1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, [2]Boston University/Boston Medical Center, Boston, MA, [3]Boston University, Boston, MA, [4]Department of Rheumatology, Boston University School of Medicine, Milton, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Epidemiology & Public Health I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Individuals with axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) have increased cardiovascular risk compared to the general population, which is partly explained by systemic inflammation. While emerging evidence suggests tumor necrosis factor inhibitors (TNFi) may be cardioprotective, there are safety concerns for Janus kinase inhibitors (JAKibs) in regard to major adverse cardiovascular events (MACE) and venous thromboembolism (VTE). We aimed to assess the risk of MACE and VTE in axSpA and PsA comparing users of JAKibs versus TNFi.

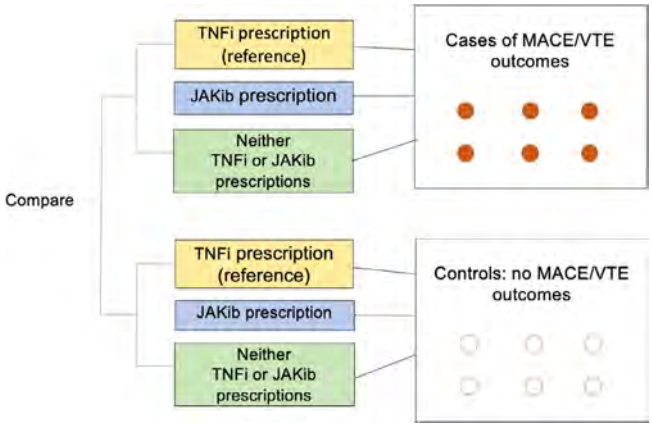

Figure 1. Study design for nested case-control study with cases and controls identified by outcome status and 3-level medication exposure status assessed in 6 months prior to outcome (index date).

Table 1. Baseline demographics and clinical characteristics of study subjects for each case-control sample stratified by MACE and VTE outcomes.

	MACE outcomes		VTE outcomes	
	Cases N=1065	Controls N=4260	Cases N=1554	Controls N=6216
Age (mean, years)	55.5	55.1	52.9	52.8
Female (%)	47.2	47.2	53.3	53.3
Obesity (%)	47.3	36.2	53.9	35.8
Tobacco Use (%)	20.8	10.1	16.9	10.2
Chronic kidney disease (%)	19.0	6.9	15.8	6.3
Cardiovascular disease history* (%)	52.5	20.9	60.5	18.7
Diabetes (%)	37.3	23.1	31.0	21.2
Hypertension (%)	78.7	59.0	73.2	55.7
Hyperlipidemia (%)	67.0	59.5	62.2	54.5
Malignancy$^{\Delta}$ (%)	8.1	5.3	12.2	4.6
Antihypertensives/Antianginal meds (%)	60.5	45.2	55.0	42.4
Anti-arrhythmic meds (%)	3.0	1.2	2.4	1.0
Aspirin/Antiplatelets/Anticoagulants (%)	19.2	6.9	39.8	5.5
Lipid lowering meds (%)	38.2	31.9	32.1	28.9
Oral DMARDs# (%)	30.4	33.1	36.9	33.5
Glucocorticoids (%)	42.2	31.7	50.1	32.8
Non-TNF Biologics+ (%)	14.8	12.5	13.6	13.9
NSAIDs (%)	38.9	39.7	37.3	40.9

* Includes history of atrial fibrillation/flutter, heart failure and non-ischemic heart disease, cerebrovascular accident/TIA, ischemic heart disease, peripheral vascular disease or acute myocardial infarction, venous thromboembolism

$^{\Delta}$ Includes breast, colorectal, endometrial, lung, prostate and urologic (kidney, renal pelvis and ureter) cancers; and leukemias/lymphomas

Includes apremilast, auranofin, azathioprine, chloroquine, cyclophosphamide, cyclosporine, hydroxychloroquine, leflunomide, methotrexate, mycophenolate, sulfasalazine and thiomalate

+ Includes abatacept, Tocilizumab, sarilumab, ustekinumab, guselkumab, Risankizumab, secukinumab, ixekizumab, rituximab, rilonacept, canakinumab and anakinra.

Table 2. Association of each drug treatment category with major cardiovascular event and venous thromboembolism outcomes, among individuals with axial spondyloarthritis and psoriatic arthritis

Medication use	Cases, N		Controls, N		Crude Odds Ratio (95% CI)		*Adjusted Odds Ratio (95% CI)	
	MACE	VTE	MACE	VTE	MACE	VTE	MACE	VTE
TNFi (ref)	273	452	1348	2055	ref	ref	ref	ref
JAKib	8	26	39	70	1.01 (0.46-2.20)	1.71 (1.07-2.72)	0.86 (0.37-1.99)	1.39 (0.79-2.44)
Non-users	784	1076	2873	4091	1.36 (1.16-1.58)	1.20 (1.06-1.36)	1.27 (1.08-1.50)	1.12 (0.96-1.29)

*Adjusted for age, cardiovascular disease history, diabetes, hypertension, hyperlipidemia, use of aspirin, antiplatelets, and/or anticoagulants, obesity and tobacco use

Abbreviations: TNFi: tumor-necrosis alpha inhibitors; etanercept, adalimumab, golimumab, certolizumab and infliximab. JAKib: Janus kinase inhibitors; tofacitinib, upadacitinib, baricitinib and abrocitinib

Methods: We conducted two nested case-control studies (**Figure 1**) using 2006-2021 data from the MarketScan Commercial Claims and Encounters (Merative) Database, which includes de-identified, patient-specific data of reimbursed healthcare claims. We included adults aged 18-65 years with ≥1 inpatient or 2 outpatient axSpA or PsA ICD-9/-10 diagnosis codes separated by ≥7 days.

For the first case control study, MACE was defined as the first inpatient claim for myocardial infarction or stroke/transient ischemic attack; for the second case control study, VTE was defined using the first inpatient/outpatient claim. The index date was the date of the MACE or VTE outcome among cases; or matching the case's outcome date among controls. Cases and controls were matched 1:4 by age, gender and axSpA/PsA diagnosis date using risk-set sampling. We evaluated drug exposure (TNFi or JAKib use or neither) using pharmacy claims and CPT codes within 6 months prior to the index date.

We assessed the association of drug exposure (referent: TNFi use) with the outcomes of MACE and VTE in separate models, using conditional logistic regression with adjustment for potential confounders (age, cardiovascular disease history, comorbidities, and tobacco use) to calculate odds ratios (OR) and 95% confidence intervals (CI).

Results: We identified 1065 MACE cases among 5325 adults with AxSpA or PSA and 1554 VTE cases among 7770 axSpA/PsA subjects. Demographics and clinical characteristics are shown in **Table 1**. Comorbidities including cardiovascular disease history, obesity, diabetes and hypertension were more commonly seen in cases versus controls.

In the MACE nested case control study, 47 (0.9%) were JAKib users, 1621 (30.4%) were TNFi users and 3657 (68.7%) were non-users of JAKib and TNFi. In the VTE sample, 96 (1.2%) were JAKib users, 2507 (32.3%) were TNFi users and 5167 (66.5%) were non-users.

Non-users of TNFi and JAKibs had 1.3 times the odds of MACE relative to TNFi users (95% CI 1.08-1.50; **Table 2**). In JAKib users versus TNFi users, the odds of MACE was not increased (OR 0.86, 95% CI 0.37-1.99). The odds ratio for VTE was 1.39 among JAKib users however, this was not statistically significant after confounder adjustment (95% CI 0.79-2.44).

Conclusion: Using a large US insurance claims database, we did not find a statistically significant association between JAKib use and risk of MACE or VTE, compared with TNFi use among individuals with axSpA and PsA, although there was a trend toward increased VTE events among JAKib users. The accrual of further data is needed to better study the comparative safety of JAKibs versus TNFi in this study population.

Renal Arteriosclerosis in Index Lupus Nephritis Biopsies Predicts Future Cardiovascular Disease

Shivani Garg[1], Brad Astor[2], S. Sam Lim[3], Amish Raval[2], Weixiong Zhong[2], Sarah Panzer[2], Brad Rovin[4] and Christie M. Bartels[2], [1]Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]University of Wisconsin, School of Medicine and Public Health, Madison, WI, [3]Emory University, Atlanta, GA, [4]Ohio State University, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Epidemiology & Public Health I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Patients < 40 years old with lupus nephritis (LN) face 42-fold higher risk of cardiovascular disease (CVD) compared to peers. Traditional CVD risk calculators fail to accurately predict future CVD risk in young LN patients, making decisions to prescribe empiric CVD prevention wrought with uncertainty. While a kidney biopsy is routinely performed to diagnose LN, renal arteriosclerosis (ASCL) is not routinely reported. Renal arteriosclerosis (ASCL) in kidney biopsies at LN diagnosis might represent changes in systemic arteries and could guide CVD risk stratification when most probably don't take this into account. Thus, in this study we systematically graded renal arteriosclerosis in kidney biopsies at LN diagnosis and examined its role as an early predictor of future incident CVD events.

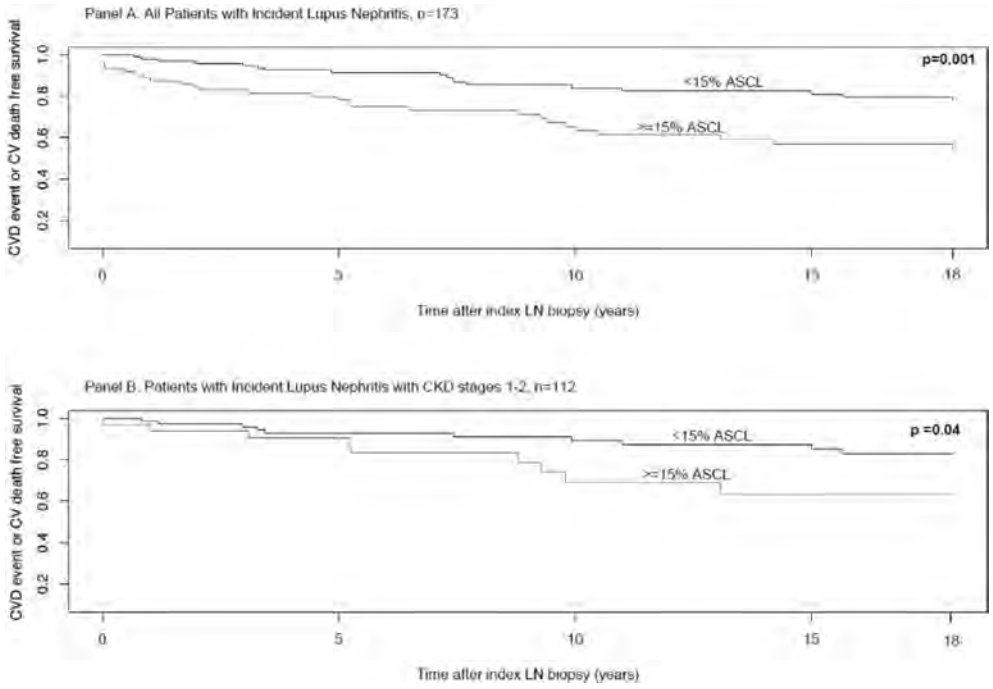

Figure 1. Survival curves showing CVD event or CVD related death free survival over 18-year follow-up period by 15% or more luminal narrowing of renal arteries (ASCL) in diagnostic LN biopsies in all patients with LN (Panel A.) and in patients with LN with preserved kidney function defined as CKD stages 1-2 (Panel B)

Methods: Data were abstracted from adult LN patients who underwent diagnostic kidney biopsy between 1994-2021, including socio-demographics, traditional CVD risk factors, and pathology reports. Incident CVD-related deaths and non-fatal CVD events (ischemic heart disease, cerebrovascular accident, transient ischemic attack, and peripheral vascular disease) were adjudicated using published guidelines. Index standard of care kidney biopsies performed to diagnose LN were re-read by a pathologist to grade renal arteriosclerosis (ASCL) by calculating percent luminal narrowing of renal arteries using

Bold font indicates that better predictive values and specificity of renal ASCL and combined risk factors vs. traditional CVD risk factors. CVD=Cardiovascular Disease; PPV=Positive Predictive Value; NPV=Negative Predictive Value; ASCL=Arteriosclerosis; HTN=Hypertension; CKD=Chronic Kidney Disease

the Banff criteria. We examined the role of renal ASCL in diagnostic LN biopsies as an early predictor of future CVD using a Cox proportional hazards model in: a) all LN patients; b) those with preserved kidney function defined as chronic kidney disease stages 1-2.

Results: Among 173 adult patients with incident LN, 75% were female and 35% were of Black race or Hispanic ethnicity, and mean age at diagnosis was 38±17 years. Mean eGFR was 79±38 ml/min/1.73m^2; 65% of patients had preserved kidney function. We noted 47% and 32% of patients had renal ASCL ≥15% and 25%.

A total of 45 CVD-related deaths and events were observed during up to 18 years of follow-up after LN diagnosis. Mild renal ASCL changes (15% and 25% luminal narrowing) were associated with 2-3-fold higher risk of future CVD (Adjusted HR 2.2 & HR 2.8; Table 1A). The Cox proportional hazard model highlighted accelerated CVD events in patients with renal ASCL ≥15% compared to those without renal ASCL (Fig. 1A). Renal ASCL had higher specificity compared to traditional CV risk factors (Table 2A).

In those with persevered kidney function (n=112), mild renal ASCL predicted 2-fold higher risk of CVD (Adjusted HR 2.2 & HR 2.4; Table 1B). Again, patients with renal ASCL had accelerated CVD events even in this low-risk group (Fig. 1B). Renal ASCL was an early independent risk factor of future CVD with higher specificity than traditional CV risk factors in this low-risk group (Table 2B).

Conclusion: Renal arteriosclerosis found in kidney biopsy at LN diagnosis was a strong, early, and independent risk factor for future CVD events, outperforming traditional CVD risk factors. This observation held consistent even in LN patients with preserved kidney function. This suggests systematic grading of renal ASCL in LN biopsies may help to identify patients who could benefit from aggressive CVD prevention.

Abstract Number: 0741

Adverse Events Among Patients with and Without Autoimmune Rheumatic Disease Prescribed SGLT2 Inhibitors

Emily G. Oakes[1], Jack Ellrodt[1], May Choi[2], Jeong Yee[1], Hongshu Guan[1] and Karen Costenbader[3], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Calgary, Calgary, AB, Canada, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Epidemiology & Public Health I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Sodium glucose cotransporter 2 inhibitors (SGLT2i) are oral hypoglycemic agents for Type II diabetes mellitus (T2D) now prescribed for renal and cardiovascular indications. Patients with autoimmune rheumatic diseases (ARD) have been excluded from SGLT2i clinical trials due to theoretical increased infection risk in the immunosuppressed. We compared adverse events associated with SGLT2i prescription in patients with vs. without ARD.

Methods: Using a large data repository, we identified patients with ≥2 ICD10 diagnostic codes for ARD who were prescribed dapagliflozin, canagliflozin, or empagliflozin from 1/1/2016 to 12/10/2021. Each ARD patient was matched by age, sex, and race to a patient without ARD prescribed the same SGLT2i. Baseline demographic and clinical data, prescription dates, and adverse events were collected from electronic health records for all subjects and compared in univariable analyses. Multivariable Cox models, adjusting for clinical and demographic variables, calculated hazard ratios (HR) for adverse events, following from prescription date (index) and censoring at 1st adverse event, discontinuation/last day prescription, death, or study period end. Models were then stratified by sex.

Table 1. Baseline Characteristics of Patients with and without Autoimmune Rheumatic Disease at Date of SGLT2 Prescription in the Mass General Brigham Healthcare System, 2016-2021

Results: We matched 519 patients with ARD to 519 patients without ARD prescribed SGLT2i: 466 and 427 in the two groups started the prescription and were studied **(Table 1)**. The two groups were comparable (mean age 64 years; 61% female), except for past smoking, more common in patients with ARD. Empagliflozin accounted for 78% of prescriptions and T2D was the most common indication (86%). Mean hemoglobin A1c in T2D patients at index date was comparable between groups (8.08 vs 8.10 mg/dL)**.** We identified 12 categories of adverse events and reasons for discontinuation **(Table 2)**. Yeast infections (9.9% vs 6.1%; p 0.04) and muscular symptoms (e.g., myalgias and weakness; 3.4% vs 0.9%, p 0.01) were more frequent in ARD patients. Other adverse event categories were numerically more common in ARD patients. ARD patients also had significantly shorter SGLT2i use duration (8.7 vs 12.6 months; p< 0.0001) and time to adverse event (0.62 vs 0.96 years; p< 0.0001). We found a significant increased risk in adverse events in those with ARDs (HR 1.74 [95% CI 1.33, 2.29]), persisting upon adjustment for glucocorticoid and DMARD use (HR 1.80 [95%CI 1.34, 2.40]). Kaplan Meier curves showed separation of event-free survival over time (all log-rank p < 0.001; **Figure 1**). Significantly more adverse events occurred among females than males (p< 0.00001). Adverse event risk was also higher in women with ARD vs without ARD, even upon adjustment for glucocorticoid and immunosuppressant use (HR 2.05 [95% CI 1.47, 2.85]).

Conclusion: This observational study identified significant increased adverse event risk in patients with vs. without ARDs using SGLT2i. Both ARD and non-ARD female patients were more likely to have adverse events than males, with female ARD patients most affected. To our knowledge, this is the first study to consider SGLT2i adverse events in ARD vs. non-ARD patients. Further rigorous testing of safety and efficacy of SGLT2i among patients with ARDs is warranted.

Table 2. Adverse Events Following SGLT2i Usage in Patients with and matched Patients without Autoimmune Rheumatic Disease (ARD) in the Mass General Brigham Healthcare system, 2016-2021

Abstract Number: 0742

Risk of Incident Gout Associated with Initiation of Sodium-glucose cotransporter-2 Inhibitors versus Other Second-line Agents Among Metformin Users with Type 2 Diabetes

Natalie McCormick[1], Chio Yokose[2], Na Lu[3] and Hyon K. Choi[4], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Waltham, MA, [3]Arthritis Research Canada, Vancouver, BC, Canada, [4]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Epidemiology & Public Health I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) are a revolutionary second-line treatment for type 2 diabetes associated with lower risk of cardiovascular and all-cause mortality, heart failure, and chronic kidney disease progression. Many trials have also found SGLT2i lower serum urate levels. However, data on gout risk are limited and the few available prior studies were not specific to those using metformin, the primary target populations of recent landmark trials like GRADE [GRADE Study Research Group, NEJM 2022;387:1075-88].

Our objective was to emulate recent clinical trials and compare incident gout risk among metformin-treated patients with type 2 diabetes initiating SGLT2i versus other second-line type 2 diabetes treatments (dipeptidyl peptidase 4 inhibitors [DPP-4i], glucagon-like peptide-1 receptor agonists [GLP1-RA], or sulfonylureas).

Methods: We performed a new user, active comparator, population-based cohort study using administrative health data for nearly all residents of British Columbia, Canada from Jan 2014 to June 2022, including all dispensed prescriptions, regardless of funder. A cohort of adults with type 2 diabetes using metformin (first-line therapy) was identified from ICD codes and dispensing data. Primary outcome was incident gout, defined as inpatient or outpatient diagnosis of gout plus dispensing of a gout medication (colchicine, corticosteroids, or NSAIDs) within 7 days, and no prior recorded gout diagnosis. We also stratified by sex, age, and baseline diuretic use.

Cox proportional hazards models were used with propensity score overlap weighting, stratified by calendar year of initiation. We also assessed for risk of genital infection (for which we expected SGLT2i would have a positive association), and for the risk of any osteoarthritis encounter, a negative control outcome for which we expected a null association.

Results: We included 27,791 type 2 diabetes patients in the SGLT2i vs. DPP-4i cohort (58% male, mean age 61), 19,875in the SGLT2i vs. GLP1-RA cohort (44% male, mean age 57), and 71,625in the SGLT2i vs. sulfonylurea cohort (60% male, mean age 59).Baseline characteristics, including diabetes duration and presence of complications, were well balanced between SGLT2i and comparators after overlap weighting (SMD < 0.1) (**Table 1**).Weighted hazard ratio (wHR) for incident gout associated with SGLT2i initiation was 0.54 (95% CI: 0.39, 0.74) vs. DPP-4i initiation, 0.39 (0.24, 0.62) for SGLT2i

vs. GLP1-RA, and 0.61 (0.46, 0.80) for SGLT2i vs. sulfonylureas (**Table 2**).Results were consistent regardless of sex or age or baseline diuretic use.

For control outcomes, SGLT2i initiators had higher risk of genital infection than initiators of each comparator, as expected, while there was no difference in risk of osteoarthritis (**Table 2**).

Table 1. Selected baseline characteristics among metformin-treated type 2 diabetes patients initiating SGLT2i vs. DPP-4i, GLP1-RA, or sulfonylureas, before and after propensity score overlap weighting. * difference < 0.1 indicates negligible differences. n, number; y, years; SD, standard deviation; SGLT2i, sodium glucose cotransporter-2 inhibitors; DPP-4i, dipeptidyl peptidase 4 inhibitors; GLP1-RA, glucagon-like peptide-1 receptor agonists.

Control Outcomes	**Weighted Hazard Ratio (95% CI)**		
Genital infection (POSITIVE CONTROL)	2.35 (1.85, 2.99)	3.50 (2.43, 5.04)	1.69 (1.46, 1.95)
Osteoarthritis (NEGATIVE CONTROL)	1.06 (0.86, 1.30)	0.91 (0.65, 1.27)	1.12 (0.95, 1.30)

SGLT2i, sodium glucose cotransporter-2 inhibitor; DPP-4i, dipeptidyl peptidase 4 inhibitor; GLP1-RA, glucagon-like peptide-1 receptor agonist

Conclusion: SGLT2i initiation among metformin-treated patients with type 2 diabetes was associated with substantially lower risk of incident gout (i.e., primary prevention), compared with any other second-line option. Along with its known urate-lowering effects, as well as cardiovascular and survival benefits, SGLT2i could substantially reduce risk of incident gout for patients needing a second-line agent after metformin.

Risk and Temporal Trends of Heart Failure Subtypes in Rheumatoid Arthritis: A National Veterans Affairs Matched Cohort Study

Tate Johnson[1], Yangyuna Yang[1], Punyasha Roul[1], Joshua Baker[2], Brian Sauer[3], Grant Cannon[4], Ted R Mikuls[5] and Bryant England[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pennsylvania, Philadelphia, PA, [3]Salt Lake City VA/University of Utah, Salt Lake City, UT, [4]University of Utah and Salt Lake City VA, Salt Lake City, UT, [5]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Epidemiology & Public Health I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: There has been limited study of the risk of heart failure (HF) subtypes in RA at a population level, given the requirement for left ventricular ejection fraction (LVEF) from unstructured echocardiographic data to define HF with preserved (HFpEF) or reduced (HFrEF) ejection fraction. As the underlying pathophysiology differs, understanding the burden of HF subtypes in RA and whether advances in RA management have impacted their development is critical. Thus, we examined the risk and temporal trends of HFrEF and HFpEF in RA, leveraging LVEF values derived from natural language processing (NLP) in national Veteran's Health Administration (VA) data.

Methods: We conducted a retrospective, matched cohort study of RA patients (≥2 RA ICD codes, rheumatologist diagnosis, and positive autoantibody or DMARD fill) matched up to 10 comparators (no RA ICD codes) on age, sex, and VA enrollment year. Patients with prevalent HF (≥1 ICD code prior to index) were excluded. Incident HF events were defined as a primary hospital discharge diagnosis or HF-related death, linking VA, Medicare, and National Death Index data. Echocardiogram-derived LVEF values were extracted from clinical notes using a validated NLP tool. HFrEF (EF < 50%)

Table 1. Risk of HF subtypes in RA compared to matched non-RA controls in the Veteran's Health Administration

Table 1. Risk of HF subtypes in RA compared to matched non-RA controls in the Veteran's Health Administration

	RA (N=67,850)		Non-RA (N=570,933)

*Estimated using Cox regression, stratified by case-control pairs matched on age, sex, and calendar year of enrollment into the VA. Multivariable models further adjusted for race/ethnicity, body mass index, smoking status, comorbidity burden as assessed by the Rheumatic Disease Comorbidity Index, and healthcare utilization as assessed by the number of hospitalizations in the year prior to index.

Abbreviations: CI, confidence interval; HF, heart failure; HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction; IR, incidence rate; PY, person years; RA, rheumatoid arthritis;

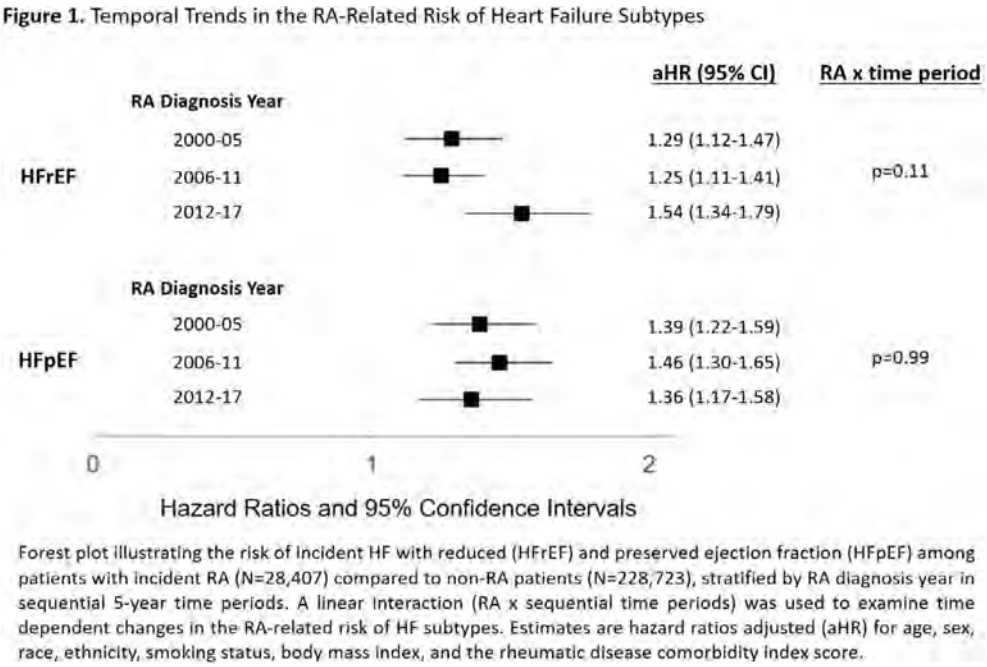

Figure 1. Temporal Trends in the RA-related Risk of Heart Failure Subtypes

and HFpEF (EF ≥50%) were defined using the most proximate LVEF within 1 year prior to a HF event, or if missing, < 30 days following the event. We examined the association of RA with incident HFrEF and HFpEF separately in multivariable Cox regression models, stratified on matched pairs and censoring patients if they developed HF with no available LVEF, the alternative HF subtype, death, or reached end of study period (01/2020). Models were adjusted for demographics, smoking status, BMI, comorbidity burden, and healthcare utilization (number of hospitalizations in the year prior to index). Temporal trends were evaluated in an incident RA subcohort (no RA diagnostic codes or medication for >365 days following VA enrollment) by testing the interaction of RA status and sequential time periods in a linear manner, then stratifying analyses on RA diagnosis year (2000-2005, 2006-2011, 2012-2017).

Results: We matched 67,850 RA patients (mean 62 years, 87% male) to 570,933 patients without RA. Over a mean follow up of 8.9 years (5,663,152 person-years), we observed 5,983 incident HF events in RA (10.9 per 1000 PY) vs. 40,283 events in non-RA (7.9 per 1000 PY) **(Table 1)**. LVEF values were identified in 82% of RA vs. 68% of non-RA patients who developed incident HF. After multivariable adjustment, RA patients were at an increased risk of HFpEF (adjusted HR [aHR] 1.58, 95% CI 1.49-1.68) and HFrEF (aHR 1.40, 1.33-1.48). Among the incident RA subcohort (N=28,407 RA; 228,723 non-RA), we observed no improvement in the RA-related risk of HFpEF (range aHR 1.36-1.46) or HFrEF (range aHR 1.25-1.54) over time **(Figure 1).**

Conclusion: In this large, matched cohort study, patients with RA experienced a 58% increased risk of HFpEF compared to a 40% increased risk of HFrEF. No significant change was observed in the RA-related risk of either HF subtype over time. These findings suggest that RA-related HF risk persists despite major RA treatment advances and highlights the need to elucidate the factors contributing to the ongoing heightened risk of HF in RA.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Epidemiology & Public Health I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Cardiovascular disease (CVD) risk is elevated in patients with SLE but underestimated by current general population prediction algorithms that do not include SLE-related variables. We aimed to develop a novel SLE-specific prediction tool, SLECRISK, to estimate CVD risk more accurately in SLE.

Methods: We studied patients in the Brigham and Women's Hospital SLE cohort. We collected 1-year baseline data on traditional CVD risk factors, demographic and SLE-related clinical features from the electronic medical records at cohort enrollment. Ten-year follow-up for 1stmajor adverse cardiovascular event (MACE, non-fatal myocardial infarction [MI], non-fatal stroke, and cardiac death) began at day +1 after baseline period (index date). ICD-9/10 codes identified MACE, adjudicated by medical record review by board-certified cardiologists. Least absolute shrinkage and selection operator (LASSO) regression selected SLE-related variables to add to the American College of Cardiology (ACC)/American Heart Association (AHA) Pooled Cohort Risk Equations 10-year risk Cox regression model. Model fit statistics and performance for predicting moderate- and high-risk (≥10%) of MACE were assessed and compared to ACC/AHA alone, Framingham risk score (FRS), and modified FRS (FRS multiplied by 2, mFRS). Optimism adjustment was performed using bootstrapping with 300 samples.

Results: We included 1,243 patients with 90 MACEs (46 MIs, 36 strokes, 19 cardiac deaths) over 8,946.5 person-years follow-up (**Table 1**).

Our best **SLECRISK 10-Year CVD Risk equation** was: 1-0.92*exp(βx-1.84), whereby βx = 5.44*Base ACC/AHA Risk Score + 0.31*disease activity (remission/mild vs. moderate/severe) + 0.04*disease duration (years) + 0.17*Creatinine (mg/dL) + 0.35*Anti-dsDNA + 0.22*Anti-RNP + 0.47*Lupus anticoagulant + 0.31*Anti-Ro + 0.49*low C4.

Sensitivity for detecting moderate/high-risk (≥10%) of MACE (0.64) and c-statistic for model discrimination (0.76) were improved vs. traditional models (**Table 2**). The AIC estimate of model fit improved (1190.5 to 1162.2) and Hosmer-Lemeshow goodness-of-fit tests yielded favorable results (P 0.02 in base ACC/AHA model and P 0.77 in SLECRISK), indicating good model calibration. SLECRISK identified >3-fold more high-risk patients, particularly more young women with few traditional risk factors, but more severe SLE, including lupus nephritis, higher creatinine, more autoantibodies, including antiphospholipid antibodies, hypocomplementemia, and more taking azathioprine (**Fig 1**).

Conclusion: We derived and internally validated a novel SLE-specific CVD risk tool based on the ACC/AHA score and SLE-related factors. SLECRISK was more sensitive and accurate than the traditional CVD generic tools for predicting moderate- and high-risk for MACE over 10 years of follow-up. If externally validated, SLECRISK may be incorporated into SLE management guidelines to help guide decision-making in the primary prevention of CVD in clinical practice.

Table 1. Baseline demographic, cardiovascular, and clinical features among 1,243 patients with SLE in the Brigham and Women's Hospital Lupus Cohort with vs. without Major Adverse Cardiovascular Event (MACE)[1] in follow-up, according to Definite (Adjudicated[2]) and Probable MACE definitions.

	CVD Event (n=90)	No CVD Event (n=1153)

Artificial Intelligence Models for Computer-Assisted Joint Detection and Sharp-van Der Heijde Score Prediction in Hand Radiographs from Patients with Rheumatoid Arthritis

Carol Hitchon[1], Saqib Al Islam[1], Daryl LX Fung[1], Qian Liu[1], Leann Lac[1], Susan Bartlett[2], Louis Bessette[3], Gilles Boire[4], Vivian Bykerk[5], Glen Hazlewood[6], Edward Keystone[7], Janet Pope[8], Orit Schieir[9], Carter Thorne[10], Diane Tin[11], Marie-France Valois[12], Désirée van der Heijde[13], Canadian Early Arthritis Cohort (CATCH) Investigators[14], Liam O'Neil[1] and Pingzhao Hu[15], [1]University of Manitoba, Winnipeg, MB, Canada, [2]McGill University, Montreal, QC, Canada, [3]Centre de l'Ostéoporose et de Rhumatologie de Québec, Quebec City, QC, Canada, [4]Université de Sherbrooke, Sherbrooke, QC, Canada, [5]Hospital for Special Surgery, New York, NY, [6]University of Calgary, Calgary, AB, Canada, [7]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [8]University of Western Ontario, London, ON, Canada, [9]McGill University, Montréal, QC, Canada, [10]Southlake Regional Health Centre, Newmarket, ON, Canada, [11]The Arthritis Program Research Group, Newmarket, ON, Canada, [12]McGill University, Pointe-Claire, QC, Canada, [13]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [14]CATCH, Winnipeg, MB, Canada, [15]Western University, London, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Imaging of Rheumatic Diseases

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Radiographs are used to detect and monitor joint damage due to rheumatoid arthritis (RA).Scoring methods such as the Sharp van der Heijde tool (SVH) quantify joint space narrowing (JSN) and erosions. Obtaining SVH scores is time-consuming and requires expertise not always available. We aimed to develop and validate a deep learning system for automated detection and prediction of SVH scores in hand radiographs of patients with RA**.**

Methods: We used a convolutional neural network (CNN) based algorithm (You Only Look Once (YOLO)v5l6) trained on an object detection model (COCO-Common Objects in Context) to detect joints in 240 training and 89 test pediatric hand radiographs from the Radiologic Society of North America database. Radiographs were annotated by boxing and labeling the joints of interest: proximal interphalangeal, metacarpophalangeal, wrist, distal radius, distal ulna. Images were augmented using mix-up (mixing features of different images into one), mosaic (combining 4 training images into 1 image), rotation, translation, scaling, and shearing. The joint detection model was validated with 54 clinician-annotated radiographs from 4 adult RA patients followed for 9-13 years (10-12 images per patient) (joint detection gold standard). We applied a supervised vision transformer model (VTM) to predict each joint's SVH erosion and JSN score. The VTM was validated using 2249 hand radiographs with clinician-assigned SVH scores from 381 RA patients from the Canadian Early Arthritis Cohort

Table: Accuracy of model for joint detection

	RSNA radiographs pre-trained on COCO						
	Images	Number targets	F1 score	Mean precision	Mean recall	map0.1	map
All	89	1157	0.991	0.998	0.983	0.993	0.854
PIP	89	445	0.994	1	0.987	0.994	0.772
MCP	89	445	0.991	0.993	0.989	0.994	0.624
Wrist	89	89	0.993	1	0.986	0.994	0.958
Radius	89	89	0.998	1	0.976	0.994	0.983
Ulna	89	89	0.987	0.997	0.978	0.988	0.933
	Adult Rheumatoid Arthritis radiographs pre-trained on COCO						
All	54	1354	0.812	0.923	0.725	0.871	0.627
PIP	54	518	0.880	0.893	0.869	0.823	0.615
MCP	54	521	0.860	0.939	0.794	0.814	0.601
Wrist	54	102	0.883	0.965	0.814	0.886	0.876
Radius	54	109	0.821	0.909	0.750	0.828	0.661

(SVH score gold standard). We applied techniques used to train highly class-imbalanced datasets including weighted sampling, stratified data-split, data augmentation and transfer learning (TL). As the joint detection model was trained to detect the whole wrist and we had clinician-assigned SVH scores for individual wrist joints, we trained a separate multi-task model to predict wrist joint scores from whole wrist images. The performance of the VTM to predict joint scores was compared to CNN-based EfficientNetV2 and MobileNetV3. Model accuracy for joint detection is reported as the F1-score (reflecting model precision and model recall) and mean absolute precision (mAP) for a range of Intersection-over-Union (IoU) measures

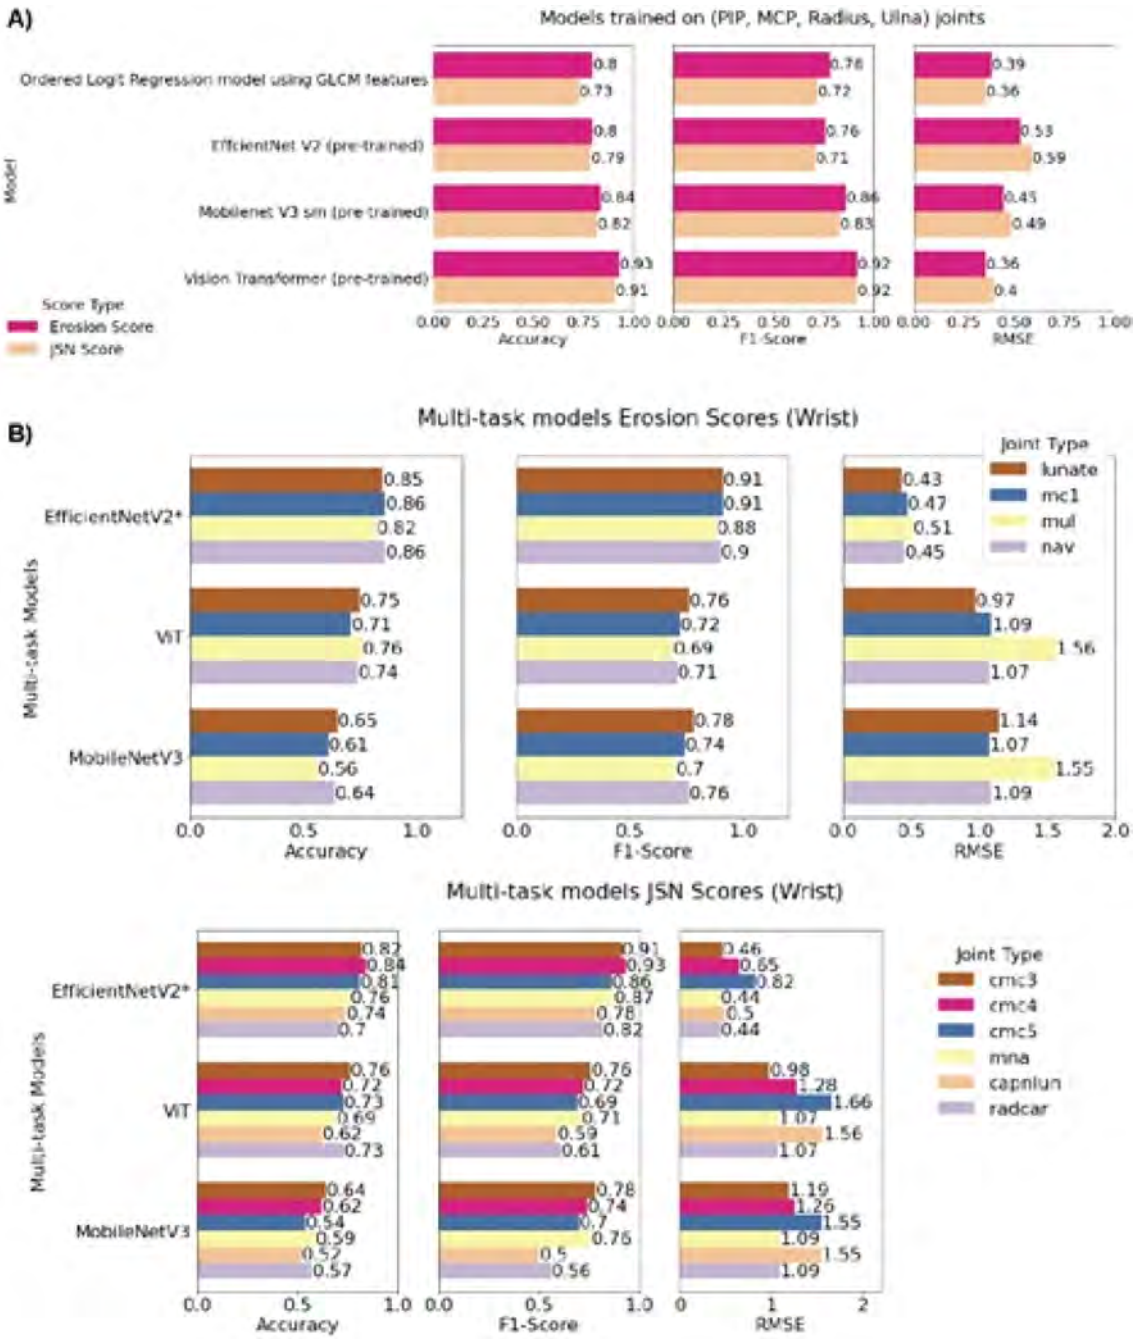

Figure: Joint damage score prediction models. A) Models trained on all joints except wrist. The metrics reported were balanced accuracy, F1-Score and Root Mean Square Error (RMSE) predicting Joint Space Narrowing (JSN) and Erosion scores. B) Models were trained on wrist joints. Separate models trained to detect the erosion score and JSN scores. PIP=proximal interphalangeal, MCP=metacarpophalangeal, JSN= joint space narrowing, Vit= Vision Transformer, mc = metacarpal, nav = navicular, cmc = carpometacarpal

reflecting the overlap between clinician and model assigned bounding boxes of detected joints. Accuracy for SVH score prediction is reported as root mean squared error (RMSE) and balanced accuracy.

Results: The joint detection model accurately identified target joints (pediatric data FI-score = 0.991, map0.1 = 0.993 with an IoU threshold of 0.1 ; adult data F1-score = 0.812, map0.1 = 0.871 (n=54) (Table 1). Applying TL improved the joint detection model's mean precision by 0.05 over the COCO model. The VTM predicted JSN and erosion SVH scores with high accuracy (RMSE JSN 0.91, erosion 0.93). The multi-task models predicted SVH erosion and JSN scores of wrist joints with moderately high accuracy (0.6-0.91). EfficientNetV3 performed better for wrist joints (VTM vs EfficientNetV3 average difference 0.10) (Figure 1).

Conclusion: Automated deep learning systems accurately identify and predict joint damage in hand radiographs from patients with rheumatoid arthritis and may aid in monitoring joint damage.

The Association Between Sonographic Imaging Phenotype and Response to Treatment in Patients with Psoriatic Arthritis

Jessica Gutierrez Manjarrez[1], Sydney Thib[2], Richard J. Cook[3] and Lihi Eder[4], [1]Women's College Research Institute / Department of Medicine, University of Toronto, Toronto, ON, Canada, [2]Women's College Research Institute, Toronto, ON, Canada, [3]Department of Statistics and Actuarial Science, University of Waterloo, Waterloo, ON, Canada, [4]Women's College Research Institute, Division of Rheumatology, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Imaging of Rheumatic Diseases
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Ultrasound (US) may improve characterization of psoriatic arthritis (PsA) phenotypes and help predict disease outcomes. We aimed to assess whether US phenotypes are associated with clinical features and treatment outcomes in patients with active PsA.

Methods: We conducted a prospective cohort study of patients with active PsA prior to initiation of systemic therapy. Disease activity in various PsA domains was clinically assessed.

Baseline US assessment of inflammatory and structural lesions was conducted for the following features: synovitis, peritenonitis, tenosynovitis, new bone formation (NBF), bone erosion, and enthesitis for inflammatory (inflm) and structural (str) lesions. The following treatment outcomes were analyzed: drug persistence, Disease Activity in PsA (DAPSA) change, and DAPSA low disease activity (LDA) at 3-6 months.

**Models are adjusted for medication class (targeted DMARD vs. conventional DMARD) and prior exposure to tDMARDs*
CI – confidence intervals; NBF- new bone formation; PTI- peritenon inflammation
Ultrasound scores are standardized.

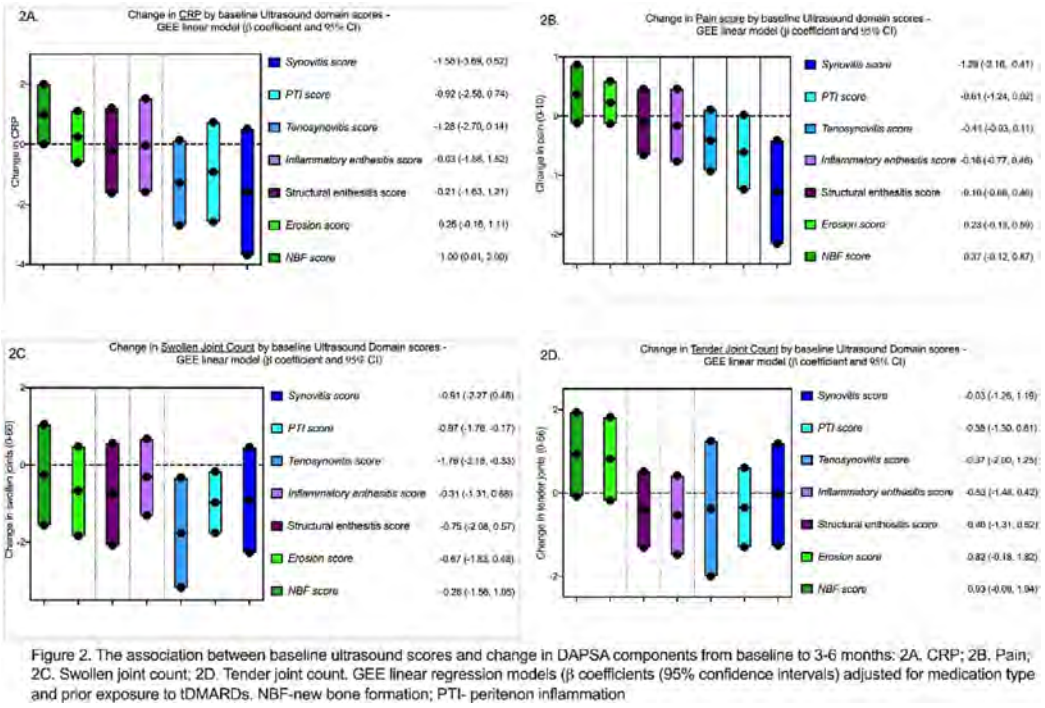

Figure 2. The association between baseline ultrasound scores and change in DAPSA components from baseline to 3-6 months: 2A. CRP; 2B. Pain; 2C. Swollen joint count; 2D. Tender joint count. GEE linear regression models (β coefficients (95% confidence intervals) adjusted for medication type and prior exposure to tDMARDs. NBF-new bone formation; PTI- peritenon inflammation

Figure 2 - The association between baseline ultrasound scores and change in DAPSA components from baseline to 3-6 months: 2A. CRP; 2B. Pain; 2C. Swollen joint count; 2D. Tender joint count. GEE linear models adjusted for medication type and exposure to tDMARDs

The correlation between various baseline clinical and US features was assessed (r >0.3 was considered moderate correlation). The association between baseline US features and treatment outcomes were assessed using Cox proportional hazards models (for drug persistence), linear models via GEE (for DAPSA change) and logistic GEE models (for DAPSA-LDA). Models were adjusted for type of drug (targeted (t) vs. conventional DMARDs) and prior exposure to tDMARDs.

Results: A total of 135 treatment periods (107 patients) with PsA (49% females) were analyzed. The mean age and disease duration were 47.7 (SD=13.7) and 4.7 (SD=6.8) years, respectively.

Highest correlations were found for US synovitis and peritonitis with physician global assessment (PhyGA) and swollen joints (Figure 1). PhyGA correlation with other US features was low. Synovitis and peritenonitis US scores correlated moderately with CRP and tender joints. Tenosynovitis and enthesitis-inflm showed moderate correlation with swollen joints and enthesitis score, respectively.

Drug persistence was analyzed in 105 treatment periods (40% drug discontinuation). The only US feature associated with drug discontinuation was US erosion score (adjusted Hazards Ratio 1.28, 95% confidence interval 1.03, 1.61).

87 treatment periods were analyzed for DAPSA response at 3-6 months (54% achieved DAPSA-LDA). No association was found between any US feature and DAPSA-LDA. Greater reduction in DAPSA scores was associated with higher baseline synovitis, peritenonitis and enthesitis-str scores (Table 1). Restriction of the analysis to users of TNFi (N=41) resulted in numerically higher effect sizes for several US features.

A multivariable analysis was performed to assess which components of DAPSA are influenced by US features (Figure 2). We found significant associations between US synovitis and reduction in pain (b= -1.28), US NBF and increase in CRP (b= 1.00), US tenosynovitis (b= -1.76) and peritenonitis (b= -0.97) and reduction in swollen joint count. None of the US features were associated with changes in tender joint count.

Conclusion: Discordance between imaging and clinical features of PsA exists. Sonographic synovitis, peritenonitis and tenosynovitis correlate more strongly with clinical features of disease activity and response outcomes.

Clinical Phenotype of Patients with Subclinical Giant Cell Arteritis in Polymyalgia Rheumatica

Sharon Cowley[1], Colm Kirby[2], Patricia Harkins[3], Richard Conway[4] and David Kane[5], [1]Tallaght University Hospital, Dublin, Dublin, Ireland, [2]Tallaght University Hospital, Dublin, Ireland, [3]St James's Hospital, Dublin, Ireland, [4]Trinity College Dublin, Dublin, Ireland, [5]Tallaght University Hospital & Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Imaging of Rheumatic Diseases
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: It has been reported that more than a quarter of patients with polymyalgia rheumatica (PMR) have subclinical giant cell arteritis (GCA). It remains unclear if all PMR patients should have ultrasound assessment for subclinical GCA or if there are certain phenotypes of patients that are more at risk of having subclinical GCA.

Methods: Newly diagnosed PMR patients who met a clinical diagnosis for PMR, verified by two rheumatologists were examined with vascular ultrasound (US) of their temporal and axillary arteries. US of all 6 branches of the superficial temporal and both axillary arteries was performed using a GE P9 device. Sonographic abnormalities considered indicative of vasculitis in the temporal arteries included the halo sign and non-compressible arteries with a thickened intima-media complex. An intima-media thickness of 0.42mm for the common superficial temporal branch, 0.34mm for the frontal branch, and 0.29mm for the parietal branch was considered positive. In the axillary arteries, a halo sign, and an intima-media thickness of >1.0mm was considered positive. Clinical and laboratory characteristics were recorded. Halo scores were calculated for positive cases. Ultrasound findings were compared to a cohort of GCA patients.

Results: 91 patients with newly diagnosed PMR and 57 patients with newly diagnosed GCA were included. ACR/EULAR classification criteria were met in 67 of those with PMR (primarily due to prior corticosteroid use in primary care resulting in normal ESR/CRP) and all of those with GCA. Of the 91 patients with PMR, 16 were identified as having subclinical GCA on ultrasound (17.5%).

	PMR (75)	PMR with subclinical GCA (16)	GCA (47)
Age (mean and range)	69 (51-89)	70 (53-84)	74 (56-92)
Female	48	4	24
Male	27	12	33
Mean BMI	28.2	28.1	27.8
Mean ESR at baseline	38mm/hr	49mm/hr	58mm/hr
Mean CRP at baseline	29mg/l	39.9mg/l	66mg/l
Mean halo count	0	4.33	4.36
Mean temporal artery halo score	0	4.68	13.17
Mean axillary artery halo score	0	9.75	13.28

Figure 1: Results

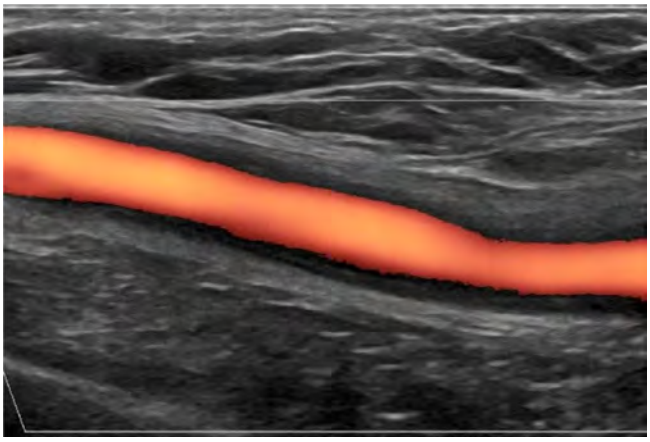

Figure 2: Axillary artery with halo sign

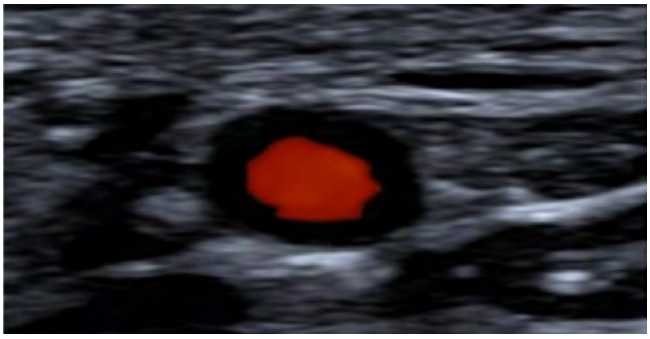

Figure 3: Temporal artery with halo sign

The mean age at time of diagnosis was 69 years for those with PMR, 70 years for those with subclinical GCA in PMR and 74 years for those with GCA. Males were more likely to have subclinical GCA in PMR, accounting for 12 (75%) of the subclinical GCA group compared to 27 (36%) of the pure PMR group (p=0.045). The mean ESR at baseline for those with subclinical GCA in PMR was higher than those with isolated PMR; 49mm/hr compared to 38mm/hr (p=0.18).

The extent of involvement of the temporal and axillary arteries of the 16 patients in the subclinical GCA group was compared to a cohort of 57 GCA patients. The total halo count was similar for both subclinical GCA in PMR and classic GCA patients at 4.33 and 4.36 respectively. However, GCA patients had higher halo scores in both temporal and axillary vessels of 13.17 and 13.28 respectively, compared to those with subclinical GCA with halo scores of 4.68 and 9.75. This suggests that patients with subclinical GCA in PMR have less vessel wall oedema than those with GCA. The subclinical GCA group had higher halo scores in the axillary arteries versus the temporal arteries, (p=0.0074) suggesting a predilection for the axillary vessels.

Conclusion: Patients with subclinical GCA had higher halo scores in the axillary arteries compared to the temporal arteries suggesting an extracranial phenotype. Male gender and a higher ESR at the time of PMR diagnosis appear to be risk markers for subclinical GCA though this requires analysis in larger cohorts of patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Imaging of Rheumatic Diseases

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Interstitial lung disease (ILD) is a common manifestation of idiopathic inflammatory myopathies (IIM) ranging up to 78% in IIM and is a key contributor to hospitalization, excess morbidity and mortality. In-vivo visualization evidence of ongoing tissue remodeling in IIM-ILD is scarce. In this study, we aimed to quantify and compare fibroblast activation in the lungs of IIM-patients and control subjects using ^{68}Ga-labelled inhibitor of Fibroblast-Activation-Protein based (^{68}Ga-DATA.SA.FAPI) positron emission tomography combined with computed tomography (FAPI PET/CT) imaging.

Methods: Patients with IIM recruited prospectively from the rheumatology outpatient clinic, and control subjects without rheumatic conditions or ILD recruited from the cardiology outpatient clinic underwent FAPI PET-CT imaging. Pulmonary FAPI accumulation was assessed by measuring the maximal standardized uptake (SUV) value (SUVmax) and mean SUV (SUVmean) over the whole lung (wl) using the liver as internal reference, respectively. Values of SUV were compared across IIM patients with and without ILD and controls using analysis of variance test and displayed as mean ± standard deviation (SD). Standard-of-care procedures such as high-resolution computed tomography (hr-CT) and pulmonary function testing (PFT) were performed in all IIM-patients at baseline and in patients with ILD at follow-up.

Results: The clinical characteristics of patients with IIM (14 patients with ILD confirmed by hr-CT and 5 non-ILD patients with primary muscular affection) and control subjects (n=19) are displayed in Table 1. Three (n=3) patients in the control group were excluded from analysis due to pulmonary disease or cardiac decompensation. In individuals with IIM-related ILD, whole-lung ^{68}Ga-DATA.SA.FAPI uptake assessed by wlSUVmax (Figure 1A) and wlSUVmean (Figure 1B) corrected for the liver was significantly increased as compared to both non-ILD IIM patients and the control group. No differences of wlSUVmax or wlSUVmean were observed between non-ILD IIM patients and the control group. FAPI uptake in the lungs correlated significantly with pulmonary function tests, severity of dyspnea and serum concentration of acute phase reactants at baseline. Moreover, IIM-patients with progressive ILD (defined as worsening in pulmonary function tests at 1-year follow up and/or need for intensification of immunosuppressive therapy) had significantly increased pulmonary FAPI uptake at baseline (Figure 2).

Conclusion: Our study demonstrates higher FAPI uptake in patients with IIM-ILD. Intensity of pulmonary FAPI accumulation was associated with progression of ILD. Thus, ^{68} Ga-DATA.SA.FAPi PET/CT may serve as a useful non-invasive tool for risk stratification of lung disease in IIM.

Impact of Sprifermin on Denuded Areas of Subchondral Bone (dABs): A Post Hoc Analysis of the FORWARD Study

Felix Eckstein[1], Wolfgang Wirth[2], Philip Conaghan[3], Marc Hochberg[4], Ali Guermazi[5], Jade Andrade[6], Luping Zhao[6] and Niti Goel[7], [1]Paracelsus Medical University, Institute of Anatomy & Ludwig Boltzmann Institute, and Chondrometrics GmbH, Salzburg, Austria, [2]Paracelsus Medical University, Institute of Anatomy & Ludwig Boltzmann Institute, and Chondrometrics GmbH, Freilassing, Germany, [3]University of Leeds, Leeds, United Kingdom, [4]University of Maryland School of Medicine, Baltimore, MD, [5]Boston University, Boston, MA, [6]TrialSpark, New York, NY, [7]TrialSpark, Duke University, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Imaging of Rheumatic Diseases
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Sprifermin, recombinant human fibroblast growth factor 18 (rhFGF-18), is being investigated as a potential disease-modifying osteoarthritis drug. The Phase 2 FORWARD study demonstrated that intra-articular (IA) sprifermin significantly and dose-dependently improved cartilage thickness in knee OA (KOA).Cartilage defects, the most severe of which present as dABs, are known to increase in size with KOA progression and be associated with KOA pain and incident knee replacement. This analysis investigates the impact of sprifermin treatment on dABs in KOA.

Methods: In FORWARD, participants (pts) were randomized 1:1:1:1:1 to 3 weekly IA injections (1 cycle) of either PBO or sprifermin 30 μg or 100 μg every 6 or 12 months (Q6M, Q12M) for 18 months, then followed through year 5. The modified (with baseline [BL] and ≥1 post-BL MRI) intent-to-treat (mITT) and subgroup at risk (mSAR, enriched for more severe KOA [BL WOMAC Pain ≥40, minimum medial or lateral joint space width {mJSW} 1.5-3.5 mm]) populations were analyzed. dABs, derived from manual, quality-controlled cartilage and subchondral bone segmentations, were computed as the percentage (%) of the total area of subchondral bone not covered by cartilage of femorotibial joint (FTJ) regions. Measurements were analyzed at BL and Week 104 (W104) for the a) 30 and 100 μg arms individually, b) 30 and 100 μg arms combined, and c) pts with BL dAB. No imputation was performed for missing data; only descriptive data are provided.

x 2=cycle every 12 months; x 4=cycle every 6 months; Δ=change; cLF=central lateral femur; cMF=central medial femur; LFTC=lateral femorotibial compartment; LT=lateral tibia; MFTC=medial femorotibial compartment; mITT=modified intent-to-treat; MT=medial tibia; mSAR=modified subgroup at risk; N=total sample size; n=sample evaluated; SD=standard deviation; W104=Week 104.

Results: Characteristics at BL showed 52% (n=255/494) of the mITT population had some FTJ dAB (Table 1); in the SAR, 61% (n=98/161). Those with FTJ dAB at BL had more severe radiographic disease by Kellgren-Lawrence (KL) grade (44.3% vs 17.6% KL3) and medial mJSW (3.6 mm vs 3.9 mm).Baseline dABs were associated with more structural progression by quantitative cartilage thickness measures, independent of treatment arm (Table 1). Table 2 presents the %dAB and absolute change from BL (CFB) in %dAB data for the 6 FTJ regions analyzed. Of these, the weight-bearing (central) medial femur (cMF) showed the greatest %dAB (range 1.74-4.75) in the different treatment arms at BL in the mITT (Table 2). In the medial compartment, the absolute %dAB CFB at W104 also tended to be greater (worse) in the PBO- (range 1.04-1.22) vs the sprifermin-treated arms (eg, range 0.38-0.79 for sprifermin 100 μg combined), with the cMF showing the greatest differentiation. The degree of the differences in longitudinal changes between treatment arms in the medial compartment was more pronounced in the mSAR than mITT population, eg, W104 CFB of cMF %dAB mSAR 3.56 vs 1.01 and mITT 1.22 vs 0.79 in the PBO vs sprifermin 100 μg combined group. Yet, little difference was seen in the longitudinal changes in %dAB between the sprifermin- and PBO-treated arms in the lateral compartment.

Conclusion: The presence of dAB appears to be associated with more severe radiographic OA and structural progression of KOA. Sprifermin treatment, particularly at the highest dose, appears to slow the increase (worsening) of dAB compared to PBO, especially in the medial compartment. Further evaluation of these findings and the relationship of dAB with symptomatic outcomes is warranted, including in prospective clinical trials.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Imaging of Rheumatic Diseases

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Multispectral optoacoustic tomography (MSOT) is a novel imaging platform that combines ultrasound (US) with optoacoustic imaging to allow non-invasive in vivo quantification of key metabolites of inflammation such as hemoglobin (Hb), oxygen saturation (SO2), and collagen and lipid levels by analyzing the wavelength spectra of the target tissues when exposed to near-infrared laser light (Regensburger AP, Biomedicines (2021)). MSOT has already proven capable of identifying arthritis and enthesitis in patients with PsA and RA (Tascilar K, Rheumatology (2023)). In our study, we aimed to assess metabolic and inflammatory changes at the entheses in patients with psoriasis (PsO), PsA, and healthy controls (HC) using MSOT in order to identify new potential imaging biomarkers for enthesitis.

Methods: A cross-sectional study in bDMARD-naïve PsA and PsO patients and HC was performed. Participants underwent sequential clinical, US and MSOT examination of six entheses (lateral humeral epicondyle, distal patellar tendon attachment, Achilles). MSOT wavelength spectra were determined and the corresponding values of Hb, SO2, collagen, and lipid were quantified. Mean differences between groups were calculated using linear mixed effects models. MSOT-measured analytes were compared between tender and non-tender entheses and between entheses with and without OMERACT-defined US anomalies. The study was approved by the Ethics Committee of the University of Erlangen-Nuremberg (464_18 B; 7) and was registered as a clinical trial (DRKS00024360).

Figure 1 MSOT wavelength spectra for psoriasis, psoriatic arthritis and healthy controls stratified by examination site.

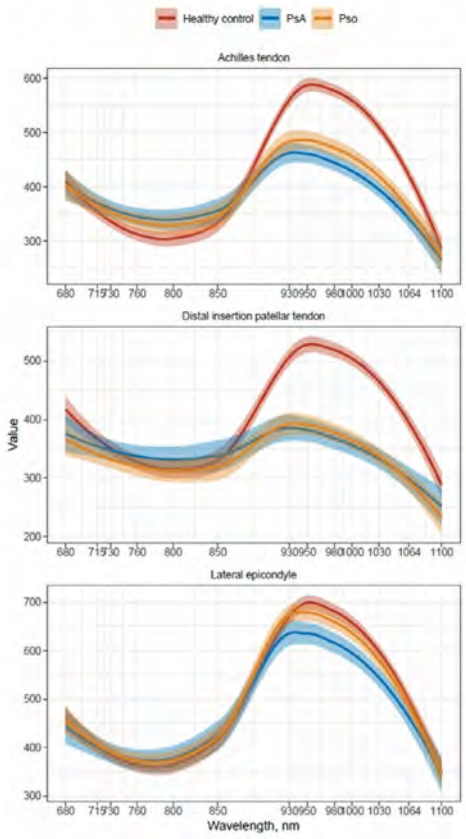

Figure 1 – MSOT wavelength spectra for psoriasis, psoriatic arthritis and healthy controls stratified by examination site.

Results: Ninety participants were included (30 PsO, 30 PsA, 30 HC). Clinical and demographic characteristics are shown in table 1.540 entheses were clinically assessed, 540 US and 830 MSOT scans were obtained. Comparing MSOT wavelength spectra, significant differences from HC emerged for PsA between 800 nm and 1064 nm, and for PsO between 930 nm and 1100 nm (Figure 1). The corresponding metabolites distribution was obtained. Both PsA and PsO patients showed significantly increased oxygenated Hb (PsA: p=0.005; PsO: p=0.001) and SO2 (PsA: p< 0.001; PsO, p=0.001) levels and decreased collagen signals (PsA: p< 0.001; PsO: < 0.001) compared to HC, with more pronounced changes in the PsA group (Table 2). Significantly lower collagen levels (p=0.01) and increased signal for lipids (p=0.02) were recorded in tender entheses compared with non-tender ones. The presence of at least one US anomaly was associated with a significant positive difference in SO2 (p=0.003).

Conclusion: PsO and PsA patients show a distinct entheseal metabolic profile that is common to all psoriatic patients independently from clinical and US-detected signs of inflammation, thereby supporting the notion of a psoriatic disease spectrum characterized by varying degrees of musculoskeletal inflammation. Furthermore, MSOT can detect differences between inflamed and uninflamed entheses that are more pronounced in PsA than in those with skin psoriasis alone. Research efforts should now focus on defining MSOT cutoff values for enthesitis and longitudinal analyses should be conducted to assess the utility of MSOT as a risk stratification tool for the risk of progression to PsA in at-risk patients.

Recombinant Zoster Vaccination Among U.S. Veterans Receiving Immunosuppressive Medications 2017-2023

Sharon Abada[1], Jing Li[1], Gary Tarasovsky[2], Cherish Wilson[3], Jinoos Yazdany[1], Mary Whooley[1] and Gabriela Schmajuk[3], [1]University of California San Francisco, San Francisco, CA, [2]San Francisco VA, San Francisco, CA, [3]UCSF / SFVA, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Patients receiving immunosuppressive therapies are known to have a higher risk of herpes zoster and subsequent complications compared to the general population. The recombinant zoster vaccine (Shingrix, hereafter referred to as "RZV") has been shown to be both safe and efficacious among such patients. In 2021, the Centers for Disease Control and Prevention (CDC) and the Food and Drug Administration (FDA) updated their recommendations and approval for the administration of RZV to include all immunosuppressed adults (any age). We assessed patient characteristics associated with RZV vaccination rates among U.S. veterans.

Methods: We performed a cross-sectional observational study using national Veterans Affairs (VA) data from the VA Corporate Data Warehouse. The study population included all VA patients aged ≥ 18 who were prescribed at least one immunosuppressive medication (including conventional synthetic (cs) DMARDs, biologics, and targeted synthetic (ts) DMARDs) for ≥ 90 days between 2017 and 2023. We identified patients with one or more doses of RZV documented. We examined whether demographic and clinical characteristics (age, sex, race, ethnicity, rurality of residence, medication type, rheumatology specialty care) were associated with receiving RZV using multivariate logistic regression, accounting for clustering by facility and report the predicted marginal proportions of patients vaccinated.

Results: We identified 142,336 veterans across 130 facilities as prevalent users of csDMARDs, biologics, or tsDMARDs between 2017 and 2023 (Table 1). Most patients were male (85.8%), white (73.6%), non-Hispanic (89.2%), and lived in urban areas (64.0%). Mean age (SD) was 66.5 (14.0) years. Of these patients, 34.8% had received at least two doses of RZV (fully immunized), 7.7% had received 1 dose of RZV, and 57.4% had not received any doses of RZV. Multivariate logistic regression revealed the largest differences in vaccination rates were for patients < 50 years vs ≥ 50 years (11.2% vs 47.8%, $p < 0.05$), African American vs white patients (36.9% vs 43.8%, $p < 0.05$), and those without a recent visit with a rheumatologist vs those with at least one rheumatology visit since 2018 (38.8% vs 46.0%, $p < 0.05$; Table 2). Patients receiving tsDMARDs (vs receiving neither a biologic nor tsDMARD) were more likely to receive at least 1 dose of RZV (48.6% vs 41.8%, $p < 0.05$).

Conclusion: Among adult U.S. veterans receiving immunosuppressive medications, less than half have received at least one dose of RZV. Patients under 50 years old were least likely to have received RZV, likely reflecting a lag in implementing updated CDC guidance for this group. Quality improvement efforts should specifically focus on younger patients and African American patients. Future work should explore the development of population-health management tools (such as clinical dashboards in electronic medical records) to support quality improvement in RZV administration rates for immunosuppressed patients.

Table 1. Demographic characteristics of patients on immunosuppressive medications, with or without at least one dose of recombinant zoster vaccination (RZV)

Tuberculosis Screening Among New Users of a Biologic or Targeted Synthetic DMARD: Gaps in Coverage Overall and Among JAKi Initiators

Eric Roberts[1], Gabriela Schmajuk[2] and Jinoos Yazdany[1], [1]University of California San Francisco, San Francisco, CA, [2]UCSF / SFVA, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Measures & Measurement of Healthcare Quality

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Screening for latent tuberculosis (TB) is recommended prior to starting biologics or targeted synthetic DMARDs (b/tsDMARDs). With a growing number of these drugs available in rheumatology, it is important to investigate whether TB screening practices have kept pace with recommendations. Using national data, we aim to describe the proportion of new users of a b/tsDMARD who were screened for TB, and evaluate potential gaps in testing by drug type, patient characteristics and practice.

Methods: Data come from RISE, an electronic health record-based registry of US rheumatology practices with linkage to Medicare Parts A, B, and D claims. Individuals in RISE with continuous Medicare enrollment in 2017 and 2018 who were new users of a qualifying b/tsDMARD in 2018 in Medicare were included. New users were defined as those with a prescription for a b/tsDMARD in 2018 but no prescription (in Medicare or RISE) in the year prior. Use of b/tsDMARDs, information on TB testing (IGRA, TST or medical exception), and patient demographics were extracted from Medicare and RISE, to gather the most comprehensive data on b/tsDMARD use and TB testing. We calculated the proportion of patients tested in either

Table 1. Percent of new b/tsDMARD users screened for TB within 1 year and 3 years with a 30 day grace period overall and by TB screening method.

	New users of Biologics or tsDMARDs (n=2821)	
	1-year lookback	3-year lookback with 30-day grace period
Any screening	65.19	72.78
Screened with IGRA	61.75	69.20
Screened with TST	4.71	6.88
Documented medical exception	3.44	5.10

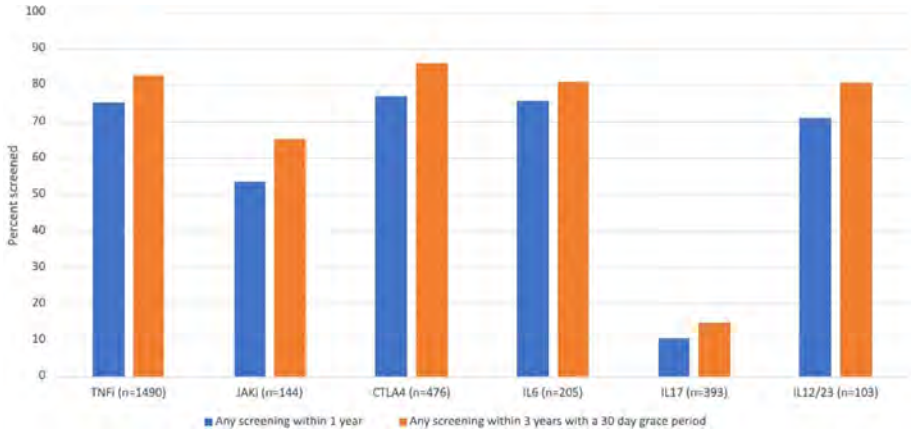

Figure 1. Proportion of new b/tsDMARD users screened for TB by DMARD type.

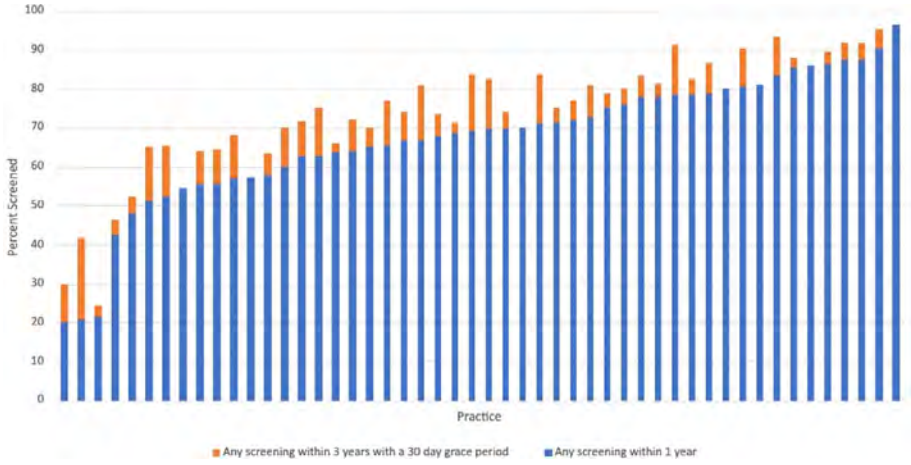

Figure 2. Proportion of new b/tsDMARD users screened for TB by practice among practices with at least 20 patients.

RISE or Medicare claims in the year prior to the new b/tsDMARD, consistent with the Quality Payment Program measure. In a sensitivity analysis we permitted TB screening in the 3 years before up to 30 days after the patient's start date. We computed screening rates by b/tsDMARD type. Using logistic regression we tested for differences in screening by age, sex, race-ethnicity, insurance and socioeconomic status (using the area deprivation index). We calculated the proportion of patients screened among practices with at least 20 new users.

Results: Among 2821 new b/tsDMARD users, mean age was 73±8.6 years, 72% female, 73% non-Hispanic White, 6.8% Black, 4.7% Hispanic and 1.2% Asian. In the year prior to drug starts, 65.2% of patients had any TB screening documented, including 61.8% with an IGRA, 4.7% with a TST, and 3.4% with a documented medical exception. In our sensitivity analysis, 77.9% had any TB screening (Table 1). Rates of screening within 1 year by drug type were greater or equal to the overall screening rate for most drugs with the exception of JAKi (53.5%) and IL17i (10.4%) (Figure 1). In a fully adjusted logistic regression, patients in the highest quartile of SES had significantly lower odds (OR=0.64; 95%CI 0.48-0.87) of being screened within 1 year compared to the lowest quartile. 50 practices had at least 20 patients; screening rates ranged from 20-96.3% of patients (Figure 2).

Conclusion: Using a comprehensive data source that includes both registry data and Medicare claims, we found that just over 1 in 3 new users of a b/tsDMARD did not receive TB screening within the recommended time window. When the screening window was expanded, performance only slightly improved with approximately 1 in 4 new users not receiving screening. Although lower TB screening rates for IL-17i may reflect greater uncertainty about TB risk with this drug mechanism, emerging evidence suggests that TB risk for JAKi is significant. Filling these gaps in care are important areas for quality improvement.

Facility Variation in HLA-B*58:01 Allele Testing for Asian and Black Patients Receiving Allopurinol in the Veterans Affairs Healthcare System

Jeremy Sullivan[1], Anna Ware[2], Gary Tarasovsky[3], Cherish Wilson[4], Mary Whooley[3], Jasvinder Singh[5], Jinoos Yazdany[6] and Gabriela Schmajuk[4], [1]University of California San Francisco, San Francisco, CA, [2]Palo Alto VA, Minneapolis, MN, [3]San Francisco VA, San Francisco, CA, [4]UCSF / SFVA, San Francisco, CA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]University of California, General Department of Medicine, Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: New guidelines published in 2020 conditionally recommend HLA-B*58:01 allele testing for South Asian and Black patients receiving allopurinol to reduce the risk of severe cutaneous adverse events. However, no data exists on population-wide genetic testing rates. We investigated HLA-B*58:01 testing among allopurinol users in the Veterans Health Administration (VHA) Healthcare System.

Methods: Using data from the VHA Corporate Data Warehouse (CDW), we identified facilities with structured fields available for capturing HLA-B*58:01 test results. From these facilities, we identified all patients with a current, active prescription for allopurinol as of December 2022. We assessed the proportion of patients with a documented HLA-B*58:01 test at any time

within the CDW, by race or ethnicity. We repeated this analysis among incident users of allopurinol (defined as users with a prescription in 2022 and no allopurinol use in the preceding 3 years). Finally, we examined variation in HLA-B*58:01 testing among self-identified Asian or Black patients by VHA facility, among facilities with ≥ 20 eligible patients. We contacted the top performing facility to learn about local workflows for obtaining genetic testing for allopurinol users.

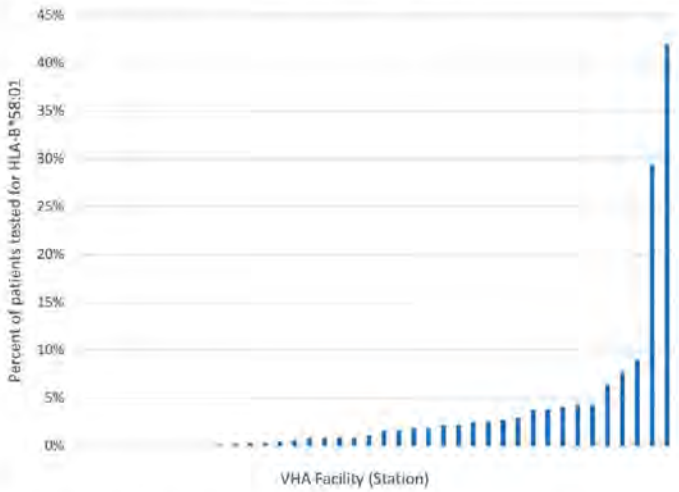
Results: Only 40 out of 130 facilities had a structured field available for capturing HLA-B*58:01 test results. We identified 79,361 users of allopurinol at these facilities; 98% of them were male, and mean age was 70 years (SD 12). Among prevalent users, 13.8% of Asian and 2.4% of Black patients were ever tested for the HLA-B*58:01 allele (**Table**). Among incident users, testing was documented among 10.1% of Asian and 3.0% of Black patients. We observed wide variation in HLA-B*58:01 testing across facilities (range 0% - 42.0%; **Figure**). The top-performing facility (proportion tested 42.0%) relayed that they had developed an allopurinol order set and pharmacy workflow that prevented allopurinol prescribing prior to completion of genetic testing.

Table. Percent of allopurinol users with HLA-B*58:01 testing documented in the VHA electronic health record, stratified by race or ethnicity, among facilities with a structured field available for HLA-B*58:01 results (N facilities = 40)

	Prevalent Allopurinol Users		Incident Allopurinol Users†	
	N	% with HLA-B*58:01 testing	N	% with HLA-B*58:01 testing
Overall	79,361	1.57%	7,925	1.70%
Race or Ethnicity‡				
American Indian or Alaska native	532	0.94%	58	1.72%
Asian	3,123	13.83%	356	10.11%
Black or African American	18,117	2.44%	1,844	2.98%
Hispanic	2,703	1.70%	292	2.74%
Native Hawaiian or other Pacific Islander	1,766	3.96%	196	4.59%
Non-Hispanic White	48,069	0.35%	4,472	0.42%
Multiple	267	4.49%	24	0.00%
Unknown	4,784	1.57%	683	1.02%

† Incident users defined as patients with a current prescription and no allopurinol use in the preceding 3 years
‡ Race or ethnicity were self-reported. Patients reporting one or more race or ethnicity categories were grouped into the "Multiple" category

Figure. Percent of self-identified Asian or Black prevalent users of allopurinol who were tested for the HLA-B*58:01 allele, by VHA facility (N facilities = 36)*



*Facilities without a structured field for HLA-B*58:01 results and with fewer than 20 self-identified Asian or Black patients were excluded.

Conclusion: Across the VHA Healthcare System, testing for HLA-B*58:01 in high-risk groups was very low, and variation across facilities was high. Most facilities lack a structured field for HLA-B*58:01 results, which hinders measurement of quality gaps. In order to improve testing rates, facilities should consider implementing order sets or pharmacy "hard stops" that require HLA-B*58:01 testing for high-risk groups.

Abstract Number: 0754

Towards a Guide for Evidence-based Remote Monitoring: Sensitivity of Patient Reported Outcomes to Change in Disease Activity Status in Early and Established Rheumatoid Arthritis

Agnes Loiojen[1], Elise van Mulligen[2], Annette van der Helm-van Mil[3] and Pascal de Jong[2], [1]Erasmus Medical Center, department of rheumatology, Rotterdam, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: In the treatment and follow-up of rheumatoid arthritis (RA) patients, it has become more desirable to detect changes in disease activity through remote monitoring. Patient reported outcomes(PROs) might be useful for this purpose. So far associations between PROs and changes in disease activity have been mostly investigated on a continuous scale. However, in daily practice, and in line with the current recommendations, treatment decisions are mainly based on the patient's disease activity status. Earlier literature has shown that functionality, morning stiffness, health-related quality of life (HRQoL), general health (GH), joint pain and fatigue change with the development and resolution of a disease flare.

Therefore, our aim is to determine if PROs that cover functionality, joint pain, morning stiffness, HRQoL, GH and fatigue are sensitive to disease activity status alterations in patients with early and established RA.

Methods: Early RA patients from the tREACH trial and established RA patients from the TARA trial were included. Both studies are multicentre, single-blinded trials with a treat-to-target approach. Treatment alterations were based on the disease activity score (DAS44) and PROs were collected at 3-montly intervals. The following PROs were studied: (1) the Health Assessment Questionnaire-Disability Index(HAQ-DI), (2) morning stiffness severity (numeric rating scale, NRS 0-10), (3) the 3-level EQ-5D(EQ-5D-3L) (4) GH (visual analogue scale, VAS 0-100mm), (5) joint pain (NRS 0-10) and (6) fatigue (VAS 0-100mm).

Disease activity status were defined as: (1) active disease (DAS≥2.4), (2) low disease activity (LDA, DAS< 2.4 and ≥1.6), and (3) remission (DAS< 1.6). Differences in disease activity status between two consecutive visits were compared to changes in PROs. Mean changes in PROs per disease activity status alteration were compared to stable disease activity status using linear mixed models.

Results: A total of 587 early and 189 established RA patients were included. The median symptom duration (interquartile range, IQR) was 0.4 (0.2-0.6) and 6.2 (4.1-8.9) years respectively. The mean DAS (95% confidence interval, CI) at baseline was 3.0 (3.0-3.2) in the early and 1.0 (0.9-1.1) in the established RA group.

Figure 1 mean changes in patient reported outcome after disease activity status alteration

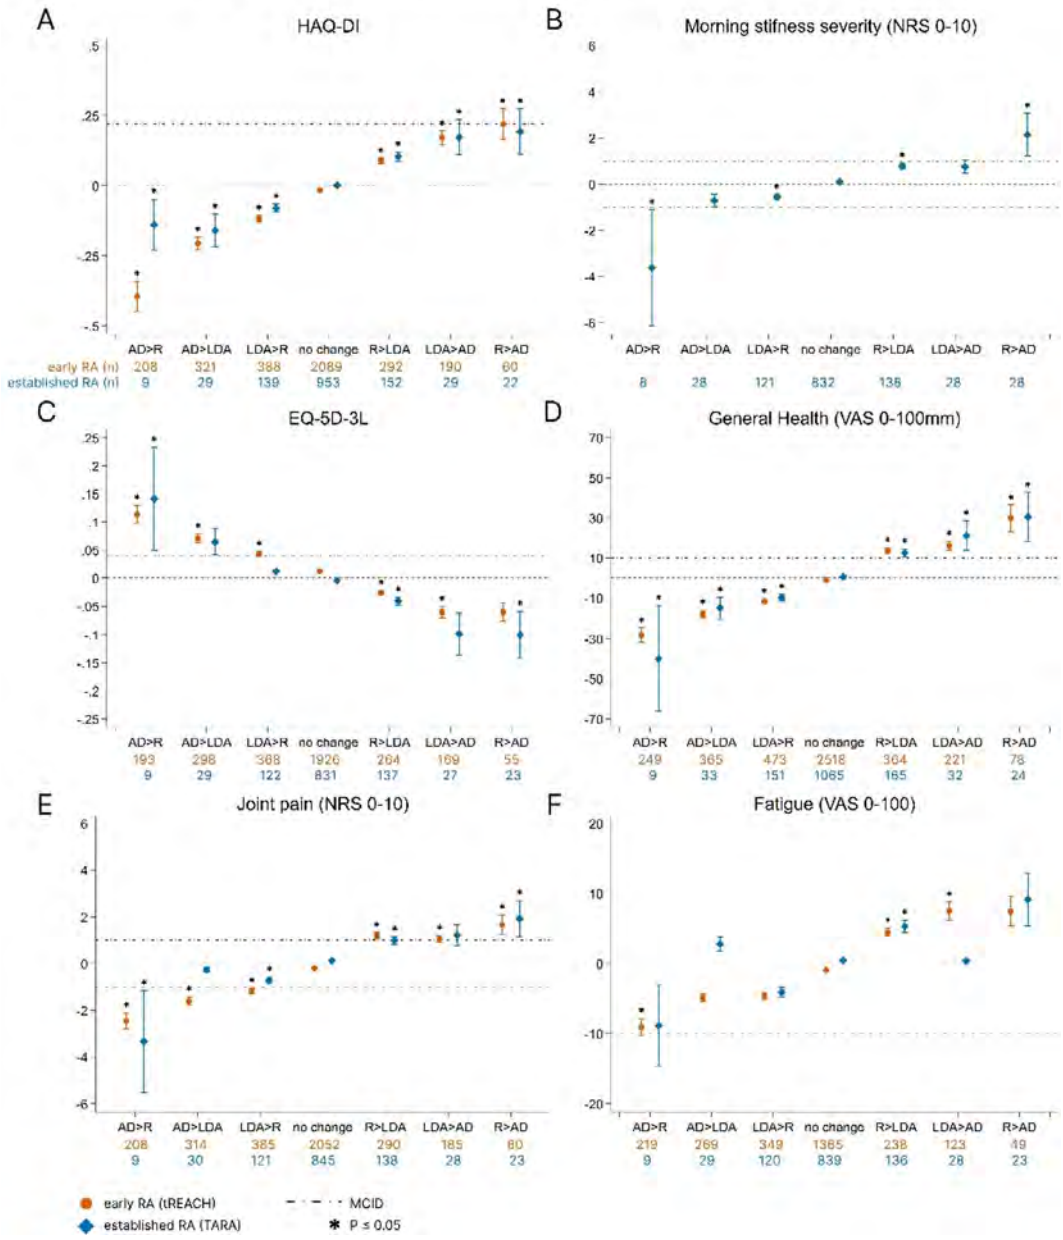

Figure 1A-F show the mean change (95%CI) in PRO after disease activity status alteration for early and established RA patients. * indicates that change in PRO is significantly (p<0.05) different compared to stable disease activity status. Abbreviations: AD, active disease; EQ-5D-3L, 3-level EQ-5D; HAQ-DI, health assessment questionnaire-disability index; LDA, low disease activity; NRS, numeric rating scale; R, remission; VAS, visual analogue scale.

Figure 1 shows the mean change in PROs per change in disease activity status(with 95%CI and significance). Changes in HAQ-DI, morning stiffness severity, EQ-5D-3L, GH, joint pain and fatigue (in early RA) were in concordance with improvement or worsening of the disease activity status. Changes from remission or LDA to active disease and vice versa had a bigger impact on the change in PRO compared to changes between LDA and remission.

Conclusion: HAQ-DI, morning stiffness, EQ-5D-3L, GH and joint pain are sensitive to changes in disease activity status. These results suggest that aforementioned PROs may be helpful in remote monitoring of RA.

Changes in Rheumatology Providers' Perceptions of Telehealth Appropriateness from 2021 to 2022

David Leverenz[1], Mary Solomon[2], Ricardo Henao[2], Isaac Smith[3], Catherine Howe[4], Nicoleta Economou-Zavlanos[5], Bhargav Adagarla[6], Theresa Coles[7], AJ Overton[8], Jayanth Doss[9] and Megan Clowse[10], [1]Duke University School of Medicine, Durham, NC, [2]Duke University, Department of Biostatistics, Durham, NC, [3]Duke University, Department of Medicine-Rheumatology and Immunology, Durham, NC, [4]New York University, New York, NY, [5]Duke AI Health, Durham, NC, [6]Duke University Clinical Research Institute, Durham, NC, [7]Duke University, Department of Population Health Sciences, Durham, NC, [8]Consultant, Durham, NC, [9]Duke University, Durham, NC, [10]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Measures & Measurement of Healthcare Quality
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Telehealth in rheumatology rapidly expanded in the wake of the COVID-19 pandemic, however it remains unknown how provider perceptions of telehealth changed as the pandemic evolved and providers gained additional experience with telehealth. In this project, we describe rheumatology providers' perceptions of telehealth appropriateness from 2021 - 2022, along with the clinical and demographic factors that align with telehealth appropriateness.

Methods: Providers at a single academic rheumatology practice in the U.S. documented their perception of telehealth appropriateness by recording the Encounter Appropriateness Score for You (EASY) in their progress notes immediately following each in-person or telehealth encounter. The EASY score asks providers, "Which of the following encounter types would have been most appropriate for TODAY'S visit? (Irrespective of the pandemic)." Response options include: (1) Either in-person or telehealth acceptable; (2) In-person preferred; (3) Telehealth preferred. For this analysis, EASY scores 1 and 3 were consolidated into a single variable, "telehealth acceptable." We analyzed changes in EASY scores and encounter modality from 1/1/2021 – 10/30/2022. In addition, we analyzed the distribution of EASY scores according to patient demographic and clinical variables. This analysis was limited to return encounters.

Results: Over the study period, 27 providers documented EASY scores for 21,670 return encounters. Of these, 6,551 (30.2%) were rated as telehealth acceptable and 15,119 (69.8%) in-person preferred. The proportion of EASY scores rated as telehealth acceptable declined over time, from approximately 47% in January 2021 to 25% from August 2021 - October 2022 (**Figure 1**). The proportion of visits that occurred by telehealth also declined from 33% in January 2021 to approximately 15% in 2022. The proportion of EASY scores matching the actual encounter type (indicating the appropriate type of visit actually occurred) increased for all encounters from 69% in January 2021 to approximately 80% throughout 2022

(**Figure 2**). Among the 27 providers, there was substantial variability in the proportion of visits each provider rated as telehealth acceptable (median 35%, IQR 12-43%, full range 3-72%). Patient characteristics, including demographics, diagnoses, and patient-reported symptom severity (RAPID3), were related to telehealth appropriateness (**Figure 3)**, with the most telehealth acceptance among patients with RAPID3 scores indicating remission (45%) and the least acceptance with high disease activity (22%).

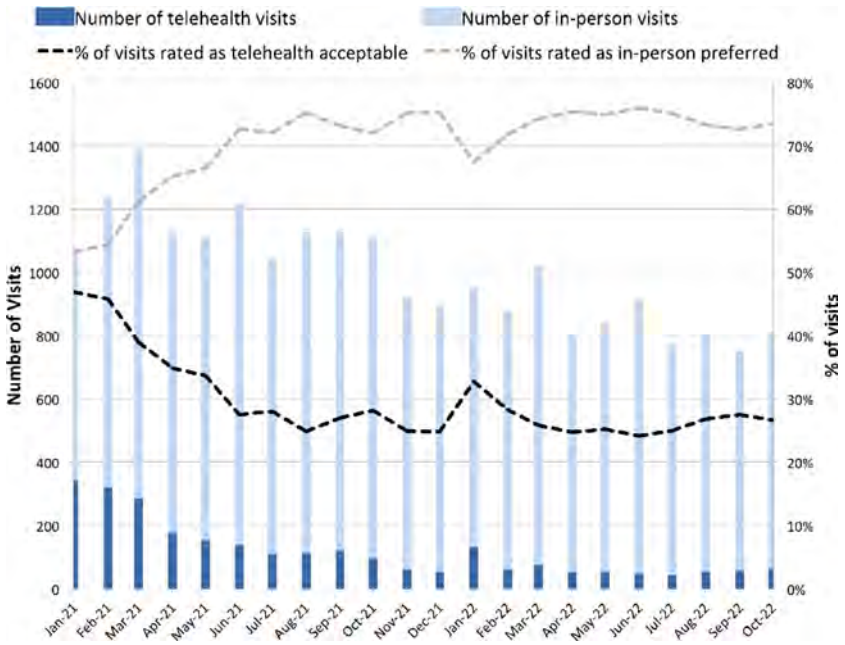

Figure 1. Provider ratings of telehealth appropriateness according to EASY scores (dotted lines) and actual visit modalities (bars) for all return encounters with a documented EASY score, January 2021 through October 2022.

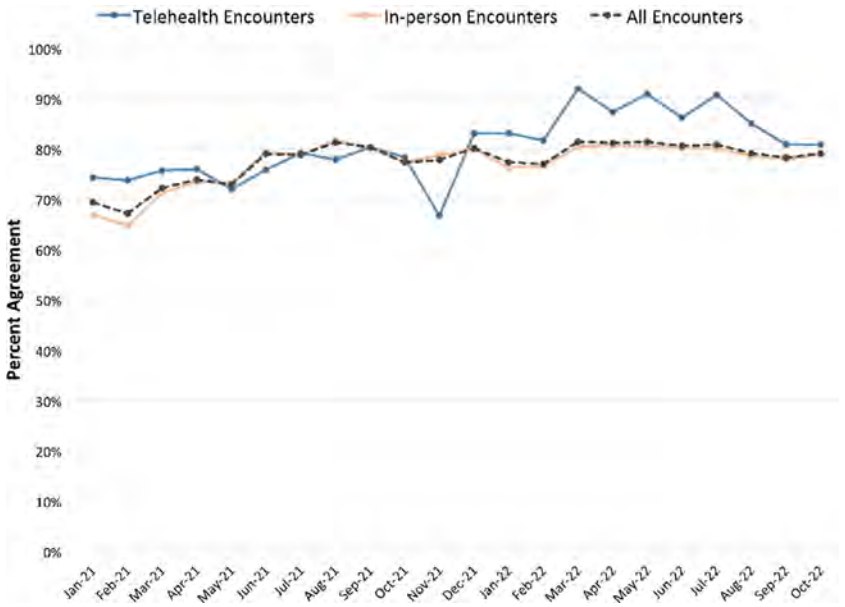

Figure 2. Percent of encounters where the provider EASY score and encounter modality matched per month for telehealth encounters (blue), in-person encounters (orange), and all encounters (black).

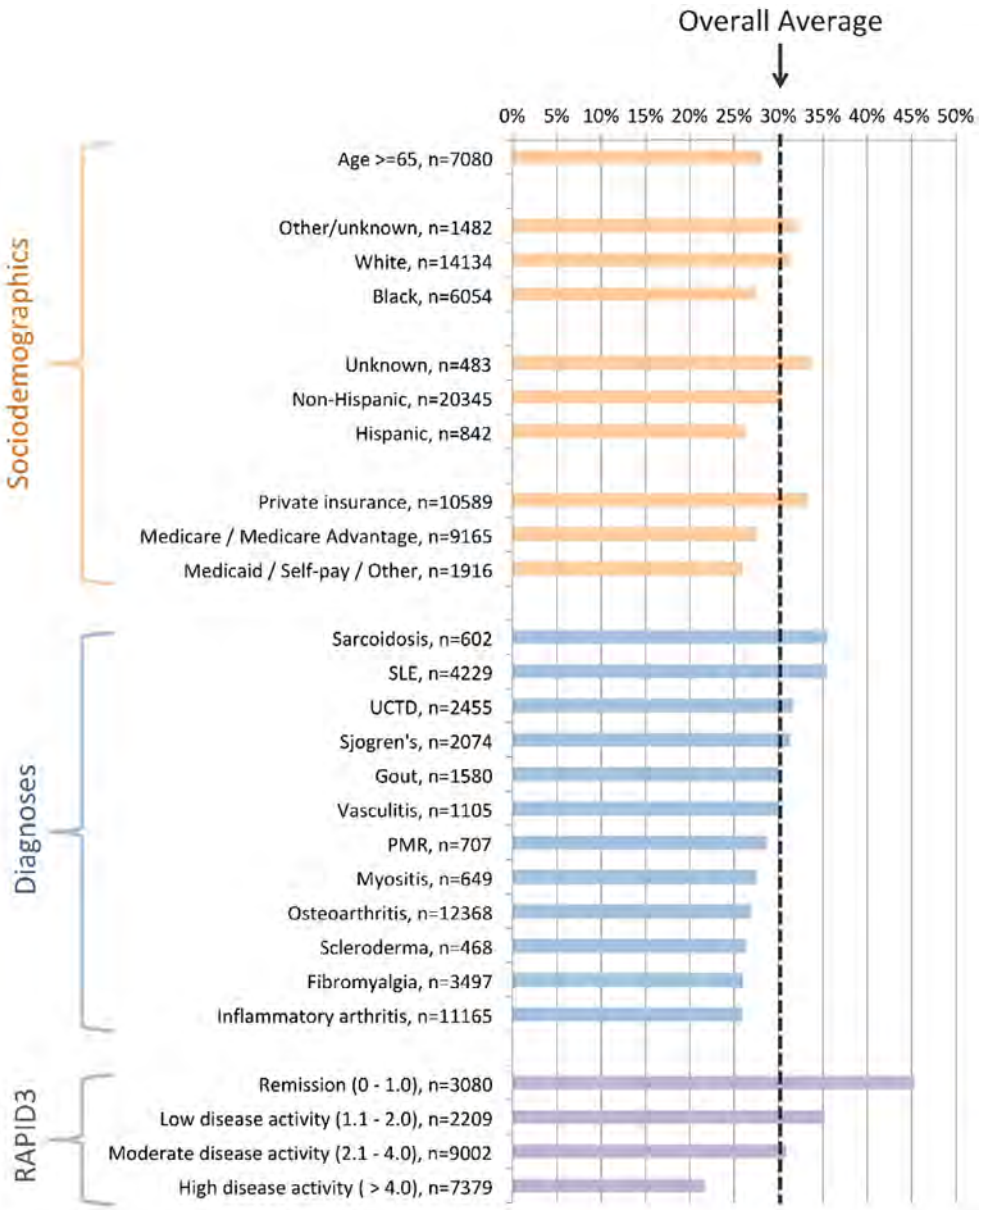

Figure 3. Proportion of return encounters where EASY score indicated telehealth acceptable (EASY = 1 or 3), according to sociodemographics, diagnoses, and RAPID3 scores from January 2021 – October 2022. Diagnoses are grouped using ICD-10 codes. Inflammatory arthritis includes patients with rheumatoid arthritis, psoriatic arthritis, spondyloarthritis, and juvenile idiopathic arthritis. Abbreviations: PMR = polymyalgia rheumatica; SLE = systemic lupus erythematosus; UCTD = undifferentiated connective tissue disease.

Conclusion: Providers became progressively less likely to consider a visit appropriate for telehealth over the first half of 2021, but then stabilized estimating approximately 25% of all return visits telehealth-appropriate. Frequency of telehealth visits followed a similar pattern, though generally telehealth visits accounted for fewer than 25% of visits in 2022, suggesting that telehealth is under-utilized. For example, providers report telehealth as appropriate in over 35% of encounters when the patient reports low symptom severity, suggesting that this sub-population of patients could be a good target for increased telehealth use.

Validation of Quantitative Effusion-synovitis Volume Measured by Deep-learning: Data from the Osteoarthritis Initiative

Banafshe Felfeliyan[1], Stephanie Wichuk[2], Abhilash Hareendranathan[3], Janet Ronsky[4] and Jacob Jaremko[2], [1]University of Alberta, Calgary, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada, [3]Radiology and Diagnostic Imaging, Edmonton, AB, Canada, [4]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

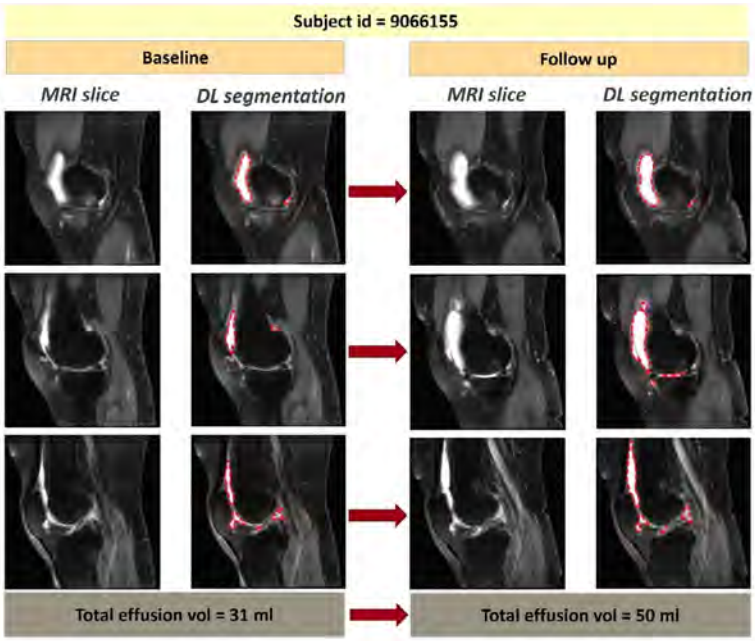
Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Measures & Measurement of Healthcare Quality

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Knee effusion-synovitis (ES) is an attractive target for therapeutic interventions in arthritis, since it is associated with stiffness, pain, and disease progression to arthroplasty. Rapid, objective methods to assess ES on MRI are desirable. Currently, ES is assessed by global user impression or semi-quantitative tools such MRI OA Knee Score (MOAKS); these approaches have high inter-user variability, are insensitive for change if categories are broad, or are time-



Deep learning effusion segmentation result for one subject at baseline and follow-up

	All cases (n=656)	Kellgren-Lawrence Grade at Baseline			
		1 (n=221)	2 (n=240)	3 (n=195)	p-value
Baseline DL Extracted Effusion-Synovitis Volume Median (IQR)	19.8 (15.6-26.2)	17.3 (13.7-21.2) *	19.9 (15.8-26.0) *	24.1 (18.4-31.9) *	<0.00001
1 year change in DL Extracted Effusion-Synovitis Volume Median (IQR)	1.3 (-2.1-5.3)	1.2 (-2.0-4.2)	1.3 (-2.0-5.6)	1.8 (-3.7-5.6)	0.605

* Significantly different from all other K-L grades

Deep learning effusion segmentation result for one subject at baseline and follow-up

consuming if scoring is detailed. To address these limitations, we have developed a novel deep learning (DL) approach to automatically measure ES volume (DL-ES), with high inter-rater reliability ICC=0.96 vs. human expert readers [1].

Here, we automatically generated ES volumes in a from a large subset of **Osteoarthritis Initiative (OAI)** dataset and assessed validity vs. other imaging scoring systems and clinical findings.

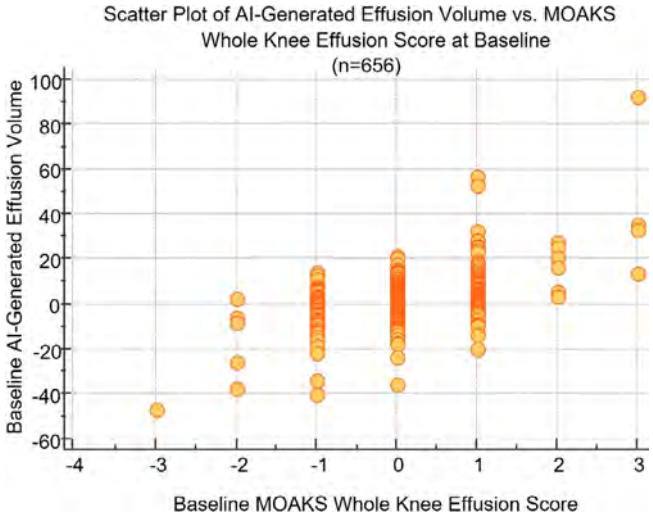
Methods: Total of 4659 MRIs from 1165 individuals with baseline (BL) and 1-year follow-up MOAKS and WOMAC scores were available from the OAI dataset. Scans were processed using a custom IMaskRCNN DL model, previously trained on 700 MRI slices with gold-standard effusion labels from an expert radiologist.

Cases with follow-up time≥11 months, total WOMAC score >0, and KL grades < 4 were analyzed(n=656). Criterion validity of DL-ES was assessed through comparison of BL and 1-year change(Δ) in volume with MOAKS whole knee effusion and WOMAC scores via Kendall's tau and Spearman rank correlation. Differences in DL-ES volumes between KL grades were evaluated via Kruskal-Wallis test.

Results: DL-EF calculation took 35 seconds/scan (Fig1). Median (IQR) baseline DL-ES volume was 19.8 (15.6-26.2) mL, with median (IQR) 1-year Δ of 1.3 (-2.1-5.3) mL. Median (IQR) DL-ES volume at BL increased significantly with BL KL Grade [17.3 (13.7-21.2) mL, 19.9 (15.8-26.0) mL, and 24.1 (18.4-31.9) mL for KL grades 1,2, and 3, respectively, p< 0.0001]. There was no significant difference in 1-year Δ in DL-ES between BL KL grades.

	All cases (n=656)	Kellgren-Lawrence Grade at Baseline			
		1 (n=221)	2 (n=240)	3 (n=195)	p-value
Baseline DL Extracted Effusion-Synovitis Volume Median (IQR)	19.8 (15.6-26.2)	17.3 (13.7-21.2) *	19.9 (15.8-26.0) *	24.1 (18.4-31.9) *	<0.00001
1 year change in DL Extracted Effusion-Synovitis Volume Median (IQR)	1.3 (-2.1-5.3)	1.2 (-2.0-4.2)	1.3 (-2.0-5.6)	1.8 (-3.7-5.6)	0.605
* Significantly different from all other K-L grades					

Deep-Learning Extracted Effusion-Synovitis Volume in cases with Kellgren-Lawrence Grades 1,2, and 3.



Kendall's tau=0.30 (95% C 0.24-0.36, p<0.0001)

There was significant moderate positive correlation between DL-ES and MOAKS effusion BL and Δ scores [Kendall's tau=0.27 (95% CI 0.21-0.32, p< 0.0001) and 0.30 (95% C 0.24-0.36, p< 0.0001), respectively].

DL-ES volumes showed a small significant positive correlation with WOMAC pain [Spearman's rho=0.11 (95% CI 0.033-0.18, p=0.005) and 0.1 (95% CI 0.03-0.18, p=0.007) for BL and Δ, respectively], and WOMAC stiffness [Spearman's rho= 0.08 (95% CI 0.01-0.16, p=0.03) and 0.11 (95% CI 0.04-0.19, p=0.004 for BL and Δ, respectively].

Conclusion: ES volume measured automatically using DL shows promising correlations to manual semiquantitative effusion scoring (MOAKS) and clinical features of knee arthritis (pain and stiffness). As others have found when measuring ES in other ways, we found higher (KL) grades (e.g., 3-4) were associated significantly with larger effusions. These results demonstrate validity of the proposed method for fully automated knee effusion quantification, which may ultimately prove useful in clinical care and clinical trials. SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: COPA syndrome is a rare, severe monogenic autoinflammatory/autoimmune disorder with variable penetrance, most commonly affecting the lungs and joints. It is caused by dominant negative mutations located in a specific hot spot (from the 7th to the 10th exons) of the *COPA* gene on chromosome 1, encoding the α subunit of the COP1 complex involved in protein transport from the Golgi apparatus to the endoplasmic reticulum. COPA syndrome is associated with autoimmunity and upregulation of both the type 1 interferon pathway and T helper-17 cells. Clinical manifestations usually start during childhood, but late-onset diseases have been described with up to 30% of asymptomatic carriers. We aimed to identify additional novel non-synonymous variants (NSV) in *COPA* and to describe their associated phenotypes.

Methods: All individuals from a large institutional biobank of adults with available whole-exome sequencing (WES) data were included in this study. All NSV from the 7th to the 10th exons of *COPA* were identified and annotated according to allele frequency reported in an online database (gnomAD) and functional predictive tools (SIFT, POLYPHEN-2, and CADD score).

Table 1. List of the identified non-synonymous variants in the COPA hot spot. *CADD score: Combined Annotation Dependent Depletion score, variants with scores over 20 are predicted to be the 1% most deleterious possible substitutions in the human genome. MAF: minor allele frequency, SNP: single nucleotide polymorphisms.

Medical record review was performed for all NSV-carrying individuals to collect personal and family medical history as well as results of autoantibody testing and chest imaging obtained through routine clinical care.

Results: Among the 53,364 adults with available WES data, 24 unique NSV in the *COPA* hot spot were identified in a total of 48 individuals (prevalence 0.09%, **Table 1**); 33 were women (69%), median age at medical record review was 51.7 years (IQR 39.6, 64.5). Only one NSV (p.R281Q) had been previously reported as a mutation in a COPA syndrome. This patient developed seronegative RA at age 18 and autoimmune hepatitis at age 35 without clinically diagnosed COPA syndrome. All other identified NSV were novel to COPA syndrome: 15 with a frequency < 0.0001 and 8 never previously identified so unable to estimate known frequency. Deleterious impact was predicted by both SIFT and POLYPHEN-2 for 12 variants (50%). Autoimmune or inflammatory disease was reported for 21 of the 48 carriers (44%); median age at disease onset was 42.9 years (IQR 28.2, 56.0; **Table 2**). 19/21 (91%) had adult-onset of these diseases. Inflammatory arthritis occurred in 6 patients, 4 diagnosed as rheumatoid arthritis (RA). Interstitial lung disease was observed in 5 patients. Five patients had psoriasis and/or Crohn's disease. Antinuclear antibodies, anti-CCP, and rheumatoid factor were positive for 9/15, 3/8 and 4/9 patients, respectively. A family history of autoimmune/inflammatory disease was reported in 9 patients. Two individuals died, both from acute on chronic heart failure, at ages 64 and 79.

Conclusion: In this first investigation of *COPA* in a large adult biobank, we identified 23 novel NSV beyond the known causal mutations and described associations with inflammatory and autoimmune diseases among nearly half of SNV, most of which were adult-onset. If functional impact of the newly identified NSV is proven, rare exonic NSV in *COPA* could contribute to the genetic architecture of several common autoimmune and inflammatory phenotypes.

Table 2. Characteristics of patients identified to be COPA hotspot NSV carriers. ANA: anti-nuclear antibodies, anti-CCP: anti-citrullinated peptides, CT: computed tomography, CTD: connective-tissue diseases; ILD: interstitial lung disease; JIA: juvenile idiopathic arthritis, PANDAS: Pediatric Autoimmune Neuropsychiatric Disorder Associated with Streptococcal infections, PsA: psoriatic arthritis, RA: rheumatoid arthritis, RF: rheumatoid factor, UCTD: undifferentiated connective tissue disease

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) and adult-onset Still's disease (AOSD) are part of the non-familial (sporadic) systemic inflammatory disorders and are frequently mentioned as being the same disease occurring at different ages. However, they are studied disconnectedly leading to lost opportunities in therapeutic innovation and variability in clinical management. In this context, the European Alliance of Associations for Rheumatology (EULAR) and the Paediatric Rheumatology European Society (PReS) established a Task Force to issue the first recommendations for the diagnosis and management of sJIA and AOSD, acknowledging they are the same disease. The following work was undertaken to inform the Task Force. The objective was to analyze the prevalence of clinical manifestations (including complications) and laboratory findings in sJIA and AOSD.

Methods: Two systematic reviews (SRs) were performed. The first SR included cohort studies comparing sJIA vs AOSD with a description of clinical and biological manifestations (including complications) and with more than 20 patients per group ("prevalence SR"); the second SR identified studies in which biomarkers were tested in both diseases and their diagnostic performance evaluated ("diagnostic SR"). Medline (via PubMed), Embase, and Cochrane Library were systematically searched. The risk of bias was assessed with an adapted form of the Hoy scale for prevalence studies in prevalence SR and with the QUADAS in the diagnostic SR. We performed meta-analyses of proportions for the different qualitative descriptors using the Stata command *metaprop*.

Results: Eight studies were included in the prevalence SR (n= 1005 participants) and 33 in the diagnostic biomarker SR. There was no difference in the pooled estimated prevalence of clinical manifestations between sJIA and AOSD, except for myalgia, sore throat, and weight loss, which were more frequently reported in AOSD, as they are likely ascertained incompletely in sJIA, especially in young children (Figure 1). Except for AA amyloidosis, more frequent in sJIA, there was no statistical difference between sJIA and AOSD in terms of complication prevalence (Figure 2). Likewise, biological findings did not differ between groups (Figure 3). Ferritin, S100 proteins and interleukin-18 were the most frequently used diagnostic biomarkers, and showed overlapping diagnostic performance parameters in sJIA and AOSD.

Conclusion: All these similarities argue for a continuum between sJIA and AOSD. We postulate that a common name is warranted, as well as a novel common set of classification criteria and disease activity score.

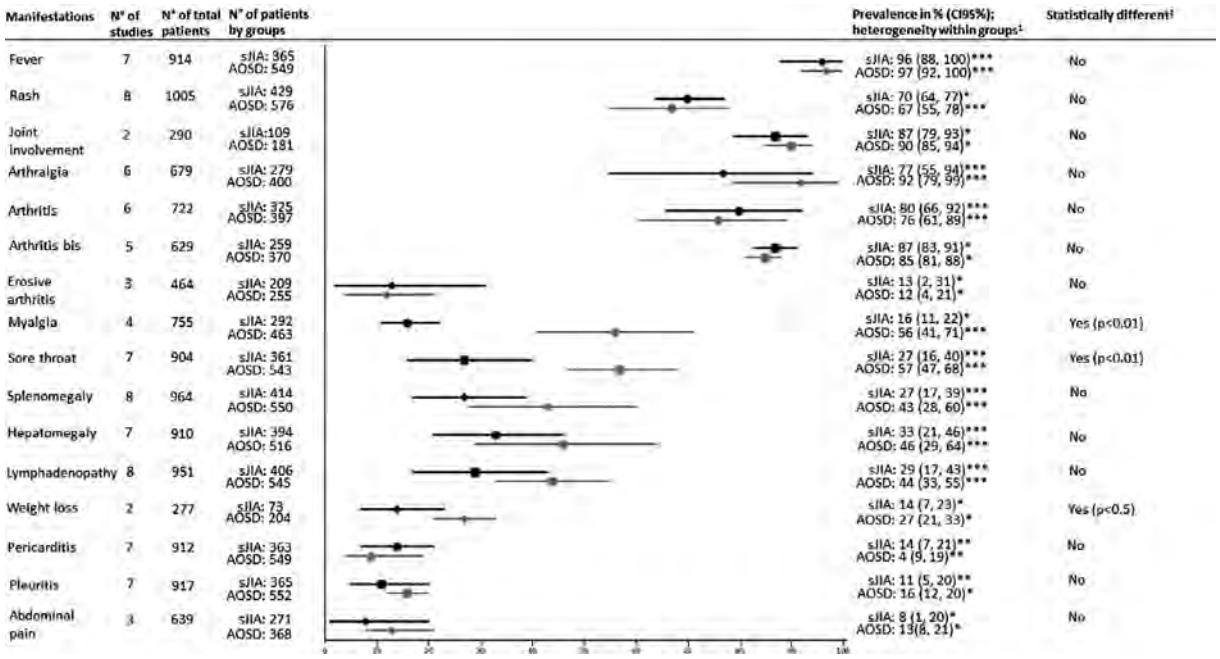

Figure 1. Prevalence (pooled estimates) of clinical manifestations in sJIA and AOSD. Values are pooled estimates of prevalence (95% CI). For each parameter, prevalence is represented in black for sJIA and in grey for AOSD. 1Heterogenity is summarised visually by asterisks: *, low heterogeneity (I2 <50%); **, moderate heterogeneity (50 < I2< 75%); ***, high heterogeneity (I2 > 75%). 2This line gives the arthritis pooled estimate prevalence without one study by Inoue 2016, because it had a very low rate of arthritis in both age groups, accounting for the large part of variability when taken into account. CI, confidence interval.

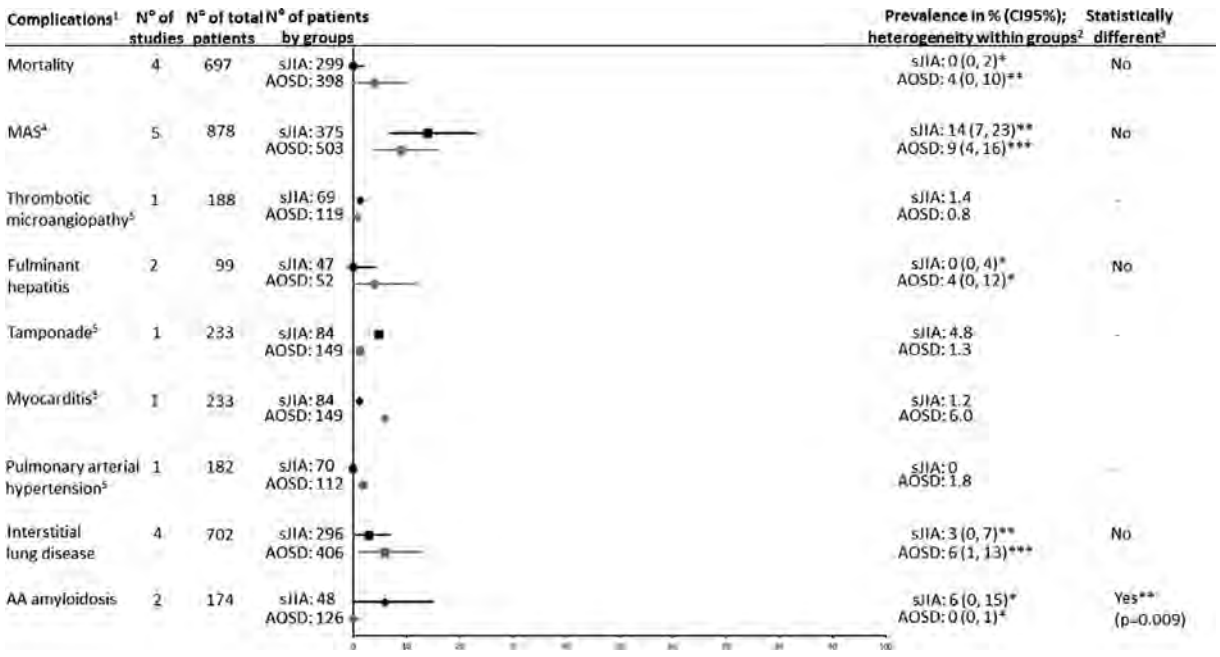

Figure 2. Prevalence (pooled estimates) of complications in sJIA and AOSD. Values are pooled estimates of prevalence (CI95%). For each parameter, prevalence is represented in black for sJIA and in grey for AOSD. 1In Neau 2022, the details of MAS, thrombotic microangiopathy, tamponade, myocarditis and interstitial lung disease for each group (sJIA and AOSD) have been obtained directly from the authors (not published data). 2Heterogenity is summarised visually by asterisks: *, low heterogeneity (I2 <50%); **, moderate heterogeneity (50 < I2< 75%); ***, high heterogeneity (I2> 75%). 3Heterogeneity between groups is statistically different if p<0.05. 4Note that for Neau 2022, the authors reported a total n=26 in the published data, but in their Excel file n=24 (12 in sJIA group, 12 in AOSD group), so we considered n=24 for our meta-analysis. 5 Only one study (Neau 2022) reported on the frequency of thrombotic microangiopathy, tamponade, myocarditis or pulmonary hypertension, and so meta-analysis was not performed for these complications.

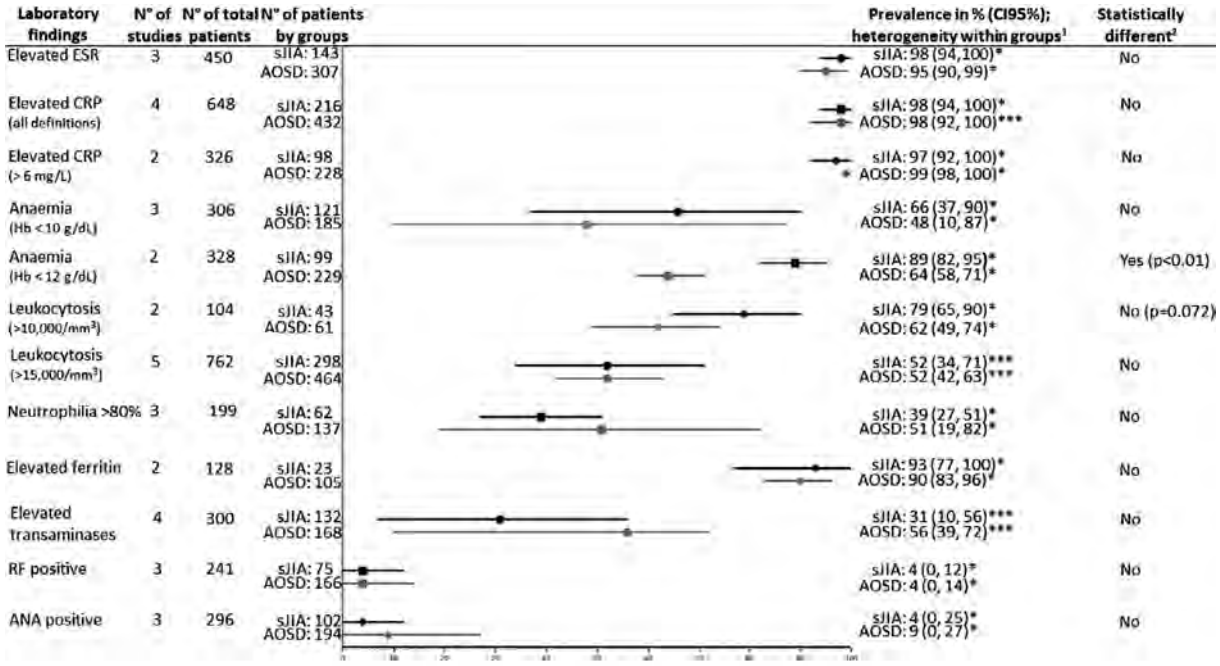

Figure 3. Prevalence (pooled estimates) of modified biological features in sJIA and AOSD Values are pooled estimates of prevalence (CI95%). For each parameter, prevalence is represented in black for sJIA and in grey for AOSD. 1Heterogenity is summarised visually by asterisks: *, low heterogeneity (I2 <50%); **, moderate heterogeneity (50 < I2< 75%); ***, high heterogeneity (I2 > 75%). For details of the I^2s and p-values of each group, please refer to the supplementary material. 2Heterogeneity between groups is statistically different if p<0.05. For details of p-values, please refer to the supplementary material. ANA, antinuclear antibody – CI, confidence interval – Hb, haemoglobin – RF, rheumatoid factor.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Still's disease is a rare inflammatory disorder, these patients have a highly heterogeneous disease according to age of onset, clinical presentation, presence of life-threatening complications, and outcomes. Thus, we aimed at deriving and validating disease clusters in a multicentre, observational, prospective study to stratify these patients.

Methods: Patients included in GIRRCS AOSD-study group and AIDA Network Still Disease Registry were selected to be assessed in this analysis if clinical variables selected for cluster analysis were available [i.e., age, systemic score, erythrocyte sedimentation rate (ESR), C reactive protein (CRP), and ferritin]. A cluster analysis was performed to devise deeper levels of categorization. The k-means algorithm with Euclidean metric was performed, setting 100 random assignments to the cluster seeds. Z-scores were also provided to account for the different units of the selected variables. The Elbow plot was used to devise an adequate number of clusters, avoiding too large choice which could underwent to overfitting. Besides the cluster plot enabled the view of the separation among clusters using the first two principal components. After that a descriptive assessment of the clusters was performed.

Results: By combining clinical selected variables, the K-means clustering assessment provided 4 clusters based on means standardized according to z-scores on 349 patients. The "within" and "between" separation properties were also derived. Within cluster sum of squares (SS) by cluster was estimated: i. cluster 1: 251.69; ii. cluster 2: 283.22; iii. cluster 3: 159.98; iv. cluster 4: 323.76. $SS_{between}/SS_{total}$ was derived to be 41.5%. The latter is not particularly high, but not affected by overfitting phenomena. In fact, the derived clusters showed reasonable "within" and "between" variability properties. After that, randomly sampling 50% of the original records, the same number of clusters was provided by the elbow plot with a similar $SS_{between}/SS_{total}$ of 42.6%.

All clusters mainly presented fever, skin rash, and joint involvement but each one of these has some different clinical features from others. Cluster 1 ("Juvenile/Transitional") was composed by 115 patients distinguished by the lowest value of age and characterized by skin rash myalgia, sore throat, and splenomegaly. Cluster 2 ("Common") included 128 patients identified by the lowest levels of ESR, ferritin, and systemic score; multiorgan manifestations were less frequently observed. Cluster 3 ("Hyperferritinemic") comprised 31 patients categorised by the highest levels of CRP and ferritin, they were characterized by fever and joint involvement. Cluster 4 ("Catastrophic") contained 75 patients derived by the highest values of age and systemic score. Myalgia, sore throat, liver involvement, and life-threatening complications, leading to a high mortality rate, were observed in these patients.

Conclusion: Four patient clusters in Still's disease may be recognized by a multidimensional characterization. Each one of these has some different clinical features from others; cluster 4 was burdened by an increased rate of life-threatening complications and mortality, suggesting a more severe patient group.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Macrophage activating syndrome (MAS) is a rare, potentially fatal complication of systemic juvenile idiopathic arthritis (sJIA) and adult-onset Still's disease (AOSD). MAS (a form of secondary HLH) is associated with overproduction of proinflammatory cytokines, such as interferon gamma (IFNγ). The REAL-HLH study assessed the real-world utilization of emapalumab, an anti-IFNγ antibody, among patients in the US. Treatment patterns and outcomes in patients with MAS secondary to Still's disease and treated with emapalumab are presented.

Methods: A retrospective medical chart review conducted across 33 US hospitals identified patients treated with≥1 dose of emapalumab between November 20, 2018 and October 31, 2021. Data extracted on the subset of patients with MAS secondary to Still's disease from the time of emapalumab initiation to end of data availability, death, or study end (December 31, 2021) were analyzed.

Results: Of the 105 patients identified, 10 had Still's disease (sJIA, n=9; AOSD, n=1). Most patients were female (8/10; 80%) and white (6/10; 60.0%). At diagnosis, mean (SD) age was 5.6 (6.4) years, and 70% (7/10) of patients met the 2016 ACR MAS diagnostic criteria. At diagnosis, the patient with AOSD was 22 years of age. At time of emapalumab initiation, all patients had received or were receiving other HLH-related therapies, including corticosteriods and anakinra; 60% of patients were in the intensive care unit. Emapalumab was mainly initiated to treat refractory (4/10; 40%), recurrent (3/10; 30%), or progressive (2/10; 20%) disease. Median (range) time from diagnosis to emapalumab initiation was 13.0 (1, 101) days, and median (range) treatment duration was 65.5 (25, 367) days. Emapalumab treatment doses are shown in the Table. Median (range) number of emapalumab doses was 15.5 (2, 35). The majority of patients achieved normal levels of ferritin (5/10; 50%), fibrinogen (6/10; 60%), platelets (8/10; 80%), alanine transaminase (8/10; 80%), absolute neutrophil count (9/10; 90%), and absolute lymphocyte count (9/10; 90%) during treatment. Median time to first normalization of these laboratory parameters ranged from 7 to 46 days. Overall survival and 12-month survival probability following emapalumab initiation was 90% (9/10) for patients with Still's disease. One patient died due to uncontrolled viremia, which was deemed by the investigator to be unrelated to the clinical condition for which emapalumab was used.

Conclusion: This is the first study to report real-world treatment patterns and outcomes among patients with MAS secondary to Still's disease treated with emapalumab. A phase 3 clinical trial of emapalumab in patients with sHLH/MAS and underlying rheumatologic disease is ongoing (NCT05001737).

Table. Emapalumab Treatment Doses in Patients With Still's Disease

	Median (range), mg/kg
Starting dose	3.7 (0.9-5.9)
Maximum single dose	5.8 (0.9-6.6)
Cumulative administered dose	53.2 (6.7-171.3)

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) and adult-onset Still's disease (AOSD) are supposed to be age counterparts of the same disease, but no consensus has been reached yet on a common approach to diagnosis and management across ages.

Methods: In May 2022, EULAR (European Alliance of Associations of Rheumatology) and PReS (Pediatric Rheumatology European Society) endorsed a proposal for a joint task force (TF) to develop recommendations for the diagnosis and management of sJIA and AOSD. The TF included 2 convenors (BF, FdB), a methodologist (LC), three fellows (SM, AdM, SB), 25 medical experts and 2 patient research partners (AdB, TW). The TF agreed during a first meeting in September 2022 to cover four main topics: similarity between sJIA and AOSD, novel diagnostic biomarkers, therapeutic targets and strategies, and complications including macrophage activation syndrome (MAS). Four systematic reviews (SRs) were conducted accordingly. Their results were presented to the TF members during a second meeting in March 2023, which enabled the production of overarching principles (OP), recommendations (R) or items for research agenda (RA).

Results: The TF based their recommendation on three OPs (Table): 1) SJIA and AOSD one disease and should be designated by one name, Still's disease, 2) A treat-to-target approach and a shared decision making should be implemented, with the final goal of reaching drug-free remission, and 3) although several innovative therapies are available, MAS should remain a concern for the physician throughout disease evolution.

Table: Overarching principles (OP) and recommendations (R) for the diagnosis and management of children and adults living with Still's disease (formerly called sJIA/AOSD)

		LoE	Strength	A	LoA
OP1	sJIA and AOSD are the same disease, that should be designated by the same unique name, Still's disease (formerly called sJIA / AOSD)	2a	B	100%	9.7
OP2	The treatment targets and the therapeutic strategy should be based on shared decision making between the parents/patients and the treating team. Treatment to Target (T2T) by regularly assessing disease activity and adapting therapy accordingly is important. The ultimate goal is drug-free remission.	2b	C	96%	9.9
OP3	MAS should be detected promptly and treated rapidly.	2b	D	100%	10
R1	To facilitate rapid diagnosis and initiate early treatment, operational definitions should be used to identify patients with Still's disease, - Fever is typically spiking with temperature ≥ 39°C (102.2°F) for at least 7 days, - Rash is transient and coinciding with fever spikes, preferentially involving the trunk. It is typically erythematous (salmon pink), but other rashes (e.g., urticarial) may be consistent with the diagnosis, - Musculoskeletal involvement is usually present with arthralgia / myalgia. Overt arthritis is supportive but not necessary for diagnosis and may appear later, - High levels of inflammation are typically identified by neutrophilic leukocytosis, increased serum CRP and ferritin.	2a	B	94%	9.6
R2	Marked elevation of IL-18 and/or S100 proteins (e.g. calprotectin) strongly supports the diagnosis, and therefore should be measured if available	4	C	90%	8.9
R3	Alternative diagnoses such as malignancies, infectious diseases, other immune-mediated inflammatory diseases and monogenic autoinflammatory disorders should be carefully considered	5	D	83%	9.8
R4	Clinically inactive disease (CID) is defined as absence of Still's disease-related symptoms and normal ESR or CRP. Remission is defined as a period of at least 6 months with clinically inactive disease	5	D	85%	9.4
R5	In order to achieve the ultimate goal (drug-free remission), the following intermediate targets are recommended: - At day 7, resolution of fever and reduction of CRP by > 50%, - At week 4, no fever, reduction of active (or swollen) joint count by > 50%, normal CRP and physician and patient/parent global assessment less than 20 on a 0-100 VAS, - At month 3, clinical inactive disease with glucocorticoids less than 0.1 or 0.2 mg/kg/day, - At month 6, clinical inactive disease without glucocorticoids.	5	D	86%	9.0
R6	NSAIDs are symptomatic treatments and can be used as bridging therapy during the time of investigations. GCs are efficacious; however, long-term use of systemic GCs to achieve and maintain the target must be avoided. The efficacy of IL-1 and IL-6 inhibitors is supported by a high level of evidence and therefore their use should be prioritized.	1b	A	96%	9.8
R7	An IL-1 or an IL-6 inhibitor should be initiated as early as possible when the diagnosis is established.	2b	B	96%	9.4
R8	Maintenance of CID for 3 to 6 months without glucocorticoids should be achieved before initiating bDMARD tapering	5	D	96%	9.2
R9	Severe / life-threatening complications, including macrophage activation syndrome or lung disease, may develop at any point during the disease course. Patients should be actively screened and monitored.	2a	B	100%	9.9
R10	MAS should be considered in patients with persistent fever, splenomegaly, elevated or rising serum ferritin, inappropriately low cell counts, abnormal LFT, intravascular activation of coagulation, elevated or rising serum triglycerides. To facilitate MAS diagnosis, scores (M- or H-score) or classification criteria (MAS 2016 criteria) could be used.	2a	B	100%	9.9
R11	MAS treatment must include high dose glucocorticoid. In addition, treatments including anakinra, ciclosporin and/or IFNγ inhibitors should be considered as part of initial therapy.	2b	B	100%	9.8
R12	Lung disease should be actively screened by search for clinical symptoms (e.g., clubbing, persistent cough, shortness of breath) and pulmonary function tests (pulse oxygenometry, DLCO measurement). High resolution CT-scan should be performed in any patients with clinical concerns.	2b	B	98%	9.7
R13	There is insufficient evidence to withhold first line IL-1 or IL-6 inhibitors in pts with new onset Still's disease and LD risk factors. There is insufficient evidence to withdraw IL-1 or IL-6 inhibitors in pts developing Still's-LD. Based on the current understanding of the pathogenesis, a T cell directed therapy may be considered in patients developing Still's-LD.	2b	B	96%	9.4
R14	Difficult-to-treat patients, those with severe MAS and those with LD should be managed in collaboration with Still's disease expert centers.	5	D	96%	9.9

LoE: Level of Evidence – A: Agreement among the TF experts – LoA: Level of Agreement

Fourteen specific recommendations were issued and are detailed in the Table. Two therapeutic targets were defined: clinically inactive disease (CID) and remission, i.e., CID maintained for at least 6 months. The optimal therapeutic strategy relies on glucocorticoids (GCs) for a maximal duration of 6 months with prioritization of IL-1 or IL-6 inhibitors initiated as early as possible after diagnosis. Life-threatening complications can occur any time during disease course, i.e., at diagnosis, under targeted therapies, and after CID achievement. MAS treatment should rely on high-dose GCs, IL-1 inhibitors, cyclosporin and IFNγ inhibitors. A specific concern rose recently with cases of severe lung disease in children with Still's disease. The

main characteristics are the following: initially mild clinical symptoms including erythematous clubbing, dry cough or shortness of breath; subpleural and septal thickening on CT-scan; interstitial lymphocytic expansion, evidence of T cell activation and features of alveolar proteinosis on biopsy. Risk factors include eosinophilia, increased serum IL-18, history of MAS, exposure to IL-1 or IL-6 inhibitors, and presence of HLA DRB1*15 allele. Adding T-cell directed immunosuppressant seems to be the most appropriate treatment option. Finally, the recommendations emphasized the key role of expert centers, notably those of the RITA European Reference Centers.

Conclusion: These recommendations are the first recommendation for the diagnosis and management of children and adults affected with Still's disease. All OPs and recommendations were agreed by over 80% of the TF experts with a high level of agreement (9 or more).

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Heterozygous loss-of-function *TNFAIP3* mutations cause A20 haploinsufficiency (HA20), an early-onset immune dysregulatory disease[1]. While HA20 was initially described as an inherited form of Behcet's syndrome, it is now known to cause wider range of phenotypes including psoriasis, lymphoproliferation, membranous nephropathy, and liver injury.[2] Prior work suggests that liver disease is seen in only 8% of HA20 patients.[3-7] Contrary to this paradigm, we noted a high prevalence of liver injury when evaluating a cross-section of 41 HA20 patients by virtual consultation. We therefore systematically assessed our cohort of 25 HA20 patients, finding an unexpectedly high prevalence of liver disease with significant morbidity.

Methods: 41 HA20 patients from 5 countries were referred for virtual consultation. 24 of these patents were evaluated at the NIH Clinical Center or at UPMC; 1 subject was deceased at time of assessment but had been evaluated at the referring institution. Clinical laboratory and imaging data were obtained via chart review. Interferon stimulated genes (ISGs) were measured in whole blood (Nanostring) from 15 patients. Fisher's t-test with multiple comparison adjustment (Benjamini-Hochberg) was used to compare patients with vs. without liver disease.

Results: Liver disease was described in 19 virtual consultation patients (44%). 12 (29.3%) were diagnosed with autoimmune hepatitis, 2 of whom (4.9%) died from complications of HA20. Serial laboratory results were available for all 25 retrospectively evaluated patients, abdominal imaging was available for 14, and liver biopsies had been done in 6. 12 patients (48%) had liver disease: 8 (29.2%) were diagnosed clinically, and 4 occult cases were found on abdominal imaging.

Mean age of onset was 11.2. Mutations involved various domains of A20; the entire coding sequence was deleted in 4 patients from 2 families (**Figure 1**). 6 patients were diagnosed with autoimmune hepatitis, 1 had recurrent transaminase elevation (>3x upper limit of normal), 2 had hepatic steatosis, and 3 had isolated hepatomegaly (**Table 1**). Fibroscan scores ranged from 2.7–22.7 kPa. 6 patients had biopsy-proven fibrosis: 4 had cirrhosis and 3 had portal hypertension. ISGs were checked in 9 patients and elevated in 8 (88.8%). 4 patients (33.3%) complete or partial prior response to azathioprine (AZA); 6 (50%) patients had complete or partial prior response to JAK inhibitors (JAKi). Compared with the rest of the cohort (n = 13), patients with liver disease had significantly more cytopenias (**Table 2**). There was a trend towards more immunodeficiency, more autoimmunity, more ISG induction, and fewer Behcet's-like features.

Conclusion: Hepatitis is highly prevalent in HA20 and has a substantial morbidity and mortality. Occult steatosis and hepatomegaly are common; longitudinal studies are needed to determine the significance of these features. We recommend screening all HA20 patients periodically (hepatic panel, ultrasound) and referring patients with abnormal findings to hepatology. In HA20 patients with liver disease, we recommend AZA as a reasonable first-line treatment. JAK inhibitors may be effective in patients with incomplete responses to AZA.

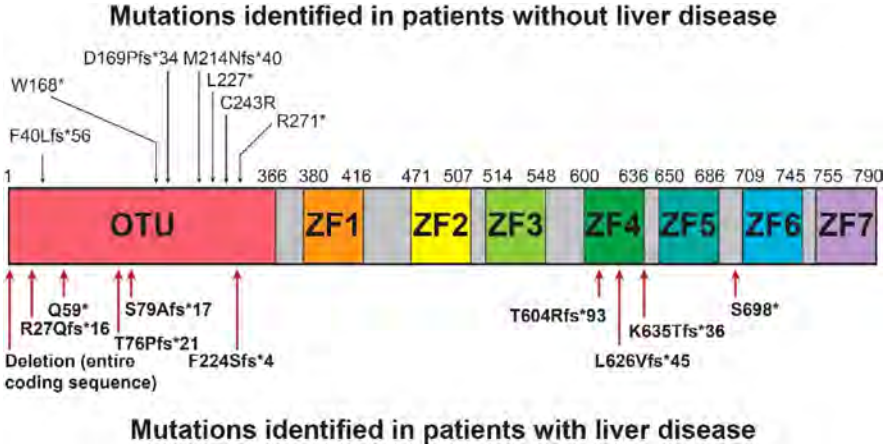

Figure 1. TNFAIP3 mutations in patients with and without liver injury. Liver disease associated mutations involve multiple domains of HA20, including deletion of the entire coding sequence

Table 1. Features of HA20 patients with liver disease. AIH: autoimmune hepatitis, CS: corticosteroids; AZA: azathioprine, ISG: interferon stimulated genes, ITP: Immune thrombocytopenic purpura, JAKi: Janus Kinase Inhibitor, N/A: not applicable, N/C: not checked

Abstract Number: 0763

Sticking the Landing: A 3-Year Qualitative Longitudinal Study on Navigating Transitions in Pediatric Rheumatology Fellowship

Sarah Bayefsky[1], Hannah Anderson[2], Dorene Balmer[2] and Jay Mehta[2], [1]University of Pennsylvania/Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Professional Education
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Transitions present many challenges for medical trainees, and a lack of preparedness for these transitions is associated with negative outcomes, including higher rates of burnout (Westerman et al., 2013). Fellowship program directors are tasked with guiding trainees as they transition from residency to fellowship and from earlier to later years of fellowship. Yet little is known about what facilitates successful transitions. A longitudinal study is well-poised to explore transitions and to arm program directors with the knowledge to support fellows through these vulnerable periods.

Methods: We conducted a qualitative longitudinal study of 6 pediatric rheumatology fellows, each at a different institution in the United States that varied by size, geography, and hospital setting. Consistent with qualitative longitudinal research methodology (Balmer et al. 2021), we completed in-depth, recursive interviews of the fellows annually during their three years of training. We created inductive codes from patterns in the data and clustered codes into more abstract themes. We organized the findings into an explanatory model analogized to a Rubik's cube, drawing from multiple and multidimensional transitions (MMT) theory (Jindal-Snape & Hannah, 2014), which posits that individuals inhabit multiple, non-static domains (for

Figure 1. The search for a faculty position ("job search") represents the culmination and merging of each theme that influenced the fellows' transitions into and through fellowship.

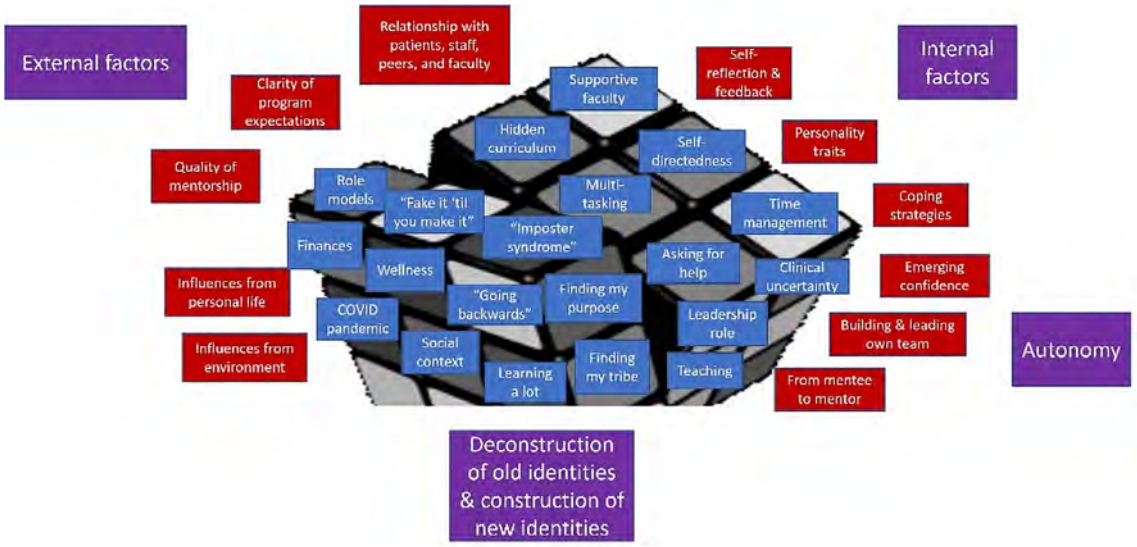

Figure 2. Explanatory model of the factors influencing the successful transitions of pediatric rheumatology fellows, based on multiple and multidimensional transitions (MMT) theory. The blue items are examples of codes; the red items are sub-themes; and the purple items are themes. A transition related to any one domain (code, sub-theme, or theme) prompts additional transitions in other domains.

example, distinct and evolving roles at work and at home) and that a transition in one domain triggers transitions in other domains.

Results: The successful transitions of pediatric rheumatology fellows were facilitated by: (1) deconstructing old identities and constructing new ones, (2) navigating internal and external factors, and (3) acting with increasing autonomy. Fellows who were initially plagued by imposter syndrome later expressed excitement about their integration into the rheumatology community. Internal factors included personality traits; coping strategies; and self-reflection and feedback. External factors included influences from personal life, professional life, and the environment; close relationships (with patients, peers, staff, and superiors), clarity of program expectations, and quality of mentorship all play roles. For fellows, recognizing their emerging confidence, building and leading their own teams, and shifting from mentees to mentors allowed for the development of graded autonomy. Ultimately, the search for a faculty position ("job search") in the final year of fellowship requires the assembling of new identities, navigation of internal and external factors, and autonomous actions (Figure 1).

Conclusion: Our qualitative longitudinal study closes a gap in the literature by elucidating successful transitions for pediatric rheumatology fellows. MMT theory provides a theoretical framework to explain the interplay of the many factors facilitating these transitions (Figure 2). Program directors can guide fellows through transitions and "stick the landing" in the job search by directly managing external factors related to professional life, aiding in the development of autonomy and of skills that mediate the impact of internal factors, and supporting fellows through challenges in their personal lives.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Professional Education
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: To evaluate the evolving impact of RheumMadness, an online educational tournament of competing rheumatology concepts, over three years by describing changes in participant engagement, learner experience via the Community of Inquiry (CoI) framework, and incorporation of RheumMadness into local programs.

Methods: RheumMadness 2021, 2022, and 2023 presented single-elimination brackets of 16, 16, and 22 concepts, respectively, represented by scouting reports written by volunteer groups. During the 2021 and 2022 seasons the RheumMadness leadership team selected the concepts, whereas in 2023, authors selected the concepts. Participants submitted brackets predicting matchup outcomes, listened to the RheumMadness podcast, and discussed concepts on social media.

Table 1: Direct and self-reported participant characteristics and engagement with each curricular element in RheumMadness. Direct metrics (left columns) are derived from bracket and scouting report submissions, Google Analytics, Buzzsprout.com, and Keyhole as indicated. Self-reported data are derived from a survey distributed via social media, newsletter, and email. * Direct metrics of participant training level and country of residence are not available for 2021. † Data from Google Analytics from the time the reports were posted until tournament completion each year of the tournament. Scouting report views are not available in 2022 as the reports were hosted on an external website. ‡ Data from Buzzsprout.com hosting service from July through April each season. § Data from Keyhole.co, measuring engagement (primarily on Twitter) with the hashtag #RheumMadness from January through April of each tournament year.

Web-based analytics tracked engagement. A Qualtrics survey was distributed each year to assess self-reported engagement and CoI presences. The 2023 survey asked additional questions about incorporation of RheumMadness content into local programs. Prism v.9.3.1 was used to analyze normalized and non-normalized data with one-way ANOVA and the Kruskal-Wallis test by ranks, respectively.

Results: Participation increased annually from 105 bracket submissions in 2021 to 142 in 2023 (**Table 1**). Similarly, the number of authors contributing to a scouting report grew from 52 in 2021 to 123 in 2023. Scouting report views grew from 92 per report in 2021 to 130 per report in 2023, and over 60% of participants reported reading at least half of the scouting reports all three years. Despite an increase in direct metrics of social media engagement (users, posts, and engagements) from 2021 to 2023, there was a non-significant decrease in self-reported reading (p= 0.7531) or posting (p= 0.2560) related content on social media. Across all three years, over half of respondents agreed or strongly agreed with CoI prompts related to each cognitive, social, and teaching subdomain (**Figure 1**). Within the cognitive presence, there was a significant increase in knowledge integration in 2023 versus prior years (p= 0.04). Other subdomains did not change significantly over time. In 2023, 26/56 (46%) of respondents reported that their local training program incorporated RheumMadness content in some way, primarily by creating a scouting report. Some programs also reviewed RheumMadness content in a didactic session, hosted a journal club, or created quizzes (**Figure 2**). Further curricular integration at the undergraduate and graduate medical education may be warranted, as RheumMadness increased interest in rheumatology for 23/26 (88%) medical student and resident respondents.

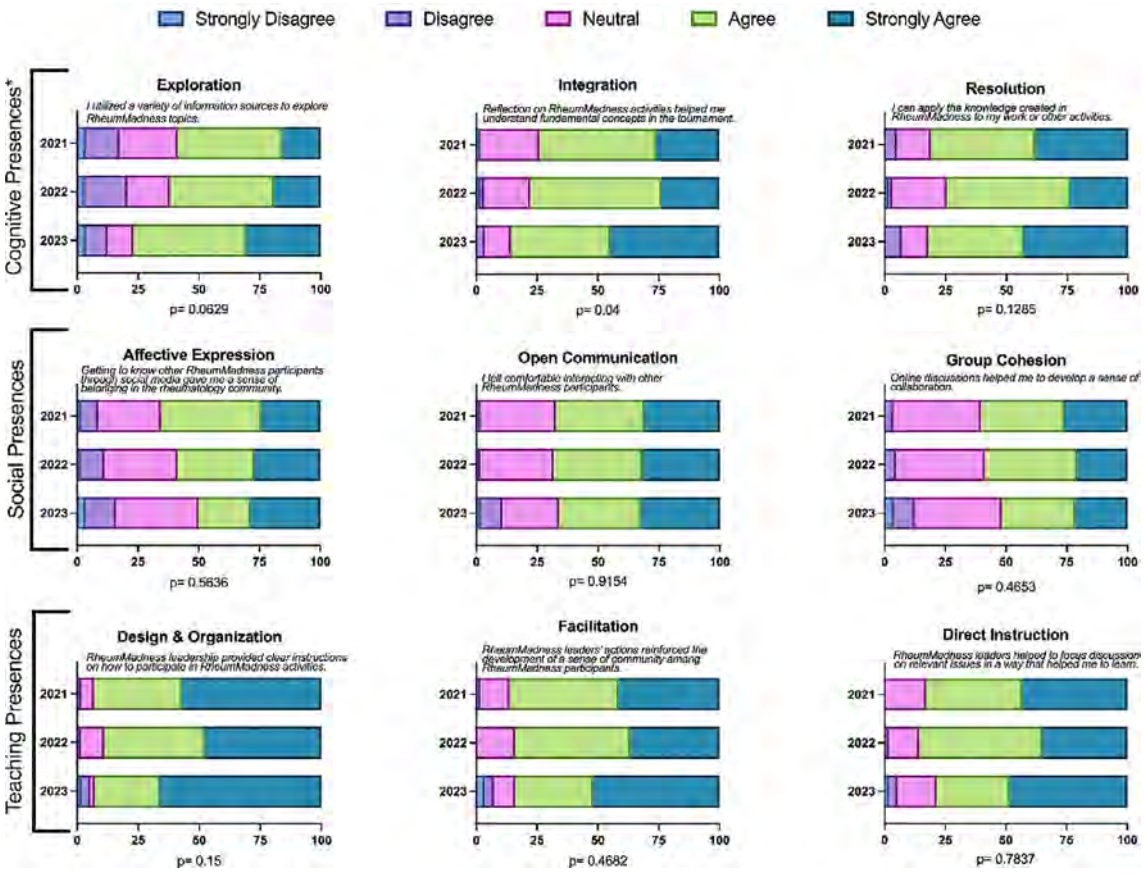

Figure 1: Changes in agreement with Community of Inquiry (CoI) presences across time. Participant responses to four* cognitive, three social, and three teaching presences (written in italics) on a 1-5 point Likert scale during the 2021, 2022, and 2023 seasons. The proportion of respondents selecting a given level of agreement are represented by size of colored bar. Group averages by year were compared using one-way ANOVA or the Kruskal-Wallis test by ranks for normalized or non-normalized data, respectively, with p values represented below corresponding graph. *The triggering presence (I can apply the knowledge created in RheumMadness to my work or other activities) was omitted from representation of cognitive presences due to space; participants demonstrated stable (p= 0.7075) agreement.

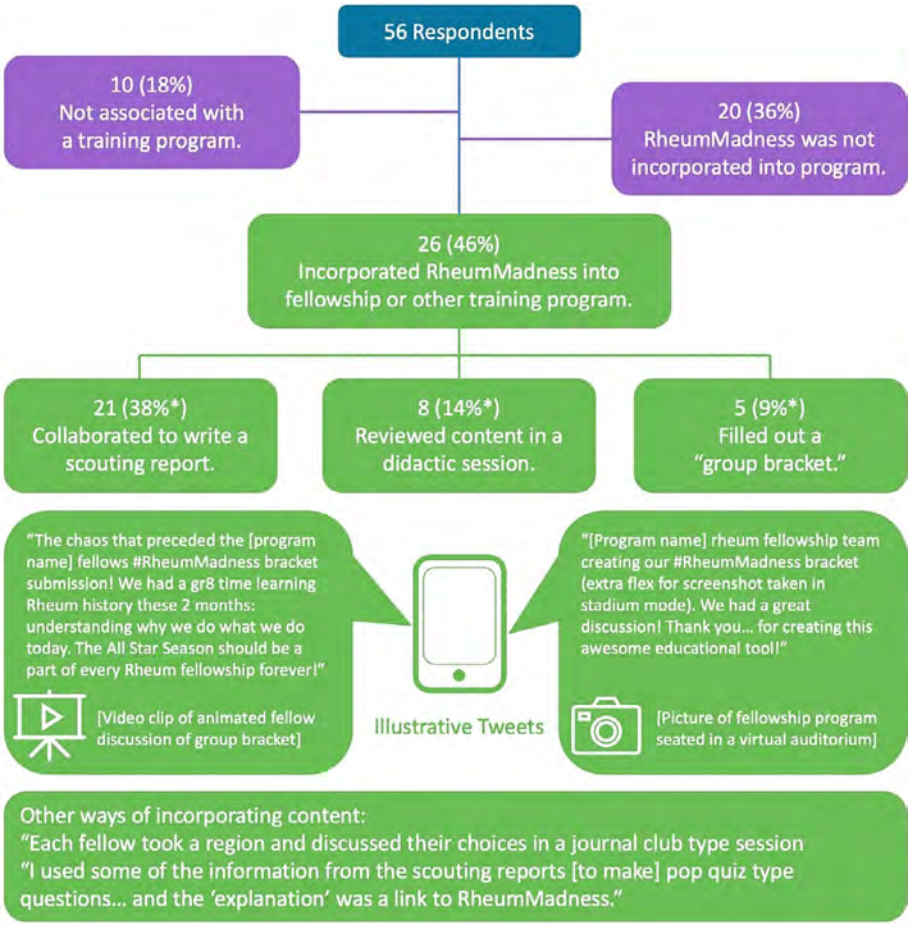

Figure 2. Incorporation of RheumMadness into fellowship or other training program amongst 56 survey respondents in 2023. Respondents could select more than one response option. Illustrative tweets demonstrating incorporation of #RheumMadness were selected by the leadership team. *Percent reflects the proportion of all respondents (n= 56) selecting a response.

Conclusion: Growth in engagement metrics and stable positive self-reported CoI experience suggests that RheumMadness continues to foster an online rheumatology community of learning. Enhanced knowledge integration in 2023 suggests effective improvement efforts, such as team selection by scouting report authors. Incorporation of RheumMadness content into rheumatology training programs and positive impact on early trainees indicates utility as an educational and recruitment tool, with opportunity for expansion as a novel curricular element for graduate and continuing medical education alike.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Professional Education
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: RheumMadness is an online tournament of rheumatology concepts that has been shown to engage learners using the Community of Inquiry (CoI) framework. theMednet is another online educational platform in which physician users submit clinical questions that are answered by experts in the field in an interactive question and answer forum. We sought to evaluate the educational impact of integrating content and engagement between these two independent learning platforms.

Methods: The 2023 RheumMadness tournament consisted of 22 teams of competing concepts that were presented as scouting reports written by trainees and rheumatologists. On the day that scouting reports were published, 7 clinically-focused questions relating to specific RheumMadness teams (6 curated by theMednet team, 1 user-submitted) were posted on theMednet along with expert responses. Leadership teams from both RheumMadness and theMednet publicized updates about each other's initiatives on their respective platforms. At the conclusion of the tournament, all participants, excluding leadership team members, were invited to complete a voluntary survey that assessed engagement in RheumMadness and theMednet as well as educational impact using the CoI framework. Surveys used Likert scores (1=very dissatisfied/strongly disagree, 5=very satisfied/strongly agree). Engagement in RheumMadness content on theMednet was examined and compared to that of its 5 most recent comparable educational programs. Statistical analyses were performed using Chi-square tests and unpaired T tests as appropriate.

Table 1. Questions associated with RheumMadness teams on theMednet. DMARD: disease-modifying antirheumatic drug; ANA: antinuclear antibody; ANCA: antineutrophil cytoplasmic antibody; ULT: urate-lowering therapy; SLE: systemic lupus erythematosus; HCQ: hydroxychloroquine; RA: rheumatoid arthritis; HAQ: Health Assessment Questionnaire; CPPD: calcium pyrophosphate deposition disease; NSAIDs: nonsteroidal anti-inflammatory drugs; MSU: monosodium urate.

theMednet Question	Associated RheumMadness Team	Views	Poll Voters
Do you use conventional DMARDs aside from methotrexate to prevent anti-drug antibody development for patients on infliximab?	Etanercept + MTX	521	77
How do you approach follow up in pts with isolated +ANA, but no current clinical signs or sx of SLE?	Abs before SLE	624	N/A
Is there a role for monitoring serum ANCAs to assess ANCA associated vasculitis disease activity?	Pathogenic ANCA	469	80
Are there patients in whom you would avoid initiating of ULT during acute gout flare?	ULT During Flare	278	N/A
Do you ever consider discontinuing hydroxychloroquine SLE patients in longstanding remission except in cases of overt toxicity?	HCQ Withdrawal	627	64
What target do you utilize in clinical practice for defining disease remission in RA?	HAQ	244	73
Do you use IL-1 inhibitors to prevent flares of gout or CPPD in patients who experience flares despite prophylaxis with colchicine, NSAIDs, and/or low-dose prednisone?	MSU & NLRP3	451	53

Results: RheumMadness-related questions posted on theMednet and associated engagement are shown in **Table 1**; views per question ranged from 244 to 627, and number of poll voters per question from 53 to 80. When compared with the 5 most recent comparable educational programs on theMednet (**Table 2**), RheumMadness questions reached more users and institutions, and RheumMadness questions had significantly more views than questions from other educational programs (mean 459 vs. 249 views/question, respectively). Among RheumMadness participants, demographics and engagement with other RheumMadness curricular elements were similar between participants who engaged with theMednet content (n=24) and non-engagers (n=34), but CoI engagement was significantly higher in the overall cognitive presence and 3 of its components as well as the overall social presence among theMednet engagers (**Table 3**). Participants who engaged with theMednet Q&A reported that it contributed positively to the educational experience of RheumMadness (mean Likert score 4.25).

Conclusion: Establishing a collaboration between RheumMadness and theMednet strengthened learning in both programs. In addition to an effect of the collaboration, engagement with RheumMadness-related questions compared with previous educational programs on theMednet may have also been enhanced by the growing overall number of users over time and more varied nature of the topics presented in RheumMadness compared with previous programs. Collaborations

Table 2. Engagement with RheumMadness questions compared with the five other most recent educational programs on theMednet. *Values for five educational programs combined and reported as mean (SD) unless noted otherwise. Other educational programs were journal clubs consisting of questions relating to recent landmark publications with answers from manuscript authors and other experts.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Professional Education

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Ultrasonography has been validated as a diagnostic tool for giant cell arteritis (GCA). There is a need to develop training resources, because the glucocorticoid responsiveness of abnormalities of affected vessels and the uun-predictability and relative scarcity of presentation makes it challenging to predictably use real patients for educational

purposes. To address this, we have developed cost-effective ultrasound phantoms using high-resolution 3D printing techniques [1]. The aim of this study is to validate these models within the subgroup on large vessel vasculitis of the Outcome Measures in Rheumatology (OMERACT) ultrasound working group.

Methods: Normal and pathological phantoms of the axillary (AA) and temporal artery (TA) were developed and printed using a Formlabs SLA 3D printer. The phantoms were then embedded in a special gelatine as eight sets of three (AA) or two (TA). Participants from twelve European countries were provided with eight sets of both AA and TA phantoms. The phantoms were evaluated individually in a blinded fashion using a predefined protocol and the OMERACT definitions of abnormalities in GCA [2], [3]. The artificial intima-media thickness (IMT) of each vessel phantom was measured at most prominent site in mm, preferably on the distal wall [4]. The phantoms were classified by each investigators normal (AA&TA), acute (AA&TA), chronic (AA only), or none of the above (AA&TA). Descriptive parameters and interrater-reliability were calculated. Furthermore, we conducted a one-way analysis of variance.

Results: The phantoms were correctly classified in 87% of cases resulting in a Fleiss' kappa of 0.80 (95%CI 0.78-0.82). The published cut-off values for normal and pathological IMT were met, with the exception of the parietal branch of the TA [5]. Excellent agreement among participants was demonstrated for IMT measurements, with an intraclass correlation coefficient (ICC 1.1) of 0.98 (95% CI 0.98-0.99). The results of IMT measurements are shown in Table 1. A one-way analysis of variance (ANOVA) revealed a significant difference in average IMT between pathological and healthy phantoms for both AA and TA. Detailed results of the ANOVA, divided by the different arteries, are presented in Table 2.

Table 1 – Results of the IMT measurements and Interrater-reliability Notice, that there are no chronic phantoms of temporal arteries (SD: standard deviation; ICC: intra-class correlation coefficient; CI: confidence interval)

Vessel	Measurements	Mean (SD) Normal	Mean (SD) Acute	Mean (SD) Chronic	ICC 1.1 (95%CI)	Fleiss Kappa (95%CI)
Common superficial temporal arteries	416	0,35 (0,10)	0,72 (0,14)	-	0,99 (0,98-0,99)	0,70 (0,68-0,73)
Frontal rami	416	0,32 (0,09)	0,63 (0,11)	-	0,99 (0,98-0,99)	0,82 (0,79-0,85)
Parietal rami	416	0,35 (0,10)	0,66 (0,08)	-	0,98 (0,97-0,99)	0,85 (0,82-0,87)
Axillary arteries	558	0,66 (0,14)	1,26 (0,19)	1,19 (0,27)	0,96 (0,93-0,98)	0,75 (0,73-0,77)

Table 2 – Results of the analysis of variance The table shows the results of the analysis of variance along with their significance (p-value) and their effect size (η2) (p-value: probability value; η2: partial eta square; df: degrees of freedom; CI: confidence interval)

Vessel	F-value	df1, df2	p-value	η^2 (95%CI)
Common superficial temporal arteries	501,812	2; 413	<0,001	0,71 (0,67-0,74)
Frontal rami	526,936	2, 413	<0,001	0,71 (0,66-0,74)
Parietal rami	599,231	2, 413	<0,001	0,78 (0,74-0,81)
Axillary arteries	37,499	3, 518	<0,001	0,62 (0,57-0,66)

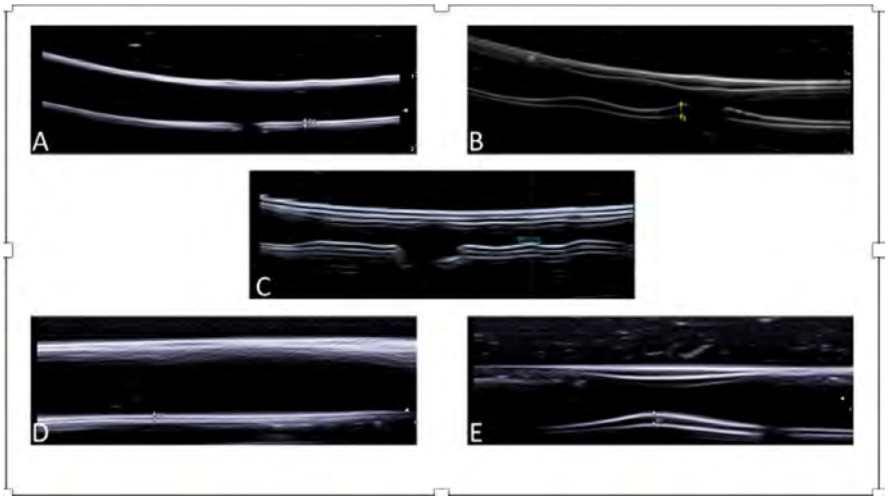

Figure 1 – Ultrasound of the phantoms A=Normal axillary artery; B=Axillary artery with acute GCA pathology; C=Axillary artery with GCA chronic pathology; D=Normal temporal artery; E=Temporal artery with acute GCA pathology

Conclusion: Our novel ultrasound models accurately represent the normal state and pathology of GCA adhering to the OMERACT definitions and cut-off values for IMT. There was a high agreement among investigators to correctly classify the models and good reliability with measurement of artificial IMT. This is also a first step in the evaluation of the phantom for educational purposes.

Abstract Number: 0767

Current Musculoskeletal Ultrasound Practices of 12 Years of past Participants of a 10-Months Rheumatology Ultrasound Training Program (Ultrasound School of North American Rheumatologists)

Midori Nishio[1], **Fawad Aslam**[2], Sonja Ziniel[3] and Eugene Kissin[4], [1]John Muir Specialty Medical Group, Walnut Creek, CA, [2]Mayo Clinic, Arizona, Scottsdale, AZ, [3]Univ of Colorado School of Medicine and Childrens Hospital Colorado, Aurora, CO, [4]Boston University, Newton, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Professional Education

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Musculoskeletal ultrasound (MSKUS) is an integral part of rheumatology training. The Ultrasound School of North American Rheumatologists (USSONAR) has been a leader in rheumatology MSKUS training for fellows (Fundamentals in Musculoskeletal Ultrasound (FMU) track) and practitioners (Train the Trainer (TTT) track). Limited data exits regarding the practices of rheumatology US professionals trained through USSONAR. The survey aimed to determine the current use of MSKUS for diagnostic and/or procedural MSKUS among past participants of USSONAR's training program and explore barriers to successful implementation.

Methods: A 28 question survey was sent in September 2022 to 482 participants of the USSONAR FMU/TTT courses who completed a final examination (2009-2020). Each respondent was given a unique identifier matched to their exam scores and total number of practice studies submitted in their training year.

Results: After removing 108 non-deliverable emails, the survey received a response rate of 105/374 (28%). Participant track influenced survey participation, 31.5% in the TTT versus 19.5% in the FMU, (p=0.006). Analyses using background variables such as FMU vs. TTT status, year of graduation, number of studies submitted or exam scores did not show evidence of nonresponse bias.

The median years practicing MSKUS was 6, with 70.9% practicing in academic medical centers. 71% of the respondents held a MSKUS certification. 81.9% and 19.8% were adult and pediatric rheumatologists respectively. 86.7% performed and/or interpreted diagnositc MSKUS themselves and 81% performed their own procedures (Figure1). 58.8% billed for at least 50% of diagnostic studies and 78.8% of procedural studies.

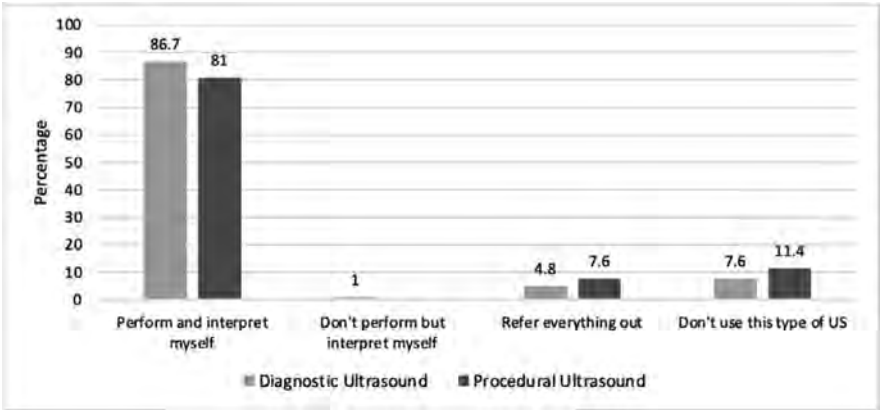

Figure 1: Performing Diagnostic or Procedural Ultrasound (n=105)

Table 1: Reasons for Not Billing or Billing Less than 50% of the Time for Diagnostic or Procedural Ultrasound (multiple selections possible)

Reasons	Diagnostic Ultrasound (n=37)	Procedural Ultrasound (n=18)
	% (n)	
Lack of time to document my study	43.2 (16)	44.4 (8)
Lack of certification	24.3 (9)	22.2 (4)
Poor reimbursement for the amount of effort	35.1 (13)	38.9 (7)
Concern over legal liability	32.4 (12)	22.2 (4)
Other	32.4 (12)	22.2 (4)

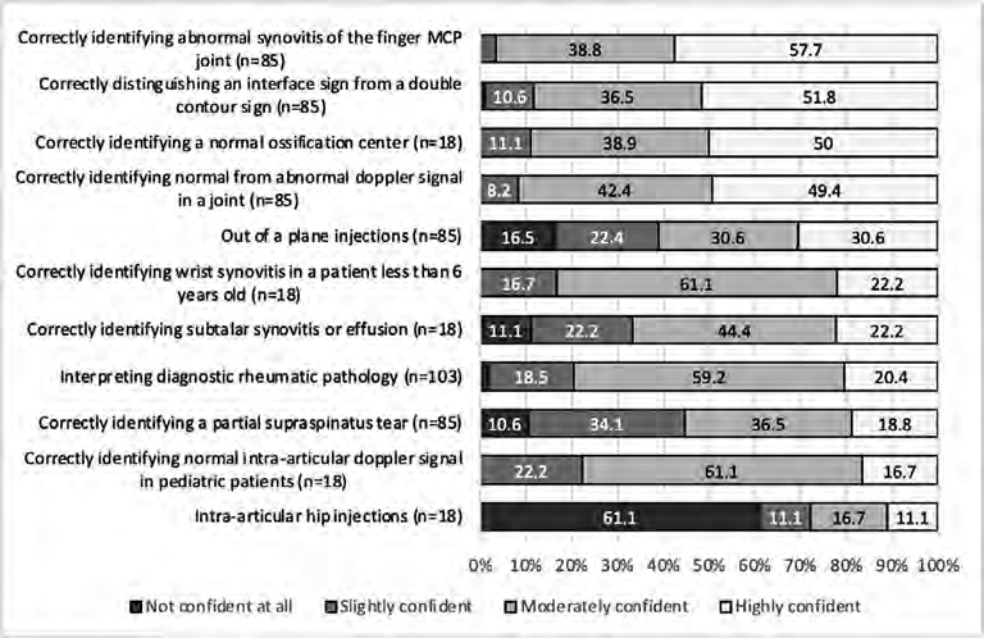

Figure 2: Confidence of adult providers and pediatric providers overall and in scenarios 2 years after participation in the USSONAR FMU/TTT Course

The leading reason for not personally doing diagnostic US was lack of administrative support.

The leading reason for not personally doing procedural MSKUS was lack of time (Table 1).

When asked to rate their confidence in a set of MSKUS skills 2 years after their USSONAR course, the majority of adult rheumatologists felt moderately to highly confident in their skills, similarly the vast majority of pediatric rheumatologists felt moderately confident in a set of pediatric MSKUS skills (Figure 2). Adult clinicians were least confident about performing out of plane injection and identifying partial supraspinatus tendon tears, while pediatric clinicians were least confident performing intra-articular hip injection.

