Synovial Lymphocytic Inflammation	**1.92**	**1.09, 3.57**	**0.024**
DAS28	**3.89**	**1.46, 11.96**	**0.006**
DAS28 = disease activity score in 28 joints Removed from the model as insignificant(P>0.1): recent anxiety, recent depression, synovial lining hyperplasia, RA pain			
Predicting Fatigue in Patients with High Disease Activity (DAS28 ≥ 3.2)			
Variable	Odds	Confidence Interval	P Value
Sex	**3.68**	**1.06, 13.63**	**0.04**
Anxiety/Nervousness	**2.08**	**1.26, 3.52**	**0.004**
Synovial Lining Hyperplasia	**1.57**	**1.01, 2.5**	**0.047**
DAS28 = disease activity score in 28 joints Removed from the model as insignificant (P>0.1): recent depression, synovial lymphocytic inflammation, RA pain			

Methods: 152 patients meeting ACR/EULAR 1987 and/or 2010 RA criteria were recruited prior to elective total joint replacement. At a pre-operative visit, patients were given questionnaires to assess global function and RA disease activity. Patient reported fatigue ("How much of a problem has unusual FATIGUE or TIREDNESS been for you in the PAST WEEK?") was rated by patients on a 0-10 scale and stratified into mild (0-3), moderate (4-7), or severe (8-10). Patients were also asked how they dealt with depression/feeling blue and nervousness/anxiety over the last week through the Multi-Dimensional Health Assessment Questionnaire (MDHAQ). Demographics, RA characteristics, tender and swollen joints to measure disease activity, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were collected. Hematoxylin and eosin (H&E) stains were prepared from the synovium of the operative joint and 10 characteristics were systematically scored by a pathologist as previously described. Relationships between patient fatigue and studied variables were measured with Kendall's Tau and compared in patients with high (DAS28$\geq$3.2) vs low (DAS28< 3.2) disease activity. Backward stepwise selection and multivariable ordered logistic regression were used to study the association of patient fatigue with other variables.

Results: Of the 152 patients in the study, 86.2% were women, with age 62.7 (±11.4) (mean±SD) years old, disease duration 14.75 (±12.4) years, and DAS28 3.87 (±1.30), indicating overall moderate disease activity. Among mild, moderate, and severe fatigue groups, there were no differences in comorbidities, such as history of diagnosed mental illness, anemia, fibromyalgia, thyroid disease, and cancer (Table 1). However, patients with higher fatigue reported higher recent anxiety and depression. Fatigue was correlated with DAS28, synovial lymphocytic inflammation (SLI), synovial lining hyperplasia, recent anxiety, recent depression, RA pain, and global pain (Figure 1). Of the patients with low disease activity, 46.5% had moderate, marked, or band-like SLI. In multivariable models, fatigue was significantly associated with SLI in low diseases activity patients (1.92[1.09,3.57]; p=0.024) but not with recent anxiety or depression. In high disease activity patients, fatigue was associated with anxiety and synovial lining hyperplasia (1.57[1.01,2.5]; p=0.047) but no other synovial histopathologic features.

Conclusion: In patients with low disease activity, fatigue is associated with chronic lymphocytic joint inflammation but not with anxiety or depression, suggesting an association with subclinical synovitis. In contrast, in RA patients with high disease activity, fatigue is associated with anxiety and synovial lining hyperplasia but not chronic lymphocytic inflammation.

Comparison of Peripheral Biomarker Profiles Across Unique Multimorbidity Patterns in Rheumatoid Arthritis

Chloe Peyton[1], Tate Johnson[1], Joshua Baker[2], Yangyuna Yang[1], Punyasha Roul[1], Michael Duryee[1], Jill Poole[1], Geoffrey Thiele[1], Ted R Mikuls[3] and Bryant England[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pennsylvania, Philadelphia, PA, [3]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Comorbidities
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Rheumatoid arthritis (RA) predisposes affected individuals to develop multiple chronic conditions (i.e., multimorbidity). Mechanisms underlying multimorbidity onset in RA are incompletely understood, particularly for different multimorbidity patterns. We examined how peripheral biomarker profiles encompassing pro-inflammatory, autoantibody, tissue remodeling, and metabolic measures are associated with the clinical expression of distinct multimorbidity patterns.

Methods: From a multicenter, prospective cohort of U.S. Veterans with RA fulfilling ACR classification criteria (Veterans Affairs Rheumatoid Arthritis registry), we measured 61 peripheral biomarkers including 37 pro-inflammatory cytokines/chemokines, 4 matrix metalloproteinases, rheumatoid factor (RF), anti-CCP antibody, 12 antibodies to malondialdehyde-acetaldehyde (MAA), 3 adipokines, and 3 alarmins by the MesoScale platform, ELISA, or nephelometry on serum or plasma from registry enrollment. Principal component analysis (PCA) was performed to generate distinct biomarker profiles (PCs)

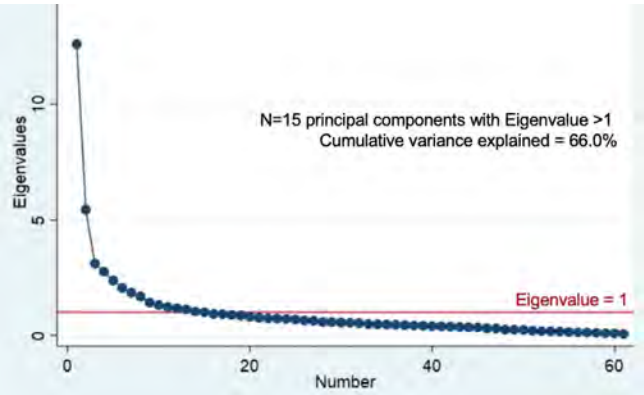

Figure 1. Scree plot from principal component analysis of 61 pro-inflammatory, autoantibody, tissue remodeling, and metabolic measures.

Table 1. Associations of peripheral biomarker profiles with multimorbidity patterns in rheumatoid arthritis. Values shown are odds ratios, with 95% confidence intervals, per 1-unit change in principal component (PC) score from logistic regression models adjusting for age, sex, race, and smoking status. Biomarkers listed are those with significant loadings (>0.3) onto the PC. P < 0.05 indicated in bold. Positive associations indicated in red and negative associations indicated in green with color gradient based on effect size.

from log-transformed and normalized analyte concentrations. The presence of forty-four pre-defined conditions at enrollment was determined using diagnostic codes from outpatient and inpatient encounters within linked administrative claims. Four previously developed multimorbidity patterns were then applied (mental health and substance abuse; metabolic; cardiovascular; chronic pain; England et al. Arthritis Care Res, 2023). Cross-sectional associations of PC scores with multimorbidity patterns were assessed using multivariable logistic regression models adjusting for age, sex, race, and smoking status.

Results: Among 2,007 participants with RA (89% male, mean age 64 years), 64% had metabolic, 47% had chronic pain, 21% had mental health and substance abuse, and 13% had cardiovascular multimorbidity. PCA identified15 unique peripheral biomarker PCs with Eigenvalues >1 that together explained 66% of the variance (Figure 1). PC8 scores, primarily characterized by adipokines (FGF-21, FLT3L, fractalkine, leptin), were positively associated with all multimorbidity patterns (aORs range: 1.25-1.35). In contrast, PC6 scores (anti-CCP and RF) were negatively associated with all multimorbidity patterns (aORs range: 0.85-0.88). Cardiovascular multimorbidity was positively associated with PC5 (IL12/IL-23p40, IL-17a) and PC11 (MMP3 and MMP7), but negatively associated with PC10 (IL-17e, IL-25, TSLP) and PC15 (IL-23, anti-MAA vimentin IgA). Several additional associations of smaller magnitude were observed between other PCs and multimorbidity patterns (Table 1).

Conclusion: Biomarker profiles consisting of cytokines/chemokines, MMPs, RA autoantibodies, adipokines, and alarmins were differentially associated with multimorbidity patterns in a large, RA cohort. These findings may indicate shared pathophysiologic mechanisms underlying multimorbidity in RA, such as obesity, metabolic dysfunction, and tissue remodeling. Further, they highlight pathways that could potentially be targeted to reduce multimorbidity burden or prevent its onset.

Incident Malignancies in Patients with Rheumatoid Arthritis in Daily Rheumatological Care

Martin Schaefer[1], Yvette Meissner[1], Bernhard Manger[2], Sylvia Berger[3], Karin Rockwitz[4], Anne Regierer[5] and Anja Strangfeld[1], [1]German Rheumatism Research Center, Berlin, Germany, [2]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Germany, [3]Rheumatologist, Naunhof, Germany, [4]Rheumatologist, Goslar, Germany, [5]Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Comorbidities

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: In 2021, the European and US-American regulatory agencies EMA and FDA issued warnings about malignancy risk associated with the Janus kinase inhibitor (JAKi) tofacitinib and required changes in labelling. These actions were based on results of the post-authorisation safety trial Oral Surveillance (OST)[1]. We aimed to analyse incident malignancies under treatment with JAKi, tumour necrosis factor inhibitors (TNFi), abatacept (ABA), rituximab (RTX), interleukin

6 inhibitors (IL6i) or conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs - bionaive) in patients with rheumatoid arthritis (RA) observed in daily rheumatological care.

Methods: Data from patients without cancer history enrolled in the biologics register RABBIT and initiating any DMARD treatment between 01/2017 - 04/2022 were included. Incidence rates (IR) of malignancies (without non melanoma skin cancer) per 1000 patient-years (PY) with 95% confidence intervals (CI) and adjusted hazard ratios (HR) were calculated for all and for selected patients according to OST inclusion criteria (age ≥ 50 years and ≥ 1 cardiovascular (CV) risk factor) to compare treatment groups to the reference (TNFi). Andersen-Gill regression analysis was used with a 6-months risk window, adjusted via stabilized and winsorized inverse probability of treatment weights taking into account age, sex, smoking, disease activity, prior therapies, comorbidities, and type of enrolling institution (clinic vs. private practice) as covariates. Multiple imputation of missing data was applied.

Results: 2763 JAKi, 3403 TNFi, 744 ABA, 834 RTX, 1125 IL6i and 1130 csDMARD initiations were documented. Patients with a JAKi start were less often men and (with exception of RTX) slightly older and had a longer RA disease duration (table). The proportion with positive autoantibodies and the number of previous treatments with biological (b) or targeted

Table: Patient characteristics at the start of a JAKi, TNFi, ABA, RTX, IL6i or csDMARD episode.

*Values are given as mean or percentage. *Age ≥50 years and ≥ 1 CV risk factor (hypertension, coronary heart disease, diabetes, hyperlipoproteinaemia, current smoking)*

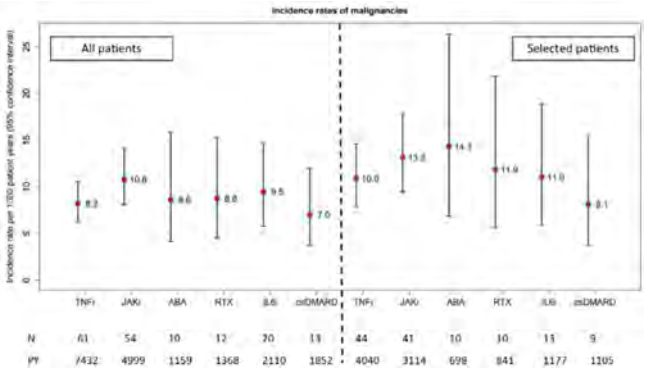

Figure: Incidence rates of malignancies (without non-melanoma skin cancer) per 1000 patient years by treatment group, for all patients (left) and selected patients only (right).

(ts) synthetic DMARDs was higher than in the TNFi and csDMARD group, but lower than in the ABA and RTX groups.

151 incident malignancies were reported. Across treatments, patients showed comparable IRs between 7 and 11 events per 1000 PY (10.8 events per 1000 PY in JAKi patients, 95% CI: 8.1 – 14.1, see figure). Among selected patients IRs were higher (13.2 events per 1000 PY in JAKi patients, 95% CI: 9.5 – 17.9). In adjusted analyses, neither JAKi (HR 1.07, 95% CI: 0.71 - 1.62), ABA (HR 0.73, 0.38 - 1.40), RTX (HR 0.86, 0.42 - 1.75), IL6i (HR 0.79, 0.44 - 1.40) nor csDMARDs (HR 2.07, 0.87 - 4.94) showed a significantly altered risk for malignancies compared with TNFi in unselected patients, with similar results in selected patients.

Conclusion: IR of malignancies in selected patients receiving JAKi in a real-world setting was numerically higher than the IR reported for tofacitinib in the Oral Surveillance study. However, we found no statistical evidence of an increased risk of malignancies with JAKi compared to TNFi, although patients on JAKi were older and had longer disease duration and more previous b/tsDMARDs treatments. Further analyses assessing exposure in terms of treatment duration are needed.

Dose Dependent Modulation of a B Cell Protein Signature by Ianalumab in Patients with Sjögren's Disease

Stephanie Finzel[1], Andrea Grioni[2], Benjamin A Fisher[3], Athena S Papas[4], Alexandre Avrameas[2], Danny Tuckwell[2], Jonas Zierer[2], Celine Rauld[2], Valeria De Luca[2], Enrico Ferrero[2], Andre Nogueira da Costa[2], Rainer Hillenbrand[2], Isabelle Isnardi[2] and Wolfgang Hueber[2], [1]Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, University of Freiburg, Freiburg, Germany, [2]Novartis Pharma AG, Basel, Switzerland, [3]University of Birmingham, Birmingham, United Kingdom, [4]Division of Oral Medicine, Tufts School of Dental Medicine, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Ianalumab (VAY736) is an afuscosylated monoclonal antibody targeting the B cell activating factor receptor (BAFFR) that depletes B cells via enhanced antibody dependent cellular cytotoxicity with concurrent blockade of BAFF:BAFFR mediated survival signals. Sjögren's disease (SjD) is an autoimmune disorder which primarily affects exocrine glands along with diverse systemic manifestations. It is characterized by elevated BAFF levels, hypergammaglobulinemia and autoantibodies to nuclear autoantigens. A phase 2b dose finding trial of ianalumab (NCT02962895) in 191 patients with active SjD met its primary endpoint, identifying 300 mg as the most clinically efficacious dose, despite a similar reduction in blood B cells as seen with 50 mg. We explored the changes in autoantibody and proteomic signatures of patients with SjD pre- and post-treatment with ianalumab to characterize pharmacodynamic and biological biomarkers associated with disease activity and clinical response.

Methods: Patients with active SjD (N=191) were randomly assigned 1:1:1:1 to receive placebo or one of three different doses of ianalumab (5 mg, 50 mg, or 300 mg). Serum samples were collected at baseline and Week 24. Serum protein profiling was performed using the SomaScan(R) v4.1 platform measuring >7000 aptamers. The interferon protein signature (IFNPS) was derived from the SomaScan data. Autoantibodies and BAFF levels were assessed by Luminex-based and ELISA assays. A linear mixed effect model was used to identify longitudinal changes in protein concentration at Week 24 versus baseline, and proteins with FDR < 0.05 and log fc >0.1 were selected for further analysis. Results were visualized using heatmaps and hierarchical clustering based on protein expression patterns.

Results: A cluster analysis performed on autoantibodies and proteins, including IFNPS at baseline did not reveal significant correlations between ESSDAI scores (including subdomains) and levels of autoantibodies or proteins of interest **(Fig 1)**. Administration of ianalumab led to marked changes in autoantibody and serum protein levels. The 300 mg dose group showed an increased number of significantly modulated serum proteins (42), versus the 5 mg (9) and 50 mg (20) dose groups, along with a more pronounced modulation of their expression **(Fig 2)**. Several B cell surface proteins were consistently downregulated by ianalumab, including F_CRL4, expressed by B cells hypothesized to be involved in the pathogenicity of SjD. The 50 mg and 300 mg doses induced the downregulation of additional proteins such as BCMA, specifically expressed by antibody producing cells, or the chemokines CXCL13 and CCL21, associated with immune infiltration of glandular tissues in patients with SjD. Although statistically non-significant, a downregulation of IFNPS was also seen with 50 mg and 300 mg doses.

Conclusion: No differential proteomic signatures related to baseline disease activity were identified. The dose response in clinical efficacy of ianalumab in treating patients with SjD as observed in the phase 2b trial is reflected at the protein level, with increased depth and breadth of proteomic changes by Week 24 correlating with increasing dose.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Sjögren's disease (SjD) is an autoimmune disease affecting secretory glands and other organs with no approved systemic treatments. Iscalimab (CFZ533) is a mAb directed against CD40, a novel way to target underlying disease pathophysiology. TWINSS is an ongoing phase 2b dose-ranging trial assessing safety and efficacy of multiple CFZ533 doses in two distinct patient (pt) populations with SjD of moderate/severe systemic disease (Cohort 1/C1) and of low systemic disease and high symptom burden (Cohort 2/C2). We report Week 24 primary results from both cohorts (N=273).

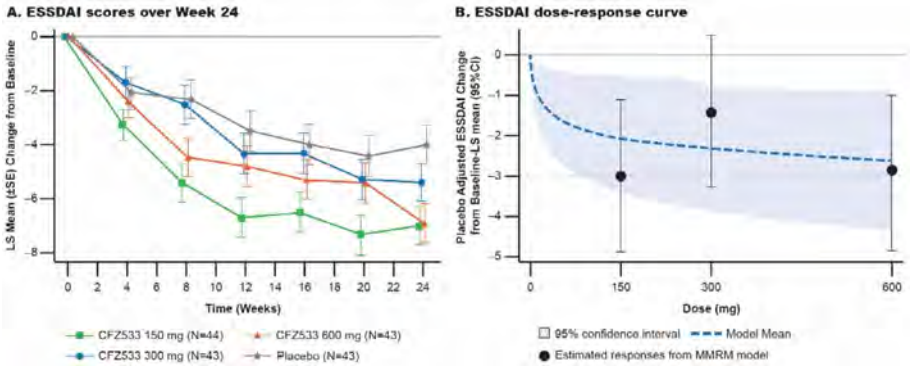

Figure 1: Least-square mean of change from baseline in ESSDAI scores over time up to Week 24 and estimated dose-response curve in Cohort 1

Methods: In C1, 173 pts were randomized (1:1:1:1) to CFZ533 150 mg or 300 mg or 600 mg s.c. q2w or placebo (PBO). In C2, 100 pts were assigned (1:1) to CFZ533 600 mg or PBO. Key inclusion criteria were: fulfilled ACR/EULAR 2016 classification criteria; stimulated salivary flow rates of ≥0.1 mL/min; anti-Ro/SSA positivity; **C1**: EULAR Sjögren's Syndrome (SS) Disease Activity Index (ESSDAI) ≥5 (on 8 selected domains), EULAR SS Patient Reported Index (ESSPRI) ≥5; and **C2**: ESSDAI < 5 with presence of activity in biologic domain (>0), ESSPRI (fatigue or dryness ≥5, impact of dry eye on everyday life [IDEEL] ≥30). Statistical methods included Multiple Comparison Procedure – Modelling methodology to assess the dose response of the ESSDAI change from baseline (C1) and mixed model for repeated measures to estimate the adjusted mean change from baseline and difference vs PBO (C1 and C2). Similar methods were applied to all other endpoints including ESSPRI.

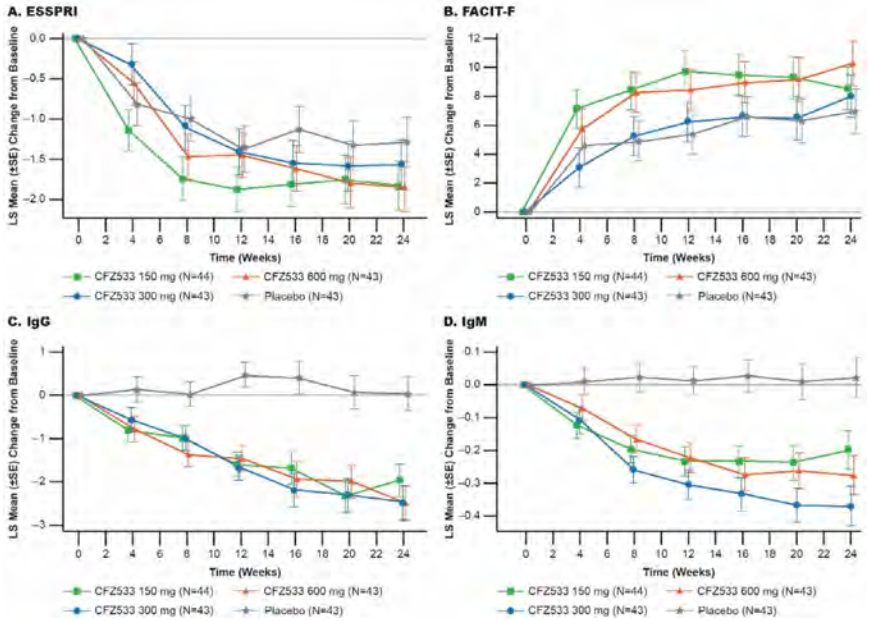

Figure 2: Least-square mean of change from baseline in patient-reported outcomes (secondary outcome measures) and pharmacodynamic markers up to Week 24 in Cohort 1

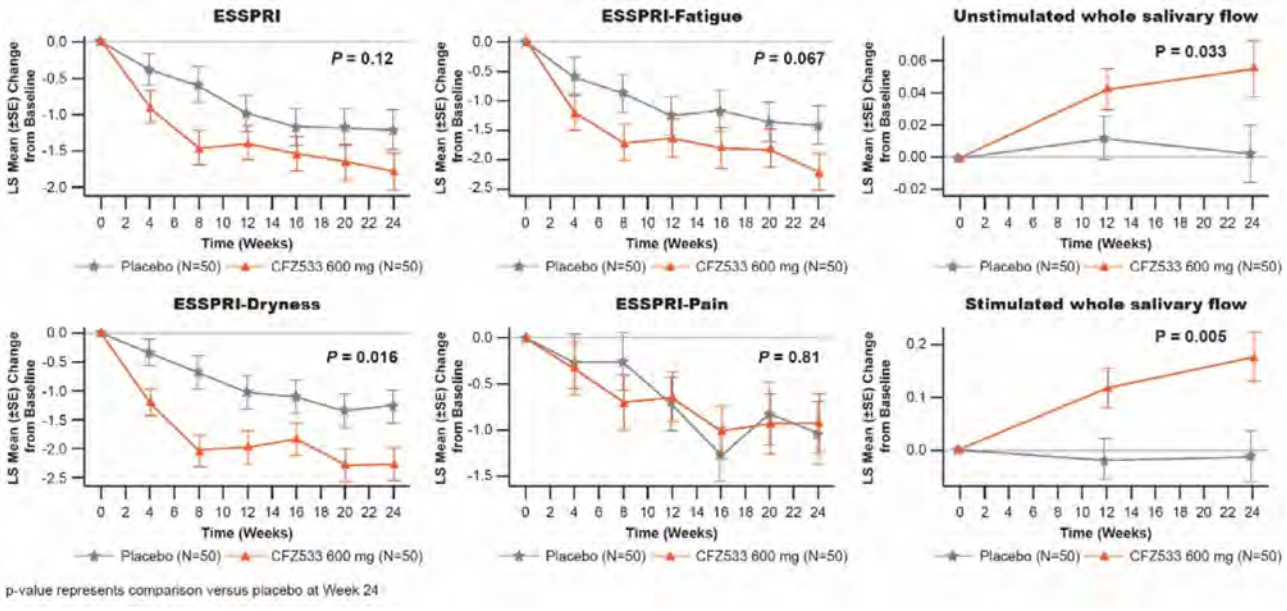

Figure 3. Least-square mean of change from baseline in ESSPRI and its subdomains and whole salivary flow up to Week 24 in Cohort 2

Results: Baseline characteristics were balanced across treatments except in C1 where more pts on iscalimab 300 mg had severe disease activity (ESSDAI >13; 44%) and used HCQ (70%), compared to the other treatment arms (ESSDAI >13, 19-28% and HCQ, 47-64%, respectively).

In **C1**, ESSDAI change from baseline at Week 24 showed statistically significant improvements compared to PBO for CFZ533 150 and 600 mg (least square mean difference (Δ) = –3.0 and –2.9; $p < 0.005$), and 300-mg dose showed a similar trend (Δ= –1.4; $p = 0.16$) (**Fig 1**). Primary objective of significant dose response of ESSDAI change from baseline at Week 24 ($p = 0.004$) with a log-linear dose-response was met. Predicted dose-response curve suggested that the drug effect plateaued at ≥150 mg. ESSPRI, FACIT-F **(Fig 2)**, tear flow, and salivary flow (SF) rates showed numerical trends for improvement with active treatment. By Week 24, IgG/IgM as objective pharmacodynamic markers showed significant and similar plateaus of reduction for all doses of CFZ533 compared to PBO. In **C2**, the primary objective of ESSPRI change from baseline showed a strong trend (Δ = –0.57; $p = 0.12$) toward improvement with dryness (Δ = –1.0; $p = 0.016$) and fatigue (Δ = –0.8; $p = 0.067$) as the response drivers **(Fig 3**). For exploratory outcomes, statistically significant increases in SF were seen.

At Week 24, SAE rates in **C1** (PBO, CFZ533 150 mg, 300 mg, 600 mg) were 2.3%, 2.3%, 7.1%, and 9.1%, respectively, in **C2** (PBO or CFZ533 600mg) 4% each. Infection rates in C1 were 39.5%, 45.5%, 26.2%, and 43.2%; and in C2 42.0% and 56.0%, respectively.

Conclusion: Iscalimab showed a clinically important improvement over placebo in 2 distinct populations of SjD patients and was well tolerated without obvious safety signals.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Primary Sjögren Syndrome (pSS) diagnosis relies on the weighted sum of three EULAR/ACR 2016 criteria: i) quantification of lymphocyte infiltration in labial salivary gland (LSG) biopsies, ii) autoantibody status and iii) objective quantification of eye and mouth dryness. Diagnosing pSS is highly challenging and the histological interpretation of LSG tissue requires specific expertise. It poses a challenge to non-specialized centers as highlighted by Vivino et al. [1] who show up to 53% of diagnosis reclassification after expert center rescoring. This analysis is critical and involves the determination of the focus score (FS), where a score ≥1 confirms the histological criteria for pSS. With mounting evidence underlining the potential of artificial intelligence in assisting pathologists, we aimed to develop two deep learning models using LSG biopsies only: one to automatically assess the FS (≥ 1 or < 1), and one to predict pSS diagnosis. Furthermore, we put effort in implementing explainable models highlighting the subregions of the biopsy leveraged for the prediction.

Methods: Deep learning models were developed using digitalized LSG slides from patients from three European expert centers taking part in the NECESSITY consortium, a European H2020 IMI2 project. Three patient groups were included: sicca patients with a FS < 1, pSS patients with a FS ≥ 1, and pSS patients with a FS < 1. All pSS diagnoses were confirmed by rheumatologists from expert centers and satisfied the EULAR/ACR 2016 classification criteria. Models were trained on 70% of the patients and validated on the remaining 30%. Algorithm performance was measured using the area under the receiver operating characteristic curve (AUROC), positive and negative predictive values (PPV and NPV), specificity and sensitivity. The models provide risk scores for each biopsy subregion, these scores explain how predictions of FS and pSS are computed.

Results: The dataset included a total of 325 patients: 145 from Paris-Saclay University (Bicêtre Hospital), 71 from Queen Mary University of London and 109 from the University of Birmingham. In the validation set, the model achieved an AUROC of 0.88 (95% CI 0.85 to 0.90) for binary assessment of the FS (≥ 1 or < 1); and 0.84 (95% CI 0.83 to 0.86) for predicting pSS

Table 1: Detailed performance results on the validation set of the models predicting the FS (≥ 1 or < 1) and pSS diagnosis (PPV: positive predictive value, NPV: negative predictive value, mean confidence interval (CI)).

Task	AUROC	PPV	NPV	Specificity	Sensitivity
FS≥1/<1 prediction	**0.88** (0.85, 0.90)	**0.77** (0.74, 0.80)	**0.83** (0.79, 0.87)	**0.79** (0.77, 0.82)	**0.81** (0.76,0.87)
pSS+/- prediction	**0.84** (0.83, 0.86)	**0.83** (0.81, 0.84)	**0.67** (0.63, 0.71)	**0.64** (0.60, 0.67)	**0.84** (0.81, 0.87)

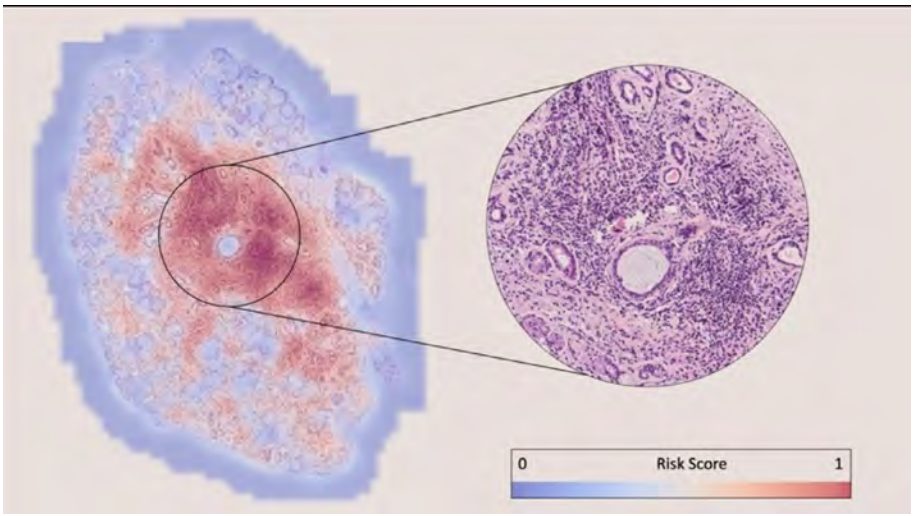

Figure 1: LSG biopsy with computed FS ≥ 1 probability (blue is low, red is high). Note that subregions with high-risk score (red; left) highlight lymphocytes aggregates (right).

diagnosis. Analysis of histological subregions selected by the model determining the FS unsurprisingly revealed regions with a high concentration of lymphocytes (Figure 1). Detailed performance results for both models are available in Table 1.

