Table of Contents

ACR Convergence 2023 Abstract Sessions

Sunday, November 12

8:30 AM – 4:00 PM
Poster Session A
(#0001–0721)

11:00 AM – 12:30 PM
Plenary Session I
(#0721–0725)

2:00 – 3:30 PM
Oral Abstract Sessions
(#0727–0732) Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
(#0733–0738) Abstracts: Genetics, Genomics & Proteomics
(#0739–0744) Abstracts: Epidemiology & Public Health I
(#0745–0750) Abstracts: Imaging of Rheumatic Diseases
(#0751–0756) Abstracts: Measures & Measurement of Healthcare Quality
(#0757–0762) Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases I
(#0763–0768) Abstracts: Professional Education
(#0769–0774) Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: RA-ILD
(#0775–0780) Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: PsA
(#0781–0786) Abstracts: SLE – Treatment I: Renal
(#0787–0792) Abstracts: Systemic Sclerosis & Related Disorders I: Translational

4:00 – 5:30 PM
Oral Abstract Sessions
(#0793–0798) Abstracts: RA – Animal Models
(#0799–0804) Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
(#0805–0810) Abstracts: Health Services Research I
(#0811–0816) Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science
(#0817–0822) Abstracts: Osteoarthritis I: Clinical Trials
(#0823–0828) Abstracts: Patient Outcomes, Preferences, & Attitudes I: Assessment Tools
(#0829–0834) Abstracts: Pediatric Rheumatology – Clinical I: JIA
(#0835–0840) Abstracts: RA – Treatments I: Novel RA Treatments & Mechanisms of Action
(#0841–0846) Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: AxSpA
(#0847–0852) Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: Biomarkers
(#0853–0858) Abstracts: Vasculitis – ANCA-Associated I

Monday, November 13

8:30 AM – 4:00 PM
Poster Session B
(#0859–1578)

11:00 AM – 12:30 PM
Plenary Session II
(#1579–1584)

2:00 – 3:30 PM
Oral Abstract Sessions
(#1585–1590) Abstracts: Innate Immunity
(#1591–1596) Abstracts: Osteoarthritis & Joint Biology – Basic Science
(#1597–1602) Abstracts: SLE – Etiology & Pathogenesis
(#1603–1608) Abstracts: Antiphospholipid Syndrome
(#1609–1614) Abstracts: Fibromyalgia & Other Clinical Pain Syndromes
(#1615–1620) Abstracts: Health Services Research II
(#1621–1626) Abstracts: Pediatric Rheumatology – Clinical II: Connective Tissue Disease
(#1627–1632) Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Comorbidities
(#1633–1638) Abstracts: Sjögren's Syndrome – Basic & Clinical Science
(#1639–1644) Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Psoriatic Arthritis
(#1645–1650) Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: Imaging
(#1651–1656) Abstracts: Interprofessional Exemplary

4:00 – 5:30 PM
Oral Abstract Sessions
(#1657–1662) Abstracts: Pediatric Rheumatology – Basic Science
(#1663–1668) Abstracts: Systemic Sclerosis & Related Disorders – Basic Science
(#1669–1674) Abstracts: Infection-related Rheumatic Disease
(#1675–1680) Abstracts: RA – Treatments II: RA Treatment Safety

(#1681–1686) Abstracts: Reproductive Issues in Rheumatic Disorders
(#1687–1692) Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: PsA
(#1693–1698) Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Omics
(#1699–1704) Abstracts: Systemic Sclerosis & Related Disorders II: Clinical Research

Tuesday, November 14

8:30 AM – 4:00 PM
Poster Session C
(#1705–2424)

11:00 AM – 12:30 PM
Plenary Session III
(#2425-2430)

2:00 PM – 3:30 PM
Oral Abstract Sessions
(#2431–2436) Abstracts: RA – Etiology & Pathogenesis
(#2437–2442) Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
(#2443–2448) Abstracts: SLE – Animal Models
(#2449–2454) Abstracts: Epidemiology & Public Health II
(#2455–2460) Abstracts: Healthcare Disparities in Rheumatology
(#2461–2466) Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I
(#2467–2472) Abstracts: Osteoarthritis II: Novel Insights from Observational Studies
(#2473–2478) Abstracts: Pediatric Rheumatology – Clinical III: Potpourri
(#2479–2484) Abstracts: RA – Diagnosis, Manifestations, & Outcomes III: Predicting & Optimizing Outcomes
(#2485–2490) Abstracts: SLE – Treatment II: Nonrenal
(#2491–2496) Abstracts: Vasculitis – ANCA-Associated II
(#2497–2502) Abstracts: Interprofessional OA & Lupus

4:00 – 5:30 PM
Oral Abstract Sessions
(#2503–2508) Abstracts: Cytokines & Cell Trafficking
(#2509–2514) Abstracts: Immunological Complications of Medical Therapy
(#2515–2520) Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II
(#2521–2526) Abstracts: Orthopedics, Low Back Pain, & Rehabilitation
(#2527–2532) Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
(#2533–2538) Abstracts: Patient Outcomes, Preferences, & Attitudes II: Patient Experience
(#2539–2544) Abstracts: RA – Treatments III: Predictors of Response & Tapering
(#2545–2550) Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: AxSpA
(#2551–2556) Abstracts: SLE – Diagnosis, Manifestations, & Outcomes III: Disease Activity
(#2557–2562) Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II: Clinical

Wednesday, November 15

9:00 AM – 10:30 AM
Oral Abstract Sessions
(#2563–2568) Abstracts: Epidemiology & Public Health III
(#2569–2574) Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III
(#2575–2580) Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II

11:00 AM – 12:30 PM
Oral Abstract Sessions
(#2581–2586) Abstracts: RA – Diagnosis, Manifestations, and Outcomes IV: Pre-RA & RA Diagnosis
(#2587–2592) Abstracts: SLE – Diagnosis, Manifestations, & Outcomes IV: Outcomes & Comorbidity
(#2593–2598) Abstracts: Systemic Sclerosis & Related Disorders III: Clinical Trials
(#2599–2604) Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders III: Innovation

Late-Breaking Abstracts

Tuesday, November 14

9:00 – 11:00 AM

Abstract Embargo Policy

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online supplement of our scientific journal, *Arthritis & Rheumatology*. Information contained in those abstracts may not be released until the abstracts appear online. Academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR Abstract website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until **November 7 at 10:00 AM ET.** Journalists with access to embargoed information also cannot release articles before this time.

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying colleagues, institutions, communications firms, and all other stakeholders related to the development or promotion of the abstract about this policy. If you have questions about the ACR abstract embargo policy, please contact ACR abstracts staff at abstracts@rheumatology.org.

Abstract Reprint (Reproduction) Policy

Copyright law covers all ACR Convergence abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means without the prior permission of the publisher, except as permitted under section 107 and 108 of the 1976 United States Copyright Act

For the purposes of this statement, the term **ACR Abstracts** refers to all ACR Convergence abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARP sessions and the late-breaking category.

For the purposes of this statement, the term **ACR Posters** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during ACR Convergence. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All **ACR Posters** are the property of the ACR and the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

- For the purposes of this statement, the term "reproduce" includes all forms of reproduction, including, but not limited to, print, electronic and photographed formats.
- For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during ACR Convergence, as identified through the abstract submission process.

Approval Process for ACR Abstracts

- Excerpts or the entirety of **ACR Abstracts** may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:

  Permissions Department

  c/o John Wiley & Sons, Inc.
  111 River Street
  Hoboken, NJ 07030
  Fax: 201-748-6008
  wiley.com/go/permissions
  - Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. The ACR cannot provide any materials.

Approval Process for ACR Posters

- Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).
- Requests to reproduce individual ACR posters, figures from ACR posters, or booklets of poster presentations (e.g., two or more) must be submitted via e-mail to abstractreprints@rheumatology.org.
- Poster reproduction requests must include the following:
  – Abstract ID Number
  – Abstract Title
  – Presenting Author's Name
  – A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)

Reproducing ACR Abstracts and Posters for Dissemination Prior to ACR Convergence

- Requests to reproduce abstracts for dissemination prior to ACR Convergence *will not be approved*.

- Per the ACR Embargo Policy (see above), academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the ACR Embargo Policy; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR public relations department at pr@rheumatology.org.

Reproducing ACR Abstracts and Posters for Dissemination During ACR Convergence

Following approval (see approval process above), an exhibiting organization may:

- Following approval (see approval process above), an exhibiting organization may disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Following approval, an exhibiting organization may disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.

Reproducing ACR Abstracts and ACR Posters for Dissemination After ACR Convergence

ACR Abstracts

Following approval from Wiley (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following ACR Convergence.

- Abstracts and booklets of abstracts (e.g., two or more) must include the following statement on the front of the abstract/booklet:
  Abstract(s) reprinted from ACR Convergence held [insert meeting dates]. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by [insert name of supporting company].
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Posters

Following approval from the presenting author and the ACR (see approval process above), copies of actual ACR poster presentations (i.e., the actual graphic file of the poster) may be reproduced.

1. Reprint requests for the actual poster abstract text published in the *Arthritis & Rheumatology* supplement are considered **ACR Abstracts** and must submitted to Wiley (see approval process above).

- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint:
  Reprinted from ACR Convergence held [insert meeting dates]. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by [insert name of supporting company].

Use of the ACR Name

The names, insignias, logos and acronyms of the ACR, the ARP, and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during ACR Convergence is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the prior written permission of the ACR and the presenter.
- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

None: Has no relevant financial relationship to disclose.

1. Advisor or Review Panel member
2. Consultant
3. Employee
4. Officer or Board Member
5. Grant/Research Support
6. Speaker/Honoraria includes speakers bureau, symposia, and expert witness
7. Independent Contractor
8. Ownership Interest
9. Royalties
10. Intellectual Property / Patents
11. Stock options or bond holdings in a for-profit corporation or self-directed pension plan
12. Other Financial or Material Support

Abstract Number: 0001

Loss of the Complement Regulator CD55 Alters Marginal Zone B Cell Homeostasis

Iris Lee[1], Sonam Verma[2], Ivana Ling[2], Christine Pham[3] and Peggy Kendall[2], [1]Washington University in St. Louis, St. Louis, MO, [2]Washington University, Saint Louis, MO, [3]Washington University, St. Louis, MO

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Complement and B cells are implicated in the pathophysiology of rheumatoid arthritis, an autoimmune disease characterized by synovial inflammation. Loss of complement regulator CD55 leads to delayed onset of inflammatory arthritis in the collagen-induced mouse model of arthritis (CIA).[1] Marginal zone (MZ) B cells, an innate-like B cell population, serve as first responders to blood-borne pathogens by rapidly differentiating into antibody producing plasmablasts, and are important initiators of CIA.[2] Whether and how CD55 regulates MZ B cells in CIA pathogenesis is unknown.

Methods: We examined naïve and sorted MZ B cell populations in 3-5 week-old and 10-12 week-old CD55-/- and compared to wildtype (WT) C57BL/6 mice using flow cytometry, immunofluorescence, bromodeoxyuridine (BrdU) incorporation, and bulk RNAseq. Differential gene expression analysis was performed, followed by Gene Sequence Enrichment Analysis (GSEA).

Results: We found that loss of CD55 decreased the number of MZ B cells in 10-12 week-old, but not 3-5 week-old mice. The precursors to MZ B cells were unchanged at both endpoints, indicating that loss of MZ B cells was not due to failure of MZ B cell differentiation. *En vivo* BrdU incorporation showed no difference between CD55-/- and WT, indicating MZ B cell differences are not due to loss of proliferative capacity. Differential gene expression analysis showed decreased expression of genes involved in preventing apoptosis in MZ B cells of CD55-/- compared to WT mice (*HSP90b1*, *STIP1*, *AHSA1*, and *FKBP4*). GSEA showed decreased expression of cell cycle/cell survival pathways in CD55-/- cells relative to WT. Flow cytometry revealed that CD55-/- MZ B cells had corresponding increases in activated caspase-3 and caspase-7.

Conclusion: Loss of CD55 led to increased reactive oxygen species and activation of caspases in MZ B cell populations, which may prevent the normal expansion of the MZ B cell subset over time. These studies suggest a role for the complement regulator CD55 in MZ B cell homeostasis and survival. Future experiments are aimed at defining whether loss of CD55 impacts MZ B cell survival through complement dependent or independent mechanisms.

Abstract Number: 0002

Population Pharmacokinetic and Pharmacodynamic Analyses of Obexelimab in Healthy Volunteers and in Patients with Rheumatoid Arthritis or IgG4-Related Diseases

Xiaodong Wang, Rachel Kirk, Simon Lowry and Hua Mu, Zenas BioPharma, Waltham, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Obexelimab is a novel bifunctional antibody that inhibits B-cells, CD19-expressing plasma cells, and plasmablast activity and has the potential to provide clinical benefits across multiple autoimmune disorders. The purpose of this analysis was to 1) develop a population pharmacokinetics (PK) and pharmacodynamics (PD) model of obexelimab from clinical studies following intravenous (IV) or subcutaneous (SC) administration; and 2) conduct simulations using this PK/PD model to support the proposed obexelimab Phase 3 dosing regimen in patients with immunoglobulin G4-related disease (IgG4-RD).

Methods: A population PK/PD model, which described obexelimab serum PK and PD [absolute B cell (ABC) count or CD19 receptor occupancy (RO)] following single and multiple IV or SC administration to healthy subjects, and IV administration to patients with rheumatoid arthritis (RA) or IgG4-RD, was established based on 4 clinical studies: 1) a first-in-human, single-ascending dose study with obexelimab in healthy volunteers (0.03 to 10 mg/kg IV); 2) a multiple-ascending dose study in patients with RA (0.3 to 10 mg/kg every other week); 3) an open-label study assessing the effect of obexelimab on disease activity in patients with IgG4-RD (5 mg/kg or 90/180 mg IV every other week); and 4) a PK and relative bioavailability study of obexelimab given IV or SC (125 to 375 mg SC or 250 mg IV every other week or 125 mg SC weekly).

Population PK analyses were performed using nonlinear mixed effects modeling software (NONMEM®). The final population PK/PD model was used to simulate obexelimab PK exposures and changes in ABC counts and in CD19 RO following various SC dosing regimens.

Results: A population PK/PD model was successfully developed which described the PK (concentrations) and PD (both ABC and CD19 RO) of obexelimab following single and multiple IV or SC administration to healthy subjects, and patients with RA or IgG4-RD. The final PK model was a two-compartment model with first-order absorption for SC administration and first-order elimination. Intrinsic and extrinsic subject factors were assessed as covariates in population PK full model development. These covariates included ethnic-related covariates such as race, body weight, age, and gender. The population PK analysis demonstrated that none of these ethnic-related covariates impacted the PK of obexelimab.

The PD simulation predicts a 250 mg SC weekly dosing will achieve the complete (~100%) CD19 RO and the maximum reduction in ABC count of approximately 50% of baseline during the entire dosing interval. Following discontinuation of the 250 mg SC weekly dosing, approximately 8 and 10 weeks is required for CD19 RO and ABC counts to return to baseline levels, respectively.

Conclusion: The population PK analysis of obexelimab demonstrates the ethnic insensitivity of obexelimab PK. Robust RO and PD following 250 mg SC weekly further supports clinical development of obexelimab to treat B-cell mediated autoimmune diseases.

Abstract Number: 0003

Expanded Extrafollicular B Cells Were Improved by RTX in IgG4-related Disease

Yusho Ishii[1], Aakriti Alisha Arora[1], Scott Jenks[1], Iñaki Sanz[2] and Arezou Khosroshahi[1], [1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is an immune-mediated disease characterized by fibrotic masses with expansion of $IgG4^-$producing plasma cell in multiple organs such as pancreas, lacrimal and salivary glands, and retro-peritoneal tissues. Antibody secreting cells (ASC) such as plasmablasts expand in peripheral blood in IgG4-RD, resulting in high titer of serum IgG4 in active state.

ASC accumulated in extrafollicular masses, suggesting that B cell precursors of ASC may differentiate through extrafollicular pathways. However, the detail of B cell profile in IgG4-RD remains unclear. Clinically, IgG4-RD responds very well glucocorticoid and B cell depleting therapy, but the change of B cell profile including extrafollicular B cells after these treatments are unknown.

Methods: IgG4-RD patients were enrolled from Emory IgG4-RD Clinic. Disease activity was assessed by IgG4-RD responder index. Fresh and frozen peripheral blood mononuclear cells (PBMCs) were stained by 3 sets of antibody panels and analyzed by flow cytometer. The first cohort used fresh PBMCs and a simple B cell panel (n: 11 healthy control (HC), 13 inactive and 12 active IgG4-RD). The second cohort and third cohort used the same frozen PBMCs with an extended B cell panels (n: 10 HC, 10 or 11 RTX-naïve and 13 RTX-treated (6-51 months after RTX) IgG4-RD).

Results: Analysis of cohort 1 focused on the difference of B cell profile by disease activity. IgD and CD27 double negative (DN) B cells were increased, and unswitched memory B cells (USM) were reduced in active patients. However, IgG4-RD patients were split into the high or low proportion of DN B cells in $CD19^+$ B cells. In DN B cells, DN2 ($CD19^{+/++}$/$CD38^-$/$CD27^-$/IgD^-) expanded, while DN1 ($CD19^{+/++}$/$CD38^{-/+}$ $CD27^-$/IgD^-) were decreased, resulting in high DN2+DN3/DN1 ration in IgG4-RD. In 2nd and 3rd cohorts, we compared HC, RTX-naïve and -treated IgG4-RD. increased DN2 ($CD19^+$/$CD27^-$/IgD^-/$CD11c^+$/$CD21^-$) and reduced USM ($CD19^+$/$CD27^+$/IgD^+) were consistent with 1st cohort though DN B cells did not expand. In addition to DN2, increased ASC, DN3 ($CD19^+$/$CD27^-$/IgD^-/$CD11c^-$/$CD21^-$) and $CD11c^+$switched memory (SWM) B cells also were observed. Moreover, these expanded populations in IgG4-RD were repressed by RTX treatment. In $CD3^+$ T cells, CD4/CD8 ratio was elevated in IgG4-RD, and this ratio was reverted by RTX.

Conclusion: Extrafollicular effector B cells including DN2, DN3, $CD11c^+$ SWM and ASC were expanded in IgG4-RD. Intriguingly, this abnormal expansion was mostly reverted by RTX treatment, consistently with a good clinical response. In addition to B cells, elevated CD4/CD8 ratio was also normalized by RTX. These results suggest that promoted extrafollicular pathway-derived B cell might be a precursor of tissue-infiltrating plasma cell in IgG4-RD.

Abstract Number: 0004

CD22 X CD79b Bispecific Ab Potently Inhibits B Cell Activation and Plasmablast Accumulation

Timothy Burwell[1], Jeffrey Hall[1], Suzanne Cole[2], Sarah Tursi[1], Isabelle Baribaud[3], Kyle Bednar[1], Naresh Kumar[1], Julie Carman[1], Navin Rao[2] and **Edith Janssen**[2], [1]Janssen Research and Development, LLC, Spring House, PA, [2]Janssen Research & Development, LLC, Spring House, PA, [3]IGM Biosciences, Inc., Doylestown, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: B cells contribute to the development and progression of autoimmune diseases through multiple mechanisms. Consequently, modulating B cell activation, B cell effector function, and plasmablast development holds great therapeutic potential. CD22 (Siglec-2) is an inhibitory receptor selectively expressed on B cells and has been shown to inhibit BCR downstream signaling. Here we tether CD22 to the B cell receptor (BCR) with a CD22 x CD79b bispecific Ab (bsAb) to potently inhibit B cell activation, proliferation, cytokine production, Ig production, and plasmablast accumulation.

Methods: Binding of the bsAb to different B cells was analyzed by flow cytometry using directly conjugated-bsAb. Potential for *in vitro* antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) was assessed in PBMC cultures in the presence of fresh serum. Impact on BCR downstream signaling upon IgM cross-linking was determined by phospho-flow of p-Syk and p-PLCg in purified B cells. PBMC and B cells were used to assess inhibitory capacity of the bsAb on B cell activation, proliferation, and cytokine production upon IgM cross-linking. PBMC from 15 RA patients and 17 matched healthy donors (HD) were used to verify inhibitory potential in rheumatologic disease.

For *in vivo* pharmacology studies, CD34+ reconstituted NSG mice were dosed as indicated, and serum IgM, frequency and composition of B cells and plasmablasts (spleen, blood), and splenic B cells functionality upon IgM cross-linking were assessed at indicated time points.

Results: Our CD22xCD79b bsAb showed strong, selective binding to all CD22 expressing B cell subsets without *in vitro* depletion. The bsAb potently inhibited the phosphorylation of BCR downstream signaling molecules Syk and PLCg upon IgM cross-linking, which correlated with significant reductions in B cell proliferation and cytokine production. Moreover, our bsAb potently inhibited the activation of B cells in PBMC from both HD and RA patients (CD69, CD83, CD86).

In vivo treatment of CD34+NSG mice with the bsAb showed a potent, dose-dependent reduction in serum IgM levels, concomitant with profound reductions of plasmablasts in the blood and spleen. In addition, splenic B cells from treated animals showed a significant dose-dependent reduction in their capacity to produce proinflammatory cytokines upon IgM cross-linking *in vitro* (IL-6, IL-8, CCL3, CCL4, CCL22).

Conclusion: Together this data shows that our CD22xCD79b bsAb is a potent inhibitor of B cell activation *in vitro* and *in vivo*, making it a promising approach for the treatment of autoimmune diseases with a pathogenic B cell component.

Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Obexelimab is a bifunctional, non-cytolytic, humanized monoclonal antibody that binds CD19 and ligates FcγRIIb with high affinity. Data from a phase 2 clinical trial of patients with IgG4-related disease (IgG4-RD), a chronic immune-mediated fibro-inflammatory disease, demonstrated rapid, and sustained clinical improvement, including complete remission in most patients following treatment with obexelimab. Although not shown to drive rapid apoptotic death of B cells, obexelimab treatment does result in an approximate 50% reduction in circulating B cell numbers, as well as near complete reduction in circulating plasmablasts. We have shown that obexelimab dampens the activation of BTK in B cells, easily ascribable to the loss of PIP3 that would result from the predicted activation by FcgRIIb of the SH2-domain containing inositol phosphatase SHIP-1. Here, we aimed to examine the changes in gene expression induced by obexelimab in B cells from treated patients with IgG4-RD to better understand its mechanism of action.

Methods: Peripheral blood was collected from patients with IgG4-RD before and after treatment with obexelimab (two days after the eighth dose). PBMCs were isolated using standard density gradient centrifugation. Naïve ($CD19^+IgD^+CD27^-$) and memory ($CD19^+IgD^-CD27^+$) B cell populations were FACS purified and used for subsequent ATAC-sequencing (N = 3 with 3 technical replicates for each sample) and RNA-sequencing (N = 16).

Results: We observed many changes in gene expression and chromatin accessibility attributed to treatment with obexelimab in naïve B cells. RNA sequencing identified 775 genes upregulated and 808 genes downregulated in post- compared to pre-obexelimab treated B cells. ATAC sequencing analysis identified 1040 increased and 708 decreased differentially accessible genes in post- versus pre-obexelimab treated B cells. Gene ontology biological process analysis of ATAC sequencing were consistent with altered cytoskeleton organization, chemotaxis and migration. In addition, nucleotide and purine metabolic processes were impacted after treatment. Furthermore, KEGG pathway analysis demonstrated key components of actin cytoskeleton regulation associated with altered phosphoinositide regulation. Gene ontology biological process analysis of RNA-seq data aligned with ATAC-seq analysis, confirming alteration of cell-cell adhesion and cytoskeletal pathways.

Conclusion: Collectively, these chromatin accessibility and transcriptromic data suggest that reciprocal changes in PIP3 and PI(3,4)P2 dependent events induced by obexelimab on B cells alter B cell activation and migration. Paired with the previous published data demonstrating attenuation of BCR signalling, obexelimab not only reduces PIP3-dependent BCR-induced BTK activation in B cells from IgG4-RD patients but could also enhance PI(3,4)P2 phosphoinositide-mediated B cell

migration, possibly causing sequestration of B cells. Together, these two mechanisms may eliminate the potential of pathogenic, self-reactive B cells to respond to self-antigen, migrate out of secondary lymphoid organs, and infiltrate inflamed tissues.

Preclinical Characterization of a Novel anti-CD40 Antagonist Antibody-glucocorticoid Conjugate with Superior Preclinical Efficacy and Favorable Safety Profile

Dianru wang[1], **Wenming Ren**[2], lu su[1], yuan lin[1] and cheng liao[1], [1]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China, [2]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Pudong New District, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GCs) are the first-line anti-inflammatory treatment for many autoimmune diseases, but long-term systemic administration of GCs is associated with unwanted side effects, which may be overcome by targeted delivery of GCs via antibodies. The CD40-CD40L costimulatory pathway regulates a wide array of immune cell effector function. The blockage of CD40/CD40L pathway is effective in autoimmune diseases such as Sjögren's syndrome, but exhibits limited efficacy in severe disease such as systemic lupus erythematosus (SLE). We generated a first-in-class anti-CD40 antibody-glucocorticoid conjugate (anti-CD40 conjugate) that allowed the targeted delivery of GCs to the corresponding immune cells, while blocking CD40/CD40L pathway simultaneously. Here we describe the preclinical characterization of this novel antibody-glucocorticoid conjugate.

Methods: The targeted delivery of GCs was measured by using a CD40-expressing GC reporter cell line. Inhibitory activity of the anti-CD40 conjugate was evaluated in human B and dendritic cells under CD40L stimulation. In addition, Fc-dependent effector functions, including antibody-dependent cellular cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC), were assessed by co-culturing natural killer (NK) cells or complement proteins with CD40-expressing cell lines. By using human-CD40-transgenic mice, the efficacy of anti-CD40 conjugate was determined in T cell-dependent antibody responses (TDAR) model and skin graft model. Furthermore, a 4-week GLP repeated-dose toxicity study in cynomolgus monkeys was conducted to evaluate the *in-vivo* safety.

Results: The anti-CD40 conjugate displayed GC receptor activity after being internalized via the membrane CD40 and inhibited CD40L-induced activation of human B or dendritic cells. The anti-CD40 antibody is a humanized antagonist antibody with Fc-silencing mutation to eliminate Fc-dependent effector functions and therefore is unable to mediate ADCC and

CDC.We proved that the anti-CD40 conjugate blocked the generation of KLH-specific antibodies in TDAR model. Compared to the anti-CD40 antibody or the combination of anti-CD40 antibody with GC treatment, the anti-CD40 conjugate supported a longer survival of the transplanted skin tissues in the skin graft model. Further, the repeated-dose toxicity study in cynomolgus monkeys showed that the anti-CD40 conjugate was safe and generally well tolerated up to 75 mg/kg. We did not observe adverse effects in cardiovascular, respiratory, and neurobehavioral endpoints. Reduced follicle size and suppression of germinal center in lymph nodes and spleen were seen with immunophenotyping and histology.

Conclusion: Overall, these data demonstrate that the novel anti-CD40-glucocorticoid conjugate has a promising efficacy and safety profile in preclinical models and support the clinical application in diverse autoimmune diseases, including organ transplantation, systemic lupus erythematosus, etc.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: B cells have gained increased interest in ANCA-associated vasculitis (AAV) research, as the treatment of this autoimmune disease with rituximab (an anti-CD20 B cell targeted therapy) resulted in beneficial clinical outcomes. Despite its advantages, this treatment strategy results in long-term B cell depletion and fails in the targeting of long-lived plasma cells, rendering an unmet need for more reversible and combined B and plasma cell targeting approaches to achive long-term (drug-free) disease remission. This aim may be fullfilled upon targeting essential signaling pathways for B cell biology. The NF-κB signalling pathways regulate fundamental B and/or plasma cell responses, downstream of various B cell surface receptors, including the B cell receptor, CD40, and TLRs, making them potential targets. Furthermore, alterations in NF-κB have been described in other autoimmune diseases and in B cell malignancies. Our research aims to study the potential effects of inhibition of NF-κB signalling on B cell responses in general, and more specifically on plasmablast differentiation and (auto)antibody production in B cells from AAV patients as a novel therapeutic approach.

Methods: Memory B cells were obtained from patients with AAV and healthy donors (HD), and gene expression profiles were generated by RNA-sequencing. Functional assays were performed culturing PMBCs from AAV patients and HD with stimuli mimicking T cell-dependent (anti-CD40/IL-21) and T cell-independent (CpG/IL-2) conditions. Pharmacological inhibitors of NF-κB inducing kinase (NIK, non-canonical pathway) and Inhibitor-of-κB-kinase-β (IKKβ, canonical pathway) were

added to the cultures. Downstream NF-κB signalling was determined by Western blot. After 6-day cultures, B cell proliferation and differentiation were determined by flow cytometry, and ELISA was performed for detection of (auto)antibody production.

Results: Memory B cells from AAV patients with active disease had an upregulated expression of NF-κB-associated genes compared to patients in remission and HD. Targeting of NIK and IKKβ in AAV and HD B cells effectively inhibited downstream non-canonical or canonical NF-κB signalling, respectively. NIK and IKKβ inhibition significantly reduced B cell proliferation in both stimulatory conditions in functional assays. In addition, NK and IKKβ inhibitors attenuated B cell differentiation into plasmablasts and antibody production, including anti-proteinase-3 (PR3) autoantibodies. Interestingly, the effects of NIK inhibition appeared to be B cell-specific, remdering T cell proliferation unaffected.

Conclusion: These data reveal that NF-κB-associated genes were highly expressed in memory B cells from AAV patients with active disease and that interfering with NF-κB signalling inhibits essential B cell responses that are important in the autoimmune process. These findings suggest that targeting NF-κB, particularly NIK, may be a more reversible and B cell directed novel treatment modality for AAV.

Differential Induction of Anti-Muscarinic Type-3-Receptor Antibodies by Immunization with 4-Hydroxy-2-nonenal-Modified Ro60 in BALB/c Mice

Biji T Kurien[1], Devavrat Dave[1], Martha Tsaliki[1], Valerie Lewis[1] and R Hal Scofield[2], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma City Veterans Affairs Medical Center, Oklahoma City, OK

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's Disease is an autoimmune condition in which patients exhibit decreased salivary/lacrimal gland function and express autoantibodies that target the 60k molecular weight Ro autoantigen. Published works have proposed autoantibodies that target M3R as potential clinical markers for **Sjögren's** Disease. Our studies show that 4-hydroxy-2-nonenal (lipid oxidation byproduct) immunized rabbits develop antibodies against G-protein-coupled acetylcholine receptor muscarinic-type-3-receptor (M3R) second (ECL2) and third (ECL3) extracellular loops. We hypothesized that there will be a differential induction of antibodies against ECL2 or ECL3 dependent on the degree of 4-hydroxy-2-nonenal (HNE)-modification of Ro60 in BALB/c mice.

Methods: Five groups of BALB/c mice were used in this study. Group I was immunized with Ro60. Groups II to IV were immunized with Ro60, modified with 0.4 mM (low), 2 mM (medium) and 10 mM (high) HNE respectively. Group V controls received Freund's adjuvant. Antibodies to M3R ECL2 (amino acids 213-228) and ECL3 (amino acids 514-527) were detected by multiple antigenic peptide ELISA using sera from the immunized mice.

Results: Immunization with unmodified Ro60 induced a rapid and differential intermolecular epitope spreading to the second loop of M3R, but not to the third loop. Bleed 2 sera from Group 1 mice immunized with unmodified Ro60 had an average reactivity of OD_{405} 0.69±0.3 to ECL2 peptide, while Group 2 mice immunized with low HNE-Ro60 showed an average reactivity of OD_{405} 0.58±0.21. The medium HNE-Ro60 immunized mice (Group 3) had the highest reactivity (OD_{405} 1.02 ±0.39), and the Freund's control group (Group 5) had the lowest reactivity (OD_{405} 0.01±0.06), while Group 3 mice immunized with high-HNE-Ro60 had a reactivity of OD_{405} 0.25±0.11 to the ECL2 peptide. The anti-ECL2 antibody levels induced in the medium HNE-Ro60 group was significantly higher than the levels induced by immunization with unmodified Ro60 ($p< 0.0003$). The anti-ECL2 levels correlated well with the induction of anti-Ro60 and anti-La antibodies in the mice immunized with medium HNE-Ro60. A similar trend was observed in Bleed 6 of the five experimental groups, with the medium HNE-Ro60 immunized group having significantly higher anti-ECL2 antibody levels compared to Ro60 immunized group ($p< 0.0005$). However, there was no significant induction of antibodies to ECL3 in any of the groups for both bleeds.

Conclusion: We found a differential induction of antibodies against the second extracellular loop of M3R, with Group 3 mice immunized with medium HNE-Ro60 developing significantly higher reactivity when compared to all other groups. Such a differential intermolecular epitope spreading may have significant implications for developing a deeper understanding of the progression of autoimmunity in Sjögren's Disease.

Impact of Psilocybin on Peripheral Cytokine Production

Dana DiRenzo[1], Frederick Barrett[2], Jamie Perin[2], Erika Darrah[2], Lisa Christopher-Stine[2] and Roland Griffiths[2], [1]University of Pennsylvania, Bala Cynwyd, PA, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psilocybin is a psychedelic drug with potential therapeutic effects in patients with mood and substance use disorders. Little is known about its impact on the immune system. In alignment with previous research showcasing psilocybin's influence on cortical and subcortical brain regions, we hypothesized a connection between these enduring personality changes to alterations in the immune system. Psilocybin, known for its psychoactive properties, has shown potential in increasing positive personality traits and reducing stress and anxiety in previous studies. Our current research considers psilocybin's potential anti-inflammatory properties, given its role as a serotonin 2A (5-HT2A) receptor agonist. The existing literature suggests that 5-HT2A activation could play a key role in regulating cytokine responses, thereby influencing the immune system.

Methods: Sera from 91 participants were included from our three prior randomized controlled clinical trials (RCTs). Multiplex immunoassay pro-inflammatory cytokine panels (Meso-Scale Discovery) were used to examine the serum from participants in three separate RCTs wherein a range of doses of psilocybin were administered (methods reported previously). Participants represented a range of clinical histories including those with no-known health problems/long-term meditation practice, depression, anxiety, and cancer (various types). Linear mixed models with random effects for each participant were fit to determine relative cytokine levels both before and at various time points after psilocybin administration.

Table 1. Description of 91 participants in three separate studies.

	Mean (SD)	N (%)
Study #1 (n = 35)		
Age in years, mean (SD)	55.0 (12.1)	
Male, N (%)		16 (46%)
Study #2 (n = 25)		
Age in years, mean (SD)	38.9 (12.6)	
Male, N (%)		9 (36%)
Study #3 (n = 31)		
Age in years, mean (SD)	57.3 (9.9)	
Male, N (%)		14 (45%)

SD, standard deviation; N, number

Results: In our linear models, sera collected ≤1-week post-psilocybin revealed increased levels of IL-8 (β=0.164, 95% CI (0.10, 0.23); p=0.004) and TNF-α (β=0.10 (0.05, 0.15); p=0.027). At ≥4-week time points compared to baseline, there was a relative increased level of IL-10 (β=0.08 (0.04, 0.12); p=0.035) and IFNα (β=0.259, 95% CI (0.11, 0.41); p=0.035).

Conclusion: This preliminary study indicates that psilocybin may have impacts on peripheral cytokine concentrations., There was a transient increase in pro-inflammatory cytokine production ≤1-week post-psilocybin followed by delayed anti-inflammatory cytokine production at ≥4 weeks. More broadly, peripheral cytokine production does appear to be altered

Table 2. Differences between cytokine measures after exposure to psilocybin in 91 participants from three separate studies. Only study #2, 3 had delayed (≥4 weeks) time points (n=56). Regression coefficients are for comparing log transformed cytokine concentrations, adjusted fo study.

by psilocybin administration. . Further research is required to understand psilocybin's broad immunologic impacts on cytokine concentrations in the central nervous system and innate immune signaling. Despite certain limitations, these findings underscore the need to further investigate psilocybin's influence on the immune system.

Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's Disease (SjD) has high glandular IFNg levels, associated with disease activity and lymphoma risk. We showed that IFNg-stimulated minor salivary gland (SG)-mesenchymal stromal cells (MSCs) produced CXCL-9, -10, and -11 through JAK2→STAT1 phosphorylation. Chemokine production and STAT1 phosphorylation by SG-MSCs were inhibited by the JAK1/2 inhibitor, ruxolitinib, a potential promising therapy for SjD. Using culture adapted SG MSC as an in vitro rosetta stone of SG-resident parenchymal cells, we investigated the IFNg →JAK/STAT biochemical response of SG-MSCs to FDA approved JAK inhibitors.

Methods: We treated human SG-MSCs with IFNg and JAK1/2 inhibitors. The JAK inhibitors included ruxolitinib and baricitinib, which bind the JAK conformation poised to phosphorylate its STAT substrates (kinase active conformation). We also studied the novel JAK inhibitor, CHZ868, which binds the kinase inactive JAK conformation. We performed western blotting of cell lysates, probing for JAK1/2 or STAT1/3. We performed RNA sequencing and confirmed results with qPCR and ELISA. ANOVA or paired t-tests were used to calculate p-values across multiple variables.

Results: We determined that ruxolitinib treatment *increased* phospho JAK1 (pJAK1) and phospho JAK2 (pJAK2) of IFNg-stimulated SG-MSCs in a dose-dependent manner (Fig 1a-b). pSTAT1 and pSTAT3 were suppressed by ruxolitinib upon treatment (Fig 1c-d). Discontinuation of ruxolitinib resulted in decreased pJAK1/2 (Fig1e). We found a marked and rapid *increase* of pSTAT1 upon discontinuation of ruxolitinib and baricitinib, but not CHZ868 (Fig 1f). Next, we wanted to determine the downstream effects of this pSTAT cascade. We performed RNA-seq of three conditions: 1) IFNg throughout; 2) IFNg with ruxolitinib, discontinue ruxolitinib, and collect conditioned media 3 hours later; 3) IFNg with CHZ868, discontinue CHZ868, and collect conditioned media 3 hours later. We found that ruxolitniib withdrawal was associated with increased PLAT and PLAU expression when compared to IFNg treatment or CHZ868 discontinuation (Fig 2a-b). We confirmed that PLAU (plasminogen activator, urokinase [uPA]) increased in response to ruxolitinib discontinuation but not in control or CHZ868 discontinuation by qPCR (Fig 3a-b) and ELISA (Fig 3c).

Conclusion: Our findings suggest that ruxolitinib and baricitinib bind the active phosphorylated form of JAK and lead to a paradoxical cellular accumulation of functionally defective pJAK. Upon inhibitor withdrawal, the primed pJAKs are derepressed and initiate a pSTAT signaling cascade, ultimately resulting in high levels of uPA. In contrast, CHZ868, which binds the inactive JAK kinase conformation, does not lead to pJAK accumulation, a pSTAT cascade, or uPA production. CHZ868 does not cause this phenomenon. High uPA, associated with human atherosclerotic plaques, might cause proteolysis and plaque rupture. In conclusion, JAK1/2 inhibitors that bind the active pJAK configuration, but not those that bind the inactive JAK configuration, increase STAT signaling on withdrawal. This signaling results in high uPA and might promote plaque rupture (Fig 3d).

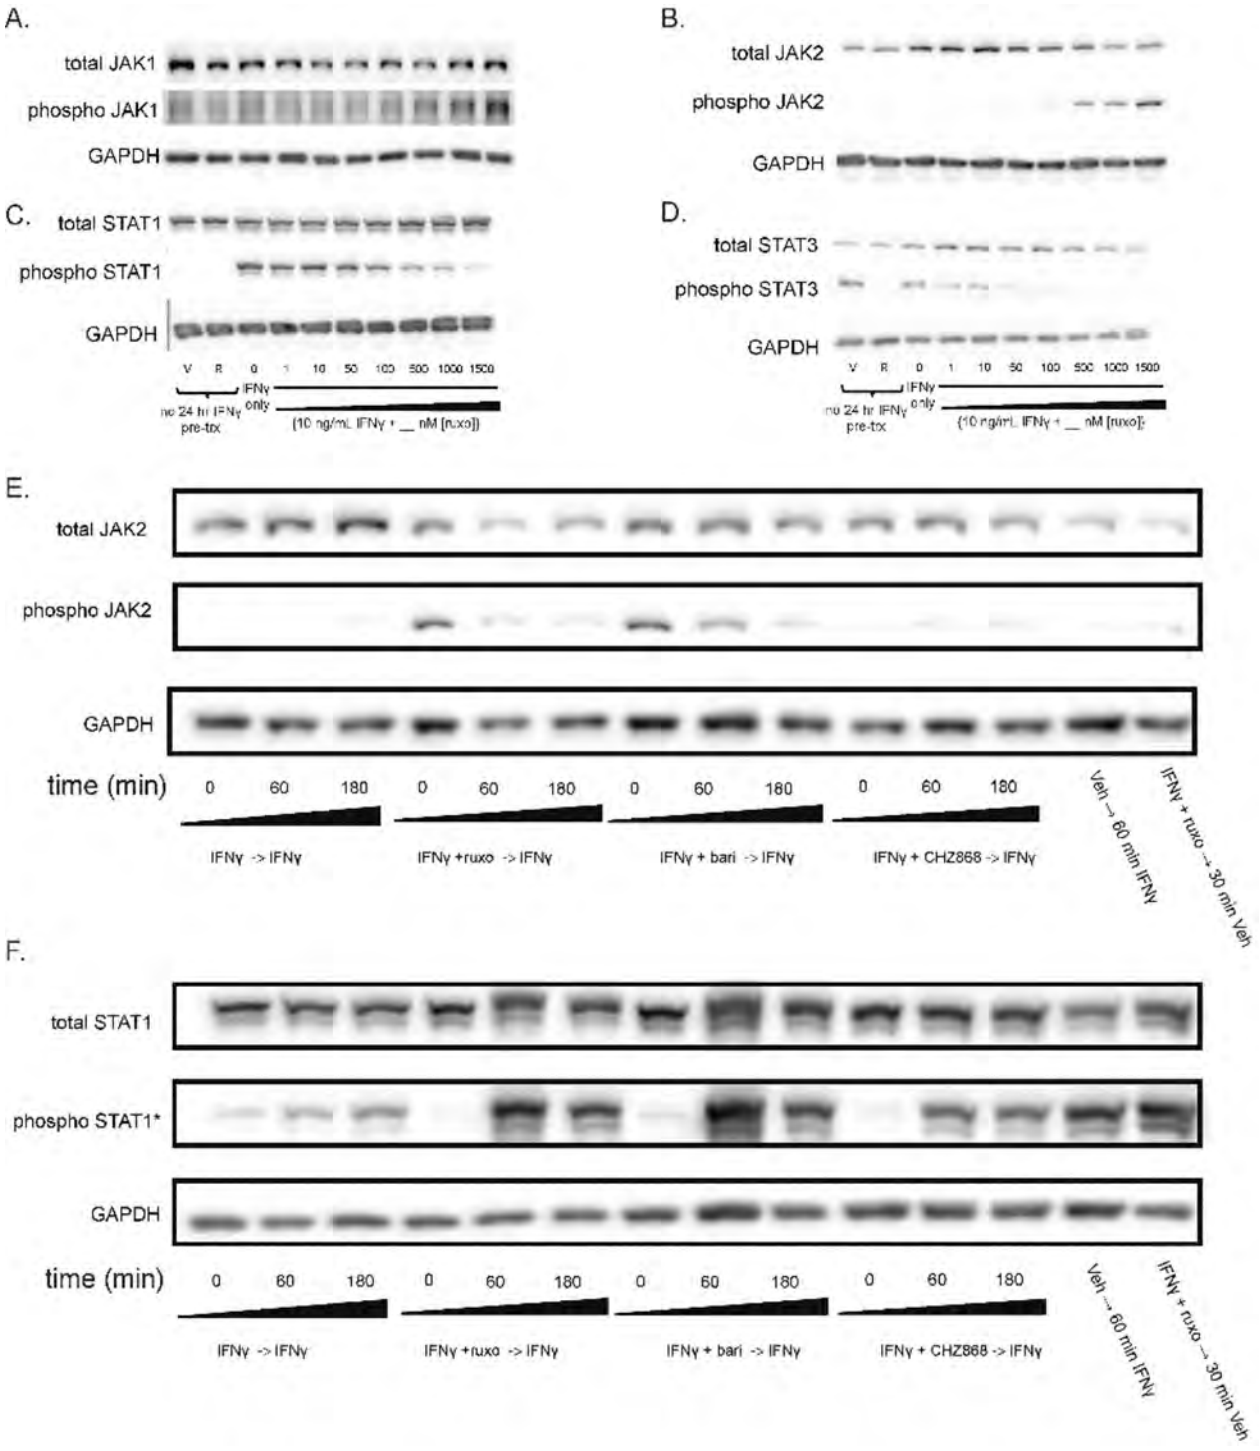

Figure 1. Withdrawal of ruxolitinib and baricitinib, but not CHZ868 causes transient increased phospho STAT1. We treated salivary gland-derived MSCs with vehicle, IFNγ (10 ng/mL), ruxolitinib (1000 nM), baricitinib (1000 nM) or CHZ 868 (1000 nM). A)Total JAK1 remains stable with increasing concentrations of ruxolitinib whereas phospho JAK1 increases with increasing ruxolitinib concentrations; B) total JAK2 peaks at 50 nM ruxolitinib, subsequently decreasing, whereas phospho JAK2 increases with ruxolitinib concentration; C) Total STAT1 remains stable with increasing ruxolitinib concentrations, whereas phospho STAT1 is inversely correlated with ruxolitinib dose; D) Total STAT3 decreases with increasing ruxolitinib concentrations, whereas phospho STAT3 is inversely correlated with ruxolitinib dose; E-F) MSCs treated with IFNγ alone served as controls in lanes 1-4. After treatment of MSCs with IFNγ and either ruxolitinib, baricitinib, or CHZ868 for 24 hours, we withdrew each JAKI and harvested cells at 15-180 minutes. Phospho JAK decreases with ruxolitinib withrawal as expected. Total STAT1 remains stable, whereas phospho STAT1 increases with ruxolitinib withdrawal, peaking at 60 minutes post-withdrawal. A similar trend is seen with baricitinib withdrawal, but not CHZ868 withdrawal.

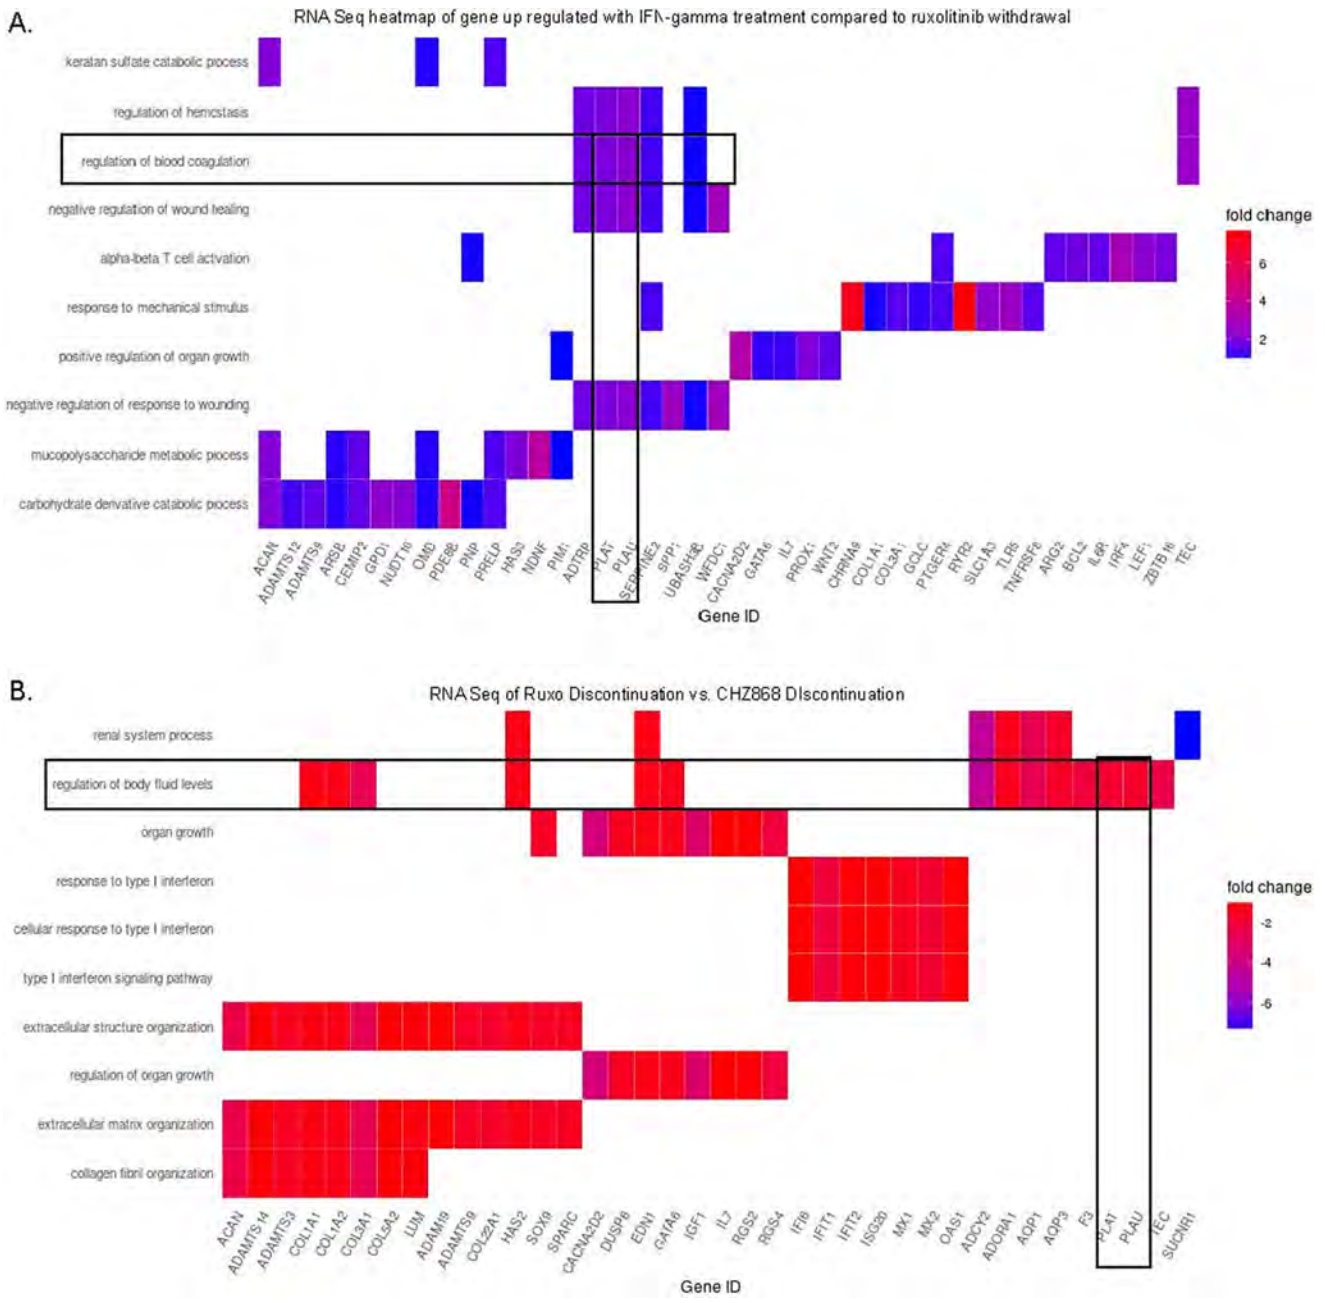

Figure 2. RNA Sequencing identifies PLAT and PLAU and genes differentially regulated upon ruxowithdrawal. Salivary gland MSCs were treated with IFNγ (10 ng/mL), ruxolitinib (1000 nM), or CHZ 868 (1000 nM) and then the either ruxolitinib or CHZ868 were withdrawn. Cells were harvested 6 hours later for RNA Sequencing. A) Compared to continuous IFNγ treatment, ruxolitinib withdrawal causes differential expression of genes associated with keratin sulfate, hemostasis, coagulation, wound healing, T cell activation, response to mechanical stimulus, organ growth, wounding response, mucopolysaccharide metabolic process, and carbohydrate derivative catabolic process. Genes associated with blood coagulation include PLAT and PLAU; B) Ruxo withdrawal compared to CHZ868 withdrawal revealed differential expression of genes related to renal systems, body fluid, organ growth, type I interferon response and signaling pathway, extracellular structure/matrix, and collagen fibril organization. PLAT and PLAU were upregulated in the ruxo withdrawal compared to CHZ868 withdrawal.

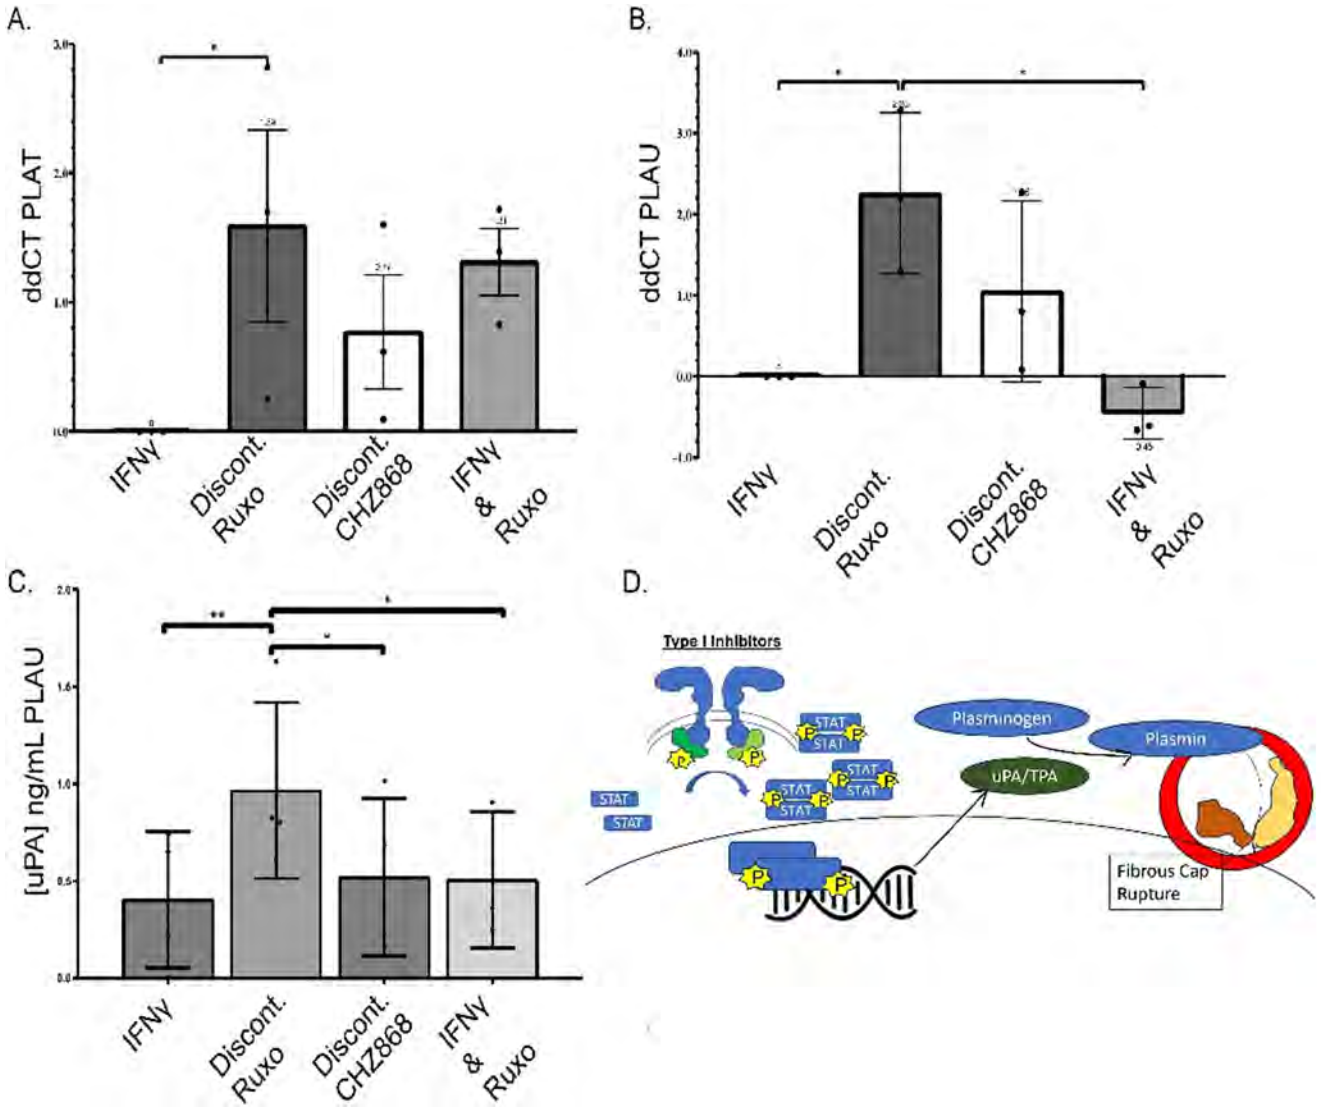

Figure 3. Confirmation that PLAU (plasminogen activator, urokinase [uPA]) increases after type I withdrawal. MSCs were treated with IFNγ (10 ng/mL), ruxolitinib (1000 nM), or CHZ 868 (1000 nM). Withdrawal was performed by treating cells with IFNγ plus JAKI, removing the JAKI by washing cells, and adding back media with IFNγ. After three hours, conditioned media were collected. A-B) qPCR of PLAT (plasminogen activator, tissue type) and PLAU show ruxo withdrawal increases expression of these genes compared to controls. This response was more prominent with PLAU than PLAT; C) uPA ELISA of conditioned media from cells treated with IFNγ treatment, ruxo discontinuation, CHZ868 discontinuation, or continued treatment with IFNγ and ruxolitinb

Clock Gene Bmal1 Promotes Transcriptional Activity of NF-κB to Regulate Production of Inflammatory Mediators in RA-FLS

Hikari Tsukamoto[1], Kenta Kaneshiro[2], Kohsuke Yoshida[1], Koji Tateishi[3], Yasuhiro Terashima[3], Nao Shibanuma[4], Yoshitada Sakai[5] and Akira Hashiramoto[1], [1]Kobe University Graduate School of Health Sciences, Kobe, Japan, [2]Kobe University Graduate School of Health Sciences, Osaka, Japan, [3]Kohnan Kakogawa Hospital, Kakogawa, Japan, [4]Kobe Kaisei Hospital, Kobe, Japan, [5]Kobe University Graduate School of Medicine, Kobe, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA), an autoimmune polyarthritis characterized by 'tumor-like' proliferation of RA fibroblast-like synovial cells (RA-FLS), has characteristic symptoms such as "morning stiffness of joints" related to circadian rhythms. Furthermore, the concentrations of inflammatory cytokines such as TNF-α, IL-6, and IFN-γ in sera of RA patients is also known to peak at midnight, prior to arthritic symptoms in the morning. Circadian rhythms in individual cells are regulated by the expressions of clock genes (*Bmal1*, *Clock*, *Per*, and *Cry*). We previously reported that TNF-α increased the expression of *Bmal1* in RA-FLS which induced osteochondral destruction via production of inflammatory mediators. It has been reported that BMAL1 binds to NF-κB/p65 in breast cancer cells, leading to promotes MMP-9 transcription (Wang et al. Cancer Cell Int, 2019, 19:182), however, it remains unclear how Bmal1 is involved in the pathogenesis of RA. In this study, we examined the function and the mechanism that Bmal1 contributed the productions of inflammatory mediators in RA-FLS under cytokine stimulations.

Methods: After transfected *Bmal1*/siRNA, RA-FLSs were stimulated with or without TNF-α (20 ng/ml), IL-1β (20 ng/ml) or IFN-γ (20 ng/ml) for 32 hours to examine the expressions of inflammatory mediators; CCL2, IL-6, MMP-3 by qPCR. Next, we investigated NF-κB/p65 activity and an interaction between BMAL1 and NF-κB/p65 by immunofluorescence and co-immunoprecipitation. Total protein was extracted from RA-FLS to analyze the expression of phospho-p65/total p65 by western blotting.

Results: Under stimulation of TNF-α and IL-1β, the mRNA expression of CCL2 were significantly suppressed by silencing *Bmal1*. Similarly, under stimulation of IL-1β and IFN-γ, silencing *Bmal1* suppressed the mRNA expressions of IL-6 and MMP-3, respectively (Fig 1). Under fluorescence observations, NF-κB/p65 translocated into the nucleus following TNF-α and IL-1β stimulation though it appeared to be suppressed by silencing *Bmal1*. Stimulation with IFN-γ had no effect on p65 (Fig 2). Furthermore, BMAL1 was combined with p65 (Fig 3-a), and a phosphorylation of p65 was suppressed by silencing *Bmal1* under stimulations with TNF-α (Fig 3-b).

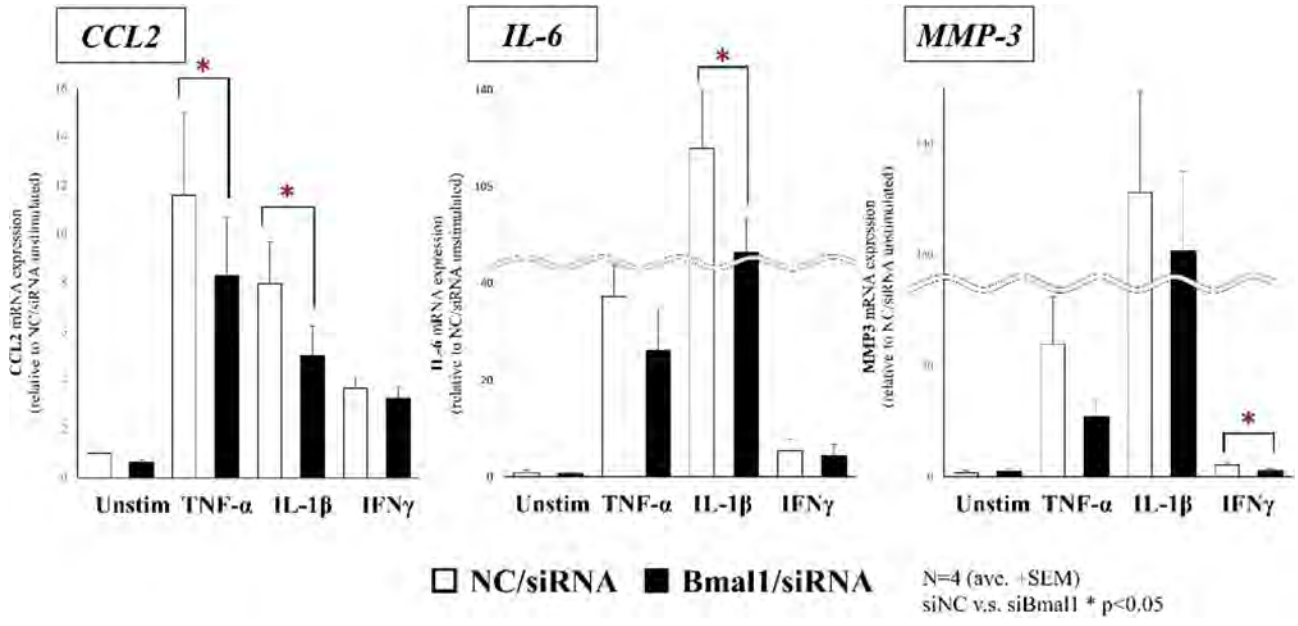

Fig 1

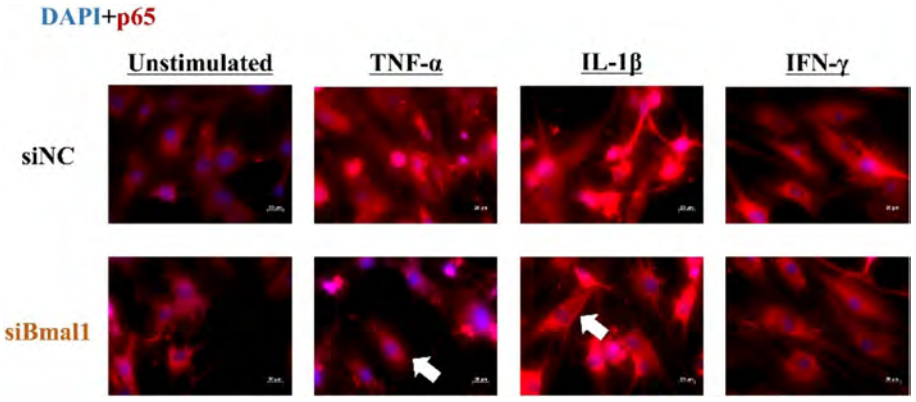

Fig 2

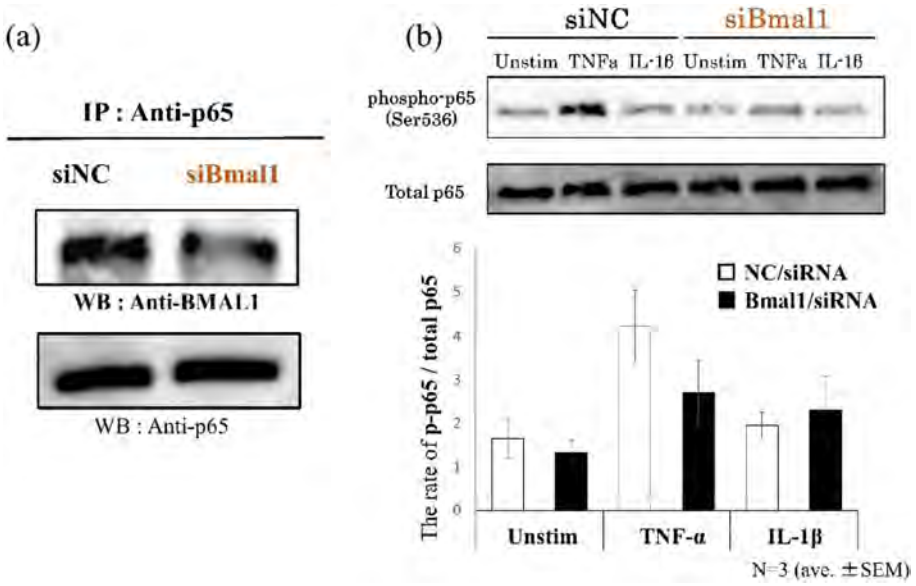

Fig 3

Conclusion: The results indicated Bmal1 promoted the phosphorylation and nuclear translocation of p65 via forming the complex, subsequently contributing to the production of inflammatory mediators in RA-FLS, which might consequently induce osteochondral destruction in RA.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Cytokines & Cell Trafficking Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) encompass two of the most common forms of Inflammatory Arthritis. While common pathogenic mechanisms are involved in driving inflammation in both arthropathies there are significant differences, including the presence/absence of autoantibodies, immune-cell infiltrates, molecular signaling, enthesitis and response to therapy. Therefore, the aim is to identify unique mediators that drive differential synovial fibroblast (FLS) populations and function in RA vs PsA, with implication for the inflammatory responses.

Methods: Single cell (Sc) RNAseq was performed on RA and PsA synovial cell suspensions and FLS populations were then defined by advanced bioinformatic analysis. Subsequently, primary RA FLS were cultured with IL-1β (1ng/ml), TGF-β (10ng/ml), or a combination of both. Analysis of key FLS activation and functional markers was performed by flow cytometry, and secreted pro-inflammatory cytokines and matrix metalloproteinases were quantified by ELISA/MSD multiplex assays. Metabolic capacity was assessed using the Seahorse-XFe-technology and fluorescence-lifetime imaging (FLIM) and glycolytic genes were quantified by real-time PCR. mRNA expression of mitochondrial fission/fusion proteins (DRP1/MFN1/MFN2) and endoplasmic reticulum (ER) stress proteins (XBP1S/BIP/ATF6) were quantified by real-time PCR and immunofluorescent staining was utilized to examine ER stress.

Results: ScRNAseq analysis demonstrated 11 distinct FLS populations in RA and PsA, with FAPα+THY1+ invasive FLS enriched in RA patients. ScRNAseq receptor-ligand interactions demonstrated that T cell-derived TGF-β and macrophage derived IL-1β synergistically drive the transcriptional profile of these FAPα+THY1+ invasive FLS in RA. We further demonstrated at a functional level that IL-1β and TGF- β synergistically interact to promote secretion of pro-inflammatory cytokines IL-6, IL-8, and MCP-1, the growth factor VEGF (all $p< 0.05$), cell surface expression of the adhesion molecule ICAM-1 ($p< 0.01$), in addition to secretion of MMP3 ($p< 0.05$), with no synergistic effects observed for MMP1, CXCR3, CXCR4 and CXCR5. Furthermore, this synergistic interaction also altered the metabolic profile of the RA FLS, towards a more glycolytic phenotype, with synergistic induction of basal glycolysis ($p< 0.05$), proton efflux rate ($p< 0.05$), % PER from glycolysis ($p< 0.05$) and compensatory glycolysis ($p< 0.001$), which supports their invasive phenotype. Significant increases were also observed in key glycolytic markers GLUT-1, HIF1A and PKM2 (all $p< 0.05$) and ER stress genes XBP1S, BIP and ATF6. In parallel, a reduction in mitochondrial size ($p< 0.05$) which was associated with an increase mitochondrial fission protein DRP-1 ($p< 0.05$) with no effect observed for fusion proteins MFN1/MFN2 was demonstrated.

Conclusion: Distinct FLS subtypes were identified in RA and PsA, the invasive phenotype of which were driven by synergistic interactions between T-cell and macrophage derived cytokines. Blocking specific immune-stromal cell interactions may offer new therapeutic intervention in RA and PsA.

A Proliferating T Cell Signature in Blood Is Associated with Response to JAK Inhibitor Therapy in Rheumatoid Arthritis Patients

Mehreen Elahee[1], Kathryne Marks[2], Ifeoluwakiisi Adejoorin[2], Lin Chen[2], Derrick Todd[2], Jonathan Coblyn[2], Elena Massarotti[2], Susan Ritter[2], Michael Weinblatt[3], Daniel Solomon[4] and Deepak Rao[2], [1]University of Pittsburgh Medical Center, Pittsburgh, PA, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard Medical School, Waban, MA, [4]Brigham and Women's Hospital, Newton, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: There are multiple DMARDs available to treat rheumatoid arthritis (RA) yet there are no widely used predictive biomarkers to guide selection of a specific DMARD. We hypothesize that immunophenotyping of blood immune cells will provide potential biomarkers associated with response to specific DMARDs. We profiled circulating lymphocytes in RA patients before and after treatment with JAK inhibitors (JAKi) or anti-TNF (aTNF) to identify immune cell features associated with treatment response.

Methods: We applied single-cell RNA sequencing (scRNA-seq) and mass cytometry to PBMCs from RA patients before and after treatment with JAKi (scRNAseq n=19, mass cytometry n=27) or aTNF (scRNAseq n=9, mass cytometry n=32) as prescribed by treating physician. RA patients met ACR/EULAR 2010 classification criteria, and treatment response was ascertained by CDAI and medical record review. T cell subsets were identified by unsupervised analysis and specific populations were validated by biaxial gating. Wilcoxon paired tests were used for comparison between the timepoints and Mann-Whitney was used to compare responders vs non-responders.

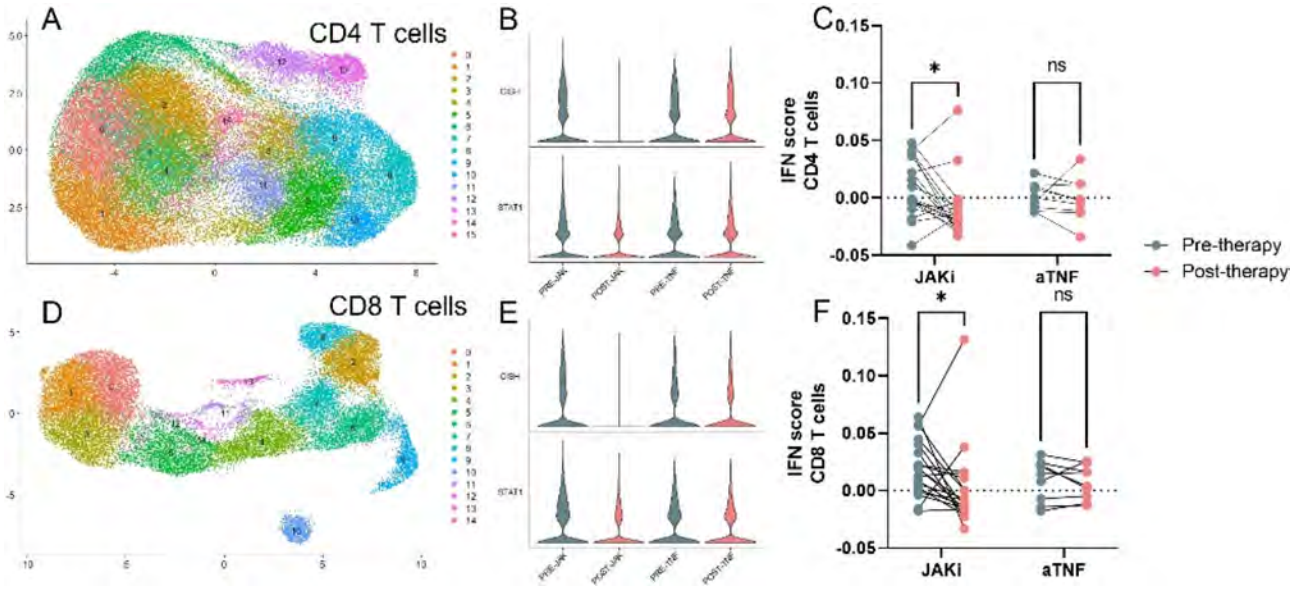

Figure 1. A) UMAP visualization of single cell RNA sequencing of CD4 T cells. B) Expression of CISH and STAT1 in CD4 T cells before and after JAKi or aTNF therapy. C) IFN gene module score in CD4 T cells of each sample before and after JAKi or aTNF therapy. D)UMAP visualization of single cell RNA sequencing of CD8 T cells. E)Expression of CISH and STAT1 in CD8 T cells before and after JAKi or aTNF therapy. F) IFN gene module score in CD8 T cells of each sample before and after JAKi or aTNF therapy.

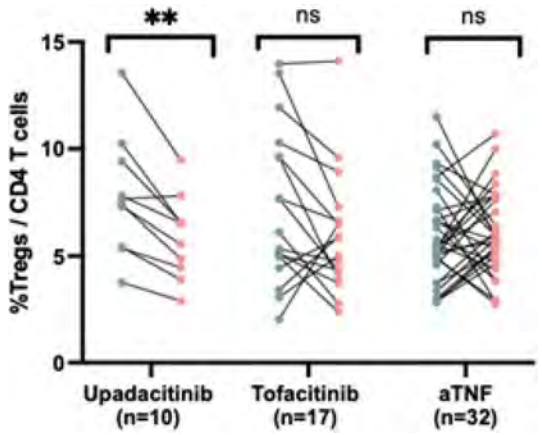

Figure 2. Frequency of regulatory T cells (CD25+FoxP3+) in CD4+ T cells as measured by mass cytometry. Frequencies are shown before and after upadicitinib, tofacinitib, or anti-TNF therapies (**p<0.001 by Wilcoxon signed-rank test).

Results: Comparison of lymphocytes from RA patients before and after treatment with JAKi by scRNA-seq revealed changes in lymphocyte transcriptomic signatures, including reduction in JAK signaling-associated genes such as CISH, SOCS2, and STAT1 and reduction in interferon-stimulated genes, consistent with effective JAK inhibition. These changes occurred similarly in JAKi responders and non-responders, yet they were not observed in the aTNF-treated cohort. Comparison of lymphocyte populations pre- and post-JAKi treatment revealed several changes in T cell composition, including a reduction in a regulatory T cell (Treg) subset following treatment with upadacitinib but not tofacitinib or aTNF. Comparing pre-treatment samples from responders and non-responders, we observed higher frequencies of a PD-1^{hi} CD4 T peripheral helper (Tph) cell cluster and an activated CD8 T cell cluster in JAKi responders compared to non-responders at baseline. Both of these cell clusters had high expression of the proliferation marker Ki67 and increased expression of a gene signature associated with proliferation. These proliferating clusters did not differ between responders vs non-responders in the aTNF-treated cohort.

Unsupervised analysis of mass cytometry data from a larger cohort of JAKi-treated patients similarly identified a reduced Treg frequency in patients treated with upadacitinib and higher frequency of Ki67$^+$ HLA-DR$^+$ Tph cells and Ki67$^+$ HLA-DR$^+$ CD8 T cells specifically in JAKi responders compared to non-responders, but not in the aTNF-treated cohort. Cells in the JAKi responder-associated clusters were characterized by expression of CD38 and PD-1. Biaxial gating on Ki67 and HLA-DR reproduced results from unsupervised clustering.

Conclusion: Broad lymphocyte immunophenotyping revealed a signature of proliferating lymphocytes in blood that was enriched in JAKi responders but not aTNF responders. These results suggest that cellular features detectable in blood may be leveraged as predictive biomarkers and may distinguish likelihood of response to different DMARD therapies.

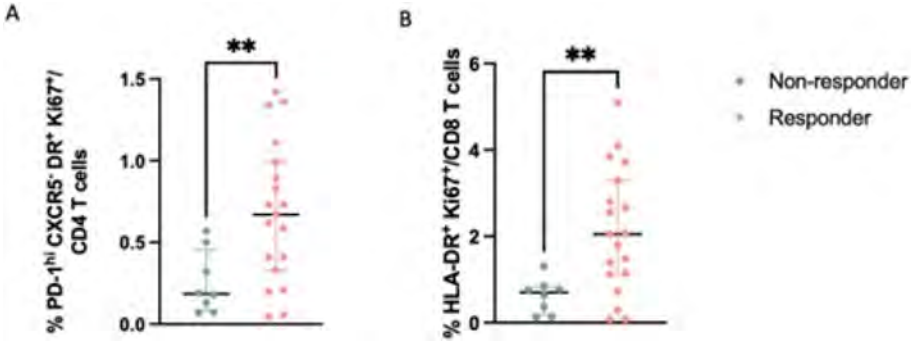

Figure 3. A) Frequencies of PD-1hiCXCR5-HLA-DR+Ki67+ CD4 T cells in responders and non responders to JAKi as measured by mass cytometry (**p<0.001 by Mann-Whitney) B) Frequencies of HLA-DR+Ki67+ CD8 T cells in responders and non responders to JAKi as measured by mass cytometry (**p<0.001 by Mann-Whitney).

The 330 Genetic Risk Loci of Systemic Lupus Erythematosus (SLE) Now Known Are Consonant with Multiple Causal Mechanisms Involving Epstein-Barr Virus (EBV)-Encoded Transcription Co-factors (TFs) in EBV-Infected B Cells

Viktoryia Laurynenka[1], Xiaoting Chen[2], sreeja Parameswaran[2], Leah Kottyan[2], Matthew Weirauch[2], Iouri Chepelev[3], Kenneth Kaufman[3] and John Harley[3], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]US Department of Veterans Affairs Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Association of EBV infection with SLE, data suggesting an anti-EBNA1 molecular mimicry fostering SLE autoimmunity, and mechanisms in EBV infected B cells support a model for EBV inducing SLE autoimmunity and clinical illness (Figure 1).

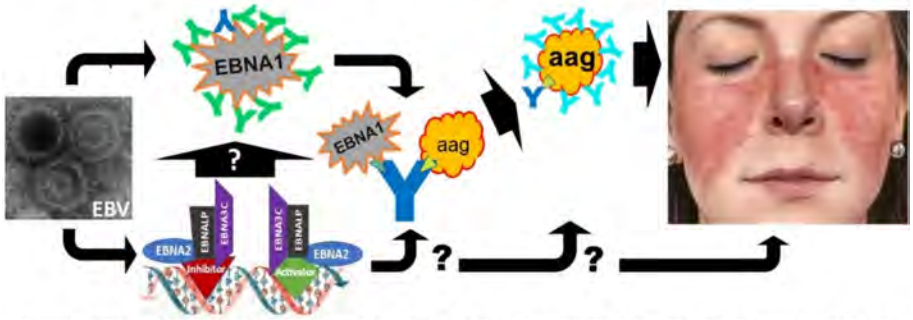
Methods: Literature review identified SLE risk loci at $p< 5x10^{-8}$. We curated 9,862 ChIP-seq (Chromatin ImmunoPrecipitation with DNA sequencing) datasets from 1,339 transcription factors (TFs) in 3,531 "cellular sources" and assessed TF binding to DNA with Multimode RELI (Regulatory Element Locus Intersection (modified from PMID: 29662164)).

Results: 330 SLE risk loci ($p< 5x10^{-8}$) were published prior to 2023. Of these, 255 are found in East Asians (EAS), 106 in Europeans (EU), 11 in African-Americans, and 18 in mixed Americans. 77 of 330 have been established at $p< 5x10^{-8}$ in ≥3 separate studies. 40 of the 330 loci are established independently in both EAS & EU ancestries. KEGG analysis of candidate target genes and genes located near the top variant of the 330 loci, show strong associations related to, among others, IFNγ, IL-12, IL-23, B-cell receptor, & EBV pathways ($6.1< OR< 16$, $10^{-30}< p_a< 10^{-8}$).

Enrichment of TFs binding to SLE loci, with disequilibrium to $r^2>0.8$, using ChIP-seq datasets separately in EAS & EU ancestries, reveals that 200 (14.9%) of 1,339 tested TFs found in 1,871 (19.0%) of the 9,862 TF ChIP-seq datasets are associated with SLE loci at $p_c< 10^{-6}$ in both ancestries. The TF dataset association ranks are highly similar in EAS & EU ancestries ($r=0.73$ (Spearman), $p< 0.0001$) (Figure 2).

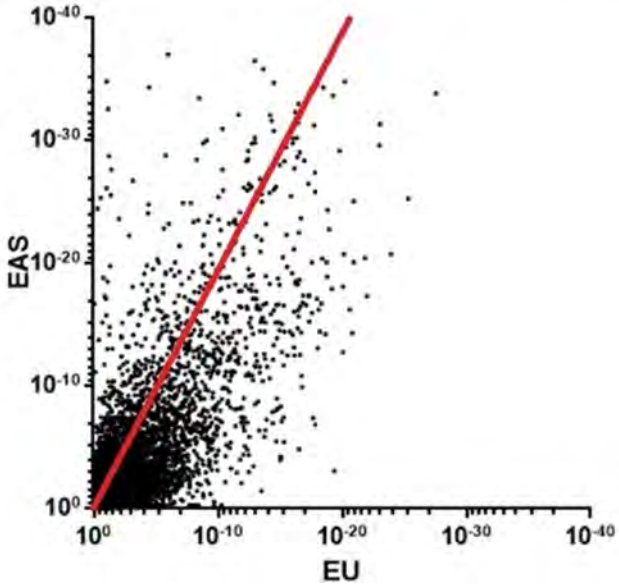
Of the 3,531 cellular sources, EBV-infected and transformed human B cells are most closely associated with both the EAS & EU risk loci ($OR >19$, $p< 10^{-300}$), compared to all other cellular sources, even including B cells that are not EBV-infected. The proportions of significant ($p_a< 10^{-6}$) TF ChIP-seq datasets in all other tested infections are negatively associated in aggregate ($OR< 0.17$, $p< 5.3x10^{-34}$), as are cellular sources with no known infection ($OR< 0.36$, $p< 3x10^{-112}$).

Figure 1. Pathogenesis model for SLE incorporating anti-EBNA1 & EBV-encoded TFs: EBNA2, EBNA3C, & EBNALP. (agg=autoantigen)



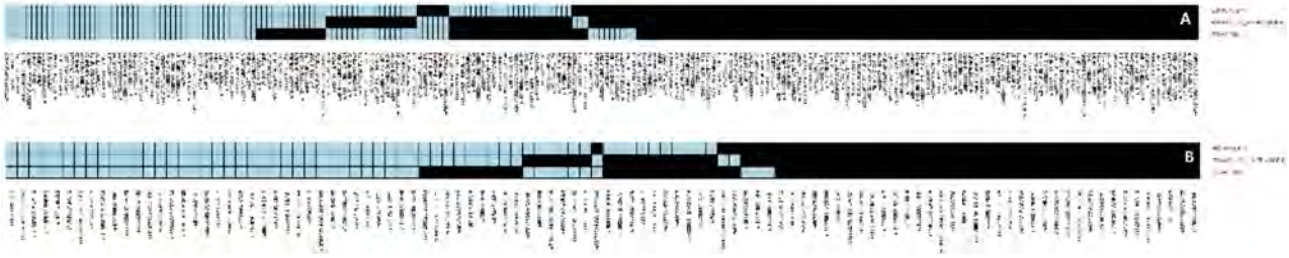
Images courtesy of NIAID (left) & Mayo Foundation (right), all rights reserved. Figure is not otherwise published.

FIGURE 2. P-values for the association of TF DNA binding of 9,862 ChIP-seq datasets with the SLE risk loci of EAS and EU ancestries using multimode RELI.



Of the associated host DNA binding of TFs at $p_a < 10^{-6}$, EBNA2, EBNALP, & EBNA3C, all EBV-encoded Latency III expression products, are separately associated ($2.1 < OR < 2.6$, $p < 10^{-11}$) with the SLE risk loci in both EAS & EU ancestries (Figure 3). At $OR > 3.2$, $p \leq 10^{-4}$, human TFs, known to form super-enhancers in EBV-infected, Latency III expressing transformed B cells, are

Figure 3. Intersection plots (colored boxes) of EBNA2, EBNA3C, & EBNALP ChIP-seq datasets with SLE risk loci for EAS (Panel A) and EU (Panel B) ancestries.



enriched among the significant TF ChIP-seq datasets, compared to uninfected B cells independently at the EAS & EU loci. When the SLE risk loci bound by all 3 of the most closely associated EBV-encoded TF datasets in EBV transformed B cells are removed (see Figure 3), then >95% of formerly significant ($p_a < 10^{-6}$) TF ChIP-seq data sets are no longer significant in either the EAS or EU ancestry, which would also be true for many of the significant human-encoded TF datasets.

Conclusion: The genetic mechanisms of SLE appear similarly dependent upon EBV-encoded TF gene regulation operating in EBV-transformed B cells in both EAS and EU ancestries. The distortion of gene expression, possibly driven through EBV-encoded TFs, is present in both EAS and EU ancestries and potentially important in the pathogenesis of SLE.

Genetic Predisposition to a Positive Antinuclear Antibody Test Is Not Associated with Increased Risk of Disease

Gul Karakoc[1], Ge Liu[1], Jacy Zanussi[2], Cecilia Chung[2], Jorge Gamboa[1], Jonathan Mosley[1], Nancy Cox[1], C. Michael Stein[1] and **Vivian Kawai**[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]University of Miami, Miami, FL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antinuclear antibodies (ANA) are biomarkers that are frequently used in the diagnosis of common autoimmune (AI) disorders, but are also present in ~12-20% of general population. Several small studies have suggested that a positive ANA test (ANA+) is associated with adverse outcomes such as cardiovascular events, cancer, and infections in the general population, but results have been inconsistent. To define the clinical consequences of ANA+, and mitigate confounding and reverse causation related with clinical testing for ANA, we used a genetic approach to test the hypothesis that a predisposition for ANA+ is associated with adverse clinical outcomes.

Methods: In BioVU, a DNA biobank linked to the de-identified electronic health record system at Vanderbilt, we studied participants of European ancestry (defined by principal components [PCs] and HapMap reference) who had genome-wide SNP genotyping performed on the Illumina Infinium MEGA® Array. We performed a genome-wide association analysis (GWAS) for ANA+ using individuals who had been tested for ANA as part of their clinical care but did not carry a diagnosis of SLE or other common AI diseases. The GWAS used an additive model, and the results were used to develop a polygenic risk score for positive ANA (PRS_{ANA+}) using Bayesian framework with continuous shrinkage. The PRS_{ANA+} was then calculated among BioVU participants not included in the GWAS analysis. A phenome-wide association study (PheWAS) using the PRS_{ANA+} as a predictor was performed adjusting for sex, median age, and 5 PCs of ancestry. For each condition, cases were participants having two or more phecodes for that condition and controls were those with not closely related phecode. Individuals with only one phecode for the condition were excluded. Phecodes with less than 100 cases were excluded to assure power. A false discovery rate (FDR) adjusted P-value < 0.05 was considered significant.

Results: There were 5,081 participants included in the GWAS, and ~7.6 million SNPs were included in the PRS_{ANA+}. The PheWAS was performed in 89,486 individuals and used 1220 phecodes. There were 10 phecodes significantly associated with the PRS_{ANA+} at FDR≤0.05. Providing proof of concept, the top clinical associations with the PRS_{ANA+} were phecodes

Figure: Phenome wide association study of genetic predisposition for a positive antinuclear antibody test. Triangles in green depict significant associations at FDR ≤0.05. All significant associations at FDR≤0.05 are described in the table on the right and sorted by P-value.

related to an abnormal immunological test: "Other immunological findings" and "Nonspecific findings on blood examination" with an odds-ratio (OR)≥1.3 (P < 5.0E-05). The remaining 8 associations had an inverse association (OR < 1.0) and included neurological and back pain-related conditions, fever of unknown origin, hypertensive heart and/or renal diseases (Figure).

Conclusion: A polygenic risk score for ANA+ that captures the genetic predisposition for a positive ANA test was associated with a decreased risk for osteoarthritis, spondylosis, hypertensive renal and/heart disease, and neurological disorders. There was no evidence that a genetic predisposition to a positive ANA test was associated with an increased risk of autoimmune, cardiovascular, or other disease.

Abstract Number: 0016

Role of TP53 in Inflammatory Reprogramming of Rheumatoid Arthritis Synovial Fibroblasts

Anil Singh and Salahuddin Ahmed, Washington State university, Spokane, WA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: TP53, a tumor-suppressor protein known as the guardian of the genome, plays a critical role in regulating genomic stability and cellular function. When TP53 function is lost, it can lead to uncontrolled cell division and the development of tumors. Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation and the destruction of joints. In the synovial microenvironment of RA, hyperplastic fibroblasts form a structure called pannus, which resembles a tumor. The downregulation of TP53 is influenced by TNF-α and IL-1β, two inflammatory molecules involved in RA.

Methods: We conducted RNA-seq analysis on human rheumatoid arthritis synovial fibroblasts (RASFs) to investigate the impact of TP53 loss in the synovial microenvironment. TP53 was transiently knocked down using siRNA. Additionally, we employed Gene Ontology studies, ELISA, and Western blot analyses to assess the effects of TP53 loss on inflammatory responses, specifically in the presence of TNF-α and IL-1β. These experiments utilized at least three donor lines of RASFs, with statistical significance set at $p< 0.05$.

Results: Our findings reveal that RASFs exhibit a significant (>40%) decrease in endogenous TP53 levels compared to normal synovial fibroblasts (NSFs). Proinflammatory conditions, such as treatment with IL-1β and TNF-α, further reduce TP53 expression in RASFs by more than 35% within 30 minutes (N=3, $p< 0.05$). RASFs display higher endogenous expression of the MDM2 E3 ubiquitin ligase, responsible for TP53 degradation. Inhibition of p38 MAPK restores TP53 levels, suggesting the involvement of MAPK pathways in TP53 stability. Inhibition of TAK1 and the ubiquitin-proteasome system rescues TP53 loss in response to IL-1β stimulation (N=3, $p< 0.05$). Subcellular fractionation reveals TP53 loss in both the cytoplasmic and nuclear compartments. RNA sequencing analysis identifies 241 differentially regulated genes in TP53-knockdown RASFs (N=3, $p< 0.05$), including an upregulation of inflammatory gene signatures. Gene ontology studies confirm the inflammatory phenotype of RASFs following TP53 loss. These findings suggest that TP53 loss predisposes RASFs to inflammation and may contribute to the progression of rheumatoid arthritis.

Conclusion: This study provides insights into how RASFs are predisposed to proinflammatory reprogramming through selective loss or gain of TP53 functions, affecting resistance to apoptosis and proliferation in response to inflammation during the progression of rheumatoid arthritis. The identification of gene networks, protein factors, and epigenetic changes involved in this process will facilitate the development of novel targeted therapies, enabling a deeper understanding of fibroblast-directed molecular events with significant clinical implications in precision medicine.

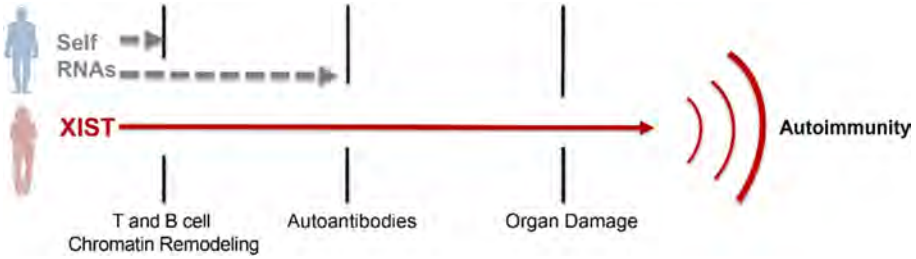
SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM



Proposed model of XIST ribonucleoproteins (RNPs) in autoimmune progression: Autoreactivity to Xist RNPs first causes changes in the chromatin landscape impacting genomic accessibility and changes in lymphocyte gene expression programs prior the development of autoantibodies. Prolonged self-reactive activity damages organs in the final stages of autoimmunity.

Background/Purpose: Autoimmune diseases disproportionately affect females more than males. The XX sex chromosome complement is strongly associated with susceptibility to autoimmunity. *Xist* long noncoding RNA (lncRNA) is expressed only in females to randomly inactivate one of the two X chromosomes to achieve gene dosage compensation. The *Xist* lncRNA complexes with numerous proteins associated with autoimmune diseases as autoantigens. The goal of our study is to determine whether the *Xist* ribonucleoprotein (RNP) complex is a driver for female-biased autoimmunity.

Methods: We developed a unique transgenic mouse to confer inducible expression of a non-silencing form of *Xist* in male animals. We assessed disease severity/progression in *Xist*-expressing/non-expressing mice in the pristane-induced systemic lupus erythematous (SLE) model using ATAC-seq, RNA-seq and single cell multiomic analyses of splenic immune cells, histopathology of physical disease markers in tissue sections, and serum autoantibody levels. We screened ChIRP-MS datasets to develop an *XIST* protein antigen array to test autoimmune disease patient serum for reactivity to XIST complex proteins.

Results: Inducible transgenic expression of *Xist* in male mice introduced *Xist* RNP complexes and sufficed to produce autoantibodies. Male SJL/J mice expressing transgenic *Xist* developed more severe multiorgan pathology in pristane-induced model of lupus than wild-type males. *Xist* expression in males reprogrammed T and B cell population and chromatin states to more resemble wild type females. Human autoimmune disease patients displayed significant levels of autoantibodies to multiple components of the *XIST* RNP.

Conclusion: *Xist* is a sex-specific lncRNA that scaffolds ubiquitous RNP components to drive sex-biased immunity.

Abstract Number: 0018

Alternative Splicing and Expected Protein Changes in Muscle Biopsies from Different Types of Idiopathic Inflammatory Myopathies

Rayan Najjar[1], Iago Pinal-Fernandez[2], Andrew Mammen[3] and Tomas Mustelin[1], [1]University of Washington, Seattle, WA, [2]National Institutes of Health, Bethesda, MD, [3]NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Alternative splicing of mRNA results in important biological impacts with increasing evidence implicating it in the pathology of autoimmune diseases. However, it is understudied in idiopathic inflammatory myopathies (IIM).

Methods: We studied alternative splicing in 152 muscle biopsies from IIM patients and controls. Patients included subgroups with myositis-specific autoantibodies including (anti-Jo1, anti-HMGCR, anti-SRP, anti-NXP2, anti-TIF1g, anti-Mi2, anti-MDA5), and inclusion body myositis (IBM). RNA sequencing data were aligned to the reference genome (GRCh38.p13), then alternative splicing events were quantified using SplAdder. Expected protein changes were identified and visualized using RiboSplitter. The percent spliced-in (PSI) was calculated as reads supporting isoform 2 divided by total reads supporting either isoform per event. We used an alpha of 0.05 and adjusted p values for multiple comparisons. Statistically significant events were filtered based on magnitude of difference to detect events more likely to be biologically meaningful. Finally, we identified outlier splicing events with PSI difference of 3 times the interquartile range, when compared to all other IIM and control samples.

Results: There were hundreds of statistically significant alternative splicing events in each IIM subgroup vs controls. Overall, there were 337 events (in 265 protein coding genes) with larger delta PSI. For each subgroup, we subtracted events that were also present in other subgroup comparisons, resulting in a smaller list of altered splicing that is unique to each subgroup (Table 1). We discovered unique splicing in two patients with anti-SRP myositis where exons 7 and 8 of SRP72 were skipped leading to loss of a tetratricopeptide repeat region (Fig 1A) that is involved in protein binding. SRP72 encodes one of the 6 protein subunits of the signal recognition particle (SRP). An intron retention event in the anti-Jo1 subgroup introduced a stop codon after exon 9 of FBXO9 that would result in a truncated protein (Fig 1B). Patients with HMGCR were more likely to express isoform 1 of an event in EWS RNA binding protein 1, skipping exons 8 and 9 (Fig 1C). One patient with TIF1g, and two with NXP2 had 49, 26, and 10 outlier events, respectively. One of the TIF1g outlier events was an alternative 5´event in

Table 1. Frequencies of statistically significant alternative splicing events in muscle biopsies from myositis patients. NT= Normal tissue

Myositis subgroup	Statistically significant vs NT	Events with larger differences vs NT	Unique events
Anti-Jo1	395	107	22
Anti-HMGCR	566	68	16
Anti-SRP	207	39	8
Anti-NXP2	236	65	11
Anti-TIF1g	215	55	10
Anti-Mi2	428	101	22
Anti-MDA5	307	57	18
IBM	382	80	16

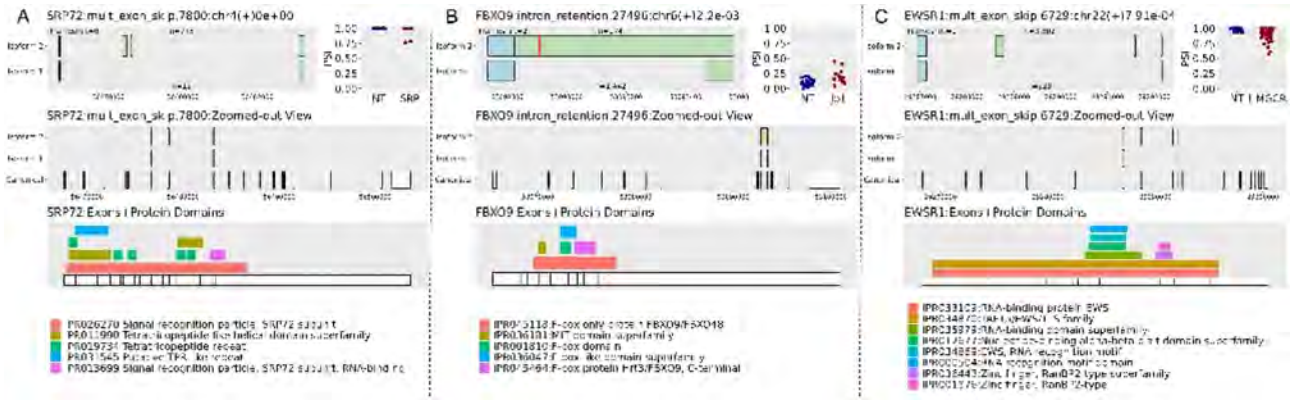

Fig 1. Illustrations of select alternative splicing events in muscle biopsies from myositis patients. Top left figure shows a zoomed-in view of the alternative splicing event. The title includes gene name, event ID, chromosome, strand, and adjusted p value. n is the number of reads supporting isoform 1 or 2. Red lines represent the first stop codon per isoform. Light blue exons indicate same protein product, while light green indicate altered peptides when translated. Top right figure shows percent-spliced in (PSI) of isoform 2 by myositis subgroup and normal tissue (NT). Middle figure shows a zoomed-out view of the alternative splicing event with complete exons of the canonical transcript. Bottom figure shows exons aligned with protein domains of the gene. Panels A, B, and C illustrate three events in SRP, Jo1, and HMGCR subgroups, respectively

the muscle-specific phosphofructokinase gene resulting in a longer 12th exon with introduction of a stop codon that would disrupt the C-terminal phosphofructokinase domain and conserved site (Fig 2A). Additionally, there was a single event that only appeared in two patients with IBM where the 15th exon of ankyrin 2 was skipped, which corresponds to an ankyrin repeat domain (Fig 2B).

Conclusion: We present results of a systematic unbiased search of alternative splicing in IIM muscles. Splicing events that are unique to a myositis subgroup are more likely to be relevant to disease pathology since they were not differentially present in any other subgroup. We discovered a unique event in SRP72 in the anti-SRP subgroup, connecting a genomic feature

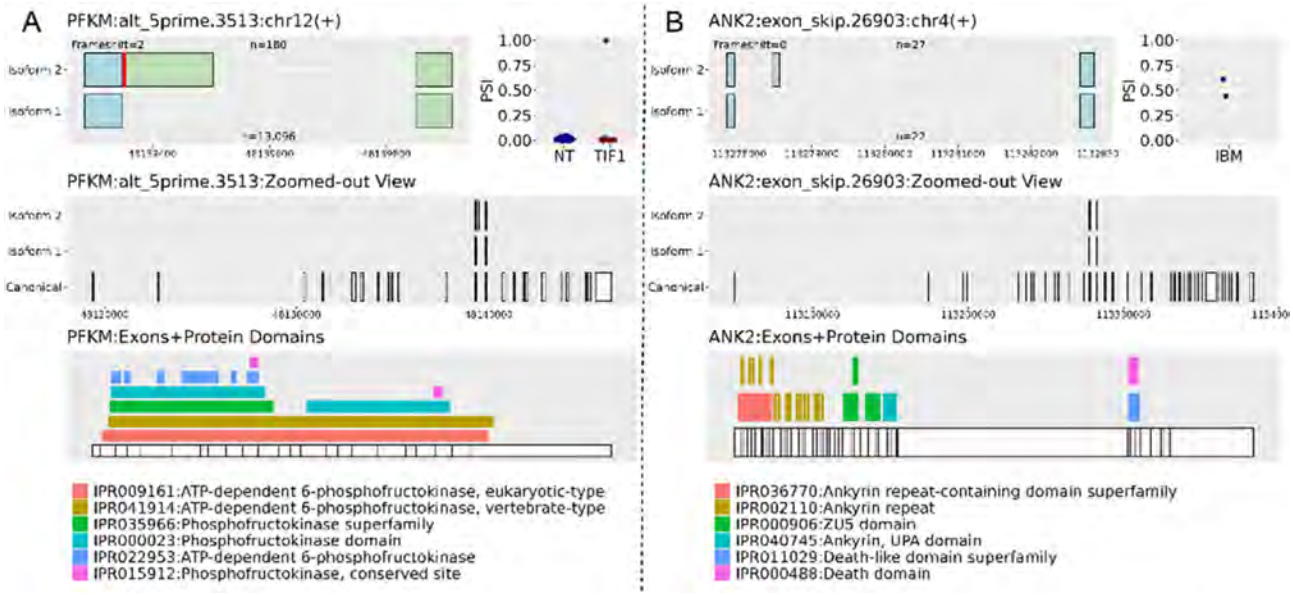

Fig 2. Alternative splicing events in muscle-specific phosphofructokinase and ankyrin 2 genes in muscle of myositis patients. Top left figure shows a zoomed-in view of the alternative splicing event. The title includes gene name, event ID, chromosome, strand, and adjusted p value. n is the number of reads supporting isoform 1 or 2. Red lines represent the first stop codon per isoform. Light blue exons indicate same protein product, while light green indicate altered peptides when translated. Top right figure shows percent-spliced in (PSI) of isoform 2 by myositis subgroup and normal tissue (NT). Middle figure shows a zoomed-out view of the alternative splicing event with complete exons of the canonical transcript. Bottom figure shows exons aligned with protein domains of the gene. Panel A illustrates an outlier event in TIF1 subgroup. Panel B illustrates an event only seen in inclusion body myositis (IBM)

to the disease's specific autoantibody. A few patients expressed roughly two thirds of the total outlier events, suggesting generally perturbed splicing in these patients.

Use of High-plex Data Reveals Novel Insights into the Temporal Artery Processus of Giant Cell Arteritis

Simon Parreau[1], Elsa Molina[2], Stéphanie Dumonteil[1], Radjiv Goulabchand[3], Thomas Naves[4], Melanie Bois[5], Anne-Laure Fauchais[1], Eric Liozon[6], Marie-Odile Jauberteau[4], Cornelia M. Weyand[7] and Kim-Heang Ly[1], [1]Dupuytren Hospital, Limoges, France, [2]Next Generation Sequencing Core, Salk Institute for Biological Studies, La Jolla, CA, [3]University of California San Diego, La Jolla, CA, [4]INSERM U1308, Limoges, France, [5]Mayo Clinic, Rochester, MN, [6]Department of Internal Medicine, University Hospital of Limoges, Limoges Cedex, Limoges, France, [7]Mayo Clinic School of Medicine and Stanford University, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Uncover the key coding genes to define new biomarkers or pathways associated with GCA by performing the first *in situ* spatial profiling characterization of molecular actors involved in temporal arteries from GCA patients in comparison to normal arteries.

Methods: From human formalin-fixed paraffin-embedded temporal artery biopsy samples (GCA n=9; controls n=7), we performed a whole transcriptome analysis by using NanoString GeoMx Digital Spatial Profiler (DSP) (2). A total of 59 individual regions of interest (ROIs) were created within each of the 4 layers for each individual artery. After ROIs collection and library construction, samples were sequenced on the Illumina NovaSeq 6000 platform and reads were digitally quantified and normalized using GeoMx DSP Data Analysis software. Differential expressed genes (DEGs) (fold change >2 or < -2, p-adjusted < 0.05) were compared for each layer, to build a spatial and pharmacogenomic network in disease course.

Results: Overall, we found that most of the transcriptome studied (12076 genes) was upregulated in GCA arteries. Precisely, 350, 340, 142 and 5 DEGs were found in intima, media, adventitia, and perivascular tissue respectively. Enrichment analysis highlighted that inflammation/immune-related functions and vascular remodeling were significantly limited to intima and media layers. Upregulated immune-related functions concerned macrophage differentiation & T cell, B cell, complement activations. Regarding vascular remodeling pathways, we found an upregulation of: (i) collagen metabolic process and fibroblast proliferation concerning the 3 artery layers, (ii) angiogenesis & epithelial cell migration in intima and media layers, (iii) smooth muscle cell proliferation & ossification in intima layer. Our pharmacogenomic network analysis identified genes that could potentially be targeted by immunosuppressive drugs currently approved or new immunotherapies.

Conclusion: Our findings provide the first *in situ* spatial profiling characterization of molecular actors involved in GCA which is essential for the discovery of potential new therapeutic targets to cure this disease. The differential spatial upregulation of genes involved in inflammatory process and vascular remodeling suggests a differential chronological involvement of each layer of the artery.

The Inflammatory Proteome in Sjögren's Syndrome Identifies New Biomarkers and Relevant Clinical Subgroups

José Miguel Sequí-Sabater[1], Carlos Perez-Sanchez[2], Clarissa Meoni[3], Tomás Cerdó-Ráez[4], Maria del Carmen Abalos-Aguilera[5], Desiree Ruiz Vilchez[5], Francisco Cepas[4], Nuria Barbarroja[6], Alejandro Escudero[7], Mª Angeles Aguirre[8], Chary Lopez-Pedrera[9] and Lorenzo Beretta[10], [1]Agencia Valenciana de Salut/ Hospital Universitari de la Ribera/ Unitat de Reumatología, Gandía, Spain, [2]IMIBIC, Córdoba, Spain, [3]Ospedale Policlinico di Milano, Milan, Italy, [4]Maimonides Institute for Biomedical Research (IMIBIC), Córdoba, Spain, [5]Rheumatology Department, Reina Sofia University Hospital/ Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Córdoba, Spain, [6]University of Cordoba, Córdoba, Spain, [7]SAS, Córdoba, Spain, [8]Reina Sofía University Hospital/ Rheumatology Department, Córdoba, Spain, [9]IMIBIC - Reina Sofia Hospital, Córdoba, Spain, [10]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di MIlano, Milan, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune disease characterised by glandular involvement of the eye and salivary glands, leading to xerostomia and xerophthalmia. In addition, this involvement can damage other organs such as the lung, kidney, central and peripheral nervous system. Sustained inflammatory activity can lead to non-Hodgkin's lymphoma. At present, our knowledge of the molecular alterations underlying different clinical phenotypes is still limited.

We aim to characterise the circulating inflammatory profile of pSS patients, using next-generation proteomic studies, in order to identify new biomarkers and distinctive clinical subgroups.

Methods: In an 89 SSp patients cohort from a multicentre study between Ospedale Maggiore Policlinico in Milan and Hospital Reina Sofia in Cordoba, a 92 inflammation-related serum proteins panel was analysed using the innovative Proximity Extension Assay (PEA, Olink) technology. In parallel, a comprehensive clinical profile was performed, including measures of activity (ESSDAI), cumulative damage (SSDDI), patient-reported damage (ESSPRI), health-related quality of life (HRQoL) questionnaires for general health (SF-36), patient-reported damage (ESSPRI), as well as main clinical complications and the prevalence of circulating autoantibodies.

Unsupervised clustering analysis (ward's method) was applied to identify subgroups of patients based on their proteomic profile; associations with clinical and laboratory variables were performed by means of ANOVA and Fisher's test.

Results: Unsupervised clustering analysis in pSS patients distinguished three groups based on their inflammatory profile. Clusters 1 and 3 had a well characterized proteomic profile (high and low expression, respectively) Further analyses showed that the biological profile well mirrored clinical characteristics: Cluster 1, the most inflammatory, showed higher prevalence of interstitial lung disease, arthritis and aphthous ulcers, higher ESSDAI activity index and lower SF36 physical function score; cluster 3, had the lowest prevalence of symptoms.

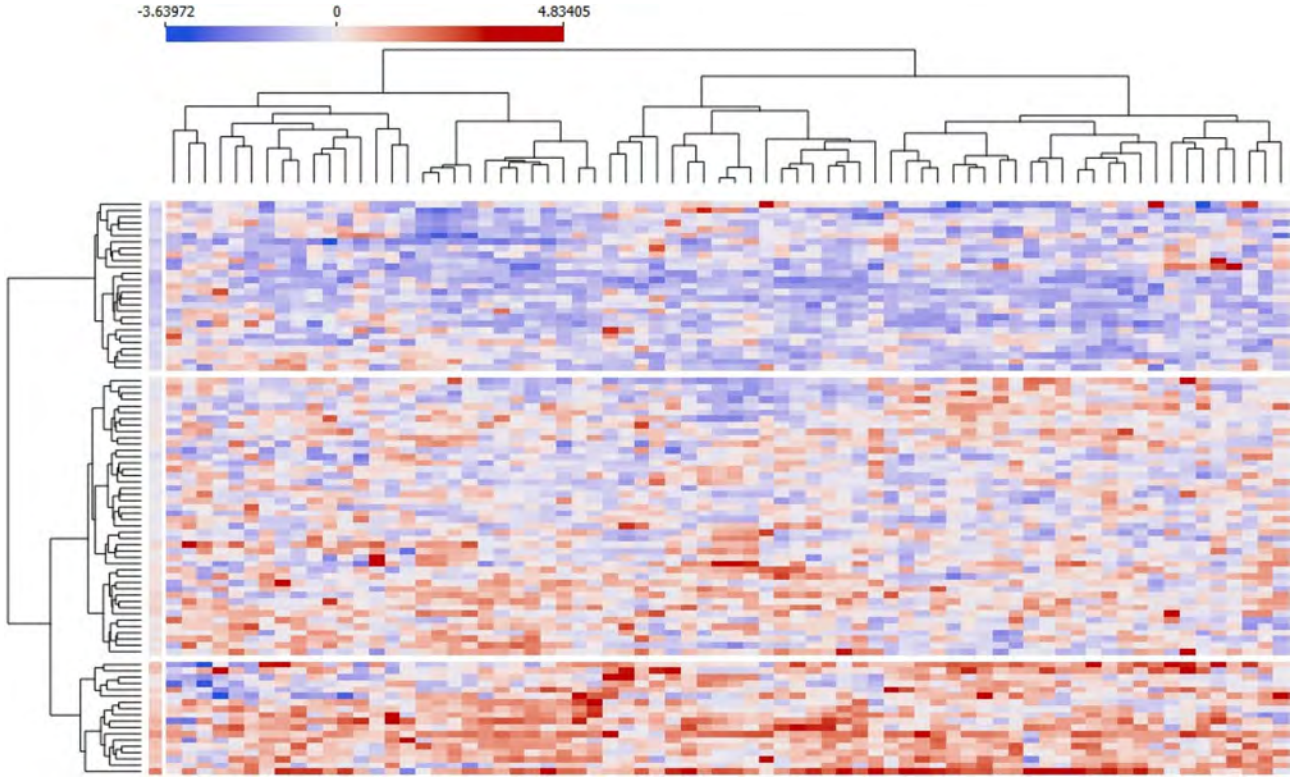

Figure 1: Analysis of the inflammatory proteome highlighting 3 distinct clusters

43 differentially expressed proteins were identified among clusters. Cluster 1 highlighted chemokines (MCP-1, CXCL11, CXCL9, CCL4, SLAMF1, MCP-4, CCL11, CCL19, CCL3, CXCL10, X4E-BP1, IGN-gamma, MCP-2, CASP-8, CCL20), growth factors (VEGF-A, TGFb-1, TGF-α, FGF-23, GFG-21, HGF, CSF-1), interleukins (IL8, IL6, IL17C, IL18, IL10Ra, IL10Rb, IL18R1, IL12b, TNFSF14, TNF, TNFRSF9, TNFB), membrane proteins (CD8A, CDCP1, OPG, PDL1, CD5,

CD40) and enzymes (uPA, MMP1, ADA). These alterations could be associated with an increased invasive capacity of immune cells. Furthermore, these proteins levels correlated with clinical ESSDAI, highlighting their potential as biomarkers of disease activity.

Conclusion: The analysis of the circulating inflammatory profile of pSS patients, using new high-throughput proteomic technologies, allows the identification of distinctive molecular signatures associated with relevant clinical profiles. Identifying novel biomarkers of activity has the potential to significantly enhance the precision and personalization of disease monitoring for this condition.

Shared Genetic Susceptibility Between Rheumatoid Arthritis and Bipolar Disorder: Analyses from Genome-Wide Association Studies

Jiayi Zheng[1], Ruoning Ni[2], Nevena Barjaktarovic[3] and Yiming Luo[4], [1]The Wright Center for Graduate Medical Education, Scranton, PA, [2]University of Iowa Hospitals and Clinics, Coralville, IA, [3]The Wright Center for Community Health, South Abington Township, PA, [4]Division of Rheumatology, Department of Medicine, Columbia University Irving Medical Center, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has been associated with bipolar disorder (BD) in epidemiological studies, including a recent Mendelian randomization analysis. This study aims to prioritize candidate genes that contribute to the shared genetic susceptibility between these two conditions, using data from genome-wide association studies (GWAS).

Methods: We obtained the summary statistics of the most recent GWAS in RA (PMID: 36333501, 22,350 cases and 74,823 controls) and BD (PMID: 34002096, 41,917 cases and 371,549 controls) of European ancestry. First, we performed linkage disequilibrium score regression (LDSC) to estimate the genetic correlation between the two conditions. We then conducted a cross-trait GWAS meta-analysis in RA and BD to identify shared genetic loci, using a fixed-effect model with METAL software. An additional analysis was carried out reversing the effect direction of BD to detect genetically associated loci with opposite effects. Next, we performed Bayesian genetic colocalization analysis between RA and BD in loci that were significant in the cross-trait GWAS meta-analysis ($p < 5x10^{-8}$) to predict whether the shared genetic susceptibility was due to the same causal single-nucleotide polymorphisms (SNPs). To evaluate the functional consequences of the discovered signals, loci that were significant in cross-trait meta-analysis and predicted to share the causal SNPs (pp.H4 > 70%) were selected for colocalization with tissue-specific expression quantitative trait loci (eQTL) from the Genotype-Tissue Expression (GTEx), as well as plasma-based protein quantitative trait loci (pQTL) from the Atherosclerosis Risk in Communities (ARIC) dataset. We prioritized genes that colocalized with QTL signals of tissues relevant to RA and BD.

Results: Our analysis showed a modest negative genetic correlation between the two conditions (r_g = - 0.1183, se = 0.0315, p = 0.0002). Two genomic loci, near rs112219496 (same effect direction, meta-analysis $p = 1.35 \times 10^{-10}$, pp.H4 = 91.2%) and rs1569723 (opposite effect direction, meta-analysis p-value = 2.22×10^{-13}, pp.H4 = 98.9%), were significant in the cross-trait GWAS meta-analysis and colocalized between RA and BD (Table 1). The genomic locus near rs112219496 colocalized with pQTL and eQTLs for *CILP2* in plasma, lung, and brain tissues. The genomic locus near rs1569723 colocalized with eQTLs for *CD40* in the lung and brain tissues (Figure 1).

Conclusion: This study uncovers a complex relationship between the genetic susceptibilities of RA and BD. By implementing post-GWAS analyses, we identified *CILP2* and *CD40* as being associated with both RA and BD. Interestingly, *CILP2* exhibited the same effect direction in both conditions, while *CD40* demonstrated the opposite effect direction.

Table 1: Cross-trait meta-analysis of RA and BD and colocalization results of the regions +/- 500 kb of lead SNPs identified in cross-trait meta-analysis.

SNP	Position (hg19)	A1	Meta		RA		BD		PP.H4
			β	p	β	p	β	p

Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously developed a novel machine learning (ML) pipeline leveraging analysis of gene expression data to identify subsets of SLE patients with common molecular patterns of disease, endotypes[1]. These molecular subsets had significant differences in clinical characteristics, the frequency of subsequent flares, and clinical responsiveness to a lupus biologic, tabalumab. The current study makes use of the ML classifier to determine endotype membership in an independent validation cohort of SLE patients.

Methods: Gene expression by RNA-sequencing of whole blood and clinical metadata were collected from 91 SLE patients from two clinical trials (NCT03626311 and NCT03180021). Patients met ACR classification criteria of SLE and patients from one trial had renal biopsies at the time gene expression was measured. A random forest classifier trained on 2183 lupus patient gene expression profiles was used to predict endotype membership of the 91 patients. Lupus Cell and Immune Score (LuCIS), a continuous score measuring the extent of modular immunologic abnormalities determined by ridge-penalized logistic regression, was also calculated for each patient.

Results: The ML prediction of independent SLE patients into endotypes yielded eight subsets with molecular patterns mirroring those found previously in a development and testing cohort of 3166 patients (Figure 1). Endotypes were designated A-H, with A representing the group with the least number of transcriptional lupus-related aberrancies and H representing the group with the greatest immunologic perturbations. Groups H, A, C, and E were comprised of the greatest number of patients whereas B and G were small and underrepresented in this cohort. Endotype H contained the greatest number of patients with proliferative lupus nephritis (LN) whereas no patient with LN was found in subset A or B. Serum complement differed among the subsets, with the more immunologically active having lower levels. LuCIS values reflected the immunological activity of the subsets but did not correlate with SLEDAI, although they were moderately, inversely correlated with serum C3 and C4 levels (Figure 2). Eight patients had moderate/severe flares during the six months of the trials, of whom all had elevated LuCIS scores at baseline.

Conclusion: A novel endotyping pipeline based on transcriptional profiles and ML accurately identified patient endotypes in new datasets. Patients in the endotypes with the least immunologic activity did not have proliferative nephritis and also experienced no lupus flares during the subsequent six months. Endotyping SLE patients based on gene expression profiles can provide important prognostic information and provide novel molecular insights in support of personalized management.

Proteomic Analysis of Plasma-derived Extracellular Vesicles Renders Glutathione Peroxidase 3 a Biomarker for Dermatomyositis

Avital Baniel[1], Mariko Ogawa-Momohara[2], Muhammad Bashir[3], Rachita Pandya[1], Julianne Kleitsch[1], Felix Chin[4], Ming-Lin Liu[1] and Victoria P. Werth[5], [1]University of Pennsylvania, Philadelphia, PA, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan, [3]Philadelphia VAMC, Philadelphia, PA, USA and Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [5]University of Pennsylvania, Wynnewood, PA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

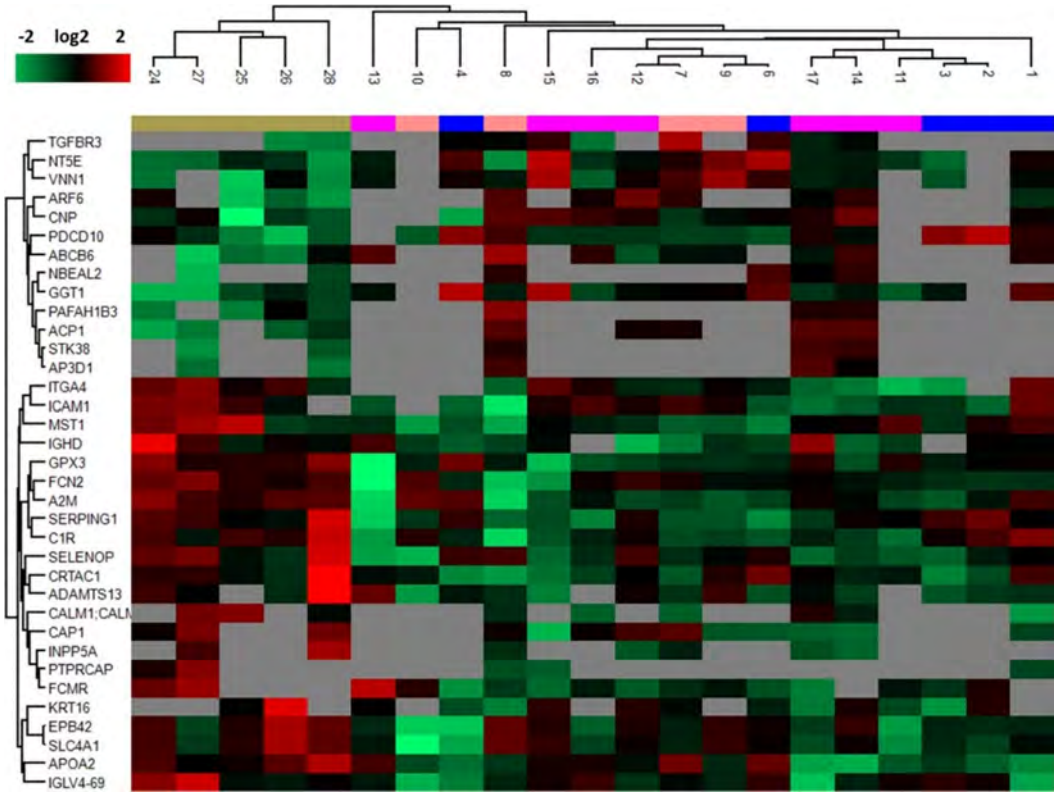
Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

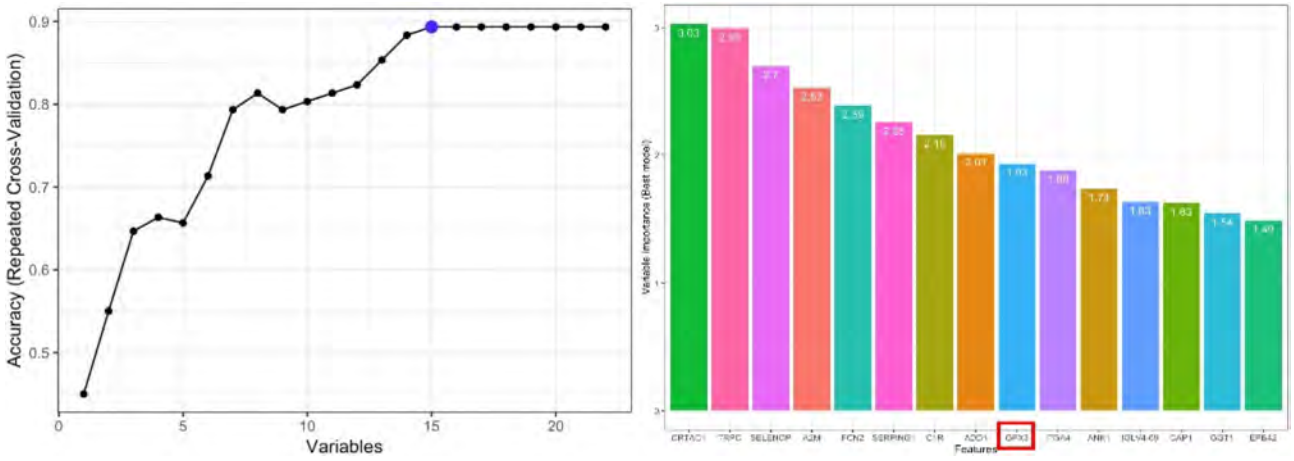
Session Time: 9:00AM–11:00AM

Background/Purpose: Extracellular vesicles (EVs) have been implicated in autoimmune disease pathogenesis. Plasma-derived DNA containing EVs have been shown to induce STING-mediated proinflammatory responses in dermatomyositis (DM), but their protein content is not well characterized (Li Y et al. Plasma-derived DNA containing-extracellular vesicles induce STING-mediated proinflammatory responses in dermatomyositis. Theranostics. 2021 May 21;11(15):7144-7158).

Methods: We collected EVs from plasma of 16 DM patients and 5 controls. EVs were isolated using sequential ultracentrifugation and size- exclusion chromatography, and their content analyzed by mass spectrometry (LC-MS/MS in DIA mode). Over-representation analysis was conducted via http://webgestalt.org based on KEGG,GO and Reactome databases.



Differentially expressed proteins.

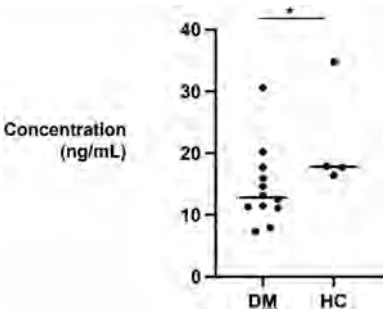


Biomarker prediction. Recursive random forest feature selection predicts a group of 15 proteins to have optimal predictive value for disease state and (left panel) and lists them with top-down probability scores (right panel).

Protein biomarkers that distinguish patients with DM from controls were assessed using the random forest algorithm. GPX3 abundance was validated in a second cohort by ELISA and data was analyzed by the Mann Whitney test.

Results: Sixty-seven proteins were uniquely detected in the patient cohort. Thirty-five proteins were significantly differentially expressed, of which 13 were upregulated and 22 downregulated. Over-representation analysis found unique and upregulated proteins enriched for myeloid mediated immunity, glutathione metabolism, nucleic acid synthesis and vesicle transport pathways. Downregulated proteins were enriched for the classical and lectin complement pathways. The diminution of complement components in vesicles may reflect its abundance in target tissues but may also reflect host inability to circulate these molecules to damaged tissue, which in a chronic stage of disease may have a protective role. The antioxidant enzyme glutathione peroxidase 3 (GPX3) was significantly less abundant in patients' EVs compared to controls ($p = 0.04$) and was assessed by machine learning to be amongst a group of proteins that distinguish patients from controls. GPX3 is a well-known biomarker of certain types of cancer, where its downregulation is correlated with higher inflammatory burden and increased cell proliferation (Nirgude S, Choudhary B. Insights into the role of GPX3, a highly efficient plasma antioxidant, in cancer. Biochem Pharmacol. 2021 Feb;184:114365). A similar mechanism may apply to DM patients, that may be susceptible to oxidative stress due to defective transport of GPX3 by EVs. Alternatively, its lower abundance in EVs may indicate the exhaustion of GPX3 in chronic inflammation.

Conclusion: Our findings indicate GPX3 as biomarker of disease in DM and underlines the importance of oxidative stress in disease mechanism. This finding, along with a growing body of evidence, suggests roles for EVs as disease biomarkers and prompts further mechanistic studies to elucidate the role of GPX3 transport by EVs not only in plasma, but also in muscle and skin.



GPX3 abundance. EVs isolated from healthy control plasma contained more GPX3 than EVs isolated from dermatomyositis patients, as indicated by ELISA performed on a second validation cohort of patients and controls. *$p<0.05$.

Detection of Synovial Signatures in Peripheral Blood of Patients with Rheumatoid Arthritis via a Novel Blood-Based DNA Capture Assay

Peter C. Taylor[1], Jenya Antonova[2], Jennifer Geis[3], Katharine Dilger[3], David Chernoff[4], Diana Abdueva[3], Nancy Shadick[5] and Michael Weinblatt[6], [1]Nuffield Department of Orthopedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]Compass Strategy and Research, Inc., San Francisco, CA, [3]Aqtual Inc., Hayward, CA, [4]Chernoff Consulting, Sausalito, CA, [5]Brigham and Women's Hospital, Boston, MA, [6]Harvard Medical School, Waban, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis [RA], synovial biopsies were shown to guide therapy selection[1]. However, biopsies require special training for clinicians and are semi-invasive for patients. Blood-based tests are a common procedure in clinical practice. Prior research failed to capture synovial signals in RA patients via blood because of the limited circulation of synovial-specific biomarkers and the dilution of molecular signals within the bloodstream. The study aims to investigate synovium-specific transcriptomic signal in blood plasma by employing a novel DNA capture platform to comprehensively analyze and characterize the molecular signatures in RA.

Table 1. Patient demographic characteristics

	Number of patients	Number of samples	White, %	Female, %	Age	
					Range	Mean
Overall, including:	191*	229	63.3%	67.9%	19 – 88	53.6 (16.63)
Rheumatoid Arthritis* **	89	89	58.4%	86.5%	28 - 66	57.0 (14.20)
Non-RA:	102	140	67.7%	51.8%	19 - 88	50.6 (18.06)
Healthy controls	29	66	42.3%**	53.6%	20 – 63	42.6 (12.15)
Ankylosing spondylitis	13	13	84.6%	30.8%	28 – 66	50.5 (14.80)
Crohn's Disease	10	11	80.0%	30.0%	23 – 87	55.7 (21.97)
Psoriasis	18	18	66.7%	50.0%	27 – 70	46.1 (13.74)
Psoriatic arthritis	10	10	70.0%	50.0%	46 – 88	65.8 (11.62)
Ulcerative colitis	10	10	70.0%	50.0%	19 – 67	33.9 (16.03
Osteoarthritis	12	12	91.7%	91.7%	47 – 87	73.3 (10.46)

* One patient did not have demographic characteristics recorded but was included in the sample because plasma and healthy status were known.
** Race was not known for three patients in the *healthy control* group.
*** Among RA patients, 70% were seropositive and 96% were biologic-naïve.

Table 2. Methodological definitions

Metric	Definition	Interpretation
Receiver operating characteristic (ROC)	A graph showing the performance of a classification model at all classification thresholds. This curve plots two parameters: True Positive Rate (Y-axis) and False Positive Rate (X-axis).	Steepest curvature indicates the most accurate test.
Area under the curve (AUC)	UC measures the entire two-dimensional area underneath the entire ROC curve (think integral calculus) from (0,0) to (1,1). The AUC ranges 0–1.	The closest AUC approaches 1, the higher test accuracy is.
Sensitivity	The degree to which a test accurately identifies the presence of a condition (e.g., RA). It is expressed as a percentage of true positive predictions over the sum of true positive and false negative predictions.	Highest sensitivity indicates best ability to accurately detect the presence of condition (e.g., RA).
Specificity	The degree to which a test accurately identifies the absence of a condition (e.g., OA). It is expressed as a percentage of true negative predictions over the sum of true negative and false positive predictions.	Highest specificity indicates best ability to accurately detect the absence of condition (e.g., OA)

Table 3. Synovial fibroblast genes identified within synovial signatures

- Interleukin 6 (IL6),
- Matrix metalloproteinases (MMP1, MMP9, MMP13, MMP16, MMP17), collagen genes (COL3A1, COL4A1, COL4A4, COL5A2, COL6A1, COL8A1, COL10A1, COL11A1, COL12A1, COL21A1, COL22A1, COL24A1)
- Tissue inhibitor of metalloproteinases 3 (TIMP3),
- Transforming growth factor beta (TGFB1, TGFB2) and its receptor (TGFBR2),
- Cathepsin K (CTSK),
- Fibronectin 1 (FN1),
- A disintegrin and metalloproteinase domain-containing protein 12 (ADAM12),
- Vascular endothelial growth factor C (VEGFC),
- Notch 1 (NOTCH1). The remaining 58% of the features showed significant enrichment of immune cell types, including, CD4+ and CD8+ T-cells, B-cells, and macrophages.

Methods: Plasma samples (n=229) from 89 individuals meeting 2010 ACR/EULAR classification criteria for RA, 62 with inflammatory conditions, 12 with OA, and 29 healthy controls (Table 1) were processed using a blood-based assay that enriches for non-hematopoietic signals. The epigenome atlas, comprised of 600,000 features, was evaluated using bootstrap methods to select features that robustly differentiate RA from non-RA samples to generate a candidate list of genomic feature locations. These were mapped to genes and compared to the reported pathways[2] identified in whole blood and synovial tissue of patients with RA. A machine-learning training used 5-repeat 10-fold cross validation of the candidate features that have overlapping genes with synovial pathways. The training generated the average area under the curve (AUC) and performance metrics (sensitivity and specificity; Table 2)

Results: Participants had a mean (standard deviation, SD) age of 53.6 (16.63) years and were mostly female (67.9%) and white (63.3%; Table 2). The RA patients were mostly seropositive (70%) and biologic-naïve (93%). In the list of identified genomic features, 88% overlapped with synovium pathway genes and 30% with blood pathway genes. Within identified synovial signatures, 42% represent synovial fibroblast genes (Table 3); the remaining 58% of the features showed significant enrichment of immune cell types, including, CD4+ and CD8+ T-cells, B-cells, and macrophages.

Conclusion: The developed non-invasive DNA capture assay identified synovium-specific gene expression signatures in blood plasma of RA patients. Further clinical research is needed to validate these synovial signatures and confirm the clinical utility of the developed classification system.

Relationship Between Genetic Variants in Cannabinoid Receptor 2 and Self-Reported Effectiveness of Cannabis for Pain Management in Rheumatoid Arthritis

Kristin Wipfler[1], Joanna Zeiger[2], Adam Cornish[1] and Kaleb Michaud[3], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]Canna Research Foundation, Boulder, CO, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cannabinoid receptor 2 (CB2) is a member of the cannabinoid receptor family and is encoded by the CNR2 gene. CB2 receptors are found primarily in immune cells, and their activation exerts anti-inflammatory effects. Genetic variants in CNR2 have been linked to pain, autoimmune disorders, and depression. The objective of this study was to examine relationships between CNR2 variants and self-reported effectiveness of cannabis in the treatment of RA-related pain.

Methods: Data were provided by adults with RA participating in FORWARD, The National Databank for Rheumatic Diseases, who provided blood samples and reported the use of cannabis or cannabis-derived products for the purpose of treating arthritis-related pain. Genotyping was performed with the Illumina Infinium Global Screening Array platform, and CNR2 variants with minor allele frequencies greater than 0.05 were included in this analysis (SNPs rs4625225, rs7512349, and rs9424399). Multivariable logistic regression was used to determine whether the presence of the minor allele in each variant was associated with self-reported effectiveness of cannabis in managing RA-related pain. Models were adjusted for age, sex, race, cigarette smoking history, RA duration, BMI, glucocorticoid use, NSAID use, opioid use, Rheumatic Disease Comorbidity Index (RDCI), history of depression, and Patient Activity Scale-II (PAS-II).

Results: A total of 134 participants met inclusion criteria, of whom 79 (59%) found cannabis effective in treating their RA-related pain. Respondent characteristics are presented in Table 1 and genotype distributions of the three variants are presented in Table 2. Adjusted models indicated that for all three variants, the presence of at least one copy of the minor allele was associated with reduced odds (rs4625225 OR [95% CI] = 0.34 [0.14, 0.79], p=0.013; rs7512349 0.26 [0.11, 0.64], p=0.003; rs9424399 0.28 [0.12, 0.69], p=0.005) of finding cannabis effective for pain management, compared to those homozygous for the major allele. (Figure 1).

Table 1. Characteristics of study participants by self-reported effectiveness of cannabis in RA pain management.

Characteristic	Not Effective n=55	Effective n=79
Age, years, mean (SD)	68.9 (9.7)	64.3 (10.9)
Female, %	88.9	92.4
White race, %	94.5	91.0
Hx cigarette smoking, %	41.8	40.5
RA duration, years, mean (SD)	25.1 (13.5)	24.8 (11.7)
BMI, kg/m^2, mean (SD)	28.7 (6.6)	27.5 (6.3)
Glucocorticoid use, %	25.5	14.1
NSAID use, %	27.3	30.8
Opioid use, %	20.0	20.5
RDCI, 0-9, mean (SD)	2.2 (1.8)	2.2 (2.0)
Hx depression, %	54.5	73.4
PAS-II, 0-10	3.7 (1.9)	4.4 (2.1)

BMI=body mass index; NSAID=non-steroidal anti-inflammatory drugs; RDCI=Rheumatic Disease Comorbidity Index; PAS-II=Patient Activity Scale II

Conclusion: Our results indicate that the perceived effectiveness of cannabis in the treatment of RA-related pain varies significantly by CNR2 genotype. The three variants appear to be in linkage disequilibrium and are also all silent, so a related variant not assessed by the array used in this study may be causative of the identified relationship. These results highlight the possible impact of genetic variations on the therapeutic potential of cannabis for arthritis pain management, which may be relevant for personalized medicine as legalization and medicinal use of cannabis continue to become more widespread in the United States. Further research is warranted to confirm these findings, to elucidate the underlying mechanisms, and to better understand the relationships between CB2 and pain, cannabis use, and any potential immunomodulatory effects.

Table 2. Genotype distributions of the investigated CNR2 variants.

Variant	Genotype	n (%)
rs4625225	TT	83 (62)
	TC	48 (36)
	CC	3 (2)
rs7512349	TT	89 (66)
	TC	43 (32)
	CC	2 (1)
rs9424399	AA	88 (66)
	AG	43 (32)
	GG	3 (2)

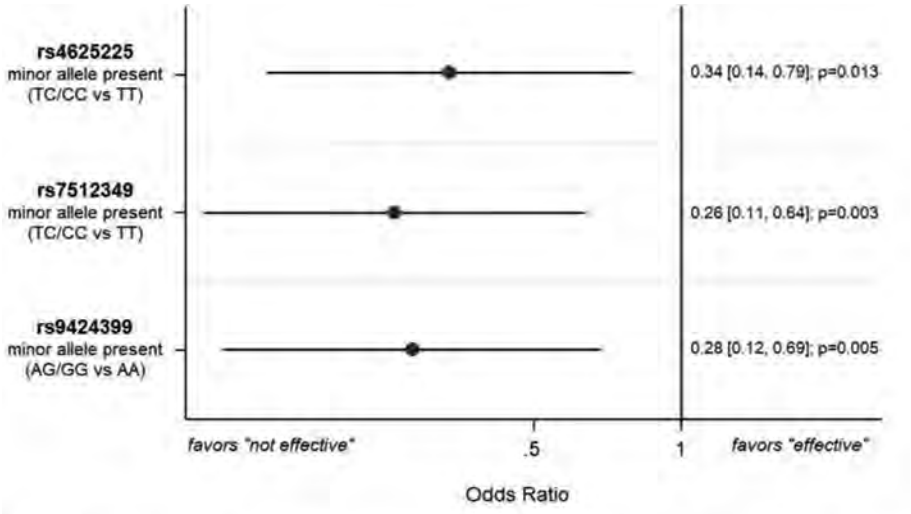

Figure 1. Adjusted odds ratios and 95% confidence intervals for each minor allele's association with reported effectiveness of cannabis in treating RA-related pain. Each model was adjusted for age, sex, white race, cigarette smoking history, calendar year, RA duration, BMI, glucocorticoid use, NSAID use, opioid use, Rheumatic Disease Comorbidity Index (RDCI), history of depression, and Patient Activity Scale II (PAS-II).

Mapping Cellular Landscape of Esophageal Epithelium in Systemic Sclerosis Using Single-cell Transcriptomics

Matthew Dapas[1], Hadijat Makinde[2], Tyler Therron[2], Margarette Clevenger[2], Cenfu Wei[2], Mary Karns[3], Kathleen Aren[3], Dustin Carlson[2], Alexandra Soriano[1], Lutfiyya Muhammad[4], John Pandolfino[5], Harris Perlman[2], Deborah Winter[6] and Marie-Pier Tetreault[2], [1]Northwestern University FSM Division of Rheumatology, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Northwestern University Division of Rheumatology, Chicago, IL, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Northwestern University, Feinberg School of Medicine, Wilmette, IL, [6]Northwestern University, Skokie, IL

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Esophageal involvement is one of the strongest predictors of early mortality in individuals with systemic sclerosis (SSc). Individuals with SSc and esophageal involvement typically suffer from chronic acid reflux and dysphagia due to loss of esophageal motility. However, the pathogenesis of esophageal dysmotility in SSc is still poorly understood.

Recently, studies have demonstrated that esophageal epithelial cells (EECs) in the mucosa may play a more central role in the pathogenesis of SSc esophageal dysmotility than previously thought. Most studies implicating EECs, however, have been performed in mice or in vitro, and molecular analyses in humans have so far been limited to bulk tissues using microarrays with inadequate controls. In this study, we performed a thorough transcriptomic investigation of the SSc esophageal epithelium in humans using single-cell RNA sequencing (scRNA-seq) to determine whether distinct molecular and cellular changes in EECs contribute to impaired motility of the esophageal wall in SSc.

Methods: We performed scRNA-seq of paired proximal and distal esophageal mucosa biopsies from 10 individuals with SSc and 6 healthy controls (HCs). We also evaluated samples from 4 individuals with gastroesophageal reflux disease (GERD) to distinguish primary SSc effects from secondary reflux effects. We further assessed esophageal motility (normal, weak, absent) in individuals with SSc using functional lumen imaging probe panometry and high-resolution manometry. Cells were encapsulated using the 10X Genomics Chromium platform and sequenced on the Illumina Novaseq 6000. Reads were aligned and quantified using Cell Ranger v6.1.2 and cell-specific gene expression was analyzed using Seurat v4.3.0.

Results: ScRNA-seq generated 12.4 billion reads from 434,582 cells across 40 sequenced samples. Following quality control, we annotated 230,720 EECs according to their differentiation state (basal, suprabasal, superficial). Overall proportions of basal, suprabasal, and replicating EECs were similar across conditions, but SSc and GERD samples had significantly fewer terminally differentiated, superficial cells than HCs. Differential gene expression analyses revealed dysregulated gene sets dependent on condition, biopsy region, and EEC layer. A surge of gene dysregulation in the transition from suprabasal to superficial states was observed in both SSc and GERD. We then modeled EEC differentiation as a continuous metric based on cumulative average expression of layer-specific markers and identified genes with condition-dependent expression trends as a function of EEC differentiation, highlighting genes uniquely dysregulated in SSc, including those correlated with esophageal dysmotility.

Conclusion: Esophageal dysmotility in SSc is associated with cellular and molecular changes in EECs distinct from secondary reflux effects. This work serves as an atlas for the human esophageal epithelium in SSc to direct future efforts to identify actionable targets for treatment.

Association of *HLA-DRB1* and *ANKRD55/IL6ST* Regions with Polymyalgia Rheumatica Diagnosis: A Genome Wide Association Study from UK Biobank and FinnGen

Mehmet Hocaoglu[1], Jamal Mikdashi[2], James Perry[2] and Charles Hong[2], [1]University of Maryland School of Medicine, Pittsburgh, PA, [2]University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The existing literature on the genetics of polymyalgia rheumatica (PMR) is limited to candidate gene studies with small sample sizes. There is a need for larger genetic studies in PMR to investigate genetic associations throughout the whole genome. In this study, we aimed to perform a genome wide association study (GWAS) of PMR in the UK Biobank and compare our results with the FinnGen cohort.

Methods: UK Biobank is a cohort study of around 500,000 individuals from United Kingdom. The study collected genomic information on all participants which include 850,000 measured variants with over 90 million imputed variants using reference databases. The genetic data is linked with patient's clinical record through International Classification of Diseases

(ICD)-10 in addition to procedure and treatment codes. Patients with ICD-10 codes M31.5 Giant cell arteritis with polymyalgia rheumatica and M35.3 Polymyalgia rheumatica were included as cases. Controls were drawn from the same cohort in 1:20 case-control fashion and matched with regards to age, sex, and ancestry. The genome wide association analysis was performed using PLINK 2.0 software through firth logistic regression using age, sex and first 5 principal components (PC) as covariates. Single nucleotide polymorphisms (SNP) were filtered to include those with mean allele frequency greater than 5% and imputation quality score greater than 0.95. Summary statistics for GWAS in the FinnGen cohort was downloaded from the most recent publicly available data release. The FinnGen GWAS was performed by defining individuals with ICD-10 code M35.3 as cases and using REGENIE software with a two-step associated test utilizing firth logistic regression and having sex, age, first 10 PCs and genotyping batch as covariates.

Results: There were 1890 and 3501 patients of PMR in the UK Biobank and FinnGen respectively. In the GWAS analysis in the UK Biobank, 2460 variants in the MHC locus at chromosome 6 passed the genome wide significance level at $5x10^{-8}$ and our quality filters. Our top hit was rs34535888, a SNP close to *HLA-DRB1* gene. In the FinnGen, the top hit was rs34434863, a variant close to *HLA-DRB1* gene. Outside of the MHC locus, only rs7731626, an intronic variant at the *ANKRD55* gene passed genome-wide significance. Prior literature shows that the *ANKRD55* variants affect the expression of the neighboring gene IL6ST in various immune cells. There were three further loci with genome wide suggestive association (< $1x10^{-6}$) in either UK Biobank or FinnGen, but none of these variants were replicated in both cohorts (Table 1). When we restricted the

analysis to patients without concomitant RA or GCA diagnosis in the UK Biobank, the effect sizes were similar albeit with larger p-values (Table 2).

Conclusion: In this study, we report the first genome-wide association analysis of patients diagnosed as PMR in the population from the UK Biobank and FinnGen cohorts. We show that *HLA-DRB1* and *ANKRD55/IL6ST* regions are associated with PMR diagnosis. Both regions have strong biological plausibility due to previous research implicating *HLA-DRB1* variants in genetic susceptibility to PMR and the evidence for the role of IL-6 in the disease pathogenesis.

Adenosine Deaminase 2 Is Expressed as a Short Isoform Lacking Deaminase Activity in the Endothelium: Implications for DADA2 Vasculitis

Andrew Porter[1], Robert Maughan[1], Charis Pericleous[1], Lida Kabir[1], Richard Stratton[2], Dorian Haskard[1], Pui Lee[3], Taryn Youngstein[1] and Justin Mason[1], [1]National Heart & Lung Institute, Imperial College London, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Division of Immunology, Boston Children's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) is an autosomal recessive condition caused by biallelic variants in the Adenosine deaminase 2 (ADA2) gene. Clinical manifestations are broad, but a vasculitis phenotype is widely recognised. Although ADA2 expression is conventionally associated with myeloid cells, a recent report identified expression in endothelial cells (ECs) and demonstrated Interferon (IFN) β induction in the absence of ADA2. The current study aimed to investigate the expression and role of ADA2 in the endothelium.

Methods: ADA2 transcript expression was explored across different tissues and cell types using Blueprint, GTEX and in-house short and long read RNA-seq datasets. Findings were validated by qRT-PCR, immunoblot and an ADA2 activity assay in primary human umbilical vein and aortic ECs (HUVEC, HAEC) and the pro-monocytic cell line U937.

Endothelial colony forming cells (ECFC) were cultured from peripheral blood mononuclear cells (PBMCs) isolated from patients with DADA2 and healthy donors, following our established protocols.

Results: We identified 3 human ADA2 isoforms: ADA2 201 and 203, the classically described myeloid derived isoforms (511 amino acids, aa) and ADA2 202 which was predicted to encode a shorter protein lacking a signal peptide and part of the deaminase domain (270 aa) (Fig 1A). In contrast to 201 and 203, the 202 isoform appears widely expressed across tissue types but absent from immune cells (Fig 1B & C).

Analysis of RNA-seq data identified 202 as the sole ADA2 transcript expressed in ECs (Fig 2A). This was confirmed by qPCR using transcript-specific primers: 202 was the predominant isoform in ECs and 201/203 in PBMCs and U937 (Fig 2B).

Inflammatory response	1.47	0.031

Figure 3B

Despite the presence of ADA2 202 mRNA, no protein or deaminase activity were detected in HUVEC or HAEC lysates or supernatants (Fig 2C). Overexpression of 201 isoform demonstrated deaminase activity and protein secretion as expected; in contrast 202 was enzymatically inactive, not secreted and retained in the insoluble protein fraction.

Since 202 was expressed at the mRNA but not protein level, we explored a possible regulatory function by siRNA knockdown (KD) in HUVEC (90% KD achieved). ADA2 KD resulted in dysregulation of 352 genes and enriched inflammatory (IFN, TNF), coagulant and apoptotic signalling suggesting an important role for 202 in endothelial homeostasis (Fig 3B).

Consistent with this, initial ECFC analysis demonstrated a lower proliferative and more inflammatory phenotype in DADA2 compared to healthy donor ECFC, characterised by increased ICAM-1, VCAM-1 and IFN-related gene expression (n=4 per group).

Conclusion: Endothelial ADA2 is expressed exclusively as the shortened 202 transcript but its protein form is undetectable. Artificially overexpressed 202 accumulated in the insoluble protein fraction, lacked deaminase activity and thus appeared non-functional. ADA2 knockdown in ECs led to upregulation of inflammatory apoptotic gene expression, potentially indicating a role for 202 in endothelial homeostasis as a non-coding RNA. Given its widespread tissue expression, genetic variants affecting 202 could have implications for understanding the heterogenous manifestations of DADA2.

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Cellular interactions between alveolar macrophages (MΦ) and human lung fibroblasts (HLFs) contribute to excessive pro-inflammatory and pro-fibrotic responses in rheumatoid arthritis interstitial lung disease (RA-ILD), leading to pulmonary fibrosis. Our laboratory has previously shown that malondialdehyde-acetaldehyde (MAA) and citrulline (CIT) modifications co-localize in the lung tissue of RA-ILD patients. However, the mechanism by which MAA and CIT

Figure 1. Representative top 5 genes from Nanostring Human Fibrosis Panel for mRNA levels of inflammation, initiation, modification, and proliferation fibrosis markers from stimulated HLF cells. HLF cells were stimulated with either supernatants from modified antigens-treated U937 cells or with directly modified antigens. The data is represented as the relative quantity (Rq) of fibrosis markers. The blue color represents an increase in mRNA levels, while the yellow color represents a decrease.

modified proteins alter cellular interactions between MΦ and HLFs has not been well delineated. The purpose of this study was to identify fibrotic gene expression and activation of signaling pathways by HLFs in response to: 1) macrophage supernatants (MΦ-SN) collected post-stimulation with MAA and/or CIT modified fibrinogen (FIB); or, 2) direct stimulation with MAA and/or CIT modified FIB.

Methods: Primary HLFs were treated with either MAA and/or CIT modified FIB or with MΦ-SN collected from PMA-activated U-937 cells following stimulation with MAA/CIT modified FIB. RNA was isolated 8-hours post-treatment and evaluated for the expression of 770 genes using the NanoString® Human Fibrosis Panel. The top 30 genes with the highest values for fold increase (compared to FIB or MΦ-SN^{FIB}) were categorized into four stages (inflammation, initiation, modification, and proliferation) in the Nanostring® software based on their role in the fibrotic pathway, with several genes exerting influence on multiple pathways. Additionally, HLFs were evaluated by Western Blot for phosphorylation of signaling pathways involved in fibrosis.

Results: Treatment ofHLFs with MΦ-SN upregulated pro-fibrotic genes in all 4 pathways beyond the effects of direct antigen stimulation (Fig.1). For inflammatory genes, exposure of HLFs to MΦ-SN$^{FIB\text{-}MAA\text{-}CIT}$ yielded the highest mRNA fold increase vs. other groups. The top 5 inflammatory genes expressed following stimulation with MΦ-SN$^{FIB\text{-}MAA\text{-}CIT}$ vs. MΦ-SN^{FIB} were CD36 (9-fold; critical in fibroblast activation), C8A (8-fold; component of complement system), BST2 (7-fold; bone marrow stromal antigen), BPM-10 (6-fold; bone morphogenic protein belonging to TGF-b family), MMP9 (5-fold; plays a role in matrix remodeling). The top genes for initiation, modification, and proliferation upregulated in the MΦ-SN$^{FIB\text{-}MAA\text{-}CIT}$

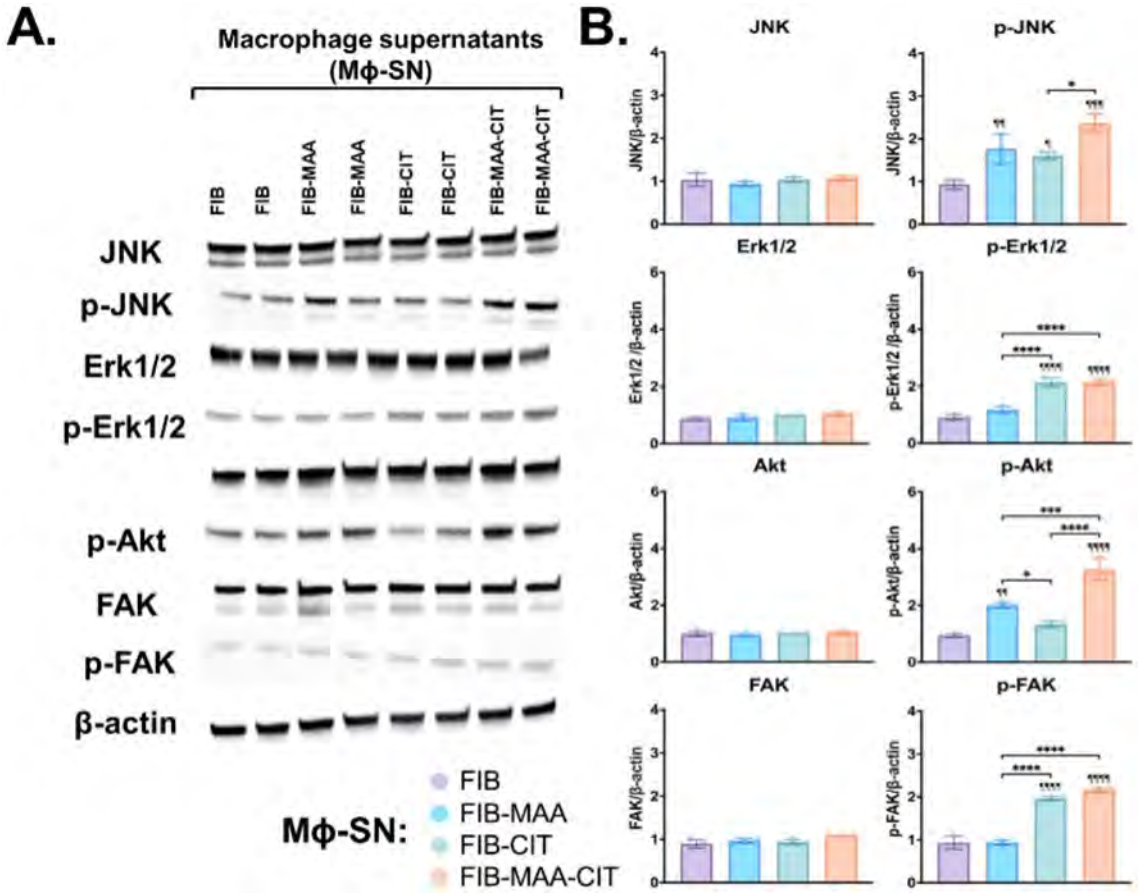

Figure 2. Phosphorylation of fibrosis signaling pathways in stimulated HLF cells. HLF cells were incubated with MΦ-SN for 90 minutes. MΦ-SN were collected from U-937 activation with the modified fibrinogen antigens. (A) Representative Western Blots of HLF lysates probed with signaling molecule antibodies. (B) Densitometry of normalized values (mean with SEM) to β-actin of signaling molecules. Comparisons made to FIB are illustrated above each bar: ¶¶¶¶p<0.0001; n=3. Only significant differences between groups are illustrated: ***p<0.001, ****p<0.0001.

group were; CETP (14-fold), TJP2 (7-fold), and CD36 (9-fold), respectively. HLFs treated with MΦ-SN$^{FIB\text{-}MAA\text{-}CIT}$ in comparison to MΦ-SN$^{FIB\text{-}MAA}$ and MΦ-SN$^{FIB\text{-}CIT}$ showed an increased expression of phosphorylated; (p-) JNK ($p < 0.001$ vs. MF-SN^{FIB}), p-Erk1/2 ($p < 0.0001$), p-Akt ($p < 0.0001$), and p-FAK ($p < 0.0001$) (Fig.2). Direct antigen stimulation did not upregulate any of the signaling pathways examined (data not shown).

Conclusion: Our studies demonstrate that HLF interaction with MΦ released mediators, particularly those initiated by exposure to dually modified antigens, are necessary to engage all 4 relevant pathways involved in fibroblast-mediated pulmonary fibrosis that characterizes RA-ILD. Identification of MΦ released soluble factors may serve as an important mediator of the inflammatory and fibrotic processes underlying RA-ILD pathogenesis and could serve as a potential novel target for treatment.

A Pathogenetic Model of IgG4-related Disease Developed from Familial IKZF1 and UBR4 Gene Variants

Qingxiang Liu[1], Kenneth Warrington[1], Matthew Koster[1], Cornelia M. Weyand[2] and Jorg Goronzy[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic School of Medicine and Stanford University, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Most autoimmune diseases are polygenic, frequently with more than 100 gene variants contributing to genetic predisposition. Given this complexity, conclusions on disease mechanisms are generally difficult to draw. Monogenic autoimmune diseases, while rare, offer a unique opportunity to develop models that enable a more mechanistic understanding of the disease process. Here, we have identified a family with IgG4-related disease (IgG4-RD) and dominant atopic features. All three affected members shared mutations in the IKZF1 (c. 548G >A, p. Arg183His) and UBR4 (c. 12537T >A, p. Cys4179Ter) genes, suggesting that either one of them or the combination of both conferred disease with high penetrance. *UBR4* encodes a ubiquitin ligase involved in protein degradation, *IKZF1* the transcription factor IKAROS.

Methods: PBMCs from patients and healthy controls were phenotyped by mass cytometry and flow cytometry. The influence of the variants on the transcriptome and proteome was determined and confirmed by gene silencing. In functional studies, T cell receptor signaling, T cell activation and polarization were examined in patient-derived T cell lines. Gene silencing and forced overexpression of candidate molecules was used to confirm their role in disease-relevant pathways and construct a model of distorted T cell activation and T cell differentiation due to the variants' functions.

Results: Consistent with previous findings in non-hereditary IgG4-RD, all three patients had a prominent Th2 bias as determined by cytokine production, transcription factor expression and chemokine receptor profiles. The *UBR4* mutation caused truncation resulting in reduced function. The *IKZF1* mutation was mapped to the DNA-binding domain, predicting increased transcriptional regulation. Flow studies showed increased CD45 levels in all patients' T and B cells. Consistent with

increased CD45 phosphatase activity, LCK phosphorylation at inhibitory and stimulatory sites were reduced. Unexpectedly, TCR signaling and T cell activation were upregulated in patients. Despite reduced LCK activity, the enhanced TCR signaling was SRC family kinase (SFKs) dependent. After further examination of SFKs, FYN abundance was identified to be upregulated in the patients. In contrast to its inhibitory effect on LCK, CD45 abundance activated FYN, which resulted in augmented T cell activation. Mechanistically, the *IKZF1* mutation resulted in increased binding to the FYN promoter and elevated transcription of FYN. The *UBR4* mutation affected CD45 levels post-transcriptionally by preventing its lysosomal degradation. The hyperactivity of FYN not only reduced the threshold for T cell activation but also accounted for the increased Th2 polarization by phosphorylating JunB.

Conclusion: We identified variants of the *IKZF1* and *UBR4* genes in familial IgG4-RD. The two mutations synergize to promote the expression and activity of the kinase FYN in T and B cells. Increased FYN activity induces unopposed T cell activation and enhances Th2 differentiation. Based on this disease model, we propose several molecular targets that can be explored for therapeutic interventions in IgG4-RD and possibly other atopic diseases.

A Systematic Approach for Identifying Causal Variants and Their Target Genes on JIA Risk Haplotypes

Kaiyu Jiang[1], tao liu[2], Ryan Tewhey[3], Susan Kales[3], Yungki Park[4] and James N Jarvis[5], [1]University at Buffalo, Buffalo, NY, [2]Roswell Park Cancer Institute, Buffalo, NY, [3]Jackson Laboratories, Bar Harbor, ME, [4]University at Buffalo Jacobs School of Medicine & Biomedical Sciences, Buffalo, NY, [5]University at Buffalo Jacobs School of Medicine, Buffalo, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: GWAS have identified multiple genetic regions that confer risk for juvenile idiopathic arthritis (JIA). However, identifying the single nucleotide polymorphisms (SNPs) that drive disease risk has been impeded by the fact that the SNPs used to identify risk loci are in linkage disequilibrium (LD) with hundreds of other SNPs. Since the causal SNPs remain unknown, it is difficult to identify target genes, and thus use genetic information to elucidate disease biology and inform patient care. We have therefore developed a functional genomics pipeline to identify causal variants and their target genes on JIA risk haplotypes.

Methods: We designed 180 bp oligonucleotides ("oligos") representing 7,312 SNPs in LD with the tag SNPs on JIA risk loci (r^2 = 0.80).Oligos were bar coded and cloned into a green fluorescence protein (GFP)-carrying plasmid vector behind a minimal promoter. We transfected our oligo libraries into myeloid K562 cells to conduct a massively parallel reporter assay (MPRA) in which GFP expression for each of the 7,312 SNPs was compared to the common allele. We then used 3D chromatin data to identify the chromatin loops harboring the enhancers carrying SNPs that screen positive on MPRA. We used K562 cells stably transfected with the epigenome editing enzyme dCas-KRAB and gRNAs across the enhancer regions in the *TRAF1* and *LNPEP/ERAP2* loci, inducing dCas-KRAB with doxycycline and using qrtPCR to query expression levels of genes within the same chromatin loops.

Results: We identified n=44 SNPs that showed a significant difference in gene expression (FC $\geq$ 2.0, FDR = 0.05) when compared to the common allele. After stimulating K562 cells with IFNγ (250 ng/ml), we identified an additional 42 SNPs that showed significant effects on gene expression that were not identified in unstimulated cells. In many cases, we identified multiple alleles on the same haplotype, although these alleles were not necessarily within the same functional element (e.g., intergenic vs intronic enhancers). Ablating the intergenic enhancer harboring rs10985080 on the *TRAF1* haplotype using CRISPRi significantly reduced the expression of *PHF1*, but not *C5*, which is in the same chromatin loop. Using a similar approach for an intergenic enhancer in the *LNPEP/ERAP2* locus, we found reduced expression of both *LNPEP* and *ERAP2* but not *CAST*.

Conclusion: We demonstrate proof-of concept for identifying causal variants on JIA risk haplotypes based on observed functional properties that distinguish them from the SNPs in which they are in LD. We also demonstrate that, once these variants are identified, target genes can be quickly identified using publicly available 3D chromatin data and additional functional assays such as CRISPRi.

CRISPi identifies target genes of enhancers harboring JIA-associated variants detected on MPRA. (A). gRNAs used for epigenome editing experiments. The scrambled gRNA is a non-targeting negative control gRNA. For each experiment, 4 gRNAs were targeted to the functional regions of intergenic enhancers in the TRAF1 locus and the ERAP2/LNPEP locus. (B) Attenuation of the intergenic enhancer at the TRAF1 locus significantly reduced expression of PHF19, but not C5 (not shown). Off-target effects are monitored by showing that these gRNAs have no effect on HBE1 expression, but that gRNAs directed to an enhancer known to regulated HBE1 attenuates expression. Bar graphs summarize the results of 4 independent experiments. (C) Attenuating the intergenic enhancer in the LNPEP/ERAP2 locus reduces expression of both LNPEP and ERAP2, but not the adjacent gene, CAST, nor the HBE1 gene (not shown). In each experiment, scrambled versions of the gRNAs had no effect on expression of the putative targets. **p<0.01; ***p<0.001.

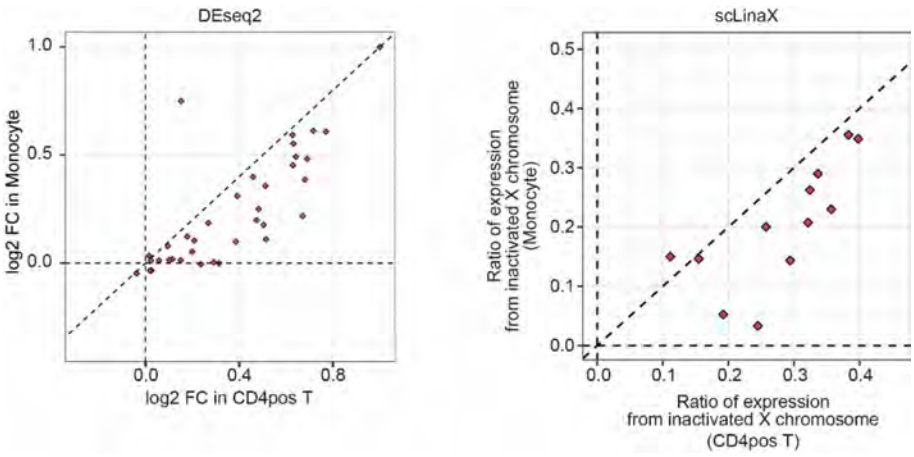
Quantification of the Escape from X Chromosome Inactivation with the Million Cell-scale Human Blood Single-cell RNA-seq Datasets Reveals Heterogeneity of Escape Across Immune Cells and Escape in the Autoimmune Disease Conditions

Yoshihiko Tomofuji[1], Ryuya Edahiro[1], Yuya Shirai[1], Kyuto Sonehara[2], Qingbo Wang[1], Atsushi Kumanogoh[1] and Yukinori Okada[3], [1]Osaka University, Suita, Japan, [2]University of Tokyo, Tokyo, Japan, [3]University of Tokyo / Osaka University / RIKEN, Tokyo, Japan

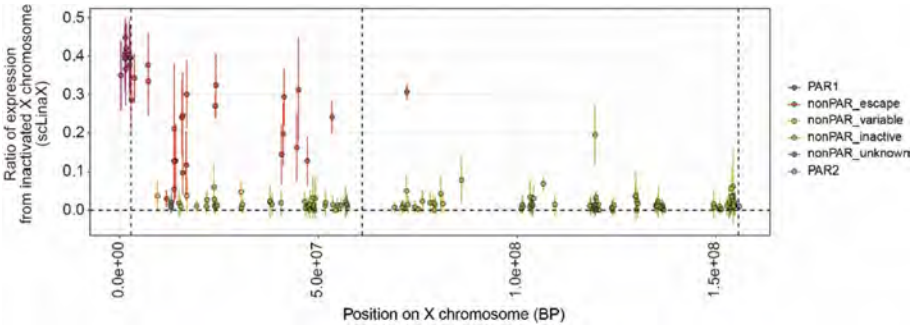
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Understanding the differences in the immune system between sexes is important to elucidate the pathogenesis of autoimmune diseases which are more prevalent in females than males. One of the two X chromosomes of females is silenced through X chromosome inactivation (XCI) to compensate for the difference in the X chromosome dosage between sexes. There exist several genes which 'escape' from XCI, which could contribute to the differential gene expression between sexes. The differences in the escape across cell types are still poorly characterized, especially across immune cell types, even though a large number of immune-related genes are located on the X chromosome. Although previous studies suggested that abnormal escape of a few immune-related genes could contribute to autoimmune diseases, systematic evaluation of the association between escape and autoimmune diseases has not been conducted.

Methods: We investigated the escape across immune cell types utilizing the largest scale scRNA-seq datasets



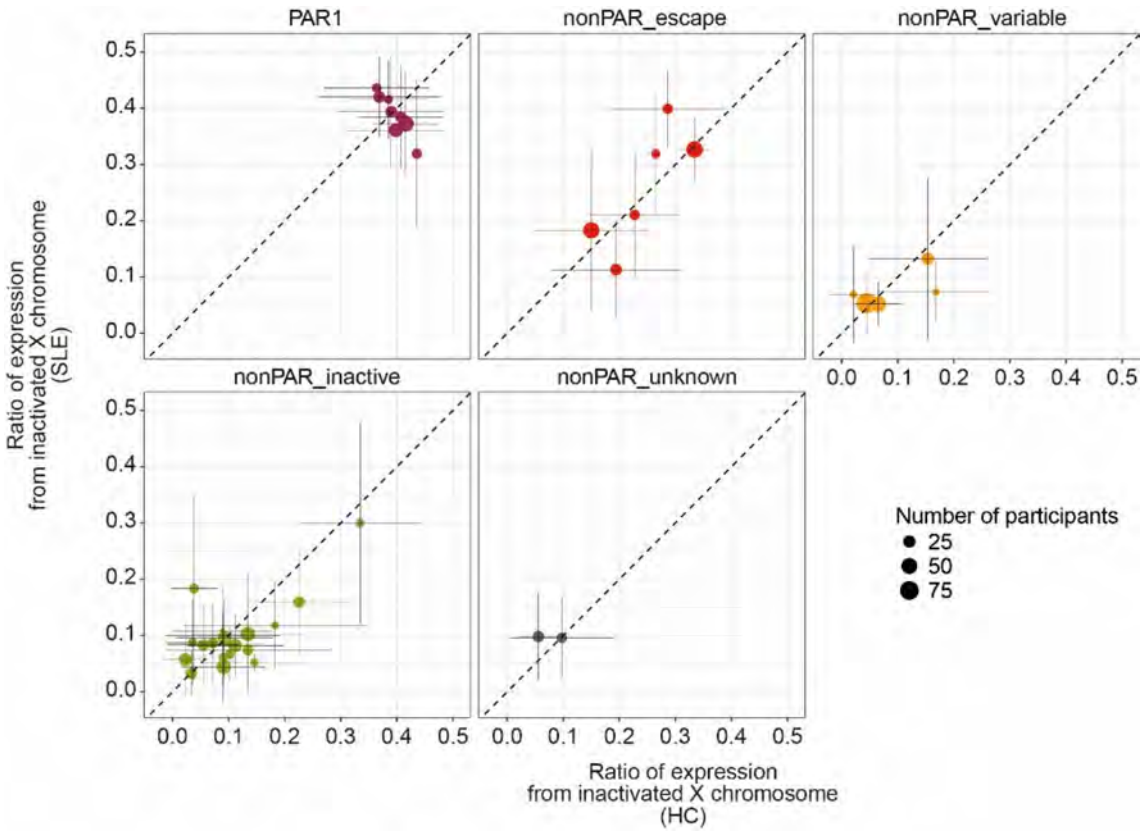
Degree of escape tended to be higher in lymphoid cells than in myeloid cells. The plots indicate the result of the comparison of log2 fold changes in the DEG analysis (left) and the ratio of the expression from the inactivated X chromosome (right) between CD4 positive T cells (x-axis) and monocytes (y-axis). The dashed lines indicate y = x.



The scLinaX successfully detected the escape from the inactivated X chromosome for the previously reported escapee genes. A plot indicating the ratio of the gene expression from inactivated X chromosome quantified by scLinaX (y-axis) and the positions on the X chromosome (x-axis). The color of the points indicates whether the genes escape from the X chromosome inactivation or not based on the previous literature. The error bar indicates the standard deviations.

(1) ~1,000,000 peripheral blood mononuclear cells (PBMCs) from 489 East Asian participants (Asian Immune Diversity Network), (2) ~1,000,000 PBMCs from 147 Japanese (72 COVID19 patients and 75 healthy participants) (3) ~1,000,000 PBMCs from 162 systematic lupus erythematosus patients and 99 healthy participants including East Asian and European.

We performed differential expression gene (DEG) analysis between sexes across immune cell types. In addition, we newly developed a method, **s**ingle-**c**ell **L**evel **ina**ctivated **X** chromosome mapping (**scLinaX**), which directly quantifies gene expression from the inactivated X chromosome (Xi). Although the previous studies required plate-based scRNA-seq data



Comparison of the ratio of the gene expression from inactivated X chromosome between healthy control (HC) subjects (x-axis) and systemic lupus erythematosus (SLE) subjects (y-axis). The error bar indicates the standard deviations.

which had rich per-cell information at the cost of throughput and cost efficiency for analyzing escape, scLinaX could be applied to the droplet-based scRNA-seq data which are high throughput and widely used.

Results: DEG analysis for each immune cell type revealed that degree of female-biased expression of escapee genes was stronger in lymphocytes than in myeloid cells (**Figure 1**). The scLinaX successfully detected the gene expression from the Xi for the previously reported escapee genes (**Figure 2**). The scLinaX revealed the stronger degree of escape in lymphocytes than in myeloid cells suggesting that difference in escape makes the heterogeneity of sex-associated differential gene expression across cell types (**Figure 1**). We also found several genes which had female-biased expression while showing little evidence of the escape in scLinaX analysis, emphasizing the limitation of DEG analysis and the importance of complementary analysis, such as the scLinaX. We evaluated the association between diseases (e.g. SLE) and escape and found little evidence of association, suggesting that abnormal escape in disease conditions might be not common but rather specific for a limited set of reported genes and cell types (**Figure 3**).

Conclusion: As demonstrated with several public datasets, scLinaX could be applied to a wide variety of scRNA-seq datasets. This study would contribute to expanding the current understanding of the XCI and escape and their contribution to autoimmune diseases.

A Novel Transcriptome-Based Machine Learning Pipeline Predicts Phenotypes of Lupus Patients

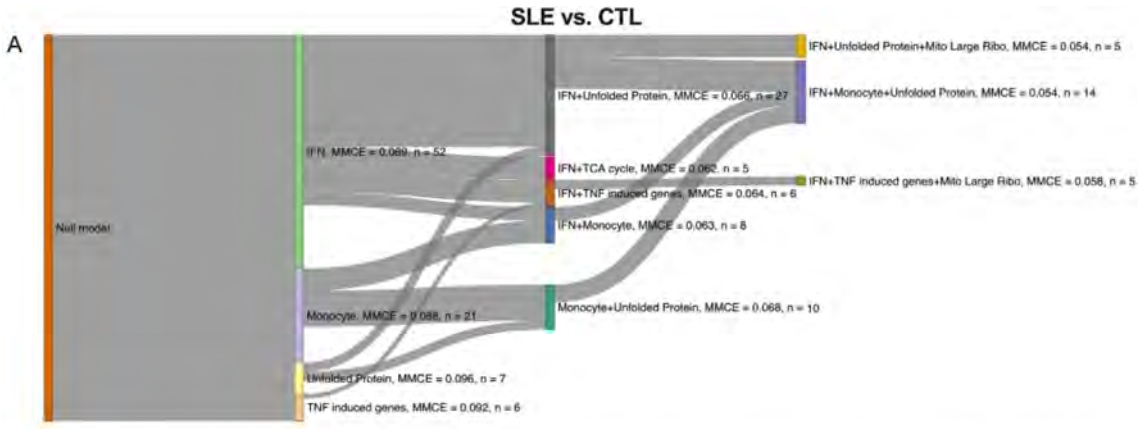
Emily Leventhal[1], **Andrea Daamen**[1], Amrie Grammer[2] and Peter Lipsky[2], [1]AMPEL BioSolutions, LLC, and The RILITE Research Institute, Charlottesville, VA, [2]AMPEL BioSolutions, Charlottesville, VA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gene expression analysis coupled with machine learning (ML) holds the promise of identifying subsets of patients with heterogeneous diseases, such as systemic lupus erythematosus (SLE), a multi-organ autoimmune disease with known diversity in both clinical presentation and gene expression profiles. However, phenotype prediction based on gene expression has often relied on the performance of individual genes without a systems biology context. To address this, we created an interpretable ML approach to predict clinical phenotype of SLE patients in a non-invasive manner using blood transcriptomic profiles.

Methods: We developed a sequential grouped feature importance algorithm to assess the performance of gene sets, including those identifying immune and metabolic pathways and cell types known to be abnormal in SLE, in predicting the presence of lupus as well as disease activity and organ involvement. We normalized, merged, and batch-corrected publicly available datasets and created six ML models to predict SLE from healthy controls (CTL), inactive SLE from CTL, active from inactive SLE, lupus nephritis (LN) from CTL, LN from non-renal lupus, and rheumatoid arthritis (RA) from SLE.

Results: The SGFI algorithm first selects the best gene set to predict phenotype for the model, and then sequentially adds in additional gene sets if they improve the performance of the model (Figure 1A). SGFI provides a way to reduce the high dimensionality of transcriptomic datasets meaningfully, as it incorporates prior knowledge of biology into the data while also selecting pathways in an unbiased manner, leading to biologically informative conclusions. After feature selection, the best gene set combination was found via 10-fold cross validation on the train set and then evaluated on the test set (Figure 1B-D). We then performed gene set variation analysis to examine how these pathways differ across clinical phenotypes (Figure 1E). Gene sets related to interferon, tumor necrosis factor, the mitoribosome, and anergic/activated T cell were the



B

Features	No. genes	F1	Accuracy	Sensitivity	Specificity	AUC
Genes from *IFN*, *TNF induced genes*, and *Mito Large Ribo*	189	0.828	0.929	0.934	0.906	0.979

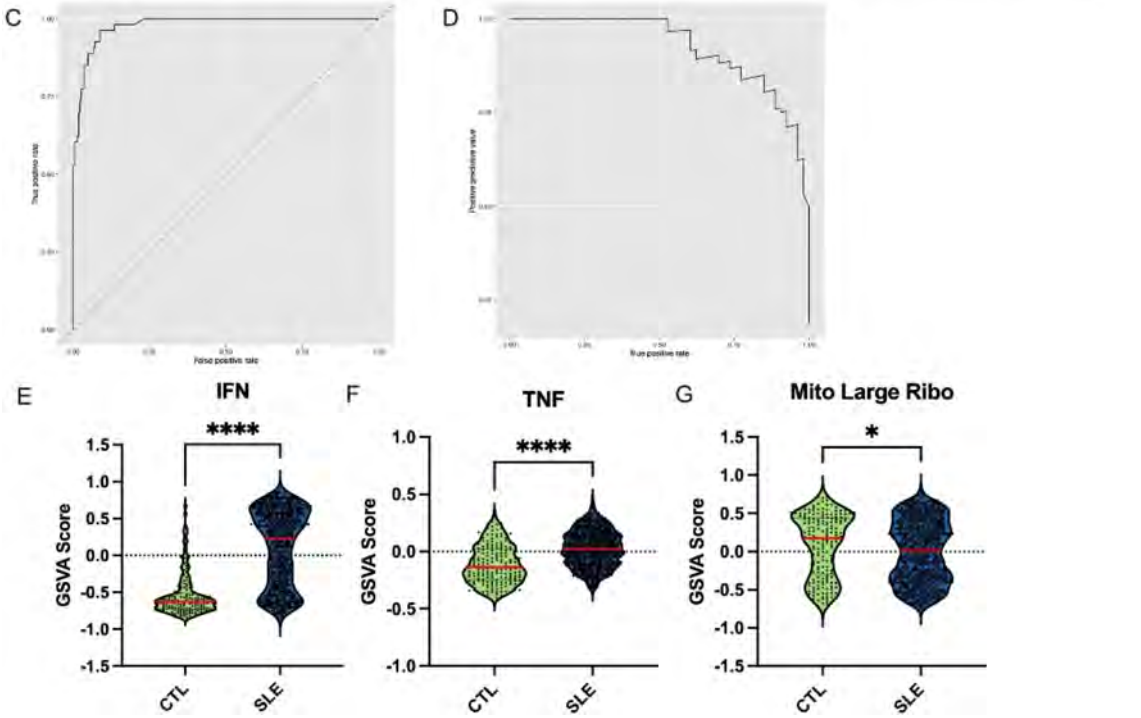


Figure 1. Results from the SLE vs. CTL ML pipeline. A) Sankey plot of the results from feature selection. Feature groups chosen in five or more subsamples are shown in the plot. Feature groups are separated by the symbol, '+'. The average mean misclassification error (MMCE) of each combination across the subsamples and the number of subsamples (n) that module was shown is next to the gene sets. B) Results from evaluation of the final model on the test set. C) Receiver operating characteristic and D) precision-recall curves of final model on the test set. GSVA results of E) interferon (IFN), F) large subunit of mitoribosome (Mito Large Ribo), and G) tumor necrosis factor induced genes (TNF).

Table 1. Summary of the accuracy metrics in the six machine learning models constructed for different patient classification problems.

Classification problem	Gene sets	No. genes	F1	Accuracy	Sensitivity	Specificity	AUC
SLE vs. CTL	*IFN, TNF induced genes, and Mito Large Ribo*	189	0.828	0.929	0.934	0.906	0.979
Inactive SLE vs. CTL	*IFN and Anergic/Activated T Cells*	39	0.857	0.911	0.929	0.868	0.965
Active SLE vs. Inactive SLE	*IFN*	30	0.869	0.824	0.711	0.884	0.842
LN vs. CTL	*IFN and TNF induced genes*	143	0.848	0.831	0.929	0.731	0.943
LN vs. NRL	*IFN and Mito Large Ribo*	80	0.888	0.847	0.732	0.904	0.894
RA vs. SLE	*IFN and TNF induced genes*	147	0.925	0.942	0.963	0.910	0.989

best predictors of phenotype in all classifications (Table 1). The ML models created with those genes as features had excellent performance with AUCs ranging from 0.842 to 0.989 and accuracies of 0.824 to 0.942 (Table 1).

Conclusion: A novel feature selection approach combined with interpretable ML performs extremely well in predicting SLE phenotypes and in separating patients with lupus from both normal and those with RA. Moreover, since interpretable ML can be used to suggest potential causal relationships, these results point to associations between the molecular pathways identified in each model and manifestations of SLE pathogenesis. This innovative ML approach can help improve recognition of SLE phenotypic subsets and additionally be applied to other diseases and tissues.

Genome-Wide Association Study for Loci Associated with Positive Antinuclear Antibodies in a Large Hospital Biobank

Jing Cui[1], Jeong Yee[2], Liming Liang[3], Jack Ellrodt[2], Emily G. Oakes[2], Hongshu Guan[2] and Karen Costenbader[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Harvard T.H. Chan School of Public Health, Boston, MA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antinuclear antibodies (ANA) to intranuclear particles are found in the blood of people with and without autoimmune diseases. To our knowledge, only 1 past genome-wide association study (GWAS) has sought to identify genetic factors related to ANA positivity, reporting association with HLA-DR in a Japanese population (Terao C. et al *Arthritis Rheum* 2014). Dissecting the genetic basis for ANA positivity would allow new insights into susceptibility to autoimmunity.

Methods: We employed data from the Mass General Brigham Biobank, containing linked electronic health records and genotyping (Illumina's Multi-Ethnic Genotyping Array or Global Screening Array chips) for >65,000 consented patients. We identified subjects with genotyping and results for either hep2 or ML immunofluorescence ANA assays (1989-2022). ANA+, those with ≥1 result of ≥ 1:80 titer, were compared to ANA-, those with no positive ANA results. After quality control, we imputed using the Haplotype Reference Consortium, excluding variants with imputation score < 0.5. Classical HLA alleles and amino acids for HLA genes were imputed with SNP2HLA using TopMed HLA data as reference. We restricted analyses to those with predicted European ancestry (1000 Genomes EUR group; 82% of biobank subjects). Diagnostic codes identified 8 autoimmune diseases: systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), scleroderma (SSc), Sjogren's

Table 1. GWAS for ANA Positivity (≥1:80 titer) vs. Negativity: Top results from the Mass General Brigham Biobank among those of European genetic ancestry (N=12,875)

AA: amino acid sequence; HLA: classical HLA alleles

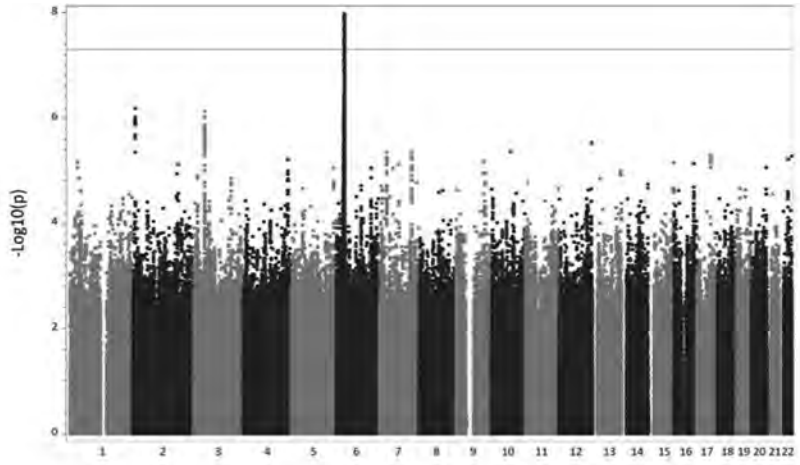

Figure 1. Manhattan Plot for GWAS for ANA positivity (ANA+ 1:80 vs. negative) with threshold for genome-wide significance at p= 5×10^{-8}, showing a strong signal in chromosome 6.

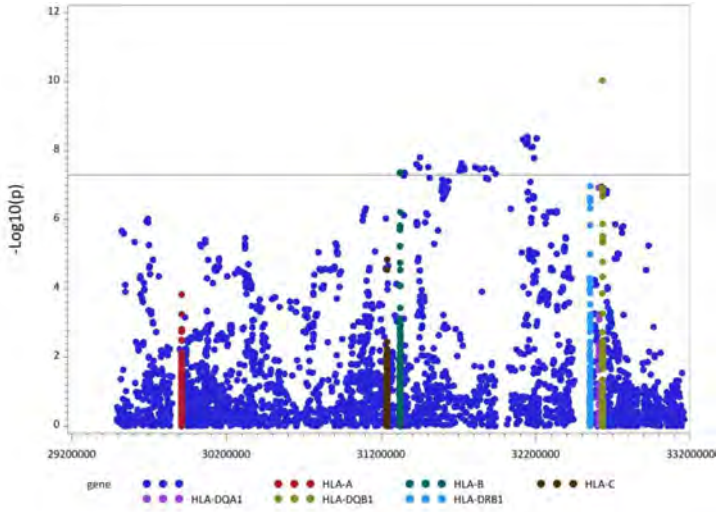

Figure 2. Manhattan Plot for association for ANA positivity (ANA+ 1:80 vs. negative) in the HLA region, with threshold for genome-wide significance at p= 5×10^{-8}, showing a strong signal in HLA-DQB1.

syndrome, mixed connective tissue disease (MCTD), multiple sclerosis (MS), primary biliary cirrhosis (PBC), and autoimmune thyroid disease (ATD). GWAS for ANA + vs – was done in PLINK2, with logistic regression adjusted for age, sex and 4 genetic principal components. We also tested for associations with HLA alleles and amino acids, adjusting for these variables.

Results: We studied 12,875 subjects with ANA and genotyping results: 7,035 ANA + vs. 5,840 ANA -. The female/male ratio was similar in both groups: 62.9% female in ANA+ vs. 62.1% in ANA- (p 0.39). Patients who were ANA+ were older than the ANA- (56.1 ± 15.8 vs. 52.1 ± 15.2 years, p< 0.0001). Overall, by billing codes, SLE, RA, SSc, Sjogren's syndrome, MCTD, MS, PBC and ATD were present in 538, 1425, 159, 370, 65, 354, 63 and 408 subjects (with ANA+ proportions 71%, 55%, 78%, 74%, 82%, 55%, 63%, and 62% respectively).Of ANA+ patients, 33% had ≥1 of the 8 autoimmune diseases, as did 19% of ANA- patients. 8,073,314 SNPs with MAF >=0.01 were included. The strongest GWAS association with ANA+ was for rs3134951 on chromosome 6 in the HLA region with OR 1.2 (95% CI 1.1-1.3, p 1.6×10^{-9}) (**Table 1, Figure 1**). HLA region association analysis revealed *HLA-DQB1:0201* allele had strong association with OR 1.3 (95% CI 1.2-1.3, p 9.2×10^{-11}). *HLA-DRB1:03* and *HLA-B:08* alleles also had significant associations (**Figure 2**). We identified 2 suggestive novel loci for ANA +, one in LOC105373419 gene (rs60343674) and the other in *ABHD5* gene (rs12489159). (**Figure 1)**

Conclusion: These results confirm that *HLA-DRB,* as well as newly identified *HLA-DQB1* and *HLA-B,* are strong genetic factors predisposing to ANA positivity in this European ancestry population. We are pursuing stratified analyses by ANA pattern and titer, sex, and autoimmune disease.

Session Title: Genetics, Genomics & Proteomics Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: GWAS have identified multiple genetic regions that confer risk for juvenile idiopathic arthritis (JIA). However, identifying the single nucleotide polymorphisms (SNPs) that drive disease risk has been impeded by the fact that the SNPs that identify risk loci are in linkage disequilibrium (LD) with hundreds of other SNPs. Since the causal SNPs remain unknown, it is difficult to identify target genes, and use genetic information to inform patient care. GWAS are also unable to identify the cells impacted by disease-driving variants. We have shown that disease-driving variants on JIA haplotypes are likely to impact monocytes and macrophages. We therefore used genotyping and functional data in primary human monocytes/macrophages to nominate disease-driving SNPs on JIA risk haplotypes and identify their likely target genes.

Methods: We identified JIA risk haplotypes using Immunochip data from Hinks et al (Nature Gen 2013) and the meta-analysis from McIntosh et al (Arthritis Rheum 2017), setting r^2 at 0.80.We used existing genotyping data from 3,939 children with JIA and 14,412 healthy controls to identify SNPs that: (1) were situated within open chromatin in multiple immune cell types and (2) were more common in children with JIA than the controls ($p< 0.05$).We next identified those SNPs that occured within regulatory regions. We intersected the chosen SNPs (n=846) with regions of bi-directional transcription initiation characteristic of non-coding regulatory regions detected using dREG to analyze GROseq data. Finally, we used MicroC data to identify gene promoters interacting with the regulatory regions harboring the candidate causal SNPs.

Results: From the list of n=846 SNPs, we identified 190 SNPs that overlap with dREG peaks in monocytes and126 SNPs that overlap with dREG peaks in macrophages. Of these SNPs, 101 were situated within dREG peaks in both monocytes and macrophages, suggesting that these SNPs exert their biological effects independent of the cellular activation state. MicroC data in monocytes identified 20 genes/transcripts whose promoters interact with the enhancers harboring the SNPs of interest and therefore are the likely target genes. These included genes known to regulate interferon responses (*IRF1, ERAP2*) and well as genes broadly associated with leukocyte activation (*JAK1, PIK3CG*).

Conclusion: We demonstrate that SNPs on JIA risk haplotypes that are candidate causal variants can be further screened using functional data such as GROseq. This screening process identifies a finite number of candidate causal SNPs, the majority of which are likely to exert their biological effects independent of cellular activation state in monocytes. Three dimensional chromatin data generated with MicroC identifies the genes likely to be influenced by these SNPs. These studies demonstrate the importance of investigations into the role of innate immunity in JIA.

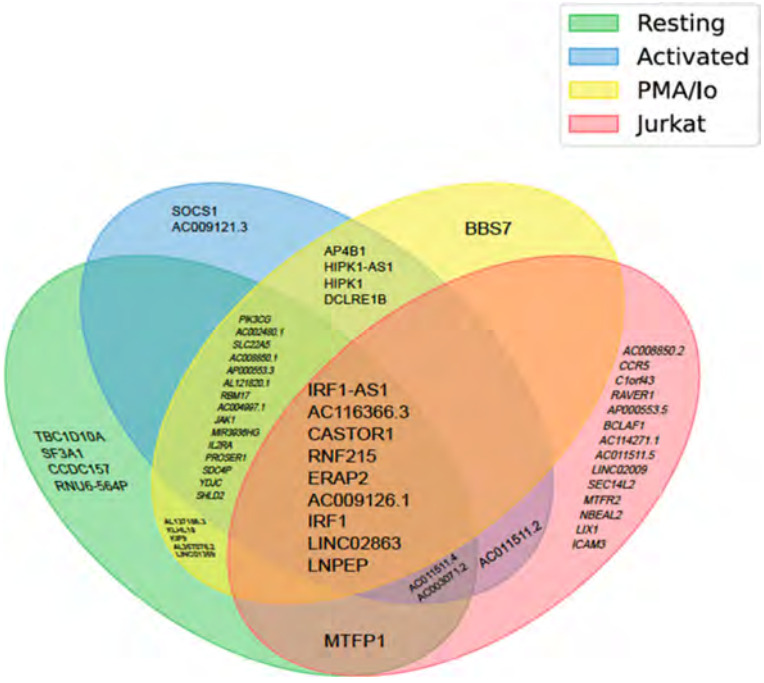
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: GWAS have identified multiple genetic regions that confer risk for juvenile idiopathic arthritis (JIA). However, identifying the single nucleotide polymorphisms (SNPs) that drive risk has been impeded by the fact that the SNPs that identify risk loci are in linkage disequilibrium (LD) with hundreds of other SNPs. Since the causal SNPs remain unknown, it is difficult to identify target genes or use genetic information to inform treatment. GWAS are also unable to identify the cells whose function is impacted by the disease-driving variants. We used genotyping and functional data in primary human CD4+ T cells to nominate disease-driving SNPs and identify their likely target genes.

Methods: We identified JIA risk haplotypes using Immunochip data from Hinks et al (Nature Get 2013) and McIntosh et al (Arthritis Rheum 2017), setting r^2 at 0.80.We used existing genotyping data from 3,939 children with JIA and 14,412 healthy controls to identify SNPs that were present within open chromatin in multiple immune cell types and more common in children with JIA than the controls ($p < 0.05$) .We next sought to identify those SNPs most likely to occur within regulatory



Venn diagram showing the overlap of genes interacting with enhancers harboring candidate causal SNPs on JIA risk haplotypes. Results from Jurkat T cells, commonly used in models of T cell activation, are shown for comparison.

regions in both resting and activated human primary CD4+ T cells by overlaying the chosen SNPs (n=846) with bi-directional transcription initiation characteristic of non-coding regulatory regions detected using dREG to analyze precision run-on sequencing (PROseq) data. Finally, we used MicroC to detect gene promoters interacting with the regulatory regions harboring the candidate causal SNPs.

Results: We identified 138 SNPs situated within dREG peaks in resting CD4+ T cells, 119 in PMA-stimulated CD4+ T cells (2 hr stimulation), and 150 that occurred in dREG peaks in CD3-CD28-IL2-stimulated CD4+ T cells (7 days' stimulation). We identified n=74 SNPs that appeared in dREG peaks under all 3 conditions, suggesting that their biological effects are exerted on both resting and activated cells, while those unique to activation phases (20 in resting cells, 20 in PMA-activated cells, and 39 in CD3-CD28-IL2-activated cells) may exert their effects only under specific biological conditions. MicroC studies identified n=41 genes that interacted with enhancers harboring the candidate causal SNPs in resting CD4+ T cells, n=39 in CD4+T cells activated with ionomycin and PMA (30 min) and n=38 in CD4+ T cells activated with CD3/CD28/IL2 (7 days).There was considerable overlap in these gene sets, as shown in the figure, while other gene-enhancer interactions were cell-state-specific.

Conclusion: We demonstrate that SNPs on JIA risk haplotypes that are seen more frequently in patients than controls can be further filtered by their presence within functional regulatory elements (detected by PROseq) in primary human CD4+ T cells. Some of these regulatory elements are unique to the activation state of the cells, supporting the idea that some SNPs may exert their biological effects only in specific biological contexts. Finally, we demonstrate that newer methods for querying 3D chromatin structures (e.g., MicroC) can crisply identify the genes influenced by regulatory elements harboring these SNPs, and, thus, the immunological processes impacted by disease-driving genetic variants.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: 10X Visium spatial transcriptomics evaluates gene expression in a 50μm tile coordinate of a sectioned tissue, yielding heterogeneous cell sampling. Spatial PCA algorithm was developed using homogenous tissue types with distinct boundaries to identify like tissue regions and determine the cellular context of spatial coordinates for spatial transcriptomic analyses [1]. However, it is less effective at differentiating like tiles from heterogenous tissue types such as the minor salivary gland; the target tissue of Sjögren's disease (SjD). This study introduces a novel approach, HistoPCA, that connects pathologically annotated and segmented images with spatial coordinates derived from minor salivary gland biopsies to group like tiles based on similar cellularity.

Methods: Histopathological images of minor salivary gland biopsies were annotated based on tissue type (fibrosis, glandular, inflammatory, fat), then annotations were combined with spatial coordinates using the novel HistoPCA algorithm. Image segmentation was used to obtain cell numbers in tiles and combined with pseudo-color percentages associated with certain tissue types to perform unsupervised KMeans clustering. Differential expression (DE) between SjD cases and controls was analyzed using pseudo-bulk gene expression, then analyzed by Ingenuity Pathway Analysis (IPA).

Results: HistoPCA and UMAP with KMeans clustering outperformed Spatial PCA (Adjusted Rand Index (ARI) of 0.52 vs 0.51), identifying four distinct clusters in minor salivary gland. Despite distinct features such as inflammation in Cluster 1 (21% inflammatory, 32% fibrosis, and 23% glandular tiles) and increased glandular involvement in Cluster 3 (0% inflammatory, 48% fibrosis, and 41% glandular tiles), DE and pathway analyses showed similar patterns of dysregulation in SjD cases (n=28) compared to controls (n=16). As a positive control, elevated interferon signatures were observed in all SjD cases and anti-Ro positive SjD cases (n=19) compared to controls across all clusters [2]. Additional immune pathways (T cell receptor, Th1, Th2, and IL-4 signaling, etc.) were also upregulated in SjD cases while CTLA4, IL-10, and IL-12 signaling pathways were downregulated.

Conclusion: HistoPCA is a novel approach that uses histopathological and segmentation data to successfully group like tiles from spatial transcriptomic analysis of heterogeneous tissues, e.g., minor salivary gland. Cluster annotation of HistoPCs (principal components), followed by pseudo-bulk DE and pathway analyses identified four clusters with dysregulated immune pathways in SjD.Further, dysregulation of immune pathways in Cluster 3, which was devoid of tiles associated with inflammation, indicates potential glandular involvement in SjD pathogenesis. Future analyses within spatial contexts will provide additional insights into the role of different cell/tissue types in SjD pathobiology of the salivary gland.

Specific Binding of Uric Acid to NDFIP1 Associates with Hyperuricemia-induced Ferroptosis

Qiunan Zhu[1], Hiroshi Arakawa[2], Yoshiyuki Shirasaka[2] and Ikumi Tamai[2], [1]Kanazawa University, Kanazawa, Japan, [2]Faculty of Pharmaceutical Sciences, Kanazawa University, Kanazawa, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Hyperuricemia (HU) is reported as a risk factor for gout and associates with diverse diseases, including ulcerative colitis (UC), while its mechanism remains unclear. In this study, we aim to explain UA effect based on the hypothesis that UA-binding proteins function as UA sensors and regulate various physiological processes.

Methods: UA-binding proteins were detected by proteomics following a pull-down assay with UA-binding beads and human colorectal Caco-2 cells homogenate. Specific binding of these candidate binding proteins was confirmed by binding assay with *in vitro* synthesized proteins using cell-free method. UA was exposed to the cells after filtering by 0.2 μm filter to avoid UA crystals. The cellular levels of iron, ROS, and lipid peroxidation (MDA) were measured with FerroOrange, CellROX®, MDA assay kit, respectively.

Results: Six proteins were found to be potential to bind to UA by pull-down assay. Specific binding of UA to these proteins was confirmed by binding assay using *in vitro* synthesized proteins, where NDFIP1 showed the highest binding rate (Fig. 1). Binding domain was narrowed down by binding assay with UA-binding beads and *in vitro* synthesized partial NDFIP1 protein. To find the binding sites, docking simulation of AlphaFold2-predicted NDFIP1 and UA was carried out. As a result, intracellular C-terminal sequences of NDFIP1 was suggested as UA-binding region.

Exposing UA to Caco-2 cells caused cell death and the viability decreased with increasing UA concentration (Fig. 2A). In addition, as UA significantly increased intracellular iron, ROS and MDA level (Fig. 2B-D), suggesting that high UA level could induce ferroptosis, which is associated with UC.

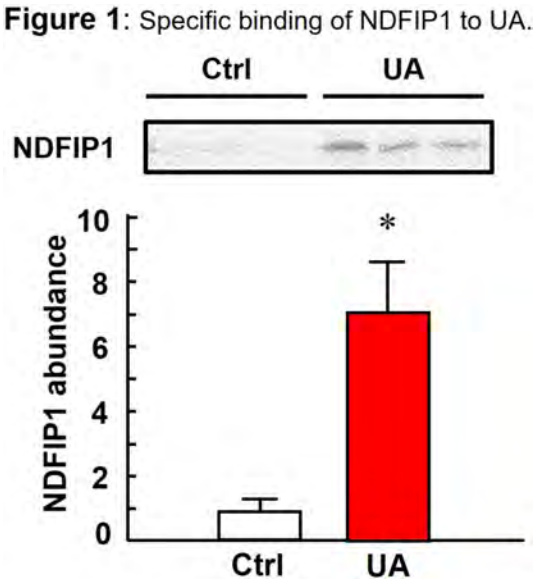

Figure 1. Specific binding of NDFIP1 to UA. NDFIP1 bound to UA-binding beads was approximately 7 times as much as that of control.

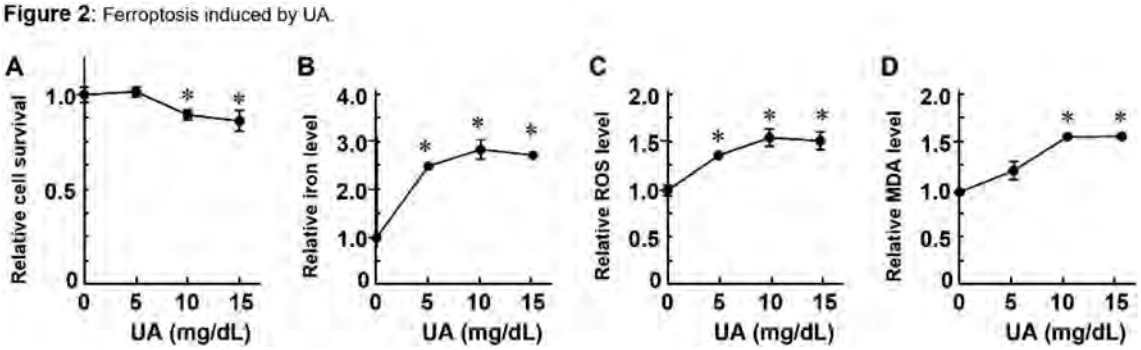

Figure 2. Ferroptosis induced by UA. Exposing UA to Caco-2 cells caused cell death (A) and led to higher intracellular iron (B), ROS (C), and MDA (D) levels.

Figure 3: Effect of UA on DMT1 expression.

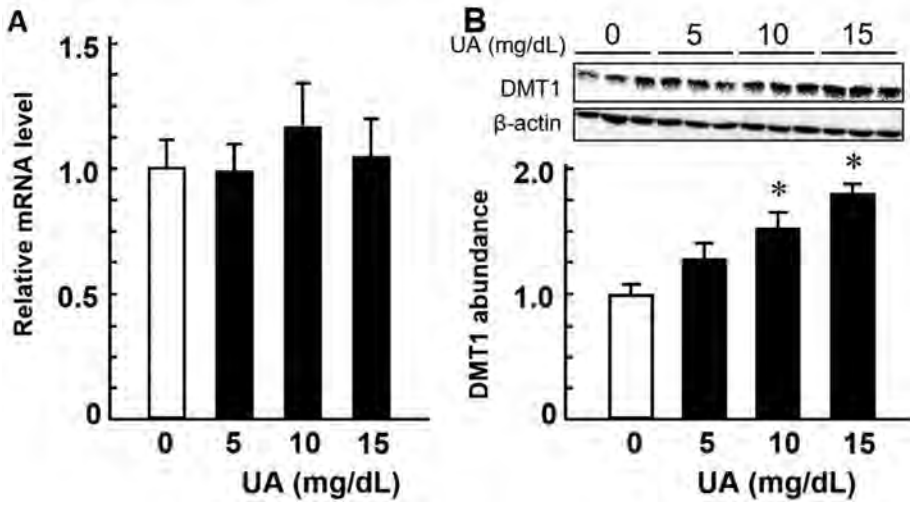

Figure 3. Effect of UA on DMT1 expression. Exposing UA to Caco-2 cells increased DMT1 protein expression significantly (B), but not the mRNA level (A).

Since NDFIP1 is known as a ubiquitin ligase adaptor and promotes ubiquitination of DMT1 (divalent metal transporter 1, an iron transporter), mRNA and protein expressions of DMT1 were measured as Fig. 3, where UA increased DMT1 protein significantly but not mRNA level.

Exposure of DMT1 blocker 2 reduced UA-induced ferroptosis. Furthermore, knockdown of NDFIP1 by transfecting siRNA lowered the difference of ferroptosis level between UA exposed and control groups.

Conclusion: NDFIP1 was found as UA binding protein and was suggested as a UA sensor that regulates HU-induced ferroptosis by modulating DMT1.

SESSION INFORMATION

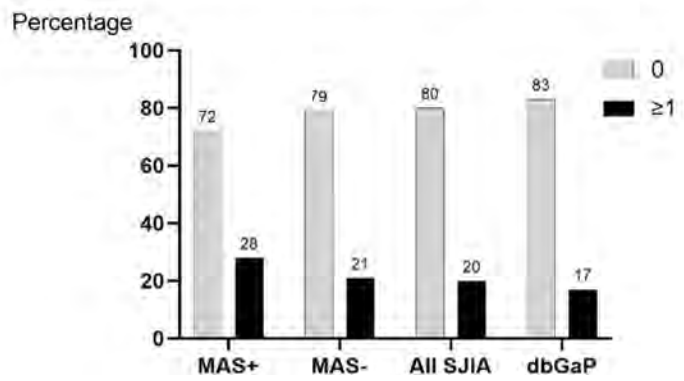
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a complex inflammatory condition of childhood. It can be complicated by macrophage activation syndrome (MAS), a secondary form of hemophagocytic lymphohistiocytosis (HLH). Studies have identified an enrichment of HLH variants in sJIA patients with MAS compared with those without it. However, the role of these variants in sJIA in general is not known. The goal of our study is to determine whether rare variation in HLH genes contributes to the risk of developing sJIA.

Methods: Targeted sequencing of HLH genes (*LYST, PRF1, RAB27A, STX11, STXBP2, UNC13D*) was performed in sJIA subjects with European ancestry from the International Childhood Arthritis Genetics Consortium cohort using Illumina Nextera Custom Capture Assays and Illumina sequencers. Data processing and quality control were performed using a Genome Analysis Toolkit-based pipeline. Variants were filtered to retain high-quality, protein-altering variation on Ensembl canonical transcripts and stratified by minor allele frequencies (MAF). Healthy control exomes were extracted from the database for genotypes and phenotypes (accession number: phs000280.v8.p2). Rare variant association testing (RVT) was done with sequence kernel association test (SKAT). A burden test was also performed with the SKAT package. Significance was defined as $p < 0.05$ after 100,000 permutations.

Results: Sequencing data from 524 sJIA cases were jointly called and harmonized with exome-derived target data from 2952 controls. Subjects were excluded if they had a monogenic disease (n=6), dissimilar genetic ancestry (39 cases, 22 controls), or > 10% missingness (6 controls). Analysis of the remaining 479 sJIA cases revealed 71 rare HLH gene variants, including recurrent ultra-rare (MAF < 0.001) variants in *LYST* and *UNC13D*.We also observed 2 people in the sJIA cohort who had the *STXBP2* mutation Ala429Val, which has been associated with secondary HLH and severe Covid. RVT comparing the variant distributions of sJIA cases and controls revealed a significant association with rare (MAF < 0.01) variants of *STXBP2* (p=0.019) and ultra-rare variants of *STXBP2* (p=0.006) and *UNC13D* (p=0.045). Sub-analysis of patients with known MAS status showed that the distribution of rare variants of *UNC13D* was different in 32 sJIA patients with MAS than in 90 without it (p=0.0047) or 2930 controls (p=0.03). There was an increased frequency of individuals with ≥1 rare HLH variants in all sJIA groups compared to the controls (Figure 1), with sJIA patients with a history of MAS having the highest frequency. Similarly, the full cohort (p=0.009) and those with MAS (p=0.025) had a higher burden of HLH variants than controls, whereas those without MAS did not (p=0.12).

Figure 1. Percentages of Individuals with Rare HLH Variants in Each Subgroup



HLH: hemophagocytic lymphohistiocytosis, MAS: macrophage activation syndrome, sJIA: systemic juvenile idiopathic arthritis, dbGaP: database of Genotypes and Phenotypes

Conclusion: We found that the association of HLH variants with sJIA is not purely linked to MAS. *STXBP2* was significantly associated with sJIA while showing no association with MAS. Moreover, the frequency of HLH gene variants trended higher in MAS-negative sJIA than in control subjects. As seen in prior studies, *UNC13D* was associated with MAS. Taken together, this suggests that HLH variants may play a role in the pathophysiology of sJIA in general, and not only in MAS.

Cytokine-induced Transcriptome Modification Elucidates the Similarity and Dissimilarity Across 10 Immune-related Diseases

Haruka Takahashi[1], Hiroaki Hatano[2], Masahiro Nakano[3], Haruka Tsuchiya[4], Mineto Ota[4], Tomohisa Okamura[5], Keishi Fujio[4] and Kazuyoshi Ishigaki[6], [1]Laboratory for Human Immunogenetics, RIKEN Center for Integrative Medical Sciences and Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [2]Laboratory for Human Immunogenetics, RIKEN Center for Integrative Medical Sciences, Tokyo, Japan, [3]Laboratory for Autoimmune Diseases, RIKEN Center for Integrative Medical Sciences, Tokyo, Japan, [4]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [5]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo and Department of Functional Genomics and Immunological Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [6]RIKEN, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Genetics, Genomics & Proteomics Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Abnormal cytokine regulation is the fundamental pathology of immune-mediated diseases (IMDs). Clinical transcriptome data has a potential to monitor real-time cytokine pathway activities of each IMD patient and guide treatment choices. However, multiple confounders including immunosuppressive therapies and experimental batch effects obscures the biologically relevant signals underlying clinical transcriptome data. The aim of this study is i) to establish an analytical strategy to accurately quantify cytokine pathway activities excluding the confounder effects and ii) elucidate the similarity and dissimilarity across 10 immune-related diseases by applying our strategy to the clinical transcriptome database.

Methods: We utilized the ImmuNexUT database, the largest open-access database of clinical transcriptome data with 28 FACS-sorted immune cell subsets obtained from 10 IMDs: SLE, idiopathic inflammatory myopathy (IIM), SSc, MCTD, SS, RA, Behcet's disease (BD), adult-onset Still's disease (AOSD), ANCA-associated vasculitis (AAV), and Takayasu arteritis (TAK) (Figure 1). Using the combination of supervised and unsupervised approaches, we learned the cytokine-induced transcriptome alterations from a large-scale in-vitro cultured fibroblast experiments stimulated by eight cytokines: IFN-α, IFN-γ, TNF-α, IL-1β, IL-6/sIL-6R, IL-17, IL-18 and TGF-β1 (n=506 samples in total). We then transferred the knowledge to the clinical transcriptome data. To mitigate the different statistical power due to unbalanced sample sizes across 10 IMDs, we applied the multivariate adaptive shrinkage approach.

Results: We first took an unsupervised approach and conducted the principal component analysis (PCA) of the cytokine-stimulated fibroblast datasets to learn the transcriptome axes reflecting multiple cytokine signatures. We then projected clinical transcriptome data onto the PC space and confirmed that IMDs were separated by cytokine signatures, with a pronounced shift in SLE. We next took a supervised approach and detected the IMD- and cytokine-related transcriptome signatures from both datasets. By jointly analyzing both signatures simultaneously, we successfully characterized the transcriptome similarity and dissimilarity across 10 immune-related diseases from a viewpoint of cytokine-related signatures. The cytokine signatures grouped IMDs into two clusters: the autoimmune diseases (MCTD, SLE, IIM, SSc, RA and SS) and autoinflammatory diseases (BD, AAV, and TAK).

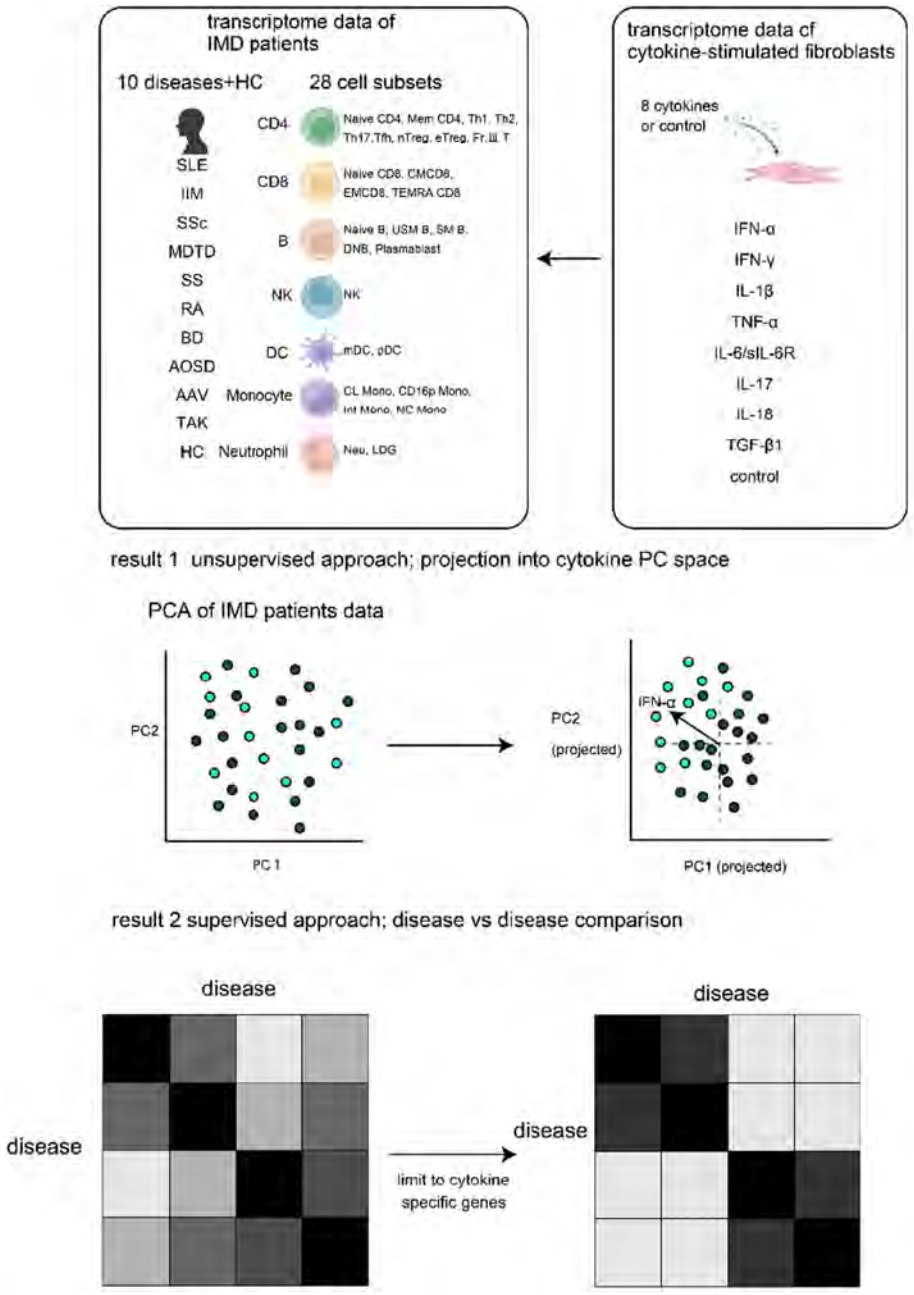

Figure 1. The overview of datasets and analytical strategies. We analyzed transcriptome data of 10 immune-related diseases using the knowledge obtained from transcriptome data of cytokine stimulated fibroblasts. We utilized both unsupervised and supervised approaches.

Conclusion: Our new analytical strategy successfully detected cytokine-related transcriptome characteristics of 10 IMDs, which would be a foundation to elucidate the IMD pathology.

Non-canonical NF-κB Signalling Is Required for Extrathymic AIRE Expression and Immunoregulatory Molecules in Cells of the Dendritic Lineage

Guus van Laar[1], Leonie Huitema[1], Boy helder[1], Joanna Fergusson[1], Hergen Spits[1], Jan Piet van Hamburg[1] and Sander Tas[2], [1]Amsterdam University Medical Centers, Amsterdam, Netherlands, [2]Amsterdam UMC, locatie AMC, Utrecht, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The transcription factor Autoimmune Regulator (AIRE) is crucial for the establishment of central tolerance in the thymus. Recently, peripheral $CD45^+$ extrathymic AIRE-expressing cells (eTACs) have been identified, which share features with antigen presenting cells, such as dendritic cells (DCs). Although, nuclear factor (NF)-κB signaling has been implicated in thymic AIRE expression, stimuli and pathways that induce extrathymic AIRE expression are hitherto unknown. We aimed to unravel the molecular mechanisms underlying the regulation of extrathymic AIRE expression in eTACs and DCs.

Methods: Confocal imaging was performed on secondary lymphoid tissues, including tonsils and lymph nodes to identify and characterize eTACs. Second, we employed a novel sorting strategy to isolate DCs and eTACs from tonsil tissue for RNA-sequencing (seq) to generate transcription profiles. To study the regulation of AIRE, monocyte-derived DCs (moDCs), DCs and eTACs were stimulated by anti-CD40 to induce NF-κB activation. Gene transcription and protein expression levels of AIRE, indoleamine-2,3-dioxygenase (IDO), programmed death ligand-1 (PD-L1) and non-canonical NF-κB signalling components were detected by real time-PCR, flow cytometry, Western blot and/or confocal microscopy. Activation of NF-κB signalling was modulated by siRNA-mediated silencing or using a small molecule inhibitor (SMI) of activating kinases.

Results: In human tonsil and lymph node tissue $AIRE^+$ cells were identified, which displayed DC characteristics, including MHCII and CD40, but were relatively low for CD11c. Bioinformatic analysis on RNA-seq derived gene expression profiles of sorted eTACs and DCs from tonsil tissue revealed an increased expression of AIRE and immunoregulatorygenes, including IDO and PD-L1 in eTACs compared to DCs. In addition, the expression of genes implicated in non-canonical NF-κB signaling, including NIK and CD40, were significantly higher in eTACs compared to DCs. CD40 stimulation has been shown to

be critical for IDO production by moDCs. CD40-stimulation of moDCs resulted in the activation of non-canonical NF-κB signaling, which was accompanied by upregulation of AIRE, IDO and PD-L1 expression. Interestingly, the induction of AIRE expression was abrogated by siRNA-mediated silencing of NF-κB-inducing kinase (NIK) . Likewise, CD40 stimulation of sorted eTACs and DCs resulted elevated AIRE, IDO and PD-L1 expression levels. Subsequently, modulation of NIK via an SMI resulted in the abrogation of AIRE, IDO and PD-L1 expression in eTACs and DCs. In contrast, specific modulation of canonical NF-κB signaling had no significant effects on AIRE, IDO and PD-L1 expression in CD40-stimulated eTACs and DCs.

Conclusion: Collectively, our data demonstrate that AIRE expression, as well as the expression of the immunoregulatory molecules IDO and PD-L1 in eTACs and DCs can be induced through CD40 stimulation in a non-canonical NF-κB signaling dependent manner. These findings concerning the regulation of AIRE and immunoregulatory molecule expression may point towards a novel role of eTACs in peripheral tolerance.