Conclusion: USSONAR training provided the majority of FMU and TTT participants the knowledge and skills to use and bill for MSKUS in practice. Participants had confidence in performing diagnostic and procedural studies and also passed a certification exam in MSKUS. Most participants agreed that USSONAR training made them a better rheumatologist.

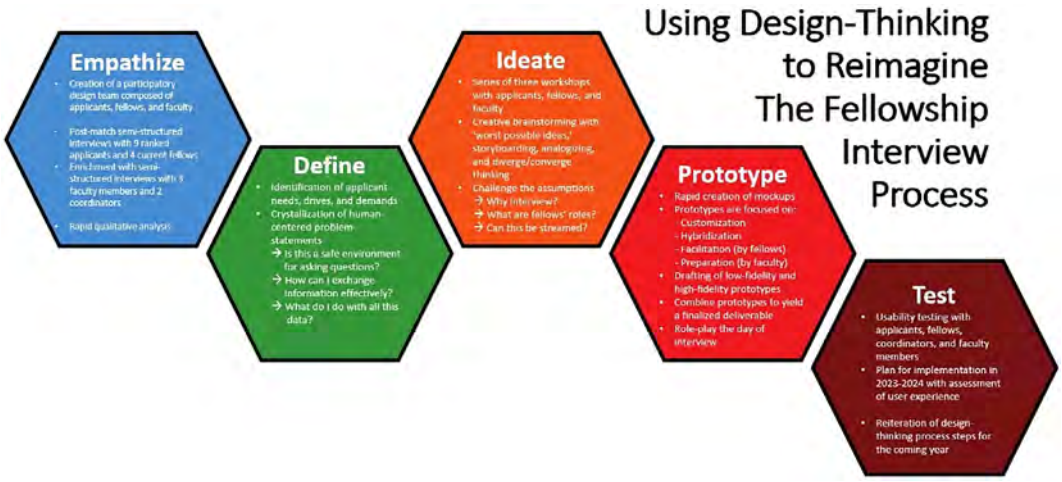
Abstract Number: 0768

Using Participatory Design-Thinking Process to Create a More Applicant-Centered Rheumatology Fellowship Interview Experience

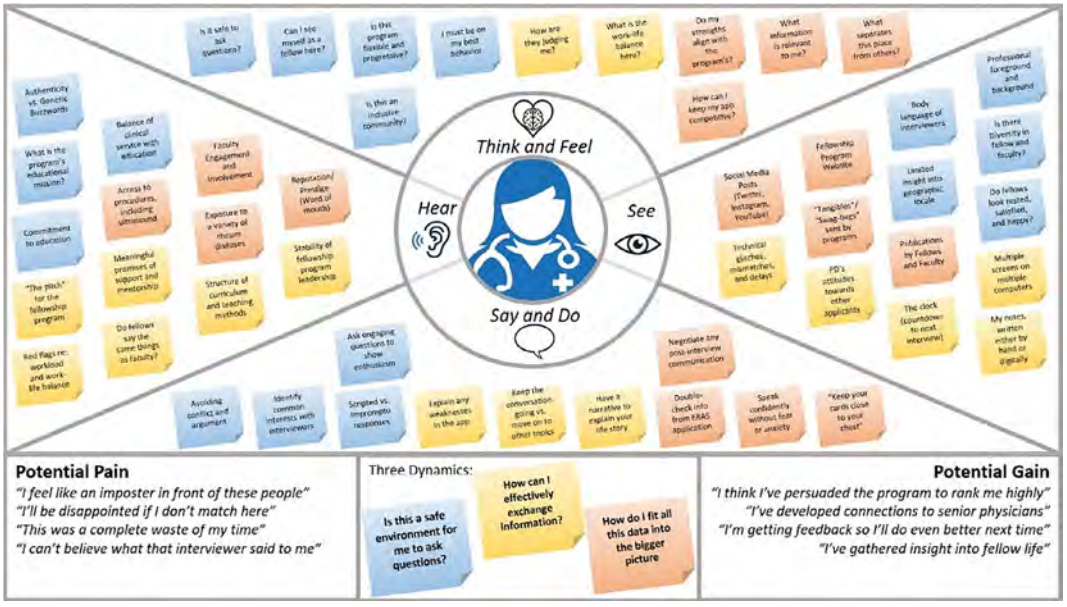
Alick Feng, Ayesha Iftekhar, Ruoning Ni, Gatra Gheriani and **Bharat Kumar**, University of Iowa Hospitals and Clinics, Iowa City, IA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Professional Education
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

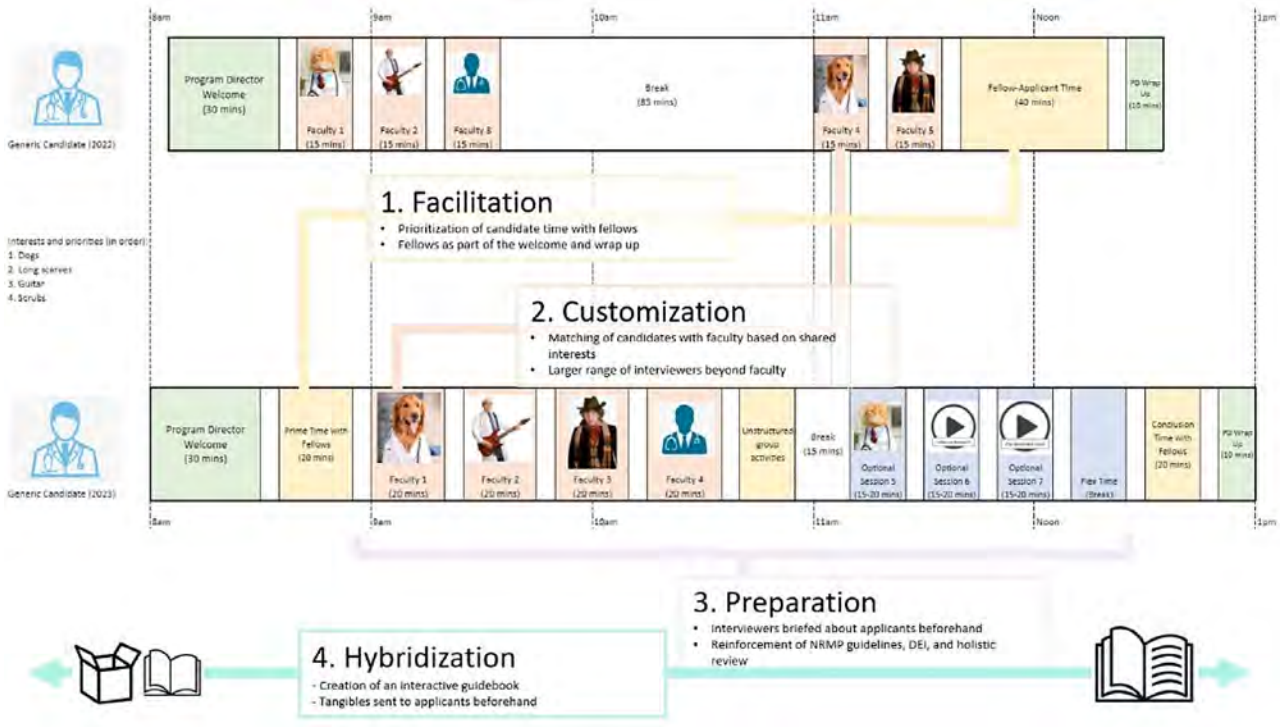
Background/Purpose: Design-thinking is a creative problem-solving process used to better understand users' needs and experiences so that a product or service can be improved. Its emphasis on empathy, iterative prototyping, and participatory collaboration make it an ideal methodology for innovation in medical education. We apply this framework to refine the virtual rheumatology fellowship interview process, a relatively new and ad hoc development emerging as a necessity during the COVID pandemic, so that virtual interviews can become more applicant-centered.



Design-Thinking Principles were employed in an iterative fashion through the five steps in order to create a final set of prototypes for testing



Interviews with 9 fellowship candidates revealed a variety of perceptions and observations that were organized into this empathy map. Three major themes predominated: (1) Is this a safe environment for me to ask questions? (2) How can I effectively exchange information? and (3) How do I fit all this data into the bigger picture?



As a result of the design-thinking process, four prototypes were conceived emphasizing (1) Facilitation, (2) Customization, (3) Preparation, and (4) Hybridization.

Methods: This educational quality improvement project uses a design-thinking framework to identify opportunities and challenges for rheumatology fellowship applicants. The investigators use the 5-step process (Empathize, Define, Ideate, Prototype, Test) and incorporate rapid qualitative analysis of semi-structured interviews to innovate the interview experience. The iterative and collaborative nature of this process has empowered participants to co-design an applicant-centered interview experience.

Results: Interviews with fellowship applicants (n=9), fellow physicians (n=4), and faculty members (n=3) identified three major dynamics of the interview process: (1) Is it a safe environment to ask questions? (2) how do I exchange information effectively? and (3) how do I fit all this data into the bigger picture? Creative brainstorming techniques at a series of 3 workshops yielded 4 prototypes emphasizing customization, hybridization, facilitation, and preparation. A finalized applicant-centered interview template was devised in preparation for the 2023-2024 application season.

Conclusion: Design-thinking has yielded insights into three important dynamics that drive applicant experiences. These insights allow for a redesign of processes so that virtual interviews can be more applicant-centered. This framework allows for further iterations and modifications as the needs of applicants and programs evolve over time.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: RA-ILD

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is an extra-articular manifestation of RA that causes substantial morbidity and mortality. Although some clinical and genetic risk factors (predominantly *MUC5B* rs35705950) have been identified, there are no routinely used tools for risk stratification. We sought to develop a risk model for ILD in a large, multicenter RA cohort.

Methods: Participants were enrollees in the Veterans Affairs Rheumatoid Arthritis (VARA) registry, a multicenter prospective cohort of U.S. Veterans with RA. Participants were genotyped for single nucleotide polymorphisms (SNPs) associated with idiopathic pulmonary fibrosis, including *MUC5B* rs35705950 and 11 other SNPs. ILD was validated through systematic medical record review of provider diagnosis, imaging, and biopsy findings. A meta-analytic odds ratio for ILD was calculated for each SNP by pooling results from VARA (N=2386; N=224 ILD) and Juge et al. (N=514; N=272 ILD) (**Table 1**). A genetic risk score (GRS) was computed from variant alleles weighted by their effect size with ILD, using backwards predictor selection. The GRS was combined with established clinical risk factors (age, sex, smoking history, DAS28-CRP, and RF positivity)

Table 1. Genotype frequencies for each allele and pooled odds ratio (OR) for associations with interstitial lung disease (ILD).

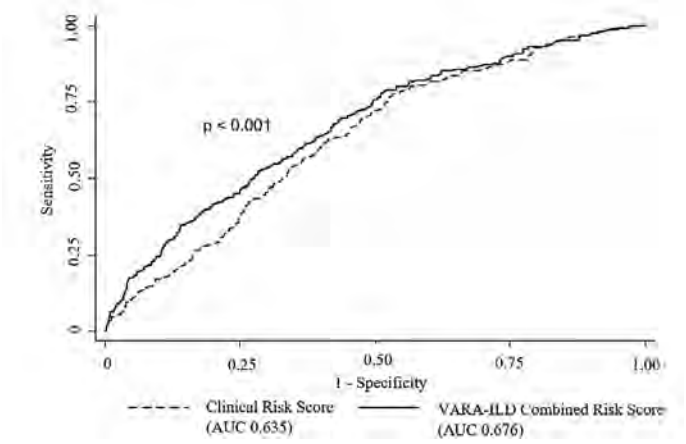
Table 2. VARA-ILD Combined Risk Score Model.

Variable	Odds Ratio (95% CI)	P Value	Beta Coefficient
VARA-ILD GRS	2.64 (1.92, 3.62)	<0.001	0.9706451
Age, per 1-yr increase over age 69.5 years	1.03 (1.01, 1.04)	0.001	0.0253936
Male sex	1.37 (0.75, 2.50)	0.31	0.3115712
Smoking history (ever)	1.50 (1.00, 2.23)	0.05	0.4026723
DAS28-CRP (mean)	1.27 (1.12, 1.44)	<0.001	0.2362551
RF positive (≥15 IU/mL)	1.84 (1.23, 2.75)	0.003	0.6091225
Model constant			-4.240544

Abbreviations: interstitial lung disease (ILD), RA (rheumatoid arthritis), CI (confidence interval), DAS-28-CRP (disease activity score with 28 joints and c-reactive protein), RF (rheumatoid factor), single nucleotide polymorphism (SNP)

Figure 1. Comparison of ROC curves for clinical risk factors and VARA-ILD Combined Risk Score model for presence of RA-ILD.



Abbreviations: ROC (receiver operating characteristic), ILD (interstitial lung disease), AUC (area under the curve), P value calculated via nested likelihood ratio test.

using logistic regression to generate the VARA-ILD Combined Risk Score. Internal validation and calibration were completed using bootstrapping techniques to address over-fitting and determine a shrinkage-corrected performance. Model performance was assessed using the area under the receiver operating curve (AUC), and models were compared via nested likelihood ratio tests as well as Akaike and Bayesian information criterion (AIC, BIC).

Results: Of 2,386 participants (89% male, mean age 69.5 years), 9.4% had ILD. VARA-ILD Combined Risk Score containing the GRS (based on 5 SNPs) and clinical factors (**Table 2**) outperformed clinical risk factors alone in discriminating ILD (AUC 0.686 vs. 0.635, p< 0.001; **Figure 1**). Following internal validation and bootstrapping, the shrinkage-corrected performance for combined and clinical-only models was 0.675 (95% CI 0.635, 0.709) and 0.623 (95% CI 0.584, 0.651). VARA-ILD Combined Risk Score also outperformed a model including clinical factors and the *MUC5B* rs35705950 promoter variant alone (AUC 0.648 [95% CI 0.612, 0.681]) based on AIC (1408 vs. 1429) and BIC (1448 vs. 1469). Demonstrating its potential role in ILD screening, utilizing a risk score cut-point of 0.05 (sensitivity 90%) would eliminate 25% (N=582) of participants from undergoing low-yield ILD diagnostic testing.

Conclusion: The VARA-ILD Combined Risk Score, including multiple genetic risk variants, discriminated ILD in a large, multicenter RA cohort better than established clinical risk factors alone. These results demonstrate the potential utility of genetic risk scores in RA-ILD identification and will support further investigation into individualized risk stratification and screening.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: RA-ILD

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Matrix metalloproteinases (MMPs) are enzymes involved in extracellular matrix remodeling that have been implicated in the pathogenesis and progression of rheumatoid arthritis (RA) and interstitial lung diseases (ILD). We aimed to assess the associations of plasma MMPs with the presence and severity of RA-ILD, as well as RA-ILD sub-groups defined by imaging and genetic risk.

Methods: We performed a cross-sectional study of participants with/without ILD in the Veterans Affairs Rheumatoid Arthritis registry, a multicenter prospective cohort of U.S. Veterans with RA. Participants who developed ILD after registry enrollment were excluded. Prevalent ILD diagnoses were systematically validated through medical record review of clinical diagnoses, imaging findings, and biopsy reports. Imaging pattern was classified as usual interstitial pneumonia (UIP) when documented in the clinical read or if honeycombing was present vs. non-UIP for all others. Plasma MMP-1, -3, -7, and -9 concentrations (MesoScale Discovery platform) and the *MUC5B* rs35705950 promoter variant (Illumina Infinium Global Screening Array) were measured on plasma and DNA samples, respectively, collected at enrollment. MMP values were log-transformed, standardized, and categorized into quartiles. The most proximate forced vital capacity (FVC) result within three years of registry enrollment was collected from the electronic health record. Associations of MMPs with prevalent RA-ILD were assessed with logistic regression models adjusted for age, sex, race, smoking status, anti-CCP positivity, and RA disease activity. Associations of MMP values with FVC were assessed with Pearson's correlation coefficient. MMP values were compared across *MUC5B* genotypes (positive vs. negative) and ILD patterns using Kruskal-Wallis tests. In sensitivity analyses, we included RA-ILD cases developing within one year after enrollment given disease latency.

Results: Among 2,189 participants (89% male, mean age 64 years), RA-ILD was present in 93 at the time of registry enrollment (point prevalence 4.2%). Higher plasma concentrations of MMP-7 (OR 1.64 [95% CI 1.31, 2.05] per standardized unit) and MMP-9 (OR 1.27 [1.01, 1.59]) were significantly associated with prevalent RA-ILD, but MMP-1 and -3 were not. Participants with the highest quartile of MMP-7 had over 3 times the odds of prevalent RA-ILD (OR 3.63 [1.80, 7.34], **Figure 1**) compared to the lowest quartile. The highest quartile of MMP-9 was also associated with >2-fold higher odds of RA-ILD.

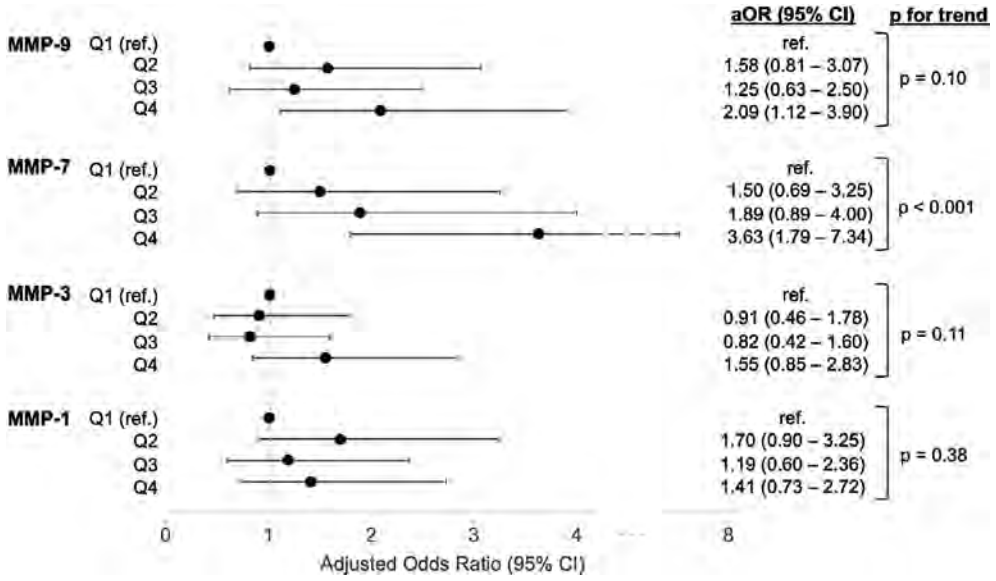

Figure 1. Forest plot illustrating the associations of plasma MMP concentrations in quartiles with prevalent ILD in patients with RA. Odds ratio adjusted for age, sex, race, smoking status, anti-citrullinated peptide antibody status, and rheumatoid arthritis disease activity in logistic regression model. Quartile 1 (referent) was the lowest values. Abbreviations: MMP = matrix metalloproteinase, ILD = interstitial lung disease, RA = rheumatoid arthritis, aOR = adjusted odds ratio, ref. = referent.

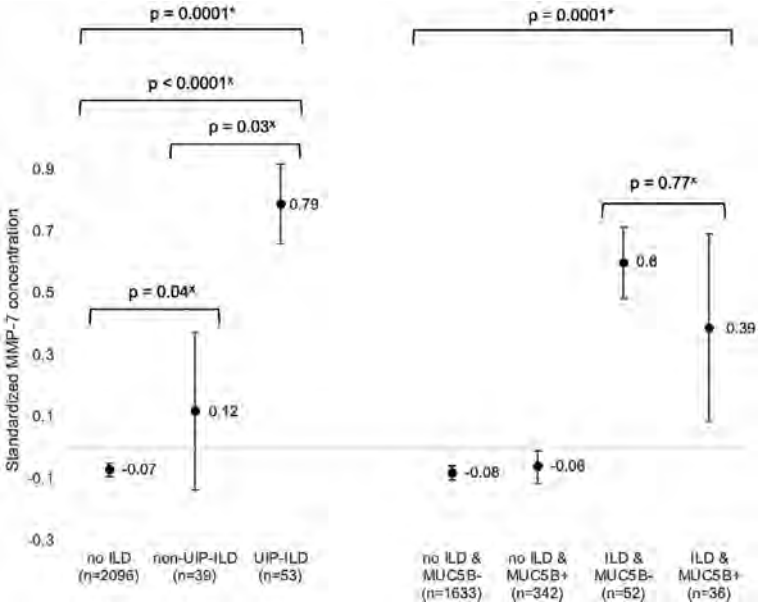

Figure 2. Mean plasma MMP-7 concentrations (per 1 SD) by ILD pattern and MUC5B rs35705950 promoter variant. Standardized values of log-transformed MMP-7 concentrations were calculated by subtracting the sample mean value and dividing by the standard deviation. Error bars indicate standard error of the mean. *across entire sample by Kruskal-Wallis test x pairwise comparison by post hoc Dunn test Abbreviations: MMP = matrix metalloproteinase, ILD = interstitial lung disease, UIP = usual interstitial pneumonia

MMP-9 concentrations, but not other MMPs, were weakly negatively correlated with FVC (r = -0.28, p = 0.015) among those with ILD. MMP-7 was higher among participants with a UIP vs. non-UIP pattern (**Figure 2**). MMP concentrations did not differ by the presence of the *MUC5B* promoter variant (MMP-7 shown in **Figure 2**). Similar results were observed in sensitivity analyses (data not shown).

Conclusion: Plasma concentrations of MMP-7/9 were strongly associated with prevalent RA-ILD, which was largely driven by patients with a UIP pattern of ILD. MMP-9, but not MMP-7, was weakly correlated with RA-ILD severity by FVC. These findings add to a growing body of literature suggesting MMPs may have a potential pathogenic role in RA-ILD.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: RA-ILD
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Based on the overlap in peripheral blood biomarkers associated with rheumatoid arthritis interstitial lung disease (RA-ILD) and idiopathic pulmonary fibrosis (IPF), a composite biomarker score based on IPF-molecular profiles was previously derived that correlated with RA-ILD disease stage (Kass et al. *Arth Rheum*, 2022; 74(suppl 9)). In this study, we aimed to externally validate the predictive value of a modified version of this biomarker score with prevalent and incident ILD in a large, multicenter RA cohort.

Methods: We performed cross-sectional and longitudinal analyses of participants in the Veterans Affairs Rheumatoid Arthritis registry, a prospective cohort of U.S. veterans with RA. RA-ILD diagnoses were validated by medical record review, with prevalent and incident ILD defined pre- and post-enrollment, respectively. Concentrations of 7 of 8 previously proposed IPF mediators (matrix metalloproteinase [MMP]-7, MMP-9, eotaxin, macrophage-derived chemokine [MDC], monocyte

chemoattractant protein-1 [MCP-1], Fms-like tyrosine kinase 3 ligand [Flt3L] and interleukin-8 [IL-8]; MMP-2 unavailable and not included) were measured from serum/plasma at enrollment (MesoScale Discovery platform). Log-transformed and standardized values (per cohort mean and standard deviation for each analyte) were summed to compute a composite biomarker score. Associations of the biomarker score (continuous and quartile) with prevalent and incident RA-ILD were assessed in multivariable regression models (logistic and Cox), adjusted for age, sex, race, smoking status, anti-CCP positivity, and RA disease activity. Discrimination of prevalent RA-ILD was evaluated with receiver operating characteristic (ROC) curves, initially using the aforementioned clinical predictors alone and subsequently with the addition of the biomarker score.

Results: Among 2,092 participants (89% male, mean age 64 years), prevalent RA-ILD was identified in 86 and incident RA-ILD developed in 116 participants during a mean follow-up of 7.7 years. Mean composite biomarker scores were significantly lower in participants without RA-ILD than in those with prevalent ILD or incident RA-ILD (-0.35 vs. 0.89 and 0.54, respectively, both $p < 0.02$). Higher biomarker scores were significantly associated with prevalent (aOR 1.08 [1.01, 1.15]) and incident (aHR 1.06 [1.01, 1.12] per 1 point increase) RA-ILD. Participants with biomarker scores in the highest quartile had over 2-fold higher odds of prevalent RA-ILD (**Figure 1**) and risk of incident RA-ILD (**Figure 2**). The addition of the biomarker score to clinical predictors did not significantly improve prevalent RA-ILD discrimination (AUC 0.653 [0.595, 0.711] clinical vs. 0.669 [0.613, 0.725] clinical and biomarker score, $p = 0.30$).

Conclusion: A modified composite biomarker score based on IPF molecular profiles was associated with prevalent and incident ILD in a large, multicenter RA cohort. While externally validating prior findings by Kass et al. and implicating IPF mediators in RA-ILD pathogenesis, the IPF-derived composite biomarker score had modest discriminative performance. Further

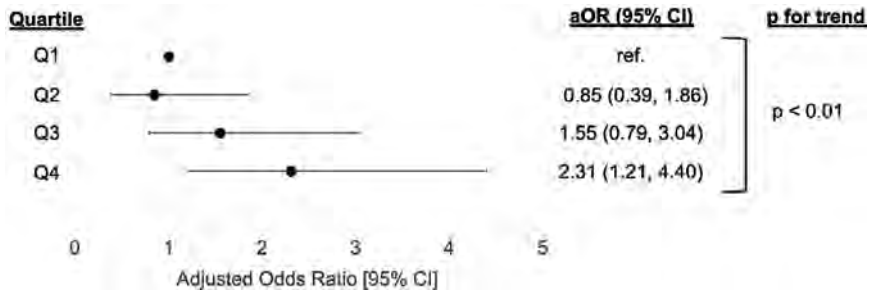

Figure 1. Forest plot illustrating the associations of an IPF-derived composite biomarker score (quartiles) with prevalent ILD in a multicenter RA cohort. SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: RA-ILD

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: The gain of function *MUC5B* rs35705950 promoter variant is the strongest genetic risk factor for the development of RA-ILD (specific to a usual interstitial pneumonia (UIP) pattern) and idiopathic pulmonary fibrosis (IPF). Since it remains uncertain whether the variant also impacts disease prognosis in RA-ILD or IPF, we examined the association of the *MUC5B* promoter variant with survival in a multicenter cohort of U.S. Veterans with RA-ILD.

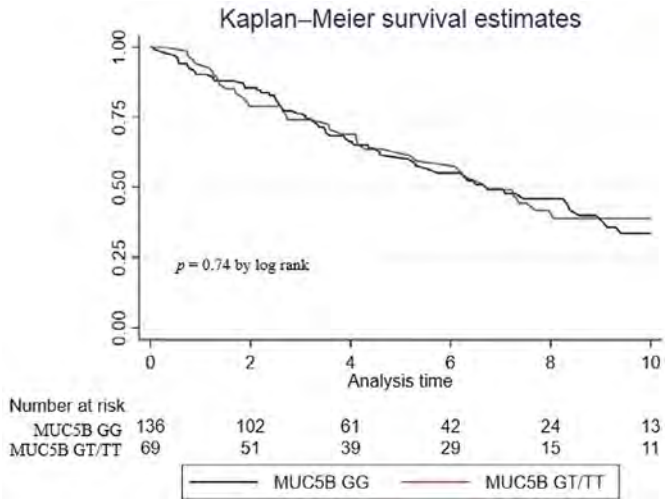

Figure 1. Kaplan-Meier survival curve with log-rank test by MUC5B promoter variant status in RA-ILD.

Table 1. Associations of MUC5B promoter variant status with survival in RA-ILD

	Deaths / PY	Unadjusted HR (95% CI)	Adjusted* aHR (95% CI)
Overall (n=205)			
MUC5B (GG)	62 / 625.79	Ref	Ref
MUC5B (GT/TT)	34 / 365.07	0.93 (0.61, 1.42)	0.75 (0.45, 1.24)
Incident RA-ILD (n=113)			
MUC5B (GG)	37 / 332.98	Ref	Ref
MUC5B (GT/TT)	16 / 155.93	0.90 (0.50, 1.62)	0.84 (0.38, 1.87)

Adjusted for: age, sex, smoking history, baseline DAS28, baseline FVC % predicted, and ILD duration (overall only).
*Adjusted models with n=158 overall, and n=86 incident.
Abbreviations: aHR, adjusted hazard ratio; CI, confidence interval; HR, hazard ratio; PY, person years;

Methods: We studied participants in the Veteran Affairs Rheumatoid Arthritis (VARA) registry with validated ILD diagnoses based on standardized medical record review requiring a provider diagnosis of RA-ILD and either imaging or biopsy findings consistent with ILD. Participants were followed from the latest of either VARA enrollment or ILD diagnosis (index date; to prevent immortal time bias) until death or the end of the study period (12/31/2019). The *MUC5B* rs35705950 promoter variant was measured via the Infinium Global Screening Array-24 v2.0 (Illumina, Inc; San Diego, CA). The major allele was the guanine (G) nucleotide while the minor allele was the thymine (T) nucleotide. An autosomal dominant inheritance pattern was assumed. Survival was determined from Veterans Affairs death records and linkage with the National Death Index. Kaplan-Meier curves were generated and stratified by the *MUC5B* variant. Associations of the *MUC5B* promoter variant with survival were tested in unadjusted and adjusted Cox regression models adjusting for age, sex, smoking history, baseline DAS28, baseline FVC % predicted, and ILD duration. To explore potential survival bias among prevalent ILD cases, a subgroup analysis was completed examining *MUC5B* status and survival among only incident RA-ILD cases. A sensitivity analysis was also performed restricting to participants with UIP or honeycombing on chest computed tomography (CT) reports.

Results: We studied 205 participants with RA-ILD (mean age 69 years, 94% male, 73% white). A smoking history was present in 85%, and the mean ILD duration at index date was 1.7 years. The *MUC5B* promoter variant was detected in 33.7%. Over 990 patient-years of follow-up, 96 deaths occurred. Mortality rate was similar between those with (9.3/100PY [6.7, 13.0]) and without (9.9/100PY [7.7, 12.7]) the variant (**Figure 1**; p = 0.74 by log rank test). In the overall RA-ILD cohort, *MUC5B* status was not significantly associated with survival in unadjusted or adjusted (aHR 0.75 [0.45, 1.24]) models **(Table 1).** Restricting RA-ILD to incident cases produced similar results, with no significant association between the *MUC5B* promoter variant and survival in unadjusted or adjusted (aHR 0.84 [0.38, 1.87]) models (**Table 1**). Findings were similar when restricting to participants with UIP or honeycombing on chest CT (data not shown).

Conclusion: While associated with RA-ILD risk, the *MUC5B* gain of function promoter variant was not predictive of survival in this multicenter RA-ILD cohort. Further studies are needed to identify and evaluate other potential genetic and non-genetic prognostic factors in RA-ILD to inform disease prognostication and management.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: RA-ILD

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) develops in 5-10% of RA patients and more often manifests as the fibrotic subtype of ILD known as usual interstitial pneumonia (UIP). Fibrotic ILD can also be detected early in patients with RA before meeting criteria for UIP or becoming clinically apparent. RA-UIP contributes significantly to morbidity and mortality, yet the pathophysiology remains poorly understood. In idiopathic pulmonary fibrosis (IPF), which shares significant clinical and pathophysiologic overlap with RA-UIP, lung microbial dysbiosis has been associated with lung disease progression, exacerbations of the underlying ILD and mortality. We evaluated the lung microbiome using induced sputum in RA patients with pulmonary fibrosis (RA-PF) compared to RA patients without pulmonary fibrosis (RA-no-PF) to establish lung microbial relationships with RA-PF and lung disease severity.

Table 1. Patient demographics and clinical characteristics

	RA-no-PF	RA-PF	P-value
n	32	33	
Age	50.9 (14.6)	64.5 (10.8)	<0.001
Sex (Female)	92%	57%	0.001
Smoking status			
Former/Current smokers	32%	51%	0.157
Pack-years	15.6 (16.4)	24.2 (21.9)	0.271
Serum autoantibodies			
RF+	79%	82%	1.0
CCP +	81%	78%	1.0
Lung disease parameters			
% pred FVC	104.9 (14.9)	88.3 (18.0)	<0.001
% pred DLCO	94.6 (20.9)	76.9 (18.6)	0.001
% DTA fibrosis	N/A	7.8 (11.6)	N/A
Radiographic fibrosis	N/A	51%	N/A
RA-ILD (UIP)	N/A	49%	N/A

Methods: We included 33 patients with RA-PF and 32 patients with RA-no-PF. Presence or absence of PF was determined by high resolution computed tomography (HRCT) read by two chest radiologists blinded to patient characteristics. The RA-PF group included 1) patients with HRCT evidence of early fibrosis but no clinical diagnosis of ILD and 2) patients with established ILD in a radiographic pattern of UIP. Patients with other forms of ILD (e.g., nonspecific interstitial pneumonia) were excluded. Induced sputum was collected from all participants and underwent 16s rRNA microbiome sequencing (MiSeq). Sputum was also tested for levels of pro-inflammatory cytokines (multiplex immunoassay, Meso Scale Discovery). Pulmonary function tests and HRCT were performed within 3 months of sputum collection. Lung fibrosis was quantified by HRCT using the data-driven textural analysis (DTA) computer method. Linear discriminant effect size analysis (LEfSe) was used to identify differences in relative abundance of genus-level taxa between groups.

Results: Demographics and clinical data are shown in Table 1. There were no differences in alpha or beta diversity between groups. In the LEfSe analysis, we found a significantly lower abundance of *Lautropia, Bergeyella, and Haemophilus* in RA-PF compared to RA-no-PF (Figure 1). Of these taxa, lower abundance of *Lautropia* significantly correlated with reduced % predicted forced vital capacity (%FVC; r=0.364, p=0.004) and increased extent of lung fibrosis (r=-0.414, p=0.032) (Figure 2). Additionally, decreased abundance of all three taxa were significantly associated with increased levels of various inflammatory cytokines within sputum, including MCP-1, TNF-α, IL-1β, IL-6, and IL-8 (Figure 2).

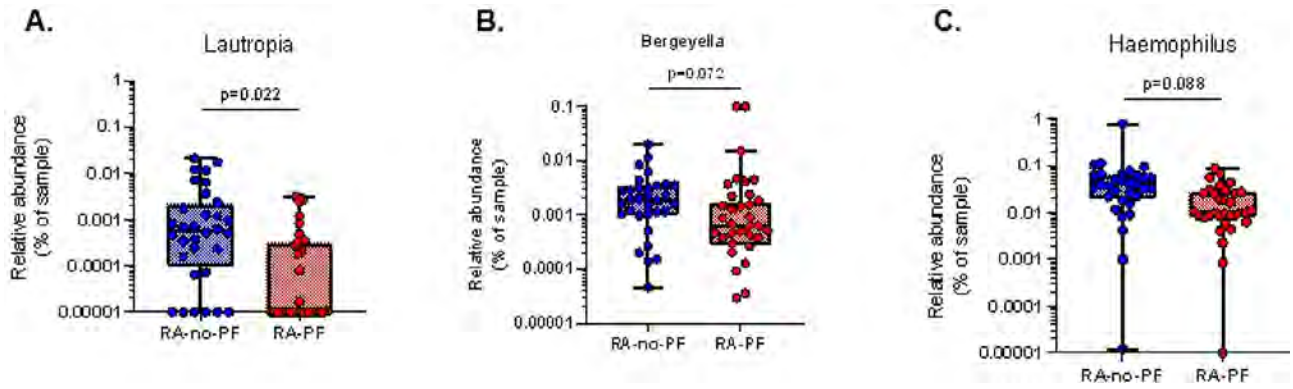

Figure 1. Significant taxa differences at genus level in RA-PF compared to RA-no-PF (A. Lautropia; B. Bergeyella; C. Haemophilus). Read count data was filtered with a minimum read count cutoff of 4 and prevalence in samples of 20%, and a feature low variance cutoff of 10% based on inter-quartile range (IQR). Read counts were rarefied to the minimum library size and scaled using the cumulative sum scaling (CSS) method. Significant differences determined using a linear discriminant effect size analysis (LEfSe) and false discovery rate (FDR) adjusted p-value <0.1.

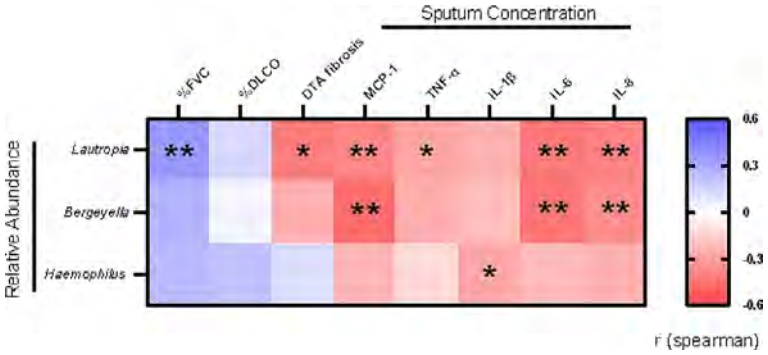

Figure 2. Heatmap of spearman correlation analysis of taxa abundance with markers of lung disease severity and sputum cytokine levels. %FVC = % pre-dicted forced vital capacity, %DLCO = %predicted diffusion capacity carbon monoxide, DTA fibrosis = data drive textural analysis HRCT fibrosis score, MCP-1 = monocyte chemoattractant protein 1, TNF-α = tumor necrosis factor alpha, IL-1β = interleukin 1 beta, IL-6 = interleukin 6, IL-8 = interleukin 8. P-value based on spearman correlation, <0.05 = *, <0.01 = **.

Conclusion: We found taxonomic level differences in the lung microbiome of RA patients with pulmonary fibrosis. Of particular interest, *Lautropia* was lower in RA-PF and lower abundance significantly correlated with impaired lung physiology, higher lung fibrosis and higher levels of local inflammatory cytokines. Future studies are needed to investigate the role of *Lautropia* and other respiratory microbes in driving fibrotic, or perhaps anti-fibrotic, changes within the lungs of RA patients.

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: RA-ILD

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: RA-associated interstitial lung disease (ILD) is not a single entity as illustrated by different HRCT patterns, different risk factors and prognoses suggesting heterogenous phenotypes. Our objective was to identify definite subphenotypes among a large RA-ILD dataset performing unsupervised clustering analysis.

Table 1. Distribution of active variables within the clusters among patients with RA-ILD (n=1696). Data are numbers (percentages) for categorical variables or means (Standard Deviation) for continuous variables. 95% confidence interval for clustering analysis are indicated in the brackets for each variable. Normalized ACPA and RF represents fold above upper limit normal. ACPA: anti-citrullinated peptides antibodies; DLCO: diffusion capacity of the lung for carbon monoxide; HRCT: high-resolution computed tomography; ILD: interstitial lung disease; LIP: lymphocytic interstitial pneumonia; NSIP: non-specific interstitial pneumonia; OP: organizing pneumonia; RF: rheumatoid factor; UIP: usual interstitial pneumonia

Active variable	Cluster 1 n=1015	Cluster 2 n=681	p-value
Male	462 (45.5)	261 (38.3)	**0.003**
Duration between RA and ILD (years)	8.4 (10.3)	8.1 (11.2)	0.531
Age at RA onset (years)	56.9 (13.3)	53.8 (14.5)	**<0.001**
Age at ILD onset (years)	65.5 (10.1)	61.9 (12.3)	**<0.001**
Ethnicity (self-reported) - European - Turk - Hispanic - Black - Asian - Other	 872 (85.9) 137 (13.5) 2 (0.2) 4 (0.4) 0 (0) 0 (0)	 465 (68.3) 4 (0.6) 102 (14.5) 50 (7.3) 12 (1.8) 48 (7.1)	**<0.001**
Pulmonary symptoms at ILD onset	867 (85.4)	519 (76.2)	**<0.001**
Sjogren syndrome	110 (10.8)	140 (20.6)	**<0.001**

Normalized ACPA titers	27.7 (32.8)	32.0 (162.2)	0.494
RF positive	972 (95.8)	459 (67.4)	**<0.001**
Normalized RF titers	16.1 (25.4)	18.7 (44.7)	0.170
Ever smoker at RA onset	651 (64.1)	373 (54.8)	**<0.001**
Current smoker at RA onset	233 (23.0)	126 (18.5) [15.6-21.4]	**0.025**
Pack-year at RA onset	17.6 (21.5)	14.4 (21.8)	**0.002**
Ever smoker at ILD onset	652 (64.2)	379 (55.7)	**<0.001**
Current smoker at ILD onset	176 (17.3)	100 (14.7)	0.141
Pack-year at ILD onset	19.4 (23.1)	15.1 (21.1)	**<0.001**
HRCT pattern - UIP - Indeterminate for UIP - NSIP - OP - LIP - Other	 736 (72.5) 0 (0) 227 (27.3) 0 (0) 1 (0.1) 1 (0.1)	 210 (30.8) 189 (27.8) 117 (17.2) 39 (5.7) 10 (1.5) 116 (17.0)	**<0.001**
Forced vital capacity (%)	86.2 (21.7)	84.2 (23.8)	0.069
DLCO (%)	58.51 (19.6)	59.8 (21.3)	0.192

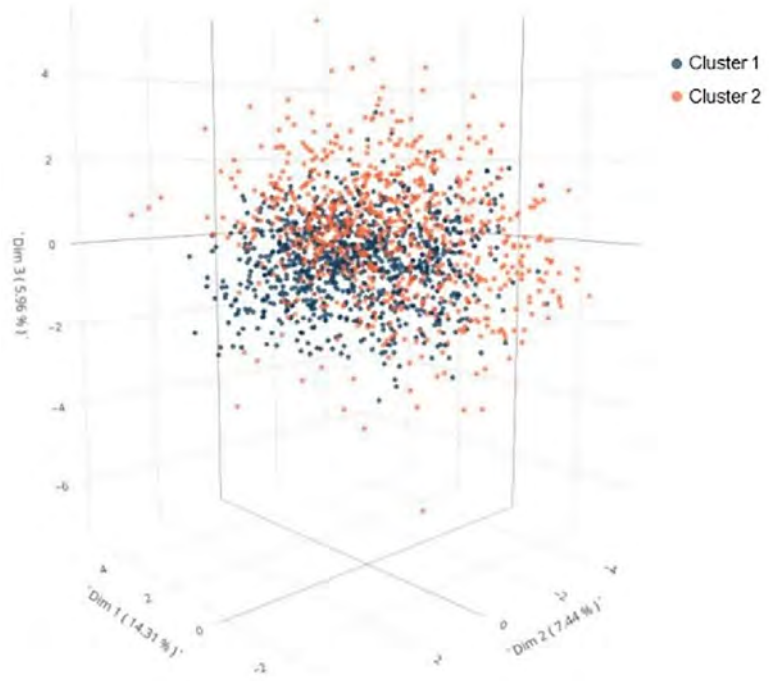

Figure 1. Clusters representation on the first three dimensions of Multiple Correspondence Analysis (MCA) The map is a 3D representation of patients and their clusters (n = 1696). A point represents a patient, and its color represents the cluster assigned to this patient (cluster 1 in blue and cluster 2 in orange). The first three dimensions of MCA together explain 27.7% of the total variance.

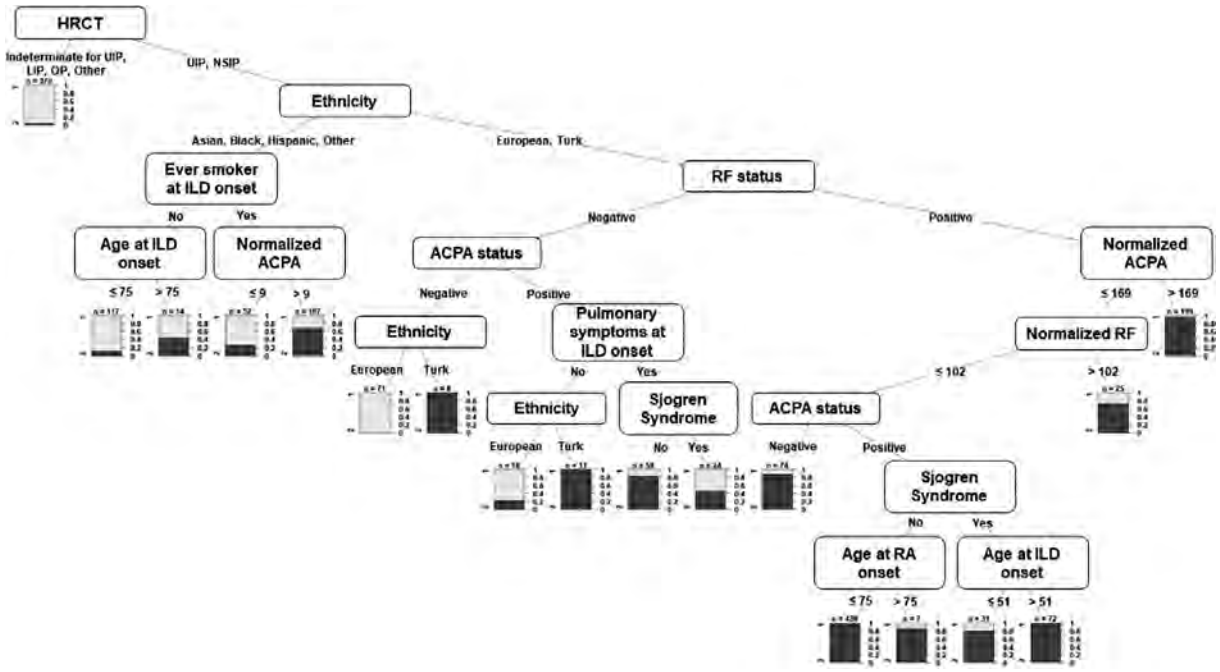

Figure 2. Decision tree to predict a cluster for a new patient with RA-ILD The tree is a set of paths. Each path is a sequence of conditions that lead to a decision (cluster 1 or cluster 2). The nodes present active variables that are important in the decision-making and the edges present conditions to be checked by a patient in order to classify him in one of the two clusters. The barplot (final node of each path) presents the two clusters (cluster 1 and cluster 2) on the left and the probability to be in cluster 1 on the right. ACPA: anti-citrullinated peptides antibodies; HRCT: high-resolution computed tomography; ILD: interstitial lung disease; LIP: lymphocytic interstitial pneumonia; NSIP: non-specific interstitial pneumonia; OP: organizing pneumonia; RF: rheumatoid factor; UIP: usual interstitial pneumonia

Methods: In this international collaborative study (22 centers from 13 countries), we included patients with RA (ACR/EULAR 2010 classification criteria) having ILD defined by high-resolution computed tomography (HRCT) chest scan. Clinical, biological, imaging, and functional data were retrospectively collected from extensive chart review. Missing data were handled using multiple imputation with chained equations. A multiple correspondence analysis was performed on each sample to reduce dimensions and a non-parametric Bayesian algorithm was used to attribute a cluster to each patient. The clusters were aggregated over the multiple imputations using weighted Non-negative Matrix Factorization.*MUC5B* rs35705950 T risk allele distribution in the identified clusters was investigate for patients with available genotype. A surrogate decision tree was conducted using the non-imputed dataset to predict a cluster for each patient. The prediction error rate of the tree was estimated using cross-validation.

Results: A total of 1696 patients with RA-ILD were included in the cluster analysis; **Table 1**. Among the 37 collected variables, 20 active variables were used to construct clusters. The non-parametric Bayesian clustering algorithm detected 2 definite clusters: cluster 1 (n=1015) and cluster 2 (n=681); **Table1, Figure 1**. Compared to cluster 2, patients from cluster 1 were more frequently male (45.5% vs 38.3%, p=0.003), older at RA onset (56.9 ± 13.3 vs 53.8 ± 14.5, p< 0.001) and at ILD onset (65.5 ± 10.1 vs 61.9 ± 12.3, p< 0.001), more frequently with European ethnicity (85.9% vs 68.3%, p< 0.001), more frequently ever smokers at ILD onset (64.2% vs 55.7%, p< 0.001) and had less Sjogren syndrome (10.8% vs 20.6%, p< 0.001). They were more frequently positive for anti-citrullinated peptides antibodies (90.7% vs 70.0%, p< 0.001) and for rheumatoid factor (95.8% vs 67.4%, p< 0.001). UIP HRCT pattern was predominant in cluster 1 (72.5%) whereas various patterns were observed in cluster 2 (UIP = 30.8%, NSIP = 17.2%), p< 0.001. There was no difference in lung function at ILD onset between the 2 clusters. *MUC5B* rs35705950 genotype was available for 444 patient (26.2%) with a higher minor allele frequency (MAF) in cluster 1 (33% compared to 18%, p< 0.001). **Figure 2** shows the decision tree that can be used to predict the cluster for a new patient with a prediction error rate of 9.8%.

Conclusion: Our results provide evidence that RA-ILD is a heterogeneous disease and allow the identification of at least two distinct subsets. This heterogeneity is illustrated by a contribution of the *MUC5B* promoter variant restricted to cluster 1, promoting the identification of specific risk scores for each RA-ILD subset. This heterogeneity underlies distinct physio pathological mechanisms which could influence not only the prognosis of patients with RA-ILD but also their therapeutic management.

Effectiveness of Dose Reduction and Withdrawal Strategies of TNF Inhibitors in Psoriatic Arthritis and Axial Spondyloarthritis: Long Term Extension of the DRESS-PS Study

Amy Peeters, C.A.J Michielsens, Elien Mahler, Lise Verhoef, Alfons den Broeder, Nathan den Broeder and Noortje van Herwaarden, Sint Maartenskliniek, Nijmegen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: PsA
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Tumor Necrosis Factor inhibitors (TNFi) are effective in PsA and axial SpA, but are associated with increased infections risk, patient burden and high costs. The DRESS-PS study[1] was the first study to show that a Treat-To-Target (T2T) tapering strategy in PsA and axSpA patients is non-inferior compared to T2T without tapering regarding Low Disease Activity (LDA) status at 12 months, with a considerable reduction of TNFi use. If these effects can be maintained up to 2 years is unknown.

The aim of this study was to describe effectiveness of disease activity guided dose optimization of TNFi up to 24 months follow-up in patients with PsA and axSpA who participated in the DRESS-PS study.

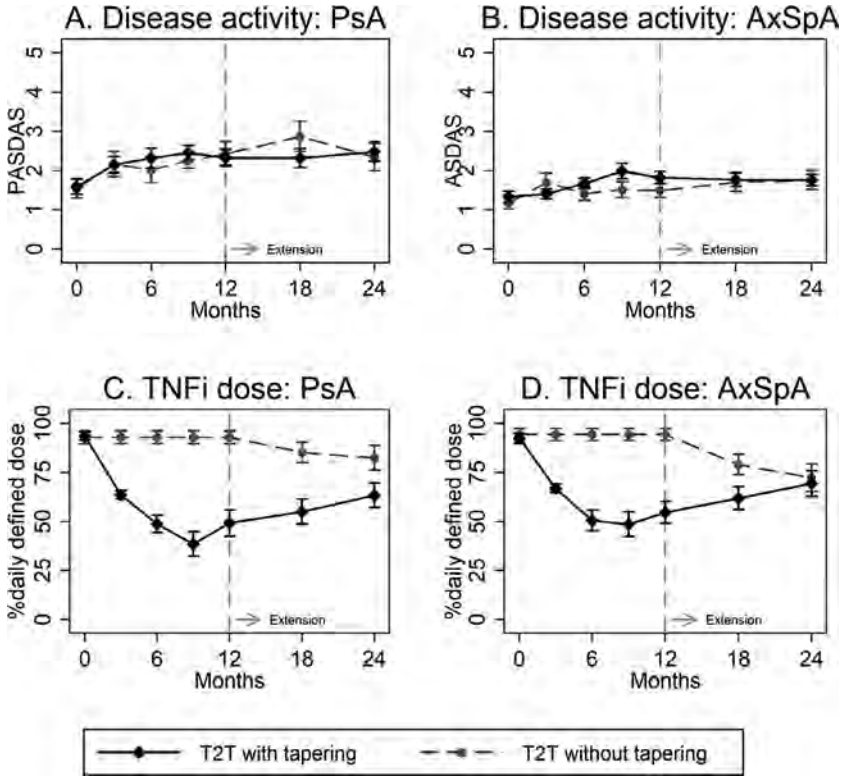

Figure 1: Mean disease activity presented as PASDAS in patients with PsA (A) and ASDAS in patients with AxSpA (B) and mean TNFi dose presented as percentage of daily defined dose in patients with PsA (C) and patients with AxSpA (D), between T2T with tapering and T2T without tapering.

Methods: This study is a 12-month observational extension of the DRESS-PS study. In the DRESS-PS study, patients were allocated to protocolized T2T tapering (intervention) or to T2T without tapering (control). During the extended follow-up, treatment decisions were according to usual care and T2T tapering was allowed for all patients. Patients visited the outpatient clinic bi-annually.

Primary outcomes were disease activity (presented as proportion in LDA and mean disease activity), and TNFi use (presented as percentage of the current daily dose to the defined daily dose (DDD)). Secondarily, functioning measured with HAQ-DI and BASFI and quality of life measured with EQ5D, SF12 and ASAS-HI at 24 months are reported.

We also compared effects of protocolized tapering to routine care tapering, by comparing the intervention group at 12 months to the control group at 24 months.

Results: 114 patients (of 122) were included in the extension study (table 1). The proportion in LDA state at 24 months was 67% (45 of 67) in patients originally allocated in the intervention group and 72% (23 of 32) in patients originally allocated in the control group (difference 4.7% (95%CI: -15% to 24%)). Mean disease activity remained stable during the extension period (Figure 1A and 1B).

Table 1. Baseline characteristics of patients with PsA or axSpA treated with a T2T strategy with tapering attempt (intervention) or a T2T strategy without tapering attempt (control)

Characteristics	Intervention (n=79)	Control (n=35)
Diagnosis, n (%)		
PsA	40 (51)	18 (51)
axSpA	39 (49)	17 (49)
Female, n (%)	28 (35)	16 (46)
Age in years at inclusion, mean (sd)	49 (14)	52 (16)
Disease duration at inclusion, years, median (IQR)	11 (5 to 21)	11 (5 to 25)
CASPAR criteria, n (%)	32 (80)	15 (83)
ASAS criteria, n (%)	35 (90)	15 (88)
Disease activity, mean (SD)		
PASDAS	1.60 (1.25)	1.54 (1.00)
ASDAS	1.33 (0.89)	1.18 (0.64)
Duration of current bDMARD use, years, median (IQR)	2 (1 to 6)	3 (2 to 9)

Baseline ASDAS was missing for 1 SpA patient
PsA, Psoriatic Arthritis; axSpA, axial SpondyloArthritis; CASPAR, Classification Criteria for Psoriatic Arthritis; ASAS, Assessment of SpondyloArthritis; PASDAS, Psoriatic Arthritis Disease Activity; ASDAS, Ankylosing Spondylitis Disease Activity Score

Table 2. Results of questionnaires on Quality of life and functioning in patients with PsA and axSpA in a T2T tapering strategy (intervention) and T2T strategy without tapering (control) at 24 months

Quality of life (24 months)	Intervention Median (iqr)	Control Median (iqr)
EQ-5D-3L	0.84 (0.78 to 0.93)	0.84 (0.78 to 0.93)
SF-12 PCS	44.4 (38.5 to 49.6)	44.0 (36.6 to 46.4)
SF-12 MCS	55.0 (46.6 to 59.4)	56.1 (48.2 to 59.3)
ASAS-HI	5 (2 to 7)	4 (2 to 8)
Functioning (24 months)	**Intervention Median (iqr)**	**Control Median (iqr)**
HAQ-DI	0.25 (0 to 0.63)	0.31 (0.13 to 0.81)
BASFI	1.95 (1.15 to 3.45)	1.70 (0.80 to 3.60)

Results are presented as median with interquartile range. EuroQol five-dimension scale with three levels (EQ-5D-3L), ranges from 0 to 1, with higher scores indicating better quality of life. Short Form Health Survey 12 (SF-12), ranges from 0 to 100, consists of a physical and mental component score, higher scores indicate better quality of life. Assessment of SpondyloArthritis International Society-Health Index (ASAS-HI), ranges from 0 to 17, this questionnaire was only fulfilled by patients with axSpA , with higher scores indicating worse quality of life. Health Assessment Questionnaire-Disability Index (HAQ-DI), ranges from 0 to 3, higher scores indicate lower functioning. Bath Ankylosing Spondylitis Functional Index (BASFI), ranges from 0 to 10, this questionnaire was only fulfilled by patients with axSpA, with higher scores indicating lower functioning. Not all patients fulfilled all questionnaires.

101/114 (89%) patients attempted tapering during follow up (100% intervention vs 63% control). TNFi %DDD at 24 months was 66% (95%CI: 57% to 75%) in the original intervention group and 77%% (95%CI: 68% to 87%) in the original control group (Figure 1C and D). Functioning and quality of life at 24 months was similar between patients originally randomized to intervention and control (table 2).

The comparison between protocolized tapering and routine care tapering showed no difference in patients in LDA state 12 months after start of tapering: 70% vs 72%% (difference 2.3% (95%CI: -16% to 21%)). However, there was a significant difference in TNFi use: %DDD 52% in the intervention group at 12 months and 77% in the control group at 24 months (difference 26% (95%CI: -13% to 38%)).

Conclusion: T2T tapering of TNFi remains effective and safe regarding disease control up to two years. However, the % DDD seems to increase somewhat in the intervention group, and is higher compared to studies in RA, and tapering in usual care seems less frequent. Whether this is by chance, or caused by a disease-specific need for higher dosing or more subjective disease activity measures, remains a topic for further research.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: PsA
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: To investigate the long-term efficacy, safety, and tolerability of intravenous (IV) secukinumab (SEC) in patients with active psoriatic arthritis (PsA) through 52 weeks.

Methods: INVIGORATE-2 (NCT04209205) is a randomized, double blind, placebo (PBO)-controlled, parallel group, phase 3 study. All patients met the CASPAR criteria for active PsA, had symptoms for ≥6 months, and had a Tender Joint Count of 78 joints (TJC78) ≥3 and a Swollen Joint Count of 76 Joints (SJC76) ≥3 at baseline. Patients were randomized 1:1 to receive IV SEC (6 mg/kg at baseline followed by 3 mg/kg q4w) or PBO. At Week 16, patients randomized to SEC continued

receiving SEC and patients randomized to PBO were switched to IV SEC (3 mg/kg q4w) through Week 52. The primary efficacy endpoint was American College of Rheumatology (ACR) 50 response rate at Week 16 versus PBO. Secondary efficacy outcomes included achievement of ACR20, minimal disease activity, PASI90, dactylitis resolution, and enthesitis resolution. All efficacy outcomes were assessed through Week 52, and safety was evaluated through Week 60. Data through week 16 are reported using nonresponder imputation; data from Week 20 through Week 52 are reported as observed.

Table 1. Patient demographics and baseline disease characteristics

Characteristic	Secukinumab (n=191)	Placebo/Secukinumab (n=190)
Age, mean (SD), years	47.5 (13.5)	48.1 (13.7)
Sex, n (%)		
Male	87 (45.5)	85 (44.7)
Female	104 (54.5)	105 (55.3)
Weight, mean (SD), kg	84.6 (22.9)	85.1 (22.7)
Previous TNFi exposure, n (%)		
Naive	165 (86.4)	162 (85.3)
Inadequate responder	26 (13.6)	28 (14.7)
Enthesitis (LEI), n (%)	126 (66.0)	110 (57.9)

** P<.005 vs placebo.
*** P<.0001 vs placebo.

Figure 2. Proportions of patients with PsA who achieved binary secondary efficacy outcomes at Week 16 (nonresponder imputation) and Week 52 (observed data)

Results: Demographics and baseline characteristics were balanced across treatment groups (**Table 1**). Among patients randomized to IV SEC (n=191) and IV PBO/SEC (n=190), similar proportions of patients completed the entire study period (90.6% and 87.9%, respectively). A higher proportion of patients receiving SEC than PBO achieved ACR50 at Week 16 using nonresponder imputation (60/191 [31.4%] vs 12/190 [6.3%]; P< .0001; **Figure 1**). An increase in ACR50 response was observed by Week 20 among patients initially randomized to PBO who were switched to SEC at Week 16. Both groups had similar ACR50 response rates by Week 52 based on observed data (SEC, 58.0%; PBO/SEC, 64.0%). Patients receiving SEC had greater improvements in secondary efficacy outcomes compared with PBO at Week 16, and both SEC and PBO/SEC groups had comparable efficacy outcomes by Week 52 (**Figure 2**). Through Week 16, the incidences of adverse events (AEs; 37.7% vs 38.4%), serious AEs (1.6% vs 2.1%), and AEs leading to treatment discontinuation (0.5% vs 1.6%) were similar for patients receiving SEC or PBO. Among patients receiving any SEC through the entire study period, 63.4%, 5.9%, and 1.9% reported any AE, serious AEs, and AEs leading to treatment discontinuation, respectively. One death was reported in the PBO group prior to Week 16. No new safety signals were observed with IV SEC.

Conclusion: IV SEC (6 mg/kg at baseline followed by 3 mg/kg q4w) was safe and effective for the long-term treatment of active PsA. Treatment responses were maintained up to Week 52 for patients randomized to IV SEC. For patients originally randomized to PBO who switched to receive IV SEC at Week 16, an increase in efficacy responses comparable to those in patients randomized to IV SEC was observed up to Week 52. Safety was consistent with the known safety profile of subcutaneous SEC, and no new safety signals were observed.

Characteristics of Difficult-To-Treat Psoriatic Arthritis: A Comparative Analysis

Cecile PHILIPPOTEAUX[1], Anne Marty-Ane[1], Emeline Cailliau[1], Peggy Philippe[1], Bernard Cortet[1], Julien Paccou[1], Rene-Marc Flipo[1] and Jean-Guillaume Letarouilly[2], [1]University Hospital Center of Lille, Lille, France, [2]CHU Lille, Lille, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: PsA
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The EULAR task force recently published the difficult-to-treat RA (D2T RA) definition [1], however, a definition of D2T PsA is still lacking. To date, we have little data concerning D2T PsA, especially in real-world. One of the limitations of the D2T RA EULAR definition is the absence of a temporal criterion. The primary endpoint of this work was to study the characteristics of D2T PsA patients using the EULAR definition. The second objective was to study a sub-group of patients with a predefined more stringent definition including a temporal criterion.

Methods: A retrospective study was performed in a tertiary center. PsA patients 18 years old or older starting a b/tsDMARDs with at least two-year follow-up were included. D2T PsA was defined as failure of ≥ 2 b/tsDMARDs with different mechanism of action among TNF inhibitors, anti-IL 17, anti-IL 23 and JAK inhibitors. Very D2T PsA was defined as failure of ≥ 2 b/tsDMARDs in less than 2 years of follow-up. D2T and Very D2T PsA patient's characteristics were compared between with non-D2T (nD2T) patients using statistical tests. The significant factors at the level of 0.10 were introduced into a multivariable multinomial logistic regression model.

Results: 150 PsA patients were included: 49 D2T PsA (32.7%) and 101 non-D2T (nD2T) PsA (67.3%). Results showed a significant difference in clinical PsA features at baseline including axial involvement, with a proportion of 43.8% in the D2T group vs. 26.0% in the nD2T group (p=0.03) (**Table 1**). Structural damage at baseline (axial and/or peripheral) concerned 76.2% of the D2T patients and 51.0% of the nD2T patients (p=0.006). In multivariate analysis, structural damage was found to be a predictive factor for D2T PsA with an OR of 2.49 (1.05 to 5.89; p=0.038) (**Table 2**).

There was no significant difference regarding comorbidities such as obesity, smoking status, fibromyalgia or depression. The median delay to first b/tsDMARD in the D2T group was 42 (12 to 120) months vs. 36 (14,5 to 108) months in the nD2T group (p=0,95). Treatment trajectory of D2T PsA patients were reported from 1st to 5th line (**-Figure 1**). There was at least one therapeutic switch for dermatological ineffectiveness in 40.4% of patients in the D2T group vs 18.8% in the nD2T group (p=0.005). In multivariate analysis, bDMARD discontinuation due to poor dermatological control was found to be more frequent in the D2T population with an OR of 2.75 (1.23 to 6.14; p=0.013) (**Table 2**).

17 patients (11.3%) were categorized as Very D2T. When compared to the nD2T group, proportion of obesity was higher (p=0.015) and axial involvement at baseline was more prevalent in the Very D2T group (p=0.020).

Table 1 – Baseline characteristics of D2T PsA and nD2T PsA patients

Parameters	N	D2T PsA n = 49	N	nD2T PsA n = 101	p value
Men	49	29 (59.2)	101	52 (51.5)	0.37
Age (years), mean ± SD	49	54.3 ± 11.9	101	53.7 ± 14.2	0.82
BMI, mean ± SD	46	29.6 ± 7.2	96	27.7 ± 5.7	0.093

Uveitis	49	1 (2.0)	101	2 (2.0)	NA
Psoriasis at baseline	49	43 (87.8)	101	89 (88.1)	0.95
Structural damage at baseline (axial and/or peripheral)	42	32 (76.2)	96	49 (51.0)	0.006
IBD at baseline	49	0 (0.0)	101	3 (3.0)	NA
Positive HLA B27 status	24	10 (41.7)	51	18 (35.3)	0.59
Baseline CRP (mg/L), median (IQR)	40	13.6 (6.0 to 31.5)	86	8.1 (3.0 to 20.0)	0.11
BASDAI Baseline, mean ± SD	8	65.1 ± 16.6	22	58.5 ± 11.7	0.23
Main comorbidities					
Diabetes mellitus	49	6 (12.2)	101	15 (14.9)	0.67
Fibromyalgia	49	2 (4.1)	101	0 (0)	NA
Depression	49	7 (14.3)	101	9 (8.9)	0.32
HBP	49	16 (32.7)	101	25 (24.8)	0.31
Dyslipidaemia	49	8 (16.3)	101	17 (16.8)	0.94
Treatments received					
Infliximab		9 (18.4)		12 (11.9)	0.28
Etanercept		26 (53.1)		42 (41.6)	0.19
Adalimumab		30 (61.2)		46 (45.5)	0.072
Golimumab		30 (61.2)		46 (45.5)	0.57
Certolizumab		30 (61.2)		46 (45.5)	0.18
Secukinumab		30 (61.2)		46 (45.5)	0.81
Ustekinumab		13 (26.5)		22 (21.8)	0.52
Guselkumab		0 (0.0)		2 (2.0)	NA
Ixekizumab		0 (0.0)		2 (2.0)	NA
JAKi		0 (0.0)		1 (1.0)	NA
bDMARD discontinuation due to poor dermatological control	47	19 (40.4)	101	19 (18.8)	0.005

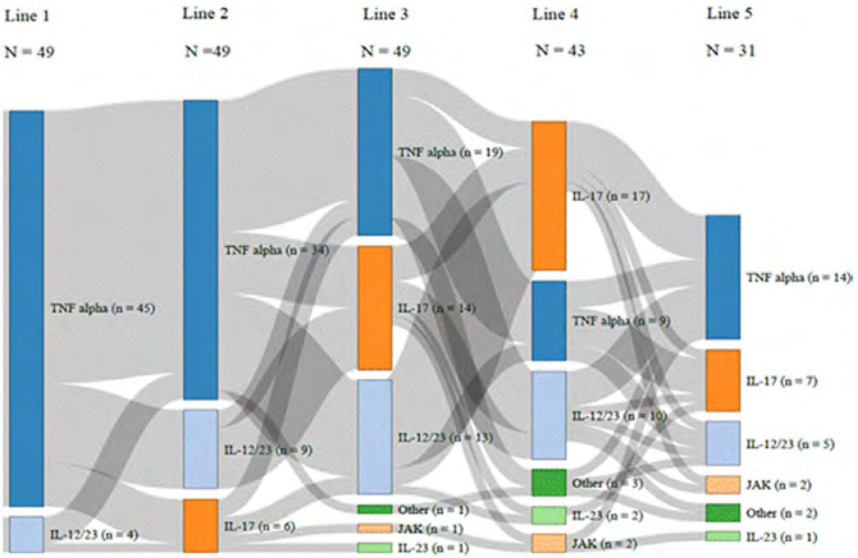
Values are expressed as number (%) unless otherwise stated. BASDAI: Bath Ankylosing Spondylitis Disease Activity; bDMARD: biological disease modifying antirheumatic drug; BMI: body mass index; CRP: C-reactive protein; (n)D2T: (non) difficult-to-treat; HBP: High blood pressure; HLA: human leukocyte antigen IBD: inflammatory bowel disease; IQR: interquartile range; N: number of available observations; NA: not applicable; PsA: psoriatic arthritis; SD: standard deviation.

Conclusion: D2T PsA was associated with a higher prevalence of axial involvement, structural damage and therapeutic discontinuation due to poor dermatological control. Very D2T PsA patients were more likely obese with axial involvement. Very D2T PsA represent a minim proportion of patients when applying a more stringent definition. Pending the PsA D2T definition by the European and American societies, this study highlights some characteristics that may help practitioners better identify D2T patients.

Table 2 - Multivariate analysis for D2T PsA predictive factors

	Odds-ratio (95%CI)	p-value
BMI	1.26 (0.92 to 1.71)[1]	0.14
Axial involvement at baseline	1.80 (0.82 to 3.93)	0.14
Structural damage at baseline (axial and peripheral)	2.49 (1.05 to 5.89)	**0.038**
bDMARD discontinuation due to poor dermatological control	2.75 (1.23 to 6.14)	**0.013**
Previous treatment with Adalimumab	1.69 (0.80 to 3.56)	0.17

Abbreviations: BMI=body mass index; CI=confidence interval.[1]Expressed for an increase of 5 units.



Abbreviations: JAK: JAK inhibitors (tofacitinib, upadacitinib); IL 12/23: IL 12/23 inhibitors (ustekinumab, guselkumab); IL 17: IL 17 inhibitors (secukinumab, ixekinumab) Other: abatacept, rituximab. TNF alpha: TNF alpha inhibitors (infliximab, certolizumab, golimumab, adalimumab, etanercept).

The Effect of Probiotic Modulation of Enteral Dysbiosis on Disease Activity in Patients with Psoriatic Arthritis - A Randomized Controlled Trial

Anirudh Subramanian Muralikrishnan[1], Barbara Dreo[2], Angelika Lackner[1], Rusmir Husic[3], Florentine Moazedi-Fuerst[3], Josef Hermann[4], Philipp Bosch[1], Johannes Fessler[1], Jens Thiel[5] and Martin Stradner[1], [1]Medical University of Graz, Graz, Austria, [2]Division of Rheumatology and Immunology, Medical University of Graz, Graz, Austria, [3]Meduni Graz, Graz, Austria, [4]Division of Rheumatology and Immunology, Department of Internal Medicine, Medical University Graz, Graz, Austria, [5]University Hospital Freiburg, Freiburg, Germany

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: PsA
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Psoriatic Arthritis (PsA) is a painful disease of the joints and spine. Recent studies have described enteric dysbiosis as a possible pathological mechanism in PsA and hence could be a target for therapy. In an open label pilot study, probiotic supplementation ameliorated enteric dysbiosis and reduced disease activity of PsA patients. The aim of this

study was to test the effect of probiotic supplementation on disease activity in PsA in a larger randomized controlled trial (RCT).

Methods: The study was designed as a single center, double-blind, RCT (NCT04588623) on consecutive patients with PsA in Moderate Disease Activity (MoDA) (Psoriatic ArthritiS Disease Activity Score [PASDAS] >3.2 - < 5.4) under stable treatment. Patients were randomized to either placebo or probiotic containing Bifidobacterium and Lactobacillus strains (OMNi-BiOTiC® STRESS Repair, Institut Allergosan, Graz, Austria) for 12 weeks. After week 12 (W12) patients received probiotics, irrespective of the initial grouping and were followed up again at week 24 (W24). The patients enrolled were given a full clinical assessment and samples (stool, serum, and PBMCs) were collected at baseline (BSL), W12, W24. Immune cell composition in the peripheral blood was analyzed using flow cytometry. Stool microbiome was analyzed via 16s rRNA sequencing and levels of Zonulin, Calprotectin and Anti-Trypsin were assayed through ELISA as a measure of gut permeability and intestinal inflammation. The primary end point of the study was the reduction of disease activity to low DA or remission (PASDAS < 3.2) at W12.

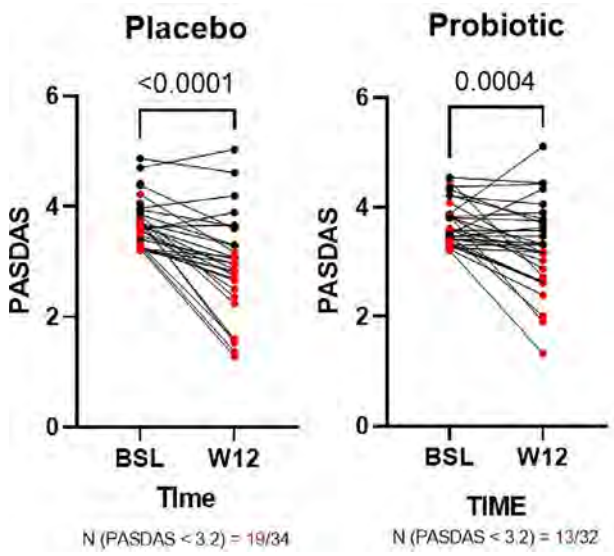

Fig1 Changes in PASDAS score in patients grouped by probiotic intervention. Samples in red denote specifically the patients that achieved low DA or remission (PASDAS < 3.2).

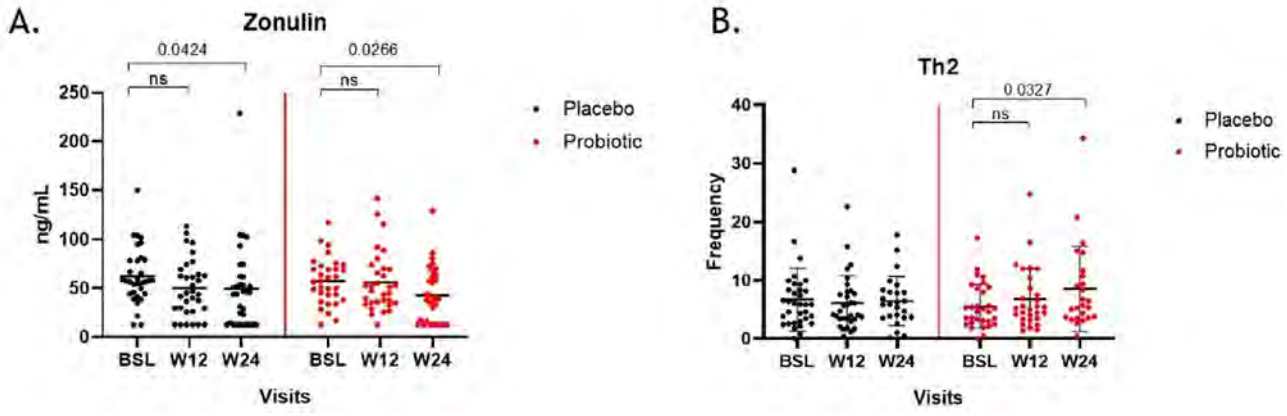

Fig2. A. Changes in concentration of zonulin in stool samples at different time points as measured by ELISA (ng/ML). B. Frequency of Th2 cells at different time points in both intervention groups as a frequency of the parent population. In both graphs black dots denote placebo group and red denotes probiotic group.

Results: A total of 65 patients were recruited and off these 32 patients were randomized into the probiotic group and 34 patients into the placebo group. A significant reduction in disease activity was observed as measured by the PASDAS score in both groups irrespective of probiotic intervention (Fig1). The proportion of patients reaching low DA or remission was not different between probiotic and placebo (55.8% vs 40.63%). A significant reduction in zonulin levels was observed in the probiotic group at W24 compared to BSL, whereas only a slightly weaker effect was seen in the placebo group (Fig2A). Results from immune cell phenotyping, revealed a significant increase in the frequency of Th2 cells in the probiotic group at W24 (Fig2B). No significant differences were observed in the frequencies of other lymphocyte subsets like Th1, Th17 and Tregs.

Conclusion: In this double-blind RCT, supplementation of probiotics in PsA patients showed limited effects on the dysbiosis of the gut measured by marker Zonulin and also had minor effects on the T-cell composition. However, no difference was seen in the amelioration of disease activity compared to placebo treatment, which could be due to the small samples size and the short recording period of the trial.

Abstract Number: 0779

Influence of Sex on the Persistence of Different Classes of Targeted Therapies for Psoriatic Arthritis: A Cohort Study of 14,778 Patients from the French Health Insurance Database (SNDS)

Laura PINA VEGAS[1], Laetitia Penso[2], Emilie Sbidian[3] and pascal claudepierre[4], [1]Henri Mondor University Hospital (APHP), Rheumatology Department, Créteil, France, [2]Université Paris Est Créteil, Créteil, France, [3]Hôpital Henri Mondor, Université Paris Est Créteil, Créteil, France, [4]Universitary Henri Mondor Hospital, Creteil, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: PsA
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous condition and sex differences in phenotypic presentation, disease trajectory, and treatment response have been reported. Nevertheless, it remains unclear whether classes of targeted therapies differentially impact men and women with PsA.

Our objective was to assess the influence of sex on the long-term persistence of each class of targeted therapies in a national healthcare database.

Methods: This nationwide cohort study involved the administrative healthcare database of the French health insurance scheme linked to the hospital discharge database (SNDS). We included all adults with PsA, new users of targeted therapies (not in the year before the index date) during 2015-2021, and studied each different treatment line during the study. Persistence was defined as the time from treatment initiation to discontinuation and was estimated by the Kaplan-Meier method. Comparison of persistence by sex involved using multivariate frailty model and adjusting on csDMARDs and prednisone as time-dependant variables. Similar analyses were performed in patients receiving first-line targeted therapy only. To control the risk of type 1 error, a Bonferroni adjustment was applied: a $p \leq 0.01$ was considered significant, and 99% confidence intervals (CI) were calculated.

Table: Comparison of targeted therapies persistence by sex and therapeutic classes

	Women vs. Man	
	HR_a (99%CI)	p-value
All lines		
TNFi n = 15,654	**1.39 (1.32-1.47)**	**<10^{-4}**
IL17i n = 6,195	**1.18 (1.08-1.29)**	**<10^{-4}**
IL12/23i n = 2,809	1.14 (0.97-1.33)	0.03
IL23i n = 798	1.07 (0.75-1.52)	0.64
JAKi n = 863	1.21 (0.89-1.63)	0.11
First line		
TNFi n = 10,407	**1.48 (1.38-1.58)**	**<10^{-4}**
IL17i n = 2,310	**1.40 (1.18-1.65)**	**<10^{-4}**
IL12/23i n = 1,541	1.17 (0.97-1.41)	0.03
IL23i n = 287	1.57 (0.74-3.32)	0.12
JAKi n = 233	1.00 (0.51-1.83)	0.95

Adjusted for age, morbid or complicated obesity, smoking (proxy), alcohol (proxy), Charlson comorbidity index, hospitalization for psoriatic arthritis within 2 years, consultations with a rheumatologist within 2 years, csDMARDs at index date, NSAIDs at index date, prednisone at index date, csDMARDs within 2 years, NSAIDs within 2 years, and prednisone within 2 years, and then on prednisone and csDMARDs as time-dependent variables. Values in bold correspond to significant results: the p value is considered significant if <0.01 (Bonferroni correction). *TNFi: tumor necrosis factor inhibitor; ILi: interleukin inhibitor; JAKi: Janus Kinase inhibitor; HR_a: adjusted hazard ratio; 99%CI: 99% confidence interval.*

Results: We included 14,778 patients with PsA new users of targeted therapies: 8,475 (57%) women (mean age 50 ±13 years), 6,303 (43%) men (51±13 years). The number of lines of therapy were: within women, 9,462 (60%) TNF inhibitors (TNFi), 3,762 (24%) IL17i, 1,639 (10%) IL12/23i, 392 (2%) IL23i, 576 (4%) JAKi, and within men 6,192 (59%) TNFi, 2,433 (23%) IL17i, 1,170 (11%) IL12/23i, 406 (4%) IL23i and 287 (3%) JAKi. Overall, 1-year persistence rates were 52% for women and 62% for men. Persistence decreased markedly over time in both sexes to 27% and 39% respectively at the end of the third year, although in varying proportions by therapeutic class. After adjustments, persistence was statistically lower in women than in men for TNFi (adjusted hazard ratio (HR_a) 1.4, 99%CI 1.3-1.5) and IL17i (HR_a 1.2, 99%CI 1.1-1.3), but not for IL12/23i (HR_a 1.1, 99%CI 0.9-1.3), IL23i (HR_a 1.1, 99%CI 0.7-1.5) and JAKi (HR_a 1.2, 99%CI 0.9-1.6). Results were similar for patients receiving first-line therapy (*Table*).

Conclusion: Treatment persistence is lower in women than in men for TNFi and IL17i, but no longer significant for IL12/23i, IL23i and JAKi. This may be due to differences in rheumatic phenotype, disease activity/severity or immunogenicity, but also to disparities in healthcare-seeking behavior due to gender norms. This highlights the need for sex- and gender-based studies to better understand the underlying mechanisms, but also for face-to-face studies with sex-stratified analyses to optimize the management of PsA patients and achieve the ambitious goal of personalized medicine in the coming years.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: PsA

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Individualized treatment strategies are of high importance in the treatment of patients with active psoriatic arthritis (PsA), a heterogeneous immune-mediated disease. IL-17 inhibition has demonstrated efficacy in all domains of PsA. Nevertheless, approx. 30% of patients will not achieve remission after initiation of therapy. Therefore, the identification of patient characteristics with a high impact on treatment response is important to guide treatment choice and its adjustments in clinical routine care to promote an improved outcome. An adapted machine learning approach (cluster analysis) was used to analyze baseline (BL) patient characteristics to detect clinical patterns of disease activity in PsA patients treated in a non-interventional trial with secukinumab (SEC).

Methods: Data from 1257 patients from the German non-interventional study AQUILA with active PsA whose first SEC treatment occurred no more than 4 weeks prior to BL was analyzed. All patients were included irrespective of treatment response. We identified patient groups by applying an extended version of the machine learning method of hierarchical density-based clustering to the BL data, where features included patient and disease characteristics variables as well as standardized patient-reported outcomes (Table 1). Feature groups with high numbers of missing values were initially excluded, and subsequent clustering was performed to achieve stepwise integration of all features. At each step, an additional feature group was included in a re-clustering using a complete subset of subjects. This led to a further split of some of the original clusters. For every final cluster, disease activity over the course of the study was visualized including patient and physician-derived assessments.

Results: The machine learning approach resulted in the categorization of 14 different clusters of patients and outliers (n=391, cluster -1) (Fig. 1). The focus is directed towards two medically relevant clusters that differ primarily in their pretreatments prior to SEC. Cluster 1 included PsA patients with predominantly bDMARD pretreatment incl. IL-23-inhibitors, while cluster 2 primarily received csDMARD pretreatments including apremilast (Fig. 2). Cluster 1, showed a greater reduction in disease activity than cluster 2 as measured by PASI and PGA (mean reduction: PASI: cluster 1: 8.0, cluster 2: 5.6; PGA: cluster 1: 2.8, cluster 2: 2.4) by week 52 (Fig. 2). However, these comparisons did not reach statistical significance for this sample.

Conclusion: We present a machine-learning approach to exploring the association between BL features of patients treated with SEC and their disease activity scores in the large PsA cohort of the AQUILA trial. The cluster analysis revealed that pretreatment with bDMARDs did not affect the efficacy of SEC compared to the predominantly csDMARD patient cohort

Table 1: Overview of dataset characteristics of 1,257 PsA patients at baseline, across all 14 clusters. *Total n can differ from 1,257 in table, due to missing values, ** stroke, chronic heart failure or coronary heart disease, *** for enthesitis patients only

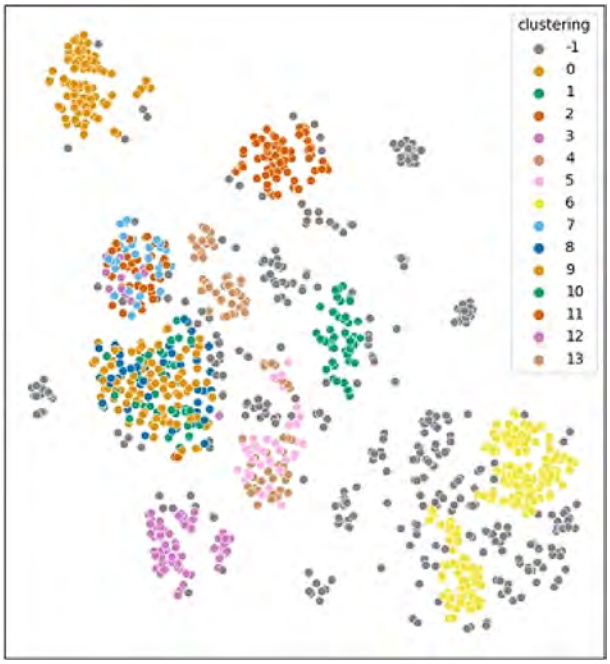

Figure 1: Result of multistage clustering of BL characteristics of 1,257 active PSA patients. The clustering reveals 14 clusters and outliers (cluster –1). Important cluster characteristics: Cluster 1, pretreatment with bDMARDs (including IL-23i); Cluster 2, pretreatment with csDMARDs (including apremilast). The scatterplot of the patient characteristics is created by the dimension reduction TSNE to 2 dimensions and thus has, resulting in arbitrary units on the axes.

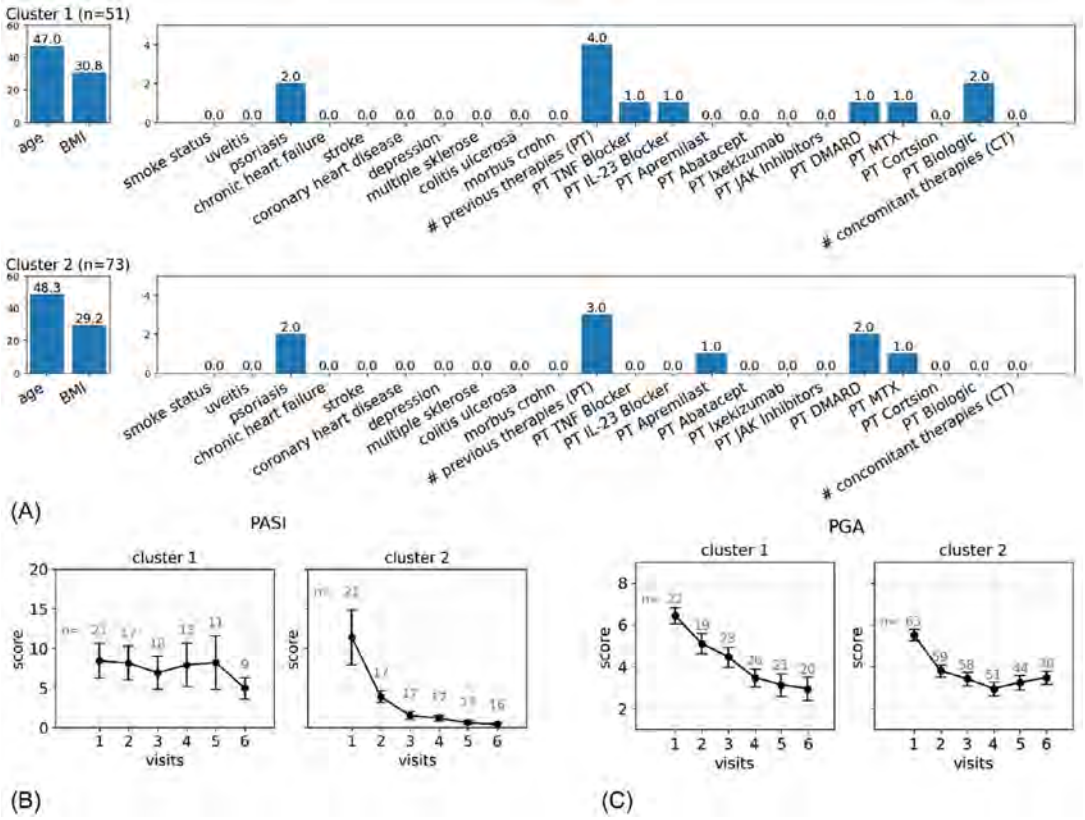

Figure 2 (A) Median BL characteristics of patients of cluster 1 and cluster 2 (B) Mean PASI with standard error of patients of cluster 1 and cluster

(predominantly bDMARD naïve). PASI and PGA tend to have a stronger improvement in patients pretreated with bDMARDs than in patients pretreated with csDMARDs including apremilast after 52 weeks of treatment with SEC.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: SLE – Treatment I: Renal

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Traditional induction treatment regimens for proliferative or membranous lupus nephritis (LN) have utilized oral glucocorticoids (GC) in initial doses up to 1.0 mg/kg/day prednisone equivalent with or without a preceding intravenous (IV) methylprednisolone pulse. More recent management guidelines have recommended lower starting oral GC doses following a short IV steroid course, with several clinical trials suggesting this protocol may yield similar results to those using higher GC doses. As there have been no large studies directly comparing responses in patients receiving low vs. high initial oral GC doses for LN treatment, this pooled analysis of randomized controlled trials (RCTs) aims to evaluate differences in efficacy and safety among these groups.

ACT: Rituximab Controlled Trial; LN: Lupus Nephritis; UPCR: Urine protein/creatinine ratio; IV: Intravenous; N/A: Not available; MMF: Mycophenolate mofetil; CYC: Cyclophosphamide; Aza: Azathioprine; AA: African American; SD: Standard deviation; ACE-I: Ace inhibitor; ARB: Angiotensin II Receptor Blocker; CRR: Complete renal response; PRR: Partial renal response; SAE: Serious adverse event; ULN: Upper limit of normal; RBC: Red blood cells; HPF: High powered field

a) CRR: Normal serum creatinine level if abnormal at baseline, or a serum creatinine level of ≤115% of baseline if normal at baseline, inactive urinary sediment (<5 RBCs/HPF and absence of RBC casts), and UPCR <0.5 mg/mg
PRR: serum creatinine level ≤115% of baseline, RBCs/HPF ≤50% above baseline and no RBC casts and at least a 50% decrease in the UPCR to <1.0 mg/mg (if baseline UPCR ≥1.0 mg/mg) or to ≤1.0 (if baseline UPCR <1.0 mg/mg)

b) CRR: Normal serum creatinine (≤25% increase from baseline) and improvement in UPCR to <0.5 mg/mg
PRR: Serum creatinine ≤25% above baseline, and 50% improvement in UPCR, and if baseline ratio >3.0 mg/mg, then UPCR <3.0 mg/mg

c) CRR: UPCR <0.5 based on 24-hour urine collection, serum creatinine ≤1.2 mg/dL or ≤125% of baseline, and adherence to the prednisone taper to 10 mg/d by week 12
PRR: 50% reduction of UPCR based on a 24-hour urine collection, serum creatinine ≤1.3 mg/dl, or ≤104% of baseline, adherence to the prednisone taper to 10 mg/d by week 12

d) CRR: UPCR <0.5 mg/mg and inactive urinary sediment
PRR: Serum creatinine level normal or ≤125% of baseline; UPCR <50% of baseline and <3.0 mg/mg if nephrotic, or <1.0 mg/mg if non-nephrotic; urinary sediment inactive or >50% reduction in RBC/HPF from baseline

e) CRR: UCR% <2.5 mg/mg, eGFR that is ≤15% below the pre-flare value or at least 60 ml/min/1.73 m^2, and no rescue therapy
PRR: eGFR ≤10% below baseline value or within normal range and ≥50% decrease in the ratio of UPCR with one of the following: UPCR <1.0 mg/mg if the baseline ratio was ≥3.0 mg/mg, or a UPCR <3.0 mg/mg if the baseline ratio was >3.0 mg/mg; no treatment failure; not a complete renal response.

Methods: Published data was analyzed from RCTs that assessed variable doses of GC and an experimental LN treatment with standard of care (SOC) compared to GC and SOC alone. SOC regimens consisted of either mycophenolate mofetil or Euro-Lupus cyclophosphamide followed by azathioprine. Patients from SOC arms receiving a starting prednisone dose of up to 0.5 mg/kg/day (low dose) were compared to those receiving up to 1.0 mg/kg/day (high dose). Complete renal response 0.5 (CRR 0.5) was defined as patients with urine protein/creatinine ratio (UPCR) < 0.5 mg/mg at study completion, along with other parameters that varied between studies (Tables 1, 2). CRR 0.5, serious adverse events (SAE), and where available, isolated UPCR < 0.5 mg/mg, partial renal response (PRR, defined in Tables 1, 2) and SAE due to infections were compared between groups using Fischer's exact tests.

Results: 377 patients from the SOC arms of 4 studies were exposed to low dose initial GC while 589 patients from 5 studies were treated with high dose GC. LN class and UPCR required for inclusion were generally similar across studies, as were baseline characteristics including white race and, where reported, Hispanic ethnicity, UPCR and percentages on ACE-I/ARB medications (Tables 1, 2). All low dose oral GC studies required an IV steroid pulse compared to only one high dose study. In patients receiving initial low dose oral GC, 23.6% achieved CRR 0.5 at the end of study compared to 24.7% in high dose patients (p=0.75). In reports with available data, similar percentages were seen between groups for isolated UPCR < 0.5 mg/mg (26.7% low dose vs. 30.9% high dose, p=0.29) and CRR or PRR (46.3% low dose vs. 42.8% high dose, p=0.32). SAEs were less common in patients receiving lose dose GC, present in 20.7% compared to 30.7% in high dose patients, p=0.0006. In studies reporting SAE due to infection, low dose GC patients had less frequent events (11.6% vs. 16.4%, p=0.08).

Conclusion: Based on data pooled from multiple published trials utilizing SOC treatment for LN, there is no significant difference in renal responses between patients receiving IV steroid followed by low dose prednisone compared to those receiving high prednisone doses as initial oral GC during induction. Serious adverse events were less frequent in patients receiving low

dose initial GC, although other study-specific considerations may factor in that association. These findings support the use of lower oral GC doses in LN treatment.

Abstract Number: 0782

Comparison of Dual-immunosuppressive Therapy with a Voclosporin-based, Triple-immunosuppressive Regimen for Lupus Nephritis in the ALMS and AURORA 1 Studies

Maria Dall'Era[1], Ernie Yap[2], Matt Truman[2], Lucy Hodge[2] and Neil Solomons[3], [1]University of California San Francisco, San Francisco, CA, [2]Aurinia Pharmaceuticals Inc., Edmonton, AB, Canada, [3]Neil Solomons Consulting Inc., Victoria, BC, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Treatment I: Renal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Dual-immunosuppressive regimens consisting of high-dose glucocorticoids and higher doses (>2 g/day) of mycophenolate mofetil (MMF) are still frequently used for the initial management of active lupus nephritis (LN) despite the known serious and dose-dependent safety risks associated with both of these agents.

To understand the safety and efficacy of a voclosporin-based, MMF and glucocorticoid-sparing, triple immunosuppressive regimen as an initial approach to treatment in active LN compared to more conventional regimens, we compared and analyzed safety and efficacy data in propensity-matched patients from the ALMS and AURORA 1. We hypothesized that a

Table 1 Key Baseline Disease Characteristics

Parameter	ALMS N=96	AURORA 1 N=96
Duration of SLE, years		
Mean (SD)	5.33 (5.5)	5.18 (6.2)
Albumin, g/dL		
Mean (SD)	2.9 (0.6)	2.8 (0.7)
UPCR, g/g		
Mean (SD)	4.2 (4.5)	4.3 (2.9)
C3, mg/dL		
Mean (SD)	76.8 (29.53)	79.1 (34.3)
Low <90 mg/dL, n (%)	66 (68.8)	59 (61.5)
C4, mg/dL		
Mean (SD)	15.6 (12.3)	15.8 (10.0)
Low <10 mg/dL, n (%)	37 (38.5)	31 (32.3)
anti-dsDNA, IU/mL		
Mean (SD)	117.9 (93.2)	118.3 (133.6)
High >10 IU/mL, n (%)	94 (97.9)	77 (80.2)

Propensity score methodology was used to generate two groups of matched patients (n=96) from the ALMS and AURORA 1 studies based on the following parameters: age, duration of lupus nephritis, duration of SLE, albumin, C3, C4, creatinine, anti-dsDNA, eGFR, UPCR, biopsy class, sex, and geographical region.
Anti-dsDNA, anti-double strand deoxyribonucleic acid; C3, complement 3; C4, complement 4; SLE, systemic lupus erythematosus; SD, standard deviation.

voclosporin-based, triple immunotherapy approach would reduce patient exposure to the toxicities associated with glucocorticoids and MMF, resulting in an improved safety profile without compromising efficacy.

Methods: Both studies enrolled patients with active LN. In ALMS, MMF was dosed to a target of 3 g/day with oral glucocorticoids initiated at a maximum dose of 60 mg/day and tapered every 2 weeks to 10 mg/day. In AURORA 1, patients received voclosporin 23.7 mg BID in combination with MMF (target dose 2 g/day) and oral glucocorticoids (starting dose of 25 mg/day tapered to 2.5 mg/day by Week 16). Propensity score matching was used to generate two groups of matched patients based on a set of demographic and disease characteristics. Safety and efficacy outcomes were assessed at 3 and 6 months.

Results: Propensity matching identified 96 pairs of patients with similar demographics and baseline disease characteristics (Table 1). At 3 and 6 months, MMF and glucocorticoid exposure was more than two-fold higher in ALMS than AURORA 1. Overall, fewer adverse events were observed in AURORA 1 across the majority of organ systems, including gastrointestinal, skin and subcutaneous tissues, endocrine, and psychiatric disorders, although more patients in AURORA 1 were reported to experience GFR decrease (Table 2). The incidence of serious adverse events was similar in both groups at 3 and 6 months. In the first 3 months, significantly more patients in AURORA 1 achieved >25% UPCR reduction from

UPCR reduction >50%, n (%)	61 (63.5)	69 (71.9)
OR (95% CI) vs ALMS, p-value	1.54 (0.8, 2.95) 0.1956	

Based on data from 96 patients from ALMS and AURORA 1 matched using propensity scoring. CI, confidence interval; MMF, mycophenolate mofetil; OR, odds ratio; UPCR, urine protein creatinine ratio.

baseline (p=0.011; Table 3); the proportions of patients achieving UPCR ≤0.5 g/g and >50% UPCR reduction from baseline were numerically greater in the voclosporin arm; the differences were not statistically significant.

Conclusion: Patients treated with voclosporin in combination with low-dose glucocorticoids and lower-dose MMF demonstrated an improved safety profile and earlier reductions in proteinuria compared to patients treated with high-dose glucocorticoids and higher doses of MMF. These findings affirm the KDIGO 2023 recommendation that a voclosporin-based, triple-immunotherapy regimen should be considered as an initial therapy in patients with active LN.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Treatment I: Renal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: We have previously shown that CD19 CAR T cell therapy can lead to improvement of severe forms of B cell mediated autoimmune disease including SLE (1,2), idiopathic inflammatory myopathy (IIM) (3) and systemic sclerosis (SSc) (4). In hematologic malignancies, CD19 CAR T cell therapy is often associated with side effects such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS). We therefore addressed

the incidence, severity and reversibility of CRS and ICANS in patients with autoimmune disease receiving CD19 CAR T cell therapy.

Methods: Patients with active and treatment-refractory SLE, IIM and SSc received a single infusion of 1 million CD19 CAR T cells manufactured from autologous T cells and transfected with the lentiviral vector MB-CART19.1 (Miltenyi) encoding the CD19 CAR. Immunosuppressive treatment was stopped before CAR T cell infusion. Standard conditioning treatment (1g/m2 cyclophosphamide, 75 mg fludarabine) was administered before CAR T cell infusion. Incidence, severity and reversibility of CRS and ICANS were monitored during the first 14 days after infusion. CRS was graded as 1 (fever), 2 (hypotension), 3 (one vasopressor, high-ventilation) and 4 (multiple vasopressors, positive airway pressure). ICANS was graded as 1 (dizziness, fatigue), 2 (somnolence, delirium), 3 (spoor, seizures) and 4 (coma). In addition, reversibility of CRS and ICANS in response to anti-pyretic drugs and/or tocilizumab was documented.

Results: Between March 2021 and June 2023 15 patients (mean ± SD age: 35,7± 11,2 years) received treatment with CD19 CAR T cell therapy (8 SLE, 3 IIM and 4 SSc). SLE patients were younger (28.0 ± 7.2) than IIM (43.0 ± 1.0) and SSc patients (45.7 ± 11.1 years). CRS was observed in 60% (9/15) and was graded mild (grade 1) in 8/9 cases (4 SLE, 2 IIM and 2 SSc) and moderate (grade 2) in 1/9 cases (1 IIM). The moderate CRS was based on pre-existing dyspnea based on interstitial lung disease, which worsened during the fever bout and required oxygen treatment for one day. CRS events happened between day 1 and day 4 after CAR T cell therapy. CRS resolved fast after using anti-pyretic drugs. Tocilizumab was given in 40% (6/15) of the patients, mostly as single infusion, which lead to immediate resolution of CRS. Only one patient received three tocilizumab infusions. Mild ICANS (1IIM) was observed in one patient, presenting with dizziness 7 days after infusion. The patient received a short course of glucocorticoids, which led to resolution of ICANS. The cases of CRS grade 2, ICANS grade 1 and repeated tocilizumab treatment occurred in different patients.

Conclusion: Overall safety of CD19 CAR T cells therapy in autoimmune disease appears to be high. Low-grade CRS is frequent but can be managed well. Higher grade CRS was not found and seems to be infrequent. Also ICANS appears to be infrequent in patients with autoimmune disease. Tolerability of CD19 CAR T cell therapy seems to be similar in SLE, IIM and SSc and no influence of age was observed.

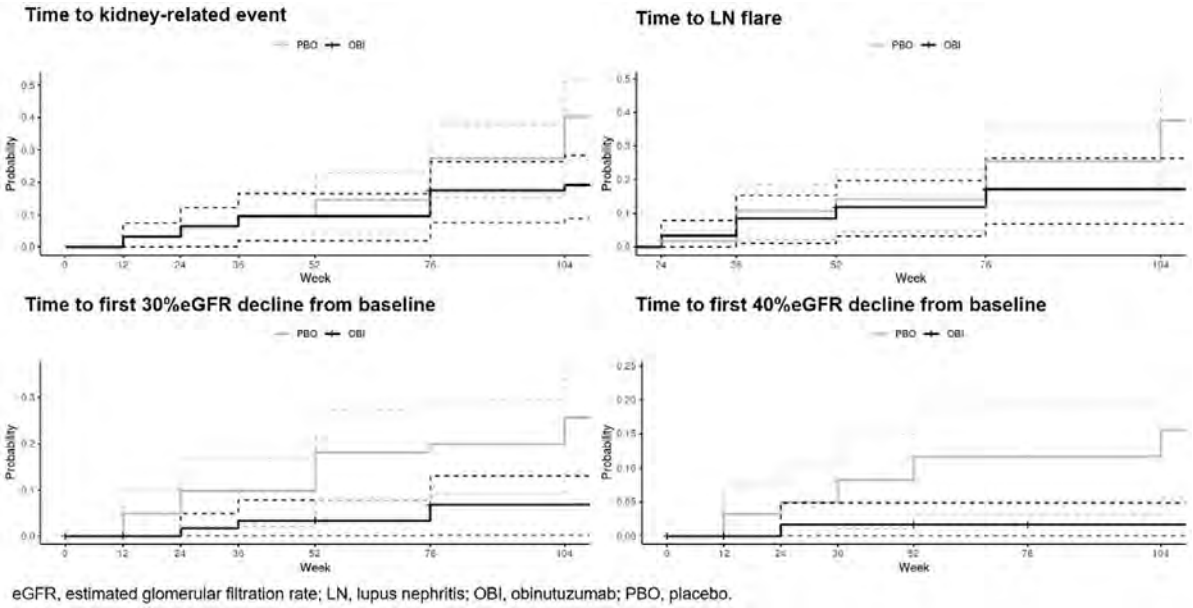
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Treatment I: Renal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Preservation of long-term kidney function and sustained reduction of glucocorticoid use are major therapeutic goals in lupus nephritis (LN). In the randomized, double-blind, placebo-controlled, Phase 2 NOBILITY trial (NCT02550652), patients with proliferative LN receiving obinutuzumab with standard-of-care therapy showed clinically meaningful improvement in complete and overall renal responses (CRR and ORR) at Weeks 52, 76 and 104 compared with those receiving placebo and standard-of-care therapy.[1] We conducted a post hoc analysis of NOBILITY to assess kidney-related outcomes and steroid-sparing effects.

Methods: Cox regression analysis was conducted for the time to first kidney-related event (death, doubling of serum creatinine and treatment failure), LN flare and first 30% and 40% eGFR decline from baseline. The eGFR slope was assessed in a linear mixed-effects model. Assessment of a steroid-sparing effect of ≤7.5 mg/day of prednisone while achieving CRR at Weeks 76 and 104 without use of >7.5 mg/day of prednisone between Weeks 64 and 76 and Weeks 92 and 104, respectively, was calculated by the Cochran–Mantel–Haenszel test stratified for race (Afro-Caribbean/African American vs others) and country (US vs non-US). Glucocorticoid dose was imputed by the LOCF method for patients who discontinued the study and/or for missing data. All patients met ACR classification criteria for systemic lupus erythematosus and had biopsy-proven proliferative LN.

Results: Obinutuzumab significantly reduced the risk of kidney-related events or death (HR, 0.40; 95% CI, 0.20 to 0.80), LN flare (HR, 0.43; 95% CI, 0.20 to 0.95) and time to first eGFR decline of 30% (HR, 0.20; 95% CI, 0.06 to 0.61) and 40% (HR, 0.09; 95% CI, 0.01 to 0.73) (**Figure**). Risk of sustained eGFR decline of 30% and 40% was numerically lower, and a significant difference in attenuation of eGFR slope decline was observed between patients receiving obinutuzumab and standard-of-care therapy and those receiving placebo and standard-of-care therapy (annual slope difference, 4.10 mL/min/year; 95% CI, 0.14 to 8.08). Patients receiving obinutuzumab and standard-of-care therapy were significantly more likely to achieve



eGFR, estimated glomerular filtration rate; LN, lupus nephritis; OBI, obinutuzumab; PBO, placebo.

CRR at Week 76 without receiving >7.5 mg/day of prednisone from Week 64 through 76 than those receiving placebo and standard-of-care therapy (24 of 63 patients [38.1%] vs 10 of 62 [16.1%], respectively; $P< 0.01$). A similar trend was observed at Week 104 without receiving >7.5 mg/day of prednisone from Week 92 through 104, but this did not reach statistical significance.

Conclusion: Obinutuzumab, in addition to increasing the possibility of achieving CRR, significantly reduced the risk of kidney-related events, eGFR decline, time to LN flare and eGFR slope decline in a post hoc analysis, suggesting that obinutuzumab in combination with standard-of-care therapy may positively impact kidney-related outcomes. In addition, a significant steroid-sparing effect was observed at Week 76. Obinutuzumab is being evaluated in patients with active proliferative LN in the global registrational Phase 3 REGENCY trial (NCT04221477).

Therapeutic Range of Hydroxychloroquine Blood Levels May Reduce Odds of High Lupus Disease Activity

Shivani Garg[1], Betty Chewning[2], Brad Astor[3] and Christie M. Bartels[3], [1]Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]University of Wisconsin, School of Pharmacy, Madison, WI, [3]University of Wisconsin, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Treatment I: Renal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is the cornerstone of lupus (or SLE) treatment. Yet the optimal dosing of HCQ in SLE is unknown. Reducing HCQ dose to 5 mg/kg to limit toxicity per American Academy of Ophthalmologists (AAO) guidelines, increases lupus flare risk by 6-fold. Therefore, establishing effective reference ranges of HCQ blood levels with upper and lower bounds for efficacy may inform individualizing HCQ dosing to maximize efficacy and limit toxicity. While studies suggest various thresholds for therapeutic HCQ blood levels, none have offered a therapeutic range with upper and lower bounds for HCQ levels that predict minimum and maximum efficacy. Moreover, clinical interpretation of a threshold is difficult as it may not account for changes in patient-level factors such as weight and kidney function and fluctuations in HCQ blood levels over time. Thus, the objectives of this study were to: 1) examine the association between HCQ blood levels and high lupus disease activity (HDA) in a prospective SLE cohort; 2) define therapeutic thresholds of HCQ blood levels with upper and lower bounds for HCQ blood levels that predict maximum and minimum efficacy.

Methods: This study measured HCQ blood levels in unique SLE visits using liquid chromatography-tandem mass spectrometry. HCQ blood levels and SLE disease activity index (SLEDAI) scores were measured on the day of the visit for each patient. High lupus disease activity (HDA) was defined as SLEDAI scores of ≥6. We performed nonparametric spline regression analysis to identify HCQ blood levels cut-points associated with reduction in the odds of HDA. To identify an effective therapeutic range with lower and upper limits of HCQ blood levels that are associated with lower odds of HDA, we examined associations between HDA and every 50-100 ng/ml increase in HCQ blood levels starting at 100 ng/ml through 1500 ng/ml using univariable and multivariable logistic regression models. Factors that can affect HCQ levels, such as kidney function, HCQ dose and timing, were included in analyses.

Results: Among 158 SLE patients in whom HCQ blood levels were measured, 92% were women and 32% were of Black race or Hispanic ethnicity. HDA was noted in 18% of patients.

Using nonparametric spline regression models, we noted that HCQ blood levels, 750 and 1100 ng/ml, significantly reduced the odds of HDA (Figure 1A). HCQ blood levels < 700 & >1150 did not reduce the odds of HDA (Figure 1B & Table 1). Levels of 750 ng/ml lowered the lower odds of HDA by 76% (OR 0.24, p=0.016, Fig 1B & Table 1). A sustained reduction in the odds of HDA with HCQ blood levels was noted through 1000 ng/ml. Peak effects were noted at levels of 1100 ng/ml with a 90% reduction in the odds of HDA (Figure 1B. & Table 1). Figure 2. illustrates how these findings could guide clinicians to individualize HCQ dosing to achieve therapeutic blood levels to maximize efficacy, while balancing safety.

Conclusion: An effective therapeutic range of HCQ levels, 750-1100 ng/ml, significantly reduced the odds of high lupus disease activity by 76-90%. These findings could be guide clinicians to individualize HCQ dosing to maximize efficacy during routine lupus visits.

Abstract Number: 0786

A Retrospective Analysis of the Efficacy of the Euro-Lupus Nephritis Cyclophosphamide Regimen versus NIH Regimen in a South Carolina Lupus Nephritis Cohort

Anna Arar, Diane L. Kamen, Paul Nietert and Melissa Cunningham, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Treatment I: Renal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Manifestations of systemic lupus erythematous (SLE) vary in severity and presentation; lupus nephritis (LN) affects up to half of SLE patients and confers a high risk of morbidity and mortality. Since the early 1990s, the standard regimen for SLE patients with glomerulonephritis was high-dose IV cyclophosphamide (CTX) given once monthly for 6 months with 2 additional quarterly doses. This was widely accepted until the Euro-Lupus Nephritis Trial (ELNT) results were published in 2002 and demonstrated non-inferiority. It is now accepted to give a fixed dose of 500mg IV CTX every two weeks for 12 weeks (6 doses). However, the trial population in ELNT differs significantly than the population of SLE patients treated in the United States and more specifically, South Carolina, where African Americans represent 26.7% of the population. African Americans have a higher prevalence of LN and often more severe disease which may suggest the need for more aggressive therapy. Additionally, renal damage progressing to ESRD is still more common in African Americans. We hypothesized that the two regimens may not have equivalent efficacies in multiethnic patient cohorts.

Methods: We undertook a retrospective analysis to compare the Euro-Lupus Nephritis regimen to the NIH regimen in patients with lupus nephritis treated at the Medical University of South Carolina. Data was collected from patients with LN age 18-90 years old treated with CTX at MUSC from 2012 to 2022. There were no exclusion criteria. Data includes demographics, dates of visits and treatments, renal histological parameters, clinical laboratory values of lupus disease activity and renal status, medications, and dosing data.

Results: Eighty-five patients fit the inclusion criteria. Of these, 40 received ELNT, and 45 received the NIH protocol. There are 80 females and 5 males. Of the 85 subjects, 73 are African American (85.9%). In the ELNT cohort, 33 are African American (82.5%). There are 40 African Americans in the NIH group (88.9%). Demographics are provided in Table 1. Baseline and

Table 1: Enrollment Demographics

	Total	ELNT	NIH
Enrolled	85	40	45
Average Age at Treatment (Years)	30	32	29
Gender			
Male	5 (6%)	2 (5%)	3 (6.7%)
Female	80 (94%)	38 (95%)	42 (93.3%)
Race			
African American	**73 (85.9%)**	**33 (82.5%)**	**40 (88.9%)**
White	4 (4.7%)	3 (7.5%)	1 (2.2%)
Asian	3 (3.5%)	2 (5%)	1 (2.2%
Hispanic	4 (4.7%)	2 (5%)	2 (4.4%)
Other	1 (1.2%)	0	1 (2.2%)

Table 2: Laboratory value averages with standard deviations at baseline and 1 year from last treatment.

	Baseline Laboratory Values		1 Year from Treatment End	
	ELNT	NIH	ELNT	NIH
Serum Creatinine	1.65 (±1.15)	1.84 (±1.69)	2.60 (±2.99)	1.77 (±2.40)
eGFR	47.44 (±35.99)	38.38 (±33.79)	43.38 (±36.58)	53.23 (±38.83)
C3	62.94 (±33.44)	64.15 (±35.18)	97.77 (±33.35)	117.68 (±34.38)
C4	14.99 (±11.48)	13.25 (±0.58)	30.04 (±23.74)	26.43 (±13.44)
dsDNA	78.53 (±75.02)	63.4 (±71.71)	43.66 (±52.30)	24.45 (±33.16)

Table 3: Average change of serum creatinine in patients between 1 year and baseline laboratory values. The increase in ELNT was 0.91 while NIH improved by an average of 0.13.

	Average Change Between Patients	
	ELNT	NIH
Serum Creatinine	0.91 (±3.02)	-0.13 (±2.83)

one year laboratory averages with standard deviations are provided in Table 2. Table 3 shows the average change in serum Cr amongst patients in each treatment group. In the ELNT group, the average change showed an increase in creatinine by 0.91 (±3.02). The serum creatinine in the NIH cohort decreased by 0.13 (±2.83). Findings from this ongoing analysis suggest that at the one-year mark, patients in the ELNT group on average have an increase in serum creatinine, with 10 patients (25%) needing to be put on hemodialysis versus only 4 patients (8.8%) in the NIH cohort (p=0.0468).

Conclusion: No known prior studies have evaluated the efficacy of the ELNT protocol in a predominantly African American cohort. This project is currently ongoing. Preliminary results indicate that patients receiving the ELNT protocol at MUSC have increased serum creatinine at 1 year, possibly suggesting that the therapy is not aggressive enough. This is also shown in the proportion of patients requiring hemodialysis within 1 year. Additional research is needed to identify the optimal choice for cyclophosphamide regimen in different populations of patients with lupus nephritis.

Abstract Number: 0787

Understanding Distinct Resident and Migratory Fibroblast Populations in Systemic Sclerosis Skin Through Single-cell RNAseq and Immunohistochemistry

Kristina Clark[1], Shiwen Xu[2], Voon Ong[3], Christopher Buckley[4] and Christopher Denton[2], [1]Barts Health NHS Trust, London, United Kingdom, [2]University College London, London, United Kingdom, [3]UCL Medical School Royal Free Campus, London, United Kingdom, [4]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders I: Translational
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: We previously described distinct migratory and resident fibroblast populations from lesional skin biopsies in SSc patients. Both populations are profibrotic compared with those from healthy control (HC) skin, however migratory SSc fibroblasts display increased expression of αSMA, greater gel contraction, and faster migration in the scratch-wound assay. The two SSc populations differ by bulk RNAseq expression, with resident fibroblasts overexpressing CCL2, CXCL8 and ICAM1, whereas migratory fibroblasts overexpress genes such as COMP, TRIP3. Here we describe the use of scRNAseq of whole skin to define the functional differences between these two fibroblasts subsets

Methods: scRNAseq was performed on 12 SSc whole skin biopsies and 3 HC, using the 10X genomics platform. The markers identified in bulk RNAseq for each fibroblast populations were used to identify corresponding clusters in scRNAseq. Candidate gene sets to identify the resident and migratory fibroblast populations were developed, and KEGG gene set enrichment pathways (GSEA) identified.

We explored differences in relative frequency of resident and migratory fibroblasts populations in whole skin by stage and subset between ATA (anti-topoisomerase) and ARA (anti-RNA pol III), as well as late and early-stage disease.

Finally, we utilised CellDive® multiplex imaging to localize the two fibroblast populations within the dermis of skin biopsies

Results: Bulk RNAseq revealed 739 genes significantly overexpressed genes in the migratory fibroblast population, whereas 745 genes were significantly upregulated in the resident fibroblasts (Table 1).

10 clusters of fibroblasts were identified on scRNAseq. Cluster 0 and 4 showed gene expression similar to migratory fibroblasts, whereas the resident fibroblasts gene expressions paralleled clusters 3 and 6 (Figure 1).

Interrogating the scRNAseq clusters, revealed the migratory fibroblasts are the most abundant cell population. Subgrouping by autoantibody identified migratory fibroblasts as most abundant in the ATA subgroup, whereas resident fibroblasts are most abundant in the ARA subgroup, suggesting autoantibody status tracks distinct fibroblast subsets (Figure 2).

GSEA of KEGG pathways confirmed concordance between migratory and resident fibroblast clusters in bulk and scRNAseq analysis. Resident fibroblasts showed upregulation of complement and coagulation genes, and JAK/STAT signalling pathway. There was upregulation of glycolysis gluconeogenesis, and PPAR signalling in migratory fibroblasts.

Table 1: Table showing top 20 statistically significant differentially expressed genes between SSc migratory and SSc resident fibroblasts by fold change (FC).

Using CellDive® multiplexed technology, and markers of resident and migratory fibroblasts, the fibroblast populations localise to different areas of the dermis, with migratory fibroblasts being more perivascular, and resident being scattered throughout the dermis

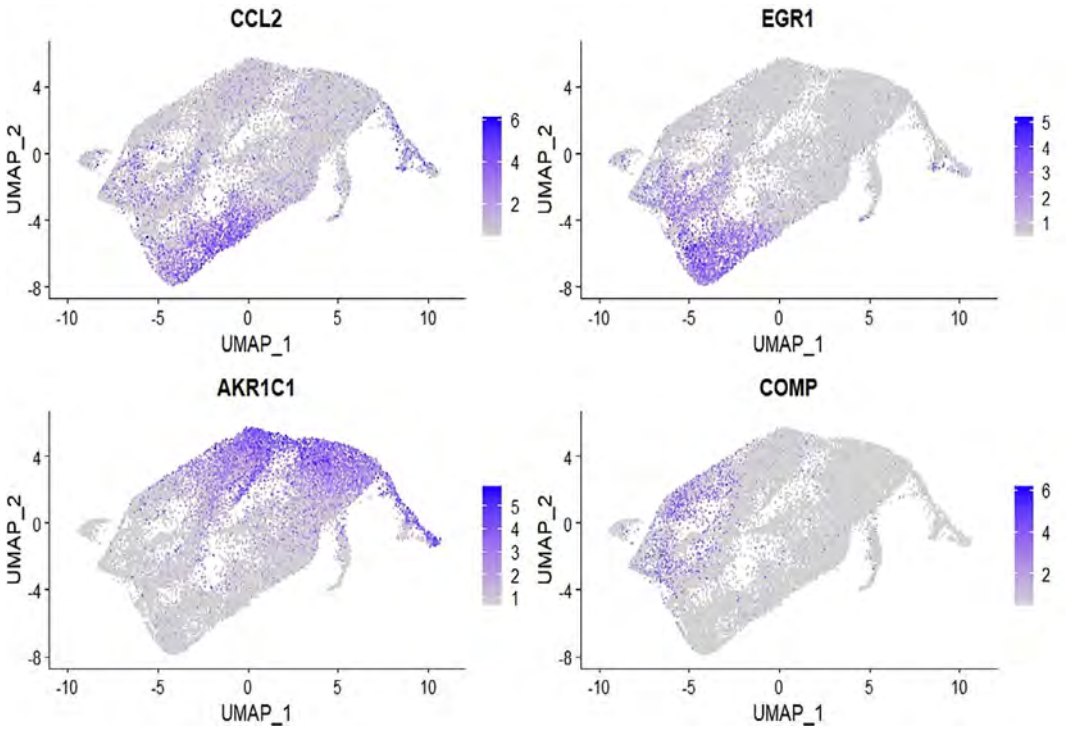

Figure 1: Identifying resident and migratory fibroblasts in scRNAseq. Migratory fibroblasts were identified with COMP and AKR1C1, whereas CCL2 and EGR1 were more specific for resident fibroblasts.

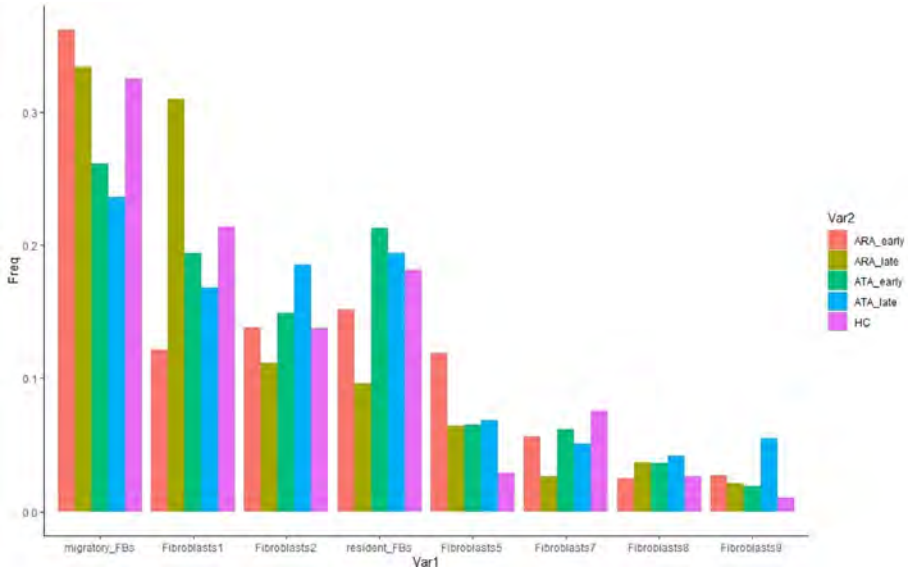

Figure 2: Abundance of fibroblast populations by antibody and stage. Migratory fibroblasts first column and resident fibroblasts 4th column

Conclusion: We extended our understanding of two fibroblast populations in SS and describe a molecular basis for their functional differences and location within the dermis. Understanding their different functions, and appreciating their tight association with auto antibody subset, begins to explain the differences in clinical phenotype and response to therapeutics linked to disease stage and subset of SSc.

Whole Exome Sequencing and Evolutionary Action Missense Mutation Analysis Identifies *MICB* as a New SSc Susceptibility Locus and the Interferon Pathway as Contributors to SSc Pathogenesis

Shamika Ketkar[1], Hongzheng Dai[1], Brian Dawson[1], Lindsay Burrage[1], David Murdock[1], Jennifer Asmussen[1], Kevin Wilhelm[1], Olivier Lichtarge[1], Martin Kerick[2], Javier Martin[3], Shervin Assassi[4], Brendan Lee[1] and **Maureen Mayes**[5], [1]Baylor College of Medicine, Houston, TX, [2]Spanish National Research Council, Granada, Spain, [3]Instituto de Parasitologia y Biomedicina Lopez-Neyra - CSIC, Granada, Spain, [4]University of Texas McGovern Medical School at Houston, Houston, TX, [5]Division of Rheumatology, University of Texas McGovern Medical School, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders I: Translational
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic Sclerosis (SSc) is characterized by fibrosis of the skin and internal organs associated with vasculopathy and autoantibodies and exhibiting wide clinical heterogeneity. Contributors to pathogenesis include genetic variants and currently unidentified external triggers. Several genome-wide association studies (GWASs) have shed light on the genetic component and estimated that it contributes 30% to the risk of developing SSc. We used Whole Exome Sequencing (WES) data to identify novel SSc susceptibility loci, and to identify putative causative pathways.

Methods: Exome sequencing (ES) was performed by Regeneron in an academic-industry partnership. ES data was provided to the study team and all analyses were performed by the authors independently of Regeneron. We first performed GWAS analysis of 2,865 Caucasian cases and 1,043 controls from samples in the SSc Registry and DNA Repository. Genotype imputation was performed with the 1000 Genome Project Phase 3 panel which yielded 5,522,961 variants. Case-control association analysis was performed using PLINK v1.9 logistic regression model of additive effects, including gender and the first two principal components (PCs) as covariates. Replication testing was performed in an independent case-control set of European ancestry (949 SSc patients, 998 controls from collaborators Kerick and Martin).

The **evolutionary action method** estimates the functional and clinical impact (mutational harm) of missense protein coding variations.

Results: We identified a novel susceptibility locus at *MICB* (rs2516497, $P = 8.42 \times 10^{-15}$) within the HLA region. *MICB* (MHC class I chain-related gene B) is a protein coding gene in the MHC region whose gene product is a stress-inducible cell surface molecule that labels malfunctioning cells for targeting by cytotoxic lymphocytes such as natural killer cells.

Additionally, we confirmed and firmly established the role of *HLA-DQA1* (rs1048372, $P = 2.95 \times 10^{-21}$) and *HLA-DQB1* (rs2647032, $P = 1.32\times 10^{-16}$) gene regions as SSc genetic risk factors. Replication testing in an independent case-control set of European ancestry confirmed association of this *MICB* SNP (rs2516497, $P = 7.17 \times 10^{-9}$) to SSc. In addition, the replication cohort also confirmed that the association of this *MICB* SNP is an independent event, i.e., it is not in linkage disequilibrium with other HLA class genes.

Next, we applied the evolutionary action method to investigate genes and pathways associated with SSc. Evolutionary action predicts the impact of missense variants on protein function. Using the *de novo* missense variants from the ES data, this method corroborated genes associated with SSc and identified additional genes in the interferon pathway among others. *IFI44L* and *IFIT5* are interferon genes and are shown to be dysregulated in SSc blood and skin.

Conclusion: Using a GWAS analysis applied to WES data, we identified *MICB* as a novel SSc susceptibility locus independent of other HLA class genes. Additionally, by application of the evolutionary action analysis method to this dataset, we identified missense mutations in the interferon pathway that may contribute to SSc pathogenesis.

Telomere Length of Peripheral Blood Cells Predicts More Severe Pulmonary Disease and Worse Survival in Systemic Sclerosis

Monica Yang[1], Shuo Liu[2], Seoyeon Lee[3], Sarah French[1], Paul Wolters[1] and Francesco Boin[4], [1]University of California San Francisco, San Francisco, CA, [2]Fourth Hospital of China Medical University, Shenyang, China, [3]Yale University School of Medicine, New Haven, CT, [4]Cedars-Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders I: Translational
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Peripheral blood leukocyte telomere length (PBL-TL) has been associated with disease and organ specific morbidity and mortality in conditions associated with pulmonary fibrosis including connective tissue disorders. TL shortening has been implicated in SSc-related interstitial lung disease (ILD), but its association with other organ involvement, disease severity, and overall survival remains unknown. The goal of this study was to define the relationship of PBL-TL with SSc-specific disease manifestations and clinical outcomes including mortality.

Methods: A retrospective longitudinal cohort study was performed using a large, well characterized cohort of SSc patients fulfilling the ACR/EULAR 2013 classification criteria and healthy controls (HC). PBL-TL was measured by quantitative PCR from DNA isolated from the blood. Age adjusted TL was calculated using linear regression of TL from HC. Multivariate modeling was utilized to assess the association of PBL-TL with SSc disease presence and severity of skin thickening, ILD, pulmonary arterial hypertension (PAH), peripheral vascular disease (PVD), and event free survival (lung transplantation and/or death) from disease onset and time of TL measurement. To assess concordance of findings between blood and SSc target

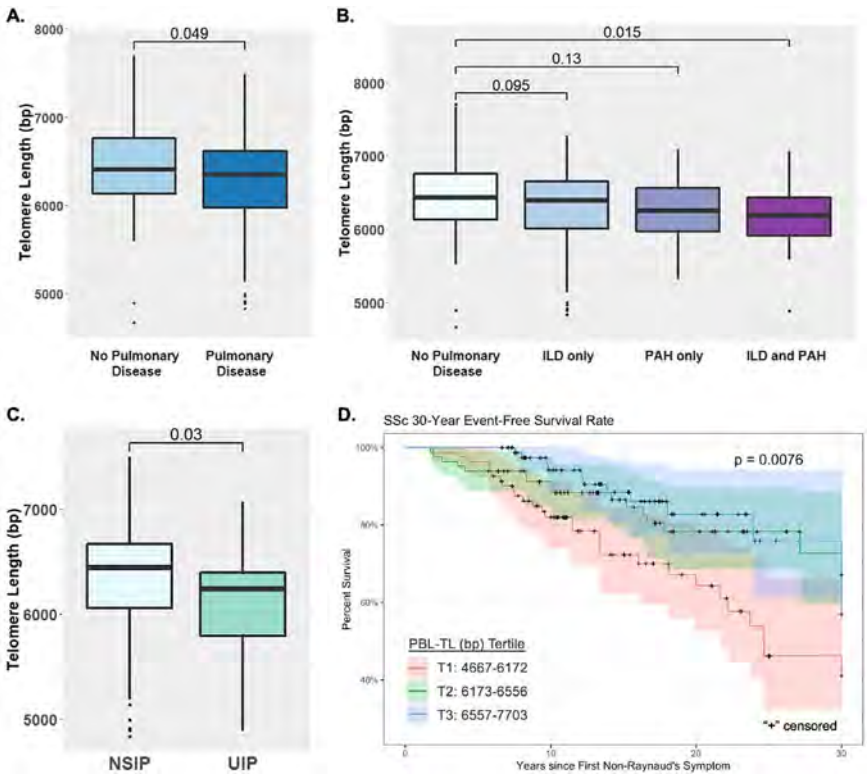

Figure 1: PBL-TL was significantly shorter in patients with pulmonary involvement (A), especially in those with concurrent ILD and PAH (B) and with UIP pattern of ILD on chest CT (C). PBL-TL associates with survival as patients with shortest TL (Tertile 1) had significantly worse 30 year survival (D).

tissues, TL was measured in skin and lung tissue by telomere fluorescence in situ hybridization (Telo-FISH) in SSc and HC, and compared using Wilcoxon rank-sum test.

Results: 558 participants (244 SSc and 314 controls) were included in this study (Table 1). PBL-TL was significantly shorter in SSc than healthy controls. In multivariate modeling, controlling for age, sex, race, smoking, disease duration and autoantibody status, shortened TL was significantly associated with presence of SSc related pulmonary involvement (OR 1.98 per 1000bp shortening, p=0.03) (Fig1A). PBL-TL was not associated with SSc skin disease (p=0.21) or PVD (p=0.20). Within pulmonary disease, TL shortening was strongly associated with ILD presence (OR 2.21, p =0.009). The shortest PBL-TL was found in subjects with concurrent ILD and PAH (Fig 1B). Shortened TL was also associated with lung disease severity including lower DLCO% (p=0.006) and UIP pattern by chest CT compared to NSIP (p=0.03, Fig 1c). Patients requiring hospitalization for respiratory or right ventricular failure had shorter TL (6169 ±434 vs. 6350±535, p=0.02) and TL shortening was associated with worse event free survival among all SSc patients from both time of TL measurement (p=0.03) and disease onset (p=0.008) (Figure 1D). TL was shorter in type II alveolar cells in lung tissues from SSc-ILD patients compared to healthy controls (p=0.014). In contrast, no difference was found in TL in epidermal cells (KRT5+) of skin (p=0.82).

Conclusion: This cohort study found a strong association between TL measured in the peripheral blood of SSc patients and more severe pulmonary involvement, particularly with concurrent ILD/PAH, and worse clinical outcomes including increased hospitalization due to respiratory failure as well as worse survival. This study provides rationale to further investigate the role of telomere dysfunction in SSc-ILD pathogenesis and to validate TL as a potentially useful biomarker in SSc.

Transcriptomic Analyses of Lung Tissues Reveals Potential Key Genes Associated with Progression of Systemic Sclerosis-Interstitial Lung Disease (SSc-ILD)

Yehya Al-Adwi[1], Johanna Westra[1], Harry van Goor[1], Leon.C.L.T van Kempen[2], Wim Timens[1], C.Tji Gan[1] and Douwe J Mulder[1], [1]University Medical Center Groningen, Groningen, Netherlands, [2]UMCG and University of Antwerp, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders I: Translational
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: SSc-ILD is the leading cause of death in SSc affecting around 50% of the patients. Lung tissue of patients with early-stage SSc-ILD is characterized by a predominant inflammatory response with inconspicuous fibrosis, which can progress to honeycombing fibrosis. Although several biomarkers and drug targets have been proposed to monitor and halt SSc-ILD progression, none has reached clinical application. A better understanding of the molecular mechanisms underpinning SSc-ILD pathogenesis is needed to improve treatment options and progression prediction. This transcriptomic study aims to reveal the differential gene expression between healthy control (ctrl) lung sections and regions of interest (ROIs) within SSc-ILD lung tissue.

Methods: The nanoString (nS) nCounter Human Fibrosis Panel containing 770 genes related to all stages of fibrosis was used to analyze gene expression in formalin-fixed and paraffin-embedded lung tissues with varying stages of SSc-ILD (n=18) and control lung tissue (n=6). The SSc-ILD tissues were stratified by an experienced lung pathologist into three ROIs, inflammatory (inf), prefibrotic (prefib), or fibrotic (fib). Every group comprised 6 samples. This stratification aimed to define a longitudinal simulation of early to late phases of SSc-ILD: ctrl à inflammation à prefibrosis à fibrosis. nSolver and Rosalind software were used for data and statistical analysis. The immunohistochemistry was performed using specific antibodies in the same tissues used for nS analysis to confirm protein expression.

Results: To validate our simulation model, we performed subgroup analysis that showed an incremental increase in pathway scores related to the severity of fibrosis including, among others, ECM and collagen 1 biosynthesis, PDGF signalling, and myofibroblast regulation (Fig.1). Ctrl vs SSc-ILD comparison demonstrated 24 differentially expressed genes, two of which had the most pronounced *p*-values. Cyclin-Dependent Kinase Inhibitor 2C (CDKN2C) was significantlyoverexpressed ($p = 0.00052$) in SSc-ILD compared to ctrl, while expression of Pellino E3 ubiquitin-protein ligase 1 (PELI1) showed lower expression significantly ($p = 0.0012$). Additionally, the expression of CDKN2C and PELI1 showed an incremental increase and decrease in the four groups, respectively (Fig.2). Immunohistochemistry of CDKN2C and PELI1 showed consistent results with the nS analysis with incremental increase and decrease of positive staining in the 4 groups, respectively.

Conclusion: Expression of CDKN2C and PELI1 was associated with more severe stages of SSc-ILD on histologic assessment. PELI1 decrease is probably due to loss of bronchial tissue during the fibrosis processes and thus secondary to the already existing pathology. We report the potential of the cell cycle inhibitor, CDKN2C to predict fibrosis progression. Further

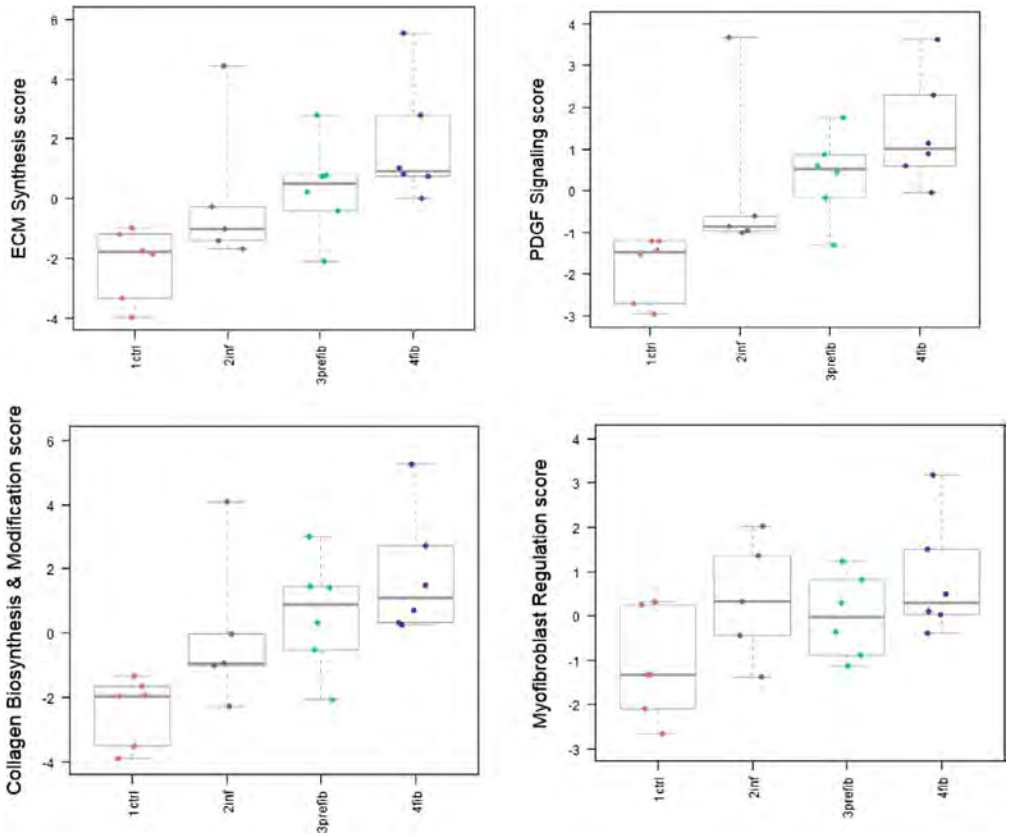

Figure 1: Pathway score analysis. Four pathways related to fibrosis and tissue remodeling are shown. Control (Ctrl) samples scored lowest while fibrotic samples scored highest. Among others, these pathways were the most differentially elevated in 51 annotated pathways within the fibrosis panel. ECM, Extracellular matrix; PDGF, Platelet-derived growth factor; Inf, inflammatory; prefib, prefibrotic; fib, fibrotic.

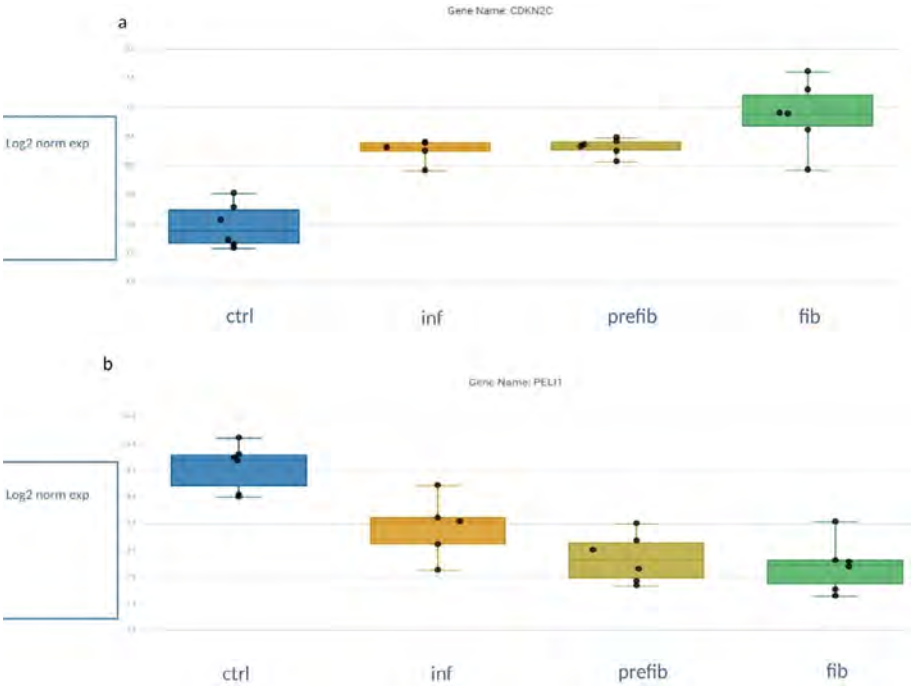

Figure 2: CDKN2C and PELI1 gene expression change between the four groups shown as (Log2) fold-change. (a) CDKN2C expression increases from the ctrl group up until the fibrotic group incrementally through inflammatory and prefibrotic groups. (b) PELI1 gene expression decreases from the ctrl group up until the fibrotic group incrementally through inflammatory and prefibrotic groups.

research is required to validate these findings and correlate additional cell cycle regulation and/or senescence markers with CDKN2C. determine the potentiality of CDKN2C as a putative progression marker candidate.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders I: Translational
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic sclerosis (SSc) is a multiorgan disease characterized by systemic vascular injury, inflammation, and fibrosis. While SSc mainly affects the skin, pulmonary manifestations such as interstitial lung disease (ILD) are the leading cause of morbidity and mortality. Tumor necrosis factor–like cytokine 1A (TL1A) is a membrane costimulatory

protein and cytokine that drives multiple inflammatory and fibrotic pathways implicated in SSc. TL1A can induce lung fibrosis and tissue remodeling in mice and can stimulate cellular proliferation and extracellular matrix protein production in human lung fibroblasts. The present study evaluated the expression of TL1A and related pathways in serum, skin, and lung tissue in patients with SSc. An anti-TL1A monoclonal blocking antibody, PRA023, is currently in phase 2 trial for SSc-ILD.

Methods: Soluble TL1A was measured in serum samples from early diffuse (< 2yr; n=58) and late diffuse (>5yr; n=57) SSc and matched healthy control sera (n=60) (University of Texas cohort). Bulk and single-cell transcriptomic public data from SSc lung and skin were analyzed for gene expression. Gene expression and chromatin accessibility from the same cell were profiled in skin biopsies and peripheral blood mononuclear cells (PBMCs) from patients with SSc with (n=4) and without (n=4) ILD and healthy controls (n=4) using 10X Genomics Chromium Single Cell Multiome technology (University of Michigan cohort). TL1A and its receptor, DR3, proteins were detected in SSc skin (n=15), SSc-ILD (n=5), and healthy control lung tissue (n=5) by immunohistochemistry in both cohorts.

Results: TL1A levels were elevated in late diffuse SSc compared with early diffuse and healthy control sera ($p< 0.05$). In bulk transcriptomic SSc skin public datasets, Th1, Th2, Th17, and TL1A-induced T cell and fibrosis gene signatures were increased. In the skin, single-cell gene expression and chromatin accessibility analysis showed that TL1A was expressed in myeloid and epithelial cells, while DR3 was expressed on T cells. Differential gene expression analysis between SSc and control skin revealed several genes upregulated in fibroblasts (eg, *COL16A1, ELN, PRRX1*; $p< 0.05$) and in myeloid cells (eg, *HLA-DRB1, NRP1, SRGN*; $p< 0.05$). TL1A-induced genes were upregulated in myeloid cells and fibroblasts of SSc skin compared with controls ($p< 0.001$). In donor-matched PBMCs, single-cell gene expression and chromatin accessibility data indicated TL1A expression in myeloid cells, a cell population expanded in SSc, and DR3 expression in T cells. In lung tissue bulk RNA, TL1A gene expression was increased in SSc-ILD compared to healthy controls. In single-cell RNAseq SSc-ILD lung data, TL1A was expressed by myeloid and epithelial cells, while DR3 was expressed by T cells and epithelial and endothelial cells. Although SSc skin showed relatively low levels of TL1A and DR3 protein expression, TL1A and DR3 proteins were relatively abundant in SSc-ILD compared with healthy control lung tissues.

Conclusion: TL1A expression and pathway activity analyses suggest that TL1A may modulate immune and fibrotic pathways in SSc skin and the lung, with higher activity of the pathway in lung tissue compared with the skin.

Single Cell RNA-seq of Myeloid Cells from Systemic Sclerosis Patients Identifies Circulating Monocyte Population with Interferon Signature Associated with Interstitial Lung Disease

Richard Ainsworth[1], Kim Taylor[2], Ye Cao[3], Takanori Sasaki[4], Deepak Rao[5], Nunzio Bottini[6] and Francesco Boin[1], [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]University of California San Francisco, San Francisco, CA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [5]Brigham and Women's Hospital, Boston, MA, [6]University of California, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders I: Translational
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Growing evidence supports a critical role for innate immunity in systemic sclerosis (SSc) pathogenesis. Altered myeloid cell numbers and functions have been implicated in the initiation and progression of SSc, but their functional characterization and relationship with specify disease manifestations such as interstitial lung disease (ILD) remain

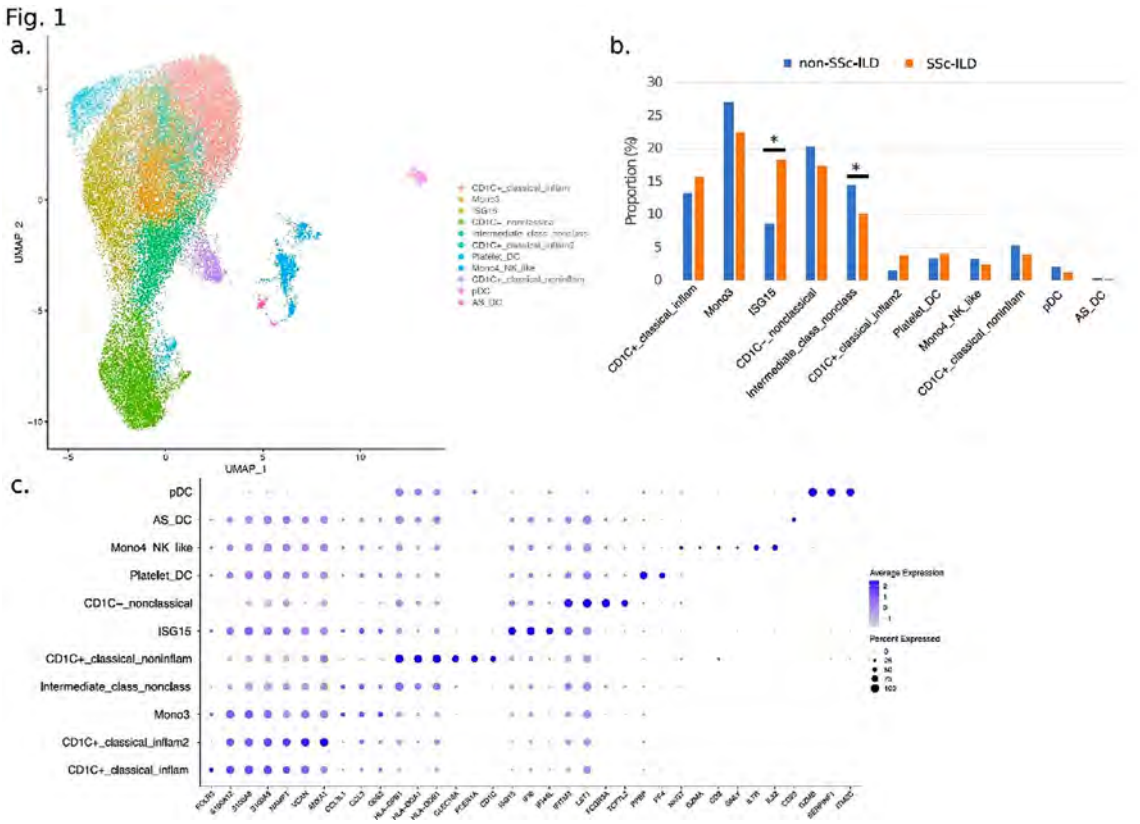

Fig. 1. a. UMAP of myeloid cells split into 11 clusters. b. Frequency barplot for each cell-type split by ILD status. c. Bubble plot of selected marker genes.

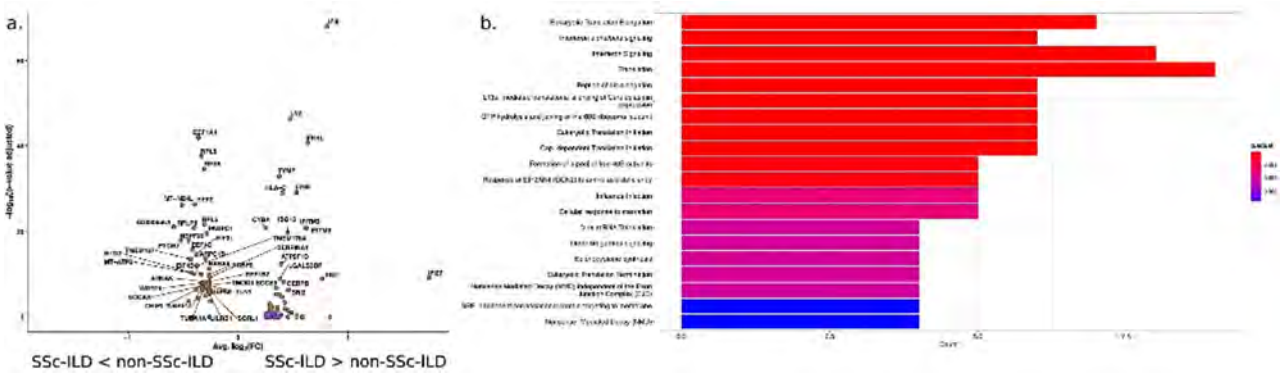

Fig. 2. a. Volcano plot for ISG15 monocytes ILD vs non-ILD. b. Pathways for 33 differentially expressed genes.

poorly understood. We sought to characterize specific myeloid populations associated with SSc-ILD and investigate how disease severity affects the transcriptional regimen.

Methods: Single cell RNA-seq was performed on peripheral blood obtained from 60 SSc patients meeting 2013 ACR/EULAR criteria. Unsupervised clustering identified dendritic/monocyte populations which were then selected for further sub-clustering analysis and annotation. Differential expression analysis and sub-type frequency analysis was conducted between 40 patients with SSc-ILD and 20 patients without (non-SSc-ILD). Using the worst recorded forced vital capacity (fvc) value (%-predicted), correlation analysis against pseudo-bulk expression was performed for an unbiased genome-wide assessment of SSc-ILD severity associations.

Results: Clustering and annotation of 39,582 dendritic/monocyte cells identified 11 myeloid cell types (Fig.1a). Comparison of relative cell type proportions between SSc-ILD and non-SSc-ILD (Fig.1b) revealed a 2.1-fold increase (p-value=1.7x10-2) in a "ISG15-hi" monocyte population expressing high levels of interferon (IFN)-inducible markers (i.e. IFI6 and IFI44L, Fig.1c). Concomitantly, an "Intermediate" monocyte population (expressing classical NAMPT and non-classical IFITM3, Fig.1c) showed a significantly decreased frequency (1.4-fold, p-value=2.8x10-2) in SSc-ILD subjects, and a strong negative correlation with ISG15hi subset counts (Pearson r=-0.70; p-value=2.45x10-7). Differential expression analysis identified 33 genes (1.2-fold, FDR < 2x10-2) between SSc-ILD and non-SSc-ILD in ISG15-hi monocytes (Fig.2a), with robust enrichment in the "Interferon signaling" pathway (FDR=1.5x10-10) (Fig.2b). For the Intermediate monocyte population, 61 genes had a significant negative correlation (-0.50 < Pearson r< -0.31; p-value < 0.05) associated with SSc-ILD severity and were enriched in pathways including "Cytokine signaling in immune system" (FDR=3.27x10-5) and "Innate immune system" (FDR=8.07x10-3). Of note, 18/61 genes were found to be significantly differentially expressed in SSc-ILD patients with the highest ILD severity (fvc < 55%), including the innate immunity gene FPR1 (Pearson r =-0.48, p-value=1.15x10-3).

Conclusion: Using single cell analysis, we identified a novel cluster of circulating monocytes expressing high levels of type I IFN-inducible markers that exhibits a significant association with presence and severity of SSc-ILD. Our findings suggest that these ISG15-hi monocytes may be cellular effectors critically involved in the dysregulated type I IFN activation driving SSc pathogenesis and identify them as promising targets for disease-specific therapeutic intervention.

The Dual Specificity Phosphatase 6 (DUSP6) Regulates Arthritis Severity and IL10 Production

Teresina Laragione, Carolyn Harris, Natasha Rice and Percio Gulko, Icahn school of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Animal Models
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

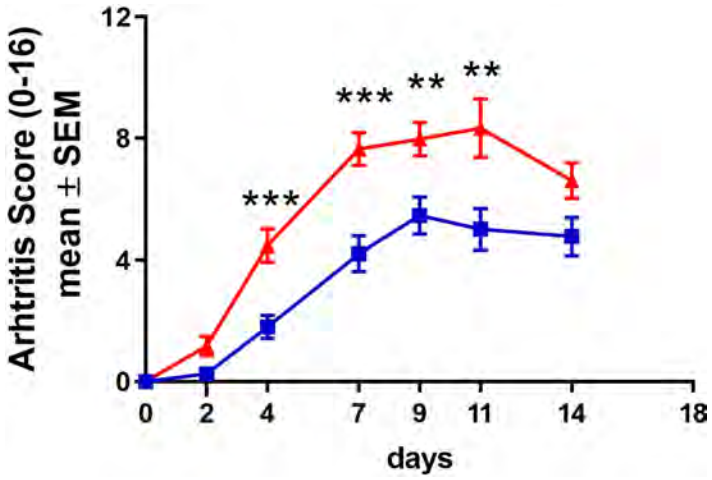

Figure 1. DUSP6 KO mice (BLUE line) were significantly protected in KSIA, compared with DUSP6 wild-type (RED line). (**P<0.001; ***P<0.0007).

Background/Purpose: We have previously identified the Huntingtin-interacting protein-1 (HIP1) as a new gene implicated in the regulation of the rheumatoid arthritis (RA) fibroblast-like synoviocyte (FLS) invasiveness induced by receptor tyrosine kinases, and in arthritis severity. Following that observation we examined genes and proteins regulated by HIP1 as those might generate important understanding of disease pathogenesis, and potentially new targets for treatment.

Methods: We used a combination of siRNA knockdown, gene expression and invasion assays in RAFLS, followed by immunoprecipitation and western blots. DUSP6 knockout (KO) mice were studied in the KRN serum induced arthritis (KSIA) model.

Results: In RA FLS knockdown for HIP1 we detected increased mRNA levels of the dual specificity phosphatase 6 (DUSP6). We confirmed protein expression of DUSP6 in RA FLS cell lines and binding of DUSP6 to HIP1 by immunoprecipitation in RA FLS cell extracts, followed by western blotting. We hypothesized that, like HIP1, DUSP6 might also be involved in FLS invasiveness. Knockdown of DUSP6 with siRNA significantly decreased RA FLS invasiveness by more than 50% ($P< 0.001$). In the arthritis model of KSIA, both male and female DUSP6 KO mice were significantly protected compared with wild-type mice, developing a significantly milder disease (maximum disease reduction of nearly 50% at day seven; figure). DUSP6 KO mice also had increased numbers of $CD4^+CD45^-CD49b^+LAG3^+IL10^+$ Tr1 regulatory T cells ($P< 0.01$) in the spleen, increased serum levels of IL10, and lower serum levels of IL6 ($P< 0.01$). RNA sequencing analyses revealed significantly increased representation of ERK and MAPK pathways and genes in the spleens of DUSP6 KO mice, compared with DUSP6 wild-type. DUSP6 is known to inactivate MAPK pathway proteins and therefore the RNA sequencing finding were consistent with decreased DUSP6 activity.

Conclusion: We identified a new HIP1-binding protein, DUSP6, and demonstrated that like HIP1, DUSP6 regulates arthritis severity and joint damage. Our findings suggest that DUSP6 interferes with disease severity by modulating FLS invasiveness and regulating IL10 production by Tr1 cells and suppression of IL6. This new discovery has the potential to become the basis for the development of new treatments for RA and possibly other autoimmune and inflammatory diseases.

Microbiota-dependent Indole Production Is Required for the Development of Collagen-induced Arthritis

Brenda Seymour[1], Brandon Trent[2], Brendan Allen[3], Sucai Liu[3], Sunny Sneed[4], Robert Anthony[4] and kristine Kuhn[3], [1]University of Colorado School of Medicine, Denver, CO, [2]University of Colorado School of Medicine, Eugene, OR, [3]University of Colorado School of Medicine, Aurora, CO, [4]Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Animal Models
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: While alterations in tryptophan (Trp) metabolism have been broadly implicated across autoimmune diseases (including RA, SpA, SLE, and MS), the specific role(s) of Trp metabolites in the development of disease are not well characterized. We previously identified significant alterations in tryptophan metabolism in mice with collagen-induced arthritis (CIA) that occurred in a microbiome-dependent manner, including significantly elevated indole. As indole is exclusively produced via microbial Trp metabolism, we modulated indole production through either antibiotic-mediated microbiome depletion or reduction of dietary Trp to dissect the effects of tryptophan, indole, and the microbiome on the development of CIA.

Methods: To regulate dietary Trp, 6wk-old male DBA/1J mice were maintained on either a Trp-sufficient (TS, 0.18% Trp) or Trp-low (TL, 0.05% Trp) diet. For the microbiome depletion studies, mice were treated with broad-spectrum antibiotics (ampicillin, neomycin, metronidazole, and vancomycin) in the setting of a Trp-sufficient diet. CIA was induced by immunization of bovine type II collagen (CII) emulsified in CFA at days 0 and 21. Indole or vehicle were added back either in drinking water or by oral gavage. CIA severity was assessed clinically and histologically. On day 35, serum and tissues were analyzed by flow cytometry, ELISA, and immunohistochemistry.

Results: Depletion of either the microbiome or dietary Trp protected mice from developing CIA. Adding back indole in either setting rescued CIA severity, suggesting that indole is sufficient to incite disease. These findings were confirmed further by amelioration of disease in mice colonized with tryptophanase-deficient bacteria, which are unable to produce indole. Indole supplementation in the TL setting lead to significant increases in RA-relevant serum cytokines (IL-6, TNF, IL-1β) and IL-17-producing, CII-reactive Th17 cells. Indole supplementation also resulted in increased activation of complement by CII-specific antibodies, C3 deposition in the joints, CII-specific IgG2b, and antibody galactosylation compared to the Trp-sufficient group.

Conclusion: Altogether, our data suggest that the presence of either the microbiota or dietary Trp alone are insufficient to induce disease, and that microbial metabolism of Trp into indole is essential for CIA development. Indole supplementation induces a pro-inflammatory, Th17-skewed immune signature. As IgG2b and galactosylation are thought to promote complement binding and activation, our findings suggest that indole supplementation may enhance pathogenic autoantibody function, which is consistent with the observed increase in complement activation and C3 deposition in the joints. While the cellular target(s) of indole are yet to be identified, this data provides a novel mechanism through which altered tryptophan metabolism promotes disease development in the CIA model. Furthermore, these findings identify microbiome-mediated modulation of Trp metabolism as a potential pathway to block or treat disease.

The Focal Adhesion Protein Lasp1 Links the Arp2/3 Complex to Cell-to-cell Contact Formation in Arthritic Fibroblast-like Synoviocytes

Denise Beckmann[1], Annika Krause[1], Uwe Hansen[2], Hans-Peter Kiener[3], Joachim Kremerskothen[1], Hermann Pavenstädt[1], Adelheid Korb-Pap[1] and Thomas Pap[1], [1]University Hospital Münster, Münster, Germany, [2]University Muenster, Muenster, Germany, [3]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Animal Models
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: In rheumatoid arthritis (RA), fibroblast-like synoviocytes (FLS) undergo a stable transformation leading to an aggressive phenotype that mediates cartilage damage through increased levels of adhesion molecules. In this context, Lasp1 and the Arp2/3 complex are of interest as they modulate actin organization and turnover of focal adhesions. Therefore, we investigated the effects of Arp2/3 on cadherin-11 mediated cell-to-cell contact formation using the arthritic hTNFtg mouse model.

Methods: The expression levels of Lasp1 and Arp2/3 protein complex were examined in synovial tissue of wild type (wt) and hTNFtg hind paws by using Western blot analysis and their subcellular distribution was investigated by immunofluorescence stainings. In addition, *lasp1*$^{-/-}$ mice were crossed with hTNFtg animals, and offspring were examined for disease progression and joint destruction. Primary FLS were isolated from wt, *lasp1*$^{-/-}$, hTNFtg and *lasp1*$^{-/-}$hTNFtg mice, and co-immunoprecipitation experiments with cell lysates using G-labelled Dynabeads were performed. Furthermore, the effects of the Arp2/3 inhibitor CK666 on the formation of cadherin-11 mediated cell-to-cell contacts in FLS from hTNFtg and *lasp1*$^{-/-}$hTNFtg mice were analyzed by immunofluorescence stainings. To determine the functional effects of CK666 on FLS migration, all genotypes were examined in a modified scratch assay, to also assess the effects on pathway activation, cells were stimulated with the growth factor PDGF.

Results: Elevated levels of Lasp1 were detected in synovial tissue and FLS of hTNFtg compared to wt mice. Assays showed that Arp2/3 is part of the adherens junction (AJ) machinery in wt and hTNFtg FLS, although Arp2/3 expression levels were not altered between genotypes. *In vivo*, assessment of *lasp1*$^{-/-}$hTNFtg mice revealed a milder arthritis score, less cartilage degradation and reduced FLS attachment to articular cartilage compared with hTNFtg mice.*In vitro*, β-catenin expression was found mainly at adhesion sites between adjacent cells, but the loss of Lasp1 resulted in an altered β-catenin pattern and marked changes in AJ arrangement. In hTNFtg FLS, these structures were characterized by a zipper-like pattern. In contrast, these structures were interrupted in *lasp1*$^{-/-}$hTNFtg FLS. Interestingly, CK666 induced zipper-like structures in hTNFtg FLS comparable to the pattern were found in *lasp1*$^{-/-}$hTNFtg cells. Quantification of scratch assay data revealed a significantly reduced migration rate of *lasp1*$^{-/-}$hTNFtg FLS compared to hTNFtg FLS (-75.2.%, $p< 0.05$) and even more prominently in the presence of CK666 the hTNFtg FLS showed a reduction in migration compared to controls (-42.7%, $p< 0.05$). Furthermore,*lasp1*$^{-/-}$hTNFtg FLS showed decreased Src phosphorylation following PDGF stimulation compared with hTNFtg FLS. Interestingly, the presence of CK666 also blocked the phosphorylation of Src in hTNFtg FLS.

Conclusion: Lasp1 represents an interesting target involved in RA-related joint destruction, as its loss leads to significantly reduced cartilage destruction and altered FLS contacts mediated by Arp2/3.

Role of Group 2 Innate Lymphoid Cells in the Pathogenesis of Rheumatoid Arthritis

Anders Nguyen[1], Agnieszka Lastowska[1], Miriam Bollmann[1], Symeon Kourmoulakis[1], Charlotte E. van der Plas[1], Anna-Karin Hultgård Ekwall[2], Dietmar M. Zaiss[3], Gary S Firestein[4] and Mattias N.D Svensson[5], [1]Department of Rheumatology and Inflammation research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [2]Department of Rheumatology and Inflammation research, Sahlgrenska Academy, University of Gothenburg, Kullavik, Sweden, [3]Faculty of Medicine, Department of Immune Medicine, University of Regensburg, Regensburg, Germany, Regensburg, Germany, [4]Department of Medicine, University of California San Diego, La Jolla, CA, [5]University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Animal Models
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Immune-cell mediated activation of joint-lining fibroblast-like synoviocytes (FLS) play a key role in joint inflammation and destruction during Rheumatoid arthritis (RA). Thus, identifying factors that promote aggressive and joint-destructive FLS behavior is viewed as a high priority in the development of novel anti-RA therapies. Innate Lymphoid Cells (ILC) are a family of tissue resident innate immune cells that are the innate counterparts to T cells. A major function of ILCs is to interact with local tissue stromal cells in order maintain tissue homeostasis. Although ILCs have been identified in the synovium of RA patients, their role in disease pathogenesis and their potential interaction with FLS remains largely unknown. Here, we identified a novel pathogenic role for ILC2 in arthritis that is mediated through their production of the fibroblast-activating growth factor amphiregulin (AREG).

Methods: Subsets of synovial ILC were assessed in the active K/BxN model and the K/BxN serum transfer-inducing arthritis (STIA) model. Role of ILCs in arthritis was determined by subjecting Rag2-deficient ($Rag2^{-/-}$) and ILC-deficient ($Rag2^{-/-}IL2rg^{-}$) mice to STIA. Role of AREG in the STIA model was evaluated using AREG-KO mice and mice with a conditional deletion of AREG in ILC2 ($Rag2^{-/-}$ IL5-Cre Areg-floxed). Clinical scoring of arthritis was followed by histological assessment. Effect of ILC-derived cytokines on FLS migration was evaluated in vitro. Mann-Whitney or un-paired T tests were used for statistical differences.

Results: Assessment of ILC subsets revealed that ILC2 is the predominant ILC population in the arthritic synovium of mice with active K/BxN arthritis and STIA (*P=0.05* vs. non-arthritic control). ILC-deficient mice ($Rag2^{-/-}IL2rg^{-}$) showed reduced development of STIA (*P=0.0072* vs. $Rag2^{-/-}$ mice), indicating that ILCs promote arthritis development. Assessment of ILC signature cytokines identified the ILC2-derived growth factor AREG to be significantly increased in arthritic joints (*P=0.0001* vs. non-arthritic control). A pathogenic role for AREG in arthritis development was supported by a significant alleviation in disease severity in AREG-KO mice subjected to STIA (*P=0.05* vs. control littermate mice). We identified ILC2 as the

major source of synovial AREG during arthritis and conditional deletion of AREG in ILC2 resulted in reduced arthritis development (*P=0.0044* vs. WT littermate controls). Mechanistically, we found that AREG promotes activation and migration of FLS (*P=0.0001* vs control).

Conclusion: We find that ILC2 is the predominant ILC subset in arthritic joints of mice with K/BxN arthritis. Furthermore, ILC2-derived AREG enhances development of arthritis in mice and promotes FLS activation and migration. We propose that the AREG signaling pathway may provide a novel therapeutic option for the treatment of RA.

Abstract Number: 0797

Innate Lymphoid Cells Enhance Development of CD4+ T-cell Driven Autoimmune Arthritis

Agnieszka Lastowska[1], Charlotte E. van der Plas[1], Anders Nguyen[1], Symeon Kourmoulakis[1], Miriam Bollmann[1] and Mattias N.D Svensson[2], [1]Department of Rheumatology and Inflammation research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [2]University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Animal Models
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Innate Lymphoid cells (ILCs) are innate counterparts to T-cells that, based on their functional phenotype, can be divided into three subpopulations called Group 1 (ILC1), Group 2 (ILC2) and Group 3 (ILC3). ILC subsets in autoimmune and chronic inflammatory diseases have been shown to display altered distribution and function, indicating subset-specific involvement. Although these tissue resident immune cells have been identified in the synovium of patients with rheumatoid arthritis (RA), their role in disease pathogenesis still remains largely unknown. SKG mice, which carry the Zap70W163C point mutation, develop autoimmune arthritis due to a defective negative selection of CD4+ T-cells in thymus. Here, we use the SKG mouse model to further assess the role of ILCs in arthritis development and find that ILCs have an important role in aggravating disease progression.

Methods: Arthritogenic CD4+ SKG T-cells were transferred to T and B cell deficient Rag2-knock out (Rag2-/-) mice to induce development of SKG arthritis. ILC subsets were evaluated in arthritic joints of mice with either spontaneous or mannan- induced SKG arthritis by flow cytometry. The role of ILCs in SKG arthritis was evaluated by transferring CD4+ SKG T-cells to ILC-deficient Rag2 and IL2rg double knockout (Rag2-/-IL2rg-) mice. Additionally, ILCs were isolated by flow cytometry, expanded in vitro and adoptively transferred in combination with CD4+ SKG T-cells into ILC-deficient (Rag2-/-IL2rg-) mice. Development of arthritis was monitored by clinical scoring. Mann-Whitney or un-paired T tests were used for statistical differences.

Results: Phenotypic characterization of ILC subsets in arthritic ankles revealed that ILC2 is the dominant synovial ILC population in joints of mice in both mannan-induced and spontaneous arthritis. ILC1 expanded in joint of mice during both mannan-induced and spontaneous arthritis. However, a synovial presence of ILC3 could only be observed in mice with mannan-induced arthritis. Surprisingly, there was no significant difference in severity between mannan-induced and

spontaneous arthritis in Rag2$^{-/-}$ mice after transfer of CD4^{+} SKG T cells. The role of ILC in SKG arthritis was supported by an alleviated arthritis development in ILC-deficient mice (P=0.041) after transfer with CD4+ SKG T cells. Finally, reconstitution of ILC-deficient mice with ILCs aggravated arthritis development after transfer with CD4+ SKG T cells (P=0.027).

Conclusion: Here we identify that ILC2 is the dominant ILC population in joints of mice with SKG arthritis. In addition, the aggravated development of arthritis in ILC-deficient mice after reconstitution of ILCs demonstrates the pathological effect of ILCs in SKG arthritis. Furthermore, the mannan-specific expansion of ILC3 in arthritic joints, suggest that synovial ILC3 are either directly or indirectly activated by inflammatory signals induced via the lectin pathway. Together, our results show that ILCs play a key role in promoting development of SKG arthritis and that different inflammatory triggers (e.g. mannan) induce unique synovial ILC distribution, which could result in specific synovial pathotypes.

A Novel 3D Model of Rheumatoid Arthritis Synovial Tissue Incorporating Fibroblasts, Endothelial Cells and Macrophages

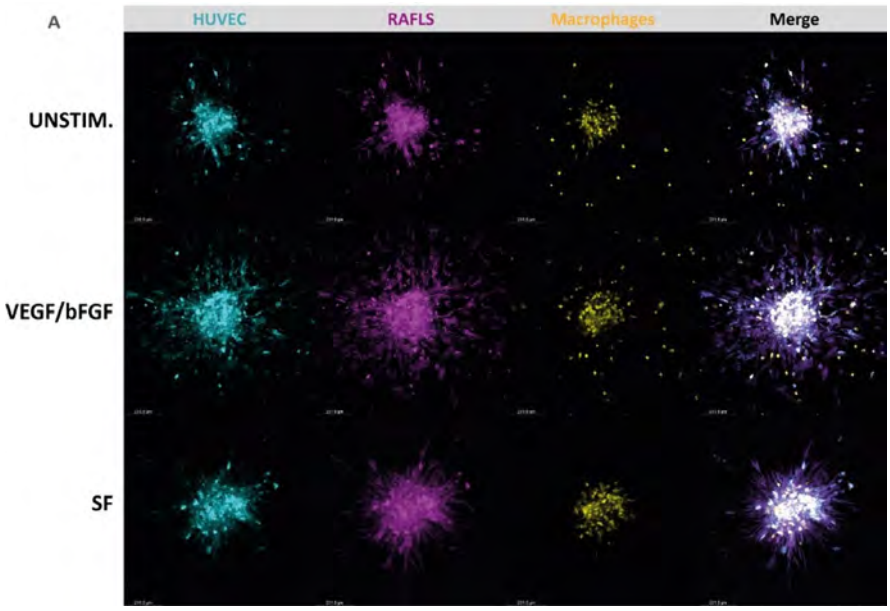
Eva Philippon[1], Lisanne van Rooijen[1], Jan Piet van Hamburg[1], Fatemeh Khodadust[1], Conny Van der Laken[2] and Sander Tas[3], [1]Amsterdam University Medical Centers, Amsterdam, Netherlands, [2]Amsterdam UMC - location VUMC, Amsterdam, Netherlands, [3]Amsterdam UMC, locatie AMC, Utrecht, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Animal Models
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Rheumatoid Arthritis (RA) is a progressive and systemic autoimmune disorder associated with chronic and destructive inflammation of the joints. The hallmarks of RA are synovial cell proliferation, extensive neoangiogenesis and infiltration of numerous immune cells into the synovial tissue. *In vitro* approaches simulating RA synovial tissue are crucial in preclinical and translational research to expand our knowledge on RA human pathophysiology and to test new diagnostic and therapeutic applications. Here, we present the engineering of a spheroid-based model of RA synovial tissue which mimics the close interaction between cells and key pro-inflammatory mediators present in the inflamed synovium.