Conclusion: Deep learning can predict both the FS and pSS diagnosis with high accuracy using digitalized LSG slides only. The FS model could serve as a valuable tool to assist pathologists who may not specialize in oral pathology, reducing their reliance on reference centers. Furthermore, this study paves the way for a better understanding of pSS physiopathology: the determination of the regions selected by the algorithm for the diagnosis of pSS in FS negative patients is in progress, with up to now a highlight on lympho-epithelial lesions.

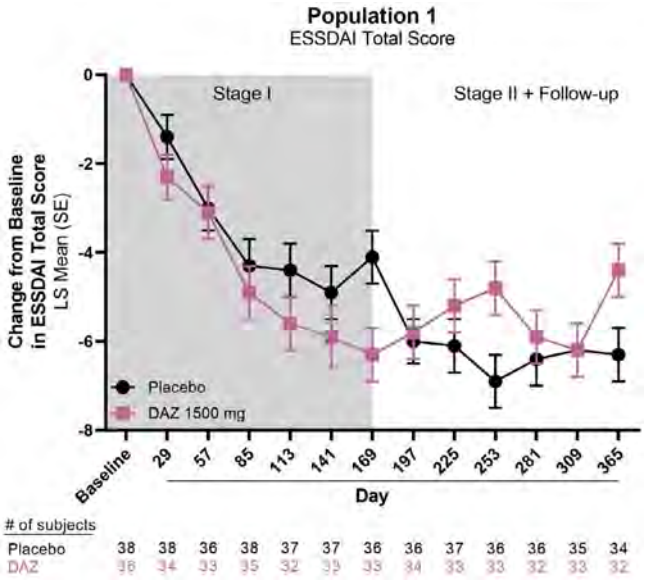
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Dazodalibep (DAZ) is a non-antibody fusion protein that acts as a CD40L antagonist and blocks costimulatory signals between immune cells, including T cells, B cells, and antigen-presenting cells. Previously, we reported that the primary endpoint, the change from baseline to Day 169 in the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI), was achieved in the population of subjects with moderate-to-severe systemic disease activity (NCT04129164).[1] Here, we evaluated the efficacy and safety of DAZ therapy in this population through the crossover period of the study.

Methods: We performed a randomized, double-blind, placebo-controlled, crossover study to evaluate DAZ therapy in adult subjects with Sjögren's having moderate-to-severe systemic disease activity, as defined by an ESSDAI ≥ 5. Eligible subjects were randomized 1:1 to receive intravenous DAZ 1500 mg or PBO Q2W x 3 doses, and then Q4W x 4 additional doses (Stage I). Starting on Day 169, subjects initially randomized to DAZ transitioned to PBO Q4W x 5 doses (DAZ-PBO) and subjects randomized to PBO were switched to DAZ Q4W x 5 doses (PBO-DAZ); all were then followed for 12 weeks (Stage II).



Adjusted mean change from baseline in ESSDAI total score. DAZ, dazodalibep; ESSDAI, EULAR Sjögren's Syndrome Disease Activity Index; LS, least squares; SE, standard error.

Results: A total of 74 eligible subjects were randomized (DAZ, N=36; PBO, N=38) and received study medication, with 71 (95.9%) completing Stage I and 67 (90.5%) completing Stage II. In the PBO-DAZ group (N=37), the change in ESSDAI score improved from baseline to −4.1 ± 0.6 at Day 169 and to −6.3 ± 0.6 at Day 365 in Stage II. In the DAZ-PBO group (N=34), the change in ESSDAI score was −6.3 ± 0.6 at Day 169 and −4.4 ± 0.6 at Day 365. The proportions of subjects achieving ESSDAI responses (3- or 4-point improvements from baseline) at Day 365 were greater in the PBO-DAZ group compared with the DAZ-PBO group (ESSDAI [3]: 66.7% [24/36] vs 55.9% [19/34]; ESSDAI [4]: 66.7% [24/36] vs 52.9% [18/34]). During Stage II, the PBO-DAZ group showed greater improvement in the EULAR Sjögren's Syndrome Patient Reported Index, Functional Assessment of Chronic Illness Therapy-Fatigue, and Ocular Surface Disease Index relative to DAZ-PBO group.

Treatment-emergent AEs in Stage II Preferred term, n (%)	PBO-DAZ N=37	DAZ-PBO N=34
COVID-19	6 (16.2)	6 (17.6)
Upper respiratory tract infection	5 (13.5)	5 (14.7)
Diarrhea	2 (5.4)	3 (8.8)
Arthralgia	3 (8.1)	2 (5.9)
Blood creatinine increased	0	2 (5.9)
Chronic gastritis	0	2 (5.9)
Constipation	0	2 (5.9)
Enteritis	0	2 (5.9)
Headache	4 (10.8)	2 (5.9)
Nausea	1 (2.7)	2 (5.9)
Rash macular	0	2 (5.9)
Urinary tract infection	2 (5.4)	2 (5.9)

Most frequently reported treatment-emergent AEs occurring in ≥5% of subjects in Stage II. The PBO-DAZ group received PBO in Stage I and transitioned to DAZ in Stage II. The DAZ-PBO group received DAZ in Stage I and transitioned to PBO in Stage II. AE, adverse event; DAZ, dazodalibep; PBO, placebo.

In Stage II, 53 of 71 subjects reported an AE (DAZ-PBO: 25 [73.5%]; PBO-DAZ: 28 [75.7%]) and the majority were mild/moderate in severity. Four SAEs were reported in three subjects in the DAZ-PBO group (drug-induced liver injury and deep vein thrombosis [DVT; also captured as an AESI] in one subject, multiple injuries, and cervical dysplasia). The subject with a lower extremity DVT also had acute liver injury, with onset of SAEs occurring 180 days after the final dose of DAZ. One SAE was reported in the PBO-DAZ group (chronic cholecystitis). One subject in the DAZ-PBO group discontinued the study during Stage II due to an AE (COVID-19) compared to none in the PBO-DAZ group.

Conclusion: The results during Stage II provide further evidence of DAZ clinical efficacy in Sjögren's disease and support the primary endpoint result. DAZ was generally safe and well tolerated in Stage II, although larger trials of DAZ therapy for this indication are warranted to further explore its safety profile and confirm its clinical efficacy.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Loss of galactose and sialic acid structures attached to the IgG-Fc-fragment switches the antibody effector function from anti-inflammatory to pro-inflammatory[1]. This study investigated the IgG- Fc-N-glycosylation profiles in patients from the *Belgian Sjögren's Syndrome Transition Trial* (BeSSTT) in relation to disease state, salivary gland ultrasonography SGUS) and histopathology, and autoantibodies against SSA (Ro52/Ro60) and SSB.

Methods: The relative amount of N-sialylated and N-galactosylated IgG was determined by capillary electrophoresis after using the endo-S glycosidase based assay. 300 serum samples of patients of the BeSSTT, an observational cohort of patients with definite pSS (n=177), fulfilling the 2016 ACR/EULAR classification criteria, and of patients with suspected pSS (n=111) due to presence of either objective sicca or one immunological criterion, were investigated. Groups were made based on the presence or absence of sicca complaints, objective sicca, anti-SSA reactivity and histopathology focus score. SGUS was assessed by Hocevar Score, categorized in negative (0-14), low positive (15-26) and high positive (27-48)[2].

Table 1. Relative amount of Fc-N-sialylated and Fc-N-galactosylated IgG in relation to disease state, salivary gland damage (SGUS and histopathology) and autoantibody profile.

	Number	IgG-Fc-sialylation Median (IQR)	IgG-Fc-galactosylation Median (IQR)
Disease state	288	P <0.001	P <0.001
Sicca complaint	22	0,096 (0,017)	0,599 (0,089)
Sicca	53	0,083 (0,027)	0,552 (0,130)
Probable pSS	36	0,090 (0,034)	0,584 (0,137)
Definite pSS	177	0,068 (0,030)	0,472 (0,150)
SGUS	300	P<0.001	P<0.001
Negative Hocevar (0-14)	149	0,077 (0.033)	0,539 (0.143)
Low positive Hocevar (15-26)	71	0,081 (0.026)	0,540 (0.116)
High positive Hocevar (27-48)	80	0,061 (0.027)	0,439 (0.145)
Histopathology FS	119	P<0.05	P<0.01
FS <1	75	0,082 (0.026)	0,549 (0.121)
FS≥1	44	0,070 (0.034)	0,481 (0.122)
Autoantibody profile	288	P<0.001	P<0.001
anti-SSA-	97	0,086 (0,027)	0,553 (0.129)
mono anti-Ro52+	24	0,067 (0,026)	0,484 (0.151)
mono anti-Ro60+	30	0,086 (0,037)	0,571 (0.133)
double anti-Ro52+Ro60+	77	0,071 (0.036)	0,481 (0.136)
triple anti-Ro52+Ro60+ SSB+	60	0,064 (0.028)	0,460 (0.137)

Differences in levels of IgG-Fc-N-sialylation and -galactosylation were determined using Kruskal-Wallis testing. *P*-values ≤0.05 were considered statistically significant. Bonferroni correction was applied for post-hoc analyses.

Results: IgG-Fc-N-sialylation and -galactosylation were significantly lower in definite pSS than in patients with sicca complaints, objective sicca or anti-SSA/SSB reactivity only (probable pSS) (Fig 1). Besides, IgG-Fc-N-sialylation and IgG-Fc-N-galactosylation were significantly lower in high positive SGUS- versus low positive and negative SGUS-scores and in positive versus negative focus scores. IgG-Fc-N-sialylation and -galactosylation were significantly lower in anti-Ro52+Ro60+SSB+,

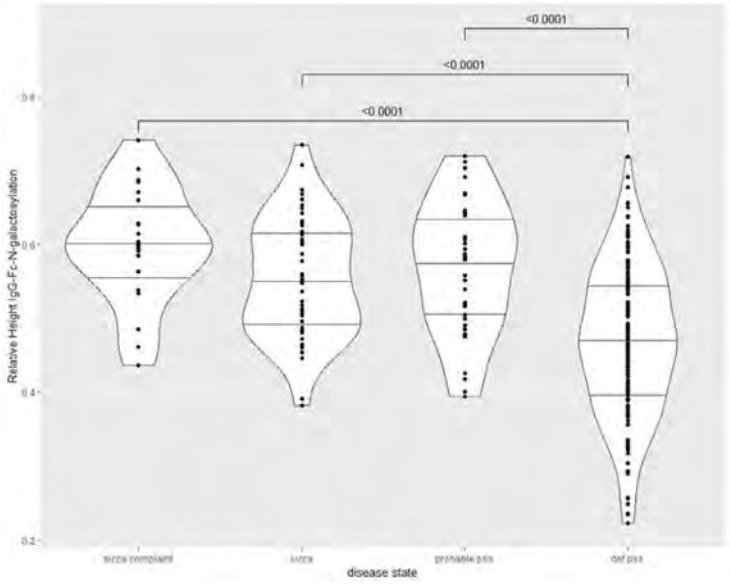

Figure 1. IgG- Fc-N-galactosylation in function of disease state

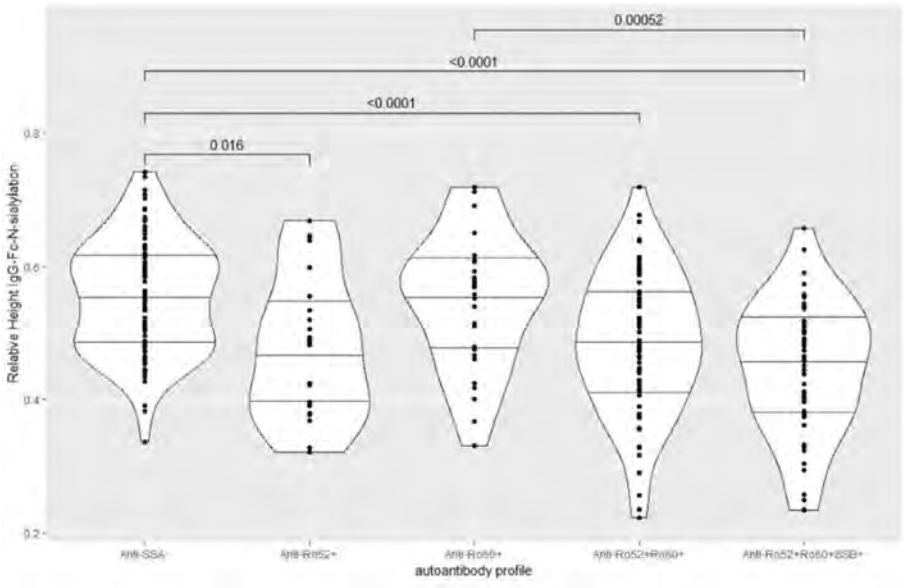

Figure 2. IgG-Fc-N-galactosylation level in function of autoantibody profile

anti-Ro52+Ro60+ and anti-Ro52+ patients than in anti-SSA-/SSB- patients. Strikingly, IgG-Fc-N-sialylation and -galactosylation were also significantly higher in anti-Ro52+60+ and anti-Ro52+Ro60+SSB+patients than in anti-Ro60+ patients (Fig 2). Results are shown in Table 1.

Conclusion: There was a gradual loss of IgG-Fc-N-sialic acid and IgG-Fc-N-galactose as the disease became more prominent, as observed from sicca and probable pSS to definite pSS. The IgG-Fc-N-glycosylation profile was associated with the degree of salivary gland damage in pSS. Anti-Ro52+Ro60+SSB+, Anti-Ro52+Ro60+ and Anti-Ro52+ patients had a more pro-inflammatory IgG-Fc-N-glycosylation profile than anti-SSA- and strikingly also than anti-Ro60+ patients.

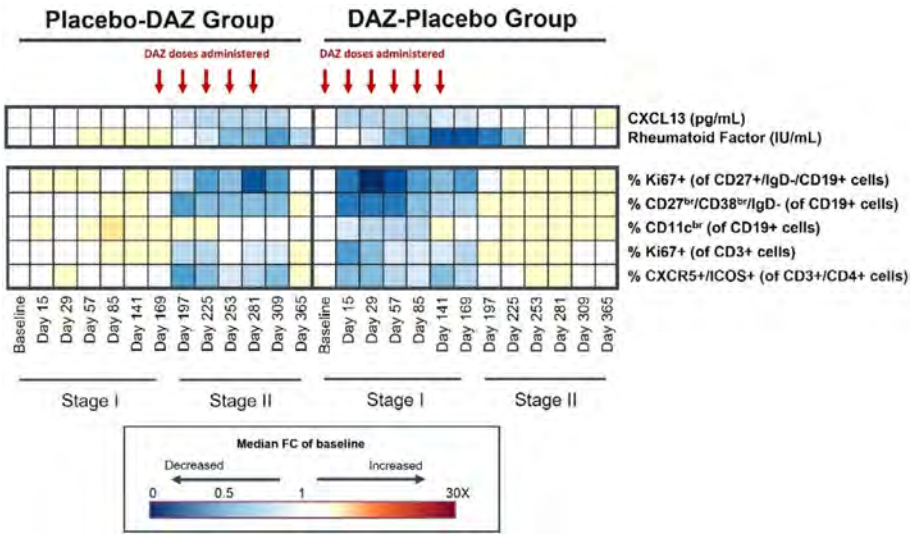
CD40L Inhibition with Dazodalibep Rapidly Reduces Blood Biomarkers of T and B Cell Costimulation in Subjects with Sjögren's Having High Disease Activity or High Symptom Burden

Tuyet-Hang Pham[1], Michael A. Smith[1], Nannette Mittereder[1], William A. Rees[2], Ilias Alevizos[2], E. William St. Clair[3] and Claire Emson[1], [1]Horizon Therapeutics plc, Rockville, MD, [2]Horizon Therapeutics, Rockville, MD, [3]Duke University Medical Center, Durham, NC

SESSION INFORMATION

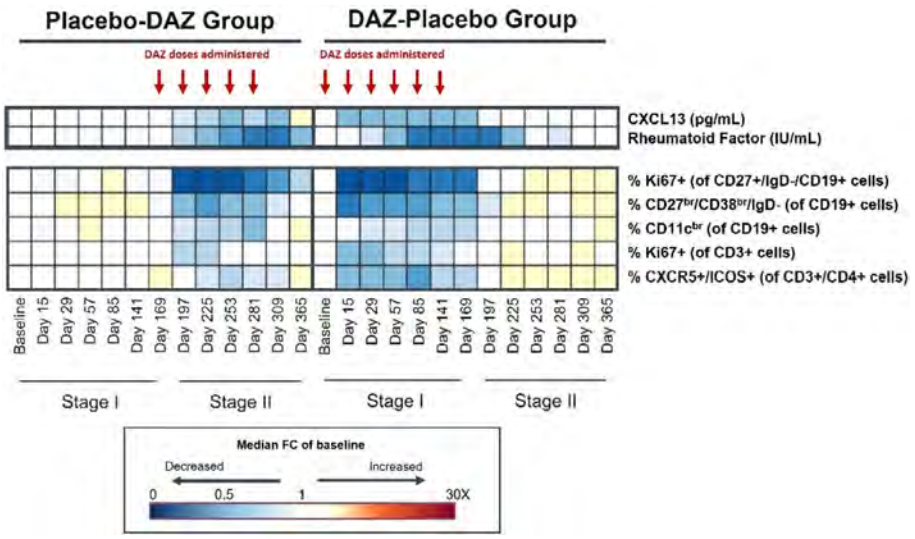
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM



Impact of dazodalibep on blood biomarkers of T and B cell costimulation in Population 1: Subjects with moderate-to-severe systemic disease activity. DAZ, dazodalibep; FC, fold-change.

Background/Purpose: Dazodalibep (DAZ) is a non-antibody fusion protein that acts as a CD40L antagonist and blocks costimulatory signals between immune cells, including T cells, B cells, and antigen-presenting cells. CD40L inhibition disrupts costimulatory signals that lead to activation of germinal centers (GC), pathogenic B cells, plasma cells, and autoantibodies that are hallmarks of Sjögren's disease. Among the previously studied biomarkers in Sjögren's, CXCL13 is produced by activated T Follicular Helper (Tfh) cells and is essential for GC formation and activity.

Methods: This study enrolled two distinct populations of subjects with Sjögren's (NCT04129164). Population 1 (Pop1) included 74 pts with moderate-to-severe systemic disease activity as defined by a EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) ≥ 5. Population 2 (Pop2) consisted of 109 pts with unacceptable symptom burden and limited extraglandular systemic involvement as defined by a EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) ≥ 5 and ESSDAI < 5. Eligible subjects were randomized 1:1 to receive intravenous DAZ 1500 mg or placebo (PBO) Q2W x 3 doses, then Q4W x 4 additional doses (Stage I). Starting on Day 169, subjects initially randomized to DAZ transitioned to PBO Q4W x



Impact of dazodalibep on blood biomarkers of T and B cell costimulation in Population 2: Subjects with an unacceptable symptom burden, and limited extraglandular systemic organ involvement. DAZ, dazodalibep; FC, fold-change.

5 doses and those initially randomized to PBO were switched to DAZ Q4W x 5 doses and then followed for 12 weeks (Stage II). B and T cell subsets (Ki67+ post-switch memory B cells [of CD27+/IgD-/CD19+ cells], $CD27^{br}/CD38^{br}$/Ig D- plasmablasts, $CD11c^{br}$ atypical memory cells, CXCR5+/ICOS+ TfH, and Ki67+ T cells) were immunophenotyped using flow cytometry. Serum levels of CXCL13 and rheumatoid factor (RF) autoantibodies were assessed by immunoassay and nephelometry, respectively.

Results: Baseline immune profiles of the subjects in Pop1 and Pop2 revealed similar levels of autoantibodies and CXCL13. Baseline levels of $CD27^{br}/CD38^{br}$/Ig D- plasmablasts, and $CD11c^{br}$ atypical memory cells were higher in Pop2 than Pop1, while composition of other blood immune cell phenotypes remained similar. In Pop2, compared with the PBO group, DAZ treatment produced significant and rapid reductions from Day 15 onwards in the percentage of Ki67+ post-switch memory B cells, $CD27^{br}/CD38^{br}$/Ig D- plasmablasts, $CD11c^{br}$ atypical memory cells, and CXCR5+/ICOS+ TfH cells, as well as decreases in the serum levels of CXCL13 and RF. These results were similar to those previously observed in Pop1 Stage I. In Stage II, when PBO-treated subjects transitioned to DAZ treatment, there were similar sustained reductions in these biomarkers. In DAZ-treated subjects that transitioned to PBO in Stage II, these biomarkers returned to baseline values.

Conclusion: DAZ-mediated CD40-CD40L blockade in subjects with Sjögren's disease reduced biomarkers by inhibiting T/B cell costimulation and downstream biomarkers of GC formation, activity, and autoantibody production. These findings demonstrate the biological impact of DAZ in subjects with Sjogren's across populations with either moderate-to-severe systemic disease activity or unacceptable symptom burden.

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Individuals of diverse ethnic and racial backgrounds are generally underrepresented in psoriatic arthritis (PsA) research and clinical trials, despite evidence that their disease presentation, severity and course may be distinct. Here we aimed to characterize a cohort of patients with PsA to evaluate how race, ethnicity, and sex may inform features of clinical presentation, comorbidities, disease course and outcomes.

Table 1. Baseline Characteristics by Race and Ethnicity

Characteristics	All (n=817)	Non-Hispanic, white (n=632)	White Hispanic + Nonwhite (n=185)	p-value
Age- mean (SD)	46.47 (14.42)	47.16 (14.73)	44.1 (13.06)	**0.007**
Female- n (%)	398 (48.71)	307 (48.58)	91 (49.19)	0.883
Race/Ethnicity- n (%)*				0.000
White	632 (77.4)	632 (100.00)	--	
Black	15 (1.84)	--	15 (8.11)	
Asian	58 (7.10)	--	58 (31.35)	
Other	81 (9.92)	--	81 (43.78)	
Hispanic	93 (11.38)	--	93 (50.27)	
Body Mass Index- mean (SD)	27.75 (6.69)	27.61 (6.59)	28.28 (7.05)	0.296
Comorbidities- n (%)				
Depression	182 (22.36)	150 (23.73)	32 (17.30)	0.072
Anxiety	166 (20.32)	141 (22.31)	25 (13.51)	**0.009**
Cardiovascular disease	313 (38.31)	239 (37.82)	74 (40.00)	0.591
Metabolic disease	132 (16.16)	90 (14.24)	42 (22.70)	**0.006**
Diabetes	69 (8.45)	45 (7.12)	24 (12.97)	**0.012**
Current smoker	63 (7.71)	43 (6.80)	20 (10.81)	0.072
Disease involvement—n (%)				
Axial disease	179 (21.91)	129 (20.41)	50 (27.03)	0.056
Axial (radiographic)	150 (18.36)	103 (16.30)	47 (25.41)	**0.005**
Axial (non-radiographic)	29 (3.55)	26 (4.11)	3 (1.62)	0.107
Enthesitis	274 (33.54)	211 (33.39)	63 (34.05)	0.866
Dactylitis	263 (32.19)	208 (32.91)	55 (29.73)	0.415
Nail disease	467 (57.16)	360 (56.96)	107 (57.84)	0.832
Skin disease	807 (98.78)	622 (98.42)	185 (100.00)	0.085
Radiographic erosion	227 (27.78)	171 (27.06)	56 (30.27)	0.391
Medication use—n (%)				
Any	610 (74.66)	479 (75.79)	131 (70.81)	0.171
Biologic	354 (46.15)	273 (46.19)	81 (46.02)	0.968

* Patients may identify as more than one race/ethnicity.

Methods: 817 consecutive patients with PsA from a large, diverse metropolitan area (NYU Psoriatic Arthritis Center, New York) were enrolled in an observational, longitudinal registry. Demographics, medical history, medication use, and psoriatic disease phenotype and activity were all recorded and analyzed.

Results: The population was 77.4% non-Hispanic, White, 7.1% Asian, 1.8% Black, with 9.9% identified as other races or multiracial, and 11.8% identified as Hispanic (Table 1). Non-white individuals (include white Hispanic participants) were younger, more likely to have concomitant metabolic disease and diabetes, and less likely to have anxiety compared to non-Hispanic white individuals. Phenotypically, they were also more likely to have radiographic axial disease (p=0.005). Non-white individuals had higher tender joint counts (4.0 vs. 3.0, p=0.03) with similar swollen joint counts (2.2 vs. 1.8, p= 0.31) and proportion of individuals receiving PsA medication (70.8% vs. 75.8%, p=0.17) (Figure 1). Even when adjusting for age, sex, and medication use, the tender joint count of non-white individuals was estimated to be 1.03 joints more than white individuals (Figure 2). In the subgroup of medication naïve patients (n=207), non-white individuals also had significantly higher precent body surface area (BSA) affected by psoriasis (5.4% vs. 2.2%, p=0.02). Hispanic individuals were significantly more likely to have higher tender joint counts (4.4 vs. 3.0, p=0.03), higher RAPID3 scores (14.6 vs. 10.3, p=0.004), and moderate-severe psoriasis (30.7% vs. 17.5%, p=0.01) compared to non-Hispanic white individuals. Compared to men, women demonstrated higher RAPID3 scores (11.5 vs. 9.8, p=0.011), despite similar tender and swollen joint counts (3.5 vs. 3.0, p=0.27 and 1.8 vs. 2.0, p= 0.29 respectively) and skin involvement (3.5% BSA vs. 2.9%, p=0.37). Women continued to have higher estimated RAPID3 scores when adjusting for race/ethnicity, age, and medication use (mean difference 1.66 points higher, 95% CI 0.4-2.9, p=0.01).

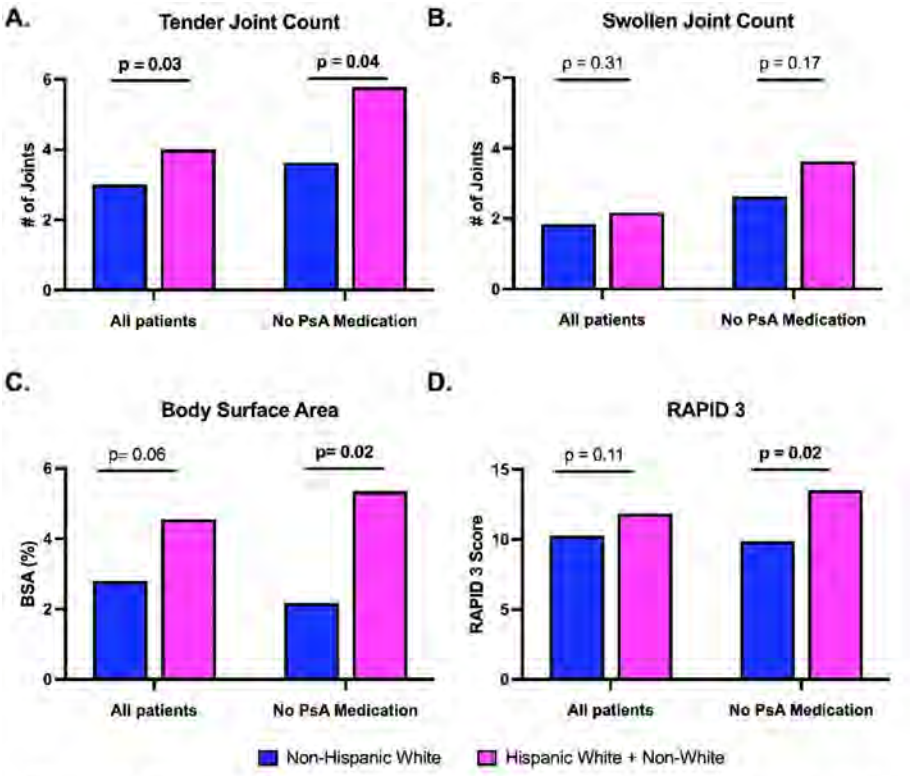

Figure 1. Disease activity measures by race and ethnicity. Unadjusted activity measures for tender joint count (A), swollen joint count (B), percent body surface area (BSA) covered by psoriasis (C) and RAPID 3 score (D). Left side of each graph shows all participants (n= 817) and right side shows only those patient naive to immunomodulatory treatment (n=207, right). Blue represents non-Hispanic White individuals and pink represents non-White individuals (including those identifying as Hispanic and White).

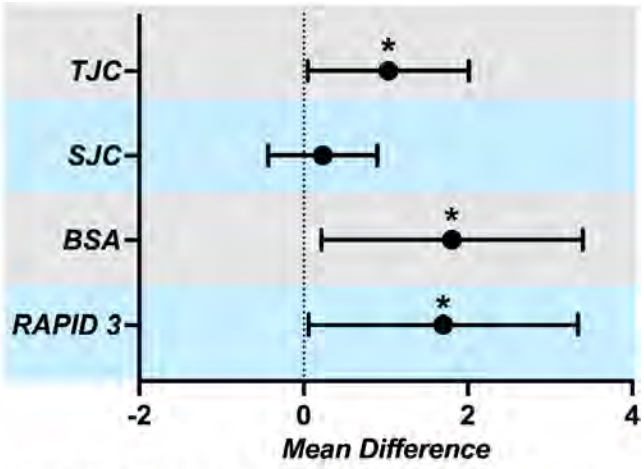

Figure 2. Estimated mean differences based on regression model analysis adjusted for age, sex, and medication use. Mean difference represents non-White and Hispanic White patients as compared to non-Hispanic White individuals as the reference.