Interactions Between Synovial Fibroblasts and Macrophages: Implications for Tissue Remodeling in Chronic Inflammatory Diseases and Macrophage Differentiation in Response to the Immune Microenvironment

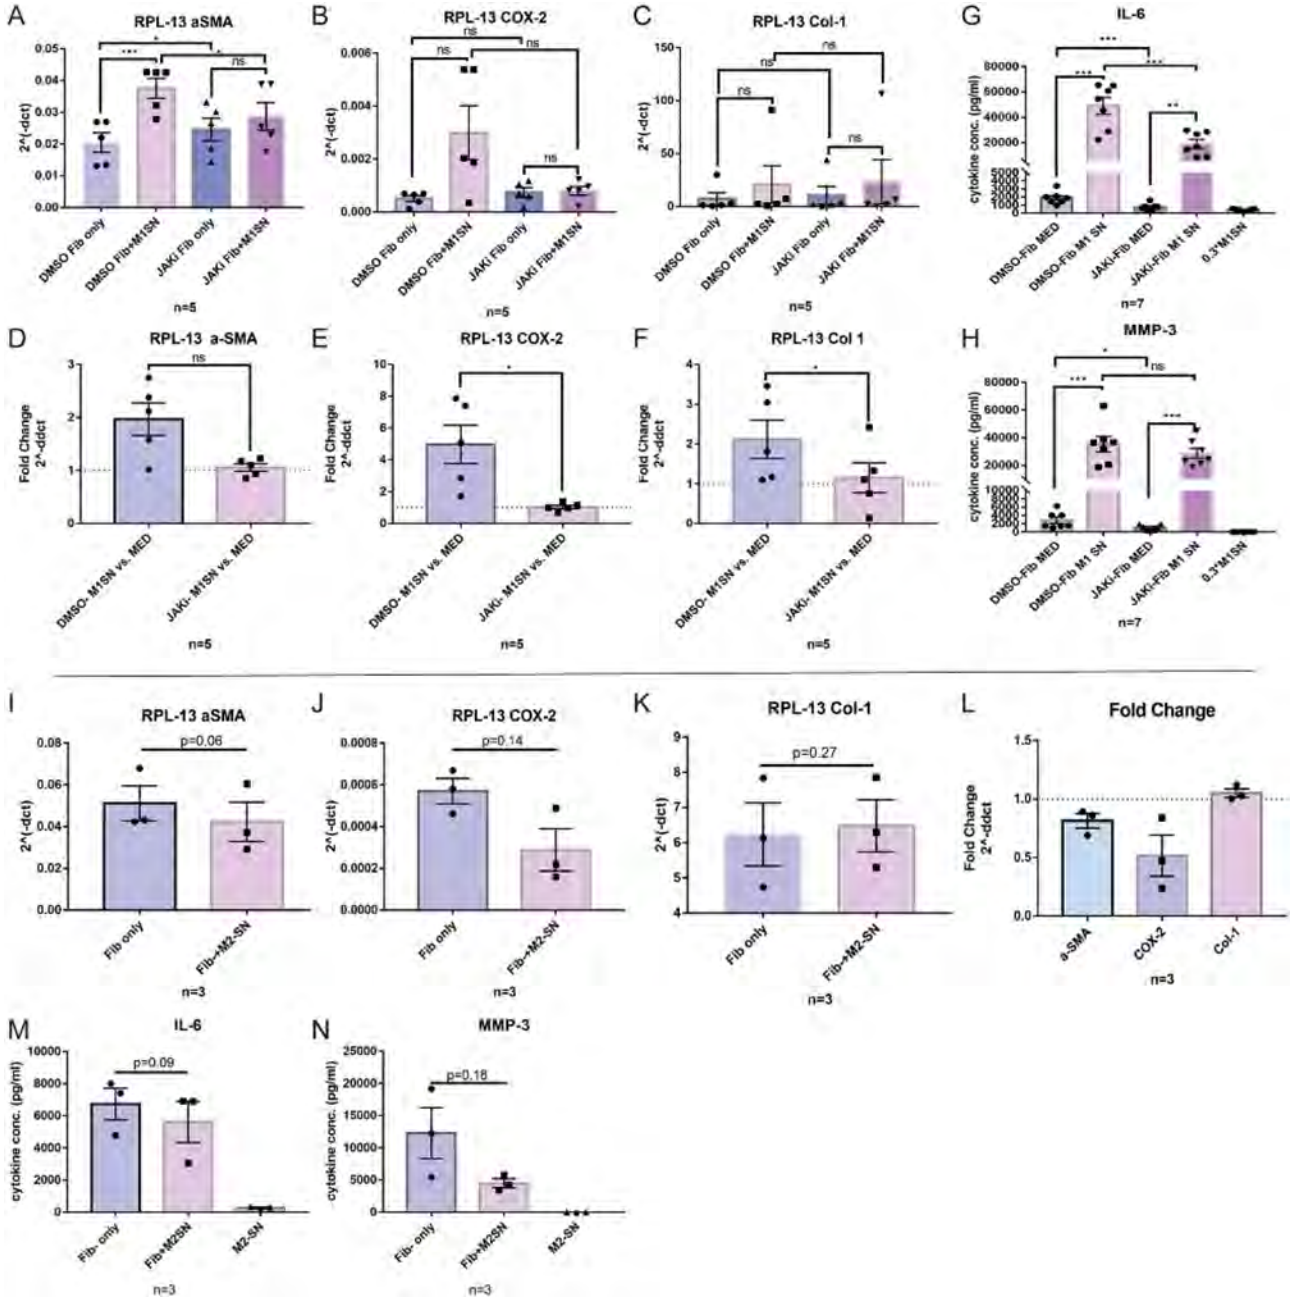
Jia Li, Yanrong Cai, Xin Guan, Meike Ewald, Lars-Oliver Tykocinski, Hanns-Martin Lorenz and Theresa Tretter, Department of Internal Medicine V, Div. of Rheumatology, University Hospital Heidelberg, Heidelberg, Germany

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

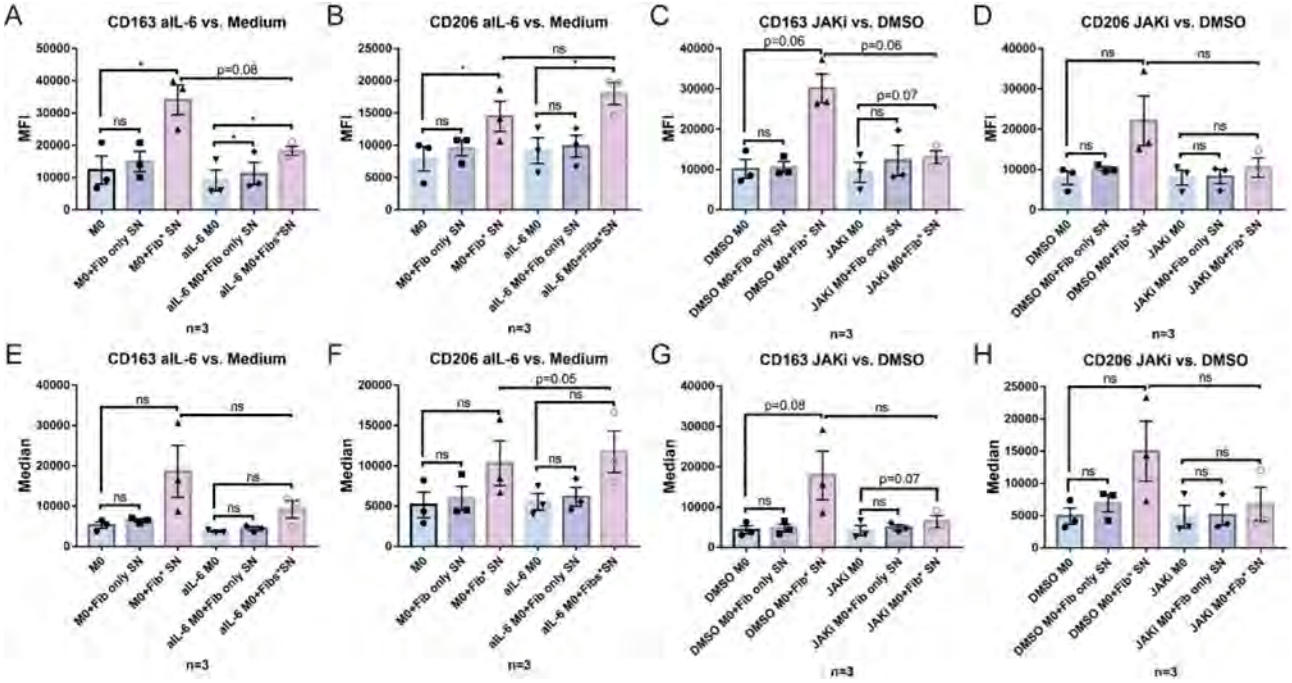
Background/Purpose: Activated macrophages (Mph) can be subdivided in at least 2 major subgroups according to their polarization into classical pro-(M1-Mph) or anti-inflammatory (M2-Mph) subtypes. Together with fibroblasts they are considered key mediators of tissue remodeling in chronic rheumatic diseases. Mph possess high plasticity and it is suggested that an imbalance of M1/M2 Mph polarization might contribute to aberrant activation of fibroblasts (Fib) during tissue remodeling and destruction, like in rheumatoid arthritis (RA). However, the causes of disrupted M1/M2 homeostasis are still not clear. We conducted a project in order to investigate the interactions between synovial fibroblasts and differentiating and polarized macrophages in vitro.

Methods: Macrophages were differentiated from purified monocytes out of peripheral blood from healthy donors and polarized into M1 and M2 Mph over several days. Expression of CD80 TNFa and IL-12 were considered representative for M1 and expression of CD163, CD206 and IL-10 for M2. Fib isolated from osteoarthritis (OA) patients at passage 4-8 were co-cultured with cell culture supernatant (SN) of polarized M1/M2-Mph. Similarly, Fb-SN was added to differentiating Mph. For some experiments Fib were pre-stimulated with TNFa/IL1b to induce a proinflammatory RA-like phenotype. Fib read-out included cytokine and MMP secretion and transcriptional expression of key markers COX-2, COL-1 and aSMA.

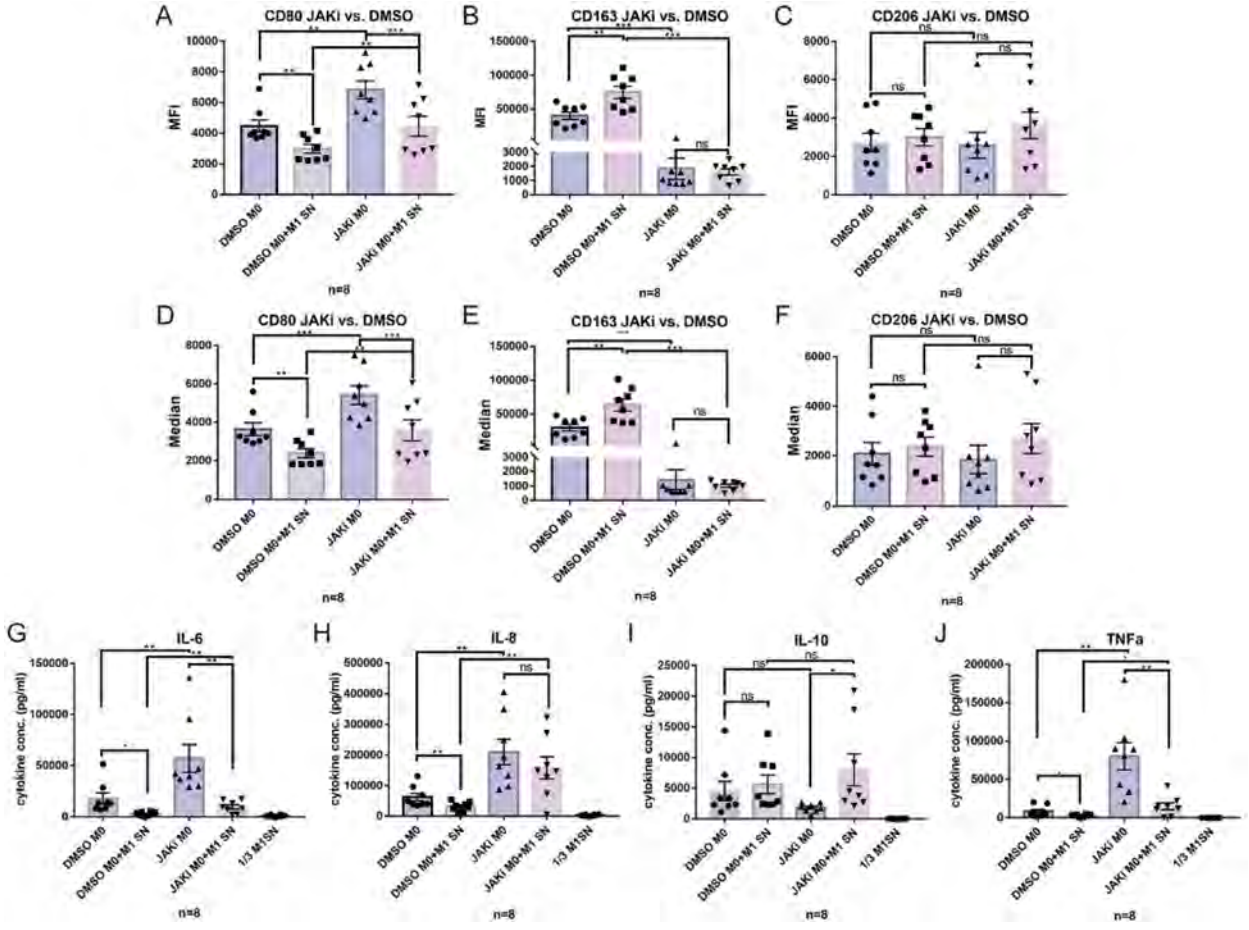
Results: M1-SN had both pro-inflammatory and pro-fibrotic effects on Fib, as evidenced by upregulation of COX-2, aSMA and COL-1. In addition, M1-SN induced a significant upregulation of IL-6 and MMP-3 in Fib. These effects were significantly suppressed in presence of the selective JAK inhibitor (JAKi) Upadacitinib. M2-SN slightly downregulated IL-6, MMP-3, COX-2 and aSMA expression. SN from TNFa/IL-1b pre-stimulated Fib induced a polarization of undifferentiated M0 Mph towards the M2 phenotype as evidenced by expression of high levels of CD163, CD206 and IL-10. Addition of an anti-IL-6 receptor Ab (tocilizumab) and JAKi both inhibited development of this anti-inflammatory phenotype. M0 polarization towards M2 was also induced by M1-SN: CD163 was significantly upregulated by M1-SN, while IL-6, IL-8 and TNFa were evidently downregulated by M1-SN. On the other hand, JAKi forcefully suppressed the effects of M1-SN on M0 Mph.



The Effects of M1/M2 Mph Supernatant on Synovial Fibroblasts in Vitro



The Effects of TNFa/IL1b Pre-stimulated Synovial Fibroblasts Supernatant on M0 Mph in Vitro



The Effects of M1 Mph Supernatant on M0 Mph in Vitro

Conclusion: Polarized Mph have s strong modulatory effect on the Fibs. On the other hand, pre-activated pro-inflammatory Fib and polarized M1 themselves have also a significant effect on Mph polarization, supporting M2 differentiation. JAKi abrogate proinflammatory and profibrotic responses in Fib, while JAKi and anti-IL-6 also inhibited differentiation of Mph into M2, thereby pointing to a new functional aspect of this Immunomodulator.

Effect of the Inflammatory Microenvironment Induced by Monocytes on Fibroblasts and Modulatory Action of Human Dental Pulp Stem Cells

Monia Maccaferri[1], Alessandra Pisciotta[1], Gianluca Carnevale[1], Carlo Salvarani[2] and **ELISA PIGNATTI**[1], [1]University of Modena and Reggio Emilia, Modena, Italy, [2]Azienda USL -IRCCS di Reggio Emilia and Università di Modena e Reggio Emilia, Reggio Emilia, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The pathophysiology of viral infection is related to elevated levels of inflammatory cytokines therefore also of the excessive activation of monocytes. Prolonged inflammation can cause fibrosis, a process involving the accumulation of fibrous connective tissue and excess of extracellular matrix (ECM). The effector cells of fibrosis are myofibroblasts, an activated phenotype of fibroblasts. Monocytes can be modulated in their action by the release of paracrine factors from adult stem cells. Human dental pulp stem cells (hDPSCs) appear to be cells of low immunogenicity and easily isolated. The aim of this study was to observe the action exerted by monocytes in an inflammatory and profibrotic environment of viral induction and the effect on fibroblasts, as well as the modulating role of hDPSCs on monocytes and consequently on fibrosis.

Methods: An in vitro model of fibroinflammation was set up using human fibroblasts and monocytes isolated respectively from the skin and blood of healthy donors. Monocytes were activated with an imidazoquinoline (CL097) to simulate a viral infection and then characterized by cytofluorimetric analysis. Fibroblasts were treated with activated monocyte conditioned medium and the effect was verified by real-time PCR and western blot. Monocytes and hDPSCs were then co-cultured for 48 hours. Subsequently, the fibroblasts were treated for different times with the conditioned medium obtained from the co-cultures. The expression level of the main inflammatory mediators and profibrotic factors was determined by real-time PCR, western blot, immunofluorescence and ELISA immunoassay.

Results: Already after 48 hours of treatment with the conditioned medium of activated monocytes, a significant increase in the expression of proinflammatory cytokines (IFNγ, IL-6 and *IL-1β*), immunomodulatory genes (*CD55, COX2, CCL2* and *HLA-DRB1*), *Col1A1* and metalloproteinase 2 (*MMP2*) was observed in fibroblasts, while only prolonged exposure to the conditioned medium for seven days induced an increase in the other profibrotic genes *FN1*, *ICAM1* and *αSMA* (IFNγ $p < 0,05$, the others $p < 0,0001$) (FIG.1).

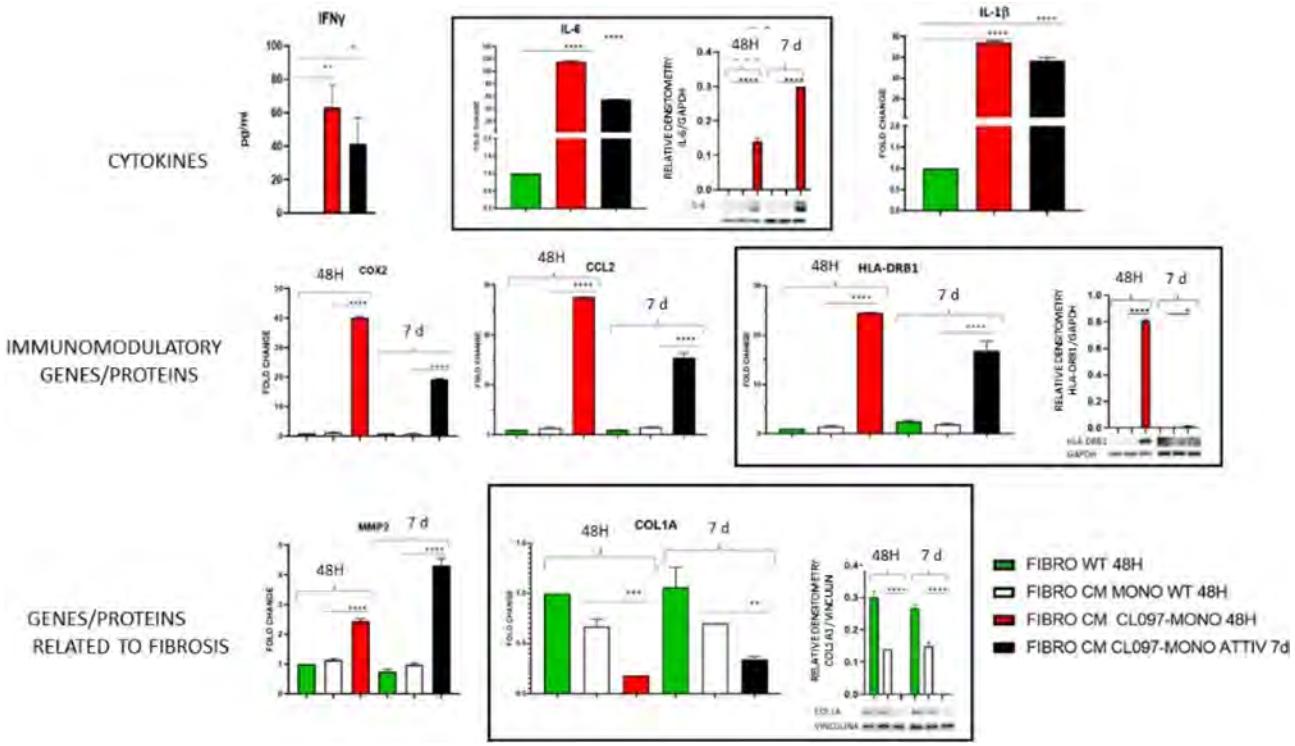

FIGURE 1 FIBROBLASTS TREATED FOR 48 HOURS OR 7 DAYS WITH CONDITIONED MEDIUM OF MONOCYTES ACTIVATED OR NOT WITH CL097

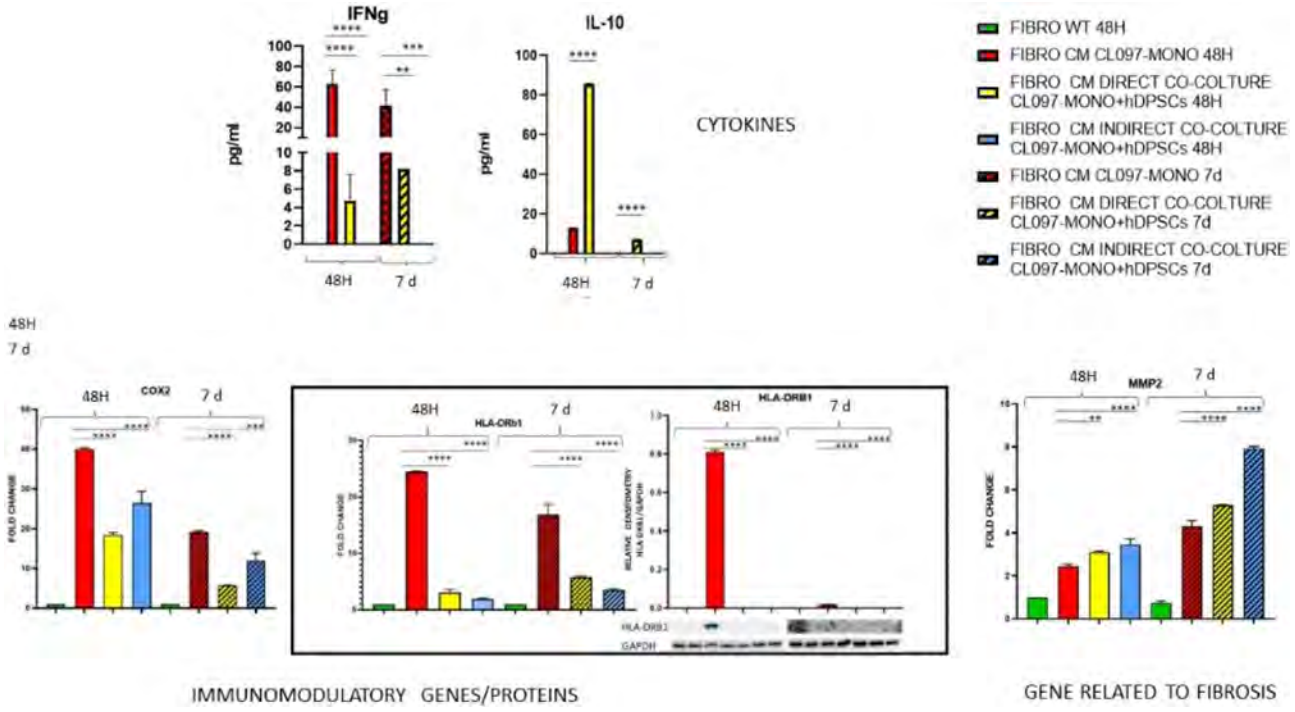

FIGURE 2 FIBROBLASTS TREATED FOR 48 HOURS OR 7 DAYS WITH CONDITIONED MEDIUM OBTAINED FROM DIRECT/INDIRECT CO-COLTURE OF CL097-MONOCYTES + hDPSCs

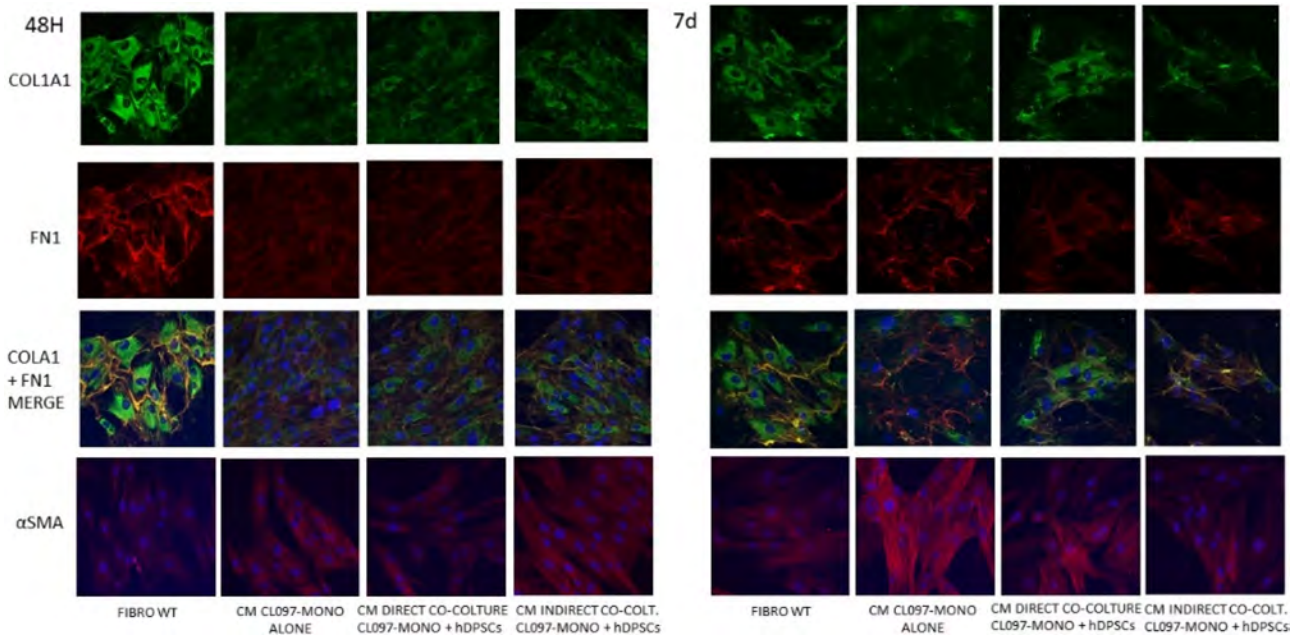

FIGURE 3 FIBROBLASTS TREATED FOR 48 HOURS OR 7 DAYS WITH CONDITIONED MEDIUM OF DIRECT/INDIRECT CO-COLTURE OF CL097-MONOCYTES + hDPSCs. COL1A1, FN1 AND αSMA PROTEINS WERE REVEALED IN FIBROBLASTS BY IMMUNOFLUORESCENCE

Treatment for 48 hours of fibroblasts with the conditioned medium of activated monocytes maintained in co-culture with hDPSCs induced a reduction in the expression of *COX2* ($p < 0{,}001$) and *HLA-DRB1* ($p < 0{,}0001$), an increase in the expression of *MMP2* ($p < 0{,}0001$) and *Col1A1* ($p < 0{,}05$), decrease in IFNγ ($p < 0{,}001$) and increase in IL-10 ($p < 0{,}0001$) secreted by fibroblasts, effect which persisted even after 7 days of treatment (FIG.2, 3).

Conclusion: The induction of a viral-type inflammatory environment by activated monocytes results in the early overexpression of proinflammatory cytokines and immunomodulatory genes and subsequently profibrotic genes in fibroblasts. The anti-inflammatory effects exerted by hDPSCs on monocytes are revealed in the indirect modulation of the immune response of fibroblasts by downregulation of HLA-DRB1, COX2, IFNγ and upregulation of IL-10. hDPSCs also exert antifibrotic and ECM remodeling effects by inhibition of αSMA and increased expression of Col1A1 and MMP2. The next step will be to evaluate the role of hDPSCs secretoma in inflammatory conditions to modulate the fibrotic process.

Assessing the Ability of Human Dental Pulp Stem Cells to Modulate the Macrophages Phenotype

Monia Maccaferri, Alessandra Pisciotta, Gianluca Carnevale, Carlo Salvarani and **ELISA PIGNATTI**, University of Modena and Reggio Emilia, Modena, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophages have been found to have a key role in Rheumatoid Arthritis. Depending on the microenvironment, macrophages exist in a dynamic functional state which could be mainly grouped in a pro-inflammatory state (M1 macrophages) and an anti-inflammatory state (M2 macrophages). *In vitro*, these conditions can approximately be reproduced by means of cytokines such as lipopolysaccharide (LPS) and IFNγ for M1 classically polarized macrophages or IL-4 and IL-13 for M2 alternatively polarized macrophages. Human dental pulp stem cells (hDPSCs) are adult stem cells which have been found to exert immunomodulatory functions both by cell-to-cell contact and in a paracrine way. The aim of our study was to assess the ability of hDPSCs to modulate the phenotype of human macrophages.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from buffy coats by density-gradient centrifugation. PBMCs were differentiated to macrophages for 7 days in RPMI supplemented with M-CSF to obtain M0 macrophages. M0 macrophages were then polarized for 48 hours to M1 with LPS and IFNγ and to M2 macrophages with IL-4 and IL-13. hDPSCs were seeded at 1:1 ratio both directly on macrophages and into Transwell insert for indirect co-culture. Macrophages in direct co-culture with hDPSCs were separated with human anti CD14 micro beads. Protein expression was measured by Western Blot. Gene expression was assessed by RT-PCR.

Results: Surface markers expression analysis showed that M1 macrophages were *CD80*$^{+}$, *HK2*$^{+}$, *HLA-DRB1*$^{+}$($p < 0.0001$). Following co-culture, *CD80* and *HLA-DRB1* gene expression was further increased ($p < 0.0001$) (Fig. 1a), data were also confirmed by protein expression (Fig. 1b). M1 macrophages showed elevated expression of the transcriptional regulators *JAK-1*, *-2*, *-3,STAT3*, *NF-kB* and of pro-inflammatory cytokines (*IL-6*, *TNFα*, *IL-1β*, *IFNγ*) levels ($p < 0.0001$) (Fig. 2). They also express elevated levels of the immune modulators *IDO*, *PD-L1* and *ICAM-1* confirmed by protein expression (Fig. 3a, -b) and, of *Fas-L* and *COX2* (Fig. 3a). The indirect co-culture enhanced the expression of *STAT3*,

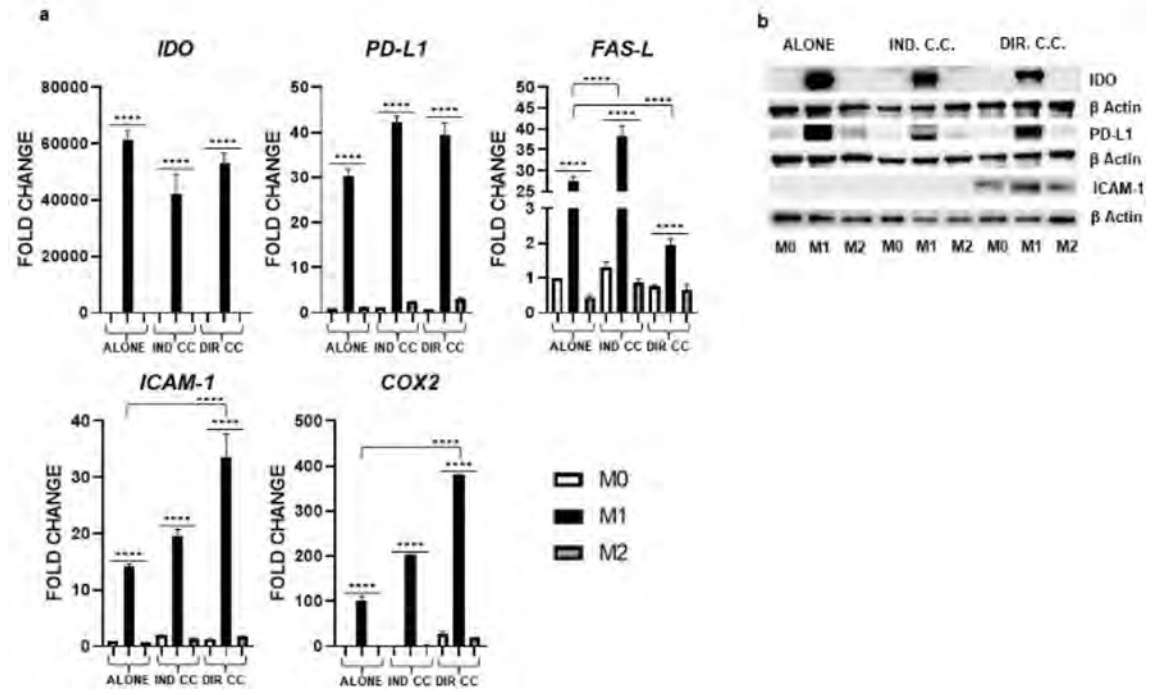

Figure 3. Immune-modulator expression. a) Relative mRNA expression as fold change. b) Representative western blot lanes. ****p<0.0001. Indirect co-culture (IND CC), direct co-culture (DIR CC).

NF-kB, *IL-1β, IL-6, Fas-L* and decreased *IFNγ* expression ($p < 0.0001$) (Fig. 2, 3). The direct co-culture increased *IL-6,-ICAM-1* and *COX2* expression and diminished *IFNγ* and *Fas-L* expression ($p < 0.0001$) (Fig. 2, 3). M2 macrophages were *CD206*$^{+}$*, DC-SIGN*$^{+}$ *and ALOX15*$^{+}$ and only the direct co-culture was able to enhance the *HLA-DR, CD206*, *DC-SIGN* and *IL-10* expression ($p < 0.0001$) (Fig. 1, 2). The direct co-culture increased the expression of *CD206* and *IL-10* in M0 non-polarized macrophages too ($p < 0.0001$) (Fig. 1, 2).

Conclusion: The biological factors secreted by hDPSCs supported the macrophages response to inflammation activating the STAT3 and NF-kB pathways and, in contrast, enhancing the inhibitory membrane molecule FasL expression. The cell-to-cell contact was shown to be the best immunomodulatory way reducing the IFNγ expression in inflammatory condition. Further, in presence of anti-inflammatory cytokines, hDPSCs directly promoted the polarization of M0 macrophages towards M2 phenotype and enhanced IL-10 expression which is a key cytokine in limiting the host immune response.

Menghao Zhang[1], Na Kang[2], Xin Yu[1], Wanli Liu[2] and Wenjie Zheng[1], [1]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Beijing, China, [2]Beijing Key Lab for Immunological Research on Chronic Diseases, School of Life Sciences, Institute for Immunology, Tsinghua University, Beijing, China

Background/Purpose: Behçet's disease (BD) is a chronic vasculitis characterized by polymorphonuclear neutrophils (PMNs) hyperactivation with unknown etiology. The over-productions of neutrophil extracellular traps (NETs) and pro-inflammatory cytokines are increasingly implicated in BD (Clin Immunol. 2023; 250:109318). Aberrant metabolic intermediates have been identified as endogenous danger signals to elicit natural immune responses (Trends Endocrinol Metab. 2020; 31:712-724), yet relevant mechanisms in BD remained unexplored. Farnesyl pyrophosphate (FPP) is a key isoprenoid intermediate in the mevalonate (MVA) pathway that triggers pro-inflammatory responses (Sci China Life Sci. 2015; 58:328-35) and cell death (PLoS Biol. 2021;19:e3001134). Thus, we aimed to reveal the immunometabolic aberrations of BD, and highlight the pathogenic implications of FPP in BD-PMN hyperactivation.

Methods: Focusing on immunometabolism, we integrated and analyzed our published data of serum lipidomics and peripheral blood immunocyte transcriptomics. Transcriptomic analysis and qRT-PCR validated the enhanced MVA pathway and suggested its metabolite FPP accumulated in BD-PMN.To elucidate the involvement of the MVA pathway in BD-PMN hyperactivation, we intervened with its key enzymes using appropriate inhibitors and agonists (Fig 2). We assayed the level of FPP in serum and PMN from BD and HC by targeted mass spectrum, and clinical correlations by Pearson correlation analysis. We stimulated PMNs with FPP, and measured their production of pro-inflammatory cytokines by qRT-PCR and NETs by

immunofluorescence. Then, we stimulated vascular endothelial cells (VECs) with the supernatant from FPP-stimulated PMNs and measured the expression of activation/injury markers in the VECs by qRT-PCR.

Results: Our multi-omics analysis revealed that steroid biosynthesis was significantly elevated in BD serum, with consistent metabolic aberration noted only in PMN (Fig 1A-1B), particularly in cholesterol biosynthesis (Fig 1C). More precisely, the upregulation of enzymes upstream of FPP suggested the enhanced MVA pathway and accumulated intermediate FPP (Fig 2). Furthermore, FPP was confirmed to be the key component of the MVA pathway promoting PMN activation, as its inhibition decreased PMN cytokine productions (zoledronic acid, $p< 0.0001$), while its metabolism inhibition had facilitative effects (BPH-652, $p< 0.0001$), and vice versa (FIN56, $p< 0.0001$). FPP was overexpressed in BD serum ($p=0.0022$) and PMN ($p=0.0397$), and positively correlated with BD disease activity. Notably, FPP specifically promoted PMN to produce proinflammatory cytokines and NETs in a dose-dependent manner, further damaging VECs and leading to the

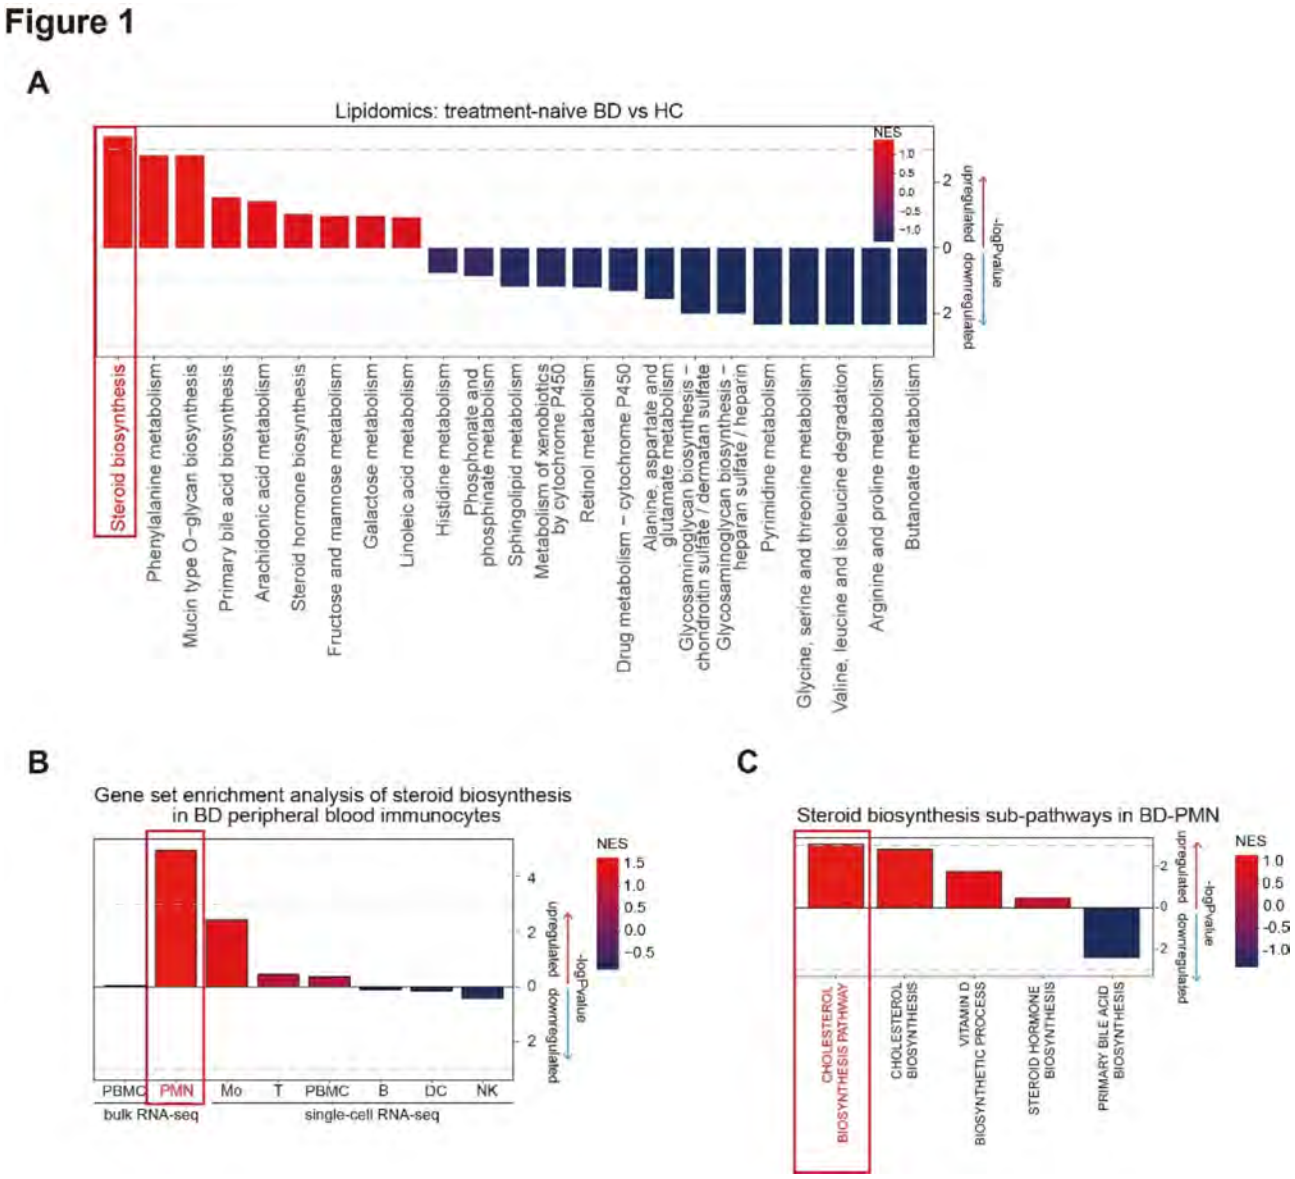

Figure 1: Elevated Steroid Biosynthesis in BD Serum and PMN. A: Lipidomic analysis between treatment-naïve BD and HC serum. B: Gene Set Enrichment Analysis (GSEA) of steroid biosynthesis pathway in BD and HC peripheral blood immunocytes, including bulk RNA-seq of PBMC (GSE198533), PMN (GSE205867) and single-cell RNA-seq of PBMC (GSE198616). C: GSEA of steroid synthesis sub-pathways, such as bile acids, steroid hormones, vitamin D, and cholesterol synthesis, in BD and HC PMN (GSE205867).

overexpression of molecules related to inflammation (TNF-α, p< 0.0001), adhesion (ICAM-1, p=0.0006), and permeability (VEGF, p=0.0004). And BD-PMN was hyper-responsive to FPP (Fig 3).

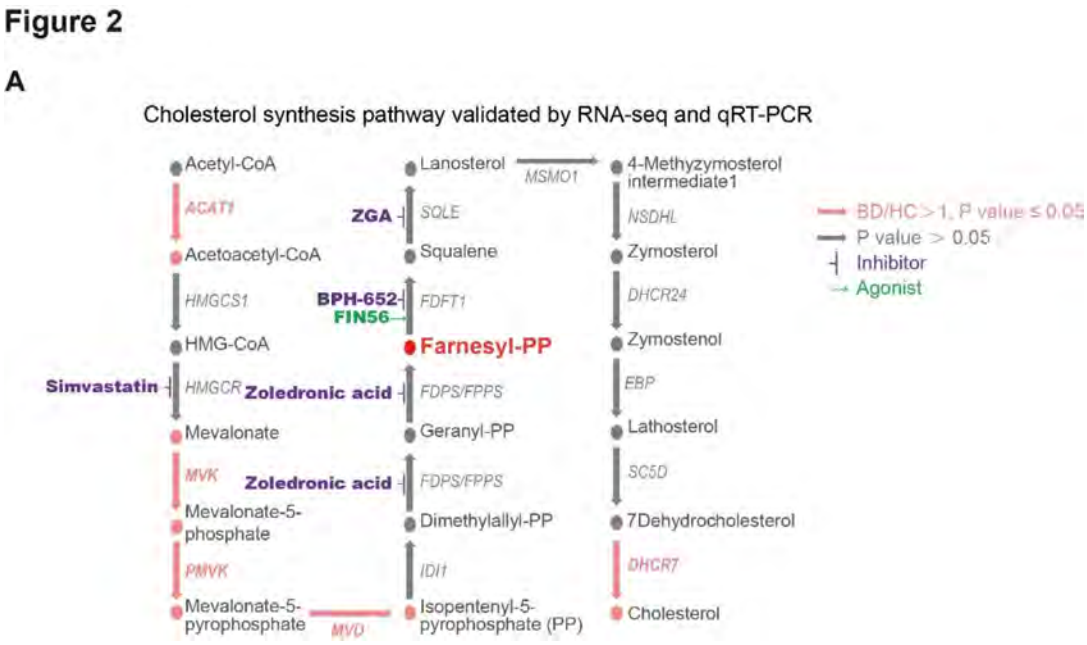

Figure 2: Aberrant Mevalonate Pathway in BD-PMN. A: A schematic diagram of the cholesterol biosynthesis pathway. Enzymes with significantly elevated expression levels in BD-PMN, as verified by both RNAseq and qRT-PCR (N = 20), were marked in red. Potential agonists and inhibitors were highlighted with green and purple arrows, respectively.

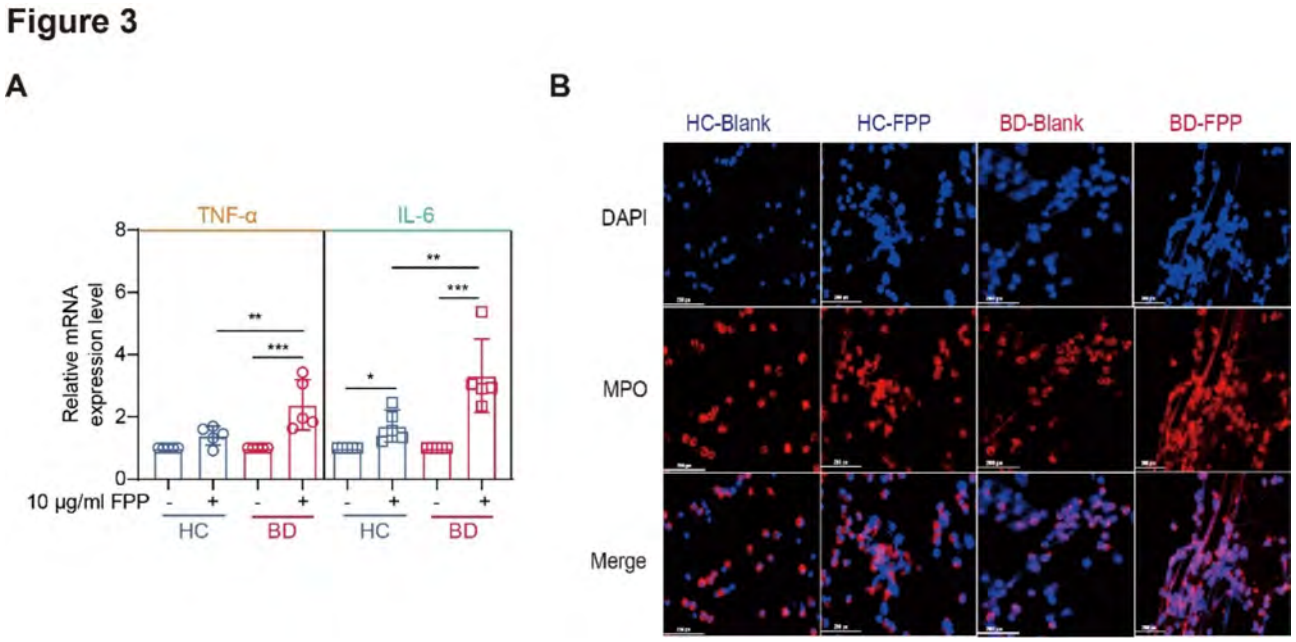

Figure 3: FPP Enhances Pro-Inflammatory Cytokine Production and NETosis in PMNs, with Hyper-Responsiveness in BD-PMN. A: qRT-PCR measurement of TNF-α and IL-6 expression levels in PMNs from BD (red), and HC (blue), after stimulation with 10 μg/ml FPP (N=5). *, p<0.05; **, p<0.01; ***, p<0.001; B: Representative immunofluorescence staining diagrams of 60 μg/ml FPP-induced NETosis in PMNs from BD and HC, showing MPO (red) and DAPI-stained nuclei (blue); scale bar = 50 μm. MPO: Myeloperoxidase.

Conclusion: Overall, our study revealed the aberrant immunometabolic profiles of BD and highlighted the effect of FPPon promoting PMN hyperactivation, providing insight into the potential of targeting FPP for BD treatment. Further investigations are in progress to elucidate the mechanisms.

Discovery and Characterization of a Selective, Orally Bioavailable PAD4 Inhibitor to Target NETs Driven Autoimmune and Inflammatory Diseases

Min Yang[1], song feng[1], yuling wen[1], Xiaoming ren[1], Huijuan Li[1], lili yao[1], Zhi xie[2] and Wenge zhong[1], [1]Regor Therapeutics, Shanghai, China, [2]Regor Pharmaceuticals, Inc., San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Protein arginine deiminases (PAD) 4 is an enzyme that catalyzes the conversion of protein-embedded arginine to citrulline. It is essential for neutrophil extracellular traps (NETs) formation which is implicated in multiple immune-mediated pathological conditions. Importantly, PAD4 deficiency does not lead to increased infection of immune suppression, suggesting that PAD4 is an attractive therapeutic target for autoimmune and inflammatory diseases. However, the development of a drug-like PAD4 inhibitor has been challenging. Here, we report the discovery and characterization of a potent, selective and orally bioavailable small molecule PAD4 inhibitor.

Methods: By leveraging Computer Accelerated Rational Design (rCARD^{TM}) and Structure-Based Drug Discovery (SBDD) platforms, we rationally designed and synthesized a small molecule RGT-691. The biochemical activities against PAD4 and PAD2 were measured by ammonia release assays using BAEE as the substrate. The cellular activity was determined by inhibition of citrullination of histone 3 (Cit H3) in differentiated HL-60 cells stimulated with calcium ionophore (A23187). The absorption (MDCK based permeability assay and kinetic solubility), distribution (free fraction in plasma), and metabolism (liver microsomes, hepatocytes, plasma stability) were characterized in *in vitro* assays. The pharmacokinetic study was performed in preclinical species to evaluate the exposure and bioavailability. Proof-of-mechanism study was performed using the LPS challenged airway inflammation mouse model in which the bronchial alveolar lavage fluid (BALF) was collected to measure the concentration of Cit H3 and pro-inflammatory cytokines as efficacy readouts.

Results: The biochemical and cellular activities of RGT-691 were determined. Its IC_{50} in PAD4 ammonia release assay is 46 $\pm$ 12 nM; while its IC_{50} against PAD2 is > 10 mM. It demonstrated a cellular IC_{50} of 22 $\pm$ 11 nM in A23187 stimulated differentiated HL-60 cells. The binding mode of RGT-691 with PAD4 was determined at 2.8 Å by crystallography, providing structural basis for the high potency and selectivity of RGT-691 for PAD4. RGT-691 demonstrated moderate permeability and good solubility. PK studies in mice showed good drug exposures via oral dosing and achieved desired efficacious exposure. In LPS induced airway inflammation model, RGT-691 potently inhibited neutrophil trafficking to lung, reduced the level of dsDNA and Cit H3. Furthermore, it suppressed the pro-inflammatory cytokines including TNF-a and IL-6 in a dose-dependent manner.

Conclusion: In summary, RGT-691 is a potent, selective, orally bioavailable small molecule PAD4 inhibitor which provides therapeutic opportunities in multiple NETs-driven autoimmune and inflammatory diseases.

Circulating Monocytes in RA, SSc, and SLE Have Radically Altered and Unique Transcriptional & Epigenetic Profiles

Kieran Woolcock[1], Nila Servaas[2], Maarten van der Kroef[2], Stephen Delaney[3], John Cole[1], Aridaman Pandit[2] and Carl Goodyear[1], [1]University of Glasgow, Glasgow, United Kingdom, [2]University Medical Center Utrecht and Utrecht University, Utrecht, Netherlands, [3]Research and Early Development, Respiratory and Immunology (R&I), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA), Systemic lupus erythematosus (SLE), and Systemic sclerosis (SSc) are all systemic rheumatic autoimmune diseases with a dysregulated myeloid compartment. Monocytes are poised to rapidly mobilise in large numbers to sites throughout the body, where they provide pro-inflammatory or pro-resolving roles. A key and unaddressed question is are circulating monocytes similarly perturbed on the transcriptional and epigenetic level across different rheumatic diseases. Despite the extensive research in the field, it is still poorly understood how these profiles influence the response to stimuli in disease environment. Understanding this may help understand how monocytes respond at disease sites and how this varies across different conditions. To comprehensively profile monocytes, we performed paired RNA-Seq and ChIP-Seq of activating histone 3 lysine 4 tri-methylation (H3K4me3), and repressive histone 3 lysine 27 tri-methylation (H3K27me3), modifications.

Methods: Fresh peripheral blood samples were collected from active RA patients (DAS28 > 2.7), SLE patients (1997 ACR criteria), SSc (ACR/EULAR 2013 criteria), as well as age- and gender-matched healthy controls (HC). SSc patients were subdivided into diffuse cutaneous (dcSSc), limited cutaneous SSc (lcSSc), and early SSc (eaSSc) subsets. CD14+ monocytes were isolated from peripheral blood and genome-wide profiling of RNA (HC, n=15; RA, n=9; SLE, n= 10; dcSSc, n=10; lcSSc, n=10; eaSSc, n=10), H3K4me3 (HC, n=20; RA, n=20; SLE, n=8; dcSSc, n=9; lcSSc, n=8; eaSSc, n=10), and H3K27me3 (HC, n=15; RA, n=10; SLE n=8, dcSSc, n=9 ; lcSSc, n=7; eaSSc, n=10) was performed. Statistical significance was determined using an adjusted $p < 0.05$ & absolute log2fold > 0.58 for RNA-Seq or an adjusted $p < 0.05$ for ChIP-Seq.

Results: We observed substantial differentially expressed genes (DEGs) in RA monocytes in comparison to HC (3,504 DEGs), whereas much fewer transcriptional changes were observed in SLE and SSc subsets. Similarly, much greater changes were seen in active H3K4me3 profiles in RA in comparison to HC (3,141 differential peaks), than those seen in SLE and SSc subsets (50 and 10, respectively). Moreover, the majority (~65%) of increased H3K4me3 peaks in RA were bivalent; contained a repressive H3K27me3 peak with either no or very low transcriptional expression. Notably, the H3K27me3 profile in RA was comparable to those seen in HC. This was also the case lcSSc and SLE. In contrast,

numerous increases in repressive H3K27me3 peaks were identified in dcSSc and eaSSc (424 and 647, differential peaks respectively).

Conclusion: We found that systemic rheumatic diseases displayed a range of transcriptional and epigenetic profiles. Of note, we identified that in RA, there is an abundance of active H3K4me3 modifications that occur in repressed (H3K27me3) and transcriptionally inactive loci. We propose that the increased epigenetic activation of bivalent genes in RA could prime these monocytes for activation within the diseased joint microenvironment and could subsequently detrimentally contribute to disease pathogenesis.

Identification of Specific Monocyte Epigenetic Signatures in Sarcoidosis and Tuberculosis

Marie Robert[1], Nader Yatim[2], Arthur Mageau[3], Nicolas Charles[4], Tiphaine Goulenok[2], Tom Dott[1], Violaine Saint Andre[1], Darragh Duffy[1] and Karim Sacre[3], [1]Institut Pasteur Paris, Paris, France, [2]Assistance Publique Hopitaux de Paris, Paris, France, [3]Université Paris Cité, Paris, France, [4]INSERM, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is an inflammatory disease characterized by granuloma tissue lesions that most commonly affect the lungs, but can target any other organ. While the cause of sarcoidosis and the mechanisms underlying granuloma formation and progression are still unknown, the disease shares many similarities with tuberculosis, including histological characteristics, organ tropism and clinical presentation. We hypothesized that circulating monocytes from patients with sarcoidosis or tuberculosis may retain a specific epigenetic signature, distinguishing from healthy controls and each disease.

Methods: To test this, we performed genome-wide epigenetic profiling of circulating monocytes from newly diagnosed patients with tuberculosis or sarcoidosis using the CUT&Tag technology, and assessed the acetylation of lysine 27 of histone 3 (H3K27Ac) (the most appropriate histone mark to identify enhancers of expressed genes).

Results: Using unbiased principal component analysis (PCA) of genome-wide histone H3K27Ac profiles we identified genomic regions that specifically separated sarcoidosis patients, from tuberculosis patients and healthy donors (**Figure 1**). There were 648 H3K27Ac enriched regions of the genome in sarcoidosis as compared to tuberculosis, while 203 regions were H3K27Ac depleted ($log_2FC > 0.3$ or < 0.3, adj-$p < 0.1$). Interestingly, the genes associated with these regions can discriminate sarcoidosis from tuberculosis patients.

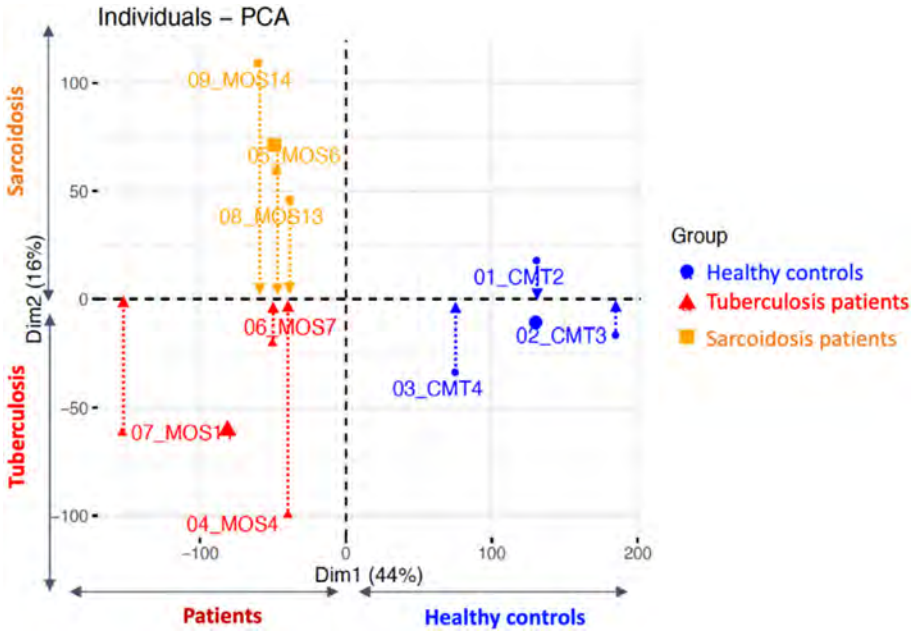

Figure 1. Unbiased principal component analysis (PCA) of genome-wide histone H3K27Ac profiles using CUT&Tag technology.

Conclusion: Our findings provide evidence that there are distinct monocyte epigenetic signatures associated with sarcoidosis and tuberculosis, and raise new and challenging perspectives on the role played by trained immunity in inflammatory diseases. Ongoing work will extend this analysis and integrate with additional immune phenotyping and functional assays for a more comprehensive understanding of sarcoidosis.

Monosodium Urate Crystals Activate an Immune Tolerance Program That Restrains the Activation of Inflammatory Signaling in Macrophages During Gout Flares

Mohnish Alishala[1], Stephen Calderon[1], Anyan Chen[1], Monica Guma[2], Christopher glass[1] and Isidoro Cobo[1], [1]University of California San Diego, San Diego, CA, [2]University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most frequent form of inflammatory arthritis, with episodes of self-resolving acute inflammation in the joint caused by the deposition of monosodium urate crystals (MSUc). MSUc activates a battery of transcription factors and epigenetic regulators in macrophages during gout flares, which orchestrates a unique inflammatory and metabolic program. Much effort has been put into understanding the role of cytokine and inflammatory mediators, including

inflammasome activation during gout flares. However, the mechanisms underlying the activation of a resolution program and the induction of immune tolerance in macrophages during the resolution phase of gout flares remain unknown.

Methods: We stimulated bone marrow-derived macrophages (BMDM) with LPS or MSUc for 10 min, 30 min, one hour, two hours and five hours and performed RNA-Seq. We primed BMDM with MSUc before stimulation with LPS for five hours and performed RNA-Seq. We incubated BMDM with the conditioned media of BMDM stimulated with MSUc before stimulation with LPS and performed RNA-Seq and promoter scanning analysis on the differentially expressed genes.

Results: We found that stimulation of BMDM with MSUc leads to a divergent response compared to that observed in BMDM stimulated with LPS (Figure 1A). Furthermore, the genes that are uniquely upregulated by LPS are significantly downregulated in BMDM stimulated with MSUc (Figure 1B, left), and the genes uniquely upregulated by MSUc are significantly downregulated in BMDM stimulated with LPS (Figure 1B, right). This data indicates that MSUc downregulates the transcriptional program induced by LPS.

Furthermore, we found that priming the BMDM with MSUc ablates the effect of LPS (Figure 2A, grey square). Interestingly, a similar effect is observed when BMDM are primed with MSUc, but we let the BMDM rest without MSUc for one, two, five and eight hours (Figure 2A, grey square). This data indicates that MSUc signaling ablates the signaling induced by LPS by activating a macrophage immune memory program.

We next investigated whether a non-cell autonomous activation mediates the anti-inflammatory program by MSUc in neighbouring cells. We incubated BMDM for one, two and eight hours with the conditioned media of BMDM stimulated with MSUc, before stimulation with LPS. Interestingly, the media conditioned by cells stimulated with MSUc abrogates the BMDM response to LPS (Figure 2B, grey square).

In addition, we demonstrated that MSUc activates the BHLHE/circadian clock and LXR TF while reducing interferon response factor activity (Figure 3A-F).

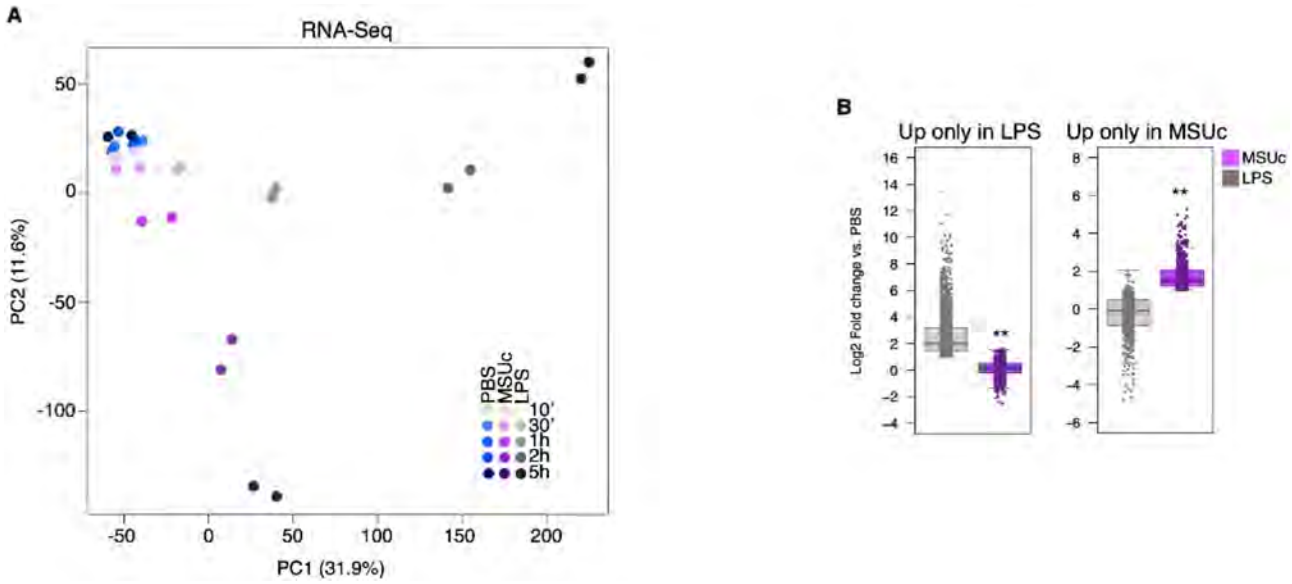

Figure 1. MSUc activates a distinct transcriptional program in macrophages (A) Principal component analysis of RNA-Seq experiment of BMDM stimulated with PBS, LPS or MSUc at various time points (n=2/condition). (B) Boxplot showing the genes uniquely upregulated by LPS (left) or MSUc (right) and their degree of expression in BMDM stimulated with LPS or MSUc (n=2/condition). Except for RNA-Seq experiments, Student's T-test was used to calculate statistical significance.

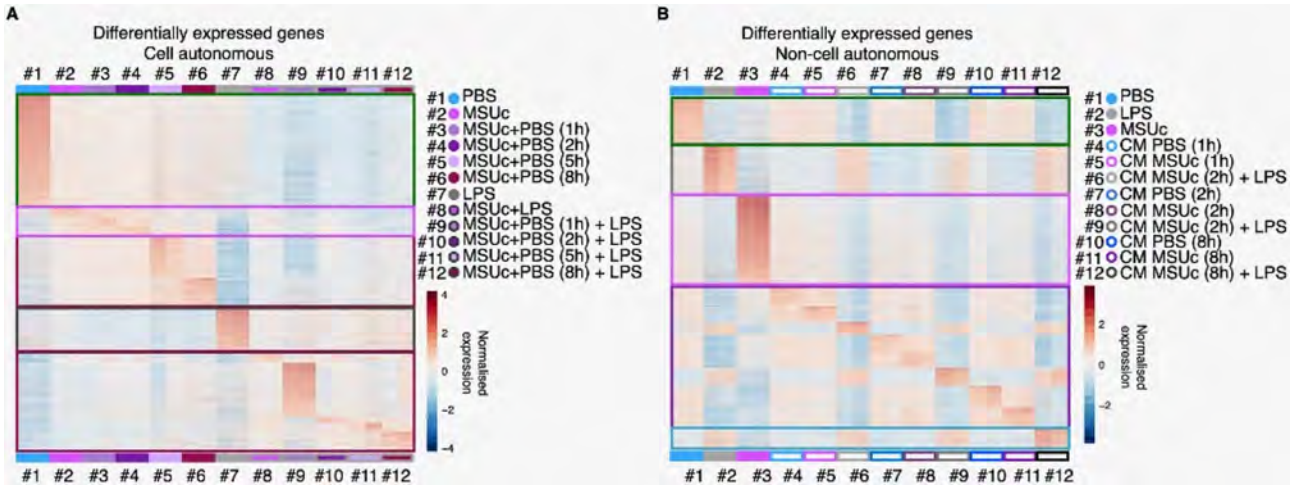

Figure 2. MSUc signaling ameliorates the effect of LPS and activates an immune memory program in macrophages. (A) Pheatmap of differentially expressed genes of BMDM stimulated with LPS or MSUc under various conditions (n=2/condition). (B) Pheatmap of differentially expressed genes of BMDM stimulated with LPS or MSUc or conditioned media from BMDM stimulated with MSUc under various conditions (n=2/condition). MSUc +PBS (1h, 2h, 5h or 8h)= BMDM stimulated with MSUc, culture media was removed, and fresh media without MSUc was added for 1h, 2h, 5h or 8h, respectively. CM= conditioned media. Except for RNA-Seq experiments, Student's T-test was used to calculate statistical significance.

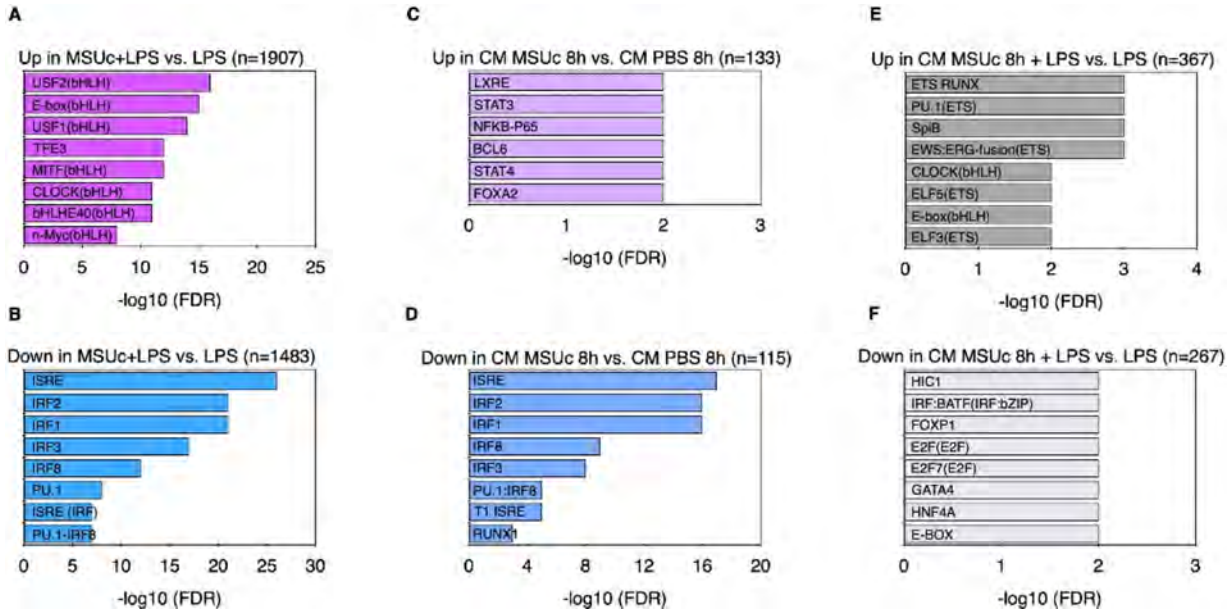

Figure 3. MSUc leads to the activation of the BHLHE/Circadian clock transcription factor and reduces the activity of interferon response factors. (A-F) HOMER analysis of the promoter of differentially expressed genes at various conditions from experiments shown in Figure 2. CM= conditioned media.

Conclusion: Our data indicate that MSUc activates an anti-inflammatory, pro-resolution program with immune memory properties governed by BHLHE/circadian clock TF and abrogates interferon response factors.

Soluble Uric Acid Is an Endogenous Inhibitor of CD38

Shijie Wen[1], Hiroshi Arakawa[1], Shigeru Yokoyama[2], Yoshiyuki Shirasaka[1], Haruhiro Higashida[3] and **Ikumi Tamai**[1], [1]Faculty of Pharmaceutical Sciences, Kanazawa University, Kanazawa, Japan, [2]Research Center for Child Mental Development, Kanazawa University; Division of Socio-Cognitive-Neuroscience, United Graduate School of Child Development, Osaka University, Kanazawa University, Hamamatsu University School of Medicine, Chiba University and University of Fukui, Kanazawa University, Kanazawa, Japan, [3]Research Center for Child Mental Development, Kanazawa University, Kanazawa, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: CD38 is the main NAD^+-degrading enzyme that plays a key role in innate immunity, aging, cancer, and metabolic disorders. Pharmacological inhibition of CD38 has been proposed as a promising strategy for various diseases, including rheumatic diseases. Recently, we and another laboratory demonstrated that monosodium urate (MSU) crystals upregulate the protein expression of CD38 to promote inflammation. In the present study, we aim to clarify the effect of soluble uric acid (sUA) on CD38 and explore its unique role in purine metabolic pathways.

Methods: In enzyme assays, recombinant hCD38, and homogenates or crude membrane fractions of cells and tissues were used as enzyme sources, nicotinamide guanine dinucleotide (NGD) and epsilon-NAD^+ were used as substrates for the measurement of CD38 activity. In metabolic assays, NAD^+ was incubated with recombinant hCD38 in the presence or absence of sUA or other CD38 inhibitors. Then, NAD^+ concentrations in the reaction buffers were measured by LC-MS/MS.

Results: sUA directly inhibited the hydrolase and cyclase activities of CD38. Kinetic analysis revealed that sUA is a non-competitive inhibitor of CD38, suggesting its binding to the allosteric sites of CD38. The inhibitory effects of sUA on CD38 activity were reversible. The precursors and metabolite of sUA hardly inhibited the enzymatic activity of CD38. A structural comparison using analogs revealed that 1,3-dihydroimidazol-2-one is the main functional group for CD38 inhibition, although the adjacent uracil-like heterocycles are also essential. Metabolic assays using NAD^+ as substrate also confirmed the direct inhibitory effect of sUA on CD38. In addition, these findings were further verified by several physiological and pathological models in WT and CD38 KO mice.

Conclusion: sUA directly inhibits CD38 via a reversible non-competitive mechanism, and the inhibitory effect is restricted to sUA in purine metabolic pathways. These findings may promote understanding of sUA physiology, and the development of CD38 inhibitors. The opposite effects of sUA and MSU crystals on CD38 may explain why rapid urate lowering increases the risk of gout flares in the initiation of therapy.

Anti-Citrullinated Histone Antibody CIT-013, a Dual Action Therapeutic for Neutrophil Extracellular Trap Associated Autoimmune Disease

Maarten van der Linden[1], Sangeeta Kumari[1], Daphne Montizaan[1], Stephanie van Dalen[1], Annemarie Kip[1], Martyn FOSTER[2], Inge Reinieren[1], Elsa Neubert[3], Luise Erpenbeck[4], Tirza Bruurmijn[1], Peter van Zandvoort[1], Paul Vink[1], Eric Meldrum[5], Helmuth van Es[1] and **Renato Chirivi**[1], [1]Citryll BV, Oss, Netherlands, [2]Experimental Pathology Consultancy, Benfleet, United Kingdom, [3]Leiden Academic Centre for Drug Research, Leiden, Netherlands, [4]University Medical Center Münster, General Dermatology and Venereology, Münster, Germany, [5]Citryll BV, Basel, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophil extracellular traps (NETs) contribute to the pathophysiology of multiple inflammatory and autoimmune diseases (Chirivi *et al*., 2021; DOI: 10.1038/s41423-020-0381-3). Targeting the NETosis pathway has demonstrated significant therapeutic potency in various disease models. Here we describe a first in class monoclonal antibody (CIT-013) with high affinity for citrullinated histones H2A and H4 which inhibits NET formation and reduces tissue NET burden *in vivo* with significant anti-inflammatory consequences. CIT-013 is currently in phase 1 clinical trials with phase 2a studies in RA due to commence in 2024.

The objective of the current study was to further unravel CIT-013's mode of action. Questions which we wanted to answer are: 1) How and when does CIT-013 interfere with the NETosis pathway?; and 2) what is the faith of CIT-013 opsonized NETs and NETting neutrophils? Furthermore, we investigated whether CIT-013's epitope is expressed in rheumatoid arthritis (RA) synovial tissue.

Methods: *In vitro* life imaging studies using neutrophils and macrophages in combination with monovalent as well as bivalent CIT-013 have been performed to investigate CIT-013's mode of action. An *in vivo* lung inflammation mouse model was used to investigate CIT-013's effect on NET burden as well as phagocytic macrophages. Finally, the presence of CIT-013's epitope in human RA synovial tissues have been investigated using immunohistochemistry techniques.

Results: Detection of CIT-013 epitopes in RA synovium provides evidence that RA is an autoimmune disease with excessive citrullinated-NETs that can be targeted by CIT-013. We show that CIT-013 acts upon the final stage of NET formation, binding to its chromatin epitopes when plasma membrane integrity is compromised to prevent NET release. Bivalency of CIT-013 is necessary for NETosis inhibition. In addition, we show that CIT-013 binding to NETs and netting neutrophils enhances their phagocytosis by macrophages. Furthermore, we demonstrate that a mouse variant of CIT-013 reduces tissue NET burden *in vivo* at least in part through enhanced macrophage phagocytosis.

Conclusion: Since NETs contribute to the pathophysiology of many immune mediated inflammatory diseases, including autoimmune diseases such as RA, CIT-013's unique ability to both inhibit NET release and enhance NET clearance indicates the importance of this first in class therapeutic antibody as a new emerging therapy.

$CD14^+CD64^+$ Classical Monocytes Are the Main Producers of IL-23 at the Enthesis

Nicole McDermott[1], Thomas Macleod[1], Ala Altaie[1], Liz Straszynski[2], Robert Dunsmuir[3], Vishal Borse[3], Peter Loughenbury[3], Davide Simone[4], Stevephen Sansom[4], Christopher Buckley[4] and Dennis McGonagle[5], [1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom, [2]Leeds Institute of Medical Research at St. James's, Leeds, United Kingdom, [3]Leeds Teaching Hospital NHS Trust, Leeds, United Kingdom, [4]Kennedy Institute of Rheumatology, Oxford, United Kingdom, [5]Leeds Biomedical Research Centre, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: (0040–0064) Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IL-23 is a key cytokine involved in diseases such as psoriasis, psoriatic arthritis and spondyloarthropathies (SpA) and inflammatory bowel disease.IL-23 is produced by activated monocytes, dendritic cells and neutrophils. Guselkumab, IL-23 p19 subunit inhibitor binds to native FcR1 (CD64) but Risankizumab, another p19 blocker, has a mutated Fc domain and lacks this binding. Entheses are relatively avascular sites and may be difficult for antibody penetration and normal entheseal macrophages have inducible IL-23 protein expression. In this work we investigated the phenotype and functionality of normal and activated entheseal macrophages to explore CD64 expression and which monocyte population had predominant IL-23 expression.

Methods: Immune cell populations were flushed from spinous process; samples were obtained from patients undergoing surgery for spinal decompression with no known chronic inflammation. Cells are sorted into two populations $CD64^+$ and $CD64^-$, sorting was gated on live cell and $CD3^+$ depleted. The populations that were sorted are $CD64^+CD14^+CD16^-$ and $CD64^-CD14^-CD16^+$. Cells were cultured for 48hrs with LPS (100ng/ml) & IFN-γ (50ng/ml) and then assessed for IL-23 production by ELISA and cells phenotyped to assess their CD64 profile (N=4). Single cell sequencing has been performed on bone and soft tissue from the enthesis following collagenase digest and CD64 expression identified (N=4).

Results: Sorting profiles indicated that the $CD64^+$ cells were $CD14^+CD16^-$ and $CD64^-$ cells were $CD14^-CD16^+$, the enthesis showed some cells that are $CD64^+$ have intermediate CD14 expression (Figure 1). Following 48hrs in culture cells maintained their respective CD64 expression profile confirming that CD64 expression does not fluctuate upon cell activation (Figure 2). Analysis of the supernatant reveals that IL-23 expression distinctly comes from the $CD64^+CD14^+$ cells from the enthesis and predominantly from the PBMCs following activation with LPS & IFN-γ (Figure 2). Single cell analysis confirms

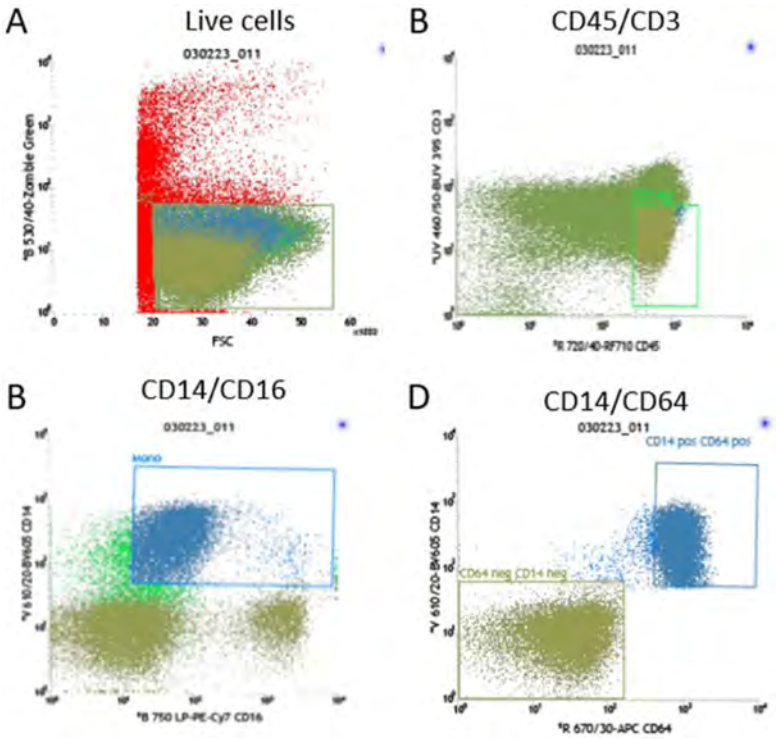

Figure 1: Gating strategy for sorting CD64+ and CD64- cells. Cells flushed from the spinous process are stained for cell sorting using the panel of markers: Live/dead-Zombie Green, CD45-RF710, CD3-BUV395, CD14-BV605, CD16-PE-Cy7 & CD64-APC. The gating strategy uses FSC/SSC to remove the granulocytes and then gates on the live cells (A), from the live cell population the CD3+ cells are gated out (B) which we have shown previously to be CD64 negative. Cells are then separated by CD14 and CD16 (C), the CD64+ cells collected are CD14+ as shown in the bottom left plot and the CD64- cells are CD14- (D).

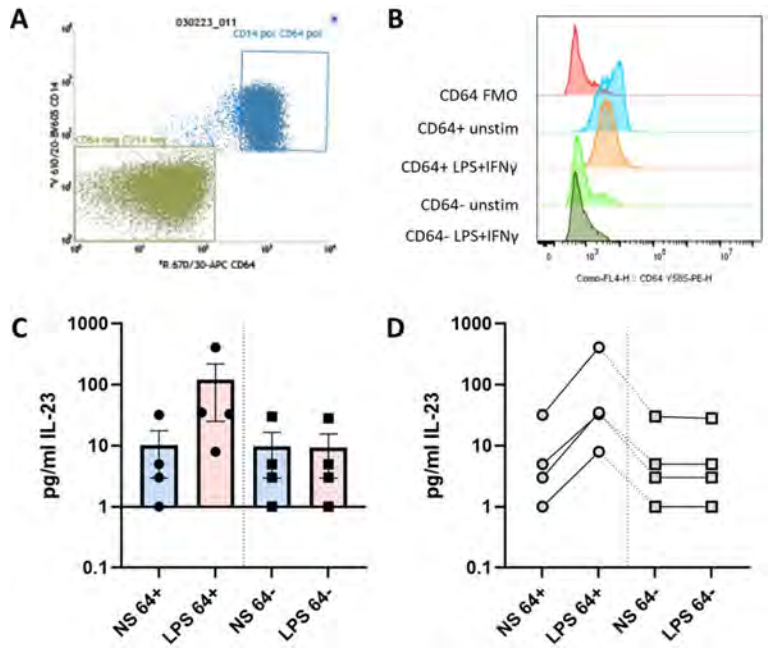

Figure 2: IL-23 production is from activated entheseal monocytes. Sorting of entheseal CD64+ cells correlated with CD14 positivity and CD64- cells correlated with CD14 negativity (A), these two cell populations were put into culture for 48hrs stimulated with LPS (100ng/mL) and IFN-γ (50ng/mL) or with no stimulation. After 48hrs in culture CD64 profiles were reassessed by flow cytometry (B), from both CD64+ and CD64- populations, expression was compared to a CD64 FMO. Supernatants collected after 48hrs were assessed via ELISA to measure the levels of IL-23 Nf4 (C), each of the four donors was plotted and shows levels of IL-23 for each condition follows the same trend (D).

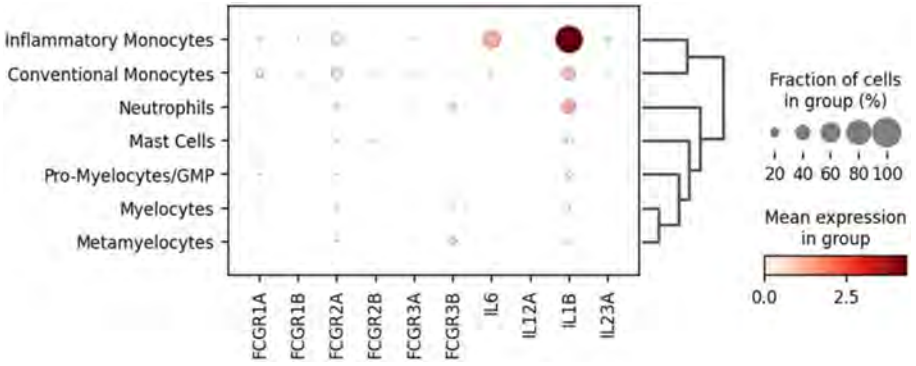

Figure 3: Singe-cell sequencing reveals gene expression for FCGR1A/B and IL23A is only present in the monocyte populations. Single-cell sequencing was performed on spinal entheseal bone and soft tissue, samples were prepared by performing a collagenase digest. Bone and soft tissue were analysed, and cluster analysis reveals that the FGR1A and FCGR2A genes which encode for CD64 are present in approximately 20% of the conventional and inflammatory monocytes, this also correlates with expression of the IL23A gene encoding for IL-23 Nf4. Together this data confirms what has been seen at the protein level.

that CD64 expression is found on the conventional and inflammatory monocytes which makes up approximately 20% of the cell population and even in health a proportion of these cells had IL23A gene expression which encodes the P19 subunit (Figure 3).

Conclusion: In this work, we have shown that $CD64^{+}CD14^{+}$ conventional monocytes are the main producers of IL-23 at the axial enthesis. This has been confirmed by flow cytometry and single cell analysis showing that these make up approximately 20% of the total cell population. Given that the key entheseal cell producing IL-23 also expresses CD64, the receptor for the rapid removal of Guselkumab bound IL-23 at the enthesis. These findings highlight that there could be differences between Guselkumab and Risankizumab in IL-23 neutralisation at the key enthesis territory.

Possible Involvement of TLR4 in the Pathogenesis of Primary Sjögren's Syndrome Through Induction of the Expression of BAFF Receptor, BR3 in Peripheral Monocytes

Keiko Yoshimoto[1], Yumi Ikeda[1], Katsuya Suzuki[2], Hiroyuki Fukui[1], Kotaro Matsumoto[1], Masaru Takeshita[1], Tsutomu Takeuchi[3] and Yuko Kaneko[4], [1]Keio University School of Medicine, Tokyo, Japan, [2]Keio University, Shinjuku, Japan, [3]Keio University School of Medicine and Saitama Medical University, Tokyo, Japan, [4]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Toll-like receptors (TLRs) play a pivotal role in innate immune system and chronic inflammation in autoimmune diseases. It has been reported that signaling pathways via TLRs, such as TLR2, TLR3, TRL4, TLR7 and TLR9 are involved in onset and/or development of primary Sjögren's syndrome (pSS), and that immune cells expressing TLRs, such as macrophages, dendritic cells, monocytes and B cells play a crucial role in the pathogenesis of the disease. We reported that elevated expression of BAFF receptor, BR3, in peripheral monocytes in pSS patients is correlated with clinical parameters of the patients and is involved in abnormal B cell functions. Therefore, clarification of regulatory mechanisms of the BR3 expression in monocytes is required not only for elucidation of pathogenesis of pSS, but also for search for therapeutic targets of the disease. In this study, we investigated possible involvement of signaling through TLRs in the enhanced expression of BR3 in peripheral pSS monocytes.

Methods: The expression levels of CD14, CD16, BR3 and TLRs in peripheral monocytes from pSS patients (n = 67) and healthy controls (HC; n = 19) were analyzed by FACS.The mRNA levels of BR3 and TLR4 in the monocytes were analyzed by quantitative PCR (qPCR). The serum level of S100A9, one of the ligands for TLR4, was measured by ELISA. PBMCs were stimulated with LPS or S100A9 for 3 days and the expression level of BR3 in the cells was analyzed by FACS.

Results: FACS analysis revealed that the expression of TLR4 was significantly higher in $CD14^{++}CD16^{+}$ cells (intermediate monocytes, IM) than that of $CD14^{++}CD16^{-}$ (classical monocytes) and $CD14^{+}CD16^{++}$ (non-classical monocytes) in pSS. Interestingly, not only the proportion of BR3-positive cells, but also that of TLR4-positive cells among IM was significantly higher in pSS than that of HC ($p < 0.001$ for BR3 and TLR4). The data is consistent with the results with qPCR. In addition, the proportion of TLR4-positive cells was significantly and positively correlated with that of BR3-positive cells only in pSS ($p < 0.01$). Notably, TLR4 ligands such as LPS or S100A9 enhanced the BR3 expression in peripheral monocytes. It may be noteworthy that the serum level of S100A9 was significantly higher in pSS than HC ($p< 0.001$) and the proportion of TLR-positive cells among IM was significantly correlated with the S100A9 level in pSS ($P < 0.05$).

Conclusion: Our results together with the data that the BR3 expression level is correlated with clinical parameters of pSS collectively suggest that TLR4 signaling pathways are involved in the pathogenesis of pSS.

Nintedanib Downregulates the Profibrotic M2 Phenotype of Macrophages Obtained from Systemic Sclerosis Patients Affected by Interstitial Lung Disease

Stefano Soldano[1], Paola Montagna[1], Emanuele Gotelli[1], Andrea Cere[1], Rosanna Campitiello[1], Sabrina Paolino[1], Carmen Pizzorni[1], Alberto Sulli[1], Vanessa Smith[2] and **Maurizio Cutolo**[3], [1]Laboratory of Experimental Rheumatology and Academic Division of Rheumatology, Department of Internal Medicine, University of Genoa, IRCCS San Martino Polyclinic Hospital, Genoa, Italy, [2]Ghent University Hospital, Gent, Belgium, [3]Laboratory of Experimental Rheumatology, Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic, Genova, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a systemic autoimmune connective tissue disease, characterized by microvascular damage, alteration of immune response and progressive fibrosis of skin and internal organs, including lungs (1). The lung involvement, either interstitial lung disease (ILD) or pulmonary arterial hypertension, contributes to the highest mortality of SSc patients (1).

Macrophages, primarily alternatively activated (M2) macrophages, seem to have a profibrotic role in SSc, being fundamental cells of the immune inflammatory infiltrate of skin and lungs (3).

M2 macrophages express specific surface markers such as mannose receptor (CD206), macrophage scavenger receptors (CD204 and CD163), and functional markers, including the MER proto-oncogene tyrosine kinase (MerTK). Moreover, they release profibrotic cytokines and growth factors, including interleukin-10 (IL10) and transforming growth factor-β1 (TGFβ1) (2).

Nintedanib is an intracellular tyrosine kinase inhibitor targeting several fibrotic mediators such as the receptors of platelet-derived growth factor, fibroblast growth factor, vascular endothelial growth factor, and colony-stimulating factor 1 (3).

To investigate the capability of nintedanib to downregulate the profibrotic M2 phenotype of cultured monocyte-derived macrophages (MDMs) obtained from SSc-ILD patients.

Methods: Monocytes isolated from the peripheral blood of nine female SSc-ILD patients (mean age 64±14 years) were differentiated into MDMs with phorbol myristate acetate (5ng/ml). Cultured SSc-ILD MDMs were maintained in growth medium without any other stimulation (untreated cells) or treated with nintedanib (0.1 and 1μM) for 3, 16 and 24 hours. SSc-ILD patients fulfilled the 2013 ACR/EULAR criteria for SSc diagnosis (during their standard diagnostic procedures and untreated with nintedanib, glucocorticoids or tocilizumab) and were enrolled after obtaining patients informed consent and Ethical Committee approval.

Gene and protein expression of CD204, CD163, CD206, MerTK and IL10 were evaluated by quantitative RT-PCR and Western blotting. TGFβ1 level was evaluated in the conditioned medium by ELISA.

The statistical analysis was carried out using non-parametric Wilcoxon test.

Results: In cultured SSc-ILD MDMs, nintedanib 0.1 and 1μM significantly downregulated the gene expression of CD204, CD206, CD163 and MerTK after 24 hours of treatment compared to untreated cells. Nintedanib also significantly downregulated gene expression of MerTK and IL10 after 16 hours of treatment compared to untreated cells.

In cultured SSc-ILD MDMs, nintedanib 0.1 and 1μM significantly reduced the protein synthesis of CD204, CD206, CD163, MerTK and the TGFβ1 production after 24 hours of treatment compared to untreated cells.

Conclusion: Nintedanib seems to downregulate the M2 phenotype and the profibrotic activity of cultured MDMs obtained from SSc-ILD patients, through the reduction of the gene expression and protein synthesis of CD206, CD163, MerTK, TGFβ1 and IL10.

RA Monocytes and Monocyte-Derived Macrophages Display Heightened Inflammatory Responses, Reduced Endocytic Capacity and Distinct TET Expression Compared to PsA Monocytes

Success Amaechi[1], Megan Hanlon[2], Alyssa Gilmore[2], Dumitru Anton[2], Mary Canavan[3], Sonia Sundanum[4], Carl Orr[5], Douglas Veale[6], Viviana Marzaioli[7] and Ursula Fearon[8], [1]Trinity College Dublin, Mullingar, Ireland, [2]Molecular Rheumatology Department, Trinity Biomedical Sciences Institute, Trinity College Dublin, EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland, [3]Molecular Rheumatology Department, Trinity Biomedical Sciences Institute, Trinity College Dublin, EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, School of Biochemistry & Immunology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland, [4]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland, [5]Saint Vincent's University Hospital, Dublin, Ireland, [6]St.Vincent's University Hosp, Dublin, Ireland, [7]Trinity College Dublin and University College Dublin, Dublin, Ireland, [8]Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: RA and PsA share various pathogenic features, while also displaying significant differences at the clinical, cellular and molecular levels. In this study, we investigate the inflammatory capacity of RA and PsA monocytes and monocyte-derived macrophages (MO-MACs), in addition to other effector functions.

Methods: Peripheral blood mononuclear cells (PBMCs) were obtained and $CD14^+$ monocytes isolated from RA and PsA patients and assessed under *ex vivo* and LPS-stimulated conditions. MO-MACs were generated via 7-day stimulation with M-CSF (50ng/mL) and polarised to M1 and M2. Inflammatory responses (IL-6, IL-1β, TNF-α, CXCL9-11, SLAMF1-7) were assessed by Real-time PCR (RT-PCR). Frequency of monocyte subsets and expression of activation (CD40) and macrophage signature markers (CD64, CD163, CD206, SLAMF7) were assessed by flow cytometry. Endocytosis assays were performed on monocytes and MO-MACs. Demethylation genes TET1-3 were assessed by RT-PCR. Finally, monocytes were cultured with a methylation inhibitor (RG108) and activator (budesonide), and pro-inflammatory responses assessed.

Results: Significant increases in LPS-induced expression of IL-6, IL-1b and CXCL9-11 (all $p< 0.05$) were observed in RA compared to PsA monocytes. Expression of SLAMF1 and 2 were significantly increased in LPS-induced RA and PsA monocytes, with SLAMF4 significantly decreased (all $p< 0.05$). Heightened responses for SLAMF7 were observed in RA vs PsA monocytes ($p< 0.05$).The increased pro-inflammatory response of LPS-stimulated monocytes in RA vs PsA was paralleled by a significant decrease in monocyte endocytic capacity, an effect that was more pronounced for RA ($p< 0.01$). Analysis of monocyte-derived macrophages demonstrated that both RA and PsA retain the hyper-inflammatory phenotype of their

precursor cell. Expression of IL-6, CXCL9 and CXCL11 were significantly higher in RA MO-M1 (all $p< 0.05$), whereas IL-1b was higher in PsA ($p< 0.05$). Heightened responses for SLAMF7 were observed for RA MO-M1 ($p< 0.05$), in contrast to SLAMF2 which was significantly increased in PsA MO-M1 ($p< 0.05$). Similarly to monocytes, endocytic capacity was reduced in RA compared to PsA M0 macrophages. RA PBMCs exhibited decreased classical ($CD14^+CD16^-$) but increased intermediate ($CD14^+CD16^+$) monocyte frequencies compared to PsA, though non-classical monocytes ($CD14^-CD16^+$) frequencies were comparable. Frequencies of CD64, CD163, CD206 and SLAMF7 were higher in all RA monocyte subsets compared to PsA, suggesting that RA monocytes have a primed pro-inflammatory macrophage phenotype. Finally, we demonstrated increased expression of methylation markers TET2 in RA monocytes ($p< 0.05$) and of TET3 in PsA monocytes ($p< 0.05$). Budesonide decreased the expression of IL-6, TNF-a and IL-1b in *ex vivo* and LPS-stimulated monocytes.

Conclusion: Monocytes are inherently more pro-inflammatory and activated than PsA monocytes, an effect that is maintained following differentiation into macrophage. The distinct inflammatory pre-programming of monocytes may also involve altered epigenetic alterations.

Elevated LINE-1 Expression in SLE Keratinocytes Leads to LINE-1 Reverse Transcriptase-dependent Type I Interferon Responses

Wenyan Miao[1], Daniel Rios[1], Mehrnaz Gharaee-Kermani[2], Craig Dobry[2], Artur Jaroszewicz[1], Cedric Arisdakessian[1], Enrique Garcia-Rivera[1], Nafeeza Hafeez[1], Brian Desrosiers[1], Jess Floro[1], Jared Steranka[1], Menachem Fromer[1], Dennis Zaller[1] and J. Michelle Kahlenberg[2], [1]Rome Therapeutics, Boston, MA, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Long Interspersed Element-1 (LINE-1) are retrotransposable DNA elements that make up ~17% of the human genome, and their role in health and disease is still being evaluated. Published studies have suggested that LINE-1 may contribute to the development and progression of autoimmune diseases such as lupus by triggering the type I interferon (IFN) production via activation of the innate immune system through nucleic acid sensing pathways. Additionally, studies have shown that lupus patients have higher level of LINE-1 in kidneys and blood compared to healthy controls, but expression of LINE-1 in SLE skin, where type I IFN signatures are dominant, has not been studied. We thus examined LINE-1 RNA and protein expression in lupus patient skin biopsies, and the impact on inflammatory signals upon a LINE-1 reverse transcriptase (RT) inhibitor in cellular and murine models.

Methods: All human subjects gave informed, written consent for the study. Formalin-fixed, paraffin embedded skin sections from non-lesional, non-sun exposed and UVB-treated skin were examined for changes in interferon-stimulated gene (ISG) expression via RNA-seq, LINE-1 ORF1p and phospho-STING via immunohistochemistry, and for LINE-1 *ORF1* and *ORF2* transcripts by RNA-scope. A novel, potent LINE-1 RT inhibitor, RPT-A, was characterized using LINE-1 RT enzyme assay, cellular LINE-1 retrotransposition assay, a cellular model of Aicardi-Goutières syndrome, and a UV-irradiated keratinocyte model. To investigate its impact on type I interferon pathway in lupus settings, we assessed its activity in regulating ISGs

in UV-irradiated keratinocytes from lupus patients and healthy controls by RNA-seq. We also studied the impact of RPT-A on disease in a TREX1 knockout interferonopathy mouse model.

Results: Non-lesional biopsies from SLE skin exhibit increased ORF1p protein and increased ORF2 transcript staining and a concurrent increase in phospho-STING staining, suggestive of activation of nucleic acid sensing pathways. UV stimulation increased expression of LINE-1 transcript and protein in both healthy control and SLE skin. Tri-phosphorylated form of RPT-A inhibited enzymatic activity of LINE-1 RT with an IC_{50} of 0.03 μM. RPT-A inhibited cellular LINE-1 retrotransposition, decitabine-induced interferon response in TREX1 deficient THP-1 cells, and UV-induced phospho-TBK1 in human HaCaT keratinocytes. LINE-1 knockdown with shRNA and siRNA in the THP1 and HaCaT cells mimicked the inhibitory effect of RPT-A. Keratinocyte cell lines derived from lupus patients pre-treated with RPT-A exhibit reduced ISGs upon UV irradiation in a dose-dependent fashion. Further, 5-6 week old TREX1 knockout mice dosed with RPT-A orally once a day for 28 days exhibited reduced serum anti-dsDNA antibodies, reduced myocardial ISGs and reduced immune infiltrates in the heart and kidney.

Conclusion: LINE-1 RNA and protein are increased in SLE skin and is induced by UV exposure. Inhibition of LINE-1 RT activity results in decreased ISG expression and improved disease activity in a murine interferonopathy model. Inhibition of LINE-1 reverse transcriptase holds promise as a novel therapy for diseases in which type I IFNs drive disease.

Abstract Number: 0056

The Activation of cGAS-STING Pathway in Systemic Lupus Erythematosus

Jie An[1], Stephen Wilson[2], Jill Henault[3] and Keith Elkon[1], [1]University of Washington, Seattle, WA, [2]Bristol Myers Squibb, Cambridge, MA, [3]Bristol Myers Squibb, Acton, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The majority of patients with SLE show a striking Type I Interferon (IFN-I) signature in their peripheral blood. Although this signature can be generated by immune complex activation of Toll Like Receptors (TLRs) in vitro, the in vivo mechanisms are not known. Using ex vivo derived peripheral blood mononuclear cell (PBMC) samples from patients, we previously showed that another IFN-I pathway, called cGAS-STING, is activated in ~15% of SLE patients. In the present study, our aims were i) to determine the frequency of cGAS-STING activation in additional SLE cohorts as well as patients with Sjogren's syndrome; ii) to perform longitudinal studies of cGAS-STING positive (cGAMP+) SLE patients; and iii) to evaluate whether activation of downstream pathways such as phospho-STING (P-STING) could be detected.

Methods: The following groups were studied: Healthy Controls (HC) (n=25), SLE (n=52), primary Sjögren's syndrome (SS) (n=20), and secondary SS (SLE/SS) (n=8). SLE disease activity was determined by the SLEDAI. PBMCs were purified from blood by Ficoll density gradient centrifugation and the cells were lysed with sonication. cGAMP concentrations were quantified with 2'-3' cGAMP ELISA kit (Cayman Chemical). Phosphorylated STING and total STING protein were measured with Homogeneous Time Resolved Fluorescence (HTRF) Phospho-STING Ser366 and Total STING Cellular detection Kit. Results were expressed as the ratio of P-STING to STING.

Results: When compared to HC, the new cohorts of SLE patients had a significant increase of cGAMP concentration in PBMCs ($p < 0.05$). There was no statistically significant increase in cGAMP concentrations in SS and SLE/SS PBMC compared to HC. The concentrations of cGAMP in PBMC from SLE patients were also higher compared to SS ($p < 0.01$) but not SLE/SS.The overall frequency of detection of cGAMP by ELISA was 17% in SLE, 0% in SS, and 25% in SLE/SS patients. When longitudinal studies were performed in 6 SLE patients who had tested positive for PBMC cGAMP, 3 of the 6 SLE patients (50%) showed cGAMP positivity on at least two different occasions whereas the other 3 SLE patients only showed cGAMP positivity in their initial clinic visit. Of note, the SLEDAI score and cGAMP level from one patient showed same trend of continued decrease over the course of three different clinic visits. Although no statistically significant difference in the P-STING/STING ratio determined by the HTRF assay was detected when SLE, SS and SLE/SS were compared to HC, it is of interest that SLE patients with higher cGAMP expression also had higher P-STING/STING ratios.

Conclusion: Detection of both cGAMP and phospho-STING in new cohorts of SLE patients confirm activation of the cGAS-STING pathway in a proportion of SLE patients and indicate that the cGAS-STING pathway likely contributes to IFN-I production in SLE. Longitudinal detection of cGAMP in 50% of cGAMP+ patients suggest that activation of this pathway may be persistent. Further defining the molecular mechanisms responsible for activation of the cGAS-STING pathway will contribute to our understanding of IFN-I stimulation and targeted approaches to inhibit cGAS-STING pathway activation may be a useful therapeutic strategy in a subset of SLE patients.

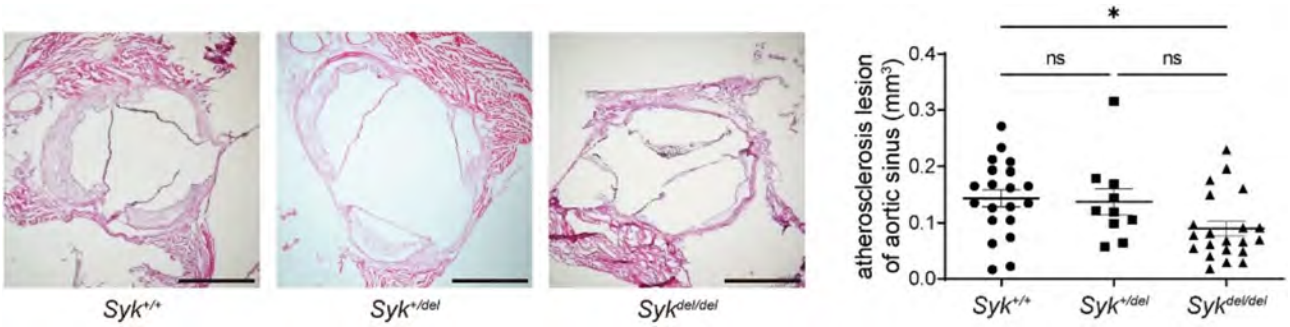
Session Time: 9:00AM–11:00AM

Daisuke Tsukui[1], Kimura Yoshitaka[1] and Hajime Kono[2], [1]Teikyo University School of Medicine, Itabashi-ku, Japan, [2]Teikyo University School of Medicine, Tokyo, Japan

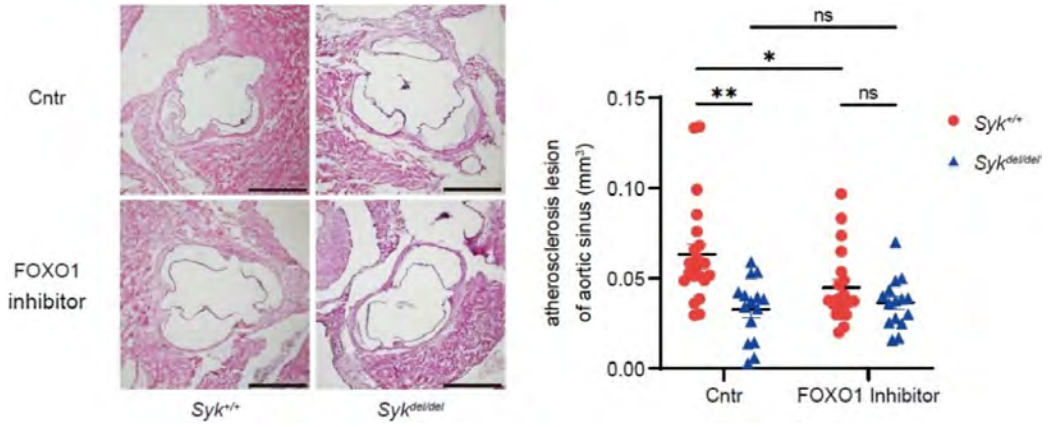
Background/Purpose: Atherosclerosis involves both dyslipidemia and chronic inflammatory disease; however, lipid-lowering agents do not completely eliminate the risks of cardiovascular events. In addition, chronic systemic inflammatory diseases such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) are complicated by atherosclerosis. This mutual relationship suggests that a shared physiological pathway might regulate inflammatory responses in both atherosclerosis and inflammatory diseases. Interestingly, spleen tyrosine kinase (SYK), an enzyme abundantly expressed in hematopoietic cells, is involved in atherosclerosis, RA, and SLE. We aimed to identify a shared therapeutic target related to *Syk* for atherosclerosis and inflammatory diseases.

Methods: To determine whether SYK is involved in atherosclerosis through the inflammatory response and elucidate the mechanism of SYK signaling, we utilized *Syk*-knockout atherosclerosis-prone mice. Cell migration capacity was assessed using wound scratch and transwell migration assays. RNA-seq, flow cytometry, and adhesion assay were performed to identify a cell migration-related gene. We investigated the transcription factor that regulates the identified cell migration-related gene using reporter assays and flow cytometry. Additionally, we identified a molecule downstream of SYK signaling that mediates the transcription factor's activity using flow cytometry. Furthermore, we evaluated whether the inhibition of the transcription factor could suppress the identified cell migration-related gene in monocyte and ameliorate atherosclerosis.

Results: Our results revealed that *Syk*-knockout mice exhibited reduced atherosclerosis. Wound scratch and transwell migration assays showed reduced cell migration in *Syk*-knockout bone marrow-derived macrophages (BMDM). RNA-seq analysis demonstrated decreased expression of CD11c, an adhesion molecule involved in inflammatory cell infiltration, in



SYK promotes atherosclerosis in mice



FOXO1 inhibitor suppresses atherosclerosis in mice

Syk-knockout bone marrow monocytes. Peripheral monocytes from *Syk*-knockout mice also exhibited reduced CD11c expression. Bocking CD11c protein resulted in inhibited adhesion capacity. A reporter assay showed SYK associated with approximately 1,000 upstream of the CD11c transcription starting site. The in silico analysis predicted forkhead box protein O1 (FOXO1) might bind to the predicted sequences by the reporter assay. The inhibitor of FOXO1 suppressed the CD11c expression of granulocyte–macrophage colony-stimulating factor receptor (GM-CSF) primed BMDM using flow cytometry. In addition, the inhibition of c-Jun amino-terminal kinase (JNK) suppressed the CD11c expression of GM-CSF primed BMDM. Finally, the FOXO1 inhibitor reduced the CD11c expression of bone marrow and peripheral monocyte and mitigated atherosclerosis in mice.

Conclusion: We discovered the GM-CSF receptor/SYK/JNK/FOXO1/CD11c signaling pathway. FOXO1 could be a novel potential therapeutic target for atherosclerosis and inflammatory diseases.

Macrophage Extracellular Traps Induced by Monosodium Urate or Calcium Pyrophosphate Crystals Form Independently of NLRP3 Inflammasome Activation

Douglas Daoudlarian[1], André Tiaden[2], Stavros Giaglis[3], Ulrich Walker[4], Petr Broz[5], Tobias Maningold[6] and **Diego Kyburz**[1], [1]University Hospital Basel, Basel, Switzerland, [2]Laboratory for Experimental Rheumatology, Department of Biomedicine, University of Basel, Basel, Switzerland, [3]University of Basel/University Hospital of Basel, Basel, Switzerland, [4]Basel University Hospital, Basel, Switzerland, [5]University of Lausanne, Lausanne, Switzerland, [6]Department of Rheumatology, University Hospital Bern (Inselspital), University Bern, Bern, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals are potent inducers of inflammation by activation of the inflammasome in neutrophils phagocytosing the crystals and undergoing cell death by extracellular trap formation (NETosis), resulting in flares of gout or pseudogout. However, crystal deposition does not always lead to inflammatory flares. Whether there are homeostatic mechanisms preventing activation of the inflammasome in the presence of crystal deposits is unclear. We have investigated the role of extracellular trap formation of macrophages (MET) stimulated with MSU and CPP crystals.

Methods: MET formation was assessed in THP-1 cells, differentiated with phorbol-12-myristate-13-acetate (PMA), and human monocytes from healthy donors, isolated by magnetic bead separation and differentiated in vitro with GM-CSF or M-CSF respectively, to obtain M1 and M2 macrophages. Macrophages were stimulated with MSU and CPP crystals with or without priming with IFNg/LPS. METs were detected by DNA staining with SytoxGreen and Hoechst and immunostaining of citrullinated Histone 3 and myeloperoxidase and subsequently quantified with an automated imaging system. IL-1b production was measured by ELISA. To assess the dependence of METosis on NLRP3, macrophages were stimulated in the presence or absence of inhibitors of NLRP3, caspase 1 and in THP-1 cells deficient for NLRP3 and gasdermin D

(GSDMD). In addition, MET formation was assessed in peritoneal cavity macrophages of C57BL6/c and caspase-1/-11^{KO}, NRLP3^{KO} and GSDMD^{KO} mice.

Results: THP-1 cells were able to release MET after both MSU and CPP crystal stimulation independent of priming with LPS/IFNg. Whereas crystal stimulation of primary human monocytes did not lead to MET formation, in vitro differentiated M1 and M2 macrophages released METs upon stimulation with crystals. In contrast, crystal stimulation alone did not result in IL-1b production but required LPS/IFNg priming in M1 macrophages, whereas M2 did not secrete IL-1b irrespective of priming. Using pharmacological inhibitors of NLRP3 and Caspase 1/4 did not inhibit MET formation after crystal stimulation. Likewise, MET were found in crystal stimulated THP-1 cells deficient for NLRP3 and GSDMD. Furthermore, MET formation could be detected in peritoneal macrophages from wild type C57BL6/c as well as NLRP3, Caspase-1 and GSDMD deficient mice, documenting independence of inflammasome activation in tissue resident macrophages.

Conclusion: We report the novel observation of MSU and CPP crystal induced formation of MET. METosis required differentiation of monocytes to M1 or M2 macrophages, was independent of inflammasome activation and did not induce IL-1b secretion in the absence of priming with LPS/IFNg. These results suggest that MET formation may represent an alternative mechanism by which macrophages may trap crystals without provoking pyroptosis and inflammatory flares.

GM-CSF by Natural Killer Cells Drives Inflammatory Arthritis in HIV-Infected Humanized Mice

Can Sungur[1], Li-ping Yang[2], Liang Shan[1] and wayne Yokoyama[3], [1]Washington University, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Human immunodeficiency virus (HIV) remains a significant life-threatening agent and burden on public health. Lesser studied and understood aspects of HIV include HIV-associated inflammatory arthritis and the role NK cells and cytokines like GM-CSF have on its development. By utilizing humanized mice with human cytokine knockins that better support a human immune system than other models, we studied HIV-associated arthritis to better understand its development and progression.

Methods: MISTRG-IL15 mice (human M-CSF/GM-CSF, IL-3, SIRPα, TPO, RAG2 -/-, IL2rg-/-, and IL-15 knocked into the respective endogenous mouse loci) were reconstituted with CD34+ hematopoietic stem cells obtained from human fetal cord blood. After checking for engraftment after 6-8 weeks, we infected reconstituted mice with HIV. Synovial tissues were obtained from the knee joints of the hind limbs at different time points and processed into single cell suspensions. Intercellular staining was performed on cells incubated with PMA/Ionomycin for 4 hours and then permeabilized and fixed for flow

cytometry. NK cells were defined as CD3-CD56+. Histochemistry was also performed on hind paws that were fixed in 4% paraformaldehyde. Samples were then sectioned and stained with H&E for histologic analysis. Studies also involved depletion of NK cells and macrophages, Antiretroviral therapy (ART), and viral strains with unique tropisms.

Results: The majority of humanized MISTRG-IL15 mice developed inflammatory arthritis after HIV infection. Significant increases in total inflammatory cells and NK cells were seen in the synovial tissue throughout the course of infection. GM-CSF producing NK cells also increased throughout the course of HIV infection. Late in the course of infection, IFNγ- and granzyme B-producing NK cells increased, along with a pro-inflammatory environment in the synovial tissue. Histologic analysis showed increased cellular infiltrate in the synovium by at 8 weeks of infection with erosive changes. ART eliminated cellular infiltration while cessation of therapy resulted in return of cellular infiltration in synovial tissue. Use of a chemokine receptor-tropic HIV virus that does not infect macrophages (X4-tropic) showed reduced pro-inflammatory cytokine production by NK cells, strongly suggesting HIV-infected macrophages induced the NK cell changes. Depletion of NK cells resulted in blockade of development of inflammatory arthritis.

Conclusion: We have found a unique role of GM-CSF produced by NK cells contributing to the development of HIV-associated inflammatory arthritis in our unique mouse model. In addition to providing a model to study arthritis induced by other human pathogens, findings from such studies will provide mechanistic understanding of inflammatory arthritis.

Abstract Number: 0060

Serpin B1 Modulation of Immune Complex-Mediated Neutrophil Activation and NET-formation Requires Its Chymotrypsin-like Inhibitory Activity

Ting Wang[1], Philip Pemberton[2] and **Christian Lood**[1], [1]University of Washington, Seattle, WA, [2]Redd Pharmaceuticals, Belmont, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibody-antigen complex-driven formation of neutrophil extracellular traps (NETs) is a major contributing factor to the pathophysiology and clinical manifestations of many different autoimmune diseases including SLE and RA. Inhibition of NET formation improves outcomes in animal models of autoimmune diseases. It has been previously shown that a neutrophil-resident proteinase inhibitor, serpin B1 (sB1) can regulate NET formation mediated by several agonists. However, it is currently unknown if sB1 can block immune complex (IC)-mediated NET formation. This study was designed to determine if sB1 can inhibit IC-mediated NET formation and if so, explore the molecular basis of the inhibition.

Methods: Recombinant forms of wild-type and variant sB1 that lacked protease-inhibitory activity or specifically inhibited elastase-like (neutrophil elastase [hNE], proteinase 3 [hPR3]) or chymotrypsin-like (e.g. cathepsin G [hCatG]) neutrophil serine proteases (NSP's) were tested for their ability to block NET formation driven by RNP-containing ICs. In brief, human neutrophils were incubated in poly-L-lysine-coated tissue culture plates for 60 minutes in the presence of select reagents at

varying concentrations prior to addition of ICs, PMA or A23187. After 4 hours of incubation, NETs were detached with micrococcal nuclease and analyzed for DNA content by staining with sytox green and peroxidase activity using the synthetic substrate TMB. Relative surface levels of CD66b, CD11b, and CD63, as well as ROS production, on treated neutrophils were measured by flow cytometry. Data were analyzed by FlowJo (Tree Star, Inc.).

Results: sB1 variants lacking protease inhibitory activity were unable to block NET formation. In contrast, the sB1 protein that could specifically inhibit chymotrypsin-like proteinases blocked NET formation whereas the sB1 protein that could specifically inhibit elastase-like proteinases did not. Consistently, the specific neutrophil elastase inhibitor had limited effect on NET formation, whereas the specific small molecule hCatG inhibitor also blocked NET formation providing further evidence implicating hCatG in the process of IC-driven NET formation. An oxidation resistant sB1 variant (C344A) effectively inhibited IC-mediated NET formation and was the only agent tested that significantly increased the levels of all three adhesion/activation markers on the surface of activated neutrophils. In addition, it significantly boosted intracellular ROS production.

Conclusion: sB1 can inhibit IC-mediated NET formation and does so in a hNE- and hPR3- independent manner. Our evidence is the first to suggest that hCatG released during neutrophil activation is directly involved in triggering IC-mediated NET formation. Future studies are needed to determine the role of sB1 on other neutrophil effector functions, including phagocytosis, adhesion and trafficking.

Discovery of a RIPK2 Scaffolding Inhibitor for the Treatment of Joint Autoimmune Diseases

Marta Wlodarska[1], Chad Van Huis[2], Florian Hoss[3], Rosana Meyer[1], Xiaokang Lu[2], Dominik Koelmel[2], Brian Sanchez[2], Chuck Lesch[2], Alissa Telling[2], Martin Minns[1], Nneka Mbah[2], Isabelle Lacan[1], Robert Aversa[1], Charles Lesburg[1], Carmen Yu[2], Stephen Soisson[1], Natalie Dales[1], Darryl Patrick[1], Anthony Opipari[2], Shifeng Pan[4] and Luigi Franchi[2], [1]Odyssey Therapeutics, Boston, MA, [2]Odyssey Therapeutics, Ann Arbor, MI, [3]Odyssey Therapeutics, Frankfurt, Germany, [4]Odyssey Therapeutics, San Diego, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Receptor interacting protein kinase 2 (RIPK2) is a key signaling node for inflammation caused by peptidoglycan (PGN). In the intestine, RIPK2 integrates signaling originating from the microbiota and amplifies pro-inflammatory responses. Hence, blocking RIPK2 is an attractive strategy to treat inflammatory bowel disease. Since peptidoglycan is present in the serum and joints in patients with rheumatic diseases and is thought to drive sterile inflammation, RIPK2 inhibitors may also be a novel approach to treat rheumatoid arthritis, osteoarthritis, and spondyloarthritis. While the kinase function of RIPK2 is dispensable for downstream signaling, its ability to recruit and activate

the E3 ubiquitin ligase, XIAP, is critical for RIPK2 ubiquitination and signal transduction. On this basis, we developed a RIPK2 scaffolding inhibitor that binds to RIPK2, prevents interaction with XIAP, and blocks proinflammatory responses in vitro and in vivo.

Methods: Direct inhibition of RIPK2 scaffolding with XIAP was demonstrated using surface plasmon resonance and a cellular nanoBRET assay. Inhibitory activity was evaluated by NF-kB dependent gene expression in NOD1 and NOD2 reporter cell lines and cytokine production in primary human cells stimulated with PGN fragments or Toll like receptor (TLR) ligands. Potency and selectivity was compared to GSK-559, a RIPK2 kinase inhibitor, and efficacy of the Odyssey RIPK2 scaffolding inhibitor in vivo was evaluated in a PGN-challenge mouse model.

Results: RIPK2 scaffolding inhibitor blocks the binding of recombinant XIAP with RIPK2 in vitro and in cells. RIPK2 scaffolding inhibitor blocks MAPK pathway activation, NF-kB activation, and cytokine production (e.g., TNF, IL-23, and TL1A) in human monocytes and macrophages stimulated with PGN fragments, but not TLR ligands. We observed a synergistic cytokine response in human monocytes stimulated by both NOD1/2 and TLR ligands. This synergistic response is blocked by treatment with a scaffolding inhibitor, but not a RIPK2 kinase inhibitor. Oral administration of the RIPK2 scaffolding inhibitor dose-dependently reduced production of TNF, IL-6, and MCP-1 in response to PGN.

Conclusion: We describe a potent and selective RIPK2 scaffolding inhibitor and demonstrate that blocking scaffolding is necessary to maximally inhibit RIPK2 activation in response to the microbiota. These data show the therapeutic potential of using a RIPK2 scaffolding inhibitor to prevent pathogenic responses to microbiota from which inflammatory intestinal and rheumatic diseases originate.

Differential Metabolic Profiles, Activation and Circadian Dynamics in Rheumatoid Arthritis and Psoriatic Arthritis Circulatory Monocytes

Alyssa Gilmore[1], Success Amaechi[2], Megan Hanlon[3], Dumitru Anton[4], Carl Orr[5], Viviana Marzaioli[6], Douglas Veale[7] and Ursula Fearon[1], [1]Trinity College Dublin, Dublin, Ireland, [2]Trinity College Dublin, Mullingar, Ireland, [3]Molecular Rheumatology, Dublin, Ireland, [4]Molecular Rheumatology Department, Trinity Biomedical Sciences Institute, Trinity College Dublin, EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland, [5]Saint Vincent's University Hospital, Dublin, Ireland, [6]Trinity College Dublin and University College Dublin, Dublin, Ireland, [7]St.Vincent's University Hosp, Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: While Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) share many features, they are distinct in clinical presentation and molecular profile. As monocytes are crucial innate effector cells, we investigate metabolic reprogramming of circulating monocytes in RA and PsA, and pathways involved in activation, circadian rhythm and mitochondrial dynamics.

Methods: PBMCs and CD14^{+} monocytes were isolated from RA and PsA patients. Frequency of monocyte subsets and immune/metabolism markers (PDL-1, HIF1a, pS6, TLR2 and pAKT) on specific subsets were assessed by flow cytometry. Metabolic analysis was performed on basal and LPS stimulated monocytes by RT-PCR, Seahorse-XFe-technology and mitotracker assays. In parallel, genes involved in circadian rhythm (BMAL1, PER1, PER2) and mitochondrial fission and fusion (DRP1, MFN1) and related effectors (RORα and NFIL3) were assessed by RT-PCR.

Results: Baseline ECAR following LPS stimulation was induced, with minimal effect observed for OCR, resulting in a significant shift of RA and PsA monocytes towards glycolysis ($p< 0.05$). A significant reduction in max respiratory capacity and ATP synthesis was also observed for PsA vs RA (all $p< 0.05$). Differential expression of PDL-1, pS6 and HIF1α were observed between RA and PsA monocytes, with inverse expression observed between classical and intermediate sub-populations. LPS modulated key metabolic genes HIF1α ($p< 0.001$) and NDufB5 ($p< 0.05$), an effect more prominent in RA monocytes. Supporting mitochondrial dysfunction in RA, LPS stimulation induced mitochondrial fission regulator DRP1 in RA ($p< 0.0001$), but not PsA. For circadian rhythm genes, LPS-stimulation inhibited BMAL1($p< 0.05$) and PER1 ($p< 0.001$) in both RA and PsA, with reduction in PER2 only observed in PsA ($p< 0.05$). Finally, downstream effectors RORα and NFIL3 were increased with LPS in RA monocytes, with no effect observed for PsA.

Conclusion: RA and PsA CD14+ monocytes display a shift towards a glycolytic phenotype. Metabolic/immune markers are differentially expressed between RA and PsA monocytes, expression of which are inversed in classical vs intermediate monocytes. Altered regulation of genes involved in circadian rhythm suggest differences in the cellular clock, and effect that was more pronounced in RA compared to PsA monocytes. This was paralleled by altered mitochondrial dynamics, with significant induction of mitochondrial fission regulator DRP1 in RA monocytes. Taken together, this data, supports differential metabolic dysregulation and activation of RA and PsA monocytes, effects that may involve changes in the cellular clock, inducing monocyte pathogenic mechanisms.

Abstract Number: 0063

Investigating Macrophage Repopulation in the Synovium

Jessica Maciuch[1], Yidan Wang[2], Slim Fourati[1], Harris Perlman[1] and Deborah Winter[3], [1]Northwestern University, Chicago, IL, [2]Northwestern University, Hanover Park, IL, [3]Northwestern University, Skokie, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is an autoimmune disease characterized by chronic inflammation of the joints. Macrophages are a key mediator of pro-inflammatory signaling, contributing to inflammation and subsequent joint destruction seen in RA. Recent research has revealed that macrophages in the joint synovium exhibit phenotypically distinct subpopulations, which may diverge in contributing towards either RA pathogenesis or potential remission. There is a need to further understand how synovial macrophage subpopulations are repopulated after disruption to better characterize varying phenotypic trajectories.

Methods: Bone marrow chimeras (BMC) were generated by transplanting cells from CD45.1 mice (donor) into CD45.2 mice (recipient) that were irradiated with shielded ankle joints. Ankle joints were extracted from BMC controls (day 0) and those treated with clodronate-laden liposomes (day 7) to deplete circulating monocytes. CITE-seq was performed on sorted synovial macrophages (CD45+CD11b+CD4-CD8-Ly6G-SiglecF-NK1.1-CD64+ cells) using the 10x Chromium instrument and processed using the CellRanger pipeline. Clustering, differential gene expression analysis, and pathway analysis was performed using Seurat and fgsea for each timepoint separately and combined. Trajectory analysis was performed using Monocle after merging day 0 and day 7 data.

Results: Distinct macrophage subpopulations were seen in both day 0 and day 7 samples. MHCII genes (H2-Eb1, H2-Ab1, H2-Aa) were differentially expressed in CD45.1-enriched clusters at day 0. For both timepoints, clusters of synovial lining macrophages (CX3CR1+) were CD45.2-enriched. Genes associated with toll-like receptor signaling pathways (Tlr2, Tlr7, Tlr8) marked CD45.2-enriched clusters at day 0. Genes coding for Ap1 (Jun), a major transcription factor regulating the pro-inflammatory program of macrophages, were repressed at day 7 compared to day 0. Macrophages at day 7 differentially expressed genes coding for metalloproteases (Mmp12, Mmp14, Mmp19) implicated in extracellular matrix degradation, suggesting heightened migratory capacity. Enrichment for pathways associated with extracellular matrix interactions were confirmed in our trajectory analysis from day 0 to day 7.

Conclusion: These results suggest the existence of transcriptional heterogeneity among macrophages in the synovium, as well as changes over time following disruption. Future experiments will test how macrophage repopulation is altered under inflammatory conditions.

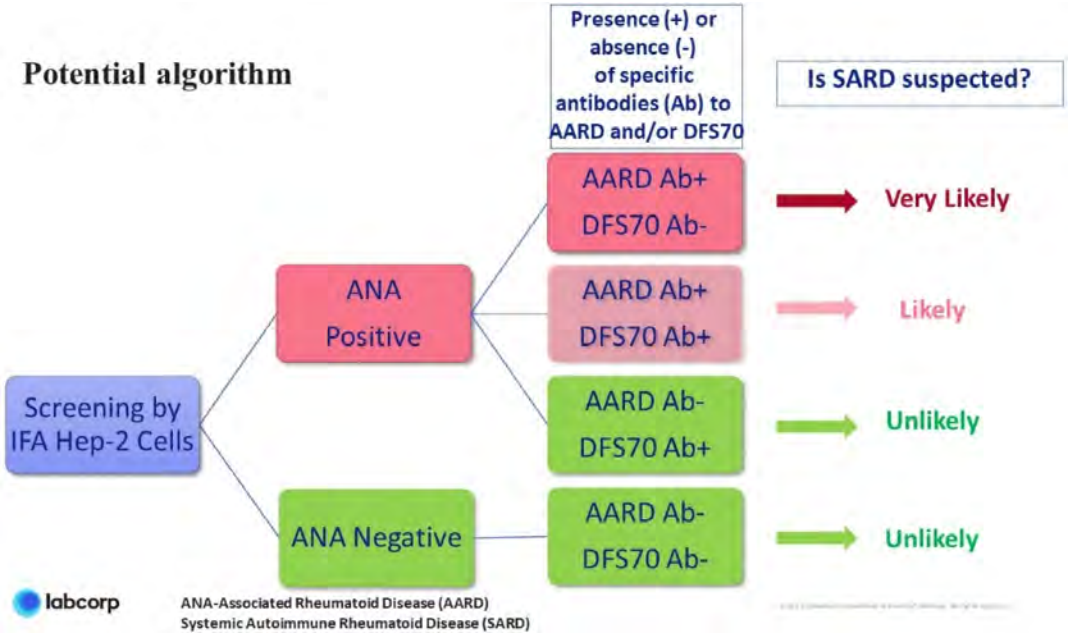
Abstract Number: 0064

Correlation of Anti-DFS70 Autoantibodies by ELISA with HEp-2 Cells DFS Pattern by IFA

Vincent ricchiuti[1], Michael Nappi[2], Kelly Chun[2], Ajay Grover[1] and Rubio Punzalan[2], [1]Labcorp, Dublin, OH, [2]Labcorp, Calabasas, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Innate Immunity Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The discovery and characterization of the dense fine speckled (DFS, ICAP AC-2) nuclear pattern of antinuclear autoantibodies (ANA) detected in HEp-2 cells by indirect immunofluorescence assay (IFA) more than 20 years ago has transformed our view on ANA testing. Anti-DFS70 antibodies are associated with this DFS pattern by IFA while their clinical associations remain an immunological enigma. Unlike other ANA, there is a growing body of evidence that anti-DFS70 antibodies, when present in high titers and in isolation (i.e. in the absence of any accompanying autoimmune disease-specific antibodies) are useful to aid in the exclusion of systemic autoimmune rheumatic diseases (SARD), also called ANA-associated rheumatic diseases (AARD). The correlation between the DFS pattern by IFA observed through HEp-2 cells and the presence of anti-DFS70 antibodies detected by enzyme-linked immunosorbent assay (ELISA) has been



the subject of increasing interest in autoimmune research. This study provides supporting evidence of the significant association between the DFS pattern by IFA and anti-DFS70 antibodies by ELISA and offers a potential algorithm to triage patients to exclude SARD/AARD.

Methods: 150 positive and 20 negative serum specimens for DFS pattern by HEp-2 cells by IFA, (Sprinter XL/EuroPattern, Euroimmun, NJ), were analyzed for presence of anti-DFS70 antibodies by ELISA (QuantaLyzer 3000, Werfen CA). The agreement of the DFS70 by ELISA was established by direct comparison of results with those generated by an established or reference method HEp-2 cells DFS pattern by IFA.

Results: When compared, samples between DFS pattern by HEp-2 cells IFA and anti-DFS70 antibodies by ELISA yielded an agreement of 97.1% (95% confidence intervals of 93.1-98.7%), McNemar's Test Chi Square of p >0.999, with a relative sensitivity of 98.0% and a specificity of 90.0%.We propose the following potential algorithm to triage patients with or without SARD/AARD (see figure).

Conclusion: This study demonstrated that accurate reading of DFS pattern by HEp-2 IFA identification provided a significant rate of anti-DFS70 antibodies detected by ELISA. The correlation between the DFS pattern by HEp-2 IFA observed and the presence of anti-DFS70 antibodies detected by ELISA could provide valuable insights into autoimmune diseases. The combined use of these techniques allows for a more comprehensive assessment of autoantibody profiles, aiding in accurate classification, prognosis, and personalized treatment strategies. Further research is needed to elucidate the clinical implications and significance of this anti-DFS antibodies in different conditions.

Mitochondrial Dysfunction and Fatigue in Sjögren's Disease

Biji T Kurien[1], Rebecca Wood[2], Gavin Pharaoh[3], Joshua Cavett[1], Valerie Lewis[1], Bhaskaran Shylesh[1], Lida radfar[1], Astrid Rasmussen[1], Christopher Lessard[1], A. Darise Farris[1], Kathy Sivils[4], Kristi Koelsch[1], Holly Van Remmen[1] and R Hal Scofield[5], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Sciences Center, Edmond, OK, [3]University of Washington, Seattle, WA, [4]Janssen Research & Development, LLC, Edmond, OK, [5]Oklahoma City Veterans Affairs Medical Center, Oklahoma City, OK

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's disease (SjD) is a chronic, autoimmune condition with diminished lacrimal and salivary gland secretion leading to keratoconjunctivitis sicca and xerostomia, respectively. In addition, subjects with SjD experience significant fatigue. We hypothesized that SjD subjects have mitochondrial dysfunction and that fatigue will be associated with mitochondrial dysfunction in a subset of subjects with SjD.

Methods: Seventeen SjD subjects and eight age-matched subjects underwent a fasting blood draw and completed fatigue questionnaires (Bowman's SjD, Fatigue Impact Scale, Multidimensional assessment of fatigue, Centers for Epidemiological Studies-Depression Scale, Fatigue Severity Scale, The Rheumatology Attitudes Index or Helplessness Score, Modified Health Assessment, Validation of the Functioning in Chronic Illness Scale, SLEEP 1, and SLEEP 2). T cells were purified through negative selection using Miltenyi Biotech B and T cell isolation kit and analyzed for mitochondrial oxygen consumption rate and extracellular acidification rate (glycolysis) using the Seahorse XF24 assay. Mitochondrial macrostructure of PBMC's isolated from SjD or control subjects was analyzed using transmission electron microscopy.

Results: There was no significant difference in the ages of the controls and the SjD subjects (52.25 years ± 3.21 vs 59.88 years ± 3.17 respectively, p=0.17) and there were no age-related changes in the oxygen consumption rate. However, we observed significantly decreased basal, ATP-linked, and maximal respiration as well as reserve capacity in the T cells of SjD subjects compared to controls. We found that scores from the Bowman fatigue questionnaire correlated the best with basal oxygen consumption (r^2=0.34, p=0.014), ATP-linked respiration (r^2=0.36, p=0.011), maximal respiration (r^2=0.491, p=0.0017), and reserve capacity (r^2=0.486, p=0.0019) in SjD. Scores from the general fatigue category (pain/discomfort) related to the question "the worst problem with pains, the worst discomfort I've experienced in 2 weeks" provided most of the power for these associations. Scores from Bowman mental fatigue questionnaire showed a trend towards correlating with ATP-linked respiration (r2=0.22, p=0.0588). Fatigue Severity Scale scores correlated only with mitochondrial reserve capacity in SjD (r^2=0.244, p=0.044). Transmission electron microscopy studies clearly show swollen mitochondria in the lymphocytes from SjD, with the cristae appearing to be prominently disorganized compared to mitochondria from the control.

Conclusion: Mitochondrial dysfunction, associated with fatigue, appears to be a significant problem in SjD.

Dimethyl Fumarate Modulates T Cell Metabolism and Function in Systemic Lupus Erythematosus Patient Samples

Loren Kell[1], Samuel Taylor[2], Kavina Shah[2], Roel De Maeyer[2], Debajit Sen[2], Madhura Castelino[2], Jo Cambridge[2], David Isenberg[2], Maria Leandro[3], Arne Akbar[2] and **venkat Reddy**[2], [1]University College London, Oxford, United Kingdom, [2]University College London, London, United Kingdom, [3]University College London/UCLH, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Activated T cells make a significant contribution to inflammation in systemic lupus erythematosus (SLE). We know that cellular metabolism regulates the activation of T cells. Evidence from patients with multiple sclerosis indicates that dimethyl fumarate (DMF), an electrophile, targets cellular metabolism to modulate CD4+T cell activation and function.

Here, we investigated whether DMF modulates T cell metabolism and function in samples from patients with SLE in a series of in vitro experiments.

Methods: All experiments were performed using isolated T cells from freshly drawn whole blood samples from patients with SLE. T cells were isolated using negative selection using Stem cell or Miltenyei magnetic bead separation kit. Isolated T cells were activated with anti-CD3 and IL-2 and incubated with either DMF at 25μM concentration or DMSO alone for three or seven days at 37°C and 5% CO_2 before harvesting.

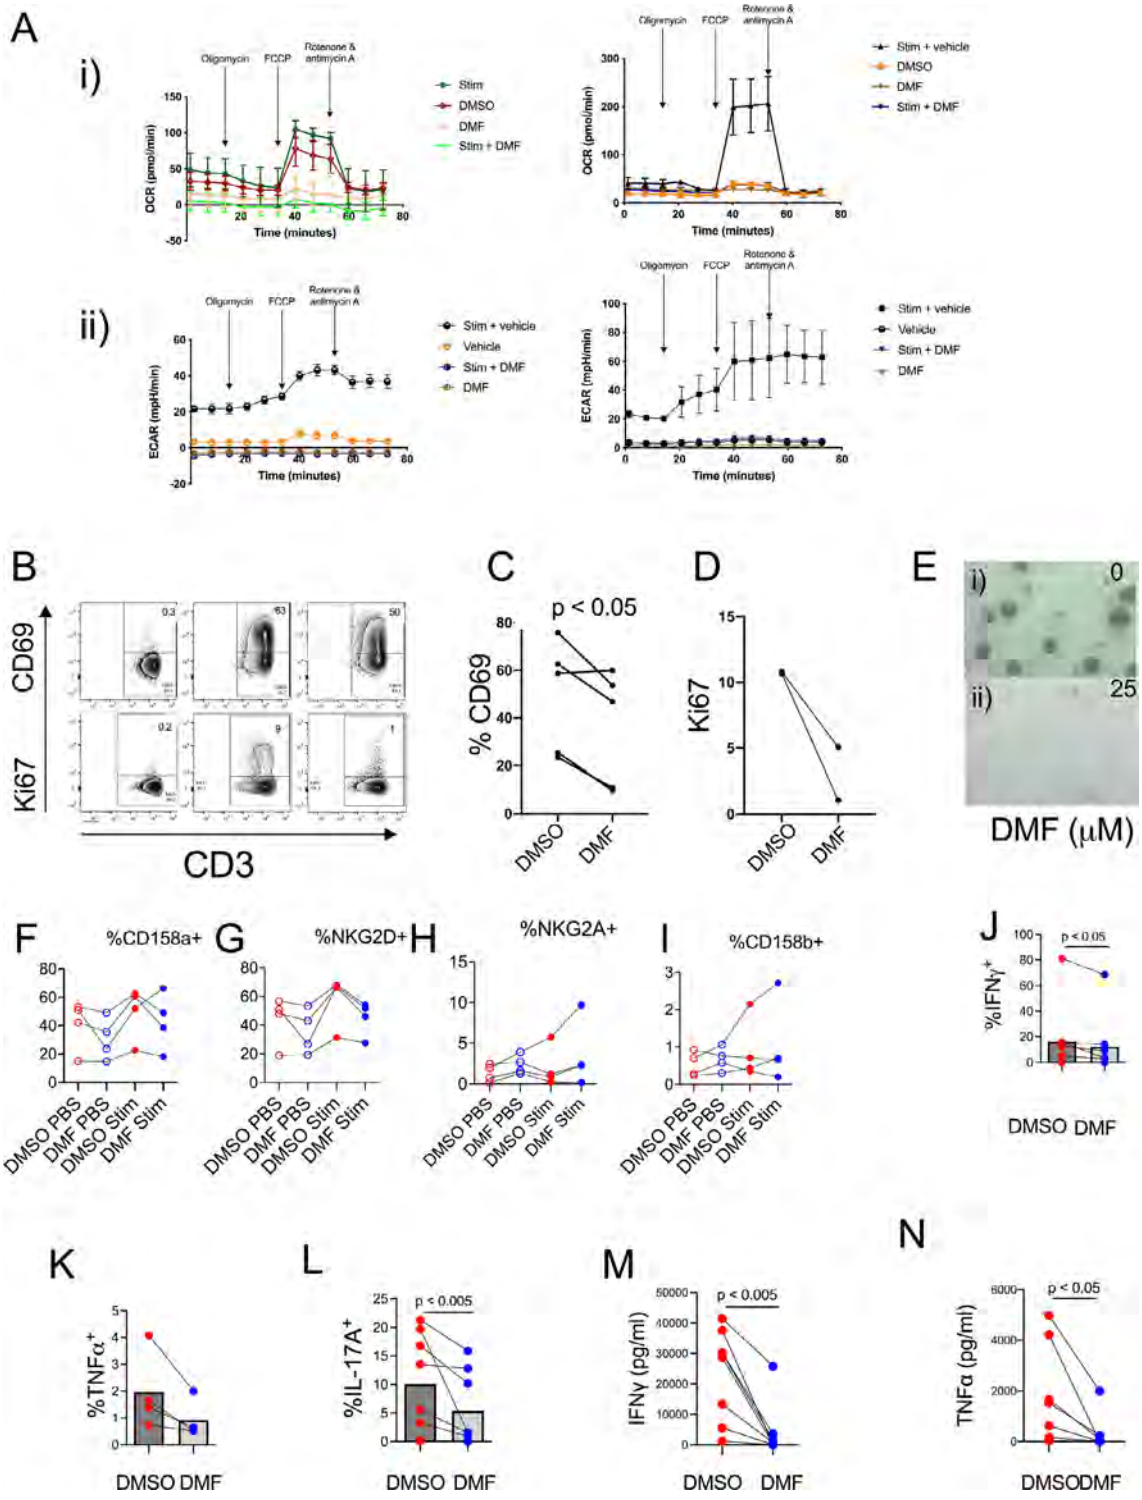
Results: In Seahorse experiments, after three days of incubation dimethyl fumarate (DMF) inhibited Figure A-i) the oxygen consumption rate (OCR) and A-ii) extra cellular acidification rate (ECAR) in isolated T cells when compared with samples incubated with vehicle, dimethyl sulfoxide (DMSO). Our results revealed that DMF significantly inhibited: 1) aerobic glycolysis and oxidative phosphorylation in activated T cells from patients with SLE (n=4) (Figure A- i and ii), in vitro; 2) T cell activation and proliferation as assessed by a reduction in the frequency of CD69 (n=4) and D) Ki67 (n=2) positivity, respectively (Figure B-E); 3) Collectively, these results suggest that DMF inhibits T cell activation and proliferation in samples from patients with SLE.

After 7 days of incubation, DMF significantly inhibited the expression of activating NK receptors CD158a and NKG2D on T cells whereas there was a trend toward enhancing the expression of inhibitory NK receptors NKG2A and CD158b (Figure F-I).

After 7 days of incubation, DMF significantly reduced intracellular expression of IFN-γ, TNF-α, IL-17 and secretion of pro-inflammatory cytokines IFN-γ and TNF-α in supernatants (Figure J – N).

Conclusion: Our preliminary data indicated that DMF modulates metabolic programming to inhibit activation, proliferation, and secretion of proinflammatory cytokines from T cells patients with SLE.

DMF inhibits glycolysis and effector functions of CD4+ T cells from patients with SLE. All experiments were performed using isolated T cells from freshly drawn whole blood samples from patients with SLE. T cells were isolated using negative selection using Stem cell or Miltenyei magnetic bead separation kit. Isolated T cells were activated with anti-CD3 and IL-2 and incubated with either DMF dissolved in 0.0025% DMSO to achieve 25μM concentration or DMSO alone for three or seven days at 37°C and 5% CO2 before harvesting. A-I) In Seahorse experiments, after three days of incubation dimethyl fumarate (DMF) inhibited the oxygen consumption rate (OCR) and A-ii) extra cellular acidification rate (ECAR) in isolated T cells when



compared with samples incubated with vehicle, dimethyl sulfoxide (DMSO). These results revealed that DMF significantly inhibited aerobic glycolysis and oxidative phosphorylation in activated T cells from patients with SLE (n=4), in vitro. B) Flow cytometry gating strategy to analyse for activated T cells CD3+CD69+ and proliferating T cells CD3+Ki67+. C) After three days of incubation, DMF significantly inhibited T cell activation and proliferation as assessed by a reduction in the frequency of CD69 (n=4) and D) Ki67 (n=2) positivity, respectively. E-i) After 7 days of incubation, the density of T cells at 10 X magnification in flat bottom wells without DMF was higher than E-ii) in the well in the presence of DMF. Collectively, these results suggest that DMF inhibits T cell activation and proliferation in samples from patients with SLE. After 7 days of incubation, DMF significantly inhibited the expression of activating NK receptors F) CD158a and G) NKG2D on T cells whereas DMF seemed to have a trend toward enhancing the expression of inhibitory NK receptors H) NKG2A and I) CD158b. After 7 days of incubation, DMF significantly reduced intracellular expression of J) IFN-γ, K) TNF-α, L) IL-17 and secretion of pro-inflammatory cytokines M) IFN-γ and N) TNF-α in supernatants. Thus our preliminary data indicated that DMF modulates metabolic programming to inhibit activation, proliferation and secretion of proinflammatory cytokines from T cells patients with SLE.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Regulatory T cells (Treg) are a population of lymphocytes with immunosuppressive function. Activation and expansion of Treg is an attractive therapeutic approach for autoimmune diseases currently being evaluated clinically. In addition to inducing Treg activation and expansion, an effective Treg-directed therapy needs to generate cells with a stable immunosuppressive phenotype that is resistant to conversion to T effector function under inflammatory conditions. Nevertheless, current clinical approaches to stimulate Treg to treat autoimmunity expand Treg by increasing homeostatic proliferation (e.g., via IL-2 muteins) without improving Treg stability.

TNFR2 agonism induces Treg proliferation and activation. We hypothesized that TNFR2 stimulation will also increase Treg stability based on the phenotype of TNFR2 knockout mice in which Treg are unstable and convert into effector cells. To test this hypothesis, we developed multivalent anti-TNFR2 VHH proteins with agonist activity on TNFR2 and assessed their impact on Treg proliferation, activation, immune suppressive function and stability compared to IL-2 muteins.

Methods: VHHs specific for human TNFR2 were obtained by immunization of alpacas, followed by panning of phage-display VHH libraries against recombinant protein. VHH binding to TNFR2 was characterized by surface plasma resonance and flow cytometry. VHH identified as binders were formatted as multivalent fusion proteins. Human naïve Treg treated with anti-TNFR2 VHH or IL-2 mutein (PT-101) were evaluated to detect effects on proliferation, activation, suppressive function and stability in inflammatory conditions. The effects of anti-TNFR2 VHH agonists on spleen lymphocyte population in human TNFR2 knock in mice were assessed by flow cytometry 5 days after a single injection.

Results: Agonistic TNFR2 VHH induced the expansion of naïve human Treg, increased the expression of activation markers and stimulated suppressive effects against CD4+ T effector cells. Consistent with these in vitro findings, administration to mice increased Treg by 3-fold, without increasing conventional effector T cells. TNFR2 VHH constructs, but not IL-2 muteins, increased human Treg stability in the presence of proinflammatory cytokines based on sustained presence of FOXP3 bright cells and prevention of conversion of Treg into IL-17A- or IFNg-secreting cells.

Conclusion: Anti-TNFR2 VHH agonistic proteins are effective at expanding Tregs that have a more stable immunosuppressive phenotype compared to IL-2 muteins and may provide a durable and disease modifying therapy for multiple autoimmune diseases.

All-*trans* Retinoic Acid (atRA) Enhances FoxP3 Protein Stability Under Inflammatory Conditions Through Altering the FoxP3 Protein-interactome

William Willis[1], shane Bruckner[2] and wael Jarjour[2], [1]Ohio State University, Reynoldsburg, OH, [2]Ohio State University, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Treg cells play a central role in the tolerance of self-antigens and prevention of autoimmune disease. FoxP3 is a Treg-specific transcription factor that plays a critical role in Treg differentiation and function. The vitamin A metabolite all-*trans* retinoic acid (atRA) has a wide range of biological activity including cellular differentiation and proliferation. Previous studies have shown that atRA regulates Treg stability under inflammatory conditions and promotes plasma-derived Treg development in-part through regulating FoxP3 gene expression. Although these transcriptional effects have been characterized, post-transcriptional effects of atRA on FoxP3 protein stability have not been investigated. The aim of the present study was to test the hypothesis that atRA suppresses FoxP3 protein degradation under pro-inflammatory conditions through altering FoxP3 protein-protein interactions.

Methods: To examine the effect of atRA on FoxP3 protein levels in the absence of FoxP3 transcriptional regulation, FoxP3 was genetically fused to an N-terminal HaloTag reporter protein (Promega) and expressed in the immortalized T lymphocyte jurkat cell line under control of the human cytomegalovirus (CMV) promoter. cDNAs encoding HaloTag and FoxP3 or HaloTag alone were assembled into a lentiviral expression vector via In-Fusion cloning technology (Takara) and transfected into 293T cells to produce VSV-G pseudotyped virus for cell transductions. Halo-FoxP3 and Halo-control expressing cells were then selected with puromycin, creating stable cell lines for experiments. FoxP3 protein levels were assessed in the presence or absence of atRA with IL-6 or IL-1β alone or in combination by Western blot. To characterize the effect of atRA on FoxP3 protein interactions, Halo-FoxP3 was isolated and purified from cell lysates with HaloLink resin (Promega). FoxP3-interacting proteins were then eluted from the resin, digested with trypsin and profiled by nano LC-MS/MS with a Waters M-Class HPLC system interfaced to a ThermoFisher Fusion Lumos mass spectrometer. The resulting Mascot DAT files were parsed into Scaffold (Proteome Software) for validation and filtering to create non-redundant FoxP3-interacting protein lists for each sample.

Results: atRA increased Halo-FoxP3 protein levels in the Halo-FoxP3 expressing cells. In contrast, both IL-6 and IL-1β alone or in combination induced Halo-FoxP3 protein degradation without affecting Halo levels in the Halo-control cells. However, concomitant treatment with atRA abrogated IL-6/IL-1β-induced FoxP3 degradation. Profiling of FoxP3-interacting proteins in cell lysates from Halo-FoxP3 expressing cells by LC/MS-MS indicated that atRA treatment had extensive effects on FoxP3 protein-protein interactions, which included suppression of IL-6/IL-1β-induced interaction with the 26S proteasome and a novel FoxP3-interacting E3 ubiquitin ligase, RNF213.

Conclusion: These results suggest that in addition to previously characterized transcriptional mechanisms, atRA may suppress FoxP3 degradation under inflammatory conditions through preventing interaction with RNF213, a novel FoxP3-interacting E3 ubiquitin ligase.

Activation of Joint CD8+ T_{RM} Localize Autoantibody Mediated Arthritis

Sahar Lotfi-Emran, Nicole Koziol and David Masopust, University of Minnesota, Minneapolis, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In humans, upper respiratory infections have been associated with onset of Rheumatoid Arthritis. In mice, following viral infection, CD8+ T cells take up residence in joints and a portion become tissue resident memory cells (T_{RM}). As these CD8+ T_{RM} are not specific for a Rheumatoid Arthritis specific self-peptide, it is not clear if they contribute to disease activity. In the mouse uterus, re-activation of CD8+ T_{RM} increases the permeability of the tissue to circulating antibodies. Utilizing the K/BxN serum transfer model, we demonstrate that local activation of CD8+ T_{RM} generates persistent clinical arthritis at that site.

Methods: C57BL/6 mice received adoptive transfer of OT-1 transgenic CD8+ T cells, whose cognate antigen is SIINFEKL peptide. The next day, they are infected with vesicular stomatitis virus encoding SIINFEKL. Acute infection resolves over the course of a few weeks, virus is cleared, but tissues are persistently populated by OT-1 CD8+ T_{RM}. These mice are OT-

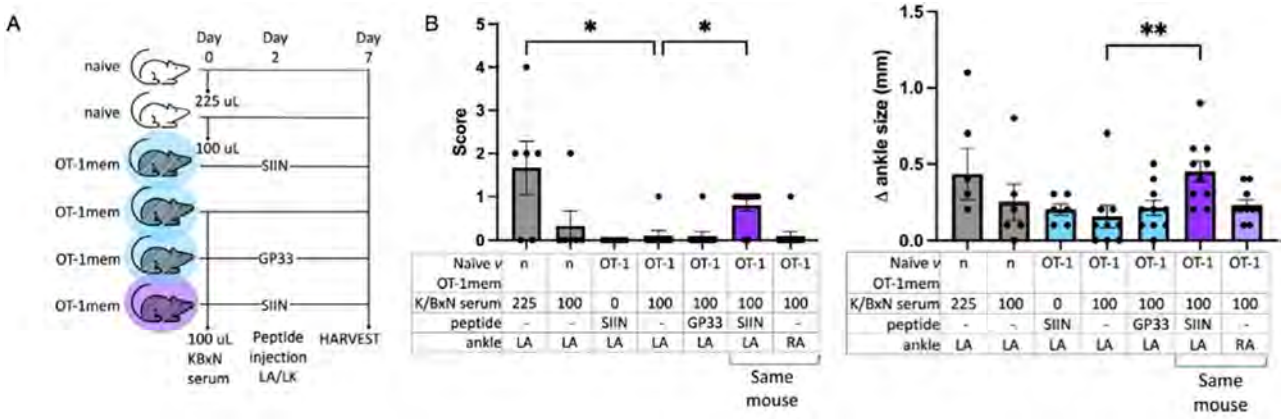

Figure 1. OT-1 CD8+ TRM activation in joints generates persistent clinical inflammation following K/BxN serum transfer arthritis. OT-1mem mice were generated by adoptive transfer of OT-1 cells followed by infection with VSV-OVA. OT-1 transgenic TCR recognizes the SIINFEKL peptide of ovalbumin and OT-1 cells rapidly expand and respond to VSV-OVA. 30+ days after infection, and well after clearance of virus, OT-1mem mice retain OT-1 TRM in tissues. OT-1mem and naive mice receive limited dose of K/BxN arthritogenic serum such that naive mice develop minimal disease. Two days after K/BxN serum, some mice receive SIINFEKL peptide or irrelevant peptide GP33 injections into left ankle and knee. Clinical disease activity is assessed daily by standardize scoring (0, no inflmmation, to 3, maximal swelling and ankylosis) and caliper measurements of ankles from malleolus to malleolus. A, Illustrated experimental groups. B, Left ankle score and change in ankle size. Two separate experiments. *p<0.05, **p<0.01ANOVA followed by Kruskal-Wallis comparison of each OT-1mem group to OT-1mem that received only K/BxN serum.

1mem mice. Naïve and OT-1mem mice receive dose limited volumes of arthritogenic serum from K/BxN mice. Two days later, they receive an injection of SIINFEKL peptide in their left ankle and left knee to reactivate OT-1 T_{RM}. Ankles were scored for severity of clinical inflammation (0, no swelling/redness; 1, mild swelling/redness +/- swollen digits; 2, moderate swelling/redness; and 3, maximal swelling/redness with ankylosis) and their size was measured by calipers daily (from lateral to

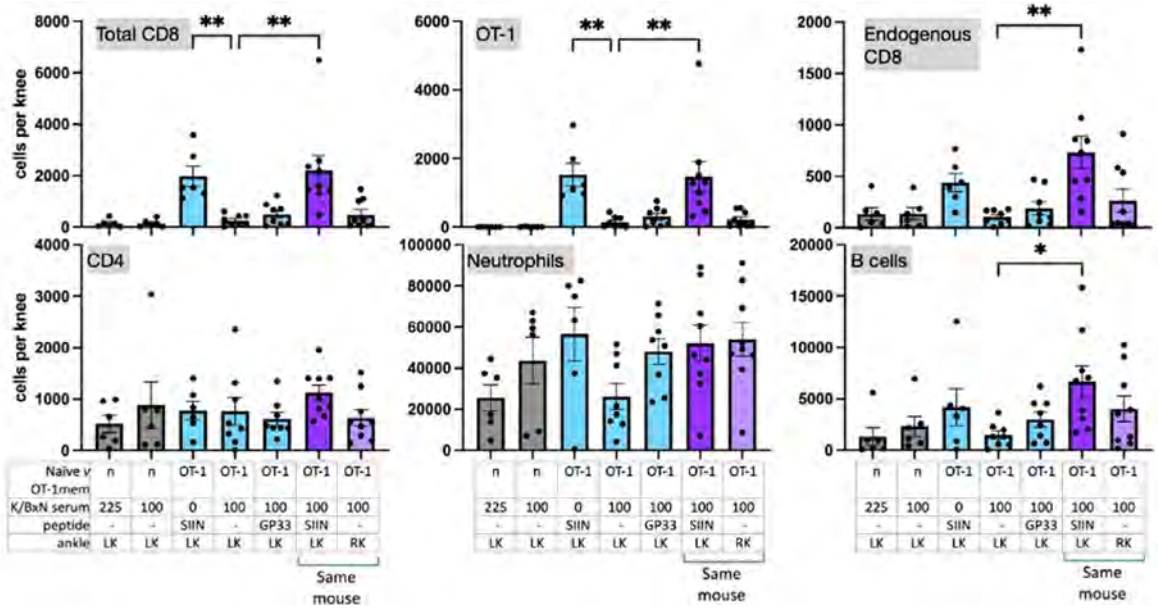

Figure 2. OT-1 CD8+ TRM activation locally increases CD8+ T cells and B cells at the the joint. Figure 1A illustrated experimental groups. Mouse knees were collected following intravascular staining, tissues were disaggregated in collagenase and DNAse solution, a single cell suspension was obtained, stained, and evaluated by flow cytometry with bead based counting to estimate total per tissue. Bead based counts for total CD8+ T cells, OT-1 CD8+ T cells, and non-OT-1 (endogenous) CD8+ T cells are shown in addition to CD4+ T cells, neutrophils (Ly6G+), and B cells (B220+). *p<0.05, **p<0.01ANOVA followed by Kruskal-Wallis comparison of each OT-1mem group to OT-1mem that received only K/BxN serum.

medial malleolus). After seven days, mice were sacrificed following intravascular stain injection, ankles fixed and decalcified for histology, and knees collected and processed to a single cell suspension for flow cytometry. (See Figure 1A for illustration of experimental groups.)

Results: Persistent clinical inflammation and increased size was found in the left ankle of OT-1mem mice that received K/BxN serum and injection of SIINFEKL, but not their right ankle, not in the left ankle of memory mice injected with an irrelevant peptide GP33, and not in the left ankle of memory mice that received SIINFEKL. (Figure 1B) By flow cytometry, the left, but not right, knee of memory mice that received K/BxN serum and injection of SIINFEKL contained significantly more OT-1 cells, endogenous CD8+ T cells, and B220+ B cells compared to Ot-1mem mice that received only K/BxN serum. This was not true of the left knee of OT-1mem mice that received K/BxN serum and left knee injection with GP33, nor the left knee of OT-1mem mice that received only SIINFEKL injection. (Figure 2)

Conclusion: Persistent clinical inflammation is dependent on both K/BxN serum and local activation of virus specific joint CD8+ T_{RM} and characterized by increased number of OT-1 transgenic CD8+ T cells, endogenous CD8+ T cells, and B220+ B cells. Thus, 'bystander,' virus specific, CD8+ T_{RM} activation can localize systemic autoantibody mediated processes to the joint.

Sex Based Differences in Morphological and Functional Niches of the Human Thymus, Identified by Non-supervised Spatial Transcriptomic Profiling, May Underlie Sex Bias in Autoimmune Disease

Viktoria Hennings, Anneke van Dijk, Andri Lemarquis, Christina Lundqvist and **Olov Ekwall**, University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Females exhibit a more robust response to both self- and non-self-antigens than males which manifests as higher prevalence of autoimmune disease, eg. rheumatic diseases, and more effective response to infection in females. Both hormonal and genetic differences have been suggested as underlying factors, but the precise mechanisms that lead to sex-based differences in immune responses remain unknown. We hypothesize that a sex bias in thymic central tolerance induction is of importance for the female predominance in autoimmune diseases.

Methods: The 10X Genomics Visium Spatial Transcriptomic method was applied on fresh frozen human thymic tissues from girls (n=2) and boys (n=2), age 4 months. RNAseq data was acquired, and after quality control and filtering, approximately 3000 spots per section were analyzed using the Scanpy toolkit (Fig 1a). After integration of data using Harmony, unsupervised spatial clustering (Leiden_0.1) identified distinct regions that translated to the main functional and morphological compartments of the human thymus; medulla and cortex, which was validated by the expression of marker genes (Fig 1 b, c).

Results: Differential gene expression analyses of the medullary compartment identified sex-biased expression of genes and biological pathways of key importance in central tolerance induction such as chemotaxis, negative selection and regulatory T cell formation (Fig 1 d, e). Interestingly, we also found that the female medullary compartment showed a more pronounced pro-inflammatory milieu with upregulated type 1 and type 2 interferon gene signatures. Further sub-clustering of the medulla showed heterogenicity in this compartment, identifying spatial niches with differences both in cellular composition, spatial organization and functional characteristics.

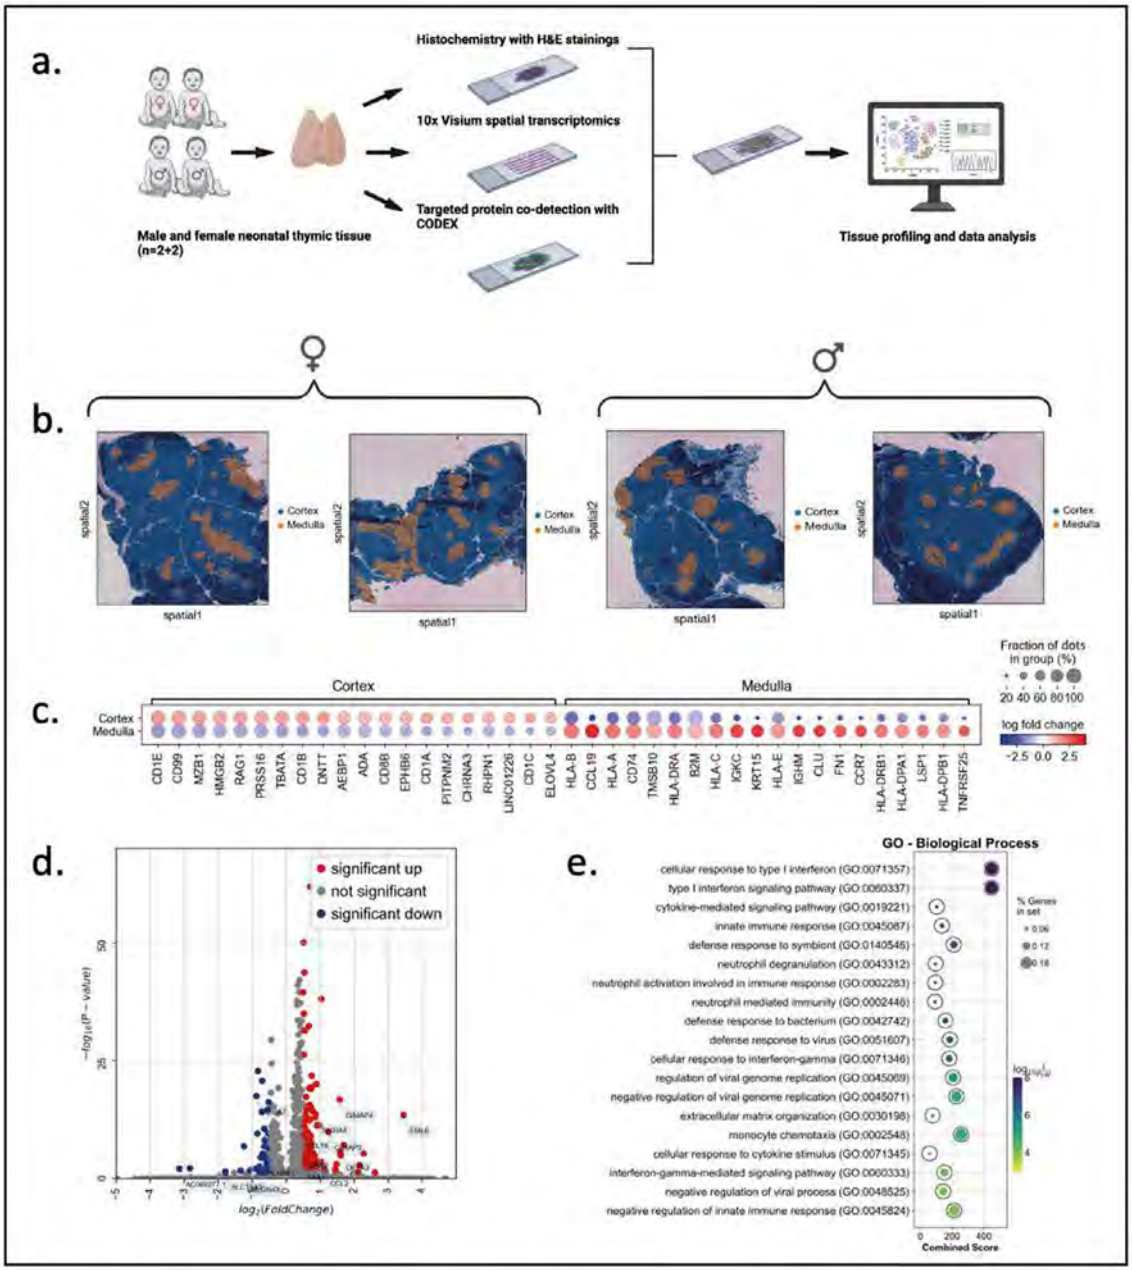

***Figure 1**. Project workflow (a). Unsupervised clustering identified cortical and medullary regions (b), which was validated using marker genes (c). Volcano plot showing the up- and downregulated genes in the female medulla (d). GO-term analysis identified biological pathways upregulated in the female medulla (e).*

Conclusion: The results expand our knowledge regarding the functional and spatial organization of the human thymus and strengthen the importance of sex-biased thymic central tolerance induction a possible explanation for the observed higher prevalence of autoimmune disease in females.

Circulating T-cell Immunosenescence Is High in Patients with Immune-Mediated Inflammatory Diseases (IMIDs) and Is Associated with Interferons

Marie Naingeon[1], **Samuel Bitoun**[2], Matthieu roulleaux Dugage[1], Caroline de Oliveira[1], Caroline Berthot[1], Xavier Mariette[3], Nathalie Chaput[1] and Gaetane Nocturne[4], [1]LIO, Department of Medicine, Gustave Roussy Université Paris Saclay, Villejuif, France, [2]CHU Bicêtre APHP, Le Kremlin-Bicêtre, France, [3]Université Paris-Saclay, Le Kremlin-Bicêtre, France, [4]APHP, Le Kremlin-Bicêtre, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunosenescence is a global remodeling of immune functions that has been first described with aging. It can also occur in pathologies associated with chronic antigenic stimulation and notably cancer. High proportion of circulating senescent CD8+ T cells (T_8sen, CD3+CD8+CD28-CD57+KLRG1+ cells) is observed in more than 25% of the patients with advanced non–small cell lung cancer (aNSCLC) and has been associated with resistance to immune checkpoint blockers. The mechanisms leading to accumulation of T_8sen are still only partially understood. Chronic inflammation is a potential driver. Here we sought to assess the level of T_8sen in patients with IMIDs, its dynamic under TNF inhibitors (TNFi) and the link with the plasmatic concentration of different cytokines.

Methods: T_8sen have been identified by flow-cytometry on fresh whole blood samples from 68 patients with IMIDs [25 with rheumatoid arthritis (RA), 23 with spondyloarthritis (SA) and 20 with Sjogren disease (Sjo], 228 patients aNSCLC and 25 healthy volunteers (HV). Patients with RA and SA were evaluated at baseline and 3 months after TNFi initiation. Baseline plasmatic concentrations of IFNα2a, IFN-β, IFNγ, IFNλ1, and IP-10 were quantified using MSD technology. Associations between proportions of T_8sen and categorical or continuous variables were performed by Mann–Whitney test and Pearson coefficient, respectively.

Results: Patients with IMIDs harbor higher levels of T_8sen compared to aNSCLC patients and HV (Figure 1 left panel). The median level [Q1-Q3] of T_8sen was of 26.34% [16.75-47.33] in IMIDS patients compared to 22.18% [12.41-33.84] in aNSCLC patients and 12.11% [5.56-21.28] in HV. Among the three IMIDs, T_8sen rates were higher in patients with Sjo (Figure 1, right panel). We did not observe any significant correlation between T_8sen and diseases characteristics at baseline. Importantly, TNFi initiation did not modulate T_8sen levels in RA and SA patients. Interestingly, we observed significant positive correlations between plasmatic IFN- λ1, IFN- γ and IP-10 with the levels of T_8sen (Figure 2).

Conclusion: Patients with IMIDs exhibit high levels of T8sen cells that exceed those observed in patients with lung cancer. This senescence is not altered under TNFi treatment and appears to be primarily driven by IFNs. The link between T_8sen and the evolution of the disease as well as with the response to treatment remains to be evaluated. Likewise, since T_8sen is

mainly driven by IFNs, it would be important to evaluate the effect of anti-IFN treatments and JAK inhibitors on senescence with potential implications in autoimmunity and cancer.

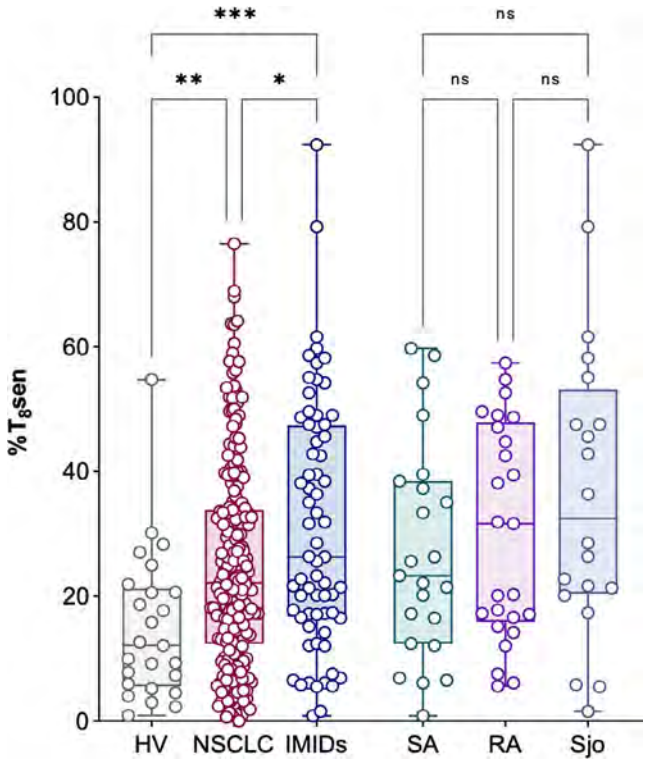

Figure 1. Percentage of senescent CD8+ T (T8sen) cells in patients with AID compared to HV and aNSCLC (right panel) and between AID types. HV : healthy volunteers, NSCLC: advanced lung cancer, IMIDs: immune-Mediated Inflammatory Diseases, SA: spondyloarthritis, RA : rheumatoid arthritis, Sjo: Sjogren disease.

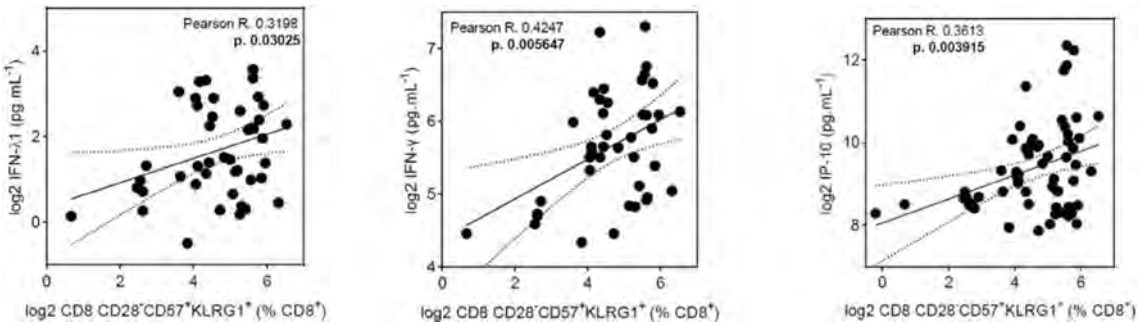

Figure 2. Correlation of IFNλ1, IFN- γ and IP-10 plasmatic levels with the percentage of senescent CD8+ T cells in patients with autoimmune diseases.

PD-1hi Cells Are Highly Present in the Rheumatoid Joint, and Express Regulatory Capacities

Sofie Rask[1], Christian Andersen[2], Malene Hvid[1], Kim Ravnskjær[2], Bent Deleuran[1] and Stinne Greisen[3], [1]Aarhus University, Aarhus, Denmark, [2]University of Southern Denmark, Odense, Denmark, [3]Aarhus University/Aarhus University Hospital, Aarhus, Denmark

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Programmed death 1 (PD-1) is an immune checkpoint receptor expressed by activated T cells, and of major importance in maintaining peripheral tolerance. Expression of PD-1 has been associated with T cells exhaustion, plasma cell differentiation and bone homeostasis. With emerging treatments engaging the PD-1 pathway in Rheumatoid Arthritis (RA) this pathway is of continued interest.

We aimed to investigate PD-1hi T cells from RA synovial fluid (SF).

Methods: SF was collected from RA patients with disease flare (n=7). Cells were stained for flow and sorted in CD3+ PD-1hi/PD-1lo populations. Post sorting, bulk RNA seq was performed, and cells were stimulated with antiCD3/CD28. Cytokines in the supernatants were investigated using V-plex multipanel assay. Supernatants were added to fibroblast cultures and the osteoblast cell line SaOs-2.

Results: Evaluated by flow cytometry, PD-1+ cells represented 42% of CD4+ T cells and 34% of CD8+ T cells in the SF. When comparing co-expression of checkpoint receptors and transcription factors between PD-1hi and PD-1lo CD4+ T cell; Tigit, Tim3 and NFAT were all increased in PD-1hi (all $p < 0.05$), Lag-3 was slightly elevated ($p=0.07$), whereas TCF1 and TOX expression did not differ. These differences were not observed between PD-1hi and PD-1lo CD8+ T cells.

Post sorting, RNAseq revealed PD-1hi and PD-1lo cells to cluster separately. In PD-1hi cells, gene expression corresponded to structural signatures, including tubulin binding and cytoskeletal motor activity ($p < 0.01$). Genes related to peripheral T helper cells, including *IL21* and *CXCL13* were highly upregulated (all $p< 0.05$) The gene *PHEX* was highly expressed (log2

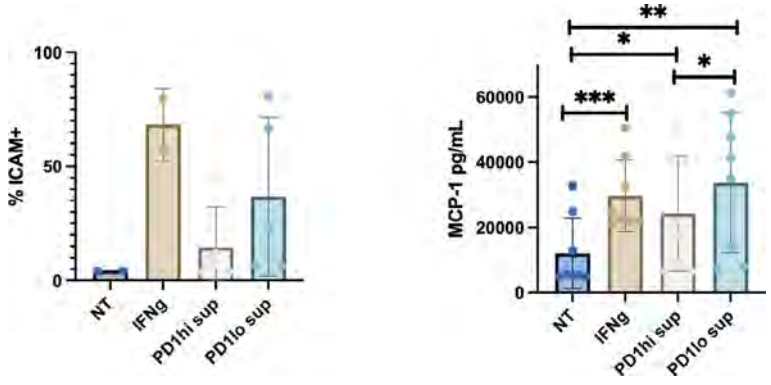

Figure 1: Left: Expression of ICAM on fibroblasts after culturing with PD-1 hi/PD-1lo supernatant. IFNg used as a positive control. Right: MCP-1 production measured in the supernatant from fibroblasts after culturing with PD-1 hi/PD-1lo supernatant. IFNg used as a positive control.

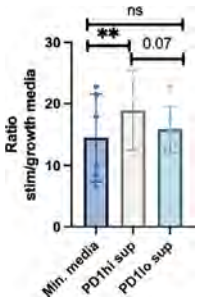

Mineralization measured in the SaOs-2 osteoblast cell line after culturing with PD-1hi and PD-1lo supernatant. Data are normalized to the cell line in growth media.

fold change=5.2), suggesting an association with bone mineralization. The signature in PD-1lo cells was associated with immune activation genes ($p < 0.005$). Stimulating cells with CD3/CD28 post sorting resulted in lower production of IL-2, IFNg, TNFa, IL-8, IL-10, IL-13, IL-12, and IL-1b from PD-1hi cells compared to PD-1lo. The supernatant from PD-1hi cells only slightly activated fibroblasts, whereas the PD-1lo supernatant significantly activated fibroblasts, as measured by by MCP-1 production and surface ICAM expression (fig 1). When adding the PD-1hi and PD-1lo supernatant to osteoblast cultures, bone mineralization was significantly increased by the PD-1hi supernatant (fig 2).

Conclusion: PD-1hi cells are present in the synovial joint. They are not exhausted but express multiple checkpoint receptors, suggesting regulatory capacities. They could play a central role in structural maintenance through effects on fibroblasts and osteoblasts.

Distinct PD-1 Receptor Engagement Leads to Different Pharmacodynamic Effects

Yevgeniya Orlovsky, Melissa Swiecki, Kimberly Colby, Changbao Liu, Josephine Wixted, Olesya Chornoguz, Navin Rao, Edith Janssen and **Ling-Yang Hao**, Janssen Research & Development, LLC, Spring House, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: T cells play an important role in the development and progression of many autoimmune diseases. Inhibition of T cells and their effector mechanisms has therefore been an area of great therapeutic interest. PD1 (CD279) is a CD28/CTLA4 family coinhibitory receptor that is mainly found on activated lymphocytes. Ample evidence links the PD1 pathway to autoimmune diseases, ranging from genetic evidence, correlations between PD1 expression and disease severity in patients, and autoimmune-like immune-related adverse events (irAE) from blocking PD1 pathway therapies in oncology. Consequently, the activation of the PD1 pathway through agonist antibodies holds promise as a therapeutic

approach in autoimmune disease. With the first PD1 targeting drugs entering the rheumatoid arthritis clinical trial space, there is a need to increase our understanding of the mechanistic underpinnings of agonist PD1 antibody (Ab) on T cells to support further drug development. Here we assess the impact of various Ab configurations on the potential of novel PD1 Ab to inhibit T cell activation *in vitro*.

Methods: PD1 Abs were assessed for affinity and capacity to interfere with endogenous ligands interaction. Selected anti-PD1 reagents were expressed with different molecule configurations and tethering partners. Naïve and activated CD4+ T cells were cultured with soluble or scaffold/bead-bound PD1 Abs and anti-CD3 to determine inhibitory potential on proliferation and cytokine production. Antigen stimulation-based studies in PBMC were used to assess impact in a multi-cellular setting. Potential to promote Treg development was assessed in naïve CD4+ T cells stimulated with anti-CD3 coated beads and recombinant interleukin 2.

Results: In purified T cell assays, several of the anti-PD1 molecules showed clear impact of tethering on the agonist capacity. Importantly, inhibition of T cell function and Treg development was observed when the PD1 Abs were bound to the same scaffold (cis), but not on separate scaffolds (trans). Some PD1 Abs that showed agonism in the purified T cell assay failed to do so in the PBMC assay, and some architectures, such as the PD1xCD4 tetrapod, shifted from agonist to antagonist.

Conclusion: Our data indicate that more potent agonist effects correlated with close proximity engagement of PD1 and T cell receptor. Therefore, strategies that preserve or enhance the natural behavior of PD1 localization to immune synapses are likely to yield more successful agonists.

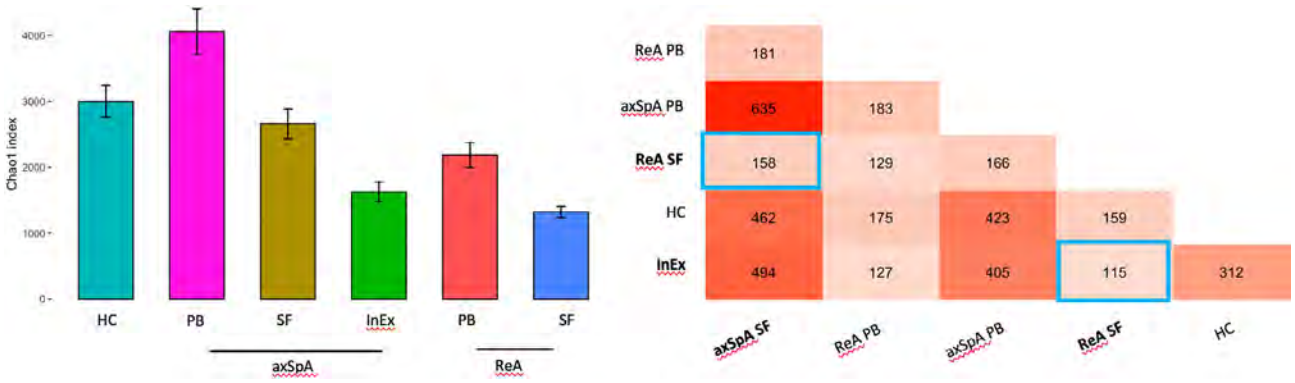
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The strong clinical and genetic associations between axial spondyloarthritis (axSpA) and inflammatory bowel disease (IBD) underscore the pathogenic role of the gut-joint axis. The prevailing arthritogenic peptide hypothesis suggests that CD8+ T cells mount an immunological response upon recognition of a self or microbial arthritogenic peptide at inflammatory sites such as the gut. This could result in a clonal expansion of these cells, ultimately leading to their aberrant migration to other sites such as the joint. We previously identified a subpopulation of pathogenic mature CD8+ T cells in the axSpA synovial fluid (SF), expressing CD103+ and CD49a+ integrins (InEx cells). The expression of integrins on InEx cells

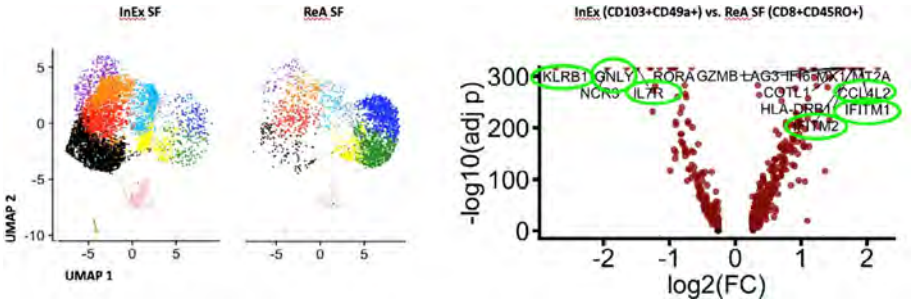
implicates their role in aberrant migration between the gut-joint axis. Whether InEx cells recognize an arthritogenic peptide remains unclear. We hypothesize that InEx cells may incite and perpetuate chronic inflammation in axSpA. To this end, we characterized their T-cell receptor (TCR) repertoire and gene expression profile.

Methods: Patients fulfilling the ASAS classification for axSpA were recruited (n=4). Active joint effusion from these patients is reflective of active joint inflammation which coincided with high disease activity (BASDAI >4). We isolated peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs), followed by FACS-sorting of mature CD8+ T cells and InEx cells. Subsequently, single-cell TCR (both α and β chains) and RNA sequencing were performed on these cell types. An HLA-B27+ reactive arthritis (ReA) sample were used as a comparison since it is the paradigm for antigen-driven inflammation initiated in the gut. Mature CD8+ T cells from ReA PBMCs and SFMCs were also FACS-sorted. These were all compared to HLA-B27+ healthy controls (n=4).

Results: The InEx TCR repertoire from axSpA patients was less diverse than mature CD8+ T cells from axSpA PBMCs or SFMCs, indicating a clonally expanded population. The TCR V/J pairings from the β chain in InEx cells confirm existing literature. Interestingly, their TRBV9/TRBJ2-3 usage was also found in mature CD8+ T cells from ReA SFMCs. Assessing the TCR V region from paired α/β chains revealed that the InEx cells shared similar usage with mature CD8+ T cells from ReA PBMCs or SFMCs: TRBV20-1/TRAV1-2, TRBV6-1/TRAV1-2, and TRBV6-2/TRAV1-2. Further, the CDR3 region of the β chain in InEx cells differed from mature CD8+ T cells from ReA SFMCs by only three amino acids. On a transcript level, InEx cells differed from ReA mature CD8+ T cells based on elevated genes such as *CCL4L2*, *IFITM1*, and *IFITM2*, and downregulated genes such as *IL7R*, *GNLY*, and *KLRB1*.



Left panel displaying the Chao1 index, a measure of TCR repertoire diversity, stratified by sample type. Right panel displaying the overlapping alpha and beta TCR chain gene usage of the V region. Highlighted in blue boxes are features similar between InEx and ReA SF and axSpA SF (mature CD8+ T cells) and ReA SF. HC = healthy controls, PB = peripheral blood, SF = synovial fluid.



Left panel displaying transcriptome profile of InEx vs mature CD8+ ReA SFMCs on UMAP plots. Genetic profile of InEx cells cluster differently to ReA SF. Right panel displaying differently expressed genes between the two groups, with most informative genes circled in green. UMAP = Uniform Manifold Approximation and Projection. SF = synovial fluid.

Conclusion: These observations suggest that the autoimmune mechanism employed by InEx cells could be mediated by HLA-B27+. This may enable them to incite inflammation similarly to ReA due to potential recognition of similar peptides, ultimately driving the selection of specific T cell clones. However, InEx cells' ability to perpetuate inflammation may be distinct from ReA due to a varied transcriptome. This has important implications for therapeutic designs attempting to target integrin blockade in axSpA.

Abstract Number: 0076

Characterizing GMCSF Producing T-cells in Rheumatoid Arthritis and Effect of Methotrexate on Them

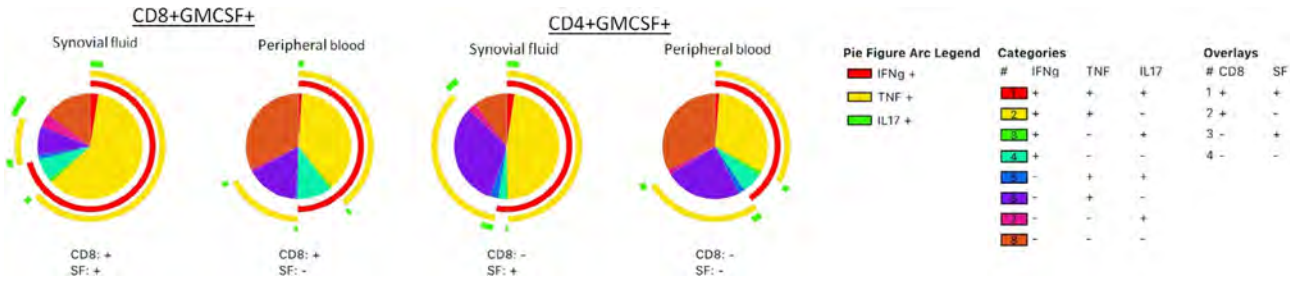
AASTHA KHULLAR[1], Varun Dhir[2], Leishangthem Bidyalaxmi[1], Chandra Bhushan Prasad[3], Sankar Jayaprakash[1], Siddharth Jain[4], Biman Saikia[1], Aman Sharma[5], Shefali Sharma[6], Ashok Kumar Yadav[1], Shankar Naidu[1] and Sanjay Jain[7], [1]PGIMER, Chandigarh, India, [2]PGIMER, CHD, INDIA, Chandigarh, India, [3]Healthway Hospital, Goa, Zuarinagar, India, [4]AIIMS, Delhi, India, [5]PGIMER, Chandigarh, India, Chandigarh, India, [6]PGIMER< Chandigarh, Chandigarh, India, [7]Post Graduate Institute of Medical Education and Research, Chandigarh, India

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: GMCSF producing T-cells may be implicated in the pathogenesis of autoimmune diseases like rheumatoid arthritis (RA), multiple sclerosis (MS) and psoriatic arthritis. Few studies reported higher frequencies of CD4+GMCSF+ T-cells in the MS lesions and RA synovial fluid; however, there is no data on CD8+GMCSF+ T-cells. Thus, we planned to assess their frequencies in blood and synovial fluid, and characterize based on polyfunctionality, phenotype, cytotoxic ability and the effect of methotrexate on them.

Methods: The frequency of GMCSF producing CD8 and CD4 T-cells was assessed by stimulation with PMA/Ionomycin, followed by immunostaining and flowcytometry. Subsequently, polyfunctionality for other cytokines (TNFα, IFNγ and IL-17), memory/naïve phenotype and perforin/granzyme expression was also assessed by flowcytometry

Results: Enrichment of GMCSF producing T-cells was found in the synovial fluid, with elevated frequencies of both CD8+-GMCSF+ T-cells (5.8, 3.9%, p= 0.0045) and CD4+GMCSF+ T-cells (8.5, 4.5%, p=0.0008) compared to peripheral blood. These cells were characterised as extremely polyfunctional, with higher frequencies of triple cytokine positive GMCSF +TNFα+IFNγ positive CD8 T-cells (81, 36%, p=0.049) and CD4+GMCSF+TNFα+IFNγ+ (48, 32%, p=0.01)) in synovial fluid



compared to blood. Majority of GMCSF producing T-cells had an effector memory (EM) phenotype, besides CD8+GMCSF+ T-cells also having increased expression of granzyme B. After MTX treatment, there was a significant reduction in circulating CD4+ T-cells producing GMCSF (4.6% to 2.9%, p= 0.0014) and a similar trend was seen in the CD8 T (3.7% to 2.9% p= 0.068) cells.

Conclusion: Synovial fluid enrichment with GMCSF producing CD8 T-cells (and CD4 T-cells) was observed, demonstrating elevated polyfunctionality and granzyme B expression with majority belonging to EM phenotype. Upon treatment with methotrexate a reduction in the frequencies of these cells was found.

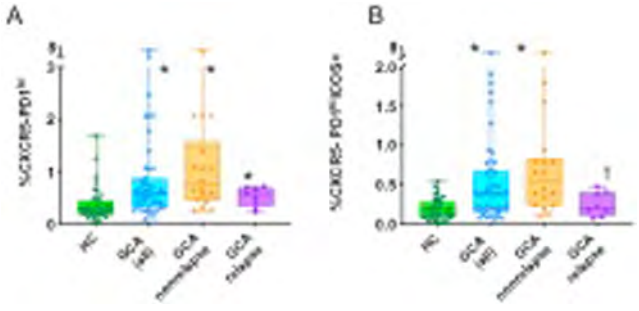
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a large-vessel granulomatous vasculitis. It is characterized by the presence at the inflamed arterial walls, of activated PD-1+ CD4 T cells; this contrasts with observations indicating that a defect of PD-1 signaling is implicated in the pathogenesis of GCA. A population of CD4+CXCR5-PD-1^{hi} cells, termed Tph cells, has been described at the inflamed synovium and peripehral blood of patients with Rheumatoid Arthritis, and seem to play a pathogenic role in this condition. Our objective was to study the frequencies of circulating total Tph (cTph) and activated ICOS+Tph (cICOS+Tph) cells in the peripheral blood of patients with newly diagnosed GCA (nGCA) and examine whether they are related with the clinical outcome.



Methods: This is a prospective non-interventional study performed on consecutive patients referred to our ultrasound (US) GCA fast track clinic, in whom newly diagnosed GCA (nGCA) was clinically confirmed (2022 ACR/EULAR criteria) over a period of 18 months. Peripheral blood was drawn immediately upon confirmation and after obtaining written informed consent. For each patient, an age and gender-matched healthy control (HC) was also studied. PBMCs isolated by Ficoll- Hypaque gradient were stained with antibodies to CD3, CD4, CD45RA, CD45RO, CXCR5, ICOS, PD-1, and examined by flow cytometry. Patients were treated with standard therapy according to clinical response.

Results: A total of 48 nGCA patients were included (mean age 81,5 years, 50.0 % female). As compared with HC, nGCA patients presented at baseline with an increased frequency of cTph and cICOS+Tph cells. Among the 26 patients who could be followed up for 12 months (the remaining 22 have been diagnosed less than 12 months ago),8 experienced a relapse (2018 EULAR recommendations; symptoms plus: elevation of acute phase reactants and/or positive US). Interestingly, the basal frequency of cICOS+Tph cells had been significantly lower in patients who relapsed as compared with those who did not; the frequency of cTph cells also tended to be lower in relapsing subjects but the difference with non-relapsing patients was not statistically significant.

Conclusion: Newly diagnosed GCA patients demonstrate an increased frequency of cTph and cICOS+Tph cells. Lower basal proportions of cICOS+ Tph cells are associated with relapse.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: CD4+CXCR5+PD-1^{hi} follicular helper (Tfh) T cells dwell in the germinal centers (GCs), help B cells, and are implicated in Rheumatoid Arthritis (RA) pathogenesis. Circulating counterparts of Tfh (cTfh) cells are expanded in patients with autoimmune conditions and their frequencies seem to correlate with the pool of GC Tfh cells. Abatacept (ABT), interfering with costimulation, can restrain Tfh cell generation and the role of Tfh cells may be pre-eminent in patients with higher cTfh cell frequencies. Therefore, our objective was to examine a). The effect of treatment escalation with TNF blockers (TNFb) or ABT, on the cTfh cell frequency in RA, and b). The relation of baseline cTfh cells with the clinical response.

Methods: Peripheral blood was drawn from seropositive RA patients with an incomplete response to csDMARDS (n=41) who initiated, according to routine clinical practice, TNFb (n= 19) (10 Etn, 3 Adal, 3 Certo, 2 goli, 1 Ifx) or ABT (n= 22). cTfh cell frequencies were determined by flow cytometry of freshly isolated PBMCs at the basal visit and 12 months (12M) after treatment escalation. Age and gender-matched healthy controls (HC) were also studied at both time points (n=41).

Results: a). As compared with HC, RA patients receiving csDMARDs showed increased frequencies (fr.) of cTfh and activated ICOS+ cTfh cells (a-cTfh). A significant improvement of disease activity(ΔDAS28 >2.0) was seen in all of the patients at 12M. The cTfh cell fr. did not vary in patients receiving TNFb but it dropped down to HC levels in those receiving ABT. The fr. of a-cTfh cells was significantly reduced in both groups; however, in the TNFb group it remained above HC whereas in the ABT group it dropped down to HC levels. b). In the ABT group, the baseline fr. of cTfh and a-cTfh had been higher for patients who went on to achieve remission at 12M (12Mr), as compared with those who remained active (12Ma) [Tfh logistic regression OR for remission 25.3,95% CI (12.2-39.8); ROC AUC 0.94(0.83-1), p< 0.0005]; as stated above, the 12M fr. were no longer elevated; in addition there were no differences between the 12Ma and 12Mr subjects. Conversely, in the TNFb group, the baseline fr. of cTfh and a-cTfh had been lower for 12Mr as compared with 12Ma patients [Tfh OR for not achieving remission 8.5 (4.3-15.5); ROC AUC 0.77(0.54-0.99), p< 0.05]; furthermore, the 12M fr. showed the same pattern: they had not significantly changed, persisted elevated above HC and remained lower in 12Mr as compared with 12Ma patients. The baseline cTfh cutoff fr. for achieving remission in the ABT group was >0.35% (sensitivity 92.7%, specificity 90%). The baseline cTfh cutoff fr. for not achieving remission in the TNFb group was >0.44% (sensitivity 67.7%, specificity 90%).

Conclusion: ABT but not TNFb, is able to curtail cTfh cell numbers in RA, suggesting that costimulation blockade can restrain germinal center overactivity. Higher baseline cTfh cell frequencies predict a good response to ABT and at the same time, a poor response to TNFb. Therefore, immunophenotyping of patients with an incomplete response to csDMARDs can facilitate a personalized therapeutic strategy for treatment escalation.

CD4 T Cell Repertoire Features in RA Patients with High-risk HLA-DRB1 Alleles

Amit Lakhanpal[1], Kazuyoshi Ishigaki[2], Anvita Singaraju[1], Alejandro Kochen[3], Miriam Fein[1], Soumya Raychaudhuri[4] and Laura Donlin[1], [1]Hospital for Special Surgery, New York, NY, [2]RIKEN, Tokyo, Japan, [3]Yale School of Medicine, New Haven, CT, [4]Brigham and Women's Hospital, Boston, MA

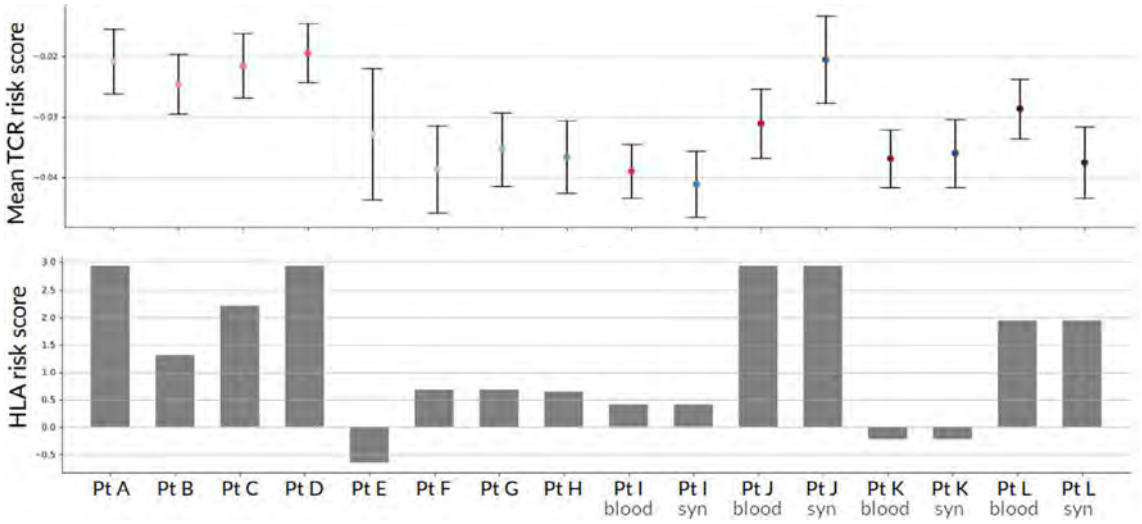
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: A role for CD4 T cells in RA pathology is supported by the effectiveness of T cell therapies, genetic studies implicating T cell gene regulation, and association with specific MHC Class II HLA-DRB1 alleles. Using expansive healthy cohorts, Ishigaki *et al* (Nat Gen 54:393-402 (2022)) previously identified CD4 T cell receptor (TCR) repertoire features associated with the presence of HLA-DRB1 RA risk alleles. These features can be combined into a TCR risk score. This TCR risk score included a positive association with high risk HLA alleles and specific amino acids in certain positions of the CDR3 region (for example, negative charged residues at position 110). Here, we computed TCR repertoire risk scores for 12 RA patients. Understanding these properties would have implications for our conception of the underpinnings of RA pathology.

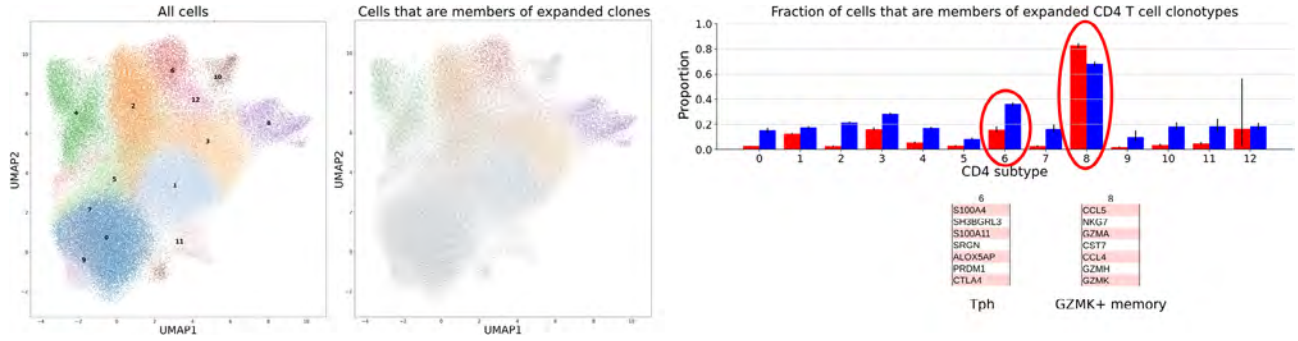
Methods: We obtained synovial tissue (n=8) and blood (n=8) from patients satisfying either the 1987 or 2010 ACR/EULAR RA classification criteria, with informed consent and IRB approval. We flow-sorted CD4 T cells and applied single-cell transcriptome and T-cell receptor sequencing (10X platform). We used our custom computational pipeline, implemented with scanpy, to assign CD4 transcriptional subtypes. We quantified TCR repertoire including clonal expansion and the Ishigaki *et al* TCR risk score, We also inferred HLA-DRB1 genotypes (using arcasHLA) from which HLA-RA risk scores were computed. ~5,000-9,000 cells per sample were analyzed.

Results: Across 12 RA patients, the TCR repertoire risk score positively correlated with the HLA-RA genetic risk score in each subject [Fig 1]; the degree of association is similar to that seen in the large-scale healthy cohorts. Three patients had the highest possible HLA-risk score (~3.0), due to both HLA-DRB1 copies containing the highest scoring risk alleles, which were all shared-epitope alleles. Notably, these patients also demonstrated the highest TCR risk score across their repertoires. For patients from which we had paired blood and synovial tissue CD4 T cells, the patient with the maximal HLA risk score demonstrated a larger overall TCR repertoire risk score in the synovium. Examining features of clonal CD4 T cell populations, we noted a preponderance of cells from expanded clones within two specific CD4 subsets, the T peripheral helper (Tph) and GZMK+ memory CD4 cells [Fig 2].

Conclusion: Our study has defined TCR receptor repertoire patterns that associate with high-risk HLA-DRB1 alleles in RA patients. Indeed, we now show that having two risky HLA-DRB1 alleles increases the total number of risk-associating T cell clones. Given the low frequency of clone sizes for CD4 T cells in general, the total number of risky T cell clonotypes may be a new marker of increased RA risk and argue for a broader repertoire-wide view of CD4 T cell involvement in RA rather than singular antigenic focused hypotheses. Future studies on these particular clones in high-risk repertoires may become highly relevant in further understanding RA disease etiology and treatment.



For each sample, the average of the TCR risk score (with standard error bars) in the upper plot, and the HLA risk score of the corresponding subject in the lower plot. Shades of red in the upper plot denote a blood origin of the sample, while shades of blue denote a synovial origin. Across all samples, there is a general tendency toward higher mean TCR risk score with higher HLA risk score. Looking within the paired samples (the rightmost 8 bars), there is no consistent relationship between the TCR risk score based on blood or synovial origin of the CD4 cells



Two-dimensional UMAP projection of high-dimensional scRNAseq data demonstrates quality of unsupervised Leiden clustering to isolate distinct CD4 T cell subtypes (by color, far left). Combining scRNAseq data with TCR repertoire data allows identification of cells belonging to CD4 T cell clonotypes that show evidence of expansion (i.e., a clonotype that appears more than once across data from all cells) (colored dots on right-side UMAP) The table summarizes genes found to be characteristic of the CD4 subtypes in which the most clonal expansion was observed, based on the scRNAseq data (circled in bar plot above, blue bars for synovium, red bars for blood). Based on those marker genes, two of the CD4 subtypes are identifiable as previously distinguished populations, T peripheral helper cells (Tph) and GZMK+ memory CD4 cells

Pharmacological Inhibition of PRMT5 Demonstrates Broad Efficacy in Multiple Preclinical Models of Autoimmunity and Inflammation by Suppressing Th1, Th17 and TNF-Mediated Inflammatory Responses

Neha Bhagwat[1], Kumar Penmetsa[2], Matt Devalaraja[3], Suzana Marusic[4], Cornelia M. Weyand[5], Shozo Ohtsuki[6], Peggy Scherle[1] and Kris Vaddi[1], [1]Prelude Therapeutics, Inc, Wilmington, DE, [2]Thermo Fisher Scientific, Philadelphia, PA, [3]Nipuna Therapeutics, Waltham, MA, [4]Hooke Laboratories LLC, Lawrence, MA, [5]Mayo Clinic School of Medicine and Stanford University, Rochester, MN, [6]Mayo Clinic College of Medicine and Science, Stanford University School of Medicine, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

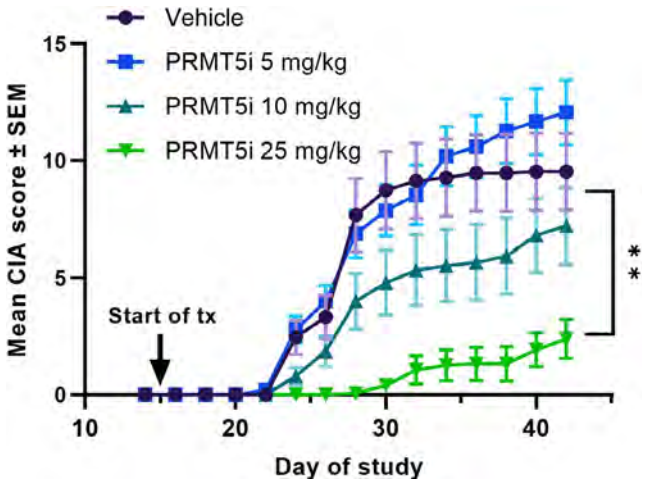
Background/Purpose: Protein arginine methyltransferase 5 (PRMT5) is the major type II PRMT that catalyzes the formation of symmetrical dimethyl arginine (SDMA) on protein substrates and is involved in the regulation of key inflammatory genes. In particular, PRMT5 plays an essential role in T cell homeostasis and activation-induced expansion by maintaining cytokine signaling. It has been shown to promote inflammatory T-cell responses, particularly those driven by Th1 and Th17 cells. Therefore, targeting PRMT5 with selective inhibitors offers a novel therapeutic approach to target T-cell mediated autoimmune and inflammatory disorders. We have previously reported that treatment with selective small-molecule inhibitors of PRMT5 leads to potent suppression of pro-inflammatory cytokines in preclinical models of acute graft-vs-host disease and myeloproliferative neoplasms. We therefore evaluated the effects of novel, selective and orally bioavailable PRMT5 inhibitors in rodent models of T-cell-driven autoimmunity and inflammation.

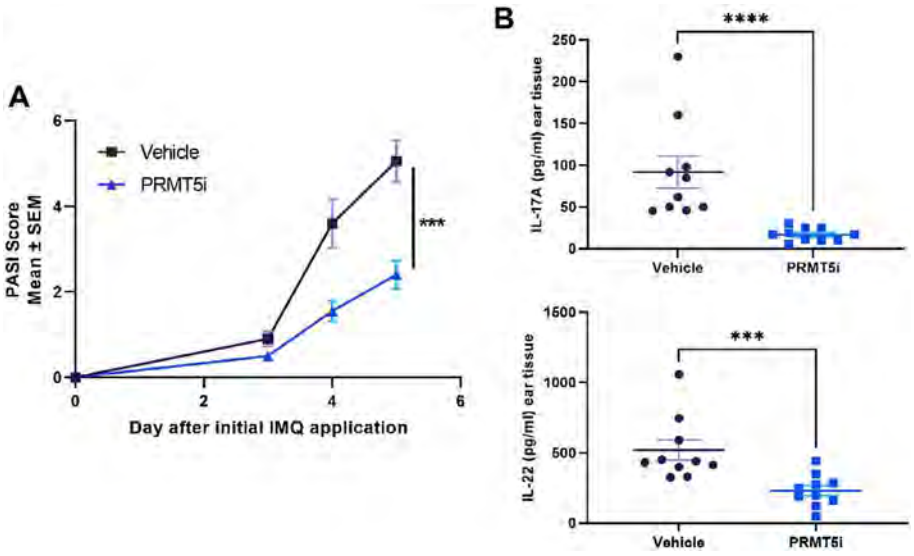
Methods: Orally administered PRMT5 inhibitors (PRMT5i) were evaluated in vivo in several rodent models including an MRL/lpr model of systemic lupus erythematosus, an imiquimod (IMQ)-induced model of psoriasis, a CIA mouse model of rheumatoid arthritis, an experimental autoimmune neuritis (EAN) rat model, and a human artery/NSG mouse chimera model of giant cell arteritis (GCA). In vitro, proliferation (Ki67), IFNγ and IL-17 production was measured in healthy human CD4+ T cells following stimulation and treatment with PRMT5i.

Results: In vitro, PRMT5i treatment significantly inhibited T-cell proliferation and differentiation of Th1 and Th17 cells. Consistent with these effects, PRMT5i treatment of MRL/lpr mice led to significant, dose-dependent reduction of disease severity including reduction in proteinuria, anti-dsDNA antibodies in serum, kidney pathology and key serum cytokines such as TNF, IFNγ and BAFF. Treated animals showed decreased pro-inflammatory CD4+ cells and increased Tregs in kidneys and spleens compared to vehicle controls. In addition, PRMT5i were efficacious at reducing disease severity (PASI score) in the IMQ-induced psoriasis model. Inhibitor treated animals had significantly lower IL-17A and IL-22 serum concentrations compared to vehicle controls. In the CIA model, PRMT5i administration reduced disease incidence and severity in a dose-dependent manner. PRMT5i treatment in a rat model of EAN also resulted in significant reduction of disease severity as evidenced by reduced inflammatory infiltration and higher myelination of peripheral neuronal tissue. Finally, in a humanized mouse model of GCA, treatment with PRMT5i reduced inflammatory mononuclear cell infiltration in the blood vessel wall and reduced levels of IFNγ and IL-21 compared to either vehicle or prednisolone treated animals.

Conclusion: PRMT5 inhibitors were highly effective in suppressing Th1, Th17 and IFNγ-mediated immune responses in a number of preclinical models of human autoimmune diseases at well-tolerated doses. These data support the potential development of PRMT5i as a therapy for inflammatory and autoimmune diseases.

PRMT5 inhibitors show dose-dependent efficacy in a mouse CIA model.





Oral administration of PRMT5i shows (A) significant improvement in erythema and skin thickness (represented by PASI score) and (B) reduction in key cytokines in ear tissue in an IMQ-induced psoriasis model.

RA Disease Activity Influence the Frequency and Phenotype of Citrulline Reactive CD4 T Cells in DRB1*04:04 ACPA+ RA Patients

Cliff Rims[1], Anne Hocking[1], Sylvia Posso[1], Bernard Ng[2], Jeffrey Carlin[3], Jane Buckner[4] and Eddie James[4], [1]Benaroya Research Institute, Seattle, WA, [2]Veteran Affairs, Seattle, WA, [3]Virginia Mason Medical Center, Seattle, WA, [4]Benaroya Research Institute at Virginia Mason, Seattle, WA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of ACPA in RA signifies an immune response toward citrullinated auto-antigens in disease pathogenesis and persistence. RA is a T cell mediated disease based on response to T cell directed therapy, enrichment of T cells in the joint, and association with HLA class II alleles.DRB1*04:01 cit-epitopes have been well described originating from auto-antigens aggrecan, cartilage intermediate layer protein (CILP), α-enolase, α-fibrinogen, and vimentin. Despite DRB1*04:04 inclusion among the shared epitope alleles and over-representation in RA, literature identifying

DR0404 restricted cit-epitopes have been scarce. The purpose of this study was to determine antigen specificities and to describe the character of DR0404 cit-reactive CD4 T cell responses in RA.

Methods: RA and control subjects were recruited with informed consent and sampled through the IRB approved Benaroya Research Institute (BRI) rheumatic disease and control registries. All subjects had at least one copy of the HLA-DRB1*04:04 allele. All RA subjects met the 2010 ACR criteria for RA, were ACPA+, and represented a range of characteristics that included duration of disease, therapy treatment, and disease activity at the time of draw.

Cit-peptides were designed starting from antigens reported in the literature to be associated with RA, synthesized based on predicted binding to DR0404 using a calculation matrix, and binding is confirmed using a competition assay. The peptides were assessed for immunogenicity using a 14-day in-vitro peptide stimulation assay using cognate-peptide loaded DR0404 tetramers to report response. T cell clones that target cit-peptides were isolated from responders. Finally, to characterize cit-specific CD4 T cells, blood from 23 RA and 20 healthy DR0404 subjects were stained with a multi-color cit-tetramer panel along with antibodies to determine CD4 subtype.

Results: A 74 cit-peptide library from aggrecan, CILP, α-enolase, α-fibrinogen, and vimentin was synthesized based on results from a DR0404 cit-prediction binding matrix. Next, a competition assay confirmed 23 peptides as DR0404 binders. All 23 peptides elicited an immune response in RA PBMC using a 14 day in-vitro stimulation assay and 6 clones were isolated and verified using tetramers. These results were used to create a multi-color 13 tetramer DR0404 ex-vivo panel where PBMC was stained from RA and healthy subjects. Ex-vivo analysis revealed all RA subjects having detectable cit-specific CD4 T cells whose memory cells consisted of either CXCR3+ or CCR4+. The frequency of memory cit-specific CD4 T cells was elevated among RA subjects with high disease activity and also enriched of Th1 and Th2 lineage.

Conclusion: These findings identify novel DR0404 restricted cit-epitopes and provide tools to capture and interrogate cit-reactive CD4 T cells in patients with RA and those at-risk for disease. In particular, we show cit-reactive T cell frequency and it's inflammatory subsets are influenced by disease activity using a multiplexed tetramer assay, which can be used to better understand the interplay of antigen specificities and phenotypes in the pathogenesis of RA.

RA disease activity influence the frequency and phenotype of citrulline CD4 T cells. (A) The frequency of CD45RA-negative tetramer cells were analyzed based on RA subjects RAPID3 score outcome (Near-Remission/Low <2.3; Moderate activity <4.3; and High activity >4.3) along with healthy subjects. RA subjects with high disease activity were those with the highest frequency compared to healthy subjects among citrulline antigens combined, alpha-enolase, CILP, vimentin, and fibrinogen. (B) The dominant phenotype of citrulline antigens among high RA active disease are Th1 and Th2 type cells respectively. The p-values of both A and B were calculated using Kruskal-Wallis test.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: VAV1 is a member of the VAV family of guanine nucleotide exchange factors (GEFs) and plays a critical role in mediating T- and B-cell receptor activity. VAV1 expression is primarily restricted to immune cells, positioning it as an attractive target for the treatment of inflammatory and autoimmune diseases. In knockout mice and human-based CRISPR screens, *VAV1/Vav1* loss has been linked with reduced T- and/or B-cell function. Despite being a well-validated target for T- and/or B-cell mediated autoimmune disease, VAV1 has remained undruggable to date using small molecule inhibitor approaches. MRT-6160 is a highly selective first-in-class oral VAV1-targeting molecular glue degrader (MGD), which induces proteasomal degradation of VAV1 through formation of a ternary complex with the E3 ligase cereblon. We propose that targeting VAV1 will have broad therapeutic implications in a variety of autoimmune disorders driven by the underlying dysregulation of T- and B-cells, including rheumatoid arthritis.

Methods: Human cells were treated with MRT-6160 and profiled for VAV1 levels and selectivity. To determine effects of MRT-6160-mediated VAV1 degradation on lymphocyte function, pharmacodynamic and functional readouts were assayed in TCR- and BCR-stimulated purified human T- and B-cells. To test pharmaco-kinetics and -dynamics of MRT-6160 *in vivo*, healthy mice were treated with a single oral administration of MRT-6160 followed by assessment of compound and VAV1 levels in multiple tissues over time. The *in vivo* activity of MRT-6160 was evaluated in the collagen-induced arthritis (CIA) autoimmune disease setting where female DBA/1 mice were immunized on day 0 (intravenously) and boosted on day 21 (subcutaneously) using chicken type II collagen emulsified in complete or incomplete Freund's adjuvant respectively. Following disease onset (average clinical score of ~1.5), mice were randomized into treatment groups and orally administered vehicle or 10 mg/kg MRT-6160 daily. In positive control groups, mice were administered either 1 mg/kg dexamethasone (daily via intraperitoneal injection) or 500 μg anti-TNF (three times weekly via intraperitoneal injection). Mice in all treatment groups were dosed for a duration of 20 days and assessed daily for body weight and clinical signs of arthritis in all four paws.

Results: MRT-6160-mediated selective degradation of VAV1 attenuated TCR- and BCR-mediated activation and function in primary human T- and B-cells. *In vivo*, oral dosing of MRT-6160 elicited Vav1 degradation across multiple tissues in a dose-dependent manner. Over the course of 20 days dosing in the CIA autoimmune disease setting, MRT-6160 significantly decreased disease progression and endpoint clinical scores (3.2±2.6) compared to vehicle (12.5±4.0) and was comparable to anti-TNF (4.4±3.7).

Conclusion: The VAV1-targeting MGD MRT-6160 attenuates disease progression in the autoimmune CIA model with a therapeutic treatment regimen. This warrants further investigation of MRT-6160 in a clinical setting.

Expression of mRNA Vaccine Antigen in Hematopoietic Cells Is Necessary for Induction of Optimal Vaccine-Specific CD4$^+$ T Cell Responses

Julia Rood[1], Stephanie Suh Kyung Yoon[2], Mary O'Mara[3], Mary Kate Heard[3], Chaitali Bhadiadra[3], Nhu Le[3], Christabel Ameyaw Baah[3], Norbert Pardi[4] and Laurence Eisenlohr[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]School of Engineering and Applied Science, University of Pennsylvania, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA, [4]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: mRNA vaccines are safe and remarkably effective, but rare cases of vaccine-induced autoimmunity have been reported, particularly in patients with underlying inflammatory disease. Mechanistic insight into such cases is limited by the fact that little is known of the proximal events leading to CD4$^+$ T cell priming after mRNA vaccination. Vaccine antigen derived from cells at the immunization site, such as muscle cells, is presumed to activate CD4$^+$ T cells through uptake by antigen presenting cells (APCs) and processing via the classical exogenous pathway. However, APCs themselves efficiently produce mRNA-encoded antigen, and in analogous viral infection models, virus-specific CD4$^+$ T cell responses are driven primarily by endogenous antigens presented via non-classical pathways. We investigated whether a similar phenomenon underlies CD4$^+$ T cell responses to mRNA vaccines.

Methods: We developed a series of mRNA vaccines that encode a model viral protein (influenza nucleoprotein, NP), followed by specific microRNA (miR) targeting sequences that allow for differential expression of vaccine antigen in different cell types. Three different NP-miR mRNA constructs were generated. "NP-miR142t" contains the targeting sequence for hematopoietic-specific miR-142, leading to inhibition of NP expression within hematopoietic cells – and thus reliance on exogenous antigen for presentation to CD4$^+$ T cells. "NP-miR206t" contains the targeting sequence for muscle cell-specific miR-206, thus excluding NP expression from muscle cells and forcing APCs to rely primarily on endogenous antigen. A control "NP-scrambled" construct contains scrambled miR binding sites that are not targeted by any miRs. Cell-type specificity of miR targeting was validated *in vitro* by flow cytometry and Western blot. Mice were immunized intramuscularly with mRNA encapsulated in lipid nanoparticles to evaluate NP-specific CD4$^+$ T cell responses *in vivo*.

Results: Mice immunized with NP-miR142t demonstrated significantly lower frequencies of NP-specific $CD4^+$ T cells by both IFNg ELISpot and tetramer staining, compared to mice immunized with NP-scrambled, suggesting that antigen expressed within hematopoietic cells is critical to the $CD4^+$ T cell response. Immunization with NP-miR206t resulted in only a modest reduction in NP-specific $CD4^+$ T cells, despite significantly decreased NP protein levels within muscle.

Conclusion: Optimal $CD4^+$ T cell activation by mRNA vaccines requires antigen expression in APCs and other hematopoietic cells, suggesting that endogenous antigen presentation is a major driver of the $CD4^+$ T cell response. Contrary to the prevailing paradigm, exogenous vaccine antigen derived from muscle and other cells may not be the primary source of antigen activating vaccine-specific $CD4^+$ T cells. Future studies will expand upon these findings to determine how restriction of antigen source – and therefore processing via exogenous or endogenous pathways – impacts adaptive immune responses to mRNA vaccines more broadly.

Excess IL-18 Protects from Experimental Autoimmune Encephalomyelitis Mainly via Preferential Augmentation of Suppressor/Regulatory over Autoreactive T-cell Function

Jeremy Morrissette[1], Vinh Dang[2], Jemy Varghese[2], Zachary Lanzar[1], Junior Nguyen[2], Emily Landy[3], Anastasia Frank-Kamenetskii[4] and Scott Canna[2], [1]University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]CHOP/UPENN, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Interleukin 18 (IL-18) is an inflammasome-activated cytokine that canonically amplifies interferon-gamma (IFNg) production and cytotoxicity by CD8 T-cells (CD8Ts) and Th1 CD4 T-cells (CD4Ts). It is inhibited by the circulating high affinity antagonist, IL-18 binding protein (*Il18bp*). In certain contexts, IL-18 amplifies non-Th1 responses including Th2, Th17, and Treg. Despite its likely pathogenic role in autoinflammation, clinical observations suggest a possible immunoregulatory role in CD4T-mediated autoimmunity. We sought to understand the role of excess IL-18 in the mixed Th1/17 experimental autoimmune encephalomyelitis (EAE) model of central nervous system autoimmunity.

Methods: EAE was induced via immunization with a complete Freund's adjuvant/Myelin Oligodendrocyte Glycoprotein peptide (MOG^{35-55}) emulsion and pertussis toxin in the following mice: mice deficient in Il-18bp ($Il18bp^{-/-}$), with transgenic overproduction of mature IL-18 (Il18tg), transgenic for a T-cell receptor recognizing MOG^{35-55} (2D2 mice), and relevant controls . EAE was monitored by daily clinical scoring of ascending paralysis. Cell number and cellular protein phenotype were determined by flow cytometry.

Results: We hypothesized that systemic excess IL-18, would amplify autoreactive T-cell activation and lead to more severe EAE, but both $Il18bp^{-/-}$ and Il18tg mice were profoundly protected from EAE (Fig. 1). Protection from EAE in $Il18bp^{-/-}$ mice depended on IFNg. Draining lymph nodes and spleens from $Il18bp^{-/-}$ mice showed a modest increase in IFNg-producing

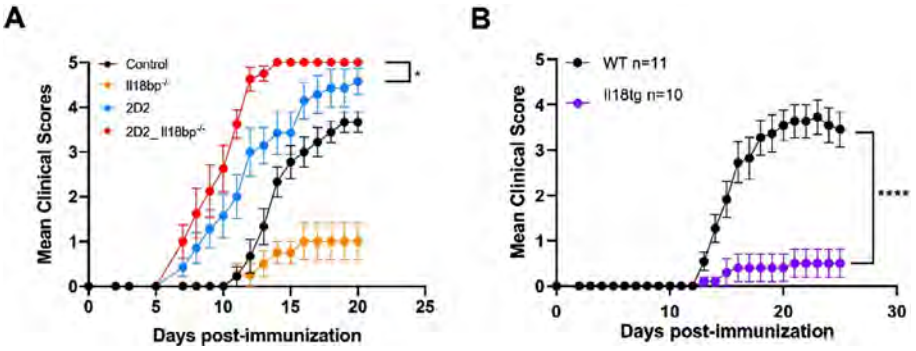

Figure 1: Excess IL-18 protects against EAE development with a physiologic T cell repertoire. Il18bp-/-, 2D2, 2D2;Il18bp-/- (A), or Il18tg (B) mice underwent EAE immunization on day 0 with daily clinical EAE scoring compared to WT control mice.

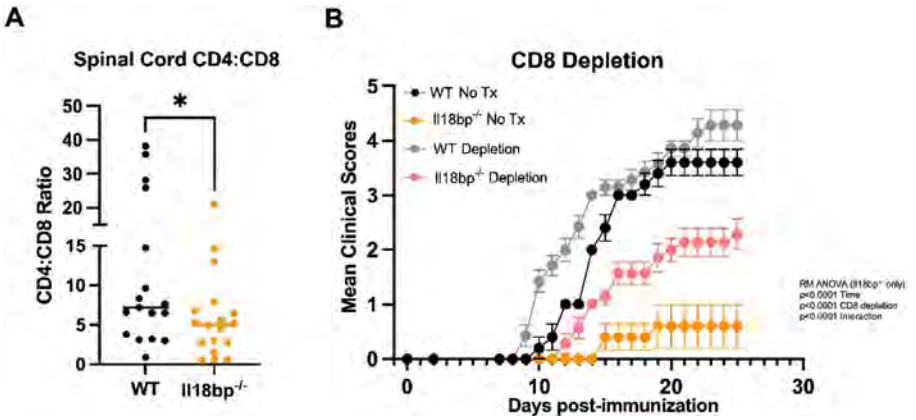

Figure 2: Excess IL-18 enriches CD8 T cells and depends on CD8 T cell function for protection. Spinal cords were analyzed by flow cytometry from WT and Il18bp-/- mice at peak disease (day 19 to 21) and the ratio of CD4 to CD8 T cells is represented (A). Mean clinical EAE score of WT and Il18bp-/- mice receiving isotype control (LIF2 Rat IgG2b) or CD8 depleting antibody (YTS169.4) q3d starting on day 0 (B).

CD4Ts and equivalent IL-17-producing CD4Ts. Spinal cords demonstrated fewer CD4T cells but comparable markers of Th function/polarization on a per-cell basis. There was increased infiltration of CD8Ts relative to CD4Ts in spinal cords of $Il18bp^{-/-}$mice (Fig. 2A). 2D2 mice have an abundance of MOG autoreactive CD4Ts and very few CD8Ts (due to allelic exclusion). Paradoxically, $Il18bp^{-/-}$;2D2 mice developed more severe EAE than control 2D2 mice (Fig.1A), suggesting that an increase in precursor autoreactive CD4Ts and/or loss of CD8Ts switches the effect of excess IL-18 from protective to pathogenic. Sensitivity to EAE was restored in $Il18bp^{-/-}$mice only after transfer of >5 million autoreactive 2D2 CD4Ts. Further, ex vivo culture with IL-18 improved CD8Ts ability to inhibit EAE while CD8-depletion substantially, but incompletely, diminished protection in $Il18bp^{-/-}$ mice (Fig.2B).

Conclusion: These data suggest the IL-18 can amplify both autoreactive CD4T and previously described CD8 T suppressor cells but the latter dominate with a physiologic T cell repertoire. Excess IL-18 may function to preferentially augment CD8T suppressor function to clear autoreactive CD4T and mediate protection in EAE. This may inform novel strategies to amplify endogenous suppressive T cells or enhance cellular therapeutics in the treatment of autoimmune diseases.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is a chronic, systemic autoimmune disease affecting the skin, muscle, and lungs. The activation of CB2R has been shown to reduce several, key proinflammatory cytokines implicated in DM. Our group has previously shown that CB2R expression was significantly increased in in DM skin compared to blood, possibly due to increased production of local inflammatory cytokines. CB2R stimulation alleviates inflammatory response by down-regulating the expression of TNF-α, IL31, IFN-γ, and type I interferon expression in the early stage of inflammation and reducing the infiltrated inflammatory cells. Having more CB2R on inflammatory cells will lead to enhanced effects of a CB2R agonist. We hypothesized that fibroblasts (FBs) in the skin may play an important role in upregulating CB2R on inflammatory cells within the skin. Dermal fibroblasts produce and organize the extracellular matrix of the dermis. They also communicate with each other and other cell types. Therefore, we sought to examine the role of FBs in CB2R activation.