Methods: Monocyte-derived macrophages were cultured at different concentrations with RA fibroblast-like-synoviocytes (RAFLS) and endothelial cells (ECs) for 24 hours to allow for spheroid formation. Then, the spheroids were placed in a collagen-based matrix for 40 hours to study spheroid outgrowth in 3 dimensions. The spheroids were left unstimulated, or cultured in the presence of growth factors VEGF/bFGF or RA synovial fluid (SF). Spheroid outgrowth and cell migration were quantified for all conditions using confocal microscopy and a new quantification approach by machine learning (QuPath).

Results: Addition of macrophages to the previously established 3D model of RA angiogenesis consisting of ECs and RAFLS resulted in close interaction of macrophages with RAFLS and ECs within the spheroid structure. The number of macrophages that migrated out from the core increased with the initial macrophage input while slightly promoting spheroid outgrowth. The optimal ratio between RA-FLS, ECs and macrophages in our system was established accordingly as 1:2:0.8.



Representative confocal Z-stack projection pictures of the 3D model containing 3.75x10^4 RAFLS (magenta), 7.5x10^4 EC (cyan) and 3.0x10^4 macrophages (yellow). Spheroids were left either unstimulated (UNSTIM.), stimulated with VEGF/bFGF (10 ng/ml) or SF (20%). VEGF/bFGF induces spheroid outgrowth in the new 3D model containing macrophages, whereas RASF enhances macrophage containment and compaction.

Addition of growth factors (VEGF/bFGF) significantly promoted spheroid outgrowth compared to the unstimulated condition in the new model *($p< 0.05$)*. The presence of SF significantly enhanced cell containment of the ECs and macrophages within the core ($p< 0.05$).

Conclusion: We present a novel 3D-spheroid based model consisting of RA-FLS, ECs and macrophages that mimics the RA synovial tissue microenvironment. This model is useful to dissect the role of specific cell types in inflammatory responses in RA, to study specific signaling pathways involved in the disease pathogenesis and examine the potential of novel diagnostic (molecular imaging) and therapeutic compounds, including small molecule inhibitors and biologics.

Human Chimeric Antigen Receptor (CAR)-Tregs Targeting OX40L for Treatment of Systemic Lupus Erythematosus

Holly Wobma[1], Xianliang Rui[2], Francesca Alvarez-Calderon[2], Ulrike Gerdemann[2], Connor McGuckin[2], Bruce Blazar[3], Victor Tkachev[4] and Leslie Kean[2], [1]Division of Immunology, Boston Children's Hospital, Boston, MA, [2]Division of Hematology-Oncology, Boston Children's Hospital, Boston, MA, [3]Division of Pediatric Blood & Marrow Transplant & Cellular Therapy, University of Minnesota, Minneapolis, MN, [4]Center for Transplantation Sciences, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Chimeric Antigen Receptor Regulatory T cells (CAR-Tregs) are an emerging strategy to restore immune tolerance during auto- or allo-immune conditions. However, most autoimmune diseases do not have a single or consistent pathogenic antigen to target. OX40L is a co-stimulatory protein expressed on activated antigen presenting cells (APCs). Polymorphisms in OX40L that lead to increased expression are associated with systemic lupus erythematosus (SLE), and the frequency of OX40L+ APCs tracks with disease activity in SLE patients. OX40L may thus serve as an ideal CAR-Treg target in SLE.

Methods: We engineered a CAR construct containing a single chain variable fragment of anti-OX40L IgG (αOX40L scFv CAR) under transcriptional control of the *FOXP3* promoter to constrain CAR expression to canonical Treg. CAR-Tregs were compared with polyclonal Control-Tregs, transduced with a Neon Green reporter-encoding construct, for key features, including expression of immune regulatory proteins, suppression of T cell activation, and inhibition of APC functions *in vitro*.

Results: αOX40L scFv CAR expression was stable and selectively expressed in FOXP3+ Tregs during *in vitro* expansion over three weeks. CAR-Tregs were strongly activated by OX40L+ K562 cells **(Figure 1)**, which, relative to wild type K562 cells, drove expression of Treg-associated immune regulatory proteins LAG3 (5.6-fold), CTLA4 (14.8-fold), GARP (6.9-fold), and LAP (5.5-fold) without induction of pro-inflammatory cytokines (IL-2, TNFα, IL-17A, IFNγ). CAR-Tregs more potently

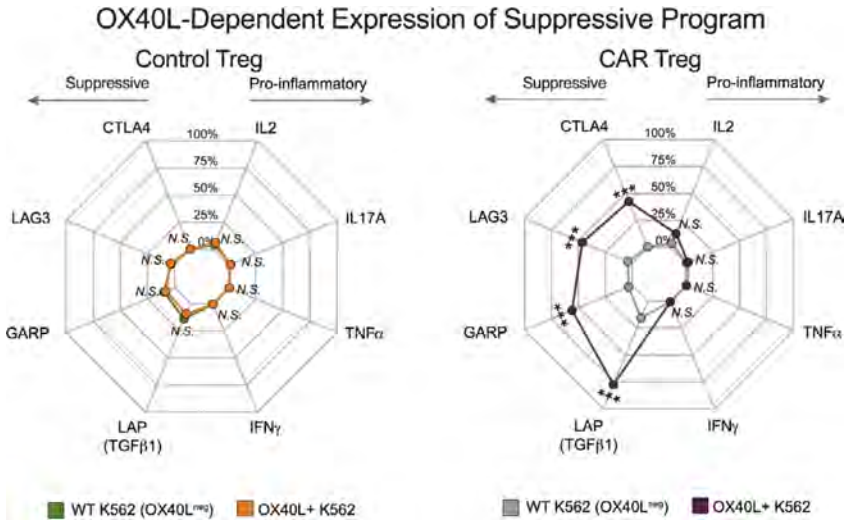

Figure 1: Activation of Treg suppressive program in OX40L-exposed CAR-Tregs. OX40L+ K562 cells led to a suppressive program in CAR-Tregs that was not seen in Control Tregs or when wild type (WT) K562 cells were used as stimulators. Expression of suppressive and inflammatory markers was measured by flow cytometry with the average values shown on radar plots.

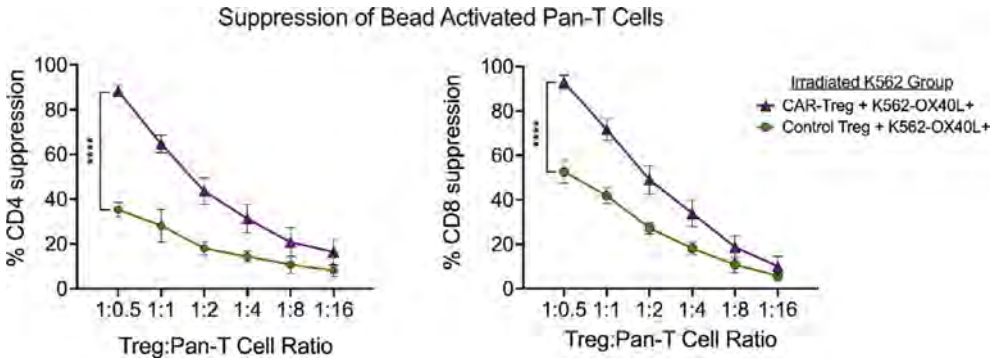

Figure 2: Superior T cell suppression by CAR-Tregs. CAR-Tregs exhibited a superior in vitro capability to suppress anti-CD3/CD28 mAb (bead) mediated CD4+ (left) and CD8+ (right) T cell proliferation. Tregs were co-cultured with irradiated OX40L+ K562 cells for one day prior to assay. Percent suppression was calculated based on cell division, comparing the 'with Treg' to the 'no Treg' conditions.

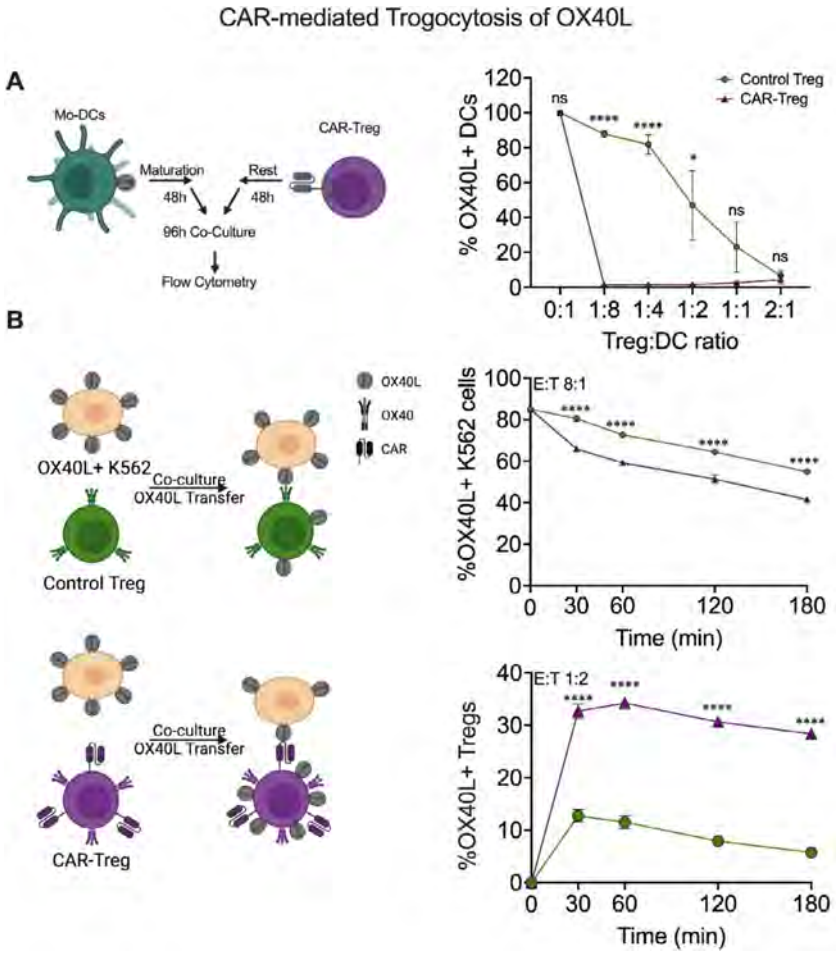

Figure 3. Superior trogocytosis of OX40L by CAR-Tregs. A. %OX40L+ cells gated on CD83+CD14+CD4- mo-DCs after co-culture with either Control- or CAR-Tregs for four days. B. Time-course assay showing rapid loss of OX40L from OX40L+ K562 cells (top) and gain on Control- or CAR-Tregs (bottom) upon co-culture. E:T indicates effector (Treg) to target (K562) cell ratio.

suppressed anti-CD3/CD28 mAb mediated CD4+ and CD8+ T cell proliferation than Control-Tregs (maximum suppression at a 2:1 Treg:T-cell responder ratio: 88.5%±3.7% vs.35.3±4.6% for CD4+ responders, $p < 0.0001$) **(Figure 2)**. CAR-Tregs also led to a greater reduction of OX40L on the surface of monocyte-derived dendritic cells (mo-DCs) relative to Control-Tregs as a result of enhanced OX40L trogocytosis – findings confirmed using OX40L+ K562 cells **(Figure 3)**.

Conclusion: We designed a novel CAR-Treg stimulated by OX40L on activated APCs. The αOX40L scFv CAR was selectively expressed in Tregs due to control by a *FOXP3* promoter, and CAR-Tregs preserved their anti-inflammatory expression profile. CAR-Tregs had superior *in vitro* suppression of both activated T cells and dendritic cells relative to Control-Tregs. This may be due to universal and potent activation of CAR-Tregs vs. polyclonal Control-Tregs but also from CAR mediated trogocytosis of OX40L on APCs making it unavailable for T-cell co-stimulation. Future work will be aimed at designing a mouse OX40L targeted CAR-Treg to assess in traditional murine SLE models. Overall, we demonstrate a unique approach to CAR-Treg design for treating autoimmune disorders by directing CAR-Treg against activated, disease-associated APCs.

CD4$^+$ CD96$^+$ T Cells Are Pathogenic Effector Cells in Giant Cell Arteritis

Shozo Ohtsuki[1], Jose Morales[2], Yuki Sato[2], Chenyao Wang[2], Matthew Koster[3], Kenneth Warrington[3], Gerald J. Berry[4], Jorg Goronzy[3] and Cornelia M. Weyand[5], [1]Mayo Clinic College of Medicine and Science, Stanford University School of Medicine, Rochester, MN, [2]Mayo Clinic College of Medicine and Science, Rochester, MN, [3]Mayo Clinic, Rochester, MN, [4]Stanford University School of Medicine, Stanford, CA, [5]Mayo Clinic School of Medicine and Stanford University, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: In Giant Cell Arteritis (GCA), granulomatous infiltrates occupy the vessel wall and elicit maladaptive vascular remodeling with intimal hyperplasia. The major cell types of the granulomatous lesions are CD4$^+$ T cells and macrophages, some of which differentiate into multinucleated giant cells. Lesional CD4$^+$ T cells undergo clonal expansion and vasculitic arteries contain mRNA and protein of multiple T cell effector cytokines, but it is unclear whether GCA patients possess specialized T cell subsets that promote macrophage multinucleation and granuloma formation in the vessel wall.

Methods: Patients with a positive temporal artery biopsy or unequivocal evidence for GCA aortitis were enrolled into the study. Patients with granulomatosis with polyangiitis served as disease controls and age-matched healthy controls were recruited through the Biobank. Tissue lesions were analyzed by immunofluorescence staining of temporal artery sections. T cell phenotyping relied on multiparametric flow cytometry and T cell reactivity was tested against anti-CD3-loaded antigen-presenting cells. The functional relevance of CD4$^+$ T cell subsets was examined in immunodeficient mice engrafted with human arteries and immuno-reconstituted with immune cell populations from GCA patients (human artery-SCID chimeric mice).

Results: Memory CD4$^+$ T cells isolated from GCA patients and age-matched controls fell into 10 clusters based on the combinatorial expression of 8 immunoreceptors (CD45RA, CCR7, PD1, LAG3, CD226, CD96, TIGIT, TIM3). GCA patients selectively expanded CD4$^+$CD96$^+$ memory T cells (10.9% control, 16.9% GCA), while CD4$^+$TIGIT^{high} populations were reduced (24.5% control, 17.4% GCA). CD4$^+$CD96^{low} T cells, generated by siRNA transfection, induced vascular inflammation in artery-SCID chimeric mice (p=0.0044), indicating that CD96 delivers a negative signal and opposes T cell activation. The expansion of CD4$^+$CD96$^+$ T cells was dependent on interaction of CD96 with its ligand CD155 on the surface of antigen-presenting cells. Maldifferentiation of CD4$^+$ T cells in GCA patients was associated with the excessive production of three effector cytokines: IL-9 (p=0.02), IL-21 (p=0.028), and IFN-γ (p=0.03). In vivo testing identified IL-9 as a strong driver of vascular inflammation, associated with marked damage of the vessel wall smooth muscle cell layer. Anti-IL-9 treatment efficiently suppressed vascular inflammation (p=0.0025). In single cell RNA sequencing from tissue derived T cells, CD96 expression mapped to the T follicular helper cell population.

Conclusion: In GCA patients, the differentiation of CD4$^+$ memory T cells is abnormal, leading to the selective expansion of immature and multifunctional T cells, while the transition into effector T cells is decelerated. The underlying defect lies in antigen-presenting cells that withdraw opposing signals as T cells progress through their differentiation cycle. Resulting CD4$^+$ memory T cells hyperproduce IL-9, IL-21, and IFN-γ. Blocking T cell effector functions in GCA will therefore require targeting an array of cytokines.

LncRNA PIGL-217 Regulates Th17 Differentiation by Targeting miR-5008-5p and Suppressing FoxO1 in Behçet's Disease

Zhimian Wang, Xin Yu, Hua Chen and Wenjie Zheng, Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Beijing, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Dysregulated Th17 cells are implicated in Behçet's disease (BD). However, the underlying mechanism remains unclear. Here we aim to elucidate the mechanism of forkhead box O1 (FoxO1) and its regulating long non-coding RNA (lncRNA) in modulating Th17 cells in BD.

Methods: Th17 cells in peripheral blood mononuclear cells (PBMCs) from BD and healthy controls (HCs) were analyzed by flow cytometry. Naïve $CD4^+$T cells from both groups were isolated for further experiments. Microarray analysis was performed on naïve $CD4^+$T cells of six BD patients and six gender- and age-matched HCs to gain insight into their respective gene expression profiles, which was validated by qRT-PCR analyses. To investigate the role of lncRNA in Th17 differentiation, naïve $CD4^+$T cells were transfected using siRNA, overexpression plasmids or miRNA mimics as required, and were incubated under Th17-polarizing condition for 5 days. A dual-luciferase reporter assay was used to confirm the target of miRNA.

Results: Circulating Th17 cells were elevated in active BD patients ($p< 0.0001$), which were positively correlated with BDCAF. BD naïve $CD4^+$T cells showed enhanced Th17 cell differentiation capacity compared to HC cells ($p< 0.001$) (Fig. 1). Microarray analysis revealed that Th17-related FoxO signaling pathway was inhibited in BD naïve $CD4^+$T cells, along with downregulation of FoxO1 and its related lncRNA PIGL-217 (Fig. 2A-B), which was confirmed in vitro ($p< 0.0001$ and $p< 0.001$, respectively). We further demonstrated that PIGL-217 silencing in naïve $CD4^+$T cells decreased FoxO1

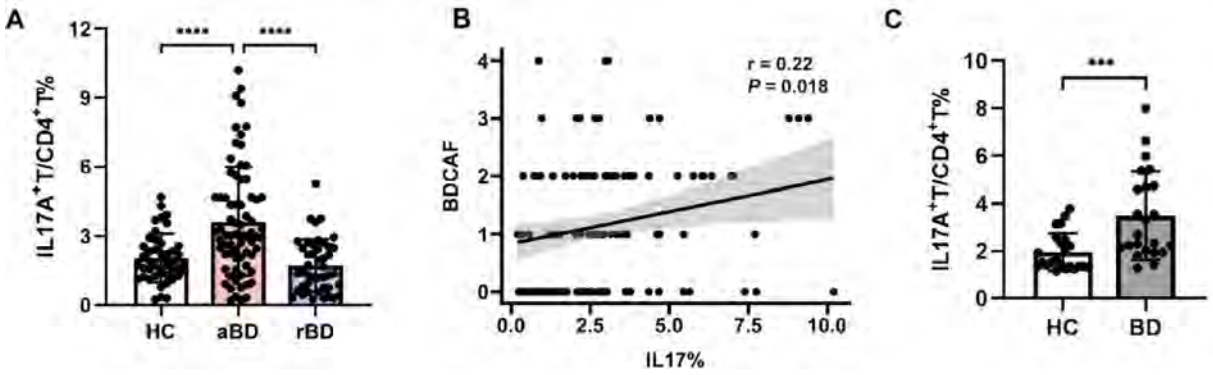

Fig. 1 Aberrant Th17 cells in BD patients. (A) Level of IL-17A+T cells in peripheral CD4+T cells of HC (n=43), active (n=71) and inactive (n=44) BD patients. (B) Pearson correlation of BDCAF with frequency of circulating IL-17A+T cells. (C) Level of IL-17A+T cells induced from HC (n=23) and BD (n=23) naïve CD4+T cells under Th17-polarizing condition for 5 days. ***p < 0.001, ****p < 0.0001.

expression ($p< 0.05$) and enhanced Th17 differentiation ($p< 0.05$), which was attenuated by FoxO1 overexpression ($p< 0.01$) (Fig. 2C). Using competing endogenous RNA (ceRNA) prediction, we identified miR-5008-5p as a candidate gene (Fig. 3A), with increased expression in BD naïve $CD4^+$T cells ($p< 0.0001$). Dual-Luciferase reporter assay confirmed FoxO1 and PIGL-217 were targeted by miR-5008-5p (Fig. 3B), the expression of which was significantly increased after PIGL-217 knockdown ($p< 0.05$). Finally, miR-5008-5p mimics significantly down-regulated FoxO1 expression ($p< 0.001$) and promoted Th17 differentiation ($p< 0.01$), which was reversed by PIGL-217 overexpression ($p< 0.001$) (Fig. 3C).

Conclusion: Our data suggest that Th17 cell differentiation is enhanced and plays a role in BD. We identify PIGL-217 as a novel lncRNA regulating Th17 differentiation, which acts as a sponge for miR-5008-5p to regulate FoxO1 expression via the ceRNA mechanism.

Targeting Fibroblasts in Inflammatory Disease Using Engineered T Cells

Samuel Kemble[1], Christopher Mahony[2], Charlotte Smith[2], Joel Rurik[3], Haig Aghajanian[3], Jonathan Epstein[3], Mark Coles[4] and Adam Croft[2], [1]University Birmingham, Rugeley, United Kingdom, [2]University of Birmingham, Birmingham, United Kingdom, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

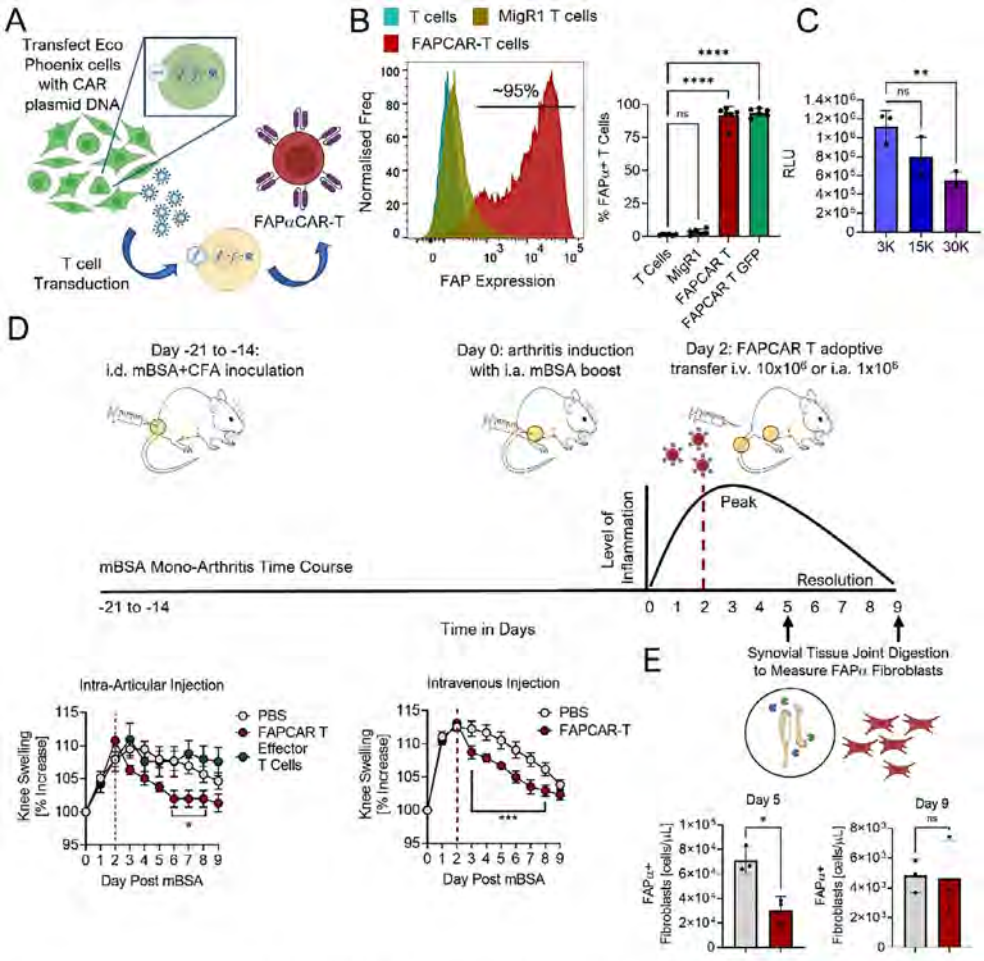

Figure 1: A) A schematic of FAPCAR-T cell generation. B) FAPCAR-T cell FAP expression measured by flow cytometry compared to non-transduced T cells and MigR1 (vector only) transduced T cells. C) In vitro killing assay: FAPCAR-T cells ($3x10^3$-$30x10^3$) were cultured for 24h with FAPα+luciferase HEK293T cells. After culture the remaining HEK293T cells were lysed and luciferase was measured by luminometer to determine cell targeting (the greater the cell death the lower the luciferase signal). D) The mBSA mono-arthritis model of inflammatory arthritis time course. Following induction of arthritis in a single knee joint (day 0), mice were administered FAPCAR-T cells i.v. ($10x10^6$) or i.a. ($1x10^6$) prior to peak of inflammation (day 2) and joint swelling was measured using callipers. E) At day 5 and day 9, synovial tissue from PBS and FAPCAR-T treated mice was enzymatically digested and the number of FAP expressing synovial fibroblasts was measured by flow cytometry.

Background/Purpose: Fibroblast activation protein alpha (FAPa) expressing fibroblasts orchestrate tissue inflammation and damage in rheumatoid arthritis (RA) as well as tissue immunity in primary Sjögren's syndrome (PSS) through the formation of tertiary lymphoid structures (TLS; Croft et al., Nature 2019 & Nayar et al., PNAS 2019). As a result, therapeutic targeting of these resident cells has the potential to reset the inflammatory tissue microenvironment, in favour of resolution. Our aim was to determine the therapeutic efficacy of FAPa-targeted chimeric T (FAPCAR-T) cell immunotherapy in inflammatory disease.

Methods: FAPCAR-T cells were generated and functionally tested as previously described (Aghajanian et al., Nature 2019) and were administered systemically and/or locally prior to peak of inflammation in murine models of inflammatory arthritis, or an inducible salivary gland inflammation model. Arthritis severity was determined by clinical scores and caliper measurements of swollen joints and changes in fibroblast activation states using 3′ single cell RNA profiling of CD45- sort-purified, CAR-treated synovial tissue. TLS characterization was determined by immunohistochemistry. FAPCAR-T-GFP, Fibroblast FAPa expression and leukocyte infiltration in enzymatically digested synovial or salivary gland tissue was measured by flow cytometry to determine CAR-T homing, FAPa targeting and inflammation, respectively.

Results: In arthritis, targeted deletion of FAPa fibroblasts was achieved through the adoptive transfer of FAPCAR-T cells that homed to the site of inflammation upon systemic administration and resulted in significant FAPa fibroblast cell depletion in the inflamed tissue. In both mono-articular and polyarticular arthritis models the intravenous or direct intra-articular administration of FAPCAR-Tcells prior to peak of inflammation suppressed disease severity by significantly attenuating joint inflammation. Single cell RNA profiling of CD45- sort-purified, FAPCAR-T treated synovial tissue identified a global defect in the stromal cell landscape. Systemic administration of FAPCAR-T cells in the salivary gland model significantly decreased the proportion of T and B cells and influenced TLS formation and maturity.

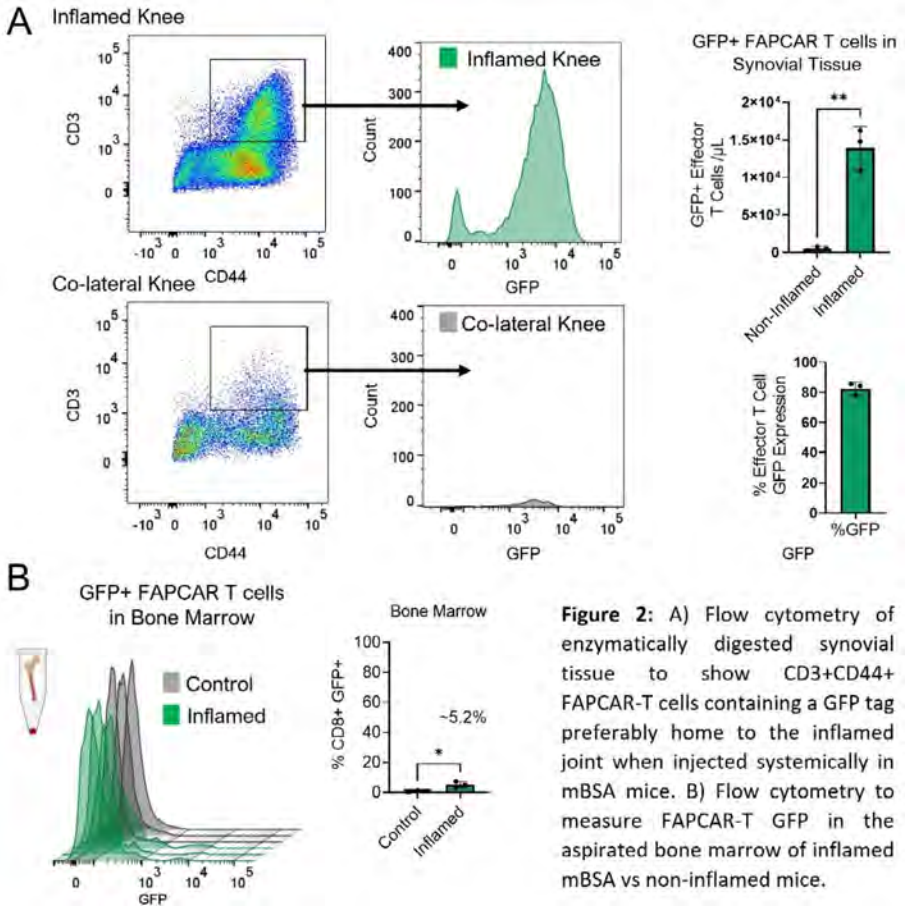

Figure 2: A) Flow cytometry of enzymatically digested synovial tissue to show CD3+CD44+ FAPCAR-T cells containing a GFP tag preferably home to the inflamed joint when injected systemically in mBSA mice. B) Flow cytometry to measure FAPCAR-T GFP in the aspirated bone marrow of inflamed mBSA vs non-inflamed mice.

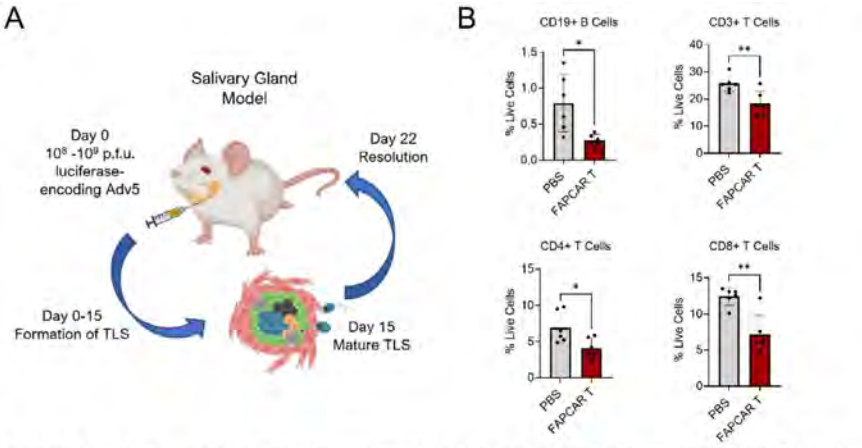

Figure 3: A) A schematic of the salivary gland PSS model. B) Mice were systemically administered 10x10^6 FAPCAR-T cells or PBS on day 10 and the % live T and B cells were measured by flow cytometry on day 15 (when mature, fully developed TLS are normally present).

Conclusion: FAPα is an attractive, therapeutically targetable biomarker of pathogenic fibroblasts. This study demonstrates potential therapeutic efficacy of fibroblast-targeted immunotherapy as a novel treatment in inflammatory disease.

IL10 Inhibits Toll-like Receptor-9-induced T Cell Receptor-mediated T Cell Activation in Macrophage Activation Syndrome

Matthew Eremita[1], Omar Geier[2], Joyce Hui-Yuen[1] and Matthew Taylor[3], [1]Division of Pediatric Rheumatology, Cohen Children's Medical Center, Lake Success, NY, [2]Sepsis Research Laboratory, Feinstein Institutes for Medical Research, Manhasset, NY, [3]Division of Pediatric Critical Care, Cohen Children's Medical Center, Manhasset, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Macrophage activation syndrome (MAS) is a potentially fatal complication of systemic juvenile idiopathic arthritis (sJIA). Gene expression pathway analyses have identified altered Toll-like receptor (TLR) signaling in sJIA and MAS. Repeated administration of CpG, a TLR-9 agonist, induces an MAS-like phenotype in mice; fulminant disease is induced with co-administration of intereukin-10 receptor blocking antibody (αIL10R). IL10 is an anti-inflammatory cytokine that induces T cell immune tolerance. Deficient production of IL10 by antigen presenting cells drives pathology in sJIA patients and animal models of the disease. Polymorphisms in the IL10 gene family confer susceptibility to sJIA. We hypothesized that IL10 inhibits T cell activation (TCA) in TLR-9-induced inflammation, and that TCA contributes to hypercytokinemia in TLR-9-induced inflammation.

Methods: Five experimental groups of C57Bl6 mice were studied: 1) untreated, negative controls; 2) MAS: treated with CpG 50 μg intraperitoneally (ip) every other day for 5 doses days -8 – 0; 3) CpGHi: treated with CpG 500 μg ip on day 0; 4) CpGHi+αIL10R: treated with CpG 500 μg plus αIL10R 1000 μg (both ip) on day 0; 5) αCD3ε (positive controls): treated intravenously with 50 μg of anti-CD3ε stimulating antibody on day 0. On day 1 following completion of treatment animals were sacrificed. Spleens were harvested and digested, and leukocytes were isolated. Cells were cultured in brefeldin A to entrap expressed products intracellularly or were stained directly post-isolation. Stained cells were analyzed with flow cytometry. Cytokine-driven-TCA was quantified by CD69 staining on flow cytometry. T cell receptor-mediated- (TCR-) TCA was quantified by Nur77 staining on flow cytometry. Data were analyzed using one-way Analysis of Variance with Šídák post-hoc tests.

Results: MAS exposure did not affect cytokine-driven-TCA. CpGHi-exposure increased cytokine-driven-TCA in CD4+ T cells compared to MAS-exposed mice and untreated controls (Fig. 1, $p < 0.05$). CpGHi+αIL10R exposure increased cytokine-driven-TCA compared to MAS- and CpGHi-exposed mice, and untreated controls (Fig. 1, $p < 0.05$). MAS exposure did not affect TCR-TCA. CpGHi exposure increased TCR-TCA compared to MAS-exposed mice and untreated controls (Fig. 2, $p < 0.05$). CpGHi+αIL10R exposure increased TCR-TCA compared to MAS- and CpGHi-exposed mice, and untreated controls (Fig. 2, $p < 0.05$). CpGHi+αIL10R exposure increased the proportion of CD8+ T cells expressing TNFα compared to untreated controls and CpGHi-exposed mice (Fig. 3B, $p < 0.05$), but not MAS-exposed mice. CpGHi+αIL10R exposure increased serum concentrations of TNFα, IL6, and IL12 compared to MAS- and CpGHi-exposed mice, and

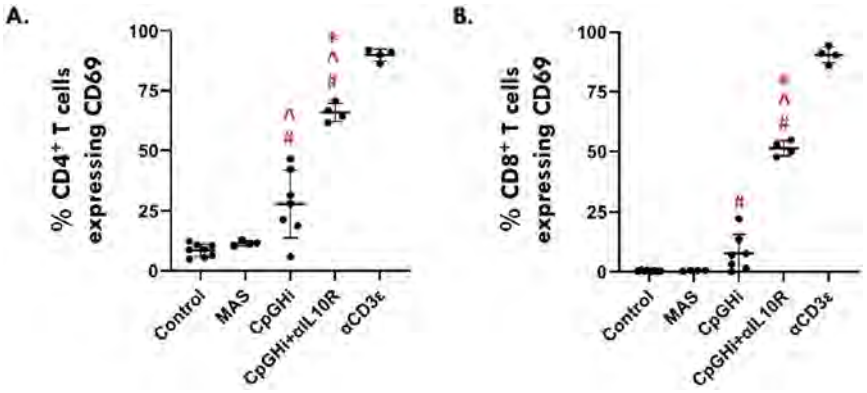

Figure 1. Flow cytometric data showing the relative proportions of CD69+ splenic (A) CD4+ and (B) CD8+ T cells. Data are pooled from three experiments of 12, 7 and 8 10-12-week-old mice. Gates defining T cell populations were unique to individual experiments. αCD3ε-exposed mice served as positive controls for individual experiments (%CD69+ CD4+ and CD8+ T cells set at 90%). Data were analyzed using one-way Analysis of Variance with Šídák post-hoc tests. # vs Control; ^ vs MAS; * vs CpGHi; $p < 0.05$.

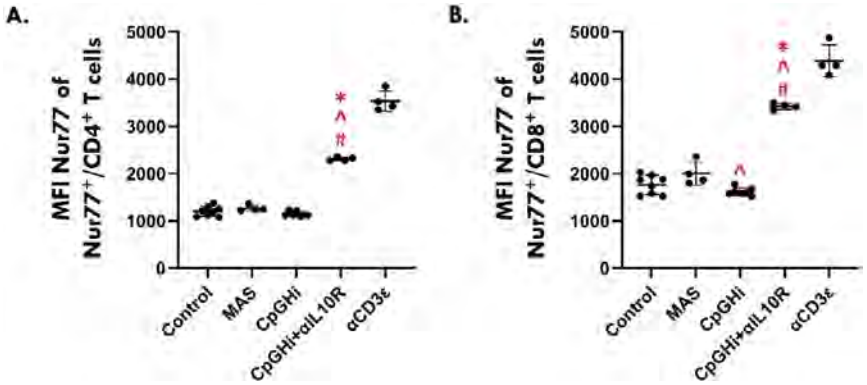

Figure 2. Flow cytometric data showing the median fluorescence intensities (MFIs) of Nur77+ splenic (A) CD4+ and (B) CD8+ T cells. Data are pooled from three experiments of 12, 7 and 8 10-12-week-old mice. Gates defining T cell populations were unique to individual experiments. αCD3ε-exposed mice served as positive controls for individual experiments (%Nur77+ CD4+ and CD8+ T cells set at 90%). Data were analyzed using one-way Analysis of Variance with Šídák post-hoc tests. # vs Control; ^ vs MAS; * vs CpGHi; $p < 0.05$.

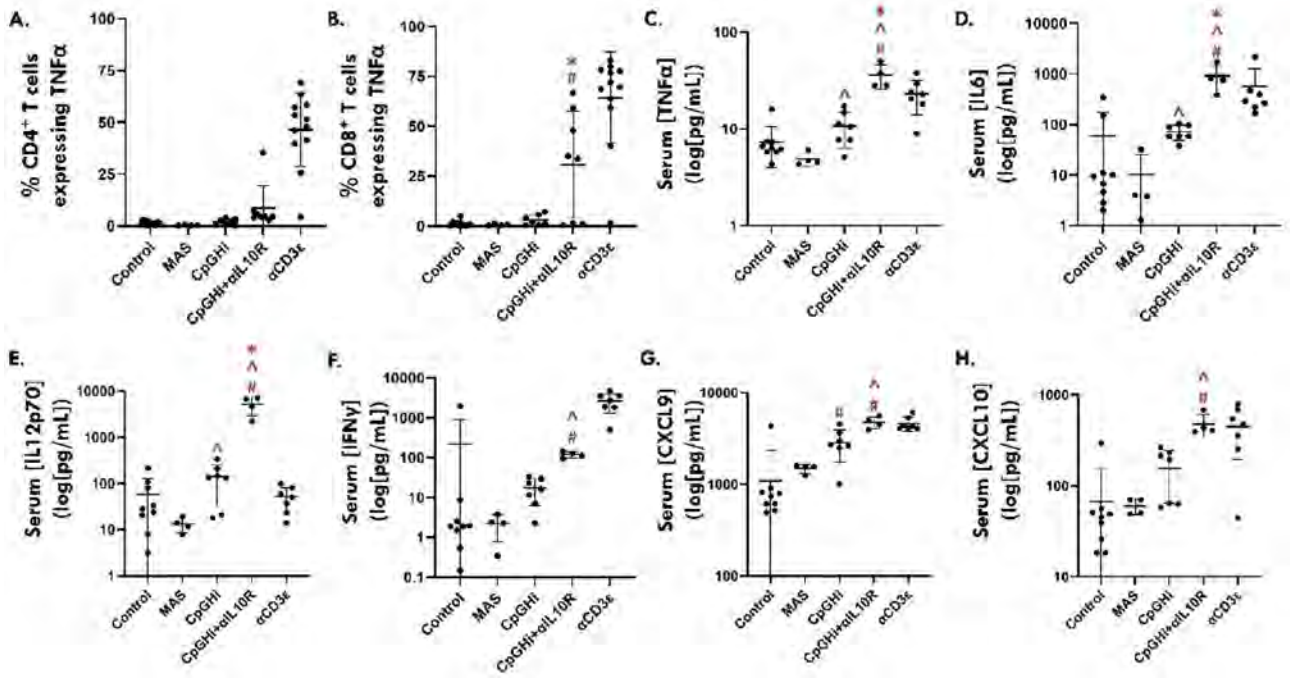

Figure 3. Flow cytometric data showing the relative proportions of TNFα+ splenic (A) CD4+ and (B) CD8+ T cells. Data are pooled from four experiments of 12, 11, 8 and 12 10-12-week-old mice. (C-H) Serum cytokine levels obtained via submandibular cheek bleed. Data are pooled from three experiments of 12, 11, and 8 and 10-12-week-old mice. (C-H) Statistical analyses were performed following log transformation of the data owing to failure of tests for normality. Data were analyzed using one-way Analysis of Variance with Šídák post-hoc tests. # vs Control; ^ vs MAS; * vs CpGHi; $p < 0.05$.

untreated controls (Fig. 3C-E, $p < 0.05$). CpGHi+αIL10R exposure increased serum concentrations of IFNγ, CXC-motif chemokine ligand 9 (CXCL9), and CXCL10 compared to MAS-exposed mice and untreated controls (Fig. 3F-H, $p < 0.05$).

Conclusion: IL10 prevents TLR-9-induced TCA. TCA contributes to TLR-9-induced hypercytokinemia. The established, non-infectious model of MAS with repeated administration of low-dose CpG does not adequately capture the contribution of T cells to the development of fulminant disease.

Mutated NOD2 Controls IL-2 Production in Blau Syndrome Patients and Mice

Leah M. Huey[1], Emily Vance[1], Holly L. Rosenzweig[2], Bryce Binstadt[3] and Ruth J. Napier[2], [1]Oregon Health & Science University, Portland, OR, [2]Oregon Health & Science University, VA Portland Health Care System, Portland, OR, [3]University of Minnesota, Minneapolis, MN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Microbial sensing molecule nucleotide-binding oligomerization-domain containing protein 2 (NOD2) is expressed by CD4+ T cells and plays a novel T cell-intrinsic role within CD4+ T cells in protecting against Th17-mediated experimental uveitis and arthritis. It is known that CD4+ T cells from Nod2-deficient (*Nod2*$^{-/-}$) mice have increased IL-17A responses and decreased IL-2 compared to WT mice. However, it is unknown how *NOD2* mutations that cause the rheumatic disease Blau Syndrome affect T cell function. Here, we investigated how mutated *NOD2* controls T cell activation and cytokine production in Blau patients and Blau knock-in mice (*Nod2*^{R314Q}).

Methods: Peripheral blood mononuclear cells from Blau patients or healthy controls were treated with T cell receptor (TCR) activator, anti-CD3, and co-stimulatory agent, anti-CD28, either overnight or for 5 days followed by a 4-hour incubation with anti-CD28 or phorbol myristate acetate (PMA) and ionomycin. After incubation, cytokine expression was quantified by ELISA and flow cytometry in supernatants and cells, respectively. Patient plasma IL-2 was quantified by ELISA. Splenocytes from wildtype (WT) naïve mice or Blau knock-in mice expressing *Nod2*^{R314Q}, a mutation in *Nod2* known to cause Blau in humans, were stimulated with T cell activators and analyzed for cytokine production by ELISA and flow cytometry. Data were analyzed by unpaired two-sided student T test, and $p < 0.05$ were considered significant.

Results: Blau patients had decreased plasma IL-2 compared to control subjects (29 pg/mL vs. 320 pg/mL). TCR-activation of Blau patients' CD4+ T cells resulted in lower production of IL-2 after 5 days, supporting of a role for mutated NOD2 in controlling T cell function. Conversely, Blau patient T cell incubation with PMA and ionymin, a T cell stimulant which bypasses the TCR, resulted in similar levels of IL-2, indicating NOD2 plays a role directly downstream of the TCR. In corroboration, TCR-activation of T cells from naïve Blau *Nod2*^{R314Q} mice resulted in decreased IL-2 production compared to WT mice. Mechanistically, freshly isolated and overnight stimulated CD4+ T cells from naïve Blau *Nod2*^{R314Q} mice had increased expression of Nur77 (T cell activation molecule directly proportional to the strength of TCR engagement) and Ki67 (indicator of proliferation) compared to WT T cells, yet similar levels of CD69 (early TCR-activation molecule) and CD25 (IL-2 receptor alpha). Cumulatively, these data suggest that *NOD2*^{R314Q} expression results in dysregulated T cell responses downstream of TCR-specific activation including enhanced TCR-signaling strength, increased proliferation, and reduced IL-2 production.

Conclusion: Our data suggest that defective IL-2 signaling is driving aspects of systemic inflammation in Blau patients as similar patients with loss-of-function mutations in IL-2 signaling have unchecked CD4+ T cell proliferation and develop systemic autoimmunity. Additionally, our data indicate that *Nod2*^{R314Q} expression may be altering TCR signaling strength, resulting in a dysregulation of T cell activation. Thus, further studies investigating how NOD2 is controlling TCR signaling will contribute to novel T cell-targeted therapeutics for Blau patients.

De-escalation of Anti-TNFs in Older Adults with Rheumatoid Arthritis

Jiha Lee[1], Navasuja Kumar[1], Mohammed Kabeto[1], Andrzej Galecki[1], Chiang-Hua Chang[1], Namrata Singh[2], Raymond Yung[3], Una Makris[4] and Julie Bynum[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Washington, Bellevue, WA, [3]Michigan Medicine, Ann Arbor, MI, [4]UT Southwestern Medical Center and Dallas VA, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Health Services Research I
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Biologic disease modifying anti-rheumatic drugs (bDMARDs) such as anti-tumor necrosis factors(anti-TNFs) improve clinical and radiographic outcomes in rheumatoid arthritis (RA). However, their use is associated with dose- and age-dependent adverse effects including increased risk of serious infections. In recent years, de-escalation (or deprescribing or tapering/discontinuing) has been proposed as an approach to reduce polypharmacy and optimize medication use in older adults more prone to the negative, often additive, adverse effects of medications. Current clinical practice guidelines recommend de-escalating bDMARDs in RA patients with low disease activity or in remission. We evaluated the prevalence of and factors associated with anti-TNF de-escalation among Medicare beneficiaries with RA in usual care.

Methods: We identified adults ≥66 years of age with RA, on anti-TNF therapy within 6-months of RA diagnosis with at least 6-7 months duration (proxy for stable use), using 20% Medicare data from 2009-2017. Patient demographic and clinical characteristics including concomitant use of glucocorticoid (GC) and conventional synthetic DMARDs (csDMARDs) were collected. Anti-TNF use was categorized as either de-escalation, identified by dose reduction, dosing interval increase or cessation of use, or continuation. We used (1) prospective cohort design with Cox regression models to analyze the association between patient characteristics and time to de-escalation event and, (2) case-control design with propensity score

Table 1: Compare characteristics by patterns of TNF inhibitor use among Medicare beneficiaries with RA

Variables	Continuation N=4528	De-escalation N=1192

Long-term glucocorticoids	0.83 (0.72, 0.96)	0.0094	0.80 (0.70, 0.93)†	0.0031

† statistically significant with p<0.05
*Propensity score calculated based on age and comorbidity at event, gender, race, low-income subsidy status and year of index date.

adjusted logistic regression to retrospectively assess the association of de-escalation with different clinical conditions and concomitant medication use.

Results: We identified 5720 Medicare beneficiaries with RA on anti-TNF. Average age at index was 74.0 (SD 5.8), 78% were female, 83% were non-Hispanic white, 26% had low income subsidy (LIS), and average Elixhauser comorbidity score was 2.2 (SD 1.9). One in five (21%) met criteria for de-escalation, of whom 61% either reduced dose or increased dosing interval and 39% ceased use. De-escalation was less likely in those with LIS status (HR 0.70, 95% CI 0.60-0.82), adjusting for patient age, sex, race/ethnicity, and comorbidity. Lower odds of de-escalation was associated with serious infection (OR 0.54, 95% CI 0.42-0.69), new cancer diagnosis (OR 0.37, 95% CI 0.18-0.78), and long-term GC use (OR 0.80, 95% CI 0.70-0.93), whereas higher odds was associated with concomitant methotrexate use (OR 1.19, 95% CI 1.04-1.36).

Conclusion: Although older adults with greater burden of polypharmacy and multimorbidity are more likely to benefit from de-escalation, anti-TNFs are de-escalated in 21% of older adults with RA in usual care. This in comparison to clinical trials showing 30-50% of younger adults with RA can de-escalate bDMARDs without significant disease progression. Further study to understand sub-groups of older adults with RA most likely to benefit from and the impact of de-escalation can help optimize the use of anti-TNFs in this population.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Health Services Research I
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: To achieve optimal health outcomes, people with rheumatoid arthritis (RA) need to know their symptom patterns and be able to practice self-care activities. With patient partners, we co-developed a Fitbit®-compatible app (OPERAS) for monitoring symptoms, disease activity, physical activity, and self-care goals. This study assessed a remote physical therapist (PT) counselling intervention using self-monitoring tools for enhancing self-management ability, physical activity participation, and health outcomes.

Methods: Eligible participants had a physician-confirmed diagnosis of RA. After baseline assessment (T0) and randomization, the *ImmediateGroup (IG)* received group education (2 hours), a Fitbit®, the app, and phone calls from a PT at weeks 2, 4, 6, 8, 13 and 26 to review their symptoms, treatment use, physical activity, and self-care goals. The *Delay Group (DG)* received a monthly e-newsletter unrelated to RA management until week 26, and then the intervention. Participants were assessed again at 27 weeks (T1) and 53 weeks (T2). Primary Outcome: Self-management ability assessed with the Patient Activation Measure (PAM-13). Secondary Outcomes: 1) RA Disease Activity Index (RADAI), 2) McGill Pain Questionnaire, 3) Fatigue Severity Scale, 4) Patient Health Questionnaire-9 (PHQ-9), 5) Self-Reported Habit Index for sitting/walking,6) daily time in moderate/vigorous physical activity and sedentary activity, and step count(SenseWear®).

Table 1: Participant outcomes

* $P < 0.05$
† MVPA (moderate/vigorous physical activity) was performed at ≥3 MET and in bouts ≥10 minutes with allowance for 2-minute interruptions
†† Purposeful activity was performed at ≥4 MET and in bouts ≥10 minutes with allowance for 2-minute interruptions
‡ Sedentary behaviours were performed at ≤1.5 MET in bouts ≥20 minutes

We conducted intention-to-treat analysis using Generalized Linear Mixed-effect Models, adjusting forage and sex. The dependent variable was the change in outcome variable between two assessment time points. Three contrasts were assessed: 1) between-group difference (*DG* vs. *IG*) in the outcome change at T1 from T0 (T1-T0); 2) within-group difference (*DG* only): T2-T1 vs. T1-T0; and 3) average of contrasts 1 and 2. Contrast 3 was the primary contrast as it combined the between-group intervention effect and the within-group intervention effect.

Results: We recruited 132 participants (*IG*: n=66, 92.4% women; *DG*: n=66, 90.9% women). Both groups were similar in age [*IG:* 55.1 years (SD 13.3); *DG*: 56.9 years (SD 13.2)]. 80.3% completed the study during the COVID-19 pandemic. The adjusted mean difference in PAM-13 was 5.4 (95% CI: 0.9, 9.9). Contrast 3 was statistically significant for PAM-13 (Contrast coefficient: 5.3, 95% CI: 2.0, 8.7; $p = 0.002$).Examination of Contrasts 1 and 2 revealed that the effect on PAM-13 was underpinned by both the between group difference at T0-T1 and the within group change in the *DG* from T0-T1 (no-intervention period) to T1-T2 (intervention period) (**Tables 1 & 2**). Intervention effects were also found in RADAI (Contrast 3: -0.6, 95% CI: -1.1, -0.2), Fatigue Severity Scale (Contrast 3: -0.3, 95% CI: -0.5, -0.1), PHQ-9 (Contrast 3: -1.3, 95% CI: -2.3, -0.3), and Self-Reported Habit Index - walking subscale (Contrast 3: 0.4, 95% CI: 0.0, 0.7).

Conclusion: Remote PT counselling paired with use of self-monitoring tools improved self-management ability in people with RA. We also found significant effects in disease activity, fatigue, depression, and perceived walking habit at 26 weeks, suggesting the intervention had a positive effect on symptom management.

Inferring Disease Activity Scores and Low Disease Activity at Registry Visits Based on Structured and Narrative Data from Electronic Health Records

David Cheng[1], Dana Weisenfeld[2], Kumar Dahal[2], Qing Liu[2], Vidul Ayakulangara Panickan[3], Mary Jeffway[2], Thany Seyok[2], Gregory McDermott[2], Michael Weinblatt[4], Nancy Shadick[5], Tianxi Cai[6] and Katherine Liao[2], [1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard Medical School, Boston, MA, [4]Harvard Medical School, Waban, MA, [5]Brigham and Women's Hospital, Boston, MA, [6]Harvard T.H. Chan School of Public Health, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

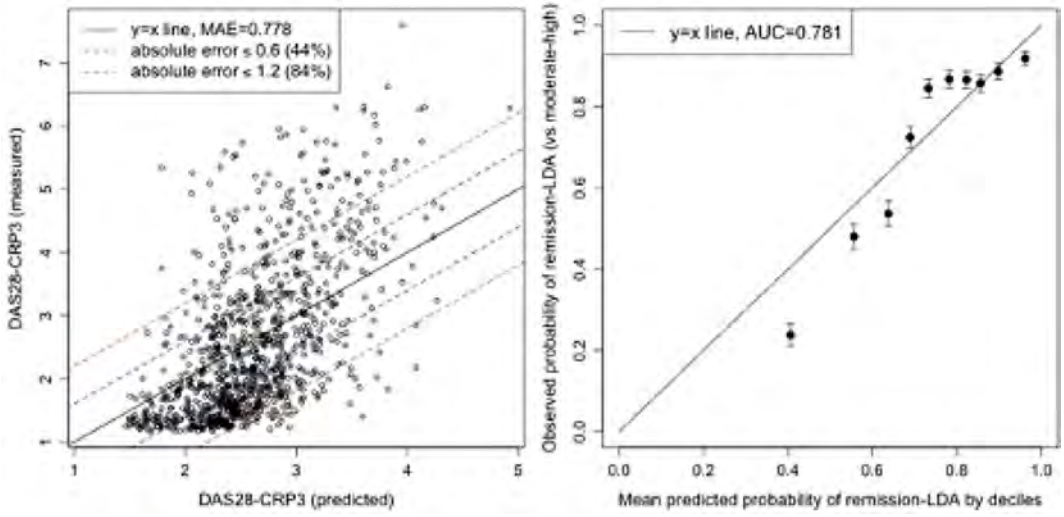
Session Title: Abstracts: Health Services Research I

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Real-world data including electronic health records (EHRs) are a promising resource for learning to optimize treatment strategies for rheumatoid arthritis (RA). A major challenge in leveraging real-world data in rheumatology is the lack of standardized collection of disease activity measures. Previous studies had limited success inferring disease activity with administrative claims and EHR data. This study aimed to assess the accuracy of inferring disease activity as measured by the Disease Activity Score in 28 joints with CRP (DAS28-CRP) using both structured and narrative EHR data extracted from notes with natural language processing (NLP).

Methods: We studied RA patients from a single center registry linked with EHR data. The structured data included RA-related diagnosis and procedure codes, medication prescriptions, and laboratory test encounters and values. The NLP data included mentions of RA and disease activity concepts. Models were trained on DAS28-CRP obtained during in-person study visits from the registry. For each visit, structured and NLP data were extracted from EHR encounters within 24 weeks. In 80% of the visits, we fit separate random forest models to predict the continuous DAS28-CRP value and the binary



Observed vs. predicted DAS28-CRP values among the validation set based on structured + NLP features (left). Calibration plot (right) shows observed probability of LDA and corresponding 95% confidence intervals vs. mean predicted probability of LDA by deciles of predicted probability based on structured + NLP features.

Features	Performance Metrics
DAS28-CRP values	
Structured (diagnosis codes, procedure codes, medications, lab encounters and values)	MAE=0.843 (79% ≤1.2, 44% ≤0.6)
Structured + NLP concepts from notes	MAE=0.778 (84% ≤1.2, 44% ≤0.6)
Disease activity status (remission-LDA vs moderate-high by DAS28-CRP ≤ 3.2)	
Structured (diagnosis codes, procedure codes, medications, lab encounters and values)	AUC=0.677
Structured + NLP concepts from notes	AUC=0.781
Manual chart review (in 67 visits)	Sensitivity=73.3%, Specificity=45.5%, AUC=0.705

Performance of phenotyping models with and without RA-related NLP concepts from notes and relative to manual chart review. MAE: mean absolute error, AUC: area under the curve, NLP: natural language processing.

disease activity status categorized into remission/low (LDA; DAS28≤3.2) vs moderate/high disease activity (DAS28 >3.2). We validated the predictions in the remaining 20%. To assess the accuracy of predicting DAS28-CRP values, we estimated the mean absolute error (MAE; lower values indicate lower error), percentage of predictions within 0.6 (reported measurement error for DAS28-CRP), and 1.2 (minimal clinically important difference (MCID)) of the observed values. For LDA status, we calculated the area under the curve (AUC). Observed values and probabilities were plotted against predicted values and mean predicted probabilities in deciles to further assess prediction performance. We identified influential EHR features for predictions using Gini impurity. These analyses were repeated with and without including NLP data. We benchmarked against manual chart-review for inferring LDA, using LDA defined by DAS28-CRP as reference, in a sample of 67 visits.

Results: We identified 4,883 visits among 1,059 patients with a DAS28-CRP score. The mean age at first visit was 60.5 years old, with 83.6% of patients being female and 89.4% White. The MAE for DAS28-CRP values was 0.778, with 84% and 44% of absolute errors within 1.2 (MCID) and 0.6 (measurement error). The AUC for LDA was 0.781 (Figure 1). Incorporating NLP data consistently improved prediction performance (Table 1). Features with the highest importance included CRP and ESR values, age, receiving a CRP test, and NLP mentions of disease activity and glucocorticoids. The model incorporating NLP data achieved a higher AUC over manual chart review.

Conclusion: Inferring disease activity with EHR data collected from routine care, particularly with the addition of data from narrative notes, achieved moderate accuracy against prospectively collected DAS28-CRP measures. Further work is needed to validate whether these inferred disease activity measures can be applied to reliably assess response to treatment in observational data.

Real-World Disease Monitoring Patterns in Rheumatoid Arthritis-Associated Interstitial Lung Disease in the Veterans Affairs Health Care System

Bryant England[1], Tate Johnson[1], Yangyuna Yang[1], Punyasha Roul[1], Daniel Hershberger[1], Brian Sauer[2], Grant Cannon[3], Joshua Baker[4] and Ted R Mikuls[5], [1]University of Nebraska Medical Center, Omaha, NE, [2]Salt Lake City VA/University of Utah, Salt Lake City, UT, [3]University of Utah and Salt Lake City VA, Salt Lake City, UT, [4]University of Pennsylvania, Philadelphia, PA, [5]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

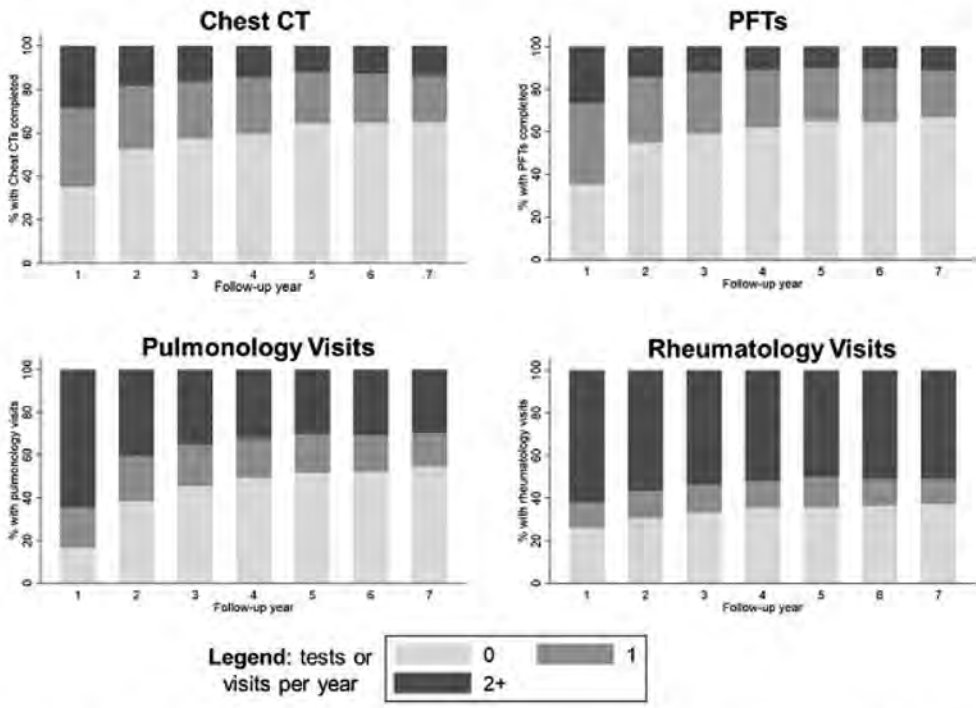
Session Title: Abstracts: Health Services Research I

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: There are currently no clinical practice guidelines for monitoring RA-associated interstitial lung disease (RA-ILD). Pulmonary function tests (PFTs) and chest computed tomography (CT) imaging are among the most common tests utilized for RA-ILD surveillance, but the frequency of these tests in real-world settings is unclear. We examined real-world disease monitoring patterns in RA-ILD within the Veterans Affairs (VA) Health Care System, the largest integrated health care system in the U.S., from 1999-2021.

Figure 1. RA-ILD Disease Monitoring During the Disease Course.



Figures show the percent of patients with 0, 1, or 2+ tests/visits during each 1-year interval after the index date (date fulfilling RA-ILD algorithm).

Abbreviations: CT, computed tomography; PFTs, pulmonary function tests

Figure 1. RA-ILD Monitoring During the Disease Course

Methods: We performed a cohort study within national VA data warehouses, identifying individuals with RA-ILD (prevalent and incident) using validated algorithms that required multiple RA and ILD diagnostic codes (PPV >70%). The index date was the date patients fulfilled RA-ILD algorithm, and patients were followed for up to 7-years post-index date (reflecting the median survival in RA-ILD), censoring for death. Over the entire follow-up period and by sequential one-year intervals following the index date, we assessed completion of PFTs, chest CT imaging (any type), and outpatient visit frequency to rheumatology and pulmonology. PFTs, chest CTs, and outpatient visits (rheumatology and pulmonology) were obtained from VA administrative data and linked Centers for Medicare Services data. Vital status was determined from VA death records. Descriptive statistics were used to summarize RA-ILD monitoring patterns.

Results: We identified n=6,232 patients with RA-ILD (92.6% male, mean age 69.1 years). During follow-up, RA-ILD patients underwent monitoring with PFTs every 1.4 years (median [IQR] 0.5 [0.2, 1.0] tests/year) and chest CT imaging every 1.1 years (median 0.7 [0.3, 1.2] tests/year). PFT and CT monitoring frequency steadily decreased over the duration of disease, with PFTs or chest CTs being obtained in fewer than 50% of RA-ILD patients each year after the first year of follow-up (**Figure 1**). Among RA-ILD patients who did undergo PFTs or chest CTs during each 1-year interval, the majority had a single PFT or chest CT test during that year. Rheumatology visits (median 1.8 [0.6, 2.9]) per year) occurred more frequently than pulmonology visits (median 1.3 [0.5, 2.4]] per year) throughout the follow-up period. However, pulmonary visit frequency more closely correlated with PFT ($r=0.51$, $p < 0.001$) and chest CT ($r=0.35$, $p < 0.001$) testing frequency than rheumatology visits (PFT $r=0.20$, $p < 0.001$; chest CT $r=0.09$, $p < 0.001$). Baseline forced vital capacity negatively correlated with PFT ($r=-0.13$, $p< 0.001$) and CT ($r=-0.04$, $p=0.01$) testing rate.

Conclusion: RA-ILD monitoring is highly variable and appears to be sub-optimal (relative to idiopathic pulmonary fibrosis guidelines; Raghu et al. AJRCCM, 2022) in real-world settings. Sources of this variability could include the heterogeneity of the disease and prognosis, involvement of multiple medical specialties, a lack of evidence-based guidance for disease monitoring, and patient preferences, among others. These findings highlight the need for clinical practice guidelines on RA-ILD monitoring to inform rheumatologist and pulmonologist engagement in RA-ILD surveillance, particularly with the emergence of additional therapeutic options in RA-ILD.

Underserved by Rehabilitation: Characteristics Among Adults with Rheumatoid Arthritis

Chris Lane[1], Lauren Mihalek[2], Kelli Allen[3], Beth Jonas[4], Patti Katz[5] and Louise Thoma[6], [1]UNC Chapel Hill, Chapel Hill, NC, [2]University of North Carolina - Chapel Hill, Chapel Hill, NC, [3]University of North Carolina, Durham, NC, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]University of California San Francisco, San Rafael, CA, [6]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Health Services Research I

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Adults with rheumatoid arthritis (RA) often experience functional limitations (e.g., difficulty walking, dressing oneself), even with low disease activity and good pharmaceutical management. Rehabilitation services (i.e. physical therapy and occupational therapy) improve function, yet rehabilitation service use is low among adults with RA. Taken together, this suggests that many adults with RA are underserved by rehabilitation, conservatively defined as high functional burden (moderate-severe functional limitation) with no prior use of rehabilitation for RA. To better understand the gaps in care, we must understand rehabilitation use among those with functional needs and identify characteristics associated with being underserved. The purpose of this study was to examine the associations of demographic and clinical characteristics with being underserved by rehabilitation among adults with RA.

Methods: Data were cross-sectionally collected from online surveys from patients with RA who received care at UNC Health rheumatology clinics in 2020 and 2021. The primary outcome was being underserved by rehabilitation, which was defined as reporting moderate-severe functional limitation (PROMIS PF10a score < 40) and never previously using rehabilitation services related to RA (self-reported use yes vs. no). The demographics and clinical exposure variables were race and ethnicity (non-Hispanic Black, non-Hispanic White, Hispanic of any race), gender (women, men), health insurance (private, Medicare, Medicaid, none), income (higher [exceeding basic needs], lower [not exceeding basic needs]), education status (higher [at least some college], lower [no college]), work status (disabled, other), and BMI (normal, overweight, obese). We calculated the proportion of the sample with moderate-severe functional limitation, no prior rehabilitation use for RA, and underserved by rehabilitation. We examined associations of the exposure variables with being underserved using logistic

Table 1: Associations of Exposure Variables with being Underserved by Rehabilitation

Characteristic	n	Proportion with moderate-severe functional limitation % (n)	Proportion with no prior rehabilitation use for RA % (n)	Proportion who are underserved by rehabilitation % (n)	Odds of being underserved by rehabilitation *Adj. OR (95% CI)

Obese	122	65% (79)	64% (78)	35% (43)	**2.63 (1.29, 5.37)**

*Adjusted for age, disease duration, and prior joint replacement

regression models adjusted for self-reported age, disease duration, and joint replacement. Odds ratios and 95% confidence intervals were presented.

Results: Of 294 adults with RA who participated (age 56.3±14.2 years, disease duration 10.1±10.7 years), 45% reported moderate-severe functional limitation, 64% never used rehabilitation services related to RA, and 25% were underserved by rehabilitation. The following characteristics were strongly associated (adjusted OR range 2.4-5.6) with being underserved by rehabilitation: Hispanic ethnicity (compared to Non-Hispanic White), Medicare, Medicaid, or no health insurance (compared to private insurance), lower income (compared to higher), lower education (compared to higher), disabled work status (compared to other work status), and obesity (compared to normal weight), as detailed in Table 1.

Conclusion: Strikingly, at least one in four adults with RA were underserved by rehabilitation using a conservative definition. There is a clear unmet need for rehabilitation, particularly in historically marginalized groups. Future work must develop strategies for facilitating rehabilitation referral and use for those with functional needs.

Telehealth Utilization and Satisfaction Among Patients with Rheumatic Diseases: Trends Since the Onset of the COVID-19 Pandemic

Kristin Wipfler[1] and Kaleb Michaud[2], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Health Services Research I
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: The COVID-19 pandemic prompted a rapid transition to increased telehealth utilization, with many rheumatology providers replacing in-person clinical visits with telehealth visits or expanding their telehealth offerings. Understanding trends in telehealth utilization and satisfaction among people with rheumatic diseases (RDs) is crucial as telehealth options continue to be offered and used even as COVID-19 safety measures are scaled down. We investigated trends in telehealth utilization and satisfaction among individuals with RDs from the onset of the pandemic to the present.

Methods: The study population included participants in the FORWARD Databank who completed semiannual questionnaires from June 2020 to April 2023 with items related to their telehealth utilization in 6-month time periods from January 2020 through December 2022. In each of the questionnaires offered, participants were asked if they had any telehealth appointments and if so, they were asked to rate their satisfaction on a Likert scale. Descriptive statistics were calculated for participant characteristics, and comparisons were made by telehealth vs no telehealth and by satisfied vs not satisfied with telehealth. Multivariable logistic regression models (adjusted for age, sex, race, education, rural/urban residence, smoking history, BMI, autoimmune diagnosis, Rheumatic Disease Comorbidity Index, glucocorticoid use, opioid use, and Patient Activity Scale-II) were used to identify factors associated with telehealth utilization and satisfaction over time.

Table 1. Characteristics of FORWARD participants by telehealth utilization and telehealth satisfaction. Data were collected from 2020 to 2023 (six semiannual questionnaires). For participants who reported any telehealth utilization between January 2020 and December 2022, the observation included here was the first report of telehealth use. For participants who reported no telehealth utilization during that time period, the observation included here was the first observation.

Respondents who selected "somewhat satisfied" or "very satisfied" on the Likert scale were included in the "Satisfied" group. Respondents who selected "neutral," "somewhat dissatisfied," or "very dissatisfied" were included in the "Not Satisfied" group. Healthcare visits included general practice, rheumatologist, other specialist, nurse, and other health worker visits within the previous six month time period, both in person and telehealth. BMI=Body Mass Index; DMARD=disease-modifying antirheumatic drug; csDMARD=conventional synthetic DMARD; TNFi=tumor necrosis factor inhibitor; bDMARD=biologic DMARD; nTNFi=non-TNFi; JAKi=Janus kinase inhibitor; PRO=patient-reported outcome; HAQ-II=Health Assessment Questionnaire II; PAS-II=Patient Activity Scale II.

Results: Of 5,287 unique respondents, 3,846 (73%) reported telehealth utilization between January 2020 and December 2022. Respondent characteristics are presented in Table 1, and temporal trends are presented in Figure 1. Telehealth utilization peaked at 61% in the second half of 2020 and stabilized at approximately 40% throughout 2022. Higher education, younger age, urban residence, greater comorbidity burden, and worse disease activity were consistently associated with telehealth use throughout the pandemic thus far. Telehealth users earlier in the pandemic had significantly higher odds of having an autoimmune diagnosis, but since July 2021 this was not statistically significant. Telehealth satisfaction demonstrated a steady increase over time, rising from 63% to 73%. Higher education and younger age were consistently associated with greater telehealth satisfaction.

Figure 1. Factors associated with (A) telehealth utilization and (B) telehealth satisfaction over time. Multivariable logistic regression models were generated at each time point for each of the two outcomes. All models were adjusted for age, sex, race, education, rural/urban residence, smoking history, BMI, autoimmune diagnosis, Rheumatic Disease Comorbidity Index (comorbidity burden), and Patient-Activity Scale-II (disease activity). Significant covariates from each model are marked with a filled circle.

Conclusion: Rates of telehealth utilization among individuals with RDs has remained substantial throughout the COVID-19 pandemic, although rates have decreased since 2020. Improved telehealth infrastructure and growing familiarity with the technology may have contributed to increased satisfaction over time, but individuals who are younger and more highly educated continue to have higher odds of telehealth satisfaction. Those with greater comorbidity burdens and higher disease activity have very consistently been the most likely to utilize telehealth services. Ensuring quality of care for these higher risk populations remains essential as telehealth continues to become a more integral part of rheumatology practice.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) lower serum urate (primary prevention); however, whether this translates into preventing recurrent flares among gout patients (secondary prevention) and gout-primary emergency department visits or hospitalizations remains unknown. Furthermore, their potential role on cardiovascular risk has not been studied.Our objective was to compare gout flares and cardiovascular (CV) events among gout patients initiating SGLT2i versus dipeptidyl peptidase 4 inhibitors (DPP-4i), another second-line glucose-lowering agent not associated with serum urate lowering or CV risk.

Methods: This new-user, active comparator cohort study used administrative health data covering nearly all residents of British Columbia, Canada from Jan 2014 to June 2022, including all dispensed prescriptions, regardless of funder. Primary outcome was recurrent gout flare counts, ascertained by emergency department (ED), hospitalization, outpatient, and medication dispensing records (PPV 95% for ≥ 1 flare over a similar period). We also specifically investigated flares requiring hospitalization or ED visit, and stratified by sex, age, diuretic and urate-lowering therapy (ULT) use, and gout intensity (presence of ≥1 gout-coded encounter or colchicine dispensing over the past year). Myocardial infarction and stroke were secondary outcomes. We also assessed genital infection as positive control and osteoarthritis encounter as negative control. Poisson and Cox proportional hazards regressions were used with 1:1 propensity-score matching (primary analysis) and overlap weighting (sensitivity analysis).

Results: We included 8150 gout patients with type 2 diabetes whose characteristics, including baseline flare rate and gout medication use, were well balanced after propensity matching (standardized mean difference< 0.1) (**Table 1**). During follow-up, flare rate was lower among SGLT2i initiators than DPP4i initiators (52.4 and 79.7 events per 1000 person-years, respectively), with rate ratio (RR) for SGLT2i initiation 0.66 (95% CI: 0.57, 0.75) and rate difference (RD) of -27.4 (-36.0, -18.7) fewer flares per 1000 person-years (**Table 2**).RR and RD for flares requiring hospitalization or ED visit were 0.52 (0.32, 0.84) and -3.4 (-5.8, -0.9), respectively. Findings were similar during the first year of SGLT2i initiation (among those without prior ULT use), suggesting no apparent paradoxical flares (**Table 2**). Results were consistent across subgroups, though absolute RD was higher in patients with greater gout intensity: -71.6 [-111.1, -32.1] vs. 20.8 [-28.8, -12.7] per 1000 person-years, respectively (**Table 2**). Hazard ratio (HR) and RD for myocardial infarction were 0.69 (0.54, 0.88) and -7.6 (-12.4, -2.8) per

1000 person-years; HR, 0.81 (0.62, 1.05) for stroke. For control outcomes, SGLT2i initiators showed higher risk of genital infection, as expected, and no altered risk of osteoarthritis encounter (**Table 3**).Results were similar when applying propensity-score overlap weighting.

Conclusion: Among gout patients, SGLT2i may reduce recurrent flares and gout-primary ED visits/hospitalizations, along with cardiovascular benefits, without apparent paradoxical flares.

Table 2. Recurrent gout flare count among gout patients with type 2 diabetes initiating SGLT2i vs. DPP-4i, after propensity-score matching, overall and sensitivity and subgroup analyses. Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science

Session Type: Abstract Session

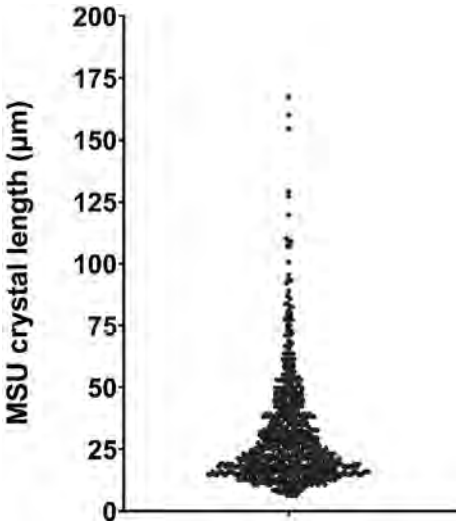
Session Time: 4:00PM–5:30PM

Background/Purpose: We described bands of fibers having deposited orderly arrayed monosodium urate (MSU) crystals suggesting the need for protein templates to start crystallization [PMID 9709185]. However, tophi sections demonstrate the presence of longer crystals, highly arranged in a fan display, likely formed after other crystals [PMID 26369610]. Hence, a double mechanism of crystallization may exist in the joint. Here, we aimed to assess whether synovial fluid MSU crystals found in joints with organized sonographic deposits (likely, many crystals deriving from them) are longer than when deposits are absent or not visible.

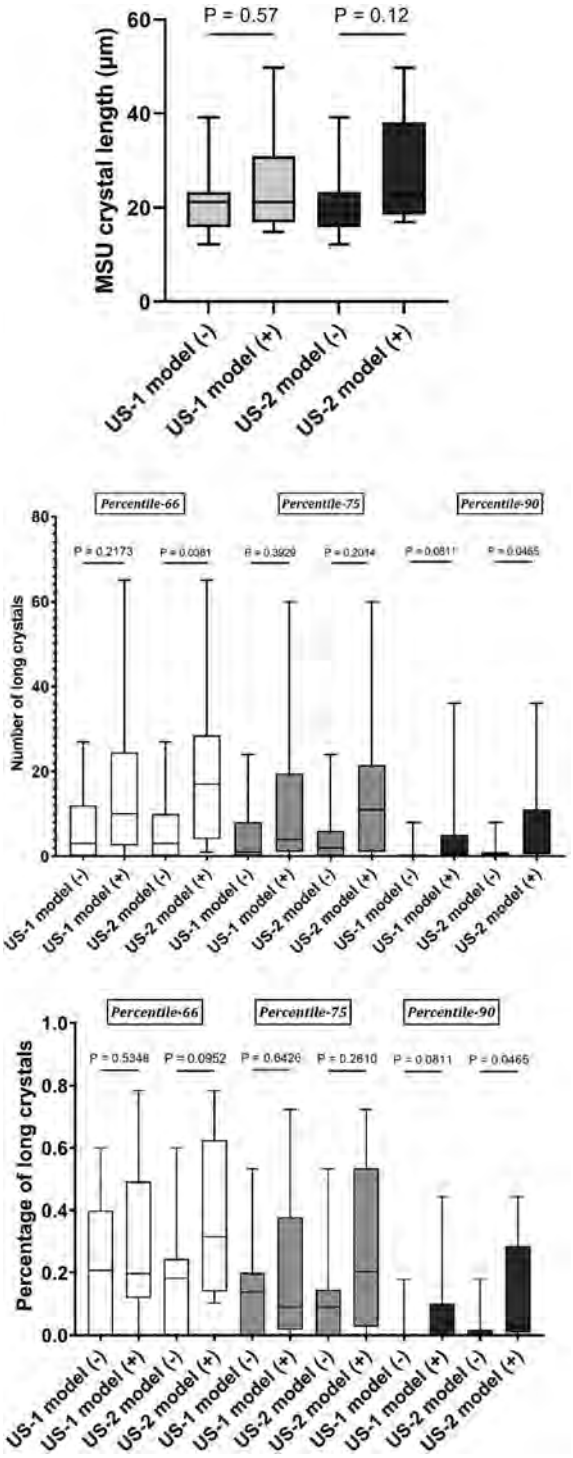
Methods: We recruited patients with crystal-proven gout during a flare. Ultrasound of the target joint was performed to detect elementary gout lesions [OMERACT 2021]: double-contour (DC) sign, tophi, and aggregates. Two sonographic models were assessed: *US-1 model*, grade 2-3 of any deposit (DC sign, tophi, or aggregates), and *US-2 model*, limited to grade 2-3 DC sign or tophi. Later, synovial fluid was aspirated. The length of MSU crystals was measured by a blinded observer using a calibrated polarized light microscope. The distribution of MSU crystal length (in μm) and the presence of long crystals (defined according to percentiles 66, 75, or 90) were tested with each sonographic model using Mann-Whitney U's test. Quantitative variables are shown as median (p25-75).

Results: We analyzed 742 crystals from 20 joints in 17 patients (three with an oligo-polyarticular flare), median aged 62.5 years (55-73), and 30% with subcutaneous tophi. The 2-year median serum urate was 7.5mg/dL (7.1-8.2), with current urate-lowering therapy in 35% of patients. The median length of MSU crystals was 21.2μm (95%CI 17.7-26.5), where crystals mostly gathered [Figure 1]. Applying the *US-1* model (fulfilled by 13 joints, 65%), no difference in crystal lengths was noted (21.2μm in those with deposits vs. 21.2μm in those without deposits; p=0.588) [Figure 2, top], with a similar distribution of long crystals (P66, P75 or P90) [Figure 2, middle and bottom]. However, those with deposits according to *US-2* model (n=9, 45%) showed a numerically greater crystal length (22.8μm vs. 18.5μm; p=0.112) [Figure 2, top] and more presence of long crystals [Figure 2, middle and bottom] compared to patients without deposits. Crystal lengths and the presence of long crystals showed no association with gout characteristics or serum urate levels.

Conclusion: Our synovial fluid analysis from different individuals with gout suggests two different mechanisms of MSU crystallization, one of reduced length shared by most crystals and the other with longer crystals better identified by the presence of sonographic deposits (but not aggregates), which resembles what is seen in tophi pathological sections. This exploratory finding adds evidence to the hypothesis that a secondary formation using as templates previously formed crystals occurs in the process of MSU crystallization.



Distribution of monosodium urate crystals length in the whole sample.



Comparisons between ultrasound models in crystal length (top), number of long crystals - according to percentiles 66, 75, or 90 - (middle), and percentage of long crystals - according to percentiles 66, 75, or 90 (bottom).

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The prevalence of sonographic monosodium urate (MSU) crystal deposition and inflammation in patients with gout in remission is unknown. In 2022, we reported a preliminary estimation of 88.7% of patients with persistent deposits, while one out of three had a positive power-Doppler (PD) signal [1]. This abstract communicates the sonographic evaluation of our initial 115 patients with gout in remission.

Methods: Observational cross-sectional multicenter study. Consecutive patients with gout (ACR/EULAR classification criteria +/- MSU crystal-proven) who met preliminary remission criteria [2] were recruited at eleven Spanish rheumatology units. They underwent a sonographic scanning of the first metatarsophalangeal and second metacarpophalangeal joints, knees, talar cartilages, and patellar and Achilles tendons. The sonographers were blinded to participants' clinical and laboratory data. We determined the prevalence (with 95% confidence interval -CI) of sonographic MSU crystal deposits (tophi,

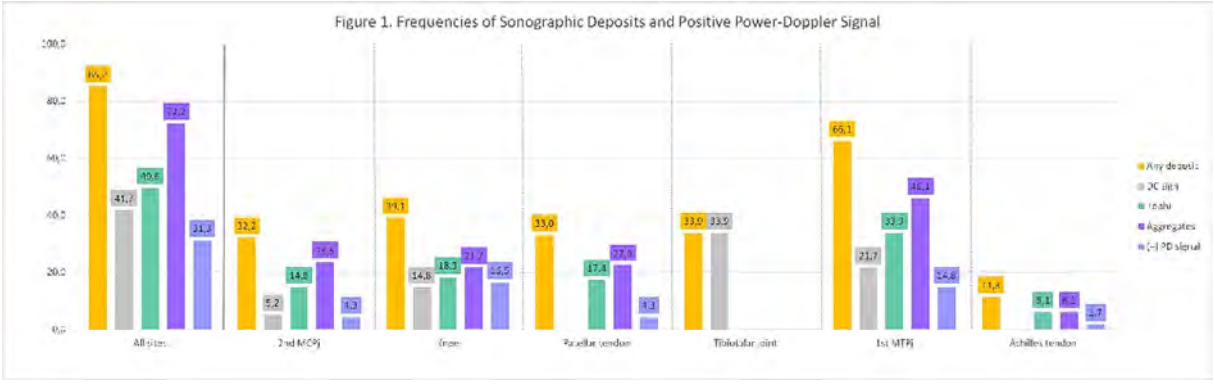

Figure 1.

aggregates, and double contour sign) and inflammation by power Doppler [PD] signal (graded as 0-3, positive if ≥1). Associations between deposits and PD signal and clinical and laboratory variables were also analyzed by chi-2 and logistic regression.

Results: The sample includes 115 participants, mean age of 65.2 years (SD 9.7), 93.9% males. The mean gout duration was 13.9 years (SD 10.9), and the disease was tophaceous at baseline in 15.7%. The mean serum urate level in the preceding year was 4.5 mg/dl (SD 0.9), with a mean duration of urate-lowering therapy of 55.8 months (SD 34.7). The prevalence of deposits in at least one location was 85.2% (95%CI 77.6-90.6%), with a median of 3 locations with deposits (range 0-9). Articular deposits (80.0%) were more common than tendinous deposits (39.1%), and aggregates were the most frequent sonographic finding (83.0%) [Figure 1]. If aggregates are not considered, prevalent deposits dropped to 73.0% (95%CI 64.3-80.3%). A positive PD signal was present in 31.3% of participants (95%CI 23.6-40.3%), mainly at joints (27.8%). Rates of deposits and positive PD signals were mildly lowered when restricted to four locations (82.6% and 27.8%, respectively) and any site except 1MTP joints (77.4% and 22.6%). A significant association between deposits and positive PD signal was confirmed at joints (p=0.005) and tendons (p=0.033). No secondary variable was associated with deposits or positive PD signal.

Conclusion: Our updated multicenter dataset confirms that most patients with gout fulfilling remission criteria still show sonographic MSU crystal deposits and one third, sonographic inflammation. The relevance of persistent deposits and inflammation in this setting needs further clarification.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: To optimally manage gout, the ACR recommends a treat-to-target (T2T) strategy, which entailsthe titration of urate-lowering therapy (ULT) to achieve and maintain a serum urate (SU) level of <6.0 mg/dL.Current data indicates that T2T using conventional ULT may be required for up to 2 years to reduce gout flare frequency compared to usual care (Doherty et al, Lancet 2018). Using data from the STOP Gout Study (O'Dell JR et al. NEJM Evidence 2022), a recently completed multicenter, randomized, double-blind, non-inferiority trial, we examined whether achievement of SU goalat 48 weeks reduces gout flare burdenas early as 48-72 weeks after T2T initiation.

Methods: Trial participants with gout and SU concentration ≥6.8 mg/dL were randomized 1:1 to receive allopurinol or febuxostat. ULT was titrated during weeks 0-24 (Phase 1) and maintained during weeks 25-48 (Phase 2), with escalation as necessary to reach goal SU of <6.0 mg/dl (<5 mg/dl if tophi) or until maximum dosing achieved. Participants were then observed on stable ULT with a primary study outcome of at least 1 flare occurring during weeks 49-72 (Phase 3).SU goal achievement was assessed at 48 weeks. For this analysis, the association of SU goal achievement at the end of Phase 2 with flare during Phase 3 was assessed in a multivariable logistic regression model, adjusting for covariates significantly associated with flare in univariate analysis. Covariates assessed included baseline age, sex, race, education, comorbidities, body mass index (BMI), quality of life (EQ5D score), and gout-related factors (baseline SU, tophi, gout duration, diuretic use, prior allopurinol use).

Results: Of the 940 trial participants (mean age 62 years, 98% male, mean [SD] baseline SU 8.5 [1.4] mg/dl), 749 had flare data available during Phase 3 and were included in this analysis. The most common reasons for early termination were either participant decision (n=99) or loss to follow-up (n=41). Of the 749 with flare data, 449 (60%) remained flare-free between week 49 and week 72. Patients achieving SU goal at 48 weeks were more likely than those not achieving SU goal to remain flare-free during Phase 3 (62% vs. 49%; p = 0.004 by chi-square). In unadjusted analyses, other baseline factors associated

Table 1: Baseline characteristics of trial participants based on occurrence of flare between 49 and 72 weeks

Characteristic	Flare-free	≥ 1 Flare
	N=449	N=300
GOUT RELATED FACTORS

Age, year, Mean (SD)	62.4 (12.0)	62.0 (12.5)
Male, %	97.6	99.3
Race, %		
White/Caucasian	70.6	68.0
Black/African American	21.2	19.0
Other	8.2	13.0
CORMOBIDITY & HEALTH FACTORS		
Chronic kidney disease – Stage III, %	37.9	35.7
Hypertension, %	78.8	73.3
Diabetes, %	34.5	31.0
Cardiovascular disease, %	25.8	25.7
Overweight or obese by BMI (>25 kg/m^2), %	68.6	63.3
EQ-5D-3L index, Mean (SD)	0.7 (0.2)	0.7 (0.2)

**Significant differences ($p < 0.05$) observed for gout duration, tophi, and diuretic use; all other differences non-significant; education status not shown*

Table 2. Multivariable associations of SU response at week 48 and baseline covariates with remaining flare-free between weeks 49 and 72 (n = 749)

	Odds Ratio (95% CI)	P-value
Responders (sUA <6 mg/dl or <5 if tophi present) at week 48	1.60 (1.09, 2.36)	0.018
Presence of tophi at baseline	0.48 (0.31, 0.72)	<0.001
Duration of gout (per year)	0.99 (0.97, 1.00)	0.084
Diuretic use	1.62 (1.18, 2.22)	0.003

with flare during Phase 3 included longer duration of gout (p = 0.009) and presence of tophi (p-value < 0.001), while baseline diuretic use was associated with a lower risk (p = 0.004) (Table 1). After adjusting for tophi, disease duration, and diuretic use, SU goal achievement at 48 weeks was associated with remaining flare-free in Phase 3(OR 1.60; 95% CI 1.09-2.36, p = 0.018; Table 2).

Conclusion: In this post-hoc analysis from a large, randomized double-blind, non-inferiority trial, we found that SU achievement following a T2T strategy was associated with a 60% greater odds of remaining flare-free between 49 and 72 weeks of follow-up. These results support ACR guidelines that endorse a T2T strategy in gout management and demonstrate that benefits in flare prevention may begin to occur as early as 12 to 18 months.

Intermittent Fasting Reduces Crystal-induced Inflammation

Nghia Pham[1], Twinu Wilson Chirayath[2], Florence Castelli[3], François Fenaille[3], Anvi-Laetitia Nguyen[3], François Brial[4], Augustin Latourte[4], Frédéric Lioté[4], Pascal Richette[5], Thomas Bardin[6] and Hang Korng EA[7], [1]INSERM 1132, BIOSCAR, Lariboisière hospital, Paris, France, [2]INSERM, Paris, France, [3]Laboratoire d'études du métabolisme des médicaments UMS 28, CEA Saclay, Gif-sur-Yvette, France, [4]INSERM 1132, BIOSCAR, Paris, France, [5]Lariboisière Hospital, Paris, France, [6]Université de Paris Cité, Paris, France, [7]INSERM-BIOSCAR, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Inflammation induced by monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals depends on interleukin (IL)-1β activated by the NLRP3 inflammasome. The inflammatory response can be modulated by diet, fasting, and caloric restriction.

Ojective: To determine whether intermittent fasting reduces MSU and CPP crystal-induced inflammation.

Methods: Crystal-induced inflammation was assessed using both types of crystals in vivo in the air pouch model in 8-week-old wild-type male mice fed either with a normal ad libitum diet or intermittent fasting (IF) (every over day fast, 2 days during 1 week). Inflammatory cytokine production (IL1β and CXCL-1) was assessed in the pouch lavages and the cellular infiltrate analyzed by histology (H&E staining). Metabolomic analyses were performed by high-performance liquid chromatography coupled to high-resolution mass spectrometry (LC-HRMS) on air pouch membrane, serum, and liver samples.

In vitro, human monocytes THP-1 were stimulated by sterile synthetic crystals of MSU and CPP while the production of inflammatory cytokines was quantified by ELISA.

To assess the role of glutamine/glutamate metabolism pathway related to IF in microcrystalline disease, the concentrations of glutamine/glutamate in synovial fluids (SF) from patients with gout, CPP-related disease and osteoarthritis (OA) were quantified by ultra-performance liquid chromatography coupled to tandem mass spectrometry (UPLC-MS/MS).

Results: Inflammation induced by MSU and CPP crystals was drastically decreased by IF compared with normal diet: IL-1β (MSU 0.0 vs. 30.0 pg/ml; CPP 0.0 vs. 47.5 pg/ml $p< 0.0001$); CXCL-1 (MSU 67.5 vs. 186.8 pg/ml, CPP 156.1 vs. 549.5 pg/ml, $p< 0.005$); as were cell infiltration assessed by number of cells in the air pouch lavages (MSU 0.2 x 106 vs. 1.1 x 106 ; CPP 0.4 x 106 vs 2.9 x 106; $p< 0.0001$) and membrane histology semi-quantitative score (MSU 0.6 vs 3.0; CPP 0.8 vs 2.7; $p< 0.0001$).

Reduction of inflammation by IF was associated with significant changes in membrane, serum and liver metabolites. Many metabolic pathways were altered by IF such as galactose, starch, sucrose, aspartate, glutamate, alanine and arginine metabolism. Interestingly, the glutamine and glutamate metabolic pathway was enriched in serum, membrane and liver compartments.

Glutamine/glutamate involvement in microcrystal-induced inflammation was evidenced in SFs. The glutamine/glutamate ratio was decreased in synovial fluids of crystal-related diseases compared to OA (gout 1.4 and CPP 6.1 vs OA 9.4, $p< 0.0001$ and $p< 0.05$ respectively).

In vitro, crystal-induced inflammatory cytokine production was decreased by overnight serum deprivation (IL-1β: MSU 1446 vs 5464 pg/ml; CPP 3670 vs 7797 pg/ml, $p< 0.005$; TNF-α: MSU 7.0 vs 47.0 pg/ml; CPP 15.6 vs 89.3 pg/ml, $p< 0.05$; IL-8: MSU 2896 vs 9781 pg/ml; CPP 3984 vs 6820 pg/ml, $p< 0.01$).

Conclusion: Intermittent fasting alleviates crystal-induced inflammation by altering many metabolic pathways, particularly those associated with glutamine and glutamate. Further studies are needed to determine how crystals modulate metabolism and potential anti-inflammatory effects.

HUA, Hyperuricemia.

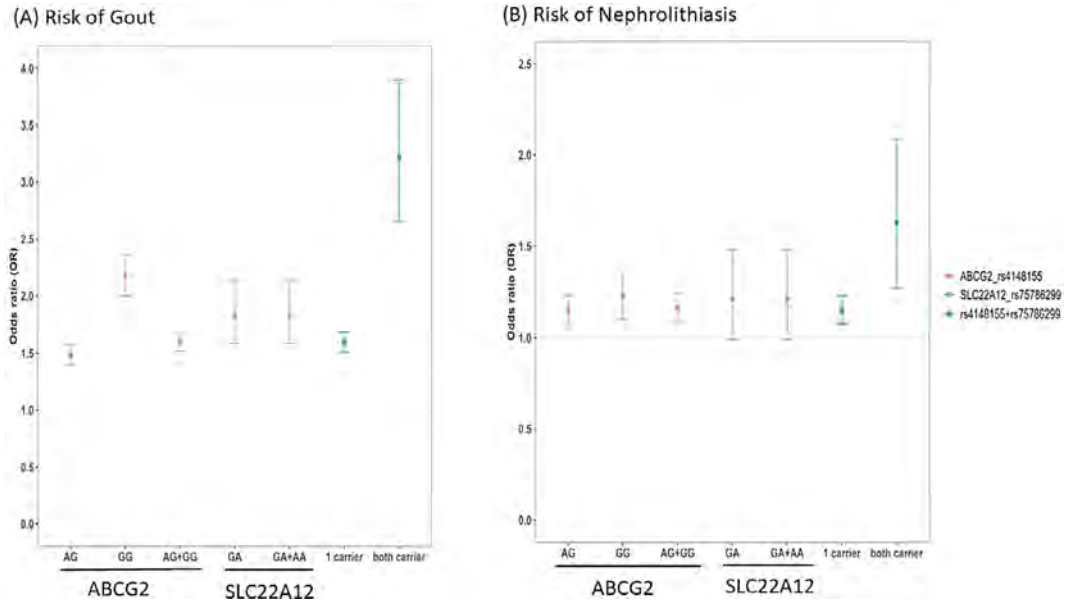

Figure 1 Risk of gout (A) and nephrolithiasis (B) among the carriers of ABCG2 rs4148155, SLC22A12 rs75786299 genotypic variants. Error bars represent the 95% confidence intervals (CI) of the odds ratios (ORs). (A) The univariable ORs (95% confidence intervals [CI] and p-values) for ABCG2 rs4148155 GG, AG, and AG+GG compared to the AA genotype were 2.18 (2.00-2.36, p<0.0001), 1.48, (1.4-1.57, p<0.0001), 1.61, (1.52-1.70, p<0.0001) and for SLC22A12 rs75786299 GA was 1.84 (1.59-2.14, p<0.0001) polymorphisms which were significantly associated with gout risk, respectively. Furthermore, under an additive model of inheritance, one and two carriers of ABCG2 rs4148155 (G) and SLC22A12 rs75786299 (A) remained independently associated with gout (OR = 1.60, 95% CI 1.51-1.69, p<0.0001; and OR = 3.22, 95% CI 2.66-3.90, p<0.0001, respectively). (B). The univariable ORs for the rs4148155 AG, GG, and AG+GG genotypes compared to the AA genotype were 1.15 (1.07–1.23, p=0.0001), 1.23 (1.10–1.37, p=0.0002), and 1.16 (1.06–1.24, p<0.0001), which were significantly associated with risk of nephrolithiasis respectively. In addition, the ORs for incident nephrolithiasis in individuals carrying one and two copies of the ABCG2 rs4148155(G) and SLC22A12 rs75786299(A) genotypic variants were 1.15 (1.08–1.23, p<0.0001) and 1.63 (1.27–2.09, p=0.0001).

Methods: This retrospective case-control study involved 35,280 adults from the Taiwan Precise Medicine Initiative (TPMI) database. We examined the prevalence of gout and ultrasound confirmed nephrolithiasis as the primary and secondary outcome. Univariable and multivariable logistic regression models were used to explore the associations between genetic variants, serum uric acid levels, incident gout, and nephrolithiasis.

Results: The frequencies of the rs4148155 G allele and the rs75786299 A allele was 33% and 2.4%, respectively. Among participants, 7,056 were gout, and 4,110 had nephrolithiasis. Multivariable odds ratios (ORs) for gout were 1.65 (1.56-1.75) and 3.59 (2.92-4.41) among one and two carriers, respectively (p=0.01 and p< 0.001). For nephrolithiasis, the multivariable ORs were 1.09 (1.02-1.17) and 1.40 (1.09-1.81) for one and two carriers, respectively (p=0.01 and p=0.009). Sex-stratified analysis revealed an additive risk of gout and nephrolithiasis among carriers of these genetic variants, regardless of gender. Independent risk factors for nephrolithiasis included higher age, male gender, and the presence of gout, hypertension, and hyperlipidemia.

Conclusion: The study highlights a significant association between the rs4148155 (G) and rs75786299 (A) alleles and the development of gout and nephrolithiasis, indicating an additive risk among carriers. These findings support precision healthcare approaches for individuals with these genetic variants to target hyperuricemia, gout, and systemic comorbidities, ultimately preventing nephrolithiasis.

Abstract Number: 0817

Comparative Effectiveness of Yoga and Strengthening Exercise for Treating Knee OsteoArthritis: A Randomised Controlled Trial (YOGA Trial)

Bedru Abafita[1], Ambrish Singh[1], Dawn Aitken[1], Steffany Moonaz[2], Andrew J Palmer[1], Leigh Blizzard[1], Changhai Ding[1], Stan Drummen[1], Graeme Jones[3], Kim Bennell[4] and Benny Samuel Antony[1], [1]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia, [2]Department of Clinical and Health Services Research, Southern California University of Health Sciences, Whittier, CA, [3]Menzies Institute for Medical Research, University of Tasmania, Melbourne, Australia, [4]University of Melbourne, Melbourne, Australia

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Osteoarthritis I: Clinical Trials
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: There is uncertainty about the best type of exercise to optimise outcomes for people with knee osteoarthritis (OA). Strengthening exercise is commonly recommended. However, yoga may have greater effects than strengthening given its focus on the mind and body with purposed benefits on flexibility, muscle strength, balance, fitness, while addressing the psychosocial sequelae. This study compared the effectiveness of a 24-week yoga program to strengthening exercise for knee OA.

Methods: The YOGA trial is an assessor-blinded (for non-patient-reported outcomes) randomised, active controlled superiority trial that included pre-specified non-inferiority outcomes. We recruited eligible symptomatic knee OA participants aged ≥40 years who fulfilled ACR clinical criteria with knee pain ≥40mm on 100mm visual analog scale (VAS). Participants were randomly assigned to a 24-week yoga program or strengthening exercise program (two supervised sessions and one home-based session per week for 12 weeks + three home-based sessions per week from 13-24 weeks). The primary outcome was change

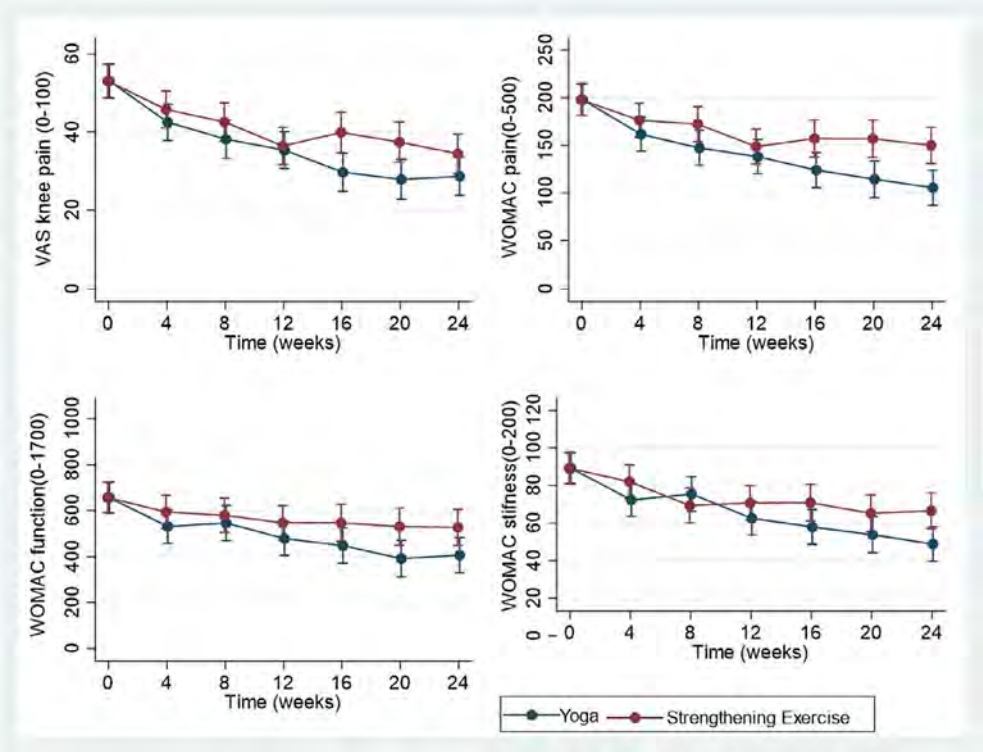

Figure 1. Mean visual analog scale (VAS) and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) subscale scores (95%CI) in the yoga and strengthening exercise groups during 24 weeks of intervention.

in knee pain over 12 weeks, assessed on a 100mm VAS. Secondary outcomes included, WOMAC scores, patient global assessment, physical performance measures, quality of life, depression, and neuropathic pain over 12 and 24 weeks.

Results: We screened 213 participants for eligibility between June 2021 and June 2022 and randomly assigned 117 participants to a yoga program (n=58) or a strengthening exercise program (n=59). Baseline characteristics of the participants between the groups were similar, with a mean (SD) age of 62.5(8.3) years, and 72.6% were female. Over 12 weeks, VAS knee pain score did not differ significantly between yoga and strengthening exercise groups with a between-group difference of -1.1mm [95%CI:-7.8,5.7]. Similarly, the VAS knee pain over 24 weeks was not significantly different (-5.8 mm [95%CI:-12.8,1.2]). The yoga group showed significantly greater improvements than the strengthening exercise group over 24 weeks (between-group difference) for WOMAC pain (-44.5mm [95%CI:-70.7,-18.3]), WOMAC function (-139mm [95% CI:-228.3,–49.7]), WOMAC stiffness (-17.6mm [95%CI:-30.9,-4.3]) and patient global assessment (-7.6mm [95%CI:-15.1,-0.2]). Additionally, yoga group had a significantly greater improvement than the strengthening exercise in depression (-1.1 [95%CI:-1.9,-0.2]) over 12 weeks and quality of life (0.04 unit [95%CI:0.0,0.07]) over 24 weeks. No serious adverse events were reported. There were 31 non-serious adverse events in 22(39%) participants in the yoga group and 23 in 16 (28%) participants in the strengthening exercise group over 24 weeks, mostly not related to the interventions.

Conclusion: A 24-week yoga program did not significantly reduce knee pain more than a strengthening exercise program over 12 weeks in participants with knee OA. However, the yoga program was non-inferior to strengthening exercise, as per the predetermined non-inferiority margin. Secondary outcomes indicated that the yoga program resulted in modestly greater improvements in knee symptoms, depression, and quality of life over 24 weeks compared to strengthening exercise.

Efficacy of XT-150, a Novel Non-Viral Gene Therapy Delivering IL-10v, on Moderate to Severe Pain Due to Osteoarthritis of the Knee: Results of a Phase 2 Trial

Eric Grigsby[1], Stephen D. Collins[2], Leonard Kapural[3], Mark McBride[4], Jayson Rieger[5], Morgan Stokes[6], **Howard Rutman**[6] and Flavia Cicuttini[7], [1]Neurovations Clinical Research, Napa, CA, [2]Xalud Therapeutics, Inc., Chicago, IL, [3]Center for Clinical Research, Winston-Salem, NC, [4]Instat Clinical Research, Chatham, NJ, [5]PBM Capital, Charlottesville, VA, [6]Xalud Therapeutics, Inc., Berkeley, CA, [7]Monash University, Melbourne, Australia

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Osteoarthritis I: Clinical Trials

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Interleukin (IL)-10 is a regulator of cytokine activity and has the potential to restore homeostasis in osteoarthritis (OA) of the knee. Unfortunately, relatively short half-life has limited the therapeutic potential of native IL-10 protein.[1] The primary objective of this study (NCT04124042) was to establish the safety and tolerability of a single intra-articular (IA) dose of XT-150, a non-viral gene therapy designed to transiently express a proprietary version of the anti-inflammatory cytokine IL-10. The secondary objective was to establish the analgesic efficacy of a single IA dose of XT-150. Exploratory analyses evaluated effects on pain and function following single and repeat doses.

Methods: This was a two-stage double-blind Phase 2 study. Stage A compared 2 active doses of XT-150 to a placebo control arm. Stage B was a 6-month follow-up with the option to randomly receive a single injection of XT-150 at one of two doses (0.15 or 0.45 mg) between Day 180 and Day 330. The dose range was chosen from supportive evidence in previous clinical (XT-150-1-0201 & XT-150-1-0202) and preclinical studies. Participants 45-85 years of age with symptomatic knee

Table 1: Summary of Participant Demographic Data

Demographic Parameter	Sub-group	Treatment Sequence/Dose (mg) Sequence					
		XT-150 – XT-150				Placebo – XT-150	
		0.15 – 0.15 (N=49)	0.15 – 0.45 (N=47)	0.45 – 0.15 (N=47)	0.45 – 0.45 (N=47)	0 – 0.15 (N=48)	0 – 0.45 (N=48)
Age (years), Mean (SD)		62.1 (8.15)	62.0 (6.68)	64.9 (7.09)	62.6 (7.82)	62.9 (7.35)	65.3 (9.52)
Gender, n (%)	Female	20 (40.8)	20 (42.6)	22 (46.8)	33 (70.2)	27 (56.3)	33 (68.8)
	Male	29 (59.2)	27 (57.4)	25 (53.2)	14 (29.8)	21 (43.8)	15 (31.3)
Race, n (%)	White	35 (71.4)	41 (87.2)	39 (83.0)	38 (80.9)	31 (64.6)	39 (81.3)

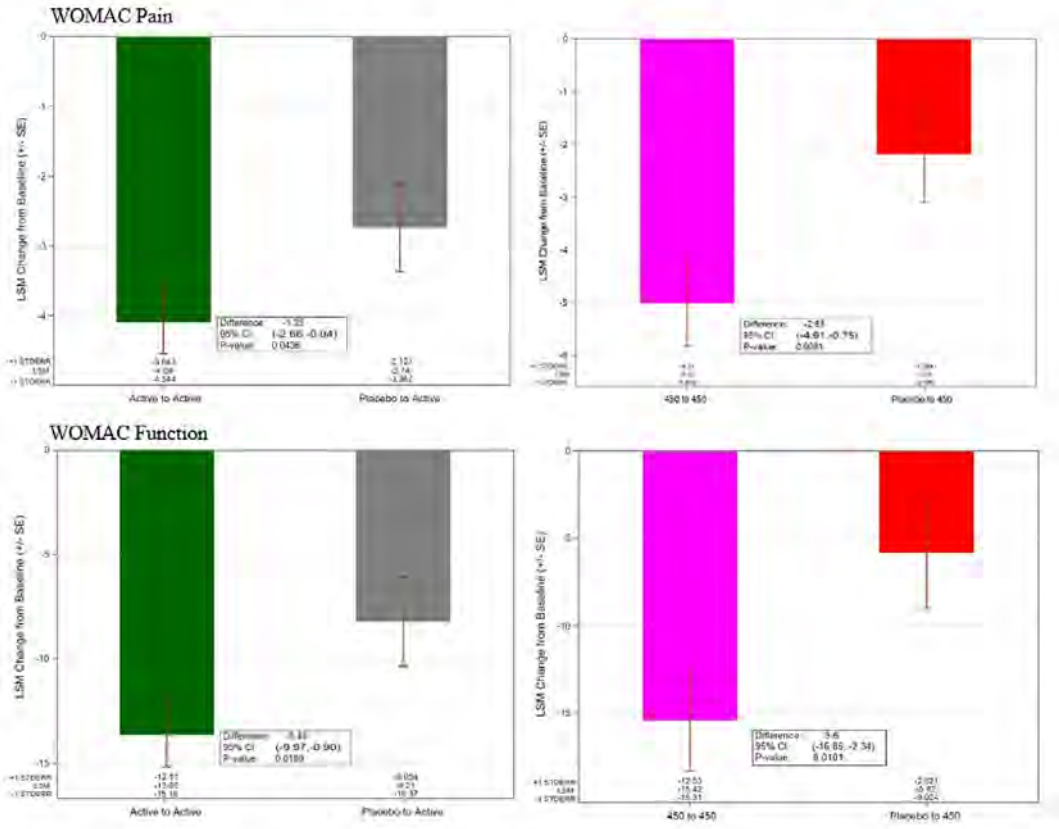
Figure 2: Stage B: Post Hoc Analyses (mITT Population)



Abbreviation: WOMAC=Western Ontario and McMaster Universities Osteoarthritis Index
Active to active=2-doses XT-150 (pooled active followed by active [0.15 mg to 0.15 mg; 0.15 mg to 0.45 mg; 0.45 mg to 0.15 mg; 0.45 mg to 0.45 mg XT-150]); placebo to active=1-dose XT-150 (pooled placebo followed by active [placebo to 0.15 mg XT-150; placebo to 0.45 mg XT-150]); 450 to 450=2 doses 0.45 mg XT-150 (0.45 mg to 0.45 mg); placebo to 450=1 dose 0.45 mg XT-150 (placebo to 0.45 mg)
Least squares mean (LSM), standard error (SE), LSM difference and 95% confidence interval (CI) of LSM difference by mixed-model analyses. Note difference in scale between left and right panels.

OA (defined as a WOMAC Pain score of ≥8 at screening and Kellgren-Lawrence grade 2 or 3) were randomized on Day 0 to one of 6 treatment sequences. Injections were completed under imaging guidance to confirm positioning within the joint prior to injection. Screening evaluation took place up to 30 days before enrollment. Efficacy measures were evaluated at baseline and at follow-up visits on Day 7, 30, and monthly thereafter. In Stage A, 286 participants received at least one dose of XT-150 or placebo (phosphate buffered saline) as a single IA injection into the knee. In Stage B, 244 received a second injection, all with XT-150. Separate analyses were conducted for Stages A and B. Stage A analyses included the primary intent to treat (ITT) population to assess the efficacy of XT-150. The primary efficacy outcome measure was at least 30% improvement from Baseline in WOMAC Pain score (obtained from KOOS questionnaire) at Day 180. Stage B analyses included a post hoc modified ITT (mITT) population with a baseline WOMAC Pain score of 9-20. Post hoc analyses in the ITT and mITT populations compared single active doses with repeat active doses.

Results: Demographic data are summarized in **Table 1**. There was no statistically significant difference in patients achieving at least 30% improvement in WOMAC Pain score between either dose (0.15 mg or 0.45 mg) of XT-150 vs placebo when given as a single dose by Day 180 **(Figure 1)**. Statistically significant changes from baseline WOMAC Pain scores were observed at Day 360 comparing 2 doses of 0.45 mg XT-150 vs 1 dose of placebo followed by 1 dose of 0.45 mg XT-150 in post hoc analyses (p=0.0081, **Figure 2**). The two-dose regimen of 0.45 mg XT-150 also showed a statistically significant reduction in WOMAC function score at Day 360 vs the single-dose regimen of 0.45 mg XT-150 (p=0.0101).

Conclusion: These data suggest improvement in pain and function with two doses vs one dose of XT-150 and support the future development of repeat doses of XT-150 for the potential treatment of pain from moderate-to-severe knee OA.

Abstract Number: 0819

Regression to the Mean for Physical Function and Quality of Life in Trials for Symptomatic Knee Osteoarthritis

Martin Englund and Aleksandra Turkiewicz, Lund University, Lund, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Osteoarthritis I: Clinical Trials
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Improvement in pain reported in clinical trials for osteoarthritis (OA) is typically strongly depending on the regression-to-the-mean phenomenon. Regression to the mean has been estimated to explain about 1 NRS point (0-10 scale) of the absolute improvement since baseline. However, the potential effects of regression to the mean on typical secondary outcomes in trials for knee OA are unknown. Thus, our purpose was to estimate the absolute size of improvement in knee physical function and knee-related quality of life (QOL) explained by regression to the mean in a typical trial for symptomatic knee OA.

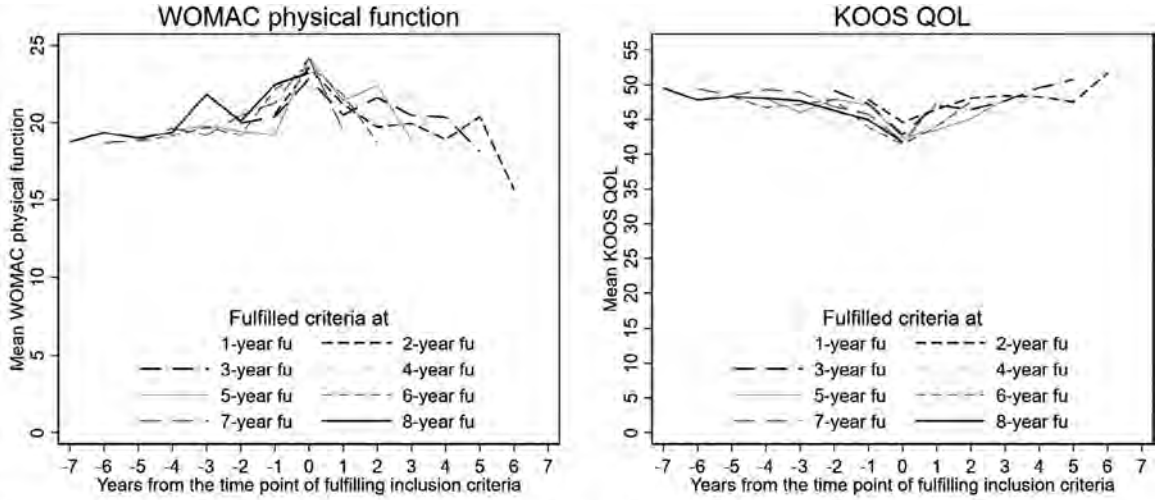

Figure. Mean levels of physical knee function and knee-related quality of life (QOL) among 547 persons fulfilling criteria for inclusion in a hypothetical knee osteoarthritis trial, illustrating the occurrence of regression to the mean when conditioning on knee pain at inclusion. Time 0 means the moment when fulfilling the criteria. Each line represents a cohort of subjects fulfilling criteria at one follow-up occasion (between year 1 and year 8 post baseline).

Methods: We included participants of Osteoarthritis Initiative who fulfilled inclusion criteria typically required for enrolment in a clinical trial (Hochberg *et al*. JAMA 2019). These included: age 40-79 years, symptomatic knee OA, Kellgren-Lawrence grade 2-3, use of pain medication more than half the days of a month in past 12 months, numerical rating scale (NRS) pain of 4 to 9 in the target knee. We studied observed changes in the mean levels of WOMAC physical function (scale 0 to 68; higher score = worse function) and KOOS QOL (scale 0 to 100; higher score = better QOL) with respect to conditioning on current knee pain. To account for the fact, that a person could fulfil the criteria at more than one time point and the longitudinal measurements, we used linear mixed models for estimation of means and differences over the follow-up time.

Results: We identified 547 subjects who fulfilled inclusion criteria on at least one annual follow-up between year 1 and year 8. The mean level of WOMAC knee physical function and KOOS QOL at each follow-up time point was similar, about 18, and 52 respectively. However, at the time of fulfilling the inclusion criteria (theoretical inclusion in a trial), the mean level of physical function and QOL in the same subjects were about 23 and 43, respectively. The mean improvement in WOMAC physical function between the theoretical point of inclusion in a trial and one and two years later, was -2.5 (95% CI to -3.2 to -1.7) and -3.1 (95% CI to -3.8 to -2.3), respectively. The corresponding improvement in KOOS QOL was 2.7 (95% CI ,1.7 to 3.7) and 4.2 (95% CI, 3.1 to 5.3) (figure).

Conclusion: Regression to the mean in typical trials for knee OA is not only likely to explain substantial improvement in pain, but also albeit to a lesser extent, improvement in knee function and QOL. Regression to the mean is a phenomenon that often misleads the investigators to exagerate effectiveness as the phenomenon neither represents improvement from the intervention nor placebo response from the intervention and its context.

Radiographic and Pain Outcomes from a Phase 3 Extension Study Evaluating the Safety and Efficacy of Lorecivivint in Subjects with Severe Osteoarthritis of the Knee (OA-07): 36 Month Single Blind and Placebo Crossover Phase Results

Yusuf Yazici[1], Christopher Swearingen[2], Victor Lopez[3], Jon Britt[4], Sarah Kennedy[5], Jeyanesh Tambiah[2] and Timothy McAlindon[6], [1]NYU Grossman School of Medicine, La Jolla, CA, [2]Biosplice Therapeutics, Inc., San Diego, CA, [3]Biosplice Therapeutics, Inc., Santa Clarita, CA, [4]Biosplice Therapeutics, Inc., Los Angeles, CA, [5]Biosplice Therapeutics, Inc., Superior, CO, [6]Tufts Medical Center, Arlington, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Osteoarthritis I: Clinical Trials

Session Type: Abstract Session

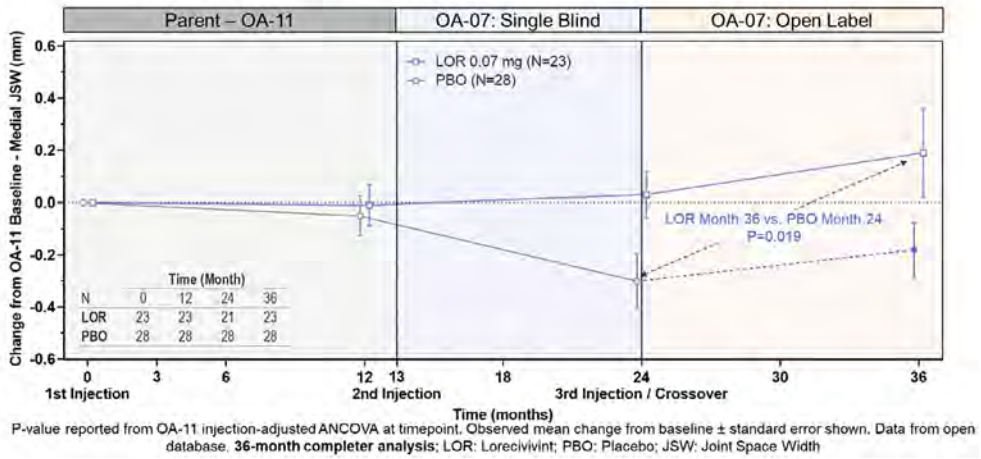
Session Time: 4:00PM–5:30PM

Background/Purpose: Knee osteoarthritis (OA) has unmet need for safe, efficacious symptom and disease-modifying treatments. Lorecivivint (LOR), an intra-articular (IA) CLK/DYRK inhibitor thought to modulate Wnt and inflammatory pathways has previously appeared safe, demonstrated patient-reported outcome (PRO) improvements compared with placebo (PBO), and maintenance of radiographic medial joint space width (JSW). A Phase 3 extension study, OA-07 (NCT04520607), evaluated LOR safety and efficacy with outcomes of medial JSW (mm), Pain Numerical Rating Scale (NRS [0-10]), WOMAC Pain [0-100], and WOMAC Function [0-100].

Methods: Participants had structurally advanced knee OA (medial JSW 1.5-4 mm) and completed the parent Phase 3 trial. A repeat injection according to original randomization (LOR / PBO) was given at the beginning of the single-blind (participants and investigators) extension Year 1. In Year 2 of the extension, all participants received open-label 0.07 mg LOR, while still blind to original treatment assigments. Baseline-adjusted ANCOVA was used to estimate differences between LOR and PBO outcomes using the OA-07 baseline. Treatment effect at Month 36 was estimated using marginal comparison from baseline-adjusted ANCOVA to last PBO observation prior to crossover for LOR only. Concordance between OA-07 baseline-adjusted medial JSW change and pain response was conducted for 36 month completers using logistic regression. Final data are expected Q4 2023.

Figure 1: Change in Medial Joint Space Width in OA-07 from OA-11 Baseline

FAS 36-month completer analysis



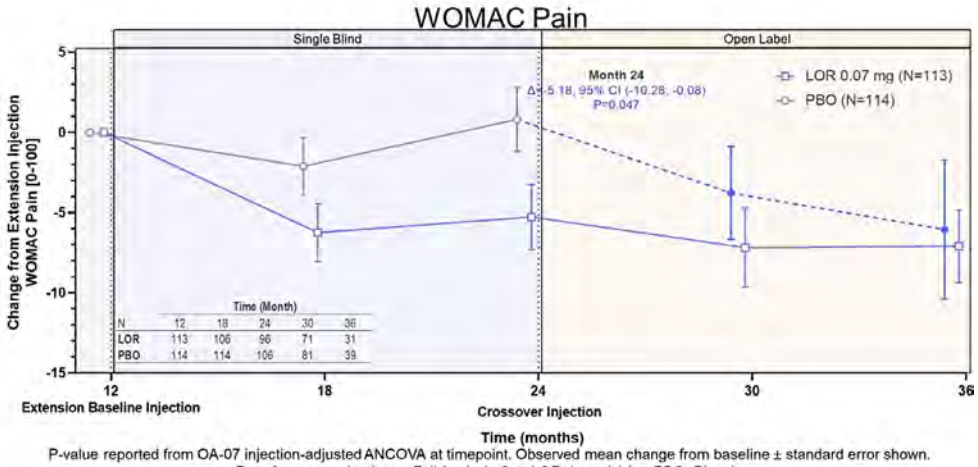
P-value reported from OA-11 injection-adjusted ANCOVA at timepoint. Observed mean change from baseline ± standard error shown. Data from open database. **36-month completer analysis**; LOR: Lorecivivint; PBO: Placebo; JSW: Joint Space Width

Results: 277 participants (mean age 61.0 ± 8.2 years, BMI 31.8 ± 4.9 kg/m^2, female 62.8%, KL3 45.5%, medial JSW 2.63 ± 0.69 mm, 67.1% bilaterally symptomatic, 68.6% medial JSW < 3 mm) were enrolled. LOR appeared safe and well-tolerated. At 24 months, LOR showed numerically reduced medial JSW loss compared to placebo: LOR -0.11 (± 0.05) mm (n=111) vs. PBO -0.20 (± 0.05) mm (n=119) (Δ=0.09 mm, 95% CI [-0.06, 0.23], *P*=0.246). At 36 months, LOR completers (n=23) medial JSW change was +0.19 (± 0.14) mm, difference -0.49 mm (*P*=0.019) LOR compared to last PBO measure before crossover at 24 months (Figure 1).

Average change from extension baseline to 24 months in Pain NRS was LOR -0.25 (± 0.19, n=121) compared to PBO 0.09 (± 0.19, n=130) (Δ=-0.34, 95% CI [-0.87, 0.19], *P*=0.207). Similar trends were seen for LOR treatment effect over PBO at 24 months for WOMAC Function Δ=-4.90 (95% CI [-9.92, 0.13], *P*=0.056) and WOMAC Pain Δ=-5.18 (95% CI [-10.28, -0.08], *P*=0.047). Additional improvements were seen at 36 months in LOR (n=35) Pain NRS with change from OA-07 baseline of -0.91 (±0.34) and cross-over from PBO to LOR (n=45) improving -0.43 (±0.30). Good concordance was shown between change in medial JSW and at least a 20% improvement in Pain NRS at 36 months (n=20, AUC=0.719).

Figure 2: **Change in WOMAC Pain in OA-07 from OA-07 Baseline**

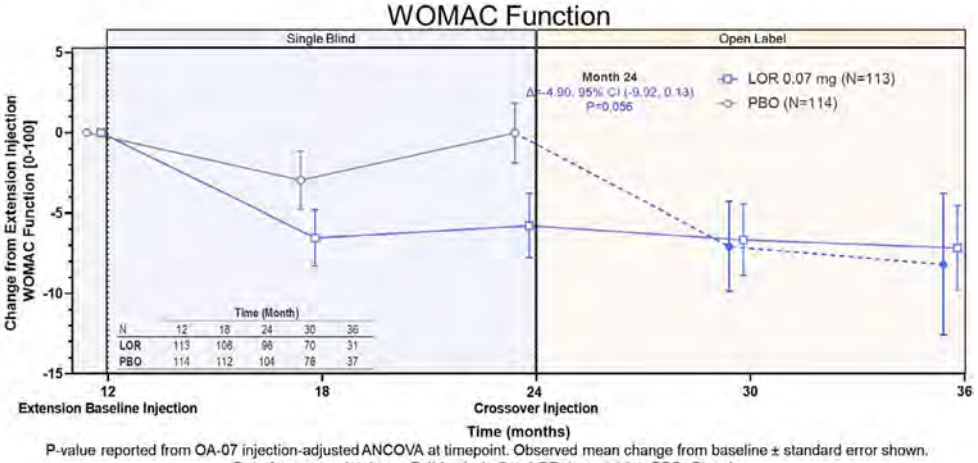
FAS



P-value reported from OA-07 injection-adjusted ANCOVA at timepoint. Observed mean change from baseline ± standard error shown.
Data from open database. Full Analysis Set; LOR: Lorecivivint; PBO: Placebo

Figure 3: **Change in WOMAC Function in OA-07 from OA-07 Baseline**

FAS



P-value reported from OA-07 injection-adjusted ANCOVA at timepoint. Observed mean change from baseline ± standard error shown.
Data from open database. Full Analysis Set; LOR: Lorecivivint; PBO: Placebo

Conclusion: LOR continued to appear safe and well tolerated. A potential benefit of LOR 0.07 mg compared with PBO in medial JSW was observed 12 months after the extension baseline (second) injection, which persisted in those who completed an additional 12 months (total 36 months, 3 injections) and in PBO participants who crossed to LOR treatment. Potential LOR benefit compared to PBO is also seen across PROs with preliminary good concordance between medial JSW and pain improvement.

Abstract Number: 0821

Effects of Sprifermin on a Novel Outcome of Osteoarthritis Symptom Progression: Post Hoc Analysis of the FORWARD Study

Philip Conaghan[1], Nathaniel Katz[2], david Hunter[3], Marc Hochberg[4], Ali Guermazi[5], Kenneth Somberg[6], Julia Clive[6], Mary Johnson[6] and Niti Goel[7], [1]University of Leeds, Leeds, United Kingdom, [2]Tufts University and Ein Sof Innovation, Boston, MA, [3]Sydney Musculoskeletal Health, University of Sydney, St. Leonards, Australia, [4]University of Maryland School of Medicine, Baltimore, MD, [5]Boston University, Boston, MA, [6]TrialSpark, New York, NY, [7]TrialSpark, Duke University, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Osteoarthritis I: Clinical Trials
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: People with knee OA (KOA) desire therapies which delay or reverse disease progression supporting the need for disease-modifying OA drugs (DMOADs). Sprifermin, truncated recombinant human fibroblast growth factor-18, demonstrated dose-dependent increased cartilage thickness in KOA in the Phase 2 FORWARD study. Improvement from baseline (BL) in WOMAC Pain and Function occurred in all sprifermin study arms with a lack of differentiation from placebo (PBO), potentially due to including participants (pts) not at risk of KOA progression. Minimum clinically meaningful changes (improvement or worsening) in WOMAC Pain and Function have been defined as ~10 points (0-100 scale). A post hoc analysis of FORWARD identified a subgroup at risk (SAR) enriched for disease progression, in which improvement in WOMAC Pain ≥10 points for sprifermin over PBO was seen by Year (Y) 3. Worsening WOMAC Pain ≥10 points has been predictive of worsening function, structural progression, and knee replacement in KOA natural history studies. This post hoc analysis of the FORWARD study evaluates the effect of sprifermin on the symptomatic progression of KOA.

Methods: Pts were randomized 1:1:1:1:1 to intra-articular PBO or sprifermin 30 μg or 100 μg every 6 or 12 months (Q6M or Q12M) for 18 months and followed through Y5. WOMAC was collected Q3M and MRI Q6M through Y2 and then Q6M and Q12M, respectively. In this Kaplan-Meier analysis, time to symptomatic progression (ie, first occurrence of worsening [increase] of WOMAC Pain of ≥10 points with no improvement [≤9 point decrease] in WOMAC Function) was evaluated through Y3. All treatment arms of the intent-to-treat population (ITT) and SAR (ie, BL WOMAC Pain 40-90, minimum joint space width 1.5-3.5 mm) were analyzed, as well as the sprifermin 100 μg groups combined for additional power. Time to symptomatic progression was also analyzed by changes in cartilage thickness (decrease or no change/increase) for those with evaluable MRIs at BL and ≥1 post-BL timepoint, ie, modified (m) ITT and mSAR.

Results: Baseline characteristics were comparable across the FORWARD ITT and SAR treatment arms (Table). Sprifermin showed dose-dependent benefits in the time to symptomatic progression compared to PBO, with clinically meaningful and statistically significant separation from PBO for the sprifermin 100 µg groups combined (nominal logrank p-value ITT < 0.05, SAR < 0.01; HR [95% CI] ITT 0.59 [0.37, 0.95], SAR 0.35 [0.16, 0.81]) (Figure); separation from PBO was more pronounced in the SAR compared to the ITT. The sprifermin 100 µg combined group also demonstrated less symptomatic progression than PBO regardless of an increase or no change/decrease in cartilage thickness in the mSAR and mITT.

Conclusion: These post hoc results support that sprifermin may prevent symptomatic progression of KOA, with benefits seen in both ITT and SAR populations for the sprifermin 100 µg combined group. Further study is needed to confirm the symptomatic and structural benefits of sprifermin. As differences between the sprifermin- and PBO-treated groups were detectable in a 3-year time frame, time to symptomatic progression of KOA could be a meaningful endpoint for a DMOAD trial.

Figure: Time to Symptomatic Progression in FORWARD

From Biomarkers to Endotypes: Data-driven Identification of Knee Osteoarthritis Patients Subtypes

Monica Hannani[1], Zofia Lisowska-Petersen[2], Morten Karsdal[2], Cecilie Bager[2], Anne-Christine Bay-Jensen[2] and Christian Thudium[2], [1]University of Copenhagen, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Osteoarthritis I: Clinical Trials
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Osteoarthritis (OA) is a diverse and multifaceted condition. Despite its widespread incidence, the core mechanisms of the disease remain elusive, and therapeutic interventions are restricted. The complexity of OA is compounded by the absence of well-defined subgroups or "endotypes" that could elucidate specific triggers and guide towards more personalized treatments. Recent studies propose that molecular biomarkers could distinguish various OA endotypes. For instance, certain biomarkers might show elevated levels in OA patients experiencing inflammation, while others might increase in those with advanced cartilage deterioration.

This study aimed to uncover OA endotypes via soluble biomarkers of tissue turnover, using unsupervised machine learning methodologies.

Methods: The study measured biomarkers of cartilage alteration (CTX-II, C2M, T2CM, PRO-C2), bone modification (N-MID, UCTX-I, SCTX-I), and tissue inflammation (CRPM, VICM, C1M, C3M) were measured at baseline in phase III clinical trials SMC01 (n=1176) and SMC02 (n=1030) which tested the effectiveness and safety of oral salmon calcitonin in knee OA patients.

Table 1 – A summarization of the dispersion of subjects within each cluster, i.e., endotype and the change of clinical parameters as an indicator of patients in the placebo-groups natural OA progression. For each cluster age, BMI and relevant clinical parameters are reported in terms of median and IRQ (Q1,Q3). KL proportions are proportions of subjects with a change in KL score.

Endotype	Cluster 1 Low tissue turnover	Cluster 2 Systemic inflammation	Cluster 3 Structural damage	P-value KW-test

The study included only placebo group patients who had more than 5 biomarkers available (n=528). About 4% of data was missing and was imputed using Random Forest. K-Means clustering was employed on UMAP dimensionality-reduced data. Associations between the changes in symptomatic and radiographic parameters over two years with the identified clusters were compared using the Kruskal Wallis test for numerical variables and chi-square test for categorical variables.

Results: The K-Means clustering resulted in three unique clusters; 1) a low tissue turnover endotype, 2) a systemic inflammation endotype and 3) a structural damage endotype (figure 1). The structural damage endotype showed elevated levels of bone remodeling markers CTX-I, N-MID, and the cartilage degradation marker CTX-II. The systemic inflammation endotype was characterized by higher levels of C1M, C2M, C3M, CRPM, and VICM associated with tissue inflammation. Conversely, the low tissue turnover endotype displayed generally lower levels of both tissue-related and inflammatory markers. A difference in JSW change over two years was noted among the three groups (Cluster 1: -0.28 mm, Cluster 2: -0.16 mm, Cluster 3: -0.32 mm; p=0.049), but the difference was not statistically significant in the adjusted analysis. Broadly, the three endotypes showed similar progression.

Conclusion: These findings indicate the presence of unique biomarker-based endotypes in OA, underlining the fact that several mechanistic pathways may result in joint degradation. Identifying these endotypes could facilitate the development of more precise treatments that are designed to address specific causes of OA in distinct patient subgroups.

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes I: Assessment Tools

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Despite taking strong immunosuppressive medications to control inflammation, many patients with rheumatoid arthritis (RA) continue to experience moderate to severe pain that does not correlate with laboratory or clinical findings. Sleep disturbances are extensively reported among patients with RA and could influence pain perception. Prior investigations have demonstrated that one night of partial sleep loss is associated with increases in next day pain in patients with RA. However, there is a knowledge gap regarding the impact of sleep disturbances on long-term pain outcomes. The

objective of the present study was to determine whether sleep disturbances early in the disease are associated with future pain interference.

Methods: Data were from adults with early RA (joint symptoms ≤12 months) enrolled in the Canadian Early Arthritis Cohort between 2016-2023 who completed PROMIS (Patient-Reported Outcomes Measurement Information System) measures at 0, 6-, 12-, 18-, and 24-months to assess sleep disturbance (primary predictor) and pain interference (primary outcome). PROMIS sleep disturbance assesses perceptions of sleep quality, depth, and restoration. PROMIS pain interference measures the extent to which pain interferes with physical, mental, and social functioning. To estimate longitudinal associations between sleep disturbance and pain interference, the dataset was lagged so that repeat measures of sleep disturbance at 0, 6, 12 and 18 months were specified to predicted pain interference 6-months later at 6-,12-, 18- and 24-months follow up. Linear mixed effects regression was used to estimate crude and adjusted effects of sleep disturbance on pain interference over the 24-month study period adjusted for age, sex, body mass index (BMI), education, income, smoking status, comorbidity index, steroid use, and treatment.

Results: The sample included 502 patients with early RA. At baseline, the sample was 68% female, 81% Caucasian, 73% seropositive (RF/ACPA), and 77% met the 1987 ARA Classification Criteria for RA or the 2010 ACR/EULAR RA Classification Criteria; with a mean (SD) age of 56 (14) years, BMI of 28.4 (6.7) kg/m^2,and disease duration of 5.4 (2.9) months (Table 1). The mean (SD) T-score for PROMIS pain interference was 60.4 (8.6) and PROMIS sleep disturbance was 53.5

Table 1. Baseline demographic and clinical characteristics of sample (N = 502).

Characteristic	Value

JAKs	0 (0)
Other MOA	0 (0)
PROMIS T-score, mean (SD)	
Sleep disturbance	53.5 (8.8)
Pain interference	60.4 (8.6)

Note. [§] % of non-missing
Abbreviations: BMI, body mass index. RDCI, rheumatic disease comorbidity index. TJC, tender joint count. SJC, swollen joint count.

Table 2. Mean change and 95% CI in PROMIS Pain Interference T-score from univariate and multivariable mixed effects models with 6-month time lag (sleep disturbance predicting pain interference 6 months later).

	Univariate (unadjusted)			Multivariable (adjusted[B])		
Predictor	Mean Change	95% CI	N (visits)	Mean Change	95% CI	N (visits)
Sleep disturbance, *T-score*[A]	0.74	0.47, 1.01	1,153	0.77	0.44, 1.09	844

Note. [A]Per 5-unit increase in PROMIS sleep disturbance T-score. [B]Model includes covariates: age, sex, BMI, education, income, current smoking status, comobidity index, SJC28, CRP, lagged treatment from previous visit (MTX, oral steroids, and advanced therapy).

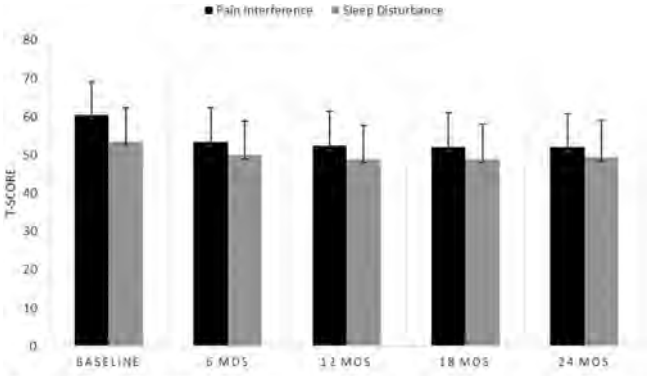

Figure 1. Mean PROMIS pain interference and sleep disturbance T-scores at 6-month intervals from baseline to 24 months (error bars indicate SD). Higher T-score indicates more of the concept being measured with a score of 50 (10) representing the general population mean (SD).

(8.5) at baseline (Figure 1). The unadjusted and adjusted linear mixed effects regression models revealed a significant association between sleep disturbance and pain interference scores, indicating that better sleep 6-months prior was associated with less pain interference at the following 6-month evaluation (Table 2).

Conclusion: In this cohort of patients with early RA, more disturbed sleep predicted greater pain interference 6 months later. These findings underscore the importance of addressing sleep disturbances as part of pain management strategies. Identifying and targeting problematic sleep disturbances early on may help improve long-term pain outcomes. Further work is needed to explore the underlying mechanisms and to investigate potential interventions targeting sleep to alleviate pain in RA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes I: Assessment Tools

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: In axial Spondyloarthritis (axSpA) it is recommended to assess global functioning and health, a concept close to health-related quality of life (HR-QoL), using the ASAS Health Index (ASAS-HI), a patient-reported outcome measure [1]. Impairment status of poor global health (GH) has been defined as an ASAS-HI score of ≥ 12/17 [1]. However, the ASAS-HI is a recent outcome measure and is not always available in existing datasets. Our objective was to explore the link between ASAS-HI and a frequently used measure of GH and utility, the EuroQol-5D-3L (EQ-5D) and to explore the possibility of defining a cut-off value for EQ-5D, corresponding to the ASAS-HI cut-off of 12 points.

Methods: This was a reanalysis of a cross-sectional observational study: PERSPA, analyzing the subgroup of patients fulfilling ASAS criteria for axSpA, and with available EQ-5D and ASAS-HI scores [2]. The ASAS-HI is a specific composite measure for GH in axSpA, scored 0-17, with a validated cut-off of ≥ 12/17 for poor health status [1]. The EQ-5D is a generic score for utility and HR-QoL, with an index value between 1 (perfect health) and 0 or negative (health state equivalent to death or worse) [3] – here we reversed the scores to align with better health being lower scores (as for the ASAS-HI). Distributions of EQ-5D and ASAS-HI were visually compared with assessment of normality by Shapiro-Wilk test. The correlation between ASAS-HI and EQ-5D (Spearman) was computed. Patients were grouped into deciles based on EQ-5D and ASAS-HI scores, and weighted kappa was calculated. Then, to determine a cut-off for EQ-5D corresponding to an ASAS-HI ≥ 12, a ROC curve of EQ-5D according to ASAS-HI category was obtained; the Youden index for EQ-5D that maximizes sensitivity and specificity was then determined.

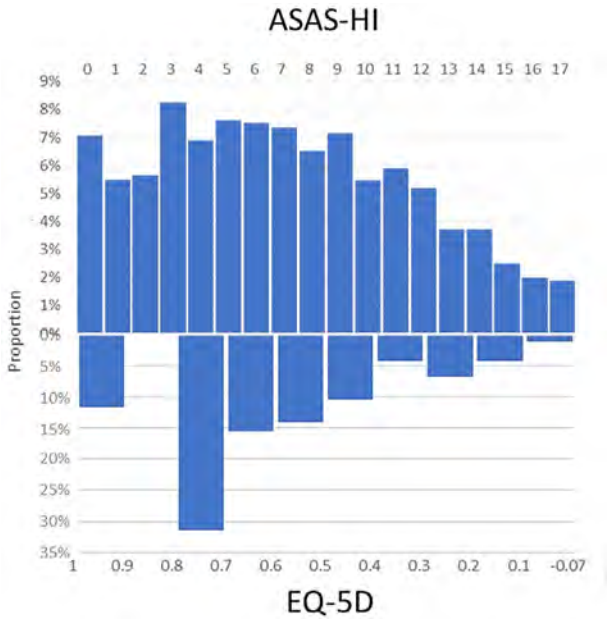

Figure 1 Distributions of EQ-5D and ASAS-HI in 2651 axSpA patients (The axis for EQ-5D is reversed to present best results on the left for both scores)

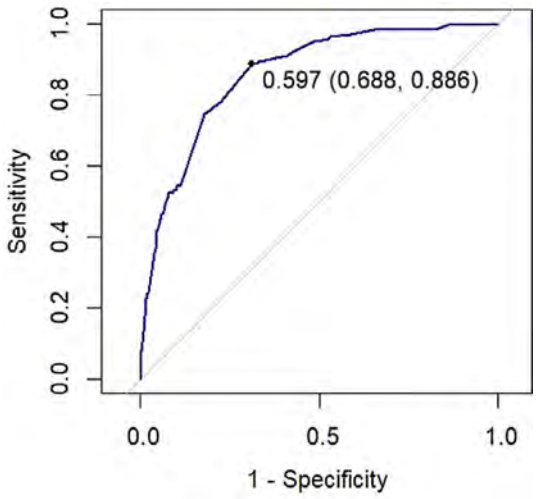

Figure 2: ROC curve of EQ-5D according to ASAS-HI category

Results: In 2651 patients (mean age 42.0 years, 66.5% men), GH was generally moderate to good using both the ASAS-HI and EQ-5D: mean ASAS-HI was 7.05 (SD 4.49) (median 7.00) and mean EQ-5D was 0.63 (SD 0.23) (median 0.65). The distributions appeared similar overall though neither distribution was normal (Shapiro-Wilk $p< 0.001$) **(Figure 1).** ASAS-HI had a high negative correlation with EQ-5D ($r = -0.71$, $p < 0.001$), however the agreement between deciles was moderate (weighted kappa = 0.51)**.** Using the published cutoff of 12 for ASAS-HI, we established that 448 (16.9%) patients had severe impairment of GH. The ROC curve showed a satisfactory link between the 2 scores: area under the curve was 0.86 (**-Figure 2).** The threshold of 0.597 for EQ-5D maximized both sensitivity (0.89) and specificity (0.69) against the ASAS-HI cut-off of 12.

Conclusion: The EQ-5D, a widely validated, widely-available generic score to assess utility, can be used to assess overall GH in axSpA, which is usually assessed through the ASAS-HI. In a large group of patients, we have shown that the two outcome measures are linked, with a high correlation but no full overlap. Furthermore, we propose an EQ-5D threshold corresponding to the published ASAS-HI threshold for severe impairment in GH. These results may be useful for comparing GH when only one of the outcome measures is available.

A Revised Outcome Measure for Dermatomyositis Clinical Trials: The Dermatomyositis Outcomes for Muscle and Skin (DMOMS)

Rachita Pandya[1], Joshua Dan[2], Julianne Kleitsch[1], Darosa Lim[3], Barbara White[4] and Victoria P. Werth[5], [1]Philadelphia VAMC, Philadelphia, PA, USA and Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Icahn School of Medicine at Mount Sinai, New York, NY, [3]University of Pennsylvania, Philadelphia, PA, [4]SFJ Pharmaceuticals, Towson, MD, [5]University of Pennsylvania, Wynnewood, PA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes I: Assessment Tools

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Current clinical trials in dermatomyositis (DM) are largely focused on muscle improvement, and use the Total Improvement Score (TIS) as the primary efficacy measure. The TIS consists of Patient Global Assessment (PtGA), Physician Global Assessment (PGA), Extramuscular Global Assessment (EMGA), Manual Muscle Testing (MMT), serum muscle enzymes, and Health Assessment Questionnaire (HAQ). TIS may contain redundant measures and lacks a skin-specific measure. Skin is a defining feature of DM that should be directly measured in the primary endpoint. This study evaluated a new composite outcome measure, the Dermatomyositis Outcomes for Muscle and Skin (DMOMS), which includes components of TIS and a skin-specific measure. DMOMS consists of improvement from baseline in MMT, PGA, and PtGA, all scored as in TIS with the exception of a 50% increase in weight for PtGA. It also includes the Cutaneous Dermatomyositis Disease Area and Severity Index-Activity (CDASI-A) score, weighted equally to the MMT score.

Methods: Data was collected from the lenabasum phase 3 trial in DM. All components of TIS and CDASI-A scores were collected at Baseline and at Week 52. Pearson's correlation on TIS components tested for redundancy ($r > 0.8$). Additionally, patients that had at least a 10-point improvement in MMT scores or 11-point improvement in CDASI-A scores at Week 52 compared to Baseline were considered to be responders. To assess efficacy of TIS and DMOMS scores in capturing skin and muscle disease improvement, a Student's t-test ($p < 0.05$) was used to compare mean percent improvement in scores for both responders (R) and non-responders (NR).

Results: Ninety-six DM patients were included in the analysis, with a majority of the patients being female (77%) and self-identifying as Caucasian (87%). Their mean (SD) age was 53 (11) years. Pearson's correlation on TIS components showed that PGA and EMGA were redundant measures (r=0.827).CDASI-A R (n = 36) vs NR had a mean improvement in TISof 47.2% vs 29.8% ($p < 0.001$) and a mean improvement in DMOMS of 63.6% vs 28.8% ($p < 0.001$). MMT R (n = 27) vs NR had a mean improvement in TIS of 49.4% vs 31.2% ($p < 0.001$) and a mean improvement in DMOMS of 65.7% vs 32.5% ($p < 0.001$).

Conclusion: Compared to TIS, DMOMS is a simpler composite score, with four versus six component measures, and does not contain the redundant measure of EMGA. DMOMS also contains a skin-specific measure scored equally to a muscle-specific measure and assigns greater weight to PtGAto reflect clinical benefit as assessed by patients. It provides about twice the treatment effect for R vs NR in both muscle and skin response, without any increase in score in NR. DMOMS is a more sensitive outcome measure to reflect improvement from baseline in DM and may be better suited to determine treatment effect in future DM clinical trials.

Development of a Decision Aid for Clinical Trial Participation in Systemic Lupus Erythematosus

Leila Khalili[1], Rita Kukafka[2], Laura Geraldino-Pardilla[1], Nancyanne Schmidt[1], Sean Inzerillo[1], Julia Weiner[1], Wei Tang[1] and Anca Askanase[3], [1]Division of Rheumatology, Columbia University Irving Medical Center, New York, NY, [2]Department of Biomedical Informatics, Columbia University Irving Medical Center, New York, NY, [3]Columbia University Medical Center, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes I: Assessment Tools
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Standard of care therapy for SLE relies heavily on broad-spectrum immune suppressants. Therapeutic drug development is critical to the approval of targeted therapies; however, patient recruitment in lupus clinical trials faces many challenges that include patient, provider, and community barriers, as well as clinical trial design constraints. Here we describe the development of a decision aid (DA) for participation in clinical trials, outlining the choice to continue with standard of care (SOC) vs. enroll in the clinical trial for the treatment of moderate to severe SLE disease activity or flares.

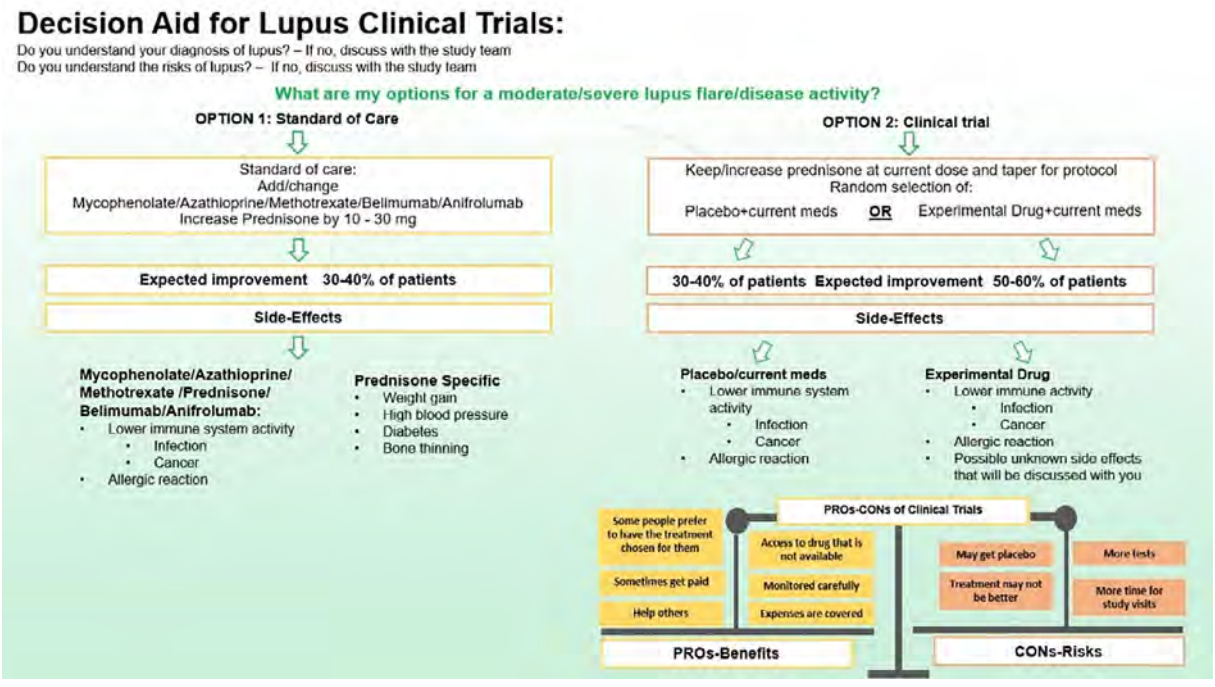

Figure 1. Decision Aid for Lupus Clinical Trials

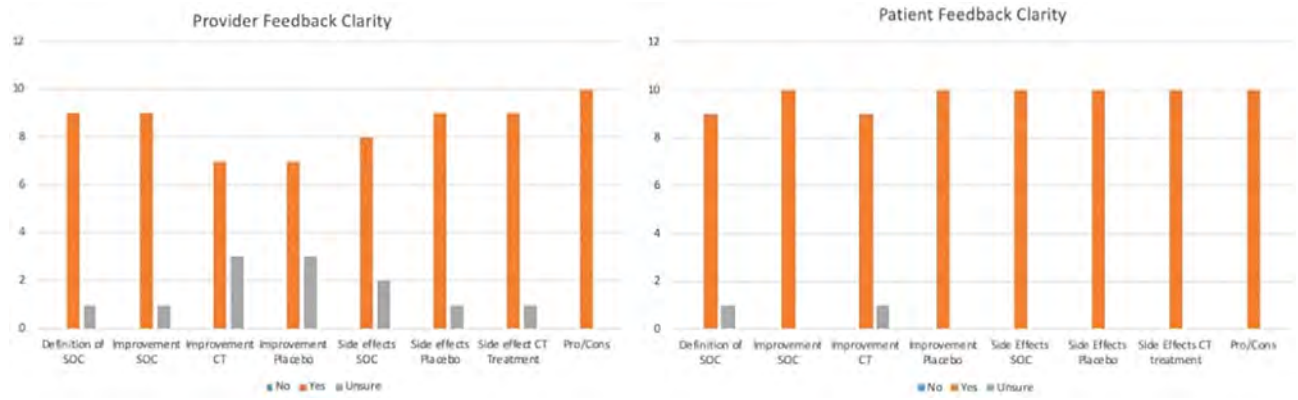

Figure 2. Decision Aid Feedback

Methods: The DA was developed using a collaborative, iterative process. The development working group included lupus clinical trialists, clinicians, methodologists, and patients. The initial draft based on the International Patient Decision Aid Standards (IPDAS) guidelines was evaluated and refined in semi-structured focused interviews with 10 lupus providers and 10 patients and working version of the decision aid was finalized, see Figure 1. Patients and providers were asked if the components of the DA, including definitions of treatments, expected improvement were clear (yes, no, unsure) and helpful (on a scale of 0-5). Interviews were conducted until thematic saturation was achieved. Responses on usefulness were accumulated, and mean usefulness scores were calculated.

Results: The 10 providers (9 physicians and one advanced practice provider) that participated in the focus group were well versed in the care of patients with lupus and had a mean of 8.1 years of practice. All 10 patients met the 2019 ACR/EULAR criteria for SLE and had been involved in clinical trials, clinical research, and advocacy work in the past. Their mean disease duration was 9 years. Findings of the semi structured interviews are summarized in Figure 2: 90% of providers and patients reported that the definition of SOC treatment was accurate. Additionally, the expected improvement for SOC (90% of providers, 100% of patients), clinical trial drug (70%, 90%), and placebo were clear (70%,100%). Side effects of SOC (80%,100%), placebo (90%, 100%), and clinical trial drug treatment (90%,100%) were also noted to be clear. 100% of providers and patients thought that the figure outlining pros/cons of participating in clinical trials was appropriate. The overall mean usefulness scores were 4.45/5 for providers and 4.72/5 for patients.

Conclusion: We developed a lupus clinical trial DA for patient-provider shared decision-making outlining the choice to continue with SOC vs. enroll in a clinical trial for the treatment of moderate to severe SLE as required by the majority of SLE clinical trials. More data on the usability and performance of the DA is needed to fully understand its role in clinical trial participation.

Development and Initial Validation of a Brief Measure of Uncertainty in Rheumatic Disease

Caleb Bolden[1], Claire Cook[1], Lucy Finkelstein-Fox[1], Xiaoqing Fu[1], Flavia Castelino[1], Hyon K. Choi[2], Cory Perugino[1], John Stone[3], Elyse Park[1], **Zachary Wallace**[4] and Daniel Hall[1], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital and Harvard Medical School, Lexington, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Concord, MA, [4]Massachusetts General Hospital, Newton, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes I: Assessment Tools

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Patients with systemic autoimmune rheumatic disease (SARD) are often tasked with monitoring ambiguous and unpredictable physical symptoms on their own. Higher levels of uncertainty in rheumatic disease (URD) are associated with increased anxiety, depression, and sickness impact (J Rheum 2022;49:1059). Existing measures to evaluate URD are adapted from longer instruments (e.g., 22 items), limiting the ability to implement routine assessment in clinical practice. We aimed to develop a brief measure of URD and perform an initial validation of this brief measure.

Methods: Patients with antineutrophil cytoplasmic antibody-associated vasculitis (AAV), IgG4-related disease (IgG4-RD), and systemic sclerosis (SSc) seen at a rheumatology clinic at a large academic hospital completed a cross-sectional survey assessing URD (rheumatology-adapted version of the Mishel Uncertainty in Illness Scale, Survivor Version; MUIS-S), anxiety (GAD-7), depression (PHQ-8), and sickness impact (SIP). First, we performed an exploratory factor analysis of the previously adapted rheumatology-specific 22-item MUIS-S to identify the amount of variance loaded across each item following the established convention of 0.6 (stopping rule of 75% variance explained per factor) to select the final items. Second, we tested the brief URD measure for internal consistency (Cronbach's alpha) and convergent validity. Third, we performed a series of hierarchal regression models assessing variance explained, controlling for age and sex.

Table 1: Demographics of Survey Respondents

	Total	AAV	IgG4-RD	SSc
N %	132	41 (31%)	61 (46%)	30 (23%)
Age (Mean, SD)	64.7, 11.3	64.7, 10.3	64.5, 12.0	64.9, 11.8
Race/Ethnicity n (%)				
American Indian or Alaskan Native	1 (0.8)	0(0.0)	1 (1.6)	0 (0.0)
Asian	13 (9.8)	2 (4.9)	9 (14.8)	2 (6.7)
Black or African American	1 (0.8)	0 (0.0)	1 (1.6)	0(0.0)
Hispanic or Latino	6 (4.5)	1 (2.4)	3 (4.9)	2 (6.7)
Native Hawaiian or Other Pacific Islander	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)
White	110 (83.3)	38 (92.7)	46 (75.4)	26 (86.7)
Other	4 (3.0)	1 (2.4)	3 (4.9)	0 (0.0)
Sex n (%)				
Female	69 (52.3)	23 (56.1)	17 (27.9)	29 (96.7)
Relationship status n (%)				
Single, never married	12 (9.1)	7 (17.1)	2 (3.3)	3 (10.0)
Married/Living with partner	101 (76.5)	28 (68.3)	54 (88.5)	19 (63.3)
Widowed/Divorced	16 (12.1)	5 (12.2)	4 (6.6)	7 (23.3)
Other	2 (1.5)	1 (2.4)	0 (0.0)	1 (3.3)
Comorbidities n (%)				
Cardiovascular disease (i.e. heart disease, stroke, high blood pressure, high cholesterol)	59 (44.7)	16 (39.0)	27 (44.3)	16 (53.3)
Diabetes	15 (11.4)	3 (7.3)	11 (18.0)	1 (3.3)
Kidney disease	17 (12.9)	4 (9.8)	11 (18.0)	2 (6.7)
Liver disease	3 (2.3)	0 (0.0)	3 (4.9)	0 (0.0)
Lung disease (e.g., asthma, COPD, sleep apnea)	43 (32.6)	20 (48.8)	16 (26.2)	7 (23.3)
Overweight/obesity	26 (19.7)	9 (22.0)	12 (19.7)	5 (16.7)
Underweight	2 (1.5)	0 (0.0)	0 (0.0)	2 (6.7)
Other	31 (23.5)	11 (26.8)	13 (21.3)	7 (23.3)
Self-Reported Disease activity n (%)				
In remission	56 (42.4)	21 (51.2)	32 (52.5)	3 (10.0)
Not in remission	42 (31.8)	13 (31.7)	13 (21.3)	16 (53.3)
I do not know	34 (25.8)	7 (17.1)	16 (26.2)	11 (36.7)

Results: We included 132 patients: 41 (31%) with AAV, 61(46%) with IgG4-RD, and 30 (23%) with SSc (**Table 1**). The mean age was 64.7 years, the majority were White (83%) and female (52%). The exploratory factor analysis of the 22-item MUIS-S identified 9 items to retain (**Table 2**). In further factor analysis of these 9 items, 7 were retained and captured 2 factors: ambiguity and unpredictability (**Table 3**). There was high internal consistency for the overall composite 7-item URD measure (alpha=.85) and its subscales: ambiguity (alpha=.79) and unpredictability (alpha=.81). Convergent validity was found between the 7-item measure with anxiety (r=0.417, p< .001), depression (r=0.473, p< .001), and sickness impact (r=0.335, p< .001). URD, as measured using the 7-item measure, explained a significant amount of variance: 14.2% in anxiety (r^2 = 0.142, F(2,113) = 11.25, p< .001), 23.2% in depression (r^2 = 0.232, F(2,113) = 19.685, p< .001), and 14.8% in sickness impact (r^2 = 0.148, F(2,113) = 10.177, p< .001) after controlling for age and sex.

Conclusion: We developed a brief, 7-item measure of URD with high internal consistency and convergent validity with measures of anxiety, depression, and sickness impact. Given the burden of anxiety, depression, and other mental health comorbidities in these conditions, this instrument can be useful for tailoring screening and referral pathways for healthcare services and consultation visits (e.g., specialists, supportive care). This measure may also be useful as part of research studies developing interventions aimed at improving resiliency in the face of URD. Additional validation is needed.

Table 2: Factor Analysis of the Original 22 Item Rheumatology Adapted MUIS

Abstract Number: 0828

Item Reduction and Validation of the Cutaneous Lupus Erythematosus Quality of Life Questionnaire

Maya Adams[1], Linda Hynan[2], Motolani Ogunsanya[3] and Benjamin Chong[1], [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Peter O'Donnell Jr. School of Public Health and Department of Psychiatry, Dallas, TX, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes I: Assessment Tools
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Cutaneous lupus erythematosus (CLE) symptoms often require patient-reported outcome measures (PROMs) to monitor disease progression. The CLE quality of life (CLEQoL) instrument was devised as a disease-specific PROM. However, its 37-item length can be time-consuming. Creating a brief version could reduce respondent burden and increase clinical utility. Thus, we sought to develop a brief version of the CLEQoL, while maintaining clinical relevance and psychometric properties including internal consistency, structural and convergent validity.

Methods: This retrospective cohort study analyzed data from CLE patients recruited in outpatient dermatology clinics at University of Texas Southwestern Medical Center and Parkland Health from June 2016 to November 2022. Patients completed the CLEQoL, Short-Form-36 (SF-36), and a visual analogue scale (VAS). Item reduction was conducted by evaluating each item's response distribution and local dependency with other items. Internal consistency of the reduced scale was

assessed using Cronbach's alpha. Structural validity was examined via exploratory factor analysis with principal component analysis and varimax rotation. Convergent validity was determined via Spearman correlations between CLEQoL, SF-36, VAS, and Cutaneous Lupus Erythematosus Disease Area and Severity (CLASI) scores. Data were analyzed using SPSS version 29.0 and significance was set at $p< 0.05$.

Results: 185 patients completed the CLEQoL (Table 1). Thirteen items were removed, resulting in a 24-item scale (Figure 1). Internal consistency was satisfactory (Cronbach's alpha: 0.842-0.939). Exploratory factor analysis identified three domains (each with and eigenvalue greater than 1): *"Emotions and Social Interactions," "Symptoms and Functioning," and "Lupus Specific Questions"*– each factor had an eigenvalue greater than 1 and contributed more than 5% unique variability (Table 2). The brief CLEQoL demonstrated convergent validity with relevant domains of the SF-36 (*r* range: -0.243 to -0.172) and VAS (0.348 – 0.671). However, it did not demonstrate convergent validity with CLASI activity or damage scores. The limited convergent validity between the scale and CLASI scores may be attributed to the small range of observed CLASI activity scores (median 5, IQR 1.25-10).

Conclusion: The brief 24-item CLEQoL was found to be a valid and reliable PROM for assessing CLE patients' quality of life, and establishing its psychometric properties is crucial for its use in outpatient clinics and clinical trials. The nonconvergence between the brief CLEQoL and CLASI can be attributed to their measurement of different constructs. The brief CLEQoL captures subjective patient experiences such as social functioning, and emotional well-being. In contrast, the CLASI relies on clinical observations to assess disease severity. Integrating information from both measures allows for a more comprehensive and holistic assessment of the patient's condition. Future plans involve prospectively administering the brief CLEQoL to a larger and more heterogeneous CLE patient cohort to further evaluate its psychometric properties.

Brief CLE-specific quality of life measure (CLEQoL)

Decreased History of Breastfeeding During Infancy in Juvenile Spondyloarthritis: A Case-Control Study

Katelyn Baggett[1], Timothy G. Brandon[2], Rui Xiao[3] and Pamela F. Weiss[4], [1]Penn State College of Medicine, Newtown Square, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Department of Pediatrics Division of Biostatistics, Children's Hospital of Philadelphia, Philadelphia, PA, [4]Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Pediatric Rheumatology – Clinical I: JIA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: The pathogenesis of juvenile spondyloarthritis (JSpA) is multifactorial, and includes a genetic predisposition of the HLA-B27 allele, and environmental exposures such as the microbiome. Breastfeeding during infancy is the most robust source of microbiome colonization and differs markedly from the microbiota offered through formula feeding. Early breastfeeding practices are associated with the development of various autoimmune conditions, though this was yet to be investigated in JSpA. This study aims to evaluate 1) differences in parent-reported infant feeding type and duration between children with JSpA and matched controls and 2) if an association exists between early nutrition practices and JSpA disease severity at presentation.

Methods: This retrospective case-control study included 195 children with JSpA and 195 age- and sex-matched healthy controls. Demographics and early nutrition practices of cases and controls were parent-reported via electronic questionnaires. The type and duration of feeding was limited to the first 6 months of life and included the options of breastmilk only, breast and formula, formula only, breast and cereal or other food, or "other". Between-group comparisons were made using the Pearson's χ^2 or Fisher's exact test. JSpA disease activity was quantified by the modified JSpA disease activity-6 (JSpADA-6) index, a validated tool consisting of patient- and physician-reported measures (score range 0-6). Components of the JSpADA-6 index were collected as part of a JSpA registry. Linear regression was used to assess the association of JSpA disease activity at the index visit and infant feeding type and duration. Index visit was defined as the first visit in the JSpA registry that occurred within 6 months of diagnosis or prior to the initiation of disease-modifying antirheumatic drugs or biologic therapy.

Table 1. Characteristics of children with JSpA versus healthy controls

Characteristic	All	Controls	JSpA	p-value
No. of subjects	390	195	195	
Age, mean ± SD	13.03 ± 0.24	13.03 ± 0.24	13.03 ± 0.24	
Female, n (%)	186 (47.69%)	93 (47.69%)	93 (47.69%)	
Race, n (%)				0.54
African American	25 (6.41%)	11 (5.64%)	14 (7.18%)	
American Indian/Alaskan Native	1 (0.26%)	1 (0.51%)	0	
Asian American	18 (4.62%)	8 (4.10%)	10 (5.13%)	
Multiracial	26 (6.67%)	10 (5.13%)	16 (8.21%)	
Native Hawaiian or Other Pacific Islander	1 (0.26%)	1 (0.51%)	0	
White	306 (78.46%)	159 (81.54%)	147 (75.38%)	
Other/Unknown	13 (3.33%)	5 (2.56%)	8 (4.10%)	
Form of delivery, n (%)				0.51
Vaginal delivery	268 (68.72%)	131 (67.18%)	137 (70.26%)	
Cesarean delivery	122 (31.28%)	64 (32.82%)	58 (29.74%)	

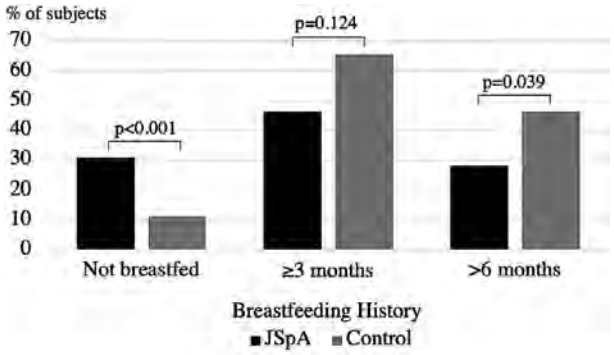

Figure 1. For the 173 controls and 135 patients with JSpA who were exposed to breastfeeding, the % that were breastfed exclusively for ≥3 or >6 months are shown above. The ≥3 and >6-month groups are not mutually exclusive.

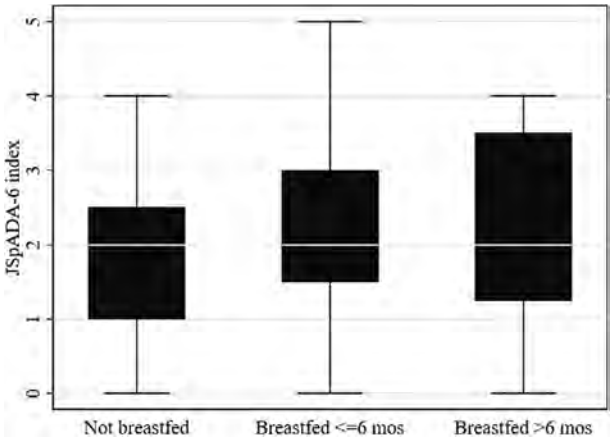

Figure 2. The JSpADA-6 index and parent-reported infant feeding type was available for 103 JSpA patients at the index registry visit, a median of 0.3 months after diagnosis and prior to the initiation of disease-modifying antirheumatic drugs or biologic therapy (IQR 0-10.5). The above groups are mutually exclusive.