Conclusion: We describe the NYU Psoriatic Arthritis Cohort, a relatively more diverse cohort compared to other registries and clinical trials, which includes 22.6% non-white individuals, mostly identifying as Asian or Hispanic. Non-white individuals had higher tender joint counts compared to white individuals despite similar swollen joint counts and medication use. Unexpectedly, they also had higher rates of radiographic axial disease. Additionally, women had higher RAPID 3 scores despite similar joint and disease measures. These findings may reflect differences in PsA presentation and outcomes as experienced by racial, ethnic, and sex groups, which need to be taken into consideration in clinical care and research design.

Psoriatic Disease Associated with Neuroconnectivity Alterations in the Default Mode Network

Rebecca Haberman[1], Sydney Catron[1], Yu Veronica Sui[1], Sarah Moussavi[1], Soumya Reddy[2], Eileen Lydon[3], Andrea Neimann[1], Alexis R Ogdie[4], Mariana Lazar[1] and Jose Scher[5], [1]NYU Grossman School of Medicine, New York, NY, [2]NYU School of Medicine, New York, NY, [3]New York University, New York, NY, [4]University of Pennsylvania, Philadelphia, PA, [5]New York University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Psoriatic Arthritis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Despite significant advances in psoriatic disease (PsD) therapeutics, treatment response remains suboptimal. Even in patients with psoriatic arthritis (PSA) that achieve seemingly controlled inflammation, up to half continue to experience residual symptoms, notably pain and fatigue, which can prevent meaningful improvement in symptoms and quality of life. However, the pathophysiology and effectors of residual pain are not well understood. Functional brain MRI

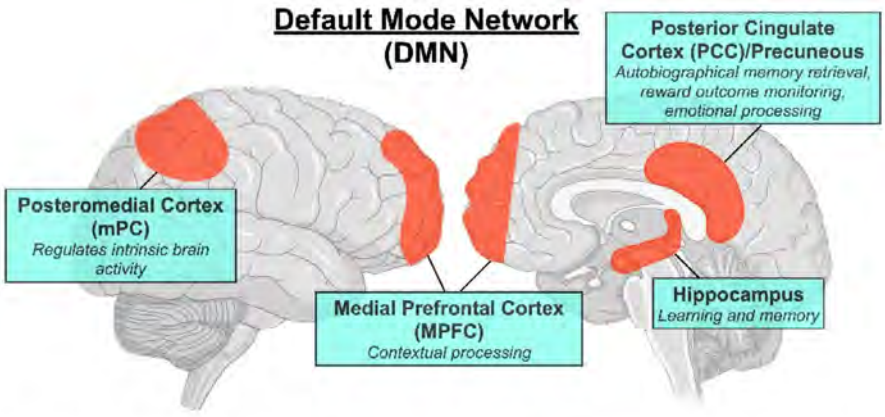

Figure 1. The Default Mode Network (DMN) is often altered in chronic pain states. The main structures include the posteromedial cortex (mPC), the medial prefrontal cortex (MPFC), the posterior cingulate cortex (PCC), the precuneous, and the hippocampus.

(fMRI) can be used to identify alterations in brain connectivity as a possible basis for residual pain and have the potential to discern inflammatory driven pain from centrally-provoked pain. Here we describe pilot fMRI data showing neuroconnectivity changes in those with PsD.

Methods: Seven patients with PsD were enrolled from the NYU Psoriatic Arthritis Center (PAC). Patients on psychotropic medications were excluded. Demographics, medical history, and medication use were recorded and focused musculoskeletal and skin exams were performed. Participants completed patient reported outcomes including the SF-36, Beck Depression Index, fatigue numeric rating score, and RAPID 3. Four healthy controls were used as a comparison group. fMRI sequences were obtained in all participants at both rest and with a fatigue inducing task (Paced Auditory Serial Addition Test) using a 3 Tesla Siemens Prisma scanner. fMRI time series were analyzed using the independent component analysis, with a focus on connectivity within the default mode network (DMN, Figure 1) which has been previously implicated in depression and chronic pain states such as fibromyalgia.

Results: Compared to healthy controls, those with PsD had decreased connectivity between the DMN's posteromedial cortex node and the superior parietal lobule ($p = < 0.05$ FDR-corrected at cluster level) (Figure 2). Additionally, for the 7 participants with PsD, levels of pain, depression, and fatigue all correlated with strength of connectivity in pathways of the DMN (Figure 3).

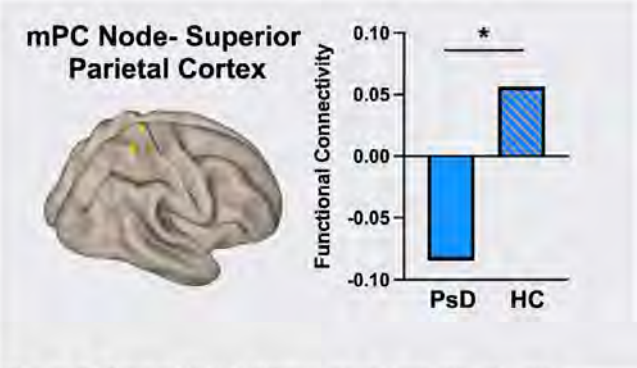

Figure 2. Connectivity differences in individuals with psoriatic disease (PsD) and healthy controls (HC). The posteromedial cortex (mPC) is involved in intrinsic brain activity and the superior parietal lobule in cognitive function, attention, and higher order thinking. *p < 0.05

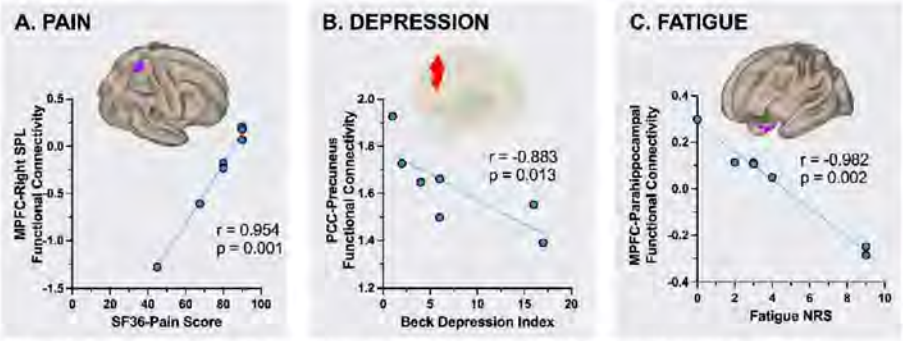

Figure 3. Functional connectivity patterns in the DMN (default mode network) correlate with pain, depression, and fatigue. (A) Standard Form (SF)-36 Pain Subscale (higher number indicating less pain) correlates with activity of the medial prefrontal cortex (MPFC, creating active associations within a contextual frame to generate predictions and expectations of what will be encountered next in the environment) to right superior parietal lobule (SPL, cognitive function, attention, and higher order thinking). (B) Beck depression index (higher number indicating higher level of depression) correlates with activity of the posterior cingulate cortex (PCC) to precuneus (memory retrieval, reward out coming monitoring, and emotional processing). (C) Fatigue numerical rating scale (NRS, 0-10 with higher number indicating less fatigue) correlates with activity of the MPFC to parahippocampus (contextual processing).

Conclusion: This initial data demonstrates the feasibility and acceptability of using fMRI to characterize neuroconnectivity in patients with PsD. We observed differences in functional connectivity between healthy participants and patients with PsD, even with well controlled disease. Furthermore, identifying networks and connections associated with pain, depression, and fatigue may ultimately help in identifying and characterizing residual pain that contributes to worse clinical outcomes. Future studies will confirm and further characterize these findings using larger sample sizes.

The Window of Opportunity in Psoriatic Arthritis: Similar to Rheumatoid Arthritis?

Selinde Snoeck Henkemans[1], Pascal de Jong[1], Jolanda J. Luime[1], Marc r. Kok[2], ilja Tchetverikov[3], Annette van der Helm-van Mil[4] and marijn vis[1], [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Albert Sweitzer Hospital, Dordrecht, Netherlands, [4]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: In rheumatoid arthritis (RA), initiation of treatment within the window of opportunity, i.e. 12 weeks after symptom onset, results in higher remission rates, and less radiographic progression and functional impairment. In contrast, in psoriatic arthritis (PsA) a diagnostic delay of 1-2 years is still common. PsA guidelines state that DMARDs should be started early, with a maximum delay of 1 year. However, it is unknown whether a shorter delay of 12 weeks yields better clinical outcomes. We aimed to investigate what the window of opportunity is in PsA.

Methods: All newly diagnosed, DMARD naïve PsA patients who participated in the Dutch southwest Early PsA cohort (DEPAR) were included (n=855). First, we calculated total delay, and then split this into patient and general practitioner (GP) delays to assess where potential gains could be made. Thereafter, patients were categorized in 3 groups, based upon total delay:

1. < 12 weeks delay (early diagnosis)
2. 12-52 weeks delay (late diagnosis)
3. > 52 weeks delay

Aforementioned groups were compared on their probability of achieving Minimal Disease Activity (MDA) and Disease Activity in PSoriatic Arthritis (DAPSA) remission, defined as DAPSA < 5. We also assessed differences in radiographic progression and functional impairment. Radiographic progression is measured with the modified Sharp van der Heijde score (mTSS), while functional impairment is measured with the Health Assessment Questionnaire–Disability Index (HAQ-DI). Mixed models were used to compare outcomes over time (3 years).

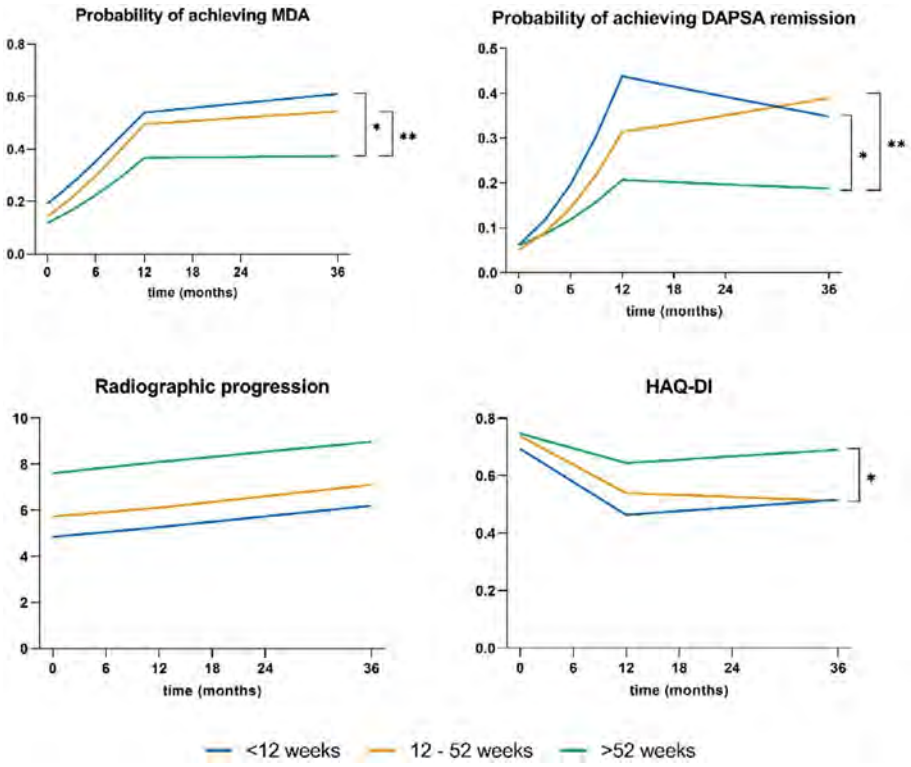

Figure 1. Probability of achieving MDA and DAPSA remission, and radiographic progression and functional ability over 3 years. *Indicates a significant difference between the >52 weeks delay and early diagnosis group, ** indicates a significant difference between the >52 weeks delay and late diagnosis group.

Results: Median total delay was 42.0 weeks. Patient and GP delay were 4.4 and 18.0 weeks, respectively. PsA patients with > 52 weeks delay were more often female, had less swollen joints and lower CRP and ESR. They also more often had enthesitis. In contrast, no baseline differences were found between early and late diagnosis groups, respectively < 12 weeks and 12-52 weeks. The group with > 52 weeks delay was significantly less likely to achieve MDA and DAPSA remission over 3 years of follow-up compared to both the early and late diagnosis groups (**Figure 1**). The > 52 weeks delay group also scored significantly worse on HAQ-DI than the early diagnosis group. Radiographic progression did not differ significantly between groups. Although all outcomes were numerically better in PsA patients who were diagnosed within 12 weeks compared to those with a diagnosis within 52 weeks, no significant differences were found (**Figure 1**).

Conclusion: Early referral and diagnosis is associated with better clinical outcomes. Therefore, disease outcomes of PsA patients may improve with timely referral to a rheumatologist.

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Despite an increasing number of therapeutic options, less than one-third of patients with PsA achieve remission. A major cause of non-response is that PsA is studied and managed as if it were a single disease, without accounting for heterogeneity in disease presentation and prognosis. Understanding heterogeneity better can improve

Table 1. Baseline characteristics overall and by psoriatic arthritis phenotypes in the PARC cohort. SD, Standard Deviation; N (%), Number of patients (Percentage); BMI, body mass index; TJC, total joint count; SJC, swollen joint count; BSA, body surface area involved by psoriasis; Pt, patient; PsO, psoriasis; IBD, inflammatory bowel disease; CRP, C-reactive protein †p-values from Kruskal-Wallis and Fisher's exact test for continuous and categorical variables respectively *From the BASDAI questionnaire Missing variables: race, 47 and ethnicity, 85

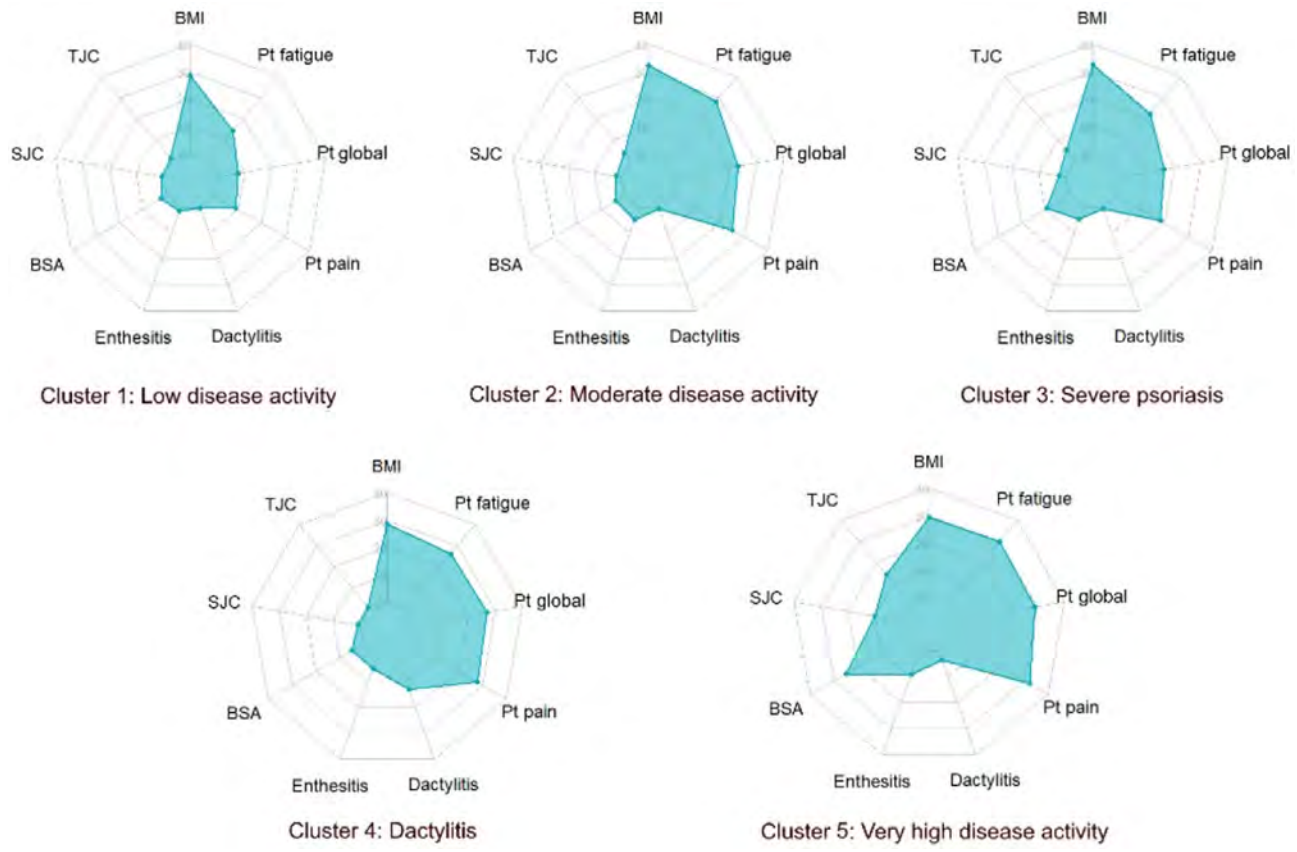

Figure 1. Radar chart comparison of the mean values of the continuous variables across the five phenotypic clusters of psoriatic arthritis in the PARC cohort (n=529). Note: The variables are not standardized for better interpretability and hence on different scales plotted from 0 (lowest at the center) to maximum value for the variable (highest at the outside). Maximum value for the different variables is as follows: BMI 40, TJC 68, SJC 66, BSA 20, Enthesitis count 8 (Leeds enthesitis index + proximal plantar fascia), Dactylitis count 20, Pt pain 10, Pt global 10, and Pt fatigue 10. Abbreviations: BMI, body mass index; TJC, total joint count; SJC, swollen joint count; BSA, body surface area involved by psoriasis; Pt, patient

treatment selection, shorten exposure to suboptimal therapies, reduce potential for side effects, and improve long-term outcomes. The objective of this study was therefore to identify distinct phenotypes in PsA using the PsA Research Consortium (PARC) cohort.

Methods: Baseline disease characteristics from the multicenter PsA Research Consortium (PARC) study was used to cluster PsA patients. Variable selection was performed by clinical relevance and continuous variables were standardized. Multiple Imputation by Chained Equations (MICE) was used to impute missing values. Factor analysis of mixed data (FAMD) was applied for dimensionality and collinearity reduction, followed by hierarchical clustering on the principal components to group similar patient phenotypes. The optimal number of clusters was determined by evaluating the balance between within-cluster variance reduction and between-cluster variance reduction for each level of the hierarchical clustering tree (tree method). Kruskal-Wallis and Fisher's exact tests were performed to examine differences in continuous and categorical variables respectively across the clusters.

Results: In this analysis of 21 clinical variables from 529 PsA patients, five distinct phenotypic clusters were identified. The baseline characteristics of the cohort are presented in **Table 1**. Cluster 1 (50.09%) represented patients with low disease activity, joint counts, and PROs. Cluster 2 (36.86%) displayed moderate disease activity with higher BMI and joint counts compared to Cluster 1. Cluster 3 (5.10%) was characterized by severe psoriasis, higher guttate, palmoplantar, inverse, genital psoriasis, nail dystrophy (59.26%), and the highest mean BMI (32.44 kg/m^2). Cluster 4 (0.37%) exhibited dactylitis with relatively low joint counts, but worse patient-reported outcomes (PROs). Cluster 5 (7.56%) represented very high disease

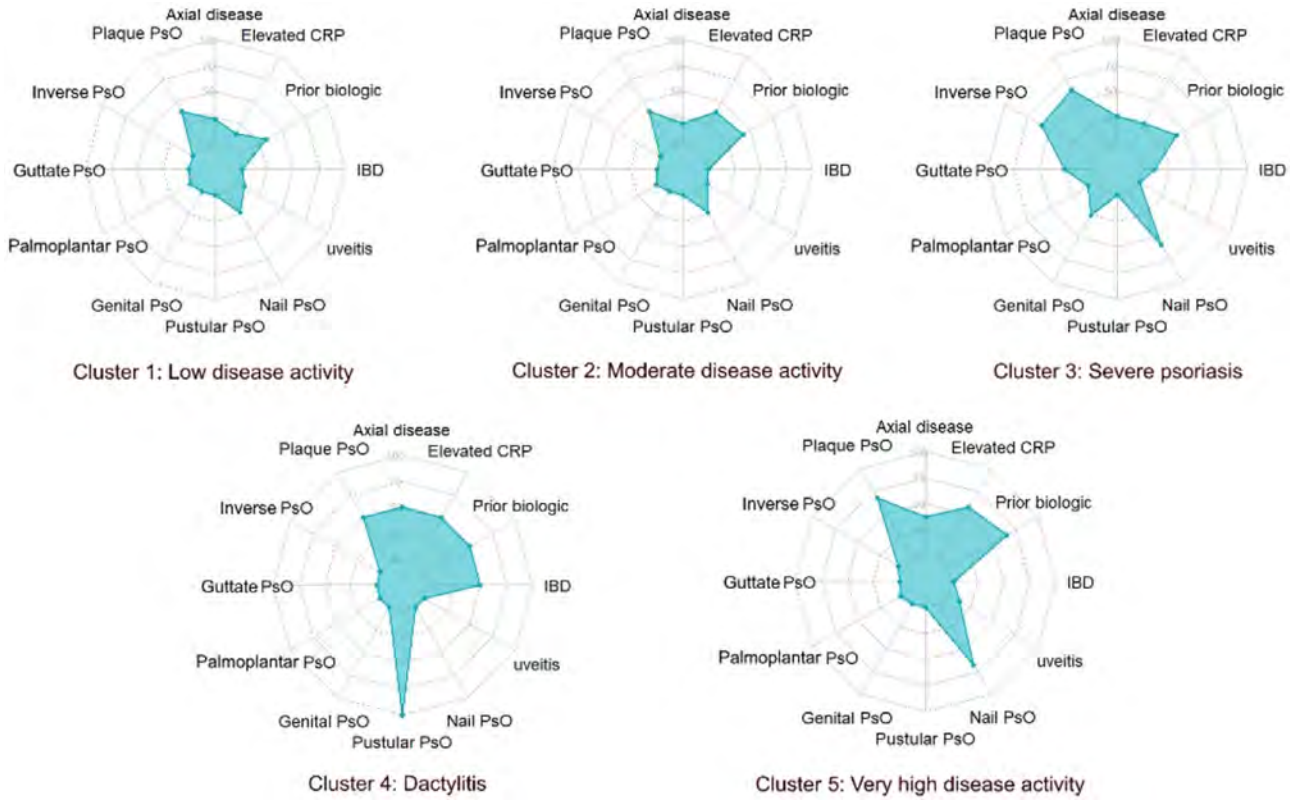

Figure 2. Radar chart comparison of the mean percentages of the categorical variables across the five phenotypic clusters of psoriatic arthritis in the PARC cohort (n=529). Note: The variables are plotted from 0 (lowest at the center) to 100 percent (highest at the outside). Abbreviations: PsO, psoriasis; IBD, inflammatory bowel disease; CRP, C-reactive protein

activity patients with the highest joint counts, BSA, and PROs (**Figures 1 & 2**). The proportion of females was significantly higher in the moderate/high disease activity clusters and all patients in the dactylitis cluster were females. The very high disease activity cluster had a significantly higher proportion of non-white population (15%) compared to other clusters although overall numbers were small. The clusters were significantly different across all clustering variables except axial disease, uveitis, and palmoplantar psoriasis ($p > 0.05$).

Conclusion: The data-driven clusters identified in this real-world study highlight the extensive heterogeneity in PsA. The variability in clinical parameters across clusters underscores the need for personalized treatment approaches in PsA, accounting for unique disease features. Future studies should focus on validating these clusters in different cohorts and exploring their application in precision medicine to transform PsA treatment paradigms.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory immune-mediated musculoskeletal skin disease that affects approximately 25% of psoriasis patients causing progressive disability. As a heterogeneous disease, with sometimes subtle manifestation, accurate assessment of PsA is difficult. As such, there is a need for early detection diagnostic tests for PsA. A liquid chromatography – high resolution mass spectrometry (LC-HRMS) general untargeted metabolomics analysis following solid phase microextraction (SPME) was applied to serum samples collected from patients with PsA and psoriasis without PsA (PsC), to perform discovery analysis to investigate potential diagnostic markers of PsA.

Methods: Serum samples were obtained from a biobank of carefully phenotyped PsC (n=100) and PsA (n = 101) patients who had no history of cancer, had no active infection nor received previous treatment with biologics. Novel high throughput technique – SPME – was used to prepare all samples simultaneously followed by LC-HRMS analysis.

Data (pre)processing and feature identification was performed using 2 workflows - Compound Discoverer 3.3 and an independent Rscript. Supervised multivariate analysis and various Machine Learning (ML) algorithms including logitboost, adaptive boosting, support vector machine (SVM), logistic regression, and random forest (RF), were used for predictive feature analysis. Area Under the Receiver Operating Characteristic (AUROC) was then used to evaluate the performance of these features. Only features in models with an area under the curve (AUC) of 0.85 or greater were considered as candidate biomarkers.

Results: Table 1 provides the demographic and disease characteristics of the included subjects. Table 2 provides a summary of the results from predictive feature analyses. A minimum of ten features and a maximum of eighty features from the adaptive boost models produced an AUC of 0.896 and 0.921 respectively. All other models with feature numbers ranging

Table 1: Summary of patient demographics and disease characteristics

Patient category	Total No. of patients	Gender	Age (median) (yrs)	BMI	Avg. Ps. Dur. (yrs)	Avg. PsA Dur. (yrs)
PsC	101	Males (54), Females (47)	19-73 (42)	27.5	16.8	-
PsA	102	Males (55), Females (47)	19-70 (46)	27.8	15.5	1.9

Table 2: Confirmed and tentatively identified features of statistical significance. These features were implicated in a cross validated PLS-DA model. Features containing a (*) were also found to perform well (>0.85) using Area Under the Receiver Operating Characteristic (AUROC).

3146	*784.5516	18.05	783.5414	$[M+H]^+$	2.4	2) PC(20:4(5Z,7E,11Z,14Z)-OH(9)/15:0);
6149	*521.384	17.7	520.3764	$[M+H]^+$	2.3	DG(20:4(5Z,7E,11Z,14Z)-OH(9)/0:0/8:0)
6176	*913.6059	16.9	985.5727	$[M+NH_4]^+$	2.2	PC(22:5(4Z,7Z,10Z,13Z,19Z)-O(16,17)/22:5(7Z,10Z,13Z,16Z,19Z))
5871	*703.4923	17.8	702.4836	$[M+H]^+$	2.2	PA(18:1(9Z)-O(12,13)/i-17:0)
5628	555.3918	18.0	554.3819	$[M+H]^+$	2.1	DG(PGD1/0:0/8:0)

between twenty to eighty produced AUC between 0.891 and 0.915. Several small molecules could be validated via MS Level 2 spectral database matching. Trihydroxyoctadecenoic acid and N-nervonoyl cysteine contributed significantly to the multivariate supervised analysis and performed well according to high AUROC scores. Interestingly, lipids such as docosahexanoyl-sn-gylcerophosphocholine were identified via MS level 2, but there were several other features that were found to be significant that could only be tentatively identified as glycero-lipids and fatty acids. Results from this metabolomics workflow were integrated with top-down multi-omics data for the same patients. Data integration revealed that confirmed and tentatively identified features like glycero- and phospholipids overlapped differentially expressed pathways from the transcriptome.

Conclusion: SPME-LC-HRMS based untargeted metabolomic analyses have identified small molecules (lipids) with excellent discriminative ability between PsA and PsC. Thus, the development of quantitative targeted assays for these metabolites and subsequent validation may provide diagnostic markers for PsA.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes II: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Nearly 8% of patients with spondyloarthritis (SpA) manifest symptoms that are compatible with active inflammatory bowel disease (IBD), despite not having any previous diagnosis of chronic intestinal pathologies. It is well established that the microbiome plays an important role in immunity, and there is growing evidence showing that intestinal dysbiosis of microbial communities is associated with different immune-mediated diseases. This association is particularly notable in IBD, which is characterized by aberrant microbiome communities and can also be treated by restoring homeostasis through fecal microbiota transplants. We therefore hypothesize that the gut microbiome could be a determining factor in the etiology of psoriatic arthritis (PsA), a type of SpA, and a potential modulator of co-occurrence with intestinal inflammation.

Methods: As part of the EISER study, we selected a subset of 196 subjects diagnosed with with axial, periferic or mixed forms of PsA, who had no prior diagnosis of IBD or other chronic intestinal pathologies. The presence of subclinical and clinical IBD was evaluated at time of enrollment. Subjects with fecal calprotectin (CP) levels less than 80μg/g of fecal matter were considered negative for IBD. For patients with CP levels of 80 μg/g or higher, IBD was diagnosed based on colonoscopy and histological analysis of biopsies collected during the procedure. Capsule endoscopy was performed on those patients with a negative colonoscopy result for additional confirmation. Stool samples were collected from all participants, and microbial DNA was extracted for shotgun metagenomic sequencing using the Illumina HiSeq platform. Sequenced data was processed using MetaPhlAn 4 to estimate microbial composition and HUMAnN 2 to annotate bacterial pathways.