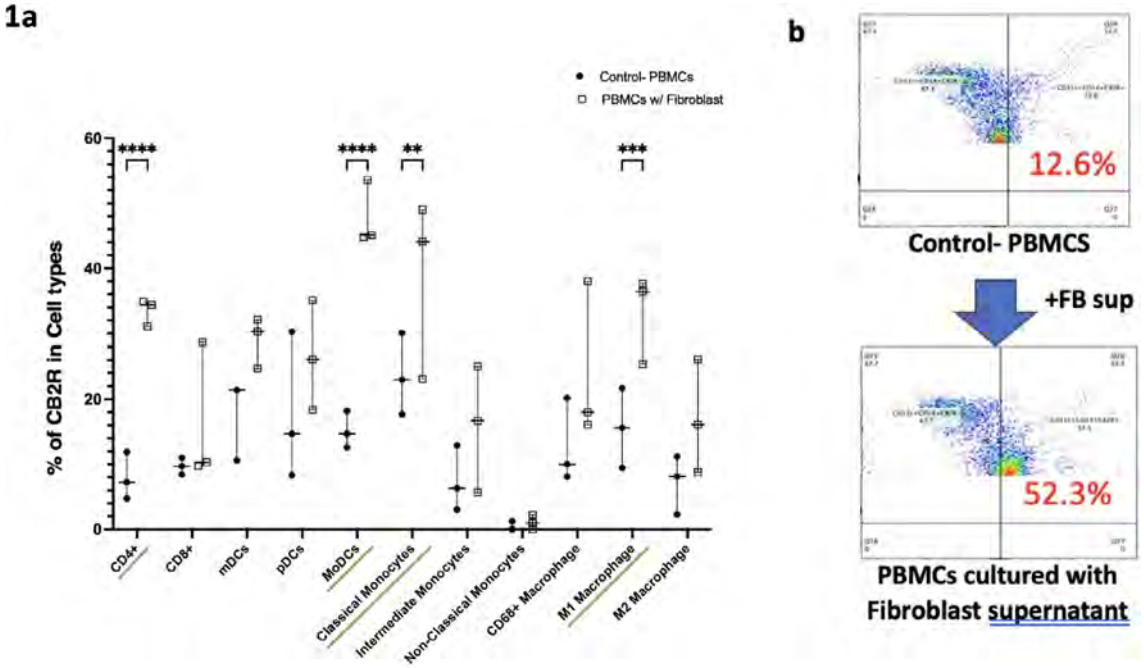

Figure 1. (a) Flow cytometric analysis showing % of CB2R when PBMCS were cultured with fibroblast supernatant. (b) Representative figure in a single DM pt. demonstrates a higher percentage of CB2R on PBMCs cultured with fibroblast supernatant than control.

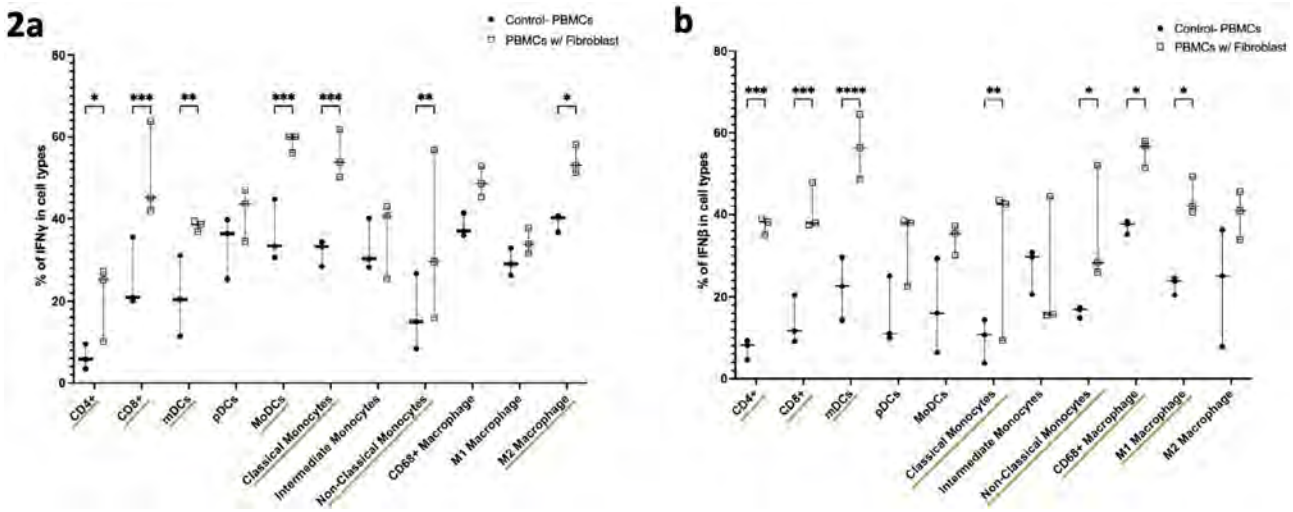

Figure 2. Flow cytometric analysis showing % of IFNγ and IFNβ when PBMCS were cultured with fibroblast supernatant.

Methods: DM PBMCs, which typically have minimal CB2R expression, were cultured with medium with or without human FB supernatant. PBMCs from DM patients were cultured for 24 hrs with control medium at 1:1 dilution with or without fibroblast supernatant retrieved from a 6 well plate of 40-50% confluent primary fibroblast. We then utilized multiplexed flow cytometry to further analyze the expression of CB2R and inflammatory cytokines on 12 cell lineages.

Results: When comparing PBMCs cultured with and without FB supernatant, cells cultured with FB supernatant had a significant increase in CB2R expression on CD4+ T cells ($p < 0.0001$), monocyte-derived dendritic cells (moDCs) ($p < 0.0001$), classical Monocytes (CM) ($p < 0.001$), and M1 Macrophages ($p < 0.0001$). (Figure 1a) There was also a significant increase in inflammatory cells cytokines. When comparing PBMCs cultured with and without FB supernatant, cells cultured with FB supernatant had a significant increase in intracellular IFNγ and IFNβ expression in CD4+ T cells ($p < 0.01$);$p < 0.001$), CD8+T cells ($p < 0.001$; $p< 0.001$), CD11c+ cells ($p < 0.001$; $p< 0.0001$), moDCs in IFNγ ($p < 0.0001$), CMs ($p < 0.0001$; $p< 0.001$), and macrophages ($p < 0.01$). (Figure 2a-b). There was also a significant increase in inflammatory cells cytokines such as TNFα, IL31 and IL4 in CD4+ T cells, moDCs, CD11c+ myeloid dendritic cells, CMs and CD68+ macrophages (data not shown).

Conclusion: These data suggest fibroblasts play a role in increasing CB2R on inflammatory cells, as well as stimulate production of cytokines in DM skin. This suggests that drugs that activate CB2R, leading to downregulation of proinflammatory cytokines, may have enhanced efficacy in the skin due to FB-induced local upregulation of CB2R on inflammatory cells in the skin.

Optimizing PD-1 Agonist Signaling with Membrane Proximal Binding of Rosnilimab, a Clinical Stage PD-1 Agonist IgG1 Antibody

Stephen Parmley, Benjamin Szylyk, Richard Frank, Matthew Hsu, Polina Brodsky, Cailin Sibley, Paul Lizzul and Martin Dahl, AnaptysBio, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Checkpoint antagonist therapeutics have transformed the field of oncology while advancing the understanding of adequate checkpoint activity in preventing autoimmunity. Checkpoint agonism represents a promising and expanding class of therapies for the treatment of autoimmune diseases, including rheumatoid arthritis (RA), where unmet needs persist despite available therapies. The characteristics that confer agonistic properties to an antibody targeting a checkpoint receptor is an evolving science. Binding to membrane proximal regions of suppressive receptors, together with Fc interactions with receptors on opposing cells, can contribute to tight immune synapse formation between the immune cell and antigen presenting cell. This has been proposed to improve potency of agonistic signaling by excluding activating phosphatases from the immune synapse and promoting receptor clustering. Optimization of these characteristics results in improved agonism and depletion carrying the potential for restoration of immune balance and differentiated clinical efficacy. Rosnilimab has been engineered to leverage these important characteristics. It is a PD-1 agonist antibody with an IgG1 backbone designed to optimize inhibitory signaling through the PD-1 receptor and to deplete PD-1-high pathogenic T cells. It is currently in clinical development for RA and other inflammatory conditions.

Methods: Mutations were targeted to surface exposed regions of the PD-1 extracellular domain where antibodies are likely to bind. Surface plasmon resonance of PD-1 structural mutants were used to locate the epitopes of PD-1 agonist molecules. Membrane proximal and distal binding antibodies were studied in *in vitro* functional assays to assess T cell proliferation and antibody-dependent cellular toxicity (ADCC).

Results: Epitopes of agonistic antibodies were mapped to locations on the PD-1 receptor. The membrane proximal epitope location of rosnilimab was confirmed and binding epitopes for other reference antibodies were identified. Rosnilimab and a membrane distally binding antibody (Reference 1 Antibody) were selected for comparison in functional assays. Rosnilimab demonstrated better inhibition of T cell proliferation and depletion of PD-1+ T cells compared to Reference 1 Antibody, consistent with the hypothesis that membrane proximal binding improves agonistic activity and target cell depletion.

Conclusion: By therapeutically targeting and leveraging natural immune regulatory mechanisms to modulate the pathogenic T cells driving disease, there is an opportunity to dampen the inflammatory cycle and restore immune balance via agonism. Rosnilimab binds to a membrane proximal region of the PD-1 receptor, resulting in optimized inhibition of T cell proliferation, inhibition of cytokine signaling, and PD-1-high T cell depletion. These mechanistic data, robust Phase 1 healthy volunteer safety, PK and translational PD data, and recognized persistent unmet needs in the treatment of RA provide rationale for an ongoing global Phase 2 dose-ranging study of rosnilimab in RA patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitor (ICI) therapies used to treat cancer can induce immune related Adverse events (irAEs) such as ICI-induced arthritis (ICI-arthritis). We have previously identified a cytotoxic, CD38^{hi}CD127^{-} CD8 T cell population that is expanded in the joints of ICI-arthritis patients and characterized by an IFN signature. The extent to which these cells can also be found in the circulation and their potential relationship to T cells in inflamed joints has been unclear. In this study we assessed T cell phenotypes in the circulation following ICI therapy and the clonal relationship between anti-PD-1-bound CD8 T cells in the joints and circulation of ICI-arthritis patients.

Methods: We applied mass cytometry on PBMCs from patients with advanced melanoma in the ADAPT-IT trial who received nivolumab plus ipilimumab, with analysis of PBMC pre-treatment and post-2 cycles (n = 48; 31 with paired pre/post samples) . An anti-IgG4 antibody was included to detect nivolumab (an IgG4 antibody) bound on the cell surface. Separately, bulk TCR sequencing was performed on memory CD8 T cells from paired blood and synovial fluid samples of 3 ICI-arthritis patients.

Results: Unbiased clustering and differential abundance analysis of T cell populations in PMBC from before and after treatment identified several changes in T cell populations, including an increase of a GZMB+ CD8 T cells subset (p=0.0002), a FoxP3+CD25+ regulatory CD4 T cell subset (p< 0.0001) and a CCR6+CD161+ Th17 cell subset (p=< 0.0001). The most dramatic change observed across all PBMCs was a significant induction of CD38^{hi}CD127^{-} CD8 and CD4 T cells

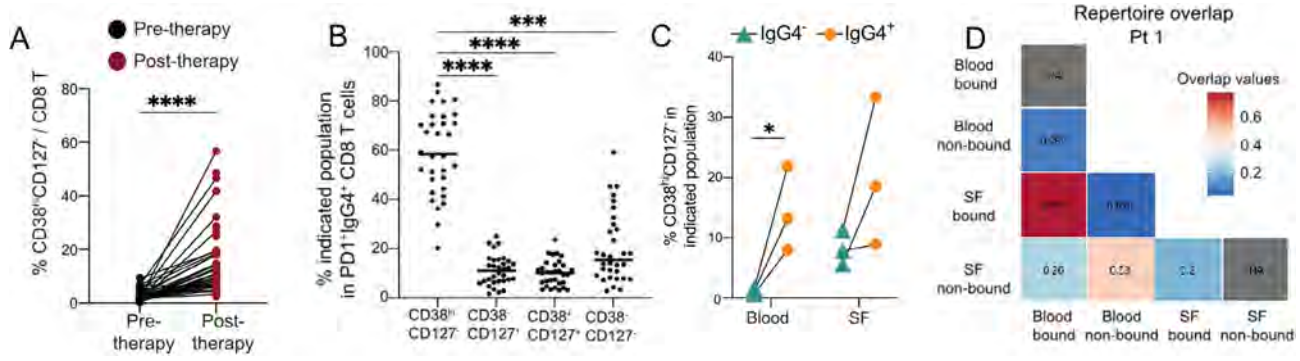

Figure 1.(A) Frequency of CD38hiCD127- CD8 T cells before and after combination ICI therapy. (B) Frequency of anti-PD-1-bound CD8 T cells divided by their expression of CD38 and CD127. (C) Frequency of CD38hiCD127- CD8 T cells in IgG4+ or IgG4- CD8 T cells in either blood or synovial fluid of ICI-arthritis patients. (D) Representative plot of Morisita index values for each comparison demonstrating the repertoire overlap of patients in (C).

($p< 0.0001$,$p< 0.0001$) (Fig 1A). Both the CD8 and CD4 $CD38^{hi}$ T cells were often bound by anti-PD-1 therapy and were Ki67+, indicating that they are proliferative (Fig 1B).

We further investigated the anti-PD-1 drug-bound CD8 T cells in paired blood and synovial fluid samples of those with ICI-arthritis. In both blood and synovial fluid, $CD38^{hi}CD127^{-}$ CD8 T cells were more frequent in anti-PD-1-bound samples than non-drug-bound samples (Fig 1C). In ICI-arthritis patients, anti-PD-1 drug-bound CD8 T cells in blood had marked clonal overlap with drug-bound CD8 T cells in synovial fluid (Fig 1D). There was minimal overlap between drug-bound cells in the synovial fluid and non-drug-bound cells in blood.

Conclusion: $CD38^{hi}CD127^{-}$ CD8 T cells are expanded following ICI therapy and exhibit clonal overlap in the synovial fluid and circulation of ICI-arthritis patients. These results suggest that anti-PD-1 therapy directly targets CD8 T cells to induce $CD38^{hi}$ cytotoxic CD8 T cells. Further, drug-bound, activated cells in the circulation may provide a unique view into the activated T cell populations that accumulate within joints of ICI-arthritis patients.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: $CD4^{+}$ $Foxp3^{-}$ conventional T cells (Tconv) play a key role in the inflammatory process involved in rheumatoid arthritis (RA). Recent studies, aided by a substantial advance in available technologies (RNA sequencing, multiparameter flow cytometry and mass cytometry), identified additional $CD4^{+}$ T cell subpopulations that are expanded or dysregulated in RA. It notably included peripheral helper (T_{PH}) T cells ($PD\text{-}1^{hi}$ $CXCR5^{-}$) and cytotoxic $HLA\text{-}DR^{+}$ $CD27^{-}$ $CD4^{+}$ T cells ($CD4^{+}$ CTLs). Regarding pro-inflammatory Tconv, a major remaining objective is to identify additional parameters that support their pathological functions, and then to focus on those that are therapeutically targetable. Among the receptors potentially capable of upregulating the Tconv response, SLAMFs (Signaling lymphocytic activation molecule) represent a family of nine receptors. In RA, our objectives were to determine whether SLAMF receptors are involved in the establishment of the Tconv pro-inflammatory response.

Methods: In RA, we used a multiparametric approach, including multiple flow cytometry panels, cells sorting, RNA sequencing, and various bioinformatics analysis to immuno-phenotyped Tconv from peripheral blood (PB) and synovial fluid (SF). SLAMFs expression was determine among four Tconv subpopulations with different activation status (naive, central memory, effector memory and terminally differentiated effector $CD4^+$ T cells). To assess the inflammatory tropism of Tconv subpopulations, CCR5 expression was studied. The transcriptome of $SLAMF4^+$ $CCR5^+$ Tem was compared to that of their $SLAMF4^-$ counterpart using RNA sequencing. Unpaired and paired data were analyzed usinga parametric test or a non-parametric test according to data distribution. In analyses involving more than 2 comparisons, appropriate post-hoc comparisons were systematically used. Correlations between quantitative parameters were assessed using the Spearman test.

Results: In RA, the study of SLAMF expression among four Tconv subpopulations from peripheral blood (PB), showed that effector memory $CD4^+$ T cells (Tem, $Foxp3^-$ $CCR7^-$ $CD45RA^-$) overexpressed SLAMF4 in patients with active disease. This association was restricted to Tem co-expressing SAP and the chemokine receptor CCR5 (figure 1 a-b). Moreover, RNAseq experiments,

Figure 1:

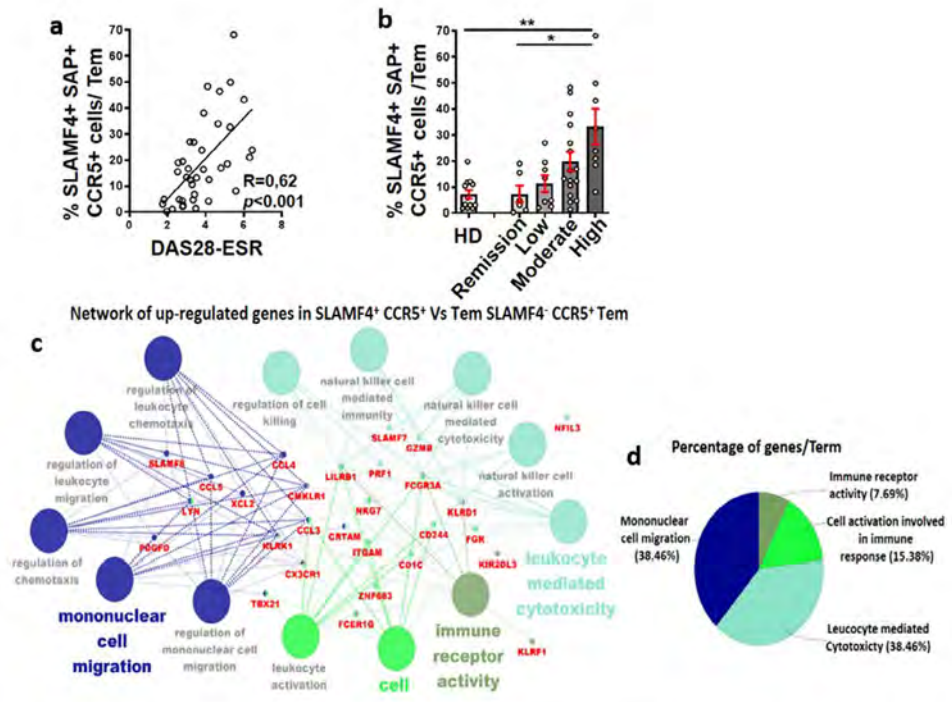

Figure 1: $SLAMF4^+$ effector memory T cells represent a subpopulation of Th1 like cytotoxic Tem associated with RA activity. (a-b) Flow cytometry experiments were performed using PBMCs from RA patients (n=38) and from HD (n=12). **(a)** Spearman correlation between the DAS28-ESR and the % of $SLAMF4^+$ SAP^+ $CCR5^+$ cells among Tem (RA patients). **(b)** % of $SLAMF4^+$ SAP^+ $CCR5^+$ cells among Tem in PBMCs from HD and RA patients according to disease activity defined using DAS28-ESR. A Kruskal-Wallis test was applied. **(c-d)** RNAseq experiments were performed from sorted $SLAMF4^+$ $CCR5^+$ and $SLAMF4^-$ $CCR5^+$ Tem from PBMCs of RA patients (n=4). The Wald test with the contrast function and the Benjamini-Hochberg FDR control procedure were used to identify the differentially expressed genes. A FDR <0.05 and a log2(Fold change) >1 were used as cutoff to determine differentially expressed genes (DEGs). **(c)** Enriched functions and pathways of the 100 most significantly up-regulated genes in $SLAMF4^+$ $CCR5^+$ Vs $SLAMF4^-$ $CCR5^+$ Tem. The network of pathways was created using the ClueGo and CluePedia plugins in Cytoscape. The most significant term of each group appeared in bolt. **(d)** Pie chart showing the most significant terms. *p<0.05 and **p<0.01.

Figure 2 :

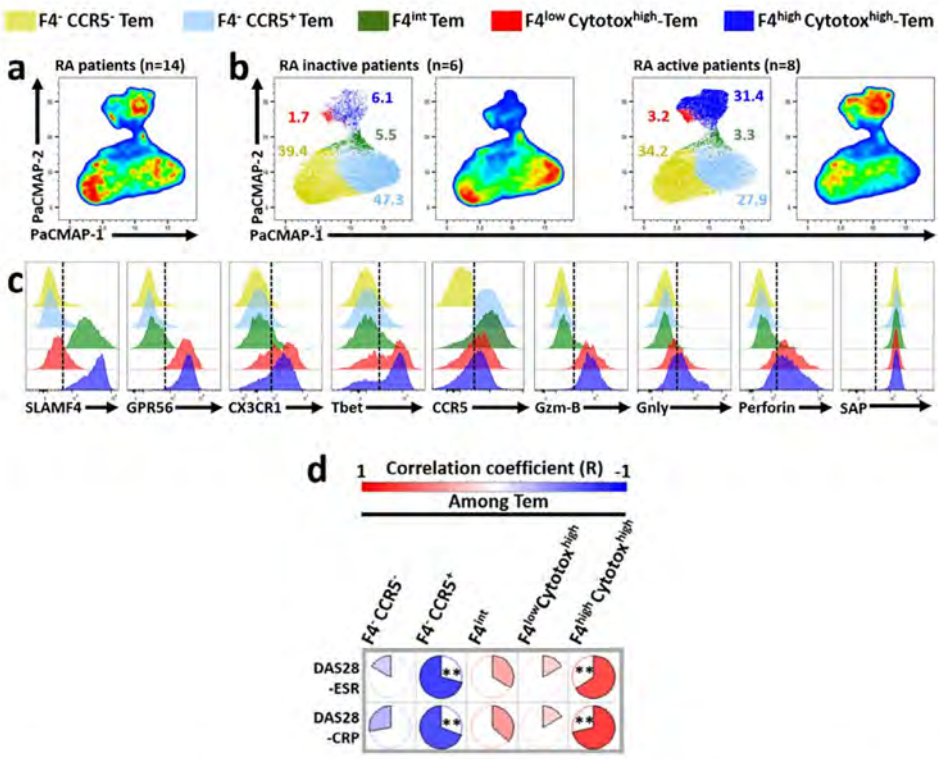

Figure 2: CD4⁺ SAP⁺ CCR5⁺ CTL subpopulations need to express SLAMF4 to be related to RA activity. (a-d) Flow cytometry experiments were performed using PBMCs from RA patients (n=14). **(a)** PaCMAP analysis was done among CD3⁺ CD4⁺ Foxp3⁻ CD45RA⁻ CCR7⁻ cells using concatenated flow cytometry files from 14 RA patients. Cell subsets were determined among Tem (CD3⁺ CD4⁺ Foxp3⁻ CD45RA⁻ CCR7⁻ cells) by the expression of SAP, SLAMF4, GPR56, CX3CR1, Tbet, CCR5, granzyme-B, granulysin and perforin, using the FlowSOM algorithm. **(b)** Same PaCMAP projections as in **(a)**, showing cell subset distribution and frequency in patients according to RA activity (Inactive RA: DAS28-CRP≤3.2; Active RA: DAS28-CRP>3.2). **(c)** Mono-parametric histograms showing the expression of SLAMF4, GPR56, CX3CR1, Tbet, CCR5, granzyme-B, granulysin and perforin among the different Tem subsets identified in **(b)**. **(d)** Graphical representation of Spearman correlations between RA activity (DAS28-ESR and DAS28-CRP) Vs % of F4⁻ CCR5⁻ Tem (gold population in b), % of F4⁻ CCR5⁺ Tem (light blue population in b), % of F4^{int} Tem (green population in b), % of F4^{low} Cytotox^{high}-Tem (red population in b) and % of F4^{high} Cytotox^{high}-Tem (dark blue population in b) among Tem. **(d)** A Spearman test was applied. (**p<0.01 and ***p< 0.001).

followed by gene set enrichment analysis (GSEA),clearly identified that SLAMF4⁺ CCR5⁺ Tem from RA patients corresponded to a subpopulation of Th1-like CD4⁺ CTLs (figure 1 c-d). Based on the differential expression of cytotoxicity markers, multiparameter flow cytometry data identified distinct SAP⁺ CCR5⁺ cytotoxic Tem subpopulations. Remarkably, among them, only those highly expressing SLAMF4 were related to RA activity (figure 2). Finally, our data showed that in the synovial fluid (n=8), SLAMF4⁺ Tem represented the only CD4⁺ T cell subpopulation that maintained a significant expression of granzyme-B and perforin.

Conclusion: By providing a comprehensive immunoprofiling of the cytotoxic CD4⁺ T cell response in RA, our study identified SLAMF4^{high} SAP⁺ CCR5⁺ CD4⁺ effector memory T cells as the main cytotoxic subpopulation involved in this disease.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In healthy individuals, CD8 Treg activation leads to selective elimination of aberrantly activated self-reactive CD4 T cells to maintain immune balance. The CD8 Treg network appears dysfunctional in autoimmune diseases and insufficient to kill self-reactive CD4 T cells, in part due to expression of inhibitory KIR2DL1/2/3 that serves as an autoimmune checkpoint. We have developed MTX-101, a bispecific CD8 Treg modulator targeting CD8 and KIR2DL1/2/3, which are co-expressed on the surface of CD8 Treg cells. MTX-101 selectively binds CD8 Treg and enhances their killing of self-reactive CD4 T cells by blocking KIR2DL1/2/3 binding to its ligand. Enhanced CD8 Treg function prevents self-reactive CD4 T cell expansion and inflammation, without increasing unwanted immune cell activation or pro-inflammatory cytokines.

Methods: To determine the applicability of MTX-101 to the treatment of rheumatologic autoimmune disorders, we evaluated PBMCs derived from patients with systemic lupus erythematosus (SLE), Sjögren's, ankylosing spondylitis, and psoriatic arthritis for KIR2DL1/2/3 expressing CD8 Treg. We observed that KIR2DL1/2/3 expressing CD8 Treg are present in all patients including in patients without active disease. Immunophenotyping and functional analysis suggest that CD8 Treg are impaired in these patient populations, showing reduced responsiveness to stimulation and expression of proteins critical to CD8 Treg functions relative to healthy donor CD8 Treg.

Results: We used human PBMCs and tissue resident immune cells to demonstrate selective binding to and activation of CD8 Treg of MTX-101. In vitro and in mouse models engrafted with human immune cells, MTX-101 increased cytolytic capacity, activation, and prevalence in healthy donor and autoimmune patient-derived CD8 Treg. In a model of acute inflammation, we observed CD8 Treg binding in peripheral blood and tissues, a reduction in inflammatory cytokines, reduced tissue pathology, and delayed onset of disease in mice treated with MTX-101. Pharmacokinetic and tolerability studies performed using IL-15 transgenic humanized mice, in which human lymphocytes engraft at physiologic ratios, demonstrated a half-life of 11.5 days following a single dose, and selective CD8 Treg binding and expansion, without unwanted immune cell activation or pro-inflammatory serum cytokines in animals treated with doses up to 10 mg/kg. Treatment with MTX-101 reduced the prevalence of activated CD4 T cells, and selectively increased the Granzyme B content and prevalence of the CD8 Treg population, but not of non-Treg CD8 T cells or NK cells, which may serve as clinical biomarkers.

Conclusion: Collectively, our data suggest that MTX-101-mediated disruption of the inhibitory autoimmune checkpoint KIR2DL1/2/3 can improve CD8 Treg dysfunctions observed in patients with rheumatologic autoimmune diseases to support durable re-balancing of the immune system.

Session Date: Sunday, November 12, 2023

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (AxSpA) is an inflammatory disease that predominantly affects the spine and the sacroiliac joints. Dysregulation of Type 3 immunity has been implicated in AxSpA pathogenesis, as AxSpA is characterized by overactive IL-17A-producing cells, including Th17 and γδ T cells. Therapeutically, biologics such as secukinumab, that target the cytokine IL17A, have demonstrated improved clinical outcomes in a significant percentage of patients. Despite this translational success, there is a gap in understanding how type 3 immunity is regulated and normalized by secukinumab. Our study aims to measure the frequencies of type 3 pro-inflammatory and anti-inflammatory cell subsets in AxSpA patients following secukinumab treatment and to discriminate these profiles between responders and non-responders. We hypothesized that patients that respond to secukinumab are able to reduce the frequency of IL-17A producing cell subsets by normalizing the frequency of CD4+ regulatory T cells (Tregs).

Methods: 65 Patients with AxSpA treated with secukinumab were recruited to the study. Peripheral mononuclear cells (PBMCs) were collected at baseline prior to treatment, and at 16- and 24- week post-treatment. Flow cytometry analysis of several IL-17A-producing cell subsets was used to assess differences in frequency between responders (n=13) and

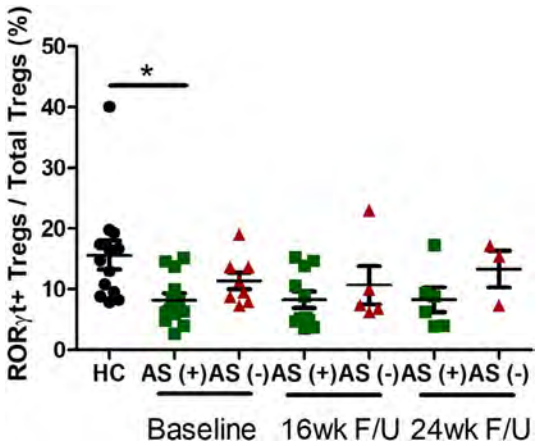

Figure 1. Analysis of RORyt+ Tregs in the Periphery of AxSpA patients. Dot plots represent frequencies of RORyt+ Tregs from PBMCs of Healthy Control (HC) and Axial Spondyloarthritis (AS) patients. Data represent 13 healthy controls, 13 secukinumab responders (green squares), and 7 nonresponders (red triangles). *p<0.05 significant by Mann-Whitney test. Frequencies analyzed using FlowJo 10.8.0 and plotted using GraphPad Prism 5.

nonresponders (n=7) during secukinumab treatment.Age and sex-matched healthy controls (n=13) were used to compare the frequencies of cell subsets in patients to a control population sample. Transcripts from FACS-sorted mature CD45RO +CD4s were measured in secukinumab responders (n=8) and nonresponders (n=7) using NanoString.

Results: Compared to baseline, we found no difference in the Treg frequencies relative to total CD4+ T cells in patients after secukinumab treatment. However, baseline frequencies of RORγt+ Tregs in PBMC of AxSpA patients that responded to secukinumab treatment were significantly reduced by 47.1% compared to healthy controls (Fig 1, $p< 0.05$). The frequency of RORγt + Tregs negatively correlated with BASDAI ($r(18)=-0.4751$, $p< 0.05$). At 16 and 24 weeks after treatment, the frequencies of RORγt+ Tregs in AxSpA responders appeared unchanged compared to baseline frequency. Secukinumab treatment had a significant effect on IL17+FOXP3+CD4 frequency (Fig 2, $p< 0.05$) but none on IL17+RORγt+CD4s frequency ($p=0.138$).When compared to secukinumab nonresponders, secukinumab responders had a significant downregulation of OAS2, IFI44L and OAS1 in mature CD4s (Fig 3). Gene ontology pathway analysis indicate that these genes are involved in viral response.

Conclusion: In AxSpA, frequencies of IL-17A-producing FOXP3+CD4+ cells correspond to clinical improvement after secukinumab treatment. Frequencies of RORγt+ Tregs were significantly decreased in AxSpA patients compared with controls. This subset correlates with clinical activity and may be an informative biomarker with diagnostic potential for AxSpA. These findings underscore the importance of regulating type 3 immunity to control inflammation in AxSpA patients.

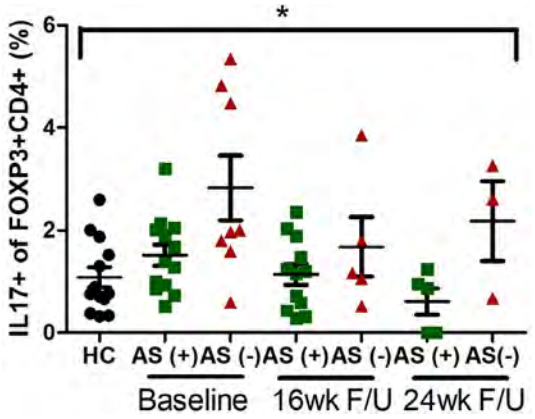

Figure 2. Analysis of IL17+FOXP3+CD4s in the Periphery of AxSpA patients. Dot plots represent frequencies of IL17+ FOXP3+CD4s relative to FOXP3+CD4s in PBMCs of Healthy Control (HC) and Axial Spondyloarthritis (AS) patients. PBMCs were stimulated with PMA and ionomycin for 5 hours. Data represent 13 healthy controls, 13 secukinumab responders (green squares), and 7 nonresponders (red triangles). *p<0.05 significant by Kruskal-Wallis test. Frequencies analyzed using FlowJo 10.8.0 and plotted using GraphPad Prism 5.

Impaired X-Chromosome Inactivation Maintenance in T Cells Is Associated with Features of Reduced Disease Severity in a Toll-Like Receptor 7-Driven Model of Systemic Autoimmunity

Nikhil Jiwrajka[1], Zowie Searcy[2], Claudia Lovell[2], Natalie Toothacre[2], Katherine Forsyth[2] and Montserrat Anguera[2], [1]Divison of Rheumatology, Department of Medicine, Hospital of the University of Pennsylvania, Phildelphia, PA, [2]Department of Biomedical Sciences, University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Many systemic autoimmune rheumatic diseases, including systemic lupus erythematosus (SLE), Sjögren's syndrome, and systemic sclerosis are highly female-biased. Although these diseases are more prevalent in females, disease severity is often greater in affected males. Transcriptional profiling of tissues from patients with these diseases has consistently revealed a prominent Type 1/2 interferon (IFN)-stimulated gene signature (ISG). The mechanisms by which sex modulates IFN-associated inflammatory responses in autoimmunity is unclear. The X chromosome contains several genes with roles in immune functions and IFN signaling, and our lab has shown that females with SLE exhibit impaired maintenance of X-chromosome inactivation (XCI) in circulating B and T cells. We therefore sought to determine how perturbed XCI maintenance in T cells modulates susceptibility to an inducible model of systemic autoimmunity using a toll-like receptor 7 (TLR7)-driven model associated with a strong ISG signature.

Methods: Female wild-type C57BL/6, CD4cre^{+}Xist$^{+/+}$ (n= 12; "WT"), and CD4cre^{+}Xist$^{fl/fl}$ (n=4; "Xist CKO") mice were treated topically with Imiquimod cream (IMQ; a TLR7 agonist; n=9) or Cetaphil lotion (VEH; n=7), thrice weekly for 10 weeks. Serum, spleen, kidney, and lung tissue were harvested upon euthanasia and processed for autoantibody quantitation, flow cytometry, and histology.

Results: Chronic IMQ treatment resulted in marked splenomegaly, T-cell activation, autoantibody production, and dermal, pulmonary, and renal inflammation. IMQ-treated Xist CKO mice tended to exhibit less splenomegaly and autoantibody production, fewer activated CD4^{+} and CD8^{+} T cells, and more Foxp3^{+} (X-linked) regulatory T cells (Tregs) compared to their WT counterparts. Xist CKO mice also tended to exhibit a greater proportion of Tregs expressing *Cxcr3*, an X-linked chemokine receptor integral for chemotaxis to sites of Type 2 interferon-mediated inflammation that has been shown to variably escape XCI.

Conclusion: These initial data suggest that impaired XCI maintenance in T cells may modulate Type 1/2 interferon-associated inflammation through an expansion of Foxp3^{+} Tregs, resulting in a less severe phenotype in this TLR7-driven model. Though further validation of these findings in larger experimental cohorts is required, our studies could provide new insights into factors influencing disease severity in female-biased autoimmune diseases associated with strong ISG signatures.

Multi-omics Immune Profiling of Cytotoxic T Cells from Ankylosing Spondylitis Patients Identified a Subset of Clonally Exapnded CTLs That Evade Immune Exhaustion

Michael Tang[1], Zoya Qaiyum[2], Melissa Lim[1] and Robert Inman[1], [1]University Health Network, Toronto, ON, Canada, [2]Krembil Research Institute, Toronto, ON, Canada

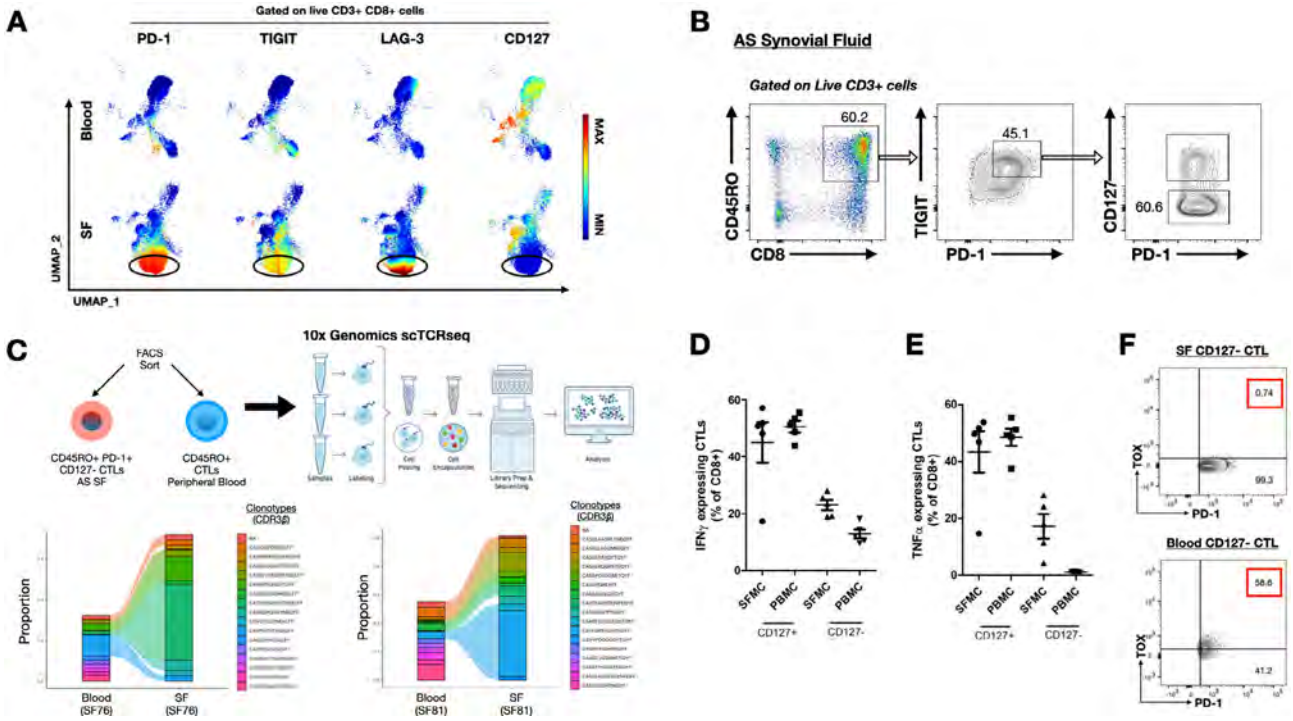
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sustained chronic inflammation in the spine and of the sacroiliac joints is a key feature in Ankylosing Spondylitis (AS). A central role of CTL involvement in AS inflammation is supported by recent discoveries of chronically activated CTLs with distinctive cytotoxic and integrin expression profiles enriched at sites of inflammation. Yet, the immunophenotype of the CTL compartment which may perpetuate AS inflammation has not been fully defined. The microenvironment that is conducive to AS chronic inflammation is reminiscent to settings found in chronic viral infection and cancer. Here, we seek to unravel the complex heterogeneity of CTLs in AS patients to determine whether CTLs in AS are truly immunologically exhausted. We hypothesize that a loss of CTL immune homeostasis and evasion of T cell exhaustion contribute to autoinflammation in AS.

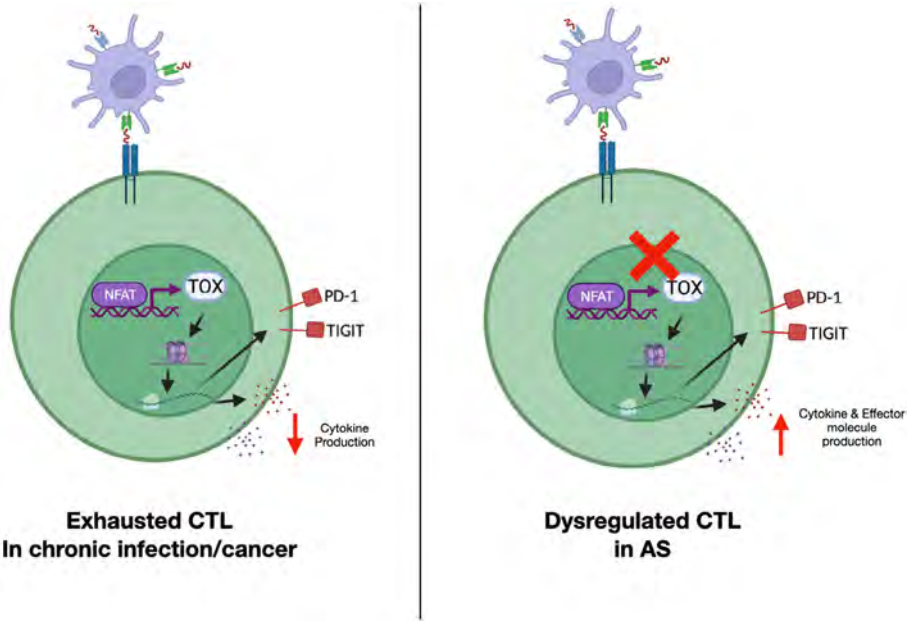
Methods: 8 pairs of PBMCs and SFMCs from patients with active (mean BASDAI=8) Axial Spondyloarthritis meeting the ASAS classification criteria were analysed. Additionally, age and sex-matched healthy control PBMCs (n=18) were analysed. We applied multi-omics single-cell immune profiling strategies to delineate the complex heterogeneity of CTLs in AS. Mass cytometry (CyTOF) of PBMCs and SFMCs was used to simultaneously measure protein expression of more than 30 surface and intracellular markers. Single-cell RNA sequencing (scRNAseq) and T cell receptor sequencing (scTCRseq) of FACS-sorted mature CTLs were used to immune profile AS CTL transcriptome and to perform clonal andTCR diversity analyses.

Results: Unsupervised clustering analysis of CyTOF data identified a subset of CTLs that co-express checkpoint receptors PD-1, TIGIT, and LAG-3 in SF CTLs of AS patients; while these markers are downregulated in the peripheral CTLs compared to healthy controls, implicating CTL dysregulation. This subset of SF CTLs downregulates CD127 expression, while retaining the capacity for CTL effector functions including the ability to express granzyme B, perforin and produce IFNγ and TNFαupon stimulation. Additionally, CD8+ T cell tissue residency markers (CD103, CD69, and CD49a) are highly upregulated in this subset of SF CTLs. scRNAseq of FACS-sorted CD45RO+ PD-1+ TIGIT+ CTLs revealed that transcripts that are normally expressed in canonically exhausted CTLs (e.g. *CD244, HAVCR2, ENTPD1, NT5E, TOX*) are downregulated. Differential gene analysis revealed that the top 5 genes (*IFI6*, *MX1*, *ISG16*, *MT2A*, *IFITM1*) upregulated in these cells are related to the interferon signalling pathway. Single cell TCR sequencing demonstrated that this CTL subset is clonally expanded at sites of inflammation. Intracellular flow cytometry confirmed that this CTL subset downregulated the master transcription factor regulating T cell exhaustion- TOX, suggesting that these CTLs are not truly immunologically exhausted.

Conclusion: Multi-omics immune profiling of CTLs from AS patients identified a subset of clonally expanded CTLs in SF that appear to resist immune exhaustion, while retaining classical cytotoxic capacities. This findings implicates that dysregulation of T cell exhaustion and homeostasis could potentially exacerbate AS autoinflammation.



Mass cytometry and single cell TCR sequencing identified a population of clonally expanded SF CTL that evades immune exhaustion. A) Live CD3+ CD8+ cells from single file representations of paired AS SFMC and PBMC (n=8) were entered into the UMAP algorithm for high dimensional analysis of immune checkpoint molecules. UMAP projections display expression levels of indicated surface molecules. B) Representative flow cytometric analyses of CD127+ and CD127- PD-1+ TIGIT+ CTL from SF of AS patient. C) Schematic workflow of single cell TCR sequencing. Mature CD45RO expressing CTLs were sorted from matched SFMC and PBMC from 2 AS patients. Alluvial plots demonstrating proportion of clonotypes based on amino acid sequences of CDR3b chains of CTLs from blood and SF of 2 AS patients. D-E) Cytokine release assay; CD127+ and CD127- PD-1+ TIGIT+ CTLs were FACS sorted from paired SFMC and PBMC samples, then stimulated with PMA/ionomycin for 4 hours in the presence of Brefeldin A. Intracellular IFNg and TNFa were measured by flow cytometry. Graphs display proportion of CD8+ T cells expressing the cytokines. F) Flow cytometric analysis to quantify frequency of TOX+ CD127- PD-1+ CTL.



Dysregulation of CTLs in AS synovial fluid. In contrast to canonically exhausted CTLs in settings of chronic inflammation such as chronic viral infection and cancer, a distinct subset of CTLs expressing classical immune checkpoint markers appear to resist immune exhaustion, retain effector functions, and progressively perpetuate autoinflammation in AS.

Single Cell RNA-seq and Mass Cytometry Reveal a Cytotoxic CD8 Effector T Cell Population Associated with Interstitial Lung Disease in Systemic Sclerosis Patients

Ye Cao[1], Takanori Sasaki[2], Richard Ainsworth[3], Kim Taylor[4], Nunzio Bottini[5], Mehreen Elahee[6], Edy Kim[7], Francesco Boin[3] and Deepak Rao[7], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]University of California San Francisco, San Francisco, CA, [5]University of California, San Francisco, CA, [6]University of Pittsburgh Medical Center, Pittsburgh, PA, [7]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a major cause of morbidity and mortality in systemic sclerosis (SSc). We aimed to identify features of circulating immune cells associated with SSc-ILD to develop biomarkers and to find treatment targets of SSc-ILD.

Methods: We employed single cell RNA-seq (scRNAseq) using cryopreserved peripheral blood mononuclear cells (PBMC) from 20 SSc patients without ILD and 38 SSc patients with ILD and implemented covarying neighborhood analysis (CNA) to identify cell features associated with SSc-ILD. Detailed surface maker expression was also examined using mass cytometry (CyTOF) with a 39-marker panel using PBMC from 18 controls, 53 SSc patients with ILD and 29 SSc patients without ILD. Differentiation paths and inducing factors were explored through RNA velocity analysis and in-vitro culture.

Results: A broad analysis of the scRNAseq dataset across mononuclear cells highlighted a significant enrichment in a specific CD8 T cell phenotype, captured as CD8 T cell cluster 2, in patients with ILD compared to those without ILD. This cluster expressed *CD8A* and *GZMB* but not *CD27* or *GZMK* (Figure 1A). T cell receptor repertoire analysis indicated cluster 2 was clonally expanded, suggesting the antigen recognition of this CD8 T cell population in SSc-ILD (Figure 1B). In parallel, analysis of an overlapping set of PBMC samples by mass cytometry demonstrated that CD57+ CD27- CD56- CD45RO+ CCR7- effector memory CD8 T cells (CD57+ TEM) were significantly increased in the SSc-ILD cohort (Control: 0.74%, SSc without ILD: 1.42%, SSc with ILD: 2.71%), suggesting that a similar CD8 T cell population associated with SSc-ILD was captured by scRNAseq and mass cytometry. In contrast to CD57+ TEM cells, TEMRA were not statistically different between SSc patients with and without ILD. Independent flow cytometry analysis confirmed that CD57+ TEM highly expressed GZMB but not GZMK. On the contrary, CD57- CD27+ TEM (CD57- TEM) expressed GZMK but not GZMB, indicating there are two distinct populations in CD8 TEM. RNA velocity analysis of CD8 T cell clusters suggested that CD57+ TEM may differentiate from CD57- TEM (Figure 2). In-vitro culture experiments demonstrated that type I IFN facilitates differentiation from CD57- TEM to CD57+ TEM that highly produce GZMB (Figure 3).

Conclusion: ScRNAseq and mass cytometry analyses revealed that a cytotoxic effector memory CD8 T cell subset is expanded in SSc-ILD, and that a type I IFN signal may drive differentiation towards this phenotype.

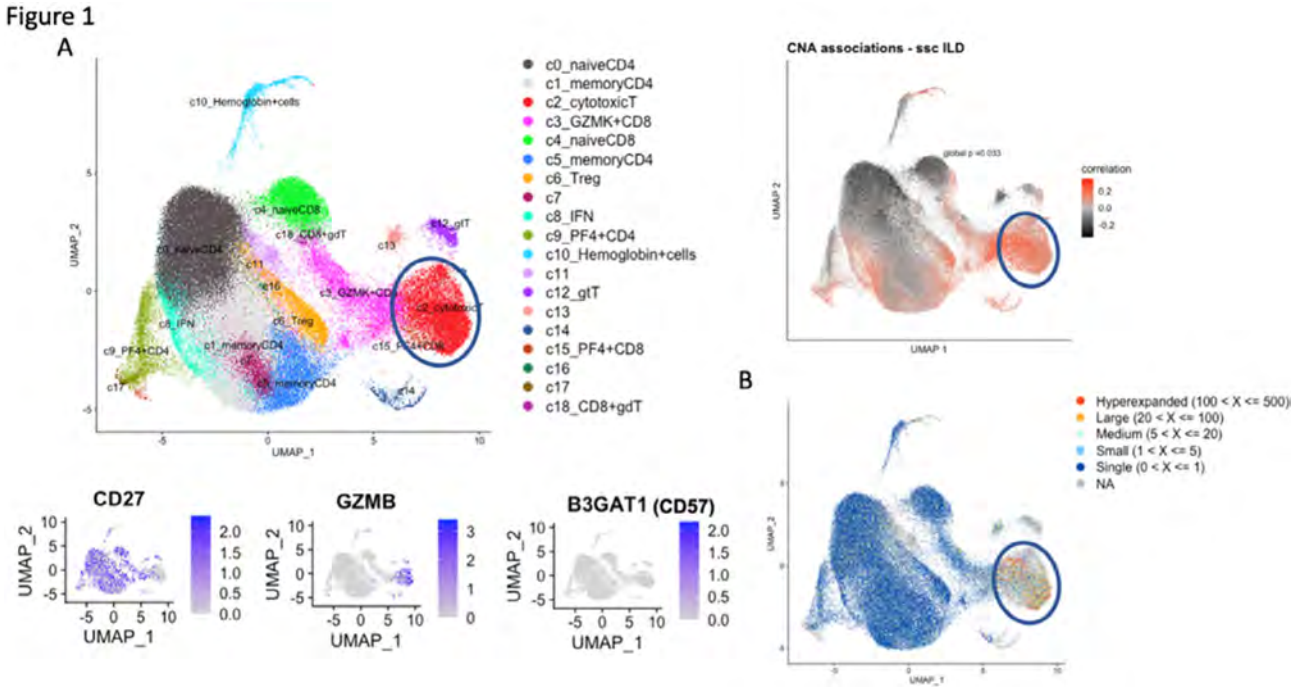

Figure 1. scRNAseq analysis of our SSc-ILD cohort. A. Covarying neighborhood analysis indicated cluster 2 is associated with lung disease in SSc, which expressed GZMB and B3GAT1 (CD57) but not expressed CD27. B. T cell receptor repertoire analysis demonstrated cluster 2 is a clonally expanded population.

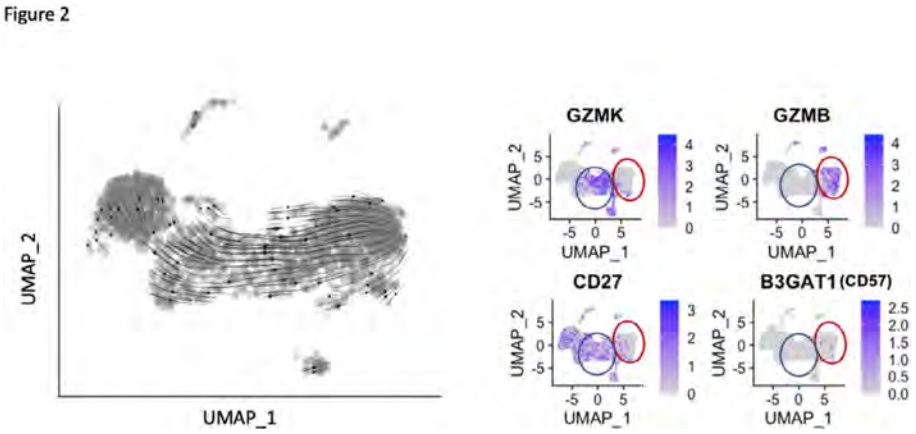

Figure 2. Differentiation pathway analysis of CD57+ TEM. RNA velocity analysis of CD8 T cell clusters indicated that CD57+ TEM (red circle) is differentiated from CD57- TEM (blue circle).

Figure 3

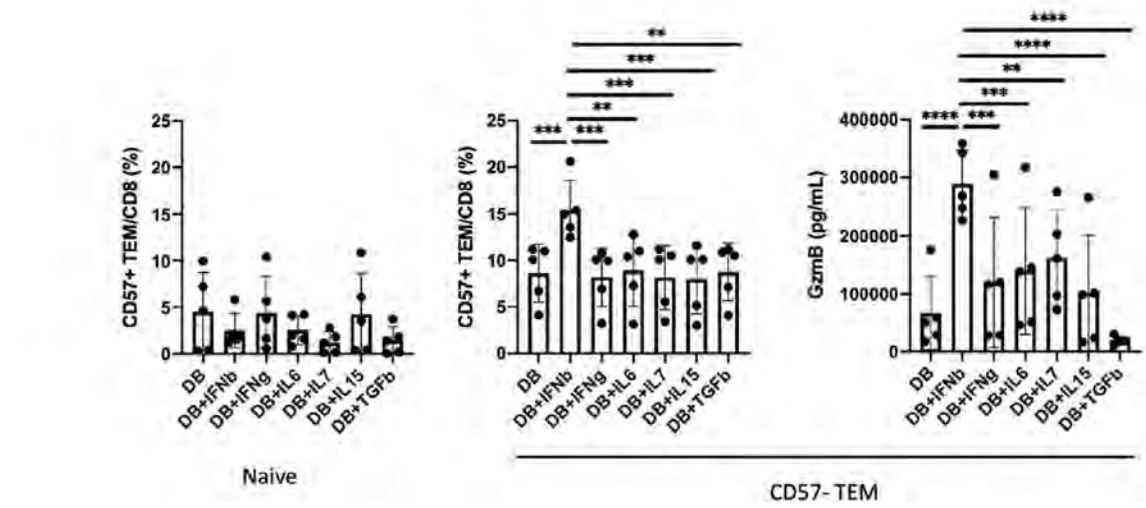

Figure 3. Type I IFN promotes differentiation from CD57- TEM to CD57+ TEM. Proportion of CD57+ TEM after 4 days culture of Naïve or CD57-TEM from 5 different donors with CD3/CD28 + cytokine stimulation. Granzyme B production was assessed by ELISA using culture supernatant after 4 days of culture of CD57- TEM with CD3/CD28 + cytokine stimulation. P value was calculated by One-Way repeated measures ANOVA.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: T cells are major drivers of rheumatoid arthritis (RA) pathogenesis. While most research has focused on CD4+ T cells, we have found that $CD8^+$ T cells – specifically granzyme K (GzmK)-expressing CD8 T cells – are strikingly abundant in inflamed RA synovium as well as other tissues affected by autoimmune disease. Unlike granzyme B (GzmB), GzmK does not cleaves caspases to induce target cell apoptosis, and the function of GzmK in inflamed synovium and other tissues is unclear. Here, we describe that GzmK is continuously released from CD8+ T cells and activates a new

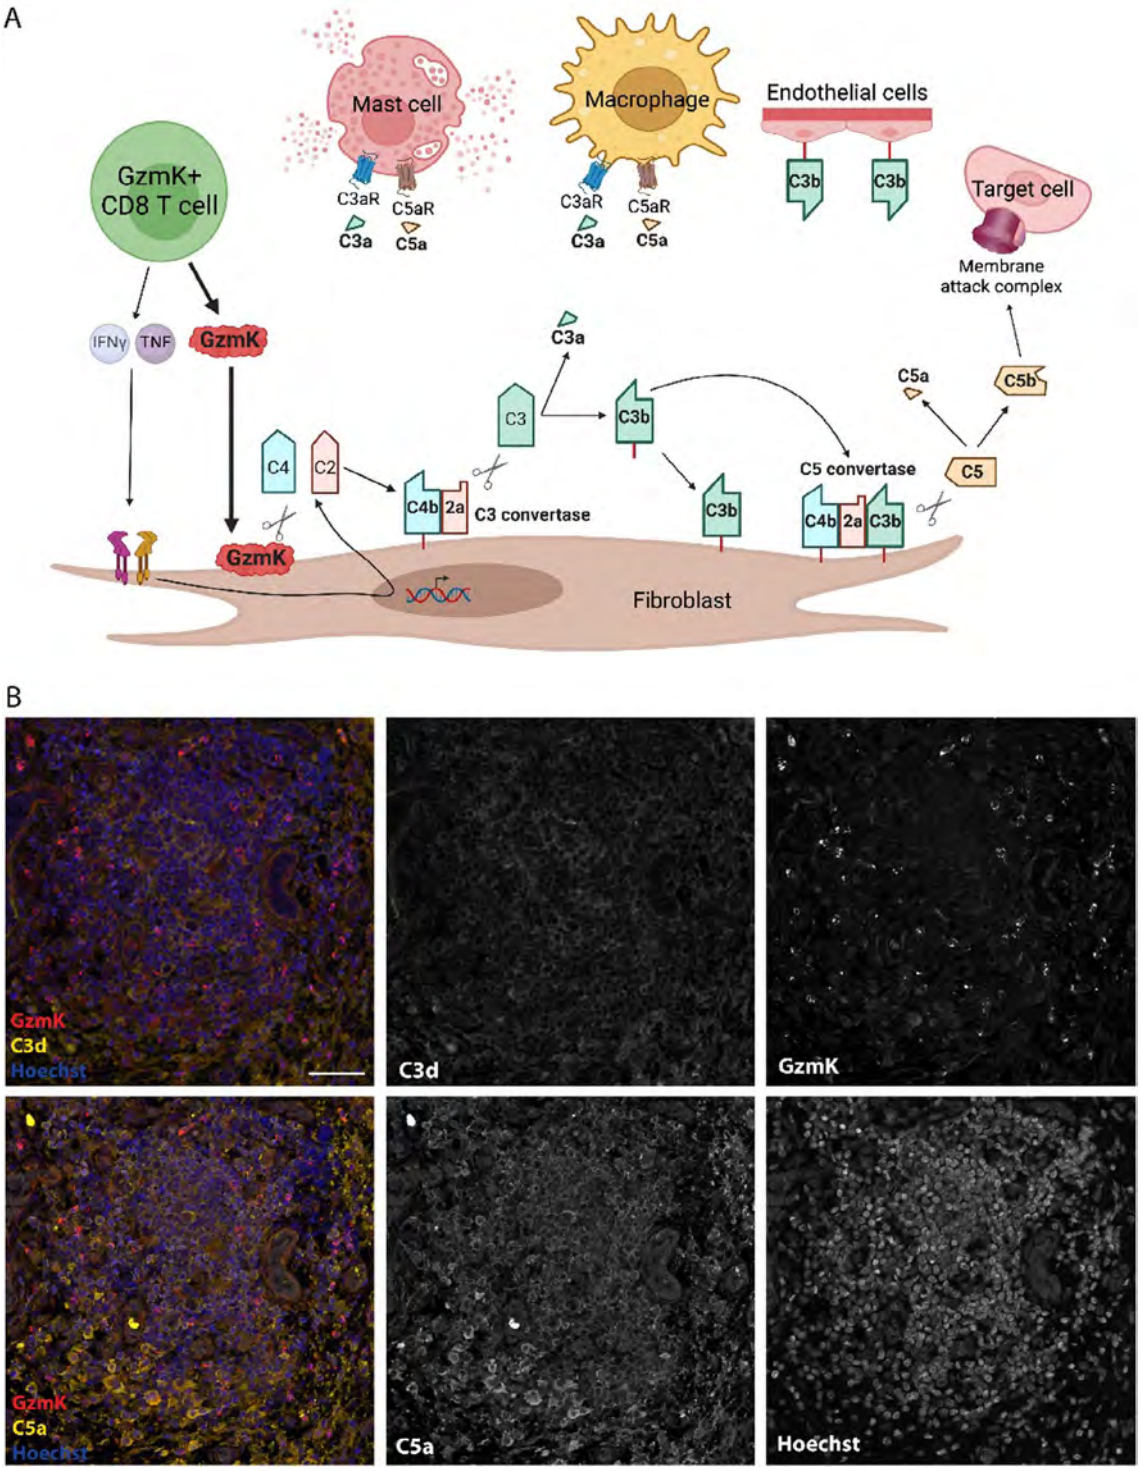

Figure 1. Granzyme K activates a new complement pathway in rheumatoid arthritis synovial tissue. (A) Illustration of the new pathway of complement cleavage activated by GzmK. (B) RA synovial tissue stained for GzmK, C3d, C5a, and Hoescht nuclear stain and imaged by confocal microscopy.

complement pathway, opsonizing target cells and releasing anaphylatoxins C3a and C5a that recruit and activate innate immune cells. In inflamed RA synovium, we find complement fragments C3d and C5a in proximity to GzmK^{+} CD8 T cells, supporting a role for this complement activation mechanism *in vivo*.

Methods: We incubated recombinant enzymatically active GzmK with serum-purified complement fragments to investigate the molecular effects of GzmK on complement proteins. We measured cleavage of C2, C3, C4, and C5 using Western blots. We used flow cytometry to assess C3b and terminal complement complex (TCC) deposition on cell membranes. We performed multicolor immunofluorescence microscopy of human rheumatoid arthritis synovial tissue to assess complement activation and deposition relative to GzmK$^+$ CD8+ T cells.+

Results: GzmK is expressed by a wide range of T cells and innate-like lymphocytes in human synovial tissue and fluid in RA and in other autoimmune and inflamed tissues. Resting GzmK$^+$ CD8+ T cells continuously release GzmK, which binds to negatively charged residues on cell surfaces. Synovial fibroblasts express complement components C2, C3, and C4, and this production is amplified by T cell-associated cytokines IFNγ and TNF. GzmK cleaves C4 to C4b and C2 to C2a to form an active C3 convertase (C4b + C2a) that cleaves C3 to C3a and C3b, which covalently deposits on cell membranes due to the surface localization of GzmK. These complement fragments then form the C5 convertase C4b2b3b, ultimately leading to release of biologically active anaphylatoxin C5a and surface deposition of the terminal complement complex (C5b-C9) (Figure 1A). Using multicolor immunofluorescence microscopy, we find complement products C3/C3d and C5a in proximity to GzmK+ CD8+ T cells in inflamed RA synovium (Figure 1B).

Conclusion: GzmK activates a novel complement pathway that is independent of the classical, alternative, and lectin pathways of complement activation. GzmK can cleave locally generated complement components to generate C3a, C3b, C5a, and terminal complement complex, which promote inflammatory cell recruitment and antigen uptake. In inflamed RA synovium, C3/C3d and C5a deposition occurs near GzmK$^+$ cells, supporting the *in vivo* relevance of this new mechanism of complement activation. Together, these findings reveal a new pro-inflammatory in RA that is likely active in other autoimmune diseases as well.

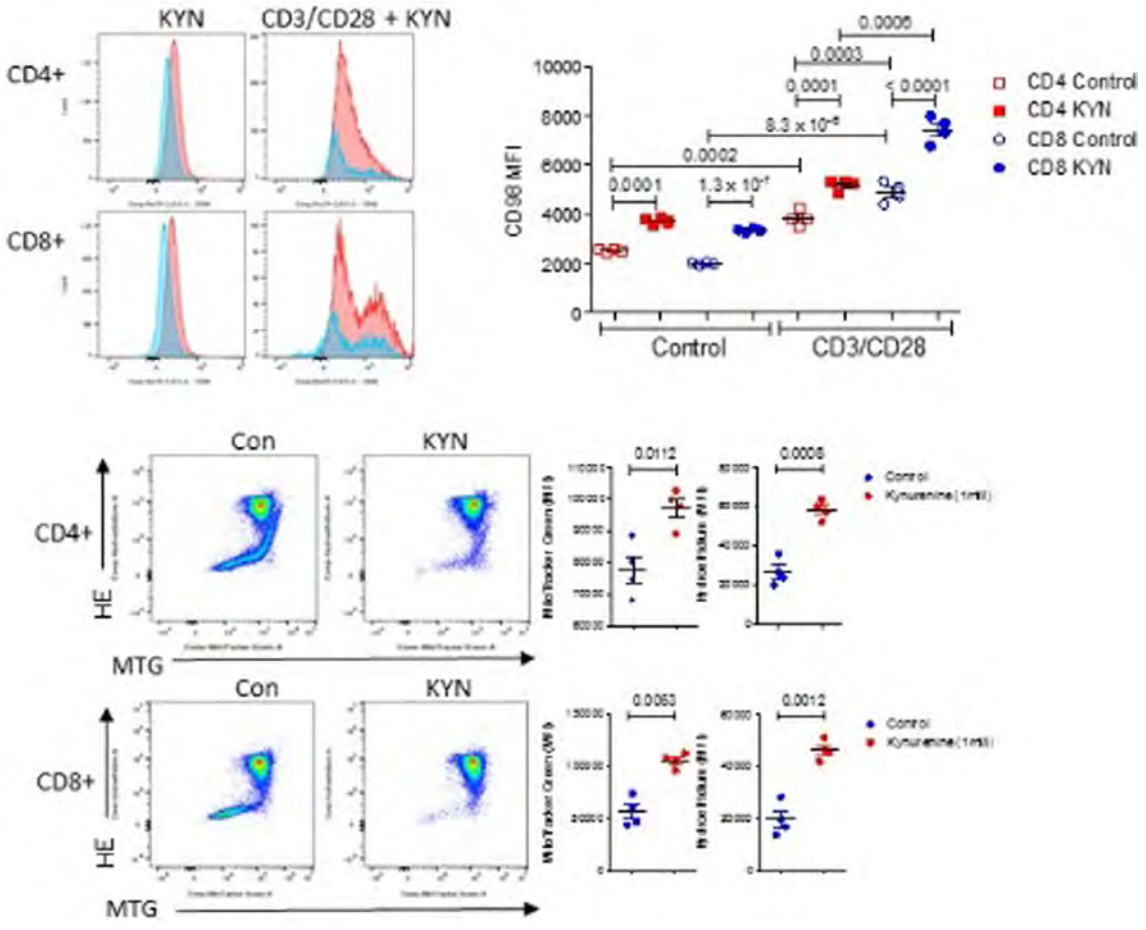
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The kynurenine (KYN) pathway has been linked to disease pathogenesis in patients with systemic lupus erythematosus (SLE) (https://pubmed.ncbi.nlm.nih.gov/26366134/). Genetically enforced overexpression of Rab4A activates the mechanistic target of rapamycin in SLE patients (https://pubmed.ncbi.nlm.nih.gov/31805010/. The present

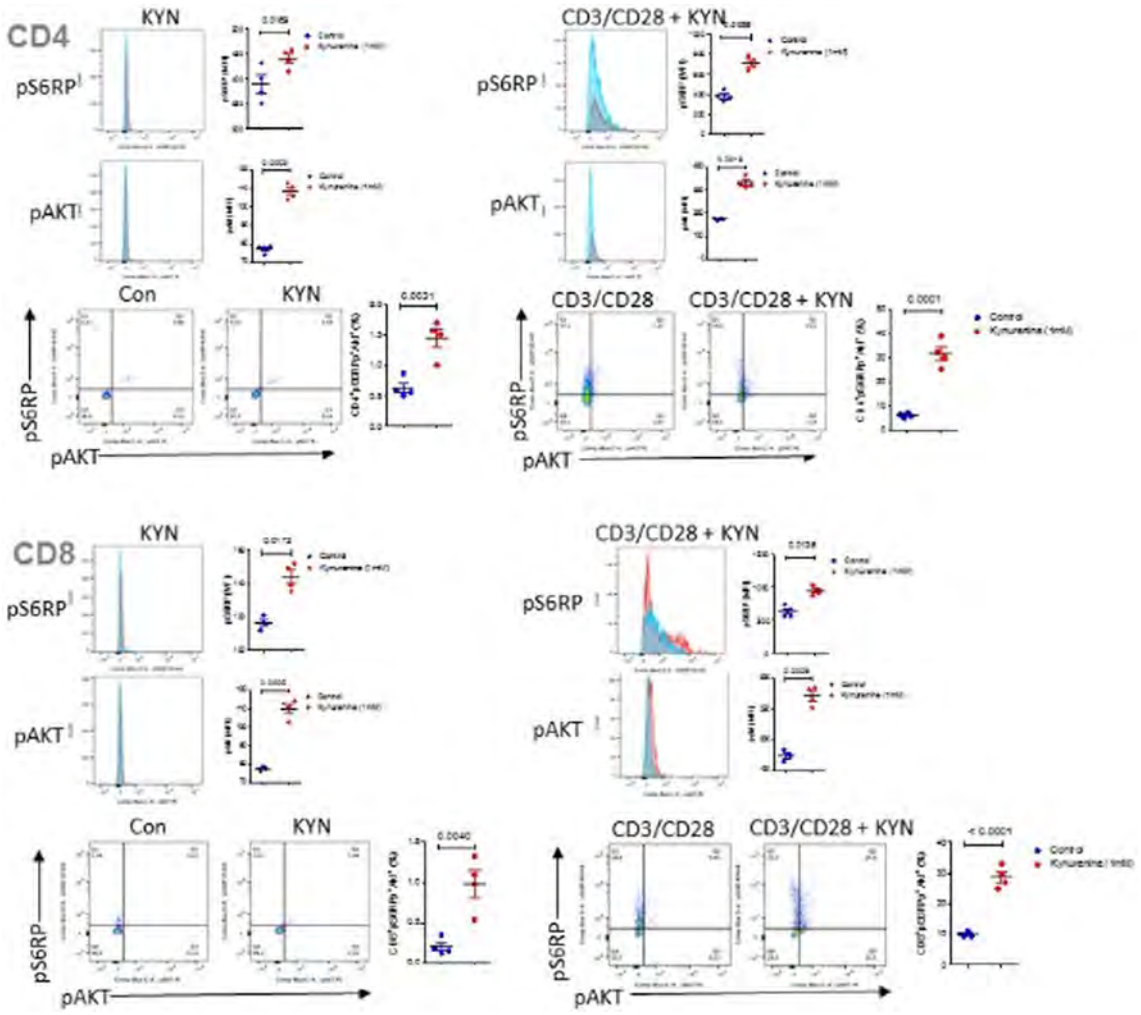
study was initiated to determine the pro-inflammatory mechanism of action of KYN in lupus-prone SLE1.2.3 triple congenic mice on the C57Bl/6 background (B6.TC) carrying constitutively active Rab4A^{Q72L} alleles (Rab4AKI) or lacking Rab4A in T cells (Rab4AKO).

Methods: KYN levels were measured within T cells and sera of mice carrying wild-type (WT), Rab4AKI and Rab4AKO alleles in female C57Bl/6 (B6) control mice and lupus-prone B6.TC mice using LC/MS. The effects of KYN on expression of its receptor CD98 and activation of mTOR complexes 1 (mTORC1, via pS6RP) and 2 (mTORC2, via pAkt) were studied by flow cytometry. Splenocytes were cultured *in-vitro* for 72 hours with or without KYN along with or without concurrent stimulation with lipopolysaccharide (LPS) or CD3/CD28. Mitochondrial mass and reactive oxygen species (ROS) were measured by flow cytometry using mitotracker Green (MTG) and hydroethidine (HE).

Results: KYN was accumulated in T cells and sera of B6.TC/Rab4A^{Q72L} female mice that exhibited increased expression of CD98 and activation mTORC1 and mTORC2 relative to B6.TC and B6.TC/Rab4A^{KO} controls. In C57Bl/6 splenocytes, KYN increased CD98 expression in CD4 and CD8 T cells (CD4 Unstim: FC=1.48, p=0.00012, CD8 Unstim: FC=1.68, p=2.1E-5, CD4 Stim: FC=1.36, p=0.00069, CD8 Stim: FC=1.51, p=0.00058) and significantly increased both mTORC1 (CD4 Unstim: FC=1.13, p=0.0169, CD4 Stim: FC=1.86, p=0.0086 CD8 Unstim: FC=1.24, p=0.0172, CD8 Stim: FC=1.49, p=0.0136) and mTORC2 (CD4 Unstim: FC=1.41, p=0.0003, CD4 Stim: FC=1.91, p=0.0018, CD8 Unstim: FC=1.42, p=0.0005, CD8 Stim: FC=1.55, p=0.0006). KYN increased mitochondrial mass (CD4 Stim: FC=1.25, p=0.0112, CD8 Stim: FC=1.87, p=0.0053) and ROS production (CD4 Stim: FC=2.2, p=0.0008, CD8 Stim: FC=2.34, p=0.0012) in both CD4 and CD8 T cells following KYN and CD3/CD28-stimulation.



MFIs of CD98 expression in response to KYN only or concurrent KYN and CD3/CD28 stimulation. Metabolic dyes mito-tracker green and hydro-ethidine dot plots after 72 hour stimulation with KYN and CD3/CD28.



Flow cytometry dot plots and histograms of mTORC1 and mTORC2 downstream phosphorylated substrates, pS6RP and pAkt.

KYN also expanded CD19+CD11c+ age-related B cells (ABCs) with or without LPS. KYN activated mTORC1 (CD19+: FC=1.15, p=0.012, ABCs: FC=1.97, p=0.0019) and mTORC2 (CD19+: FC=6.289, p=1.21E-5, ABCs: FC=3.70, p=0.00165) and CD98 expression (ABCs: FC=2.06, p=0.0144). Remarkably, the expression of CD138, a plasma cell marker, was also increased by concurrent LPS and KYN treatment (FC=2.76, p=0.001).

Conclusion: This study suggests that KYN accumulation in lupus-prone T cells causes a CD98-KYN-mTOR positive feed-back loop which is enhanced by Rab4A activation, conferring secondary KYN-mediated expansion of ABCs and plasma cells. The Rab4A-CD98/mTOR/KYN positive feed-back loop may represent a mechanistic target for therapeutic intervention in SLE.

Performance Assessment of Lupus Anticoagulant Tests Using Taipan and Ecarin Snake Venom Clotting Times: An International Study from Antiphospholipid Syndrome Alliance for Clinical Trials and International Networking (APS ACTION) Core Laboratories

Maria Efthymiou[1], Ian Mackie[1], Rohan Willis[2], Vittorio Pengo[3], Danieli Andrade[4], Elisa Bison[3], Olga Amengual[5], Zurina Romay-Penabad[6], Yuichiro Fujieda[5], Maria Laura Bertolaccini[7], Doruk Erkan[8], Hannah Cohen[9] and On Behalf Of APS ACTION[10], [1]University College London, London, United Kingdom, [2]University of Texas Medical Branch, Galveston, TX, [3]Department of Cardiac-Thoracic-Vascular Sciences and Public Health University of Padova, Padova, Italy, [4]University of São Paulo, São Paulo, Brazil, [5]Hokkaido University, Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Sapporo, Japan, [6]Antiphospholipid Standardization Laboratory, Division of Rheumatology, University of Texas Medical Branch, TX, [7]King's College London, London, United Kingdom, [8]Hospital for Special Surgery, New York, NY, [9]University College London Hospitals NHS Foundation Trust, London, United Kingdom, [10]on behalf of APS ACTION, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus anticoagulant (LA) test performance is critical for APS diagnosis and management. However, variability remains a challenge in LA testing, particularly in anticoagulated samples, with the activated partial thromboplastin time and dilute Russell's viper venom time (DRVVT) the most commonly used tests. The prothrombin-activating Taipan snake venom time (TSVT) screening test and Ecarin clotting time (ECT) confirmatory test are insensitive to vitamin K antagonists (VKA) and may offer improved LA detection. APS ACTION is an international research network involving 34 centres, a prospective registry and repository, and five core laboratories (CL) worldwide. The aim of this study was to evaluate the performance of the TSVT/ECT in VKA-anticoagulated samples between APS ACTION CLs and examine agreement in LA status with the DRVVT.

Methods: Four CL (A-D) used the same analyser, protocol, and lot of reagents. The manufacturer's cut-off values for TSVT/ECT were verified in each CL using plasmas from at least 40 healthy normal subjects, to determine normal ranges for TVST, ECT and TVST/ECT ratios (Diagnostic Reagents Ltd). Results were normalised with pooled normal plasma (PNP), while equal volume mixtures of patient and PNP were tested to confirm the presence of an inhibitor. George King LA Positive plasma and IL LA Negative control plasma (Werfen) were used for quality control (QC). In a validation exercise, each CL tested six positive and six negative blinded VKA-anticoagulated samples, previously identified as such, with status confirmed by a second CL. VKA-anticoagulated samples were also tested with DRVVT Screen and Confirm (Werfen) in 50:50 mixtures with PNP. A precision study was also performed, testing LA-positive and LA-negative QC plasma x 6 in the same run, to determine intra-assay variability.

Core Laboratory:	A		B		C		D	
		50:50 PNP		50:50 PNP		50:50 PNP		50:50 PNP
TSVT ratio	0.92-1.08	0.94-1.06	0.92-1.12	0.96-1.10	0.98-1.16	0.95-1.10	0.92-1.07	0.95-1.10
ECT ratio	0.92-1.08	0.97-1.03	0.86-1.08	0.93-1.13	0.90-1.07	0.81-0.90	0.93-1. 08	0.81-0.90
TSVT/ECT ratio	0.89-1.11	0.93-1.07	0.95-1.17	0.92-1.08	0.96-1.22	1.13-1.27	0.88-1.10	1.13-1.27

Results: Precision and agreement were acceptable in all CL for both positive and negative control plasma [Coefficient of Variation (CV) 0.7-5%]: CV for clotting times ≤2.5% for LA Negative control plasma and ≤4% for George King LA Positive plasma, CV for TSVT/ECT < 4% for all CLs All CL confirmed the manufacturer's reference range with minor differences (Table 1). All CL correctly identified the six positive and six negative blinded LA samples (CL D identified one LA positive sample as equivocal). In the ongoing patient sample testing phase of this study, 134 VKA anticoagulated samples showed an overall 66.4% agreement between DRVVT and TSVT/ECT LA status. When results were subcategorised according to INR, agreement was 70.6% for INR <2.0, 66.6% for INR 2.0-3.0, 75.7% for INR 3.0-4.0, and 42.9% for INR >4.0. Of the 45 overall samples with a disagreement between DRVVT and TSVT/ECT, 80% were identified as positive with TSVT/ECT.

Conclusion: LA testing in VKA-anticoagulated samples using the TVST/ECT has been established in four international APS ACTION CL. LA status determined to be negative with DRVVT but positive with TSVT/ECT might be due to dilution of the inhibitor in the 50:50 mixture in the DRVVT, required for clotting factor level normalisation. Preliminary results suggest that the TVST/ECT could provide an adjunctive test to DRVVT testing without the need for mixing studies and with high specificity.

Reference ranges for TSVT, ECT and TSVT/ECT established by the four Core laboratories, presented as normalised ratios. Manufacturer's reference range: TSVT ratio=0.93-1.10, ECT ratio=0.90-1.10. Abbreviations: TSVT: Taipan snake venom time, ECT: Ecarin snake time

Hydroxychloroquine	11 (50%)	40 (57%)	0.62
Statin	10 (45%)	37 (53%)	0.62

* 14/22 with one TIA and 8/22 with >1 TIA; ** 48/70 with one TIA and 22/70 with >1 TIA; ***Based on the Updated Sapporo APS classification Criteria; ****: all received warfarin or low-molecular weight heparin except one patient who received fondaparinux. **CVD:** cardiovascular disease, **LA:** lupus anticoagulant, **aCL/aβ2GPI**: anticardiolipin antibody / Anti-β_2-Glycoprotein-I Antibody

Background/Purpose: APS ACTION Registry aims to study the course of disease in antiphospholipid antibody (aPL)-positive patients. Although transient ischemic attack (TIA) can develop in aPL-positive patients, the ascertainment of TIA can be challenging due to the need to exclude other conditions, e.g., complex migraine with aura or seizure. Our primary objective was to analyze the clinical characteristics of persistently aPL-positive patients who were reported to have had "TIA" prior to recruitment and/or during prospective follow-up.

Methods: The registry inclusion criteria are positive aPL based on the Updated Sapporo APS Classification Criteria within one year prior to enrollment. Patients are followed every 12±3m with clinical data and blood collection. Firstly, we retrospectively compared the baseline characteristics of patients with a history of TIA among those without or with a history of imaging-confirmed thrombosis (at any time prior to registry entry). Secondly, in patients who completed 1-10 year follow up, we prospectively analyzed those with new onset TIA, which was defined as "a transient episode of neurologic dysfunction caused by focal brain, spinal cord, or retinal ischemia, without acute infarction lasting less than 24 hours" (confirmation status by a neurologist is also recorded).

Table 2: Follow-up Characteristics of 11 Antiphospholipid Antibody (aPL)-positive Patients with New Transient Ischemic Attack (TIA)

	History of TIA Without Thrombosis (N: 2/22)	History of TIA and Thrombosis (N: 5/70)	No History of TIA (N: 4/759)

Statin	2	2	1

*Based on the Updated Sapporo APS classification Criteria; **Concomitant cardiovascular disease (CVD) and venous thrombosis risk factors at the time of event. **LA:** lupus anticoagulant, **aCL/ aβ2GPI:** anticardiolipin antibody/ Anti-β_2-Glycoprotein-I Antibody, **OCP:** oral contraceptive preparation

Results: As of April 2023, 1,166 patients were included in the registry and 92 (8%) had a history of TIA at enrollment: 22/92 (24%) without and 70/92 (76%) with history of imaging confirmed arterial/venous thrombosis. *Of 22 TIA patients without history of thrombosis* (mean age 54.8 ± 11, female 17 [77%], White: 20 [91%]), 15 (68%) were confirmed by a neurologist. *Of 70 TIA patients with history of imaging-confirmed thrombosis* (mean age 56.7 ± 11, female 39 [56%], White: 48 [69%], arterial thrombosis 59 [84%], and venous thrombosis 29 [41%]), 46 [66%] were confirmed by a neurologist. At baseline, TIA patients without thrombosis were more likely to receive antiplatelet agent alone and have single LA positivity, whereas TIA patients with history of imaging-confirmed thrombosis were more likely to have hypertension and receive warfarin (Table 1). During the prospective follow up of 92 patients with a history of TIA (mean follow-up: 4.5 ± 3.0 years), seven new TIA were reported: a) two (9%) in 22 patients with no history of thrombosis (1.41 per 100 patient-years), and b) five (7%) in 70 patients with history of thrombosis (2.71 per 100 patient-years) (Table 2). In addition, four of 759 (0.5%) patients with no history of TIA at baseline and who completed at least one year follow-up developed a TIA during the mean follow-up of 5.12 years (0.09 per 100-patient years).

Conclusion: In our large international cohort of persistently aPL-positive patients, 8% were reported to have history of "TIA" at the registry entry. The TIA recurrence rate during follow-up was 7-8%; however, the new TIA rate was less than one percent. Approximately two-thirds of patients without a history of imaging-confirmed thrombosis were treated with anticoagulation; all patients with recurrent/new TIA during the follow-up were on anticoagulation. Our findings underscore the need for well-designed controlled studies of TIA in aPL-positive patients with strict definitions.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: APS ACTION "Registry" was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases. Our objective was to determine the mortality rate as well as the causes and predictors of mortality in aPL-positive patients with/without APS classification.

Methods: A web-based data-capturing system is used to store patient demographics, history, and medications. The inclusion criteria are positive aPL according to the Updated Sapporo Classification Criteria tested within one year prior to enrollment. Patients are followed every 12 ± 3m with clinical data and blood collection. In this prospective analysis, firstly we analyzed descriptively the causes of death (based on investigators' reports) for patients reported as "deceased" during the follow-up. Secondly, we compared the clinical and laboratory characteristics of deceased versus non-deceased patients using the adjusted Cox proportional hazards model and calculated the survival probability by Kaplan-Meier Model based on different age groups.

Table 1: Associations Between Baseline Characteristics at Registry Entry and Mortality in the APS Action Cohort, Adjusted for Age

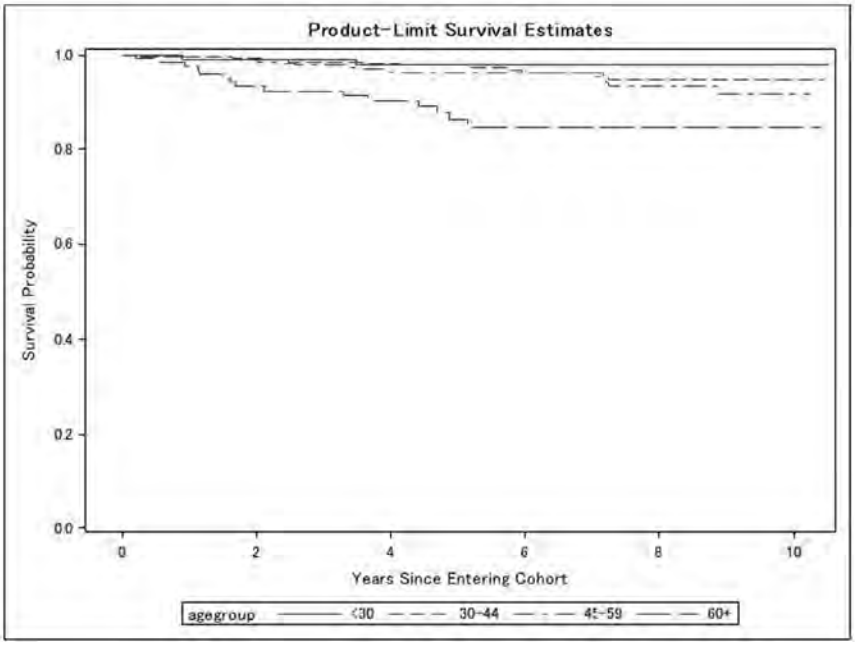
Baseline Characteristics N: 963	Hazard Ratio (95% CI)	P-value
Arterial Thrombosis (AT) (n: 327, 34%)	**2.99 (1.56,5.74)**	**.0010**
Venous Thrombosis (VT) (n: 408, 42%)	1.24 (0.67,2.32)	.4908
AT or VT (n: 630, 65%)	**4.20 (1.49,11.8)**	**.0066**
Microvascular APS (MAPS) (n: 82, 9%)*	1.60 (0.67,3.84)	.2937
Catastrophic APS (CAPS) (n: 11, 1%)	**5.87 (1.35,25.4)**	**.0180**
MAPS or CAPS (n: 93, 10%)	1.79 (0.79,4.08)	.1662
Active Thrombocytopenia (n: 53, 6%)**	1.85 (0.65,5.27)	.2462
Triple aPL positive (n: 323, 34%)	0.74 (0.37,1.49)	.4012
Cardiovascular Risk Factors (564, 59%)* **	**2.85 (1.23,6.58)**	**.0144**
Other Autoimmune Diseases (381, 40%)	**2.85 (1.52,5.36)**	**.0011**
Hydroxychloroquine (n: 459, 48%)	1.57 (0.84,2.92)	.1579
Statins (229, 24%)	1.73 (0.88,3.40)	.1143
Corticosteroids (204, 21%)	1.94 (0.98,3.81)	.0556

*Mostly lung, skin, and/or kidney disease; ** Platelets persistently < 100,000 x10^9/L; ***Hypertension, diabetes, hyperlipidemia, obesity, nephrotic range proteinuria, chronic or end-stage renal disease, and/or current smoking.

Table 2: Independent Associations Between Baseline Characteristics at Registry Entry and Mortality in the APS Action Cohort, Adjusted for Age and Each Other for the Four Strongest Predictors

Patient Characteristic	Hazard Ratio (95% CI)	P-value
Arterial Thrombosis	2.94 (1.50,5.76)	.0017
Catastrophic APS	2.52 (0.57,11.3)	.2248
Other Autoimmune Diseases	2.97 (1.56,5.63)	.0009
Cardiovascular Risk Factors	2.43 (1.04,5.71)	.0414

Figure 1: Kaplan Meier Curves for Survival Probability Based on Different Age Groups (see results for the estimated 5-year survival probabilities; 10-year survival probabilities were not calculated due to limited information)



Results: As of May 2023, of 1,174 patients recruited, 215 (18%) were excluded due to incomplete follow-up data. Of the remaining 963 (mean age at registry entry: 53.0 ± 13.3, female: 723 [75%], and White: 657 [68%]), 43 (5%) were reported as deceased after a median follow-up of 5.3 years (interquartile range 2.4 to 7.9). The main causes of death (not mutually exclusive) were: infection (15, 35%), thrombosis (9, 21%), and malignancies (8, 19%). Based on the univariate analysis, history of arterial thrombosis or catastrophic APS (CAPS), selected baseline cardiovascular disease (CVD) risk factors, baseline active thrombocytopenia, and concomitant systemic autoimmune disease (SAID) were significantly more common in deceased patients, compared to non-deceased (data not shown). Based on the Cox proportional hazards model adjusted for age, arterial thrombosis, CAPS, CVD risk factors combined, and SAID were significantly and independently associated with mortality (Tables 1 and 2). Estimated 5-year survival probabilities starting from the registry entry (by age groups) were 0.98 (95% CI 0.92-0.99), 0.98 (0.95-0.99), 0.96 (0.93-0.98), and 0.86 (0.77-0.92) for ages < 30 (n:119), 30-44 (n: 362), 45-59 (n: 340), and >60 (n: 142), respectively (Figure 1).

Conclusion: Based on analysis of the largest multi-center international prospective cohort of persistently aPL-positive patients, the mortality rate was 5% after a median follow-up of five years. The estimated 5-year survival probability decreased with age; lowest (0.86) for patients over 60 years old at registry entry. History of arterial thrombosis, catastrophic APS, CVD risk factors, and concomitant systemic autoimmune diseases independently predicted future mortality

Cell-bound Complement Activation Products in Antiphospholipid Antibody-positive Patients Without Other Systemic Autoimmune Diseases

Doruk Erkan[1], JoAnn Vega[1], Tyler O'Malley[2] and Andrew Concoff[3], [1]Hospital for Special Surgery, New York, NY, [2]Exagen, Vista, CA, [3]Exagen, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Based on animal models, complement activation is part of Antiphospholipid Syndrome (APS) pathogenesis. However, studies investigating complement activation in antiphospholipid antibody (aPL)-positive patients are limited. Our objective was to analyze complement activation in subgroups of aPL-positive patients, using complement 3/4 (C3, C4) andcell-bound complement activation products (CB-CAPs)(B-lymphocytes [BC4d], erythrocytes [EC4d], and platelets [PC4d]).

Methods: Persistently aPL-positive (>12 weeks apart; last within six months (m) prior to entry) adult patients without other systemic autoimmune diseases (SAID) were enrolled in a single center study. For those with aPL-related manifestations, i.e., microvascular APS (MAPS), thrombotic APS (TAPS), obstetric APS (OAPS), thrombocytopenia(TP) (< 150x109/L), and/or hemolytic anemia (HA),at least one event within five years prior to enrollment was required. Selected exclusion criteria wereactive infection, cancer, and corticosteroids >20mg/d. Blood and clinical data were collected at baseline; a subgroup of

Mean EC4d (MFI)	18.2 (25.4)	25.7 (30.3)	8.6 (3.8)	4.9 (0.8)	4.8 (1.8)
PC4d (10-15 MFI)[g]	2/32 (6%)	1/20	1/4	0	0
PC4d (16-20 MFI)	1/32 (3%)	1/20	0	0	0
PC4d (>20 MFI)[h]	9/32 (28%)	7/20	2/4	0	0
Mean PC4d (MFI)	38.3 (104.6)	26.8 (35.1)	154.9 (282.8)***	5.1 (2.0)	3.0 (0)

Positive 61-200 mean fluorescent intensity (MFI), 15-75 MFI, and 10-20 MFI, and **strongly positive** above 200 MFI, 75 MFI, and 20 MFI for BC4d, EC4d, and PC4d, respectively. *Two patients with no C3/C4 and BC4d results. ** Two patients with no BC4d results, and one with no PC4d result. *** Based on four samples with levels of 6 MFI, 11.5 MFI, 23 MFI, and an outlier of 579 MFI. [a] Six month (m) repeat BC4d was in the same range (SR) (1 of 1 tested); [b] 6m BC4d SR (2/2); [c] 6m EC4d SR (3/4) and 31-75 range (1/4); [d] 12m EC4d SR (1/3), negative (1/3), and 31-75 range (1/3); [e] 6m EC4d SR (2/2); [f] 6m EC4d SR (1/1); [g] 6m PC4d negative (2/2), and 12m PC4d SR (1/2) and negative (1/2); and [h] 6m PC4d SR (3/5) and negative (2/5), and 12m PC4d SR (1/1).

patients completed 6-12mfollow-up(Table 1 footnote). Positive aPLwas defined as positive lupus anticoagulant (LA) test, anticardiolipin antibody (aCL) IgG/M ≥ 40 ELISA units, and/or aβ2GPI IgG/M ≥ 40 ELISA units. C3/C4 were measured by turbidimetry and CB-CAPs by quantitative flow cytometry. Following a descriptive analysis of baseline results based on aPL profiles and clinical phenotypes, C3/C4 and CB-CAPswere correlated (Pearson).

Results: Between 8/20 and 11/22, 33 patients(female 23 [70%], mean age 50.6+12.5, White 30 [91%]) were enrolled. Four of 31 (13%) had decreased C3/C4, while 7/29 (24%)had elevated BC4d (no strong positivity [SP]), 13/33 (33%) EC4d (2% SP), and 12/32 (37%) PC4d (28% SP). Based on different aPL profiles, all patients with decreased C3/C4 or elevated BC4d, EC4d, and PC4d had triple aPL positivity, or LA positivity with/without aCL or aβ2GPI(additionally, higher mean EC4d and PC4d levels were observed in these groups) (Table 1).Based on different aPL clinical phenotypes, the number of patients with strongly positive EC4d and PC4dwere proportionally higher (14% and 36%) in those with MAPS/TP/HA, compared to those with TAPS (0 and 18%) or no APS (0 and 29%) (additionally higher mean EC4d and PC4d levels were observed in the former group) (Table 2).There was a weak correlation between C3/C4 and CB-CAPs, especially for PC4d (r=-0.098 and 0.068 for C3 and C4, respectively) (Figure 1).

Conclusion: Assessment of complement activation in persistently aPL-positive patients without other SAID demonstrated that13%, 24%, 33%, and 37% had abnormal baseline C3/C4, BC4d, EC4d, and PC4d, respectively; all in patients with triple aPL-positivity, or LA-positivity with/without aCL or aβ2GPI. Number of patients with strongly positive EC4d and PC4d were proportionally higher (14% and 36%) in those with MAPS, thrombocytopenia, and/or hemolytic anemia. Given the higher

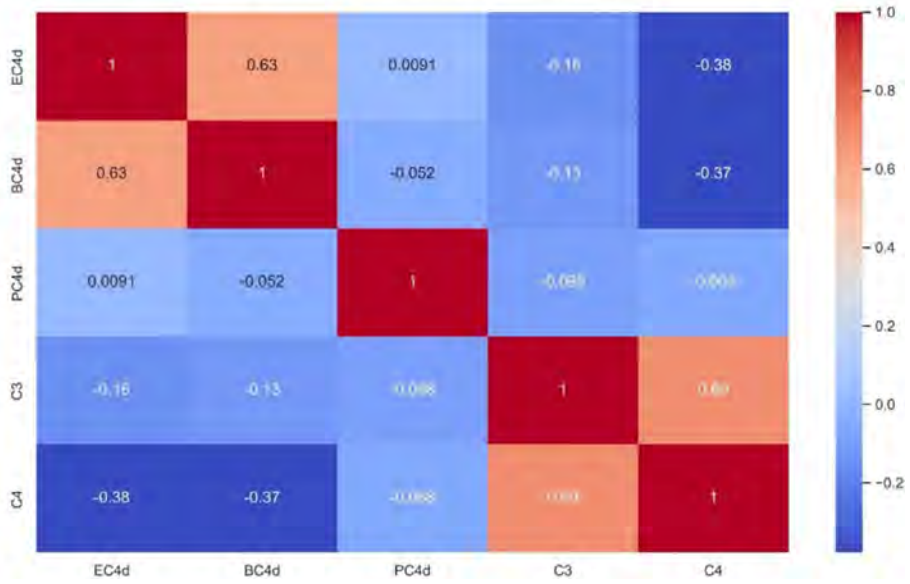
(Pearson's correlation coefficient (r) is shown with darker red shades representing strong positive correlations and darker blue shades representing strong inverse correlations between biomarkers [two patients did not have C3, C4, and BC4d, and one did not have PC4d results])



percentage of aPL-positive patients with abnormal CB-CAPs vs C3/C4, and the poor correlation between CB-CAPs and C3/C4, our study generates the hypothesis that CB-CAPs have a role in measuring disease activity in aPL-positive patients.

Abstract Number: 0100

The Clinical Relevance of Different Antiphospholipid Antibody Profiles in Pediatric Rheumatology Patients

Jheel Pandya, Karen Onel and Doruk Erkan, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The clinical relevance of different antiphospholipid antibody (aPL) profiles, including low level anticardiolipin (aCL) and anti β_2-glycoprotein-I (aβ_2GPI) antibodies, is ill-defined in the pediatric population. The purpose of this project is to describe the demographic, clinical, and laboratory characteristics of aPL "positive" pediatric patients based on different aPL profiles.

Methods: In this single center retrospective cohort study, based on the screening of our pediatric (age ≤18yo) rheumatology electronic medical records (2016—2022), we identified patients who had at least one "positive" aPL (lupus anticoagulant [LA], aCL IgG/M, or aβ_2GPI IgG/M) result. First, we grouped patients based on initial high- (LA positive and/or aCL/aβ_2GPI

IgG/M≥40U [ELISA]) vs low- (LA negative and aCL/aβ$_2$GPI IgG/M 20-39U) risk aPL profiles to evaluate subsequent aPL testing frequency and results. Secondly, we descriptively analyzed the demographic and clinical characteristics of patients with persistently positive (at least 12 weeks apart) aPL results based on different aPL profiles.

Results: Of 113 aPL "positive" patients identified, 56 (50%) were excluded as they had very low aCL/aβ$_2$GPI IgG/M positivity (above laboratory normal range but < 20U). Of the remaining 57 patients (female: 48 [84%], lupus classification: 21 [37%]), 35 (61%) had an initial high-risk profile and 22 (39%) had an initial low-risk profile. Based on the subsequent aPL results available in 42/57 (74%) patients, 26/28 (93%) in the high-risk, and 5/14 (36%) in the low-risk group remained still positive (Table 1). Of these 31 patients with persistent aPL positivity, thrombosis occurred in eight (26%) patients with high-risk aPL profile and in none with low-risk aPL profile; other aPL-related manifestations were reported in 15 (48%) patients with persistent aPL positivity (Tables 2 and 3). Of 26 patients without persistent aPL results (repeat test either negative or not available), none developed thrombosis, one had livedo reticularis, and two had migraines.

Conclusion: An initial low-risk aPL profile (negative LA and aCL/aβ$_2$GPI IgG/M levels 20-39U) is persistent in only approximately one-third of the pediatric patients, which was not associated with thrombosis in our cohort. Meanwhile, a high-risk profile defined as LA positivity and/or aCL/aβ$_2$GPI IgG/M levels ≥ 40U is persistent in 90% of pediatric patients, about a third of

whom had history of thrombosis, and half had non-thrombotic aPL-related manifestations. Our results underscore the need for a large-scale international effort to better characterize the aPL-related manifestations in pediatric patients with persistent high-risk aPL-profiles, which can eventually guide the development of future pediatric-specific APS classification criteria.

Non-Criteria Antiphospholipid Antibodies and Calprotectin as Potential Biomarkers in Pediatric Antiphospholipid Syndrome

Elizabeth Sloan[1], Katarina Kmetova[2], NaveenKumar K. Somanathapura[2], Lyndsay Kluge[2], Emily Chong[2], Claire Hoy[2], Srilakshmi Yalavarthi[2], Jacqueline Madison[2], Cyrus Sarosh[2], Lynnette Walters[3], Jeanine Baisch[4], Jessica Turnier[2], Virginia Pascual[4], Tracey Wright[1], Jason Knight[2], Ayesha Zia[1] and Yu Zuo[2], [1]UT Southwestern, Dallas, TX, [2]University of Michigan, Ann Arbor, MI, [3]Scottish Rite Hospital for Children, Dallas, TX, [4]Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: While classification criteria for pediatric APS are not yet available, recent research suggests pediatric APS patients are unique, and many present with extra-criteria manifestations as their primary clinical features. Criteria aPL may identify classical APS manifestations, but a clinically actionable biomarker for features unique to pediatric APS is not yet available. Here, we aimed to evaluate the presence, clinical associations, and potential mechanistic roles of non-criteria aPL and circulating NETs markers in pediatric APS patients.

Methods: Children with APS (n=19), venous thrombosis without APS (VT, n=20), systemic lupus erythematosus without aPL (SLE, n=11), and healthy controls (n=13) were evaluated for nine different types of aPL by Werfen assays (**Table 1**). Calprotectin, a well-known marker of circulating neutrophil extracellular traps (**NETs**), was measured in plasma using the Human S100A8/S100A9 heterodimer DuoSet ELISA (R&D). Univariate logistic regression was used to identify potential clinical associations. A platelet viability dye-based assay was performed to assess the potential impact of calprotectin on platelet survival (**Fig 2A**).

Table 1. Prevalence of antiphospholipid antibodies in children with APS (n=19)

aPL	Number positive (manufacturer's threshold)	%	Number positive (titer ≥40 U)	%
aCL IgG*	7	37%	5	26%
aCL IgM*	5	26%	3	16%
aCL IgA	1	5%	1	5%
aβ2GPI IgG*	8	42%	5	26%
aβ2GPI IgM*	9	47%	5	26%
aβ2GPI IgA	1	5%	1	5%
aPS/PT IgG	11	58%	11	58%
aPS/PT IgM	13	68%	13	68%
anti-D1 IgG	10	53%	9	47%
Lupus anticoagulant*†	16	84%		
Any non-criteria aPL	15	79%	15	79%

*Current adult APS classification criteria aPL, remaining are non-criteria aPL

†Lupus anticoagulant as determined by clinical laboratory data

aPL=antiphospholipid antibodies; aCL=anticardiolipin; aβ2GPI=anti-beta-2 glycoprotein I; aPS/PT=anti-phosphatidylserine/prothrombin; anti-D1=anti-Domain 1 of beta-2 glycoprotein I

Manufacturer's thresholds:

- aCL IgG/M/A ≥ 20 GPL/MPL/APL
- $a\beta_2$GPI IgG/M/A ≥ 20 SGU/SMU/SAU
- aPS/PT IgG/M ≥ 30 arbitrary units
- anti-Domain 1 IgG ≥ 20 arbitrary units

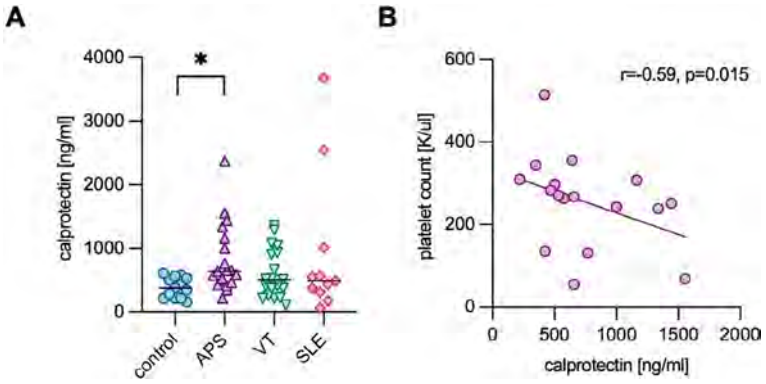

Figure 1. Calprotectin in pediatric APS plasma. A, Levels of calprotectin were measured in patients with pediatric APS, pediatric venous thrombosis (VT), pediatric SLE, and healthy pediatric controls. Calprotectin levels were compared with healthy controls by the Kruskal-Wallis test adjusted for multiple comparisons by Dunn's method; *p<0.05. B, Correlation between circulating calprotectin and platelet count in pediatric APS patients. Spearman's correlation coefficient was calculated and is shown in the panel.

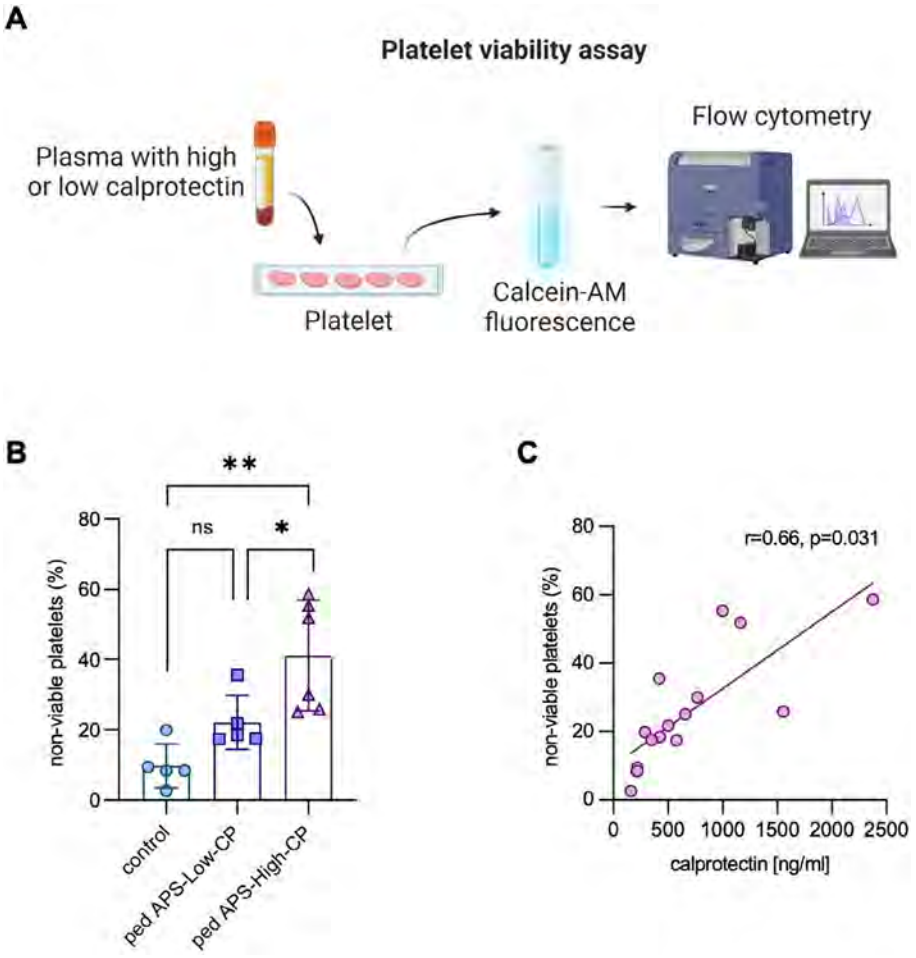

Figure 2. Effect of calprotectin on platelet viability. A, Schematic illustration of platelet viability assay. Created at www.biorender.com. B, Healthy donor platelets were incubated with 5% plasma from pediatric APS patients with low calprotectin, pediatric APS patients with high calprotectin, or pediatric controls. Platelet viability was measured by flow cytometry using Calcein-AM dye. The percentage of non-viable platelets was then compared between groups by the Kruskal-Wallis test adjusted for multiple comparisons by Dunn's method (*p<0.05, **p<0.01, ns=not significant). C, Calprotectin levels from pediatric APS patients were positively correlated with the percentage of non-viable platelets (r=0.66, p=0.031).

Results: Among the 19 pediatric APS patients (median age of 13 [range 3 to 18]), 74% were female, and 58% had primary APS. Most (89%) had experienced at least one venous thrombosis, and four had recurrent thrombotic events. The remaining two children with APS exhibited extra-criteria manifestations, persistent aPL, and a clinical diagnosis of APS. Almost half (47%) had at least one extra-criteria manifestation. Interestingly, 79% of pediatric APS patients had at least one non-criteria aPL at ≥40 units (**Table 1**). Aside from lupus anticoagulant, aPS/PT IgG and IgM were the most prevalent aPL followed by anti-D1 IgG. Univariate logistic regression demonstrated that positive anti-D1 (p=0.0109), positive aPS/PT IgG ($p < 0.0001$), and IgM ($p < 0.0001$) were significantly associated with venous thrombosis. Positive anti-D1 IgG (p=0.0116) and aPS/PT IgG (p=0.0116)/IgM (p=0.0321) were also associated with extra-criteria manifestations such as thrombocytopenia. Increased levels of calprotectin, which is a marker of NETs, were detected in children with APS (**Fig 1A**). Calprotectin levels correlated moderately with levels of aPS/PT IgM (r=0.49, p=0.0345) and absolute neutrophil count (r=0.63, p=0.0079), whereas they were negatively correlated with hemoglobin (r=-0.74, p=0.0189) and platelet count (r=-0.59, p=0.0150) (**Fig 1B**). Mechanistically, plasma from pediatric APS patients with high calprotectin levels impaired platelet survival *in vitro* in a dose-dependent manner (**Fig 2A-B**), and APS calprotectin levels correlated with decreased platelet viability (**Fig 2C**).

Conclusion: Our study suggests non-criteria aPL and circulating calprotectin were highly prevalent among pediatric APS patients and associated with extra-criteria manifestations more common in pediatric APS. The role of non-criteria aPL and calprotectin as clinically actionable biomarkers that might enable earlier diagnosis and inform targeted therapy for some pediatric aPL-positive patients warrants further evaluation.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Acute myocardial infarction (AMI) can be divided into coronary artery disease (MICAD) or nonobstructive coronary arteries (MINOCA) according to the severity of artery stenosis on coronary angiography. Antiphospholipid syndrome (APS) can present with AMI, but the subtype and prognosis of these patients were not fully understood.

Methods: A single-center study was conducted based on the APS cohort in Peking Union Medical College Hospital. According to coronary angiography, AMI patients were classified as MICAD (≥50% stenosis) or MINOCA(<50% stenosis). Baseline and follow-up data were compared to identify differences between the two subgroups. Cox analysis was used to find prognostic factors associated with AMI recurrence.

Results: The study enrolled 36 APS-AMI patients underwent coronary angiography, 26 (72%) patients were diagnosed with MICAD and 10 (28%) patients with MINOCA. Comparison between the two subgroups showed MINOCA patients were more likely to present in APS secondary to SLE than MICAD (70% VS 23.1%, p=0.018), and less likely to comorbid with previous atherosclerotic cardiovascular disease (ASCVD) (0 VS 50%, p=0.006). Anti-cardiolipin antibody (aCL) was more common in MINOCA (100% VS 65.4%, p=0.039). Treatment strategies were different, MINOCA patients tended to receive glucocorticoid (80% VS 26.9%, p=0.007), immunosuppressant (80% VS 26.9%, p=0.007), hydroxychloroquine (100% VS 26.9%, p=0.000) and anticoagulation (90% VS 42.3%, p=0.022), while MICAD patients were more likely to receive revascularization (47.6% VS 0%, p=0.002). 2 (5.5%) patients died and 13 (36.1%) patients experienced a relapse of AMI during a mean follow-up time of 42.25 months. Recurrence occurred only in MICAD group (13/26, 50%), over 60% (8/13) had recurrence more than once. Hydroxychloroquine was found to be a protective factor for AMI recurrence by Cox analysis [HR (hazard ratio) = 0.106, CI (confidence interval) = 0.014-0.823, p= 0.032], only 1 (5.8%) patient on hydroxychloroquine relapsed. While 66.7% (10/15) patients received revascularization suffered AMI recurrence caused by stent stenosis/thrombus, and the HR of recurrent AMI with revascularization therapy was 4.041 (CI = 1.087-15.021, p = 0.037).

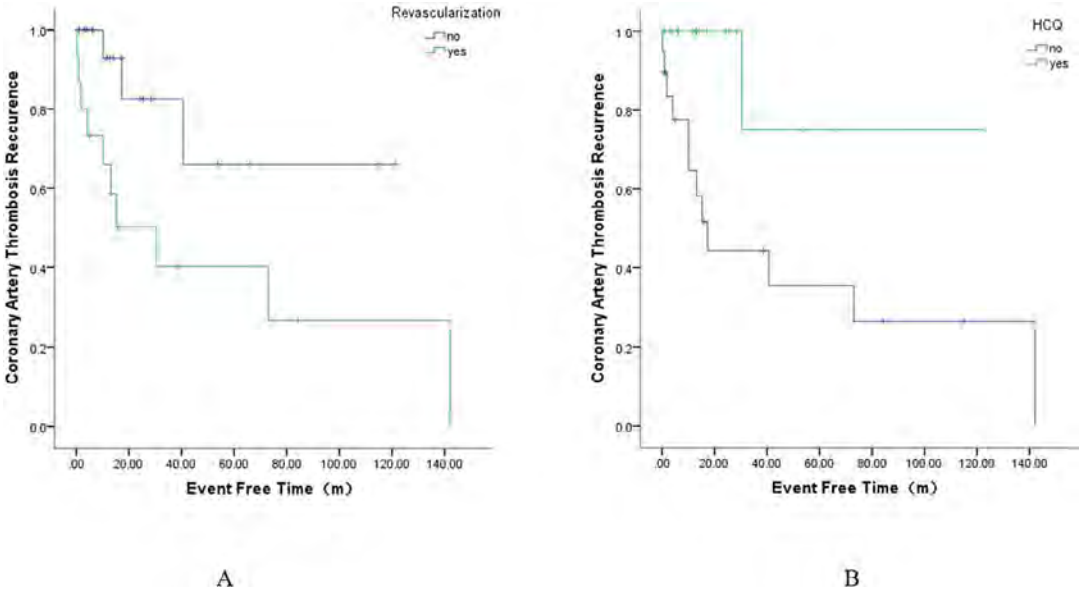

Figure 1. Kaplan-Meier curve of AMI recurrence in APS-AMI patients. (A) Recurrence in patients with revascularization and without. HR = 4.041, CI = 1.087-15.021, p = 0.037. (B) Recurrence in patients with hydroxychloroquine and without. HR=0.106, CI=0.014-0.823, p=0.032.

Criteria and Non-criteria Antiphospholipid Autoantibodies Screening in Women with Unexplained Fetal Death, Pre-eclampsia And/or Fetal Growth Restriction: A Cross-sectional Study

Tiphaine Goulenok[1], Clothilde Gros[1], Arthur Mageau[2], Tiphaine Barral[1], Pascale Roland Nicaise[1], Marie Helene Saint Frison[1], Margot Bucau[1], Valerie Vivier[1], Valentine Marie Ferre[2], Agnes Bourgeois Moine[1], Thomas Papo[2] and Karim Sacre[2], [1]Assistance Publique Hopitaux de Paris, Paris, France, [2]Université Paris Cité, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is a cause of pregnancy morbidity. Late pregnancy morbidity occurs in up to 25% of pregnant women with APS and may be the presenting manifestation of the autoimmune disease. We recently showed that aPL testing was performed in only 20% patients who displayed late pregnancy morbidity consistent with obstetrical APS. We aimed to determine the frequency of criteria and non-criteria anti-phospholipid (aPL) autoantibodies in patients admitted for unexplained fetal death (UFD), pre-eclampsia (PE) and/or fetal growth restriction (FGR).

Methods: All consecutive patients with UFD, PE and/or FGR followed in the department of Obstetrics, Bichat Hospital, University of Paris, Paris, between January 2019 and December 2021 were screened. Only patients with available serum stored from the index pregnancy were included. Patients with previously known APS or twin pregnancy were excluded. Testing for aPL autoantibodies included anti-cardiolipin (aCL), anti-β2GPI (aβ2GPI), anti-phosphatidylethanolamine (aPE), anti-phosphatidylserine/prothrombin (aPS/PT) IgG/IgM and anti-annexin V IgG. When available, placenta specimens were analysed by a pathologist blinded to the aPL status. All clinical characteristics, pregnancy features, and comorbidities were extracted from electronic medical records.

Results: Overall 167 (32 (28.8-35.7) years) patients with UFD (n=28; 16.8%), PE (n=60; 35.9%) and/or FGR (n=105; 62.9%) were screened for aPL autoantibodies. Moderate titers of aPL autoantibodies were detected in 33 (n=33/167, 19.8%) patients. aPL autoantibodies were non-criteria aPE IgG/IgM in most cases (n=28/33, 84.8%). aPS/PT IgG/IgM were found in 11 (n=11/33, 33.3%) cases and aCL or aβ2GP1 IgG/IgM in 4 (n=4/33, 12.1%). Multivariable logistic regression model showed that aPL autoantibodies were mostly associated with UFD (OR 4.37 [1.72-11.20], p=0.002), PE ≤34th week of gestation (3.22 [0.86-11.90], p=0.070) and chronic deciduitis (8.03 [0.89-67.2], p= 0.060) (Tables 1 and 2).

Conclusion: The frequency of aPL autoantibodies, mostly aPE, is high in patients with late pregnancy morbidity and may qualify obstetrical APS

Table 1. Cluster Analysis of Antiphospholipid Antibodies Associated Adverse Pregnancy Outcome Patients: Based on a 13-year Longitudinal Cohort Study

Yin Long[1], Jiuliang zhao[2], Mengtao Li[2], Xinping Tian[2] and xiaofeng Zeng[3], [1]Peking Union Medical College Hospital Department of Rheumatology and Clinical Immunology, Beijing, China, [2]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [3]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid antibodies (aPLs) play a pivotal role in the etiology of adverse pregnancy outcomes (APOs). (1) Women with persistently aPLs positivity present heterogeneous clinical manifestations and APOs. We aimed to stratify aPLs positivity patients with APOs and assess the subsequent pregnancy outcomes.

Methods: This was a retrospective study of persistent aPLs positive women cohort in Peking Union Medical College Hospital. Baseline demographic characteristics, clinical manifestation, previous APOs and antibodies profiles were analyzed. Placentae from patients were collected and performed the histopathologic diagnoses during the follow up.

Results: Four clusters among 209 patients with 477 pregnancies were identified. Cluster 1 comprised patients with triple aPLs positivity and demonstrates a high incidence of gestational hypertension (34.92%, P = 0.008) and preterm delivery (20.63%, P = 0.021). Patients in cluster 2 were characterized by lupus anticoagulant (LA) positivity, with high risk of whole

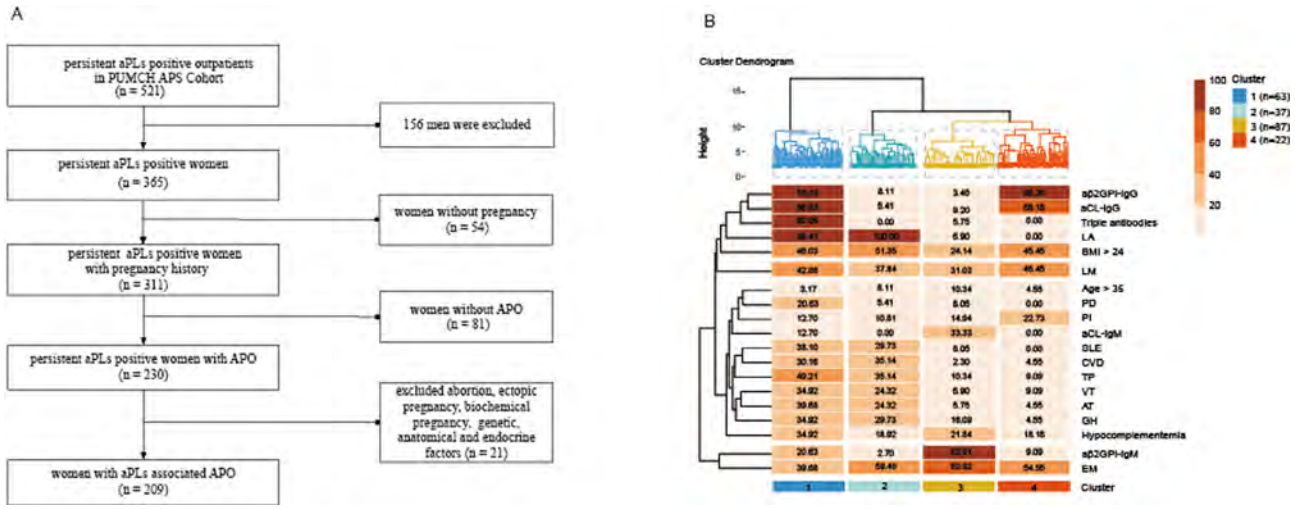

Figure 1. Study flowchart and cluster analysis; A. Study flowchart; B. Cluster analysis

gestational APOs. Cluster 3 included patients with isolated aPLs-IgM isotype combined with early miscarriage (60.92%, P = 0.01). Patients in cluster 4 majorly presented aPLs-IgG isotype combined with placenta insufficiency (22.73%, P = 0.016). During the follow up, the live birth rate in cluster 1 and 2 was only 69.20%. Gestational hypertension was much higher in cluster 1 (15.4%, P = 0.05). Placenta pathology revealed that the patient in cluster 1 exhibited a conspicuous reduction in the number of capillaries present within the placental villi, coupled with hypoplastic chorionic capillaries. The representative placental pathology of the cluster 3 likewise showed a reduced number of stem villi capillaries and slight swelling and degeneration of the endothelium in the stem villi vessels. Placenta in cluster 4 had mildest placental lesions.

Conclusion: In conclusion, our study identified four clusters of patients with aPLs-associated APO. There exists a correlation between specific aPLs isotypes and the occurrence of adverse pregnancy events at different stages of gestation. Triple aPLs positivity is associated with gestational hypertension and preterm delivery. LA positivity is a significant risk factor for the whole gestational APOs. While patients with isolated aPLs-IgM isotype are more likely to have early miscarriage. Patients in cluster 4 majorly present aPLs-IgG isotype combined with placenta insufficiency. The four identified clusters based on

clinical and laboratory features showed distinct differences in pregnancy outcomes and placental damage. These findings suggest that an individualized risk stratification approach to the management of persistent aPLs positive women may improve pregnancy outcomes, taking into consideration the clinical phenotype and placental pathology.

Characterization of B-Cell Subsets in Antiphospholipid Syndrome Patients: Implications for Disease Phenotype and Pathogenesis

Yin Long[1], Jiuliang zhao[2], Mengtao Li[2] and Xiaofeng Zeng[2], [1]Peking Union Medical College Hospital Department of Rheumatology and Clinical Immunology, Beijing, China, [2]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary antiphospholipid syndrome (PAPS) is an autoimmune disorder characterized by the presence of pathogenic autoantibodies. The key immune cell subsets change in PAPS patients remains unclear.

Methods: We enrolled 35 primary APS (PAPS) patients fulfilling the 2006 Sydney criteria, five antiphospholipid antibody (aPLs) carriers, and 10 healthy controls (age-, gender-matched). Peripheral blood mononuclear cells (PBMCs) were analyzed using Mass Cytometry (CyTOF) with 42 markers to identify immune cell subsets. Plasma cytokine profiling of 55 PAPS patients was performed using the procartaPlex 65 panel assay. Peripheral B cells from PAPS patients and healthy individuals were isolated for RNA sequencing (RNAseq). Flow cytometry and RT-qPCR were used to validation. FlowJo and R software packages were utilized for CyTOF data analysis.

Results: Our study investigated that APS patients had a significant difference in peripheral blood subtype distribution . Using CD19 as a baseline for dimensionality reduction clustering, we identified 20 subgroups of B cells (Figure 1). Naïve B cells, characterized by IgD+CD27-CD38+CD24+, were the predominant B cell subset in APS patients (C14, 21.04%), while plasmablasts accounted for 1.55%. C01 and C02 subpopulations within B cells were significantly increased in the peripheral circulation of patients (C01: 1.89±1.68 vs 0.58±0.41, P=0.02; C02: 2.16±1.78 vs 0.71±0.67, P=0.015; Figure 2). Both were characterized as IgD-CD27- double negative B cells, with C01 expressing high levels of CD11c and Tbet, which are a subset of age-associated B cells (ABC). In APS patients, C01 cells showed a positive correlation with ESR. C02 showed a positive association with β2GPI IgG expression in patients without extra-criteria organ involvement. We further validated these findings by expanding the sample size and analyzing an additional 23 APS patients using flow cytometry (Figure 3A). The results demonstrated a significant increase in DN B cells in APS patients, along with a marked increase in the CD11cTbet signaling intensity of DN B cells (Figure 2). This suggests that DN cells, especially ABC cells, may be involved in the sustained production of high levels of aPLs in APS patients. Interestingly, we found that the C19 (IgD-CD27++CD38+++CD24-) plasmablasts showed a negative correlation with the production of IgG subtype antibodies in OAPS patients, which contrasts with TAPS patients. This suggests that different mechanisms may be involved in B cell participation in APS with different phenotypes.

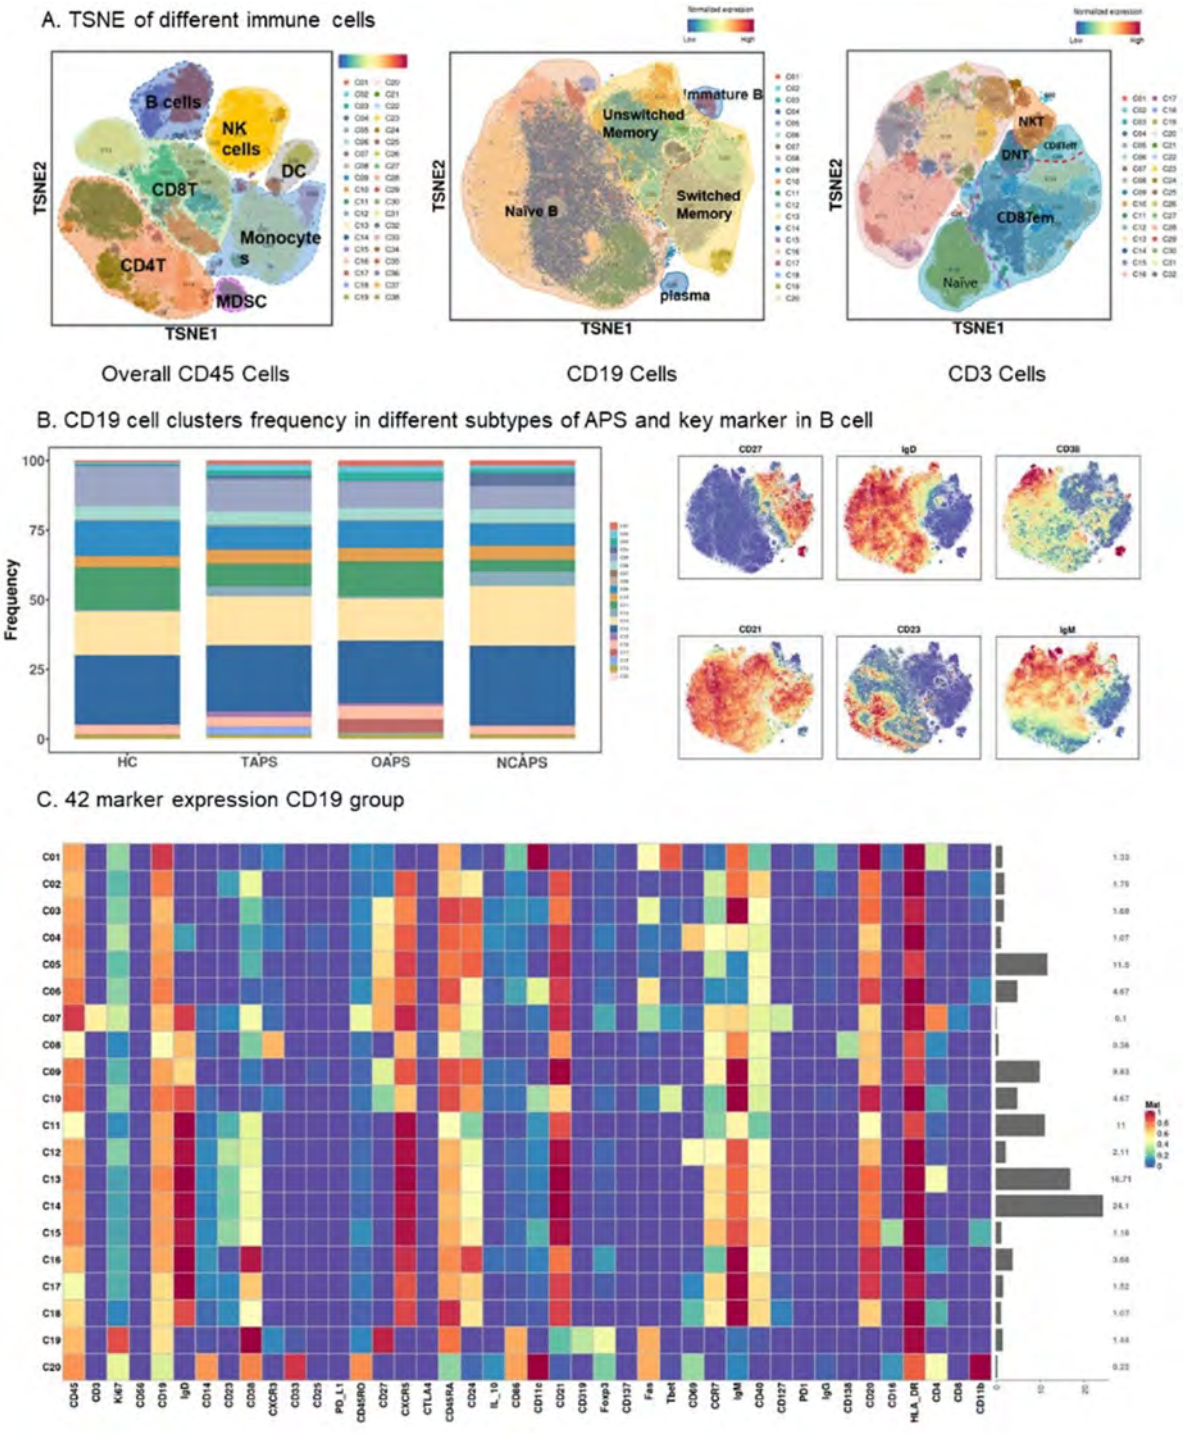

Figure 1. Distribution of peripheral blood immune cells and expression of key markers in patients with APS.

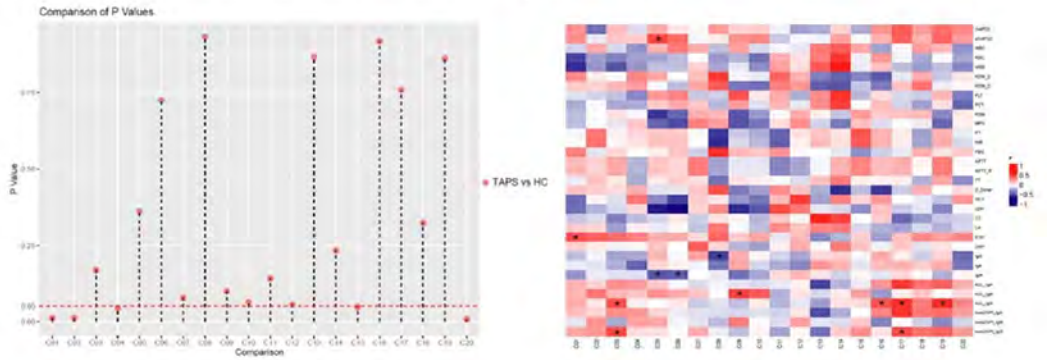
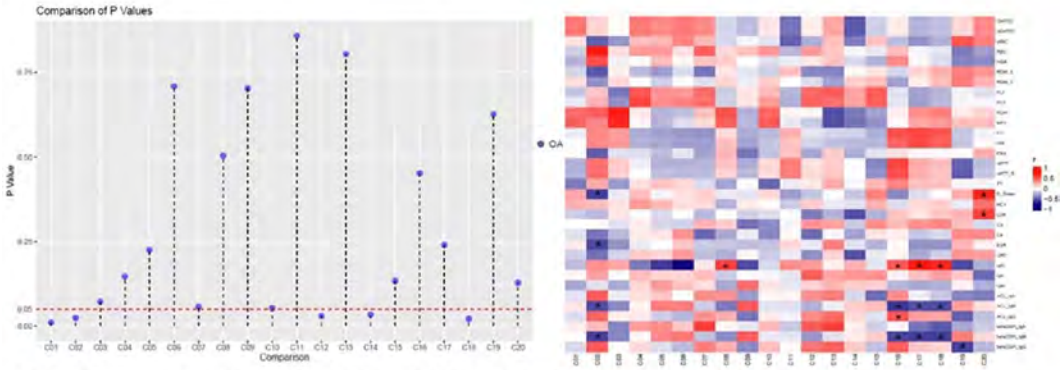
Based on the results of plasma cytokine analysis, we observed elevated expression of BLC/CXCL13 and BAFF in the plasma of APS patients. We then identified upregulation of TNFRSF13B, a gene associated with the Transmembrane activator and CAML interactor (TACI) protein by RNAseq. Furthermore, GSEA analysis revealed activation of the MAPK and NF-κB pathways within B cells (Figure 3B).

Figure 2. CD19 cell types and clinical characteristics

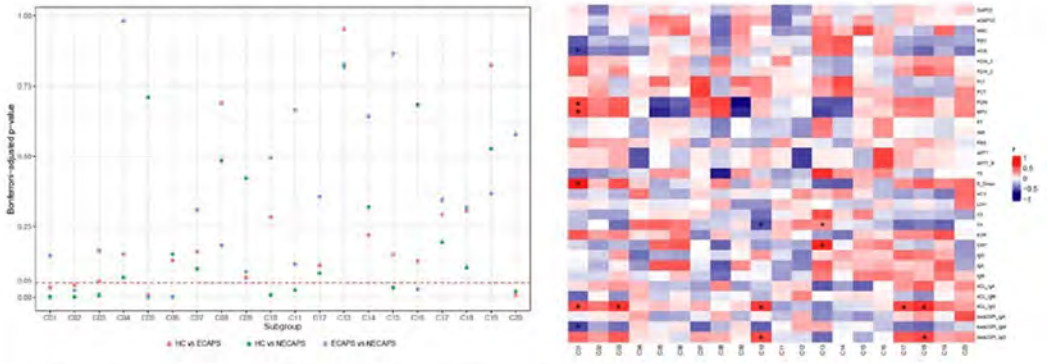
A. B-cell subtype differences and clinical correlation in TAPS patients



B. B-cell subtype differences and clinical correlation in OAPS patients



C. B-cell subtype differences and clinical correlation in extra-criteria manifestation APS patients



D. Different expression of plasma cytokines in patients APS patients

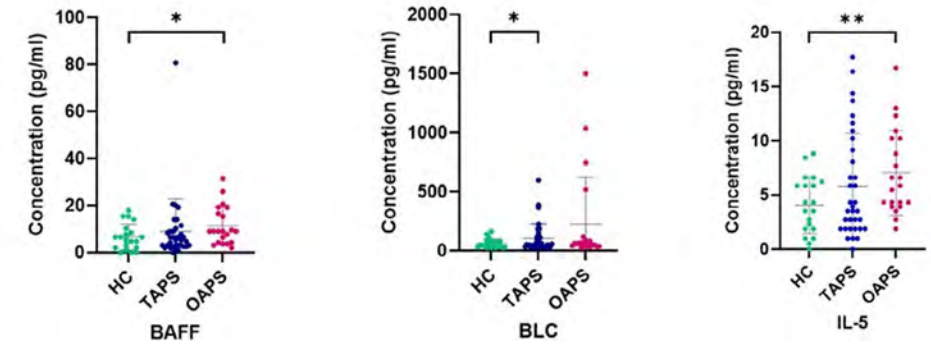


Figure 2.. CD19 cell types and clinical characteristics

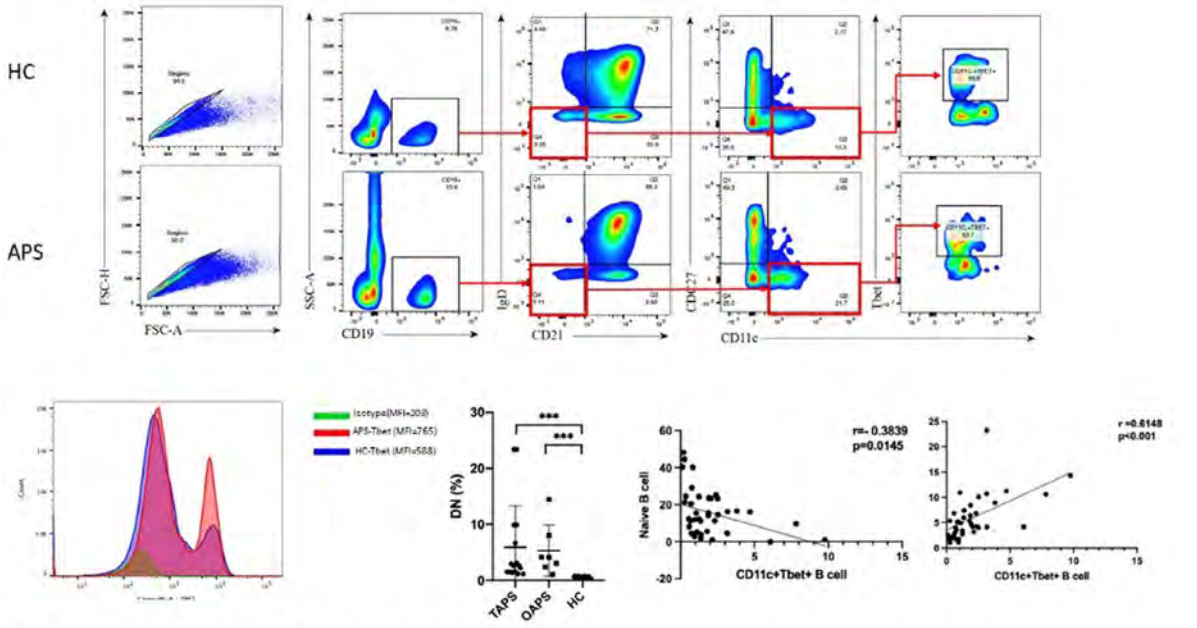
Figure 3. Validation and GSEA analysis

A. Gating strategy of CD11c⁺ Tbet+ in peripheral blood of APS patients and healthy donors



B. B cell RNAseq and GSEA analysis APS patients

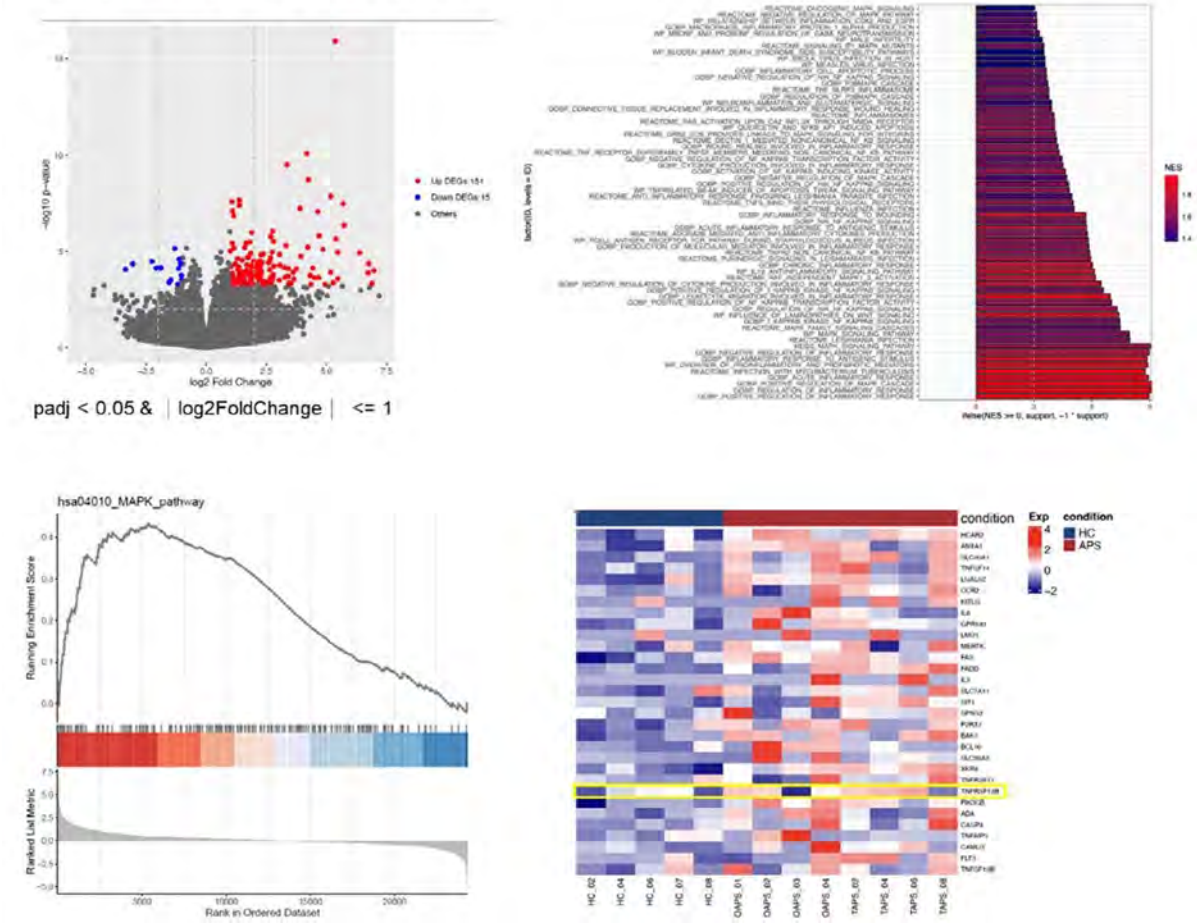


Figure 3. Validation and GSEA analysis.

Conclusion: Double-negative B cells are significantly higher in APS patients, where ABC cells may play a role in aPLs production. The aberrant differentiation and maturation of B cells in APS patients may be triggered by TACI downstream cascade.

Positive Antiphospholipid Antibodies Are Associated with a Higher Risk of Cerebral Microbleeds

Junna Ye[1], Yijun You[2], Zhuochao Zhou[2], Fan wang[2], Jingyi Wu[2] and Chengde Yang[2], [1]Ruijin Hospital affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Persistent presence of antiphospholipid antibodies (aPLs) are important thrombosis-related laboratory parameters, as well as an indication of anticoagulation use which usually cause higher bleeding risk. Cerebral microbleeds (CMBs) are strongly associated with both bleeding propensity and ischemic events. Till now, the correlation between aPLs and CMBs remained unclear.

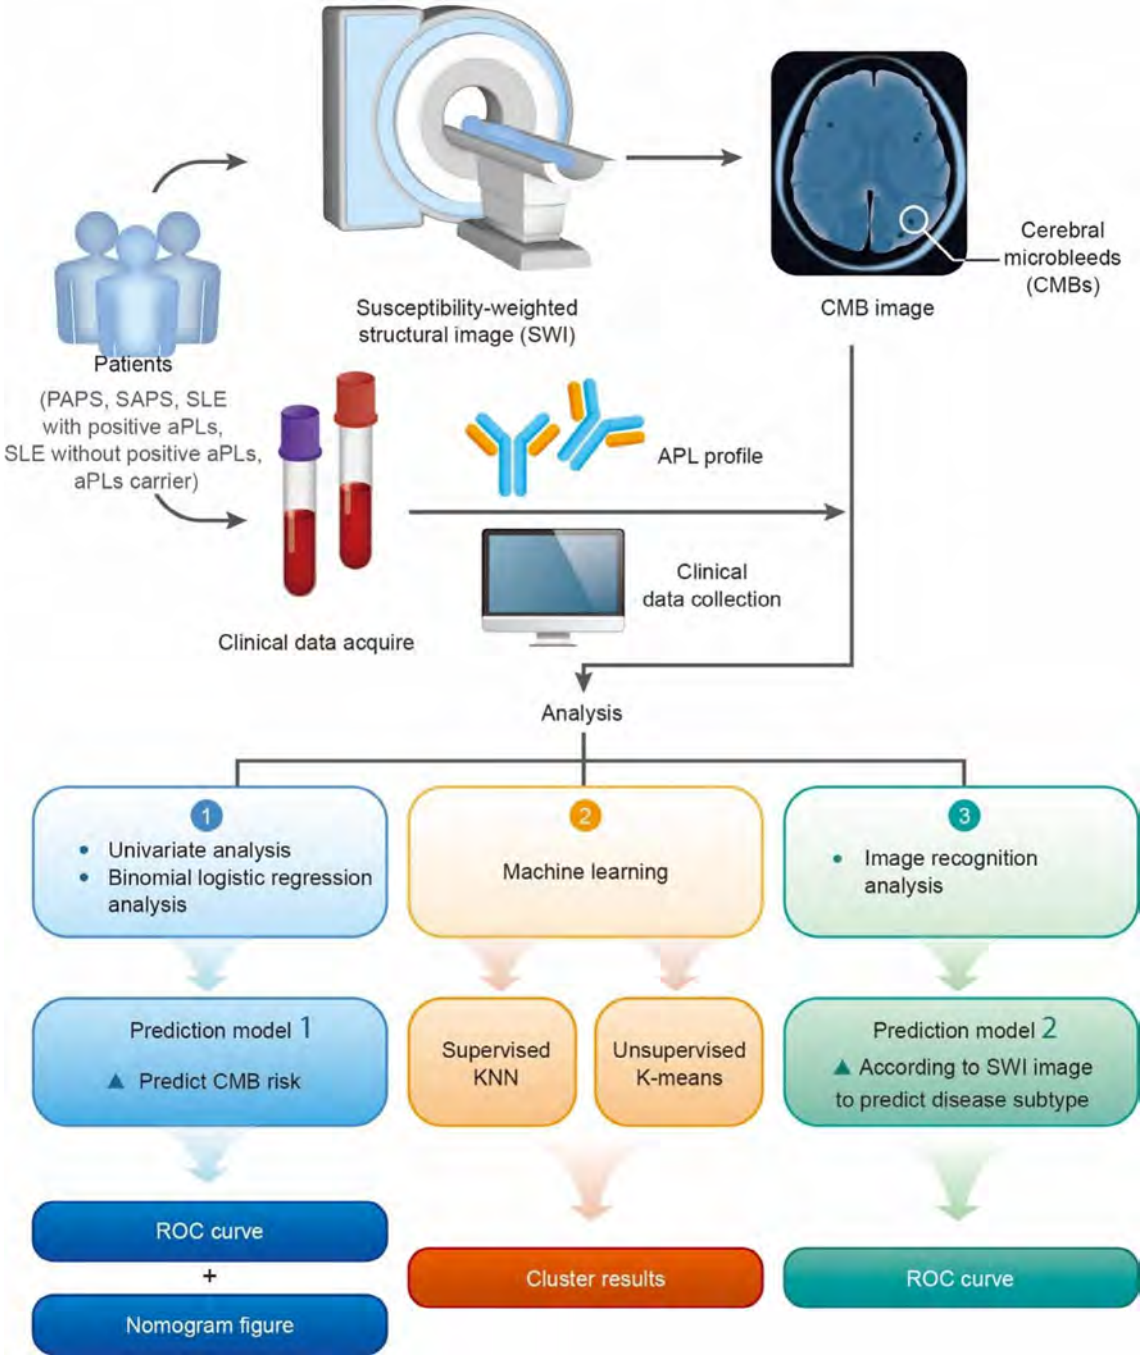
Methods: 31 primary antiphospholipid syndrome (APS), 50 secondary APS, 19 systemic lupus erythematosus (SLE) with positive aPLs, 44 SLE without positive aPLs and 16 aPLs carriers were enrolled from 2018 to 2021 in the Department of Rheumatology and Immunology in Ruijin Hospital. Clinical data, aPLs profile and susceptibility-weighted imaging(SWI) data were collected. Statistical analysis, machine learning, and image recognition analysis were performed from September 2022 to December 2022. Univariate and binomial logistic regression (prediction model 1) analysis was performed to investigate the risk factors of CMBs. Differences in CMBs between those with or without aPLs were analyzed by machine learning (supervised K-Nearest Neighbor (KNN) classification and unsupervised K-means clustering analysis) in SLE patients. Then, an image recognition analysis (prediction model 2) was conducted to build a model to predict the disease subtypes. Receiver operating characteristic (ROC) curve and nomogram representation of the binomial logistic regression analysis for CMBs risk and ROC curve of the image recognition analysis were set up. The area under the curve (AUC) was calculated to reflect the model performance. The results of machine learning were visualized by dimension reduction.

Results: Anti-cardiolipin antibody (aCL) IgG, lupus anticoagulant (LA), and apL-positive number showed a significant difference in the univariate analysis. In prediction model 1 (AUC=0.86), LA played an important role ($p< 0.05$, OR(95%CI): 1.31–13.24). The results of machine learning illustrated that SLE patients with positive aPLs had more CMBs numbers, more CMBs sites, and the possibility of infratentorial region hemorrhage. In addition, prediction model 2 (AUC=0.81) possessed good accuracy to predict the disease subtypes.

Conclusion: APLs were closely related to CMBs, of which LA played the most important role. It could be considered to screen CMBs by SWI in aPLs-positive patients.

Workflow and analytical plans of this study. First, the study subjects were divided into CMBs group and no-CMBs group. A univariate analysis was conducted to identify the different variables between the two groups. Further binomial logistic regression analysis was performed to explore the risk factors correlated with CMBs, and prediction model 1 was built to predict the probability of CMBs occurrence based on the risk factors. Second, we investigated the correlation between aPLs and CMBs in SLE patients using machine learning. Finally, image recognition analysis was conducted to build prediction model 2 to predict the disease type by algorithm-based integration of the location and number of CMBs.

ROC curve and nomogram representation of the binomial logistic regression analysis for CMBs risk. In the ROC curve, the X-axis presents the specificity, and the Y-axis presents the sensitivity. The area under the curve (AUC) was 0.86. In the nomogram figure, for each predictor, points are scored and then added up to a total point score, which indicated to CMBs



risk. Abbreviations: CMBs: Cerebral microbleeds; ROC: Receiver operating characteristic curve; AUC: Area under the curve; LA: Lupus anticoagulant.

Results of KNN (K-Nearest Neighbor) classification analysis in all the SLE patients. (A) showed that SLE patients were divided into SLE group 1 (including SAPS and SLE patients with positive aPLs) and SLE group 2 (SLE patients without aPLs). Orange dots represented SLE group 1, orange area represents the positive aPLs area, blue dots represented SLE group 2, blue area represents the negative aPLs area. (B) showed the corresponding loci classified according to total CMBs (CMBs total level count from three locations) label. Red dots represented CMBs total number>=2; green dots represented CMBs total number<2. Orange area represents the positive aPLs area, blue area represents the negative aPLs area. Next, the corresponding loci was classified according to the bleeding site of the CMBs. Next, the corresponding loci was classified according to the bleeding site of the CMBs (C). Classification labels: 1=deep area, 2=brain lobes, 3=infratentorial region, 4=both deep area and brain lobes, 5=both deep area and infratentorial region, 6=both brain lobes and infratentorial region, 7=triple places, 8=none of these places. Orange area represented the positive aPLs area; blue area represented the negative aPLs area. (D) demonstrated a separate assessment of the infratentorial region. Orange area represented the positive apLs area; blue area represented the negative apLs area; pink dots represented the patient with CMBs appearing in the infratentorial region; grey dots represented the patient without CMBs appearing in the infratentorial region. Abbreviations: KNN: K-Nearest Neighbor; SLE: Systemic lupus erythematosus; aPLs: Antiphospholipid antibodies: SAPS: Secondary antiphospholipid syndrome; CMBs: Cerebral microbleeds.

Abstract Number: 0107

Impact of Antiphospholipid Syndrome on Mortality of Hospitalized Ischemic Stroke Patients: A Retrospective Analysis of the National Inpatient Sample Database 2020

Sami Rabah, Lincoln Medical Center, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is recognized for its association with an elevated risk of ischemic strokes and other thromboembolic events. This study aims to compare the epidemiology and hospitalization outcomes of ischemic stroke patients with and without a secondary diagnosis of APS using a nationwide inpatient database.

Methods: Patients who were 18 or older, and were hospitalized between January 1, 2020, and

December 31, 2020, with a primary diagnosis of ischemic stroke with and without a secondary diagnosis of antiphospholipid syndrome (APS), were identified from the National Inpatient Sample (NIS) database using the International Classification of Diseases, Tenth Revision (ICD-10) codes. The NIS is the largest publicly available all-payer inpatient care database in the United States. The primary outcome was inpatient mortality, and the secondary outcomes were the length of stay (LOS) and the total hospital charge. The odds ratio was calculated using logistic multivariate regression analysis to adjust for age, race, gender, Charlson comorbidity index, and several high-risk comorbidities.

Results: Out of 503,344 patients admitted with a primary diagnosis of ischemic stroke, 1090 (0.21%) had APS. Ischemic stroke patients with APS were younger (54.3 vs 69.7; p=0.000), had more females (67.8% vs 49%; p=0.000), and had a higher prevalence of prior history of pulmonary embolism (14.22% vs 1.8%; p=0.000), and venous thrombosis (24.31% vs 3%; p=0.000) compared to stroke patients without APS. The APS group had a lower prevalence of diabetes (22.4% vs 39.8%; p=0.000), hypertension (45.8% vs 55.5%; p=0.004), and hyperlipidemia (43.58% vs 54.16 %; p=0.002) compared to Ischemic stroke patients without APS. Other differences in demographic and comorbidity trends were insignificant between both groups.

Table 1: Demographics And Comorbidities Of Ischemic Stroke Patients With And Without Antiphospholipid Syndrome (APS)

	Ischemic Stroke (n=503,344)		
	Without APS (n= 502,254)	With APS (n=1090)	P-value

Congestive Heart Failure	17.60%	16.50%	0.658
Obesity	15.60%	17.43%	0.459
Atrial Fibrillation/Flutter	11.10%	4.60%	0.358
Smoking	23%	22.40%	0.844

Table 2: Primary and Secondary Hospitalization Outcomes of Ischemic Stroke Patients With and Without Antiphospholipid Syndrome (APS)

	Ischemic Stroke (n=503,344)			
	Without APS (n= 502,254)	With APS (n=1090)	Adjusted odds ratio	P-value
	%	%	(95% Confidence Interval)	
Primary Outcomes				
Inpatient Mortality	3.9%	8.7%	3.19 (1.91- 5.34)	0.000
Secondary outcomes				
			Adjusted mean difference	
Mean Length of Stay, Days	5.13	7.9	2.59 (1.07-4.12)	0.001
Total charge, Mean $	77,192	121,662	40,271 (14,284-66,258)	0.002

Demographics and prevalence of comorbidities are summarized in Table 1.

Ischemic stroke hospitalizations with APS were significantly associated with higher inpatient mortality (adjusted odds ratio [AOR] 3.19; 95% Confidence Interval [CI] 1.91- 5.34; p=0.000),

longer mean length of stay (2.59 more days; CI 1.05-4.12; p=0.001), and higher total hospital charges ($121,662 vs $77,192; CI $14,284-$66,258; p=0.002) compared to ischemic stroke patients without APS.

Primary and secondary hospitalization outcomes are summarized in Table 2.

Conclusion: Patients hospitalized with ischemic stroke and APS had higher inpatient mortality rates, longer hospital stays, and incurred greater hospital charges compared to ischemic stroke patients without APS.

Decoding Antiphospholipid Syndrome Laboratory Test Outcomes in a Large Multicenter Electronic Health Record Database

Emily Balczewski, Wenying Liang, Amala Ambati, Yu Zuo, Karandeep Singh and Jason Knight, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Electronic health record (EHR) data provide an inexpensive, information-rich tool to study rare diseases like antiphospholipid syndrome (APS). Many such studies rely on structured EHR data, e.g., diagnostic codes, laboratory testing, medication information. As a first step toward assessing the feasibility of using structured EHR data to study APS, we evaluated the presence and positivity of APS antibody testing in a diverse, US-based cohort using the All of Us Research Network Database (AOU).

Methods: Possible APS patients were identified by the presence of SNOMED-CT codes: 26843008 (Antiphospholipid syndrome) and 19267009 (Lupus anticoagulant disorder). Among possible APS patients, APS laboratory tests – anticardiolipin (aCL), anti-beta-2 glycoprotein I (aβ2GPI), and lupus anticoagulant (LA; confirmatory tests only) – were identified with a hand-curated list of LOINC and SNOMED-CT codes. Tests were identified as positive if they had a) a text result indicating positivity (e.g. positive, high, abnormal), b) a numeric result exceeding the normal reported range for that test, or c) a numeric result exceeding 40 if the test lacked a range, but included units of GPL, MPL, SGU, or SMU; negative tests were identified analogously. Tests without text or numeric results, ranges, or units, or tests with units other than those referenced above were classified as indeterminate. T-tests were two-sided with Bonferroni correction.

Results: Out of 372,082 total AOU patients, 883 (2.4 in 1,000) were identified as possible APS patients with demographic characteristics of 74% female, 55% White, and 17% Black, and a mean age of 55. Despite having testing information on 613 (70%) patients, only 434 (49%) had enough data to classify a test as positive or negative. Of these, 245 (28%) had

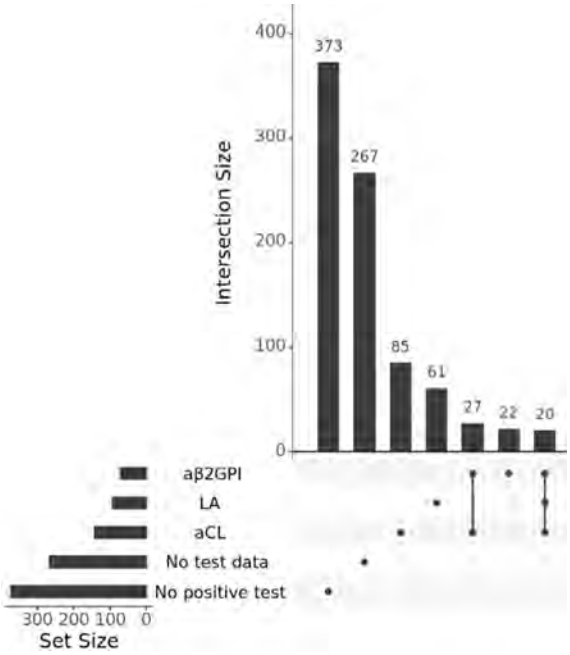

Figure 1. Upset plot of APS antibody testing outcomes by patient. Possible APS patients are sorted into one of the following test outcome categories: no test data, no positive test (i.e., only negative or indeterminate results), or positive test for one or more different APS antibodies. A single patient may have multiple tests within a single category. Categories with fewer than 20 participants are excluded for patient privacy.

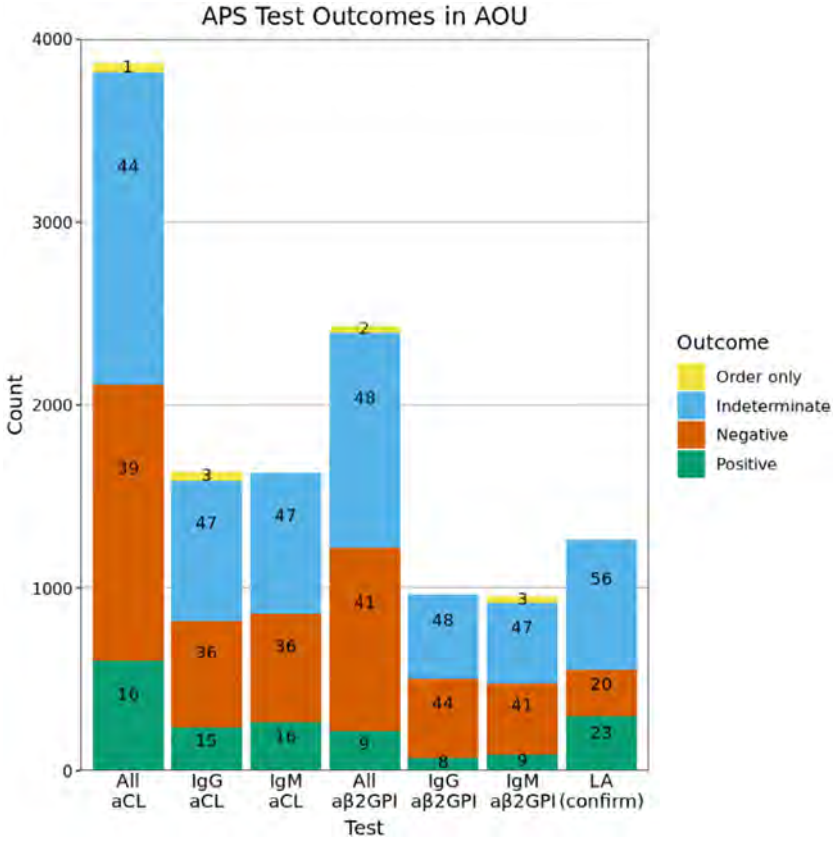

Figure 2. Per-test outcomes of antiphospholipid antibody testing. Outcomes of possible APS patient lab results in the All of Us Research Network Database (AOU). Indeterminate: insufficient data to assess positivity or negativity of test; order only, EHR order without reported results. Labels on bars correspond to a per-bar percentage.

any positive antiphospholipid test (**Figure 1**). Additionally, only 119 (13%) had two positive tests greater than 12 weeks apart, in accordance with APS classification criteria. Despite these low rates of positive tests, possible APS patients had on average 40 rows (i.e., orders and results) of APS test data compared to 1.7 rows among the non-APS patients. Percentages of positive tests were higher for LA (possibly because of its confirmatory nature) than aCL or aβ2GPI; percentages of indeterminate test results were high (44-56%) across all tests (**Figure 2**).

Conclusion: AOU offers one of the largest and most diverse datasets for studying the epidemiology and effects of APS. However, poor data quality can complicate the identification of a robust cohort of APS patients; only 1 in 8 patients with an APS diagnostic code in AOU met the laboratory criteria for APS, despite having an over-enrichment of APS test data compared to the whole database. This result is partially driven by half of all tests having an indeterminate result due to missing data. While improved standardization for testing and documentation could ameliorate data quality issues, creating a "digital phenotype" which combines many and different data types from the EHR will be needed to confidently identify likely APS patients for further study.

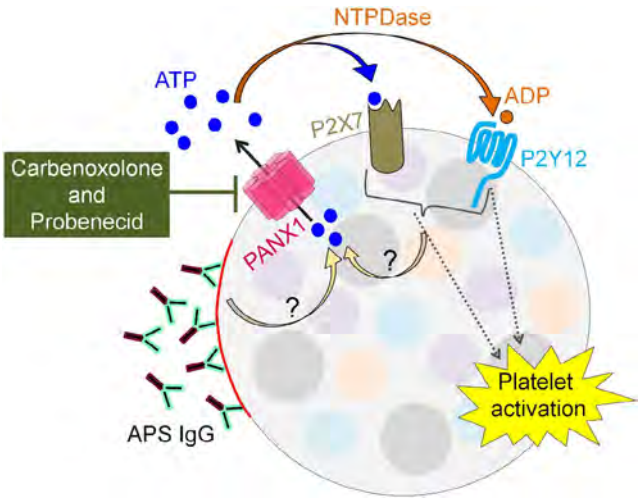
Persistent Prothrombotic Activation of Platelet Pannexin 1 Channels in Antiphospholipid Syndrome

Bruna Mazetto, NaveenKumar Somanathapura, Claire Hoy, Christine Rysenga, Srilakshmi Yalavarthi, Cyrus Sarosh, Caroline Ranger, Katarina Kmetova, Jacqueline Madison, Yu Zuo and Jason Knight, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Inappropriately amplified inflammatory responses are hallmarks of many diseases, with extracellular ATP often playing a central role in the orchestration of inflammation. Regulated cellular ATP release is mainly through selective anion channels such as pannexin-1 (**PANX1**) channels. When cells are under stress, PANX1 channels may become constitutively opened after the cleavage of the C-terminal regions of channel subunits. While hyperactivated platelets contribute to at least a subset of antiphospholipid syndrome (**APS**)-associated thrombotic events, the most effective way to restrain their activation has remained elusive. Here, we aimed to evaluate the potential role of platelet PANX1 channels in the pathophysiology of APS.

Methods: Extracellular ATP release was evaluated in platelets freshly isolated from patients with positive antiphospholipid antibodies and features of APS (n=51) or from healthy controls (n=16) by standard assay kits and flow cytometry. No patients in this study had concomitant lupus. PANX1 inhibitors included carbenoxolone (**CBX**) and probenecid (**PRB**). In some experiments, platelets were stimulated with standard platelet agonists (thrombin, convulxin, and U46619) or with IgG purified from triple-positive APS patients or healthy controls. The participation of purinergic receptors in ATP-mediated platelet activation was assessed with specific inhibitors of various relevant P2X and P2Y purinergic receptors.



Results: The basal release of ATP from APS platelets was significantly higher than from healthy platelets (median 4-fold, $p< 0.0001$). This ATP release was strongly reduced in the presence of CBX (2-fold reduction, $p< 0.05$). Although the difference between APS and healthy platelets was obscured upon activation with thrombin, ATP release in this context was still prevented by either CBX (3-fold reduction, $p< 0.0001$) or PRB (3-fold reduction, $p< 0.0001$). Beyond thrombin, the PANX1 inhibitors also significantly reduced platelet ATP release in response to the thromboxane mimetic U46619 (2-fold reduction, $p< 0.05$). Interestingly, treatment with APS IgG was even more effective than the standard platelet agonists in opening PANX1 channels (4-fold, $p< 0.0001$) in just 30 minutes. This effect was completely neutralized by CBX treatment (4-fold decrease, $p< 0.01$). Notably, PANX1 channel-dependent ATP release was blunted by blocking either P2Y12 ($p< 0.0001$) or P2X7 ($p< 0.0001$) receptors, suggesting self-perpetuating purinergic pathways for PANX1 activation.

Conclusion: These data highlight the potential role of platelet PANX1 channels in contributing to vascular inflammation in APS by excessive extracellular ATP release. The accumulation of extracellular ATP promotes even further ATP release (and likely platelet activation) via P2Y12 and P2X7 receptors. PANX1 channel blockers such as CBX and PRB could be novel ways to restore platelet homeostasis in APS, potentially restraining thrombosis without a major impact on hemostasis (**-Figure 1**). Experiments are now underway to further evaluate the upstream and downstream signaling partners of activated PANX1 channels in APS platelets.

Illustration of platelet PANX1 channel and downstream purinergic receptors in APS.

Abstract Number: 0110

Neutrophil Extracellular Traps as Mediators of Antiphospholipid Antibody-Induced Trophoblast Dysfunction and Fetal Loss

Christine Rysenga, Srilakshmi Yalavarthi, Wenying Liang, Claire Hoy, Cyrus Sarosh, Richard Lieberman, Yu Zuo and Jason Knight, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid antibodies (**aPL**) induce obstetric complications associated with placental insufficiency by promoting trophoblast dysfunction and inflammation at the maternal-fetal interface. Neutrophils have been found to play a critical role in aPL-mediated pregnancy loss in mice; however, the role of neutrophil extracellular traps (**NET**s) in obstetric APS has not been well studied. Here, we aimed to characterize the role of NETs in aPL-mediated trophoblast dysfunction and fetal loss, as well as the ability of NET inhibition to prevent these effects.

Methods: IgG was purified from patients with triple-positive APS (referred to as aPL going forward) or healthy controls. To evaluate trophoblast dysfunction, the supernatants of human neutrophils cultured with either aPL or control IgG were transferred onto human first-trimester extravillous trophoblasts (HTR-8/SVneo), and proliferation was quantified after 24 hours by BrdU. In mice (n=10-15/group), obstetric APS was modeled via intraperitoneal injection of aPL (2mg) to WT (C57BL/6) mice on days 0, 3, 6, 9, and 12 of pregnancy. On day 15, plasma was collected, and uteri were dissected to assess fetal resorption frequency. NET inhibition was modeled via knockout of the genes for neutrophil elastase (*Elane-/-*) or peptidylarginine deiminase 4 (*Pad4-/-*). An additional group of WT mice was treated with the irreversible neutrophil elastase inhibitor GW311616A. Circulating NET remnants were quantified as plasma myeloperoxidase-DNA complexes.

Results: In culture, supernatants from aPL-stimulated neutrophils significantly diminished trophoblast proliferation, compared to supernatants from control IgG-stimulated neutrophils (p=0.033) or to aPL alone (p=0.018). In the mouse model, aPL-treated mice experienced higher fetal resorption rates versus mice treated with control IgG (mean 30.1% vs. 13.1%, p=0.006). Plasma NET remnants were also higher in the aPL-treated mice (p=0.003). Compared to the 30% resorption of WT mice, *Elane-/-* mice (8.2% resorption, p=0.006) and *Pad4-/-* mice (9.6% resorption, p=0.04) were protected from aPL-mediated fetal loss. Oral treatment with the neutrophil elastase inhibitor GW311616A also prevented aPL-mediated fetal loss in WT mice (16.4% resorption; p=0.04). Importantly, there was no difference in resorption rates among these groups when treated with control IgG, suggesting a protective effect specific to aPL-mediated loss. Compared to aPL-treated WT mice, plasma myeloperoxidase-DNA complexes levels were 46% lower in aPL-treated *Elane-/-* mice (p=0.012) and 41.5% lower in aPL-treated *Pad4-/-* mice (p=0.006).

Conclusion: In addition to the direct anti-proliferative effect of aPL that has been documented by others, we found that aPL-triggered NETs further reduced normal trophoblast proliferation. In mice, we demonstrated that NET inhibition (by targeting either neutrophil elastase or PAD4) was remarkably effective in preventing aPL-mediated fetal loss and lowering circulating NET levels. Cumulatively, these data suggest that therapies targeting NETs could be effective in preventing APS obstetric morbidities and warrant further study.

Hippo-YAP1-CCN2 Signaling by Microvascular Endothelial Cells Licenses Vascular Smooth Muscle Cell Proliferation in Antiphospholipid Syndrome

Wenying Liang[1], Allison Billi[1], Srilakshmi Yalavarthi[1], Christine Rysenga[1], Claire Hoy[1], Cyrus Sarosh[1], Yu Zuo[1], Eliza Pei-Suen Tsou[1], Jason Knight[1] and Hui Shi[2], [1]University of Michigan, Ann Arbor, MI, [2]Department of Rheumatology and Immunology, Ruijin Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Some patients with antiphospholipid syndrome (**APS**) are afflicted by an insidious small-vessel vasculopathy that results in the accrual of organ damage over time. While the neotima formation that heralds this vasculopathy is most commonly visualized upon kidney biopsy, other organs such as the brain, heart, and skin may also be at risk. We previously used single-cell RNA sequencing of APS skin biopsies to identify the upregulation of various proliferation-supporting genes in microvascular endothelial cells (**MVECs**). The most notable example was CCN2 (also known as CTGF),

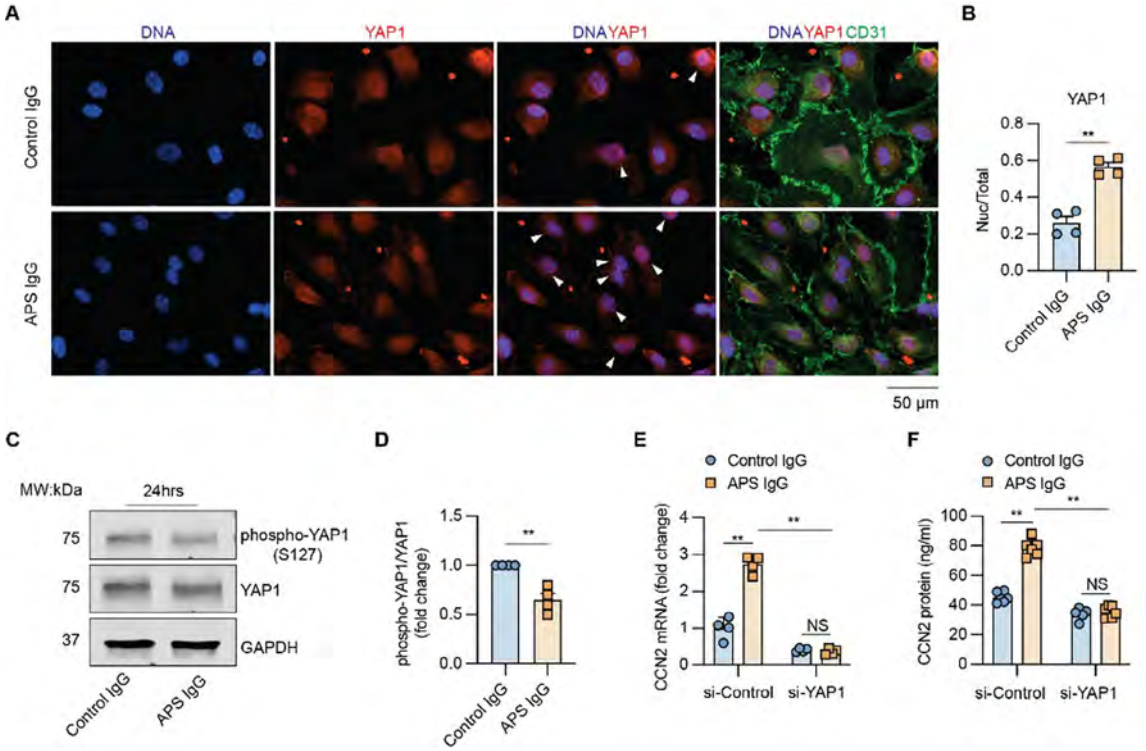

Figure 1. YAP1 mediates APS antibody-induced endothelial cell CCN2 expression. A, Representative images of YAP1 expression (red) in control IgG- or APS IgG-stimulated MVECs (both 100 μg/ml), accompanied by markers of endothelial cells (CD31, green) and nuclear DNA (Hoechst, blue). Arrowheads indicate cells with YAP1 nuclear translocation. Scale bar=50 μm. B, The ratio of cells with YAP1 nuclear translocation in the indicated groups. C, Representative Western blot of phospho-YAP1 (S127) and total YAP1 in control IgG- or APS IgG-stimulated MVECs. D, The band intensity of phospho-YAP1/total YAP1 from four independent western blots was quantified and normalized with GAPDH. MVECs stimulated with control IgG were set as 1. E-F, The relative mRNA and secreted protein levels of CCN2 in control or YAP1-knockdown MVECs stimulated with control or APS IgG. Data are presented as mean ± SEM. Unpaired t-test for B and D. Two-way ANOVA followed by Sidak post hoc analysis for E and F. n=4/group. si-Control, nontargeting small interfering RNA control. si-YAP1, small interfering RNA targeting YAP1. **p < 0.01, NS: not significant.

a classic downstream target of Hippo-YAP1 signaling. Furthermore, the previous bioinformatic analysis demonstrated the potential for strong communication between secreted MVEC ligands such as CCN2 and vascular smooth muscle cells (**VSMC**) receptors—a potentially critical interaction given the important role of VSMC proliferation and migration in neointima formation. Here, we aimed to determine the potential role of the Hippo-YAP1-CCN2 axis in APS micro-vasculopathy.

Methods: Isolated healthy MVECs were cultured with APS patient serum or patient-derived IgG. CCN2 expression was measured by quantitative PCR and ELISA. Immunofluorescence (IF) microscopy and western blotting were used to assess YAP1 signaling. To study cellular communication, human VSMCs were cultured with conditioned media from APS-stimulated MVECs. The proliferation and migration of VSMCs were determined by BrdU-staining and wound-scratch assays, respectively. Finally, CCN2 expression was assessed in kidney biopsies from patients with APS nephropathy by IF microscopy.

Results: Culture of MVECs with APS patient serum or patient-derived IgG led to upregulation of CCN2 mRNA (fold change 2.3 ± 0.3 and 2.8 ± 0.1, respectively, both $p < 0.01$). Concomitantly, secreted CCN2 protein in the supernatant was increased as assessed by ELISA (data not shown). In parallel studies, the activation of the Hippo-YAP1 pathway was confirmed by increased YAP1 nuclear translocation and reduced YAP1 phosphorylation (**Figure 1A-D**). Notably, the knockdown of YAP1 in MVECs abolished APS IgG-induced CCN2 expression and secretion (**Figure 1E-F**). Regarding MVEC-VSMC communication, conditioned media from APS IgG-stimulated MVECs triggered a noncontractile phenotype in VSMCs, accompanied by increased proliferation and migration. These phenotypes were mitigated by the humanized CCN2-blocking antibody, pamrevlumab (**Figure 2**). Finally, kidney biopsies from patients with APS nephropathy showed markedly enhanced CCN2 expression in the thickened intima and media of microvessels, indicating the in vivo relevance of this pathway (**Figure 3**).

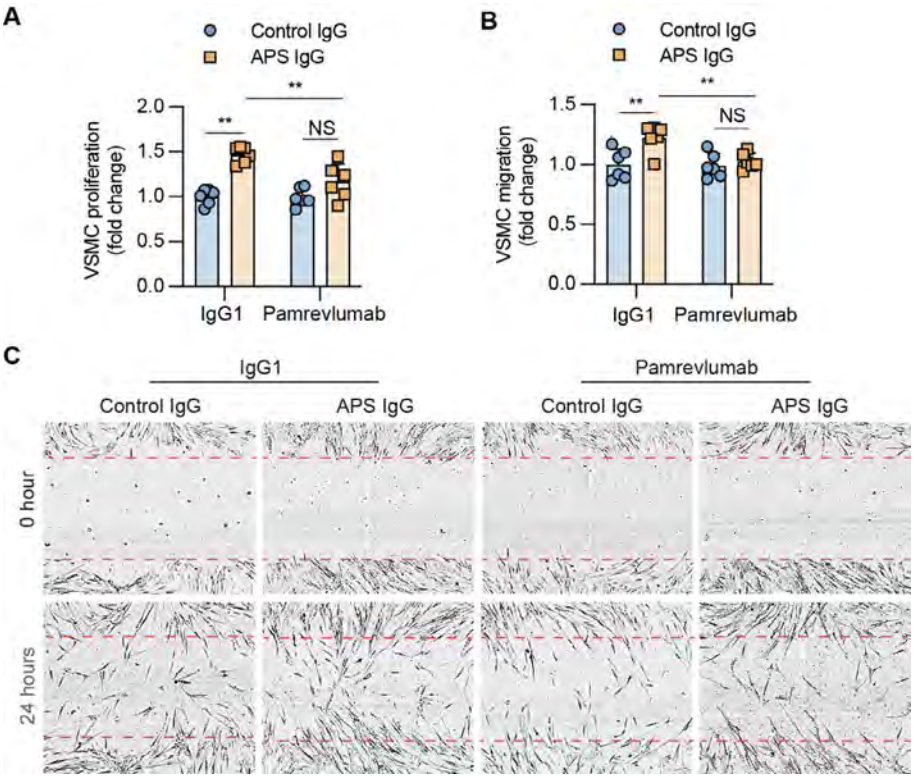

Figure 2. Communication between microvascular endothelial cells (MVECs) and vascular smooth muscle cells (VSMCs) in APS. A-B, Proliferation (A) and migration (B) of VSMCs were quantified and presented as the relative fold change compared to the group stimulated by control IgG1 and conditioned media from control IgG-stimulated MVECs. Migration was quantified by wound confluence (%). C, Representative images of each group at 0 or 24 hours after scratch. Data are represented as mean ± SEM and p values were calculated by two-way ANOVA followed by Sidak post hoc analysis. n=6/group. **$p < 0.01$, NS: not significant.

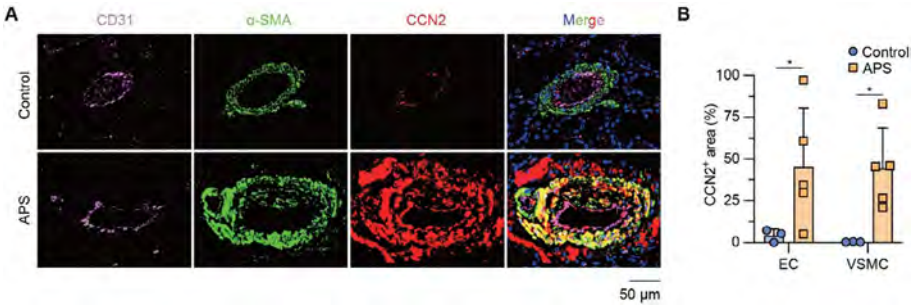

Figure 3. High expression of vascular CCN2 in patients with APS nephropathy. A, Representative images of CCN2 expression (red) in the kidney vessels from healthy controls or APS nephropathy patients. Endothelial cells (CD31+ area) and vascular smooth muscle cells (α-SMA+ area) were labeled in purple and green, respectively. Nuclear DNA was labeled by Hoechst (blue). Scale bar=50 μm. B, The percentage of CCN2+ area in kidney endothelium of indicated groups was calculated as CCN2+CD31+ area/CD31+ area. The percentage of CCN2+ area in kidney vascular smooth muscle cells of indicated groups was calculated as CCN2+α-SMA+ area/α-SMA+ area. Data are presented as mean ± SEM and p values were calculated by two-way ANOVA followed by Sidak post hoc analysis. n=3 for control, n=5 for APS nephropathy patients. *p<0.05. EC, endothelial cell. VSMC, vascular smooth muscle cell.

Conclusion: We found that APS serum and patient-derived IgG triggered YAP1 nuclear translocation in MVECs, which was accompanied by increased CCN2 expression and secretion. The secreted CCN2 was then able to trigger a phenotypic switch in VSMCs toward the migratory and proliferative characteristics that are necessary for neointima formation. Blocking either YAP1 or CCN2 might be a novel approach for the treatment of APS-associated microvasculopathies.

Abstract Number: 0112

Molecular Stratification of Antiphospholipid Syndrome Patients Through Integrative Analysis of the Whole-blood RNA Transcriptome

Amala Ambati[1], Feiyang Ma[1], Katarina Kmetova[1], Sherwin Navaz[1], Claire Hoy[1], Cyrus Sarosh[1], Ajay Tambralli[1], Johann E. Gudjonsson[1], J. Michelle Kahlenberg[1], Jacqueline Madison[1], Ali Duarte-Garcia[2], Jason Knight[1] and Yu Zuo[1], [1]University of Michigan, Ann Arbor, MI, [2]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (**APS**) is an acquired thrombo-inflammatory disease associated with diverse clinical manifestations in the setting of persistent antiphospholipid antibodies (**aPL**). Early diagnosis and more targeted therapies would likely improve outcomes, but both are hindered by clinical and pathogenic heterogeneity. There is an urgent need for modern approaches to the diagnosis and endotypic stratification of aPL-positive patients. We aimed to utilize integrative analyses of data derived from the whole-blood RNA transcriptome to cluster aPL-positive patients by gene expression to identify pathogenic pathways that might be therapeutic targets.

Methods: Whole-blood RNA sequencing was performed on 102 patients with primary APS, 29 with secondary APS, and 43 with persistently positive aPL but without "criteria" APS manifestations. Unsupervised machine learning of the whole-blood transcriptome was undertaken. Deconvolution analysis was further used to estimate the different cell types and their abundance in each sample.

Results: We found that aPL-positive patients could be stratified into four major clusters defined by unique gene expression modules (**Fig 1A-B**). Pathway analysis revealed that neutrophil extracellular trap (**NET**) formation, mammalian target of rapamycin (**mTOR**) signaling, and Hippo pathway signaling were top-upregulated pathways among patients in cluster 4. In contrast, patients in cluster 1 tended to have upregulated genes related to cytoplasmic ribosomal proteins, tyrosine metabolism, and fatty acid biosynthesis, amongst other pathways (**Fig 1C**). When looking at the associations between pathway-focused gene expression modules and various extra-criteria clinical manifestations of APS, white matter lesions were associated with

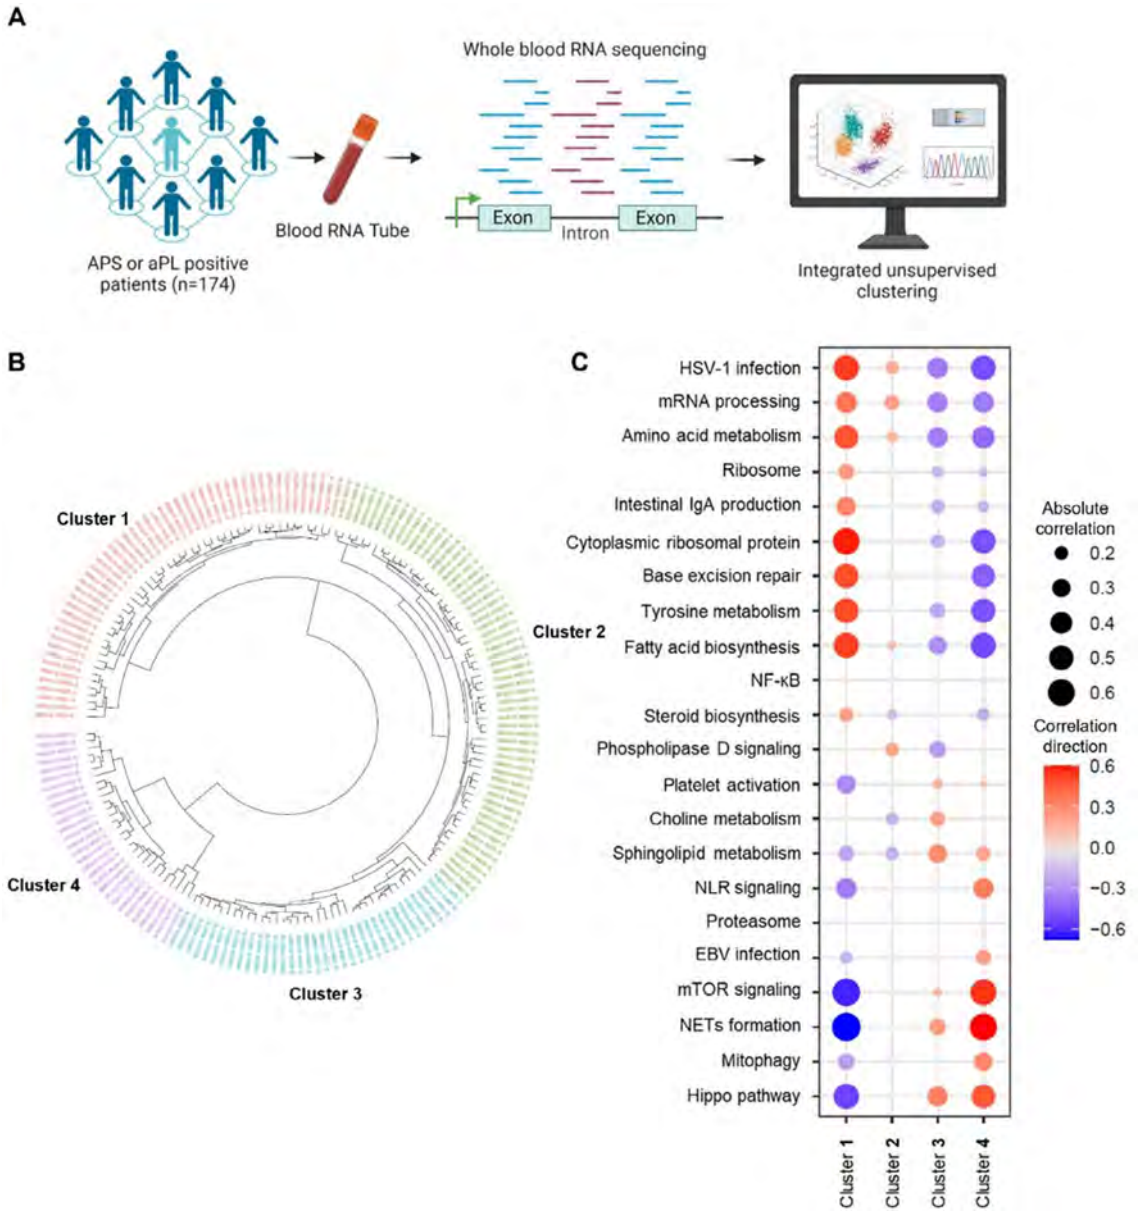

Figure 1. A, Schematic illustration of study design and whole-blood RNA sequencing. The figure was created at www.biorender.com. B, Unsupervised hierarchical clustering was used to stratify aPL-positive patients into four clusters. C, Dot plots demonstrating associations between pathway-specific gene modules and each cluster of aPL-positive patients. Only statistically significant associations are shown.

upregulated NF-κB-related genes (r=0.33, p< 0.0001), and seizures were associated with upregulated choline metabolism-related genes (r=0.2, p=0.009). Meanwhile, cardiac valve disease was associated with NET formation (r=0.18, p=0.02) and the Hippo pathway (r=0.18, p=0.02). Deconvolution analysis demonstrated distinct immune cell type distributions among different clusters of patients (**Fig 2A**). For example, patients in cluster 4 were predicted to have more myeloid cells, such as neutrophils, eosinophils, and dendritic cells. In contrast, patients in cluster 1 had high proportions of lymphoid cells, such as B cells, plasma cells, and CD8 T cells (**Fig 2B**). Our analysis also revealed several significant associations between immune cell types and pathway-focused gene modules, including an association between neutrophils and the Hippo pathway, the mTOR pathway, and NET formation (**Fig 2C**). Clinically, patients in cluster 4 were more likely to have positive testing for anti-beta-2 glycoprotein I IgG, higher absolute neutrophil counts, and increased urine protein-to-creatinine ratio (**Table 1**).

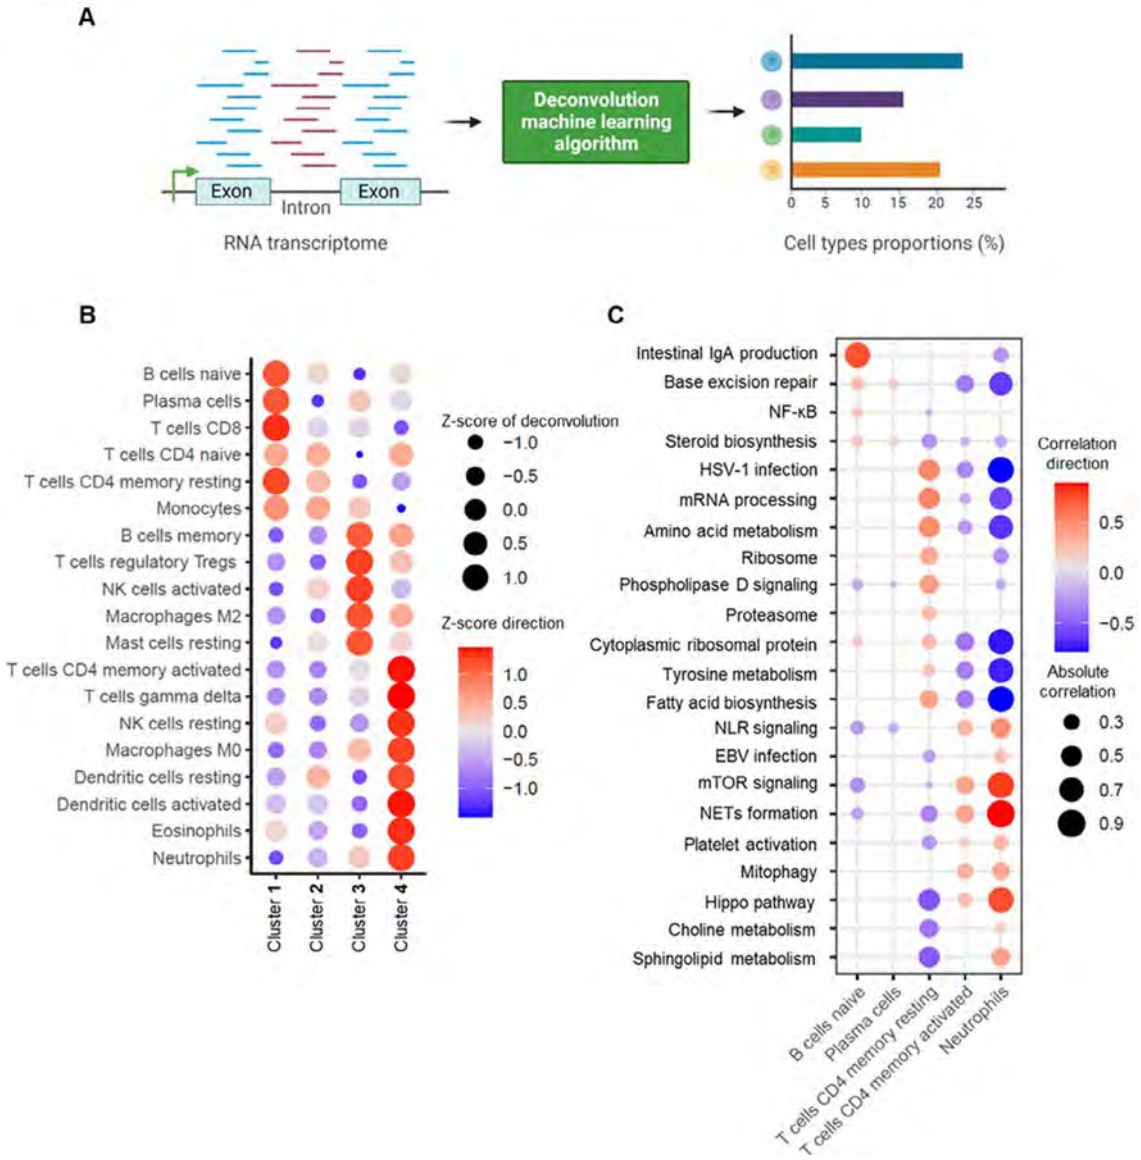

Figure 2. A, Schematic illustration of deconvolution analysis of whole-blood transcriptomic data. Cell type deconvolution was performed using CybersortX with the LM22 (22 immune cell types) as the signature matrix. The figure was created at www.biorender.com. B, Dot plot demonstrating associations between immune-cell types and each cluster of aPL-positive patients. C, Dot plot demonstrating associations between pathway-specific gene modules and immune-cell types. Only statistically significant associations are shown.

Conclusion: Our study shows, for the first time, that aPL-positive patients can be stratified into four major clusters defined by pathway-focused gene expression modules and predicted immune cell-type compositions. The results obtained in this study are a first step toward the goal of personalized medicine for patients living with APS.

Serum Myeloperoxidase (MPO)-DNA Complexes and Serum Calprotectin Differentiate Isolated Thrombotic Antiphospholipid Syndrome from Isolated Obstetric Antiphospholipid Syndrome

Ruyu Liang[1], Ranran Yao[2], Ziye Wang[3], Wenwen Pei[2], Renge Liang[3] and Chun Li[4], [1]Peking University, XiCheng, China, [2]Peking University, Beijing, China, [3]Peking University People's Hospital, Beijing, China, [4]Peking University People's Hospital, Beijing, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a lack of serum markers to differentiate thrombotic APS (tAPS) and obstetric APS (oAPS). Neutrophil extracellular traps (NETs) are involved in the pathogenesis of antiphospholipid syndrome (APS). This study aims to evaluate the difference of NETs markers between tAPS and oAPS.

Methods: A total of 253 adult patients diagnosed APS and fulfilled Sydney criteria were recruited from the Department of Rheumatology and Immunology at Peking University People's Hospital. Demographic characteristics and clinical features of patients were recorded. Serum concentrations of aPLs, MPO-DNA complexes, cell-free DNA and calprotectin were measured. Results are shown as mean±SD. The results were analyzed by independent t tests, Mann-Whitney U test, and chi-square tests as appropriate.

Results: In comparison to those with oAPS, patients with tAPS had older age (46.89±17.69 vs. 36.95±8.88 years, P< 0.001), higher rate of cardiovascular risk (at least one positive of smoke, coronary heart disease, hypertension, obesity, diabetes, and hyperlipidemia) (65.63% vs. 36.56%, P < 0.001), and lower lymphocyte count (1.51±0.74 vs. 1.77±0.69 10^9/L, P < 0.05) and neutrophil-to-lymphocyte ratio (4.11±3.89 vs. 3.07±2.17 10^9/L, P < 0.05). Both lupus anticoagulant (61.72% vs. 29.63%, P < 0.001), and anti-cardiolipin (61.90% vs. 30.95%, P < 0.001) positivity were higher in patients with tAPS, and there was no significant difference in anti-β2GPI positivity. Compared with oAPS patients, tAPS patients had higher concentration of MPO-DNA complex [1107.77(689.90, 2107.62) vs. 583.62(313.78, 1498.41), ng/ml, P < 0.01) but lower calprotectin (21.22(20.40, 22.60) vs. 22.85(21.43, 24.19), ng/ml P < 0.05), but there was no significant difference in cell-free DNA level in two groups.

Table 1. Demographic characteristics and clinical features and laboratory assessment of patients with isolated obstetric and thrombotic APS

	tAPS(n=160)	oAPS(n=93)	P-values
Age(years) mean ± SD	46.89±17.69	36.95±8.88	< 0.001*
Cardiovascular risk factors, n (%)	105 (65.6)	34 (36.6)	< 0.001*
Hypertension	32 (20)	27 (45.8)	0.123
Coronary heart disease	7 (4.4)	8 (8.6)	0.179
Smoking history, n (%)	15 (9.4)	11 (11.8)	0.528
Diabetes mellitus	16 (10)	10 (10.8)	0.833
Hyperlipidemia	9 (5.6)	12 (12.9)	0.058

*: P< 0.05

Table 2. Laboratory assessment of patients with isolated obstetric and thrombotic APS

	tAPS(n=160)	oAPS(n=93)	P-values
WBC (10^9/L), mean ± SD	7.21 ± 3.92	7.25 ± 3.26	0.946
Neutrophil Count (10^9/L), mean ± SD	4.96 ± 3.40	4.91 ± 2.89	0.917
Lymphocyte Count (10^9/L), mean ± SD	1.51 ± 0.74	1.77 ±0.69	0.012*
NLR, mean ± SD	4.11 ± 3.89	3.07 ± 2.17	0.012*
Anemia, n (%)	56 (37.6)	15 (21.1)	0.020*
Thrombocytopenia, n (%)	64 (42.1)	21 (29.2)	0.077
LA positivity, n (%)	79 (61.7)	24 (29.6)	< 0.001*
ACL positivity, n (%)	91 (61.9)	26 (31.0)	< 0.001*
anti-β2GPI positivity, n (%)	91 (62.8)	46 (51.7)	0.103

a: NLR, Neutrophil-to-lymphocyte Ratio.

*: P< 0.05

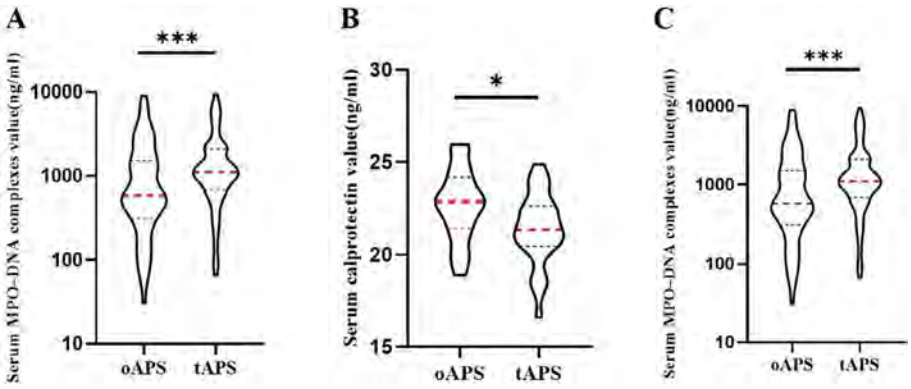

Figure 1. Patients with tAPS had higher level of MPO-DNA complex (A) but lower calprotectin (B). There was no significant difference in cell-free DNA level (C). *P < 0.05, ***P < 0.001 Data are presented as the mean ± SD.

Conclusion: Our data suggest that patients with tAPS had higher level of MPO-DNA complex but lower calprotectin, and higher lupus anticoagulant and anti-cardiolipin. It is worth further research distinct mechanisms of pathogenesis.

Platelets Are Highly Activated and Could Participate in Immune Abnormality of APS

Yu Shi[1], Xiaofan Luo[2], Quan Chen[3], Jiuliang zhao[4], Mengtao Li[4] and xiaofeng Zeng[5], [1]Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [2]Nankai University, Tianjin, China, [3]Nankai University, Beijing, China, [4]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [5]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Platelets play a pivotal role in the process of coagulation and other biological process. Studies have shown multiple evidences that platelets are highly activated in APS, and have the ability to enhance the activity of other cells like endothelial cells, monocytes, and neutrophils. Emerging evidences have indicated that platelets are more than a part of coagulation process.

Methods: We included 35 patients who fulfilled the 2006 Sydney classification criteria of APS and 18 age, sex matched heathy controls (HC). Activation of platelet was measured by flow cytometry. Reactive oxygen species (ROS) production and mitochondrial respiration was measured. RNA-sequencing was performed.

Results: The baseline characteristics of studied patients are shown in Table 1. Platelet activation was detected by the surface expression of CD62p after gating with CD41a. As presented in Figure 1A, the mean fluorescent intensity of CD62p was significantly increased in APS patients compared with HC ($p< 0.05$) . After stimulated with adenosine diphosphate (ADP, 0.1U/ml) and thrombin (2U/ml), the activation was similar between patients and HC. Previous research showed platelets treated with immune thrombocytopenia plasma was induced to shed GPIbα(CD42b), so we examined the surface expression of CD42b and found no statistic difference (Figure 1B). Then we detected the ROS production (Figure 1C-D) and found that platelets of APS patients both in original state and activated with thrombin produced significantly more ROS than the HC. Then we want to explore if platelets from APS patients contain more mitochondria or it is because the metabolism is more activated. Mitotracker was used to label mitochondria in platelets. As shown in Figure1E, the quantity of mitochondria was similar. We used seahorse analysis to examine mitochondrial respiration and found that maximum respiration was evidently higher in platelets from APS patients (Figure 1F).

Table 1. Baseline demographic, clinical, and laboratory characteristics of study patients.

Characteristics	Study patients (n = 35)
Gender, female, n (%)	17 (50)
Age, year, mean (SD)	39.6 (12.4)
Time since diagnosis, months, median (IQR)	36 (32, 46.5)
BMI, kg/m^2, mean (SD)	25.2 (4.2)
Smoking, n(%)	15 (24.9)
Hypertension, n(%)	4 (11.4)
Diabetes mellitus, n(%)	2 (5.7)
Dyslipidemia, n(%)	2 (5.7)
Thrombosis, n(%)	35 (100)
Arterial thrombosis, n(%)	11 (31.4)
Venous thrombosis, n(%)	27 (77.1)
Pregnancy morbidity, n(%) of female	6 (35.3)
Extra-criteria manifestations, n(%)	9 (25.7)
aPL profile	
aCL, n(%)	22 (62.9)
Anti-β 2GPI, n(%)	22 (62.9)
LA, n(%)	28 (80)
Triple positivity, n(%)	14 (40)
PLT count, $\times 10^9$/L, mean (SD)	189 (76.8)

We performed RNA sequencing in 14 APS patients and 6 age, sex matched HC. 748 differently expressed genes with adjusted p-value < 0.01 and $|\log_2 FoldChange| > 1.5$ were screened and tested enrichment in KEGG pathways (Figure 2). It is evident that multiple immune related pathways were enriched including inflammatory signaling pathways (JAK-STAT, IL-17 signaling pathways) and T cell associated pathways (Th1, Th2, and Th17 differentiation).

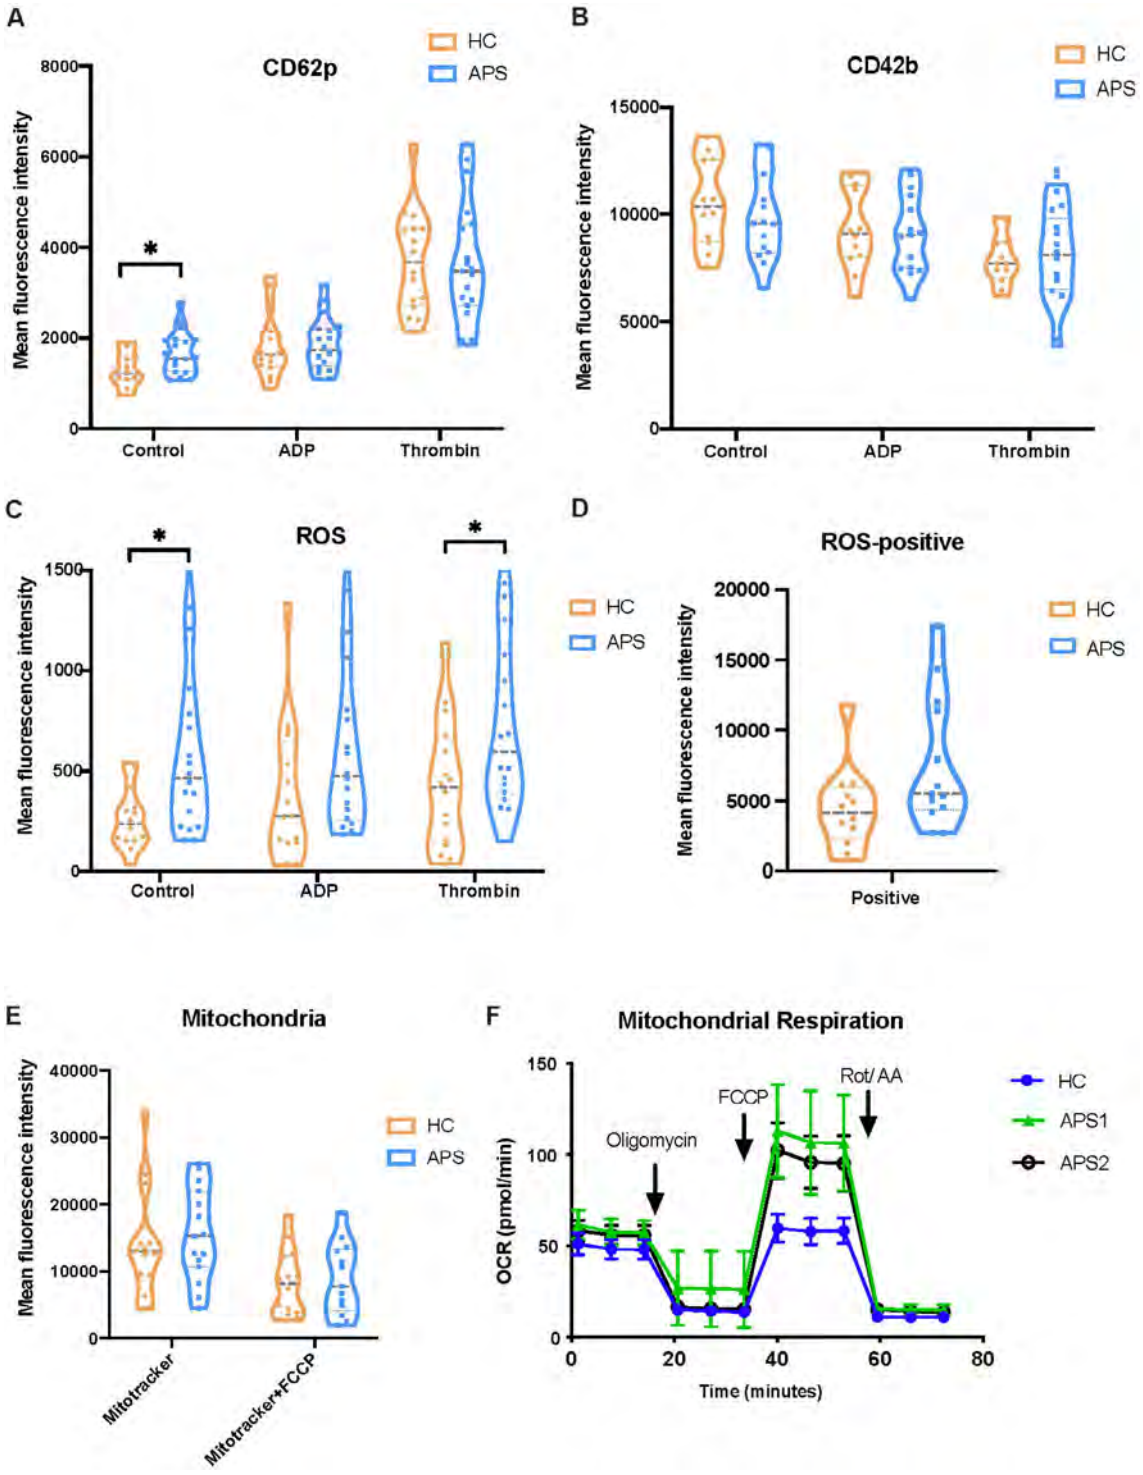

Figure 1. Platelet flow cytometry and mitochondrial respiration of study patients.

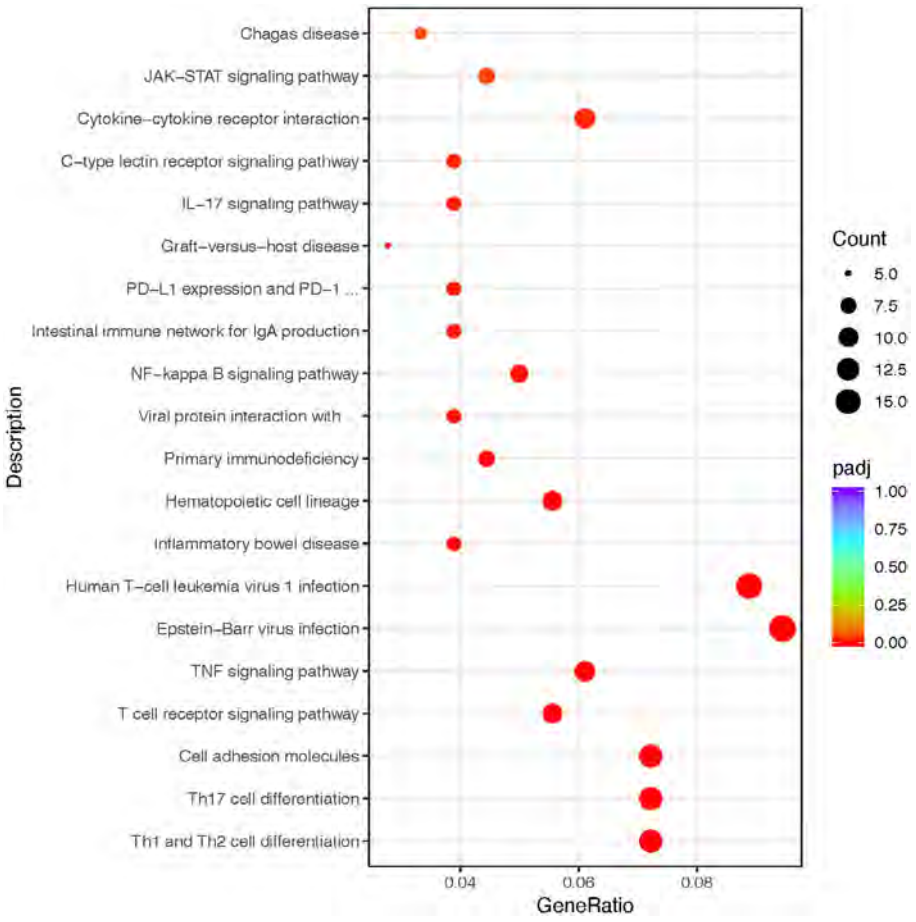

Figure 2. KEGG pathway enrichment of differently expressed genes from platelet RNA sequencing.

Conclusion: Platelet activation and mitochondrial respiration is highly increased in APS. The platelet transcriptome of APS is significantly different from HC. Platelets could interact as immune cells to modulate T cell activity.

Risk Factors of First Thrombosis in Obstetric Antiphospholipid Syndrome

liang luo[1], Qingmeng Cai[2], xiangjun liu[2], Yuke Hou[3] and Chun Li[4], [1]Department of Chinese Medicine, the People's Hospital of Yubei District of Chongqing City, Chongqing, China; Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China, [2]Department of Rheumatology and Immunology, Peking University People's Hospital, Xicheng District, Beijing, China, [3]Peking University People's Hospital, Beijing, China, [4]Peking University People's Hospital, Beijing, China

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Limited evidence exists regarding the long-term risk of thrombosis in patients with obstetric antiphospholipid syndrome (OAPS). This study aimed to investigate the clinical features and risk factors associated with the first thrombosis in isolated OAPS patients.

Table 1 Comparison of baseline characteristics, clinical features and treatment between OAPS patients with or without thrombotic events.

	Thrombosis group (n=11)	Non-thrombosis group (n=175)	*P* value
Age at onset (years), mean ± SD	27.6 ± 4.0	31.3 ± 4.8	**0.013**
Disease duration (years), IQR	5.0 (1.0, 25.0)	1.0 (0.3, 3.0)	**0.049**
BMI (kg/m^2), mean ± SD	24.3 ± 4.8	24.4 ± 3.9	0.924

LDA+LMWH	3 (27.3)	85 (48.6)	0.170
HCQ	5 (45.5)	135 (77.1)	**0.045**

* P <0.05, compared between the two groups. OAPS, obstetric antiphospholipid syndrome; BMI, body mass index; SLE, systemic lupus erythematosus; RA, rheumatoid arthritis; SS, Sjögren syndrome; FGR, fetal growth restriction; LA, lupus anticoagulant; aβ2GPI, anti-β2-glycoprotein I antibodies; aCL, anticardiolipin antibodies; aPLs, antiphospholipid antibodies; LMWH, low-molecular-weight heparin; LDA, low-dose aspirin; HCQ, hydroxychloroquine.

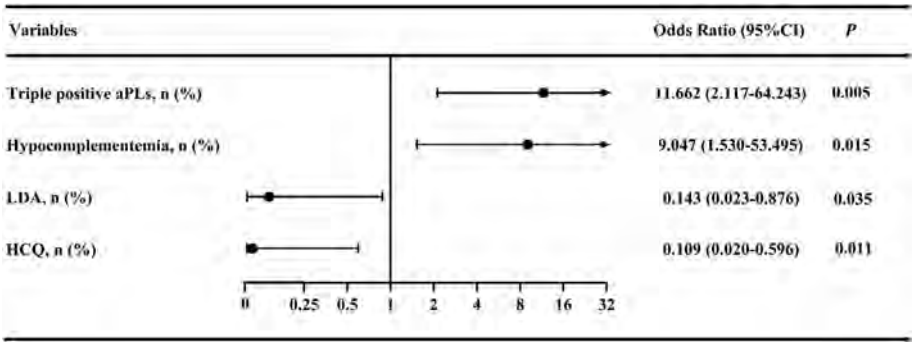

Figure 1 Multivariate logistic regression of first thrombosis in OAPS patients. OAPS, obstetric antiphospholipid syndrome; CI, confidence interval; aPLs, antiphospholipid antibodies; LDA, low-dose aspirin; HCQ, hydroxychloroquine.

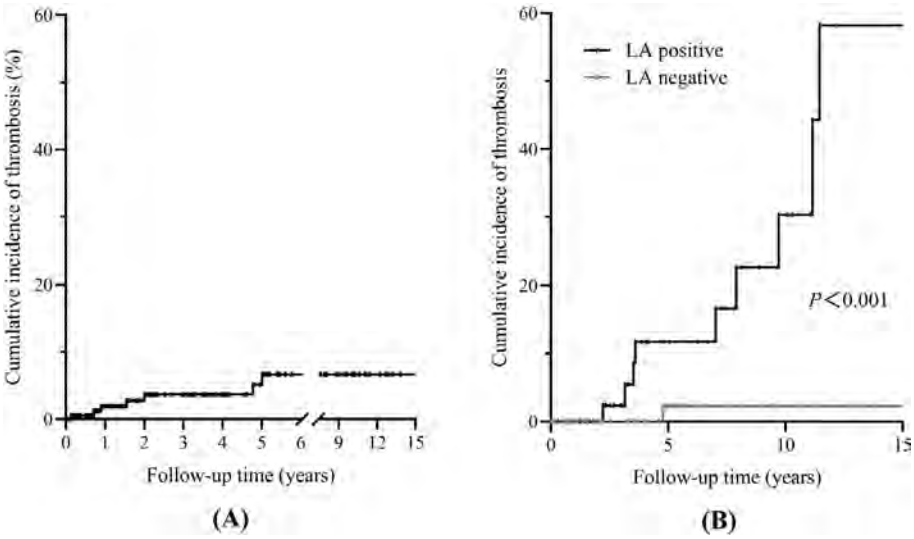

Figure 2 Kaplan-Meier survival analysis. (A) Cumulative incidence of thrombosis in OAPS patients. (B) Cumulative incidence of thrombosis in the LA-negative and LA-positive groups. OAPS, obstetric antiphospholipid syndrome; LA, lupus anticoagulant.

Methods: Clinical and laboratory data from female patients with isolated OAPS were collected. All patients were followed up until the first thrombotic event or until the end of the study. The first thrombotic event during or after delivery was recorded. Logistic regression analysis was used to identify independent risk factors associated with the first thrombosis in isolated OAPS patients.

Results: A total of 186 OAPS patients were included in the study. During a mean follow-up period of 5.4 years, 11 patients experienced thrombotic events, resulting in a 15-year cumulative thrombotic incidence of 6.7%. Triple positive antiphospholipid antibodies [aPLs, odds ratio (OR) = 11.662, 95% confidence interval (CI) = 2.117–64.243, $P = 0.005$] and hypocomplementemia (OR = 9.047, 95% CI = 1.530–53.495, $P = 0.015$) were identified as independent risk factors for the first thrombosis in OAPS patients. Additionally, the use of low-dose aspirin (LDA, OR = 0.143, 95% CI = 0.023–0.876, $P = 0.035$) and hydroxychloroquine (HCQ, OR = 0.109, 95% CI = 0.020–0.596, $P = 0.011$) were associated with a decreased risk of thrombosis.

Conclusion: Triple positive aPLs and hypocomplementemia are risk factors for the first thrombosis in OAPS patients. The use of LDA and HCQ may be associated with a reduced risk of thrombosis.

Integrated Metabolomic and Proteomic Analyses Stratified Patients with Antiphospholipid Syndrome According to Their Atherothrombotic Risk

Chary Lopez-Pedrera[1], Beatriz Vellón[2], Mª Angeles Aguirre[3], Ismael Sanchez-Pareja[2], Laura Muñoz-Barrera[2], Tomás Cerdó[2], Pedro Segui[2], Christian Merlo-Ruiz[2], Desiree Ruiz-Vilchez[2], Maria del Carmen Abalos-Aguilera[4], Nuria Barbarroja[5], Alejandro Escudero Contreras[6], Rafaela Ortega-Castro[2] and Carlos Perez-Sanchez[7], [1]IMIBIC - Reina Sofia Hospital, Córdoba, Spain, [2]IMIBIC/Reina Sofia Hospital/University of Cordoba, Córdoba, Spain, [3]Reina Sofía University Hospital/ Rheumatology Department, Córdoba, Spain, [4]Rheumatology Department, Reina Sofia University Hospital/ Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Córdoba, Spain, [5]University of Cordoba, Córdoba, Spain, [6]Reina Sofia University Hospital, Córdoba, Spain, [7]IMIBIC, Córdoba, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune disorder characterized by a hypercoagulable state, leading to arterial, venous, or microvascular thrombosis and accelerated atherosclerosis. Timely diagnosis and accurate monitoring are crucial for optimizing therapeutic interventions.

Methods: A cohort of primary APS patients (n=150) and 43 healthy donors (HD) underwent serum nuclear magnetic resonance (NMR) metabolomics (>250 metabolites, Nightingale) analysis, covering glycolysis metabolites, amino acids, and 130 lipid measures. Serum levels of 92 cardiovascular-related proteins were evaluated using proximity extension immunoassay (PEA, Olink). Extensive clinical and analytical profiling was conducted. Unsupervised hierarchical clustering analyses explored molecular profile contributions to atherothrombotic risk. Additionally, 33 APS patients receiving adjuvant treatment with Ubiquinol (Qred, reduced CoQ10) at 200 mg/day for one month were studied.

Results: APS patients exhibited significant alterations in 53 metabolites compared to healthy donors. These included decreased levels of atheroprotective HDL subsets, sphingomyelins, and phospholipids, as well as increased levels of proatherogenic VLDL subsets and fatty acids. Unbiased hierarchical clustering analysis identified two patient groups with distinct metabolomic profiles. Cluster 2 (C2) patients had a higher prevalence of arterial thrombosis, elevated thrombotic risk score (aGAPSS over 9), and more CV risk factors such as atheroma plaques, dyslipidemia, and hypertension. Molecular analysis revealed 143 deregulated metabolites between clusters, including decreased HDL and increased VLDL and LDL lipoproteins, triglycerides, fatty acids, apolipoproteins (ApoB), glycolysis-related metabolites, and other lipids involved in immune cell activity. Proteomic analysis identified proteins associated with increased cardiovascular risk in these metabolomic clusters. Remarkably, significant correlations were found between deregulated protein and metabolite levels, suggesting their involvement in underlying disease mechanisms. In the *in vivo* study, Qred supplementation partially reversed the altered serum metabolic and proteomic profiles associated with APS-related thrombosis.

Conclusion:

1. "APS patients exhibit distinct metabolomic and proteomic profiles associated with the disease's pathogenesis, partially modifiable by in vivo Qred supplementation.
2. We have identified for the first time a combined metabolomic/proteomic fingerprint able to stratify APS disease according to their thrombotic risk. Ongoing studies will provide further insights into the underlying mechanisms and physiological implications of these alterations, potentially leading to the discovery of diagnostic biomarkers and therapeutic strategies for APS.

The Patient Journey to a First Diagnosis of Systemic Sclerosis: Temporal Disease Pattern Identification Using Machine Learning and Data Mining Among US and Japanese Patients

Francesco Del Galdo[1], Yahui Tian[2], Stefano Di Donato[1] and Mario Ehlers[2], [1]University of Leeds - Leeds Institute of Rheumatic and Muskuloskeletal Medicine, Leeds, United Kingdom, [2]Boehringer Ingelheim Pharmaceuticals, Inc., Ridgefield, CT

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disease characterized by skin and organ fibrosis and vasculopathy. The Very Early Diagnosis of SSc (VEDOSS) project (Bellando-Randone S, et al. Lancet Rheum. 2021. 3(12); E834-E843) recently identified the value of predefined red flag symptoms or signs as a stratification tool for the risk of fulfilling the 2013 ACR/EULAR classification criteria for SSc. However, to date, an analysis of symptoms and signs prior to an SSc diagnosis has not been performed. Understanding pre-diagnostic patient pathways can help identify other major signs preceding a diagnosis, identify the burden of very early disease in patients with scleroderma and the potential barriers to early intervention. This study aimed to categorize temporal disease patterns leading to the initial diagnosis of SSc using US and Japanese health insurance claims data.

Methods: Patients with a diagnosis of SSc were identified from two claims databases (Optum® Clinformatics® and JMDC for the US and Japan, respectively). Patients with at least two concordant medical claims associated with SSc (International Classification of Diseases [ICD]-9 710.1, 517.2) on different dates within a 1-year period and who were ≥18 years old at the time of first SSc diagnosis were included. In the US, records were gathered from January 1, 2007 to September 30, 2015, and in Japan from January 1, 2005 to November 30, 2019. ICD codes of the differential diagnostic claims in the 3 years before SSc diagnosis were recorded. Network analysis and sequential pattern mining were used to identify and visualize temporal disease patterns prior to the diagnosis of SSc.