Results: For each group of 195 controls and 195 cases, the mean age was 13.03 ± 0.24 years and 47.69% were female (Table 1). Of the healthy controls and children with JSpA, 88.72% and 69.23% were exposed to breastfeeding of any duration, respectively (p< 0.001).The frequency of exclusive breastfeeding for longer than 6 months was significantly lower in children with JSpA than in healthy controls (28.36% of children with JSpA vs 46.47% of healthy controls; p=0.039; figure 1). There was no significant difference in form of delivery, vaginal or cesarean delivery, between children with JSpA and healthy controls. The JSpADA-6 index and parent-reported breastfeeding duration was available for 103 JSpA patients at the index registry visit, a median of 0.3 months after diagnosis (IQR 0-9.4). The median JSpADA-6 index was 2 (IQR: 1.5-3; range: 0-5) and was not significantly different in children with a history of no breastfeeding and exclusive breastfeeding for ≤6 months (β=0.13, 95% CI: -0.39-0.66) or exclusive breastfeeding for >6 months (β=0.21, 95% CI: -0.41-0.84).

Conclusion: This study suggests a potential association of early breastfeeding practices and the occurrence of JSpA. A shorter duration of exclusive breastfeeding or absence of breastfeeding was higher in cases with JSpA than controls. Breastfeeding for >6 months was not associated with JSpA disease severity at diagnosis.

The Upregulation of MAP Kinase Pathway Genes Is Associated with Poor Treatment Response to Tofacitinib in Polyarticular Course Juvenile Idiopathic Arthritis

Esraa Eloseily[1], Alex Pickering[2], Sanjeev Dhakal[1], Hermine Brunner[3], Sherry Thornton[4] and Alexei Grom[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Harvard Medical School Department of Biomedical Informatics, Boston, MA, [3]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Cincinnati, OH, [4]Cincinnati Children's Hospital, Cincinnati, OH

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical I: JIA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Despite significant progress in understanding the pathophysiology of Juvenile Idiopathic Arthritis (JIA), the availability of tools to accurately predict treatment response remains limited. Our objective was to identify gene expression patterns that may predict treatment response to tofacitnib in patients with polyarticular course JIA.

Methods: Whole blood samples were collected from JIA patients using PAXgene tubes prior to starting tofacitinib treatment as part of the clinical trial NCT02592434. Patients were categorized as treatment responders (TR) if they achieved a JIA-ACR70 response or higher at week 18, while those with a JIA-ACR response of 30 or less were considered poor responders (PR). Bulk RNA sequencing was performed using Illumina Nova-seq, generating 50 million reads per sample. Gene expression levels were measured at baseline. Differential gene expression analyses were conducted using the dream method from variance Partition. Gene ontology overrepresentation analyses were subsequently performed using the dseqr adaptation of the goana function from the limma R package.

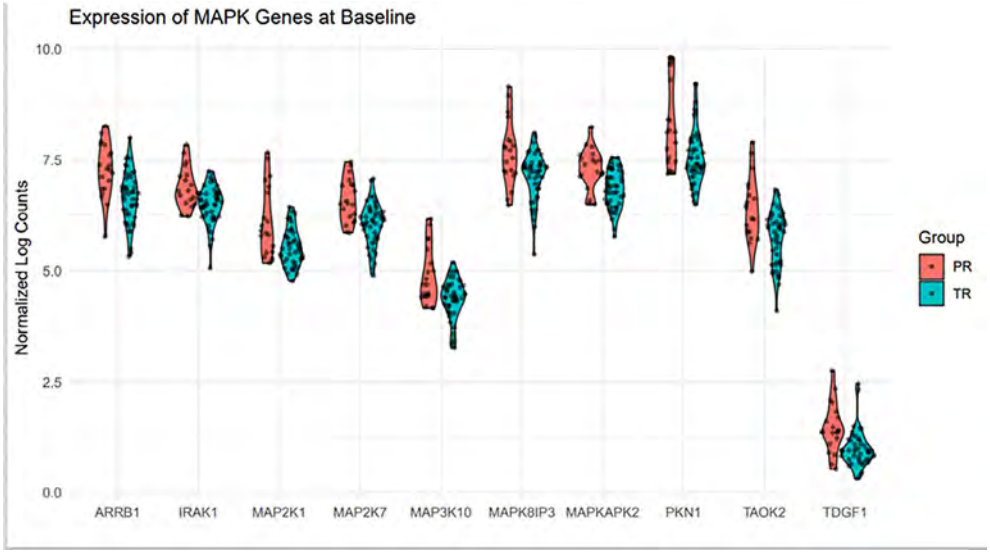

Figure 1.a: Expression of MAPK genes at baseline in treatment responders versus poor responders after covariate modeling

Results: 663 of 31,799 genes assayed were identified as differentially expressed in PR as compared to TR (FDR< 0.05) from samples acquired prior to treatment initiation. Gene ontology analysis revealed a significant upregulation of genes associated with MAP kinase pathway activation in PR (p=9.40E-05) (Figure 1.a &1.b). Other ontologies that were upregulated in PR included myeloid stem cell development (p=8.13E-05), activation of GTPase activity (p=0.00015), and organelle transport along microtubule (p= 0.00021) (Table 1).

Conclusion: Assessment of MAP kinase pathway gene expression prior to treatment may aid in identification of polyarticular course JIA patients that could exhibit poor response to tofacitinib. If confirmed, this finding could be used to personalize treatment of JIA patients for whom tofacitinib treatment is considered.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical I: JIA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The STOP-JIA study was designed to compare the effectiveness of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Consensus Treatment Plans (CTPs) for untreated polyarticular JIA (pJIA) in achieving ACR clinically inactive disease (CID) at 1 year. The CTPs differ in the timing of initiation of biologic disease modifying anti-rheumatic drug therapy (bDMARD). The objective of this study was to measure the impact of CARRA STOP-JIA CTPs on clinical outcomes at 2 and 3 years.

Table 1: Patient characteristics at enrollment for participants with 2- and/or 3- year data

Characteristic	Follow-up at 2-3 Years (n=325)	No Follow-up (n=75)	SMD
Age - years (mean (SD))	10.2 (4.8)	11.4 (5.5)	0.235
Male (%)	90 (27.7)	16 (21.3)	0.148

Active Joint Count - median [IQR]	10 [6, 17]	9 [6, 16.5]	0.124
CHAQ - median [IQR]	0.87 [0.25, 1.47]	0.75 [0.25, 1.12]	0.171

Abbreviations: SMD: standardized mean difference; IQR: interquartile range; RF=rheumatoid factor; MD Global=Physician Global Assessment of Disease Activity; cJADAS10=clinical Juvenile Arthritis Disease Activity Score based on 10 joints; CHAQ: Childhood Health Assessment Questionnaire.

Methods: STOP-JIA compared 3 CARRA CTPs in 400 children with pJIA: 1) Step-Up (SU) – starting conventional, synthetic DMARD monotherapy (csDMARD), adding bDMARD if needed after 3 months; 2) Early Combination (EC) – starting csDMARD and bDMARD within the first 3 months; and 3)Biologic First (BF) – starting bDMARD monotherapy and adding csDMARD if needed after 3 months. There was no randomization. Patients with 2 to 3 years of follow-up were included. The primary outcome was the percentage of children achieving CID off glucocorticoids at 2 and/or 3 years. Propensity score (PS) weighting was used to balance baseline differences in potential confounders between CTPs. Secondary outcomes included comparison of proportions of patients with clinical Juvenile Arthritis Disease Activity Score based on 10 joints inactive disease (cJADAS10-ID £ 2.5), clinical remission on medications (CRM; consecutive visits with CID ^{3} 6 months), and proportion of time spent in CID or cJADAS10-ID.

Table 2: Propensity Score-adjusted difference between CTP groups in estimates of CID at 24 months, CRM at any time up to 24 months, and percentages of time spent in CID and JADAS10-ID over 24 months

24-Month Outcomes			
		Difference Between CTPs	
CTP	Estimate % [upper, lower 95%CI)	vs. Biologic First	vs. Step Up
Percentage of patients in CID at 24 months			
Early Combination	57.7 [45.5, 70.0]	5.3 [-19.6, 30.4; p=0.68]	15.9 [1.2, 30.5; p=0.03]
Biologic First	52.4 [30.7, 74.0]	-	10.6 [-12.6, 33.7; p=0.37]
Step Up	41.8 [34.4, 49.3]	-	-
Percentage of patients with CR at any time over 24 months			
Early Combination	46.3 (32.9, 59.7)	16.1 [-8.8, 41.1; p=0.21]	17.6 [2.5, 32.6; p=0.02]
Biologic First	30.2 (9.2, 51.2)	-	1.4 [-20.7, 23.5; p=0.9]
Step Up	28.8 [22.3, 35.2]	-	-
Mean percentage of time in CID over 24 months			
Early Combination	32.4 [25.4, 39.4]	6.4 [-9.5, 18.8; p=0.52]	6.4 [-1.6, 14.4; p=0.12]
Biologic First	27.7 [15.3, 40.2]	-	1.7 [-11.3,14.8; p=0.79]
Step Up	26.0 [22.4, 29.6]	-	-
Mean percentage of time in cJADAS10 inactive disease over 24 months			
Early Combination	43.9 [36.2, 51.5]	8.2 [-6.6, 22.9; p=0.28]	8.4 [-0.3, 17.2; p=0.06]
Biologic First	35.7 [23.0, 48.5]	-	0.3 [-13.3, 13.8; p=0.97]
Step Up	35.4 [31.4, 39.5]	-	-

Abbreviations: PS: propensity score; CTP: Consensus Treatment Plan; cJADAS10=clinical Juvenile Arthritis Disease Activity Score based on 10 joints; CI: Confidence interval.

Table 3: Propensity Score-adjusted difference between CTP groups in estimates of CID at 36 months, CRM at any time up to 36 months, and percentages of time spent in CID and JADAS10-ID over 36 months

36-Month Outcomes			
		Difference Between CTPs	
CTP	Estimate % [upper, lower 95%CI)	vs. Biologic First	vs. Step Up
Percentage of patients in CID at 36 months			
Early Combination	34.7 [20.8, 48.5]	-7.5 [-33.3, 18.3; p=0.57]	-0.7 [-16.9, 15.5; p=0.93]
Biologic First	42.2 [20.1, 64.2]		6.8 [-16.9, 30.5; p=0.58]
Step Up	35.4 [27.4, 43.4		
Percentage of patients with CR at any time over 36 months			
Early Combination	66.1 [54.4, 77.8]	25.6 [1.6, 49.6; p=0.04]	26.0 [11.6, 40.4; p<0.001]

Biologic First	41.1 [27.7, 54.5]	-	1.7 [-12.5, 15.9; p=0.82]
Step Up	39.4 [35.3, 43.5]	-	-

Abbreviations: PS: propensity score; CTP: Consensus Treatment Plan; cJADAS10=clinical Juvenile Arthritis Disease Activity Score based on 10 joints; CI: Confidence interval.

Results: 325 participants had a 2- and/or 3-year visit (n=210 SU, 83 EC, 32 BF; Table 1). Percentage of patients in CID at 2 years was 42% for SU, 58% EC, and 52% BF (p=0.03 for SU versus EC; Table 2). CID differences were not statistically significant at 3 years. Likewise, there was no significant difference between CTPs for JADAS10-ID at 2 or 3 years. However, there were significant percentage differences in CRM, which were higher for EC compared to SU over 2 years (46.3% versus 28.8% [p=0.02]) and 3 years (66.1% versus 40.1% [p< 0.01]), and for percentages of time spent in CID (42.8% versus 28.8% [p< 0.01]) and cJADAS10-ID (52.5% versus 39.4% [p< 0.01]) at 3 years.

Conclusion: These data support improved effectiveness of EC versus SU and BF at 2 and 3 years for most outcomes, but did not reach statistical significance for all comparisons. There were significant differences favoring EC versus SU in outcomes that reflected duration of time spent with less disease activity at 2 and 3 years, which may be most important in limiting disease burden. More research is needed to improve understanding of which pJIA patients will respond to a particular CTP in order to optimize individual outcomes.

Cumulative Social Disadvantage Is Associated with Disease Activity and Functional Disability in Juvenile Idiopathic Arthritis: An Analysis of the CARRA Registry

William Soulsby, Erica Lawson, John Boscardin and Emily von scheven, University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Pediatric Rheumatology – Clinical I: JIA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: The impact of race and social determinants of health (SDoH) on health outcomes in juvenile idiopathic arthritis (JIA) remains poorly understood. Prior disparities research in JIA has largely analyzed these complex, intertwined social variables as independent risk factors and have reported inconsistent results of their impact on clinical outcomes, such as joint damage, pain, and disability. These inconsistencies may result from a failure to investigate interrelationships between social variables. A recent analysis demonstrated an association between cumulative social disadvantage and childhood arthritis using a combined score. In this analysis of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, we used a similar method to investigate the effect of cumulative social disadvantage on disease activity and functional disability in JIA.

Methods: This is a cohort study of subjects with JIA enrolled in the CARRA Registry between July 2015-January 2022 with at least one Registry visit including all components of the clinical Juvenile Arthritis Disease Activity Score (cJADAS) and Child Health Assessment Questionnaire (CHAQ) score. A cumulative social disadvantage score was created, with a score of 1 given for each of the following: income (household income < $50,000/year), guardian education (high school or less), insurance (public insurance or none), and non-White race. Any missing components were given a score of 0.Univariate and

multivariable logistic regression models, adjusted for age at enrollment, sex, JIA category, and any use of a conventional (cs-), biologic (bs-) DMARD, or small molecule, were used to estimate the odds of persistent disease activity (oligoarticular JIA – cJADAS ≥1.1; all other categories >2.5) and functional disability (CHAQ score > 0).Random effect was included in the regression models to account for repeated measures.

Results: 9,672 subjects with JIA were identified (Table 1).Oligoarticular and RF- polyarticular JIA were the most common JIA subtypes reported. The majority of cohort required DMARD treatment (68.7%).48.9% of the cohort had exposure to at least one variable associated with the combined score.47.9% of patients were classified as having high cJADAS, and 56.8% had a high CHAQ score. In both unadjusted and adjusted analysis, cumulative social disadvantage with higher odds of active

Table 3: Mixed effects model to estimate the effect of cumulative social disadvantage on persistent functional disability in children with JIA in the CARRA Registry

Cumulative Social Disadvantage Score	Unadjusted OR (95% CI), p-value	Adjusted[†] OR (95% CI), p-value
0	—	—
1	1.62 (1.41, 1.87), <0.001	1.64 (1.42, 1.88), <0.001
2	3.61 (3.02, 4.31), <0.001	3.49 (2.92, 4.17), <0.001
3	3.89 (3.11, 4.89), <0.001	3.94, (3.15, 4.93), <0.001
4	3.81 (2.59, 5.59), <0.001	3.91 (2.67, 5.74), <0.001

[†]Model adjusted for age at enrollment, sex, JIA category, and any use of a cs- or bDMARD or small molecule

disease, highest for a score of 3 (Table 2 - adjusted odds ratio [aOR] 2.31, 95% CI: 1.97-2.71), and functional disability, also highest for a score of 3 (Table 3 - aOR 3.94, 95% CI: 3.15-4.93).

Conclusion: Cumulative social disadvantage was associated with higher odds of active disease and functional disability compared to those not experiencing these exposures among JIA subjects in the CARRA Registry. Exposure to multiple variables associated with social disadvantage confers higher risk of poor outcomes in JIA. To mitigate these disparities, targeted social risk screening adopted within pediatric rheumatology clinics should be studied as a potential intervention to identify at-risk patients who may benefit from social network support or other programming, such as patient navigation services.

Machine Learning Detected Healthcare Encounter Patterns Leading to Diagnosis of Juvenile Arthritis in a Population-Based Canadian Cohort

Lily Lim, Connor Hryhoruk, Ruth Ann Marrie, Christine Peschken, Carson Leung and Lisa Lix, University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Pediatric Rheumatology – Clinical I: JIA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Increases in health care visits precede the first diagnosis code for inflammatory arthritis (IA) by an average of 5 years in adults, but it is unknown if this occurs in children. Reports of symptoms before juvenile arthritis (JA) are usually < 6 months but could be longer for some. We hypothesized that patterns of visits that precede JA diagnosis differ from those in non-JA controls. We aimed to discover visit patterns preceding JA diagnosis in health administrative databases (HAD).

Methods: ***Populations:*** JA patients diagnosed from 1983-2012 in the only paediatric rheumatology centre in Manitoba, Canada were linked to provincial population-based HAD. Controls were matched 5:1 to JA patients by age ± 1 year, sex, health regions, JA diagnosis dates (index dates for controls) and did not have an IA code ≤ 18 years old in HAD. Visits since birth or immigration until diagnosis/ index dates were used for analysis (1980-2018). ***Data preprocessing:*** Diagnosis codes (International Classification of Diseases versions 9-CM and 10-CA) from all inpatient and outpatient visits were clustered into clinically-relevant categories using open-source Clinical Classification Software. Visits were examined in 6-month intervals

Table: Top 10 discriminating patterns of JA

Pattern Number	Patterns	Percent of JA patients	Percent of controls	Odds ratio of JA vs controls (95% confidence intervals)
1	Joint Disorders @6-0 months	65.80	1.40	135.62 (87.85, 209.37)
2	Joint Disorders @6-0 months , Joint disorders @6-0 months	37.82	0.21	292.91 (107.5, 798.09)
3	Other musculoskeletal @6-0 months	32.12	3.47	13.16 (9.52, 18.20)
4	Upper Respiratory Infections @12-6 months, Joint Disorders @6-0 months	23.83	0.52	60.08 (30.93, 116.72)
5	Upper Respiratory Infections @24-18 months, Joint Disorders @6-0 months	23.32	0.52	192.48 (60.52, 612.16)
6	Upper Respiratory Infections @18-6 months, Joint Disorders @6-0 months	23.06	0.16	58.38 (30.03, 113.48)
7	Upper Respiratory Infections @30-24 months, JD @6-0 months	21.50	0.00	Not applicable
8	Skin disorders @6-0 months	24.87	4.15	7.66 (5.55, 10.56)
9	Upper Respiratory Infections @36-30 months, Joint Disorders @6-0 months	19.95	0.00	Not applicable
10	Joint Disorders @6-0 months , Joint Disorders @6-0M, Joint Disorders @6-0 months	18.91	0.05	449.89 (62.3, 3248.64)

Top 10 Most Common Healthcare Encounter Patterns Preceding Juvenile Arthritis Diagnosis and Odds Ratio (95% Confidence Intervals Compared to Controls

from birth until diagnosis/index date. ***Analysis:****Prefixspan*, a sequential pattern mining (SPM) machine learning algorithm was applied to visits of JA cases and controls to detect ***patterns (temporal sequence of events)*** preceding diagnosis/ index dates. We modified the algorithm to assign lower weights to encounters that were more remote to diagnosis than those closer in time to diagnosis (time fading). JA and control patterns were compared by relative percentages (of patterns) and odds ratios (of JA compared to controls) thresholds. Patterns were screened and evaluated for face validity by the clinical team.

Results: 386 JA patients (65% females) were matched to 1930 controls. Median age of JA patients at diagnosis was 8 years. JA subgroups: oligoarticular 42%, polyarticular 28%, spondyloarthropathy 13%, others 17%. We studied 98649 visits: 20946 JA, 77703 controls. JA patients had more visits compared to controls, respectively with median (25-75thpercentile) of 19.5 (7.0-38.5) versus 15 (5-31) general practitioner visits, and 15 (4.5-35) versus 8 (1-23) specialist visits. ICD codes were classified into 101 chronic diseases, 116 acute diseases/ poisoning/trauma categories. We detected 544 discriminating patterns. Patterns of JA were detectable ≤3 years pre-JA diagnosis. The most common 10 patterns that discriminated between JA patients and non-JA controls, before diagnosis are presented (Table).

Conclusion: Machine learning methods detected healthcare encounter patterns more likely associated with JA relative to controls in a population-based cohort, ≤ 3 years before diagnosis. Visits preceded IA codes, providing an insight into heterogeneity in JA presentations and potential associated events before JA. Once validated, our method may be used to: i) identify potential JA patients for earlier management, ii) define disease cohorts for outcome studies at a population level in HAD.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical I: JIA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in children. Tumor necrosis factor inhibitors (TNFi) have demonstrated efficacy and safety in older JIA patients and are approved for use in children over age 2 years. However, use of these therapies in children ≤2 years is not well described despite frequent use in clinical practice. Children ≤2 yo who would benefit from these medications may have delays in treatment due to the lack of FDA approval, resulting in increased morbidity. Our aim was to describe the demographics, medication use, and changes in medication use over time in the cohort of children diagnosed with non-SJIA ≤2 yo enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry.

Methods: The CARRA registry is a national multicenter observational database for children with rheumatic diseases in the United States. Demographics, disease phenotype, and medication use of patients diagnosed with non-SJIA before the age of 2 years enrolled in the CARRA Registry were analyzed using descriptive statistics. Those who started a TNFi ≤2 yo, >2 yo, and those who never used TNFi were analyzed; summary statistics are presented using median with interquartile range (IQR) for continuous variables and count with frequency for categorical variables. Group comparisons were completed using Welch's ANOVA for continuous variables and Chi Square test for categorical variables with a significance level of 0.05.

Results: 1,458 patients diagnosed with non-SJIA ≤2 yo were enrolled in the CARRA registry between 2015 and 2021. Consistent with known demographics of JIA subtypes, there were fewer enthesitis related arthritis and RF + polyarticular JIA patients diagnosed before the age of 2. Of these, 259 (18%) started a TNFi before the age of 2. Patients started on TNFi after their 2nd birthday tended to have a longer disease duration at time of registry enrollment as compared to those that started before age 2 ($p < 0.01$). Early initiation of TNFi did not vary based on race or average income. Half of patients with RF - polyarticular JIA were started on TNFi ≤2 yo, and joint counts of ≥5 had higher rates of early TNFi initiation (Table 1). DMARD and TNFi use before age 2 increased over time but decreased from 2018-2021 (figure 1). Less than 1% of our cohort was started on a non-TNFi biologic at ≤2yo.

Conclusion: Our findings demonstrate that despite the lack of FDA approval, TNFi medications are being utilized in 18% of patients under the age of 2, with higher early utilization rates when olig-JIA patients are removed from the analysis. Possible explanation for decreased use from 2018-2021 could be due to early concerns regarding immunosuppresion in COVID19; future data will clarify. Overall, TNFi medications are an accepted treatment amongst pediatric rheumatologists in early-onset JIA. Future analysis will look at patients diagnosed ≤2yo enrolled in the registry near time of diagnosis, and assess the relationship between disease activity and TNFi initiation, efficacy, and adverse events in this population.

Table 1: Demographics and Medication use of Patients with Non-Systemic JIA Diagnosed at ≤2yo

	Total diagnosed with JIA at < or =2yo (n = 1,458)	Started TNFi ≤ 2 yo (n = 259)	Never started TNFi (n = 569)	Did not start TNFi <2 yo but started TNF after age 2 (n = 630)	p-value

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: RA – Treatments I: Novel RA Treatments & Mechanisms of Action

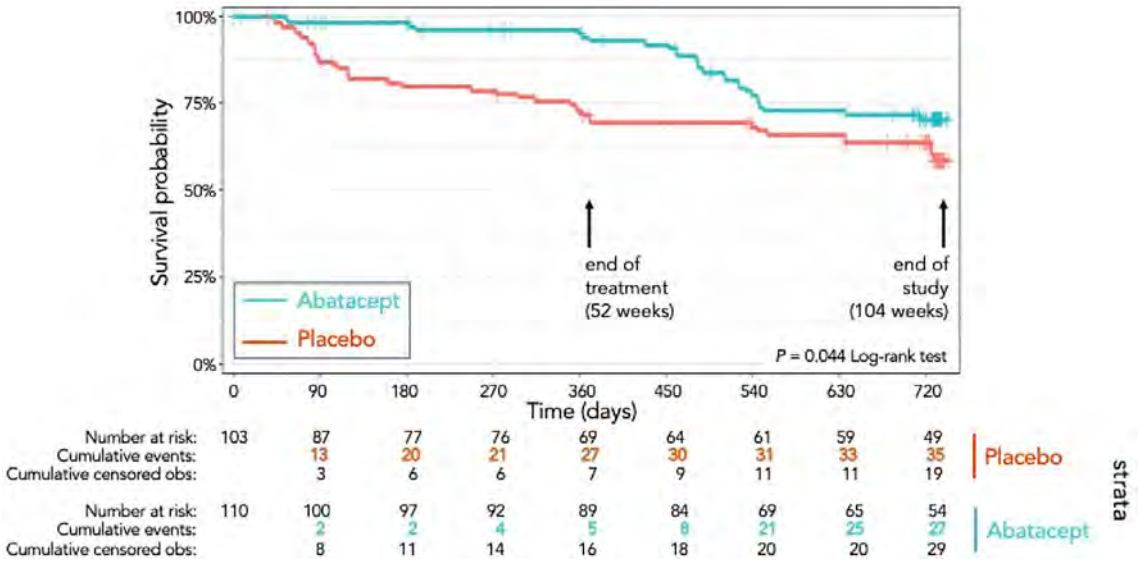
Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The definition of higher risk states for rheumatoid arthritis (RA) has been refined in more recent years through inclusion of serum autoantibodies and symptom complexes, such as inflammatory joint pain. Data from at risk cohorts have reported rates of progression to RA in excess of 50% over 24 months. These combined features have provided a framework for the design of interception studies, aimed at delaying or preventing RA. We set out to evaluate the feasibility, efficacy and acceptability of T-cell co-stimulation modulation with abatacept in individuals at risk of developing RA in the Arthritis Prevention In the Pre-clinical Phase of RA with Abatacept (APIPPRA) study.

Methods: APIPPRA is a Phase IIB randomised, double blind, placebo-controlled trial recruiting $ACPA^{+}RF^{+}$ or $ACPA^{hi}RF^{-}$ individuals with arthralgia. Consenting participants were randomised to receive 52 weekly subcutaneous injections of placebo or 125mg abatacept, and followed up for a further 52 weeks. Exclusion criteria included previous episodes of clinical synovitis, prior corticosteroids or DMARDs. The primary endpoint was the time to development of either clinical synovitis in 3 or more joints, or RA according to ACR/EULAR 2010 criteria, whichever was met first. Joint synovitis was confirmed by ultrasonography. Secondary endpoints included multiple disease activity assessments, including ultrasound scores, as well as safety data.

Results: Between December 2014 and January 2019, 280 individuals were evaluated for eligibility across 31 study sites, 28 in the UK and 3 in the Netherlands. Two hundred and thirteen were randomised, 103 to placebo and 110 to abatacept. Mean age was 49 and 77% were female. Ninety-three percent of individuals were $ACPA^{hi}$. Ultrasonography at baseline



suggested modest levels of active sub-clinical synovitis (73% of participants with power Doppler score of 0). In total, there were 65 primary outcome events. At 52 weeks there were 30 events (29%) in the placebo arm and 7 (6%) in the abatacept arm. By the end of the study there were 38 (37%) and 27 (25%) events, respectively, resulting in differences in mean arthritis-free survival time between arms of 99.2 days (95% CI 37.5 – 160.9; *p*-value=0.002), in favour of abatacept. The respective log-rank test for difference in the survival distribution was *p*=0.044, reflecting a large effect in the first year and convergence over the second year (see Figure 1). The per protocol analysis showed similar results. Pre-specified exploratory analysis revealed that individuals with high levels of ACPA or who had an extended autoantibody profile at baseline were more likely to remain arthritis-free following abatacept therapy. Those treated with abatacept had lower HAQ-DI and pain scores, and higher EQ-5DL scores during the treatment period, when compared to placebo. There were 4 serious adverse events in the abatacept group and 10 in the placebo group, including two deaths, one in each arm, none deemed attributable to study drug.

Conclusion: Therapeutic intervention during the RA at risk phase is feasible, with acceptable safety profiles. T cell co-stimulation modulation with abatacept for 52 weeks showed a reduction in the development of RA over two years. There were no new safety signals.

Vagotomy and Subsequent Risk of Rheumatoid Arthritis and Osteoarthritis: A Danish Register-Based Cohort Study

Matthew Baker[1], Dávid Nagy[2], Suzanne Tamang[3], Erzsébet Horváth-Puhó[2] and Henrik Toft Sørensen[2], [1]Stanford University, Menlo Park, CA, [2]Aarhus University Hospital, Aarhus, Denmark, [3]Stanford University, Palo Alto, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Treatments I: Novel RA Treatments & Mechanisms of Action
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Vagus nerve stimulation (VNS) is an emerging potential therapy for rheumatoid arthritis (RA). Given preliminary benefit observed with VNS in RA, we hypothesized that vagotomy might increase the risk of developing RA, without impacting the risk of developing osteoarthritis (OA). Historically, patients underwent vagotomy to treat refractory peptic ulcer disease by one of three methods: 1) full truncal vagotomy, 2) selective vagotomy (in which the celiac branch remains intact), and 3) superselective vagotomy (in which only the direct vagal inputs to the stomach are affected). The aim of this study was to examine the risk of developing RA or OA after various methods of vagotomy.

Methods: We performed a population-based cohort study in Denmark utilizing the Danish National Patient Registry and Danish Civil Registration System (CRS) from January 1, 1977 to December 31, 1995. We identified individuals who underwent vagotomy using International Classification of Diseases (ICD)-8 codes. A comparison cohort of patients who had not undergone vagotomy was randomly selected from the general population and matched on year of birth, sex, and date of vagotomy (index date). We excluded patients who were not registered in the CRS at least two years before the index date and those with prior diagnoses of OA or RA at any time before the index date. We examined the incidence of RA or OA based on two or more diagnosis codes for RA or OA 7-365 days apart, as well as OA with joint replacement based on a diagnosis of OA and a procedure code for knee or hip arthroplasty. Incidence of RA and OA was calculated using cumulative incidence function and treating death as a competing event. We used Cox proportional hazards regression models to compute hazard ratios (HRs) adjusted for age, sex, and comorbidities and corresponding 95% CIs, comparing patients with truncal vagotomy versus a matched general population comparison cohort and superselective vagotomy versus a matched comparison cohort.

Results: We identified 2,260 patients who underwent truncal vagotomy, matched with 22,610 comparators (Table), as well as 3,810 superselective vagotomy patients matched with 38,090 comparators (Table). The cumulative incidence estimates for truncal vagotomy are shown in Figure 1 and for superselective vagotomy in Figure 2. After adjusting for confounders, the HR for developing RA was 2.62 (95% CI 1.47-4.67) among patients who underwent truncal vagotomy compared with matched pairs. The HR for OA was 1.23 (95% CI 0.86-1.78), and for OA with joint replacement it was 0.73 (95%CI 0.36-1.50). For superselective vagotomy patients compared with a general population comparison cohort, the HR for developing RA was 1.05 (95% CI 0.51-2.17), for OA it was 1.01 (95% CI 0.70-1.45), and for OA with joint replacement it was 0.73 (95% CI 0.36-1.50).

Table. Characteristics of vagotomy and matched comparison cohorts.

Table. Characteristics of vagotomy and matched comparison cohorts.

	Truncal Vagotomy Cohort (*n* = 2260)	Truncal Vagotomy Comparison Cohort (*n* = 22610)	Superselective Vagotomy Cohort (*n* = 3810)	Superselective Vagotomy Comparison Cohort (*n* = 38090)

Calendar year, n (%)				
1977-1981	500 (21.8)	4960 (21.9)	1540 (40.3)	15360 (40.3)
1982-1986	660 (29.1)	6600 (29.2)	1270 (33.3)	12720 (33.4)
1987-1991	760 (33.7)	7640 (33.8)	730 (19.2)	7280 (19.1)
1992-1995	340 (15.0)	3410 (15.1)	270 (7.2)	2730 (7.2)
Charlson comorbidity score, n (%)				
0	1780 (77.5)	20260 (89.6)	3570 (93.7)	36450 (95.7)
1-2	410 (18.3)	2080 (9.2)	210 (5.6)	1520 (4.0)
≧ 3	90 (3.7)	270 (1.2)	30 (0.7)	120 (0.3)

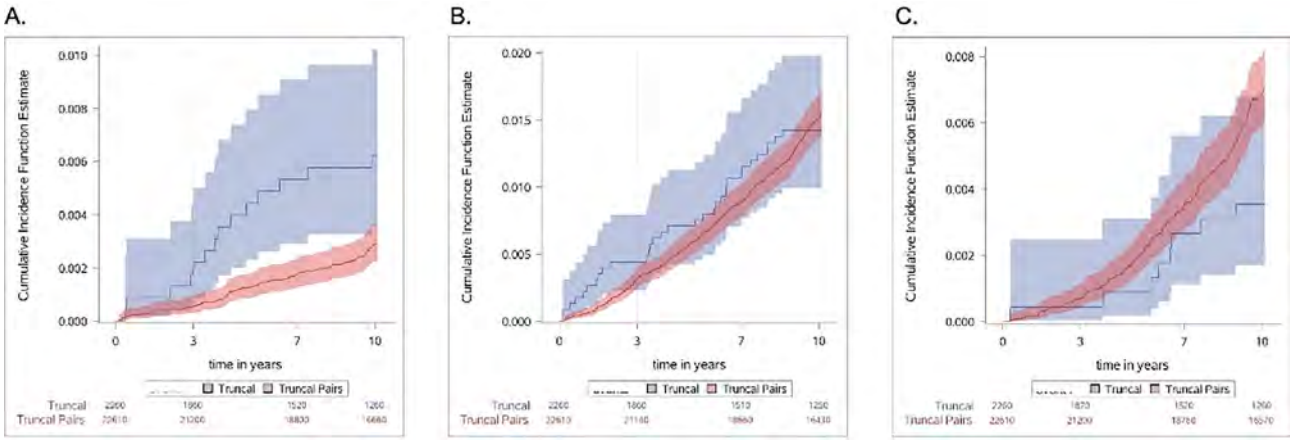

Figure 1. Cumulative incidence estimates for A. rheumatoid arthritis, B. osteoarthritis, and C. osteoarthritis with joint replacement, in subjects who underwent truncal vagotomy compared with a general population comparison cohort.

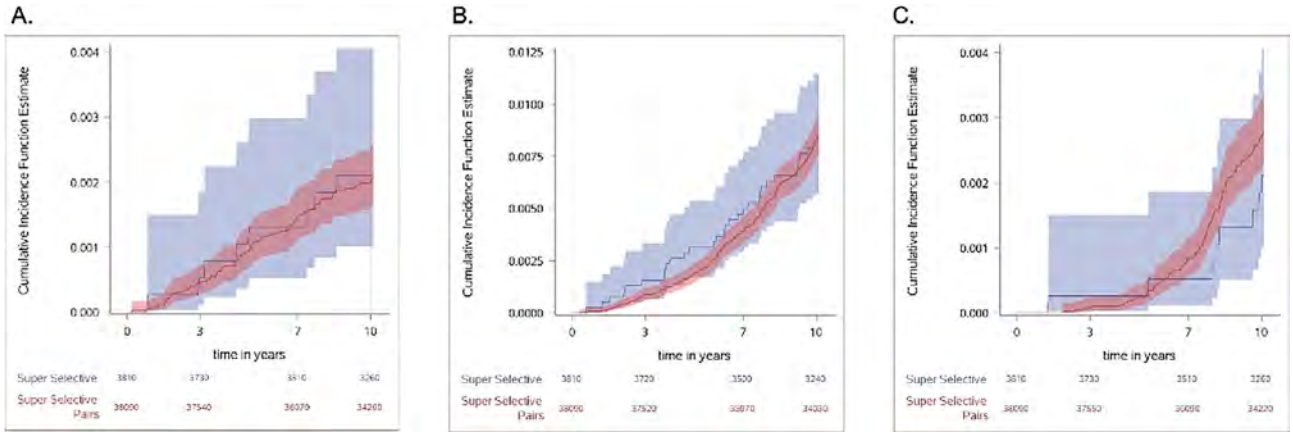

Figure 2. Cumulative incidence estimates for A. rheumatoid arthritis, B. osteoarthritis, and C. osteoarthritis with joint replacement, in subjects who underwent superselective vagotomy compared with a general population comparison cohort.

Conclusion: Truncal vagotomy was associated with an increased risk of developing RA. No difference in the risk of RA was seen in the superselective vagotomy group. Neither truncal nor superselective vagotomy were associated with an increased risk of developing OA. These results support the hypothesis that disruption of vagus nerve signaling may contribute to the development of RA.

A Randomized, Double-Blind, Sham-Controlled, Clinical Trial of Auricular Vagus Nerve Stimulation for the Treatment of Active Rheumatoid Arthritis

Matthew Baker[1], Sarah Kavanagh[2], Stanley Cohen[3], Alan Matsumoto[4], Ara Dikranian[5], John Tesser[6], Alan Kivitz[7], Konstantinos Alataris[8] and Mark Genovese[9], [1]Stanford University, Menlo Park, CA, [2]Kavanagh Statistical Consulting, LLC, Apex, NC, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Arthritis and Rheumatism Associates, Wheaton, MD, [5]Cabrillo Center for Rheumatic Disease, San Diego, CA, [6]Arizona Arthritis & Rheumatology Associates, Phoenix, AZ, [7]Altoona Center for Clinical Research, Duncansville, PA, [8]Nēsos, Menlo Park, CA, [9]Stanford University, Sunnyvale, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Treatments I: Novel RA Treatments & Mechanisms of Action
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Vagus nerve stimulation (VNS) has emerged in recent decades as a potential therapy for RA.We have previously shown that auricular VNS produced an average reduction of 1.4 in the disease activity score of 28 joints with C-reactive protein (DAS28-CRP) and significant improvements in the American College of Rheumatology (ACR) responses in an open-label study of 30 patients with active RA. Similarly, studies with an implantable cervical vagus nerve stimulator have shown reduced signs and symptoms of RA. However, studies to date have been relatively small and/or uncontrolled. The purpose of this study was to investigate the safety and efficacy of auricular vagus nerve stimulation for the treatment of RA in a randomized, double-blind, sham-controlled study.

Methods: This randomized, double-blind, sham-controlled trial enrolled patients aged 18-75 years with active RA who had failed or were intolerant of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and were naïve to biologic and/or targeted synthetic DMARDs. All patients received an auricular vagus nerve stimulator and were randomized 1:1 to active stimulation or sham. The primary endpoint was the proportion of patients achieving 20% improvement in American College of Rheumatology criteria (ACR20) at week 12. Secondary endpoints included mean changes in disease activity score of 28 joints with C-reactive protein (DAS28-CRP) and Health Assessment Questionnaire-Disability Index (HAQ-DI).

Results: A total of 113 patients received study therapy, and 101 patients (89.4%) completed the study visits through week 12. Baseline characteristics are shown in Table 1.

ACR20 responses at week 12 were not significantly different in patients receiving active unilateral stimulation versus sham: 25.0% for active stimulation vs 26.9% for sham (difference vs sham: -1.9% [-18.8% to 14.9%]; p=0.823) (Table 2 and Figure). The LS mean (SE) changes in DAS28-CRP from baseline to week 12 were –0.95 (0.16) for active unilateral stimulation and –0.66 (0.16) for sham, with a difference in LS means (SE) vs sham of –0.29 (0.23) (p=0.201) (Figure). The LS mean

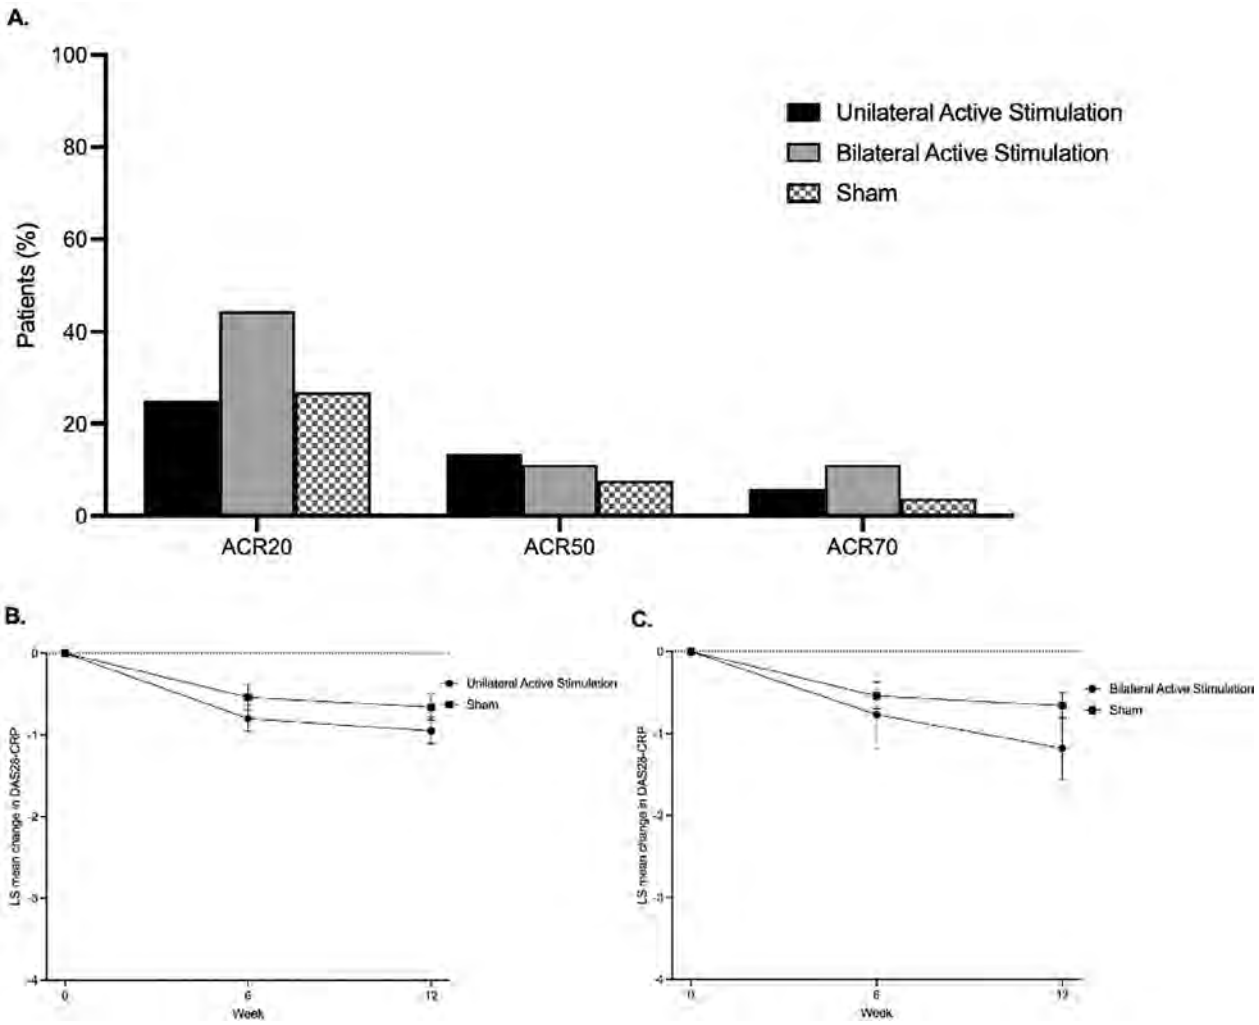

Figure. Primary and secondary efficacy end points. Panel A shows the percentage of patients who had 20% improvement in American College of Rheumatology response criteria (ACR20), 50% improvement (ACR50), and 70% improvement (ACR70) at week 12, respectively, with non-responder imputation. Panels B and C show the least square mean change from baseline in the 28-joint disease activity score based on the level of disease activity score in 28 joints using C-reactive protein (DAS28-CRP). For Panels B-C, a mixed-effects model with repeated measures was used to evaluate treatment effect on change from baseline with fixed effects for treatment, visit, and treatment-by-visit interaction and baseline value as a covariate. Comparison of bilateral active stimulation vs sham is a post-hoc analysis.

(SE) changes in HAQ-DI from baseline to week 12 were –0.19 (0.06) for active unilateral stimulation and –0.02 (0.06) for sham, with a difference in LS means (SE) vs sham of –0.17 (0.08) (p=0.044). No significant differences were seen in DAS28-CRP of 2.6 or less, ACR50, ACR70, CDAI, or SDAI between the unilateral active stimulation and sham groups (Table 2, Figure).

Treatment-emergent AEs were reported in 10 patients (18.9%) receiving unilateral active stimulation, 2 patients (22.2%) receiving bilateral active stimulation, and 5 patients (9.8%) receiving sham. No AEs were grade 3 or greater in severity by Common Terminology Criteria for Adverse Events, and no serious adverse events (SAEs) or deaths occurred.

Conclusion: Auricular VNS was safe and well tolerated, but it did not meaningfully improve RA disease activity. More large, controlled studies of VNS for the treatment of RA are needed to better understand its potential future role.

LS mean change from baseline (SE)	-16.67 (3.85)	-18.06 (8.99)	-8.33 (3.80)	-8.34 (5.41)[b]	-9.73 (9.76)[b]	0.126	0.321
CRP, mg/L							
Mean (SD)	9.57 (10.81)	8.79 (7.90)	19.80 (59.89)				
LS mean change from baseline (SE)	-4.14 (6.23)	-4.57 (14.69)	7.35 (6.12)	-11.49 (8.73)[b]	-11.92 (15.91)[b]	0.192	0.456

ACR = American College of Rheumatology; DAS28 = disease activity score in 28 joints; CRP = C-reactive protein; SD = standard deviation; LS = least squares; SE = standard error; CDAI = Clinical Disease Activity Index; SDAI = Simple Disease Activity Index; HAQ-DI = Health Assessment Questionnaire-Disability Index; TJC = tender joint count; SJC = swollen joint count; GADA = global assessment of disease activity.
[a]Percentage difference (95% CI).
[b]LS mean difference (SE).
For ACR20/50/70 and DAS28-CRP < 2.6, non-responder imputation was used. For all other endpoints, the analysis was based on a mixed model for repeated measures with fixed effects for treatment, visit, and treatment-by-visit interaction and baseline value as a covariate with no imputation for missing data.

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: RA – Treatments I: Novel RA Treatments & Mechanisms of Action

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The lymphatic system serves as a conduit for transporting immune cells and inflammatory molecules present in arthritic joints to lymph nodes (LN), playing a critical role in the pathology of RA[1], yet all bDMARDs are dosed systemically potentially limiting the delivery to the target site of action. Therefore, targeting bDMARDs, like etanercept, to joint draining lymphatics could increase neutralization of inflammatory molecules and reduce unwanted immune cell activation that propagates the inflammatory cascade in RA. Nanotopography-microneedles (NTM) have previously been shown to increase the infusion of etanercept into the peripheral lymphatics and draining LNs in collagen-induced arthritic rats[2]. Here we report results from a 10-patient Phase 1b clinical trial in RA patients with an inadequate response to 50 mg etanercept SC injections who were switched to 25 mg peripheral lymphatic infusions of etanercept via the NTM device. All patients had been on SC injections of etanercept for more than 3 months prior to the study.

Methods: The NTM device was applied to the dorsal forearm and 25 mg of etanercept was infused for 1.25 hours. Once weekly dosing was performed for the first 12 weeks, followed by biweekly and monthly dosing to explore reduced dose frequency in responding patients for a total of 36 weeks. The device was alternated between the left and right dorsal forearm every other dose. Lymphatic imaging was conducted using Near-Infrared Fluorescence with indocyanine green dye[2]to measure lymphatic pump rates before and after etanercept lymphatic infusions.

Results: Switching patients from weekly 50 mg SC injections to 25 mg NTM infusions significantly reduced global disease activity without drug delivery-related immune responses. DAS28(CRP) scores were reduced from 5.40 ± 0.16 to 3.55 ± 0.21 and Patient Global Assessment of Disease Activity and Pain decreased by 66% and 77%, respectively, in the first 12 weeks and remained stable as dosing frequency was reduced to biweekly and monthly dosing (Figure 1). SJC and TJC were concomitantly decreased and remained stable (Figure 1). Lymphatic pumping rates increased from 1.0 ± 0.2 to 2.9 ± 0.3 pumps/minute after 12 weeks and TNFα levels initially increased and were significantly reduced by week 36 (Figure 2). No SAEs were reported, and primary AEs consisted of mild erythema at the NTM infusion site.

Conclusion: The NTM device effectively infused etanercept into the peripheral lymphatics that drain to the LN. The NTM device was well accepted by all patients with an application pain rating of 3.8 ± 3.6 mm on a 100 mm VAS scale. DAS28(CRP) scores, 28TJC and 28SJC, and Global Disease Activity and Pain were improved in all patients infused with the NTM device at half the SC injection dose administered weekly, biweekly, and monthly. These results suggest that administering TNFα inhibitors to arthritic joint draining LN may reduce dose frequency and improve both TNFα neutralization and impaired lymphatic function, and reduce unwanted immune cell activation that contributes to the inflammatory cascade in RA.

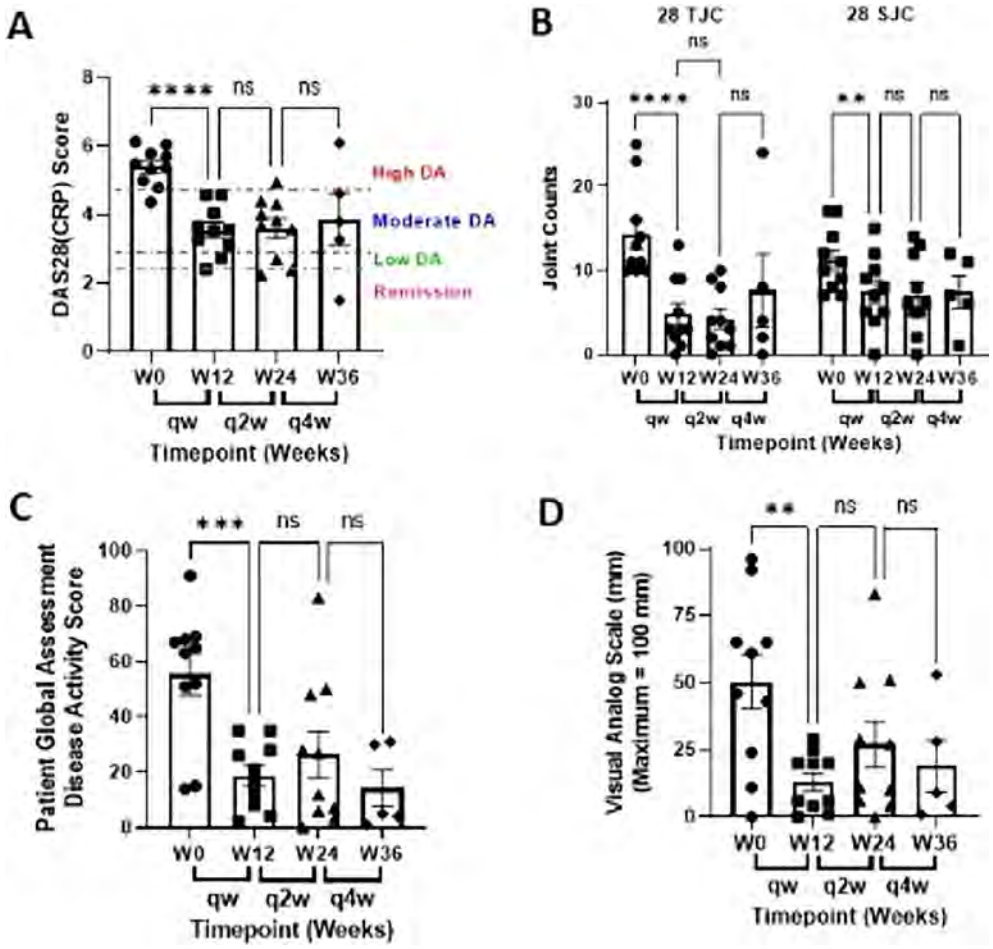

Figure 1: Disease Activity Scoring and Assessments in patients treated using lymphatic infusion of etanercept. A) DAS28(CRP) levels at W0 (baseline), W12, W24, and W36. W0 to W12 was weekly dosing (qw), W12 to W24 was bi-weekly dosing (q2w), and W24 to W36 was monthly dosing (q4w). B) 28 Tender Joint Counts (28 TJC) and 28 Swollen Joint Counts (28 SJC). C) Patient Global Assessment of Disease Activity, and D) Patient Assessment of Pain. Data represent mean ± SEM and *p<0.0332, **p<0.0021, ***p<0.0002, ****p<0.0001, ns denotes no significance.

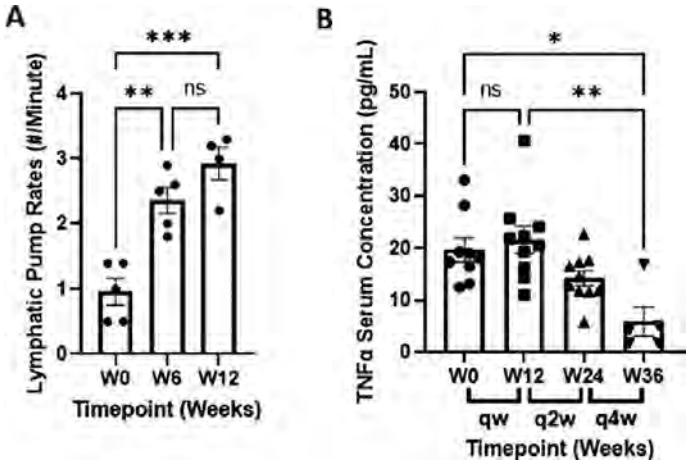

Figure 2. Lymphatic pumping rates and TNFα serum concentrations in patients treated using lymphatic infusion of etanercept. A) Lymphatic pump rates were measured by delivering ICG via the NTM device and performing visual inspection of lymphatic vessels and pumping at W0, W6, and W12. B) TNFα concentrations were measured at W0, W12, W24, and W36. W0 to W12 was weekly dosing (qw), W12 to W24 was bi-weekly dosing (q2w), and W24 to W36 was monthly dosing (q4w). Data represent mean ± SEM and *p<0.0332, **p<0.0021, ***p<0.0002, ****p<0.0001, ns denotes no significance.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: RA – Treatments I: Novel RA Treatments & Mechanisms of Action
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: RA is a chronic inflammatory disease associated with autoantibodies. Despite the use of targeted therapies, up to half of patients fail to achieve remission or low disease activity (LDA). Anti-citrullinated protein antibodies (ACPAs), key autoantibodies that predict progression of joint destruction in RA, are largely an immunoglobulin G (IgG)

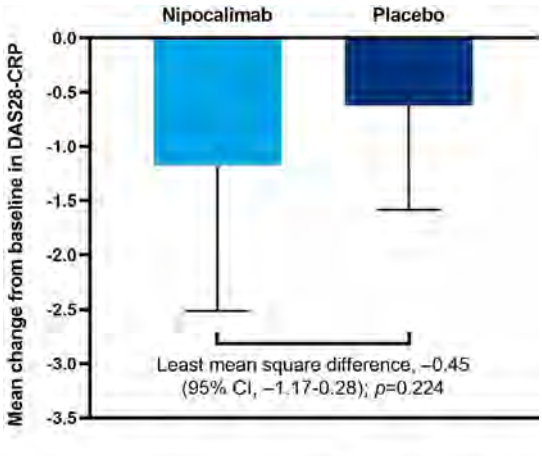

Figure 1. Change from Baseline in DAS28 (CRP) Score after 12 Weeks

isotype. Nipocalimab is a high affinity, fully human, IgG1 monoclonal antibody that is designed to selectively block the neonatal Fc receptor (FcRn), preventing recirculation and thereby lowering IgG levels, potentially including ACPAs and other pathogenic antibodies. In this phase 2a proof-of-concept study (IRIS-RA; NCT04991753), we report the efficacy and safety of nipocalimab in patients with moderate to severe, active RA.

Methods: Eligible adult patients with moderate to severe RA (≥6 swollen/tender joints), positive for ACPA or rheumatoid factor, and ≥1 advanced therapies, were randomized 3:2 to receive intravenous 15 mg/kg nipocalimab or placebo every 2 weeks for 10 weeks. The primary endpoint was the change from baseline in the Disease Activity Score 28 using C-reactive protein (DAS28-CRP) at Week 12. Secondary endpoints included the proportion of patients who achieved ACR20, ACR50, ACR70, and ACR90 responses, DAS28-CRP remission, and change from baseline in Health Assessment Questionnaire – Disability Index (HAQ-DI) at Week 12.

Table 1. Number of Patients Who Achieved ACR20, ACR50, ACR70, and ACR90 Responses at Week 12 Using CMH

Response, n (%)	Nipocalimab (n = 33)	Placebo (n = 20)	Treatment difference[a], % (95% CI)	*P* value
ACR20	15 (45.5)	4 (20.0)	27.0 (3.2-50.9)	0.055
ACR50	5 (15.2)	1 (5.0)	8.6 (–6.7-23.8)	0.390[b]
ACR70	4 (12.1)	0	11.6 (0.9-22.3)	0.285[b]
ACR90	2 (6.1)	0	5.8 (–2.0-13.6)	0.521[b]

[a]The treatment difference between nipocalimab versus placebo and the CIs was based on the Wald statistic with the CMH weight.
[b]The *p* value was based on the CMH chi-square test, stratified by random stratification factor; baseline MTX use. The Mantel Fleiss criterion was not satisfied with the indicated *p* values and was therefore based on the Fisher's exact test.
ACR, American College of Rheumatology; CI, confidence interval; CMH, Cochran-Mantel-Haenszel; MTX, methotrexate.

Table 2. Overall Summary of TEAEs

Patients, n (%)	Nipocalimab (n = 33)	Placebo (n = 20)
Patients with ≥1 TEAE	27 (81.8)	12 (60.0)
Related TEAEs[a]	12 (36.4)	3 (15.0)
Most common (≥10%) TEAEs		
Rheumatoid arthritis	9 (27.3)	6 (30.0)
Headache	4 (12.1)	1 (5.0)
COVID-19	4 (12.1)	0
Serious TEAEs	3 (9.1)	0
Related serious TEAEs	1 (3.0)	0
Burn infection	1 (3.0)	0
Infusion-related reaction	1 (3.0)	0
Deep vein thrombosis	1 (3.0)	0
TEAEs leading to treatment discontinuation	6 (18.2)	6 (30.0)
Related TEAEs leading to treatment discontinuation[a]	1 (3.0)	1 (5.0)
Infections and infestations	13 (39.4)	5 (25.0)
Related infections[a,b]	0	0
Burn infections[b]	1 (3.0)	0
Infusion reactions[c]	4 (12.1)	1 (5.0)
Infusion site reactions[b]	2 (6.1)	1 (5.0)
Hypersensitivity	3 (9.1)	0
Hypoalbuminemia (<20 g/L)	0	0
Markedly abnormal cholesterol	6 (18.2)	3 (15)

[a]Assessed by the investigator as related to study treatment.
[b]Assessed by the investigator.
[c]Temporally associated with infusion (during or within 1 hour of infusion).
TEAE, treatment-emergent adverse event.

Results: In total, 53 patients were enrolled (nipocalimab, n=33; placebo, n=20). Most patients were female (67.9%) and white (90.6%) with a median age of 59 (range, 26-74) years. Demographic and baseline disease characteristics were comparable between groups except higher CRP in placebo. At Week 12, patients treated with nipocalimab showed a numerically greater mean (standard deviation [SD]) change in DAS28-CRP score compared to the placebo group (–1.17 [1.34] vs –0.62 [0.96]; mean difference [95% confidence interval], –0.45 [–1.17-0.28]; p=0.224); **Figure 1**). A numerically higher proportion of patients achieved ACR20, ACR50, ACR70, and ACR90 responses compared to placebo (**Table 1**). In the nipocalimab group, 7 (21.2%) patients achieved DAS28-CRP remission compared to 2 (10.0%) patients in the placebo group (treatment difference, 9.9% [–9.5-29.3%]; p=0.456). Similarly, patients in the nipocalimab group had a numerically greater mean (SD) improvement in HAQ-DI score (–0.27 [0.55] vs –0.11 [0.36], respectively). Median post-dose serum nipocalimab concentrations ranged from 411.0-426.0 μg/mL across Weeks 0, 2, and 8. The proportion of patients with treatment-emergent adverse events (TEAEs) were 81.8% vs 60.0% in the nipocalimab vs placebo groups (**Table 2**). In the nipocalimab group, 3 serious TEAEs were reported, including burn infection, infusion-related reaction, and deep-vein thrombosis. There were no TEAEs that led to death.

Conclusion: Treatment with nipocalimab resulted in consistent and numerically higher improvements across ACR20, ACR50, ACR70, and ACR90 responses, as well as DAS28-CRP, DAS28-CRP remission, and HAQ-DI, with acceptable safety profile. Nipocalimab showed activity in patients with moderate to severe RA and warrants further investigation to understand the predictors of nipocalimab response.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: RA – Treatments I: Novel RA Treatments & Mechanisms of Action

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: None of the currently approved treatments for rheumatoid arthritis (RA) can achieve ACR50 in >50% of the patients, and 5 – 20% of the RA patients are considered "difficult to treat", failing ≥2 targeted therapies. TLL-018 is a highly selective dual JAK1/TYK2 inhibitor. Its TYK2 activity might contribute to efficacy in RA patients. The objective is to compare efficacy of TLL-018 with tofacitinib in RA patients.

Methods: 101 patients with moderate-to-severe active RA who had inadequate response or were intolerant to methotrexate were randomized (1:1:1:1 ratio) to receive twice-daily oral TLL-018 10mg, 20mg, 30mg or tofacitinib 5mg. After 12-weeks of treatment, patients who achieved ACR50 continue the same treatment, and those who didn't change treatment as follows: patients on tofacitinib and TLL-018 10mg change to TLL-018 20mg; patients on 20mg and 30mg change to or continue 30mg TLL-018 (Figure 1). The Primary endpoint is the proportion of patients achieving ACR50 at Week 12. Secondary endpoints include the proportion of patients achieving DAS28-CRP < 2.6, ACR20, ACR70 at all scheduled time points, ACR50 at scheduled time points exclude week 12, CDAI and other parameters at 12 week. Safety was assessed via adverse event (AE) and laboratory examinations.

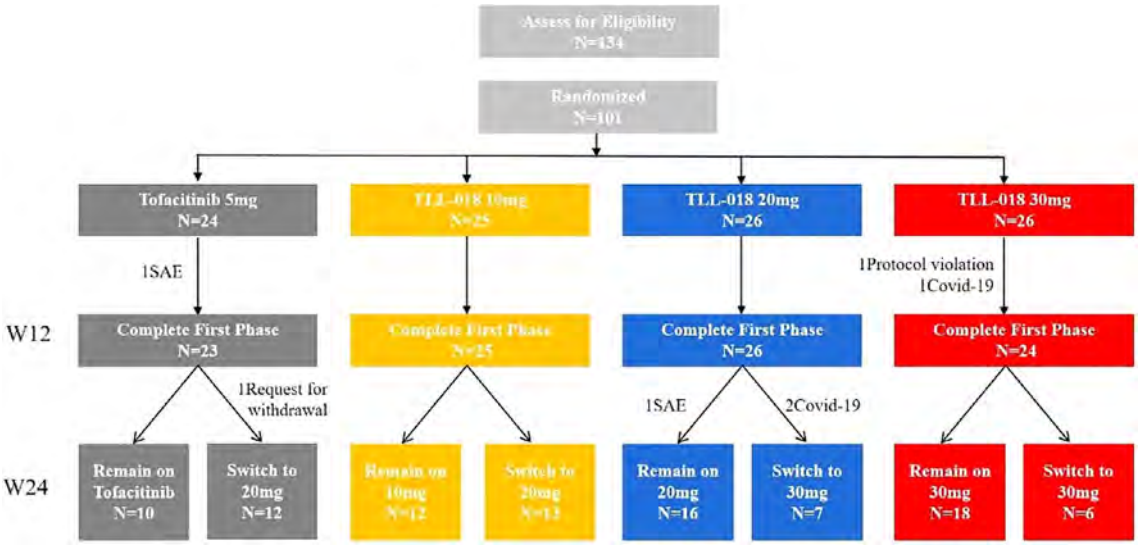

Figure 1: Trial design.

Table 1: Efficacy, number (%) of patients who achieved ACR50.

Cohort		Tofacitinib		TLL-018		TLL-018		TLL-018	
	Dose	5mg BID		10mg BID		20mg BID		30mg BID

	ACR50	10 (100.0)	5 (41.7)	10 (90.9)	4 (30.8)	12 (80.0)	4 (57.1)	17 (100.0)	3 (100.0)
Week 20	n (nmiss)	10 (0)	12 (1)	12 (0)	13 (0)	14 (3)	7 (0)	17 (1)	5 (1)
	ACR50	9 (90.0)	9 (75.0)	11 (91.7)	4 (30.8)	11 (78.6)	2 (28.6)	16 (94.1)	3 (60.0)
Week 24	n (nmiss)	10 (0)	12 (1)	12 (0)	13 (0)	15 (2)	7 (0)	18 (0)	6 (0)
	ACR50	8 (80.0)	10 (83.3)	11 (91.7)	5 (38.5)	12 (80.0)	3 (42.9)	18 (100.0)	4 (66.7)

Table 2: Safety, AEs of interest.

	Tofacitinib 5mg BID (N=24)	TLL-018 10mg BID (N=25)	TLL-018 20mg BID (N=26)	TLL-018 30mg BID (N=26)
ADR n (%)	19 (79.2)	16 (64.0)	23 (88.5)	20 (76.9)
Lipids abnormalities	10 (41.7)	10 (40.0)	13 (50.0)	12 (46.2)
Upper respiratory tract infection	2 (8.3)	3 (12.0)	3 (11.5)	3 (11.5)
Urinary tract infection	0	3 (12.0)	2 (7.7)	0
Herpes zoster	0	0	2 (7.7)	0
GI system	4 (16.7)	0	2 (7.7)	3 (11.5)
Peripheral edema	1 (4.2)	1 (4.0)	1 (3.8)	2 (7.7)
Anemia	1 (4.2)	0	3 (11.5)	1 (3.8)

Results: 101 patients were randomized, ~50% of them also had prior bDMARDs and ~30% had prior JAK inhibitors, but the responses to those treatments were unknown. Demographics and baseline disease characteristics were balanced across treatment arms. At week 12, ACR50 response rates in TLL-018 treated groups (10mg, 20mg and 30mg, 48.0%, 65.4%, 72.0%, respectively) were higher than that for tofacitinib (41.7%) (Table 1). TLL-018 20 and 30mg were statistically superior to tofacitinib ($p < 0.05$). Proportions of patients achieving clinical remission (DAS28-CRP< 2.6) at week 12 were 39.1%, 37.5%, 57.2% and 17.4% at week 12 for the 10, 20, 30mg TLL-018 and tofacitinib, respectively. TLL-018 20mg dramatically improved responses in patients who didn't achieve ACR50 on tofacitinib at week 12.

The most frequently reported treatment-emergent AEs were hyperlipidemia and respiratory infection in TLL-018 or tofacitinib-treated patients(Table 2). There were one case of malignancy in tofacitinib treatment group, and two cases of herpes zoster in the 20mg group. No death, venous thromboembolism or major adverse cardiovascular event was observed in the study.

Conclusion: TLL-018 20 and 30mg demonstrated superior efficacy over tofacitinib in RA patients, suggesting that inhibition of TYK2, in addition to JAK1, enhances efficacy. TLL-018 was well tolerated with most AEs being Grade 1 or 2 as expected from this class of compounds. No unexpected safety concerns were observed in the study. TLL-018 20 and/or 30mg BID warrants further studies in "difficult to treat" RA patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: AxSpA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: In the United States (US), the diagnosis of axial spondyloarthritis (axSpA) continues to be delayed by an average of 10 years from symptom onset. This diagnostic delay prevents effective management that controls disease activity, and maintains mobility, function, and quality of life. We developed the first SPARTAN recommendations for the referral of adults with chronic back pain to a rheumatologist for evaluation of axSpA by convening a multidisciplinary group comprised of clinicians that manage patients with back pain and conditions related to axSpA, expert rheumatologists and axSpA patient partners.

Methods: A systematic literature review (SLR) was conducted including studies through March 2022 to address individual clinical, laboratory, and imaging features associated with diagnosis or classification of axSpA. Sensitivity, specificity, positive likelihood ratios (LR+), and positive predictive values for each axSpA feature were calculated. At the 2022 SPARTAN annual meeting, members were asked the minimal probability of axSpA diagnosis that was appropriate for an adult with chronic back pain to be referred to a rheumatologist. In a Delphi exercise, members were asked to review test characteristics for each axSpA feature and to vote whether to include or exclude that feature in draft referral recommendations. Features gaining 70% consensus for inclusion were carried forward while those with consensus to exclude were omitted. Features that did not gain consensus for inclusion/exclusion were evaluated using discrete choice experiments (DCE). LR+ of individual axSpA features were used to calculate the probability of axSpA for combinations of features to develop draft referral recommendation for expert and stakeholder consideration. Draft recommendations in the form of a 'major and minor criteria', and a 'points-based' system were discussed and put to vote by SPARTAN members at the 2023 annual SPARTAN meeting.

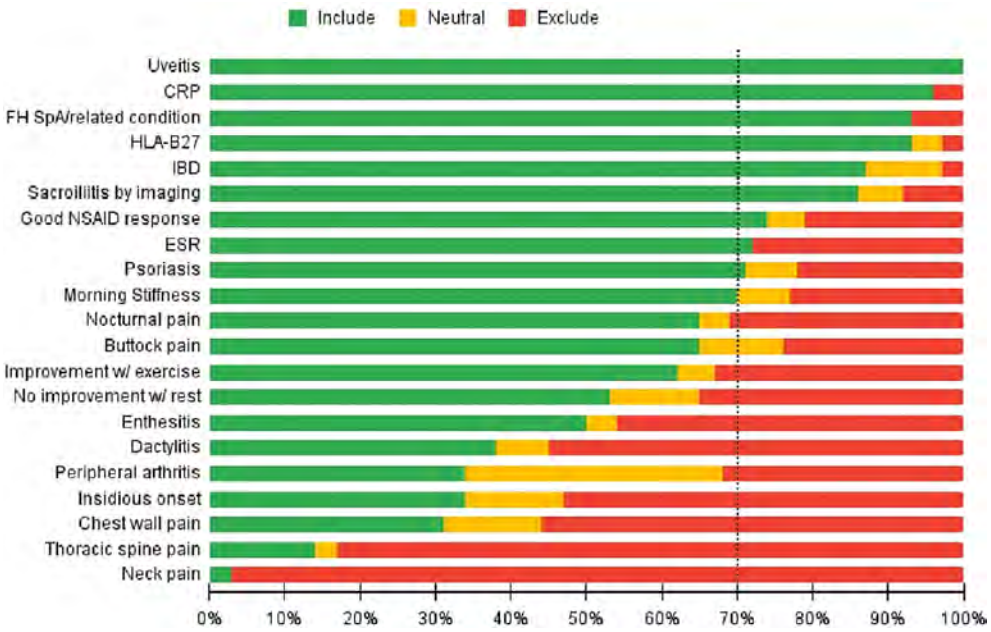

Figure 1. Delphi exercise results: AxSpA experts' votes for inclusion or exclusion of features in referral recommendations. Consensus was considered present if >70% voted to include or exclude.

Refer adults with chronic (>3 months) back/hip/buttock pain with onset before age 45 and a score of 3 or more	Points
X ray or MRI sacroiliitis	3
Elevated ESR or CRP	2
HLA-B27+	2
Uveitis	2
Inflammatory bowel disease	1
Psoriasis	1
Back pain has a good response to NSAIDs	1
Back pain improvement with exercise and not with rest	1
Alternating buttock pain	1
Family history of axial spondyloarthritis, uveitis, psoriasis or inflammatory bowel disease	1
Total	**Refer if score of 3 or more**

Figure 2. SPARTAN Draft Referral Recommendations for Axial Spondyloarthritis

Results: SLR uncovered 28 features associated with axSpA. LR+ ranged from 0.5 to 10. A probability of 33% or higher was considered adequate for referral by 90% of SPARTAN members. The Delphi process resulted in consensus to include: uveitis, elevated ESR or CRP, family history of SpA or a related condition, HLA-B27 positivity, inflammatory bowel disease (IBD), sacroiliitis by imaging, good response to NSAIDs and psoriasis (Figure 1). There was consensus to exclude neck pain and thoracic spine pain. DCE-derived relative importance values of several features were approximately half as important as uveitis. Eighty-six percent of SPARTAN members preferred a point-based referral strategy and 89% voted in favor of its adoption (Figure 2).

Conclusion: SPARTAN members and a diverse stakeholder group used a data-driven process to develop the first draft SPARTAN recommendations for referral of adults with chronic back pain to a rheumatologist for evaluation of axSpA. Validation is needed to determine if application of these recommendations leads to approximately 33% probability of axSpA among those referred, and ultimately whether diagnostic delay of axSpA is reduced through their implementation.

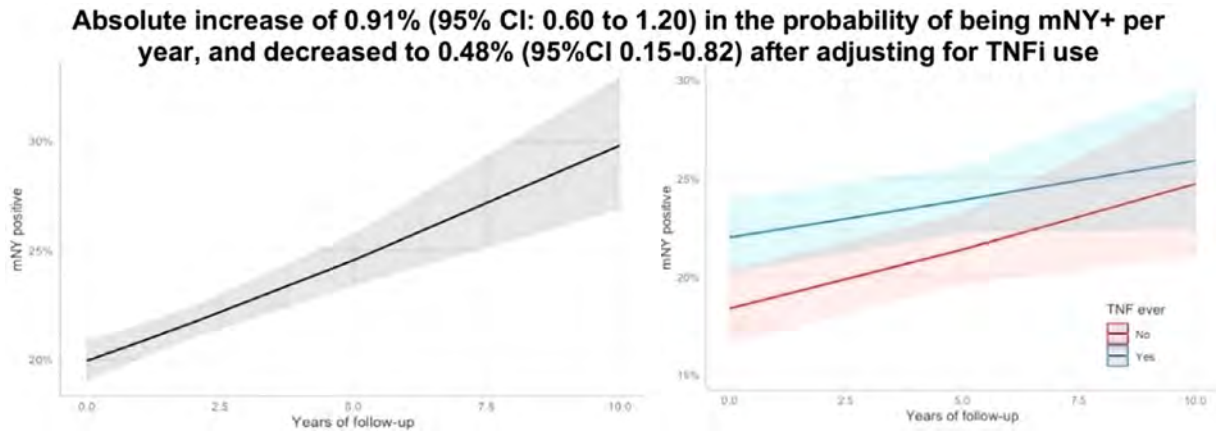
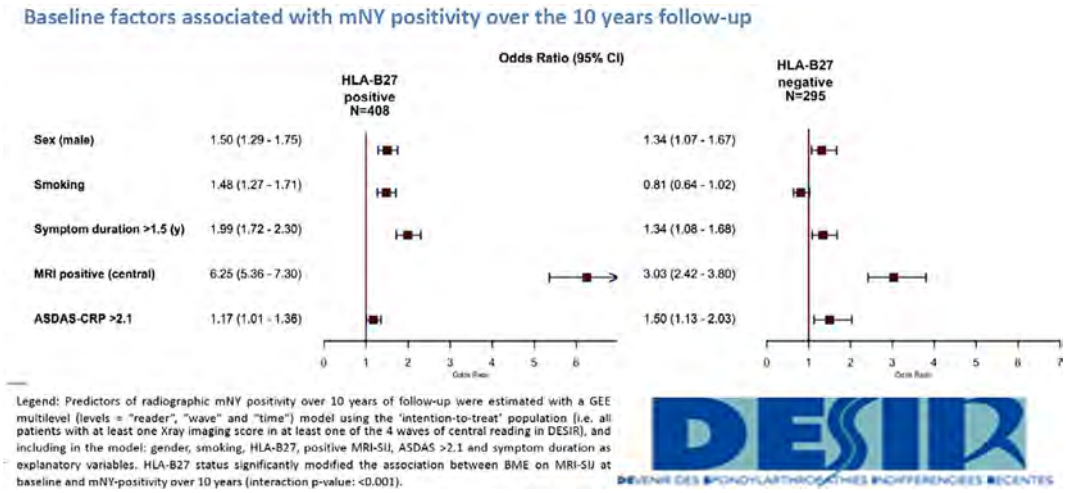
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: AxSpA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: The objective of this analysis was to evaluate the proportion of patients switching from non-radiographic axSpA (nr-axSpA) toradiographic axSpA (r-axSpA) after 10 years of follow-up and whether BME on MRI-SIJ at baseline is associated with the r-axSpA status over time.

Methods: Patients with ≤3 years axSpA onset from the DESIR cohort were included. The radiographic status of the patients (r-axSpA versus nr-axSpA) was based on the mNY criteria (i.e. at least a bilateral grade 2 or a unilateral grade 3 on pelvic radiographs according to 2 out of 3 central readers). BME on MRI-SIJ was defined as positive ASAS definition according to 2 out 3 central readers at baseline. Information on mNY criteria was obtained in four reading waves (0 to 10y). Images were scored by 3 trained central readers, all of them unaware of the chronology of the images and the results of the other modality. A "progressor" was defined as a patient switching from nr-axSpA to r-axSpA. A "regressor" was defined as a patient switching from r-axSpA to nr-axSpA. The % of mNY net progressors (i.e. number of "progressors" minus number of "regressors" divided by the total number of patients) was assessed in "completers" (i.e., with pelvic radiographs available at BL and 10y in wave 4). A sensitivity analysis was conducted using a multilevel GEE model ('integrated analysis') that included all waves from all patients with at least one available mNY score from at least one reader available ("intention-to-follow" population). From this model, we estimated the absolute change per year in the percentage of mNY positive cases with and without adjusting for the use of anti-TNF drugs. Finally, the effect of BME on MRI-SIJ at baseline on mNY positivity over 10 years, adjusting for potential confounders (Figure) were evaluated in a multivariable GEE model in the "intention-to-follow" population.

Results: Completers included 299 patients (mean age 34.5Y and 48.2% males), while the intention-to-follow population included 704 participants (mean age 33.7Y and 46.2% males). In the completers, the net % of progressors (switch from nr-axSpA to r-axSpA) was 5.7%. In the intention-to-follow population, there was a 0.91% (95%CI 0.60-1.20) increase per year in the probability of being mNY-positive (i.e. a progression of 9.1% after 10Y). After adjusting for anti-TNF use, this percentage decreased to 0.48% (95%CI 0.15-0.82) per year. The HLA-B27 status modified the association between BME on MRI-SIJ at baseline and mNY-positivity over 10 years (interaction pvalue: < 0.001). BME on MRI-SIJ was associated with being mNY positive over time in both HLA-B27 positive (OR 6.25 (95%CI 5.36-7.30)) and HLA-B27 negative patients (OR 3.03 (95%CI





2.42-3.80)), but the association was stronger in the former (Figure). In addition, male sex, symptom duration >1.5Y, ASDAS >2.1 (in HLA-B27 negatives) and smoking (in HLA-B27 positives) were also associated with being mNY-positive over 10 years.

Conclusion: Patients with early axSpA have a low likelihood of changing from nr-axSpA to r-axSpA over 10 years, especially when considering the use of anti-TNF. Local inflammation on MRI-SIJ is strongly associated damage accrual in the SIJ over time, in particular in patients who are HLA-B27 positive.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: AxSpA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The Assessment of Spondyloarthritis international Society MRI (ASAS MRI) group has proposed definitions for active and structural lesions typical for axial SpA (axSpA) on SI joint MRI (MRI-SIJ), based on high specificity and positive predictive values (PPV; ≥95%) for the rheumatologist's diagnosis of axSpA (Maksymowych et al., 2021). These

cut-offs have not been validated in other cohorts nor assessed in early disease. Here, we analyze the predictive validity of the proposed cut-offs for active and structural MRI-SIJ lesions in early axSpA after 2 years follow-up.

Methods: Patients with chronic back pain (unknown origin; ≥3 months; ≤2 years; onset < 45 years) from the SpA Caught Early (SPACE) inception cohort were followed-up and diagnosed (axSpA/no axSpA) by a rheumatologist after 2 years (Marques et al., 2023). Three central readers scored baseline MRI-SIJ for bone marrow edema (BME), erosion, fat lesions, and sclerosis. Patients with a certain (level of confidence about the diagnosis ≥7) or very probable (level of confidence < 7 and a consistent diagnosis in the last 2 available visits) diagnosis were included for analysis. When data were available for ≥2 readers, the MRI SIJ were analyzed for consensus between ≥2 readers on scored lesions and each individual reader. The lesions were assessed for quadrants, consecutive slices, or combinations between different lesions (Table 1 & 2). We calculated sensitivity, specificity, PPV and negative predictive values (NPV) for each cut-off. Based on consensus, a combination of specificity ≥95% and PPV ≥95% was required for a cut-off to be considered validated. For the individual readers, a PPV of ≥94% in ≥2 readers was accepted.

Results: We analyzed 447 patients (age 30 (SD 8) years; 45% males; 66% axSpA). BME in ≥1 quadrant, or ≥2 consecutive slices met the threshold based on consensus (Table 1). BME in ≥2 quadrants or ≥2 consecutive slices met the threshold in ≥2 individual readers (Table 1 & 2). Erosions in ≥2 quadrants or ≥4 consecutive slices, and fat in ≥1 quadrant or ≥2 consecutive slices met the threshold based on consensus. Erosion in ≥3 consecutive slices met the threshold in ≥2 individual readers, and fat in ≥2 quadrants or ≥3 consecutive slices met the threshold in all individual readers. All combinations of BME-fat met the threshold based on consensus (Table 1). Combinations of BME-erosions and fat-erosion in ≥1 quadrants,

Table 1. Predictive validity of the consensus between readers for singular active and structural lesions typical in axSpA, by assessing each definition against the rheumatologist's diagnosis at 2-year follow-up.

N=380; $N_{axial\ SpA}$=296; $N_{no\ axial\ SpA}$=151. The yellow color indicates a definition was proposed by the ASAS MRI group (Maksymowych et al., 2021). ✓ indicates that in ≥2 readers the cut-off has a specificity of ≥95% and positive predictive value of ≥94%. If definitions met the threshold in ≥2 readers, the readers' values are presented in blue. AxSpA: axial Spondyloarthritis; BME: bone marrow edema; PPV: positive predictive value.

each and/or one of both ≥2 quadrants, or ≥3 quadrants with fat lesions and/or ≥2 quadrants with erosion met the threshold based on consensus. Combined lesions did not outperform single item lesions.

Conclusion: In early axSpA, the proposed ASAS MRI cut-offs for active SIJ lesions have been validated in consensus and individual reading. For structural SIJ lesions, the proposed cut-offs for fat in quadrants and consecutive slices as well for erosions in quadrants have been confirmed. However, we propose a higher cut-off of ≥4 consecutive slices for erosions. All these cut-offs have now shown a high specificity and PPV in both early and established axSpA.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: AxSpA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: To assess whether posterior element (PE) inflammation, in particular in the facet joints (FJ), is associated with new facet joint ankylosis on MRI one year later, in patients with radiographic axial spondyloarthritis (r-axSpA).

Methods: Patients with an r-axSpA diagnosis recruited from Germany (Herne) and the Netherlands (Leiden) were included in the Sensitive Imaging in Ankylosing Spondylitis (SIAS) observational cohort when all following criteria were met: 1) presenting with ≥1 inflammatory lesion on MRI-spine according to SPondyloArthritis Research Consortium of Canada score, 2) presenting with 1-18 syndesmophytes (assessed with modified Stoke Ankylosing Spondylitis Spinal Score), and 3) fulfilling the modified New York criteria. Spinal MRIs were performed at baseline, after 1 year and after 2 years. PE inflammatory lesions and facet joint ankylosis were assessed on MRI, per vertebral unit level (VU) by 3 readers independently. FJ inflammation in the cervical spine was not assessed. With conditional probability tables the probability of developing facet joint ankylosis after one year was described. Multilevel time-lagged auto-regressive GEE was used for the association between PE (or FJ) inflammation and the development of facet joint ankylosis one year later, taking the reader and VU levels into account.

Results: In 58 patients MRI data of at least 2 readers was available. Their average age was 49±10 years and 85% was male. Inflammation in the PE or FJ at baseline was seen in 34 (58.6%) and 14 (24.1%) patients respectively. PE inflammation was distributed throughout the whole spine but emphatically more prevalent in the lower part of the thoracic spine (8.6%-15.5%). FJ inflammation was infrequently present, it was more often reported in the higher thoracic segment of the spine (1.7%-5.2%) (heatmap). Facet joint ankylosis was reported in 15 patients (25.9%) at baseline and in 17 patients (29.3%) with follow up visits. Facet joint ankylosis was mainly present in the upper half of the spine (heatmap). In 19 patients (32.8%) the development of new facet joint ankylosis over 1 or 2 years was seen by at least 1 reader.

	Baseline			1 year vitis			2 years vitis

23	0	0	0	1	0	0	2	0	1	23

The extent of posterior element lesions on MRI across the 23 vertebral units (VU) in radiographic axial spondyloarthritis patients with 2 years follow-up.

Table. Probability of developing facet joint ankylosis with and without posterior element inflammation present one year before, in r-axSpA patients from the SIAS cohort. PE; posterior elements, *; number of VU levels with inflammation in at least 1 part of the posterior elements (pedicle, facet joint, processes spinosi, soft tissue), #; number of facet joints, FJ; facet joint, P; probability

Inflammation in any part of the posterior elements			
PE inflammation	New facet joint ankylosis after one year	N*	P (FJ ankylosis/ PE inflammation)
0	0	7195	P (FJ ankylosis/0) = 43/7238 = 0.0059
0	1	43	
1	0	511	P (FJ ankylosis/1) =2/511 = 0.0039
1	1	2	
Inflammation only in the facet joint			
Facet joint inflammation	New facet joint ankylosis after one year	N#	P (FJ ankylosis/ FJ inflammation)
0	0	5934	P (FJ ankylosis/0) = 38/5972 = 0.0064
0	1	38	
1	0	93	P (FJ ankylosis/1) =1/94 = 0.0106
1	1	1	

Of the VU levels with PE or FJ inflammation only very few showed new facet joint ankylosis after one year; 2 and 1 VU levels, respectively (table). There was no association between PE inflammation and the development of new facet joint ankylosis in the same level after one year (OR=1.15, 95%CI 0.55-2.42). However, FJ inflammation was associated with the development new facet joint ankylosis one year later (OR=3.79, 95%CI 1.47-9.75).

Conclusion: PE inflammation and facet joint ankylosis on MRI were uncommonly present in r-axSpA patients. No association was found between inflammation in the PE and the development of facet joint ankylosis. However, when inflammation in the FJ is present the likelihood of developing facet joint ankylosis after 1 year is over 3 times higher compared to FJ without inflammation. This finding adds to the pathophysiological relationship between inflammation and damage at the same anatomical location.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: AxSpA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: We have shown in the SPACE cohort that a diagnosis of early axial Spondyloarthritis (axSpA) can be reliably made in patients with chronic back pain (CBP) of less than two years (2y). However, diagnostic uncertainty can be an obstacle to initiating appropriate treatment. The value of repeated assessments of SpA features for a definite diagnosis is yet to be determined. Here we aimed to assess the yield of repeated assessments of SpA features over 2y to make a *definite axSpA* diagnosis in patients with recent onset CBP referred to the rheumatologist, and to describe the characteristics of patients who change to *definiteaxSpA* over time.

Methods: We used the 2y data from the SPACE cohort, a European multicentre inception cohort of patients (< 45y) with CBP of recent onset (≥3 months, ≤2y) included from 2008 to 2016. The diagnostic work-up consisted of patient history, physical exam, acute phase reactants (APR) and HLA-B27 testing, radiographs, and MRI of the sacroiliac joints (SI-CR and SI-MRI) and of the spine (not shown). In patients with ≥1 major or ≥2 minor prespecified SpA features, clinical assessments, APR, and imaging were repeated at 3 months, 1y and 2y visits. At each visit, the rheumatologist reported a clinical diagnosis of *axSpA* or *no axSpA* with level of confidence (LoC; numeric rating scale from 0 (*not confident at all*) to 10 (*very confident*)). Herein, we categorized patients by diagnosis likelihood (baseline and 2y definitions in ***Figure 1***). The ASAS classification criteria were applied using local reading. We explored the diagnostic course over 2y. In patients with a new diagnosis of *definite axSpA* at 2y, SpA features were investigated over time.

Results: We included 552 patients. *Definite axSpA* was attributed to 175 (32%) patients at BL and 165 (30%) at 2y (***Figure 2***), 155/175 (89%) and 145/165 (87%) fulfilled ASAS classification criteria, respectively. Of the 175 patients with *definite axSpA* at BL, 133 (76%) retained the diagnosis, and only 11 (6%) changed to *no axSpA* at 2y. Although still considered as axSpA by the rheumatologist, 31/175 (17%) *definite axSpA* patients at baseline were no longer *definite axSpA* at 2y, due to a decrease in LoC < 7 (n=14/31) or incomplete follow-up (n=17/31). Overall, the diagnosis changed to definite axSpA over 2y in 32 patients (BL: 16 uncertain axSpA, 11 uncertain no axSpA, and 5 definite no axSpA); on average, 3 to 4 SpA features were already present at BL and 1 new SpA feature developed over 2y (***Table 1***), with response to NSAIDs (9/24 patients) and MRI sacroiliitis (8/24 patients) being the most frequently developed over time. Of the 8 patients with new MRI sacroiliitis over time, 7 (88%) were HLA-B27+ and 5 (63%) were male.

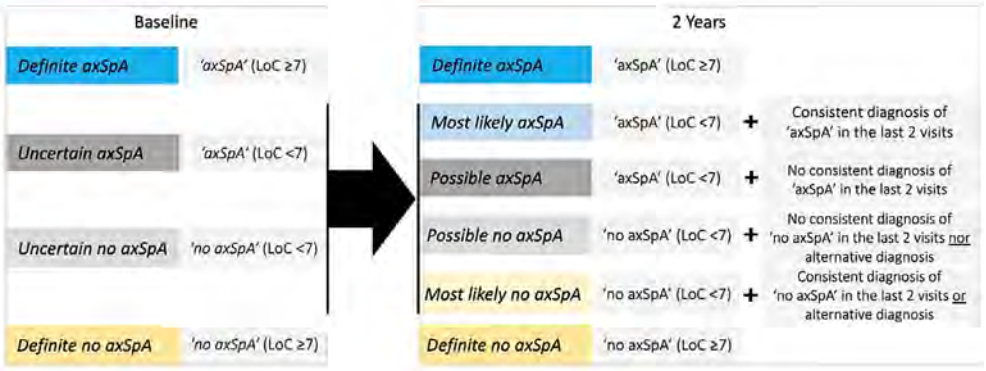

Figure 1. Definitions for diagnostic categories at baseline and at two years. If two-year visit data was missing, a last observation carried forward approach was used. axSpA – axial Spondyloarthritis; LoC – level of confidence.

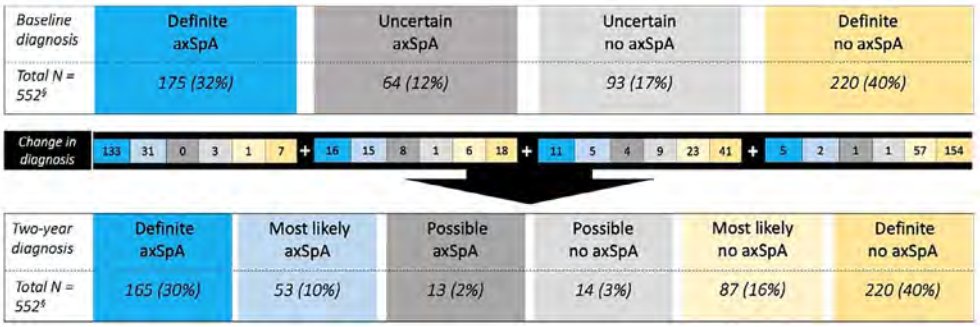

Figure 2. Course of diagnosis from baseline to two years in patients with recent onset chronic back pain of unknown origin. axSpA – axial Spondyloarthritis.

Table 1. Characteristics of 32 patients changing to definite axSpA with newly developed SpA features over 2 years Data presented as mean (SD), % or n of patients. §Local readings. ^including HLA-B27 positivity and sacroiliitis on imaging. $Of the 32 patients, 24 (75%) developed new SpA features over time. #Cumulative numbers over the two-year follow-up. BL – baseline; MRI – magnetic resonance imaging.

Baseline diagnosis	Uncertain axSpA at BL N=16		Uncertain no axSpA at BL N=12		Definite no axSpA at BL N=5	
	BL	2Y#	BL	2Y#	BL	2Y#
Age at inclusion, years	30.3 (8.6)	-	35.1 (7.9)	-	25.8 (6.1)	-
Male	50%	-	73%	-	40%	-
Symptom duration, months	12.7 (6.8)	-	12.5 (6.8)	-	12.0 (4.7)	-
HLA-B27 +	81%	-	55%	-	80%	-
Family history of SpA	8	9	3	4	3	4
Inflammatory back pain	14	15	6	7	5	5
Good response to NSAIDs	4	10	5	7	3	4
Peripheral manifestations	4	8	1	3	1	2
Extra-musculoskeletal manifestations	4	6	3	4	0	1
Increased acute phase reactants	4	4	1	3	2	2
Sacroiliitis on radiographs§	0	0	1	2	0	1
Sacroiliitis on MRI§	3	8	3	5	0	1
Total nr of SpA features^	3.4 (1.1)	4.6 (1.4)	2.6 (1.0)	3.7 (1.3)	3.6 (0.5)	4.8 (0.8)
Nr of new SpA-features over follow-up^§	-	1.3 (1.0)	-	1.1 (0.9)	-	1.2 (0.8)
ASAS classification criteria	-	81%	-	58%	-	80%

Conclusion: The yield of repeated assessments of SpA features in patients with CBP suspected of axSpA was modest for the increase of new *definite axSpA* diagnosis at 2y. Most SpA features were already present at BL, with sacroiliitis on MRI and response to NSAIDs being the two most frequently incident SpA features potentially adding to a *definite axSpA* diagnosis over time. Usefulness of repeating MRI in terms of diagnostic yield is low but can be considered in HLA-B27+ patients, especially if male.

D, Correlation between PDGFB and BASFI. E, Correlation between PDGFB and ΔmSASSS in Chinese AS patients in validation II-40. F, Expression level of PDGFB secreted from monocytes after stimulation with M-CSF and RANKL for 7 days, which were analysed by ELISA. G, Collagen expression of FOB1.19 in the two groups (PDGF-, PDGF+). H, Relative protein level of collagen expression in FOB1.19 in the two groups (PDGF-, PDGF+). The expression levels of cytokines and the relative protein levels were compared by unpaired sample t-tests. *** $P < 0.005$, ** $P < 0.01$.

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease that mainly affects the sacroiliac joint and spine. However, the real mechanisms of immune cells acting on syndesmophyte formation in AS are not well identified. We aimed to find the key AS-associated cytokine and assess its pathogenic role in AS.

Methods: A protein array with 1000 cytokines was performed in five AS patients with the first diagnosis and five age- and gender-matched healthy controls to discover the differentially expressed cytokines. The candidate differentially expressed cytokines were further quantified by multiplex protein quantitation (3 AS-associated cytokines and 3 PDGF-pathway

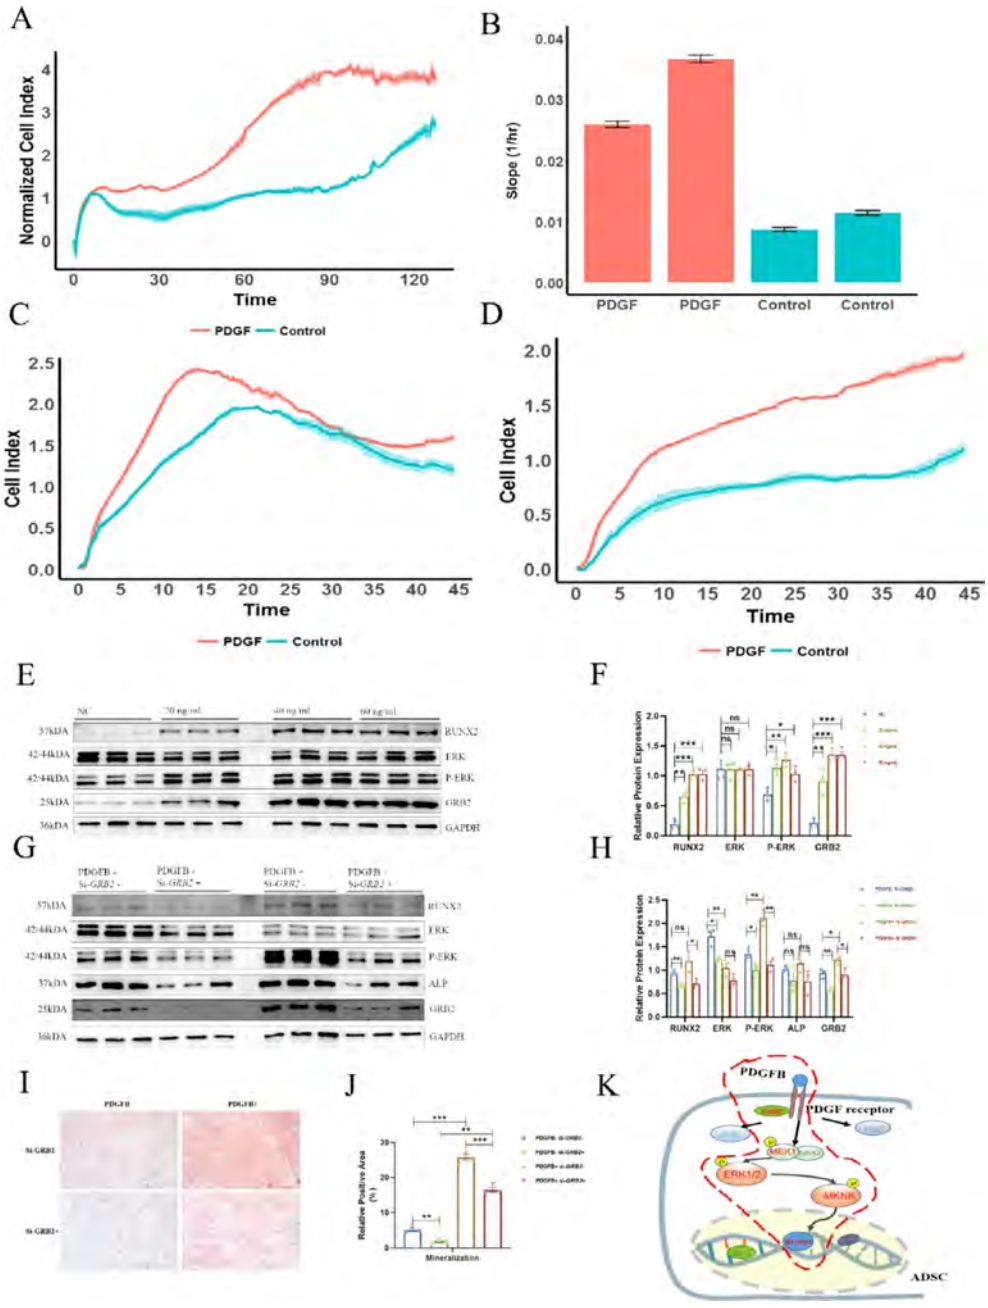

Figure 2 Effects of PDGFB on ADSCs. A, Proliferation in the two groups. B, Slope of proliferation in the two groups. C, Chemotaxis in the two groups. D, Migration results for the two groups. E-F, PDGFB activated the GRB2-pERK-RUNX2 axis in a dose-dependent manner. G-H, Western blot of several key molecules in the GRB2-pERK-RUNX2 axis with/without the treatments of PDGFB and si-GRB2. I-J, The mineralization ability of ADSCs with/without the treatments of PDGFB and si-GRB2, examined by Alizarin red S staining. K, Differential enrichment of phosphopeptides in ADSCs. MEK1, ERK1/2 and MKNK were identified as differentially phosphorylated in the MAPK pathway. The gene and protein levels were compared by unpaired sample t-tests. *** $P < 0.005$, ** $P < 0.01$, * $P < 0.05$.

cytokines) and ELISA (PDGFB) in independent samples (a total of 140 AS patients vs 140 healthy controls). The effects of PDGFB, the candidate cytokine, were examined by using adipose-derived stem cells (ADSCs) and human fetal osteoblast cell line (hFOB1.19) as *in vitro* mesenchymal cell and preosteoblast models, respectively. Furthermore, whole-transcriptome sequencing and enrichment of phosphorylated peptides were performed by using cell models to explore the underlying mechanisms of PDGFB. The xCELLigence system was applied to examine the proliferation, chemotaxis, and migration abilities of PDGFB-stimulated or -unstimulated cells.

Results: The PDGF pathway was observed to have abnormal expression in the protein array, and PDGFB expression was further found to be up-regulated in 140 Chinese AS patients (Figures 1A-C). Importantly, PDGFB expression was significantly correlated with BASFI (Pearson coefficient/p value = 0.62/6.70E-8) and with the variance of the mSASSS score ($mSASSS_{\text{two years} - \text{baseline}}$, Pearson coefficient/p value = 0.76/8.75E-10) (Figures 1D-E). In AS patients, preosteoclasts secreted more PDGFB than the healthy controls (p value = 1.16E-2) (Figure 1F), which could promote ADSCs osteogenesis and enhance collagen synthesis (COLI and COLIII) of osteoblasts (hFOB 1.19) (Figures 1G-H). In addition, PDGFB promoted the proliferation, chemotaxis and migration of ADSCs (Figures 2A-D). Mechanismly, in ADSCs, PDGFB stimulated ERK phosphorylation by upregulating GRB2 expression, and then increased the expression of RUNX2 to promote osteoblastogenesis of ADSCs (Figures 2E-K).

Conclusion: PDGFB stimulates the GRB2/ERK/RUNX2 pathway in ADSCs, promotes osteoblastogenesis of ADSCs, and enhances the extracellular matrix of osteoblasts, which may contribute to pathological bone formation in AS.

Abstract Number: 0847

Development of an IFN 5-Gene Signature Score to Identify IFN-high and IFN-low Subsets and as a Pharmacodynamic Biomarker for Deucravacitinib Treatment in a Phase 2 Trial in Patients with Systemic Lupus Erythematosus

Chun Wu[1], Yanhua Hu[1], Mary K. Crow[2], Amit Saxena[3], Cristina Arriens[4], Coburn Hobar[1], Adrian Coles[5] and Ian M. Catlett[6], [1]Bristol Myers Squibb, Princeton, NJ, [2]Hospital for Special Surgery, New York, NY, [3]NYU Langone, New York, NY, [4]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Department of Arthritis & Clinical Immunology, Oklahoma City, OK, [5]Bristol Myers Squibb, Lawrenceville, NJ, [6]Bristol Myers Squibb, Pennington, NJ

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: Biomarkers
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Elevated IFN activity is observed in a subset of lupus subjects suggesting that those with higher levels of IRGs may benefit from interferon targeted therapies, however, to date responses by this dichotomization have been inconsistent. Tyrosine kinase 2 (TYK2) mediates cytokine pathways (eg, type I IFN, IL-12 and IL-23) linked with SLE pathogenesis. Deucravacitinib is a first-in-class, oral, selective, allosteric TYK2 inhibitor and was found to be efficacious in a phase

2 SLE trial.[1] We developed a customized IFN 5-gene signature score, assessed the pharmacodynamic effects of deucravacitinib on the IFN score, and evaluated the score's association with SLE disease activity and clinical response in the phase 2 trial (NCT03252587).

Methods: Patients were randomized equally to placebo or deucravacitinib (3 mg twice daily [BID], 6 mg BID, or 12 mg once daily [QD]). DxTerity chemical ligation-dependent probe amplification was used to measure 51 immune system–related genes from whole blood. IFN genes were selected based on distribution, correlations, hierarchical clustering, and consistency of k-means clusters. Serum proteins, blood cell subsets, and antibodies were measured by immunoassays and flow cytometry. Systemic Lupus Erythematosus Responder Index-4 (SRI[4]) and British Isles Assessment Group–based Composite Lupus Assessment (BICLA) were measured at weeks 32 and 48.

Results: An IFN 5-gene (*MX1*, *HERC5*, *IFIT1*, *RSAD2*, and *EIF2AK2*) signature score was identified and used to classify patients into IFN-high or IFN-low subgroups (Figure 1). Higher baseline score was associated with higher baseline SLEDAI and Cutaneous Lupus Erythematosus Disease Area and Severity Index scores, higher IFN activity biomarker (eg, IFNα, IFNλ, B-cell activating factor, C-X-C motif chemokine ligand 10) and anti–double-stranded DNA levels, and lower complement and lymphocyte counts. Deucravacitinib reduced the IFN score from weeks 4 through 44 by > 50%. Patients with high IFN

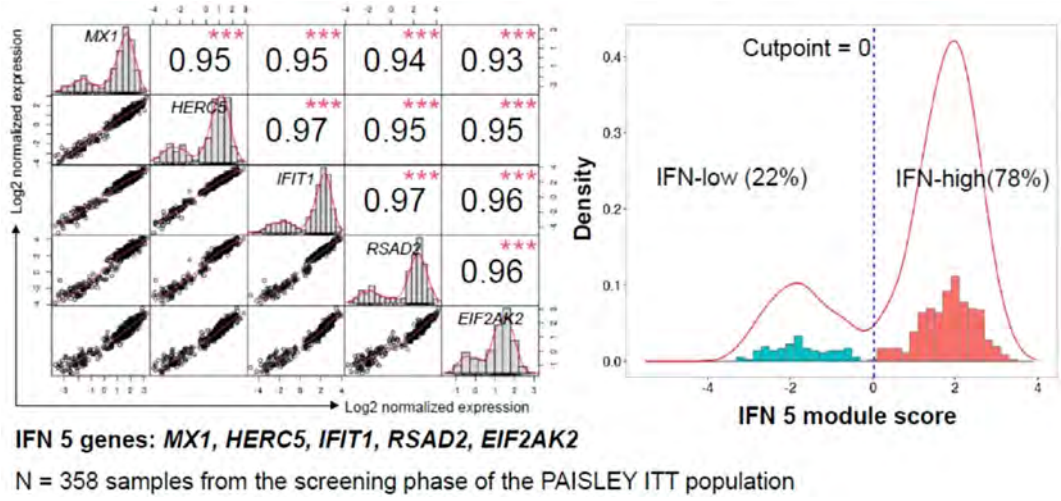

Figure 1. IFN 5-gene signature score with k-means clustering–derived cut point in the PAISLEY trial

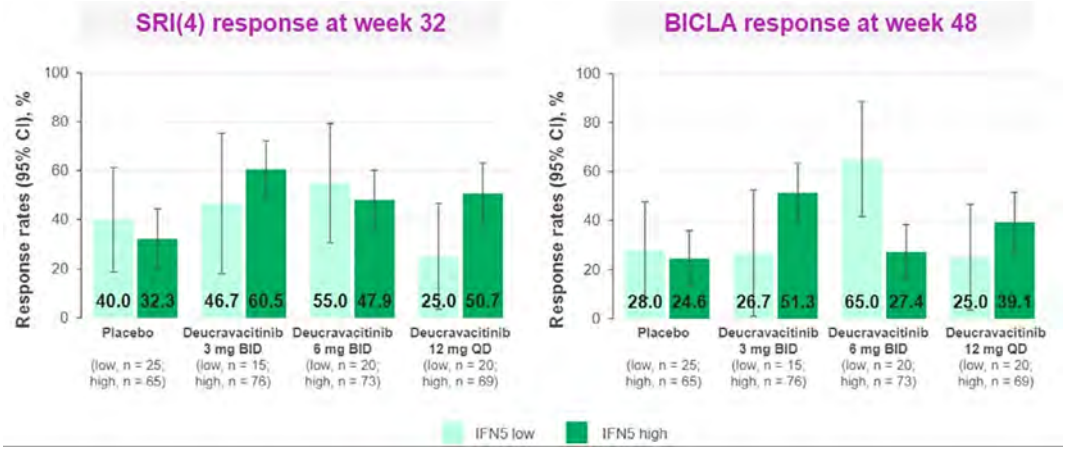

Figure 2. Clinical response by IFN 5-gene score subgroup

scores had numerically higher SRI(4) response rates at week 32 and BICLA response rates at week 48 in the 3-mg BID and 12-mg QD dose groups, but not in the 6-mg BID group, compared with patients with low IFN score (Figure 2).

Conclusion: These data support the IFN 5-gene signature score as a biomarker to classify patients with SLE into IFN-high or IFN-low subgroups; however, clinical response by IFN score was inconsistently improved. IFN-regulated gene expression performs well as a pharmacodynamic biomarker to confirm deucravacitinib mechanism of action and to aid in phase 3 dose selection.

Performance of Serum MRP8/14, sCD14, IL-6 and Neutrophil CD64 in Isolation and in Combination for Differentiating Flare from Bacterial Infection in Febrile SLE Patients

Kishan Majithiya[1], Komal Singh[1], Pankti Mehta[2], Chengappa Kavadichanda[3], seema Sharma[1], Able Lawrence[1] and **Amita Aggarwal**[1], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Lucknow, India, [2]King George's Medical University, Mumbai, India, [3]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: Biomarkers
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Disease flare and infections are the major causes of fever in a patient with SLE. It is vital to differentiate between these two as escalation of immunosuppressive treatment can be disastrous in a patient with infection. A low-cost calculator was recently described for differentiation (*Lupus. 2022;31:1254-1262*). Newer biomarkers are being explored and data on sepsis markers like MRP8/14, IL-6, sCD14 and neutrophil CD64 is limited in SLE. Thus, we evaluated these 4 markers in febrile SLE patients for their utility as well as their ability to improve performance of this low-cost calculator.

Methods: Patients with SLE who had fever of more than 2 days, but less than 2 weeks duration were included in the study. Patients were evaluated in detail for infection and fever episode was classified as infection, disease activity or combination of both. Complete blood counts, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), procalcitonin, complement C3 and C4, anti-dsDNA antibodies were measured. In addition, soluble CD14 (sCD14), Myeloid related protein (MRP) 8/14 and interleukin (IL)-6 were measured by ELISA. neutrophil CD64 expression was measured by flowcytometry and is expressed as % of neutrophil expressing CD64.

Among patients with infection episode and disease flare the variables were analyzed using Mann Whitney-U test for continuous and chi-square for categorical variables respectively, ROC curve analysis was used for test performance.

Results: 156 episodes of fever were studied. The mean age of the patients was 26.8 years while the mean duration of disease was 3.5 years. Among 156 episodes, 52 were because of infection while 65 were related to disease flare and 38 were due to combination of two and 1 due to malignancy.

Among 52 patients with infection, 46 had bacterial infection, 4 had tuberculosis and 1 each had fungal and viral infection. Among patients with bacterial infection, the site of infection was lower respiratory tract in 17, urinary tract infection in 14, skin and soft tissue in 3, meningitis in 2 and gastrointestinal in 4 and others in 6.

Patients with infection had higher CRP, procalcitonin, neutrophil to lymphocyte ratio while patients with disease activity had lower C3, C4 and higher anti-dsDNA antibodies and SLEDAI2K (Table 1).

Table 1: Comparison between bacterial infection and disease flare group

	Infection (n=46)	Disease flare (n=65)	p
Age(mean) (years)	29.26±12.21	24.62±8.54	0.02
Gender Female	39	61	0.11

51- 100	5	7	
>100	19	51	
Procalcitonin(ng/ml)	10.8±27.46	0.79±2.20	0.0067
C3 (mg/dl)	94.30±42.25	60.5±31.60	0.0001
C4 (mg/dl)	23.23±14.76	14.21±9.65	0.0002
Number with low C3 or C4	22	52	0.0009
SLEDAI 2K	5.58±6.27	14.14±9.31	<0.0001
SLEDAI2KG	8.58±7.46	7.61±10.29	<0.0001
MRP8/14(µg/ml)	19.87±22.28	49.31±109.60	0.15
Soluble CD14(µg/ml)	6.84±4.72	5.37±2.67	0.04
IL-6 (pg/ml)	53.33±79.62	56.98±136.5	0.87
Neutrophils expressing CD64 (%)	73.84±38.02	66.93±36.14	0.38

SLEDAI 2K- Systemic Lupus Erythematosus Disease Activity Index 2000.

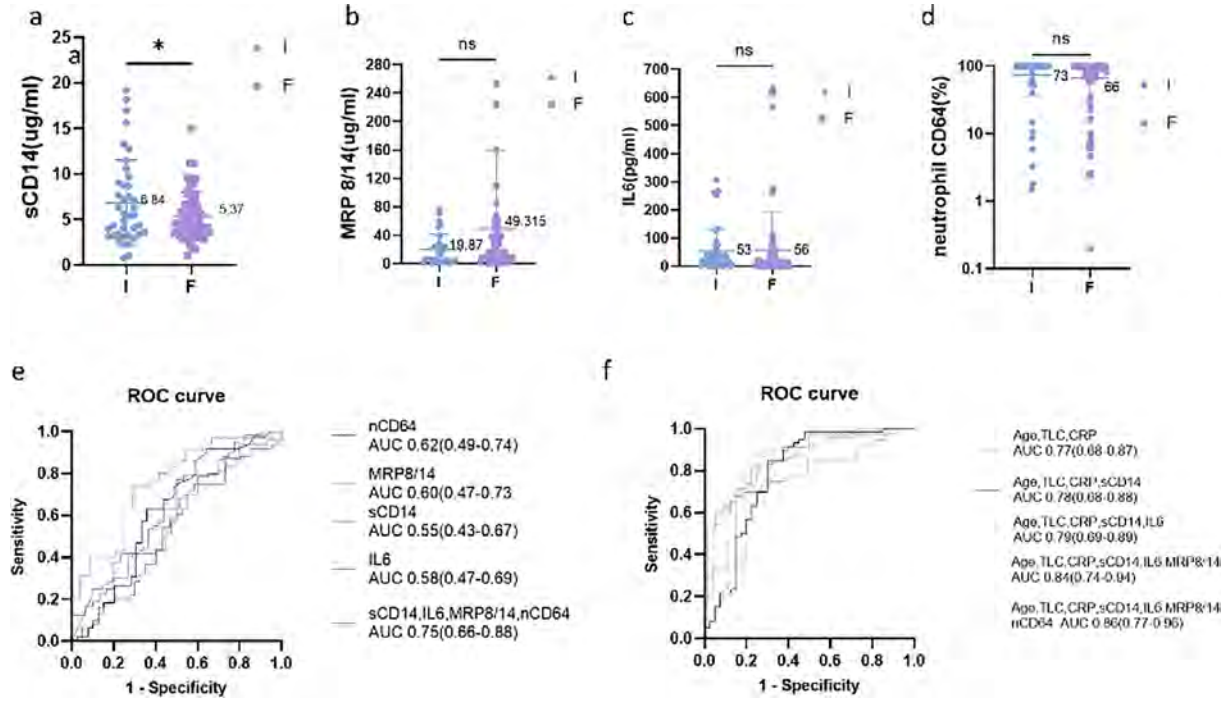

Figure 1: Scatter plot showing differences in level of a) sCD14 b) MRP8/14 c) IL-6 and d) neutrophil CD64 between patients with infection and flare. Panel e depicts the ROC curve for the 4 markers and their combination. Panel f shows the ROC curve for addition sCD14 alone and in combination with other new biomarkers to low cost biomarker panel.

The levels of sCD14 were higher in patients with infection whereas the level of IL-6 and MRP8/14 were no different between the two groups. Neutrophil CD64 expression was also not different between the two groups. (Figure 1a-d).

On ROC curve analysis the new biomarkers had AUC between 0.55 to 0.62 and in combination they had an AUC of 0.75. (Figure 1e). When three or all of the newer biomarkers were added to a recently described calculator comprising of age, TLC, and CRP, it improved its performance from AUC of 0.77 to 0.86. (Figure 1f)

Conclusion: Newer biomarkers of sepsis like MRP8/14, IL-6, sCD14 and neutrophil CD64 expression in combination have modest performance to differentiate flare from infection. Addition of these biomarkers in combination improved the accuracy of recently described calculator.

Multiplex Profiling and Machine Learning Reveal Distinct Signatures of Circulating Cytokines Associated with Autoantibody Profiles and Disease Severity in Systemic Lupus Erythematosus

Sarit Pattanaik[1], Ratnadeep Mukherjee[2], Rina Tripathy[3], Birendra Prusty[4], Balachandran Ravindran[5] and Bidyut Das[6], [1]SCB Medical College and Hospital, Cuttack, Odisha, Cuttack, India, [2]Norwegian Institute of Public Health, Oslo, Norway, [3]Sardar Vallabhbhai Patel Post Graduate Institute of Pediatrics, Cuttack, India, [4]Fisheries & Animal Resources Development Department, Phulbani, India, [5]Institute of Life Sciences, Bhubaneswar, India, [6]SCB medical college, Cuttack, India

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: Biomarkers
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: SLE is one of the leading causes of death in young females suffering from autoimmune disorders. Nephritis, afflicts 60-70% of patients which contribute significantly to morbidity and mortality despite therapeutic advances. Disrupted cytokine networks and autoantibodies play an important role in disease pathogenesis. However, conflicting reports and non-reproducibility have hindered progress with regards to translational potential of cytokines. This study attempts to address the existing knowledge gap using a multiplex cytokine assay and machine learning algorithms.

Methods: 69 SLE patients fulfilling SLICC criteria were recruited. Baseline characteristics along with disease activity was recorded for all patients. Cytokines were measured by a commercially available multiplex cytokine kit (Millipore). Fluorescence values were logarithmically transformed before analysis. To visualize relationships between cytokines, Network graphs were constructed based on Spearman correlation values. For stratifying individuals based on cytokine profiles, we used Sparse Partial Least Squares Discriminant Analysis (sPLS-DA) followed by factor loadings plots to assess which cytokines contribute most to the observed differences between groups. Patterns of co-occurrence of autoantibodies within the SLE patients were identified by the K-Modes algorithm and the patients were visualized on a dimensionally reduced plot obtained by constructing a 2-dimensional representation by multiple correspondence analysis (MCA).

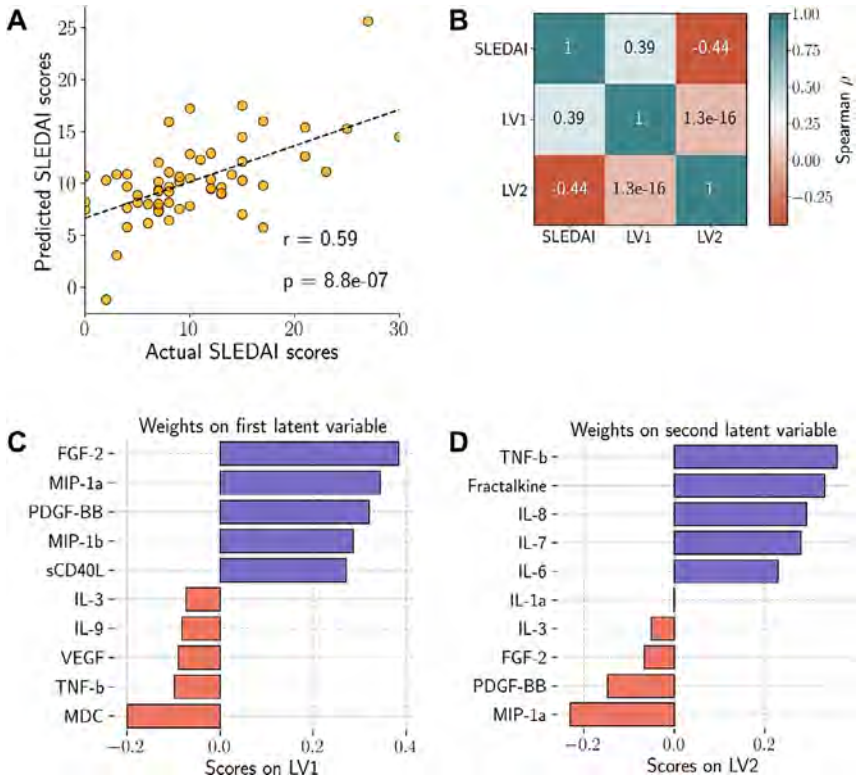

Figure 1: Combined cytokine response in SLE is predictive of disease severity. (A) Correlation between observed vs. predicted SLEDAI scores in patients with SLE. The SLEDAI scores were predicted from a PLSR model with cytokines. (B) Correlation of SLEDAI scores with the first two components of the PLSR model. (C) Cytokine contributions towards the first PLSR component (LV1: Latent variable 1). (D) Cytokine contributions towards the second PLSR component (LV2: Latent variable 2).

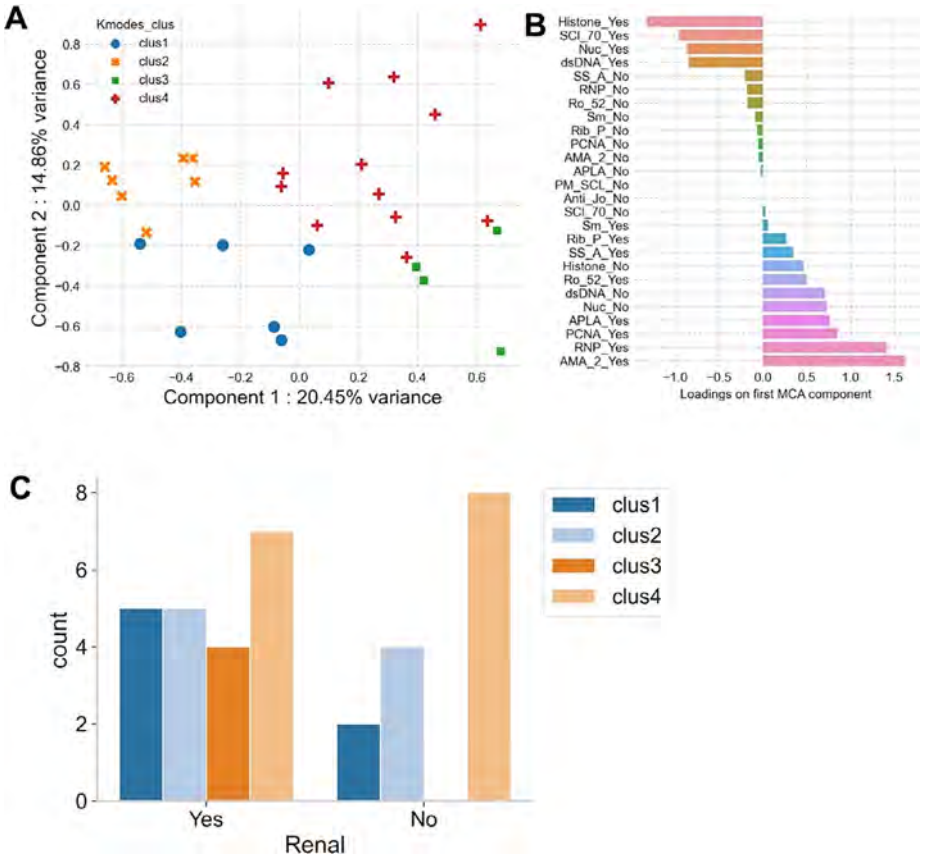

Figure 2: SLE patients have distinct combinations of autoantibody profiles that associate with lupus nephritis. (A) K Modes clustering algorithm identifies 4 distinct clusters of patients based on combined autoantibody profiles. The patients are then visualized on a 2D representation of the multidimensional data by multiple correspondence analysis (MCA). (B) Factor loadings plot demonstrating the relative contributions of the individual autoantibodies to the separation observed in (A). (C) Counts of patients presenting with or without lupus nephritis with the corresponding autoantibody clusters.

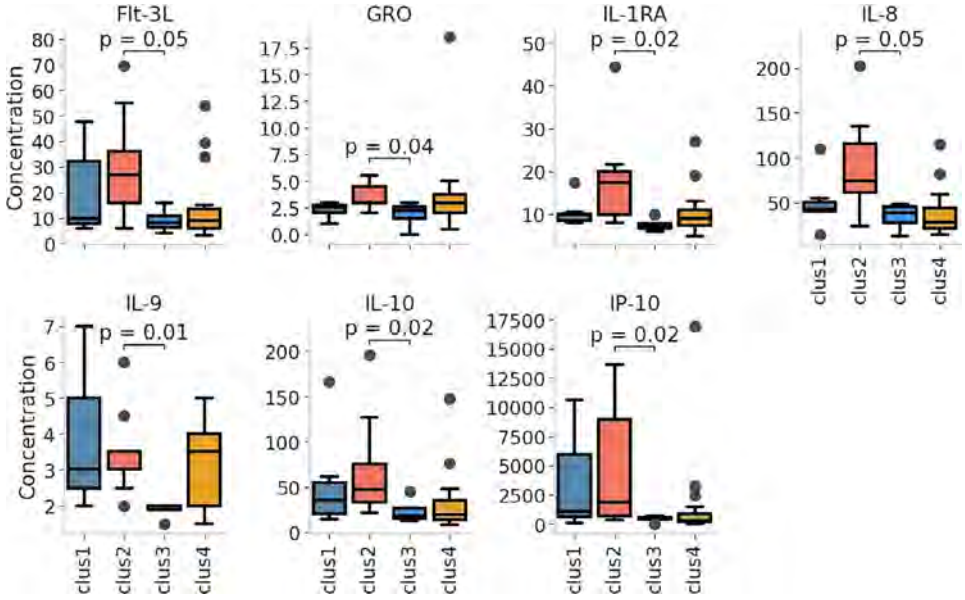

Figure 3: Cytokine profiles associated with autoantibody clusters. Comparison of cytokine levels between Clusters 2 and 3 was done by a Mann-Whitney U test, corrected for multiple tests by the Bonferroni method.

Results: We observed a positive association between actual disease activity scores (SLEDAI) and predicted scores from a partial least squares regression (PLSR) analysis of multivariate cytokine response data (Figure 1a). A study of the first two PLSR components revealed the SLEDAI scores to be positively associated with the first component (LV1) and negatively associated with the second component (LV2) (Figure 1b). Analysis of cytokine contributing towards the first two PLSR components revealed MIP-1α to have a strong positive influence towards component 1 and a negative influence on component 2, indicating a strong association with increased disease severity (Figure 1c and d). K-Modes clustering analysis identified 4 distinct clusters of patients with specific autoantibodies (Figure 2a and b), with clusters 2 and 3 being the most well-separated. Furthermore, we also observed striking differences in distributions of lupus nephritis between the clusters, with all patients in cluster 3 presenting with nephritis (Figure 2c). Finally, our results also demonstrate unique cytokine signatures associated with autoantibody profiles, with patients in cluster 3 showing significantly lower levels of cytokines responsible for modulating inflammation and maintaining cellular homeostasis (Figure 3), an observation that is in line with the clinical feature of nephritis.

Conclusion: Cytokine response can predict disease activity. Nephritis is associated with specific autoantibody profiles and cytokine signatures.

Persistence of Urinary Biomarkers of Intrarenal Inflammation Precedes Loss of Kidney Function in Lupus Nephritis

Andrea Fava[1], Mohamed G. Atta[1], Jose Monroy-Trujillo[2], Derek Fine[2], Daniel Goldman[3], Izmirly peter[4], H Michael Belmont[5], the Accelerating Medicines Partnership in RA/SLE[6], Jill Buyon[7] and Michelle Petri[3], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins School of Medicine, Baltimore, MD, [3]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [4]NYU, New York, NY, [5]NYU School of Medicine, New York, NY, [6]Multiple, Multiple, [7]NYU Grossman School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: Biomarkers
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: One third of lupus nephritis (LN) patients develop irreversible kidney damage despite achieving a clinical response based on resolution of proteinuria. Furthermore, per protocol kidney biopsies in patients with proteinuria < 0.5 g/g showed clinically significant histological activity in 50% despite the minimal proteinuria. We hypothesized that persistence of intrarenal inflammation (=LN histological activity) after treatment leads to accrual of kidney damage. We have previously identified several urinary biomarkers that correlate with the NIH Activity Index (histological activity). Here, we tested whether the elevation of these candidate biomarkers of LN immunological activity at 6 and 12 months from the diagnostic kidney biopsy predict loss of kidney function at 3 years.

Methods: We quantified 1200 biomarkers (Kiloplex, RayBiotech) in urine samples collected on the day of (73%) or within 3 weeks (27%) of kidney biopsy and week 12, 24, or 52 in LN patients (ISN class III, IV, V, or mixed) with proteinuria > 1 g/d. Glomerular filtration rate (GFR) was estimated using the CKD-EPI equation. Significant GFR loss was defined as a decline of >15 ml/min below 90 ml/min at 3 years from biopsy or end-stage kidney disease (ESKD) by year 3 requiring dialysis or transplant.

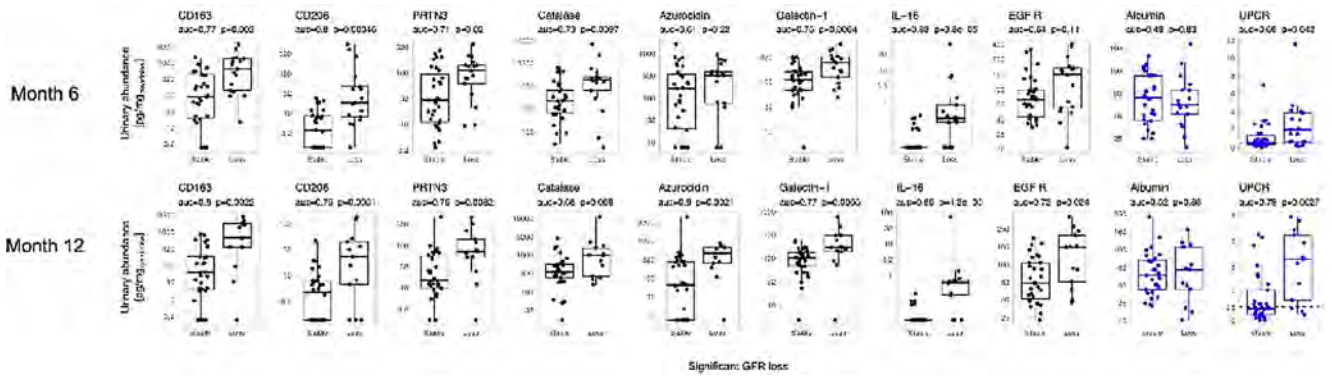

Figure 1. Association of candidate urinary biomarkers of histological activity with significant GFR loss. Urinary abundance (pg/mgcreatinine) of urinary biomarkers selected a priori based on their correlation with histological activity (NIH Activity Index) in a matching kidney biopsy of LN according to GFR loss at 3 years. Urine protein and albumin to creatinine ratios are reported for reference as clinically used biomarkers.

Results: We included 73 patients: 85% female, 46% identified as Black, 40% as White, 10% as Asian, and 4% as Other. ISN classification included 25% pure proliferative (III or IV), 40% pure membranous (V), and 35% mixed (III or IV + V). Mean GFR at biopsy was 85 (SD 34.7) ml/min. There were 32/73 (44%) patients who developed significant GFR loss. **Figure 1** shows the associations of candidate urinary biomarkers at 6 and 12 months with significant GFR loss at 3 years. Most urinary biomarkers of histological activity were higher at 6 and 12 months in patients who ultimately lost GFR at 3 years. For example, IL-16 outperformed UPCR both at 6 and 12 months (**Figure 1**) and was independent of proteinuria (not shown). UPCR at 12 months predicted 3-year GFR loss with AUC 0.79, but albuminuria did not. In a multivariable model, the combination of CD163 (macrophage activation), PRTN3 (degranulation), and IL-16 (cellular inflammation in LN) urinary levels at 12 months predicted GFR loss at 3 years with an AUC of 0.96.

Conclusion: Elevation of urinary biomarkers of histological activity after 6 or 12 months of treatment predict GFR loss at 3 years better than proteinuria, especially IL-16. These findings suggest that insufficient immunosuppression results in persistent intrarenal immunological activity in LN that increases the risk of kidney function loss. The ultimate treatment goal in LN is long term preservation of kidney function. Therefore, clinical trial endpoints should include response definitions that best associate with GFR preservation. Because noninvasive urinary biomarkers of immunological activity parallel intrarenal inflammation and predict future GFR, they could be used to 1) monitor treatment response/failure, 2) allow early treatment changes, and 3) serve as surrogate endpoints in clinical trials.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: Biomarkers

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with gut microbiota dysbiosis, and community imbalance can coincide with flares of Lupus nephritis (LN). Herein, we sought to understand the blood cell gene expression patterns and antibody responses to a gut pathobiont in longitudinal assessments of SLE patients with LN and concurrent gut colonization blooms of *Blautia (Ruminococcus) gnavus* (RG).

Methods: In a well-characterized SLE cohort, we performed bulk RNA-seq from whole-blood PAXGene tubes. Our cohort consisted of 24 female subjects (8 controls, 8 with non-renal SLE, 4 LN without RG blooms, and 4 LN concurrent with RG blooms) with longitudinal assessment of whole-blood RNA sequencing, lupus activity, and serum anti-RG lipoglycan antibody levels. After quality control and filtering, gene expression profiles were analyzed. Serum levels of the platelet factors, P-selectin and platelet factor 4 (PF4), were assessed by ELISA.

Results: Differential expression and unsupervised clustering analysis revealed distinct gene expression patterns between LN patient without and with RG gut blooms (372 differentially expressed genes; p< 0.01. Gene set enrichment analysis of the differentially expressed genes revealed significant enrichment for "platelet activation", "platelet alpha granule" and "platelet degranulation" pathways (Figure 1A, FDR < 0.001). Gene expression levels in SLE samples were compared to

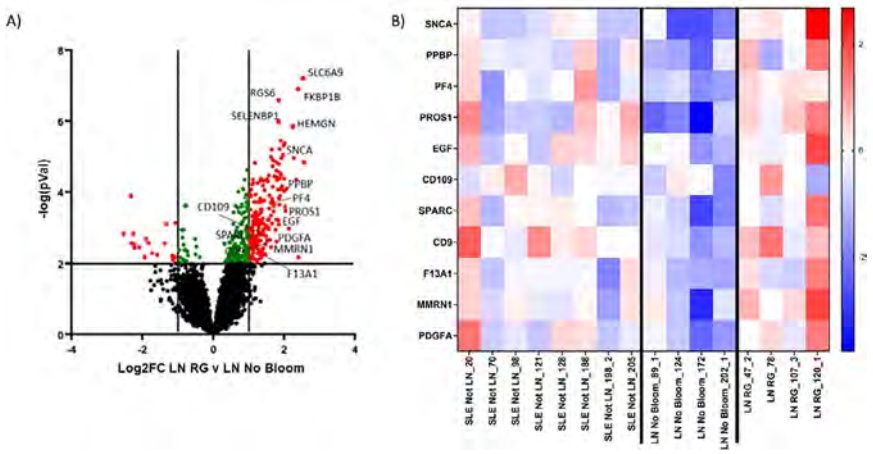

Figure 1. LN patients with RG gut blooms overexpress genes, including for platelet activation. (A) Volcano plot of genes differentially expressed in LN patients with (LN RG) and without RG bloom (LN No Bloom) (Red indicates p<0.01 and log2FC>1 or <-1, and green p<0.01 with Log2FC <1 or >-1). (B) Heatmap illustrates differential gene expression in patients with non-renal SLE (SLE Not LN), LN (LN No Bloom), and RG blooms (LN RG), compared to control samples, for 11 genes that intersect with the "Platelet Activation" pathway.

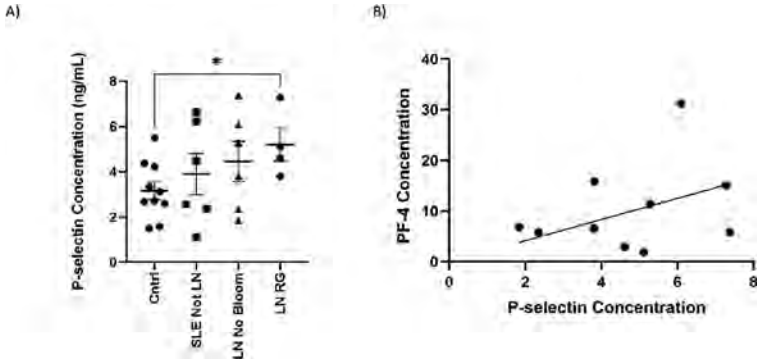

Figure 2. P-selectin levels are increased in patients with LN and RG bloom. (A) P-selectin/CD62-P levels in SLE patients and (B) correlation of P-selectin and PF-4 s in sera of patients with LN and levels of serum RG anti-LG antibodies above level in healthy individuals (p=0.003). *indicates p<0.05, non-parametric Mann-Whitney U analysis of LN RG vs. Control. Based on commercial ELISA of serum (P-selectin 1:400, PF4 1:20, ng/mL).

controls (Figure 1B). As platelet degranulation was found to be upregulated in a subset of LN patients with RG blooms, we interrogated serum levels of P-selectin/CD62P, a protein produced by activated platelets affecting leukocyte activation/migration. We found that P-selectin was increased in LN patients with RG blooms. No significant difference was observed in LN patient without RG blooms or non-renal SLE patients (Figure 2A). The gene expression of PF4, a chemokine protein primary secreted by platelets upon activation was found to be higher in LN RG, compared to controls (Figure 1A). Serum P-selectin directly correlated with PF4 levels (p=0.003)(Figure 2B).

Conclusion: Patients with LN and RG gut blooms displayed upregulated expression of genes for platelet activation and degranulation. Gut blooms with the pathobiont RG, known to cause gut leakiness from the gut and induce high serum anti-RG lipoglycan antibodies, are herein associated with increased platelet activation and raised serum P-selectin and PF4. Taken together, our data point to a potential role for platelet activation and thrombo-inflammation in LN pathogenesis.

Screening for Specific Antinuclear Antibodies Using an Artificial Intelligence-enabled Antinuclear Antibody HEp-2 Substrate by Indirect Immunofluorescence Assay

Patrick Vanderboom, Surendra Dasari, Anne Tebo, Melissa Snyder and **Ali Duarte-Garcia**, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: Biomarkers
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Antinuclear antibodies (ANA) are key biomarkers in the diagnostic evaluation of systemic autoimmune diseases and are widely used in clinical practice. The most accepted ANA screening is ANA by immunofluorescence (IFA) on HEp-2 cells, which allows the detection of antibody binding to specific intracellular targets, resulting in diverse

Table. Performance characteristics of the convolutional neural network (CNN) image analysis models and traditional immunofluorescence staining patterns for predicting specific autoantibody positivity among patients with a positive ANA.
*p<0.001 AUC in CCN model vs. traditional pattern

Performance characteristics. AUC (95 CI)	Anti-Smith*	Centromere antibodies*	Anti-SSB/La*	Anti-dsDNA*	Anti-SSA/Ro*	Anti-U1 RNP*

AUC, area under the curve; CI, confidence intervals

Performance characteristics of the convolutional neural network (CNN) image analysis models and traditional immunofluorescence staining patterns for predicting specific autoantibody positivity among patients with a positive ANA.

staining patterns. While a HEp-2 IFA pattern(s) can guide confirmatory testing and may be useful for elucidating a specific clinical diagnosis or prognosis, pattern recognition is observer-dependent and subjective. We tested the hypothesis that applying artificial intelligence (AI) to Hep2 IFA could identify specific autoantibodies associated with systemic autoimmune diseases.

Methods: Using paired ANA by Hep-2 images and autoantibody testing data, we trained a convolutional neural network (CNN) to identify patients with positivity for anti-dsDNA, Smith, U1RNP (recombinant human antigens for RNP68 or RNPA), SS-A/Ro (combined for Ro52 and ro60), SS-B/La, and Centromere B antibodies. We included patients with at least one digital image of an ANA by Hep-2 between 12-12-2016 and 6-2-2022 who also were tested for the indicated autoantibodies ≤ 90 days of the ANA by Hep2. If a patient had multiple ANA by Hep2, only the first result was included. We allocated the positive ANA images (those with a titer of ≥ 1:80) to the training, internal validation, and testing datasets on an 80:10:10 ratio. The validation dataset was used to monitor the training process for each autoantibody model. The performance of each model was then evaluated in a separate holdout testing data set by performing receiver operator characteristic analysis to determine the area under the curve from (AUC). For reference, the predictive performance of each image analysis model was compared to the IFA staining patterns classically associated with each respective autoantibody.

Results: In total, 410,075 patients tested for ANA by HEp-2 IFA were included in the dataset. Of these, 136,156 had a positive ANA, and 47,093 also had specific autoantibody serology testing within 90 (mean age = 55.0 ± 17.7 years, % female = 78.6%). The results are detailed in the table. All models, except anti-RNP, had an AUC ≥ 0.80. The CNN image models had a superior predictive performance in all cases than the traditional staining patterns ($P < 0.001$), except centromere antibody, where the performance was similar ($P=0.135$).

Conclusion: The application of AI to the widely used ANA by HEp-2 IFA permits the identification of specific autoantibody detection without relying on stain patterns. This model requires further refinement and external validation. However, it holds promise as a revolutionary way to screen for autoantibodies, eliminating concerns about technical staff expertise and inter-rater reliability, increasing access to care, information obtained from the ANA by HEp-2 IFA, and decreasing costs.

Early Experience with Avacopan for ANCA-Associated Vasculitis in a Large Integrated Healthcare System

Shruthi Srivatsan[1], Zachary Williams[1], Claire Cook[1], Xiaoqing Fu[1], Naomi Patel[1] and **Zachary Wallace**[2], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Newton, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated I
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: ANCA-associated vasculitis (AAV) is a small-to-medium vessel vasculitis associated with substantial morbidity and mortality, in part due to glucocorticoid exposure. Avacopan, an oral C5a inhibitor, is non-inferior to a standard glucocorticoid regimen, as part of usual remission induction treatment for AAV. Avacopan is increasingly used but little is known about real-world experience with this drug.

Methods: We identified all prescriptions for avacopan in a large integrated healthcare system in the US that includes 12 hospitals, including their primary care practices, community health centers, specialty clinics, and inpatient settings. The study period was from the date of FDA approval of avacopan (October 8, 2021) through March 30, 2023. Patients were followed through May 15, 2023. Details extracted from the medical record included: date of initiation, reason for non-initiation (if applicable), ANCA type, BVAS/GPA, glucocorticoid use, duration of avacopan use, flares, and concomitant immunosuppression. We used the Kaplan-Meier method to estimate the time to treatment without glucocorticoids after avacopan initiation.

Table 1: Demographic features and concomitant treatments in patients prescribed avacopan

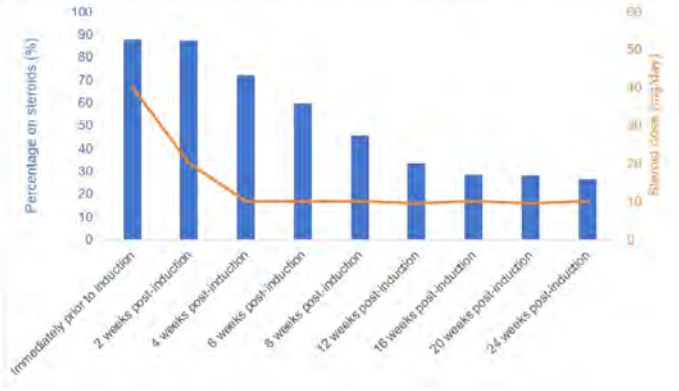
N	66
Age at Diagnosis (mean, SD)	56.8 (17.0)
Age at Time of Prescription (mean, SD)	60.0 (16.7)
Female (n, %)	45 (68.2%)
ANCA Type	
MPO-ANCA+	38 (57.6%)
PR3-ANCA+	22 (33.3%)
Dual	1 (1.5%)
ANCA-negative (n, %)	5 (7.6%)
AAV Status	
New diagnosis	46 (69.7%)
Relapse	20 (30.3%)
Setting of Avacopan Prescription	
Inpatient	19 (28.8%)
Outpatient	47 (71.2%)
Features Among those who Initiated Avacopan After Prescription	
AAV Features (Among Those Initiating)	
Baseline BVAS/WG (median, IQR)	4 (2, 6)
Renal Involvement	27 (46%)
Baseline eGFR (median, IQR)	61.5 (28.8, 83.3)
eGFR < 15ml/min	9 (16%)
Pulmonary Hemorrhage	12 (21%)
Concurrent Treatment at Avacopan Initiation	
Rituximab	26 (46.4%)
Rituximab with short oral bridging course of cyclophosphamide	26 (46.4%)
Cyclophosphamide	2 (3.6%)
Azathioprine	2 (3.6%)
Treatment 6 Months After Avacopan Initiation *(among those reaching month 6)*	27
Rituximab	24 (88.9%)
Cyclophosphamide	1 (3.7%)
Other	2 (7.4%)

Table 2: Characteristics and management of flares in avacopan users

Number with a Flare During Follow-Up	10 (18%)
Major Relapse*	4 (40%)
Minor Relapse	6 (60%)
Flare on Prednisone Treatment	5 (50%)
Prednisone Dose Range at Flare	2.5mg/d-12mg/d
Prednisone Dose Range for Treatment	12.5mg/d-40mg/d
Flare Off of Prednisone Treatment	5 (50%)
Prednisone Dose Range for Treatment	5mg/d-40mg/d
Time from induction to flare (mean, median)	100.3, 77

*Major relapse was defined as a relapse involving at least one major item on the BVAS/WG. Other relapses were defined as minor.

Figure: Steroid tapering trends among avacopan users in a large healthcare system.



Results: Avacopan has been prescribed to 66 patients (**Table 1**). The mean age was 66 years; the majority were female (68.2%), MPO-ANCA+ (57.6%), and newly diagnosed (69.7%). Most initial prescriptions were in the outpatient setting (71.5%). Of the 66 patients, 56 (84.9%) began avacopan; 10 (15.1%) never initiated avacopan because of insurance-related barriers (n=5), intubation (n=2), and patient preference (n=1). The median time from prescription to initiation was 14.5 days. The most common induction regimens were rituximab (46.4%) or rituximab with a short oral course of cyclophosphamide (46.4%). Of the 56 patients who began avacopan, 49 (87.5%) were also treated with steroids. The median time to discontinuing steroid was 56 (28-168) days (**Figure**). At 8 weeks, 45.7% remained on prednisone (median dose 10mg/d). At 24 weeks, 26.5% were on prednisone (median dose 10mg/d). The median time on avacopan was 159 days (total exposure of 9,184 days). Avacopan was discontinued by 19 (33.9%), most often because of completion of the intended course (n=10; at 6 months in n=8). Avacopan was discontinued by 5 (8.9%, 0.05/100 person days) because of an adverse event (e.g., transaminitis, paresthesia, pruritis). Ten (18%) patients had a disease flare; 6 were minor and the median time to flare was 77 days (**Table 2**). Five patients were on steroids at the time of flare and increased their dose; the other five started prednisone. One patient who initiated avacopan died during their initial presentation because of hypoxemic respiratory failure attributed to infection.

Conclusion: This is among the first reports of real-world experience with avacopan. Avacopan users quickly tapered prednisone doses but low-to-moderate doses of prednisone were commonly used for prolonged periods. Nearly one-in-five patients experienced a flare. We identified insurance-related barriers to access. Studies are needed to determine the optimal use of steroids with avacopan and factors associated with relapse.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Vasculitis – ANCA-Associated I

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The Rituximab in Eosinophilic Granulomatosis With Polyangiitis (REOVAS) trial compared rituximab (RTX) infusions to conventional strategy for remission-induction in eosinophilic granulomatosis with polyangiitis (EGPA). This trial failed to show a superiority of RTX over the conventional strategy to induce remission at 180 days. However, the long-term efficacy and safety of RTX as compared with conventional strategy in EGPA remains unknown. We report here the long-term results of the REOVAS trial.

Methods: After completion of the 12-month REOVAS trial, patients were followed prospectively, with data on disease activity, medications and adverse events collected by the patients' physicians every 6 months until the last follow-up. The primary endpoint was the minor and major relapse-free survival. Secondary endpoints were major relapses and asthma and ENT exacerbations were also assessed.

Results: Among 105 enrolled patients, only one was lost to follow-up. The median follow-up was 45 months (IQR 34-53).

At month 45 (median follow-up), for the RTX and conventional strategy arms, respectively, the minor and major relapse-free survival rates were 63.5% (95%CI 49.9%-75.2%) and 50.9% (95%CI 37.9%-63.9%) (p=0.24) ; major relapse-free survival rates were 90.4% (95%CI 79.4%-95.8%) and 79.2% (95%CI 66.5%-88.0%) (p=0.17); asthma and/or ENT exacerbation-free survival rates were 42.3% (95%CI 29.9%-55.8%) and 34.0% (95%CI 22.7%-47.4%) (p=0.42) ; and overall EGPA-related event-free survival rates were 32.7% (95%CI 21.5%-46.2%) and 22.6% (95%CI 13.5%-35.5%) (p=0.28). We then

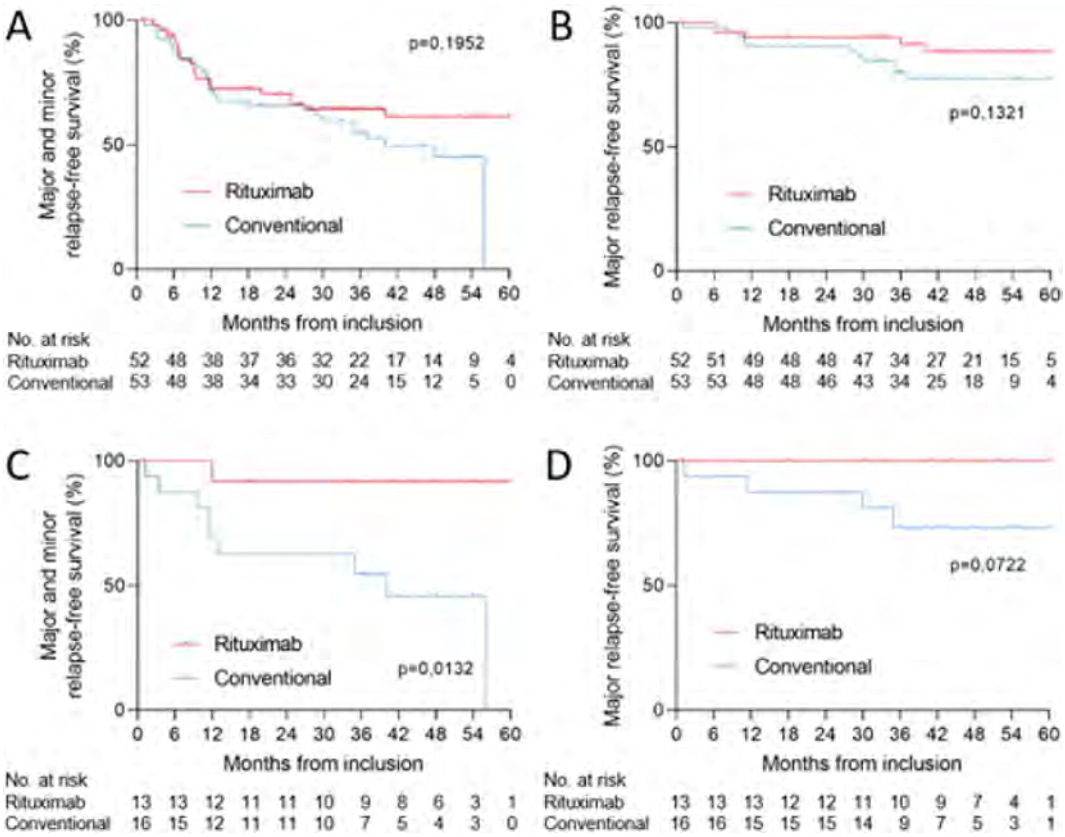

Figure 1. Kaplan-Meier curves of the risk of all (major and minor) relapse (A), major relapse (B) in all patients; all relapse (C) and major relapse (D) in MPO-ANCA-positive patients, according to treatment group. Patients were randomly assigned to receive remission induction therapy with rituximab strategy or conventional strategy, stratified according to disease-flare category, ANCA positivity and the Five Factor score

Table 1. Baseline characteristics of the patients included in the REOVAS study

	Rituximab n=52	Conventional n=53	Total n=105
Age - yr	57 (48 - 69)	64 (51 - 70)	61 (49 - 70)
Female sex, n (%)	27 (51.9%)	28 (52.8%)	55 (52.4%)
Patient status			
New diagnosis, n (%)	37 (71.2%)	37 (69.8%)	74 (70.5%)
Relapsing EGPA, n (%)	15 (28.8%)	16 (30.2%)	31 (29.5%)
ANCA positivity, n (%)	24 (46.2%)	22 (41.5%)	46 (43.8%)
MPO-positive patients, n (%)	13 (25%)	16 (30.2%)	29 (27.6%)
Severity of disease			
FFS = 0, n (%)	31 (59.6%)	32 (60.4%)	63 (60%)
FFS ≥ 1, n (%)	21 (40.4%)	21 (39.6%)	42 (40%)
Cardiac involvement, n (%)	14 (26.9%)	18 (34.0%)	32 (30.5%)
BVAS	13.5 (9 - 16)	16.0 (12 - 20)	14.0 (10 - 18)
Eosinophils count - /mm3	3800 (1255 - 9645)	4915 (1148-7082)	4400 (1310 - 8810)

ANCA : antineutrophil cytoplasmic antibodies, BVAS : Birmingham activity score, EGPA : Eosinophilic Granulomatosis with Polyangiitis, FFS : Five-Factor Score, MPO : myeloperoxidase.

Table 2. Numbers of patients with SAE according to treatment group

	Rituximab n=52	Conventional n=53
Severe infection	16	14
Bronchopulmonary (excluding SARS-Cov2)	5	5
SARS-CoV-2	2	4
Cardiovascular event	6	5
Cancer	5	3
Liver disorder	2	1
Hematologic disorder	2	1
Pulmonary embolism	2	0
Bronchospasm	0	1

SAE: severe adverse event.

focused our analysis on patients with MPO-ANCA and showed that the minor and major relapse-free survival rates were 92.3% (95% CI 66.7% - 99.6%) and 50% (95% CI 58% - 72%) for the RTX and conventional arms, respectively (p=0.02).

As 39 patients were enrolled during follow-up in the double-blind MAINRITSEG trial evaluating RTX versus azathioprine for maintenance in EGPA, we focused our analysis on the 66 patients (63%) who were not enrolled in MAINRITSEG. At month 45, the minor and major relapse-free survival rates for the RTX (n=30) and conventional strategy (n=36) arms were 60.0% (95%CI 42.3%-75.4%) and 38.9% (95%CI 24.8%-55.2%), respectively (p=0.14), and the major relapse-free survival rates were 90.0% (95%CI 73.6%-97.3%) and 72.2% (95%CI 55.9%-84.3%), respectively (p=0.12). When analyzing only ANCA-positive patients (14 in the RTX and 14 in the conventional arms), the minor and major relapse-free survival rates were 78.6% (95%CI 51.7%-93.2%) and 35.7% (95%CI 16.2%-61.4%), respectively (p=0.054). Similar results were found when analyzing only MPO-ANCA positive patients (6 in the RTX and 9 in the conventional arms), showing that minor and major relapse-free survival rates were 100.0% (95%CI 55.7%-100.0%) and 22.22% (95%CI 5.3%-55.7%), respectively (p=0.007).

Conclusion: Among EGPA patients with active disease, long-term follow-up supports that RTX and the conventional strategy have similar efficacy in inducing and maintaining remission. However, in ANCA-positive patients, RTX was associated with a better relapse-free survival compared to the conventional strategy.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Abstracts: Vasculitis – ANCA-Associated I

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Avacopan (AVP) is a recently approved adjunct therapy for remission induction of ANCA-associated vasculitis (AAV). Data on real-world use of AVP in AAV are lacking. The objective of this study was to describe the current practice in the use of AVP for the treatment of AAV and associated outcomes.

Methods: We performed a multi-center retrospective cohort study of 80 adult patients with new and relapsing AAV treated with AVP. Follow-up time was up to 52 weeks from diagnosis. The primary outcome measure was clinical remission, as determined by the investigator. Secondary outcome measures included Birmingham Vasculitis Activity Score (BVAS) 3, cumulative glucocorticoid dose, estimated glomerular filtration rate (eGFR) (mL/min/1.73m^2), proteinuria (g/g), hematuria, disease relapses, hospitalizations, end-stage kidney disease (ESKD), infections, and death. Data are presented as mean (±SD), median (IQR), or number (percent).

Results: Mean age was 59 years (±17), 65% were female, 59 (74%) had MPO ANCA, and 76 (95%) had kidney involvement. At diagnosis, 19 patients (24%) had eGFR < 15 mL/min/1.73m^{2,} and 8 (10%) were dialysis-dependent. Rituximab plus cyclophosphamide was the most common induction regimen (49%), followed by rituximab only (46%). AVP was started 8.8 weeks (SD ± 19.6) after glucocorticoid initiation with 58 patients (73%) discontinuing prednisone 7.5 weeks (±18) after

Table 1. Outcomes of patients with AAV treated with avacopan AVP = avacopan, BVAS = Birmingham Vasculitis Activity Score, uPCR = urine proteine creatinine ratio, eGFR = estimated glomerular filtration rate

	Time points			
	At diagnosis	At AVP initiation	Follow-up	
Outcomes	T = 0 weeks n = 80	T = 8.8 weeks (20) n = 80	T = 26 weeks n = 59	T = 52 weeks n = 32
BVAS, median (IQR)	13 (10 – 19)	6 (3 – 12)	0 (0 – 0)	0 (0 – 0)
eGFR, mL/min/1.73m^2, mean (SD)	47 (34)	42 (32)	59 (34)	62 (38)
Change in eGFR from baseline, mL/min/1.73m^2, mean (SD)	-	-4.4 (19)	+8.3 (28)	+14 (29)
uPCR, g/g, median (IQR)	1.5 (0.3 – 2.7)	1.3 (0.3 – 2.3)	0.4 (0.2 – 1.1)	0.3 (0.1 – 0.7)
Hematuria, n (%)	60 (75%)	37 (46%)	11 of 30 (37%)	3 of 10 (30%)
Clinical remission, n (%)	-	-	54 (92%)	29 (91%)

AVP = avacopan, BVAS = Birmingham Vasculitis Activity Score, uPCR = urine protein creatinine ratio, eGFR = estimated glomerular filtration rate

starting AVP. Outcomes are summarized in **Table 1**. Among the 60 patients (75%) with hematuria at diagnosis, 70% had resolution of hematuria 14 weeks (±14) after AVP initiation. Nadir proteinuria of 0.3 g/g (0.1 – 0.7) was achieved 10 weeks (±21) after AVP initiation. The cumulative dose of IV methylprednisolone was 2.4 g (±1.4), and 12-week oral prednisone was 1.8 g (±1.1). At week 26, 5 of 59 patients (8%) remained on prednisone. Of the 80 patients, 60 were started on remission maintenance therapy with rituximab (n = 56), azathioprine (n = 3), and intravenous immunoglobulin (n = 1).

AVP was stopped in 25 patients (31%): 11 (14%) after completing 52 weeks of treatment, and 14 (18%) before 52 weeks due to adverse events, including 4 patients with transaminitis. At a mean follow-up time of 8 months (±6), 5 (6%) had a disease relapse, 7 (9%) had infections requiring hospitalization, 3 (4%) progressed to end-stage kidney disease, and 3 (4%) patients died.

Conclusion: Patients with AAV treated with AVP in conjunction to standard remission-induction therapy have a high rate of clinical remission at weeks 26 and 52 and demonstrate a sustained improvement in eGFR. There was variability in the time till initiation of AVP and glucocorticoid discontinuation. AVP was discontinued in a group of patients due to adverse events or after 1-year of continuous treatment. Further data on the longer-term use of AVP is needed.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated I
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is an ANCA-associated vasculitides characterized by asthma, blood and tissue eosinophilia and systemic manifestations. Glucocorticoids (GCs)-dependent asthma and/or disabling ear, nose and throat (ENT) symptoms may persist in half of the patients. Mepolizumab represent an important strategy in these situations. Nevertheless, some patients may show poor or dissociated response between asthma and ENT involvement, requiring alternative options. Dupilumab, a monoclonal antibody directed against the IL-4/IL-13 receptor, has been approved for the treatment of eosinophilic asthma and chronic rhinosinusitis with nasal polyposis, raising the question of its efficacy and its tolerance in EGPA. We aimed to describe the safety and efficacy of the off-label use of dupilumab to treat relapsing and/or refractory EGPA.

Methods: We conducted a European multicenter retrospective study including patients with EGPA fulfilling 2022 ACR/EULAR classification criteria and treated with dupilumab. We collected safety and efficacy data. Response was defined as complete by BVAS=0 and prednisone dose ≤4 mg/day, and partial by BVAS=0 and prednisone dose >4 mg/d

Results: Fifty patients were included, with a median age of 52 years (IQR, 45-57), 29 were women (58%). Dupilumab was initiated for disabling ENT manifestations in 41 (82%) cases, GCs-dependency in 28 (56%) and/or poorly controlled asthma in 27 (54%). Dupilumab was associated with methotrexate in 5, azathioprine in 3, and mycophenolate in 1. Median follow-up after dupilumab initiation was 13.2 (5.4-17.8) months.

Twenty-one patients (42%) achieved a complete response and 12 (24%) a partial response. Median BVAS was 2 (1-4) at dupilumab initiation and dropped to 0 (0-1.5) at 12 months (p=0.01). Baseline prednisone dose was 8 mg/d (5-13.8) and decreased to 2.5 mg/d (0-5) at 12 months (p=0.04).

Seventeen (34%) patients reported adverse events (AE). Main AE were mild-to-moderate and included headache (n=4), injection-site reaction (n=3), myalgia (n=3), arthralgia (n=3). Two patients experienced non-fatal anaphylactic shock. Dupilumab-induced eosinophilia was reported in 33 patients (66%), with a median peak eosinophil count of 1980/mm3 (IQR 560-9800) occurring 13 weeks (IQR 5-18) after starting dupilumab. This dupilumab-induced eosinophilia remained asymptomatic in 42% cases.

Fifteen (30%) patients presented a EGPA flarewhich was associated with blood eosinophilia in 13/15 (87%) cases leading to dupilumab discontinuation in 11 cases (73%), including systemic flares in 7 cases, asthma exacerbation in 6 cases, ENT relapse in 1 and inflammatory arthralgia in 1.

In total, 21 (42%) patients discontinued dupilumab: vasculitis flare (n=11), dupilumab-induced eosinophilia (n=7), anaphylactic shock (n=2), cancer (n=1). No deaths were reported.

Conclusion: These results suggest that dupilumab may be effective in relapsing and/or refractory EGPA, particularly in ENT manifestations. However, dupilumab-induced eosinophilia is common and may remain asymptomatic or be associated with relapse, so caution is warranted.

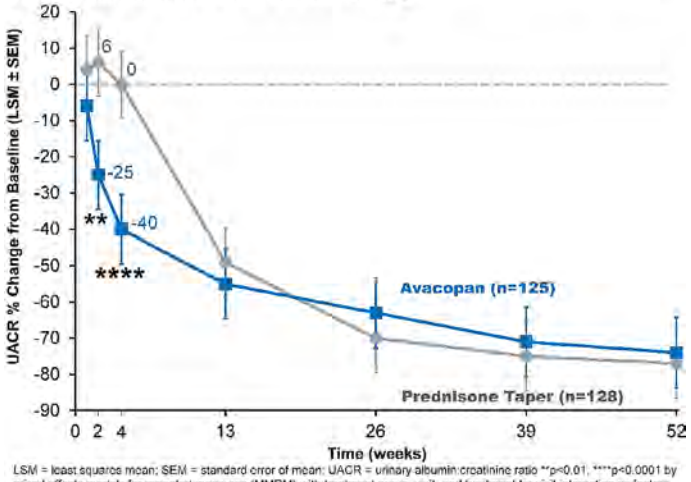
SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated I
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

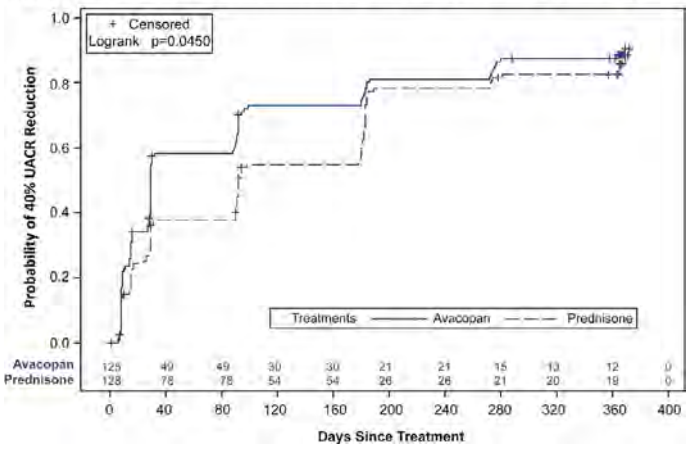
Background/Purpose: Urinary albumin:creatinine ratio (UACR) is an important biomarker of active glomerulonephritis, a common complication of antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV). In most glomerular diseases, high UACR levels and low estimated glomerular filtration rate are associated with the long-term risk of end-stage kidney disease, cardiovascular disease, and death (Levey AS et al, *N Engl J Med* 2022).In the double-dummy, double-blind, controlled ADVOCATE Phase 3 trial (Jayne DRW et al, *N Engl J Med* 2021), patients were randomized to receive avacopan, an oral C5a receptor (C5aR) antagonist that blocks C5a-mediated neutrophil activation and migration, or a prednisone taper. All patients received background immunosuppression with either cyclophosphamide followed by azathioprine, or

Figure 1. Percent Change in UACR from Baseline in the Avacopan vs Prednisone Taper Groups in Patients with Kidney Involvement and UACR≥10 mg/g



LSM = least squares mean; SEM = standard error of mean; UACR = urinary albumin:creatinine ratio **p<0.01, ****p<0.0001 by mixed effects models for repeated measures (MMRM) with treatment group, visit, and treatment-by-visit interaction as factors and baseline as covariate. Percent changes from baseline are based on ratios of geometric means of visit over baseline.

Figure 2. Time to 40% UACR Reduction in the Avacopan vs Prednisone Taper Groups



rituximab. Primary endpoints were remission at week 26 and sustained remission at week 52. Prespecified secondary endpoints included the evaluation of kidney function. The effect of avacopan on UACR in patients with AAV is described.

Methods: This post hoc analysis compared the time to achieve the maximum mean difference in percent change in UACR from baseline between the avacopan and prednisone taper groups using Kaplan-Meier survival analysis. Change in UACR from baseline was a prespecified secondary endpoint but was not adjusted for multiplicity. This analysis included patients from the ADVOCATE trial with kidney involvement (based on the Birmingham Vasculitis Activity Score) and a UACR of at least 10 mg/g at baseline.

Results: The baseline geometric mean UACR mg/g (range) in the avacopan group (n=125) and the prednisone taper group (n=128) was 433 (20 to 6461) and 312 (11 to 5367), respectively. A statistically significant UACR reduction (based on least-square means) in the avacopan group compared to the prednisone taper group occurred as early as week 2 (-25% vs. 6%, p=0.0068, difference between groups: -29%, 95% confidence interval (CI) [-45%, -9%]). UACR continued to decrease at week 4 to the maximum difference between the two groups (-40% vs. 0%, p< 0.0001, difference between groups: -40%, 95% CI [-53%, -22%]) (**Figure 1**). UACR was comparable between the two groups by week 13 (-55% vs. -49%, p=0.3028, difference between groups: -12%, 95% CI [-32%, 13%]). During the 52-week treatment period, 84% (105/125) of patients in the avacopan group achieved a 40% UACR reduction from baseline within a median time of 29 days (95% CI [29, 88]), compared to 83% (106/128) of patients in the prednisone taper group within a median time of 92 days (95% CI [91, 180]) (logrank p=0.0450) (**Figure 2**). There was an overall mean improvement in estimated glomerular filtration rate (eGFR) of 7.6 mL/min/1.73 m^2 in the avacopan group and 4.6 mL/min/1.73 m^2 in the prednisone taper group at week 52.

Conclusion: In the ADVOCATE trial, UACR, an important early indicator of improving kidney function, improved three times faster in the avacopan group compared to the prednisone taper group. The rapid reduction in UACR seen in patients with AAV receiving avacopan suggests more rapid control of glomerular inflammation which may have contributed to the observed subsequent improvement in eGFR.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated I
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Despite more effective therapeutic strategies in ANCA-associated vasculitis (AAV), there is still a significant risk of morbidity and mortality, mainly due to infection, and cardiovascular disease. Carotid intima-media thickness (cIMT) is a marker of subclinical atherosclerosis associated with cardiovascular risk factors and is predictive of major cardiovascular events (MACE). We hypothesized that patients with AAV might benefit from statin treatment in primary prevention to reduce subclinical markers of atherosclerosis and the incidence of major cardiovascular events.

Methods: This phase 3, multicentre, randomized, controlled, double-blind, superiority study compared rosuvastatin with placebo in reducing the progression of subclinical markers of atherosclerosis. Patients with AAV in remission after a first flare or relapse were randomized 1:1 to receive the experimental strategy based on the use of rosuvastatin 20 mg/day or placebo for 24 months. The primary endpoint was the mean change in mean cIMT (distal wall of primary carotid arteries) at 24 months.

Results: A total of 111 participants underwent randomization (55% male, mean age 54.8 (13.3) years, 63.1% GPA, 28.8% EGPA, 8.1% MPA), with 54 participants assigned to receive rosuvastatin and 57 to placebo.

The primary endpoint was not met. The mean change in cIMT at month 24 was not different between the two study groups (difference -0.002 [-0.034 ; 0.030], p=0.89) (**Figure 1**). The annualized rate of change in mean cIMT was 0.0110 (0.0617) mm/year in the rosuvastatin group and 0.0189 (0.0556) mm/year in the placebo group (difference -0.0062 [-0.0318 ;

0.0193], p=0.61). Similar results were found for the mean change in the number of plaques in the carotid and femoral arteries and abdominal aorta (difference 0.01 [-0.39 ; 0.42], p=0.94).

Mean LDL-cholesterol levels were significantly different between the two study groups at all time points evaluated (P< 0.001, P< 0.001, and P< 0.001 for reductions between the rosuvastatin and the placebo groups at months 6, 12 and 24, respectively) (**Figure 2**). Also, high-sensitivity CRP levels were significantly different between the two study groups at month 24 (difference -3.16 [-5.58 ; 0.74], p=0.011 for reductions between the rosuvastatin and the placebo groups).

There was only one MACE in the rosuvastatin group. Vasculitis relapse-free survival did not differ between the two groups (HR 1.59, 95%IC = [0.81 ; 3.09], p=0.18).

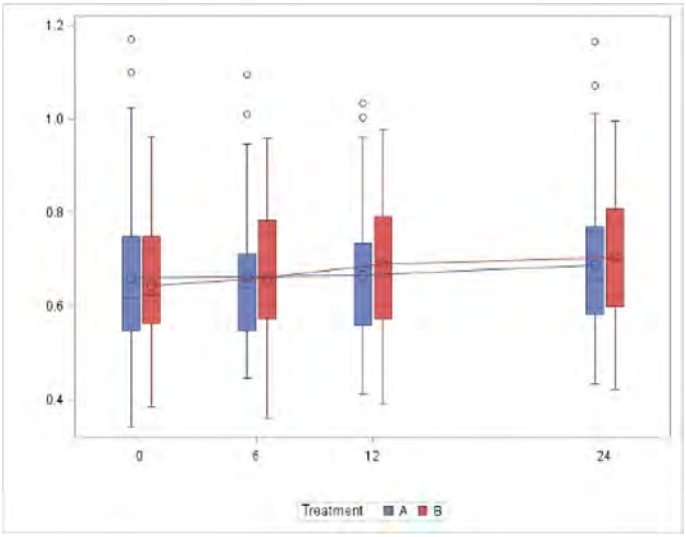

Figure 1. Evolution of mean carotid intima-media thickness (in mm) during the study period in the two groups. Rosuvastatin arm is group A and placebo arm is group B.