Results: Twenty-five out of 196 subjects in our cohort (12.75%) had subclinical IBD (sIBD), two of whom (1.02% of total) were confirmed to have clinical IBD (cIBD). The use of proton-pump inhibitors (PPI) resulted in significant differences in overall beta diversity (PERMANOVA, $p < 0.008$). The levels of fecal CP were significantly correlated with the abundance of multiple species within the *Streptococcus* genus and with *Rothia mucilaginosa*. Patients with sIBD had lower abundance of *Dialister,Barnesiella spp* and *Eubacterium rectale,* and higher abundance of taxa including *Blautia* spp, *Prevotella copri and Roseburia* compared with non sIBD patients. These findings were further confirmed in the two cIBD patients.

Conclusion: Microbiome composition was impacted by the use of PPIs, in agreement with previous reports. Bacteria typically found in the oral cavity were significantly correlated with CP levels, suggesting a potential role for oral taxa in pro-inflammatory responses in PsA patients. We identified taxa differentially enriched in sIBD patients consistent with patterns observed in the two patients with confirmed IBD diagnosis, suggesting a potential role for these taxa as biomarkers. Further

analysis will evaluate differences in microbial pathways associated with disease groups and medications, as well as the relation between gut microbiome composition, function and blood proteomic biomarkers.

Aortic Dilatation and PET/CT Vascular Activity at Diagnosis and 5 Years in an Inception Giant Cell Arteritis (GCA) Cohort

Anthony Sammel[1], Ivan Ho Shon[2], Daniel Moses[1], Fredericks Stacey[1], Gita Mathur[1], Claudia Hillenbrand[3], Edward Hsiao[4], Schembri Geoffrey[4], Rodger Laurent[4] and Eva Wegner[2], [1]Prince of Wales Hospital, Randwick, Australia, [2]The Prince of Wales Hospital, Sydney, Australia, [3]University of NSW, Randwick, Australia, [4]Royal North Shore Hospital, St. Leonards, Australia

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: Imaging

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Aortic dilatation is typically a late complication of giant cell arteritis (GCA) but there are no tools to risk stratify patients at the time of diagnosis. We assessed the prevalence of aortic dilatation at 5 years in an inception giant cell arteritis cohort and assessed the relationship with FDG-PET/CT detected vascular activity at diagnosis, 6 months and 5 years.

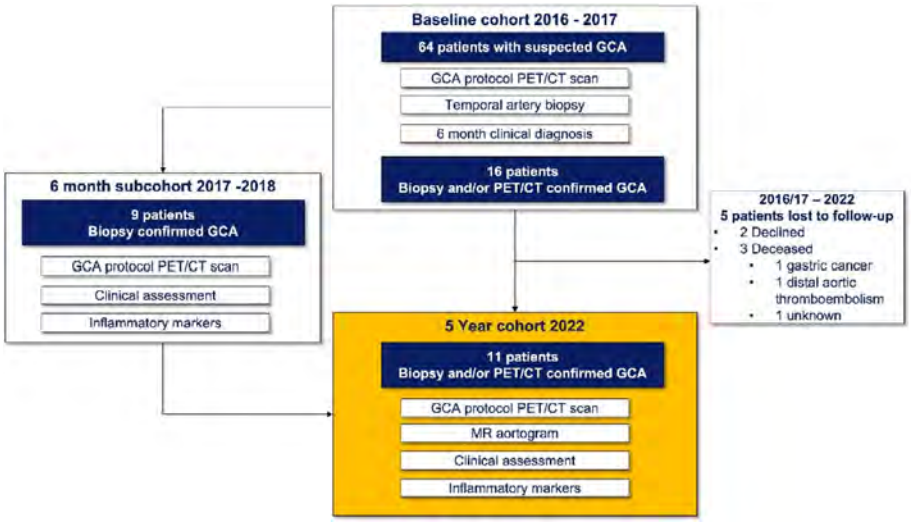

Figure 1: Patient flow

Methods: Patients were eligible for this 5-year study if they had been enrolled in the Giant Cell Arteritis and PET Scan (GAPS) cohort in 2016 or 2017, had a clinical diagnosis of GCA and a positive temporal artery biopsy (TAB) and/or a positive FDG-PET/CT scan at diagnosis. Patients underwent an FDG-PET/CT scan including assessment of cranial and large vessels, non-contrast MRI of the aorta, trans-thoracic echocardiogram (TTE) of the ascending aorta, blood collection and clinical assessment. PET/CT scans were dual reported by 2 blinded nuclear medicine physicians. Scans were reported overall positive or negative for disease activity and a visual grading of FDG avidity in each vascular territory was made with comparison to blood pool. MRI was reported by a single blinded cardiovascular radiologist and thoracic aortic dilatation was defined as external diameter >= 40 mm in ascending or >= 30 mm in the descending aorta.

Results: 16 of the original 64 "suspected GCA" patients in the GAPS cohort met inclusion criteria and 11 participated in the 5-year study (3/16 deceased, 2/16 declined). The median age was 75, 73% were female and all were in clinical and serological remission with a median CRP of 1 (range 1 - 8). 4/11 (36%) patients had aortic dilatation (range 40 - 43mm) and 5/11 (45%) had globally active FDG-PET/CT scans. There was a trend towards a higher median aortic diameter in those with positive scans at 5 years (42 mm vs 35 mm, p=0.08) but aortic avidity at diagnosis did not predict 5-year dilatation. The distribution of FDG-PET/CT detected activity changed from a mix of cranial and large vessel disease at diagnosis to exclusively large vessel disease at 5-years. Aortitis developed in 4 patients who previously had inactive aortas. All 6 patients with inactive scans were taking an immunosuppressive agent (methotrexate, leflunomide, azathioprine or tocilizumab) at 5 years while all patients with active scans were not on therapy (p=0.02). TTE had excellent correlation with MRI for maximum aortic diameter (Pearson's correlation coefficient 0.91).

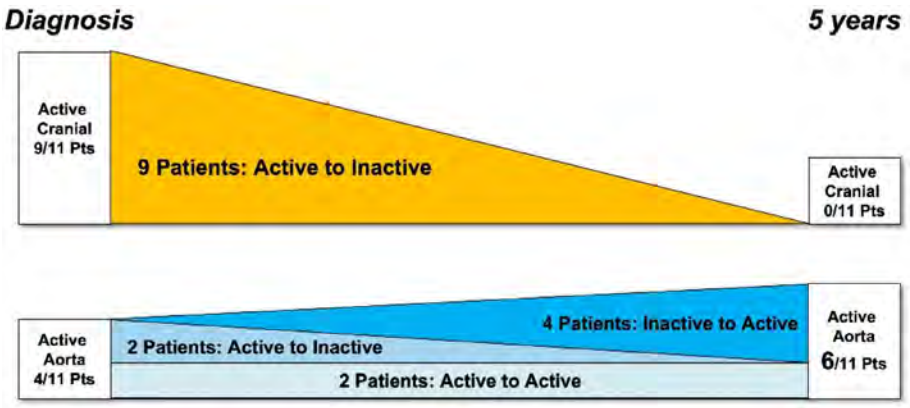

Figure 2: FDG-PET/CT activity by vascular region at diagnosis and 5 years

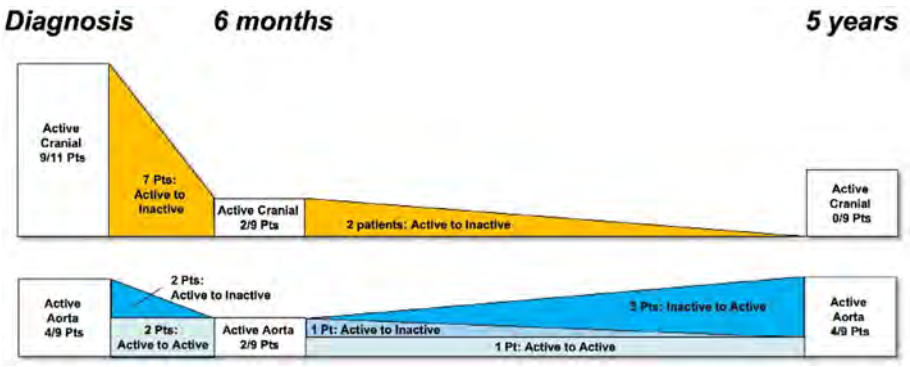

Figure 3: FDG-PET/CT activity by vascular region at diagnosis, 6 months and 5 years (subcohort who underwent 6 month scans)

Conclusion: Aortic dilatation was present in 36% GCA patients at 5 years. The distribution of FDG PET-CT detected avidity changed from predominantly cranial to exclusively large vessel disease and this may explain the lack of association between aortic avidity at diagnosis and dilatation at 5 years. Long-term use of steroid sparing agents may protect against subclinical vascular disease activity. TTE was a reliable screening modality for late aortic dilatation.

The Real-World Experience of Combined Cranial and Large Vessel FDG-PET/CT in the Investigation of Giant Cell Arteritis

Keren Port[1], Ivan Ho Shon[1], Sally Ayesa[1], Rachel Langford[1], Olivia Bennett[1], Andrew Csillag[1], Stacey Fredericks[1], Luz Palacios-Derflingher[2], Eva Wegner[1] and Anthony Sammel[1], [1]The Prince of Wales Hospital, Sydney, Australia, [2]University of New South Wales, Sydney, Australia

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: Imaging
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: GCA is a systemic medium-large vessel vasculitis (M-LVV) involving the cranial arteries, aorta and its major branches. Recent studies have shown that PET/CT including the cranial and large vessels offers high diagnostic accuracy for GCA in research settings. At our institution in Sydney, Australia, PET/CT is the protocolized first-line investigation for GCA, and here we report its diagnostic performance in this "all comer" real world setting.

Methods: We audited all inpatients and outpatients investigated with PET/CT for suspected new onset GCA between July 2019 and March 2022. Patients were scanned from vertex to thighs with arms by their side, 90 minutes post-fluorodeoxyglucose (FDG) administration. Patients completed a self-reported questionnaire at the time of scan. Scans were reported by the experienced nuclear medicine physician of the day as overall positive, equivocal or negative for M-LVV. FDG uptake by vascular region was also reported. The gold standard comparator was the treating clinician's diagnosis of active M-LVV at a minimum of 6 months post the time of the scan. Active M-LVV included diagnoses of GCA, large vessel vasculitis and aortitis. Temporal artery biopsy (TAB) and vascular US results conducted within 4 weeks of scan were recorded.

Results: 135 patients underwent PET/CT for suspected new onset GCA, with a median age of 73 years (range 48-98), 70% were female. 86 (63.7%) patients were taking glucocorticoids at the time of scan. 44 (32.6%) patients had a final clinical diagnosis of active M-LVV. 35 (25.9%) scans were reported as positive, 27 (20%) equivocal and 73 (54.1%) negative for M-LVV. The likelihood ratio for a diagnosis of active M-LVV with a positive scan was 70.3, equivocal scan 0.59, and a negative scan 0.12. Sensitivity (Sn) and specificity (Sp) of PET/CT was dependent on treatment of equivocal scans in the binary analysis. If equivocal scans were excluded, Sn was 89.5% and Sp 98.6%. If equivocal scans were considered positive, Sn was 90.9% and Sp 75.8%. If equivocal scans were considered negative, Sn was 77.3% and Sp 98.9%. 55/135 (40.7%) patients underwent TAB and/or US (27 TAB, 33 US, 5 both TAB and US) as an additional investigation to PET/CT. 13/55 (23.6%) in this cohort had equivocal PET/CT scans, and 11/13 of the additional test (TAB/US) results matched the clinical diagnosis. In the total cohort, TAB had a Sn of 42.9% and Sp of 100%, and US had a Sn range of 53.3% to 66.7% (dependent on

Table 1: Patient baseline characteristics Values are number (%) of patients, except where indicated otherwise PMR = polymyalgia rheumatica TAB = temporal artery biopsy US = vascular ultrasound temporal +/- axillary arteries High dose glucocorticoid use = prednisone ≥40mg oral daily or methylprednisolone ≥500mg IV daily M-LVV = medium-large vessel vasculitis

Baseline characteristic	All patients at time of PET/CT (N=135)	In patients with final clinician diagnosis M-LVV (N=44)
Age median (range), years	73 (48-98)	74.5 (61-90)
Sex, female	95 (70.4%)	29 (65.9%)
Headache	94 (69.6%)	32 (72.7%)
Visual disturbance	67 (49.6%)	17 (38.6%)
Fevers	39 (28.9%)	11 (25.0%)

TAB within 4 weeks of PET/CT	27 (20.0%)	7 (15.9%)
US within 4 weeks of PET/CT	33 (24.4%)	15 (34.1%)

Table 2: Overall interpretation of PET/CT compared to clinician final diagnosis

Overall PET/CT interpretation for M-LVV	Clinician final diagnosis M-LVV	Clinician final diagnosis not M-LVV	Total	Post-test probability	Likelihood ratio
Positive	34 (77.3%)	1 (1.1%)	35 (25.9%)	97.1%	70.32
Equivocal	6 (13.6%)	21 (23.1%)	27 (20.0%)	22.2%	0.59
Negative	4 (9.1%)	69 (75.8%)	73 (54.1%)	5.5%	0.12
Total	44 (32.6%)	91 (67.4%)	135		

treatment of the 2 equivocal US) and Sp of 88.9%. For the 34 patients with positive PET/CT scans and a clinical diagnosis of M-LVV, significant FDG uptake was most commonly reported in the supra-aortic (88.2%), followed by cranial (55.9%), aortic (52.9%) and infra-aortic (23.5%) regions.

Table 3: PET/CT performance analysis for clinician final diagnosis of M-LVV, M-LVV = medium-large vessel vasculitis PPV = positive predictive value NPV = negative predictive value CI = confidence interval AUC = area under the receiver operating curve

PET/CT cohort	Total # scans	Sensitivity - 95% CI (%)	Specificity - 95% CI (%)	PPV (%) - 95% CI	NPV (%) - 95% CI	AUC
Equivocal overall scans excluded	108	89.5 (75.2-97.1)	98.6 (92.3-100)	97.1 (85.1-99.9)	94.5 (86.6-98.5)	0.940
Equivocal overall scans included as 'positive for M-LVV'	135	90.9 (78.3-97.5)	75.8 (65.7-84.2)	64.5 (51.3-76.3)	94.5 (86.6-98.5)	0.834
Equivocal overall scans included as 'negative for M-LVV'	135	77.3 (62.2-88.5)	98.9 (94.0-100)	97.1 (85.1-99.9)	90.0 (82.4-95.1)	0.881

Conclusion: This is the largest real-world study of combined cranial and large vessel PET/CT as a first-line test for GCA. PET/CT had good diagnostic performance with sensitivity ranging from 77.3 to 90.9%, and specificity 75.8 to 98.9% for a clinician diagnosis of active M-LVV, dependent on treatment of equivocal scans. TAB and/or US can be used as ancillary tests to help confirm a diagnosis when PET/CT is indeterminate or discordant with the clinical presentation.

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Patients with giant cell arteritis (GCA) have an increased risk of developing thoracic aortic aneurysms. Retrospective studies have shown that ^{18}F-fluorodeoxyglucose (FDG) uptake in large vessels at diagnosis increases the risk of developing aortic complications during follow-up. The aim of this study was to prospectively evaluate the association between FDG uptake in large vessels at diagnosis and the evolution of aortic diameter and volume in GCA patients.

Methods: GCA patients who have had FDG positron emission tomography (PET) imaging at diagnosis ≤3 days after initiation of glucocorticoids and who were prospectively followed for ≥2 years were included. PET scans were semi quantitatively scored (0-3) at 7 vascular areas and a total vascular score (TVS) was calculated, ranging from 0 to 21. PET scans were

Table 1: Evolution of the aortic diameters (in mm) and volumes (in cm^3) in 5 years in patients with (PET positive) and without (PET negative) FDG uptake ≥ grade 2 in any large vessel. The linear mixed models were adjusted for age, sex, AORTA score, CT or PET/CT scan, and intravenous contrast. Abbreviations: 95% CI, 95% confidence interval; CT, computed tomography; FDG, fluorodeoxyglucose; PET, positron emission tomography

	5-year progression (95% CI)		Difference in 5-year progression (95% CI)	P-value
	PET negative	PET positive		
Volume of thoracic aorta	12.59 (-1.44-26.61)	32.88 (24.34-41.47)	20.29 (4.07-36.57)	0.01
Volume of abdominal aorta	0.97 (-2.80-4.81)	0.94 (-1.25-3.19)	-0.04 (-4.35-4.26)	0.99
Diameter of thoracic aorta				
○ **Ascending aorta**	0.45 (-0.56-1.45)	1.98 (1.36-2.60)	1.53 (0.36-2.70)	0.01
○ **Aortic arch**	1.02 (0.25-1.79)	1.75 (1.28-2.23)	0.73 (-0.15-1.62)	0.11
○ **Descending aorta**	0.50 (-0.31-1.31)	1.72 (1.23-2.22)	1.22 (0.28-2.16)	0.01
Diameter of abdominal aorta				
○ **Suprarenal aorta**	0.13 (-0.36-0.64)	0.57 (0.28-0.88)	0.44 (-0.13-1.01)	0.13
○ **Juxtarenal aorta**	0.60 (0.05-1.15)	0.65 (0.31-0.98)	0.04 (-0.59-0.68)	0.89
○ **Infrarenal aorta**	0.68 (0.30-1.07)	0.35 (0.13-0.58)	-0.33 (-0.77-0.11)	0.14

considered positive in case of FDG uptake ≥ grade 2 in any large vessel. Patients underwent computed tomography (CT) imaging at diagnosis and yearly thereafter for a maximum of 10 years. The association between vascular FDG uptake and aortic dimensions was estimated by linear mixed effect models with random intercept and slope in time adjusted for age, sex, AORTA score, CT or PET/CT scan and intravenous contrast. The ascending aorta, aortic arch, and descending aorta were considered aneurysmatic when the diameter was ≥45, ≥40, and ≥35 mm, respectively.

Results: Hundred patients (mean age 70 years, 68% females) were included, of which 74 (74%) had FDG uptake ≥ grade 2 in any large vessel. The 2022 ACR/EULAR GCA criteria were fulfilled in 89 (89%) patients. Median follow-up was 80 months (IQR 47-110). The increase in ascending and descending aortic diameter and in thoracic aortic volume was higher in patients with a positive PET scan compared to those without (difference in 5-year progression 1.53 mm [95%CI 0.36-2.70 mm],

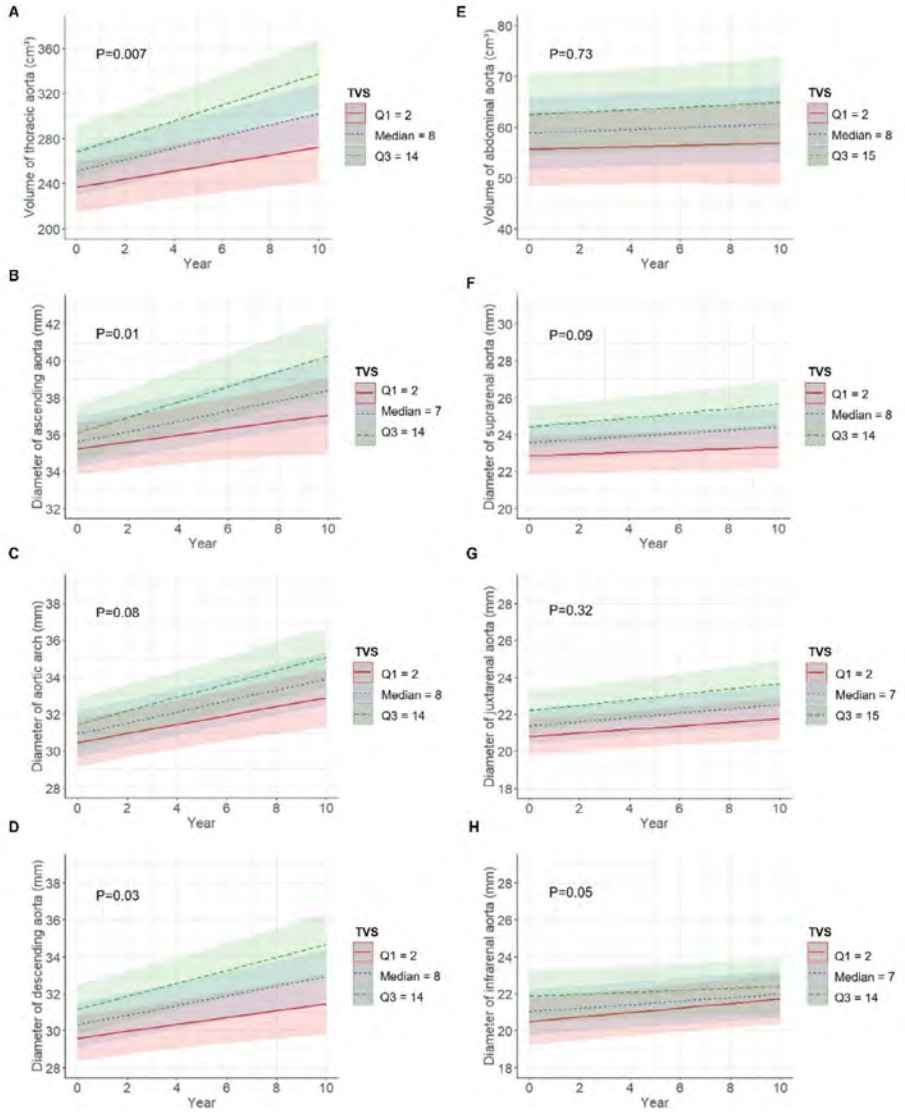

Figure 1: Linear mixed model analysis of the association between the total vascular score and the evolution in aortic dimensions. The x-axis represents the time (in years) since the diagnosis. The y-axis represents the size of the aorta: A. volume of thoracic aorta (in cm^3), B. diameter of ascending aorta (in mm), C. diameter of aortic arch (in mm), D. diameter of descending aorta (in mm), E. volume of abdominal aorta (in cm^3), F. diameter of suprarenal aorta (in mm), G. diameter of juxtarenal aorta (in mm), and H. diameter of infrarenal aorta (in mm). The lines and bands represent the mean trajectory and 95% confidence interval of each subgroup. The red solid line represents the first quartile of the total vascular score, the blue dotted line the median and the green dashed line the third quartile. The linear mixed models were adjusted for age, sex, AORTA score, CT or PET/CT scan, and intravenous contrast. Abbreviations: CT, computed tomography; PET, positron emission tomography; TVS, total vascular score

1.22 mm [95%CI 0.28-2.16 mm] and 20.29 cm^3 [95%CI 4.07-36.57 cm^3], respectively) (**Table 1**). These thoracic aortic dimensions were also significantly associated with TVS (**Figure 1**). FDG uptake was not associated with an increase in abdominal aortic diameters nor volume. Patients with a positive PET scan had a higher risk of developing thoracic aortic aneurysms (aHR 13.61, 95%CI 1.63-113.50) with a median time since diagnosis of 40 months (IQR 18-61). Thoracic aortic aneurysm developed in 13 of the 15 (87%) patients in a region with elevated FDG uptake at diagnosis. Two patients with high TVS (15 and 16) needed surgery for ascending aortic aneurysm.

Conclusion: Higher TVS was associated with greater yearly increase in thoracic aortic dimensions. Vascular FDG uptake at diagnosis was an independent risk factor for developing thoracic aortic aneurysm in GCA patients. Performing PET imaging at diagnosis may help to estimate the future risk of aortic aneurysm formation. Follow-up of aortic dimensions may be warranted in patients with thoracic aortic FDG uptake or high TVS.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: Imaging

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Table 1. Recommendations for the use of imaging in large vessel vasculitis in clinical practice

Overarching principles
A. In patients with suspected GCA, an early imaging test is recommended to support the clinical diagnosis of GCA, assuming high expertise and prompt availability of the imaging technique. Imaging should not delay initiation of treatment.
B. Imaging examination should be done by a trained specialist using appropriate equipment, standardized operational procedures and settings.
C. In patients in whom there is a high clinical suspicion of GCA and a positive imaging result, the diagnosis of GCA may be made without an additional test (biopsy or further imaging). In patients with a low clinical probability and a negative imaging result, the diagnosis of GCA can be considered unlikely. In all other situations (including the case of an inconclusive imaging result), additional efforts towards a diagnosis are necessary.
Recommendations
1. Ultrasound of temporal and axillary arteries should be considered as the first imaging modality to investigate mural inflammatory changes in patients with suspected GCA.
2. High resolution MRI or FDG-PET can be used as alternatives to ultrasound for the assessment of cranial arteries in patients with suspected GCA.
3. FDG-PET, alternatively MRI or CT, can be used for the detection of mural inflammation or luminal changes of extracranial arteries in patients with suspected GCA.
4. In patients with suspected TAK, MRI to investigate mural inflammation or luminal changes should be used as the first imaging test to make a diagnosis of TAK.
5. FDG-PET, CT or ultrasound may be used as alternative imaging modalities in patients with suspected TAK. Ultrasound is of limited value for assessment of the thoracic aorta.
6. Conventional angiography is not recommended for the diagnosis of GCA or TAK as it has been superseded by the previously mentioned imaging modalities.
7. In case of a suspected relapse of GCA or TAK, particularly when laboratory markers of disease activity are unreliable, ultrasound, FDG-PET or alternatively MRI may be considered for the assessment of vessel abnormalities. Imaging is not routinely recommended for patients in clinical and biochemical remission.
8. In patients with GCA or TAK, MRA, CTA or ultrasound of extracranial vessels may be used for long-term monitoring of structural damage, particularly at sites of preceding vascular inflammation. The frequency of screening as well as the imaging method applied should be decided on an individual basis.

Background/Purpose: Imaging recommendations for primary large vessel vasculitis (LVV) were developed in 2018. Several new studies have emerged since then, and an update of the original statements was required. The objective of this project was to update the recommendations for the use of imaging in LVV.

Methods: A systematic literature review update was performed to retrieve new evidence on ultrasound (US), magnetic resonance imaging (MRI), computed tomography (CT) and [18F]-fluorodeoxyglucose positron emission tomography (FDG-PET) for diagnosis, monitoring and outcome prediction in LVV. The task force consisted of 24 physicians, health professionals and patients from 14 countries.

Results: Three overarching principles and eight recommendations were agreed (Table 1). Compared to the 2018 version, US is now recommended as first line imaging test in all patients with suspected GCA, and axillary arteries should be included in the standard examination. As an alternative to US, cranial and extracranial arteries can be examined by FDG-PET or MRI. For Takayasu arteritis, MRI is the preferred imaging modality; CT or FDG-PET are alternatives. Although imaging is not routinely recommended for follow-up, US, FDG-PET or MRI may be used for assessing vessel abnormalities in LVV patients with suspected relapse, particularly when laboratory markers of inflammation are unreliable. MRA, CTA or US may be used for long-term monitoring of structural damage, particularly at sites of preceding vascular inflammation.

Conclusion: The 2023 recommendations provide up-to-date guidance for the role of imaging in the diagnosis and assessment of patients with (suspected) LVV.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: Imaging

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: In recent years, ultrasound has become a standard tool in the diagnosis of giant cell arteritis (GCA). Typical findings are increased intima media thickness (IMT) of the temporal and other arteries, caused by inflammation. To date, only few studies evaluated the role of ultrasound in follow-up and monitoring of GCA. [1,2] The purpose of this study was to prospectively evaluate changes of IMT of cranial and extra-cranial arteries during a 12-month follow-up of newly diagnosed GCA patients.

Methods: We prospectively enrolled patients with a new diagnosis of GCA who received glucocorticoid (GC) therapy up to seven days. Patients underwent ultrasound examinations of the axillary, carotid, vertebral, facial, and temporal arteries. IMT, total number of affected arteries, and the Omeract GCA ultrasonography score (OGUS)[3], alongside laboratory parameters, current GC dose, and GCA symptoms were evaluated at baseline, after three, six, nine and 12 months. Additionally, a

Table 1. reduction of intima media thicknesses (IMT) over the follow-up time compared to baseline IMT

	Axillary artery		Carotid artery		Vertebral artery		Common temporal artery		Frontal temporal artery		Parietal temporal artery		Facial artery	
	ß	p	ß	p	ß	p	ß	p	ß	p	ß	p	ß	p

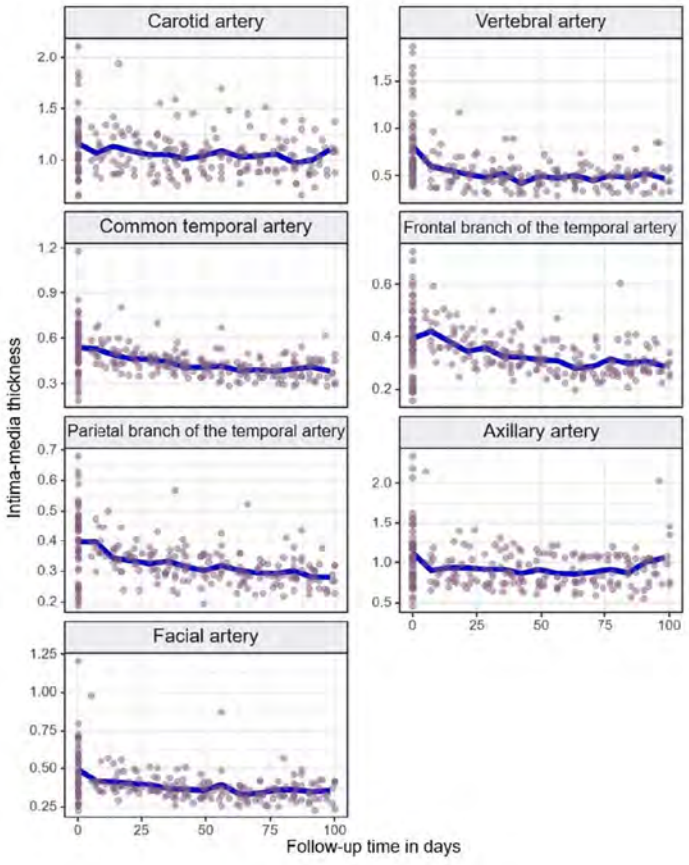
GCA: giant cell arteritis; OGUS: provisional OMERACT GCA ultrasonography score; p: p-value, values<0.05 are statistically significant; n: number of affected arteries/ OGUS at respective follow-up time; OGUS: provisional OMERACT GCA ultrasonography score; Large arteries: axillary artery, carotid artery, vertebral artery; Medium-sized arteries: superficial temporal artery with parietal and frontal branch, facial artery

subgroup of patients underwent weekly exams during the first 100 days. We conducted further sub-analyses to compare ultrasound findings between patients with GCA versus GCA plus polymyalgia rheumatica (PMR), and between patients receiving GC therapy only and those receiving GC plus tocilizumab.