Results: In total, 2550 patients with continuous insurance history for ≥3 years prior to their SSc diagnosis (1765 from the US and 785 from Japan) were analyzed. Mean age at first SSc diagnosis was 61 and 51 years for the US and Japan, respectively. Approximately 80% of patients were female. In the US, the five most common diagnoses prior to SSc were related to fatigue, pain or discomfort, followed by esophageal reflux and chest pain in Japan, the most common diagnoses included upper respiratory infection, gastritis and rheumatoid arthritis (Figures 1a & 2a). In both countries, the mean time to diagnosis was shorter when the presenting complaint was Raynaud's-related (428 days

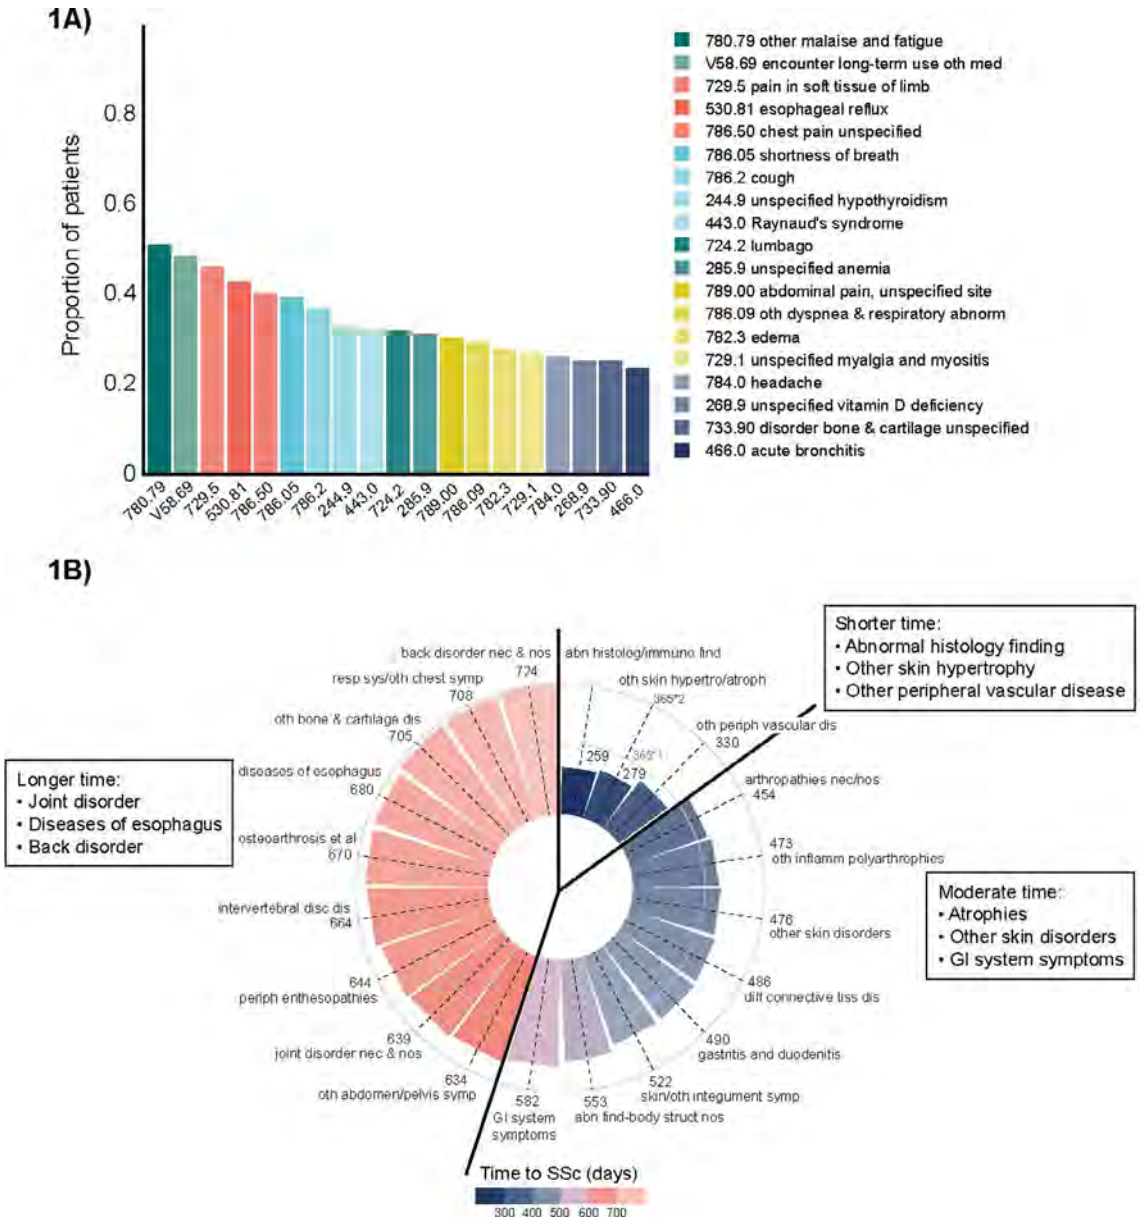

Figure 1. Diagnoses prior to SSc (A) and time to SSc diagnosis (B) in the USA

in the USA and 327 days in Japan), whereas it was almost double this when the complaint was more related to joint pain, fatigue or GI symptoms (Figures 1b & 2b).

Conclusion: Collectively, within the limitations of analyzing data from insurance claims and ICD codes, these real-world data showing a range of diagnoses prior to SSc help to identify the health burden leading to a diagnosis of SSc. These findings suggest that symptoms not directly related to Raynaud's or skin manifestations such as upper GI involvement and joint pain may not be recognized as early signs of SSc. Further deconvolution of the frequency and temporal distribution of symptoms that patients commonly present with prior to being diagnosed with SSc could help identify other "red flags" that physicians should consider when triggering a diagnostic workup for SSc, ultimately improving early detection and long-term outcomes.

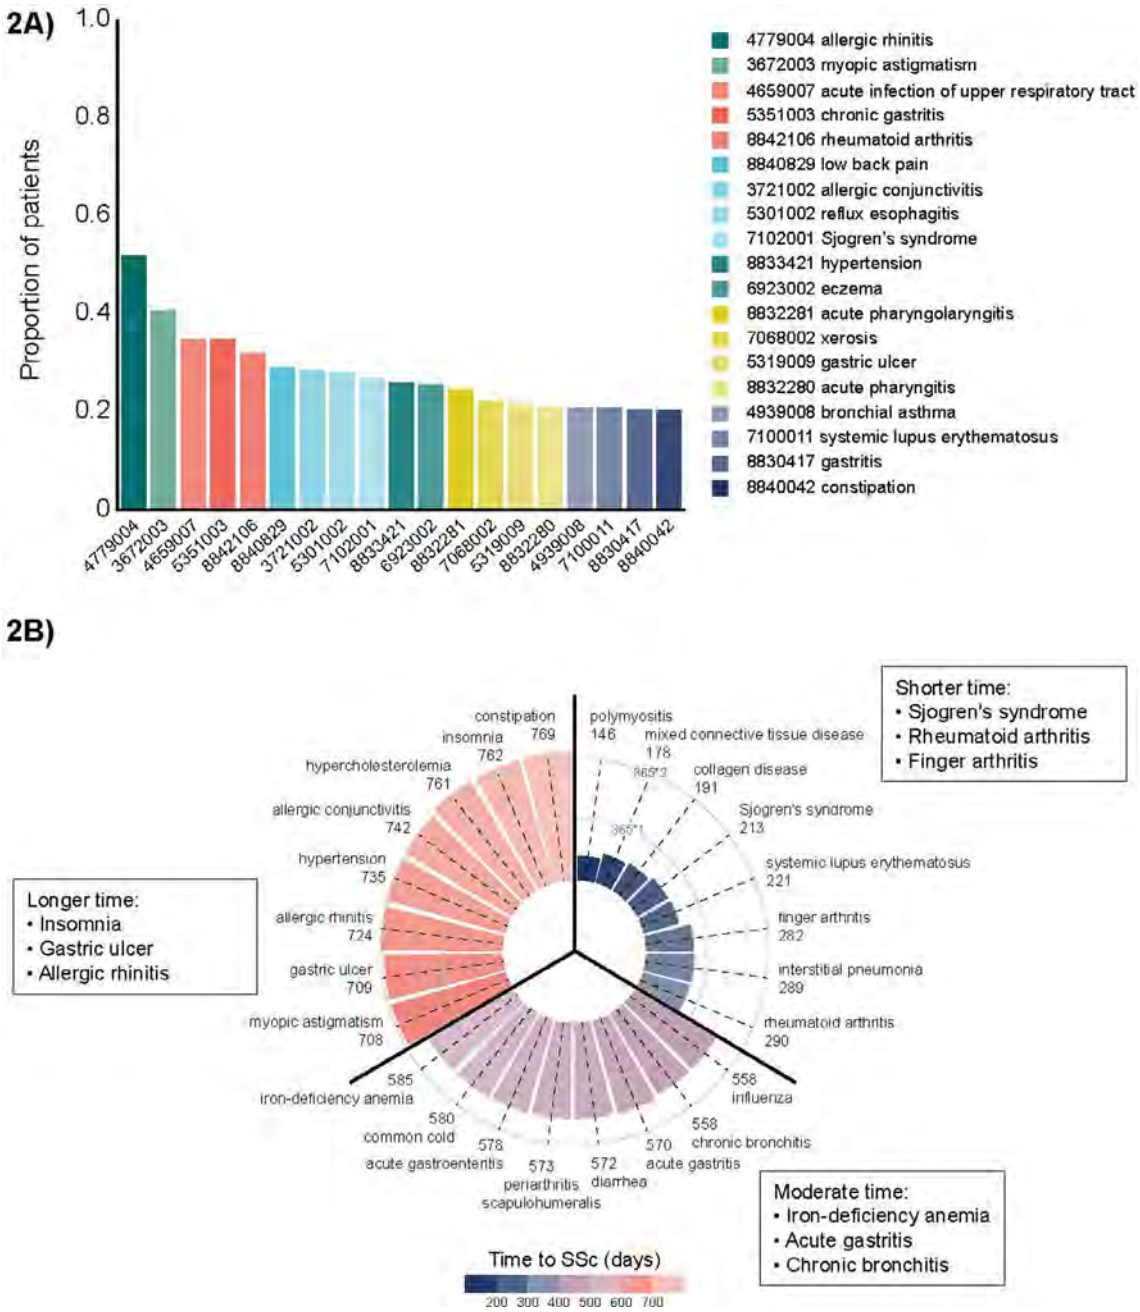

Figure 2. Diagnoses prior to SSc (A) and time to SSc diagnosis (B) in the Japan

Physical Performance Among Individuals with Systemic Lupus Erythematosus in a Diverse Population-Based Cohort

Courtney Hoge[1], C. Barrett Bowling[2], Charmayne Dunlop-Thomas[1], Bradley Pearce[1], S. Sam Lim[1], Cristina Drenkard[1] and Laura Plantinga[1], [1]Emory University, Atlanta, GA, [2]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Physical performance is often not measured in clinical settings, despite its association with increased risk of disability, loss of independence, and mortality. Here, we sought to examine the prevalence and correlates of poor physical performance among individuals with systemic lupus erythematosus (SLE) who were recruited from a primarily Black, population-based cohort in Atlanta.

Methods: Participants were recruited for an ancillary study from the ongoing, population-based Georgians Organized Against Lupus (GOAL) cohort of individuals with SLE. Those who had complete Short Physical Performance Battery [SPPB: score range, 0-12; intermediate-low (< 10) vs. high (≥10)] data from either an in-person or a remote study visit (10/8/19-5/12/22) were included. Demographic, clinical, and psychosocial variables were summarized, and the associations [adjusted odds ratios (aOR)] of intermediate-low vs. high physical performance with these characteristics were estimated via multivariable logistic regression.

Results: Among 446 participants (mean age 46.2, 91.7% female, and 82.5% Black), more than half (59.6%) had poor (intermediate-low) overall physical performance (**Figure 1**). Only 7% of the cohort received the maximum score on the lower body strength task, as opposed to 90% and 76% receiving the maximum scores on balance and gait speed tasks, respectively

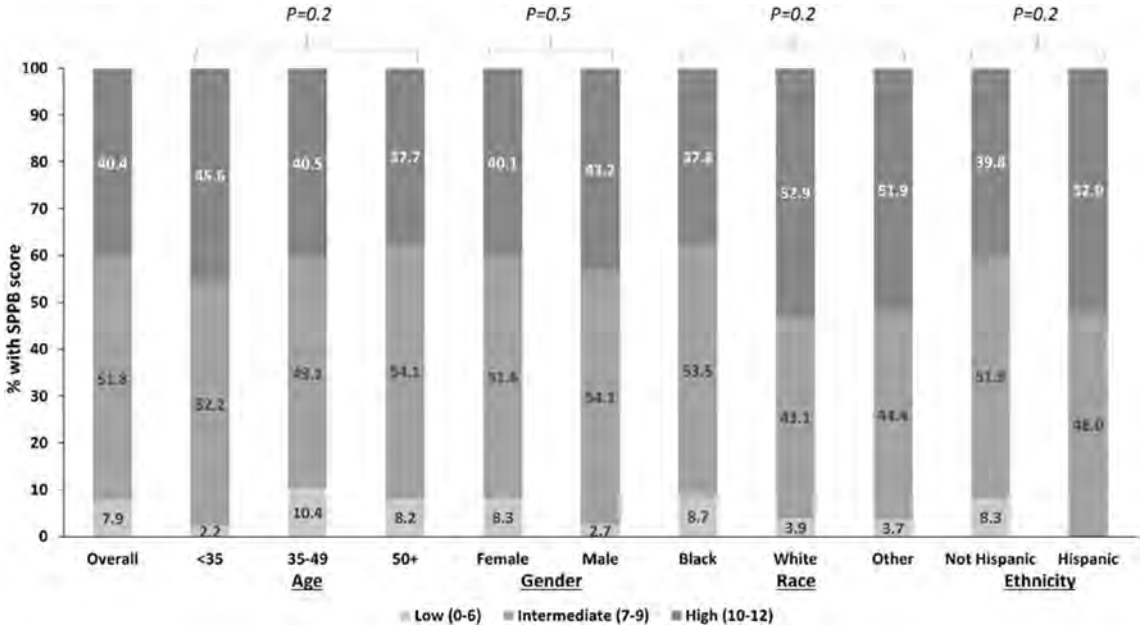

Figure 1. Short Physical Performance Battery scores (range 0-12, higher scores indicating higher levels of physical performance) among study participants, overall and by participant demographics.

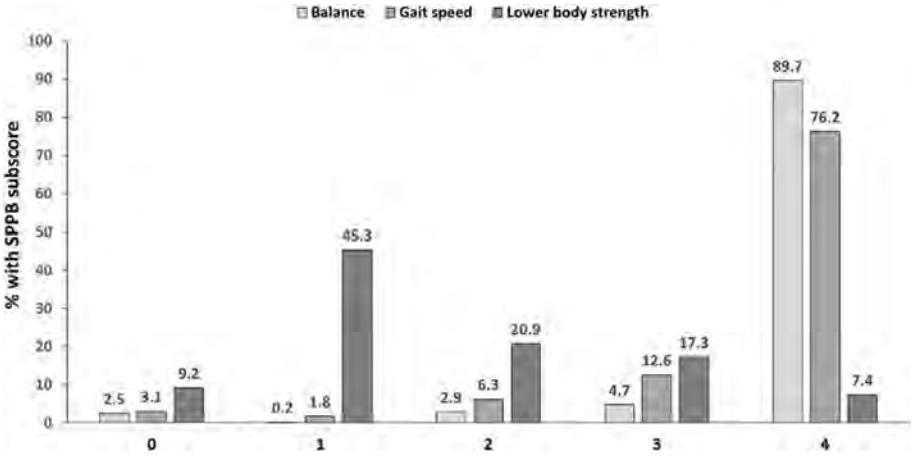

Figure 2. Short Physical Performance Battery subscores (range 0-4, 0=inability to perform task, 4=highest level of performance) for balance, gait speed, and lower body strength (chair stands) among study participants.

Table 1. Associations of intermediate or low (<10) vs. high (10-12) physical performance scores with participant characteristics.

Characteristic	aOR[a] for intermediate-low vs. high SPPB score (95% CI)
Age category	
18-34 vs. ≥50	0.85 (0.23-3.14)
35-49 vs. ≥50	0.92 (0.43-1.98)
Male vs. female gender	0.98 (0.46-2.06)
Race	
White vs. Black	0.59 (0.31-1.11)
Other vs. Black	0.62 (0.27-1.41)
Hispanic vs. not Hispanic	0.95 (0.35-2.55)
Highest level of education completed	
≤High school graduate vs. ≥college graduate	1.71 (0.99-2.96)
Some college vs. ≥college graduate	1.17 (0.74-1.85)
Currently working vs. not	0.69 (0.45-1.05)
SLAQ score, per 1 SD	1.59 (1.27-1.98)
BILD score, per 1 SD	1.38 (1.08-1.77)
Currently taking steroids vs. not	0.95 (0.62-1.45)
BMI, per 1 SD	1.25 (1.01-1.56)
Depressive symptoms T-score, per 1 SD (10 points)	1.23 (0.96-1.58)
Perceived stress score, per 1 SD	1.15 (0.91-1.46)
Fluid cognition T-score, per 1 SD (10 points)[b]	0.57 (0.42-0.77)

BILD, Brief Index of Lupus Damage; BMI, body mass index; SLAQ, Systemic Lupus Activity Questionnaire; SPPB, Short Physical Performance Battery.
[a]Adjusted for age in years, gender, race, visit type (in-person vs. remote), and SLAQ score.
[b]For in-person visits only.

(**Figure 2**). Current employment status and higher cognitive functioning were associated with 31% and 43% lower odds of intermediate-low physical performance (**Table 1**). Higher body mass index, disease activity, and disease burden were associated with 25%, 59%, and 38% higher odds of poorer performance, as were higher depressive symptom and perceived stress scores and lower educational attainment.

Conclusion: In our diverse cohort of individuals with SLE, we found a high burden of low to intermediate physical performance and identified SLE- and non-SLE-related factors associated with poorer performance. Clinicians may use these results to identify patients who are most at risk for suboptimal physical performance and intervene to maintain or improve performance levels, which could delay or prevent associated poor outcomes and help ensure continued independence.

Mortality-related Health Metrics in Systemic Autoimmune Diseases: An Epidemiological Analysis of a Nationwide Register-based Cohort

Mucong Li[1], Chanyuan Wu[2], Peng Yin[3], Qian Wang[4], Dong Xu[5], Xiaomei Leng[2], Xinping Tian[1], Ali Duarte-Garcia[6], Mengtao Li[1], xiaofeng Zeng[4] and Maigeng Zhou[3], [1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [2]Peking Union Medical College Hospital, Beijing, China, [3]Chinese Center for Disease Control and Prevention, Beijing, China, [4]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [5]Department of Rheumatology, Peking Union Medical College, Beijing, China, [6]Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Epidemiology & Public Health Poster I

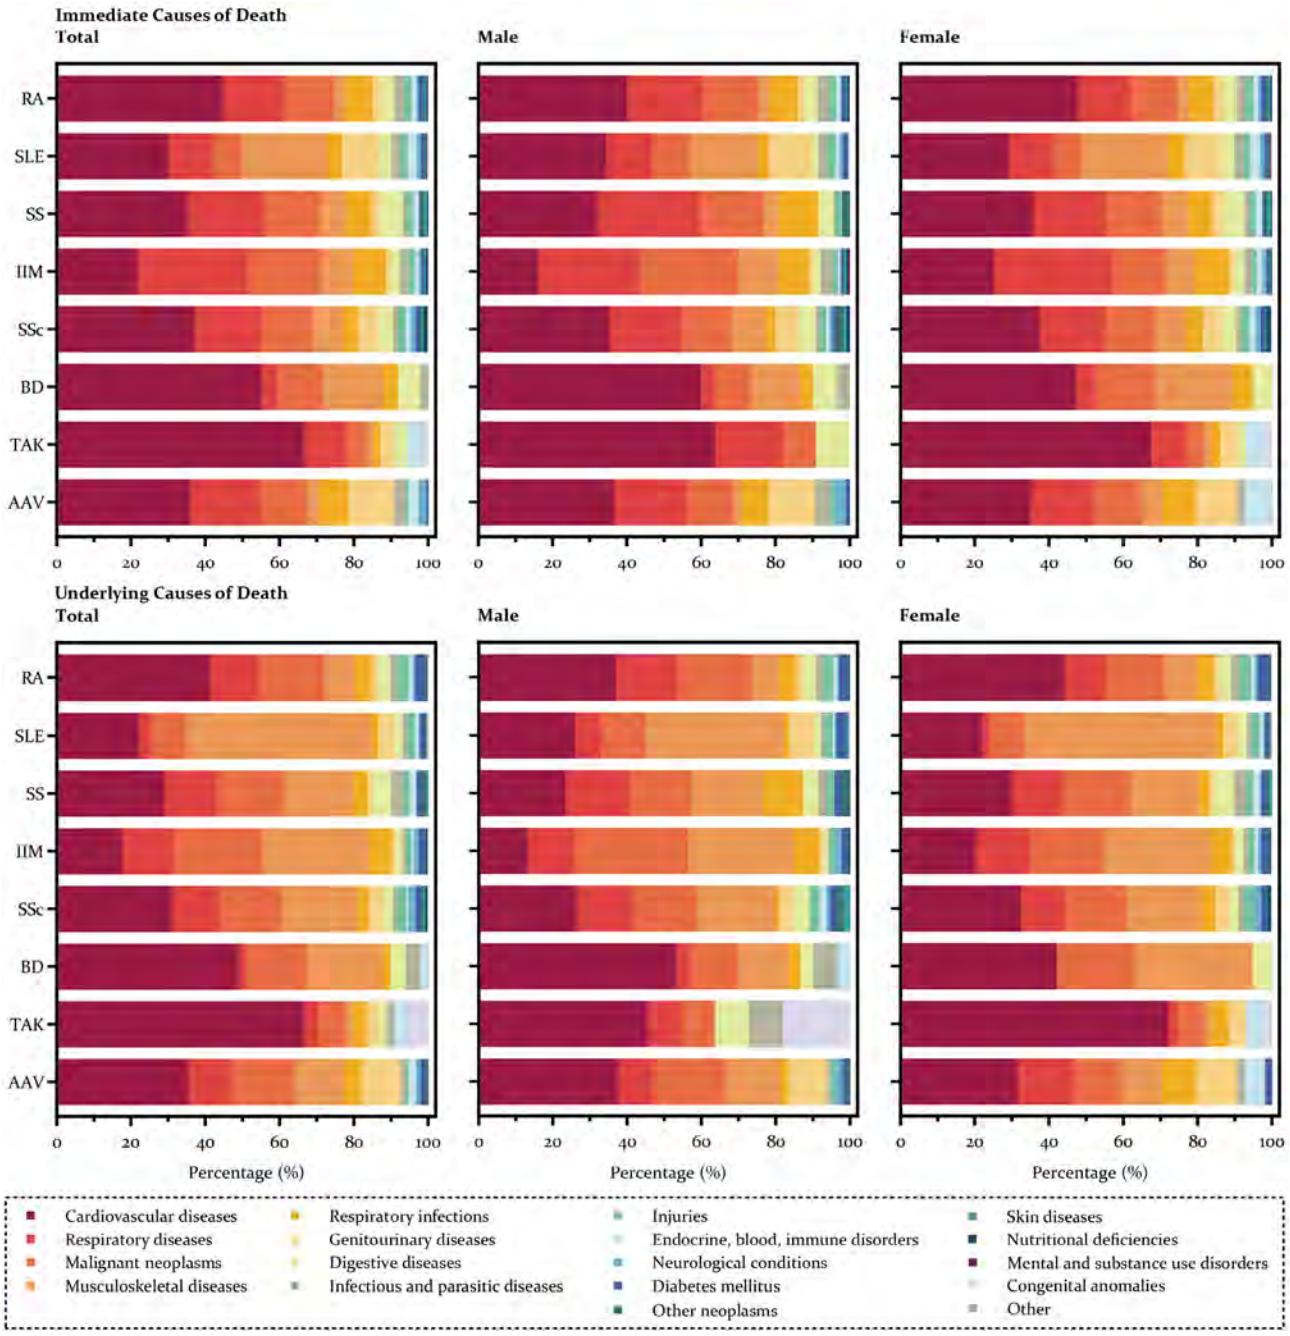
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic autoimmune diseases (sAIDs) have become leading contributors to premature death. Meanwhile, regional disparities exist in capacity of rheumatology healthcare services delivery. However, no rigorous epidemiological studies have provided an integrated overview of mortality burden of various sAIDs, especially in low-to-middle income countries (LMICs). In this study, we comprehensively analyzed mortality rates, survival probabilities, causes of death, and standardized mortality ratios (SMRs) of eight sAIDs in China and examined the associations between disease burden of sAIDs and development indicators.

Methods: In this nationwide, register-based cohort study, we used data from Chinese Rheumatism Data Center, Nation Mortality Surveillance System, and public databases with a universal coverage of 31 provinces in mainland China between Jan 1, 2011, and Dec 31, 2021. We collected data on patient demographics, clinical status, and vital outcomes of individuals with RA, SLE, SS, IIM, SSc, Behçet's disease (BD), Takayasu's arteritis (TAK), and AAV. Mortality rates, survival probabilities, causes of death, and SMRs were estimated in patients classified by gender, age at disease onset, and area-level socioeconomic status (including a composite indicator, human development index [HDI], and indicators in economy, healthcare, and education).

Results: Between 2011 and 2021, 156 862 individuals (87132 with RA, 44658 with SLE, 11668 with SS, 4864 with IIM, 4065 with SSc, 1762 with BD, 1558 with TAK, and 1155 with AAV) were included, with a median duration of follow-up 5.12 (IQR 3.08-8.67) years. AAV, IIM, and SSc were top three diseases with the highest fatality rates and lowest survival rates. Cardiovascular, respiratory (non-infection), musculoskeletal, malignancy, and genitourinary diseases were the leading causes of death (Figure 1). The age-, gender-, and calendar year-adjusted SMR was highest for TAK (5.45, 95%CI 4.00-6.91), followed by IIM (5.08, 4.66-5.50), SSc (4.94, 4.49-5.39), SLE (3.50, 3.32-3.68), AAV (2.97, 2.50-3.45), BD (2.27, 1.64-2.91), SS (1.53, 1.37-1.69), and RA (0.96, 0.93-1.00). Early disease-onset is a risk factor of excess death in patients with sAIDs (Figure 2). Additionally, higher HDI was associated with significant increases in mortality risks in both RA and SLE (SMR ratio 12.24 and 5.15 for 1-unit increase in HDI, $p< 0.001$ and $p=0.080$) patients compared with region-specific general population. More medical institutions (SMR ratio 0.95 for one more medical institution per 10 000 resident population, $p=0.005$) and hospital beds (SMR ratio 0.35 for one more hospital bed per 100 resident population, $p=0.131$) were protect factors of excess mortality in SLE.



Conclusion: The mortality risk in patients with sAIDs can be in substantial excess versus general population, and sAIDs are becoming important contributors to premature mortality in China. Increasing mortality burden associated with sAIDs implied the relative insufficiency of capacity building of diagnosis and treatment in sAIDs in LMICs, raising important need for establishing universal health coverage systems for the affected patients.

Causes of death in systemic autoimmune diseases

Standardized mortality ratios of systemic autoimmune diseases. (A) Point estimates and 95% CIs of standardized mortality ratios (SMRs) in total, male, and female patients are presented for 8 systemic autoimmune diseases. (B) SMRs are presented in early- and late-onset patients with 8 systemic autoimmune diseases, stratified by gender.

Incidence and Prevalence of Systemic Lupus Erythematosus in Urban China, 2013-2017: A Nationwide Population-based Study

Mucong Li[1], Chaiquan Li[2], Mengzhuo Cao[3], Ke Lu[2], Chanyuan Wu[3], Jiuliang zhao[1], Qian Wang[4], Xinping Tian[1], Xun Tang[2], Mengtao Li[1], xiaofeng Zeng[4] and Pei Gao[2], [1]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [2]Peking University, Beijing, China, [3]Peking Union Medical College Hospital, Beijing, China, [4]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Epidemiology & Public Health Poster I

Session Type: Poster Session A

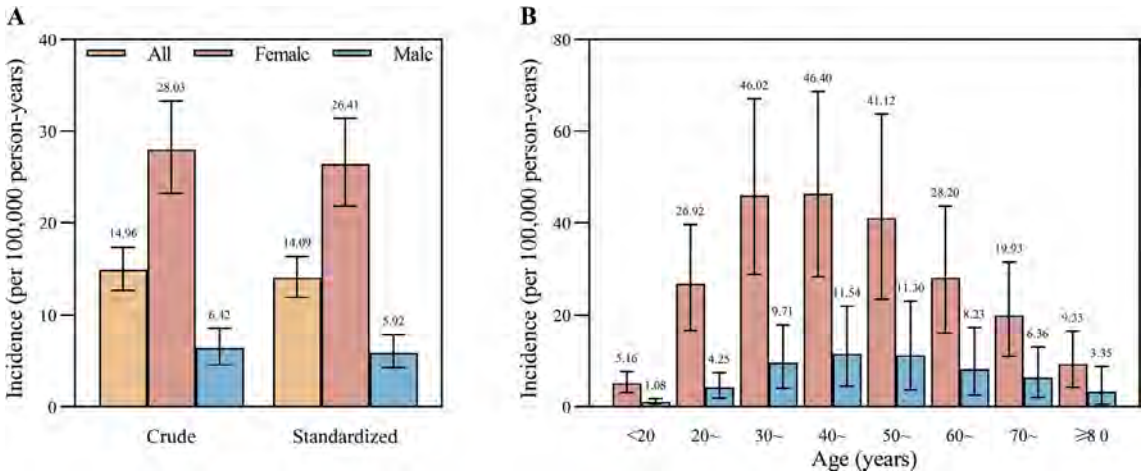
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is becoming a public health concern because of increasing disease and economic burdens. Epidemiological information on SLE, especially its incidence rate, was limited in developing countries. We aimed to investigate the incidence, prevalence, and cost burdens of SLE in urban China.

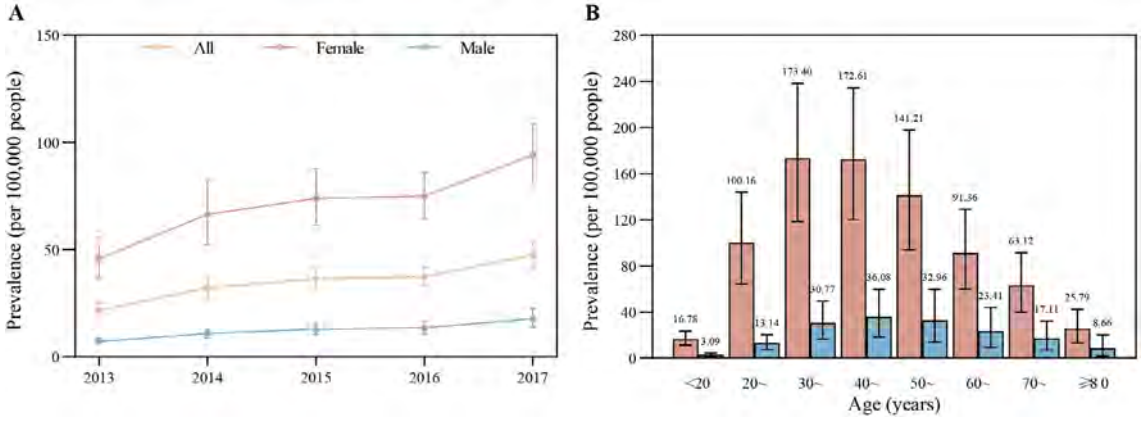
Methods: We conducted a nationwide population-based cohort study using the databases of Urban Employee Basic Medical Insurance and Urban Resident Basic Medical Insurance between 2013 and 2017, covering 23 provinces in China. Incidence and prevalence rates were age- and gender-standardized to China 2010 national census data. Average annual costs and hospital visit times were also calculated.

Results: Total 132,258 patients with SLE were identified during the study period. The mean age was 43.03 (SD, 15.29) years. Overall 81.33% of patients were women. The standardized incidence of SLE in China in 2017 was 14.09 (95%CI, 11.95-16.41) per 100,000 person-years (Figure 1). Women had higher incidence than men (26.41 vs 5.92 per 100,000 person-years). The standardized prevalence in 2017 were 47.61 (95%CI, 41.77-53.83), 94.16 (80.67-108.69), and 17.86 (13.84-22.38) per 100,000 people in overall, female, and male patients (Figure 2). The average annual rates of increase in prevalence were 21.50%, 19.72%, and 25.67% from 2013 to 2017 in overall, female, and male patients. The age-specific incidence peaked at 30-49 years old in women and at 40-59 years old in men. SLE incident and prevalent cases were most common in northwestern and less in south and east China (Figure 3). Additionally, the average estimated annual cost per-capita was US $1,599.34 in SLE patients. Costs of adolescent and young adult patients were the highest among age groups.

Conclusion: SLE population in China is rapidly expanding. Younger age at onset, especially in women, has placed considerable burdens in China. The distinct signatures of different incidence rates with respect to geographic variations were consistent with regions' exposure to ultraviolet radiation in China.



Incidence of SLE in urban China in 2017



Standardized prevalence of SLE in urban China from 2013 to 2017

Standardized incidence and prevalence rates of SLE by regions in China in 2017

Abstract Number: 0121

High Prevalence of Mental Health Disorders Among Patients with Rheumatoid Arthritis and Systemic Lupus Erythematosus

Jeong Yee[1], Candace Feldman[1], Emily G. Oakes[1], Elizabeth Karlson[1], Jack Ellrodt[1], Laura Kubzansky[2], Karestan Koenen[2] and Karen Costenbader[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) are complex autoimmune diseases associated with pain and decreased quality of life. Mental health conditions related to stress and emotional distress, in particular depression, anxiety, and post-traumatic stress disorder (PTSD), appear to be common among those with these rheumatic diseases, but estimates in large diverse populations are not yet available. We assessed the prevalence of these three mental health conditions among patients with RA and SLE, comparing them to those without in a large and diverse healthcare center-based nationwide cohort.

Methods: We conducted a cross-sectional study within the All of Us Research Program, an ongoing NIH-funded cohort that enrolled US adults age ≥18 from May 6, 2018 - July 1, 2022 (release v7). It includes consented electronic health record (EHR) data for >287,000 people. RA and SLE patients were identified by ≥ 2 International Classification of Diseases (ICD)-9, ICD-10, and Systematized Nomenclature of Medicine (SNOMED) codes >2 months apart but within ≤2 years prior to enrollment. Depression, anxiety, and PTSD were also identified by ICD-9 or-10, and SNOMED codes within 1 year prior to enrollment. Prevalence of each mental health disorder among patients with RA and SLE was compared to age-, sex-, and race/ethnicity-matched patients (1:4 matched). Conditional logistic regression models estimated odds ratios (ORs) for these mental health conditions, adjusting sequentially for socioeconomic factors (Model 1), + smoking, obesity, and other comorbidities (Model 2). Age-stratified analysis was performed for groups aged 18-44, 45-64, and ≥65 years.

Results: After matching for age, sex, and race/ethnicity, we studied 4,370 RA patients, 1,977 SLE patients, and their matched controls (17,479 for RA; 7,908 for SLE) (**Table 1**). Both RA and SLE patients had lower educational attainment, and were less frequently privately insured, and more comorbidities than their matched controls. Compared to controls, RA patients had higher prevalence of depression (24.2 % vs. 11.5%), anxiety (21.4% vs. 11.2%), and PTSD (3.5% vs. 1.6%) (**-Figure 1**). Similarly, compared to controls, SLE patients had higher prevalence of depression (23.6% vs. 11.9%), anxiety (22.8% vs. 12.0%), and PTSD (3.7% vs. 2.1%). **Table 2** shows sequential modeling results. While adjusting for potential confounders, which attenuated the ORs, RA patients vs controls had 1.7-fold (95% CI 1.5-1.9) higher odds of these mental health conditions in fully-adjusted models. For SLE patients, the adjusted OR was 1.9 (95% CI: 1.6-2.4). In the age-stratified analysis, the adjusted ORs were similar in each group, ranging from 1.5 to 1.8 in RA patients and from 1.8 to 2.3 in SLE patients.

Conclusion: Patients with RA and those with SLE had elevated prevalence of mental health conditions related to stress, trauma, and emotional distress than controls in the year prior to their cohort enrollment. These highly prevalent stress-related mental health conditions may complicate the care and treatment of rheumatic diseases. Research is ongoing to understand how mental health treatments affect rheumatic disease outcomes.

Table 1. Demographic and survey data of patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) vs. their matched controls in All of Us (data release v7, through July 2022)

	RA (n=4,370)	Controls for RA (n=17,479)	SMD (Controls vs. RA)	SLE (n=1,977)	Controls for SLE (n=7,908)	SMD (Controls vs. SLE)
Age, mean ± SD, y	59.6 ± 13.5	59.6 ± 13.5	<0.01	50.6 ± 14.2	50.6 ± 14.2	<0.01

Depression, Anxiety and Post-Traumatic Stress Disorder in Association with Cardiovascular Disease Among Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis in the All of Us Research Program

Jeong Yee[1], Emily G. Oakes[1], May Choi[2], Candace Feldman[1], Elizabeth Karlson[1] and Karen Costenbader[3], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Calgary, Calgary, AB, Canada, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) risk is increased for patients with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Mental health conditions such as depression, anxiety, and post-traumatic stress disorder (PTSD) are not traditional CVD risk factors but have been associated with CVD risk and are highly prevalent in SLE and RA populations. We assessed the contribution of these 3 mental health conditions related to stress and emotional distress to CVD risk among patients with RA and/or SLE in a large, diverse U.S. cohort.

Methods: We used data from the All of Us Research Program (v7), a NIH cohort with >287,000 adult participants in the U.S. who gave consent for linkage to their electronic health records. RA/SLE patients were identified by ≥2 ICD-9, ICD-10, or SNOMED codes >2 months apart within 2 years of enrollment. We excluded patients with acute myocardial infarction (MI) and stroke at baseline (1 year pre-enrollment). Depression, anxiety, and PTSD were identified by ICD-9/10, and SNOMED codes in the baseline period. The primary outcome was a composite of acute MI, stroke (identified by ICD9/10

and SNOMED codes), and all-cause mortality. Patients were followed until the 1st acute MI, stroke, or death, through 4 years or end of study period (July 1, 2022). Covariates included age, sex, and race/ethnicity, income, educational level, smoking, obesity, and comorbidities. We estimated incidence rates (IRs) and incidence rate ratios (IRRs). Adjusted Cox regression models compared risks of the endpoint of acute MI, stroke, or all-cause mortality among RA/SLE patients with and without these 3 mental health conditions.

Results: We studied 3,825 patients with RA only, 1,862 with SLE (including 383 with meeting both definitions). Among them,1,790 (31.5%) had depression, anxiety, and/or PTSD (**Table 1**). Compared to patients without, those with ≥1 mental health conditions were more likely to be less educated, in a low-income group, to have ever smoked, to be obese, and to

Model 2 adjusted for smoking, obesity, and Charlson comorbidity index (calculated with 16 comorbidities, excluding rheumatic disease) in addition to the factors adjusted in Model 1.

have comorbidities. Patients were followed for a mean of 31.0 months (SD 14.7). 155 events (64 MI, 55 strokes and 36 deaths) occurred among RA/SLE patients with mental health conditions in 55,856 person-months (IR 33.3/1000 person-years) vs. 232 (75 MI, 117 strokes and 40 deaths) among those without mental health diagnoses in 120,422 person-months (IR 23.1/1000 person-years; IRR 1.44). The risk of acute MI, stroke, and death was significantly higher among patients with these mental health conditions than without for both RA and SLE (**Figure 1**). After adjustment for smoking, obesity, and Charlson comorbidity index, the HR of incidence of MI, stroke, or all-cause mortality for patients with concomitant mental health conditions was 1.28 (95% CI 1.02-1.60, **Table 2**).

Conclusion: In this large diverse U.S. cohort of patients with RA/SLE without prior CVD events, depression, anxiety and PTSD were associated with increased risk of developing acute MI, stroke, or death. These results suggest greater awareness of increased CVD risk among rheumatic disease patients with concurrent mental health conditions is needed. Research is ongoing to dissect the likely multifactorial causal pathways underlying this relationship.

Improving Interpretation of Work Outcomes in Patients with Inflammatory Rheumatic Musculoskeletal Disease: General Population Reference Curves for Work Ability and At-work Productivity

Dafne Capelusnik[1], Wouter Smeets[2], Casper Webers[3], Sofia Ramiro[4], Elena Nikiphorou[5], Roel Braekers[2], Laura Boekel[6], Gertjan Wolbink[7] and Annelies Boonen[8], [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Data science institute, Hasselt University, Hasselt, Belgium, [3]Maastricht University, Maastricht, Netherlands, [4]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [5]King's College London, London, United Kingdom, [6]Amsterdam Rheumatology and Immunology Center, Location Reade, Department of Rheumatology, Amsterdam, Netherlands, [7]Reade, Amsterdam, Netherlands, [8]Care and Public Health Research Institute (Caphri), Maastricht University, Maastricht, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Data on self-reported presenteeism (limitations or reduced work productivity at work) in persons with inflammatory rheumatic and musculoskeletal diseases (iRMD) are challenging to interpret without a population benchmark, as presenteeism likely also occurs in the general working population. Our objective was to establish percentile curves (reference intervals [RI]) for ability and productivity while at paid work in a general working population.

Methods: A cross-sectional study was nested within an ongoing prospective Dutch cohort study on COVID-19, including patients with iRMD and general population controls. Participants with paid work (≥12 working hours/week) reported on work ability (Work Ability Index, range 0-10 [worst-best ability]) and work productivity (Work Productivity and Activity Impairment scale item 5 on productivity loss, range 0-100% [no-complete productivity loss]). A generalized additive model for location, shape and scale parameters (GAMLSS) with a zero-one inflated beta distribution was chosen to assess the association of age, gender, educational level, full- or part time employment and job demands with each presenteeism instrument (work ability, work productivity). Next, GAMLSS was used to establish age-specific RIs percentile curves for controls, stratified by relevant determinants when needed. Finally, the proportion of controls compared to patients with optimal outcomes (work ability=10 and productivity loss=0%) was calculated.

Results: A total of 446 controls were included; 327 (73%) were female, mean age 53 (SD 11) years, 188 (42%) had university education, mean work ability was 8.7 (1.6) [median 9 (IQR 2-10)] and mean at-work productivity loss 11% (25%) [0 (0-100)]. Education influenced work ability as well as work productivity loss. Percentile curves revealed that work ability decreases and productivity loss at work increases with age (Fig 1). While more than 50% of controls reported at least some impairment in work ability, more than 75% indicated having no productivity loss at work. Non-university education was strongly associated with both presenteeism outcomes. Stratification of percentile curves for work ability by education showed high variability in work ability with worse as well as better scores in small proportions of the older (compared to younger) controls (Fig 2). For productivity loss, non-university educated controls experienced increase in productivity loss in the older age groups. Plotting data form 494 patients with iRMD into the percentile curves revealed patients were less likely to have optimal work ability [151/494 (31%) vs 169/390 (43%) in controls] or no productivity loss [305/494 (62%) in patients vs 328/390 (83%) in controls]. Across percentiles, differences between patients and controls were larger for work productivity than work ability independent of age.

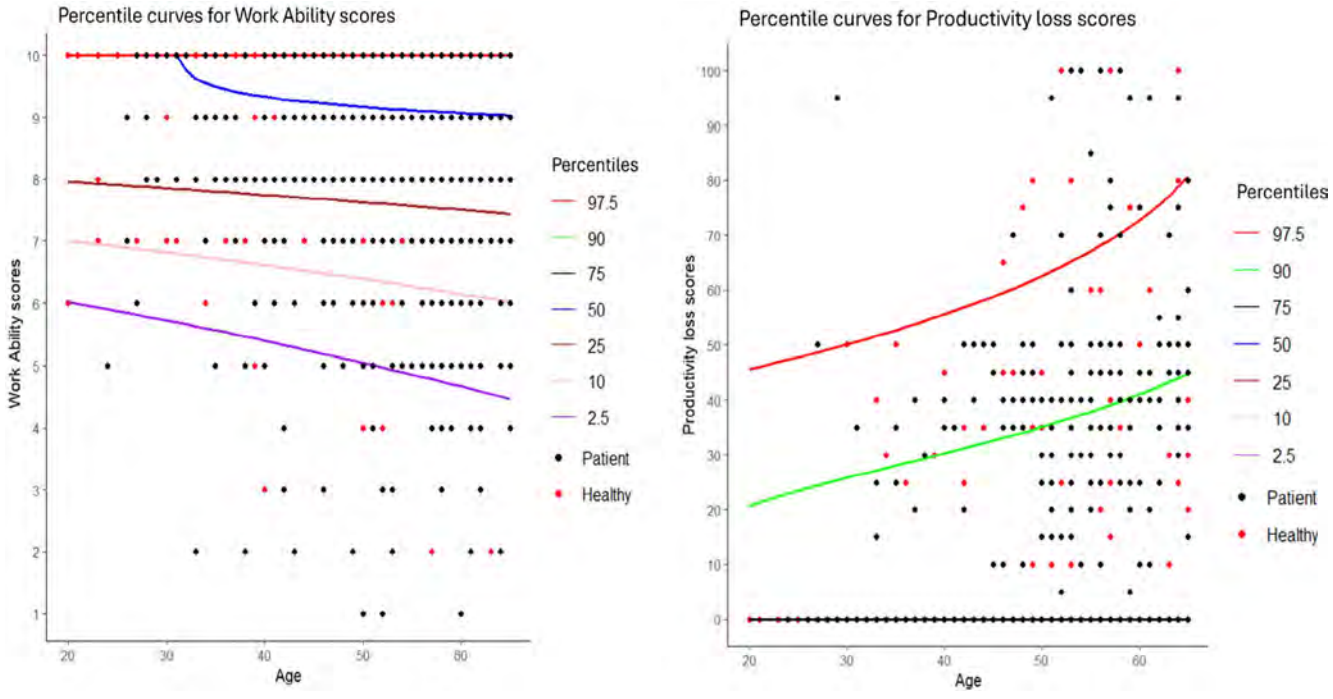

Figure 1. Reference intervals and percentile curves for a) work ability and b) productivity loss at work.

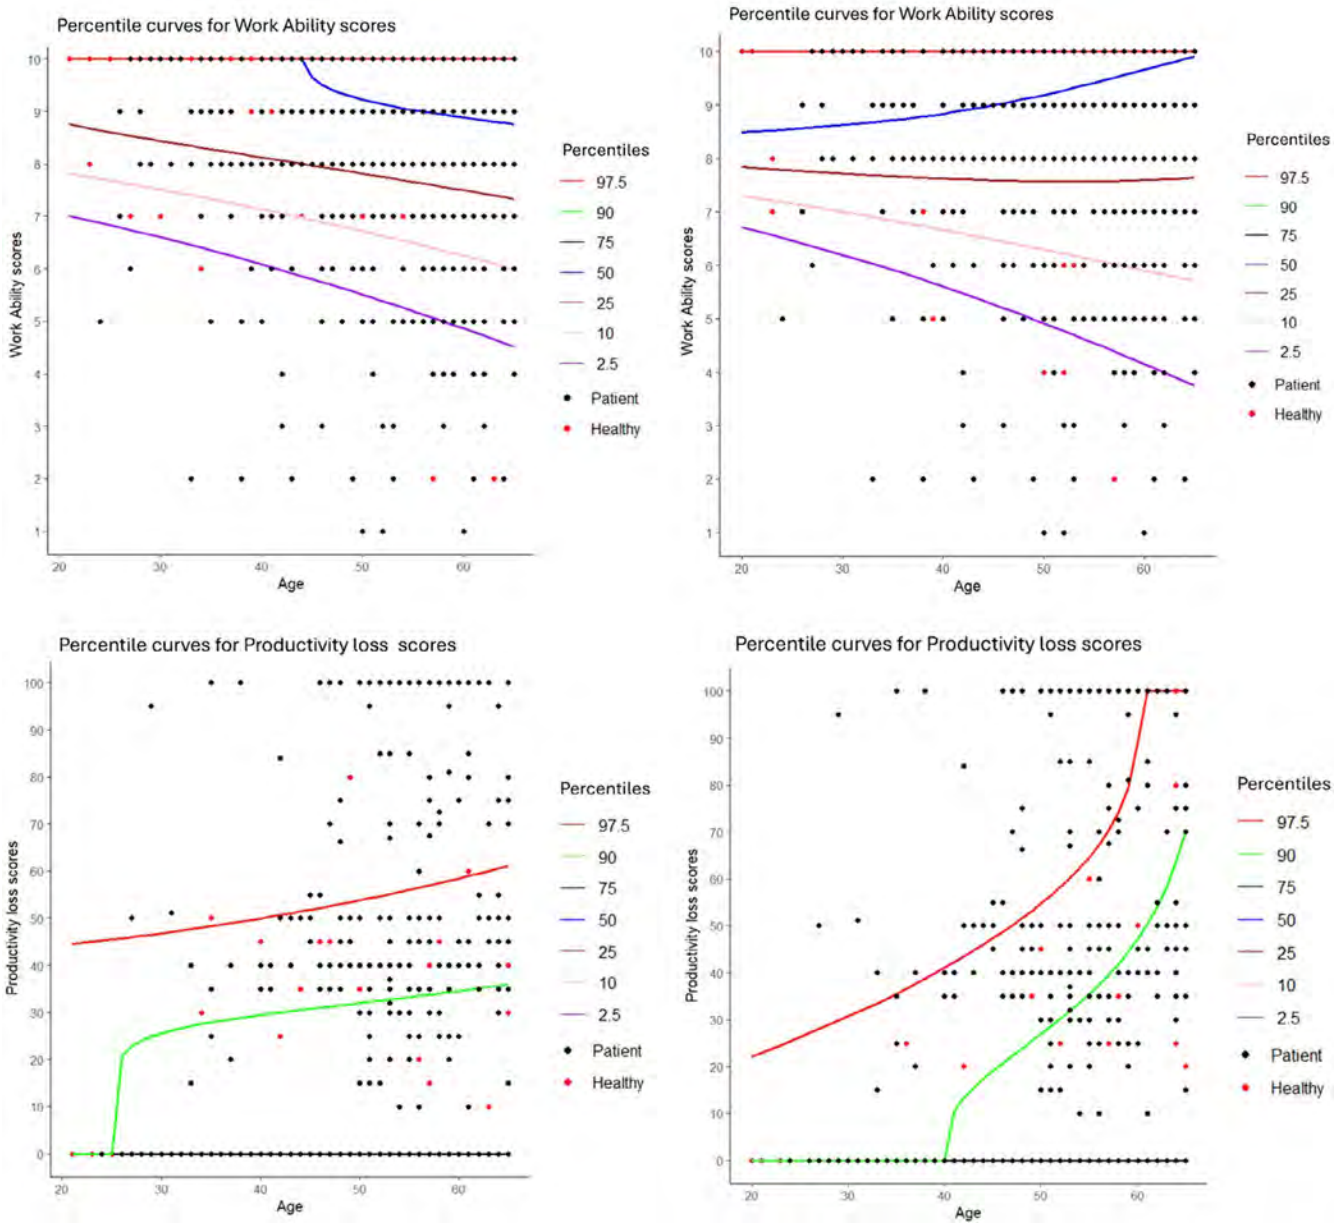

Figure 2. Reference intervals and percentile curves for work ability and productivity loss at work in high educated (left) vs low/middle educated (right) population.

Conclusion: In the general working population work ability and productivity while at work are not perfect, indicating we should be cautious to not overestimate impact of iRMD on presenteeism. Notwithstanding, iRMD had evident impact on presenteeism compared to population controls, and this effect is stronger on productivity (output) than on ability (difficulty).

Abstract Number: 0124

Utility of the 2019 EULAR/ACR SLE Classification Criteria Score as Predictor for Mortality and Hospitalizations in a Population-Based Cohort: The Lupus Midwest Network

Gabriel Figueroa-Parra[1], Andrew Hanson[2], Alain Sanchez-Rodriguez[3], Jose Meade-Aguilar[1], Cynthia Crowson[3] and Ali Duarte-Garcia[3], [1]Division of Rheumatology, Mayo Clinic, Rochester, MN, [2]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with SLE experience increased all-cause mortality and have a higher risk of hospitalization than the general population. Recently the classification criteria for SLE were updated resulting in an additive score to classify patients with SLE.

A higher score (≥20) in this classification criteria has been associated with disease severity in populations from referral centers (susceptible to referral bias), but this strategy has not been explored in a community setting. We aimed to assess the utility of the 2019 SLE classification criteria score for predicting mortality and hospitalizations in a population-based cohort of patients with recent SLE classification.

Methods: All incident patients meeting the 2019 EULAR/ACR SLE classification criteria in a population-based cohort between 1976-2018 were included. The EULAR/ACR SLE criteria components were abstracted by retrospective review of medical charts. We used EULAR/ACR score at 1 year from meeting classification. We evaluated the association between a score ≥20 points and mortality and the first unplanned hospitalization using Cox proportional hazards models adjusted for age, sex, and calendar year. Hospitalization data was available starting in 1995, and only incident patients after this were included in the hospitalizations analysis. Additionally, we re-fit multivariable models with EULAR/ACR score included as a penalized spline to explore possible non-linear relationships with outcomes and assess potential cut-off points. Patients were followed until March 2022, death, or lost to follow-up. A p-value < 0.05 was considered statistically significant.

Results: We included 270 patients with SLE. The median age was 45 (IQR 33-60) years; 80% were female and 82% were non-Hispanic White. The median length of follow-up was 9 (IQR 5-16) years. The most common clinical manifestations within 1 year of index date were inflammatory arthritis (66%), leukopenia (47%), and acute cutaneous lupus (25%). 73% were anti-dsDNA positive and 20% had proteinuria (**Table 1**). During follow-up, 68 patients died and 122 experienced unplanned hospitalization. 38% of patients had a score ≥20 points within 1 year of index.

A EULAR/ACR score ≥20 points within the first year of classification were not predictive for mortality (HR 1.42, 95% CI 0.82-2.48; p=0.22) but was for hospitalizations (HR 1.60, 95% CI 1.04-2.46, p=0.031) compared to a score ≤19 points. Assessing the EULAR/ACR score as a continuous predictor, we did not find a statistically significant association with mortality (HR 1.16 per 4-point increase, 95% CI 0.98-1.36, p=0.078), however, we estimated an 18% increase in the hazard for hospitalization (HR 1.18 per 4-point increase, 95% CI 1.06-1.13, p=0.003) (**Table 2**). We did not find any evidence of meaningful non-linear effects between the EULAR/ACR score and mortality (p=0.075) or hospitalizations (p=0.805) that suggested another potential score threshold to test (**Figure 1**).

Table 1. Clinical characteristics of patients with systemic lupus erythematosus.

	N = 270
Age, years, median (IQR)	45 (33-60)
Sex, n (%)	
Female	216 (80%)
Male	54 (20%)
Race/Ethnicity, n (%)	
Non-Hispanic White	222 (82%)
Hispanic/Latino	13 (5%)
Non-Hispanic Asian	20 (7%)
Non-Hispanic Black	9 (3%)
American Indian	0 (0%)
Other/Mixed/Refusal/Unknown	6 (2%)
Length of follow-up, years, median (IQR)	9 (5-16)
EULAR/ACR domain and criteria within 1 year of index*	
Constitutional	
Fever	18 (7%)
Hematologic domain	
Leukopenia	127 (47%)
Thrombocytopenia	58 (21%)
Autoimmune hemolysis	5 (2%)
Neuropsychiatric domain	
Delirium	3 (1%)
Psychosis	1 (<1%)
Seizures	4 (1%)
Mucocutaneous domain	
Non-scarring alopecia	11 (4%)
Oral ulcers	35 (13%)
Subacute cutaneous or discoid lupus	41 (15%)
Acute cutaneous lupus	68 (25%)
Serosal domain	
Pleural or pericardial effusion	45(17%)
Acute pericarditis	22 (8%)
Musculoskeletal domain	
Arthritis	178 (66%)
Renal domain	
Proteinuria >0.5g/24hrs	55 (20%)
Class II or V lupus nephritis	16 (6%)
Class III or IV lupus nephritis	31 (11%)
Immunology domains	
Antiphospholipid antibodies	63 (23%)
Low C3 or C4	100 (37%)
Low C3 and C4	83 (31%)
Anti-dsDNA	196 (73%)
Anti-Smith	61 (23%)

IQR: interquartile range.

*Including manifestations of patients who died or were lost to follow-up within the first year (n = 13).

Table 2. Association between the 2019 EULAR/ACR SLE classification score (within 1 year) and the outcomes of mortality and hospitalizations among patients with SLE classification in a population-based cohort.

Outcome	Hazard ratio (95% CI)	p-value
Mortality		
EULAR/ACR score ≥20	1.42 (0.82, 2.48)	0.215
EULAR/ACR score, per 4-point increase	1.16 (0.98, 1.36)	0.078
Hospitalizations		
EULAR/ACR score ≥20	1.60 (1.04, 2.46)	0.031
EULAR/ACR score, per 4-point increase	1.18 (1.06, 1.31)	0.003

Conclusion: Among patients with recent SLE classification from a population-based cohort, the EULAR/ACR SLE classification score (≥20 points) was not a useful predictor for mortality compared to patients with SLE from referral centers, but it was predictor for hospitalizations.

Figure 1. Absence of non-linear relationship between the EULAR/ACR SLE classification score and the hazard for mortality and hospitalizations. Suggesting there is no evidence for establishing a threshold.

Decreasing Ischemic Heart Disease, but Increasing Cancer Among the Underlying Causes of Death in Decedents with Lupus Nephritis

snehin Rajkumar[1] and Ram Singh[2], [1]University of California Los Angeles, Irvine, CA, [2]UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with lupus nephritis may die of active systemic lupus erythematosus (SLE) disease, end-stage renal disease (ESRD) and its complications as well as of comorbidities and treatment complications. Previous studies have utilized the national registry of patients with ESRD to examine causes of death in lupus nephritis, identifying

cardiovascular disease and infection as the two leading causes of death. However, the ESRD database may not have information on lupus nephritis patients who may have died of infections or other complications prior to developing ESRD. Furthermore, there are no nationwide population-based studies on causes of death in all, unselected, patients with lupus nephritis across the entire U.S. population.

Methods: We used the Center for Disease Control and Prevention's WONDER database, which compiles data on over 99% deaths from all 50 states and the District of Columbia. We used ICD-10 codes for SLE + a renal condition from the Multiple-Causes-of-Death files to obtain lupus nephritis death counts, overall and by the leading underlying causes of death. We then compared the underlying causes of death in two 10-year periods: 1999-2008 (period 1) versus 2011-2020 (period 2) using the Fisher's exact test.

Results: 4,423 and 4,225 deaths were attributed to lupus nephritis during the first and second 10-year periods, respectively. The 10 leading underlying causes of death in lupus nephritis during 1999-2020 in the decreasing order were SLE (61.5%), diseases of heart (9.7%), renal disease (5.5%), malignant neoplasms (2.2%), septicemia (2.0%), diabetes mellitus (1.6%), cerebrovascular disease (1.4%), chronic lower respiratory disease (0.9%), chronic liver disease (0.8%), and hypertension with hypertensive renal disease (0.7%). The most significant decrease was seen in acute myocardial infarction (102 deaths [2.31%] in period 1 to 45 deaths [1.07%] in period 2, $p< 0.0001$), followed by SLE (64.5% in period 1 to 59.4% in period 2, $p< 0.0001$). Diabetes mellitus (p, 0.002) and chronic ischemic heart disease (p, 0.01) also significantly decreased. However, malignant neoplasms significantly increased from 72 deaths (1.63%) in period 1 to 113 deaths (2.67%) in period 2 (p, 0.0008). Chronic lower respiratory diseases (p, 0.006), chronic obstructive pulmonary disease (p, 0.006), unintentional injuries (p, 0.007), hypertensive renal/heart disease with renal failure ($p< 0.05$), and enterocolitis due to Clostridium difficile ($p< 0.05$) also increased during period 2 compared to period 1. Infections as the underlying causes of death remained unchanged during the study period.

Conclusion: A focus on cardiovascular disease risk in lupus over the past two decades has resulted in decreasing ischemic heart disease as the underlying cause of death in lupus nephritis. However, increased cancers and respiratory diseases and persistent infections among the leading causes of death in lupus nephritis are concerning. Prospective studies are needed to verify these findings and to identify patients at high risk for these complications.

Epidemiology and Retrospective Case-Control Analysis of IIM in the US Veteran Population

Vladimir Liarski, University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic Inflammatory Myopathy (IIM) - comprising polymyositis (PM), dermatomyositis (DM), and inclusion body myositis (IBM) - is rare and difficult to study. We sought to study its' epidemiology in the US veteran population – an understudied area.

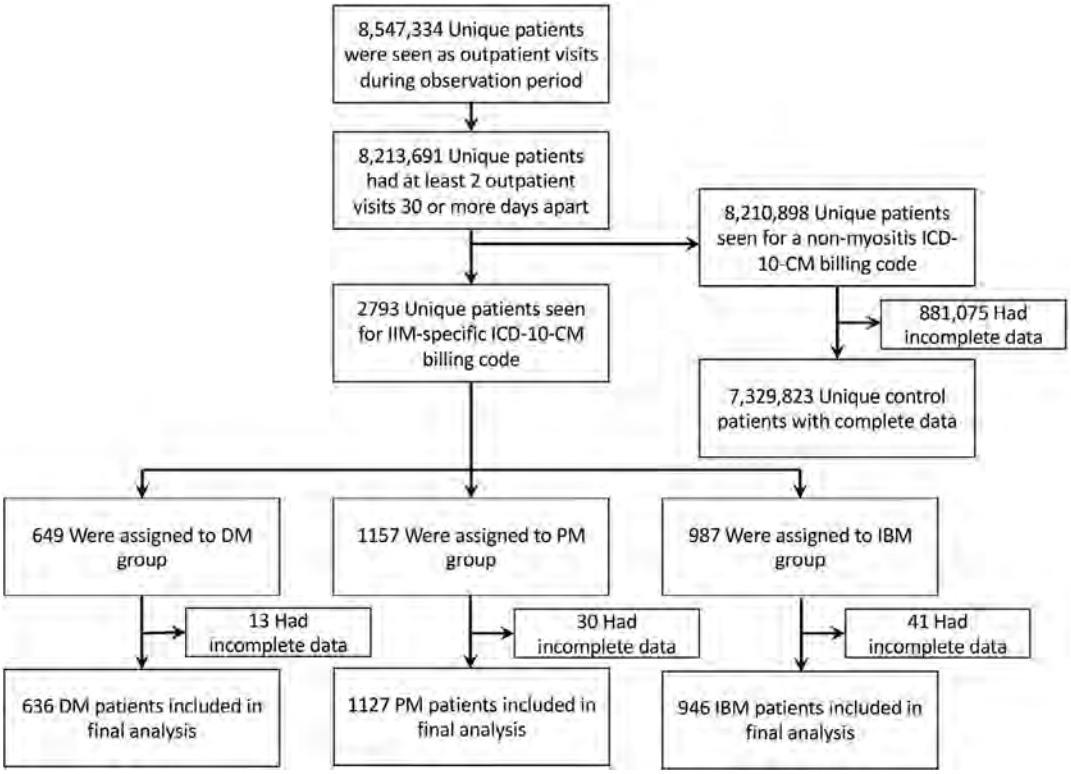

Figure 1.- Overview of study design

Table 1.- Characteristics of patients in final Idiopathic Inflammatory Myopathy cohort.

Characteristic	DM (N = 636)	PM (N = 1127)	IBM (N = 946)
Mean age of cohort (range) - yr	65.0 (27-96)	68.2 (27-104)	75.1 (33-98)
Mean age at first visit (range) – yr	58.2 (25-93)	60.9 (22-100)	69.9 (29-94)
Female sex – no. (%)	130 (20.4%)	132 (12.5%)	23 (2.4%)
Deceased during observation period – no. (%)	116 (18.2%)	307 (27.2%)	365 (38.6%)
Mean age at death (Range) – yr	73 (34-96)	74 (43-104)	77 (48-98)
Race – no. (%)			
White	423 (65.2%)	624 (53.9%)	730 (74.0%)
Black	155 (23.9%)	430 (37.2%)	156 (15.8%)
Native Hawaiian/Pacific Islander	8 (1.2%)	11 (0.9%)	4 (0.4%)
American Indian/Alaska Native	8 (1.2%)	10 (0.9%)	7 (0.7%)
Asian	10 (1.5%)	8 (0.7%)	5 (0.5%)
Other	48 (7.4%)	70 (6.1%)	56 (5.7%)
Presence of ILD – no. (%)	97 (15.2%)	178 (15.8%)	28 (3.0%)
Presence of oncological diagnosis – no. (%)	134 (21.1%)	220 (19.5%)	189 (20.0%)

Table 1. Characteristics of patients in final Idiopathic Inflammatory Myopathy cohort.

Methods: We conducted a retrospective case-control analysis using the Veterans Affairs Corporate Data Warehouse. Cases were identified based on billing data: adults aged 18 to 110, seen between 1/1/2016 and 12/31/2021, with a minimum of two visits denoted by an IIM-specific ICD-10 code. Interstitial Lung Disease (ILD) and oncological comorbidities were identified similarly. DM, PM, and IBM cohorts were randomly matched with age-, sex-, and ethnicity-paired controls on a 3:1 basis. The primary outcome examined was all-cause mortality with secondary outcomes examining the impact of age, sex, and presence of ILD and oncological diagnoses on IIM patient survival.

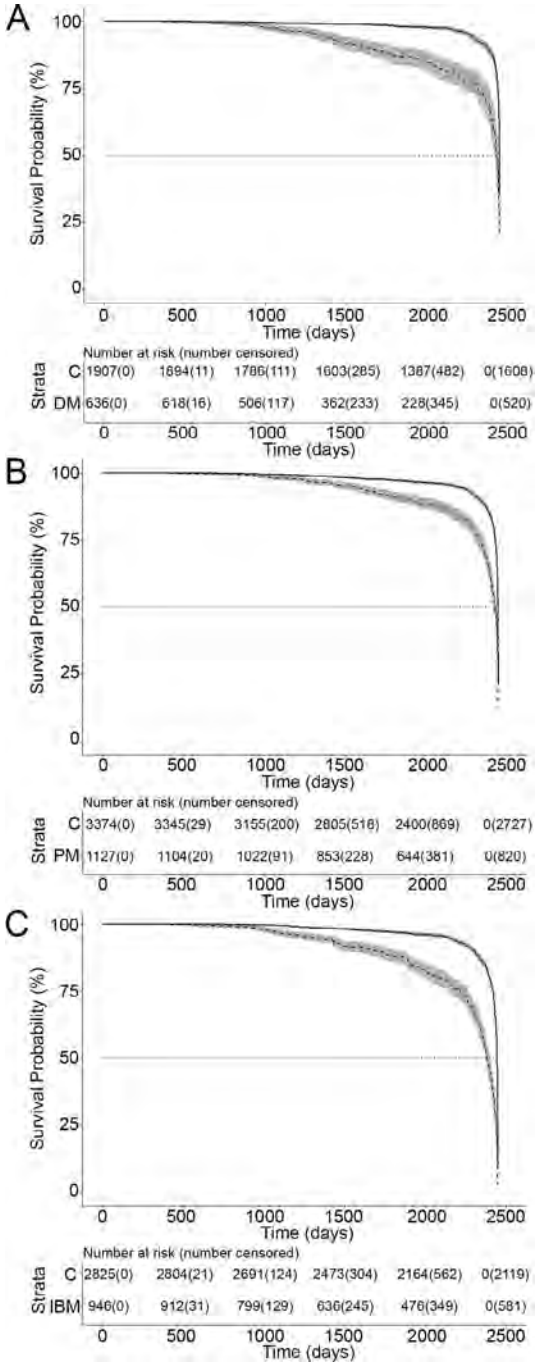

Figure 2.- Kaplan Meier survival plots for dermatomyositis (a), polymyositis (b), and inclusion body myositis (c) matched patient cohort. (a-c) Mean control (solid line) and myositis (dashed line) patient survival, based on all-cause mortality, plotted as labelled with 95% confidence intervals in gray.

Results: Complete data was available for 636 DM, 1127 PM, and 946 IBM patients (**Figure 1**). Calculated prevalence was 79.0 cases of DM/million, 140.9 cases of PM/million, and 120.2 cases of IBM/million. Male:female ratios were lowest for DM at 0.4, intermediate for PM at 0.8, and highest for IBM at 4.2. IBM was the highest prevalence IIM in veterans over 65 (198.5 cases/million). Age-adjusted prevalence was 65.7 cases of DM/million, 91.7 cases of PM/million, and 45.1 cases of IBM/million for individuals over 15. Estimated average annual incidence was 11.8 cases/million for DM (range: 6.1 - 15.4), 13.3 cases/million for PM (range: 4.4 – 20.1), and 12.9 cases/million for IBM (range: 7.4 – 17.7).

The mean age of DM patients (65.0±13.5 years) was similar to the non-IIM VA population (65.1±17.2 years, $p = 0.15$), while the mean ages of PM (68.2±11.9 years) and IBM (75.1±8.9 years) patients were higher ($p < 0.0001$ for both) (**Table 1**). PM had the highest proportion of Black patients (429, 37.2%), with DM (155, 23.9%) also above the non-IIM veteran population (1,296,904, 17.3%, $p < 0.0001$ for both). IBM did not show a significant difference in racial makeup (156, 15.8%, $p = 0.31$).

In terms of comorbidities, only 0.7% (51,158) of the non-IIM VA population had an Interstitial Lung Disease (ILD)-associated ICD-10 code compared to 15.2% (97) of DM, 15.4% (178) of PM, and 2.8% (28) of IBM patients ($p < 0.0001$ for 3 pairwise comparisons). 12.6% (940,933) of non-IIM veterans had an oncological diagnosis, which was significantly lower than rates seen in either IIM group (134, 21.1%; 220, 19.5%; and 189, 20.0% for DM, PM, and IBM respectively, $p < 0.0001$ for 3 pairwise comparisons).

Mean (±SD) survival was 1614.2±620.9 for DM ($p < 0.0001$); 1901.3±563.4 for PM ($p < 0.0001$); and 1789.8±628.2 days for IBM ($p < 0.0001$) versus matched controls (**Figure 2**). Male sex (HR 2.6, $p < 0.017$), older age (HR 2.2, $p < 0.001$) and concurrent oncological diagnosis (HR 2.3, $p < 0.001$) were associated with worse survival in DM while older age was the only factor for PM (HR 2.44, $p < 0.001$) and IBM (HR 1.59, $p < 0.001$) patients. COVID infection or suspected infection had no statistical effect on survival.

Conclusion: All IIMs exhibited decreased survival compared to matched controls. Male sex and concurrent oncological diagnosis were unique poor prognostic factors in DM.

Disclosure: V. Liarski: None.

Time Trends, Cumulative Incidence, and Impact on Survival of Interstitial Lung Disease in Systemic Sclerosis: Results from a Population-based Cohort Study

Anukul Karn[1], Sara Achenbach[2], Alicia Hinze[3], Cynthia Crowson[1] and Ashima Makol[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, MN, Rochester, MN, [3]Mayo Clinic - Rochester, MN, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiopulmonary complications are the number one cause of mortality in Systemic sclerosis (SSc). We studied the prevalence, cumulative incidence, predictors and impact of interstitial lung disease (ILD) on survival in a recent inception cohort of SSc patients.

Methods: A comprehensive retrospective review of individual medical records was done to assemble a population-based cohort of incident SSc patients from January 1, 2010, through December 31, 2020, who were followed until death, migration from the geographic area, or September 30, 2022. ILD at baseline was identified on high-resolution CT scan, and cumulative incidence of ILD adjusting for competing risk of death was estimated. Cox models were used to examine risk factors for ILD and its time-dependent impact on survival.

Results: We identified 146 incident SSc patients (81% F, 90% Caucasian, mean age = 59.5 ± 13.6 y, mean follow-up 4.8 ± 3.1 y) over the 11-y period. Majority had limited cutaneous SSc (122), followed by diffuse cutaneous SSc (18), and SSc sine scleroderma (6). Anti-nuclear antibody (ANA) was positive in 94% of (134/143) patients, anticentromere in 53%

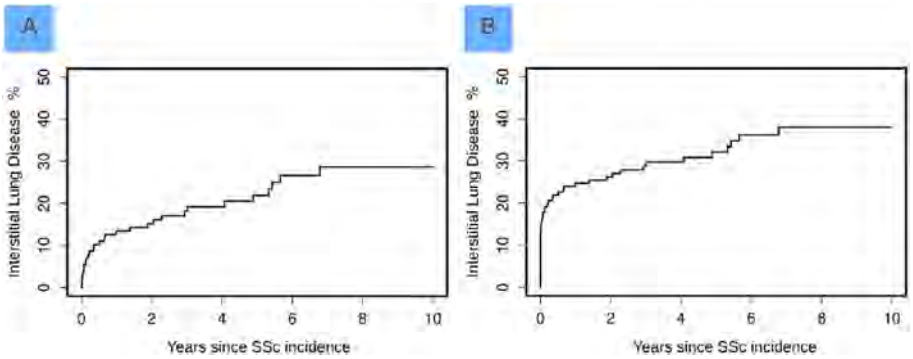

Figure 1. a. Cumulative incidence of Interstitial lung disease (ILD) adjusting for competing risk of death (Excluding 19 patients with ILD prior to index). Twenty-nine of the remaining 127 Systemic sclerosis (SSc) cases had ILD following index date. b. Cumulative incidence of ILD adjusting for competing risk of death (Including 19 patients with ILD prior to index and 29 patients with ILD following index)

Table 1. Risk factors for ILD in SSc (Age-Adjusted Cox Models with Time to ILD following diagnosis)

Parameter	Total (ILD)	HR (95% CI)	p-value
Age per 10-year increase	127 (29)	0.81 (0.62-1.06)	0.13
Male gender	127 (29)	1.24 (0.50-3.05)	0.64
Year of diagnosis	127 (29)	1.05 (0.92-1.19)	0.48
Ever smoked	127 (29)	1.53 (0.73-3.20)	0.26
Current smoker	127 (29)	0.82 (0.19-3.50)	0.79
Body mass index ≥ 30	127 (29)	1.02 (0.98-1.07)	0.33
Skin Involvement (Reference = Limited)	127 (29)		
Skin Involvement = Diffuse		2.15 (0.91-5.07)	0.08
Skin Involvement = Sine scleroderma		--	0.99
Anti-centromere	125 (29)	0.37 (0.17-0.80)	0.01
Anti Scl-70	127 (29)	4.36 (1.72-11.1)	0.002
Anti RNA polymerase III	123 (29)	1.03 (0.39-2.72)	0.95
Anti-nuclear antibody by any method	125 (29)	2.07 (0.28-15.25)	0.48
Nailfold capillary abnormalities (TD)	94 (22)	1.57 (0.64-3.85)	0.33
Telangiectasia (TD)	127 (29)	0.99 (0.47-2.08)	0.98
Digital ulcers/pitting (TD)	127 (29)	2.21 (1.05-4.66)	0.04
Pulmonary arterial hypertension[1] (TD)	127 (29)	5.48 (2.18-13.77)	<0.001
Raynaud's (TD)	127 (29)	1.29 (0.17-9.60)	0.80
Calcinosis (TD)	127 (29)	0.95 (0.22-4.08)	0.95
Scleroderma renal crisis (TD)	127 (29)	2.30 (0.69-7.67)	0.16

*Count of time dependent (TD) variables is at any time point
Interstitial lung disease (ILD), Systemic Sclerosis (SSc)
[1]Pulmonary arterial hypertension: defined based on right heart catheterization with mean pulmonary artery pressure >20 mmHg, or echocardiogram criteria of right ventricular systolic pressure >45 mmHg and tricuspid regurgitant velocity >3.8 m/s.

(77/144), anti-Scl 70 in 11% (16/146), and anti-RNA polymerase III in 18% (25/142). Of 146 patients, 19 (13%) had ILD prior to SSc diagnosis, and 29 (out of remaining 127) developed ILD during follow-up. The cumulative incidence of ILD in SSc (excluding 19 cases with ILD prior to index date) was highest in the initial few years after diagnosis of SSc with 13.4% (95% CI 8.6%-21.0%) at 1 y, 21.9% (95% CI 15.3%-31.3%) at 5 y, and 28.7% (95% CI 20.5-40.3%) at 10 y. Overall, the cumulative incidence of ILD in SSc (including 19 cases with ILD prior to index date was 24.7% (95% CI 18.6-32.8%) at 1 y, 32.1% (95% CI 24.9-41.2%) at 5 y, and 38.0% (95% CI 29.8-48.6%) at 10 y. (**Figure 1**)

Age, gender, and smoking did not affect the risk for the development of ILD in patients with SSc. A higher risk was associated with digital ulcers/pitting (HR 2.21, 95% CI 1.05-4.66; p=0.04) and a trend towards higher risk with diffuse skin involvement (HR 2.15, 95% CI 0.91-5.07; p=0.08). Anti-centromere antibody was a protective factor (HR 0.37, 95% CI 0.17-0.80; p=0.01), while anti-Scl 70 strongly increased the risk for ILD (HR 4.36, 95% CI 1.72-11.1; p=0.002). Pulmonary arterial hypertension (PAH) was also associated with a significantly increased risk of ILD (HR 5.48; 95%CI 2.18-13.77). (**Table 1**)

ILD increased the risk of overall mortality in patients with SSc (HR 3.65, 95% CI 1.72-7.71 adjusted for age, sex and index year). This higher but non-statistically significant risk persisted after adjusting for age, sex, and PAH (as a time-dependent variable) (HR 1.96, 95% CI 0.89-4.33).

Conclusion: ILD is a common visceral complication of SSc and a major contributor to morbidity and mortality in these patients. While it is known to be a complication of 'early' disease, a substantial portion of patients continue to develop ILD between 5-10 years after disease onset. ILD confers a nearly 4-fold higher risk of overall mortality in SSc patients, which may be complicated by co-existing PAH. These findings highlight the importance of thorough pulmonary evaluation not only at diagnosis and in the early years of disease but also during long-term follow-up in SSc patients.

Incidence, Trends, and Determinants of Multimorbidity in Systemic Sclerosis: Data from a Population-based Cohort

Anukul Karn[1], Sara Achenbach[2], Alicia Hinze[3], Cynthia Crowson[1] and Ashima Makol[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, MN, Rochester, MN, [3]Mayo Clinic - Rochester, MN, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the burden, longitudinal trends, and drivers of multimorbidity (MM; the presence of ≥2 morbidities) in patients with Systemic Sclerosis (SSc) vs. age- and sex-matched non-SSc comparators in a community-based incident cohort.

Methods: A population-based cohort of incident SSc patients from Jan 1, 1980, to Dec 31, 2020, were identified and compared to age- and sex-matched comparators (2:1) from the same population. They were followed till death, migration from the geographic area, or Sept. 30, 2022. Data on 21 morbidities identified by the US Department of Health and Human

Table 1. Time to multimorbidity (at follow-up)

Event type	SSc (events)	Non SSc (events)	HR (95% CI)	p-value
DHHS[1]				
Hypertension	116 (48)	269 (104)	1.45 (1.01-2.08)	0.04
Congestive heart failure	180 (44)	398 (29)	3.85 (2.35-6.31)	<0.001
Coronary artery disease	172 (31)	381 (44)	1.91 (1.17-3.12)	0.01
Arrhythmia	154 (71)	369 (113)	1.88 (1.38-2.56)	<0.001
Stroke	185 (26)	397 (32)	2.01 (1.15-3.50)	0.01
Arthritis	125 (58)	318 (112)	1.50 (1.08-2.08)	0.02
Chronic kidney disease	177 (59)	383 (69)	1.83 (1.28-2.63)	0.001

Chronic Pulmonary Disease	153 (52)	357 (47)	3.03 (2.00-4.60)	<0.001
Any renal disease	180 (49)	394 (50)	2.34 (1.55-3.52)	<0.001
Any liver disease	180 (23)	401 (23)	2.25 (1.22-4.16)	0.01
Charlson-MM2+	149 (88)	366 (100)	3.60 (2.67-4.86)	<0.001
Charlson-MM5+	186 (27)	405 (31)	1.44 (0.84-2.47)	0.19

[1]The following DHHS comorbidities did not reach statistical significance: hyperlipidemia, asthma, cancer, dementia, depression, diabetes, substance abuse, and anxiety.
[2]The following Charlson comorbidities did not reach statistical significance: myocardial infarction, dementia, diabetes, and cancer.

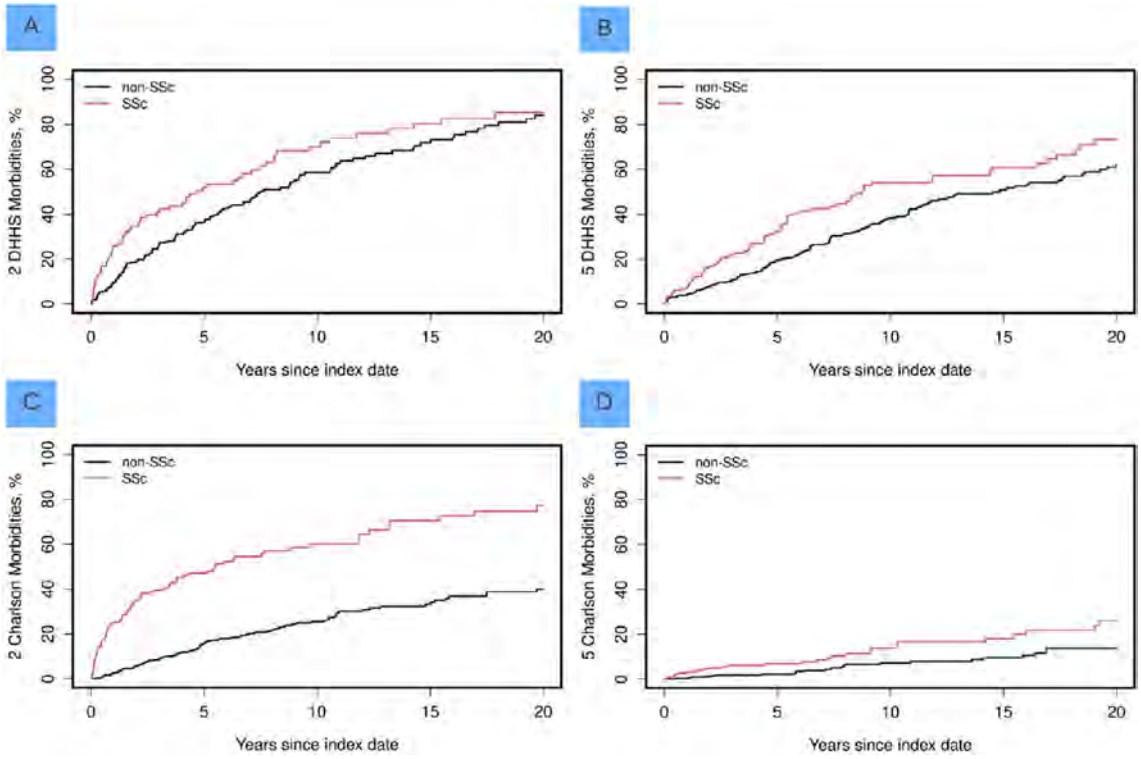

Figure 1. A and B. Cumulative incidence for time to DHHS-MM2+ and DHHS-MM5+ morbidity events adjusted for the competing risk for death. C and D. Cumulative incidence for time to CCI-MM2+ and CCI-MM5+ events adjusted for the competing risk of death. Abbreviations: DHHS (Department of Health and Human Services), MM (Multimorbidity), CCI (Charlson comorbidity index), SSc (Systemic Sclerosis)

Services (DHHS) and 13 morbidities in the Charlson Comorbidity Index (CCI) was retrieved. Cumulative incidence of MM (MM2+) or substantial MM (MM5+; ≥ 5 morbidities) adjusting for the competing risk of death was estimated. Cox models adjusted for age, sex, index year and morbidity count at index date were used to compare cases and comparators. Patients with < 1 year of prior medical history and who met the criteria of event type before the index date were excluded.

Results: We included 189 SSc patients and 408 comparators (mean age 58.2 y, 85% female, 91% white).

The prevalence of cardiac arrhythmia (19% vs 10%, p=0.002), arthritis (34% vs 22%, p=0.002), COPD (12% vs 5%, p=0.007), MI (3% vs 0%, p=0.023), peripheral vascular disease (33% vs 4%, p< 0.001), chronic pulmonary disease (19% vs 13%, p=0.035), and any liver disease (5% vs 2%, p=0.032) were higher at index date, but the prevalence of hyperlipidemia (30% vs 39%, p=0.043) was lower in SSc.

During a mean length of follow-up of 9.7 y (SD 8.7) for non-SSc and 8.5 y (SD 8.0) for SSc, the development of hypertension (HR 1.45; 95% CI 1.01-2.08), congestive heart failure (DHHS: HR 3.85, 95% CI 2.35-6.31; CCI: HR 3.86, 95% CI 2.41-6.18), coronary artery disease (HR 1.91, 95% CI 1.17-3.12), arrhythmia (HR 1.88, 95% CI 1.38-2.56), stroke (HR 2.01, 95% CI 1.15-3.50), arthritis (HR 1.50, 95% CI 1.08-2.08), chronic kidney disease (HR 1.83, 95% CI 1.28-2.63), COPD (HR 2.00, 95% CI 1.24-3.24), osteoporosis (HR 2.13, 95% CI 1.32-3.43), peripheral vascular disease (HR 5.65, 95% CI 3.85-8.31), cerebrovascular disease (HR 2.25, 95% CI 1.31-3.85), chronic pulmonary disease (HR 3.03, 95% CI 2.00-4.60), any renal disease (HR 2.34, 95% CI 1.55-3.52), and any liver disease (HR 2.25, 95% CI 1.22-4.16) were significantly higher in SSc when compared to non-SSc. (**Table 1**)

The risk of development of DHHS MM2+, DHHS MM5+, and CCI-MM2+ was significantly higher in SSc patients vs non-SSc, but CCI-MM5+ was statistically insignificant after adjusting for baseline morbidity count. (**Figure 1 and Table 1**)

Conclusion: There is a high burden of MM and substantial MM in SSc patients at baseline and during the disease course. Witha1.5-4-fold risk of development of cardiopulmonary diseases, 2-fold risk of neurological, renal and liver diseases, and 6-fold risk of peripheral vascular disease in SSc patients during follow-up, there is an urgent need for systematic assessment and management of multimorbidity to reduce healthcare burden and improve prognosis in this population.

Abstract Number: 0129

Rising Incidence and High Mortality of Systemic Sclerosis: A Population-based Cohort Study (2010-2020)

Anukul Karn[1], Sara Achenbach[2], Alicia Hinze[3], Cynthia Crowson[1] and Ashima Makol[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, MN, Rochester, MN, [3]Mayo Clinic - Rochester, MN, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a rare chronic inflammatory disease characterized by immune-mediated dysfunction, vasculopathy and widespread internal organ fibrosis; and the highest case fatality among all rheumatic diseases. We aimed to study trends in incidence and mortality in a physician-diagnosed population-based cohort of SSc patients.

Methods: An inception cohort of incident SSc patients aged ≥18 years with a confirmed physician diagnosis of SSc made by a rheumatologist (supported by compatible clinical presentation, autoantibody testing, and/or appropriate imaging) between Jan 1, 2010, to Dec 31, 2020, was identified based on comprehensive individual medical record review. Fulfillment

Table 1. Clinical Characteristics of Incident Systemic Sclerosis (2010-2020)

Clinical characteristic	Total (N=146)
Mean Age on Index Date, years	59.5 ± 13.6
Sex, Female	118 (81%)
Ethnicity	
Caucasian	131 (90%)
African American	4 (3%)
Hispanic	6 (4%)
Asian	1 (1%)
Others	4 (3%)
Obese (Body mass index≥30 kg/m^2)	49 (34%)
Smoking Status	
Never	80 (55%)
Ex smoker	54 (37%)
Current smoker	12 (8%)
Cutaneous phenotype	
Limited	122 (84%)
Diffuse	18 (12%)
Sine scleroderma	6 (4%)
Systemic Sclerosis related antibodies	
Anticentromere	77/144 (53%)
Anti Scl-70	16/146 (11%)
Anti RNA polymerase III	25/142 (18%)
Raynaud's phenomenon	135 (92%)
Positive Anti-nuclear antibody	134/143 (94%)
Sclerodactyly	80 (55%)
Telangiectasia	69 (47%)
Nailfold capillary abnormalities (37 not done)	63/109 (58%)
Digital ulcers/pitting scars	35 (24%)
Interstitial Lung Disease [1]	19 (13%)
Pulmonary Arterial Hypertension [2]	10 (7%)
Myositis	7 (5%)
Calcinosis*	23 (16%) (7/23 were at baseline)
Inflammatory arthritis*	58 (40%) (32/58 were at baseline)
GI dysmotility*	49 (34%) (15/49 were at baseline)
Scleroderma renal crisis *	11 (8%) (5/11 were at baseline)

*Features appearing at any time during disease course.

[1] Interstitial lung disease: defined based on characteristic findings on high-resolution CT scan of chest.

[2] Pulmonary arterial hypertension: defined based on right heart catheterization with mean pulmonary artery pressure >20 mmHg, or echocardiogram criteria of right ventricular systolic pressure >45 mmHg and tricuspid regurgitant velocity >3.8 m/s

of ACR/EULAR 2013 criteria was ascertained. Patients were followed until death, migration from the geographic area, or Sept. 30, 2022. Incidence rates were age- and sex-adjusted to the 2020 US white population. Survival rates were compared with expected rates in the general population.

Results: A total of 146 incident SSc patients (81% female, 90% White, mean age 59.5 ± 13.6 y) were identified between 2010-2020. A 138 (94.52%) met the classification criteria for SSc. The overall age- and sex-adjusted annual incidence was 23.4 (95% confidence interval = 19.6–27.3) per million population, with a significant increase in incidence over time [SIR (Standardized Incidence Ratio) per 10-year increase=1.92, 95% CI = (1.67-2.20)]. Age-adjusted incidence was 36.7 (95% CI = 30.0-43.3) per million for females and 9.5 (95% CI = 6.0-13.0) per million for males. Thirty patients died during the study period. Patients with SSc had significantly higher mortality compared to the general population, with a standardized mortality ratio of 3.46 (95% confidence interval = 2.34-4.95). (**Table 1 and Figure 1**)

Age, smoking (current and ever), diffuse cutaneous disease, telangiectasias, digital ulcers/pitting and significant internal organ involvement (interstitial lung disease, pulmonary arterial hypertension, renal crisis) were associated with a higher mortality risk. (**Table 2**)

Table 2. Age-Adjusted Cox Models: Risk factors for mortality in SSc (2010-2020)

Parameter	Count of patients with risk factor*	Total (Deaths)	HR (95% CI)	p-value
Age per 10-year increase	--	146 (30)	1.71 (1.21-2.41)	0.002
Male gender	28	146 (30)	1.68 (0.74-3.82)	0.22
Year of diagnosis	--	146 (30)	0.95 (0.82-1.10)	0.51
Ever smoked	66	146 (30)	2.93 (1.33-6.46)	0.008
Current smoker	12	146 (30)	5.23 (2.03-13.43)	<0.001
Body mass index	--	146 (30)	0.98 (0.93-1.04)	0.50
Skin Involvement (Reference = Limited)		146 (30)		
Skin Involvement = Diffuse	18		2.41 (1.01-5.78)	0.05
Skin Involvement = Sine scleroderma	6		1.41 (0.19-10.75)	0.74
Abnormal Nailfold capillaries (TD)	84	109 (15)	2.48 (0.68-8.98)	0.17
Telangiectasia (TD)	100	146 (30)	3.47 (1.41-8.54)	0.007
Digital ulcers or fingertip scars (TD)	54	146 (30)	3.14 (1.51-6.55)	0.002
PAH (TD)	44	146 (30)	7.25 (3.33-15.8)	<0.001
ILD (TD)	48	146 (30)	3.41 (1.66-7.00)	<0.001
Raynaud's (TD)	141	146 (30)	0.91 (0.12-6.89)	0.93
Scleroderma renal crisis (TD)	11	146 (30)	4.00 (1.70-9.38)	0.001

*Count of time dependent (TD) variables is at any time point
PAH (pulmonary arterial hypertension), ILD (Interstitial lung disease)

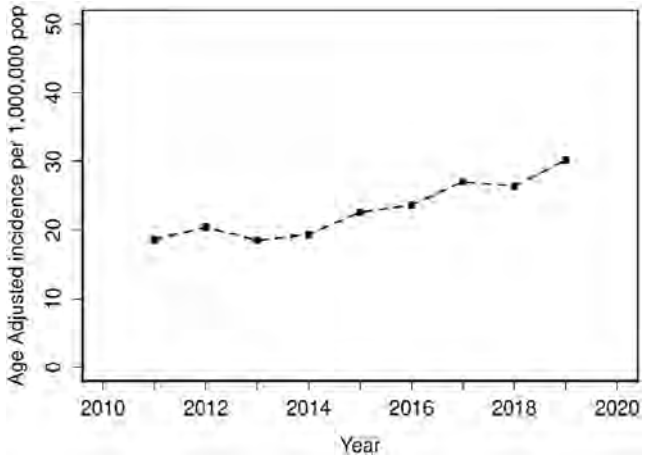

Figure 1. Incidence of Systemic Sclerosis (2010-2020) using 3 year moving averages

Conclusion: In this population-based cohort, the incidence of SSc has been rising, by nearly 2-fold in the last decade. The reasons for this need better understanding but could in part be explained by better recognition of SSc with newer classification criteria. The survival in SSc remains poor, with more than 3-fold higher mortality than the general population with no evidence of improvement over time, highlighting an urgent need for better therapeutics to modify disease activity and course in this morbid disease.

Association of HLA-DRB1 Alleles with Coronary Artery Calcium, Abdominal Aortic Calcium, and Carotid Intima-media Thickness in a Multi-ethnic Community-living Population

Manmeet Kaur[1], Ronit Katz[2], Michael H. Criqui[1], Maripat Corr[3], Wendy S. Post[4], Matthew Budoff[5], Gerald P. Morris[3] and Jan M. Hughes-Austin[3], [1]University of California San Diego, San Diego, CA, [2]University of Washington, Seattle, WA, [3]University of California San Diego, La Jolla, CA, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]Harbor-UCLA Medical Center, Torrance, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Human leukocyte antigen (HLA) DRB1 alleles with specific common amino acids referred to as the shared epitope (SE) have been linked to endothelial dysfunction in patients with rheumatoid arthritis (RA). However, less is known about the HLA-DRB1 alleles with endothelial dysfunction and subclinical cardiovascular disease (CVD) in people without RA. We aimed to determine associations betweenHLA-DRB1 SE alleles (04:04, 04:05, 04:01, 04:08, 01:01, 14:02, 10:01, 03:01, 03:02) and coronary artery calcium (CAC), abdominal aortic calcium (AAC), and carotid intima-media thickness (cIMT) in a multi-ethnic community-living population.

	Frequency	Coronary artery calcium				Abdominal aortic calcium				Carotid intima-media thickness	
	N (%)	RR (CAC>0)	95% CI	RD	95% CI	RR (AAC>0)	95% CI	RD	95% CI	RD	95% CI
Shared Epitope[1]											
SE +/+ vs SE -/-	75 (8%)	1.19	0.98, 1.43	1.33	0.79, 2.23	1.06	0.93, 1.21	1.02	0.92, 1.14	1.02	0.98, 1.07

Footnotes:
[1] Total frequense for SE +/- : 521 (55%)
Legend:
Bolded in table represents statistically significant
RR = relative risk
RD = relative difference in Agatston score per increment in risk factor estimated from linear regression with Ln(Agatston score) as the dependent variable, adjusted for all risk factors listed . For example RD of 1.50 represents a 50% increase.

Methods: Within the Multi-Ethnic Study of Atherosclerosis (MESA), a prospective cohort study designed to determine risk factors and progression of subclinical and clinical CVD, a subset of 955 participants who completed the AAC ancillary study and had complete measures of HLA typing and cardiac imaging were evaluated. We defined shared epitope positive, SE(+) for genotypes with the HLA-DRB1 SE alleles listed above; and evaluated associations of SE positivity and each of the individual SE alleles with CAC, AAC, and cIMT. CAC and AAC were evaluated as present vs. absent and as ln(Agatston score) in those with CAC and ACC > 0. cIMT was evaluated in millimeters. We calculated the relative risk (RR) for prevalence of CAC and AAC; and relative difference (RD) for continuous measures of CAC, AAC, and cIMT using linear regression. Our analysis was adjusted for age, sex, race/ethnicity, diabetes mellitus, systolic blood pressure, current smoking, eGFR, current use of anti-hypertensive medications, non-steroidal anti-inflammatory drugs, current use of lipid lowering medications, and IL-6.

Results: Among the 955 MESA participants, 46% were SE(+)—38% carried a single allele and 8% carried two double alleles. Average age was 60±9, 47% were women, and 51% were White, 9% were Asian, 16% were Black, and 24% were Hispanic/Latino. Age, sex, blood pressure, cholesterol, and inflammatory markers (CRP, TNF-α, IL 6), were similar between SE(+) and SE(-) participants, but racial distributions differed where SE(+) had a higher proportion of White (51% vs 38%) and lower proportion of Asian (9% vs 17%) and Black (16% vs 21%) participants. SE positivity was not significantly associated with a higher risk of CAC, AAC, or cIMT. However, individual allele 10:01 demonstrated 2.63-fold higher risk for CAC (95% CI: 1.17-5.99); 14:02 demonstrated 42% higher risk for AAC, (95% CI: 1.17-1.74); and 04:05 demonstrated 24% lower risk for AAC (95% CI: 0.58-0.99).

Conclusion: SE positivity was not associated with higher risk of CAC, AAC, or cIMT in a multi-ethnic community-living population. Alleles 10:01 and 14:02 were associated with a higher risk for CAC and AAC, respectively, and 04:05 with lower risk for AAC.

Associations of HLA-DRB1 alleles with coronary artery calcium, abdominal aortic calcium, and carotid intima media thickness in the Multi-Ethnic Study of Atherosclerosis

Identifying Antinuclear Antibody Positive Individuals at Risk for Systemic Autoimmune Disease: Development and Validation of a Real-Time Risk Model

April Barnado, Ryan Moore, Hank Domenico, Sarah Green, Alex Camai, Ashley Suh, Bryan Han, Katherine Walker, Audrey Anderson, Lannawill Caruth, Anish Katta, Allison McCoy and Daniel W. Byrne, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 20% of the general population has a positive ANA without having autoimmune disease. Currently, no tools exist to help clinicians interpret the significance of a positive ANA. We developed and validated a risk model that uses readily available data in the electronic health record (EHR) to identify positive ANA individuals at risk for developing systemic autoimmune disease.

Methods: Using a large de-identified EHR, we randomly selected 2000 individuals with a positive ANA (titer ≥ 1:80) to perform chart review to determine if they were diagnosed with a systemic autoimmune disease by a rheumatologist. Non-rheumatic conditions such as autoimmune thyroiditis and autoimmune hepatitis were not counted as cases. Patients with prior diagnoses of systemic autoimmune disease at time of first positive ANA were excluded. *A priori,* we selected variables for the risk model including demographics, billing codes, and labs, previously identified in lupus risk models. We performed logistic regression using the following predictors: age at time of first positive ANA, sex, ANA titer, presence of another autoantibody (i.e. dsDNA), platelet count, and billing codes. A random selection of individuals was set aside for model validation. We assessed model performance in the training and validation sets using c-statistic and calibration curves.

Table 1. Characteristics of positive ANA individuals with vs. without systemic autoimmune disease in the training set.

Characteristics	No systemic autoimmune disease n = 878	Systemic autoimmune disease n = 152	*p* value
Age at positive ANA, years, mean ± SD	47.9 ± 19.3	41.8 ± 21.5	**0.003**
Race % (n) White Black Asian Native American Other	 85% (680) 12% (94) 2% (16) 0.1% (1) 1% (10)	 85% (127) 13% (19) 0% (0) 1% (1) 1% (1)	 0.26
Ethnicity Hispanic	 4% (30)	 1% (2)	 0.13
Gender Female Male	 70% (612) 30% (266)	 84% (127) 16% (25)	 **< 0.001**
ANA titer 1:80 ≥ 1:160	 21% (186) 79% (692)	 11% (16) 90% (136)	 **0.002**
White blood cell count K/uL, mean ± SD	 6.9 ± 3.4	 7.1 ± 3.2	 0.49
Platelet count K/uL, mean ± SD	 229 ± 96	 274 ± 113	 **< 0.001**
Serum creatinine mg/dL, mean ± SD	 1.2 ± 1.0	 0.9 ± 0.6	 **< 0.001**
Ever present autoantibody (i.e. dsDNA, SSA) Yes	 9% (78)	 51% (77)	 **< 0.001**
Total any billing codes, mean ± SD **Count of specific billing codes** (range: 0-9)	3.2 ± 6.2 0.6 ± 0.8	7.3 ± 4.3 0.9 ± 0.9	**0.02** **< 0.001**

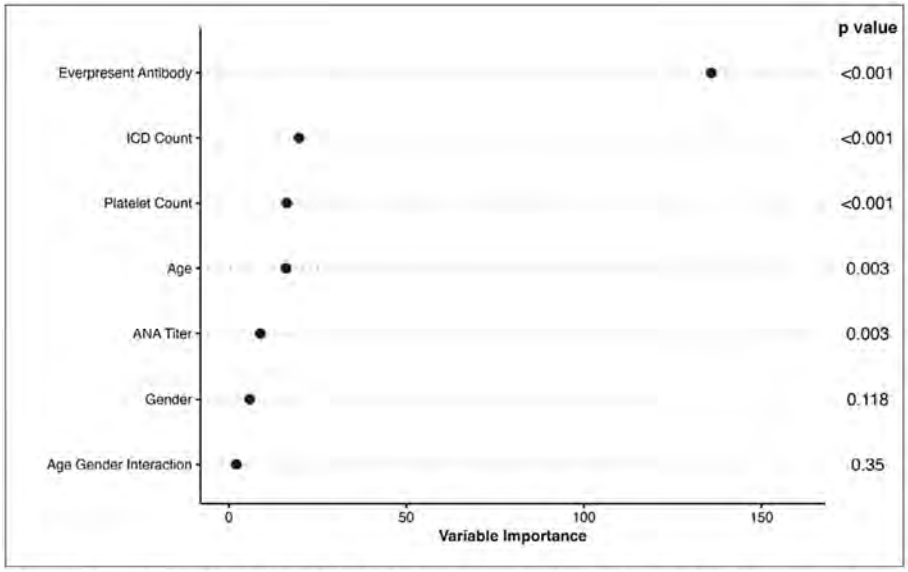

Figure 1. Importance of Variables in ANA Risk Model. The list of variables in the final ANA risk model are shown to the left with p values to the right. The x axis shows variable importance using a Wald statistic. Ever present antibody refers to having a disease-specific autoantibody such as a rheumatoid factor or dsDNA. ICD count refers to billing code category count that ranges from 0 to 9.

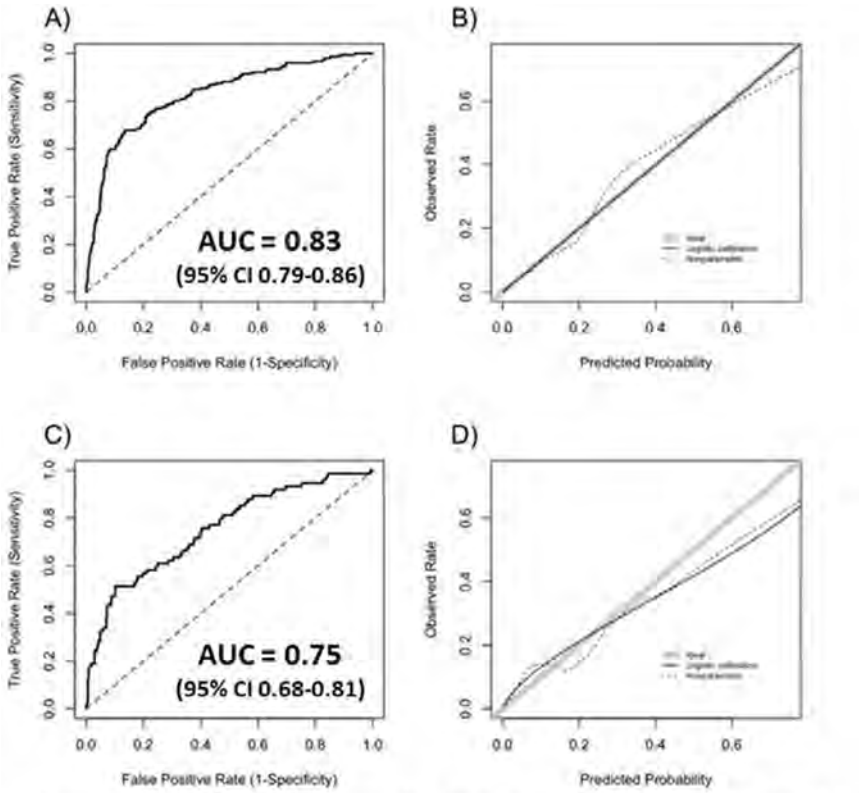

Figure 2. Model performance for training and validation sets. (A) shows ROC for the training set with an AUC 0.83 (95% CI 0.79-0.86). (B) shows the calibration curve with a slope of 1 and intercept of 0 for the training set. Slopes that approach 1, as shown by the shaded grey line, demonstrate ideal calibration, agreement between predicted risk for systemic autoimmune disease and observed rate. (C) shows ROC for the validation set with an AUC 0.75 (95% CI 0.68-0.81). (D) shows the calibration curve for the validation set. Calibration slope was equal to 0.71 and intercept was equal to 0.08.

Results: We assembled training (n = 1030) and validation (n = 449) sets with 15% (n = 152) and 16% (n = 74) having systemic autoimmune disease, respectively. The most frequent systemic autoimmune diseases in the training set were SLE at 18% (n = 28), other at 16% (n = 24), undifferentiated connective tissue disease at 16% (n = 24), and rheumatoid arthritis at 15% (n = 22). Other consisted of psoriatic arthritis/plaque psoriasis and inflammatory bowel disease. Individuals with systemic autoimmune diseases were younger (41.8 ± 21.5 vs. 47.9 ± 19.3 years, p = 0.003), more likely to be female (84% vs. 70%, p < 0.001), have a higher ANA titer (≥1:160 vs. 1:80) (90% vs. 79%, p = 0.002), higher platelet count (274 ± 113 vs. 229 ± 96 K/uL, p < 0.001), more likely to have a disease-specific autoantibody (51% vs. 9%, p < 0.001), and a higher count of the nine billing code categories (scale 0 to 9) compared to individuals without disease (0.9 ± 0.9 vs. 0.6 ± 0.8, p < 0.001) (Table 1). No significant differences were found in race, ethnicity, or white blood cell count. The most important variables in the model included having a disease-specific autoantibody, billing code count, and platelet count (Figure 1). For the training set, model AUC was 0.83 (95% CI 0.79-0.86) with good calibration (Figure 2). For the validation set, model AUC was 0.75 (95% CI 0.68-0.81).

Conclusion: We developed and validated a risk model for systemic autoimmune disease in positive ANA individuals. The model is important because it utilizes readily available EHR data and helps risk stratify positive ANA individuals. In the setting of a national shortage of rheumatologists and frequent referrals for positive ANAs, a risk stratifying tool for positive ANA

individuals is critical. High-risk individuals could be evaluated urgently to prevent delays in diagnosis while low-risk individuals could be reassured.

Feasibility of a Real-Time Risk Model to Identify Antinuclear Antibody Positive Individuals at Risk for Systemic Autoimmune Disease

April Barnado, Ryan Moore, Hank Domenico, Sarah Green, Alex Camai, Ashley Suh, Bryan Han, Katherine Walker, Audrey Anderson, Lannawill Caruth, Anish Katta, Allison McCoy and Daniel W. Byrne, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Positive antinuclear antibodies (ANAs) cause diagnostic dilemmas for clinicians across multiple specialties. We previously developed and validated a risk model using a de-identified electronic health record (EHR) database to distinguish individuals with positive ANAs who develop systemic autoimmune diseases from individuals who do not. We assessed the feasibility of deploying the risk model in the EHR. We also examined how the model performed in individuals with different systemic autoimmune diseases.

Methods: This logistic regression model contains the following predictors: age at time of first positive ANA, sex, ANA titer, platelet count, billing codes, and presence of another autoantibody (i.e. dsDNA, SSA). The most important variable in the model was presence of another autoantibody. We applied our risk model to data extracted from our EHR-provided data warehouse (Epic Clarity) to assess feasibility of deploying the model in real-time. We calculated risk probabilities for individuals with positive ANAs from 2017-2021. This time period captured an updated ANA titer reporting to the most current data available. Additionally, we combined training (n = 1030) and validation (n = 449) sets from the de-identified EHR. We compared risk scores for individuals in each of the autoimmune disease categories and in individuals without autoimmune diseases. Risk scores are reported as medians with interquartile ranges (IQR) and compared using the Mann-Whitney U test.

Results: We assessed the risk model using Epic EHR data for all individuals with a positive ANA from 2017-2021 (n = 22,234). We observed a similar distribution of risk scores in Epic compared to our model training set that used a de-identified EHR database (Figure 1). Risk scores for positive ANA individuals with and without autoimmune diseases from the combined training and validation sets from the de-identified EHR are shown in Figure 2. Individuals with systemic lupus erythematosus (SLE) had the highest risk scores with a median of 0.481 and IQR of 0.312-0.685 followed by Rheumatoid Arthritis with 0.423 (0.144-0.582). Individuals labeled as other, with predominantly seronegative conditions, had the lowest median risk score of 0.107 (0.061-0.269). Seronegative conditions included plaque psoriasis, psoriatic arthritis, and inflammatory bowel disease. Individuals with seropositive diseases had a higher risk score compared to individuals with seronegative diseases ($p < 0.001$). For individuals without autoimmune diseases, when available alternative diagnoses were documented by rheumatologists, the most frequent diagnoses were fibromyalgia, osteoarthritis, and gout.

Conclusion: To our best knowledge, a risk model that focuses on individuals with positive ANAs and predicts risk for multiple systemic autoimmune diseases does not currently exist. We demonstrate a validated risk model that uses readily available EHR data and can be successfully deployed in the EHR. For future studies, we will assess our risk model prospectively in real-time in the EHR and its impact on time to diagnosis and treatment for autoimmune diseases.

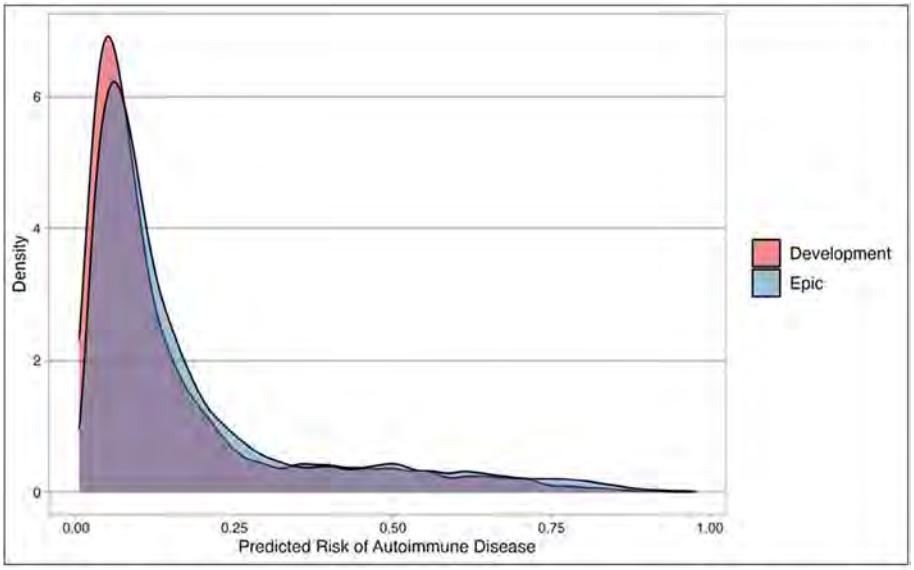

Figure 1. Distribution of risk scores in training set and in the electronic health record (EHR). The density plot shows the distribution of risk scores in our training or development set in the Synthetic Derivative, a de-identified EHR database, (pink) and in our EHR system (EPIC). X axis shows predicted risk for autoimmune disease and y axis density of data.

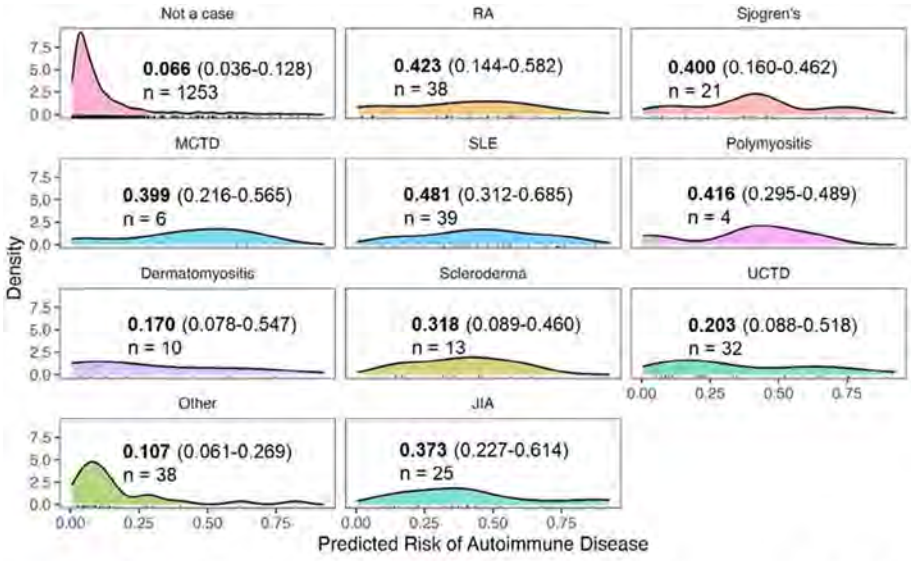

Figure 2. Distribution of risk scores by autoimmune disease type. Data is from a de-identified EHR database that includes training and validation sets. Different colors representing different autoimmune diseases are shown with the disease label above each box. For each autoimmune disease type including subjects without autoimmune disease or not a case, distribution of risk scores with a rug plot on the x axis are shown and density on y axis. Bolded numbers represent median risk score with interquartile ranges in parentheses. RA = rheumatoid arthritis, MCTD = mixed connective tissue disease, SLE = systemic lupus erythematosus, UCTD = undifferentiated connective tissue disease. Other represents seronegative conditions such as plaque psoriasis, psoriatic arthritis, and inflammatory bowel disease. JIA = juvenile idiopathic arthritis.

Background/Purpose: COVID-19 vaccines have been proven to be safe in healthy populations. However, data on delayed adverse effects (AEs) in people with autoimmune diseases (AIDs), including SLE has been lacking.

Methods: COVID-19 vaccination-related AEs reported longer than 7 days post-vaccination were assessed in the "COVID-19 Vaccination in Autoimmune Diseases 2" (COVAD-2) study in patients with SLE, rheumatic autoimmune diseases other than SLE (rAIDs), non-rheumatic autoimmune diseases (nrAIRDs), and healthy controls (HC). rAIDs included connective tissue diseases, inflammatory myopathies, and inflammatory arthritis, yet not SLE, whereas nrAIDs included inflammatory

bowel disease and multiple sclerosis, among others. The COVAD-2 study comprised 157 collaborators across 106 countries and was conducted between February and June 2022. An online survey captured self-reported data related to COVID-19 vaccination-associated AEs in SLE, AIDs, and HC. We compared COVID-19 vaccination-related delayed AEs between groups using multivariable binary regression adjusting for age, gender, and ethnicity.

Results: Among 7203 participants, 882 (12.2%) SLE, 3161 (43.9%) rAIDs, 426 (5.9%) nrAIDs, and 2734 (38%) HC were included from a total of 10 783 respondents, with 74% female and 42.2% Caucasian (Table 1). People with SLE were young and middle-aged adults [median age 39 (31–50); rAIDs, 52 (41–62); nrAIDs 43 (34–53); HC 38 (30–49)].

When compared to HC, people with SLE reported higher overall major [OR 1.6 (1.2–2.0)] and minor AEs (Table 2). SLE patients when compared to rAIDS reported more frequent episodes of severe rashes [OR 2.4 (1.3–4.2)], while compared to nrAIDs, SLE individuals reported an increased number of several minor AEs (joint pain [OR 2.4 (1.3–4.3)], fatigue [OR 2.0 (1.2–3.2)], body ache [OR 2.1 (1.2–3.7)]), and hospitalization [OR 2.3 (1.1–4.9)].

Table 3. Effects of COVID-19 vaccination in patients with Systemic Lupus Erythematosus (SLE) and no autoimmune comorbidities vs SLE with rheumatic autoimmune disease (rAIDs). Factors included as covariates in multivariable binary logistic regression analysis included age, sex, and ethnicity.

Vaccination with ChadOx1 nCOV-19 (Oxford/ AstraZeneca) in SLE patients led to a higher frequency in the incidence of diarrhea compared to other vaccines [OR 2.6 (1.1 – 6.2)], whereas the Moderna vaccine was associated with increased hospitalization frequencies [OR 3.0 (1.6–5.6)].

Patients with active versus non-active SLE reported similar frequencies of COVID-19 vaccine-related delayed minor AEs [17.5% versus 17.6%; OR 1.1 (0.8–1.6)]. SLE patients without autoimmune comorbidities reported fewer major and minor AEs compared to SLE patients with other concurrent rAIDs (Table 3). People with SLE and mental health disorders reported a higher frequency of severe rash [OR 3.2 (1.3–7.5)] and headache [OR 2.2 (1.3–3.6)].

Conclusion: COVID-19 vaccination is linked with increased risks of delayed AEs in patients with SLE compared to HC. Co-existence of rAIDs other than SLE yielded an increased risk for delayed AEs. By contrast, the degree of disease activity did not appear to have an impact.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic rheumatic diseases (SRDs) are complex multi-organ immune-mediated disorders that arise from the interaction of environmental exposures in genetically predisposed individuals. Stressful life events have been associated with disease flares and progression, but their impact on SRD development is unclear. This study explored the association between life events, psychosocial stress, and the development of SRD in adult and pediatric siblings discordant for SRDs.

Methods: Life events data from the NIEHS Study of Twins or Siblings Discordant for SRDs was examined in 96 Adults, 129 Children (YC, 1-11 years), and 41 Teen (12-17 years) Probands within 5 years of diagnosis of one of four SRDs, and in their same gender unaffected Siblings (SIBs) and Healthy Controls (HCs), within 5 years of Probands' ages. Life events in the year prior to SRD diagnosis were queried using validated questionnaires, adapted from Paykel's List of Recent Life Events for adults and the Adolescent Perceived Event Scale for YC and Teens. Life events were categorized and rated by

Table 1. Life events questionnaires with scoring system and scale ratings by age group.

Questionnaire	Event Scores* (range)	Stress or Desirability Scale†	Weighted Event Scores‡ (potential range)
Adults, Interview for Recent Life Events§	Total (0-65) Major (0-16) Controllable (0-12) Uncontrollable (0-27) Desirable (0-6) Undesirable (0-40) Highly Stressful (0-65)	0 = "not all all" 1 = "a little stressful" 2 = "somewhat stressful" 3 = "very stressful"	Total (0 - 195) Major (0 - 48) Controllable (0 - 36) Uncontrollable (0 - 81) Desirable (0 - 18) Undesirable (0 - 120)
Young Children, Adolescent Perceived Event Scale‖	Total (0-76) Negative Positive Neutral Highly Undesirable	-2 = Very Bad -1 = Somewhat Bad 0 = Neither Good Nor Bad +1 = Somewhat Good +2 = Very Good	Total (-152 - 152) Negative (-152 - 0) Positive (0 - 152)
	Major (0-23) Negative Positive Neutral		Major (-46 - 46) Negative (-46 - 0) Positive (0 - 46)
Teens, Adolescent Perceived Event Scale‖	Total (0-99) Negative Positive Neutral	-4 = Extremely Bad -3 = Very Bad -2 = Somewhat Bad -1 = Slightly Bad 0 = Neither Good Nor Bad +1 = Slightly Good +2 = Somewhat Good +3 = Very Good +4 = Extremely Good	Total (-396 - 396) Negative (0 - 396) Positive (0 - 396)
	Major (0-26) Negative Positive Neutral		Major (-104 - 104) Negative (-104 - 0) Positive (0 - 104)

* Number of events endorsed, by categories within the year of the Proband's diagnosis of systemic rheumatic disease (SRD), which was also used as a reference date for Siblings and Healthy Controls .

*Models were adjusted for age, sex, race/ethnicity, parental highest level of education, parental cigarette smoking, time from reference date to study enrollment.
† Multivariate logistic regression analysis was not shown in the Teen group, given lack of significant results in the univariate logistic analysis.
§ Young Children: Probands and Sibings (n=129 each), Healthy Controls (n=65); Teens: Probands and Siblings (n=41 each), Healthy Controls (n=16).

their associated stress or desirability (Table 1). The same reference period was used for SIBs and HCs. Pediatric questionnaires were completed by parents. Unconditional and conditional logistic regression were used to calculate odds ratios (OR) of SRD diagnosis.

Results: In adults, the number of total, uncontrollable, undesirable, and highly stressful life events was higher in probands compared to HCs (P values < 0.01–0.03), but there was no difference in the frequency of life events between Probands and SIBs. Perceived stress ratings in the same categories were higher in Probands compared to HCs (P-values < 0.01–0.04). In the YC and Teen combined analysis and in the YC group alone, probands had fewer positive and total life events than HCs (P≤0.04). These events were rated as more desirable by YC HCs than by Probands (P≤0.05). From multivariate logistic regression analyses, adjusted for demographics, time from reference date to study enrollment, and smoking, the number of total, major, uncontrollable, undesirable, and highly stressful life events and their corresponding stress ratings were associated with an increased odds of SRD diagnosis in adult Probands compared to HCs (OR 1.22–2.03, P values ≤0.05, Table 2). The frequencies of total, major negative, and major total events were associated with SRD diagnosis in YC and Teens combined (OR 0.69–0.96, P values ≤0.05, Table 3), and in YC alone. However, higher undesirable ratings for major negative life events were associated with SRD diagnosis in children (OR 2.25, P=0.04).

Conclusion: This retrospective study suggests that negative life events and their stress perception are associated with greater odds for SRD in adult Probands compared to HCs. The relationship between life events and SRD diagnosis is more nuanced in the pediatric group, where more frequent life events were associated with a lower odds of SRD, but a greater perception of undesirability with major negative life events was associated with subsequent SRD diagnosis. These findings support the need for better understanding the role of stress in the development of SRD.

Background/Purpose: The increased cancer risk in patients with systemic lupus erythematosus (SLE) has received considerable attention. However, there is a lack of studies examining the cancer risk in newly diagnosed SLE patients, and the estimation of risk factors remains inadequate. This study aims to profile cancer incidence and identify risk factors in patients with newly diagnosed SLE.

Methods: From 2008 to 2018, all incident SLE patients were recruited from a comprehensive dataset combining information from the National Health Insurance Service, Health Insurance Review & Assessment Service, and Korea Central Cancer Registry. The study calculated the incidence rates (IRs) per 1,000 person-years (PYs) for site-specific cancers using the Surveillance, Epidemiology, and End Results (SEER) stage classification. Multivariable logistic regression analysis was employed to determine the association between incident SLE patients and risk factors.

Results: A total of 5,531 patients with newly diagnosed SLE were included, with a mean age of 38.0 ± 16.6 years, and 89.7% of them were female. Table 1 shows the baseline characteristics of the study population. During a follow-up period of 29,453 PYs, 156 SLE patients developed cancer. The IRs per 1,000 PYs for all cancers, solid cancers, and hematologic cancers were 5.23 (95% CI 4.40-6.05), 4.58 (95% CI 3.80-5.35), and 0.70 (95% CI 0.40-1.00), respectively. Based on SEER stage, a higher proportion of SLE patients were diagnosed with solid cancers at localized (64 events) and regional (43 events) stages, rather than distal stage (16 events).Site-specific cancers predominantly included thyroid (0.97, 95% CI 0.62-1.33) and breast cancer (0.74, 95% CI 0.43-1.04), followed by colon and rectal (0.53, 95% CI 0.27-0.80), cervix uteri (0.40, 95% CI 0.17-0.63), and stomach cancer (0.37, 95% CI 0.15-0.58) (Table 2). In the multivariable analysis (Table 3), the risk factors associated with cancer development in incident SLE patients were age above 30 years (adjusted hazard ratio [aHR] 2.22, 95% CI 1.18-4.18), whereas hypertension (aHR 0.56, 95% CI 0.35-0.89) was associated with a lower risk of cancer. Medication, such as hydroxychloroquine and immunosuppressive agents, did not correlate with the risk of cancer.

Conclusion: This study provides insights into the cancer incidence characteristics in Korean patients with newly diagnosed SLE over a long follow-up period. The distribution of cancer incidence was predominantly in the early stages, with thyroid and breast cancers being commonly diagnosed. The risk of cancer increased with older age in SLE patients, while there was no clear association between the use of immunosuppressive agents and cancer.

Abstract Number: 0136

The Prevalence and Risk Factors of Retinal Toxicity Associated with Long-term Hydroxychloroquine Use

Sophie Do, Jennifer Du, Jaejin An, Jim Wang and **Antony Lin**, Kaiser SCAL, Fontana, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is commonly used for the treatment of various autoimmune diseases. The medication is generally well-tolerated. However, long-term use after 5 years may increase the risk of retinopathy. One study in 2014 has demonstrated the risk can be as high as 7.5%. Optical Coherence Tomography (OCT) has become a

major modality in screening retinopathy. Our study is to evaluate the prevalence of retinal toxicity among patients using HCQ and to determine various risk factors associated with HCQ-associated retinal toxicity.

Methods: We performed a retrospective chart review on a cohort of adult patients with long-term use (> 5 years cumulative) of HCQ between January 1st, 2011 to December 31st, 2018 from the Kaiser Permanente San Bernardino County and Riverside Medical Center areas in Southern California, USA. Patients were excluded if they had previous been diagnosed with retinopathy prior to HCQ use, were deceased, or had incomplete OCT exam. Our primary endpoint was the prevalence of patients who developed retinal toxicity detected by OCT, and later confirmed by retinal specialist. Potential risk factors (age, duration of therapy, daily consumption per actual body weight, cumulative dose, confounding diseases and medications) for developing retinopathy were also evaluated. Univariable and multivariable logistic regression analyses were used to determine risk factors associated with retinal toxicity.

Results: Among 676 patients exposed to more than 5 years of HCQ, the overall prevalence of retinal toxicity was 6.8%, and ranged from 2.5% to 22.2% depending on the age group, weight-based dosing, duration of use and cumulative dose. Duration of therapy for 10 years or more increased risk of retinopathy by approximately 5 to 19 folds. Similarly, weight-based dose of 7mg/kg/day or greater was associated with increased risk of retinopathy by approximately 5 times. Patients with cumulative dose of 2000 grams or more had greater than 15 times higher risk of developing retinopathy. Duration of use for 10 years or more (odd ratio 4.32, 95% CI 1.99-12.49), age (odd ratio 1.04; 95% CI 1.01-1.08), cumulative dose of more

Table 2. Hydroxychloroquine Treatment Exposure

	No Retinal Toxicity (N=630)		Retinal Toxicity (N=46)		
	Mean	Std Dev	Mean	Std Dev	p-value
Dose per day (mg)	326.6	96.2	337	92.8	0.479

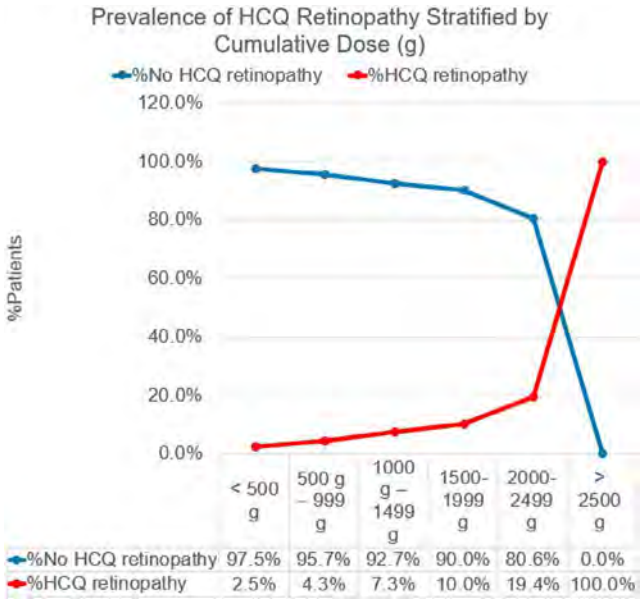
Duration of use					
Months	**99.3**	**33.4**	**141.5**	**64.5**	**< 0.0001**
Years	**8.3**	**2.8**	**11.8**	**5.4**	**< 0.0001**
Cumulative dose (mg)	**983.2**	**445.2**	**1483.6**	**891.5**	**< 0.0001**

Results: HCQ Treatment Dosage, Duration, and Cumulative Dose



Results: Cumulative Dose of HCQ Therapy Distribution

than 1500 grams(odd ratio 7.4; 95% CI 1.40-39.04) and atherosclerosis of the aorta (odd ratio 2.59; 95% CI, 1.24-5.41) correlated with higher risk of retinal toxicity.

Conclusion: The overall prevalence of retinopathy was 6.8%. Routine OCT screening, especially in patient with hydroxychloroquine use for more than 10 years, daily intake > 7 mg/kg, or cumulative dose > 1500 grams is important in detecting HCQ-associated retinal toxicity.

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Myelodysplastic syndrome (MDS) is a hematologic disorder characterized by dysplasia of bone marrow, leading to ineffective hematopoiesis and cytopenia. Despite sporadic reports of associations between rheumatologic diseases and MDS, the exact incidence rate of MDS in these patient populations, and the specific risk factors associated with MDS development, remain unclear. We investigated the incidence rate and risk factors of MDS in patients with rheumatologic disease.

Methods: We conducted a retrospective cohort study of patients who were diagnosed with rheumatologic diseases at a tertiary-care hospital between May 2009 and July 2022 and identified the patients who were subsequently diagnosed with MDS. Patients under 18 years of age and patients with a prior diagnosis of MDS were excluded. Each patient with MDS was matched with five age- and sex-matched controls chosen from the cohort of patients with each specific rheumatologic disease.

Results: During a total follow-up of 55,841 person-years (PY), MDS occurred in 64 patients, yielding an incidence rate of 1.15/1000 PY (median age, 57.0 [IQR, 41.0-69.0]; median duration to MDS diagnosis, 6.5 years [IQR, 3.0-9.0]). In an age- matched analysis, systemic lupus erythematosus (SLE) was a significant risk factor for MDS (adjusted hazard ratio, 2.61 [CI, 1.19–36.06], P=0.01). Refractory cytopenia with multilineage dysplasia was the most common phenotype of MDS (35.9%), and more than half of the patients had karyotypes with favorable prognoses (54.7%). Compared to matched controls, rheumatoid arthritis, SLE, and ankylosing spondylitis patients with MDS had lower levels of hemoglobin at the time

	n	Total observation period (PY)	MDS incidence rate (/1000 PY)	Unadjusted hazard ratio		Adjusted hazard ratio (age)	
				HR (95% CI)	P	HR (95% CI)	P
All rheumatologic diseases†	64	55841	1.15

Palindromic rheumatism	1	1847	0.54	-		-	
Relapsing polychondritis	1	126	7.94	-		-	
Antiphospholipid syndrome	1	1092	0.92	-		-	

†All rheumatologic diseases include rheumatoid arthritis, systemic lupus erythematosus, Behcet's disease, relapsing polychondritis, palindromic rheumatism, idiopathic inflammatory myositis, anti-phospholipid syndrome, adult-onset Still's disease, polymyalgia rheumatica, systemic vasculitis, spondyloarthropathy, Sjogren syndrome, psoriatic arthritis, crystal arthropathy, systemic sclerosis, and IgG4-related disease.

of diagnosis of rheumatologic disease. Furthermore, the MDS patients with SLE and Behcet's disease had higher levels of glucocorticoid use in terms of frequency of use or mean dose than the control patients.

Conclusion: SLE is a significant risk factor for MDS among patients with rheumatologic diseases. A lower hemoglobin level at the time of diagnosis of rheumatologic disease was associated with the future development of MDS.

Prevalence of myelodysplastic syndrome in patients with various rheumatologic diseases

Abstract Number: 0138

Prevalence and Incidence of Sjögren's Syndrome: A Systematic Literature Review

Jiyoon Choi[1], Kimberly Hofer[2], Nishu Gaind[2], Mir Sohail Fazeli[2], Robert Carroll[3], Antoine G Sreih[3] and Antonia Christodoulou[3], [1]Bristol Myers Squibb, Lawrenceville, NJ, [2]Evidinno Outcomes Research Inc., Vancouver, BC, Canada, [3]Bristol Myers Squibb, Princeton Pike, NJ

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's syndrome (SjS) is a chronic autoimmune disease that has been historically categorized into primary (manifesting alone; pSjS) or secondary (appearing alongside another underlying autoimmune condition; sSjS) disease. Recent work has criticized this dichotomy, and instead recommends that SjS be described as a singular disease, with or without comorbidity. Previous literature reviews on the prevalence and incidence of SjS have shown varied estimates and focused on pSjS only. Epidemiological studies on overall SjS are needed to estimate the burden of illness on patients and society. We conducted a systematic literature review to describe prevalence and incidence rates of SjS, with specific focus on key countries, and to investigate geographic variations.

Methods: We searched Embase and MEDLINE® from database inception to 09/27/2022 using predefined search strategies. Gray literature searches were also conducted. Included were studies reporting prevalence or incidence rates of adults with SjS within the United States (US), EU5 (France, Germany, Italy, Spain, and the United Kingdom), China, and Japan.

Results: Of 7,121 abstracts identified from the literature searches, we included 19 studies that reported prevalence of SjS cases within a population, incidence of new cases, or both (Figure 1). We identified various designs: 10 studies were cross-sectional, 7 were retrospective cohort studies, and 2 were prospective cohort studies. Sample size ranged from 341 to 7.2 million participants (median: 25,885 participants). Baseline patient characteristics as well as the population in which prevalence or incidence were measured varied across studies; however, all study samples primarily consisted of female patients, which aligns with the real-world prevalence of SjS.

Prevalence of SjS among the general population (cases per 100,000 persons), reported in 16 studies (table 1), ranged from 13.1 to 103 in the US, from 10.2 to 3300 in Europe, and from 338.8 to 774.4 in Asia. Notably, the upper bound of the European range was from a dated survey with a small sample size; the next highest value was 748.8 cases per 100,000 persons. Prevalence was also calculated among populations with autoimmune disease such as rheumatoid arthritis (29,998 cases per 100,000 persons), systemic lupus (20,341), and multiple sclerosis (up to 12,174); these figures are much higher

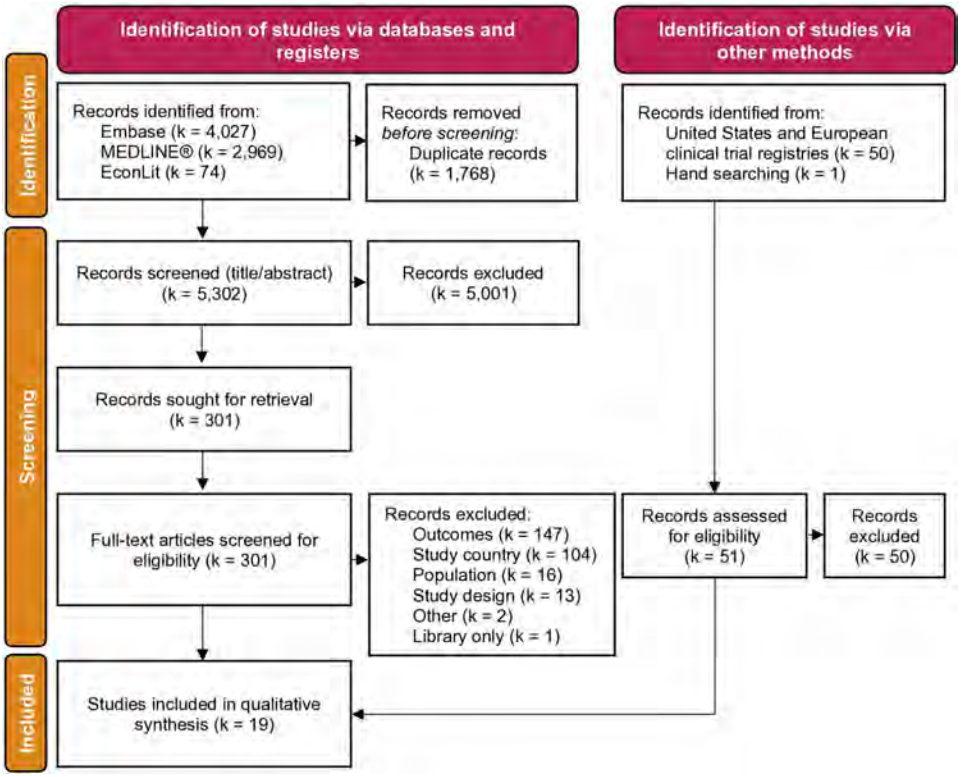

Figure 1. PRISMA flow diagram

Table 1. Prevalence rates of Sjögren's syndrome across included studies

Reference	Group	N	Prevalence, n (%)
Prevalence in the General Population			
Babazade 2015	SjS patients discharged based on administrative health data from the State Inpatient Databases, **US** from 2009-2010	5,539,875	5,463 (0.1%)* or 98.6 per 100,000 persons
Izmirly 2019	pSjS among adults in Manhattan, **US**, physician-diagnosed in 2007	1,585,873	0.01% or 13.1 per 100,000 person-years
Maciel 2017	pSjS in general population of Olmsted County, **US**, physician-diagnosed in 2015	113,306	0.1% or 103 per 100,000 persons
	pSjS in general population of Olmsted County, **US**, diagnosed using classification criteria in 2015	113,306	0.02% or 22 per 100,000 persons
Maldini 2014	pSjS in general population of Greater Paris Area, **France**, using AECG criteria in 2007	1,172,482	133 (0.01%) or 10.2 per 100,000 person-years
	pSjS in general population of Greater Paris Area, **France**, using study-specific enlarged criteria in 2007	1,172,482	203 (0.02%) or 15.2 per 100,000 person-years
Seror 2021	pSjS in general population of **France** from 2011-2018	NR	0.02-0.03% or 22-32 per 100,000 person-years
	pSjS + other autoimmune disease in general population of **France** from 2011-2018	NR	0.02% or 17-22 per 100,000 person-years
Albrecht 2020	SjS in general population of **German** statutory health insurance fund in 2018	7,200,000	53,917 (0.7%) or 748.8 per 100,000 persons
Sardu 2012	SjS in general population in South of Sardinia, **Italy** in 2009	25,885	0.03% or 31.0 per 100,000 persons
Narvaez 2020	SjS in general population of 78 municipalities in **Spain** from 2016-2017	4,916	16 (0.3%) or 325.5 per 100,000 persons
	pSjS in general population of 78 municipalities in **Spain** from 2016-2017	4,916	12 (0.3%) or 250 per 100,000 persons
Thomas 1998	SjS in general population of Manchester, **UK**	341	3.3% or 3300 per 100,000 persons
Zhang 1995	pSjS in general population of a Beijing suburb village, **China**, diagnosed using Modified Fox criteria	2,066	7 (0.3%) or 338.8 per 100,000 persons
	pSjS in general population of a Beijing suburb village, **China**, diagnosed using Copenhagen criteria	2,066	16 (0.8%) or 774.4 per 100,000 persons
Prevalence in Other Populations			
Aggarwal 2015	sSjS in systemic lupus erythematosus patients from the Lupus Family Registry and Repository in the **US**	2,694	548 (20.3%) or 20,341.5 per 100,000 persons
	pSjS in healthy relatives of systemic lupus erythematosus patients from the Lupus Family Registry and Repository in the **US**	7,390	71 (1.0%) or 960.8 per 100,000 persons
Harrold 2020	SjS in rheumatoid arthritis patients, in **US** from 2010-2018	24,528	7,358 (30.0%) or 29,998.4 per 100,000 persons
Miller-Archie 2020	SjS in adults exposed to 9/11 terrorist attack in **US** from 2015-2017	37,135	22 (0.1%) or 59.2 per 100,000 persons
Annunziata 2011	SjS in multiple sclerosis patients receiving disease-modifying drugs, in **Italy** from 2006-2007	230	28 (12.2%) or 12,173.9 per 100,000 persons
	SjS in treatment-naïve multiple sclerosis patients, in **Italy** from 2006-2007	210	14 (6.7%) or 6666.7 per 100,000 persons
Bowman 2004	pSjS in Caucasian females in Birmingham, **UK**	548	2 (0.4%) or 365.0 per 100,000 persons
Hida 2008	SjS in Nagasaki atomic bomb survivors in **Japan** from 2002-2004	1,008	23 (2.3%) or 2281.7 per 100,000 persons

*Value likely represents a mix of incident and prevalent cases. The primary survey used to estimate the prevalence of Sjögren's syndrome covered 4,729 Japan-wide hospital departments. AECG – American-European Consensus Criteria; N – Total sample size; n – Number of patients; NR – Not reported; pSjS – Primary Sjögren's syndrome; SjS – Sjögren's syndrome; sSjS – Secondary Sjögren's syndrome; UK – United Kingdom; US – United States.

than those within the general population. Incidence of SjS was reported in 6 studies (Table 2). Annual incidence rates of pSjS ranged from 3.2 to 5.8 cases per 100,000 person-years within the US, and 0.1 to 4.1 cases per 100,000 person-years in France. Prevalence and incidence data for sSjS were scarce.

Conclusion: Global incidence of SjS ranges from 0.1 to 5.8 cases per 100,000 person-years and prevalence of SjS in the general population ranges from 10.2 to 3300 cases per 100,000 persons. Some of the variations may be related to, in part, the difficulty in diagnosing SjS. Prevalence rates are higher among patients with other autoimmune diseases. Large cohort studies on the prevalence and incidence of SjS alone and SjS associated with other autoimmune diseases are warranted, in particular those that look at treated versus untreated patients.

Table 2. Incidence rates of Sjögren's syndrome across included studies

Reference	Group	N	Incidence, n (%)
Incidence in the General Population			
Izmirly 2019	pSjS among adults in Manhattan, **US**, physician-diagnosed from 2007-2009	1,585,873	3.5 per 100,000 person-years
Maciel 2017	pSjS patients receiving care in the Olmsted Medical Center or affiliate centers within Olmsted County, **US** from 1976-2015	113,306	5.8 per 100,000 person-years
Pillemer 2001	pSjS amongst residents of Olmsted County, **US** from 1976-1992	108,145	3.2 per 100,000 person-years
Albrecht 2020	SjS amongst citizens with statutory health insurance, **Germany** in 2018	7,200,000	102 per 100,000 person-years*
Seror 2021	pSjS in general population of **France** from 2012-2018	NR	0.3-4.1 per 100,000 person-years
	pSjS + other autoimmune disease in general population of **France** from 2012-2018	NR	0.1-2.1 per 100,000 person-years
Incidence in Other Populations			
Nannini 2013	pSjS patients with interstitial lung disease in Olmsted County, **US** from 1976-2005	NR	5.1 per 100,000 person-years

*This value was considered an outlier. The higher value may be explained by the data source being a health insurance database, which may not be representative of the true general population. N – Total sample size; n – Number of patients; NR – Not reported; pSjS – Primary Sjögren's syndrome; SjS – Sjögren's syndrome; US – United States.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The epidemiology of vasculitis varies widely across different geographic areas of the world which may be due to different ethnic and environmental factors. Brazil has a heterogeneous population with influences from Indigenous, African, Asian, and European countries, while Portugal has a very ethnically homogeneous background. This study aims to assess the main differences in the profile of systemic vasculitides between Portugal and Brazil.

Table 1.– Comparison of features in vasculitis patients between Portugal and Brazil.

Variables	Portugal	Brazil	*p*
Behçet's disease			
Females, %	75.5	67.2	0.033*
Age at diagnosis, years	33.3 (25.0-42.3)	33.3 (27.0-40.7)	0.878
Time between symptoms and diagnosis, years	4.00 (1.00-12.00)	0.99 (0.32-4.00)	< 0.0001*
Giant cell arteritis			
Females, %	66.0	80.6	0.076
Age at diagnosis, years	75.3 (69.4-80.4)	68.6 (61.7-75.4)	< 0.0001*
Time between symptoms and diagnosis, years	0.16 (0.05-0.37)	0.43 (0.08-1.83)	0.014*
Takayasu arteritis			
Females, %	85.2	93.9	0.066
Age at diagnosis, years	37.0 (24.3-49.6)	30.3 (23.3-40.4)	0.020*
Time elapsed between symptoms and diagnosis, years	1.16 (0.58-4.61)	1.08 (0.41-4.37)	0.692
Polyarteritis nodosa			
Females, %	56.8	70.0	0.316
Age at diagnosis, years	43.1 ± 17.1	32.3 ± 14.4	0.027*
Time between symptoms and diagnosis, years	1.00 (0.49-2.87)	0.48 (0.29-3.83)	0.463
Granulomatosis with polyangiitis			
Females, %	58.6	60.2	0.818
Age at diagnosis, years	51.5 ± 15.8	43.9 ± 14.2	0,001*
Time elapsed between symptoms and diagnosis, years	0.67 (0.24-3.00)	0.99 (0.29-2.08)	0.600
Microscopic polyangiitis			
Females, %	57.3	75.0	0.239
Age at diagnosis, years	64.3 (54.8-74.1)	58.2 (38.2-74.5)	0.352
Time elapsed between symptoms and diagnosis, years	0.42 (0.10-0.91)	0.33 (0.23-1.58)	0.738
Eosinophilic granulomatosis with polyangiitis			
Females, %	61.0	54.5	0.598
Age at diagnosis, years	54.7 ± 15.8	49.6 ± 11.1	0.176
Time elapsed between symptoms and diagnosis, years	1.56 (0.26-6.50)	2.00 (0.83-4.00)	0.480

Continuous data are presented as median and interquartile range or as mean and standard deviation; * - Flags significant results.

Methods: Collaborative project between the Portuguese and the Brazilian Societies of Rheumatology in which centres from both countries were invited to register data in the vasculitis module of the Rheumatic Diseases Portuguese Register, Reuma.pt/vasculitis. A cross-sectional analysis was performed comparing demographic, ethnic and diagnostic information between Brazilian and Portuguese centres.

Results: A total of 1,955 patients were analysed: 74.2% from 30 Portuguese centres and 25.8% from 7 Brazilian centres. Portuguese patients were predominantly European White (89.2%) and in Brazil the most common ethnic groups with vasculitis were the non-European White (48.3%) and Mestizos (40.1%); 5.4% of all participants were born in other countries. Brazilian patients were younger at the onset of symptoms [35.2 (24.1-46.6) vs.48.1 (27.4-70.1) years; $p< 0.05$]and diagnosis of vasculitis [37.0 (27.6-48.3) vs. 50.8 (32.7-70.4) years; $p< 0.05$] than Portuguese patients, respectively. When analysing individual forms of vasculitis, Brazilian patients with giant cell arteritis (GCA), Takayasu arteritis (TAK), polyarteritis nodosa (PAN) and granulomatosis with polyangiitis (GPA) were significantly younger than Portuguese patients at diagnosis ($p< 0.05$). The proportion of females was higher in Portuguese patients with Behçet's disease (BD) than in Brazilian patients ($p=0.03$). No differences regarding the proportion of females were observed for other vasculitides (Table 1). The most common form of vasculitis in both countries was BD followed by GCA in Portugal and by TAK in Brazil. Regarding ANCA-associated vasculitis, GPA was more common in Brazil and microscopic polyangiitis (MPA) in Portugal. Both countries had similar proportions of patients with PAN and eosinophilic granulomatosis with polyangiitis (EGPA) (Figure 1 and Table 2). Time elapsed between the onset of

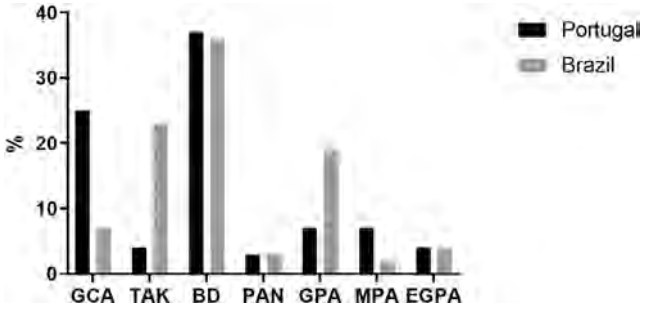

Figure 1.- Frequency of systemic vasculitis in Portugal and Brazil. GCA, giant cell arteritis; TAK, Takayasu arteritis; BD, Behçet´s disease; PAN, polyarteritis nodosa; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; EGPA, eosinophilic granulomatosis with polyangiitis

Table 2.– Frequency of systemic vasculitis in Portugal and Brazil.

Vasculitis	Portugal (n = 1451)	Brazil (n = 504)
Behçet's disease, n (%)	473 (34.2)	180 (35.7)
Giant cell arteritis, n (%)	329 (23.8)	36 (7.1)
Granulomatosis with polyangiitis, n (%)	99 (7.2)	93 (18.5)
Takayasu arteritis, n (%)	54 (3.9)	114 (22.6)
Microscopic polyangiitis, n (%)	96 (6.9)	12 (2.4)
Eosinophilic granulomatosis with polyangiitis, n (%)	59 (4.3)	22 (4.4)
Polyarteritis nodosa, n (%)	44 (3.2)	20 (4.0)
IgA vasculitis, n (%)	38 (2.7)	7 (1.4)
Cryoglobulinemic vasculitis, n (%)	24 (1.7)	4 (0.8)
Cogan syndrome, n (%)	14 (1.0)	0 (0.0)
HCV cryoglobulinemic vasculitis, n (%)	6 (0.4)	1 (0.2)
Antiglomerular basement antibody disease, n (%)	5 (0.4)	1 (0.2)
Kawasaki's disease, n (%)	2 (0.1)	0 (0.0)
Hypocomplementemic urticarial vasculitis, n (%)	2 (0.1)	0 (0.0)

HCV – Hepatitis C virus; n – Number of patients.

symptoms and the diagnosis of GCA was higher in Brazil than in Portugal (p=0.014) while Portugal had a longer interval between the onset of BD symptoms and its diagnosis compared to Brazil (p< 0.05) (Table 1).

Conclusion: In this large multicentre binational study, Portugal and Brazil had a different profile of systemic vasculitis concerning the proportion of GCA and TAK patients, as well as GPA and MPA patients. In addition, both countries had differences in the age of onset, female gender, and ethnicity of patients with systemic vasculitis.

Abstract Number: 0140

Extent of Recording of 2019 EULAR/ACR Classification Criteria for Systemic Lupus Erythematosus in a UK Healthcare Database

Jessica Ellis[1], Anita McGrogan[2], Neil McHugh[2], Ben Mulhearn[3], Eleanor Korendowych[4], John Pauling[5], Ian Bruce[6], Jenny Humphreys[7] and Sarah Skeoch[1], [1]University of Bath; Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]University of Bath, Bath, United Kingdom, [3]Royal United Hospital Bath | University of Bath, Bath, United Kingdom, [4]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [5]North Bristol NHS Trust, Bristol, United Kingdom, [6]University of Manchester, Manchester, United Kingdom, [7]University of Manchester, Stockport, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2019 EULAR/ACR Classification Criteria allow classification of patients with systemic lupus erythematosus (SLE) for research. They reflect updates in current understanding of SLE and their value has been extensively documented in traditional research cohorts. Their functionality in electronic healthcare records is not well established. The purpose of this study was to describe the recording of the 2019 EULAR/ACR Classification Criteria within a UK electronic health database, the Clinical Practice Research Datalink (CPRD) to aid understanding of their utility in research studies in this setting.

Methods: Ethical approval was obtained from the CPRD Independent Scientific Advisory Committee (21_000697). The study period was 01/01/1990 to 31/12/2020. Read code lists were devised to identify adult patients with possible SLE within the CPRD, defined as cases. Codes relating to discoid, tuberculous or drug-induced lupus were excluded. Valid patients within the CPRD without a record of a SLE code were defined as non-cases. EULAR/ACR criteria definitions were adapted for use within the CPRD. Patient records were searched for the presence of criteria items. Descriptive statistics

Table 1. 2019 EULAR/ACR criteria counts in cases and non-cases and odds ratio (with confidence intervals and P value)

	Case (n)	Non case (n)	OR	95% CI	*P*-value
Total	12,376	11,397,308	-	-	-
Fever	128	44509	2.666	2.239,3.173	<0.0001
Delirium	324	133874	11.44	10.4,12.57	<0.0001
Psychosis	205	116822	1.626	1.417,1.867	<0.0001
Seizure	413	157447	1.392	1.386,1.399	<0.0001
Alopecia	1134	249777	4.502	4.235,4.786	<0.0001
Ulcers	954	263568	3.528	3.302,3.77	<0.0001
ACLE	79	1230	59.52	47.39,74.78	<0.0001
Discoid	1990	7996	272.9	258.9,287.7	<0.0001
Joint	3087	461074	44.76	42.95,46.64	<0.0001
Effusion	352	54729	6.067	5.455,6.748	<0.0001
Pericarditis	211	16971	11.63	10.14,13.34	<0.0001
Nephritis	48	1359	32.65	24.47,43.56	<0.0001
APLS Ab	1837	40138	49.32	46.89,51.88	<0.0001
Autoimmune haemolysis	101	4871	19.24	15.79,23.45	<0.0001
Proteinuria	284	9133	29.29	25.99,33.0	<0.0001
DsDNA/ anti-Sm	2956	81516	43.56	41.77,45.42	<0.0001
ANA positive	191	3127	57.12	49.3,66.17	<0.0001
Complement	2007	29356	74.95	71.36,78.73	<0.0001
Leucopaenia	141	6922	25.42	24.49,30.07	<0.0001
Thrombocytopaenia	447	37225	11.44	10.4,12.57	<0.0001

were used to describe the capture of ACR criteria for patients. Odds ratios were used to compare the presence of individual criteria in cases vs non-cases.

Results: 12,376 cases and 11,397,308 non-cases were identified. Counts for each criteria, for both groups, are presented in Table 1. Only 1.5% (n=191) of cases had a record of a positive ANA test. The most common criterion seen for cases was joint involvement (24%, n=3087, and the least common was autoimmune haemolysis (0.8%, n=101). Odds ratios and 95% confidence intervals for the presence of criteria items in cases and non-cases are presented in Table 1. The odds of all EULAR/ACR criteria items were significantly higher in cases than non-cases. This was most pronounced for discoid rash (OR 272.9, 258.9-287.7, $P< 0.0001$) and least for seizure (OR 1.392, 1.386-1.399,$P< 0.0001$).

Conclusion: These data show that the 2019 EULAR/ACR SLE criteria can be identified within the CPRD. The prevalence of these items is lower than those seen in traditional research studies which reflects differences in recording practices between primary and secondary care. Researchers should be cautious when using absolute counts of these items within the CPRD and possibly other primary care databases. Low prevalence of ANA positivity will preclude this as an entry criteria in this setting. The higher odds of criteria in cases compared to non-cases, suggests use of Read codes is likely to identify true SLE cases; combining these with 2019 EULAR/ACR SLE criteria and other parameters may further aid this process.

Abstract Number: 0141

In-patient Outcome Difference in Systemic Lupus Erythematous Patient Between Medicare and Non-Medicare Group, a Nationwide Analysis

Mishouri Paul, **Prodip Paul**, Birendra Amgai and Julio Ramos, Geisinger Community Medical Center, Scranton, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus is a chronic inflammatory disorder that significantly burdens our health system. The study aimed to understand the difference in in-patient outcomes based on insurance status, especially between Medicare and non-Medicare groups.

Methods: Using National Inpatient Sample databases from 2016 - 2020, we identified patients with underlying systemic lupus erythematosus. Patients were divided into two main groups (with Medicare and with non-Medicare insurance). Our primary outcome of the study was in-patient mortality, length of stay and hospital cost. Multivariate logistic regression, and student t-test were used for analysis using STATA 17.0.

Results: Out of 789,720 SLE admissions, 49.9% were non-Medicare, and 51.1% had Medicare as an insurance. Medicare cohort were older (mean age 62±15.0 vs 44±14.2, P value < 0.001) and predominantly Caucasians compared to Non-Medicare cohort. Medicare cohort was associated with a higher prevalence of Hypertension (74.7% vs 50.4, P value < 0.001), peripheral vascular disease (10.1% vs 4.5%, P value < 0.001), chronic kidney disease (32.4% vs 16.6%, P value < 0.001) and Congestive heart failure (29.5% vs 14.5%, P value < 0.001) when compared to a non-Medicare cohort. However, there were fewer patients with Obesity in Medicare cohort when compared to the non-Medicare cohort (19.1% vs 20.6%, P value < 0.001). In-patient mortality between Medicare and non-Medicare group (10090 vs 6075, OR 0.76, 95% CI 0.68-0.84 P value < 0.001) showed significant better outcome in non-Medicare group. There was higher in-hospital cost in Medicare cohort compared to non-medicare cohort ($17475 vs $17128, P value < 0.001) and slightly longer length of stay in Medicare cohort compared to non-medicare cohort (5.5±6.1 vs 5.2±7.1, P value < 0.001).

Conclusion: This study shows that having a Non-medicare payer is better than Medicare. However, the difference is minimal even though it is statistically significant, so we should assess the clinically significant difference between the two cohorts.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Epidemiology & Public Health Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: We aim to describe the profile of new-onset systemic autoimmune diseases (SAID) developed in individuals following COVID-19 vaccination and to characterize the potential risk factors for their occurrence using a large-scale international survey.

Methods: A retrospective cohort study was conducted among participants who self-reported new-onset SAID in the COVAD-2 study - a global, validated, patient-reported e-survey involving 167 collaborators from 110 countries, to collect data on the long-term safety and tolerability of COVID-19 vaccines in patients with SAID (1). Responses are summarized using descriptive statistics including median (IQR) on the new onset of SAID. Baseline characteristics between those with new-onset SAIDs diagnosed by a rheumatologist and vaccinated healthy controls (HCs) are compared after 1:4 propensity

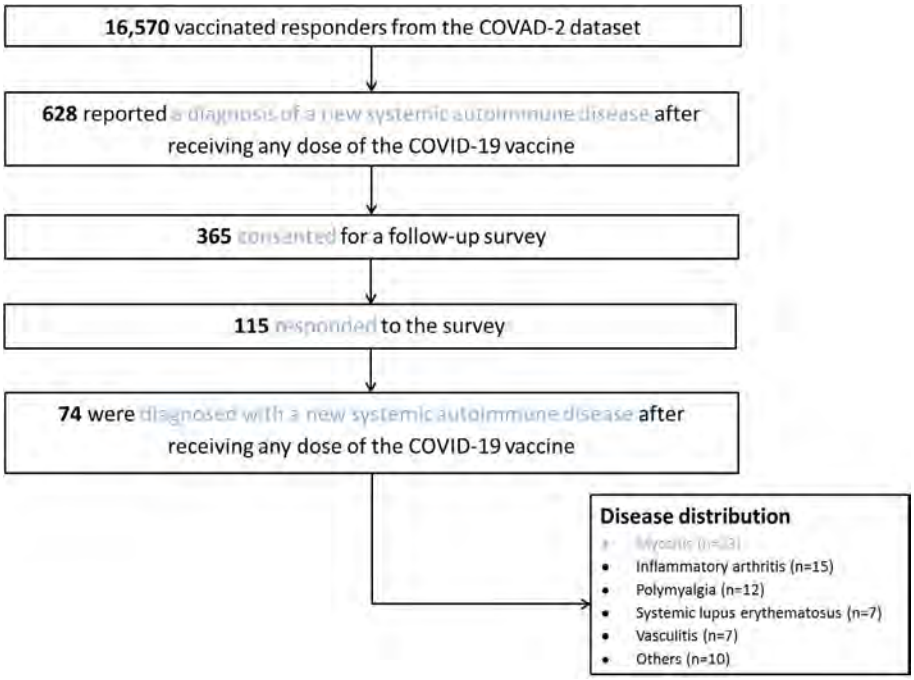

Figure 1. Flowchart showing process of study participants' selection

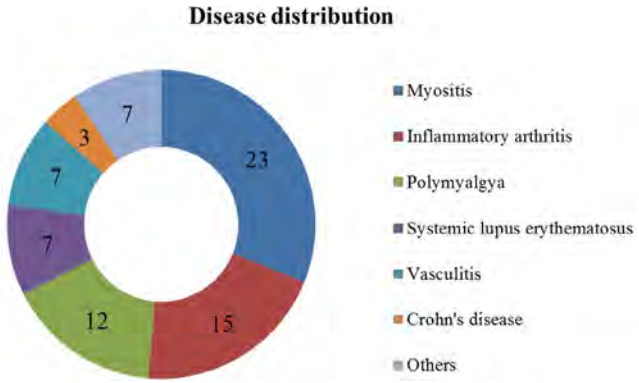

Figure 2. Disease distribution of respondents developing new autoimmune disease after COVID-19 vaccination

score (PS) matched analysis based on age and gender variables. Predictors of new-onset SAIDs were assessed using binary logistic regression adjusting for age, gender, ethnicity, and country by HDI.

Results: Out of a total of 16,570 vaccinated respondents to the COVAD-2 survey, 628 reported a diagnosis of a new-onset SAID after receiving any dose of a COVID-19 vaccine. Of them 365 consented for a follow-up survey and 115 completed the survey. A total of 74 respondents with confirmed diagnosis of new-onset SAID were included in the final analysis (mean age was 52 years (range 18-82 years; SD: 14) and more than three-quarters were females (n=59, 79.7%)) (fig. 1). The most commonly reported new-onset SAIDs were idiopathic inflammatory myopathies (n=23, 31.1%) followed by inflammatory arthritis (n=15; 20.3%) and polymyalgia rheumatica (n=12, 16.2%) (fig. 2). The most commonly received COVID-19 vaccines leading to new-onset SAID were Pfizer (n=37, 37.4%) followed by Moderna (n=32, 32.3%) and then Oxford/AstraZeneca (n=26, 26.3%). The median (IQR) duration from vaccination to symptom onset was 14 (5-30) days. PS matched analysis between vaccinated HCs and new-onset SAIDs showed higher odds of new-onset SAIDs among Caucasians (OR: 5.3; 95%CI: 2.9-9.7; p< 0.001) and mRNA-1273 (Moderna) vaccine recipients (2.7; 1.3-5.3; 0.004) and lower odds among Asians (0.2; 0.1-0.7; 0.011) and BNT162b2 (Pfizer-BioNTech) vaccine (0.3; 0.2-0.7; 0.003) recipients. The predictors of new-onset SAIDs included presence of SAID multimorbidity (1.4; 1.1-1.7; < 0.001), mental health disorders (1.6; 1.3-1.9; < 0.001), and mixed race (2.2; 1.2-4.2; 0.010). Whereas, those with age >60 years (0.6; 0.4-0.8; 0.007), increasing vaccine doses (0.3; 0.2-0.5; < 0.001) and high/medium HDI countries (compared to very high HDI) (0.6; 0.4-0.8; 0.002) reported fewer new onset SAIDs.

Conclusion: This large case-series from the COVAD data set provides the first insights to new-onset SAID following COVID-19 vaccination in a global population. Due to disparity between patient and physician reporting, it is imperative to identify the correct diagnosis in individuals reporting new-onset SAID. Further research is therefore needed to facilitate counselling of individual risks and benefits, particularly if risk could be reduced by different COVID-19 vaccines schedules in predisposed individuals.

Cancer Incidence in Familial Mediterranean Fever

Sura Nur Baspinar[1], Berkay Kilic[2], Feyza Azman[3], Mebrure Burcak Yuzbasioglu[1], Yelin Guler[2], Muhammet Kadir Tanin[2], Ulgar Boran Gunay[2], Gunay Can[4] and Serdal Ugurlu[5], [1]Department of Internal Medicine, Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Istanbul, Turkey, [2]Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Istanbul, Turkey, [3]Cerrahpasa Faculty of Medicine, Istanbul, Turkey, [4]Department of Public Health, Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Istanbul, Turkey, [5]Istanbul University-Cerrahpasa, Istanbul, Turkey

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is the most common hereditary monogenic fever syndrome characterized by recurrent attacks of fever and polyserositis. Anti-inflammatory drugs, with colchicine being the first-line therapy, have been used in FMF treatment to provide improvement in attacks and prevent amyloidosis, the most serious complication of the disease. Various types of cancer may be observed in FMF patients. This study aimed to evaluate the association between FMF and the risk of cancer, by using the cancer-related outcomes of a cohort of Turkish FMF patients and those of the general Turkish population.

Methods: We retrospectively screened the cancer statistics of our study group consisting of 1734 Turkish FMF patients registered at our division. Data were gathered from patient files, digital records, or from patients themselves verbally. Cancer-related estimates of the Turkish population were published by the Ministry of Health of Turkey in the Turkey Cancer Statistics Report (TCSR), in 2017. Standardized incidence rates (SIR) were calculated to compare the cancer incidences observed in our study group with the expected cancer incidences of the Turkish population. Indirect age adjustment was used,

Table 1. Distribution of cancer types among Turkish Familial Mediterranean Fever patients

Cancer type	Female (n)	Male (n)
BCC[a]	0	1
Breast	7	-
Cervical	2	-
Colorectal	2	1
Endometrial	3	-
Gallbladder	1	-
Hodgkin lymphoma	-	1
Laryngeal	-	1
Leiomyosarcoma	-	1
Lung cancer	1	-
MDS/MPNs[b]	-	3
Malignant melanoma	-	1
Multiple myeloma	1	-
Non-hodgkin lymphoma	1	-
Osteosarcoma	-	1
Peritoneal	1	-
PTC[c]	3	-
RCC[d]	1	1
Testicular	-	1
Total	23	12

[a]: Basal cell carcinoma
[b]: Myelodysplastic/myeloproliferative neoplasms
[c]: Papillary thyroid carcinoma
[d]: Renal cell carcinoma

assuming the TCSR data as standard population outcomes. Considering FMF as a hereditary disorder, the onset of disease exposure was set as the year of birth. Statistical analysis was conducted in the general study group and subgroups based on gender and usage of biological agents (anti-IL-1 and anti-TNF-α drugs). Proportions of patients with a cancer diagnosis were calculated for the analysis of biological agent treatment subgroups. Our study protocol was compliant with the Helsinki Declaration and approved by the local ethics committee.

Results: Females made up 1054 (60.8%) of the patients in our study group . The mean age of the patients was 39.8 ±11.6 years while the mean duration of disease exposure was 15.1±7.43 years. Total follow-up was 68,784 person-years. Malignancy occurred in 35 (2%) patients and 23 (65.7%) of them were female. Breast cancer was the most common cancer type in females (n=7, 30.4%), and among all cancer diagnoses (20%). Males were most frequently diagnosed with myelodysplastic/myeloproliferative neoplasms (n=3, 25%) (Table 1). The incidence of cancer was significantly lower in Turkish FMF patients, compared with the Turkish population [SIR 0.34 (95% CI 0.24-0.46), p< 0.01]. Cancer incidences were decreased among female patients [SIR 0.66 (95% CI 0.43-0.98), p=0.048] and among male patients likewise, but the association didn't reach statistical significance for males [SIR 0.62 (95% CI 0.34-1.06), p=0.096]. No significant difference in risk of cancer was found for patients using anti-IL-1 or anti-TNF-α drugs.

Conclusion: Our findings suggest that Turkish FMF patients have a significantly lower incidence of cancer than the general population of Turkey. Patient characteristics, such as continuous exposure to anti-inflammatory drugs (primarily colchicine) and pathophysiological mechanisms of the disease can be interpreted for the explanation of this association.

Table 2. Subgroup analysis of the association between cancer biologic agent treatment among Turkish Familial Mediterranean Fever patients

COVID-19 Infection in People with Immune Mediated Inflammatory Diseases Who Received SARSCo-V2 Vaccines

Tetiana Shcholok[1], Charles N Bernstein[1], Catherine Card[2], RuthAnn Marrie[1], Christine Mesa[2], John Kim[2] and **Carol Hitchon**[1], [1]University of Manitoba, Winnipeg, MB, Canada, [2]Public Health Agency of Canada, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Vaccines targeting the SARSCo-V2 virus protect against severe COVID-19 infection. Some immunosuppressive therapies impair SARSCo-V2 vaccine mediated immunogenicity and may increase the risk of severe COVID-19 infection even after vaccination. In people with Immune Mediated Inflammatory Diseases (IMIDs) who received at least one SARSCo-V2 vaccine, we aimed to describe the symptom profile and severity of COVID-19 infections.

Methods: As part of a single-center prospective observational cohort study of patients with diagnosed IMIDs who received SARSCo-V2 vaccines, we collected self-reported data regarding COVID-19 infection (test-confirmed vs suspected vs none), COVID-19 infection severity (ambulatory management, hospitalization, death), infection symptom profile, and risks for SARSCo-V2 virus exposure. Infection symptoms were categorized as constitutional (fever, fatigue), respiratory (rhinorrhea, sore throat, dyspnea, cough, chest pain), gastrointestinal (abdominal pain, nausea, emesis, diarrhea, loss of appetite), neurologic (headache, loss of taste/smell), and dermatologic (rash). IMID treatment was categorized as none vs immunomodulators, vs immunosuppressants, vs biologics/small molecules alone or in combinations. Participants provided blood samples 1, 3, and/or 6 months post each vaccination which were tested for anti-nucleocapsid (NC) IgG reflecting infection mediated immunogenicity and anti -Spike (S), and -receptor binding domain (RBD) IgG reflecting vaccine mediated immunogenicity. We describe the profile of COVID-19 infections across IMIDs.

Results: COVID-19 self-reported infection data was available for 322 participants [Inflammatory Arthritis (IA) N=78; Systemic Autoimmune Rheumatic Diseases (SARDs) N=84; Inflammatory Bowel Disease N=88; Multiple Sclerosis N=72] who were predominantly female (79.8%) white (82.0%) with mean (standard deviation-SD) age 58.3(14.2) years and received a median (range) of 4 (1,5) vaccines (Table). Test-confirmed infections were reported by 64 (20%) participants (p=NS across IMIDs and sexes), viral symptoms by 109 (33.9%), no symptoms by 148 (46%). Those reporting infection were younger than those without infection [(median (interquartile range) years 59.0 (24.9) vs 62.2 (18.9) p=0.03]. Eighteen infections were seronegative for anti-NC a median of 33 days (range 3-178) post diagnosis. Most infections were mild, but 5 people were hospitalized and 3 died from COVID-19 (2 IA, 1 SARDs, age >75 years, with comorbidities and on biologics or IS; 2 were seronegative for anti-S and anti-RBD after 1 or 2 vaccines; 1 had low titers after 3 vaccines). COVID-19 symptoms were similar across IMIDs with constitutional and respiratory symptoms being most common (Figure 1). Of 85 new anti-NC positive infections, 26 were asymptomatic (p=NS across IMIDs). Most participants reported having no risk exposures to SARSCoV2 over the course of the study (Figure 2).

Table: Baseline characteristics of participants IA= Inflammatory arthritis; CTD=Connective tissue disease; IBD=Inflammatory bowel disease; IMIDs=Immune Mediated Inflammatory Diseases MSK=musculoskeletal. 1. depression, anxiety, bipolar disorder, schizophrenia; 2. migraine, epilepsy, transient ischemic attack/stroke)

Conclusion: The symptom profile of COVID-19 is similar across IMIDs and to the general population. A subset of people with IMIDs may not generate robust anti-NC responses to documented COVID-19 infection. This may impact the reliability of surveillance studies relying on these assays.

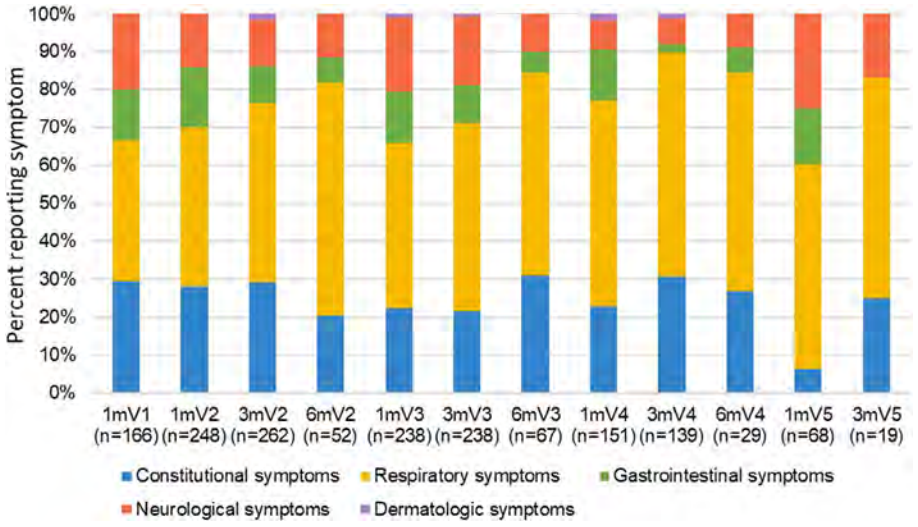

Figure 2. Self-reported symptom profile of COVID-19 infections in vaccinated patients with immune mediated inflammatory diseases V1=vaccine 1; V2=vaccine 2; V3=vaccine3; V4=vaccine 4; V5=vaccine 5 Symptom categories adapted from: Reaney, M., et al. Development of an Item Bank to Assess Patient-Reported Outcomes: Signs, Symptoms, and Impacts of COVID-19. Patient 15, 703–713 (2022).

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Epidemiology & Public Health – Interprofessional Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases (RD) can have a negative impact on many aspects of a patient's life, including sexual health. Sexual dysfunction (SD) has been negatively associated with quality of life and disease severity, yet there's still a barrier to the evaluation and assessment of this impact (1). This study aims to evaluate and describe how patients perceive their sexual performance and characterize their demographics.

Clinical characteristics

Methods: We conducted a cross-sectional study in patients with at least one rheumatologic disease at an outpatient rheumatology clinic in at Hospital Universitario Dr. José Eleuterio González. Those without active sexual life, or pregnancy, and those unwilling to answer the questionnaire reliably were excluded. Patients over 18 years old were evaluated from August 2022 to April 2023 with the Arizona Sexual Experiences Scale (ASEX), Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) and Hospital Anxiety and Depression Scale (HADS). Sociodemographic and medical data were collected from patient files.

Results: We included 893 patients. A third (30%) of patients refused to answer and only 40.54 % (362) reported an active sexual life. Sexual dysfunction (SD) was reported in 60 (17%), with a higher prevalence observed in women (95%) than men (5%) (table 1). The mean age in patients with SD was 38.7± 11.2. Being married, younger, and having menopause were associated with a higher prevalence of SD. The most related diagnosis to SD was Rheumatoid Arthritis (n=34, 56.7%) (Table 2) Patients with SD also presented a tendency for depression and fatigue in clinical scales analysis, but not to anxiety. Less education and having children are also associated with SD.

Conclusion: We found a prevalence of SD of 17% in our population. The presence of menopause, a younger age, and offspring was more frequent in patients with SD. Special attention should be take to these factors in the evaluation of sexuality in patients with rheumatic diseases.

Abstract Number: 0146

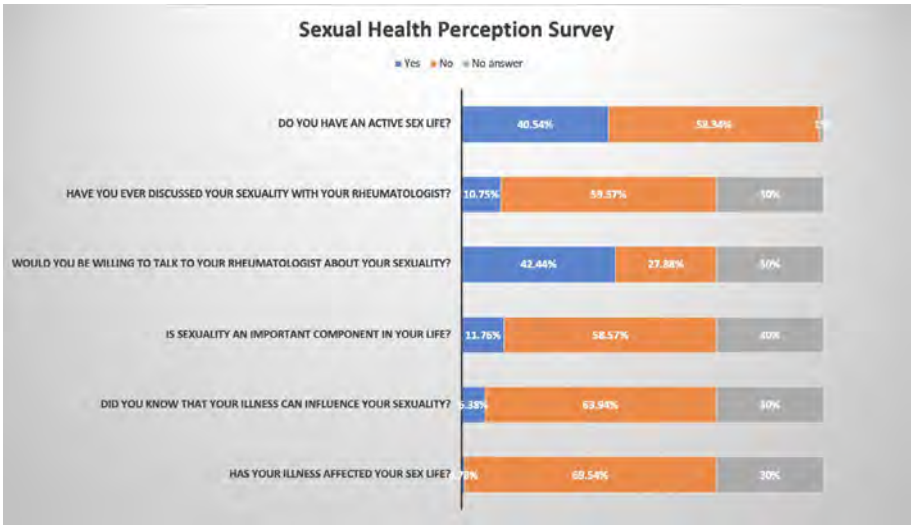
Sexual Health and Self-Perception in Rheumatologic Patients: Has Your Rheumatologist Ever Talked to You About Sexual Health?

Luis Vega Sevilla[1], Griselda Serna-Peña[2], **Diana Paola Flores-Gutierrez**[3], Jesus Alberto Cardenas-De la Garza[4], Dionicio A. Galarza-Delgado[5] and Ivan Hernandez Galarza[6], [1]Hospital Universitario UANL, Garcia, Mexico, [2]Universidad Autónoma de Nuevo León, Guadalupe, Mexico, [3]Hospital Universitario "Dr. José Eleuterio González", Monterrey, Mexico, [4]Hospital Universitario "Dr. José Eleuterio González", San Nicolas, Mexico, [5]Hospital Universitario UANL, Monterrey, Mexico, [6]University Hospital, UANL, San Pedro Garza Garcia, Mexico

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There's a high prevalence of sexual dysfunction (SD) in patients with rheumatic diseases (RD). Studies show that it goes from a 36% to a 70%, and still they are not regularly addressed in a routine rheumatologic assessment. Self-perception questionnaires applied to patients with rheumatoid arthritis (RA) have reported that most patients don't share their sexual health concerns with their rheumatologists, even when 32.5% wished their rheumatologist did establish the possibility of doing so. (1)This study aims to describe the prevalence of self-perceived and knowledge of sexual health in patients with RD.

Methods: We conducted a cross-sectional study in patients with at least one rheumatologic disease at an outpatient rheumatology clinic. Those unwilling to answer the questionnaire reliably were excluded. The Sexual Health Perception Survey (SHEPS) was applied and consists of the following questions: 1) Do you have an active sexual life? 2) Have you ever talked



to your rheumatologist about your sexuality? 3) Would you be willing to talk to your rheumatologist about your sexuality? 4) Is sexuality an important component in your life? 5) Did you know that your disease influences your sexuality? 6) Has your disease affected your sexual life? Sociodemographic and medical data were collected from patient files.

Results: We screened 893 patients. A third (30%) of patients refused to answer. Of the 628 patients who answered, 362 (40.5%) had an active sex life, and 105 (11.76) considered sex an important part of their life. While 379 (42.4%) patients reported they are willing to speak to their rheumatologist about their sexuality, only 96 (10.7%) had spoken to their rheumatologist about it. Only 6.3% (57) patients previously knew their rheumatic disease could affect their sexual life, and less than 1% (7) of the patients considered that their rheumatic disease was affecting their sexual life. A higher prevalence of auto-perceived sexual dysfunction (APSD) was observed in women (91.2%) than men (18.9%). Mean (SD) age in patients with self-perceived APSD was 56.14 (22.74). Most related diagnosis to APSD was Rheumatoid Arthritis (n=3).

Conclusion: The SHEPS results show that even when an important percentage of patients are willing to speak to their rheumatologist about their sexuality, only a small percentage has done it. Also, only a few patients knew their rheumatic disease could influence their sexual life, and even a smaller percentage considers it has been affected by it.

Leukotriene Inhibitors Effect on Post-Traumatic Osteoarthritis: A Real-World Evidence Comparative Effectiveness Study

S. Reza Jafarzadeh[1], Matthew Baker[2], Christine E. Peloquin[3], William H. Robinson[4] and David Felson[3], [1]Boston University Chobanian & Avedisian School of Medicine, Boston, MA, [2]Stanford University, Menlo Park, CA, [3]Boston University, Boston, MA, [4]Stanford University, Palo Alto, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Joint injuries frequently lead to post-traumatic osteoarthritis (OA), a disabling condition often affecting young adults, impacting their quality of life and creating substantial economic consequences for society. To fill the therapeutic void, drug repurposing is an attractive alternative to traditional drug development, which is costly and slow-moving. The aim of this work is to assess the effectiveness of leukotriene inhibitors on preventing post-traumatic OA compared with long-acting beta agonists, both of which are commonly used drugs for asthma. Leukotriene inhibitors suppress mast cell products, and data from mouse models suggest that inhibiting mast cell activation and downstream inflammatory processes can prevent OA.

Table 1. Odds of subsequent osteoarthritis and knee replacement in users of leukotriene inhibitors vs. long-acting beta agonists undergoing ACL or meniscal surgery.

Outcome definition	*Odds ratio (95% CI)	
n = 10,973 (prior OA/KR excluded)	**5-year odds**	**10-year odds**
One OA claim	0.96 (0.82, 1.12)	0.81 (0.62, 1.12)
OA claim + NSAID/opioid	0.95 (0.81, 1.12)	0.94 (0.88, 1.01)
OA claim + knee imaging claim	0.99 (0.85, 1.17)	0.86 (0.66, 1.12)
Two OA claims ≥7 days apart	1.03 (0.88, 1.20)	0.96 (0.86, 1.07)
n = 13,800 (only prior KR excluded)		
TKR	0.96 (0.81, 1.12)	0.89 (0.71, 1.12)
Composite OA/KR	0.95 (0.84, 1.08)	0.80 (0.62, 1.03)

* Adjusted for age, sex, geographical region, obesity, a history of chronic kidney disease, diabetes, liver disease, and depression

Methods: Persons with a claim for anterior cruciate ligament (ACL) or meniscal surgery between 2006 and 2020 were drawn from MarketScan Commercial Claims and Encounters (Merative) databases. The date of the surgery claim was defined as the index date. Enrollees were eligible if aged 18-45 years on index date and if they had continuous enrollment for at least 6 months prior to the index date (baseline period) and 12 months after the index date (follow-up period). Additionally, subjects had to be users of leukotriene inhibitors (montelukast, zafirlukast, or zileuton) or an active comparator that consisted of long-acting beta agonists (albuterol, arformoterol, formoterol, indacaterol, olodaterol, salmeterol, terbutaline, or vilanterol) for any duration from the index date up to 6 months after. The study outcomes were identified as claims for OA and/or knee replacement (KR) during the follow-up period, which for OA was the first claim 12 months after the index date to minimize misclassifying trauma as OA. Various definitions of outcome were considered, which included OA claims with and without NSAIDs or opioid prescription or knee imaging (X-ray or MRI) within a year, and a composite outcome of OA and KR. Exclusions consisted of subjects with a history of chronic obstructive pulmonary disease, a prior KR, or a prior OA diagnosis (for OA outcomes only). We used causal inference-based targeted learning estimated through ensemble machine learning to compare incident outcomes among users of leukotriene inhibitors with comparator users within 5 and 10 years, accounting for loss to follow-up by incorporating inverse probability weighting for censoring.

Results: Data included 13,800 persons (50.0% female, mean age = 35.4 [SD = 8.5] years) who underwent ACL/meniscal surgery. Compared with users of long-acting beta-agonists, the odds of KR, adjusted for confounders and loss to follow-up, was about 4% lower at 5 years and 11% lower at 10 years follow-up in users of leukotriene inhibitors undergoing surgery (Table 1). For OA outcomes, the odds of short- and long-term outcomes similarly showed a modest decrease for leukotriene inhibitor users compared with users of comparator drugs, however, estimated confidence intervals crossed the null.

Conclusion: Users of leukotriene inhibitors undergoing ACL or meniscal surgery may have lower odds of post-traumatic OA compared with users of long-acting beta agonists.

Recreational Activities in Adults with Rheumatoid Arthritis: Relevance, Difficulty, and Associations with Clinical Outcomes

Sarah Novroski[1], Chris Lane[1], Joshua Torrey[2] and Louise Thoma[3], [1]UNC Chapel Hill, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) can limit one's ability to participate in recreational activities. Participation in recreational activities enhances quality of life, yet limited literature addresses recreational activity. The Short-Valued Life Activities (SVLA) questionnaire specifically assesses difficulty with five categories of recreational activities including if accommodations (e.g., extra time, assistance) are needed to participate. Respondents can also indicate if an item is not relevant to their lives, which is a feature absent from many common patient-reported outcomes. The purpose of the study was to (1) describe the relevance and difficulty with recreational activities among adults with RA and (2) examine the association of difficulty with recreational activity with physical function (PF), fatigue, and pain.

Methods: In this cross-sectional study, participants with RA (n=290) completed an online survey regarding their current clinical outcomes and demographic information. Participants were eligible if they were 18 years old or older and received care between 2020-2021 from UNC Rheumatology for RA. We assessed participation in recreational activities using items 5, 7, 10, 11 and 12 from the SVLA (i.e., gardening/yardwork, attending social events, leisure activities, hobbies, and physical recreation). Participants first identified if each item activity was relevant to them. If relevant, they selected their level of difficulty to perform the activity (i.e., none, some, a lot or unable to participate) and if they used an accommodation or not (e.g., extra time, assistance, tools). PROMIS short forms were used to assess physical function, fatigue, and pain interference. For purpose one, we calculated the proportion of the sample who identified each item as relevant, and as relevant and difficult (defined as at least some difficulty or accommodation use). For purpose two, we identified the item that was most frequently relevant and difficult and tested the association of this item with physical function, fatigue, and pain using a general linear model. Significance was set at alpha < 0.05. If the association was significant, Tukey's tests were used to evaluate pairwise differences between groups.

Results: The recreational activities were relevant for most of the sample (86%-95%, Table 1). Physical recreation was the most frequently relevant and difficult activity (75% of the sample). Greater difficulty with physical recreation was associated with worse physical function, fatigue, and pain ($F_{7,282}$ = 20.1 – 41.6, all p < 0.001). Participants who reported no difficulty and no accommodation use with physical recreation had better physical function, fatigue, and pain compared to nearly all other response categories (p< 0.05, Table 2).

Conclusion: Recreational activities were highly relevant and difficult for most adults with RA. Even small increases in difficulty, such as accommodation use, were associated with worse clinical outcomes, suggesting accommodation use could be an early indicator of declining functional abilities. Further research is needed to understand how to best support participation in recreational activity.

Table 1.

Table 1. Proportion of the sample reporting recreational activities as relevant and difficulty

SVLA Item	Total respondents	Proportion who reported the activity as relevant	Proportion who reported the activity as relevant and difficult*
	n	% (n)	% (n)
Gardening/Yardwork	292	86% (252)	66% (193)
Attending social events	290	95% (275)	50% (146)
Leisure activities	290	95% (276)	46% (134)
Hobbies	289	87% (251)	56% (162)
Physical Recreation	290	95% (274)	75% (216)

*difficult indicates any level of difficulty or accommodation use with the activity

Table 2.

Table 2. Association of Physical Recreation Difficulty with Clinical Outcomes

SVLA Item Response to the Physical Recreation Item	n	PROMIS Physical Function t-score Mean (95% CI)	PROMIS Fatigue t-score Mean (95% CI)	PROMIS Pain Interference t-score Mean (95% CI)
No difficulty + no accommodation	58	50.9 (48.8, 53.1)	49.3 (47.8, 50.9)	47.5 (45.3, 49.7)
No difficulty + accommodation use	11	42.3 (37.6, 47.0)*	59.1 (56.3, 62.0)*	58.9 (55.6, 62.1)*
Some difficulty + no accommodation	28	44.9 (42.4, 47.4)*	51.7 (49.3, 54.0)	53.1 (50.3, 55.8)*
Some difficulty + accommodation use	84	42.1 (40.7, 43.5)*	57.3 (55.7, 58.8)*	56.4 (54.8, 58.0)*
A lot of difficulty + no accommodation	4	36.9 (23.5, 50.2)*	54.4 (33.3, 75.5)	56.1 (39.3, 73.0)
A lot of difficulty + accommodation use	67	34.1 (32.8, 35.5)*	62.0 (60.2, 63.9)*	63.5 (62.2, 64.9)*
Unable to do	22	28.7 (26.5, 30.9)*	63.7 (60.6, 66.8)*	66.9 (63.8, 69.9)*
Not relevant	16	37.2 (32.8, 41.6)*	57.8 (53.2, 62.4)*	59.5 (53.9, 65.1)*

*indicates significantly different ($p<0.05$) than 'No difficulty + no accommodation' group in post-hoc testing

Impacts of Social Determinants of Health and the Immune System in Adults with Acute-to-Chronic Low Back Pain: An Observational Study

Colleen Burke[1], Michael Brown[2], Kenneth Taylor[2], Stephanie Danyluk[2], Kelley Seebeck[2] and Adam Goode[3], [1]Duke University School of Medicine, Chapel Hill, NC, [2]Duke University School of Medicine, Durham, NC, [3]Duke University, Durham, NC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic low back pain (cLBP) is common worldwide yet poorly understood due to the combination of biological, psychological, and sociological factors. An individual's social determinants of health (SDOH) may influence biology by inducing immune responses. While these immune responses likely contribute to the development of cLBP, the mechanisms of how they contribute remain unknown. The purpose of this study is to investigate the relationship between SDOH and the immune system both in individuals who did and did not transition from acute to cLBP.

Methods: Adults (n=26) experiencing acute LBP (< 4 weeks) were recruited from the community. Data was gathered at baseline and 3-month follow-up to determine the participant's low back pain status (i.e., transition to cLBP). Data on SDOH included measures of social connection and social roles, which were measured using the Social Network Index (SNI) recommended by the Institute of Medicine as well as the PROMIS Short Form - Global - Version 1.2 Global Social Activities and Roles Item. We also collected self-reported demographics (i.e., age, gender, and race) and peripheral blood samples.

Peripheral blood mononuclear cell (PBMC) and plasma cytokines were analyzed, and cell-type specific immune activation or tolerance features were analyzed by high dimensional flow cytometry. Multiplex cytokine secretion after PBMC stimulation with innate immune activators were used to measure immune function and tolerance.

Results: Of the social factors, social roles were most associated with immune cell changes and plasma cytokines. Relative to inability to uphold social roles, confidence in one's ability to uphold social roles was associated with lower inflammatory cytokines at baseline and follow-up, lower monocyte expression of TNF at baseline; but higher CD8 T cell proliferation/differentiation and relative increase in monocyte inflammation from baseline to follow-up (Figure 1). For self-reported demographic factors, when sub-grouped by race, White participants had higher inflammatory cytokines in plasma. Several immune cell differences between Black vs White race were observed, including higher levels of B cells; lower monocytes, CD141+ DCs, and regulatory T cells; lower immune suppressing ligands on B cells; and increased markers of T cell differentiation (Figure 1). PBMC functional measurements (i.e., responses to stimulation) revealed similar patterns within each race, wherein individuals who did not transition to cLBP mounted weaker responses than those who did transition to cLBP, possibly indicating immune tolerance/desensitization in participants that do not progress to cLBP (Figure 2).

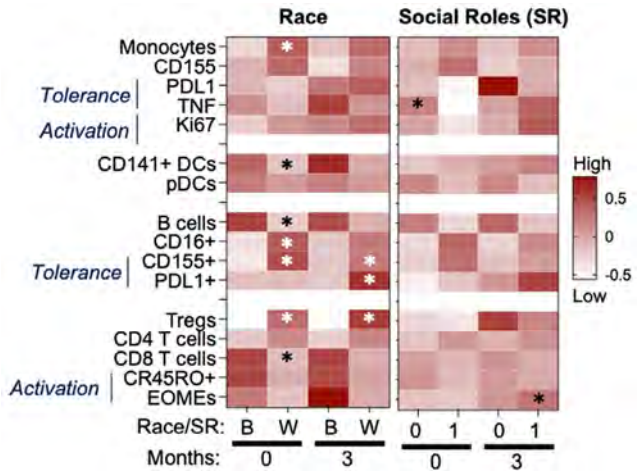

Figure 1. Immunological features on indicated cell types for each time point stratified by race (left) or social roles (SR, right). SR= 0 indicates inability to uphold social roles, SR= 1 indicates ability to uphold with social roles. Asterisks (*) indicate unpaired t-test within time point p<0.05 and heatmaps depict z-scores.

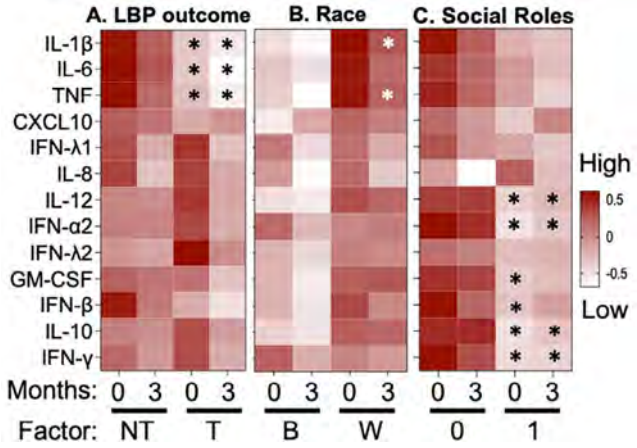

Figure 2. Plasma cytokine differences by LBP outcome (A), race (B), and social roles (C). Plasma cytokine levels at each time point separated by each indicated factor, z-scores for each cytokine are shown; (*) Mann-Whitney test p<0.05 vs by factor at each time point. From left to right: NT= no transition, T= transition to cLBP; B=Black, W- White; 0= inability to uphold social roles, 1= ability to uphold social roles.

Conclusion: SDOH such as race and social roles are associated with immune status and inflammation. Peripheral inflammation is lower in more desirable social factors (connection, roles, and stress) over time, with differences in monocyte inflammation at baseline. Differences in the immune system are observed based on race. While race alone does not explain these differences, it points to the need for further investigation into how SDOH influence the immune system leading to disparities in health outcomes.

Self-reported Levels of Physical Activity and the Association to Pain, Fatigue, Anxiety and Depression Among Patients with Idiopathic Inflammatory Myopathies

Kristofer Andreasson[1], Fabricio Espinosa-Ortega[2], Heléne Sandlund[3] and Helene Alexanderson[4], [1]Karolinska Institutet & Karolinska University Hospital, Stockholm, Sweden, [2]Division of Rheumatology, Department of Medicine, Karolinska Institutet; Department of Gastroenterology, Dermatology, Rhematology, Karolinska Universitetssjukhuset, Stockholm, Sweden, [3]Karolinska University Hospital, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with inflammatory diseases such as rheumatoid arthritis exhibit reduced levels of physical activity (PA) compared to the normative population and suffer from anxiety and/or depression. Physical activity at a health-enhancing level can help alleviate these symptoms and other co-morbidities. This study aims to assess the self-reported levels of PA and associations, to depression, anxiety, pain and fatigue among adults with idiopathic inflammatory myopathies (IIM) in Sweden.

Methods: All patients with IIM at the Rheumatology clinic at Karolinska University Hospital have been invited to participate, at a visit or by mail, during 2019-2022. To assess self-reported levels of PA, and screen for anxiety and depression the International Physical Activity Questionnaire – short form (IPAQ) and Hospital Anxiety and Depression Scale (HADS) were used.

Table 1. HADS-A, Hospital anxiety and depression scale - anxiety; HADS-D, Hospital anxiety and depression scale - depression; IPAQ, International physical activities questionnaire - short form; VAS, visual analog scale – 0-100 mm; * = p<0.05; **p<0.01; ***p<0.000; IPAQ is compared between levels, Pain and Fatigue is compared between HADS ≥8 and <8

Table 1. Distribution of patients based on HADS score.

Table 1	HADS-A		HADS-D		Total
	≥ 8, n=62 (25 %)	<8, n=184 (75 %)	≥ 8, n=34 (14 %)	<8, n=212 (86 %)	n = 246
IPAQ-low, n (%)	17 (40)*	26 (60)	14 (33)**	29 (67)	43 (17.5)
IPAQ-moderate and high, n (%)	45 (22)*	158 (78)	20 (10)**	183 (90)	203 (82.5)
Pain, mm-VAS, mean (SD)	38 (28)***	15 (18)***	31 (27)*	19 (22)*	21 (23)
Fatigue, mm-VAS, mean (SD)	50 (27)***	24 (25)***	50 (24)***	27 (27)***	30 (28)

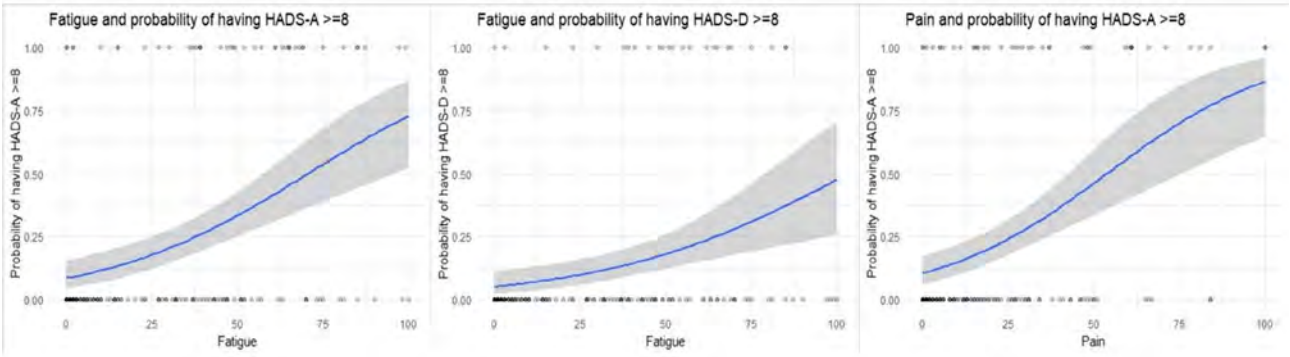

Figure 1. Probability of having a HADS-A as a factor of Fatigue (Panel A) and Pain (Panel B), and probability of having a HADS-D ≥8 as a factor of Pain (Panel C). HADS-A: Hospital Anxiety and Depression Scale for Anxiety, HADS-D: Hospital Anxiety and Depression Scale for Depression

HADS is scored in two sub-scales, one for depression (HADS-D) and one for anxiety (HADS-A). Maximal score is 21 and ≥8 is cut-off for probable depression or anxiety disorder. IPAQ-results were scored as low-PA, (not reaching moderate/high), moderate-PA, (≥600 MET-minutes/week) and high-PA, (≥1500 vigorous or 3000 moderate MET-minutes/week). Pain and fatigue on visual analogue scale (VAS), 0-100 mm were collected from the Swedish Quality Register. Multivariate logistic regression analysis was used to test the association between pain, fatigue, and IPAQ with HADS-A and HADS-D and χ^2 for group differences.

Results: A majority of patients reached or exceeded recommended PA-levels (82.5 %). Anxiety and depression were more prevalent in patients reporting low PA (Table 1). Moderate or high level of PA was associated with a 70 % lower risk of probable depression ($p< 0.01$). Each millimeter worsening in fatigue increased the risk of probable anxiety or depression by 2 % and 3 %, respectively. Each millimeter worsening in pain increased the risk of probable anxiety by 2.5 % (Figure 1).

Conclusion: Physical activity seems to significantly lower the risk of depression. There is an association of worsened pain and fatigue to increased risk of anxiety and worsened fatigue to increased risk of depression. Further, anxiety and depression are more prevalent among those failing to reach moderate/high levels of physical activity.

Arthritis: A Wealth Gap

Risha Fayyaz[1] and Anum Akhlaq[2], [1]University of Mississippi Medical Center, Flowood, MS, [2]University of Mississippi Medical Center, Jackson, MS

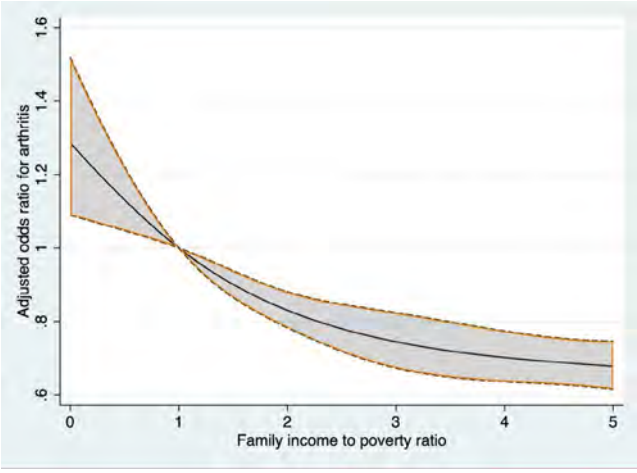
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lower socioeconomic status (SES) has been associated with worse health outcomes . Family income is a key component of SES. This study aimed to assess the association of family income with arthritis in the adult population in the United States.

Methods: Data from the National Health and Nutrition Examination Survey (NHANES) from 2005 to 2018 were analyzed. The family income to poverty ratio (FIPR) was used as a measure of SES. FIPR was calculated by dividing family (or individual) income by the poverty guidelines specific to the survey year. FIPR was categorized in 6 levels: FIPR < 1 (for the lowest income), 1-1.9,2-2.9,3-3.9,4-4.9, ≥5 (for highest income). Arthritis was defined by the participants' response to the following question: "Has a doctor or other health professional ever told you that you had arthritis?".

Results: The unadjusted prevalence of arthritis was 24.73% in the lowest income group (FIPR < 1). The prevalence of arthritis decreased with increasing FIPR, and was 23.87% in the highest income group (FIPR ≥ 5). After adjusting for age, race/ethnicity, and sex, the prevalence odds of arthritis were lower in participants with FIPR 1-1.9 (aOR, 95% CI: 0.79 (0.70-0.88), p < 0.001); FIPR 2-2.9: (aOR, 95% CI: 0.66 (0.58-0.75), p < 0.001); FIPR 3-3.9 (aOR, 95% CI: 0.64 (0.55-0.75), p< 0.001); FIPR 4-4.9: (aOR 95% CI: 0.67 (0.57-0.77), p < 0.001), and FIPR ≥5: (aOR, 95% CI: 0.57 (0.50-0.65), p < 0.001).

Conclusion: These findings suggest that lower family income is associated with an increased prevalence of arthritis. Targeted interventions should be directed toward closing this socioeconomic gap which can potentially alleviate the disease burden.



Relationship between FIPR and adjusted odds ratio for arthritis

Long Covid in Persons with Self-Reported Arthritis - Symptoms, Associated Factors and Functional Limitations

Debbie Ehrmann Feldman[1] and Barbara Mazer[2], [1]Université de Montréal, Montreal, QC, Canada, [2]McGill University, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Long covid, a condition whereby signs and symptoms post covid-19 infection continue for more than 12 weeks and are not explained by an alternative diagnosis, may be more frequent among persons with arthritis. Currently, little is known whether persons with arthritis are at higher risk for long covid and how long covid affects their function. Our objectives are 1) to describe long covid in a cohort of persons with a self-reported history of arthritis who had been diagnosed with covid-19 in terms of frequency, symptoms and associated factors; and 2) to describe change in function in persons with arthritis and long covid compared to pre-covid status, focusing on: perceived global health status, mobility, personal care, participation in daily activities, and employment.

Methods: Among 2764 persons with a confirmed covid-19 diagnosis who responded to an online survey, 171 reported a history of arthritis and formed our study sample. The survey included validated questionnaires: the Newcastle Post-Covid Syndrome Questionnaire and the Covid-19 Yorkshire Rehabilitation Screen. We calculated the frequency of long covid (defined as those still troubled by symptoms) and persistent symptoms, and evaluated associated factors using bivariate analysis and multivariable logistic regression. Among those with long covid, we describe limitations in activity and function in comparison to pre-covid status. Change was calculated by subtracting the current functional score from the pre-covid 19 score and we categorized degree of change as small, moderate and severe.

Results: In our sample, 53.5% were still troubled by symptoms and the most frequent symptoms were: fatigue, myalgia, weakness, breathlessness, low mood, anxiety, and sleep disturbance. Factors associated with long covid were female sex, having been hospitalized for covid, and having at least one other chronic disease. Persons with long covid had substantial declines in function, notably in global health status, usual activities, mobility, personal care, and employment status. For example, 9.3% had major problems with usual activities pre-covid and this proportion rose to 52.5% with long covid. Fatigue was a big problem with 88% reporting a change and 52% reporting the decline as being moderate to severe. Also, 37% reported moderate to severe increase in pain.

Conclusion: Persons with arthritis and long covid have substantial limitations in function compared to pre-covid status. There is a need to implement effective interventions to improve functional status in persons with arthritis and long covid.

Diminished Vibration Perception and Greater Pressure Pain Sensitivity Are Associated with Worse Knee Osteoarthritis Outcomes Across Sex and Race

Chris Lane[1], Louise Thoma[2], Carolina Alvarez[3], Deborah Givens[4], Amanda Nelson[4], Adam Goode[5], Kharma Foucher[6] and Yvonne Golightly[7], [1]UNC Chapel Hill, Chapel Hill, NC, [2]University of North Carolina, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Miami, FL, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, [5]Duke University, Durham, NC, [6]University of Illinois at Chicago, Chicago, IL, [7]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sex and race differences have been observed in clinical outcomes such as patient-reported pain and function in adults with knee OA. However, few studies have examined sex and race differences in vibration sensitivity and pressure pain sensitivity, which may better represent neurophysiological changes suggestive of longer-term symptoms. The purpose of the study was to examine if associations of these neurophysiological assessments with knee OA outcomes differ across sex and race, which may contribute to known sex and race disparities in clinical outcomes.

Methods: Data were from the 2013-2015 follow-up of the Johnston County Osteoarthritis Project. Exposures were vibration perception threshold (VPT) and pressure pain threshold (PPT). VPT was measured using a biothesiometer operating at 120 Hz at the bilateral medial femoral condyle (MFC) and first metatarsophalangeal joint (MTP). PPT was measured on a 0-4 kg scale using a standard mechanical pressure-based dolorimeter operating at 1 kg/sec at the bilateral upper trapezius. Outcomes were frequency of radiographic knee OA (rKOA, defined as Kellgren-Lawrence grade 2–4), Ksx (defined as knee pain, aching, or stiffness on most days of any one month in the last 12 months regardless of rKOA status), symptomatic knee OA (sxKOA, defined as having both rKOA and knee symptoms), and knee pain severity (measured with Knee Injury and Osteoarthritis Outcome Score (KOOS) Pain Subscale) in each knee. We examined cross-sectional associations of the exposures with the outcomes using separate logistic regression models to calculate odds ratios for dichotomous outcomes and log linear models to calculate density ratios for knee pain severity, with 95% confidence intervals. Limb-level models were assessed using generalized estimating equations to account for correlations between limbs and adjusted for relevant covariates (Table 1). Results were presented for the overall sample and separately by sex or race.

SxKOA	324 (18.9%)	1.11 (0.91, 1.35)	259 (22.3%)	1.11 (0.91, 1.36)	65 (11.8%)	1.09 (0.56, 2.11)	193 (16.9%)	1.11 (0.87, 1.41)	131 (23.0%)	1.12 (0.84, 1.50)
Knee Pain Severity	94.4 (72.2-100)	**1.23 (1.12, 1.36)**	91.7 (69.4-100)	**1.21 (1.09, 1.33)**	100 (77.8-100)	**1.50 (1.14, 1.99)**	94.4 (75.0-100)	**1.15 (1.02, 1.29)**	94.4 (69.4-100)	**1.39 (1.20, 1.61)**

* Outcome Frequency [n (%)] or Summary [Median (IQR)]

^ adjusted odds ratio (aOR) or adjusted density ratio (aDR), adjusted for age, sex, race, body mass index, presence of depressive symptoms, presence of any conditions related to peripheral neuropathy, presence of any conditions related to sensation/vibration, prior knee injury; for pain outcomes: Pain Catastrophizing Scale, Tampa Scale of Kinesiophobia-6 were also included

Bold indicates significant association at an alpha level of 0.05.

Results: Of 851 and 862 participants available for the VPT and PPT analysis (mean age 71 years, 2/3 female, 1/3 Black, BMI 31 kg/m^2), 1585 and 1660 knees were used for complete case analysis, respectively. Higher VPT (higher threshold for vibration perception) at the MFC and MTP was associated with the presence of all outcomes. Lower PPT (lower threshold for pain) was associated with greater knee pain severity. Estimates of associations of VPT with all outcomes were similar among women and men but some estimates were less precise (wider confidence interval) among men than women. Estimates for PPT were similar among men and women. Estimates of associations of VPT and PPT with all outcomes were similar among White and Black adults but some estimates were less precise among Black adults than White adults (Table 1).

Conclusion: Diminished vibration perception and greater pressure pain sensitivity were cross-sectionally associated with worse knee OA outcomes. Associations were similar across sex and race groups, suggesting the neurophysiological assessments do not largely inform established sex and race disparities in clinical outcomes.

Impact of Social Determinants of Health (SDoH) on Survey Response Times Among Lupus Patients

Daniel Bao[1], Charmayne Dunlop-Thomas[2], Cristina Drenkard[2] and S. Sam Lim[2], [1]Johns Creek High School, Johns Creek, GA, [2]Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Epidemiology & Public Health – Interprofessional Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Social determinants of health (SDoH) significantly impact outcomes of Systemic lupus erythematosus (SLE) patients. However, little is known about the influence of SDoH on research participation in this population. We examined whether SDoH are associated with survey response times in a population-based SLE cohort. This is crucial as patient-reported outcomes are fundamental in capturing patient perspectives and informing healthcare interventions.

Methods: Data was sourced from the Georgians Organized Against Lupus (GOAL) 2018-2019 annual patient-reported survey, a population-based cohort study of validated SLE patients established in Atlanta, Georgia. Survey response times and completion methods (mail, web, in-person, and by-phone) were collected. Social Vulnerability Index (SVI), a census tract-based metric linked to participants' home addresses, was used given its compressive characterization of neighborhood-level SDoH. Differences in the mean response times by sociodemographic factors and survey completion methods were tested using two-tailed two-sample t-tests or ANOVA. Associations between response time and SVIs (overall and four thematic SVIs) were explored using linear regression analysis.

Results: 695 participants were included in this analysis. The mean age was 50.3 years old [SD 13.4]. The majority of participants were female (93.5%) and black (81.1%). 11.5% of participants had no insurance, and 39.7% were below the federal poverty level. 188 (27.1%) surveys were completed by mail, 440 (63.3%) by web, and 66 (9.5%) in-person or by-phone (Table). The mean response time was significantly higher for surveys completed by mail than by web (91.0 vs. 52.8, $p< 0.001$). Among the surveys completed by mail, quicker response times were associated with participants with lower

Theme 4): Housing & Transportation	692	-18.9 (11.1)	0.088	437	-16.7 (13.7)	0.22	188	-50.4 (22.8)	***0.028***
Overall Social Vulnerability Index	692	-35.0 (11.5)	***0.0023***	437	-23.7 (14.0)	0.092	188	-96.4 (23.0)	***<0.001***

education (p=0.037), less insurance coverage (p=0.002), a non-married status (p=0.019), and income below the federal poverty level (p=0.004). Survey response times were negatively associated with overall SVI (slope=-96.4, p< 0.001), as well as all of its four subindices: socioeconomic status (slope=-84.5, p< 0.001), household composition & disability (slope=-76.6, p=0.001), minority status & language (slope=-70.9, p=0.008), and housing & transportation (slope=-50.4, p=0.028). No such associations were found in web surveys, though younger participants completed the survey faster online.

Conclusion: Our study shows that SDoH impact mail survey response times in the Georgian SLE population. The overall SVI and all of its subindices are significantly and negatively linked with response times. SDoH's influence on response times varies based on the survey completion method, with insurance, marital, education, and poverty status significant for mail surveys but not web surveys. While requiring web-based surveys would be ideal, mail surveys are unavoidable, especially for those with limited access to technology. Tailored strategies are needed to address SDoH disparities when surveying the SLE populace, especially for underrepresented groups. Further studies are necessary to explore additional interventions to mitigate SDoH-related barriers in SLE patient surveys.

Abstract Number: 0155

Cost Analysis of Subcutaneous Methotrexate Compared to Oral Methotrexate Treatment for Rheumatoid Arthritis

Aniket Kawatkar, David Yi, Erika Estrada and Cecilia Portugal, Kaiser Permanente Southern California, Pasadena, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA)patients who switch from oral to subcutaneous methotrexate (MTX) may experience better response to treatment due to increased bioavailability, enhanced tolerability, increased adherence, fewer side effects and better clinical response rates. However, the economic impact of such a switch is unknown. The study objective was to evaluate the incremental cost associated with subcutaneous (Rasuvo®) vs. oral MTX treatment in RA patients.

Methods: A comparative effectiveness study was conducted in adult (18+ years) RA patients on MTX treatment, identified from the Kaiser Permanente Southern California health plan member population. We employed a prospective cohort study design with 1:1 matching of oral vs. Rasuvo® users. After obtaining informed consent, patients completed either a web based or mailed paper survey which recorded their baseline disease activity scores using the MDHAQ's RAPID3 measure. We analyzed direct medical expenditure associated with medical office visits (routine and urgent care), hospital outpatient and ED visits, inpatient and observation stays, pharmacy utilization, laboratory, and radiology utilization during the one-year following the index prescription fill for MTX. To mitigate potential bias due to non-random treatment assignment, we used 2-stage residual inclusion instrumental variables (2SRI) techniques to evaluate the incremental effect of oral MTX vs Rasuvo® on total all cause expenditure as well as subgroups of utilization. Depending on the degree of zero mass, either one part or two part generalized linear model with log link and gamma family distribution with 2SRI correction were specified while confidence intervals were based on 1000 bootstrapped repetitions of these outcome models. Each utilization model adjusted for baseline disease activity (based on MDHAQ survey), duration of RA (early within 2-years of diagnosis); duration of MTX use; age, female sex, white race, Hispanic ethnicity, smoking status, body mass index over 30, income category and Charlson comorbidity index.

Table 1. Baseline Demographics and Disease Activity Levels

	Oral Methotrexate (n = 286)	Rasuvo® (n = 283)
Age (in years) at baseline survey mean (SD)	59 (± 15.0)	55 (± 14.6)
Early RA (%)	27.6%	24.7%
Prior methotrexate use over 2-years (%)	59.1%	25.4%
Female sex (%)	75.2%	90.1%
White race (%)	66.4%	58.3%
Hispanic ethnicity (%)	32.5%	41.3%
Never smoked (%)	65.0%	68.6%
Obese (BMI 30+) (%)	43.7%	45.2%
Low income (%)	19.6%	25.4%
2 or More Charlson comorbidities (%)	23.8%	29.0%
MDHAQ		
Baseline disease activity Remission (Score 3 or Less) (%)	9.90%	4.20%
Low disease activity (score 3.1–6) (%)	17.60%	9.90%
Moderate disease activity (score 6.1–12) (%)	36.60%	32.0%
High disease activity (score 12.1 and up) (%)	35.90%	54.0%

Table 2. Marginal Mean Expenditure and Marginal Difference Between Rasuvo® vs Oral MTX

Cost	Utilization Subgroups Included in Category	Marginal Mean Expenditure (Std Error. of Mean)*@		
		Oral MTX (N=286)	Rasuvo® (N=283)	Marginal Difference between Rasuvo® vs Oral MTX^@@ (95% Confidence Interval)
Total all cause cost	Summation of all subcategories of utiliznition	$8,676 (±1156)	$13,380 (±945)	**$4,704 ($1,758 to $7,650)**
All cause Pharmacy cost	Expenditures for pharmacy fills for any condition	$5,680 (±1163)	$9,903 (±759)	**$4,223 ($1,460 to $6,986)**
Office visits costs	Medical office visit to primary care, or specialist for any condition. Includes all procedures and imaging or laboratory orders associated with that visit	$820 (±103)	$874 (±106)	$54 (-$231 to $338)
Inpatient and Observation Stays Costs	Inpatient stay and observation stay	$1,458 (±4,832)	$1,187 (±3,809)	-$270 (-$11,210 to $10,669)
Emergency department costs	Emergency department visits	$407 (±215)	$504 (±303)	$97 (-$383 to $576)
Urgent care costs	Urgent care department cost	$50 (±35)	$97 (±39)	$47 (-$47 to $140)
Imaging/radiology cost	Imaging orders	$530 (±64)	$698 (±71)	$168 (-$24 to $360)
Laboratory cost	Laboratory tests	$286 (±35)	$282 (±19)	-$4 (-$80 to $71)

##Bold Font indicate statistically significant differences

@ Generalized linear model (GLM) with log link and gamma family distribution which included the first stage residual (2SRI) along with covariates was used to estimate marginal expenditures

@@ Bootstrapping (1000 reps) of GLM was used to estimate the standard errors and for hypothesis testing

*All Models adjusted for baseline disease activity (based on MDHAQ survey), duration of RA (early within 2-years of diagnosis), duration of MTX use, age, female sex, white race, Hispanic ethnicity, smoking status, body mass index over 30, income category and Charlson comorbidity index.

Results: The baseline self-report survey completion rate was 20% (569/2885; oral methotrexate = 286 and Rasuvo® = 283). The mean age of the sample was 57 (±15) years with the majority (83%) of female (Table 1). Rasuvo® arm included a higher proportion of patients with multiple comorbid conditions (29% vs 24%) and who also had higher proportion reporting high disease activity (54% vs 36%) (Table 1). Rasuvo® use was associated with significantly higher all cause total expenditure $4,704 (95% CI $1,758 to $7,650) which was predominantly a result of higher costs associated with all cause pharmacy utilization $4,223 (95% CI $1,460 to $6,986) (Table 2). None of the other subgroups of utilization had statistically significant differences.

Conclusion: In this prospective comparative effectiveness study, patients on subcutaneous methotrexate were associated with higher total cost which was driven by increased pharmacy expenditure.

Factors Associated with Adherence to Cervical Cancer Screening in Ethnically Diverse Women with Systemic Lupus Erythematosus

Sebastian Bruera[1], Savannah Bowman[1], Yinan Huang[2], Maria Suarez-Almazor[3], Grace Lo[1], Elizabeth Chiao[4], Maria A. Lopez-Olivo[4] and Sandeep Agarwal[1], [1]Baylor College of Medicine, Houston, TX, [2]Department of Pharmacy Administration, University of Mississippi School of Pharmacy, Oxford, MS, [3]MD Anderson Cancer Center, Houston, TX, [4]The University of Texas, MD Anderson Cancer Center, Houston, TX

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Health Services Research Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Women living with systemic lupus erythematosus (SLE) are at an increased risk of infections from human papillomavirus (HPV), and cervical cancer, especially women with higher disease activity who require immunosuppression. The objective of this study was to determine cervical cancer screening rates in women with SLE, and to evaluate their attitudes and beliefs towards screening.

Methods: We conducted a cross-sectional study in which we enrolled consecutive women with a diagnosis of SLE by 2019 ACR criteria. Eligible women were ≥21 years old, without a prior hysterectomy or history of cervical cancer. We collected demographics, clinical characteristics, constructs of the Health Beliefs Model (HBM) (susceptibility, severity, perceived barriers, benefits, cues to action, and self-efficacy) and self-reported last cervical cancer screening (confirmed with the electronic medical record). Our primary outcome was adherence to cervical cancer screening according to the American Society for Colposcopy and Cervical Pathology (ASCCP) guidelines. Multivariable logistic regression models were used to examine the association between the SLE disease activity attributes and the cervical cancer screening and to explore the mediation effect of HBM constructs between disease activity and screening adherence.

Results: We enrolled 130 women with SLE to our study, the majority of whom were Black (35%) or Hispanic (52%), with a median age of 42. The cervical cancer screening adherence rate was 61.5%. Women with higher disease activity (SLEDAI < 6) underwent screening less frequently than those with low disease activity (76% vs 24%, $p < 0.05$). Multivariable logistic regression adjusting for demographics and clinical factors showed higher disease activity had a decreased odds of being screened than low disease activity (aOR 0.24, 95% CI 0.08-0.76, $p < 0.02$). HBM constructs, particularly perceived barriers ($r=-0.30$, $p< 0.01$) and self-efficacy ($r=0.21$, $p< 0.05$) were significantly correlated with the receipt of cervical cancer screening. Multivariable regression models adjusting for covariates and mediation effects of each HBM construct showed that SLE patients with high disease activity had decreased probability of cervical cancer screening ('perceived susceptibility': aOR 0.2548, $p < 0.01$; 'perceived severity': aOR 0.2552, $p< 0.01$; 'perceived barriers': aOR 0.2809, $p< 0.01$; 'perceived benefits': aOR 0.2491, $p< 0.01$; 'self-efficacy': aOR 0.2734, $p< 0.01$; 'cues to action': aOR 0.2602, $p< 0.01$).

Conclusion: Our results show that only 61.5% of women with SLE underwent screening according to ASCCP guidelines. Concerningly, only 24% of those with high disease activity, the highest risk population, had been screened. While some individual attitudes and beliefs partially explained these low rates, low odds for screening remained after adjustment. Our findings indicate the need for ascertainment of cervical cancer screening utilization in this high risk population as needed following ASCCP recommendations.

Discovering the Potential of Digital Biomarkers in the Work Process of the Rheumatology Healthcare Professionals, a Design Thinking Approach; Preliminary Results of the Healthcare Professionals Perspective

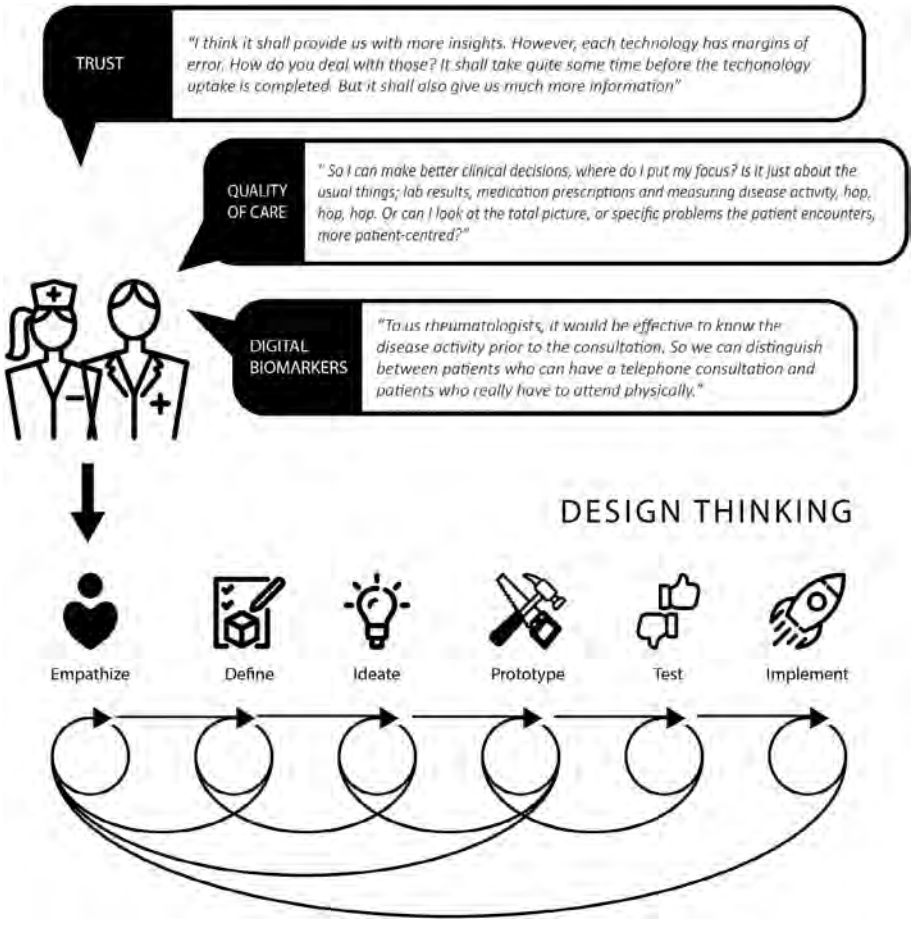
patty de Groot[1], Jolanda J. Luime[1], Marc r. Kok[2], marijn vis[1] and ilja Tchetverikov[3], [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Albert Sweitzer Hospital, Dordrecht, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: During times of social-distancing, in-person outpatient visits were greatly reduced. Health care professionals (HCPs) were dependent on the patient's reported experience of their disease activity in their assessments of the wellbeing and inflammatory state, due to lack of physical assessments. *Digital biomarkers* can support real-world continuous measurements and offer a method for remote quantification of inflammatory joint disease. They are defined as objective, quantifiable, physiological and behavioural data that are collected and measured with digital devices.

This study uncovers the HCPs perspective on current manners of disease activity monitoring, easing their workload and the potential of digital biomarkers.

Methods: A Design Thinking approach is followed for digital biomarker development. It is a human-centered problem solving approach that leverages iteration, empathy and collective idea generation to tackle complex challenges. Semi-structured online focus group discussions were conducted. Pilot 1-1 interviews were executed to assess the interview script. The script is underpinned by the graphical framework for clinical decision making (Charlin 2012) and the theoretical domain framework (Cane 2012). One moderator and three alternating observers facilitated the sessions. All interviews were audio-recorded, transcribed to verbatim and coded.



Quotes of the HCPs and the design thinking process

Results: Six focus groups were organised, with a total of 28 HCPs. Participants were rheumatologists (N= 19, age 47 ± 9, 50% male) and rheumatology nurses (N = 9, age 51 ± 6, 0% male). The main findings about digital biomarkers in relation to current practices were: *Trust;* HCPs felt self-assured about their own abilities of physical evaluation, reading patients and their gut feeling. Trust in flare detection with digital biomarkers and machine learning was low. It was expected that much disease activity is missed and many false-positive flares are detected. Biomarkers should be valid, reliable and sensitive to change. *Innovation should improve quality of care;* No consensus about a golden standard of care exists. HCPs were afraid that with digital biomarkers personal interaction recedes to the background and quality of care is compromised. Personal interaction was marked as essential to raise sensitive topics and stimulate therapy adherence. *Benefits of digital biomarkers;* HCPs enjoyed the delivery of efficient and effective care. They disliked repetition and the high administrative burden. In the HCPs opinion digital biomarkers could establish disease activity prior to the consultation, so time could be spent on what matters to the patient. New technologies should however not add to frustrations and make way for things that really matter.