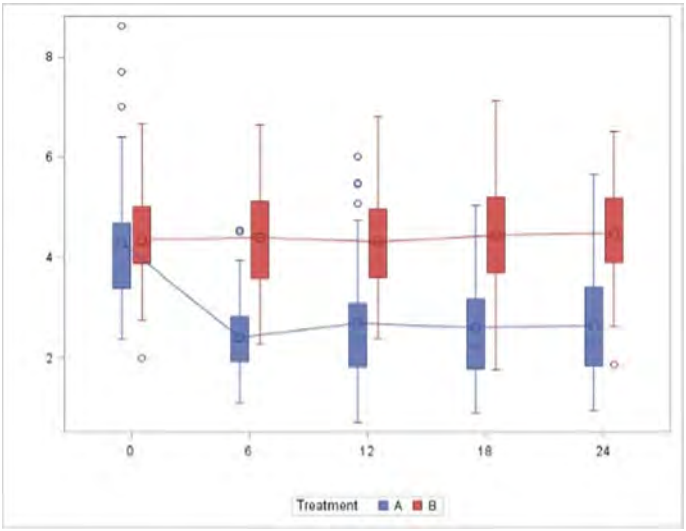

Figure 2. Evolution of mean LDL-cholesterol (in mmol/L) during the study period in the two groups. Rosuvastatin arm is group A and placebo arm is group B.

Eleven and seventeen patients discontinued intervention in the rosuvastatin and the placebo groups, respectively. The incidence of serious adverse events was similar in the two groups: 27.8% in the rosuvastatin group and 22.8% in the placebo group.

Conclusion: Among patients with ANCA-associated vasculitis, 24 months of rosuvastatin reduced LDL-cholesterol but did not reduce the progression of subclinical markers of atherosclerosis (Funded by the French Ministry of Health; STATVAS ClinicalTrials.gov number, NCT02117453).

Single Injection AAV2-hFGF18 Demonstrates Superior Safety and Efficacy over Repeat rhFGF18 Protein Injections in a Model of Induced Osteoarthritis

Alex Goraltchouk[1], Judith Hollander[2], Francesco Luppino[3], Li Zeng[2] and Alexey Seregin[3], [1]Remedium Bio, Inc, Needham, MA, [2]Tufts University, Boston, MA, [3]Remedium Bio, Inc., Needham, MA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is the largest unmet need in rheumatology, affecting 1 in 7 adults, with no approved disease modifying treatments. A recent placebo-controlled clinical study of rhFGF18 demonstrated, for the first time, the ability to reverse cartilage loss in OA - with the highest dose/frequency arresting progression to joint replacement.

Figure 1

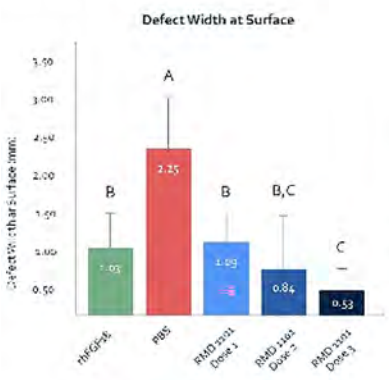

Figure 2

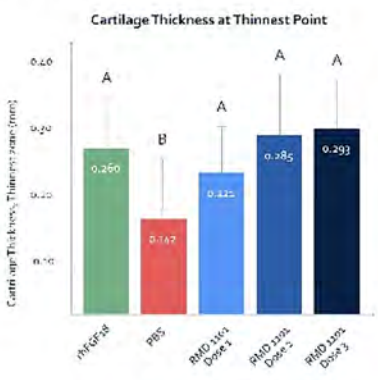

Figure 3

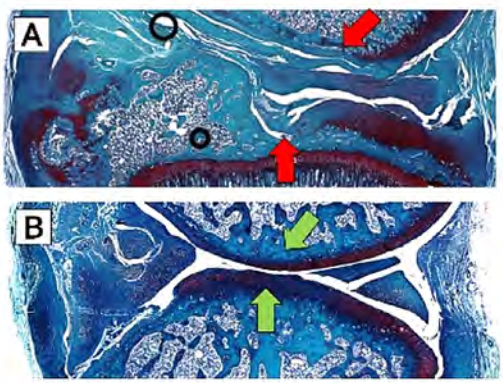

While promising, the safety and efficacy of this approach is limited by the required frequency of intra-articular injections, due to synovial joint pharmacokinetics. In this study, we compared the effects of repeated rhFGF18 protein injections and a single injection AAV2-hFGF18 on cartilage anabolism in healthy and arthritic joints.

Methods: Chondrogenic properties of AAV2-hFGF18 were compared to rhFGF18 protein, AAV2-GFP, and PBS. Cytocompatibility was assessed by cellular viability over 168h in culture. Gene expression was analyzed by RNA-seq on primary human chondrocytes. In vivo durability of gene expression was confirmed using bioluminescence imaging. Cartilage anabolism was evaluated by measuring thickness of the tibial plateau in 300-375g healthy and OA male Sprague-Dawley rats, with OA induced by destabilization of the medial meniscus. Effect on disease progression was assessed by measuring cartilage defect width and depth following administration of AAV2-hFGF18, rhFGF18 protein, and PBS.

Results: At multiplicities of infection (MOIs) of 0.1k and 1k, AAV2-hFGF18 induced proliferative increases of 36 and 84%, respectively, which was in line with rhFGF18 protein dosed at 1-10k ng/ml (38-110%), and statistically above PBS (8%). At the same time, AAV2 demonstrated cytocompatibility through MOIs up to 50k. RNA-seq revealed rhFGF18- and AAV2-hFGF18-induced upregulation of hyaline cartilage-associated HAS2 and COL2A1, and downregulation of fibrocartilage-associated COL1A1. AAV2-hFGF18, but not rhFGF18, upregulated SOX9, a chondrocyte differentiation marker, and PRG4, an articular cartilage lubricating protein, while downregulating the aggrecan-targeting protease ADAMTS15. Compared to healthy cartilage, a significantly more pronounced chondrogenic effect was observed in arthritic joints. Defect widths were reduced in the gene therapy-treated knees by 51.6 – 76.4% relative to PBS, with the highest dose achieving statistical significance over rhFGF18 (54.2% reduction) (Fig 1). Similarly, cartilage thickness at the thinnest point increased in the gene therapy treated joints, reaching 2.06x of PBS (Fig 2). Severe OA pathology was observed in the placebo-treated knees (Fig 3A), including significant cartilage loss, subchondral bone collapse, and formation of bone voids; in contrast, such phenotypes were not observed in the high-dose gene therapy group (Fig 3B). Finally, repeat injections of rhFGF18, while chondroprotective, induced synovitis-mediated joint swelling even in healthy joints, that remained unresolved through 2-months post treatment.

Conclusion: Our findings suggest that a single injection of AAV2-hFGF18 demonstrates superior safety and efficacy over a multi-injection rhFGF18 protein treatment regimen in a model of Osteoarthritis.

Vagus Nerve Stimulation Enhances Bone Morphology in a Rodent Model of Central Nervous System Inflammation

Chandramohan Natarajan[1], Julia Lucchino[1], David Chenoff[2] and **Yaakov Levine**[1], [1]SetPoint Medical, Valencia, CA, [2]SetPoint Medical, Sausalito, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Electrical stimulation of the vagus nerve activates the inflammatory reflex to inhibit cytokines and decrease clinical signs and symptoms of chronic inflammatory disease such as rheumatoid arthritis (RA)[1]. Joint preservation (cartilage and bone) was reported in rat collagen induced arthritis and derosions were observed by MRI in early human clinical

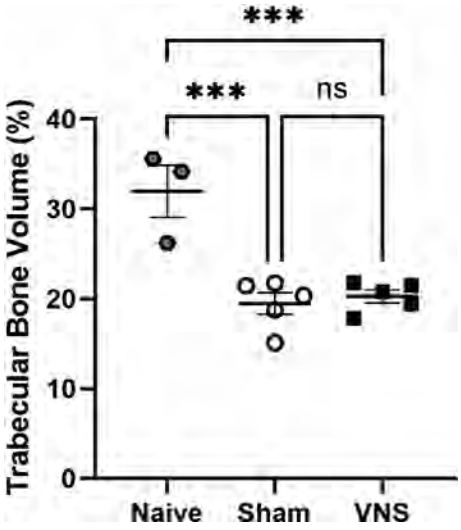

Figure 1.

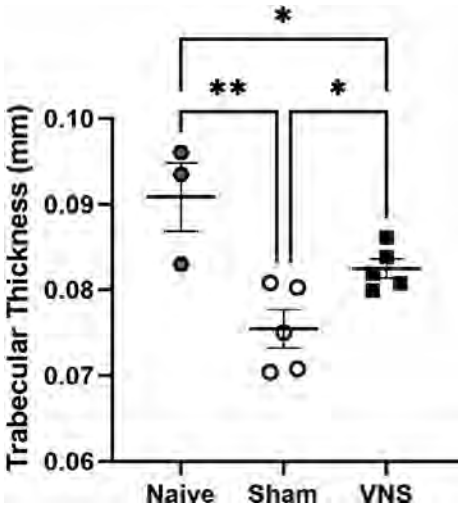

Figure 2.

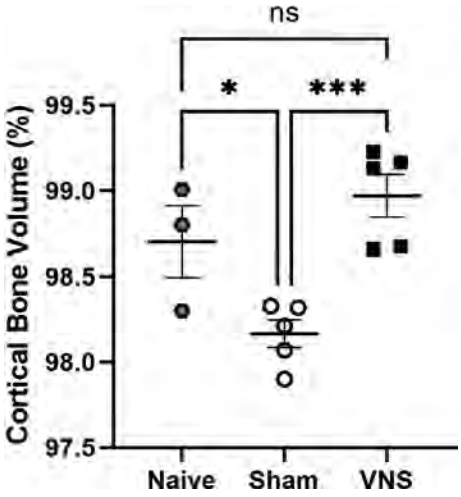

Figure 3.

studies for treatment-resistant RA[1,2]. It is currently unclear whether the beneficial effects of vagus nerve stimulation on bone in RA are specific to bone remodeling, or are simply secondary to a decreased synovial inflammatory milieu. To separate the bone turnover-related effects from the amelioration of joint-specific inflammation, we stimulated the vagus nerve of rats with experimental autoimmune encephalomyelitis (EAE), a CNS-specific disease model with bone resorption as a known comorbidity.

Methods: Vagus nerve stimulation devices (SetPoint Medical, CA) were implanted in 6-week-old female Lewis rats. Following recovery, EAE was induced with myelin basic protein (0.1 mg/rat) and complete Freund's adjuvant (Hooke Laboratories, CT). Conscious rats (n=5/group) were treated with active or sham stimulation from 7 days post-induction (DPI), the day prior to the typical onset of clinical neurologic symptoms, through 21 DPI. Cortical and trabecular bone parameters were calculated through μCT analysis of the proximal femurs and difference in means compared by ANOVA.

Results: On 21 DPI, both active and sham stimulated rats had a significant decrease in trabecular bone mineral density vs. naïve (Fig 1). Trabecular thickness was significantly higher in actively stimulated rats vs. sham (Fig 2). Cortical bone mineral density was numerically reduced in the sham, but not in the active stimulation group. There was a significant reduction in cortical bone volume in the sham, but not in the active stimulation group (Fig 3). *$p < 0.05$, **$p < 0.01$, ***$p < 0.001$

Conclusion: The data show that subacute vagus nerve stimulation enhances trabecular thickness and cortical bone volume in the femurs of rats with EAE. This is an important indicator of a bone-specific protective effect of vagus nerve stimulation, in addition to, and independent of, amelioration of joint-specific inflammation. Studies to further understand of the mechanisms of action are underway.

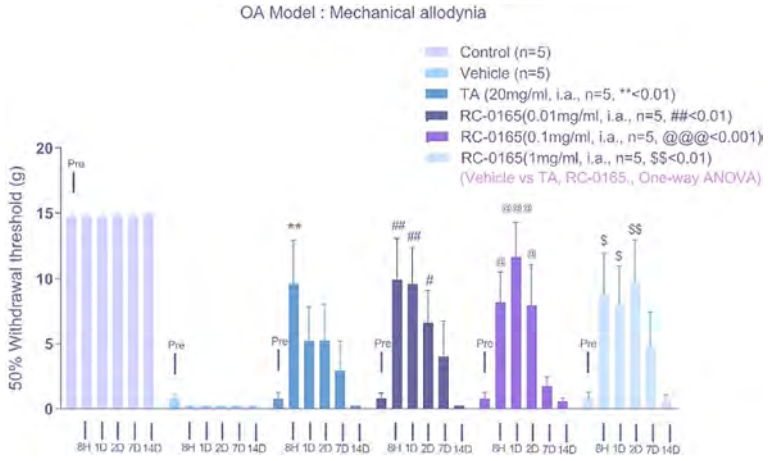
The Analgesic Effect of RC-0165, a TRPV1 Antagonist, for Osteoarthritis Pain

Donghui kim, Juil park, Minjung kim and Yongho kim, RudaCure, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA), the most common form of arthritis, arises from the deterioration of cartilage within joint bones, resulting in pain and functional disability with limited range of motion. Despite many studies that aimed to find a new target to treat OA pain or regenerate cartilage, OA remains an area of high unmet need due to the lack of effective analgesics and disease-modifying drugs.

The Transient Receptor Potential Vanilloid 1 (TRPV1) cation channel is a member of the Transient Receptor Potential (TRP) channels that acts as a molecular detector of noxious signals in primary sensory neurons. Many companies have attempted to develop TRPV1 antagonists to treat OA pain, however due to TRPV1's role in thermoregulation, most have been halted from side effects such as hyperthermia.



effects of RCI002 compare to TA for OA

RC-0165 is a potent and selective peptide TRPV1 antagonist that potently blocks capsaicin activation of the TRPV1 channel with negligible influence on pH or heat activation modes. We found that when injected intraarticularly, RC-0165 attenuates neuropathic and OA pain without causing any effect on body temperature in both primates (marmosets) and non-primates (rat&mouse).

In this study, calcium imaging was used to assess the effects of RC-0165 on HEK293T cells expressing TRPV1. We also evaluated the efficacy of RC-0165 through pain-related behavioral test using a Monosodium iodoacetate (MIA)-induced OA rat model.

Methods: In vitro, the level of calcium influx after TRPV1 antagonism by RC-0165 in TRPV1-expressing human embryonic kidney (HEK) 293T cells were measured via calcium imaging experiments. In vivo, pain-related behavioral effects were compared to RC-0165 and triamcinolone acetonide (TA)as positive control in a MIA-induced OA rat model, which was assessed using Von Frey, Hargreaves, open field, and rotarod tests.

Results: We confirmed that RC-0165, a novel peptide TRPV1 antagonist, diminishes calcium influx in cells related to pain signals through TRPV1 inhibition. Analgesic efficacy was also investigated in-vivo studies by injecting RC-0165 intraarticularly in MIA-induced OA rat model. In the Von Frey test, which measures the pain in response to mechanical stimulation, the RC-0165(0.01, 0.1 and 1mg/ml) group showed a significant increase in pain threshold compared to TA group and its efficient pain-reducing effect lasted for 3 days. In the open field and rotarod tests, the RC-0165 group showed meaningful increase in exercise capacity and promising results of improvement in OA pain.

Conclusion: The results of our study suggest that RC-0165 may be a promising approach to significantly reduce OA pain compared to TA by suppressing pain signals mediated by TRPV1

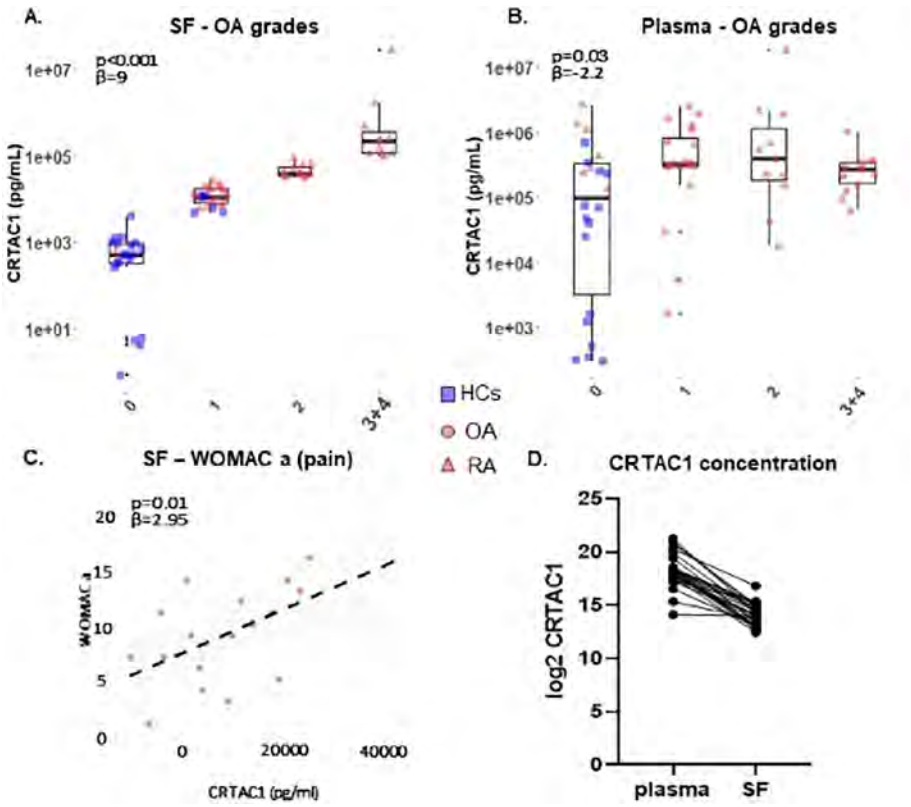
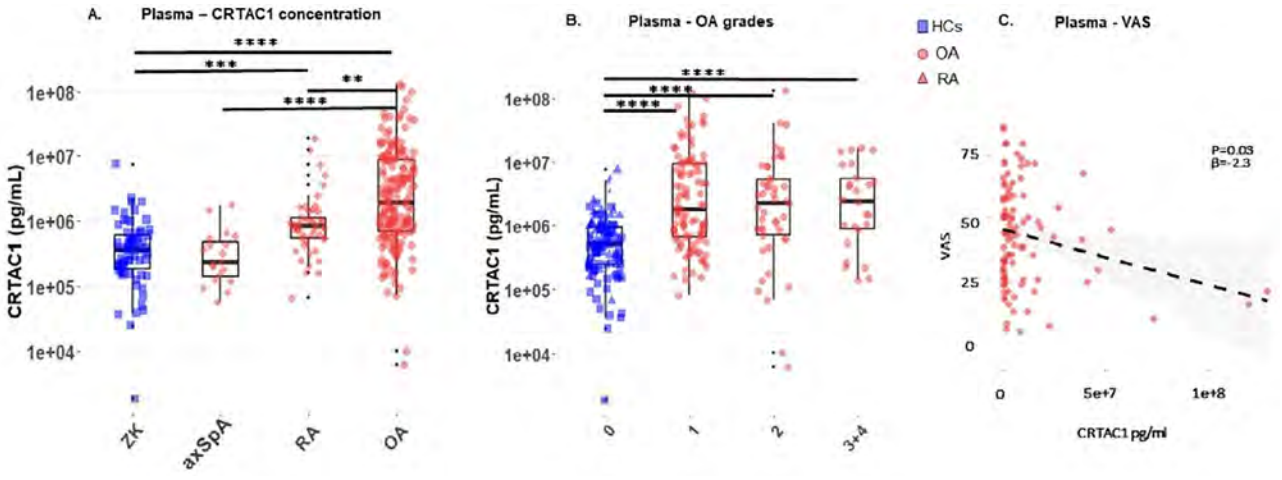
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Cartilage acidic protein-1 (CRTAC1) has been recently considered a promising biomarker of osteoarthritis (OA) progression (1,2). The aim of this study is to compare CRTAC1 levels in paired synovial fluid (SF) and plasma samples from patients with knee OA and rheumatoid arthritis (RA) with unpaired samples from healthy controls (HCs). Secondly, to compare plasma CRTAC1 levels in patients with OA and patients with other inflammatory musculoskeletal diseases. Thirdly, to evaluate the association between CRTAC1 levels and OA severity.

Methods: Paired plasma and synovial fluid (SF) samples were obtained from patients with knee OA (n=26) and from RA patients who had knee effusion (n=19) and underwent therapeutic arthrocentesis. Control samples were obtained from HCs with post-traumatic knee effusion (n=25). Plasma samples were obtained from 67 HCs, 130 patients with OA (including knee, hip, and hand OA), 49 patients with RA, and 20 patients with axial spondyloarthritis (axSpA). CRTAC1 levels were



A. CRTAC1 levels in SF of patients with different OA severity. B. CRTAC1 levels in paired plasma samples of patients with different OA severity. The p-values show the statistical significance of linear regression, including healthy individuals (blue, square), OA patients (red, circle) and RA patients (red, triangle). C. Association of CRTAC1 and WOMAC a (pain) in SF of OA patients, computed via linear modelling. D. Comparison of CRTAC1 concentration in paired SF and plasma samples.



A. CRTAC1 levels in a wider cohort of plasma samples in HCs and patients with axSpA, RA and OA. B. CRTAC1 levels in plasma samples of patients with different OA severity. The p-values show statistical significance between healthy individuals (blue, square), axSpA (red, rhombus), OA patients (red, circle) and RA patients (red, triangle) and were computed using ANOVA. Linear modelling did not reveal the association between CRTAC1 levels and OA severity. C. Association of CRTAC1 and VAS in the wider cohort in plasma samples, computed via linear modelling.

measured using the CRTAC1 ELISA (Bio-Rad). Knee radiographs were evaluated by a blinded assessor using the Kellgren-Lawrence grading scale. Patients were examined by experienced rheumatologists and filled out the Visual Analog Scale (VAS) pain, the Western Ontario and McMaster Universities Arthritis Index (WOMAC), the AUStralian CANadian Osteoarthritis Hand Index (AUSCAN), and the Health Assessment Questionnaire (HAQ).

Results: CRTAC1 levels in SF and plasma were significantly higher in patients with OA compared to HCs ($p< 0.001$). Regression analysis showed a positive relationship between CRTAC1 levels in SF and OA severity ($p< 0.001$; $\beta=9$); however, systemic CRTAC1 levels showed the opposite trend ($p=0.03$, $\beta=-2.2$). We found a positive association between SF levels of CRTAC1 and WOMAC-A ($p=0.01$, $\beta=2.95$).In wider cohort, plasma CRTAC1 levels were higher in patients with OA compared to patients with RA, axSpA, and HCs (all $p< 0.01$). We found a negative association between systemic CRTAC1 levels and VAS pain ($p=0.03$, $\beta=-2.3$) in OA. There were no significant differences in CRTAC1 levels among OA subtypes.

Conclusion: This study provides the first evidence of a distinct local and systemic profile of CRTAC1 in patients with knee OA. CRTAC1 levels in synovial fluid may better reflect pain and severity of joint involvement compared to its plasma counterparts, which likely reflect other physiological and pathophysiological processes.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Changes in chondrocyte phenotype and energy metabolism occur in osteoarthritis (OA). The prevalence of OA is higher in females compared to males however whether there are sex differences in OA chondrocytes is unknown. The purpose of this study was to compare phenotype and energy metabolism in OA chondrocytes from male and female patients.

Methods: OA chondrocytes were isolated from male and female patients undergoing knee arthroplasty for end-stage primary OA (Kellgren-Lawrence Grade 4). Phenotype was determined by polymerase chain reaction, western blot and enzyme-linked immunoassays. Energy metabolism was determined by measuring glucose/fat consumption, lactate production, oxygen consumption rate and extracellular acidification rate.

Results: Protein levels of SOX9, a transcriptional regulator of *COL2A1* and *ACAN* as well as a promoter of glycolysis, were higher in OA chondrocytes from male compared to female patients (Figure 1). OA chondrocytes from males secreted higher amounts of type II collagen, had higher protein levels of the GLUT1 glucose transporter, higher glucose consumption, higher lactate production and higher glycolytic rate than OA chondrocytes from females. Knockdown of SOX9 reduced expression of *ACAN* and the glycolytic gene *PGK1,* in chondrocytes from male but not female patients. SOX9 knockdown reduced *COL2A1* expression in chondrocytes from both males and females, however the magnitude of effect was greater for males. OA chondrocytes from female patients consumed higher amounts of fat and had a higher oxygen consumption rate than OA chondrocytes from males indicating greater usage of oxidative energy metabolism.PGC1α protein levels (which promotes mitochondrial oxidative energy metabolism and potentiates SOX9-mediated collagen synthesis) were also higher in OA chondrocytes from females (Figure 1). Knockdown of PGC1α reduced *COL2A1* expression in OA chondrocytes from female but not male patients.

Conclusion: SOX9 and PGC1α are differentially expressed in OA chondrocytes from male compared to female patients resulting in differences in energy metabolism pathway usage and the transcriptional control of *COL2A1*. OA chondrocytes from male patients synthesise higher amounts of type II collagen compared to OA chondrocytes from females. This may render females more susceptible to rapid cartilage loss in OA. Differences in chondrocyte biology between male and female

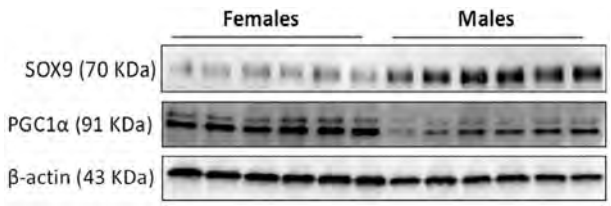

Figure 1 Protein levels of SOX9 and PGC1α (as measured by western blotting) in osteoarthritic chondrocytes isolated from male versus female patients.

patients raise the possibility that the mechanisms involved in OA development may also differ between the two highlighting the importance of considering gender and sex when studying OA pathogenesis and evaluating the efficacy of candidate OA treatments.

Proteomic Analysis of Circulating Neutrophils from Osteoarthritis Patients Shows Metabolic Dysregulation That Is Associated with Decreased Physiologic Apoptosis

Jennifer Amsler[1], Morgane Le Gall[2], Camille Daste[3], François Rannou[3] and Véronique Witko-Sarsat[2], [1]Institut Cochin, Bern, Switzerland, [2]Institut Cochin, Paris, France, [3]Hôpital Cochin, Paris, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) has long been thought to be only of local mechanical origin. However, it has been shown recently that there is a phenotype of OA with inflammatory properties. Here, we hypothesize that circulating neutrophils could be involved in disease pathogenesis suggesting a systemic involvement in this "local" disease.

Methods: We investigated the cytosolic proteome of blood neutrophils from four OA patients with an inflammatory knee osteoarthritis and compared it to the cytosolic proteome of blood neutrophils from three healthy controls (HC) of similar age. Functional analysis was generated through the use of the software Ingenuity Pathway Analysis (IPA). We further investigated in vitro the physiological apoptosis of isolated circulating neutrophils from OA patients compared to neutrophils from HC and measured the glycogen content in neutrophil cytosol.

Results: Based on the differentially regulated proteins, IPA predicts a downregulation of the glycogen degradation pathway as the most important difference between blood neutrophils from OA patients and those from HC, suggesting a disturbance in glycogen storage or use in OA neutrophils. Further, IPA predicts an inhibition of cell death of immune cells and an activation of senescence of cells. One of the differentially regulated proteins involved in survival is PCNA, which is found to be increased in neutrophils from OA patients. When measuring the glycogen content in blood neutrophils from OA patients compared with that from HC, we found no difference in glycogen content. However, we found a significant difference in the content of glycogen between neutrophils at a basal state and apoptotic neutrophils in both groups, suggesting that neutrophils use glycogen during their apoptosis. There was no correlation between the basal glycogen concentration of the cells and the percentage of apoptosis in neutrophils from both HC and OA, suggesting that the initial glycogen concentration has not a direct impact on the process of apoptosis of neutrophils. Preliminary results of Annexin-V labeling showed that neutrophils from OA patients have a significant delayed apoptosis compared with HC.

Conclusion: Our findings uncover for the first time a dysregulation in circulating neutrophils in OA that could have an impact on the disease pathogenesis and demonstrate a systemic involvement in OA. We provide evidence that cytosolic proteins of circulating neutrophils of OA patients are disturbed in terms of glycogen metabolism and apoptosis, which might result in a higher survival rate. Molecular mechanisms underlying these disturbances remain to be elucidated.

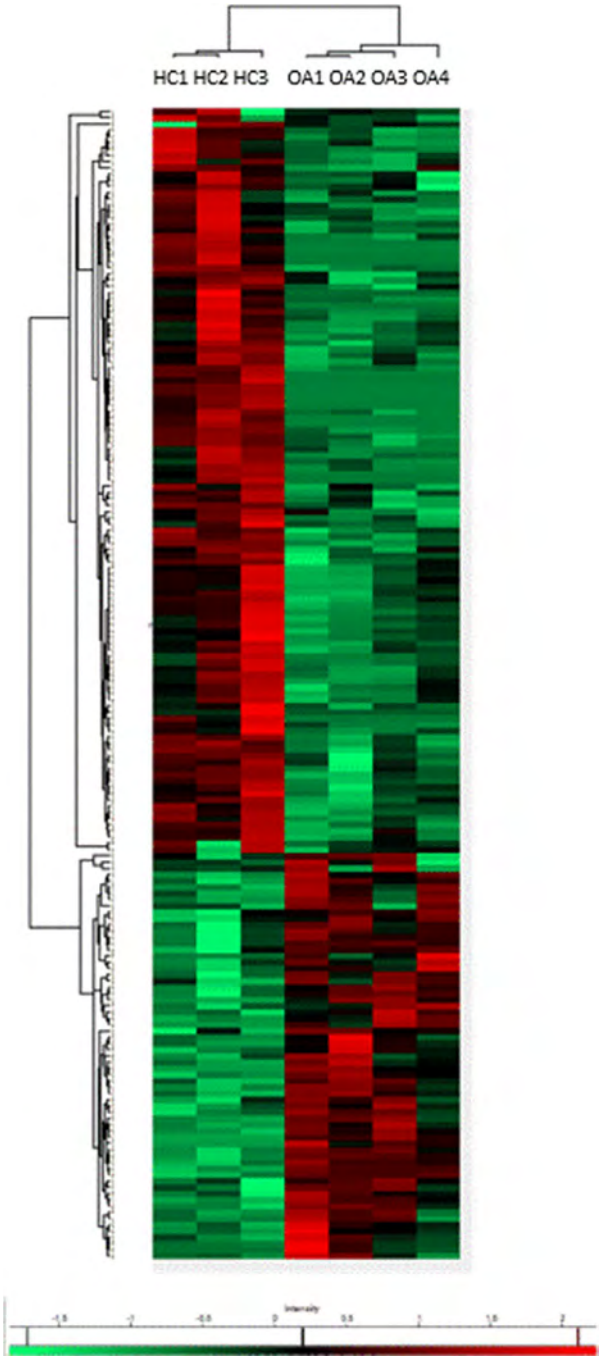

Figure 1: Heat map of differentially expressed proteins between neutrophil cytosol from blood of healthy control (HC) and osteoarthritis patients (OA). The proteins (rows) and samples (columns) are hierarchically clustered using Pearson correlation and average linkage on z-score quantification intensities. Each number indicates one patient. Color depicts the z-score changes in protein intensities respective to baseline expression levels, red: overexpression and green: underexpression.

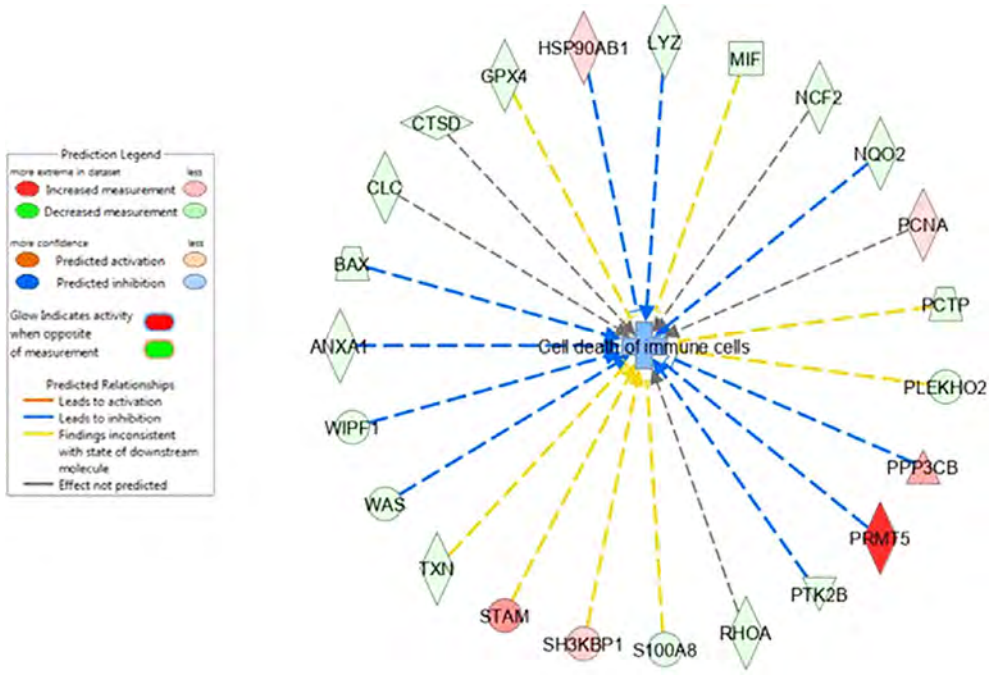

Figure 2: Specific network of cell death pathway shows differentially expressed proteins in the cytosol of blood neutrophils from OA patients and HC. Red indicates increased measurement of proteins, green indicates decreased measurements of proteins in neutrophils from OA patients compared to HC. Blue and orange indicate predicted inhibition and activation as shown in the colored legend.

Reactive Oxygen Species-scavenging Nanoparticles Target Macrophage Polarization for Osteoarthritis Therapy

Caifeng Deng[1], Yongbing Xiao[2], Xuan Zhao[1], Hui Li[2], Yuxiao Chen[1], Chao Zeng[2] and Guanghua Lei[2], [1]Xiangya Hospital, Changsha, China, [2]Department of Orthopaedics, Xiangya Hospital, Central South University, Changsha, China

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Unbalanced M1/M2 polarization of synovial macrophages plays vital roles in the symptomatic and structural progression of osteoarthritis (OA). The accumulation of intracellular reactive oxygen species (ROS) and the inflammation response cooperatively regulate the phenotype of M1macrophages.The compensatory pathwaysbetween ROS and inflammation in M1macrophages limited the efficacy of treatment regimen modulating a single element (oxidative stress or inflammation). Therefore, we developed a ROS-scavengingand anti-inflammatory agent (licofelone, LCF)-loaded nanoplatform (termed LCF-CSBN) for simultaneously down-regulating inflammatory response and reducing ROS in M1macrophages. The purpose of this study was to investigate the phenotypic reprogramming effect of LCF-CSBN on M1 macrophages and evaluate the efficiency and safety of intraarticular (IA) injection of LCF-CSBN in dealing with OA rat models.

Methods: Cell internalization of LCF-CSBN in M1macrophages was examined by flow cytometry analysis and colocalization study. Scavenging of intracellular ROS were detected by ROS assay kit. RNA sequencing analysis, immunofluorescence (IF) staining, and enzyme-linked immunosorbent assay were performed to measure the mRNA and protein expressions of pathogenic mediators and macrophage polarization markers inM1macrophages treated with LCFand LCF-CSBN. The intra-articular retention time and biodistribution of LCF-CSBN in vivo were evaluated by vivo imaging system and IF staining. Furthermore, LCF-CSBN was injected intra-articularly into the osteoarthritic knee of rats at 3 days after monosodium iodoacetate (MIA) injection and at 5 weeks and 8 weeks after anterior cruciate ligament transection combined with partial medial meniscectomy surgery. Pain behavior assessments, histological analysis, immunohistochemical staining, micro-computerized tomography analysis, and serum enzyme analysis were performed to evaluate the therapeutic effect and safety of IA injection of LCF-CSBN.

Results: Results of RNA sequencing revealed that LCF-CSBN significantly down-regulated the expression of inflammation related genes and reprogrammed the phenotype of M1macrophages. LCF-CSBN was demonstrated to successfully transform M1 macrophages into the M2 phenotype by eliminating cellular ROS and inhibiting expression of inflammatory factors. Additionally, LCF-CSBN was retained in the joint for up to 28 days and selectively distributed into synovial macrophages. In both MIA induced and surgically induced OA rat models, LCF-CSBN effectively and safely relieved pain and suppressed synovial inflammation, as well as alleviated cartilage degradation.

Conclusion: LCF-CSBN has an extended joint-retention time and good capacity of reprogramming the phenotype of synovial M1 macrophages, which exhibits satisfying effect on relieving OA pain and delaying OA progression.Taken together, LCF-CSBN is a promising nanomedicine for OA therapy.

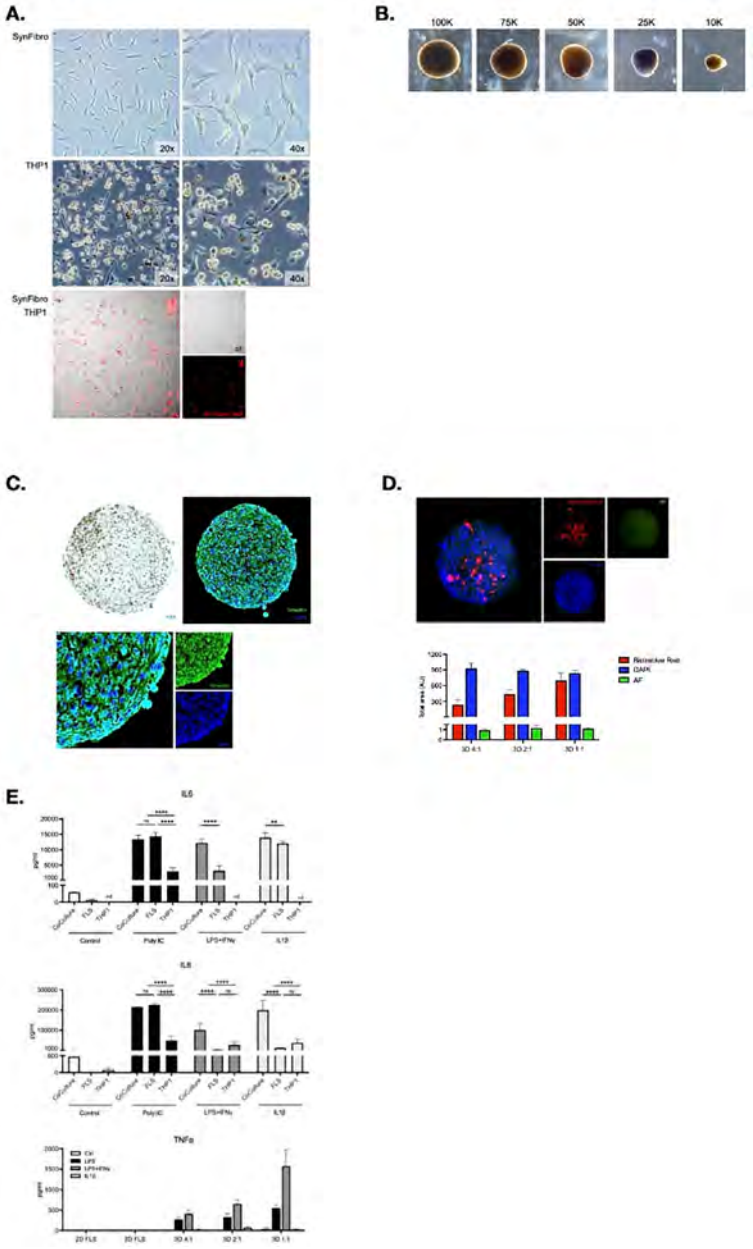
A Novel 3D-Synovium-Immune Microenvironment Mimics Macrophage-Synovial Fibroblast Interactions in Inflammatory Arthropathies

André Tiaden[1], Simone Häner Massimi[1], Ulrich Walker[2], Diego Kyburz[3] and **Stavros Giaglis**[1], [1]Laboratory for Experimental Rheumatology, Department of Biomedicine, University of Basel, Basel, Switzerland, [2]Basel University Hospital, Basel, Switzerland, [3]University Hospital Basel, Basel, Switzerland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmunity, trauma, or infection lead to devastating arthropathies, within enormous socioeconomic impact due to its high frequency and chronicity. The development of novel treatments remains a significant challenge. Moreover, disease a etiology, sequence and drug responsiveness are exceptionally patient-specific, underscoring the need for personalized therapeutic strategies. Invitro cultures and animal models have been helpful in identifying and describing the pathological processes in arthritis; still, they cannot predict individual responses to treatment due to the complexity of the synovium. In the present study we sought to establish a reproducible organoid model that emulates the complex biological interactions within the human synovium, mimicking pathological conditions of the inflamed joint.

Figure 1



Methods: For the establishment of 2D and 3D cell cultures, native synovial fibroblasts and THP1 macrophages were utilized. Patient sample collection and biobank storage at the Rheumatology Department and Orthopedics Department USB was approved by the ethics review board EKNZ (2019-01391). Organoids were assembled by adding biocompatible magnetic nanoshuttles and subsequent bioprinting (m3D, Greiner BioOne), allowing self-assembly of cells into 3D structures by building autologous extracellular matrix. This highly scalable, reproducible, independent of artificial scaffolds approach, supports a native microenvironment preserving endogenous tissue phenotypes. Optimal setup parameters - growth status, cell number, size and culture conditions - organoid maturation, and medium formulation were tested, and inflammatory responses were assessed in the presence of RA-relevant stimuli by measuring the secretion of cytokines (ELISA) and the expression of cellular phenotypes (IHC).

Results: Biological material from 6 OA patients, including synovial tissue, plasma, serum, and synovial fluid was collected and stored. 2D and 3D synovial fibroblast and THP1 macrophage cultures (Figure 1A), cocultures (Figure 1B) and organoids (Figure 1C) were established. Macrophage incorporation in the synovial organoids was confirmed in different coculture

schemes (Figure 1D). Data from a restricted set of RA-relevant markers displayed a synergistic effect of the coculture setting on proinflammatory cytokine secretion after stimulation; moreover, initial assessments comparing the 2D cultures and 3D organoids upon inflammatory stimulation showed that macrophages are the main source of TNFα (Figure 1E).

Conclusion: The establishment of an engineered human 3D synovial tissue model, emulating the human synovium by utilizing targeted tissue material, serves to functionally test essential aspects of synovial inflammation. The ability to induce inflammatory responses in the organoids provides a proof of concept for cytokine-driven inflammation in autoimmunity. This may serve as an important tool in drug development and personalized medicine, and tackle the limited predictive value of existing in vitro and in vivo animal models.

(A.) Representative bright-field microphotographs of 2D cultures of synovial fibroblasts (upper panel), THP1 macrophages (middle panel) in two different magnifications, and respective cocultures (lower panel); THP1 derived macrophages are stained with BioTracker Red (magnification: 10x). (B.) Representative bright-field microphotographs of organoids depicting the process of optimization of the synovial fibroblast number (10.000-100.000) used in the 3D organoid cultures. (C.) Representative bright-field microphotograph depicting a synovial fibroblast-derived organoid with gold-iron oxide polylysine magnetic nanoparticles (upper left panel). A similar culture setup was confirmed by fluorescent IHC of the synovial fibroblast marker vimentin (upper right panel); a detail of vimentin spatial distribution is provided in the lower panel. (D.) Successful incorporation of the THP1 macrophages in the synovial organoid was confirmed by Biotracker Red cellular stainings (left panel), in different proportional schemes of cocultruring -1:1, 1:2, 1:4 (right panel). (E.) Protein secretion of IL6 (upper panel) and IL8 (middle panel) in supernatants of single culture and cocultures of synovial fibroblasts and THP1 cells. Macrophages appear to be the main producers of TNFα in the 3D organoids, as assessed by ELISA (lower panel).

Pentosan Polysulfate Sodium, a Glycosaminoglycan Mimetic Demonstrates Durable Effects on Pain, Function and Joint Structure in Canine Naturally Occurring Osteoarthritis

Ravi Krishnan[1], Catherine Stapledon[2], Christian Reiter[2], Stewart Ryan[3], Sebastien Bauquier[3] and Thierry Beths[3], [1]Paradigm Biopharmaceuticals, Adelaide, Australia, [2]Paradigm Biopharmaceuticals, Melbourne, Australia, [3]U-Vet Werribee Animal Hospital, University of Melbourne, Melbourne, Australia

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pentosan Polysulfate sodium (PPS) is a semi-synthetic polysaccharide and a glycosaminoglycan mimetic. The multiple actions of PPS involve anti-inflammatory effects via inhibition of NF-κB; analgesia by normalising the pain mediator, NGF; and chondroprotection by inhibiting ADAMTS-5 degradation of aggrecan in cartilage. The study objectives were to evaluate the durability of effect of PPS therapy in companion dogs with naturally occurring osteoarthritis (OA) at six months (26 weeks) and to evaluate the effects of PPS for disease modifying potential.

*Effect size (ES) of PPS Treatment Compared to Placebo demonstrate durability of favourable outcome measures in pain, function, joint structure, and serum biomarker: Hedges' g analysis at week 8 and 26 from baseline

Outcome Measures	8 Weeks (ES)	26 Weeks (ES)
HCPI	0.39#	1.79##
TPI%	0.55	0.5
Cartilage Volume	1.06	0.73
CTX-1	1.15	1.6
HA	0.58	1.19
TIMP-1	0.96	1.27

*Effect Size Ranges: Small (0.2 – 0.49); Medium (0.5 – 0.79); Large (>0.8)
% change from week 6
% change from week 8

Methods: In a double-blinded study, twenty dogs (12 males and 8 females; mean weight: 26.05 kg, (SD 4.5); mean age: 9.9 years, (SD 2.0)) with OA were randomised to subcutaneous PPS injections (3 mg/kg; human equivalent dose of 1.7 mg/kg) or placebo weekly for 6 weeks in a 2:1 ratio, respectively. At baseline, week 8 and week 26, the index stifle or elbow were analysed by the Helsinki Chronic Pain Index (HCPI) for pain; gait analysis by Total Pressure Index % (TPI%) for joint function; and total cartilage volume by MRI for joint structural changes. Validated ELISAs for serum biomarkers of joint degeneration (CTX-I, Hyaluronic acid (HA), TIMP-1) were assayed. The mean percentage change from baseline (%CFB) at weeks 8 and 26 were used to determine the effect size (ES) of PPS treatment compared to placebo using the Hedges' *g* test.

Results: PPS treatment showed meaningful ES improvement in pain at week 26 compared to placebo with a reduction in mean percentage change from the previous follow-up at week 8 in HCPI (ES 1.79). The improvement in pain was reflected by a larger effect size at the later time of 26 weeks relative to week 8 (ES 0.39) suggesting durability of PPS effects on pain. Long-term functional improvements in gait were demonstrated by an increase in mean %CFB in TPI% and sustained by ES of 0.55 and 0.5 at weeks 8 and 26, respectively. Furthermore, the mean %CFB in TPI% for PPS treatment at weeks 8 and 26 was 7.3% and 8.2%, respectively, whereas clinically meaningful increases reported at 5% were not met by placebo. There were larger reductions in cartilage volume in the placebo group compared to PPS treatment at 8 and 26 weeks with a large PPS ES of 1.06 and 0.73, respectively suggesting reduction in structural degeneration of the articular cartilage. PPS favourably affected serum levels of CTX-1, HA and TIMP-1 supporting the in vivo mechanisms of drug action.

Conclusion: Compared to placebo, the long-term effect of PPS therapy results in the improvement of pain, function, cartilage volume and serum biomarkers at 26 weeks from baseline suggesting that PPS stabilises disease progression in canine OA and may translate to disease modification in humans. PPS was well tolerated during treatment and follow up.

Enhancing Oxidative Phosphorylation Through PDK2 Depletion Alleviates Cartilage Degradation in Surgically Induced Osteoarthritis

Seungwoo Han[1], Jin Han[2], Yujung kim[2], Yoonhee Kim[2] and Donghwi Park[3], [1]Kyungpook national university hospital, Daegu, South Korea, [2]Kyungpook National University, Daegu, South Korea, [3]Daegu Fatima hospital, Daegu, South Korea

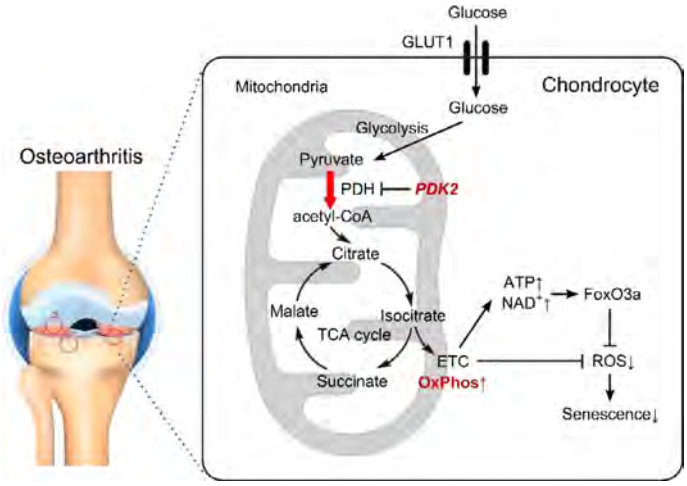
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Although chondrocytes rely primarily on glycolysis to meet their cellular energy needs, they have the metabolic flexibility to shift toward oxidative phosphorylation (OxPhos) in the early stage of osteoarthritis (OA). As the disease progresses, however, this metabolic adaptation of OA cartilage reaches its limit and eventually fails, resulting in mitochondrial dysfunction and oxidative stress which are hallmarks of OA. The objective of this study was to determine whether the modulation of OxPhos through pyruvate dehydrogenase kinase (PDK)-2 affects metabolic flexibility of chondrocytes, and cartilage degeneration in surgical model of OA.

Methods: Primary chondrocytes were obtained from E15.5 C57BL/6J long bones of PDK2 KO mice and their WT littermates. Interleukin (IL)-1β (10 ng/mL) was applied to recapitulate the catabolic stress mimicking OA conditions. Surgical OA was induced in 12-week-old male WT (C57BL/6J) and PDK2 KO mice by destabilization of the medial meniscus (DMM). Metabolic shift by PDK2 deficiency was analyzed with XF96 Extracellular Flux Analyzer.

Results: Among PDK isoforms (PDK1-4), only PDK2 expression was increased by IL-1β at both RNA and protein levels in vitro, and in the articular cartilage of the DMM OA model in vivo. PDK2-deficient mice exhibited significant protection from DMM-induced cartilage destruction, which was accompanied by a decrease in oxidative stress and pain-related behaviors. PDK2 deficiency partially restored oxidative phosphorylation and decreased glycolysis in IL-1β-treated chondrocytes, which led to an increase in ATP concentration, and the NAD+/NADH ratio. PDK2 deficiency significantly increased the phosphorylation of pyruvate dehydrogenase (PDH), the inactive form, which was accompanied by a decrease in reactive oxygen species (ROS) and chondrocyte senescence, as well as the expression of MMP-13 and IL-6 induced by IL-1β treatment. At the signaling level, PDK2 deficiency enhanced FoxO3a and decreased p38 signaling, but did not affect AMPK, mTOR, and NF-kB pathways upon IL-1β stimulation. FoxO3a knockdown masked the reduction of ROS and senescence brought about by PDK2 deficiency, implying that PDK2 effects are FoxO3a-dependent.

Conclusion: Our study provides the proof-of-concept of PDK2-mediated metabolic reprogramming of chondrocytes towards OxPhos as a new therapeutic strategy for OA.



PDK2 is predominantly expressed under catabolic conditions, and its deficiency promotes oxidative phosphorylation and ATP production in chondrocytes. It induces FoxO3a activation, subsequently leading to the reduction of oxidative stress and cellular senescence.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Defects in homeostatic mechanisms, such as autophagy, contribute to joint aging and Osteoarthritis (OA) and precede joint damage (1). OA is a complex and multifactorial disease where systemic metabolic status plays a key role. Hence, patients with Type 2 Diabetes (T2D) present more prevalent and severe OA, so it has been recognized as an independent clinical phenotype of OA. However, mechanisms underlying this comorbidity are poorly understood. Previous results from our group showed that diabetic conditions compromise autophagy in chondrocytes, and this facilitates OA development and progression, suggesting that impaired autophagy can be one of the mechanisms involved in OA-T2D interaction (2). Moreover, pharmacological activation of autophagy was sufficient to protect against diabetes-induced joint destruction (3). These observations support studies exploring autophagy markers at systemic and tissue levels to identify key mechanisms of OA-T2D interactions.

Methods: To address this objective a comparative analysis of 35 autophagy genes was performed using an autophagy expression gene array from blood of non-OA subjects (n=18) and Knee OA subjects (n=18, OA grade III-IV) from the Prospective Cohort of OA of A Coruñ a (PROCOAC) and then validated in a second set of subjects (Non-OA and Knee-OA subjects (n=30) by qPCR. Differentially regulated candidate genes were analyzed by qPCR in blood from Knee OA-T2D subjects (n=30, OA grade III-IV) and cartilage from Knee OA and OA-T2D subjects (n=12, OA grade III-IV). Contribution of candidate marker to chondrocyte homeostasis was explored by using a model of diabetes exposing human chondrocytes to high glucose and insulin (3).

Results: The gene expression array and the validation studies confirmed a significant downregulation of *PTEN*, *HSP90AA1* and *MAP1LC3B* in blood from knee OA subjects compared to non-OA subjects. Then, these candidate genes were analyzed in a subgroup of subjects from the PROCOAC cohort with knee OA-T2D. The results confirmed a significant downregulation of *HSP90AA1* in knee OA-T2D subjects ($p < 0.01$) and no significant differences were found for *MAP1LC3B* (4). Interestingly, *PTEN,* a potent tumor suppressor gene that inhibits the PI3K/Akt signaling pathway and governs basic celular metabolic processes, was significantly upregulated in blood and cartilage from subjects with knee OA-T2D compared to knee OA subjects ($p < 0.01$). In addition, the regression analysis showed that upregulation of *PTEN* is associated with a risk incidence for knee OA-T2D. Preliminary data from in vitro model of diabetes in human chondrocytes reveals that PTEN is increased upon high glucose and insulin exposure. Moreover, this increase was correlated with defective autophagy flux and increased chondrocyte senescence.

Conclusion: These results suggest that PTEN is a promising candidate marker for Knee OA-T2D subjects. Further studies of this homeostasis mechanism in OA associated to diabetes might elucidate its relevance in the progression of disease.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Disease-modifying therapeutic agents to prevent progression of Osteoarthritis (OA) are an urgent clinical need. Targeting senescence and autophagy in chondrocytes with small molecules is a useful strategy to prevent against chondrocyte death, cartilage aging and OA. Fenofibrate (FN), a peroxisome proliferator activated receptor α (PPARα) agonist employed as a therapy for dyslipidemiaswas identified as a senolytic and pro-autophagy molecule showing chondroprotective properties. Here, we evaluated the efficacy of FN in preclinical models as a disease modifying therapy targeting lipid metabolism for OA. To test the effect of this mechanism, FN was administered by both oral route and intra-articular delivery in surgical models of OA.

Methods: Surgical OA was performed by transection of the medial meniscotibial ligament and the medial collateral ligament in the right knee of 4 months-old C57BL/6 male mice. Left knee was employed as a Sham knee. Mice were randomized according to body weight in two groups for oral administration of FN (O-FN) [Vehicle group (DMSO), N=8 and Treated group (100 mg/kg body weight/day, daily, N=8). An intra-articular drug delivery by extended-release of FN in microspheres for 3 months (IA-FN) was developed to 1) to extend the delivery of FN, which is insoluble in water 2) to provide direct access to the joint enhancing the bioavailability in damaged tissue, and 3) to diminish the effects of systemic administration. Mice were divided into three groups for IA-FN efficacy study [Vehicle group (empty microspheres), N=8, Treated group 1 (1 μg FN) and Treated group 2 (10 μg FN). Determination of pain was performed by using the incapacitance test to measure pain by assessing the dynamic weight bearing of spontaneous postural changes. Pain was evaluated every two weeks until euthanasia. Histopathological changes in articular cartilage and synovium were evaluated. The target engagement studies were performed by immunohistochemistry.

Results: In a preclinical model of OA in mice, the treatment with O-FN did not induce changes in body weight and no liver toxicity occurred after the treatment. The histopathological changes in joint cartilage were significantly reduced in the FN treated group ($P < 0.05$). In addition, the histological evaluation showed a significant decrease in synovitis after O-FN (*P*

< *0.05*). This protective effect was correlated with increased expression of PPARα in mouse knee joints after O-FN treatment (*P < 0.001*). The IA-FN was prepared and comprehensively characterized. IA-FN comprises a PLGA matrix in an optimized ratio, adequate size, appropriate molecular weight, and exhibits a 3-month extended-release profile in human synovial fluid. The preclinical results showed a reduction of joint pain after intra-articular injection of FN (*P < 0.01*). Moreover, IA-FN improved joint function (*P < 0.01*) compared to vehicle condition, suggesting that IA-FN is a disease-modifying therapy for OA.

Conclusion: These findings support further non-clinical regulatory studies to develop IA-FN formulation as a candidate therapy for OA. A GMP manufactured formulation could be used to test the safety of this treatment in patients with OA of the Knee in a Phase 1 clinical trial.

Mitochondrial Transfer Functionally Restores the Human Osteoarthritis (OA) Chondrocyte, Is Protective Against Oxidative Stress and Improves OA in a Clinical Model of Disease

Fernando Figueroa[1], Angela Court[2], Patricia Luz Crawford[2], Ana Maria Vega Letter[2], Francesca Velarde[2], Cynthia Garcia[2] and Maroun Khoury[2], [1]IMPACT, Santiago de Chile, Chile, [2]IMPACT, Santiago, Chile

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthrosis (OA) is a leading cause of pain, disability and early mortality, with no disease modifying treatments. Mitochondrial dysfunction is a known driver of disease. Mesenchymal stromal cells (MSCs) -widely tested in OA- transfer their mitochondria (MT) to damaged tissues in response to stress. **Aim**: To characterize the functional impact of MT transfer (MitoT) from umbilical cord-derived MSC (MSCs) to the human OA chondrocyte (OA-Ch) and clinical effect of MSC-derived MT in a murine model of OA.

Methods: Primary chondrocytes from OA patient surgery were tested for MitoT using *in vitro* co-culture with MSCs. MitoT was evidenced by flow cytometry and confocal microscopy of MitoTracker stained and YPF-tagged MT protein. To single out effects of MitoT on target cells, we employed direct transfer of MSC-derived MT to OA-Chs (Mitoception). The response of target cells was gauged by ATP production, oxygen consumption (OCR), extracellular acidification (ECAR) rates, levels of reactive oxygen species (ROS) superoxide dismutase (SOD), MT network fussion/fission and OA-Ch viability by TUNEL assays. Intra-articular injection of MSC-derived MT was tested in a collagenase induced murine model of OA.

Results: Dose-dependent cell-to-cell MitoT from MSCs to cultured OA-Chs was detected starting at 4 hours of co-culture, with increasing (3.2x) MT-fluorescence levels at higher MSC:Ch ratios. PCR analysis confirmed the presence of exogenous MSC-MT within MitoT$^+$ OA-Chs up to 9 days post Mitoception. Metabolic analysis showed a 2x increase ($p< 0.001$) in ATP and a higher OXPHOS/Glycolysis ratio ($p=0.0213$) in target OA-Chs revealing a switch towards an activated energy state of chondrocytes after MitoT. Increased SOD2 mRNA transcripts ($p< 0.05$), protein levels (1.8-fold), MT-SOD activity (2.9-fold)

and reduced ROS levels (p=0.039) were coincident with enhanced resistance of OA-Chs to apoptosis, indicating this effect of MitoT is related to the control of ROS. In parallel, the change in mRNA transcripts and proteins that control the fusion/fission state of the MT network, showed increased expression of MFN2 ($p< 0.01$) and decreased p-DRP1 ($p< 0.05$) that promote a predominantly fused MT network, that contributes to chondrocyte preservation. In the preclinical OA model, intra-articular treatment with MSC-derived MT improved histologic scores ($p< 0.001$) and MicroCT imaging of the diseased joints ($p< 0.01$).

Conclusion: MSC-derived MT transferred to the OA-Ch convey significant changes in energy balance, MT dynamics, resistance to oxidative stress and OA-Ch apoptosis. Intra-articular MT treatment improved disease in a murine model of OA. These findings might represent a new strategy in the treatment of this disease.

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session B

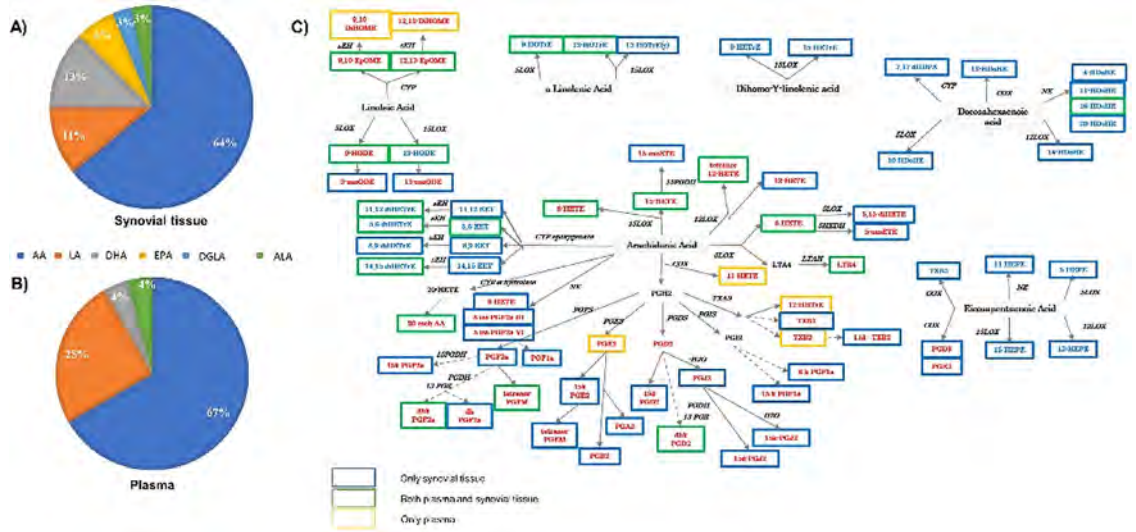
Session Time: 9:00AM–11:00AM

Background/Purpose: Oxylipins are bioactive lipids derived from polyunsaturated fatty acids (PUFAs) that modulate inflammation and may remain overexpressed in refractory synovitis. These mediators in plasma could also be biomarkers of synovial pathology. The aim of this study is to determine synovial oxylipins in active inflamed joints and their correlation with plasma oxylipins.

Methods: Patients with established rheumatoid or psoriatic arthritis with active disease despite treatment were recruited and paired synovial tissue (ST) and plasma were collected. Oxylipins were determined by liquid chromatography with tandem mass spectrometry and were classified into groups according to their PUFA precursor and enzyme. The expression of CD20, CD68, CD3 and CD138 were obtained to describe synovial histology. Cell specific expressions of oxylipin-related genes were identified by examining available synovial scRNA-seq data.

Results: We included a total of 32 ST and 26 paired-plasma samples. A total of 64 oxylipins were identified in ST but only 28 were identified in plasma (**Figure 1**). Only levels of 11,12-di-HETrE, 15-HETE, 16-HDoHE and tetranor-PGFM had a statistically significant positive correlation between plasma and ST. Multivariate approaches were conducted to capture the global picture of oxylipins disturbances according to the histological classification. Although PLS-DA with the identified

Figure 1. Oxylipin profile in tissue and plasma. A-B) Pie chart representing the percentage of oxylipins grouped by precursors in tissue A) and B) plasma. C) Scheme showing the panel of oxylipins found in both tissue and plasma in a green box. The oxylipins found only in plasma are highlighted in yellow, and the oxylipins found only in synovial tissue are highlighted in blue. Pro-inflammatory oxylipins are marked in red and oxylipins associated with resolution of inflammation are marked in blue. AA: arachidonic acid; LA: linoleic acid; DHA: docosahexaenoic acid; EPA: eicosapentaenoic acid; DGLA: dihomo gamma linolenic acid; ALA: alpha-linolenic acid. The abbreviations list for oxylipin names can be found in Supplementary Table 1. COX – cyclooxygenase; LOX – lipoxygenase; CYP – cytochrome P450; NE – non-enzymatic; PGFS – prostaglandin F synthase; PGES – prostaglandin E synthase; PGDS – prostaglandin D synthase; PGIS – prostaglandin I synthase; TXAS – thromboxane A2 synthase; LTAH – leukotriene A4 hydrolase; MDB – membrane dipeptidase; HEDH - hydroxyeicosanoid dehydrogenase; PGDH - hydroxyprostaglandin dehydrogenase; 13-PGR – 15-ketoprostaglandinΔ13 reductase; sEH – soluble epoxide hydrolase.



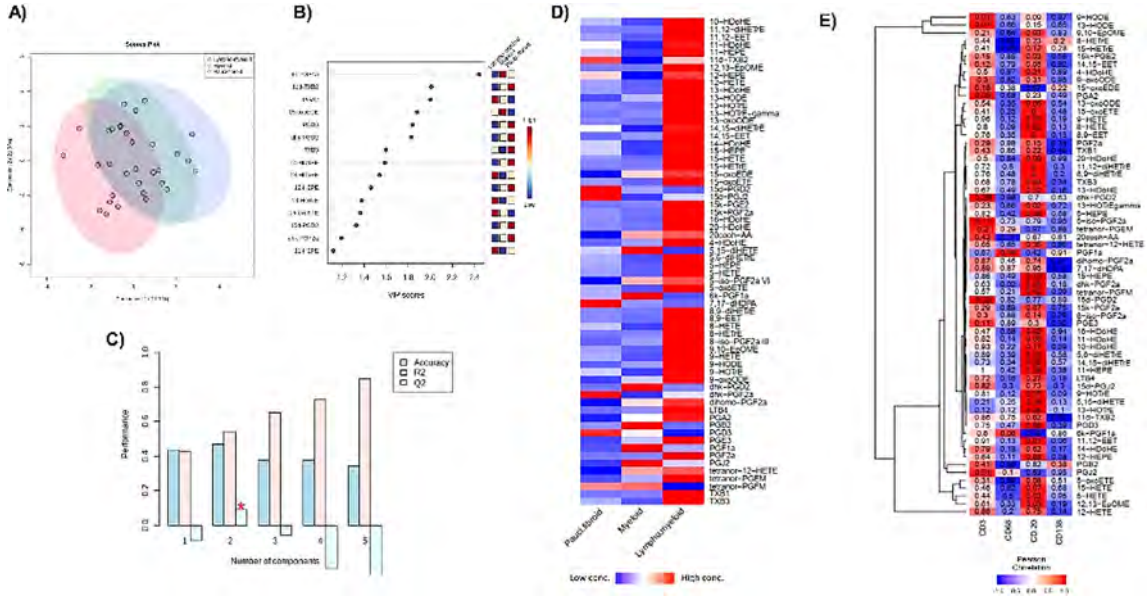


Figure 2. Discrimination between pauci-fibroid, myeloid and lympho-myeloid phenotypes in tissue. A) PLS-DA considering all samples of tissue (n=32) where is observed an overlap within the 3 phenotypes and B) VIP score obtained from the second component of PLS-DA analysis. C) Cross validation analysis using a maximum of 5 components to search and leave-one-out cross validation. Component 2 showed positive predictive ability to separate the three phenotypes with an accuracy= 0.47, R2= 0.54 and Q2= 0.09. D) Heatmap of mean concentrations of oxylipins by histological phenotypes where red is high concentration and blue shows low concentration. E) Pearson correlation adjusted by age and BMI between histological markers semi quantification and concentration of oxylipins in tissue using Euclidean distance and ward clustering algorithms where red color indicates positive strength of association while blue indicates negative correlation. P value is stated on each cell.

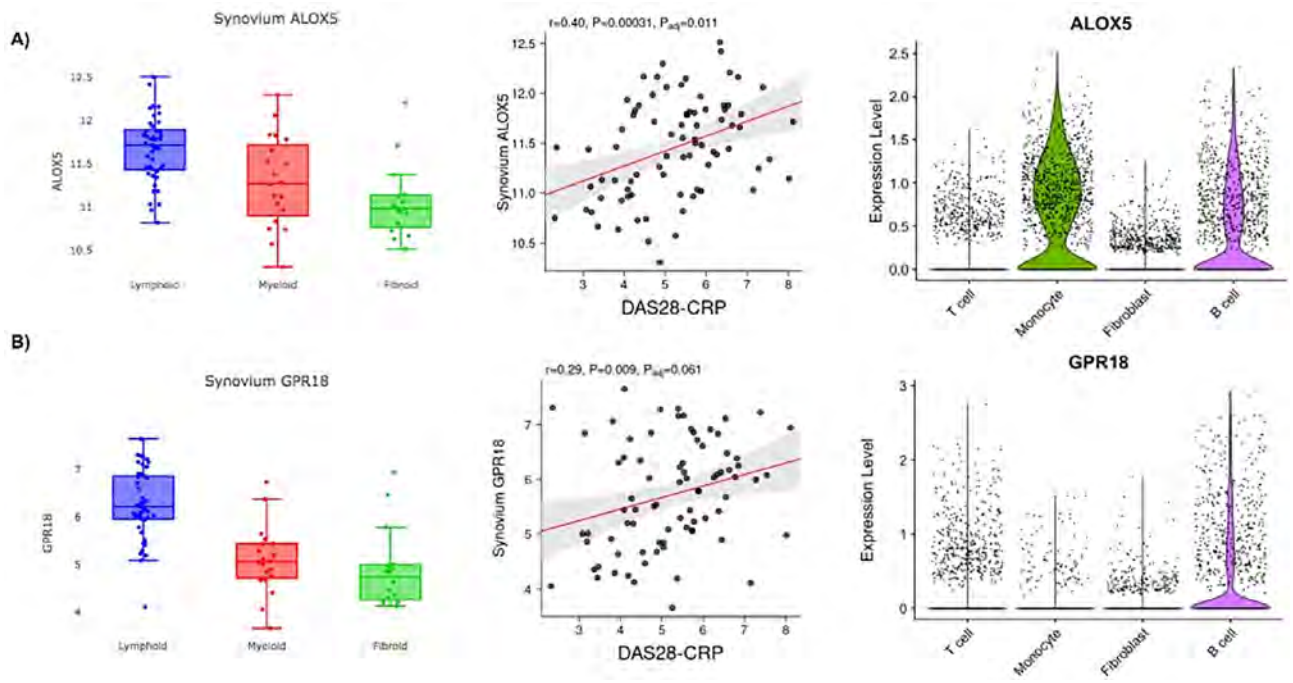

Figure 3. Synovial 5-LOX-derived oxylipins define the synovial lympho-myeloid phenotype. RNA-seq expression of 5-LOX (A) and GPR18 (B) in the different histologic phenotypes and correlation with disease activity from PEAC "gene view", and violin plots from scRNA-seq data2. Boxplots of ALOX5 showed a higher expression in lymphoid group compared to myeloid (p= 0.009) and pauci-fibroid (p< 0.001) phenotypes and positive correlation with disease activity (r=0.40, p=0.01). In violin-plot is observed that ALOX5 was highly expressed in monocytes and B cells. GPR18 shows in boxplot higher expressed in the lymphoid group compared to myeloid (p <0.001) and pauci-fibrotic (p= <0.001), showing a tendency with a positive correlation with disease activity (r= 0.29, p= 0.06), and highly expressed in B cells observed in violin plot.

metabolites in the tissue showed some overlap between the 3 groups (**Figure 2A**),6k-PGF1a, 11d-TXB2 and PGA2 were the most important metabolites in component 2 to discriminate between the three groups with a VIP score >2 (**Figure 2B).** This component showed a positive predictive ability to separate the three phenotypes with an accuracy= 0.47, R2= 0.54 and Q2= 0.09 (**Figure 2C)**. We found higher concentration of several oxylipins in the lymphoid-myeloid phenotype (**-Figure 2D**) which a positive correlation with CD3 and CD20 semiquantification (**Figure 2E**). Several oxylipins and oxylipin-related genes were differentially expressed among synovial phenotypes. Specifically, several 5-LOX-derived oxylipins were statistically elevated in lympho-myeloid phenotype and associated with B cells expression (**Figure 3**).

Conclusion: The lack of correlation between synovial tissue and plasma oxylipins suggests that synovial lipid profiling better characterizes active pathways in treated joints. Synovial 5-LOX-derived oxylipins were more highly expressed in B cell-enriched synovium, thus combination therapy with 5-LOX inhibitors to improve refractory inflammation may be needed in patients with this histological group.

Abstract Number: 0873

FOXO Activators as Drugs for Osteoarthritis

Ichiro Kurakazu, Merissa Olmer, Kevin Myers and Martin K Lotz, Scripps Research Institute, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Forkhead box O (FOXO) proteins are a family of transcription factors involved in lifespan, aging, and autophagy. FOXO are essential for maintaining cartilage homeostasis as reduced expression of FOXO1 and FOXO3 with aging, results in osteoarthritis (OA) due to reduction in the expression of autophagy-related genes. FOXO activity is strictly regulated by nuclear-cytoplasmic shuttling. Drugs that promote nuclear FOXO and activity could be promising therapeutics for OA. Here, we discovered candidates of FOXO activators and evaluated their effects on chondrocytes.

Methods: We performed in silico drug prioritization of small molecules that enhance nuclear accumulation of FOXO1 or FOXO3 and selected 5 drug candidates, selinexor, dactolisib, cyproheptadine, LOM612, and psammaplysene-A from previously identified FOXO activators and confirmed their effects on FOXO nuclear translocation in human chondrocytes. Next, chondrocytes were treated with FOXO activators to evaluate their effects on the expression of autophagy-related genes, and the induction of catabolic factors after IL1β stimulation by qRT-PCR. RNA-sequencing of chondrocytes treated with cyproheptadine with or without IL1β stimulation was performed to clarify the target genes and mechanisms.

Results: Selinexor induced the nuclear accumulation both of FOXO1 and FOXO3, dactolisib and cyproheptadine induced FOXO3 nuclear accumulation, whereas LOM612 and psammaplysene A did not change FOXO translocation in chondrocytes. Among the 3 drugs which induced FOXO nuclear accumulation, cyproheptadine most effectively upregulated the expressions of autophagy-related genes (*MAP1LC3B*, *GABALAPL1*, *ATG14*) and inhibited the induction of catabolic factors (*IL6* and *MMP13*) under IL1β stimulation (Figure 1). Enrichment analysis with the upregulated genes in RNA-seq showed that 'Cholesterol metabolism' was the most highly enriched pathway, suggesting that cyproheptadine modulates cholesterol

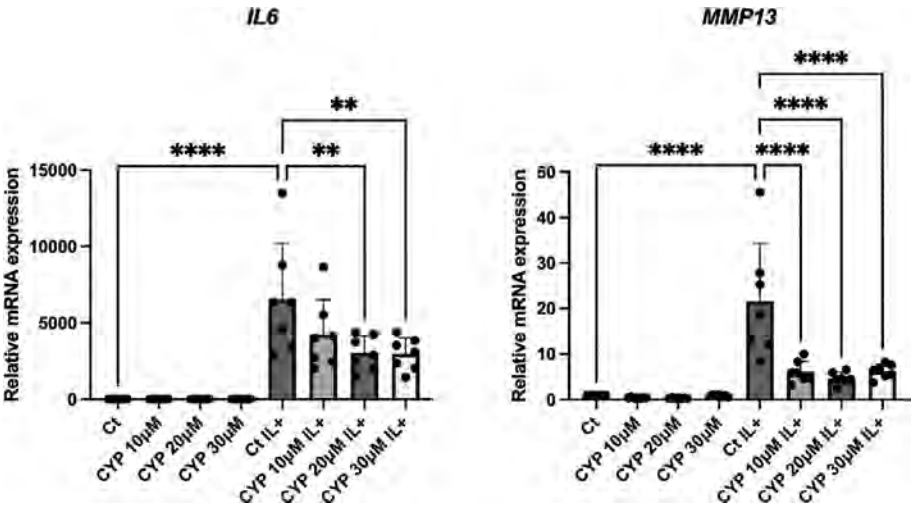

Figure.1: Gene expression of IL6 and MMP13 in human primary chondrocytes with or without IL1β stimulation (1ng/mL) for 6 hours after pretreatment with cyproheptadine (CYP) for 24 hours. **P<0.01, ****P<0.0001 (One-way ANOVA with the Tukey-Kramer post hoc test).

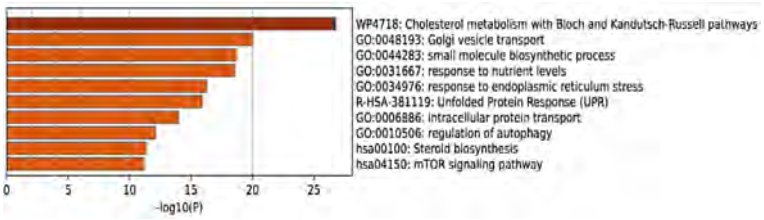

Figure.2: Enrichment analysis with the upregulated genes in RNA-seq of human primary chondrocytes treated with cyproheptadine (30μM) for 24 hours.

levels in chondrocytes (Figure 2). Cyproheptadine also regulated 'Autophagy'. In the presence of IL1β, the enrichment analysis with the downregulated genes showed cyproheptadine inhibited 'Cytokine signaling' via NFκB pathway.

Conclusion: Cyproheptadine induced FOXO3 nuclear accumulation and autophagy-related genes expression and inhibited catabolic factors. In addition, cyproheptadine showed a potential as a modulator of cellular cholesterol biosynthesis, which is associated with age-related diseases including OA. Further experiments in vitro and in vivo are ongoing to clarify the detailed effects of cyproheptadine as a candidate for drug-repurposing in OA.

RNA-Binding Proteins That Are Highly Expressed and Enriched in Healthy Cartilage but Suppressed in Osteoarthritis

Hannah Swahn, Merissa Olmer and Martin K Lotz, Scripps Research Institute, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: RNA-binding proteins (RBPs) have diverse and essential biological functions, but their role in cartilage health and disease is largely unknown. The objectives of this study were (i) map the global landscape of RBPs expressed and enriched in heathy cartilage and dysregulated in osteoarthritis (OA); (ii) prioritize RBPs for their potential role in cartilage and in OA pathogenesis and as therapeutic targets.

Methods: Our published bulk RNA-sequencing (RNA-seq) data of healthy and OA human cartilage, and a census of 1,542 RBPs were utilized to identify RBPs that are expressed in healthy cartilage and differentially expressed (DE) in OA. Next, our comparison of healthy cartilage RNA-seq data to 37 transcriptomes in the Genotype-Tissue Expression (GTEx) database was used to determine RBPs that are enriched in cartilage. Finally, expression of RBPs was analyzed in our single cell RNA-sequencing (scRNA-seq) data from healthy and OA human cartilage.

Results: We first investigated in an RNA-seq dataset of healthy human knee cartilage the expression patterns of genes encoding RBPs. Expression of RBPs was higher than nonRBPs, transcription factors (TFs) and long non-coding RNAs (lncRNAs) in healthy cartilage. We next asked which RBPs were specifically enriched in cartilage compared to 37 other issues in GTEx. This analysis revealed 313 cartilage-enriched genes, 11 of which were RBPs (Figure 1). In OA cartilage,

188 RBPs were DE, with a greater proportion downregulated (Figure 2). After identifying the DE RBPs, we investigated their protein associations using STRING. The 188 DE RBPs formed a highly dense protein-protein interaction network. We next investigated both the gene ontology programs and biological pathways associated with the up- and downregulated RBPs. Ribosome biogenesis was enriched in the upregulated RBPs, while splicing and transport were enriched in the downregulated. ChIP-X Enrichment Analysis 3 (ChEA3) was used to identify potential TFs that regulate the DE RBPs. Of the top

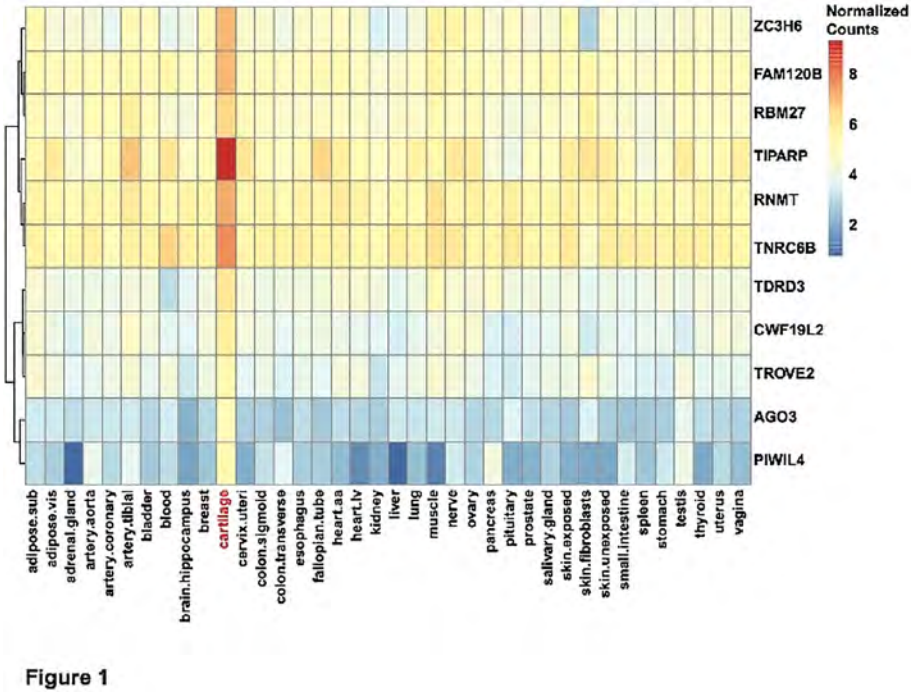

Figure 1. Heatmap showing average normalized counts of cartilage-enriched RBPs compared to all other GTEx tissues.

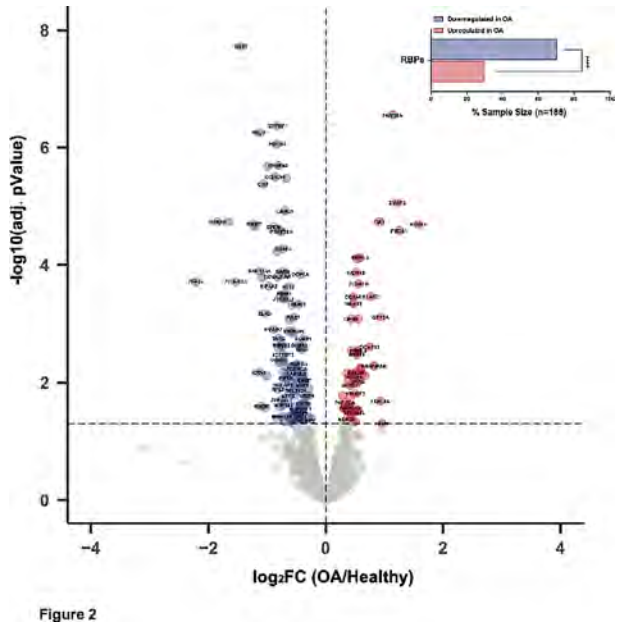

Figure 2. Volcano plot showing 188 DE RBPs. Blue indicates downregulation in OA cartilage compared to healthy, and red indicates upregulation. Gray indicates no significance. Bar chart showing proportion of downregulated (blue) vs upregulated (red) RBPs in OA cartilage. ****p<0.0001 by comparison of proportions test.

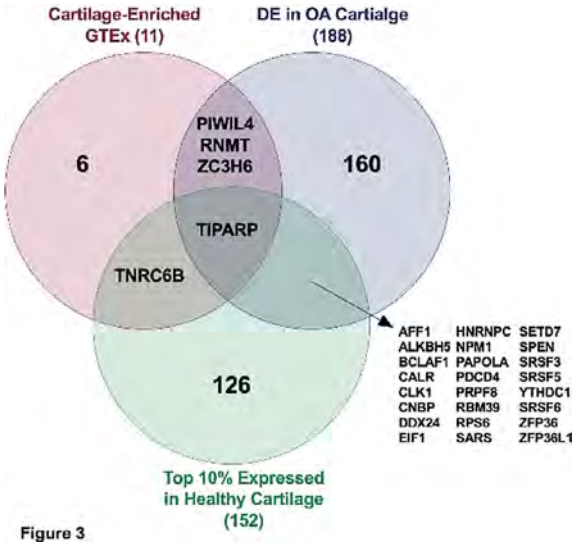

Figure 3. Venn diagram showing intersection of highly expressed (top 10%) RBPs in healthy cartilage, GTEx cartilage-enriched RBPs and DE RBPs in OA cartilage.

20 TFs, the MYC proto-oncogene (MYC) was predicted to regulate the largest number of upregulated RBPs at 42. Of the top 20 TFs, Activating Transcription Factor 1 (ATF1) was predicted to regulate the largest number of downregulated RBPs at 58. To identify a candidate RBP for further studies and as potential therapeutic targets, we investigated other parameters in addition to differential expression including: (i) the top 10% expressed RBPs in healthy cartilage and (ii) those that were cartilage-enriched according to GTEx. Intersecting these three criteria, we identified Tetrachlorodibenzodioxin (TCDD) Inducible Poly(ADP-Ribose) Polymerase (TIPARP) as a candidate RBP (Figure 3). TIPARP was downregulated in OA at both the gene expression and protein levels. scRNA-seq data revealed TIPARP was most significantly downregulated in the 'pathogenic cluster' as well as other fibrocytic clusters, suggesting a context-specific effect for TIPARP in chondrocyte function, which was not evident in the bulk RNA-seq data alone.

Conclusion: Our global analyses reveal expression patterns of RBPs in healthy and OA cartilage. We also identified TIPARP and other RBPs as novel mediators in OA pathogenesis and as potential therapeutic targets.

INV-1498, a Promising Caspase Inhibitor, Exhibits Dose-dependent Therapeutic Efficacy in a Canine Model of Osteoarthritis

Jung Gyu Park[1], **Yurim Lee**[1], Joonghoon Park[2] and myungjin Kim[3], [1]Innovo Therapeutics Inc., Daejeon, South Korea, [2]Institute of Green Bio Science and Technology, Seoul National University, Pyeongchang, South Korea, [3]HLB bioStep Co. Ltd, Incheon, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis poses a substantial medical challenge, as the available treatments primarily target symptom relief and fail to effectively halt the progressive cartilage deterioration that ultimately leads to joint replacement. Addressing this therapeutic gap, the development of interventions capable of preventing or slowing down the progression of osteoarthritis is imperative. This study unveils INV-1498 as an advanced late pre-clinical candidate that exhibits noteworthy, dose-dependent effects on joint structure, function, and pain, offering a promising avenue for addressing osteoarthritis.

Methods: A total of thirty-five purpose-bred dogs were selected for this study. Prior to surgery, the knees of each animal were shaved and the animals were anesthetized. Anterior cruciate ligament resection and excision of the medial meniscus were performed, followed by wound closure. Antibiotics and analgesics were administered for 7 days post-surgery. One week after surgery, the animals underwent artificial exercise for 14 days, with daily sessions lasting 30 minutes. The experimental groups received different doses of the study product (10 mg, 1 mg, or 1 mg in a 1 mL volume) every 5 weeks, while one group received a single 10 mg dose. Triamcinolone 12.5 mg was administered intra-articularly every 5 weeks as an active comparator. After 14 weeks, a CT scan of the knee joint was performed. Pain assessment was conducted throughout the study using the LAMNESS GRADE scale (0-4). At 15 weeks post-osteoarthritis (OA) induction, the dogs were euthanized, and a comprehensive macroscopic evaluation of the operated knee joint was conducted. Tissue sections were prepared and stained with H&E and Safranin O for blinded OARSI histologic scoring.

Results: In the gait assessment, all doses of INV-1498, including the highest dose (10 mg, p=0.0009), exhibited significant improvements, indicating reduced pain. Although there was no statistical significance between doses, a dose-dependent trend of improvement was observed (Figure 1). Analysis of joint structure by CT scan revealed significant improvement only in the highest dose group (10 mg, p=0.0135). Histopathologic evaluation, using the OARSI histopathology method, demonstrated that the highest dose of INV-1498 (10 mg, p=0.0021) significantly reduced proteoglycans, chondrocytes (p=0.0109), and femur-layer lining cells (10 mg, p=0.025). Although not statistically significant, synovial membrane hyperplasia and inflammation tended to be reduced in the INV-1498 group compared to the control group (Figure 2).

Conclusion: Taken together, these data provide compelling evidence of the efficacy of INV-1498 in controlling osteoarthritis progression and symptoms. We found that even a dosing scheme of every 5 weeks prevented the most important pathophysiological changes that promote osteoarthritis progression. These findings position INV-1498 as a highly promising candidate for clinical development as a disease-modifying therapy for osteoarthritis, offering the additional benefit of pain reduction.

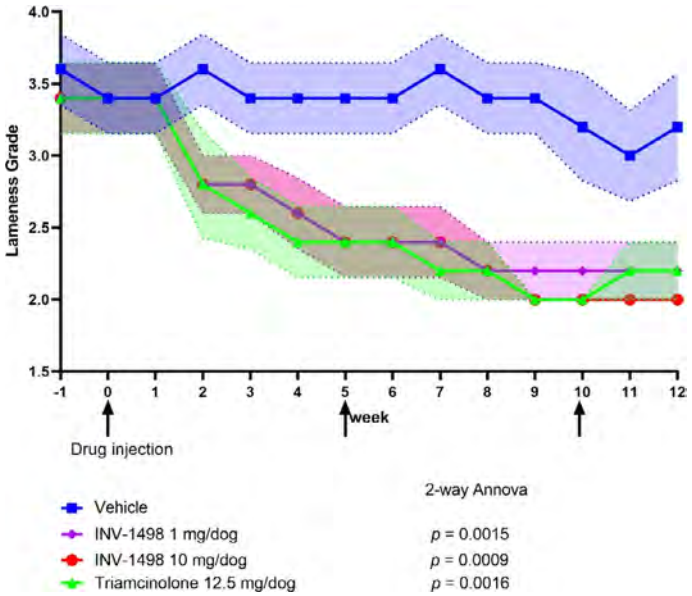

Figure 1. Evaluation of pain relief using gait assessment in a beagle dog meniscectomy model. The line and bar graphs represent mean ± SEM (n = 5).

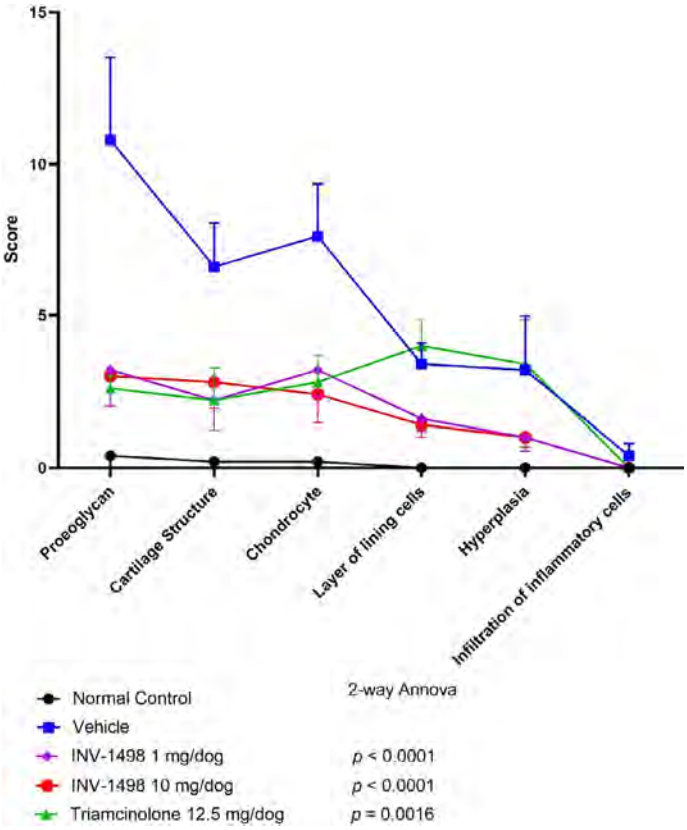

Figure 2. Histopathologic evaluation of the femoral cartilage layer and synovium in a beagle dog meniscectomy model. The Bars represent the mean ± SEM (n = 5).

Metabolomic Analysis Reveals Associations Between Calcium Crystals and Metabolites in Osteoarthritic Synovial Tissue

Nathan Argel[1], Sina Stücker[2], Adnan Cutuk[3], Robert Meyer[3], Nancy Lane[4], Jessica Bertrand[2], Monica Guma[3] and Jessica Murillo-Saich[1], [1]Department of Medicine, University of California San Diego, La Jolla, CA, [2]Department of Orthopaedic Surgery, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany, [3]San Diego VA Healthcare Service, La Jolla, CA, [4]University of California, Hillsborough, CA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Emerging research suggests that synovial inflammation and metabolic alterations are involved in the progression of osteoarthritis (OA). Additionally, the presence of calcium-containing crystals (CC), such as basic calcium phosphate (BCP) and calcium pyrophosphates (CPP) crystals, has been implicated in the development of OA, potentially contributing to inflammatory responses and pain. However, our understanding of the impact of CC on synovial tissue

(ST) in OA remains limited. Therefore, the aim of this study is to investigate the relationship between synovial CC, histological composition, pain as well as the synovial metabolic profile in OA.

Methods: A total of 28 ST samples were collected from patients diagnosed with OA during total joint replacement surgeries. The ST samples were either fixed in formalin for subsequent histological analysis, or snap-frozen for metabolomic analysis. The histological assessment of ST samples was performed using the Krenn histopathological synovitis score, which categorized the samples into two groups: inflammation grade 0-I and inflammation grade II-III. Synovial CD68 positive cells and synovial area containing CC (%Ca++) were assessed by immunohistochemistry and Von Kossa staining respectively, and semi-quantified using Image J. The severity of OA disease was evaluated using the Western Ontario and McMaster

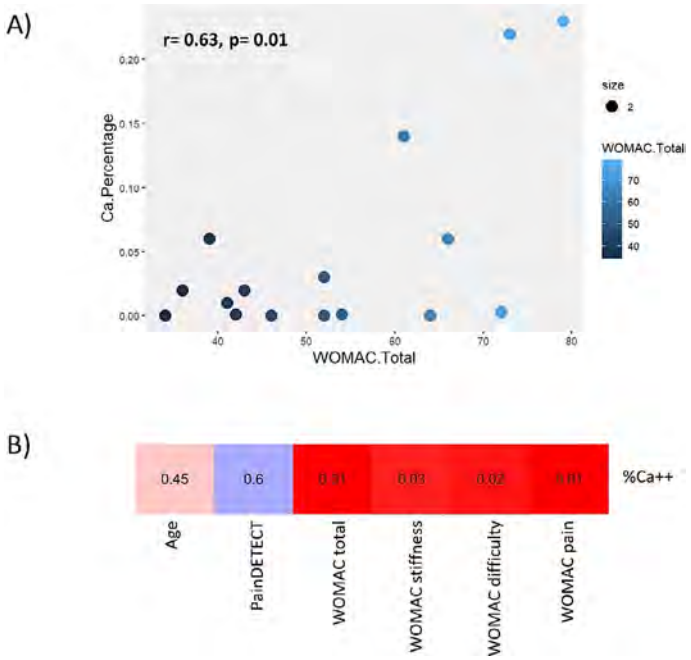

Figure 1. A) Scatter plot showing Pearson correlation between %Ca++ in synovial tissue and total WOMAC. B) Pearson correlation between the % Ca++ in synovial tissue and age, painDETECT and WOMAC scores.

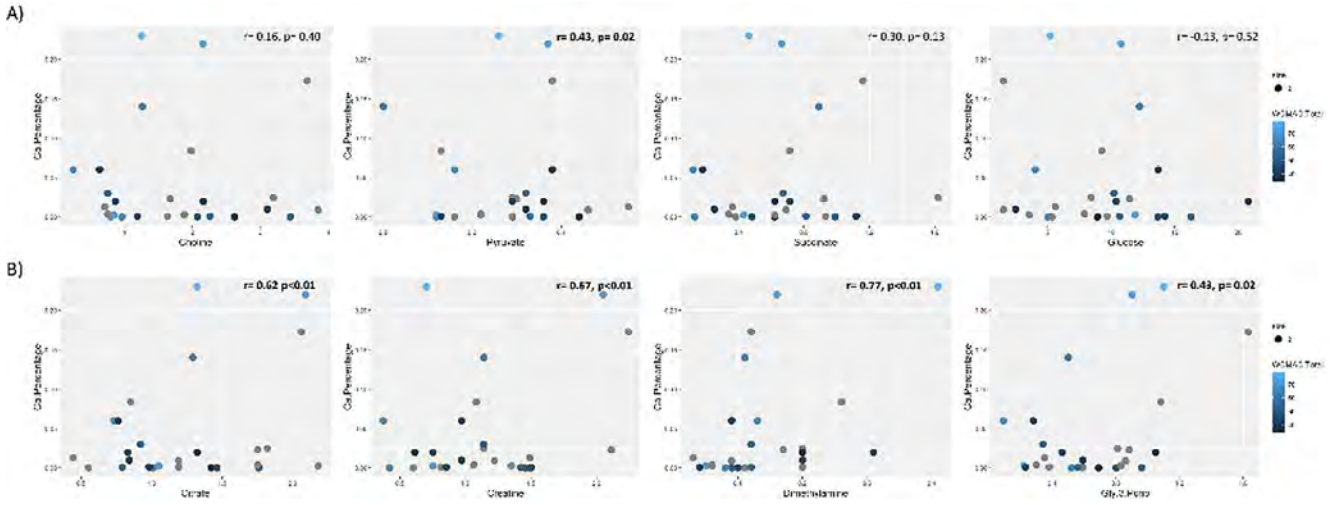

Figure 2. Scatter plot showing Pearson correlation between %Ca++ in synovial tissue and A) metabolites associated to inflammation and B) other metabolites statistically significant.

Universities Arthritis Index (WOMAC). Nuclear Magnetic Resonance (NMR) spectra of the ST samples were acquired using a 600 MHz Bruker Avance III spectrometer with 1H-NMR. The Chenomx NMR Suite 8.5 professional software was employed for metabolite identification and quantification(μM). For statistical analysis, MetaboAnalyst 5.0, SPSS v26, and R Studio software were utilized.

Results: 13 samples with inflammation grade 0-I and 15 samples with inflammation grade II-III samples were included. There were no significant differences observed in the synovial area containing CC (%Ca++) between the two inflammation groups (p=0.48). Furthermore, no correlation was found between %Ca++ and CD68 expression (p=0.84). However, WOMAC scores showed a positive correlation with %Ca++ (**Figure 1A-B**). Regarding metabolites associated with %Ca++, we observed a positive association between pyruvate and %Ca++ (r=0.43, p=0.02) and a tendency for a positive correlation between succinate and %Ca++ (r=0.30, p=0.13). However, metabolites such as choline and glucose did not show any correlation with %Ca++ in ST (**Figure 2A**). Interestingly, we also found positive correlations between %Ca++ and citrate (r=0.62, p< 0.01), creatinine (r=0.67, p< 0.01), dimethylamine (r=0.77, p< 0.01), and sn-glycero-3-phosphocholine (r=0.43, p=0.02) (**Figure 2B**).

Conclusion: Our findings provide evidence supporting the association between synovial CC and the pain phenotype in OA. Although no direct correlation between inflammation and %Ca++ was observed, our results suggest that these crystals may contribute to metabolic alterations in the ST. Further investigations are warranted to elucidate whether the presence of CC in OA triggers pain and to identify the underlying metabolic pathways.

Loss of Transient Receptor Potential Channel 1 (TRPC1) Links Regulation of Intracellular Calcium to Cellular Senescence and Leads to Development of Osteoarthritis

Meike Sambale[1], starlee lively[2], Osvaldo Espin-Garcia[2], Pratibha Potla[2], Chiara Pastrello[3], Alexandra Schaefer[1], Jessica Bertrand[4], Mohit Kapoor[5], Thomas Pap[1] and **Joanna Sherwood**[1], [1]University Hospital Münster, Münster, Germany, [2]University Health Network, Toronto, ON, Canada, [3]Osteoarthritis Research Program, Division of Orthopaedic Surgery, Schroeder Arthritis Institute and Data Science Discovery Centre for Chronic diseases, Krembil Research Institute, Toronto, ON, Canada, [4]Department of Orthopaedic Surgery, Otto-von-Guericke-University Magdeburg, Magdeburg, Germany, [5]Division of Orthopaedics, Osteoarthritis Research Program, Schroeder Arthritis Institute, and Krembil Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Transient receptor potential channel 1 (TRPC1) is a widely expressed mechanosensitive ion channel located within the endoplasmic reticulum membrane. It is crucial for the refilling of depleted internal calcium stores as part of calcium-dependent signaling. Considering the impact of calcium signaling regulation on both homeostatic and inflammatory signaling in chondrocytes, we aimed to examine the role of TRPC1 within cartilage homeostasis and osteoarthritis by monitoring expression during human and murine osteoarthritis (OA) and by assessing the impact of TRPC1 deficiency on OA development and chondrocyte phenotypic stability.

Methods: 10-week old male WT and *Trpc1*$^{-/-}$ mice were subjected to destabilization of the medial meniscus (DMM) and were analyzed by microCT, RNA sequencing, histology and immunofluorescence staining at either 2 weeks or 8 weeks post-surgery for OA severity, TRPC1 expression and phenotypic marker expression. TRPC1 protein expression was evaluated in human OA cartilage samples by immunohistochemistry. *In vitro*, the phenotype of knee articular chondrocytes obtained from 4 day old mice was compared by QPCR, Western blot, SA-b-Gal staining and immunofluorescence. Intracellular calcium mobilization was measured by fluo-4 calcium influx assay.

Results: TRPC1 was found to be depleted from chondrocytes during both human and murine OA development. *Trpc1*$^{-/-}$ mice subjected to DMM developed a more severe OA-like phenotype than wild type (WT) controls. Analysis 2 weeks post-DMM revealed an increased rate of chondrocyte survival in *Trpc1*$^{-/-}$ cartilage, with remaining cells expressing less SOX9 and increased levels of MMP13 and the senescence marker p16^{INK4a}. RNA sequencing followed by GO analysis of articular cartilage from *Trpc1*-/- and WT mice identified a set of differentially expressed genes related to cell number, apoptosis and extracellular matrix organization biological processes.*In vitro*, stimulation of WT chondrocytes with bFGF, ionomycin or thapsigargin all led to an increase in intracellular calcium, however these effects were significantly reduced in *Trpc1*$^{-/-}$chondrocytes. Although *Trpc1*$^{-/-}$ chondrocytes expressed similar levels of chondrocyte differentiation markers at basal level as WT controls, *Trpc1*$^{-/-}$ chondrocytes lost expression of type II collagen and increased type I collagen expression significantly faster than WT during serial passage. Replicative senescence and p16^{INK4a} expression was found to be significantly higher in *Trpc1*$^{-/-}$, both during passage and following IL1 stimulation.

Conclusion: *Trpc1*$^{-/-}$ chondrocytes were less able to maintain a stable chondrocyte phenotype *in vitro* than WT, indicating that TRPC1 activity is required for chondrocyte phenotypic stability. TRPC1 loss was associated with early stages of OA development, while *Trpc1*$^{-/-}$ mice developed a more severe OA-like phenotype following DMM surgery. Both *in vivo* following DMM, and*in vitro* during passage and following IL1 stimulation, *Trpc1*$^{-/-}$ chondrocytes demonstrated an increased susceptibility to cellular senescence. These findings suggest that TRPC1 is a protective factor required for cartilage homeostasis during conditions of physiological challenge.

Synovial Fibroblasts Undergo a Phenotypic Shift from Early- to Late-stage Knee Osteoarthritis

Kabriya Thavaratnam[1], Eric Gracey[2], Anusha Ratneswaran[1], Jason Rockel[1], Shabana Vohra[1], Chiara Pastrello[3], Igor Jurisica[4], starlee lively[5], Sam Dupont[6], Raja Rampersaud[1], Nizar Mahomed[7], Rajiv Gandhi[8], Dirk Elewaut[9] and **Mohit Kapoor**[10], [1]Schroeder Arthritis Institute, Toronto, ON, Canada, [2]Ghent University Hospital, Gent, Belgium, [3]Osteoarthritis Research Program, Division of Orthopaedic Surgery, Schroeder Arthritis Institute and Data Science Discovery Centre for Chronic diseases, Krembil Research Institute, Toronto, ON, Canada, [4]Schroeder Arthritis Institute, Krembil Research Institute and Departments of Medical Biophysics and Computer Science and Faculty of Dentistry, University of Toronto and Institute of Neuroimmunology, Slovak Academy of Sciences, Bratislava, Slovakia, [5]University Health Network, Toronto, ON, Canada, [6]Ghent University Hospital, Ghent, Belgium, [7]Division of Orthopaedics, Osteoarthritis Research Program, Schroeder Arthritis Institute, Krembil Research Institute, and Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [8]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network and Division of Orthopaedics, Department of Surgery, University of Toronto, Toronto, ON, Canada, [9]Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [10]Schroeder Arthritis Institute, University Health Network and Department of Surgery, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The synovium is a connective tissue that lines the joint capsule and is emerging as a key contributor to joint destruction during osteoarthritis (OA). During knee (K)OA pathogenesis, the synovium undergoes substantial changes including inflammation, cellular proliferation and fibrosis. However, the contributions of distinct synovial cell types, particularly fibroblasts (major synovial cells), to synovial pathologies in early and late-stages of KOA are unknown. To identify if distinct cell subtypes and their transcriptomic profiles exist in the synovium during distinct stages of OA disease severity, we used synovium from early (KL1) and late stages (KL3/4) of radiographic KOA and from a knee OA mouse model and subjected these samples to high throughput transcriptomic technologies such as single nucleus RNA sequencing (snRNAseq), bulk RNA sequencing, advanced bioinformatics and functional assays.

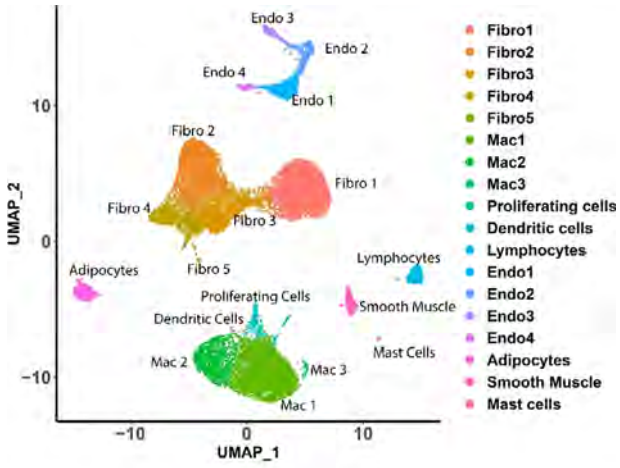

Figure 1: Clustering analyses illustrating all cell types found in KL1 & KL3/4 human radiographic knee OA synovium.

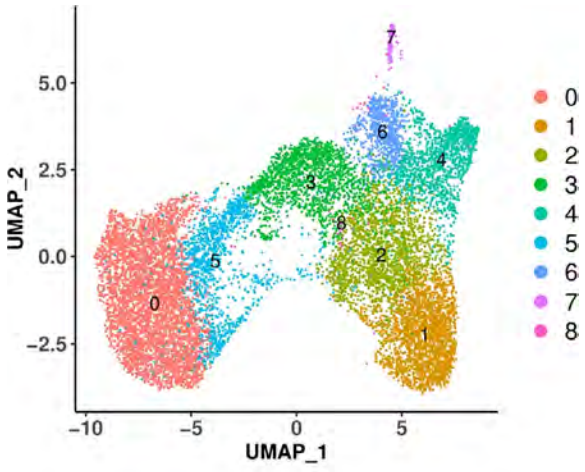

Figure 2: Fibroblast cell clustering analyses identifying 9 fibroblast subtypes.

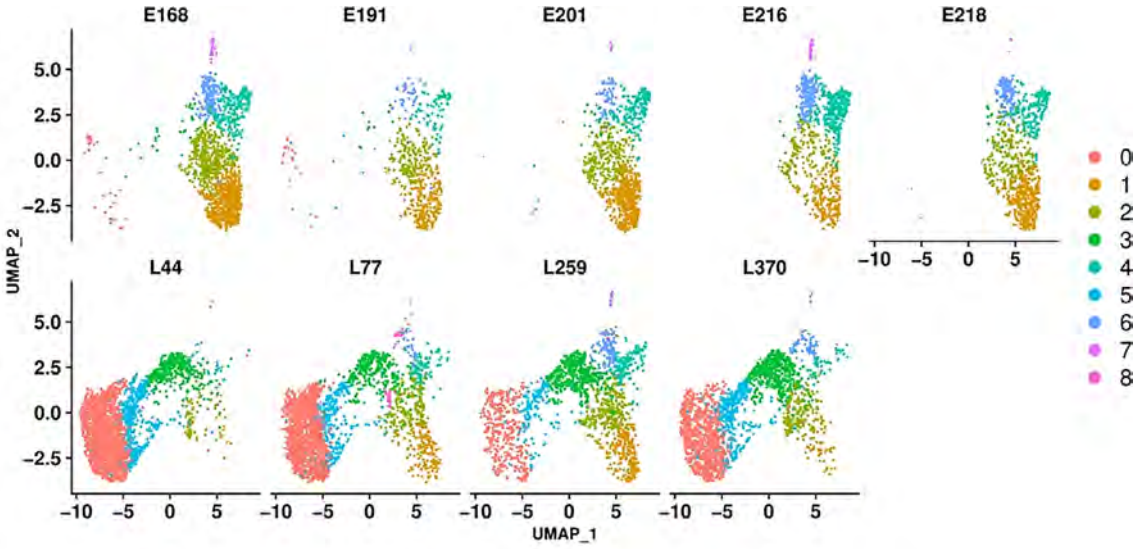

Figure 3: Individual patient fibroblast cell subtype clustering analyses illustrating differences in presence of subclusters between KL1 and KL3/4 radiographic knee OA patients.

Methods: Synovia from early- (n=5; KL=1) and late-stage (n=4; KL=3/4) radiographic KOA patients were subjected to single nucleus (sn)RNAseq. Bulk RNA sequencing was performed in the synovium of n=6 early and n=8 late-stage radiographic KOA patients. Knee synovia isolated from naïve (control mice; n=4), 2 weeks (n=3) and 10 weeks (n=4) post-DMM surgery were also subjected to snRNAseq. Sequencing data was subjected to clustering analysis, differential expression analysis (to identify transcriptomic profiles), pathway analysis and upstream transcriptional regulator analyses.

Results: Up to 50% of the cells from early and late-stage KOA human synovium were of fibroblast origin (Fig 1). Clustering analysis identified 8 distinct fibroblast subclusters in the KOA synovium (Fig 2). A phenotypic shift in fibroblast subsets was observed from early to late stages of KOA (fibroblast clusters 1, 2, 4 and 6 were predominantly associated with early-stage while fibroblast clusters 0, 3 and 5 were predominantly associated with late-stage OA) (Fig 3). Unique transcriptomic profiles were identified for each fibroblast subset, some being cell surface markers that were confirmed by immunohistochemistry to be differentially expressed in the synovium of early or late-stage KOA in vivo. Furthermore, pathway analyses suggest that the two major fibroblast subclusters, clusters 1 (early) and cluster 0 (late), may play crucial roles in ECM/fibrosis related pathways. Computational analysis has also identified putative upstream transcriptional regulators that may play key roles in ECM regulation and fibrosis. snRNAseq data of mouse synovium also identified some overlapping fibroblast clusters in human and mouse synovium. Specifically, late-stage cluster 0 identified in human snRNAseq analysis showed expansion in mouse synovium 10 weeks post DMM surgery compared to 2 week-DMM and naïve (control) synovium. Current efforts are focussed on targeting select transcription factor(s) using in vitro and in vivo gain and loss of function studies to identify their role in OA synovial pathology.

Conclusion: snRNAseq analysis has led us to identify distinct synovial fibroblast subsets with unique transcriptomic profiles in early and late-stages of KOA that may play a key role in driving OA synovial pathology.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Synovial pathology is an active component of osteoarthritis (OA) that has been linked to disease progression and pain in patients. Macroscopic and microscopic grading systems for synovial pathology in human OA have been extensively described. However, a comprehensive histologic scoring system for murine models of OA is lacking. Thus, we sought to develop a reproducible approach and set of recommendations for evaluation of synovial changes in murine models of OA.

Methods: Coronal sections from murine knee joints as part of other studies were used as follows: 1. Hematoxylin and Eosin (H&E) or Toluidine Blue (T-Blue) stained sections from mice 6 weeks after destabilization of medial meniscus (DMM) or sham surgery and age matched naïve controls (n=5/group), 2. Safranin O (Saf-O) sections from mice 16 weeks after DMM or sham surgery (n=5-6/group), 3. T-Blue sections from mice 16 weeks after DMM or sham surgery (n=10/group), 4. T-Blue sections from 12 weeks after partial meniscectomy (PMX) or sham surgery (n=10/group), 5. H&E sections from 12 weeks after PMX or sham surgery (n=5/group). Four blinded readers graded four pathological features (hyperplasia, cellularity, inflammation, and fibrosis) at four anatomic locations (lateral and medial femoral gutters, and lateral and medial tibial gutters) using midjoint sections. Inter-reader reliability tests (IRR) (Kendall's coefficient of concordance (W) for hyperplasia, inflammation, and cellularity; Fleiss Kappa test (κ) for fibrosis) were performed to assess agreement between readers.

PMX	Toluidine Blue				H&E			
	Cellularity	Inflammation	Hyperplasia	Fibrosis	Cellularity	Inflammation	Hyperplasia	Fibrosis
W	0.745	0.665	0.727	-	0.830	0.525	0.888	-
κ	-	-	-	0.736	-	-	-	0.687

DMM	Toluidine Blue				Safranin O/Fast Green			
	Cellularity	Inflammation	Hyperplasia	Fibrosis	Cellularity	Inflammation	Hyperplasia	Fibrosis
W	0.607	0.526	0.723	-	0.431	0.737	0.607	-
κ	-	-	-	0.736	-	-	-	0.687

Table 3: Inter-reader reliability scores of murine knee joints 12 weeks after PMX or sham surgery and 16 weeks after DMM or sham surgery. Kendall's coefficient of concordance (W), for the variables graded from 0-3, and Fleiss Kappa tests (κ) for fibrosis which was simply graded 0 or 1

Results: IRR measures (Table 1) demonstrate that there was acceptable to very good agreement between raters. Inflammation scores were excluded because of poorer concordance between readers and overlap with the cellularity assessment. Increased hyperplasia and cellularity and a trend of increased fibrosis were observed in the medial tibial and medial femoral gutters compared to controls 6wks after DMM (Fig 1A-C). At 16-weeks post-DMM, significant increase in cellularity and fibrosis were observed in the medial side with no significant hyperplasia (Fig 1D-F). No significant lateral changes were observed in any of DMM groups. At 12 weeks after PMX, a significant increase in hyperplasia, cellularity and fibrosis were observed in the medial gutters compared to sham mice (Fig 1G-I). Increased cellularity and hyperplasia were evident in the lateral gutters of PMX mice. Additionally, we assessed 4 sections/knee from PMX mice and found that synovial changes were consistent from section to section (Fig 2). Finally, we assessed the effect of different stains on IRR (Table 1). Higher reliability was observed using H&E and T-blue stains.

Conclusion: Based on our findings, we suggest evaluating 3 pathological features at 4 anatomic areas of the joint to assess synovial pathology in murine models of OA. A minimum of 3 readers are recommended, for which the IRR should be determined. A single midjoint section is likely sufficient for analysis, and a careful choice of stain should be considered. It is important to note that these recommendations are considered an initial step to allow comparison across labs and models, and to be used to guide more detailed subsequent analyses.

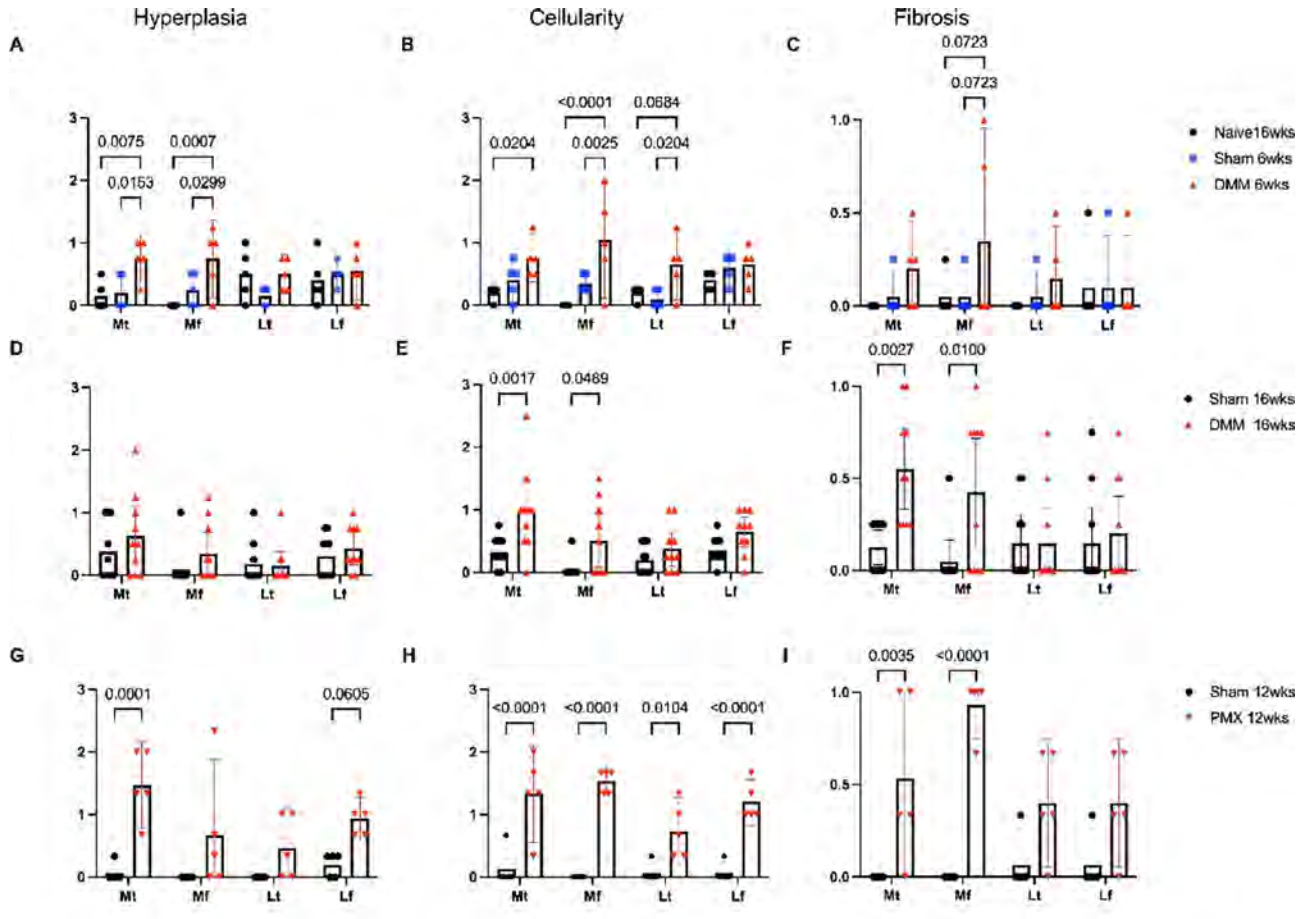

Figure 1: (A-I) Histopathologic scoring of synovial hyperplasia, cellularity and fibrosis for medial tibial (mt), medial femoral (mf), lateral tibial (lt) and lateral femoral (lf) areas in 16-week old naïve mice and mice 6 weeks after sham or DMM surgery (n=5/group) in (A-C); mice 16-week after sham or DMM surgery (n=10/group) in (D-F), and mice 12 weeks after PMX or sham surgery (n=5/group) in (G-I). Each score represents the average score of 4 blinded scorers. 2way ANOVA with Tukey's multiple comparisons test. Mean ± 95% CI.

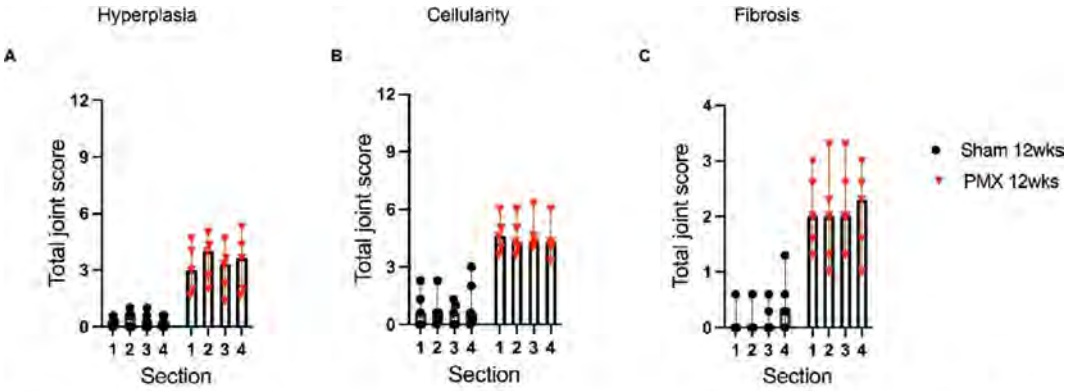

Figure 2: (A-C) Histopathologic scores of synovial hyperplasia, cellularity and fibrosis respectively summed for 4 joint areas in mice 12-week after sham and PMX surgery (n=5/group). 4 mid-joint sections per mouse were used to evaluate synovial changes, sections were H&E stained. 4 sets of data are shown in x-axis, each set represents one section per mouse for n=5 mice/group. 2way ANOVA with Tukey's multiple comparisons test. Mean ± 95% CI.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is the most common joint disorder, and growing evidence has identified inflammation to be a major driver of disease progression. During disease, the synovium is identified as a reservoir of inflammatory mediators and immune cells, primarily consisting of monocyte/macrophages.[1] CD14, a co-receptor of inflammatory toll-like receptor signaling and a macrophage-activation-related protein, has been identified within synovial fluid and positively associated with joint space narrowing and knee pain.[2] We previously reported that global genetic CD14 deficiency in mice protects against OA-associated bone-remodeling and pain-related joint dysfunction.[3] Thus, **we hypothesize an anti-CD14 therapeutic will mediate inflammatory activation in the synovium during OA, and mitigate disease progression and pain.**

Methods: *OA model (n=12-14):* We performed destabilization of the medial meniscus (DMM) surgery to induce OA in skeletally mature (10-12 wk old) C57BL/6 mice.[3] *Intervention:* Mice were treated intra-articularly with either an anti-CD14 monoclonal antibody (mAb, clone biG53) or an IgG2a control (both 0.5mg/kg), two dosing strategies were tested: 1) *Prevention strategy:*mice received anti-CD14 or IgG control weekly x 3 doses, starting 48 hrs post DMM. 2) *Treatment strategy:* mice received 3 weekly injections beginning 4 wks post DMM. *Behavioral analysis*: Evaluation of spontaneous cage behaviors was performed via the laboratory animal behavior observation registration and analysis system (LABORAS, Metris).[3] Paw weight bearing analysis was performed via the advanced dynamic weight bearing (ADWB, Bioseb) system.[4]

Immunohistochemistry (n=3): In a separate early dosing 4-wk study, whole knee joints were fixed, decalcified, paraffin embedded, and sectioned. Sagittal sections underwent antigen retrieval and overnight incubation with primary antibodies (monocyte: Ly6C/D, macrophage: CD64), followed by incubation with fluorescent secondary antibodies, and lastly cover-slipped with mounting medium containing DAPI nuclear dye and imaged.

[1]Sanchez 2012 [2]Lieberthal 2015 [3]Sambamurthy 2018 [4]Krug 2019

Results: Prevention strategy: Early CD14 blockade increased total distance traveled and rearing time at 4- and 8-wks post DMM, compared to control mice ($p < 0.05$) (**Fig. 1**). Front to rear paw weight ratio 8-wks post DMM had a strong decreasing trend ($p=0.057$) in CD14 inhibitor treated mice compared to controls (**Fig. 1**). Treatment strategy: When treatment was delayed (4 wks post-DMM), no significant behavior or weight bearing changes were observed between groups (**Fig. 2**). Evaluating inflammation, early CD14 blocked increased the presence of Ly6C/G+ cells within the synovial lining layer compared to control at 4-wks post DMM (**Fig. 3**). Few CD64+ cells were observed (**Fig. 3**).

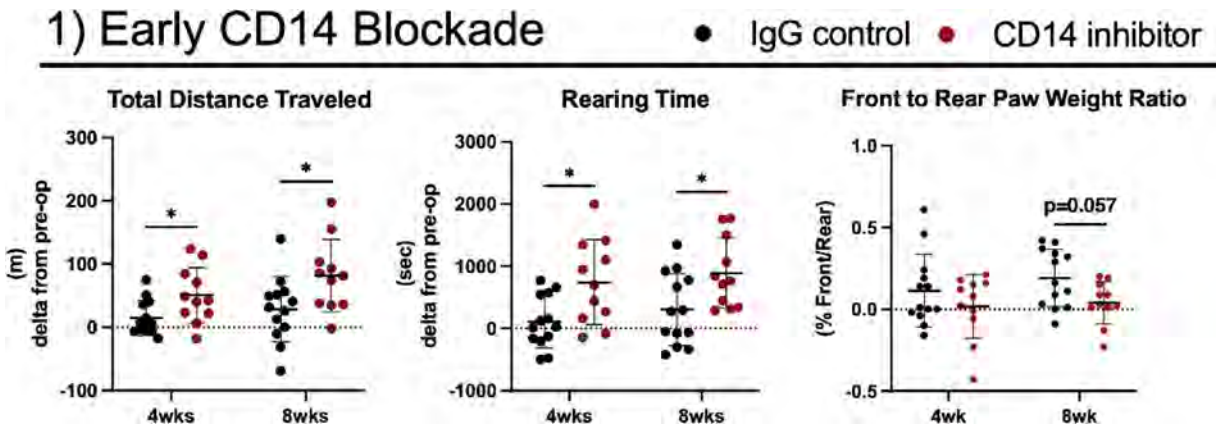

Figure 1: Spontaneous behavioral testing results from the early CD14 blockade groups. LABORAS behavioral analysis of the change from pre-op in total distance traveled (m) and time spent rearing (s). ADWB weight bearing analysis of the change from pre-op of front to rear paw & weight % ratio. *p<0.05 Student's T-test.

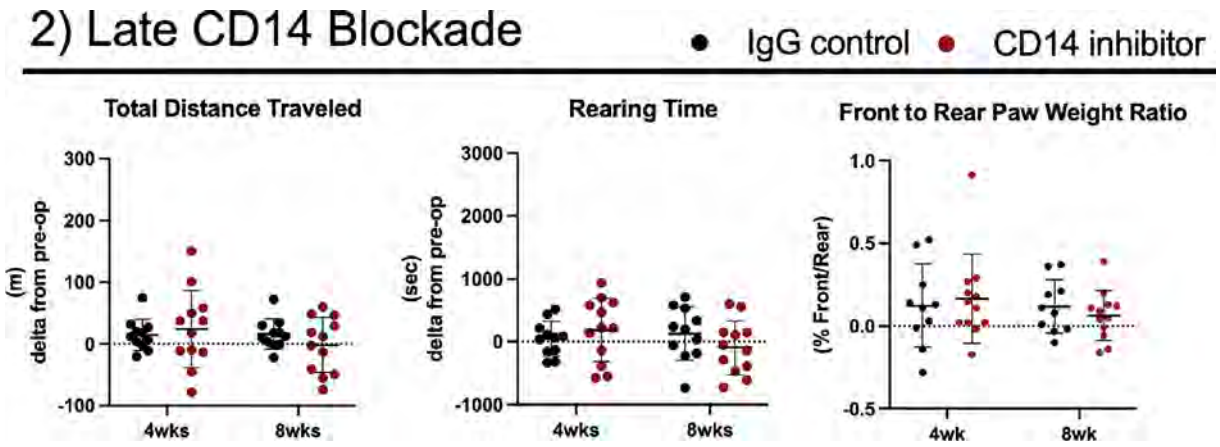

Figure 2: Spontaneous behavioral testing results from the late CD14 blockade groups. LABORAS behavioral analysis of the change from pre-op in total distance traveled (m) and time spent rearing (s). ADWB weight bearing analysis of the change from pre-op of front to rear paw & weight % ratio. *p<0.05 Student's T-test.

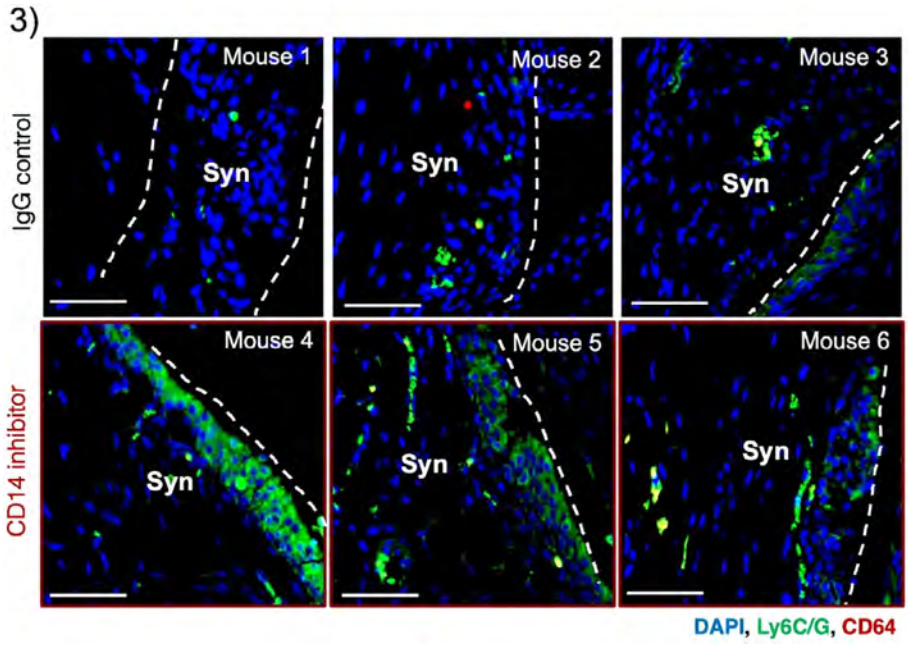

Figure 3: Immune cell presence following DMM. Fluorescent images of mice from IgG control and CD14 blockade treated mice (n=3) at 4 wks post DMM, stained for a general myeloid cell marker (Ly6C/G) and mature macrophage marker (CD64). Synovium (syn) is labeled with the lining layer indicated (white dashed line). Scale bar = 50μm.

Conclusion: Results revealed early delivery of a CD14 blocking mAb after DMM injury was more effective at improving mobility, compared to delayed dosing. Immunostaining suggests that anti-CD14 treatment may be modulating myeloid cell activation, clearance, or differentiation within the synovium during OA progression. **Results provide significant support for further evaluation of CD14 as a therapeutic for painful OA.**

Deficiency of the Pattern-recognition Receptor CD14 Protects Against LPS-induced Inhibition of Osteoclastogenesis *in Vitro*

Lance Murphy[1], Kevin Burt[2], Baofeng Hu[3], Vu Nguyen[2], Robert Mauck[2] and Carla Scanzello[2], [1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Wynnewood, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis is associated with bone changes such as subchondral sclerosis, bone marrow lesions, and osteophyte formation (Donel S, 2019). Prior work has demonstrated that CD14-deficient mice show significantly less OA-associated subchondral bone (Sambamurthy N, 2018). CD14 is a GPI-anchored surface protein and co-

receptor for several inflammatory TLRs, and is highly expressed in myeloid cells including osteoclast precursors (Zanoni, I 2013; Xue, J 2020). TLR activation can both activate and inhibit osteoclastogenic potential. Therefore, using a CD14-deficient mouse model we **hypothesized that inhibitory effects of TLR-stimuli on RANKL-mediated osteoclast differentiation would be ameliorated in CD14 deficient cells.**

Methods: *Cell isolation and culture (n=3-5):* Bone Marrow was isolated from femurs and tibiae of skeletally mature (10-12 wk old) C57BL/6 (WT) and CD14-deficient mice. Following 24 hr suspension culture, cells were cultured in complete DMEM with 30 ng/mL M-CSF, for 5 days to expand osteoclast precursors (macrophages). Cells were passaged on day 6 and cultured (24 well plate, 50,000 cells/well) in the presence or absence of RANKL (100 ng/mL). In a separate study, cells were stimulated with a TLR4-stimulus (LPS, 1 ng/mL), soluble CD14 (1 μg/mL), and a TLR4-inhibitor (CLI-095, 1 μg/mL).

Osteoclast staining and image analysis: Cells were stained for Tartrate-resistant acid phosphatase (TRAP) on days 3 and 4 after addition of RANKL. Cells were imaged at 10x (3 images/well over 4 wells per timepoint) and quantified (% area covered) using ImageJ (NIH) and CellProfiler. Number of osteoclasts (cells with >3 nuclei) per 10X field was also quantitated. Multiple unpaired t-test were performed with Holm-Sidak correction.

Results: CD14-deficient cells showed more rapid differentiation than WT cells at baseline (**Fig. 1**). Numbers of osteoclasts (**Fig. 1E**) and area of the plate covered by osteoclasts (**Fig. 1F**) were higher in CD14-deficient cells on day 3 and day 4 ($p < 0.001$ and $p < 0.05$, respectively). TLR4-stimuli: With LPS stimulation, CD14-deficient cells differentiated more quickly compared to WT at day 3 ($p < 0.001$) (**Fig. 3G**). LPS stimulation led to a 77% decrease of osteoclastogenesis in the WT cells, but only a 7.5% decrease in osteoclastogenesis on the CD14-deficient cells **(Figure 2G, 3G)** Addition of CLI-095 mitigated

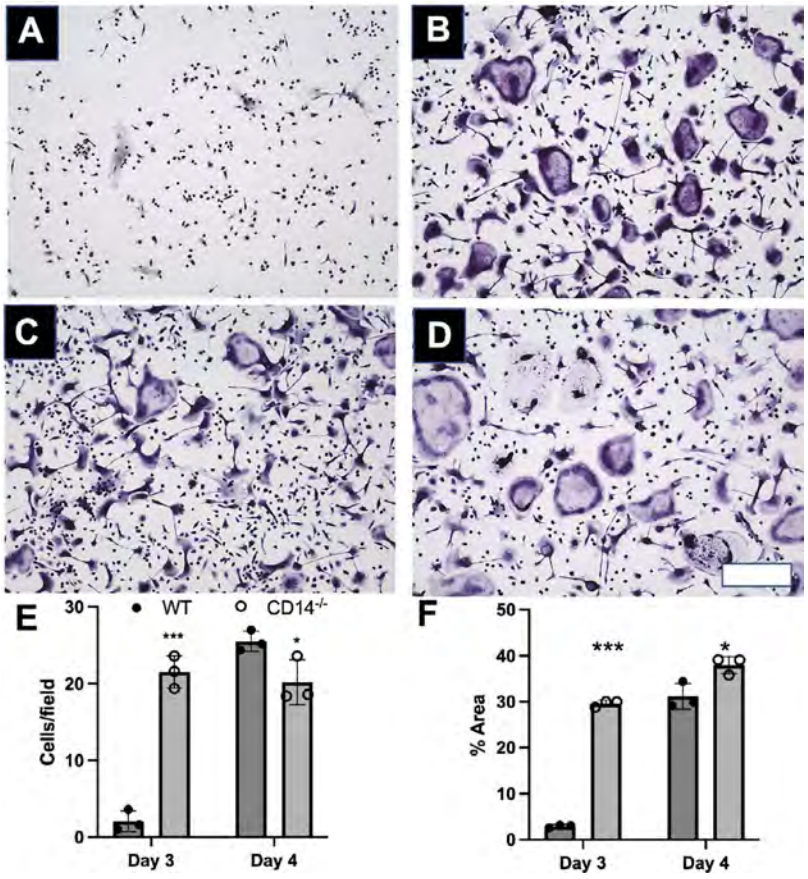

Figure 1: TRAP staining and quantification of osteoclasts at baseline: WT osteoclasts on days 3 and 4 (A,C) and CD14-/- (B,D) . Quantification of osteoclasts/field (E), % Area of frame of osteoclasts (F) *p<.05, ***p<.001 compared to WT. Scale bar 100 μM

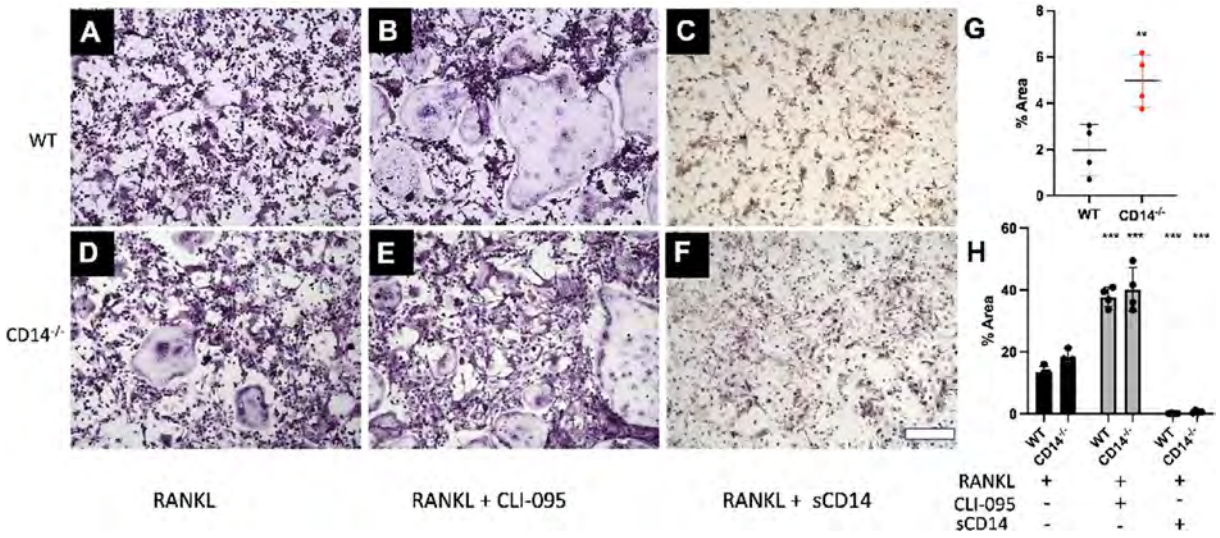

Figure 2: TRAP staining of Osteoclasts treated with TLR4 inhibitor and soluble CD14: Osteoclasts derived from WT (A,B,C) and CD14-deficient precursors (D,E,F) treated with RANKL, RANKL + CLI-095, and RANKL+ sCD14, respectively. Quantification of RANKL treatment at day 3 (G) and all treatments at day 4 (H).**p < .01 compared to WT, ***p < .001 compared to RANKL within mouse strain. Scale bar 100 μM

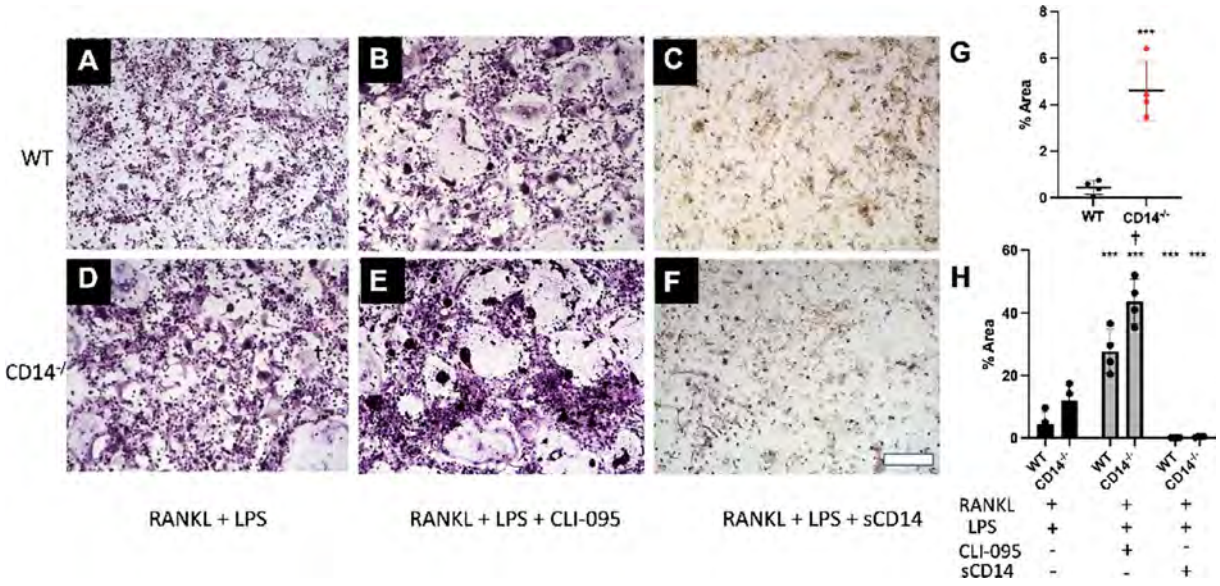

Figure 3: TRAP staining of osteoclasts treated with LPS: Osteoclasts derived from WT (A,B,C) and CD14-deficient cells (D,E,F) treated with RANKL + LPS, RANKL + LPS + CLI-095, and RANKL + LPS + sCD14, respectively. Quantification of RANKL + LPS treatment at day 3 (G, *** p < .001 compared to WT) and all treatments at day 4 (H). ***p < .001 compared to RANKL + LPS within mouse strain. † p<.001 compared to WT within treatment. Scale bar is 100 μM.

some inhibitory effects of LPS in WT, but had a synergistic effect on CD14-deficient cells (Fig 3H). The addition of sCD14 inhibited osteoclastogenesis in the CD14-deficient group, both with and without LPS.

Conclusion: Our results show that at baseline, CD14-deficient osteoclasts precursors differentiate more quickly than WT cells. **Further, during TLR4 stimulation studies, CD14-deficient cells were protected from LPS-TLR4 mediated inhibition of osteoclastogenesis, compared to WT cells.** Though mechanism of early differentiation remains unclear, with possible intervention of TLR-ligand production during differentiation, further work will investigate this production, and further effects of OA-relevant TLR ligands on osteoclastogenesis in the setting of CD14 deficiency or blockade.

Activation of Ovarian Cancer G-Protein Coupled Receptor (OGR1) Attenuates Chondrocytes Inflammation via ERK1/2 Signaling Pathways in an in Vitro Model of Osteoarthritis

Omar Syed, Bhakti Patel, William Martin, Martha Diaz-Hernandez, Hicham Drissi and Mohd Nazir Khan, Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is the most prevalent joint disease, accounting for 50% of the musculoskeletal burden. Inflammation plays a crucial role in the development of OA and is often accompanied by synovial fluid acidosis and an acidic extracellular environment.As OA progresses, chondrocytes experience changes in osmolarity and acidity in their surrounding environment. However, the mechanism by which chondrocytes detect and respond to acidic stress is currently unknown. Recently, there has been growing interest in the role of proton-sensing GPCRs such as Ovarian Cancer G-Protein Coupled Receptor (OGR1 or GPR68) in musculoskeletal tissues. Nevertheless, the expression and function of OGR1 in cartilage during OA remain unexplored. This study aims to examine whether the OGR1 contributes to the regulation of inflammation during OA progression.

Methods: High throughput RNA-Seq data (GSE114007) in healthy donors and OA cartilage was analyzed to determine the role of proton-sensing orphan GPCRs during OA pathogenesis. Primary human OA chondrocytes were obtained from discarded cartilage of patients undergoing arthroplasty. siRNA mediated OGR1 knockdown was used to determine its role in inflammatory signaling in human chondrocytes. Activation of OGR1 was done by treating chondrocytes with Ogerin and activity was measured using Ca+ release and fluorescent based biosensor assay. Western immunoblotting was performed to analyze the expression at protein level. Statistical analyses were performed using one-way analysis of variation (ANOVA) with Tukey's post-hoc tests.

Results: Differential gene expression analysis of RNA-seq data identified OGR1 was highly expressed in human OA cartilage. Immunohistochemistry and qPCR further confirmed the expression of OGR1 in human OA cartilage and in chondrocytes treated with IL1β. Low density array analysis of OGR1 knockdown showed that silencing of OGR1 significantly induced the expression of various inflammatory cytokines and chemokines including IL6, NOS2, CSF2, CXCL6, CCL3, CXCL2. Interestingly, Ogerin mediated OGR1 activation in chondrocytes repressed the expression of these inflammatory genes suggesting the role of GPR68 in the regulation of inflammatory gene expression. Furthermore, MAPK inhibitors studies showed that inhibition of ERK and P38 MAPK pathways significantly reverse the effect of OGR1 knockdown on the induction of IL6 gene expression in IL1β stimulated OA chondrocytes. These data suggest the involvement of ERK1/2 and P38 MAPK signaling in OGR1 mediated regulation of inflammatory genes in chondrocytes during OA pathogenic conditions.

Conclusion: Our data suggest that OGR1 is highly expressed in human OA cartilage and regulates inflammatory gene expression via MAPK activation. Our results showed the involvement of OGR1 in the inflammatory pathways and highlights its potential as a therapeutic target for OA treatment. Exploring the mechanisms through which OGR1 influences the development of OA could offer novel perspectives and lead to the development of novel therapies that can modify the course of the disease for individuals with OA.

Abstract Number: 0883

The Role of Plasmin and Fibrinolysis Pathways in Osteoarthritis

Qian Wang, heidi Wong, Audrey Bai, Zelda Love, Constance Chu and William Robinson, Stanford School of Medicine, Stanford, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is the major cause of joint failure. Increasing evidence suggests that activation of fibrinolysis is involved in the pathogenesis of OA. Here we used gene expression, proteomic, in vitro assays, and mouse models to further define the role of fibrinolysis in OA.

Methods: Gene expression in synovial membranes from individuals with early- or end-stage OA and healthy individuals were analyzed, and ELISA and immunohistochemistry on human OA synovium and cartilage samples performed. Genetic and pharmacologic studies were performed targeting plasmin, tPA, uPA in an OA mouse model. We performed MicroPET/CT imaging studies on mouse OA model to further define the role of uPA in OA pathogenesis.

Results: We identified dysregulated expression of plasmin and the plasmin activators tPA, uPA and uPA receptor uPAR in human OA joints. Pharmacologic blockade of plasmin attenuated the progression of OA in DMM mice, while genetic deficiency in plasmin activator inhibitor PAI-1 or injection of plasmin protein exacerbated OA in DMM mice. We detected increased uptake of uPA/uPAR in mouse OA joints by microPET/CT imaging. Further *in vitro* studies identified that plasmin

Figure 1. Key molecules in fibrinolysis pathways are dysregulated in human OA joints (A) Unsupervised hierarchical clustering of uPA and uPAR expression in microarray dataset on synovial membranes from healthy individuals (n=7) or those with early- (n=10) or end-stage OA (n=9). Scale bar indicates z score. (B) ELISA analysis of plasmin levels in knee joint synovial fluids from individuals with OA (n=6), ACL tear (n=8), DMT (n=3) and in the plasma from healthy individuals (n=8). (C, D) ELISA analysis of activated uPA (C) or uPAR (D) levels in synovial fluid of knee joints and serum from individuals with confirmed OA (n=10). (E) Representative images from immunohistochemical staining of tPA, uPA, uPAR, and isotype control in damaged knee cartilage (left) and synovium (right) of OA from individuals underwent total knee replacement. The arrowhead indicates positive staining for tPA, uPA, and uPAR. For panels B-D, data are the mean ± SEM of duplicates or triplicates and are representative of ≥2 independent experiments. *P < 0.05, **P < 0.01, and ***P < 0.001 by t test or one-way ANOVA. For panel E, scale bar, 200μm; cartilage and synovial tissues from n = 5 individuals were analyzed and the representative images were shown.

Figure 2. Genetic deficiency or pharmacological blockade of plasmin attenuates OA in mice (A) Representative cartilage degeneration in Safranin-O–stained sections of the medial region of stifle joints from plg+/+ (n=10) and plg-/- (n=5) male mice 20 weeks after DMM, and quantification of the cartilage degeneration. (B) Representative cartilage degeneration in Safranin-O–stained sections of the medial region of stifle joints from C57B/6J mice treated for 12 weeks with intra-articular injected plasmin (n=10) or PBS (n=10), and quantification of the cartilage degeneration. (C, D) Representative cartilage degeneration in Safranin-O–stained sections of the medial region of stifle joints from C57B/6J mice subjected to DMM and treated with intra-articular injection of anti-plasmin antibody (n=10), α2-macroglobulin (n=10), or PBS (n=10) (C), or with i.p. injection of tranexamic acid (n=6) or PBS (n=6) (D) for 12 weeks, and quantification of the cartilage degeneration. Arrowheads indicate areas of cartilage degeneration. Scale bars, 200μm. All data are the mean ± SEM of triplicates and are representative of three independent experiments. *P ≤ 0.05, **P ≤ 0.01 by t test or one-way ANOVA.

Figure 5. Another key fibrinolysis molecule uPA and its receptor uPAR also play critical roles in the pathogenesis of OA (A, B) Representative cartilage degeneration in Safranin-O–stained sections of the medial region of stifle joints from plau+/+ (n=10) and plau-/- (n=9) (A), and plaur+/+ (n=9) and plaur-/- (n=9) mice (B) 20 weeks after DMM, and quantification of the cartilage degeneration. Arrowheads indicate areas of cartilage degeneration. Scale bar, 200μm. (C, D) MicroPET/CT imaging of mouse knee joints 20 weeks after DMM or sham surgery, and quantification of relative 68Ga uptake levels in these joints (n=7). Mice were i.v. injected with 68Ga-NODAGA-AE105 (C), or 68Ga-NODAGA-AE105 plus unlabeled AE105 (D). (E, F) qPCR analysis of relative mRNA expression levels of OA-related inflammatory, degradative mediators as well as VEGFα in synovial tissues from plau+/+ (n=5) and plau-/- (n=5) mice (E) or plaur+/+ (n=5) and plaur-/- (n=5) mice (F) 20 weeks after DMM. Data are the mean ± SEM of duplicates or triplicates and are representative of ≥2 independent experiments. NS P > 0.05, *P ≤ 0.05, ** P ≤ 0.01, and *** P ≤ 0.001 by t test.

promotes OA development through multiple mechanisms including the degradation of lubricin and cartilage proteoglycans, activation of matrix metalloproteinases (pro-MMPs), and induction of inflammatory and degradative enzymes.

Conclusion: Our results demonstrate that fibrinolysis contributes to the development of OA through multiple mechanisms. We demonstrated that uPA and uPAR contribute to OA by activating the PI3K, PDK1, AKT, and ERK signaling cascades which mediate the production of inflammatory and degradative enzymes. Together, our results suggest that therapeutic targeting of the fibrinolysis pathways provides the potential to reduce development of OA.

Identification of a Mast Cell-high Synovial Pathotype of Osteoarthritis

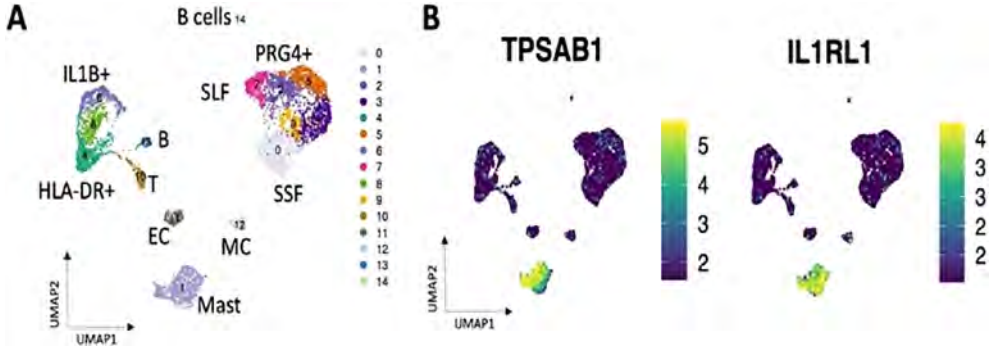
Shady Younis, Audrey Bai, heidi Wong, Zelda Love, Qian Wang and William Robinson, Stanford School of Medicine, Stanford, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Mast cells in the osteoarthritis (OA) synovium correlate with disease severity. This study aimed to further elucidate the role of mast cells in OA by RNA-Seq analysis and pharmacological blockade of the activity of histamine, a key mast cell mediator, in murine OA.

Methods: WeexaminedOA synovial tissues and fluids by flow cytometry, immunostaining, single-cell and bulk RNA-Seq, qPCR, and ELISA.Cetirizine,a histamine H1 receptor (H_1R) antagonist, was used to treat the destabilization of the medial meniscus (DMM) mouse model of OA.

Results: Flow cytometry and immunohistology analysis of OA synovial cells detected the frequencies of KIT^+ $Fc\varepsilon RI^+$ and $TPSAB1^+$ mast cells. Single-cell RNA-Seq of OA synovial cells identified the expression of prototypical mast cell markers *KIT, TPSAB1, CPA3* and *HDC*, as well as distinctive markers *HPGD, CAVIN2,IL1RL1*, *PRG2*, and *CKLF*, confirmed by bulk



Single cell RN-seq of OA synovial tissues. (A) Detection of major cell types present in OA synovial tissues including mast cells, synovial lining fibroblasts (SLF), synovial sub-lining fibroblasts (SSF), endothelial cells (EC) , muscle cells (MC), T B cells. (B) Mast cells expressing high level of TPSAB1 and IL1RL1 genes.

RNA-Seq and qPCR.A mast cell prototypical marker expression score classified 40 OA patients into three synovial pathotypes: mast cell-high, -medium, and -low. Additionally, we detected mast cell mediators including histamine, tryptase AB1, CPA3, PRG2, CAVIN2, and CKLF in OA synovial fluids. Elevated H_1R expression was detected in human OA synovium, and treatment of mice with the H_1 receptor antagonist cetirizine reduced the severity and OA-related mediators in DMM.

Conclusion: Based on differential expression of prototypical and distinct mast cell markers, human OA joints can be stratified into mast cell-high, -medium, and -low synovial tissue pathotypes. We further show that pharmacologic blockade of histamine activity reduces development of OA in mice, suggesting that targeting of the mast cell mediator histamine has the potential to provide benefit in subsets of OA in which mast cells contribute to pathogenesis.

Mice Fed a Well-formulated Ketogenic Diet After OA Induction Develop Worse OA Outcomes and Increased Pain Sensitivity

Montana Barrett[1], Gabby Dyson[2], Meeshal Khan[3], Nicholas Hanebutt[2], Cindy Miranda[2], Leoni Schlupp[2], Emmaline Holmlund[2] and **Matlock Jeffries**[2], [1]Oklahoma State University, Guthrie, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK

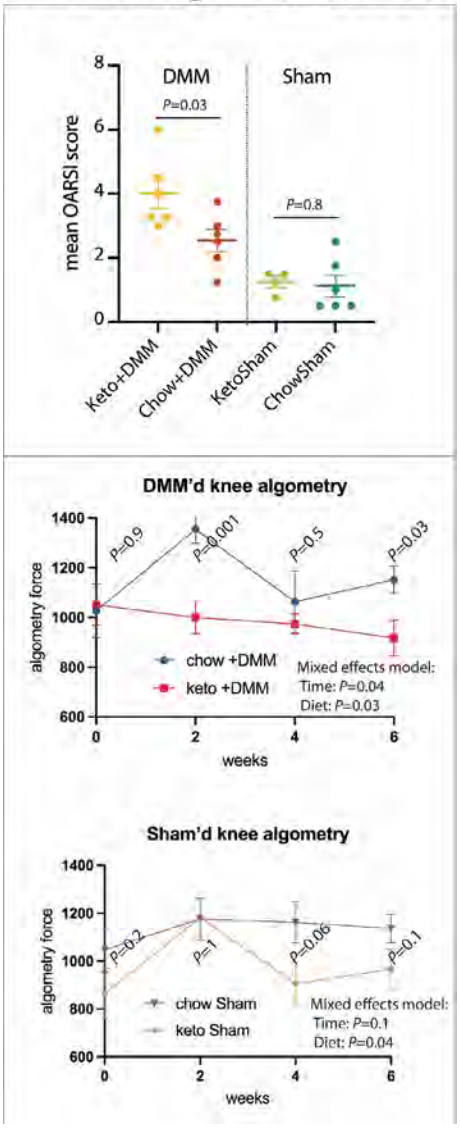
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A ketogenic diet (KD) has beneficial effects in preclinical models of a variety of systemic autoimmune diseases. In this study, we set out to evaluate whether KD would alter OA outcomes in a commonly-used mouse model.

Methods: Adult male B6 mice (n=6 per group) had disruption of the medial meniscus (DMM) surgery performed on a unilateral knee joint, then were placed in clean cages and fed a standard chow diet or KD (carbohydrates replaced by plant-based oils including medium-chain triglycerides). A second set of mice were fed KD or chow and had sham DMM surgery performed. Pain sensitivity around the operated knee was tested by a handheld algometer at baseline, 2, 4, and 6 weeks after DMM and analyzed with a mixed-effects model. Eight weeks after DMM, mice were sacrificed, knee joints fixed, paraffin-embedded, stained with Safranin-O and histologically graded for OARSI score. Serum cytokines were evaluated with a Bioplex-pro 23 assay. Serum lipopolysaccharide (LPS) was determined by chromogenic assay. Gut microbiome analysis was performed via 16S sequencing.

Results: KD mice had worse histologic OA compared to chow diet mice (Figure 1) (OARSI score 4.0±1.8 mean±SEM vs. 2.5±0.4, P=0.03) despite losing weight on KD (final weight chow: 31±0.7 vs. 25±0.7g, P=2E-4). OARSI scoring was no different in sham mice (1.25±0.2 vs. 1.13±0.3, P=0.8); sham mice lost a similar amount of weight on KD (chow: 33 ±0.6 vs. 29±0.8, P=0.002). Pain sensitivity was similar at baseline in DMM mice (P=0.9) and sham mice (P=0.2); however, KD mice demonstrated increased pain sensitivity, evidenced by reduced algometry force-at-paw-withdrawal, in both DMM (mixed effects model P=0.03) and sham (mixed effects model P=0.04) (Figure 1). LPS was reduced in KD-DMM mice vs. to chow-DMM mice (P=0.04), but no different in KD-Sham mice vs. chow-Sham mice (P=0.1). Microbiome analysis demonstrated several significantly different clades between KD and chow diet. *Lactobacillus*, *Blautia*, and *Clostridium* were all

Figure 1: Histologic and pain sensitivity OA outcomes in ketogenic diet and chow diet



correlated with better histology and pain outcomes, whereas *Bacillales* and *Oscillospira* were correlated with worse histology and pain outcomes.

Conclusion: Initiation of a KD immediately after DMM induction in mice is associated with worse histologic and pain outcomes, findings which correlate with disruption of particular gut microbiome clades. Further research is needed to evaluate the effects of KD initiation prior to OA induction, as well as pathophysiological investigations into this observed phenotype.

Neonatal Roseolovirus Infection Predisposes to Development of Lupus-like Disease After TLR7 Stimulation

Tarin Bigley[1], Eden Xue[1], Lifei Zhu[1], Li-ping Yang[1] and wayne Yokoyama[2], [1]Washington University in St. Louis, St. Louis, MO, [2]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Viral infections have been implicated as major factors in autoimmune disease but demonstrating causality is often challenging. We found that neonatal infection with a roseolovirus (murine roseolovirus, MRV) resulted in transient thymic atrophy, CD4+ T cell depletion, and disruption of central tolerance. Although mice recovered from infection, we observed durable immune dysregulation manifested as autoimmune gastritis and a broad repertoire of autoantibodies. In these studies, we found that additional immune stimulation resulted in systemic autoimmunity.

Methods: We developed a mouse model in which neonatally infected C57BL/6 mice were treated with a toll-like receptor 7 (TLR7) agonist as adults to induce a lupus-like phenotype. Histology, immunofluorescence, ELISA, transcription analysis as well as flow cytometry were used to characterize disease and evaluate immune dysregulation. We used depletion and adoptive transfer experiments to identify the contribution of specific cell types to disease.

Results: We found that MRV replication during the first seven days of life induced a loss of central tolerance and development of autoimmune gastritis and autoantibodies, including those typically associated with autoimmune connective tissue disease. Interestingly, treatment with a TLR7 agonist induced a systemic autoimmune disease with characteristics observed in systemic lupus erythematosus, including splenomegaly, cytopenia, positive ANA, and multi-organ system inflammation in mice. In C57BL/6 mice, this lupus-like disease was only observed after neonatal MRV infection. Although a feature of MRV-induced lupus-like disease was significant thymic disruption, we did not observe MRV reactivation after TLR7 stimulation. We also observed major changes in the phenotype of T and B cells in the blood and spleen, suggesting a shift in the number and activation of different subsets. Moreover, we found that T and B cells play different roles in development of disease.

Conclusion: We have shown that MRV induces autoimmune after neonatal infection in a murine system. Moreover, our data suggest that neonatal MRV infection not only induces mild, organ-specific autoimmunity, but also results in durable immune dysregulation and predisposition to severe systemic autoimmunity after additional immune stimulation.

Dapagliflozin Modulates Inflammation and Germinal Centers in Lupus by Increasing Regulatory T Cells

Javier Rangel-Moreno[1], Maria de la Luz Garcia-Hernandez[2], Mary O'Connell[3], Daria Krenitsky[4], Maria Fernanda Ossa-Echeverri[1], Mark Lusco[5], John Looney[6] and Jennifer Anolik[3], [1]University of Rochester, Rochester, NY, [2]University of Rochester, West Henrietta, NY, [3]University of Rochester Medical Center, Rochester, NY, [4]Division of Allergy, Immunology

and Rheumatology/University of Rochester Medical Center, Rochester, NY, [5]Department of Pathology and Laboratory Medicine/University of Rochester, Rochester, NY, [6]Division of Allergy, Immunology and Rheumtology, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Nephritis is one of the most severe manifestations of lupus, affecting 40-70% of patients. Though immune-targeted therapies have improved, a significant number of patients experience renal damage and even progression to end-stage renal disease (ESRD). Recently, sodium and glucose cotransporter 2 inhibitors (SGLT2i) have proven efficacious in preventing adverse renal outcomes in patients with a variety of chronic diseases. The mechanisms of protection by SGLT2i include their capacity to modulate hypoxia and fibrosis. Other literature supports the role of local hypoxia in the lupus nephritis (LN) kidney in driving pathogenic immune cell function, including in CD8 T cells. Here, we hypothesized that by alleviating hypoxia, SGLT2i will modulate local inflammation and fibrosis in LN.

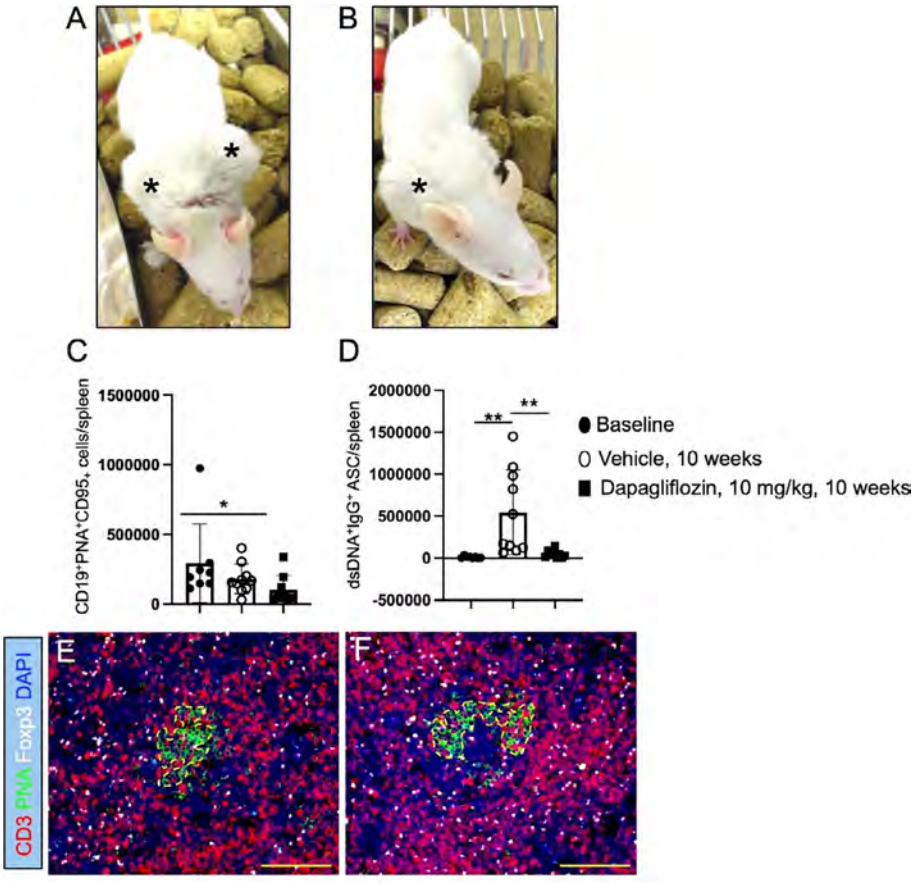

Figure 1. Immunomodulatory effects of dapagliflozin on lupus prone mice. 10 weeks old MRL/lpr female mice were daily treated for 10 weeks with dapagliflozin at 10 mg/kg by gavage or received same volume of vehicle. A) MRL/lpr female mice receiving vehicle show increased inflammation in peripheral lymph nodes, compared to B) aged matched MRL/lpr mice treated with dapagliflozin. Asterix point to inflamed peripheral lymph nodes (LNs). C) Germinal center B cells were decreased in the spleen of MRL/lpr female mice treated with dapagliflozin for 11 weeks. D) Production of autoreactive dsDNA antibody-secreting cells (ASC) in the spleen was significantly reduced by dapagliflozin therapy. E) T follicular regulatory T cells (TFHregs) were less numerous in the germinal centers (GCs) and contiguous areas in the LNs of control mice, compared to F) the significant accumulation of TFHregs in GCs of dapagliflozin-treated mice. 200x magnification pictures. Scale bars = 100 μm. n = 8-10 mice/group. Unpaired t test, Mann Whitney test: *, $p \leq 0.05$, **, $p \leq 0.005$.

Methods: Ten weeks old MRL/lpr female mice were treated daily with dapagliflozin at 10 mg/kg or vehicle by gavage for 11 weeks. Sera was collected to measure autoantibodies and creatinine by ELISA. Immune cells and Sodium and Glucose Co-Transporter 2 (SGLT2) expression were quantitated in the spleen, lymph nodes (LNs) and kidneys by flow cytometry and immunofluorescence. Inflammation, fibrosis, and infiltration by CD8 T cells or regulatory T cells were assessed in the kidneys of MRL/lpr mice at baseline and 11 weeks after starting SGLT2i therapy.

Results: Consistent with a slow induction of SGLT2i therapeutic effect in humans and despite the efficient targeting of SGLT2 in MRL/lpr mice, proteinuria was not affected after 11 weeks of daily SGLT2i administration. Unexpectedly SGLT2i therapy had a remarkable impact on the formation of germinal centers (GCs) (vehicle vs. dapagliflozin: *, $p = 0.0205$) and the production of autoreactive plasma cells in the spleen (vehicle vs. dapagliflozin: **, $p = 0.009$). In line with the induction of regulatory T cells by SGLT2i in diabetic kidney disease, T follicular helper cells with a regulatory phenotype significantly increased in the GCs of mice treated with dapagliflozin (vehicle vs. dapagliflozin: **, $p = 0.003$). In addition, skin and lymph node inflammation were attenuated by SGLT2i. However, inflammatory cell infiltration in the kidney was not affected by SGLT2i.

Conclusion: Despite modest effects on kidney inflammation, SGLT2i surprisingly modulated splenic autoreactive GCs via significant accumulation of T follicular regulatory T cells, impairing the production of autoreactive plasma cells. One of the potential explanations for the modest kidney effects is the rapid disease progression in MRL/lpr mice and the slow therapeutic induction with SGLT2i. Thus, future studies are planned in NZB/NZW mice treated for longer periods of time and with combined immune suppressive therapy.

Functionally Selective Immunomodulator Shows Robust Efficacy in Spontaneous Lupus Mouse Model

Helene ASNAGLI[1], Simon TESSIER[1], Martyn FOSTER[2], Sofie DENIES[3], Eef HOEBEN[4], Joël CROUZET[1] and **Annegret VAN DER AA**[1], [1]Ermium Therapeutics, Paris, France, [2]Experimental Pathology Consultancy, Benfleet, United Kingdom, [3]SD Analytics, Bellem, Belgium, [4]2-Bridge, Zoersel, Belgium

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex, heterogeneous autoimmune disease. There is still a high unmet need to improve current treatment options. Type 1 interferon (IFN) has recently been validated as clinical target for SLE.

CXCR4 antagonist IT1t has shown to selectively induce an immunomodulating profile through downmodulation of IFN-α release by plasmacytoid dendritic cells (pDCs)[1]. Functionally selective immunomodulators derived from IT1t, with low/no CXCR4 antagonism and increased immunomodulating activity, not limited to the control of type 1 IFN, have been discovered and may represent a novel therapeutic approach for interferonopathies, like SLE.

In vivo efficacy of one representative compound, ER000145 was evaluated in (NZB x NZW) F1 mice. This spontaneous lupus mouse model is sharing several pathophysiological features of human SLE, with clear kidney development starting around 22 weeks of age.

Methods: As of 24 weeks of age female (NZB x NZW) F1 mice received daily intraperitoneal (ip) administrations of ER000145 at either 3, 10 or 30 mg/kg for 16 weeks. Cyclophosphamide was administered once a week at 50 mg/kg ip as positive control. Body weight was recorded twice per week and proteinuria were measured weekly up to week 40 of age. At week 40 of age, kidney function readouts were performed by assessing the levels of blood urea nitrogen (BUN) and creatinine. At week 24, 34 and 40 of age, anti-dsDNA antibody titers were evaluated by ELISA. After 16 weeks of treatment, mice were sacrificed and cytokine levels were determined in serum using ELISA. Furthermore, kidneys were prepared for histopathological scoring using hematoxylin and eosin (H&E) staining for assessment of nephritis. In addition, spleen and bone pathology was performed to assess potential for immunosuppression using haematological and histological endpoints.