Figure 1. Changes in intima media thickness (IMT) within the first 100 days



Vertical: Intima-media thickness (IMT), horizontal: follow-up time in days, the blue line indicates the mean values that were observed for each time point. Each point indicates one examination.

Results: Fifty patients were enrolled, 36 completed the 12-months follow-up. The cohort consisted of 23 (46%) females at a mean age of 73.6 years (SD ±8.3). The mean GC intake at baseline was 130 mg (SD ±266) at a mean of 1.7 days (SD ±2.5). In 18 patients, up to weekly exams were performed. Figure 1 displays the changes in mean IMT of all examined arteries in the first 100 days. The mean IMT of the axillary and temporal artery were normal after seven and 50 days, respectively. After six months, mean IMT of all examined arteries and OGUS were below published cut-off values.[3,4,5] During the follow-up period, we observed a significant and consistent decrease in mean IMT, total number of affected arteries and OGUS (Table 1 and 2). After termination of GC therapy, follow-up visits were continued and no increase of ultrasound parameters was observed. Additionally, we found no significant differences in the reduction of these parameters between patients with GCA only and those with GCA and polymyalgia rheumatica (PMR), as well as between patients receiving GC therapy only and those receiving additional tocilizumab therapy.

Conclusion: IMT, OGUS and the total number of affected arteries decreased significantly over a 12-months follow-up period under GC with/without immunosuppressive treatment. In the first 100 days, the mean IMT of the axillary artery was found to decrease the fastest, while the mean IMT of the temporal artery was elevated for up to 50 days. Especially, the parameters did not increase after end of GC therapy. Our study underlines the important role of ultrasound examinations in monitoring of GCA.

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders I: Imaging
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Recently, optic nerve sheath (ONS) enhancement using contrast-enhanced magnetic resonance imaging of the brain and orbits was observed in most patients with biopsy-proven GCA. In addition, we recently showed that ONS diameter (ONSD) and ONS thickness (ONST) measured by ultrasound are increased in patients with new-onset, active GCA. The objective of this study is to assess whether ONSD and ONST measurements improve when clinical remission is achieved in patients with GCA.

Table 1 – Clinical features and treatments at diagnosis (active GCA) and month 3 (clinical remission) of 9 patients with new-onset GCA.

GCA features	Diagnosis (month 0)	Follow-up (month 3)
Symptoms, n (%)		
Headache	7 (78)	0 (0)
Scalp tenderness	4 (44)	0 (0)
Constitutional symptoms	4 (44)	1 (11)
Jaw claudication	5 (56)	0 (0)
PMR	3 (33)	0 (0)
Diplopia	1 (11)	0 (0)
Amaurosis fugax	1 (11)	0 (0)
Complete vision loss	4 (44)	3 (33)
Physical examination, n (%)		
Abnormal temporal artery exam	5 (56)	0
AION	4 (66.7)	N/A
Inflammatory markers, median (IQR)		
C-reactive protein (mg/L)	60 (41 – 88)	4 (3 – 23)
ESR (mm/h)	62.5 (58 – 64)	21 (13 – 32)
GC dosage (prednisone equivalent)		
Days on GC prior to assessment, median (IQR)	5 (2 – 6)	106 (98 – 107)
GC dose at assessment (mg), median (IQR)	50 (50 – 50)	15 (10 – 25)
Intravenous methylprednisolone, n (%)	5 (56)	N/A
Immunosuppressive therapies, n (%)		
Tocilizumab	0	5 (56)
Methotrexate	0	0
Leflunomide	0	1 (11)

GCA: Giant cell arteritis, PMR: polymyalgia rheumatica, AION: anterior ischemic optic neuropathy, N/A: not applicable, IQR: interquartile range, ESR: erythrocyte sedimentation rate, GC: glucocorticoid

Methods: A prospective inception cohort study was conducted at the vasculitis clinic of Sacre-Coeur Hospital, in Montreal, Canada, from June 2022 to January 2023. Patients who had an optic nerve (ON) ultrasound at GCA diagnosis as part of a previous cross-sectional study were approached. Participants in clinical remission after 3 months of therapy were included if (1) ON ultrasound had successfully been performed at the time of GCA diagnosis, (2) GCA was confirmed on color doppler ultrasound (CDUS) of temporal/axillary arteries, (3) they satisfied the 2022 ACR/EULAR classification criteria for GCA.

At month 3, a standardized clinical assessment, bloodwork, CDUS of temporal/axillary arteries and ON ultrasound were performed. ON ultrasound was performed by the same investigator at diagnosis and month 3, unblinded to clinical information. Ultrasound measurements were performed for both eyes, 3mm distal to the posterior aspect of the ocular globe. Optic nerve sheath diameter (ONSD, includes ON and its sheath) and optic nerve diameter (OND) were measured. Optic nerve sheath thickness (ONST) was obtained by subtracting OND from ONSD.

Table 2 – Comparison of Optic Nerve Measurements on ultrasound at diagnosis (active GCA) and month 3 (clinical remission) in 9 patients with new-onset GCA.

Measurements (in mm), mean (SD)	Diagnosis (month 0)	Follow-up (month 3)	Mean difference (M0-M3)	95% CI	*P* value
Right ONSD	6.10 (1.16)	4.14 (1.14)	1.96 (0.98)	1.20 – 2.71	< 0.001
Left ONSD	5.86 (1.38)	3.38 (0.44)	2.48 (1.41)	1.39 – 3.56	< 0.001
Right OND	3.22 (0.35)	2.90 (0.66)	0.32 (0.50)	-0.06 – 0.70	0.09
Left OND	2.72 (0.76)	2.37 (0.43)	0.36 (0.89)	-0.33 – 1.04	0.26
Right ONST	2.88 (0.93)	1.24 (0.66)	1.63 (0.80)	1.02 – 2.25	< 0.001
Left ONST	3.13 (1.14)	1.02 (0.31)	2.11 (1.15)	1.23 – 2.99	< 0.001

Dotted line: threshold of ONSD ≤ 4.5mm is considered normal in healthy adults.
ONSD: optic nerve sheath diameter, ONST: optic nerve sheath thickness, GCA: giant cell arteritis

Figure 1. Evolution of ONSD and ONST Measurements on Ultrasound from diagnosis (active GCA) to Month 3 (clinical remission) in 9 patients with new-onset GCA.

Descriptive statistics for baseline characteristics and paired sample t-test were performed to assess the mean difference in OND, ONSD, and ONST between diagnosis and month 3. One-Way ANOVA was used to explore the association between clinically persistent vision defect at month 3 and ON ultrasound measurements.

Results: Nine patients with a diagnosis of GCA were included in our study. The median age at disease onset was 79 years (interquartile range (IQR) of 79 – 82 years) and 7 patients were males. All patients were in clinical remission at month 3. GCA characteristics and therapy at diagnosis and month 3 are presented in table 1.

There was strong evidence that the mean ONSD and ONST measured in millimeters were lower at month 3 (clinical remission) than at diagnosis (active GCA) for both eyes (table 2, figure 1). Furthermore, in 7/9 patients, ONSD decreased below 4.5mm (considered normal in healthy adults). As anticipated, OND measurements did not vary between diagnosis and month 3. There was no evidence of an association between persistent vision defect at month 3 and mean difference in ONSD and ONST measurements.

Conclusion: In patients with active, new-onset GCA, we demonstrated that ONSD and ONST measured on ultrasound improved with therapy. Thus, ONSD and ONST may be dynamic biomarkers in GCA and allow detection of disease relapse. These findings and hypothesis will be addressed in a larger, longer prospective trial (ClinicalTrials.gov id: NCT05749094).

Abstract Number: 1651

Beneficial Effect of Temporary Methotrexate Interruption on B and T Cell Responses upon SARSCoV-2 Vaccination in Patients with Rheumatoid Arthritis or Psoriatic Arthritis

Esther Vicente Rabaneda[1], Pedro Martínez-Fleta[2], Ana Triguero-Martínez[2], Emilia Roy[3], Miren Uriarte-Ecenarro[4], Francisco Gutiérrez-Rodríguez[4], Patricia Quiroga[4], Ana Romero[4], Nuria Montes[2], Laura Esparcia Pinedo[2], María Aranzazu Alfranca[2], Rosario Garcia-Vicuna[5], Francisco Sánchez-Madrid[2], Isidoro González-Álvaro[4] and Santos Castañeda[5], [1]Rheumatology, Hospital Universitario de La Princesa, Madrid, Spain, [2]Division of Immunology, Hospital Universitario de La Princesa, Madrid, Spain, [3]Division of Internal Medicine, Hospital Universitario de La Princesa, Madrid, Spain, [4]Division of Rheumatology, Hospital Universitario de La Princesa, IIS-Princesa, Madrid, Spain, [5]Hospital Universitario de la Princesa, Madrid, Spain

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Interprofessional Exemplary

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Previous published works have raised the concern that methotrexate (MTX) might have a negative effect on immune response upon vaccine administration. At the beginning of the COVID-19 vaccination campaigns, there were controversial opinions regarding the possibility of temporary interrupting immunomodulatory treatments in rheumatic patients.

The objective of this study was to evaluate B and T cell responses in patients with rheumatoid arthritis (RA) or psoriatic arthritis (PsA) after 1 or 2 weeks of MTX withdrawal following each COVID-19 vaccine dose and compare them with that of those who maintained MTX unchanged.

Methods: This is a single-centre, randomised, prospective study. Adult RA and PsA patients treated with MTX were recruited and randomly assigned to 3 groups: MTX-maintenance (n=72), MTX-withdrawal for 1 week (n=71) or MTX-withdrawal for 2 weeks (n=73) after each vaccine dose. Samples were collected before and 30 days after complete vaccination in 2021. Multi-antigen cytometric bead array assays to detect specific antibodies to several SARS-CoV-2 antigens and ELISPOT assays measuring interferon (IFN)-γ and interleukin (IL)-21 were performed. Multivariable analyses were used to control the effect of possible confounding variables.

Results: The study population consisted of 216 patients (178 RA and 38 PsA), of which 47 had COVID-19 before vaccination. Participants were vaccinated with BNT162b2 (71%), ChadOX-1-S (14%), mRNA-1273 (6%) and Ad26.COV2.S (9%). Population characteristic are shown in Table 1. The types of COVID vaccines, the vaccine protocols and the occurrence of COVID, prior and after vaccination, as well as the differences of these variables across groups are shown in Table 2. MTX withdrawal in patients without previous COVID-19 was associated with higher levels of anti-RBD IgG (p=0.01) and neutralising antibodies (p=0.004), especially in the 2-week withdrawal group and with higher IFN-γ secretion upon stimulation with pools of SARS-CoV-2 S peptides (p< 0.001). Interestingly, no significant differences in the number of RA/PsA relapses were detected across groups (Table 2).

Conclusion: Our data indicate that a brief MTX interruption following COVID-19 vaccination doses in patients with RA or PsA improves humoral and cellular immune responses, without significant increase of relapses, especially in patients without previous infection.

Lupus Research Action Network: Increasing Minority Clinical Trial Participation Through Peer Leaders

Melicent Miller[1], Stephanie Slan[1], Rosalind Ramsey-Goldman[2], Rodlescia Sneed[3], Candace Feldman[4], Patrick Wildman[1], Tori Justin[5], Lydia Oberholtzer[5] and Joy Buie[6], [1]Lupus Foundation of America, Washington, DC, [2]Northwestern University, Chicago, IL, [3]Wayne State University, Detroit, MI, [4]Brigham and Women's Hospital, Boston, MA, [5]Sharp Insight, LLC, Montgomery County, MD, [6]Lupus Foundation of America, York, SC

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Interprofessional Exemplary

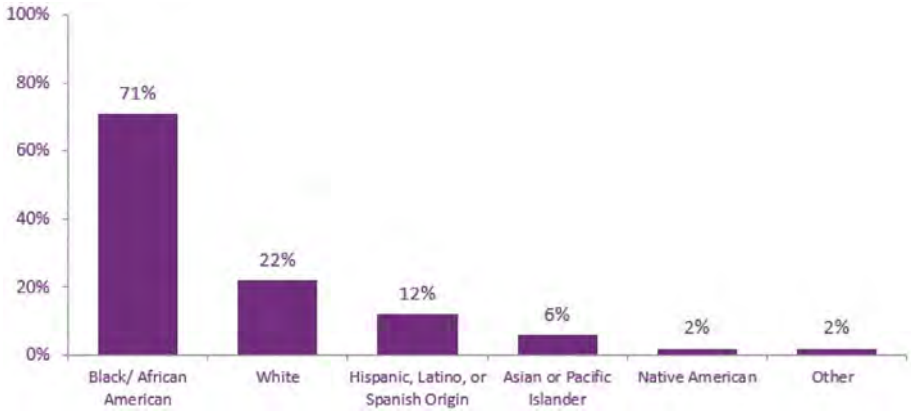
Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

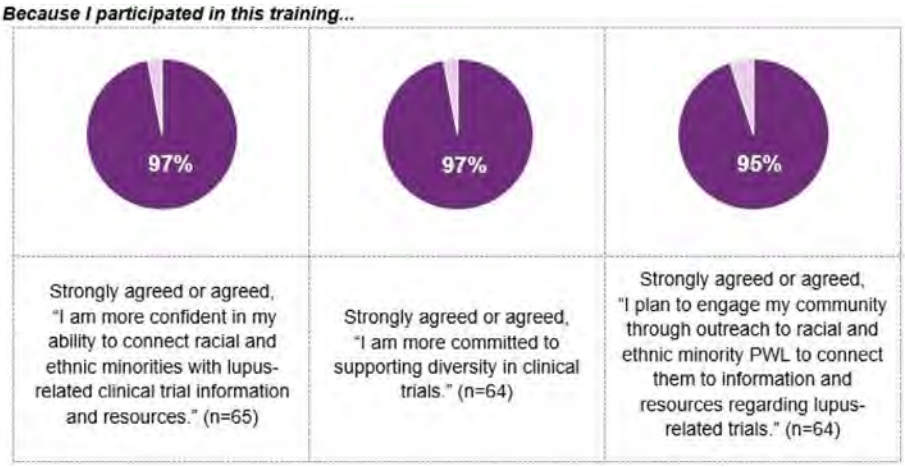
Background/Purpose: Black/African American people with lupus (PWL) experience greater disease prevalence and severity than White PWL. The need for more racial and ethnic diversity amongst lupus clinical trial (CT) participants is needed as there continues to be a high level of unmet medical need within this population. Lack of trust has been found to negatively influence Black/African American participation in CT that contributes to higher perceptions of bias and racism among this population. Peer-to-peer models such as CDC's Popular Opinion Leader (POL) has been shown to be effective in building trust and confidence within the community while empowering PWL to take leadership roles in communicating the importance of diversifying CT participation.

Methods: The Lupus Conversations Program, an evidence-based curriculum based on the POL model, aims to improve the awareness of lupus CT, increase knowledge of the CT process as well as addressing barriers, facilitators, and mediators to CT participation such as structural racism in research among Black/African American PWL. This model was adapted and employed through virtual and in-person training sessions for Lupus Research Action Network (LRAN) members with goals of increasing knowledge, confidence, and intent to engage in peer-to-peer outreach opportunities to discuss the importance of participation in lupus CT among Black/African American PWL. A retrospective pre-post survey was developed to assess participant demographics and increases in CT knowledge and awareness of trials, self-efficacy, and confidence to share CT information with peers, and examine training satisfaction.

Results: LRAN members participated in one of two trainings in September 2022 (n=40) and April 2023 (n= 27). Almost all LRAN survey respondents identified as female. The average age of participants was 42 (n=63). Over two-thirds of the training participants identified as Black/African American. Almost a quarter identified as White, 12% as Hispanic, Latino or



Race and Ethnicity of LRAN Training Participants



Changes in confidence, commitment, and behavioral intentions for diversifying minority participation in CT

Spanish origin, 6% as Asian or Pacific Islander, and 2% as Native American. LRAN members resided in 12 states. Over 90% of LRAN members reported satisfaction with LRAN training content, facilitation, and engagement. Sixty percent reported an increased understanding of CT needs and barriers to enrollment among racial and ethnic minority PWL. Eight out of ten increased their understanding of CT and racism and increased their awareness of lupus CT and outreach markets. Nearly all participants increased their commitment to diversifying CT participation for PWL, confidence in connecting target population with lupus CT information and resources, and behavioral intention to engage their community through outreach to racial and ethnic minority PWL to connect them to information and resources related to lupus CT.

Performance Measure: Evidence of program participant satisfaction	
●	**94-97%** LRAN trainees will report satisfaction with the Lupus Conversation program content, facilitation, and engagement. *Target = 75%*
Performance Measure: Evidence of increased understanding, commitment, self-efficacy, and behavioral intentions among LRAN participants related to racial and ethnic minority PWL in lupus clinical trials	
●	**80%** Increased understanding (knowledge areas) of clinical trials and racism among LRAN participants. *Target=75%*
●	**76%** Increased awareness of lupus clinical trials and outreach markets among LRAN training participants. *Target=60%*
●	**97%** Increased commitment to diversifying clinical trials for PWL among LRAN training participants. *Target=50%*
●	**97%** Increased confidence in connecting target population with lupus-related clinical trial information and resources in LRAN training participants. *Target=50%*
●	**95%** Increased behavioral intention of LRAN training participants to engage their community through outreach to racial and ethnic minority PWL to connect them to information and resources related to lupus-related clinical trials. *Target=50%*
○	**60%** Increased understanding of clinical trial needs and barriers to enrollment among racial and ethnic minority PWL in LRAN training participants. *Target=75%*
Performance Measure: Evidence of program participation	
●	**67** By the end of the grant period, at least 50 people with lupus (PWL) will attend an LRAN training that incorporates Lupus Conversations. *Target=50 PWL*

● Met ○ Not Met -- Data Not Available

Overall LRAN Training Performance Measures

Conclusion: An adapted, community-based POL model can be used to increase awareness of and commitment to diversifying participation in lupus CT among Black/African American PWL. Further research is needed to determine the degree to which a peer-to-peer education module may reduce disparities in CT participation among Black/African American PWL. Existing level of CT knowledge must be considered when developing patient-centered content.

Abstract Number: 1653

Up or Down: Does Direction of Stair Climbing Difficulty Matter for Incident Functional Limitation and Knee Replacement in Knee Osteoarthritis?

Jason Jakiela[1], Thomas Bye[1], Sydney Liles[2] and Daniel White[1], [1]University of Delaware, Newark, DE, [2]University of Delaware, Elkton, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Interprofessional Exemplary
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Knee osteoarthritis (OA) is a leading cause of functional limitation (FL) in older adults, with difficulty climbing stairs often the first-reported limitation. Overall increased difficulty with stair climbing is associated with greater risk of developing FL and receiving a knee replacement (KR). However, little is known about the relation of the direction of stair climbing difficulty (ascending or descending) with the development of knee OA-related outcomes. Therefore, the purpose of this study was to examine the relationship of difficulty ascending and descending the stairs with incident FL and KR in adults with or at high risk for knee OA.

Methods: We used data from the Osteoarthritis Initiative (OAI). Stair climbing difficulty was assessed at baseline (BL) using two questions from the WOMAC: 1.) What degree of difficulty do you have with ascending stairs? and 2.) What degree of difficulty do you have with descending stairs? Choices included: none, mild, moderate, severe, extreme. A 4-level exposure

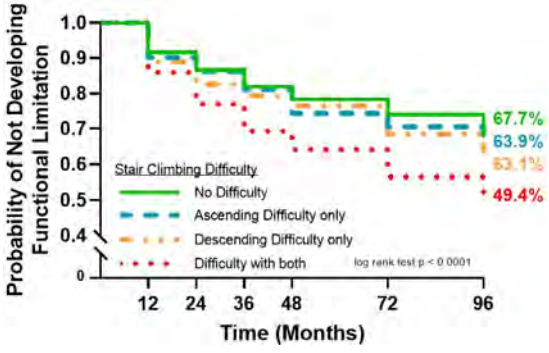

Figure 1: Kaplan-Meier survival curves for functional limitation by stair climbing difficulty group.

combining difficulty with ascending and descending stairs was created: no difficulty with either, difficulty with ascending only, difficulty with descending only, difficulty with both ascending and descending. FL was defined as walking speed < 1.22 m/s over 20 meters and was collected at BL, 12-, 24-, 36-, 48-, 72-, and 96-month follow-up. 1.22 m/s has been previously used to represent poor function. KR was defined as any type of KR and was collected from the BL visit until 10 years later. Separate analytic samples were used for each outcome and only included those without the outcomes at BL. We produced Kaplan-Meier survival curves for cumulative incidence of FL and KR and used Cox proportional hazards regression to calculate hazard ratios (HR) and 95% confidence intervals (CI), adjusted for age, sex, BMI, race, radiographic knee OA, VAS pain, and presence of comorbidity.

Results: 2866 participants (mean age = 60.3 years old, 53.8% female, mean BMI = 28.1 kg/m^2) were included in the FL sample and 4523 participants (mean age = 61.3 years old, 58.3% female, BMI = 28.7 kg/m^2) were included in the KR sample. 957 participants developed FL (Figure 1) and 438 participants received a KR (Figure 2) during follow-up. Compared to those without any difficulty ascending and descending stairs, those with difficulty in both ascending and descending stairs were at a 44% greater hazard of FL and a 132% greater hazard of KR, those with only difficulty ascending but not descending stairs were at a 7% greater hazard of FL and a 64% greater hazard of KR, and those with only difficulty descending but not ascending stairs were at a 10% greater hazard of FL and a 40% greater hazard of KR (Table 1).

Conclusion: Adults with knee OA who have any amount of difficulty with both ascending and descending stairs are at greater risk of developing both walking speed FL and receiving a KR compared to those with no difficulty. Self-reported stair climbing difficulty may be useful as a functional vital sign for identifying those at early risk for FL and KR and in need of further evaluation and treatment.

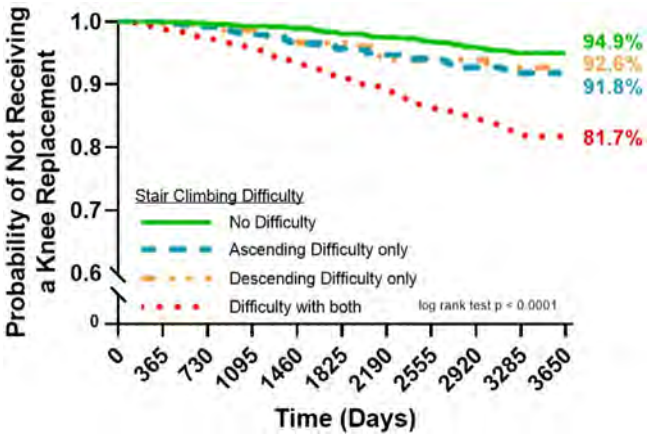

Figure 2: Kaplan-Meier survival curves for knee replacement by stair climbing difficulty group.

Table 1: Hazard ratios (HRs) & 95% confidence intervals (95% CIs) for walking speed functional limitation and knee replacement by stair climbing difficulty group.

Stairs Difficulty	Functional Limitation n/N (%)	HR [95% CI] (adjusted)	Knee Replacement n/N (%)	HR [95% CI] (adjusted)
No difficulty	348 / 1284 (27.1%)	1.0 [REF]	75 / 1728 (4.3%)	1.0 [REF]
Ascending only	92 / 310 (29.7%)	1.07 [0.85, 1.36]	31 / 445 (7.0%)	1.64 [1.07, 2.52]
Descending only	44 / 143 (30.8%)	1.10 [0.79, 1.52]	14 / 212 (6.6%)	1.40 [0.79, 2.50]
Difficulty with both	473 / 1129 (41.9%)	1.44 [1.23, 1.70]	318 / 2138 (14.9%)	2.32 [1.75, 3.08]

Resilience, score, mean (SD)	26.2 (6.5)	26.1 (5.6)	26.3 (6.9)

T-scores are compared to a US normative population in which 50 is the mean and SD is 10. Fatigue Severity Scale is a 9-item questionnaire that assesses perceived fatigue on a 7-point Likert scale (1 = strongly disagree to 5 = strongly agree). Eligible participants had an average score of at least 4 on Fatigue Severity Scale. Abbreviations: SSc, systemic sclerosis; PROMIS, Patient Reported Outcomes Measurement Information System; FACIT, functional assessment of chronic illness therapy.

resilience-based energy management program (called RENEW) designed to be delivered through a website or app. Trained peer health coaches, who also have SSc, provided health coaching during regular online sessions over a 12-week period. This study examined whether participants in the RENEW program had clinically important improvements in fatigue, pain interference, depressive symptoms, and resilience.

Methods: In this randomized controlled trial (NCT04908943), participants were assigned to either RENEW or a wait list control group in a 2:1 ratio. Participants were ≥18 years old with doctor-diagnosed SSc of any subtype. Eligible participants had moderate to severe fatigue (≥4 on the Fatigue Severity Scale). The RENEW program included a comprehensive educational website and app with instructions for goal setting around specific topics plus 9 one-on-one health coaching sessions via Zoom over 12 weeks. The primary outcome was fatigue (assessed by PROMIS FACIT-Fatigue). Secondary outcomes were PROMIS measures of pain interference and depressive symptoms, and Connor-Davidson Resilience Scale. Outcomes were assessed at baseline, 6 weeks, and 12 weeks. Intent-to-treat linear mixed models were used to assess group differences over time, controlling for age, sex, race, SSc subtype, SSc duration, and baseline values of each outcome. A three-way interaction with group, time, and SSc duration was examined in each model.

Results: Among 173 participants (mean age 54.5 years ± 11.7), most were female (93%) and White (85%). 47% had diffuse SSc, and 57% had early SSc duration (≤5 years diagnosed) (Table 1). At 12 weeks, participants in RENEW had significantly reduced fatigue compared to controls (β=-5.1, 95% CI: -7.2 to -2.9; $p < 0.001$), which was considered clinically meaningful (>3 point change). Participants also had significantly improved pain interference (β=-2.6, 95% CI -4.9 to -0.4; $p = 0.021$), depressive symptoms (β=-3.8, 95% CI: -6.2 to -1.5; $p = 0.002$), and resilience (β=2.9, 95% CI: 1.2 to 4.5; $p < 0.001$) compared to controls (Figures 1 & 2). Within the RENEW group, fatigue and pain at 12 weeks were found to be significantly moderated by SSc

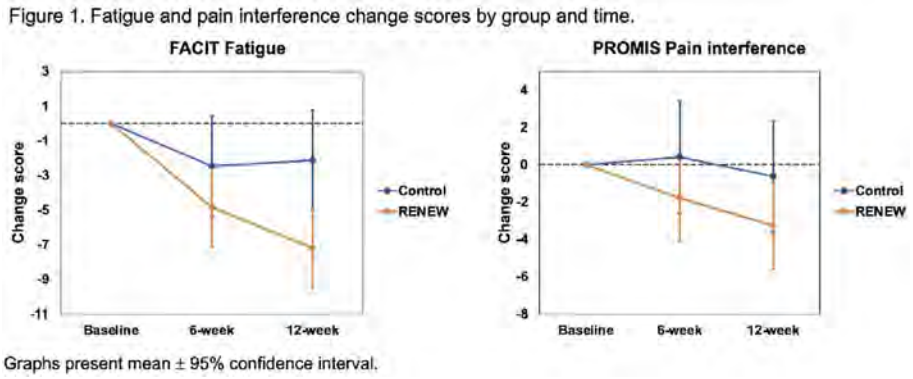

Figure 1. Fatigue and Pain Interference Change Scores by Group

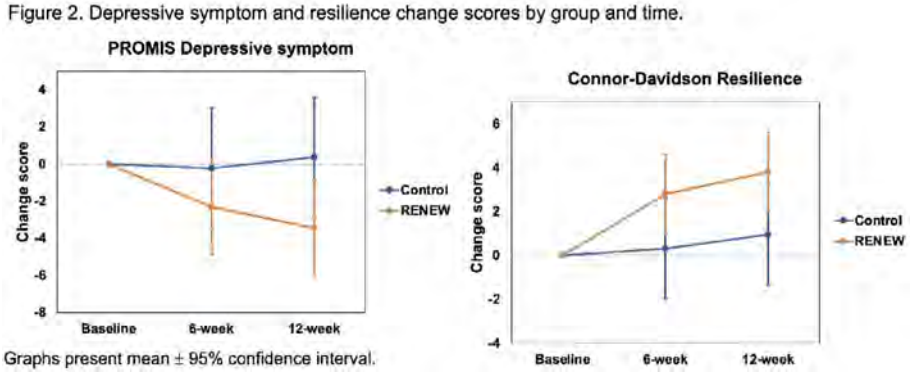

Figure 2. Depressive Symptoms and Resilience Change Scores by Group

duration. Participants with ≤ 1 year SSc duration had significantly reduced fatigue compared to those with >5 year SSc duration (β=-3.1, 95% CI: -5.9 to -0.3; p = 0.032). Participants with 2-5- year SSc duration had significantly reduced pain compared to those with >5 year SSc duration (β=-4.2, 95% CI: -7.0 to -1.4; p = 0.004). No other three-way interaction effects were found.