Conclusion: The following problem statement from the HCPs perspective can be formulated: "In limited time we take many actions. We spend time on both disease and emotional support of our patients. Our workload is high and trivial tasks such as administration take too much of our time. Instead we want to focus on what's relevant to the patient. We are confident about our own abilities and, only if technology is proven to be valuable, valid, reliable and accepted by our patients it can be used in clinical practice."

Analyzing User Log Data to Track Provider Use of an EHR-based Dashboard for Rheumatoid Arthritis Outcomes

Lindsay Jacobsohn[1], Emma Kersey[1], Jing Li[1], Catherine Nasrallah[1], Cherish Wilson[2], Cammie Young[3], Cammie Young[3], Alicia Hamblin[1], Jinoos Yazdany[1] and Gabriela Schmajuk[2], [1]University of California San Francisco, San Francisco, CA, [2]UCSF / SFVA, San Francisco, CA, [3]University of California San Francisco, Oakland, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

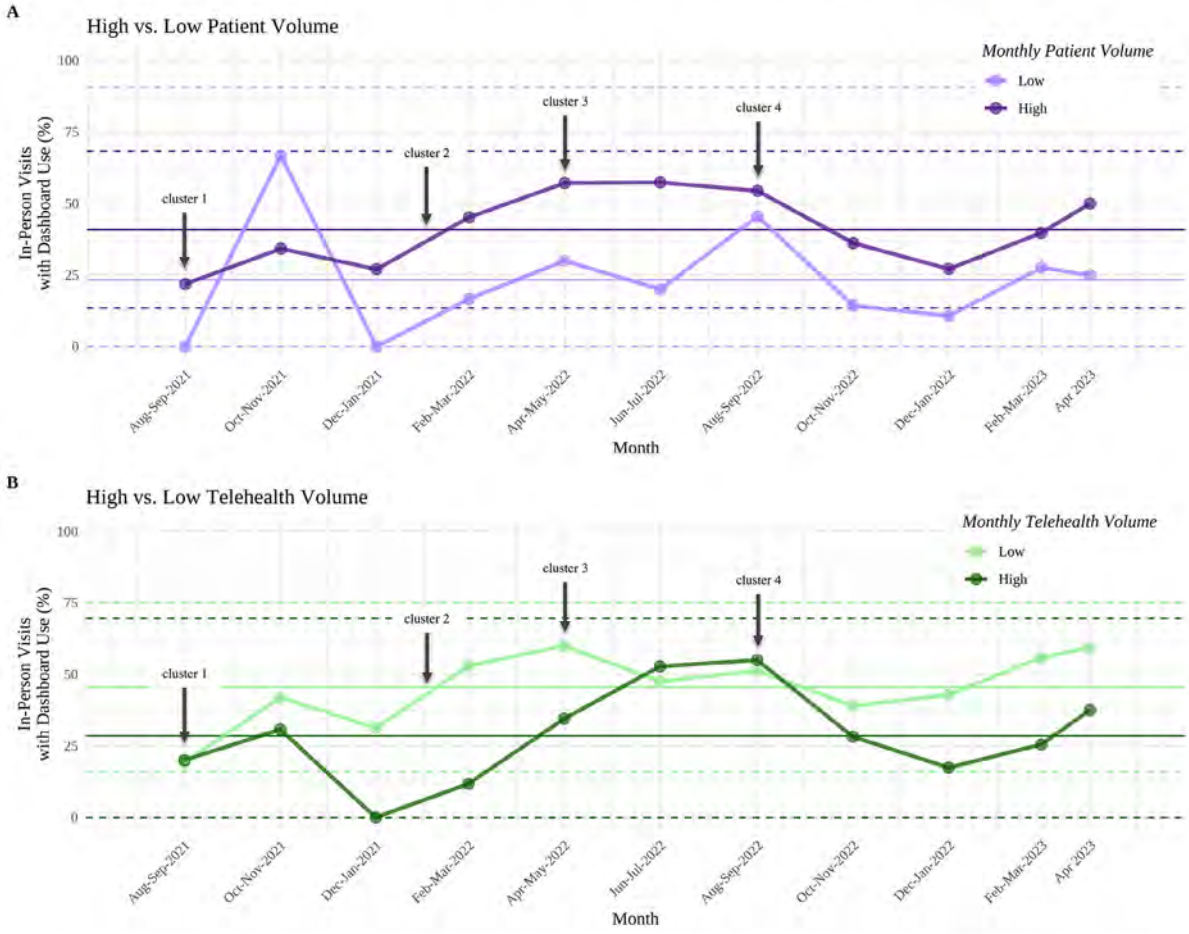
Background/Purpose: We developed an electronic health record (EHR)-based patient-facing sidecar dashboard application to display RA outcomes, including disease activity, functional status, and pain scores over time ("RA dashboard"). User log data is a novel data source that makes it possible to examine provider engagement with technology. We analyzed user log data from the RA dashboard to examine patterns of provider engagement with this health-information technology (IT) tool in the context of a pragmatic clinical trial.

Methods: The RA dashboard was implemented at a single academic rheumatology clinic as part of a stepped-wedge pragmatic trial in which 24 providers were randomized into 4 trial clusters between August 2021 and September 2022. User log data were collected from the initial roll-out through April 2023. The primary outcome was the number of "actions" taken by providers on the dashboard: possible actions included refresh, print, show/hide different sections of the dashboard, and scrolling up/down on the page or backward/forward through historical data. Provider characteristics included level of

Table 1. Characteristics of Providers with Access to the RA Dashboard (N = 24)

Provider Characteristic	*N (%)*
Dashboard Access (Trial cluster, date)	
1 (08/11/2021)	4 (16.7)
2 (02/01/2022)	5 (20.8)
3 (05/02/2022)	5 (20.8)
4 (09/26/2022)	10 (41.7)
Provider Training	
Attending Physician	16 (66.7)
Rheumatology Fellow	7 (29.2)
Physician Assistant	1 (4.2)
Average Patient Visits (N) per Month	
< 10 patients	8 (33.3)
≥ 10 patients	16 (66.7)
Average Telehealth Visits (%) per Month	
Quartile 1 (0 - < 35%)	6 (25.0)
Quartile 2 (35 - < 50%)	6 (25.0)
Quartile 3 (50 - < 58%)	4 (16.7)
Quartile 4 (58+%)	8 (33.3)

Figure. Percent of In-Person Patient Visits with RA Dashboard Use by Provider Characteristics



Panels A and B depict the percent of in-person patient visits with RA dashboard use over the study period by providers with high vs. low patient volume (A) and providers with high vs. low telehealth volume (B). High patient volume was defined as ≥10 patients and high telehealth volume was defined as ≥50% of visits. Each **data point** is the percent of in-person visits with dashboard use during the 2-month period. The **solid horizontal lines** represent the mean (μ) percent of in-person patient visits with dashboard use and the **dashed horizontal lines** represent the upper and lower bounds of the control limits ($\mu \pm 3\sigma$). Data points outside of the control limits are considered outliers, while consecutive data points on either side of the mean line are considered a shift, and consecutive points in a steady increase or decrease are considered trends. **Arrows** indicate dashboard introduction of each of the 4 study clusters.

training, monthly patient volume (for patients with any diagnosis); percent of total visits that were completed via telehealth (video or telephone), and randomization cluster (**Table**). We examined engagement with the dashboard (proportion of visits with at least 1 action) overall, over time, and by provider characteristics using proportions and statistical control charts.

Results: Most providers were attendings with ≥ 10 patient visits per month; 50% of providers performed more than half of their visits via telehealth (**Table**). In total, 2,066 RA visits occurred after the dashboard was rolled out, 998 (48%) of which occurred in-person. Overall, the dashboard was used during 23% of RA patient visits, although this percentage was higher among in-person visits compared to telehealth visits (37% vs. 10%). Among in-person visits with any dashboard actions (N=372), there was a mean (SD) of 15.6 (20.5) actions of any kind. Refresh was the most common action (occurring in 81% of in-person visits with any actions), followed by scrolling up/down (67%) and show/hide (7%). Engagement with the dashboard was relatively stable over time (range 0-30% for all visits; 0-56% for in-person visits over the study period). Providers with ≥ 10 patient visits per month and providers who performed fewer visits via telehealth had more engagement compared to providers with lower patient volumes, and providers with more telehealth, respectively.

Conclusion: User log data is a feasible method to monitor provider engagement with a novel health IT tool in the context of a pragmatic trial. Overall engagement with the RA dashboard was low, although we observed more engagement for in-person visits and among providers with higher patient volumes. Trials of technology need to plan for high variability in provider engagement and consider strategies to include highly engaged providers in order to accurately measure the effect of technology on health outcomes.

Abstract Number: 0159

Understanding the Economic Impact of Autoimmune Eye Disease in the United States

Krati Chauhan[1], Steven Scaife[2] and Michael Buhnerkempe[1], [1]Southern Illinois University - School of Medicine, Springfield, IL, [2]Southen Illinois University - School of Medicine., Springfield, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Eye involvement is an important cause of morbidity in rheumatology patients. Inflammatory eye diseases include conditions like scleritis, uveitis, retinitis and orbital inflammation. The complexity of these conditions requires specialized care resulting in significant financial burden for patients and the healthcare system. Identifying this financial burden is the first step towards developing strategies to address it. However, there is a lack of national data for the health care cost associated with inflammatory eye diseases. This study assesses health care cost due to ocular inflammatory diseases using the National Inpatient Sample (NIS), a nationally representative sample of hospital discharges in the United States.

Methods: We have conducted a retrospective analysis of the National Inpatient Sample (NIS) from 2016-2019. Patients with a primary diagnosis of uveitis and ocular inflammation were identified using International Classification of Diseases, Tenth Revision (ICD-10) codes. NIS is the largest all payer database developed by the Healthcare Cost and Utilization Project (HCUP) in the US and is ideal for investigating national estimates for health care cost. Healthcare costs are identified by analyzing aggregate and average hospital charges, aggregate and average hospital cost and length of stay.

Charge is the amount hospital billed and cost is the actual cost of hospital stay. Charges are converted to costs using cost-to-charge ratios based on hospital accounting reports from the Centers for Medicare and Medicaid Services (CMS). Descriptive statistics are used to present the demographics and cost characteristics of patients.

Results: A total of 6105 uveitis and ocular inflammation related hospitalizations were identified in the NIS database from 2016-2019. The average age of patients during the study period ranged between 50-54 years and a higher number of patients were males. The mean length of hospital stay was 6.3 (±.5) days.

The total healthcare costs for uveitis and ocular inflammation related hospitalizations for the years 2016-2019 was $ 82,739,013 and it increased from the years 2016 to 2019. Breakdown of patient demographics, total and aggregate hospital charges, total and aggregate hospital cost and length of stay for individual years from 2016-2019 are shown in the table.

Conclusion: Inflammatory eye diseases impose substantial economic burden on both the patients and the healthcare system. Identifying the financial impact will help patients and healthcare providers in making informed treatment decisions. Further research is necessary to identify the cost-effectiveness of management strategies for inflammatory eye diseases.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Health Services Research Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) is frequently used in patients with chronic back pain (CBP) to diagnose mechanical and inflammatory diseases, including axial spondyloarthritis (axSpA). Recent data suggest sacroiliac joints (SIJ) MRI findings in axSpA may differ according to sex[1]. Whether this holds true for spinal MRI and other causes of CBP is currently unknown. Our aim was to analyze spinal and SIJ MRI findings in young male and female patients with CBP.

Methods: The "Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis" (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with CBP asked to undergo an MRI of the spine by other specialists different than rheumatologists in a tertiary hospital, starting in September 2021. After inclusion, an additional MRI of the SIJ,

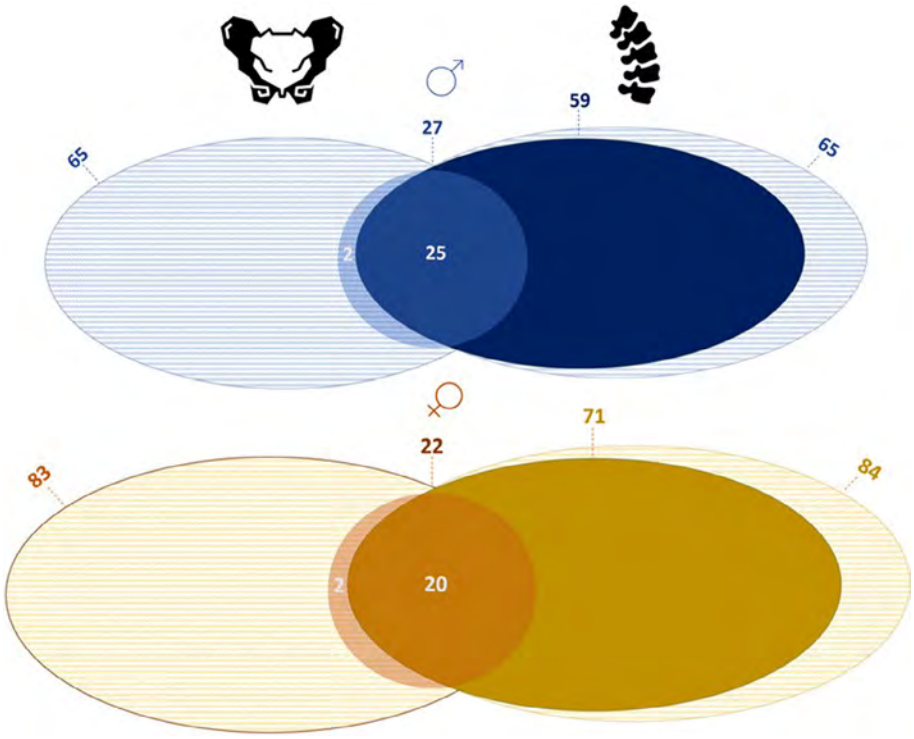

Figure. Patients with any reported finding (structural or inflammatory) in spine or sacroiliac joint magnetic resonance imaging. Colored: any finding. Striped: no findings.

Table. Findings in spinal and sacroiliac joints magnetic resonance imaging

	Total	Male	Female	p-value
Spine MRI	n=149	n= 65	n= 84	
Any finding	130 (87.2)	59 (90.8)	71 (84.5)	0.3
Structural findings	129 (86.6)	58 (89.2)	71 (84.5)	0.3
Spondylolisthesis	5 (3)	3 (4.6)	2 (2.4)	0.6
Spondylolysis	2 (1)	1 (1.5)	1 (1.2)	1
Disc herniation	34 (23)	15 (23.1)	19 (22.6)	1
Disc protrusion	64 (43)	31 (47.7)	33 (39.3)	0.3
Facet joints abnormalities	8 (5)	1 (1.5)	7 (8.2)	0.1
Other	16 (11)	7 (10.8)	9 (10.7)	1
Inflammatory findings	1 (1)	1 (1.5)	0	0.5
No findings	19 (13)	6 (9.2)	13 (15.5)	0.4
Sacroiliac Joint MRI	n=148	n= 65	n= 83	
Any finding	50 (33.5)	27 (41.5)	23 (27.4)	0.07
Structural findings	31 (20.9)	15 (23.1)	16 (19.3)	0.7
Inflammatory findings	11 (7.4)	6 (9.2)	5 (6.0)	0.5
Structural and Inflammatory findings	7 (4.7)	6 (9.2)	1 (1.2)	0.04
No findings	99 (67.8)	38 (58.5)	61 (73.5)	0.08

followed by a rheumatology visit and eligible blood tests were performed. Dataset for this interim analysis was locked in October 2022. The protocol for MRI of the spine used a 1.5T scanner to acquire sagittal T1-weighted turbo spin echo (TSE) and T2- weighted TSE, both for the lateral sides of vertebral bodies, and T2-Multistack. On top of this, an MRI of the SIJ, which involved T1-TSE, T2- weighted SPAIR and short-tau inversion recovery (STIR) sequences, was performed. MRI findings were assessed according to clinical practice by one of the four musculoskeletal radiologists working in the centre, describing the presence of mechanical lesions (spondylolisthesis, spondylolysis, disc herniation, disc protrusion, facet joints abnormalities), inflammatory findings (both SIJ and spine), and SIJ structural findings. For this analysis, results were stratified by sex.

Results: Among152 recruited patients, 85 (55.9%) were female; mean age was 34.2 (5.3) years. Spinal MRI findings were reported in 130 (87.2%) patients, with no differences between sexes (male 90.8% vs female 84.5%, p=0.3). As shown in **Table**, the most frequent diagnosis in both sexes were disc protrusion, followed by disc herniation. Inflammatory spinal findings were detected only in one male patient. No differences were found for any of the spinal lesions. SIJ MRI findings were reported in 49 (33.1%) patients, being numerically more frequently observed in males than females (41.5% vs 26.5%; p=0.08). Concurrence of both structural and inflammatory lesions was more frequently in males (9.2% vs 1.2%, p< 0.05), while no differences in isolate SIJ MRI findings were found between sexes. Overall, 45 (29.6%) patients presented findings both in the spine and SIJ (**Figure**).

Conclusion: In young patients who are requested a spinal MRI by other specialists different than rheumatologists, spinal lesions are reported in most patients, and similarly in males and females. Remarkably, SIJ MRI findings are reported in one out of three patients in this population, being more frequently in males.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Health Services Research Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: National treatment recommendations are often used to optimize patient care and may differ from international recommendations. The aim of this study was to assess differences and similarities between the EULAR and ASAS-EULAR recommendations for the treatment of patients with PsA and axSpA, respectively, versus national PsA and axSpA treatment recommendations across Europe.

Methods: Rheumatologists from 15 European countries (Czech Republic, Denmark, Estonia, Finland, Iceland, Italy, Netherlands, Norway, Portugal, Romania, Slovenia, Spain, Sweden, Switzerland, and the United Kingdom) compared the most recent national treatment recommendations for PsA and axSpA with the "EULAR recommendations for the management of PsA with pharmacological therapies: 2019 update"[1] and the "2016 update of the ASAS-EULAR recommendations for axSpA"[2], in an online survey conducted between October 2021 and April 2022. The study was an initiative of the European Spondyloarthritis Research Collaboration Network (EuroSpA RCN).[3]

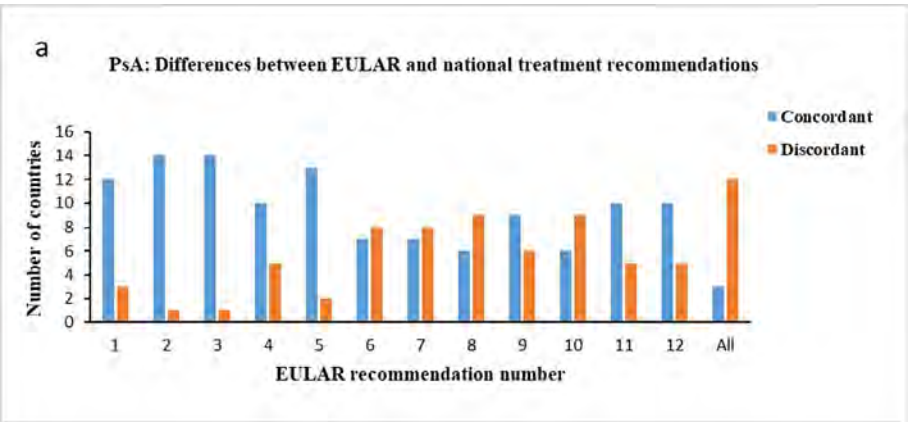

Figure 1a, Differences and similarities between EULAR and national treatment recommendations for patients with PsA

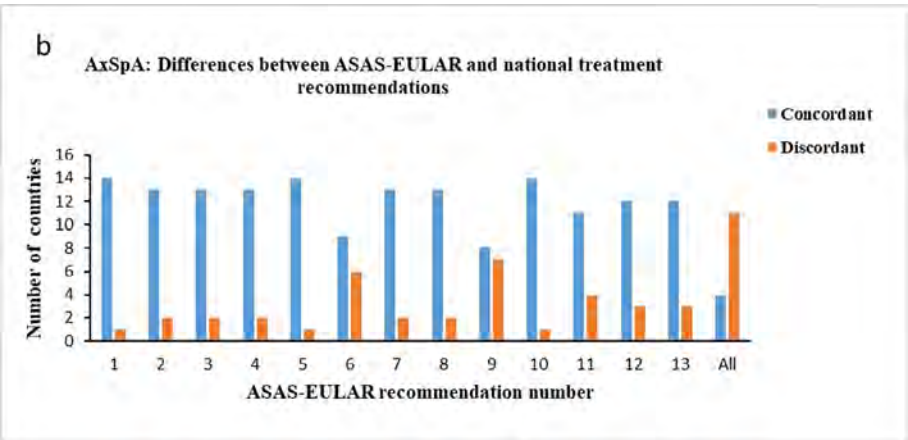

Figure 1b, Differences and similarities between ASAS-EULAR and national treatment recommendations for patients with axSpA

Results: Three countries (Czech Republic, Netherlands, and Spain) followed all EULAR recommendations for treating patients with PsA and four countries (Czech Republic, Italy, Spain, and Switzerland) all ASAS-EULAR recommendations for axSpA. Five countries had no national treatment recommendations for PsA and/or axSpA, but had other rules or regulations to follow, for which the comparisons in this study were performed. In six countries, the national treatment recommendations for PsA predated the 2019 EULAR recommendations and in one country the national treatment recommendations for axSpA predated the 2016 ASAS-EULAR recommendations. More differences were seen between the EULAR and the national treatment recommendations for PsA than between the ASAS-EULAR and the national treatment recommendations for axSpA (Figure 1a,b).

Discrepancies between international and national treatment recommendations included: Entry criteria for start of a biologic/targeted synthetic disease-modifying anti-rheumatic drug (b/tsDMARD) varied and were the most stringent in Romania, where DAPSA >28 for PsA and BASDAI >6 and ASDAS ≥2.5 for axSpA were required for the start of a bDMARD. Regarding PsA, in two countries (Finland and Switzerland) a conventional synthetic DMARD should be initiated before a b/tsDMARD including in patients with predominantly enthesal or axial disease. In several countries, no preference for interleukin-17 inhibitors was given for PsA patients with significant skin involvement. The positioning of Janus Kinase inhibitors (JAKi) differed across countries, e.g. in Estonia JAKi were indicated after failure of two tumor necrosis factor inhibitors and in Romania JAKi were positioned at the same level as bDMARDs. Phosphodiesterase-4 inhibitors were not in use or not reimbursed in most countries. Analgesics were not specifically mentioned in several of the national treatment recommendations.

Conclusion: Only a few European countries incorporated all EULAR and ASAS/EULAR treatment recommendations in their national recommendations. The potential impact of this on access to b/tsDMARD treatments needs to be further explored.

Abstract Number: 0162

Assessing Reproductive Health Counseling and Provider Attitudes in Rheumatology Post *Roe v. Wade* in Houston, Texas

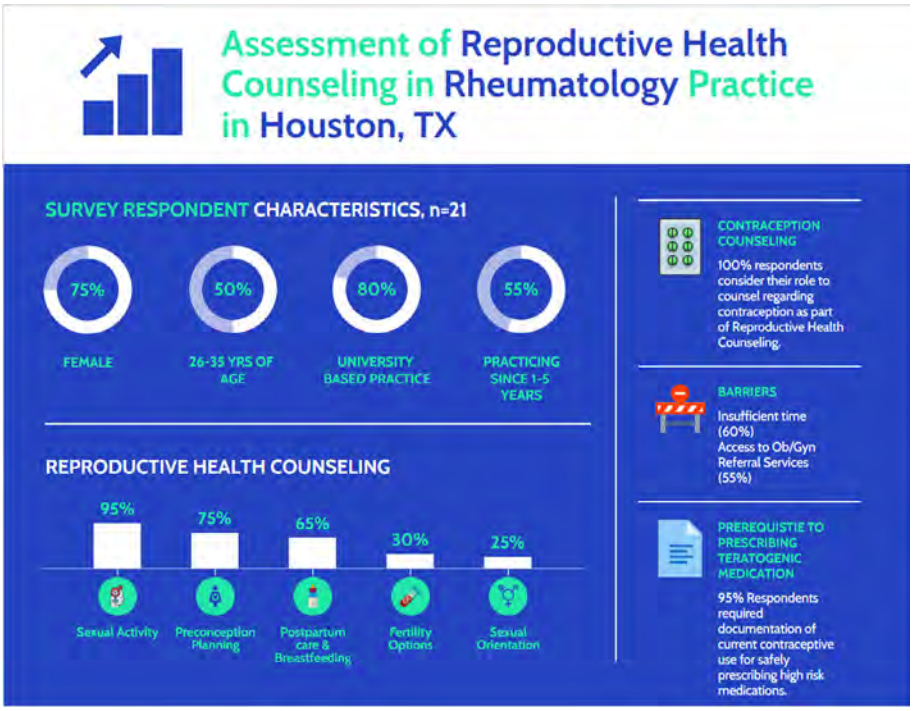
Ruhani Desai and Meera Subash, University of Texas Health Science Center at Houston, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Many rheumatic diseases disproportionately affect women of childbearing age. Advances in the field of rheumatology have led to an increase in targeted treatment agents. Many of these agents have known adverse effects on pregnancy and the developing fetus. At this crossroads of rheumatology and reproductive health, outcomes can be improved by proper planning and education. Guidelines for contraception use based on disease states are available; however, very few studies have evaluated the current rates of contraception counseling and family planning services made available to patients receiving rheumatological care. There are multiple barriers to health care delivery, and with the change in the recent legislature affecting access to abortion services, we hypothesize that more barriers may have been added. We aim to describe current practices for reproductive health counseling in practicing rheumatologists in academic affiliated institutions and describe the barriers to providing such care through an electronic survey.

Methods: A cross-sectional survey designed in REDcap was sent to rheumatologists in the city of Houston associated with academic institutions. The survey inquired about physician demographics, practice characteristics, knowledge and beliefs regarding reproductive health counseling and physician-reported barriers to providing reproductive health. The information from the survey was extracted as de-identified data and analyzed using REDcap.

Results: 59 participants were approached via e-survey. Of the 21 survey responders (35.6%), most were between 26-45 years of age, female physicians in university-based practice. The providers reported they see on an average >30 patients in a week with 25 to 50% these patients being female of reproductive age group. All providers reported it is their role to ask about sexual activity and contraception use. About 60% of physicians reported counseling regarding postpartum and breastfeeding as a part of reproductive health counseling. Only one third (28.6%) considered counseling regarding fertility as part of their role in reproductive health counseling. Most providers (90.5%) reported documentation of current contraceptive use as a requirement before initiation of teratogenic medication - with the same requirement for refill. The common barrier to provide reproductive health counseling was time (61.9%) and the second most common barrier reported was access to OBGYN services (57.1%). Most providers (42.9%) reported medico-legal implications as a barrier since the ruling, while 38.1% noted no changes in barriers since the ruling.



Conclusion: The survey suggests Houston rheumatologists consider reproductive health counseling as an integral part of their role with focus on pregnancy planning, breastfeeding, and postpartum care. Fertility counseling is not considered part of routine counseling. 38.1% respondents noted lack of change in practice or barriers following the legal ruling, which indicates there are existing barriers in the system, which can be optimized to provide comprehensive reproductive counseling. A follow up interview with select survey respondents is planned to define these barriers, beliefs and practices.

Self Reported Survey Results for Reproductive Health Counseling in Rheumatology Practice in Houston, TX

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Understanding glucocorticoid (GC) exposure is critical for observational analyses in rheumatology. However, obtaining an accurate measure of GC exposure, including dosage and duration, has been challenging, particularly using electronic health record (EHR) data. In this study, we compared GC medication data derived from the EHRs of 234 rheumatology practices to corresponding Medicare claims for patients with rheumatoid arthritis (RA).

Methods: Data derived from RISE, a national, EHR-enabled registry that passively collects data on all patients seen by participating rheumatology practices, and linked Medicare Part D claims. We included patients ≥ 18 years with RA (≥ 2 visits with RA codes ≥ 30 days apart) with oral GCs documented in both the EHR and Medicare during 2018. We extracted GC records from 3 sources: EHR e-prescriptions (orders), EHR medication lists ("med list"), and Medicare claims. GCs were identified using NDC codes and brand and generic names; all doses were converted to prednisone equivalents. EHR records with missing stop dates (37% of e-prescription records and 86% of med list records) were assumed to last 90 days. GC records from each data source were aggregated to the patient level and daily dose was calculated as the sum of all GC records active on a given day. Daily doses were averaged over 365 days to calculate an average daily dose during 2018.

Table. Characteristics of patients with RA with oral glucocorticoids documented in EHR data and Medicare claims in 2018.

	E-prescription Analysis*	Medication List Analysis**
N	12,537	3,177
Age, mean (SD)	72.3 (8.0)	71.0 (9.3)
Female, N (%)	9521 (75.9)	2454 (77.2)
RISE practice type, N (%)		
Single Specialty Group Practice	10197 (81.3)	1453 (45.7)
Multi-Specialty Group Practice	1326 (10.6)	965 (30.4)
Solo Practitioner	982 (7.8)	737 (23.2)
Health System	32 (0.3)	22 (0.7)
EHR vendor, N (%)		
Nextgen	7653 (61.0)	279 (8.8)
eClinicalWorks	3327 (26.5)	368 (11.6)
GE Centricity	741 (5.9)	163 (5.1)
Allscripts	40 (0.3)	687 (21.6)
eMDs	18 (0.1)	1135 (35.7)
Other EHR	758 (6)	545 (17.2)
Average daily GC dose during 2018 calculated from Medicare claims, median (IQR)	2.5 (0.9-4.8)¶	3.0 (1.2-5.2)¶
Average daily GC dose during 2018 in RISE, median (IQR)	3.1 (1.4-5.1)†	2.5 (1.2-4.9)‡

* The E-prescription analysis included any patients from practices with e-prescriptions available and compared this data to Medicare claims from RISE prescribers only, since e-prescription orders would all come from RISE prescribers.

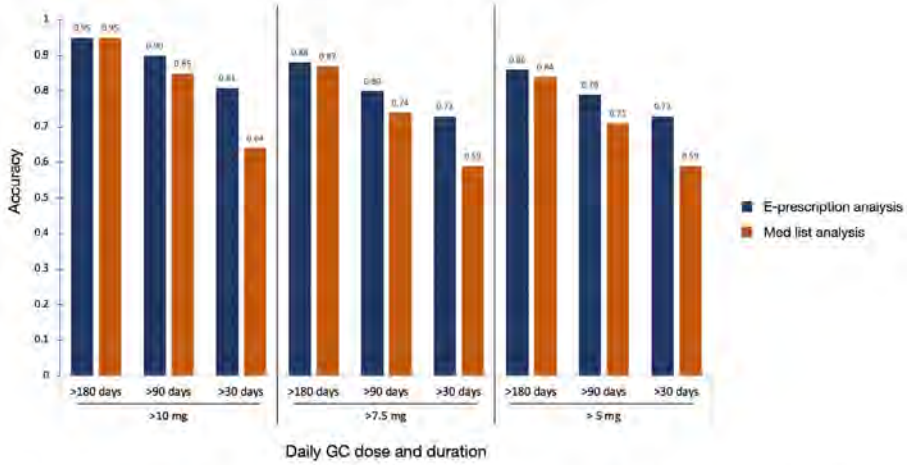
**The Medication List analysis included patients from practices without e-prescriptions available and compared this data to Medicare claims from any prescriber, since patients would report medications taken from any prescriber.

¶ For Medicare Part D records, GC dose was calculated from pill size, quantity dispensed, and days' supply based on established algorithms.

† For EHR e-prescription records, quantity and days' supply were not available, so we used regular expressions to standardize the most common patterns for medication instructions ("sig") (representing ≥ 100 records; 68.7%). Records with sigs that were complex (e.g., tapers; 10.5%), vague ("as directed;" 9.1%), or existed in < 100 records (11.7%) were assumed to be taken once per day.

‡ For EHR medication list records, quantity, and days' supply were not available, nor were medication instructions; therefore all records were assumed to be taken once per day.

Figure. Accuracy of EHR records versus Medicare Part D claims for classifying patients as users (yes/no) of glucocorticoids at different daily doses and durations (EHR e-prescription analysis - blue bars; EHR medication list analysis - orange bars).



Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

We compared GC exposure calculated from 1. EHR e-prescriptions with Medicare claims (from RISE prescribers only); and among those patients for whom e-prescription data was not available, 2. EHR med lists with Medicare claims (from any prescriber). We calculated the accuracy of EHR records vs. Medicare claims for classifying patients as users (yes/no) of GC at different daily doses and durations.

Results: We included 12,537 patients with RA in the e-prescription analysis and 3,177 in the med list analysis (Table). Both groups had similar demographics (>75% female, mean (SD) age 72.3 (8.0) years) but most patients in the e-prescription analysis came from practices using NextGen, while the majority in the med list analysis came from practices using eMDs. Nearly all GC records were for prednisone (90%). In the e-prescription analysis, the median average daily GC dose was higher in EHR data compared to Medicare claims (median (IQR) 3.1 mg (1.4-5.1) vs. 2.5 mg (0.9-4.8)); on the contrary, median average daily dose was lower in EHR med lists compared to Medicare claims (median 2.5 mg (1.2-4.9) vs. 3.0 (1.2-5.2)). In both analyses, 83-88% patients had an EHR average daily GC dose within 5 mg of their Medicare dose; 30-40% were within 1 mg. Accuracy for classifying patients as GC users of particular doses and durations based on EHR data varied from 0.59 to 0.95 but was highest for patients receiving >10 mg prednisone daily for durations > 180 days (Figure).

Conclusion: In this national study, we found discrepancies between GC exposure derived from two sources of EHR data (e-prescription orders and medication lists) and Medicare Part D claims among patients with RA. Caution should be exercised when using EHR data to derive GC exposure over short periods but may be suitable for ascertaining GC exposure at higher daily doses taken for longer periods of time.

Abstract Number: 0164

Development and Validation of a Virtual Musculoskeletal Examination Method for Disease Activity Assessment in Rheumatoid Arthritis Patients

Sandeep Yadav, Asna Shaikh and C Balakrishnan, P D Hinduja national Hospital and medical Research centre, Mumbai, India

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The rapid adaptation of telemedicine in rheumatology practice brings standardization, reliability and legality challenges. Therefore, it is necessary to develop dependable virtual instruments for the accurate assessment of patients, which are comparable to the standard face-to-face examination. We have developed a virtual musculoskeletal examination, and this communication highlights its usefulness in assessing the disease activity in patients with rheumatoid arthritis (RA).

Methods: Thirty follow-up patients with RA (29 women) attending the rheumatology OPD clinic of a tertiary care hospital were recruited over a month. Disease activity was independently assessed using a novel virtual MSK (Virtual DAS 28 ESR/ CDAI) examination method (Table 1 and 2) and a standard in-person method (DAS 28 ESR/CDAI) by two different examiners blinded to each other's results. (Table 3)To determine test-retest reliability, we used intra-class correlation coefficients, and for the degree of agreement, we used Bland-Altman plots

Results: The reliability of assessments between the two examiners, as judged by inter-class correlation, was excellent for Diease Activity Score of RA (DAS–28 ESR) and Clinical Disease Activity Index (CDAI) (ICC > 0.9), good for the total tender joint count and swollen joint count (ICC 0.75-0.91), and moderate for global physician assessment (0.50-0.75). (Table 3) Thus, the observations of two examiners to calculate disease activity using virtual and standard methods are reliable and reproducible across all measurements, based on an excellent intraclass correlation coefficient. The level of agreement tested using a Bland Altman plot showed that the mean absolute difference (bias) between Virtual DAS ESR 28 and DAS 28 ESR was 0.084 (% 95 CI -0.05782 to 0.2265) with p = 0.2348, which was well below the minimal clinically important difference (MCID) for DAS-ESR, which was 1.2, suggesting an acceptable level of agreement. Similarly, the mean absolute difference (bias) between the Clinical disease activity index (CDAI) and Virtual CDAI was 0.9667 (% 95 CI-0.1705 to 2.1039) with P=0.0927, which was well below the MCID for CDAI, which is 12, suggesting an acceptable level of agreement. There was a significant difference in the level of agreement concerning the total number of swollen joints counted. Thus ,there was an acceptable level of agreement between the two examiners in calculating disease activity virtually and in person using the novel MSK examination method.

Conclusion: Our novel virtual MSK test is consistent and comparable to the in-person assessment of follow-up patients in rheumatoid arthritis with regard to the measurement of disease activity. Although there was some variability in the number of swollen joints, the new approach showed good reliability and an acceptable level of agreement. It is pragmatic, and we recommend its further refinement for routine use in tele-consultancy.

Table 1. Showing method of virtual musculoskeletal examination (MSK) at the Proximal interphalangeal joint (PIP), metacarpophalangeal joint (MCP) and Wrist joint .

Over aching principle of examination: Common questions about all six joint sets are to be asked while examining the joints.1) All joint manoeuvres are to be mirrored by the examiner and explained simultaneously.2)Which joint is painful? Does the painful joint also stiff in the morning? 3)Which joint is swollen? Does the swollen joint also stiff in the morning? Has the swelling/deformity been new or persisted for over three months?

Method of examination	Defining Tender joint	Defining Swollen Joint
	PIP joint	
LOOK- Virtual inspection of PIP 1 foot from the front camera. **POINT**- Patients point towards the painful PIP. **MOVE**: Patient makes Half claw, and ROM of the joint is assessed. **Press:** Ask the patient to now face his palm in front and press the PIP with another hand, checking for tenderness in the PIP (crack your fingers)	The patient pointing toward the painful PIP Pointed PIP is associated with early morning stiffness > 15 minutes. Associated with pain during ROM and by pressing it with other hands PIP having all three above characters should be considered tender joint	Joints appear swollen on inspection. Pointed PIP is associated with early morning stiffness > 15 minutes. Associated with recent onset (< 3 months).PIP having all three above characters should be considered Swollen
		
	MCP joint	
LOOK: Ask the patient to make a full fist and point both fists towards the screen at 1 foot from the screen. Look for swelling /absent gutter between MCP, deformity, and decreased ROM. **Point**: Patient points toward the painful MCP **Move**: Patient makes full Fist. ROM of a joint is assessedPress: Press the Fist of one hand with the others	The patient pointing toward the painful MCP Pointed MCP is associated with early morning stiffness > 15 minutes. Associated with pain during ROM and aggravated by pressing it on other hands MCP having all three above characters should consider tender joint.	Joints appear swollen on inspection Pointed MCP is associated with early morning stiffness > 15 minutes. Associated with a recent-onset (< 3 months) decrease in ROM MCP having all three above characteristics should consider swollen
		
	Wrist	
LOOK- Ask the patient to face the back of the wrist towards the screen 1 foot from the screen. Look for swelling, an asymmetry between bilateral wrists and deformity. **POINT:** Ask the patient to point to a painful wrist. **MOVE**: Ask the patient to Form a prayer or "Namaste" sign keeping your elbows as high as possible/with support on a flat surface, and then make an inverted prayer or "inverted Namaste" with the back of your hand touching each other. Look for asymmetry /deformity / bony prominences/decreased ROM.	The patient is pointing toward the painful wrist. The pointed wrist is associated with early morning stiffness > 15 minutes. Associated with pain during ROM and aggravated by namaste sign. A wrist having all three above characteristics should consider a tender joint.	Wrist joints appear swollen on inspection. The pointed wrist is associated with early morning stiffness > 15 minutes. Associated with recent-onset (< 3 months) decrease in ROM on Namaste sign. A wrist with all three above characteristics should be considered a swollen joint.
		

Table 2. Showing method of virtual musculoskeletal examination (MSK) at the elbow joint ,Shoulder and Knee joint .

ELBOW JOINT		
LOOK- patient seated 3 feet from the screen was asked to extend his elbow completely and look for asymmetry, visible swelling, and bony prominences **POINT** - Ask the patient to point to the side of the painful elbow and the site of the pain. **MOVE**- Ask the patient to sit laterally 3 feet from the screen and ask to flex and extend the elbows to check for the ROM.**Press:** Ask the patient to press the flexed elbow towards the shoulder and look for pain and ROM.	The patient is pointing toward the painful elbow. The pointed elbow is associated with early morning stiffness > 15 minutes. Associated with pain during ROM and aggravated by pressing towards the elbow by another hand. An elbow having all three above characteristics should consider a tender joint.	The elbow appears joints appear swollen on inspection. The pointed elbow is associated with early morning stiffness > 15 minutes. Associated with recent-onset (< 3 months) decreased ROM and unable to flex completely with other hands An elbow having all three above characteristics should be considered a swollen joint.
		
Shoulder joints		
Screening of the shoulder through the following manoeuvres to check its complete ROM Look for any restriction on ROM. If the whole manoeuvre is performed with pain shoulder joint is likely normal. The shoulder joint is exposed for examination if any pain or restriction is found. **Look** – For visible swelling over the shoulder. **Point**- To the area of maximum tenderness. **Move:** Ask the patient to stand 3 feet from the screen and ask them to mirror the shoulder movement as performed. **Press**: Ask the patient to put the painful shoulder around the neck and over the opposite shoulder and hyper-adduct it with other hands to look for aggravation of pain.	The patient points toward the painful shoulder. The pointed elbow is associated with early morning stiffness > 15 minutes. Associated with pain during ROM and aggravated by pressing towards the shoulder by another hand. A shoulder having all three above characteristics should be considered a tender joint.	The shoulder appears joints appear swollen on inspection The pointed shoulder is associated with early morning stiffness > 15 minutes. Associated with recent-onset (< 3 months) decreased ROM and unable to flex completely with other hands A shoulder with all three above characteristics should be considered a swollen joint.
		
Knee		
Look- Ask the patient to move back from the camera, expose the knee, and point the camera towards the knee in a standing position. Check bilateral for asymmetry, muscle wasting, fixed flexion, swelling or deformity "bow-legged" (varus) or "knock-kneed" (valgus). **Point**- Ask the patient to point towards the painful knee and, if possible, to point towards one medial or lateral site or the whole knee. **Move:** Ask the patient to do one squat and then try to sit on the floor, cross legs, and get up. Look for ROM of the knee joint. **Press:** Ask the patient to put one ankle over the opposite thigh and try to fold it towards the body by grabbing at the ankle.	Patient pointing toward the painful knee The pointed knee is associated with early morning stiffness > 15 minutes. Associated with pain during squatting and aggravated during ankle grab and folding A knee having all three above characteristics should be considered a tender joint. Patient points toward the pain in the knee joint	The knee appears joints appear swollen on inspection The pointed knee is associated with early morning stiffness > 15 minutes. Associated with recent-onset (< 3 months) during squatting, unable to flex completely with other hands by ankle grab The knee joint with all three above characteristics should be considered swollen joint.
		

Table 3.: Showing methodology and mean arithmetic differences across individual joint counts derived from Bland Altman Plot.

Hypothyroidism Is Associated with Worse Clinical and Utilization Outcomes After Primary Total Knee Arthroplasty

Sumanth Chandrupatla[1], Kranti Rumalla[2] and Jasvinder Singh[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Northwestern School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Limited information is available regarding how medical comorbidities affect the outcomes of total knee arthroplasty (TKA). The association of medical comorbidities with post-TKA outcomes may vary by the primary underlying cause leading to TKA. We evaluated the association of hypothyroidism with TKA outcomes, overall and by the primary diagnoses categorized as knee osteoarthritis (OA), avascular necrosis (AVN), fractures, and inflammatory arthritis including rheumatoid arthritis (RA), or spondylarthritis (SpA) (ankylosing spondylitis (AS), psoriatic arthritis (PsA)).

Methods: We identified all patients in the 2019 national inpatient sample (NIS) that received primary TKA and stratified them based on primary diagnoses. The population was stratified into knee OA (N=529,621), traumatic arthritis (N=7,690) and inflammatory arthritis (RA, AS, or PsA; N=1,175) and other diagnoses. Hypothyroidism was determined using secondary diagnoses. We assessed clinical and healthcare utilization outcomes as endpoints using multivariable-adjusted regression analyses adjusted for race, age, sex, hospital bed size, census region and teaching status.

Results: Total cohort population was 563,381 Mean age was 67.18 years, 61.6% were female, and mean length of stay was 2.12 days.

Overall, hypothyroidism was associated with increased adjusted odds of non-routine discharge, blood transfusion, acute renal failure (ARF), and anemia ($p \leq 0.037$ each). In the knee OA cohort, hypothyroidism was associated with increased adjusted odds of non-routine discharge, ARF, and anemia ($p \leq 0.025$ each). Hypothyroidism was not associated with any complications or adverse patient outcomes in the traumatic or inflammatory arthritis cohorts.

Conclusion: Hypothyroidism impacts TKA outcomes, particularly in patients with knee OA. These findings hold crucial implications for patient care and guidance for orthopedic surgeons, emphasizing the necessity for thorough preoperative evaluations and care plans. By better understanding these risks, we can enhance patient outcomes and streamline surgical protocols.

Table-1: Baseline Hospital and Patient Characteristics with hypothyroidism who underwent primary total knee Arthroplasty (TKA) in the National Inpatient Sample (2019, N=532736)

Variable	Non-Hypothyroidism (N=496735; 83.9%)	Hypothyroidism (N=95155; 16.1%)	Overall (N=591891)	p value

Annual Economic Burden for Patients with Familial Hypophosphatemia in the United States

Zhiyi Li[1], Elizabeth Marchlewicz[2], Danae Black[2], Hana Schwartz[2], Yang Zhao[1] and Erik Imel[3], [1]Kyowa Kirin North America, Bedminster, NJ, [2]Merative, Cambridge, MA, [3]Indiana University School of Medicine, Indianapolis, IN

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Familial hypophosphatemia (FH) is most commonly due to phosphate regulating endopeptidase X-linked (*PHEX*) gene mutations resulting in renal phosphate wasting, which leads to rickets, osteomalacia and other musculoskeletal consequences. X-linked hypophosphatemia, the most common form of FH, may be treated with burosumab.

However, the healthcare utilization and economic burden of FH among burosumab-naïve patients has not been characterized in the United States (US). This study aimed to examine healthcare utilization and costs for burosumab-naïve patients with FH, compared with demographically matched controls without FH.

Methods: Using the Merative™ MarketScan® Commercial and Medicare US administrative claims databases, patients with ≥1 diagnosis code for FH (ICD10:E83.31) between 1/1/2018-12/31/2021, and continuous database enrollment for 12-months pre-and post-index were identified. The index date was defined as the date of the first FH diagnosis. FH patients were demographically matched 1:3 to non-FH control patients based on age group (0-11, 12-17, 18-29, 30-39, 40-40, 50-64, 65+), sex, geographic region, payer, and index year. Healthcare utilization and costs were assessed in the 12-month post-index period and adjusted to 2021 dollars using the medical care component of the Consumer Price Index. The Charlson Comorbidity index (CCI) score was reported in the 12-month pre-index period as a measure of baseline health status. Results were reported overall and stratified by age groups.

Results: Matched burosumab-naïve FH patients (n=570) and non-FH controls (n=1,710) were 57.0% female, 53.0% with an index year in 2018-2019, and with a mean (standard deviation [SD]) age of 47.2 (19.9) and 46.2 (18.3) years (10.4%, 76.2%, and 13.5% were < 18, 18-64, and 65+ years respectively). Baseline CCI score was significantly greater among FH patients than controls (1.9 [2.6] vs. 0.2 [0.9], $P< 0.001$). Annual all-cause healthcare utilization was greater among FH patients compared with controls: inpatient (IP) admissions (60.4% vs. 4.3%), emergency room (ER) visits (51.6% vs. 15.7%), and outpatient (OP) pharmacy (95.8% vs. 71.1%) (all $P< 0.001$). FH patients also had a higher mean number of IP admissions (1.2 [1.8] vs. 0.1 [0.3]), ER visits (1.3 [2.1] vs. 0.2 [0.6]), and OP pharmacy prescriptions (36.8 [32.1] vs. 8.3 [14.8]) (all $P< 0.001$). Annual mean total healthcare costs were significantly higher among FH patients than controls ($118,770 [$316,629] vs. $5,627 [$18,381]), driven by greater IP costs ($67,671 [$277,681] vs. $1,526 [$12,268]), OP costs ($35,347 [$86,914] vs. $3,154 [$11,026]), and OP pharmacy costs ($15,753 [$86,994] vs. $947 [$4,379]) (all $P< 0.001$). Similar trends were observed among age-stratified FH patients and non-FH controls.

Conclusion: FH patients incur substantially higher healthcare utilization, costs, and comorbidity burden compared with non-FH controls.

Healthcare Resource Utilization Associated with Tumor-Induced Osteomalacia: Review of Patient Histories Prior to Entry in Clinical Trial UX023T-CL201

Suzanne Jan de Beur[1], Thomas Carpenter[2], Kathryn Dahir[3], Erik Imel[4], María Belén Zanchetta[5], Angela Williams[6], **Zhiyi Li**[7], Matthew Sharp[6] and Ben Johnson[6], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Yale School of Medicine, New Haven, CT, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Indiana University School of Medicine, Indianapolis, IN, [5]Universidad del Salvador, Buenos Aires, Argentina, [6]Kyowa Kirin International, Marlow, United Kingdom, [7]Kyowa Kirin North America, Bedminster, NJ

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor-induced osteomalacia (TIO) is an ultra-rare paraneoplastic disorder, characterized by renal phosphate wasting due to increased production of fibroblast growth factor 23 (FGF23). Chronic hypophosphatemia causes the accumulation of severe musculoskeletal morbidities, and delays in diagnosis are common, which can lead to considerable healthcare resource use (HCRU). The objective of this study is to estimate HCRU from histories of adults with TIO not curable by surgery, prior to enrollment in the UX023T-CL201 burosumab phase 2 trial.

Methods: Histories of the 14 TIO patients enrolled in UX023T-CL201 were assessed independently by two reviewers. Data related to clinical events directly associated with HCRU were extracted and categorized.

Results: Mean age of TIO subjects enrolled in the trial was 56.9 ± 10.3 years (range 33-68); 57% (8) were male. Mean time between first symptoms and TIO diagnosis was 4.2 ± 4.1 years (range 0.1-13.2); mean time since diagnosis was 13.7 ± 13.0 years (range 0.7-35.8). Tumors were identified in 71% (10) patients, with surgical removal attempted in 64% (9).

Subjects underwent a mean of 11.1 ± 13.2 tumor investigations (range 1-46). The most frequent were magnetic resonance imaging (mean 4.9 ± 7.5 per patient; range 0-29), positron emission tomography/computed tomography (mean 1.9 ± 5.3; range 0-20), octreotide scan (mean 1.4 ± 2.3; range 0-7), and computed tomography (mean 1.3 ± 1.8; range 0-5).

All patients had a history of active vitamin D treatment, and 93% (13) had a history of oral phosphate treatment, with a mean duration of 10.4 ± 12.5 (range 0.3-35.0) and 10.5 ± 12.2 years (range 1.2-35.0), respectively.

History of fracture was reported in 93% (13) patients, with a mean of 5.4 ± 6.8 fractures per patient (range 0-28). The most frequently reported fracture locations were the ribs (mean 1.6 ± 3.3 fractures; range 0-13), foot/ankle (mean 1.0 ± 2.1; range 0-8), and femur (mean 0.7 ± 0.9; range 0-2).

Orthopedic procedures included spinal laminectomy in 21% (3) subjects, spinal corpectomy in 14% (2) subjects, and hip and knee arthroplasty in 14% (2) subjects each.

Conclusion: TIO is associated with substantial HCRU resulting from diagnosis, attempted tumor localization/removal, and disease management.

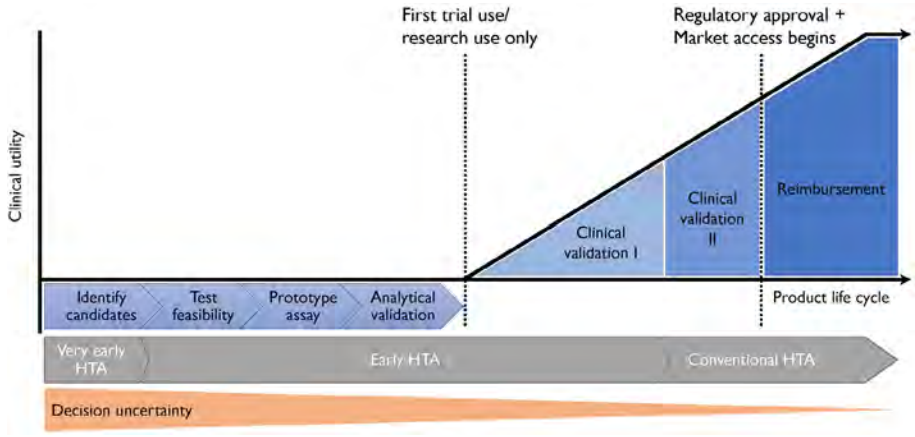
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

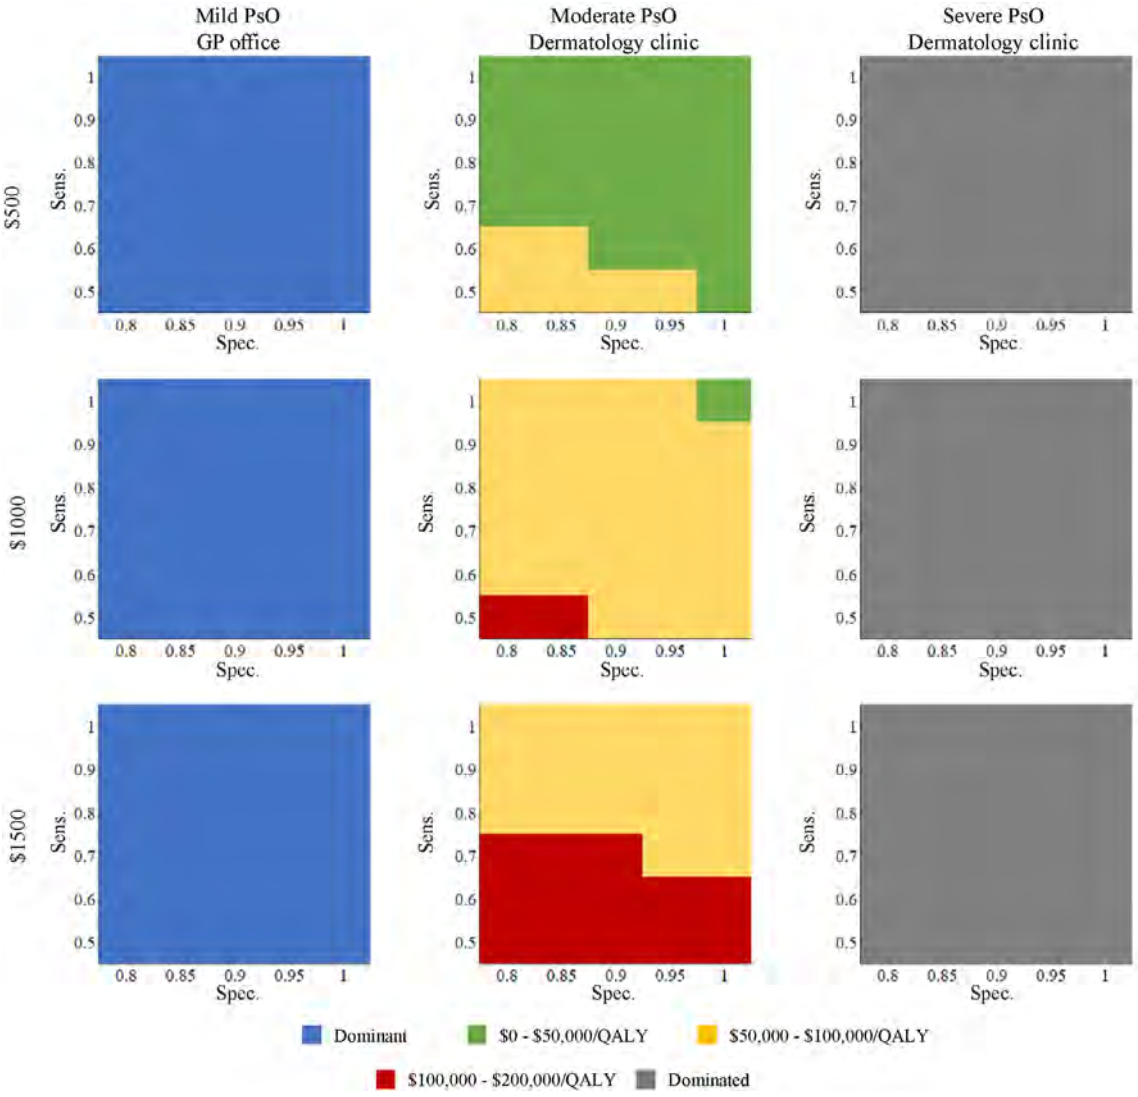
Background/Purpose: Initiating treatment in patients with psoriasis (PsO) who have unrecognized Psoriatic arthritis (PsA) may slow disease progression and improve long-term outcomes. Several candidate biomarkers are currently being studied to identify patients with unrecognized PsA. A biomarker test will ultimately only be successful if it is used – not just because of its clinical utility, but also its value which leads to reimbursement by payors. With product development process for biomarkers being expensive and subject to uncertainties, Early Health Technology Assessment (eHTA) can help indicate the commercial potential of a product to guide decisions in development decision-making. This study aimed to identify the required performance metrics that potential PsA biomarkers would need to achieve in order to be considered cost-effective.

Methods: We developed further an existing Markov model informed by literature and expert opinion. The model followed a cohort of patients aged 45-years with moderate PsO seen at a dermatology clinic and in which PsA was prevalent but unrecognized. In the biomarker arm, candidate biomarker tests were assumed to be administered at baseline, and patients who screened positive would accept combination conventional Disease-Modifying Antirheumatic Drug (cDMARD) and biologic treatment to slow disease progression. In the current practice are, patients with PsA were assumed to be clinically detected. Disease progression was modeled as linear changes in Health Assessment Questionnaire (HAQ) and PASI scores. We assumed a range of values for sensitivity, specificity, and biomarker price based on currently development progress. The time horizon was 40 years. Scenario analyses considered biomarker use in patients with mild and severe PsO separately.

Results: In the base case, using a biomarker test with a sensitivity of 70%, specificity of 80% and a price of $500 was associated with increased cost of $817.49 and additional 0.02 QALY per patient compared to no screening (ICER $47,566.29). Multi-way analyses showed that sensitivity could be as low as 60% and considered cost-effective if specificity was at least 88% and the biomarker was priced at $500. At a price of $1,000, only a near perfect test would be considered cost-effective. Model results were sensitive to the HAQ progression under combination treatment, cDMARD costs, and the



The product development stages of biomarker tests and timing of economic evaluation models assessing product viability. Clinical validation I and II reflect retrospective and prospective trial/study designs, respectively. Adapted from Ijzerman and Steuten (2011)



assumed start time of biologic DMARD treatment. Using a biomarker test in patients with mild PsO seen in primary care was a dominant strategy while screening in patients with severe PsO seen at a dermatology clinic was a dominated strategy (more benefit at less cost) compared to no screening.

Conclusion: This eHTA found that future PsA biomarker tests can be considered cost-effective if they can achieve modest performance, are used in a patient population with moderate PsO, and priced appropriately. Results support the continued product development of biomarker tests, and provide thresholds to guide decision-making on which biomarkers to pursue.

Two-way sensitivity analysis plots showing incremental cost-effectiveness ratios for combinations of sensitivity and specificity at three price points for a hypothetical biomarker test used in three patient populations. Abbreviations: GP = General practitioner, PsO = Psoriasis, Sens. = Sensitivity, Spec. = Specificity, QALY = Quality-adjusted life-years.

Abstract Number: 0169

Added Value of Anti-HMGCR and Anti-SRP Antibodies in the Diagnosis of Immune Mediated Necrotizing Myopathy: An Outcome and Cost Comparison from the USA Perspective

Alejandro Figueroa-Lara[1], **Mary Ann Aure**[2] and Carmen Andalucia[1], [1]Werfen, San Diego, CA, [2]Werfen, Chula Vista, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune-mediated necrotizing myopathies (IMNM) is a subgroup of immune-mediated myopathies (IMM). The diagnosis of IMNM relied on the presence of proximal muscle weakness, high levels of creatinine kinase (CK) and myofiber necrosis assessment through muscle biopsy. In 2018, the European Neuromuscular Centre (ENMC) recommended running anti-HMGCR and anti-SRP tests on patients with suspected IMNM and if the results were negative, then patients will undergo muscle biopsy for a diagnostic confirmation. Clinical practice is moving gradually towards ENMC diagnosis criteria, but no economic analysis has been done yet. This study assessed the economic consequences of following the ENMC guidelines through a cost-effectiveness analysis of IMNM when specific biomarkers are added in the diagnostic algorithm.

Methods: A decision tree model was designed to simulate a 1,000 hypothetical cohort of patients ≥40 years old with proximal muscle weakness and elevated creatine kinase levels under two interventions: 1) anti-HMGCR + anti-SRP + muscle biopsy (in seronegative cases); and 2) direct muscle biopsy (assumed as current clinical practice). Model parameters were derived from systematic literature review. The prevalence of IMNM was 8% based on a secondary care setting US study. Health related quality of life parameters were measured through utilities of phlebotomy and muscle biopsy. Direct medical costs were standardized to 2022 US dollars (therefore, this analysis did not include patient cost e.g., transport to the healthcare center, loss of productivity). Sensitivity analyses were conducted to assess changes in model output by varying several input data.

Results: The serological intervention was associated with a decreased of 79 muscle biopsies. Therefore, the cost per IMNM correctly diagnosed decreased by 83% ($2001). The cost per suspected IMNM patient decreased $160. Quality of life parameter is 8% higher in the serological intervention compared to the biopsy intervention. Results were sensitive to the IMNM prevalence, and the cost of biopsy and serological tests. In a clinical setting with a 1% IMNM prevalence, the cost-effective alternative is muscle biopsy, unless its cost is above $2,400 and the anti-HMGCR test cost is between $10-$15. At an 8% prevalence the serological intervention is more cost-effective unless the anti-HMGCR test cost is above $35 and cost of biopsy is above $600. At prevalence ≥19% the serological intervention is dominant at any anti-HMGCR test cost and muscle biopsy cost.

Conclusion: Our findings suggest that adding anti-HMGCR and anti-SRP test in the diagnostic algorithm of inflammatory idiopathic myopathies, as recommended by ENMC, results in less invasive diagnostic procedures a therefore having patients with a higher quality of life, at a lower cost. Confirmation of these economic results using real-world data is warranted.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Health Services Research Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: There is growing attention to gender inequity within rheumatology with persistent challenges in achieving pay parity, career progression, & access to leadership roles. In order to promote rheumatology as a career & improve job satisfaction, we need to understand the current gender climate & develop potential solutions.

Methods: The CHANGE e-survey is a cross-sectional self-reported survey, adapted from the GEAR taskforce. It was available in 6 languages, & distributed to rheumatology organizations & social media, until April 2023. Descriptive statistics were used, & survey responses were compared by gender.

Results: Of 782 respondents, 682 had complete data & were analyzed. There were 205 male & 479 females (M:F 1:2.5), of age 35 (37-55) years from 83 countries (Figure 1) Two-thirds were rheumatologists (65%) the rest were allied healthcare professionals. Half were academics (59%) & 73% worked full time. 49% of respondents worked within the public sector & median career duration was 18 (11-29) years

Women were working in the public sector (52%) while men were distributed in the public (42%) & private sectors (43%). Both male and female respondents reported working >40 hours per week & having active leadership (55%) and academic roles (58%). Internationally, there was no difference between participation by men vs women, but at national & local levels there was more participation by women. (national: 514 vs 1043, p=0.04; local: 498 vs 962 , p=0.02) 30% of women, and 57% of men reported equal division of roles, whereas 50% of women reported these roles to be carried out predominately by women, compared with 30% of men. The most common family caretaking responsibilities were caring for children (F=57%, M=36%, p=0.41). 14% of women reported more than two responsibilities compared with 10% of men (p=0.001). 62% of women report taking previous parental leave compared with to 22% of men

Notably, both genders report a negative impact of having children on their career (10% vs. 2%); women were more likely to report a lack of career advancement opportunities due to family commitments (49 % vs. 35%). Bullying was reported by both genders, with 84% experiencing ongoing bullying. Perceived gender discrimination is described in figure 3; women reported feeling that they were 'less likely to receive a promotion' (p=0.04), to not be 'groomed for leadership positions' (p=0.05), receive less remuneration (p=0.012), assigned 'below expertise' tasks (p=0.05) & deal with an intimidating work environment (p=0.007). Women reported discrimination more common from older colleagues (p=0.03), nurses (p=0.04), patients (p=0.03) & administrators (p=0.019).

The most common recommendations were conference related, including no 'male-only panels' and family-friendly rheumatology conferences. Other suggestions include country specific support, writing & presentation skills training. 13% of women reported a desire to increase visibility of female role models

Conclusion: This e-survey is the first in rheumatology to highlight challenges faced by female rheumatologists globally. The results of the e-survey will be used to investigate the drivers of these inequities, as well as develop strategies and interventions to promote gender equity.

A Conceptual Framework to Characterize the Indirect Burden of Systemic Lupus Erythematosus (SLE): Findings from Qualitative Patient Interviews

Vibeke Strand[1], Prajakta Masurkar[2], Jennifer Reckleff[3], Taylor Schwartz[4], Alison Silverstein[4], Jennifer Osborne[4], Josie Lloyd[4], Brian Leinwand[4], Elaine Karis[5], Fatima Barbar-Smiley[6] and Karen Costenbader[7], [1]Stanford University, Portola Valley, CA, [2]Amgen, Inc., Atlanta, GA, [3]Amgen, Inc., Westlake Village, CA, [4]Inovalon Insights, Bowie, MD, [5]Amgen, Inc., Colts Neck, NJ, [6]Amgen, Inc., Dublin, OH, [7]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Health Services Research Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Table 1. Demographic and disease characteristics of SLE patients who were interviewed via teleconference

Characteristics	SLE patient cohort (N = 20) n (%)
Age group	
18-29	1 (5%)
30-39	8 (40%)
40-49	7 (35%)
50-64	3 (15%)
65 or older	1 (5%)
Gender	
Female	19 (95%)
Male	1 (5%)
Race/ethnicity*	
African American/Black	9 (45%)
Asian	1 (5%)
Caucasian/White	8 (40%)
Hispanic/Latino	5 (25%)
Marital status	
Single, never married	5 (25%)
Married or domestic partnership	11 (55%)
Divorced	4 (20%)
Annual household income	
$50,000 or less	3 (15%)
$50,000 to $99,999	11 (55%)
$100,000 or more	6 (30%)
Location of residency	
Urban	4 (20%)
Suburban	15 (75%)
Rural	1 (5%)
Cohabitants (not mutually exclusive)	
Parent(s)/parent(s)-in-law	4 (20%)
Spouse/partner	14 (70%)
Child(ren)	10 (50%)
Roommate(s)	2 (10%)
Caretaker	1 (5%)
Self only	1 (5%)
Health insurance status (not mutually exclusive)	
Insurance through employer	14 (70%)
Medicare (including Medicare Advantage)	7 (35%)
Medicaid	2 (10%)
Other government program (e.g., TRICARE, VA, OPM)	3 (15%)
Flares experienced over the previous 12 months	
0	3 (15%)
1-3	10 (50%)
4-6	2 (10%)
7 or more	5 (25%)
Ever diagnosed with lupus nephritis	
Yes	9 (45%)
No	10 (50%)
Not sure	1 (5%)

*Not mutually exclusive as patients may have selected more than one category; OPM = Office of Personnel Management, SLE = systemic lupus erythematosus; VA = Veterans Affairs

Background/Purpose: SLE is a chronic autoimmune disorder that affects multiple organs and leads to a variety of symptoms, including joint pain, fatigue, and skin rashes, that significantly impact patients' lives. Despite the known increased risk of morbidity and mortality in affected populations, there has been limited research about the impact of SLE on a patient's daily life, such as career achievements, social/leisure activities, and family dynamics. A qualitative study was conducted to examine the impact of SLE on daily life from a patient's perspective and to develop a conceptual framework for overall impact.

Methods: A literature review was conducted to identify domains of interest to discuss in the interviews. A semi-structured interview guide was developed to gather patients' perspectives on previously identified areas of SLE impact and identify other ways in which SLE affects daily life. Twenty adult patients with SLE consented to teleconference interviews to discuss how SLE impacted their lives. Transcripts were then analyzed to identify themes. Based on literature review and patient interviews, a preliminary conceptual framework was developed for understanding the indirect burden of SLE on patients.

Results: The literature review identified 10 domains of interest which were used as the topics of the in-depth interviews: career/education, social impact, physical activity, cost (direct/indirect), patient burden, family planning, treatment preference, clinical perspective, family burden, and mental health. Of the patients interviewed, a majority were female (95%), aged 30-39 years (40%), African American/Black (45%), and had employer-based insurance (70%) (**Table 1**). Over half of the patients reported ≥1 flare in the previous 12 months. Content analysis of interview transcripts revealed 8 domains based on patients' perceptions of how SLE impacts their daily lives (percentage of patients reporting): physical activity/mobility

Table 2. Themes that emerged from in-depth patient interviews (N = 20)

Major themes	Example patient quotes
Education/career	*"The first year I went to college, I was really anti-social. And I had a lot of symptoms, like skin rashes and weight gain from the steroids, and I just kind of felt like that freak show... it was kind of hard to stay... to keep up with school, with my lupus being so active."*
Productivity	*"My lupus symptoms were preventing me from potential career [advancement] because I knew I wasn't able to take on more responsibility of a higher role."*
	"Usually during the week I wouldn't do much after work just because I was tired."
Other indirect costs	*"...heat pads, creams, ointments, and things like that."* *"For me, I'm a huge reader, so the cost of entertaining myself... different aids can look like different things to different people. I'm home all day. I kinda need Netflix. You know, so things like that start adding up."*
Caregiver burden	*"My husband had to help me get dressed... he had to put my backpack on. I couldn't do [it]."*
Daily life	*"If someone is going out to the park, I gotta make sure it's a park that has shade and/or chairs because I get tired, or I'll bring stuff.* *"I [missed] Christmas once before, [and] my birthday because I was in the hospital..."*
Mental health	*"Mentally, it's taking me to a really dark place, not like a dark place where I would ever hurt myself or anything, but I've become really negative, really angry all the time, because I'm just like, [why] am I so sick?"*
Social and family life	*"Even for an event not even long term, even like a month or a couple weeks away, I don't like to make plans with friends."*
Future planning	*"I feel like the whole discussion was very difficult in terms of family planning and in terms of, you know, what is it gonna look like if I do get pregnant and then having the conversation of, like, what is it gonna look like postpartum?"*

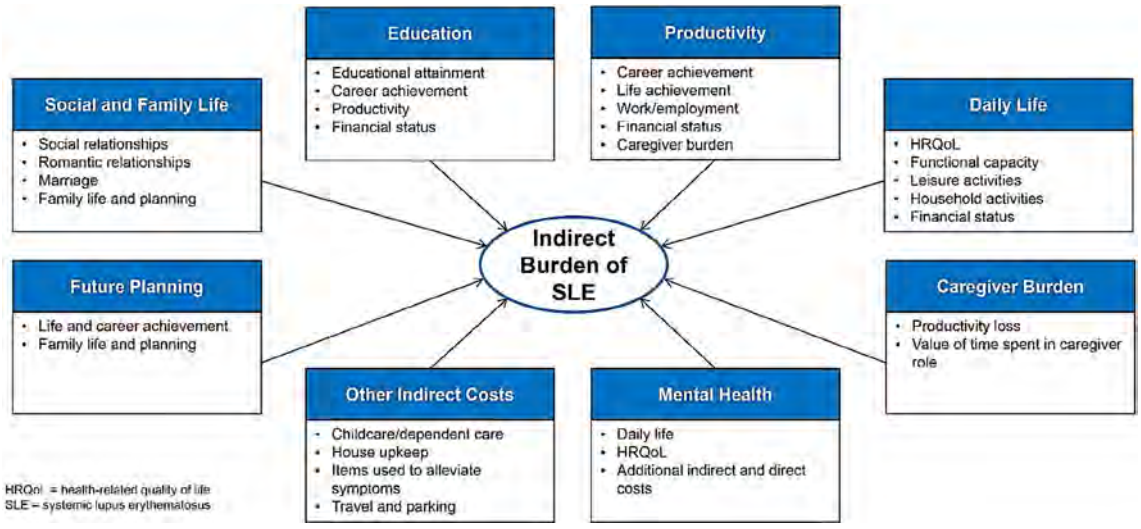

Figure 1. A Conceptual Framework for Understanding the Indirect Patient Burden of SLE

(20%), reduced flares (15%), ability to work (10%), relationships/social life (45%), mental health (20%), fatigue (15%), inflammation/pain (20%), and direct/indirect healthcare costs (15%) (**Table 2**). Patients reported that the overall burden of SLE persisted despite treatment and increased with flares. The conceptual framework illustrates domains identified from the literature review and patient interviews (**Figure 1**). Previously studied domains included productivity, daily life, caregiver burden, and mental health. However, education, family/social lives, future planning, and other indirect costs were newly identified as domains that have not been well characterized.

Conclusion: Based on the literature review and in-depth patient interviews, a conceptual framework was developed for understanding the numerous factors contributing to the impact of SLE on patients' lives in 8 discrete yet interrelated domains. Data reflecting the patient-centered burden of SLE in the literature are limited, especially with respect to the impact on education, family/social lives, future planning, and indirect costs. Future research should target these evidentiary gaps to better establish a holistic view of patient-centered SLE burden.

Abstract Number: 0172

Barriers and Strategies to Enhance Patient Research Partner Involvement in Rheumatology Research: A Systematic Literature Review

Krystel Aouad[1], Maarten de Wit[2], Muriel Elhai[3], Diego Benavent[4], Heidi Bertheussen[5], Jette Primdahl[6], Codruta Zabalan[7], Paul Studenic[8] and Laure Gossec[9], [1]Saint George Hospital University Medical Center, Beirut, Lebanon, [2]Patient Research Partner, Stichting Tools, Amsterdam, Netherlands, [3]University Hospital zurich, University of Zurich, Zurich, Switzerland, [4]Hospital la Paz, Madrid, Spain, [5]Patient Research Partner, Oslo, Norway, [6]University Hospital of Southern Denmark, Danish Hospital for Rheumatic Diseases, Sønderborg, Denmark, [7]Patient Research Partner, Romania, Romania, Romania, [8]Medical University of Vienna and Karolinska Institutet (sweden), Vienna, Austria, [9]Sorbonne Université and Pitié Salpêtrière Hospital, Paris, France

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Health Services Research Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient research partners (PRPs) participate in research teams and provide unique and valuable input. Their integration as equal partners is recommended (1). However, PRP involvement still faces significant challenges that need to be addressed (2). This study aimed to assess PRPs' roles, identify barriers to their involvement, and propose strategies to improve involvement.

Methods: A systematic literature review was conducted in PubMed/Medline, focusing on studies reporting PRP involvement in rheumatology published between 2017 and January 2023. Keywords such as "patient research partner," "patient expert," "patient and public involvement (PPI)", and relevant acronyms (PRP, PPI) were used. Data collection encompassed quantitative and qualitative data on PRP definition, roles, added value, and barriers and facilitators to their involvement. The analysis included descriptive statistics for quantitative data (frequencies, n%) and inductive thematic analysis for qualitative data.

Concept	Barriers	Strategies to Enhance Patient Involvement
Emotional and Personal Factors	• Emotional burden • Fatigue • Need to accommodate PRP needs • Lack of trust • Time constraints	• Provide a supportive environment • Provide flexibility and accommodations • Allocate adequate resources • Provide ongoing feedback
Communication and Relationship	• Feeling unheard • Power imbalance • Inconsistent and poor communication • Loss of confidentiality	• Coordinator to facilitate PRP involvement • Open and transparent communication • Clarify patient roles, expectations and objectives
Training and Support	• Inadequate training and support of PRP • Lack of resources and compensation of PRP • Lack of awareness about PRP involvement among researchers • Overburdening of PRPs	• Provide training to PRP and researchers • Recognition of PRP contributions and encouragement • Increase awareness
Research Process	• Anxiety about delays • Time commitment for researchers • Forced changes in working practice • Challenges to recruit PRPs	• Establish realistic timelines • Address recruitment challenges • Build trust through open
Collaboration and Engagement	• Lack of PRP diversity • Discrepancies in views • Uncertainty in incorporating patient experience	• Ensure diversity of PRPs • Involve PRPs from project inception with clear roles • Discuss diverging perspectives

Results: A total of 1481 studies were identified, 108 full-text articles were assessed for eligibility, and 53 were included. Among these, 69% were qualitative studies, reviews, opinion papers, or reports, with 62% published in rheumatology journals. Geographically, 50% of the studies were from Europe, and 31% from North America. 60% of articles reported a definition of PRPs identifying terms such as ''equal partnership'', ''active engagement'', and ''collaboration with researchers''. When PRP involvement was reported, the number of PRPs per project ranged 1 to 4 in 51% of the articles and more than 5 PRPs in 25% of the articles. Various roles of PRPs were described ranging from research partners to patient advocates, advisors, and patient reviewers. PRPs were reported to be involved in all phases of research in 30% of papers, from the conception, conduct to the implementation of outcomes. Barriers to PRP involvement (Table 1) included emotional and personal factors, communication and relationship challenges, inadequate training and support, difficulties following the research process and pace, as well as collaboration and engagement issues. Effective strategies to enhance PRP involvement (Table 1) included early involvement, a supportive environment, effective communication and trust, and providing support and training for PRPs and researchers.

Conclusion: This systematic literature review identified barriers and proposes solutions to enhance PRP involvement in rheumatology research. Addressing these barriers and implementing effective strategies is crucial for meaningful PRP involvement. Further efforts are needed to promote and facilitate patient engagement in research to ensure its relevance and impact.

Abstract Number: 0173

Review of Published Literature Reporting Economic Burden of Treatment Switching in Rheumatoid Arthritis

Peter C. Taylor[1] and Jenya Antonova[2], [1]Nuffield Department of Orthopedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]Compass Strategy and Research, Inc., San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: For rheumatoid arthritis (RA) American College of Rheumatology (ACR) recommends the *treating to target* approach, starting with conventional synthetic antirheumatic drugs (DMARDs). ACR advises as many switches as necessary to achieve the target. Patients may switch therapy because of adverse reactions, response failure, or non-medical

(e.g., economic) reasons. Prior research has reported that treatment switching is associated with increased healthcare burden and costs, however a summary of the published literature is lacking. We aimed to summarize published literature reporting clinical and economic burden of treatment switching in RA.

Methods: We used PubMed and desktop search to identify literature reporting healthcare resource use (HCRU) or costs associated with treatment switching in RA patients. Keywords: RA AND treatment switch* AND [HCRU OR cost].

Results: The PubMed search yielded 100 titles; 48 were selected for abstract review, 16 selected for full-text review (8 articles excluded as not relevant). Three articles were identified via desktop search.

Eleven articles reported research conducted in USA (n=9; commercial claims), Sweden (n=1), and Italy (n=1). Nine articles reported results for RA only; two reported RA within a mix of inflammatory conditions. Outcomes were for patients who switched therapy after initiating oral methotrexate (n=1), first biologic DMARD (n=5), biologic DMARD (n=4), or first targeted DMARD (biologic or JAKi; n=1).

After treatment initiation, treatment switch was reported in 12%-18% patients (8% in one study) within 1 year and 30% within 2 years (Figure 1). Treatment switching was associated with 5%-51% increase in adjusted all-cause healthcare costs (Figure 2). One study (Vanderpoel, et al., 2019) reported switching to be associated with increased adjusted HCRU: hospitalization (adjusted odds ratio [aOR]: 3.03; P< 0.05), emergency department use (aOR: 1.73, P: NS), and outpatient visits (aOR: 1.05, P: NS).

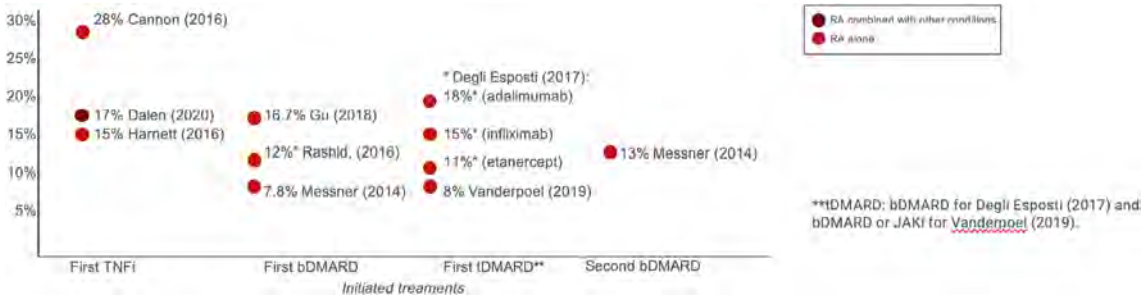

Figure 1. Rates of treatment switching reported in the literature

Figure 2. Adjusted total healthcare costs treatment costs for RA patients who switched therapy at least once (switchers) or twice (twice switchers) within 12 months post-initiation in comparison with alternatives, defined as persisters (A) or non-switchers (B)

Within studies, risks of bias included: reporting of unadjusted estimates (failing to account for between-group differences; n=3), combining RA with other inflammatory conditions (n=2), combining outcomes [switchers and discontinuers (n=1) and non-switchers into one group (n=5)]. All studies had bias towards reporting data from US commercial databases (all prior to 2016), mostly biologic DMARD; few studies reported HCRU.

Conclusion: Published literature consistently reported frequent therapy switching in RA. The switching was associated with increased HCRU and costs, highlighting the health economic need for prognostic markers of sustained response. Additional research is needed to report contemporary trends, outcomes in Medicare and Medicaid, and trends outside of the US.

Abstract Number: 0174

Evaluation of Healthcare Utilization in Members with Rheumatoid Arthritis, Psoriatic Arthritis, and Systemic Lupus Erythematosus

Jean Park, W. Cliff Rutter, Elisea Avalos-Reyes, Chen Liu, Will Cavers, Dorothea Verbrugge and Kjel Johnson, CVS Health, Woonsocket, RI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Healthcare utilization is increasing among patients with rheumatic diseases. While several studies have assessed healthcare utilization in rheumatoid arthritis (RA) patients, few studies have assessed utilization among psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE) patients. The objective of this study was to examine healthcare utilization trends among patients with RA, PsA, or SLE.

Methods: This was a cohort study of fully insured commercial or Medicare members of a large national health plan between 1/1/2018 and 1/1/2023. Members ≥ 18 years old were included if they had at least 2 visits for RA (ICD-10 code: M05 or M06), PsA (L40.5), or SLE (M32) during the study period. Members were excluded if they did not maintain continuous

High	20024 (18.4)	2826 (21.5)	14360 (17.8)	2838 (18.8)	
Very High	6846 (6.3)	1063 (8.1)	4803 (5.9)	980 (6.5)	

eligibility for 6 months before or after entrance into the study, had multiple conditions of interest, or had missing socioeconomic status (SES) data. Healthcare utilization metrics were examined as use of telemedicine, emergency room (ER), or inpatient services and were identified by place of service codes on medical claims. ER and inpatient claims were aggregated by day and are presented by days utilizing the service. Utilization rates were calculated based on total person years observed in each cohort and the sum of telemedicine claims. ER days and inpatient days are presented as claims or days per 100 person years observed. Rate differences and rate ratios were calculated with 95% confidence intervals (CI) with direct bivariable cohort comparisons. Continuous variables were assessed with analysis of variance or Kruskal-Wallis tests; categorical variables were assessed with the Chi^2 test. P-values < 0.05 are significant, except for cohort comparisons of rate ratios, where the Bonferroni correction was applied and $p< 0.005$ is considered significant.

Results: Of the 109,006 members included in this study, 80,724 (74.1%) had RA, 15,122 (13.9%) had SLE, and 13,160 (12.1%) had PsA. Table 1 demonstrates significant differences in baseline demographics between disease states, with RA members being older (mean age (standard deviation (SD)): 59.6 (15.2) vs. 53.7 (13.7) and 51.2 (15.7) years in PsA and SLE members, respectively; $p< 0.001$) and having more comorbidities at baseline (mean Charlson Comorbidity Index (SD): 3.3 (2.8) vs. 1.7 (2.4) and 3 (2.6) in PsA and SLE members, respectively; $p< 0.001$). Tables 2 and 3 demonstrate the differences in healthcare utilization between disease states. In general, SLE members utilized all healthcare services more than PsA and RA members, except for inpatient services compared to RA members (rate ratio (95% CI): 0.973 (0.963-0.983); $p< 0.005$). Members with RA utilized ER and inpatient services significantly more than PsA members but utilized telemedicine services less ($p< 0.005$).

Table 2. Healthcare utilization by rheumatic condition

Utilization metric	Overall N=108,063	PSA N(%) = 13,024 (12.1)	RA N(%) = 80,048 (74.1)	SLE N(%) = 14,991 (13.9)	P-Value
Telemedicine users, n (%)	32990 (30.3)	4780 (36.3)	22343 (27.7)	5867 (38.8)	<0.001
Telemedicine claims in users, mean (SD)	14.6 (27.3)	13.7 (25.1)	14.2 (26.5)	16.7 (31.4)	<0.001
Telemedicine claims in users, median [Q1,Q3]	6.0 [3.0,15.0]	6.0 [3.0,14.0]	6.0 [3.0,15.0]	7.0 [3.0,18.0]	<0.001
Telemedicine (claims per 100 PY), rate (95% Confidence interval)	218 (217.9-219.1)	248.5 (246.6-250.4)	194.8 (194.2-195.5)	317.9 (315.9-319.9)	<0.001
ER users, n (%)	43885 (40.3)	4162 (31.6)	32947 (40.8)	6776 (44.8)	<0.001
ER days in users, mean (SD)	3.0 (3.9)	2.5 (2.8)	3.0 (4.0)	3.2 (4.4)	<0.001
ER days in users, median [Q1,Q3]	2.0 [1.0,3.0]	2.0 [1.0,3.0]	2.0 [1.0,3.0]	2.0 [1.0,4.0]	<0.001
ER (days per 100 PY), rate (95% Confidence interval)	59.1 (58.8-59.4)	39.3 (38.5-40)	60.3 (59.9-60.6)	70 (69-70.9)	<0.001
Inpatient users, n (%)	27335 (25.1)	2331 (17.7)	21041 (26.1)	3963 (26.2)	<0.001
Inpatient days in users, mean (SD)	10.1 (18.8)	7.7 (13.0)	10.4 (18.8)	10.2 (21.7)	<0.001
Inpatient days in users, median [Q1,Q3]	4.0 [2.0,10.0]	3.0 [1.0,8.0]	4.0 [2.0,11.0]	4.0 [2.0,10.0]	<0.001
Inpatient (days per 100 PY), rate (95% Confidence interval)	125.8 (125.4-126.3)	67.7 (66.7-68.7)	134.3 (133.8-134.9)	130.7 (129.4-132)	<0.001

Table 3. Healthcare utilization rate ratios by rheumatic condition

Rate Ratios (95% CI)	RA vs. PSA	SLE vs. PSA	SLE vs. RA
Telemedicine claims	0.784 (0.777-0.791)*	1.279 (1.266-1.292)*	1.631 (1.62-1.643)*
ER days	1.535 (1.504-1.566)*	1.782 (1.74-1.824)*	1.161 (1.144-1.178)*
Inpatient days	1.984 (1.954-2.015)*	1.93 (1.896-1.965)*	0.973 (0.963-0.983)*

Conclusion: Members with SLE utilize significantly more healthcare services compared to RA and PsA members. In this current study it is not clear what other factors are influencing these utilization patterns. Further studies of healthcare utilization are needed in these patients.

Predicting Cost-Related Medication Non-Adherence in US Adults with Chronic Arthritis: A Machine Learning Approach

Ashkan Ara[1], Matthew Chenoweth[1] and Christopher Scannell[2], [1]University of California Los Angeles, Los Angeles, CA, [2]UCLA / West Los Angeles VA Medical Center, Los Angeles, CA

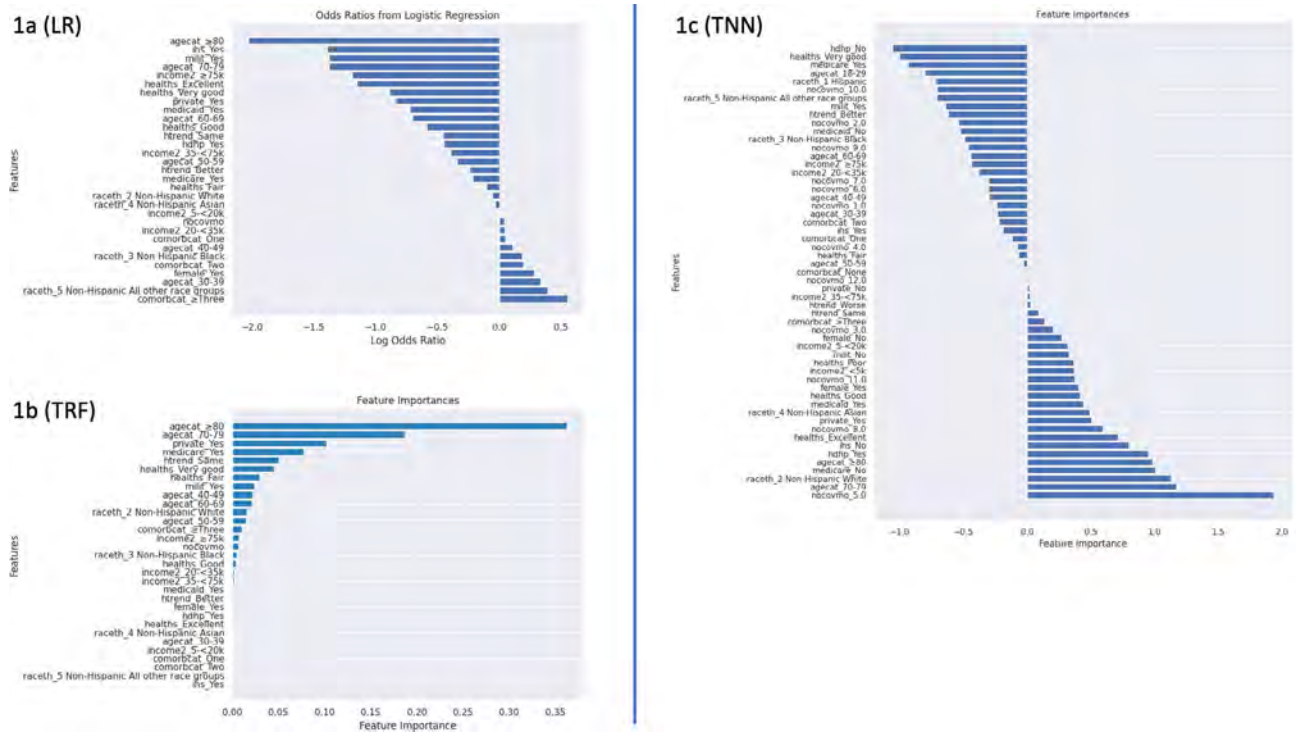
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Health Services Research Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cost-related medication non-adherence (CRN) occurs when patients are unable to follow their prescribed medication regimen due to financial constraints, such as high costs or lack of insurance coverage. This situation often leads patients to skip doses, take lower dosages, or delay refilling their prescriptions, resulting in negative health outcomes. Accurately predicting CRN is crucial for allocating resources effectively to those who are at higher risk. The objective of this study was to utilize machine learning classifiers to predict CRN in a nationally representative sample of US adults with chronic arthritis.

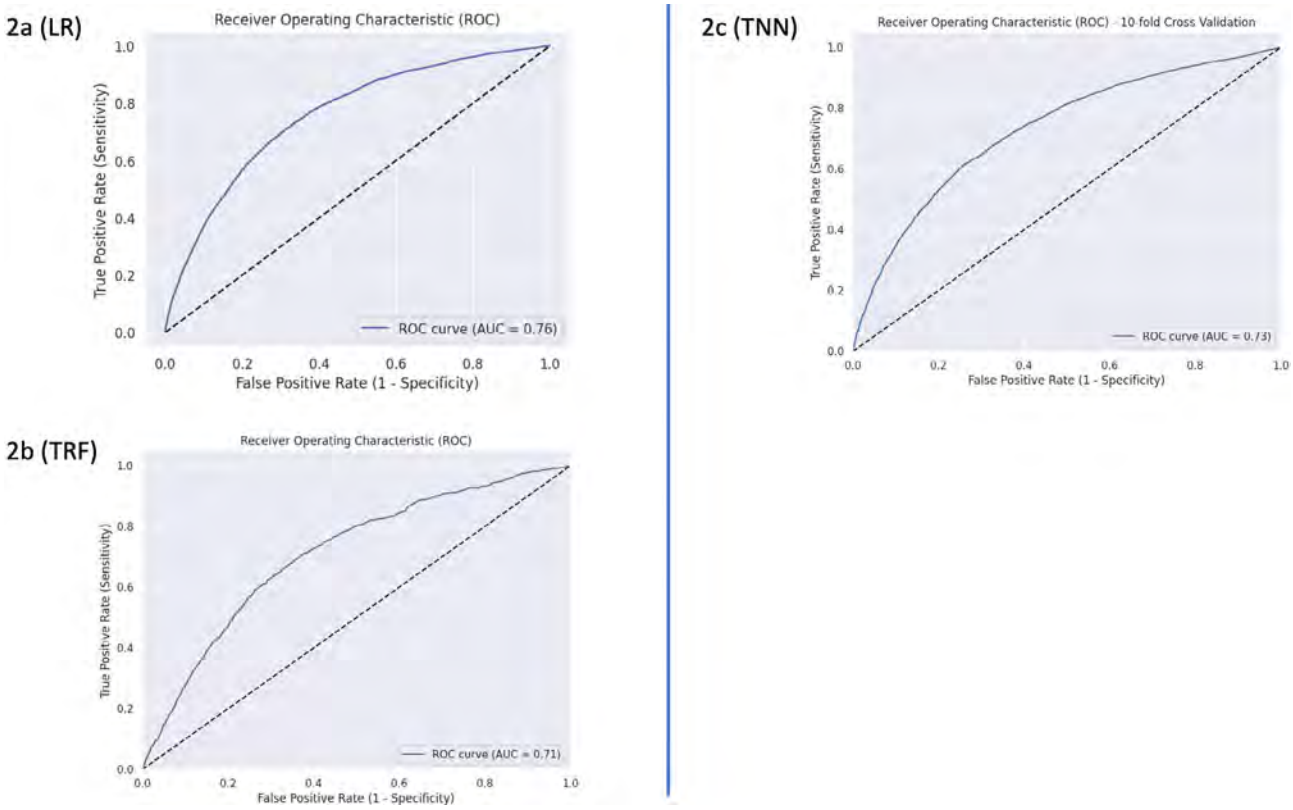
Methods: Data from the National Health Interview Survey (NHIS) collected between 2013 and 2018 were analyzed. Logistic regression (LR), tuned random forest (TRF), and tuned neural network (TNN) classifiers were employed to predict CRN using various demographic and health-related factors, including gender, race/ethnicity, age, health coverage attributes, self-

Table 1. Characteristics of the machine learning classifiers used to predict CRN.

Classifier	Key Features	Optimization Method	Optimized model settings
Logistic Regression (LR)	A linear model that predicts the relationship between predictors and an outcome. It is commonly used for binary classification tasks.	Standardization of features using StandardScaler	Standard
Tuned Random Forest (TRF)	An ensemble method that combines multiple decision trees to make predictions. It is effective for handling complex relationships and interactions.	Grid search for hyperparameter optimization	n_estimators=300; max_depth=3, max_features=0.5
Tuned Neural Network (TNN)	A non-linear model capable of capturing complex relationships between predictors and the outcome. It is suitable for tasks involving intricate interactions.	Grid search for hyperparameter optimization	alpha=0.1, hidden_layer_sizes=(50,)



Machine learning classifier inputs (features) with the most important in predicting CRN. 1a: Logistic regression (LR). 1b: Tuned random forest (TRF). 1c: Tuned neural network (TNN).



Receiver operating characteristic (ROC) curves for the machine learning classifiers. 1a: Logistic regression (LR). 1b: Tuned random forest (TRF). 1c: Tuned neural network (TNN).

reported health status, and comorbidity burden. The characteristics of the models are summarized in Table 1. Feature importance plots were utilized to assess the significance of each input in predicting CRN. Additionally, model performance was evaluated using five-fold cross-validation, and the results were visualized using receiver operating characteristic (ROC) curves.

Results: The study included 23,952 participants with chronic arthritis, among whom 4,632 (19.33%) experienced CRN. The LR classifier identified advanced age as having the smallest odds ratio, while a high comorbidity burden had the largest odds ratio (Figure 1a). Similarly, the TRF classifier indicated that advanced age was the most influential factor, followed by having private or Medicare coverage (Figure 1b). The TNN classifier identified the absence of a high-deductible health plan (HDHP) as the most significant predictor of not having CRN; on the other hand, a lapse in health coverage emerged as the most influential factor in predicting the presence of a CRN (Figure 1c). All three classifiers demonstrated comparable prediction powers, with areas under the curve (AUC) of 76%, 71%, and 73% for LR, TRF, and TNN classifiers, respectively (Figure 2).

Conclusion: Our classification models exhibited promising performance with AUC values close to three-fourths. These AUC values were obtained using five-fold cross-validated test sets, indicating robustness. However, further enhancements are necessary to improve prediction accuracy. Nevertheless, this study highlights the potential of machine learning classifiers in identifying patients at higher risk of CRN.

Impact of Social Determinants of Health Factors on Medication Adherence in Members with Rheumatoid Arthritis, Psoriatic Arthritis, and Systemic Lupus Erythematosus

Jean Park, W. Cliff Rutter, Elisea Avalos-Reyes, Chen Liu, Will Cavers, Dorothea Verbrugge and Kjel Johnson, CVS Health, Woonsocket, RI

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Social determinants of health (SDOH) have a significant impact on the health outcomes of many chronic conditions, including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE). The purpose of this study is to assess the impact of SDOH on adherence in RA, PsA and SLE patients.

Methods: In this cohort study of fully insured commercial and Medicare members of a large national health plan between 1/1/2018 and 1/1/2023, members ≥ 18 years old were included if they had at least 2 visits for RA (ICD-10 code: M05 or M06), PsA (L40.5), or SLE (M32) during the study period and received medication therapy for their disease. Members were

Table 1. Demographic characteristics

excluded if they did not maintain continuous eligibility 6 months before or after entrance into the study, had multiple conditions of interest, or had missing socioeconomic status (SES) data. Medication adherence was measured using proportion of days covered (PDC), defined as the number of days with medication coverage divided by the number of days between index date into the study and the exhaust date of the last prescription. Adherence was defined as PDC ≥ 0.8. Continuous variables were assessed with analysis of variance or Kruskal-Wallis tests; categorical variables were assessed with the Chi^2 test. Logistic regression was used to examine the impact of SDOH factors on medication adherence; p-values < 0.05 are significant.

Results: Of the 50,817 members included in this study, 35,573 (70%) had RA, 7,083 (13.9%) had SLE, and 8,161 (16.1%) had PsA. There were significant differences (Table 1) in baseline demographics between disease states, with RA members being older (mean age [standard deviation (SD)]: 58.4 [14.3] vs. 51.6 [12.7] and 48.7 [14.7] years in PsA and SLE, respectively; p< 0.001) and more ill at baseline (mean Charlson Comorbidity Index [SD]: 3.1 [2.7] vs. 1.5 [2.1] and 2.8 [2.4] in PsA and SLE, respectively; p< 0.001). Adherence was high during this study (mean PDC [SD]: 0.88 [0.19]). RA members had the highest PDC (mean [SD]: 0.88 [0.19] vs. 0.87 [0.18] and 0.85 [0.21] compared to PsA and SLE members, respectively; p< 0.001). In regression analysis, RA members were more likely to be adherent compared to PsA members (odds ratio [OR, 95% confidence interval (CI)]: 1.19 [1.02-1.39]); SLE was not associated with changes in adherence (Figure 1). Other factors associated with increased adherence include male gender (OR [95%CI]: 1.15 [1.10-1.21]); cancer diagnoses (OR [95%CI]: 1.07 [1.00-1.15]); and increasing age. Factors associated with decreased adherence were: low SES compared to high SES (OR [95%CI]: 0.89 [0.81-0.97]); liver disease (OR [95%CI]: 0.75 [0.66-0.86]); cardiovascular disease (OR [95%CI]: 0.92

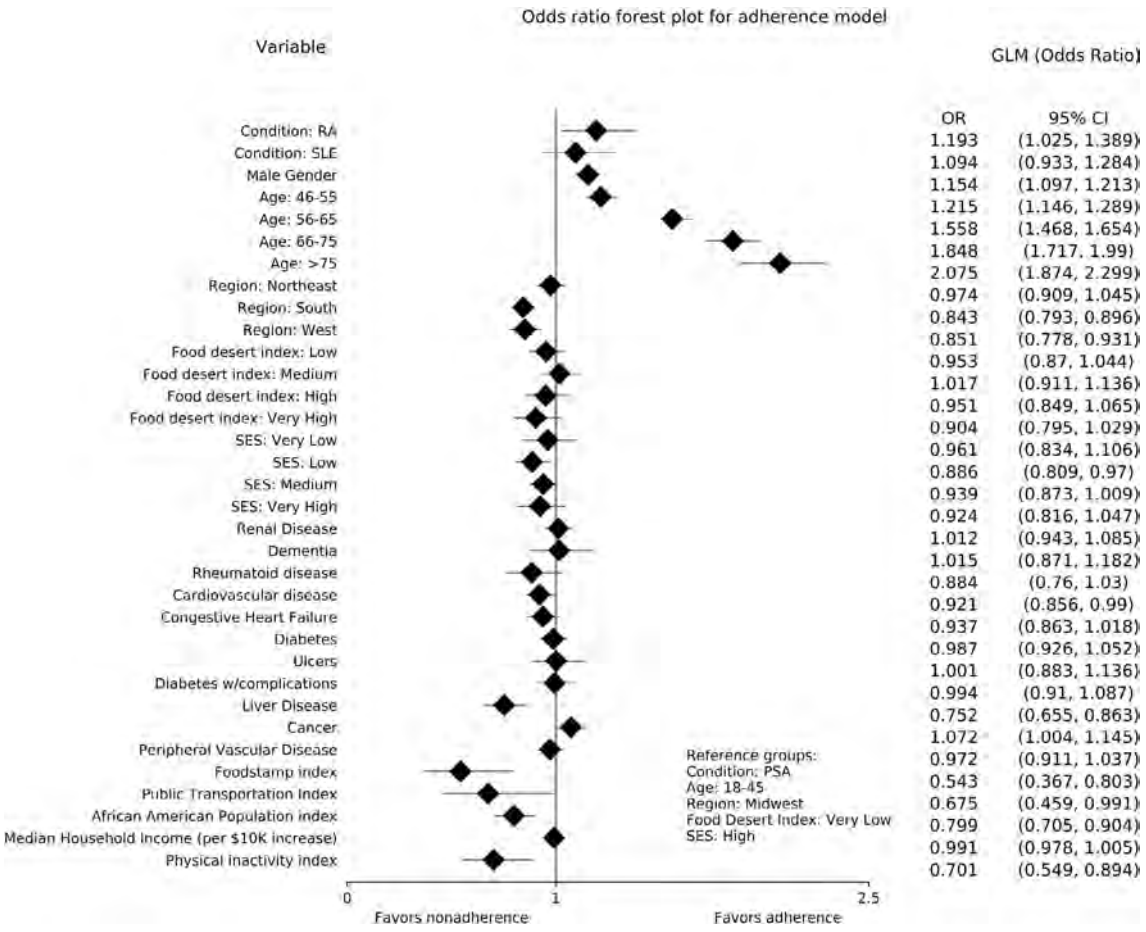

Figure 1. Variables associated with medication adherence

[0.86-0.99]); increases in food stamps (OR [95%CI]: 0.54 [0.37-0.80]), public transportation (OR [95%CI]: 0.68 [0.46-0.99]), African American population (OR [95%CI]: 0.80 [0.71-0.90]), and physical inactivity (OR [95%CI]: 0.70 [0.55-0.89]) indices.

Conclusion: Members with RA had significantly higher rates of adherence compared to members with PsA and SLE. SDOH factors associated with decreased adherence included SES, increases in food stamps, public transportation, African American population, and physical inactivity indices.

Abstract Number: 0177

Cost-Related Medication Non-Adherence Among US Adults with Chronic Arthritis: Trends, Comparisons, and Disparities

Ashkan Ara[1], Matthew Chenoweth[1], Christopher Scannell[2] and John FitzGerald[1], [1]University of California Los Angeles, Los Angeles, CA, [2]UCLA / West Los Angeles VA Medical Center, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

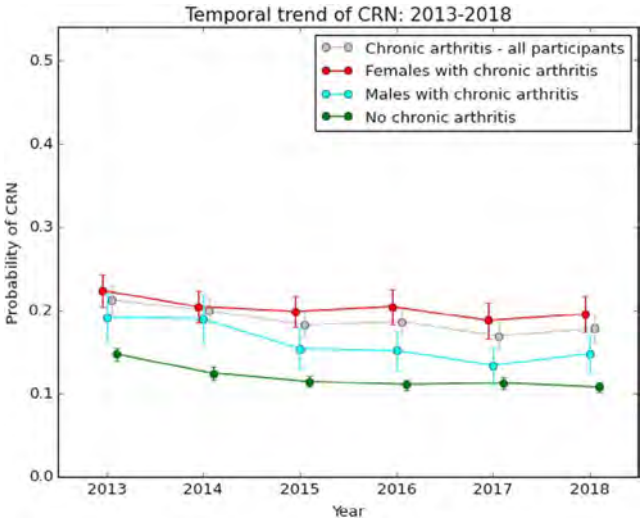
Background/Purpose: Cost-related medication non-adherence (CRN), a measure of drug affordability, refers to a patient's inability to adhere to a prescribed medication regimen due to high medication costs or lack of insurance coverage. Financial burden may lead patients to skip doses, reduce dosages, or delay refilling their prescriptions, which can have negative effects on their health outcomes. In this study, we aimed to investigate CRN in a nationally representative sample of US adults with chronic arthritis.

Methods: We utilized data from the National Health Interview Survey (NHIS) spanning the years 2013 to 2018. By applying survey weights, we calculated the proportion of individuals experiencing CRN among those with and without chronic arthritis of any type. We also calculated the proportion of CRN among individuals with cancer (any type), diabetes mellitus (any type), and heart disease (any type) as comparison groups. Additionally, we calculated the proportion of CRN in subgroups based on gender and race/ethnicity. To ensure accurate calculations, we limited the denominator samples to individuals who received at least one prescription drug. Significant differences were determined using 95% confidence intervals. Data analyses were performed using Stata and Python.

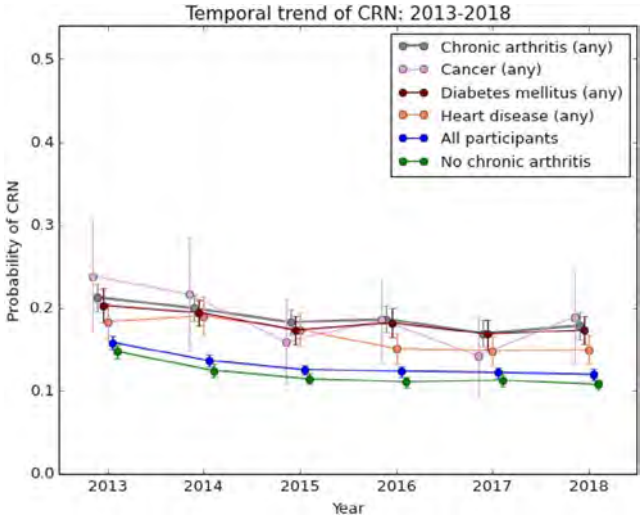
Results: The study included 163,579 participants without chronic arthritis and 26,534 participants with chronic arthritis, of which 17,840 were females with chronic arthritis. Among those with chronic arthritis, there were 19,047 non-Hispanic Whites, 3,917 African Americans/Blacks, 2,497 Hispanics, 625 Asians, and 421 individuals belonging to other races/ethnicities. From 2013 to 2018, the likelihood of experiencing CRN showed a downward trend among individuals with chronic arthritis (21.26% vs. 17.83%, $p< 0.05$) as well as those without chronic arthritis (14.72% vs. 10.76%, $p< 0.05$). CRN was consistently higher across all years in individuals with chronic arthritis versus those without, and the likelihood of experiencing CRN in this group was comparable to that of individuals with cancer and diabetes (Figure 1). Throughout 2013 to 2018,

females with chronic arthritis were significantly more likely to experience CRN than males, and the gender disparities in CRN widened during this period (Figure 2). Furthermore, African Americans/Blacks and Hispanics exhibited trends indicating a higher likelihood of experiencing CRN compared to non-Hispanic Whites and Asians. Nonetheless, those differences were not statistically significant throughout all the years analyzed. (Figure 3).

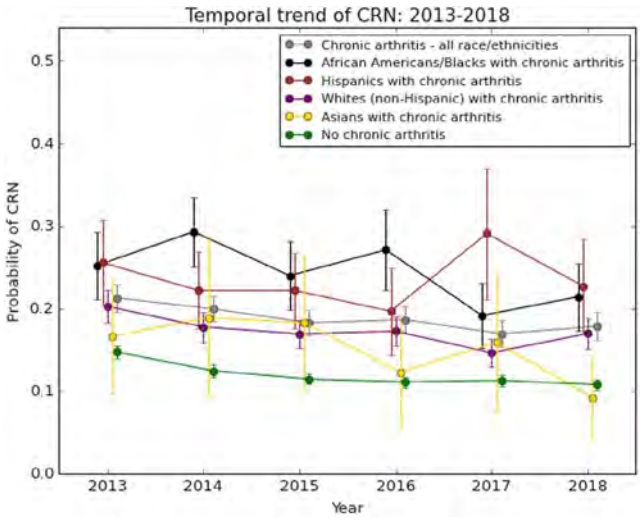
Conclusion: The likelihood of experiencing CRN is gradually decreasing among individuals with and without chronic arthritis. However, individuals with chronic arthritis have a similar likelihood of experiencing CRN compared to those with cancer and diabetes mellitus. Furthermore, our findings raise concerns about potential gender and racial/ethnic disparities in the risk of CRN among US adults with chronic arthritis. In light of these findings, it is crucial to conduct further research and implement targeted policy solutions to address such disparities, ensuring equitable access to affordable medications for all individuals with chronic arthritis.



Comparison of CRN among participants with and without chronic arthritis, as well as those with cancer, diabetes, and heart disease (any type).



Comparison of CRN among females and males with chronic arthritis.



Comparison of CRN among participants with chronic arthritis from various racial/ethnic backgrounds.

Abstract Number: 0178

Traditional and Lupus-Specific Risk Factors for Cardiovascular Events Among Patients with Systemic Lupus Erythematosus

Saloni Patolia, Dulaney Wilson, Jim Oates and Diane L. Kamen, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Even among young women with systemic lupus erythematosus (SLE), accelerated atherosclerosis and coronary artery disease are common complications. Traditional risk scoring methods underestimate cardiovascular (CV) risk in patients with SLE, highlighting the need to account for both traditional and lupus-specific risk factors. Our goal is to evaluate the influence of traditional and lupus-specific risk factors on CV outcomes, and examine potential health disparities in these outcomes, among patients with SLE.

Methods: Data was obtained from an ongoing IRB-approved longitudinal single-center registry of patients with SLE and non-SLE population-matched controls. Demographics, medical / social history, and SLE characteristics (if applicable) was obtained from interviews, exams, and medical record review. Disease damage was determined by SLICC/ACR Damage Index ("any damage" if score ≥1).Descriptive analyses, Pearson's chi-squared testing, two-sample t-tests, and multivariable logistic regression were performed as appropriate.

Results: 854 patients with SLE and 663 non-SLE population-matched controls were included in our study. Compared to the controls, the risk of myocardial infarction (MI) was higher among SLE patients (OR 10.53, p< 0.01) and risk of stroke was higher among SLE patients (OR 18.55, p< 0.01), adjusted for age, race, and gender.

Age of SLE diagnosis and current age were both lower among Black patients compared to non-Black patients (**Table 1**), with no significant difference in disease duration. Significantly higher rates of hypertension, lupus nephritis (LN), disease damage and steroid use were observed among Black patients, and a higher rate of smoking was observed among non-Black patients. Diabetes, hypertension, and hyperlipidemia were associated with higher risk of stroke and MI in univariate analysis (each $p < 0.01$). In a multivariate model of the risk among patients with SLE of either a stroke or MI, highest odds were for hypertension (OR 5.24, $p< 0.01$), adjusted for age, race, gender, education, smoking, hyperlipidemia, diabetes, steroid use, and nephritis.

Table 1. Characteristics of study participants comparing Black and non-Black patients with SLE

Characteristics	All patients with SLE N = 854	Black patients with SLE n = 623	Non-Black patients with SLE n = 231	P-value
Current age (mean years +/- SD)	50.2 (15.8)	49.1 (15.3)	53.5 (16.7)	**<0.01**
Age of SLE diagnosis (mean years +/- SD)	31.1 (13.9)	30.1 (12.8)	34.0 (16.6)	**<0.01**
Childhood-onset SLE (%)	16.0	16.2	15.6	NS
Female (%)	91.0	90.7	91.8	NS
Graduated high school (%)	85.2	75.6	81.0	**0.01**
Health insurance coverage (%)	74.0	76.2	68.0	NS
Ever smoker (%)	25.1	20.9	36.4	**<0.01**
Hypertension diagnosed (%)	49.9	55.9	33.8	**<0.01**
Hyperlipidemia diagnosed (%)	18.6	19.1	17.3	NS
Diabetes diagnosed (%)	11.0	12.4	7.4	NS
Stroke diagnosed (%)	10.2	10.8	8.7	NS
Myocardial infarct diagnosed (%)	4.0	3.4	5.6	NS

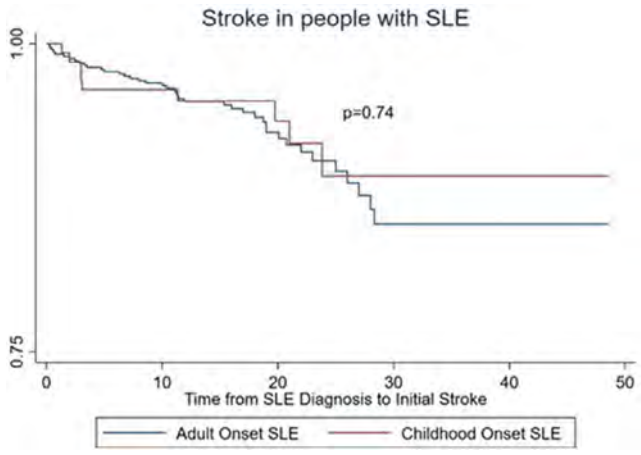

Figure 1. Percent event-free survival over time (in years) from SLE diagnosis to initial stroke comparing adult onset to childhood onset SLE

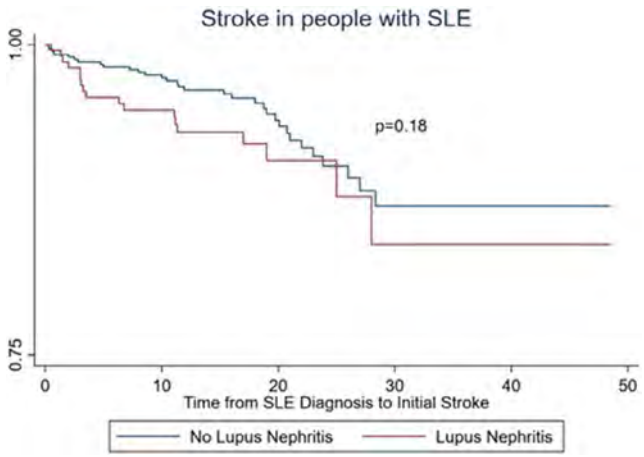

Figure 2. Percent event-free survival over time (in years) from SLE diagnosis to initial stroke comparing lupus nephritis patients to those without lupus nephritis

In multivariate regression models those with childhood onset SLE had a similar mean length of time between SLE onset to stroke compared to adult onset SLE (**Figure 1**), but the stroke age was younger for childhood-onset SLE (23.3 ±10.5 vs 43.3 ±13.8, p< 0.01). Age of MI was also younger for childhood-onset SLE (22.1 ±7.5 vs 47.1 ±11.2, p=0.01). Those with LN had a younger stroke age (32.5 ±14.6 vs 45.0 ±13.5, p< 0.01) and a shorter time to initial stroke compared to those without LN (**Figure 2**).

Conclusion: We found an increased prevalence of CV indicators and CV outcomes among patients with SLE at a significantly younger age compared to population controls, which is even more striking among patients with childhood onset SLE. Continued racial disparities in several important lupus and CV outcomes were evident, highlighting the need to identify and address care gaps for these high-risk patients. Continued progress in understanding what underlies these outcomes will support needed well-informed clinical interventions in risk factor modification for patients with SLE.

Social Disparities and Pathology Markers at Lupus Nephritis Diagnosis Predict Worse Kidney Outcomes

Shivani Garg[1], Brad Astor[2], Amish Raval[2], S. Sam Lim[3], Weixiong Zhong[2], Sarah Panzer[2], Brad Rovin[4] and Christie M. Bartels[2], [1]Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]University of Wisconsin, School of Medicine and Public Health, Madison, WI, [3]Emory University, Atlanta, GA, [4]Ohio State University, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: At diagnosis, a typical 30-year-old with lupus nephritis (LN) already has 10-fold higher chronic kidney disease (CKD) risk than peers and LN is a leading cause of end-stage kidney disease (ESKD) in young patients. Moreover, Black race is associated with a 6-fold higher risk of developing LN associated ESKD suggesting interactions between biological, socio-economic, and pathological factors can accelerate CKD progression and ESKD risk in

LN. Examining early risk factors and interactions between socio-economic and biological factors can improve precision in identifying high-risk patients, yet these are under-examined in LN. Thus, we examined socio-economic and biological factors at LN diagnosis, and pathological markers in index kidney biopsies as predictors of CKD progression and ESKD among a longitudinal inception LN cohort.

Methods: Data including demographics, social factors, comorbidities, LN therapy, and pathology reports at LN diagnosis were abstracted from adult LN patients who underwent index kidney biopsy between 1994-2021. We abstracted LN chronicity and activity indices from index kidney biopsy slides and reports, and re-read biopsy slides to grade renal arteriosclerosis (ASCL) by calculating percent luminal narrowing. We measured two outcomes: a) time to CKD progression defined as a sustained decrease in eGFR ≥30% below the baseline, confirmed by ≥3 values for ≥ 3 months and progression to CKD stage ≥2 (eGFR < 90); b) time to ESKD with up to 12 years follow-up. Cox hazards models and Kaplan Meier (KM) survival analyses were used to examine whether socio-economic factors and pathology markers such as ASCL and activity and chronicity indices predict CKD progression and ESKD.

Results: Among 173 incident adult patients with LN, 75% were female and 35% were from Black and other racial groups. Mean age at LN diagnosis was 38±17 years, and 46% had public or no insurance. Mean renal ASCL (percent luminal narrowing), activity, and chronicity indices were 23%, 2.2, 1.9, respectively.

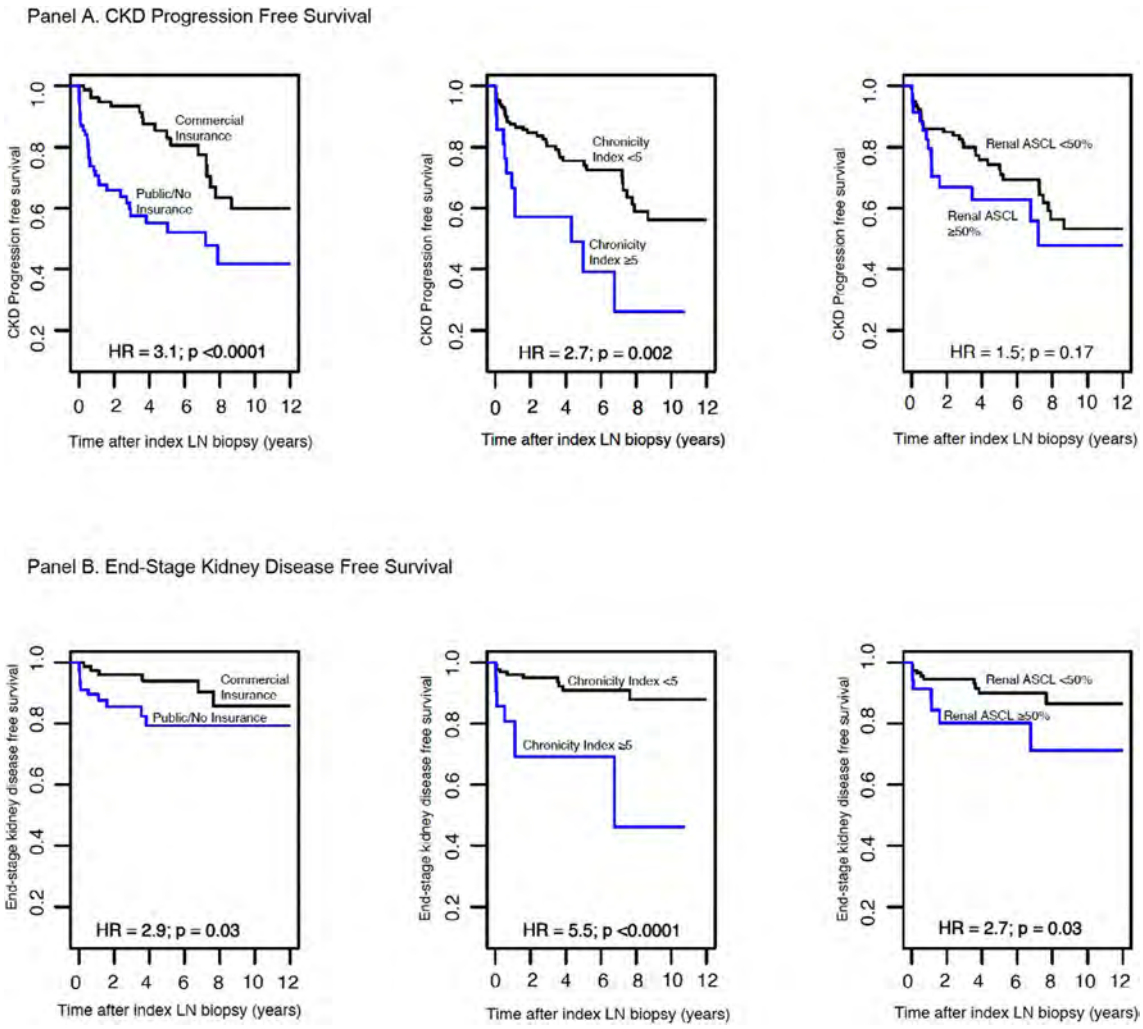

Figure 1. Kaplan Meier Curve shows: Panel A. CKD progression defined as kidney function impairment with sustained decrease in eGFR by 30% and eGFR <90 (CKD stage ≥2); Panel B. ESKD occurrence over 12-year follow-up period after LN diagnosis.

**Full model includes all socio-demographics, LN chronicity index, and other variables with p-value <0.1 on univariable analysis. Statistically significant values (p <0.05) in bold font. +Trend towards significance.*

A total of 49 patients developed CKD progression over 12 years after LN diagnosis. KM survival curves highlighted accelerated CKD progression in patients with public or no insurance and LN chronicity index ≥5 (Fig. 1A). Patients with public or no insurance had 2-fold higher risk of CKD progression (Adjusted HR 2.2; Table 1). Increase in LN chronicity determined 40% higher CKD progression (Table 1).

Next, 19 patients developed ESKD. KM survival curves noted higher ESKD risk in patients with public or no insurance, severe renal ASCL, and LN chronicity index ≥5 at diagnosis (Fig. 1B). In a limited multivariable model, not including LN chronicity, severe renal ASCL was associated with 2.7 fold higher ESKD risk (Table 2). However, after including LN chronicity, only LN chronicity was associated with 40% higher ESKD risk (Table 2).

Conclusion: Socioeconomic barriers such as public or no insurance at diagnosis were the strongest, independent risk factor of CKD progression to stage ≥2. Additionally, higher LN chronicity in diagnostic biopsies was associated with greater ESKD risk. Future CKD prevention efforts should focus on patients with socioeconomic barriers and those with high LN chronicity index at LN diagnosis to improve outcomes in LN.

Multiplicative Impact of Adverse Social Determinants of Health on Outcomes in Lupus Nephritis: A Meta-analysis and Systematic Review

Shivani Garg[1], Brianna Boderman[2], Nadia Sweet[2], Daniel Montes[3], Brad Astor[2], S. Sam Lim[4] and Christie M. Bartels[2], [1]Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]University of Wisconsin, School of Medicine and Public Health, Madison, WI, [3]Mayo Clinic, Rochester, MN, [4]Emory University, Atlanta, GA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus results in 58% more organ damage in people of Black race in the US compared to African descendants living in 11 other developed countries. This highlights that social determinants of health (SDH) likely contribute to disparities in LN outcomes in the US. However, the overall burden of adverse SDHs on LN outcomes and how each SDH domain contributes to observed health disparities have not been fully examined. In the absence of such information, health disparities between racial/ethnic groups may be interpreted as inherently "biological" or "cultural" differences. Thus, there is a need to understand the underlying mechanisms explaining how SDHs influence outcomes and contribute to health disparities in LN to advance equity. Objectives of this systematic review and meta-analysis were to: 1) determine the odds of poor LN outcomes in patients with i) any adverse SDHs, and ii) specific SDH domains; 2) develop a framework for the multidimensional impact of SDH on LN outcomes.

Methods: A comprehensive search was performed using MeSH headings and keywords (e.g., lupus nephritis, insurance, poverty, neighborhood socio-economic status, death, etc.) in Medline, Embase, CINAHL and Web of Science. We included observational and interventional studies on human subjects measuring associations between SDHs and LN outcomes. Risk of bias was assessed using standard tools for all studies.

We examined pooled odds of severe LN outcomes (primary outcome) including mortality, end-stage kidney disease (ESKD), or cardiovascular disease (CVD) in patients with and without any adverse SDHs using a random effects model. Additionally, we calculated the pooled odds of poor outcomes by each SDH domain: individual (e.g., race, insurance), healthcare (e.g., fragmented care, hospital experience), community (e.g., neighborhood socioeconomic status), and behavioral (e.g., smoking) (Fig. 1). Heterogeneity was assessed using I^2.

Results: Among 531 manually reviewed abstracts, 31 met inclusion. Only 13 studies comparing LN outcomes in patients with and without adverse SDHs were included in the meta-analysis. Overall 92% of studies had low risk of bias. The pooled odds of poor outcomes (death, ESKD, or CVD) in patients with any adverse SDHs were 45% higher compared to those without any adverse SDHs (OR 1.45, 95% CI 1.10-1.91, p = 0.008, I^2 85%, Fig. 2). Among the four SDH domains, 64% and 77% higher odds of poor outcomes were noted in patients with adverse SDHs in individual and healthcare domains (OR 1.64, 95% CI 1.13-2.39, I^2 92%; OR 1.77, 95% CI 1.2-3.0, I^2 0%; Fig. 3A-D). Our framework highlighted a multiplicative impact of adverse SDHs in different domains on poor LN outcomes (Fig. 1). As illustrated in Fig. 1, patients of Black race with fragmented care and public insurance had 12-fold higher odds of mortality/ESKD.

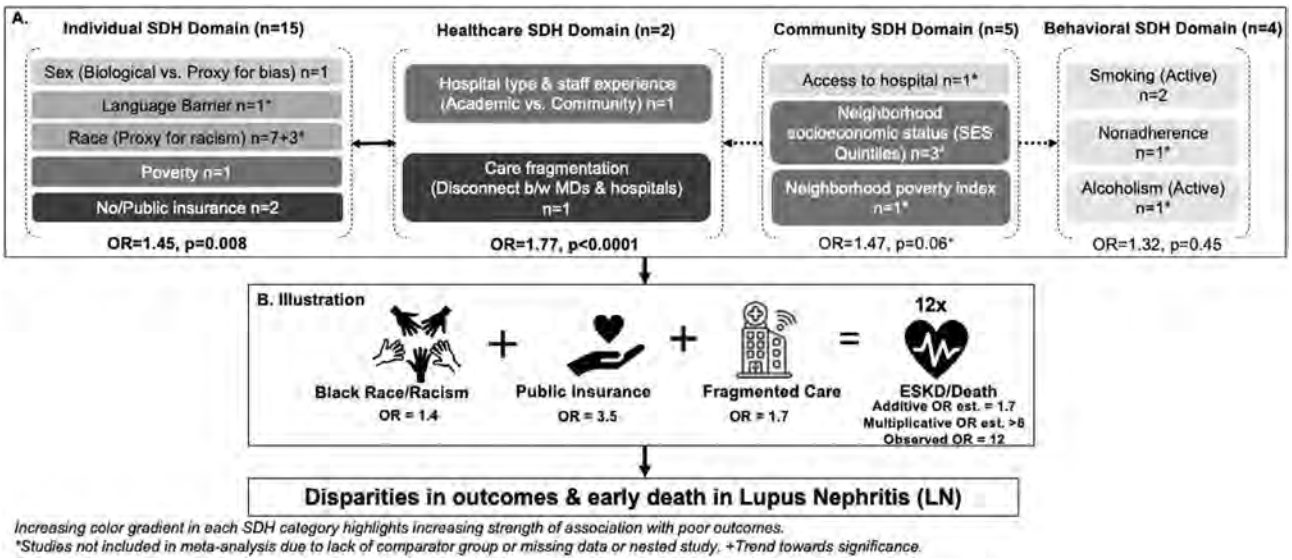

Figure 1. Conceptual model highlighting the impact of adverse individual, community, healthcare, and behavioral SDHs on severe LN outcomes. Data in row B. illustrate multiplicative effects of SDH on LN outcomes.

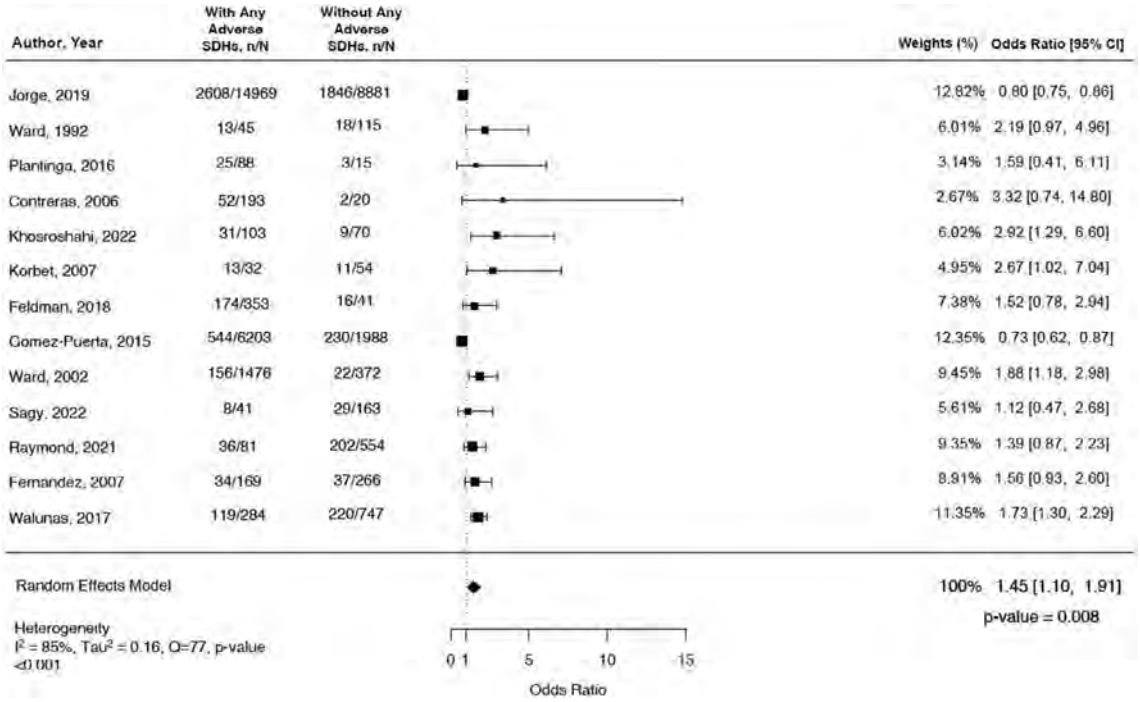

Figure 2. Forest plot showing the odds of ESKD or death in patients with or without any adverse social determinants of health

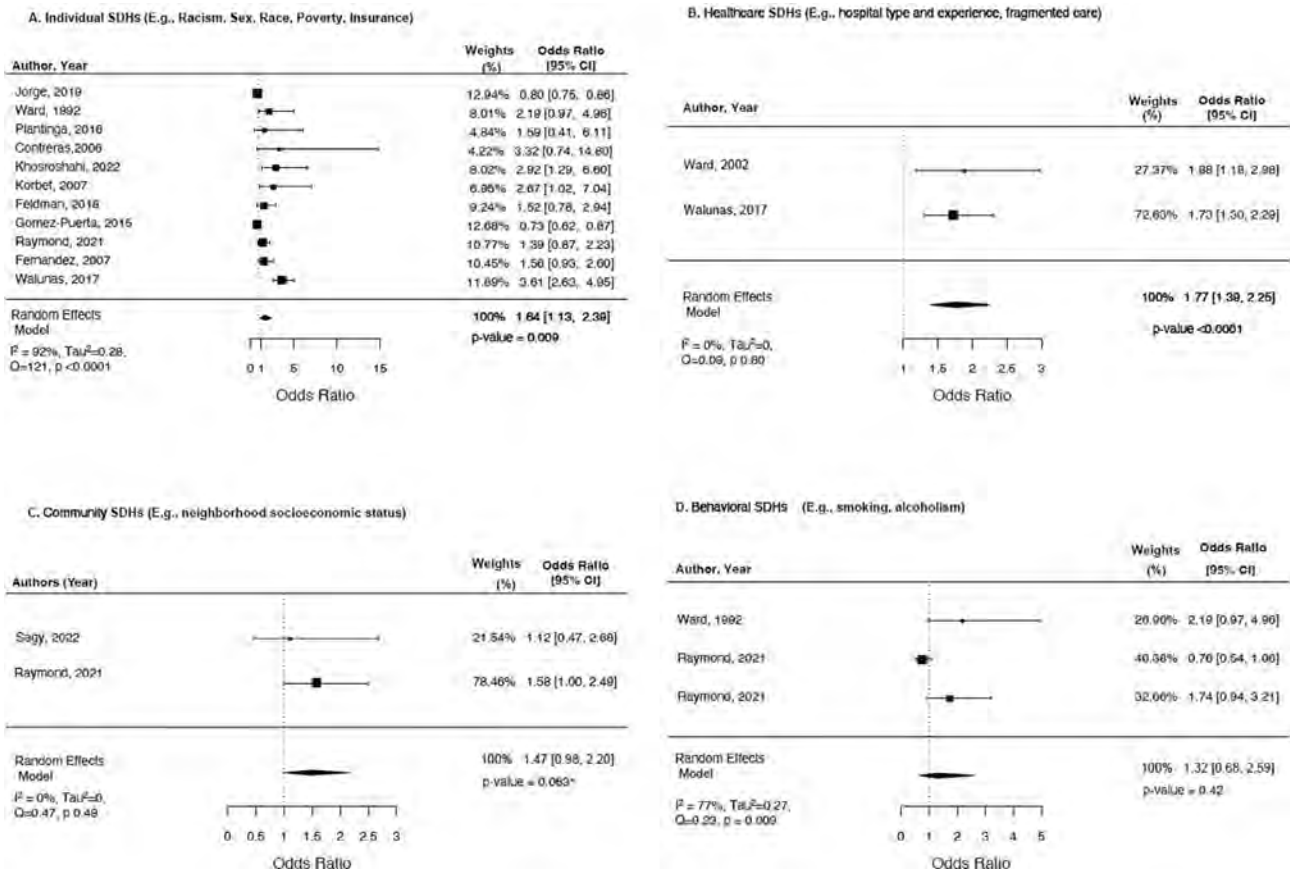

Figure 3. Forest plot showing the odds of ESKD or death with or without adverse social determinants of health in each SDH domain

Conclusion: Our study reports a strong negative impact of adverse SDHs on LN outcomes, with the worst impact in patients with adverse individual and healthcare SDH domains. Moreover, having adverse SDHs in ≥2 domains had a multiplicative impact leading to 12-fold higher odds of poor outcomes, widening health disparities in LN. These findings could guide future health-equity focused interventions to address outcome disparities in LN.

Abstract Number: 0181

Increased Prevalence of and Acute Hospital Events Among Medicare Systemic Lupus Erythematosus Patients Living in Socially Vulnerable Counties in the United States

Emily Cosentino, John Pearce and Jim Oates, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is more prevalent and has greater adverse health outcomes in women, minorities, and individuals with low socioeconomic status (SES), particularly in Medicaid populations. These associations have not been reported in the Medicare population of older or disabled individuals. Our purpose is to analyze the association between environments of social vulnerability and SLE prevalence and acute hospital events in a Medicare population within the United States.

Table 1. Demographics of the total Medicare SLE population with 2 or more ICD-10 codes at least 30 days apart

Characteristics	Frequency (n)	Percentage
Sex		
Male	11,806	10.7%
Female	98,771	89.3%
Race/Ethnicity		
White	75894	68.6%
Black	24838	22.5%
Hispanic	4474	4.0%
Asian	1755	1.6%
Native American	960	0.87%
Other	1590	1.4%
Unknown	1066	1.0%
Age		
19-49	20520	18.6%
50-64	29611	26.8%
65-74	38419	34.7%
75-80	12786	11.6%
80+	9241	8.6%
Total	110577	100%

Table 2. Spearman's correlation r values and 95% confidence intervals between prevalence of SLE, ER visit rates, and hospitalization rates with SVI themes rank, themes, and subthemes.

	R values	95% Confidence Intervals (2-tailed)
Prevalence:		
SVI rank	0.408	0.363 to 0.452
Themes:		
Theme 1: Socioeconomic Status	0.431	0.386 to 0.473
Theme 2: Household Composition & Disability	0.364	0.317 to 0.410
Theme 3: Minority Status & Language	0.135	0.082 to 0.187
Theme 4: Housing Type & Transportation	0.135	0.082 to 0.187
ER visits:		
SVI rank	0.222	0.168 to 0.274
Themes:		
Theme 1: Socioeconomic Status	0.227	0.174 to 0.279
Theme 2: Household Composition & Disability	0.224	0.170 to 0.276
Theme 3: Minority Status & Language	0.122	0.067 to 0.176
Theme 4: Housing Type & Transportation	-0.009	-0.065 to 0.047
Hospitalization Rates:		
SVI rank	0.113	0.051 to 0.174
Themes:		
Theme 1: Socioeconomic Status	0.130	0.068 to 0.191
Theme 2: Household Composition & Disability	0.096	0.034 to 0.157
Theme 3: Minority Status & Language	0.075	0.013 to 0.137
Theme 4: Housing Type & Transportation	-0.010	-0.072 to 0.052

Table 3. Logistic regression modeling of the relationship between SVI subtheme variables and SLE prevalence and ER visit rate.

Prevalence:

Variables	Beta	t	Sig.	95% CI for B
Minority	0.301	6.390	<0.001	0.058 to 0.110
No HS Diploma	0.180	4.966	<0.001	0.037 to 0.085
Age 17 or Younger	0.104	3.867	<0.001	0.018 to 0.056
Civilian with Disability	0.108	2.700	.007	0.009 to 0.056
Percent Uninsured	0.138	4.178	<0.001	0.002 to 0.006
Crowding	-0.088	-2.940	.003	-0.065 to -0.013
Age 65 or Older	-0.146	-4.301	<0.001	-0.067 to -0.025
Multi-Unit Structures	-.141	-5.012	<0.001	-0.093 to -0.041
Limited English	-0.174	-5.323	<0.001	-0.115 to -0.053

ER Visits:

Variables	Beta	t	Sig.	95% CI for B
Single-Parent Households	0.111	3.521	<0.001	0.127 to 0.445
Below Poverty	0.087	2.468	0.014	0.029 to 0.257
Mobile Homes	0.086	2.347	0.019	0.010 to 0.220
Age 65 or Older	-0.067	-2.125	.0.034	-0.206 to -0.008
Multi-Unit Structures	-0.060	-1.853	0.064	-0.304 to 0.009
Limited English	-0.063	-2.134	.033	-0.305 to -0.013

Methods: This was a cross-sectional study utilizing the Centers for Disease Control and Prevention (CDC)/Agency for Toxic Substances and Disease Registry (ATSDR) Social Vulnerability Index (SVI) and Lupus Research Alliance Lupus Index Medicare data at a county level. Individuals enrolled in fee-for-service Medicare in 2016 who were diagnosed with SLE by 2 or more ICD-9 codes 30 or more days apart were included. We examined the association between the prevalence of and acute hospital event rates among SLE patients and overall, SVI rank, 4 themes, and 15 subthemes within each county.

Results: The Medicare SLE population was primarily composed of female and White patients (Table I). Using ranked correlation, SVI themes and each of subthemes 1-4 were positively correlated with SLE prevalence, especially themes 1 and 2 (SES and Household Composition and Disability) (Table II). Themes 1 and 2 were positively correlated with ER visits, while theme 4 (Household type and Transportation) was negatively associated with ER visits (Table II). SVI themes and hospitalization rates were the least strongly correlated, however themes 1,2 and 3 (Minority and Non-English-speaking) were positively correlated, while theme 4 was negatively correlated (Table II). In backward stepwise logistic regression analysis, several subthemes were important in the models of prevalence and ER visit rates (Table III). SLE Prevalence was the variable most strongly correlated with SVI themes.

Conclusion: These findings mirror those from studies of SLE prevalence and ED visits in Medicaid populations as well as COVID prevalence and heat-exposure ED visits in socially vulnerable non-SLE patients. This suggests that environments of social vulnerability are an independent risk factor, but the elements of the environments (social stress, toxins, infrastructure, and proximity to care providers) that may drive risk are not addressed by this study. To our knowledge, no other study has examined SLE prevalence and acute hospital events within the Medicare population. These findings inspire the hypothesis that risk models can be used as a tool to identify at risk populations for strategic intervention to reduce disparities in outcomes.

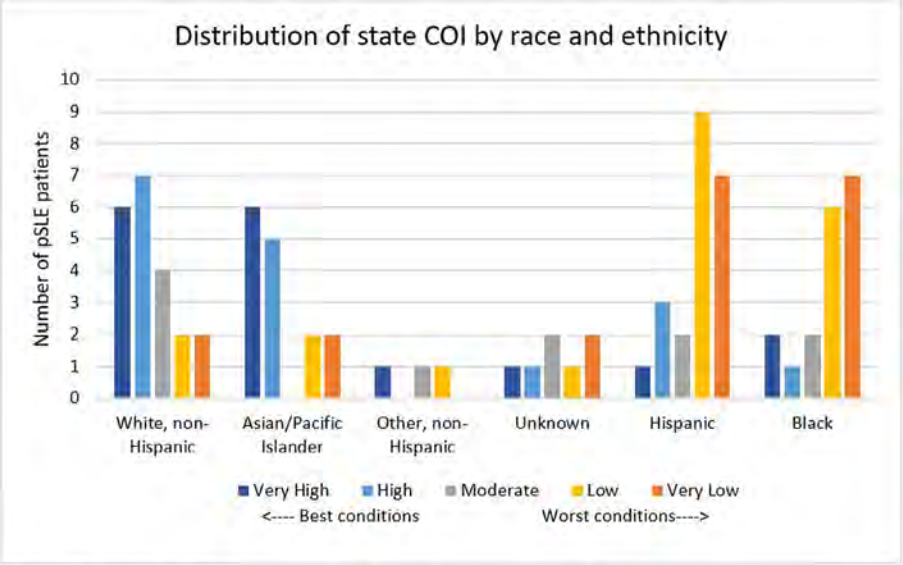
Impact of Neighborhood-level Child Opportunity on Disease Activity in Children with Lupus

Joyce Chang[1], Gabrielle Alonzi[1], Emily Smitherman[2], Pooja Patel[3], Gabrielle Morgan[4], Livie Huie[5], Karen Costenbader[6] and Mary Beth Son[7], [1]Boston Children's Hospital, Boston, MA, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Ann and Robert H. Lurie Children's Hospital of Chicago and Northwestern University Feinberg School of Medicine, Chicago, IL, [5]University of Alabama at Birmingham, Gardendale, AL, [6]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [7]Division of Immunology, Boston Children's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Racial disparities in outcomes of pediatric SLE (pSLE) have persisted over time. This may be mediated by structural racism, which segregates children belonging to minority groups into neighborhoods with lower childhood opportunity, defined as resources and conditions that promote healthy childhood development across domains of education, socioeconomics, and physical environment. We determined whether lower neighborhood-level opportunity associates with greater disease activity at initial SLE presentation or over time.



Methods: We conducted a cohort study of children newly diagnosed with SLE between 2016-2022, inclusive, in the Boston Children's Hospital Lupus Registry. The index visit was the first inpatient or outpatient rheumatology encounter with a physician diagnosis of SLE. The primary outcome was the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). Geocoded addresses were linked to the Child Opportunity Index 2.0 (2015) by census tract and categorized as: very high, high, moderate, low, or very low opportunity, based on national and state level rankings. Median SLEDAI-2K at the index visit for children in each state-ranked COI category was compared to those living in very high COI areas using Wilcoxon rank sum tests. Associations between COI and disease activity over time were estimated using linear mixed effects models adjusted for time, insurance status, nephritis and neurologic involvement at presentation; additional covariates tested included age at SLE onset, sex assigned at birth, race and ethnicity, non-English primary language, and initial SLEDAI-2K.

Results: We included 644 visits with calculable SLEDAI-2K scores, comprised by 86 patients with pSLE, with a median of 7 visits/patient [2-11] during the study period. The majority of Black (13/18, 72%) and Hispanic children (16/22, 73%) lived in low or very low state-ranked COI areas, whereas a 62% of Non-Hispanic White and 73% of Asian children lived in high or very high COI areas (**Figure 1**). In this cohort, nationally ranked COI was skewed towards very high (37%) and high (16%) average opportunity (**Table 1**). Children living in low opportunity areas ranked within state had higher SLEDAI scores at initial presentation compared to patients living in very high opportunity areas (median 14 [6-22] vs. 7 [4-8.5], p=0.03). Living in census tracts with moderate, low or very low COI (vs. very high) associated with significantly higher SLEDAI-2K over time compared to living in very high COI areas, both with or without adjustment for time, insurance status, race and ethnicity, and major organ involvement (Table 2). There was a significant test of trend (p=0.001). Results were similar when adjusting for initial SLEDAI-2K at presentation.

Conclusion: For children with pSLE in an area of the U.S. with high average opportunity levels, lower relative neighborhood-level childhood opportunity associated with higher SLE disease activity at initial presentation to care and during follow-up, independent of initial disease severity. Area-level conditions, among other factors in lower resourced areas, may mediate inequitable outcomes of pSLE at numerous points, including initial access to subspecialty care and after establishing care.

Table 1. Characteristics of Newly Seen Children with SLE in the BCH Lupus Registry (2016-2022)

	N = 86
Age at index SLE visit, median (IQR)	15.2 (12.8 - 17.0)

Barriers and Facilitators to Recruiting Underrepresented Participants for Clinical Trials: Insights from the Lupus Clinical Investigators Network (LuCIN)

Tessa Englund[1], Christine Lee[2], Julie Hsieh[2], Richardae Araojo[2], Julia Mariano[1], Emily McCormick[3], Stacie Bell[4], Albert Roy[5] and Saira Sheikh[1], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]U.S. Food and Drug Administration, Silver Spring, MD, [3]Thurston Arthritis Research Center, Chapel Hill, NC, [4]Lupus Therapeutics, Lakewood, CO, [5]Lupus Research Alliance, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite greater prevalence of lupus among diverse, racial and ethnic minority populations, marked gaps exist between populations affected by lupus and those enrolled in clinical trials. Sponsored by the Lupus Research Alliance, the Lupus Clinical Investigators Network (LuCIN) is the largest lupus clinical trials network in North America, comprised of 57 leading academic institutional sites across the US and Canada. This study aimed to describe and discuss prominent barriers and potential solutions to support recruitment and participation in lupus clinical trials conducted through the LuCIN network.

Methods: Data from the LuCIN annual survey of site investigators and research staff (site representatives) collected between March and July 2022 were prepared for analysis. The survey included questions to assess perspectives and practices around clinical trial recruitment. Descriptive statistics were computed to identify the most common barriers and facilitators to recruitment and retention of patients in lupus clinical trials.

Results: Completed survey responses were collected from representatives of 55 LuCIN sites. When asked about sources of patient referrals at their site, most respondents reported receiving patient referrals to LuCIN clinical trials from physicians within their institution (94.5%), while referrals from external community clinicians were reported by 52.7% of respondents. The most frequently reported barriers to LuCIN clinical trial recruitment were restrictive inclusion/exclusion criteria (89.1%), participant mistrust in research (38.2%), and a lack of referrals from healthcare providers (32.7%). Approximately half (49.1%) of sites reported that they had not received training on recruitment of underrepresented patients in clinical trials. When asked about the barriers to establishing a plan to improve recruitment of diverse participants, over half of site

Table. Selected LuCIN site survey respondent characteristics and perspectives on clinical trial recruitment (n=55 site representatives)

Survey Question	n	%
Do you receive patient referrals from the following? Check all that apply.		
Physicians at your institution	52	94.5%
Community providers	29	52.7%
We do not receive any patient referrals	2	3.6%
There are several barriers to recruiting participants for clinical trials/research studies at a given institution. Please select the top 3 barriers your institution faces while recruiting participants.		
Lack of email/phone response	13	23.6%
Lack of participant awareness of clinical trials	12	21.8%
Participant mistrust in research	21	38.2%
Poor attendance at clinics	6	10.9%
Lack of recruitment staff	12	21.8%
Lack of funding for advertisements, translation, or other study related needs	6	10.9%
Restrictive inclusion/exclusion criteria	49	89.1%
Health care providers not referring patients	18	32.7%
Lack of cultural/diversity training	1	1.8%
Competing clinical trials/studies that are recruiting the same type of participants	11	20.0%
Has your site received training for recruitment of underrepresented groups in clinical trials?		
Yes	28	50.9%
No	27	49.1%
What are the barriers to setting up a plan to increase diversity of participants recruited into clinical trials/research studies? Check all that apply.		
Lack of appropriate staff to carry out a plan	20	36.4%
Lack of cultural/diversity training	5	9.1%
Lack of funding for this type of planning and program development	32	58.2%
Lack of time	31	56.4%
What recruitment methods below have you found to be the most effective in recruiting eligible participants for clinical trials? Check all that apply.		
Incentives	21	38.2%
More time to answer participants' questions about the study	17	30.9%
Healthcare provider referral or recommendation	43	78.2%
Conversation with other individuals living with lupus	13	23.6%
Shorter informed consent documents	13	23.6%
The support/backing of their health care provider	37	67.3%
Text messages	5	9.1%
Calls	15	27.3%
Emails	12	21.8%
Brochures	13	23.6%
Posters	6	10.9%
Bulletin Boards	1	1.8%
Recruitment Events	2	3.6%
Online Advertisements	9	16.4%

respondents identified a lack of funding (58.2%) and time (56.4%) as barriers. The patient recruitment strategies respondents most frequently identified as effective approaches included healthcare provider referrals or recommendation (78.2%), support/endorsement from patients' healthcare providers (67.3%), study incentives (38.2%), and additional time to answer potential participants' study-related questions (30.9%).

Conclusion: This work provides valuable insights into key barriers and facilitators reported by sites to the recruitment of underrepresented participants into lupus clinical trials conducted through LuCIN. Findings underscore the need to support opportunities for effective provider-patient communication, as well as engagement between academic and community practices, to improve access and referrals to lupus clinical trials. Future research is needed to explore how these barriers and facilitators relate to clinical trial participation outcomes among underrepresented patients. By understanding these

challenges and leveraging successful recruitment strategies, LuCIN clinical trial sites can promote equity in clinical trial participation among underrepresented groups and further advance lupus research.

Material Need Insecurities Are Associated with Worse Patient-Reported Outcomes Among Individuals with SLE

Donavon Sandoval-Heglund[1], Eric Roberts[2], Joonsuk Park[2], Maria Dall'Era[2], Kamil Barbour[3], Cristina Lanata[4], Kurt Greenlund[3], Caroline Gordon[5], Patti Katz[6] and Jinoos Yazdany[2], [1]University of California San Francisco School of Medicine, La Quinta, CA, [2]University of California San Francisco, San Francisco, CA, [3]Centers for Disease Control and Prevention, Atlanta, GA, [4]National Human Genome Research Institute, Washington, DC, [5]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom, [6]University of California San Francisco, San Rafael, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Lower socioeconomic status is associated with greater disease activity and mortality in systemic lupus erythematosus (SLE); however, mechanisms driving this are yet to be understood. Qualitative research suggests that material need insecurities, such as concerns about housing, food, or medical costs, impair patients' ability to manage SLE, exacerbating the effects of poverty. We describe the prevalence of food, housing, SLE healthcare, and financial insecurity in an SLE cohort and test their associations with patient-reported outcomes (PROs).

Methods: Data were derived from a statewide SLE epidemiology study involving a cohort of individuals with physician-confirmed SLE. Food, housing, healthcare, and financial material need insecurities were assessed by validated screening tools. PROs were obtained via PROMIS, Neuro-QoL, Patient Health Questionnaire-8, and General AnxietyDisorder-7 instruments. Poverty was defined as household income ≤125% of the federal poverty limit.Lower education was defined as less than a bachelor's degree. The association of material need insecurities with PROs was assessed by multivariable linear regression models adjusting for demographics, lupus characteristics, and comorbidities. We examined the relationship between insecurities with poverty and education via unadjusted ANOVA and by including interaction terms in the adjusted regression model.

Results: Among 252 participants, 53.6% had at least one insecurity (Table 1). Insecurities were highly prevalent, and more common in those with poverty and lower education (79.3% vs. 44.8% of those with low vs. higher incomes, respectively, had any insecurities and 71.7% vs. 39.1% of those with lower vs. higher education, respectively, had any insecurities). Unadjusted analyses examining the relationship between material need insecurities and PROs revealed significant differences in all PROs between those with and without any material needs insecurity and by the number of insecurities. In the unadjusted models of the insecurity-poverty groups, overall significant differences between groups were noted for each PRO. In each case, the post-hoc means test after ANOVA analyses indicated differences between one or both insecurity groups (either "insecurity + no poverty" or "insecurity + poverty") and the no insecurity + no poverty group. Similar results were noted for the insecurity-education group analysis (Table 2). Adjusted multivariate analyses revealed that participants with any

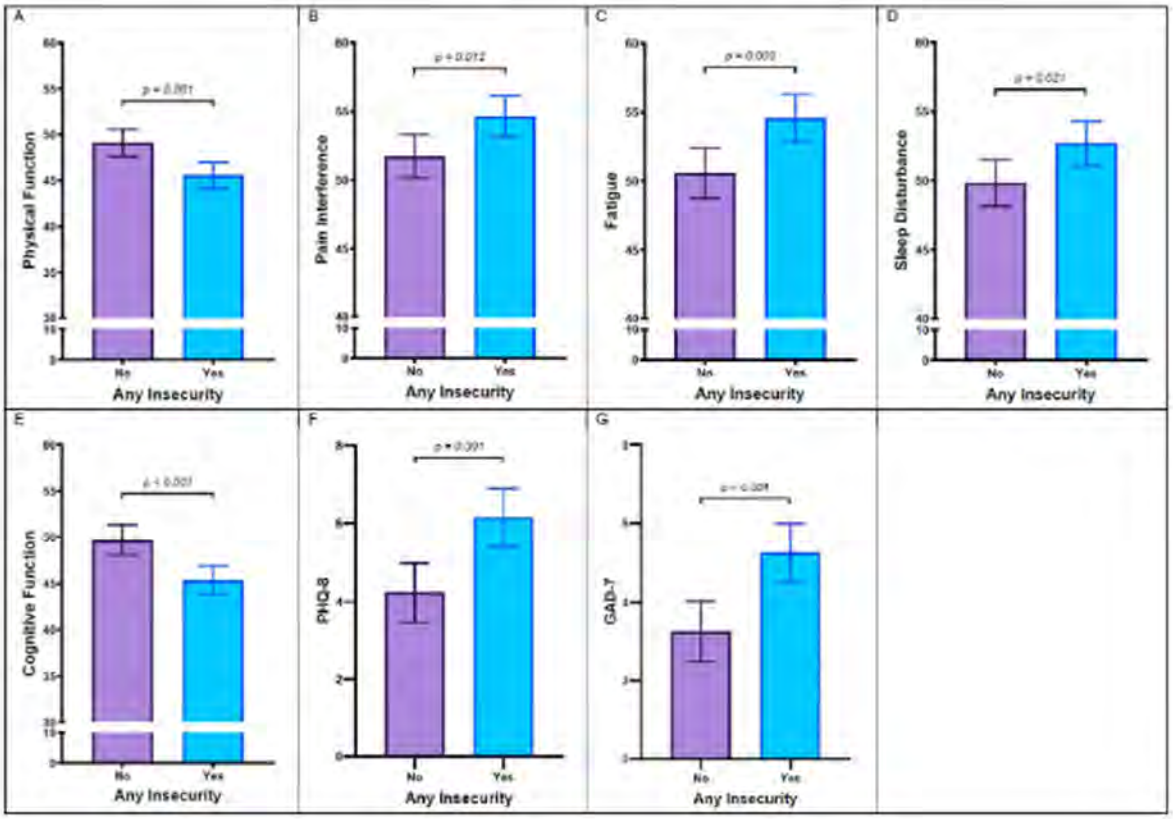
Data are mean ± SD. Differences in group means were tested with t-tests or analyses of variance.
* Significantly different from "No insecurity, income>poverty/high education" group based on post-hoc means test.
[a] Higher scores reflect better outcomes
[b] Higher scores reflect worse outcomes

Figure: Adjusted marginal means from multivariable analysis, by any insecurity



Adjusted means (95% confidence interval) calculated from multivariable linear regression analyses controlling for age, sex, race and ethnicity, marital status, education, income, comorbid conditions, obesity, disease duration, disease damage, high glucocorticoid use, and immunosuppressive use·

P values from multivariable linear regression, compared to no insecurities group

PHQ-8 = Patient Health Questionnaire, measure of depressive symptoms; GAD-7 = Generalized Anxiety Disorder questionnaire

insecurity had significantly worse scores across all PROs measured (Figure); individuals with more insecurities had worse PROs. There were no statistically significant interactions between insecurities and poverty or education.

Conclusion: Having any material need insecurity was associated with worse outcomes for patients with SLE regardless of poverty or education. Findings provide insight into mechanisms by which social risk factors can affect SLE outcomes and underscore the need for provider awareness of these modifiable factors and knowledge of relevant resources for interventions.

Abstract Number: 0185

Classifying Individuals with Rheumatic Conditions as Financially Insecure Using Electronic Health Record Data and Natural Language Processing: Algorithm Derivation and Validation

Mia Chandler[1], Tianrun Cai[2], Leah Santacroce[2], Sciaska Ulysse[2], Katherine Liao[2] and Candace Feldman[2], [1]Boston Children's Hospital, Milton, MA, [2]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Social determinants of health (SDoH) such as financial insecurity contribute to disparities in rheumatic disease care and outcomes but are not routinely included in structured electronic health record (EHR) data, (e.g., ICD-10 billing codes). SDoH described in clinical notes are not readily extractable and therefore cannot be easily incorporated into research studies. We leveraged natural language processing (NLP) to extract terms related to financial insecurity and used machine learning models to develop and validate an algorithm to identify individuals with this critical SDoH.

Methods: We randomly selected 600 patients from 20,395 with rheumatic or musculoskeletal conditions enrolled in an integrated care management program (iCMP) between 1/1/12-10/18/21. iCMP provides care for medically and psychosocially complex patients. The study team (social epidemiologists, pediatric and adult rheumatologists, bioinformaticians) defined the construct "financial insecurity" using nominal group technique. Reviewers (MTC, SU, CHF) operationalized this definition with manual EHR reviews to establish the gold standard. Individuals were classified as having definite, possible, or no financial insecurity in separate training and validation cohorts. We constructed a context-driven lexicon containing terms for financial insecurity using data from PubMed, the Unified Medical Language System, and previous EHR reviews (Table 1). All available notes were then processed using NLP with the context-driven lexicon. We developed models using logistic regression, LASSO regression, and random forest, trained on EHR-based review of cases of financial insecurity (definite or definite and possible combined) and determined the performance metrics for each model.

Table 1. Terms and Phrases Selected for Use in Models to Classify Individuals as Ever Financially Insecure Based on Their Presence in Clinical Notes

Can't Afford	AFFORD.N*, CAN.T.AFFORD, CANNOT.AFFORD, DIFFICULTY.AFFORDING, UNABLE.TO.AFFORD
Enough Money	ENOUGH.MONEY.N, FINANCIAL.LIMITATIONS, NO.MONEY
Financial Difficulties	FINANCIAL.DIFFICULTIES, FINANCIAL.HARDSHIP, FINANCIAL.HARDSHIPS, FINANCIAL.ISSUES, FINANCIAL.ISSUE
Financial Resources	FINANCIAL.RESOURCES.N, JOB.LOSS, LIMITED.INCOME, LIMITED.FINANCIAL.RESOURCES, LOSS.OF.EMPLOYMENT, LOSS.OF.INCOME, LOW.INCOME, LOWER.INCOME, NO.INCOME, ONLY.INCOME
Financial Stress	FINANCIAL.STRESS, FINANCIAL.STRUGGLES, STRUGGLING.FINANCIALLY, FINANCIAL.STRESSES
Financial Stressor	FINANCIAL.STRESSOR, FINANCIAL.STRESSORS
High Copay	HIGH.COPAY, HIGH.CO.PAY, HIGH.COPAYMENTS, HIGH.COPAYMENT, HIGH.CO.PAYS
Pay Rent	PAY.RENT.N, PAY.RENT, RENT.BURDEN, RENTAL.ASSISTANCE, RENTAL.ASSISTANCE.N, PAYING.RENT, PAYING.RENT.N
Public Housing	PUBLIC.HOUSING, SUBSIDIZED.HOUSING
Voucher	VOUCHER, VOUCHERS, WELFARE
Eviction	EVICTION
Financial Concerns	FINANCIAL.CONCERNS
Financial Situation	FINANCIAL.SITUATION

*"N" indicates that the feature is negated in context (e.g., AFFORD.N means "can't afford").

Results: Among 600 identified patients, we excluded 62 due to lack of notes, clear rheumatologic diagnoses, or iCMP enrollment confirmation (N=538). 245,142 notes were processed from the training (N=366) and validation cohorts (N=172). Financial insecurity was present among 100 individuals (27%) in the training cohort and 63 (37%) in the validation cohort (Table 2). All models (logistic regression, LASSO, random forest) classifying the presence of financial insecurity performed similarly regardless of the algorithm used, with logistic regression models achieving the overall highest positive predictive value (PPV) of 0.98. (Table 3). The logistic regression models had specificities ranging from 0.94-0.98, sensitivities

Table 3: Model Performance for Definite and Definite and Possible Financial Insecurity

Definite Financial Insecurity Models			
	Logistic Regression	**Lasso Regression**	**Random Forest**
Sensitivity	0.27 (0.17, 0.37)	0.29 (0.19, 0.38)	0.29 (0.19, 0.38)
Specificity	0.98 (0.84,1.00)	0.98 (0.84, 1.00)	0.98 (0.84, 1.00)
PPV	0.89 (0.76, 1.00)	0.9 (0.77, 1.00)	0.9 (0.77, 1.00)
Definite and Possible Financial Insecurity Models			
	Logistic Regression	**Lasso Regression**	**Random Forest**
Sensitivity	0.54 (0.50, 0.58)	0.20 (0.08, 0.32)	0.48 (0.46, 0.51)
Specificity	0.94 (0.80, 1.00)	0.99 (0.84, 1.00)	0.96 (0.82, 1.00)
PPV	0.91 (0.78, 1.00)	0.95 (0.81, 1.00)	0.94 (0.80, 1.00)

PPV=Positive Predictive Value

ranging from 0.27-0.54 and PPVs of 0.89-0.91. LASSO regression models had specificities ranging from 0.98-0.99, sensitivities of 0.20-0.29, and PPVs of 0.90-0.95. The random forest models had specificities ranging from 0.96-0.98, sensitivities of 0.29-0.48, and PPVs of 0.90-0.94.

Conclusion: Using a context-driven general lexicon for financial insecurity, NLP enabled the development of algorithms to classify individuals with terms or phrases indicative of financial insecurity in free-text EHR notes. These models with high positive predictive values could be leveraged to identify patients with this SDoH for future health equity interventions.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Gaps in systemic lupus (SLE) care are believed to contribute to higher kidney failure (ESKD), acute care use, mortality, and disease damage in US patients who are Black or disadvantaged. Such disparities in HIV declined >20% by addressing key care steps. We hypothesized that, SLE retention in care by visits or labs would differ by neighborhood disadvantage. We also examined how gaps in SLE care associate with ESKD, acute care, or death to inform actions to reduce disparities.

Methods: This cohort study used a 20% US Medicare sample of patients ≥18 yrs with >12 mos of Medicare A-B in 2013-14 (subset: Part D). SLE was identified by validated criteria: 1 SLE hospital code, 1 rheumatologist code, or 2+ SLE codes 2 mos apart. Baseline comorbidity was measured 6 mos prior. Over 6 mos, 4 care steps were examined: 1) visit retention: ≥ 1 rheumatology visit; 2) lab retention: a C3, C4 or a double-stranded DNA test (two if nephritis); 3) HCQ use: any HCQ claim; and 4) HCQ adherence: >80% of days covered. Outcomes included acute care (emergency or hospital visits) or death, ESKD or death followed until end of data, 12/31/2014. We assessed for disparities by racial identity and neighborhood disadvantage area deprivation index (ADI) quintile. Cox proportional hazards models were used to report hazards ratios (HR) and 95% confidence intervals (CI) for 2 outcomes by 4 care steps controlling for covariates.

Results: Among 15,395 patients with SLE, 88.6% were female and 17.4% identified as Black (Table 1). Overall, 27.9% had prior Medicaid; 35.2% of Black identifying patients lived in the most disadvantaged ADI quintile neighborhoods. Patients living in high ADI (more disadvantage) had 16% lower visit retention (44.5% vs 60.8%, p< 0.001 Table 2), lower lab retention

Table 1. Characteristics of Medicare patients with SLE by rheumatology visit retention (n=15,395)

n=15,395 for visits and labs, n=10,880 Part D for HCQ items

	Unadjusted hazard ratio	95% CI	p	Full Model Hazard Ratio	95% CI	p
Acute care or death						
Visit retention	0.66	(0.63, 0.70)	< 0.001	0.84	(0.79, 0.89)	< 0.001
Lab retention	0.60	(0.55, 0.65)	< 0.001	0.70	(0.64, 0.76)	< 0.001
Any HCQ	0.66	(0.61, 0.70)	< 0.001	0.82	(0.77, 0.88)	< 0.001
80% HCQ adherence	0.66	(0.61, 0.71)	< 0.001	0.80	(0.73, 0.87)	< 0.001
ESKD or death						
Visit retention	0.55	(0.50, 0.61)	< 0.001	0.78	(0.70, 0.87)	< 0.001
Lab retention	0.62	(0.53, 0.73)	< 0.001	0.81	(0.69, 0.95)	0.009
Any HCQ	0.65	(0.57, 0.73)	< 0.001	0.88	(0.78, 1.00)	0.058
80% HCQ adherence	0.58	(0.49, 0.68)	< 0.001	0.73	(0.63, 0.86)	< 0.001

Full model includes: age, sex, race/ethnicity, Medicaid status, disability, RUCA, ADI quintile, HCC score, diabetes, CKD, anxiety disorder, depression, tobacco use, fibro pain fatigue, and baseline nephrology visit.
Abbreviations: ESKD=end stage kidney disease; HCQ=hydroxychloroquine; HCC=hierarchical condition category comorbidity; CKD=chronic kidney disease. Associations persisted conditioned on visit retention (data not shown).

lower ESKD or death (HR 0.73-0.81, all p< 0.05, except any HCQ, p=0.058). Lab retention associated most with reduced acute care/death HR 0.70 (0.64, 0.76); HCQ adherence most strongly associated with lower ESKD/death, HR 0.73 (0.63, 0.86).

Conclusion: Lupus outcomes correlated with lupus visits and labs, with strongest associations between SLE labs and acute care-free survival. HCQ 80% adherence most strongly correlated with ESKD-free survival. Care varied more by ADI than race alone, supporting ADI use in ACR quality reporting, and a need for new care strategies to advance health equity using a social determinants lens to improve SLE outcomes.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) care and outcomes are associated with significant racial and socioeconomic disparities in the US, particularly among young Black and Hispanic/Latina women. We previously identified disparities, including gaps in SLE retention in care (defined as a rheumatology clinic visit or lupus-specific lab test every 6 months) and hydroxychloroquine (HCQ) use and adherence. We sought to address these modifiable gaps in SLE care by adapting intervention approaches from other chronic diseases. We engaged patients and healthcare community stakeholders to garner input to prioritize actionable steps and intervention strategies to reduce disparities in SLE retention in care and HCQ use to improve outcomes and equity.

Methods: We recruited SLE experts and stakeholders, including patients, providers, and advocates (State Public Health Department, Lupus Foundation, and the American College of Rheumatology) to adapt intervention strategies from other chronic conditions to be tested in SLE. The patient advisory board (PAB; n=8) included patients with SLE representing racial,

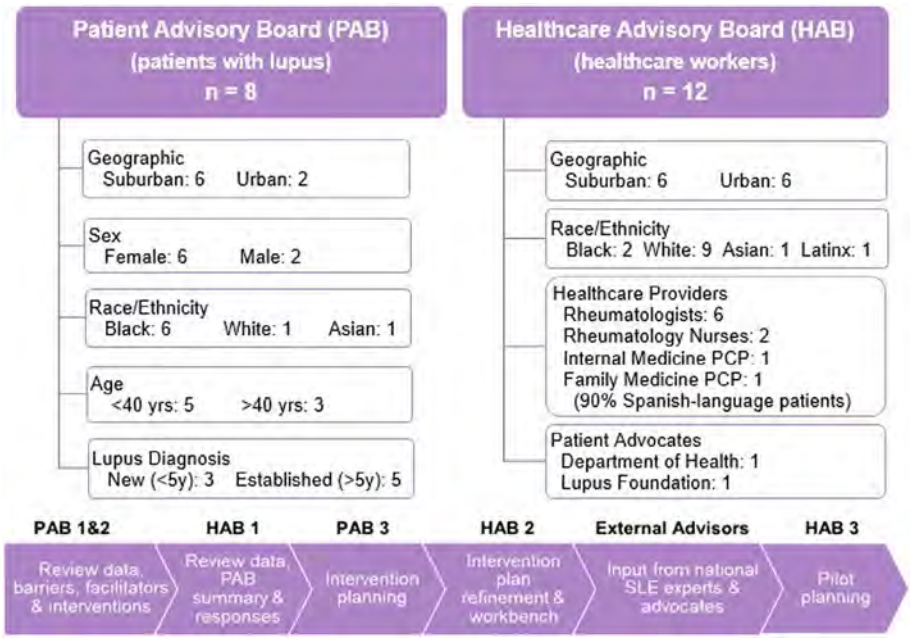

Figure 1. Focus Group Demographics and Meeting Schedule

geographic, age, and sex diversity (**Figure 1**). PAB insights were presented to a healthcare advisory board (HAB; n=12) of 6 rheumatologists, 2 rheumatology nurses, 2 primary care providers, and 2 patient advocates (**Figure 1**). The HAB reviewed prior findings on SLE care gaps and evaluated proven interventions for a pilot. Each group had 3 virtual meetings of 90 minutes (total=6) scheduled to be alternating and iterative. Sessions were audio-video recorded and analyzed using direct content analysis with NVivo software (Melbourne, AU).

Results: The PAB discussed several barriers to SLE retention in care and HCQ, categorized as: labs, visits, and medication adherence (see **Table 1** quotes and meta-themes). Facilitators were similarly identified and grouped (**Table 1**). The main evidence-based interventions considered were electronic health record (EHR) workbench decision support (e.g., HIV Fast-Track) that cues staff action upon missed visits and labs; shared decision making; and patient navigators (**Table 2**). All HAB members and 5 of 8 PAB members supported implementing EHR workbench decision support. PAB and HAB members also suggested including a patient navigator as a supplement to answer patient questions and address challenges in scheduling, medication dosing, and cost barriers, among others. Among HAB members, 8 of 12 recommended EHR workbench decision support as high-impact and low-effort; while 7 of 12 rated patient navigator as high-impact but high-effort.

Table 1. Selection of Patient Identified Barriers (B) and Facilitators (F) to Labs, Visits, and Medication Adherence with List of Predominant Meta-themes

Labs	B	"I'm a 24-hour caregiver…so I have to be real cognizant of…hours for the labs…Are they going to be closed when I get there?" "[Also, labs] charge different amounts of money…I'm rubbing my nickels together…down the street versus…5 miles…to save $20…I have to make those kinds of decisions." [Pt-3, established patient]
	B	"[MyChart results] can be difficult…to understand…can be tricky to read." [Pt-4, established patient]
	F	"[MyChart] will give you like some kind of range…I always like to…double check the levels. And I do a lot of Googling…I like to remind my rheumatologist…if we are not doing labs…if I feel like I need them, I'll really push." [Pt-5, young patient]
Visits	B	"[Sometimes] you'd have to travel 4 hours to get treatment. But…if you don't feel comfortable with them…you're not going to ask questions, you're not going to let them know what's going on." [Pt-1, established patient]
	F	"Your own personal healthcare is so important…you need to drive back to [academic center] or whatever…prioritize yourself…get your visits in." [Pt-1, established patient]
Med Plans	B	"[But] some of the medications are very, very expensive…we will use the [flexible spending] card, but I'm on so many medications…that money don't last all year" [Pt-6, young, newly diagnosed patient] "[The] price of the medication varies…all the time…it's never the same…" [Pt-3, established patient]
	B	"[It] would be really awesome if they would let you make an [eye] appointment the same day…the eye doctor keeps moving all their times…I'll try to refill my pills and they'll be like, well, 'you have to schedule your eye exam because you haven't been there in a year'…if they could straighten out their scheduling…" [Pt-5, young patient (idea supported by 2 established patients)]
	F	"Pharmacists told me about GoodRx [app]…After a while, I couldn't afford that either. So I actually ditched my medication insurance and now I buy all my pills online…doctors don't know how much these things cost." [Pt-5, young patient]
PREDOMINANT META-THEMES Access to Expert Care ● Burden of Disease & Adverse Effects ● Cost Communication & Rapport ● Motivation & Understanding ● Time & Transportation		

Table 2. Patient and Healthcare Members' Reactions to Proposed Evidence-Based Interventions

EHR Workbench Decision Support (e.g., HIV FastTrack) 	**DEFINITION**: EHR alerts flag those who have not had a rheumatology visit or SLE labs for >6mos; +/- medication gap flags. Staff outreach to patients for clinic visits, labs or medication adherence.
	PATIENT: "I like the FastTrack idea…sounds good to me because lupus fog attacks me all the time…I understood it, it was self-explanatory…it works…it's doable…" [Pt-4, established patient]
	PATIENT: "I just might forget…not in my immediate purview…to do get my labs done…so I would appreciate something like that." [Pt-3, established patient]
	PATIENT: "[W]hatever's going to take for me to make sure that I'm up on…my appointments or refills." [Pt-8, newly diagnosed patient]
	PROVIDER: "[It's] quite possible from a technology standpoint…doesn't cost a lot to be able to do something like that…I love the idea of pairing them…maybe leverage the technology to identify who needs outreach…a human connection as the outreach-er…has more potential to be impactful." [PCP-2, urban center]
Patient Navigator 	**DEFINITION**: Personal help with barriers (e.g., cost, transportation) by a nurse, pharmacist, social worker, scheduler, or other (e.g., insurance navigator); consistent person with some medical and resource knowledge in SLE.
	PATIENT: "My insurance…had one…nurse…[who] would call me like every couple of months, just to see if there was something I needed…I wasn't required to use them, but they were available if I needed them…always the same nurse…make it available, but not a requirement." [Pt-1, established patient]
	PATIENT: "I used to have a pharmacist call me…switch the pills around so that I wouldn't be taking so many in the morning…it's time to take the medicine, she might remind me…we had a good rapport…feels more personal." [Pt-4, established patient]
	PROVIDER: "[N]avigators that could also facilitate transportation…basically try to cover all the needs that patients can have as…obstacles…besides reminding someone that they need labs and visit…that would have even more impact…it may also require a little bit more resources." [PCP-1, suburban center, majority Spanish-language patients]
	PROVIDER: "[Navigator is] even high impact than FastTrack…just advocating…so people higher up who are going to decide the resources allotted to the clinic…making them understand why such a navigator is required [as] it is a very high impact factor…[that] will definitely sort the patient in the right way." [Rheum-1, suburban center]

Many discussed that the two could be complementary, recommending EHR workbench decision support first, followed by patient navigator. Indicators for additional support recommended by HAB members were social determinants of health, missed labs or clinic visits, and frequent acute care.

Conclusion: Patient and healthcare stakeholders endorsed implementing EHR workbench decision support, potentially followed by a patient navigator, to reduce disparities and care gaps in SLE. An external advisory board of national SLE leaders is advising scalability for a larger study, and the findings will inform addressing key gaps and unique factors in SLE.

Abstract Number: 0188

Association Between Area Deprivation Index and Organ Damage Accumulation in a Statewide Incident Lupus Cohort

Jonathan Katz[1], Bryn Sutherland[2], Ang Yu[3], Jenna Cormier[2], Yiran Jiang[2], David Gazeley[4], Felix Elwert[3] and Christie M. Bartels[5], [1]Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Department of Sociology, University of Wisconsin, Madison, WI, [4]Medical College of Wisconsin, Wauwatosa, WI, [5]University of Wisconsin, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a heterogenous systemic autoinflammatory disease that disproportionately effects young women and minoritized populations. Disparities are multifactorial with genetic, hormonal, and environmental contributors. Literature has implicated the role of social determinants of health, specifically low individual socioeconomic status (SES) not just with SLE risk, but also cumulative SLE end organ damage due to disease and consequences of therapy. The area deprivation index (ADI) describes neighborhood social risk by integrating 17 census block factors that correlate with many disease outcomes. We hypothesized that patients with incident SLE in more disadvantaged ADI neighborhoods would more rapidly accumulate damage compared to more advantaged ADI groups.

Methods: This observational cohort study included incident SLE patients from three systems representing urban, suburban, and rural patients across one state. Abstractors manually validated incident SLE cases that fulfilled the 1997 American College of Rheumatology (ACR) and 2012 SLE International Collaborating Clinics (SLICC) criteria. Sociodemographic data and diagnoses related to end organ damage through 2020 were manually abstracted. We used the original US ADI publication to produce ADI rank quintiles. Time to damage, as defined by abstracted events of the SLICC/ACR Damage Index, was assessed at SLE diagnosis and through death or study end (12/31/2020). We used Cox regression to estimate survival curves of time to first damage event from SLE diagnosis stratified by ADI to test our hypothesis.

Results: In a total cohort of 611 incident lupus cases, 524 had complete data. Table 1 shows 88% female and 88% White patients with a low proportion in the most disadvantaged US ADI group. Of those in the most disadvantaged ADI, 67% came from the urban system. Figure 1A shows survival curves of patients from the urban system demonstrating a trend of reduced damage-free survival within the most disadvantaged ADI (median 806 days) compared to those more advantaged (least disadvantaged median 1100 days; log rank insignificant). Total cohort survival (Figure 1B) showed no significant association by ADI. Table 2 shows multivariable hazards with no significance by ADI; significance for age, smoking, and baseline renal disease.

Conclusion: While many studies have investigated associations between individual SES and SLE, ours is among the first to investigate the relationship between neighborhood SES, measured by ADI, and damage in incident SLE. In contrast to our hypothesis, ADI was not statistically associated with damage-free survival. The urban cohort demonstrated the expected reduced damage-free survival trend in the most disadvantaged ADI, suggesting high neighborhood disadvantage may impact SLE damage. Limitations include risk of sampling bias with the small sample size of the most disadvantaged ADI group. Furthermore, neighborhood-level factors may be distinct between urban vs non-urban areas; more research is needed to determine if or how neighborhood disadvantage impacts outcomes in SLE.

Table 1. Statewide Incident Lupus Cohort Demographics

		Incident SLE n=611 (%)
SLE by ACR Criteria		89.85
SLE by SLICC Criteria		87.73
Age at SLE diagnosis (mean, SD)		45.63 (16.14)

Abstract Number: 0189

Influence of Social Support on Systemic Lupus Erythematosus (SLE) Outcomes in a Health Disparity Population

Sarah Smith, Chloe Mattila, Lori Ann Ueberroth, L. Quinnette King, Diane L. Kamen, Paula Ramos and bethany wolf, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: SLE disproportionately impacts African American women. Social support may have a positive impact in SLE and as such could potentially reduce disease burden. However, the relationship between social support and SLE disease outcomes has not been investigated in African American female patients with SLE. The goal of this study is to evaluate the relationship between social support and disease outcomes using data from validated participant questionnaires.

Methods: In this study of African American women, we examined differences in social support between healthy controls and patients with SLE and associations with disease severity among the patients. Social support was measured using the validated Medical Outcomes Study-Social Support (MOS-SS) survey. The physician assessed SLE Disease Activity Index (SLEDAI) and the patient reported Brief Index of Lupus Damage (BILD) were used to assess SLE severity. Associations between SLE status and overall MOS-SS score as well as the MOS-SS support domains were analyzed using a series of Wilcoxon rank-sum tests. Hodges-Lehmann estimation was used to calculate the confidence intervals for the difference in medians. Among participants with SLE, associations between MOS-SS score with disease activity (SLEDAI) and with patient reported organ damage (BILD) were evaluated using Spearman's rank correlation. All analyses were performed on RStudio v4.0.3.

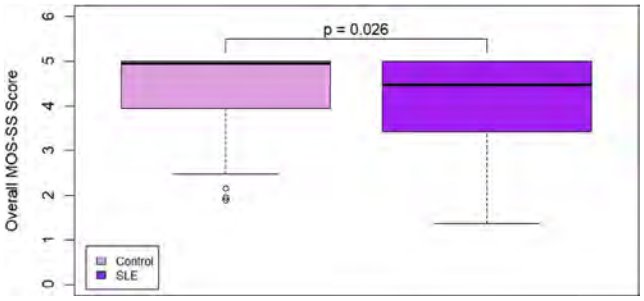

Figure 1. Distribution of overall MOS-SS score by disease status. Boxes in the plots show the median, 25th, and 75th percentiles for the overall MOS-SS scores by disease status. Whiskers extend to 1.5 times the interquartile range (IQR), with measurements outside 1.5 times the IQR being represented by open circles.

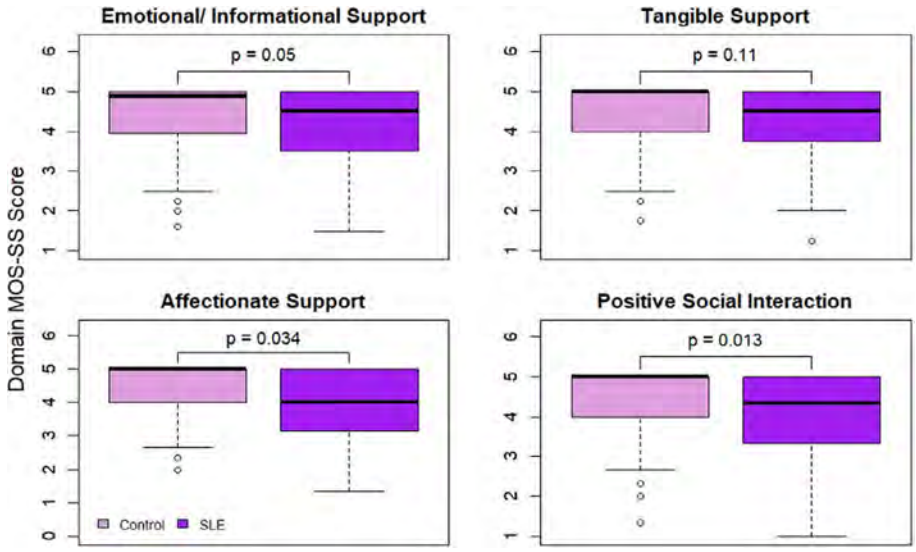

Figure 2. Distribution of MOS-SS score by disease status for each support domain of the MOS-SS. Boxes in the plots show the median, 25th, and 75th percentiles for the overall MOS-SS scores by disease status. Whiskers extend to 1.5 times the interquartile range (IQR), with measurements outside 1.5 times the IQR being represented by open circles.Figure 2: Distribution of MOS-SS score by disease status for each support domain of the MOS-SS. Boxes in the plots show the median, 25th, and 75th percentiles for the overall MOS-SS scores by disease status. Whiskers extend to 1.5 times the interquartile range (IQR), with measurements outside 1.5 times the IQR being represented by open circles.

Table 1. Descriptive statistics for overall MOS-SS score and each support domain for the MOS-SS by disease status. Median (IQR) and difference in medians reported. + Only 69 SLE cases had complete MOS-SS questions applicable for the emotional/ informational domain. ^ Only 68 SLE cases and 59 controls had complete MOS-SS questions applicable for the affectionate support domain. ~ Only 59 controls had complete MOS-SS questions applicable for the positive social interaction domain.

	Controls (n=70)	SLE Cases (n=60)	Difference in Medians (95% CI)	p-value
Overall MOS-SS Score, Median (IQR)	4.95 (3.97 – 5)	4.46 (3.45 – 5)	-0.11 (-0.47, 0)	0.026
Emotional/Informational Support, Median (IQR) +	4.89 (0.94 – 5)	4.5 (3.5 – 5)	-0.12 (-0.38, 0)	0.05
Tangible Support, Median (IQR)	5 (4 – 5)	4.5 (3.8 – 5)	0 (-0.25, 0)	0.11
Affectionate Support, Median (IQR) ^	5 (4 – 5)	4 (3.17 – 5)	0 (-0.67, 0)	0.034
Positive Social Interaction, Median (IQR) ~	5 (4 – 5)	4.33 (3.33 – 5)	-0.33 (-0.67, 0)	0.013

Results: This study was comprised of 70 SLE patients and 60 healthy controls, all self-identified African American females. SLE patients had significantly lower overall MOS-SS scores compared to healthy controls ($p = 0.026$); the distribution of overall MOS-SS scores by disease status is seen in Figure 1. When considering the MOS-SS support domains, SLE patients had significantly lower scores for the emotional/informational support, affectionate support, and positive social interaction domains ($p \leq 0.05$ for all three groups). No notable difference between SLE patients and healthy controls was found for the tangible support domain. Figure 2 shows the distribution of MOS-SS score by disease status for each support domain of the MOS-SS. Table 1 shows the median (IQR) and difference in medians for the overall MOS-SS and each support domain of MOS-SS. Among SLE patients, a significant association was found between overall MOS-SS score and physician reported disease activity (using SLEDAI), such that SLE patients with higher SLEDAI scores have lower MOS-SS scores ($\rho = -0.36$, $p = 0.0003$). No significant association was found between patient reported organ damage (BILD score) and overall MOS-SS score ($p = 0.48$).

Conclusion: This study found significant differences in the overall MOS-SS score between SLE patients and healthy controls and furthermore, the groups differed for the emotional/ informational support, affectionate support, and positive social interaction domains. Among the SLE participants, a significant inverse correlation between SLEDAI total score and overall MOS-SS score was also observed. The potential clinical relevance of these findings suggests that targeted interventions to improve social support could potentially improve SLE outcomes, though further research is needed.

Racial Disparities in Self-reported Extent and Reasons for Nonadherence in SLE

Kai Sun[1], Londyn Robinson[2], Amanda Eudy[3], Jennifer Rogers[1], Rebecca Sadun[1], Lisa Criscione-Schreiber[4], Jayanth Doss[1] and Megan Clowse[5], [1]Duke University, Durham, NC, [2]University of Minnesota Medical School, Minneapolis, MN, [3]Duke University, Raleigh, NC, [4]Duke University School of Medicine, Durham, NC, [5]Duke University, Chapel Hill, NC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication nonadherence is common in SLE and disproportionately affects Black patients. Nonadherence leads to increased hospitalizations, morbidity, and mortality and is a modifiable factor that can reduce racial disparities in SLE outcomes. To better recognize nonadherence and address adherence barriers, we previously adapted and validated a self-reported measure of *extent of nonadherence* and *reasons for nonadherence* called Domains of Subjective Extent of Nonadherence (DOSE- nonadherence-SLE) (Figure 1). In this study, we examined frequencies of reasons for nonadherence to explore possible item reduction and reasons that disproportionately affect Black patients.

For one reason or another, many people can't or don't always take all of their medications as prescribed. We want to know how often you have missed your lupus pills. If you took your pills later than usual, do not count it as a missed dose.

Over the past 7 days...	None of the time	A little of the time	Some of the time	Most of the time	Every time
I missed my medicine(s).	☐	☐	☐	☐	☐
I skipped a dose of my medicine(s).	☐	☐	☐	☐	☐
I did not take a dose of my medicine(s).	☐	☐	☐	☐	☐

People miss doses for various reasons. Please tell us which reasons contribute to you missing a dose of your lupus pills. We recognize that the past 7 days may not represent what you do over longer time periods. However, we are only interested in the past 7 days. When responding, please think only about your lupus pills.
Skip this section if you have not missed any lupus pills.

Over the past 7 days, I missed my lupus pills...	Not at all				Very Much
.....because they **cost too much.**	☐	☐	☐	☐	☐
.....because I **could not fill** the medicine on time.	☐	☐	☐	☐	☐
.....because I **forgot,** or I was **busy.**	☐	☐	☐	☐	☐
.....because I **do not have a regular schedule.**	☐	☐	☐	☐	☐

I missed my lupus pills for another reason not listed above: _____

Of the reasons listed above (on this page), circle 3 that you feel are the biggest challenges for you.

Figure 1. DOSE-Nonadherence-SLE survey

Methods: Patients from an academic clinic who met ACR or SLICC criteria for SLE and were prescribed ≥1 SLE medication completed demographic information and the DOSE-Nonadherence-SLE survey, which measures the extent of and reasons for nonadherence over the past 7 days. We limited the analysis to include only patients who self-identified as Black or White race due to small numbers of patients who self-identified as belonging to other races. We compared racial differences in reasons for nonadherence using Chi squared or Fisher's exact tests. We used step-wise multivariable logistic regression to examine factors independently associated with reasons that differentially affected Black patients.

Results: A total of 282 surveys were completed (median age 47, 90% female, 57% Black, 94% HCQ, 48% MMF, 13% AZA, 10% MTX). Black compared to White patients were more likely to be single, working full time, have annual household income < $50,000, and less like to have private insurance (Table 1).

Rates for nonadherence were 53% among Black patients compared to 38% among White patients (p=0.01). The most common reasons for nonadherence were "I forgot or I was busy" (69%), "I was too tired" (33%), and "I am tired of taking medicines every day" (32%). The least common reasons were missing doses due to "the medication instructions were hard to follow" (4.6%), "my family or friend suggested I not take them" (4.5%), and "I heard that someone had a bad experience taking them" (1%).

Most reasons for nonadherence were reported at similar rates by Black and White patients (Table 2). However, Black compared to White patients were more likely to report missing doses due to "I felt well" (31% vs 7%, p=0.004) and "I am worried that the medicine would affect my ability to have children in the future" (9% vs. 0, p=0.08), whereas White patients were more likely to report missing doses due to "I felt too depressed" (24% vs. 9%, p=0.048) and "I had no one to help me" (15% vs 4%,

Table 1. Sociodemographic characteristics of patients.

Patient characteristics		All (n=282)	White (n=122)	Black (n=160)	P-value
Age, median (IQR)		46 (35-57)	49(36-60)	45 (36-56)	**0.04**

	50-75K	17%	19%	14%	
	75-100K	10%	11%	9%	
	100-150K	12%	25%	3%	
	>150K	6%	12%	2%	
Employment					**0.003**
	Full time	61%	51%	70%	
	Part time	11%	11%	11%	
	Retired	17%	19%	15%	
	Home maker	2%	2%	1%	
	Do not plan to work	9%	18%	2%	
On disability		28%	25%	31%	0.3
Rate of nonadherence*		46%	38%	53%	**0.01**

*Based on the DOSE-Nonadherence-SLE survey

Table 2. Comparing reasons for nonadherence between nonadherent Black and White patients

I missed my lupus pills because...	All (n=112)	White (n=41)	Black (n=71)	p-value
I forgot or I was busy	69%	68%	69%	0.9
I was too tired	33%	33%	33%	1
I was tired of taking medicines every day	32%	36%	30%	0.5
I needed to take them with food but could not eat at the time	27%	22%	30%	0.5
I do not have a regular schedule	25%	21%	26%	0.7
I felt well	23%	**7%**	**31%**	**0.004**
when I skip a dose I don't feel any difference	23%	24%	23%	1
I am worried about possible side effects	23%	26%	21%	0.6
they caused side effects	21%	25%	19%	0.4
I could not fill the medicine on time	20%	20%	20%	1
I take too many pills	18%	17%	19%	1
I feel that nothing will get better even if I take them	18%	19%	17%	0.8
I was too stiff	17%	24%	13%	0.2
I felt too depressed	14%	**24%**	**9%**	**0.048**
I was feeling too sick	13%	20%	10%	0.2
I still felt so bad I thought the medicine was not working	12%	17%	9%	0.2
I had a hard time swallowing them	11%	12%	10%	0.8
I had no one to help me	8%	15%	4%	0.08
I do not understand why I need to take them	6%	3%	9%	0.4
I am worried that my doctor did not prescribe the right medicine for me	6%	5%	7%	1
it cost too much	6%	5%	7%	1
I am worried that they would affect my ability to have children in the future	5%	0	9%	0.08
the medication instructions were hard to follow	4.60%	7%	3%	0.4
my family or friends suggested I not take them	4.50%	7%	3%	0.4
I heard someone had a bad experience taking them	1%	0	1%	1

p= 0.08). After adjusting for other demographic factors, nonadherent due to feeling well was dependently associated with Black race (OR 15, p=0.001).

Conclusion: While busyness and forgetting, physical fatigue, and pill fatigue commonly affect all patients, Black patients were much more likely to report missing doses due to feeling well, and there is a trend that Black patients were more concerned about medication effects on fertility. These represent unique opportunities to improve adherence for Black patients. Our results also suggest that some items can be eliminated to reduce response burden due to their low frequencies.

Denomination of Christianity not Catholic	16 (26.7%)
Other religious group	4 (6.7%)
No religious affiliation	8 (13.3%)
Sexual Activity	
Never sexually active with a male partner	9 (15.3%)
Have been sexually active with a male partner but not currently active	17 (28.8%)
Currently sexually active with a male and trying to get pregnant	1 (1.7%)
Currently sexually active with a male and trying to AVOID a pregnancy	21 (35.6%)
Currently sexually active with male and neither trying to get pregnant or avoid it	11 (18.6%)
Methods of Contraception	
Abstinence or not sexually active with a male partner	14 (23.0%)
Natural methods	3 (4.9%)
Barriers or spermicidal methods	17 (27.9%)
Short-acting birth control	4 (6.6%)
Long-acting reversible birth control	10 (16.4%)
Sterilization	3 (4.9%)
None – I don't use any kind of contraception	15 (24.6%)

Background/Purpose: Systemic lupus erythematosus (SLE) primarily affects women of childbearing age, with a higher burden in non-Caucasian populations. Due to the increased risk of adverse pregnancy outcomes in SLE, especially among non-Caucasian patients, it is essential for rheumatologists to engage patients in reproductive health discussions. Our study aims to gain insight into the conversations surrounding reproductive health between rheumatology providers and a primarily Hispanic SLE population, with a focus on disparities between English-speaking and Spanish-speaking populations.

Methods: A 28-question survey based on the American College of Rheumatology 2020 Reproductive Health Guideline was developed, covering contraception, preconception counseling, and pertinent peri-partum issues. The survey was offered in either English or Spanish to female patients with SLE between the ages of 18 – 50, at a safety-net outpatient rheumatology clinic in urban Los Angeles. Data were presented using frequency (%) or median (IQR) and evaluated using Fisher's exact or Wilcoxon rank sum test, as appropriate.

Results: From March 15 2023, to May 16 2023, 61 surveys were collected. Response rate was 92%. Participants identified as Hispanic (84%), with 71% expressing an English-language preference (Table 1). For all respondents who reported being sexually active with a male partner, 29% denied use of any kind of birth control, and only 25% noted effective contraception (long-acting reversible contraception or sterilization) (Table 1). Approximately 60% of all patients who sought pregnancy after SLE diagnosis took hydroxychloroquine (Table 2). However, while 73% of English-survey respondents noted that a rheumatologist advised them to be on hydroxychloroquine during the pre-conception/pregnancy period, only 60% of Spanish-speaking individuals were given the same counsel (Table 2). English-language respondents reported a significantly higher frequency of conversations in the past one year regarding contraception and pregnancy planning compared to Spanish-speaking respondents (72% vs. 33% and 76% vs. 39%, respectively; Table 2).

Conclusion: This study highlights the importance of thorough reproductive health discussions for patients with SLE, especially in a primarily Hispanic population. For a population known to have high rates of teratogenic medication use and/or poorly controlled disease activity, suboptimal contraception was common. Some disparities between the English and Spanish speaking population include the English-speaking population had a higher rate of conversations surrounding contraception and pregnancy in the past one year, compared to the Spanish speaking patients. This suggests potential barriers in the Spanish-speaking patient population. Hydroxychloroquine use during pregnancy or for those trying to conceive was low, although only patients who ever attempted to conceive or had a pregnancy after SLE diagnosis answered this question.

Table 2. Pre-conception questions by survey language(1) Numbers represent frequency (column percent). *While 17 respondents noted that they prefer receiving medical care in Spanish, only 14 of these elected to take the Spanish language survey (1)Some respondents did not answer all questions (2)Due to branching logic, not all participants answered each question and not all cells will add to the full study population. Individuals who did not attempt and/or experience a pregnancy after SLE diagnosis did not answer questions about hydroxychloroquine use during the pre-conception period or pregnancy.

Variable	Survey Language Group		p-value
	English Survey (n=47)	Spanish Survey* (n=14)	
In the past one year, my lupus doctor has had at least one discussion regarding contraception with me			0.020
No	13 (28.3%)	8 (66.7%)	
Yes	33 (71.7%)	4 (33.3%)	
In the past one year, my lupus doctor has asked what my plans are, if any, for pregnancy			0.018
No	11 (23.9%)	8 (61.5%)	
Yes	35 (76.1%)	5 (38.5%)	
My lupus doctor has told me that I should take hydroxychloroquine when I'm trying to become pregnant or when I'm pregnant[1]			0.613
No	4 (26.7%)	2 (40.0%)	
Yes	11 (73.3%)	3 (60.0%)	
I took hydroxychloroquine during pregnancy or when I was trying to get pregnant[2]			0.999
Yes, I was already on it and continued it	8 (53.3%)	3 (60.0%)	
Yes, I was not already on it but started	1 (6.7%)	0	
No, stopped taking when I found out/was trying	1 (6.7%)	1 (20.0%)	
No, I was not taking it and did not start	3 (20.0%)	1 (20.0%)	
Other	2 (13.3%)	0	

Further research should explore ways of optimizing reproductive health conversations, especially regarding hydroxychloroquine and contraception use, in the management of Hispanic SLE populations.

Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Participation in clinical trials is part of treatment for many patients with chronic diseases. However, patients with systemic lupus erythematosus (SLE), especially those of African American and Hispanic descent, have been reluctant to participate in clinical trials. Qualitative research identified patient, provider, community, and study design factors as the main reasons for this hesitancy. Concerted efforts to increase awareness of and engagement in SLE clinical trials are underway. We evaluated factors associated with challenges to clinical research enrollment in the Columbia University (CU) and Albert Einstein College of Medicine (AECOM) lupus cohorts in New York City (NYC) that serve the low socioeconomic status communities of Washington Heights and the Bronx.

Table 1. Demographic and Clinical Factors Among SLE Patients (n=163)

	Enrolled in the study (n=103)	Refused (n=35)	Clinical Trial Participants (n=25)	p-value

Medication				
Hydroxychloroquine (n, %)	91, 88%	29, 83%	24, 96%	0.298
Corticosteroid (n, %)	27, 26%	5, 14%	14, 56%	**0.001**
MMF, MPA, AZA (n, %)	47, 46%	15, 43%	5, 20%	0.064
Fibromyalgia (n, %)	17, 17%	1, 3%	0, 0%	**0.013**
Admissions in the Past Year (mean ± SD)	1.36 ± 1.50	1.09 ± 1.82	0.52 ± 0.96	**0.044**
Office Visits in the Past Year (mean ± SD)	2.99 ± 2.15	2.63 ± 2.07	4.76 ± 3.35	**0.001**

Methods: This study sponsored by the U.S. Department of Health and Human Services, Office of Minority Health, plans to enroll 200 patients in an engagement program modeled after the Lupus Research Alliance Patient Advocates for Lupus Studies (PALS) program. SLE patients were invited to participate during routine clinic visits. Patients were apprised of the study in detail and their decision to participate or refuse was recorded. Socio-demographics and disease characteristics were collected. Data from recent therapeutic clinical trial participants was included for comparison. One-way ANOVA was used to detect differences among the 3 groups: enrolled in the study, refused participation and clinical trial participants.

Results: Of the 138 patients asked to participate, 103 (74.6%) agreed while 35 (25.4%) refused. Additionally, 25 clinical trial participants were included. Participants enrolled in the educational sessions, demonstrating willingness to engage in clinical trial education, were more likely to have been admitted during the past year (1.36 vs 1.09 vs 0.52, p=0.044) and have co-morbid fibromyalgia (17% vs 3% vs 0%, p=0.013). While there were more African American and Hispanic patients in the education study groups, these differences did not reach statistical significance. Detailed data is summarized in Table 1. The major reasons for refusal were lack of interest in clinical trials (17, 49%), time constraints (14, 40%) and negative prior experiences relating to clinical trials (4, 11%). Clinical trial participants were more likely to have arthritis (84% vs 71% vs 96%, p=0.043), mucocutaneous manifestations (67% vs 69% vs 88%, p=NS) and be on steroids (26% vs 14% vs 56%, p=0.001) as required for inclusion in clinical trials. Also, the clinical trial group displayed a higher zip-code median income (54K vs 51K vs 77K, p=0.001) and more rheumatology office visits in the past year (2.99 vs 2.63 vs 4.76, p=0.001).

Conclusion: These data suggest that people's intention to participate in clinical research is influenced by disease severity (admissions and office visits), patient factors (income and co-morbid fibromyalgia) and study design (arthritis, steroid use). It is difficult to ascertain if racial and ethnic factors affect the current study enrollment. More data is needed to confirm the role of these factors and additional qualitative data will help identify factors that affect a patient's decision at the individual level.

Social Vulnerability Associations with Mortality in a Lupus Cohort

Sean Carter[1], Dulaney Wilson[1], Samantha Minkin[2], David Dillon[3], Baxter Murray[1], John Pearce[1] and Jim Oates[1], [1]Medical University of South Carolina, Charleston, SC, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Rheumatology Associates of South Florida, Delray Beach, FL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The goal of this study is to identify characteristics of socially vulnerable environments associated with increased mortality in a South Carolina systemic lupus erythematosus (SLE) cohort.

Methods: Address, demographic, medication use, and SLE International Collaborating Clinics (SLICC) disease damage data were gathered prospectively from patients and their medical record enrolled in the Medical University of South Carolina's (MUSC's) lupus registry that met SLE criteria. Death certificate data for patients in the cohort were obtained from the

state Department of Health. Standardized mortality ratios (SMR) were calculated using expected mortality rates from the CDC WONDER database, and characteristics between deceased and living patients were compared. The cohort was linked with geospatial analysis to publicly available census tract contextual data, which was CDC's Social Vulnerability Index (SVI). Then, we applied spatial regression models to assess associations between neighborhood characteristics and SLE outcomes after controlling for age, sex, education, disease characteristics and also examined effect modification of each characteristic by presence of disease damage

1	Total Theme	0.88	4.67E-01	1.8824017	5.98E-02

Results: 712 subjects were included in the final analysis, and 102 died before the study data cutoff. The total SMR adjusted for age, race, and gender was 12.29 (95% CI 9.97-14.61). Of the deceased, there was a statistically significant increased mortality in association with self-identified Black race (p=0.02), with high vulnerability census tracts, and total, renal-related, and steroid-related SLICC damage index (SDI) of 1 or more (p< 0.01) and a reduced mortality associated with hydroxychloroquine use. Black patients had higher SDI compared to White patients. Patients with SDI of 1 or more were at increased risk of mortality if they lived in a minority neighborhood, had no high school diploma, had low socioeconomic status, or spoke English less than well

Conclusion: Mortality and SDI were significantly greater in Black patients, which, as race is a social construct, prompted evaluation of socially vulnerable environments using SVI which found an increased risk of mortality in socially vulnerable census tracts and this effect was greater in patients with disease damage. The cause of this association is not known. However, the significant association between socially vulnerable environments and mortality suggests the need to study environmental factors that influence the high rate of mortality among lupus patients in SC and should prompt awareness. The significant association between hydroxychloroquine and lower mortality is consistent with other prospective cohort studies and reinforces the current guidelines regarding its use in SLE.

Reproductive Health Conversations with a Primarily Hispanic Systemic Lupus Erythematosus Population: Influences and Barriers

Zarmeen Zaheer[1], Martha Delgado[2], Jack Rodman[3], Julia Simard[4], Sandy Lee[5] and Leanna Wise[6], [1]Huntington Health, Tampa, FL, [2]LAC+USC/Keck School of Medicine, Los Angeles, CA, [3]University of Southern California, Los Angeles, CA, [4]Department of Epidemiology & Population Health, Stanford University School of Medicine, Stanford, CA, [5]University of Southern California, Walnut, CA, [6]LAC+USC/Keck Medicine of USC, Pasadena, CA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease most commonly seen in women of childbearing age, with a greater burden in non-Caucasian populations. The American College of Rheumatology (ACR) published guidelines in 2020 to inform a shared decision-making process on reproductive health management between patients and their physicians. However, there is little data as to how these guidelines are experienced by patients in the "real world" setting, and specifically by Hispanic patients, who have high rates of poor SLE outcomes. Our patient survey assesses influences on and barriers to reproductive health conversations and explores how a predominantly Hispanic SLE population obtains reproductive health information.

Methods: A 28-question survey was distributed in either English or Spanish to female patients with SLE ages 18 - 50 in our outpatient urban Los Angeles rheumatology clinic. Questions focused on four areas – contraception, preconception counseling, pregnancy management, and medication safety – and were informed by the ACR guidelines. The majority of the

Table 1. Demographic and clinical characteristics for all 61 patient respondents

Characteristics	Frequency (%)/ Median (IQR)
Age (years)	34.0 (16.0) (min=20, max=50)
Race	
White	22 (41.5%)
Black/African American	2 (3.8%)
Asian American	6 (11.3%)
American Indian/Alaska Native	0
Native Hawaiian/Pacific Islander	0
Mixed race	2 (3.8%)
Prefer not to state	7 (13.2%)
Other	14 (26.4%)
Ethnicity	
Hispanic	51 (83.6%)
Non-Hispanic	10 (16.4%)
Preferred Language for Medical Care	
English	43 (70.5%)
Spanish	17 (27.9%)
Other	1 (1.6%)
Education Level	
Less than high school	8 (13.3%)
High school diploma or equivalent	31 (51.7%)
Technical/vocational training	11 (18.3%)
Bachelor's degree	10 (16.7%)
Master's degree or above	0
Marital Status	
Never married	32 (53.3%)
Married/in a domestic partnership	20 (33.3%)
Widowed	0
Divorced or separated	5 (8.3%)
Prefer not to state	3 (5.0%)

questions were multiple choice. Patients were not required to answer all questions and branching logic was used depending on patients' unique reproductive history. Data were presented using frequency (%) or median (IQR) and evaluated using Fisher's exact or Wilcoxon rank sum test, as appropriate.

Results: From March 15, 2023 to May 16, 2023, 61 surveys were collected (Table 1). Response rate was 92%. 40% of patients noted that the rheumatologist was most likely to initiate a conversation about reproductive health-related topics; 31% reported that patient and rheumatologist were equally likely to initiate such a conversation, and 19% noted never having any such conversation (Table 2).86% of respondents believed that their rheumatologist had sufficient expertise to answer questions about the effect of SLE on contraception use and pregnancy planning, however, this was observed more frequently in the English survey (91%) compared to the Spanish survey (69%) (p = 0.062) (Table 3). 56% of patients identified that there were difficulties with reproductive health care discussions, most commonly noting: "I don't think it's safe for me to become pregnant" (19.7%), and "my lupus doctor has suggested that I talk with an OBGYN instead" (18%). Respondents noted their top three sources for reproductive health information as their rheumatologists (73.8%), the internet (32.8%), and their OBGYN (16.4%) (Table 2).

Conclusion: Our data show that most respondents of our primarily Hispanic SLE population in a safety-net clinic rely on the rheumatologist as a crucial source of reproductive health information. However, more than half reported that there were difficulties with reproductive health conversations, including patients' perception about the safety of pregnancy, and rheumatologists deferring to OBGYNs. Furthermore, *nearly 20% noted never having a reproductive health conversation with a*

Assessing Cardiovascular Risk in Black and Latino Patients with Systemic Lupus Erythematosus

Glorielly Gonzalez[1], Zerai Manna[2], Alice Fike[3], Jun Chu[2], sarfaraz Hasni[2] and Brian Dizon[1], [1]National Institute of Arthritis and Musculoskelatal and Skin Diseases, Bethesda, MD, [2]Lupus Clinical Trials Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Healthcare Disparities in Rheumatology Poster I: Lupus
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) is a major cause of mortality among patients with systemic autoimmune disease. Patients with systemic lupus erythematosus (SLE) exhibit accelerated cardiovascular disease compared with age matched healthy controls. While Black and Latino patients with SLE have worse autoimmune disease than white patients, understanding of SLE-associated CVD in these marginalized patients has been limited by the exclusion of Black and Latino patients from these studies. We aim to assess cardiovascular risk in Black and Latino patients with SLE.

Methods: Retrospective cohort study of patients enrolled in a single center SLE natural history study. Healthy volunteers and patients with SLEwho had cardiac CT imaging from 2003-2023 were selected for review. Variables of interest were obtained at the time of imaging, and include coronary artery calcium score (CAC), patient demographics, statin use,

Framingham CVD risk factors, and laboratory parameters (total cholesterol, HDL). Data were analyzed by Wilcoxon rank sum test or Fisher's exact test when appropriate, and a p-value < 0.05 was considered statistically significant.

Results: There were 61 healthy and 141 SLE patients available for review. Of the patients with SLE, 89% were women and the average age at the time of imaging was 45 years. 27% identified as Black/African American and 33% identified as Hispanic Latino. CAC was present in 26% of the SLE patients with a mean CAC score of 49.9, while in healthy controls, CAC was present in 5% of volunteers with a mean CAC score of 2.6. Hypertension was present in 47.5% of healthy controls and 68% of SLE patients (p=0.007). Comparison of other CVD risk factors including obesity, any smoking history, cholesterol level, and diabetes mellitus did not reveal any significant differences between groups. Mean HDL was 58.5 in SLE patients without significant differences between groups. Use of statin in SLE patients with an elevated CAC score was 16%.

Non-Latino White	14	28	0.17
Overall			

Conclusion: Our preliminary findings describe a multi-ethnic cohort of patients with SLE. CAC was present in 26% of affected patients and 5% of healthy controls. CAC was more prevalent and higher in white patients compared to Black and Latino patients. While hypertension was more prevalent patients with SLE, many other traditional risk factors were not present. We found that Black and Latino patients with SLE had significantly lower mean CAC scores when compared to non-Latino white patients. Our findings may indicate that calcium scores are not as reliable of a risk factor to guide secondary prevention in Black and Latino patients with SLE. It may be that Black and Latino patients have more non-calcified plaque burden when compared to non-Latino white patients with SLE. Further study is needed to examine mechanisms to explain these differences and replicate our findings in larger groups. These findings begin to address CVD health disparities in marginalized populations by providing additional information on SLE-associated CVD in Black and Latino patient

Limited Regulatory T Cell Response in Post-Chikungunya Viral Arthritis: A Therapeutic Opportunity?

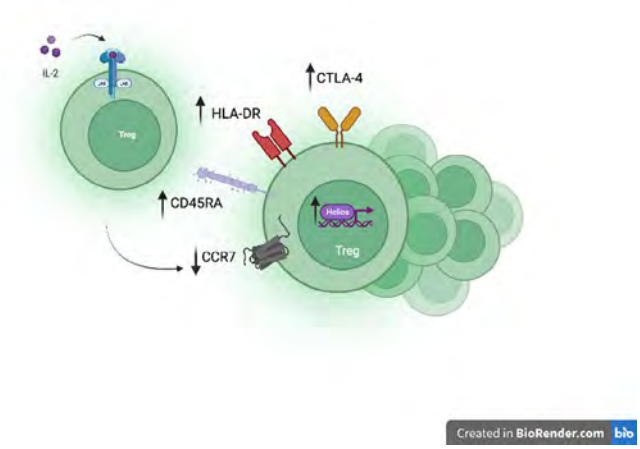
Aileen Chang[1], Sarah Tritsch[1], Carlos Herrera[1], Liliana Encinales[2], Andres Cadena[3], Wendy Rosales[4], Evelyn Mendoza[5], Samuel Simmens[1], Richard Amdur[6], Paige Fierbaugh[1], Abigale Proctor[1], Alfonso Sucerquia[1], Christopher Mores[1], David Boyle[7], Gary Firestein[7] and Gary Simon[1], [1]George Washington University, Washington, DC, [2]Allied Research Society, Barranquilla, Colombia, [3]Clinica de la Costa, Barranquilla, Colombia, [4]Universidad Libre, Barranquilla, Colombia, [5]Universidad Libre, Bogotá, Colombia, [6]Northwell, Washington, DC, [7]University of California San Diego, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The objective was to define the relationship between chronic chikungunya (CHIKV) post-viral arthritis disease severity, interleukin (IL)-2, and T cell subsets in order to determine if arthritis therapies targeting enhanced regulatory T cell (Treg) activity such as low-dose IL-2 may provide benefit.

Methods: Participants with CHIKV arthritis were recruited from Colombia from 2019–2021. Arthritis disease severity was quantified using the Disease Activity Score (DAS)-28 and an Arthritis-Flare Questionnaire adapted for CHIKV arthritis. Plasma cytokine concentrations (IL-1β, IL-2, IL-4, IL-6, IL-8, IL-10, IL-12p70, IL-13, interferon-γ and tumor necrosis factor (TNF)) were measured using a Meso Scale Diagnostics assay. Peripheral blood Treg subsets were measured using flow cytometry.

Results: Among participants with CHIKV arthritis (N=158),IL-2 levels and frequency of Tregs were low. Increased arthritis disease activity was associated with higher levels of inflammatory cytokines (IL-6, TNF and CRP) and immunoregulatory cytokine IL-10 without increases in IL-2 ($p< 0.05$). Increased arthritis flare activity was associated with higher Treg frequencies ($p< 0.05$) without affecting Teff frequencies, Treg/Teff ratios and Treg subsets. Finally, elevated levels of IL-2 were correlated with increased Treg frequency, percent Tregs out of $CD4^+$ T cells, and Treg subsets expressing immunosuppressive markers, while also correlating with an increased percent Teff out of live lymphocytes ($p< 0.05$).



Conclusion: CHIKV arthritis is characterized by increased inflammatory cytokines and deficient IL-2 and Treg responses. Greater levels of IL-2 were associated with improved Treg numbers and immunosuppressive markers, suggesting that low-dose IL-2 therapies targeting enhanced Treg activity may be a plausible objective for further investigation.

Increasing IL-2 in chikungunya arthritis is associated with increased Treg numbers and expression of immunomodulatory markers. Herein we report that higher levels of IL-2 in chikungunya arthritis patients were associated with greater numbers of Tregs. Greater IL-2 was also associated with enhanced expression of CTLA-4, which suppresses effector T cell activation by decreasing antigen presenting cell costimulatory function (CD80/CD86). Additionally, higher IL-2 levels of IL-2 were associated with higher expression of HLA-DR, which functions in Treg activation; CD45RA, found in resting Tregs; and Helios, a transcription factor that acts on the Foxp3 promotor to increase immunosuppressor function. Last, increased IL-2 levels correlated with decreased CCR7, whose deficiency permits Treg retention in inflamed tissue.

Stiffness

Circle the number that best describes the STIFFNESS you have felt due to your chikungunya arthritis in the last week:

No stiffness 0 – 1 – 2 – 3 – 4 – 5 – 6 – 7 – 8 – 9 – 10 Extreme stiffness

How to score the CHIK-DAS

Variable	Value
DAS-28 Tender Joint Score	
Ankle Tenderness Score	
Stiffness Score	
C-reactive Protein (CRP) (mg/dL)	
CHIK-DAS + CRP = .219 + .067 x Stiffness Score + .235 x Ankle Tenderness + .015 x DAS28 Tender Joint Count + .021*CRP	
CHIK-DAS = .262 + .069 x Stiffness Score + .248 x Ankle Tenderness + .015 x DAS28 Tender Joint Count	

CHIK-DAS Interpretation

With and without CRP	Disease Activity
<0.22	Remission
0.23 to 0.75	Mild
.75 to 1.29	Moderate
≥1.30	High

Background/Purpose: Chikungunya virus is an alphavirus spread by mosquitos that causes a debilitating chronic arthritis that has no standard treatment to date. The objective of this expert group was to develop a measure of chikungunya arthritis that would be useful for clinical trials and patient care.

Methods: A group of chikungunya experts, rheumatologists and biostatisticians identified component measures for evaluation for inclusion in a chikungunya arthritis disease activity score (CHIK-DAS). Utilizing data from a Colombian cohort of chikungunya arthritis patients (N=84), linear regression was used to identify the components that were independently associated with patient reported outcomes assessing disability, pain, physical and mental quality of life and mobility. A preliminary instrument was developed and assessed for internal consistency and test-retest reliability. Cutoffs for grading disease severity were determined.

Results: A CHIK-DAS was developed including a 30 tender joint count and a stiffness item in a form with and without CRP. Disease activity was defined as remission (< 0.22), mild (< 0.75), moderate (0.75-1.29) and severe (≥1.30) disease.

Conclusion: The CHIK-DAS may be used as a specific measure of disease activity in chikungunya arthritis in clinical trials and patient care. This metric should be further validated in additional cohorts.

Chikungunya Disease Activity Score (CHIK-DAS). The items 30 tender joint count including the 28 joints from the DAS-28 and the ankle joints and a stiffness score with and without C-reactive protein. The 28 joints included in the DAS-28 are the bilateral shoulders, elbows, wrists, metacarpophalangeal, proximal interphalangeal and knees.

Improving Vaccination Uptake of Herpes Zoster in Young Rheumatic Disease Patients Ages 18-49 Using Specialty Pharmacy Partnership

Stephen Lindsey[1], **Brittany Hill**[2], Sheela Sheth[3] and Arya Loghmani[2], [1]LSU Health Science Center, New Orleans, LA, [2]Louisiana State University, New Orleans, LA, [3]Tulane University, New Orleans, LA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Herpes zoster (HZ), also known as shingles, causes an estimated one million cases annually in the United States. Many studies have shown that the risk for herpes zoster infection is higher in inflammatory rheumatic diseases (IRDs) and those who are immunocompromised (IC). The severity of herpes zoster correlates with underlying immunosuppression, also seen in immunosenescence. The rate of Shingles in our young IRD patients is similar to a healthy 65-year-old with a rate of 8-10 per thousand patient years. Some immunosuppressants (IS) especially JAKs further increase this risk.

Shingrix, approved in 2017 for adults over 50 years old, a non-live recombinant herpes zoster vaccine (RZV) is administered in two doses. In July 2021, the indication was expanded by the Federal Drug Association (FDA) to include patients eighteen years and older with IRDs or on IS. The purpose of our study was to study the prevalence of RZV in our young IRD cohort and to evaluate methods to increase vaccination rates, including utilization of the specialty pharmacy.

Methods: The patient cohort was collected utilizing the electronic medical record reporter system (EMRRS). All patients 18-49 years old who were seen in rheumatology clinic from July 2021 to mid-April 2022 were included to determine current RZV vaccination rates and eligibility. Eligibility criteria included young IRD patients and IC.

After determining which patients required RZV, the team coordinated with the specialty pharmacy to ensure a central location for inoculation and to keep a record of vaccinated patients. In addition, it ensured that patients would receive a reminder to return for the second dose of RZV. The pharmacists were provided with a list of eligible patients and the patients were given a flyer with pharmacy information. In addition, patients were electronically sent a copy of the flyer through the online patient portal or through email.

Cross-sectional analysis using EMRRS from July 2022 to June 1, 2023 was utilized by investigators to determine new eligible patients and the percentage of patients age 18-49 years old seen in rheumatology clinic that had received vaccination.

Results: A total of 1,009 patients ages 18-49 years old were seen in rheumatology clinic since the FDA expanded the indication for RZV. Of those patients, 458 were eligible to receive the vaccine. Prior to intervention, only two (0.2%) patients had received partial vaccination due to previous disseminated zoster infection. To date, 35.5% of eligible patients had been vaccinated, with 109 (23.8%) patients having received two doses of the vaccine and 58 (12.7%) patients having received the

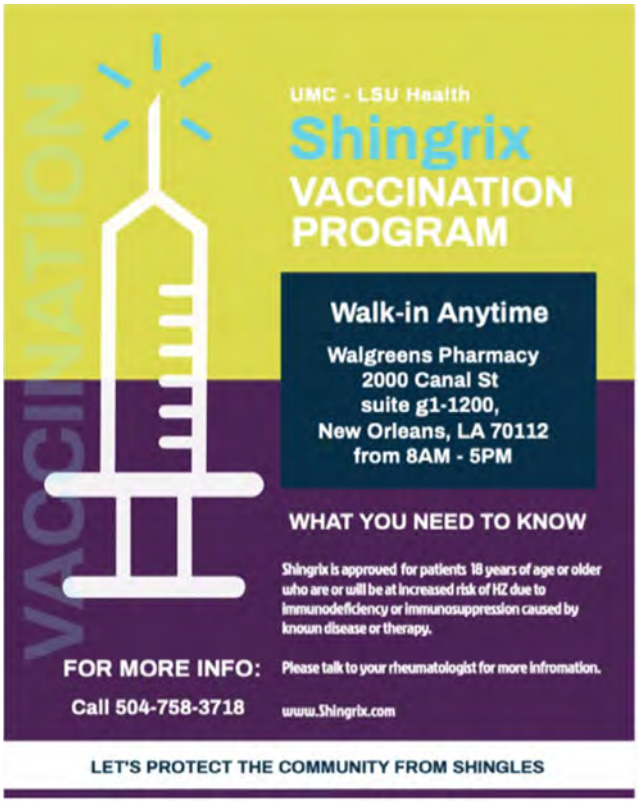

Figure 1. Shingrix Vaccination Patient Flyer

first vaccine dose. A majority of those receiving full vaccination were completed in the specialty pharmacy. The goal is to have 80% of eligible patients seen in rheumatology to be vaccinated.

Conclusion: RZV vaccination uptake has been markedly improved in our 18-49 years old eligible IRD patients, from 0.2% in April 2022 to 35.5% as of June 1, 2023. Even though the FDA may approve new guidelines, uptake is delayed, especially in the younger patient populations. The combination of multiple reminder avenues along with the coordination of specialty pharmacy proved successful in vaccinating eligible patients.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

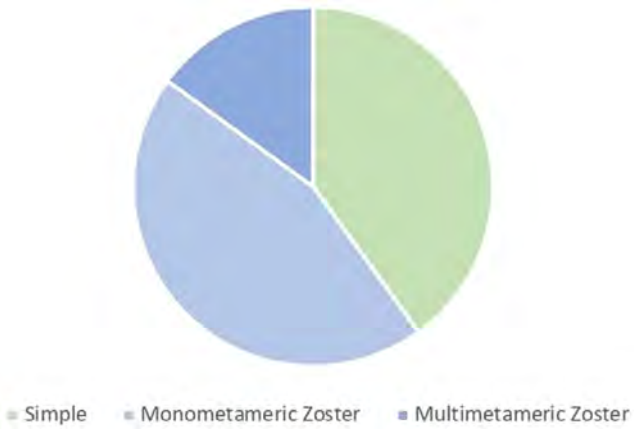
Background/Purpose: Herpes zoster infection is due to the reactivation of the varicella-zoster virus (VZV), having a high prevalence in elderly and immunocompromised patients. Since the beginning of 2022, a new vaccine that prevents herpes zoster virus reactivation has been approved and commercialized. However, there are few studies analyzing its effectiveness in real-world conditions.