Results: Daily treatment of mice for 16 weeks with ER000145 did not show compound-induced body weight loss. Significant dose-dependent decreases in proteinuria, BUN levels and anti-ds DNA antibody titers were shown at week 40 of age for the 10 mg/kg and 30 mg/kg ER000145 treatment groups versus the vehicle control group. Despite overall low systemic cytokine levels, a reduction of serum TNF-α and IL-6 was observed for mice treated with ER000145. Histopathological analysis of the kidney confirmed a significant dose-dependent reduction of glomerular and tubular scores upon ER000145 treatment versus the vehicle control group at week 40 of age, confirming the inhibition of nephritis development. Haematology and histopathology of lymphoid organs showed no overt cell atypia nor cell depletion, a histological profile consistent with an absence of immunosuppression as opposed to the cyclophosphamide-treated group.

Conclusion: ER000145 showed robust and dose-dependent efficacy upon once daily ip treatment for 16 weeks in (NZB x NZW) F1 lupus-prone mice. No signs of immunosuppression were detected.

Based on these promising efficacy data obtained in vivo with ER000145, orally available functionally selective immunomodulators are currently being developed as a potentially novel and innovative treatment option for SLE.

Axl Receptor Tyrosine Kinase Ameliorates Pristane Induced Diffuse Alveolar Hemorrhage in Mice by Regulating Macrophage Polarization

Wenwen Pei[1], Ranran Yao[1], Ziye Wang[2], Ruyu Liang[3], Renge Liang[2], Xiaolin Sun[4] and Yin Su[2], [1]Peking University, Beijing, China, [2]Peking University People's Hospital, Beijing, China, [3]Peking University, XiCheng, China, [4]Peking University People's Hospital, Beijing, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Diffusealveolar hemorrhage (DAH) is an infrequent but life-threatening complication in patients with systemic lupus erythematosus (SLE). Cells of the monocyte/macrophage lineage are essential to the pathogenesis of lung hemorrhage.An increasing number of research proved that Axl receptor tyrosine kinase(AxlTK)was especially highly expressed in macrophages. In this study, we explore whether AxlTK affects pathogenesis in DAH mice model by regulating macrophage polarization.

Methods: Bone marrow cells were obtained from femurs and tibias of Axl KO and WT Mice. Bone marrow-derived macrophages (BMDMs) were stimulated with 50ng/ml LPS and 20 ng/ml IFN-γ to promote M1 polarization, or 50ng/ml IL-4 to induce M2 polarization, respectively. Then, macrophages were examined by flow cytometry (FCM). At 8-10 weeks of age, wild type (WT) and Axl KO mice received a single intraperitoneal injection of 1 ml of pristane. After 14 daysof incubation, lung tissues were harvested and stained with H&E. And single-cell suspensions from lungs tissues were stained with the corresponding Ab mixtures for marking M1 and M2 macrophages. Cells were analyzed using a flow cytometry system.

Results: The expression of iNOS(M1 marker)and CD206(M2 marker) on BMDMs were significantly decreased in Axl KO compared to WT mice, respectivety. Significantly, lungs tissues from Axl KO mice with no or partial or complete hemorrhage, whereas those from WT mice showedpartial or complete hemorrhage in pristane-induced DAH micemodel. Mechanically, the expression of iNOS on macrophges in lungs tissues of Axl KO mice also showed a significantly decreased, while the expression of CD206 were slightly increased as compared to WT mice.

Conclusion: AxlTK may promotes macrophage polarization towards M1 and M2and ameliorates pristane induced diffuse alveolar hemorrhage in mice.

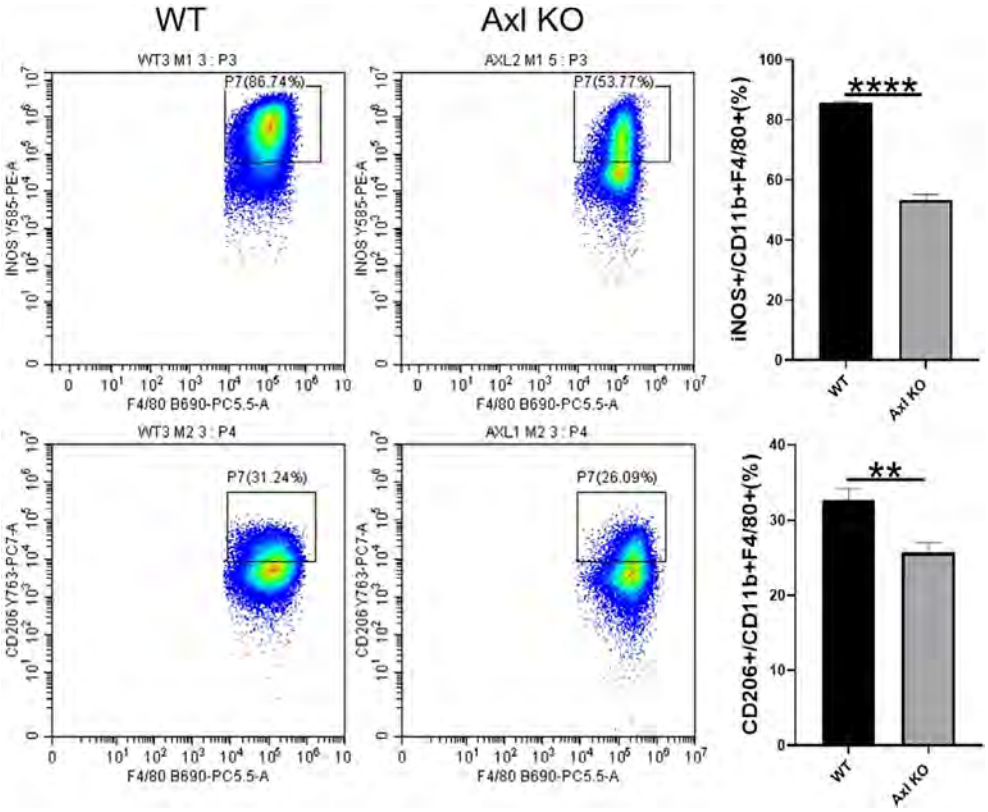

Figure1 BMDMs from WT and Axl KO mice were induced M1 and M2

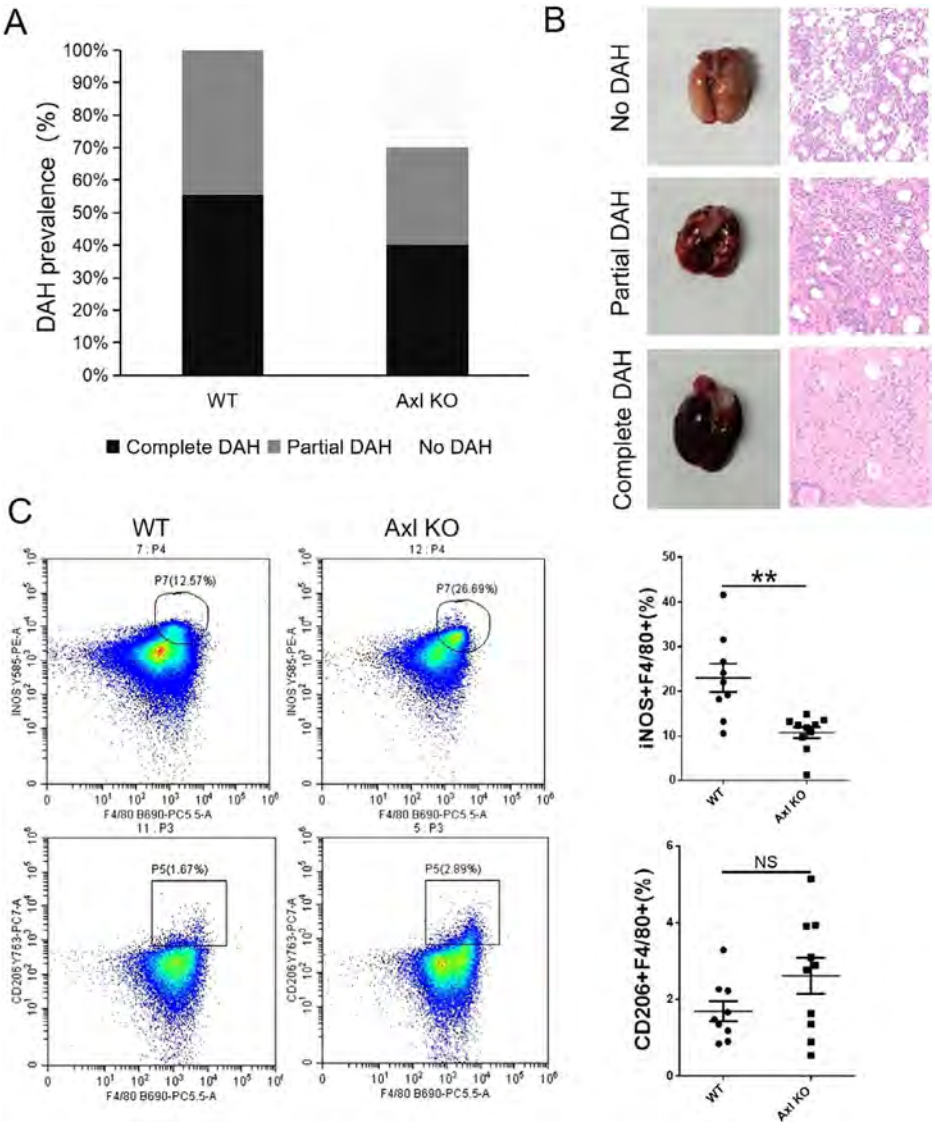

Figure2 Axl KO mice were prevented pristane induced diffuse alveolar hemorrage

Specificity of Brain-Intrinsic and Hematopoietic-Derived Mechanisms in Mediating Neuropsychiatric Symptoms of Systemic Lupus Erythematosus

Hadijat Makinde, Yidan Wang, Stumpf Cecilia and **Carla Cuda**, Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease that affects multiple end organs including the brain. Despite a prevalence of over 50% in SLE patients depending on the attribution model, neuropsychiatric symptoms of SLE (NPSLE) are among the least understood complications. Notwithstanding the paucity of data examining underlying mechanisms, accumulating evidence points to microglia, a brain-resident innate immune cell population, as a driver of disease. Our group was the first to show that microglial expression of disease-associated genes correlates with the severity of behavioral deficits in a NPSLE model prior to overt systemic disease. Previous data suggest NPSLE-like disease persists in bone marrow (BM) chimeric $MRL^{lpr/lpr}$ mice (MRL BM $MRL^{lpr/lpr}$) despite mitigation of systemic disease, suggesting a brain-intrinsic mechanism. However, these findings do not negate the contribution of circulating mediators of SLE-like disease at subclinical levels (antibodies, proteins, immune cells) to brain dysfunction. Indeed, the reciprocal chimera ($MRL^{lpr/lpr}$ BM MRL) was not evaluated. Further, radiation impacts microglial function and recipient mice from this study were not head-shielded.

Methods: Young female CD45.1 (Jackson 033076) and SLE-prone B6.*Sle1Sle2Sle3* (B6.TC; Jackson 007228) mice were used to generate head-shielded reciprocal BM chimeric mice with busulfan treatment to clear remaining BM (CD45.1 BM CD45.1; B6.TC BM CD45.1; CD45.1 BM B6.TC; B6.TC BM B6.TC). Mice underwent a behavioral tasks and PET imaging of activated microglia 10 weeks post-transfer. Perfused brains were extracted, meninges were removed and live $CD45^+$ cells were FACSorted from pooled cell suspensions (n=3/group to account for biological variability) for cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq; 10X Genomics 3' v3.1).

Results: Introduction of B6.TC BM into CD45.1 hosts yields 95% reconstitution and induces systemic inflammation indicative of SLE-like disease. Conversely, B6.TC hosts receiving CD45.1 BM showed a trend towards dampened SLE-like disease resulting from only 50% reconstitution. Optimization (increased busulfan, transfer of double CD45.1 BM cells) was unsuccessful following head-shielded irradiation of B6.TC mice, suggesting that the minor fraction of B6.TC host-derived progenitors remaining will still outcompete CD45.1 donor progenitors. Similar to NPSLE patients, B6.TC mice exhibit heightened anxiety. Anxiety persists in chimeric mice of B6.TC, but not CD45.1, host origin, suggesting that brain-intrinsic defects in B6.TC mice are required for this behavior. However, impaired motor learning in B6.TC mice is recapitulated by both brain-intrinsic and hematopoietic-derived defects in B6.TC mice. Analysis of PET tracer uptake and CITE-seq data are pending and will provide critical insight into the activation status of microglia and other immune cell subsets.

Conclusion: We find that NPSLE manifestations diverge in mechanistic origin within the same organism. Further understanding this specificity of brain-intrinsic and/or hematopoietic-derived mechanisms mediating NPSLE will be critical for developing treatment strategies.

Selective and Potent Inhibition of Cyclic GMP-AMP Synthase (cGAS) Fully Normalizes Autoinflammation Across Tissues in a Trex1-/- Mouse Model for Type I Interferonopathies

Arnaud Bourin[1], Zuzana Hořejší[2], Isabelle Cambré[1], Juraj Dobiaš[2], Mikhail Klychnikov[2], Radek Liboska[2], Maroš Smolíček[2], Zdeněk Vavřina[2], Wanda Haeck[1], Hugo Klaassen[1], Marnik Nijs[1], Kristine Metzger[1], Sandro Boland[1], Dries De Clercq[1], Sara Allasia[1], Gunter Carlens[1], Patrick Chaltin[3], Arnaud Marchand[1], Ondřej Páv[2], **Matthias Versele**[1] and Gabriel Birkuš[2], [1]Centre for Drug Design and Discovery (CD3) - Cistim, Leuven, Belgium, [2]Institute of Organic Chemistry and Biochemistry, Prague, Czech Republic, [3]Centre for Drug Design and Discovery (CD3) - KU Leuven, Leuven, Belgium

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The cGAS enzyme is a sensor of cytosolic double-strand (ds) DNA. It serves to detect viruses and elicits an acute, transient cGAMP-STING mediated type I interferon (IFN) response as part of anti-viral immunity. Recently, evidence has accumulated pointing to chronic stimulation of cGAS through endogenous (self) cytosolic dsDNA in the context of a wide variety diseases associated with a type I IFN signature. Clear examples of such auto-inflammatory diseases include Aicardi-Goutières Syndrome (AGS) and Systemic Lupus Erythematosus (SLE), which can harbour loss-of-function mutations in the gene encoding a 3' repair exonuclease, TREX1, which functions to prevent accumulation of cytosolic dsDNA. Indeed, mice deficient for Trex1 exhibit severe chronic systemic inflammation, which can be completely reversed by concomitant deletion of cGAS or STING. Other diseases associated with strong activation of cGAS include, among others, dermatomyositis, age-related macular degeneration, and Parkinson's disease (PD).

Methods: We report on the discovery and optimization of a novel series of small-molecule inhibitors of cGAS. The molecular binding mode is supported by crystallography, direct binding assays and multiple enzymatic assay formats. Compounds are assessed across different cellular contexts (including monocytes, microglia and retinal epithelial cells) using distinct sources of dsDNA as a stimulus. Lead compounds are prioritized based on DMPK (Drug Metabolism and Pharmacokinetics) properties, including distribution to the brain in mice. Mouse models have been used to prioritize compounds based on the ability to suppress acute HSV-mediated cGAS activation and chronic systemic autoimmunity (in Trex1-/- mice).

Results: Best compounds in the series have low nM potency in enzymatic assays using either mouse or human cGAS. No cross-reactivity with other enzymes that also use ATP or GTP as substrates were detected. Unlike many previously reported cGAS inhibitors, our compounds exhibit potent inhibition of cGAMP production and IFN response in cells, either stimulated with an exogenous source of dsDNA or mimicking a pathologic chronic stimulation of the pathway (e.g. using TREX1 deficient monocytes). Likewise, examples of the series display potent inhibition of microglia activation using alpha synuclein fibrils. The orally bioavailable lead compound, which displayed robust brain distribution, showed dose-dependent inhibition of autoimmunity across tissue types (PBMCs, kidney, lungs, heart and brain) in Trex1-/- mice and was significantly superior to the previously reported STING inhibitor, H151. In most cases, inflammation markers were restored to levels of WT mice within 2 weeks of dosing our cGAS inhibitor to Trex1-/- mice.

Conclusion: We discovered novel cGAS inhibitors and demonstrated their potential in preclinical models as therapeutics to treat peripheral auto-immune diseases such as AGS and SLE, and neurodegenerative diseases associated with a strong neuro-inflammation component such as PD.

Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibrosis is characterized by collagen deposition, fibro/myofibroblast (MYOFB) accumulation, and extracellular matrix remodeling. In some subtypes of cutaneous lupus erythematosus (CLE), particularly discoid lupus erythematosus (DLE) scarring alopecia and fibrotic lesional resolution may be widespread with no effective treatment. However, mechanisms of scar formation in CLE are not understood. We have shown that epidermal-directed overexpression of murine Vgll3 causes fibrotic-appearing skin lesions suggestive of CLE, and thus, we aimed to explore the role of Vgll3 in cutaneous fibrosis.

Methods: 2–3-month-old male and female transgenic (TG) mice overexpressing *Vgll3* in the epidermis under the K5 promoter were compared to wildtype (WT) C57Bl/6 mice (n=3-5 per group). Fibrotic biomarkers of human DLE and scleroderma were compared via immunohistochemistry. In addition, single-cell-RNA-sequencing (scRNA-seq) via 10x platform of lesional and nonlesional skin was completed to investigate the transcriptomes of the potential cellular fibrotic players. Several subclusters of fibroblasts (FBs), MYOFBs, and T cells were identified and fibrotic markers for each FBs subcluster were analyzed in lesional and non-lesional skin.

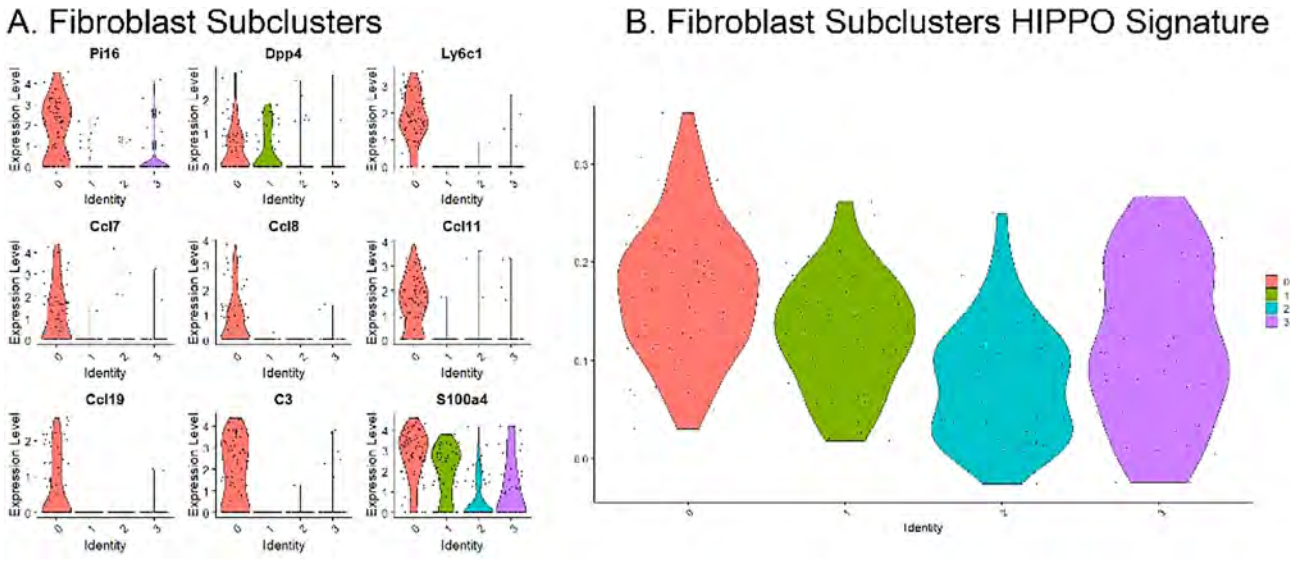

Fig. 1 Single-cell RNA-sequencing identified a fibroblast subcluster and Hippo signature. A) Lesional Vgll3 TG specific-fibroblasts (FB) subcluster (subcluster 0) express Pi16+ adventitial FB phenotype and express chemokines uniquely. This subcluster Pi16+ adventitial FB (disease FB) is unique to lesional Vgll3 TG skin which express chemokines (CCL7, CCL8, CCL11, CCL19) and exhibit higher MHC class I pathway genes. B) Cluster 0 has highest HIPPO Signature.

Results: 2–3-month-old male and female transgenic (TG) K5-Vgll3 exhibit cutaneous inflammation and fibrosis as evidenced by trichrome staining. TG lesional skin demonstrated a significant increase in fibrotic markers (*Acta2, Col1a1, Col1a2, Tgfb1, Ctgf)* and pro-fibrotic cytokines (*Il4, Il13*) also found in human DLE and scleroderma lesions compared to non-lesional skin. ScRNA-seq of lesional and nonlesional skin from TG vs WT skin showed increased inflammatory infiltrate in lesional TG greater than nonlesional TG, and nonlesional TG, higher than WT skin, which was verified by immunohistochemistry. Increased myeloid cells in lesional TG was higher than nonlesional TG and WT skin. Increased inflammatory gene expression (*Nfkb1, Cxcr4, Cxcl2, Il1b, Tnf, Cd14*), and CD4+ T cells in lesional TG skin exhibited greater *Foxp3, Gata3,* and *Tgfb1* expression than nonlesional TG and WT skin**.** Additionally, lesional TG skin exhibited higher expression of *Tgfb1,Col1a1,* and *Col1a2* compared to nonlesional TG and WT mouse skin (transcript and protein). Further, we identified a FB subcluster unique to lesional TG skin representing adventitial Pi16+ FB which expressed chemokines (*Ccl7, Ccl8, Ccl11, Ccl19*) and exhibited higher MHC class I pathway genes **(Fig.1.A)** and a higher Hippo signature **(Fig.1.B).** Finally,

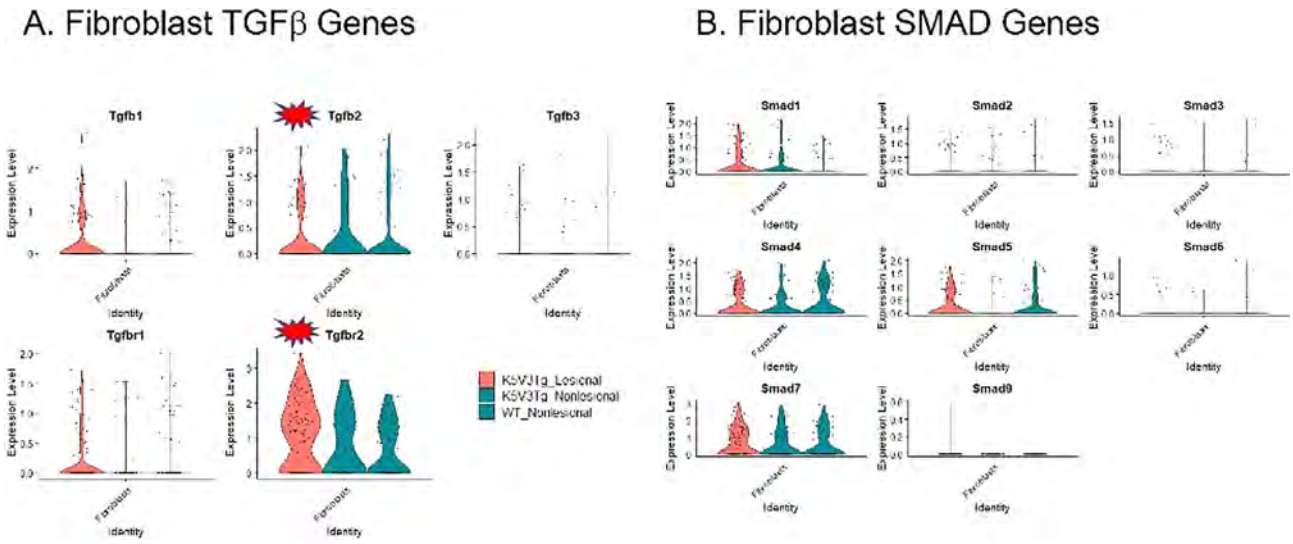

Fig.2 Single-cell RNA sequencing shows Tgfb gene expression and Smad gene expression in fibroblasts. A) Lesional Vgll3 TG Fibroblast have higher Tgfb2 and Tgfbr2 expression compared to nonlesional or wild type (WT). B) Lesional Vgll3 TG fibroblasts have higher Smads 1, 3, 4, and 5 gene expression compared to nonlesional or wild type (WT).

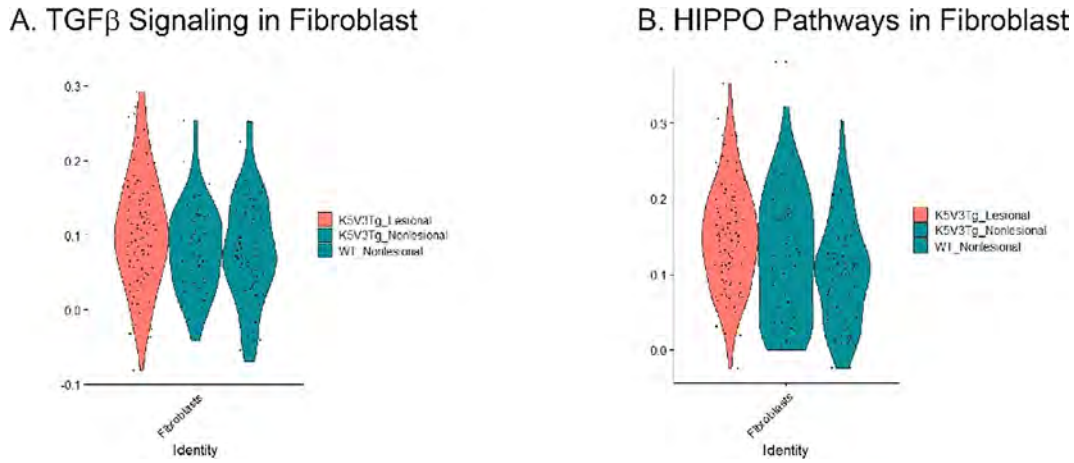

Fig.3 Single-cell RNA sequencing shows Hippo and Tgfb signaling in fibroblasts. A) Lesional Vgll3 TG fibroblasts have higher TGFb signaling score compared to nonlesional. B) Lesional Vgll3 TG fibroblast have higher HIPPO pathways score compared to nonlesional.

increased expression of Hippo and TGFβ pathway-regulated genes in FBs **(Figs.2-3),** and keratinocytes from lesional and nonlesional TG skin was seen, suggesting Hippo target dysregulation is an early event in fibrosis driven by epidermal Vgll3 that may drive pathologic myofibroblasts differentiation.

Conclusion: Overall, we have linked Vgll3-driven dysregulation of the Hippo and TGFβ pathways to fibrotic phenotypes, which may provide a critical novel target for the alleviation of disfiguring fibrosis in CLE.

Abstract Number: 0893

Involvement of Type I Interferon-responsive Myeloid Cells in Renal Inflammation in a Lupus Mouse Model

Trine Jorgensen and **Lindsey Han**, Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that can cause damage to multiple organs, including the kidneys in Lupus Nephritis (LN). Current treatments for SLE are limited to conventional disease-modifying anti-rheumatic drugs, while treatments for LN are limited to corticosteroid therapy, as well as Calcineurin inhibitors or Leflunomide, both of which have been studied mainly in Asian populations and are lacking in data. A more targeted therapy is necessary to address the underlying pathogenesis of the disease. Type I interferon (IFN-I) and its receptor (IFNAR) are known to play a significant role in the progression of SLE/LN, making them a major focus of research and therapy. The exact mechanism by which IFNAR expression on myeloid cells affects SLE/LN activity remains unclear.

Methods: Female mice were used to investigate whether deficiency of IFNAR on myeloid cells will drive or reduce disease progression of SLE/LN in B6.Nba2 lupus-prone mice. Study mice were: B6.Nba2.LysMcre/cre.IFNARflx/flx (n=16) (cKO), and control mice were: B6.Nba2 (WT) lupus-prone mice (n=18) and B6 (C57Bl/6) healthy mice (n=4). The tests performed included flow cytometry of kidney cells from 9 month old mice, and ELISA of urine biomarkers S100a8, VCAM-1, and PF4, a novel methodology scarcely done in LN mouse-model studies to analyze LN-related kidney damage without invasive biopsy.

Results: Kidney 9mo flow data revealed elevated neutrophil and decreased monocytic infiltration in the WT, but normalized levels in cKO, as well as specifically reduced levels of B cells in cKO. Furthermore, we found that CD4+ T cells were reduced, CD8+ T cells were elevated, and Double positive (DP) T cells were normalized in 9mo cKO kidneys as compared to WT mice. We observed nephromegaly in cKO mice at 9 mo of age, but the urinary biomarkers S100a8 and PF4 were decreased in 9mo cKO mice compared to WT mice.

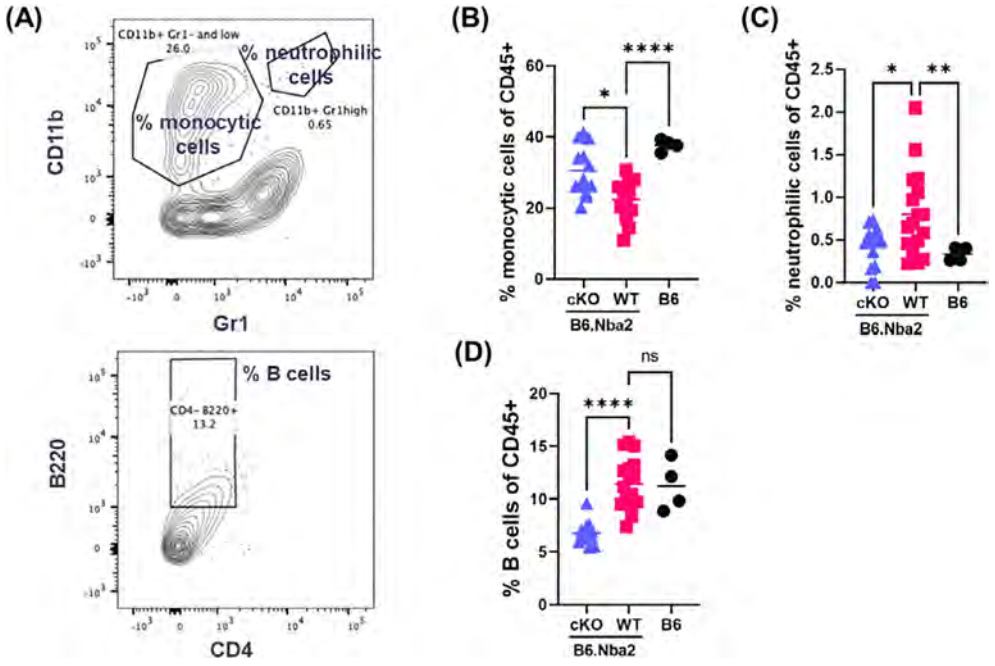

Figure 1: Kidney infiltrating myeloid cells approach levels seen in B6 mice, while B cells are specifically reduced in cKO mice. Myeloid inflammatory cell subsets were analyzed in 9-month-old female B6.Nba2 cKO, B6.Nba2, and B6 control mice. (A) Gating strategy: All cells were gated as CD45+. (B-C) The proportion of monocytic and neutrophilic cells in myeloid-cell specific B6.Nba2 cKO mice were closer to the B6 non-autoimmune controls. (D) In B6.Nba2.IFNAR cKO, B cells were specifically and significantly reduced compared to both B6.Nba2 and B6. Each symbol represents one mouse. * p<0.05, ** p<0.01, *** p<0.001, **** p<0.0001

Conclusion: In summary, we observed that reduced levels of neutrophilic cells, B cells, CD4+ T cells and DP T cells were associated with reduced levels of urinary biomarkers S100a8 and PF4 in cKO mice, suggesting that neutrophils infiltrate the kidney in a type I interferon-dependent manner, which subsequently results in the secretion of urinary markers previously found to be associated with nephritis in both pediatric and adult SLE-LN patients. Thus, we suggest that in response to type I interferons neutrophilic cells are recruited to the kidney, leading to the release of chemokines and the further recruitment of inflammatory lymphocytes, ultimately resulting in renal cell damage and the development of LN.

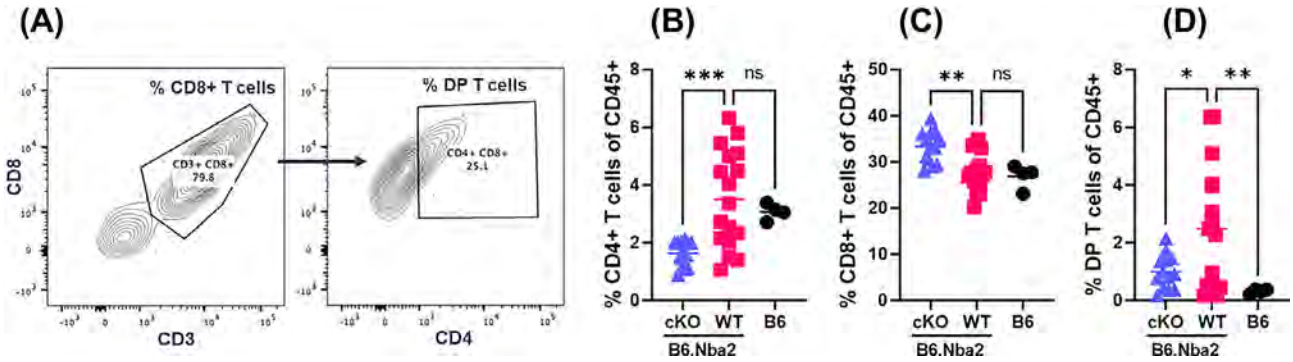

Figure 2: Lack of IFNAR on myeloid cells affect the type of T cells infiltrating kidneys of cKO mice. T cells were detected in 9-month-old female B6.Nba2 cKO, B6.Nba2, and B6 control mice. (A) Gating strategy. All cells were gated as CD45+. (B) In CD4+ Helper T cells, WT and B6 were unaltered, while the cKO mice were specifically reduced. (C) In CD8+ T cells, WT and B6 were also unaltered, while the cKO mice were specifically increased. Further studies to determine if elevated population is representative of CD8+ Tregs. (D) In double positive T cells, cKO mice were closer to levels of B6 healthy mice compared to the WT. Each symbol represents one mouse. ** p<0.01, *** p<0.001, **** p<0.0001

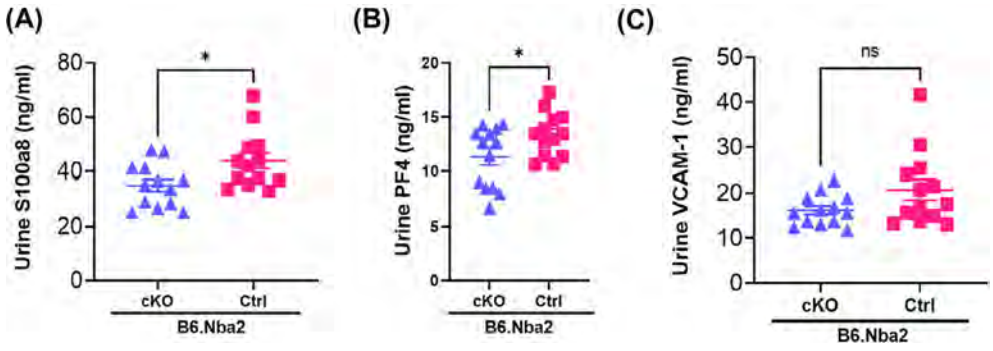

Figure 3: Decreased concentrations of urinary biomarkers suggest reduced LN disease activity in cKO mice. Concentrations of urinary biomarkers were analyzed in 9-month-old female B6.Nba2 cKO, B6.Nba2, and B6 control mice. (A) Concentration of S100a8 (Saliva 100 calcium-binding protein a8) was significantly reduced in cKO mice. (B) Concentration of PF4 (Platelet Factor 4) or CXCL4 (CX Chemokine ligand 4) was significantly reduced in cKO mice. (C) Concentration of VCAM-1 (Vascular cell adhesion molecule 1) was reduced in cKO mice. Each symbol represents one mouse. * p<0.05, ** p<0.01, *** p<0.001, **** p<0.0001

The Cellular and Spatial Type I Interferon Response Following Skin Exposure to Ultraviolet Light

Jie An[1], Xizhang Sun[1], Rayan Najjar[1], Connie Zhao[1], Paul Kong[2], Stephanie Weaver[2], Amanda Koehne[2], Matt Fitzgibbon[2] and Keith Elkon[1], [1]University of Washington, Seattle, WA, [2]Fred Hutchinson Cancer Center, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients characteristically have a prominent type I interferon (IFN-I) signature in lesional and non-lesional skin. We recently demonstrated that, following a single exposure to ultraviolet light (UVB), UVB induces an IFN signature not only in the skin but also in the blood and kidneys of wild type mice. We asked three questions: which cells (skin or immune) are responsible for IFN-I production? 2) which subset of immune cells or which part of the skin are responsible for IFN-I production after UV? And 3) What are the different Type I IFNs (IFN-a, IFN-b, IFN-k) being made after UV exposure?

Methods: Shaved mouse skin received a single exposure of 500 mJ/cm^2 UVB and biopsies taken at time 0 and then 6, 12 and 24 hours after UVB exposure (n=3 per groups). Single cell nuclear RNA sequencing (snRNAseq) used Illumina Nextseq protocols with bioinformatics utilizing Monocle and Seurat pipelines. In situ hybridization (ISH) was performed with IFN-alpha consensus (IFNac), beta (b) and kappa (k) probes with HALO software for quantification. For spatial transcriptomics analysis, fixed tissue was first stained with antibodies to CD45 and to cytokeratin (CK) to mark immune cells and keratinocytes respectively. 7 regions of interest were selected and processed on the GeoMx digital spatial profiler. We used the mouse whole transcriptome probe set for next generation sequence analysis and results processed on the nanoString software Suite 2.5.1.145. Pathway analysis was determined by Gene Set Enrichment Analysis using the curated mouse gene set collection from MSigDB (2626 gene set).

Figure 1:

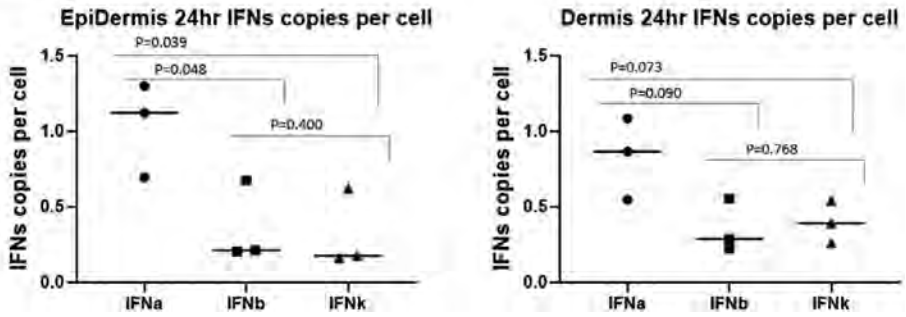

Figure 1. Average copy number of interferon alpha (consensus), beta and kappa in the epidermis (left) and dermis (right) at 24 hrs following skin exposure to UV light.

Results: SnRNAseq revealed that ISGs such as Ifit1, Isg15 and Isg20 were significantly increased at 24 hr post UV (p adj $< 10^{-5}$) relative to baseline. When ISG expression was clustered by cell type, the highest Isg15 and Isg20 expression was seen in two epidermal clusters (p adj $< 10^{-5}$ and 10^{-10} respectively). Utilized the ISH approach, we observed the highest signals in the epidermal region for IFN-ac (> 1 copy/ cell) versus IFN-b and IFN-k (< 1 copy/ cell). Whole transcriptome spatial analysis confirmed highest Isg15 and 20 expression in the cytokeratin positive cells. When the top 20 pathways activated by UV at 6 hr in the epidermis and dermis were compared, statistically significant differences (p adj < 0.01) in the cytokeratin positive cells included apoptosis, epigenetic (H3K27ME3), and NFkb targets whereas in the CD45 cell population, differences in GVHD, innate immune system, platelet activation and brown myeloid cell development were observed. At 24 hr post UV, significant changes were observed in multiple RNA processing reactomes in both cytokeratin and CD45+ cells. In the dermis, an increase in several lipid and fatty acid reactomes occurred.

Conclusion: We have identified the spatial locations of different IFN-I species in the skin following UV light injury. Copy number was highest in the epidermis for IFN-ac. Spatial transcriptomics also illuminates differences in inflammatory versus metabolic programs that are activated in immune (CD45) versus epidermal (cytokeratin positive) and dermal locations. These studies will lead to better understanding of how UV inflammation provokes lupus in susceptible individuals.

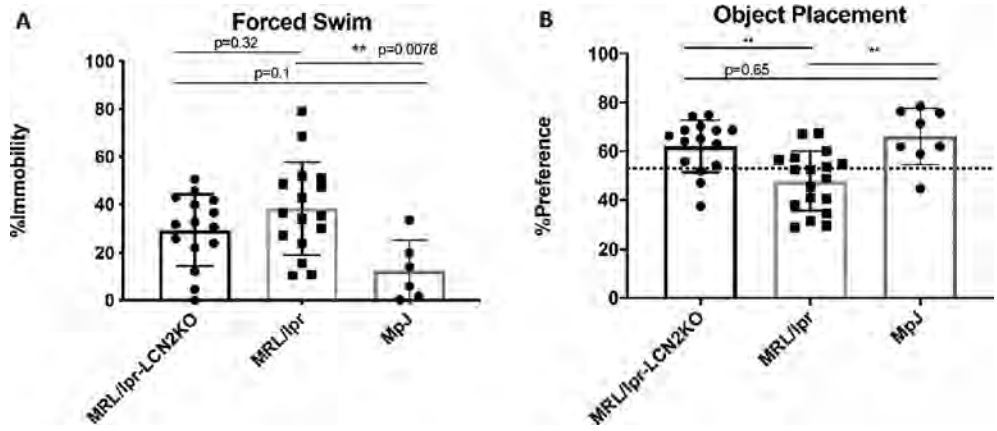
Lipocalin-2 Promotes Cutaneous and Neuropsychiatric Disease in Murine Lupus

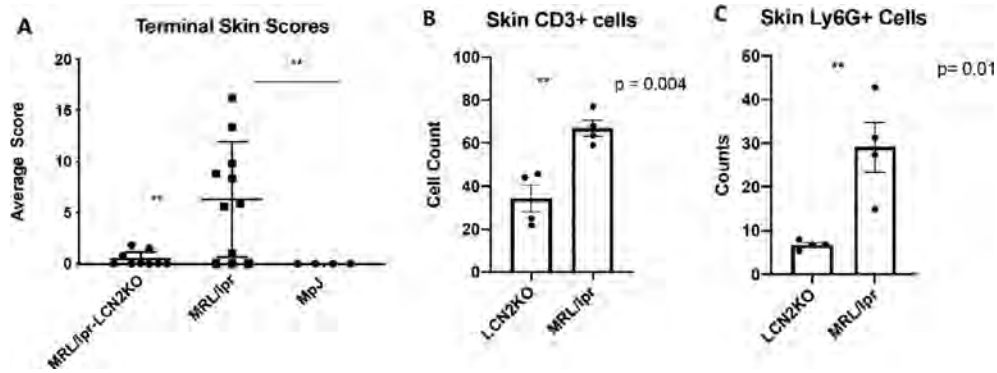
Chaim Putterman[1], Elise Mike[2] and **Sayra Garcia**[1], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Johns Hopkins, Bronx, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM



LCN2 deficient MRL/lpr mice (n=15) showed a significant improvement in the Porsolt swim test, which evaluates depression like behavior (A) and the object placement test, which evaluates spatial memory (B) compared to MRL/lpr wild type mice.



Macroscopic lesion scores in LCN2 deficient MRL/lpr mice were significantly improved compared to the MRL/lpr wildtype lesions (A). Lesional skin taken from LCN2-deficient MRL/lpr mice had a reduction of infiltrating CD3+ T cell (B) and Ly6G+ neutrophil (C) counts compared to the MRL/lpr wildtype mice as determined by immunofluorescent staining.

Background/Purpose: One central mechanism believed to contribute to the pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE) is temporary disruption of the blood brain barrier (BBB). Astrocytes are abundant glial cells in the brain that work with endothelial cells to regulate tight junctions, which maintain BBB integrity. Astrocyte end-feet localized along the BBB can sense and detect inflammatory cytokines and cells in the periphery; thus, the systemic inflammatory milieu present in SLE can lead to the activation of astrocytes, temporarily breaching the BBB and compromising the brain's immune privilege. BBB dysfunction can also lead to the migration of immune cells into the brain and further activation of astrocytes and microglia, resulting in neuronal damage and subsequent cognitive defects. The MRL/lpr mouse is the most widely used spontaneous murine model of NPSLE. MRL/lpr mice show behavioral abnormalities such as cognitive deficits in the form of impaired memory (spatial recognition) as well as depressive-like behavior. Lipocalin-2 (LCN2) is an acute phase protein implicated in immune-mediated and neuroinflammatory diseases, including multiple sclerosis and traumatic brain injury. To examine a possible role of LCN2 in the pathogenesis of SLE we generated aMRL/lprLCN2 knockout (KO) mouse strain, and evaluated end organ disease, including neuropsychiatric, skin, and kidney disease. Furthermore, we focused on uncovering specific mechanisms by which LCN2 improves disease in lupus target organs.

Methods: Seventeen week old MRL/lpr-LCN2KO (n=15)and MRL/lprLCN2 wild type (n=16) mice underwent standardized behavioral testing, and were subsequently bled and sacrificed. Skin lesions were scored using a validated scoring protocol. Serum was tested for anti-dsDNA antibodies and IgG levels via ELISA. Skin and brain tissues were processed for

immunofluorescent staining for T cells, B cells, macrophages, and neutrophils. Brain tissue was stained for NeuN (a neuronal marker) and glial fibrillary acidic protein (GFAP, an astrocyte activation marker).

Results: We found that MRL/lpr-LCN2KO mice had significantly improved cognitive performance on spatial recognition memory and tests of behavioral despair, but unchanged levels of serum IgG and anti-dsDNA antibodies, compared to MRL/lpr mice. Additionally, we found that skin scores (macroscopic) in LCN2KO mice were significantly improved, together with a reduction in infiltrating T-cell and neutrophil counts. In the brain, we found diminished GFAP expression in MRL/lpr-LCN2KO mice, indicating reduced astrocyte activation. Moreover, NeuN expression was decreased inMRL/lprLCN2KO-derived hippocampal neurons, consistent with improved hippocampal neuron viability in LCN2 deficient mice.

Conclusion: LCN2 deficiency improves skin and neuropsychiatric disease in MRL/lpr lupus prone mice. While investigation of additional mechanisms is in progress, we found that skin disease is improved through reduction of infiltrating immune cells known to contribute to the severity of cutaneous lesions, while in the brain LCN2 deficiency reduces astrocyte activation and improves hippocampal neuron damage.

Targeting Toll-Like Receptor 7 with DS-7011a, a Promising Novel Antagonistic Antibody for the Treatment of Systemic Lupus Erythematosus

Atsushi Manno[1], Tomohiro Honda[1], Chiharu Kuwata[2], Shiho Ito[2], Michinori Kadokura[1], Reiko Mizutani[3], Shinnosuke Yamada[1] and Yoshiaki Tomimori[1], [1]Daiichi Sankyo Co., Ltd., Shinagawa-ku, Japan, [2]Daiichi Sankyo Co., Ltd., Edogawa-ku, Japan, [3]Daiichi Sankyo RD Novare Co., Ltd., Edogawa-ku, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The centrality of Toll-like receptor 7 (TLR7) to the pathogenesis of systemic lupus erythematosus (SLE) was recently underscored by a report that high TLR7 gene expression drives autoantibody production in SLE (Wang et al., 2019)and reaffirmed by a report that TLR7 gain-of-function mutations confer susceptibility to SLE (Brown et al., 2022). It was also reported that an antagonistic anti-mouse TLR7 monoclonal antibody (mAb) improves survival and inhibits autoantibody production in NZBWF1 mice, which spontaneously develop lupus (Murakami et al., 2021). We have identified DS-7011a, an antagonistic anti-human TLR7 mAb, and examined its preclinical pharmacological activity and safety. We have also examined the expression of the TLR7 gene signature (GS) as an indicator of target engagement in NZBWF1 mice.

Methods: The species cross-activity and the binding specificity of DS-7011a were evaluated using Lenti-X 293 T cells over-expressing either TLR7 ortholog proteins of several animal species or human TLR family proteins. To evaluate the modulation of cytokine and antibody production by anti-TLR7 antagonistic antibodies, human or mouse peripheral blood mononuclear cells (PBMCs) were stimulated with CL264 or ssRNA9.2s, which are TLR7 agonists. A surrogate antagonistic anti-mouse TLR7 mAb was administered to NZBWF1 mice intraperitoneally at 0.2 mg/mouse once a week from Week 21 to Week 30 of age to study the impact on the lupus model along with the modulation of TLR7 GS. TLR7 GS was defined using

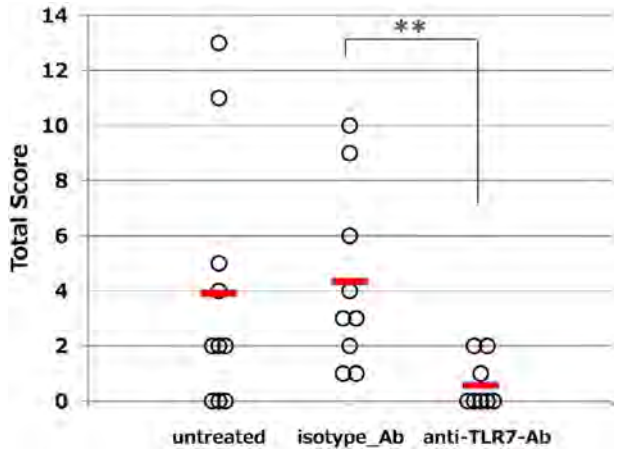

Figure 1. Renal histological scores in untreated, isotype antibody-treated, and anti-TLR7 antibody-treated mice (**: $p < 0.01$ by Wilcoxon rank sum test)

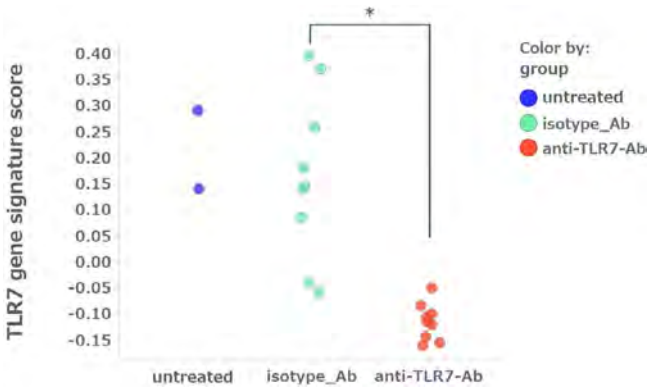

Figure 2. TLR7 gene signature scores in untreated, isotype antibody-treated, and anti-TLR7 antibody-treated mice (*: $p < 0.001$ by Welch two sample t-test)

public microarray data of mouse macrophages treated with R848, a TLR7 agonist. TLR7 GS scores were calculated using blood gene expression data from NZBWF1 mice treated with anti-TLR7 mAb or isotype control antibody or left untreated. To evaluate safety, DS-7011a was administered intravenously once every 2 weeks for 3 months to cynomolgus monkeys at doses up to 400 mg/kg.

Results: DS-7011a bound to both human and cynomolgus monkey TLR7 but not to mouse or rat TLR7. DS-7011a bound to human TLR7 but not to other human TLR family proteins. DS-7011a suppressed the TLR7-stimulated production of IL-6 and IFN-alpha by human PBMCs. The surrogate anti-mouse TLR7 mAb suppressed the TLR7-stimulated IL-6 production by mouse PBMCs and it reduced kidney tissue damage (Figure 1), inhibited autoantibody production, and suppressed TLR7 GS expression in NZBWF1 mice (Figure 2). There were no toxicity findings in monkeys treated for 3 months at doses up to 400 mg/kg.

Conclusion: DS-7011a shows the ability to inhibit the TLR7-stimulated production of inflammatory cytokines and shows no toxicity in monkeys after 3-month treatment up to and including the maximum administered dose. An anti-mouse TLR7 mAb ameliorated manifestations of a mouse lupus model, suppressing the expression of TLR7 GS. These findings indicate that, by targeting TLR7, DS-7011a is a promising therapeutic option for the treatment of SLE.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Animal Models Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with extensive phenotypic heterogeneity due to the underlying molecular diversity of dysregulated pathways. Patients with SLE receive glucocorticoids as part of standard-of-care treatment but can develop resistance over time, making steroid resistance an important unmet need. Furthermore, side effects make long-term use undesirable. Toll-like receptor (TLR)7 and TLR8, endosomal receptors that play a key role in innate immunity, are expressed in immune cells, where they recognize single-stranded RNA and initiate downstream signaling via the nuclear factor kappa B (NFκB) and interferon regulatory factor pathways. NFκB signaling activation via TLR7 and TLR8 pathways could be a driving factor in steroid resistance. We evaluated the steroid-sparing potential of afimetoran, an equipotent, dual TLR7 and TLR8 antagonist, currently in clinical development for SLE and cutaneous lupus erythematosus.

Methods: NZB/W mice with moderate disease (proteinuria, 60–100 mg/dL) were treated therapeutically once daily with vehicle or selected doses of afimetoran and/or prednisolone. Survival, kidney injury, splenomegaly, age-associated B cells (ABCs), serum auto-antibody titers (anti-double-stranded DNA antibodies, anti-nuclear antibodies), and interleukin-12p40 (IL-12p40) were assessed in all treatment groups. To assess the impact of afimetoran on TLR7 activation–mediated steroid resistance in vitro, C57 wild-type (WT) mouse bone marrow cells (BMCs) were challenged with the TLR7 agonist gardiquimod and treated with prednisolone alone or in combination with afimetoran. B-cell and plasmacytoid dendritic cell (pDC) apoptosis was evaluated by annexin V staining using flow cytometry in C57 WT BMCs treated in vitro and NZB/W BMCs from mice dosed orally.

Results: Afimetoran alone and in combination with prednisolone improved survival in the NZB/W mouse model. Significant, dose-dependent suppression of kidney injury markers such as proteinuria, neutrophil gelatinase-associated lipocalin (NGAL), or tissue inhibitor of metalloproteinases 1 (TIMP1) was observed. Splenomegaly was improved, particularly when afimetoran was combined with prednisolone; suppression of ABCs was also improved with this combination. Significant, dose-dependent suppression of plasma IL-12p40 and serum auto-antibody titers was also observed, demonstrating the potential of afimetoran in this mouse model of SLE. An improved steroid response was seen with afimetoran in vitro in gardiquimod-stimulated C57BL/6 mouse BMCs, which showed a significant increase in prednisolone-induced apoptosis of pDCs and B cells compared with baseline control or prednisolone alone. A similar trend was seen in vivo for BMCs collected from NZB/W mice dosed with combinations of afimetoran and prednisolone.

Conclusion: Afimetoran, alone or in combination with low-dose (1mg/kg) prednisolone, showed robust efficacy in NZB/W mice with moderate disease. Bone marrow pDCs and B cells showed afimetoran-induced reversal of resistance to prednisolone-induced apoptosis. These data confirm that afimetoran has the clinical potential to be steroid sparing.

The Role of the Endothelin System in the Development of TLR7-accelerated Lupus-Associated Cardiac Dysfunction

Kennedy Hawkins, Marice McCrorey, C. Alex Colvert, Kristine DeLeon-Pennell, Melissa Cunningham and Justin Van Beusecum, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Animal Models Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease characterized by autoantibody formation and immune complex deposition in target organs. While it is known that plasma endothelin-1 (ET-1) is elevated in patients with lupus and is associated with high rates of hypertension, renal injury, and cardiovascular disease, the underlying mechanisms contributing to cardiac complications associated with lupus are still unknown. Herein, we hypothesized that disease acceleration with the toll-like receptor 7/8 agonist, Resiquimod, would promote higher incidence of cardiac pathology and dysregulation of the ET system in a preclinical lupus murine model.

Methods: Female B6.Nba2 lupus prone mice aged 10-14 weeks were treated topically with either 30 uL of acetone or Resiquimod (R848;100μg/30μl) twice weekly for 4 weeks. Echocardiograms were performed every 4 weeks for 16 weeks to evaluate ejection fraction (EF), left ventricular wall thickening, and end-systolic and diastolic volumes. At 16 weeks, hearts and spleens were harvested, weighed and frozen or fixed for histological analysis. ET-1, endothelin receptor A (ET_A), and endothelin receptor B (ET_B) were analyzed by real-time PCR (RT-PCR), immunoblotting, and immunohistochemical analysis.

Results: Cardiac imaging showed R848-treated mice had increased left ventricular wall thickness at 4 weeks compared to acetone treatment ($p< 0.01$). After 16 weeks, mice previously treated with R848 for 4 weeks had profound cardiac dysfunction indicated by decreased EF ($p< 0.001$) and increased end-systolic volume ($p< 0.01$) compared to acetone treatment. R848-treated mice also exhibited profound cardio- (118.6 ± 1.014 vs. 187.7 ± 2.967; $p< 0.0001$) and splenomegaly (162.4 ± 33.3 vs. 658.3 ± 205.7; $p< 0.05$) at 16 weeks. Interestingly, histological analysis of the left ventricle demonstrated significantly increased perivascular fibrosis in the R848-treated mice compared to acetone ($1.174 \pm 0.1\%$ vs. $1.651 \pm 0.1\%$; $p< 0.05$). Interrogation of the cardiac ET system showed that R848-treated mice had significantly elevated ET-1 levels ($p< 0.05$), without a significant change in ET_A or ET_B receptor expression.

Conclusion: These data demonstrate that acceleration of lupus with the TLR7 agonist R848 increases cardiac dysfunction and pathological production of cardiac ET-1. Moreover, our model presents a novel avenue to better understand the role and contributions that the ET system plays in the development of lupus associated cardiac dysfunction.

Complement Factor I (CFI) Gene Expression by Kidney Tubular Cells Is Increased in Lupus Nephritis Patients with Interstitial Fibrosis and Tubular Atrophy

Shudan Wang[1], John Greally[2], Masako Suzuki[3], Jee-Young Moon[2], Tao Wang[2], Yvonne M Saenger[2], Brad Rovin[4] and J. Michelle Kahlenberg[5], [1]Albert Einstein College of Medicine / Montefiore Medical Center, New York, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Texas A&M University, College Station, TX, [4]Ohio State University, Columbus, OH, [5]University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Tubulointerstitial injury is a strong predictor of progression to kidney failure in lupus nephritis (LN). Prior animal studies suggest intrarenal complement activation has an important and underrecognized role in tubulointerstitial fibrosis in LN, yet this has not been shown in LN patients. This study aimed to identify complement markers of

*Kidney tubular cells include proximal tubule, loop of Henle, distal tubule and collecting duct cells. The average gene expression per subject was calculated and compared between the groups using the Wilcoxon rank sum test.

References:

1. [illegible] applied to lupus nephritis reveal type I IFN and fibrosis relevant pathways. Nat Immunol. 2019;20(7):915-27.

2. Zhang Y, Goodfellow RX, Ghiringhelli Borsa N, Dunlop HC, Bicat SA, et al. Complement Factor I Variants in Complement-Mediated Renal Diseases. Front Immunol. 2022;13:866330.

Methods: We used data from the Accelerating Medicine Partnership/ Multi-Ethnic Translational Research Optimization Lupus cohort, which applied scRNA-seq to 20 LN kidney tissue samples [1]. Cells between 200 and 2500 detected features were included. The data was normalized, scaled, and underwent principal component analysis and clustering using Uniform Manifold Approximation and Projection plots to identify distinct cell subtypes. Specific marker genes were used to identify the kidney tubular cell subtypes: ALDOB (proximal tubules), UMOD (loop of Henle), CALB1 (distal convoluted tubules), and SLC4A1/ TMEM213 (collecting duct). Complement gene expression was compared between LN patients with and without IFTA in the overall tubular cells and in each tubular cell subtypes using two approaches: 1) subject-based analysis where the average gene expression per subject was calculated and compared between the groups using the Wilcoxon rank sum test. 2) single-cell analysis using a linear mixed effects model. IFTA was defined as ≥10% of interstitium with fibrosis and atrophy.

Results: Of the 20 LN patients, 9 had IFTA on kidney biopsy. Table 1 compares demographics, medication use, laboratory, and histopathology between LN patients with (≥ 10%) and without (< 10%) IFTA on biopsy. LN patients with IFTA had a higher proportion with tubulointerstitial inflammation as compared with those without IFTA (56% vs. 1%, p=0.05) and higher chronicity index median score 3 (IQR= 3, 4) vs 1(0,1). There was no difference in other variables. A total of 1162 kidney tubular cells were identified: 287 proximal tubular, 171 loop of Henle, 587 distal tubular and 117 collecting duct cells. LN patients with IFTA had significantly higher overall tubular expression of Complement Factor I (CFI) as compared to those without IFTA: median average expression 0.298 (0.258, 0.383) vs. 0.059 (0.019, 0.100), p=0.0005, Figure 1. No differential expression of other complement genes was found (Table 2). When evaluating each tubular cell subtype, no difference in average CFI expression was found. Single cell analysis also showed increased overall tubular expression of CFI (β=0.27, SE=0.05, p< 0.001) and C7 (β=0.31, SE=0.15, p=0.049) among LN patients with IFTA. Specifically, CFI expression was increased in the distal tubular cells (β=0.27, SE=0.06, p< 0.001) but not in the other tubular cell subtypes.

Conclusion: This study identifies CFI, a regulator of the alternative complement pathway, as a potential marker of IFTA in LN. Increased CFI has been found in other kidney diseases [2] and may overcompensate for a dysfunctional complement system.

Complement Deposition on Extracellular Mitochondria Induces Platelet Activation *in Vitro*

Marina Barguil Macedo and Christian Lood, University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Mitochondria are extruded upon cell death and platelet activation, being elevated in several inflammatory conditions, including systemic lupus erythematosus (SLE). Mitochondria are immunogenic, with SLE patients having anti-mitochondrial antibodies (AMA), including anti-cardiolipin antibodies, which are associated with thrombosis. However,

the role of AMAs, as well as other opsonins such as complement, in regulating mitochondrial-mediated platelet activation, has not been carefully investigated. In the current study, we set out to determine the role of AMAs and complement components in modifying the ability of extracellular mitochondria to promote platelet activation.

Methods: Ultra-pure mitochondria were isolated from HepG2 cells through Dounce homogenization and differential centrifugation. Mitochondria were pre-opsonized with isolated IgG from SLE patients or healthy controls, as well as complement C3-deficient or sufficient plasma, prior to adding the washed opsonized mitochondria to platelets from healthy individuals. Markers of platelet activation were assessed by flow cytometry (P-Selectin; CD62P) or by ELISA of the supernatant (platelet factor 4; PF-4, and thrombospondin-1; TSP-1).

Results: Extracellular mitochondria were able to induce CD62P on the platelet surface (8x increase from baseline, $p< 0.0001$, Figure 1A), even to a higher extent than ADP, a known platelet activator, used as positive control. Surprisingly, opsonization of mitochondria with SLE IgG only marginally amplified platelet activation. Mitochondria supported complement activation, with binding of both C1q and activated C3 to the outer membrane. Importantly, C3-sufficient, but not deficient, sera supported enhanced mitochondrial-mediated platelet activation as determined by CD62P, PF-4 (3x increase from baseline, $p< 0.001$) and TSP-1 levels (4x increase from baseline, $p< 0.001$, Figure 1B). Of note, EDTA, a chelator of divalent cations, $Ca2+$ and $Mg2+$ necessary for complement activation, prevented mitochondrial opsonization with C3, and prevented subsequent platelet activation.

Conclusion: Extracellular mitochondria were able to induce CD62P on the platelet surface (8x increase from baseline, $p< 0.0001$, Figure 1A), even to a higher extent than ADP, a known platelet activator, used as positive control. Surprisingly, opsonization of mitochondria with SLE IgG only marginally amplified platelet activation. Mitochondria supported complement activation, with binding of both C1q and activated C3 to the outer membrane. Importantly, C3-sufficient, but not deficient, sera supported enhanced mitochondrial-mediated platelet activation as determined by CD62P, PF-4 (3x increase from baseline, $p< 0.001$) and TSP-1 levels (4x increase from baseline, $p< 0.001$, Figure 1B). Of note, EDTA, a chelator of divalent cations, $Ca2+$ and $Mg2+$ necessary for complement activation, prevented mitochondrial opsonization with C3, and prevented subsequent platelet activation.

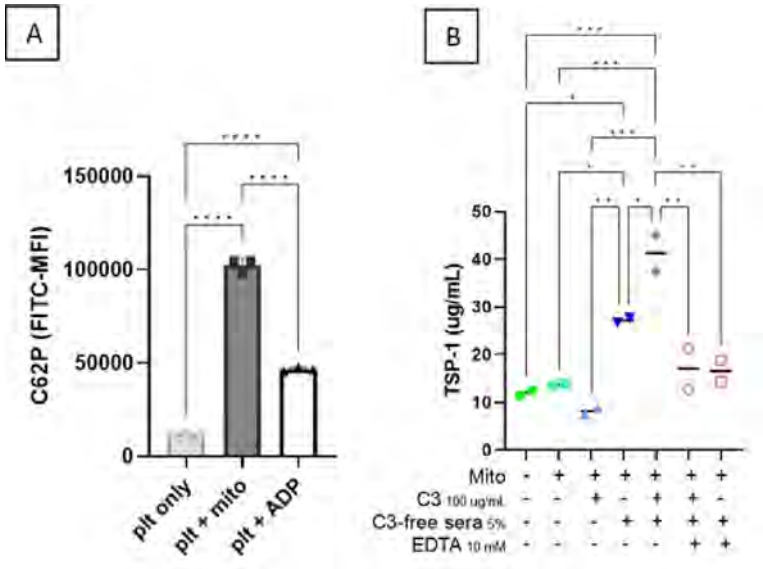

Figure 1. Mitochondrial-mediated platelet activation. A) Platelet P-selectin (CD62P) expression upon co-culture with mitochondria (mito) or ADP. B) Platelet activation (TSP-1) upon co-culture with mitochondria pre-opsonized with C3-sufficient (purple diamond) or deficient (blue down-pointing triangle) sera in presence of absence of EDTA (pink open circle).

Scavenging of Isolevuglandins Attenuates Neutrophil Expansion and Aortic NETosis in Systemic Lupus Erythematosus

Jaya Krishnan[1], Néstor de la Visitación[1], Jonathan Williams[1], Leslie Crofford[2] and **David Patrick**[3], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Melbourne, AR, [3]Department of Veterans Affairs, Nashville, TN

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Atherosclerosis and vascular inflammation are a cause of morbidity and mortality in systemic lupus erythematosus (SLE). Vascular NETosis is a driver of atherosclerosis and vascular inflammation. Isolevuglandins (IsoLGs) are lipid-aldehydes formed by peroxidation of arachidonic acid or prostaglandin-H_2. IsoLGs are efficiently scavenged by 2-hydroxybenzylamine (2-HOBA). Treatment of SLE-prone *B6.SLE123* mice with 2-HOBA attenuates systemic inflammation and reduces blood pressure. Additional studies have shown that isoLGs directly contribute to the formation of neutrophil extracellular traps (NETosis). We hypothesized that isoLGs contribute to neutrophil expansion and aortic NETosis in SLE-prone mice.

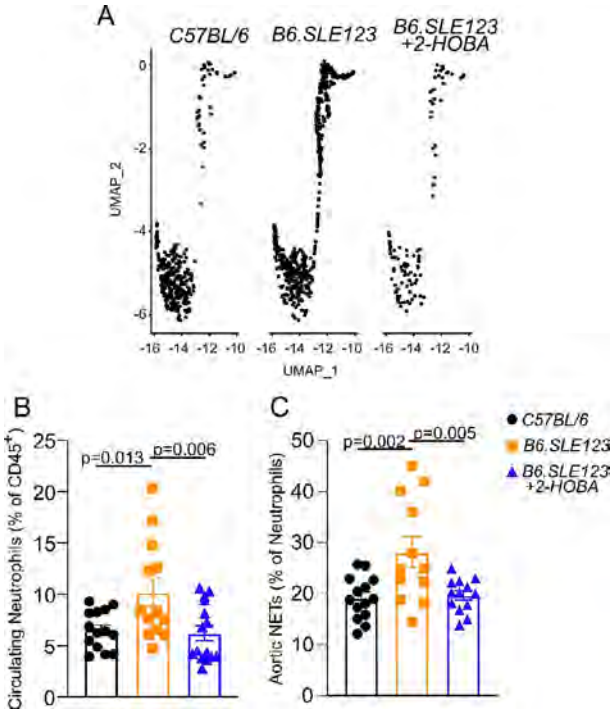

Figure 1. (A) UMAP of neutrophil clusters from cells isolated from spleens of C57BL/6, B6.SLE123, and B6.SLE123 mice treated with 2-HOBA following single cell sequencing. Significant expansion of neutrophils is present in SLE prone mice. This expansion is attenuated by 2-HOBA. (N=3) (B) Circulating neutrophils were quantified by flow cytometry. (C) NETs were quantified in aortas by flow cytometry. (N=12-14, data were compared with one-way ANOVA followed by Dunnett's multiple comparison test).

Methods: We treated 8-week-old female SLE prone *B6.SLE123* mice with 1g/L 2-HOBA in the drinking water for 4-weeks. *C57BL/6* mice were used as healthy controls. Spleens were harvested and splenocytes were submitted for single cell sequencing. Data were analyzed with Seurat v4.0.0 in R v4.0.4. NETosis in mouse tissue was measured by flow cytometry. Peripheral blood was obtained from a research subject with SLE that was recruited as part of the Memantine for the Treatment of Cognitive Impairment in Systemic Lupus Erythematosus clinical trial (IRB# 180256). To determine the role of isoLGs in NETosis, neutrophils were harvested from peripheral blood. Cells were seeded onto poly-L-lysine coated plates and incubated at 37°C for 2-hours in the presence of 200 μM ethyl-2-hydroxybenzylamine (ethy-2-HOBA), an isoLG scavenger with improved nuclear penetrance, or phosphate buffered saline as a control. Human NET formation was determined with immunofluorescence and quantified using the Imaris Cell Imaging Software (Oxford Instruments).

Results: Single cell sequencing revealed an increase in splenic neutrophils in *B6.SLE123* mice compared to *C57BL/6* controls. Treatment with 2HOBA attenuated this increase (*C57BL/6* 2.1%, B6.SLE123 3.8%, B6.SLE123+2HOBA 0.6% of total sequenced cells, N=3) (Figure 1A). Flow cytometry revealed an increase in circulating neutrophils in *B6.SLE123* mice that was attenuated with 2HOBA (*C57BL/6* 6.5 ± 1.9%, *B6.SLE123* 10.2 ± 4.8%, *B6.SLE123*+2HOBA 6.2 ± 2.8% of $CD45^+$ cells, N = 12-14)(Figure 1B). Aortic NETs were also increased in SLE prone mice which was attenuated following 2HOBA treatment (*C57BL/6* 19.2 ± 4.2%, *B6.SLE123* 28.1 ± 10.17%, *B6.SLE123*+2HOBA 19.7 ± 3.2% of neutrophils, N = 12-14)-(Figure 1C). Human SLE subject neutrophils showed a reduction in total NET area after treatment with ethyl-2-HOBA (Control 4,415 ± 1238 μm^2/field vs 2,215 ± 1372 μm^2/field, n = 5, p = 0.029).

Conclusion: In a murine model of SLE, scavenging of isoLGs reduces neutrophils in secondary lymphoid tissue and peripheral blood. Additionally, we observe a reduction in vascular NETosis. Treatment of human neutrophils with an isoLG scavenger attenuates NET formation. These findings describe a role of isoLGs in SLE-associated NETosis and resultant vascular inflammation. Moreover, these findings suggest a potential role for isoLGs in NET-driven autoinflammation and vascular disease in SLE.

Neutrophils in Systemic Lupus Erythematosus Demonstrate Heterogeneity Based on Sex

William Ambler[1], Gustaf Wigerblad[1], Eduardo Patino-martinez[1], Shuichiro Nakabo[1], Norio Hanata[1], Stephen Brooks[2], Kan Jiang[2], Carmelo Carmona-Rivera[1] and Mariana Kaplan[3], [1]Systemic Autoimmunity Branch, National Institute of Arthritis and Musculoskeletal and Skins Diseases, National Institutes of Health, Bethesda, MD, [2]Biodata Mining and Discovery Section, National Institute of Arthritis and Musculoskeletal and Skins Diseases, National Institutes of Health, Bethesda, MD, [3]Lupus Clinical Trials Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH); Systemic Autoimmunity Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Sex differences in the immune system may contribute to o an increased incidence of autoimmunity in women and an increased susceptibility to infection and cancer in men. Human neutrophils, which have a putative role in systemic lupus erythematosus (SLE) disease initiation, propagation and tissue injury, display sexual dimorphism. This is

characterized in healthy controls by female neutrophils exhibitingheightened type I-interferon (IFN) response and enhanced activation and NET formation compared to males, while men have less mature and activated neutrophils compared to women. SLE has a significant female bias (9:1 ratio). However, men with SLE often have very severe disease. It is not currently well understood if there are different immunological drivers in lupus between men and women and if sex differences in immune cells are present in SLE. There is a subset of neutrophils in SLE called low density granulocytes (LDGs) that have been reported to have important pathogenic roles in the disease but whether these cells exhibit sexual dimorphism is also not known. Understanding sex differences in immune cell subsets in SLE may improve understanding of disease heterogeneity and could provide insight for sex- specific treatment targets.

Methods: Age matched male and female patients with SLE were recruited from a comprehensive lupus clinic. Peripheral blood mononuclear cells (PBMC), LDGs and normal dense neutrophils (NDN) were purified and then subjected to cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq) via the 10x platform. Downstream analysis was performed with Cell Ranger and the Seurat package in R. Functional assays were performed.

Results: Six patients with SLE (3 male and 3 female) have been analyzed thus far. The average age in years was 36.7 and 36.3 for males and females, respectively. Average SLEDAI was 6.7 and 4.7 male and female, respectively. All patients were on less than or equal to 15 mg of daily prednisone. There was significant heterogeneity between males and females in neutrophil analysis by CITE-Seq compared to other immune cells. Overall, females had an increased proportion of a type I IFN-stimulated gene (ISG)^{hi} LDG cluster compared to males. Female LDGs had a higher IFN-I signature score. Female NDNs were similarly enriched in the ISG^{hi} cluster and also had a higher IFN-I score compared to males. Male LDGs and NDNs were enriched in less mature neutrophil clusters. Other cell types did not display as much heterogeneity.

Conclusion: These preliminary results show sex differences in SLE by single cell transcriptomics with much of the heterogeneity arising from the neutrophils. More patients are currently being recruited to further understand neutrophil heterogeneity and functional implications in male and female lupus. This information may provide insight into SLE heterogeneity between sexes and could lead to stratified lupus treatments.

Effects of Hydroxychloroquine on Maternal Outcomes in Pregnant Patients with Systemic Lupus Erythematous

Yurilu Gonzalez[1] and Irene Tan[2], [1]Albert Einstein Medical Center, Wyncote, PA, [2]Einstein Medical Center Philadelphia, Bala Cynwyd, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease, that affects women of childbearing age. SLE is a high-risk condition in pregnant patients due to increased maternal and fetal mortality and morbidity. Hydroxychloroquine (HCQ) has demonstrated beneficial effects on pregnancy outcomes in patients with SLE based on

Table 1. Pregnancy outcomes of women with systemic lupus erythematosus grouped by Hydroxychloroquine usage

	HCQ n=9805	Non HCQ n=8869	OR (95% CI) p value
Recurrent pregnancy loss/spontaneous abortion	118	151	0.77 (0.60-0.98) p=0.03
Gestational DM	113	161	0.69 (0.54-0.88) p=0.003
Prolonged pregnancy	35	84	0.41 (0.27-0.61) p<0.0001
Fetal malpresentation	188	200	0.94 (0.76-1.15) p=0.55
Hypertensive disorders of pregnancy [a]	460	430	1.12 (0.98-1.29) p=0.08

Abbreviations: CI, confidence interval; HCQ, hydroxychloroquine; OR, odds ratio.

[a]Hypertensive disorders in pregnancy denotes any diagnosis of preeclampsia, eclampsia, chronic hypertension, preeclampsia superimposed upon chronic hypertension and gestational hypertension.

Pregnancy outcomes of women with systemic lupus erythematosus grouped by hydroxychloroquine usage

immunomodulatory, metabolic, and vasculoprotective properties. This study aims to describe the effects of HCQ use on maternal outcomes in pregnant SLE patients.

Methods: This is a nationwide, cross-sectional study. We used the global, multicenter research network (TriNetX) database from 82 large healthcare organizations across multiple countries. We included pregnant women from age 18 to 55 with diagnosis of SLE between January 1^{st,} 2010, and December 31^{st,} 2022 using International Classification of Disease-10 codes. We compared pregnant SLE patients on HCQ with pregnant-SLE patients not on HCQ, using a 1:1 propensity score matching that accounted for demographics variables (age, race, ethnicity), comorbidities [hypertension, overweight/obesity, diabetes mellitus (DM), dyslipidemias], laboratory results, including levels of C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), cholesterol, triglycerides, hemoglobin A1C (HbA1c) and use of steroids (prednisone or prednisolone) at baseline. The outcomes of interest include recurrent pregnancy loss/spontaneous abortion, hypertensive disorders of pregnancy, gestational DM, prolonged pregnancy, and fetal malpresentation events. The exposure time window for outcomes was any time during the pregnancy duration. Odds ratios with 95% confidence intervals were calculated for each outcome. A two-sided p-value less than 0.05 was considered statistically significant.

Results: We identified 9,805 pregnant SLE patients on HCQ and 8,869 pregnant SLE patients not on HCQ. At baseline, patients who were not taking HCQ, had higher levels of CRP (14.1±31.4 vs 11.4±28.7 mg/L, p=0.002), cholesterol (174 ±41.3 mg/dL vs 171±44.8 mg/dL, p=0.02), triglycerides (125±113 mg/dL vs 118±85.6 mg/dL, p=0.02) and HbA1c (5.71 ±1.54% vs 5.57±1.19%, p=0.001). When compared both groups, the odds of developing recurrent pregnancy loss/spontaneous abortion (OR=0.77, CI95% 0.60-0.98, p=0.03), gestational DM (OR=0.69, CI95% 0.54-0.88, p=0.003) and prolonged pregnancy (OR=0.41, CI95% 0.27-0.61, p< 0.0001), were significantly lower among patients taking HCQ, whereas the odds of developing fetal malpresentation (OR=0.94, CI95% 0.76-1.15, p=0.55) and hypertensive disorders of pregnancy (OR=1.12, CI95% 0.98-1.29, p=0.08) was not statistically different when compared both groups.

Conclusion: Pregnant patients with SLE taking HCQ appear to have lower odds of recurrent pregnancy loss/spontaneous abortion, gestational DM, and prolonged pregnancy compared with ones not taking HCQ. Larger studies, preferably randomized and blinded, will be required to confirm these findings.

KYV-101, a Fully Human Anti-CD19 CAR T Cell Therapy, Demonstrates CAR-Mediated and CD19-Dependent Activity Against Autologous B Cells from Patients with Autoimmune Disease

Soo Park[1], Gloria Lutzny-Geier[2], Natalia Giltiay[1], Jazmin Bravo[1], Simone Sandoval[1], Joseph Cheng[1], Catherine Dong[1], Nicole Khoshnoodi[1], Ames Register[1], Daniel Anaya[1], Michael Aigner[3], Andreas Mackensen[3], Georg Schett[4], Charles Kaplan[1], Dominic Borie[1], James Chung[1] and Tom Van Blarcom[5], [1]Kyverna Therapeutics, Emeryville, CA, [2]Friedrich Alexander Universität Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany, [3]Department of Internal Medicine 5, Hematology and Oncology, Universitätsklinikum Erlangen and Friedrich-Alexander-Universität Erlangen Nürnberg, Erlangen, Germany, [4]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany, [5]Kyverna Therapuetics, Emeryville, CA

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: A significant unmet need remains in the treatment of relapsed and/or refractory B cell-driven autoimmune diseases, including systemic lupus erythematosus (SLE),systemic sclerosis (SSc), and idiopathic inflammatory myopathy (IIM). The presence of autoantibodies is a hallmark of such diseases and implicates dysregulated B cell function in their pathogenesis. The central role of B cells in these diseases is also supported by the presence of B cells in diseased tissues. We have recently shown that anti-CD19 chimeric antigen receptor (CAR) T cells are well tolerated and highly effective in patients with B cell-driven autoimmune diseases including SLE, IIM,and SSc (Mackensen Nat Med 2022, Muller Lancet 2023, Bergman Ann Rheum Dis 2023).KYV-101 is an autologous anti-CD19 CART cell therapy designed to deplete B cells, including autoreactive B cells. Importantly, the human anti-CD19 CAR used in KYV-101 was previously tested in B-cell lymphoma patients and demonstrated similar efficacy with an improved safety and immunogenicity profile compared to historical controls (Brudno Nat Med 2020).Since anti-CD19 CART cells target and kill a broad set of B cells in both circulation and tissues, a more complete depletion of autoreactive B cells is expected with KYV-101 leading to a greater magnitude and durability of disease control than current immunotherapies. These studies examined the CAR-mediated and CD19-dependent activity ofKYV-101 against autologous, patient-derived B cells.

Methods: Autologous CD4+ and CD8+ T cells were enriched from healthy donors (HD) or SLE, SSc, or IIMpatients.KYV-101 CAR T cells were produced following transduction with a lentiviral vector encoding a fully human second generation anti-CD19 CAR. The CAR-mediated and CD19-dependent activity of KYV-101 was monitored in vitrovia cytotoxicity, cytokine release, and proliferation studies in response to CD19+ target cell lines or autologousCD19+ B cells.

Results: Following an overnight incubation, KYV-101 generated from HDs or autoimmune patients induced greater cytotoxicity against both the human CD19+ NALM6 cell line and autologous, patient-derived primary B cells than untransduced(UNTD) control T cells. An increase in the production of cytokines such as IFNγ was also observed following co-culture. In contrast, no differences in cytotoxicity nor cytokine production were observed whenKYV-101 or UNTD control T cells were co-cultured with CD19- target cell lines. In addition, following a 96-hour incubation, KYV-101 generated from HDs or autoimmune patients proliferated when co-cultured with the NALM6 cells or autologous B cells, whereas substantially lower levels of proliferation were observed in the UNTD control T cells co-cultured with NALM6 or autologous B cells, or in KYV-101 and UNTD control T cells co-cultured with the CD19- cell lines.

Conclusion: KYV-101 generated from autoimmune disease patient lymphocytes demonstrates CAR-mediated and CD19-dependent activity against autologous B cells and thus may represent a novel therapeutic option for B cell-driven autoimmune diseases. KYV-001 is being investigated in a Phase 1 trial in adults with refractory lupus nephritis. *Soo Park and Gloria Lutzny-Geier contributed equally.

Low-Density Granulocytes and Neutrophil Extracellular Traps in Incomplete Systemic Lupus Erythematosus

Svenja Henning[1], Tobias Reimers[2], Berber Doornbos-van der Meer[2], Barbara Horvath[3], Hendrika Bootsma[4], Karina de Leeuw[2] and Johanna Westra[2], [1]University Medical Center Groningen, Department of Rheumatology and Clinical Immunology, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands, [3]University Medical Center Groningen / Department of Dermatology, Groningen, Netherlands, [4]Department of Rheumatology, University Medical Centre Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Incomplete SLE (iSLE) defines a group of patients with symptoms typical of SLE but not meeting sufficient criteria required for the classification of SLE. Up to 55% of patients with iSLE will eventually develop SLE, but it is unclear which patients are at risk of progression.(1) Neutrophil dysfunction, among which aberrant neutrophil extracellular trap (NET) formation driven by low density granulocytes (LDGs), has been implicated in SLE pathogenesis.(2) However, the role of neutrophil dysfunction in early forms of SLE is still unclear. Therefore, the aim of this study was to investigate whether LDGs are elevated in iSLE patients, compared to healthy controls (HCs) and SLE patients with quiescent disease (SLEDAI $\leq$ 4). Next to that, we investigated presence of circulating NETs in plasma of iSLE as well as SLE patients and HCs.

Methods: Circulating plasma NETs were measured cross sectionally in 38 iSLE patients, 30 SLE patients with quiescent disease and 12 HCs while LDGs were measured in 18 iSLE patients, 13 SLE patients and 14 HCs. SLE patients were classified according to the Systemic Lupus International Collaborating Clinics (SLICC) criteria. Patients with iSLE had to meet at least one clinical and one immunological criterion but less than four SLICC criteria in total. LDGs ($CD14^{low}CD15^{+}$) were measured in freshly isolated PBMCs with flow cytometry and were expressed as percentage of total PBMCs. Circulating plasma NETs were measured with a sandwich enzyme linked immunosorbent assay using a plate coated with an anti-myeloperoxidase antibody.

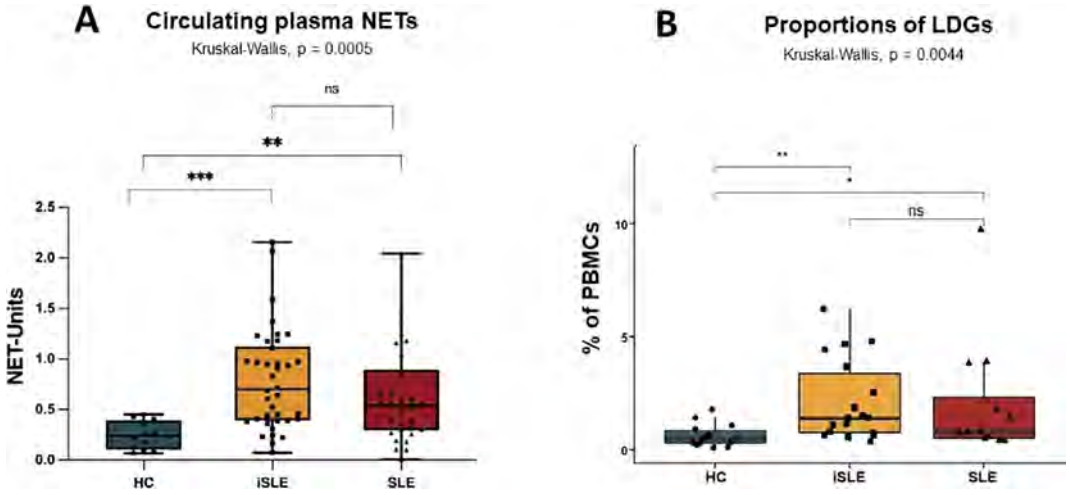

Figure 1. A: Circulating plasma NETs (neutrophil extracellular trap) per group measured with enzyme linked immunosorbent assay. B: Low density granulocytes (LDGs) measured with flow cytometry; Single data points represent individual cases. Median and interquartile range are depicted per group. Stars represent p-values for pairwise comparison calculated with Mann Whitney tests. *p <0.05, ** p<0.01, *** p<0.0001. HCs: healthy controls; iSLE: incomplete systemic lupus erythematosus, SLE: systemic lupus erythematosus.

Results: Proportions of LDGs and NET-levels were significantly increased in iSLE patients compared to HCs, as shown in Figure 1. The proportion of LDGs and circulating plasma NETs was similar between SLE and iSLE patients.

Conclusion: Our data shows significantly higher amounts of LDGs and circulating NETs in the iSLE and SLE cohort compared to healthy controls, suggesting that aberrant NET formation and clearance is present in early stages of the disease. In future studies, we aim to investigate the correlation between LDGs, circulating NETs and other immunological parameters, such as interferon signature, and anti-dsDNA levels.

Paired Autoantibody Specificities from Serum and Immune Complexes Do Not Fully Explain the Circulating Immune Complex Load in Systemic Lupus Erythematosus: A Study on 530 Patients

Enrico Fuzzi[1], Anna Svanqvist[2], Christine Westerberg[2], Agneta Zickert[3], Iva Gunnarsson[4], Johan Rönnelid[2] and Elisabet Svenungsson[5], [1]Karolinska University Hospital, Stockholm, Sweden, [2]Department of Immunology, Genetics and Pathology, Uppsala University Hospital, Uppsala, Sweden, [3]Karolinska University Hospital, Stockholm, Sweden, Stocksund, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Department of Medicine Solna, Unit of Rheumatology, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a prototypical autoimmune disease where autoantibody production and immune complex (IC) formation play a key role. Which antibodies contribute to the load of circulating C1q-binding ICs (CIC) in SLE is still unclear. We investigated whether either serum and/or IC-derived levels of typical SLE antibodies could explain the observed CIC levels of a large SLE cohort.

Methods: We studied n=530 consecutive SLE patients (≥ 4 ACR 1982 revised SLE criteria) who received care at a tertiary referral center for SLE. The control population consisted of region of residence, age and sex-matched controls (n=192) and n=200 local experimental controls. Serum was obtained at inclusion, and was stored at -80°C. To obtain IC-derived antibodies, a novel validated method was employed. Briefly, aliquots of sera were incubated with C1q-coated beads and C1q-bound ICs were then eluted through two sequential buffers, yielding disassembled IC eluates with conserved antibody specificity (Sohrabian et al. Ann Rheum Dis 2018;77:1345). Antibody levels of Anti-dsDNA, Anti-Histone, Anti-Sm, Anti-U1RNP, Anti-Ro52, Anti-Ro60, Anti-SSB were measured in IC eluates and in serum with a bead-based multiplex assay. Parallel analyses of autoantibody levels in serum and in IC eluates were performed. CIC levels were measured with a commercial ELISA according to the manufacturer's instructions. Results were reported on a standard curve; the 98th percentile of the standard curve values of control sera were set as the threshold for positivity in serum and IC respectively.

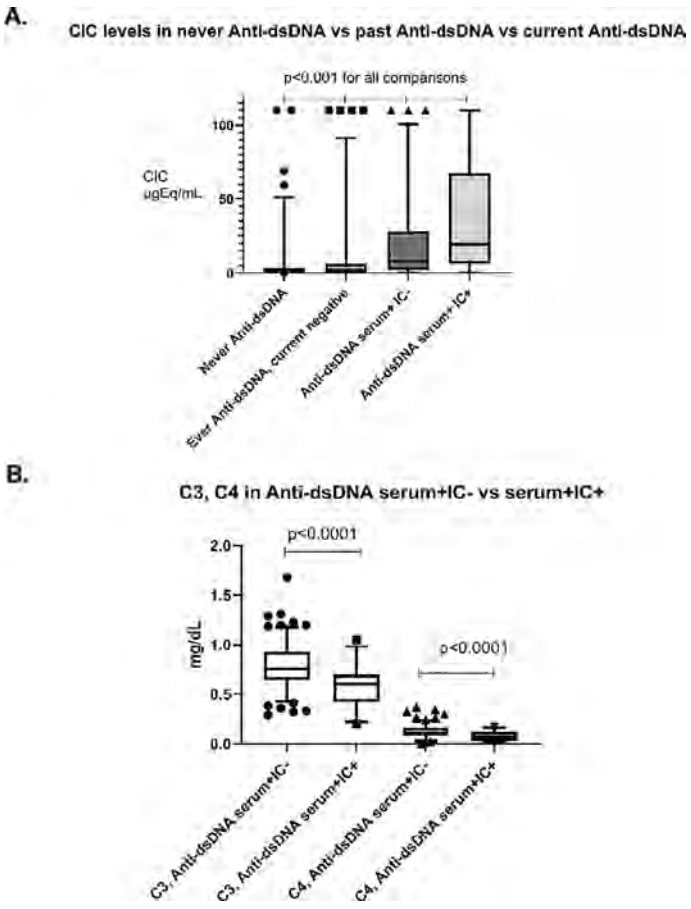

Figure 1 A. and 1 B.

Results: CIC levels were higher and with a wider variance in SLE patients than controls (p< 0.0001). A higher CIC load was associated with nephritis, arthritis and SLEDAI > 6 (p< 0.0001). Among autoantibody specificities, Anti-dsDNA in serum was independently associated with a high CIC load (OR 4.8, 95% CI 2.5-9.5, p< 0.0001, Figure 1 A). Concordance between serum and IC-eluate positivity varied strongly among autoantibody specificities, being highest for Anti-SSA/SSB, and lowest for Anti-dsDNA (Table 1). Among serum Anti-dsDNA+ patients, carriers of Anti-dsDNA from ICs displayed higher Anti-dsDNA titers, lower complement levels, and higher SLEDAI scores (p< 0.01 for all, Figure 1 B). Despite this, anti-dsDNA from ICs had a limited, although significant, explanatory power for total CIC levels (Figure 2).

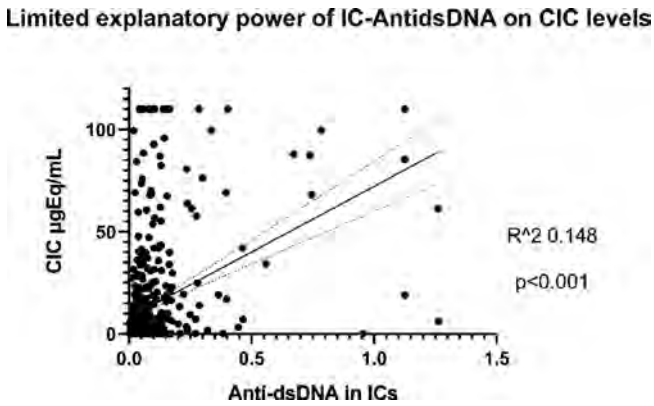

Figure 2

Table 1

	Of which Anti-Ro52 IC +, %	Of which Anti-Ro60 IC +, %	Of which Anti-SSB IC +, %	Of which Anti-Sm IC +, %	Of which Anti-U1RNP IC +, %	Of which Anti-dsDNA IC +, %	Of which Anti-Histone IC +, %
Anti-Ro52+ sera n= 139	**84.9%**	90.6%	56.8%	17.9%	23.7%	12.2%	16.5%
Anti-Ro60+ sera n= 192	62%	**94.3%**	49.5%	17.2%	22.4%	13%	17.7%
Anti-SSB+ sera n= 95	**74.7%**	90.5%	**91.6%**	13.7%	16.8%	15.8%	17.9%
Anti-Sm+ sera n= 88	39.7%	47.7%	26.1%	**45.5%**	54.5%	31.8%	32.9%
Anti-U1RNP+ sera n=99	29.3%	35.4%	17.2%	32.3%	**66.7%**	17.2%	23.2%
Anti-dsDNA+ sera n= 196	27.6%	38.8%	21.9%	16.8%	28%	**20.9%**	30.1%
Anti-Histone+ sera n=160	32.5%	42.5%	23.8%	19.4%	30.6%	21.9%	**38.1%**

Conclusion: Anti-dsDNA indicates the capacity to assemble immune complexes in SLE patients, and recoverable Anti-dsDNA antibodies from IC eluates are associated with more complement activation and disease activity. Importantly, Anti-dsDNA, either alone or in combination with common ANA specificities, has a limited explanatory power for the variation in CIC levels among different SLE patients, i.e. it is unlikely to form the majority of the observable CIC in SLE. The constituents of the circulating immune complex load in SLE remain elusive and deserve further elucidation.

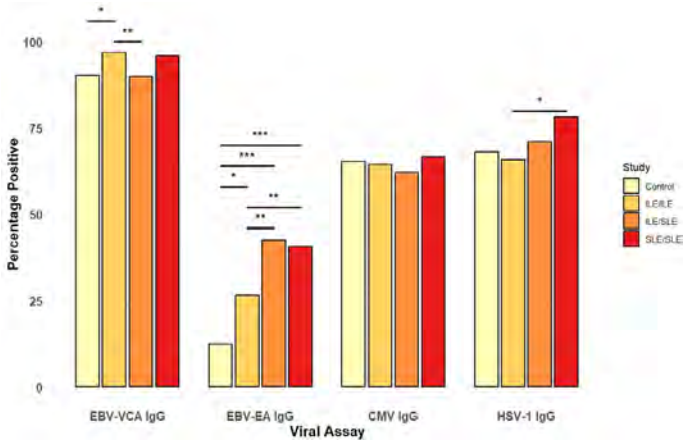
Epstein Barr Virus Reactivation May Associate with Transition from Incomplete to Systemic Lupus Erythematosus

Benjamin Jones[1], Carla Guthridge[1], Marci Beel[1], Catriona Wagner[2], Stan Kamp[1], Cristina Arriens[3], Joan Merrill[1], Teresa Aberle[1], Nancy Redinger[1], Rebecca Wood[4], Lauren Guthridge[1], Susan Macwana[1], Wade DeJager[1], Joel Guthridge[1] and Judith James[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Santa Cruz, CA, [3]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Department of Arthritis & Clinical Immunology, Oklahoma City, OK, [4]University of Oklahoma Health Sciences Center, Edmond, OK

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with incomplete lupus erythematosus (ILE) have evidence of SLE but do not fulfill SLE classification criteria. Although most ILE patients maintain a relatively mild disease course, about 20% will transition to SLE. However, the factors influencing SLE development in subsets of ILE patients are largely unknown. We previously found that serological markers of EBV reactivation, measured by antibodies against EBV-early antigen (EBV-EA), were associated with increased numbers of SLE-associated autoantibodies and eventual SLE transition in SLE relatives. In addition, EBV reactivation is associated with increased disease activity in SLE patients. Therefore, this study determined whether reduced EBV

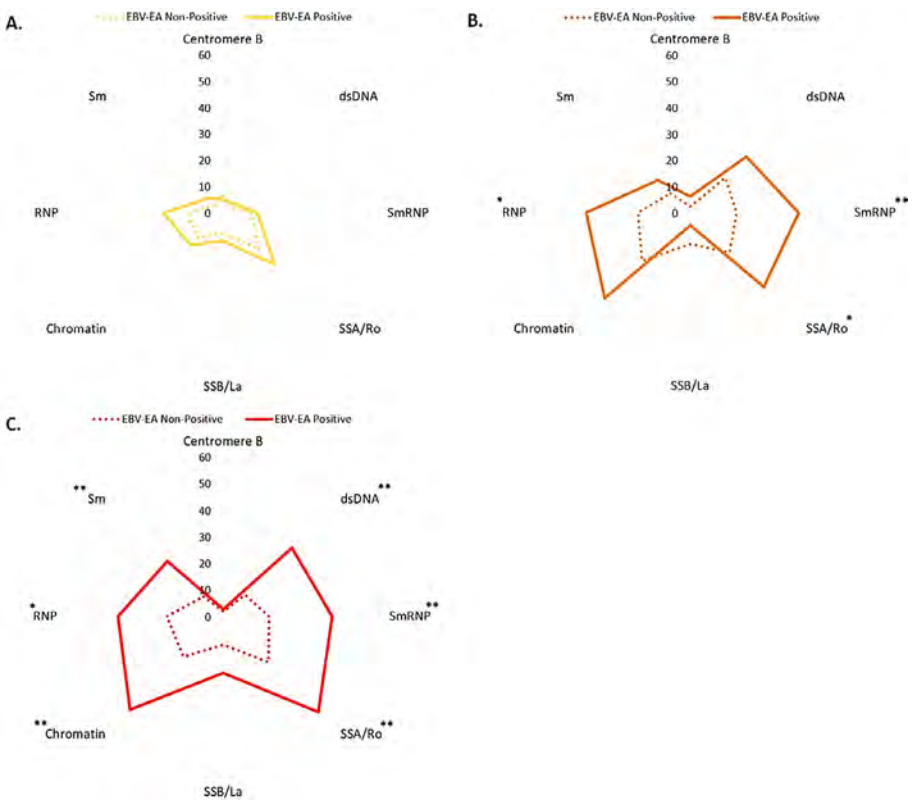


Percentage of positive viral assay results in controls (n=72), ILE/ILE (n=286), ILE/SLE (n=148), and SLE (n=173). * $p < 0.05$, **$p < 0.01$, *** $p < 0.001$ by Fisher's exact test with a Benjamini-Hochberg correction.

reactivation contributes to milder disease course in ILE and whether increased EBV reactivation may influence transition to SLE in ILE patients.

Methods: Serum samples consented for use in these studies were obtained from existing collections in the Arthritis & Clinical Immunology Biorepository at the Oklahoma Medical Research Foundation. Healthy controls (n=72) were ANA-negative with no ACR 1997 criteria. ILE/ILE subjects (n=286) met less than 4 ACR criteria and were categorized as ILE by SLICC criteria. ILE/SLE subjects (n=148) met less than 4 ACR criteria but met SLE classification by SLICC criteria. SLE subjects (n=173) were classified as SLE by both ACR and SLICC criteria. Subjects were matched by age, sex, and ancestry. Serum autoantibodies against dsDNA, chromatin, SSA/Ro, SSB/La, Sm, SmRNP, RNP, and centromere-B were determined by BioPlex 2200® ANA kit. Serum antibodies against EBV-Viral Capsid Antigen (VCA), EBV-EA, CMV, and HSV-1 were determined by ELISA.

Results: EBV-EA positivity was more prevalent in ILE/ILE, ILE/SLE, and SLE patients compared to controls (Figure 1). However, EBV-EA positivity was less prevalent in ILE/ILE compared to ILE/SLE and SLE patients (Figure 1). EBV-VCA positivity was more prevalent in ILE/ILE compared to controls or ILE/SLE, but neither ILE/SLE nor SLE significantly differed from controls, consistent with previous studies (Figure 1). In contrast, CMV and HSV-1 positivity did not differ between the groups, except for a slight increase in SLE patients compared to ILE/ILE patients (Figure 1). In ILE/ILE patients, SLE-associated autoantibodies were not associated with EBV-EA positivity (Figure 2A). However, EBV-EA positivity was associated with anti-SmRNP, -SSA/Ro, and -RNP autoantibodies in ILE/SLE patients (Figure 2B). In addition to these autoantibodies, EBV-EA positivity also associated with anti-dsDNA, -chromatin, and -Sm in SLE patients (Figure 2C).



Percentage of positive autoantibody results according to EBV-EA result in (A) ILE/ILE (n=286) (EBV-EA Positive n = 176, Non-Positive n = 210), (B) ILE/SLE (n=148) (EBV-EA Positive n = 63, Non-Positive n = 85), and (C) SLE (n=173) (EBV-EA Positive n = 71, Non-Positive n = 102). * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ by Fisher's exact test with a Benjamini-Hochberg correction.

Conclusion: Serological markers of EBV reactivation are lower in ILE/ILE patients compared to ILE/SLE and SLE patients, suggesting that reduced EBV reactivation may contribute to the milder disease course observed in ILE patients. In addition, EBV-EA positivity was associated with SLE-associated autoantibodies in ILE/SLE patients but not ILE/ILE patients. EBV-EA positivity correlated with positivity for a higher number of SLE-associated autoantibodies in SLE patients compared to those with ILE/SLE. Therefore, increased EBV reactivation may be a harbinger of disease transition in ILE patients.

Association of Biologic Sex with Glycosphingolipids and the N-glycome in Lupus Nephritis and Renal Mesangial Cell Function

Tammy Nowling, bethany wolf, Calvin Blaschke, Richard Drake, Sandra Sanchez, Mariia Stefanenko, Mykhailo Fedoriuk, Oleg Palygin, Hongxia Bai and Jessalyn Rodgers, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE primarily afflicts women and many SLE patients develop nephritis, a serious complication of lupus. Identification of biomarkers and the pathogenic mechanisms underlying LN is crucial to better understand sex bias and disease progression. Therefore, we interrogated glycosphingolipid (GSL) metabolism and the N-glycome with respect to disease and biologic sex in LN patient samples. We also evaluated response of human primary renal mesangial cells (hRMCs) with respect to disease and biologic sex.

Methods: Urine and serum were collected from 20 healthy control (HC) subjects and 20 LN patients who met the ACR criteria for active disease. Ten males and 10 females were included in each group. N-linked glycans attached to proteins (N-glycans) were measured by matrix-assisted laser desorption/ionization quadrupole time of flight (MALDI-QTOF) and the GSL lactosylceramide (LacCer) was quantified by *Supercritical fluid chromatography-tandem mass spectrometry* (SFC-MS/MS). Responses of male- and female-derived hRMCs to treatment with sera from each LN or HC subject were assessed by measuring intracellular calcium (Ca^{2+}) using fluor8 indicator, cytokine secretion by ELISA, GSLs levels by SFC-MS/MS, and N-glycans by MALDI-QTOF. Associations between N-glycans with LN status and biologic sex were evaluated using linear mixed models.P-values were adjusted using False Discover Rate with < 0.05 considered meaningful.

Results: All major LacCer species and total LacCers were significantly elevated and 72 urine N-glycans were significantly altered in LN patients compared to HCs. In particular, there was a significant increase in the N-glycans associated with pro-inflammatory IgGs and a decrease in N-glycans associated with anti-inflammatory IgGs in the urine of LN patients. The increase in urine LacCers (LN vs HC) was 2-3 fold higher in males, and three urine N-glycans differed significantly

between the sexes. Three individual N-glycans provided perfect separation of LN and HC (AUC of 1.0) when added to a model that included only total LacCers and biologic sex. In the serum, 2 of the major LacCer species and 21 N-glycans were significantly altered in LN compared to HC. *In vitro*, no differences were observed in the responses of hRMCs to female- vs male-derived sera. However, the female-derived hRMCs exhibited significantly higher Ca^{2+} flux and cytokine secretion compared to male-derived hRMCs in response to LN sera. The female-derived hRMCs expressed higher levels of GSLs than the male-derived hRMCs.

Conclusion: Urine LacCers levels and changes in the N-glycome may serve as robust biomarkers of LN and likely reflect renal disease activity. The larger increase in LacCers in LN males compared to LN females may underscore worse renal disease in males once tolerance is broken. The significantly higher levels of LacCers observed in the female-derived hRMCs may partly explain the heightened pathologic response. Thus, elevated GSL metabolism in females may poise renal cells to be more sensitive to or respond more robustly to inflammatory stimuli.

Rab4A Controls the Depletion of IL-2 in CD4+ T Cells via Enhanced CD38 Expression: Potential Involvement in Proinflammatory Lineage Development in Systemic Lupus Erythematosus

Joy Park[1], Xiaojing Wang[2], Aparna Godavarthy[1], Akshay Patel[2], Krakko Daniel[1], Jessica Nolan[1], Joanne Chilton[1], Bryan Blaker[1] and Andras Perl[3], [1]Upstate Medical University, Syracuse, NY, [2]SUNY Upstate Medical University, Syracuse, NY, [3]SUNY, Syracuse, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: HRES-1/Rab4 (Rab4A) is a small GTPase that is overexpressed in SLE patient T cells[1,2], mediates the enhanced recycling of CD3 and CD4 cell surface receptors[1,2], and the activation of the mechanistic target of rapamycin (mTOR)[3]. Recently, increased expression of CD38[4], mTOR activation[5], and loss of IL-2 production[6,7] have been implicated in pro-inflammatory T cell development in SLE. In this study, we investigated the impact of Rab4A on the expression of CD38 and the secretion of IL-2 and characterized the impact of CD38 expression on the activation of mTOR in $CD4^+$ T cells.

Methods: To understand the cellular consequences of Rab4A overexpression, our lab has created unique Rab4A-mutant Jurkat cell lines, which contain GFP-expressing vector alone (control), doxycycline-inducible vectors that overexpress Rab4A ($Rab4A^{++}$) or the dominant-negative mutant $Rab4A^{S27N}$ ($Rab4A^{DN}$)[8]. We also CRISPR knocked out (KO) CD38 in these cell lines, leading to six different lines: (1) $Rab4A^{WT}$ $CD38^{WT}$, (2) $Rab4A^{WT}$ $CD38^{KO}$, (3) $Rab4A^{++}$ $CD38^{WT}$, (4) $Rab4A^{++}$ $CD38^{KO}$, (5) $Rab4A^{DN}$ $CD38^{WT}$, and (6) $Rab4A^{DN}$ $CD38^{KO}$. These cells were cultured with doxycycline and co-stimulated with anti-CD3 mAb (OKT3) and phorbol myristate acetate (PMA) to induce cytokine production[9]. Cell surface markers and cytokines were analyzed by flow cytometry and protein levels by western blot. NAD^+ levels were measured by LC-MS/MS. To understand the impact of CD38 expression on mTOR activation, we isolated peripheral blood mononuclear

cells from SLE patients (n=21) and age, sex, and race matched healthy controls (n=18). The cells were cultured for 24 hours with and without CD3/CD28 co-stimulation and were analyzed by flow cytometry.

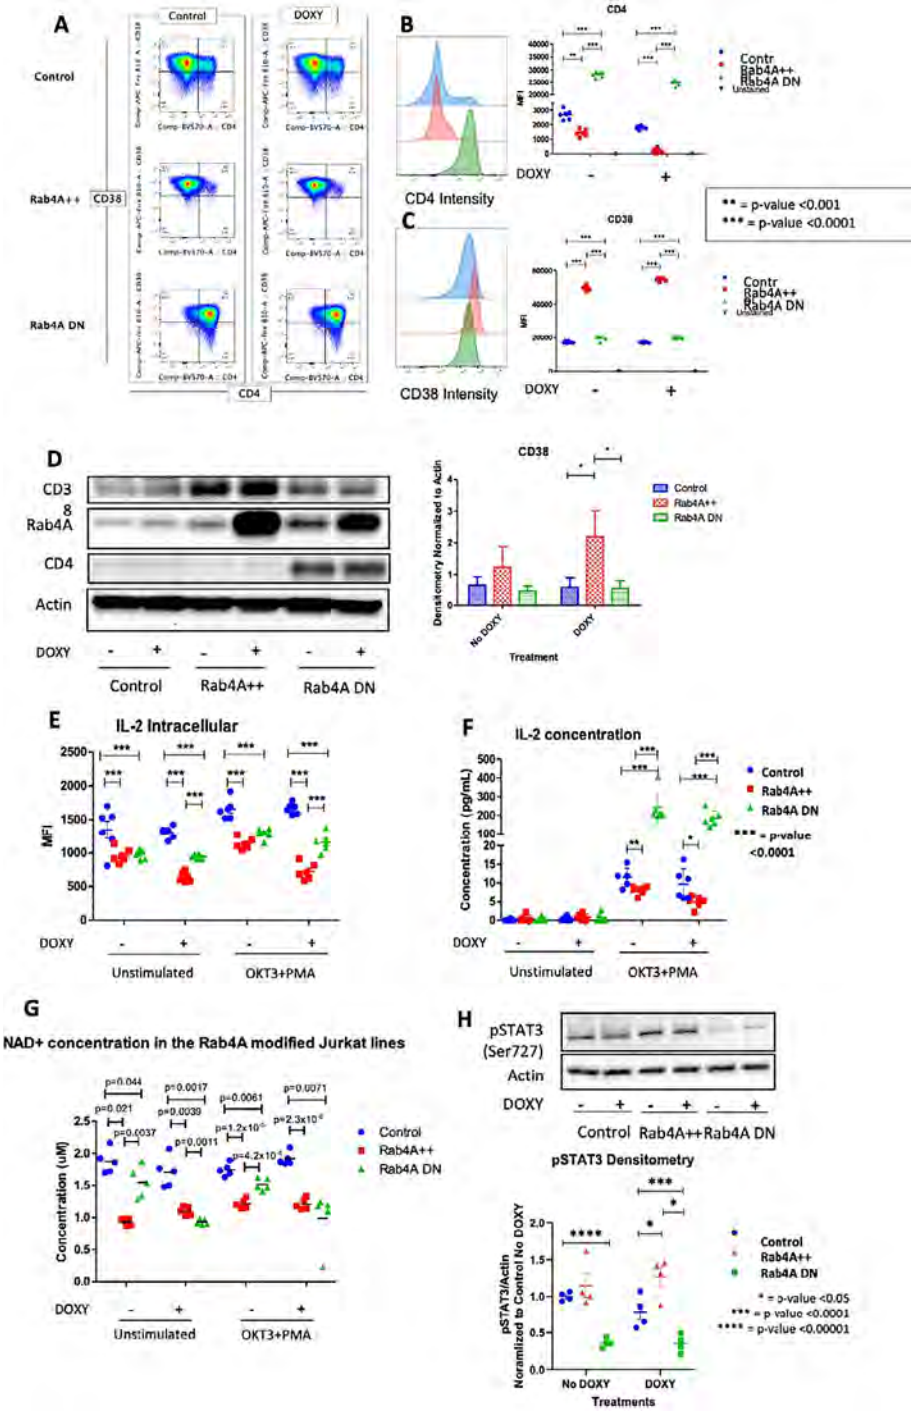

Fig. 1. Rab4A controls the surface expression of CD4 and CD38 in Jurkat cells. (A) Flow cytometry and (D) Western Blot results show that Rab4A++ cells have increased CD38 expression compared to the control and Rab4A-DN cells. Rab4A effects on CD4 expression is shown for confirmation. Quantified fluorescent intensity of (B) CD4 and (C) CD38. Rab4A controls the (E) intracellular expression and (F) production of IL-2, (G) NAD+ levels and (H) pSTAT3 (Ser727) levels in Jurkat cells. (E) Intracellular production and (F) secretion of IL-2 were significantly decreased in the Rab4A++ cells (fold change=-0.566, p=1.16x10-7 and fold change=-0.481, p=0.0401, respectively) compared to the control. In the Rab4ADN cells, IL-2 secretion was significantly increased (fold change=18.091, p=7.513x10-7, respectively). (G) LC-MS shows NAD+ is significantly decreased in in the Rab4A++ cells, compared to the control (doxycycline only: fold change=0.647, p=0.0039; doxycycline treated and stimulated: fold change=0.632, p=2.3x10-6). (H) In Rab4A++ cells, pSTAT3 is increased compared to the control (fold change=2.052, p=0.0318).

Results: In the Rab4A^{++} cells compared to the control, CD38 expression was upregulated ($p=2.49x10^{-13}$), intracellular production and secretion of IL-2 significantly decreased ($p=1.16x10^{-7}$ and $p=0.0401$, respectively), NAD^{+} concentration decreased ($p=0.0039$), while pSTAT3 levels increased ($p=0.0318$). In the Rab4A^{++} CD38^{KO} cells compared to the Rab4A^{++} CD38^{WT} cells, secretion of IL-2 significantly increased ($p=0.0145$) and pSTAT3 levels decreased. pAkt1 was increased

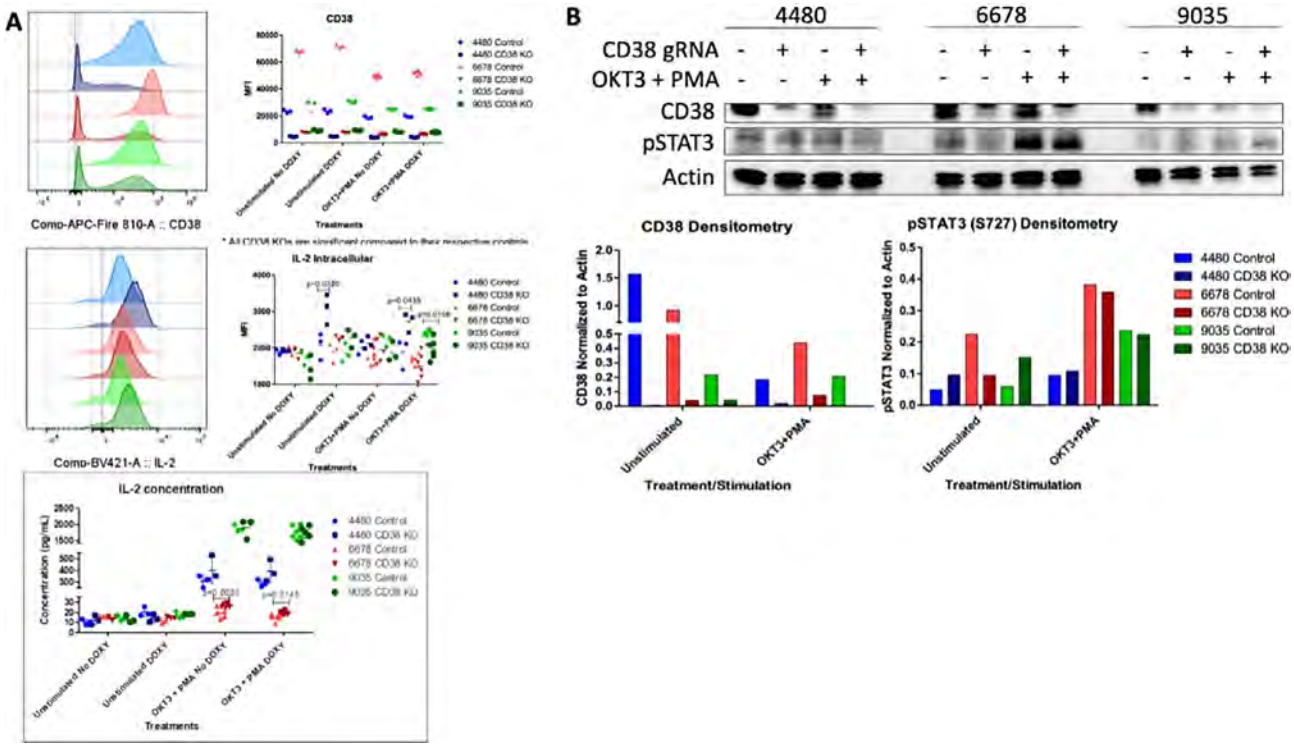

Figure 2. Knocking out CD38 in Rab4A-overexpressed Jurkat cells (A) increases IL-2 production ($p=0.0145$) and (B) decreases pSTAT3.

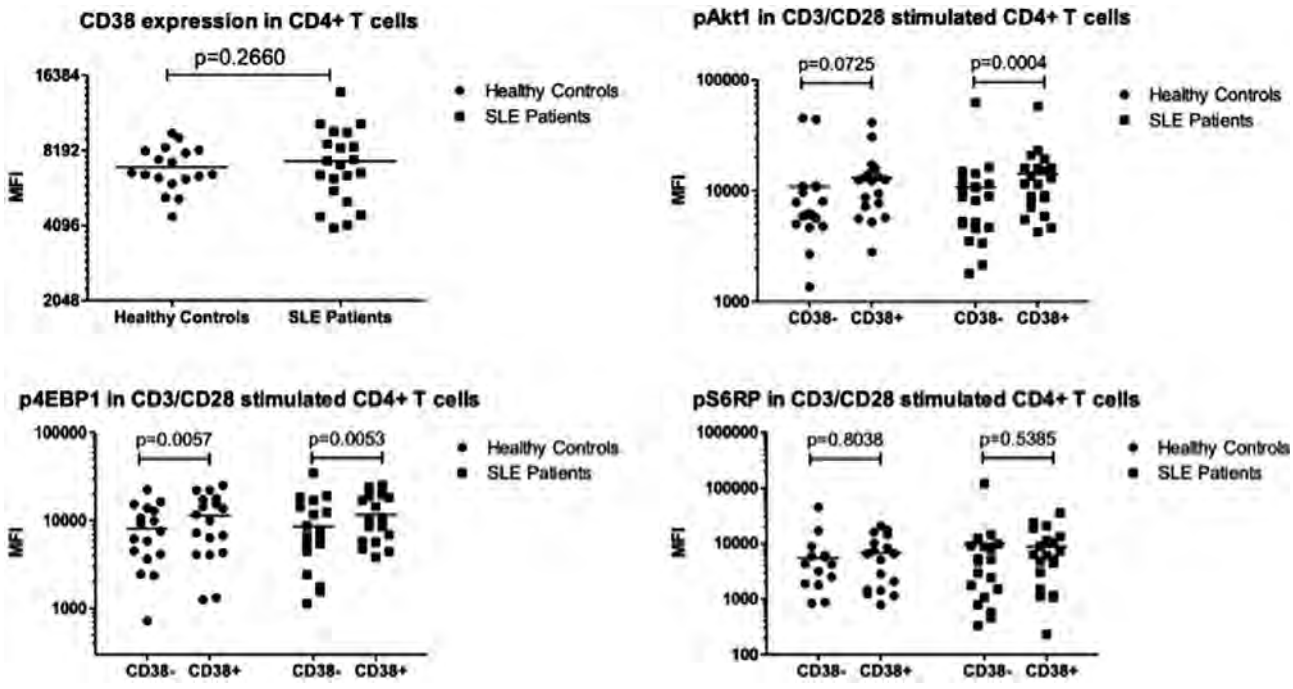

Figure 3. In SLE patients' CD38+ CD4+ T cells compared to CD38- CD4+ T cells, pAkt1 ($p=0.0004$) and p4EBP1 ($p=0.0053$) are increased.

significantly in CD38$^+$ CD4$^+$ T cells compared to CD38$^-$ CD4$^+$ T cells in only the SLE patients (p=0.0004), while p4EBP1 increased significantly in CD38$^+$ CD4$^+$ T cells compared to CD38$^-$ CD4$^+$ T cells for both the SLE patients (p=0.0053) and healthy controls (p=0.0057).

Conclusion: The increased pAkt1 and p4EBP1 in SLE patients' CD38$^+$ CD4$^+$ T cells suggests that CD38 activates mTOR via Akt, coinciding with a recent finding of CD38/PI3K/Akt/mTOR axis in cervical cancer[10]. CD38 is an NAD$^+$ hydrolase, which regulates Sirtuin-1 activity, a NAD$^+$-dependent histone deacetylase that suppresses STAT3 activity. STAT3 activation is also known to be regulated by mTOR[11–13]. Elevated pSTAT3 levels may underlie diminished IL-2 production by binding to the promoter of *FoxO1,* which inhibits IL-2 production. The overexpression of Rab4A, increased CD38, pAkt1, p4EBP1, and pSTAT3, and diminished IL-2 production reflect changes observed in SLE patients. Our results suggest that increased expression of Rab4A and CD38 may underlie the diminished secretion of IL-2 in SLE.

17β-estradiol and B-cell Intrinsic Type I Interferon Amplify Toll-like Receptor 7 Signaling Loop in B Cells of Female Lupus Prone BXD2 Mice

Kathryn Sullivan, Yong Wang, Winn Chatham, John Mountz and Hui-chen Hsu, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: While systemic lupus erythematosus (SLE) disproportionally affects women versus men, elevation in estradiol (E2) alone is not sufficient to promote the development of autoantibody producing B cells. The objective of the present study is to determine if B-cell intrinsic mechanisms contribute to the increased TLR7 response to E2 stimulation.

Methods: Serum levels of E2 and anti-Smith (Sm), and expression of IFNb in naïve B cells were evaluated in African American (AA) SLE patients (24-41yr-old), compared to older AA (42-56yr-old) and European American SLE patients (24-66-yr-old). Similarly, serum levels of E2, anti-Smith (Sm), anti-DNA, and anti-Sm/RNP were compared between female lupus prone BXD2 mice post-puberty (12-wk-old) versus pre-puberty (4-6-wk-old). TLR7-induced expression of interferon-beta (IFNb) and CD69 in transitional stage 1 (T1: CD23$^-$IgM$^+$ CD93$^+$) B cells after stimulation with E2 with or without TLR7 agonist R848 were evaluated using female BXD2 mice, compared to male mice.

Results: We identified that there were elevated circulating levels of E2 in young African American (AA) SLE patients (24-41yr-old), compared to older AA (42-56yr-old) and European American SLE patients (24-66-yr-old). Circulating E2 levels positively correlated with the levels of anti-Smith (Sm) and the expression of IFNb in naïve B cells of SLE patients (n=39). Mouse studies were used to determine if E2 stimulates the expression of IFNb in B cells and if sex plays a role to influence B cell responses to E2.Serum levels of Sm/RNP and RNP autoAbs positively correlated with the levels of E2 in female lupus prone BXD2 mice post-puberty (12-wk-old) but not pre-puberty (4-6-wk-old).At the post-puberty stage (>12 wk-old), there were significantly elevated levels of anti-DNA and anti-Sm in female BXD2 mice, compared to male mice.This was associated with

an increased TLR7-induced expression of interferon-beta (IFNb) and CD69 in transitional stage 1 (T1: $CD23^{-}IgM^{+}$ $CD93^{+}$) B cells in female BXD2 mice, compared to male mice. Interestingly, E2 stimulation promoted intracellular levels of IFNb and TLR7 in T1 B cells from female but not male BXD2 mice.

Conclusion: Together, our results suggest that elevation of E2 in combination with an increased B-cell susceptibility to E2 induction of IFNb may play a role in the increased B cell responses to TLR7 stimulation in individuals predisposed to the development of SLE.

Spatial Transcriptomics Reveals Normal-density and Low-density Neutrophils Are More Prevalent Than Macrophages in Lupus Nephritis Glomeruli, and Urine DNA Methylation Analyses Capture Both Myeloid Populations

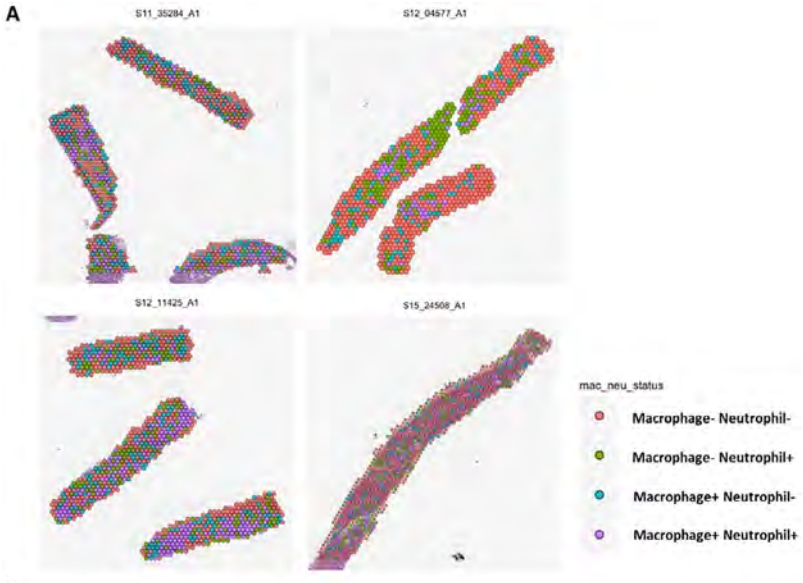
Sladjana Skopelja-Gardner[1], Joshua Skydel[2], Alecia Roy[3], Brenna Kerin[3], James Whitley[3], Fred Kolling[4], Noelle Kosarek[4], Michelle Petri[5], Andrea Fava[6], Lucas Salas[7] and Christopher Burns[3], [1]Department of Medicine, Dartmouth Hitchcock Medical Center, Geisel School of Medicine at Dartmouth, Lebanon, NH, [2]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [3]Dartmouth Hitchcock Medical Center, Lebanon, NH, [4]Geisel School of Medicine at Dartmouth, Hanover, NH, [5]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [6]Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, [7]Department of Epidemiology, Geisel School of Medicine at Dartmouth, Lebanon, NH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite compelling evidence that normal-density (NDN) and low-density neutrophils (LDN) are activated in the blood of lupus patients, their role in lupus nephritis (LN) remains elusive. This large gap in knowledge stems from the limitations in approaches to capture and profile neutrophils. Neither NDNs nor LDNs are usually captured in scRNAseq studies of LN kidneys and urine due to their loss by sample freezing, potentially skewing the conclusions that monocytes or macrophages are the dominant pathogenic myeloid cell population in LN.

Methods: Neutrophils were detected in LN kidneys by IHC staining of neutrophil elastase (NE, n = 19). Spatial transcriptomics was performed on class III/IV LN patients using Visium 10X Genomics. Differential expressed genes (DEGs) between neutrophils (NDN, LDN) and Mos were defined using publicly available RNAseq data. Spots containing NDNs, LDNs, and Mos and their glomerular vs tubular location were defined using Variance Adjusted-Mahalanobis to compute cell-specific pathway scores based on DEGs. Neutrophils and macrophages were quantified in urine cell pellets of SLE patients (+/- LN), collected at Dartmouth Hitchcock Lupus Clinic and the Johns Hopkins Lupus Center, by deconvolution of DNA methylation data (DNAm, Illumina EPIC).

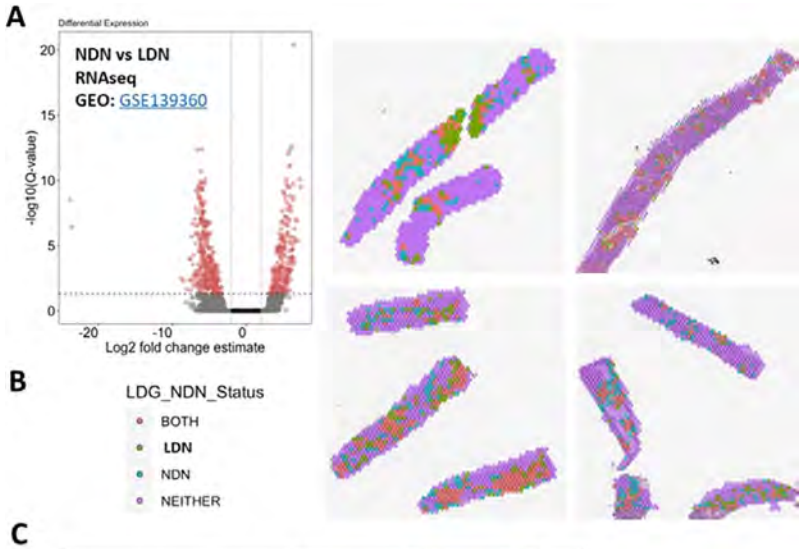
Results: Glomerular neutrophil numbers in LN kidneys (#NE+ cells/glomerulus) inversely correlated with serum C3 levels ($r = -0.671$, $^{**}p = 0.0056$), supporting a role for neutrophils in disease pathogenesis. Neutrophils were equally or more represented in LN kidneys compared to macrophages: 35% vs. 32% of all spots (**Fig. 1**). Macrophages preferentially localized



B

	Neutrophils	Macrophages
% All spots	35.1	31.9
% Tubular spots	10.1	27.6
% Glomerular Spots	88.4	40.8
% Interstitium	35.5	33.5

Fig. 1 Lupus Nephritis kidney spatial transcriptomics data reveal Macrophage and Neutrophil populations in situ. (A) Transcriptional pathways scores are defined by Variance Adjusted-Mahalanobis (VAM) method to compute cell specific pathway scores based on differentially expressed genes between neutrophils and macrophages on the 10x Visium (n = 4 LN class III/IV). (B) Percent NDN+ and LDN+ spots in LN kidney regions defined by VAM scores of unique gene signatures.



C

	NDN	LDN	Both
% Tubular spots	7.03	5.50	10.10
% Glomerular Spots	65.41	75.83	88.42
% Interstitium	26.95	19.16	35.50

Fig. 2 Both NDNs and LDNs localize to LN kidneys. (A) Differentially expressed genes between lupus NDNs and LDNs were defined using RNAseq data from the Mistry et al 2019 PNAS study (n = 6 samples per group). (B) Spots containing NDNs and LDNs were defined using Variance Adjusted-Mahalanobis (VAM) to compute cell-specific pathway scores based on differentially expressed genes in A. (C) Percent NDN+ and LDN + spots in LN kidney regions defined by VAM scores of unique gene signatures.

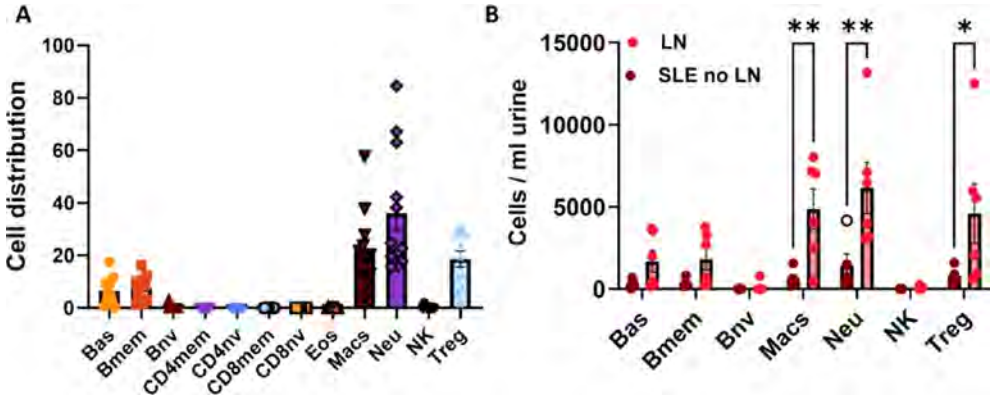


Fig. 3 Urine DNAm Deconvolution reveals (A) high Macrophage (Macs) and Neutrophil (Neu) cell distribution in lupus urine and (B) Increased Macs and Neu cells/ml urine in lupus (SLE) patients with LN vs. SLE patients without LN. One-way ANOVA, *p< 0.05, **p < 0.01

to the tubules vs. neutrophils (27% vs. 10%) but, strikingly, neutrophils localized to glomerular regions to a much greater extent (41% vs 88%). Similar interstitial distribution was found for both myeloid cell populations. Both NDNs and LDNs infiltrated LN tissues at comparable levels (**Fig. 2**). LDNs were the more predominant neutrophil population in the glomeruli: 76% LDN+ spots vs. 65% NDN+ spots. NDNs were the more predominant neutrophil population in both tubular and interstitial areas: 5% LDN+ spots vs. 7% NDN+ spots in tubules; 19% LDN+ spots vs. 27% NDN+ spots in the interstitium. The most prevalent NDN subtype in tubular regions was mature and transcriptionally quiescent neutrophils (Nh2), whereas immature and interferon+ NDNs were the prevalent subtype in glomeruli. DNAm analysis of urine cell pellets recapitulated high neutrophil and macrophage presence in LN kidneys (**Fig. 3**). Higher macrophage levels were found in urine cell pellets of SLE patients with active LN. There was a significant correlation between urine macrophage levels with UPCR (r = 0.64, **p = 0.008) and disease activity (SLEDAI >5, *p = 0.05).

Conclusion: Neutrophils, not only macrophages, are highly abundant in LN kidneys. Both NDNs and LDNs are highly prevalent myeloid cells in LN kidneys with predominantly glomerular localization. Spatial transcriptomics and urine DNA methylation approaches overcome the shortcomings of scRNAseq and are useful tools to define the pathogenic role of myeloid cells in LN.

Inadequate Screening for Antiphospholipid Syndrome with Antiphospholipid Antibodies in Patients with Systemic Lupus Erythematosus

tooba Munawar[1], Mahnoor Sherazi[2] and Andras Perl[3], [1]Upstate University Hospital, Jamesville, NY, [2]Upstate University Hospital, Syracuse, NY, [3]SUNY, Syracuse, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid Syndrome (APS) is classified into primary and secondary; the latter being associated with connective tissue disease. Systemic lupus erythematosus (SLE) is the most common cause of secondary APS, and the prevalence of antiphospholipid antibodies (APLAs), in patients with SLE is reported to be as high as 30% to 50% (1). The aim of our study was to determine what percentage of our SLE patients have had a complete APLA profile with or without thrombosis. We also looked at the timing these antibodies were obtained in regard to thrombotic events.

Methods: We reviewed EMR of patients with a diagnosis of SLE from 2012-2022. Data was obtained on presence or absence of antiphospholipid antibodies testing in these patients along with the timing of these tests in relation to thrombotic events. Deep vein thrombosis, Cardiovascular accidents, Pulmonary Embolism and History of Miscarriages were few of the thrombotic events included for review.

Results: A total of 5965 patient's charts were used for analysis. 5207 of these were females. Only 898 (15%) patients were found to have an entire antiphospholipid antibodies panel tested in them. 571 of SLE patients had a thrombotic event and 309 of these were without an APLA panel prior to the event. When number of SLE patients who had APLA testing done with and without thrombotic events were compared to those without APLA testing, the results were found to be statistically significant. (p value < 0.0001 ; Table 1).

Conclusion: Despite the increased risk of APS and thrombosis in patients with SLE, there is inadequate screening with antiphospholipid antibodies in these patients. Most of the times antibody testing in these patients is driven by a thrombotic event. We purpose an EMR alert to obtain antiphospholipid antibodies testing in all SLE patients who are without one to better categorize their risk of APS and thrombosis.

	SLE patients with thrombotic event	SLE patients without thrombotic event	Total
With APLA testing	262	636	898
Without APLA testing	309	4758	5067

Table 1- Number of SLE patients with APLA testing with and without thrombotic events as compared to those without it.

Two-tailed chi square p value < 0.0001

Neutrophils in Patients with Systemic Lupus Erythematosus Show Pronounced Inflammatory Signals

Annie Law[1], Chee Jian Pua[2], Dianyang Guo[3], Chin Teck Ng[4], Julian Thumboo[1], Andrea Hsiu Ling Low[5] and **Xiubo Fan**[1], [1]Singapore General Hospital; Duke-NUS Medical School, Singapore, Singapore, [2]National Heart Centre, Singapore, Singapore, [3]Singapore General Hospital, Singapore, Singapore, [4]Singapore General Hospital; Duke-NUS Medical School, Singapore, Malaysia, [5]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: IFN response, plasmablasts and neutrophils are three hallmarks of systemic lupus erythematosus (SLE). Studies showed that the netting neutrophils stimulated plasmacytoid dendritic cells to secret type I interferon directly and further promoted the expansion of plasmablasts indirectly, suggesting the upstream position of neutrophils in the pathogenesis of SLE. The blood transcriptomic profiling of human SLE, with a focus on lymphoid (T cells, B cells and NK cells) and partial myeloid (monocytes and dendritic cells) lineages, has been uncovered. However, due to the sample processing challenge – a rapid process of fresh blood sample for optimal cell quality, the transcriptomic profiling of neutrophils remains incomplete.

Methods: To determine cell-type specific signatures, we planned to decipher neutrophil transcriptional changes in human SLE using single cell RNA sequencing (scRNA-seq). Briefly, freshly isolated white blood cells from healthy controls (n = 3) and SLE patients (SLEDAI ≤ 4, n = 3) were collected for scRNA-sq sample preparation and sequencing with BD Rhapsody microwell-based single-cell partitioning technology. For data analysis, Scrublet was used for multiplet removal, BBKNN for batch correction, Python-based Scanpy pipeline for data pre-processing, visualization, clustering and differential expression testing and UMAP for data plotting.

Results: Neutrophils were clustered to 5 subpopulations (pre-neutrophils (PreNeu), early neutrophils (EarlyNeu), middle neutrophils (MidNeu), late neutrophils (LateNeu) and late IFN-expressing neutrophils (LateIFNNeu), according to Gustaf et al. In SLE patients (cases), the frequency of EarlyNeu in myeloid cells was markedly increased (48.7% vs 26.3%), whereas the frequencies of MidNeu (18.8% vs 25.4%), LateNeu (7.3% vs 13.3%), LateIFNNeu (10.4% vs 14.8%) were reduced compared to healthy controls. Gene set enrichment analyses were performed using hallmark gene sets to identify the possible pathophysiology of the disease. In line with our speculation, interferon (IFN-αand IFN-γ) response, inflammatory response and TNF-α/NF-κB signals were found to be enriched in cases for PreNeu, EarlyNeu and LateNeu. In addition, relative to controls, IL-6/JAK/STAT3 and apoptosis signals were enriched in cases for EarlyNeu and LateNeu; complement signal was enriched in cases for LateNeu; IL-2/STAT5 signal was enriched in cases for MidNeu and LateNeu; cell cycle (e.g., G_2M checkpoints, E2F targets and mitotic spindles) and DNA repair signals were under-represented in cases for PreNeu. Conversely, IFN-γ signal was under-represented in cases for MidNeu and LateIFNNeu.

Conclusion: In SLE patients, pronounced inflammatory signals were observed in neutrophils across different stages.

Transcription Factor RFX1 Promotes M1 Macrophage Polarization in Systemic Lupus Erythematosus via Regulating APOBEC3A

shuang Yang[1], Pei Du[1], Sujie Jia[2] and **Ming Zhao**[2], [1]Department of Dermatology, Hunan Key Laboratory of Medical Epigenomics, The Second Xiangya Hospital of Central South University, Changsha, China, [2]Institute of Dermatology, Chinese Academy of Medical Sciences and Peking Union Medical College, Nanjing, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Aberrant macrophage polarization is generally present in autoimmune diseases. Overwhelming M1 macrophage induces the continuous progression of inflammation, which is one of the vital reasons for the development of autoimmune diseases. However, the underlying mechanism is still unclear. This study mainly explores the role of regulation factor X1 (RFX1) on macrophage polarization in systemic lupus erythematosus (SLE), and elucidates the mechanism of RFX1 regulating abnormal macrophage polarization.

Methods: Western blot (WB) was used to detect RFX1 expression in $CD14^+$ monocyte-derived macrophage (hMDMs) and mouse peritoneal macrophages (PMAs). The conditional knockout mice-$Rfx1^{f/f}$Lyz2-Cre (CKO) was constructed to inhibit RFX1 expression specifically in macrophages. The RNA-seq was used to detect the differently expressed genes in RFX1-overexpressed or knockout PMAs. The expression levels of macrophage markers and pro-inflammatory cytokines in macrophages were detected by RT-qPCR, Flow cytometry or ELISA. The CKO and WTmice with colitis or lupus-like symptom were induced by dextran sulfate sodium (DSS) or IMQ respectively. The damage of intestinal or kidney tissue was examined by H&E staining. The infiltrations of $CD45^+$, neutrophils, macrophages, $CD4^+$ and $CD8^+$ cells in colon or kidney were detected by flow cytometry, as well as markers of M1 and M2 subtypes. ChIP-seq was used to screen the target genes regulated by RFX1.

Results: The protein expression of RFX1 was increased significantly in LPS induced M1 macrophage. Compared with control group, the expressions of M1-related genes were increased in RFX1-overexpressed PMAs, while the expressions were significantly reduced in *Rfx1*-deficient PMAs. We also found that the relative mRNA and protein expression of RFX1 in $CD14^+$ monocyte from the peripheral blood of SLE patients was significantly increased compared with healthy control (HC).

In addition, deficiency of Rfx1 protect the integrity of the intestinal structure in colitis mice and inhibited the damage to kidney from lupus-like mice. The infiltration of immune cells was obviously reduced in colon or kidney form CKO mice. The M1-related gene expression such CD86 or MHCII was decreased in macrophages from CKO mice. Besides, the concentrations of pro-inflammatory cytokines including Il-6 and Tnf-a and Il-1b were lessened significantly in serum from CKO mice.

Dual luciferase reporter and ChIP-qPCR assay indicated that APOBEC3A transcription was regulated by RFX1 directly. And the methylation of *IL6* and *TNF* promoter in macrophage was decreased by APOBEC3A or RFX1 overexpression. Besides, the methylation of *IL6* and *TNF* promoter were also decreased in monocyte and macrophage from SLE patients.

Conclusion: Both *in vitro* and *in vivo* experiments show that RFX1 promotes M1 polarization by APOBEC3A-mediated demethylation. And RFX1 may promoted the autoimmune inflammation in SLE.

IL-16+ Is Abundantly Expressed by Kidney-infiltrating Myeloid and Lymphoid Cells in Lupus Nephritis: A Spatially Resolved Multiplexed Approach

Alessandra Ida Celia[1], Xiaoping Yang[2], Hana Minsky[2], Silvia Malvica[2], Michelle Petri[3], the Accelerating Medicines Partnership in RA/SLE[4], Avi Rosenberg[5] and Andrea Fava[2], [1]John Hopkins University of Medicine, Rome, Italy, [2]Johns Hopkins University, Baltimore, MD, [3]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [4]Multiple, Multiple, [5]Department of Pathology, The Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: We previously discovered that IL-16 is the urinary protein most strongly correlated with histological activity in lupus nephritis (LN), followed by neutrophil degranulation products such as PR3. IL-16 is a proinflammatory chemokine that binds to CD4 and CD9 which are also expressedby myeloid cells. IL-16 is a key mediator in renal ischemia-reperfusion injury. Furthermore, IL-16 polymorphisms carry a higher risk of SLE (OR 3.3-10.4), suggesting a potential causal role. Our hypothesis is that IL-16 critically amplifies the immune response in proliferative LN, thereby attracting myeloid populations that can ultimately lead to kidney damage. The aims of our study are to investigate IL-16+ cells in LN kidney, define their immunophenotype, and to explore the presence of PR3+ cells in the same spatial area in order to gain insight on the spatial relation between the two populations.

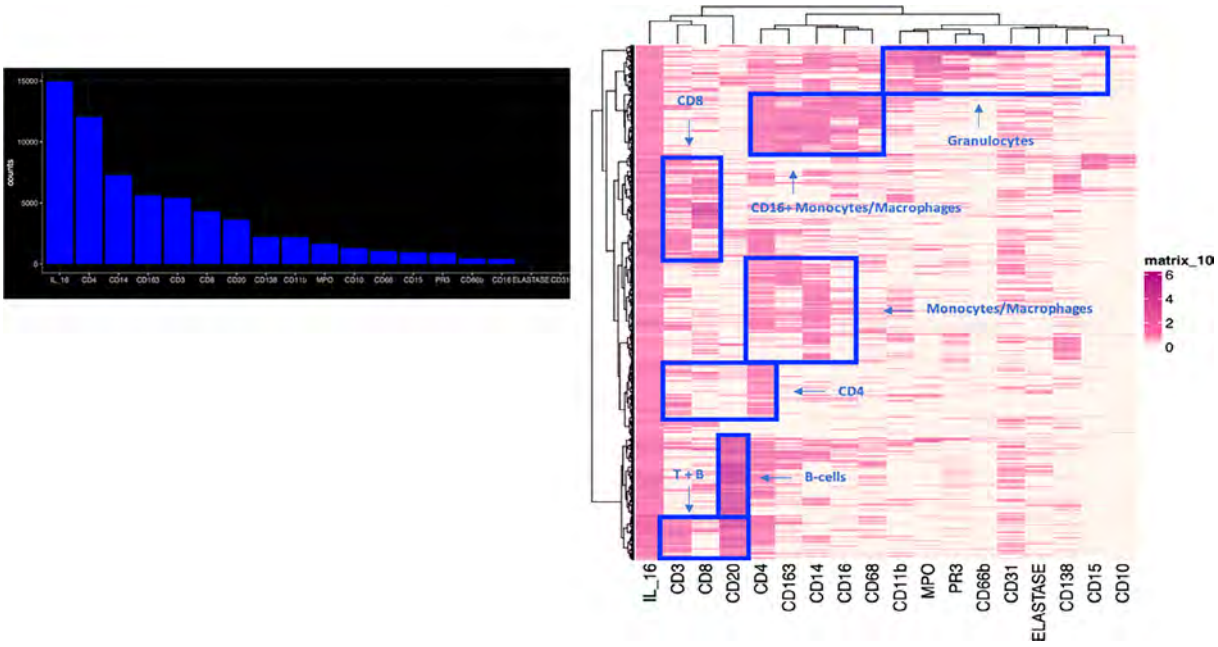

Figure1. IL-16+ cells immune phenotype (A) Coexpression of lineage markers in IL-16+ cells. Values indicate number (count) of positive cells. (B) Heatmaps displaying the heterogeneity of marker coexpression at the single cell level for IL-16+ cells (B). Data from one representative kidney biopsy (class IV lupus nephritis, NIH Activity Index 8/24, Chronicity Index 6/12).

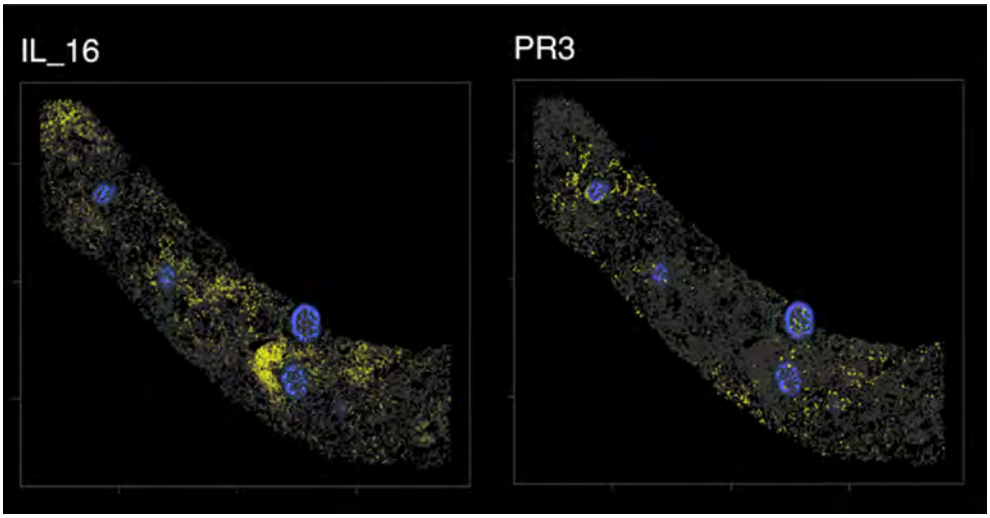

Figure2. Spatial distribution of IL-16+ and PR3+ cells Biopsy detail mapping IL-16 and PR3+ cells (in yellow); glomeruli in blue. There was no obvious spatial relation between IL16+ and PR3+ cells. Data from one representative kidney biopsy (class IV lupus nephritis, NIH Activity Index 8/24, Chronicity Index 6/12).

Methods: We performed 20-plex serial immunohistochemistry (sIHC) on one archival LN kidney biopsy (ISN/RPS class IV) to identify IL-16+ and PR3+ cells and evaluate the expression of multiple cell lineage markers. We utilized Indica HALO to perform image analysis, including deconvolution, cell segmentation, glomerular annotation, and quantitative histology.

Results: A total of 95,619 cell objects present in the sample were analyzed. We observed an abundant IL-16+ infiltrate, mostly in the tubulointerstitium. Multiple kidney-infiltrating immune cell types produced IL-16. The co-expression of lineage markers by IL-16+ cells is summarized by **Figure1A. Figure 1B**displays the heterogeneity of marker co-expression at the single cell level for IL-16+ cells. Most IL-16+ cells also expressed CD4, a ligand for IL-16. **Figure 2** illustrates the tissue distribution of IL-16 and PR3+ cells showing how IL-16 and PR3 are not spatially related.

Conclusion: IL-16+ cells abundantly infiltrate the kidney in LN. IL-16 is producedby most types of immune cells including lymphoid and myeloid cells. There was no spatial relationship between IL-16+ and PR3+ cells suggesting no obvious chemotactic activity. The release of IL-16 by multiple immune cell types may promote and amplify LN.

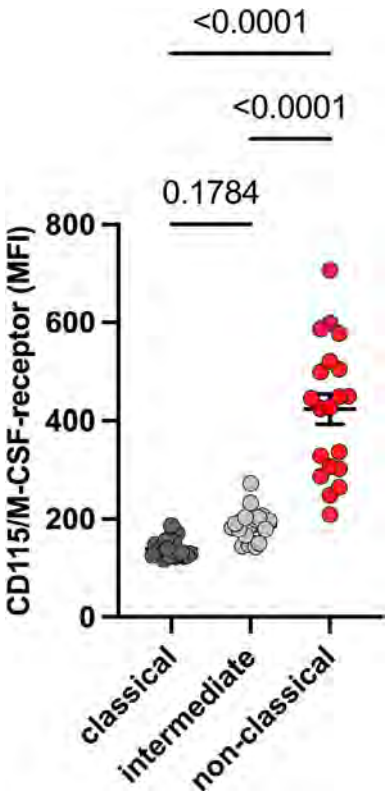
Upregulation of the M-CSF Receptor on Non-Classical Monocytes from SLE Patients as an Indicator for Premature Monocyte Aging

Markus Zeisbrich[1], Stephanie Finzel[2], Nils Venhoff[1] and Reinhard Voll[1], [1]University Medical Center Freiburg, Freiburg, Germany, [2]Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, University of Freiburg, Freiburg, Germany

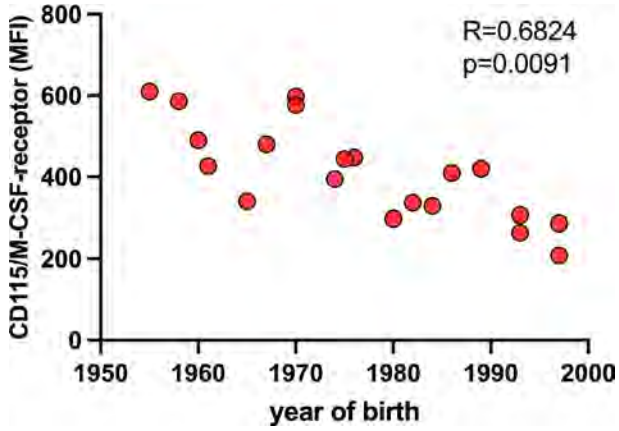
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Circulating monocytes are divided into three subsets: classical, intermediate, and non-classical monocytes. Monocytes egress from the bone marrow as classical monocytes and develop into intermediate and later non-classical monocytes. In patients with systemic lupus erythematosus (SLE), the proportion of non-classical monocytes is increased in the peripheral blood and kidneys in case of glomerulonephritis. However, the biology of non-classical monocytes in patients with SLE and their implications in the disease process are not fully characterized.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from patients with SLE (defined by the 2019 EULAR/ACR criteria; n=20), healthy controls (n=20), and patients with connective tissue diseases other than SLE (n=10). PBMC were stained for CD14, CD16, and CD115 and analyzed by flow cytometry. In additional experiments, mitochondrial



Surface expression of CD115 (MFI) on classical (CD14+CD16-), intermediate (CD14+CD16+), and non-classical monocytes (CD14dim CD16++) in healthy control donors (n=20).



Correlation of the surface expression of CD115 (MFI) on non-classical monocytes (CD14dim CD16++) and the year of birth of the respective healthy blood donor (n=20).

membrane potential and mitochondrial reactive oxygen species were measured by flow cytometry, expression of miR146a was quantified by RT-qPCR. All patients and blood donors gave written informed consent and the study was approved by the ethical review board of the University of Freiburg.

Results: Surface expression of CD115, the receptor for macrophage colony stimulating factor (M-CSF), a key survival factor for myeloid cells, is markedly upregulated on non-classical monocytes from patients with SLE. While CD115 is almost absent on the classical monocyte subset and intermediate monocytes show low levels of CD115, only non-classical monocytes exhibit a relevant surface expression of the M-CSF receptor (Figure 1). Non-classical monocytes from SLE patients increase their CD115 expression not only in comparison with healthy age-matched controls (p=0.004) but also compared to patients with connective tissue diseases other than SLE (p=0.009), identifying the upregulation of the M-CSF receptor as biological signature of non-classical monocytes in SLE. These CD115+ monocytes in SLE patients display a senescent cell phenotype with increased mitochondrial membrane potential (p=0.012), higher production of mitochondrial reactive oxygen species (p=0.021) and upregulation of the senescence marker miR146a (p=0.008). When investigating CD115 expression in different age groups in healthy individuals, CD115 receptor levels on non-classical monocytes were age-dependent with low levels on cells from young adults and significantly higher levels in individuals over 50 years of age (Figure 2). Thus, the upregulated CD115 expression of non-classical monocytes from young SLE patients was indicative for premature monocyte aging in line with the upregulation of senescence markers in those cells.

Conclusion: We identified the upregulation of the M-CSF receptor (CD115) as a biological signature of non-classical monocytes from SLE patients. CD115+ non-classical monocytes are increased only in the peripheral blood of patients with SLE and not in patients with other connective tissue diseases and display a senescent phenotype indicative of premature monocyte aging in SLE.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease partly characterized by production of autoantibodies, causing inflammation and tissue damage. In this study we investigated whether cumulative genetic risk for elevated immunoglobulin G (IgG)-levels in the general population, represented by an IgG polygenic risk score (IgG-PRS) is associated with an increased risk of SLE, clinical manifestations or autoantibody-profile.

Methods: Patients with SLE, fulfilling the ACR-82, ACR-97 or SLICC-2012 criteria (n=1532) and healthy controls (n=1947) were genotyped using Illumina's Global Screening Array. Clinical data was retrieved from medical charts. A weighted IgG-PRS was assigned to each individual including 13 single nucleotide polymorphisms (SNPs) associated with elevated IgG-levels in the general population, as reported by Jonsson *et al*. (1). Next, two sub-PRSs were developed to investigate the SLE and non-SLE genetic effect of the IgG-PRS, one including SLE-associated SNPs ($r^2 > 0.2$, n=5) and another including non-SLE associated SNPs (n=8), table 1. Multiple logistic- and linear regression analyses were performed, adjusting for sex and SLE-duration. P-value < 0.05 was considered significant.

Results: The IgG-PRS did not differ between SLE patients and healthy controls or between men and women (both p >0.05). Out of the ACR-82 criteria, high IgG-PRS was most significantly associated with increased prevalence of arthritis (OR 4.39 (1.13-17.09), p=0.033), table 2. Further, a high IgG-PRS was associated with a greater number of different types of

autoantibodies including anti-SSA, anti-SSB, anti-RNP, anti-Sm, anti-dsDNA and anti-cardiolipin antibodies (p=0.02). When investigating the autoantibodies separately, a high IgG-PRS was associated with higher prevalence of anti-SSB (OR 4.39 (1.06-18.19), p=0.04) and lower prevalence of anti-RNP (OR 0.19 (0.043-0.85), p=0.03) antibodies. In total, 38% of the SNPs included in the IgG-PRS were in linkage disequilibrium with SLE-associated SNPs (r^2 = 0.26-0.96). Separating the SLE and non-SLE genetic effect for the IgG PRS, demonstrated a positive association for the SLE associated IgG PRS, and conversely a negative association for the IgG PRS excluding SLE associated SNVs (OR 22.2(8.06-61.30), p<0.001 and OR 0.17(0.06-0.44), p <0.001, respectively), table 2.

Conclusion: The cumulative effect of genetic variants affecting IgG-levels in the general population is associated with both the type and the number of different autoantibodies in SLE. Investigating common genetic variants linked to immunological functions in the general population may provide further insight into the genetics driving SLE. References: < !1. Session Date: Monday, November 13, 2023

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, systemic autoimmune disorder. The pathogenesis of SLE is not fully understood, but high twin/sibling concordance rates suggest a genetic component triggered by environmental events. Childhood-onset SLE (cSLE) patients have an extreme phenotype, therefore is an ideal population to study genetic contributors to SLE. Historically, studies have focused on unrelated individulas who share variants in individual genes. However, this approach doesn't consider that rare variants in SLE could cluster in genes participating in related biological processes. We performed genome sequencing in a diverse cohort of cSLE patients and parental controls, and describe a network-of-pathways approach to identify biological pathways enriched in genes with rare variants that may contribute to cSLE pathogenesis.

Methods: SLE patients met at least 4 of 11 revised American College of Rheumatology classification criteria, with disease onset 18 years. Whole blood samples were collected from 83 patients with cSLE and 109 unaffected parents and whole genome sequencing was performed. The genome sequences were filtered to select for rare (minor allele frequency< 0.01), nonsynonymous variants in coding exons. Selected variants had to be present only in cSLE patients or in both patients and parents, but at a significantly higher level in patients (Fisher's exact test (p0.05)).This resulted in 501 unique variants, which

Table 1. Demographic data of the cSLE cohort

	cSLE (n=83)

Dyads (%) n	30 (25)
Singletons (%) n	19 (16)

corresponded to 232 genes.Using the 232 genes, we performed pathway enrichment analysis based on Gene Ontology biological processes with Metascape. We generate a network of enriched pathways, weighted by enrichment values and overlap coefficients with Cytoscape. Pathway clusters in the network were manually reviewed and classified. We analyzed clinical phenotypes and CADD-Phred for each pathway cluster.

Results: Rare genetic variants in cSLE patients are enriched in biological pathways such as RNA processing and apoptosis (Figure 1). Some pathways(i.e. nucleic acid regulation) are well-established causes of monogenic SLE, while others are novel. The median CADD-Phred score for each of the 18 networks ranges from 11.5-23.6.The mitochondrial functions cluster had higher rates of lupus nephritis, and the cell adhesion cluster had higher rates of CNS SLE compared to other clusters (Figure 2).

Conclusion: Network analysis is a useful approach to identify biological pathways and specific genes that could contribute to cSLE risk. Ongoing detailed analysis of the specific variants identified in each pathway will allow us to prioritize key genes and pathways for further study. In total, this analysis may contribute to advancing the understanding of cSLE beyond a broad clinical phenotype and towards a more precise molecular diagnosis.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease with unpredictable flares interspersed with prolonged periods of disease quiescence. Interferon (IFN) is a hallmark of disease and has been linked to disease flares, but the precise mechanism by which this occurs remain unclear. To address this question, we examined the association between IFN and the immune changes in flaring and quiescent SLE patients at a single cell level.

Methods: A 41-marker panel was developed that enabled measurement of IFN-induced proteins (IIPs) in peripheral blood immune populations using CyTOF.Fifteen healthy controls (HCs), 26 quiescent (clinical SLEDAI-2K = 0 for one year) and 42 recently flaring (< 1 month, change in clinical SLEDAI-2K ≥ 1 requiring escalation of therapy) SLE patients were examined. Expression of individual IIPs normalized to healthy controls, as well as a composite IIP score incorporating the expression of all seven proteins was assessed.

Results: Twenty-six distinct immune populations were identified, all of which demonstrated a strong correlation between IIP levels and the IIG score in SLE (Figure 1).In all immune populations, the levels of IIPs were significantly elevated in SLE patients compared to HCs. In most cell populations, the levels of IIPs were elevated in flaring compared to quiescent SLE patients (Figure 2A) and correlated with the clinical SLEDAI-2K. Comparison of the abundance of the 26 immune populations between flaring and quiescent patients revealed that only classical monocytes, intermediate activated classical monocytes, and age-associated B cells (ABCs) were significantly elevated in flaring patients (Figure 2B). Very limited changes were seen between these 2 groups of patients for markers of cellular activation, such as CD86, TLR7, TLR9, FOXP3, HLA-DR, Ki67, and PD1. In contrast, in many relevant immune populations, elevations of these markers were associated with IIP levels suggesting that IFN, rather than disease status (i.e., flare vs quiescence), is driving this activation. In patients who were flaring at baseline, elevations of IIPs in pre-ABCs, ABCs, low density granulocytes (LDGs), and intermediate activated monocytes were associated with clinical disease activity one year later (Figure 3A).In contrast, quiescent patients that subsequently flared and were active at one year had elevations of IIPs in multiple T and B cell populations (Figure 3B).

Conclusion: The findings suggest that IFN initiates flares by promoting B and T cell activation, while sustained or recurrent disease activity appears to be more dependent upon its impact on ABCs, LDGs, and monocytes.

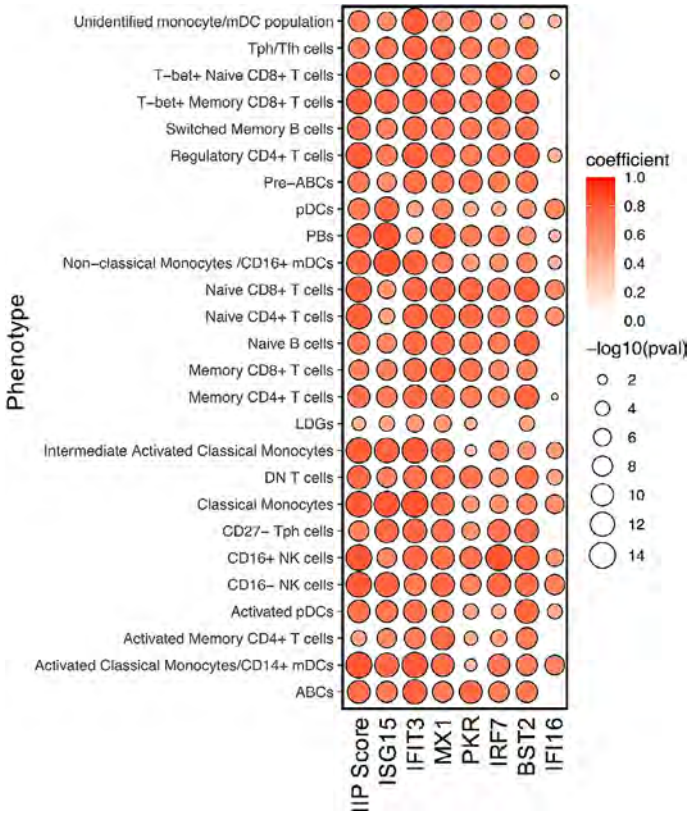

Figure 1. IFN induced protein (IIP) expression is significantly correlated with IFN induced gene (IIG) expression. Correlation between IIP expression (shown on the x axis) in individual cell populations (shown on the y axis) and IIG expression, as measured by a composite score calculated by summing the log2 transformed, normalized expression of 10 IFN-induced genes. R values are denoted by colour, and p values by the size of the dots.

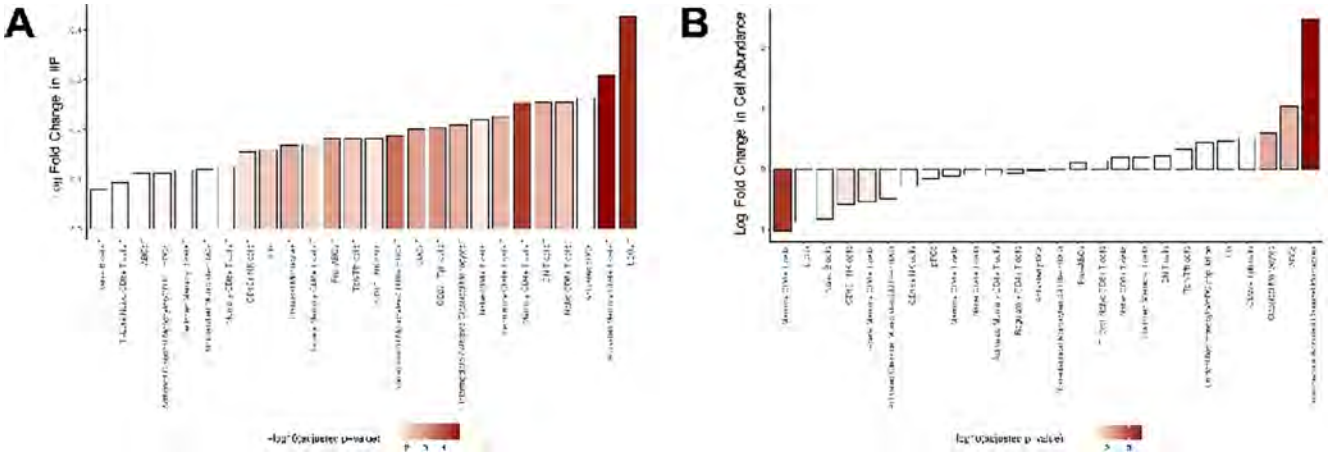

Figure 2. Immunologic differences between flaring and quiescent patients. Waterfall plots showing the fold change differences between flaring and quiescent SLE patients. Bars above the x axis are increased and below the x axis are decreased in flaring relative to quiescent patients. A) Waterfall plot of IIP scores showing that flaring patients have significantly higher levels of IIP expression in 21 out of the 26 immune populations surveyed. B) Waterfall plot of cellular abundance showing that flaring patients have significantly increases in some monocyte subsets and ABCs as compared to quiescent patients.

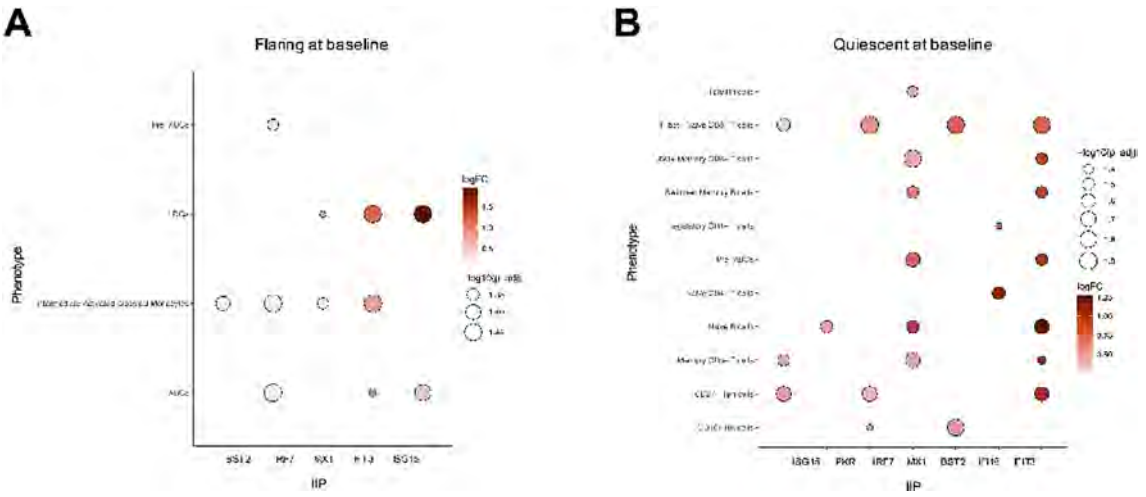

Figure 3. Interferon-induced protein (IIP) levels in distinct immune populations at baseline inform disease status at one year follow up. A) Patients who were flaring at baseline and were active at one year had significantly higher expression of IIPs in their ABCs, LDGs, and some monocyte cell subsets when compared to those who had inactive disease activity at follow up. B) Patients who were quiescent at baseline and eventually experienced an increase in disease activity at 1 year had significantly higher expression of IIPs in their B and T cell subsets than those who had sustained disease quiescence at one year follow up.

Proinflammatory Neutrophils and NETs Mediate Skin and Kidney Inflammation During Lupus Flare in Asymptomatic Lupus-prone Mice Triggered by UVB

Xing Lyu[1], minghui li[1], ping zhang[2], Wei Wei[3], victoria werth[4] and **Ming-Lin Liu**[5], [1]Tianjin Medical University, Tianjin, China, [2]Beaumont Hospital Royal Oak, Royal Oak, MI, [3]Tianjin Medical University General Hospital, Tianjin, China, [4]University of Pennsylvania, Wynnewood, PA, [5]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultraviolet B (UVB) exposure triggers lupus flare by worsening both skin lesions and systemic symptoms, i.e. lupus nephritis. We recently reported that UVB exposure induces skin inflammation with infiltration of neutrophils, which can form neutrophil extracellular traps (NETs) in wild-type mice. Interestingly, we recently found that UVB exposure of asymptomatic MRL-lpr lupus-prone mice induced lupus flare with not only skin inflammation, but also proteinuria. However, the underlying mechanisms remain unclear.

Methods: To study the relevant mechanisms, we investigated skin lesions, proteinuria, infiltrated neutrophils, their expression of cytokines or complement C3, and formation of NETs in both skin and kidneys of UVB-irradiated asymptomatic young female MRL-lpr lupus-prone mice.