Conclusion: A remotely-delivered, peer health coached energy management program had positive effects on fatigue and other outcomes, particularly in early diagnosed patients. This program has the potential for broad scalability to assist with SSc symptom management.

Abstract Number: 1655

Usability Testing of JIActiv, an Instagram-Based Program Promoting Engagement in Physical Activity Among Young People Living with Juvenile Idiopathic Arthritis

Zeinab Ahmadian Sangkar[1], Fatou Bagayogo[2], Karina Cristea[2], Ciaran Duffy[3], Jennifer Stinson[4], Karine Toupin April[3], Michele Gibbon[5], Marianne Boulet[1], Élodie Bolduc[1], Aymane Alilou[6], Sara Ahmed[7], Claudine Auger[1], Laurie Proulx[8], Alexandra Sirois[9] and Sabrina Cavallo[10], [1]University of Montreal, Montreal, QC, Canada, [2]CRIR, Montreal, QC, Canada, [3]University of Ottawa, Ottawa, ON, Canada, [4]The Hospital for Sick Children, Toronto, ON, Canada, [5]Children's Hospital of Eastern Ontario RI, Ottawa, ON, Canada, [6]Unviersity of Montreal, Montreal, QC, Canada, [7]McGill University, Montreal, QC, Canada, [8]Canadian Arthritis Patient Alliance, Ottawa, ON, Canada, [9]CARRA, Outremont, QC, Canada, [10]University of Montreal, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Interprofessional Exemplary
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: This study evaluated the usability (user performance and satisfaction) of an Instagram-based educational and interactive program promoting physical activity among young people living with juvenile idiopathic arthritis (JIA).

Methods: A descriptive qualitative study design was used. A convenience sample of adolescents and young adults (13 to 25 years) with JIA (n = 28; mean age = 18.69, SD=± 2.28 years) was recruited from arthritis-patient organizations, rehabilitation, and hospital centers to participate in two iterative cycles of online (Zoom platform) semi-structured interviews. The audio recordings of the interviews were transcribed verbatim, sorted, organized, and coded using the MAXQDA 11 software. The interview questions were grouped into 10 main categories including: 1. Privacy and Safety, 2. Design Aesthetics, 3. Functionalities, 4. Organization of the program, 5. Content of page, 6. Motivating factors, 7. Willingness to follow the program, 8. Language display (preferences),9. Suggestions for improvement to the JIActiv program and 10. Willingness to recommend the program.

Results: All participants used a computer, a smartphone or a tablet to access and navigate the JIActiv program. Overall, participants did not report any significant concerns about privacy and safety while using the JIActiv program. Participants provided positive feedback regarding the program's user-friendly navigation and appealing visual design. Most participants

reported that the featured information was relevant and of good quality. They appreciated the structure of the intervention program (overall length of the program, frequency of posts and weekly time requirements). The interactive features supporting group-based activities were highly appreciated as they offered opportunities to communicate and share information and experiences with peers. Peer interactions and the opportunity to communicate with healthcare providers were identified as motivating factors to use the JIActiv program. Some participants suggested shortening the videos length and presenting English and French content on separate Instagram pages, however this was not identified as a barrier to the use of the program. Participants suggested some minor modifications to the program. Based on these, modifications were implemented after each cycle if semi-structured interviews including edits to the informational videos to facilitate navigation.

Conclusion: Findings showed that the JIActiv program demonstrated good usability. This testing has allowed us to optimize end users' (young people with JIA) ability to access, to navigate, to understand and to implement the informational content and practical strategies featured through this program in a culturally competent, efficient and satisfying manner.

Abstract Number: 1656

Nothing About Us Without Us: Top 10 Research Priorities from Patients - A James Lind Alliance Project for Public and Patient Involvement (PPI)

anna Fryxelius[1], Amy Martinsen[2], Ida Løchting[3], Linda Aimee Hartford Kvæl[4], Astrid Lunestad[2], Astrid Bergland[4] and Kjersti Storheim[2], [1]Norwegian Rheumatism Association / REMEDY - Center for Treatment of Rheumatic and Musculoskeletal Diseases, Oslo, Norway, [2]Oslo University Hospital, Oslo, Norway, [3]REMEDY - Center for Treatment of Rheumatic and Musculoskeletal Diseases, Oslo, Norway, [4]OsloMET, Oslo, Norway

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Interprofessional Exemplary
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Patient and public involvement (PPI) is gaining increasing recognition as important to ensure research is relevant and to reduce avoidable research waste. Active collaboration between patients and researchers in development and implementation of scientific projects is important to ensure a good match between patient's priorities and the scientific focus in research, contribute to more patient-oriented medical research agendas, enhance patient friendly design of research projects, and creating support for implementation. Bemden et al. in BMJ Rheumatology - states that "Patient and public involvement in rheumatic and musculoskeletal research is an idea whose time has firmly come" (2023) 7:12.

Interest in improved PPI also stems from knowledge that 85% of all research funds are avoidably wasted (Chalmers, Glasziou, Lancet 2009). Identifying knowledge gaps in partnership with end users of medical research, in this case both clinicians and patients, can help reduce research waste.

PPI can be most effective when used to identify and prioritise knowledge gaps for producing new research projects - so that patients are effectively involved in the early planning stages of new projects, but this process can be time consuming and complicated.

Table: Top ten research priorities for RMDs

Top ten research priorities for RMDs
1. Which interventions can prevent persistent RMDs?
2. How is overall health affected by living with persistent musculoskeletal pain?
3. Are there higher rates of gastrointestinal issues in people with RMDs?
4. Why do symptoms fluctuate and flare unpredictably?
5. Are different RMDs connected to one another?
6. Which criteria should be used for the diagnosis of RMDs?
7. What kind of rehabilitation is best for treating RMDs?
8. What does personalised medicine mean for people with RMDs?
9. What treatments are effective against fatigue?
10. How should healthcare services be organised to best meet the needs of people with RMDs?

Organising effective PPI processes to ensure value for all parties and increase effectiveness of research funds, requires new systems and structures to be developed and tested. The James Lind Alliance initiative has developed methods for Priority Setting Partnerships that ensure real engagement.

Methods: To identify key questions most relevant for patients with RMDs, a priority-setting project was conducted using methods established by the James Lind Alliance (JLA)[4]. A steering group comprised of patients and multidisciplinary clinicians led the process. 239 questions were first gathered from patients living with RMDS who were members of five collaborating RMD patient organisations. The questions covered six broad themes including diagnosis, treatment, aetiology, symptoms and comorbidities, healthcare systems and daily life.

After rejecting out-of-scope submissions, removing duplicates, and merging similar questions, 56 questions remained and were included in a web-based ranking survey distributed to more than 40,000 patient organisation members.

5346 individuals responded to the survey, the results of which were used to generate a shortlist of 20 questions in line with the James Lind Alliance methodology. Fourteen patient representatives from all 5 organisations were then brought together for a final prioritising workshop in Oslo, Norway September 2022.

Results: The result of the workshop was a consensus on a final ranked list of questions, including the top ten priorities for future research.

The top ten identified priorities (panel) reflect patients' leading concerns around uncertainties in the field of RMDs. These concerns were thematically focused primarily on understanding symptoms and improving treatments.

Conclusion: The identified priorities are intended to provide a platform for ensuring responsiveness of future research activity and funding to questions that are most important for people living with RMDs.

Mapping the Network of Coordinated Immune Dysregulation in Juvenile Dermatomyositis at Single-cell Resolution

Gabrielle Rabadam[1], Camilla Wibrand[2], Emily Flynn[1], George Hartoularos[1], Yang Sun[1], Susan Kim[3], Chun Jimmie Ye[1], Zev Gartner[1], Marina Sirota[4] and Jessica Neely[1], [1]University of California San Francisco, San Francisco, CA, [2]Aarhus University, Aarhus, Denmark, and University of California San Francisco, San Francisco, CA, [3]UCSF Benioff Children's Hospital, San Francisco, CA, [4]Bakar Computational Health Sciences Institute, University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

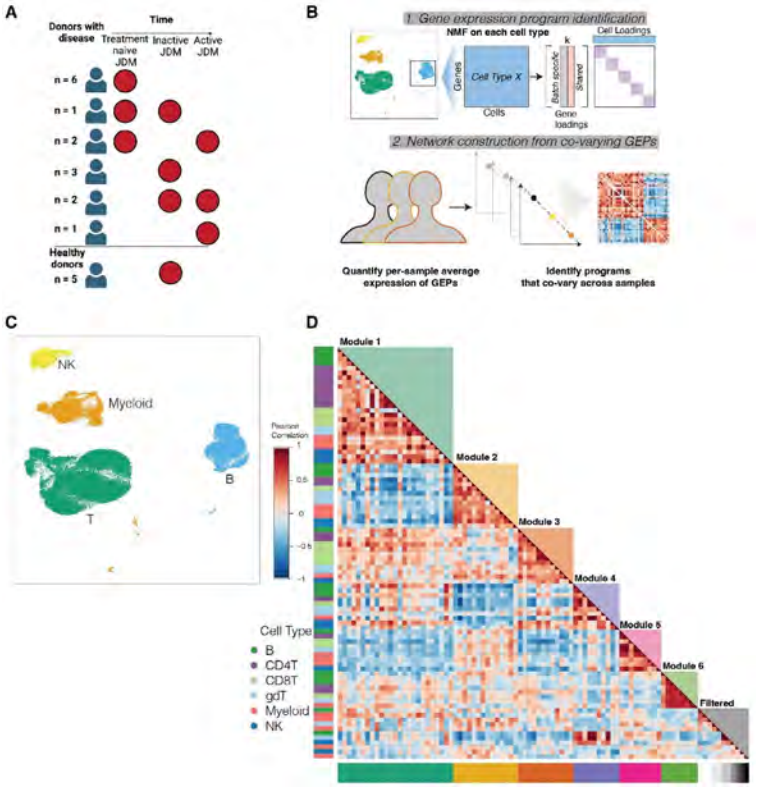
Session Title: Abstracts: Pediatric Rheumatology – Basic Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Juvenile Dermatomyositis (JDM) is a rare multisystem autoimmune condition that involves complex immune responses in both innate and adaptive compartments. Currently, we have a limited systems-level understanding of how cellular immunophenotypes functionally cooperate and are dysregulated in JDM. Increasing knowledge of

Fig. 1: A) Table showing samples included from JDM donors (n=15) and HCs. Some patients with JDM have longitudinal samples with a change in disease activity level included. B) UMAP reduction showing major immune cell types in peripheral blood samples annotated based on canonical markers. C) Overview of the DECIPHERseq workflow. Briefly, major cell types are subsetted and reduced via non-negative matrix factorization (NMF) into a set of GEPs defined by gene loadings quantifying the contribution of individual genes to that GEP and cell loadings quantifying how strongly expressed that GEP is in each cell. Cell loadings are averaged per PBMC sample and pairwise correlations are calculated between all the programs to identify co-varying GEPs. D) Heatmap showing 6 "blocks" (Modules 1-6) identified by DECIPHERseq from all pairwise correlations of GEPs across 6 major cell types. GEPs are clustered into modules using a Constant Potts Model for community detection, with isolated GEPs filtered out (greyscale).



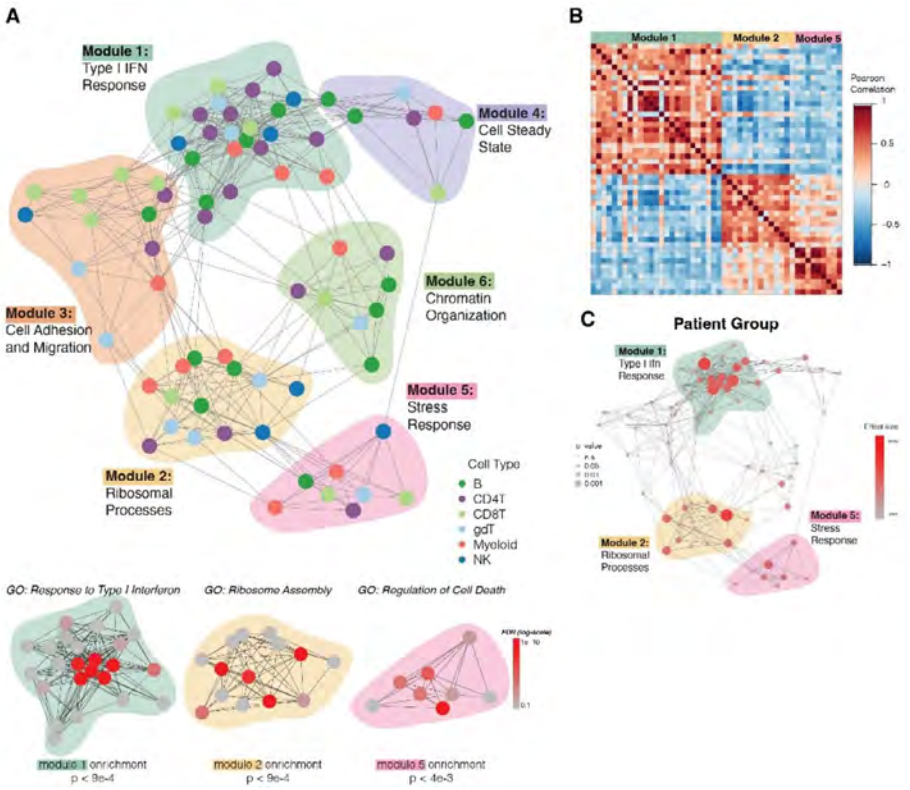


Fig. 2: A) Force-directed network graph (top) constructed from correlated GEPs in PBMCs from JDM patients and healthy controls, where strongly positively correlated programs appear closer and strongly anti-correlated programs appear further apart. Nodes represent biological activity programs in the given cell types and plotted edges represent significantly positively correlated activity programs (Pearson, $p<0.05$). Modules were identified using a Constant Potts Model for community detection. Module labels were annotated from the top 20 gene sets significantly enriched for each module relative to the rest of the network (module enrichment $p < 0.05$). Selected network modules (bottom) are colored by FDR of enrichment for indicated gene ontology set. B) Subsetted heatmap highlighting the negative correlations between Module 1 and Modules 2 and 5. C) Network graph of activity programs in PBMCs, colored by the relative effect size (linear scale) calculated by 4 group ANOVA of disease activity categorized by TN-JDM, active JDM, inactive JDM, and HCs. Significance level is indicated by node size.

the immune regulatory networks associated with JDM could lead to identification of precision treatment strategies and biomarkers.

Methods: We used multiplexed single cell RNA sequencing to profile 27 peripheral blood samples from JDM patients (n=15, samples=22) and healthy pediatric controls (n=5, HCs). We performed standard processing, dimensional reduction, and clustering steps to identify 6 major cell types (B, CD4T, CD8T, gdT, NK & Myeloid). We applied an unsupervised network inference method, DECIPHERseq, which uses non-negative matrix factorization to identify coordinated regulatory networks of functional gene expression programs (GEPs) across cell types and community detection to identify hubs or 'modules' of GEPs. The network was annotated using 1) gene set enrichment analysis to identify pathways overrepresented in each program and 2) the DECIPHERseq enrichment method, which relies on resampling to identify gene sets enriched within modules compared to the rest of the network. To determine JDM disease activity-associated changes in network structure, we performed ANOVA on mean patient expression of GEPs between treatment-naive (TN), active, and inactive JDM, and HC samples.

Results: We analyzed ~110,000 cells. DECIPHERseq inferred a network of 76 activity programs that formed 6 modules. All modules contained multiple cell types, highlighting that biological processes are coordinated across many cell types in JDM. Module enrichment analysis revealed consensus biological themes for each GEP hub. Module 1 was enriched in type I IFN responses and many programs in this module were increased in TN-JDM, as expected. Several disease-associated programs were highly correlated to this central IFN hub suggesting these cell-specific responses may be either up or downstream of IFN signaling. These included NK12, a proliferative NK program *(MKI67, HIST1H1B)*; gdT4, a cytotoxic Th1

polarized gdT program *(GZMB, CX3CR1, TBX21)*; CD4T10, an activated and proliferative Treg program *(FOXP3, IL2RA, PRDM1, MKI67)*; and B9, an immature naïve B cell program *(CD9, TCL1A, CD24)*, all of which were expressed higher in TN-JDM. Module 2, enriched in ribosomal processes, and Module 5, enriched in stress responses and regulation of cell death, were negatively correlated with Module 1.Several programs within Modules 2 and 5 were expressed significantly lower in TN-JDM suggesting dysfunction of these cellular processes in new-onset disease.

Conclusion: By employing unsupervised network analyses, we identified a central IFN hub highly correlated with novel cell-specific GEPs as well as dysfunction of ribosome and cell stress responses across many cell types in TNJDM. This systems-level perspective highlights coordinated peripheral immune responses that are both over- and underactive in JDM providing a foundation for future work to identify therapies to reprogram this dysregulation.

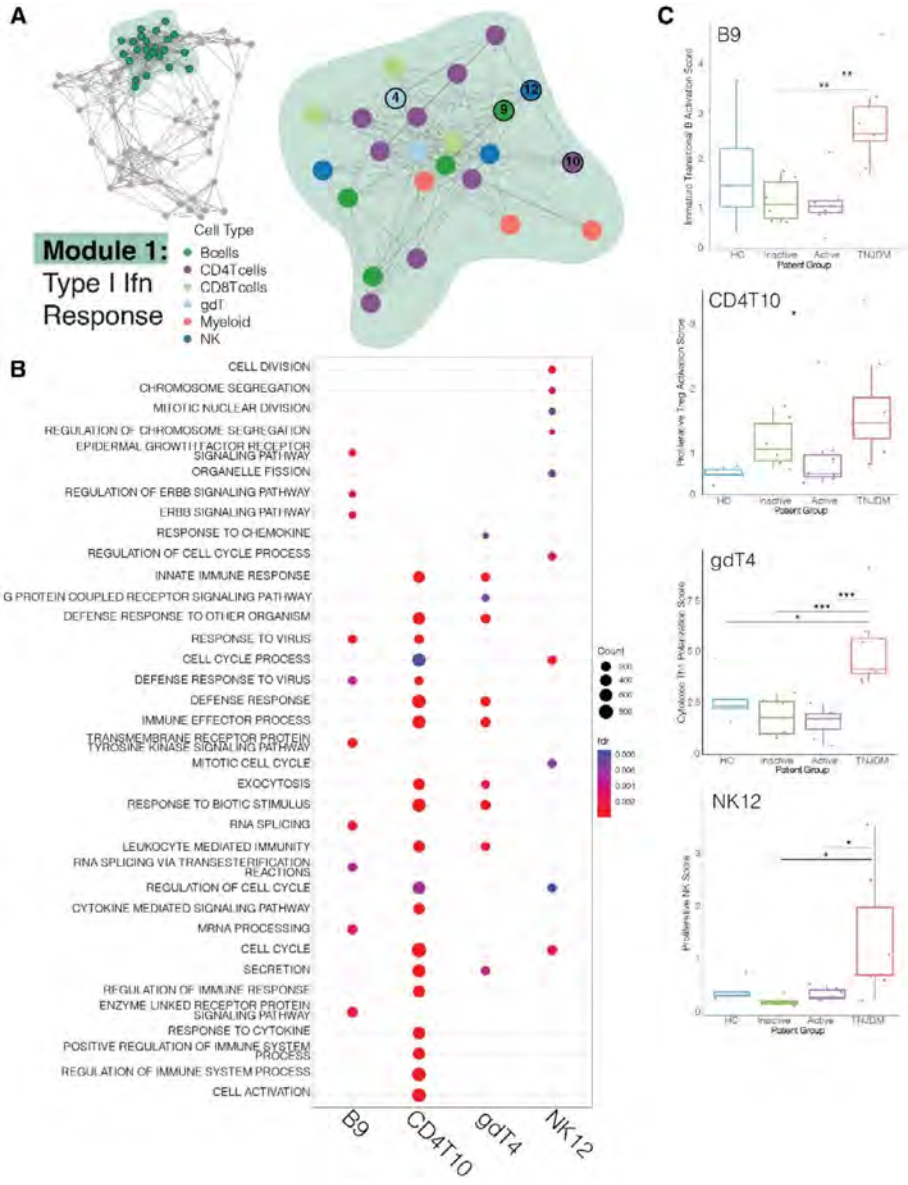

Fig. 3: A) Diagram showing GEPs in Module 1, indicating IFN hub-associated programs B9, CD4T10, gdT4, and NK10. B) Dotplot comparing top 10 enriched gene ontology (GO) sets for each program (FDR < 0.01). C) Boxplots for indicated disease-associated programs (4 group ANOVA, $p < 0.05$). Significant post-hoc pairwise comparisons between groups (Tukey HSD) are shown as * $p<0.05$, ** $p<0.01$, ***<0.001 (BH adjusted p value).

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Pediatric Rheumatology – Basic Science

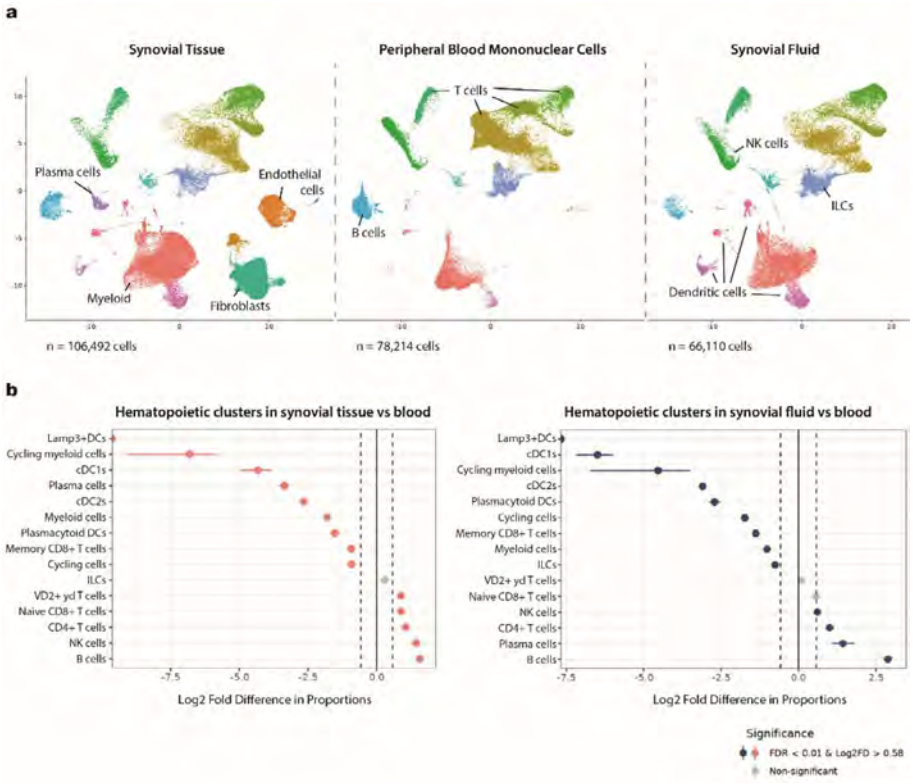
Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Understanding the unique and shared pathogenic processes between childhood-onset and adult-onset inflammatory arthritides is needed to guide more effective drug development and their application to different age groups. Difficulties in accessing samples from the inflamed tissue site in children has limited our understanding of disease mechanisms that operate locally in the joint. As part of the Tissue Research in Childhood Onset Inflammatory Arthritis (TRICIA) Consortium, we have established the first single cell multi-omic atlas of the inflamed joint in Juvenile Idiopathic Arthritis (JIA).

Methods: Ultrasound-guided needle biopsies of synovial tissue, with matched synovial fluid and peripheral blood mononuclear cell samples were obtained from n=12 pediatric patients with JIA, who were naïve to disease-modifying anti-rheumatic drugs. Multimodal single-cell characterisation of cells (n = 250, 816 cells, with scRNA-seq, VDJ-sequencing and TotalSeq surface assays) and multiplexed imaging of synovial tissue fragments were performed.

Results: Transcriptomic profiles of hematopoietic cells at a global level of clustering revealed that synovial tissue and synovial fluid were proportionally enriched in the same cellular subtypes (dendritic cell subsets, myeloid and memory CD8+ T cells) compared to blood (> 0.58 log2 fold difference, FDR < 0.01, Fig 1). Core tissue-enriched populations identified in adult rheumatoid arthritis (Zhang *et al*., 2022, the AMP RA/SLE network) were also prominent in pediatric synovial tissue samples, including *GZMK*+ memory *CD8*+ T cells, *CXCL13*+ *CD4*+ T peripheral helper cells and *NR4A*+ germinal centre-like B cells. Evidence for a distinct immune environment of the synovial fluid cavity relative to synovial tissue included upregulation of interferon-response genes, greater proportions of dendritic cells (Fig 1), less diversity of αβ T cell receptors on CD8+ T cells



Comparative analysis highlights conserved proportions of hematopoietic cells between synovial tissue and fluid in children with Juvenile Idiopathic Arthritis a) Integrated scRNA-seq global UMAP of major cellular clusters and their b) proportional difference between different specimen types, with bootstrap confidence intervals shown (10,000 permutations).

(P = 0.02) and more hyperexpanded CD8+ T cell clones: 13.6% of total T cells in synovial fluid had the same clonotype in ≥ 20 cells, compared to 3.8% in synovial tissue (n = 8091 and 7039 cells respectively).

Conclusion: Our work implicates the synovial fluid cavity in disease pathogenesis, with synovial fluid providing a reservoir of free-flowing activated cells as barrier integrity breaks down. Despite distinct disease features and physiology, our analysis identifies shared cellular phenotypes within inflamed synovium between children and adults. This suggests that certain pathogenic mechanisms extend across the age-spectrum in inflammatory arthritis, enabling a more informed approach to clinical trials in children in the future.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Pediatric Rheumatology – Basic Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The synovial membrane is the primary target tissue during the effector phase of inflammatory arthritis in children and young people with Juvenile Idiopathic Arthritis (JIA). However, due to difficulties accessing synovial tissue in children, little is known of the disease mechanisms that operate locally in the synovium. As part of the UK Tissue Research in Childhood Arthritis Consortium we have generated the first single cell multiomic atlas of the inflamed synovium in JIA.

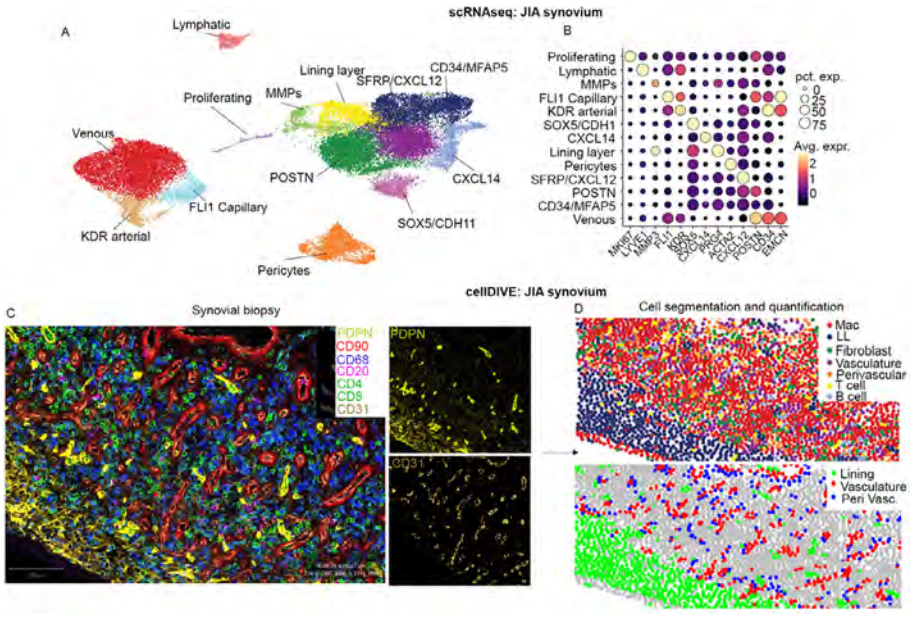

Figure 1. Multiomic characterisation of JIA inflamed synovium. (A) scRNAseq of stromal cells and assigned clusters. (B) Dotplot of key marker genes defining stromal cell subpopulations. (C) example of multiplex cellDIVE imagines. (D) analysis cellDIVE pipeline whereby cells are segmented and fluorescence quantified.

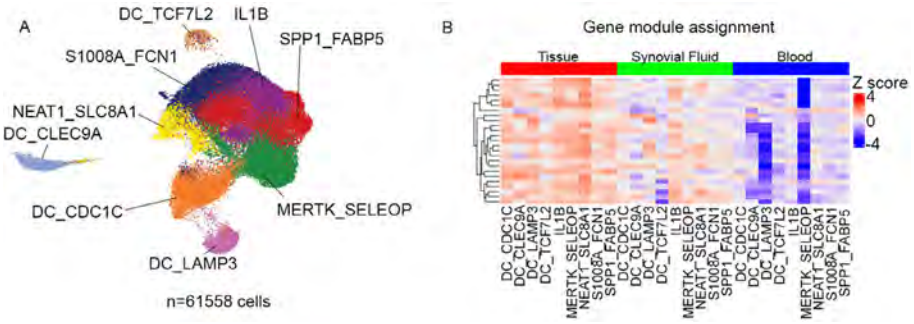

Figure 2. Transcriptional characterisation of JIA myeloid cells. (A) scRNAseq of myeloid cells and assigned clusters. (B) gene module assignment based on co-expression of top 10,000 highly variable genes.