Our purpose is to analyze the incidence and rate of herpes zoster disease in a population at risk due to suffering from rheumatic diseases and therefore being subsidiary of receiving VZV vaccination.

Methods: A retrospective observational study of patients who started treatment with JAK inhibitors from 2013 to 2022 was performed. Demographic and clinical features were collected from the electronic clinical history. Vaccination of patients against VZV was analyzed, as well as the incidence of herpes simplex (HSV) and herpes zoster reactivation before and after January 2022, date on which the vaccination program began. In addition, the rate of the VZV disease was calculated based on the follow-up time for both vaccinated and unvaccinated patients and was adjusted by exposure in events/100 patients-year (E/100 PY).

	Total of patients (n=236)
Age - years (sd)	62.45 (8.2)
Female sex - n (%)	188 (79.66%)
Diagnosis - n (%)	
RA	179 (75.84%)
PsA	28 (11.86%)
AS	14 (5.93%)
Others	10 (4.23%)
JIA	5 (2.11%)
Comorbidities - n (%)	
Dyslipidemia	69 (29.23%)
Arterial hypertension	65 (27.54%)
Smoking	40 (16.95)
Mellitus diabetes	22 (9.32%)
Vaccination	
No	206 (87.29%)
Yes	30 (12.71%)

Demographic and clinical characteristics of the patients.



Frequency of Herpes Virus infection.

Results: 236 patients with an indication for vaccination against VZV due to being treated with JAK inhibitors were included, of whom the majority diagnosis was Rheumatoid Arthritis (n=179). Their demographic and clinical features are shown in the following table. 30 patients were vaccinated against VZV (12.71%). An incidence of 20 herpes cases was observed in unvaccinated patients, of them, 8 corresponded with HSV and 12 with VZV. 3 of the VZV reactivations were of multimetameric involvement (see graph). No cases of herpes were found in the vaccinated population. The unvaccinated patients were followed up for 3500 months, remaining with a herpes rate in this population of 4.12 E/100 PY. The total follow-up of vaccinated patients was 102 months, with a herpes rate of 0 E/100 PY.

Conclusion: An incidence of 12 VZV is observed in unvaccinated patients compared to an incidence of 0 in vaccinated patients. The herpes rate in non-vaccinated patients was 4.12 E/100 PY compared to 0 E/100 PY in vaccinated patients. Therefore, we conclude that the herpes zoster vaccine shows its effectiveness in our population but it would be necessary to carry out more studies in the future with a longer follow-up time.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Herpes zoster (HZ) is a painful rash that is commonly known as shingles. People that had a primary infection caused by the varicella-zoster virus known as chicken pox can present herpes zoster at any age.[1] The infection manifests as a vesicular rash with the characteristic of following a dermatomal pattern followed by postherpetic neuralgia. Herpes zoster is commonly observed in the elderly and immunocompromised populations such as patients with autoimmune diseases or malignancies. On average HZ incidence in a normal population is 1.2 to 4.9 cases per 1000 person per year; however, herpes incidence is multiplied in those with autoimmune diseases.[2]

Methods: We conducted a cross-sectional study that included consecutive patients with RD who were ≥ 18 years attending the rheumatology service in a northeast referral hospital in Mexico. We excluded patients who refused to participate. The following data was collected between December 2022 to May 2023: demographics, medical history, and RD diagnosis. We applied a paper-based questionnaire and reviewed medical records to identify HZ events in patients with RD, demographics, onset, recurrence, vaccination status, and hospital admissions related to HZ and HZ-related factors.

Results: A total of 182 patients with RD were screened for HZ. Patients with HZ had a median and IQR age of 57 (48.5 – 69). Thirty-three (18.13%) patients reported an HZ event; of which 14 (42.4) had their first HZ event over more than 10 years ago. Thirty-two (96.97%) were treated with antivirals, 3 (9.09%) were hospitalized due to severe disease, and 31 (93.94%) were not vaccinated against HZ. Regarding rheumatic diseases 9 (32.1) SLE patients, 20 (17.5) RA patients, and 2 (12.5%) OA patients had HZ. (See Tables 1 and 2).

Conclusion: Herpes zoster events are six folded in patients with rheumatic diseases. The prevalence of HZ-events is higher in patients with autoimmune diseases, specifically in those with SLE. The frequency of HZ events and severe disease can be prevented through vaccination; however, the vaccine may not be accessible to everyone.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Herpes zoster (HZ) is common in the elderly, with a lifetime risk of 25%. The primary risk factors for HZ are advanced age and immunosuppression. The aim is to describe the safety of recombinant zoster vaccine in patients with inflammatory rheumatic and musculoskeletal diseases (RMD)

Methods: Adult patients with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA), and giant cell arteritis (GCA) were prospectively enrolled in this ongoing study. Data on demographics, vaccination, RMD diagnosis, disease activity, immunosuppressive treatments, flares, and zoster breakthrough infections were collected at months 0, 2, 3, 6 and 12. Safety assessments were performed at 2, 3, 6, and 12 months. A flare was defined as change in ASDAS ≥ 0.9 for axSpA, change in DAS-28 >1.2 for RA, or clinical signs for GCA and/or CRP ≥ 0.5 mg/dl and/or ≥30 mm. Descriptive analyses were performed

Results: 81 patients were enrolled, of whom 21 (25.9%) had a history of HZ (Table 1). All patients received RZV at month 0 and 66 patients at month 2. Safety assessments in 66, 56, 48, and 5 patients at month 2, 3, 6 and 12, respectively. A total of 87, 68, 15, 8 AEs were reported in 53, 37, 13, and 6 patients, respectively. Localized AEs (n=97 (67.0%)) were more common than generalized AEs (n=48 (33.1%)). Pain at the injection site (55 (30.9%)) was the most common AE, followed by fatigue (20 (11.2%)), musculoskeletal pain (19 (10.7%)), fever (14 (7.9%)), redness at the injection site (10 (5.6%)), and swelling at the injection site (7 (3.9%)). Serious adverse events (AE) were reported in 8 patients (3 RA, 5 GCA), none of which were vaccine-related. No patient reported an AE of special interest. 5, 4, 5 and 2 episodes of self-reported disease worsening were reported by patients at months 2, 3 and 6, respectively, 12 but none met predefined flare criteria. However, 3 patients (2 GCA, 1 RA) were hospitalized as a result. No episodes of HZ occurred during follow-up

Variable	RA (n=32)	AxSpA (n=29)	GCA (n=20)
Age	54.6 (12.2)	45.5 (10.2)	73.3 (6.8)
Sex, female (No., %)	18 (56.3)	9 (31.0)	14 (70.0)
History of zoster (No., %)	8 (25.0)	3 (10.3)	11 (55.0)
CRP, mg/dl	0.5 (0.7)	0.7 (1.2)	0.2 (0.3)
Prednisolone, mean dosage mg/dl	6.4 (8.2)	0	14.1 (15.6)
csDMARD(No., %)	29 (90.6)	0	8 (40.0)
bDMARD(No., %)	23 (71.9)	23 (79.3)	8 (40.0)
tsDMARD(No., %)	6 (18.8)	6 (20.7)	0
Physician global	0.94 (1.5)	1.5 (1.6)	0.8 (1.5)
Patient global	3.6 (2.4)	3.5 (2.1)	3.9 (2.6)
Pain	3.4 (2.5)	3.2 (2.3)	3.6 (2.6)
Disease activity	DAS-28 2.6 (1.4)	ASDAS 2.1 (0.9)	NA
Physical function	FFbH 77.4 (21.7)	BASFI 3.5 (2.7)	FFbH 71.2 (23.3)

Patients and disease characteristics

Conclusion: Most patients tolerated RZV well with few reports of flare and serious AEs. The majority of AEs occurred within a few days of vaccination. These findings are reassuring for rheumatologists and potential vaccine recipients and support confidence in the safety of RZV in patients with RMD

Analysis of the Effects of Immunosuppressive Therapy on Herpes Zoster Events After Each of Three Doses of the BNT162b2 mRNA Vaccine in Patients with Spondyloarthritis (SpA)

Tal Gazitt[1], Noa Hayat[2], Amir Haddad[2], Joy Feld[3], Nili Stein[2], Idit Lavi[2], Ilan Feldhamer[4], Arnon Dov Cohen[5], Walid Saliba[2] and Devy Zisman[2], [1]Carmel Hospital, Haifa, Israel, [2]Carmel Medical Center, Haifa, Israel, [3]Carmel and Zvulun Medical Centre, Haifa, Israel, [4]Chief Physician's Office, Clalit Health Services, Tel Aviv, Israel, [5]Ben-Gurion University of the Negev, Beer-Sheva, Israel

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The importance and efficacy of mRNA COVID-19 vaccination in coping with the pandemic are well established, but inconsistencies remain in the data regarding side effects, especially in patients with rheumatic diseases treated with immunosuppressive therapy.

We aimed to assess the effect of immunosuppressive therapy on the incidence of Herpes Zoster (HZ) in patients with psoriatic arthritis (PsA) and ankylosing spondylitis (AS) after each of the three doses of the BNT162b2 mRNA vaccine compared to HZ incidence in a similar time period two years prior to vaccination.

Methods: The database of Clalit Health Services, the largest health care provider of approximately 4.7 million members in Israel, was retrospectively analyzed for patients with a diagnosis of PsA and AS starting from 12/2018 and who later received 3 doses of the BNT162b2 mRNA vaccine in a national vaccination campaign from 12/2020-12/2021. For each individual, data on demographic, socioeconomic, and selected chronic comorbidities, as well as use of glucocorticosteroids, conventional/ biologic/ targeted-synthetic disease-modifying anti-rheumatic drugs (DMARDs) and previous HZ vaccination status were retrieved.

The incidence of HZ events was calculated during the 6 weeks following each of the three mRNA COVID-19 vaccine doses and compared to a similar time period within this group of patients two years prior by NcNemar test, and also relative to fully-vaccinated controls from the general population matched by sex and age at 1:10 ratio. For each SpA patient, multivariable logistic regression was used to assess for any association between DMARD use within 3 months prior to each HZ event and HZ reactivation risk relative to SpA patients not on these medications.

Results: The study population consisted of 6460 SpA patients, 4648 (72.0 %) with PsA, 1812 (28.0%) with AS and 115 (1.8%) with both PsA and AS with a mean age of 57.6±15.0 years, of whom 3107 (48.1%) male. Of SpA patients, 18.2% (n=1173), 35.5% (n=2293), and 1.2% (n=79) were on cDMARDs, bDMARDs, and tsDMARDs, respectively. The incidence of HZ events was higher among SpA patients in comparison to the general population both pre- (p=0.004) and post- (p=0.027) mRNA COVID-19 vaccination, even after controlling for multiple covariates, with no significant difference in HZ reactivation occurring in the PsA vs AS subgroups pre- and post mRNA vaccination. The number of HZ events was not increased in SpA patients with HZ events who received bDMARDs (p=0.372), TNF-α inhibitors in particular (p=0.095), or cDMARDs (p=0.365) in comparison to patients not on these medications (too few HZ cases occurred in patients on tsDMARDs to allow for statistical analysis).

Conclusion: The risk of HZ after each one of the three BNT162b2 mRNA vaccine doses was not increased in PsA and AS patients compared to a similar time period two years prior to vaccination, and was not influenced by the type of DMARD used.

Abstract Number: 0203

Projecting the Impact on Clinical Outcomes in ANCA-Associated Vasculitis of Delaying Retreatment with Rituximab for Vaccine Optimization

Zachary Wallace[1], Aaron Wu[2], Shruthi Srivatsan[2], Naomi Patel[2], Jeffrey Sparks[3], Eli Miloslavsky[2], Hyon K. Choi[4], Peter Merkel[5], John Stone[6] and Emily Hyle[2], [1]Massachusetts General Hospital, Newton, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Massachusetts General Hospital and Harvard Medical School, Lexington, MA, [5]University of Pennsylvania, Philadelphia, PA, [6]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Concord, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX) is effective for maintaining remission in ANCA-associated vasculitis (AAV) but increases risks for vaccine-preventable severe infections and reduces the immune response to vaccination. There is uncertainty regarding risks and benefits of holding RTX to improve vaccine efficacy by permitting B cell repopulation (e.g., seasonal flu, COVID-19). We used the previously validated microsimulation model, AAV-Sim, to project the clinical impact of delaying treatment with RTX in people with AAV in remission.

Methods: We evaluated 2 strategies: (1) **Continuous B cell depletion** with routine RTX retreatment; or (2) **Permissive B cell repopulation** with RTX delayed for 4 weeks to optimize vaccination, then resuming RTX. At model start, individuals are in remission, B cell depleted, and have an eGFR ≥45ml/min. They are assigned demographics, ANCA type, and other characteristics based on probabilities, and transition monthly between active (e.g., major/minor relapse) or inactive AAV states. They are monitored monthly for B cell repopulation and are at risk for severe infection, end-stage renal disease (ESRD), or death. Transition rates are stratified by demographic and disease-specific characteristics (**Table 1**). We projected the primary outcomes of relapse-free remission and vaccine optimization over 12 months. We defined vaccine optimization as: B cell repopulated, retreatment delayed, and no relapse prior to vaccination. We performed sensitivity analyses to identify influential factors.

Results: Permissive B cell repopulation (Strategy 2) would be associated with lower relapse-free survival than continuous B cell depletion (Strategy 1) (81.0% vs 95.9%). However, 72.8% of patients would be optimized for vaccination in Strategy 2, whereas none would be optimized in Strategy 1 (**Figure 1**). Minimal differences between strategies would occur in model-projected new renal involvement, ESRD, and death. Varying B cell repopulation rates and ANCA type would strongly influence relapse-free survival. Relapse-free survival in Strategy 2 would be higher in MPO-ANCA+ vs PR3-ANCA+ across B

Table 1: Input Parameters for AAV-Sim Stratified by Treatment Strategy

Input Parameter	Base Case Value		
Baseline Cohort Characteristics[1]			
Age (mean [SD], years)	60.6 (13.0)		
Male (%)	58.2%		
PR3-ANCA (N, %)	58.0%		
Renal Involvement (N, %)	71.1%		
Relapse (monthly probability)[1-6]	**Permissive B Cell Repopulation**		**Continuous B Cell Depletion with RTX**
	B Cells Detected*	No B Cells Detected	
PR3-ANCA Major Relapse	0.026412	0.013158	0.00171
PR3-ANCA Minor Relapse	0.046489	0.023521	0.00292
MPO-ANCA Major Relapse	0.013158	0.006601	0.00085
MPO-ANCA Minor Relapse	0.023521	0.046489	0.00143
B Cell Repopulation[7]	0.174596		N/A
Severe Infection (monthly probability)[1, 2]			
Active Disease^	0.00944		0.00944
Inactive Disease	0.00419		0.00785
Risk of New Renal Involvement with Major Relapse	0.10		0.10
End-Stage Renal Disease (monthly probability)			
Active Disease			
History of Renal Involvement	0.00966[8]		
No History of Renal Involvement	*Age- and sex-stratified*[9]		
Inactive Disease			
History of Renal Involvement	*2.0 * Age- and sex-stratified*[9]		
No History of Renal Involvement	*Age- and sex-stratified*[9]		
Mortality (monthly probability)			
Active Disease	*SMR of 2.5 * age- and sex-stratified*[10]		
Inactive Disease	*SMR of 1.5 * age- and sex-stratified*[10]		
ESRD	*Age- and sex-stratified*[9]		
Severe Infection	*Age- and sex-stratified*[11]		

*Risk of relapse stratified by B cell status based on assumption that B cell repopulation associated with 2-fold increased risk of relapse. ^Risk of severe infection in active disease is the same in both strategies because treatment will be similar for active disease in both strategies. RTX: Rituximab; CDC: Centers for Disease Control and Prevention; USRDS: United States Renal Data System; HCUP: Healthcare Cost and Utilization Project; SMR, standardized mortality ratio; References: 1. Charles P, et al. Ann Rheum Dis. 2018;77(8):1143-9. 2. Smith RM, et al. Ann Rheum Dis. 2020;79(9):1243-9. 3. Guillevin L, et al. N Engl J Med. 2014;371(19):1771-80. 4. Lionaki S, et al. Arthritis Rheum. 2012;64(10):3452-62. 5. Hogan SL, et al. Ann Intern Med. 2005;143(9):621-31. 6. Walsh M, et al. Arthritis Rheum. 2012;64(2):542-8. 7. Stone, et al. NEJM 2010;363:221. 8. Rhee RL, et al. Arthritis Rheumatol. 2016;68(7):1711-20. 9. United States Renal Data System. 2020 USRDS Annual Data Report. 2020. 10. Arias E, Xu J. United States Life Tables, 2017. 11. HCUP

cell repopulation rates (range, 85.0%-89.4% [difference 4.4%] vs 72.7%-80.3% [difference 7.6%], respectively) (**Figure 2**). Further, a greater portion of MPO- vs PR3-ANCA+ patients would have vaccine optimization across scenarios (range, 58.6%-87.9% vs 51.0%-78.5%, respectively).

Conclusion: A strategy that permits B cell repopulation would be associated with a higher risk of relapse but would optimize many patients for vaccination. ANCA type (i.e., relapse risk) and B cell repopulation rates strongly influence these risks and benefits. A strategy of permissive B cell repopulation may be more acceptable in MPO-ANCA+ AAV and people with faster B cell repopulation. B cell repopulation rates had a stronger influence on model-projected relapse-free survival in PR3- than MPO-ANCA+ AAV. To further weigh the risks and benefits of each strategy, the downstream effects of vaccination (e.g., infection severity) will be incorporated in future steps. These findings highlight the importance of improving biomarkers of relapse risk and determining predictors of B cell repopulation rate.

Figure 1: The Impact of Two Strategies for Management of Remission in ANCA-Associated Vasculitis on Relapse-Free Survival (1A), Vaccine Optimization (1A), and Other Key Outcomes (1B)

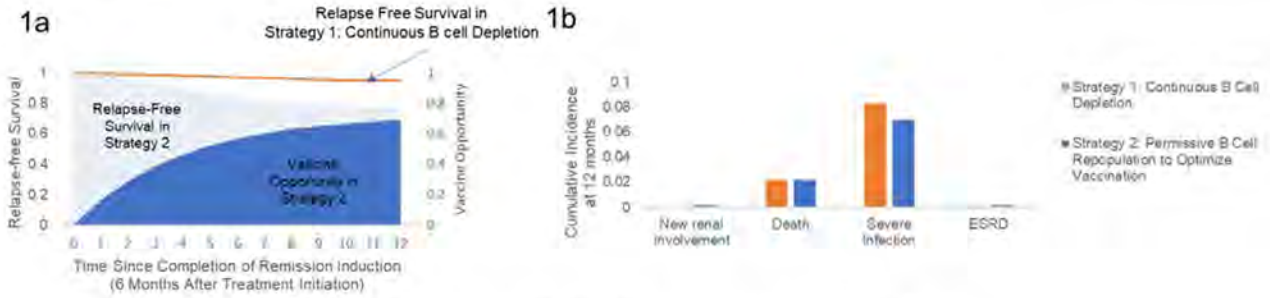

Figure 1a reflects relapse-free survival and vaccine optimization in a population with baseline features similar to those enrolled in MAINRITSAN 2. The solid line reflects the relapse-free survival with continuous B cell depletion with rituximab (Strategy 1). Because there is RTX retreatment to maintain continuous B cell depletion in Strategy 1, there is no vaccine optimization with this strategy. The patterned shade reflects relapse-free survival if B cells are permitted to repopulate to optimize vaccination (Strategy 2). The solid shade reflects vaccine optimization if B cells are allowed to repopulate and retreatment delayed (Strategy 2). Figure 1b reflects the cumulative incidence at 12 months of other key outcomes.

Figure 2: The Impact of ANCA Type and B Cell Repopulation Rates on Relapse-Free Survival and Vaccine Optimization

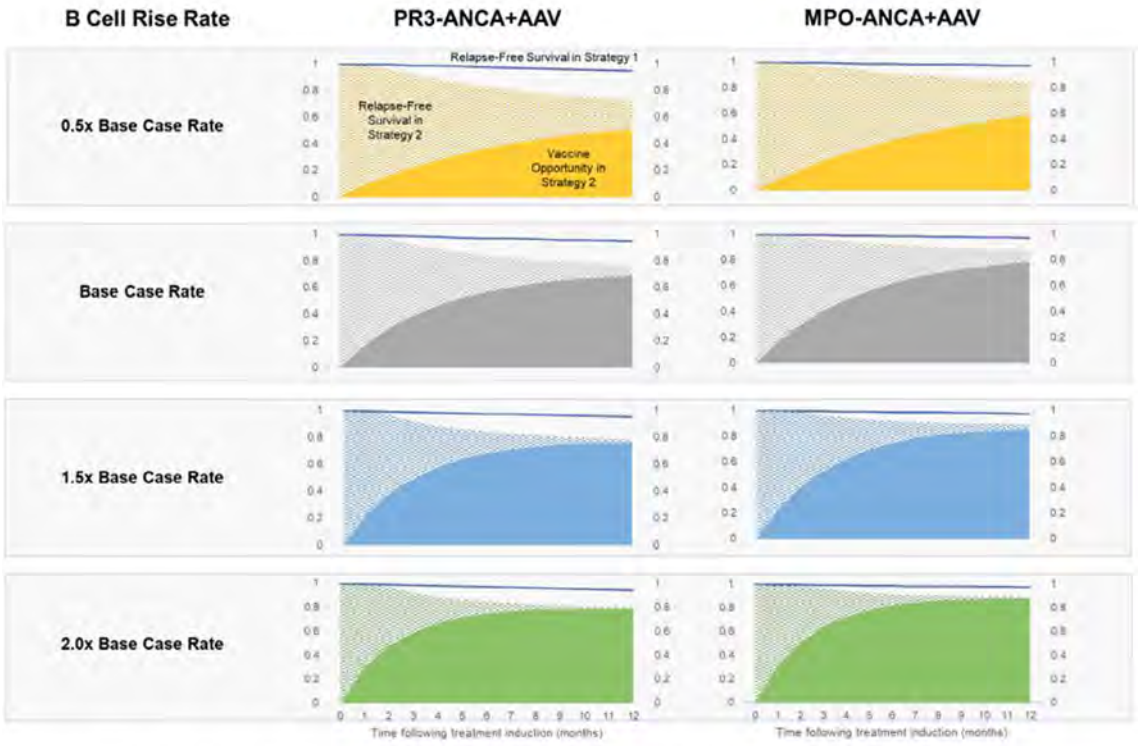

Figure 2 reflects relapse-free survival and vaccine optimization with varied B cell repopulation rates in PR3-ANCA+ and MPO-ANCA+ AAV. The solid line in each figure reflects the relapse-free survival with continuous B cell depletion with rituximab (Strategy 1). Because RTX is used to maintain continuous B cell depletion, there is no vaccine optimization in Strategy 1. The patterned shade reflects relapse-free survival if B cells are permitted to repopulate and RTX retreatment is delayed to optimize vaccination (Strategy 2). The solid shade reflects vaccine optimization if B cells are allowed to repopulate (Strategy 2). AAV: ANCA-associated vasculitis.

Risk of Severe Infections Associated with Immunoglobulin Deficiency Under Rituximab Therapy in Immune Mediated Inflammatory Diseases

Claire Rempenault[1], Cedric Lukas[2], Léa Tardivon[3], Claire Daien[4], Bernard G. Combe[5], Philippe GUILPAIN[3] and JACQUES MOREL[6], [1]Universary Hospital of Montpellier, Montpellier, France, [2]CHU Montpellier, Montpellier, France, [3]University of Montpellier, Montpellier, France, [4]University Hospital, Montpellier, France, [5]Department of Rheumatology, Montpellier University, Montpellier, France, [6]Protocole thérapeutique immuno-rhumatologie, Montpellier, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Literature data on the increased risk of severe infection regarding hypogammaglobinemia related to RTX in IMID are controversial and sparse. We proposed to evaluate the risk of severe infections in patients with IMID treated with RTX who presented Ig deficiency (prevalent or acquired).

Methods: We conducted an observational, retrospective single-center study retrieving all patients with at least one infusion of RTX in the department of Rheumatology (CHU Montpellier) between January 1st and December 31st 2017. We included all patients treated for an IMID (rheumatoid arthritis, systemic lupus erythematosus, ANCA-associated vasculitis, primary Sjögren syndrome, inflammatory myopathy, scleroderma, mixt connective diseases, cryoglobulinemia vasculitis and overlap syndrome) with at least one Ig assay performed during follow-up. Patients were followed-up at least12 months after the last infusion of RTX or until the occurrence of a severe infection or death occurring within 12 months after the last infusion of RTX or until the end of the study (May 31st 2020).Ig deficiency was defined as a rate of IgG, and/or IgA and/or IgM lower than the laboratory thresholds. Then, we categorized patients with prevalent Ig deficiency (before the first infusion of RTX), acquired Ig deficiency (normal Ig assays before the first infusion of RTX and with an occurrence of at least one Ig deficiency during follow-up), and patients with normal Ig level from the first infusion to the end of follow-up.

Results: Three hundred and eleven patients were included. Nine patients had undatable Ig deficiency. Twenty-nine patients (9,4%) had prevalent Ig deficiency. As compared with patient with normal Ig level at baseline, concomitant treatment with glucocorticoids (p=0,03) and with a higher daily dose at baseline (p=0,01) were associated with a prevalent Ig deficiency. Sixty-eight patients (22,0%) acquired an Ig deficiency after the first infusion of RTX. A longer time of follow-up and a higher cumulative dose of RTX, the type of IMIDs (SLE and AAV) and concomitant treatment with IS or GCs at baseline, diabetes mellitus and obesity were associated with the occurrence of an Ig deficiency (Table 1). Forty-three patients (14,3%) developed a severe infection within 12 months after the last infusion of RTX. Severe infections occurred more frequently in patients with prevalent Ig deficiency but without any stastistical difference with patient with normal Ig level (Table 2). In multivariate

analysis, only chronic pulmonary disease, a higher daily dose of GCs and a higher mean DAS28-CRP during follow-upwere still associated with an increased risk of severe infection (Table 3). In a time-dependant analysis, Ig deficiency in patient treated with RTX, wether acquired or prevalent, was not associated with an increased risk of severe infection (adjusted HR 1.04 [0.5-2.3], p=0.92).

Table 1.: Baseline and follow-up characterisitics of patients with IMIDs receiving RTX, in the whole cohort, and comparison of patient with acquired Ig deficiency and normal Ig level.

Patients (n)	**All patients (311)**	**Ig deficiency at the end of follow-up**		
		Acquired (68)	**No (205)**	**p**
Age (years), mean (SD)	57.9 (12.5)	57.1 (12.8)	57.6 (12.6)	0.78

Risk of severe infections, compared with patients with normal Ig levels during the entire follow-up, adjusted HR [CI95]*, p	NA	1.3 [0.5-3.4], p=0.53	0.3 [0.1-1.2], p=0.09	Ref.

PY = patients-year; RR = relative risk ; CI 95 = confidence interval with 95%

* Multivariate model, adjusted on the type of IMID, chronic pulmonary disease, diabete mellitus, previous treatment with immunosuppressor, combination with immunosuppressor at baseline, glucocorticoids at baseline, daily dose of glucocorticoids during follow-up, mean-DAS 28-CRP during follow-up .

Table 3. Risk factors associated with severe infection within 12 months after the last RTX infusion in the whole population of study (multivariate analyses).

	Multivariate analysis	
	aHR [95CI]	p
IMID		
- Rheumatoid Arthritis	Ref.	NA
- Systemic Lupus Erythematosus	0.9 [0.2-4.1]	0.86
- ANCA associated vasculitis	NA	NA
- Others IMIDs	1.9 [0.5-7.7]	0.37
Comorbidities		
- Chronic pulmonary disease	2.3 [1.2-4.5]	0.01
- DM	1.1 [0.4-3.0]	0.77
Treatment and disease activity		
- Previous treatment with immunosuppressor	1.2 [0.5-2.7]	0.63
- Combination with immunosuppressor	0.6 [0.1-4.7]	0.63
- Concomitant treatment with glucocorticoids	1.1 [0.4-2.8]	0.9
- Mean daily dose of GCs during follow-up	1.2 [1.1-1.3]	0.001
- Mean DAS28-CRP during follow-up	1.3 [1.002-1.7]	0.05
Acquired Ig deficiency	1.3 [0.5-3.4]	0.53
Prevalent Ig deficiency	0.3 [0.1-1.2]	0.09

aHR = adjusted Hazard Ratio, in multivariate analysis by Cox model , adjusted on the type of IMID, chronic pulmonary disease, diabete mellitus, previous treatment with immunosuppressor, combination with immunosuppressor at baseline, glucocorticoids at baseline, daily dose of glucocorticoids during follow-up, mean-DAS 28-CRP during follow-up and the type of immunoglobulin deficiency

Conclusion: We did not observe an increased risk of severe infection in RTX-induced Ig deficiency. In case of Ig deficiency, RTX management should be discussed on a case-by-case basis, according to an individual assessment of the infectious risk, especially when GCs therapy is used and chronic lung diseases are present.

Changes in Serum Rheumatoid Factor Following Eradication of Hepatitis C Virus Infection with Interferon or Direct Antiviral Therapy

Jamie Chieh Lo[1], Ying-Nan Tsai[2], Cheng-Hao Tseng[3], Yao-Chun Hsu[4] and Song-Chou Hsieh[5], [1]School of Medicine, I-Shou University, Kaohsiung, Taiwan, [2]Department of Gastroenterology and Hepatology, E-Da Cancer Hospital, Kaohsiung, Taiwan, [3]Division of Gastroenterology and Hepatology, E-Da Cancer Hospital, Kaohsiung, Taiwan, [4]I-Shou University School of Medicine, E-Da Hospital Center of Liver Diseases, Kaohsiung, Taiwan, [5]National Taiwan University Hospital, Taipei, Taiwan

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Infection-related Rheumatic Disease Poster

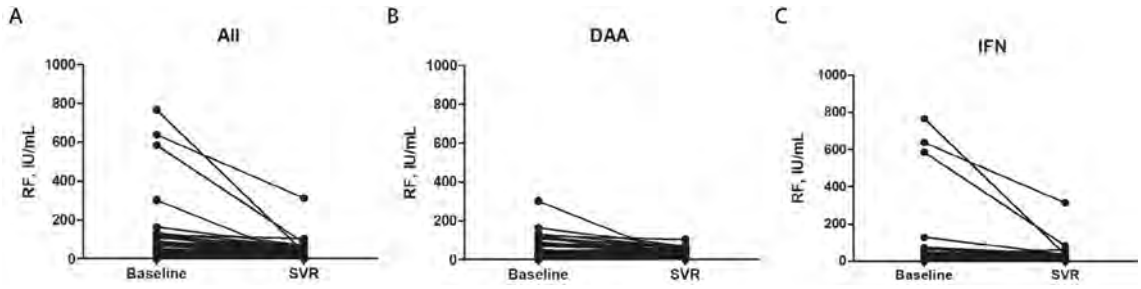
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

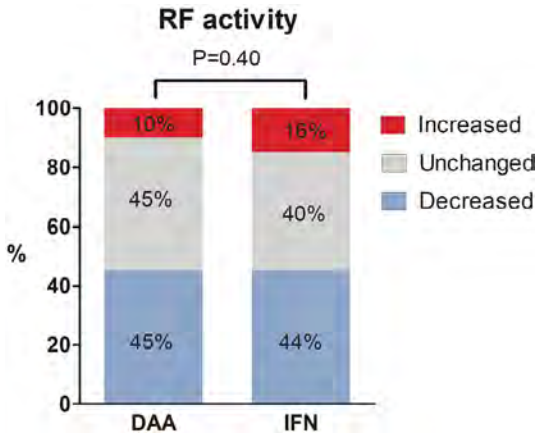
Background/Purpose: Chronic hepatitis C virus (HCV) infection is associated with autoimmune extrahepatic manifestations including increased production of autoantibodies such as rheumatoid factor (RF). Prior to the advent of direct-acting antivirals (DAAs), HCV infection was treated with pegylated interferon (Peg-IFN) which is known to induce or exacerbate autoimmunity. It remains unclear whether HCV eradication was associated with reduction in autoantibodies, and whether results would differ between IFN-based and IFN-free regimens. In our research, we aimed to investigate changes in serum RF following viral eradication in patients with chronic HCV infection who were treated with either Peg-IFN or ribavirin plus DAA.

Methods: This is a retrospective cohort study of adult HCV patients treated at a teaching hospital in Taiwan. All patients had detectable HCV RNA at baseline (BL) and achieved sustained virological response (SVR) documented 12 or 24 weeks after treatment. Serum level of IgG RF was measured using latex immunoassay with a measurement of 15 IU/mL or above defining seropositivity. The changes from BL to SVR were analyzed and the results were compared between patients treated with IFN-based regimens and those with IFN-free DAAs. Subgroup analyses according to age, sex, presence of cirrhosis, HCV genotype, and BL ANA titer were performed.

Results: This study enrolled 297 patients (median age 59; 48.5% female). Among them, 78 (26.3%) were RF-positive by qualitative serology at BL. This number decreased to 49 (16.5%) at SVR-12 or -24 ($P < 0.001$). Quantitatively, the median level of serum RF in the study cohort also decreased from 1.6 IU/mL (IQR undetectable (UD)-15.8) to UD (IQR, UD-6.6 IU/mL) ($P < 0.001$). Significant reductions in serum RF were observed in both treatment groups. The proportion with RF seropositivity decreased from 24.3% to 15.4% ($P = 0.001$) in patients treated with IFN-free agents ($n = 214$) and from 31.3% to 19.3% ($P = 0.006$) in patients treated with IFN-based regimens ($n = 83$), without significant difference between these two groups ($P = 0.40$).



Changes of serum rheumatoid factor (RF) level from baseline to sustained virological response (SVR) in all patients (panel A, left), patients treated with interferon-free (panel B, middle) or interferon-based regimens (panel C, right).



Comparison of changes in rheumatoid factor (RF) activity between interferon-free and interferon-based treatment groups.

Table 1 Baseline characteristics of chronic HCV infected patients treated with DAA and interferon-based regimens

	All (n=297)	DAA (*n* = 214)	IFN (*n* = 83)
Age	59 (48-67)	62 (54, 69)	49 (41, 58)
Female, *n* (%)	144 (48.5)	123 (57.5)	21 (25.3)
Cirrhosis, *n* (%)	50 (16.8)	47 (22)	3 (3.6)
AST, U/L	60 (40-97)	57 (36.8, 97.3)	63 (45, 97)
ALT, U/L	72 (44-119.5)	65 (39.8, 117.3)	95 (53, 137)
Bilirubin, mg/dL	1.0 (0.8-1.3)	1.0 (0.9, 1.3)	0.9 (0.7, 1.1)
White blood cell count, $10^3/\mu l$	5.9 (4.9-7.2)	5.7 (4.7, 6.9)	6.4 (5.1, 7.5)
Hemoglobin, g/dL	14.3 (13-15.4)	14.1 (12.8, 15.1)	14.8 (13.8, 16)
Platelet count, $10^3/\mu l$	181 (142-226)	175 (140, 226)	196 (148, 225)
Creatinine, mg/dL	1.0 (0.9-1.2)	1.0 (0.9, 1.3)	1.1 (0.9, 1.2)
HCV-RNA, log IU/mL	6.29 (5.49, 6.77)	6.28 (5.59,6.75)	6.30 (4.99, 6.80)
Genotype, *n* (%)			
1	170 (57.2)	132 (61.7)	38 (45.8)
2	99 (33.3)	65 (30.4)	34 (41.0)
3	4 (1.3)	1 (0.5)	3 (3.6)
6	24 (8.1)	16 (7.5)	8 (9.6)
Fibrosis 4 score	2.3 (1.5-4)	2.7 (1.7, 4.4)	1.7 (1.3, 2.7)
ANA, *n* (%)			
<1:40	276 (92.9)	194 (90.7)	82 (98.8)
1:40-1:80	13 (4.4)	12 (5.6)	1 (1.2)
1:160-1:640	8 (2.7)	8 (3.7)	0
SMA, *n* (%)			
<1:20	265 (89.2)	188 (87.9)	77 (92.8)
1:20-1:40	29 (9.8)	24 (11.2)	5 (6.0)
1:80-1:160	3 (1.0)	2 (0.9)	1 (1.2)

ALT, alanine aminotransferase; ANA, antinuclear antibody; AST, aspartate aminotransferase; DAA, direct-acting antiviral agents; HCV, hepatitis C virus; IFN, interferon; SMA, anti-smooth muscle antibody.

Baseline characteristics of chronic HCV infected patients treated with DAA and interferon-based regimens

Serum RF level decreased significantly between BL and SVR-12 or -24 in all subgroups, including age ≥ 59 (n = 150; 1.0 vs. UD IU/mL, P < 0.001), age < 59 (n = 147; 2.6 vs. 1.2 IU/mL, P < 0.001), males (n = 153; 2.1 vs. UD IU/mL, P < 0.001), females (n = 144; 1.2 vs. UD IU/mL, P < 0.001), with cirrhosis (n = 50; 0.7 vs. UD IU/mL, P < 0.001), without cirrhosis (n = 247; 1.9 vs. UD IU/mL, P < 0.001), genotype 1 (n = 170; 0.8 vs. UD IU/mL, P < 0.001), non-genotype 1 (n = 127; 2.3 vs. UD IU/mL, P < 0.001), and with BL ANA < 1:40 (n = 276; 1.4 vs. UD IU/mL, P < 0.001), except for patients with BL ANA ≥ 1:40 (n = 21; 3.0 vs. 1.3 IU/mL, P = 0.064).

Conclusion: We found that both the serum RF level and proportion of RF seropositivity significantly decreased after the eradication of HCV infection, regardless of whether the patients were treated with IFN-free or IFN-based regimens. We further analyzed different subgroups of participants and observed similarly significant reductions in serum RF in all subgroups, except for patients with ANA titers higher than 1:40 at BL. These findings indicate that effective treatment for HCV could reduce the production of RF and may alter autoimmunity in patients with chronic HCV infection.

Abstract Number: 0206

Risk of Hepatitis B Virus Reactivation in Patients with Rheumatoid Arthritis Receiving JAK Inhibitor or IL-6 Inhibitor: A Systematic Review and Meta-Analysis

Akhil Sood, Janice Lin and Neha Shah, Stanford University, Palo Alto, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Due to the use of immunosuppressants, patients with rheumatic diseases are at increased risk for Hepatitis B virus (HBV) reactivation. B-cell depleting agents and TNF-α inhibitors are known to be associated with increased risk of HBV reactivation. The risks of other biologic/targeted synthetic DMARDs are not well understood. Both Janus Kinase (JAK) inhibitors and Interleukin-6 (IL-6) inhibitors interfere with the IL-6 pathway, which is critical in the control of underlying HBV infection. We thus conducted a systematic review and meta-analysis on the incidence of HBV reactivation in patients with rheumatoid arthritis receiving JAK inhibitor or IL-6 inhibitor.

Methods: We systematically searched Pubmed/Medline and Embase from January 1, 2010-May 1, 2023, to identify eligible studies that examined Hepatitis B virus (HBV) reactivation among RA patients receiving L-6 inhibitor (Tocilizumab or Sarilumab) or JAK inhibitor (Baricitinib, Tofacitinib, Upadacitinib). Studies with information on RA patients with chronic (HBsAg +/anti-HbcAb+) or previously resolved (HBsAg-/anti-HbcAb+) status were included. Information on medication and interval of monitoring for HBV reactivation were also obtained. Hepatitis B reactivation was defined as > 10-fold increase HBV DNA level from baseline or positive HBV DNA which was previously negative. Meta-analysis was performed using R statistical software.

Results: The meta-analysis included 16 studies comprised of RA patients with previously resolved (n= 547) or chronic (n= 46) HBV infection. The proportion of users of JAK inhibitors among previously resolved HBV infection was 63% (n=362) and chronic HBV was 59% (n=27). Serial monitoring for HBV viral load and liver function tests ranged from every 4 weeks to 6 months. Among those with previously resolved HBV infection, the pooled incidence rate for HBV reactivation was 0.76% [95% CI 0.0017 – 0.0335]. In the subgroup analysis, users of JAK inhibitors showed lower reactivation rate compared to IL-6 inhibitors (0.2% vs 1.9%). Among those with chronic HBV infection, the pooled incidence rate for HBV reactivation was 26% (95% CI 0.14 – 0.44] with lower rate of HBV reactivation among those on JAK inhibitors compared to IL-6 inhibitors (19% vs 37%).

Conclusion: In this systematic review and meta-analysis, the risk of HBV reactivation among RA patients with previously resolved HBV infection was relatively low; however, the risk was higher among HbSAg carriers. In both groups, the use of JAK inhibitors was associated with lower risk of HBV reactivation compared to the use of IL-6 inhibitors. Additional studies with larger cohorts are still necessary to better inform rheumatologists managing these patients with underlying Hepatitis B infection.

Role of *Pneumocystis Jirovecii* Pneumonia Prophylaxis with Trimethoprim-Sulfamethoxazole Among Patients with Autoimmune Inflammatory Diseases Receiving High-Dose Glucocorticoids: A Systematic Review and Meta-Analysis

Athanasios Vassilopoulos[1], Stephanos Vassilopoulos[1], Fadi Shehadeh[2], Markos Kalligeros[1] and Eleftherios Mylonakis[3], [1]Division of Internal Medicine, Warren Alpert Medical School of Brown University, Rhode Island Hospital, Providence, RI, [2]Houston Methodist Research Institute, Houston, TX, [3]Department of Medicine, Houston Methodist Hospital, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Available immunosuppressive treatments for autoimmune inflammatory rheumatic diseases (AIRD) might increase the risk for opportunistic infections, such as *Pneumocystis jirovecii* pneumonia (PJP). Prophylactic trimethoprim-sulfamethoxazole (TMP/SMX) is often prescribed to prevent the occurrence of PJP among patients with AIRD. We calculate the incidence of PJP, PJP-related mortality, and TMP/SMX-related adverse events among patients with AIRD who received a prednisolone dose equivalent of ≥20 mg/day.

Methods: We searched PubMed and EMBASE for multiple-arm studies evaluating the efficacy and safety of TMP/SMX prophylaxis in individuals with AIRD. We stratified different prophylactic dose regimens of TMP/SMX in two groups: a "low-dose" group if the weekly dosage was lower than the equivalent of 400/80 mg/day, and a "standard-dose" group if the weekly dosage was equal or higher than the equivalent of 400/80 mg/day.

Results: Nine studies, performed in Japan, Korea, Thailand, and India, provided data on 1,438 individuals with AIRD receiving TMP/SMX and 1,605 individuals with AIRD not receiving prophylaxis. Studies were published between 2013 and 2021 and participants were followed from 3 to 12 months (77.75% for more than 6 months). At least one TMP/SMX treatment arm (i.e., "standard-dose", "low-dose" or both) was present in any included study. Specifically, eight studies included participants grouped in our "standard-dose" group, 6 studies included participants grouped in our "low-dose" group and 5 studies included participants that received no prophylaxis. The relative risk of PJP was 76% lower (Relative Risk 0.24; 95% CI: 0.07-0.79) among participants who received prophylactic TMP/SMX at any dose, compared to patients who did not receive any prophylaxis. The incidence of PJP for the initial 3-12 months of high-dose glucocorticoid treatment among patients who received no prophylaxis (2.95%, 95% CI: 0.65-6.46%) was significantly higher compared to the incidence of PJP among patients who received "standard-dose" (0.00%, 95% CI: 0.00-0.37%, p-value=0.009) or "low-dose" (0.00%, 95% CI: 0.00-0.04%, p-value=0.003) TMP/SMX. PJP-related mortality was 0.62% (95% CI: 0.00-1.98%) among individuals who

Vananuvat et al. 2011	Retrospective	Thailand	Outpatient /Inpatient	2006-2007	CTD	>3 months	Standard dose	400/80 qd	59
Yamamoto et al. 2014	Prospective	Japan	Inpatient	2009-2011	Multiple	1 year	Standard dose	400/80 qd	18
Yamamoto et al. 2014	Prospective	Japan	Inpatient	2009-2011	Multiple	1 year	Low dose	400/80 biw	17

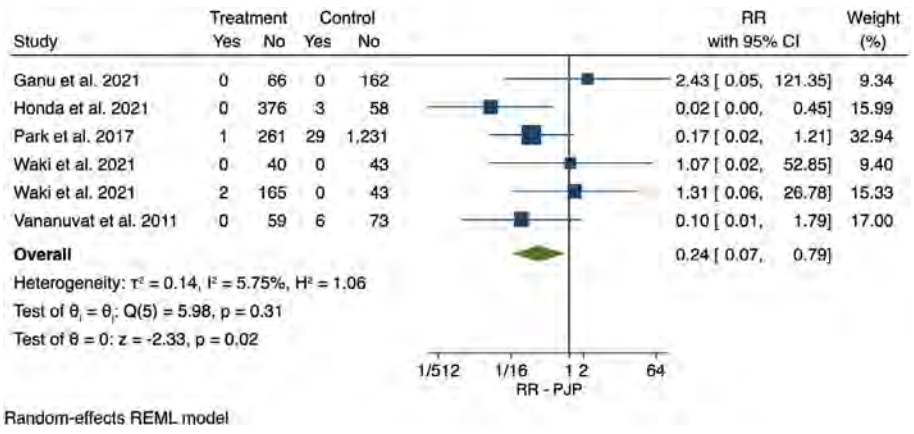

Figure 1.Relative risk of Pneumocystis jirovecii pneumonia among patients receiving trimethoprim-sulfamethoxazole prophylaxis compared to patients not receiving prophylaxis.

received no prophylaxis and 0.00% among patients who received "standard-dose" (95% CI: 0.00-0.06%, p-value=0.073) or "low-dose" TMP/SMX (95% CI: 0.00-0.00%, p-value=0.038). We found the incidence of any TMP/SMX-related adverse event was 23.59% (95% CI: 9.77-40.88%) among patients who received "standard-dose" TMP/SMX and 24.06% (95% CI: 11.90-38.63%) among patients who received "low-dose" TMP/SMX, a non-significant difference (p-value=0.946).

Conclusion: Among individuals with AIRD who were included in studies evaluating the use of prophylactic TMP/SMX, the risk for PJP was lower among participants who received TMP/SMX compared to participants who did not receive prophylaxis. The rate of TMP/SMX-related adverse events did not differ among the low-dose and standard-dose TMP/SMX subgroups. Clinical trials evaluating the efficacy and safety of different prophylactic TMP/SMX dose regimens with long term follow-up are needed to study TMP/SMX utility for preventing PJP among patients with AIRD.

Abstract Number: 0208

Pneumocystis Jirovecii Pneumonia (PJP) Prophylaxis (PPX), Investigating the Practice Patterns of Providers for Patients on Chronic, High-Dose Immunosuppression in a Rural Integrated Health System

Angela Bobak[1], Emely Pimentel[1], Jordan Jackson[2], Celia Gray[3], Hema Srinivasan[3], Andrea Berger[3] and David Bulbin[3], [1]Geisinger Medical Center Internal Medicine Residency, Danville, PA, [2]Geisinger Medical Center Medicine-Pediatrics Residency, Danville, PA, [3]Geisinger Health System, Danville, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: PJP is an opportunistic fungus causing significant morbidity and mortality in immunocompromised patients. Guidelines describe PJP PPX indications among non-HIV infected individuals with cancer and solid organ transplant; however, this is lacking for individuals with rheumatic diseases requiring immunosuppression. General consensus reveals PJP PPX should be considered in patients receiving medication associated with lymphodepletion, likely to cause defects in cell-mediated immunity. Examples include prednisone 20mg or greater, monoclonal antibodies (anti-CD52 alemtuzumab and anti-CD20 rituximab), alkylating agents (cyclophosphamide), and checkpoint inhibitors (pembrolizumab, nivolumab, durvalumab). We conducted a restrospective analysis investigating the percentage of patients, within our rural system, who received appropriate PJP PPX when on immunosuppression and if discrepancies exist among specialties. We aim to determine the incidence of PJP and if PPX causes a reduction in infection risk.

Methods: A retrospective chart review of the electronic medical record was performed for adult patients from 2016-2021 prescribed immunosuppression in the form of prednisone ≥ 20mg for at least 4 weeks or any duration of alemtuzumab, cyclophosphamide, durvalumab, nivolumab, pembrolizumab, and rituximab. Prescribers within rheumatology, hematology/oncology, neurology, pulmonology, dermatology, nephrology, and gastroenterology were included. Exclusion criteria included HIV, solid organ transplant, and active cancer. Forms of PJP PPX included TMP/SMX, atovaquone, dapsone, or inhaled pentamidine. PJP diagnosis was included if occurred within one year of immunosuppression. A chi-square test

Table 1. The proportion of patients with PPX prescriptions did differ by department (chi-square test: p < .0001). Rheumatology had the highest proportion (32.2%), followed by hematology/oncology (19.7%) and neurology (1.8%). The grouping designated "other" consisted of small sample size specialties including nephrology (n = 11), dermatology (n = 3), and unspecified.

	Hematology/Oncology (N = 66)	Neurology (N = 113)	Rheumatology (N = 118)	Other (N = 18)	Total (N = 315)	P-value
PVP prophylaxis prescribed, n (%)						<.0001
No	53 (80.3%)	111 (98.2%)	80 (67.8%)	8 (44.4%)	252 (80.0%)	
Yes	13 (19.7%)	2 (1.8%)	38 (32.2%)	10 (55.6%)	63 (20.0%)	

Table 2. This table consists of the pairwise odds ratio estimates and their 95% confidence intervals from a logistic regression model with PPX prescription as the outcome and department as the predictor. Rheumatology prescribed PPX significantly more than neurology, but rheumatology did not have significantly increased PPX rates compared with hematology/oncology or the "other" category. All departments prescribed PPX more frequenly than neurology.

	Odds Ratio	95% CI	P-Value
Hematology/Oncology vs Neurology	13.61	(2.97, 62.50)	0.0008
Other vs Neurology	69.37	(12.94, 371.88)	< .0001
Rheumatology vs Neurology	26.36	(6.18, 112.45)	< .0001
Other vs Hematology/Oncology	5.10	(1.68, 15.47)	0.0040
Rheumatology vs Hematology/Oncology	1.94	(0.94, 3.98)	0.0716
Other vs Rheumatology	2.63	(0.96, 7.20)	0.0596

and logistic regression model were used to compare PPX prescriptions by department. Odds ratio and 95% confidence intervals are reported.

Results: We identified a cohort of 16,500 individual patients with 52,409 prescription encounters. Two PJP cases occurred in individuals not on PPX but prescribed the following: (rituximab and prednisone 40mg) and (rituximab and prednisone 80mg). Initial review of alemtuzumab, cyclophosphamide, durvalumab, nivolumab, pembrolizumab, and rituximab produced 315 patients and 2,508 prescription encounters with 20% of patients receiving PPX. The proportion of patients prescribed PPX differed by department (p < .0001) with the following: rheumatology 32.2%, hematology/oncology 19.7%, and neurology 1.8%. Pairwise odds ratio estimates and 95% confidence intervals from a logistic regression model demonstrated that rheumatology prescribed PPX significantly more than neurology (odds ratio, 26.36 [95% CI, 6.18-112.45], p < .0001). Review of prednisone prescription encounters is still ongoing, with percentage of appropriate PPX and risk reduction analysis to be included at final presentation.

Conclusion: PJP carries significant morbidity and mortality for patients on immunosuppression; however, PPX is highly underutilized in our rural health care system. Further investigation is needed to identify factors leading to low PPX rates and determining the incidence and severity of adverse effects from PPX, as these often influence prescriber practices.

Munthe[5], Siri Mjaaland[6], John Torgils Vaage[5], Espen Haavardsholm[1], Kristin Kaasen Jørgensen[2], Sella Provan[7], Silje Watterdal Syversen[1] and Guro Goll[1], [1]Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Oslo, Norway, [2]Department of Gastroenterology, Akershus University Hospital, Oslo, Norway, [3]Department of Microbiology, Oslo University Hospital, Oslo, Norway, [4]Department of Immunology, Oslo University Hospital, Oslo, Norway, [5]Department of Immunology, Oslo University Hospital, Oslo, Norway, [6]Norwegian Institute of Public Health, Oslo, Norway, [7]Diakonhjemmet Hospital, Oslo, Norway

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Safety and efficacy of updated bivalent vaccines, containing both the original vaccine variant of SARS-CoV-2 Spike and either Omicron variants BA.1 or BA.4/5, are of particular interest in arthritis patients on immunosuppressive therapies. With the continuous emergence of new viral variants, it is important to evaluate whether updated vaccines induce more adverse events in this patient group. The objective of this study was examine if a second booster dose with updated bivalent vaccine increases the risk of adverse events, compared to the first booster dose with monovalent vaccines.

Methods: The prospective Nor-vaC study investigates vaccine responses in patients with immune mediated inflammatory diseases using immunosuppressive therapies (1). The present analyses included arthritis patients who received two booster doses. Patients received available vaccines according to the Norwegian vaccination program. The current recommendation

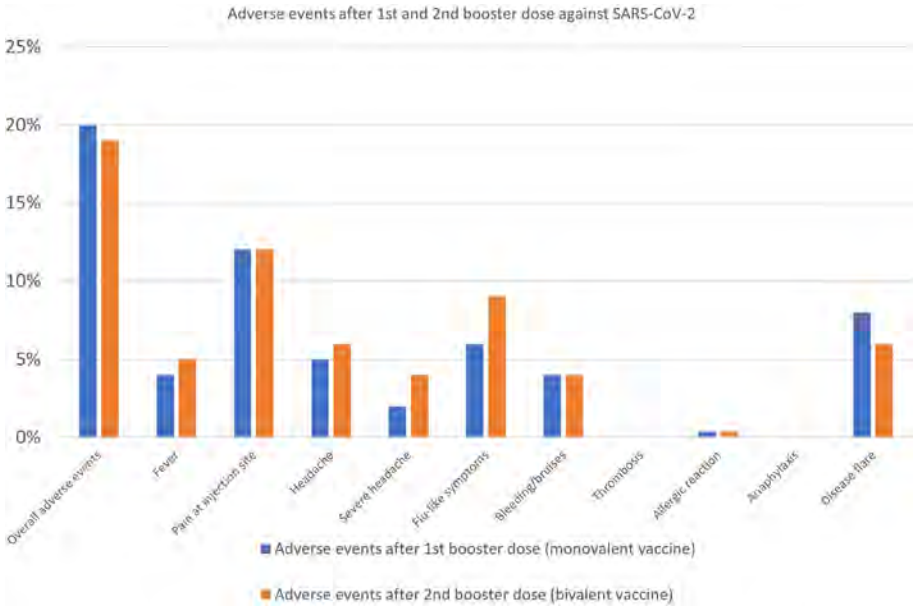

Figure: Adverse events after bivalent vaccine as a 2nd booster dose compared to a monovalent vaccine as a 1st booster dose.

in the Norwegian arthritis population is a three-dose primary vaccination series followed by two booster doses. Adverse events following vaccines doses were self-reported through questionnaires. Adverse events following the first (monovalent) and second (bivalent) booster were compared with McNemar's test.

Results: Between 7th of July 2021 and 6th of December 2022 a total of 243 arthritis patients (127 rheumatoid arthritis, 65 psoriatic arthritis, 51 spondyloarthritis) on immunosuppressive therapies (Table) received a first, monovalent (BNT162b2, mRNA-1273) and a second, bivalent booster dose (BNT162b2 (WT/OMI BA.1), mRNA-1273.214, BNT162b2 (WT/OMI BA.4/BA.5)). Adverse events were recorded within two weeks in all patients (Figure). In total, 45 vs 49 (19% vs 20 %) patients reported any adverse event after a second, bivalent booster dose, compared to the first, monovalent booster, respectively. There was no significant difference in adverse events overall (p= 0.57). The most common adverse events after the second booster were pain at injection site (12 %), flu-like symptoms (9 %) and headache (6 %). No new safety signals emerged. A total of 15 (6 %) patients reported a disease flare after receiving the second, bivalent booster, compared to 21 (8 %) after the first, monovalent booster.

Table: Demographic characteristics and immunosuppressive medication in patients receiving a 1st monovalent and a 2nd bivalent booster dose.

BNT162b2 (WT/OMI BA.4/BA.5)	120 (47)
mRNA-1273.214 (WT/OMI BA.1)	58 (23)

Results in n (%) unless otherwise specified.
[a]Tumor necrosis factor inhibitors: infliximab, etanercept, adalimumab, golimumab, certolizumab pegol.
[b]Combination therapy: methotrexate, sulfasalazine, leflunomide, azathioprine.
[c]Interleukin inhibitors: tocilizumab, secukinumab.
[d]Janus kinase inhibitors: filgotinib, baricitinib, upadacitinib, tofacitinib.
[e]Other: abatacept, sulfasalazine, leflunomide, azathioprine.

Conclusion: There was no difference in adverse events between the monovalent, first booster, and the bivalent, second booster, indicating that bivalent vaccines are safe in this patient group.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: T cells are critical for control of viral infection with SARS-CoV-2, but knowledge is lacking on cellular immune responses following repeated vaccination and breakthrough infection in immunosuppressed patients. The objective was to examine longitudinal T cell responses across diagnoses, following vaccine series and COVID-19 in patients on tumor necrosis factor inhibitors (TNFi).

Methods: The prospective, observational Nor-vaC study included patients with arthritis (spondyloarthritis, rheumatoid arthritis, psoriatic arthritis) or inflammatory bowel disease (IBD) (ulcerative colitis, Crohns disease) on immunosuppressive therapies. Here, we included patients on TNFi mono- or combination therapy immunised with up to four SARS-CoV-2 vaccine doses with or without breakthrough infection, collecting peripheral blood mononuclear cells (PBMCs) 2-4 weeks after each immunisation. Samples were incubated with SARS-CoV-2 spike, nucleocapside or membrane peptides. The percentage of responding T cells was measured by flow cytometry.

Results: Between February 2021 and December 2022, 144 patients on TNFi (monotherapy n=86 (60%), combination with methotrexate or azathioprine n=58 (40%)) were included (median age 48 years [IQR 33-57]; 51% women) (Table).

The proportions of arthritis vs IBD patients with CD4 responses after 2 vaccine doses were 75% (12/16 patients) vs 86% (25/29), and after 3 doses 83% (10/12) vs 93% (28/30). In total, 80% (4/5) of arthritis patients showed further increases in CD4 responses after a 4th vaccine dose.

Conversely, 81% (13/16) of arthritis patients vs. 55% (16/29) of IBD patients had CD8 T cell responses after two doses, and 67% (8/12) vs. 62% (18/29) after three doses. A 3rd and 4th dose induced higher CD8 responses compared to the previous dose in 55% (6/11) and 100% (5/5) of arthritis patients.

Arthritis patients had lower T cell responses than IBD patients after the 3rd dose; median CD4 response 0.024% [IQR 0.009-0.036] vs 0.098% [IQR 0.040-0.182], p=0.0004; median CD8 response 0.003% [IQR 0.001-0.016] vs 0.044% [IQR 0.009-0.140], p=0.0032 (Figure). This difference remained robust after adjusting for age and sex, p< 0.001, but was no longer detected after the 4th vaccine dose.

Breakthrough infection elicited increased T cell responses across all diagnoses to spike (p< 0.0001), and to nucleocapsid (p=0.002) and membrane proteins (p=0.001) compared to unstimulated T cells.

Also, Spike-specific T cell responses increased compared to the 3rd dose (median CD4 T cell response 0.18% vs. 0.06%, p=0.003; CD8 T cell response 0.08% vs. 0.01%, p< 0.0001), but to a lesser extent compared to the 4th dose (median CD4 response 0.18% vs. 0.12%, p=0.05; CD8 response 0.08% vs. 0.05%, p=0.26).

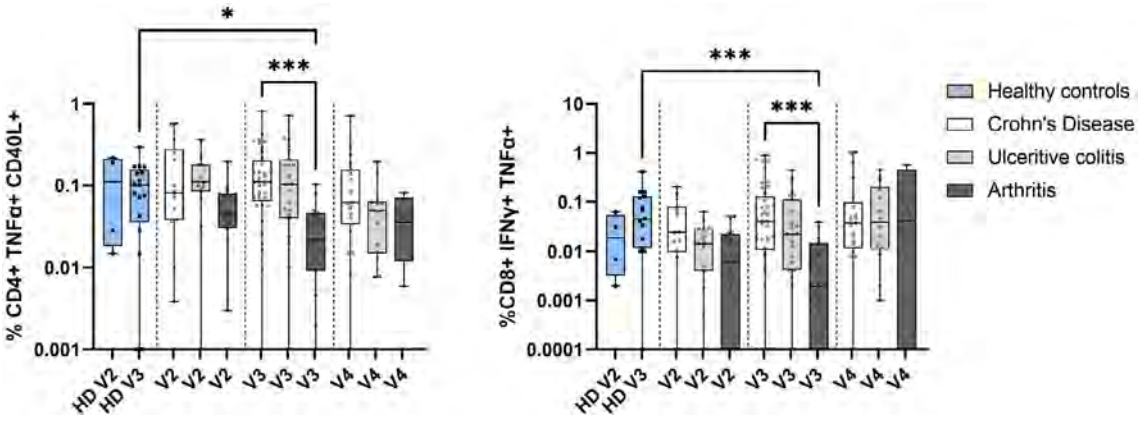

Figure: CD4- and CD8-responses in patients and healthy controls.

Table: Characteristics of patients providing T-cells after vaccine doses and after COVID-19.

Disease, n (%)	Patients in total[a] (n=144)	Two vaccines (n=49)	Three vaccines (n=86)	Four vaccines (n=44)	Hybrid immunity[b] (n=62)
Rheumatoid arthritis (RA)	9 (6)	5 (10)	7 (8)	2 (5)	3 (5)
Spondyloarthritis (SpA)	13 (9)	10 (20)	10 (12)	2 (5)	2 (3)
Psoriatic arthritis (PsA)	3 (2)	2 (4)	2 (2)	1 (2)	0
Crohns disease (CD)	73 (51)	18 (37)	44 (51)	27 (61)	31 (50)
Ulcerative colitis (UC)	46 (32)	14 (29)	23 (27)	12 (27)	26 (42)

[a]Sampled at minimum one timepoint

[b]3 or 4 vaccine doses, followed by COVID-19

Conclusion: Patients on TNFi show improved cellular responses following each immunisation, with infection generating a strong and broad T cell response. Arthritis patients had significantly lower cellular responses compared to IBD patients after three vaccine doses, but with no difference after the 4th dose. These results support giving a 4th vaccine dose to TNFi-treated patients, with particular benefit for arthritis patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with immune-mediated inflammatory diseases (IMIDs) on immunosuppressive therapies have attenuated vaccine responses and are prone to severe infections. Knowledge of COVID-19 outcome following vaccine and hybrid immunity, and identification of protective anti-Spike antibody concentrations are important to further develop vaccine strategies in this vulnerable patient group. The objectives of this study were to investigate the outcomes of COVID-19 in a large cohort of IMID patients compared to healthy controls, and in association to anti-Spike antibody concentrations and vaccine status.

Methods: In this prospective observational study, adult patients with IMID on immunosuppressive therapies were followed from February 15., 2021, to February 15., 2023. Throughout the study, patients and controls reported data regarding COVID-19 through questionnairs. COVID-19 related hospital admissions were recorded from The Norwegian Patient Registry. Anti-Spike antibodies were assessed 2-4 weeks following vaccination and COVID-19.

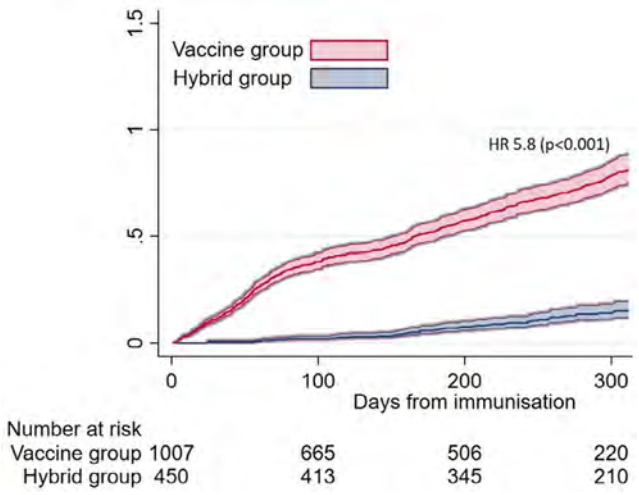

Figure: Cumulative hazards of COVID-19 in Vaccine group (four vaccine doses) vs Hybrid group (three vaccine doses plus COVID-19).

Results: A total of 1729 IMID patients with a documented COVID-19 history were included in the present analyses. 1140 (66%) of patients and 236 of 350 (67%) healthy controls (HC) reported COVID-19,the majority (85%) within the Omicron era. COVID-19 reinfection was reported in in 141 (12%) patients and 32 (14%) HC (p=0.66).

Compared to hybrid immunity (COVID-19 after a 3rd dose), the risk of COVID-19 was six times higher following vaccine series only (HR 5.8 (95% CI [4.4, 7.7]), p< 0.001) (Figure). Anti-Spike antibody concentrations < 6000 BAU/ml were predictive of COVID-19 after three (HR 1.4 (95% CI [1.1, 1.74]), p=0.01) and four vaccine doses (HR 1.3 (95% CI [1.02, 1.6]), p=0.04) and in hybrid immunity (HR 4.5 (95% CI [1·9, 10·7]), p=0.001).

In the entire cohort, the median anti-Spike antibody concentration after the 2nd vaccine dose was 2114 BAU/ml (732, 5749), after the 3rd dose 5897 BAU/ml (1939, 9761), after the 4th dose 7924 BAU/ml (3785, 15049) and following hybrid immunity 23505 BAU/ml (11423, 37007).

Hospitalisation due to COVID-19 (severe disease) occurred in 22 (2%) patients, (9 (41%) before any vaccination) and no HC. Four patients were admitted to intensive care. Prior to hospitalisation, the median anti-Spike antibody concentration was 444 BAU/ml (IQR 31-1634). Hospitalised patients with severe disease were older than non-hospitalised (median age 61 years (IQR 48-74) vs. 54 (42-64), p=0.04) and had a higher frequency of comorbidities (19/22 (86%) vs. 474/1118 (42%), p=0.02). No COVID-19 related deaths occurred.

Prolonged COVID-19 (symptoms >14 days) were reported by201 (18%) patients compared to 29 (12%) HC (p=0.05). The risk of prolonged disease was higher in the vaccine group compared to the hybrid group (HR 10.7 (95 % CI [4.8, 23.8]) p< 0.001)

Conclusion: IMID patients and healthy controls had a comparable occurrence of COVID-19, prolonged disease and reinfection. However, severe disease developed only in the patient group. Hybrid immunity protects against COVID-19 and prolonged disease. A high anti-Spike antibody concentration protects against COVID-19, supporting the role of repeated vaccination in IMID patients on immunosuppressive therapy.

Abstract Number: 0212

The Impact of Immunosuppression on the Humoral Immunogenicity of SARS-CoV-2 mRNA Vaccines in SLE

Rebecca Sadun[1], Dan Crair[2], Emmanuel B Walter[3], Jennifer Rogers[1], Megan Clowse[4], Amanda Eudy[5], Kai Sun[1], Jayanth Doss[1], Lisa Criscione-Schreiber[6], Sarah Valencia[2] and M. Anthony Moody[6], [1]Duke University, Durham, NC, [2]Duke Human Vaccine Institute, Durham, NC, [3]Duke Human Vaccine Institute, Duke University School of Medicine, Durham, NC, [4]Duke University, Chapel Hill, NC, [5]Duke University, Raleigh, NC, [6]Duke University School of Medicine, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The ACR's COVID-19 Vaccine Guidance recommends all patients with rheumatic diagnoses be vaccinated against SARS-CoV-2. The predominant SARS-CoV-2 vaccines used in the United States are based on mRNA technology. Little is known about the immunogenicity of the SARS-CoV-2 mRNA vaccines in patients with SLE, many of whom are on immune suppressing medications. This study sought to determine the humoral immunogenicity of two doses of the SARS-CoV-2 mRNA vaccines made by Moderna and Pfizer/BioNTech in SLE patients, stratified by immunosuppression.

Methods: We obtained biobanked serum from SLE patients and healthy control patients whose blood was drawn 14-180 days following dose #2 of a SARS-CoV-2 mRNA vaccine. ELISA was performed using anti-wild-type spike protein ectodomain S1+S2. Area under the curve (AUC) was calculated for each individual. An AUC threshold of 2.0 was established to distinguish between responders and non-responders (Figure 1).

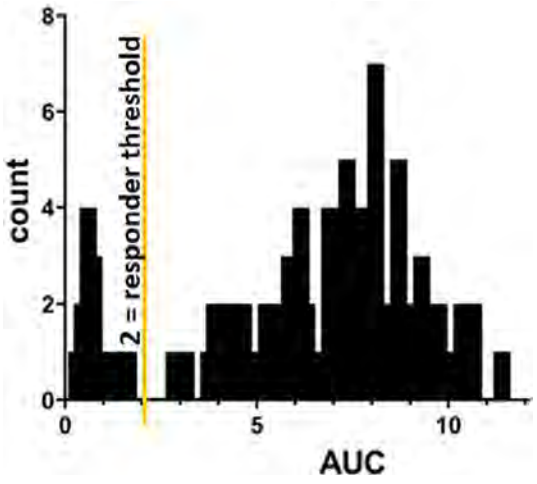

Figure 1. Histogram depicting the distribution of anti-spike antibody areas under the curve (AUC) in SLE patients (n=87), which formed the basis for establishing the responder threshold of 2.0, at which 13 SLE patients (15%) were determined to be non-responsive.

Results: Of the SLE patients (n=87), 23 (26%) were on no SLE therapy or HCQ monotherapy, 44 (51%) were on a DMARD and ≤7.5mg of prednisone, and 20 (23%) patients were on a biologic (rituximab=3, belimumab=11) and/or high-dose prednisone. Figure 2 depicts concomitant use of DMARDs and belimumab. As summarized in Table 1, the AUC for SLE patients was not significantly lower than for healthy controls (n=12): median AUC of 7.09 (range 0.34-11.45) versus 7.30 (range 5.89-8.65). The median AUC for SLE patients on no lupus medications or hydroxychloroquine monotherapy was 7.44 (range 0.34-10.52), with only one patient (4%) being classified as a non-responder. Ten (23%) of the SLE patients on DMARDs were non-responders, with mycophenolate and methotrexate having the biggest impact on AUC: seven (35%) of the patients on mycophenolate were non-responders (AUC median = 5.31; p=0.008), and 30% of the patients on methotrexate were non-responders (AUC median = 7.28; p=0.31). Three (15%) of the SLE patients on biologics and/or high-dose prednisone were non-responders, including two of the 11 belimumab patients (18%), one of whom was on concomitant

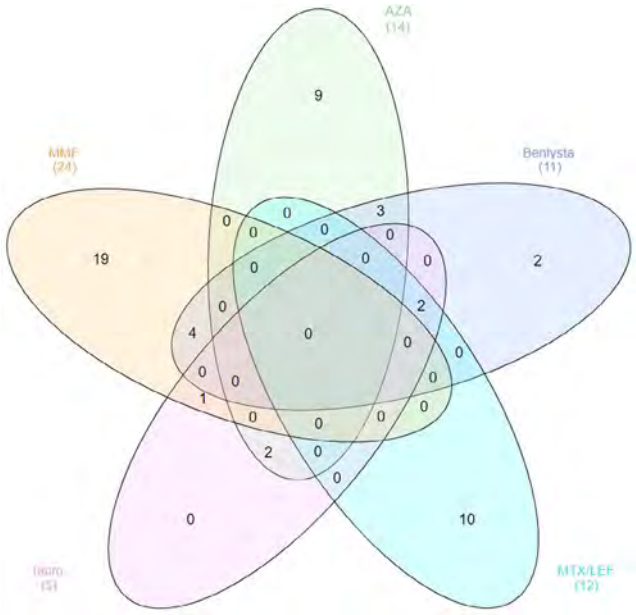

Figure 2. Concomitant use of belimumab (Benlysta) and DMARDs (AZA=azathioprine; LEF=leflunomide; MTX=methotrexate, MMF=mycophenolate; Tacro=tacrolimus).

Table 1. Serologic responses, quantified as areas under the curve (AUC) for healthy controls, patients on insignificant immunosuppression (HCQ group encompasses patients on no medication or hydroxychloroquine monotherapy), and patients on a variety of immune suppressing medications (MMF=mycophenolate; MTX=methotrexate (n=9) and leflunomide (n=1); AZA=azathioprine; RTX=rituximab). Many of the patients on belimumab were also on >10 mg of prednisone daily. P-values were calculated in reference to the HCQ group.

	Healthy Controls (n=12)	All SLE (n=87)	HCQ (n=23)	MMF (n=20)	MTX (n=10)	AZA (n=10)	Belimumab (n=11)	RTX (n=3)
Non-Responders	0 (0%)	13 (15%)	1 (4%)	7 (35%)	3 (30%)	0 (0%)	2 (18%)	0 (0%)
AUC Mean	7.71	6.23	6.99	4.80	5.89	6.67	5.77	4.68
AUC Median	7.30	7.09	7.44	5.31	7.28	6.14	6.10	4.67
AUC Range	5.89-8.65	0.34-11.45	0.34-10.52	0.50-10.34	0.44-11.45	3.09-9.65	0.51-8.35	3.73-5.65
AUC StDev	1.03	2.90	2.22	3.32	3.95	2.15	2.34	0.96
p-value (HCQ=ref)	0.35	0.08	n/a	**0.008**	0.31	0.70	0.16	0.09

mycophenolate, and the other on high-dose prednisone (20 mg daily). All three rituximab patients were classified as responders, although the median AUC (4.67) and mean AUC (4.68) were the lowest of any medication (range 3.73-5.65). The number of days between dose #2 and serum sample collection did not correlate with AUCs: the 13 non-responders were on average 66 days out from dose #2, whereas responders were on average 80 days out from dose #2.

Conclusion: SLE patients on certain immune suppressing medications, most notably mycophenolate, produce less SARS-CoV-2 anti-spike antibodies after receiving two doses of an mRNA vaccine. Neutralization assays and cell-based studies are necessary to understand the full picture of vaccine immunogenicity in SLE; nevertheless, decreased serologic response in SLE patients on certain medications should prompt studies exploring whether holding medications like mycophenolate will enhance the immunogenicity of SARS-CoV-2 and other vaccines.

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Breakthrough COVID-19 infections are still a risk after vaccination and may be more common in patients with immune-mediated inflammatory diseases (IMIDs) than in the general population. Previous studies on breakthrough infections in IMID relied on retrospective databases; however, these are subject to limitations on COVID-19 test availability, making it hard to determine true infection prevalence as asymptomatic cases may have gone untested. We performed active surveillance of breakthrough COVID-19 infections, analyzing saliva samples via quantitative polymerase chain reaction (qPCR) in vaccinated individuals with IMIDs (systemic lupus erythematosus, rheumatic arthritis, psoriatic arthritis, spondylarthritis, inflammatory bowel disease, and scleroderma).

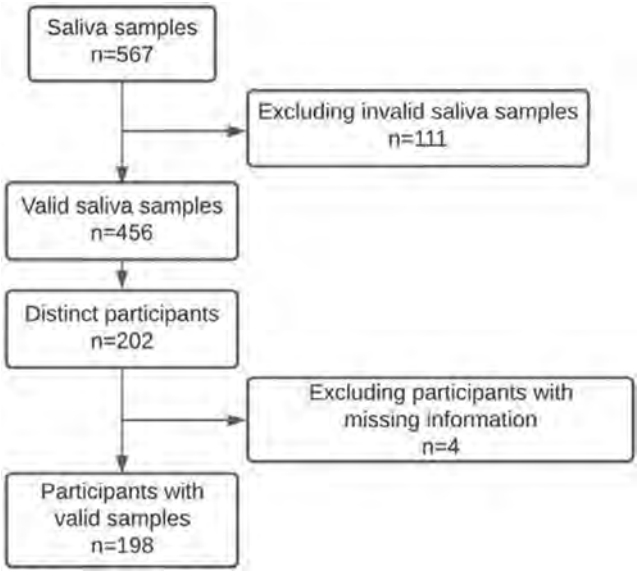

Figure 1. Participants and samples

[1] Immunosuppressive medications, including: Methotrexate, Leflunomide, Azathioprine, Mycophenolates, Cyclophosphamide, Cyclosporine, Adalimumab, Certolizumab, Etanercept, Golimumab, Infliximab, Rituximab, Abatacept, Anakinra, Secukinumab, Tocilizumab, Tofacitinib, Ustekinumab, Glucocorticoids
Patients with missing values for a medication were considered to not use it.

Methods: Adults with IMID were recruited from Canadian clinics and registries between September 2022 and March 2023 and asked to self-collect saliva samples monthly. Samples underwent batch qPCR testing, with each sample being tested twice, to qualitatively detect SARS-CoV-2 nucleic acids indicators (N1 and N2).

Results: To date, 202 patients have been enrolled, providing 458 valid samples (Fig. 1, Table 1). Most (66.2%) were on immunomodulatory medications, and the majority (78.8%) had received 3 or more vaccine doses. Only 5% of participants (n=10/202) met the N1 and N2 thresholds required to confirm COVID-19 positivity. Given the small number of positive results, we were unable to ascertain significant differences between demographic factors, including age, sex, immunosuppression, or vaccination status. However, participants who tested positive had a median time since their last vaccination that was considerably longer (278 days) than those who tested negative (165 days) (95% CI for difference,18-205). The majority (three-quarters) of positive saliva samples occurred in patients who were beyond 217 days of their last vaccine.

Conclusion: A 5% COVID-19 breakthrough infection rate aligns with a Canadian population-based cohort where breakthrough infections occurred in 5.4%-6.5% of fully vaccinated IMID patients (1). In our sample, those with breakthrough infections had a longer median time since vaccination (by 112 days), corroborating the currently held belief that protection against COVID wanes in the 3-4 months post-vaccination and beyond. Most infections occurred 7-8 months after the last vaccine dose. These findings will help patients, clinicians, and other stakeholders with decision-making in 2023-2024 and beyond.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19 vaccine uptake in autoimmune and inflammatory rheumatic disease (AIIRD) patients is an area of concern to rheumatologists and other providers. These patients are at a greater risk of infection and COVID-19-related complications due to underlying conditions and therapies. The purpose was to ascertain COVID-19 vaccine and booster uptake, reasons for hesitancy, and self-reported flare in a large rheumatology practice-based network (PBRN).

Methods: A tablet-based survey was deployed as part of routine care in 104 rheumatology practices who were members of the Excellence Network in RheumatoloGY (ENRGY) PBRN during 12/2021- 12/2022. Patients were asked about COVID-19 vaccine status and why they might not receive a vaccine or booster. Patients reporting no vaccine receipt were asked additional questions about why they did not receive the vaccine and were categorized as vaccine-hesitant. Receipt of the primary series of vaccines and a response of "not planning to" or "not sure "when asked about getting additional vaccine or booster doses defined booster-hesitant patients. We used descriptive statistics to explore the differences between vaccination status and vaccine/booster hesitancy, comparing AIIRD to non-AIIRD patients. We used multivariable logistic regression to estimate adjusted odds ratios (aOR) with confidence intervals (CI), examining the association between vaccine uptake and AIIRD status, and self-reported flare/disease worsening and AIIRD status.

Results: Of 61,158 respondents (99.9% completion rate), 89% reported at least one dose of vaccine; of the vaccinated, 68% reported at least one booster (Table 1). AIIRD patients were 32% less likely to receive a vaccine (aOR: 0.68; 95% CI: 0.65, 0.72) and 10% less likely to receive a booster (aOR: 0.90; 95% CI: 0.87, 0.94) versus non-AIIRD patients (Table 2).

Table 1: Characteristics of rheumatology patients and most recent COVID-19 vaccine status

Table 3: Reasons for primary series COVID-19 vaccine hesitancy (n=13950*) and booster hesitancy (n=21164†) among study participants

	Vaccine hesitancy 13950*	Booster hesitancy 21164†
There isn't enough long-term safety data on the COVID-19 vaccine or booster	3933 (28.2)	2426 (11.5)
I am concerned about side effects	3216 (23.1)	3674 (17.4)
I am concerned a COVID-19 vaccine will cause a flare of my health condition	2274 (16.3)	2193 (10.4)
I plan to wait and see if the COVID-19 vaccines and boosters are safe	1648 (11.8)	2334 (11.0)
I do plan to get the COVID-19 vaccine	1023 (7.3)	-
The COVID-19 vaccine or booster may not be effective for people like me	632 (4.5)	559 (2.6)
The vaccine could give me COVID-19 infection	445 (3.2)	-
I have not been told by my doctor when to get a dose or an additional dose of the COVID-19 vaccine	295 (2.1)	4926 (23.3)
I don't believe I need a vaccine or another dose of the COVID-19 vaccine	237 (1.7)	3497 (16.5)
I don't trust COVID-19 vaccines	209 (1.5)	-
I am concerned that the COVID-19 vaccine could modify my DNA	23 (0.2)	-
I am concerned the COVID vaccine might affect me being able to have healthy children	15 (0.1)	-
I had a bad reaction to the COVID-19 vaccine	-	1555 (7.4)

*Patients could answer with more than one response and some patients answered the question multiple times. The number of vaccine-hesitant patients is 7341. Vaccine hesitancy response choices were updated throughout the study.
†Patients could answer with more than one response. The number of booster-hesitant patients is 11058.

A greater proportion of AIIRD patients were vaccine-hesitant (14% vs. 10%; p< 0.0001) and booster-hesitant (21% vs. 16%; p< 0.0001) compared to non-AIIRD patients. Among those who were vaccine hesitant (n=7,341), safety concerns (28%) and side effects (23%) were the main reasons for vaccine hesitancy, while among those who were booster hesitant (n=11,058), lack of recommendation from the physician was the primary factor for booster hesitancy (23%) (Table 3). Of those who received a vaccination, 23% of patients reported experiencing symptoms consistent with reactogenicity or a flare/disease worsening following their most recent vaccination. AIIRD patients did not have increased odds of self-reported flare/worsening disease compared to non-AIIRD patients (aOR: 0.99; 95% CI: 0.94, 1.05). Among the vaccine-hesitant and booster-hesitant, 12% and 39% later reported receiving a respective dose.

Conclusion: A meaningful proportion of vaccine- and booster-hesitant patients eventually received vaccination or booster doses, suggesting that future interventions tailored to AIIRD patients to encourage vaccination or booster use may be fruitful.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Infection-related Rheumatic Disease Poster

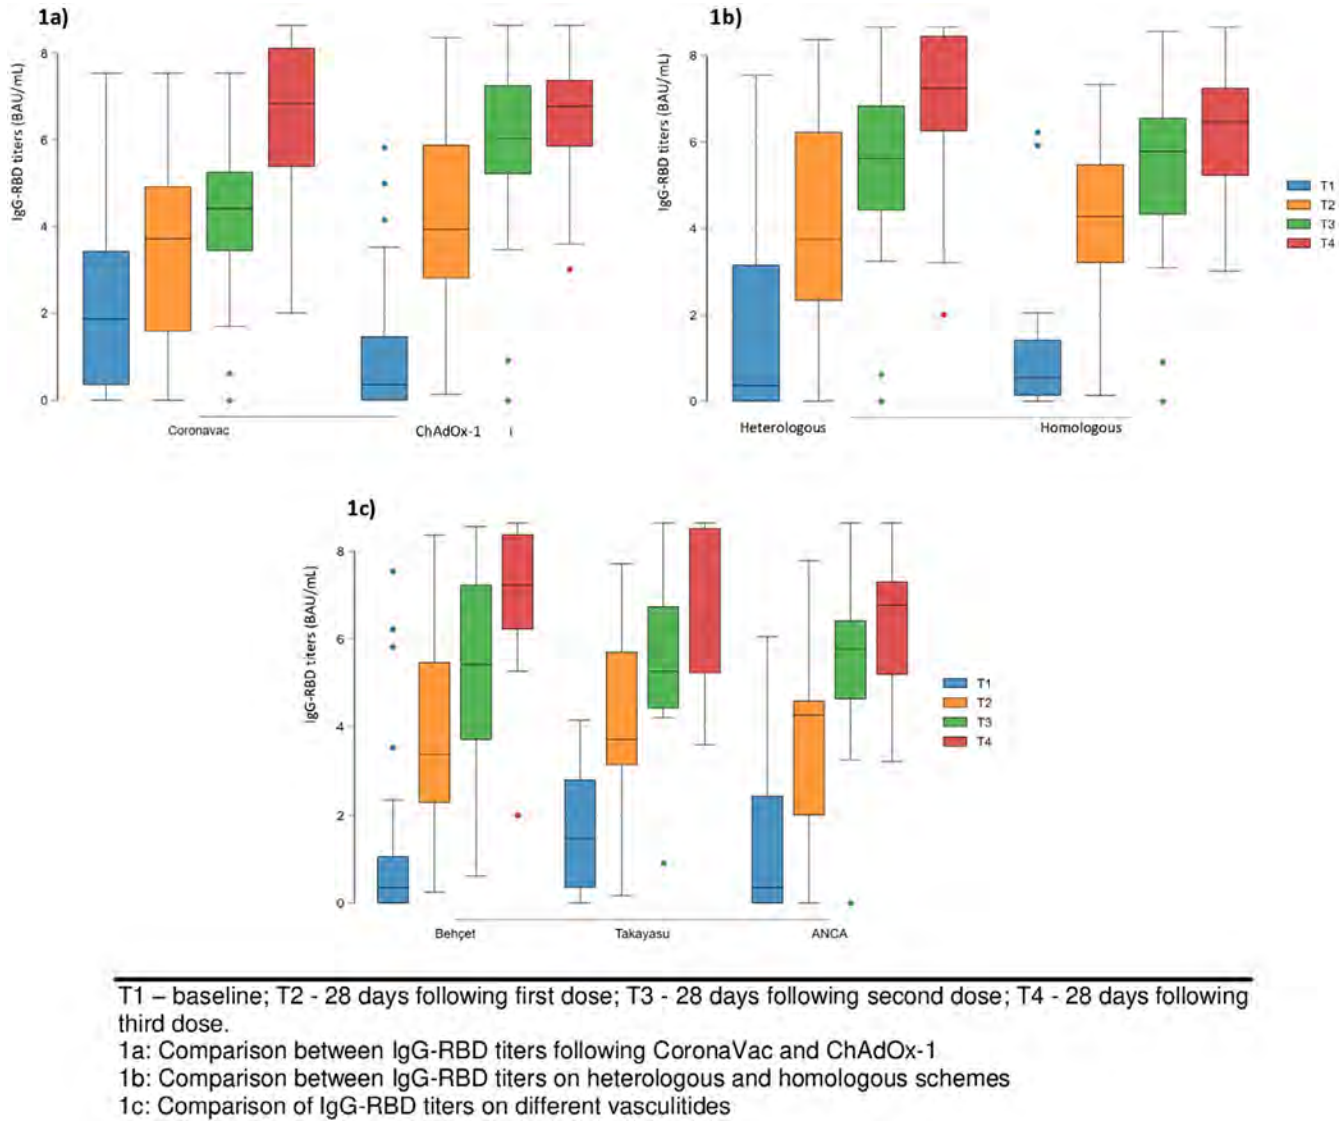
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Vaccine platforms, number of doses, and immunosuppressive drugs can influence the immunogenicity after SARS-CoV-2 vaccination in individuals with immune-mediated rheumatic diseases. Considering the heterogeneity of systemic vasculitides and their phenotypic variations according to geographic localization, there is still limited data about the immunogenic response in this population, with most studies focusing on homologous vaccine platforms. Furthermore, concerns regarding vaccine-induced vasculitides and potential disease relapse have affected vaccine hesitancy in these patients. This study evaluated the effectiveness of three doses (booster dose) of SARS-CoV-2 vaccines and the occurrence of disease relapse in systemic vasculitides.

Methods: We enrolled 99 patients with systemic vasculitides in a Brazilian multicentric prospective cohort, a subgroup of the SAFER study (Safety and Efficacy on COVID-19 Vaccine in Rheumatic Disease). All patients met international classification/diagnostic criteria for their respective diseases. Studied vaccines were inactivated SARS-CoV-2 (CoronaVac), adenoviral vectored (ChAdOx1/AstraZeneca and Ad26.COV2-S/Janssen), and mRNA (BNT162b2/Pfizer–BioNTech). The measurement of serum IgG levels against SARS-CoV-2 spike protein receptor-binding domain (IgG-RBD) using a chemiluminescence test (Abbott-Laboratories, IgG II Quant assay) assessed the immunogenicity. We collected serum samples at baseline and 28 days after each vaccine dose, with simultaneous assessment of disease activity scores, COVID-19 infections, and adverse events.

Results: Seventy-four patients received a single vaccine dose, 65 received two doses, and 59 completed the full vaccination regimen. Most patients received ChAdOx-1 (n = 36) or CoronaVac (n = 25) for the first two doses. The most administered booster dose was Pfizer–BioNTech. Behçet's disease (BD), Takayasu arteritis, and antineutrophil cytoplasmic antibody (ANCA) associated vasculitis were the most frequent diagnosis in this cohort. Up to 49% of the patients had no comorbidities. Notably, none of the patients received Rituximab at baseline. ChadOx-1 achieved higher antibody titers than CoronaVac after two doses (p=0.002), but this difference disappeared after the booster dose (Table 1). Seropositivity rates tended to be higher in the heterologous vaccine group compared to the homologous three-dose scheme (Table 1). Immunogenicity was similar across different forms of vasculitis (Figure 1-c). No increase in disease relapse rates was observed in any form of vasculitis. No severe relapses or serious adverse events were reported.



T1 – baseline; T2 - 28 days following first dose; T3 - 28 days following second dose; T4 - 28 days following third dose.
1a: Comparison between IgG-RBD titers following CoronaVac and ChAdOx-1
1b: Comparison between IgG-RBD titers on heterologous and homologous schemes
1c: Comparison of IgG-RBD titers on different vasculitides

Figure 1. Serum IgG-RBD geometric means at baseline and following each vaccine dose (BAU/mL)

Conclusion: In this Brazilian multicentric prospective cohort, the booster dose elicits a similar immune response in all patient groups, despite the initial difference in IgG-RBD titers after two doses of ChAdOx-1 and CoronaVac. Although a heterologous vaccine regimen showed a potential trend towards a more robust humoral response, this was not statistically significant, likely due to sample size limitations. Notably, the three-dose scheme was safe for all systemic vasculitides, with no increased disease activity observed.

Geometric means of IgG-RBD titers following different vaccines and different schemes of vaccination in Brazilian patients with systemic vasculitis

Table 1 - Geometric means of IgG-RBD titers following different vaccines and different schemes of vaccination in Brazilian patients with systemic vasculitis

CoronaVac vs. ChAdOx-1				
Log IgG-RBD	Total	CoronaVac	ChAdOx-1	*p*

[1]IMID denotes immune mediated inflammatory disease, DMARD disease modifying anti-rheumatic drug
*Vasculitis, dermatomyositis, adult onset stills disease, sarcoidosis, and polymyalgia rheumatic, inflammatory bowel disease
#Leflunomide, sulfasalazine azathioprine, hydroxychloroquine, mercaptopurine.
^Includes interleukin 12/23 blockers.

methotrexate (MTX) were less likely to achieve an adequate humoral response compared to healthy controls and IMID patients on other immunomodulatory medications and (2) at 6 months, those on MTX, tumor necrosis factor inhibitors (TNFis), or combination MTX-TNFi therapy were less likely to maintain an adequate humoral response. The objective of this study was to extend the characterization of the humoral immune response to mRNA COVID-19 vaccines in patients with IMID on immunomodulatory treatment to 12 months post vaccination.

Methods: Established patients with IMID and healthy controls at NYU receiving COVID-19 vaccination were assessed for humoral immune response at 4/5 weeks, 3 months, 6 months, and 12 months post first vaccine dose. Humoral response was assessed by testing IgG antibodies against the S1 domain of the spike protein of SARS-CoV-2. In line with our prior studies, adequate response was defined as greater than 5,000 RU/ml (although no titer is known to indicate immunity). Patient characteristics were summarized using means, standard deviations, and percentages as appropriate. Chi squared tests of independence and Fisher's exact tests were used for categorical variables between groups; Kruskal-Wallis tests for continuous variables as appropriate.

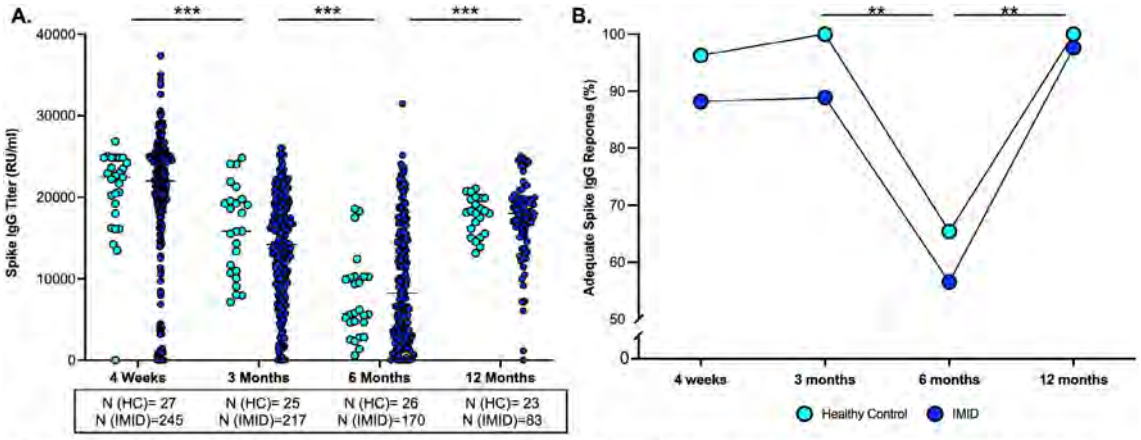

Figure 1. Anti-SARS-CoV-2 IgG levels by (A) titer and (b) percentage achieving an adequate response over time. IgG titers were significantly different at each subsequent timepoints. Percentage achieving an adequate response stayed stable between 4 weeks (96% healthy controls, 88% IMID) and 3 months post vaccination (100% healthy controls, 89% IMID) but dropped significant by 6 months (65% healthy controls, 57% IMID). At 12 months, after receiving a "booster" dose of the SARS-CoV-2 vaccination (red syringe), almost all participants demonstrated an adequate response (100% healthy controls, 97.6%% IMID). ** p< .01, *** p < 0.001.

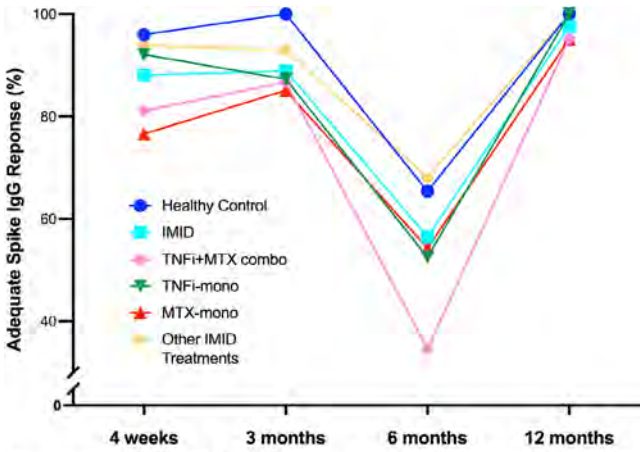

Figure 2. Percentage of IMID patients achieving an adequate response to SARS-CoV-2 vaccination by medication use. At 6 months, combination MTX+TNFi usage was associated with the lowest vaccination response (34.6%). At month 12, there was no difference observed due to medication use.

Results: By 12 months, 23/23 of the healthy controls and 79/83 of the participants with IMIDs received a supplemental dose of the COVID19 booster (Table 1). Participants with IMID were an average of 130 days since the booster dose at the time of phlebotomy (compared to 78 days in the healthy controls). All healthy controls and 81/83 IMID participants achieved an adequate humoral response and there was no difference in antibody titer levels (Figure 1). Antibody titer levels did not correlate with time since booster dose (r= -0.18, p=0.12). Of the 17 patients who had an initial non-response at week 4, all but one demonstrated an adequate response at 12 months. Additionally, there was no difference in response rate or antibody titer level by medication use (Figure 2).

Conclusion: Here, we demonstrate the immunogenicity of a COVID-19 booster dose, regardless of medication use and even in patients who did not initially mount a response. While there is no antibody titer that correlated with clinical efficacy, these findings highlight the importance of a supplemental dose in patients with IMID. Larger scale studies and those looking at the bivalent booster shot are needed to confirm and better understand these findings.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune inflammatory rheumatic disease (AIIRD) patients treated with rituximab (RTX) are at risk for severe COVID19 infection, and a blunted humoral response to SARS-CoV-2 vaccines. Evusheld (AZD7442) was a combination of tixagevimab and cilgavimab, indicated for COVID19 prevention in immunosuppressed patients.

We aimed to assess the safety and efficacy of Evusheld in AIIRD patients treated with rituximab or other immunosuppressive medications.

Methods: This prospective open label longitudinal study was conducted in February-December 2022 in 3 Israeli medical centers (Tel Aviv Sourasky, Rambam, and Carmel medical centers).

Consecutive AIIRD patients over 18 years, treated with RTX or other immunosuppressive medications, and qualifying for Evusheld administration were offered to participate in the study. Patients who refused to receive Evusheld were offered to take part as a control group. The participants were followed up to 10 months after receiving the 1st 300 mg dose of Evusheld (n=78). The control group (n=39) patients were followed for the same period of time after enrollment.

Data regarding adverse events, disease activity, and COVID19, were collected 3 days and 2 weeks after enrollment, and then every month until the end of the study.

Results: The age of participants was 63.3±13.1 (mean±standard deviation (SD) years, 77.39% were females. RA was the main indication for RTX treatment (n=65, 56.52%).

Table 1. Demographic and clinical characteristics of autoimmune inflammatory rheumatic disease patients in the Evusheld and control groups Categorical variables are presented by number (percent); continuous variables are presented by mean±standard deviation, except age which is presented by median (range). Tx, treatment; ab, antibody.

Variable	Evusheld group n=76	Controls n=39	p-value
Age, years	66 (24-89)	66.5 (38-81)	0.7128
Female sex	57 (75)	32 (82.05)	0.535
Rituximab tx ever	74 (97.37)	37 (94.87)	0.6034
Prednisone tx at study entry	32 (42.67)	19 (48.72)	0.676
Prednisone average dose in mg/day	14.516±27.006	21.868±45.736	0.5292
Mycophenolate tx	4 (5.33)	0 (0)	0.2972
Anti S1/S2 ab levels at study entry	16.98±29.52 N=23	43.93±49.85 N=23	**0.0321**
mRNA vaccination pre-study entry	76 (100)	37 (97.37)	0.3333
COVID-19 infection pre-study entry	22 (28.95)	20 (51.28)	**0.0315**
Rheumatic disease diagnosis			0.5263
Rheumatoid arthritis	40 (52.63)	25 (64.1)	
ANCA-associated vasculitis	12 (15.79)	6 (15.38)	
Idiopathic inflammatory myopathies	7 (9.21)	1 (2.56)	
Systemic lupus erythematosus	5 (6.58)	2 (5.13)	
Systemic sclerosis	9 (11.84)	2 (5.13)	
IgG4-related disease	0 (0)	1 (2.56)

Table 2. Adverse events reported by direct questioning in each visit after receiving Evusheld from day 3-month 3

Visit	Adverse event, number/total reports (%)
Day 3	Injection Site Pain 3/76 (3.95) Headache 2/76 (2.63) Chest Pain 1/76 (1.32) Diarrhea 1/76 (1.32) Myalgia 1/76 (1.32) Arthralgia 1/76 (1.32)
Week 2	Injection Site Pain 1/27 (3.7) Cough 1/27 (3.7) Malaise 2/27 (7.41) Myalgia 1/27 (3.7) Arthralgia 2/27 (7.41)
Month 1	Dyspnea 1/33 (3.03) Diarrhea 1/33 (3.03)
Month 2	Pruritus 2/24 (8.33) Chest Pain 1/24 (4.17) Diarrhea 1/24 (4.17)
Month 3	Diarrhea 1/72 (1.39) Constipation 1/72 (1.39)

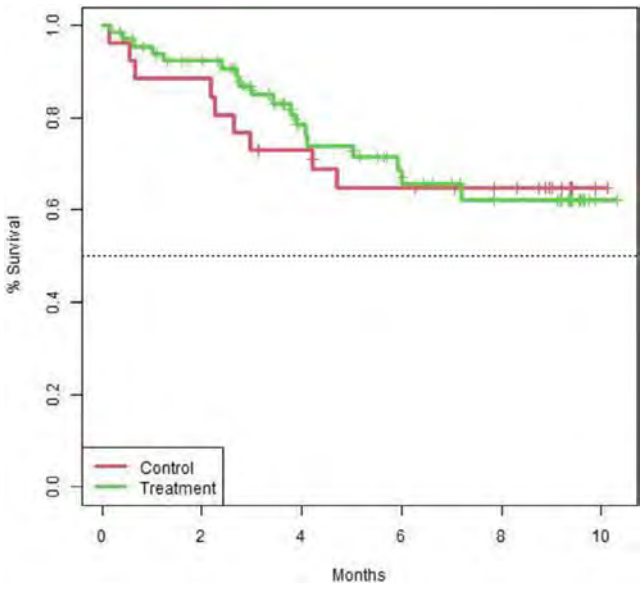

Figure 1. survival analysis of COVID-19 infection cases in the Evusheld (green) and control (red) groups during the study period. P=0.8151

The Evusheld treated group was similar to the controls in regard to age, sex, AIIRD diagnoses, immunosuppressive treatment, and rate of mRNA vaccination (table 1). However, control group participants had a higher rate of previous COVID19 (51.28% vs. 28.95%, p=0.0315, respectively), and higher anti-S1/S2 antibody titers at study entry, compared to controls (43.93±49.85 vs. 16.98±29.52, p=0.0321, respectively).

Adverse events were reported in 17.11% (n=13), most of them within 3 days following Evusheld administration, and all were mild (table 2). Injection site reactions included only pain and were reported by 3.95% of participants receiving Evusheld.

During the study, 15 patients were hospitalized, at a similar rate among the groups (10 (26.3%) Evusheld and 5 (21.7%) controls, p=0.92). One female RA patient, treated with abatacept and prednisone, died 47 days after receiving Evusheld, due to deterioration of rheumatoid lung, not considered related to the use of Evusheld.

Disease activity was generally stable and low, during the study for all indications.

The rate of COVID19 during the study was similar between the groups (n=23, 30.3% Evusheld, n=11, 28.2% controls, p=0.99) (figure 1). Three severe infections were reported in the Evusheld group including one lethal critical COVID19 in 47 years old SSc patient who received Evusheld 6 months previously, and another 2 severe COVID19 cases. Moderate COVID19 was reported in 3 patients –2 of them were in the control group.

Conclusion: Evusheld was safe in patients with AIIRD treated with B-cell depleting or other immunosuppressives medications, that commonly fail to efficiently respond to active/mRNA vaccination. Nevertheless, Evusheld did not prove efficacious in preventing omicron and post-omicron COVID19 in general, and severe disease in particular.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: During the height of the COVID-19 pandemic in the United States, tixagevimab/cilgavimab (Evusheld), a combination of monoclonal antibodies directed against the SARS-CoV2 spike protein, received emergency use authorization (EUA) for use as pre-exposure prophylaxis (PrEP) against COVID-19. However, little is known regarding real-world experience with PrEP in patients with systemic autoimmune rheumatic diseases (SARDs). We aimed to determine the incidence of and risk factors for breakthrough COVID-19 after tixagevimab/cilgavimab among patients with SARDs.

Methods: We conducted a retrospective cohort study of patients with SARDs at a large U.S. healthcare system. We identified all patients who received tixagevimab/cilgavimab as PrEP between 1/2/2022 and 11/16/2022. The index date was the date of the first dose of tixagevimab/cilgavimab. We collected demographics, medications, prior COVID-19, and SARS-CoV2 spike antibody levels prior to index date from electronic query. SARD diagnoses, the presence of additional PrEP indications (e.g., prior organ transplant, active cancer treatment), and COVID-19 course were confirmed by medical record review. The primary outcome was breakthrough COVID-19 confirmed by polymerase chain reaction or an antigen test reported to a physician. Censoring occurred at earliest of breakthrough COVID-19, death, or end of study (November 16, 2022). We used multivariable Cox regression models adjusting for baseline factors to identify risk factors for breakthrough COVID-19.

Results: We identified 444 patients with SARDs who received tixagevimab/cilgavimab (mean age 62.0 years, 78.2% female, 79.3% white) (**Table 1**). The most common SARD diagnoses were rheumatoid arthritis (43.7%), systemic lupus erythematosus (14.9%), and ANCA-associated vasculitis (11.7%). There were 83 (18.7%) breakthrough COVID-19 cases, of which 8 (1.8%) required hospitalization and 1 (0.2%) died (**Table 2**). The overall incidence rate was 31.5 per 1000 person-months (95% CI 24.70, 38.24). Older age was inversely associated with breakthrough COVID-19 (adjusted hazard ratio [aHR] 0.86 per 10 years, 95% CI 0.75, 0.99). Higher baseline spike antibody levels were associated with lower risk of breakthrough COVID-19 (aHR 0.42, 95% CI 0.18, 0.99 for spike antibody levels >200 units vs. < 0.4 units). CD20 inhibitor users had a similar risk of breakthrough COVID-19 (aHR 1.05, 95% CI 0.44, 2.49) compared to patients on conventional synthetic DMARDs (**Table 3**).

Conclusion: In this study spanning the period of viral neutralizing abilityfor tixagevimab/cilgavimab, we found that patients with SARDs had frequent breakthrough COVID-19 after PrEP, but the proportion of severe COVID-19 was low. Further, we found no associations between DMARD type, including anti-CD20 inhibitors, with the risk of breakthrough COVID-19. Older age and higher baseline spike antibody level were protective against breakthrough infection, highlighting the continued

Table 1. Baseline demographic and clinical characteristics of SARD patients at time of initial tixagevimab/cilgavimab receipt

Characteristic	SARD patients who received tixagevimab/cilgavimab (n=444)
Age (mean, SD)	62.0 (14.0)
Female, %	78.2
Race, %	
White	79.3
Black or African American	8.3
Asian	5.2
Other or unknown	7.2

Safety and Efficacy of Pre-Exposure Prophylaxis with Tixagevimab/Cilgavimab (Evusheld) in Patients with Autoimmune Diseases and Renal Involvement Who Received Rituximab

Savino Sciascia[1], MARIA LETIZIA RILAT[2], ROBERTA FENOGLIO[2], SILVIA GRAZIETTA FODDAI[3], MASSIMO RADIN[3], IRENE CECCHI[3], giacoma cinnirella[2], paola crosasso[2], maria gabriella guidetti[2], ALICE BARINOTTI[3], simone baldovino[2], ELISA MENEGATTI[4] and Dario Roccatello[5], [1]University of Turin, Torino, Italy, [2]University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases (ERK-net, ERN-Reconnect and RITA-ERN Member) with Nephrology and Dialysis Unit

and Center of Immuno-Rheumatology and Rare Diseases (CMID), Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, Turin, Italy, [3]University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases (ERK-Net, ERN-Reconnect and RITA-ERN Member) with Nephrology and Dialysis Unit and Center of Immuno-Rheumatology and Rare Diseases (CMID), Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, [4]School of Specialization of Clinical Pathology, Department of Clinical and Biological Sciences, University of Turin, Turin, Italy, [5]University of Torino, Torino, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients on B-cell depleting agents may have a suboptimal response to vaccination, placing them at a higher risk of contracting SARS-CoV-2 or suffering from a more severe prognosis. Indeed, available data on pre-exposure prophylaxis with tixagevimab/cilgavimab (Evusheld) in subjects with glomerular diseases (GD) who received rituximab is limited.

Methods: We conducted a prospective study analyzing the safety and efficacy of tixagevimab/cilgavimab for pre-exposure prophylaxis in patients with GD who received rituximab in the previous 12 months. Rate of symptomatic infections and hospitalizations were compared to patients with GD treated with rituximab who refused to receive tixagevimab/cilgavimab.

Results: Tixagevimab/cilgavimab was administered to 22 patients (12 females, mean age 58,4±19,6 years) with GD diagnoses including membranous nephropathy, lupus nephritis, ANCA-associated vasculitis and focal segmental glomerulosclerosis. No patient treated with tixagevimab/cilgavimab experienced symptomatic infection with SARS-CoV-2 during the follow-up (mean observation time follow-up was 112 ± 23 days), while 11 out 28 controls (39,3%) reported a symptomatic infection (p=0,001), requiring hospitalization in 2 cases. Reported adverse events were mild, namely self-limiting headache (4), discomfort at the injection site (3), flu-like symptoms/myalgia (3), and fever (1). No serious adverse event, (e.g., cardiac events, anaphylaxis) was reported.

Conclusion: Pre-exposure prophylaxis with tixagevimab/cilgavimab (Evusheld) seems safe and lowering of about 40% the risk of symptomatic SARS-CoV-2 infection in vaccinated subjects with GD who received anti-CD20 therapy. Possible applications in the subset of patients who need immunosuppressive therapy, especially with Rituximab, in a pandemic setting might be envisaged.

Abstract Number: 0220

Paxlovid (Nirmatrelvir Plus Ritonavir) in Patients with Underlying Rheumatological Diseases, in Preventing COVID-19 Related Hospitalization and Death

Faiza Javed, Tony Mangino and Paramarajan Piranavan, University of Kentucky College of Medicine, Lexington, KY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The benefits of antiviral therapy in the COVID-19 patients with underlying rheumatic disease with or without immunosuppression are not entirely clear. The goal of this study is to determine the utility of Paxlovid in patients with rheumatological diseases (inpatient and outpatient) in preventing COVID-19 associated hospital admissions and mortality. By preventing severe COVID-19 infection, we can potentially avoid any long-term breaks of immunosuppressive agents and disease flares in these patients.

Methods: This is an Institutional Review Board approved, retrospective study in which participants were identified as patients with diagnosis of a rheumatological condition based on ICD-9 and/or ICD-10 codes who presented to either the inpatient or outpatient setting at the University of Kentucky Hospitals between January 1, 2020, and September 30, 2022. Baseline characteristics of patients included in this study are shown in Table-1. Outcomes of interest were in-hospital mortality related to COVID-19 and inpatient or emergency admission due to COVID-19. All statistical tests were two-sided and statistical significance was defined as p-value < 0.05. All analyses were done in R programming language, version 4.1.0 (R Foundation for Statistical Computing, Vienna, Austria). For both outcomes, two logistic regression models were employed with odds ratios (OR) obtained. The first model considered patients' Paxlovid prescription status conditional on their COVID-19 vaccine status. The second model considered patients' Paxlovid prescription status conditional on their COVID-19 vaccine status while adjusting for prednisone prescription status, obesity, and diabetes diagnosis.

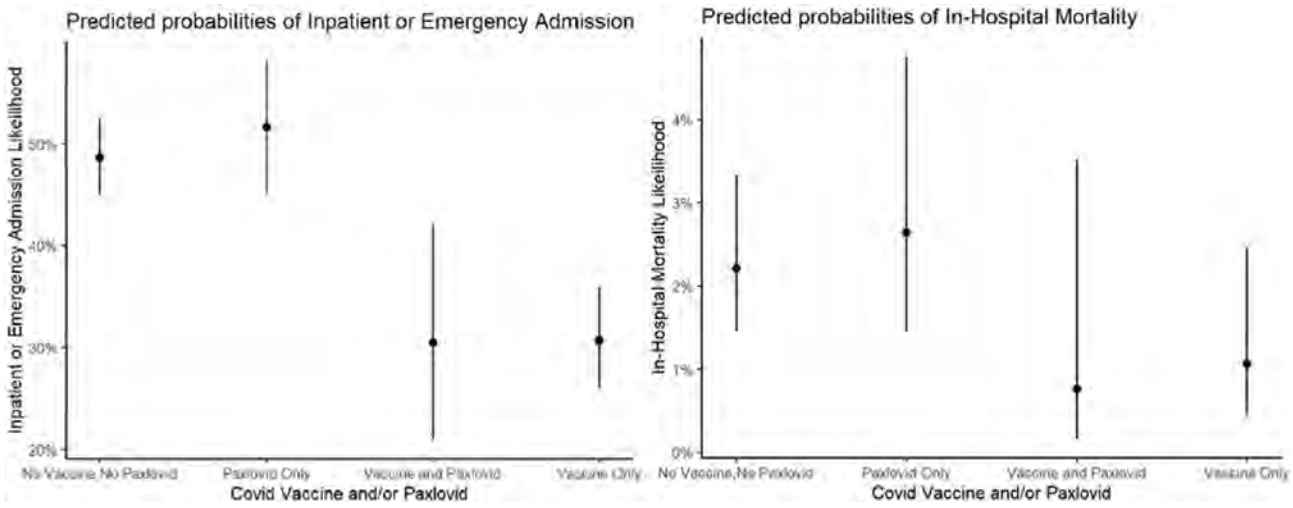
Rheumatological disease****	2387 (100%)	2387 (100%)	2387 (100%)

****Ankylosing spondylitis, gout, juvenile rheumatoid arthritis, Still's disease, adult-onset lupus erythematosus, SLE (systemic lupus erythematosus), polymyalgia rheumatica, pseudo gout, psoriatic arthritis, psoriatic spondylitis, Raynaud's syndrome w/o gangrene, Reactive arthritis (Reiter's), R/A w/ rheumatoid arthritis w/o organ or systems involvement, Sjögren's disease, spondylosis with myelopathy, Wegener's granulomatosis, Bechet's syndrome, fibromyalgia



Results: A total of 2,387 patients were reviewed in this retrospective analysis (inpatient, outpatient including tele-medicine). All these patients had diagnosis of rheumatological diseases and COVID-19 based on ICD-09 and ICD-10 codes. COVID-19 vaccination was received by 1,836 patients (76.9%); only Paxlovid prescription was received by 461 patients (18%). Patients who received both COVID-19 vaccination and Paxlovid were 86 (3.6%). We discovered that Paxlovid used alone in unvaccinated recipients was associated with lowering the rate of hospitalization or emergency room visit but was not statistically significant (OR = 1.12; CI:0.86 – 1.48; p = 0.392). However, concomitant use of both Paxlovid and COVID–19 vaccination in patients was associated with a lower likelihood of hospitalization and emergency room visit (OR = 0.46; CI: 0.27 – 0.78; p = 0.004). Additionally, Paxlovid only was not found to be associated with reduced mortality related to COVID-19 (OR = 1.2; CI: 0.65 – 2.09; p = 0.535). Similarly, the use of Paxlovid in vaccinated patients suggested decreased mortality due to COVID-19 but was not significant (OR = 0.34; CI: 0.05 – 1.35; p = 0.185) (Figure 2).

Conclusion: This study demonstrates that Paxlovid provides protection in immunosuppressed patients with rheumatological diseases against severe COVID-19–associated outcomes resulting in emergency room visit and inpatient admission, significantly so in vaccinated individuals. Further studies are needed to investigate this within a larger patient population.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmunity after COVID-19 infection has been reported. We examined connective tissue disease (CTD) symptoms and autoantibodies, SARS-CoV-2 serologies, and T and B cell immunophenotypes (found in rheumatoid arthritis, systemic lupus erythematosus, and scleroderma in past studies), by the early vs. late COVID-19 pandemic waves. We hypothesized that patients who had COVID in earlier (3/1/2020- 1/31/2021) vs. later (2/1/2021-9/1/2021) waves would have higher prevalence of new CTD symptoms, autoantibodies, and abnormal immunophenotypes.

Methods: We identified patients COVID-19 PCR positive from 3/1/2020-9/1/2021 in the Mass General Brigham system. Eligible participants ≥18 years old and ≥1-month post-COVID-19 with no prior history of CTD received the CTD Screening Questionnaire (CSQ; Karlson EW, 1995) to complete. Subjects who returned questionnaires were invited for a blood draw. Subjects were tested for 27 autoimmune and 3 SARS-CoV-2 serologies, and for T peripheral helper cells (TpH), T follicular helper cells (TfH), age-related B cells (ABCs), and plasmablasts (PBs) proportions by flow cytometry. We tested for associations between clinical variables, serologies, and immunophenotypes (% total CD4 T cells for TpH and TfH; % total CB19 B cells for ABC and PB) using t-tests, Chi-square, and multivariable logistic regression, adjusting for age, race, sex. A heatmap of the multidimensional data was generated to elucidate underlying patterns.

Results: 324 of 2,935 screening questionnaires (11%) were returned; 80 eligible subjects participated. Baseline demographics and clinical data are shown in **Table 1** by early vs. late COVID-19 wave. 17 subjects were vaccinated at infection, all in the later pandemic; 10 subjects were hospitalized for COVID-19. Among those in earlier vs. later COVID waves, a higher proportion were CSQ+ (35% vs. 17%, p 0.12), and more were ANA+ (44% vs. 13%, p 0.009) (**Table 2**). Lupus anticoagulant was positive in 11% of early vs. 4% of late COVID, p 0.38. Having ≥1 positive autoantibody was found in 77% of early vs. 74% of later COVID subjects, p 0.76. After adjustment for age, race, and sex, having early (vs. late) COVID variants was associated with increased risk of ANA positivity (MV OR 4.55, 95%CI 1.16, 16.67). The heatmap revealed more variety of autoantibody positivity in early COVID, with more antibodies to cardiolipin IgG, B2GP1 IgM, C1q, CCP3, PMScl, PR3, Scl70, while Jo-1 and MPO were only present in later COVID waves. No clear patterns were seen in T and B cell phenotypes (**Figure 1**).

CSQ= Connective Tissue Disease screening questionnaire (Karlson EW, 1995); SD= standard deviation; CTD= connective tissue diseases; ANA= antinuclear antibody; Anti-DFS70= anti-dense fine speckled 70 antibody; IgM= immunoglobulin M; IgG= immunoglobulin G; Anti-dsDNA= anti-double stranded DNA antibody; Anti-CCP= anti-cyclic citrullinated peptide antibody; ANCA= antineutrophil cytoplasmic antibodies; AntiPR3= anti-proteinase 3 antibody; Anti-Sm= anti-Smith; Anti-Sm-RNP= anti-Smith ribonucleoprotein antibody; Anti-PM-Scl= anti-polymyositis/scleroderma antibody; Anti-CENP-B= anti-centromere proteins B antibody; Anti-PCNA= anti-perinuclear anti-neutrophil cytoplasmic antibodies; RBD= receptor binding domain; TfH= T follicular helper cell; TpH= T peripheral helper cell; ABC= age-associated B cell; PB= plasmablast *Some patients had multiple autoantibodies **reported as mean of % of total CD4+ T cells or total CD19+B cells

Conclusion: Although a small study without controls, infection in earlier vs. later COVID was associated with more ANA positivity and autoimmune rheumatic disease symptoms (latter non-significantly). Heatmap analyses elucidated increased prevalence of other autoantibody positivity in the earlier wave. These results raise the possibility that more virulent SARS-CoV-2 strains circulating in the early pandemic and pre-vaccine availability were more immunogenic and more likely to result in autoantibody production.

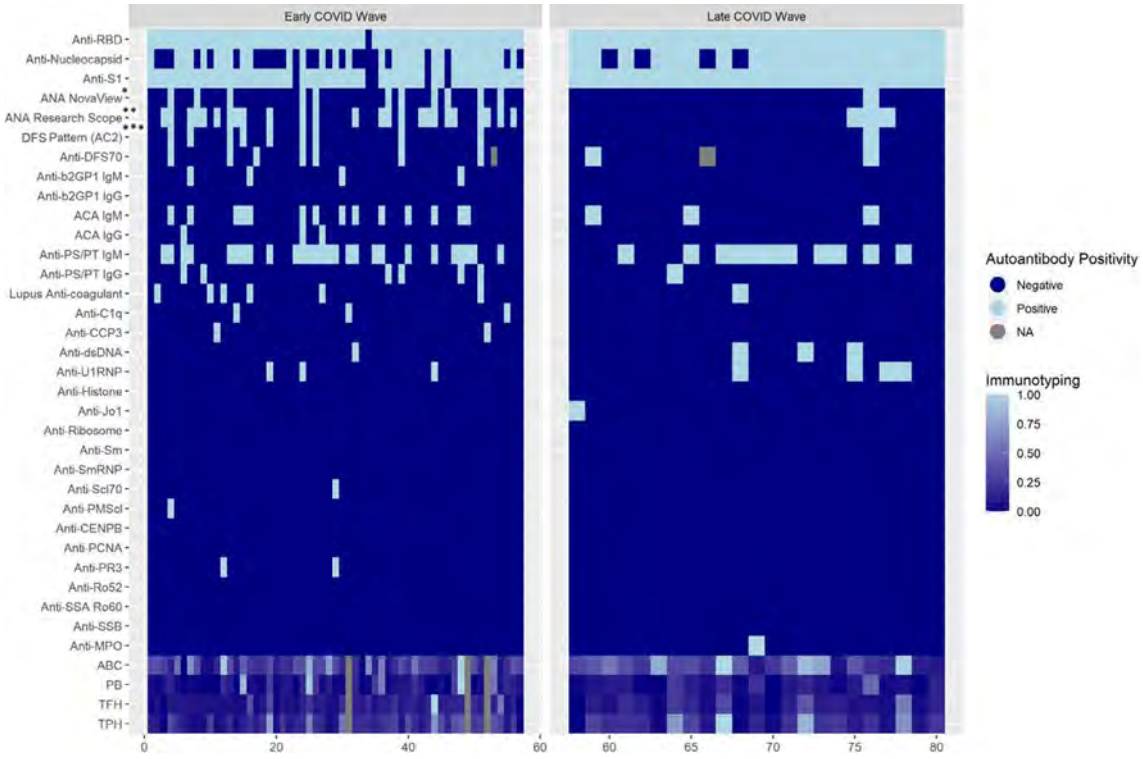

Figure 1. Hierarchical heatmap clustering of autoantibody and immune profile results among 80 subjects following COVID-19 infection stratified by COVID-19 wave (early vs. late). SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX) is widely used in immune mediated inflammatory disease (IMID) patients refractory to conventional treatment. Previous studies have indicated that RTX in IMID patients may lead to more severe COVID-19 disease outcomes. This study aims to characterize outcomes of hospitalized COVID-19 patients with IMIDs who received RTX treatment.

Methods: In this single center retrospective observational study, we included IMID patients with prior RTX use who got COVID-19 infection April 2021 to April 2023. COVID-19 was diagnosed by rRT-PCR assay detecting SARS-CoV-2 RNA. The demographics, serum markers, and medical outcomes were systematically reviewed from the electronic health records.

Table 1

Table 1. Demographics. Characteristics of IMID patients with prior Rituximab use, hospitalized with COVID-19 infection

Characteristics	N = 32
Age, median (IQR)	52 (44, 58)
Age < 50	15 (47%)
Age 50 - 65	11 (34%)
Age > 65	6 (19%)
Female	24 (75%)
Comorbidities [1]	21 (70%)
Body Mass Index (kg/m²), median (IQR)	22.9 (20.4, 26.7)
< 20	6 (19%)
20-30	20 (62%)
> 30	6 (19%)
Stationary IMID Disease Status [2]	21 (66%)
Viral RNA Cycle Threshold (Ct) [3], median (IQR)	19.4 (17.5, 21.5)
COVID-19 Severe Disease	16 (50%)
Viral Shedding Duration (Day) [4], median (IQR)	29 (17, 55)
Delayed Viral Shedding [5]	27 (84%)
Very Delayed Viral Shedding [6]	16 (50%)
Subsequent Re-infection < = 3 Months	11 (35%)
All-Cause Mortality [7]	13 (41%)
IMID Diagnosis	
ANCA vasculitis	2 (6.2)
Adult onset Still's Disease	1 (3.1%)
Rheumatoid arthritis	1 (3.1%)
Dermatomyositis	3 (9.4%)
IgG4-related disease	1 (3.1%)
Sjogren syndrome	4 (12%)
Systemic lupus erythematosus	3 (9.4%)
Spodyloarthropathies	5 (16%)
Immune thrombocytopenia	1 (3.1%)
Non-criteria antiphospholipid syndrome	4 (12%)
Autoimmune thyroid disease	3 (9.4%)
Pemphigus	2 (6.2%)
Mixed connective tissue disease	1 (3.1%)
Systemic sclerosis	1 (3.1%)

1. Comorbidities included interstitial lung disease, COPD, asthma, coronary artery disease, congestive heart failure, stroke, type 2 diabetes mellitus, hypertension, cancer, chronic kidney disease.
2. Stationary IMID disease status is defined as the absence of switch or add-on glucocorticoids, conventional synthetic/target synthetic DMARDs or biologics within 180 days prior to the COVID-19 diagnosis.
3. Sampled from nasopharyngeal swab test.
4. Viral shedding duration was defined as the interval between COVID-19 diagnosis and the first negative result in a rRT-PCR test or antigen test.
5. Delayed viral shedding was defined as a positive rRT-PCR test > = 14 days after COVID-19 diagnosis.
6. Very delayed viral shedding was defined as a positive rRT-PCR test > 28 days after COVID-19 diagnosis.
7. All-cause mortality included mortality during hospitalization and in 6 months.

Table 2.

Table 2. Results. Association of laboratory markers at COVID-19 diagnosis, medication, Rituximab use and outcomes, grouped according to COVID-19 disease severity, very delayed viral shedding status and all-cause mortality.

Outcomes / Laboratory Markers*	COVID-19 Disease Severity			Very Delayed Viral Shedding			All-Cause Mortality

* Wilcoxon rank sum test; Fisher's exact test; Pearson's Chi-squared test
1. Median albumin level within the three months before COVID-19 diagnosis
2. The most recent CRP level before COVID-19 diagnosis
3. Average daily glucocorticoid dose (prednisone equivalent) per body weight in the first 2 weeks after COVID-19 diagnosis; median (IQR)
4. Average daily glucocorticoid dose (prednisone equivalent) per body weight in the past 4 weeks before COVID-19 diagnosis; median (IQR)
5. RTX-COVID-19 interval was defined as the time between the last Rituximab infusion and the COVID-19 diagnosis

A. Only included complete cases (N = 27).
B. Only included cases with RTX infusion < 365 days before COVID-19 diagnosis (N = 30)

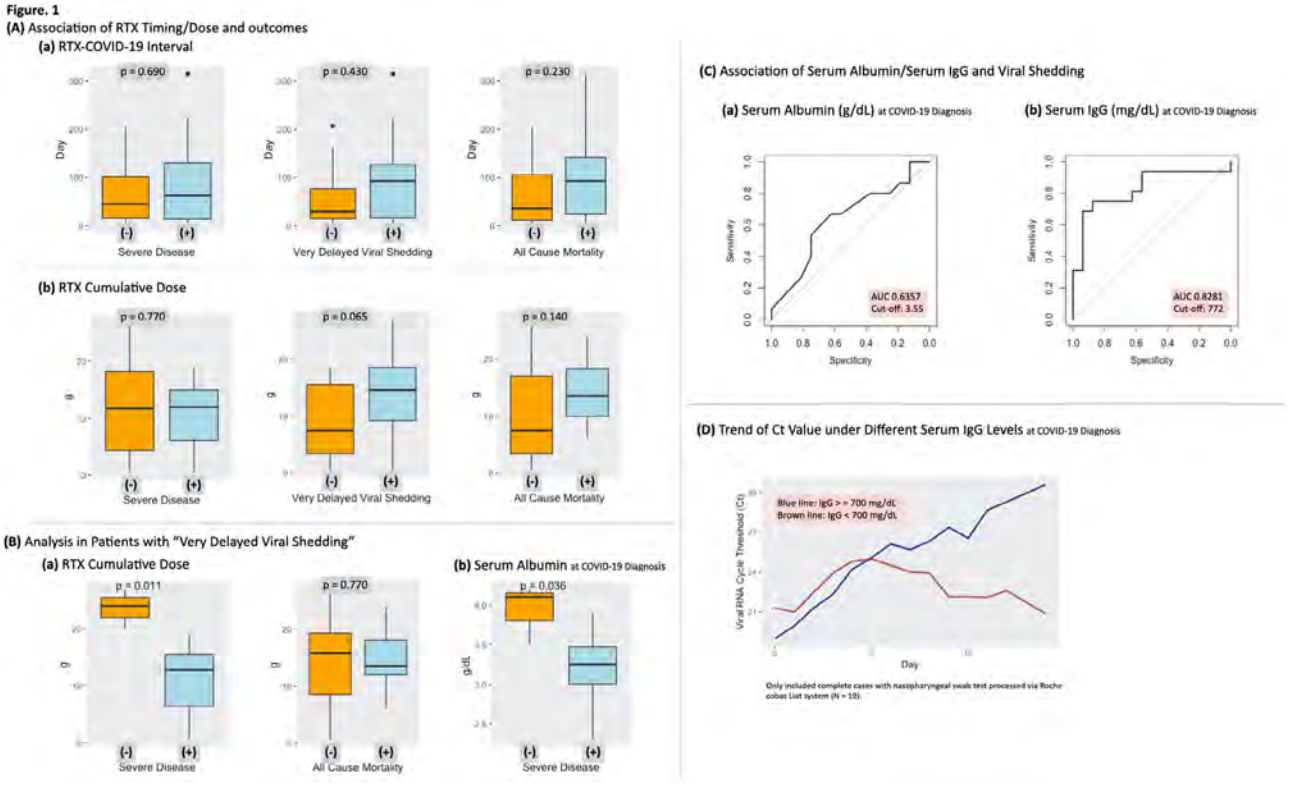

Figure 1.

Average daily glucocorticoid dose (prednisone equivalent) per body weight (mg/kg/day) in the first 2 weeks after infection was adopted for analysis. We proposed the concept "very delayed viral shedding", which referred specifically to a positive rRT-PCR result exceeding 28 days after diagnosis. COVID-19 disease severity was assessed per WHO classification. Outcomes included severe disease, very delayed viral shedding, and all-cause mortality (during hospitalization and in 6 months). For each outcome, we conducted univariate analysis and multivariate logistic regression. All analyses were conducted via R software.

Results: A total of 32 IMID inpatients were included. Their characteristics are shown in Table 1. Sixteen (50.0%) had severe disease, 16 (50.0%) had very delayed viral shedding, and 40.6% died. Factors associated with outcomes are shown in Table 2. Lower baseline serum albumin (OR 0.100, 95% CI: -5.209 to -0.253), higher serum ferritin at diagnosis (OR 1.003, 95% CI: 5x10-4 to 0.006), and higher glucocorticoid dosage (OR 5.318, 95% CI: 0.798 to 2.544) were associated with severe COVID-19 disease. Lower serum IgG at diagnosis (OR 0.994, 95% CI: -0.012 to -0.002) and higher glucocorticoid dosage (OR 2.875, 95% CI: 0.102 to 2.010) were associated with very delayed viral shedding. Routine outpatient colchicine use (OR 16, 95% CI: 0.593 to 5.983) and higher glucocorticoid dosage (OR 3.170, 95% CI: 0.176 to 2.131) were associated with mortality.

The time interval between the last RTX treatment and COVID-19 diagnosis, as well as the cumulative RTX dosage, were not associated with poor outcomes (Figure 1). However, higher cumulative dose tended to be associated with very delayed viral shedding. In patients with very delayed viral shedding, lower serum albumin levels at diagnosis, but not cumulative RTX dose, predicted severe disease. Although the viral cycle threshold (Ct) values increase during antiviral course, in the low serum IgG group, the Ct values wane as antiviral discontinued, potentially correlating with a subsequent poor prognosis (Figure 1D).

Conclusion: Lower serum albumin, higher serum ferritin and increased glucocorticoid dose, are indicative of severe inflammation. Our results suggest that severity of inflammation, rather than Rituximab dose or timing, is associated with poor outcomes. Future research should focus on determining the most optimal glucocorticoid dose for these patients, and whether extended antiviral treatment improves outcomes for those with low serum IgG.

Severity and Risk Factors of Hospitalization of Omicron in Patients with Rheumatoid Arthritis

Yan Wang[1], **mengyao zhang**[2], Sitian Zang[1], liang luo[3], Chun Li[1], Jing He[1] and zhanguo li[2], [1]Peking University People's Hospital, Beijing, China, [2]Peking University People's Hospital, Beijing, China, [3]Department of Chinese Medicine, the People's Hospital of Yubei District of Chongqing City, Chongqing, China; Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is still lack of data on the prognosis of patients with RA who have been infected with SARS-Cov-2 Omicron variant, a new strain with relatively low pathogenicity but high transmissibility. The aim of our study was to evaluate the factors influencing the infection of patients with RA and the COVID-19 outcomes.

Methods: Patients who were infected after December 5, 2022 were collected. The demographic characteristics, comorbidities, clinical profile, medication of RA, and treatment from 1107 patients with RA and 2800 controls were analyzed. The $\chi 2$ test, Fisher exact test for class variables, and Mann-Whitney U test were used for continuous variables. The independent correlation factors of hospitalization were estimated using multivariate-adjusted logistic regression.

Abbreviations: RA,rheumatoid arthritis; DMARDs, Disease Modifying Anti-Rheumatic Drugs; cDMARDs, conventional DMARDs; bDMARDs, biologic DMARDs; tsDMARDs,target synthetic DMARDs ;NSAIDs, Nonsteroidal Antiinflammatory Drugs

* Reference group: no

** Reference group: < 65 years

Results: Compared with the control group, patients with RA had significantly higher rates of COVID-19 symptoms. For all patients infected the COVID-19, RA (adjusted OR=2.69, 95%CI 1.37-5.29; p=0.004), older age (adjusted OR=1.03, 95% CI 1.01-1.05; p=0.012) and the use of glucocorticoid (adjusted OR=3.24, 95%CI 1.13-9.29; p=0.029) resulted in higher hospitalization rates. Scheduled vaccination (adjusted OR=0.46, CI 0.24-0.98; p=0.046) was a protective factor in patients with stable RA, who have a low hospitalization rate. Nevertheless, disease-modifying antirheumatic drugs (DMARDs) and non-steroidal anti-inflammatory drugs (NSAIDs), which in some studies had to a certain extent on hospitalization rates in RA patients infected with COVID-19 to a certain extent, were not significantly associated with hospitalization in our study.

Conclusion: RA is a risk factor for increased hospitalization in patients with COVID-19, and glucocorticoids is a risk factor for hospitalization in RA patients.

Risk Factors and Outcomes for Repeat COVID-19 Infection Among Patients with Systemic Autoimmune Rheumatic Diseases: A Case-control Study

Emily Kowalski[1], Xiaosong Wang[1], Naomi Patel[2], Yumeko Kawano[1], Claire Cook[2], Kathleen Vanni[1], Grace Qian[1], Katarina Bade[3], Shruthi Srivatsan[2], Zachary Williams[2], Zachary Wallace[4] and Jeffrey Sparks[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Massachusetts General Hospital, Newton, MA, [5]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: As initial COVID-19 infections become nearly ubiquitous and the available prevention and treatment strategies evolve, patients with systemic autoimmune rheumatic diseases (SARDs) may be particularly vulnerable to repeat infections due to immunosuppression. However, no studies have investigated the risk factors and outcomes of repeat COVID-19 infections among patients with SARDs.

Methods: We performed a case-control study investigating risk factors and outcomes of repeat COVID-19 infections among SARD patients at a large healthcare system. All COVID-19 infections were systematically identified from positive PCR tests, patient-reported rapid antigen tests, or physician referral (3/15/2020 through 10/17/2022). SARD diagnosis was confirmed by a medical record review. The index date was the date of repeat COVID-19 infection, defined as a second infection >60 days after the initial infection. Controls had one COVID-19 infection as of their assigned index date (verified by medical record review and survey) and were matched to cases (up to 3:1) by date of first infection and duration between first infection and index date. We collected demographics, lifestyle, comorbidities, SARD features, and COVID-19 characteristics at initial infection and index date by medical record review. We used conditional logistic regression to identify associations with repeat COVID-19 infection, adjusting for potential confounders. We described the severity of repeat COVID-19 infection among cases.

Results: Among 2,203 SARD patients with COVID-19, we identified 76 cases with repeat COVID-19 infection (80.3% female), matched to 211 matched controls (78.2% female) with no repeat infection. The most common SARD was RA, followed by psoriatic arthritis/spondyloarthritis and SLE (**Table 1**). At first infection, cases were younger (mean 49.5 vs. 60.6 years, p< 0.0001), less likely to have hypertension (32.9% vs. 46.9%, p=0.034), and less likely to have been hospitalized for COVID-19 (13.2% vs. 26.1%, p=0.021) than controls. At index date, cases were more likely than controls to be on antimalarials (26.3% vs. 13.3%, p=0.0090) or rituximab (18.4% vs. 6.2%, p=0.0017), but less likely to be on mycophenolate mofetil (0% vs. 10.4%, p=0.0008; **Table 2**). In the multivariable model, rituximab use vs. non-use (OR 3.44, 95%CI 1.27-9.33), younger age (OR 0.66 per 10 years, 95%CI 0.54-0.81), and methotrexate use vs. non-use (OR 2.31, 95%CI 1.12-4.79) were associated with repeat COVID-19 infection (**Table 3**). Among those with repeat COVID-19 infection, 5 (6.6%) were hospitalized and there were no deaths.

Table 1. Demographics, lifestyle factors, and comorbidities at first infection for cases (SARD patients with repeat COVID-19) and matched* controls (SARD patients with exactly one COVID-19 episode).

	Cases – SARD patients with repeat COVID-19 (n=76)	Controls – SARD patients with exactly one episode of COVID-19 (n=211)	p-value

*Matching factors were calendar date (+/-7 days) of first infection and duration between first infection and index date (+/-7 days).

Table 3. Multivariable odds ratios for repeat COVID-19 case status.

Covariate	Multivariable* OR (95%CI) for repeat COVID-19
Rituximab use at index date (vs. non-use)	**3.44 (1.27, 9.33)**
Age per 10 years	**0.66 (0.54, 0.81)**
Methotrexate use at index date (vs. non-use)	**2.31 (1.12, 4.79)**
Female (vs. male)	0.98 (0.48, 2.00)
Comorbidity count (per comorbidity)	1.05 (0.84, 1.32)
Rheumatoid arthritis (vs. other SARD types)	1.01 (0.52, 1.97)
Glucocorticoid use (vs. non-use)	1.54 (0.73, 3.26)
bDMARD use other than rituximab at index date (vs. non-use)	1.53 (0.80, 2.93)
Symptom count at first infection (per symptom)	1.06 (0.92, 1.23)
Hospitalization at first infection (vs. outpatient)	0.54 (0.23, 1.25)
Partially vaccinated at index date (vs. unvaccinated)	1.84 (0.17, 19.63)
Two doses mRNA or one dose J&J at index date (vs. unvaccinated)	1.46 (0.48, 4.48)
Additional vaccine doses at index date (vs. unvaccinated)	2.06 (0.75, 5.61)

*Conditioned on matching factors (calendar date [+/-7 days] and duration between first infection and index date [+/-7 days]).

Conclusion: In this first study to examine risk factors and outcomes of repeat COVID-19 infection among SARD patients, we identified rituximab use, methotrexate use, and younger age as potential risk factors for repeat COVID-19. While some of the findings may be due to risk mitigation behavior differences, these factors may be useful to raise awareness of repeat COVID-19 risk for patients and clinicians. Reassuringly, there were no deaths and the hospitalization rate was low among those with repeat COVID-19 infection.

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Existing studies have shown that disease activity of patients with rheumatoid arthritis (RA) may surge after COVID-19 infection. However, factors associated with disease flares remain unknown. This study aimed to identify factors associated with breakthrough infection and disease flares in patients with RA following COVID-19 infection.

Methods: We selected patients with RA from an online e-survey data from the COVAD study. Demographic data, patient reported outcomes, comorbidities and pharmacologic treatments were extracted from the database. Disease flare-up was derived from the e-survey database. Factors associated with disease flare-up were determined by multivariable logistic regression analysis.

Results: In total, 1928 patients with RA were extracted from the COVAD database. Older age, Caucasian ethnicity, comorbidities with chronic kidney disease and asthma, were associated with COVID-19 breakthrough infection. Moreover, younger age (odds ratio, OR: 0.98, 95% CI: 0.96 – 0.99, p< 0.001), ethnicity other than Asian, tuberculosis (OR: 3.80, 95% CI: 1.12 – 12.94, p=0.033), treatment with methotrexate (OR: 2.55, 95% CI: 1.56 – 4.17, p< 0.001), poor global physical health (OR: 1.07, 95% CI: 1.00 –1.15, p=0.044) and mental health (OR: 0.91, 95% CI: 0.87 –0.95, p< 0.001) were independent factors associated with disease flares in patients with RA.

Relationships Among Parameters of Mineral Metabolism and Bone Turnover During Acute COVID-related Hospitalization and Subsequent Follow Up: A Pilot Study

Diego Cabrera[1], Clara Wong[2], Anna Santoro[1], Christine Simpson[1], Karl Insogna[1], Mary Geda[1], Andrew Cohen[1], Alexandra Hadjuk[1], Lauren Ferrante[1] and Evelyn Hsieh[3], [1]Yale School of Medicine, New Haven, CT, [2]Yale School of Public Health, New Haven, CT, [3]Yale University, Department of Medicine, Section of Rheumatology; Yale School of Public Health; Section of Rheumatology, VA Connecticut Healthcare System, Westport, CT

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory conditions can exert direct adverse effects on bone metabolism, via increased bone resorption with inadequate compensatory bone formation. COVID-19 has been associated with high levels of inflammation, particularly in patients with severe disease. However, data exploring the impact of COVID-related inflammation on mineral metabolism and skeletal health are scarce. We aimed to explore the relationship between parameters of bone metabolism during acute COVID-related hospitalization and subsequent follow up.

Methods: We carried out a pilot study to analyze serum and plasma samples collected from a subgroup of patients ≥60 years who were enrolled in a larger longitudinal cohort of patients hospitalized with COVID-19 in a single U.S. healthcare system during 7/2020-7/2021. Patients for whom biospecimens were collected during hospitalization were subsequently invited for an in-person follow up encounter at 6-9 months post-hospitalization. IL-6, intact PTH (iPTH), total 25-hydroxy vitamin D (25OHD) and Collagen Type I C-Telopeptide (CTx) were measured at baseline and 6-9 months. Descriptive statistics and Pearson correlation analysis were used to assess the relationship between IL-6 and biomarkers of bone metabolism and turnover.

Results: 12 patients were enrolled in this pilot study with a mean age of 72.6±8 years, and a mean BMI of 35.9±12 kg/m^2; 66% were male. Median iPTH levels at the baseline and follow up were 55.2 (IQR 39.5-143.9) and 70.7 (IQR 50.4-111.3) pg/mL, respectively, with 50% of patients evidencing frankly elevated PTH levels both during hospitalization and 6-9 months later. Mean baseline and follow up 25OHD levels were 27±9.2 and 26.5±11.4 ng/mL (p=0.91); mean baseline and follow IL-6 levels were 7.3±3.9 and 5.3±3.2pg/mL (p=0.18) and mean baseline and follow up CTx levels were 0.297±0.189 and 0.467±0.439 ng/mL (p=0.23). Correlation analysis demonstrated a moderate negative correlation at baseline between

IL-6 and 25OHD (r=-0.4) and CTx (r=-0.5), and moderate positive correlation between IL-6 and iPTH (r=0.4). There was also a moderate positive correlation between IL-6 and iPTH 6-9 months after hospitalization (r=0.5).

Conclusion: In this study, half of the patients enrolled had increased levels of iPTH both during hospitalization and 6-9 months later. Furthermore, we observed a consistent positive correlation between IL-6 and iPTH levels at both time points. Interestingly CTx levels were inversely correlated with IL-6 levels in our sample, despite elevated iPTH levels. Larger prospective studies are warranted to better elucidate the impact of COVID-19 on bone metabolism.

Associations of DMARDs with Post-Acute Sequelae of COVID-19 in Patients with Systemic Autoimmune Rheumatic Diseases: A Prospective Study

Rathnam Venkat[1], Xiaosong Wang[2], Naomi Patel[3], Yumeko Kawano[2], Abigail Schiff[2], Emily Kowalski[2], Claire Cook[3], Kathleen Vanni[2], Grace Qian[2], Katarina Bade[4], Alene Saavedra[2], Shruthi Srivatsan[3], Zachary Williams[3], Zachary Wallace[5] and Jeffrey Sparks[6], [1]Tufts University School of Medicine, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Massachusetts General Hospital, Boston, MA, [4]Brigham and Women's Hospital, Boston, MA, [5]Massachusetts General Hospital, Newton, MA, [6]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Post-acute sequelae of COVID-19 (PASC, or "long COVID") is defined by the CDC as COVID-19 symptoms persisting for ≥28 days after infection. Patients with systemic autoimmune rheumatic diseases (SARDs) may be at higher risk for PASC due to their underlying disease and immunosuppressive medications. Disease-modifying antirheumatic drugs (DMARDs), particularly CD20 inhibitors, have been associated with severe COVID-19, but the effect of DMARD use on PASC risk is unclear. Therefore, we investigated the association of baseline DMARD use and PASC among patients with SARDs.

Methods: We invited all SARD patients with COVID-19 within a large healthcare system to participate in a prospective study. Participants completed a survey ≥28 days after confirmed COVID-19 infection, and we analyzed surveys completed from 3/11/2021 to 5/5/2023. The survey collected data on demographics, SARD characteristics, COVID-19 vaccination status, DMARD use at COVID-19 diagnosis, and COVID-19 symptoms and disease course. We categorized DMARD classes by mechanism of action; those taking combination DMARDs were classified by hierarchy of targeted therapy. PASC was defined by any symptom associated with COVID-19 that persisted for ≥28 days. We used logistic regression to estimate odds ratios (OR) for PASC by DMARD class, adjusting for potential confounders.

Results: We analyzed 501 patients with SARDs and COVID-19 (mean age 52.7 years, 80.2% female), of which 208 (42%) had PASC. The most common SARD type was inflammatory arthritis (53.7%), followed by connective tissue disease (21.6%). Participants with PASC were more likely to be female (88.0% vs. 74.7%, p=0.0002), less likely to have had additional COVID-19 vaccine doses beyond the primary series (45.2% vs. 55.0%, p=0.031), and more likely to be infected with

Table 1. Baseline characteristics at time of COVID-19 diagnosis according to PASC status among patients with systemic autoimmune rheumatic diseases (n=501).

Characteristic	Overall (n=501)	PASC* (n=208)	No PASC (n=293)	p-value

Not hospitalized	460 (91.8%)	179 (86.1%)	281 (95.9%)	
Median time from COVID-19 to survey completion, days (IQR)	165 (84, 276)	160.5 (80, 295.5)	165 (86, 245)	0.35

*PASC is defined by the CDC as any COVID-19 symptom persisting for ≥28 days.

**Combination DMARDs were classified by hierarchy of targeted therapy in the order of biologic/targeted synthetic DMARD and csDMARDs only.

bDMARD, biologic disease-modifying antirheumatic drug; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DMARD, disease-modifying antirheumatic drug; JAK, janus kinase; PASC, post-acute sequelae of COVID-19; SARD, systemic autoimmune rheumatic disease; TNF, tumor necrosis factor; J&J, Johnson & Johnson-Janssen.

pre-Omicron variants (53.4% vs. 37.5%, p=0.0004) compared to participants without PASC. Participants with PASC were also less likely to be on TNF inhibitors (20.2% vs. 28.7%, p=0.031) and more likely to be on CD20 inhibitors (11.1% vs. 5.5%, p=0.021). Participants with PASC were more likely to have been hospitalized for COVID-19 (13.9% vs. 4.1%, p< 0.0001). There were no statistically significant differences in age, race, comorbidity count, SARD type, and other DMARD classes, when comparing those with and without PASC (**Table 1**). After adjusting for comorbidity count, vaccination status, SARD type, and calendar time of infection, SARD patients using CD20 inhibitors had an OR for PASC of 2.61 (95%CI 1.19-5.73) compared to those on conventional synthetic DMARDs (**Table 2**).

Conclusion: In this prospective study, SARD patients on CD20 inhibitors at COVID-19 onset had increased risk for PASC. This analysis extends previous studies linking CD20 inhibitors with acute COVID-19 severity and suggests vigilance is needed to prevent COVID-19 and monitor for PASC in this vulnerable population. Mechanisms linking B cell depletion with PASC risk may include persistent infection, dysregulated immune response following acute infection, and acute COVID-19 severity from impaired humoral immunity.

Table 2. Associations of baseline use of disease-modifying antirheumatic drugs with PASC risk (n=501).

DMARD class	n PASC outcomes (% within DMARD class)	Unadjusted OR (95%CI)	Multivariable* OR (95%CI)
No DMARD	47/113 (41.6%)	1.10 (0.66, 1.82)	1.22 (0.70, 2.12)
csDMARDs only	55/140 (39.3%)	1.0 (Ref)	1.0 (Ref)
TNFi	42/126 (33.3%)	0.77 (0.47, 1.28)	0.93 (0.52, 1.68)
JAKi	11/21 (52.4%)	1.70 (0.68, 4.27)	1.77 (0.66, 4.72)
CD20i	23/39 (59.0%)	**2.22 (1.08, 4.58)**	**2.61 (1.19, 5.73)**
Non-TNFi and non-CD20i biologics	30/62 (48.4%)	1.45 (0.79, 2.65)	1.72 (0.89, 3.31)

*Adjusted for age, sex, comorbidity count, vaccination status (unvaccinated or partially vaccinated, 2 mRNA doses or 1 J&J, additional doses), SARD type, and calendar time.

bDMARD, biologic disease-modifying antirheumatic drug; CI, confidence interval; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; DMARD, disease-modifying antirheumatic drug; JAKi, janus kinase inhibitor; OR, odds ratio; PASC, post-acute sequelae of COVID-19; SARD, systemic autoimmune rheumatic disease; TNFi, tumor necrosis factor inhibitor.

Abstract Number: 0228

A Comprehensive Retrospective Analysis of Polymyalgia Rheumatica in Long COVID Patients at an Academic Medical Center in the Midwest

Hanan Ibrahim[1] and Alireza Meysami[2], [1]Henry Ford Health System (HFHS), Detroit, MI, [2]Henry Ford Health, Detroit, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia Rheumatica (PMR) is an inflammatory disorder that predominantly affects older adults. Incidence peaks at 70-80 years old [1] and is more common in people of Scandinavian and northern European descent [2]. Patients have widespread pains, stiffness, and muscle tenderness. The annual incidence is 64 per 100,000 population. Incidence is higher in females with a mean of 74 years [3].

While the exact cause of PMR is unknown, emerging research suggests a potential association between PMR and environmental triggers such as vaccination and infections [4]. It has been postulated that viral infections can incite an aberrant immune response, activating autoimmune processes [5]. Since the start of the coronavirus disease 2019 (COVID) pandemic, studies have suggested that the infection might trigger an inflammatory state, leading to an autoimmune response [6,7].

In our descriptive analysis, we look at patients who were referred to our academic Rheumatology clinics for long COVID symptoms. We also try to address how patients who develop PMR following COVID infection may differ from long COVID patients who do not.

Methods: This is a retrospective study in an academic rheumatology clinic, 132 adults (age >18 years) patients with an initial referral for persistent symptoms post-COVID infection (fatigue, myalgia, joints pains, stiffness, abnormal labs, rash) diagnosed between March 2020 and July 2021 were included using the unified record system at our institute. All patients had a documented positive COVID polymerase chain reaction test before the first rheumatology office visit.

Numeric variables were summarized using means and standard deviations or using medians and intra-quartile ranges. Categorical variables were summarized by counts and percentages. Numeric variables were compared by t-tests or Wilcoxon rank sum tests. Categorical variables were compared by chi-square or Fishers exact tests.

Results: Thirty of 132 patients had persistent arthralgia, stiffness, and myalgias and were diagnosed with long COVID syndrome prior to their rheumatology clinic visit.

Eight of 30 patients were diagnosed with PMR. Patients with PMR had a higher mean age (79 vs 59, $p< 0.001$), and a higher median ESR (48.5 vs 12.0, $p=0.013$). No statistically significant difference between the two groups regarding gender, ethnicity, severity of initial COVID infection, duration of symptoms, and Rheumatoid factor (RF) positivity was detected. (Table 1)

All 8 patients with PMR diagnosis were responsive to steroid taper and achieved remission within one year. One patient required steroid-sparing medication (Leflunomide). Two patients had newly diagnosed neoplasms within 1 year (uterine cancer and chronic myeloid leukemia).

Conclusion: Our study was consistent with patients having long-COVID symptoms experiencing a higher incidence of PMR. As might be expected with the small sample size, there was no statistical difference in demographic characteristics between our PMR population and those without PMR. We aim to stimulate further investigation into the etiology, pathogenesis, and potential therapeutic interventions for PMR and related autoimmune disorders triggered by COVID.

Abstract Number: 0229

Vegetable Consumption and Regular Exercise Are Associated with Better Quality of Life in Gout

HYUNSUE DO and Kiwon Moon, Kangwon National University Hospital, Seoul, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout, which is a prevalent form of inflammatory arthritis, is generally considered to be more effectively managed through medication. Besides of maintaining medication, they were required to modify their life style habits including eating habits. Because some gout patients failed to control their disease due to improper lifestyle. Improper lifestyle can affect the gout patient's quality of life.

The Gout Impact Scale (GIS), a part of the Gout Assessment Questionnaire 2.0, is an instrument measuring the gout-specific health-related quality of life (HRQOL). Recently, GIS was translated in to Korean, K-GIS was validated. There have been recommendations for lifestyle changes as well as medication to control gout. So far, there were no research revealing the correlation life style habits and GIS. Therefore, we aimed to evaluate the relationship of GIS and gout patient's life style habit in this study.

Table 1. Baseline characteristics of patients

Variable	Patients (N =232)
Age, years	55.08 (17.69)
Male, n (%)	210 (90.50)

[a]Bachelor's degree or higher
eGFR, estimated glomerular filtration rate

Methods: Patients with gout aged ≥18 years who fulfil the 2015 classification criteria for gout with necessity of ULT are enrolled. The case report form (CRF) lists demographic and clinical data, comorbidities, lifestyle habits, medications, quality of life (on the gout impact scale), the score on Gout Impact Scale (GIS), laboratory results, and radiological findings.

Results: The study included 232 patients, and the baseline characteristics of the patients were described in the **Table 1**. The mean scores for each GIS subscale (mean ± SD) were as follows: 80.27 ± 18.63 for gout concern overall; 64.39 ± 21.47 for gout medication side effects; 47.20 ± 13.28 for unmet gout treatment needs; 55.27 ± 26.56 for well-being during attack; 61.63 ± 22.28 for gout concern during attack.

SE, standard error; CI, confidence interval

There was a statistically significant difference of gout concern overall subscale in the number of times of soft drink, meat consumption. Also, the number of times of exercise showed difference significantly. The number of times of milk, dairy consumption, vegetables, fruits, alcohol and coffee consumption showed no significant difference. In well-being during gout attack subscale in GIS, number of vegetables consumption and exercise did show difference. Regarding well-being during gout attack, soft drink, meat, milk, dairy, fruits, alcohol and coffee consumption did not show significant results between groups according to the number of times.

In gout concern during attack subscale in GIS, the score was significantly different in vegetable consumption and exercise. **(Table 2).**

In gout concern overall subscale in GIS, the number of times of regular exercise showed a negative linear correlation (B= -5.71, *P*= 0.04). In well-being during attack subscale in GIS, the number of times of vegetable consumption showed a negative linear correlation (B= -8.90, *P*=0.01). In gout concern during attack subscale in GIS, the number of times of vegetable consumption and regular exercise showed a negative linear correlation (B= -9.70, -9.69, respectively) ($P < 0.01$) **(Table 3).**

Conclusion: It has been confirmed that the GIS score is related to specific life style, vegetable consumption, exercise regularly. Based on these results, gout patients can be encouraged to have specific life style habits.

Looking Beyond Infections in Job Syndrome: Peripheral Calcium Pyrophosphate Deposition Disease in a Cohort of Patients with Job Syndrome

Sandra Ogbonnaya-Whittlesey[1], Ecem Sevim[1], Dale Kobrin[1], sarthak gupta[2], Paul DeMarco[3] and Alexandra Freeman[4], [1]NIH/NIAMS, Bethesda, MD, [2]Lupus Clinical Trials Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Disease, Bethesda, MD, [4]NIH/NIAID, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Job syndrome or hyperimmunoglobulin E syndrome is an immunodeficiency for which the clinical picture consists largely of frequent infectious complications of the lungs, sinuses, and skin, eczematous cutaneous eruptions, and elevated immunoglobulin E levels starting early in childhood. The condition has been found to occur due mutations most commonly in the STAT3 pathway. Most patients are identified in early child and the disease frequently leads to early fatality due to infectious complication. Patients with Job's syndrome have been living longer due to earlier recognition and more readily accessible genetic testing as well as improved management of infectious complications. As these patients are living longer, new clinical manifestations in the aging Jobs' syndrome patient have been identified including musculoskeletal manifestations such as early onset degenerative joint disease which has been attributed to joint hypermobility.

Methods: We performed a retrospective review of imaging from a cohort of 160 STAT3 HIES patients to determine the prevalence of imaging findings suggestive of calcium pyrophosphate deposition disease (CPPD). Of the 160 patients, we were able to identify 22 patients over the age of 16 years with appropriate hand radiographs and 26 with knee radiographs for review. The median age of patients with findings was 53 and mean age was 47.

Results: We identified radiologic evidence of CPPD including (including narrowing of the 2nd and 3rd metacarpophalangeal joints, chondrocalcinosis) in 6 out of 22 hand radiographs (27%). 26 knee radiographs were reviewed and identified 3 patients with chondrocalcinosis (11%).

Conclusion: As patients with STAT3 HIES are living longer, attention to non-infectious complications associated with this condition is warranted. CPPD may occur at an increased frequency in patients with STAT3 HIES and at a significantly younger age than in the general population. Additional clinical and radiographic monitoring of these patients would help characterize the frequency, age of onset, and severity of this manifestation.

Febuxostat Dose Requirement for Achieving Target Serum Urate Levels According to Renal Function: A Retrospective Cohort Study

YoungEun Kim[1], **Hansun Song**[1], Wook Jang Seo[2], Jinseok Kim[3], Soo Min Ahn[1], Ji-Seon Oh[4], Yong-Gil Kim[1], Chang-Keun Lee[5], Bin Yoo[5] and Seokchan Hong[6], [1]Department of Rheumatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea, [2]Department of Rheumatology, Veteran Health Service Medical Center, Seoul, South Korea, [3]Department of Rheumatology, Jeju National University Hospital, Jeju National University School of Medicine, Jeju-si, Jeju-do, South Korea, La Jolla, CA, South Korea, [4]Department of Information Medicine, Big Data Research Center, Asan Medical Center, University of Ulsan College of Medicine, Ulsan, South Korea, [5]Asan Medical Center, Seoul, South Korea, [6]Department of Rheumatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Febuxostat clearance is not affected by kidney function, and the risk of adverse events from allopurinol, including fatal hypersensitivity reactions, is higher in patients with renal dysfunction accordingly, febuxostat is preferred for gout patients with chronic kidney disease (CKD). However, few studies have sought to determine the appropriate febuxostat dose required to achieve the target SU level. Therefore, this study aimed to investigate the febuxostat dosage needed to reach the SU target in patients with gouty arthritis, including those with renal impairment.

Methods: We conducted a retrospective cohort study at Asan Medical Center, a tertiary referral hospital in Seoul, South Korea. Of 3153 gout patients who were prescribed febuxostat, 731 patients with an initial SU > 6 mg/dL were included and categorized into three groups based on their estimated glomerular filtration rate (eGFR): chronic kidney disease (CKD) stage 1, stages 2-3, and stages 4-5. The cumulative febuxostat dose was defined as the total dose administered from initiation until the patient reached the target SU (< 6 mg/dL).

Results: The cohort of 731 gout patients had a median age of 52 years (IQR, 41-63) and comprised 667 (91.2%) men. The mean (± standard deviation) SU at febuxostat initiation was significantly higher in the CKD 4-5 group (9.6 [±3.1] mg/dL) than in the other groups (CKD 2-3 group, 8.6 [±1.6]; CKD 1 group, 8.8 [±1.8]; P < 0.001). The proportion of patients who received an initial febuxostat dose of 80 mg was lower in the CKD 2-3 group (30.7%) and CKD 4-5 group (31.7%) than in the CKD 1 group (52.0%). Of the total patients, 626 (85.6%) achieved the SU target after ULT. The proportions of patients who achieved the target SU levels were lower in the CKD 4-5 group (82.0%) than in the CKD 1 group (86.6%) or CKD 2-3 group (86.3%) (P = 0.045). Notably, the cumulative febuxostat dose was significantly lower in the CKD 4-5 group (5.9 g [IQR, 2.5–12.0]) than in the other groups (CKD 2-3, 7.1 g [IQR, 3.5–15.7], P = 0.006; CKD 1, 7.0 g [IQR, 2.7–20.1]; P = 0.010). Furthermore, the CKD 4-5 group had a significant negative correlation with the cumulative febuxostat dosage required to reach the target SU compared to the CKD 1 group (beta -2.334, P = 0.020).

Conclusion: Patients with severely decreased renal function (CKD 4-5) required a significantly lower febuxostat dose to achieve the target SU level.

Febuxostat acquirement to reach target SU level and comparison between patients with CKD 1, 2-3, and 4-5.

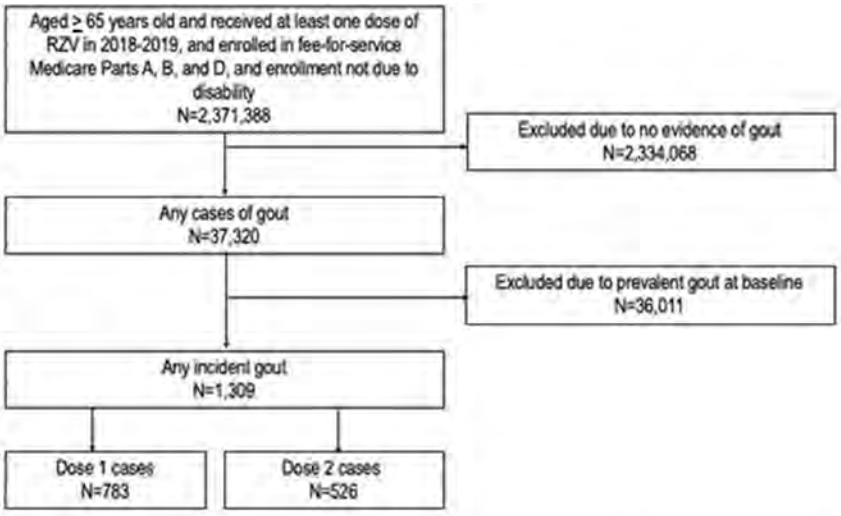
Incident Gout After Recombinant Zoster Vaccination in Adults Aged ≥65 Years in the USA

Susan dosReis[1], Chengchen Zhang[1], **Alejandro Amill-Rosario**[1], Abree Johnson[1], Haeyoung Lee[1], O'Mareen Spence[2], Driss Oraichi[2], Harry Seifert[2], Valentine Franck[3], Susan Gamble[2] and Huifeng Yun[2], [1]University of Maryland School of Pharmacy, Baltimore, MD, [2]GlaxoSmithKline, Rockville, MD, [3]GlaxoSmithKline, Wavre, Belgium

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In pre-licensure clinical trials, numerical differences in gout cases between the recombinant zoster vaccine (RZV) and placebo groups have been observed. However, real-world evidence is limited. Thus, we aimed to estimate the risk of incident gout following RZV exposure using real-world data from a large population of older US adults.

Methods: Using the Centers for Medicare and Medicaid Services Chronic Conditions Warehouse database, a case-only, self-controlled risk interval design was implemented to assess the risk of incident gout in US adults aged ≥65 years. We included adults who were enrolled in fee-for-service Medicare Parts A, B, and D and received at least one dose of the two-dose RZV regimen in 2018–2019 (Figure 1). Incident gout cases in the risk (Days 1–30 following vaccination) or control (Days 31–60 following vaccination) window (Figure 2) were defined by a gout diagnosis in an inpatient or outpatient setting followed by receipt of allopurinol, colchicine, probenecid, or febuxostat within 3 months with no prior evidence of gout diagnosis or medication in the 365 days preceding the incident gout case. Baseline descriptive characteristics in the 12 months up to RZV exposure included age, sex, calendar year–month of RZV vaccination, concomitant preventive immunizations, comorbidities, and health care service utilization. Conditional Poisson regression models estimated the relative risk (RR) of incident gout following any RZV dose in a primary (with censoring at receipt of dose 2) and secondary (30-day fixed control window without censoring) analysis. Sensitivity analyses included 1) a two-dose recipient subgroup with 60–183-day dose

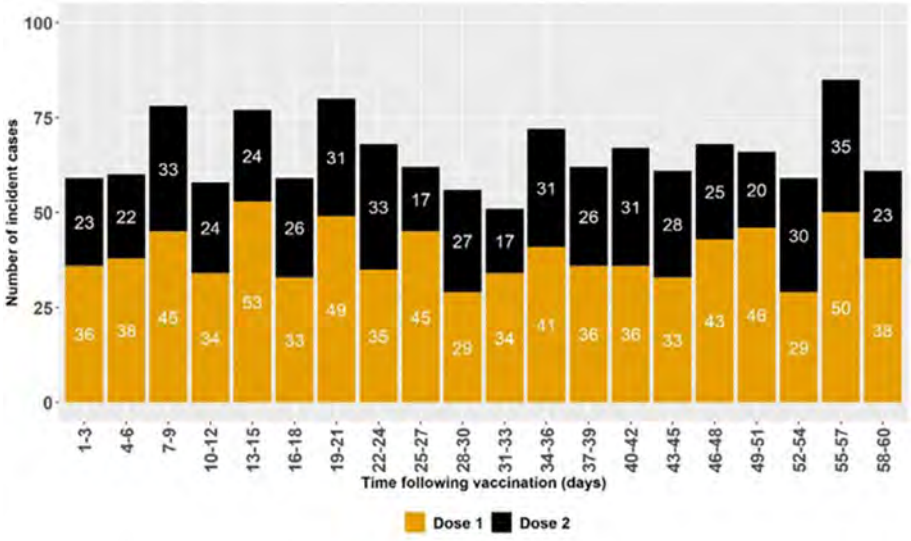


Parts A, B, and D, enrollment in Medicare Parts A (hospital insurance), B (medical insurance), and D (prescription drug coverage); RZV, recombinant zoster vaccine.

CONSORT diagram of the incident gout analytic cohort

spacing; 2) dose 1- and dose 2-specific analysis; 3) a seasonality-adjusted analysis; and 4) a COVID-19 sensitivity analysis excluding incident gout cases on or after December 2, 2019. A temporal scan tested for significant clustering of incident gout cases after vaccination.

Results: We identified 1,309 incident gout cases (Figure 1) who were predominantly White (87%; n=1137) and male (61%; n=801), and aged 70–79 years (55%; n=723). Chronic kidney disease (41%; n=531), diabetes mellitus (36%; n=473), and ischemic heart disease (33%; n=433) were common comorbidities. The majority had no prior hospitalizations (87%;



RZV, recombinant zoster vaccine.

Note: Risk window is Days 1–30 after vaccination, control window starts on Day 31.
*Dose 1 control window censored at receipt of dose 2.
CI, confidence interval; RR, relative risk; RZV, recombinant zoster vaccine; SD, standard deviation.

Risk of incident gout after RZV exposure

n=1,135) or Emergency Department visits (77%; n=1,013), and 9% (n=121) received concomitant influenza vaccine. Of the 1,309 incident gout cases, 1,074 (82%) received two RZV doses. The 783 incident gout cases after dose 1 and the 526 incident gout cases after dose 2 occurred equally in the risk and control windows (Figure 2). In the primary analysis (Table 1), the RR of incident gout was 1.01 (95% confidence interval: 0.90, 1.12). The secondary analysis and all sensitivity analyses produced similar results. The temporal scan did not detect significant clustering of incident gout cases over the 60-day follow-up.

Conclusion: The findings show no statistically significant increased risk of incident gout following receipt of RZV in US adults aged ≥65 years.

Impaired Anti-oxidant Function of HDL and Its Associated Protein, Paraoxonase-1, in Patients with Gout

John FitzGerald[1], Christina Charles-Schoeman[2], Veena Ranganath[3], Ani Shahbazian[4], Jennifer Wang[1] and Maureen McMahon[5], [1]University of California Los Angeles, Los Angeles, CA, [2]UCLA Medical Center, Santa Monica, CA, [3]David Geffen School of Medicine, UCLA, Los Angeles, CA, [4]UCLA Rheumatology, Los Angeles, CA, [5]UCLA David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Longitudinal cohorts have described the association between gout and cardiovascular disease (CVD), while other cohort and interventional studies (CANTOS) have shown the impact of inflammatory factors on CV outcomes. Our group has demonstrated that in patients with other Rheumatic Diseases, HDL functions abnormally, promoting oxidation of LDL, rather than being anti-inflammatory. Given the gout-CVD association, we sought to evaluate the function of HDL as well as the activity of its major associated protein, paraoxonase-1 (PON1) in patients with tophaceous (TG) and non-tophaceous gout (G) compared to healthy controls (HC) and subjects with asymptomatic hyperuricemia (ASH).

Methods: Patients meeting ACR-EULAR Gout Classification Criteria were recruited from a single academic center and defined as either G or TG by presence of clinically palpable tophi. HC and subjects with ASH (serum urate > 7 mg/dL in absence of gout) were recruited.

The HDL inflammatory index (HII),is defined by the ability of patient's HDL to prevent oxidation of LDL when added to a cell-free assay and reported as a ratio where levels > 1.0 indicate enhanced oxidation of LDL (pro-inflammatory) and ratios < 1.0 reduce oxidation of LDL (anti-inflammatory).PON1 activity was measured by paraoxanase, arylesterase and lactonase assays using paraoxon, phenylacetate, and dihydrocoumarin as substrates. Hs-CRP levels were measured by the clinical laboratory.

Kruskal-Wallis non-parametric analyses compared HII rank sums across clinical groups. The 5 CV biomarkers were then standardized with mean of 1 and standard deviation of 1. Generalized Linear Models compared unadjusted means across the clinical groups. Finally, multivariate regressions examined the association between gout and the 5 CV biomarkers adjusting for race, age, gender, BMI, hypertension, hyperlipidemia, diabetes, tobacco use, family history of CVD, prior heart disease and presence of kidney disease (Table 1)

Results: Among 136 subjects, mean HII were lowest (most protective) in HC and ASH subjects (0.70 and 0.82 respectively) and highest (least protective) among G and TG patients (1.04 and 1.37 respectively), p-value = 0.0035 for the model and rank sum difference between HC and TG groupsof $p < 0.05$. (Figure 1)

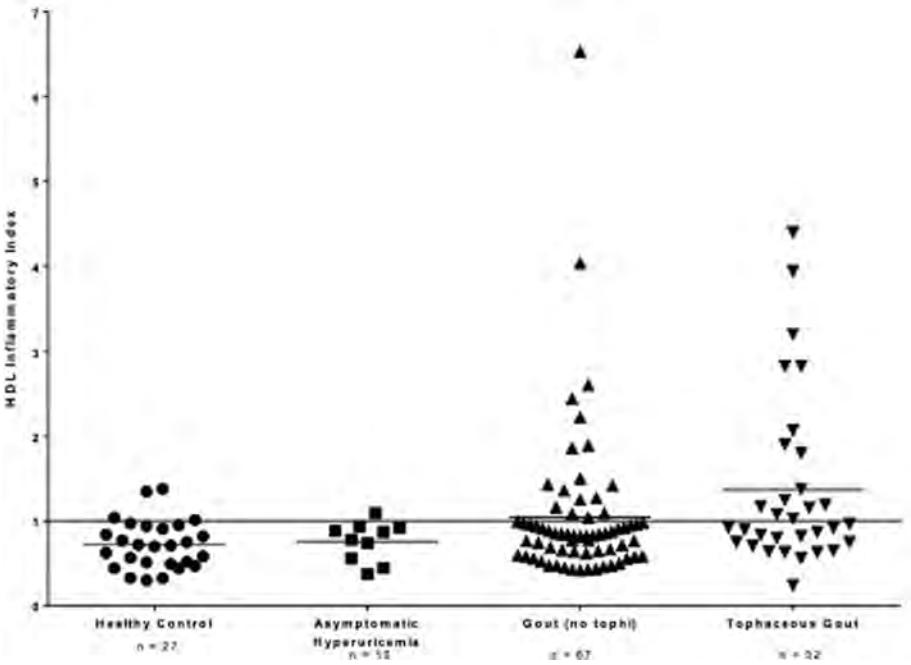

Figure 1. HDL inflammatory index by patient group Legend: HDL = High Density Lipoprotein. P-value = 0.0035 for difference across the groups in ANOVA model. Difference between rank sums for Healthy Controls vs. Tophaceous Gout, p-value < 0.05.

CKD3	0.198	0.43	-96.1	**0.01**	-7.7	0.16
CKD4	0.815	**0.01**	-73.6	**0.10**	-10.4	0.14
BMI	0.009	0.37	1.01	0.40	0.14	0.46

Similarly, standardized, unadjusted PON1 activity as measured by lactonase and arylesterase assays was highest (most protective) in the HC group, decreasing across the patient categories, to the lowest in the TG group ($p < 0.001$ for both lactonase and arylesterase differences across the groups). (Figure 2)

In multivariate analyses, PON1 activity remained most protective (arylesterase and lactonase) among HC and ASH subjects vs. G and TG patients after controlling for above covariates (p = 0.01 and 0.03, respectively). The observed gout-HII association was attenuated (p = 0.17) by the strong renal-HII association. (Table 1)

Conclusion: In this single center analysis of patients with gout (G, TG) compared to HC and patients with ASH, gout was a significant predictor of abnormal antioxidant function of HDL and decreased PON1 activity and suggests a plausible pathway for the inflammatory impact of gout, MSU crystal deposition or hyperuricemia on CVD.

Identifying Optimal Serum Urate Levels to Reduce Gout Flares in Patients Taking Urate Lowering Therapy: A Post-hoc Cohort Analysis of CARES with Consideration of Drop-out

Sara Tedeschi[1], Keigo Hayashi[1], Yuqing Zhang[2], Hyon K. Choi[3] and Daniel Solomon[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: ACR gout treatment guidelines recommend a target serum urate (SU) of < 6 mg/dL and anti-inflammatory flare prophylaxis for at least 3-6 months after initiating urate-lowering therapy (ULT). However, optimal targets for SU are not well defined. We investigated gout flare rates based on repeated measurements of SU levels in a randomized controlled trial of ULT, accounting for loss to follow up.

Methods: We performed a secondary analysis using data from the Cardiovascular Safety of Febuxostat or Allopurinol in Patients with Gout (CARES) trial. CARES participants were randomized to febuxostat or allopurinol, titrated for a target SU < 6 mg/dL; 45% did not complete all study visits. Participants received gout flare prophylaxis for 6 months with colchicine 0.6 mg daily or naproxen 250 mg twice daily if colchicine was not tolerated. For this analysis, participants were followed from month 0 (randomization) to the earliest of death, last completed visit (drop out), or end of study. SU levels were assessed at months 0, 3, 6 and then every 6 months and categorized as ≤3.9, 4.0-5.9, 6.0-7.9, 8.0-9.9, and ≥10 mg/dL. The primary outcome was self-reported gout flare in each 3- or 6-month interval. More than 1 flare/interval was permitted if they were separated by ≥14 days. Baseline variables were used to derive inverse probability of censoring weights (IPCW) to account for censoring (drop-out or death). Poisson regression models included stabilized IPCW weights and estimated gout flare incidence rate ratios (IRR) by time-varying SU category, adjusting for change in SU from prior visit, flare prophylaxis, ULT, age, sex, race, body mass index, gout duration, and tophi. Models were performed for months 0-6, 6-12, and 12-72.

Table 1. Association between time-varying serum urate level and gout flare incidence rate ratios (IRR)* in the CARES trial dataset

	Timeframe after starting urate-lowering therapy					
	Months 0-6		Months 6-12		Months 12-72	
Serum urate category (mg/dL)	Gout flare IRR (95%CI)	p value	Gout flare IRR (95%CI)	p value	Gout flare IRR (95%CI)	p value
≤3.9	0.88 (0.67-1.16)	0.36	0.89 (0.73-1.09)	0.27	0.83 (0.70-0.98)	0.03
4.0-5.9	1.00	-	1.00	-	1.00	-
6.0-7.9	0.95 (0.79-1.13)	0.55	0.96 (0.85-1.09)	0.56	1.20 (1.05-1.36)	<0.01
8.0-9.9	1.09 (0.84-1.41)	0.50	0.92 (0.71-1.20)	0.54	1.29 (1.02-1.62)	0.03
≥10	1.24 (0.85-1.79)	0.26	1.16 (0.71-1.88)	0.56	1.92 (1.28-2.87)	<0.01
p for trend		0.22		0.44		<0.01

*Gout flare incidence rate ratios from Poisson models adjusted for stabilized inverse probability of censoring weight (IPCW), absolute change in SU since prior visit, direction of change in SU, urate lowering therapy (febuxostat/allopurinol/none), prophylaxis (colchicine/NSAID/none), age, sex, race (American Indian/Alaska Native, Asian, Black, Native Hawaiian/Pacific Islander, White, Multiracial/other), body mass index, gout duration, tophi (present/absent)

Results: Among 6183 participants in this analysis, median age was 65 (IQR 58-71) years and 84.0% were male. Median follow-up was 32 months. At month 0, median SU was 8.6 (IQR 7.6-9.7) mg/dL. Seventy-one percent achieved SU < 6 mg/dL by month 3, and this percentage increased slightly over time among retained participants (**Figures 1A & 1B**). Gout flare rates were highest during nearly all intervals when SU ≥10 mg/dL and lowest when SU ≤3.9 mg/dL (**Figure 2**). Peak gout flare rates for all SU categories were observed between months 0-3, coinciding with the initiation of ULT and greatest change in SU. A second spike in gout flares occurred in all SU groups between months 6-12, coinciding with discontinuation of prophylaxis (**Figure 2**). In the initial year of ULT, flare rates did not significantly differ between SU groups, but flare rates were consistently highest when SU ≥10 mg/dL. During months 12-72, in adjusted analyses with IPCW weights, a dose-

Figure 1. Serum urate levels over time in the CARES trial dataset.

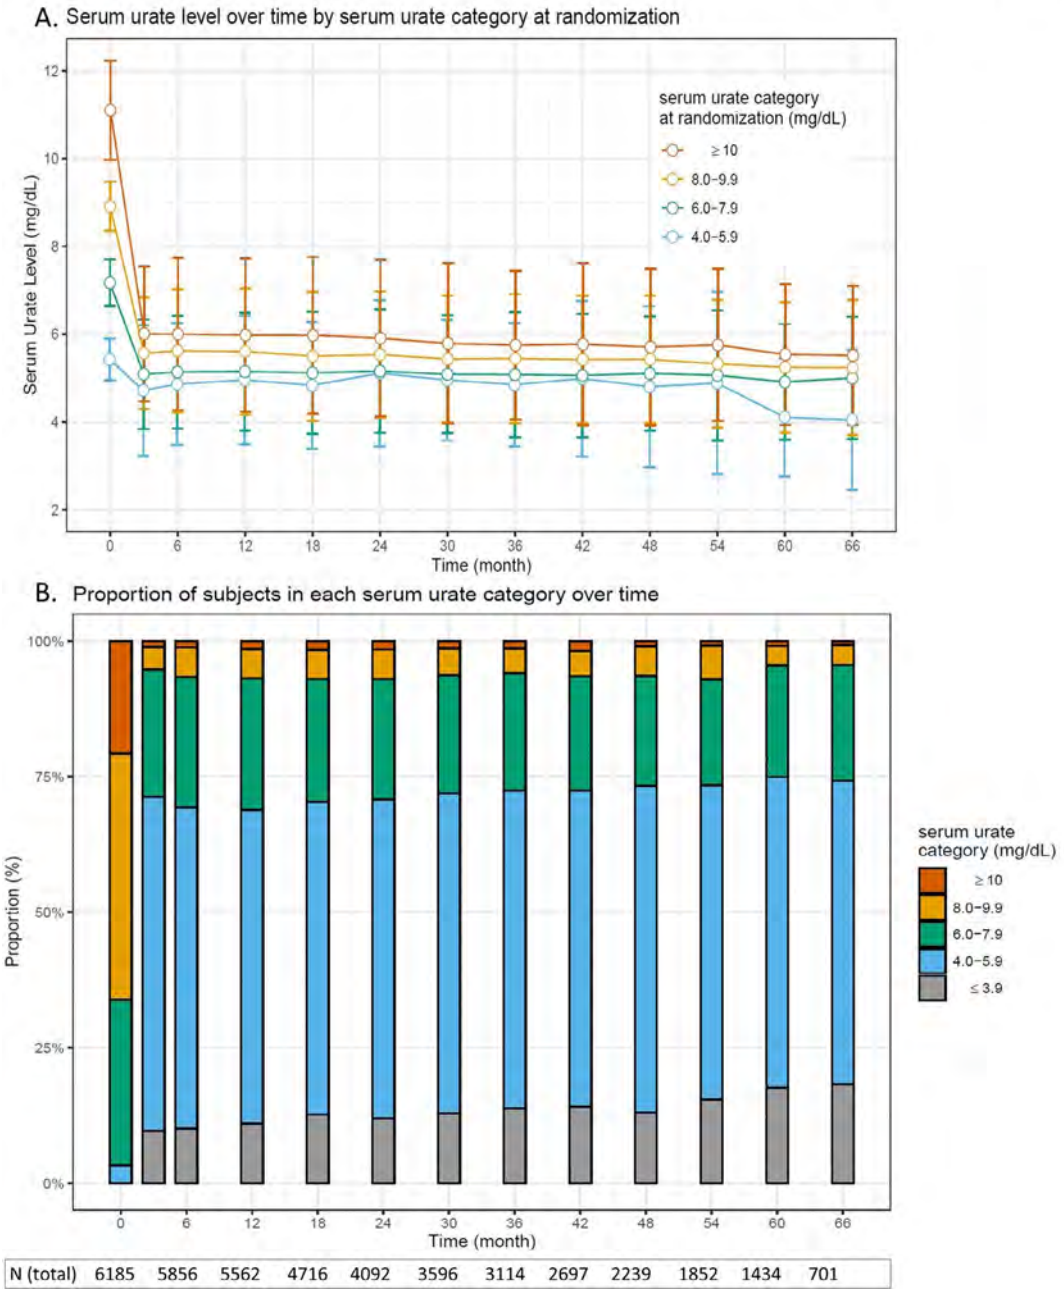

Figure 2. Gout flare rates over time by serum urate category in the CARES trial dataset. Flare rates are adjusted for stabilized inverse probability of censoring weight (IPCW), absolute change in SU since prior visit, direction of change in SU, urate lowering therapy (febuxostat/allopurinol/none), prophylaxis (colchicine/NSAID/none), age, sex, race, body mass index, gout duration, tophi

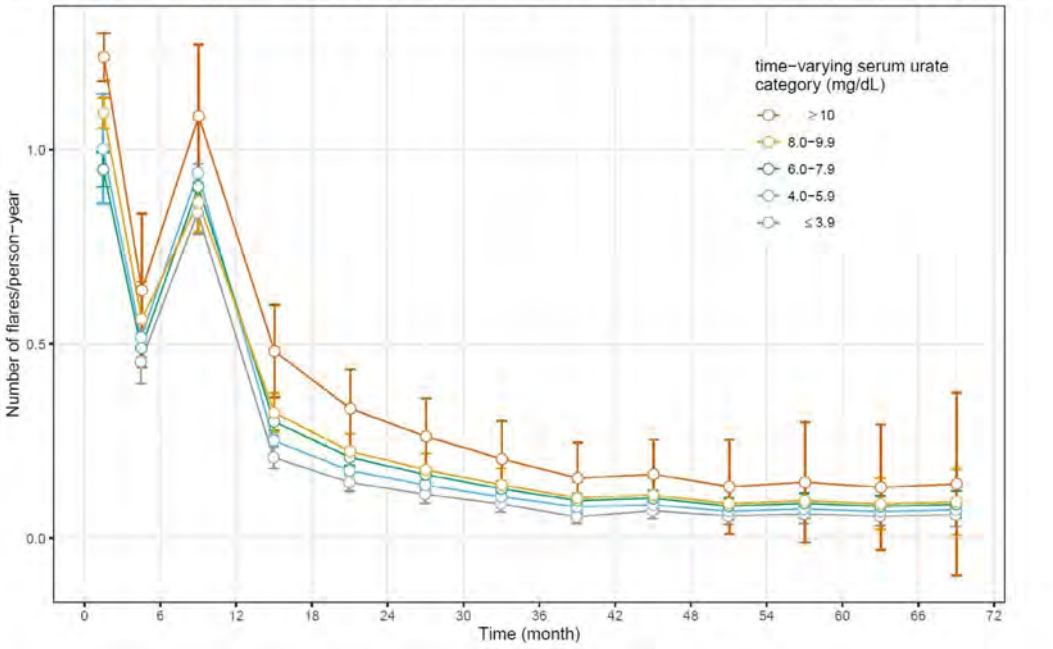

response relationship was observed between SU category and flare rate. Compared with SU 4.0-5.9 mg/dL, significantly lower flare rates were observed when SU ≤3.9 mg/dL and significantly greater rates when SU ≥10 mg/dL (p for trend < 0.01) (**Table 1**).

Conclusion: Gout flare rates were persistently higher when SU ≥6 mg/dL compared to SU at target after the first year of ULT, after accounting for censoring. These data suggest a potential benefit of achieving very low SU levels (≤3.9 mg/dL) and consideration of a longer duration of prophylaxis to reduce gout flares.

Fractures in Patients with Acute CPP Crystal Arthritis versus Matched Comparators in a Large Cohort Study

Sara Tedeschi[1], Keigo Hayashi[1], Ann Rosenthal[2], Javier Marrugo[1], Sho Fukui[1], Ellen Gravallese[3] and Daniel Solomon[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Medical College of Wisconsin, Milwaukee, WI, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Calcium pyrophosphate deposition (CPPD) disease was positively associated with osteopenia in two large cross-sectional studies, but risk of fractures has not been evaluated. We compared risk of fractures in patients with acute calcium pyrophosphate (CPP) crystal arthritis vs. matched comparators.

Methods: We performed a matched cohort study using electronic health record (EHR) data at a large academic medical center. Patients with at least one episode of acute CPP crystal arthritis, 1991-2017, were matched to comparators without acute CPP crystal arthritis on index date and year of EHR entry; comparators could have other types of arthritis. Index date was the 1st mention of "pseudogout" in notes or 1st synovial fluid analysis with CPP crystals, whichever came first. For the matched comparators, an encounter +/- 30 days was used as the index date. The primary outcome was first fragility fracture (humerus, wrist, hip, or pelvis fracture); secondary outcomes were first fracture at each separate anatomic site. Fragility fractures were identified via published algorithms using diagnosis and procedural codes with positive predictive value >90%. For patients with >1 fracture, only the earliest was included. The baseline period from EHR entry through index date was required to be ≥180 days. Patients with baseline fragility fracture were excluded. Covariates included age, sex, race, smoking, rheumatoid arthritis, hyperparathyroidism, healthcare encounters, multimorbidity index, BMI, oral glucocorticoids, osteoporosis treatment, and proton pump inhibitors. Censoring occurred at the earliest of death, fracture outcome, or last encounter before April 2023. We estimated incidence rates (IR) and IR ratios (IRR) for any fracture and for each anatomic site. Cox models estimated adjusted hazard ratios (HR) for fractures. Sensitivity analyses excluded patients prescribed glucocorticoids, osteoporosis treatment, or with rheumatoid arthritis.

Results: We identified 1148 patients with acute CPP crystal arthritis matched to 3730 comparators. Mean age was 73 years in both cohorts and more than half were female. Glucocorticoids and osteoporosis treatments were more frequent in the acute CPP crystal arthritis cohort than comparators (**Table 1**). Fracture incidence rates were twice as high in the acute CPP crystal arthritis cohort (11.2 per 1000 person-years) vs. comparators (5.6 per 1000 person-years) (**Table 2**). Cumulative incidence curves increasingly diverged, reflecting greater fracture rates in the acute CPP crystal arthritis cohort over time (**Figure 1**). Fracture risk was twice as high in the acute CPP crystal arthritis cohort vs. comparators after adjustment (HR 1.8,

Table 1. Baseline characteristics of patients with acute CPP crystal arthritis and comparators in a large electronic health record cohort study

	Acute CPP crystal arthritis n=1148	Comparators n=3730
Age at index date	72.6 (10.7)	72.5 (12.0)
Female	53.9	58.9
White race	83.1	80.0

[f] Bisphosphonate (alendronate, zolendronic acid, ibandronate, etidronate, risendronate, pamidronate), denosumab, raloxifene, or teriparatide prescribed in the 365 days before index date
[g] Prescribed in the 365 days before index date
[h] Weighted multimorbidity score based on ICD-9 codes for 40 chronic conditions (Radner H, et al. Seminars Arthritis Rheum 2015;45:167-73), range 0-156

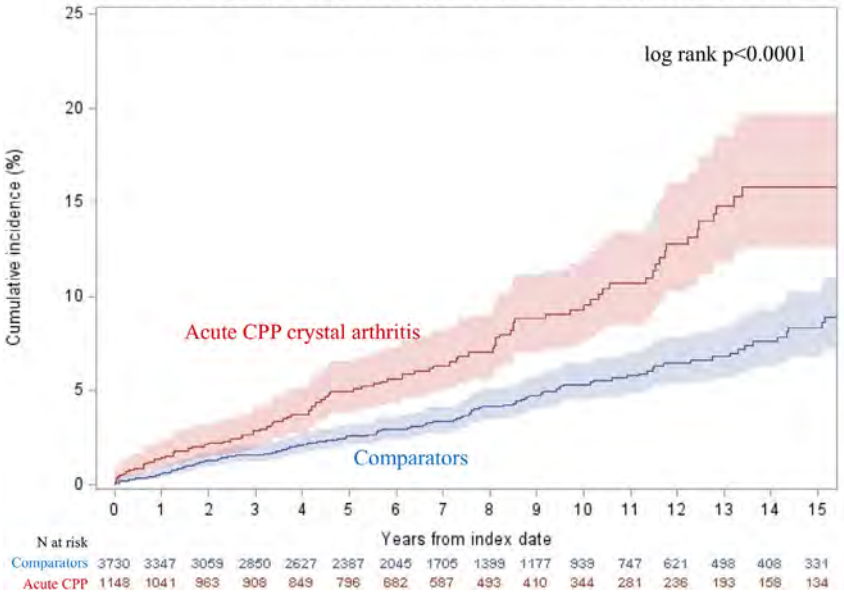
Table 2. Fracture incidence rates (IR), incidence rate ratios (IRR), and adjusted hazard ratios (HR)* in a large electronic health record cohort study

	Acute CPP crystal arthritis cohort n=1148		Comparator cohort n=3730			
	Events	IR/1000 person-years (95% CI)	Events	IR/1000 person-years (95% CI)	Fracture IRR (95% CI)	Adjusted HR* (95% CI)
Any fracture	100	11.2 (10.5, 11.9)	150	5.6 (5.4, 5.7)	2.0 (0.9, 4.3)	1.8 (1.4, 2.4)
Humerus	14	1.5 (1.2, 1.7)	24	0.9 (0.8, 0.9)	1.7 (0.8, 3.5)	1.4 (0.7, 2.8)
Wrist	23	2.5 (2.1, 2.8)	17	0.6 (0.6, 0.7)	4.0 (1.9, 8.3)	3.8 (2.0, 7.4)
Hip	32	3.4 (3.0, 3.8)	61	2.2 (2.1, 2.3)	1.5 (0.7, 3.2)	1.3 (0.8, 2.1)
Pelvis	41	4.4 (4.0, 4.8)	71	2.6 (2.5, 2.7)	1.7 (0.8, 3.6)	1.5 (1.0, 2.3)
Sensitivity analyses comparing risk of **any fracture**† for acute CPP crystal arthritis vs. comparators						
Excluding patients prescribed glucocorticoids						1.6 (1.2, 2.2)
Excluding patients prescribed osteoporosis treatment						1.9 (1.4, 2.5)
Excluding patients with rheumatoid arthritis						1.7 (1.3, 2.3)

* Adjusted for age, sex, race, healthcare utilization, body mass index, multimorbidity index, smoking, rheumatoid arthritis, hyperparathyroidism, oral glucocorticoids in the 90 days before index date, osteoporosis treatment in the 365 days before index date, proton pump inhibitor in the 365 days before index date

Analyses with the outcome of "any fracture" censored patients at the earliest fracture at any site (humerus, wrist, hip, or pelvis fracture), death, or last encounter before April 2023. Analyses of each separate anatomic site censored patients at the earliest fracture at that site, death, or last encounter before April 2023.

Figure 1. Cumulative fracture incidence among patients with acute CPP crystal arthritis and comparators in a large electronic health record cohort study



95% CI 1.4, 2.4); results were similar in sensitivity analyses excluding patients using glucocorticoids, osteoporosis treatments, or with rheumatoid arthritis (**Table 2**).

Conclusion: In this first-ever study of fractures and CPPD, we observed a doubling of fracture risk in patients with acute CPP crystal arthritis. Future studies evaluating bone turnover markers and changes in bone density over time in patients with CPPD are needed.

Treatment-emergent Major Adverse Cardiovascular and Thromboembolic Events Were Infrequent During Pegloticase Therapy: Pooled Clinical Trial Findings

orrin Troum[1], Mai Duong[2], Katie Obermeyer[2], Lissa Padnick-Silver[2] and **Brian LaMoreaux**[2], [1]University of Southern California Keck School of Medicine and Providence Saint John's Health Center, Santa Monica, CA, [2]Horizon Therapeutics, Deerfield, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is associated with high comorbidity, including cardiovascular (CV), metabolic, and renal disease,[1] with even higher burden in uncontrolled gout patients (pts).[2] CV (myocardial infarction [MI], stroke) and thromboembolic (VTE) event incidence of 17.34 and 3.65/1000 PY,[3,4] respectively, was reported in gout pts, with higher incidence after flare (CV within 120 days,[3] VTE within 30 days[4]). This link may be from systemic inflammatory consequences of seemingly local gout flares.[5,6] Maintaining serum urate (SU) < 6 mg/dL reduces flares over time.[7] However, initiating urate-lowering therapy (ULT) can induce flare, raising the question of CV/VTE event with ULT initiation. Here, we examine CV/VTE events after pegloticase initiation in this pooled post hoc analysis of clinical trial pts.

Methods: Phase 3,[8] MIRROR OL,[9] and MIRROR RCT[10] pts with ≥1 pegloticase infusion were included (244 biweekly dosing [110 with methotrexate {MTX}], 84 monthly dosing), with focus on biweekly (on-label) pts. All had uncontrolled gout and received flare prophylaxis (FP) ≥1 wk before first dose. Standard pre-infusion prophylaxis was used, including 125 mg IV methylprednisolone or 200 mg hydrocortisone. Gout flare and CV/VTE events were identified using treatment-emergent (TE) AEs during 24 wks of therapy. Flare exposure window was 120 days.[3]

Results: 5/328 pts (1.5%; 4 monotherapy colchicine FP, 1 pegloticase+MTX ibuprofen FP) beginning pegloticase had ≥1 CV/VTE event (cardiac arrest [CA, n=2]; CHF, DVT, MI, TIA [n=1 each]), with all occurring during the flare exposure window (time from first TE flare, range: 18-130 days; time from most-recent TE flare: 3-69 days). 3 CV/VTE events occurred in 244 pts receiving biweekly pegloticase (1.2%, 35.4/1000 PY), with 2 in monotherapy pts (1.5%; CA, CHF) and 1 in a pegloticase+MTX pt (0.9%; CA). 176/244 (72.1%) had ≥1 TE flare. Pts with and without flare were similar but those with flare had more frequent pre-treatment flares (10.9±13.6 vs 5.3±5.7 flares/year [median: 7 vs 3]).

Conclusion: 1.2% of pts had CV/VTE events during biweekly pegloticase therapy, with similar incidence (35.4/1000 PY) to the general gout population (20.99-44.7/1000 PY[3,4,11]) and lower than with XOI initiation (51.8-99.3/1000 PY[12]). All events occurred within the 120 days of flare when pts were at higher risk.[3,4] Of note, pts with TE flares had higher pre-treatment flare rates than those without. Maintaining SU < 6 mg/dL decreases gout flares over time[7] so a treat-to-target approach with ULT may be of critical importance for maintaining gout pt health over the long-term.

Oral Urate-Lowering Therapy Use and Efficacy Following Pegloticase Treatment: Findings from a Rheumatology Network Database

Lissa Padnick-Silver[1], Andrew Concoff[2], Hong-Ye Gao[1], Qianhong Fu[1], **Brian LaMoreaux**[1] and N. Lawrence Edwards[3], [1]Horizon Therapeutics, Deerfield, IL, [2]United Rheumatology, Happauge, NY, [3]University of Florida College of Medicine, Gainesville, FL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pegloticase, a recombinant pegylated uricase, rapidly reduces serum urate (SU) in patients refractory to/intolerant of oral urate-lowering therapies (ULTs).[1,2] However, pegloticase is generally used for ≤1 year for intensive SU-lowering and subsequent urate burden depletion. Optimal post-pegloticase treatment has not yet been established, but use and efficacy of oral ULTs remains an important unanswered clinical question. This analysis retrospectively examined data from a large US rheumatology database to better understand real-world practice patterns of post-pegloticase oral ULT use and to preliminarily examine post-pegloticase oral ULT efficacy.

Methods: Patients in the UR-NICE data repository who had first pegloticase infusion code (J2507) between 2012 and 2022 were included in analyses. The beginning and end of therapy was defined as the date of first and last pegloticase infusion code, respectively. All patients were in the database for ≥60 days following last infusion. Oral ULT use (allopurinol, febuxostat, probenecid) before and after pegloticase therapy was examined. Patients were also stratified by those that did and did not receive ≥12 infusions (considered as "full course" in prior retrospective studies[3]). Patient characteristics prior to pegloticase therapy were also examined to help characterize the pegloticase-treated population.

Results: 211 patients (77% male; mean[±SD] age: 62.7±12.8 years, BMI: 32.9±7.2 kg/m^2, eGFR: 66.0±24.7 ml/min/1.73m^2 [46% eGFR < 60]) were included. 74% had tophaceous gout and pre-pegloticase SU was 7.9±2.5 mg/dL (n=148). Available inflammatory biomarkers were moderately elevated (median CRP: 3.3 mg/dL [n=114], neutrophil-to-lymphocyte ratio [NLR][4]: 2.9 [n=41]). 141 patients (67%) had pre-pegloticase oral ULT use noted (73% allopurinol, 48% febuxostat, and/or 18% probenecid). Patients received a mean (±SD) of 12.3±12.6 pegloticase infusions (median: 9; 88 [42%] received ≥12), with a 2.2±2.0 wk dosing interval. Following last infusion, 115 patients (55%) began oral ULT (67% allopurinol, 44% febuxostat, and/or 17% probenecid), most (67%) within 30 days of last pegloticase infusion. More patients who received ≥12 infusions had an SU < 6 mg/dL when treated with post-pegloticase oral ULT than those who received < 12 infusions (first post-ULT SU < 6 mg/dL: 78% vs 36%; mean SU: 4.7±3.0 [n=37] vs 7.4±2.9 mg/dL [n=47]).

Conclusion: These pegloticase-treated patients reflected a typical uncontrolled gout population. Two-thirds of patients began oral ULT after pegloticase, most within 30 days of last infusion. Patients who had a longer pegloticase course (≥12 infusions) were more likely to have post-treatment oral ULT efficacy, perhaps because of greater urate burden depletion. These data suggest oral ULTs may be effective after successful pegloticase therapy but further prospective studies are needed to verify our findings and better understand how overall urate burden may influence oral ULT efficacy.

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

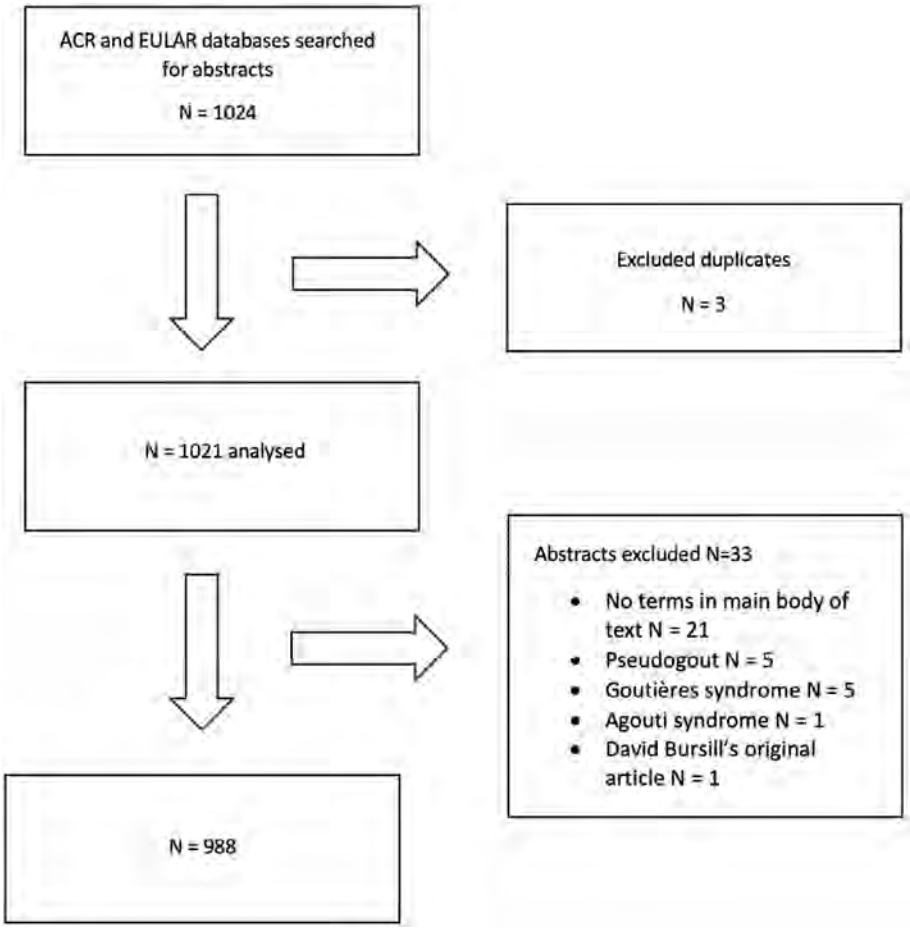

Figure 1. Consort diagram of abstract inclusion criteria

Background/Purpose: Uniform terminology with standardised definitions for the various elements and states of a disease ensure accurate and consistent technical communication. In 2019 the Gout and Crystal Arthritis Network (G-CAN) published consensus statements for the nomenclature of disease elements and disease states in gout. The aim of this study was to determine adherence to the G-CAN consensus statements since publication.

Methods: ACR and EULAR conference abstracts were searched using online databases for the keywords "gout" "urate" "uric acid" "hyperuricaemia" "tophus" and/or "tophi" before and after-publication of the consensus statements (01/01/2016-31/12/2017 and 01/01/2020-31/12/2021 (respectively)). Abstracts were manually searched for labels used to reference gout disease elements and states. Labels were extracted from text, figures, and tables. Use of the G-CAN agreed labels, as well as alternatives, were compared between the two time periods and between abstracts that included a G-CAN consensus statement author and those that did not in 2020/2021. Use of the term 'chronic gout', which G-CAN advised should be avoided, was also compared between the two time periods.

Results: There were 988 abstracts included in the analysis; 596 in 2016/2017 and 392 in 2020/2021. One or more G-CAN agreed labels were used in 445/596 (74.9%) of abstracts in 2016/2017, increasing to 311/392 (79.4%) in 2020/2021 (p=0.006). Use of the agreed labels 'urate', 'gout flare', and 'chronic gouty arthritis' increased between the two periods. There were 219/383 (57.2%) abstracts with the agreed label 'urate' in 2016/2017 compared to 164/232 (70.7%) in 2020/2021 (p=0.001). There were 60/175 (34.3%) abstracts with the agreed label for 'gout flare' in 2016/2017 compared with 57/109 (52.3%) in 2020/2021 (p=0.003). Only 1/35 (2.9%) abstracts used the agreed label for 'chronic gouty arthritis'

in 2016/2017 compared to 6/16 (37.5%) in 2020/2021 (p=0.02). Abstracts with consensus statement authors used the agreed labels in 87.4% of abstracts, compared to 74.5% without in the 2020/2021 period (p< 0.001). Use of the label 'chronic gout' reduced between the two time periods.

There were 29/596 (4.9%) abstracts in 2016/2017 that used the label 'chronic gout' compared with 8/392 (2.0%) abstracts in 2020/2021 (p=0.02).

Conclusion: Use of the G-CAN agreed gout labels has increased but gout nomenclature remains imprecise. Additional efforts are needed to ensure consistent use of agreed nomenclature for gout in the scientific literature.

Incidence and Prevalence of Cardiovascular and Metabolic Diseases Following Gout Diagnosis in the United Kingdom Using the THIN Database

Michael Garshick[1], Haridarshan Patel[2], **ada Kumar**[2], Brian LaMoreaux[2], Lissa Padnick-Silver[2], Louis Dron[3], Vinusha Kalatharan[3], Vivek Verma[3] and Michael Pillinger[4], [1]NYU School of Medicine/NYU Langone Medical Center, New York, NY, [2]Horizon Therapeutics, Deerfield, IL, [3]Cytel Canada Inc., Vancouver, BC, Canada, [4]New York University Grossman School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a common inflammatory arthropathy characterized by pain, joint swelling, and monosodium urate crystal deposits in joints, organs, and soft tissues.[1] While gout is associated with cardiometabolic disorders, there is limited data on comorbidity burden in gout patients and almost no data on their longitudinal development.[1] This study aimed to estimate the incidence and prevalence of cardiometabolic disease in patients with gout in the United Kingdom (UK).

Methods: Using The Health Improvement Network (THIN) Database (A Cegedim Proprietary Database), a cohort of patients with a first gout diagnosis between January 1, 2003 and December 5, 2021 was analyzed. Patients were excluded if death occurred before first gout diagnosis, last data point was after last data-cut or before first gout diagnosis, the patient was < 18 years old at first gout diagnosis, or there was a prior history of congenital, toxin-related, or infectious cardiovascular disease (CVD). For incidence calculations, patients with prior history of the examined condition were excluded. Patients were followed from gout diagnosis until earliest of death, database disenrollment, or last available data. Gout and outcome diagnoses were identified using Read codes (clinical terminology system used in the UK), with ≥2 codes required ≥30 days apart to minimize identified comorbidity misclassification. Prevalence (in %) and incidence (in % and rate/1,000 person-years [PY]) of gout-associated cardiometabolic diseases (**Table 1**) were calculated. This work uses data provided by patients and collected by the NHS as part of their care and support.

Table 1. Incidence and prevalence of cardiovascular and metabolic diseases following first gout diagnosis in patients from the United Kingdom.

	No. of patients with incident disease n (%)[a]	Incidence rate (per 1000 PY[a])	No. of patients with prevalent disease n (%)[b]
Cardiovascular disease			
≥1 cardiovascular disease	20,779 (25.3)	29.5	118,563 (56.9)
Hypertensive diseases	22,270 (22.7)	26.4	109,452 (52.7)
Ischemic heart diseases	18,615 (12.8)	13.5	39,721 (19.1)
Dysrhythmias (including arrhythmia)	4,699 (2.6)	2.7	7,440 (3.6)
Cerebrovascular diseases	4,144 (2.1)	2.2	5,925 (2.8)
Peripheral vascular diseases	3,102 (1.7)	1.7	4,861 (2.3)
Heart failure	2,630 (1.4)	1.4	4,254 (2.0)
Cardiac valvular diseases	834 (0.4)	0.4	1,031 (0.5)
Pulmonary circulation diseases	420 (0.2)	0.2	473 (0.2)
Conduction disorders	258 (0.1)	0.1	338 (0.2)
Cardiomyopathies	201 (0.1)	0.1	216 (0.1)
Cardiometabolic disease			
≥1 metabolic disease	25,873 (20.0)	23.3	73,744 (35.5)
Dyslipidemia	21,097 (14.9)	17.0	53,996 (26.0)
Type II diabetes mellitus	15,120 (8.6)	9.2	34,473 (16.6)
Non-alcoholic liver diseases	706 (0.3)	0.4	808 (0.39)
Metabolic Syndrome	308 (0.1)	0.2	326 (0.2)

[a]The total number of patients included in analyses varied across comorbidities (patients with prior history of the examined outcome were excluded for incidence calculations, all N≥54,029). [b] N=207,872. Abbreviations: PY, person-years.

Results: A total of 207,872 patients (74.9% male; 47.9% white [N=106,304 with known race]) were included in analyses. At first gout diagnosis, median [interquartile range, IQR] age was 61.7 [49.1, 73.5] years and BMI was 29.0 [25.9, 32.7] kg/m^2. 57.0% had ≥1 CVD code (median [IQR] follow-up: 2.6 [0.7, 8.4] years) and 35.5% had ≥1 metabolic disease code (5.4[1.6, 10.7] years) after gout diagnosis. In patients without a pre-gout cardiovascular code, ≥1 CVD code was identified in 25.3% of patients (median [IQR] follow-up: 8.0 [3.9, 12.8] years) for an overall incidence of 29.5/1000 PY after gout diagnosis. In patients without a pre-gout metabolic disease code, ≥1 metabolic disease code was identified in 20.0% of patients (median [IQR] follow-up: 7.9 [3.8, 12.9] years) for an overall incidence of 23.3/1000 PY after gout diagnosis. The incidence and prevalence of individual conditions are summarized in **Table 1**.

Conclusion: In the first 8 years after initial gout diagnosis, approximately 1 in 4 patients without prior cardiovascular disease developed a new cardiovascular comorbidity and 1 in 5 patients without prior metabolic disease developed a new metabolic comorbidity. Further, the overall prevalence of cardiovascular and metabolic disease was high in this UK gout population, with hypertension and ischemic heart disease of notable frequency among both incident and prevalent cohorts. Comorbidity development over time will be further explored in and compared between controlled and uncontrolled patients to examine potential contributions of gout.

Gout: A Gateway to Chronic Opioid Use?

Lindsay Helget[1], Bryant England[1], Punyasha Roul[1], Harlan Sayles[1], Tuhina Neogi[2], James O'Dell[1] and Ted R Mikuls[3], [1]University of Nebraska Medical Center, Omaha, NE, [2]Boston University School of Medicine, Boston, MA, [3]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Painful gout flares often lead to healthcare visits which, based on prior reports, results in the use of opioid therapy for flare management, despite opioids not being a preferred treatment. The use of opioids for flares raises concerns that uncontrolled gout may serve as a "gateway" to chronic opioid use. The objectives of this study were to: 1) compare the risk of initiating chronic opioid use in Veteran's Health Administration (VHA) patients with and without gout, and 2) to examine determinants of initiating chronic opioid use in gout patients.

Methods: We performed a matched cohort study, identifying patients with gout using national VHA data from 1/1999-1/2015 based on ≥2 ICD-9 codes for gout (274.X). Gout cases were matched to patients without gout (up to 1:10) based on birth year, sex, and VA enrollment year, then followed from the index date (fulfillment of gout algorithm) until the earliest of incident chronic opioid use, death, or 5 years after the index date. Individuals with a fill of an opioid in the year prior to the index date were excluded. Chronic opioid use was defined as ³90 cumulative days' supply with at least 2 dispenses occurring in a 6-month window with no gap >32 days. Associations of gout (vs. non-gout) with chronic opioid use were quantified using a cumulative hazard curve and multivariable Cox proportional hazards regression. Associations between patient characteristics and time-to-initiating chronic opioid use among patients with gout were examined in separate analyses. Covariates in both models included race, comorbidities, body mass index (BMI), and smoking status. In the gout-only model, additional covariates included age, sex, Rheumatic Disease Comorbidity Index (RDCI), time-varying serum urate (SU) control (average SU < 6 mg/dL in prior year) and urate-lowering treatment (ULT; ≥2 fills of ULT with ≥90 days covered by dispensing in prior year).

Table 1. The frequency, crude rate and hazard ratios of opioid exposure leading to chronic use in patients with gout (vs. non-gout) *Covariates include age, index year, race (Black/African American, Other, or Missing vs. White), BMI, smoking status (Former, Current, or Missing vs. Never), chronic lung disease, past myocardial infarction, cardiovascular disease, stroke, hypertension, diabetes, fracture, depression, stomach ulcer or cancer.

	Non-Gout (n=3,608,182)	Gout (n=419,837)
Patient initiating chronic opioid use, n (%)	137,497 (3.8)	28,948 (6.9)
Patient years (pt-yrs) of follow-up	14,951,085	1,749,357
Crude Rate (95% CI), per 1,000 pt-yrs	9.2 (9.1-9.2)	16.5 (16.4-16.7)
Unadjusted HR (95% CI)	Reference	1.78 (1.75-1.80)
Adjusted HR (95% CI)*	Reference	1.36 (1.34-1.39)

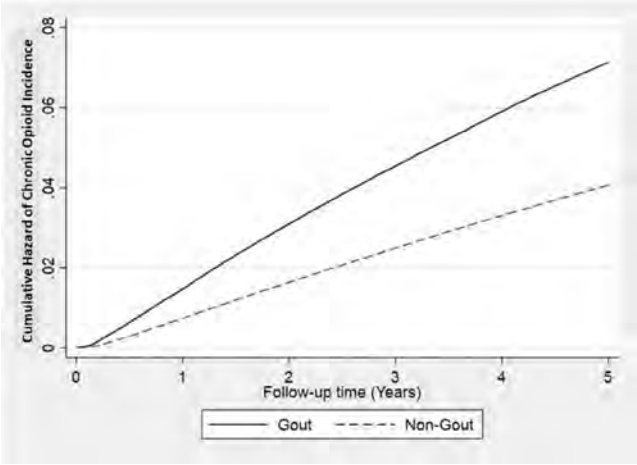

Figure 1. Cumulative hazard of opioid exposure leading to chronic use in patients with gout (vs. non-gout)

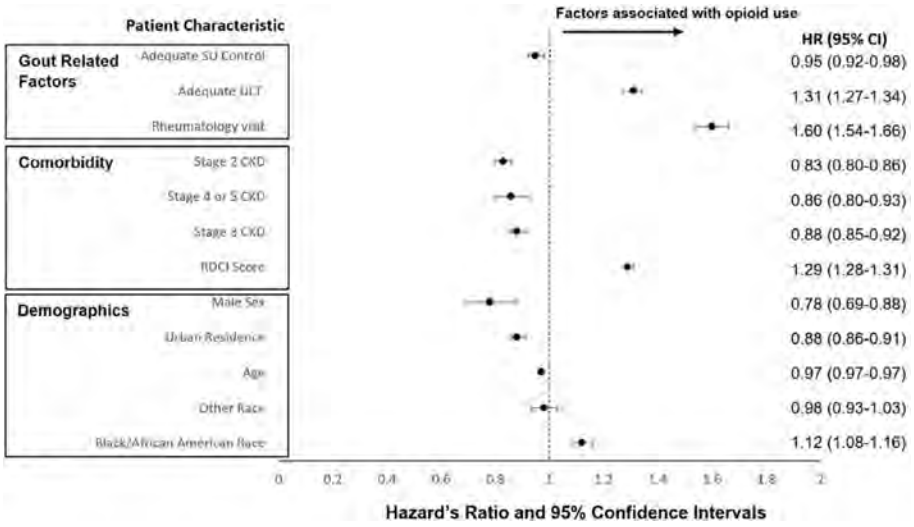

Figure 2. Factors associated with initiating chronic opioid use in patients with gout *All variables in multivariable model with p-value <0.05 are shown in the figure White/Caucasian race was referent value; Other race includes composite of Asian, Native Hawaiian/Pacific Islander, and American Indian; Adequate ULT indicates ≥2 fills of ULT –AND- at least ≥90 days covered by dispensing; Adequate SU control indicates average SU <6 mg/dL; Age reported in years; Rheumatology visit reported as presence of any visit throughout follow up period; RDCI (rheumatic disease comorbidity index) including lung disease, myocardial infarction, other cardiovascular disease, stroke, hypertension, fracture, depression, diabetes mellitus, ulcer or stomach problem, and cancer Abbreviations: urate lowering therapy (ULT), chronic kidney disease (CKD), serum urate (SU)

Results: Over 16.7 million patient-years of follow-up (median follow-up 5 years), 6.9% of gout patients initiated chronic opioids vs. 3.8% of non-gout patients (Fig. 1, Table 1). After adjusting for covariates, patients with gout were significantly more likely than non-gout patients to initiate chronic opioid use (aHR 1.36; 95% CI 1.34 to 1.39). Factors associated with gout-related chronic opioid exposure are summarized in Fig. 2.Among those with gout, factors positively associated with chronic opioid use included Black/African American race, comorbidities, ULT use, and rheumatology encounter. Factors negatively associated with chronic opioid use in those with gout included male sex, CKD, urban residence, SU control, age, and Asian, Native Hawaiian/Pacific Islander, and American Indian race.

Conclusion: In the VHA, we found that patients with gout were 36% more likely than those without gout to initiate chronic opioid use, after accounting for potential confounders, despite opioids not being recommended for management of gout flares. Associations between patient characteristics and time-to-initiating chronic opioid use highlight potential gaps in care,

particularly among underserved Black/African American and rural populations as well as the potential for adequate urate control to reduce the risk of chronic opioid use in gout.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

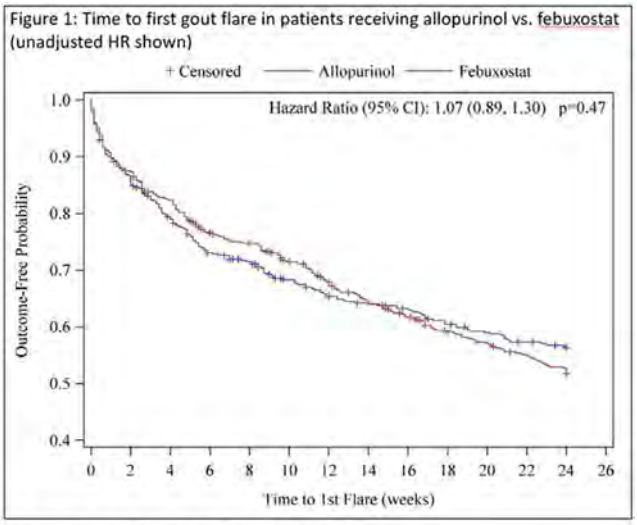
Session Time: 9:00AM–11:00AM

Background/Purpose: Initiating urate-lowering therapy (ULT) in gout is known to precipitate flares, which can lead to decreased adherence and suboptimal outcomes. Until recently, there has been limited data comparing the risk of flare complicating the initiation and escalation of allopurinol and febuxostat, administered as part of a treat-to-target strategy with appropriate anti-inflammatory flare prophylaxis. The STOP Gout study (O'Dell J et al. NEJM Evid, 2022) provided an opportunity to compare flare risk with different agents and to identify predictors for gout flare during ULT initiation and titration.

Methods: The STOP Gout Study was a randomized, double-blind, placebo-controlled, 72-week study comparing allopurinol to febuxostat with a primary outcome of flare occurring during the final study phase (weeks 48-72). This post-hoc analysis evaluated flares occurring during phase 1 (weeks 0-24) when ULT was initiated and titrated towards a serum urate (sUA)

Table 1. ULT dose increases and flares occurring during Phase 1 (weeks 0 to 24).

	Total (N = 940)	Allopurinol (N = 468)	Febuxostat (N = 472)	p-value
ULT dose increases per patient, Median (IQR)	2 (2)	3 (2)	1 (1)	<.001
Total flare rate (95% CI), per 100 pys	217.5 (203.6, 232.3)	209.5 (190.5, 230.4)	225.4 (205.8, 246.9)	0.28
Total flares per patient, Median (IQR)	0 (1)	0 (1)	0 (1)	0.24
Flares per patient, %				0.48
No Flares	55.9	57.9	53.8	
1 Flare	21.6	20.9	22.2	
2-3 flares	16.6	15.0	18.2	
≥4 flares	6.0	6.2	5.7	



goal of < 6 mg/dl (<5 mg/dl if tophi). Flares were assessed at regular intervals and based on patient report. Predictors of flare were examined using multivariable Cox proportional hazards regression with the at-risk period starting at enrollment and extending to the first of: flare, loss to follow-up or withdrawal, death, or the end of phase 1. In addition to ULT (febuxostat vs. allopurinol), baseline covariates included demographics (age, sex, race), gout-specific factors (prophylaxis used, disease duration, tophi, sUA, prior allopurinol use, CRP), and comorbidities (Stage 3 chronic kidney disease [CKD], hypertension, cardiovascular disease [CVD], diabetes, diuretic use, body mass index [BMI], and alcohol use). ULT dose escalation was modeled as a time-varying covariate based on the occurrence of any dose escalation, examining for evidence of ULT-escalation interaction.

Results: Study participants (n=940) were mean age 62.1 years and predominantly male (98.4%); 468 patients received allopurinol, 472 received febuxostat. The mean sUA was 8.5 mg/dL and all participants received prophylaxis (90% colchicine). ULT dose increases and flares experienced during phase 1 are summarized in **Table 1**, with flare rate not differing by treatment. Time to initial flare is shown in **Figure 1**. In multivariable model, there was no association of ULT treatment (aHR 1.14; 95% CI 0.87-1.49), ULT escalation (aHR 1.14; 95% CI 0.90-1.44), prophylaxis type, or comorbidity with flare and no evidence of a ULT-escalation interaction (p=0.66). In the multivariable model, factors associated with increased flare risk during ULT initiation and escalation included younger age (aHR 0.99, 95% CI 0.98-1.00), higher baseline sUA (aHR 1.09; 95% CI 1.01-1.18) and absence of tophi (aHR 0.70; 95% CI 0.54-0.91).

Conclusion: In this analysis of the STOP Gout trial, we observed no difference in flare risk between allopurinol and febuxostat during initiation and titration according to a treat-to-target management strategy using best practice gout flare prophylaxis. Neither the prophylaxis employed, nor the presence of other chronic conditions that frequently accompany gout influenced flare risk following ULT initiation. Few factors were predictive of flare during ULT initiation and titration.

Abstract Number: 0242

Venous Thromboembolism in Patients with Gout in the US

Alka Mithal[1], Maanek Sehgal[1], Brian LaMoreaux[2] and **Gurkirpal Singh**[1], [1]ICORE, Woodside, CA, [2]Horizon Therapeutics, Deerfield, IL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Venous thromboembolism (VTE), manifested by deep venous thrombosis (DVT) and pulmonary embolism (PE), is a common medical problem with an estimated incidence of 1–2 per 1000 person-years[1]. Patients who develop VTE have high mortality rates of 11–30% per annum[2,3]. While VTE is known to be associated with surgery, immobilization, and cancer (2), some studies have also reported an increased risk of VTE in patients with gout [4-6]. However, there is little nationwide data in the United States (US) on the clinical and economic consequences of VTE in persons with gout. This study examined VTE hospitalizations in patients with gout in the US and estimated their clinical and economic impact.

Methods: The National Inpatient Sample (NIS) is a stratified random sample of all US community hospitals designed to produce national estimates of inpatient utilization, cost, and outcomes. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. Unweighted it contains data from around 7 million hospitalizations a year, weighted it estimates around 35 million hospitalizations nationally. We examined all inpatient hospitalizations in the NIS in 2020, the most recent year of available data, with a primary or secondary diagnosis of gout and VTE.

Results: In 2020, there were 32.4 million all-cause hospitalizations in the US, with 19.7 million occurring in persons 45 years or older. Of these, 785,905 hospitalizations occurred in people aged 45 years and over with a diagnosis of gout. This population had a mean age of 71.8 years (95% confidence limits: 71.7–71.9 years) and were more likely to be men (68.8%). Of these hospitalizations, 79,260 (10.1%) also had a concomitant diagnosis of VTE (**Table 1**). As a comparison, only 8.2% of hospitalizations in the general population 45 years or older had a concomitant diagnosis of VTE ($p < 0.001$ compared to persons with gout). Persons with gout and VTE had a mean age of 71.6 years (95% confidence: limit 71.4–71.8 years) and were mostly men (66%, **Table 2**). The average cost of each hospitalization was $76,373 (95% confidence limit $73,343–$79,403), with a total annual national cost of over $6.1 billion.