Results: UVB exposure induced inflammatory responses in skin and kidneys with proteinuria, showing elevated skin thickness, immune cell infiltration, increased CXCR4 expression in neutrophils, and deposition of NETs, and NET-associated IFNα or C3 in both skin and kidneys. Interestingly, infiltrated cell count in skin was positively correlated with proteinuria ($r=0.57$, $p< 0.05$), indicating a link between skin infiltrates and kidney injury. In kidneys, glomerular hypercellularity ($r=0.73$, $p< 0.05$), CXCR4-positive neutrophils ($r=0.7$, $p< 0.05$), NETs ($r=0.74$, $p< 0.05$), NET-associated IFNα ($r=0.81$, $p< 0.05$) or C3 ($r=0.88$, $p< 0.01$) were correlated with proteinuria in UVB-irradiated lupus-prone mice, suggesting a role for CXCR4-positive neutrophils, NETs and their associated IFNα or C3 in kidney inflammation. To explore the origin of the pro-inflammatory neutrophils, we found that stimulation with UVB or platelet-activating factor can upregulate expression of CXCR4, IFNα or C3 *in vitro* in neutrophils from lupus-prone mice. About 20-50% of them co-expressed IFNα or C3 with CXCR4, which may mediate cross-organ communication. Given that only a portion of infiltrated neutrophils become NETotic in the skin of UVB-irradiated wildtype mice in our recent publication, we sought to explore if inhibition of CXCR4 can reduce kidney injury. Notably, intraperitoneal application of CXCR4 inhibitor IT1t significantly attenuated proteinuria, with reduced glomerular infiltration of CXCR4-positive neutrophils. Consequently, we found decreased glomerular deposition of neutrophil NETs and NET-associated IFNα (3.2% Area in UVB vs 0.43% in IT1t+UVB mice, $P< 0.01$) in kidneys of UVB-irradiated MRL/lpr mice with IT1t application as compared to those in mice without IT1t administration.

Conclusion: In conclusion, UVB-induced proinflammatory neutrophils and NETs contribute to skin and kidney inflammation during lupus flare in asymptomatic lupus-prone mice irradiated by UVB. Inhibition of CXCR4-mediated neutrophil transmigration ameliorated kidney inflammation with attenuated proteinuria in UVB-triggered lupus flare. Our results provide insights into novel therapeutics into UVB-induced lupus flare.

SAP^{high} T Peripheral Helper Cells Are a Novel Subset Associated with Lupus Nephritis

Yevgeniya Gartshteyn[1], Leila Khalili[2], Laura Geraldino-Pardilla[2], Adam Mor[3] and Anca Askanase[4], [1]Columbia University Medical Center, New York, NJ, [2]Division of Rheumatology, Columbia University Irving Medical Center, New York, NY, [3]Columbia University, New York, NY, [4]Columbia University Medical Center, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Better understanding of the abnormal immune responses in lupus nephritis (LN) is fundamental to identifying new therapies. We previously reported that the adaptor protein SAP (SLAM Associated Protein) is increased in circulating T follicular helper (T_{FH}) and T peripheral helper (T_{PH}) cells of patients with SLE. SAP regulates T cell function by binding to the co-stimulatory SLAMF (signaling lymphocytic activation molecule family) receptors. SAP and SLAMF are critical for T_{FH} and T_{PH}-dependent B cell maturation into autoantibody-producing plasma cells that characterize SLE pathogenesis. In this work, we set out to evaluate the association between circulating SAP^{hi} T cells and clinical disease activity.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated using density gradient separation from whole blood. Cells were stained for cell surface markers, followed by permeabilization and staining of intracellular SAP. T_{FH} were defined as $CD3^{+}CD4^{+}CD8^{-}PD1^{hi}CXCR5^{+}$ and T_{PH} were defined as $CD3^{+}CD4^{+}CD8^{-}PD1^{hi}CXCR5^{-}$. Other markers included CXCR3, CCR4, CCR6, CD25, CD127 and HLADR. Additionally, we analyzed SAP expression from renal infiltrating LN T cells using the publicly available single-cell RNA sequencing (sc-RNA Seq) Accelerated Medicines Partnership (AMP) in SLE dataset. (*Nat Immunol* 2019; 20: 902-914.)

Results: PBMCs from 35 patients with SLE (1997 ACR criteria), including 10 patients with LN, were analyzed. The clinical characteristics are presented in Table 1. Mean age was 34±10, 83% were female. Males were more likely to have LN (p=0.03). We found an increase in total SAP-positive CD4 and CD8 T cells in SLE compared with controls (56±16 vs. 41 ±12 and 53±16 vs 39±10, respectively). In CD4 T cells, the highest SAP expression was in the T_{PH}, detectable in > 90% of T_{PH} cells in some patients. (Fig. 1A) The percent of $SAP^{hi}T_{PH}$ in circulation was associated with SLEDAI-2K (Pearson r=0.5, p=0.01) and showed a trend for inverse association with C3 and C4 levels. $SAP^{hi}T_{PH}$ cells were expanded in SLE patients presenting with flare vs. no flare. A sub-analysis revealed an association with active urine sediment, elevated anti-dsDNA, and nephrotic syndrome. SLE patients with renal disease had higher levels of circulating $SAP^{hi}T_{PH}$, and the association between $SAP^{hi}T_{PH}$ and LN remained significant after adjusting for age, sex, race, low complements, and elevated anti-dsDNA (p=0.02).(Fig. 1B)To validate these findings we used the AMP scRNA-Seq data. Using the authors' clustering analysis, we found a small but statistically significant increase in SAP levels from renal infiltrating T cells from SLE compared with control kidney biopsy samples (p=0.03). Notably, SAP expression in CD4 T cells was differentially upregulated in the T_{FH}-like vs. the T-regulatory subsets in the SLE vs. control group. (Fig. 2)

Patient Characteristics.

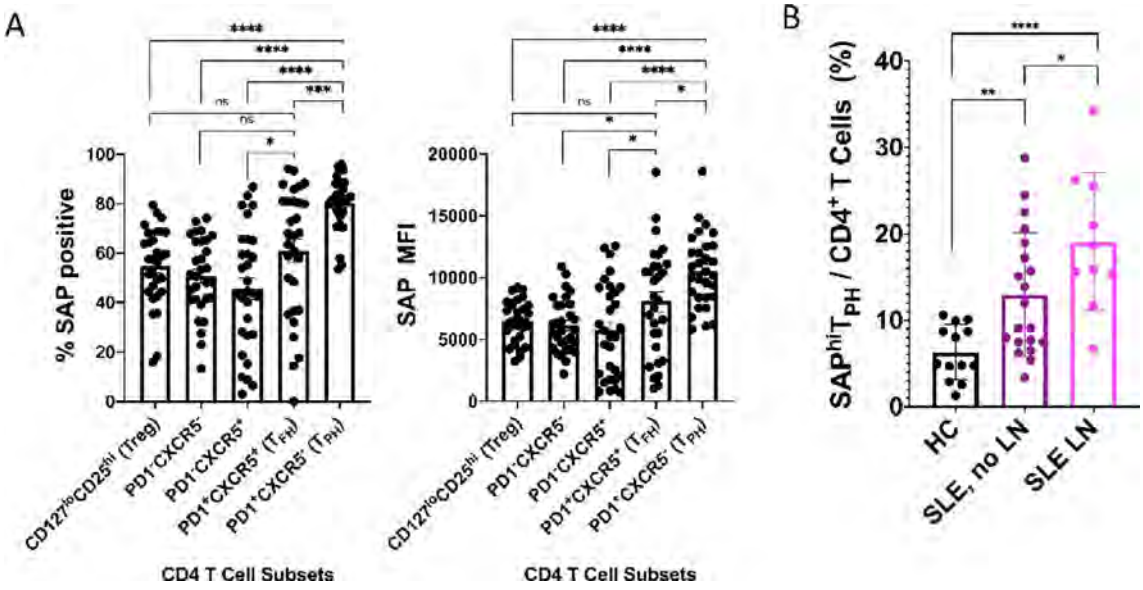

Figure 1. SAP expression in the T peripheral helper (TPH) CD4 T cells is associated with lupus nephritis. (A) SAP levels are increased in the TPH subset of CD4 T cells isolated from patients with SLE patients. (B)SAPhiTPH cells are expanded in SLE patients with LN compared to SLE patients without LN or in healthy controls (HC).

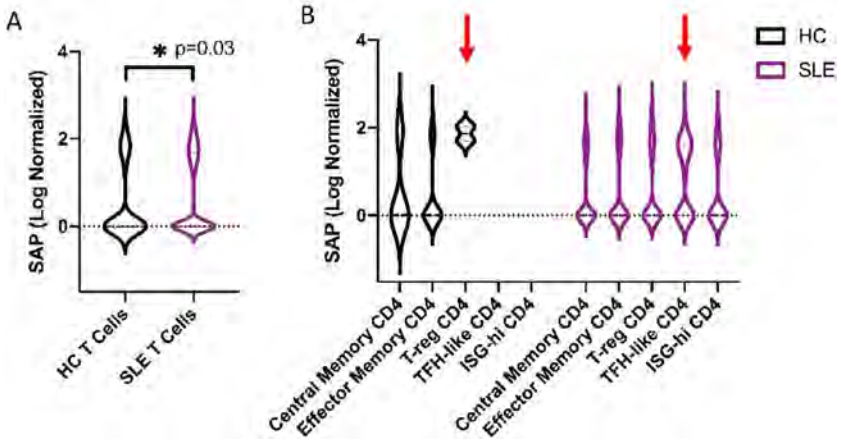

Figure 2. SAP levels are increased in the TFH-like renal infiltrating cells in LN. We analyzed the scRNA-Seq data from the publicly available Accelerated Medicines Partnership in the SLE LN dataset using the authors' original clustering algorithm. (A) SAP expression in all CD3 positive T cells. (B) Sub-analysis of SAP levels based on the authors' original T cell clustering algorithm. HC, healthy control. SLE, systemic lupus erythematosus.

Conclusion: We identified that $SAP^{hi}T_{PH}$ cells are associated with active SLE, specifically LN. Furthermore, we validated the presence of an analogous SAP^{hi} T_{FH}-like subset in the LN kidney biopsy samples, suggesting direct tissue-level infiltration by these cells. Future work to improve our understanding of SAP functions and signaling in these cells is likely to reveal novel therapeutic targets in SLE.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) poses a significant challenge at the diagnostic and treatment levels due to its severe multisystem nature and notable heterogeneity in clinical course and therapeutic response. We investigated the serum proteomic and metabolomic profiles of SLE, to uncover new mechanisms underlying relevant clinical patterns.

Methods: Proteomic and metabolomic approaches were used to assess the serum levels of 184 inflammation and organ damage-related proteins [proximity extension immunoassay (PEA, Olink)] and 168 serum metabolites, [nuclear magnetic resonance (NMR, Nightingale)] in consecutive SLE patients (n = 135) and age-matched healthy donors (HD) (n = 27). In parallel, an extensive clinical and analytical profile was conducted. To evaluate the contribution of molecular profiles to the disease severity, unsupervised hierarchical clustering analyses were developed.

Results: Fifty-three proteins related to inflammation and organ damage, and 32 metabolites, were significantly altered (p = < 0.05, FC= 1.5, FDR) in the serum of SLE patients compared to HD. Unsupervised hierarchical clustering of proteomic data differentiated 2 patient clusters, where patients belonging to one cluster were characterized by elevated disease activity (SLEDAI >5), and increased incidence of atheroma plaques, dyslipidaemia, and hypertension. The top features driving classification were CD40, PGF, PDL1 and CSF1, with area under the curve >0.9, known to be associated with immune activation. At the molecular level, these patients showed 49 overexpressed proteins (p = < 0.05, FC= 1.5, FDR), enriched in biological pathways linked to chemotaxis and lipid metabolism.

Unsupervised hierarchical clustering of metabolomic data also identified 2 patient clusters with patients in one cluster showing a greater preponderance of lupus nephropathy (LN). The top features driving classification included short chain fatty acids, total fatty acids, total lipids and total free cholesterol, with area under the curve >0.9. Molecularly, these patients showed increased levels of 60 proatherogenic VLDL and LDL subsets (p = < 0.05, FC= 1.5, FDR) and metabolite enrichment analysis identified ketone body and butyrate pathways.

Integrating proteomic and metabolomic patient clusters identified two patient subgroups with the most (N=41) and least (N=36) severe molecular and clinical profiles. The group with more severe profiles (SLEDAI >5, prevalence of LN, and higher incidence of atheroma plaques, hypertension, and dyslipidaemia) exhibited higher levels of 56 proteins associated with

chemotaxis, inflammatory response and cytokine signalling, as well as 53 proatherogenic lipoproteins, ($p = < 0.05$, FC= 1.5, FDR) confirming the original molecular stratification.

Conclusion: The simultaneous application of proteomic and metabolomic approaches for molecular profiling in SLE patients offers valuable complementary information enabling a more accurate definition of their clinical profile, providing novel therapeutic targets and biomarkers of disease.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunohistochemistry is the gold standard for antibody staining in microscopy. However, a lack of multiplexing limits its utility in the use of discovery. Here we demonstrate a serial Immunohistochemistry (sIHC) staining work-flow and analysis pipeline allowing for multiplexing of 18 antibodies on a single section.

Methods: 29 FFPE block were included for preliminary analyses from the 127 clinically indicated kidney biopsies recruited as part of the Lupus nephritis (LN) Accelerating Medicines Partnership (AMP) project).

Staining: 10mm sections from LN kidney biopsies in FFPE were deparaffinized, rehydrated, and antigen retrieved with boiling citrate. Slides were blocked for peroxidases, washed, and incubated with primary antibody, secondary HRP reagents, AEC-Red Chromogen, and Hematoxylin. Images were acquired at 40X magnification. Slides were decolored in 90% Ethanol and stripped in an antibody elution buffer, then cycled for all markers.

Image Stacks: Image files were imported into HALO-AI v3.5 (Indica Labs) for deconvolution, pseudo-coloring, co-registration, and alignment. Registered images were fused to create a single composite image with all 18 markers and a representative DNA and counterstain channel. Tissue regions were identified by a DenseNet V2 AI tissue classifier trained on an original co-registered IHC image and individual cell objects were identified by nuclear detection and segmented by cell distance boundaries.

Analysis: Single-cell marker expression datasets were analyzed in R. Cells located on the edge of the tissue or in regions classified as wrinkles were removed to reduce potential artifacts. Marker expression values underwent CLR-normalization and standardization within each sample and then combined and harmonized by Harmony to further minimize batch effect. PCA and UMAP were used for dimensional reduction, and KNN and SNN algorithms were applied to identify cell clusters. Clusters with CD45 expression levels > 2 standard deviations were selected as candidate immune cell clusters. Cell clusters with high keratin marker expression were removed to eliminate renal tubular epithelial cells. Remaining clusters were then re-clustered via KNN and SNN to identify distinct immune cell types with the help of heatmaps and feature plots.

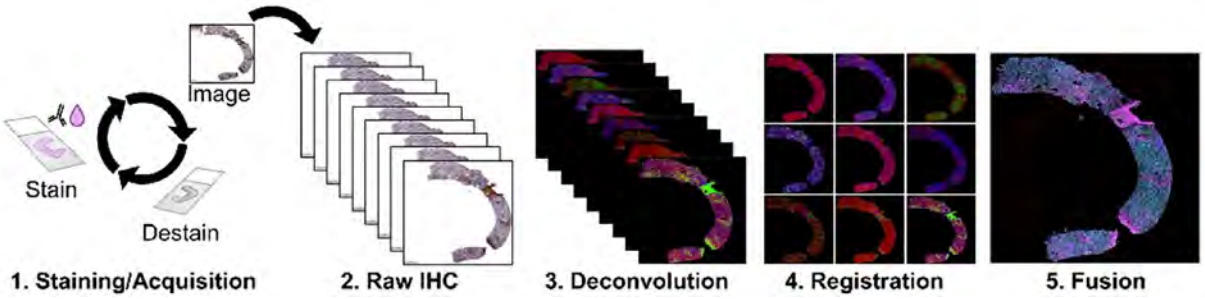

Figure 1-sIHC Staining and Image Stack Pipeline

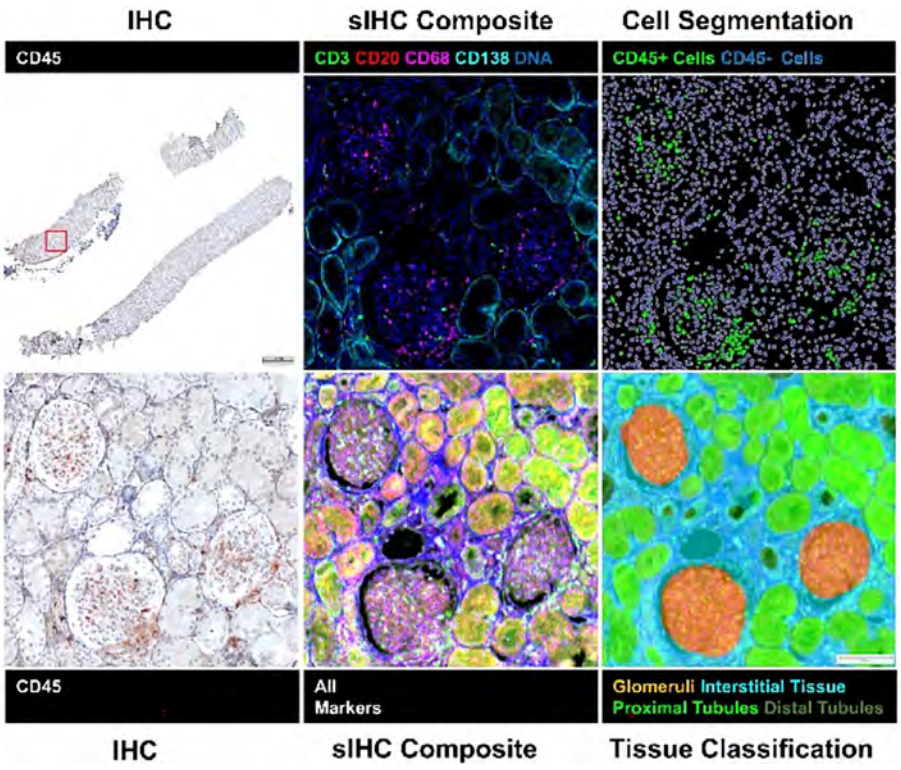

Figure 2 – sIHC Composites, Cell Segmentation, and AI-Based Tissue Classification

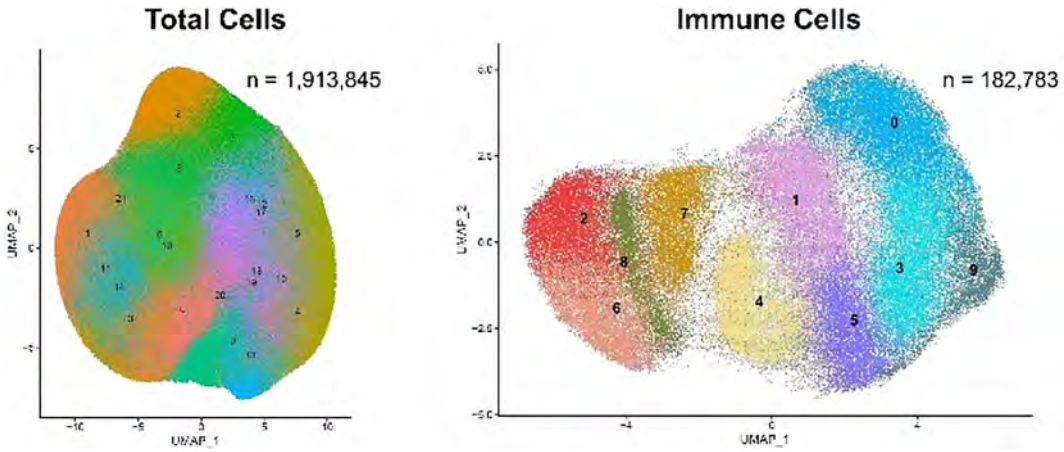

Figure 3 – Dimension Reduction and Clustering of sIHC Single-Cell Data

Results: The co-registration and fusion of images produced image stacks in which all 20 markers could be visualized within the same image. Tissue classification and single-cell segmentation allowed for clear identification of regions of the tissue and the individual cells that constituted each region. Single-cell analyses identified 1,913,845 cells and 182,783 CD45+ cells which were classified into 10 distinct immune cell phenotypes.

Conclusion: Here we demonstrate imaging and analysis of 20 markers using sIHC for the first time, while producing a large, spatially informed, clinically-relevant dataset in 29 LN Kidney Biopsies.sIHC can be successfully employed to perform multiplexed whole slide analysis harnessing both the subcellular resolution (brightfield) and the reliability of IHC.

Abstract Number: 0924

Distinct Cell-Bound Complement Activation Products Associate with Disease Activity and Immune Transcriptional Signatures in SLE

Gabriel Arguelles, Lynne Mitchell, Dennis Hourcade, John Atkinson, Elisha Roberson and **Alfred Kim**, Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Complement plays a central role in SLE, generating an array of bioactive soluble and cell-bound complement activation products (CB-CAPs) during disease activity. Data are lacking though detailing the types, quantities, and impacts of the numerous CB-CAP on SLE immune cells, especially with respect to disease activity. We applied a mass cytometry (MC) panel that can detect over 20 CB-CAPs and complement receptors to PBMCs from paired flare and remission samples from 6 patients with classified SLE. Furthermore, we analyzed single-cell transcriptional profiles on flaring samples using antibodies to the most prevalent CB-CAPs using cellular indexing of transcriptomes and epitopes (CITE)-seq.

Methods: Adults with ACR- or SLICC-classified SLE (n=6) were consented for PBMC collection at Washington University School of Medicine. Isolated PBMCs were subjected to single cell MC and CITE-seq (n=3). MC data analysis was performed with Cytobank. CITE-seq data analyses was performed with Seuret, gProfileR, and Comprehensive Multi-omics Platform for Biological InterpretatiOn (COMPBIO).

Results: We found the highest frequency of C4d, C3d, C5, and Bb deposition on B cells compared to T cells and monocytes during SLE flares (Fig 1). During disease remission, low levels of all CB-CAPs were observed in these cells. Compared to controls, transitional B cells from flaring patients with SLE had high levels of C5 and Bb with little C4d or C3d (Fig 2). $CD11c^+$ B cells from flaring patients also had elevated Bb deposition compared to controls. CITE-seq transcriptional profiling identified Bb- and C3d-bearing $CD11c^+$ B cells possessing a type I interferon signature, with Bb-bearing B cells further possessing a TNF/NF-κB transcriptional signature.

Conclusion: A high level of CB-CAP deposition was observed in B cells obtained from flaring subjects with a SLE, which was absent during disease remission. The types of CB-CAPs found on PBMCs were not uniform between cell types, potentially opening a previously undescribed heterogeneity in SLE. Additional heterogeneity was observed in the transcriptional profiles associated with specific CB-CAPs on B cells. These pilot data demonstrate the feasibility of the MC complement

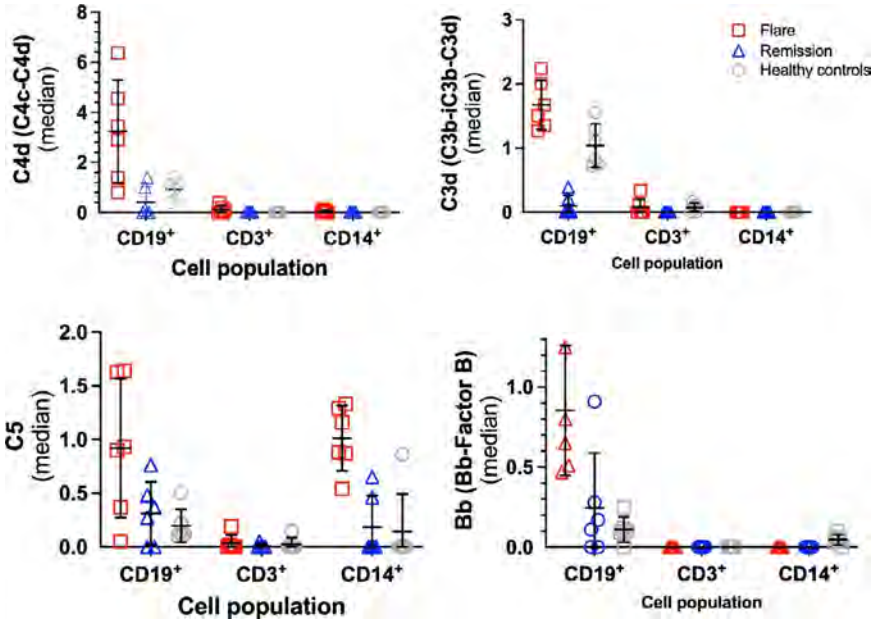

Fig 1. Mass cytometry of CB-CAP deposition on PBMCs from paired flaring and remission patients with SLE, along with matched controls.

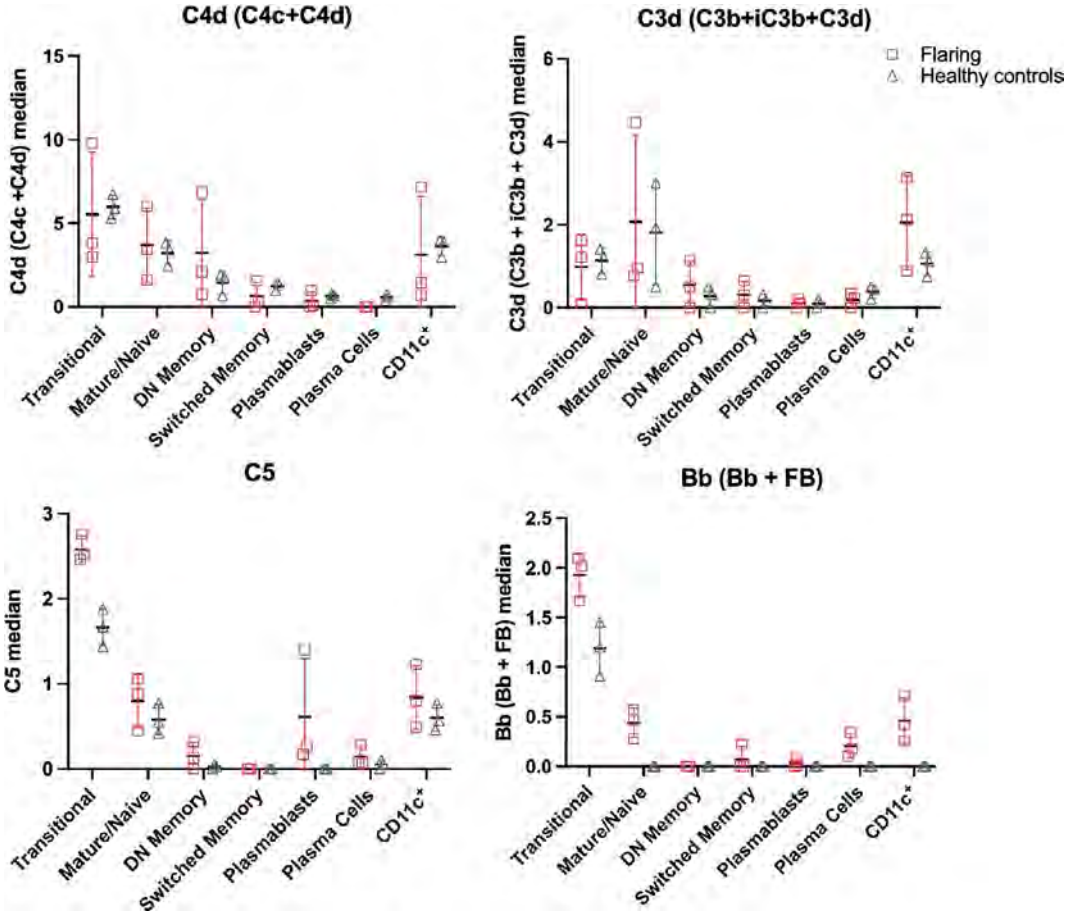

Fig 2. Mass cytometry of of CB-CAP deposition on B cell subsets from flaring patients with SLE versus matched controls.

panel on human samples, and the potential insights CITE-seq has using CB-CAPs in discovering novel mechanisms of complement activation and regulation.

IL-4 Acts Through Aryl Hydrocarbon Receptor to Antagonize TLR7-induced Double Negative 2 B Cells in Lupus

Changming Lu, Hui-chen Hsu, Min Gao, Jose Rubio, Winn Chatham and **John Mountz**, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: We recently showed that in SLE, IL-4 suppressed the development of interferon-beta (IFNβ) and TLR7-stimulated T-bet$^+$ double negative 2 (DN2) B cells. Here we investigate the potential DN2 B-cell suppressive effects of IL-4 through the IL-4-induced 1 (IL-4i1)-aryl-hydrocarbon receptor (AhR) pathway.

Methods: The mechanism of IL-4 in suppressing the development of DN2 B cells *in vivo* was studied using R848-treated BXD2 mice. The B-cell developmental trajectory was determined using single-cell RNA-sequencing (scRNA-seq) analysis. Adult patients whomet theACR 1997 revised criteria for SLE were recruited. The *in vitro* effects of IL-4 and two potent AhR agonistic ligands, Kynurenine (Kyn) and 6-formylindolo[3,2-b]carbazole (FICZ) in suppressing the development of DN2 B cell were determined using IFNβ plus TLR7 stimulated B cells. B-cell subsets and transcription factors (TFs) expression was measured by surface and intra-nuclear FACS analysis. AhR pathway and target genes were analyzed using qPCR. Autoantibodies were measured by ELISA.

Results: Administration of IL-4 significantly inhibited the development of anti-Smith, anti-DNA, and anti-histone autoantibodies induced by the TLR7 agonist R848 in BXD2 mice. This was associated with a decreased percentage of CD11c$^+$T-bet$^+$ IgD$^-$ B cells. Feature-barcoding single-cell RNA-sequencing analysis showed that IL-4 modulated B-cell development at the transitional stage 2 (T2) and skewed naïve B cells to develop into the CD23$^+$CD21$^-$ follicular B cells. IL-4 induced the gene encoding *Ii4i1*, an enzyme that metabolizes aromatic amino acids, and this was associated with the upregulation of AhR and downstream genes *Cyp1a1* and *Ido1*. In the absence of IL-4, both Kyn and FICZ significantly suppressed TLR7 plus IFNβ-induced T-bet$^+$ B-cell development *in vitro* in BXD2 mice. Analysis of AhR expression in healthy control (HC) and SLE subjects show a significantly lower expression of AhR in both the IgD$^-$CD27$^-$ DN and IgD$^+$CD27$^-$ naïve B-cell populations of SLE compared to HC. qPCR analysis further indicates a significantly lower expression of *CYP1A1* and *IL4I1* in SLE B cells compared to HC B cells. B cell culture with either IL-4 or Kyn significantly reduced the development of DN2 B cells stimulated by IFNβ plus TLR7. Kyn also significantly induced the expression of *CYP1A1* and promoted the expression of PD-1 in IFNβ plus TLR7-stimulated B cells.

Conclusion: Our results suggest that IL-4R acts through the IL4i1-AhR pathway to induce a B-cell regulatory response to TLR7 and type I IFN. Identifying small molecular metabolites that act directly in B cells to induce homeostasis may lead to the development of orally active druggable targets that are efficacious in treating SLE.

Single-cell Multi-Omic Evaluation of Differences in Immune Cell Populations in Progression Toward Systemic Lupus Erythematosus

Aleksandra Bylinska, Miles Smith, Samantha Slight-Webb, Carla Guthridge, Caleb Marlin, Kevin Thomas, Christian Wright, Marci Beel, Susan Macwana, Wade DeJager, Judith James and Joel Guthridge, Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Several groups of individuals are at higher risk for SLE, including those with African American ancestry (AA), lupus-associated autoantibodies (ANA+), or some clinical symptoms of SLE, termed incomplete lupus erythematosus (ILE). However, only a minority of ANA+ individuals develop autoimmune disease, and most ILE patients never progress

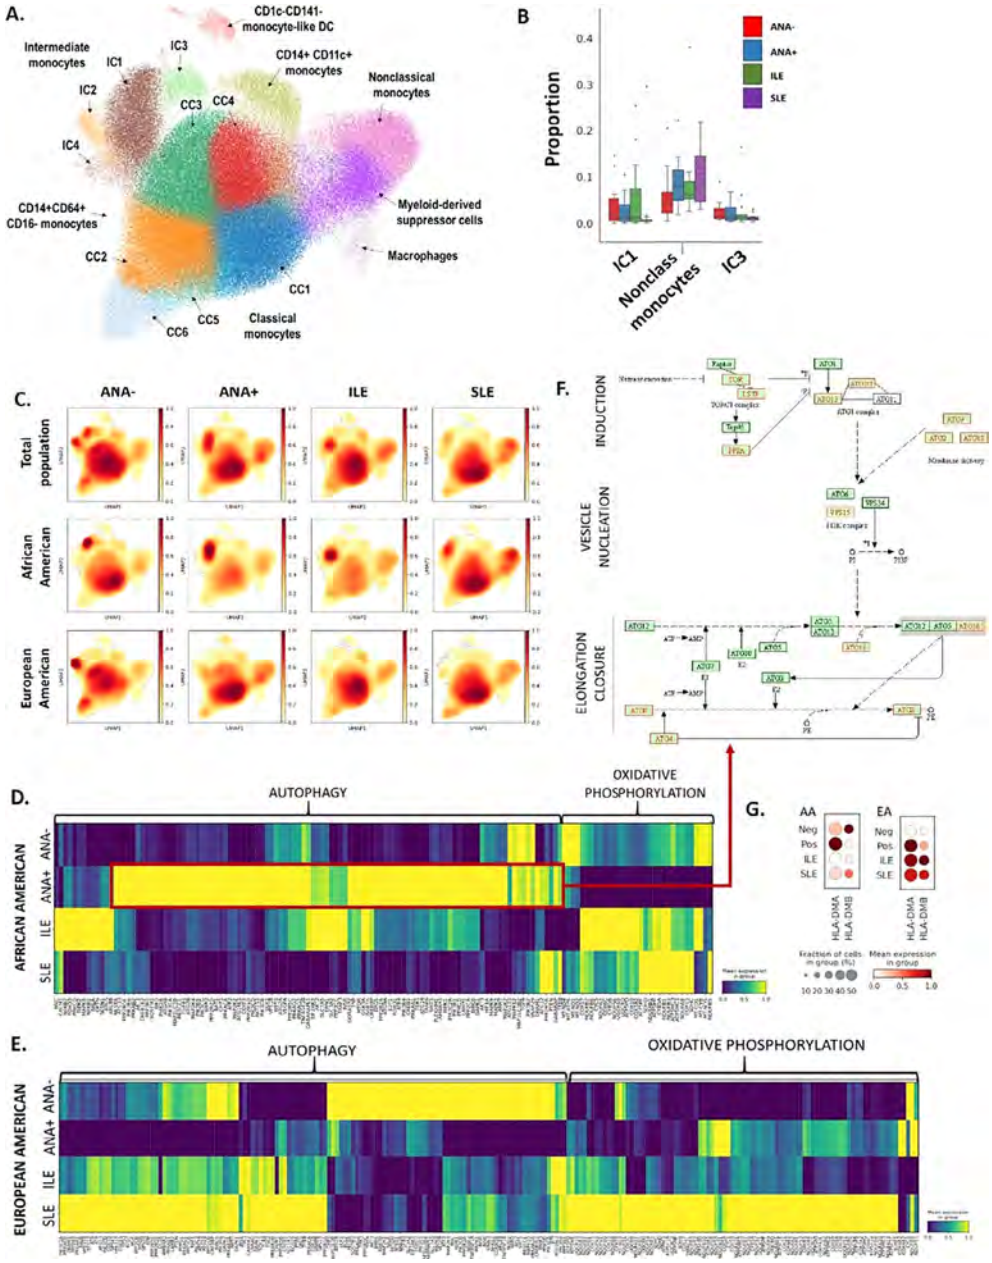

Fig.1. A. UMAP projection of distinct myeloid clusters. B. Cell fractions for distinct cluster by disease group. C. Density of myeloid cell total population and by ancestry across 4 disease groups. D, E. Expression of genes involved in autophagy and oxidative phosphorylation pathways by disease group for each ancestry. F. Autophagy pathway (genes expressed higher in AA ANA+ in red box) G. HLA-DM expression by ancestry and disease group.

to SLE. Metabolic pathways are known to be involved in myeloid cell dysregulation; however, whether they contribute to the progression of autoimmune disease remains unclear. This study determined whether alterations in myeloid and B cell population frequencies or activation of particular cellular processes are dysregulated in subjects at-risk of SLE.

Methods: PBMCs from 32 subjects from African (AA) or European ancestry (EA), divided evenly among healthy individuals (ANA-), healthy with autoantibodies (ANA+), ILE, and SLE. We performed multi-omic single-cell experiments (5' scRNA-seq/137-plex CITE-seq and BCR/TCR repertoire analysis) to assay for distinct disease-associated clusters, differential gene signatures and dysregulated pathways.

Results: We obtained profiles for 324,721 cells across all PBMCs. We identified 8 distinct myeloid (Fig 1A) and 7 B cell clusters across all subjects (Fig 2A). The proportion of cells in each cluster varied by disease group and ancestry (Fig 1B,C, 2B). The proportion of nonclassical monocytes was higher in SLE with variations between ANA+ and ILE (Fig 1B,C). Intermediate monocyte fractions were lower in SLE (Fig 1B,C). Fractions of naïve B cells were already higher in EA ANA-, while memory B cells are higher in AA ANA+ and EA ILE, EA SLE (Fig. 2B). Analysis of differentially expressed genes revealed the importance of metabolic processes in both cell types, such as autophagy and oxidative phosphorylation that varied between ancestries (Fig 1D-E, 2D-E). A discrete part of autophagy pathway is upregulated in myeloid cells of AA ANA+, while a different set of genes is upregulated in AA ILE (Fig 1D). Autophagy profile is detected earlier in EA; its progression is observed along disease transition and cell states (Fig 1E). Specific autophagy-related genes are already upregulated in EA ANA-. Oxidative phosphorylation pathway is downregulated in AA ANA+ but upregulated in AA ILE and AA SLE (Fig 1D). In EA, upregulation was mainly observed in SLE patients (Fig 1E). Involvement of antigen presentation pathways and altered expression of

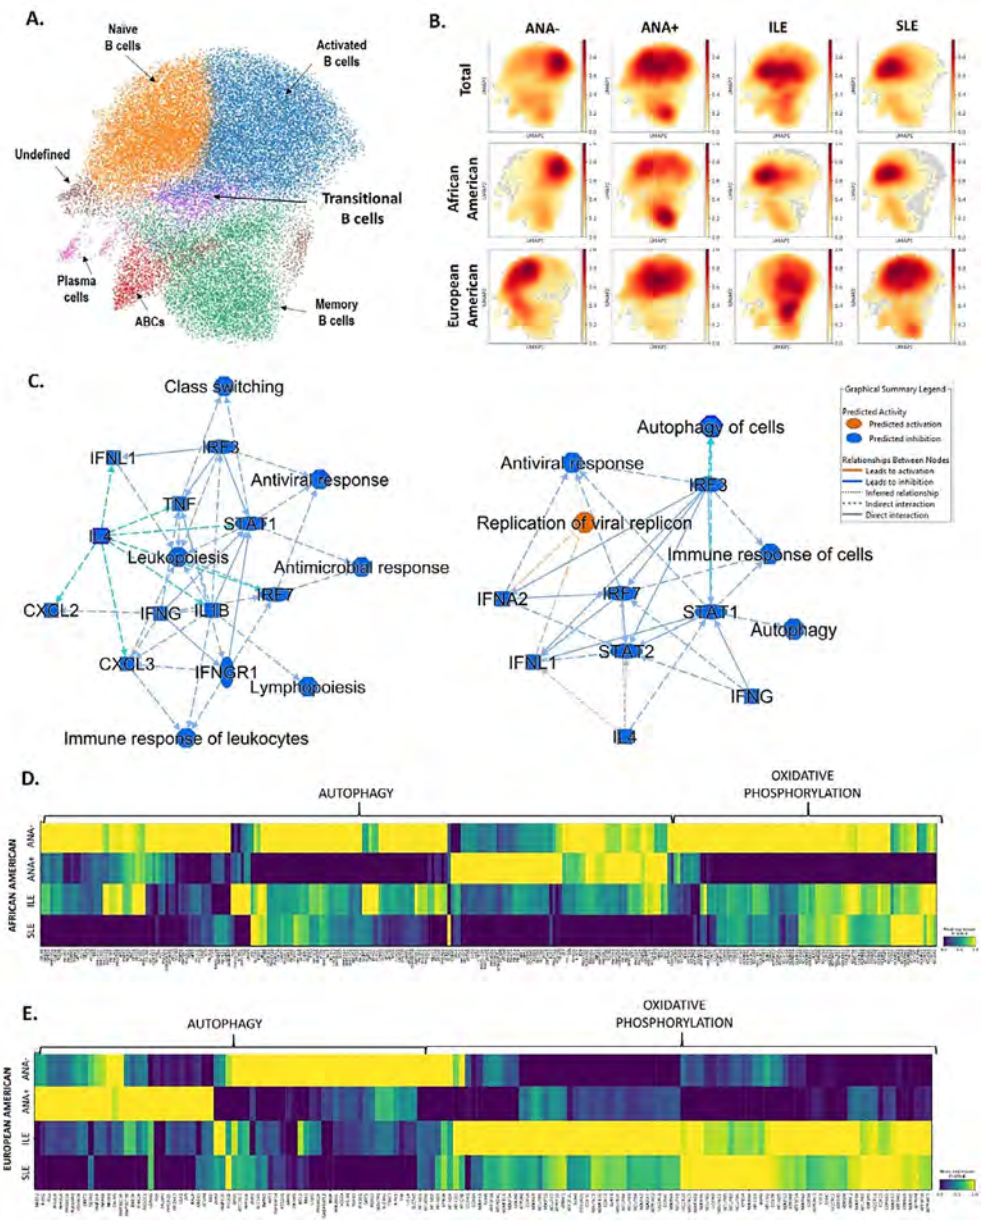

Fig.2. A. UMAP projection of distinct B cell clusters. B. Density of B cells total population and by ancestry across 4 disease groups. C. Graphical summary of pathways and transcription factors involved in B cell dysregulation. D, E. Expression of genes involved in autophagy and oxidative phosphorylation pathways by disease group for each ancestry.

HLA-DM were detected in AA, which might be related to autophagy dysregulation (Fig 1F, G). Oxidative phosphorylation pathway is upregulated in B cells of EA ILE and EA SLE (Fig. 2E), however it is downregulated in AA ANA+ (Fig. 2D). We found additional signatures in B cells suggestive of the activation of pathways related to antiviral response, class switching and lymphopoiesis, as well as the involvement of transcription factors (IFN, TNF, IL4, STAT) in SLE (Fig.2C).

Conclusion: Dysregulation of oxidative phosphorylation and autophagy pathways in both monocyte and B cell populations is suggestive of a preclinical autoimmunity development trajectory. Alterations of these processes may vary by ancestral background, reflecting the heterogeneity of SLE presentation and trajectory.

A Complex Interplay Among Gut *Lachnoclostidium*, HLA Haplotype DRB1*07:01, and the TNF Superfamily in Anti-Ro+ Women with a Spectrum of Preclinical and Clinical Autoimmunity Whose Children Have Neonatal Lupus

Robert Clancy[1], Caroline Izmirly[1], Miranda Marion[2], Nicola Fraser[1], Joel Guthridge[3], Timothy Howard[2], Peter Izmirly[4], Mala Masson[5], Jill Buyon[1], Judith James[3] and Carl Langefeld[6], [1]NYU Grossman School of Medicine, New York, NY, [2]Wake Forest University, Winston-Salem, NC, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]New York University School of Medicine, New York, NY, [5]New York University, New York, NY, [6]Wake Forest University School of Medicine, Winston-Salem, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Mothers of children with neonatal lupus (NL) are often clinically asymptomatic or have insufficient criteria for a formal rheumatologic diagnosis, despite having high titers of autoantibodies to Ro60 and 52. That some women never progress, while others transition to SLE or SS, provides a unique opportunity to identify early drivers of disease. Informed by quantifications of cytokine levels in army recruits who develop lupus, TNF superfamily factors are posited to drive progression from benign preclinical to clinical autoimmunity.While many factors have contributed to this model, the gut microbiome and its interplay with HLA haplotypes (class II, in particular) are understudied. Here, we test the specific hypothesis that levels of three cytokines (BAFF, TNFRI, TNFRII) vary as a function of gut *Lachnoclostridium* abundance and DRB1*07:01 status in anti-Ro+ NL mothers who have progressed to clinical disease.

Methods: Anti-Ro+ NL mothers (n=59) who carried the allele of interest (DRB1*03:01 at HLA, Figure, Panel A) had 16S microbiome sequencing of stool samples. Taxa relative abundances, including that of *Lachnoclostridium*, were center log ratio (CLR) transformed, hereafter referred to as relative abundance, consistent with the compositional nature of 16 S data.BAFF, TNFRI, and TNFRII were assayed using a validated multiplex bead-based (xMAP) approach in serum from NL mothers with a blood sample drawn near the time of stool specimen collection and who had HLA genotyping.

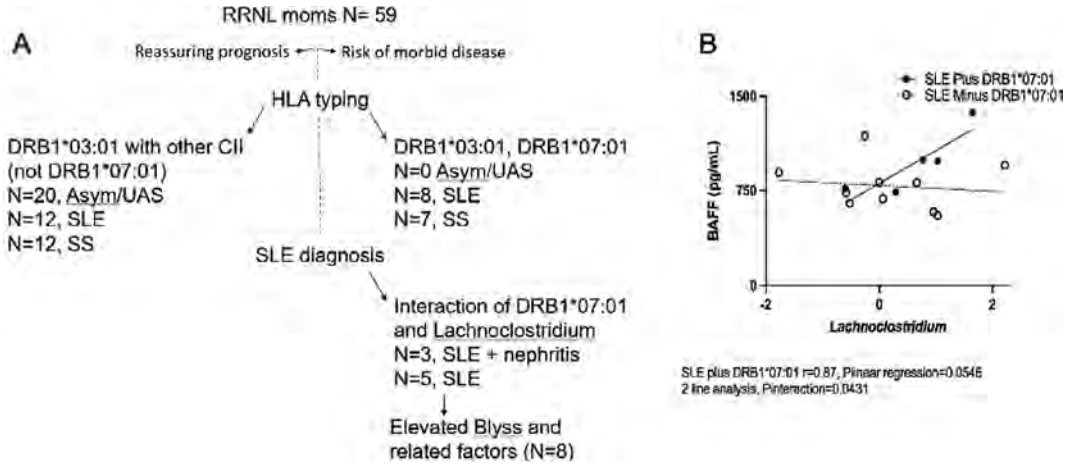

Figure. Panel A. Flow diagram of the various diseases and alleles. Panel B. Quantifications of the TNF superfamily factors (BAFF is shown, similar data with TNFRI and TNFRII) in NL mothers who develop lupus, in context of gut Lachnoclostridium and HLA haplotype.

Results: In addition to carrying DRB1*03:01, the HLA Haplotype also included DRB1*07:01, which was reported in 8/20 NL mothers with SLE and 7/19 NL mothers with SS (Figure, Panel A). Of those with SLE, 4 had lupus nephritis (LN) with 3 carrying DRB1*07:01 while only 5/16 without LN carry DRB1*07:01. In contrast to SLE and SS, DRB1*07:01 was not observed in NL mothers with preclinical disease (0 of 20; asymptomatic/undifferentiated autoimmune syndrome, Asym/UAS). Serologic levels of BAFF, TNFRI, and TNFRII were notable in the NL mothers with SLE versus subjects in the SS and Asym/UAS groups. Specifically, for TNFRI, levels (pg/mL) of 1255, 1265, and 1160 correspond to SLE, SS, and Asym/UAS, respectively.In addition there was an enrichment of SLE with DRB1*07:01 (1321 pg/mL). *Lachnoclostridium* relative abundance was positively associated with levels of BAFF, TNFRI, and TNFRII in NL mothers who carry DRB1*07:01 but not in those without DRB1*07:01 (with r values of 0.87, 0.79, 0.55, respectively, Figure, Panel B). NL mothers diagnosed with SS (N=19) did not show a parallel trend as that of those diagnosed with SLE.Specifically, those with SS had comparable TNFRI levels within groups that were stratified by DRB1*07:01 haplotype.*Lachnoclostridium* did not exhibit an association with DRB1*07:01, suggesting a dichotomy of clinical disease for NL mothers.

Conclusion: These results suggest a path to discriminate anti-Ro-positive SLE patients with a reassuring prognosis from those at risk of morbid disease based on the complex interplay between DRB1*07:01 and *Lachnoclostridium* abundance. Further, NL mothers who are DRB1*07:01 positive may trigger a higher relative abundance of *Lachnoclostridium,* leading to a cascade of events toward clinical disease.

Session Title: SLE – Etiology & Pathogenesis Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the involvement of B cells in the pathogenesis of immune-mediated diseases, the biological mechanisms underlying their function are poorly understood. To address this gap, we constructed and investigated a large-scale repertoire catalog of five B cell subsets from patients with immune-mediated diseases, including systemic lupus erythematosus (SLE).

Methods: We mapped B cell receptor regions from RNA sequencing data of sorted B cell subsets. Our dataset consisted of 595 donors with immune-mediated diseases and healthy individuals. We characterized the repertoire features from various aspects, including their association with immune cell transcriptomes and clinical features, as well as their response to belimumab treatment.

Results: In healthy individual, gene usage preference among 5 B cell subsets was observed. Principal component analysis (PCA) of VDJ gene usage revealed clear separation according to cell types, suggesting B cell development based on VDJ gene segments. In 136 SLE patient, VDJ gene usage was skewed, particularly in plasmablasts and unswitched-memory B cells. We developed a scoring system, repertoire naiveness (RN) score, to assess this skewing. RN scores in plasmablasts and USM B showed significant positive correlations with SLEDAI-2K. Moreover, RN score positively correlated with peripheral helper T (TPH) cell transcriptomic signatures and negatively correlated with the amount of somatic hypermutations in plasmablasts, suggesting an association with the extra-follicular pathway. Furthermore, this skewing led to increased usage of IGHV4-34 in unswitched-memory B cells, with its usage showing a significant positive correlation with disease activity in SLE. Mediation analysis indicated that over one-half of the association between RN scores in USM B and SLEDAI-2K was mediated by IGHV4-34 usage. Notably, belimumab treatment ameliorated gene usage skewing in unswitched-memory B cells, but not in the other subsets. These results were consistent with our previous functional genome analysis of ImmuNexUT dataset that indicated the association between generic risk of SLE and unswitched memory B cells (Ota M et al. Cell 2021;184:3006-3021).

Conclusion: Our multimodal repertoire analysis revealed the importance of unswitched-memory B cells in the pathogenesis of SLE.

Abstract Number: 0929

Persistent Up- or Down-regulation of SOCS1 Exacerbates the Pathogenesis of Systemic Lupus Erythematosus Through Several Mechanisms

Reiko Takahashi and Yoshitaka Imura, Medical Research Institute KITANO HOSPITAL, PIIF Tazuke-Kofukai, Osaka, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SOCS1 (suppressor of cytokine signaling 1) is a suppressor molecule of the JAK/STAT pathway and has been reported to be involved in the pathogenesis of SLE. T cell-specific or regulatory T cell (Treg)-specific *Socs1*-deficient mice exhibited lupus pathology with enhanced Treg plasticity, which rapidly lost the expression of Foxp3 through DNA hypermethylation of the Foxp3 promoter/enhancer and produced high levels of inflammatory cytokines (Takahashi R et al., J Immunol. 2017, Takahashi R et al., J Exp Med. 2011). In addition, loss-of-function mutant lineages of SOCS1 have recently been found to develop SLE and other diseases (Nature (2020, Nat Commun (2020)). In the present study, we examined whether the pathogenesis of SLE is suppressed in T-cell specific *Socs1* transgenic (*Socs1* Tg) mice.

Methods: Imiquimod cream was administered on the ear of age-matched 8-week-old female wild-type (WT) mice and *Socs1* Tg mice every other day for up to 8 weeks, as reported previously. Pathological and immunological analyses of the spleen, lymph nodes, and kidneys of these mice were performed. Tregs and non-Tregs ($CD4^+CD25^-$ effector cells) from *Socs1* Tg or WT mice with or without induction of lupus pathology were isolated using a cell sorter and analyzed. Peripheral blood lymphocytes of SLE patients were analyzed by gene transfer of *Socs1*.

Results: In the *Socs1* Tg mice, the lupus-like phenotype was worse than when lupus was induced in WT mice by DNA antibody measurements and pathological analysis. To analyze those mechanisms, we first analyzed Treg function and found that *in vitro*, Tregs from *Socs1* Tg mice had a more stable suppressive function than Tregs from WT mice, even under inflammatory conditions, by preventing plasticity. *In vivo*, in lupus-induced WT mice, Tregs from *Socs1* Tg mice suppressed lupus pathology more potently than those from WT mice. Furthermore, similar experiments in lupus-induced *Socs1* Tg mice

showed that lupus pathology could not be suppressed with the same amount of Tregs derived from WT or *Socs1* Tg mice as in lupus-induced WT mice, but could be suppressed by transplanting a sufficient amount of Tregs from *Socs1* Tg mice. Next, analysis of non-Tregs in *Socs1* Tg mice showed that they were activated and reduced in number in the spleen and lymph nodes, with cytokine production such as IL-17A, which was emphasized in the induction of lupus pathology. As a further cause of the reduction in non-Tregs, non-Tregs of *Socs1* Tg mice were observed to decrease IL-7 receptor expression and increase apoptosis, which was accentuated in the induction of lupus pathology. Finally, *Socs1* expression in peripheral blood lymphocytes of SLE patients did not show a characteristic relationship with lupus activity. However, transfection of *Socs1* into lymphocytes from SLE patients promoted apoptosis in some patients but was not related to the production of IFNγ or IL-17A.

Conclusion: Both sustained up- or down-regulation of SOCS1 cause changes in $CD4^+$ T cells through different mechanisms and exacerbate the pathogenesis of lupus. The importance of further exploring these pathological mechanisms to understand the dynamics of SOCS1 expression in SLE patients and to search for factors that regulate this dynamics is suggested.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Many genetic variants are associated with lupus nephritis (LN). Yet, the majority of associated variants have a small effect size; hence, they convey small risk. Polygenic risk scores (PRS) provide a unique opportunity to aggregate an individual's genetic risks. PRS are a weighted sum of genome-wide genetic risk load for an individual such that multiple variants, including variants that do not meet genome-wide cutoff, are included. We hypothesize that PRS constructed using multiple variants, along with demographic and clinical variables, are predictive of LN outcomes such as the CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) estimated glomerular filtration rate (eGFR) and end-stage kidney disease (ESKD).

Methods: Subjects with LN were genotyped using Illumina Global Screening Array V3. Ancestry was determined using principal component analysis of the genotyped data. PRS for systemic lupus erythematosus (SLE) and CKD were constructed using multi-ancestry SLE and CKD base GWAS using the clumping and thresholding (C+T) approach. The base SLE Immunochip study included 11,590 SLE cases and 15,984 controls, and the base CKD GWAS study used eGFR as outcome and included 1,201,909 individuals. Relationships between SLE and CKD PRS with CKD-EPI eGFR and ESKD were assessed using multivariable linear and logistic regression models, adjusting for ancestry, sex, age at SLE diagnosis and history (yes/no) of hypertension, diabetes, and smoking.

Results: 653 individuals (87.3% female, 19.4% smokers, 9.8% diabetic and 55.2% hypertensive) were considered in the study. Genotyping PCA identified 46.6% African American, 27.9% European American, 13.1% Argentinian, 9.6% Mexican, and 2.9% Asian individuals. Mean (SD) age at SLE diagnosis was 26.7 (11.9) years. Mean (SD) CKD-EPI eGFR at last visit was 71.0 (41.4) mL/min/1.73m^2; 86 (16.3%) individuals developed ESKD. 529 individuals were included in the final analyses following quality control and exclusion of individuals of Asian ancestry due to small sample size. Following C+T, approximately 23K SNPs were retained for both eGFR and ESKD PRS computation using SLE base data, and 482K SNPs were retained using CKD base data.

Lower eGFR was associated with higher SLE PRS (β = -8.45; 95% CI: -12.9, -3.97), older age (β = -0.44; 95% CI: -0.77, -0.12) and history of hypertension (β = -18.9; 95% CI: -27.6, -10.1); CKD PRS and ancestry were not associated with eGFR. Similarly, increased odds of ESKD were associated with higher SLE PRS (OR: 1.59; 95% CI: 1.08, 2.38), higher CKD PRS (OR: 2.61; 95% CI: 1.39, 5.01), and history of hypertension (OR: 3.01, 95% CI: 1.37, 7.12). Additionally, African American ancestry had higher odds of ESKD relative to European American (OR: 11.3; 95% CI: 2.51, 56.0) or Argentinian ancestry (OR: 9.54; 95% CI:1.92, 55.1).

Conclusion: SLE and CKD PRS are associated with LN outcomes like eGFR and ESKD and can potentially be used to identify those at risk for kidney deterioration and eventual damage. Adding assessment of genetic risk score for disease monitoring can allow physicians to focus on patients expected to do poorly and employ targeted as well as kidney-protective therapies earlier.

Down-Regulation of Human NADH-Ubiquinone Oxidoreductase Chain 6 by N6-Methyladenosine Methylation Is Associated with Lupus CD4+ T Cell Activation

Miheraiy Abdukiyum[1], Nan Zhao[2], Yuanyuan Zheng[1], Tohtihan Alim[3], Xiaojun Tang[1] and **Xuebing Feng**[2], [1]Department of Rheumatology and Immunology, Nanjing Drum Tower Hospital Clinical College, Nanjing University of Chinese Medicine, Nan Jing, China, [2]Department of Rheumatology and Immunology, Nanjing Drum Tower Hospital Clinical College, Nanjing University of Chinese Medicine, Nanjing, China, [3]Nanjing University, Nanjing, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently mitochondria have been recognized as a key player in the pathogenesis of systemic lupus erythematosus (SLE). Given that N6-methyladenosine (m^{6}A) modifications can regulate almost all aspects of RNA metabolism, such as splicing, stability, structure and translation, and are directly related to T cell function, in order to clarify the impact of epigenetic regulation on mitochondrial function, in this study, we focused on m^{6}A-associatedmitochondrial abnormalities and their effects on lupus CD4+ T cells.

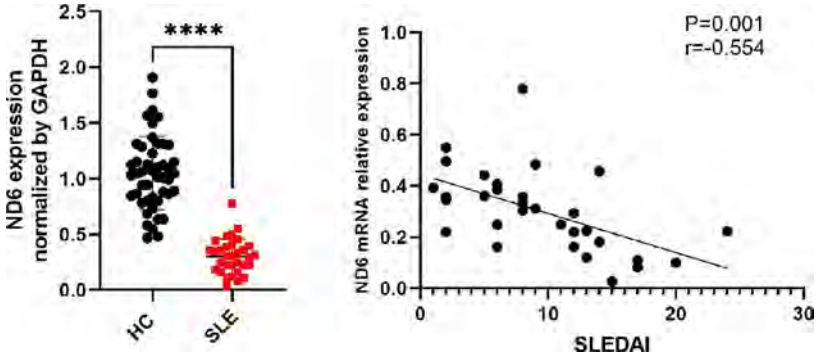

Figure.1 MT-ND6 expression decreased in PBMCs from SLE patients and was associated with SLE disease activity index score.

Methods: MethylatedRNAimmunoprecipitation sequencing (MeRIP-seq) was performed using peripheral blood mononuclear cells (PBMCs) from SLE patients and healthy controls to screen for mRNA with abnormal m6A modification and differential expression. The expression of human NADH-ubiquinone oxidoreductase chain 6(MT-ND6)in PBMCs from SLE patients and healthy controls was verified by quantitative real-time polymerase chain reaction (qPCR) and western blot, and analyzed for the correlation with clinical variables. The effects of MT-ND6 on T cell mitochondrial function were clarified by detecting reactive oxide species, mitochondrial reactive oxide species, mitochondrial membrane potential (MMP) and adenosine triphosphate (ATP). To observe the effects of MT-ND6 silencing on CD4+ T cells, small interfering RNA (siRNA) was designed and added into *in vitro* cultures.

Results: MeRIP-seq identified 370 differentially expressed genes with increased or decreased m6A methylation in lupus, including mitochondrial gene MT-ND6. Independent sample validation showed that both mRNA and protein levels of MT-ND6 in PBMCs from SLE patients were significantly lower than that of healthy controls. MT-ND6 mRNA expression was negatively correlated with SLE disease activity index score **(Figure 1)** ($r=-0.55$, $p=0.001$) and 24-hour urine protein level ($r=-0.57$, $p< 0.05$), and was lower in patients with positive anti-Sm or anti-dsDNA antibodies. The expression of MT-ND6 in CD4+ T cells from lupus patients was also significantly decreased compared to healthy controls and was accompanied by significantly increased ROS and mtROS levels, decreased mitochondrial membrane potential and insufficient ATP production. Consistently, when silencing MT-ND6 in CD4+ T cells, ROS and mtROS were significantly increased, while mitochondrial membrane potential and ATP production were reduced.After gene silencing, the levels of IFN-γ and T-bet in CD4+ T cells were significantly increased, and the levels of key inflammatory pathway factors, including STAT4, AP-1 and NF-κB, were all increased.

Conclusion: Low expression of MT-ND6 in lupus can lead to mitochondrial dysfunction, thereby activating CD4+T cells. Our result may provide new therapeutic targets for the treatment of autoimmune diseases.

The Landscape of Immune Cells in Systematic Lupus Erythematosus Patients with Epstein-Barr Virus Infection by Single-cell Sequencing

Lingzhen Hu[1], Jianxin Tu[1], Jiajun Gui[2], Mengyuan Fang[2], Xiaowei Chen[1] and Li Sun[1], [1]The First Affliated Hospital of Wenzhou Medical University, Wenzhou, China, [2]The First Clinical College, Wenzhou Medical University, Wenzhou, China

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: This study aimed to analyze the immune cell profiles, especially B cells and B-cell receptor (BCR) of systematic lupus erythematosus (SLE) patients with or without Epstein-Barr virus (EBV) infection, and to identify the differences between the two groups.

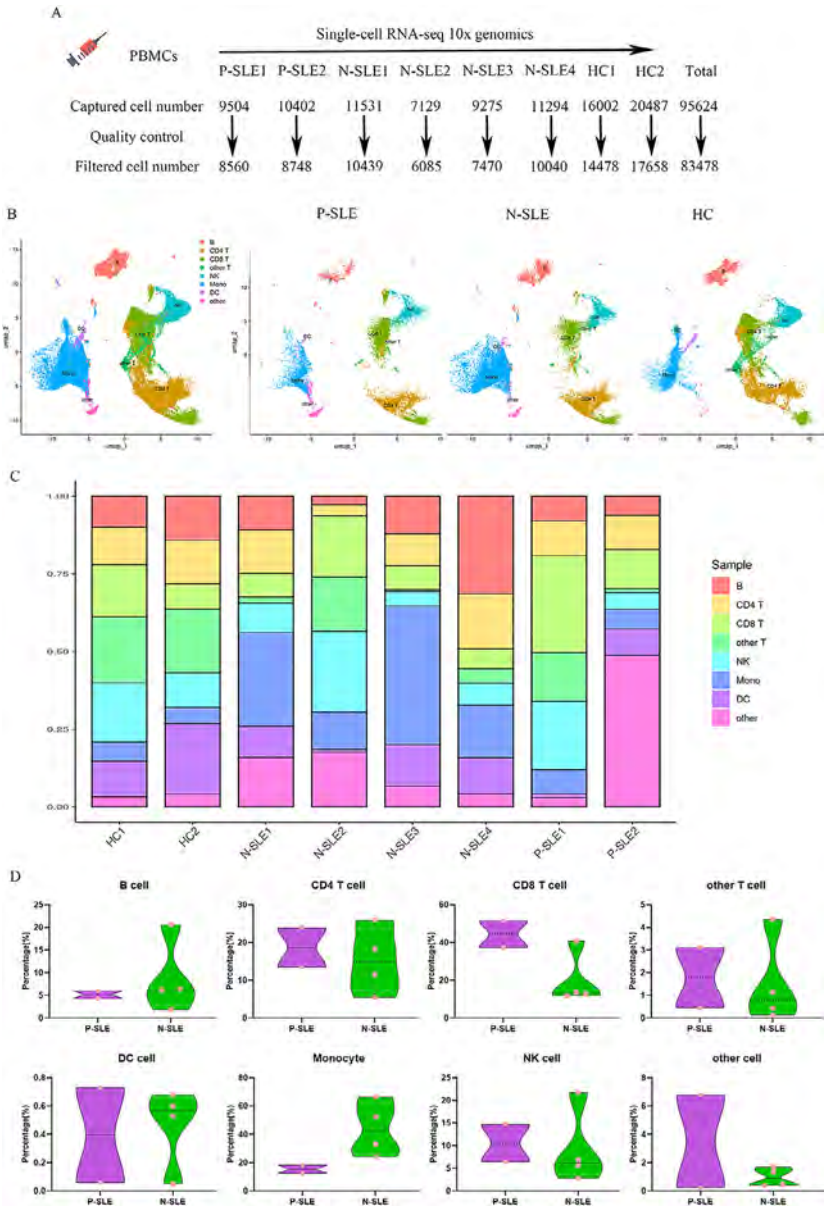

Figure 1. Study design and single-cell transcriptional profiling of PBMCs from HCs and SLE patients with or without EBV. A. The schematic shows the study design. B. Cellular populations identified from 2 P-SLE, 4 N-SLE, and 2 HC, showing the formation of 8 clusters with the respective labels. Each dot corresponds to a single cell, colored according to cell type. C. A UMAP plot representing the 8 clusters across 83478 PBMCs from 8 individuals (2 P-SLE, 4 N-SLE, and 2 HC). The cluster labels were added manually. D. Violin plots comparing the proportion of each cluster between P-SLE(n=2) and N-SLE(n=4). The results for P-SLE are shown in purple, and those for N-SLE are in green, each dot corresponds to a sample. The P values were calculated using a Wilcoxon test.

Methods: We included 2 cases of SLE patients with EBV infection (P-SLE), 4 cases of SLE patients without EBV infection (N-SLE), and 2 cases of healthy controls (HC). Using single-cell RNA sequencing (scRNA-seq) to interrogate the heterogeneity of cell populations by combining the transcriptomic profile and BCR repertoire.

Results: 83478 cells were obtained in our study and were divided into 8 major cell types or subtypes, including B cells, CD4+ T cells, CD8+ T cells, other T cells, natural killer (NK) cells, monocytes, dendritic cells (DCs) and other cells. There is no significant difference in the proportion of cell clusters between P-SLE and N-SLE. Interferon-alpha/beta pathways were upregulated in T cells, monocytes, and B cells in P-SLE compared with N-SLE. B cells were further divided into four different clusters, including naive B cells, intermediate B cells, memory B cells, and plasmablast. For V gene segments in the heavy

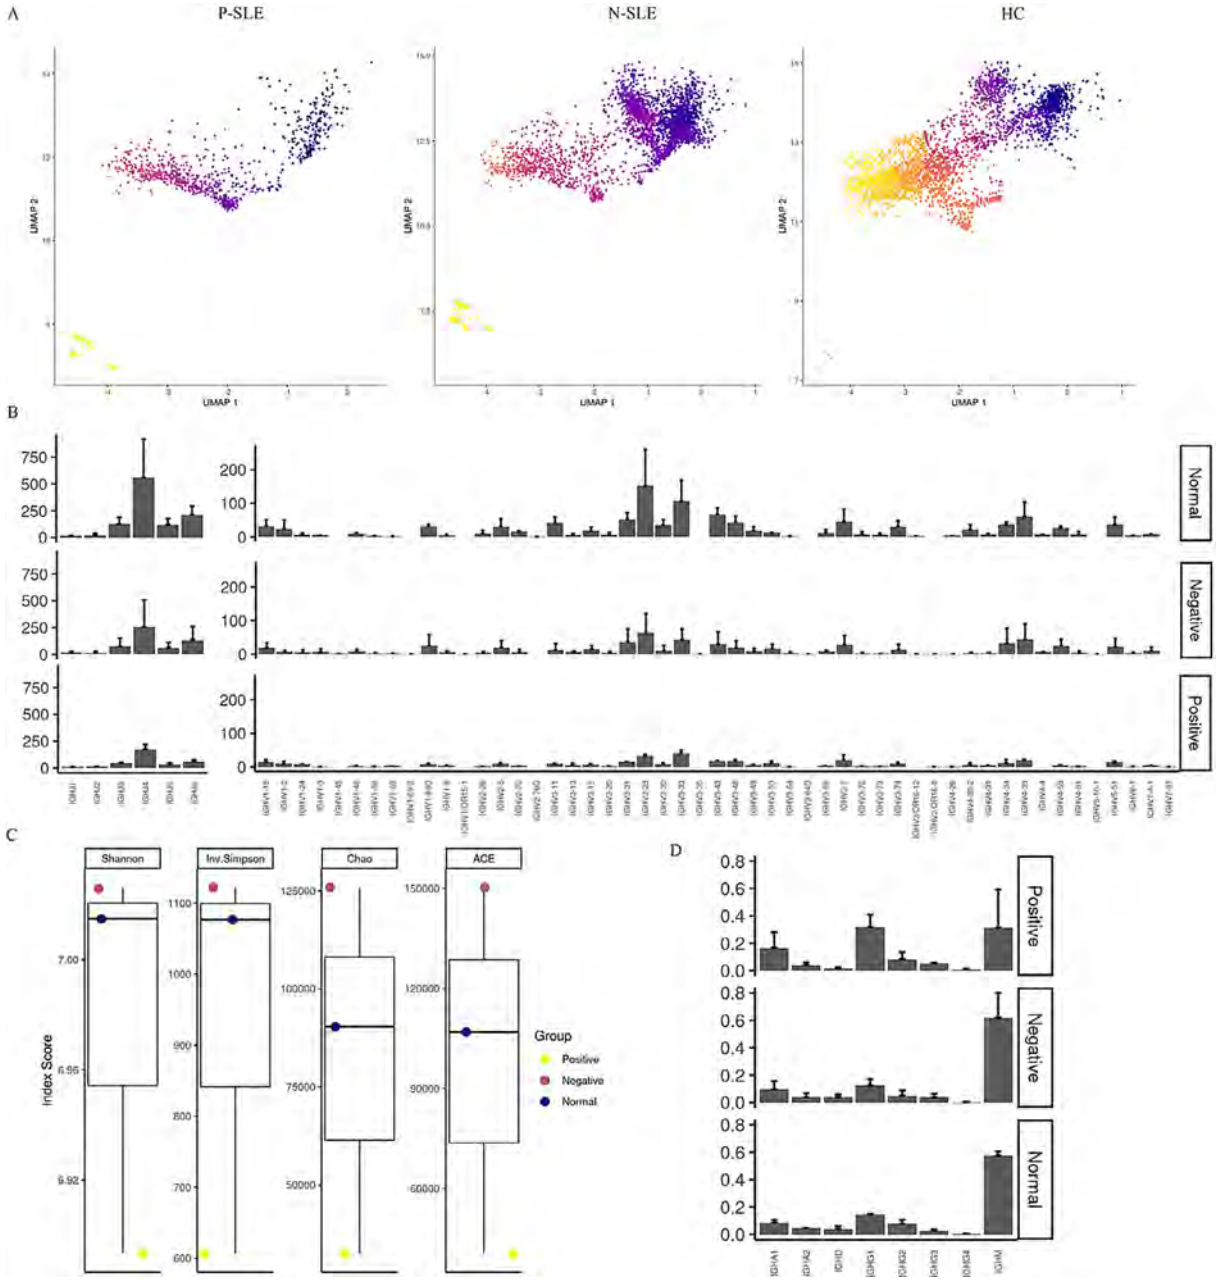

Figure 2. Comparison of B cells single-cell landscapes and BCR between P-SLE, N-SLE, and HC. A. UMAP plots representing four B cell clusters with the respective labels. B. Comparison of variable (V) and joining (J) gene usage in BCR heavy chain between three groups. C. The clonal diversity of P-SLE, N-SLE, and HC. D. Analysis of Ig isotypes in three groups.

chain, IGHV3, IGHV4, and IGHV2 gene families were frequently used in both patients and HC, especially IGHV3 and IGHV4 families. However, the frequencies of gene segments in each IGHV family were significantly different between the three groups. We also found that the BCR diversity was significantly reduced in P-SLE compared with N-SLE and HC. Moreover, IgM presents the largest proportion in all BCR repertoire, but its proportion was significantly decreased in P-SLE patients. We also observed that the proportions of IgG1, IgG3, and IgA1 were significantly increased in P-SLE than that in HC or N-SLE.

Conclusion: Our study provides a comprehensive characterization of the immune cell profiles and BCR repertoire in SLE patients with or without EBV infection, which contributes to the understanding of the mechanism for the immune response to EBV infection in SLE patients.

The 'Sweet' in Lupus - IgG Glycosylation in Lupus Nephritis

Rhea Bhargava[1], Rohit Upadhyay[2], Scott Wenderfer[3], Jing Chen[2] and George Tsokos[4], [1]Tulane University, New Orleans, LA, [2]Tulane University School of Medicine, New Orleans, LA, [3]University of British Columbia, Vancouver, BC, Canada, [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Etiology & Pathogenesis Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) occurs in 50% of patients with systemic lupus erythematosus (SLE) for which we lack biomarkers, and an understanding of its pathogenesis. We have previously demonstrated that IgG in LN is aberrantly glycosylated and can injure podocytes.

Methods: We evaluated the IgG glycome by N-glycan profiling in a pediatric cohort of 40 children with SLE and 20 paired pre and post treatment LN samples using LS-MS Mass Spectrometry. We used enzymatic treatments to evaluate the role of glycans in podocyte injury. Data were analyzed using GEE analysis, Spearman test, t-test and regression analysis. Podocyte phenotype was evaluated by wound healing assay, cytoskeleton evaluation (F-actin) and podocyte specific proteins by RT-PCR and western blotting.

Results: We found that the overall glycosylation was reduced 6 months post treatment in patients with LN. Furthermore, those decorated with terminal galactose were increased while those with terminal sialic acid were reduced. In addition, neutral glycans were increased after treatment while negatively charged glycans were decreased. To evaluate whether these differences were due to treatment rather than LN activity, we analyzed the IgG glycome in SLE without LN, LN, LN in remission 6-month after treatment. We found that neutral glycans and negatively charged glycan chains changed with LN activity. Furthermore, the presence or absence of sialic acid and galactose correlated with parameters that influence active nephritis (renal SLEDAI, dsDNA, C3, cellular crescents and proteinuria). A switch from tri to bi -antennary complex type N-Glycans was noted in those with decling GFR. More interestingly, treatment of IgG with PNGase- F, which removes glycan chains, prevented cytoskeleton and motility changes in podocytes that were induced in LN. In addition, nephrin expression was preserved following PNG-ase treatment.

Conclusion: The IgG glycome in pediatric SLE patients is altered and is further aberrantly glycosylated in LN. The magnitude of change is associated with LN activity. More importantly, the glycans on IgG can lead to podocyte injury in LN. Our data shed light on the role of IgG glycosylation in the development of podocyte injury and propose the development of approaches using the IgG glycome to diagnose and monitor LN. Further, it highlights IgG glycosylation as an important pathogenic mechanism in LN.

Anti-fibrotic Effects of MT-5562, a Novel Potent Selective Autotaxin Inhibitor, in Preclinical Studies: Roles of Lysophosphatidic Acid in Autoimmune Diseases and Clues to Treat Skin and Lung Fibrosis in Systemic Sclerosis

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Targeted small-molecule therapies to autotaxin (ATX), the lysophosphatidic acid (LPA)-producing enzyme, have been shown to be potentially effective in systemic sclerosis (SSc), but the clinical benefit and safety of selective inhibition remains unclear. To explore the potential of MT-5562, a novel oral selective inhibitor of ATX, as a therapeutic agent for SSc, its efficacy and toxicity in preclinical models were evaluated. Furthermore, the levels of LPA in plasma derived from patients with autoimmune diseases including SSc were also investigated.

Methods: We examined the inhibitory effects of MT-5562 and its free form (MT-5562F) in comparison to other autotaxin inhibitors such as ziritaxestat and cudetaxestat on ATX activity using the choline assay. We also investigated the effects of MT-5562F on the production of IL-6 and connective tissue growth factor (CTGF) by human dermal and lung fibroblasts stimulated with TGF-β. The effects of MT-5562F on skin and lung fibrosis were evaluated using murine SSc models induced by bleomycin (BLM) and the plasma concentrations of MT-5562F and LPA were also determined. The plasma levels of LPA in SSc patients (n=70) were compared with those of healthy controls (n=45) or patients with other autoimmune diseases including rheumatoid arthritis (n=69), systemic lupus erythematosus (n=37) and Sjögren's syndrome (n=18).

Results: MT-5562F, ziritaxestat, and cudetaxestat inhibited the enzyme activity of human ATX with IC50s of 0.45, 49.3, and 2.77 nmol/L, respectively. MT-5562F and ziritaxestat inhibited the enzyme activity of mouse ATX with IC50s of 0.15 and 10.9 nmol/L, respectively. MT-5562F concentration-dependently inhibited production of IL-6 and CTGF by human

fibroblasts stimulated with TGF-β. MT-5562 showed minimal effects on cell viability measured by live cell counting even at the maximum dissolved concentration (60 μmol/L). On the other hand, ziritaxestat showed more cytotoxic effects than MT-5562 on cell viability in vitro. MT-5562 did not show off-target inhibition in receptor binding and kinase profiling assays. In vivo, MT-5562F and ziritaxestat (10, 30 mg/kg) dose-dependently reduced plasma LPA C18:2concentrations in mice, and MT-5562F showed more sustained effects on LPA reduction compared with ziritaxestat. Therapeutic treatment with MT-5562F (30, 60 mg/kg, b.i.d.) significantly reduced skin thickening and the numbers of myofibroblasts in the subcutaneous BLM-induced therapeutic skin fibrosis model. In addition, MT-5562F (30, 60 mg/kg, q.d.) significantly decreased the average Ashcroft score and collagen severity score in the BLM-induced lung fibrosis model in parallel with the reduction of LPA concentration. A total of 5 different LPA species were detectable in plasma derived from patients with autoimmune diseases. Most of the LPA species had significantly higher levels in the plasma of SSc patients compared to other autoimmune diseases.

Conclusion: Our results suggest that multiple LPA species are elevated in plasma of SSc patients and that MT-5562 is a selective and potent ATX inhibitor with a good preclinical safety and efficacy profile. It may offer a good option to treat lung and skin fibrosis in SSc, which has to be analyzed in clinical trials.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systematic sclerosis (SSc) is an autoimmune disease characteristic by fibroblast transition and overproduction of extracellular matrix, yet with limited treatment. Recent studies provided evidence that aberrant fibroblast activation is at least in part due to mitochondrial dysfunction and associated metabolic changes. Sodium pyruvate is the stable form of pyruvate acid that works as a central hub in several key metabolism pathways including glycolysis, tricarboxylic acid (TCA) cycle, and fatty acid metabolism. In this study, we tested the hypothesis that supplementation with pyruvate may compensate several of the metabolic defects in SSc to improve mitochondrial fitness and that this metabolic rebalancing may dampen fibroblast activation and fibrotic tissue remodeling in SSc.

Methods: The effect of sodium pyruvate on metabolism, mitochondrial fitness, collagen synthesis and fibroblast-to-myofibroblast transition was evaluated in cultured human dermal fibroblasts from SSc patients and controls, in mice with bleomycin-induced dermal fibrosis and precision cut human skin slices. Outcomes included metabolic flux assays, real-time PCR, IF and IHC stainings, cellomics, histomorphometry, hyodroxyproline assays, RNA-seq analysis and datamining of published transcriptomic data of SSc skin.

Results: Several key regulatory components of pyruvate metabolism such as MPC1, PC and PDK2, were found to be dysregulated in the skin of SSc patients compared to matched healthy individuals in the PRESS cohort. Treatment of SSc fibroblasts with sodium pyruvate improve OXPHOS metabolism and the mitochondrial potential. Of note, these metabolic changes upon pyruvate supplementation were associated with a reduced expression of fibrotic related genes including *COL1A1* and *ACTA2*, of markers of myofibroblasts and decreased synthesis of extracellular matrix. Pyruvate supplementation also showed prominent antifibrotic effects at well tolerated doses in mice with bleomycin-induced dermal fibrosis with 55% change reduced dermal thickening, decreased hydroxyproline content of the skin and lower myofibroblast numbers. Moreover, treatment with pyruvate also reduced the expression of profibrotic genes including *COL1A1* and *ACTA2* in human skin as an *ex vivo* trial approach.

Conclusion: Sodium pyruvate, which as available as a nutrient supplementation, improves metabolic defects and improves mitochondrial fitness to inhibit fibroblast-to-myofibroblast transition and collagen in human dermal fibroblasts, in experimental murine models of fibrosis and directly in human skin. Pyruvate supplementation may thus by one of the first examples of a metabolically-directed, antifibrotic therapy and may offer potential for further evaluation in clinical studies in SSc.

Impaired DNA Repair Responses Activate a Novel FOXO1-dependent Metabolic Remodelling in Patients with Progressive Systemic Sclerosis to Promote Fibrosis

Lamia Khan, Desiree Redmond, Muhammad Elezzabi, Robert Gniadecki, Jan Willem Cohen Tervaert and Mohamed Osman, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a deadly disease characterized by immune dysregulation, vasculopathy, and fibrosis. SSc is the most lethal rheumatic disease associated with the poorest quality of life. The extent of skin fibrosis may predict internal organ involvement. The cells promoting skin fibrosis in SSc are human dermal fibroblasts (HDFs) which develop a myofibroblast (MFB)-phenotype, senescence-like-features, and resistance-to-apoptosis. We recently showed that increased genomic instability associated with double-stranded DNA breaks (DSBs) and senescence like features are present in rapidly progressive diffuse (dcSSc) HDF. In cancer, dysregulated DSBs and senescence-like-features are associated with activation of the transcription factor, forkhead box protein O (FOXO1) to promote metabolic remodelling. Therefore, we hypothesized that DSBs promotes FOXO1 activation to promote fibrosis.

Methods: Primary HDFs were generated from healthy volunteers (HC), less severe early limited (lcSSc, < 2 year disease duration), and severe dcSSc 4 mm skin biopsies (< 2 year disease duration). All our SSc patients met 2013 ACR/EULAR inclusion criteria. DSBs were quantified by measuring γ-H2AX (a DSB marker) via immunoblots (IB) and immunofluorescence/confocal microscopy (IF). Nuclear FOXO1-translocation, MFB differentiation and fibrotic markers were measured using IF, IB and qRT-PCR. HC HDFs were treated with DNA damage-inducing agents (e.g. etoposide), then nuclear FOXO1 and the MFB marker alpha-SMA were quantified using IB and IF. Pro-fibrotic signals were measured in dcSSc HDF following FOXO1 inhibition.

Results: dcSSc HDFs had the highest levels of γ-H2AX compared to HC (*p< 0.05) and lcSSc patients. They also had a substantially higher nuclear accumulation of FOXO1 which was associated with increased mRNA expression of the FOXO1 transcriptional target, pyruvate dehydrogenase kinase 4 (*p< 0.05). FOXO1 inhibition resulted in decreased fibrotic-markers and *PDK4* (*p< 0.05) in dcSSc HDF. Etoposide treatment promoted FOXO1 activation, MFB differentiation, and PDH phosphorylation.

Conclusion: DSBs are more commonly present in HDF from dcSSc patients, which may promote MFB differentiation, resistance-to-apoptosis and fibrosis. We propose that FOXO1 activation may promote a downstream metabolic remodelling and an associated senescence like signal that promotes cell survival, and propagation of acquired genomic mutations with associated downstream inflammatory signals. Our findings provide mechanistic insights that may impart a deeper understanding for the role(s) of DSB-associated FOXO1 activation in promoting fibrosis in SSc. They may also have far-reaching implications related to the development of novel therapeutic strategies in SSc.

IL-4+ and IFN-α+ Profibrotic T Cells Aggravate Systemic Sclerosis via STIM1/STING Signaling in SKG Mice

Ji Won Yang[1], Kun Hee Lee[2], Jin Seok Woo[2], Ha Yeon Jeong[2], JeongWon Choi[2], Eui-Jong Kwon[1], Mi-La Cho[2] and Sung-Hwan Park[1], [1]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea, [2]Rheumatism Research Center, Catholic Research Institute of Medical Science, College of Medicine, The Catholic University of Korea, Seoul, South Korea

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SS), also known as scleroderma, is a chronic autoimmune disease caused by inflammation, tissue fibrosis, and vasculopathy. Although the pathological mechanisms of SS are unclear, proinflammatory cytokines, such as IL-4 and IL-17, and the tissue microenvironment are important factors in its development. In this study, we aim to investigate whether T cells induce fibrosis in SS and assess the effect of simultaneous regulation of T cells and fibroblasts via dedicated signals.

Methods: SKG mice, T cell-mediated autoimmune murine models originated from a spontaneous point mutation in ZAP70, and BALB/c mice (control) were subcutaneously injected with bleomycin (BLM) to induce SS-like phenotypes including fibrosis. The degree of fibrosis, and expression levels of inflammatory or profibrotic cytokines were determined by histological assessments using immunohistochemistry and confocal microscopy. Potential molecular mechanisms related to T cell activation were determined in the same mice both in vitro and ex vivo. The profibrotic effects of human T cells were evaluated using a humanized murine SS model induced by peripheral blood mononuclear cells (PBMCs) from SS patients.

Results: Dermal thickness and expression of fibrosis markers in skin tissue were increased in BLM-treated SKG mice compared to control mice. Infiltration of T cells, particularly Th2 and Th17 cells and expression of related cytokines were increased in skin tissues from BLM-treated SKG mice than those from controls. In CD4+ T cells from SKG mice, the STING pathway including downstream factors such as STAT6 and IRF3 was activated, subsequently resulting in increased populations of IL-4 and IFN-α-producing CD4+ T cells. IL-4 and IFN-α directly promoted fibrosis in skin fibroblasts via the STING pathway. Increased fibrosis and infiltration of IL-4 and IFN-α-producing CD4+ T cells were replicated in humanized mice induced by PBMCs from SS patients. Lastly, pharmacological inhibitions of STING as well as STAT6 reduced fibrosis in the murine models.

Conclusion: Our findings suggest that STING-induced production of IL-4- and IFN-α by CD4+ T cells is a key factor of pathological fibrosis in SS. The STING and STAT6 signaling pathways can be potential therapeutic targets in SS.

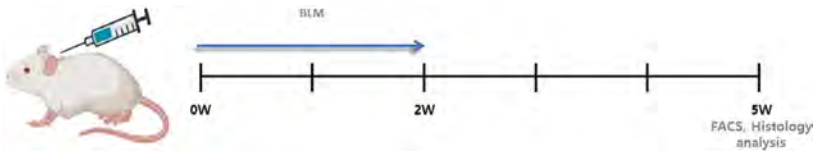

Fig 1. BALB/c and SKG mice were subcutaneously injected with BLM for 2 weeks, and euthanized 3 weeks after the final BLM treatment.

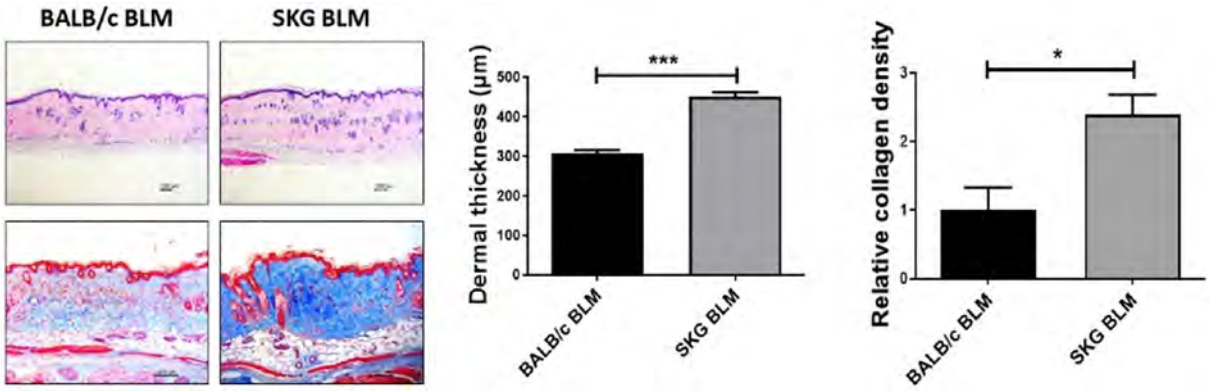

Fig 2. Skin thickness and fibrosis were increased in BLM-treated SKG mice compared to BLM-treated BALB/c mice.

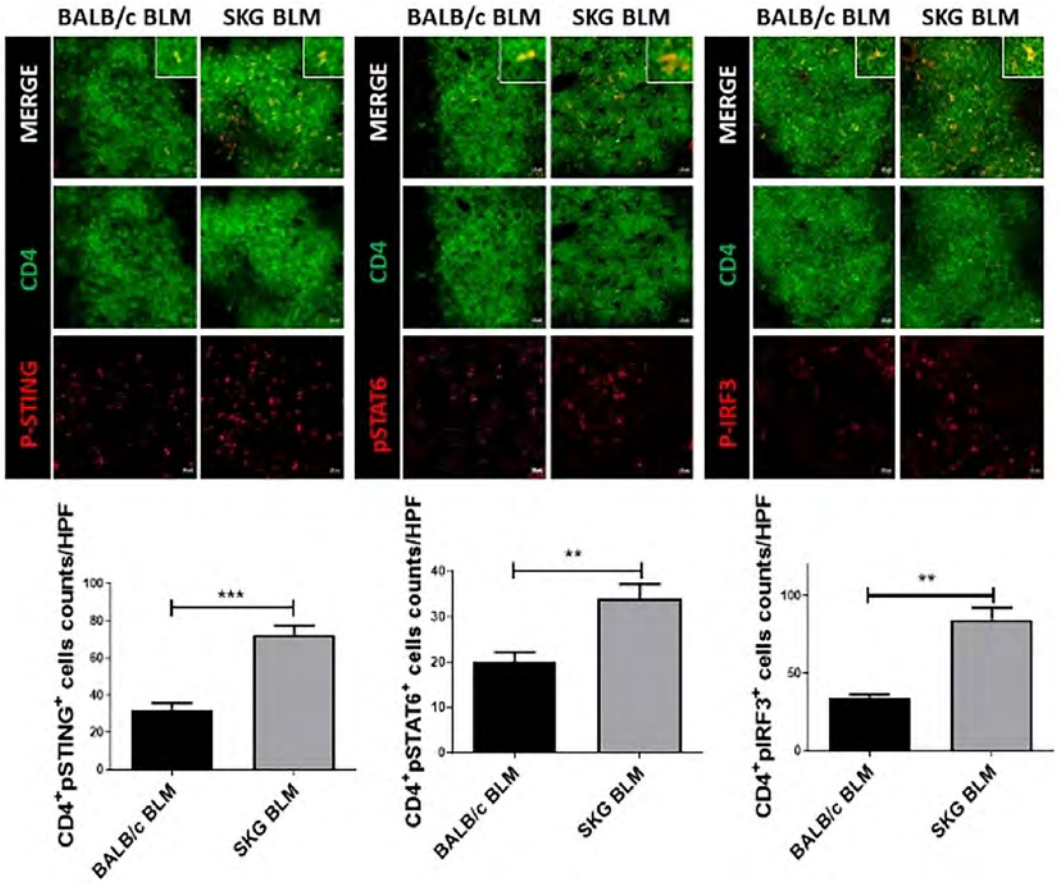

Fig 3. The STING pathway including downstream factors of CD4+ T cells in spleen tissue were activated in BLM-treated SKG mice.

Deconvolution of the Molecular Signature of Very Early Diagnosis of Systemic Sclerosis (VEDOSS) and Established Disease: A Biomarker Blueprint of Scleroderma Disease Continuum

Sunhwa Kim[1], Thierry Sornasse[2], Vishal Kakkar[3], Rebecca Ross[4], Yingtao Bi[5], Hengcheng Hu[2], Lisa Hazelwood[2], Lauren Reinke-Breen[6], jozsef karman[7], Chris Butler[2], Jennifer Van Camp[2] and Francesco Del Galdo[8], [1]AbbVie, Inc., South San Francisco, CA, [2]AbbVie, Inc., North Chicago, IL, [3]University of Leeds, Leeds, United Kingdom, [4]Medicine and Health, University of Leeds, Leeds, United Kingdom, [5]AbbVie, Inc., Worcester, MA, [6]AbbVie, Inc., Vernon Hills, IL, [7]AbbVie, Inc., San Francisco, CA, [8]University of Leeds - Leeds Institute of Rheumatic and Muskuloskeletal Medicine, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease that affects multiple organs asynchronously, leading to highly variable fibrotic damage and consequent increased morbidity and mortality. The significant heterogeneity of time, type and severity of organ involvement often challenges the robustness of short proof-of-concept (PoC) clinical studies. In this study, we integrate high-quality published skin omics datasets and new serum proteomics analysis to deconvolute molecular signatures of SSc over time and across clinical subsets.

Methods: We used the "*treat*" function from the LIMMA package to identify significantly differentially expressed genes (FDR ≤ .05) in affected early and late SSc skin (GSE130955, GSE58095, and GSE181549). These genes were further analyzed using algorithms of 1) overconnectivity, 2) causal reasoning, 3) hidden nodes, 4) interconnectivity, and 5) network propagation to identify key and significant network objectives (adjusted p ≤ .05). To identify the key affected pathways and processes, we conducted enrichment analysis using Gene Ontology and Metabase Pathway Maps and Networks. Olink Explore-1536 panel serum proteomics of patients spanning from VEDOSS (-2yrs from fulfilling Classification criteria) to late disease (>7years) allowed identification of independent and significant serum biomarkers ($p< 0.05$, $>Log_2 1$) of disease activity over time.

Results: The skin transcriptomics profiling revealed a unique set of genes (n=739 biomarkers) and network regulators (overconnected nodes with upregulated genes, n=119; causal reasoning, n=339, hidden nodes, n=89; interconnectivity, n=12; network propagation, n=208) in diffuse cutaneous SSc (dcSSc). Pathway analyses revealed significant dysregulation in inflammatory signaling (Jak-STAT, IL6, Chemotaxis, Interferon, and others) and fibroplasia (cell-matrix interaction, ECM remodeling, others) as unique for early dcSSc, whereas angiogenesis, connective tissue degradation, and blood coagulation pathways are dysregulated throughout the disease natural history and clinical subsets. Altogether, the analyses highlighted 6 biological elements as drivers and potentiators of SSc pathobiology. The analysis of the integrated VEDOSS and SSc cohort indicated that serum biomarkers of Type I IFN (STAT5, CCL5, IL10, TLR3) and inflammatory (PAI1, CCL2, IL6, vWF) signaling as well as epithelial damage (PRSS8, SFTPD, WFDC2, SFTPA1) showed continuity between patients at increased risk of progression to disease or to disease major complications over time (progressive skin and lung involvement).

Conclusion: Our comprehensive molecular profiling highlights the significance of skin and serum omics in defining a pathologic disease continuum in SSc, preceding fulfillment of classification criteria and remaining active through disease progression. The perseverance of inflammatory and epithelial damage biomarkers throughout time underlines the currently unmet therapeutic need of SSc and can be utilized to enrich patients with active disease progression and support a robust short PoC clinical study design.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Quantification of response to anti-fibrotic drugs in patients with fibrosing interstitial lung disease (ILD) relies on repeated pulmonary function tests (PFT) and visual evaluation of HRCT scans, which require long observation periods to achieve conclusive results. HRCT-derived radiomic features, capturing in-depth information of whole-organ properties without bias, may present a more sensitive approach for quantification of treatment response. Here, we studied if radiomic feature changes can classify response to treatment in experimental and human ILD.

Methods: Mice with bleomycin-induced ILD received nintedanib (n=10) or vehicle-only (n=13) from day 7 to 21. Lung μCT scans were acquired before and after treatment for calculation of delta radiomic features (n=1'386). Phosphoproteome profiles were measured in subsets to validate nintedanib target engagement. Whole-lung proteomics was performed in all sample for correlation with delta radiomics. Selected disease markers were measured by gene expression and immunohistochemistry analysis. Delta radiomic features classifying response in mice, as evaluated in univariate analysis, were validated in a nintedanib-treated ILD cohort (n=10), where pre- and post-treatment HRCT scans and PFT data were available. Response in patients was classified by FVC change ≤5% from baseline, resulting in a 5:5 class distribution. All statistical analyses were performed in R.

Results: Molecular readouts in mice indicated that response to nintedanib was heterogeneous, despite a clear separation on μCT-derived lung tissue density and on phosphoproteome level compared to vehicle treatment. Unsupervised hierarchical clustering of delta radiomic features in nintedanib-treated mice revealed two stable clusters. On molecular level, these clusters exhibited differences on expression of fibrosis (*Col1a1*, *Col3a1*, *Fn1*) and drug-related (*Tgfb1*, *Timp1*, *Cxcl1*) targets, in addition to different levels of α-SMA+ myofibroblast and F4/80+ macrophage infiltration. As such, these clusters indicated presence of different treatment response profiles. To define the biological basis underlying cluster separation, we performed correlation analysis of the top discriminative delta radiomic features (AUC≥0.9, n=44) with matched proteomics profiles. Reactome pathway analysis of correlated proteins ($\rho \geq 0.6$, $p < 0.05$) revealed significant enrichment for multiple

pathways involved in ILD pathophysiology, including extracellular matrix remodeling and collagen/elastic fiber formation. Validation of the predictive radiomic features in our human cohort demonstrated good performance for treatment response classification (AUC≥0.6 in *n*=24 features), with two of the best performing features (AUC≥0.8) showing a strong association with fibrotic pathway activation in mice. Our results highlight that molecular changes are paralleled on radiomics level in experimental lung fibrosis and that they are translatable to human ILD.

Conclusion: HRCT-derived delta radiomic signatures may provide a powerful measure for early and accurate classification of patients benefiting from anti-fibrotic therapy.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) a complex and rare immune-mediated connective tissue disorder characterized by microvascular damage, inflammatory cell infiltration, and excessive deposition of extracellular matrix proteins (ECMs) resulting in fibrosis of the skin and internal organs. Like for many chronic inflammatory diseases dysfunctional macrophage activity is linked to the failure of initiating the resolution of inflammation programs and with that a main disease driver and a central part of disease progression in affected organs. The objective of our preclinical analysis, was to evaluate the therapeutic activity of an innovative secretome drug candidate Resolvix, which was developed from experimentally induced resolution type macrophages, in experimental models of SSc.

Methods: Two established inducible preclinical models of SSc (bleomycin (BLM) and HOCl) were used to monitor the impact of Resolvix on skin (thickness and collagen deposition), lung (leucocyte infiltration and alveolar macrophage efferocytosis) and lymphoid organs (Tregs) as well as selected plasma proteins. A single treatment at predetermined therapeutic

activity or respective controls were administrated intra-venously at 3 weeks post disease induction and mice were monitored daily and sacrificed for analysis after 3 weeks post treatment.

Results: In both models we could show a significant reduction of skin thickening and collagen deposition in skin samples after a single administration of Resolvix when compared to controls. Leucocyte infiltrates particularly evident in the HOCl model were significantly reduced by the Resolvix treatment in skin and lung tissues. Furthermore, Resolvix treatment restored the efferocytosis activity in alveolar macrophages collected from broncho-alveolar lavage (BAL) fluids that were significant reduced in these models as sign of uncontrolled ongoing chronic inflammation and recently reported in SSc patients. Efferocytosis capacities were restored to comparable levels as detected in healthy mice.

Conclusion: Collectively our preclinical data demonstrate that the pro-resolution factors harnessed from these specialized macrophages are able to durably revert skin fibrosing, control inflammatory cell infiltration and restore defective macrophage efferocytosis and function as a novel and advanced therapeutic approach in SSc. Resolvix may be considered as a next generation cell-free and disease modifying biological drug candidate for further development for the treatment of SSc.

RUNX1 Expression and Binding Site Accessibility Is Associated with Increased Disease Severity in Systemic Sclerosis

Rezvan Parvizi[1], Zhiyun Gong[1], Dillon Popovich[1], Tamar Abel[2], Helen Jarnagin[1], Madeline Morrisson[1], Tammara Wood[2], Jonathan Garlick[3], Monique Hinchcliff[4], Patricia Pioli[1] and Michael Whitfield[1], [1]Geisel School of Medicine at Dartmouth, Hanover, NH, [2]Dartmouth College, Hanover, NH, [3]Tufts University School of Dental Medicine, Boston, MA, [4]Yale School of Medicine, Westport, CT

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Runt-related transcription factor 1 (*RUNX1*) is a member of the core-binding factor family that regulates proliferation, differentiation, and cell survival in multiple cell lineages. Activation of *RUNX1* in fibroblasts has been implicated in wound healing and a network analysis of transcription factor (TF) activity suggested that it is a key regulator in diffuse cutaneous systemic sclerosis (dcSSc) skin. Here, we analyze the specific contribution and function of *RUNX1* in systemic sclerosis (SSc) dermal fibroblasts.

Methods: *RUNX1* was analyzed in gene expression data from SSc forearm skin biopsies (GSE59787) and in single-cell RNA sequencing (scRNA-seq) data from Tabib et al. 2021 (GSE138669), and in SSc and control scRNA-seq and scATAC-seq data of 3D skin-like tissues. We further generated and analyzed genome-wide DNA methylation profiles and bulk ATAC-seq data to evaluate epigenetic state and genome chromatin accessibility of *RUNX1* in dcSSc-isolated fibroblasts. Fibroblasts in 2D and 3D skin-like tissues were treated with a selective *RUNX1* inhibitor, Ro5-3335 or siRNA against *RUNX1* followed by collagen contraction, proliferation assays and qRT-PCR for select target genes.

Results: Analysis of gene expression data from a cohort of 124 individuals revealed significant over-expression of *RUNX1* in skin biopsies of SSc patients. Correlation analysis demonstrated significantly increased expression of *RUNX1* and in patients with higher modified Rodnan Skin Score (mRSS) (r^2= 0.33, *p-value* = 4.4e-10) (Fig 1A, B). Analysis of scRNA-seq data from SSc and control skin showed enrichment of *RUNX1* in PDGFRA1/COL1A1 expressing fibroblasts subpopulations (Fig 1C). Analysis of scRNA-seq and scATAC-seq of *in vitro* 3D skin-like tissues showed increase expression and *RUNX1* binding site

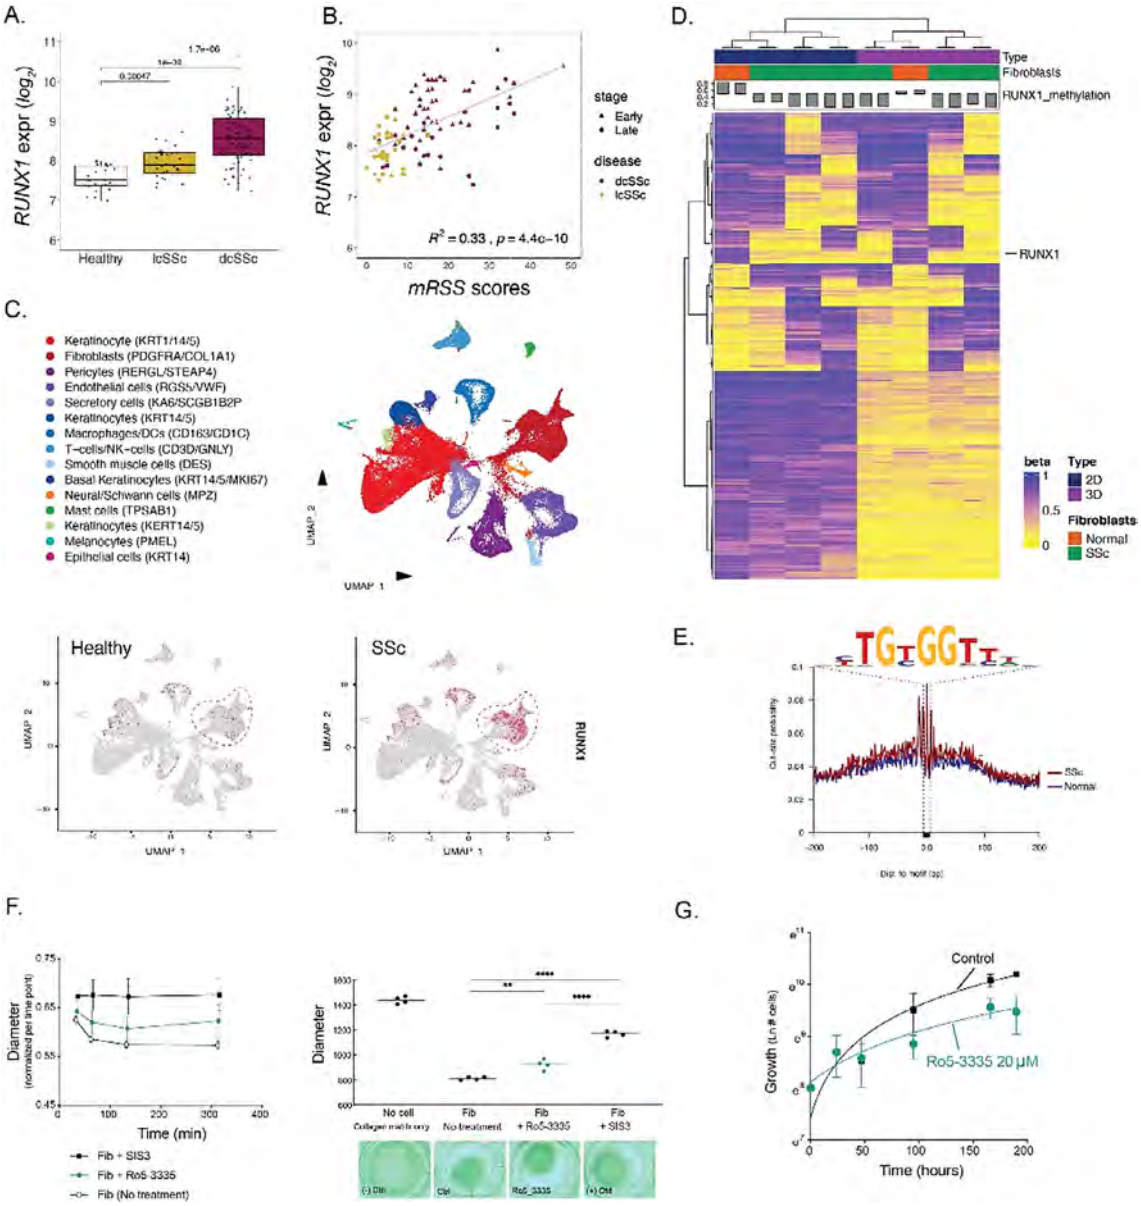

Figure 1. RUNX1 in Systemic Sclerosis Dermal Fibroblasts. A) RUNX1 expression in forearm skin biopsies of 24 healthy, 68 diffuse cutaneous systemic sclerosis (dcSSc), and 32 limited cutaneous systemic sclerosis (lcSSc) individuals. B) Pearson Correlation between RUNX1 expression and mRSS. Stage: Early, < 2 years; Late, >2 years of disease onset/diagnosis. C) UMAP projection of cell types from Tabib et al. 2021 single-cell RNA-Seq data from 10 healthy and 12 dcSSc forearm skin biopsies. Feature plots of RUNX1 is shown in heathy (left) and SSc (right) in red. Dash lines indicate fibroblast cluster. D) DNA methylation profile of 2D and 3D cultured fibroblasts that were isolated from dcSSc and healthy donors using Illumina's Infinium Methylation EPIC array. Heatmap shows top 593 methylated CpG sits with blue/yellow gradient of beta values. The bar-plot on top shows RUNX1 beta value that is labeled within the heatmap. E) Footprint profiles of RUNX1 in SSc (red) and healthy (blue) isolated fibroblasts. The consensus sequence of RUNX1 motif is shown. F) 3D collagen contraction assays, fixed (left) and floating (right) models, of normal human dermal fibroblasts treated with Ro5-3335 (RUNX1 inhibitor). SIS3 (SMAD3 inhibitor) was used as positive control and significantly eliminates the contraction ability of fibroblasts. (Student t-test P value: ** 0.001 to 0.01, **** <0.0001 in GraphPad Prism v.9). G) Normal human dermal fibroblast proliferation curve in presence and absence of Ro5-3335.

accessibility in ECM producing fibroblasts. DNA methylation profiling of isolated fibroblasts from dcSSc and healthy donors demonstrated hypomethylation of *RUNX1* in SSc fibroblasts (Fig 1D). Bulk ATAC-seq of dcSSc fibroblasts showed increased accessibility of *RUNX1* chromatin binding (Fig 1E), which facilitates TF binding. Inhibition of *RUNX1* activity by Ro5-3335 significantly reduced the ability of dermal fibroblasts to contract collagen gel matrices (Fig 1F) and reduced fibroblast proliferation rate (Fig 1G). *RUNX1* knockdown by siRNA resulted in statistically significant changes in αSMA, fibronectin (FN1) and COL1A1 expression.

Conclusion: These findings implicate *RUNX1* as a key regulator of ECM producing SSc fibroblasts. Our observations indicate a potential association between the severity of dermal fibrosis and *RUNX1* expression levels. Identifying hypomethylated CpG sites near the *RUNX1* gene suggests their potential involvement in the upregulation of *RUNX1* expression. Notably, our analysis of ATAC-seq data revealed higher accessibility of the chromatin region where *RUNX1* binding sites are located. Lastly, inhibition of *RUNX1* activity using Ro5-3335 caused a reduction in fibroblasts' contraction and proliferation rates, and the regulation of key genes implicated in SSc pathogenesis.

G Protein-coupled Receptor Kinase 5 in Fibrotic Tissue Remodeling

Cuong Tran-Manh[1], Thuong Trinh-Minh[1], Christoph Liebel[1], Chih-Wei Chen[2] and Joerg Distler[1], [1]Clinic for Rheumatology University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany; Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany, [2]3 Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany. 4 Deutsches Zentrum für Immuntherapie, Friedrich Alexander University Erlangen-Nürnberg and Universitätsklinikum Erlangen, Erlangen, Germany., Erlangen, Germany

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: G-protein coupled receptor kinase 5, GRK5, is a central regulator of G protein-coupled receptors (GPCRs), a vast family of cell surface receptors involved in a variety of physiological activities. GRK5 acts by phosphorylating GPCRs, causing desensitization and internalization. In addition, GRK5 exerts GPCR-independent effects and can enter the nucleus to modulate the expression of target genes. GRK5 has previously been implicated in the pathophysiology of inflammation and immunological responses, migration and invasion of cancer cells, neurodegenerative diseases and post-ischemic remodeling of the heart. However, its role in rheumatologic diseases and in particular in fibrotic tissue remodeling has not been investigated so far. Here, we tested the hypothesis that GRK5 might modulate the transcription of profibrotic target genes in fibroblasts to promote fibrotic tissue remodeling.

Methods: GRK5 expression was examined in SSc patients and experimental models of SSc using real-time PCR, Western Blot and immunofluorescence staining. GRK5 expression was modulated in vitro and in vivo with knockdown and knockout techniques and adenoviral overexpression. The antifibrotic efficacy of GRK5 inactivation was investigated in

three SSc animal models: bleomycin-induced dermal and bleomycin-induced pulmonary fibrosis and fibrosis produced by overexpression of a constitutively active TGF receptor type I (TBRI^{act}). Target genes of GRK5 in fibroblasts were identified by RNA-Seq.

Results: Increased mRNA levels and nuclear accumulation of GRK5 protein were observed in fibroblasts in fibrotic skin and lung samples compared to non-fibrotic control samples. GRK5 expression was also upregulated in murine models of SSc. TGFβ, but not the other profibrotic or proinflammatory mediators such as EGF, FGF9 or IL-1, induced GRK5 overexpression. Knockdown of GRK5 in fibroblasts reduced their sensitivity to the profibrotic effects of TGFβ with impaired fibroblast-to-myofibroblast transition and decreased collagen synthesis. Similarly, fibroblast-specific knockout of GRK5 demonstrated potent antifibrotic effects in the murine models of bleomycin-induced dermal and bleomycin-induced pulmonary fibrosis. In addition, GRK5 knockout mice were also protected from TBRI^{act}-induced fibrosis. Overexpression of GRK5 in fibroblasts, on the other hand, caused fibroblast-to-myofibroblast transition and collagen release. In a mouse model of bleomycin-induced dermal fibrosis, adenoviral overexpression of GRK5 exacerbated skin fibrosis. RNA-Seq unraveled GRK5 as a novel upstream regulator of numerous profibrotic genes including *COL1A1, ACTA2, CTGF* and *PAI-1*. Mechanistically, RNA-Seq also revealed that GRK5 modulated signal transducer and activator of transcription 3 (STAT3) and histone deacetylases (HDACs) activity to induce fibroblast activation.

Conclusion: We demonstrate that GRK5 is sufficient and required for fibroblast activation in response to TGFβ and serves as an upstream regulator of multiple profibrotic signals. Inactivation of GRK5 exerts potent antifibrotic effects in various preclinical models of SSc. Inactivation of GRK5 may thus offer potential as a target for antifibrotic therapies.

Attenuation of Fibroblast Activation and Fibrosis by Adropin in a Hedgehog-Dependent Manner

Minrui Liang and Joerg Distler, Clinic for Rheumatology University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany; Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Adropin is a secretory protein encoded by the energy homeostasis - associated (*ENHO*) gene. Emerging evidence indicate its role in metabolism and energy homeostasis, which is known to be deregulated in Systemic Sclerosis (SSc). However, Adropin / *ENHO* has not been linked to the pathogenesis of fibrosis, tissue remodeling or fibroblast activation so far. The aim of the current study was to investigate the role of Adropin / *ENHO* in the pathogenesis of fibroblast activation and fibrosis in SSc.

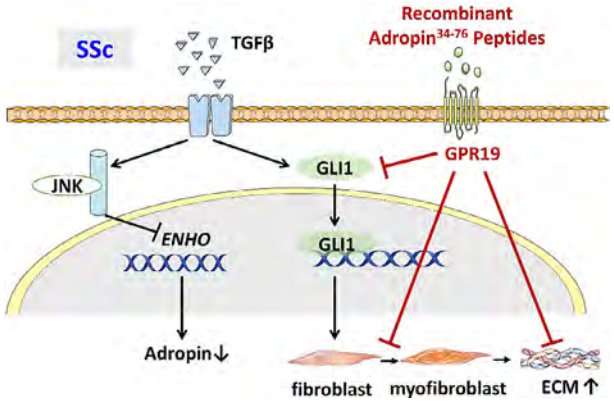

Figure 1. Proposed model of Adropin / ENHO signaling in TGFβ-stimulated fibroblasts and mode of action of Adropin34-76. The illustration was created by using images from Servier Medical Art (http://smart.servier.com/), licensed under CC BY 3.0 (https://creativecommons.org/licenses/by/3.0/).

Methods: Machine learning and bioinformatics models were used to identify candidate genes regulating fibroblast activation in SSc. The expression of Adropin / *ENHO* in skin samples of SSc patients and healthy individuals was analyzed by quantitative PCR, immunofluorescence and western blot, and validated by *in silico* data mining. The effects of Adropin were analyzed in cultured human fibroblasts, 3D skin equivalents, complimentary murine SSc models of sclerodermatous GvHD (sclGvHD) and bleomycin-induced lung fibrosis mice, and precision-cut human skin slices (PCSS). RNA sequencing (RNAseq) was performed to identify downstream regulatory pathways.

Results: Biostatistical screening of publically available datasets identified Adropin / *ENHO* as a potential molecular mediator involved in fibroblast activation with pronounced downregulation in SSc skin. We first confirmed the impaired expression of Adropin / *ENHO* in SSc patients and SSc models. TGFβ reduced Adropin / *ENHO* expression in a JNK-dependent manner. Recombinant Adropin peptides in turn inhibited TGFβ-induced fibroblast activation and subsequent fibrosis. Treatment of biologically active peptides Adropin$^{34-76}$inhibited TGFβ induced fibroblast activation and extracellular matrix (ECM) production in cultured primary dermal fibroblasts, in 3D skin equivalents, as well as in PCSS. Moreover, therapeutical administration of Adropin$^{34-76}$ in mice with preestablished fibrosis exerted potent antifibrotic effects in skin and lungs of two complimentary murine SSc models, sclGvHD and bleomycin-induced lung fibrosis mice. RNAseq demonstrated the antifibrotic effects of Adropin were functionally linked to hedgehog signaling and GLI1 deactivation, which experimentally confirmed *in vitro* and *in vivo*. Knockdown of *GPR19*, a putative receptor of Adropin, abrogated the therapeutic effect of Adropin on αSMA- and GLI1-expression in fibroblasts, indicating Adropin may regulate GLI1 signaling and fibroblast activation via GRP19.

Conclusion: We demonstrate a novel regulatory loop of Adropin / *ENHO* in TGFβ signaling: TGFβ inhibits the expression of Adropin / *ENHO*, while recombinant Adropin peptides inhibited fibroblast activation by GPR19-dependent inhibition of hedgehog / GLI1 signaling. Our findings characterize Adropin peptides as a potential approach to interfere with aberrant fibroblast activation and tissue fibrosis in SSc.

Macrophages Regulate Adipocyte Differentiation and Proliferation in Skin Fibrosis

Chanhyuk Park, Helen Jarnagin, Michael Whitfield and Patricia Pioli, Geisel School of Medicine at Dartmouth, Hanover, NH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune systemic sclerosis (SSc) is characterized by inflammation, vasculopathy, and dermal and internal organ fibrosis. A widely-reported but poorly understood aspect of SSc skin disease is the loss of hypodermal cutaneous fat or dermal white adipose tissue (DWAT), which precedes the onset of dermal fibrosis. While recent work suggests that reprogramming of adipocytic cells into activated, extracellular matrix-secreting myofibroblasts may account for the loss of DWAT and resulting fibrosis observed in SSc patient skin, the molecular mechanism that regulates this process has not been elucidated. Because we have shown that macrophages (MØs) from SSc patients secrete active TGF-β, which has been implicated in adipocyte-myofibroblast transition, we hypothesized that activated MØs in SSc modulate the differentiation and proliferation of adipocytes through release of secreted mediators, including TGF-β, leading to loss of DWAT and increased ECM deposition.

Methods: To assess the effect of MØs on DWAT deposition *in vivo*, we employed the bleomycin-induced mouse model of fibrosis and used a cellular immunotherapeutic approach to eliminate dermal MØs. To elucidate the potential mechanism by which activated MØs alter adipocyte differentiation, we developed an *in vitro* co-culture model. Adipose derived stem cells (ADSC) and bone marrow derived MØs (BMDM) were isolated from C57BL/6J mice. BMDMs were differentiated using GM-CSF, M-CSF, IL-4 and IL-13 or skin conditioned media (SCM). SCM was generated by subcutaneously implanting osmotic pumps with BLM for 7 days, harvesting the fibrotic skin, incubating the skin for 48 hours in media followed by collection of skin supernatant. ADSCs were differentiated into pre-adipocytes using media containing IBMX, dexamethasone, insulin, and rosigalitazone and co-cultured with differentiated BMDMs for 36 hours in Transwells. BMDMs and pre-adipocytes were collected for surface marker and gene expression analyses by flow cytometry and RT-qPCR. Cell supernatants were collected for analysis of secreted mediators by ELISA.

Results: Targeted elimination of dermal pro-fibrotic MØs in the bleomycin mouse model of fibrosis led to a restoration of DWAT. *In vitro* results demonstrated that expression of CD206 was increased on BMDMs differentiated with M-CSF, IL-4 and IL-13 and SCM, in contrast with GM-CSF. However, only BMDMs differentiated with SCM showed increased expression of IL-6, M-CSF, and IFNγ, which we have shown in prior studies are characteristic of SSc MØs. Furthermore, SCM-differentiated BMDMs secrete increased levels of TGF-β1 and inhibit adipogenesis.

Conclusion: Our results provide insight into a mechanism by which MØs modulate skin fibrosis through regulation of DWAT deposition. These findings suggest MØ-targeted therapies may be effective in ameliorating subcutaneous fat loss and potentially limiting excessive ECM deposition, particularly in combination with anti-fibrotic therapies.

The Nuclear Receptor TR4 Orchestrates Cytoskeletal Organization in a Gα12/ROCK-dependent Manner to Promote Myofibroblast Differentiation and Tissue Fibrosis in Systemic Sclerosis

Yun Zhang[1], Lichong Shen[2], yi-nan Li[1], Hermina Györfi[1] and Joerg Distler[1], [1]Clinic for Rheumatology University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany; Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany, [2]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Members of the superfamily of nuclear receptors have been implicated in inflammatory processes and pathologic tissue remodeling and have emerged as attractive targets for pharmaceutical intervention. However, the role of the testicular receptor 4 (TR4, also known as Nr2c2) in fibroblast activation and rheumatologic diseases has not yet been investigated.

Methods: TR4 expression in fibroblasts in the skin of systemic sclerosis (SSc) patients and in murine models of SSc were analyzed by immunofluorescence staining and Western blot. We performed bulk RNA sequencing (RNAseq) of TGFβ-stimulated fibroblasts with or without knockdown of TR4 by siRNA. The effect of TR4 on fibroblasts activation was studied using extracellular matrix staining. ROCK activity was quantified by ELISA in vitro. To confirm the findings, we applied TBRIact-, bleomycin-, cGvHD-induced dermal fibrotic as well as bleomycin-induced pulmonary fibrotic model in mice with fibroblast-specific-knockout of Tr4.

Results: Here we find that the expression of TR4 was upregulated in fibroblasts in the skin of systemic sclerosis (SSc) patients and in murine models of SSc. TGFβ stimulation induced the expression of TR4 in fibroblasts in a SMAD3-dependent manner. TR4 regulated numerous genes and functional terms associated with cytoskeletal remodeling. Knockdown of TR4 by siRNA prevented fibroblast-to-myofibroblast-transition, whereas plasmid-driven-overexpression of TR4 fostered TGFβ-induced fibroblast activation. Fibroblast-specific-knockout of Tr4 ameliorated skin fibrosis induced by overexpression of TBRIact, by bleomycin, associated with sclGvHD as well as bleomycin-induced pulmonary fibrosis. By RNA sequencing of TR4 target genes in fibroblasts and by analyzingthe functional role of ROCK and Gα12 using small molecule inhibitors and siRNA,we identified the profibrotic effects of TR4 were dependent on Gα12- and ROCK-associated cytoskeletal remodeling.

Conclusion: Our data indicate that TR4 is upregulated in SSc in a TGFβ-dependent manner to promote fibroblast activation. Inhibition of TR4 interferes with activation of ROCK, prevents cytoskeletal remodeling and fibroblast-to-myofibroblast transition and ameliorates dermal and pulmonary fibrosis. Inactivation of TR4 might thus offer therapeutic potential for the treatment of fibrosis in SSc and related diseases.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies (Aab) are frequent in systemic sclerosis (SSc). While recognized as potent biomarkers, their pathogenic role is unclear. Recently, we showed that immunoglobulins G (IgG) from SSc patients can modify the phenotype and secretome of fibroblasts (FB). The aim of this study was to gain a better understanding of the effect of purified IgG on FB by analyzing cytoplasmic and nuclear proteomic profiles.

Methods: Normal dermal FB (ATCC® Number: PCS-201-012 ™) were cultured in the presence of IgG from patients with diffuse cutaneous SSc (dcSSc, n=20), limited cutaneous SSc (lcSSc, n=10) or healthy controls (HC, n=10). Cytoplasmic and nuclear proteins were extracted and explored separately using mass spectrometry coupled with liquid chromatography.

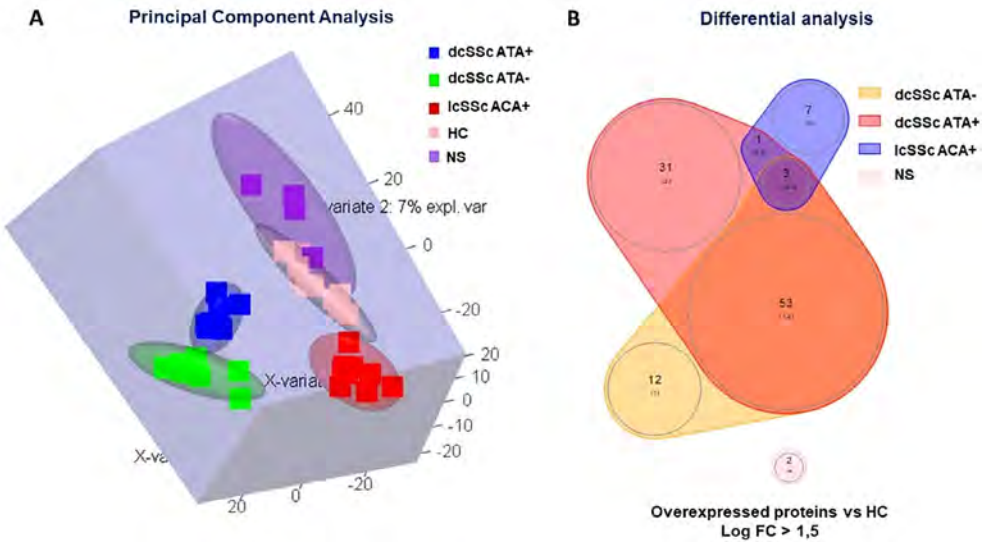

Figure 1: Cytoplasmic proteomics of FB in the presence of purified IgG from SSc patients and HC. Data visualization performed by principal component analysis (A); Venn diagram representing differential analysis vs HC (B). SSc: systemic sclerosis; dcSSc ATA+: diffuse SSc anti-topoisomerase-I positive patients; dcSSc ATA-: diffuse SSc anti-topoisomerase-I negative patients; lcSSc ACA+: limited SSc anti-centromere positive patients; HC: healthy controls; NS: non stimulated fibroblast. For differential analysis, proteins with p-value<0.05 and Log Fold Change > 1.5 were considered.

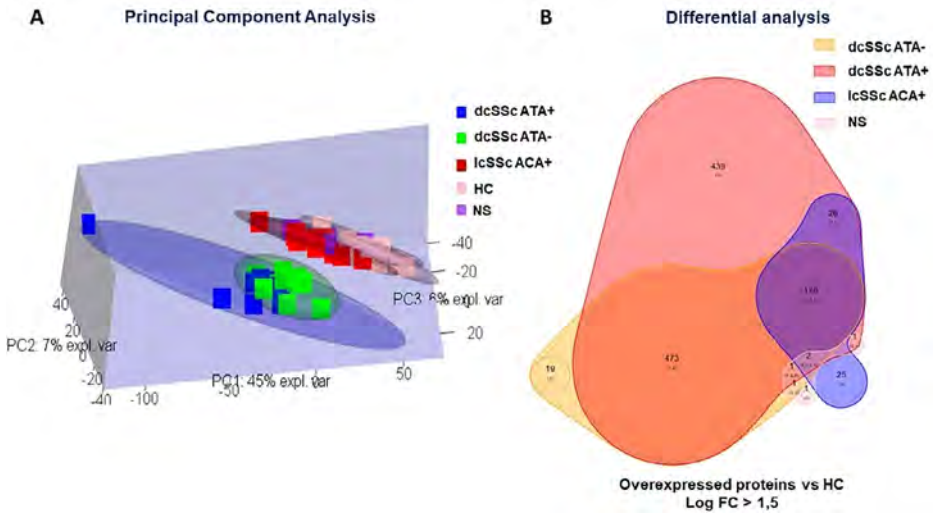

Figure 2: Nuclear proteomics of FB in the presence of purified IgG from SSc patients and HC. Data visualization performed by principal component analysis (A); Venn diagram representing differential analysis vs HC (B). SSc: systemic sclerosis; dcSSc ATA+: diffuse SSc anti-topoisomerase-I positive patients; dcSSc ATA-: diffuse SSc anti-topoisomerase-I negative patients; lcSSc ACA+: limited SSc anti-centromere positive patients; HC: healthy controls; NS: non stimulated fibroblast. For differential analysis, proteins with p-value<0.05 and Log Fold Change > 1.5 were considered.

Data were visualized using principal component analysis (PCA) and protein profile were studied by performing differential analysis and gene set enrichment analysis.

Results: Cytoplasmic proteomics identified and quantified 1,630 proteins. PCA revealed five groups of subjects according to cytoplasmic proteins expression: dcSSc anti-topoisomerase-I (ATA) positive patients (dcSSc ATA+) which appeared to be the most distinct group, dcSSc ATA negative patients (dcSSc ATA-), lcSSc anti-centromere (ACA) positive patients (lcSSc ACA+), healthy controls (HC) and non-stimulated FB (NS) (**Figure 1A**). Fifty-three proteins were commonly overexpressed in the dcSSc ATA+ and ATA- and five in all SSc subtypes. Thirty-one proteins were exclusively overexpressed in the dcSSc ATA+ condition compared to HC such as Leucine Reach Repeat Containing 15 and Tripartite Motif Containing 25 (**Figure 1B**). Nucleus proteomics identified and quantified 1593 proteins. PCA revealed two main groups of subjects according to protein expression: the first was composed of dcSSc patients and the second was composed of lcSSc ACA + patients, HC, and NS (**Figure 2A**). Four hundred and seventy-three proteins were commonly overexpressed in dcSSc conditions and 128 were commonly overexpressed in all SSc conditions compared to HC. A total of 439 proteins were exclusively overexpressed in dcSSc ATA+ such as Transgelin 2 and RuvB Like AAA ATPase 2 (**Figure 2B**).

Functional enrichment analysis revealed that cytoplasmic proteins overexpressed in the dcSSc ATA+ and dcSSc ATA- conditions were involved in protein binding. Proteins exclusively overexpressed in dcSSc ATA+ condition were involved in cell adhesion molecule binding and positive regulation of cell migration. Nuclear proteins overexpressed in dcSSc conditions were involved in protein and RNA binding.

Conclusion: IgG purified from SSc patients modified both cytoplasmic and nuclear proteins expression according to cutaneous subtype and Aab profile. The group dcSSc ATA+ induced a characteristic cytoplasmic and nuclear proteins profile. Protein binding, cell adhesion molecule binding and positive regulation of cell migration in the cytoplasm, and protein and RNA binding in the nucleus were enriched in FB co-incubated with purified IgG from dcSSc ATA+ patients.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Fcy receptors (FcγR) are opsonic phagocytic receptors, requiring tight regulations to prevent uncontrolled activation of pro-inflammatory phagocytosis. SSc macrophages display an alternatively-activated profibrotic phenotype. However, a comprehensive understanding of how this distinct macrophage phenotype can contribute to SSc pathogenesis is missing. We aimed to study if alternatively-activated macrophages from SSc patients exhibit a pro-phagocytic signature.

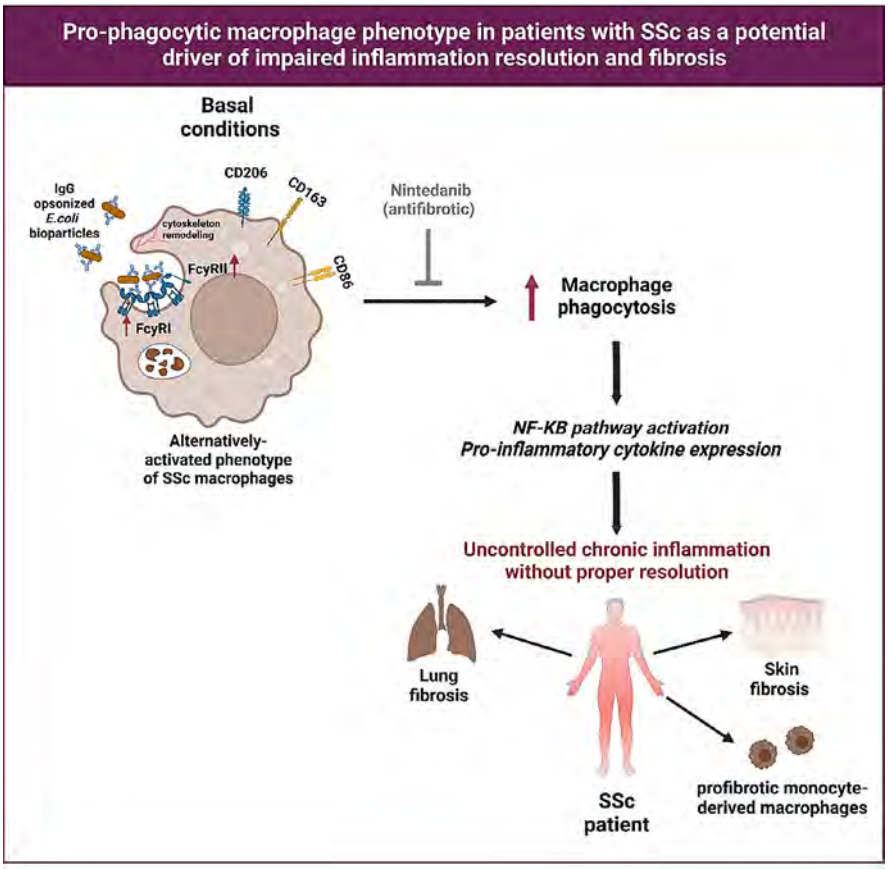

Figure 1 Proposed mechanism of impaired resolution in SSc patients leading to chronic inflammation and fibrosis driven by phagocytic FcγR. Created with BioRender.com

Methods: Publicly available single-cell RNA sequencing (scRNA-seq) datasets (GSE138669, GSE212109) on healthy control and SSc patient skin or lung macrophage populations were analyzed using Seurat v4.3.0 package. Human monocyte-derived macrophages (hMDM) were differentiated from $CD14^+$ blood-derived monocytes from healthy controls, SSc, RA, PsA and axSpA patients.For some experiments, M(0) hMDM were pre-treated for 24 hours with 0.1 μM of the antifibrotic drug Nintedanib. Phagocytic activity of M(0) hMDM was measured using pHrodo Red *E.coli* bioparticles and detected by flow cytometry. Macrophage surface markers were assessed by flow cytometry. NF-κB signalling cascade was studied on the protein level by Western Blot, and *IL6* expression was measured using RT-qPCR.

Results: scRNA-seq analysis revealed upregulated *FCGR* genes and FcγR-mediated pathways in skin macrophages from 12 dcSSc patients and in lung macrophages from 5 SSc patients with interstitial lung disease (ILD) (p.adj.≤0.05; log2FC≥0.5). We identified *FCGR3A*^{hi} macrophages in dcSSc patient skin and *FCN1*^{hi} macrophages in the lungs of SSc-ILD patients as the main phagocytic populations. Functional *in vitro* studies confirmed enhanced phagocytic activity in alternatively-activated M(0) SSc hMDM (n=57) compared to healthy control cells (n=36, p< 0.0001). Phagocytic activity was observed in M(0) hMDM from pre-early SSc (n=14, p=0.0021), lcSSc (n=38, p=0.0006) and dcSSc (n=5, p=0.0581) patients, and was therefore independent of the disease subtype. Phagocytic activity positively correlated with FcγRI (n=14, Pearson r=0.663, p=0.006) and FcγRII (n=14, Pearson r=0.5178, p=0.0478) expression. Subsequently, engulfment of pHrodo Red *E.coli* bioparticles led to NF-κB pathway activation followed by increased *IL6* expression in SSc M(0) hMDM (n=7) compared to healthy controls (n=5, p=0.0278). Pre-treatment of M(0) SSc hMDM with Nintedanib led to a reduction in phagocytic activity compared to untreated M(0) SSc hMDM (n=7, p=0.0066). In addition, we found that the pro-phagocytic phenotype of SSc M(0) hMDM is also present in other rheumatic diseases, including RA (n=10, p=0.0363) and PsA (n=11, p=0.0235), but not axSpA (n=9, p=0.4867) patients.

Conclusion: Our findings proposed enhanced FcγR expression as a novel biomarker to identify pro-phagocytic macrophages in SSc patients, which can trigger pro-inflammatory responses. Uncontrolled activation of pro-phagocytic macrophages could contribute to the aberrant resolution of inflammation followed by fibrosis in SSc patients (Figure 1). Furthermore, targeting pro-phagocytic macrophages may be an interesting approach for rheumatic diseases beyond SSc.

Nintedanib Alters Fibroblast and Macrophage Diversity in a 3D Skin Model of Systemic Sclerosis (SSc)

Noelle Kosarek[1], Tamar Abel[2], Sasha Shenk[3], Tammara Wood[2], Jonathan Garlick[4], Patricia Pioli[5] and **Michael Whitfield**[5], [1]Dartmouth Geisel School of Medicine, Lebanon, NH, [2]Dartmouth College, Hanover, NH, [3]Tufts University, Boston, MA, [4]Tufts University School of Dental Medicine, Boston, MA, [5]Geisel School of Medicine at Dartmouth, Hanover, NH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a rare autoimmune disease characterized by fibrosis of the skin and internal organs. While the tyrosine kinase inhibitor Nintedanib is now FDA-approved to treat lung fibrosis in SSc patients, the mechanism by which this drug alters fibroblast and immune cell activation in SSc is unknown.

Methods: We constructed SSc and control 3D skin-like tissues using fibroblasts, monocytes, keratinocytes, and plasma from SSc patients or healthy donors in the presence or absence of Nintedanib. Multiple samples were pooled from each 3D skin-like tissue and processed for histology, flow cytometry, and single cell RNA-sequencing (scRNA-seq). Data were analyzed in R using Seurat, Signac, monocle3, and nichenetr packages.

Results: Analysis of the 14 SSc and 14 healthy control tissues by scRNA-seq in the absence of drug treatment identified four distinct fibroblast populations and five macrophage populations. To assess the effect of Nintedanib on fibroblast and macrophage representation in SSc skin, we exposed 6 SSc and 6 healthy control 3D skin-like tissues to Nintedanib, which reduced tissue thickness and contractility. SSc-derived saSE tissues displayed measures of increased fibrosis.SSc tissues were significantly thicker (p=0.0007) than healthy control tissues. Notably, the organization of the control tissues was clearly defined with obvious dermal and epidermal layers, while the SSc tissues had a more disorganized appearance with less well-defined layers. There was a statistically significant decrease in both tissue contractility (p=0.0002) and thickness (p=0.0008) after Nintedanib-treatment of SSc tissues; healthy control tissues showed a significant decrease in contractility but did not show a significant difference in tissue thickness. Proportional shifts were noted in two of the four fibroblast populations after Nintedanib treatment. Consistent with prior reports of elevated macrophage numbers in SSc-affected tissues, macrophages were significantly increased in SSc saSE tissues compared to healthy control saSE tissues. Macrophage numbers in SSc saSE tissues were significantly reduced by Nintedanib-treatment. Gene expression analysis of Nintedanib-treated skin demonstrated significant alterations in the expression of matrix and fibrosis-related genes, suggesting these changes underlie drug-mediated anti-fibrotic activity. This included significant reductions in the expression of ELN (p=1.42*1^-61), COL1A1 (p=0.016), TNFAIP3 (p=0.007), TNFAIP2 (p=1.75*10^-8), MMP1 (p=1.26*10^-5), and TNFAIP6 (p=8.27*10^-5).

Conclusion: Our results suggest SSc fibroblast and macrophage populations are plastic and require cell-cell, cell-matrix, and circulating factors to maintain their phenotype in culture. Nintedanib resulted in changes to fibroblasts and macrophage populations, including decreased expression of matrix and secreted factors.

Development of Interstitial Pneumonia with Autoimmune Features in Conditional Tgfb3 Deletion

Toshihiko Komai[1], Tomohisa Okamura[2], Masanori Kono[1], Kazuhiko Yamamoto[3] and Keishi Fujio[1], [1]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo and Department of Functional Genomics and Immunological Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3]Department of Allergy

and Rheumatology, Graduate School of Medicine, The University of Tokyo and Laboratory for Autoimmune Diseases, Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: We found that TGF-β3 regulates humoral immunity in a context-dependent manner [1]. Recent genome-wide association study reveals that TGF-β3 might be a novel target in African American systemic sclerosis (SSc) patients [2]. Since *Tgfb3*$^{-/-}$ mice die within 20 hours of birth [3], the physiological roles of TGF-β3 have not clearly elucidated. In this study, we evaluated the immunological and fibrotic roles of TGF-β3 by using mice with conditional Tgfb3 deletion.

[1] Komai T, et al. Front Immunol. 2018;9:1364., [2] Kaundal U, et al. ACR2022, Arthritis Rheumatol. 2022; 74 (suppl 9), [3] Kaartinen V, et al. Nat Genet. 1995;11(4):415-21.

Methods: TGF-β3 conditional knockout mice in CD4$^+$ T cells (*Tgfb3*$^{fl/fl}$*CD4*^{Cre}) and B cells (*Tgfb3*$^{fl/fl}$*CD19*^{Cre}) were created. Histopathology, expression of fibrosis-related genes in lung by qRT-PCR in lungs, and flow cytometric analysis of splenocytes from these mice were conducted. Also, a continuous bleomycin infusion delivered by osmotic minipumps to these mice was conducted as an induced SSc model. To evaluate the effects of overexpression of TGF-β3, either pCAGGS-Mock, pCAGGS-Tgfb3 plasmid vectors were intravenously administered to lupus prone MRL/*lpr* mice with spontaneous interstitial pneumonia, and lung pathologies were assessed.*In vitro,* normal human lung fibroblasts (NHLFs) cultured with and without TGF-β3 were evaluated.

Results: *Tgfb3*$^{fl/fl}$*CD4*^{Cre} mice developed inflammatory cell infiltration and fibrosis in lungs spontaneously (**Figure 1A**), and low-titer anti-dsDNA antibody production and increased marginal zone B cells was observed. The bleomycin-induction exacerbated interstitial pneumonia, and fibrosis-related genes of the lung tissue such as *mCol1a1*, *mCol1a2*, *mSerpine1*, and *mSpp1* were up-regulated in both *Tgfb3*$^{fl/fl}$*CD4*^{Cre} and *Tgfb3*$^{fl/fl}$*CD19*^{Cre} mice in comparison to *Tgfb3*$^{fl/fl}$mice

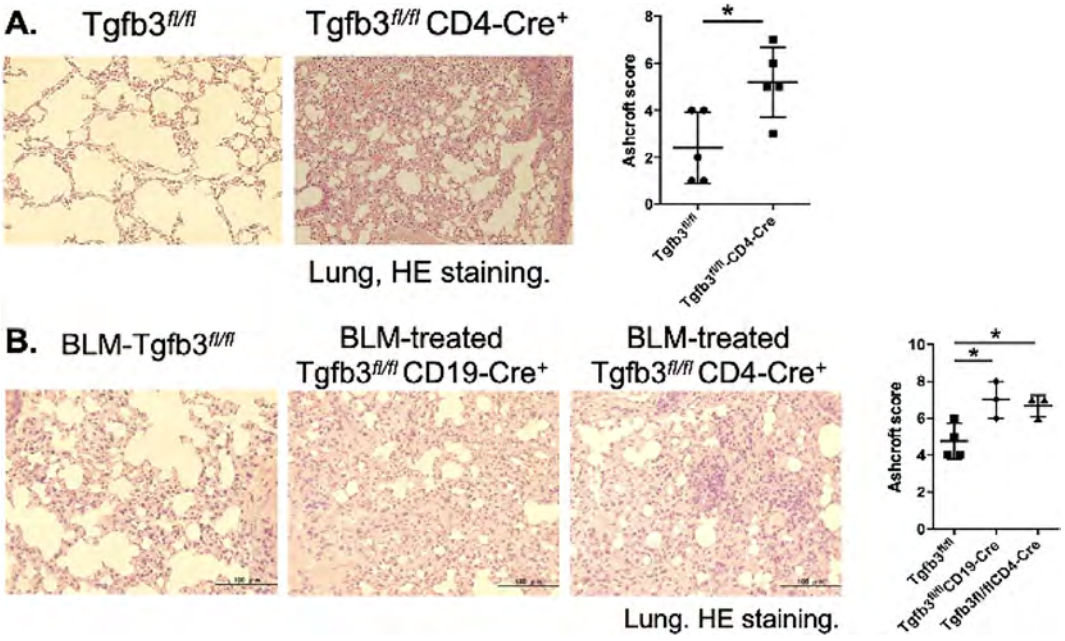

Figure 1. Exacerbation of interstitial pneumonia by conditional Tgfb3 deletion.

(**Figure 1B**). Further, the interstitial pneumonia of MRL/*lpr* mice was prone to be ameliorated by pCAGGS-Tgfb3 administration. In *in vitro* experiments, TGF-β3 inhibited the proliferation of NHLFs in a dose-dependent manner.

Conclusion: Our study suggested that TGF-β3 contributes to regulate systemic autoimmune and fibrotic responses. Anti-inflammatory and anti-fibrotic function of TGF-β3 might lead to future therapeutic target for interstitial pneumonia with autoimmune features.

KL-6 and IL-18 Levels Are Negatively Correlated with Respiratory Function Tests and ILD Extent Assessed on HRCT in Patients with Systemic Sclerosis-related Interstitial Lung Disease (SSc-ILD)

Cristiana Sieiro Santos[1], Sara Calleja[2], Javier de la Calle Lorenzo[2], Carmen López Garay[2], Clara Moriano[2], Elena Bollo de miguel[2] and Elvira Díez Álvarez[2], [1]Complejo Asistencial Universitario de León, León, Spain, [2]CAULE, León, Spain

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of the leading causes of mortality in patients with systemic sclerosis (SSc). Serum biomarkers have been suggested as indicators for pulmonary damage with clinical value in the diagnosis and prognosis of SSc-ILD.Our objectives are to investigate the role of serum biomarkers (Krebs von den Lungen-6 KL-6, IL-18 and IL-18BP) as potential biomarkers reflecting the severity of SSc-ILD as assessed through high-resolution computed tomography (HRCT) and pulmonary function tests (PFT), including forced vital capacity (%FVC) and diffusing capacity of the lung for carbon monoxide (%DLCO).

Methods: A cross-sectional study including patients with SSc fulfilling the 2013 ACR/EULAR criteria was performed. Patients were classified according to disease duration and pulmonary involvement (presence of ILD). All SSc patients underwent chest HRCT scans and pulmonary function test at baseline. Serum concentration of KL-6, IL8 and IL18BP were determined using sandwich ELISA technique (solid phase sandwich Enzyme Linked-Immunosorbent Assay), with kits from MyBiosource for KL-6 and from Invitrogen for IL18 and IL18BP. A semiquantitative grade of ILD extent was evaluated through HRCT scan (grade 1, 0–20%; grade 2, >20%). Extensive lung disease was defined as >20% of lung involvement on HRCT, and FVC < 70% predicted and limited lung involvement as ≤20% of ILD involvement on HRCT, and an FVC ≥70% predicted.

Results: 74 patients were included, 27% were male. The mean age at diagnosis was 57.5±15 years. The mean time since diagnosis was 7.67±8 years. 28 patients had ILD (38%). 64 % of patients had < 20% of ILD extent classified through HRCT scan. SSc-ILD patients had elevated serum KL-6 and IL-18 levels compared to patients without ILD (p=0.003 and p=0.04), and those findings were preserved after adjusting for age and sex (table 1). Mean erythrocyte sedimentation rate (ESR) was higher in patients with SSc-ILD. A negative correlation between KL-6 levels and %FVC (β=-0.25, p 0.037) and %DLCO (β=-0.28, p 0.02) and between IL-18 levels and %FVC (β=-0.20, p 0.03) and %DLCO (β=-0.14, p 0.04) were found. Linear

	ILD (28)	ILD (-) (46)	P value
Mean age, years	57.3±16	57.7±28	0.97
Sex, male	6 (21%)	13 (28%)	0.51
Mean ESR (mm/h)	23±16	9±8	**0.04**
Mean CRP (mg/dL)	7.1±4.3	5.03±3.25	0.36
Serum KL-6 (U/mL)	320±68	262.5±39	**0.003**
Serum IL-18BP (U/mL)	150.46±130	123.23±90	0.21
Serum IL-18 (U/mL)	300.63±167	209.65±180	**0.03**
Pulmonary function tests			
Mean FVC %	96.2±34	111±22.3	**0.01**
Mean DLCO%	65.7±18	77.5±19.7	**0.001**

Table 1: Demographic and clinical characteristics of patients with SSc-ILD and non-SSc-ILD.

regression models representing correlation between KL-6 and PFT are represented in the scatter plot in figure 1. Serum KL-6 and IL-18 levels successfully differentiated grades 1 and 2 (p = 0.028 and p=0.021). Semiquantitative grades of ILD on the HRCT scan were significantly proportional to the KL-6 (p 0.01) and IL-18 (p=0.03). A positive correlation between extensive lung disease and KL-6 (β=0.61, p 0.007) but not with IL-18 was found.

Conclusion: Serum KL-6 levels and IL-18 were increased in patients with SSc-ILD and showed a positive correlation with ILD severity as measured using a semiquantitative HRCT grading scale and a negative correlation with PFT parameters. KL-6 is positively correlated with extensive lung disease. Serum KL-6 and IL-18 could be a clinically useful biomarker in screening and evaluating SSc-ILD.

Single Cell Analysis of Transitional B Cells in Systemic Sclerosis Highlights Defective Peripheral Tolerance

Claire Beesley[1], Nina Goldman[1], David Abraham[1], Christopher Denton[1], Rizgar Mageed[2] and Voon Ong[3], [1]University College London, London, United Kingdom, [2]Queen Mary University of London, London, United Kingdom, [3]UCL Medical School Royal Free Campus, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Transitional B cells comprise a distinct population of B cells that have recently migrated to the periphery from the bone marrow. In systemic sclerosis (SSc),previous data from our laboratory has demonstrated that there are differences in the number and function of transitional B cells compared to healthy controls (HCs). In addition, we have previously isolated transitional B cells from SSc patients which are seropositive for anti-topoisomerase Iautoantibodies (ATA)demonstrating that these cells evade tolerance. To investigate why these autoreactive B cells are not tolerised in those withSSc,we performed a paired bulk and single-cell RNA sequencing study of the transitional B cell subsets in SSc and HCs.

Methods: 5000 $CD19^{+}CD24^{hi}CD38^{hi}$ transitional B cells were sorted from four HCs and four treatmentnaïveATA-positive SSc patients.Single-cell RNA-sequencing was performed on the sorted transitional B cells and the datawas analysed using Seurat in RStudio. Additionally, in a subset of this cohort paired bulk RNA-sequencing of the sorted transitional T1 ($CD19^{+}CD24^{hi}CD38^{hi}CD27^{-}IgM^{hi}IgD^{med}$) and T2($CD19^{+}CD24^{hi}CD38^{hi}CD27^{-}IgM^{hi}IgD^{hi}$) populations was carried out.

Results: As shown in Figure 1 single cell transcriptomics identified four distinct transitional B cell clusters in SSc patients and HCs. Notably, cluster 1 is diminished in the SSc group and cluster 0 is expanded in SSc compared to HCs. These clusters were characterised using relevant genes as shown in the dotplot in Figure 2. Clusters 0, 1 and 2 all share similar transcriptomic features whilst cluster 3 has upregulated expression of genes associated with commitment to the B cell lineage (EBF1). Thisindicates that cluster 3 is the earliest B cell emigrant from the bone marrow. Clusters 2, 1 and 0 can then be differentiated through expression of genes such as PLD4 and KLF2. Subsequent pathway analyses provided evidence for defective tolerance in SSc patients which may be mediated through dysregulated NF-κB signalling. In addition, differential

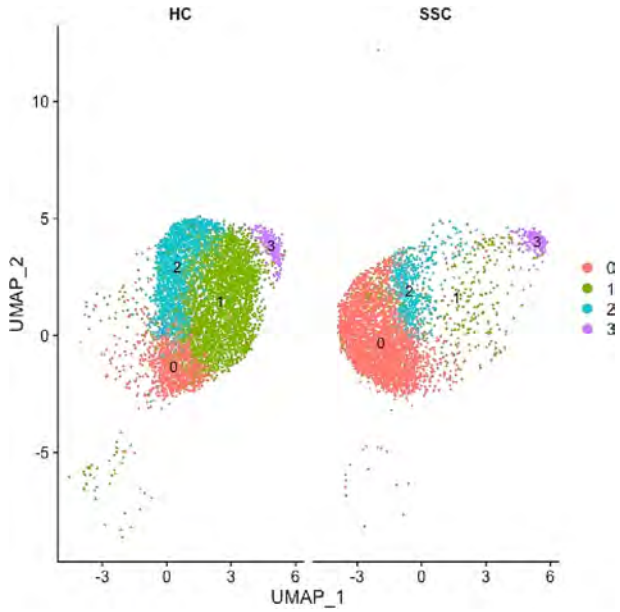

Figure 1. A UMAP plot depicting an integrated scRNA-seq analysis of transitional B cell clusters in 4 healthy controls (HC) and 4 systemic sclerosis (SSc) patients.

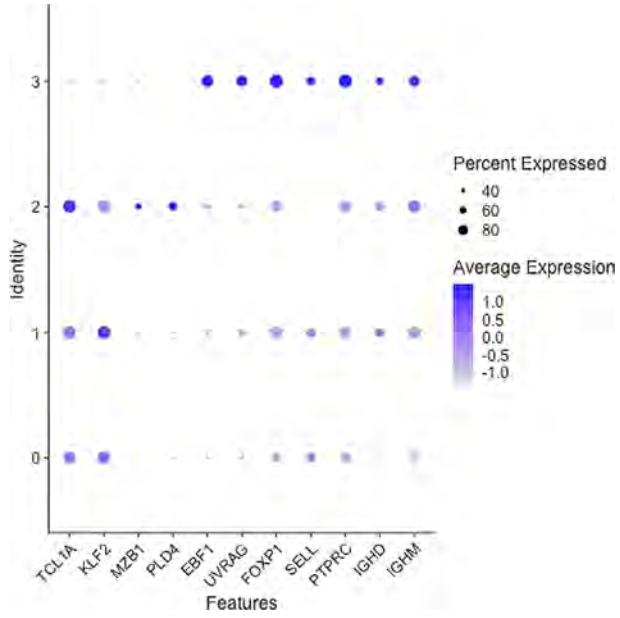

Figure 2. A dotplot of key genes used to identify transitional B cell clusters in a scRNA-seq study of 4 healthy controls (HC) and 4 systemic sclerosis (SSc) patients.

gene expression analysis using bulk RNA-sequencing of sorted T1 and T2 transitional subsets have identified five candidate gene signatures which are significantly enriched in the T2 cells compared with the T1 cells. This finding was in concordance with the single cell data and provides further evidence to support the existence of a peripheral tolerance/selection checkpoint at the transitional B cell stage.

Conclusion: Through this data we have identified four transitional B cell subsets and have characterised their transcriptomic profile. Additionally, we have found further evidence for a potential breach in tolerance in the SSc patients. Studies are ongoing to explore biological pathways through which altered gene expression impacts peripheral tolerance in SSc.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Nudix Hydrolase 21 (NUDT21, also known as CFIm25) is a master regulator of alternative polyadenylation. Previous studies have revealed that NUDT21 is significantly decreased in systemic sclerosis (SSc) skin and that its downregulation in fibroblasts potentiates both skin and lung fibrosis (Weng T et al. J Clin Invest. 2019 & J Exp Med 2020). This study aims to investigate the upstream mechanisms that lead to NUDT21 repression in skin fibrosis.

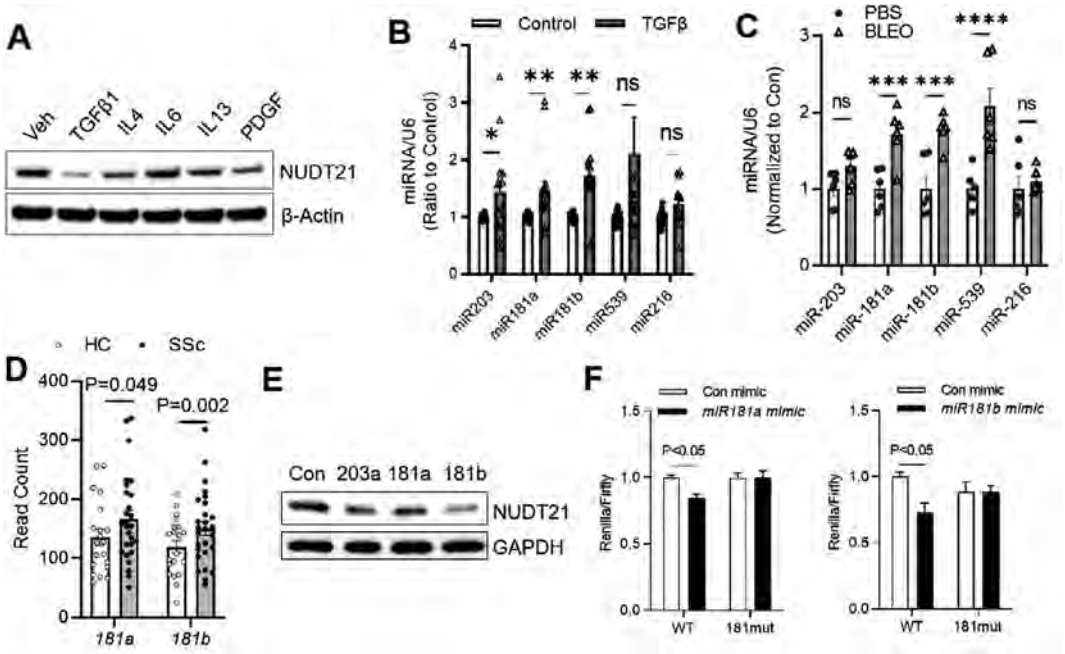

Figure 1: (A) NUDT21 levels in normal human dermal fibroblasts treated with different cytokines. Transforming growth factor β (TGFβ1) is the cytokine that most profoundly downregulates NUDT21 expression. (B-D) The levels of potential NUDT21-targeting miRNAs in (B) TGFβ treated dermal fibroblasts, (C) Day 21 mouse skin subcutaneously injected with bleomycin 5 times a week, and (D) Primary dermal fibroblasts from 20 healthy controls (HC) and 27 SSc patients. (E) NUDT21 levels in normal human dermal fibroblasts treated with MiR-203a, 181a and -181b mimics. (F) Dual-luciferase assay showing miR-181a and -181b can repress the luciferase activities of WT NUDT21 3'UTR but not the NUDT21 3'UTR that have miR-181 binding sites mutated.

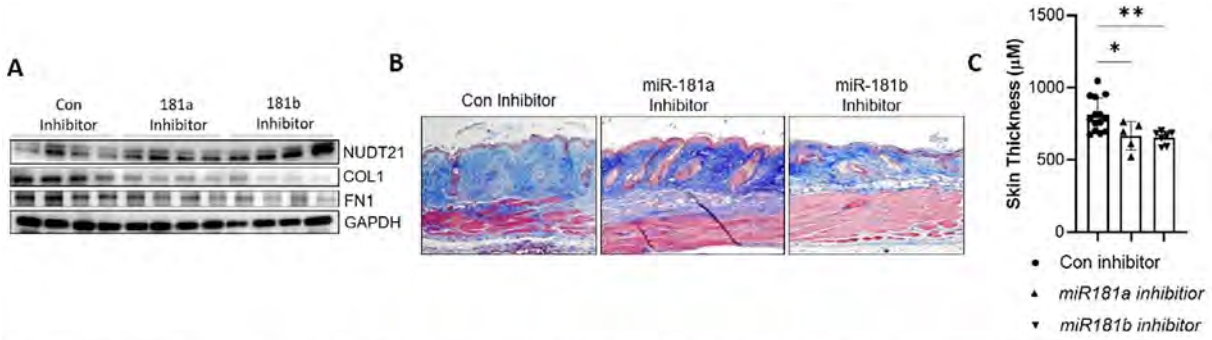

Figure 2: MiR-181a and -181b inhibitors attenuated skin fibrosis in association with increased NUDT21 protein levels. (A) Western blot demonstrates protein levels of NUDT21 and fibrotic markers. (B) Representative images of slides stained with Masson's trichrome. (C) Dermal thickness was measured in a blinded manner.

Methods: NUDT21 levels in cells treated with different cytokines were determined by western blot and RT-qPCR. Dual-luciferase assays were performed to determine the micro RNA (miRNA) regulation of NUDT21. MiR-181a and -181b mimics and inhibitors were injected subcutaneously 10 days after the initial subcutaneous bleomycin treatment to determine their effects on skin fibrosis (n≥ 5 per group).

Results: In comparison to IL4, IL6, IL13, and PDGF, transforming growth factor β (TGFβ1) led to a stronger downregulation of NUDT21 in healthy control (HC) dermal fibroblasts (Fig. 1A). Further investigation showed that TGFβ did not downregulate NUDT21 transcript until 48 hours after treatment, suggesting that it regulated NUDT21 through an indirect mechanism such as miRNA induction. Screening potential NUDT21 targeting miRNAs revealed that miR-181a and -181b were elevated in TGFβ1 treated human dermal fibroblasts and bleomycin-induced skin fibrosis in mice (Fig. 1B-C). Consistent with these findings, miR-181a and -181b were both significantly increased in primary dermal fibroblasts from 27 patients with early diffuse SSc compared to fibroblasts obtained from 20 matched HCs while the levels of other NUDT21 targeting miRNAs were not increased (Fig. 1D). Both miR-181a and -181b could directly bind NUDT21 3'UTR to repress NUDT21 expression in skin fibroblasts (Fig. 1E-F). Functional studies demonstrated that miR-181a and -181b inhibitors attenuated bleomycin-induced skin fibrosis murine models in association with decreased NUDT21 expression (Fig.2), while miR-181a and -181b mimics exaggerated bleomycin-induced skin fibrosis.

Conclusion: Taken together, these findings suggest miR-181a/b play a role in SSc pathogenesis and are potential therapeutic options for skin fibrosis.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Trimethylamine (TMA) generated by the gut microbiome is converted into trimethylamine N-oxide (TMAO) via the host enzyme FMO3. The TMA-FMO3-TMAO metaorganismal axis has been linked to chronic metabolic, renal, and cardiovascular diseases, and triggers myofibroblast reprogramming in mesenchymal cell types[1,2]. However, despite growing evidence implicating gut dysbiosis in SSc[3], the expression and pathogenic role in FMO3 in SSc has never been investigated.

Methods: The TMA-derived metabolite TMAO was measured in the circulation by LC tandem mass spectrometry in 200 adults with SSc, and 100 age-matched controls undergoing elective cardiac evaluation. FMO3 was evaluated in skin biopsies and fibroblasts via single cell RNA-seq (scRNA), immunohistochemistry and immunofluorescence. To investigate the pathogenic role of the TMAO-producing enzyme FMO3, C57BL/6 mice engineered with liver-specific gain-of-function of human FMO3 (hFMO3-TG)[4] were used in models of fibrosis and inflammation.

Results: Serum TMAO was elevated in SSc patients compared to controls (median 3.31 μM [IQR: 2.18, 5.23] vs. 2.70 μM [IQR: 1.74, 4.11]; p=0.016), with highest levels among obese and male SSc patients. Remarkably, while FMO3 is expressed in the liver, we also detected FMO3 in skin. SSc patient-derived biopsies and explanted fibroblasts showed elevated FMO3 protein and mRNA expression colocalizing with collagen production. scRNA-seq of the skin showed the highest expression of FMO3 localized to $CLDN1^+$ fibroblasts, a cellular subpopulation seen primarily in SSc biopsies and associated with extracellular matrix remodeling. Male mice engineered to express human FMO3 (hFMO3-TG) show a significant increase in circulating TMAO[4]. Bleomycin treatment caused significantly exaggerated fibro-inflammatory pathology in hFMO3-TG mice compared to identically treated wildtype mice.

Conclusion: Collectively, our results demonstrate that gut microbiome-derived vasculopathic/profibrotic TMAO is elevated in patients with SSc, and transgenic mice expressing human FMO3, the enzyme that generates TMAO, develop augmented fibrotic responses associated with elevated TMAO. This is the first study to identify a potential pathogenic role for FMO3 in SSc, linking gut dysbiosis to fibrosis and vasculopathy via a metaorganismal axis.

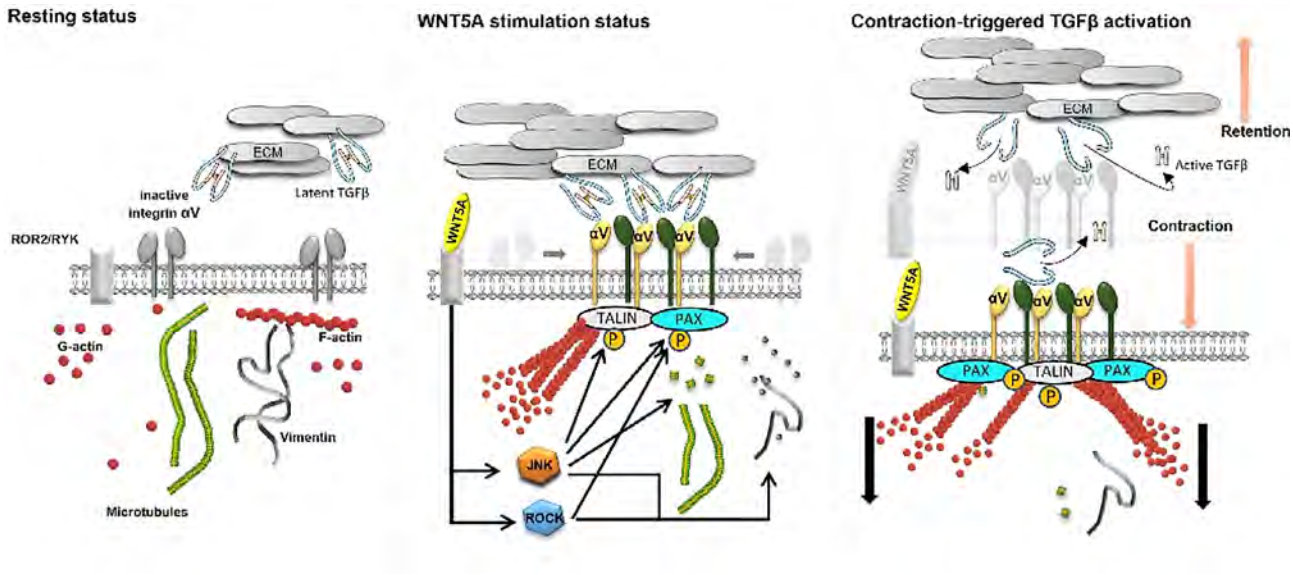
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disorder with vasculopathy, inflammation, and fibrosis of the skin and organs. Fibrosis is caused by the abnormal activation of latent transforming growth factor beta (TGFβ) by fibroblasts, resulting in excessive extracellular matrix and tissue damage. WNT5A is a non-canonical WNT ligand which significantly expresses higher in fibrotic diseases. We aimed to investigate the role of WNT5A and its downstream intracellular signaling and gene expression in fibroblast activation in SSc and other fibrotic diseases. We also tested the effect of blocking WNT5A downstream targets on latent TGFβ activation and fibrosis.

Methods: We performed bulk RNA sequencing (RNAseq) of WNT5A-stimulated fibroblasts with or without pretreatment with inhibitors of potential downstream mediators of WNT5A (small molecule inhibitors against JNK, ROCK, integrin alpha V - ITGAV, TGFβR1 and actin polymerization). To confirm the findings, we treated WNT5A-overexpressing mice with those inhibitors. We quantified the active TGFβ level in vitro and in vivo by transformed mink lung epithelial cells assays. The



WNT5A induces JNK and ROCK to promote coordinated cytoskeletal remodeling that drives ITGAV-dependent activation of latent TGFβ in fibrotic disorders

contraction force and cellular stiffness of WNT5A-stimulated fibroblasts were analyzed by 3D microtissue assays and magnetic tweezers. Formation of focal adhesions (FAs) and cytoskeleton rearrangement were evaluated by Western blot, IF staining, and live-cell imaging.

Results: 38% of DEGs of a cohort of patients with early, diffuse-cutaneous SSc (PRESS[1]) matched the genes regulated by WNT5A in cultured fibroblasts. Ubiquitous knockout of WNT5A or fibroblast-specific knockout of WNT5A are protected from experimental fibrosis. RNAseq of fibroblasts treated with respective inhibitors revealed 75% of the WNT5A-regulated DEGs were regulated by JNK- and ROCK-dependent manner. Functional analysis of the DEGs indicated that WNT5A regulates TGFβ signaling, FAs, integrin activation and cytoskeleton organization. Indeed, WNT5A induced the formation of FAs with increased levels of p-Talin and p-Paxillin, ITGAV clustering and cytoskeletal rearrangement involving Vimentin, actin filaments, and microtubules. All of these changes were dependent on the activation of latent TGFβ, which was strongly induced by WNT5A in cultured fibroblasts. Pharmacological inhibition of JNK, ROCK, TGFβR1, ITGAV, or actin polymerization blocked the activation of latent TGFβ, reduced cellular stiffening, prevented integrin activation, and in particular reduced fibroblast-to-myofibroblast transition and collagen deposition in cultured fibroblasts. Moreover, Pharmacological inhibition of the downstream mediators also reduced the levels of active TGFβ and fibrotic remodeling of skin in mice overexpressing WNT5A.

Conclusion: We demonstrate that WNT5A/JNK/ROCK signaling axis regulates the activation of latent TGFβ by induction of cytoskeletal rearrangement, cellular tension forces and clustering of ITGAV. Blocking of WNT5A or its downstream pathways prevents the aberrant activation of latent TGFβ in experimental fibrosis, prevents fibroblast-to-myofibroblast transition and tissue fibrosis. Targeting of WNT5A may thus offer potential for novel antifibrotic therapies.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by vascular and immune system dysfunction, along with tissue fibrosis. Vascular damage has been recognized as the pathological basis of SSc, but there are no medicines approved by FDA for SSc early vasculopathy treatment for the underlying mechanism remains elusive. Our previous study found *GRB2* was downregulated by salvianolic acid B, a small molecule drug that attenuated skin fibrosis of SSc by protecting endothelial cells from oxidative stress injury. Here we aim to investigate the role of GRB2 in the vasculopathy of SSc.

Methods: The microarray data of SSc skin biopsies in Caucasians were obtained from the Gene Expression Omnibus (GEO) database (GSE95065). The expression of *GRB2* was further detected in Chinese SSc patients (n = 20) and healthy controls (n = 20). To further explore the possible effects of Grb2 on skin fibrosis *in vivo*, Grb2 siRNA was used to lower the expression of Grb2 in the BLM-induced skin fibrosis mouse model. The apoptosis of EA.hy926 endothelial cells was induced by H_2O_2 and apoptosis ratio was measured by flow cytometric. Transcriptome and phosphoproteomic analyses in EA.hy926 cells transfected with NC and GRB2 siRNA were performed to explore the GRB2 regulated pathway.

Results: The expression of *GRB2* was significantly enhanced in SSc patient skin, 1.51-fold in Caucasians and 1.40-fold in Chinese. The immunohistochemical staining showed that there were more GRB2 positive cells in SSc patients than in normal controls, and double immunofluorescence staining showed the endothelial cells of SSc patient's skin highly expressed GRB2 (Figure 1). Then the *in vivo* study revealed that *in situ* apoptosis of endothelium increased under the treatment of BLM, while interfering Grb2 could reduce endothelial cell apoptosis, also proved by the protein expression of cleaved caspase-3 (Figure 2). The *in vitro* study showed that decreased GRB2 expression level could up-regulate tight junction related genes expression and inhibit apoptosis to protect endothelial cells from H_2O_2-induced hyperpermeability (Figure 3). Moreover, both transcriptome and phosphoproteomic analysis suggested the focal adhesion pathway was enriched in GRB2 siRNA transfected endothelial cells (Figure 3).