Methods: Synovial tissues were obtained from inflamed knee joints of 12 children with JIA, who were naïve to disease modifying anti-rheumatic drugs using minimally invasive ultrasound guided biopsy procedures refined for use in children. Where possible, matched synovial fluid and peripheral blood samples were obtained from the same children at the time of the procedure. Tissues were cryopreserved, thawed and disaggregated and viable cells from each sample sorted for single-cell (sc) RNAseq. Multiplex imaging of matched synovial tissue sections (GE Cell Dive) and spatial transcriptomics were performed to generate the first synovial tissue atlas of JIA.

Results: We profiled 250,816 cells from matched tissue, blood and synovial fluid samples in children with newly diagnosed JIA using scRNA sequencing. We resolved 11 major cell types, including stromal (endothelial, pericytes, fibroblasts, lymphatic) and myeloid cells. Analysis of stromal cells revealed 7 transcriptionally distinct fibroblast clusters (Fig. 1A, B). One fibroblast cluster highly expressing Sox5 and Cadherin-11 (and devoid of endothelial/pericyte/lining layer markers) was enriched in JIA synovium when compared to adult synovium of patients with rheumatoid arthritis (RA - analysis from the Accelerated Medicines Partnership (AMP) network, Zhang et al., BioRxiv, 2022). This cluster expresses several transcription factors (Fig. 1B) and ongoing neighbourhood analysis of spatial data will determine the location of these cells in synovial tissue (Fig. 1C,D). Myeloid cells were resolved into 9 clusters that are transcriptionally conserved compared to myeloid cells from adult RA inflamed synovium (AMP: Zhang et al., BioRxiv, 2022, Fig. 2A). Differential gene expression showed heterogeneity of myeloid cells between blood, tissue, and synovial fluid (Figure 2B).

Conclusion: We have generated the first single cell atlas of the inflamed synovium in children with JIA. Through a comparative analysis with adult RA synovium, we have identified a distinct fibroblast subcluster that expresses Sox5 and Cadherin-11 and is enriched in JIA synovial tissue. It is not yet known if this fibroblast subtype represents an age, developmental or disease specific transcriptional program that drives JIA pathology. Fully mapping and characterising the inflamed synovium in children is critical in understanding the cellular pathogenesis of JIA.

Still's Disease Patients with High Interferon-stimulated Gene Expression Have Enrichment of Rare, *de Novo* and Recessive Protein Altering Variants in Innate Immune Pathways

Mariana Correia Marques[1], Zuoming Deng[2], Navid Chowdhury[2], Elizabeth Schmitz[3], Alana Platukus[4], Stephen Brooks[5], Carol Lake[2], Ly-Lan Bergeron[2], Michelle Millwood[2] and **Michael Ombrello**[6], [1]National Institute of Arthritis & Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), St. Louis, MO, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Philadelphia, PA, [5]Biodata Mining and Discovery Section, National Institute of Arthritis and Musculoskeletal and Skins Diseases, National Institutes of Health, Bethesda, MD, [6]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), North Bethesda, MD

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Pediatric Rheumatology – Basic Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Still's disease (systemic juvenile idiopathic arthritis in children, adult-onset Still's disease in adults) is an enigmatic inflammatory condition that affects people of all ages. It is characterized by inflammasome activation and pyroptosis, and is often punctuated by striking elevation of IL-18. Increased interferon (IFN) signaling, which promotes pyroptosis, has been described in Still's disease complicated by either macrophage activation syndrome (MAS) or an emergent form of lung disease (LD) with drug-induced hypersensitivity reaction (DHR), but it is unclear whether IFN signaling is an active participant or is epiphenomenal. Here, we explore the relationship between genetic variation and IFN signaling in Still's disease.

Methods: We examined consecutive Still's disease patients enrolled in an IRB approved research study at the NIH Clinical Center. Whole blood expression of 28 IFN-stimulated genes (ISG) was quantified with custom NanoString arrays and expressed as a normalized score. Trio whole exome sequencing (WES) was performed in 41 probands and candidate causative variant lists (protein-altering *de novo,* recessive, or X-linked variants of canonical transcripts; popfreqmax frequency < 0.01) were generated. Lists of genes containing candidate causative variants were compiled for individuals with the highest or lowest ISG scores and subjected to pathway over-representation analysis (ORA) and network topology analysis (NTA) using the Web-based Gene Set Analysis Toolkit (webgestalt.org).

Results: ISG scores among 59 Still's patients were negatively skewed and the upper quartile included 15 people (Figure 1). DHR was more common in the top quartile than in the bottom quartile (0.6, 0.13; p = 0.02), while rates of active disease, IL-18 > 15K, use of IL-1 directed therapy, HLA-DRB1*15 carriage and history of MAS did not differ between the groups (Table 1). Trio WES identified 83 candidate genes among the top ISG quartile. ORA of these 83 candidate genes revealed enrichment in the macrophage activation (ratio = 21.7, p = 3.4E-7, FDR = 0.0055), type I IFN biosynthetic process (ratio = 77.9, p = 6.7E-6, FDR = 0.03) and myeloid leukocyte activation (ratio = 5.0, p = 1.9E-5, FDR = 0.039) pathways. Most people in the top ISG quartile (11/15) had candidate causative variation within these 3 pathways. Chemokine production, regulation of IL-18 production, and NF-KB signaling also had evidence of over-representation (p < 0.0005, FDR > 0.05). NTA also demonstrated enriched pathways, including the MyD88-dependent TLR signaling pathway (corrected

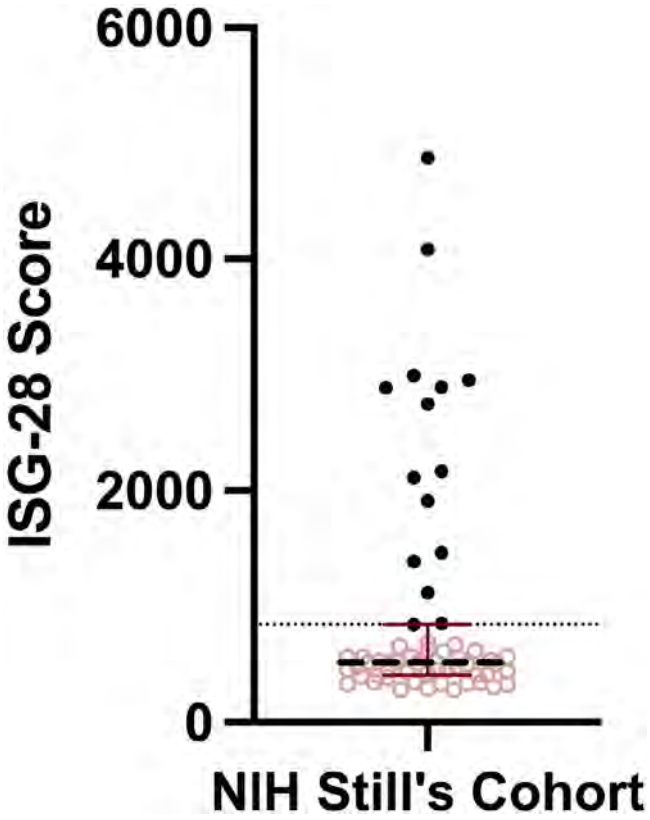

Figure 1. Scatter plot of interferon stimulated gene (ISG) scores from 59 Still's disease patients. The median and interquartile range are show by the error bars. The 75th percentile is marked by a dashed horizontal line. People in the top quartile are shown as solid circles, while all others are shown as open circles.

Table 1. Clinical characteristics of Still's patients in the top and bottom quartile of ISG scores. Active disease is defined as sJADAS > 3.

	Proportion with Characteristic		
Clinical Characteristic	**Top ISG Quartile**	**Bottom ISG Quartile**	**p-value**
Drug hypersensitivity reaction	0.60	0.13	0.02
DHR with lung disease	0.40	0.13	
DHR without lung disease	0.20	0.00	
Active disease	0.67	0.80	
History of MAS	0.40	0.27	
IL-18 > 15K pg/ml	0.40	0.20	
Current IL-1 directed therapy	0.60	0.40	
HLA-DRB1*15 positive	0.47	0.20	

p = 0.0045). ORA/NTA of 81 candidate genes from 15 subjects with the lowest ISG scores did not reveal enrichment of any pathway.

Conclusion: In our Still's cohort, high ISG score was associated with the presence of DHR but not MAS. Unbiased analysis of trio WES revealed that people with high ISG scores had specific enrichment of potentially causative variation in overlapping innate immune pathways, notably type I IFN production, MyD88/TLR signaling, and macrophage/myeloid leukocyte activation. This suggests that rare *de novo* or recessive variation contributes to the pathophysiology of Still's disease, where it promotes enhanced IFN signaling and may predispose to LD/DHR.

Session Title: Abstracts: Pediatric Rheumatology – Basic Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Recent single-cell RNA sequencing (scRNA seq) data has been generated across several tissues in autoimmune diseases, helping to understand the cellular and molecular underpinnings of disease. However, the location of cells or interest identified and their proximity to important structure in the tissues, has not been as well described. Pairing spatial transcriptomics (ST) with scRNA seq data would add the much needed in situ spatial context of cellular and extracellular matrix tissue deposition, provide detail to characterize ligand-receptor and cell-cell interaction patterns and has the potential for biomarker discovery for rare diseases like scleroderma. Our scleroderma cohort, both localized scleroderma (LS) and systemic sclerosis (SSc) patients, have two 4mm skin punch biopsies collected in tandem from same site, one sample processed with scRNAseq and the other formalin-fixed paraffin-embedded (FFPE) available for spatial transcriptomics application.

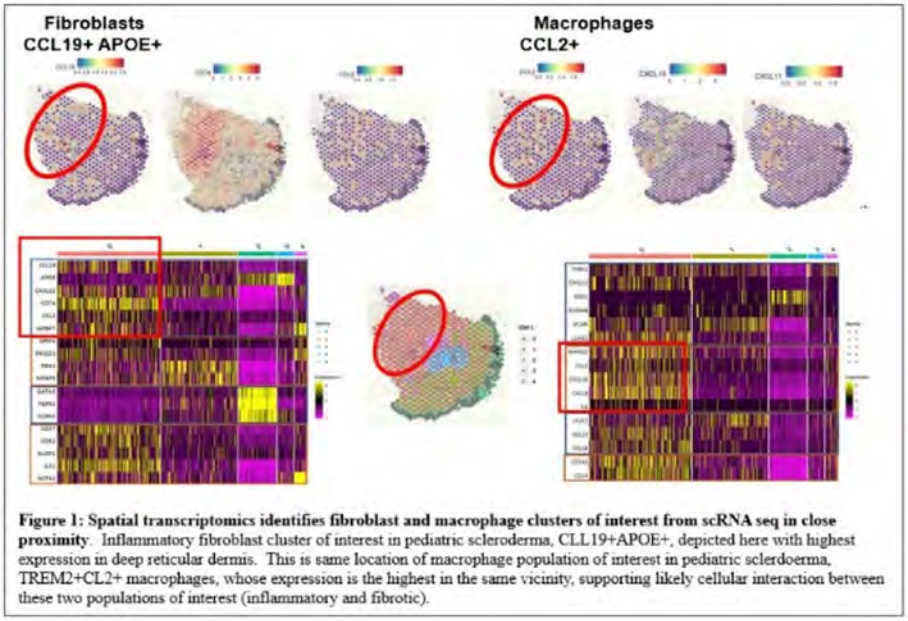

Figure 1: Spatial transcriptomics identifies fibroblast and macrophage clusters of interest from scRNA seq in close proximity. Inflammatory fibroblast cluster of interest in pediatric scleroderma, CLL19+APOE+, depicted here with highest expression in deep reticular dermis. This is same location of macrophage population of interest in pediatric sclerdoerma, TREM2+CL2+ macrophages, whose expression is the highest in the same vicinity, supporting likely cellular interaction between these two populations of interest (inflammatory and fibrotic).

Figure 1: Spatial transcriptomics identifies fibroblast and macrophage clusters of interest from scRNA seq in close proximity. Inflammatory fibroblast cluster of interest in pediatric scleroderma, CLL19+APOE+, depicted here with highest expression in deep reticular dermis. This is same location of macrophage population of interest in pediatric scleroderma, TREM2+CL2+ macrophages, whose expression is the highest in the same vicinity, supporting likely cellular interaction between these two populations of interest (inflammatory and fibrotic).

Methods: To preserve both the cellular location and architecture of the tissue while also gathering a large quantity of information about the cellular phenotypes of cells, we applied an innovative technology, VisiumSpatialGeneExpression(10XGenomics), Visium CytAssist for formalin-fixed paraffin-embedded (FFPE), which captures transcripts on spatially barcoded slide with a probe panel targeting 18,085 human protein coding genes. After sequencing, barcode information was used to determine the transcriptional profile (cellular representation) of each spot within the spatial context of the entire tissue(SpaceRanger, 10x Genomics). A novel integrative analyses approach was then applied that combines scRNA seq with spatial location of cells with in the tissue, Robust Cell-type Decomposition, which is an optimized deconvolution pipeline to decipher specific cell-type composition by anatomic location and can obtain details to the individual cell level.

Results: We performed a pilot study on 4 skin FFPE samples, 3 from pediatric LS and 1 from pediatric SSc patients using the Visium 10X CytAssist for FFPE platform. We obtained an average of a total number of 566 spots under tissue section (4 mm x 4mm) with mean reads per spot 257,119, with 96% reads mapped to probe set, with 2,896 median genes detected per spot, and a total number of 18,029 genes detected. Transcriptomic expression using either marker genes or unbiased clustering was able to distinguish epidermis, dermis, and inflammatory regions. We also investigated some of the cell subsets and upregulated genes in those clusters from our scRNA seq data and observed the co-localization of an inflammatory fibroblast (CL19+APOE+) and a macrophage population (CCL2+TREM2+) that highly expresses IL-β in pediatric scleroderma together in the deep reticular dermis (**Figure 1**).

Conclusion: Using an innovative bioinformatic approach coupling scRNA seq and ST from paired tissue samples, we are able to identify dysregulated genes of interest, cells expressing these genes and their location within the skin and surrounding cells. To our knowledge, this would be the first study to employ spatial transcriptomics in localized scleroderma and systemic sclerosis skin.

Chronic Excess IL-18 Induces NK Deficiency, but Drives Hyperinflammation via CD8 T-cell Cytokine Overproduction and Selective Immunodeficiency

Jemy Varghese[1], Scott Canna[1], Emily Landy[2], Laurence Eisenlohr[1], Elise Peauroi[3], Vinh Dang[1], Anastasia Frank-Kamenetskii[4] and Jeremy Morrissette[5], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]CHOP/UPENN, Philadelphia, PA, [5]University of Pennsylvania - Perelman School of Medicine, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Pediatric Rheumatology – Basic Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (SJIA) and Macrophage Activation Syndrome (MAS) are associated with highly elevated peripheral blood levels of the inflammasome-activated cytokine IL-18 and chronic exposure to free IL-18. IL-18 canonically acts on NK and activated T-cells in concert with other signals, like T-cell receptor engagement or IL-12 signaling, to amplify Interferon gamma (IFNg) production and cytotoxicity. We sought to determine the mechanisms by which excess IL-18 drives systemic hyperinflammation.

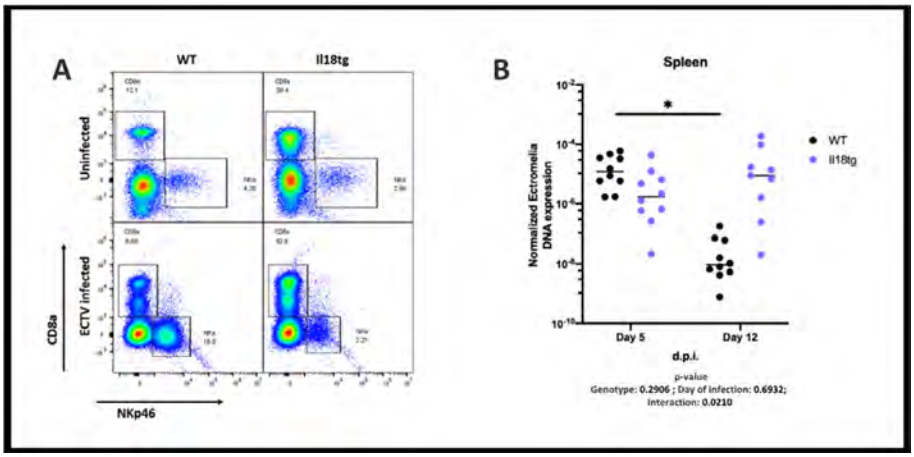

Figure 1. (A) Representative flow plots of live liver immune cells from uninfected mice or at day 5 post-infection showing sustained NK deficiency and increased CD8 T-cells. (B) 18s rRNA normalized ectromelia viral DNA (Evm003) from spleen at the indicated timepoints. Significance was analyzed with a two-way ANOVA.

Methods: We assessed lymphocyte phenotypes, distribution, and function via flow cytometry and RNAseq in mice with transgenic expression of mature, secretable IL-18 (Il18tg) and relevant controls. Lymphocytic Choriomeningitis Virus (LCMV) Armstrong strain and ectromelia virus (ECTV) were injected intraperitoneally and via footpad, respectively. Cytokines were measured by bead array and viral quantitation by quantitative PCR. Data were analyzed using descriptive statistics.

Results: Like SJIA/MAS patients, Il18tg mice demonstrated decreased numbers of NK cells and a concomitant increase in activated CD8 T-cells in peripheral blood, spleen, and liver. Splenic and hepatic NK cells from Il18tg mice showed decreased IL-18 receptor expression, and were enriched for cell cycle and gene transcription programs, suggesting rapid cellular turnover possibly due to activation-induced cell death. Il18tg mice cleared (non-lytic) LCMV infection similarly to WT, but thereafter developed CD8 T-cell and IFNg-mediated immunopathology reminiscent of MAS. To directly challenge NK function in vivo, We infected Il18tg mice with ectromelia, which causes severe viral immunopathology in NK-depleted mice. In contrast to WT, NK cells from infected Il18tg mice neither expand nor upregulated activation markers. However, Il18tg mice managed virus similarly to WT mice at early timepoints. NK depletion impaired viral clearance in WT, but not Il18tg mice. As with LCMV, Il18tg mice developed MAS at 8-12 days post-infection, the peak of the CD8 T-cell response. As expected, WT mice largely cleared ectromelia between days 5 and 12. Il18tg mice showed robust CD8 T-cell expansion and activation, but nevertheless failed to significantly decrease ectromelia DNA (Fig. 1).

Conclusion: Thus, though chronic excess IL-18 both impairs NK cell numbers and IL-18 responsiveness, NK dysfunction appears irrelevant for the development of virus-triggered MAS. Chronic IL-18 excess may overcome NK dysfunction by "pre-priming" CD8 T-cell responses at early timepoints. However, excess IL-18 induced hyperinflammation to a variety of triggers, but only with the lytic ectromelia virus did excess IL-18 also causean unexpected, selective immunodeficiency most evident at the peak of CD8 T-cell expansion. Together, this suggests IL-18 may promote MAS by both CD8 T-cell cytokine amplification and an unexpected impairment of viral clearance.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: We have previously shown that skin fibroblast activation is related to clinical severity and resolves with improvement in diffuse systemic sclerosis (dcSSc). The immune cells that associate with fibroblast activation are not fully characterized. The purpose of this study was to evaluate associations between immune cells and fibroblasts of varying stages of activation in dcSSc skin.

Methods: Histology of 137 forearm skin biopsies from 105 dcSSc patients were scored for fibroblast markers (CD34, alpha smooth muscle actin (aSMA); semiquantitative), and immune cells (B cells (CD20+), T cells (CD3+) and plasmacytoid dendritic cells (pDCs; CD123+); count per 5 HPF). 79 samples were also stained for MxA, a type 1 interferon (IFN)-related protein, scored present or absent. Non-inflammatory fibroblast pattern was defined by $CD34^{high}$/$aSMA^{low}$ scores. Inflammatory fibroblast pattern was defined as $aSMA^{high}$ and/or $CD34^{low}$ scores. Clinical variables and cell counts were compared between fibroblast immunophenotypes using Fisher's exact, t-test, or Wilcoxon rank-sum. Spearman correlation was used to assess the association between histologic features. Imaging mass cytometry (IMC) was used to visualize immune-stromal cell spatial interactions. Gene expression was analyzed by microarray for all samples. GSEA was performed using hallmark gene sets between fibroblast groups. Average expression of genes in selected pathways were ranked, and a loess curve was fit to each fibroblast group (bands represent 0.99 confidence interval).

Results: Inflammatory (vs. non-inflammatory) fibroblast samples (66 of 137, 48%) had worse clinical severity (modified Rodnan skin score ($p< 0.001$), HAQ ($p=0.012$), Patient Global ($p=0.036$) and Physician Global ($p< 0.001$)) (Table 1A) and higher median CD20+ ($p< 0.001$), CD3+ ($p=0.003$) and CD123+ cell count ($p=0.028$) (Table 1B). CD34 (key marker of non-inflammatory fibroblasts) correlated negatively with CD20 (r_s=-0.315, $p=0.0002$), CD123 (r_s=-0.281, $p=0.0009$), and CD3 (rs=-0.236, $p=0.0058$), while aSMA (key marker of inflammatory fibroblasts) correlated positively with CD20 (r_s=0.415, $p< 0.00001$) and CD3 (r_s=0.212, $p=0.0135$). Samples with detectable MxA protein expression had higher median CD123+ cells (5 vs. 1, $p=0.001$). IMC in a representative sample revealed infiltrating pDC adjacent to B cells and local interactions between these cells and aSMA+ fibroblasts (Fig. 1). Gene expression analysis demonstrated upregulation of IFN-alpha, TGF-beta, and inflammatory response as well as epithelial-mesenchymal transition among samples with inflammatory vs. non-inflammatory fibroblasts (Fig. 2).

Conclusion: Inflammatory fibroblasts in clinically severe SSc skin are associated with hallmark inflammatory response, IFN-alpha response, and TGF-beta signaling, as well as T cell, B cell, and pDC infiltration. Inflammatory fibroblasts are physically associated with B cells and pDCs in SSc skin. These data are relevant to SSc trials targeting B cell and IFN pathways. To our

Fibroblast Specific Interferon Regulatory Factor 7 (IRF7) Expression Is a Key Link Between Type I Interferon Activation and the Exaggerated Dermal and Pulmonary Fibrosis in Systemic Sclerosis

Minghua Wu[1], Jerry Alonso[2], Julio charles[2], Brian Skaug[2], Tingting Mills[3], Maureen Mayes[2] and Shervin Assassi[4], [1]Department of Internal Medicine, Division of Rheumatology, The University of Texas Health Science Center at Houston, Houston, TX, [2]Division of Rheumatology, University of Texas McGovern Medical School, Houston, TX, [3]Biochemistry Department, University of Texas McGovern Medical School, Houston, TX, [4]University of Texas McGovern Medical School at Houston, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: A prominent interferon (IFN) activation signature has been observed at the peripheral blood and end-organ levels in systemic sclerosis (SSc). However, the mechanisms by which the IFN pathway leads to the exaggerated fibrotic response in fibroblasts is not well-understood. Interferon Regulator Factor 7 (IRF7), a key transcription factor in the IFN pathway, has been identified as one of the top predicted upstream regulators of SSc transcript profile in skin bulk sequencing and SSc enriched fibroblast subpopulations in single-RNA sequencing. Herein, we investigated the role of IRF7 in fibroblasts in linking type I IFN activation to fibrosis.

Methods: Skin IRF7 expression and its clinical correlates were examined in 113 SSc patients and 44 matched healthy controls. SSc and healthy control dermal fibroblasts were treated with IFNα and nine prominent Th1, Th2, or Th17 cytokines, as well as with IFN inhibitors. *Col1a2-Cre/Irf7$^{f/f}$* fibroblast specific conditional knockout (KO) mice and *Col1a2-Cre* control mice

Figure.1

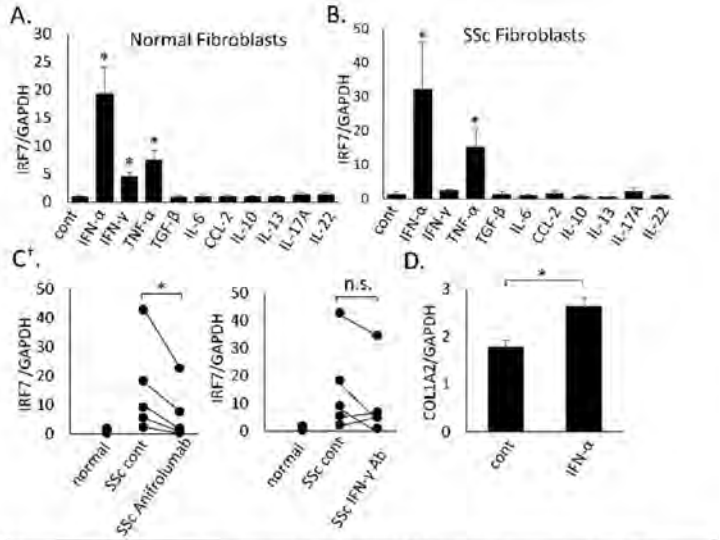

Figure 1. IFN-α induced IRF7 expression in normal and SSc dermal fibroblasts and anti-IFN treatment attenuated IRF7 expression in SSc fibroblasts: A, B. Healthy control or SSc skin fibroblasts were treated with indicated cytokines for 24 hrs and total RNA was extracted for qRT-PCR analysis. *p<0.05. **C.** Human skin fibroblasts treated with anti-type I IFN receptor antibody (Anifrolumab) or anti-IFN-γ antibody for 24 hrs. Total RNA was extracted for qRT-PCR. All results from **A,B,C** were normalized to GAPDH and present fold induction compared to controls. n=5. *p<0.05. **D.** SSc fibroblasts were stimulated with IFN-α for 72 hrs and RNA extracted for qRT-PCR analysis. n=5, *p<0.05.† Results of the same experiment shown in two panels in order to depict treatment related changes.

Figure.2

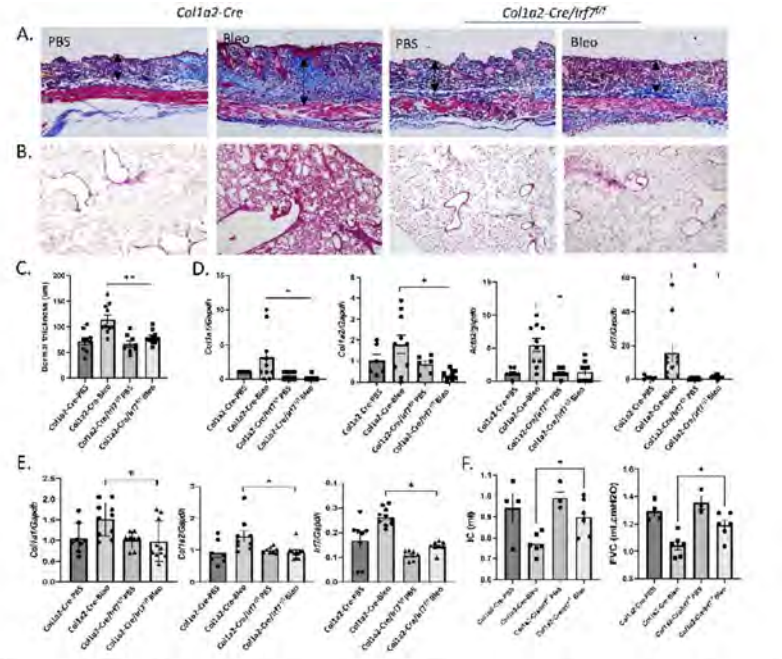

Figure 2. *Irf7* knock down in fibroblasts attenuated skin & lung fibrosis in bleomycin induced fibrosis mouse models: A. (n=10). **D.(skin)& E.(lung).** qRT-PCR showing attenuated *Col1a1*,*Col1a2*, *Acta2* and *Irf7* mRNA expression in *Col1a2-cre-Irf7*$^{f/f}$ mice. n=6-10 per group.*p<0.05. **F.** Lung function test showing attenuated IC and FVC. N=4-6. .*p<0.05.

(n=10 per experimental group) were treated either with daily subcutaneous or intraperitoneal (i.p.) bleomycin injections for 28 days to induce dermal and pulmonary fibrosis, respectively. Furthermore, *Col1a2-Cre/irf7*$^{f/f}$*Tsk*+ triple congenic mice and *Col1a2-Cre/Tsk*+ control mice received tamoxifen injections for Cre activation and were examined for hypodermal fibrosis.