Conclusion: One out of 10 hospitalizations in persons with gout have a concomitant diagnosis of VTE, with considerable clinical and economic consequences. VTE occurred more frequently in the presence of gout in hospitalized patients over the age of 45 years (1/10 vs. 1/12 patients) and resulted in considerable economic burden. These findings suggest that

Table 1. Venous thromboembolism in gout versus all-cause hospitalizations among men and women 45 years of age or older.

Age (years)	Gender	Hospitalizations with a Diagnosis of Gout N	Hospitalizations with VTE in Persons with Gout n (%)	All-cause Hospitalizations N	All-cause Hospitalizations with VTE n (%)
45-64	Male	165,325	16,710 (10.1%)	416,3365	323,625 (7.8%)
	Female	45,205	5150 (11.4%)	3,519,950	280,900 (8.0%)
≥65	Male	375,685	35,600 (9.5%)	5,756,550	473,905 (8.2%)
	Female	199,650	21,800 (10.9%)	6,300,300	547,550 (8.7%)
All patients ≥45		785,905	79,260 (10.1%)	19,741,255	1,626,055 (8.2%)

VTE, venous thromboembolism.

Table 2. Hospitalizations with a gout diagnosis in patients 45 years of age or older with and without venous thromboembolism.

	Hospitalizations with a Diagnosis of Gout (N=785,905)	Gout Hospitalizations with a VTE (N=79,260)
Age, mean (95% CI)	71.8 (71.7–71.9)	71.6 (71.4–71.8)
Male, n (%)	541,010 (68.8%)	52,310 (66.0%)
Length of hospitalization, days, mean (95% CI)	5.8 (5.7–5.8)	6.4 (6.3–6.5)
Cost of hospitalization, USD, mean (95% CI)	72,533 (70,584–74,483)	76,373 (73,344–79,403)
Medicare	572,575 (72.5%)	59,085 (70.5%)
Medicaid	48,495 (6.1%)	4975 (5.9%)
Private insurance	131,605 (16.7%)	12,305 (14.7%)

CI, confidence interval.

VTE prevention measures and patient education on VTE signs/symptoms may be of particular importance in patients with gout.

Decreased Incidence of Gout After Kidney Transplant over the Last Decade: An Analysis from a Large Academic Renal Transplant Center

Nishah Panchani[1], Angelo Gaffo[2] and Vineeta Kumar[3], [1]Tinsley Harrison Internal Medicine Residency Program, University of Alabama at Birmingham, Arlington, TX, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, AL; Birmingham VA Medical Center, Birmingham, AL, [3]Division of Nephrology/Transplant, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout has been associated with high rates of morbidity and mortality in kidney transplant (KT) patients with increased bone destruction and associated cardiovascular and kidney disease progression after transplantation. The incidence of gout after transplant has been reported to be 7-13%. [1, 2] Cyclosporine, which has been the mainstay immunosuppressive therapy after KT, has been associated with hyperuricemia and gout; however its use in KT has markedly decreased. [3] There is a paucity of studies comparing the incidence of gout and hyperuricemia in KT patients

Table 1. Demographics of KT patients.

Variables	Number of Patients n=1914, (%)
Gout at any point of time	477 (25%)
Male	1159 (60.6%)
Deceased	262 (13.7%)
Race	
African American	1010 (53%)
Caucasian	794 (41%)
Asian	54 (2.8%)
Latino	44 (2.3%)
Immunosuppression	
Tacrolimus	1904 (99%)
Cyclosporine	78 (4%)
Mycophenolate Mofetil	1905 (99.5%)
Azathioprine	117 (6%)

Table 2. Risk factors associated with gout in patients diagnosed after KT.

Variables	Number of Patients n=71, (%)
Hypertension	71 (100%)
Hyperlipidemia	59 (83%)
Diuretics	62 (87%)
BMI ≥ 30	62 (87%)
Uric acid ≥ 7	35 (49%)
Diabetes Mellitus	52 (73%)

since the adoption of newer immunosuppressive therapies and overall less to no use of cyclosporine. We hypothesize that KT recipients have lower frequencies in incidence of gout with regimens excluding the use of cyclosporine.

Methods: Our population consisted of all patients ages 18 and above who received a KT at our institution between 01/01/2013 and 01/01/2023. We excluded patients with history of gout prior to transplant. Using ICD-10 codes and our institution's medical records informatics software, we identified patients that were diagnosed with gout after receiving KT. Patient demographics and immunosuppressive therapies prior to diagnosis of gout were analyzed. Categorical variables were reported as frequency percentages.

Results: A total of 1914 patients underwent KT since 2013. A majority (60.6%) of the source population for the study were male (Table 1). Out of 1914 patients, 477 patients (25%) were identified to have a concurrent diagnosis of gout at any point of time (before or after KT). Most of the patients developing gout at any point were male (72%), and 228 identified as African American (47.8%). Only 71 out of the remaining 1437 gout-free patients (4.9%) had a new diagnosis of gout after KT. Prior to developing gout, 50 of these 71 patients were on tacrolimus, 2 on cyclosporine, 7 on mycophenolate mofetil, and 2 on azathioprine. Hyperuricemia above 7 mg/dl was appreciated in only 35 out of 71 of these patients (Table 2).

Conclusion: In a large population of patients receiving KT, our study reports an incidence of gout comparable to that of the general population and lower than historical reports in KT patients. Most cases of gout after transplant were seen in patients on tacrolimus, however this is likely a reflection of the overall decrease in use of cyclosporine in general. Further studies are warranted to investigate and characterize the burden of disease associated with gout cases associated with KT over the last decade.

Efficacy and Safety of AR882, a Selective Uric Acid Transporter 1 (URAT1) Inhibitor, in Gout Patients with Various Baseline Characteristics Following 12-Week Treatment in Patients

James Cheng-Chung Wei[1], Roy Fleischmann[2], sarah Morris[3], Vijay Hingorani[4], Elizabeth Polvent[5], Zancong Shen[6], Shunqi Yan[7], Li-Tain Yeh[8] and **Robert Keenan**[9], [1]Chung Shan Medical University Hospital, Department of Rheumatology, Taichung, Taiwan, [2]Division of Rheumatology, University of Texas Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX, [3]Arthrosi Therapeutics Inc, San Diego, CA, [4]Vanguard Healthsciences, Inc., San Diego, CA, [5]Arthrosi Therapeutics, Inc., Roseville, CA, [6]Arthrosi Therapeutics, San Diego, CA, [7]Arthrosi Therapeutics, Inc., Laguna Hills, CA, [8]Arthrosi Therapeutics, Inc., Irvine, CA, [9]Arthrosi Therapeutics, Chapel Hill, NC

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: AR882 is a novel, potent, and selective URAT1inhibitor in development for the treatment of gout and tophaceous gout. AR882-202 was a global, multi-center, randomized, double-blinded, 12-week, placebo-controlled phase 2b trial to evaluate the safety and efficacy of AR882 versus placebo in patients with gout. Here, we report the analysis of the efficacy and safety based on various demographics and baseline characteristics.

Methods: The trial recruited 140 gout patients 18 to 75 years of age with eGFR >30 mL/min across 20 sites in the US, Australia, and Taiwan. Subjects were recruited from the US (15 sites), Australia (2 sites) and Taiwan (3 sites), and were randomized into one of three treatment groups at a 1:1:1 ratio. Blood samples were collected every 2 weeks up to 12 weeks to

Table 1.Demographics and baseline characteristics

	Australia (N=30)	Taiwan (N=23)	US (N=87)	All subjects (N=140)
Age (mean, range)	52 (31,73)	46 (24,71)	58 (32,73)	56 (24,73)

Weight (kg)	91.4 (14.9)	84.1 (10.0)	101.3 (18.4)	96.38 (17.8)
BMI (kg/m^2)	30.0 (4.30)	28.7 (3.62)	32.7 (5.05)	31.5 (4.9)
Baseline sUA (mg/dL)	8.48 (1.12)	8.78 (1.24)	8.70 (1.41)	8.61 (1.29)
eGFR (mL/min)				
>=90	22 (73%)	14 (67%)	55 (63%)	92 (65.7%)
60-89	7 (23%)	7 (30%)	23 (26%)	37 (26.4%)
<60	1 (3.3%)	1 (4.8%)	9 (10%)	11 (7.9%)

Table 2. Patient comorbidities across regions

Comorbidities	Australia (n=30)	Taiwan (n=23)	US (n=87)	All subjects (n=140)
Hypertension	4 (13%)	7 (30%)	55 (63%)	66 (47%)
Hyperlipidemia /Hypercholesterolemia	6 (20%)	9 (39%)	34 (39%)	49 (35%)
Chronic kidney disease	8 (27%)	8 (35%)	32 (37%)	48 (34%)
Arthritis (other than gout)	3 (10%)	4 (17%)	25 (29%)	32 (23%)
Diabetes	3 (10%)	2 (9%)	22 (25%)	27 (19%)
Cardiovascular disease	3 (10%)	3 (13%)	15 (17%)	21 (15%)
Lung disease	3 (10%)	1 (4%)	12 (14%)	16 (11%)
Liver disease	2 (7%)	3 (13%)	2 (2%)	7 (5%)

Table 3. Response rate of sUA lowering in patients across regions (per-protocol population)

Region	Treatment	Group N	<6 mg/dL, %	<5 mg/dL, %
Australia	Placebo	6	0	0
	50 mg	9	89	78
N=27	75 mg	12	100	92
Taiwan	Placebo	9	0	0
	50 mg	5	80	40
N=22	75 mg	8	88	88
US	Placebo	27	0	0
	50 mg	22	73	41
N=67	75 mg	18	83	72

monitor sUA levels and safety measures. Efficacy endpoints included the percent of patients who reached a sUA < 6, < 5 mg/dL and lower. Safety data, including vital signs and electrocardiograms, were collected throughout the study.

Results: Baseline characteristics of enrolled participants are illustrated in **Table 1**. The mean baseline sUA level was 8.6 (±1.3) mg/dL and was similar across regions (8.5-8.8 mg/dL), while mean body weights and BMI showed slight regional differences.

Common comorbidities in participants included hypertension, hyperlipidemia, chronic kidney disease, followed by arthritis, diabetes, and cardiovascular disease. The US population had a higher rate of comorbidities than those in Australia and Taiwan (**Table 2**).

In the intent-to-treat population, in the 75 mg group 82% and 73% of patients achieved sUA < 6 and < 5 mg/dL, respectively, and in the 50 mg group, 71% and 45% of patients achieved sUA levels < 6 and < 5 mg/dL, respectively. In the per-protocol population, in the 75 mg group 89% and 82% achieved sUA levels < 6 and < 5 mg/dL, respectively, and in the 50 mg group 78% and 50% achieved sUA levels < 6 and < 5 mg/dL, respectively. Patients in Australia and Taiwan showed slightly higher response rates than those in the US (**Table 3**), likely attributable to the difference in body weight and BMI. Patients with eGFR in the 60-89 mL/min range showed similar response rates to those with eGFR > 90 mL/min, and greater response rates than those with eGFR < 60 mL/min. There were no serious adverse events in AR882 treated patients. The most frequently reported adverse event was gout flare occurring in 30% of patients overall with similar distribution among placebo and AR882 treatment groups. Mild or moderate adverse events including diarrhea, headache, and upper respiratory infection were observed. None of the AEs led to discontinuation of investigational product.

Conclusion: 12-week treatment of AR882 demonstrated safe and efficacious profiles in gout patients with various demographics and baseline characteristics. AR882 may offer improved efficacy and better safety compared to existing therapies in the treatment of patients with gout including those with severe or refractory disease across various demographics and comorbidities.

Impact of Combined Intervention with Clinical Nurse Specialist in the Management of Cardiovascular Risk in Patients with Gout

Claudia Maria Gomez[1], Patricio Cardoso Peñafiel[1], Jose Antonio Angel-Sesmero[1], Marta Novella-Navarro[2] and Enrique Calvo-Aranda[1], [1]Hospital Universitario Infanta Leonor, Madrid, Spain, [2]Hospital Universitario La Paz, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is associated with increased cardiovascular risk (CVR). Traditional CVR factors (CVRF) are frequently present in patients with gout, further worsening the prognosis. Several studies have shown that clinical nurse specialist (CNS) contributes effectively to the management of gout. To analyze the detection of CVRF in patients with gout in a rheumatology consultation with CNS and to evaluate short-term changes after a targeted approach.

Methods: Patients with gout according to ACR/EULAR 2015 criteria referred from Primary/Specialized Care due to poor control of the disease. At the first visit, demographic and clinical variables were collected: age, sex, smoking, alcohol, duration of gout, tophi, comorbidities, urate-lowering treatment (ULT) and concomitant drugs. A blood test and review of previous were performed, as well as measurement of blood pressure (BP), weight and abdominal circumference. Nurse-managed calls were made to monitor home measurements and check adherence/tolerance to pharmacological (start/adjustment of ULT, antihypertensive, lipid-lowering and antidiabetic drugs) and non-pharmacological approach (gout education, dietary/lifestyle recommendations) initiated, according to EULAR recommendations for CVR management in rheumatic diseases. We count on multidisciplinary collaboration with other specialists. After 6 months, an in-person visit was made with the same measurements to determine potential changes. A descriptive analysis of the sample was performed. Wilcoxon test was used to evaluate the variation in the parameters studied. The outcome variable was determined as improvement vs no improvement of the dependent variable. χ^2 and Mann Whitney U tests were used to evaluate the differences.

Results: Forty patients who met the inclusion criteria were included. Ninety-eight percent were male, with a median age of 66 (58-75) years, severe gout (83% tophaceous, median duration 7 years) and marked presence of CVRF (hypertension 78%, dyslipidemia 55%, smoking 23%, diabetes 23%), some of them previously undetected (10% hypertensive, 3% dyslipidemic, 3% diabetic), and related comorbidities (ischemic heart disease 8%, cerebrovascular disease 5%, chronic kidney disease 20%). Fifty-five percent were not taking ULT and 53% used NSAIDs on a regular basis. At the first visit, ULT was started/adjusted in 95% of patients, antihypertensive in 15%, lipid-lowering drugs in 13%, and anti-diabetes drugs in 8%. At 6 months, there was a significant improvement in sUA and BP, and a non-statistically significant weight reduction (Table). Serum uric acid (sUA) target was achieved in 93% of patients (37/40 < 6 mg/dl, 29/40 < 5 mg/dl). The use of NSAIDs was reduced to 5%. Four out of 9 smokers quit. Systolic BP improved in 73% of patients and diastolic BP in 70%. Dietary

Table. Anthropometric, blood pressure and serum uric acid changes 6 months after the first visit. All variables expressed as median/IQR. BP: blood pressure; sUA: serum uric acid

	Basal	6 months	p
Weight (kg)	87 (77.3-99)	85.4 (77-96.3)	0.79
Abdominal circumference (cm)	107 (102-116)	108 (103-116)	0.81
Systolic BP (mm Hg)	151 (133.3-162.5)	142.5 (124.8-155)	0.02
Dyastolic BP (mm Hg)	88.5 (76.3-95)	78.5 (70-86.8)	0.01
sUA (mg/dl)	7.7 (6.6-8.8)	4.5 (4.1-5.2)	<0.01

and habit modifications, therapeutic adjustments and multidisciplinary care were significantly associated with improved BP (p=0.02).

Conclusion: In patients with difficult-to-treat gout and high CVR, combined intervention with CNS allows substantial short-term changes in CVRF, drastic reduction in NSAID consumption and a high percentage of success in achieving sUA target.

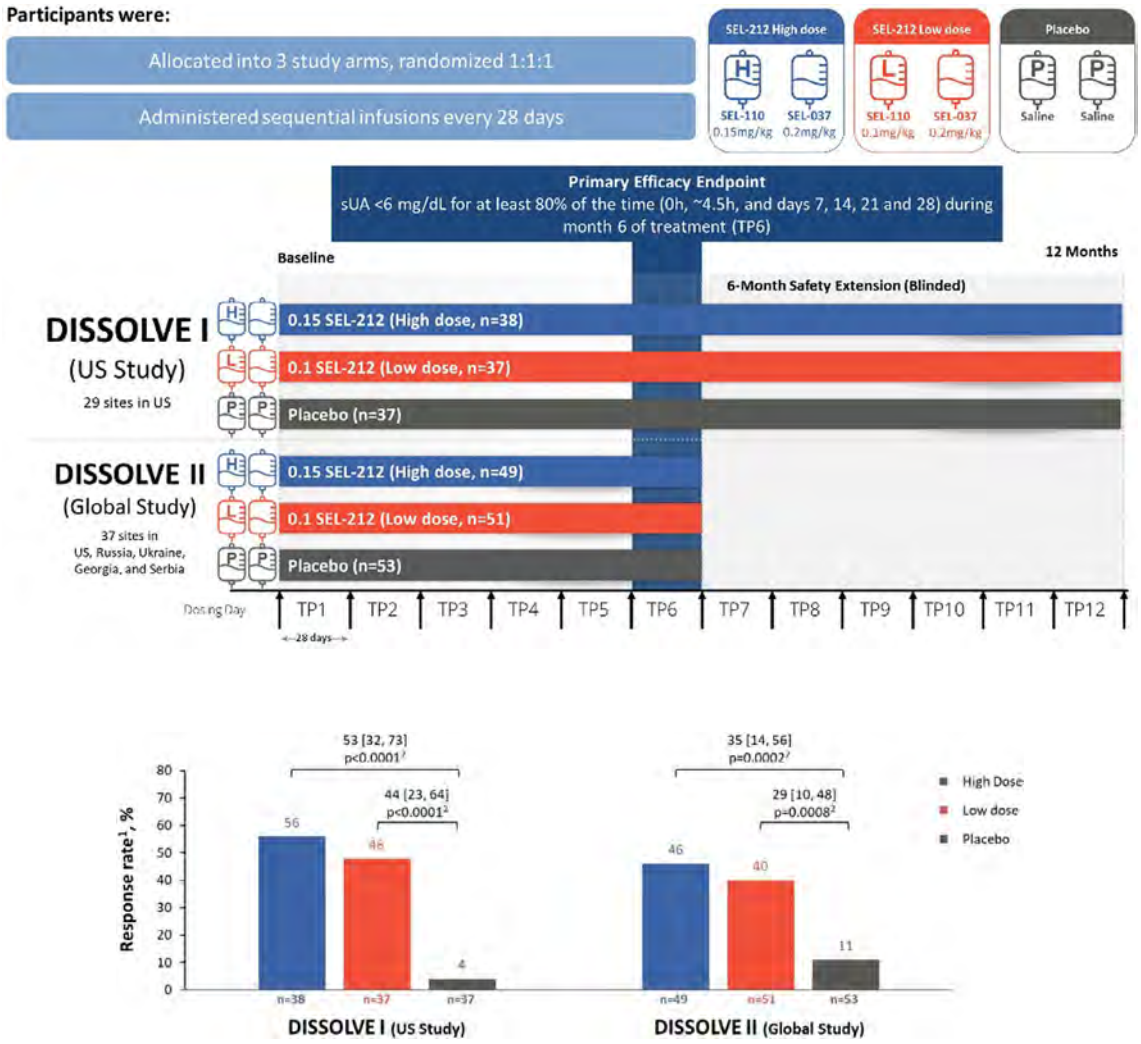
Safety & Efficacy of SEL-212 in Patients with Gout Refractory to Conventional Treatment: Primary Outcomes from Two Randomized, Double Blind, Placebo-Controlled, Multicenter Phase 3 Studies

Herbert Baraf[1], Alan Kivitz[2], Sheri Rhodes[3], Sheldon Leung[4], Olu Folarin[4], Tania Gonzalez-Rivera[5], Joanna Sobierska[5], Jacquie Christie[5], Anand Patel[6], Wesley DeHaan[4], Rehan Azeem[4] and Peter Traber[7], [1]The Center for Rheumatology and Bone Research, George Washington University, Rheumatology, Bethesda, MD, [2]Altoona Center for Clinical Research, Duncansville, PA, [3]Selecta Biosciences, Atlanta, GA, [4]Selecta Biosciences, Inc., Watertown, MA, [5]Swedish Orphan Biovitrum (Sobi), Stockholm, Sweden, [6]Pioneer Research Solutions, Houston, TX, [7]Selecta Biosciences, Gladwyne, PA

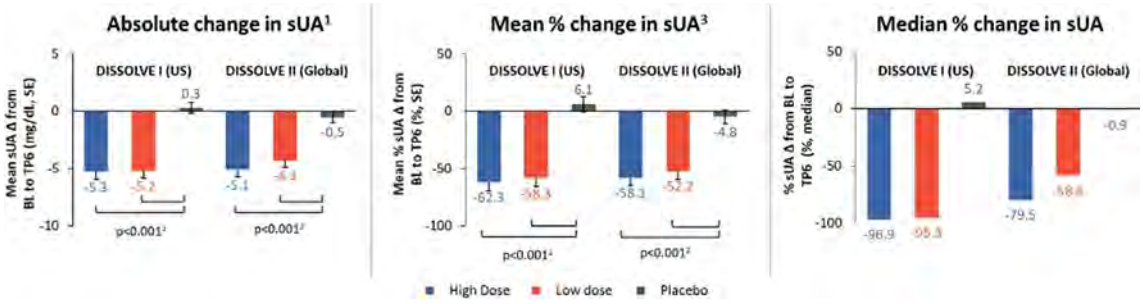
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with refractory gout, the inability to maintain serum uric acid (sUA) levels < 6 mg/dL leads to severe clinical manifestations for which uricase-based therapies can be highly effective, though also immunogenic.[1] SEL-212 is a once-monthly, novel 2-component, uricase-based infusion therapy being investigated in patients with refractory gout. SEL-212 consists of an infusion of tolerogenic nanoparticles containing rapamycin (SEL-110) followed by pegadricase (SEL-037).[2] DISSOLVE I and II (D1 and D2, respectively) evaluated the safety and efficacy of SEL-212 in adults with refractory gout.

Methods: D1 (US) and D2 (Global), were placebo-controlled, double-blind, randomized clinical trials that evaluated two dose levels of SEL-110 (0.15 mg/kg [high-dose] or 0.1 mg/kg [low-dose]) prior to SEL-037 (0.2 mg/kg) infusion. Participants were enrolled if they had ≥ 3 gout flares within 18 months prior to screening or ≥ 1 tophus or a current diagnosis of gouty arthritis, failed to normalize sUA and control symptoms with any xanthine oxidase inhibitor, and were not previously exposed to a pegylated uricase-based therapy. Participants were randomized 1:1:1 between the two doses of SEL-212 and placebo administered intravenously every 28 days for 6 treatments. D1 participants continued in a 6-month blinded extension phase under the initial treatment conditions (Fig. 1). The primary endpoint was defined as the percentage of participants who



DISSOLVE I & II study design.



achieved and maintained sUA < 6 mg/dL for ≥ 80% of the sixth treatment period (TP6). Safety and tolerability were assessed through monitoring of adverse events (AEs).

Results: 112 participants (96% male, 66% ≥ 50 years) were enrolled in D1 and 153 (97% male, 72% ≥ 50 years) in D2. Response rates in all treatment groups were significantly different from placebo ($p \leq 0.0008$), with 56% and 46% of participants responding in the high-dose group and 48% and 40% in the low-dose group for D1 and D2, respectively (Figure 2). The response rates in participants aged ≥ 50 years were 65% and 47% in the high-dose groups and 47% and 44% in the

low-dose groups for D1 and D2, respectively ($p \leq 0.0026$ vs placebo). Across all participants in the treatment groups, sUA levels were significantly reduced from baseline ($p < 0.001$ vs placebo) at TP6 (Figure 3). The safety profile of SEL-212 was favorable, with 3.4% and 4.5% of participants experiencing infusion reactions in the high and low-dose groups, respectively. Reports of gout flares were comparable between treatment groups and placebo. Six participants (3.4%) in the pooled active treatment groups experienced treatment-related serious AEs (n=4 anaphylaxis, n=2 gout flares).

Conclusion: In the DISSOLVE trials, once-monthly treatment with SEL-212 demonstrated statistically significant response rates and reductions in sUA versus placebo. The safety profile of SEL-212 was consistent with that of uricase therapies. Targeted immunomodulation with SEL-212 has the potential to provide a new uricase-based treatment option for patients with gout refractory to conventional therapies.

1. Edwards NL. *Arthritis Rheum* 2008;58(9):2587-90.
2. Sands E, *et al. Nat Commun* 2022;13:272.

Primary efficacy endpoint. (1) The primary endpoint was defined as the percentage of participants who achieved and maintained sUA < 6 mg/dL for at least 80% of the sixth treatment period (TP6). Subjects who dropped from study due to stopping rule, AE, and COVID were considered non-responders. Percentages shown are averaged over multiple imputed datasets for missing sUA for withdrawal of consent, lost to follow-up, and other as per FDA guidance. (2) Difference vs placebo [97.5% CI] and p-value versus placebo group for each treatment group are indicated above each bracket.

Serum uric acid reduction from baseline to treatment period six (TP6). (1) Reduction of mean sUA as computed by subtracting the Baseline (BL) sUA level from the mean sUA during Treatment Period 6 (TP6) defined as the area under the time curve divided by the corresponding time interval. (2) Analysis using ANCOVA model with reduction or percent reduction of mean sUA at TP6 from baseline as dependent variable and randomization stratum and baseline sUA as covariates. Missing values of change or percent change from baseline were multiple imputed by using the Recursively Partitioned Mixture Model. The means of treatment groups are pooled estimates after multiple imputation and 2-sided p-values. (3) Percent reduction mean sUA as computed by subtracting Baseline (BL) sUA level from the mean sUA during TP6 divided by the Baseline and reported as either absolute difference or percent difference.

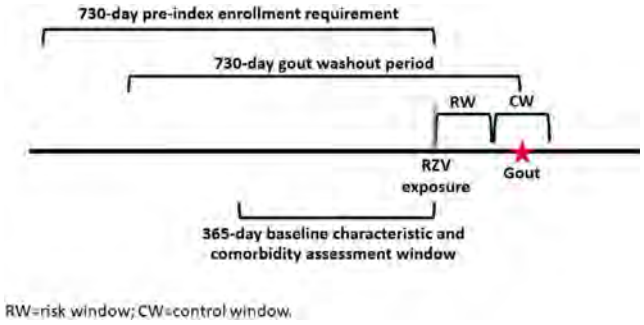
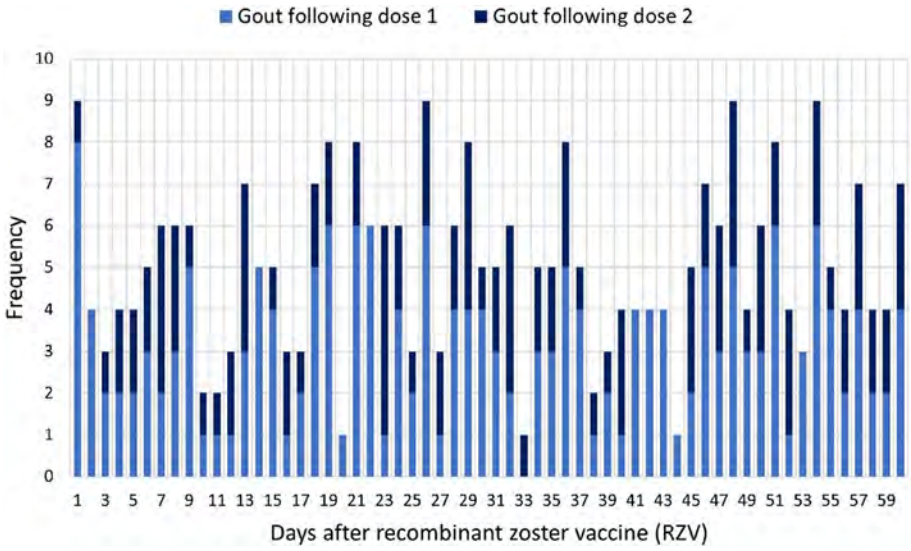
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pre-licensure clinical trials for recombinant zoster vaccine (RZV) identified more frequent gout diagnoses among recipients of RZV than placebo; however, these trials were not powered to assess the statistical significance of these differences. The current real-world safety study used administrative claims data from 4 national insurers and 1 regional insurer in the FDA's Sentinel System, a large, distributed data network, to assess whether RZV is associated with an increased risk of new-onset gout among US individuals ≥50 years of age

Methods: This retrospective study used a self-controlled risk interval (SCRI) design (Figure 1). We included health plan members ages ≥50 with RZV exposure followed by incident gout within 60 days: days 1-30 defined the risk window (RW) and days 31- 60 defined the control window (CW). We required 730 days of medical and drug coverage, allowing 45-day gaps, prior to RZV exposure, and 60 days of coverage, with no gaps, after RZV exposure. A conditional Poisson model estimated the risk ratio (RR) of gout in the RW versus CW.



RW=risk window; CW=control window.



Type of analysis	CW length		Total case count	No. cases in RW (%)	No. cases in CW (%)	RR[a] (95% CI)
	Mean (SD)	Median (IQR)				
Primary Analysis						
Includes dose 1 and dose 2[c]	30.0[b] (0.39)	30.0 (30.0 - 30.0)	302	153 (50.7)	149 (49.3)	1.03 (0.81 - 1.29)
Secondary Analysis						
Includes dose 1 and dose 2; 30-day CW for both doses	30 (fixed)	30 (fixed)	302	153 (50.7)	149 (49.3)	1.03 (0.81 - 1.30)
Sensitivity Analysis						
Includes dose 1 and dose 2; Restricted to 2-dose recipients with 60 – 183 days between doses	30 (inherent)	30 (inherent)	235	120 (51.1)	115 (48.9)	1.04 (0.80 - 1.36)
Dose 1 subset	30 (fixed)	30 (fixed)	191	99 (51.8)	92 (48.2)	1.08 (0.80 - 1.45)
Dose 2 subset	30 (fixed)	30 (fixed)	111	54 (48.6)	57 (51.4)	0.95 (0.64 - 1.40)
Seasonality-adjusted primary analysis[d]	30.0[b] (0.39)	30.0 (30.0 - 30.0)	302	153 (50.7)	149 (49.3)	1.03 (0.82 - 1.30)
COVID-19 sensitivity for primary analysis	30.0[b] (0.39)	30.0 (30.0 - 30.0)	293	149 (50.9)	144 (49.1)	1.03 (0.82 - 1.31)

RW=risk window, CW=control window, RR=risk ratio
aRR of gout in the post-RZV RW relative to the CW using conditional Poisson regression.
bMean CW length is less than 30 days but rounds to 30.0.
cDose 1 CW censored at receipt of dose 2
dThe seasonality-adjusted analysis uses the same analytic cohort as the primary analysis, but the offset term of the conditional Poisson model accounts for background gout trends around the calendar date of RZV receipt.

The exposure was receipt of at least one of the two-dose RZV regimen between January 2018 through December 2019, identified by Current Procedural Terminology (CPT) or National Drug Code (NDC). Incident gout was defined as a gout diagnosis followed by a dispensing of allopurinol, colchicine, probenecid, or febuxostat within 3 months, with no gout diagnoses or medications in the 730 days prior. Baseline characteristics (e.g., comorbidities) were evaluated in the 365 days prior to the RZV date.

The primary analysis assessed the risk of new-onset gout following any RZV dose, censoring the dose 1 CW at dose 2 receipt. The secondary analysis assumed uniform 30-day CWs. Sensitivity analyses evaluated dose 1- and dose 2-specific risks, risk among patients compliant with recommended dose spacing of 60–183 days, adjustment for seasonality, and restriction to the pre-COVID era (excluding cases after December 1, 2019).

Results: Among 461,323 members with at least one RZV dose, 302 were eligible for the SCRI analysis, with evidence of new-onset gout within 60 days. The analytic cohort had a mean age of 72.5 years (SD = 8.3); 66% (n=199) were male. The most common comorbidities were diabetes (40%; n=120), chronic kidney disease (38%; n=115), and ischemic heart disease (28%; n=83). Figure 2 illustrates the frequency of gout events for each day of follow-up after dose 1 or 2.

In the primary analysis, 153 (50.7%) gout cases occurred during the RW and 149 (49.3%) during the CW with a RR of 1.03 (95% confidence interval [CI] 0.81-1.29). In the secondary analysis of fixed 30-day CWs, the RR was 1.03 (95% CI: 0.81-1.30). All sensitivity analyses had consistent results, with no statistically significant association of RZV with incident gout (Table 1).

Conclusion: This retrospective safety study found no evidence of a statistically significant increased risk of gout in the 30 days following RZV vaccination relative to a 30-day subsequent control window among a large, diverse national patient population of adults ≥50 years of age.

Illustration of self-controlled risk interval analysis study design for assessment of the risk of new-onset gout following recombinant zoster vaccine (RZV) exposure.

Frequency of gout events on each day of follow-up after recombinant zoster vaccine (RZV) exposure among patients aged ≥50 years with incident gout following RZV dose 1 or dose 2.

Results of primary, secondary, and sensitivity analyses of the risk of new-onset gout following recombinant zoster vaccine (RZV) exposure.

In-hospital Treatment, Secondary Prevention, and Mortality After First-ever Acute Myocardial Infarction in Patients with Gout

Panagiota Drivelegka[1], Lennart Jacobsson[2], Tatiana Zverkova-Sandström[3] and Mats Dehlin[4], [1]Department of Rheumatology, Sahlgrenska University hospital, Gothenburg, Sweden, [2]University of Gothenburg, Malmö, Sweden, [3]Institution of Medicine, Gothenburg, Sweden, [4]Dept of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with gout are at increased risk of acute myocardial infarction (AMI). However, the clinical course, secondary prophylaxis and mortality after AMI has not been previously studied. The aim of this study is to investigate the in-hospital treatment, secondary prevention, and all-cause and cardiovascular disease (CVD)-related mortality after the first-ever AMI in patients with gout compared to the general population.

Methods: Using data from regional and national population-based registers, we identified all patients in Western Sweden with a diagnosis of gout at both primary and specialty care and a first-ever AMI in the period 2006-2016. Up to five individually matched controls with a first-ever AMI (matched on sex and admission year) were identified as comparators. Follow-up started at the date of admission for the first-ever AMI and ended at death, emigration, or 365 days of follow-up after the AMI, whichever occurred first. The in-hospital treatment and secondary prevention in gout cases and controls were compared by using logistic regression analysis with adjustments for age. Cox regression analysis was used to assess the 1-year mortality with adjustments for age, baseline comorbidities, and medication within 6 months before the start of follow-up.

Results: We identified 1,000 patients with gout and a first-ever AMI (men, 72.7%; mean age, 70.0 years) and 4,740 matched general population comparators (men, 73.5%; mean age, 71.5 years). At admission, patients with gout hade significantly more comorbidities (Table 1). The in-hospital treatment differed significantly between cases and controls. Patients with gout were more likely to receive treatment with diuretics and continuous positive airway pressure (CPAP), and less likely to undergo coronary angiography, percutaneous coronary intervention (PCI), or any primary reperfusion (Table 2). At discharge, patients with gout were less often prescribed statins, and more often

Table 1. Patient characteristics and comorbidities in gout patients and general population comparators at admission for the first-ever AMI.

[§] Matched on sex and admission year.

*Adjusted for age.

AMI, acute myocardial infarction; iv, intravenous; PCI, percutaneous coronary intervention; CABG, coronary artery by-pass grafting; CPAP, continuous positive airway pressure; PM, pacemaker; ICD, implantable cardioverter defibrillator; RAAS, renin-angiotensin-aldosterone system; OR, odds ratio; CI, confidence interval

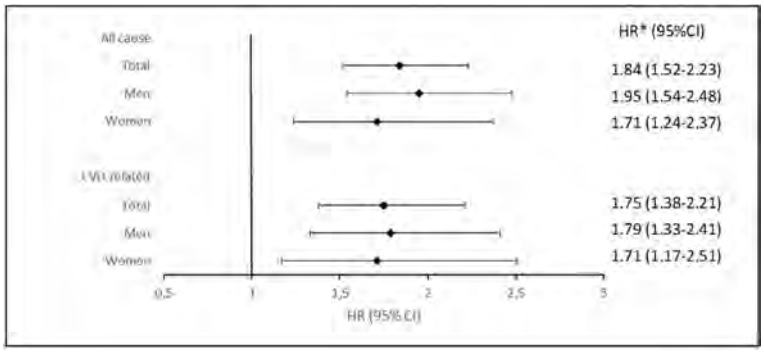

Figure 1. All cause and CVD-related mortality at 1-year after the first-ever AMI in patients with gout compared to the general population. *Adjusted for age, baseline comorbidities, and medication within 6 months before the start of follow-up. HR, hazard ratio; CI, confidence interval; CVD, cardiovascular disease

prescribed nitrates, diuretics, digitalis, and calcium antagonists (Table 2). The prescription of antiplatelets, renin-angiotensin-aldosterone inhibitors, or beta-blockers did not differ significantly between cases and controls (Table 2). The 1-year all-cause and CVD-related mortality was significantly higher in gout patients as compared to the general population (HR, 1.84; 95%CI, 1.52-2.23; and HR, 1.75; 95%CI, 1.38-2.21, respectively) (Figure 1).

Conclusion: Patients with gout were less likely to undergo coronary angiography and PCI during hospitalization for the first-ever AMI and were less likely to be prescribed statins at discharge compared to the general population. The all-cause and CVD-related mortality was significantly higher in patients with gout which might be partly related to differences in in-hospital treatment and secondary prevention.

Abstract Number: 0249

Comorbidities of Gout: Results from the Korean National Health and Nutrition Examination Survey

Hyemin Jeong and Chan Hong Jeon, Soonchunhyang University Bucheon Hospital, Bucheon, South Korea

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is associated with several comorbidities. The aim of this study was to evaluate the prevalence of comorbidities in Korean adult population with gout.

Methods: Data from 15,935 (weighted n = 39,049,167) participants aged 19 years and older in the Korean National Health and Nutrition Examination Survey from 2019 to 2021 was used for analysis. Weighted prevalence and odds ratios (OR) of comorbidities in individuals with gout were compared with the non-gout population.

Results: The weighted prevalence of gout was 2.1% (weighted n = 808,778). Among individuals with gout, 66.5% had metabolic syndrome, 46.2% had hypertension, 35.6% had dyslipidemia, 19.2% had diabetes, 13.5% had chronic kidney disease (eGFR < 60), 4.1% had myocardial infarction or angina, 3.8% had stroke, and 2.8% hand rheumatoid arthritis. After adjusting for socioeconomic and lifestyle characteristics, gout was independently associated with increased prevalence of metabolic syndrome (male OR 2.0, 95% CI, 1.5-2.8; female OR 3.7, 95% CI 1.5-9.2), hypertension (male OR 2.7, 95% CI 1.9-3.7; female OR 2.5, 95% CI 1.4-4.5), dyslipidemia (male OR 2.0, 95% CI 1.5-2.7; female OR 3.8, 95% CI 1.5-10.0), chronic kidney disease (male OR 4.5, 95% CI 2.7-7.3; female OR 16.2, 95% CI 7.5-34.9), and rheumatoid arthritis (male OR 2.8, 95% CI 1.1-7.1; female OR 3.1, 95% CI 1.1-8.7) compared to the non-gout population.

Conclusion: Gout was associated with several medical comorbidities and rheumatoid arthritis in both males and females. These results suggest that clinicians should prioritize the prevention and management of underlying comorbidities in patients with gout.

Validation of Singe-Shot Computational Polarized Microscopy for Crystal Analysis of Synovial Fluid

John FitzGerald[1], Tairan Liu[1], **Chesca Barrios**[1], Bijie Bai[1], Geraldine McCarthy[2], Ann Rosenthal[3] and Aydogan Ozcan[1], [1]University of California Los Angeles, Los Angeles, CA, [2]Mater Misericordiae University Hospital, Dublin, Ireland, [3]Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The gold standard for diagnosis of crystal arthritis relies on the identification of either monosodium urate (MSU) or calcium pyrophosphate (CPP) crystals in synovial fluid by compensated polarized light microscope (CPLM). However, CPLM analysis is labor intensive and depends on experience of the technician. Identifying CPP crystals can be difficult. We previously described single-shot computational polarized light microscopy (SCPLM), that detects MSU and CPP crystals in synovial fluid. This work evaluates the reliability and validity of crystal detection for SCPLM images using crystal experts.

Methods: Microscope slides from patients with CPP or MSU crystals in synovial fluid were obtained and de-identified from the hospital clinical lab. Digital images were acquired using Olympus IX83 microscope, standard objective lens (100x/1.4NA) and either CPLM or SCPLM methodology. Briefly, SCPLM uses a CMOS sensor where each pixel is integrated with a directional polarizing filter with four axes of polarization (0°, 90°, 45°, 135°). SCPLM further combines images from multiple focal depths into a single bright-field fused image.

Table 1. Agreement between Raters for all MSU or CPPD crystals identified by either rater by either method

CPP (n = 280 crystals)

Other	++	20%	9%

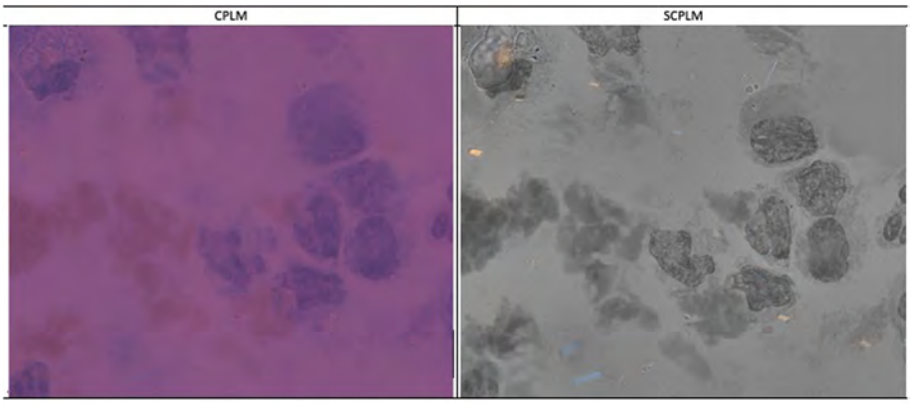

Figure 1. CPLM and SCPLM side-by-side Field of View (100x) Legend: CPLM = Compensated Polarized Light Microscopy. SCPLM = Single-shot Computational Polarized Light Microscopy

In random order, raters were presented paired CPLM images (with analyzer at orthogonal angles) and a single bright-field fused SCPLM image for 67 FOV (including 7 negative controls). For each FOV and each method, each rater recorded their level of certainty (1-5) for each suspect crystal identified and type of crystal. Crystals rated 3 or higher by both raters (++) on either method were included in a high-certainty crystal subset. After rating all of the FOV, raters were presented with side-by-side FOV (CPLM vs. SCPLM) and asked for their preferred image.

Results: 67 FOV were imaged by CPLM and SCPLM methodologies (29 CPP, 31 MSU and 7 negative controls). With an instructed limit of 15 crystals per FOV, 377 unique crystal suspects were identified: 280 CPP, 87 MSU, and 10 uncertain or discrepant crystal identity. (The 10 uncertain/discrepant crystals all came from negative control FOVs.)

Raters identified a higher number of crystals by SCPLM over CPLM for both CPP and MSU. (Table 1) SCPLM identified 239/280 CPP crystals and 86/87 MSU crystals where CPLM identified 138/280 CPP and 48/87 MSU. For SCPLM, there were only 11/239 CPP crystals (4.6%) where neither rater was certain, for CPLM, there were 13/138 (9.4%) where neither rater was certain.

To compare methods, we focused on the 144 CPP and 69 MSU crystals where both raters were certain (++) about the crystal (by at least one method). For 80-90% of included crystals, SCPLM was ++. In contrast, only 40-51% of crystals was CPLM ++. (Table 2) When CPLM was negative, SCPLM was high certain in almost all cases.

Finally, raters subjectively preferred SPCLM over CPLM in side-by-side comparison. Raters were indifferent to method for negative FOVs.

Conclusion: Subjective (rater preference) and objective measures of greater detection and higher certainty were observed for SCPLM images over standard CPLM images, particularly notable for CPP crystals. The digital data associated with these images can be incorporate into an automated scanning platform to provide quantitative reports on crystal counts and morphology perhaps providing greater insight to clinical care.

Session Date: Sunday, November 12, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Recurrent flares are the hallmark of clinical manifestation of gout. Sodium-glucose cotransporter-2 inhibitors (SGLT2i) were associated with a lower risk of incident gout; however, their impact on recurrent flares is unknown. We aimed to examine the relation of SGLT2i vs. active comparators (i.e., glucagon-like peptide-1 receptor agonist or dipeptidyl peptidase 4 inhibitors) to the risk of recurrent gout flares, the first recurrent gout flare, and all-cause mortality among patient with gout and type 2 diabetes.

Methods: Using IQVIA Medical Research Database in the United Kingdom, we identified initiators of SGLT2i and active comparators among gout patients with type 2 diabetes from a United Kingdom primary care database. We conducted cohort studies to examine the relation of SGLT2i vs. active comparators to the risk of recurrent flares, the first recurrent flare, and all-cause mortality using either Poisson regression or Cox-proportional hazards model with propensity score overlap weighting. The primary outcome was the number of recurrent gout flares that were ascertained using recorded codes and prescriptions records. Secondary outcomes were the first recurrent gout flare and all-cause mortality.

Results: During 17,729 person-years of follow-up, 318 recurrent flares occurred in the 1,548 initiators of SGLT2i and 1,714 in the 4,383 initiators of active comparators, respectively. The relative rate of the recurrent flares of SGLT2i vs. active comparators was 0.79 (95%CI: 0.64 to 0.96). Similar results were observed in the relation of SGLT2i to the risk of number of recurrent flares when compared with DPP-4i or GLP-1 receptor agonist, respectively (Table 1). The rate difference (RD) and hazard ratio (HR) of the first recurrent flare for SGLT2i vs. active comparators were -9.2 (95%CI: -18.0 to -0.4) per 1000 person-years and 0.80 (95%CI: 0.64 to 0.98), respectively. All-cause mortality per 1000 person-years was 18.5 for SGLT2i and 24.2 for active comparators, with RD and HR being -5.8 (95%CI: -10.1 to -1.5) per 1000 person-years and 0.72 (95%CI: 0.53 to 0.97) (Table 2).

Conclusion: SGLT2i were associated with a lower risk of recurrent gout flares and mortality than their active comparators in patients with gout and type 2 diabetes. Our findings suggested that SGLT2i have a potential to reduce the burden of recurrent gout flares and narrow the mortality gap between patients with gout and the general population.

Table 1. Risk of recurrent gout flares according to initiation of either SGLT2i or active comparators among patients with gout and type 2 diabetes

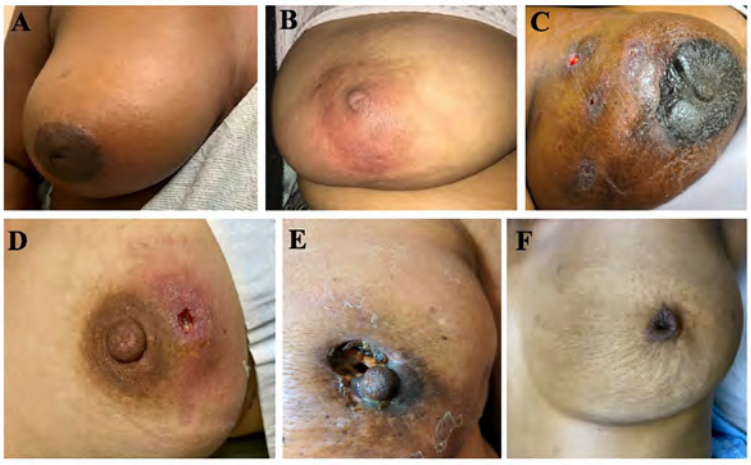
Characterizing Granulomatous Mastitis: A Retrospective, Single-Institutional Case Series of a Racially and Ethnically Diverse Cohort

Lindsay Pattison[1], Bibi Ayesha[2], Anand Kumthekar[3], Maureen McEvoy[2], Beth McLellan[2] and Inessa Gendlina[2], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Montefiore Medical Center, Bronx, NY, [3]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Granulomatous mastitis (GM) is a rare, chronic, inflammatory breast condition characterized by granulomatous inflammation affecting mainly minority women of childbearing age. Patients present with breast mass and pain that can progress to abscess, fistula, sinus, or ulcer (Figure 1). Pathogenesis of GM is unknown. Hypotheses include autoimmune, inflammatory, infectious, or benign causes. Management includes antibiotics, anti-inflammatory drugs, corticosteroids, disease-modifying anti-rheumatic drugs, biologics, and surgery.

Methods: We performed an IRB-approved retrospective analysis of patients with GM at Montefiore between 1/1/2014-1/1/2023. Inclusion criteria were age greater than 18, diagnosis of GM (clinically diagnosed or biopsy proven). Exclusion criteria were age younger than 18, concurrent alternate breast pathology. We identified 119 patients with GM. No patients fit exclusion criteria.



Various presentations of granulomatous mastitis in African American and Hispanic women. A) Right breast with large area of induration, tenderness, and erythema on the lower medial aspect. B) Right breast with erythematous tender area with some fluctuance in the 6 o'clocl position inferior to the areola. C) Entire right breast firm, indurated, erythematous, and tender to the touch with open sinus. D) Right breast with mass, erythema, and open wound. E) Left breast with open wound secondary to biopsy, with probing depth of 1-2cm, with purulent draining and diffuse induration without erythema. F) Left breast with inverted nipple, mass, and area of dense/fibrous tissue.

Results: 119 patients (118 female, 1 male) with GM were identified. Mean age at diagnosis was 36.29 years (range 20-83). Most patients were minorities (Hispanic/Latino 48.74%, African American 21.01%, Other/Unknown 19.33%, Caucasian 5.88%, Asian 4.20%) and hailed from a broad range of countries (Table 1). Most common comorbidity was obesity (20.17%) and major risk factors included pregnancy within 5 years (52.94%), lactation within 2 years (25.21%), and former/current smoker (18.49%) (Table 1). Most patients experienced unilateral symptoms (76.47%) of breast mass (79.83%), erythema (62.18%), pain (61.345%), and tenderness (50.42%) (Table 2). Mean symptom duration prior to presentation was 53.27 days (range 1-365) and symptom duration prior to diagnosis was 188.96 days (range 3-2555). Of 37 patients with positive bacterial cultures, 67.57 % had *Corynebacterium kroppenstedtii* (Table 2). 84.87% were biopsied and patients not biopsied were diagnosed with a combination of clinical presentation, imaging, and treatment response. Ultrasound, mammogram, and MRI were performed in 109, 82, and 8 patients, respectively. Most common BIRADS score was 4 for ultrasound (33.94%) and for mammogram (31.71%). Antibiotics were prescribed to 84.03% of patients, most

Birth countries, comorbidities, and risk factors for patients with GM.

commonly doxycycline (49.00%), bactrim (41.00%), and clindamycin (36.00%). Steroid immunotherapy and methotrexate were prescribed to 69.75% and 14.29% of patients, respectively. Surgical interventions included incision and drainage (43.70%) and excision (12.61%). 3 months, 1 year, and 2 years after symptom onset, 79.81%, 40.38%, and 18.27% of patients had persistent symptoms, respectively. Recurrence occurred in 6 patients.

Conclusion: This is the largest retrospective case series of GM in the United States to date. We stratified comorbidities and risk factors in patients with GM and identified several bacteria previously not reported including *Capnocytophaga ochracea, Serratia marscens, Actinomyces meyeri, Actinomyces neurii, Trueperella bernardiea, Actinotignum unspecified,* and *Proteus mirabalis*. Combining clinical anecdotal evidence with this comprehensive review, we advise physicians caring for young, female, minority patients with breast pain, mass, erythema, or drainage to be mindful for developing GM.

Clinical Phenotypes in Patients with Isolated Anti-Sm/RNP Common Motif Antibody Positivity, Compared to Those with or Without Associated Anti-RNP Antibody Reactivity

Ruoning Ni[1] and Petar Lenert[2], [1]University of Iowa Hospitals and Clinics, Coralville, IA, [2]University of Iowa Hospitals and Clinics, Iowa City, IA

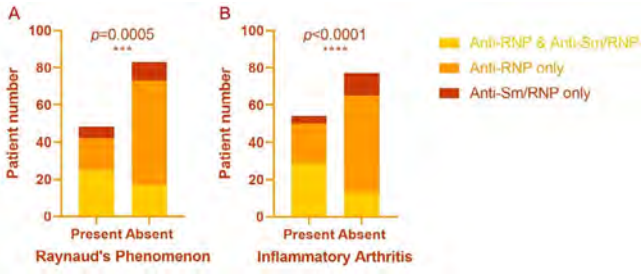
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-ribonucleoprotein (RNP) and anti-Sm/RNP common motif antibodies play a critical role in diagnosing patients with systemic lupus erythematosus (SLE), mixed connective tissue disease (MCTD) or other connective tissue disease. Despite some common features between RNP and Sm/RNP antigens, such as sharing a 14-kd-reactive protein, they also carry significant structural differences. Anti-Sm antibodies frequently target B/B', D1 and D3 proteins, whereas anti-RNP antibodies are directed towards 70-kd, A, C proteins. It is already well known that anti-RNP antibodies when presenting alone in patients with MCTD are closely related with Raynaud's phenomenon and relatively rare renal involvement. Rheumatologists encounter patients with positive anti-Sm/RNP common motif antibodies with or without anti-RNP antibodies in different clinical scenarios. However, the clinical phenotype of patients presenting solely with anti-Sm/RNP antibodies, or in association with anti-RNP antibodies remains unknown.

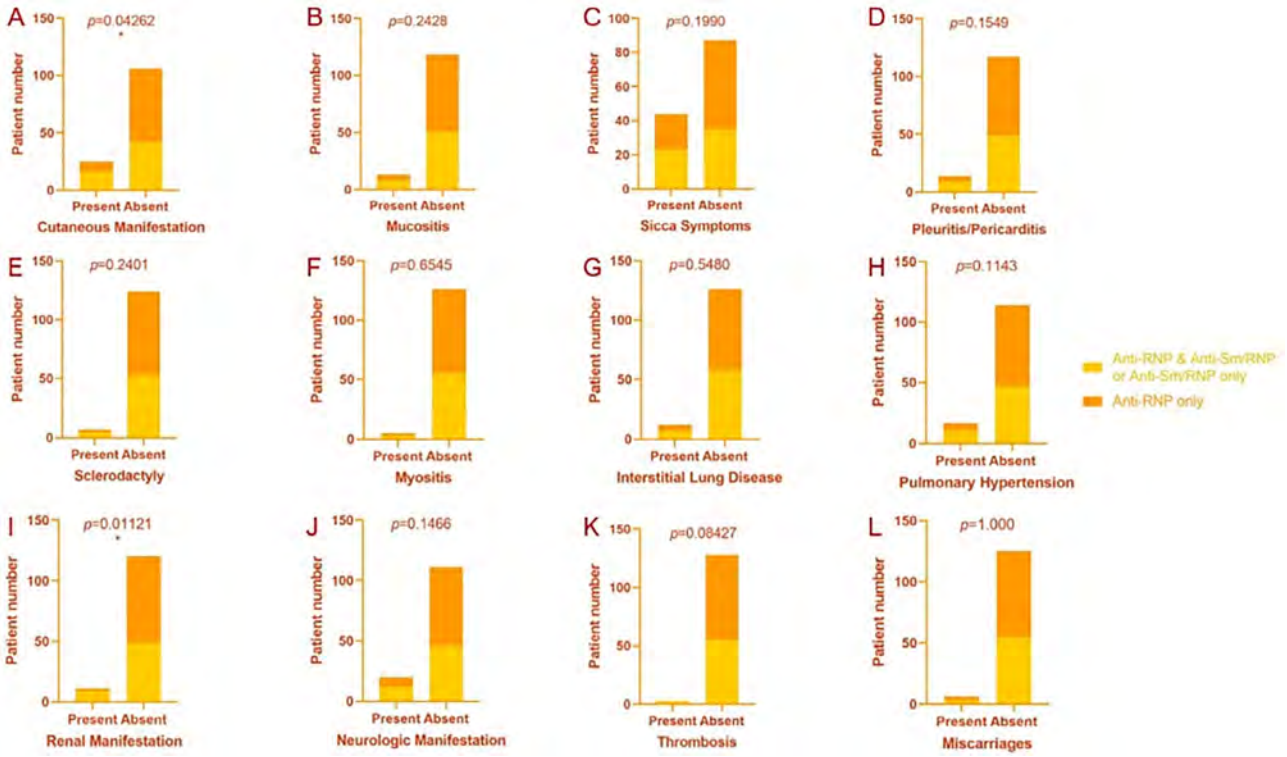
Methods: We obtained approval from the Institutional Review Board at the University of Iowa Hospitals and Clinics and conducted a retrospective cohort study of patients, who tested positive for anti-RNP, and/or anti-Sm/RNP antibodies. The antibody profile was analyzed at the time of diagnosis. All patients were followed up by rheumatology clinic.

All data were retrieved from the existing medical records available through the EPIC database. Data analysis included demographic characteristics, clinical manifestations, organ involvement, disease duration, antibody titers.

Continuous variables were expressed as means ± standard deviation (SD) or median with minimum and maximum range, categorical variables as counts and percentages. Differences between groups were evaluated with the student's t test or Mann-Whitney U test for continuous variables and Chi-square or Fisher's exact test for categorical variables.



Represents the number of patients with and without Raynaud's phenomenon (A) and inflammatory arthritis (B) in patients tested positive for anti-RNP and anti-Sm/RNP, positive for anti-RNP only, and positive for anti-Sm/RNP only.



Represents the number of patients with and without cutaneous manifestations (A), mucositis (B), sicca symptoms (C), pleuritis or pericarditis (D), sclerodactyly (E), myositis (F), interstitial lung disease (G), pulmonary hypertension (H), renal manifestation (I), neurologic manifestation (J), thrombosis (K), and miscarriage (L) in patients tested positive for anti-RNP and anti-Sm/RNP, or anti-Sm/RNP only, or positive for anti-RNP only.

Results: A total of 131 patients were included in the study, of which 42 (32.1%) were tested positive for anti-RNP and anti-Sm/RNP antibodies, 73 (55.7%) positive for anti-RNP antibody only, 16 (12.2%) positive for anti-Sm/RNP only. 91.6% of patients were female and average age at diagnosis at our institute were 45 years old. The rate of inflammatory arthritis was significantly higher in patients positive for anti-RNP and anti-Sm/RNP antibodies than anti-RNP only or anti-Sm/RNP only (69.1% vs. 28.8% vs. 25.0%, $p< 0.0001$), as well as Raynaud's phenomenon (59.5% vs. 23.3% vs. 37.5%, $p=0.0005$). Rash and renal manifestations were significantly more frequent in patients tested positive for anti-Sm/RNP with or without anti-RNP when compared with patients only positive for anti-RNP antibody. There was no significant difference in mucositis, sicca symptoms, pleuritis/pericarditis, sclerodactyly, myositis, interstitial lung disease, pulmonary hypertension, neurologic manifestations, thrombosis, or miscarriages.

Conclusion: The presence of anti-Sm/RNP common motif antibodies was more commonly associated with inflammatory arthritis, Raynaud's phenomenon, and could be associated with rash and renal involvement.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypermobile Ehlers-Danlos syndrome (hEDS) is a hereditary connective tissue disease characterized by joint hypermobility, chronic musculoskeletal pain, and systemic manifestations, primarily caused by defects in collagen synthesis or processing [1]. The microvascular morphology and functional status have not been evaluated in hEDS, as well as dermal thickness (DT) has been little investigated.

The aim of this study was to examine the nailfold microvascular morphological status, assess peripheral blood perfusion (PBP) and measure dermal thickness (DT) in patients with hEDS in comparison with sex and age-matched healthy controls (CNT).

Methods: Twelve patients diagnosed with hEDS (mean age 40±15, 75% females), classified according to the 2017 International Classification Criteria of EDS [2], were included in the study. Twelve age- and sex-matched CNT were also recruited. The Beighton score was calculated for both hEDS patients and CNT, to assess joint hypermobility. The main parameters derived from nailfold videocapillaroscopy (NVC), including dilated capillaries, giant capillaries, microhemorrhages, abnormal capillary shapes, and capillary count, were analysed and compared between the two groups to assess morphological features [3]. Furthermore, the microvascular functional status was evaluated using laser speckle contrast analysis (LASCA), measuring peripheral blood perfusion (PBP) in various regions of interest of the hand. DT was assessed by cross-sectional B-mode scans acquired using a high-frequency 22 MHz ultrasound probe, analysing seventeen different body areas, such as the upper arms, lower arms, trunk, and forehead.

Results: Microhemorrhages were found more prevalent in hEDS patients (25% vs 0%, $p = 0.09$), the capillary number per linear millimetre at the nailfold was slightly higher in hEDS patients than in CNT, as well as the NVC score for abnormal shaped capillaries was slightly lower (less abnormal shaped capillaries) in hEDS patients than in CNT. PBP was similar between hEDS patients and CNT. The DT resulted generally lower in hEDS patients than controls with significant values limited to feet and thorax ($p=0.04$). A statistically significant positive correlation was observed between the Beighton score and the score for microhemorrhages ($r=0.4$, $p=0.05$), as well as between the Beighton score and DT ($r\geq0.5$, $p\leq0.02$) at the level of feet and thorax.

Conclusion: Our study demonstrates that hEDS patients exhibit a morphologically suitable capillary morphology and normal microvascular function during resting conditions. However, there is a increased microvascular fragility in these patients. Additionally, we observed that dermal thickness appears thinner in hEDS patients compared to controls across most skin areas, with significant differences noted in the feet and thorax regions.

Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a rare, multi-system, fibro-inflammatory disorder characterized by the infiltration of lymphoplasmacytic cells, storiform fibrosis, obliterative phlebitis, and the presence of IgG4-positive plasma cells in affected tissues, accompanied by elevated serum IgG4 levels. In IgG4-RD, sinonasal involvement presents as nasal obstruction, chronic sinusitis, and bleeding. Nasal obstruction may arise from a sessile submucosal mass located in the anterior portion of the inferior turbinate, exhibiting dense lymphocytic lymphoplasmacytic infiltration. We aimed to investigate whether these lymphoid masses in the nasal inferior turbinate represent a nasal manifestation of IgG4-RD or a distinct chronic inflammatory disease entity that has yet to be defined.

Methods: This retrospective study enrolled patients who underwent endoscopy at Seoul National University Hospital between January 2020 and May 2023 due to nasal symptoms, including nasal obstruction or nasal crust. The clinical characteristics and laboratory parameters, such as erythrocyte sedimentation rate (ESR), high-sensitivity C-reactive protein (hs-CRP), and serum IgG4 levels, were evaluated (Figure 1). Biopsies were performed on nasal lymphoid masses exhibiting damaged mucosa features like crusting and bleeding. The diagnosis of IgG4-RD was based on the 2019 classification criteria of IgG4-RD from the American College of Rheumatology/European League Against Rheumatism. All data was analyzed using Chi-square test and Student's t-test.

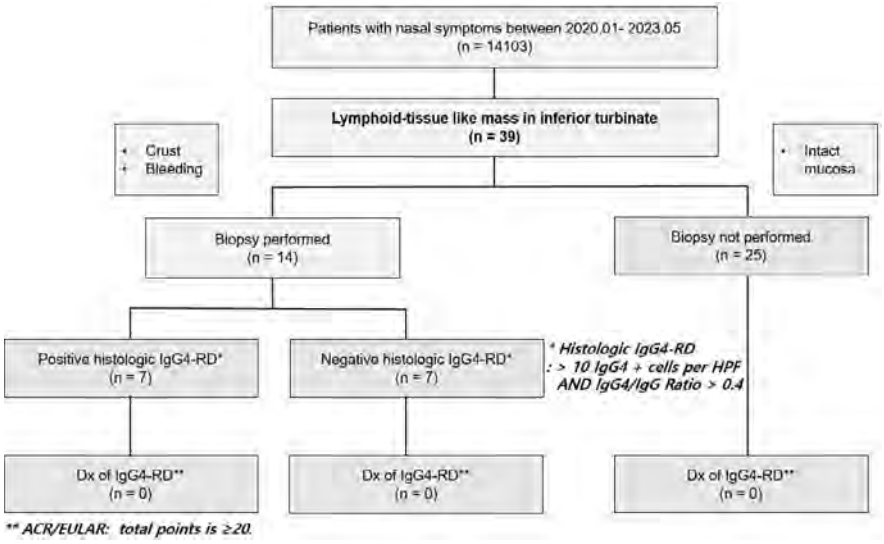

Figure 1. Patient flow

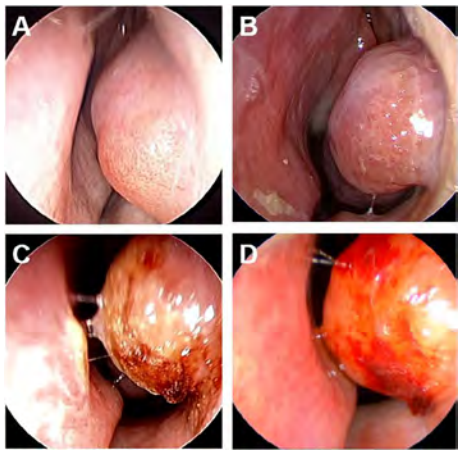

Figure 2. Representative endoscopic findings lymphoid mass. Rhinoscopy reveals yellowish sessile submucosal mass with intact overlying mucosa in the anterior portion of the inferior turbinate - (A,B) Mild and (C,D) severe cases. (D) Overlying mucosa was covered with bloody crust.

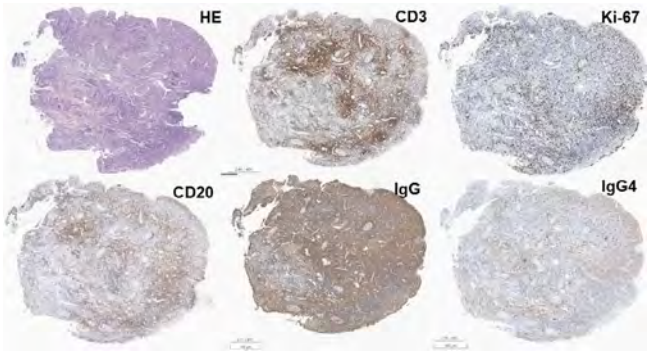

Figure 3. Histology of nasal polyp

Results: In this study, a total of 14103 patients were evaluated for nasal symptoms, and among them, 39 patients presented with lesions resembling lymphoid follicles in the inferior turbinate upon endoscopic evaluation (Figure 2). Among the 14 patients who underwent biopsy, all of them exhibited dense lymphoplasmacytic infiltrates and more than 10 IgG4-expressing plasma cells per high-power field (HPF) (Figure 3). Among these patients, 7 out of 14 (50%) had an IgG4+/IgG+ ratio exceeding 40% and met the histologic criteria for IgG4-RD. However, only 1 patient had elevated serum IgG4 levels. None of the patients were classified as having IgG4-RD based on the EULAR/ACR classification criteria. Patients with significant nasal symptoms who received surgical resection experienced improvement without recurrence of local symptoms.

Conclusion: To the best of our knowledge, this study provides the first comprehensive description of a nasal sessile lymphoid mass located in the inferior turbinate. Our findings indicate that this lymphoid mass, characterized by IgG4+ lymphoplasmacytic infiltration, is likely to represent a distinct disease entity separate from the sinonasal involvement of IgG4-RD. Further study is required to define the optimal treatment and long prognosis.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Japanese patients with connective tissue disease (CTD) are more likely to have interstitial lung disease (CTD-ILD) than those in Western countries and many CTD-ILDs were treated with various immunosuppressive agents (IS). Recently, nintedanib (NTB), a multitargeted tyrosine kinase inhibitor, has been approved for progressive fibrosing ILD (PF-ILD) including CTD-ILD. However, the efficacy of NTB in combination with IS for CTD-associated PF-ILD (CTD-PF-ILD) is unclear. We aimed to clarify the efficacy and safety of NTB in combination with IS for CTD-PF-ILD under real-world clinical settings, as well as biomarkers reflecting therapeutic efficacy.

Methods: CTD-ILD patients who met the criteria for PF-ILD (Flaherty KR, et al. N Engl J Med. 2019) and received NTB at our institution between 2020 and 2022 were included in this retrospective study. Efficacy of NTB treatment was evaluated by changes in forced vital capacity (FVC (%, mL)) at 6–12 months and the monthly change in FVC (ΔFVC (%/M)) before and after NTB administration. As biomarker reflected of ILD activity, the level of serum KL-6 (Krebs von den Lungen-6) were also analyzed. In addition, the effect of concomitant IS on CTD-PF-ILD was evaluated by comparisons of change in FVC and ΔFVC (%/M) between patients who received new IS after the initiation of NTB (Group A) and those who received only NTB (Group B). Safety was analyzed by the occurrence of adverse events (AEs) considered to be associated with NTB within 12 months.

Results: Twenty-five patients with CTD-PF-ILD (8 males and 17 females) were included in the study. Patient characteristics are shown in Table 1. Among these CTDs complicated with PF-ILD, systemic sclerosis was the most common (9 cases; 36%), followed by myositis (6 cases; 24%). Mean FVC (%) increased from 59.1% to 65.3% and mean FVC (mL) increased from 1666.2 mL to 1821.4 mL at 6–12 months after administration of NTB (Figure 1). ΔFVC (%/M) significantly improved from -0.77%/M before NTB initiation to +0.33%/M after treatment (Figure 2). Serum KL-6 decreased significantly from 1461.6 U/mL to 1145.7 U/mL after 6–12 months of treatment. A significant negative correlation was found between the change of serum KL-6 and FVC (r: -0.7618, p: < .0001). Twelve of the 25 patients had new IS started after NTB initiation (Group A). Rituximab (6 patients) was the most commonly used as IS (Table 1). Twelve patients in Group A had a predominantly higher rate of improvement in ΔFVC (%) than the 13 patients in Group B (+12.1% vs. -0.41%, respectively) (Figure 1). The improvement in ΔFVC (%/M) was also greater in Group A than in Group B, but both groups had suppressed

progressive pulmonary fibrosis (Figure 2). AEs considered to be treatment-related were diarrhea in 13 patients, nausea in 2 patients, elevated liver enzymes in 2 patients, and headache in 1 patient, respectively, and the dose of NTB was reduced in 11 patients. No patient discontinued NTB due to AEs.

Table 1. Baseline characteristics of patients enrolled in this study.

Characteristics	Total, n=25
Age, mean ± SD, years	65.4 ± 10.7
Sex, Female, number (%)	17 (68.0)
Disease duration, mean ± SD, years	8.4 ± 7.9
Former or current smoker, n (%)	12 (50.0)
Primary connective tissue diseases	
Systemic sclerosis, n (%)	9 (36.0)
Polymyositis, Dermatomyositis, n (%)	6 (24.0)
Rheumatoid arthritis, n (%)	4 (16.0)
Microscopic polyangiitis, n (%)	3 (12.0)
Eosinophilic granulomatosis with polyangiitis, n (%)	1 (4.0)
Sjögren's syndrome, n (%)	1 (4.0)
Mixed connective tissue disease, n (%)	1 (4.0)
Laboratory data / Pulmonary function tests	
KL-6, mean ± SD, U/mL	1461.6 ± 961.2
FVC (forced vital capacity)	
% of predicted value, mean ± SD, %	56.8 ± 15.1
mL, mean ± SD, mL	1600.0 ± 600.1
The monthly change in FVC before the initiation of nintedanib, mean ± SD, %/M	-0.77 ± 0.59
Previous immunosuppressive agents prior to the initiation of nintedanib	
Glucocorticoids, number (%)	18 (72.0)
prednisolone equivalent dose, mean ± SD, mg/day	8.9 ± 6.1
Tacrolimus, n (%)	9 (36.0)
Mycophenolate mofetil, n (%)	4 (16.0)
Azathioprine, n (%)	3 (12.5)
Cyclosporine, n (%)	3 (12.0)
Newly added immunosuppressive agents after the initiation of nintedanib	
Rituximab, number (%)	6 (24.0)
Glucocorticoids (≧20mg/day of prednisolone), number (%)	5 (20.0)
Cyclophosphamide, number (%)	2 (8.0)
Abatacept, n (%)	2 (8.0)
Mycophenolate mofetil, n (%)	1 (4.0)
Tacrolimus, n (%)	1 (4.0)

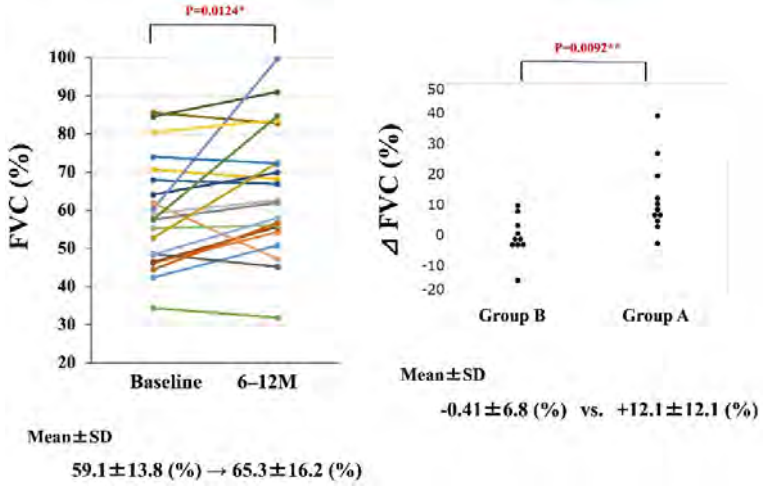

Figure 1. Changes in forced vital capacity (FVC) 6–12 months after the initiation of nintedanib. For statistical analyses * p<0.05, **p<0.01. p value: Wilcoxon signed-rank test, Wilcoxon rank sum test.

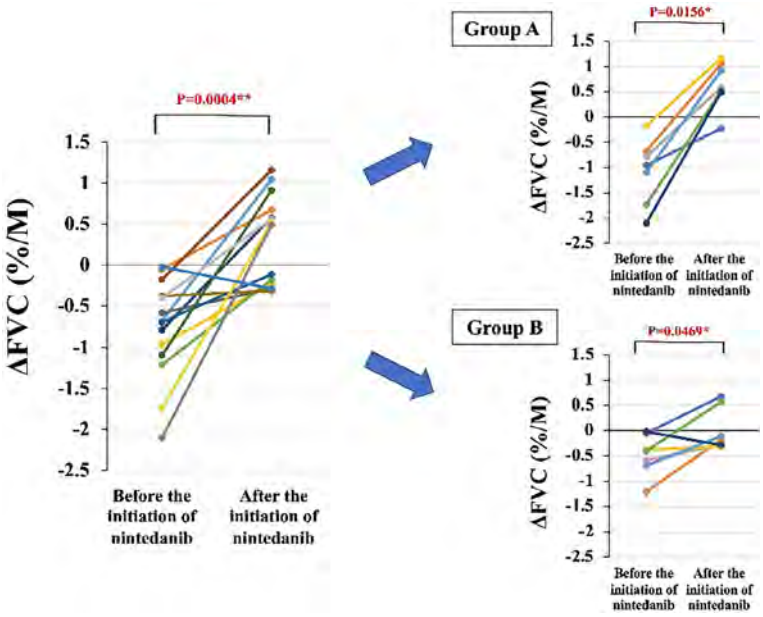

Figure 2. Changes in the monthly change in forced vital capacity (ΔFVC (%/M)) before and after the initiation of nintedanib. For statistical analyses * p<0.05, **p<0.01. p value: Wilcoxon signed-rank test.

Conclusion: NTB for CTD-PF-ILD appeared to be effective and safe in clinical practice. Our results also suggest that the combination of IS, including rituximab, may be more effective for CTD-PF-ILD than NTB treatment alone. Serum KL-6 may be a biomarker reflecting improvement in FVC during treatment with NTB.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Hypocomplementemia (HC) is often observed in IgG4-related diseases (IgG4-RD), but there are also IgG4-RD without HC. This study aimed to clarify the difference of characteristics of IgG4-RD in the presence or absence of HC.

Methods: The data of patients diagnosed with IgG4-RD at our institution were retrospectively analyzed, and these patients were divided into two groups: the HC group, which comprised patients with decreased C3 or C4 level (hypocomplementemia), and nonHC group, which comprised patients with normal C3 and C4 levels. The characteristic, affected organs, blood and imaging findings, and treatment course of the patients in both groups were compared. As additional evaluation of IgG4RD feature using imaging modality, fluorodeoxyglucose (FDG)-PET/CT was conducted. The maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycation (TLG), which indicate the level of metabolic activity of the tumor, were measured to evaluate disease activity using FDG-PET/CT.

Results: The study enrolled 65 patients. Of these patients, 19 and 46 were included in the HC and nonHC groups, respectively. Table 1 shows the characteristics of patients with IgG4-RD in this study. The HC group had lower hemoglobin levels and platelet counts and higher serum IgG4, IgG, and sIL-2R levels compared than the nonHC group. Moreover, the number of patients requiring treatment was higher in the HC group (17 patients, 89%) than in the nonHC group (28 patients, 61%). Recurrence of IgG4-RD was observed in 3 of the 17 patients in the HC group and 11 of the 28 patients in the nonHC group. Two and three patients in the HC and nonHC groups, respectively, died during the course of this study.

Two of the three index that may reflect IgG4RD activity by analyzed by FDG-PET/CT were significantly higher in the HC group.

Although there was no significant difference in SUVmax between the two groups, the MTV and TLG were significantly higher in the HC group than those of nonHC group (Figure 1).

Table 1. Characteristics of IgG4-RD patients in this study P-values were determined using Mann-Whitney U test or Fisher's exact test.

Characteristics	All (n=65)	HC group (n=19)	nonHC group (n=46)	*P* value
Age, mean (SD), y	65.3(11.6)	69.6 (8.4)	63.5 (12.4)	0.057
Sex, Male : Female, No.	41:24	12:7	29:17	1.000
Serum biomarkers, median[IQR]				
IgG4, mg/dL	458 [226, 792]	713 [412, 2100]	394.5 [201.5, 643.5]	**0.0020**

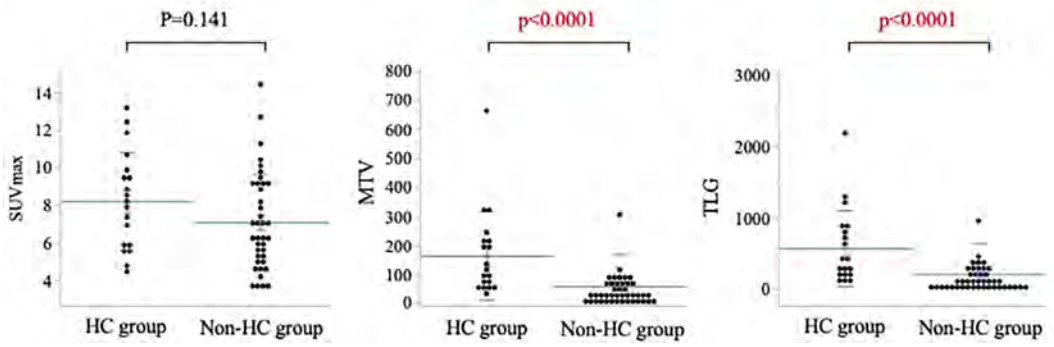
Renal pelvis thickening	2 (3.1)	0 (0)	2 (4.3)	
Pulmonary lesion	15 (23.1)	7 (36.8)	8 (17.4)	0.112
Retroperitoneum	8 (12.3)	5 (26.3)	3 (6.5)	**0.041**
Lymph node	53 (81.5)	17 (89.5)	36 (78.3)	0.484

Figure 1



Differences in fluorodeoxyglucose-PET findings of the HC and nonHC groups Maximum standardized uptake value was not significantly different between the groups; however, metabolic tumor volume and total lesion glycation were significantly higher in the HC group than in the nonHC groups. The P-value was determined by performing the Mann–Whitney U test.

Conclusion: The HC group had peripheral blood cytopenia and higher IgG4 level than the nonHC group. Moreover, more patients in the HC group required therapeutic intervention and had a poor prognosis. In assessing the activity of patients with IgG4RD using FDG-PET/CT, HC group had higher disease activity compared with nonHC group.

Understanding Monogenic Behçet's Disease Pathophysiology: Impact of Pathogenic Variant L227X Associated with Autoinflammatory A20 Haploinsufficiency on Cellular Survival and Proliferation

Patricia Aires[1], Daniela Pioto[1], Maria Teresa TErreri[2] and **Sandro Perazzio**[3], [1]Universidade Federal de São Paulo (UNIFESP), São Paulo, Brazil, [2]UNIFESP, São Paulo, Brazil, [3]Universidade de Sao Paulo (Unifesp); Universidade de São Paulo (USP); Fleury Laboratories, São Paulo, Brazil

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: A20, encoded by *TNFAIP3*, plays a critical role in NF-κB pathway regulation. A20 haploinsufficiency is a monogenic disorder form of Behçet's disease with a wide spectrum of phenotypic manifestations. This study aimed to establish an in vitro model to investigate the impact of the *TNFAIP3* L227X pathogenic variant on cellular survival and proliferation.

Methods: Jurkat (T cell neoplastic lineage) and THP-1 (monocytic lineage) cells were transfected with a plasmid engineered to express either wild-type (WT) or L227X *TNFAIP3*. A20 protein expression was assessed, and Ki-67 expression was utilized as a measure of cell proliferation. Cell resistance to apoptosis was evaluated using annexin V and propidium iodide

staining (before and after ultraviolet [UV] radiation or anti-CD95 stimulus). Jurkat and THP-1 cells were specifically stimulated with IL-2 + phytohemagglutinin (PHA) and phorbol-miristate-acetate (PMA), respectively. Non-transfected (NT) cells and empty plasmid (EP)-transfected cells served as controls. Flow cytometry was employed for all analyses.

Results: TNFAIP3-L227X transfection reduced A20 protein expression in both THP-1 (MFI=581.0 ± 329.0) and Jurkat cells (763.7 ± 17.32) compared to NT cells (respectively, 1169 ± 51.50 [$p < 0.01$] and 694.5 ± 0.5 [$p < 0.05$], figure 1). THP-1-TNFAIP3-L227X exhibited increased Ki-67 expression after PMA stimulus (19180 ± 4473), in contrast to THP-1-NT cells

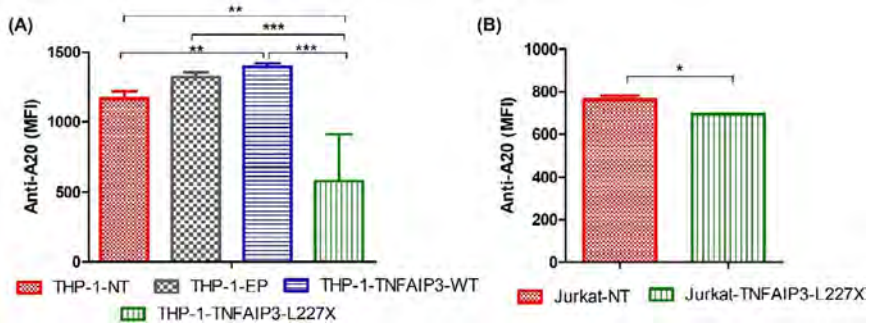

Figure 1: A20 protein expression in THP-1 (A) and Jurkat (B) cells transfected with L227X TNFAIP3 (green), compared to non-transfected cells (red) and cells transfected with WT TNFAIP3 (blue) or empty plasmid (grey). * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.

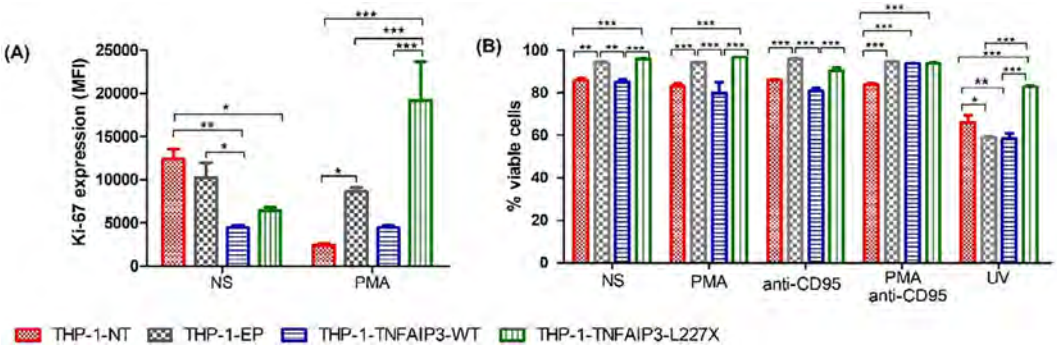

Figure 2: Proliferation rates, determined by Ki-67 expression levels (A) and resistance to apoptosis, determined by percentage of viable cells (B), in THP-1 cells transfected with L227X TNFAIP3 (green), compared to non-transfected cells (red) and cells transfected with WT TNFAIP3 (blue) or empty plasmid (grey). NS = non-stimulated. PMA = phorbol-miristate-acetate. UV = ultraviolet radiation. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.

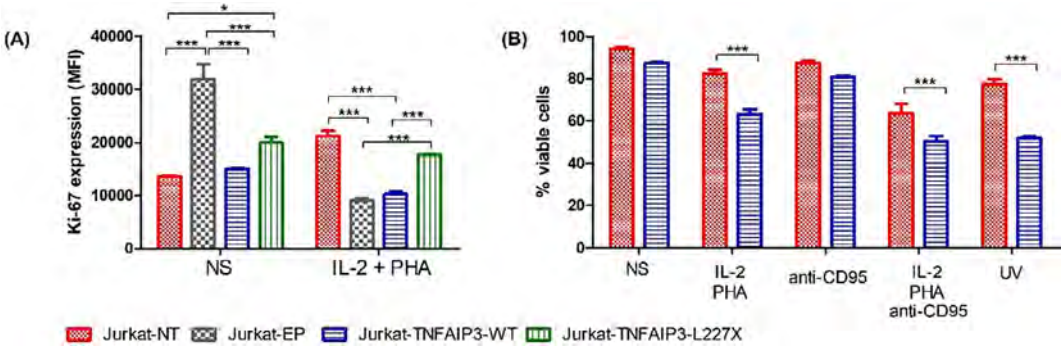

Figure 3: Proliferation rates, determined by Ki-67 expression levels (A) and resistance to apoptosis, determined by percentage of viable cells (B), in Jurkat cells transfected with L227X TNFAIP3 (green), compared to non-transfected cells (red) and cells transfected with WT TNFAIP3 (blue) or empty plasmid (grey). NS = non-stimulated. IL-2 = human interleukin-2. PHA = phytohemagglutinin. UV = ultraviolet radiation. * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$.

(2435 ± 187.4, p< 0.001, figure 2A). Moreover, THP-1-TNFAIP3-L227X cells displayed significantly higher resistance to apoptosis at baseline and when stimulated with anti-CD95 (with or without PMA) or exposed to UV radiation (figure 2B). Jurkat-TNFAIP3-L227X (19960 ± 1048) showed elevated Ki-67 levels at baseline compared to Jurkat-NT cells (13520 ± 249.5, p< 0.05), but not compared to Jurkat-EP cells (31870 ± 2843, figure 3A), which exhibited a substantial baseline increase in Ki-67 expression. Intriguingly, TNFAIP3-WT transfection produced opposite effects, including lower proliferation rates and reduced resistance to apoptosis in both THP-1 (figure 2B) and Jurkat cells (figure 3B).

Conclusion: *TNFAIP3* L227X variant significantly impacts cell survival and proliferation in monocytic and T-lymphoid cell lineages, promoting a predominantly hyperproliferative state. Reduced A20 protein expression in both Jurkat and THP-1 suggests that L227X variant may exert a dominant negative effect on the WT *TNFAIP3* gene. Despite the limitations inherent to this cell model, our results suggest the potential utility of these functional assays for diagnosing patients suspected of harboring *TNFAIP3* genetic variants.

Preliminary Experience with a Novel "Fix" for Deep Epitope and Transcriptional Phenotyping of Fragile Cells from Autoinflammatory Flares

Hallie Carol[1], Emily Landy[2] and Scott Canna[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoinflammatory diseases (AID) are characterized by inflammation and immunopathology due to primary defects in the innate immune response. Neutrophils (PMN) feature prominently in the biology of most AID, but show clear differences between AID categories (e.g. mature PMN in *NLRP3*-AID, atypical PMN in proteasome-AID, low-density granulocytes in interferonopathies). However, PMN are excluded in mononuclear cell preparations (e.g. PBMC), do not tolerate freeze/thaw, have low mRNA content, and change dramatically & quickly with treatment. Thus, optimal neutrophil studies require rapid preservation of high-quality samples from unpredictable "flare" timepoints prior to significant pharmacologic intervention. Fixed-cell Indexing of Transcriptomes and Epitopes sequencing (FITEseq) is a novel method for quickly processing and preserving epitope and transcript abundance. We sought to understand which cells were excluded from PBMC preparations, and to pilot the feasibility and quality of whole blood FITEseq in active AID patients.

Methods: Pellets from patient PBMC preparations underwent magnetic red blood cell (RBC) depletion and flow cytometry. 1mL of K-EDTA anticoagulated whole blood from a new-onset Stills-like patient and one healthy control were RBC depleted, fixed (10x Single Cell Fixed RNA Sample Preparation Kit), and stored at -80C. Parallel samples were analyzed by flow cytometry. Libraries prepared using the Chromium human fixed RNA kit, RNA integrity determined by bioanalyzer, libraries quantitated by Qbit and sequenced on NextSeq1000 (P2 reagents, 100 cycles). Analysis was performed using CellRanger7 and visualizations performed using Cellenics.

Results: In addition to CD15+ neutrophils, PBMC pellets variably included monocyte populations, predominantly in patient samples, that would not be included in buffy coats. Whole blood preparation resulted in minimal death or specific loss of neutrophils. Preliminary technical analyses highlighted the importance of timely processing, precise library quantitation, and low-RNA permissive analysis. Contemporaneous Stills-like patient serum showed dramatic total IL-18 and S100A12 elevation. The proportion of neutrophils identified transcriptionally matched well with contemporaneous differential, and was higher in the patient (Fig. 1). Exploratory analysis showed higher expression of granule, S100, and interferon-inducible genes in patient myeloid cells, and CD38 on patient CD8 T-cells.

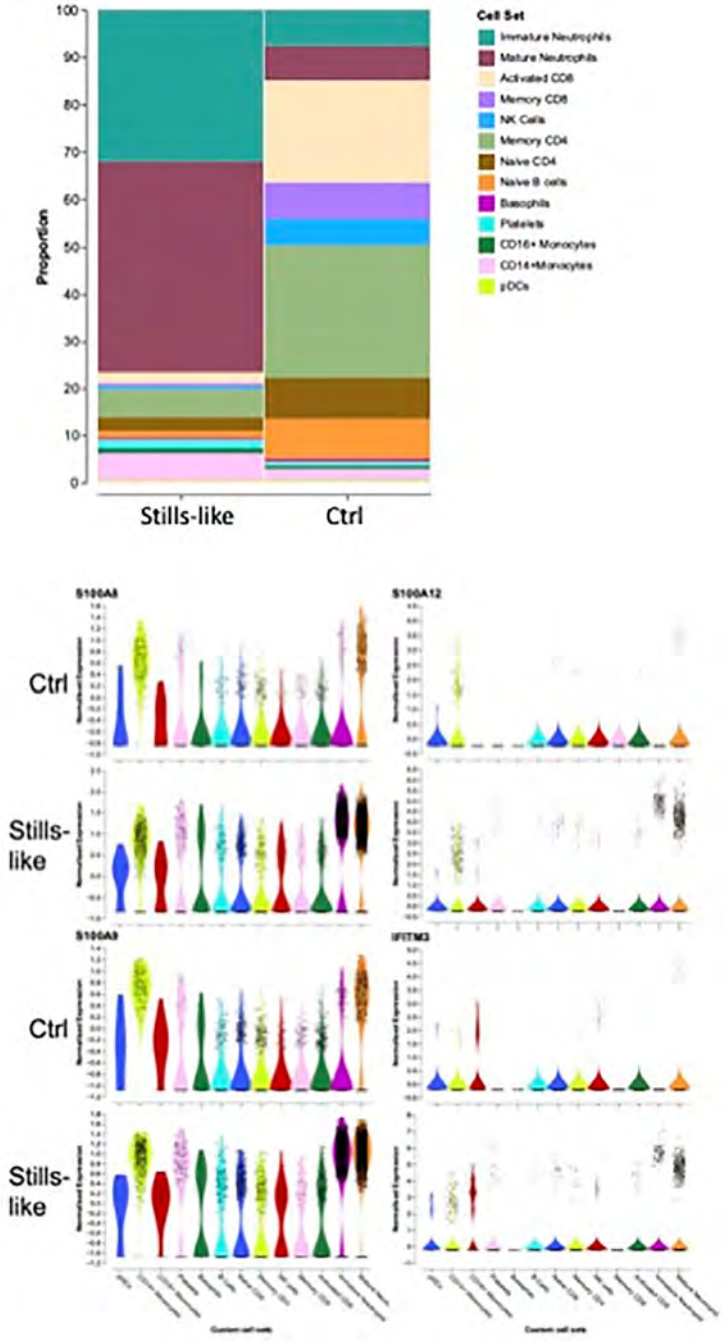

Figure 1: Proportion of total cells sequenced attributed to different cell types. Samples underwent FITE-seq. TOP: proportion of sequenced cells mapped by transcriptional signature to canonical cell types using Cellenics instance. BOTTOM: Violin plots of normalized expression of single cells of candidate genes across these canonical cell types.

Conclusion: Single-cell analysis of fixed whole blood from AID patients is feasible and demonstrates physiologically-relevant alterations in cells omitted in PBMC preparations (including PMN and monocyte populations). FITEseq may be a practical and scalable method of obtaining single-cell protein and transcriptome data from samples containing fragile myeloid cells.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: Systemic autoinflammatory disorders (SAIDs) are including a group of diseases, which are associated with genetic variations resulting in dysregulation of innate immunity and hyperinflammatory response. Pathogenic and likely pathogenic variants in certain genes have been linked to a defined phenotype, but screening of more patients with some autoinflammatory features has been revealing several variants of uncertain significance (VUS), and also patients with variants in more than one autoinflammatory gene. We herein investigated the relationship between phenotype and genotype of the patients who were screened for autoinflammatory genes and identified as carriers of variants in $^{3}2$ genes in a tertiary referral center.

Methods: Methods: Charts of the patients who had been referred to our center with a potential diagnosis of autoinflammatory disorder between April 2019 and January 2023 and the results of their genetic analyses were evaluated. All patients had the results of genetic screening of 22 genes, which were associated with different autoinflammatory disorders, and analyses covered the exons and 10 base pair intron borders of the selected genes and were carried out by using the Ion Torrent platform and Illumina platform.

Results: Results: We evaluated 146 referred patients (60 male, 85 female, mean age 41.0±12.6, range 19-82), and 38 of them (26%) identified as having ≥2 gene variants. By using the recent classification criteria for the autoinflammatory recurrent fevers,[1] eleven out of 38 (28.9%) patients were classified as FMF. Among the patients with the MEFV mutations, the

presence of additional variants may have had an effect on the phenotype such as sensorineural hearing loss in those with NLRP3 VUS. Since the Gattorno et al. criteria were aiming only 4 common SAIDs, 5 (13.2%) patients could be diagnosed with VEXAS syndrome (n=1), deficiency of ADA2 (DADA2, n=2), A20 haploinsufficiency (HA20, n=1), DADA2 and HA20 combination (n=1) (Table 1). The remaining patients were grouped as having the PFAPA-like (n=2) and Behçet disease-mimic (n=7) according to their dominant phenotype (Table 2). Thirteen (34.2%) patients could not be classified into any groups (Table 3). Two of these cases had pathogenic and likely pathogenic variants with VUS, and others had between 2-7 different VUS combinations.

Conclusion: Discussion: The criteria developed by Gattorno et al. have some limitations in daily practice since the set includes only CAPS, FMF, TRAPS, and MKD and is not validated in adults. Although those patients with pathogenic variants could be classified by using them, the contribution of additional variants to the phenotype needs further investigation. On the other hand, an important group of adult patients may have unclassified systemic autoinflammatory features mainly associated with a combination of VUS in different genes, and this "mixed autoinflammatory disorder-MAID" phenotype needs to be followed carefully for the evaluation of long-term prognosis.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Deucravacitinib, a first-in-class, oral, selective, allosteric tyrosine kinase 2 inhibitor, is approved in multiple countries for the treatment of adults plaque psoriasis. Deucravacitinib was superior to placebo and apremilast in the global, 52-week, phase 3 POETYK PSO-1 (NCT03624127) and PSO-2 (NCT03611751) trials in plaque psoriasis and is currently being investigated in several immune-mediated diseases and has shown efficacy in phase 2 trials for SLE and PsA. Upon completion of the parent trials, patients could enroll in the POETYK long-term extension (LTE) trial (NCT04036435). In the present LTE analysis, we report safety and efficacy of deucravacitinib up to 3 years (week 148) through data cutoff (June 15, 2022).

Methods: PSO-1 and PSO-2 randomized patients 1:2:1 to oral placebo, deucravacitinib 6 mg once daily (QD), or apremilast twice daily. At week 52, POETYK PSO-1 and PSO-2 patients enrolled in the LTE trial received open-label deucravacitinib 6 mg once daily. Safety was evaluated in patients who received ≥ 1 dose of deucravacitinib via exposure-adjusted incidence rate (EAIR) per 100 person-years (PY). Efficacy outcomes included ≥ 75%/≥ 90% reduction from baseline in Psoriasis Area and Severity Index (PASI 75/90) and static Physician's Global Assessment (sPGA) score of 0 (clear) or 1 (almost clear) with a ≥ 2-point improvement from baseline. Efficacy was reported using modified nonresponder imputation (mNRI) in patients who received continuous deucravacitinib treatment from day 1 of the parent trial and were enrolled and treated in the LTE trial. As-observed results by treatment failure rule imputation were also analyzed.

Results: 1519 patients received ≥ 1 dose of deucravacitinib, with 513 patients receiving continuous deucravacitinib treatment from day 1 in PSO-1/PSO-2 and who were treated in the LTE trial. Cumulative exposure from parent trial randomization was 3294.3 PY for these safety analyses. EAIRs/100 PY were similar, or decreased, from the 2- to 3-year cumulative period, respectively, for adverse events (AEs) (154.4to 144.8), serious AEs (6.1 to 5.5), discontinuation due to AEs (2.8 to 2.4), herpes zoster (0.7 to 0.6), malignancies (0.9 to 0.9), major adverse cardiovascular events (0.4 to 0.3), venous thromboembolism (0.1 to 0.1), and deaths (0.4 to 0.3). Clinical response rates were maintained at week 148 by mNRI (PASI 75, 73.2% [95% CI, 68.7–77.8]; PASI 90, 48.1% [95% CI, 43.2–53.1]; sPGA 0/1, 54.1% [95% CI, 49.1–59.1]), with similar results regardless of data imputation methodology.

Conclusion: Deucravacitinib demonstrated a consistent safety profile through 3 years with no increases in AE or serious AE rates over time and no emergence of new or long-term safety signals. Efficacy was sustained through 3 years in patients treated continuously with deucravacitinib from day 1 in the parent trials. Since it is important to provide long-term safety for this new class of drugs, these findings provide additional support for deucravacitinib having a consistent safety profile and durable efficacy for up to 3 years of use in patients with plaque psoriasis.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Whipple disease is a chronic, curable, systemic bacterial infection caused by *Tropheryma whipplei*. The classic form usually begins with recurrent arthritis, followed years later by weight loss or diarrhea, sometimes associated with fever, lymphadenopathy, neurological, cardiac or ocular signs.[1] Arthritis can occur in isolation for years, which can significantly delay diagnosis and lead to destruction and damage.

Methods: We describe a series of patients with destructive arthritis among those diagnosed with Whipple disease between 2007 and 2023 at our National Referral Center for Rare Systemic Autoimmune Diseases.

Severe bilateral cartilage loss in the radiocarpal, intercarpal, and carpometacarpal joints with ankylosis. The metacarpophalangeal and interphalangeal joints are spared.

Advanced bilateral iliofemoral joint space narrowing with subchondral cysts.

Results: Among a consecutive series of 52 patients diagnosed with Whipple disease during the study period, 48 presented joint manifestations, 14 of whom had destructive arthritis: 13 men and one woman, diagnosed at a mean (SD) age of 65.0 (9.5) years. Their first symptoms appeared at a mean age of 45.3 (12.5) years and consisted of arthritis in 13 (93%). Initially, all patients had intermittent arthritis, usually affecting one large joint at a time, with complete resolution within a week. After a mean of 11.7 (9.7) years, 12 patients developed permanent chronic arthritis with occasional additional flares. At diagnosis, all but one patient had chronically elevated CRP values (mean, 5.4 mg/dL), and neutrophil hyperleukocytosis was present in 67% of patients. Rheumatoid factor was detected in one patient and ACPA testing was negative in all. Radiographs showed narrowing of the carpal or radiocarpal joint in 12 cases (8 bilateral, 4 unilateral) (Figure 1), and global narrowing of the iliofemoral joint space in 10 cases (7 bilateral, 3 unilateral) (Figure 2), with subchondral cysts in 6. Progression to ankylosis occurred in 7 cases, at a late stage of the disease. Small joints were always spared. The diagnosis was made only after a mean delay of 19.7 (11.8) years (range, 5.4-40.1 years) after the first signs of the disease. Only 5/13 patients (38%) had positive PAS staining on duodenal biopsies. The diagnosis was confirmed by positive PCR results for *Tropheryma whipplei* on stool (73%), saliva (73%), and duodenal tissue (83%) samples; 5/8 patients (63%) were PCR positive in synovial fluid, 4/9 (44%) in blood and 3/8 (38%) in cerebral spinal fluid. Eleven patients received doxycycline and hydroxychloroquine, combined in case of CNS involvement (n=4) with sulfadiazine; 3 were treated with trimethoprim-sulfamethoxazole. Dramatic

improvement was observed after administration of antibiotic therapy in all cases, with disappearance of arthritis flares within a few days.

Conclusion: A diagnosis of Whipple disease should be considered in a middle-aged man with unexplained seronegative destructive arthritis of the large joints, especially when preceded by intermittent acute episodes of arthritis and accompanied by persistent elevated CRP levels or leukocytosis, even in the absence of the cardinal manifestations of infection. PCR testing for *Tropheryma whipplei* from saliva and stool samples, or synovial fluid if available, has become the preferred initial diagnostic test. Clinical and biological improvement is often dramatic under antibiotic treatment.

Patient, Disease, and Treatment Factors in Remission of Inflammatory Eye Disease

Taylor Koenig[1], David Fell[1], Danny Mammo[1], Chao Zhang[2], Sunil Srivastava[1], Careen Lowder[1], Sumit Sharma[1] and Rula Hajj-Ali[1], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Noninfectious inflammatory eye disease (NIIED) is a sight-threatening condition with two-thirds of patients incurring prolonged vision loss due to uncontrolled ocular inflammation. Non-glucocorticoid systemic therapy (NGST) effectively induces and maintains remission in NIIED. However, minimal research exists on the risk factors for requiring long-term NGST for NIIED control or for NIIED relapse after discontinuation of NGST.

Methods: We performed a retrospective chart review of NIIED patients who were evaluated by the Cleveland Clinic Ophthalmology and Rheumatology departments and initiated NGST between January 1, 2014 through December 31, 2018, and had at least 4 years of follow-up prior to December 31, 2022. If treatment was dictated by systemic disease, patients were excluded. Data were extracted from the electronic medical record. The association between patient characteristics and the groups were analyzed through univariate logistic regression.

Results: 94 NIIED patients were included in the study. 78 patients (83.0%) were maintained on NGST throughout the study period, designated as long-term NGST. 16 patients (17.0%) had NGST discontinued due to inactive NIIED, denoted as short-term NGST. NIIED location was significantly different between the two groups (Table 1). Patients with intermediate, posterior, or pan uveitis were more likely to require long-term NGST compared to patients with anterior uveitis (Table 2). Age, sex, race, presence of systemic disease, and treatment with biologic or nonbiologic medication were not significantly

Variable	Level	All (n=94)	Short-Term NGST (n=16)	Long-Term NGST (n=78)	P-value	N
Sex	Male	26 (27.7%)	6 (37.5%)	20 (25.6%)	0.365	94
	Female	68 (72.3%)	10 (62.5%)	58 (74.4%)		
Race	Non-white	21 (22.3%)	1 (6.25%)	20 (25.6%)	0.110	94
	White	73 (77.7%)	15 (93.8%)	58 (74.4%)		
Age at NIIED Diagnosis		44.5 (14.8)	49.1 (18.7)	43.6 (13.7)	0.279	92
Systemic Disease	Yes	41 (43.6%)	5 (31.2%)	36 (46.2%)	0.413	94
Primary Ocular Autoimmune Disease	Yes	58 (63.7%)	12 (80.0%)	46 (60.5%)	0.254	91
NIIED Location	Anterior Uveitis	13 (14.1%)	5 (35.7%)	8 (10.3%)	**0.023**	92
	Intermediate/Posterior/Panuveitis	64 (69.6%)	6 (42.9%)	58 (74.4%)		
	Scleritis	15 (16.3%)	3 (21.4%)	12 (15.4%)		
	Bilateral	12 (80.0%)	2 (66.7%)	10 (83.3%)		
History of Ocular Steroid Implant	Yes	31 (33.0%)	3 (18.8%)	28 (35.9%)	0.300	94
NGST Class	Biologic	35 (37.6%)	6 (37.5%)	29 (37.7%)	1.000	93
	Non-Biologic	58 (62.4%)	10 (62.5%)	48 (62.3%)		
Time from Symptom Onset to NGST Initiation (days)		380 [151;1201]	184 [101;1121]	448 [203;1201]	0.080	93

Short-term NGST (discontinued NGST during study period) and long-term NGST (continued NGST during study period). Continuous variables presented as Median [IQR]. Categorical variables presented as N (column %).

Descriptive comparison of risk factors between Short-Term vs Long-Term NGST groups for NIIED patients. NIIED location was significantly different between the two groups. Patients in the short-term NGST group had earlier initiation of NGST than patients in the long-term NGST group.

different between the groups. However, data trends showed that patients with white race were more likely to require long-term NGST than non-white race; earlier initiation of NGST was more represented in the short-term NGST group which may imply that earlier initiation of NGST confers a greater likelihood of discontinuing NGST due to inactive NIIED. Within the short-term NGST group, 11 patients (68.8%) had inactive NIIED for ≥ 1 year, designated as sustained remission, and 5 patients (31.3%) had relapse of active NIIED < 1 year, designated as intermediate group. NIIED patients with sustained remission tended to be diagnosed at an older age and had earlier initiation of NGST than the intermediate group (Table 3).

Conclusion: This study provides insight into the risk factors for requiring long-term NGST and sustained remission for patients with NIIED. Our results demonstrate that NIIED location of intermediate, posterior, or pan uveitis is a risk factor for requiring long-term NGST. Older age and earlier initiation NGST may be associated with sustained remission of NIIED.

Variable	Level	OR [95%CI]	P-value
Age at Diagnosis		0.76 [0.52;1.13]	0.178
Sex	Female v Male	1.74 [0.52;5.42]	0.354
Race	White v Non-white	0.22 [0.01;1.21]	0.090
Systemic Disease	Yes v No	1.85 [0.60;6.49]	0.291
NIIED Location		5.84 [1.36;25.0]	**0.019**

Abstract Number: 0264

A Novel Role for Rheumatologists: Managing Idiopathic Granulomatous Mastitis

Marcia Genta[1] and Allison DiPasquale[2], [1]Dallas Arthritis Center, Dallas, TX, [2]Texas Oncology - Medical City Dallas, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic Granulomatous Mastitis (IGM) is a rare often self-limited chronic inflammatory breast disease of unknown etiology characterized by non-caseating granulomas in breast tissue, affecting primarily women of childbearing age. The diagnosis is made by histological examination after excluding other conditions (particularly malignancy and infections).Management options are limited and include observation, antibiotics, corticosteroids, and methotrexate (MTX). Progression and recurrence are common despite treatment. We present a series of patients referred to a rheumatology practice.

Methods: We reviewed the charts of all patients referred to a rheumatology practice with biopsy-confirmed diagnosis of IGM (2019-2023). Demographics, clinical information, and treatment are summarized in Table 1. For the purpose of this report, we defined improvement as the patients' subjective assessment of their pain/discomfort; the disappearance of discharge; and a reduction/disappearance of the breast mass(es).

Table 1 – IGM patients referred to a rheumatology practice

Pt #	Ethnicity	Age	Side	Initial treatment	Rheumatologist's treatment	F/U (mo)	Outcome
Pt_01	H	23	R	Ab	Pred + MTX	17	No pain or drainage - mass reduced
Pt_02	W	34	L	Ab + Af	Pred + MTX	8	No pain or drainage - mass reduced
Pt_03	H	39	R+L	Pred	MTX	8	No pain or drainage - mass reduced
Pt_04	ME	41	R+L	Pred	MTX	12	Resolved – normal mammogram
Pt_05	H	39	L	Ab	MTX > Adalimumab	15	No pain or drainage - mass reduced
Pt_06	H	48	L	Ab	None	2	No pain or drainage - mass reduced
Pt_07	SA	39	R	Pred	Etanercept	7	No pain or drainage - mass reduced
Pt_08	AA	39	L	Medrol pack	Pred	1	No pain or drainage - mass reduced
Pt_09	SA	36	L	Ab + Pred	MTX	2	No pain or drainage - mass resolved
Pt_10	H	36	R	Ab + Pred	Etanercept	4	No pain or drainage - mass reduced
Pt_11	H	43	R	Pred	Pred	-	Reported improvement – no follow-up
Pt_12	W	42	L	Ab + Pred	Etanercept	4	No pain or drainage - mass reduced
Pt_13	H	37	L	Pred	1 mo Rifampin for TB > Etanercept	-	Reported worsening – no follow-up

Pt = Patient; H = Hispanic; W = White; ME = Middle Eastern; SA = South Asian; AA = African American; R = Right; L = Left; Ab = Antibiotic; Af = Antifungal; Pred = Prednisone; MTX = Methotrexate; F/U = Follow up; mo = Months

Results: Thirteen parous women (median age 39 yrs, range 23 – 48) were referred to us by a breast surgery practice to exclude possible causes for their granulomatous breast masses. Biopsy revealed non-necrotizing granulomas and no malignancy; cultures were negative for bacteria, mycobacteria, and fungi. All patients were otherwise in good health. We obtained ANCA panel, ACE levels, and chest X-ray to gain insights into possible non-caseating granulomatous diseases (*e.g.*, sarcoidosis and ANCA-associated vasculitis). All test results were normal. Previous treatments by the referring breast surgeon, including antibiotics or anti-fungal only (4 patients), antibiotics and corticosteroids (3 patients), and corticosteroids only (6 patients), had failed to induce improvement (as defined above). Only one patient (#6 in table 1) improved with antibiotics alone (after referral) and did not require follow-up; two patients (#8 and #11) improved with continuing corticosteroids; MTX was used in 6 patients, alone (#3. #4, #9), as steroid sparing (#1, #2), or in association with an anti-TNF-α (#5). In 5 patients with persistent or recurrent manifestations (multiple masses, marked drainage, severe pain) we added anti-TNF-α agents (etanercept or adalimumab). Four of the 5 patients (#5, #7, #10, and #12) experienced substantial clinical improvement and the lesions resolved completely (in one case confirmed by mammogram). Patient #13 reported worsening of her symptoms after one dose of etanercept and refused to return for a follow-up appointment.

Conclusion: There are no evidence-based guidelines on the management for IGM. Treatments include observation, antibiotics, systemic or intra-lesional corticosteroids, MTX (alone or as steroid sparing), and rarely surgery. Many patients do not tolerate systemic corticosteroids; MTX is contraindicated in child-bearing women without contraception. Anti-TNF-α agents may represent a safer treatment. The rationale for their use is that by blocking TNF-α, a cytokine that plays a major role in forming and maintaining granulomas, these agents may provide an effective and targeted alternative, making rheumatologists pivotal partners in the management of IGM.

Differential and Combinatorial Mechanism of Action of Golimumab and Guselkumab in Ulcerative Colitis Induction Therapy: IL-23 Blockade Drives Restoration of Normal Epithelium and Mucosal Healing

Prerak Desai[1], Patrick Branigan[2], Dylan Richards[1], **Dennis McGonagle**[3], Marion Vetter[1], Daniel J. Cua[1] and Thomas Freeman[1], [1]Janssen Research & Development, LLC, Spring House, PA, [2]Janssen Research & Development, LLC, Minneapolis, MN, [3]Leeds Biomedical Research Centre, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The combination treatment of golimumab (GOL), a tumor necrosis factor-alpha (TNFα) antagonist, and guselkumab (GUS), an interleukin (IL)-23 inhibitor was shown to induce higher rates of clinical remission, endoscopic improvement, and histologic remission than each monotherapy in a randomized Phase 2 induction study in TNFα-naïve patients with moderately to severely active ulcerative colitis (VEGA; NCT03662542). Here, we investigated the underlying mechanism of action of GOL, GUS, and the combination (GUS+GOL).

Methods: Colon biopsies were obtained at screening and at Week 12 in patients who received GOL (n=48), GUS (n=52), or GUS+GOL (n=50). Tissue transcriptional profiles were determined with RNA sequencing. Differentially expressed genes were analyzed in the context of cell-type specific transcriptional modules by first defining a gene correlation network and

	Golimumab	Guselkumab	Combination
Numbers of genes up at Week 12	633	495	4,776
Numbers of genes down at Week 12	709	613	4,867
Th17 module: Responder vs Non-Responder Week 12 (p-value)	<0.001	<0.001	<0.001
Th17 module: Responder Week 12 vs Baseline (p-value)	<0.05	<0.001	<0.001
Th17 module: Non-Responder Week 12 vs Baseline (p-value)	NS	0.01	<0.001
Epithelial module: Responder vs Non-Responder Week 12 (p-value)	<0.01	<0.001	<0.001
Epithelial module: Responder Week 12 vs Baseline (p-value)	<0.05	<0.001	<0.001
Epithelial module: Non-Responder Week 12 vs Baseline (p-value)	NS	<0.01	<0.001

P-values associated with GSVA enrichment of biologic modules associated with endoscopic response and at Week 12.

GSVA, gene set variation analysis; NS, not significant

unsupervised network clustering. We then developed a method to create a single-cell-derived co-expression network using published ulcerative colitis single-cell data to provide high resolution gene modules associated with specific cell types and pathways. Gene set variation analysis (GSVA) was used to quantitatively assess changes in specific biologic modules in the context of responder and non-responder analyses.

Results: By Week 12, combination therapy induced a greater magnitude of transcriptional changes in the colon compared with each monotherapy (**Table**). These genes were associated with IL-23/Th17/myeloid-related processes, inflammation, and epithelial homeostasis. Significant changes were observed in Th17 cell and inflammatory epithelial cell modules in patients who achieved endoscopic improvement (subscore 0 or 1) at Week 12 compared with non-responders (**Table**). The magnitude of change relative to baseline was greater in the GUS monotherapy and GUS+GOL arms compared with GOL alone. These changes were consistent with a decrease in crypt destruction in responders at Week 12 as observed by histologic changes in the Geboes score. Genes modulated by GUS+GOL were indicative of greater suppression of inflammation, particularly myeloid cell activation and inflammatory fibroblast development. In contrast, genes modulated by either GUS or GUS+GOL were associated with increased epithelial normalization and decreased Th17 activity compared to GOL alone.

Conclusion: Combination induction with GOL+GUS for 12 weeks drove a greater reduction in inflammation and improvement in epithelial homeostasis compared to each monotherapy, demonstrating differential and complementary mechanisms of action of TNFα and IL-23 blockade. Combination therapy drives a significant increase in the overall magnitude of response with marked improvement in the restoration of normal epithelium.

E-selectin, ICAM-1 and ET-1 Biomarkers Address the Concern of the Challenging Diagnosis of Interstitial Lung Disease in Patients with Autoimmune Diseases

Verónica Pulito-Cueto[1], Sara Remuzgo-Martinez[2], Fernanda Genre Romero[2], Belén Atienza-Mateo[3], Victor Mora-Cuesta[4], David Iturbe-Fernández[4], Leticia Lera-Gómez[5], María Sebastián-Mora[1], Virginia Portilla[1], Alfonso Corrales[1], Ricardo Blanco[1], Jose Cifrian[6], Miguel A Gonzalez-Gay[7] and Raquel López-Mejías[1], [1]Rheumatology Department, Immunopathology Group, Hospital Universitario Marqués de Valdecilla-IDIVAL, Santander, Spain, [2]IDIVAL, Santander, Spain, [3]Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain, [4]Immunopathology Group, Marqués de Valdecilla University Hospital-IDIVAL; Department of Pneumology, Marqués de Valdecilla University Hospital, Santander, Spain, [5]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [6]Immunopathology Group, Marqués de Valdecilla University Hospital-IDIVAL; Department of Pneumology, Marqués de Valdecilla University Hospital; School of Medicine, Cantabria University, Santander, Spain, [7]IDIVAL and School of Medicine, UC, Santander; Department of Rheumatology, IIS-Fundación Jiménez Díaz, Madrid, Santander, Spain

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) constitutes one of the most critical comorbidities in autoimmune diseases (AD), particularly in rheumatoid arthritis (RA) and systemic sclerosis (SSc) [1-2]. Therefore, its early diagnosis is pivotal to avoid irreversible lung damage in these patients. However, no definitive serum biomarkers are available to identify ILD in AD patients. In this sense, lung vasculopathy is one of the essential processes to the development of lung fibrosis [3-4]. Accordingly, we sought to determine if E-selectin, ICAM-1, and ET-1, crucial molecules in endothelial damage, could be helpful screening biomarkers for the detection of AD-ILD$^+$.

Methods: The study objective groups involved 21 patients with RA-ILD$^+$ and 21 patients with SSc-ILD$^+$. Furthermore, we included three comparative groups of patients: 25 with RA-ILD$^-$, 20 with SSc-ILD$^-$ and 21 with idiopathic pulmonary fibrosis (IPF).Serum levels of E-selectin, ICAM-1 and ET-1 were determined by ELISA.

Results: RA-ILD$^+$ patients showed increased levels of E-selectin, ICAM-1 and ET-1 compared to those with RA-ILD$^-$ ($p< 0.01$ in all the cases, **Figure 1A**). Interestingly, the ability of serum E-selectin, ICAM-1 and ET-1 levels to discriminate patients with RA-ILD$^+$ from those with RA-ILD$^-$ were confirmed by performing ROC curves analysis (AUC: 0.78, $p< 0.01$; AUC: 0.72, $p=0.01$; AUC: 0.77, $p< 0.01$, respectively, **Figure 1B**). The optimal cutoff value for E-selectin, ICAM-1 and ET-1 revealing the best sensitivity and specificity was 74.56 ng/mL, 451.70 ng/mL and 1.02 pg/mL, respectively. Furthermore, higher ICAM-1 serum levels were found in patients with SSc-ILD$^+$ compared to those with SSc-ILD$^-$ ($p< 0.01$, **Figure 2A**). Of note, the ROC curve supported a utility of ICAM-1 for differentiating patients with SSc-ILD$^+$ from those with SSc-ILD$^-$ (**Figure 2B**). The AUC was 0.79 ($p< 0.01$) and the optimal cutoff value was 484.70 ng/mL (**Figure 2B**). Moreover, a negative correlation between ET-1 serum levels and both forced vital capacity (FVC) and forced expiratory volume in one second (FEV1) was observed in patients with RA-ILD$^+$ ($r=-0.56$, $p=0.04$ and $r=-0.65$, $p=0.01$, respectively). Likely, E-selectin serum levels were negatively correlated with FVC, FEV1 and diffusing capacity of the lung for carbon monoxide (DLCO) in patients with SSc-ILD$^+$ ($r=-0.64$, $p< 0.01$; $r=-0.56$, $p=0.02$; and $r=-0.56$, $p=0.02$, respectively).

Conclusion: Our findings support a relevant role of E-selectin, ICAM-1 and ET-1 in RA-ILD$^+$ as well as of ICAM-1 in SSc-ILD$^+$, constituting potential screening blood biomarkers of subclinical ILD in AD. Moreover, this study suggests ET-1 and E-selectin as possible indicators of worsening lung function in RA-ILD$^+$ and SSc-ILD$^+$, respectively.

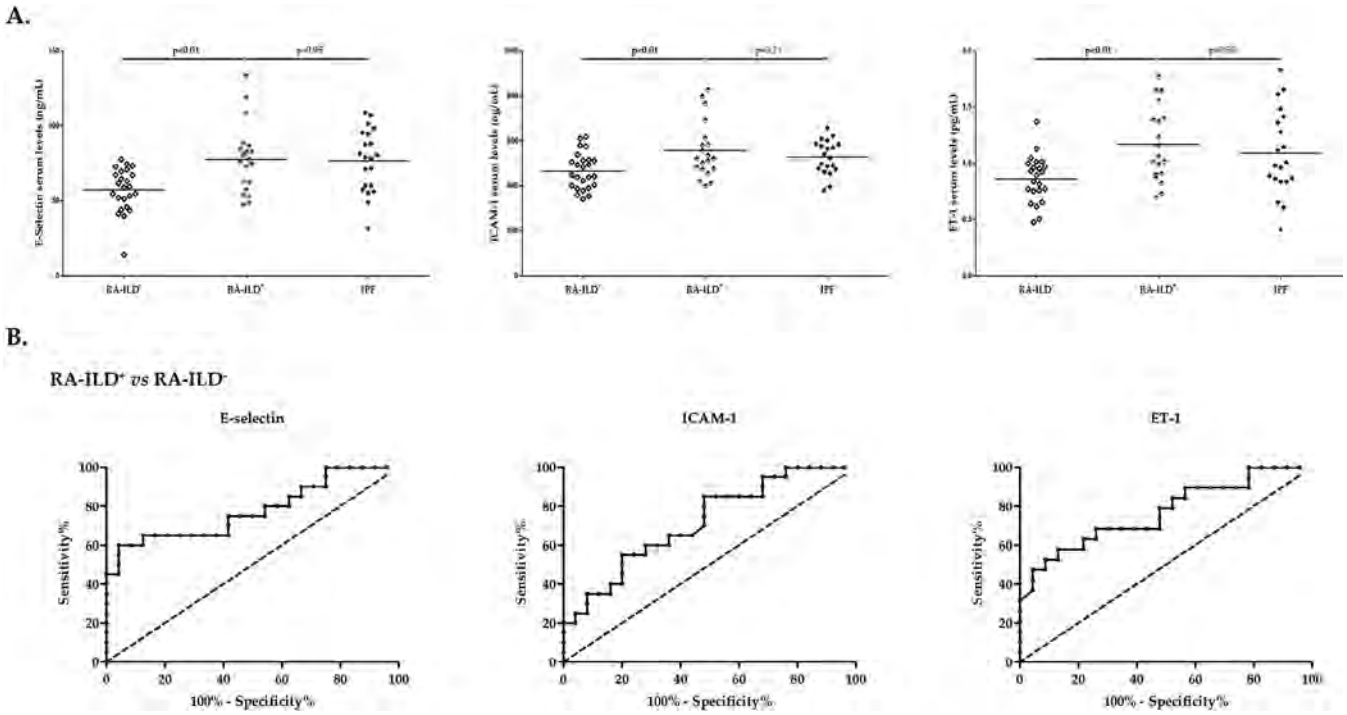

Figure 1. Differences in serum levels of E-selectin, ICAM-1 and ET-1 between patients with RA-ILD+ and those with RA-ILD- and IPF (A), as well as ROC curves analysis for the discrimination of RA-ILD+ from RA-ILD-(B). ICAM-1: intercelullar adhesion molecule 1; ET-1: endothelin 1; RA: rheumatoid arthritis; ILD: interstitial lung disease; IPF: idiopathic pulmonary fibrosis;. Significant results are highlighted in bold.

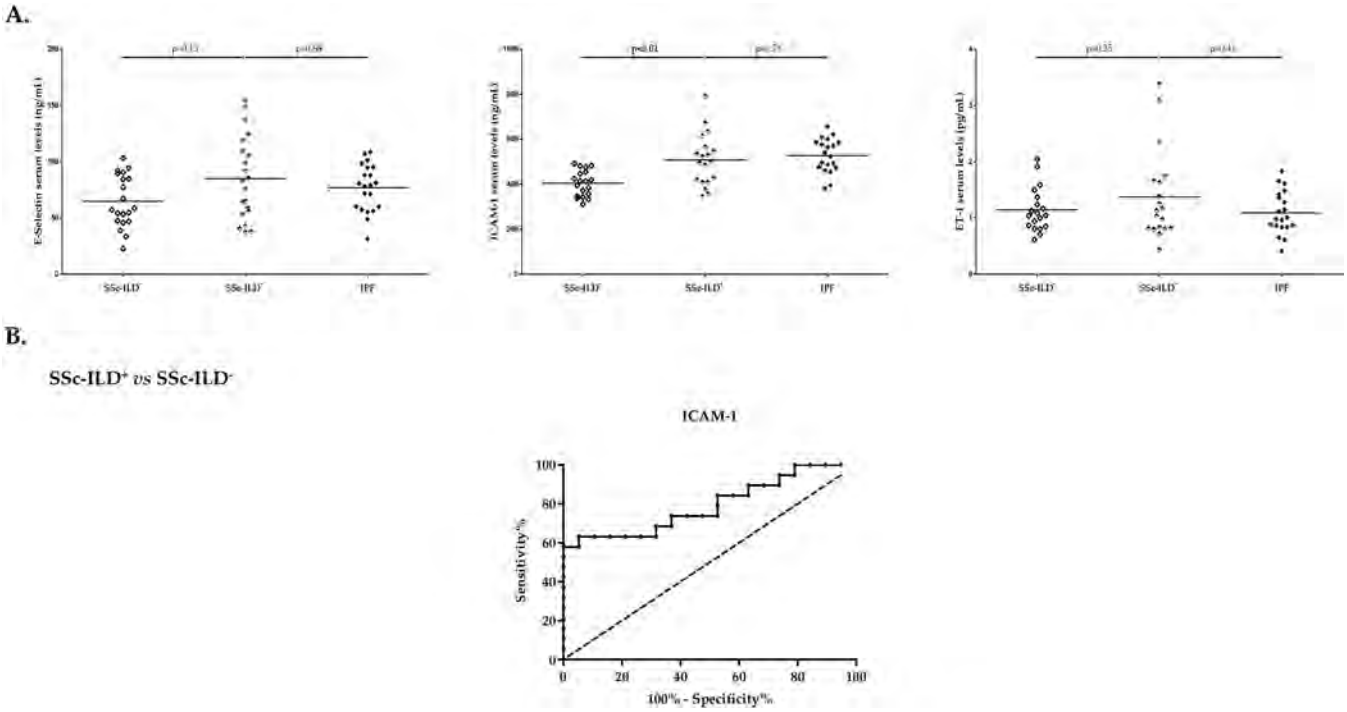

Figure 2. Differences in serum levels of E-selectin, ICAM-1 and ET-1 between patients with SSc-ILD+ and those with SSc-ILD- and IPF (A), as well as ROC curves analysis of ICAM-1 for the discrimination of SSc-ILD+ from SSc-ILD-(B). ICAM-1: intercelullar adhesion molecule 1; ET-1: endothelin 1; SSc: systemic sclerosis; ILD: interstitial lung disease; IPF: idiopathic pulmonary fibrosis;. Significant results are highlighted in bold.

Variations in Approach to the Diagnosis and Management of Polymyalgia Rheumatica Among Australian Rheumatologists

Victor Yang[1], Jem Ninan[2], David Liew[1], Helen Keen[3], Catherine Hill[4] and Jessica Leung[5], [1]Austin Health, Heidelberg, Australia, [2]University of Adelaide, Adelaide, Australia, [3]University of Western Australia, Daglish, Australia, [4]The Queen Elizabeth Hospital, Woodville, Australia, [5]Austin Health, Preston, Australia

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is the second-most common inflammatory rheumatic disease but there remains variation amongst rheumatologists in approaches to diagnosis and management. This study aimed to evaluate the perceptions and approaches to PMR in a cohort of Australian rheumatologists.

Methods: Rheumatologist and trainee members of the Australian Rheumatology Association were invited via email to participate in a survey that explored opinions and experience around PMR diagnosis and management.

Results: Responses were received from 79 clinicians, of which 57 (72%) answered the survey to completion. 51% were female, and clinical experience varied from 0-10 years (40%) to over 20 years (26%), with a mix of public hospital work (75%) and private practice (58%). 75% of respondents managed at least one patient with PMR every fortnight.

Regarding PMR presentation and diagnosis, 23% believed that bilateral shoulder involvement is necessary to make a diagnosis of PMR, while 76% believed it occurs "most of the time". 37% believed elevated inflammatory markers are necessary for diagnosis, while 59% acknowledged that inflammatory markers may be normal although an uncommon occurrence. 13% regarded peripheral involvement as preclusion of a PMR diagnosis. Imaging was largely deemed useful in the setting of diagnostic uncertainty (72%).

Regarding treatment, there was a consensus for starting prednisolone at 15 mg (83%) with 75% favoring a 12-month steroid wean. 98% reported having prescribed a steroid-sparing drug in PMR before, with almost half using this in 25-50% of PMR patients. The most common indications for initiating a steroid-sparing drug were first relapse (29%) and second or later relapse (49%), although most would consider it in patients at high risk of steroid side effects (79%). Standard choices

included methotrexate (98%), leflunomide (27%), tocilizumab (13%), and hydroxychloroquine (10%). The majority agreed there is no strong evidence to support the use of methotrexate (86%) or leflunomide (95%).

Regarding monitoring and progress, the most common issues to arise during the disease course included steroid side effects (90%), pain (87%), stiffness (82%), fatigue (79%), and impact on physical function (75%). 48% recognized two distinct patient populations – those who have self-limiting disease which remits within 24 months and those who require lifelong low-dose prednisolone.

Conclusion: Australian rheumatologists had diverse opinions around the diagnostic features of PMR and the role of imaging. Many acknowledged that a diagnosis of PMR might be appropriate even in the absence of bilateral shoulder involvement and abnormal inflammatory markers in contrast to the 2012 EULAR/ACR provisional classification criteria. The majority had initiated a steroid-sparing drug in a PMR patient despite the lacking evidence base. The need for lifelong treatment in some patients was also recognized. Substantial variation existed in other areas of practice.

These findings challenge the classic paradigm of PMR as a self-limiting disease managed with steroid monotherapy, emphasizing the need for standardization of practice and further research into consistent diagnosis and treatment.

Abstract Number: 0268

Safety and Efficacy of CT-guided Percutaneous Infra-Renal Periaortic Biopsies in Suspected Retroperitoneal Fibrosis

Cody Anderson, **Max Guarda**, Umar Ghaffar, Thomas Atwell, Kenneth Warrington, Michael Moynagh and Matthew Koster, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Retroperitoneal fibrosis (RPF) commonly affects the infrarenal abdominal aorta (irAA) and manifests with periaortic soft tissue thickening (pASTT). RPF can be either idiopathic (primary) or secondary. Secondary causes include malignancy and infection and therefore biopsy is advantageous to differentiate etiologies. However, data describing the safety and efficacy of pASTT sampling is limited. The purpose of this study was to assess the safety and efficacy of periaortic biopsies using computed tomography (CT)-guidance among a large single institution cohort of patients with RPF.

Methods: Patients undergoing CT-guided percutaneous pASTT biopsy from June 1, 1999 through September 30, 2022 were identified retrospectively. All patients were required to have radiographic evidence of soft tissue thickening/mass in direct contact with the irAA and have had CT-guided biopsy performed at Mayo Clinic. Patients with biopsies of periaortic lymph nodes or the perivascular space of the iliac vessels or inferior vena cava were excluded. Routine laboratory screening thresholds prior to biopsy included INR < 1.6 and platelet count > 50 x10^9/L). Anticoagulation/antiplatelet agents were held prior to biopsy. Charts were directly reviewed by a physician abstractor. Demographics, biopsy features, and outcomes were collected. Complications were graded based on common terminology criteria for adverse events (CTCAE) with categories 1 and 2 being minor and categories 3-5 considered major.

Table 1: Pre-biopsy suspected diagnosis and post-biopsy confirmed diagnosis following 84 biopsies where CT-guided infra-renal abdominal aorta periaortic soft tissue thickening biopsy was considered sufficient for diagnosis.

Pre-biopsy suspected diagnosis	Post-biopsy confirmed diagnosis	N=73
iRPF	iRPF	45 (54%)
iRPF	IgG4-RD	10 (12%)
iRPF	ECD	1 (1%)
IgG4-RD	IgG4-RD	2 (2%)
Malignancy	iRPF	9 (11%)
Malignancy	IgG4-RD	2 (2%)
Malignancy	Malignancy	1 (1%)
Other (Infection, Sarcoid)	iRPF	3 (4%)
ECD, Erdheim Chester Disease; IgG4-RD, immunoglobulin G subclass 4 related disease; iRPF, idiopathic retroperitoneal fibrosis		

Table 2: Initial suspected diagnosis, ultimate diagnosis, and subsequent procedure performed following initial non-diagnostic CT-guided infra-renal abdominal aorta periaortic soft tissue thickening biopsy (n=11).

Pre-biopsy suspected diagnosis	CT-guided biopsy diagnosis	Ultimate confirmed diagnosis	Reason for inconclusive biopsy	Additional Procedure / Monitoring
Lymphoma	iRPF	iRPF	Concern alternate etiology	Surgical biopsy
Lymphoma	iRPF	iRPF	Concern alternate etiology	Surgical biopsy
Lymphoma	inconclusive	iRPF	Insufficient tissue	Surgical biopsy
Lymphoma	iRPF	Lymphoma	Concern alternate etiology	Repeat CT biopsy
iRPF	inconclusive	iRPF	Insufficient tissue	Clinical monitoring
iRPF	iRPF	iRPF	Concern alternate etiology	Surgical biopsy
iRPF	inconclusive	iRPF	Insufficient tissue	Repeat CT biopsy
IgG4-RD	inconclusive	IgG4-RD	Insufficient tissue	Clinical monitoring
iRPF	iRPF	ECD	Concern alternate etiology	Biopsy alternate site (bone)
iRPF	inconclusive	iRPF	Insufficient tissue	Surgical biopsy
iRPF	inconclusive	iRPF	Insufficient tissue	Clinical monitoring
ECD, Erdheim Chester Disease; IgG4-RD, immunoglobulin G subclass 4 related disease; iRPF, idiopathic retroperitoneal fibrosis				

Results: A total of 83 patients (28 females, 55 males) with 84 biopsies of the pASTT at the level of the irAA were identified. Mean age at biopsy was 58 (range 31-83) years. Biopsy approach was paraspinal in 73 (87%) and anterior abdominal in 11 (13%). Mean number of passes was 5 (range 1-12). A 17/18 gauge needle size was most commonly used (67/84), followed by 19/20 gauge (15/84). One biopsy used a 15/16 gauge device and one report did not specify needle size. Local anesthesia only was used in 18 (21%) biopsies and moderate anesthesia in 61 (73%); anesthesia type was not specified in 5 (6%). Three of 84 (3.6%) biopsy events had minor bleeding at needle entry site. A single (1.2%) patient had a major bleeding complication with left rectus sheath hematoma from anterior abdominal approach requiring embolization of left inferior epigastric pseudoaneurysm. No post procedural infections were observed. Biopsy of the irAA soft tissue was able to confirm a diagnosis following 73/84 (87%) biopsies (Table 1). Among the 11 procedures where the diagnosis was not achieved by initial CT-guided irAA soft tissue biopsy, 6 were due to insufficient tissue for histologic characterization and 5 were due to concern for alternative etiology despite sufficient tissue. Among these 11 cases, 5 had subsequent open surgical biopsy, 2 had repeat CT-guided irAA soft tissue biopsy, 1 had alternative site biopsied and 3 were clinically followed (Table 2).

Conclusion: In this study, percutaneous CT-guided infra-renal pASTT biopsy was considered safe and confirmed diagnosis in 87% of cases. Ultimate diagnosis differed from pre-biopsy suspicion in 34%, highlighting benefit of this procedure.

Abstract Number: 0269

Acute Kidney Injury and Plasma Cell-Rich Acute Interstitial Nephritis in VEXAS Syndrome: An Under-recognized Disease Feature

Matthew Koster, Loren HerreraHernandez, Lihong Bu, Daniel Montes, Samih Nasr, Lynn Cornell, Kenneth Warrington, Mrinal S. Patnaik, Abhishek A. Mangaonkar and Kambiz Kalantari, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: VEXAS syndrome (Vacuoles, E1 enzyme, X-linked, Autoinflammatory, Somatic) is a recently identified autoinflammatory disease with a large variety of disease manifestations. While recurrent fever, auricular chondritis, recurrent venous thromboembolism/thrombophlebitis, inflammatory skin lesions, ocular inflammation and cytopenias have been well-described, understanding of renal manifestations is limited.

Methods: Medical records of all patients with genetically confirmed VEXAS syndrome were reviewed for evidence of AKI or abnormal urinalysis. Patients who met the KDIGO criteria for acute kidney injury (AKI) for at least two consecutive measurements of serum creatinine or cystatin C were considered as having AKI. Biopsy specimens (n = 4) were reviewed by four experienced nephropathologists. Clinical and laboratory features at disease onset and at time of AKI diagnosis were abstracted from direct chart review.

Results: Among a cohort of 69 patients (all men, mean age 71 ± 9) with VEXAS syndrome, 16 (23%) developed AKI (mean age 75 ± 9) at some point during their follow up. A review of urinary findings among patients with AKI revealed microscopic hematuria, mild proteinuria, and pyuria in 100%, 100% and in 82% of cases, respectively. Four patients had undergone renal biopsy for acute kidney injury. One patient had features of peri-tubular capillaritis and has been previously described. Three patients were found to have biopsy confirmation of IN. Clinical features are described in Table 1. A representative biopsy is shown in Figure 1. All three patients had IN (acute in 2 and active chronic in 1) with plasma cell-rich infiltrate and tubulitis.

Table 1: VEXAS patient characteristics

	Case 1	Case 2	Case 3
Sex	Male	Male	Male
Age at onset VEXAS symptoms	87	84	75
Age at VEXAS diagnosis	89	85	76

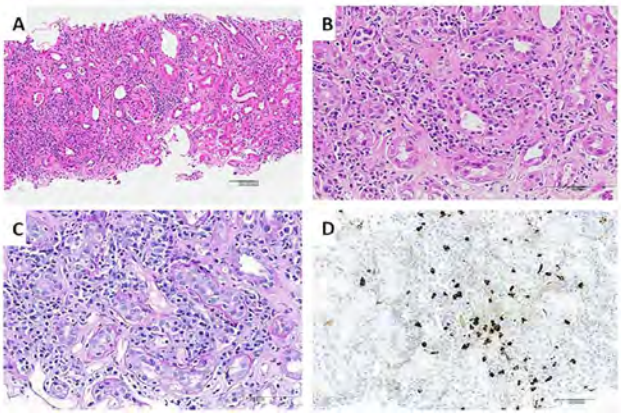

Figure 1: Renal biopsy Case 2. [A] Low power view of renal parenchyma demonstrating diffuse interstitial mononuclear inflammatory infiltrates associated with early fibrosis and tubular atrophy (hematoxylin & eosin, original magnification 100x). [B] High power image shows a plasma cell-rich inflammatory infiltrate (hematoxylin & eosin, original magnification, 400x). [C] High power image of the same region show severe tubulitis with destruction and attenuation of the tubular basement membranes (periodic acid-Schiff, original magnification 400X) . [D] IgG4 stain showing an area with increased numbers of IgG4-positive plasma cells (immunoperoxidase stain, original magnification 400x).

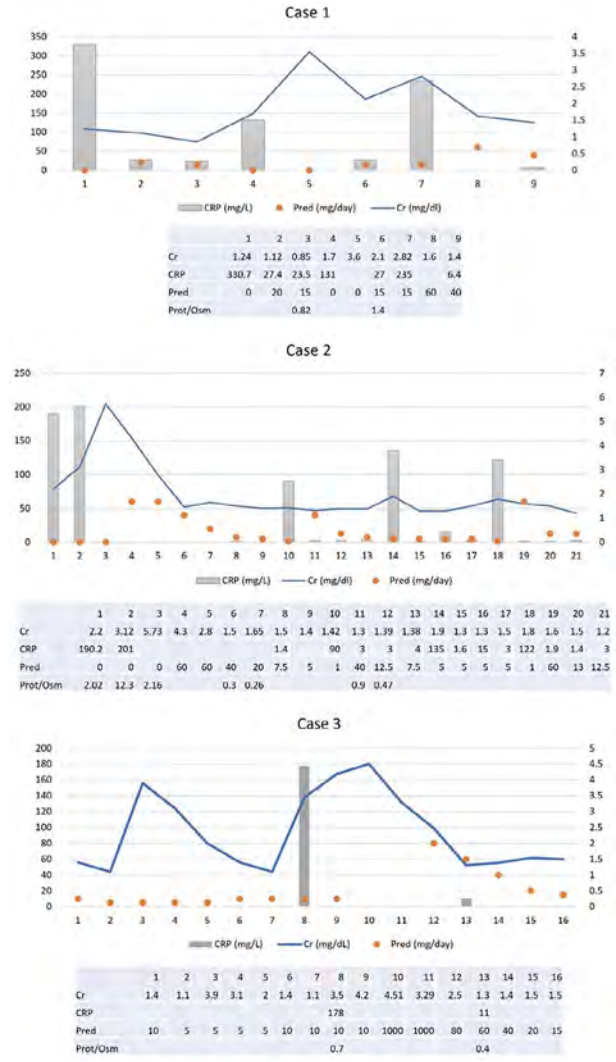

Figure 2: Laboratory trends among patients with VEXAS with Acute Interstitial Nephritis

Two patients had focal increased numbers of IgG4 staining cells (one 30/hpf, one 17/hpf) but the IgG4:IgG was low and no other pathologic features suggestive of IgG4-related disease were seen. None of the patients had clinical or radiographic features of IgG4-RD and all had normal serum IgG4 values. Arteritis, granulomatous inflammation and glomerulonephritis were absent. Immunofluorescence was negative and electron microscopy did not show glomerular or extraglomerular immune deposits. Protein/osmolality ratio was increased at the time of active systemic inflammation and renal compromise. Prednisone was initiated in all patients with biochemical improvement in renal function (Figure 2), however, subsequent decline in renal function corresponded with reduction in prednisone dose below 10-15 mg/day. All three patients carried the p.Met41Thr mutation and two patients had additional clonal hematopoietic mutations (DNMT3A, TET2).

Conclusion: AKI from Plasma cell-rich IN is an under-recognized feature in patients with VEXAS. Physicians should be aware of this complication, which should be considered in patients with VEXAS and acute kidney injury. Prompt treatment with high-dose glucocorticoids can result in improvement of renal function. Further study regarding laboratory and urinary parameters that identify active versus inactive renal disease are needed. Identification of targeted, effective therapy is necessary.

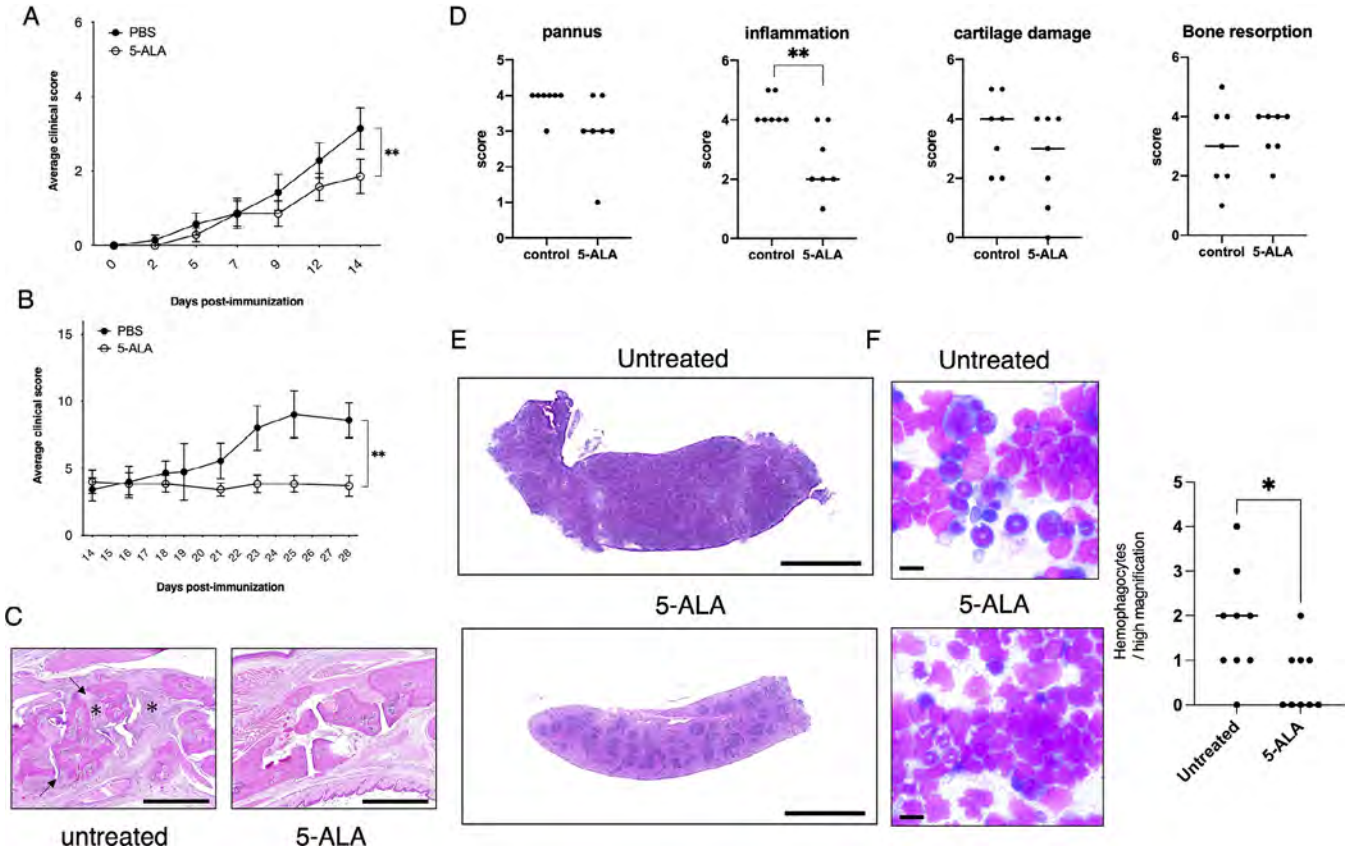
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The primary objective of this study is to elucidate the therapeutic potential of 5-aminolevulinic acid/ sodium ferrous citrate (5-ALA/SFC) in ameliorating the pathological manifestations associated with adult-onset Still's disease (AOSD), with a specific focus on arthritis and macrophage activation syndrome (MAS). This investigation entails the utilization of mouse models to examine the impact of 5-ALA/SFC on the aforementioned pathologies in AOSD. Additionally, a pilot study involving patients diagnosed with AOSD was conducted to further assess the therapeutic efficacy and safety of 5-ALA/SFC in a clinical setting.

Methods: In this study, mice were subjected to collagen-induced arthritis (CIA) by immunization with type II collagen, and to MAS by repeated administration of stimulating synthetic oligonucleotides containing CpG motifs (CpG-S-ODN) via drinking water. The objective of this investigation was to assess the preventive and therapeutic effects of 5-ALA/SFC on arthritis in CIA mice, as well as its potential to ameliorate hemophagocytosis observed in bone marrow smears of CpG-S-ODN-treated mice. AOSD patients undergoing prednisolone (PSL) treatment were enrolled in an open-label trial, wherein oral



administration of 5-ALA/SFC was conducted. The efficacy and safety of 5-ALA/SFC in facilitating prednisolone tapering were subsequently evaluated.

Results: In both experimental models for arthritis prevention and treatment, the group receiving 5- 5-ALA/SFC exhibited significantly reduced joint scores compared to the control group. Furthermore, in mice treated with CpG-S-ODN, the 5-ALA/SFC group demonstrated a decrease in hemophagocytosis (phagocytosis of red blood cells by immune cells) and splenomegaly (enlarged spleen). The anti-inflammatory properties of 5-ALA/SFC are attributed to its ability to suppress the production of CCL4 and CXCL10 in monocytes and macrophages, while also promoting the induction of M2 macrophages (a type of anti-inflammatory macrophage). These cellular responses contribute to the observed therapeutic effects. In the clinical study, four out of five participants completed the prescribed drug administration, and all patients successfully maintained a tapering regimen of PSL without experiencing any serious adverse events or worsening of symptoms throughout the study duration.

Conclusion: The administration of 5-ALA/SFC holds promise as a viable therapeutic intervention for inflammatory disorders, specifically AOSD. The utilization of 5-ALA/SFC may impart a multifaceted therapeutic impact, encompassing the regulation of arthritis symptoms and the suppression of MAS. Furthermore, our findings provide supporting evidence regarding the safety profile associated with 5-ALA/SFC treatment in individuals diagnosed with AOSD. However, further investigations are warranted to elucidate the underlying mechanisms and evaluate the clinical efficacy of 5-ALA/SFC, which should be pursued in future scientific inquiries.

Successful Treatment of Refractory IgG4-Related Disease with Tofacitinib: Experiences from 7 Patients

Huaqun Zhu, Sumei Tang, Yun Li, Feng Sun, Yuzhou Gan and Hua Ye, Peking University People's Hospital, Beijing, China

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Our observational cohort study aimed at assessing the effectiveness and safety of the Janus kinase (JAK) inhibitor tofacitinib in refractory IgG4-Related Disease (IgG4-RD).

Methods: Seven patients admitted to the Rheumatology and Immunology Department of Peking University People's Hospital were enrolled. All the patients fulfilled the 2019 American College of Rheumatology(ACR)/ European League Against Rheumatism (EULAR) classification criteria for IgG4-RD. Refractory IgG4-RD was defined to be resistant to conventional treatment of at least 3 months' duration. Patients received tofacitinib twice daily, with simultaneous continuation of immune-suppressants and glucocorticoids. They were followed-up for the shortest 3 months and the longest 12 months by the same medical team. At each visit, IgG4-RD responder index (IgG4-RD RI) [5], physician's global assessment (PGA), serum IgG4 levels (≥201mg/dL) and adverse events (AEs) were measured and assessed. Clinical remission was assessed by evaluating the changes of IgG4-RD RI scores.

Results: The demographic data and clinical features of the seven patients are described in **table 1**. Prednisone were increased from 5-10mg/d to 15-20mg/d in 4 patients with clinical recurrence at entry and the other three received previous steroids dose. Concomitant immunosuppressive treatment was continued or withdrawn. Four patients received clinical remission and two patients achieved serum IgG4 concentration improvement after tofacitinib treatment; one experienced

Table 1 Baseline characteristics, detailed treatment protocol, reduction of corticosteroids and treatment response in patients with IgG4-RD.

Patient No.	Sex	Age (year)	IgG4-RD course (month)	Organ involvement	Previous treatment	Treatment after enrolment	Serum IgG4 Level (RR 3-201mg/dL)	IgG4-RD RI	PGA	Follow-up (month)	Clinical evaluation	Reduction of corticosteroids	Adverse effects

Abbreviations: ADA, adalimumab; CYC, cyclophosphamide; CR, clinical remission; F, female; IgG4-RD, immunoglobulin G4-related disease; IgG4-RD RI, immunoglobulin G4-related disease responder index; LEF, leflunomide; M, male; MMF, mycophenolate mofetil; MTX, methotrexate; No.,number; Pred, prednisone; PGA, physician's global assessment; RR, reference range; Tofa, tofacitinib; qd, once a day; bid, twice a day; qw, once a week; q2w, once two weeks.

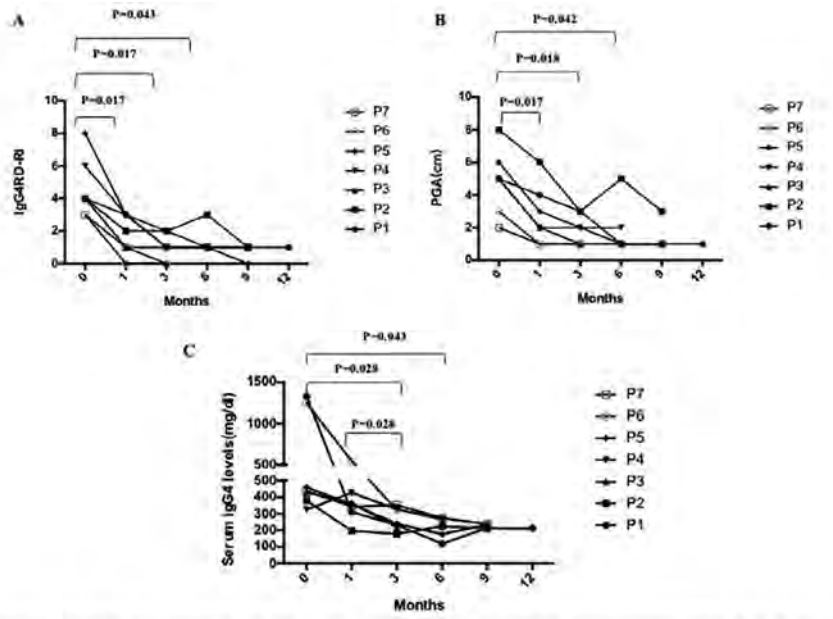

Figure 1. Figure demonstrated the variation trends of IgG4-RD RI **(A)**, PGA **(B)** and IgG4 concentrations **(C)** at baseline, 1st, 3rd, 6th, 9th and12th month on tofa treatment. Statistical analyses were performed using SPSS V.22.0. The p value was two-tailed and defined as significant if <0.05. IgG4-RD RI, immunoglobulin G4-related disease responder index; PGA, physician global assessment; Tofa, tofacitinib.

a flare during the follow-up **(table 1)**. All patients tapered their baseline prednisone dose, with 4 patients receiving doses less than or equal to 5 mg/day, and 1 even withdrawing steroids during the follow-up**(table 1)**. Both IgG4-RD RI score (p=0.017, p=0.017, p=0.043, respectively) and PGA (p=0.017, p=0.018, p=0.042, respectively) were significantly improved at 1st, 3rd and 6th month (**figure 1A, B**). Three patients (Patients 3, 5 and 6) achieved complete remission with IgG4-RD RI scores of 0 during the follow-up. Except the improvement of clinical manifestations, the serum IgG4 levels declined significantly at 3 months (p=0.028) and 6 months (p=0.043) (**figure 1C**). In addition, serum IgG4 levels decreased at 3rd month when compared to their levels at 1st month (p=0.028) (**figure 1C**). The serum IgG4 levels of patient 6 dramatically decreased from 1250mg/dL to 549 mg/dL at 1st month after tofacitinib therapy without steroid increase. Except for one patient who suffered an activation of herpes varicella zoster without serious prognosis, no probable drug-related adverse effect was reported among our other patients enrolled in the study during the follow-up visits **(table 1)**.

Conclusion: Our results proved that tofacitinib was effective for the treatment of refractory IgG4-RD, sparing steroid to reach clinical remission. Tofacitinib offers a promising treatment approach to IgG4-RD. Findings from this study may inform future's studies of other small-molecular targeted drugs for the treatment of IgG4-RD.

Risk Factors for Severe Outcome in Susac Syndrome: A National Cohort Study

Marion Peyre[1], Arthur Mageau[1], Marie-cecile Henry Feugeas[2], Serge Doan[2], Caroline Halimi[2], Isabelle Klein[3], Tiphaine Goulenok[2], Chrystelle Francois[2], Marie-Paule Chauveheid[2], Thomas Papo[1] and Karim Sacre[1], [1]Université Paris Cité, Paris, France, [2]Assistance Publique Hopitaux de Paris, Paris, France, [3]Clinique Alleray-Labrouste, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Susac syndrome (SuS) is a rare vasculitis affecting the brain, retina and inner ear in young women. Nonreversible hearing loss is the main long-term damage of SuS and requires hearing aids in more than 50% of patients. There are no known predictive factors for poor outcomes in SuS. We aimed to identify risk factors for severe hearing loss in Susac Syndrome.

Methods: SuS patients have been included in the prospective national cohort study (CarESS study) involving 20 different centres in France. CarESS study is an ongoing cohort study that started in December 2011 including all consecutive patients with SuS referred to the French reference center (Department of Internal Medicine, Bichat Claude Bernard Hospital, Paris). SuS was defined either by the triad of encephalopathy with corpus callosum ischemic lesions on brain MRI, cochleo-vestibular damage including sensorineural hearing loss and multiple occlusions of retinal central artery branches and/or retinal vasculitis on retinal fluorescein angiography. Collected data included age, gender, physical examination, fundoscopy, retinal angiography, visual acuity, visual field, audiogram, cerebrospinal fluid, brain MRI and treatment received. The CarESS study was designed with a follow-up at 1, 3 months, 6 months, 12 months after diagnosis and then annually for 5 years and/or in the event of a relapse. Fundoscopy, audiogram, and brain MRI were systematically scheduled at each time-point. The primary outcome was the occurrence of severe hearing loss (HL) at last follow-up. Severe HL was defined as the loss of 70dB in at least one ear *on audiogram or the need for* hearing aids.

Results: Overall, 36 SuS patients were analyzed for the primary outcome. Twenty-four patients (66.7%) were women and the median age at diagnosis was 37.5 [24.5-42.5] years. The triad was complete in 29 (80.6%) patients at disease onset. Thirty-three patients (91.7%) had cochlea-vestibular involvement at SuS diagnosis including tinnitus (n=16), dizziness (n=15), ataxia (n=7) and HL >20dB in at least one ear (n=25). At diagnosis, thirty-two (88.9%), 11 (30.6%) and 7 (19.4%) patients have received steroids, intravenous immunoglobulin and/or immunosuppressive drugs (IS), respectively. After a median follow up of 50.7 [24-73.4] months**,** 20 patients (58.3%) experienced severe HL that occurred a median time of 2.1 [0.3 – 13.6] months after diagnosis. Multivariable logistic regression model showed that odds of severe HL were lower in patients who received IS drugs at diagnosis (OR 0.13 95% CI [0.01-0.93], p=0.041).

Conclusion: Severe hearing loss is frequent in patients with Susac syndrome and associated with the absence of immunosuppressive drugs given at diagnosis. Our findings support the systematic use of immunosuppressive drugs in Susac syndrome to prevent poor outcome, which should be tested in a multicenter prospective randomized trial.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a systemic immune-mediated fibroinflammatory disease that can affect nearly every organ system. Autoimmune pancreatitis (AIP) is among the most common manifestations of IgG4-RD, but data are limited on its disease characteristics in the broader context of systemic IgG4-RD. In addition, the prevalence of exocrine pancreatic insufficiency (EPI) and endocrine pancreatic insufficiency (diabetes mellitus [DM]) in IgG4-related AIP is not well established. We aimed to evaluate disease features and burden of damage due to AIP in a large cohort of patients with IgG4-RD.

Methods: We performed a retrospective study using our large single-center IgG4-RD cohort. Subjects were included if they met ACR/EULAR Classification Criteria for IgG4-RD and were excluded if there were missing data or if AIP presence was unclear. Demographics and overall disease characteristics were compared between subjects with and without AIP using

Table 1. Demographics and disease characteristics in patients with IgG4-RD with and without pancreatic involvement. SD: standard deviation, AIP: autoimmune pancreatitis, ULN: upper limit of normal.

Atrophy	40/106 (38)
Calcification	15/106 (14)
Loss of T1 signal diffusely	12/106 (11)
Iatrogenic Pancreatic Damage	
Partial pancreatectomy (Whipple, modified Whipple, or other)	11 (9)
Functional Pancreatic Damage	
Atrophy, low fecal elastase, or low serum lipase	89 (74)

Chi-square and unpaired T tests for categorical and continuous variables, respectively. For subjects with AIP, we extracted details regarding clinical presentation, laboratory results, and imaging findings representing both active disease and pancreatic damage. For subjects without known EPI and no documented fecal elastase measurements, letters were sent encouraging them to have these performed.

Results: Of 305 eligible subjects, 120 (39%) had pancreatic involvement. Demographics and disease features in patients with and without AIP are shown in **Table 1**. Subjects with AIP were significantly older and more commonly male than those without AIP. Subjects with AIP had significantly more organs involved and higher ACR/EULAR Classification Criteria inclusion points, and they were significantly more likely to have had highly-elevated serum IgG4 concentrations (> 5 x upper limit of normal) than subjects without AIP. Among subjects with AIP, the most common symptoms of active AIP were weight loss or anorexia (51%), abdominal pain (46%), diarrhea or changes in stool (27%), and jaundice (26%); 25% had lipase elevations, and 33% had mass-forming AIP (**Table 2**). Damage due to AIP is summarized in **Table 3**. 47% had DM, 57% of which required insulin. Clinical EPI as defined using stringent criteria was present in 48%, while 85% had any evidence of EPI. Of 49 elastase measurements obtained, 40 (82%) were low. Functional pancreatic damage was present in 74%, defined as low serum lipase, low fecal elastase, or pancreatic atrophy. Eleven (9%) patients had partial pancreatectomies in their diagnostic workups.

Conclusion: Patients with IgG4-RD with AIP are more commonly male and have more extensive and severe disease than those without AIP. Classic acute pancreatitis, manifesting as abdominal pain and high lipase, occurs in a minority of patients with IgG4-related AIP. Features concerning for malignancy, including weight loss, painless jaundice, and pancreatic masses,

are common, and many patients have Whipple procedures as a result. Endocrine and exocrine pancreatic insufficiency are highly prevalent. The burden of clinical and functional pancreatic damage in IgG4-RD is striking and emphasizes the need for early recognition of the disease and prompt initiation of treatment.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatic diseases (RD) on rituximab (RTX) have increased mortality following COVID-19 and reduced antibody response post-vaccine. We tested whether a mix-and-match strategy using a novel protein subunit vaccine (PSV) is safe and enhances vaccine-specific responses in those who have received $\geq$3 messenger RNA (mRNA) vaccine doses.

Table 1 – Patient characteristics and time intervals between previous dose of rituximab mAb or previous vaccination and repeat vaccine.

	Study Trajectory

Anti-S = anti-spike antibody; anti-RBD = anti-receptor binding domain antibody; anti-N = anti-nucleocapsid antibody; NAb Wuhan = neutralizing antibody to Wuhan variant; NAb BA5 = neutralizing antibody to BA5 variant.

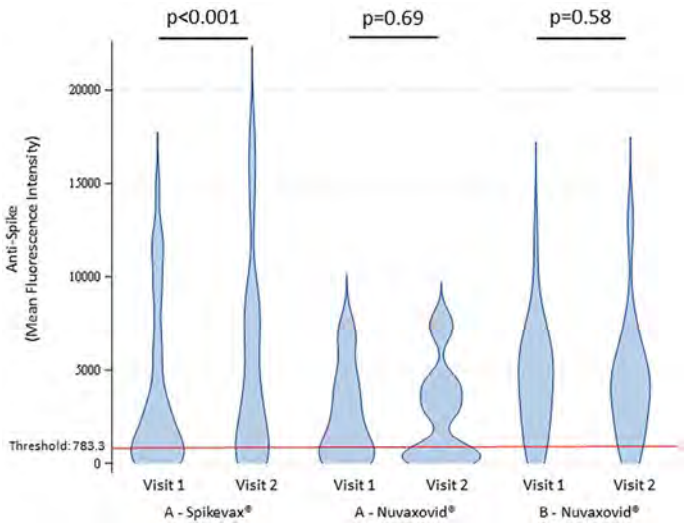

Figure 1. Anti-Spike levels pre and 28 days post-vaccination

Methods: We recruited adults with RDs on RTX post-3rd/4th dose of a mRNA COVID-19 vaccine in an open label, non-randomized, comparative trial. Post-3rd dose participants chose to receive either a 4th dose of mRNA Spikevax® (Moderna mRNA-1273) or PSV Nuvaxovid® (Novavax NVX-CoV2373) vaccines. Patients enrolled post-4th mRNA dose were offered Nuvaxovid®as their 5th. Self-reported reactogenicity at 7 days and adverse events at 28 days were noted. Humoral and cellular vaccine-responses were determined pre and 28 days post-vaccine. We tested for anti-spike (anti-S) by plasma binding on D614G Spike transfected HEK293T cells and measured by flow cytometry, anti-receptor binding domain (anti-RBD) and anti-nucleocapsid (anti-N) by in-house ELISA, and serum neutralizing antibodies (NAbs) using Wuhan and BA.5 pseudotyped lentiviruses. In 19 participants receiving a 4th dose, we tested for spike-specific B, CD4 and CD8 T cell responses by flow cytometry using RBD-B and activation-induced marker (AIM) assays. We used descriptive statistics for demographics, reactogenicity and immunogenicity and ANOVA tests to assess the impact of a booster dose on vaccine-induced immune responses.

Results: Table 1 summarizes data on the first 71 participants (4th dose Spikevax® = 30, 4th dose Nuvaxovid® = 13 and 5th dose Nuvaxovid® = 28). Reactions to the vaccine at 7 days were frequent but not severe. Most common was fatigue, headache, injection site pain and arthralgias. At day 28, five new COVID-19 infections (one requiring hospitalization) and seven disease flares were reported. Table 2 reports anti-S, anti-RBD, anti-N, and NAbs to Wuhan and BA.5. Anti-S levels (Figure 1) were higher in those receiving 5th versus 4th dose. In those to whom we gave a 4th vaccine, we observed higher anti-S levels post mRNA ($p < 0.001$) but this was not clearly seen when the 4th dose was PSV. Most (16/19) of those tested post 4th dose had no detectable RBD B cell responses while three patients had higher B cells numbers and measurable RBD B cell responses. In contrast, the cohort demonstrated good Spike-specific intact and measurable AIM+ CD4 and CD8 T cell responses that did not increase post 4th dose.

Conclusion: Mix-and-match booster dosing was not clearly associated with unusual vaccine reactions, adverse events or disease flares in RTX-treated RD patients. In those who had already received 3 mRNA doses, there was a significant increase in anti-S levels after receiving a 4th mRNA vaccine but not when the 4th vaccine was PSV. Humoral and RBD-B-cell responses increased with a fourth dose. AIM+ CD4 and CD8 T cell responses were intact, showing a disconnect with weak B cell frequencies. We did not see a clear benefit for PSV compared to mRNA booster (after primary mRNA vaccine series) in RTX-treated RD patients. This may have important implications for COVID vaccine strategies in 2023-2024.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoinflammatory diseases (AID) have been treated safely and effectively with the interleukin-1β inhibitor canakinumab (CAN) in controlled trials and routine clinical practice. The most common adverse event reported were infections. In this study infections and infection rates in patients with cryopyrin-associated periodic syndromes (CAPS), familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and tumor necrosis factor receptor-associated periodic syndrome (TRAPS) on CAN therapy were investigated in a real-world setting.

Methods: RELIANCE is a prospective, non-interventional, observational study in Germany enrolling pediatric (age ≥2 years) and adult patients with a clinically confirmed diagnosis of AID who routinely receive CAN. Efficacy and safety parameters are recorded at baseline and assessed at 6-month intervals.

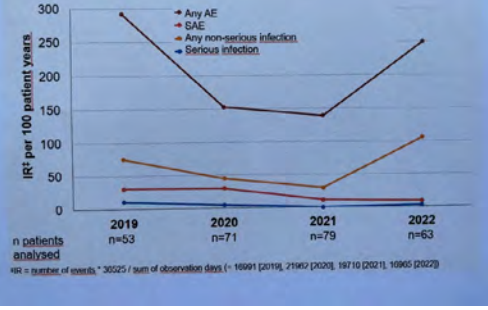
Results: The present interim analysis is based on data from a total of n=232 patients including n=101 (44%) pediatric patients under 18 years diagnosed with autoinflammatory diseases enrolled in the RELIANCE registry. The median duration of CAN treatment before and during study in the pediatric cohort was 4 years (0–15 years).

Between 2017 and 2022, 898 adverse events (AE) were recorded in n=164 patients (71%; Table 1). The incidence rate per 100 patient years (IR) was 163.82. Serious adverse events (SAE) were reported for n=35 patients (15%; 98 events, IR 17.88).

Table 1: Overview of serious and non-serious infections in pediatric patients in the course of the RELIANCE study across all study indications (2019–2022); *In bold: Respiratory tract infections*

Non-serious infections (n)	COVID-19 (24), **nasopharyngitis (19)**, **upper respiratory tract infection (13)**, **bronchitis (5)**, urinary tract infection (2), infection (5), **pharyngitis (3)**, **tonsillitis (6)**, cystitis (2), suspected COVID-19 (3), gastrointestinal infection (3), hand-foot-and-mouth-disease (4), **influenza (4)**, otitis media (2), **sinusitis (1)**, conjunctivitis (3), **respiratory tract infection (1)**, **viral upper respiratory tract infection (3)**, asymptomatic COVID-19, febrile infection, rotavirus infection (2 events each), gastroenteritis, gastroenteritis norovirus, oral herpes, **pneumonia**, pyelonephritis, appendicitis, **atypical pneumonia**, campylobacter gastroenteritis, ear infection staphylococcal, folliculitis, helminthic infection, infection susceptibility increased, **laryngitis**, **rhinitis**, salpingitis, skin infection, tinea infection, **tonsillitis streptococcal**, viral infection, **viral rhinitis** (1 event each)
Serious infections (n)	**Tonsillitis (3)**, gastroenteritis (2), anal abscess (1), genital infection fungal (1), **pneumonia (1)**, **respiratory tract infection viral (1)**, **tonsillitis bacterial (1)**, **tonsillitis streptococcal (1)**, **upper respiratory tract infection (1)**

Figure 1: Overview of adverse events and infection rates in the pediatric cohort of the RELIANCE study across all study indications over time (2019–2022)



During the study, infections occurred in 54.5% of patients (55 patients, 131 AE, including 11 SAE). To closely monitor the impact of long-term CAN treatment on infection rates in pediatric patients, data from a total of n=53, 71, 83 and 80 pediatric patients enrolled in the study in 2019, 2020, 2021, and 2022 were compared (Fig. 1). The IR of non-serious and serious infections in pediatric patients was 75.24 and 10.75 in 2019, and dropped to 44.90 and 4.99 in 2020, and 29.65 and 0.00 in 2021. The IR decrease might be caused by the periods of social distancing during the coronavirus pandemic in 2020 and 2021. In 2022, the IR of non-serious infections increased to 105.50 while the IR of serious infection stayed flat (IR 2.15). The course of upper respiratory tract infections IR in 2019, 2020, 2021, and 2022 was comparable to the IR of non-serious infections: 10.75, 8.32, 1.85, and 10.76. No cumulation of non-serious and serious infections under Canakinumab long-term treatment could be observed in the pediatric cohort.

Conclusion: Interim data of the RELIANCE study confirm that in the pediatric cohort the risk of infections including upper respiratory tract infections does not accumulate over 4 years under CAN treatment.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of autoinflammatory periodic diseases (AID) with the interleukin-1β inhibitor canakinumab (CAN) has been shown to be safe and effective in controlled trials and real-world setting. In the RELIANCE registry, long-term safety and efficacy of CAN in patients with cryopyrin-associated periodic syndromes (CAPS), familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and tumor necrosis factor receptor-associated periodic syndrome (TRAPS) on CAN therapy were investigated in routine clinical practice.

Methods: The RELIANCE registry is a prospective, non-interventional, observational study in Germany enrolling pediatric (age ≥2 years) and adult patients with a clinically confirmed diagnosis of AID who routinely receive CAN. Efficacy and safety parameters are recorded at baseline and assessed at 6-month intervals. To compare disease control between indications, parameters of 30 months visits were analyzed.

Results: In the present interim analysis, data were included from a total of n=232 patients with a diagnosis of CAPS, FMF, TRAPS and HIDS/MKD enrolled in the RELIANCE registry between October 2017 and December 2022. The median age of the total study cohort was 20.0 years (2–80 years). Most patients (n=198, 85 %) were CAN pre-treated when entering the study and the median duration of total CAN treatment before and during the study was 4 years (0–15 years).

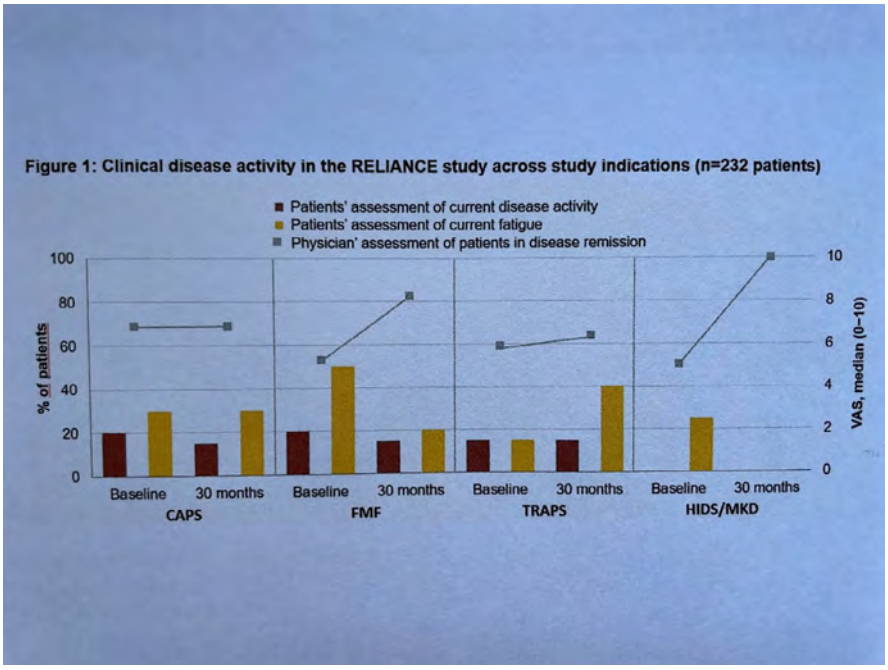

Table 1: Overview of laboratory markers and dose categories in the RELIANCE study across study indications (n=232 patients)

	CAPS		FMF		TRAPS		HIDS/MKD		Significant differences p-value
	Baseline n=107	30 months n=58	Baseline n=96	30 months n=28	Baseline n=21	30 months n=10	Baseline n=8	30 months n=5	
CRP, median (mg/dl) [25 %; 75 % quartiles]	0.1 [0.0; 0.4]	0.1 [0.0; 0.3]	0.2 [0.1; 0.6]	0.1 [0.0; 0.7]	0.2 [0.0; 2.3]	0.1 [0.1; 1.2]	0.2 [0.1; 0.5]	0.2 [0.1; 0.4]	0.465#
SAA, median (mg/dl) [25 %; 75 % quartiles]	0.4 [0.2; 1.1]	0.3 [0.2; 0.6]	0.8 [0.4; 3.1]	0.6 [0.4; 1.5]	0.5 [0.4; 2.8]	0.4 [0.2; 0.8]	0.6 [0.3; 2.3]	1.7 [0.8; 13.3]	0.027#
CAN dose category*, % of patients, less than standard / standard / higher than standard	23 % / 20 % / 58 %		35 % / 41 % / 24 %		33 % / 29 % / 38 %		14 % / 29 % / 57 %		

*Body weight > 40 kg: Standard dose is 150 mg per 8 weeks for CAPS and 150 mg per 4 weeks for any other indication. Body weight ≤ 40 kg: Standard dose is 2 mg per kg per 8 weeks (CAPS) or per 4 weeks (any other indication).

#*Kruskal-Wallis test*

Of 58/28/10/5 CAPS/FMF/TRAPS/HIDS patients with month 30 visits documented, 68/82/63/100% were in disease remission according to physician assessment. Patient-reported median disease activity and fatigue were low (1.5/1.5/1.5/0 and 3/2/4/0 on a 0–10 VAS scale). Inflammation markers (median) were within the limits of normal including neutrophil counts (2975/3420/3262/2897 n/µL). Statistical analysis confirmed similar efficacy across diseases in most parameters.

Even though these outcomes suggest an adequate disease control, an impact of the disease on patient´s social life was reported in 38/22/50/50% and negative influence on mood in 26/6/0/50% of patients.

Conclusion: The interim data of the RELIANCE study confirm sustained disease control of long-term treatment with CAN across all study indications. Even though disease activity measures suggest adequate disease control, patients´ social life and mood were negatively impacted by the disease.

Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: This is the first systematic review and meta-analysis to examine the prevalence, the diagnostic and the prognostic value of anti-carbamylated protein (CarP) antibodies in the entire spectrum of rheumatic diseases.

Methods: We systematically searched Medline, Embase, the Cochrane Library, PubMed, Scopus and Web of Science databases for studies published before June 2021. Two investigators independently screened manuscripts to evaluate their eligibility, their quality and to extract the relevant data.

Results: A total of 105 full-text articles and 48 abstracts were respectively included for further analysis. Among those, 127 papers were eligible for inclusion in the quantitative meta-analysis. 50% of the studies reported anti-Carp antibodies measured by in-house or commercial ELISA using carbamylated feta calf serum (car-FCS) as antigen. Anti-car-FCS IgG antibodies were most prevalent in RA patients with a pooled sensitivity of 37.34% (meta-analysis using random, I2=60.52%, $p< 0.0001$). A great discrepancy was observed when comparing seropositive and seronegative RA, where pooled sensitivity was 50.27% in seropositive compared to 20.18% in seronegative RA. This trend was confirmed in early RA. The pooled sensitivity in other auto-immune rheumatic diseases was between 15-20%, which was similar to the sensitivity of seronegative RA. Patients with non-inflammatory arthritis such as osteoarthritis had pooled sensitivity of 8.3% which was slightly higher than healthy controls (4.6%). The diagnostic performance of anti-CarP antibodies could be determined in RA for both car-FCS and commercial anti-carbamylated protein ELISA. The area under the summary receiver operator characteristic (ROC) curve of both type was similar, 0.668 and 0.68, respectively. Meta-analysis of correlation coefficient was performed by pooling 8 cohorts of RA assessed by anti-car-FCS ELISA and showed a statistical significant correlation with ACPA ($p< 0.001$). Meta-analysis of association with anti-Carp and risk factors was performed by pooling 9 cohorts of RA patients assessed by anti-car-FCS ELISA and showed a statistical significant association with ever smoker ($p< 0.001$), RF+ ($p< 0.001$) and ACPA+ RA patients ($p< 0.001$).

Conclusion: Anti-Carp antibodies are specifically sensitive in seropositive RA patients and are present with similar sensitivities in seronegative RA and various other inflammatory arthritis such as PsA, SLE and pSS. This could suggest that anti-CarP antibodies may rather reflect a general auto-immune response than a RA-specific immune reaction.

NOD2 Genotyping Landscape in Yao Syndrome

Hafsa Nomani[1], Ashmia Saif[2], Frank Hwang[1] and Qingping Yao[1], [1]Stony Brook University, Stony Brook, NY, [2]Stony Brook University Hospital, Syosset, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Yao syndrome (YAOS, OMIM 617321) is formerly designated NOD2-associated autoinflammatory disease. A spectrum of NOD2 mutations have been associated with this disease. This study aimed to investigate the NOD2 genetic architecture in YAOS.

Methods: In this retrospective single center study, a large cohort of patients with systemic autoinflammatory diseases (SAIDs) was analyzed in relation to genotyping results. After extensive negative workup for systemic autoimmune and related diseases, genetic testing for periodic fever syndrome 6-gene panel and an extended autoinflammatory disease gene panel was performed at Commercial Diagnostic Molecular laboratories. YAOS was diagnosed based on our published criteria, i.e., the presence of characteristic phenotype and genotype with exclusion of related diseases.

Results: There were 207 patients who carried NOD2 mutations and nearly all were Caucasian with 82% being female. Mean age at diagnosis was 40.7±0.1 years and disease duration at diagnosis was 12.2±12.2 years. Of 207 patients, 179 (86.5%) were diagnosed with YAOS and the remaining were diagnosed with mixed NOD-like receptor associated autoinflammatory disease due to coexistence of mixed genotypes. The genetic profile of patients included in our study showed that patients with two or more NOD2 variants were 26.1% (54/207), rare variants 29.5% (61/207), NOD2 IVS8+158 17.4% (36/207), NOD2 V955I 7.7% (16/207), and combined NOD2 and other SAID gene variants 19.3% (40/207). Based on the Two-hit hypothesis that has been proven true, i.e., one germline mutation and one somatic mutation for monogenic (familial cancer) and some polygenic disorders and our result that approximately 50% of patients carried two or more mutational events, we propose "Two-hit like theory" for the role of NOD2 genetics in YAOS. That is two genetic mutations in the same NOD2 gene or separate genes could be required to cause disease. The combinations could be low frequency variants, low frequency and rare variants, or rare variants only. For a minority of patients with low frequency NOD2 variants only, we assume that another unidentified NOD2 or other SAID gene related variant could be present. The disease has been recently reclassified as the new category of genetically transitional disease (GTD) because of its association with low penetrance variants. GTD refers to disease or disease status straddling monogenic and polygenic, where mutation is necessary but not sufficient to cause disease. GTD highlights the influence of genetic background on disease in concert with environment.

Conclusion: Our study indicates that most patients with YAOS carry two or more gene variants, or rare variants, suggesting Two-hit like hypothesis could be applicable to some cases of autoinflammatory disease. Further study of a large cohort of patients is warranted.

Therapeutic Exploration of Immune Checkpoint Inhibitor Induced Inflammatory Arthritis *In Vivo*

Sang Kim[1], Rene Rico[2], Naimah Turner[2], Trupti Trivedi[2], Theresa Guise[2] and Roza Nurieva[2], [1]The Univesrity of Texas MD Andesron Cancer Center, Pearland, TX, [2]The University of Texas, MD Anderson Cancer Center, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite unprecedented clinical success, immune checkpoint inhibitors (ICIs) are associated with immune-related adverse events (irAEs), including arthritis (ICI-arthritis). Management of ICI-arthritis is challenging because immunomodulatory therapy for arthritis should not impede antitumor immunity. Understanding of the mechanisms of ICI-arthritis is critical to overcome this challenge, but the precise pathophysiology remains unknown due to lack of pre-clinical murine models.

Methods: We immunized type II chicken collagen emulsified in Complete Freund Adjuvants. From Day 19, we implemented PD-1 inhibitor or combined CTLA-4 and PD-1 inhibitors (combined ICIs) and measured arthritis score until sacrifice. At sacrifice, we harvested joint (knee), bone (tibia), and serum to perform immunologic, histologic, and micro CT analyses.

Results: Four to five days after initiation of the ICIs, mice started to develop arthritis *de novo*. Clinical and histologic, and micro CT analyses revealed more severe arthritis in mice receiving combined ICIs compared to mice receiving PD-1 inhibitor alone. Importantly, like humans, collagen-specific T helper (Th)17/T cytotoxic (Tc)17 cell signatures were enhanced in inflamed joints of mice with combined ICI arthritis. Kinetic analysis revealed that upon ICI therapy, CII-specific Th1/Tc1 cells undergo plasticity into Th17/Tc17 cells which is correlated with disease severity. Inhibition of cytokines promoting Th17 cell development, function, and/or survival, including IL-1b, IL-6, IL-17A, IL-23 and TNFa, successfully ameliorate arthritis disease progression. Finally, microbial dysbiosis contributes to ICI-arthritis disease pathogenesis by enhancing production of Th17 related cytokines.

Conclusion: By modifying the collagen-induced arthritis model, we observed that mice develop arthritis *de novo* with ICI implementation. This model recapitulates ICI-arthritis and will provide insights of ICI-arthritis disease pathogenesis as well as preclinical supports to develop ideal therapeutic strategies for ICI-arthritis without abrogating ICI-antitumor efficacy.

Immunosuppression in the Treatment of Susac Syndrome: A Retrospective Evaluation of the Largest Cohort of Susac Syndrome

Adam Brown[1], Robert Rennebohm[2], Ghulam Abbas Kharal[2], Devon Conway[2], Sunil Srivastava[3], Sumit Sharma[2], Careen Lowder[2], Leonard Calabrese[4] and Rula Hajj-Ali[2], [1]Cleveland Clinic Department of Rheumatic and Immunologic Diseases, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cincinnati Eye Institute, Cincinnati, OH, [4]Cleveland Clinic / Department of Rheumatic and Immunologic Diseases, Cleveland, OH

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Susac Syndrome is a rare autoimmune condition causing microvascular occlusions in the brain, retina and inner ear leading to the characteristic triad of encephalopathy, branch retinal artery occlusion (BRAO) and sensorineural hearing loss potentially leading to permanent disability and death if untreated. Approximately 400 cases of Susac Syndrome have been reported since its initial description in the 1970s. Most cases are from small case series utilizing various combinations of immunosuppression with variable outcomes. It is unclear what immunosuppressive regimen is most likely to result in reduced risk of disease flares. The goal of this study is to retrospectively evaluate all Susac Cases in our institution and compare immunosuppressive regimens.

Table 1 Descriptive table for Demographics

Table 1. Patient Characteristics		
Variable	**Level**	**All (n=60)**
Age at Susac admission		33.3 (9.07)
Sex	Male	16 (27.1%)
	Female	43 (72.9%)
Cochlear Implant	None	53 (98.1%)
	Post-SUSAC Index Admission	1 (1.85%)
Immunosuppression Medications	Yes	59 (100%)
IV Methylprednisolone		53 (88.3%)
Prednisone		58 (96.7%)
Cyclophosphamide		15 (25.0%)
IVIG		51 (85.0%)
Rituximab		34 (56.7%)
MMF(3g)		8 (13.3%)
MMF(Other)		42 (70.0%)
Azathioprine		8 (13.3%)
Methotrexate		1 (1.67%)
Tacrolimus		2 (3.33%)
Flare	No Flare	25 (44.6%)
	Flare on Treatment	25 (44.6%)
	Flare not on Treatment	6 (10.7%)

Table 1. Patient Characteristics		
Variable	**Level**	**All (n=60)**
Flare on Combined Treatments		14 (56.0%)
Flare Treatments	Cyclophosphamide	1 (4.00%)
	IVIG	13 (52.0%)
	Rituximab	2 (8.00%)
	MMF(3g)	1 (4.00%)
	MMF(Other)	5 (20.0%)
	Azathioprine	2 (8.00%)
	Methotrexate	1 (4.00%)
Flare Treatments 2	IVIG	3 (21.4%)
	MMF(Other)	11 (78.6%)

Continuous variables presented as Median (IQR). Categorical variables presented as N (column %).

Rates of Flare with Immunosuppression

Methods: A retrospective chart review of 134 patients with Susac Syndrome ICD diagnosis code within our institute's electronic medical record system was performed. The following were recorded: patient demographics, presenting signs/symptoms, whether the full triad of encephalopathy, vision and hearing loss were present, as well as immunosuppressive medications initiated, length of follow up and whether a patient had a flare while on immunosuppression. Flares were defined by objective changes in brain MRI, fluorescein angiography or audiometry in addition to clinical symptoms.

Results: Sixty patients met the European Susac Consortium criteria. The triad of encephalopathy with MRI changes of the corpus callosum, BRAO and hearing loss documented with audiometry were present in 65% of cases. The average age at presentation was 33 years of age and females accounted for 73% of patients. Patients received the following immunosuppressive medications: glucocorticoids 100%, IVIG (85%), mycophenolate mofetil MMF (83%) most patients receiving less than 3 grams daily (84%). Rituximab was given to 56% of patients and cyclophosphamide was given in 25% of cases. Azathioprine, methotrexate or tacrolimus together made up 18% of cases.

Flares were documented in 51% of patients after the initial diagnosis of Susac Syndrome, occurring on average 24 months after disease onset. 74% of patients were on medications at the time of the flare. Flares occurred on the following therapies: IVIG 16 (32%), MMF (< 3 grams) 16 (38%), MMF (3 grams) 1 (12%), Rituximab 2 (5%) and cyclophosphamide 1 (6%).

MMF and Rituximab were two of the more commonly used therapeutics, often in combination with IVIG. MMF overall, had a higher likelihood of experiencing flares when compared to patients on Rituximab (34% vs 5%) (P=0.003). This difference was most pronounced when compared to those on doses of MMF less than 3 grams daily ($P < 0.001$). In our cohort, a patient on MMF (all doses) is 5.8 times more likely to experience a flare compared to patients on Rituximab.

Conclusion: This is the largest cohort of patients suffering from Susac Syndrome. Based upon this single center retrospective cohort analysis, we conclude flares of disease were common over the first two years of follow up. These preliminary data suggest Rituximab may be superior to MMF in maintaining remission. Further study of this rare disease, including prospective controlled trials are needed.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Cystic fibrosis (CF) is characterized by mutations within the CFTR (cystic fibrosis transmembrane conductance regulator) gene that result in a defect of the chloride transporter protein in different organs, particularly in the lung. Musculoskeletal symptoms have been reported in up to 29% of CF patients[1], most frequently as recurrent episodes of mono- or polyarthritis in joints of hands and feet. Potent CFTR modulator therapies targeting the F508del mutation in

Fig. 1

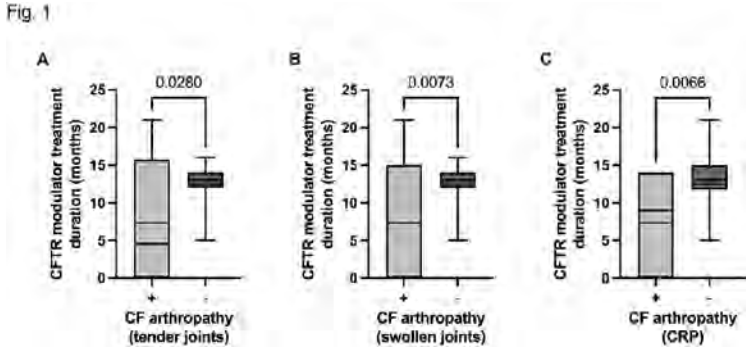

Fig. 2

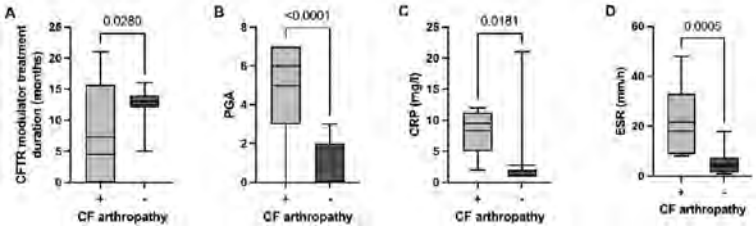

CF have become available (i.e., Trikafta© - consisting of a triple combination of elexacaftor, tezacaftor, and ivacaftor) that increase CFTR protein availability.

We seek to characterize musculoskeletal symptoms in a cohort of consecutive CF patients.

Methods: 25 CF consecutive outpatients were enrolled in this monocentric, prospective, and cross-sectional cohort study. Rheumatologic evaluation included clinical and laboratory parameters. Data were analyzed by covariance (ANCOVA) models, using the general linear model approach. Correlation analyses were performed calculating nonparametric Spearman correlation rank coefficients.

Results: Baseline characteristics are outlined in Table 1. 22/25 CF patients were under CFTR modulator treatment with a mean treatment duration of 11 ± 5 months. Arthralgias and myalgias were reported in 48% and 20% of patients, respectively. Arthritis, mainly involving small joints, was clinically detected in 6/25 (24%) patients and confirmed by ultrasound (US) in 3/6 patients. Self-reported myalgias, were significantly associated with the presence of swollen joints ($r = 0.7452$, $p < 0.0001$), tender joints, ($r = 0.6674$, $p = 0.0003$), a positive squeeze test ($r = 0.5898$, $p = 0.0019$) and morning stiffness ($r = 0.6556$, $p = 0.0004$) (Table 1). Disease activity as assessed by the SDAI was moderate (mean 18 $\pm$ 3). CCP and rheumatoid factor (RF) were detected in one patient not on CFTR modulator therapy (with PIP synovitis confirmed by US). Two patients on CFTR modulator therapy tested positive for RF. Another patient was seronegative but synovitis was confirmed by US. Of note, longer duration of CFTR modulator therapy was significantly associated with a lower number of tender joints ($r = -0.410$ $p = 0.054$), swollen joints ($r = -0.400$, $p = 0.048$) and a lower CRP ($r = -0.509$, $p = 0.048$) (Fig 1 and Fig 2).

Conclusion: The current cohort study confirms that musculoskeletal symptoms are frequent in adult CF patients. Self-reported myalgias were significantly associated with arthritis mainly involving small joints. Interestingly, longer duration of CFTR modulator therapy was associated with a decreased number of tender and swollen joints in line with the assumption that amelioration of mucosal airway inflammation may decrease the risk of developing CF arthropathy.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I

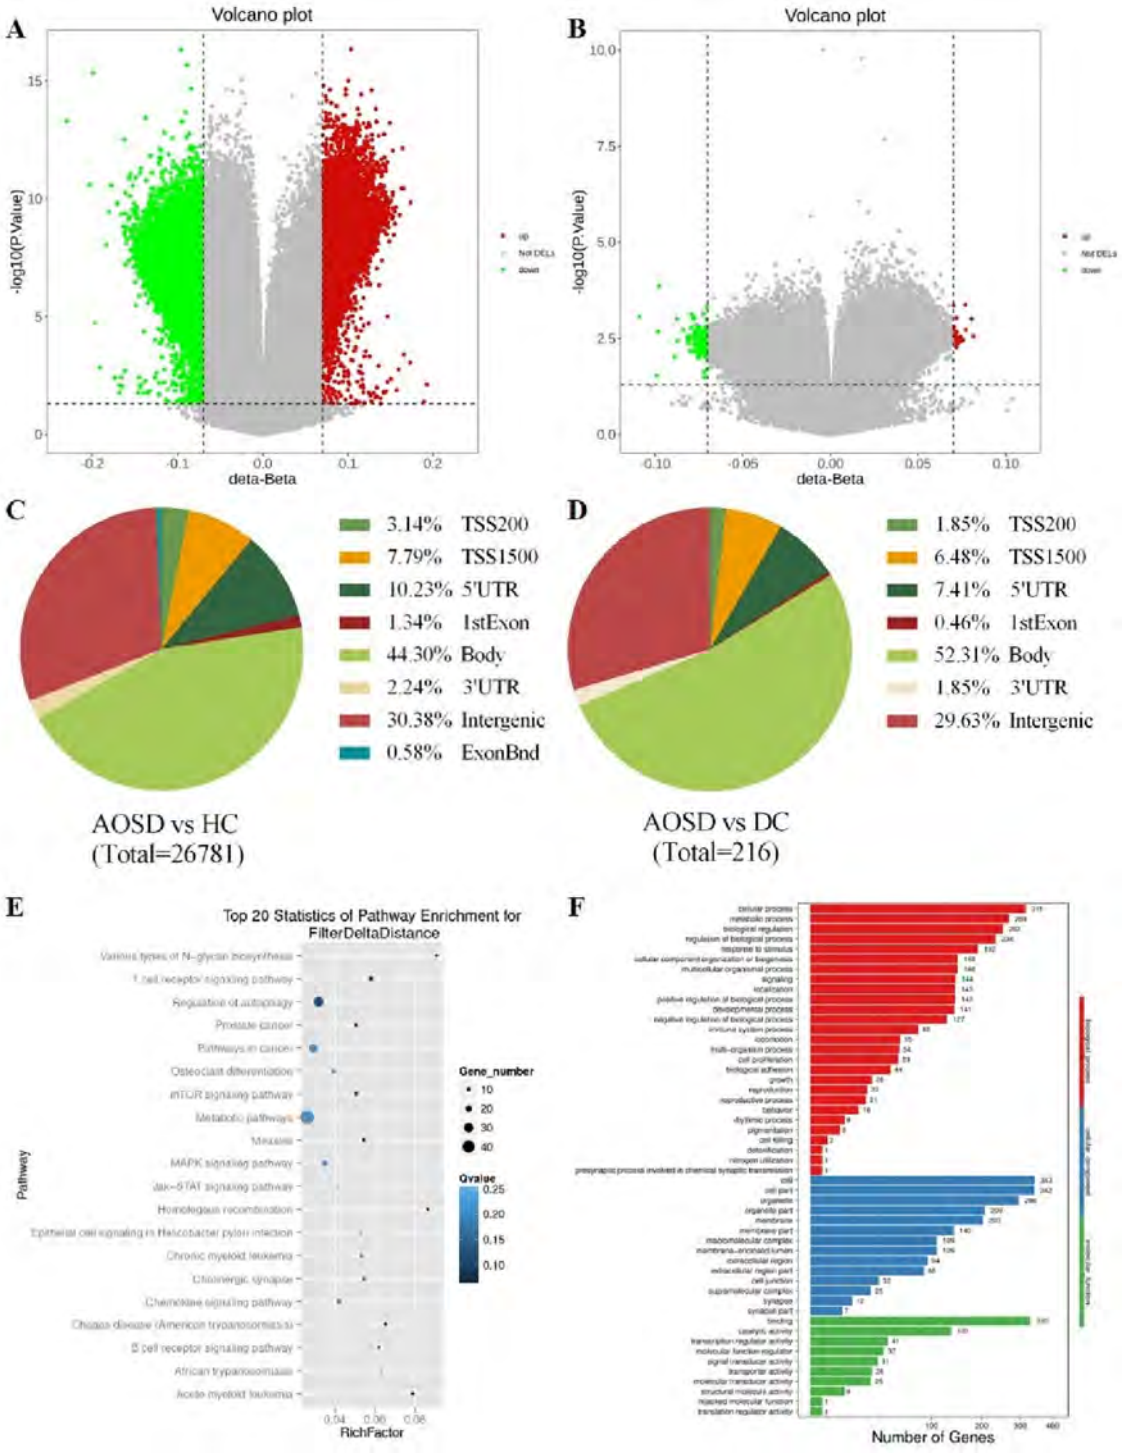
Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Adult-onset still's disease (AOSD) is an auto-inflammatory disease affecting multiple systems. The diagnostic procedures of AOSD are still a challenge. We aimed to find an effective DNA methylation biomarker for AOSD diagnosis in this study

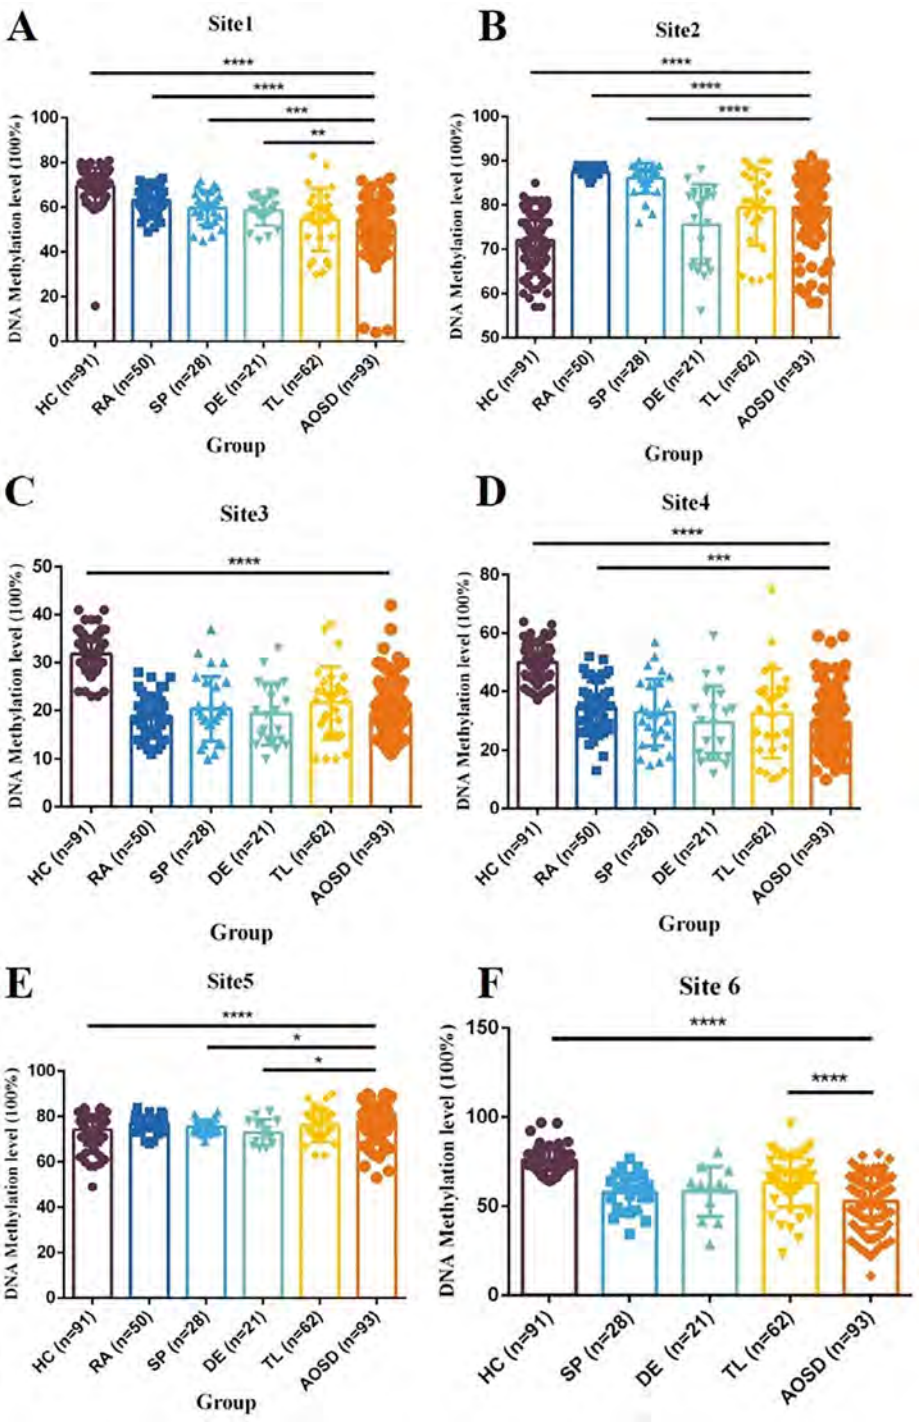
Methods: Differential methylation CpG sites (DMSs) were selected from DNA methylation array comprised of a discovery cohort including 50 AOSD patients, 49 healthy controls (HCs), 24 T cell lymphoma (TL) patients, 24 sepsis (SP) patients and 24 drug eruption (DE) patients. A cohort of 96 AOSD patients, 92 HCs, 50 rheumatoid arthritis (RA) patients, 28 SP patients, 21 DE patients and 62 TL patients was used for validation via pyrosequencing. Subsequently, four logistic regression prediction models were performed.

Results: Nine DMSs were selected from the discovery cohort via the DNA methylation array incorporating Least Absolute Shrinkage and Selector Operation (LASSO). We analyzed the methylation levels of these CpG sites by pyrosequencing in the validation cohort, and calculated four logistic regression prediction models in order to differentiate AOSD from the HCs (AUC: 0.964, sensitivity: 98.5%, specificity: 98.9%), the RA group (AUC: 0.988, sensitivity: 97.8%, specificity: 94%), the SP group (AUC: 0.885, sensitivity: 77.1%, specificity: 92.9%) and the DE group (AUC: 0.842, sensitivity: 72%, specificity: 90.5%) respectively. In addition, the methylation level of cg14887853 could be used to distinguish AOSD (AUC: 0.693, sensitivity: 79.6%, specificity: 59.5%) and active AOSD (AUC: 0.761, sensitivity: 81.5%, specificity: 67.8%) from TL respectively.

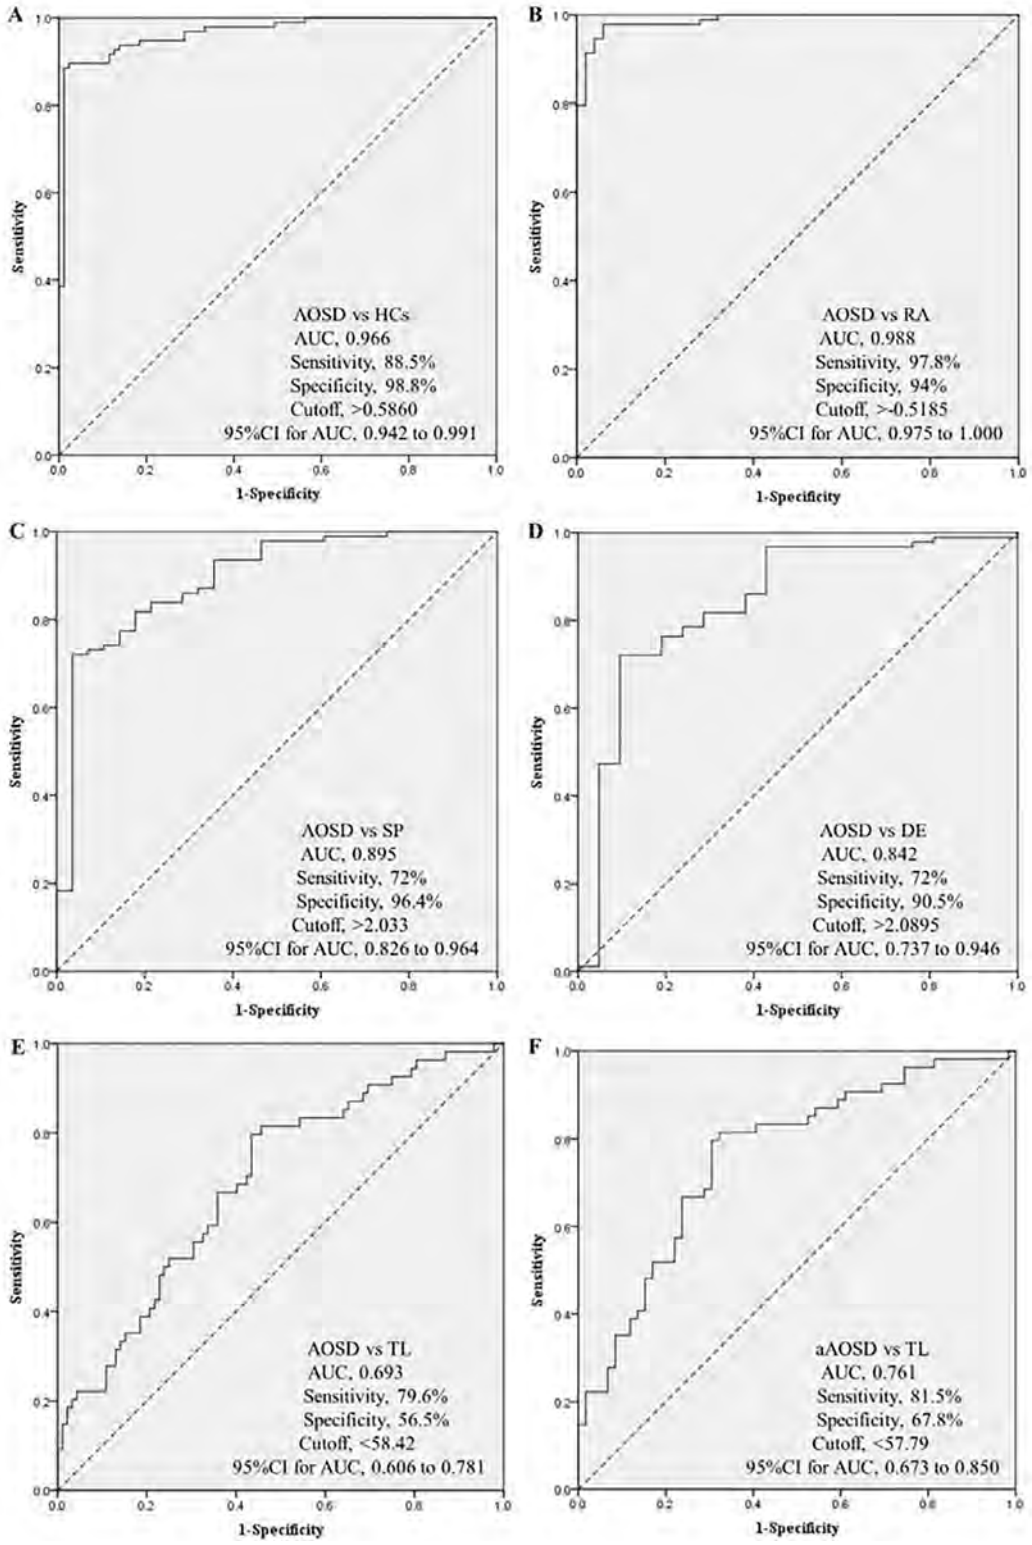


Volcano plots, location information, KEGG pathway analysis and GO analysis of differentially methylated CpG sites (DMSs) in AOSD. A Volcano plot of the distribution of DMSs between AOSD and HC group. B Volcano plot of the distribution of DMSs between AOSD and DC groups. C Location information of DMSs on genome E Top 20 statistic of pathway enrichment of DMSs between AOSD and HC group. F GO analysis DMSs between AOSD and HC group.

Conclusion: The DNA methylation levels of CpG sites can be used as biomarker for diagnosis of AOSD.



DNA methylation level of the identified six differential methylated sites (DMSs) between AOSD and healthy controls (HCs)/ disease controls (DCs) in validation cohort. A It shows that methylation level of Site1 is significantly lower in the blood of AOSD patients than that in HCs, patients with rheumatoid arthritis (RA), patients with sepsis (SP) and patients with drug eruption (DE). B It shows that methylation level of Site2 is significantly lower in the blood of AOSD patients than that in patients with RA and patients with SP, and is significantly higher in the blood of AOSD patients than that in HCs. C It shows that methylation level of Site3 is significantly lower in the blood of AOSD patients than that in HCs. D It shows that methylation level of Site4 is significantly lower in the blood of AOSD patients than that in HCs and patients with RA. E It shows that methylation level of Site5 is significantly higher in the blood of AOSD patients than that in HCs, patients with SP and patients with drug eruption (DE). F It shows that methylation level of Site6 is significantly lower in the blood of AOSD patients than that in HCs and patients with T cell lymphoma (TL).



Receiver operating characteristic (ROC) curves analysis of logistic regression prediction model. A show the ROC curve of the logistic regression prediction model based on Site1, Site3, Site4 and Site5 in patients with AOSD compared with HCs. B show the ROC curve of the logistic regression prediction model based on Site1, Site2, Site3 and Site4 in patients with AOSD compared with patients with RA. C show the ROC curve of the logistic regression prediction model based on Site1, Site2, and Site3 in patients with AOSD compared with patients with SP. D show the ROC curve of the logistic regression prediction model based on Site1, Site3, Site4 and Site5 in patients with AOSD compared with patients with DE. E show the ROC curve of Site 6 in patients with AOSD compared with patients with TL. F show the ROC curve of Site 6 in AOSD patients in active phase compared with patients with TL.

Transcriptomic Profiles in Muscle Biopsies from Systemic Sclerosis Patients with Different Autoantibodies

Maria Casal-Dominguez[1], Jose Cesar Milisenda[2], Iago Pinal-Fernandez[1], Katherine Pak[3], Sandra Muñoz-Braceras[1], Jose Jiram Torres-Ruiz[1], Stefania Dell´Orso[4], Faiza Naz[4], Gustavo Gutierrez-Cruz[4], Shamima Islam[1], Yaiza Duque-Jaimez[2], Ana Matas-Garcia[2], Francesc J Garcia-Garcia[2], Mariona Guitart-Manpel[2], Gloria Garrabou[2], Ernesto Trallero-Araguas[5], Brian Wallit[6], Lisa Christopher-Stine[7], Tom Lloyd[8], Alfredo Guillen-Del-Castillo[9], Carmen Pilar Simeon-Aznar[10], Josep Maria Grau[2], Albert Selva-O'Callaghan[5] and Andrew Mammen[11], [1]Muscle Disease Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]Muscle Research Unit, Internal Medicine Service, Hospital Clinic, Barcelona, Spain, [3]National Institutes of Health, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [5]Systemic Autoimmune Disease Unit, Vall d'Hebron Institute of Research, Barcelona, Spain, [6]National Institute of Neurological Diseases and Stroke, National Institutes of Health, Bethesda, MD, [7]Johns Hopkins University, Baltimore, MD, [8]Johns Hopkins University School of Medicine, Baltimore, MD, [9]Unit of Autoimmune Diseases, Department of Internal Medicine, Hospital Universitario Vall d'Hebron, Barcelona, Spain, [10]Department of Internal Medicine, Systemic Autoimmune Diseases Unit, Hospital Universitario Vall d'Hebronh, Barcelona, Spain, [11]NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The inflammatory myopathies (IM) include dermatomyositis (DM), antisynthetase syndrome (AS), immune-mediated necrotizing myopathy (IMNM), inclusion body myositis (IBM), and overlap myositis (OM), in which IM exists in the context of another rheumatologic disease, such as systemic sclerosis (SSc).

The objective of this study was to define the transcriptomic profiles of muscle tissue from patients with OM-SSc and to compare these with the transcriptomic profiles of muscle tissue from patients with other types of IM as well as healthy volunteers.

Methods: Bulk RNA sequencing was performed on muscle biopsies obtained from(a) OM-SSc patients with defined SSc autoantibodies recognizing PMScl, Scl70, or centromeric autoantigens, (b) patients with DM, AS, IMNM, IBM, and (c) healthy volunteers.

Results: In muscle biopsies from patients with OM-SSc, there was upregulation of genes associated with type I interferon (IFN) signaling (ISG15, MX1), type II IFN signaling (GBP2, PSMB8, IFI30), muscle regeneration (NCAM1, MYH3, MYH8, MYOD, MYOG, PAX7), immunoglobulin production (IGH1, IGH2, IGH3, IGHM, IGHA2), and specific types of immune cells (CD3E, CD4, CD8B, CD14, CD68, CD19, and CD20). The upregulation of these genes was more pronounced in biopsies from patients with OM-SSc who had anti-PMScl autoantibodies compared to those with other SSc autoantibodies. Specifically, the upregulation of type I IFN-associated genes in biopsies from patients with anti-PmScl was intermediate, resembling that observed in biopsies from patients with AS, while type II IFN-associated upregulation was high and comparable in biopsies from patients with AS and IBM. Conversely, structural muscle genes such as MYH1, MYH2, ACTA, and TTN, were downregulated in patients with all types of autoantibody-defined OM-SSc.

Conclusion: Muscle tissue from patients with OM-SSc exhibit significant upregulation of interferon type I and II signaling, immunoglobulin production, muscle regeneration-related genes, and immune cell markers. Notably, these gene expression changes are more pronounced in muscles from patients with SSc who had anti-PMScl autoantibodies compared to those with anti-Scl70 and anti-centromere autoantibodies. These findings contribute to our understanding of the molecular mechanisms underlying SSc and provide insights into potential therapeutic targets.

Phenotyping Calcinosis: A Rare Manifestation of Rare Diseases

Michele Diomedi[1], Federico Fattorini[1], Simone Barsotti[2], Elenia Laurino[1], Chiara Cardelli[1], Linda Carli[1] and Marta Mosca[1], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Internal Medicine, Ospedale di Livorno, Pisa, Italy

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are rare systemic autoimmune disorders, with a pleiotropic clinical picture, specifically characterized from the inflammatory involvement of striate muscles. Calcinosis cutis is a chronic condition, that could be associated with connective tissue diseases, being a source of pain and functional disability. The aim of the study was to evaluate the prevalence of calcinosis in a monocentric cohort of patients with IIMs, exploring possible correlations with clinical variables and quality of life (QoL).

Methods: We retrospectively analyzed medical records of consecutive patients diagnosed with IIM according the EULAR/ACR 2017 criteria, collecting data about demography, subset and duration of disease, organ involvement, serology and comorbidities. QoL and WA were evaluated with Patients Reported Outcomes (PROs): Short-Form 36 Health Survey (SF-36), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-F), Health Assessment Questionnaire (HAQ), Work Productivity and Activity Impairment Questionnaire (WPAI), Hospital Anxiety and Depression Scale (HADS). Intergroups comparisons were assessed by using Chi-square, t-test and ANOVA. P values < 0.05 were considered significant.

Results: A total of 176 patients, 116 (65,9%) female, 79 (44,9%) with DM, 74 (42%) with PM, 11 (6,3%) with CADM, 10 (5,7%) with IBM, 2 (1,1%) with JDM were enrolled; 17 of them (9.7%), 12 (70,6%) women, had calcinosis. A statistically significant difference between respectively calcinosis subgroup and the whole cohort was found for the mean age (53,3 ±18,3 years vs 67,6±11,4, $p< 0.001$), the age at disease onset (30,1±16.6 years vs 58.9±12.9, $p< 0.001$), the age at diagnosis (42.1±17.6 years vs 61.6±12.8, $p< 0.001$) and the disease duration (14.2±9.0 years vs 8.7±6.7, $p=0.003$). Taking into account patients' serological profiles, a significant correlation was observed between anti- PMScl100 positivity and calcinosis development ($p=0.007$). The majority of patients with calcinosis, as expected, had a cutaneous involvement ($p< 0.001$) and showed lower values of CPK and aldolase ($p=0.03$). Analysing patients' comorbidities, we found no patient with calcinosis had developed cancer; this result remained significant after correcting for age and disease duration. PROs analysis

showed patients with calcinosis had significantly lower values of both HADS-A, HADS-D and FACIT ($p < 0.03$); accordingly, they had significantly higher values of both Role Emotional and Social Function items of SF36 (p=0.03)

Conclusion: From the analysis of our data, calcinosis seems to be more frequent in younger patients, with an earlier disease onset and with a longer disease duration. Interestingly, we found a significant correlation with anti- PMScl100 antibodies and with a less severe muscle involvement. Notably, we found patients with calcinosis seem to have a significantly lower risk of developing cancer, independently from age. Therefore, even if calcinosis is considered a risk factor for disease severity and QoL compromission, our study highlighted a more favourable clinical profile, with a gain for patients in both their emotional and functional spheres.

Patient Reported Physical Function, Mental Health, and Treatment Patterns in Dermatomyositis

Lisa Christopher-Stine[1], Julie Paik[1], Brendan M. Johnson[2], Taryn Smith[2], Jolie Feldman[2] and Paul N. Mudd Jr.[2], [1]Johns Hopkins University, Baltimore, MD, [2]Priovant Therapeutics, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is a rare, debilitating, idiopathic inflammatory myopathy characterized by painful, itchy skin rash and proximal muscle weakness that can significantly impact daily activities and independence. Additional life-threatening manifestations include interstitial lung disease and increased risk of malignancy. The profound impacts of DM and treatment patterns on patient quality of life (QoL) are not yet well-characterized in the literature.

Methods: To capture adult patient perspectives on the impact of DM and frequently used medications on patients' QoL (e.g., physical function, mental health, personal relationships), a 60-question survey was developed via focus groups and adaptations from existing tools. After central IRB review (WCG), members of The Myositis Association with a self-reported diagnosis of DM, 18 – 75 yrs of age, and onset of symptoms ≥ 1 yr were invited to complete the online survey. Responses were collected per the following Likert scales: DM severity rated from "mild" to "very severe" (4-point scale), QoL impact rated from "never" to "always" or "not at all" to "a great deal" (5-point numeric scores). Current medications also were captured. Frequency tables and descriptive statistics were prepared.

Results: Respondents (N=195) predominantly lived in the US (97%), were female (88%), white (82%), with a median age of 57 yrs; 53% and 35% experienced DM symptoms for 3 to 10 yrs or > 10 yrs, respectively.

Arithmetic mean QoL impact scores (out of 5) for patients with mild, moderate, or severe/very severe disease, respectively, were 1.9, 2.7, and 3.6 when asked if DM limits their ability to do things they enjoy; 2.3, 2.6, and 3.2 when asked how often they worry their disease will worsen; and 1.8, 2.4, and 3.4 when asked how often they worry about their disease will limit their

ability to carry out daily activities. Across all QoL endpoints, more than 50% of participants said their social life and relationships are at least somewhat negatively impacted by DM, and that DM limits their ability to perform daily activities (65%) and the ability to climb stairs (63%). Immunosuppressants were most commonly used (72%), then over-the-counter NSAIDS (56%) and oral corticosteroids (48%).84% of respondents use more than 1 medication for DM. Use of steroids increased as disease worsens (35%, 44%, and 65% of mild, moderate, and severe/very severe respondents, respectively). There was also increased use of opioids in respondents with severe/very severe disease (32%), compared to mild/moderate disease (< 10%), despite increased use of intravenous immunoglobulins in this most severe group (35% vs < 20%, respectively). Opioid users most frequently report muscle pain as their most bothersome symptom (63%). Patients using more medications, as well as those using opioids, also reported greater impact of their disease on QoL.

Conclusion: This survey highlights the physical limitations and high emotional burden in patients living with DM. The survey also suggests an unmet need for additional steroid-sparing therapies and novel treatments that address disease pathogenesis. The self-reported use of opioids in the most severely affected patients living with DM has not previously been appreciated.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: High resolution chest computed tomography (HRCT) plays an important role in the clinical evaluation of interstitial lung disease (ILD) by demonstrating the extent of parenchymal disease and detecting serial changes over time. A quantitative CT scoring method using a computer aided diagnosis system to measure the nature and extent of parenchymal diseases has been used to measure treatment response in the scleroderma lung study II (SLSII). The current study aims to evaluate the association of quantitative CT scores and clinical/physiological disease parameters in a cohort of antisynthetase positive myositis patients with ILD.

Methods: We analyzed 20 patients enrolled at the Abatacept in Myositis Associated Interstitial lung disease (Attack My-ILD) study. Myositis patients with antisynthetase antibodies and active ILD were enrolled across 5 centers and randomized to a double blind placebo period for 24 weeks followed by an open label period for 24 weeks. HRCT were performed at 3 timepoints (week 0, 24, 48) with quantitative scores for extent of ground glass (QGG), fibrosis (QLF), total ILD (QILD) performed

using a computer aided diagnostic system. Pulmonary function tests (forced vital capacity [FVC], diffusing capacity adjusted for hemoglobin [DLCO]), 6 minute walk distance (6MWD), physician/patient reported outcomes (UCSD shortness of breath questionnaire, short form-36 (SF-36), Borg scale, myositis disease activity assessment tool (MDAAT), health assessment questionnaire (HAQ), patient global myositis activity visual analog scale, supplemental oxygen use) were all obtained over

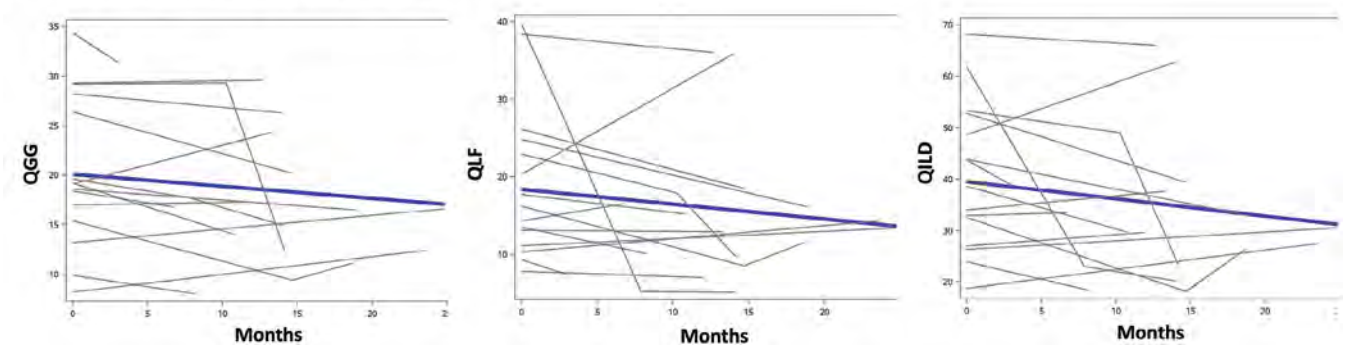
Values reported are mean change per standard deviation estimated using mixed effect models

Figure 1. Quantitative CT scores over time



Blue lines are estimated trajectories of CT scores (QGG, QLF, QILD) over time(months) using mixed effect models

5 timepoints (wk 0, 12, 24, 36, 48). Associations between quantitative CT scores with various physiologic and clinical parameters were analyzed using Spearman's correlations cross-sectionally at baseline, and mixed effect models were used to analyze associations longitudinally over multiple timepoints.

Results: Baseline quantitative CT scores for total extent of ILD (QILD) had strong inverse correlations with baseline FVC and DLCO, while ground glass (QGG) had strong inverse correlations with FVC and fibrosis(QLF) had strong inverse correlations with DLCO (Table 1). Baseline QGG and QILD also correlated with higher scores on patient reported global disease activity and worse health status on several SF-36 domains, whereas QLF correlated with shorter 6MWD and worse physical functioning (Table 1). Using mixed effect models, quantitative CT scores assessed over time demonstrated strong associations between all quantitative CT scores (QGG, QLF, QILD) and both FVC as well as DLCO (Table 2). QLF and QILD scores were also associated with worse scores of respiratory status reported by the patient and physician (UCSD shortness of breath questionnaire and pulmonary VAS on the MDAAT) but were not associated with the 6MWD. The estimated trajectories for quantitative CT scores over time trended towards improved CT scores overall (Figure 1).

Conclusion: Higher quantitative CT scores measuring the extent of ground glass (QGG), fibrosis(QLF), and total ILD (QILD) correlated with pulmonary function tests as well as patient and physician reported outcomes of respiratory status over time in patients with myositis related ILD.