Conclusion: Our results demonstrated GRB2 is highly expressed in endothelial cells of SSc skin, and inhibiting GRB2 could effectively attenuate endothelial cell apoptosis and BLM-induced skin fibrosis. GRB2 may regulate focal adhesion and VEGF signaling pathways to induce apoptosis of endothelial cells. GRB2 is expected to be a new therapeutic target for SSc.

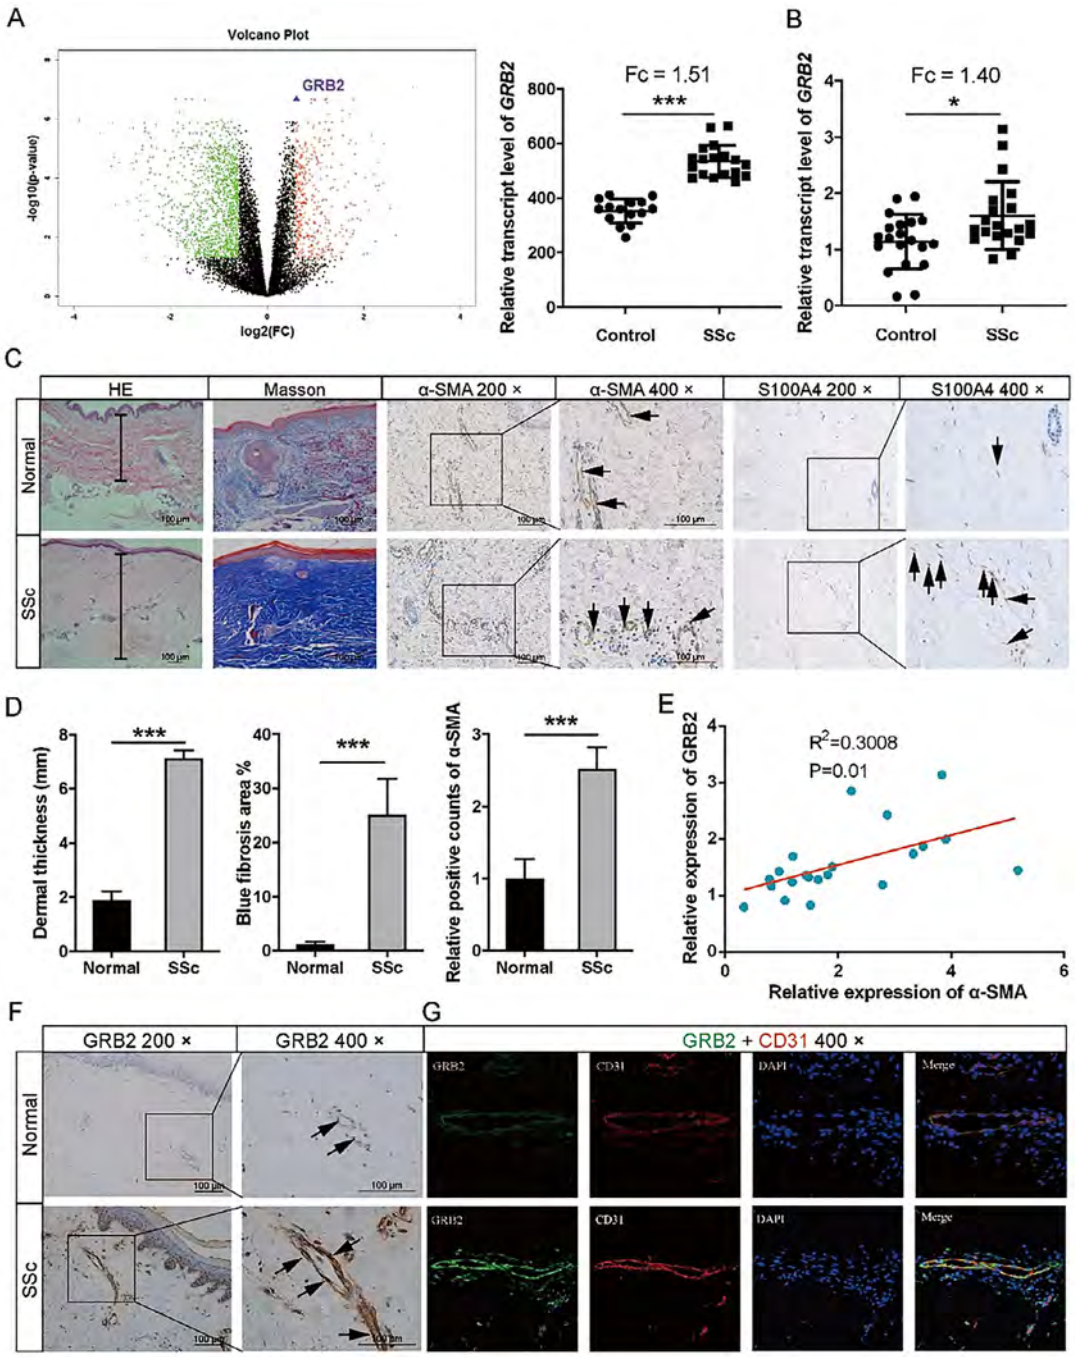

Figure 1. Expression of GRB2 was increased in the skin lesions of SSc patients. (A) Left: The volcano plot of differential expression genes between normal and SSc. Right: Relative transcription levels of GAB1 in the skin lesions from the GEO database. (B) Relative transcription levels of GAB1 in the Chinese skin lesions. (C) HE, Masson's staining, and IHC staining for healthy control and SSc patients. Black arrows indicate α-SMA/S100A4 positive staining cells. (D) The left plot shows dermal thickness calculated by measuring the distance between the dermal-epidermal junction and the dermal–subcutaneous fat junction. The middle plot shows the blue fibrosis area of Masson's staining for healthy control and SSc patients. The right plot shows the relative positive counts of α-SMA of IHC staining for healthy control and SSc patients. (E) The association of GRB2 and α-SMA expression levels were analyzed. (F) IHC staining for GRB2 in the skin of healthy control and SSc patients. Black arrows indicate GRB2 positive staining cells. (G) GRB2 and CD31 in the skin were labeled by double immunofluorescence staining, and the cell nucleus was stained with DAPI. Data are presented as mean ± SD in two groups and compared by t-test. *P < 0.05, *** P < 0.001.

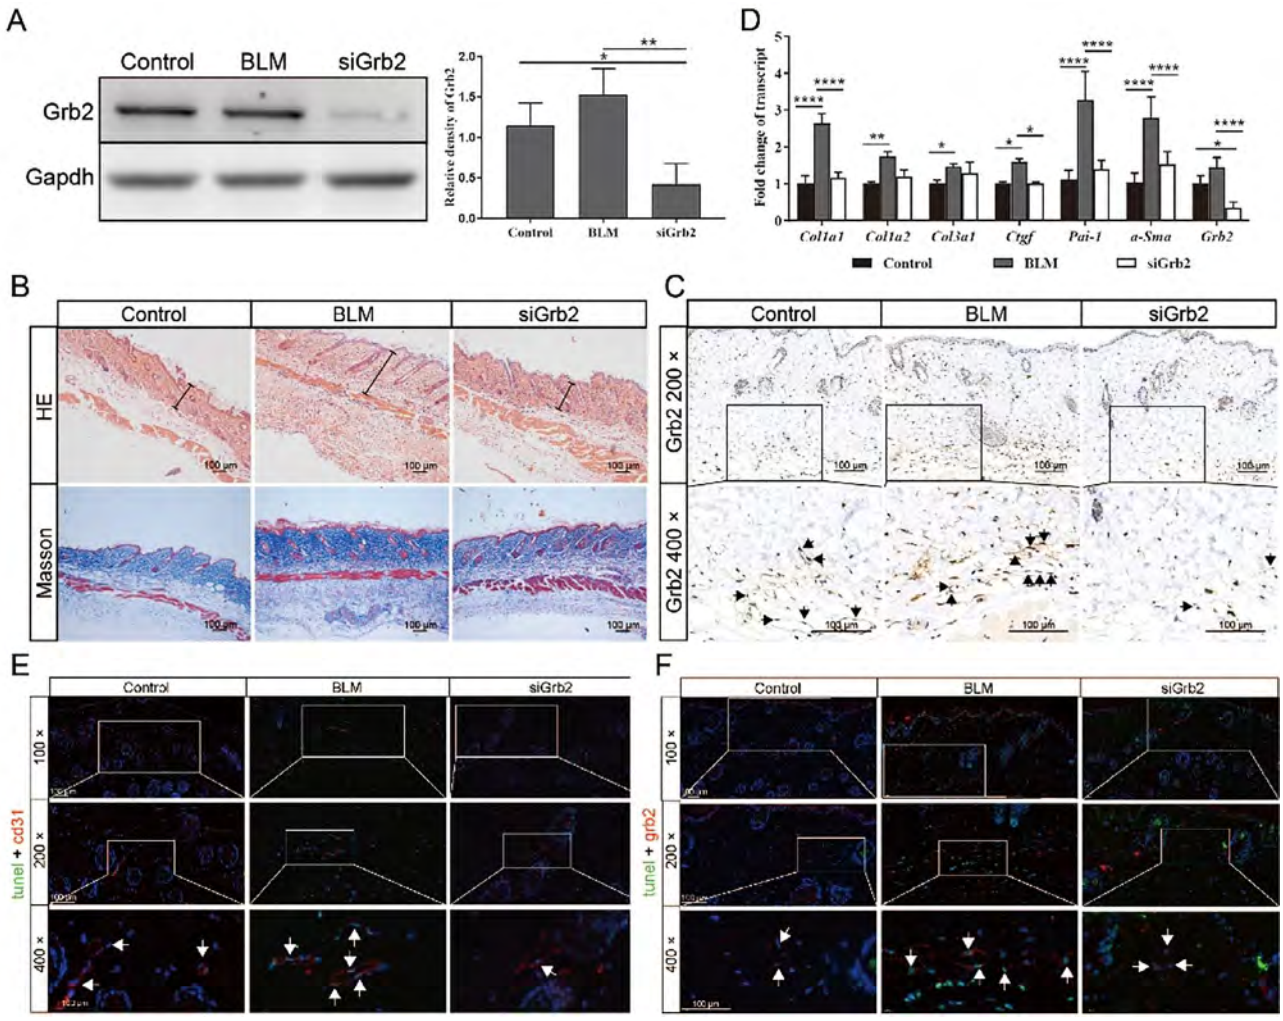

Figure 2. Grb2 knockdown alleviated skin fibrosis and endothelial apoptosis in BLM-induced SSc fibrosis model. (A) Grb2 protein expression level in the dorsal skin of mice was determined by western blot analysis and analyzed by ImageJ. (B) IHC staining for Grb2 in the mouse skin of different groups. The black arrows indicate Grb2-positive staining cells. (C) IHC staining of the dorsal skin of mice in different groups showed the relative positive number of Grb2. (D) Relative transcription levels of Grb2 and fibrotic genes in mouse skin were measured by real-time RT-PCR. (E) Double immunofluorescence staining of tunel and cd31 in normal, BLM, and siGrb2 groups. The white arrows indicate tunel-cd31-positive staining cells. (F) Double immunofluorescence staining of tunel and grb2 in different groups. Arrows indicate the positive cells. Data are presented as mean ± SD of three samples and compared with one-way ANOVA; *P < 0.05, ** P < 0.01, *** P < 0.001.

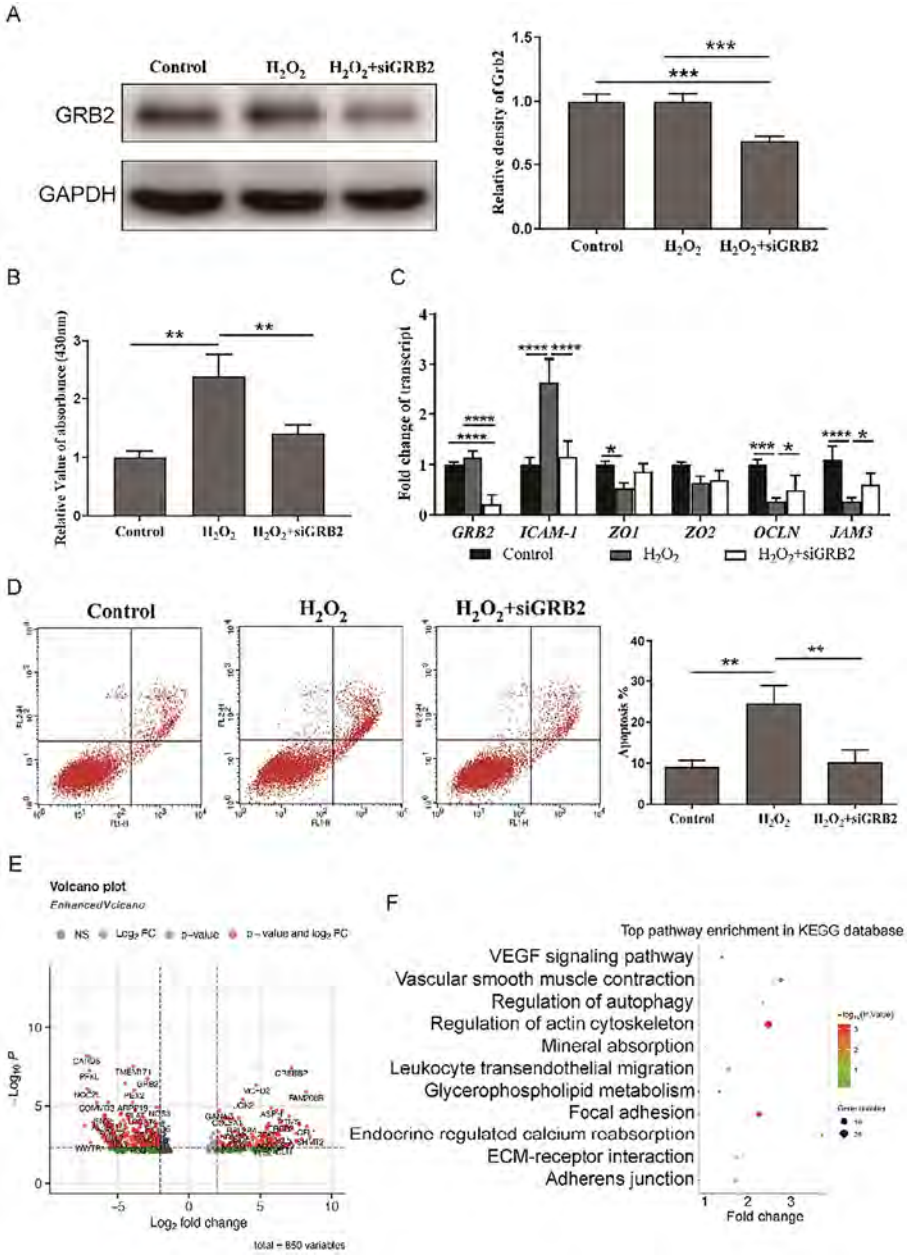

Figure 3. GRB2 siRNA transfection protected EA.hy926 endothelial cells from H2O2-induced hyperpermeability and the transcriptome analysis. (A) The protein level of GRB2 was determined by western blotting and quantified by ImageJ. (B) Effects of siGRB2 on H2O2-induced endothelial permeability in EA.hy926 cells detected by cell permeability assay. (C) The relative mRNA levels of ICAM1, ZO1, ZO2, OCLN, and JAM3 were detected by real-time RT-PCR in different groups. (D) The ratio of apoptosis detected by flow cytometry in the cells of the control, H2O2, and H2O2 + siGRB2 groups. The column plot shows the apoptosis ratio in the different groups. (E) The Volcano plot of differentially expressed genes (DEGs) in NC or GRB2 siRNA transfected EA.hy926 cells. (F) KEGG pathway analysis of DEGs. Data are presented as means ± SD of three samples and compared with one-way ANOVA; *P < 0.05, ** P < 0.01, *** P < 0.001.

Effects of B Cell Depletion by CD19-targeted CAR-T Cells in a Murine Model of Systemic Sclerosis

Jérôme Avouac[1], Anne Cauvet[2], Cindy Orvain[3], Morgane boulch[4], Philippe Bousso[4] and Yannick ALLANORE[5], [1]Service de Rhumatologie, Hôpital Cochin, AP-HP.Centre – Université Paris Cité, Paris, France, [2]INSERM U1016, Paris, France, [3]INSERM U1016, Paris, [4]Institut Pasteur, Paris, France, [5]Université Paris Cité, Paris, France

SESSION INFORMATION

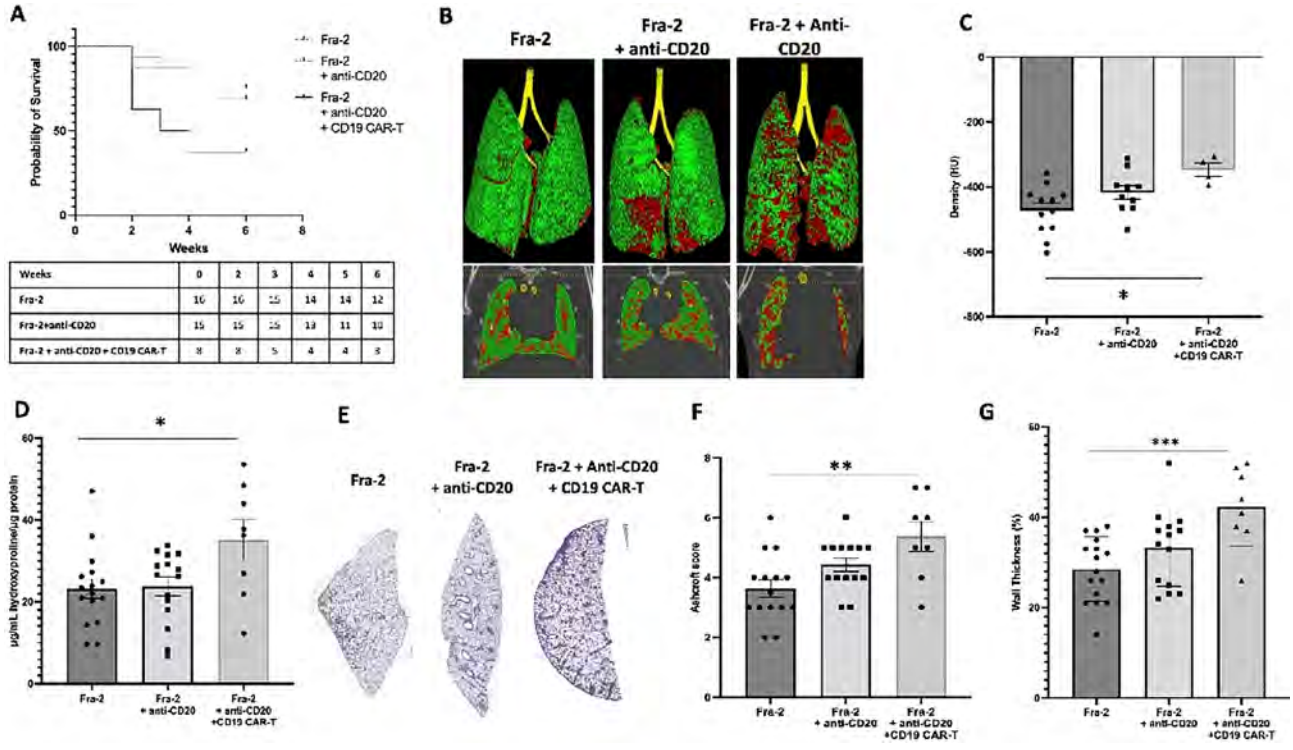
Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Chimeric antigen receptor (CAR)-T cells represent a potentially curative strategy for B cell malignancies. A first successful clinical experience has been recently reported in systemic lupus erythematosus, suggesting that CD19-targeted CAR-T cell transfer was feasible and tolerable. Since systemic sclerosis (SSc) and SLE are both severe diseases sharing B cell implication in their pathogenesis, we aimed at assessing the efficacy and tolerance of two B cell depletion strategies, including one with CD19-targeted CAR-T cells, in a preclinical model mimicking the severe lung damages observed in SSc.



Weeks	0	2	3	4	5	6
Fra-2	16	16	15	14	14	12
Fra-2+anti-CD20	15	15	15	13	11	10
Fra-2 + anti-CD20 + CD19 CAR-T	8	8	5	4	4	4

Figure 1: Effects of B cell depletion by anti-CD20 mAb in association or not with CD19-targeted CAR-T cells in Fra-2 Tg mice A, Survival curves of Fra-2 mice after anti-CD20 mAb and CD19-targeted CAR-T cell infusion. Significance was determined by log rank (Mantel-Cox; p=0.031). B, Representative pictures of micro-computed tomography. C, Y-axis shows the lung density at micro-computed tomography. D, Y-axis shows the content of collagen in a lung fragment (µg) evaluated by Sircol assay. E, Representative HES 4-µm lung sections (magnification × 8). F, Y-axis shows the Ashcroft histological score. G, Y-axis shows the right ventricular systolic pressure (RVSP). All data are shown as the mean ± SEM. * p<0.05, ** p<0.01, ***p<0.001 determined by one-way analysis of variance with Tukey's post hoc test.

Methods: B cell depletion strategies were evaluated in the Fra-2 transgenic (Tg) mouse model. We considered a first group of 16 untreated mice, a second group of 15 mice receiving a single intravenous (IV) dose (50 mg) of anti-CD20 monoclonal antibody (mAb) at day 1 and a third group of 8 mice receiving 50 mg anti-CD20 mAb IV at day 1 followed by the IV injection of $20*10^6$CD19-targeted CAR-T cells at day 3. After 6 weeks of clinical evaluation, different validated markers of inflammation, lung fibrosis and pulmonary vascular remodeling were assessed.

Results: Following treatment with anti-CD20 mAb, CD19 expression was significantly decreased in peripheral blood and lesional lungs of Fra-2 Tg mice by 59% ($p< 0.001$) and 40% ($p=0.019$), respectively, compared to control Fra-2. B cell depletion was even more pronounced in mice treated with CD19-targeted CAR-T cells: CD19 expression was decreased in peripheral blood and lungs of Fra-2 Tg mice by 92% ($p< 0.001$) and 85% ($p< 0.001$), respectively, compared to control Fra-2. CAR-T cell infusion worsened clinical score and increased mortality in Fra-2 Tg mice (**Figure 1A**). In line with the above findings, mice receiving CD19-targeted CAR-T cells displayed a significant increase in lung density (mean difference of 55 ±28 Hounsfield Units, p=0.038) (**Figure 1B-C**) and a marked reduction of functional residual capacity(mean difference of 25±9%, p=0.041) as compared to control Fra-2 when assessed by chest micro-CT imaging. CAR-T cell infusion significantly increased lung collagen content (mean difference of 11.93±4.44 mg/mL, p=0.020) (**Figure 1D**), histological fibrosis score (mean difference 1.74±0.48, p=0.002) (**Figure 1E-F**) and right ventricular systolic pressure (mean difference 8.52 ±2.70 mmHg, p=0.013) (**Figure 1G**). CAR-T cells accumulated in lesional lungs and promoted T-cell activation, with a significant increase of CD4+ effector memory T cells and the fraction of CD69 and PD1-expressing cells within the CD4+ and CD8+ subsets. Moreover, in the lung of CD19-targeted CAR-T cell-treated Fra-2 Tg mice. Moreover, the levels of inflammatory cytokines IL6, TNF-a and IFNg were markedly elevated in lesional lungs of mice treated with CAR-T cells. Treatment with anti-CD20 mAb in monotherapy had no impact on lung inflammation-driven fibrosis and pulmonary hypertension.

Conclusion: B-cell therapies failed to show efficacy in the Fra2 transgenic mice. The exacerbated Fra-2 lung inflammatory burden stimulated accumulation and expansion of activated CD19-targeted CAR-T cells, secondarily inducing T-cell activation and systemic inflammation, finally leading to disease worsening.

Rationale for Targeting Insulin-like Growth Factor Signalling in Systemic Sclerosis

Voon Ong[1], Shiwen Xu[2], Li Xue[2], Brajesh Kumar[3] and Christopher Denton[2], [1]UCL Medical School Royal Free Campus, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Horizon Therapeutics, South San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have shown that insulin like growth factor (IGF) pathways may promote extracellular matrix deposition and be upregulated in systemic sclerosis (SSc). Teprotumumab, a monoclonal antibody targeting IGF1 receptor (IGF1-R), is approved for treatment of thyroid eye disease and is being tested as a potential therapeutic in systemic sclerosis. This study explored levels of IGF ligand and receptor in serum of well characterised SSc patients and examined effects of teprotumumab on gene and protein expression in dermal explant fibroblasts from SSc or healthy control (HC) skin biopsies.

Methods: Serum levels of IGF1, IGF2 and IGF1-R were measured in SSc (n=63) and healthy controls (n=15) using commercial ELISA and levels compared across subset and organ based complication of SSc.Dermal fibroblasts from SSc (n=3) and healthy control (n=3) forearm skin biopsies were grown by explant culture and cell layer was analysed for key profibrotic proteins (alpha-SMA and pro(I)collagen) by western blot analysis and RNA analysis by quantitative PCR for alpha-SMA and

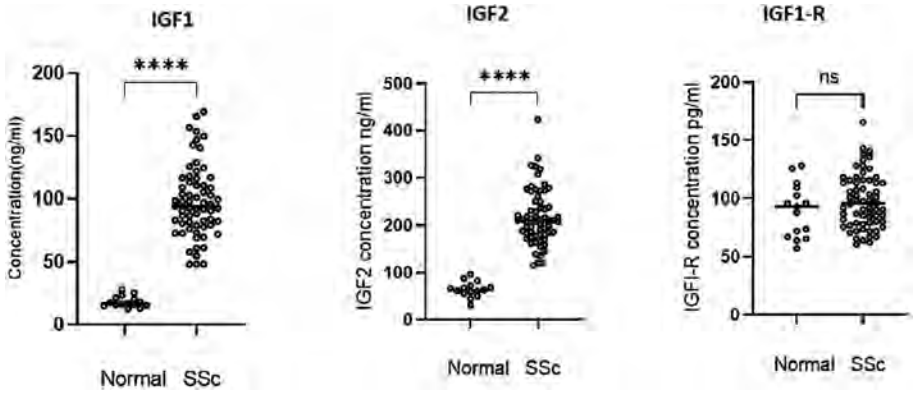

Figure 1 IGF ligand and receptor levels in SSc or control serum

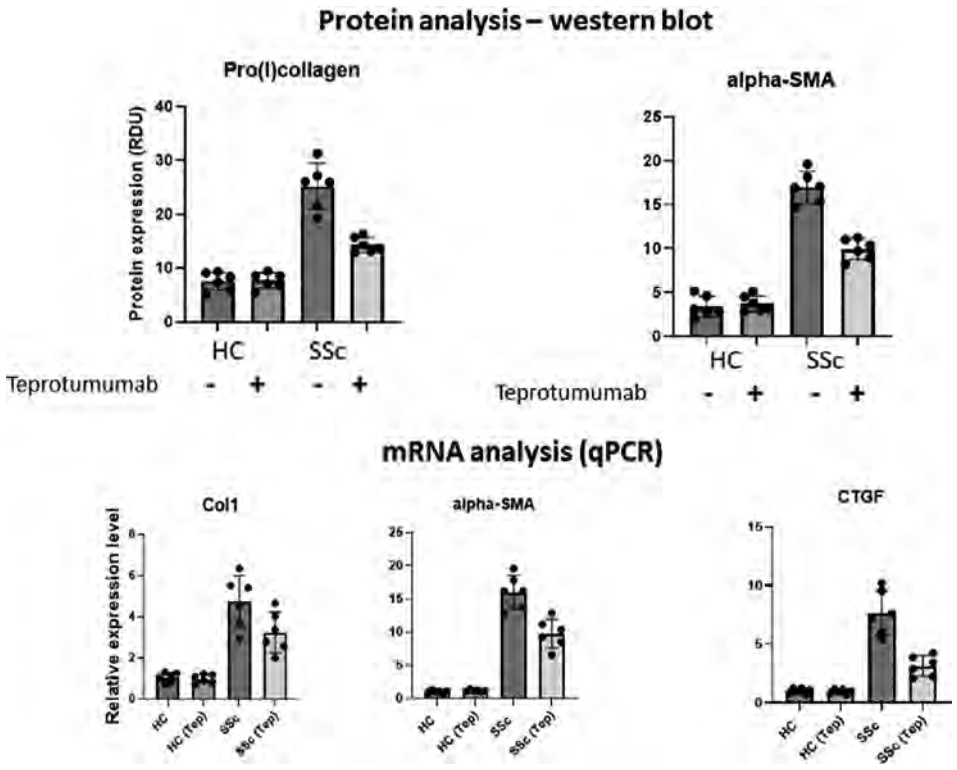

Figure 2 Effect of teprotumumab on protein and mRNA expression in SSc and HC fibroblasts

pro(I)collagen and connective tissue growth factor.For inhibition experiments, cells were pre-incubated overnight in the presence of teprotumumab (50 mg/ml).

Results: There was significant elevation in serum IGF1 in SSc compared with HC serum samples (mean[SD] ng/ml SSc 98.1 [28.4] versus HC 18.5[4.4], p< 0.0001) and IGF2 (SSc 217.6[57.9] versus HC 64.6[16.5], p< 0.0001) whereas serum IGF1-R levels were similar in both cohorts (**Figure 1**).Though elevated in SSc, no significant association was observed for major complications, including lung fibrosis and gut disease, and levels were similar for limited and diffuse skin subsets. SSc fibroblasts showed constitutive upregulation of profibrotic proteins (mean[SD] RDU Col1 SSc 25.2[4.2] vs. HC 7.6 [1.7] and alpha-SMA SSc16.9[1.8] vs. HC 3.4[1.2]) and genes compared with HC fibroblast strains (all p< 0.0001).The profibrotic phenotype in SSc fibroblasts was significantly attenuated by teprotumumab, with 43% reduction in pro(I)collagen and 41% reduction in alpha-SMA protein respectively, and similar qualitative effects on normalised mRNA levels. Teprotumumab did not significantly affect HC fibroblasts (**Figure 2**).

Conclusion: Elevated levels of IGF1 and IGF2 in SSc suggest that these proteins may be mediators or markers of pathobiology in vivo. Attenuation of hallmark profibrotic gene and protein signature in explant dermal SSc fibroblasts by teprotumumab is consistent with autocrine or paracrine activation of SSc fibroblasts by IGF1 or IGF2 via IGF1-R. Our findings are consistent with an antifibrotic effect and support clinical evaluation of teprotumumab as a possible therapy in SSc.

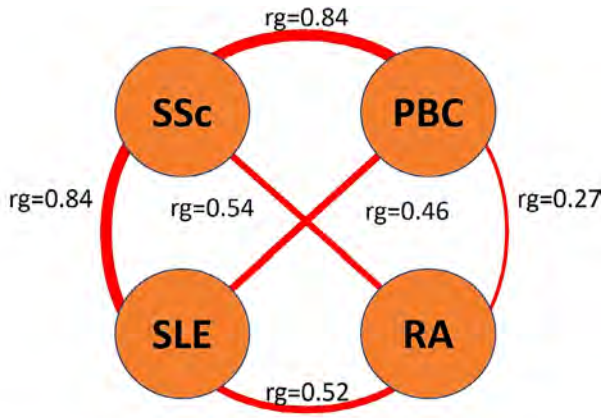
Shared Genetic Susceptibility Between Systemic Sclerosis and Primary Biliary Cholangitis: Analyses from Genome-Wide Association Studies

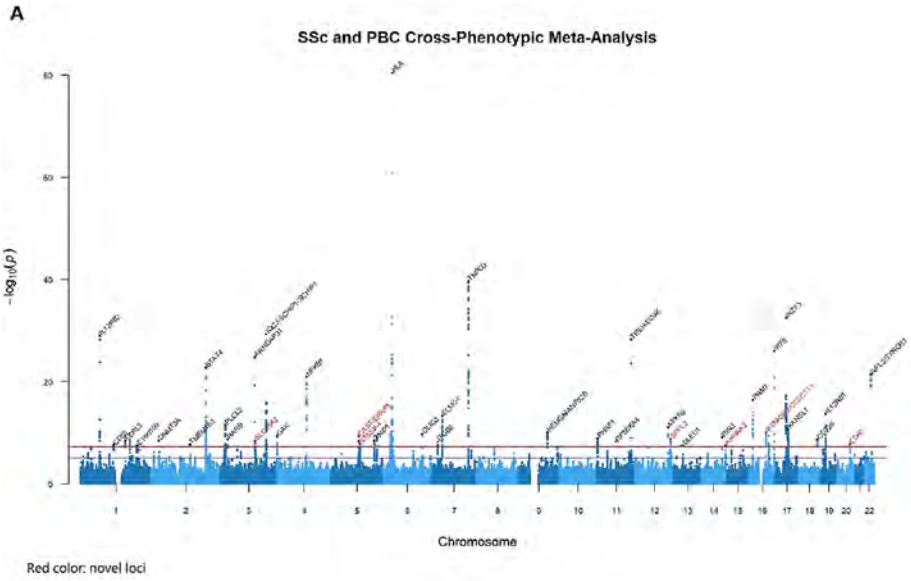
Yiming Luo[1], Atlas Khan[2], Gabriel Perreault[3], Lili Liu[2], Cue Hyunkyu Lee[4], Pravitt Gourh[5], Sydney Pomenti[3], Krzysztof Kiryluk[2] and Elana Bernstein[6], [1]Division of Rheumatology, Department of Medicine, Columbia University Irving Medical Center, New York, NY, [2]Division of Nephrology, Department of Medicine, Columbia University Irving Medical Center, New York, NY, [3]Division of Digestive and Liver Diseases, Department of Medicine, Columbia University Irving Medical Center, New York, NY, [4]Department of Biostatistics, Mailman School of Public Health, Columbia University Irving Medical Center, New York, NY, [5]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [6]Division of Rheumatology, Department of Medicine, Vagelos College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, NY

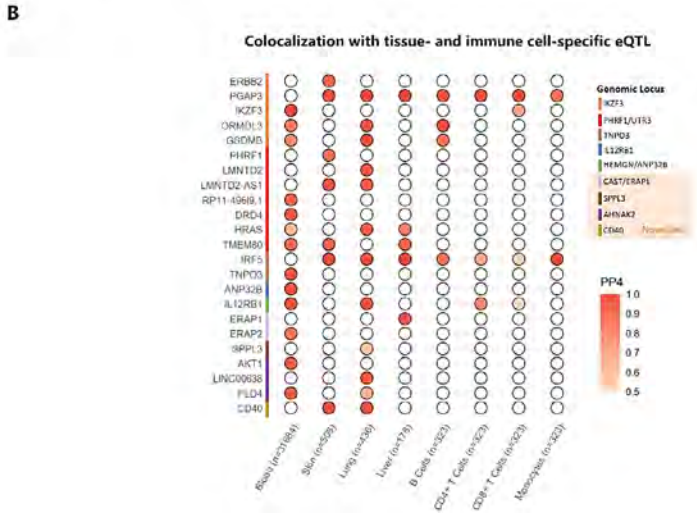
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multi-system autoimmune disorder characterized by organ inflammation, fibrosis, and vasculopathy. Primary biliary cholangitis (PBC) is an autoimmune disorder involving inflammation and fibrosis of the intrahepatic biliary tract. An increased risk of PBC has been noted in patients with SSc. Our study aims to investigate the shared genetic susceptibility between the two disorders using data from genome-wide association studies (GWAS).

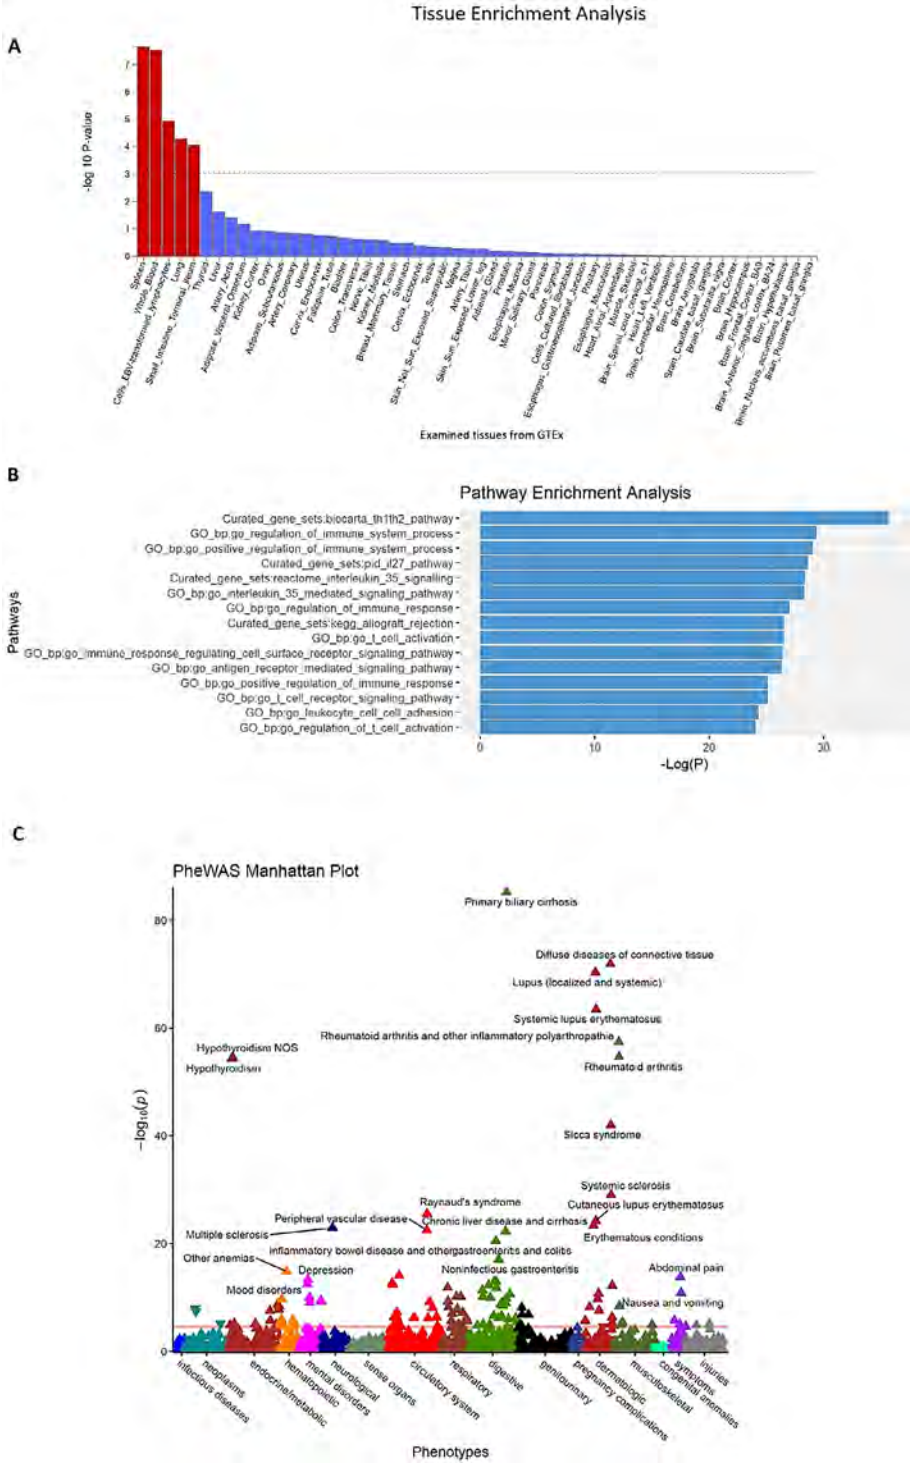


SSc: systemic sclerosis; PBC: primary biliary cholangitis; SLE: systemic lupus erythematosus; RA: rheumatoid arthritis; rg: genetic correlation





Methods: We obtained the GWAS summary statistics for SSc, PBC, rheumatoid arthritis (RA), and systemic lupus erythematosus (SLE) from the GWAS Catalog website. We performed a genetic correlation analysis using linkage disequilibrium score regression (excluding HLA region) and a cross-phenotype GWAS meta-analysis of SSc and PBC, followed by colocalization to investigate whether the pleiotropic signals were driven by shared causal variants. For genomic loci that were significant in the cross-phenotype meta-analysis and colocalized between SSc and PBC, we further performed colocalization with expression quantitative trait loci (eQTL) in relevant tissues and immune cells from the blood eQTLGen consortium, Genotype-Tissue Expression (GTEx), and Correlated Expression & Disease Association Research (CEDAR). Additionally,



we performed tissue and pathway enrichment analyses using MAGMA (Multi-marker Analysis of GenoMic Annotation) on the cross-phenotype meta-analysis statistics. Finally, we performed meta-phenome-wide association studies (meta-PheWAS) on the calculated polygenic risk score (PRS) of the SSc-PBC meta-analysis using data from the Electronic Medical Records and Genomics Network, All of Us and UK Biobank.

Results: The GWAS summary statistics included 9,095 cases and 17,584 controls for SSc and 8,021 cases and 16,489 controls for PBC. There was a strong genetic correlation between SSc and PBC (rg = 0.84, p = 1.7 x 10-6), in which the effect estimate was comparable to the genetic correlation between SSc and SLE (rg = 0.84, p = 1.6 x 10-15) (Figure 1). There were 44 non-HLA loci that reached genome-wide significance ($p < 5 \times 10\text{-}8$) in the cross-phenotype GWAS (Figure 2A). Evidence of shared causal variants between SSc and PBC was found in 13 out of the 44 significant loci in the colocalization analyses. Nine of the 13 loci showed evidence of shared causal variants with at least one expressed gene in the examined eQTL datasets. Among the 4 novel loci, eQTL colocalized transcripts included ERAP1, ERAP2, SPPL3, AKT1, PLD4, and CD40 (Figure 2B). These represented the predicted changes in gene expression resulting from the shared genomic signals between SSc and PBC. MAGMA prioritized multiple immune-related tissues and molecular pathways (Figures 3A and 3B). The meta-PheWAS revealed that the PRS calculated from the SSc-PBC meta-analysis was associated with multiple autoimmune phenotypes (Figure 3C).

Conclusion: We identified shared genetic susceptibility between SSc and PBC and prioritized several candidate genes by eQTL colocalization analyses. Our findings suggest that the genetic predisposition to SSc and PBC has pleiotropic effects across multiple autoimmune disorders.

Redirecting Macrophage Immunophenotype Attenuates Inflammation and Fibrotic Activation in Systemic Sclerosis

Heetaek Yang[1], Rajan Bhandari[1], Saemi Han[2], Chanhyuk Park[1], Chen-Yu Wang[2], Emily Morris[1], Michael Whitfield[1] and Patricia Pioli[1], [1]Geisel School of Medicine at Dartmouth, Hanover, NH, [2]Dartmouth College, Hanover, NH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a rare autoimmune disease with multiple clinical and pathological manifestations including vascular involvement, immune activation, oxidative stress, and fibrosis. In prior work, we have shown that SSc macrophages (MØs) have a pro-fibrotic activation profile that is conferred, at least in part, by crosstalk with SSc dermal fibroblast-derived exosomes, resulting in upregulation of secreted mediators of fibrosis and inflammation. Because MØs are plastic, we hypothesized that reshaping the immunophenotype of SSc MØs would alleviate inflammation and fibrotic activation in SSc.

Methods: To redirect MØ activation, we used CDDO-methyl ester (CDDO-Me), a synthetic triterpenoid derived from oleanoic acid that targets multiple signaling pathways implicated in SSc pathogenesis, including NFkB, STAT3, and Nrf2. Initial studies were performed by incubating SSc MØs with 300 nM CDDO-Me, which we have shown in previous studies alters

MØ activation, for 24 hours.To assess effects on exosome-mediated activation, an established Transwell co-culture system was used. Dermal fibroblasts were isolated from SSc patients and healthy control (HC) donors following informed written consent and cultured in complete media supplemented with exosome-depleted fetal bovine serum (FBS) to isolate exosomes. Fibroblasts were stimulated with 5 ng/ml TGF-b for 24 hours prior to exosome harvest. Exosomes were harvested from cell-free supernatants followed by quantification and characterization by immunoblot and NanoSight NS300 tracking analysis. HC monocytes were differentiated into MØs in followed by activation with SSc fibroblast-derived exosome (SSc FB-Exo) in RPMI/exosome-depleted FBS for additional 2 days. After MØ activation, SSc fibroblasts were placed into Transwell inserts and 300 nM CDDO-Me was added to cultures. MØs and fibroblasts were evaluated using flow cytometry, qRT-PCR, and multiplex.

Results: Consistent with prior reports**,** SSc MØs upregulated expression of IL-10, IL-6, IL-1b, and CCL2 compared with HC MØs. Treatment with CDDO-Me resulted in significant attenuation of these inflammatory and fibrotic mediators.CDDO-Me induced activation of Nrf2 signaling in SSc MØs, as evidenced by increased expression of HO-1 and KEAP1. Surface expression of CD163, CD206, and HLA-DR and pro-fibrotic mediator production, including CCL2, from SSc FB-Exo activated MØs was inhibited by incubation with CDDO-Me. In Transwell experiments, SSc fibroblasts co-cultured with CDDO-Me-treated SSc FB-Exo activated MØs showed decreased expression of fibrosis-related genes, including FN1 and α-SMA.

Conclusion: In this work, we demonstrated that CDDO-Me reshapes the pro-fibrotic immunophenotype of SSc activated MØs, leading to a decrease in release of cytokines implicated in SSc pathogenesis and attenuated SSc fibroblast activation. CDDO-Me targets multiple signaling pathways including oxidative stress and inflammation. Our results suggest CDDO-Me may have therapeutic utility in the reduction of oxidative stress, inflammation, and fibrosis associated with SSc.

MiR-3606-3p Alleviates Skin Fibrosis by Suppressing Fibroblast Inflammation and Migration via Inhibiting GAB1 and ITGAV

yahui chen[1], Mengkun shi[1], Wei Wang[1], Chenyi Shi[1], Xueyi Xia[1], wenyu Wu[2], Jiucun Wang[3] and Xiangguang Shi[3], [1]Fudan University, Shanghai, China, [2]Huashan Hospital, Shanghai, China, [3]Shanghai, Shanghai, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) and keloid are typical skin fibrotic diseases with unclear epigenetic mechanisms and clinical targets. As an important epigenetic regulatory factor, microRNAs play an important role in the occurrence and development of fibrosis in recent studies. This study aimed to assess the role of miR-3606-3p in skin fibrosis and the therapeutic potential.

Methods: The levels of miR-3606-3p were detected in SSc and keloid patients by qPCR and in situ hybridization. RNA-seq, in silico software and luciferase were performed to investigate the targets of miR-3606-3p. The effects of miR-3606-3p, GAB1 and ITGAV on fibroblast fibrogenesis, inflammation and migration were assessed in primary dermal fibroblasts by

qPCR, western blotting, wound healing scratch assay. Histology, immunofluorescence analysis and in vivo imaging techniques were used to evaluate the effect of miR-3606-3p on alleviating skin fibrosis in keloid-bearing mice.

Results: MiR-3606-3p was reduced in the skin tissues and fibroblasts from both SSc and keloid patients and negatively correlated with disease severity. RNA-seq analysis and in silico prediction indicated GRB2 associated binding protein 1 (*GAB1*) and integrin subunit alpha V (*ITGAV*) were potential targets of miR-3606-3p. We then found that miR-3606-3p downregulated both *GAB1* and *ITGAV* by directly targeting their 3′-UTRs, and further reduced p-AKT and p-ERK activities to inhibit collagen synthesis and NF-κB induced fibroblast inflammation. Furthermore, miR-3606-3p inhibited fibroblast migration in primary fibroblasts and keloid-bearing nude miceby wound healing scratch assay and *in vivo*imaging techniques respectively. In contrast, GAB1 and ITGAV were upregulated in SSc and keloid patients, and siRNA-mediated *GAB1* or

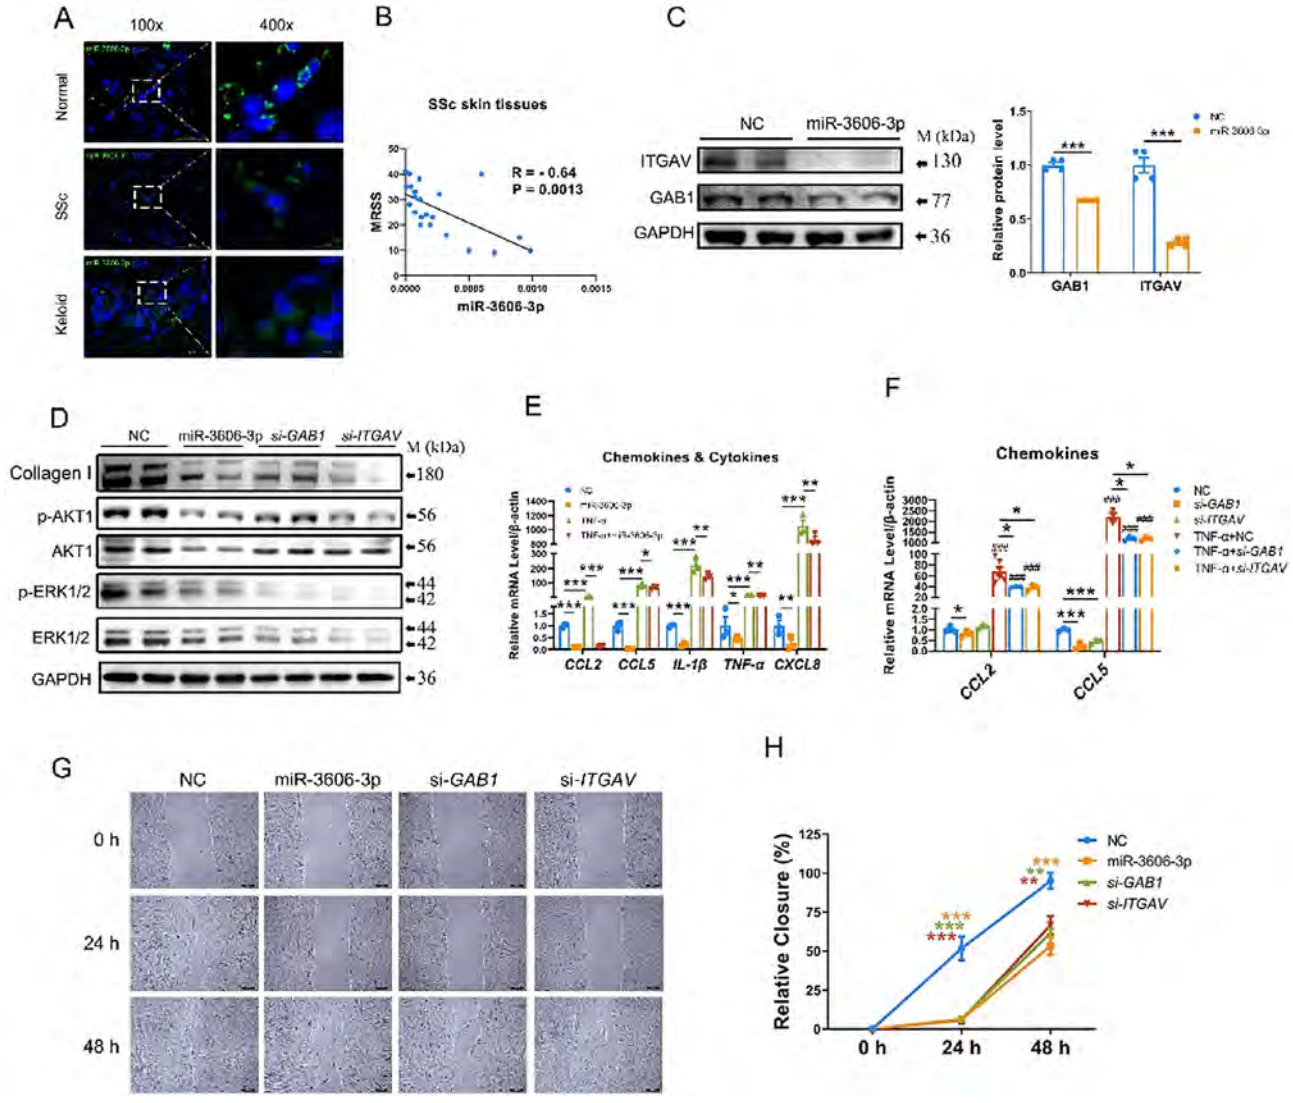

Figure 1. miR-3606-3p decreased in fibrosis skin tissue, while upregulating miR-3606-3p or inhibiting GAB1 and ITGAV supressed collagen production, inflammation and cell migration. (A) miR-3606-3p decreased in fibrosis skin tissue by in situ hybridization. (B) The relationship between MRSS and miR-3606-3p in SSc skin tissues. (C) miR-3606-3p inhibited GAB1 and ITGAV by western blotting. (D) Downregulation of type I collagen, p-AKT, AKT, p-ERK1/2, and ERK1/2 levels in SSc primary fibroblast with NC, miR-3606-3p mimics, si-GAB1 and si-ITGAV. (E) Downregulated chemokines and cytokines in miR-3606-3p overexpressing and TNF-α treated fibroblasts. (F) The effects of GAB1 siRNA and ITGAV siRNA on CCL2 and CCL5 expression in fibroblasts with or without TNF-α treatment. (G) Cell migration assay results by morphology in primary fibroblast with miR-3606-3p overexpression or GAB1 knockdown or ITGAV knockdown. N=3. (H) Relative closure distance of cell migration in fibroblasts with miR-3606-3p overexpression or GAB1 knockdown or ITGAV knockdown. N=3. *P < 0.05; **P < 0.01; ***P < 0.001.

ITGAV knockdown replicated the phenotypes observed in miR-3606-3p-overexpressing fibroblasts, including inflammation, migration and fibrogenesis (Figure 1). Finally, by constructing the humanized mouse model of transplanted keloid graft, we found that miR-3606-3p treatment inhibits GAB1 and ITGAV leading to significantly alleviate skin fibrosis (Figure 2).

Conclusion: Our results indicated miR-3606-3p inhibits ECM deposition, inflammation, and migration of fibroblasts by downregulating GAB1 and ITGAV. miR-3606-3p-enhancing strategies may have beneficial effects on skin fibrosis through lowing p-AKT/p-ERK activity.

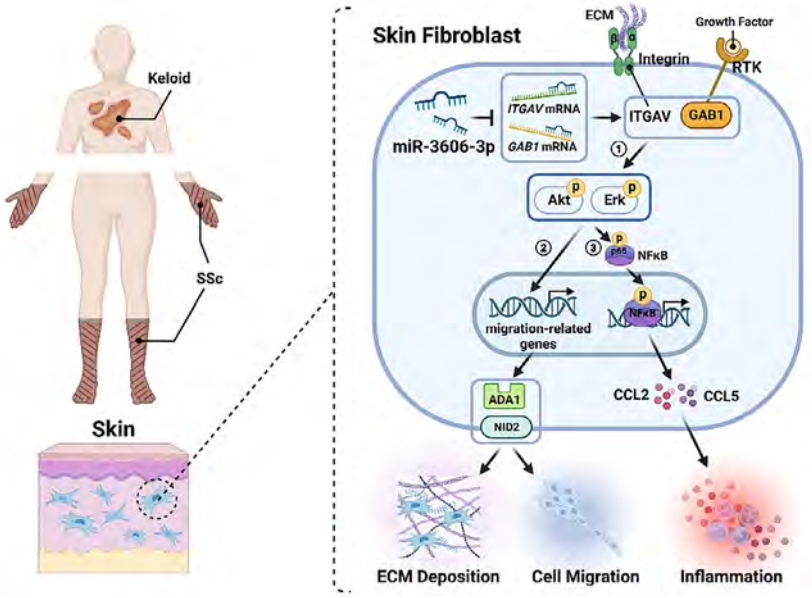

Graphical Abstract. The mechanism of miR-3606-3p on anti-inflammatory and anti-fibrotic effects. ① miR-3606-3p targeted the 3'-UTRs of GAB1 and ITGAV mRNA and subsequently inhibited their protein expression, then attenuated the phosphorylation of AKT and ERK1/2. MiR-3606-3p and knockdown of GAB1 and ITGAV exert an inhibitory effect on inflammation, migration, and collagen deposition as follows: ② Two important negative regulators of fibroblast migration, named ADA1 and NID2, were inhibited by p-AKT/ERK1/2 resulting in collagen deposition and cell migration. ③ p-AKT/ERK1/2 triggered inflammatory responses by activating p-p65 of the NF-κB signalling pathway and releasing the inflammatory factors, including CCL2 and CCL5. Collectively, miR-3606-3p repressed the expression of GAB1, and ITGAV, eventually leading to attenuation of collagen deposition, cell migration and inflammation.

Transcriptomic Analysis of Scleroderma Monocytes Identifies Distinct Clinically Relevant Clusters and Novel Genes Associated with Disease Complications

Mehmed Dinc[1], Fatima El Adili[2], Justin Lui[3], Giovanni Ligresti[3], Robert Lafyatis[4], Maria Trojanowska[3] and Andreea Bujor[3], [1]Boston University School of Medicine, Boston, MA, [2]Boston University School of Medicine, Revere, MA, [3]Boston University, Boston, MA, [4]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by skin and internal organ fibrosis, vascular abnormalities, and immunological disturbances. Monocytes play a critical role in SSc, but their contribution to disease pathogenesis remains unclear. A better understanding of gene expression changes in SSc monocytes and their associations with disease complications may lead to novel therapies.

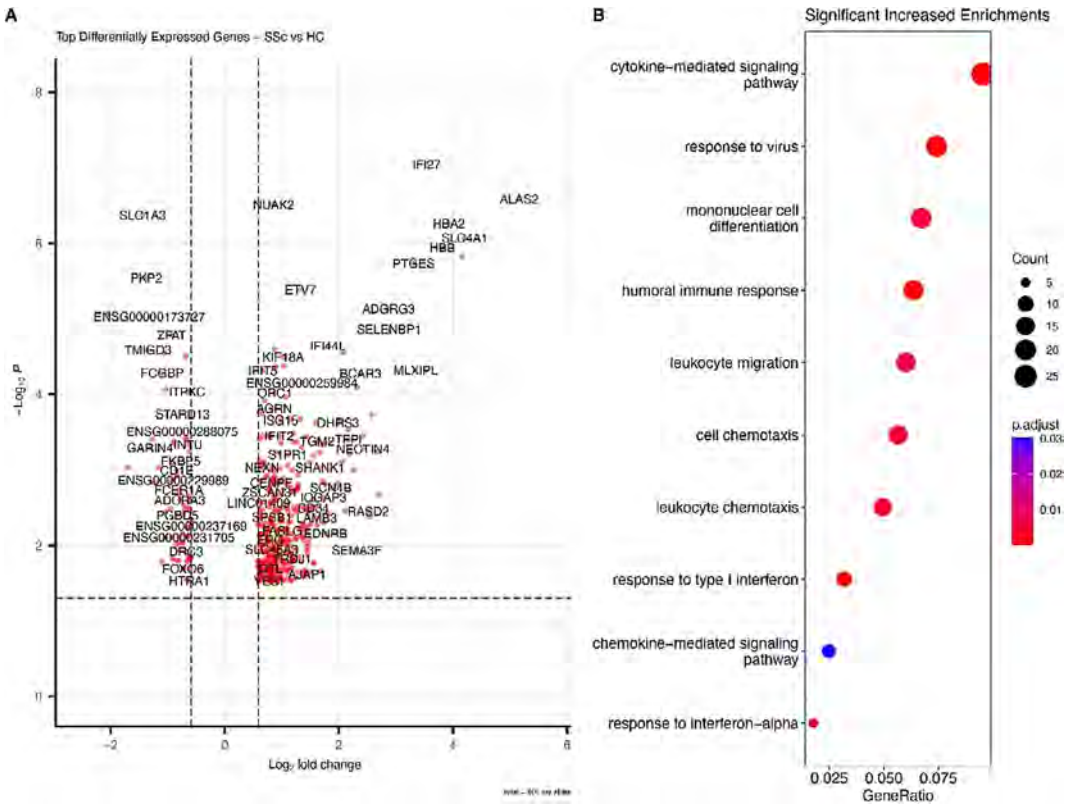

Figure 1. A. Volcano plot showing differentially expressed genes in SSc versus controls B. Pathway enrichment on differentially upregulated genes

Methods: Peripheral blood mononuclear cells were obtained from 48 SSc patients and 15 controls (HC) after informed consent and under an institutional approved IRB protocol. Magnetic bead separation was used to isolate monocytes and bulk RNA sequencing performed using the Illumina NextSeq platform. DESeq2 was used to identify differentially expressed genes between groups. We employed hierarchical clustering to group samples exhibiting similar transcriptional trends. Functional enrichment analysis was performed using ORA with the GO database to investigate the biological processes linked to each group. Pearson correlation was used for mRSS. DEG, GO and correlation analysis were conducted using R version 4.3.0. Pathways analysis for clinical features was performed using Ingenuity Pathway Analysis.

Results: 460 genes were found to be differentially regulated between SSc and HC. Interferon-related genes (IFI27, IFIT5, IFI44L, SIGLEC) were among top differentially expressed, along with genes not previously linked to SSc, including NUAK2, a TGFb induced protein kinase belonging to the AMPK family (FC 1.82, padj 0.001), and LGALS3BP, a secreted galectin-3 binding protein, that regulates cell-cell interactions and inflammation (FC 2.08, padj 0.04). Hierarchical clustering in SSc unveiled three groups. Cluster 1 ("inflammatory-like", 21 patients) predominantly displayed interferon related pathways, and included >80% of SSc patients with pulmonary hypertension (PH) from the entire SSc cohort. Cluster 2 ("T cell-like", 10 patients) exhibited enrichment in multiple pathways associated with T cell activation and contained the majority of

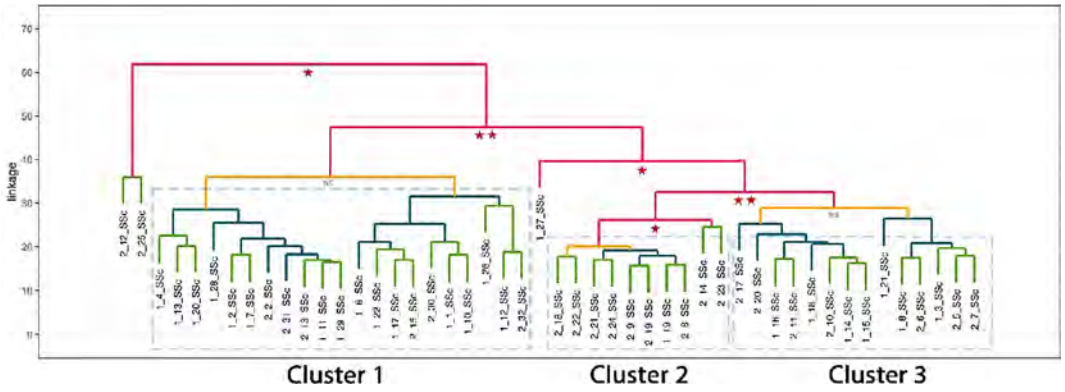

Figure 2. Hierarchical clustering analysis, revealing three significant clusters with distinct gene expression patterns.

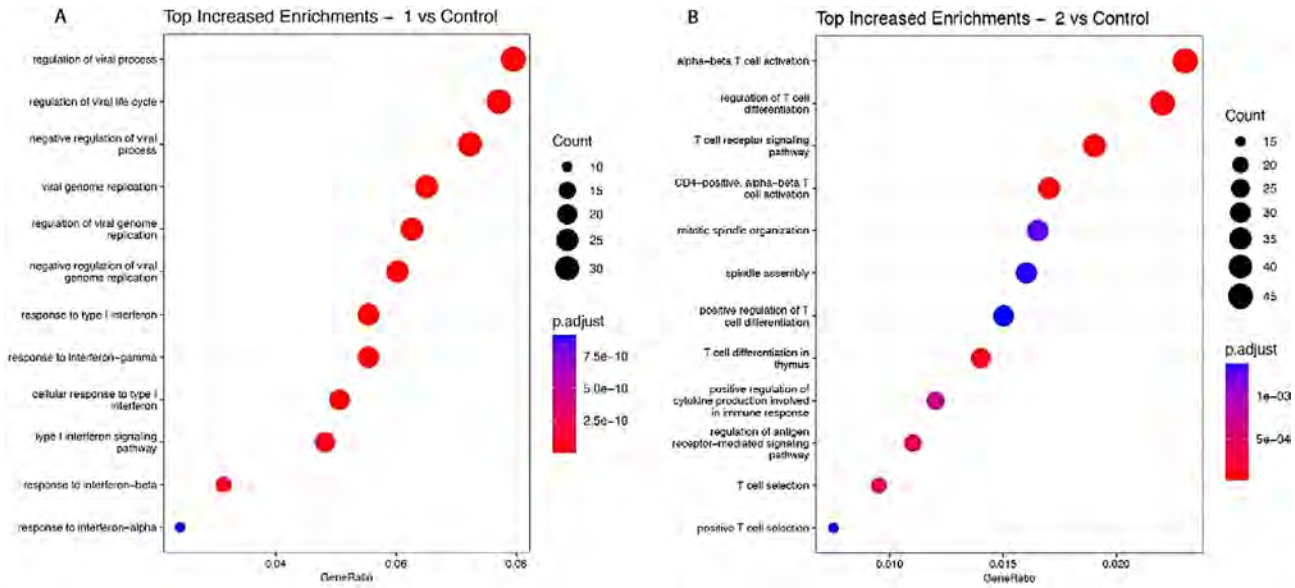

Figure 3. Pathway enrichment on differentially upregulated genes for cluster 1 (A) and 2 (B) vs controls. Cluster 3 did not reveal any significant pathways.

patients undergoing immunosuppressive therapy. Cluster 3 ("normal-like", 14) closely resembled the control group. Three patients did not belong to any clusters. There were significant associations between gene expression and clinical features. Interferon signaling pathway was the top most upregulated pathway in SSc-PH patients versus HC, but did not differentiate patients with and without PH. Cardiomyopathy patients had enhanced FAK and integrin signaling, and phagosome formation pathways. IPA analysis of SSc-ILD vs HC revealed association with pulmonary fibrosis signaling pathway with increased expression of SERPINE1 and PLAU genes. mRSS was highly correlated with XPR1, a novel gene implicated in phosphate homeostasis (r=0.72, padj 0.006).

Conclusion: Our results suggest that SSc patients can be classified into distinct groups based on transcriptomic profiles of monocytes, which correlate with specific clinical characteristics. The DEGs for clinical features revealed significant connections to the disease manifestations, potentially opening the avenue for new therapeutic targets.

Topological Proteomic Differences in Fibrotic and Unaffected Skin in Scleroderma

Irene Choi[1], Courtney Yu[2], Francesco Boin[1], Elizabeth Volkmann[3], Stephanie Stanford[2] and Nunzio Bottini[4], [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]University of California San Diego, San Diego, CA, [3]University of California Los Angeles, Los Angeles, CA, [4]University of California, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleroderma (SSc) is a chronic autoimmune and rheumatic disease characterized by varying levels of tissue fibrosis in the skin and other internal organs. It currently has no cure, with little understanding of the pathogenesis of skin fibrosis and an acute need for novel therapeutic targets. Because the skin is a complex, multi-layer organ with diverse functions, it is critical to examine the regional molecular changes throughout each distinct layer to understand the fibrotic processes that occur in the affected skin of SSc patients. To do this, we performed laser capture microdissection (LCM) to separate the epidermis, papillary dermis, and reticular dermis layers from fibrotic and unaffected skin of SSc patients for further proteomic analysis.

Methods: Skin biopsies were collected from fibrotic and unaffected skin of three patients with diffuse SSc (dSSc); subsequently, the epidermis, papillary dermis, and reticular dermis were dissected using LCM. The dissected tissue was digested and subjected to liquid chromatography with tandem mass spectrometry (LC-MS/MS) for proteomic analysis. Univariate and clustering analysis were performed using the MetaboAnalyst 5.0 package. Univariate analysis was performed using fold change analysis and t-test, and hierarchical clustering analysis was performed using Euclidean distance measurements to identify proteins significantly up or downregulated in fibrotic skin compared to unaffected skin for each skin sublayer.

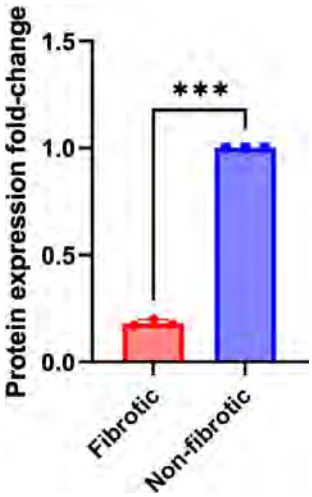

Figure 1: FAM161B is significantly downregulated in papillary dermis of fibrotic skin. Fibrotic and unaffected skin biopsies from patients with SSc (n=3) were subjected to LCM to isolate the papillary dermis, then LC-MS/MS for proteomic analysis. The graph shows fold-change for FAM161B normalized to non-fibrotic protein intensity. Statistical significance was assessed using two-tailed paired t test, ***p<0.0001

Results: All patients biopsied were female, had been diagnosed with dSSc, had early SSc (< 3 yrs from SSc diagnosis), and were being treated with mycophenolate mofetil. Univariate analysis of fibrotic versus unaffected skin revealed unique proteins that were significantly ($p< 0.05$) down or upregulated (fold-change >2) in each region. Interestingly, when comparing fibrotic and unaffected papillary dermis we identified a significant downregulation of FAM161B (fold change=-2.4573, p-value< 0.0001), a cilial protein, in all three patients. This is compelling because decreased expression of SPAG17, another cilial protein, has been correlated with increased skin fibrosis in SSc patients. Importantly, none of the differentially expressed proteins in the distinct skin layers overlapped with each other, confirming that fibrosis affects the microenvironments of the skin layers in SSc patients.

Conclusion: Through the use of LCM, we established a method for proteomic analysis of substructures from fibrotic and unaffected skin of SSc patients. This technology can be used to complement single-cell spatial transcriptomics to provide key information on in situ gene expression profiles and identify disease and substructure-specific targets for SSc skin fibrosis.

Anti-Topoisomerase Antibody in dcSSc: Unravelling Its Intracellular Effects in Systemic Sclerosis

Maithri Aspari[1], Josephine Geertsen Keller-Socin[1], Stinne Greisen[2], Esben Naeser[3], Klaus Soendergaard[4], Birgitta R Knudsen[5], Voon Ong[6], Christopher Denton[7], David Abraham[7] and Bent Deleuran[1], [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University/Aarhus University Hospital, Aarhus, Denmark, [3]Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [4]Aarhus University Hospital, Aarhus, Denmark, [5]Institute for molecular Biology, Aarhus University, Aarhus, Denmark, [6]UCL Medical School Royal Free Campus, London, United Kingdom, [7]University College London, London, United Kingdom

SESSION INFORMATION

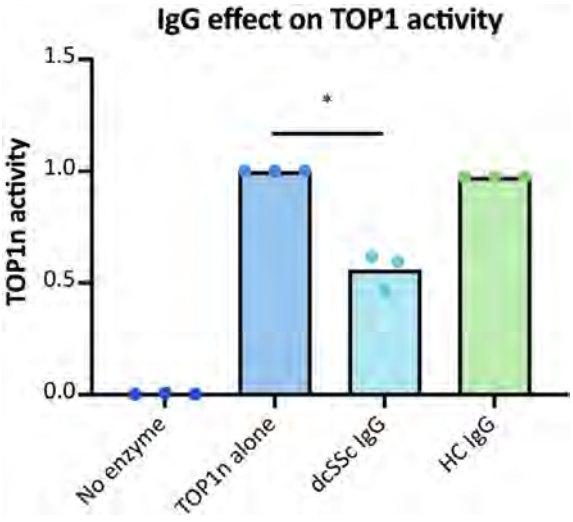
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of autoantibodies, especially directed towards topoisomerase I (ATA), in diffuse cutaneous Systemic Sclerosis (dcSSc) is known to be associated with severe clinical manifestations. Though various detection methodologies are used in the clinic, less is known about the intracellular functionality of this antibody. Analysis of ATAs ability to inhibit topoisomerase 1 (TOP1) may function as a new biomarker of progressive and severe disease.

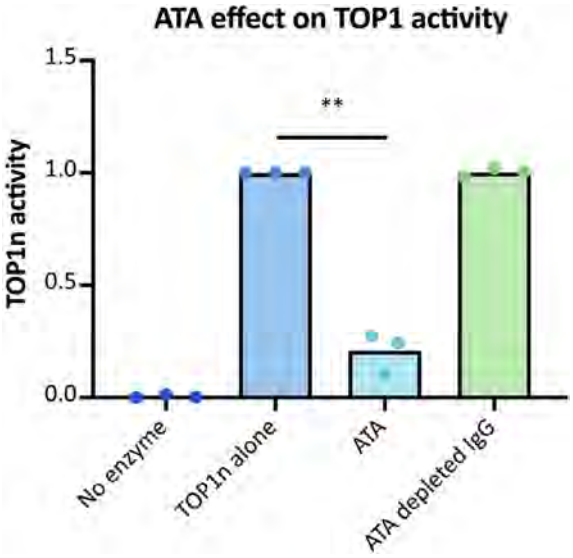
Methods: ATA was separated from serum from dcSSc patients (n=10) and healthy controls (HC, n=2). The immunoglobulin G (IgG) fraction was separated using a Protein G column (Figure A) followed by column separation towards TOP1. Sensitivity and purity were tested using western blot and biacore affinity analysis. The effect of serum, total IgG, ATA, and ATA depleted IgG from dcSSc patients and serum and IgG from HC on TOP1 catalysis were analyzed. We used a rolling circle amplification activity detection assay (REEAD) measuring the DNA cleavage-ligation activity of TOP1, as well as a nicking assay where TOP1 trapped in covalent complex with one strand of a plasmid DNA. To address the intracellular effect of ATA on TOP1 activity, dcSSc fibroblasts cultures were incubated with ATA or HC IgG mixed with lipofectamine for 6 hours, extracellular matrix protein signalling was analysed by PCR.

Results: dcSSc serum and IgG showed significant inhibition of TOP1 DNA cleavage-ligation activity when compared to HC serum and IgG, in a dose dependant manner. (Image 1). ATA separated from dSSc patients showed significant inhibition on TOP1 activity and this inhibition was abrogated when the ATA fractions were removed from the IgG pool. (Image 2). DcSSc IgG created TOP1 induced DNA nicks, suggesting that dcSSc IgG to induce accumulation of TOP1 cleavage complexes, which is a well-known inducer of DNA fragmentation in cells (Image not shown). PCR analysis of fibroblast transfected with ATA and HC IgG showed significant increase in signalling for extracellular matrix proteins such as intercellular adhesion molecule (ICAM) and Vascular cell adhesion molecule (VCAM)(Image 3).

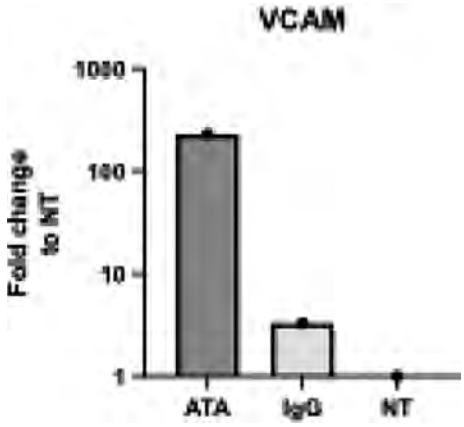
Conclusion: We have successfully separated functional ATA from dcSSc patients. These antibodies show significant effect on both nuclear and mitochondrial TOP1 activity. ATA causes DNA nicks and release free DNA into the cytosol, activating a cascade of inflammatory pathways leading to increased production of proinflammatory cytokines and extracellular matrix proteins. This study links ATA to central intracellular pathways, thus providing a better understanding of the disease pathogenesis



REEAD assay showing the inhibitory effect of dcSSc IgG on nuclear Topoisomerase activity



REEAD assay showing significant inhibitory effect of Antitopisomerase antibody(ATA) on nuclear Topoisomerase 1, this effect is lost on depleting ATA from the IgG pool



Graph representing the fold change in VCAM signalling in dcSSc fibroblasts stimulated with Antitopoisomerase antibody and normal human IgG, analysed by PCR

Systemic Sclerosis (SSc) Dermal Fibroblasts Show Shortened Primary Cilia Due to Aberrant Aurora a Kinase Activation Independently of Transforming Growth Factor β Signalling

Rebecca Wells[1], Rebecca Ross[2], Alex Timmis[1], Ioanna Georgiou[1], Colin Johnson[1], Natalia Riobo-Del Galdo[1] and Francesco Del Galdo[3], [1]University of Leeds, Leeds, United Kingdom, [2]Medicine and Health, University of Leeds, Leeds, United Kingdom, [3]University of Leeds - Leeds Institute of Rheumatic and Muskuloskeletal Medicine, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disorder characterised by abnormal activation of tissue fibroblasts, resulting in tissue and vascular fibrosis of the skin and internal organs. Aberrant activation of TGFβ signalling plays a central role in the profibrotic fibroblast phenotype. Fibroblasts cultured from SSc skin biopsies maintain their profibrotic activation in vitro. Patients with SSc do not show classic signs of primary aberrant profibrotic activation such as keloid or fibrotic responses to injury, leaving the mechanisms underlying fibroblast activation and tissue fibrosis not completely elucidated. The primary cilium (PC) is a sensory antenna-like organelle on the cell, forming a specialised signalling hub for several pathways involved in tissue homeostasis and response to the extracellular microenvironment. The aim of this study was to investigate the structure of the PC in SSc dermal fibroblasts to determine its potential contribution to SSc pathogenesis.

Methods: Dermal fibroblasts were isolated from forearm skin biopsies of healthy control (HC) and SSc patients. PC were visualised by immunofluorescence with an Acetylated-α-Tubulin antibody followed by confocal microscopy. PC length was quantified from at least 100 PC across 3 independent fields per condition. Fibroblasts were stimulated with TGFβ for 24h or a set time course with increments between 0-24h. SD208 (1μM) was used to inhibit TGFβ Receptor Kinase 1 (TGFβR1), MLN8054 (5μM) was used to inhibit Aurora A Kinase (AURKA), and Tubastatin A (1μM) was used to inhibit Histone Deacetylase 6 (HDAC6).

Results: PC length was normally distributed in both HC and SSc dermal fibroblasts. PC from SSc fibroblasts were on average 45% shorter than HC (2.5 ± 0.6 μm vs 4.6 ± 1.3 μm, respectively ($P< 0.0001$)). TGFβ treatment significantly reduced the mean PC length in both HC and SSc, reaching around 1.8 μm in both by 24 hours. Time course experiments showed a quicker response to TGFβ in SSc fibroblasts, with PC starting to shorten as soon as 2h vs 6h in HC. Inhibition of TGFβR1 prevented the ability of TGFβ to shorten PC in both, but did not 'rescue' SSc fibroblast PC length to that of HC. On the contrary, inhibition of AURKA – a kinase known to be involved in PC disassembly – did not abolish the effect of TGFβ in either cell type. However, AURKA inhibition increased PC length of SSc cells from 2.9 ± 0.4 μm to 4.4 ± 0.9 μm ($P< 0.05$), without affecting HC PC length, effectively "rescueing" the shortened PC phenotype of SSc cells, increasing PC length, indistinguishable from HC PC. The effect of AURKA was independent of its primary effector, HDAC6, as neither the difference in basal PC length nor the TGFβ effect were rescued by HDAC6 inhibition with Tubastatin A.

Conclusion: PC length is stably reduced in SSc dermal fibroblasts independently of TGFβR1 activity. Inhibition of AURKA in SSc restores "healthy" PC length via an atypical mechanism not involving its primary effector HDAC6. These observations support the notion that the profibrotic activation of dermal fibroblasts in SSc may go beyond a TGFβ-dependent mechanism. Modulation of PC length by AURKA deserves to be further explored as a contributor to profibrotic activation, and a potential therapeutic target for tissue fibrosis.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The Disease Activity index for PSoriatic Arthritis based on 66/68 joints (DAPSA66/68) and the Disease Activity Score in 28 joints with C-reactive protein (DAS28-CRP) are two widely used disease activity scores to monitor patients with psoriatic arthritis (PsA). A modified DAPSA based on 28 joints (DAPSA28) has been proposed and validated in patients with PsA. We aimed to identify and compare predictors of clinical remission according to DAPSA28 (≤4), DAPSA66/68 (≤4) and DAS28-CRP (< 2.6) in a broader population of European patients with PsA initiating a first tumor necrosis factor inhibitor (TNFi).

Methods: Prospectively collected real-world data from PsA patients initiating a first TNFi between 2009 and 2018 from nine countries participating in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were pooled. Patients with complete data on DAPSA28, DAPSA66/68 as well as DAS28-CRP at 6-month follow-up (from 90 to 270 days after treatment start date) constituted the study cohort. Logistic regression analyses on multiple imputed baseline data (20 imputed datasets) were used to identify predictors of DAPSA28, DAPSA66/68 and DAS28-CRP remission at 6 months. Fifteen baseline (from 30 days before to 30 days after treatment start date) demographic and clinical characteristics were included as potential predictors. For each remission outcome, variable selection was performed separately in each imputed dataset. Predictors that appeared in at least half of the datasets were included in the final model.

Results: Of 10,249 PsA patients, 3,159 (30.8%) had complete assessments of DAPSA28, DAPSA66/68 and DAS28-CRP at 6 months and were included in the analyses. Baseline characteristics of included patients were similar to those not included (Table 1). Among included patients, 896 (28.4%), 861 (27.3%), and 1,866 (59.1%) were in DAPSA28, DAPSA66/68 and DAS28-CRP remission at 6 months, respectively. The same eleven predictors were identified for DAPSA28 and DAPSA66/68 remission, while nine predictors were selected for DAS28-CRP remission (Table 2). Eight predictors were common for all three remission outcomes: male gender, longer disease duration and higher CRP were positive predictors, while older age, higher body mass index, patient global score, health assessment questionnaire and 68 tender joint count reduced the odds of remission (Table 2). The same predictors were identified when substituting 66/68-joint counts with 28-joint counts in the set of potential predictors (with 28 tender joint count replacing 68 tender joint count as a predictor).

Table 1. Baseline characteristics of PsA patients starting a first TNFi among patients included and excluded from the analyses

	Patients with complete data on DAPSA28, DAPSA66/68 and DAS28-CRP at follow-up (n=3,159)		Patients without complete data on DAPSA28, DAPSA66/68 and DAS28-CRP at follow-up (n=7,090)

Baseline variables that are common predictors across all outcomes are highlighted in italics.

Variable selection process: For each remission outcome, the selection was performed separately in each of the 20 imputed datasets. Initially, univariable logistic regression analyses were performed for all potential predictors. Variables with a p-value <0.20 in univariable analyses were included in the initial multivariable model, where a backward stepwise selection was applied. Next, potential predictors excluded in univariable analyses were introduced one at a time in the multivariable model and their significance tested. The final model included the predictors that appeared in at least half of the 20 separate models. Once the set of predictors was selected, the model was fitted to all 20 imputed datasets and the model estimates were pooled according to Rubin's rules. Likelihood ratio tests were used to assess all models.

BMI: Body Mass Index; CI: confidence interval; CRP: C-reactive protein; csDMARD: conventional synthetic Disease Modifying Anti-Rheumatic Drug; DAPSA28: Disease Activity index for Psoriatic Arthritis based on 28 joints; DAPSA66/68: Disease Activity index for Psoriatic Arthritis based on 66/68 joints; DAS28-CRP: disease activity score in 28 joints based on CRP; HAQ: Health Assessment Questionnaire; OR: odds ratio; SJC66: Swollen Joint Count based on 66-joint assessment; TJC68: Tender Joint Count based on 68-joint assessment; TNFi: Tumor Necrosis Factor Inhibitor.

*The CRP cut-off was decided based on the various detection limits used across registries.

Conclusion: Identical variables were found as predictors of both DAPSA28 and DAPSA66/68 remission in patients treated with a first TNFi. The majority of these variables also predicted DAS28-CRP remission, although DAS28-CRP remission was more commonly achieved. Our findings suggest that baseline determinants of remission according to different disease activity scores are similar and support the use of DAPSA28 in datasets where only 28-joint counts are available.

The Burden of Oligoarticular Psoriatic Arthritis in the United States

Abisola Olopoenia[1], Ashley Martin[2], Kate Orroth[3], Cynthia Deignan[4], Myriam Cordey[5] and **Dafna Gladman**[6], [1]Cerner Enviza, North Kansas City, MO, [2]BluePath Solutions, Los Angeles, CA, [3]Amgen, Inc., Manhattan Beach, CA, [4]Amgen, Inc., Agoura Hills, CA, [5]Amgen, Inc., Thousand Oaks, CA, [6]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Department of Medicine, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with oligoarticular psoriatic arthritis (oligo PsA), defined as four or less joints involved, often do not meet criteria for entry in trials of targeted treatments. However, clinical data suggest oligo PsA impacts the patient equally as polyarticular (poly) PsA (> 4 joints) (Gladman D, et al. J Rheumatol. 2021;48:1824-1829). Limited information exists on oligo PsA burden in the United States (US). This study aimed to describe the demographic and clinical characteristics of oligo PsA patients and compare quality of life (QoL) and economic impact of this disease relative to the general population.

Methods: Retrospective, cross-sectional data from the 2019 National Health and Wellness Survey (Cerner Enviza) conducted in the US were utilized to identify adult respondents who self-reported a diagnosis of PsA and those who did not (ie, no psoriasis or PsA), representing the general US population (non psoriasis [Pso]/PsA). Within the PsA population, the oligo PsA cohort was selected if self-reported ≤ 4 affected joints and the remainder constituted the poly PsA cohort. Prevalence estimates were weighted to the US population using US census weights. Demographic and health characteristics

^available questionnaires data

were compared across cohorts. Additional outcomes assessed included: PsA characteristics (joints affected, prescribing/diagnosing physician), health-related QoL (HRQoL), healthcare resource utilization in the prior 6 months, and work productivity and activity impairment (WPAI).

Results: A total of 374 respondents were classified as having oligo PsA (weighted count: 1.3 million); 72,431 were classified as non Pso/PsA (weighted count: 241.8 million).Individuals with oligo PsA were more likely to be younger, male, employed, smoke or consume alcohol, to have a higher annual income and to have graduated college relative to non Pso/PsA (Table 1). About 44.4% of oligo PsA patients were diagnosed by their primary care physician with 52.7% prescribed treatment (Table 2). Although the most frequently affected joints (knees, fingers, hands and feet) were similar in both oligo and poly PsA (n=305), a larger proportion of oligo PsA patients were untreated (23.3% vs. 16.7%) and a smaller proportion diagnosed by rheumatologists (23% vs. 40.7%). Respondents with oligo PsA reported higher co-morbidities, lower HRQoL, lower mental and physical functioning, higher health care provider visits and higher WPAI relative to non Pso/PsA. Additionally, while a higher proportion of individuals with oligo PsA were employed relative to poly PsA, individuals with oligo PsA reported greater work productivity losses (Table 3).

Conclusion: The oligo PsA population was active in the workforce but had significantly higher comorbidity burden and impairments in both QoL and work productivity than the general population. Furthermore, despite the perception of poly PsA as a more severe disease, the oligo PsA population had a similar QoL burden (EQ-5D) and reported greater work productivity losses than those with poly PsA. These findings suggest that the burden of oligo PsA is high in the United States and warrants further research and clinical attention.

Abstract Number: 0967

Overall Survival in Patients with versus Without Rheumatoid Arthritis Initiating Immune Checkpoint Inhibitors for Metastatic Non Small Cell Lung Cancer

Deanna Jannat-Khah[1], Jeffrey R Curtis[2], Fenglong Xie[3], Ashish Saxena[4] and Anne Bass[5], [1]Hospital For Special Surgery, New York, NY, [2]Division of Clinical Immunology and Rheumatology, University of Alabama, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Weill Cornell Medicine, New York, NY, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) increase one-year survival in metastatic non-small cell lung cancer (mNSCLC) from 49% to 69% with chemotherapy-based regimens. Patients with rheumatoid arthritis **(**RA) have a 60% higher risk of lung cancer than the general population but were not included in seminal ICI trials. The goal of this study was to compare overall survival (OS) in ICI-treated patients with mNSCLC with pre-existing RA versus without RA.

Methods: We used a curated Medicare claims dataset that consist of a 100% sample of patients with RA. ICI use was identified using Healthcare Common Procedure Coding System (HCPCS) codes. Patients with mNSCLC were defined by having two claims at least two months apart associated with an ICD-9 162.9 or ICD-10 C34.X diagnosis code for malignant neoplasm of lung and bronchus. We limited the cohort to patients who initiated ICI between 2015-2019 because ICI was only approved for mNSCLC during this period, and not for earlier stages or other types of lung cancer. RA was defined as having two claims associated with an ICD-9-CM or ICD-10-CM diagnosis code for RA. ICI-treated non-RA comparator patients were identified in the Medicare 5% sample. Descriptive statistics were calculated for each cohort and for overall survival. Kaplan Meier curves and adjusted log logistic survival models were created to measure overall survival, anchored at the time of first ICI initiation. Patients were followed through 12/31/2019 and were censored at time of death or last recorded visit in the database.

Results: A total of 10454 ICI-treated patients with mNSCLC were included in the analysis; 4,544 with RA (100% sample) and 5910 without RA (5% sample). Overall mean age was 74.3 (SD 8.22) and 85% were White and non-Hispanic (Table 1). Patients with RA were more likely to be female, White and Hispanic than non-RA patients. Median time to death

Table 1. Demographics for immune checkpoint inhibitor-treated patients with metastatic non-small cell lung cancer, with and without rheumatoid arthritis

	Total	RA	non-RA	p-value
Total	10,454	4,544	5,910

Time ICI initiation to Death or Follow Up, median (IQR)	226 (89, 472)	232 (91, 477.5)	222 (88, 468)	0.190

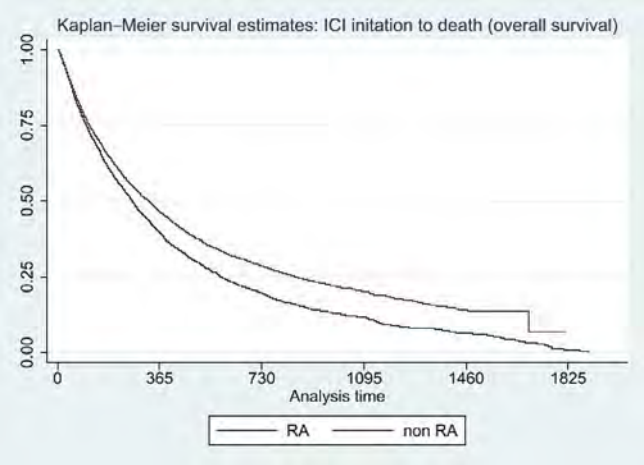

Figure 1: Overall survival in immune checkpoint inhibitor-treated metastatic non-small cell lung cancer patients with versus without rheumatoid arthritis

from first ICI initiation was 180 days (IQR 73,370) and 70% died (N=7,305). Figure 1 displays overall survival for ICI-treated mNSCLC patients with RA compared to those without RA.

Conclusion: Patients with pre-existing RA who develop lung cancer and initiate ICI for mNSCLC appear to have significantly worse overall survival compared to patients without RA. Further refinement of the cohort and further analyses of this dataset, including modeling, that incorporate prior lines of cancer therapy, receipt of concomitant chemotherapy and treatment with RA disease modifying antirheumatic drugs will be needed to confirm these findings.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular (CV) disease including heart failure (HF). HF is a heterogeneous condition that is categorized into two main subtypes: HF with reduced ejection fraction (HFrEF) and HF with preserved ejection fraction (HFpEF). Unlike HFrEF which arises primarily from ischemic myocardial

Table 1: Baseline characteristics of RA and non-RA comparators* at index date

	Non-RA (N=1919)	RA (N=1919)
Age (mean, SD)	50.5 (13.7)	50.2 (13.7)
Female (%)	78.7	78.7
Self-reported race (%)		
White	87.2	84.5
Black	5.0	5.7
Asian	1.7	2.2

Diabetes	6.8	6.9
Chronic kidney disease	2.3	2.7
Atrial fibrillation	2.6	1.9
Coronary artery disease	6.6	8.3
Stroke	4.6	4.3
Ever smoker† (%)	23.0	23.6

RA, rheumatoid arthritis; SD, standard deviation; EHR, electronic health record
*Non-RA comparators were matched to the RA cohort by birth year, sex, and EHR entry year
**Comorbidities were defined by the presence of ≥ 1 diagnosis codes prior to index date
†Smoking status was determined based on natural language processing of unstructured EHR data for positive mentions of concepts related to smoking prior to the index date

injury, the pathophysiology of HFpEF is less well understood but systemic inflammation is thought to play a role. RA may confer risk of HFrEF via ischemic heart disease and and HFpEF via systemic inflammation, but most prior epidemiologic studies have studied HF in RA as a single entity. Therefore, we sought to investigate the risk of HF and HF subtypes among patients with RA compared to non-RA patients.

Methods: Using an electronic health record (EHR)-based cohort at a large academic U.S. health system, we identified RA patients and non-RA comparators matched by age, sex, and year of entry into the EHR. Index date was defined as the RA diagnosis date (RA cohort) or an encounter date closest to the matched RA patient's index date (non-RA cohort). The primary outcome was incident HF as ascertained using a previously validated algorithm with a positive predictive value of 90%. HF subtypes were categorized based on EF extracted using natural language processing from clinical notes and cardiology reports closest to the HF incident date (HFpEF, EF ≥ 50%; HFrEF, EF ≤ 40%). Patients with prevalent HF at the index date were excluded. Covariates included age, sex, race, and CV risk factors. Patients were followed from the index date until incident HF, death, last EHR encounter, 20 years of follow up, or end of study (October 26, 2021). We estimated the incidence rate of HF and HF subtypes and used Cox proportional hazards model to estimate the adjusted hazard ratios (HR) for incident HF and HF subtypes.

Results: We studied 1919 RA patients and 1919 matched non-RA comparators (mean age 50 years, 78.7% female). Baseline characteristics, including the proportion of patients with CV risk factors, were similar between the two groups (**Table 1**). Over 42,858 person-years of follow up, we identified 128 incident HF diagnoses (6.7%) in the RA cohort and 87 in the non-RA cohort (4.5%). HFpEF was the most common HF subtype in both cohorts (64.1% in RA, 60.9% in non-RA). The overall incidence rate of HF was higher in the RA cohort than the non-RA cohort (6.11 per 1000 person-years vs. 3.97 per 1000 person-years). Patients with RA had a 56% higher rate of incident HF overall (95% CI: 1.18 - 2.06) compared to those without RA, even after adjusting for established CV risk factors (**Table 2**). Examining the HF subtypes, we found that RA patients had a 62% higher rate of HFpEF (95% CI: 1.13 - 2.30), but there was no significant difference in HFrEF rate between the RA and non-RA cohorts (95% CI: 0.81 - 2.75).

Conclusion: RA was associated with higher rate of HF overall compared to non-RA comparators, even after adjustment for CV risk factors. The elevated risk was driven by HFpEF, highlighting an opportunity to reduce HF risk in RA by targeting HFpEF. More studies are needed to identify modifiable HFpEF risk factors in RA and methods for earlier detection before clinical HF.

Table 2: Risk of incident HF and HF subtypes in RA and non-RA comparators

	Non-RA (N = 1919)	RA (N = 1919)
Follow up time (person-years)	21,901	20,957
Overall HF		
Cases (n)	87	128
Incidence rate (per 1,000 person-years)	3.97	6.11
Unadjusted hazard ratio	1.00	**1.54 (1.17 - 2.02)**
Adjusted hazard ratio*	1.00	**1.56 (1.18 - 2.06)**
HF with reduced EF**		
Cases (n)	18	25
Incidence rate (per 1,000 person-years)	0.82	1.19
Unadjusted hazard ratio	1.00	1.46 (0.80 - 2.68)
Adjusted hazard ratio*	1.00	1.49 (0.81 - 2.75)
HF with preserved EF†		
Cases (n)	53	82
Incidence rate (per 1000 person-years)	2.42	3.91
Unadjusted hazard ratio	1.00	**1.62 (1.14 - 2.28)**
Adjusted hazard ratio*	1.00	**1.62 (1.13 - 2.30)**

HF, heart failure; RA, rheumatoid arthritis; EF, ejection fraction
*Adjusted for sex, age, race, and CV risk factors: baseline history of coronary artery disease, diabetes, hypertension, hyperlipidemia, atrial fibrillation, chronic kidney disease, stroke, smoking
**Defined as having EF ≤ 40%
†Defined as having EF ≥ 50%. Those with a moderately reduced EF of 41 – 49% were included in the overall HF but excluded from the HF subtypes above

Tumor Necrosis Factor-α Inhibitors Reduces Obstructive Sleep Apnea in Patients with Juvenile Idiopathic Arthritis: A Population-based Cohort Study

Pin-Chia Huang[1], **Katharine Ching Chung**[2], Zachary S Peacock[3] and Kevin Sheng-Kai Ma[4], [1]Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, [2]University of Pittsburgh Medical Center, Mckeesport, PA, [3]Oral and Maxillofacial Surgery, Massachusetts General Hospital, Harvard School of Dental Medicine, Boston, MA, [4]Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor-α (TNF-α) plays a role in the pathogenesis of and serves as a biomarker for obstructive sleep apnea (OSA). Moreover, patients with juvenile idiopathic arthritis (JIA) had a numerically elevated risk of OSA. Given TNF-α inhibitors have been widely used to treat JIA, the aim of the present study was to assess the risk of OSA among patients with JIA on TNF-α inhibitors.

Methods: This was a population-based cohort study of patients with JIA diagnosed following the International League of Associations for Rheumatology (ILAR) classification criteria. Subjects treated between 2008 and 2023 at 92 United States hospitals were screened. Propensity score matching was used to balance the baseline differences in age of JIA onset, sex, comorbidities, and past medical history between the two groups. The primary predictor variable was any use of TNF-α inhibitor therapy. The primary outcome of interest was the occurrence of new-onset OSA during the follow-up period. A Kaplan-Meier analysis and log-rank tests were utilized to compare the incidence and risk of OSA between the two arms. A Cox proportional hazards model was utilized to estimate the association between the use of TNF-α inhibitors and new-onset OSA.

Results: A total of 608,190 patients with JIA underwent propensity score matching. This resulted in 1,299 included subjects with JIA treated with TNF-α inhibitors, 514 patients developed new-onset OSA after the use of TNF-α inhibitors. In comparison, 594 TNF-α inhibitor non-users developed incident OSA during the follow-up period. Survival analysis suggested a significantly lower incidence of OSA in TNF-α inhibitor users over non-users (log-rank test, p-value < 0.001). Cox proportional hazard regression showed subjects receiving TNF-α inhibitors were associated with a significantly lowered risk of new-onset OSA as compared to non-users (HR=0.87, 95% CI: 0.78, 0.98; RR=0.86, 95% CI: 0.76, 0.96)

Conclusion: Findings in the present study suggested that subjects with JIA treated with TNF-α inhibitors presented with a significantly decreased risk of OSA. This finding was consistent with previous studies reporting that the use TNF-α inhibitors resulted in a significantly lowered risk of OSA and better sleep quality in patients with other inflammatory arthritis such as spondyloarthritis and rheumatoid arthritis. Clinical trials are required to validate the findings.

Abstract Number: 0970

Comparison of Survival on Treatment and Severe Infection Among New Users of Biosimilar vs. Originator Biologics in Inflammatory Arthritis: Population-based Evidence from a Natural Experiment Due to a Policy Change

Diane Lacaille[1], J. Antonio Avina-Zubieta[2], Yufei Zheng[2], Na Lu[2] and Hui Xie[3], [1]Arthritis Research Canada, University of British Columbia, Vancouver, BC, Canada, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]Simon Fraser University, Richmond, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: British Columbia's health policy mandated that all new anti-TNF initiations after June 2017 use biosimilars when available, providing the context for a natural experiment. Our study objective was to compare drug survival and severe infections (as surrogate markers of effectiveness and safety) after the initiation of etanercept and infliximab for inflammatory arthritis in new users of biosimilars versus originators, using historical controls pre- and post-policy change.

Methods: Study Cohort: Using administrative health data, we identified all incident users of a new biologic (i.e., without prior prescriptions over 6 months) with rheumatoid arthritis (RA), psoriasis or psoriatic arthritis (Pso/PsA), or ankylosing spondylitis (AS). The biosimilar cohort includes users starting etanercept or infliximab between 07/01/2017 and 12/31/2019, followed until 12/31/2020 (post period). Historical controls include all incident users of etanercept/infliximab originators between 01/01/2014 and 06/30/2016, followed until 06/30/2017 (pre period). To control for temporal trend, we selected new users of adalimumab (no biosimilar available over the same time periods) as a comparison group.

Outcome: Discontinuation was defined as no prescription renewal for at least 6 months, and severe infection was defined as hospitalization with an infection diagnostic code in any position.

Statistical analyses: People were followed for up to 3 years from anti-TNF initiation until death, moving out-of-province, or the end date of the follow-up, whichever occurred first. Rates were calculated. We applied weighted Cox Proportional Hazard Models to estimate the adjusted hazard ratio (aHR) of discontinuing anti-TNFs and Quasi Poisson Models to estimate the adjusted rate ratio (aRR) of severe infections. We applied propensity overlap weights to control for potential confounders. To control for temporal trend, we employed the difference-in-difference (DID) method, comparing drug survival and severe infections among new users of biosimilar vs. originator etanercept/infliximab with new users of adalimumab post- vs. pre-policy change. The DID computes the difference between the logarithms of the aHRs/aRRs for etanercept/infliximab and for adalimumab, reported as the ratio of the two aHRs/aRRs in Table 1C.

Results: Our sample includes 827 biosimilar etanercept users (RA:576, AS:171, Pso/PsA:80) and 271 infliximab users (RA:150, AS:54,Pso/PsA:67); 1312 etanercept and 230 infliximab originator users; and 2213 adalimumab originator users post- and 1773 pre-policy change. Counts and rates of discontinuation and severe infections are reported in Table 1A. After adjusting for baseline covariates (Table 1B), and after accounting for temporal trends (Table 1C), the likelihood of discontinuation and severe infection was similar for biosimilar vs. originator etanercept and infliximab users.

Conclusion: Real-world population-based data showed that incident users of biosimilar etanercept and infliximab had similar discontinuation and severe infection rates as originators, suggesting comparable effectiveness and safety for inflammatory arthritis.

Network Meta Analyses of the Effectiveness and Safety Profiles of Janus Kinase Inhibitors and Biologic Agents in Treating Children with Non-systemic Juvenile Idiopathic Arthritis (nsJIA)

Bin Huang[1], Yuxiang Li[2], Xiaomeng Yue[3], Sandra Andorf[2], Daniel J Lovell[4] and Hermine Brunner[5], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]James L. Winkle College Pharmacy, Cincinnati, OH, [4]UC Department of Pediatrics, Cincinnati Children's Hospital, University of Cincinnati, Cincinnati, OH, [5]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib (TOFA, NCT02592434) and Baricitinib (BARI, NCT03773978) are Janus kinase inhibitors (JAKi) that are approved for or being tested for nsJIA treatment. We aim to evaluate the effectiveness and safety profiles of JAKi, vs. biological agent (BA) with or without Methotrexate (MTX) combination in treating children with nsJIA.

Methods: Studies written in English language and published in ClinicalTrial.gov, PubMed, EMBASE, Cochrane are searched from establishment of the databases to May 2023. Randomized studies conducted in the nsJIA population, investigated effectiveness of JAKi or BA, and reported JIA-ACR responses with/without adverse event outcomes are eligible. The primary outcome of clinical efficacy was measured by JIA-ACR70 responses at 16+/-4 weeks and secondary outcomes include serious adverse events (SAE). Bayesian Network meta-analyses (BNMA) evaluate the effectiveness and safety outcomes of JAKis and BAs with/without MTX.BNMA are conducted separately for efficacy and safety outcomes. League table reports results for all pairwise comparisons.

Results: The initial search query yielded 2,475 citations. Fifteen randomized controlled trials (RCT, 6 parallel and 9 withdrawal trials) met the study inclusion criteria. The meta-analyses investigated 6 BA, 3 BA+MTX combination, and two JAKi (i.e. TOFA and BARI). MTX background treatment was allowed, rarely mandated. The trial design and sample characteristics are summarized in Table 1. The aggregate summary statistics reported for the efficacy and safety outcomes are presents in Figure 1. The BNMA analyzed data from a total of 1,796 patients, estimates of odds ratio (OR) and corresponding 90% credible intervals are reported in Table 2 for the efficacy (upper triangle) and safety outcomes (lower triangle).

Conclusion: No significant differences are observed for pairwise comparisons among TOFA, BARI and BAs either alone or in combination with MTX for efficacy and safety outcomes when used for treating children with nsJIA. The BNMA indirect comparisons are limited, given that trials differ greatly in participants age, duration of disease, % of MTX background therapy, whether the trial mandate patients with inadequate responses to composition of DMARD or NSAID to be eligible, as well as the composition of JIA subtypes. The SAE may be defined differently in different studies. Future studies will expand the meta-analyses by including non RCT studies and individual patients' data.

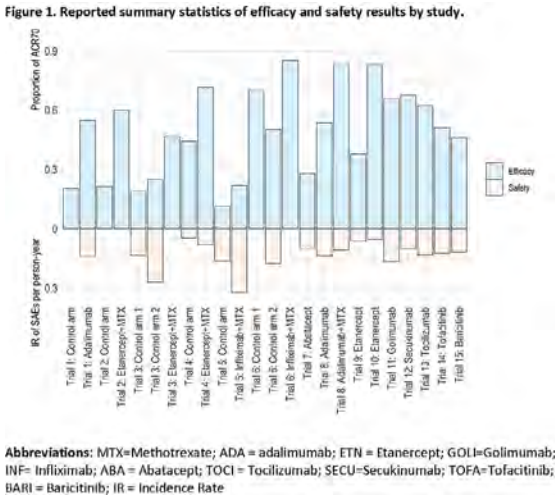
* The upper right triangle (blue shades) reports the odds ratio (OR) and corresponding 90% credible interval (CI) for efficacy (JIA-ACR70) and the lower left triangle (pink shades) reports incidence rate ratio and its 90% CI for safety outcomes (SAE). Bold fonds indicate two-sided 90% CI not including 1. Values <1 suggest the row has better efficacy or safety profile than the column.



Reported summary statistics of efficacy and safety results by study.

Increased Incidence of Inflammatory Arthritis After COVID-19 in a Colombian Population

Juan Marin[1], Enrique Mazenett[1], Mauricio Sarmiento[1], Rosalbina Perez[1], Claudia Morales[1], Jorge Dominguez[1], Juan Salazar[2] and Juan-Manuel Anaya[3], [1]Coosalud, EPS, Cartagena, Colombia, [2]Universidad Nacional, Medellin, Colombia, [3]Coosalud, EPS, Bogotá, Colombia

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: An increase in the incidence of autoimmune diseases after COVID-19 has been reported. Since many diseases exhibit population-specific causal effect sizes, we aimed to evaluate the incidence trends of inflammatory arthritis (IA), including rheumatoid arthritis (RA), after COVID-19 in a large admixed Colombian population.

Methods: Data analysis for this retrospective, population-based cohort study was carried out using the COOSALUD EPS registry. COOSALUD EPS is a health insurance company, belonging to the subsidized regime in Colombia. The registry includes demographic and epidemiological data on diagnoses identified during admission and defined by the *International Classification of Diseases* (ICD-10). The following codes were selected for analyses: M059, seropositive RA, defined by the presence of rheumatoid factor (RF) or anti-citrullinated protein antibody (ACPA); M069, unspecified RA, in which RF and ACPA were not confirmed; M060 seronegative RA, in which RF and ACPA were negative; and other RA-related diagnoses: M064, M139, M068, M058, M130 and M053. All the diagnosis were made by qualified rheumatologists. The study period was limited to January 01, 2020, through December 31, 2022. Incidence rates (IRs) and incidence rate ratios (IRRs) were assessed. IRRs were computed by comparing the IR of those who had COVID-19 prior to the IA diagnosis and those who did not have COVID-19 prior to the IA diagnosis. A Cox survival model was built to evaluate the influence of age, gender, and COVID-19 vaccination status on the development of IA.

Table. Incidence rates (IRs) of inflammatory arthritis (IA) during the pandemic period (2020-2022) according to previous diagnosis of COVID-19, and the incidence rate ratios (IRRs).

Diagnosis	IR in patients without previous COVID-19	IR in patients with previous COVID-19	IRR	95% CI
RA, seropositive	1.03	1.65	**1.60**	**1.16 -2.22**
RA, unspecified	0.44	1.29	**2.93**	**2.04 - 4.19**
RA, seronegative	0.06	0.13	2.19	0.71 - 6.81
Other RA-related diagnosis	0.06	0.13	2.08	0.67 - 6.46
Overall IA				
M	0.52	1.16	**2.21**	**1.22 - 3.98**
F	2.61	4.73	**1.81**	**1.40 - 2.33**
Total	1.60	3.21	**2.01**	**1.59 - 2.53**

Bold indicates significance.

Results: The entire population study comprised 3,335,084 individuals, of whom 1,720,579 (51.59%) were women. The IRs of IA during the pandemic period (2020-2022) according to a previous diagnosis of COVID-19 and the respective IRRs are shown in the table. The associations remained significant after controlling for sex. The fitted Cox survival model showed that all the variables considered were significant ($p< 0.05$). The age groups estimates were increased until the age group of 51-60 years (HR: 9,163 95% CI: 7,245 - 11,589) and then decreased in the age group 61 years or older (HR: 5,364, 95% CI: 4,243 - 6,781) compared to those within 18-30 years. Men were less at risk than women to develop IA (HR: 0,2115, 95% CI: 0,182 - 0,246). The greater time since COVID-19 diagnosis was associated with a lower likelihood of developing IA (HR: 0,9986, 95% CI: 0,998 - 0,999). In vaccinated population, the probability of developing IA was reduced from HR: 3.345, 95% CI: 1.617 - 6.918 to HR: 3.232, 95% CI: 1.281 - 8.155 compared to those who did not have COVID-19. The model fitted well (Likelihood ratio test =2.074 $p< 0,05$; concordance = 0.77, $p< 0,05$).

Conclusion: Our findings indicate that the incidence of IA, including RA, increased following COVID-19, with the greatest increase occurring before the first year post-covid. Women were more susceptible than men. COVID-19 vaccination appears to be a protective factor.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Although clinical trials have shown similar effectiveness between Janus kinase inhibitors (JAKi) and biologic disease-modifying anti-rheumatic drugs (bDMARDs), the choice between these two options is currently a crucial question in real-world practice. However, there is a lack of sufficient real-world evidence comparing the outcomes and safeties of these treatments in patients with rheumatoid arthritis (RA). This study aimed to assess the efficacy and safety of JAKi compared to bDMARDs in Korean patients with RA who have not previously received either JAKi or bDMARDs.

Methods: In this prospective, multicenter, quasi-experimental study conducted at 17 centers in South Korea, we enrolled patients who had an inadequate response to Methotrexate (MTX) and initiated either Janus kinase inhibitors (JAKi) or biologic disease-modifying anti-rheumatic drugs (bDMARDs). The primary objective of the study was to assess the proportion of patients achieving low disease activity (LDA) at 24 weeks, as measured by the disease activity score (DAS) 28 erythrocyte sedimentation rate (ESR). Secondary endpoints included remission rate at 24 weeks, as well as LDA rates at 12 weeks and 48 weeks. Furthermore, we compared the safety profiles of the two treatment groups during the follow-up period.

Results: A total of 506 patients were enrolled in the study, with 253 patients in each of the JAKi and bDMARDs groups between April 2020 and August 2022. Among the bDMARDs users, 60.1% received TNFi (n = 152), while 39.9% received non-TNFi (n = 101). In the JAKi group, 48.6% received baricitinib (n = 123), 24.9% received tofacitinib (n = 63), and 26.5% received upadacitinib (n = 67). The two groups were comparable in terms of age (53.2 vs. 54.2) and the proportion of females (83.0% vs. 86.2%). Most patients in both groups received combination therapy with MTX (89.3% in both groups) and glucocorticoids (89.3% vs. 83.8%). At baseline, the bDMARDs group had slightly higher DAS28-ESR compared to the JAKi group (6.1 vs. 5.9, p=0.039). The primary endpoint, achieving LDA at 24 weeks, was observed in 48.2% of the JAKi group and 42.7% of the bDMARDs group (p=0.246). Regarding secondary endpoints, the remission rate at 24 weeks was 28.9% in the JAKi group and 27.3% in the bDMARDs group. Among patients receiving glucocorticoids at baseline (n=438), the rates of achieving glucocorticoid-free remission at 24 weeks were similar between the two groups (6.2% in bDMARDs and 8.5% in JAKi). The JAKi group showed a higher rate of achieving LDA at 12 weeks compared to the bDMARDs group, with marginal significance (45.9% vs. 38.3% based on DAS28 ESR, p=0.105). Currently, these patients are undergoing follow-up to gather data on the effectiveness and safety of the treatment at the 48-week mark.

Conclusion: In this real-world study involving Korean patients with RA eligible for targeted therapy, the profiles of JAKi users were similar to those of bDMARDs users. The study found that JAKi demonstrated comparable effectiveness and safety to bDMARDs users.

Validation of Boolean 2.0 Criteria for Assessing Remission and Predicting Quality of Life in Korean Patients with Rheumatoid Arthritis Undergoing Targeted Therapy

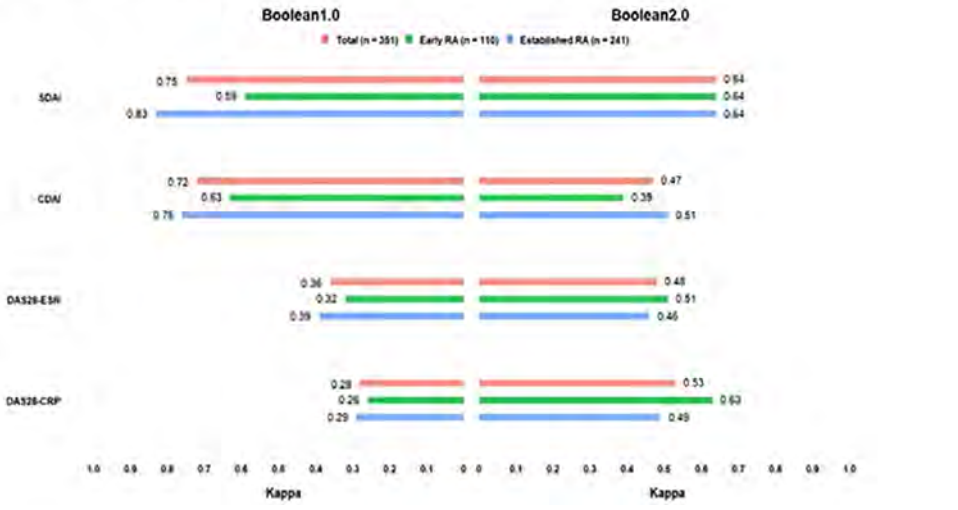
Soo-Kyung Cho[1], Yeo-Jin Song[1], Jungyong Han[2], Hye Won Kim[3], Eunwoo Nam[3] and Yoon-Kyoung Sung[1], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Hanyang University Institute for Rheumatology Research, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The management of rheumatoid arthritis (RA) focuses on achieving remission as a treatment goal. The updated ACR/EULAR remission definition (Boolean criteria 2.0) has raised the threshold for patient global assessment (PtGA) to 2 cm and received endorsement from ACR and EULAR. The revised Boolean 2.0 criteria classify more patients as achieving remission and show increased agreement with index-based criteria in US and European patients. This study aimed to validate the Boolean 2.0 criteria, assess their agreement with index-based remission criteria, and evaluate their predictive value for quality of life (QoL) compared to Boolean 1.0 criteria in Korean patients receiving targeted therapy.

Methods: Data from a multicenter prospective study of Korean patients with RA initiating biologic disease-modifying antirheumatic drugs or Janus kinase inhibitors were analyzed. Remission rates according to Boolean 2.0 and Boolean 1.0 criteria, as well as other index-based remission criteria, were measured at 24 weeks. Agreement between Boolean 2.0 criteria and index-based criteria was analyzed and compared with Boolean 1.0 criteria. Additionally, the likelihood ratio (LR) of Boolean 2.0 criteria in predicting improved QoL (health assessment questionnaire [HAQ] score ≤0.5 or EQ-5D =1) at 48 weeks was estimated and compared to Boolean 1.0 criteria.

Figure. Kappa values representing agreement between Boolean criteria and index based remission.



Results: A total of 351 RA patients were included, with a mean age of 53.2 years, and 86.9% were female. Boolean 2.0 criteria showed better agreement than Boolean 1.0 criteria for remission based on DAS28-ESR (kappa 0.48 vs. 0.36) and DAS28-CRP (kappa 0.53 vs. 0.28). However, Boolean 1.0 criteria exhibited higher concordance with SDAI (kappa 0.75) or CDAI (kappa 0.72) than Boolean 2.0 criteria (kappa with SDAI 0.64 and kappa with CDAI 0.47, respectively). Regarding predictive value for better QoL, remission based on Boolean 1.0 criteria showed higher LR compared to remission based on Boolean 2.0 criteria (6.01 vs. 2.49 for HAQ ≤0.5 and 3.53 vs. 2.37 for EQ-5D =1, respectively).

Conclusion: Among Korean patients with RA initiating targeted therapy, the Boolean 2.0 criteria showed enhanced agreement with remission assessments based on DAS28-ESR or DAS28-CRP, while the agreement with remission based on SDAI or CDAI was not improved compared to the Boolean 1.0 criteria. Furthermore, remission defined by the Boolean 1.0 criteria demonstrated a higher predictive value for improved QoL when compared to the Boolean 2.0 criteria.

Association of HLA-DRB1 Alleles with Ischemic Events and Mortality in a Multi-ethnic Community-living Population

Manmeet Kaur[1], Ronit Katz[2], Michael H. Criqui[1], Maripat Corr[1], Wendy S. Post[3], Matthew Budoff[4], Gerald P. Morris[5] and Jan Hughes-Austin[5], [1]University of California San Diego, San Diego, CA, [2]University of Washington, Seattle, WA, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]University of California Los Angeles, Los Angeles, CA, [5]University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Human leukocyte antigen (HLA) DRB1 alleles with specific common amino acids referred to as "the shared epitope (SE)", have been linked to cardiovascular mortality in inflammatory polyarthritis. Thesehaplotypes associate with ST-elevation myocardial infarction in the general population. However, less is known about the HLA-DRB1 alleles with other cardiovascular (CV) events. We aimed to determine associations of the HLA-DRB1 SE alleles (04:04, 04:05, 04:01, 04:08, 01:01, 14:02, 10:01, 03:01, 03:02) with ischemic events and mortality in a multi-ethnic community-living population.

Methods: Within the Multi-Ethnic Study of Atherosclerosis (MESA), a prospective cohort study designed to determine risk factors and progression of subclinical and clinical CVD, a subset of 955 participants who completed the Abdominal Aortic Calcium Ancillary Study and had complete measures of HLA typing and cardiac imaging were evaluated. We defined shared epitope positive [SE(+)] as being positive for any of the HLA-DRB1 SE alleles; and evaluated associations of SE positivity with all-cause mortality, CVD death (defined as secondary to stroke, coronary heart disease, other atherosclerotic death, or other CVD death), non-CVD death, angina, and myocardial infarction (MI) using Cox proportional hazards models. The covariates in our fully adjusted analysis included age, sex, race/ethnicity, diabetes mellitus, systolic blood pressure, current smoking, ever having cancer, eGFR, current use of anti-hypertensive medications, nonsteroidal anti-inflammatory drugs, and IL-6.

All-cause mortality		
Events / P-Y	30 / 520	18 / 435
Event rate (per 1000 P-Y)	3.79	2.71
Age, sex, race/ethnicity	1.00 (ref)	0.69 (0.38, 1.27)
Fully Adjusted	1.00 (ref)	0.74 (0.40, 1.37)
CVD death		
Events / P-Y	8 / 520	3 / 435
Event rate (per 1000 P-Y)	1.01	0.45
Age, sex, race/ethnicity	1.00 (ref)	0.37 (0.08, 1.79)
Fully Adjusted	1.00 (ref)	0.38 (0.08, 1.88)
Non-CVD death		
Events / P-Y	22 /520	15 / 435
Event rate (per 1000 P-Y)	2.78	2.26
Age, sex, race/ethnicity	1.00 (ref)	0.78 (0.40, 1.52)
Fully Adjusted	1.00 (ref)	0.85 (0.43, 1.67)
CVD events		
Angina		
Events / P-Y	22 / 520	28 /435
Event rate (per 1000 P-Y)	2.86	4.39
Age, sex, race/ethnicity	1.00 (ref)	1.45 (0.82, 2.56)
Fully Adjusted	1.00 (ref)	1.40 (0.79, 2.48)
Myocardial infarction		
Events / P-Y	18 / 520	14 / 435
Event rate (per 1000 P-Y)	2.31	2.13
Age, sex, race/ethnicity	1.00 (ref)	0.88 (0.43, 1.81)
Fully Adjusted	1.00 (ref)	0.88 (0.43, 1.81)

Associations of HLA-DRB1 alleles with Mortality and CVD Events in the Multi-Ethnic Study of Atherosclerosis

Results: Among the 955 MESA participants, 46% were positive for the shared epitope—38% carried a single allele, and 8% carried two alleles. Average age was 60±9, 47% were women, 51% were White, 9% were Asian, 16% were Black, and 24% were Hispanic/Latino. Age, sex, blood pressure, cholesterol, and inflammatory markers (CRP, TNF-α, IL 6) were similar between the SE(+) and SE(-) participants, but racial distributions differed where SE(+) had a higher proportion of white (51% vs 38%) and lower proportion of Asian (9% vs 17%) and Black (16% vs 21%) participants compared to SE(-). Both SE (+) and (-) had 24% Hispanic/ Latino. Being positive for the SE was not significantly associated with a higher risk of all-cause mortality, CVD death, non-CVD death, angina, or MI compared to those who were SE negative. The mean follow-up time was 15.3 ± 0.9 years.

Conclusion: HLA-DRB1 SE alleles were not associated with a higher risk of ischemic events or mortality in a multi-ethnic community-living population.

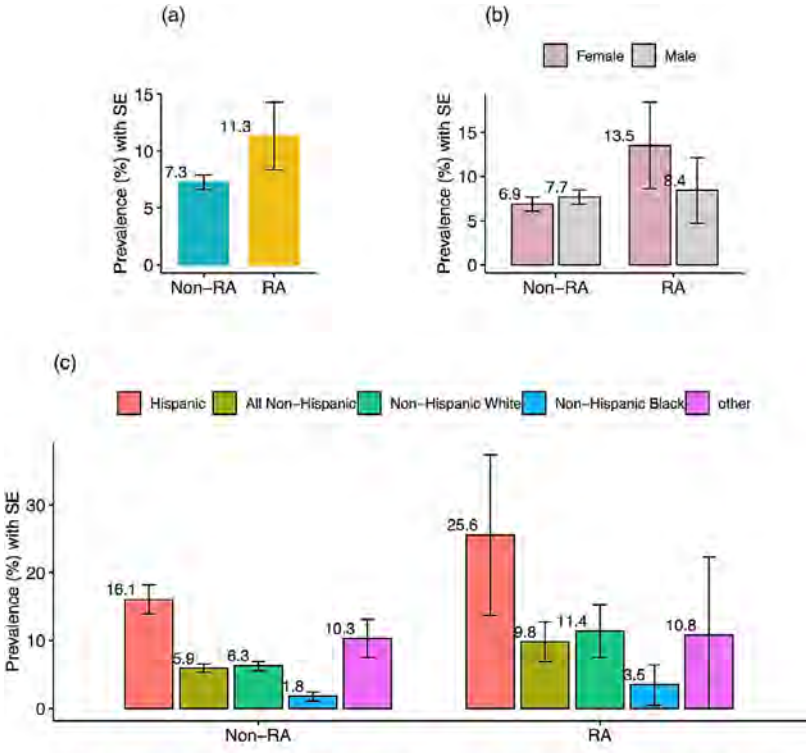

Figure 1. Age-standardized prevalence of sarcopenia among participants with and without RA (a), stratified by sex (b) and race/ethnicity (c): NHANES 1999-2006.

Background/Purpose: Sarcopenia, which refers to the loss of muscle strength and mass, has been linked to adverse health outcomes. Although several systemic reviews have reported a high prevalence of sarcopenia in rheumatoid arthritis (RA) patients, the impact of sarcopenia on all-cause mortality in this population remains unclear. This study aims to determine the prevalence of sarcopenia in RA patients in a nationally representative cohort and evaluate its association with all-cause mortality in US adults with and without RA.

Methods: The study utilized data from the National Health and Nutrition Examination Survey (NHANES) 1999–2006, along with linked mortality data from the National Death Index up to the end of 2019. Sarcopenia was defined using the Foundation for the National Institutes of Health (FNIH) 2014 sarcopenia criteria: appendicular lean mass (ALM) divided by BMI (< 0.789 in men;< 0.512 in women). Rheumatoid arthritis cases were self-reported physician diagnoses. Population estimates, including prevalence and hazard ratio (HR), were generated by incorporating sample weights and cluster information. Four multivariate Cox proportional hazard models were constructed successively to produce adjusted HRs.

Results: The final cohort included 11909 participants aged 20 to 69, among which were 558 cases of rheumatoid arthritis (table 1).Figure 1 indicates that individuals with RA had a significantly higher age-standardized prevalence of sarcopenia compared to those without RA (11.3 % vs. 7.3 %). Notably, Hispanics had a significantly higher prevalence of sarcopenia

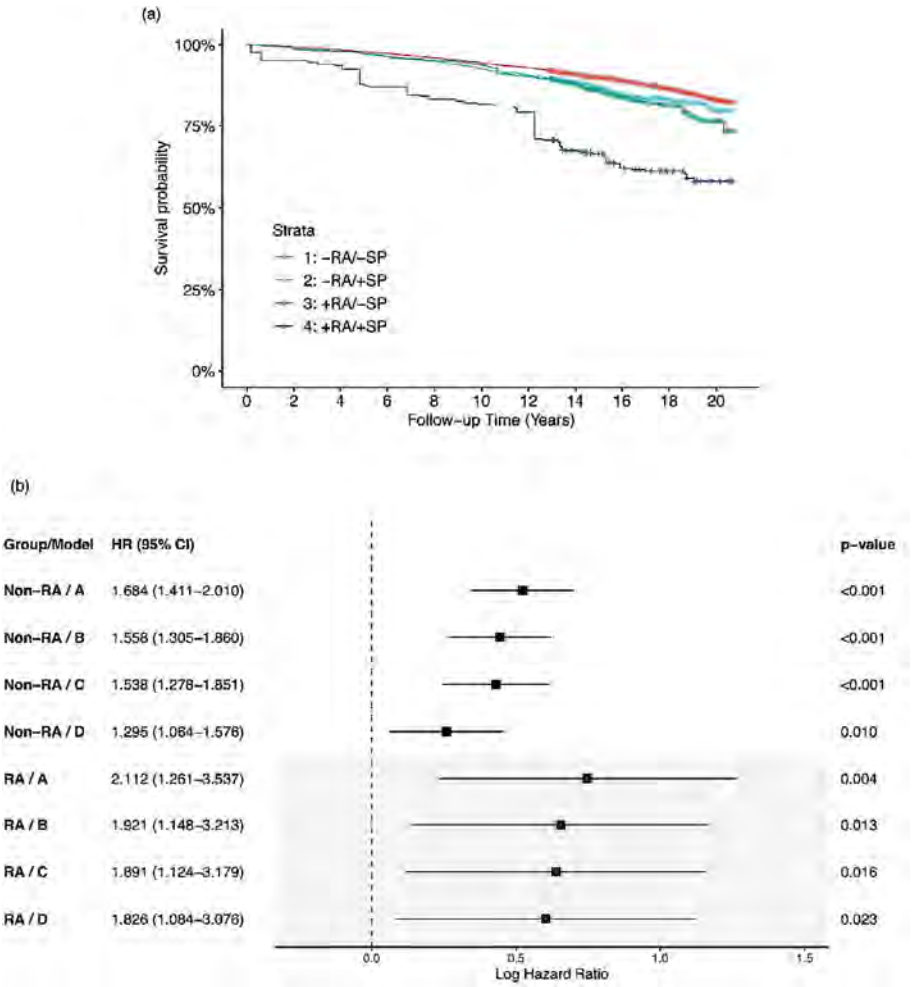

Figure 2. (a) Kaplan-Meier curves of survival probability stratified by rheumatoid arthritis (RA) and sarcopenia (SP) status. (b) Association of sarcopenia with all-cause mortality in non-RA versus RA group, as depicted by forest plot of log hazard ratios across 4 models: Model A adjusted for age and sex; Model B adjusted for age, sex, race/ethnicity, poverty status, and education level; Model C adjusted for all variables in model B, adding health behavior (smoking and physical activity); Model D adjusted for all variables in model C, adding comorbidities including obesity, diabetes mellitus, hypertension, cardiovascular disease, hyperlipidemia, and chronic kidney disease.

than the rest of the population, with rates of 25.6% and 16.1% among individuals with RA and non-RA, respectively. Regarding survival analysis, the median follow-up time for RA and non-RA group was 17 and 16.8 years. After adjusting for age and sex, the unweighted Kaplan-Meier curve revealed that sarcopenic RA patients had the highest overall mortality (Figure 2a). Across all four adjusted Cox models, individuals with sarcopenia had a higher risk of mortality regardless of whether they had RA or not (Figure 2b). Despite all four Cox models providing higher estimates of HRs for sarcopenia in the RA group as compared to the non-RA group, the differences were not statistically significant given the overlapping confidence intervals.

Conclusion: In a nationally representative cohort, the study found a higher prevalence of sarcopenia in individuals with RA, and a significant increase in all-cause mortality associated with sarcopenia with or without RA.

Abstract Number: 0977

Prevalence of Arthritis in the United States: National Estimates from a Population-based Study

Sumanth Chandrupatla[1], Kranti Rumalla[2] and Jasvinder Singh[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Northwestern School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis is the number 1 cause of disability among U.S. adults and reported to cost > $300 billion in direct and indirect costs in 2013. Theis et al. found that the prevalence of arthritis in the US grew from 54.4 million in 2013-2015 to 58.5 million in 2016-2018. These estimates were derived from the U.S. CDC National Health Interview Survey (NHIS), which has recently undergone a total redesign. With the updated NHIS, we aimed to query an updated nationally-representative estimate of the prevalence and burden of arthritis in the U.S. adult population.

Methods: We identified patients over the age of 18 years in the 2019 and 2021 National Health Interview Survey (NHIS) who had doctor-diagnosed arthritis (n=15,822; 21.3%; excluded 2020 due to unclear impact of COVID-19 on NHIS completion). Sampling weights were used to create nationally representative estimates. Unadjusted and age-standardized estimates of arthritis prevalence were generated. Sociodemographic and health characteristics were analyzed. We compared with previous years' prevalence estimates.

Results: During 2019 and 2021, an estimated 53.7 million people over the age of 18 had arthritis (21.3%; 18.8% age-standardized; **Table 1**). This represents a 5 million person decrease from 2016-2018 (58.5 million; **Figure 1**), but is similar to the estimates from 2013-2015 (54.4 million; **Figure 1**). Arthritis prevalence was greater than 50% in adults with ≥3 ADL limitations (65.2%; **Table 1**) and adults with 2 IADL limitations (50.2%; **Table 1**). Arthritis was most prevalent in adults aged ≥65 years (47.6%), non-Hispanic whites (24.9%), adults unable to work or disabled (49.5), and adults who reported fair or poor health (48.9%)

Table 1: Annual prevalence of doctor-diagnosed arthritis[1] in adults ≥18, unadjusted and age-standardized[2], National Health Interview Survey (NHIS), United States, 2019, 2021

Characteristic	Unweighted no. of adults with arthritis	No. of adults with arthritis in population (millions)[3]	Distribution among adults with arthritis (%)[3]	Prevalence of doctor-diagnosed arthritis, % (95% CI)

[4] Retired, student, or taking care of house/family

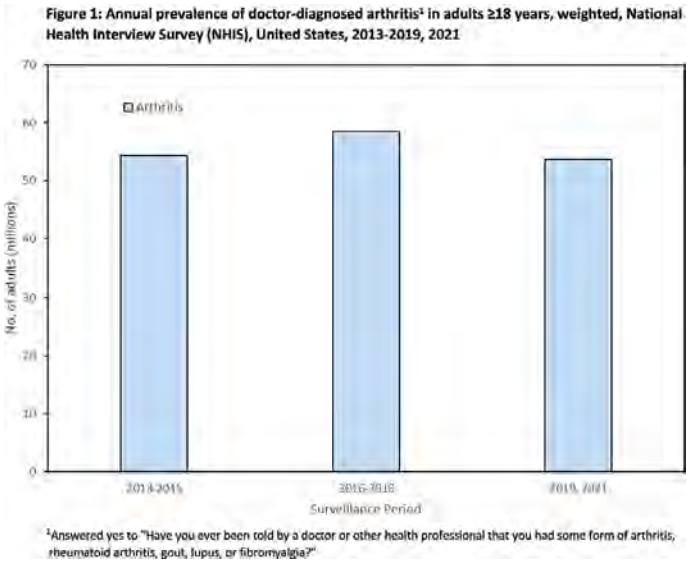

Figure 1: Annual prevalence of doctor-diagnosed arthritis[1] in adults ≥18 years, weighted, National Health Interview Survey (NHIS), United States, 2013-2019, 2021

[1]Answered yes to "Have you ever been told by a doctor or other health professional that you had some form of arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?"

Conclusion: Arthritis has significant impact on disability and functional limitation in US adults. Surprisingly, we found stabilization of arthritis prevalence in the U.S. from the 2019 and 2021 national estimates rather than an anticipated increase. Stratified analyses by age, sex, and other demographic characteristics need to be performed to understand as to which subgroup accounts for this recent stabilization/decrease in arthritis prevalence.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic disease-modifying antirheumatic drugs (bDMARDs) offer promising results for rheumatoid arthritis (RA) patients in general, but a substantial percentage of patients do not respond to them. It is important to predict the response before the treatment so that unnecessary adversities for the patients and costs for the healthcare system can be avoided. We developed a model to predict remissions in patients treated with bDMARDs and to identify important clinical features associated with remission using several machine learning (ML) models system that works with readily-available demographic and clinical factors for prediction of response to DAS-28.

Methods: We gathered the follow-up data of 1,000 patients treated with bDMARDs (etanercept, adalimumab, golimumab, infliximab, abatacept, and tocilizumab) from KRRD. Patients were recruited from public hospitals in Kuwait between February 2013 to September 2022. Remission (DAS-28 less than 2.6) was predicted at 1-year follow-up using baseline clinical data obtained at the time of enrollment. Machine learning methods system (including: lasso,

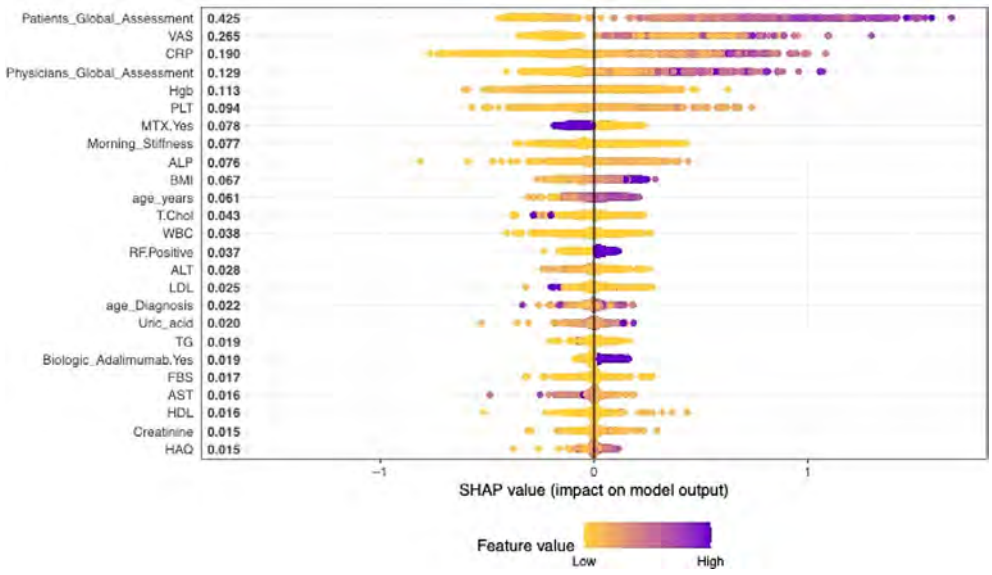

Figure 1. The SHAP results that emphasize the most clinical characteristics of RA patients using rituximab (RIT)

ridge, support vector machine, random forest, XGBoost, and Shapley additive explanation (SHAP)) were used for the predictions.

Results: The ranges for accuracy and area under the receiver operating characteristic of the newly developed machine learning model for predicting remission were 52.8–72.9% and 0.463–0.719, respectively. The Shapley plot in XAI showed that the impacts of the variables on predicting remission differed for each bDMARD. The most important features were age for adalimumab, rheumatoid factor for etanercept, erythrocyte sedimentation rate for infliximab and golimumab, disease duration for abatacept, and C-reactive protein for tocilizumab, with mean SHAP values of – 0.250, – 0.234, – 0.514, – 0.227, – 0.804, and 0.135, respectively.

Conclusion: Our proposed machine learning model system successfully identified clinical features that were predictive of remission in each of the bDMARDs. This approach may be useful for improving treatment outcomes by identifying clinical information related to remissions in patients with rheumatoid arthritis.

Use and Discontinuation of Tumour Necrosis Factor Inhibitors Among Pregnant Women with Chronic Inflammatory Diseases

Leah K. Flatman[1], Sasha Bernatsky[2], Isabelle Malhamé[3], Yvan St. Pierre[2], Olga Basso[1], Anick Bérard[4] and Evelyne Vinet[5], [1]McGill University, Montreal, QC, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [3]McGill University Health Centre, Montreal, QC, Canada, [4]University of Montreal, Montreal, QC, Canada, [5]McGill University Health Centre, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Early consensus statements recommended discontinuing tumour necrosis factor inhibitors (TNFi) during pregnancy. Despite new guidelines recommending against this, the choice to stop TNFi pre-conception is patient- and provider-dependent. Understanding TNFi discontinuation pre-conception may help inform initiatives to optimize outcomes. We examined calendar trends in TNFi discontinuation pre-conception in women with chronic inflammatory diseases and compared characteristics of those who stopped using TNFi pre-conception (without resuming in pregnancy) compared with those who used TNFi at any time during pregnancy.

Methods: We created a cohort of pregnant women with rheumatoid arthritis, ankylosing spondylitis, psoriasis/psoriatic arthritis, and/or inflammatory bowel disease who delivered between 2011 and 2019 using the MarketScan commercial database. TNFi use was defined as ≥1 filled prescription or infusion procedure claim, categorized as a) TNFi pre-conception only (i.e. ≥1 prescription filled or infusion procedure claim in the 12 weeks preceding the gestational period but not within the gestational period) or b) TNFi use at any time during pregnancy (i.e. any prescription filled or infusion procedure claim during the gestational period, including restarts, new starts, and those continuing from pre-conception).

Table 1 Characteristics of pregnant women with chronic inflammatory diseases who stopped TNFi pre-conception and those who took TNFi at any time during gestation (n=3,372)

RA only	196 (6)	31/196 (16)	165/196 (84)
PsA/PsO only	173 (5)	30/173 (17)	143/173 (83)

Abbreviations: AS, ankylosing spondylitis; DMARDs, disease-modifying anti-rheumatic drugs; IBD, inflammatory bowel disease; PsA, psoriatic arthritis; PsO, psoriasis; RA, rheumatoid arthritis; SD, standard deviation

Results: We identified 3,372 pregnancies; 14% discontinued TNFi in the 12 weeks before conception and did not restart, and 86% were exposed to TNFi during pregnancy. IBD patients accounted for 47% of all pregnancies. Comparing rheumatologic to non-rheumatologic patients, more RA individuals (difference of 18%, 95% confidence interval, CI, 15-21%) and PsA/PsO (20%, 95% CI 16-24%) discontinued their TNFi than IBD patients. Corticosteroid use was similar in both TNFi exposure groups, and those using TNFi during pregnancy were more likely to use non-biologic disease-modifying agents concomitantly (difference of 8%, 95% CI 5-12%). Across comorbidities (diabetes, asthma, and hypertension), there was no difference in discontinuation. Over time, a lower proportion of patients stopped TNFi pre-conception (2011-2013 19% vs 2014-2016 13% vs 2017-2019 10%; p-value for trend < 0.0001).

Conclusion: In our study, 14% discontinued TNFi in the 12 weeks before conception and did not restart. The proportion of patients stopping TNFi pre-conception decreased over time, possibly reflecting how changes in the observational literature pre-dated (and influenced) guidelines. Further research on TNFi discontinuation in the years after the 2020 ACR guidelines is warranted to establish guideline compliance and monitor perinatal outcomes.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: With growing availability of autoantibody testing and autoantibodies gaining more weight in the 2010 ACR/EULAR classification criteria of rheumatoid arthritis (RA), an increasing incidence rate (IR) of seropositive RA might be expected. We therefore aimed to explore the temporal trends of IRs for patients with seropositive and seronegative RA using various data sources for serostatus definition.

Table 1. Serological information on patients with rheumatoid arthritis

	2000 to 2004 (n = 6216)	2005 to 2009 (n = 7454)	2010 to 2014 (n = 8883)	2015 to 2018 (n = 6559)
Serostatus available from Autoimmune Laboratory at SSI/Register of Laboratory Results for Research	505 (8.1)	2713 (36.4)	4155 (46.8)	5423 (82.7)
Seropositive according to Autoimmune Laboratory at SSI/Register of Laboratory Results for Research*	263 (52.1)	1496 (55.1)	2727 (65.6)	3769 (69.5)
Registered in DANBIO at time of DNPR diagnosis	731 (11.8)	2619 (35.1)	5846 (65.8)	4938 (75.3)
Test result available for anti-CCP and/or IgM-RF in DANBIO	22 (0.4)	922 (12.4)	2401 (27.0)	3430 (52.3)
Seropositive according to DANBIO	15 (68.2)	594 (64.4)	1567 (65.3)	2221 (64.8)
Seropositive according to DNPR ICD-10 code at time of diagnosis	3202 (51.5)	3798 (51.0)	4679 (52.7)	3389 (51.7)
Seropositive according to Autoimmune Laboratory at SSI/Register of Laboratory Results for Research and DNPR**	3282 (52.8)	3964 (53.2)	5245 (59.0)	4301 (65.6)
Seropositive according to Autoimmune Laboratory at SSI/Register of Laboratory Results for Research, DANBIO, and DNPR***	3281 (52.8)	3978 (53.4)	5275 (59.4)	4355 (66.4)

Data are shown as n (%) unless otherwise indicated. * Outcome definition for seropositive rheumatoid arthritis using laboratory-reported autoantibodies from the Autoimmune Laboratory at Statens Serum Institut (SSI) and the Register of Laboratory Results for Research within 15 years before and 14 days after the case definition of RA was fulfilled. ** Outcome definition for seropositive rheumatoid arthritis with weighting of data by laboratory-reported autoantibodies from Autoimmune Laboratory at SSI/Register of Laboratory Results for Research > ICD-10 codes from the Danish National Patient Registry (DNPR). *** Outcome definition for seropositive rheumatoid arthritis with weighting of data by laboratory-reported autoantibodies from Autoimmune Laboratory at SSI/Register of Laboratory Results for Research > physician-reported autoantibodies from DANBIO > ICD-10 codes from DNPR. IgM-RF, immunoglobulin M rheumatoid factor; Anti-CCP, anti-cyclic citrullinated peptide.

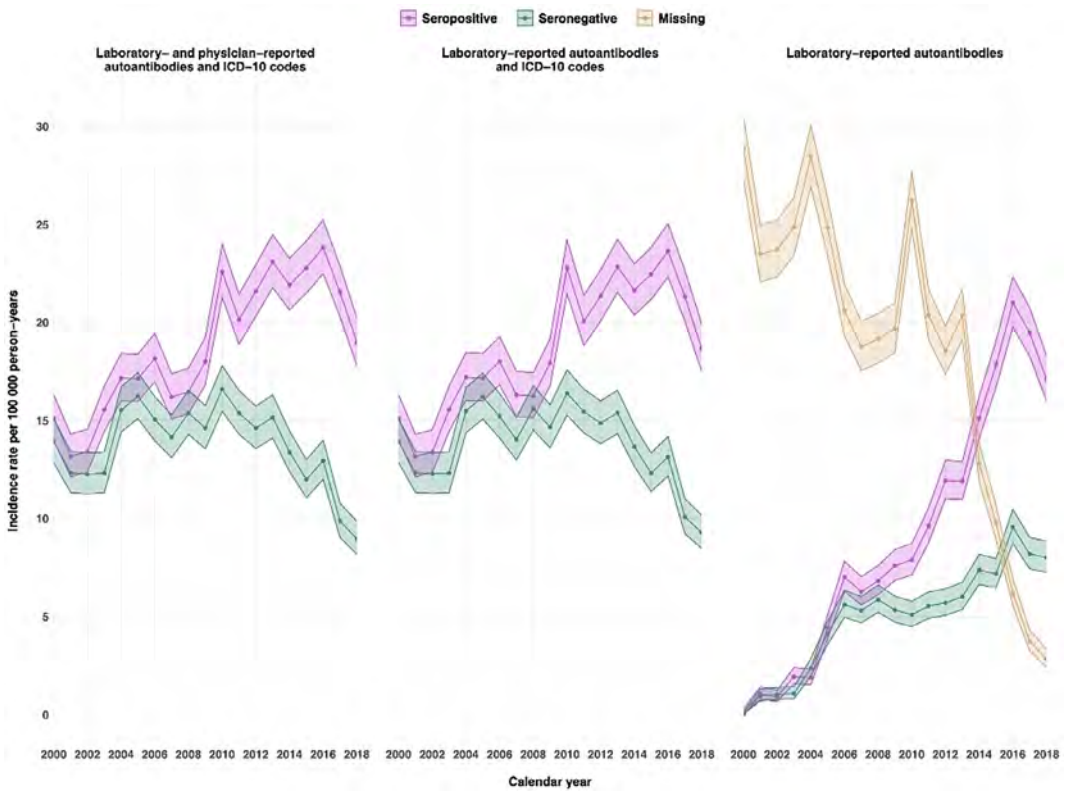

Figure 1. Temporal incidence rates for seropositive and seronegative rheumatoid arthritis using various data sources to distinguish serological subtypes. Laboratory-reported autoantibodies originated from laboratory test results of IgM-RF and/or anti-CCP in the Autoimmune Laboratory Statens Serum Institut and/or the Register of Laboratory Results for Research, physician-reported autoantibodies from physician-reported IgM-RF and/or anti-CCP in DANBIO, and ICD-10 codes from the Danish National Patient Registry. Missing values illustrated the identified patients with rheumatoid arthritis who had no available autoantibodies result in the Autoimmune Laboratory at Statens Serum Institut or the Register of Laboratory Results for Research within 15 years before to 14 days after they fulfilled the case definition of rheumatoid arthritis.

Methods: Danish nationwide population-based cohort study using healthcare and clinical quality registries from 2000 to 2018. RA patients were identified with first-time M05/M06 ICD-10 code (except M06.1) in the Danish National Patient Registry (DNPR) and a redeemed prescription of a csDMARD in the following year in the Danish National Prescription Registry.

Autoantibodies and ICD-10 codes from laboratory and register-based data sources were combined to define the outcome: serological status of each RA case. The definitions used laboratory-reported IgM-RF and anti-CCP registered in the Autoimmune Laboratory at Statens Serum Institut and/or the Register of Laboratory Results for Research. Physician-reported IgM-RF and anti-CCP available in DANBIO were added for those with no laboratory-reported autoantibodies. Imputation of serostatus according to ICD-10 codes in the DNPR, was for those with missing autoantibodies from any of the previous data sources. An outcome definition without DANBIO data was also pre-specified. The robustness of the register-estimated incidences of seropositive and seronegative RA were assessed using solely laboratory-reported autoantibodies. Registration of a positive autoantibody or an M05 diagnosis classified as seropositive RA, whereas negative autoantibody or M06 outlined seronegative RA.

Annual age- and sex-standardised IRs were calculated as the number of incident seropositive and seronegative cases, respectively, divided by number of person-years in the general population in that given year.

Results: In total, 29 112 incident patients with RA were identified from 2000 to 2018 (Table 1). An increasing temporal trend in IR of seropositive RA and decreasing trend of seronegative RA was observed. The IRs were higher for seropositive RA than for seronegative RA from 2009 and onwards with a widening of the IR gap between 2009 and 2016, leading to

approximately twofold higher IR of seropositive RA than of seronegative RA, regardless of the definition of seropositivity (Figure 1). The widening of the IR gap was driven by an initial increase in IRs with a rapid increase to year 2010 followed by a more fluctuating pattern for seropositive RA in combination with a decrease in the IR of seronegative RA. As testing for autoantibodies became more frequent, the rate of RA cases with missing values for autoantibodies decreased significantly over time.

Conclusion: The IR of patients with seropositive RA increased and decreased for seronegative RA during a period where autoantibody testing grew and the presence of autoantibodies received a greater weight in the classification criteria for RA. Temporal IR changes may be caused by a true change in RA serology subtypes, increase in autoantibodies testing or change in registration practice over time, or a combination of these factors.

Time Trends in Overall Infection Risk in Patients with Inflammatory Arthritides Treated with Tumor Necrosis Factor Inhibitors

Aron Hjalti Bjornsson[1], Telma Thrastardottir[2], Bjorn Gudbjornsson[3] and Thorvardur Love[4], [1]Landspitali University Hospital and the University of Iceland, Reykjavík, Iceland, [2]University of Iceland, Reykjavik, Iceland, [3]Centre for Rheumatology Research, University Hospital, Reykjavik, Iceland, [4]Landspitali University Hospital and the University of Iceland, Reykjavik, Iceland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Infections are a known complication of disease-modifying therapy in rheumatic patients but have also been associated with the diseases being treated. Biosimilars have increased access to TNF inhibitors (TNFi) which may have changed the composition of patients receiving TNFi therapy. We hypothesized that, over time, this could lead to a reduction in the incidence of infections and antibiotic use among patients starting TNFi treatment.

Methods: Information on all biologic-naïve adult patients with RA, SpA, and PsA initiating treatment with a TNFi was extracted from ICEBIO, a nationwide registry. Each patient was randomly matched on age, sex, and calendar time to five general population comparators. Patients were observed for two years before and after TNFi initiation (reference date). All ICD-10 inpatient and outpatient codes for infections and information on filled prescriptions were extracted from nationwide registries maintained by the Icelandic Directorate of Health. Serious infections (SI) were defined as any of the following: hospital admission with an ICD-10 code for infection, intravenous antibiotic administration in an outpatient clinic with a relevant ICD-10 code, or a filled prescription for an intravenous antibiotic. Events occurring within 30 days of one another were considered the same event. To examine time trends we split the data into four-year periods; 2003-2006, 2007-2010, 2011-2014, and 2015-2018. We calculated the incidence rate (IR) per 1000 patient-years (py) for SI and prescriptions for each period. We used Poisson exact test to calculate the 95% confidence interval (CI) and p-value when comparing IR. Incidence rate ratios (IRR) were calculated using a Fisher exact test and a Poisson regression model to adjust for previous infections, age, sex, HAQ score at baseline, diagnosis, time from diagnosis, and steroid use.

Results: We identified 1387 individuals initiating their first treatment episode with a TNFi in 2003-2018; 583 (42%) had RA, 420 (30%) PsA, and 384 (28%) SpA. The mean age ±SD was 48.8 years ± 14.2 (Table 1). There were 6916 matched comparators. We identified 139 SI (58 before vs. 81 after TNFi) in the patients and 329 for the comparators (168 before vs. 161 after the reference date).

When comparing the IR per 1000py of the first and last periods, the antimicrobial use increased among the TNFi-treated patients from 1407 (95% CI 1303 – 1517) to 1674 (1593 – 1758) prescriptions (p< 0.001), while the change was not statistically significant for the number of SI; 35.1 (20.5-50.2) to 21.9 (13.5-33.4), p=0.16 (Figure I).

Multivariate analysis showed that the between-period IRR for SI was 0.46 (0.23 – 0.94, p=0.03) for the TNFi treated patients in the last period compared to the first while it was 1.42 (0.87 – 2.41) for the comparators (Figure II). The IRR for antimicrobial use was stable in the TNFi group at 1.02 (0.93-1.13) while it increased for the comparators 1.15 (1.05-1.16, p< 0.001).

Table I
Patient characteristics between periods

	2003-2006 (N=246)	2007-2010 (N=269)	2011-2014 (N=367)	2015-2018 (N=505)	Overall (N=1387)
Age					
Median [Min, Max]	50.0 [22.0, 83.0]	50.0 [18.0, 85.0]	50.0 [18.0, 83.0]	50.0 [18.0, 87.0]	50.0 [18.0, 87.0]
Sex

Years from diagnosis					
Median [Min, Max]	8.00 [0, 47.0]	4.00 [0, 42.0]	3.00 [0, 60.0]	3.00 [0, 55.0]	4.00 [0, 60.0]
Diagnosis					
PsA	52 (21.1%)	70 (26.0%)	123 (33.5%)	175 (34.7%)	420 (30.3%)
RA	123 (50.0%)	124 (46.1%)	153 (41.7%)	183 (36.2%)	583 (42.0%)
SpA	71 (28.9%)	75 (27.9%)	91 (24.8%)	147 (29.1%)	384 (27.7%)
HAQ at baseline					
Mean (SD)	0.35 (0.56)	0.61 (0.72)	0.99 (0.74)	1 (0.67)	0.81 (0.73)
DAS28-CRP at baseline					
Mean (SD)	1.87 (2.34)	2.48 (2.25)	3.66 (1.90)	3.38 (1.91)	3.01 (2.16)
DDD of glucocorticoids for 2 years following TNFi					
Mean (SD)	85.5 (155)	91.5 (161)	76.6 (158)	80.1 (147)	82.4 (154)

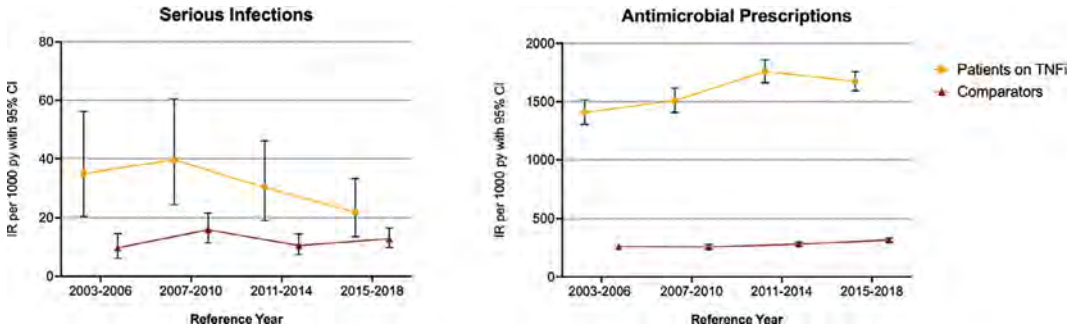

Figure I: Incidence rates (IR) per 1000 patient years (py) by time period for serious infections (left) and antimicrobial prescriptions (right) for rheumatic patients on TNFi (circle) and general population comparators (triangle). Individuals are observed for up to two years following TNFi initiation (reference year)

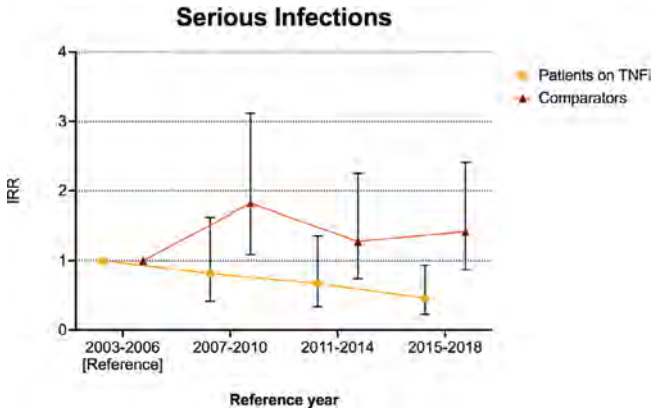

Figure II: Incidence rate ratio (IRR) estimates with 95% CI for serious infections by time period for TNFi patients (circle) and for matched general population comparators (triangle). Individuals are observed up to two years following TNFi initiation (reference year). The model corrects for age, sex, previous infections, HAQ score, time since diagnosis, steroid use, and diagnosis (RA, PsA, or AS).

Conclusion: The risk of serious infections associated with TNFi in patients with inflammatory arthritides has decreased in recent years. This trend of diminishing risk of SI needs to be considered when analyzing data over long periods or when comparing recent research to previously published data.

Abstract Number: 0982

Systemic Autoimmune Rheumatic Diseases (SARD) in the Agricultural Health Study Cohort: Rates of Rheumatoid Arthritis (RA) and Other SARD Among Medicare-linked Participants

Christine Parks[1], Karen Costenbader[2], Laura Beane Freeman[3], Jonathan Hofmann[3] and Dale Sandler[4], [1]Epidemiology Branch, National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Occupational and Environmental Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD, [4]Epidemiology Branch, National Institute of Environmental Health Sciences, National Institutes of Health, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Some systemic autoimmune rheumatic diseases (SARD), such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), have been associated with farming, specific pesticides, and other occupational exposures in the Agricultural Health Study (AHS), a prospective cohort of ~89,000 licensed pesticide applicators and spouses in North Carolina and Iowa enrolled in 1993-1997. We previously identified incident RA based on self-report confirmed by DMARD use and case validation, e.g., 220 cases (0.8%) among 26,354 male private pesticide applicators with available follow-up data through 2010. However, incomplete cohort follow-up limits the assessment of disease rates, and many rarer SARD were not included on questionnaires. Thus, we used cohort-linked Medicare claims data to enhance case ascertainment for future analyses of agricultural exposures and risk of SARD.

Methods: The AHS cohort includes licensed pesticide applicators (N=52,394 private and 4,916 commercial, 97% male) and spouses (32,345, 99% female). We assessed SARD prevalence based on Medicare claims data from 1999-2016 in 35,506 participants (21,554 male) who enrolled in Medicare at ages ≥65 years with ≥1 year of Fee for Service coverage (FFS; Parts A and B, but not Part C). We sought to identify cases of 15 SARD using ICD codes, requiring ≥2 disease-specific claims ≥30 days apart. In a subset of 33,398 (20,132 male) with a 24-month clean period (i.e., continuous FFS with no SARD-specific claims), we identified incident cases and calculated age- and sex-standardized incidence rates.

Table 1 - Prevalence of Systemic Autoimmune Rheumatic Diseases in the Agricultural Health Study

	Total N=35,506		Males N=21,514	
Claims based diagnosis of SARD	N	(%)	N	(%)
No SARD[1]	33,609	(94.67)	20,622	(95.85)
Any SARD	1897	(5.26)	892	(4.15)
Rheumatoid arthritis	1032	(2.94)	480	(2.23)
Polymyalgia rheumatica	639	(1.63)	325	(1.51)
Sicca syndrome (Sjögren's)	128	(0.36)	26	(0.12)
Systemic Lupus Erythematosus	111	(0.34)	35	(0.16)
Giant cell arteritis	108	(0.27)	45	(0.21)
Connective tissue disease	71	(0.21)	26	(0.12)
Cutaneous lupus	69	(0.16)	17	(0.08)
Psoriatic arthritis	53	(0.15)	30	(0.14)
Systemic sclerosis	54	(0.13)	11	(0.05)
Polymyositis	33	(0.09)	20	(0.09)
Dermatomyositis	18	(0.04)	<11	—

ARD = Systemic Autoimmune Rheumatic Disease

SARD with 2+ disease-specific claims 30+ days apart; Any SARD = total listed in table plus nclusion body myositis, polyarteritis nodosa, Wegener's/granulomatous polyangiitis, and Still's isease, are not shown due to small numbers of cases (<11) in one or both groups. Numbers do ot add to total due to individuals with more than one diagnosis.

Table 1 - Incidence of Systemic Autoimmune Rheumatic Diseases in the Agricultural Health Study

	Overall		Males	
Claims based diagnosis of SARD	N=33,398 N (%)	Cases per 100,000 PY[2]	N=20,132 N (%)	Cases per 100,000 PY[2]
No SARD[1]	32,093 (96)		19,501 (97)	
Any incident SARD	1305 (3.91)	422	631 (3.13)	344
Rheumatoid arthritis	592 (1.77)	191	287 (1.43)	156
Polymyalgia rheumatica	513 (1.54)	165	273 (1.36)	148
Sicca syndrome (Sjögren's)	92 (0.28)	27.1	18 (0.09)	8.9
Systemic Lupus Erythematosus	65 (0.19)	18.3	27 (0.13)	12.9
Giant cell arteritis	88 (0.26)	27.7	40 (0.20)	20.8
Connective tissue disease	53 (0.16)	15.8	19 (0.09)	10.9
Cutaneous lupus	37 (0.11)	12.5	12 (0.06)	6.7
Psoriatic arthritis	25 (0.07)	7.8	12 (0.06)	5.7
Systemic sclerosis	26 (0.08)	7.6	<11	—

[1]SARD with 2+ disease-specific claims 30+ days apart following 24 months without SARD-specific claims; Any incident SARD = total listed in table plus inclusion body myositis, polyarteritis nodosa, Wegner's granulomatosis, and Stills disease, are not shown due to small numbers of cases (<11) in one or both groups.

[2]Incidence among participants with ≥24 months follow-up time, standardized to the 2010 US population ages ≥65, adjusted for age- and gender.

Results: Overall, we identified 1987 SARD cases (5.33%), including 892 (4.15%) among males (**Table 1**). The top 5 diagnoses were rheumatoid arthritis (1,032; 2.90%), polymyalgia rheumatica (PMR, N=639; 1.80%), sicca syndrome (SS, 128; 0.36%), SLE (111; 0.31%), and giant cell arteritis (GCA; 108; 0.30%). Among males, prevalence was slightly lower for RA (480; 2.23%), PMR (325; 1.51%), and GCA (45; 0.21%), and substantially lower for SS (27; 0.12%) and SLE (35; 0.16%). A total of 1305 (3.91%) met the criteria for incident SARD, including 636 (3.13%) male cases, with 287 (1.43%) incident RA, 273 (1.36%) PMR, and the remaining rarer SARD (0-0.20%; **Table 2**).

Conclusion: In this agricultural cohort, about 1 in 20 older individuals was diagnosed with an SARD based on Medicare claims. Incidence of Medicare-based RA in males was greater than we previously identified by questionnaire. These data will facilitate comparisons of SARD in the AHS with published rates in the Medicare population and will enhance research on the role of pesticides and other exposures in the development of SARD in older AHS participants.

Abstract Number: 0983

Association Between Disease-modifying Anti-rheumatic Drugs and Short-term Outcomes of Dengue: A Population-based, Cohort Study

I-Feng Lin[1], **Hsin-Hua Chen**[2], Theodore Tsai[3] and Nicole Huang[4], [1]National Yang Ming Chiao Tung University, Taipei, Taiwan, [2]Taichung Veterans General Hospital, Taichung, Taiwan, [3]Takeda Vaccines, Cambridge, MA, [4]Master of Public Health Program, National Yang Ming Chiao Tung University, Taipei, Taiwan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Dengue is the leading vectorborne disease globally with half of the global population at risk, including Puerto Rico in the United States. Previously, we showed that rheumatoid arthritis and related disease were associated with an increased risk of death after dengue diagnosis. Disease-modifying anti-rheumatic drugs (DMARDs), categorized into conventional-synthetic (cs) DMARDs, biological (b) DMARDs and target-synthetic (ts)DMARDSs, are standard therapy for patients with RA. Rituximab (RTX) therapy has been associated with higher COVID-19 mortality but outcomes associated with dengue have not been reported. The aim of this study was to assess the association between DMARDs and dengue outcomes.

Methods: The Taiwanese National Health Insurance Research Database (NHIRD), covering 99.5% of the Taiwan population was linked to the Notifiable Disease Dataset of Confirmed Cases (NDDCC) to assess associations of short-term dengue outcomes with RTX and other b/tsDMARDs. We identified 51,769 confirmed dengue cases aged ≥ 18 years from January 1, 2014 to December 31, 2015. Those cases were linked to the NHIRD to assess DMARDs use within one year before dengue was diagnosed and study outcomes of mortality and hospitalization within 30 days after dengue diagnosis. We categorized patients with dengue into four mutually exclusive groups based on prior use of DMARDs within one year: (1) RTX use, (2) use of b/tsDMARDs other than RTX ,(3) use of csDMARDs without use of b/tsDMARDs, (4) without use of any DMARDs. We examined the adjusted odds ratios (aORs) with 95% confidence intervals (CIs) for 30-day mortality and hospitalization in dengue patients based on prior use of DMARDs (csDMARDs users as reference) by multivariable logistic regression analysis

Table 1.Incidences of mortality within 30 days after dengue diagnosis based on use of DMARDs within one year before dengue the diagnosis date.

	n	Number of events	Incidence[b]	Crude incidence ratio[b]	Adjusted odds Ratio[c]	95% CI
Mortality						
DMARD group						
csDMARD	304	5	1.6	1.00	Reference	
Rituximab	14	2	14.3	8.69	6.19	1.00–38.10*
b/tsDMARD other than rituximab	153	3	2.0	1.19	1.24	0.28–5.49
No DMARD	51,298	361	0.7	0.43	0.58	0.23–1.45
No DMARD	51,298	14,979	29.2	0.75	0.84	0.66–1.07

[a]csDMARD: conventional synthetic disease-modifying antirheumatic drugs, b/tsDMARD: biological or target-synthetic DMARD.

[b]Incidence: number of events per 100 persons; Ratio of incidence to that of the reference group

[c]Adjusted for age, sex, social economic status, year of diagnosis, and all the other comorbidities

*P-value < 0.05.

Table 1.Incidences of hospitalization within 30 days after dengue diagnosis based on use of DMARDs within one year before dengue the diagnosis date.

	n	Number of events	Incidence[b]	Crude incidence ratio[b]	Adjusted odds Ratio[c]	95% CI
Hospitalization						
DMARD group						
csDMARD	304	119	39.1	1.00	Reference	
Rituximab	14	7	50.0	1.28	1.01	0.34–3.01
b/tsDMARD other than rituximab	153	71	46.4	1.19	1.35	0.90–2.03
No DMARD	51,298	14,979	29.2	0.75	0.84	0.66–1.07

[a]csDMARD: conventional synthetic disease-modifying antirheumatic drugs, b/tsDMARD: biological or target-synthetic DMARD.

[b]Incidence: number of events per 100 persons; Ratio of incidence to that of the reference group

[c]Adjusted for age, sex, social economic status, year of diagnosis, and all the other comorbidities

adjusting for age, sex, socioeconomic status, year of diagnosis and comorbidities: RA and related disease, chronic kidney disease, diabetes, malignancy, coagulation and hemorrhagic disorders, coronary artery disease, hypertension, stroke, congestive heart failure, chronic obstructive pulmonary disease, asthma, major depressive disorder, and liver cirrhosis.

Results: Table 1 shows the numbers and incidences of death within 30 days after dengue diagnosis. Compared with patients treated with csDMARDs only, risk of 30-day mortality was higher in patients with prior rituximab use (aOR, 6.19; 95% CI, 1.00–38.1; $p < 0.05$), but not in patients receiving b/tsDMARDs other than RTX. However, the risk of 30-day hospitalization was not significantly different between patients receiving csDMARDs treatment and patients with prior use of RTX or other b/tsDMARDs (Table 2).

Conclusion: This population-based study showed that use of rituximab was associated with a higher risk of death within 30 days after dengue diagnosis compared with use of csDMARDs.

Abstract Number: 0984

Factors Associated with 5-year Mortality in Patients with Rheumatoid Arthritis Initiating Their First Biological or Target Synthetic DMARDs: A Nationwide, Population-based Cohort Study of 12,612 Patients

Hsin-Hua Chen, Taichung Veterans General Hospital, Taichung, Taiwan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease resulting in increased mortality. manifestations. involvement. The National Health Insurance Research Database (NHIRD) in Taiwan provided nationwide, population-based claim data that can be linked to death registry to assess risk factors and cause of death in patients with RA.

The aim of the study was to investigate factors associated with 5-year mortality in patients with RA starting their first biological or target synthetic disease-modifying antirheumatic drugs (b/tsDMARDs).

Methods: Using the 2000–2020 NHIRD, we identified 12,612 RA patients who initiated their first b/tsDMARDs, including tumor necrosis factor inhibitors (TNFi), tocilizumab, abatacept, rituximab and tsDMARD. A multivariable Cox regression model was used to estimate the adjusted hazard ratios (aHRs) with 95% confidence interval (CIs) for the association of the risk of 5-year mortality with the use of 5 categories of b/tsDMARDs (TNFi as a reference) after adjustment of potential confounders including age, sex, urbanization level of residence, income, comorbidities and medications.

Results: We included 8,902 TNFi-treated patients, 974 tocilizumab-treated patients, 994 abatacept-treated patients, 1,462 tsDMARD-treated patients and 280 rituximab-treated patients. Figure 1 showed the 5-year survival curve in patients treated with b/tsDMARDs categorized into 5 groups based on mechanism of actions. Compared with TNFi-treated patients, multivariable Cox-regression analyses showed that 5-year mortality risk was higher in rituximab-treated patients (aHR, 3.47; 95% CI,

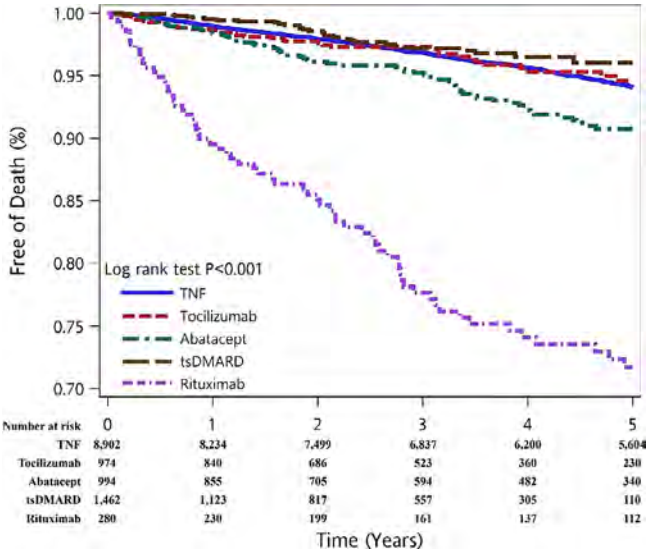

Fig 1. Five-year survival of patients with rheumatoid arthritis initiating their first b/tsDMARDs.