σ Spearman's Rho for correlation coefficient *p<0.05 Abbreviations: QILD, quantitative ILD score on HRCT; QGG, quantitative ground glass score on HRCT; QLF, quantitative fibrosis score on HRCT; FVC, forced vital capacity, DLCO Hg, diffusion capacity adjusted by hemoglobin, UCSD Dyspnea score, University of California San Diego Shortness of Breath Questionnaire with higher scores for worse dyspnea; Pulmonary VAS, pulmonary visual analog scale from the Myositis disease activity assessment tool (MDAAT); Borg scale, Borg scale for dyspnea and fatigue before and after test with higher score indicating more severe symptoms.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The 6 minute walk distance (6MWD) provides a global evaluation of sub-maximal exercise capacity that is easily performed and highly reproducible, and is used as an outcome measure for ILD. We evaluated the association of 6MWD with physiological, clinical and radiographic measures of interstitial lung disease (ILD) as well as the responsiveness to change in patients with myositis-ILD.

Methods: We analyzed 20 patients enrolled in the Abatacept in Myositis Associated Interstitial lung disease (Attack My-ILD) study. Myositis patients with antisynthetase antibodies and active ILD were enrolled across 5 centers for 24 weeks followed by an open label period for 24 weeks. 6MWD, pulmonary function tests (forced vital capacity; FVC, diffusing capacity adjusted for hemoglobin; DLCOHg), physician/patient reported outcomes (UCSD shortness of breath questionnaire, Borg scale, pulmonary visual analog scale as part of the myositis disease activity assessment tool, supplemental oxygen use) were obtained over 5 timepoints (wk 0, 12, 24, 36, 48) and high resolution CT images were done at 3 timepoints (wk 0, 24, 48) with quantitative scores for extent of ground glass (QGG), fibrosis (QLF), total ILD (QILD) performed using a computer aided diagnostic system previously used in scleroderma ILD. Mixed effect models were used to estimate the associations between 6MWD and various physiologic, clinical and radiographic parameters longitudinally over multiple time points.

Results: Shorter 6MWD was correlated with greater extent of fibrosis on HRCT (QLF) at baseline (r=-0.54, p=0.03) while other variables including physician and patient global myositis disease activity scores, MMT, muscle enzymes, HAQ and SF-36 were not correlated with 6MWD at baseline. Longitudinal 6MWD over multiple timepoints estimated by mixed effect models was significantly correlated with worse longitudinal dyspnea score by the UCSD shortness of breath questionnaire, and worse dyspnea and fatigue on the Borg scale (Table 1). Within each subject, longitudinal 6MWD was positively correlated with longitudinal FVC (Table 1, model 2), although when considering both within subject and between subject effects the correlation was no longer significant (Table 1, model 1). Change in 6MWD from baseline to each time point had significant positive correlations with FVC change from baseline as well as with pre-test Borg scale change from baseline, and similar trends were seen for changes in pulmonary VAS and changes in dyspnea score (Figure 1). We used mixed effect models

Table 1. Associations of longitudinal 6MWD over multiple time points with physiological/radiological/clinical outcome measures using mixed effect models; reported complete model as well as model for only within subject correlations

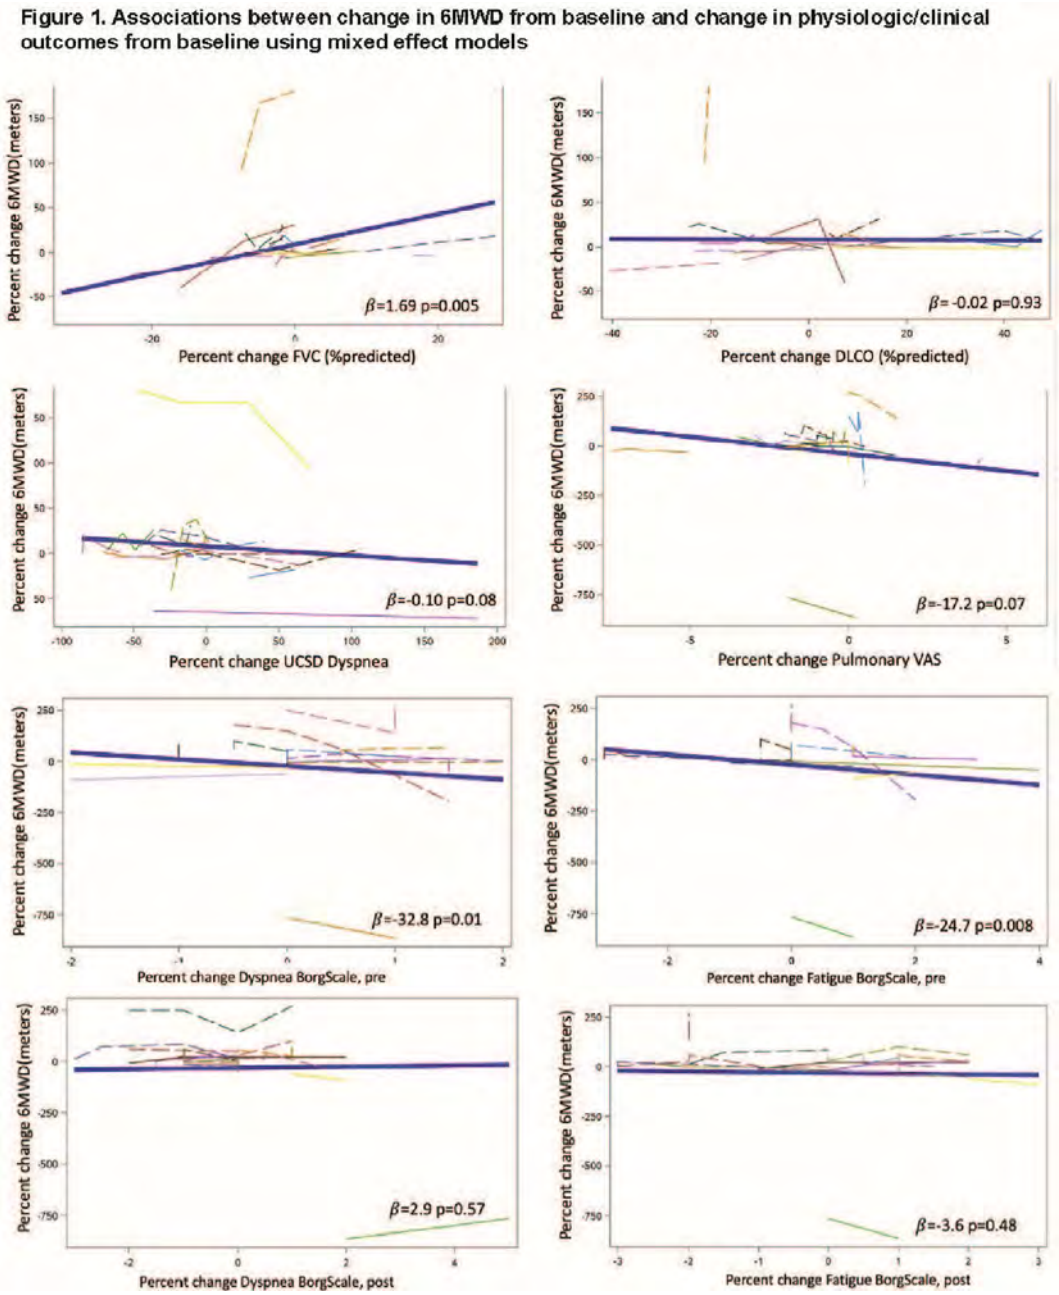
Model estimate parameters for model 1 are mean change per standard deviation of the specified units and correlation coefficients for model 2. Model 2 was calculated by conditioning between person effects as a fixed effect. Abbreviations: QILD, quantitative ILD score on HRCT; QGG, quantitative ground glass score on HRCT; QLF, quantitative fibrosis score on HRCT; FVC, forced vital capacity, DLCO Hg, diffusing capacity adjusted by hemoglobin; UCSD Dyspnea score, University of California San Diego Shortness of Breath Questionnaire with higher scores for worse dyspnea; Pulmonary VAS, pulmonary visual analog scale from the Myositis disease activity assessment tool (MDAAT); Borg scale, Borg scale for dyspnea and fatigue before and after test with higher score indicating more severe symptoms.



Blue line represents the estimated correlation between percent changes using mixed effect models. Each colored line represents percent change from baseline of each parameter in each subject at multiple time points.

to estimate the trajectories (slopes) of the 6MWD over time for each subject and found estimated slopes correlated with slopes for FVC, dyspnea score and pretest Borg scales for dyspnea and fatigue (Table 2).

Conclusion: Longitudinal measurements of 6MWD reflected parallel changes in FVC as well as patient and physician reported outcomes in patients with myositis ILD.

Proinflammatory Bioactive Lipid Mediators (BLM) Are Associated with Worse Anti-Oxidant Function of High Density Lipoproteins (HDL) in Patients with Idiopathic Inflammatory Myopathies (IIM)

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Lipid oxidation products produced by artery wall cells under oxidative stress not only regulate immune responses, but their accumulation in HDL are shown to hinder the protective properties of HDL. Our prior work demonstrated that IIM patients had impaired HDL antioxidant function and decreased activity of HDL-associated antioxidant enzyme paraoxonase-1 (PON1), and both correlated with higher disease activity. We hypothesize that higher circulating levels of certain lipid oxidation products that function as proinflammatory bioactive lipid mediators (BLM) will inhibit HDL function and perpetuate vascular damage to enhance IIM disease burden.

Methods: A panel of proinflammatory BLM were assessed from plasma samples of our myositis cohort using liquid chromatography, tandem mass spectroscopy. PON1 activity by paraoxonase, arylesterase, lactonase assays and HDL antioxidant function (HDL inflammatory index, HII) were measured as in prior studies. HDL associated Apolipoprotein A-I(HDL-ApoAI) was measured by sandwich ELISA to assess the major apolipoprotein component of HDL, which normally prevents vessel inflammation. Intercellular cell adhesion molecule-1 (ICAM) and vascular cell adhesion molecule-1 (VCAM) were assessed by ELISA as markers of endothelial dysfunction.

Results: A total of 161 IIM samples were analyzed (Table 1). When grouped by myositis autoantibodies, the anti-MDA5 group had the highest level of all 9 BLM tested with 13HODE and 11HETE showing statistically significant differences (Figure 1). HDL-ApoAI was lowest in anti-MDA5 and PON1 activity was numerically lower in patients with anti-MDA5 or anti-synthetase antibodies (ASS) compared to patients with other myositis antibodies (Table 1). Correlations between BLM and biomarkers of HDL function (HDL-ApoAI, PON1, HII; Table 2) demonstrated that 5HETE, 11HETE, 15HETE correlated with lower HDL-ApoAI and PON1 activity and worse HDL antioxidant function (higher HII). 13HODE, 14S-HDHA, 12HETE also correlated with lower HDL-ApoAI, and 13HODE, 9HODE, 17S-HDHA, and 5-oxoETE correlated with lower PON1 and worse HII. 12HETE also correlated with higher levels of ICAM-1 (r=0.28, p=0.02). Associations between BLMs and measures of myositis disease burden (MD global VAS, CPK, aldolase, hsCRP, ESR) showed 12HETE to have a modest positive correlation with MD global activity score (r=0.16, p=0.047) but otherwise no significant associations were noted. Patients with a history of cancer had numerically higher levels of all BLMs compared to those without cancer, most notably of 17S-HDHA, 15HETE and 5-oxoETE (data not shown). Other clinical characteristics including ILD, arthritis, Raynauds, calcinosis, amyopathic disease and mechanics hands were not associated with the assessed BLMs in our study.

Conclusion: Higher levels of circulating proinflammatory BLM are associated with worse HDL antioxidant function and lower levels of PON1 activity and HDL-ApoA1 in IIM patients. Patients with anti-MDA5 antibodies had the highest level of proinflammatory BLM. Further work is needed to study the relationship between BLM and abnormal HDL function and the mechanism of how they may contribute to IIM disease burden.

Markers of Endothelial Damage Are Elevated in Patients with Dermatomyositis Associated Interstitial Lung Disease and Associated with Low Paraoxonase-1 Activity

Sangmee Bae[1], Ani Shahbazian[1], Jennifer Wang[2], Tiffany De Leon[1], Yuna Lee[1], srinivasa Reddy[3] and Christina Charles-Schoeman[4], [1]UCLA Rheumatology, Los Angeles, CA, [2]University of California Los Angeles, Los Angeles, CA, [3]UCLA Department of Molecular and Medical Pharmacology, Los Angeles, CA, [4]UCLA Medical Center, Santa Monica, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Damage to the vascular endothelium is implicated in the pathogenesis of idiopathic inflammatory myopathies (IIM) and its associated interstitial lung disease (ILD), with microvascular involvement most described in the dermatomyositis (DM) subtype. Paraoxonase-1 (PON1) is a high-density lipoprotein (HDL)-associated enzyme that protects the vascular endothelium from damage due to oxidized phospholipids, that is associated with IIM disease activity and presence of severe ILD. We hypothesize that poor PON1 activity is associated with vascular damage evidenced by increased circulating levels of intercellular cell adhesion molecule-1 (ICAM), vascular cell adhesion molecule-1 (VCAM) leading to higher disease burden in DM and DM-ILD.

Methods: We performed a cross-sectional study. Plasma levels of VCAM and ICAM and PON1 activity were analyzed in 83 DM patients with anti-Jo1 (n=24), MDA5 (n=29), and TIF1gamma (n=30) and 28 age and sex matched healthy controls. PON1 activity was measured using the paraoxonase, arylesterase and lactonase assays. VCAM and ICAM levels were measured by ELISA. Multivariate models were adjusted for variables that were significantly associated with the outcome variable in univariate analysis.

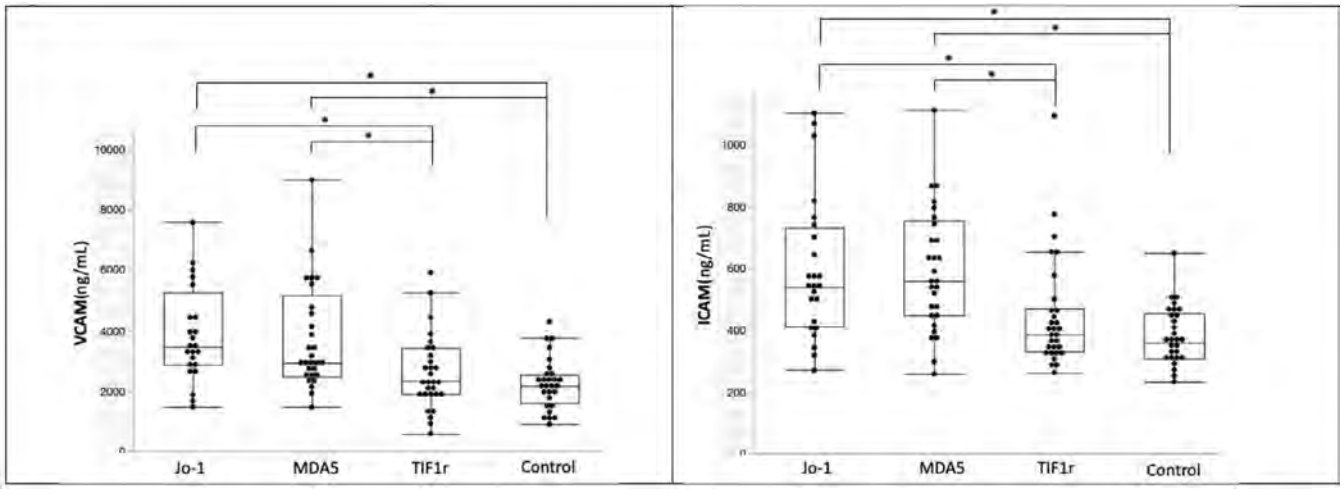

Figure 1. VCAM and ICAM levels in DM patients and Controls (n=111) *p<0.01 by Wilcoxon test Anti-Jo1 (N=24), anti-MDA5 (N=29), anti-TIF1 (N=30) and Age/sex matched healthy controls (N=28)

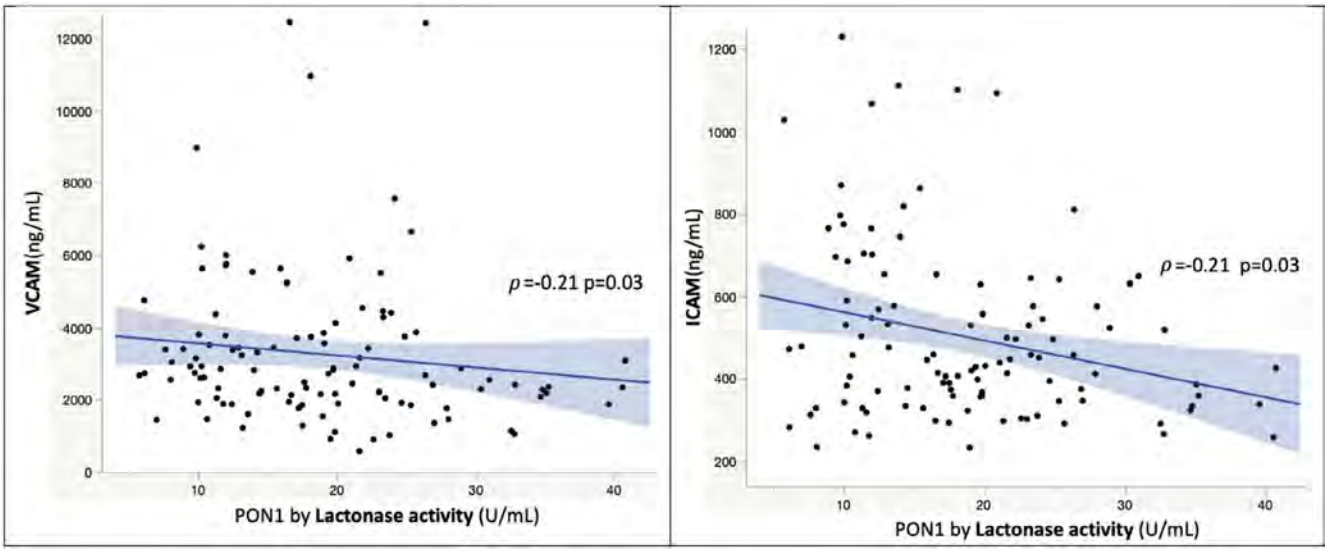

Figure 2. Correlation between PON1 activity by lactonase and VCAM/ICAM levels in DM patients and controls (n=111) Spearman correlation coefficient (ρ) between PON1 by lactonase with VCAM and ICAM levels.

Results: Plasma levels of both VCAM and ICAM were significantly higher in DM patients compared to controls (Figure 1). VCAM and ICAM were particularly higher in the anti-Jo1 and MDA5 positive DM patients compared to the anti-TIF1gamma patients and healthy controls (Figure 1). VCAM and ICAM were both correlated with worse PON1 activity measured by lactonase assay (Figure 2). ICAM remained significantly associated with worse lactonase activity after multivariate adjustment for ESR, triglyceride and Asian race, which were associated with ICAM in univariate analysis. VCAM and ICAM were both significantly higher in DM patients with ILD compared to DM patients without ILD (Table 1). Higher ICAM levels also associated with worse forced vital capacity(FVC), diffusion capacity(DLCO), higher global damage scores, cough, dyspnea, while VCAM was associated with dyspnea and fever (Table 1). Patients on Methotrexate had lower ICAM and VCAM levels compared to those not on methotrexate. In a multivariate logistic model, the presence of ILD remained significantly associated with higher ICAM levels after adjusting for Methotrexate, ESR, disease duration and Asian race.

Conclusion: Plasma VCAM and ICAM were higher in DM patients compared to matched healthy controls, particularly in anti-Jo1/MDA5 ab + patients (compared to TIF1gamma ab + patients) and in DM patients with ILD. ICAM was significantly associated with worse PON1 enzyme activity, suggesting that poor anti-oxidant function of HDL associates with evidence of endothelial activation and damage in DM and DM-ILD. Large prospective studies may be warranted to further evaluate the role of PON1 in the development and propagation of IIM and IIM-ILD.

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the health-related quality of life (HR-QoL), work productivity and activity impairment, and associated factors among patients with idiopathic inflammatory myopathy (IIM).

Methods: This was an observational, cross-sectional study. The 189 ambulatory patients with IIM were recruited from May 2019 to May 2022. HR-QoL was measured by the EuroQol 5-Dimension (EQ-5D). The work productivity and activity impairment (WPAI) questionnaire was used to evaluate work productivity and activity impairment. The IIM-related parameters were assessed by the Manual Muscle Testing-8 (MMT-8), Myositis Disease Activity Assessment Visual Analog Scale (MYOACT), Myositis Damage Index (MDI), Disease Activity Score (DAS), and Physician/Patient Global Assessment (PGA/PtGA). Quantile regression and ordinal logistic regression were performed to identify the factors, considering EQ-5D or WPAI scores as dependent variable, respectively.

Results: Of the 189 IIM patients enrolled, 60% had dermatomyositis, 13% had polymyositis, and 27% had clinical amyopathic dermatomyositis. The median EQ-5D score was 1.00 (0.73, 1.00), 28% were employed, and 45%ofoverall work was impaired due to health problems. EQ-5D values were positively associated with MMT-8, and negatively with MYOACT, DAS, MDI-global, and PGA/PtGA. For the WPAI, activity impairment was associated with lower MMT-8, older onset age, and higher PGA only in 25^{th}–75^{th} percentile. Increased PtGA was associated with increased activity and overall working productivity impairment in most quantiles ($P < 0.05$).

Conclusion: Multiple disease characteristics were associated with reduced HR-QoL or working productivity impairment in patients with IIM, especially for PtGA.

Myopathy Related to Small-to-medium-sized Vessel Vasculitis: Immunopathological Characteristics

Shun Nomura, Yasuhiro Shimojima, Takanori Ichikawa, Daigo Miyazaki, Dai Kishida and Yoshiki Sekijima, Department of Medicine (Neurology and Rheumatology), Shinshu University School of Medicine, Matsumoto, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Muscular involvement develops as the initial manifestation of small-sized vessel vasculitis (SV) and medium-sized vessel vasculitis (MV).The musculoskeletal lesion has been found as a crucial biopsy site including the histology of SV and MV unless another suitable organ for a biopsy can be found. However, immunopathological features, including the degree of myofiber damage, in the histology of vasculitic myopathy (VM) have been still unknown, while pathological assessment is an ideal procedure for the definite diagnosis of vasculitis. We elucidated the immunopathological features of skeletal muscle in VM by comparing the immunohistochemical (IHC) findings of skeletal muscle in patients with idiopathic inflammatory myositis (IIM).

Methods: The biopsied skeletal muscle tissues from 15 patients with VM, including antineutrophil cytoplasmic antibody-associated vasculitis and polyarteritis nodosa, and 15 with IIM, including polymyositis and immune-mediated necrotizing myopathy, were used in this study. IHC staining of skeletal muscle was performed as follows: CD56/neural cell adhesion molecule (NCAM) which detects myofiber damage and regeneration, major histocompatibility complex (MHC)-class I,

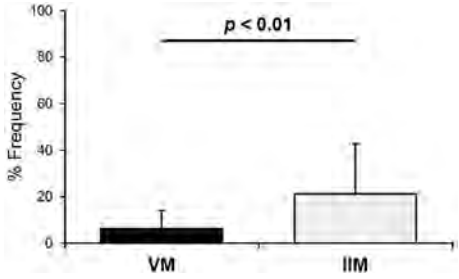

Fig. 1: The frequencies of CD56/NCAM-expressing myofibers in the total myofibers between patients with vasculitic myopathy (VM) and those with idiopathic inflammatory myopathy (IIM).

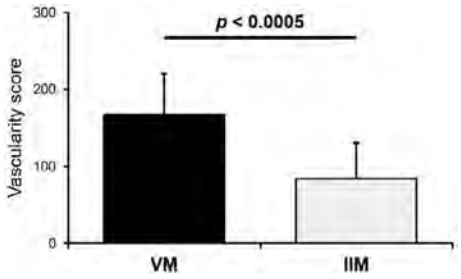

Fig. 2: The vascularity scores in the endomysium areas between patients with vasculitic myopathy (VM) and those with idiopathic inflammatory myopathy (IIM).

C5b-9/membrane attack complex (MAC), and CD31 which is an endothelial cell marker. The vascularity score was defined as the total number of CD31-expressing blood vessels.

The counts and calculations of IHC stained samples and the vascularity scores were performed in the 10 different high-power fields.

Results: The frequency of NCAM-expressing myofibers was significantly lower in patients with VM than in those with IIM ($p < 0.01$) (**Fig. 1**). In addition, the frequency of NCAM-expressing myofibers was positively correlated with serum aldolase levels ($p < 0.01$). The frequency of MHC class I-expressing myofibers was significantly lower in patients with VM than in those with IIM ($p < 0.005$). A lower number of patients with MV had MAC-expressing myofibers on sarcolemma without intracellular staining than those with IIM (33% vs. 80%, $p < 0.05$).Meanwhile, the frequency of patients, who had MAC-expressing capillaries in endomysium areas, was not significantly different between VM and IIM (73% vs. 93%). Significantly higher vascularity scores in the endomysium areas were demonstrated in patients with MV than in those with IIM ($p < 0.0005$) (**Fig. 2**).

Conclusion: Mild myofiber damage, based on the result of less involving NCAM-expressing myofiber, was demonstrated in patients with VM than in those with IIM. Our results suggest that complement component deposits on vessel walls and hypervascularity in the endomysium areas may be immunopathological features of VM.

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular (CV) risk due to accelerated atherosclerosis and impaired metabolism can be increased in idiopathic inflammatory myopathies (IIM) on behalf of systemic inflammation, limited mobility, and glucocorticoid (GC) therapy. We evaluated CV risk in IIM patients in comparison to healthy controls (HC) and assessed its association with disease-specific features.

Methods: 90 IIM (70 females; mean age 56.6; mean disease duration 5.95 years; dermatomyositis: n=29, polymyositis: n=12, immune-mediated necrotizing myopathy (IMNM): n=20, anti-synthetase syndrome: n=29) and 180 HC (130 females, mean age 54.3) with no history of manifested CV disease (both cohorts). Muscle involvement, disease activity, and tissue damage were evaluated (MMT-8, MITAX, MDI). Comorbidities and current treatment were recorded. All subjects underwent examinations of carotid intima-media thickness (CIMT), pulse wave velocity (PWV), ankle-brachial index (ABI), and body composition (densitometry, bioelectrical impedance analysis), evaluation of the risk of fatal CV events by the Systematic COronary Risk Evaluation (SCORE, for the European population) and its modifications: SCORE multiplied by the coefficient 1.5 (mSCORE), and SCORE2.

Results: Compared to HC, IIM had a significantly higher prevalence of traditional CV risk factors, carotid artery disease (CARD), abnormal ABI, and PWV ($p< 0.05$ for all). After propensity score matching (PSM) using traditional CV risk factors, the prevalence of CARD and pathologic PWV remained significantly higher in IIM ($p< 0.05$ for all), but no significant difference in SCORE was observed. Overall CV risk based on calculated risk (modifications of SCORE) and ultrasound (US) examinations was comparable between IIM ad HC after PSM (CVR-SCORE p=0.457, CVR-SCORE2 p=0.130, CVR-US p=0.126). IMNM patients had the most unfavorable CV risk profile among IIM subtypes. The calculated CV risk scores by SCORE and SCORE2 (in IIM and HC), and mSCORE (in IIM) were reclassified according to CIMT and CARD. SCORE was the most inaccurate in predicting CV risk in IIM, while there was a significantly higher proportion of reclassified patients compared to SCORE2 and mSCORE (p=0.020). Age, disease activity, lipid profile, body composition parameters, and blood pressure were the most significant predictors of CV risk in IIM ($p< 0.05$ for all variables in bivariate analysis). The length of GC therapy was positively associated with an increased count of carotid plaques and overall CV risk (by US examination) ($p< 0.05$ for both).

Conclusion: This cross-sectional cohort study in IIM patients demonstrated a significantly increased risk of subclinical atherosclerosis and CV risk, and also an increased prevalence of traditional CV risk factors compared to HC with comparable age and gender distribution. The most unfavorable findings were seen in IMNM patients. SCORE2 appeared to be the most accurate tool for prediction of fatal CV events in IIM compared to SCORE and mSCORE, although it also underestimates CV risk.

Characteristics and Outcomes of Idiopathic Inflammatory Myositis Associated Interstitial Lung Disease in Rural Appalachia

FNU Rida Ul Jannat, Sayanika Kaur, Bathmapriya Balakrishnan, Vishal Deepak, Bhanusowmya Buragamadagu, Rachel Salyer and Ty Landis, West Virginia University Hospital, Morgantown, WV

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) can affect up to 30% of the patients with idiopathic inflammatory myositis (IIM) and contributes significantly towards morbidity and mortality rates. The clinical and radiographic manifestations of IIM-ILD are variable in the affected population. The objective of our study was to recognize the patterns of IIM-ILD and determine the treatment outcomes for these patients specific to the rural Appalachian population of West Virginia.

Methods: A retrospective observational cross-sectional study was performed between January 1, 2012 through August 31, 2022, at a medium sized academic medical facility located in the WV rural Appalachia. 115 patients with IIM were identified through electronic medical record system. Out of these, 29 patients who had coexisting ILD based on radiographic findings and pulmonologist evaluation were included for the final analysis.

Results: Majority of the patients were females (n=22, 76%), never-smokers (n=19, 65%), and had a mean age of 60.17 + 12.92 years. Dyspnea (n=24, 83%) was the most common presenting symptom with mean modified Medical Research Council (mMRC) scale of 2 + 1.2. The mean duration of symptoms at first encounter was 4.57 + 6.66 years. The most common IIM phenotypes were dermatomyositis (n=15, 52%) and polymyositis (n=8, 27.6%). In patients with available serology testing (n=20), anti-Jo1 was present in 55% of the affected population(n=11). Radiographic patterns at presentation (n=27) were indeterminate for usual interstitial pneumonia (UIP) (n=12, 44%), non-specific interstitial pneumonia (NSIP) (n=5, 18%), and UIP (n=3, 11%). Treatment modalities included prednisone (n=20, 69%), azathioprine (n=14, 48%), mycophenolate mofetil (n=13, 45%), and nintedanib (n=2, 7%). Data for mMRC scale, computed tomography (CT), and pulmonary function testing (PFT) before and after treatment was available for 19, 17 and 18 patients respectively. mMRC score improved or remained stable in 89% of patients post treatment (n=17). Similarly, CT findings and PFT improved or remained stable in 59% (n=10) and 67% (n=12) of the patients. Mortality rate during the study period was 21% (n=6).

Conclusion: Dermatomyositis was the most common phenotype and anti-Jo1 was the most observed antibody associated with ILD. Similar findings were reported in larger retrospective cohort studies. The most common radiographic pattern in our cohort was indeterminate for UIP compared to other cohorts with NSIP being the predominant CT finding. While comparing the progression of ILD with other studies based on presenting symptoms, radiographic findings and PFT results, a higher proportion of patients with stable and improved ILD was observed in our study. Despite improvement in the pulmonary disease with treatment, mortality rates were remarkably higher in this cohort compared to other ILD centers. Multiple extrapulmonary factors have been associated with poor prognosis in IIM-ILD, as such, the increased mortality in our cohort may be due to non-pulmonary causes. Further prospective cohort studies are required to evaluate predictors of mortality in IIM-ILD in this region.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 1 in 4 people with RA have sarcopenia, defined as generalised loss of skeletal muscle (SKM) strength and mass, resulting in an increased risk of falls, fractures and mortality. Resistance exercise is the most effective treatment for sarcopenia and there is an unmet need for drugs that could augment or replace this, depending on an individual's physical ability. Pooled data from studies investigating tofacitinib for the treatment of RA demonstrated small increases in serum creatinine (SCr) that were not associated with renal impairment and were inversely correlated with fall in CRP. SCr levels are influenced by SKM mass, raising the possibility that tofacitinib has an anti-sarcopenia effect. The Rheumatoid Arthritis and Muscle (RAMUS) study sought to test this hypothesis.

Methods: The RAMUS study is an observational, single-arm study of RA patients commenced on tofacitinib as part of routine care. Enrolment criteria included meeting the 2010 ACR/EULAR classification criteria for RA and >1 sarcopenia risk factor (low appendicular lean mass index, CRP > 5, low grip strength or prolonged sit-to-stand test time). Prior janus kinase

Table 1: Primary, secondary and selected exploratory outcomes from the RAMUS study. Variables with significant change are highlighted in bold. Secondary outcomes underwent multiple test correction using the Benjamini-Hochberg procedure. *Mean (95% confidence interval) and P-value from one-way repeated measures ANOVA. **Median (interquartile range) and P-value from Friedman's test.

(JAK) inhibitor or recent glucocorticoid treatment were not permitted. Assessments were at baseline, 1 and 6 months. The primary outcome was thigh and calf SKM volume determined by quantitative MRI. Whole body composition was measured by DXA. Study procedures are summarised in Figure 1.

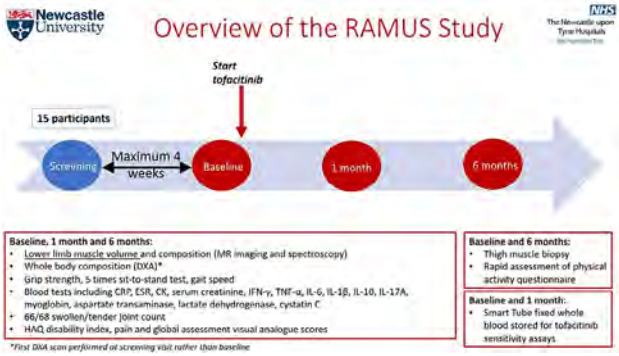

Figure 1: Time points and procedures in the RAMUS study.

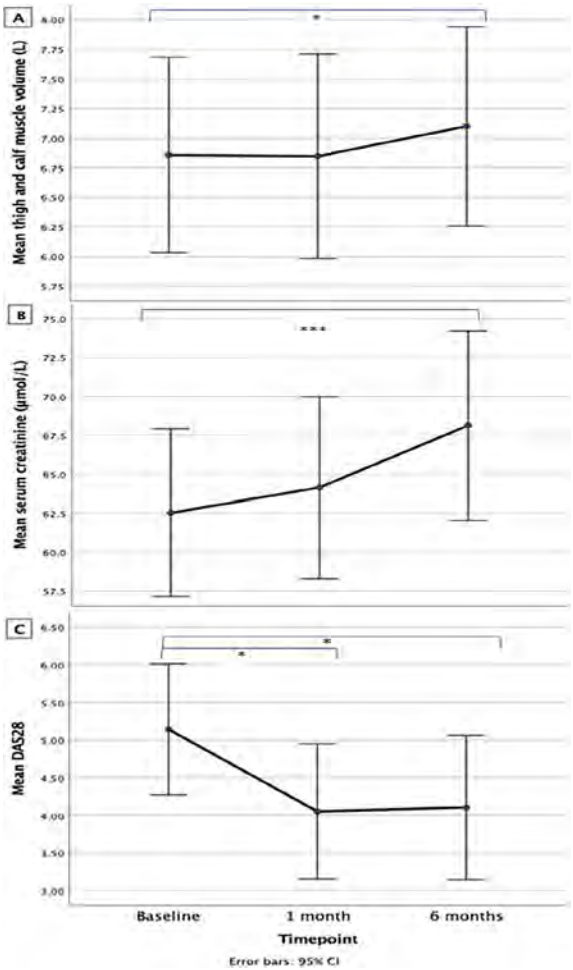

Figure 2: Mean leg muscle volume (A), serum creatinine (B) and DAS28 (C) at each timepoint. Significantly different time points are denoted by * ($p < 0.05$) or *** ($p = 0.001$).

Results: 15 participants aged 41 – 73 years (mean 59) were enrolled (87% female). Median disease duration was 3.1 years (range 1.5 – 24.8) and 60% (n = 9) were seropositive (anti-CCP, RF or both). At baseline, 67% (n = 10) took methotrexate (no other conventional DMARDs were used), 87% (n = 13) were biologic naïve and median BMI was 31.8 kg/m^2. All participants completed the study. 60% (n = 9) had >1 interruption of treatment ranging from 6 – 30 days. At 6 months, increases were observed in lower limb SKM volume (3.5% from baseline), SCr (9.0% from baseline) and self-reported physical activity; changes in disease activity manifested earlier, from 1 month (see Table 1 and Figure 2). 47% (n = 7) achieved a good (n = 3) or moderate (n = 4) EULAR response and 27% (n = 4) achieved ACR20. SKM volume increased significantly in the thigh but not in the calf. The muscle compartment fat fraction did not change. Grip strength, gait speed and fat mass index did not change. There was a trend towards increased weight. SKM volume correlated with grip strength (rs = 0.725, p = 0.003) at baseline. There was no correlation between SKM volume and SCr (either at baseline or in the difference at 6 months).

Conclusion: Treating RA with tofacitinib for 6 months was associated with increased SKM volume, increased SCr and increased self-reported physical activity. Possible mechanisms include a direct anabolic effect of JAK inhibition on SKM, reduced systemic inflammation, improved RA symptoms or a combination of the above. Analysis of SKM tissue samples from participants in the RAMUS study will provide mechanistic insight. These data merit further investigation in the form of a randomised trial to test whether the improvements are specific to tofacitinib and whether combining JAK inhibition with resistance exercise yields greater benefits.

Pneumocystis Jirovecii Pneumonia in Patients with Inflammatory Myopathies

Cody Bruggemeyer[1], Sanket Shah[2], Didem Saygin[3] and Mike Putman[4], [1]Medical College of Wisconsin, Wauwatosa, WI, [2]Medical College of Wisconsin, Milwaukee, WI, [3]University of Pittsburgh, Pittsburgh, PA, [4]Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pneumocystis Jirovecii Pneumonia (PJP) is an opportunistic fungal infection with high morbidity and mortality rates. Few studies to date have assessed the incidence of PJP among patients initiating disease-modifying antirheumatic drugs (DMARDs) for idiopathic inflammatory myopathies. The objective of this study was to determine the incidence of PJP among patients receiving treatment for idiopathic inflammatory myopathies.

Methods: Data were derived from the US-based electronic health records database, TrinetX. Patients selected for study inclusion if they had greater than or equal to 2 ICD9-CM or ICD10-CM diagnosis codes for myositis and received at least one prescription for a DMARD . Due to the retrospective and electronic medical records based nature of this study, items from the ACR Classification Criteria were not available. PJP diagnosis was defined as hospitalization with diagnosis of

PJP, any PJP code followed by any PJP treatment, or any diagnostic test positive for PJP. The primary outcome was the incidence of PJP during the first 6 months of initiating DMARD therapy. The secondary outcome was the incidence of PJP during the first 12 months of initiating DMARD therapy. Unadjusted incidence rate ratio and 95% confidence intervals were calculated.

Table 1: Demographic and Clinical Characteristics, n = 6,030	
Age at Diagnosis, mean (SD)	55.0 (14.4)
Gender	
Male	1498 (24.8%)
Female	4532 (75.2%)

6	36.5	M	White	COPD, Liver Disease	AZA, Tacro, MMF	157 Days	Alive
7	43.1	M	Black or African American	None	AZA, IVIG	42 Days	Alive
8	70.3	F	White	CHF, COPD	Rituximab, IVIG	36 Days	Alive

* Death time restricted to 12-month evaluation period
Abbreviations in Table 2 are defined as follows: COPD - chronic obstructive lung disease, CHF- congestive heart failure, HCQ - hydroxychloroquine, IVIG - intravenous immunoglobulin, MMF - mycophenolate mofetil, Tacro - tacrolimus, AZA - azathioprine

Characteristics of patients who developed PJP pneumonia

Results: This study identified 6,030 patients with myositis who initiated therapy with a DMARD, the most common being methotrexate (2,826, 46.9%), followed by azathioprine (1,531, 25.4%) and mycophenolate mofetil (1,482 ,24.6%). The majority of patients were female (4,532, 75.2%) and white (3,997, 66.3%). The average age at diagnosis of myositis was 55.0 years. A minority (982, 16%) of patients received PJP prophylaxis, the most common of which was trimethoprim/sulfamethoxazole (852, 14.1%). During the first six months of therapy after DMARD initiation, a total of 8 cases of PJP were identified for an incidence rate of 2.9 cases per thousand patient-years. Among the eight patients who developed PJP, four were female, the average age at diagnosis was 51.1 (SD 15.5 years), and 3 had received prophylaxis against PJP. The average time to PJP diagnosis from the index date was 69.6 days (SD 44.7 days). The incidence of PJP among patients with structural lung disease at baseline (defined by chronic obstructive pulmonary disease or interstitial lung disease) was numerically higher as compared to those without lung disease (incidence 5.3 cases vs. 2.0 cases per 1,000 person) with an incident rate ratio of 2.7, 95% (confidence intervals 0.67-10.67). After extending the evaluation period to 1 year after DMARD initiation, no additional cases of PJP were identified, so the 12-month incidence of PJP was 1.45 cases per thousand patient-years.

Conclusion: The incidence of PJP in patients receiving DMARDs for idiopathic inflammatory myopathy was lower than identified in previous literature. It is important to weigh this low incidence rate against potential harms of antimicrobial therapy when deciding to initiate PJP prophylaxis. The risk of PJP in this population may be elevated among patients with structural lung disease.

Does Presence of Anti-SSa and Ro52 Influence the Progression of Interstitial Lung Disease (ILD) in Idiopathic Inflammatory Myopathies (IIM)

Sonali Narain[1], Can Hu[2], Michael Liu[1], Kourosh Shargani[3] and Galina Marder[1], [1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Fort Lee, NJ, [3]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-SSa and Ro52 are commonly present in IIM. We previously reported an association of a more severe early course of IIM-ILD with positive Ro52. The aim of this study was to evaluate if presence of anti-SSa and/or Ro52 is associated with more severe radiological and functional evolution of IIM-ILD over time.

Table 1. Baseline Characteristics of Study Participants

Characteristic	Double Positive Antibody Profile (anti-SSa and anti-Ro52) (N=7)	Single Positive Antibody Profile (anti-SSa or anti-Ro52) (N=6)	Double Negative Antibody Profile (neither anti-SSa nor anti-Ro52) (N=5)

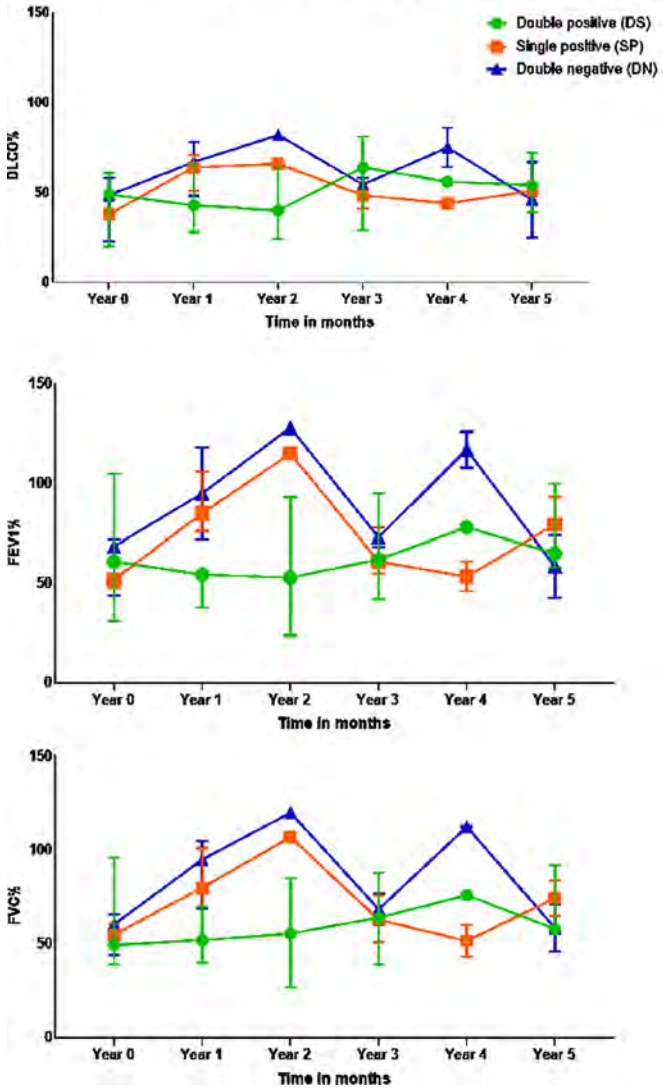
Methods: This is a longitudinal analysis of the Northwell Myositis cohort. All patients met 2017 EULAR/ACR IIM classification criteria. ILD diagnosis was validated by manual chart review. Three groups were analyzed: anti-SSa /Ro52 double positive (DP), anti-SSa/ or Ro52 single positive (SP), and both anti-SSa and Ro52 negative (DN). HRCT was scored as improved,

Table 2 - PFT and HRCT data across 3 groups

	Double Positive (DP) (n = 7)	Single Positive (SP) (n = 6)	Double Negative (DN) (n = 5)	*p-value*
Baseline PFT parameters (mean, SD)				
FVC	58.7 (19.0)	65.8 (18.2)	67.2 (22.7)	0.72
FEV1	59.9 (22.6)	65.2 (18.2)	74.2 (27.0)	0.57
DL_{CO}	42.9 (17.3)	49.2 (16.0)	49 (16.5)	0.75
PFT changes (n, %)				
Improved	5 (71.4%)	4 (66.7%)	5 (100%)	
Stable	1 (14.3%)	0 (0%)	0 (0%)	
Worsened	1 (14.3%)	2 (33.3%)	0 (0%)	
Baseline HRCT findings (n, %)				
Groundglass opacities	6 (85.7%)	5 (83.3%)	3 (60%)	
Fibrosis	4 (57%)	1 (16.7%)	2 (40%)	
Honeycombing	1(14.2%)	0 (0%)	0 (0%)	
HRCT changes (n, %)				
Improved	1 (14.3%)	2 (33.3%)	1 (20%)	
Stable	5 (71.4%)	4 (66.6%)	4 (80%)	
Worsened	1 (14.3%)	0 (0%)	0 (0%)	

Figure 1:Longitudinal PFTs Changes in ILD patients



stable or worsened on the last available scan compared to baseline. Serial FVC, FEV1, and DLCO comparisons from baseline to most recent PFT were performed, percent change with annualized relative percent change were calculated. Improvement or worsening on PFTs was defined as an increase or decrease of $\geq$ 10% in 1 PFT parameter with no $\geq$ 5% decrease or increase in other parameters respectively. Descriptive statistics, T-tests, ANOVA tests, Fisher's exact and Spearman's correlation tests were used for statistical analysis.

Results: Baseline demographics and clinical characteristics are reported in **Table 1.** Eighteen patients met inclusion criteria and had > 2 serial HRCT/ PFT of which 7/18 (38.9 %) were DP, 6/18 (33.3%) SP and 5/18 (27.8%) DN. Median follow up was 5 years (range: 1-13).At baseline, PFTs were similar between the groups (**Table 2**). On baseline HRCT, most observed pattern across all groups was groundglass opacities followed by fibrosis (**Table 2**).

Honeycombing was reported in 14.2 % of DP but not seen in SP or DN groups.

HRCT showed improvement in four patients (1 DP, 2 SP and 1 DN), but mostly recorded stability (DP: 71.4%,5/7and SP: 66.6%, 4/6). Nine patients (DP: 71.4%,5/7 and SP: 66.7%, 4/6) improved by PFT criteria while no DN patients improved (p=0.28). Four patients worsened: one by HRCT and 3 by PFT, all were seropositive (2 from SP and 2 from DP), no patients in DN group worsened. FVC or FEV 1 did not improve in seropositive groups, but in DN mean FEV1 improved from baseline 74.2 % to 90.4% (p= 0.04). Mean annualized % change of PFT was not different between groups. Overall DLCO improved in DN group (49% to 63%, p=0.03) and no improvement was seen in DP or SP groups, but weak improvement trend was observed when positive groups were combined (p=0.05). DP group had overall stability across all PFT parameters over the 5 years follow up. In contrast DN and SP groups appeared to have a modest improvement during the first 2 years that was lost by the 5th year follow up. At year 5 the change of all PFT parameters from baseline was not significant in all 3 groups (**Figure 1).**

Conclusion: While we previously reported the patients with diagnosis of IIM associated ILD with Ro52 positive antibodies may have worse outcomes, this study demonstrates that after initial decline of PFT during first 2 years, pulmonary function stabilizes over time irrespective of serological cluster. At the same time patients with negative of SSA/ Ro52 antibodies are more likely to improve over the years as determined by FEV1 and DLCO. HRCT was not sensitive to changes and mostly reported stability.

Abstract Number: 0297

Characteristics of Anti-MDA-5 Associated Dermatomyositis in Southern California with a Large Hispanic Population: Case Series

Eaman Alhassan[1], Belina Yi[2], Jack Rodman[1] and Leanna Wise[3], [1]University of Southern California, Los Angeles, CA, [2]Children's Hospital Los Angeles, Los Angeles, CA, [3]LAC+USC/Keck Medicine of USC, Pasadena, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is little to no data about the presentation and clinical course of anti-melanoma differentiation-associated gene-5 antibody (anti-MDA-5) dermatomyositis patients in a primarily U.S. Hispanic population. We describe the clinical presentation and outcomes of anti-MDA-5 dermatomyositis in our urban, majority Hispanic rheumatology patient population.

Methods: This is a multicenter, retrospective case series of patients with anti-MDA-5 dermatomyositis. All patients diagnosed with anti-MDA-5 dermatomyositis and encountered in the clinical setting from June 2015 to March 2023 at four academic medical centers in Los Angeles, California by rheumatologists or dermatologists were included. Demographics and clinical characteristics were obtained. Descriptive statistics were presented using frequency and percent for categorical variables and median (IQR) for continuous variables. Associations between categorical variables were assessed using Pearson's chi-squared or Fisher's exact test, and differences in continuous variables were evaluated using a Wilcoxon rank sum test or Kruskal-Wallis test. All tests were two-sided, and a p-value< 0.05 was considered statistically significant.

Results: A total of 30 patients with at least one positive assay for anti-MDA-5 dermatomyositis with a wide variety of clinical manifestations were included (Table 1). Nearly three-quarters of our patients (73%) were Hispanic. Twenty-one patients (70%) were female, with a median age of 40.5 years (IQR [26, 54]). Five patients were pediatric patients (< 18 years old). Hispanic patients were diagnosed with anti-MDA-5 dermatomyositis at a younger age compared to non-Hispanic patients (median age 37.5 years vs. 56.0 years; p = 0.025) (Table 2). Male patients were more frequently diagnosed with inflammatory arthritis compared to female patients (100% vs. 52.4% respectively; p = 0.027). There were 13 patients (43%) without evidence of myositis. Twenty-five patients (83.3%) had evidence of interstitial lung disease (ILD), and a higher ferritin level was associated with ILD (p = 0.049) (Table 3). There were 6 deaths in our cohort, of which 5 were ascribed to rapidly progressive ILD.

Conclusion: In our primarily Hispanic population of urban Los Angeles, anti-MDA-5 dermatomyositis has a wide spectrum of manifestations, with ILD being one of the most common clinical presentations. On average, Hispanic patients were diagnosed with anti-MDA-5 dermatomyositis at a younger age compared to the non-Hispanic patients in our cohort. Like prior

studies, there was an association between higher ferritin level and the presence of ILD. While skin ulceration has been reported to be associated with lung involvement, the association was nonsignificant in our cohort, likely due to the small sample size. This is a first study looking at clinical phenotypes of a primarily Hispanic U.S. population. Larger multi-institutional studies are needed to better understand clinical phenotypes of this population in order to recognize and treat anti-MDA-5 dermatomyositis in a timely manner, especially given the high proportion of amyopathy and ILD.

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Limitations of the 2017 EULAR/ACR classification criteria have been suggested for classifying patients with idiopathic inflammatory myopathies (IIMs) and myositis-specific antibodies (MSAs). On this point, Casal-Dominguez et al recently developed a set of MSAs-based classification criteria that demonstrated perfect sensitivity and specificity (1).

The objective of this study was to determine whether the EULAR/ACR classification criteria and the MSAs-based classification criteria appropriately classify patients with IIMs, differentiating between incident and prevalent cases

Methods: Multicenter cross-sectional study of a cohort of patients included in the Spanish Registry of patients with IIM (Myo-Spain) (2). Patients were classified as incident group (time between diagnosis and study initiation ≤12 months) or prevalent group (>12 months). The accuracy of the classification criteria according of the presence of different MSAs was described. Differences between both groups were tested by Chi-square test. The sensitivity and specificity of the MSAs-based classification criteria was determined. The percent of agreement and the Cohen's Kappa coefficient was used to measured correlations between the EULAR/ACR criteria and the MSAs-based criteria

Results: We included 542 patients with IIM diagnosis, 132 (24.4%) and 410 (75.6%) patients in the incident and prevalent group, respectively. In the overall sample, the diagnosis could be classified with the EULAR/ACR criteria in 284 patients (52.4%) and with the MSAs-based criteria in 344 patients (99.4%). Differentiating by MSAs type, patients were successfully classified by EULAR/ACR criteria as follows: 57.6 % of anti-Jo1-positive patients; 49.3% of MSAs-positive myositis patients (except anti-Jo1 antibody); 52.3% of MSAs-positive myositis patients; 52.5% of patients without MSAs antibodies (table 1). No significant differences were found between the two groups (p >0,05). Regarding MSAs-based classification criteria, patients were successfully classified as follows: 92.1% of anti-synthetase-positive patients and 100% of MSAs-positive (except anti-synthetase antibody) patients (table 2). No significant differences were found between the two groups (p >0,05).The sensitivity and specificity of the MSAs-based criteria were 100% in the incident group and 99.2% and 100%, respectively, in the prevalent group. The percentage of agreement between the EULAR/ACR criteria and the MSAs-based criteria for IIMs was 49.2% in the incident group and 50.9% in the prevalent group. This value was 48.1% and 60.2% in anti-Jo1-positive subgroup (Cohen's Kappa=0).

Table 1: 2017 EULAR/ACR classification criteria for classifying patients with IIMs

	Anti-Jo1-positive	MSAs-positive (except anti-Jo1 antibody)	MSAs-positive	Without MSAs antibodies	All patients
Total (n)	125	221	346	196	542
Classified (n,%)	72 (57.6)	109 (49.3)	181 (52.3)	103 (52.5)	284 (52.4)
No classified (n,%)	53 (42.4)	112 (50.6)	165 (47.69)	93 (47.4)	257 (47.6)
Incident group (n)	27	72	99	33	132
Classified (n,%)	13 (48.15)	35 (48.6)	48 (48.4)	16 (48.4)	64 (48.4)
No classified (n,%)	14 (51.8)	37 (51.3)	51 (51.5)	17 (51.5)	68 (51.5)
Prevalent group (n)	98	149	247	163	410
Classified (n,%)	59 (60.2)	74 (49.6)	133 (53.8)	87 (53.37)	220 (53.6)
No classified (n,%)	39 (39.8)	75 (50.3)	111 (46.1)	76 (46.6)	190 (46.34)

No significant differences were found between groups (p<0.05)
IIMs: idiopathic inflammatory myopathies
MSAs: myositis-specific antibodies

Table 2: MSAs-based classification criteria for classifying patients with IIMs and MSAs

	Anti-synthetase-positive	MSAs-positive (except anti-synthetase antibody)	MSAs-positive
Total (n)	226	120	346
Classified (n,%)	224 (92.1)	120 (100)	344 (99.4)
No classified (n,%)	2 (0.8)	0 (0)	2 (0.5)
Incident group (n)	60	39	99
Classified (n,%)	60 (100)	39 (100)	99 (100)
No classified (n,%)	0 (0)	0 (0)	0 (0)
Prevalent group (n)	166	81	247
Classified (n,%)	164 (98.8)	81 (100)	245 (99.1)
No classified (n,%)	2 (1.2)	0 (0)	2 (0.8)

No significant differences were found between groups (p<0.05)
IIMs: idiopathic inflammatory myopathies
MSAs: myositis-specific antibodies

MSAs-based classification criteria for classifying patients with IIMs and MSAs

Conclusion: The degree of accuracy of the EULAR/ACR criteria for classifying patients with IIM diagnosis was lo, however, the MSAs-based criteria showed excellent diagnostic accuracy. No agreement was found between both classification criteria. Therefore, it seems necessary to review the classification criteria for MII, in which, in addition to including all MSAs, the difficulty in classifying patients without MSAs should be considered.

Trends and Outcomes of Hospitalized Patients with Idiopathic Inflammatory Myopathy and Venous Thromboembolism: A Nationwide Inpatient Sample Analysis from US (2016-2019)

Haseeb Chaudhary[1], Biraj Shrestha[2], Sarah Abi Doumeth[3] and Maya Mattar[4], [1]Case Western Reserve University, Westlake, OH, [2]Tower Health System, Reading, PA, [3]Case Western Reserve University/University Hospitals Cleveland Medical Center, Cleveland, OH, [4]Louis Stokes VA Medical Center, Cleveland, OH

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent evidence suggests increased prevalence of venous thromboembolism (VTE) in patients with idiopathic inflammatory myopathies (IIM). The literature on the clinical implications of VTE among IIM patients remains scarce. We evaluated the recent trends in the mortality rates, length of stay (LOS), and cost of care (COC) of hospitalized patients with IIM with or without VTEs.

Methods: The 2016-2019 Nationwide Inpatient Sample (NIS) database was accessed to identify all adult (18 years and older) IIM patients hospitalized with or without VTE using ICD-10 codes. Baseline demographic characteristics and in-hospital outcomes were compared between the two groups. A multivariate logistic regression analysis was used to calculate the adjusted odds ratio (OR).

Table 1.0 (a) Baseline Characteristics, Mortality and Cost utilizations of inflammatory myositis admitted with or without VTE.

Baseline characteristics	Overall (%) (N=15,165)	No VTE (%) (N= 14,450)	Yes VTE (%) (N=715)	P-value
Mean Age, (Mean ± Standard error) (Years)	65.38 (64.78 - 65.99)	65.41 (64.79 - 66.03)	64.80 (62.29 - 67.31)	0.638
Age (years)				0.267
18-49	15.92	15.99	105	
50-64	23.67	3,420	170

In-hospital mortality	4.22	3.98	9.09	0.003
Length of stay (Mean ± Standard error) (Days)	8.17 (7.79-8.55)	7.93 (7.55 - 8.31)	13.10 (10.96 - 15.24)	<0.001
Cost of care (Mean ± Standard error) (USD)	22161.52 (20780.16-23542.89)	21441.79 (20047.29 - 22836.28)	36733.67 (28972.92 - 44494.41)	<0.001

Table 1.0 (b) - Unadjusted and adjusted odds ratios for risk of mortality in inflammatory myositis with VTE.

Mortality (N = 839)		Unadjusted OR	Adjusted OR
With VTE n (%)	Without VTE n (%)		
65 (9.09)	574 (3.90)	2.41(1.32-4.39)	2.04 (1.09 - 3.81)

Table 1.0 (b) Unadjusted and adjusted odds ratio as a measure of effect of inpatient mortality in inflammatory myositis with VTE.

Results: The total number of hospitalized patients with IIM was 15,165 of whom 715 (4.71%) had VTE. There was no significant difference in the baseline characteristics between the two groups concerning age, gender, race, co-morbidities and hospital setting as shown in Table 1.0 (a). The mean age was 64.80 years (62.29-67.71) in patients with VTE with a male predominance (58%). The inpatient mortality rate in patients with VTE was significantly higher than those without (9.09% vs. 3.98%, p< 0.003), with an adjusted OR 2.04 (95% CI 1.09-3.81), Table 1.0 (b). The highest rate of VTE was observed in patients with dermatomyositis, 8.93%, amongst all subtypes of IIM. The mean LOS in patients with VTE was 13.10 days (10.96-15.24) vs 7.93 days (7.55-8.31) in the comparison group (p< 0.001). The mean COC was significantly higher in patients with VTE than those without, $36,733.67 vs $21,441.79 (p< 0.001).

Conclusion: VTE in patients admitted with IIM was associated with significantly higher inpatient mortality, COC and increased LOS. These results may signify the need for appropriate VTE preventive strategies in IIM to improve patient outcomes and impact on the healthcare system.

Nailfold Videocapillaroscopy in Idiopathic Inflammatory Myopathy Compared with Healthy Controls

Megan Sullivan[1], Maximiliano Diaz-Menindez[2], Colleen T. Ball[2], Benjamin Wang[3] and Florentina Berianu[1], [1]Mayo Clinic Florida, Jacksonville, FL, [2]Mayo Clinic Jacksonville, Jacksonville, FL, [3]Mayo Clinic, Jacksonville, FL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) are a group of autoimmune disorders that cause inflammation of the muscle. This includes dermatomyositis and polymyositis. Literature has been strongly supportive of the use of capillaroscopy, particularly in dermatomyositis, for diagnosis and prognosis. However, many studies compare capillaroscopy in IIM to other rheumatic diseases such as scleroderma. There are few studies comparing capillaroscopy in IIM to control populations. We report our findings against a healthy control population who do not have a history of Raynaud's or connective tissue disease.

Methods: Between January 2018 and 2023 we performed capillaroscopy in patients with diagnoses of dermatomyositis or polymyositis following their first visit with active disease. For the primary analysis, we used multivariable linear regression to estimate the difference in mean NVC scores between IIM patients and controls adjusting for age, sex, and smoking history; 95% confidence intervals (CIs) were reported. NVC scores included capillaroscopy density, dilated capillaries, giant capillaries, micro hemorrhages, capillaries ramification, and capillaries disorganization. In the subset of patients with IIM, we explored associations of patient characteristics with NVC scores using single variable linear regression model; regression coefficients and corresponding 95% confidence intervals were reported. All P values are two sided without adjustment for multiple testing. P values less than 0.05 were considered statistically significant.

Table 1. Baseline Characteristics

Characteristic	IIM (N=44)	Control (N=21)
Median age (IQR), years	49 (36, 59)	50 (39, 56)
Race/Ethnicity, n (%)		
White	41 (93%)	16 (76%)
Black or African American	2 (5%)	2 (10%)
Asian	1 (2%)	3 (14%)
Female gender, n (%)	37 (84%)	14 (67%)
History of smoking, n (%)	2 (5%)	7 (33%)
Diagnosis, n (%)		
Dermatomyositis	41 (98%)	
Polymyositis	1 (2%)	

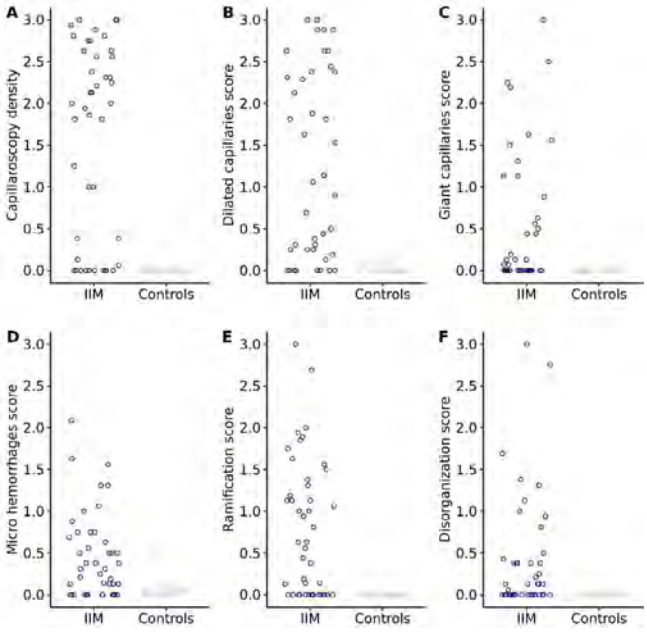

Figure 1. Jitter Plot of Nailfold Videocapillaroscopy Scores Points were jittered horizontally to minimize overlap of points.

Table 2. Single Variable Linear Regression Exploring Associations of Characteristics with Nailfold Videocapillaroscopy Scores in Patients with IIM

		Estimated difference in mean NVC scores (95% confidence interval)					
Factor	N (%) or Median (IQR)	Capillaroscopy Density	Giant Capillaries	Micro Hemorrhages	Dilated Capillaries	Ramification	Disorganization
Any constitutional symptoms (y vs. n)	13/44 (30%)	0.1 (-0.7, 0.8)	0.4 (-0.2, 0.9)	0.2 (-0.2, 0.5)	-0.0 (-0.8, 0.8)	-0.0 (-0.6, 0.5)	0.2 (-0.3, 0.6)
Diminished upper extremity muscle strength (y vs. n)	6/41 (15%)	0.8 (-0.2, 1.8)	**1.1 (0.5, 1.8)**	0.3 (-0.1, 0.8)	1.0 (-0.0, 2.0)	0.4 (-0.3, 1.0)	0.5 (-0.1, 1.0)
Diminished lower extremity muscle strength (y vs. n)	7/41 (17%)	0.0 (-0.9, 1.0)	0.5 (-0.1, 1.2)	0.2 (-0.3, 0.6)	0.3 (-0.7, 1.2)	-0.0 (-0.7, 0.6)	0.2 (-0.3, 0.7)
Associated cancer (y vs. n)	5/44 (11%)	0.6 (-0.5, 1.7)	0.4 (-0.3, 1.2)	0.1 (-0.4, 0.5)	0.4 (-0.7, 1.5)	**0.8 (0.1, 1.6)**	**0.9 (0.3, 1.5)**
CRP (+1), mg/L	3 (3, 3), n=32	0.0 (-0.1, 0.2)	0.0 (-0.1, 0.1)	0.1 (-0.0, 0.1)	-0.0 (-0.1, 0.1)	0.0 (-0.0, 0.1)	-0.0 (-0.1, 0.1)
ESR (doubling), mm/1H	6.0 (2.3, 13.5), n=34	0.1 (-0.1, 0.3)	0.1 (-0.0, 0.3)	0.0 (-0.1, 0.1)	0.1 (-0.1, 0.3)	0.1 (-0.1, 0.2)	0.1 (-0.0, 0.2)
CK (doubling), u/L	102 (71, 175), n=38	-0.2 (-0.4, 0.1)	0.1 (-0.1, 0.2)	-0.0 (-0.2, 0.1)	-0.1 (-0.4, 0.2)	-0.1 (-0.3, 0.1)	-0.0 (-0.2, 0.1)
Aldolase (+1), u/L	5.3 (4.2, 7.6), n=36	0.0 (-0.1, 0.1)	0.0 (-0.0, 0.1)	-0.0 (-0.0, 0.0)	0.0 (-0.0, 0.1)	0.0 (-0.0, 0.1)	0.0 (-0.0, 0.1)
ANA positive (y vs n)	30/44 (68%)	-0.0 (-0.8, 0.7)	0.1 (-0.4, 0.7)	0.1 (-0.2, 0.5)	-0.0 (-0.8, 0.7)	0.1 (-0.4, 0.7)	0.0 (-0.4, 0.5)
SSA-52D positive (y vs n)	12/43 (28%)	0.2 (-0.6, 1.0)	0.2 (-0.4, 0.8)	-0.3 (-0.6, 0.1)	0.1 (-0.7, 0.9)	0.3 (-0.3, 0.8)	0.3 (-0.2, 0.8)
Antisynthetase antibodies (y vs n)	6/43 (14%)	-0.3 (-1.3, 0.8)	-0.1 (-0.8, 0.6)	-0.2 (-0.7, 0.2)	-0.3 (-1.3, 0.8)	-0.4 (-1.2, 0.3)	-0.1 (-0.7, 0.5)
Serology (positive vs. negative)	33/44 (75%)	-0.6 (-1.4, 0.2)	-0.3 (-0.9, 0.2)	-0.1 (-0.4, 0.3)	-0.6 (-1.4, 0.2)	-0.3 (-0.9, 0.3)	0.1 (-0.4, 0.6)

The estimate difference in mean NVC scores and corresponding 95% confidence intervals were estimated from single variable linear regression models. Owing to highly skewed distribution, ESR and CK were transformed on the logarithm scale (base=2) such that a 1 unit increase on the logarithm scale corresponds with a doubling on the original scale.

Results: Baseline characteristics for 44 patients with IIM and 21 controls are shown in Table 1. Patients in the IIM group were more likely to have higher NVC scores compared to controls after adjusting for age, sex, and smoking history (Figure 1).

In Table 2 we explore associations of patient characteristics with NVC scores using single variable linear regression in the subset of patients with IIM. The mean giant capillaries score was 1.1 points higher for those with diminished upper extremity muscle strength (95% CI 0.5 to 1.8 points).IIM patients with associated cancer had mean ramification scores that were 0.8

points higher (95% CI 0.1 to 1.6 points) and mean disorganization scores that were 0.9 points higher (95% CI 0.3 to 1.5 points) than IIM patients without associated cancer.

Conclusion: Nailfold videocapillaroscopy shows statistically significant differences in density, dilation, giant capillaries, micro hemorrhages, ramification, and disorganization when compared with healthy controls. Exploratory analysis suggests there may be a correlation between giant capillary frequency with muscle strength as well as an increase in ramification and disorganization in those with malignancy-related myositis.

Inflammatory Myopathies and Their Relationship with Cancer in a Colombian Cohort

Bolaños Juan D.[1], Rivera-Londoño Robert[1], Ivana Nieto-Aristizabal[1], Karol Enriquez[2], Santiago Zura[2], Alex Echeverri[1], Andrés Hormaza-Jaramillo[1] and **David Aguirre-Valencia**[1], [1]Fundación Valle del Lili, Cali, Colombia, [2]Universidad ICESI, Cali, Colombia

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory myopathies (IM) constitute a heterogeneous group of autoimmune muscle diseases. These can occur in isolation, associated with other autoimmune disorders, or as a development of some neoplasia. Different types of IM include dermatomyositis (DM) and polymyositis (PM). Magnetic resonance or electromyography can be helpful in the diagnosis, along with the performance of a biopsy. These entities have a higher risk of occult neoplasms, and cancer is one of the leading causes of death. Therefore, it is essential to understand the clinical, laboratory, and imaging characteristics in patients with IM associated with cancer. Our country's information on this pathology and its association with cancer is limited. Therefore, generating new knowledge and broadening interest in research in this area is essential.

Methods: A descriptive, retrospective, cross-sectional study of a cohort of patients treated at Fundación Valle del Lili in Cali, Colombia, was performed between 2011 and 2022. All participants accomplished the American College of Rheumatology (ACR) criteria for adult inflammatory myopathies, and statistical analyzes were performed using Stata® version 14 (StataCorp, College Station, TX, USA). Quantitative variables were presented as means (standard deviation) or medians (interquartile range).

Results: A total of 112 patients from 2011 to 2022 were included. The patient's median age at inclusion was 47,4 (± 18) years, with age at onset of symptoms of 41,2 (±19,4) years, being all females (100%). The primary inflammatory myopathies diagnosed were dermatomyositis 51 (45,5%), polymyositis 39 (34,8%), and juvenile dermatomyositis 9 (8,1%), which presented a disease evolution time of 48 (120-12) months. Some of the most prevalent clinical characteristics were symmetric weakness 64 (57%), upper limb weakness 63 (56%), myalgias 56 (50%), respiratory distress 31 (27,7%), arthralgia 46 (41%), and rash in Heliotrope 20 (17,9%). Additionally, 42 (37,5%) patients had muscle biopsy confirmation, and a myopathic pattern on EMG was evidenced in 67 (59,8%) individuals. 89 (79,5%) patients were treated with corticosteroids with a weekly dose of 35 (70-5) mg; other treatment included rituximab 33 (29,5%) with 2 (3-1) cycles approximately, azathioprine 40 (35,7%) and methotrexate 18 (16,1%). 13 (11,6%) patients were diagnosed with cancer; thyroid cancer was the most

common 4 (30,8%). The time between myopathy and an oncologic diagnosis was 11 (13-2) months. A bivariate analysis was made evaluating the relationship among cancer and no cancer patients; some variables statistically significant were age (P < 0.01), use of corticosteroids (P < 0.05), Gottron´s papules (P < 0.017), digital ulcers (P < 0.036) and a myopathic

Bivariate analysis

pattern on EMG (P < 0.032). In this cohort, 4 (3.5%) patients died because of their underlying disease, and 98 (87.5%) presented a good evolution.

Conclusion: The characterization of patients with inflammatory myopathies and cancer in our country is essential due to its limited information, and it also opens the doors to generate new prospective studies that make it possible to create associations with a more significant statistical impact that guides early interventions in this type of patients.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Statin-induced immune mediated necrotizing myopathy (IMNM) is a subtype of inflammatory myopathy associated with anti-3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR) autoantibodies. This condition is characterized by progressive muscle weakness leading to severe disability. Treatment is not well established, but usually includes high doses of glucocorticoids (GCs). Therapeutic effects are often disappointing. Side effects are common and related to the high doses of GCs. Intravenous immunoglobulins (IVIG) may be effective in the treatment of IMNM.

Our aim was to compare two therapeutic protocols in IMNM; **a)** standard therapy including high doses of GCs, and **b)** a GC-free protocol.

Methods: Patients consecutively diagnosed with statin-induced IMNM in our centers from January 2017 to November 2022 and followed for at least 3 months were included.

IMNM was diagnosed according to the definition of the European Neuromuscular International Workshop 2016. Clinical data was extracted retrospectively from the patients' clinical records.

Remission was defined as no disease activity according to 2016 ACR/EULAR response criteria in myositis.

Treatment was assigned to the patients considering the current recommendations and contraindications of the therapies available. In patients with comorbidities that limit the use of glucocorticoids, a steroid-free regime was agreed through a shared decision between the physician and the patient.

Results: We included 24 anti-HMGCR positive patients. Main features and treatment of the patients are summarized in **TABLE**.

A GC-free regimen based on the use of IVIG 2g/kg every month for at least 3 months was used in 5 (20.8%) patients. The remaining received standard treatment including GCs.

At baseline, general demographic data, MMT-8 and CK levels were similar in both groups. Comorbidities were higher in patients treated with the GCs free protocol.

Table: General features of 24 patients diagnosed with HMGCR positive IMNM.

Variables	Total (n=24)	Glucocorticoid group (n=19)	Glucocorticoid-free group (n=5)	P (steroids vs no steroid)
Age (years), mean ± SD	68.2 ± 7.2	69.2 ± 6.9	64.4 ± 8	0.2
Sex (women), n (%)	10 (42)	8 (42.1)	2 (40)	0.7
Comorbidities (n, %)				
- Hypertension	17 (70.8)	13 (68.4)	4 (80)	0.96
- Diabetes mellitus	15 (62.5)	11 (57.9)	4 (80)	0.7
- Cardiovascular disease	7 (29.2)	6 (31.6)	1 (20)	0.96
Analytical values at diagnosis, mean ±SD				
- CK (ukat/L)	114 ± 104	134± 108	40 ± 34	0.07
Treatments, n (%)				
- Intravenous GC	8 (33.3)	8 (42.1)	0	0.2
- Oral GC	19 (79.2)	19 (100)	0	**0,0001***
- MTX	18 (75)	15 (78.9)	3 (60)	0.8
- AZA	3 (12.5)	3 (15.8)	0	0.8
- IVIG	18 (75)	13 (68.4)	5(100)	0,4
- RTX	4 (16.7)	3 (15.8)	1 (20)	0.7
Muscle strength assessment				
- MMT-8 at diagnosis	64.4 ± 12	63.7 ± 10.4	67.3 ± 19.4	0.6
- MMT-8 after treatment	77.6 ± 4.2	77.2 ± 4.6	79.5 ± 1.5	0.3
Remission				
- Patients achieving remission, n (%)	21 (87.5)	16 (84.2)	5 (100)	0.8
- Time to clinical remission (months), mean ± SD	5.2 ± 2.3	5.5 ± 2.5	4.1 ± 1.1	0.2
- Time to CK normalization (months), mean ± SD	4.1 ± 1.6	3.9 ± 1.7	4.9 ± 1.3	0.3

AZA: Azathioprine; CK: Creatine kinase; GC: Glucocorticoids; IVIG: Intravenous immunoglobulins; MTX: Methotrexate; RTX: Rituximab
Upper limit for CK: < 4.7 ukat/L for men and 3.5 ukat/L for women.
*: $p < 0.05$

Remission or low disease activity was achieved in 21 patients (87.5%), including all 5 patients who did not receive GCs (after a mean of 4.1 ± 1.1 months).

However, 3 (15.8%) of the 19 patients receiving glucocorticoids did not achieve remission or low disease activity.

The time to remission or CK normalization was similar in both groups.

Conclusion: In our series of patients with anti-HMGCR positive IMNM, we found that patients can achieve remission without glucocorticoid treatment.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: CD8+ cytotoxic lymphocytes (CTLs) play a crucial role in the myoinjury of polymyositis (PM). Nonetheless, conventional treatment for PM depends on high-dose glucocorticoids with or without other nonspecific immunosuppressants. Some patients are refractory to these treatments while others suffer from adverse effects. T cell activity can be suppressed with calcineurin inhibitors but often insufficiently because of their renal toxicity at high dose ranges. Abatacept was effective to PM model of mice, but it could not exhibit its efficacy against idiopathic inflammatory myositis in a phase III clinical trial. Therefore, developing novel therapeutic strategies that is specific to the pathophysiology of PM and safe are still demanded. To further investigate the pathophysiology of PM, which is idealistic to be done with human resource, we aimed to develop an ex vivo model of CTL-mediated myoinjury utilizing muscle cells and regenerative CTLs (rCTLs) derived from human induced pluripotent stem cells (hiPSCs).

Methods: Human iPSCs were established from peripheral blood-derived CD34+ hematopoietic stem and progenitor cells of PM patients, who met the Bohan and Peter criteria. Additionally, HLA-A haplotype analysis of the hiPSC-donors were performed. HLA-A*24:02+ or HLA-A*24:02- hiPSCs were transfected with adoxycycline (Dox)-inducible MyoD vector. After overnight culture with Dox, hiPSCs highly expressing MyoD were sorted and re-cultured to expand in undifferentiation medium without Dox. These cells were differentiated into muscle cells in a differentiation condition with Dox. Human iPSC-derived rCTLs established from WT1-specific primary CTLs were activated by an HLA-A*24:02+ lymphoblastoid cell line presenting a mutant WT1 peptide (mWT1), which binds more strongly to HLA-A*24:02 than the nature WT1 peptide. Activated rCTLs were cocultured with the muscle cells pulsed with mWT1. The cytotoxicity of rCTL was evaluated by fluorescence of calcein released from the pre-labeled muscle cells. Student's t-test and Tukey's test were used for statistical analysis.

Results: Mutant WT1 pulsed muscle cells derived from 2 cell lines of HLA-A*24:02+ hiPSCs were killed by rCTLs, respectively. The cytotoxicity was dependent on the number of rCTLs. In addition, the cytotoxicity was suppressed when mWT1 was not pulsed to the coculture, when tacrolimus was added to the coculture, or when the cocultured muscle cells were derived from HLA-A*24:02- hiPSCs.

Conclusion: By using hiPSCs, we established a human cell-derived cytotoxic myoinjury model, which is MHC class I restricted and antigen-specific. This model would facilitate the analysis on the mechanism of CTL-mediated myoinjury in human and dissect the pathophysiology of PM.

Abstract Number: 0304

Incidence of Disease Flares Following COVID-19 Vaccination in a Diverse Idiopathic Inflammatory Myopathy Cohort

Hillary Weisleder[1], Ana Valle[1], Xianhong Xie[2] and Shereen Mahmood[3], [1]Montefiore Medical Center, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine / Montefiore Medical Center, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune activation in the setting of vaccination against coronavirus disease 2019 (COVID-19) is a well-documented phenomenon in the medical literature. For patients with idiopathic inflammatory myopathies (IIM), there is a concern that vaccinations can cause disease flares. Data regarding this topic in this heterogenous patient population remains sparse. Our aim was to evaluate the incidence of myositis flares in IIM patients following vaccination against COVID-19 in a minority majority cohort.

Methods: Patients from Montefiore Medical Center who met 2017 EULAR/ACR classification criteria for IIM were included in this retrospective cohort study. 152 patient records from the year 2020 onwards were searched for dates of COVID-19 vaccinations and incidence of disease flares, defined as myalgias with elevations in creatine kinase over two times the upper limit of normal within 3 months of vaccination. A bivariate analysis was done in those who were vaccinated to determine possible covariates associated with disease flares, including IIM subtypes, the presence and severity of interstitial lung disease (ILD), and concurrent immunosuppressive therapy.

Results: Of the 152 IIM patients included in this cohort study, 84 (55%) were vaccinated against COVID-19. Of the 84 vaccinated patients, 5 (6%) experienced a disease flare. All flares occurred after the primary vaccine series of either Pfizer (n= 3/5, 60%) or Moderna vaccines (n= 2/5, 40%). There were no statistically significant increases in disease flare incidence in patients with Polymyositis, Dermatomyositis, Amyopathic Dermatomyositis, Mixed or Undifferentiated Connective Tissue Disease, Necrotizing myopathies, or Inclusion Body Myositis. However, there were statistically significant increases in the incidence of disease flares in patients with moderate ILD (p=0.03) and progressive ILD (p=0.05). There were also statistically significant differences noted in the incidence of disease flares in patients taking Rituximab (p= 0.01) and Cyclosporine (p=0.02), while there were no similar trends observed for those on other immunosuppressive agents or those on acute or chronic steroids, as seen in Table 1.

IBM, n (%)	5 (6.0)	12 (17.7)	0.02

Conclusion: There were no statistically significant increases in disease activity for IIM patients after COVID-19 vaccination. However, disease flare incidence was increased in IIM patients with moderate or progressive ILD, as well as those taking Rituximab and cyclosporine. More research is needed to further investigate the link between ILD and vaccination-related disease flares. In the meantime, providers should remain vigilant in monitoring for disease activity after COVID-19 vaccination in IIM patients with ILD and those on immunosuppressive agents.

Prevalence and Clinical Significance of anti-Ro52 Antibodies in Antisynthetase Syndrome

Javier Narvaez[1], Paola Vidal-Montal[2], Elena Cañadillas-Sanchez[3], Pol Maymó[2], Judith Palacios[2], Martí Aguilar[2], Montserrat Roig[2] and Joan Miquel Nolla[2], [1]Hospital Universitario de Bellvitge, Barcelona, Spain, [2]Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain, [3]Department of Rheumatology, Hospital Clínico Universitario Lozano Blesa, Zaragoza, Spain

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Antisynthetase syndrome (ASSD) is a systemic autoimmune condition characterized by the positivity of anti-aminoacyl-transfer-RNA synthetases antibodies (ARS) and the occurrence of the classic triad, encompassing myositis, arthritis, and interstitial lung disease (ILD).

There is a higher prevalence and increased severity of ILD in patients with ASSD compared to other idiopathic inflammatory myopathies (IIM). The leading prognostic role of ILD in ASSD prompted a focused search for laboratory markers able to predict lung involvement occurrence and progression. ARS specificities have been associated with phenotypically distinct

Table 1. Baseline characteristics

	Anti-Ro52 positive N=32	Anti-Ro52 negative N=24	p
Age (mean ± SD), years	61,8 ± 15	62,4 ± 13	0.879

Relapses	9 (28%)	7 (29%)	0.620
Deaths	3 (9,5%)	3 (12,5%)	0.708

subgroups at disease onset. However, it doesn't seem to be significant differences among the groups in the clinical spectrum, time course and prognosis.

Anti-Ro52 antibodies (anti-Ro52) are systemic autoantibodies addressed against the Tripartite motif-containing protein 21 found in several connective tissue diseases and up to 50% of ASSD patients. In patients with other IIM, anti-Ro52 positivity has been associated with a rapid progression (RP) of ILD and a poorer prognosis, whereas its role in ASSD is still uncertain. Our objective was to to assess the prevalence and clinical significance of anti-Ro52 antibodies in a cohort of patients with ASSD.

Methods: Ambispective analysis of clinical, imaging and laboratory characteristics, therapeutic approaches, and outcome of 56 ASSD patients progressively enrolled at our hospital.

Results: We identified 32 anti-Ro52 positive and 24 anti-Ro negative ASSD patients. The prevalence of ILD and myositis at baseline were similar between the two groups. In contrast, some skin lesions (mechanic's hands and Gottron's papules/sign) were significantly more prevalent in anti-Ro52+, whereas arthritis was more frequently seen in anti-Ro negative patients (see Table 1). We did not observe a strong association of co-occurring anti-Ro52 antibodies with any of the ARS.

No differences in oxygen need and ILD patterns, therapeutic approaches, outcome measures, and prognosis were observed (Table 2). Overall mortality was 11% (6 subjects). No differences in mortality, overall and disease-related, between anti-Ro52+ and anti-Ro52- patients were observed. Survival curves were not different at any time point (Log-rank test, p-value 0.608).

Conclusion: Overall, the presence of anti-Ro52 antibodies seems to be related to a higher prevalence of skin lesions, but not with ILD. Although they could affect the clinical characteristics of ASSD, they do not seem to influence the prognosis. No differences in relapses, RP-ILD, or mortality were observed when compared to anti-Ro52 negative patients

Fitbit Is a Valid and Reliable Physical Activity Monitor in Idiopathic Inflammatory Myopathy

Akanksha Sharma[1], shiri keret[2], Raisa Lomanto Silva[3], Tanya Chandra[4], Joel Levin[5], Siamak Moghadam-Kia[3], Chester V. Oddis[6] and Rohit Aggarwal[6], [1]UPMC Mercy Hospital, Pittsburgh, PA, [2]Bnai Zion, Atlit, Israel, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, [4]Georgetown University Hospital, Washington, DC, [5]University of Pittsburgh, Katz Graduate School, Pittsburgh, PA, [6]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM, myositis) are a systemic autoimmune disease leading to debilitating muscle weakness and significant limitations in daily activities. Physical activity monitor (PAM) are validated and recognized measures of the frequency and intensity of physical activities. Given the urgent need for objective, continuous,

longitudinal outcome measures of physical activity and function in myositis, we assessed compliance, reliability, and validity of widely used commercial PAM – Fitbit© in evaluating physical activity in myositis patients.

Methods: "Myositis Patient Centered Tele-Research (MyPACER)" is a multi-center observational prospective study conducted over 6 months. The study had two cohorts, 1. Tele-Research Cohort (TRC): patients were remotely enrolled from any location in the United States, and 2. Center-Based Cohort (CBC): a traditional cohort with enrollment from the 2 myositis centers. Functional and Patient-Reported Assessments were completed monthly, including a health assessment questionnaire, patient global disease activity, PROMIS-physical function 20 and functional tests timed up-and-go (TUG), and sit-to-stand (STS)). Participants were asked to use their waist-based Fitbit (≥10 hours/day), ≥ 7 days/month. Average steps per minute & Average peak cadence were evaluated using Fitbit data.

Results: 120 IIM patients (mean age 55.5+/- 13.43, 75% females, 80.8% white), who completed baseline visit were enrolled in the study, comprising 82 in the Main TRC group, 21 in Local TRC and 17 in the local CBC (table 1). There were 51.7% DM, 39.2% PM, and 9.1% NM. The TRC and CBC cohorts were similar in demographics and disease subtypes. Age was significantly correlated with the average steps per minute (Ave Step/min) (p=0.01) but not with ave. peak cadence, showing a decrease in steps with advancing age. Gender, race/ethnicity or disease subtypes were not associated with PAM measures.

On data analysis, 90% patients completed at least one valid day on their Fitbit devices. The compliance with Fitbit was very high with participants wearing devices on most days of the week (Ave. = 6.52 days) for the most visits (Ave. 5.73 visits), with similar results for remote or local recruitment. Ave steps per minute and peak cadence showed strong test-retest reliability (r=0.89 and r=0.86, p< 0.0001 & p= 0.0001) and were strongly correlated within-patient. Regarding validity at baseline, ave steps/mins was significantly associated with myositis, skin disease, extra-muscular global, PROMIS physical function and functional tests, HAQ score but not with other myositis core set measures (Table 2).While the ave. peak cadence was significantly associated with MMT-8, physician and patient global disease activity as well as fatigue, myalgia, myositis, TUG, but not with HAQ, CK, and extra-muscular disease activity (Table 2).

Conclusion: In a large IIM cohort, Fitbit physical activity monitor variables demonstrates favorable compliance and psychometric properties with a strong test-retest reliability and association of several patient and physician-reported measures.

Abstract Number: 0307

Long-term Prognosis and Recurrence in anti-MDA-5 Antibody-positive Dermatomyositis

Jun Nakamura[1], Takao Nagashima[2] and Kojiro Sato[2], [1]Jichi Medical University, Shimotsuke, Japan, [2]Jichi Medical University, Tochigi, Japan

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

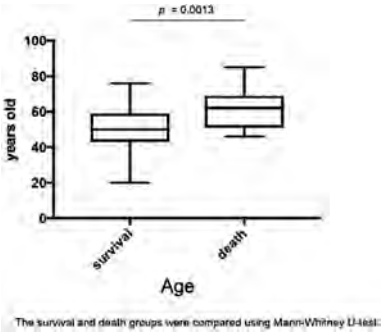
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster I

Session Type: Poster Session A

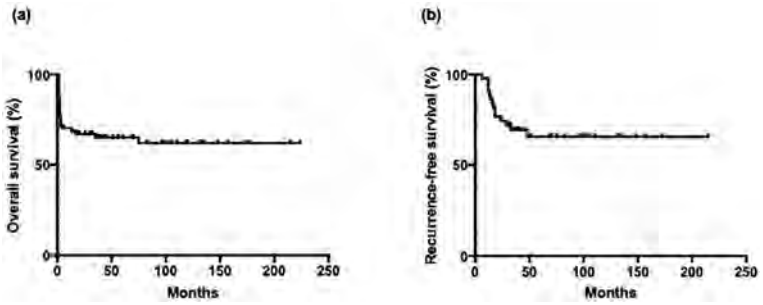
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-melanoma differentiation-associated gene 5 (MDA5) antibody-positive dermatomyositis (DM) is frequently complicated by rapidly progressive interstitial lung disease (ILD) and is life-threatening especially in the early stages. Therefore, triple therapy using glucocorticoid (GC), calcineurin inhibitor (CNI) and cyclophosphamide is recently recommended from the early onset. On the other hand, it has also been known that cutaneous symptoms including skin ulcers, papules on the palmar side, and panniculitis are common and afflict patients. However, the long-term prognosis including not only ILD but also the recurrence of skin symptoms is poorly understood. In this study, we assessed the long-term survival rate and recurrence rate in anti-MDA5 antibody-positive DM.

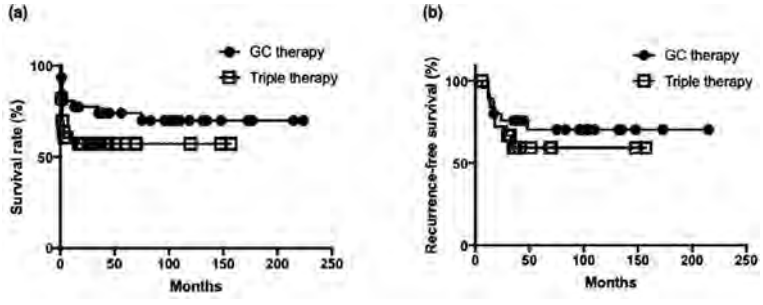
Methods: This retrospective study included patients with anti-MDA5 antibody-positive DM who were admitted to our division from January 2004 to March 2023. Patients who were alive 6 months after the initial hospitalization were classified into the survival group, and those who had died within 6 months were classified into the death group. In addition, the patients were divided into triple therapy (GC, CNI and cyclophosphamide) and GC therapy (GC alone, or GC and CNI). We first analyzed the long-term survival rate in all patients, over 10 years in some patients, and then analyzed it in each group.



The median age of the survival and death group



(a) Survival rate in all patients with anti-MDA5 antibody-positive DM, (b) Recurrence-free survival rate in survival group



(a) Long-term survival rate in Triple and GC therapy, (b) Recurrence-free survival rate in Triple and GC therapy

Results: Sixty-eight patients with anti-MDA5 antibody-positive DM were enrolled, two of whom died of malignant tumors within 6 months of onset and were excluded from the analysis. The median age of the patient was 51.5 (range, 20-85 years), and the number of women was 40 (74%). All but one of the 66 patients had ILD. Forty-seven out of 66 patients (71%) were classified into the survival group and 19 (29%) into the death group. The median age of the death group at onset was significantly higher than that of the survival group (62 and 50 years old, respectively, p = 0.0013, Figure. 1). Survival rate declined rapidly to ∼70% by 13 weeks after admission but did not decline significantly thereafter (Figure 2 (a)). However, a small number of patients died of ILD one to two years after the onset. Long-term follow-up of the survival group showed that dermatomyositis tended to recur until approximately 50 weeks after the initial admission (Figure 2 (b)). The breakdown of recurrence included not only ILD but also exacerbation of skin symptoms such as skin ulcers. Between triple therapy and GC therapy, there was no significant difference in median age (52.5 and 50 years old, respectively, p = 0.1125), female ratio (55.9% and 65.6%, respectively, p = 0.4182) and serum ferritin levels (658.9 ng/ml and 511.9 ng/ml, respectively, p = 0.2519). Furthermore, there was no significant difference in long-term survival and recurrence-free survival between triple therapy and GC therapy (p = 0.18 and 0.49, respectively, Figure 3).

Conclusion: The survival rate of anti-MDA5 antibody-positive DM rapidly declines by three months after onset. When skin symptoms are also taken into account, the recurrence rate remains relatively high until several years after the onset. There was no superiority of Triple therapy over GC therapy with respect to long-term survival and recurrence rate in this study.

Burden of Osteoarthritis Attributable to High BMI in 38 OECD Countries: A Benchmarking Analysis

Dhruvkumar Gadhiya[1], Utsav Patel[2], Hiren Chhayani[3], Krushi Shah[3], Sneh Patel[3], Victor Adedara[4], Divya Patel[3] and Hardik Desai[5], [1]St.Luke's University Health, Anderson Campus, Easton, PA, [2]Tulane University, New Orleans, LA, [3]G.M.E. R.S. Medical College, Gandhinagar, Gandhinagar, India, [4]St George's University SOM, True Blue Greneda, True Blue, Grenada, [5]Gujarat Adani Institute of Medical Sciences, Bhuj, India., Bhuj, India

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The burden of osteoarthritis related to high body mass index (BMI) in OECD countries is a significant public health concern. Osteoarthritis is strongly associated with obesity, and the increasing prevalence of obesity in many OECD countries has contributed to the rising burden of osteoarthritis. This study was aim at assessing the Global Burden of Osteoarthritis due to High BMI, in 38 OECD Countries from 1990-2019.

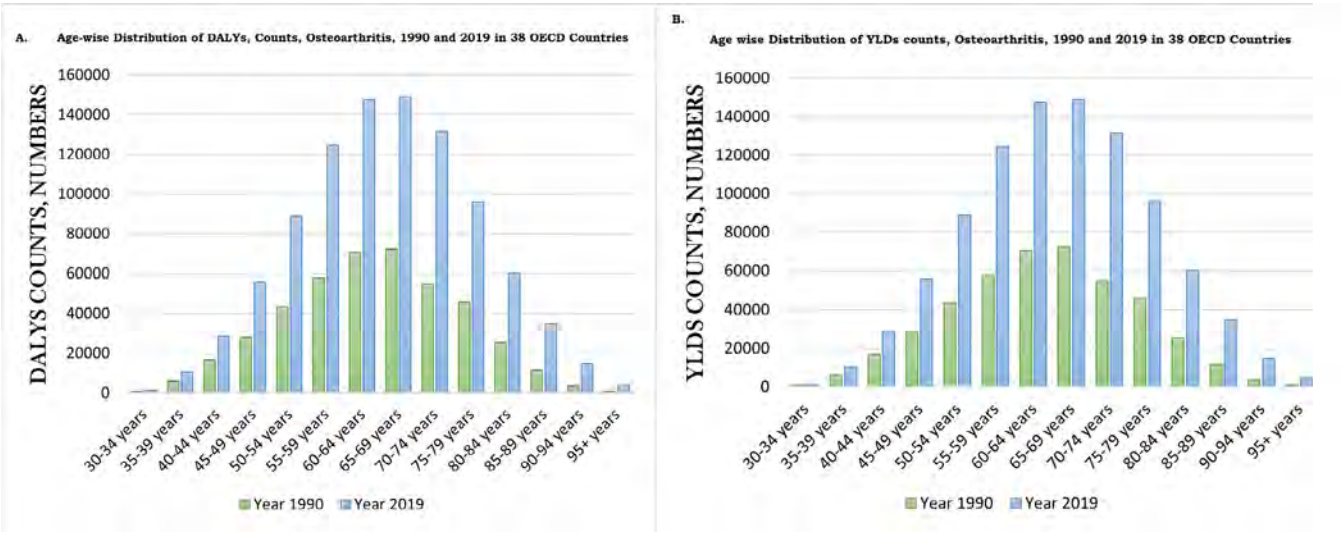
Methods: his study compiled 38 OECD Countries data on the duration of disability caused by osteoarthritis (OA) linked to high BMI from the Global Burden of Disease (GBD) 2019 dataset. The analysis systematically examined the burden of disability attributed to OA in relation to high BMI, considering factors such as age, sex, and annual percentage of change (APC).

Results: There has been a significant increase in the total number of Disability-Adjusted Life Years (DALYs) attributed to Osteoarthritis due to an alarming rise in body mass index (BMI) between 1990 and 2019. The study reveals that the DALYs increased by 116% (95%UI: 102%-144%) during this period, indicating a concerning trend in the burden of the disease.

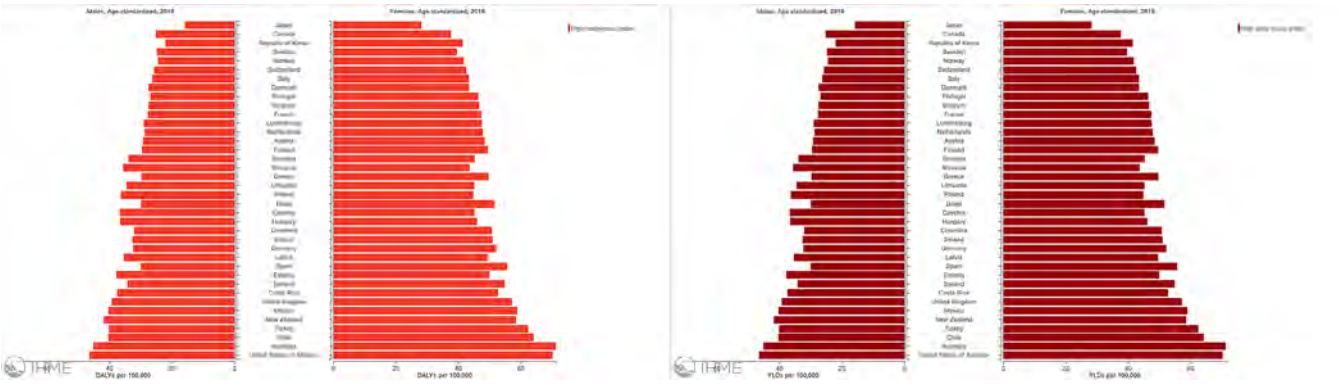
The analysis of age standardized DALYs provides further insights into the impact of Osteoarthritis across different countries. In 2019, the highest age standardized DALYs were observed in the United States, with a rate of 59 per 100,000 individuals (95%UI: 25-128). Following closely behind was Australia, with a substantial burden of Osteoarthritis reflected in the age standardized DALYs.

On the other end of the spectrum, Japan exhibited the lowest age standardized DALYs for Osteoarthritis in 2019, with a rate of 22.44. This suggests a relatively lower burden of the disease in Japan compared to other countries analyzed in the study.

Furthermore, when considering the annual percentage change in DALYs, Australia experienced the highest increase at 47%, indicating a rapid escalation of the disease burden within the population. Chile followed closely behind with a substantial annual percentage change in DALYs. These findings underscore the urgency for targeted interventions and preventive measures to address the rising burden of Osteoarthritis in these countries.



Age-wise distribution of DALYs, Counts, Osteoarthritis, 1990 and 2019 in 38 OECD Countries



Sex wise burden of Osteoarthritis due to High BMI in OECD Countries

Conclusion: The burden of osteoarthritis associated with high BMI in OECD countries is a pressing issue. Combating this burden requires collaborative efforts from policymakers, healthcare providers, and individuals themselves. By promoting healthy lifestyles, early intervention, and evidence-based management strategies, it is possible to reduce the impact of obesity-related osteoarthritis and improve the overall health and well-being of affected individuals and societies.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic pain is an unmet need in osteoarthritis (OA) as current therapies have limited analgesia and side effects. The chemokine CCL17 mediates inflammatory pain and blocking CCL17 (via anti-CCL17 monoclonal antibodies [mAb] or CCL17 knock-out) reduces pain and joint disease in murine arthritis. GSK3858279 is a novel, high affinity, human mAb that functionally inhibits CCL17. The objective of this study is to present efficacy, safety, pharmacokinetic (PK) and immunogenicity data from Part B of a first-in-human, 2-part, phase I, randomized, double-blind, placebo (PBO)-controlled study evaluating GSK3858279 for OA pain (NCT03485365).

Table. Baseline characteristics

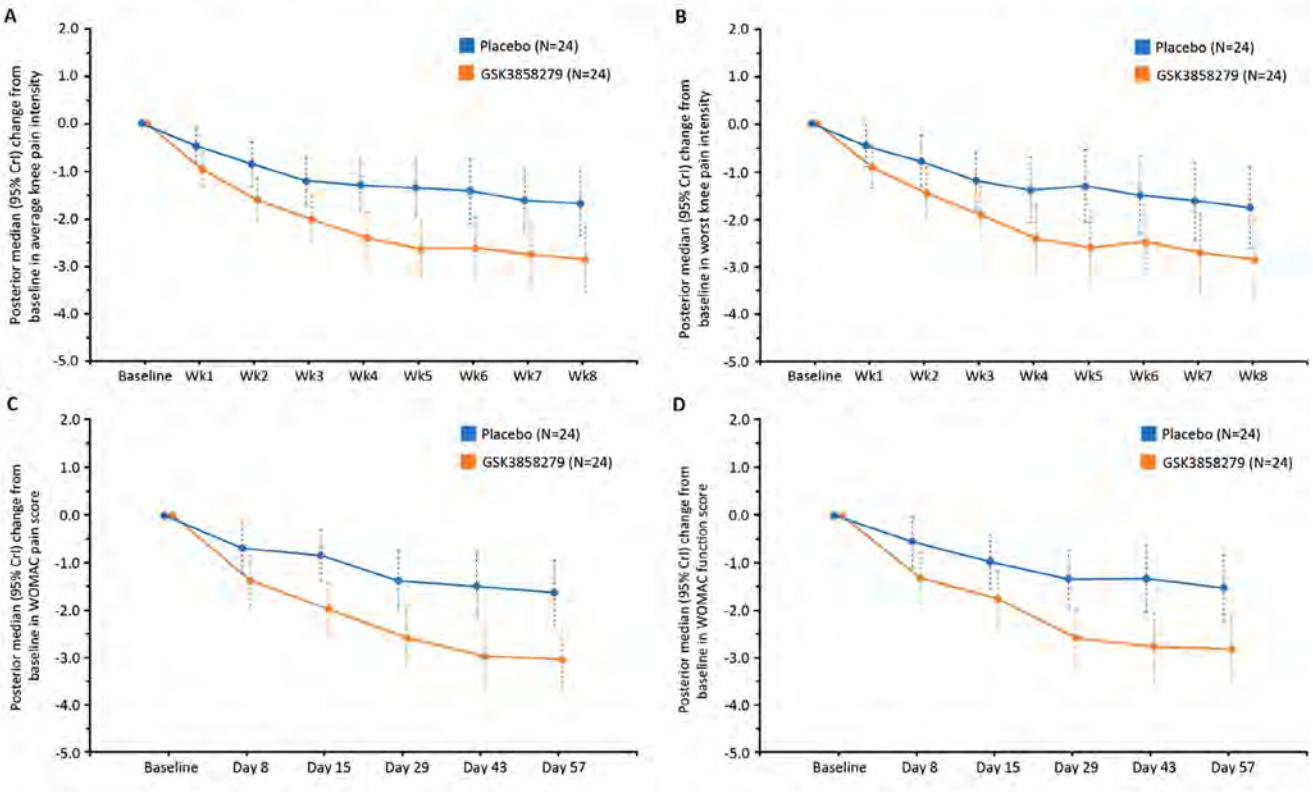
Worst knee pain intensity[a]	6.0 [4.0–8.0]	6.2 [4.2–8.6]	6.1 [4.0–8.6]
WOMAC Pain score[a]	5.3 [2.6–9.0]	5.5 [2.8–7.0]	5.4 [2.6–9.0]
WOMAC Function score[a]	5.2 [1.6–9.4]	5.5 [1.7–7.5]	5.4 [1.6–9.4]

Data are *n* (%) or median [range]. [a]11-point numerical rating scale: 0 (no pain/difficulty) to 10 (worst imaginable pain/difficulty). WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index.

Methods: Participants with knee OA per ACR criteria, Kellgren and Lawrence (KL) score ≥2 and average daily pain score 4–9 by 11-point numerical rating scale (NRS), were randomized (1:1) to weekly subcutaneous (SC) GSK3858279 or PBO for 8 weeks. Co-primary endpoints were change from baseline (CFB) to Week 8 in average and worst knee pain intensity. Participants completed a daily pain NRS. Pain medication was prohibited, except paracetamol (≤3g/day) as rescue medication (not 24h before a study visit). Exploratory endpoints included CFB in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function scores. Samples for analysis of GSK3858279 serum concentration and immunogenicity were collected to Week 20. A Bayesian repeated measures model using non-informative priors was fitted to CFB data; 95% credible intervals (CrI) for treatment differences were calculated.

Results: All 48 participants in Part B completed the study (2 participants in the PBO arm discontinued treatment). Participant characteristics were comparable; however, more participants in the GSK3858279 arm were male and KL grade 4 (**Table**). GSK3858279 was rapidly absorbed after SC administration (median T_{max} ~2 days), with steady concentrations predicted by Week 8. Anti-GSK3858279 Abs were detected in 5/24 (21%) and 1/24 (4%) participants who received GSK3858279 and PBO, respectively; PK profiles for these participants were consistent with profiles in those without anti-drug Abs. For the co-primary endpoints of average and worst knee pain intensity, GSK3858279 showed greater improvement versus PBO at all timepoints (**Figure**). At Week 8, the difference (95% CrI) in CFB for GSK3858279 versus PBO was –1.18 (–2.15, –0.20) and –1.09 (–2.29, 0.12) for average and worst knee pain intensity, respectively (probability of true difference < 0: >99% and 96%). GSK3858279 showed greater improvement in WOMAC pain and function scores versus PBO (**Figure**). At Day 57, the difference (95% CrI) in CFB for GSK3858279 versus PBO was –1.41 (–2.35, –0.46) for pain and

Figure. Posterior median change from baseline in average (A) and worst (B) knee pain intensity score, and WOMAC pain (C) and function (D) score



Average and worst knee pain intensity and WOMAC pain and function were assessed by participants using an 11-point numerical rating scale, where scores range from 0 (no pain/difficulty) to 10 (worst imaginable pain/difficulty). All analyses were performed in the intent-to-treat population using a Bayesian repeated measures model adjusting for treatment, week, baseline and the treatment by week and baseline by week interactions using non-informative priors. (A, B) For each assessment visit, the mean average and mean worst pain scores for the 7 days preceding the visit were calculated for each participant. Data available for n=24 for all visits for GSK3858279, and for n=24 (Baseline, Wks 1 and 2), n=23 (Wks 3, 4 and 6), and n=22 (Wks 5, 7, and 8) for placebo. (C, D) Across the assessed timepoints, data were available for n=22–24 for both GSK3858279 and placebo. CrI, credible interval; Wk, Week; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index.

–1.29 (–2.28, –0.29) for function (probability of true difference < 0: >99% for both). Adverse events (AE) occurred in 21/24 (88%) and 15/24 (63%) participants, GSK3858279 and PBO, respectively. There were no serious AEs or deaths.

Conclusion: Weekly dosing for 8 weeks with GSK3858279 has clinical activity (improved pain scores) and a favourable safety profile in patients with OA knee pain. These compelling data warrant further study of the effectiveness and safety of GSK3858279 in people with OA pain.

Implementing an Osteoarthritis Management Program to Deliver Guideline-Driven Care for Knee and Hip Osteoarthritis in a U.S. Academic Health System

Kathryn Miller[1], **Divya Vundamati**[2], Linda Baier[1], Roger Brown[1], Tommy Yue Yu[1] and Christie M. Bartels[3], [1]University of Wisconsin, Madison, WI, [2]UW Health, Madison, WI, [3]University of Wisconsin, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess patient outcomes from an Osteoarthritis Management Program (OAMP) situated in an academic medical center.

Methods: Eligibility for this open cohort study included adults with knee or hip osteoarthritis (OA) who attended at least one OAMP visit from 7/1/2017 to 1/15/2021. The OAMP was designed to deliver 1-5 visits across 12 months. A multidisciplinary team provided OA education and self-management; exercise and nutrition; weight loss; pharmacologic management; and assessed mood, sleep, quality of life, and disordered eating patterns. Patient BMI, pain and function were assessed at each visit. Primary patient outcomes included pain rated on the 0-10 Visual Analogue Scale (VAS) and function assessed by the 30-Second Chair Rise test and Timed-Up-And-Go (TUG).

Results: Of the 953 patients attending 2531 visits, most were female (72.6%), older (62.1 ± 10.8), and Caucasian (91.1%). Half (48.5%) were employed and most were insured by Medicare (51.2%) or commercial health insurance (38.8%). Obesity was prevalent (BMI 40.9 ± 10), and bilateral knee OA was the most common diagnosis (42.6%). Assist device use was common (32.95%). Pain changed insignificantly from an average baseline in men of 4.22 ± .177 (0-10 VAS) to 4.78 ± .63 at 12 months. Women also had no significant change in pain. Overweight or obese men had a decrease in BMI over the first 12 months from baseline BMI of 42.25 ± .58 to 40.10 ± .92. Overweight or obese women did not had a significant decrease in weight with baseline BMI 42.22 ± .37 and 12 month BMI 41.28 ± .58. Baseline functional testing scores were lower than normal values for a population of this age, with no significant differences between women and men or after completion of OAMP treatment. Patients with severe baseline pain (7-10 on the VAS) were 94% (95% CI 1.61-2.36) more likely to report decreased pain after OAMP treatment than patients with lower baseline pain. Patients with a starting BMI of 40+ were

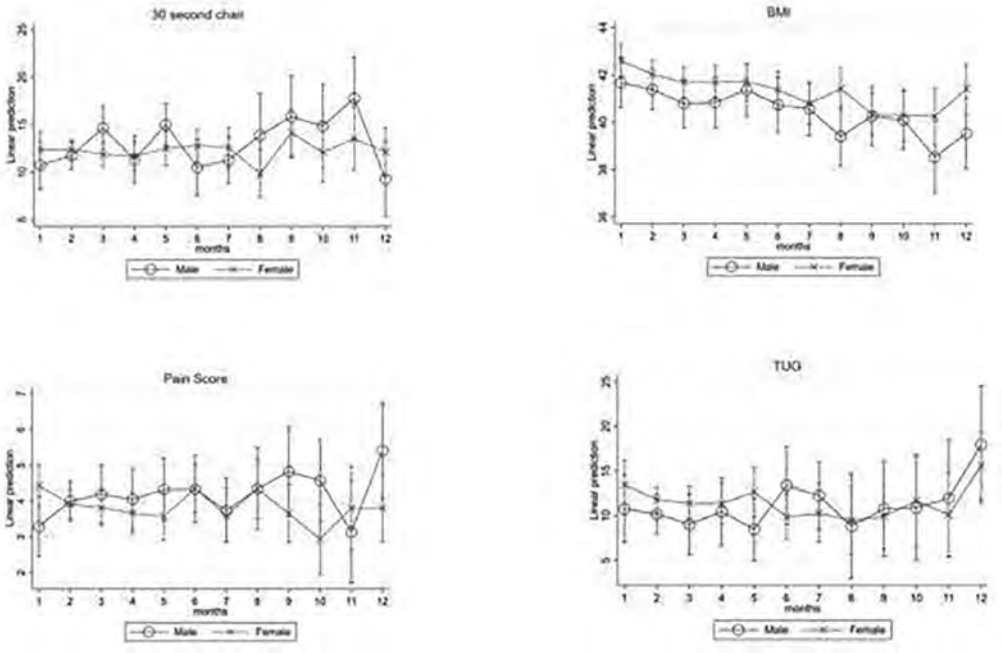

Figure 1. Change in BMI, Pain (0-10 VAS), 30 sec chair rise test, and TUG time from baseline to 12 months.

60% (95% CI 1.2-2.1) more likely to lose weight than patients with a lower BMI. Patients who did not have health insurance had a shorter treatment duration.

Conclusion: This open cohort study of a guideline-driven OAMP demonstrates that patients with the highest baseline pain and BMI were more likely to experience reductions in pain and BMI respectively. Uninsured patients had the shortest treatment duration. Next steps will be to identify the baseline characteristics of patients who will benefit most from OAMP treatment and to continue exploration of barriers to guideline-recommended care. OA continues to be an under-treated chronic disease and these results an important start to understanding patient outcomes related to OAMP programs within the U.S. healthcare system.

Heterogeneity and Natural History of Medial Fixed Joint Space Width in Healthy Knees Among Women and Men: Data from Three Large Cohort Studies

Kent Kwoh[1], Erin Ashbeck[2], Edward Bedrick[1], Yvonne Golightly[3], Zong-Ming Li[1], Jean liew[4], Amanda Nelson[5], Tuhina Neogi[6], Xiaoxiao Sun[1] and Jeffrey Duryea[7], [1]University of Arizona, Tucson, AZ, [2]University of Arizona Arthritis Center, Tucson, AZ, [3]University of Nebraska Medical Center, Omaha, NE, [4]Boston University, Boston, MA, [5]University of North Carolina at Chapel Hill, Chapel Hill, NC, [6]Boston University School of Medicine, Boston, MA, [7]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Radiographic joint space width (JSW) is commonly used to assess structural progression in randomized controlled trials and observational studies of knee osteoarthritis (KOA). No reference standards for healthy knee aging in terms of JSW have been established. Our objective is to establish healthy knee aging norms for medial fixed JSW (fJSW) by estimating sex-specific distribution percentiles in knees without OA (i.e., no osteophytes [i.e., Kellgren-Lawrence grade [KLG] grade 0]) and no frequent knee pain, from age 45 to 90 years.

Methods: We identified x-rays of healthy knees, defined as knees with no evidence of OA (i.e., KLG grade 0) and no reported frequent knee pain (i.e., pain on more than half the days of the past 30 days) from the Johnston County Osteoarthritis Study (JoCoOA), the Multicenter Osteoarthritis Study (MOST), and the Osteoarthritis Initiative (OAI). Participants in all three studies underwent fixed flexion PA knee radiography at baseline and during ~7 years of follow-up for MOST and OAI and between 1999 to 2018 for JoCoOA. We fit a linear mixed model for medial fJSW (x=0.250) with random effects for participants and knees within participants; fixed effects for age as a cubic polynomial, sex, race, and study; and all two-way and three-way interactions to allow for study heterogeneity and differences by sex and race, where age was the metameter of time. Only time-points with KLG=0 x-rays and no participant-reported frequent knee pain were included in the analysis.

Results: The sample consisted of 3,116 participants who contributed 4,670 knees with at least one healthy time point, for a total of 12,347 healthy time point observations, including 2,349 from JoCoOA, 5,760 from MOST, and 4,238 from OAI. Participants self-identified as Non-Hispanic White (83%) and African American (17%), with 58% reporting female sex. Figure 1 shows sex-specific distributions of medial fJSW in healthy knees from age 45 to 90 years, with estimated percentile curves.

Conclusion: The natural history of medial fJSW among healthy knees is gradual loss with age. Women experiencing healthy knee aging had less fJSW than men across the spectrum of age. A large heterogeneity of medial fJSW in healthy knees was observed at all ages between 45 and 90 years. Healthy knee aging reference norms will aid our understanding of the natural history of fJSW.

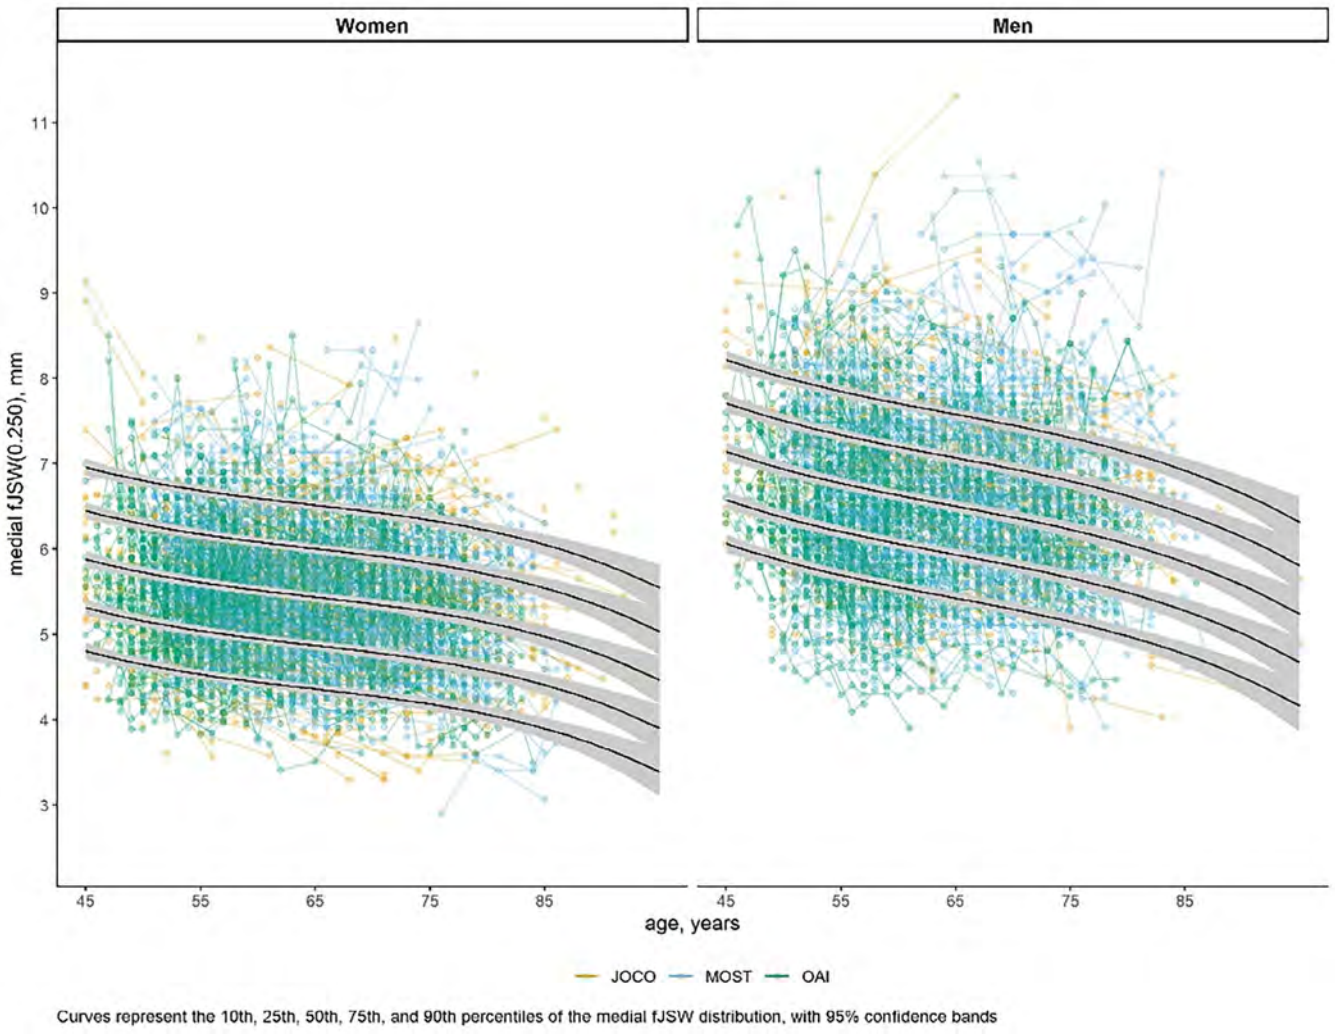

Figure 1. Healthy knees by sex

Frontal Lobe Activation and Gait Alterations During Single- and Dual-task Walking in People with Knee Osteoarthritis: A Functional Near-infrared Spectroscopy Study

Soyoung Lee, Meryem Yücel, Claudio Ferre, Baekdong Cha, Ehyun Kim and Deepak Kumar, Boston University, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Altered gait patterns, including high variability or muscular co-contraction, can increase fall risk and worsen disease progression in people with knee osteoarthritis (OA). However, the neural substrates underlying altered motor performance during walking in this population are unknown. Over-recruitment and reduced frontal lobe capacity during walking with or without a cognitive task have been reported in other populations with gait impairments but have not been examined in knee OA. Our objectives were (1) to assess frontal lobe activation during single- and dual-task walking in people with knee OA and (2) to examine the association of frontal lobe activation with motor and cognitive performance.

Methods: Individuals with symptomatic knee OA (n=20, **Table 1**) completed three tasks, (1) single-task walking (STW) at a self-selected pace for 8 bouts of 30s interspersed with 11-15s standing periods, (2) subtraction by 7 from a 3-digit number while seated (Serial 7), and (3) dual-task walking (DTW), a combination of STW and Serial 7. During these tasks, participants wore a functional Near-Infrared Spectroscopy (fNIRS) device to assess frontal lobe activation and inertial sensors on the trunk and legs for gait assessment. Activation in bilateral superior, middle, and inferior frontal lobes was assessed as the change in oxygenated hemoglobin concentration (HbO) in each task relative to quiet standing or sitting. Motor performance during walking was assessed as step time coefficient of variance (CoV) and gait speed. Cognitive performance was assessed as the percentage of correct counts during serial subtraction. We used repeated measures ANOVA to compare the outcomes between tasks and assessed the correlation between middle frontal lobe HbO and motor and cognitive performance in each task.

Results: Frontal lobe HbO was higher during STW and DTW compared to Serial 7 but not significantly different between STW and DTW (**Figure 1A**). Step time CoV was not different between STW and DTW, but gait speed was lower during DTW; cognitive performance was not different between Serial 7 and DTW (**Figure 1B**). Greater middle frontal lobe HbO was correlated with lower step time CoV during STW and DTW; none of the other correlations were significant (**Figure 2**).

Table1. Participant characteristics

	n=20
Age, (years), Mean (SD)	64.0 (8.9)
Female, n (%)	9 (45.0)
BMI, kg/m^2, Mean (SD)	30.9 (5.6)
KOOS Pain, Mean (SD)	67.5/100 (12.5)
MMSE Score	28.9 (0.8)

SD = standard deviation; KOOS = Knee injury and Osteoarthritis Outcome Score; MMSE = Mini-Mental State Examination.

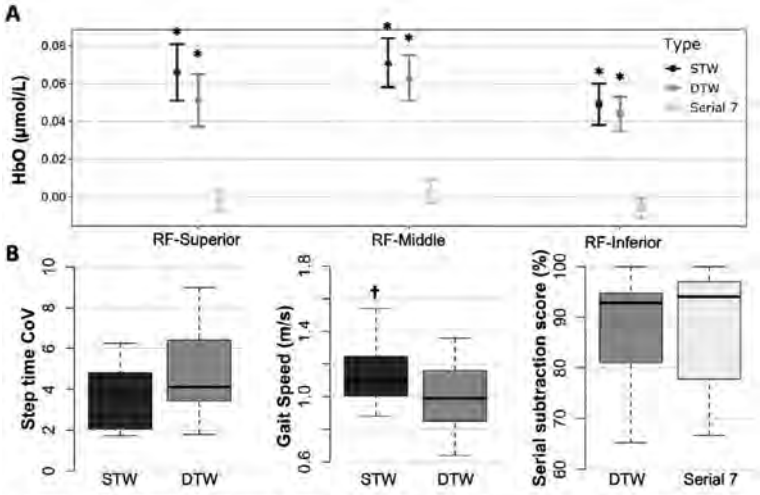

Figure 1. A. Mean and standard error for HbO in all subregions of right frontal lobe in each task. Similar patterns were found in the left side frontal lobe. *Indicates significant difference compared to Serial 7 at $p < 0.05$; HbO: concentration changes in oxygenated hemoglobin. RF: Right frontal lobe. **B.** Distribution of motor and cognitive performance outcomes between tasks. †Indicates significant difference compared to DTW at $p < 0.05$; Middle line in the box = Median; Lower and Upper line of the box = 1st and 3rd quartiles; CoV: Coefficient of Variance = (Standard deviation / Mean)*100; Serial 7 Score (%) = (Number of correct counts / Number of total counts)*100; STW: Single-task walking; DTW: Dual-task walking.

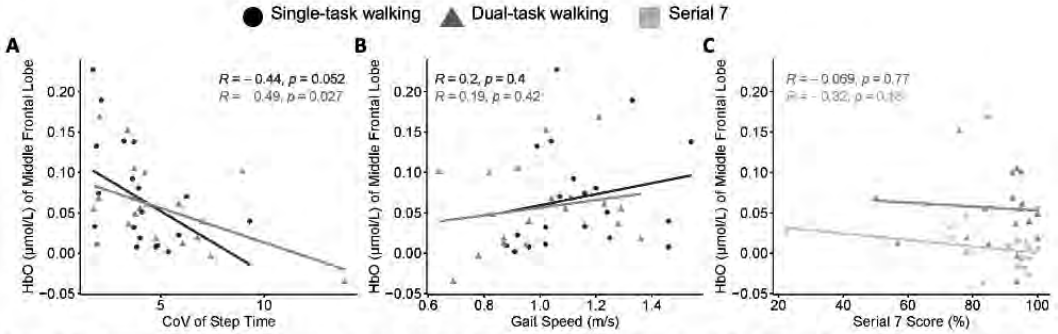

Figure 2. Correlation between bilateral middle frontal lobe HbO and (A) step time CoV during STW and DTW, (B) gait speed during STW and DTW, and (C) serial subtraction score during Serial 7 and DTW. *CoV: Coefficient of Variance; HbO: concentration changes in oxygenated hemoglobin; STW = single-task walking; DTW = dual-task walking*

Conclusion: Greater frontal lobe HbO during STW and DTW vs. Serial 7 suggests a greater need for executive control during walking. This is supported by the correlation between higher frontal lobe activation and lower gait variability (i.e., better motor performance). However, an absence of a further increase in HbO from STW to DTW reflects a lack of additional executive resources (i.e., ceiling effect). This is aligned with prior studies in other populations with gait impairments (e.g., Post-stroke, Parkinson's Disease). It also appears that people with knee OA prioritized the cognitive task during DTW given the deterioration in motor task performance compared to STW but similar cognitive performance compared to Serial 7. This may increase their risk for instability or falls during real-world walking conditions that typically require dual-tasking, and interventions to improve dual-task walking performance may need to be considered.

Abstract Number: 0313

The Influence of Pain Catastrophizing on Pain and Function After Knee Arthroplasty for Osteoarthritis

Diana, Xin Hui Chan[1], Seyed Ehsan Saffari[2], Steven, Bak Siew Wong[3], Seng Jin Yeo[1], Vikki Wylde[4], Julian Thumboo[1] and **Ying Ying Leung**[1], [1]Singapore General Hospital, Singapore, Singapore, [2]Center for Quantitative Medicine, Duke-NUS Medical School, National University of Singapore, Singapore, Singapore, [3]Sengkang General Hospital, Singapore, Singapore, [4]University of Bristol, Bristol, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the association between pre-operative pain catastrophizing and pain and function outcomes up to one year after knee arthroplasty.

Methods: We used data from a cohort study of patients undergoing primary arthroplasty (either total knee replacement or unicompartmental knee replacement) for knee osteoarthritis. Pain catastrophizing was collected pre-operatively using the Pain Catastrophizing scale (PCS). Other baseline variables included demographics, body mass index, radiographic severity, anxiety, depression, and knee pain and function assessed using the Western Ontario and McMaster University Index (WOMAC). Patients completed the WOMAC at 6- and 12-months after arthroplasty. WOMAC pain and function scores were converted to interval scale and the association of PCS and changes of WOMAC pain and function were evaluated in generalized linear regression models with adjustment with confounding variables.

Results: Of the 1,200 patients recruited into the cohort study, 1136 underwent arthroplasty, 1102 provided data at 6-months post-operative and 1089 provided data at 12-months post-operative. Mean (SD) age of participants was 65.9 (7.0) years, 70% were female, 84% were Chinese, and 92% had a total knee replacement. PCS was associated with a change in WOMAC pain at both 6- and 12-months post-operative after adjustment. PCS was associated with a change in WOMAC function in univariate analysis but not after adjustment in multivariable models.

Table 1. Variables associated with change in WOMAC pain at 6-months.

	Univariate model		Multivariable model	
Variables	β (95% CI)	p value	β (95% CI)	p value
Age	0.04 (0.01, 0.06)	0.015	-	-
Sex (female vs. male)	-0.73 (-1.15, -0.31)	0.001	-0.34 (-0.71, 0.03)	0.071
BMI	-0.07 (-0.11, -0.02)	0.002	0.03 (-0.01, 0.07)	0.142
Education (Secondary or above vs primary)	0.18 (-0.21, 0.58)	0.365	-	-
Radiographic severity (KLs3 vs. KL4)	**-0.75 (-1.15, -0.36)**	**<0.001**	**-0.87 (-1.21, -0.53)**	**<0.001**
UKA vs. TKA	0.08 (-0.63, 0.79)	0.834	-	-
Functional comorbidity index	-0.27 (-0.45, 0.09)	0.003	-0.17 (-0.18, 0.15)	0.838
HADS – anxiety	-0.11 (-0.16, -0.06)	<0.001	0.05 (-0.01, 0.11)	0.122
HADS - depression	-0.16 (-0.22, -0.10)	<0.001	0.03 (-0.05, 0.11)	0.460
Baseline WOMAC total score*	**-0.26 (-0.29, -0.24)**	**<0.001**	**-0.26 (-0.29, -0.23)**	**<0.001**
Pain Catastrophizing scale	**-0.08 (-0.10, -0.06)**	**<0.001**	**-0.02 (-0.04, -0.00)**	**0.024**

Variables with P<0.1 were entered into analysis. *Rasch transformed interval score was used.
Bold: variables statistically significantly associated with outcome of interest in the model
Abbreviations. All figures given as mean (standard deviation) unless specified otherwise.
Abbreviations. BMI: body mass index; CI: confidence intervals; HADS: hospital anxiety and depression scale; KA: knee arthroplasty; KL: Kellgren-Lawrence grading; TKA: total knee arthroplasty; UKA: unicompartmental knee arthroplasty; WOMAC: Western Ontario and McMaster University Index; vs.: versus

Conclusion: In this large cohort study, pre-operative pain catastrophizing was associated with lower improvements in pain at 6-months and 12-months after arthroplasty. Future interventional studies are needed to evaluate if reducing pre-operative pain catastrophizing can improve pain outcomes after arthroplasty.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: This study (NCT04124042) was designed to assess the safety, tolerability, and efficacy of XT-150, a non-viral gene therapy, in adult participants with moderate to severe pain due to osteoarthritis (OA) of the knee. XT-150 is a plasmid designed to locally express a proprietary version of the anti-inflammatory cytokine, interleukin (IL)-10. IL-10 has been shown to play a key role in pain reversal but has proven a challenging therapeutic candidate due to its short half-life.[1]

Table 1: Summary of Treatment Administered

	Number (%) of Participants Dosed					
	0.15 – 0.15 mg XT-150 (N=49)	0.15 – 0.45 mg XT-150 (N=47)	0.45 – 0.15 mg XT-150 (N=47)	0.45 – 0.45 mg XT-150 (N=47)	Placebo – 0.15 mg XT-150 (N=48)	Placebo – 0.45 mg XT-150 (N=48)
Stage A						
First dose administered	49 (100.0)	47 (100.0)	47 (100.0)	47 (100.0)	48 (100.0)	48 (100.0)
Dosed per protocol						
Yes	49 (100.0)	46 (97.9)	47 (100.0)	47 (100.0)	48 (100.0)	48 (100.0)
No	-	1 (2.1)[a]	-	-	-	-
Treatment						
0.15 mg XT-150	49 (100.0)	46 (97.9)	-	-	-	-
0.45 mg XT-150	-	1 (2.1)	47 (100.0)	47 (100.0)	-	-
Placebo	-	-	-	-	48 (100.0)	48 (100.0)
Stage B						
Second dose administered	39 (79.6)	41 (87.2)	37 (78.7)	41 (87.2)	43 (89.6)	43 (89.6)

We hypothesize that local expression of IL-10 via gene therapy may be a more appropriate route of administration for sustained effects and has shown acceptable safety profiles and no-anti-IL-10 antibodies in previous clinical and pre-clinical studies.[2]

Methods: We describe safety results from a two-stage double-blind Phase 2 study. Stage A compared 2 active doses of XT-150 to a placebo (phosphate-buffered saline) control arm. Stage B was a 6-month follow-up with the option to randomly receive a single injection of XT-150 at one of two doses (0.15 or 0.45 mg) between Day 180 and Day 330. All intra-articular (IA) injections of XT-150 or placebo were performed under imaging guidance **(Table 1)**. Participants 45-85 years of age had symptomatic knee OA defined as a WOMAC Pain score of ≥8 (out of 20) and Kellgren-Lawrence grade 2 or 3 at screening. After signing the Informed Consent Form (ICF), all were assessed for safety by physical examination, laboratory assessments, vital signs, adverse events (AEs) and serious AEs (SAEs) throughout the study. All participants (N=286) receiving any amount of XT-150 or placebo were included in the safety analysis. Safety data were summarized using descriptive statistics according to a prespecified statistical analysis plan (SAP).

Results: Drug-related AEs in this study were local with no systemic AEs. Local injection drug-related treatment-emergent adverse events (TEAEs) were reported by 6 patients (2%); arthralgia was the most common **(Table 2)**. Overall, XT-150 was generally well tolerated in single and multiple IA injections. No dose-, treatment-, or sequence-related trends were reported for any safety domain for XT-150 **(Table 3)**. The most commonly occurring TEAE for all participants who received active study drug was arthralgia (13% of participants). One unrelated TEAE of Grade 5 intensity, a myocardial infarction, was reported following the second dose in a patient with a history of CVD. SAEs were reported across all arms and treatment sequences with a total of 17 (6%) participants reporting 18 SAEs over the 360-day study period, all of which were considered unrelated to the study treatment. There were no AEs of special interest related to study treatment. Anti-IL-10 antibodies were not detected after single or repeat injections.

Conclusion: Safety data from this study support continued investigation of XT-150 for the management of pain and improvement of physical function in patients with knee OA. The local nature of treatment-related AEs and the absence of treatment-related SAEs support a two-dose regimen of 0.45 mg XT-150 (total dose of 0.9 mg) as safe and well-tolerated for future studies.

Abstract Number: 0315

Identification of Calcium Crystals in End-Stage Osteoarthritis with Raman Spectroscopy

Tom Niessink[1], Tim Welting[2], Matthijs Janssen[3], Cees Otto[4] and Tim Jansen[5], [1]University of Twente, Utrecht, Netherlands, [2]MUMC+, Maastricht, Netherlands, [3]Viecuri MC / Venlo, Wijgmaal, Belgium, [4]University of Twente, Enschede, Netherlands, [5]VieCuri MC, Venlo, Netherlands

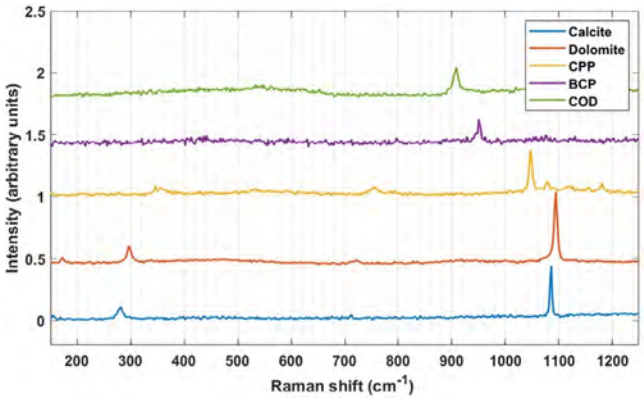
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcium containing crystals in osteoarthritis (OA) are of interest as they potentially stimulate the NRLP-3 inflammasome and may become treatable with novel therapeutics. Previous studies demonstrated a presence of calcium pyrophosphate (CPP) and basic calcium phosphate (BCP) crystals in early and advanced OA [1]. Calcium carbonate crystals have been found in cartilage specimens of advanced OA and have recently been shown to potentially occur early in development of cartilage calcification [2].

Methods: Synovial fluid samples from advanced knee OA cases were collected pre-operatively from the Maastricht University Medical Center (MUMC+). The population includes both males and females and all patients were above 18 years of age. Patients gave written informed consent before collection of their synovial fluid. Samples were analyzed with an integrated Raman polarized light microscope. Samples were considered positive for a certain type of crystal if at least one crystal with a distinctive spectrum could be identified.

Results: Calcium containing crystals were present in all (100%) of the 36 samples. 34 (94.4%) of the samples contained calcite (calcium carbonate) crystals. Dolomite (calcium magnesium carbonate) crystals were present in 10 (27.8%) samples, 9 (25.0%) samples contained both types of calcium carbonate crystals. CPP crystals were present in 33.3% of samples. Basic calcium phosphate crystals were present in 9 (25.0%) samples, all of which were hydroxyapatite. Calcium oxalate crystals were present in 7 (19.4%) samples, 3 of which were identified as calcium oxalate dihydrate (COD) and 4 of which were identified as calcium oxalate monohydrate. Most of the samples (80.6%) contained more than one type of calcium crystal, but CPP and BCP were never identified simultaneously in one sample. Raman spectra of identified particles are shown in figure 1.

Conclusion: Calcium containing crystals are common in synovial fluid samples from knee joints in patients with end-stage osteoarthritis. Raman spectroscopy is a novel technique for rheumatology which enables reliable detection and objective identification of crystals such as calcium carbonate. The observation of calcium carbonate (calcite) crystals in synovial fluids of OA patients is novel and a promising subject of further study. Pathways to presentation in synovial fluid and inflammatory properties should be investigated.



Raman spectra of identified calcium containing crystals.

Relationship of Sensitization to Pain Severity in Patients with Knee Osteoarthritis

Lindsey MacFarlane[1], Hanna Mass[1], Catherine Yang[1], Jose Acosta Julbe[1], Antonia Chen[1], Jeffrey Lange[1], Morgan Jones[1], Faith Selzer[1], Jamie Collins[1], Elena Losina[2] and Jeffrey Katz[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain in knee osteoarthritis (OA) is multifactorial and influenced by factors including pain sensitization. Most literature on sensitization and OA has contrasted persons with and without OA. We examined the association between knee pain severity and sensitization in a cohort of persons with OA. Further, within individuals with discordant knee pain, we compared sensitization between knees.

Table 1: Sensitization in differing pain levels

	Higher pain (n=44 individuals)	Moderate pain (n=44 individuals)	Lower pain (n=9 individuals)	P-value*
Person level analysis				
Pain pressure threshold wrist (lbs.), mean (SD)	7.5 (3.8)	7.5 (3.3)	8.6 (3.1)	0.50
Temporal summation 3rd digit, mean (SD)	1.5 (1.4)	1.4 (1.6)	0.3 (0.8)	0.01
Central Pain Modulation efficiency (%), mean (SD)	112.1% (29.6)	121.2% (34.0)	131.3 (28.9)	0.045
	Higher pain (n=60 knees)	Moderate pain (n=65 knees)	Lower pain (n=69 knees)	P-value*
Knee level analysis				
Pain pressure threshold knee (lbs.), mean (SD)	10.0 (5.8)	11.5 (5.4)	13.0 (6.1)	0.001
Temporal summation knee, mean (SD)	2.4 (1.7)	1.6 (2.0)	1.7 (1.6)	0.08

Pain pressure threshold range 0-25 lbs
Temporal summation range 0-10
KOOS: Knee injury and osteoarthritis outcome score
SD: standard deviation
NS: not statistically significant
*Person level: ANOVA; knee level: linear mixed effects model

Sensitization in differing pain levels

Table 2: Peripheral sensitization between knees in individuals with discordant levels of pain				
	Knee with higher pain (n=21)	Knee with lower pain (n=21)	Mean Difference (95% CI)	P-value
Knee level analysis				
Pain pressure threshold knee (lbs), mean (SD)	9.3 (6.4)	11.4 (6.6)	2.5 (1.4,3.9)	0.01
Temporal summation knee, mean (SD)	2.7 (1.6)	2.4 (1.8)	1.1 (0.5,1.7)	0.2
KOOS: Knee injury and osteoarthritis outcome score SD: standard deviation				

Peripheral sensitization between knees in individuals with discordant levels of pain

Methods: We recruited patients with knee OA from an orthopedic practice. Knee pain was assessed in each knee using the Knee Injury and Osteoarthritis Outcome Score (KOOS 0-100, 100 best) and categorized into tertiles; higher (< 47 points), moderate (^{3}47 points and < 69), and lower (^{3} 69 points). We considered individuals to have 'discordant pain' if one knee was in the highest tertile and the other in the lowest. Participants underwent quantitative sensory testing (QST) including pain pressure threshold (PPT), temporal summation (TS), and conditioned pain modulation (CPM). We measured PPT at each knee and one wrist. We assessed TS at each knee and 3rd digit. We calculated CPM efficiency as the ratio of mean PPT testing at the wrist before and after the conditioning stimulus (PPT post/PPT pre). Higher TS scores and lower PPT and CPM indicate greater sensitization. We assessed PPT and TS at the knee in knee level analyses and CPM, PPT at the wrist and TS at the digit in person level analyses.

We investigated the relationship between knee pain and sensitization in knee-level and person-level analyses. In person level analyses, we classified individuals into pain tertiles of their most painful knee and examined differences across persons in CPM efficiency, TM at the 3rd digit, and PPT of the wrist. We assessed differences in sensitization between knee pain tertiles using ANOVA. In knee level analyses, we used linear mixed effect models to account for within person correlations. We used paired t-tests to compare differences in QST between discordant knees within an individual.

Results: The sample included 194 knees from 97 participants. Participants had a mean age of 64 years (SD 11), BMI of 30 (SD 8), and 63 (72%) were female. In person level analyses, we observed differences in TS at the 3rd digit across the pain severity tertiles with TS of 1.5 (SD 1.4) in the higher pain group vs 0.3 (SD 0.8) in the lower. We observed small (< 0.5 SD) person level differences across pain tertiles in PPT of the wrist and CPM (Table). In knee level analyses, we observed PPT at the knee increased modestly across pain tertiles. Among the 21 individuals with discordant knee pain, the more painful knee demonstrated modestly lower PPT at the knee (differences < 0.5 SD).

Conclusion: These data support prior research demonstrating greater sensitization in persons with greater knee pain. Our design permitted investigation of sensitization at the knee level. While knees with more pain (across persons and within person), generally had greater sensitization than knees with less pain, the magnitude of these differences was small. The limited influence of sensitization on knee pain in these cross-sectional analyses suggests investigators should have modest expectations of the efficacy of treatments targeting sensitization.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Osteoarthritis – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The 16-week Plants for Joints (PFJ) multidisciplinary lifestyle program, based on a whole-food plant-based diet, physical activity, and stress management, significantly reduced The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score compared to usual care in people with hip and/or knee osteoarthritis (OA) and metabolic syndrome.[1,2] The objective was to determine the long-term effectiveness of the PFJ program on pain, stiffness, and function in people with OA.

Methods: People with knee and/or hip OA and metabolic syndrome were randomized to receive the PFJ program in addition to usual care, or the control group which received usual care. After this 16-week RCT period the control group also received the program. After completion of the program all participants were followed-up for one year with biannual visits and 6 adherence-promoting webinars. Medication changes (pain, cholesterol, and diabetes medication) were assessed at one year as an "increase," "stable," or "decrease" compared to baseline. Secondary outcomes included anthropometric and metabolic markers. An intention-to-treat analysis with a linear mixed model was used to analyze within-group differences.

Results: 49 of 64 participants (77%), who completed the initial 16-week clinical trial, completed the one-year follow-up. 84% of participants were female with a mean (SD) age of 63 (6) and body mass index of 33 (5) kg/m^2. In the year after completing the PFJ program the WOMAC score was lower, yet increased slightly again, whereby a mean –7.8-point difference was observed after one year compared to baseline values ($p < 0.001$) (Figure 1). All components of the WOMAC improved significantly compared to before the program (Table 1). Of the 18 participants who completed the follow-up and used pain medication, 11 (61%) decreased or stopped, 3 had stable, and 4 had increased medication. After the 1-year follow-up period

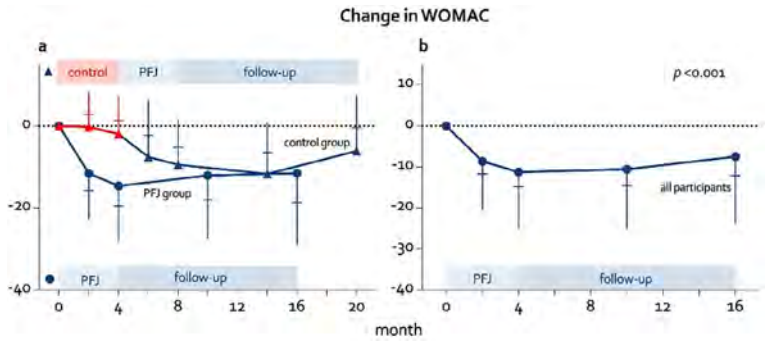

Figure 1. Mean change in WOMAC (a) during the randomized controlled trial phase and one-year follow-up period per trial arm and (b) for the whole cohort before and after completing the lifestyle intervention and one year follow-up.

Table 1. Plants for Joints cohort at start and end of the 16-week intervention period as well as during the one year extension study (6 and 12 months after completing the intervention). Continuous variables reported as mean (SD) when normally distributed or as median [IQR] when skewed. Within-group difference shown between start of the lifestyle intervention and end of the 12-month follow-up determined using the linear-mixed model when model assumptions were met. For variables in which model assumptions were not met (†) a linear-mixed model was performed after log transformation and within group differences were reported as median difference of complete paired values determined using a Wilcoxon test (p-values from the linear mixed model are shown, all were similar to the Wilcoxon test).

Body mass index (kgm-1)	33.3	32.5	31.7	31.5	32.9	−1.3 (−1.7 to −0.8)	<0.001
Waist circumference (cm)	110	105.9	104.6	105.7	107.4	−4.3 (−6.1 to −2.4)	<0.001
Metabolic markers							
HbA1c (mmol/mol)	42.6	40.7	40.3	40.2	40.5	−1.2 (−2.0 to −0.4)	0.003
Fasting blood glucose (mmol/l)	5.8	5.5	5.5	5.4	5.2	−0.4 (−0.6 to −0.2)	<0.001
LDL-cholesterol (mmol/l)	3.6	3.2	3.3	3.3	3.6	−0.1 (−0.3 to 0.2)	0.7
HDL-cholesterol (mmol/l)	1.4	1.4	1.4	1.4	1.4	0.0 (0.0 to 0.1)	0.4
Triglycerides (mmol/l)	1.6	1.4	1.6	1.5	1.4	−0.1 (−0.3 to 0.0)†	0.1
Systolic blood pressure (mmhg)	145	141	144	142	136	−8 (−13 to −3)	0.005
Diastolic blood pressure (mmhg)	91	86	89	86	85	−6 (−9 to −3)	<0.001

weight, waist circumference, HbA1c, CRP, and blood pressure became or remained significantly lower than baseline values, although there was no longer a significant difference in LDL cholesterol. Furthermore, of those completing the follow-up, 3 (33%) and 8 (44%) participants decreased diabetes and cholesterol medication respectively while only 2 participants had increased medication.

Conclusion: The PFJ lifestyle program significantly decreased pain, stiffness, and improved function in people with OA and metabolic syndrome and its effects were largely sustained till one year after program completion with reduced pain medication. Metabolic benefits found after the lifestyle intervention were partially sustained, possibly indicating attenuated adherence to the program in the follow-up.

Abstract Number: 0318

The Association of CT-Detected Intra-Articular Mineralization with MRI-Detected Effusion-Synovitis and Hoffa's Synovitis in Knee OA: The Multicenter Osteoarthritis Study

Jean Liew[1], Gabriela Rabasa[1], Mohamed Jarraya[2], Ali Guermazi[1], David Felson[1], Beth Lewis[3], John Lynch[4], Michael Nevitt[4], James Torner[5] and Tuhina Neogi[6], [1]Boston University, Boston, MA, [2]Massachusetts General Hospital, Boston, MA, [3]University of Alabama at Birimingham, Birmingham, AL, [4]University of California San Francisco, San Francisco, CA, [5]University of Iowa, Iowa City, IA, [6]Boston University School of Medicine, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Intra-articular (IA) deposition of calcium crystals (chondrocalcinosis), is common in knee OA. While calcium crystals can cause inflammatory arthritis, their contribution to joint inflammation in OA, as manifested by effusion-synovitis and Hoffa's synovitis on MRI, is unclear. Clarifying the role of calcium crystal deposition in joint-level inflammation would provide improved understanding for the role of targeted cytokine therapy in those with IA mineralization. Prior studies have been limited by use of radiographs to detect chondrocalcinosis. In contrast, CT provides higher sensitivity for detecting IA mineralization as well as identifying potential tissue-specific effects of IA mineralization in OA. We aimed to evaluate the cross-sectional and longitudinal relation of CT-detected IA mineralization to effusion-synovitis and/or Hoffa's synovitis on MRI with the hypothesis that IA mineralization contributes to the worsening of synovitis in OA.

Methods: We included participants from the Multicenter Osteoarthritis (MOST) Study who had knee radiographs, CTs, and MRIs. IA mineralization was assessed on CT at baseline using the Boston University Calcium Knee Score (BUCKS), a semi-quantitative 0-3 scoring of the extent of mineralization in Whole Organ MRI Score (WORMS) subregions. We categorized presence of mineralization as a BUCKS score >0 as follows: 1) anywhere in the knee (including cartilage, meniscus, joint capsule, ligaments); 2) cartilage; 3) meniscus. Effusion-synovitis and Hoffa's synovitis were scored on MRI in one knee using MOAKS at baseline and two years later. For cross-sectional analyses, either effusion-synovitis and/or Hoffa's synovitis were considered present with MOAKS ≥1 in either score. For longitudinal analyses, worsening was defined as an increase of ≥1 in MOAKS, for either effusion-synovitis and/or Hoffa's synovitis scores. We evaluated the relation of IA mineralization to the presence of effusion-synovitis and/or Hoffa's synovitis cross-sectionally and their worsening longitudinally, using binomial regression with generalized estimating equations. Analyses were adjusted for age, sex, and body mass index.

Results: We included 1668 participants (mean age 60±9, 56% female, mean BMI 28.5±5 kg/m^2; 21% knees with radiographic OA) (**Table**). Any IA mineralization was present in 9.2%, effusion-synovitis in 49.1%, Hoffa's synovitis in 29.3%. Overall, 16.7% had worsening of either effusion-synovitis and/or Hoffa's synovitis on MRI at 2 years. The presence of any

4	7
Effusion-synovitis present*, % knees	29.3
Hoffa's synovitis present*, % knees	49.1
Effusion-synovitis and Hoffa's synovitis present*, % knees	29.3

* Effusion-synovitis and Hoffa's synovitis considered present if MOAKS ≥1

TABLE: Baseline characteristics of participants included in this analysis, n = 1668 individuals (1809 knees)

IA mineralization was associated with 30% higher prevalence of effusion-synovitis and/or Hoffa's synovitis cross-sectionally (PR 1.3, 95% CI 1.1-1.5), and 20% higher risk of worsening longitudinally (RR 1.2, 95% CI 0.8-1.6) (**Figure**).

Conclusion: CT-detected IA mineralization in various tissues was modestly associated with effusion-synovitis and Hoffa's synovitis at baseline and with worsening over 2 years. These findings are limited by the sample size.

Knee Flexion Contracture Was Associated with Articular Cartilage Loss in the Central Region but Cartilage Preservation in the Posterior Region of the Tibia: Data from the Osteoarthritis Initiative

Mark Campbell[1], Odette Laneuville[2] and Guy Trudel[3], [1]Elisabeth Bruyere Hospital, Ottawa, ON, Canada, [2]University of Ottawa, Ottawa, ON, Canada, [3]Ottawa Hospital Research Institute, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: A knee flexion contracture (FC), present in ~1/3 of patients with knee OA[1], is the inability to fully extend the knee[2, 3]. Having a FC means that anterior and middle regions of the tibial articular surface may experience reduced contact with the femur resulting in altered force transmission, a risk factor for cartilage loss[2]. The impact of FC on the articular cartilage regions of the tibia has been studied longitudinally in animals[2], but not humans. We tested for a quantitative longitudinal association between FC and cartilage loss in the tibia in patients with or at-risk of knee OA using MRI data from the Osteoarthritis Initiative (OAI) cohort. We hypothesized that FC would be associated with cartilage loss in tibial anterior and middle regions, which experience reduced load, but cartilage preservation in the posterior regions, where load is maintained.

Methods: 578 participants with baseline knee extension data and MRI at baseline and year 1 were analyzed. Lack of full knee extension to 0° was considered a FC. Cartilage outcomes were measured using 3T knee MRI coronal views[4]. Tibial articular cartilage was segmented into medial and lateral compartments, then further divided into anterior, central, and posterior regions[4]. We looked for associations between the presence of a knee FC, and cartilage thickness or % denuded bone (0mm thickness) over the 1-year period using ANCOVA, controlling for baseline outcomes and relevant covariates.

Results: Table 1 shows participant demographics. In the medial compartment, there was reduced cartilage thickness overall and in the center region, with increased % denuded bone overall and in the center and anterior regions. In the lateral compartment, there was reduced cartilage thickness overall and in the center and posterior regions with increased % denuded bone overall and in the posterior region (Table 2).

Knee FC was associated with increased % denuded bone in the medial center (β=0.465 [0.049,0.881], p=0.029) and preserved cartilage thickness in the medial posterior (β=0.015 [0.004, 0.027], p< 0.001) regions. There was a trend between FC and increased % denuded bone in the lateral anterior region (β=0.203 [-0.020,0.426], p=0.074; Table 3).

Summary of ANCOVA findings for regional effect of contracture

	Medial	Lateral
Anterior	-	↑ % denuded bone (trend)
Middle	↑ % denuded bone	-
Posterior	Cartilage preservation	-

[a] for contracture interaction with year 1 outcome after controlling for baseline outcome and adjusting for age, sex, BMI, knee alignment, baseline KL, WOMAC total score
*p<0.05 contracture vs no contracture
**p<0.01 contracture vs no contracture
***p<0.001 contracture vs no contracture

Conclusion: Knee FC was associated with regional cartilage loss in the center region and preservation in the posterior region of the medial tibia, with a trend towards cartilage loss in the lateral anterior region. Together, these findings are consistent with knee FC negatively impacting regions of the tibia articular cartilage with reduced load. Future studies should evaluate the effects of interventions to maintain full knee range of motion on articular cartilage preservation.

Background/Purpose: There are limited non-surgical options for patients with severe pain due to knee osteoarthritis (KOA). Using geniculate artery embolization (GAE) to infarct hypervascular synovium, a known correlate of pain, has been proposed as a potential novel therapy. However, GAE is invasive and requires a lower extremity angiogram, which may limit its acceptability. Understanding patient-centered acceptability of new therapies is crucial to gauge potential uptake and to estimate enrollment for randomized controlled trials (RCTs). The goal of this study is to evaluate whether GAE is acceptable to patients with painful KOA, and to explore the feasibility of performing an RCT of GAE.

Methods: Patients >50 years with a KOA ICD-10 code (M17.0, M17.1, M17.9) were identified from practices of rheumatologists and physiatrists at a musculoskeletal specialty hospital. Exclusion criteria included Kellgren and Lawrence grade IV, systemic rheumatic disease, prior surgery to the index knee, contemplating arthroplasty, severe comorbidities and a KOOS pain subscale >70. Subjects used a remote viewing platform to watch a 20-minute PowerPoint presentation, which described GAE, including its risks and benefits, and presented a hypothetical sham-controlled RCT (i.e. angiogram with GAE vs. angiogram alone). A trained research assistant conducted the call and was available to answer questions. After completion, the subject was asked whether they would find GAE acceptable in three scenarios: 1) routine clinical care 2) an RCT where 50% of subjects would receive an angiogram but no GAE 3) the same RCT but with the option for the angiogram-only group to receive GAE later.

[1]Includes NSAIDs, COX-2 inhibitors, acetaminophen, viscosupplementation, narcotics, corticosteroid injections, glucosamine, chondroitin, colchicine
[2]Includes herbal remedies, homeopathic medication, yoga, Tai chi, acupuncture, massage, relaxation, meditation, biofeedback, hydrotherapy, aquatic therapy, balneotherapy, electrotherapy, magnetotherapy
[3]Includes knee brace, patellar band, shoe orthotics or inserts, kinesiology taping
[4]Includes walking, swimming, stretching, warm or cold compress, activity modification, other physical activity
[5]Includes periodic rest during the day, platelet rich plasma, stem cell therapies, weight loss, ultrasound, topical ointments, other therapies

Results: 66 subjects enrolled, median age 69 [IQR: 61-74] years, 83% White, 4.5% Hispanic/LatinX, median BMI 26 [IQR: 23.2-29.5] kg/m^2. Overall, 37.9% would be definitely willing and 50% probably willing to have GAE as a routine clinical intervention; 24.2% would be definitely willing and 34.8% probably willing to participate in a sham controlled RCT; this increased to 27.3% and remained 34.8%, respectively, if GAE was offered to the sham control group later. Those definitely/probably unwilling to have GAE as routine care had lower catastrophizing scores, but they were not clinically meaningfully different. There were no other clinically or statistically significant differences in age, race, ethnicity, BMI, KOOS or PROMIS-29 between those willing or not willing to have GAE in any of the three scenarios.

Conclusion: Approximately 40% of representative patients with painful KOA would be definitely willing to undergo GAE and 24.2% would be definitely willing to participate in a sham-controlled RCT. Guaranteeing access to GAE as part of an RCT may only minimally improve recruitment. These data can inform trial planning. The large proportion of subjects willing to undergo GAE underscores the unmet therapeutic need in this patient population, and similar acceptability across different demographic strata suggests GAE could benefit a wide range of patients with KOA.

Abstract Number: 0321

Use of Proton Pump Inhibitors and Risk of Hip/knee Joint Replacement Among Patients with Osteoarthritis and Rheumatoid Arthritis

Koushik Sangaraju[1], Radu Grovu[2], Michael Kwark[2], Elizabeth Cohen[2], Amira Hassan[3] and Anastasia Slobodnick[2], [1]Staten Island University Hospital - Northwell Health, Staten Island, NY, [2]Northwell Health, Staten Island, NY, [3]Northwell Health, Brooklyn, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis and rheumatoid arthritis cause significant joint replacement morbidity. Proton pump inhibitors (PPIs) may contribute to chronic inflammation and joint degeneration due to side effects like hypomagnesemia and gut microbiota dysregulation. However, research on the association between PPI use and joint replacement risk is limited in osteoarthritis and lacks data in rheumatoid arthritis. Our study investigates the link between PPI usage and joint replacement risk in both osteoarthritis and rheumatoid arthritis patients.

Methods: This retrospective analysis included osteoarthritis and rheumatoid arthritis patients diagnosed using ICD10 codes from Northwell Health electronic medical records in 2020-2021. Proton pump inhibitor (PPI) use was confirmed through manual review of medical records. Joint replacement cases (hip/knee) were identified using CPT codes for total hip and knee replacement. Multivariate logistic regression analysis was conducted to compare joint replacement occurrence in PPI users versus non-users, while adjusting for underlying comorbidities. A p-value < 0.05 indicated statistical significance

Results: A total of 1980 patients were included, with 1449 having osteoarthritis and 531 having rheumatoid arthritis. The mean ages were 55.5 and 51.8 years for osteoarthritis and rheumatoid arthritis patients, respectively. Female predominance was observed, with 904 (63%) among the osteoarthritis group and 362 (73%) among the rheumatoid arthritis group. Proton pump inhibitors were taken by 522 osteoarthritis patients (36%) and 175 rheumatoid arthritis patients (33%). Comorbidities that were taken into consideration are tobacco use, alcohol use, coronary artery disease, cerebrovascular accident, peripheral artery disease, diabetes, malignancy, gout, osteoporosis, glucocorticoid use, overweight, obesity, morbid obesity, chronic kidney disease, end-stage renal disease, vitamin D deficiency.

PPI use in individuals with combined osteoarthritis or rheumatoid arthritis significantly increased the risk of joint replacement (OR 1.24, 95% CI 1.10-1.41, $p < 0.0004$). Among those with rheumatoid arthritis alone, PPI users also had a higher risk of joint replacement (OR 1.31, 95% CI 1.13-1.52, $p < 0.0002$). However, there was no significant difference in the risk of joint replacement between PPI users and non-users with osteoarthritis (OR 1.03, 95% CI 0.82-1.28, $p = 0.78$).

Conclusion: In conclusion, our study found that proton pump inhibitors (PPIs) are linked to an increased risk of joint replacement in individuals with combined osteoarthritis or rheumatoid arthritis. This association was significant for patients with rheumatoid arthritis but not for those with osteoarthritis alone. Further research is needed to understand the underlying

Table 1 – Baseline characteristics of osteoarthritis and rheumatoid arthritis patients

Baseline characteristics	Osteoarthritis (n=1449)	Rheumatoid arthritis (n= 531)

Validation of NICE Criteria for the Diagnosis of Knee Osteoarthritis

Lauren King[1], Ian Stanaitis[2], Vivian Hung[2], Sahil Koppikar[3], Esther Waugh[4], Lorraine Lipscombe[3] and Gillian Hawker[3], [1]Women's College Hospital & St. Michael's Hospital & University of Toronto, Toronto, ON, Canada, [2]Women's College Hospital, Toronto, ON, Canada, [3]Women's College Hospital & University of Toronto, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The NICE guideline on osteoarthritis (OA) recommends that adults aged ≥45 should be diagnosed with OA clinically, without investigations, if they have activity-related joint pain and either no morning joint-related stiffness or morning stiffness that lasts no longer than 30 minutes. While the NICE criteria are frequently used and referenced as

diagnostic criteria for OA, they have not been validated. The objective of this study was to validate the NICE criteria for knee OA. This was completed within the context of a larger project focused on identifying and treating OA in people with other chronic conditions.

Methods: This was a diagnostic test study. Reporting was guided by the SIGN checklist. We recruited participants with type 2 diabetes from endocrinology clinics at three academic hospitals in Toronto, Canada. We invited individuals aged ≥45 years with and without self-reported knee pain to participate (aiming for 50% with/without). We excluded individuals with a history of inflammatory rheumatic disease. Participants first self-completed a questionnaire to identify presence of activity-related knee pain and morning joint stiffness ≤30 min (NICE criteria for OA). As history and physical exam is considered the gold standard for making an OA diagnosis, an experienced rheumatologist, blinded to the questionnaire responses, conducted a standardized clinical assessment to identify presence of knee OA (yes, no, possible). A second rheumatologist completed a subset (n=11) of assessments in duplicate for validation of the rheumatologist's assessment. We calculated the sensitivity (sens), specificity (spec), likelihood ratio positive (LR+) and likelihood ratio negative (LR-) of the NICE criteria to detect symptomatic knee OA (yes or possible).

Results: Our study included 91 participants with type 2 diabetes: mean age was 65.9 (SD 8.1) years, 50.6% women, mean BMI 29.1 (SD 6.6) kg/m^2 (Table 1). 50 (54.9%) fulfilled the NICE criteria with a spectrum of illness severity: median (range) pain numeric rating score (0-10) was 5 (1-9). Gold standard assessment identified 51 (56.0%) participants with symptomatic knee OA (yes: n=48, possible [suspected to be early knee OA]: n=3). The sens, spec, LR+, and LR- of NICE criteria for symptomatic knee OA were 86.3%, 85.0%, 5.75, 0.16, respectively (Table 2). Activity-related knee OA ("Do you have pain or aching in one or both of your knee joints that comes on, or is made worse, by activities such as standing, walking, or climbing stairs") alone, without combination with morning stiffness, improved operating characteristics (88.2%, 90.0%, 8.82, 0.12) (Table 3). There was high rheumatologist inter-rater reliability for OA diagnosis (kappa = 0.84).

Conclusion: The NICE criteria have high sensitivity and specificity for detecting symptomatic knee OA. A simplified version, assessing self-reported activity-related knee pain in individuals age ≥45 years, performed slightly better and may be a preferable OA diagnostic tool. This should be validated in other settings. Given purposeful recruiting, this study cannot assess positive and negative predictive values.

Table 1. Characteristics of participants (n=91)

Characteristic	
Age, years, mean (SD)	65.9 (8.1)
Gender (woman), n (%)	56 (50.6%)

Abstract Number: 0323

A Randomized, Double-blind, Placebo-controlled, Repeat Injection, 52-Week Study to Evaluate the Efficacy and Safety of an Intra-articular Injection (IAI) of CNTX-4975-05 (CNTX) in Subjects with Chronic, Moderate-to-severe Osteoarthritis Knee Pain (MSOAKP) - Study 304

James Connolly, James N Campbell, **Randall Stevens** and Colleen Newman, Centrexion Therapeutics Corporation, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: 30+ million US adults have OAKP. After years of using NSAIDs, analgesics, surgery and IAI, many patients remain with MSOAKP. CNTX is a 1 mg dose of capsaicin for IAI to reduce MSOAKP.

Methods: Efficacy and safety of a two IAI doses of placebo or 1 mg CNTX (Day 1 and at Week 26; ratio capsaicin/placebo 3:2; blinded randomization) were assessed in subjects with chronic, MSOAKP. Subjects were allowed specific MSOAKP concomitant and rescue medications during the study.

Pain was assessed using: a numeric pain rating scale (NPRS [0 – 10; 0 = no pain, 10 worst pain possible]). Subjects had Kellgren-Lawrence (KL) grades 2-4 (radiograph; 0=normal, 4=severe), and met knee OA (KOA) diagnostic criteria. Subjects were blindly randomized. The primary endpoint (Week 12) was the Western Ontario and McMaster Universities Osteoarthritis Index Subscale A (pain). Subjects were also assessed on WOMAC B (stiffness), WOMAC C (function), Numeric Pain Rating Scale (NPRS; 0-10), and Patient Global Impression of Change (PGIC; 0-7).

Key safety included physical exams, vital signs, ECGs, labs and bilateral fixed flexion knee radiographs at screening, and Week 52.

Results: 325 subjects received 1 dose of study drug (140 placebo, 184 CNTX); 243 randomized subjects completed out to Week 52; 89 subjects discontinued (DC) early. DC reasons were subject withdrawal (6.9%), lack of efficacy (6.3%) and other (5.1%). 15 (4.5%) subjects DC prior to Week 12. Mean age 62.8 years (range = 40-84), 61.4% female, 71.3% - not Hispanic or Latino; 70.4% Caucasian and 26.5% Back/African American.

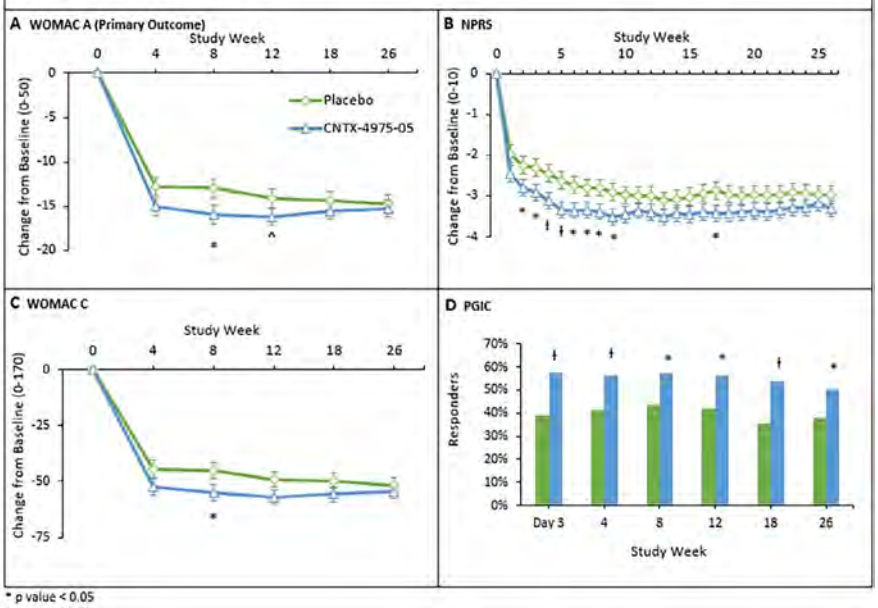
Mean index knee baseline NPRS was 7.0, WOMAC A (0-50 scale; 0 = severe pain) 31.5; WOMAC B (0-20 scale) and WOMAC C (0-170) was 13.2 and 108.8, respectively.

Table 1. Efficacy Outcomes

Outcome	CNTX-304	
	Placebo (n = 140)	CNTX-4975-05 (n = 184)
Primary Outcome^		
WOMAC A Change at Week 12	-14.3 (1.03)	-16.2 (0.96)
Key Secondary Outcomes^		
NPRS Change at Week 12	-2.99 (0.21)	-3.41 (0.2)
WOMAC B Change at Week 12	-5.36 (0.43)	-6.58 (0.4)
WOMAC C Change at Week 12	-49.03 (3.54)	-57.02 (3.31)
PGIC responders at Week 12+	59 (42.1%)	103 (56.0%)*

^ Values in parentheses denote standard error unless otherwise represented
* p value < 0.05
+ PGIC Responder = Much Improved and Very Much Improved

Figure 1. Efficacy Outcomes



* p value < 0.05
† p value < 0.01
^ Endpoint at week 12

Least-squares (LS) mean reduction was greater for CNTX than placebo (–16.20 vs -14.13, respectively; p = 0.0833). The WOMAC B / C, and NPRS were numerically better at nearly all visits through Week 26, and usually better to Week 52, for CNTX relative to placebo. Also, a greater proportion of CNTX subjects were considered PGIC responders at Week 12 and beyond – After the second IAI at Week 26, both pain and function improvements were seen in CNTX vs placebo, up to Week 52. (Table 1 and Figure 1).

There was more transient post injection pain on Day 1 in the CNTX group than placebo. Safety was acceptable out to Week 52 with knee radiographs showing no difference in KOA progression between placebo and CNTX, and no rapidly progressive osteoarthritis.

Conclusion: This study did not meet the primary endpoint. However, the numeric data suggested greater analgesic efficacy through Week 26 in CNTX compared to placebo. CNTX safety was acceptable. The NPRS difference was significant at several timepoints.

Abstract Number: 0324

A Randomized, Double-blind, Placebo-controlled, Single Injection, 52-Week Study to Evaluate the Efficacy and Safety of an Intra-articular Injection (IAI) of CNTX-4975-05 (CNTX) in Subjects with Chronic, Moderate-to-severe Osteoarthritis Knee Pain (OAKP) - Study 301

Randall Stevens, James N Campbell, Colleen Newman and James Connolly, Centrexion Therapeutics Corporation, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: 30+ million US adults have OAKP. After years of using NSAIDs and other conservative measures many patients remain with OAKP. CNTX is a 1 mg dose of capsaicin for IAI to reduce OAKP.

Methods: This was a randomized, double-blind, placebo-controlled, 52-week study with 325 subjects dosed, to evaluate the efficacy and safety of a single IAI (at Day 1) of 1.0 mg of CNTX, compared with placebo, in subjects (both sexes) with chronic, moderate-to-severe index OAKP (MSIOAKP). Subjects were allowed specific OAKP concomitant and rescue medications during the study.

Subjects with MSIOAKP using a numeric pain rating scale between 5-9 (NPRS [0 – 10; 0 = no pain, 10 worst pain possible]), Kellgren-Lawrence (KL) grades 2-4 (0-4, Normal to severe by radiographs), and met knee OA (KOA) diagnostic criteria, were blindly randomized on Day 1 to a single IAI of capsaicin or placebo (3:2) into the most painful knee (index). NPRS at Week 12 was the primary outcome measure, with supporting data from the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC; A=pain, B= knee stiffness, C= function) and Patient Global Impression of Change (PGIC; 0-7 scale). Radiographic data was taken of both knees.

Key safety included physical exams, vital signs, ECGs, labs, and fixed flexion radiographs of both knees at Screening, Weeks 12 and 52.

Results: 325 subjects received 1 dose of study drug (136 placebo, 189 CNTX); 262 randomized subjects completed; 70 subjects discontinued (DC) early. Reported reasons for study DC were subject withdrawal (7.2%), lost to follow-up (5.1%), and other (2.1%). 15 (4.5%) subjects DC prior to Week 12. Subjects: Mean age 61.8 years (range = 40-85 years), 63.4% female, 81.5% -not Hispanic or Latino; 65.5% Caucasian and 23.4% Back/African American.

Mean index knee baseline NPRS was 7.07, WOMAC A (0-50 scale; 0 = severe pain) 31.45, WOMAC B (0-20 scale) and WOMAC C (0-170) 13.26 and 106.99, respectively.

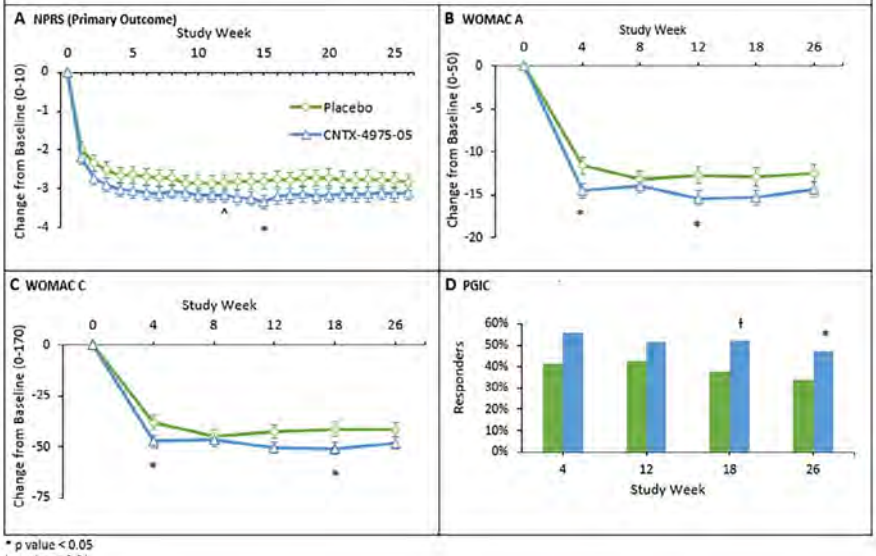
The least squares (LS) mean reduction in the average weekly pain with walking NPRS (0-10) score for the index knee was greater in the CNTX group than in the placebo group (–3.17 vs –2.84, respectively; p = 0.1904). However, the study failed to meet the primary efficacy endpoint. The WOMAC A, B and C subscales, the mean changes from study baseline were numerically better at nearly all visits through Week 26, and usually better to Week 52 for CNTX relative to placebo. Further,

Table 1. Efficacy Outcomes

Outcome	CNTX-301	
	Placebo (N = 136)	CNTX-4975-05 (N = 189)
Primary Outcomes^		
NPRS Change at Week 12	-2.84 (0.21)	-3.17 (0.182)
Key Secondary Outcomes^		
WOMAC A Change at Week 12	-12.72 (1.0)	-15.42 (0.86)*
WOMAC B Change at Week 12	-5.21 (0.45)	-6.15 (0.39)
WOMAC C Change at Week 12	-42.70 (3.42)	-50.49 (2.94)
PGIC responders at Week 12+	58 (42.6%)	98 (51.9%)

^ Values in parentheses denote standard error unless otherwise represented
* p value < 0.05
+ PGIC Responder = Much Improved and Very Much Improved

Figure 1. Efficacy Outcomes



* p value < 0.05
ǂ p value < 0.01
^ Endpoint at week 12

a greater proportion of subjects in the CNTX group were considered PGIC responders at Week 12 and beyond -(Table 1 and Figure 1).WOMAC A (pain) for CNTX was significantly ($p< 0.05$) improved over placebo at week 12.

Overall safety was acceptable and CNTX after treatment Day 1, where there was more transient post injection pain in the CNTX group. Knee radiographs (masked central reading) from Baseline to Week 52 showed no difference in KOA progression between placebo and CNTX, with no rapidly progressive osteoarthritis.

Conclusion: The study did not meet the primary endpoint, though analgesic efficacy through Week 26 in CNTX was numerically superior to placebo. Improvement in WOMAC A at 12 weeks was significantly greater for CNTX compared to placebo CNTX safety was acceptable.

Understanding the Burden of Cutaneous Lupus: A Subset Analysis from the 2022 World Lupus Federation Global Impact (WLFGI) Patient Survey

Nnenna Ezeh[1], Joy Buie[2], Mike Donnelly[3], Daria McClamb[3], Lydia Oberholtzer[4], Jana Sharp[4] and Joseph Merola[5], [1]Department of Dermatology; Department of Medicine, Harvard Medical School, Brigham and Women's Hospital, Boston, MA, [2]Lupus Foundation of America, York, SC, [3]Lupus Foundation of America, Washington, DC, [4]Sharp Insight, LLC, Montgomery County, MD, [5]Harvard Medical School, Brigham and Women's Hospital, Newton, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a paucity of data among a global population exploring the burden of CLE on patients, especially as compared to patients with SLE. This has negatively impacted research efforts including the development of new therapeutics specific to CLE. The 2022 World Lupus Federation Global Impact (WLFGI) patient survey assessed multiple aspects of patients' lupus including subsets of disease, therapeutic beliefs, quality of life burden. We utilized the WLFGI survey to characterize the burden of cutaneous disease and the comparative burden on quality of life among patients with self-reported cutaneous lupus compared to systemic lupus erythematosus.

Methods: The 2022 WLFGI survey was a multilingual, anonymous, online survey designed by the World Lupus Federation and disseminated worldwide via email during 3/1/2022-3/22/2023 with 6,704 respondents. 199 respondents had cutaneous lupus (CLE only) compared to 2,929 with systemic lupus with skin involvement (CLE+SLE) and 2,094 with systemic lupus without skin involvement (SLE only). Respondents with incomplete diagnosis data were removed from analysis, however, incomplete responses to questions were included as negative responses. Comparative statistics (odds ratio analysis) was utilized to assess comparative burden of quality of life measures between subgroups.

Results: Patient demographics and clinical manifestations are noted in Table 1. Respondents were more likely to be middle age, female, from the Americas and Europe. Impact on quality of life was observed in all groups, particularly financial insecurity (34%), mental health concerns (38%) and decreased social engagement (60%) (Table 2). There was an additive quality of life burden of 20-80% from cutaneous disease for all quality of life measures except short term disability observed in the CLE

Inability to participate in social activities	98 (49)	1935 (66)	1083 (52)	3116 (60)	**1.8 (1.6-2.0)**	**0.5 (0.4-0.7)**	0.9 (0.7-1.2)
Transportation issues	21 (11)	1128 (39)	598 (29)	1747 (33)	**1.6 (1.3-1.8)**	**0.2 (0.1-0.3)**	**0.3 (0.2-0.5)**

+SLE group, compared to the SLE only group. While respondents with cutaneous-limited disease generally had less quality of life burden compared to the SLE-only subgroup, mental health concerns and inabilities to socially engage were notable outliers. About one-third of CLE-only patients reported mental health concerns (32%), similar to the SLE-only population (31%), with CLE+SLE patients having nearly half (44%) reporting mental health concerns, highlighting the significant stigma associated with a potentially disfiguring disease.

Conclusion: This study offers a unique, global insight into the patient-reported burden of CLE +/- SLE. Skin-limited disease appears to carry as high a burden as SLE in several domains of disease impact. The presence of CLE among SLE patients is associated with higher quality of life burden, with particular impact on mental health and social interaction. These data support the need for further research dedicated to CLE and CLE disease-specific therapeutics.

Assessment of Depression in Ankylosing Spondylitis Using Center for Epidemiologic Studies Depression Scale

Yvette Farran[1], Mark Hwang[1], John Reveille[2], Lianne Gensler[3], Accelerating Medicines Partnership Program RA SLE Network[4], Mariko Ishimori[4] and Michael Ward[5], [1]The University of Texas Health Science Center at Houston McGovern Medical School, Houston, TX, [2]The University of Texas Health Science Center, Houston, TX, [3]University of California San Francisco, Department of Medicine, Division of Rheumatology, San Francisco, CA, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, US Department of Health and Human Services, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, November 12, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is a chronic inflammatory disease that primarily affects the spine and sacroiliac joints. Depression is a common comorbidity in AS patients and can have a significant impact on their quality of life. The Center for Epidemiologic Studies Depression Scale (CES-D) is a widely used self-report questionnaire for measuring depression in various populations. However, the validity of CES-D in AS patients is unclear.

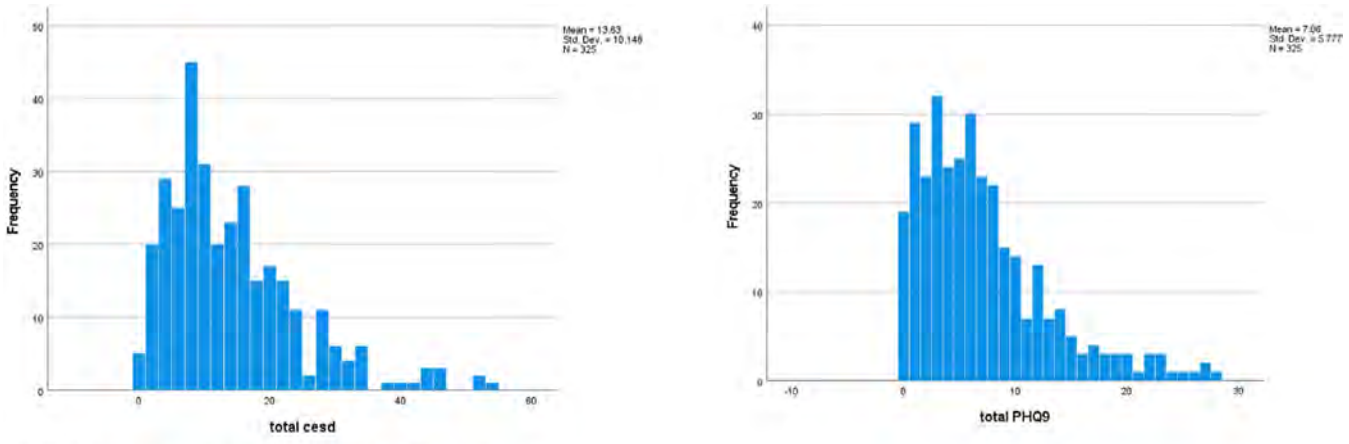

Figure 1. Histograms for total CES-D and PHQ9 score

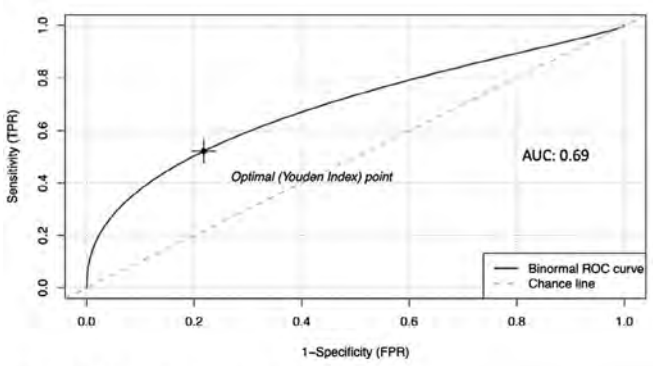

Figure 2A. CES-D vs Self reported Depression

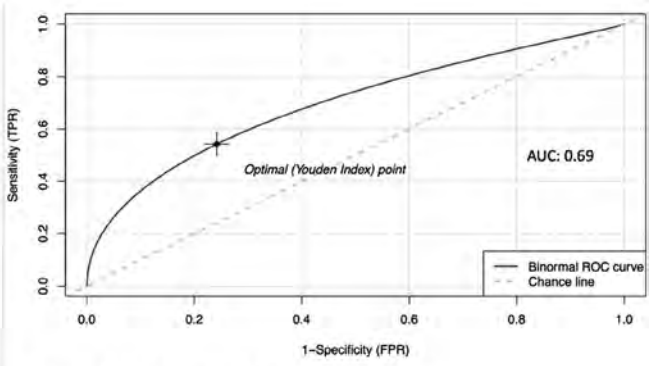

Figure 2B. PHQ9 vs Self reported Depression

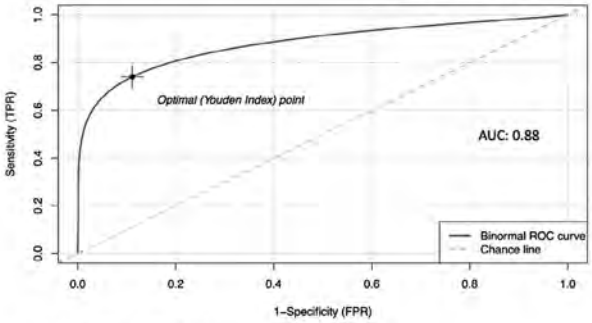

Figure 2C. CES-D vs PHQ9≥10

Methods: We investigated the psychometrics of the CES-D in AS by studying Prospective Study of Ankylosing Spondylitis (PSOAS) observational cohort patients with baseline, concomitant PHQ9 and self-reported depression. Construct validity was examined through convergent and known-groups validity. CES-D and PHQ9 was assessed using Pearson's correlation coefficient. Known groups validity for the CESD was tested using student's t-test comparing patients with and without self-reported depression. To find the optimal cutoffs, ROC curves were made plotting CES-D against Patient reported depression, PHQ9 against Patient report depression and CES-D against PHQ9≥10. The optimal cutoff point was found using Youden's index.

Results: 846 of the patients from the PSOAS cohort had completed CES-D at their initial visit. Of those, 325 had completed CES-D, PHQ-9, and self-reported depression. 25% (83/325) had PHQ9 $\geq$ 10, 34% (112/325) had CES-D $\geq$ 16 and 17% (56/325) had self-reported depression. Of the patients with self-reported depression, the average CES-D score was 19.8 and the average PHQ9 score was 10.7.The CES-D showed strong correlation with PH9 in AS patients ($r > 0.82$, $p < 0.01$) (Figure 1).T-test was significant comparing CES-D scores of AS patients with and without self-reported depression ($p < .01$) with a mean difference of 7.5 (4.6-10.3 95% CI).The ROC curves are shown in Figure 2. AUC's of these ranged from: 0.69-0.88. The optimal cut off point for CES-D in these patients based on Youden's index was 17-18.

Conclusion: In our AS patients, the CES-D scores are valid and have good construct validity. CES-D correlated well with self-reported depression and PHQ9. This suggests that CES-D is valid in this patient population and that a CES-D cutoff of 18, like that found in Rheumatoid Arthritis patients[1], may be a better cutoff value to indicate depression in AS patients.

Session Date: Sunday, November 12, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The 2021 EULAR guidelines on self-management have made recommendations (rec) to aid with the implementation of self-management strategies in inflammatory arthritis (IA) (1). Their aim is to support patients and encourage a patient-centred care approach which can improve both patient experience and outcomes in IA. Self-management can increase self-efficacy which can in turn improve adherence and outcomes for several self-management strategies (2).

Table 1. Baseline characteristics and areas addressed to patients with IA, based on the EULAR 2021 self-management recommendations *GSE score – Ranges from 10-40, where a higher score indicates more self-efficacy.

	Total	SpA	PsA	RA	p-value
	n=50	n=13	n=12	n=25	
Average Age [mean (SD)]	48 13)	44	48	51	0.29

DAS [median (IQR)]				4 (3-5)	
BASDAI [median (IQR)]		4 (2-6)			
PSA TJC [median (IQR)]			2.0 (0-10)		
PSA SJC [median (IQR)]			2.0 (0-8)		
Q1 N(%) Patient involvement in care	39 (84.8)	9 (81)	8 (72)	22 (91)	0.33
Q2 N(%) Patient education on their IA and care	30 (66.7)	10 (91)	9 (82)	11 (48)	0.021
Q3 N(%) Goal setting and practical solutions	20 (43)	9 (81)	6 (54)	5 (20)	0.002
Q4 N(%) Physiotherapy / given advice for exercise?	18 (39)	11 (100)	6 (54)	1 (4)	<0.001
Q5 N(%) Lifestyle / healthy behaviour advice given?	25 (54)	9 (81)	5 (45)	11 (45)	0.11
Q6 N(%) Was mental health addressed?	23 (50)	6 (54)	3 (27)	14 (58)	0.22
Q7 N(%) Employment advice given?	14 (30)	7 (63)	4 (36)	3 (12)	0.008
Q8 N(%) Digital health/apps discussed?	15 (32)	4 (36)	4 (36)	7 (29)	0.07
Self-management score [mean (SD)]	4 (2)	6 (2)	4 (3)	3(1)	<0.001
GSE score [median (IQR)]*	14 (12-25)	13 (11-14)	16 (12-26)	26 (23-36)	0.013

The objectives of this project were two fold; 1) to assess the implementation of self-management recommendations into routine clinical care of IA patients at a large tertiary rheumatology centre in London and 2) to explore how implementation (or not) of these recommendations may affect self-efficacy.

Methods: A retrospective analysis of the records of patients attending IA clinics at a large tertiary centre in London was undertaken from January 2022 to November 2022. Inclusion criteria included a diagnosis of either RA, PsA or AS. Specific questions addressing the uptake of the 2021 EULAR recommendations were developed (Table 1). The electronic notes were reviewed by two fellows who additionally interviewed patients via telephone, to explore whether the recommendations were addressed at their clinical encounter with the health care professional. Questions to the patients included specific ones addressing self-efficacy using the validated general self-efficacy (GSE) scale. Comparisons between groups were done with χ^2 tests, paired T-tests and Wilcoxon's Rank sum where appropriate.

Results: Fifty patients were included: 50% with RA, 24% with PsA and 26% with SpA. The mean (SD) age of participants was 48 (13) years. The median DAS was 4 (3-5) in RA, SJC and TJC was 2.0 (0.0-10.0) and 2.0 (0.0-8.0) respectively in PsA patients with the median BASDAI of 4 (2-6) in SpA (Table 1). The median GSE was 14 (12-25), where a higher score indicates more self-efficacy. 78% of patients reported feeling involved in the planning of their care and were made aware of the multidisciplinary team (rec 1). 30% felt they were given enough information on disease management (rec 2). Goals and practical points on physical and psychological interventions (rec 3) were mentioned to 50%. For patients where >50% of the self-management recommendations were addressed the mean GSE was 12.64 compared to a mean of 10.52 when < 50% of self-management recommendations were addressed.

Conclusion: This study demonstrates that self-management recommendations are not fully and consistently addressed in routine clinics. Furthermore, patient self-efficacy was low/moderate suggesting that clinicians need to do better at discussing and supporting self-management strategies to improve self-efficacy which may also improve disease outcomes.

From Patient Needs to Platform Design: Using Patient Preference to Guide the Development of a Post-Viral Fibromyalgia Management App

Marc Blanchard[1], Pedro Ming Azevedo[2], Tiffany Prétat[2], Cinja Koller[2] and Thomas Hügle[3], [1]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University Lausanne, Lausanne, Switzerland, [2]Lausanne University Hospital, Lausanne, Switzerland, [3]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University of Lausanne, Lausanne, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Post-viral fibromyalgia is a chronic condition that can develop in individuals following a viral infection, such as COVID-19. Recent studies have shown that approximately 30% of post-COVID19 patients satisfy the ACR criteria for fibromyalgia, experiencing symptoms such as chronic fatigue, widespread pain, sleep impairment, anxiety and depression.

Digital health interventions have demonstrated efficacy by providing disease monitoring, management and multimodal interventions to chronic pain patients. However, the widespread adoption and adherence to these interventions remain an obstacle. To address these challenges, this study aimed to develop a patient-centered digital health management app tailored specifically for post-viral fibromyalgia patients. By incorporating patient preferences through surveys and conducting usability testing, the study sought to enhance the usability of the app and the engagement of patients. Consequently, improving self-management, leading to improved patient outcomes and a better quality of life.

Methods: This study employed an explanatory design. Patient preference surveys were conducted among individuals recruited from "Long-COVID Schweiz", a post-COVID19 patients association. Usability testing was run with post-viral fibromyalgia patients that were enrolled in the multimodal care program for chronic pain management at the University Hospital of Lausanne (Switzerland).

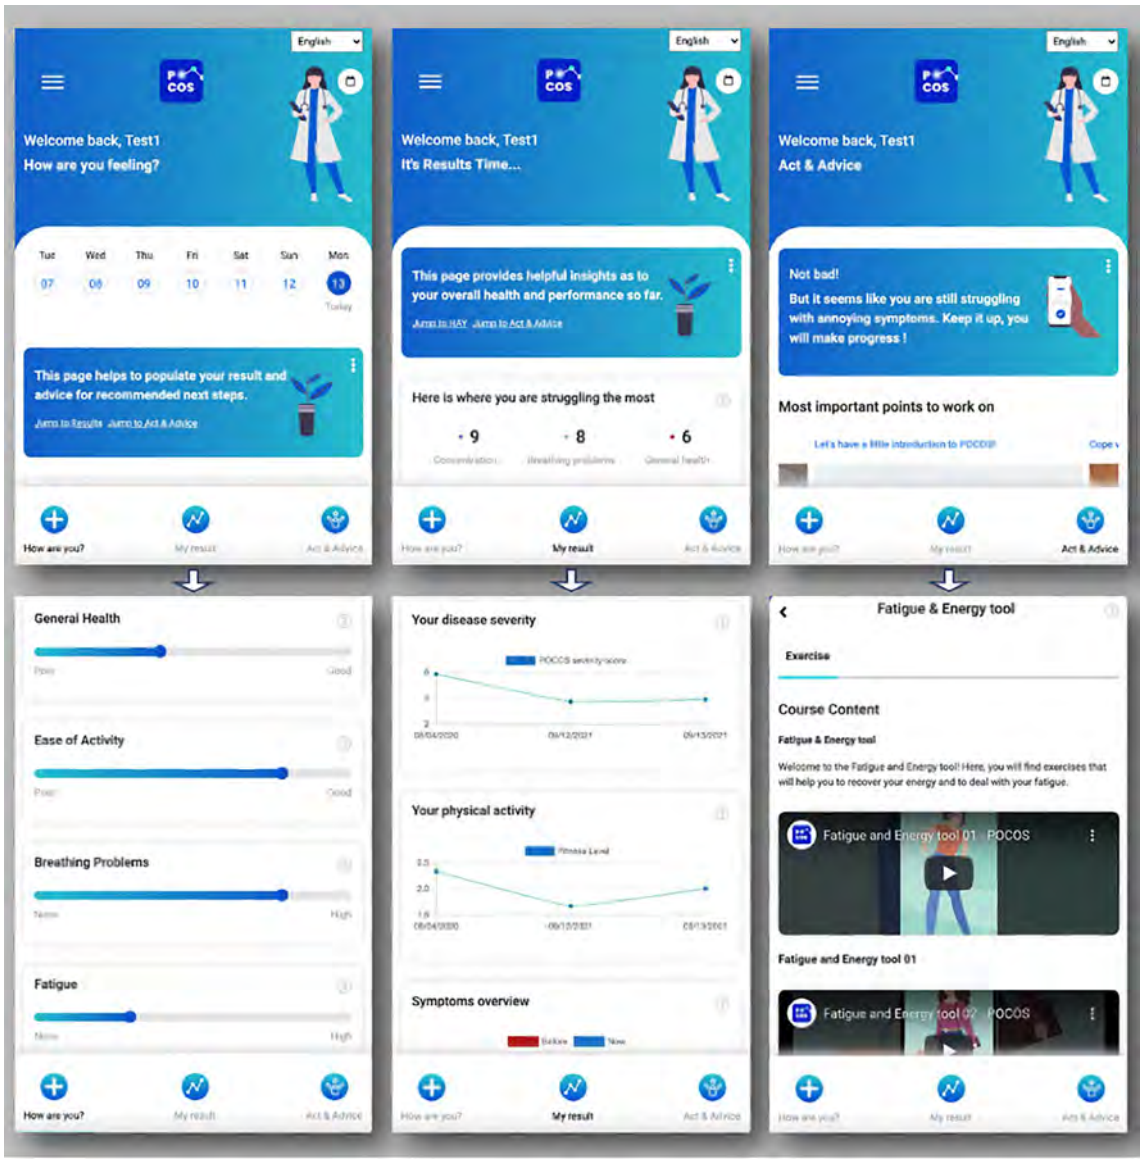

Figure 1: POCOS user interface (app): Left side: 'How are you?', with electronic patient reported outcomes and activity. Middle: 'My result', with monitoring of symptom's activity and health conditions. Right side: 'Act & Advice', with personalized training program, adapted to the user's symptoms.

Data collected from surveys consisted of qualitative preference data related to functional design, interactions with the app, patient reported outcomes, type of monitored data and expected content. Usability testing data under the form of notes, interviews and patients' feedback was collected by observing patients using the newly developed prototype.

Results: The frontend design of the app is shown in Figure 1. Among the 53 patients who responded to patient preference surveys, 90% preferred a regular symptoms list questionnaire over a chatbot to collect patient reported outcomes. Longitudinal symptom evaluation is shown in the "my result" section. 81% of patients expressed their wish that their symptoms are displayed with a benchmark of all other patients and to learn what has helped other patients with similar symptoms. A majority of them were also interested in links to patient communities (63%). Therefore, an anonymized discussion forum has been added. Patients preferred active training programs (63%) and information (59%) over interactive and gamified content (15%).

Among the 6 patients who participated in the usability testing, only 2 showed sufficient understanding of the functionalities and managed to navigate through the app without additional help, revealing the importance of the onboarding process.

Conclusion: Patient preference surveys guided the development of a patient-centric digital health solution, while usability testing identified issues with the onboarding process, requiring further study to investigate the impact of the onboarding on patient adoption and ultimately enhance engagement.

Factors Associated with Suicidal Ideation Among Patients with Inflammatory Rheumatic Musculoskeletal Disease: A Case-Control Study

Eike von Schlichting[1], Jan Dieris-Hirche[2], Imke Redeker[3], Xenofon Baraliakos[4] and **Uta Kiltz**[5], [1]Ruhr-Universität Bochum and Rheumazentrum Ruhrgebiet, Herne, Germany, [2]LWL-University Hospital, Department of Psychosomatic Medicine and Psychotherapy, Ruhr Universität Bochum, Bochum, Germany, [3]Ruhr Universität Bochum, Bochum, Germany, [4]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany, [5]Rheumazentrum Ruhrgebiet, Herne, Germany

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Mental health contributes to the morbidity of patients with inflammatory rheumatic musculoskeletal disease (iRMD). Despite extensive research conducted on the prevalence of depressive disorders, limited data on occurrence of suicidal ideation among iRMD patients is available. This study aims to evaluate the prevalence of suicidal ideation in a cohort of iRMD patients and to explore the factors that are associated with suicidal ideation.

Methods: We identified cases from the German osbeservational LORE cohort, consisting of patients with various types of iRMD, who reported suicidal ideations at least weekly (using PHQ-9). These cases were matched in a 1:3 ratio according to age and gender with patients from the same cohort who did not report any suicidal ideations. Patient and disease characteristics such as disease activity, physical function, mental health, and disease severity as well as factors that are reported

to be associated with suicidal ideations, such as previous suicidal attempts, childhood trauma, and personality factors were assessed in a case control study. A standardized clinical interview conducted by a psychosomatic expert was offered to all identified cases. Psychosomatic experts and rheumatologists rated independently whether suicidal ideation was being casual related to iRMD (NRS 0-10, 10 strong confidence in causal relationship). Five questions of the Columbia Suicidal Severity Rating Scale (C-SSRS) were used to assess lifetime suicidal ideation. According to the C-SSRS, patients were

Table1: patient characteristics of subjects with and without suicidal ideation

Variable	Controls (n= 150)	Cases (n=50)
Age, in years	56,5 (10,3)	58,3 (11,1)

Emotional neglect,0-25	4,4 (3,3)	9,0 (4,3)
Physical neglect,0-25	4,9 (2,0)	7,3 (2,8)

stratified into high risk (suicidal intent), moderate risk (suicidal thoughts with methods) and low risk (wish to be dead or non-specific active suicidal thoughts). Factors probably associated with risk of suicidal ideation were investigated using multivariable logistic regression analysis.

Results: We identified a total of 95 cases out of 2960 patients resulting in a prevalence of suicidal ideations of 3.2%. Among these cases, 50 completed the questionnaires, while 150 individuals served as controls. While demographics did not differ between cases and controls patient reported outcome was substantially higher in cases than controls (Table 1). In addition, it was observed that personality factors such as pessimism and neuroticism differed between cases and controls (Figure 1). 25 cases (50%) underwent clinical interviews in a psychosomatic clinic. Confidence in causal relationship between iRMD and suicidal ideation was reported by psychosomatic experts with higher values than by rheumatologists 5.4 (3.5) versus 1.6 (1.6). Predictors for suicidal ideation were shorter disease duration, presence of a somatoform or depressive syndrome, larger impulsivity and neurotic personality (Table 2).

Table 2: Multivariable linear regression with lifetime suicidal ideation, moderate/high vs. Low risk

Characteristic	OR[1]	95% CI[1]	p-value
Age	0.94	0.81, 1.04	0.3
Sex, male	0.56	0.05, 4.47	0.6
Disease duration	0.85	0.69, 0.96	**0.041**
Patient global	0.81	0.47, 1.26	0.4

PHQ-9, depressive syndrome	0.56	0.27, 0.90	**0.049**
PHQ-D, panic disorder	1.04	0.76, 1.40	0.8
I8, Impulsive Behaviour Urgency	2.00	1.06, 4.39	**0.048**
BFI10, Big Five Inventory, Neuroticism	5.39	1.70, 28.3	**0.014**
Family status: Married vs. living alone	3.22	0.42, 30.7	0.3

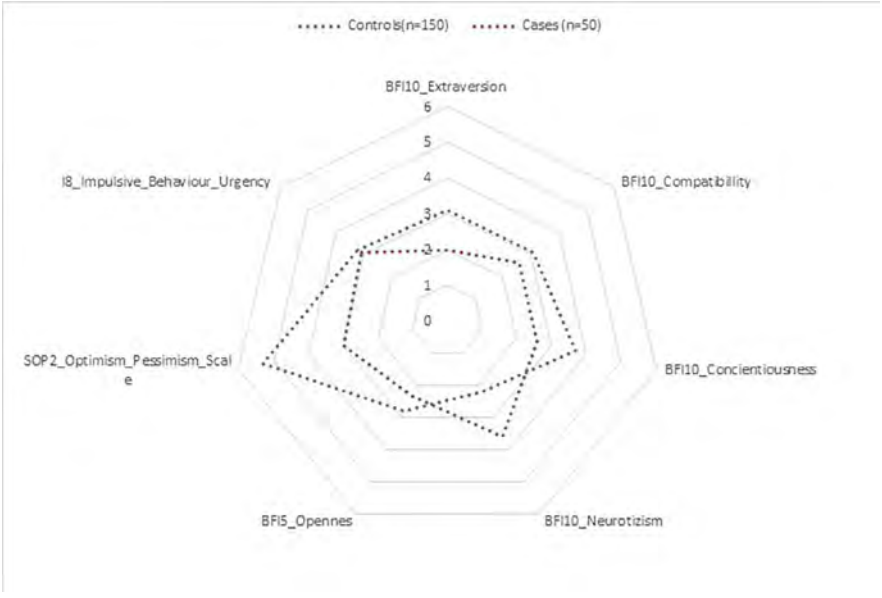

Figure 1: Factors associated with suicidal ideation

Conclusion: A substantial number of patients reported suicidal ideation in our cohort. Of interest, most vulnerable groups were patients with shorter disease duration or a concomitant somatoform or depressive syndrome. Inadequate coping might have influenced the risk for suicidal ideation. Interestingly, known risk factors for suicidal ideation were not identified as such in our study. Larger-scaled studies would be instrumental to unravel further suicidal ideation and its underlying factors.

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-Related Disease (IgG4-RD) is a systemic immune-mediated disease that commonly involves the pancreas in the form of autoimmune pancreatitis (AIP). Despite being one of the most common manifestations of the disease, the burden of abdominal symptomatology experienced by patients with IgG4-related AIP is not well-described.

Methods: We performed a cross-sectional study of patient-reported data using our large, prospective, single-center cohort of patients with IgG4-RD. Subjects were included if they met 2019 ACR/EULAR Classification Criteria. Subjects were excluded if the presence of AIP was unclear from chart review. All eligible subjects were sent surveys that contained questions regarding demographics, disease characteristics, comorbidities, treatment history, and detailed abdominal symptomatology. We compared characteristics between survey responders and non-responders as well as survey responses between patients with and without AIP using Chi-square tests for categorical and unpaired T tests for continuous variables.

Results: Of 327 eligible subjects, 164 (50%) completed surveys; the remainder did not respond to survey invitations, were deceased, or did not have accurate contact information available. Hispanic subjects were less likely to respond to the survey, while subjects with AIP were more likely to respond to the survey than those without; otherwise, demographics were similar between responders and non-responders (**Table 1**).

Disease features and abdominal symptoms in subjects with and without AIP are shown in **Table 2**. Overall, 43% of subjects characterized their general health as either "excellent" or "very good," and 23% reported a cumulative glucocorticoid exposure duration of >1 year. Subjects with AIP more commonly reported having been prescribed insulin, any antihyperglycemic medication, and pancreatic enzyme replacement than those without AIP. Subjects with AIP more frequently experienced

unintentional weight loss, abdominal pain, flatulence, and changes in stool consistency or frequency than those without AIP.

Patient-reported characteristics of abdominal pain are shown in **Table 3**. 38/83 (46%) subjects with AIP reported abdominal pain, and among these subjects, episodic pain was most common (30/38, 79%). 10/38 (26%) reported having experienced episodes of abdominal pain lasting over 6 months, compared with 2/15 (13%) of subjects without AIP who reported

Table 1: Demographics of survey responders vs. non-responders. All values reported as n (%) unless noted otherwise.

Bowel movement	10/38 (26)	6/15 (40)	0.41
Take pain medication for abdominal pain, n (%)	10/38 (26)	2/15 (13)	0.37
Degree of relief from pain medication, mean (SD)**	5.6 (3.0)	5.0 (3.2)	0.62

abdominal pain (p=0.37). High fat meals and stress were common exacerbating factors in both groups. Numerically more subjects with AIP reported taking pain medication for abdominal pain (26% vs. 13%, p=0.37).

Conclusion: In this large study using patient-reported measures, there was a high burden of symptomatology and comorbidities attributable to IgG4-RD in patients with and without AIP. Patients with AIP experience symptoms and complications attributable to both active pancreatitis (e.g., abdominal pain) and pancreatic insufficiency (e.g., insulin-dependent diabetes, weight loss requiring pancreatic enzyme replacement). These symptoms can have a significant impact on quality of life and should be assessed for and addressed by treating clinicians.

Assessment of Patient Adherence to "Sick Day Rules": A Cross-sectional Study of Rheumatology Outpatients Prescribed Immunosuppressive Medications

Mervè Aksoy[1], Pamela Gonzalez Manrique[2], Heinrich-Karl Greenblatt[1] and Katarzyna Gilek-Seibert[1], [1]Roger Williams Medical Center, Providence, RI, [2]Roger Williams Medical Center, North Providence, RI

SESSION INFORMATION

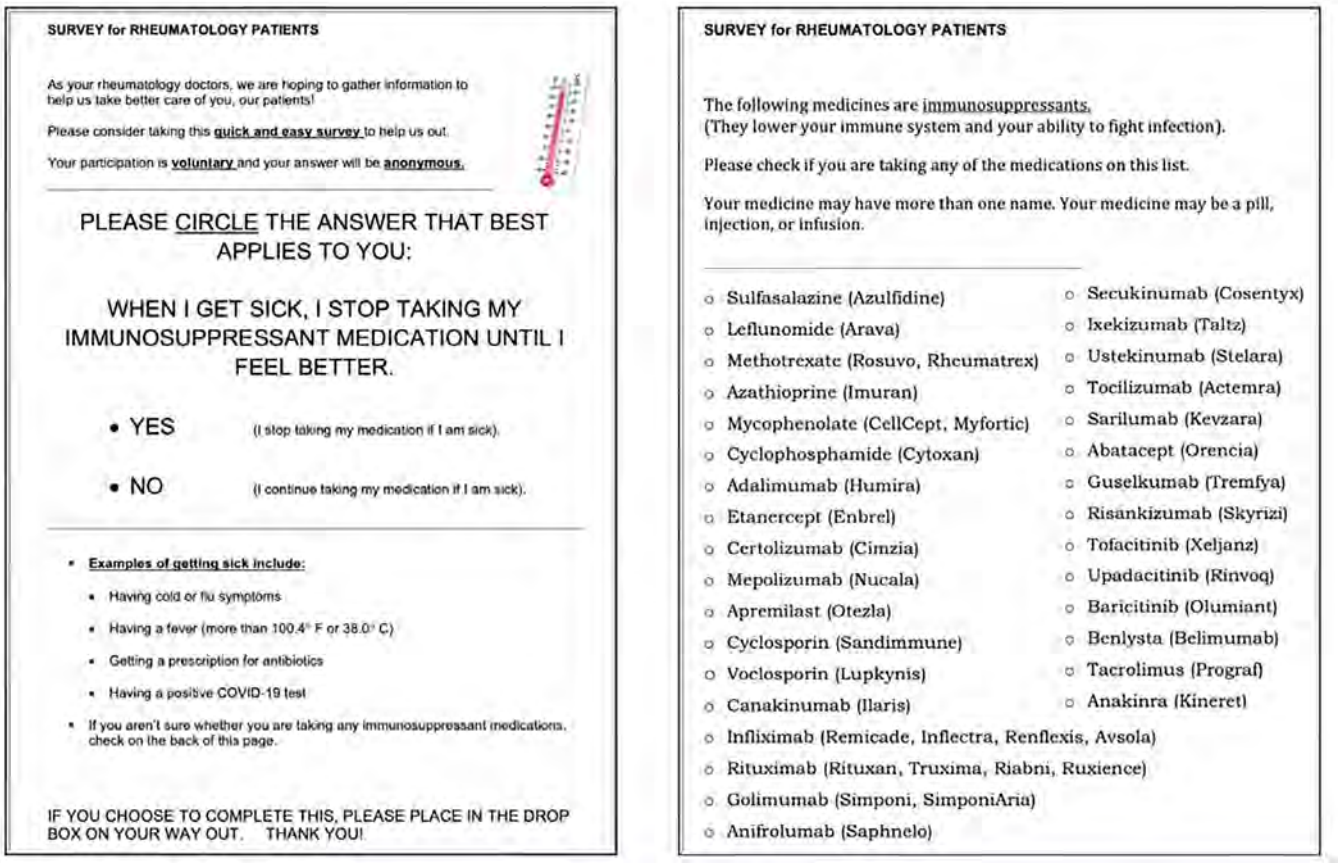
Session Date: Sunday, November 12, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatology outpatients receiving immunosuppressive medications (IS) inevitably develop acute infections. Expert guidance, in accordance with usual clinical practice, recommends counseling patients on "sick day rules." Patients are recommended to pause IS (with the exception of corticosteroids, which require dose increases) during an acute infection, resuming only when clinically improved. Prior studies have shown poor understanding of "sick day rules" specific to chronic steroid therapy in rheumatology outpatients. [Courtney, 2022]. However, the scope of this problem has not yet been described among the majority of rheumatology outpatients who receive non-steroid IS. Our study aimed to quantify



SURVEY for RHEUMATOLOGY PATIENTS

As your rheumatology doctors, we are hoping to gather information to help us take better care of you, our patients!

Please consider taking this **quick and easy survey** to help us out.

Your participation is **voluntary** and your answer will be **anonymous.**

PLEASE CIRCLE THE ANSWER THAT BEST APPLIES TO YOU:

WHEN I GET SICK, I STOP TAKING MY IMMUNOSUPPRESSANT MEDICATION UNTIL I FEEL BETTER.

- YES (I stop taking my medication if I am sick).
- NO (I continue taking my medication if I am sick).

- **Examples of getting sick include:**
  - Having cold or flu symptoms
  - Having a fever (more than 100.4° F or 38.0° C)
  - Getting a prescription for antibiotics
  - Having a positive COVID-19 test
- If you aren't sure whether you are taking any immunosuppressant medications, check on the back of this page.

IF YOU CHOOSE TO COMPLETE THIS, PLEASE PLACE IN THE DROP BOX ON YOUR WAY OUT. THANK YOU!

SURVEY for RHEUMATOLOGY PATIENTS

The following medicines are immunosuppressants.
(They lower your immune system and your ability to fight infection).

Please check if you are taking any of the medications on this list.

Your medicine may have more than one name. Your medicine may be a pill, injection, or infusion.

- Sulfasalazine (Azulfidine)
- Leflunomide (Arava)
- Methotrexate (Rosuvo, Rheumatrex)
- Azathioprine (Imuran)
- Mycophenolate (CellCept, Myfortic)
- Cyclophosphamide (Cytoxan)
- Adalimumab (Humira)
- Etanercept (Enbrel)
- Certolizumab (Cimzia)
- Mepolizumab (Nucala)
- Apremilast (Otezla)
- Cyclosporin (Sandimmune)
- Voclosporin (Lupkynis)
- Canakinumab (Ilaris)
- Infliximab (Remicade, Inflectra, Renflexis, Avsola)
- Rituximab (Rituxan, Truxima, Riabni, Ruxience)
- Golimumab (Simponi, SimponiAria)
- Anifrolumab (Saphnelo)
- Secukinumab (Cosentyx)
- Ixekizumab (Taltz)
- Ustekinumab (Stelara)

Figure 1. Paper survey (front and back) provided to patients.

the rate of proper adherence to "sick day rules" in a general rheumatology clinic. We hypothesized that we would find a high rate of non-adherence and illuminate a preventable source of patient harm.

Methods: This was a cross-sectional study of outpatients attending general rheumatology clinic visits in spring 2023. Patients who agreed to participate received the one-page document shown in Figure 1. Patients were asked to respond 'yes' or 'no' to the statement: "When I get sick, I stop taking my IS until I feel better." Patients were also asked to select the medications they were currently receiving. Surveys were de-identified. A Spanish-language version of the survey was made available. Any patient currently receiving DMARD therapy was eligible to participate. Exclusion criteria were as follows: no active prescription for a DMARD; active prescription for hydroxychloroquine, colchicine, or corticosteroids only; and inability of the patient (or family member/caregiver present) to read English or Spanish.

Results: 82 patients returned a completed survey. Overall, 32 patients (39%) responded "no," indicating that they would not interrupt IS if they became ill. 73 of 82 patients indicated which medications they were receiving. Among patients receiving biologic DMARD (bDMARD) therapy, apremilast, or JAK inhibitors, 9 of 37 (24%) responded "no" to the survey question. Among patients receiving only conventional synthetic DMARD (csDMARD) therapy, 21 of 36 (58%) responded "no" to the survey question.

Conclusion: Nearly 40% of the patients in our sample receiving IS indicated non-adherence to recommended "sick day rules." Among patients receiving only csDMARD therapy, this proportion rose to 58%. As hypothesized, our findings highlight an area for quality improvement and harm reduction. We observed particularly poor understanding among patients receiving csDMARDs only, even though these patients may still be considerably immunosuppressed. Our study was limited the risk of completion bias, potentially lowering the response rate in patients with poorer health literacy and worse disease control. We plan to intensify patient counseling in our clinic, including posting signage throughout our clinic displaying proper "sick day rules." We will repeat the same survey with a random sample from the same clinic, and we hypothesize that adherence will improve after our intervention.

SESSION INFORMATION

Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Skin disease is a hallmark of systemic sclerosis (SSc). The modified Rodnan skin score (mRSS) is physician performed measurement that assesses the extent and severity of skin thickness. However, it does not capture all of the clinical features of SSc skin disease. Patient-reported outcomes (PROs) can capture patients' perspective. The Scleroderma Skin Questionnaire (SSQ) is a novel PRO which assesses skin symptoms. To date, the SSQ has not been validated, and this study sought to assess the psychometric properties of the SSQ to generate evidence to support its further use.

Methods: We used data from CONQUER (Collaborative National Quality and Efficacy Registry), a multi-center, US-based registry of adults with early limited cutaneous (lc) and diffuse cutaneous (dc) SSc. The SSQ uses a 7-day recall period of 6 items (tight, painful, red, hard, itchy, rigid/stiff), which are graded on a 5-point Likert scale and averaged to obtain a score ranging 0-4 (4=worse). The second part of the questionnaire, the SSQ 6-Month, asks respondents to compare these symptoms to 6-months prior. Internal consistency of the SSQ was determined with Cronbach's α. Baseline response frequencies were used to investigate floor/ceiling effects. The associations between the SSQ and the mRSS and with legacy PROs [Scleroderma Health Assessment Questionnaire (SHAQ), Patient-Reported Outcomes Measurement Information System-29 (PROMIS-29), Patient Global (PtGA), and Physician Global (PGA)] were explored using Pearson's correlations. The SSQ 6-Month was correlated with 6-month changes in mRSS and in legacy PROs using mixed modeling with a bias-corrected confidence interval determined using cluster bootstrapping.

Results: We included 536 participants who completed the mRSS and SSQ (Table 1). The SSQ was higher (worse) in patients with dcSSc compared with lcSSc (1.5 vs 0.9; p< 0.001). The SSQ demonstrated internal consistency (α=0.90) and likely floor effect (Figure 1). At baseline, the SSQ was moderately correlated with the mRSS (r=0.56). The correlation was stronger among individuals with dcSSc (r=0.56) than lcSSc (r=0.22; all p< 0.05).At baseline, the SSQ was strongly correlated with PROMIS-29's physical (r=-0.52) and pain interference (r=0.61), and weakly with PROMIS-29's anxiety (r=0.24) and sleep disturbance (r=0.12; all p< 0.05). For the SHAQ, SSQ correlated strongly to HAQ (r=0.63) and severity score (r=0.61) and weakly to intestinal symptoms, breathing symptoms, Raynaud's attacks, and finger ulcers symptoms (all

[7] Diffuse cutaneous systemic sclerosis
[8] Modified Rodnan Skin Score
[9] Patient Global Assessment
[10] Physician Global Assessment
[11] Patient-Reported Outcomes Measurement Information System-29
[12] Scleroderma Health Assessment Questionnaire

p< 0.05). When stratified for SSc subtype, baseline mRSS, and disease duration, similar trends for correlation were seen (Table 2). SSQ 6-Month showed correlation of r=0.21 (p< 0.05) with 6-month change in mRSS and poor correlation with change in legacy PROs (Table 2).

Conclusion: In the CONQUER registry, the SSQ demonstrated internal consistency and moderate correlation with mRSS. The SSQ showed moderate/strong correlations with a subset of legacy PROs. However, the SSQ 6-Month showed weak correlation with change in the mRSS, suggesting either a poor recall for a 6-month time span or a disconnect between the patient perception and the mRSS. This study provides initial characterization of SSQ for future validation.

Abstract Number: 0333

Ankylosing Spondylitis Patient Perspective on Living with Flares and Impact on Quality of Life

Heather Lapidus Glassner and Elizabeth Luce, MyHealthTeam, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) leads to symptoms of pain, stiffness, swelling, and fatigue. Patients often report periods of increased symptoms (flares) followed by remission.The purpose of this study was to assess the experience of flares on quality of life from the patient perspective. Improved understanding of the experience of flares may contribute to better treatment and health outcomes.

Methods: In July 2022 an email invitation to an online survey was sent to members of MySpondylitisTeam, a social network of over 88,000 people. 253 members who self-report a doctor's diagnosis of ankylosing spondylitis (AS) completed the 25-question survey.

Results: 94% of members agreed that AS affects their quality of life and 87% agreed that AS makes it hard to do everyday activities. When asked to select the statement that best reflects flare activity in their AS, 44% selected "I have periods of increased symptoms (flares) on and off" and 43% selected "I have flares almost all the time." ***(Figure 1)*** Patients with almost constant flares indicated lower quality of life across a number of measures when compared with those whose flares were "on and off". Significant differences were evident for:

- Negatively affected their relationships with family (79% flares "almost all the time" vs. 48% flares "on and off")
- Made them feel isolated or alone (83% vs. 59%)
- Negatively affected their ability to have an active social life (93% vs. 74%)
- Made them feel stressed, anxious, or depressed (93% vs. 75%) ***(Figure 2)***

Just 27% of those who flare "almost all the time" agreed that they "lead a full life despite having spondylitis", compared 49% for those with flares "on and off". Many also indicated that obstacles to managing AS included pain or feeling unwell, as well as relentless fatigue (82% and 76% respectively). For example, one respondent wrote, "Lots of pain, fatigue. It has had an impact on my family."

Figure 1: Spondyloarthritis Flare Frequency - Among Those With Ankylosing Spondylitis

% Strongly and somewhat agree *My spondylitis…*	Those with AS (Sample=253)	Those with flares "almost all the time" (Sample=110)	Those who flare "on and off" (Sample=111)	*Net difference*
Negatively impacts my family relationships	62%	**79%***	48%	*31 points*
Makes me feel isolated or alone	70%	**83%***	59%	*24*
Interferes with my ability to have an active social life	82%	**93%***	74%	*19*
Makes me feel stressed, anxious, or depressed	82%	**93%***	75%	*18*
Makes it difficult for me to be sexually active	61%	69%	57%	*12*
Makes it hard for me to get around physically	81%	86%	76%	*10*
Makes me less productive at work, school, or home	84%	**91%***	78%	*13*
Makes it difficult to sleep at night	84%	**92%***	81%	*11*
Makes it hard to do everyday activities	87%	**93%***	83%	*10*
Makes it hard for me to exercise or to stay active	88%	92%	86%	*6*
Interferes with my quality of life	93%	95%	90%	*5*

How much do you agree or disagree with each of the following statements? My spondylitis… *95% CI (2-sample *t* test).

Figure 2: Impact on Quality of Life

% Currently taking	Those with AS (Sample=221)	Those with flares "almost all the time" (Sample=98)	Those who flare "on and off" (Sample=98)	*Net difference*
Nonsteroidal anti-inflammatory drug (NSAID)	48%	53%	43%	*11 points*
Biologic drug	46%	36%	**54%***	*18*
Opioid medication	31%	39%	28%	*11*
Disease modifying anti-rheumatic drug (DMARD)	19%	18%	19%	*24*
JAK inhibitor	2%	2%	2%	*0*
Other	25%	26%	22%	*4*

Which of the following are you currently taking to treat spondylitis or your symptoms of spondylitis? Please select all that apply. *95% CI (2-sample *t* test).

Figure 3: Treatments Currently Taking

Additionally, differences also exist with respect to doctor satisfaction and treatment. Fewer were satisfied with the doctor who primarily treats their HS (31% "extremely" or "very" satisfied compared with 42% for those who flare "on and off"). Those who flare "almost all the time" were also less likely to say that doctor "addresses symptoms of spondylitis such as pain or fatigue" (45% compared with 33% for those who flare "on and off").

Interestingly, those who flares were near-constant were significantly less likely to have been prescribed biologics (36% vs. 54% flares "on and off"). Additionally, those with almost constant flares were more likely to be treated with NSAIDs (53% vs. 43% flares "on and off" or opioids (39% vs. 28% flares "on and off") ***(Figure 3)***.

Conclusion: The extensive impact that flares have on AS patients' quality of life suggests that managing symptoms remains an ongoing concern. The obvious physical, emotional, and interpersonal toll that AS has on the lives of patients, combined with ongoing usage of opioids, indicate the need for better disease management and improved health outcomes. Frequent or near-constant flares, combined with the perception that fatigue, pain and feeling unwell act as obstacles to managing AS, is a reminder that better disease control is needed for many patients with AS.

Association of a Self-Report Screening Tool for Sarcopenia (SARC-F) with Functional Status Outcomes in Systemic Lupus Erythematosus

Sarah Lieber[1], Yvonne Shea[2], Deanna Jannat-Khah[2], John Carrino[2], M. Carrington Reid[3] and Lisa Mandl[1], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcopenia, i.e., loss of skeletal muscle mass and strength, has been associated with multiple adverse health outcomes, including mortality. Although limited data suggest that sarcopenia is more prevalent among adults with systemic lupus erythematosus (SLE) across the lifespan relative to comparators, current methods for sarcopenia assessment (e.g., body composition-specific dual energy x-ray absorptiometry) are not widely available. Therefore, we assessed associations of a simple self-report screening tool for sarcopenia (SARC-F) with functional status outcomes in adults with SLE [1].