Results: Skin IRF7 mRNA levels were higher in SSc patients than in healthy controls (p=0.0009). Moreover, skin IRF7 mRNA levels correlated significantly with modified Rodnan Skin Score (r=0.42, p< 0.0001) and were higher in patients with early diffuse SSc (disease duration < 3 years) than in the remainder of patients(p=0.006). In vitro study (Figure 1), IFNα stimulation resulted in the highest IRF7 expression levels among all examined cytokines in SSc and control fibroblasts. Moreover, treatment with an inhibitory antibody against type I IFN receptor (anifrolumab) consistently led to decreased IRF7 expression in unstimulated cultured SSc fibroblasts while a similar effect was not observed with IFNγ blockade. Linking type I IFN

Figure.3

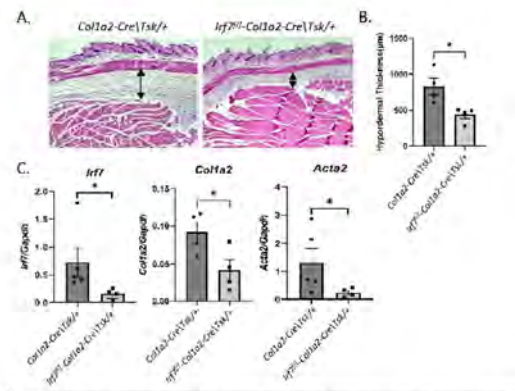

Figure 3. Knock down *Irf7* in fibroblasts attenuated skin fibrosis in *Tsk/+* mouse model: **A.** H&E stain in skin from *Irf7*$^{f/f}$*/Col1a2-Cre\Tsk/+* mice. **B.** Quantitation of hypodermal thickness. **C.** Downregulation of Irf7, Col1a2 and Acta2 mRNA expression in the skin of *Irf7*$^{f/f}$*-Col1a2-cre\Tsk/+* mice. n=4-5 per group. *p<0.05.

activation to the fibrotic response, IFNα stimulation also led to increased collagen expression in SSc dermal fibroblasts. As shown in Figure 2, in the bleomycin induced dermal fibrosis model, tamoxifen injected *Col1a2-Cre/Irf7$^{f/f}$* mice had markedly attenuated dermal fibrosis based on histology and mRNA levels. In i.p. bleomycin lung fibrosis model, tamoxifen injected *Col1a2-Cre/irf7$^{f/f}$* mice showed attenuated pulmonary fibrosis based on histology, mRNA, and lung function. In the *Col1a2-cre/irf7$^{f/f}$\Tsk+* triple congenic mice, fibroblast specific *Irf7* knock-down led to reduced hypodermal thickness, *Col1a2* and *Acta2* mRNA levels compared to control *Col1a2-Cre/Tsk+* mice after *Cre* activation (Figure 3).

Conclusion: IRF7 is upregulated in SSc skin and correlates with the severity of skin disease. Its expression in fibroblasts is induced by Type I IFN, and fibroblast-specific deletion of IRF7 abrogated skin and lung fibrosis.IRF7 therefore provides a pathologic bridge between type I IFN signaling and the fibrotic response in fibroblasts.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Type I interferon (IFN-1) signature is a hallmark of patients with systemic sclerosis (SSc). However, its significance in clinical stratification and contribution to deterioration still need to be better understood.

Methods: For hypothesis generation, we performed single-cell RNA sequencing (scRNAseq) on skin biopsies (SSc=4, control =2) using the BD Rhapsody platform. Two publicly available datasets of skin scRNAseq were used for validation (GSE138669: dcSSc=12, control=10; GSE195452: dcSSc=52, lcSSc=41, control =54). IFN-1 signature was mapped, functionally investigated in a bleomycin plus IFNα2-adeno-associated virus (IFNA2-AAV) induced model, and verified in an SSc cohort (n=61).

Results: The discovery and validation datasets shared findings. The endothelial cells (EC) had the most prominent IFN-1 response among dermal non-immune cells. EC IFN-1 signature was increased both in SSc vs. control and in dcSSc vs. lcSSc. Among EC subclusters, the elevation of IFN-1 signature in dcSSc patients compared to control was still true in capillary, post-capillary venule, and venule ECs in all datasets. Endothelial-to-mesenchymal transition (EndoMT) scores increased in parallel. IFNA2-AAV deteriorated bleomycin-induced dermal fibrosis, EndoMT, and perivascular fibrosis and caused blood vessel loss with EC apoptosis. Vascular MX1, an IFN-1 response protein, was significantly increased both in

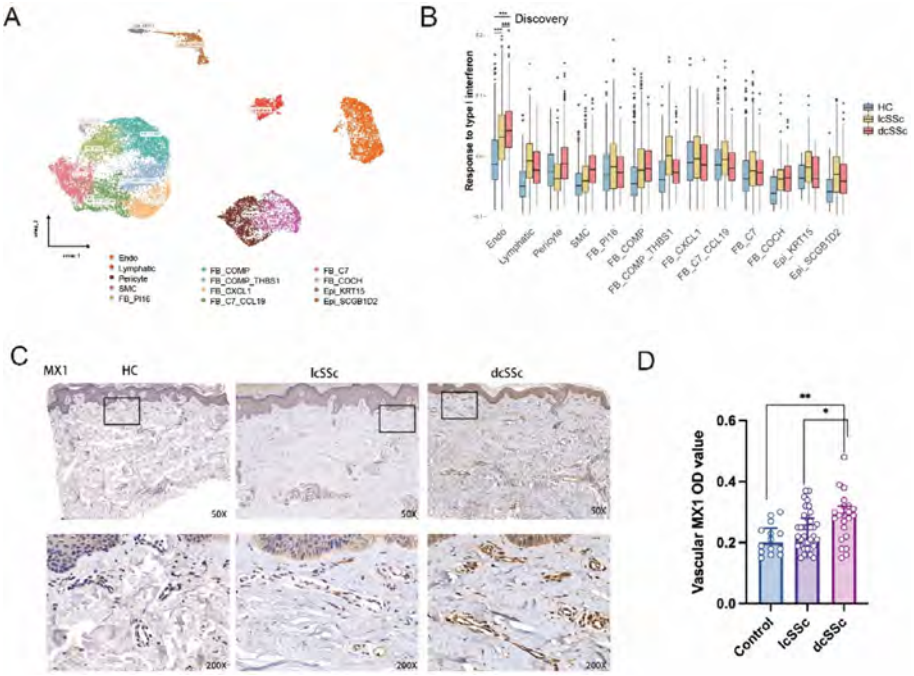

Figure1 (A)Umap plot exhibiting the identified 13 clusters in dermal stromal cells. (B)Response to type I interferon scores calculated by GSVA method in each celltype. (C)Immunohistochemical staining of MX1 in dcSSc, lcSSc, and HC skin. (D)Qualification of vascular MX1 OD value.

total SSc skin and in dcSSc vs. lcSSc. To predict disease progression in 6-34 months, the baseline vascular MX1 performed similarly to skin score in total SSc and was superior in the dcSSc subpopulation.

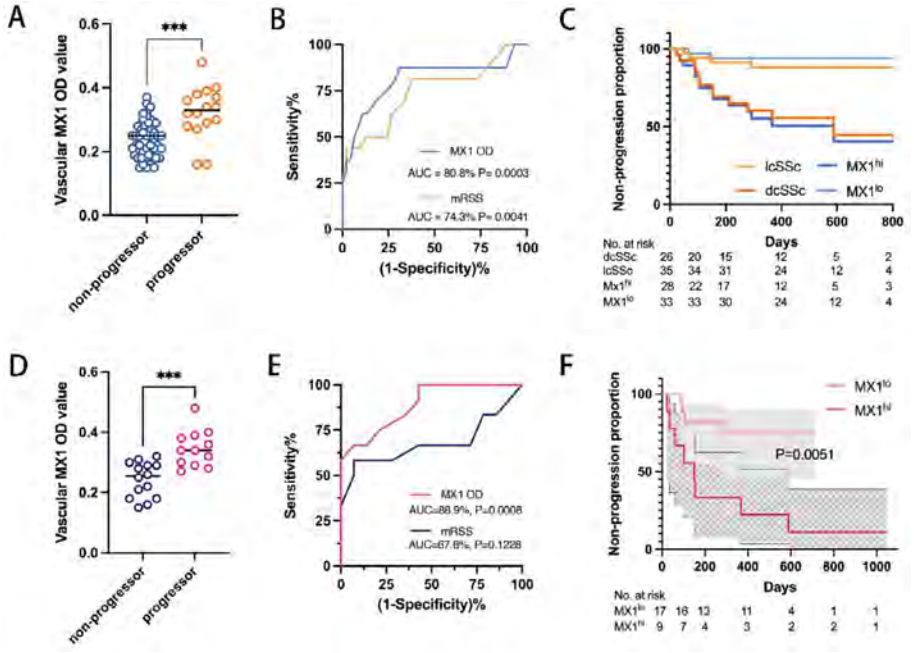

Figure2: Vascular MX1 is predictive of disease progression in SSc. (A)Vascular MX1 OD value in progressor and non-progressor among all SSc patients. (B)ROC curves of the predictive values for vascular MX1 OD value (blue) and mRSS (yellow) in all SSc patients. (C)Kaplan–Meier analysis of non-progression in patients with low and high vascular MX1 expression as well as patients with lcSSc and dcSSc . (D)Vascular MX1 OD value in progressor and non-progressor among dcSSc patients. (E)ROC curves of the predictive values for vascular MX1 OD value (red) and mRSS (purple) in dcSSc group. (F)Vascular MX1 distinguished disease worsening eddectively in Cox regression for dcSSc.

Conclusion: The EC IFN-1 signature distinguished SSc skin subtypes and disease progression and may contribute to vasculopathy and fibrosis.

TNF-mediated Pulmonary Hypertension Is Marked by Aberrant Bone Morphogenic Protein (BMP) and Integrin/Basement Membrane Ligand-Receptor Signaling

Javier Rangel-Moreno[1], Maria de la Luz Garcia-Hernandez[2], Qingfu Xu[3] and **Benjamin Korman**[1], [1]University of Rochester, Rochester, NY, [2]University of Rochester, West Henrietta, NY, [3]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: : We recently described TNF-transgenic mice as a novel model of pulmonary hypertension (PH) and have shown that they express altered endothelial and mesenchymal cell populations by single-cell RNA sequencing. Mutations in BMPR2 are known to cause genetic pulmonary arterial hypertension (PAH), and loss of BMPR2 function is seen in idiopathic forms of PAH, but the role of BMP signaling in inflammatory PH has not been well characterized.

Methods: Endothelial and mesenchymal cells were isolated from lungs from TNF transgenic mice and littermate controls at 8, 14, and 20 weeks of age (n=3-5 mice per timepoint and genotype).6000-8000 cells were used for droplet-based single cell capture (10X Genomics) and RNA sequencing. Data were analyzed using multinichenetr to assess for ligand-receptor (L:R) interactions between cell types in each condition. Putative L:R interactions were confirmed using immunostaining including stains for BMPR2, BMPR1a, BMP2, BMP4, Noggin, COL4A1, and ITGA2.Representative images were taken at both central/peribronchiolar areas and peripheral lung areas. aSMA was utilized to visualize vessels and as an anatomical landmark in other immunofluorescent stains BMPR2/Nog/aSMA, BMPR1a/Nog/aSMA, BMP4/Nog/aSMA, and Bmp2/Hjv/aSMA.

Results: Ligand-receptor analysis demonstrated an impaired interaction ofBMPR2 with BMP ligands (BMP4, BM6, and BMP7) in TNF-Tg PAH lungs, leading to the establishment of an alternative maladaptive BMP signaling cascade dominated by the interaction of BMP2 with BMPR1a and HJV (Figure 1 A-D).Immunofluorescence confirmed down-regulation of BMPR2 and BMP4 in TNF-Tg relative to WT littermates and up-regulation of BMPR1a, HJV, BMP2, and Noggin in TNF-Tg lungs (Figure 1E-H). L:R interactions between basement membrane proteins (COL4A1, HSPG2), TGF-beta family

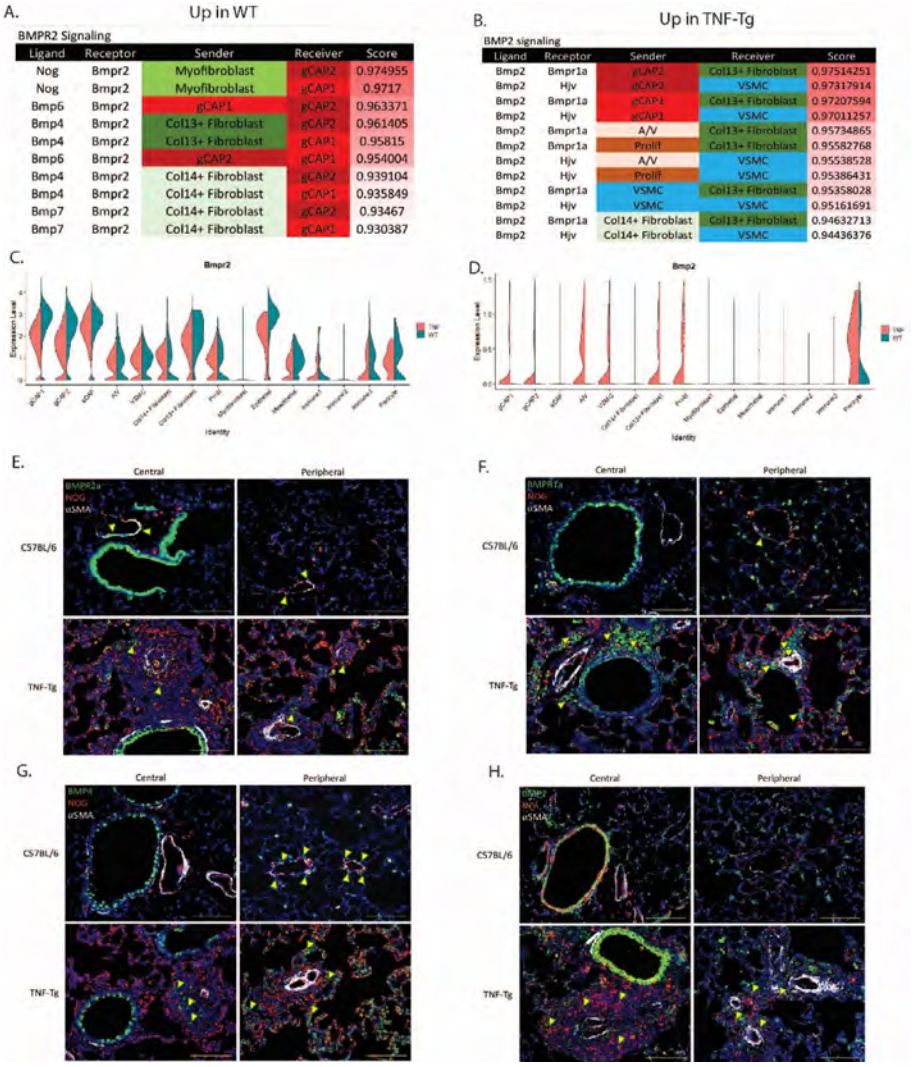

Figure 1. Altered BMP signaling in TNF-Tg lungs is a hallmark of pulmonary hypertension. A. Ligands, receptors, cells sending and receiving signals, and the strength of the predicted interaction in WT mice. Note that BMPR2 signaling has the strongest ligand-receptor interactions in WT mice. B. Ligands, receptors, cells sending and receiving signals, and the strength of the predicted interaction in TNF-Tg mice. Note that BMP2 signals through BMPR1a and HJV but the absence of BMPR2 signaling is absent in TNF Tg lungs. C. Violin plot showing differential expression of BMPR2 in endothelial and mesenchymal cell populations. Note that BMPR2 loss is most prominent in TNF-Tg gCAP cells . D. Violin plot demonstrating differential expression of BMP2 in endothelial and mesenchymal cell populations. Note that BMP2 is over-expressed in most cell types and that it is only expressed in TNF-Tg lungs in some cells. E. Representative immunofluorescence for BMPR2, Noggin, and aSMA. F. Immunostaining for BMP1a, Noggin, and aSMA. G. Immunostaining of BMP4, Noggin, and aSMA. H. Immunostaining for BMP2, Hjv, and aSMA.

proteins, and integrins increased, while a decrease in pro-angiogenic signaling was observed in TNF-Tg mice (Figure 2). Circos plot and network analysis confirmed the centrality of altered BMP signaling in TNF-mediated PH pathogenesis (Figure 3).

Conclusion: Constitutive activation of TNF leads to loss of BMPR2 signaling and formation of an alternate weaker BMP signaling profile associated with increased TGF-beta/integrin and basement membrane protein expression in the PH cellular niche. Given the centrality of BMP signaling in PAH, this suggests that TNF is a key upstream mediator of pulmonary vascular disease and might represent an essential target for modulating PAH induced by inflammation and autoimmunity.

Characterization of the Vascular Niches in Systemic Sclerosis (SSc) as a Prototypical Immune-mediated Fibrotic Disease with Prominent Vasculopathy Using Imaging Mass Cytometry

Minrui Liang[1], Aleix Rius Rigau[2], yi-nan Li[1] and Joerg Distler[1], [1]Clinic for Rheumatology University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany; Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany, [2]Department of Internal Medicine 3, Rheumatology and Clinical Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany; Deutsches Zentrum Immuntherapie (DZI), FAU Erlangen-Nürnberg and University Hospital Erlangen, Erlangen, Germany

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Systemic sclerosis (SSc) is a prototypical collagen-vascular disease with prominent vasculopathy. Although microvascular changes are the earliest histopathologic manifestation of SSc, the vascular dysregulation and immune environment of vascular niche in SSc are largely unknown. Here, we applied Imaging Mass Cytometry (IMC) as a spatial proteomic approach to deconvolute the heterogeneity of vascular cells at single-cell level *in situ* and to characterize cellular alterations of the vascular niches of SSc patients.IMC is a multiplex imaging technique that detects metal isotope-labelled antibodies in tissues using localization-specific laser mediated ablation coupled with mass-spectrometry.

Methods: Skin biopsies collected from 19 SSc patients and 14 matched healthy individuals were analyzed by IMC, yielding a total of90,755 cells including 8,865 vascular cells and 4,096 immune cells. Single cells were clustered according to marker expression, referred back to the tissue, quantified and correlated with clinical disease outcomes. Direct cellular interactions and accumulation of immune cells in the local vascular niches of specific endothelial cell subsets were analyzed.

Results: Our analyses revealed microvascular rarefaction with significant reductions in blood vessels and lymphatic vessels in SSc. However, we showed that increase in the number of apoptotic and proliferating ECs in SSc was restricted to blood vessels and was not observed in lymphatic vessels. We identified seven different subpopulations of blood endothelial cells (BECs), two subpopulations of lymphatic endothelial cells (LECs) and three subpopulations of pericytes by unsupervised clustering. A novel population of $CD34^+$;αSMA^+;$CD31^+$ BECs was more common in SSc, whereas numbers of endothelial precursor cells (EPCs) were decreased. EPCs displayed significant changes in cellular turnover in SSc patients. The micro-environment of $CD34^+$;αSMA^+;$CD31^+$ BECs, but not of EPCs, was enriched for immune cells and myofibroblasts. Monocytes, $CD4^+$ T cells, dendritic cells (DCs), classically activated macrophages (CAMs), and alternatively activated macrophages (AAMs) were found to be enriched numerically in the niche of $CD34^+$;αSMA^+;$CD31^+$ BECs, but with differential proximity in the inner niche and in the outer niche determined by distance measurement. Consistent with the expression of αSMA as a marker of myofibroblasts, the density of $CD34^+$;αSMA^+;$CD31^+$ BECs was associated with clinical markers of progression of fibrotic remodeling in SSc patients.

Conclusion: We unraveled the heterogeneity of vascular cells in healthy individuals and SSc patients using IMC. We identified $CD34^+$;αSMA^+;$CD31^+$ BECs as a novel EC population that is increased in SSc patients, and is located in close proximity to immune cells and myofibroblasts. $CD34^+$;αSMA^+;$CD31^+$ BEC counts were associated with clinical outcomes of progressive fibrotic remodeling, thus providing a novel cellular correlate for the crosstalk of vasculopathy and fibrotic remodeling.

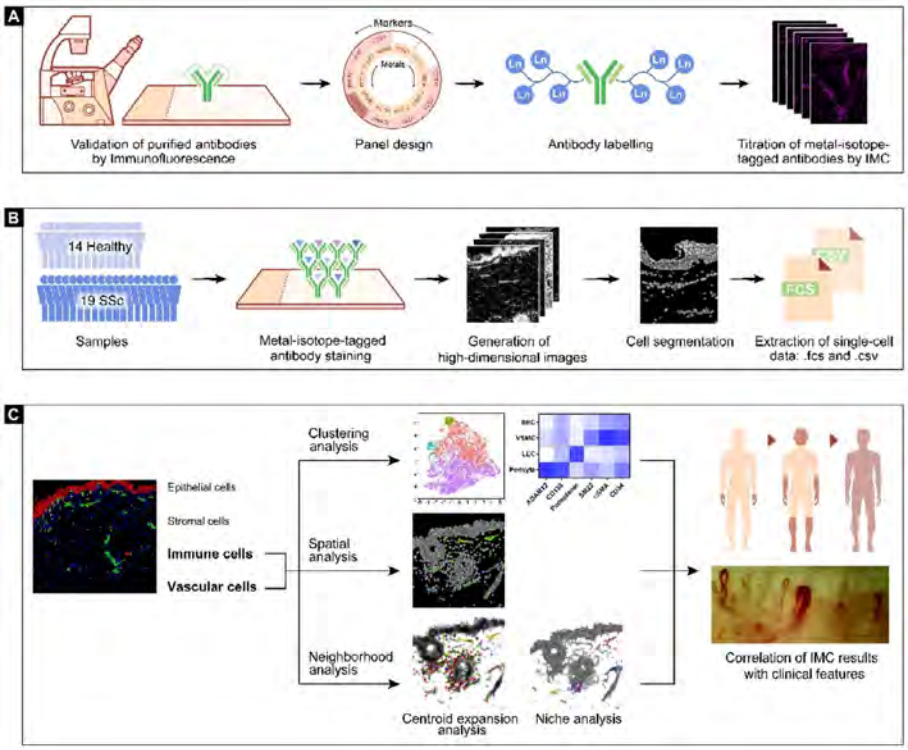

Figure 1. Schematic representation of the experimental workflow. (A) All purified antibodies were first tested by standard immunofluorescence staining. Each antibody was assigned to one channel according to its signal intensity and predicted spillover. After validation by immunofluorescence, the purified antibodies were labeled with lanthanide metal epitopes and further tested at different dilutions by IMC. (B) A total of 33 skin biopsies, 14 healthy controls and 19 SSc patients were stained with a panel of 38 metal-labelled antibodies as well as Iridium 193 and 191 isotopes, and further processed with the Hyperion IMC device. After generation of high-dimensional images and cell segmentation, the single-cell data with spatial information were generated by convertion from 40-channel stacked .tiff to .csv and .fcs files. (C) Major clusters of epithelial cells, vascular cells, immune cells and stromal cells were gated according to the specific cell markers. Populations of interest were selected and clustered using an unsupervised analysis pipeline, which was validated spatially by visualization in segmented map. Centroid expansion analysis and niche analysis were applied to describe neighborhood associations, including direct cell-cell contact and composition of the vascular niche. The above results were compared between healthy subjects and SSc patients and correlated with clinical phenotypes of SSc patients.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Interstitial lung disease (ILD) is present in up to 90% of patients with systemic sclerosis (SSc) and the leading cause of SSc-related mortality. SSc-ILD is categorized radiographically and pathologically in two subtypes: non-specific interstitial pneumonia (NSIP) and usual interstitial pneumonia (UIP). Epidemiologic studies show SSc-UIP has a significantly worse prognosis than SSc-NISP and does not respond to immunomodulating therapy. However, despite these clinical differences, little is known regarding the molecular profiles of the two SSc-ILD subtypes, making biomarker discovery and treatment development challenging. The objective of this study is to define the cellular and molecular profiles underpinning SSc-NSIP and SSc-UIP compared to idiopathic pulmonary fibrosis (IPF).

Methods: Single nuclei RNA sequencing (snRNAseq) was performed on frozen explanted lung tissue of 20 age and sex matched individuals including 10 SSc (5 NSIP and 5 UIP), 5 IPF, and 5 healthy controls (HC). Nuclei were isolated, multiplexed, and sequenced using the 10x genomics 3' v3 platform. Data were processed using standard CellRanger and Seurat pipelines and SoupX, Harmony, and Demuxlet. Cell proportions between conditions were compared using Kruskall Wallis

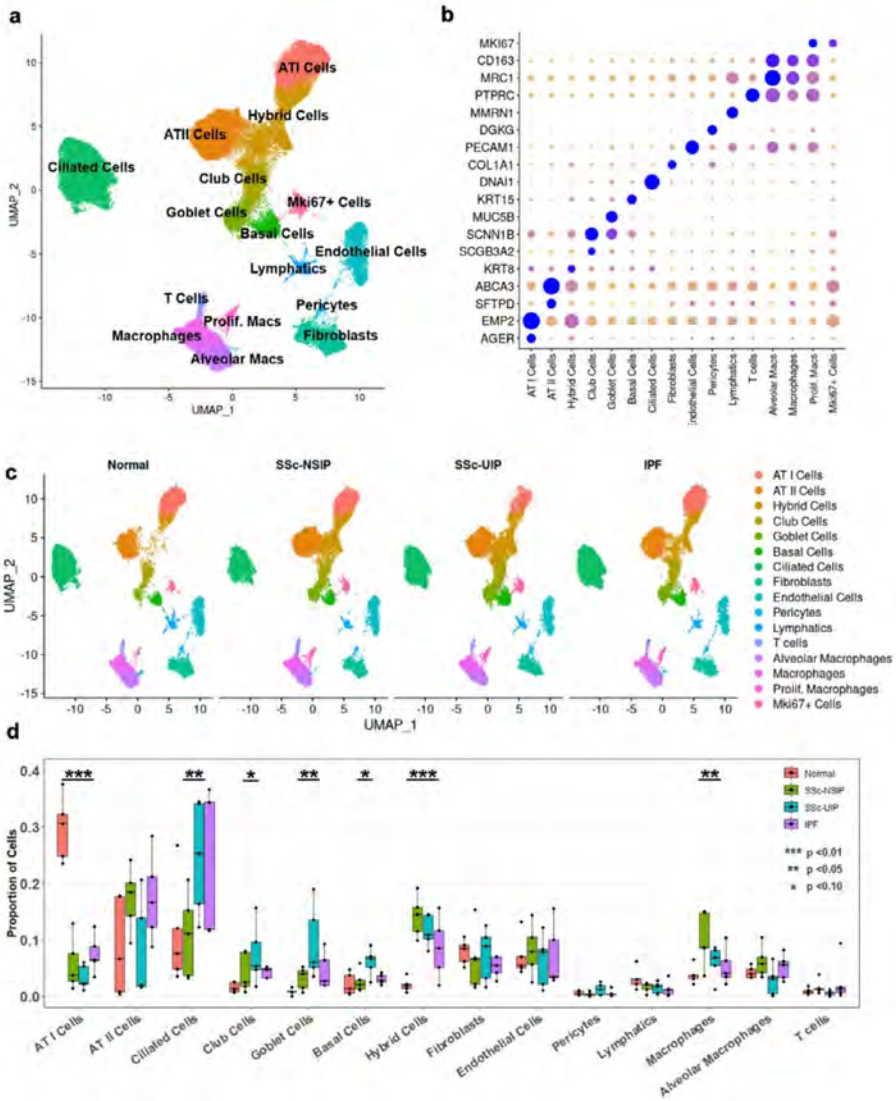

Figure 1: Profiling SSc-ILD subtypes with snRNA-seq. (a) UMAP of 92,128 nuclei from 5 SSc-NSIP, 5 SSc-UIP, 5 IPF and 5 healthy lungs demonstrates 16 distinct cell types. (b) Dot plot of gene markers for all 16 identified cell types. (c) UMAP by condition demonstrates visual differences in cell proportions and (d) compositional analysis confirms significant differences in cell proportions in AT I cells, ciliated cells, goblet cells, hybrid cells and macrophages ($p<0.05$).

test and differential expression was performed using DESeq2. Unsupervised hierarchical clustering of DEGs was used to examine similarities and differences between SSc-ILD subtypes within cell subsets.

Results: Following QC filtering, a total of 92,128 nuclei, including 20,738 SSc-NSIP, 24,012 SSc-UIP, 21,122 IPF, and 26,256 healthy nuclei, were used in downstream analysis. Clustering revealed 16 distinct cell types (Fig 1a) labeled using canonical gene markers (Fib 1b). Cell composition analysis revealed a profound loss of ATI cells in the diseased lungs compared to HC ($p < 0.01$) and an enrichment of other epithelial cells including ciliated and goblet cells in SSc-UIP and IPF. Macrophages were uniquely enriched in SSc-NSIP (Fig 1c-d). A "Hybrid" epithelial cell was identified that was unique to diseased lung and significantly increased in both SSc-ILD subtypes. DEG analysis of this cell group revealed 133 genes of which some were shared with other epithelial cells, such as ATI and ATII, while others were unique to the population (Fig 2a). Notable genes included markers of cellular senescence, i.e., GDF15 and CCND2, and previously described markers of "aberrant cells" in IPF, i.e., PLD5 and CPA6 (Fib 2b). Pathway analysis revealed upregulation of extracellular matrix organization and cell adhesion and migration processes. Comparing SSc-ILD subtypes, epithelial cells demonstrated a distinct expression pattern between SSc-NSIP and SSc-UIP which was redemonstrated in ATI cells, Club cells, and Basal Cells, while other epithelial subsets showed a more similar pattern of expression between the SSc-ILD subtypes.

Conclusion: This study provides novel insight to the molecular makeup of the SSc-ILD subtypes and demonstrates that SSc-NSIP and SSc-UIP have differing cell compositions but have both shared and distinct molecular pathways that also overlap with IPF. Ongoing analyses will further elucidate the molecular profiles underpinning the SSc-ILD subtypes.

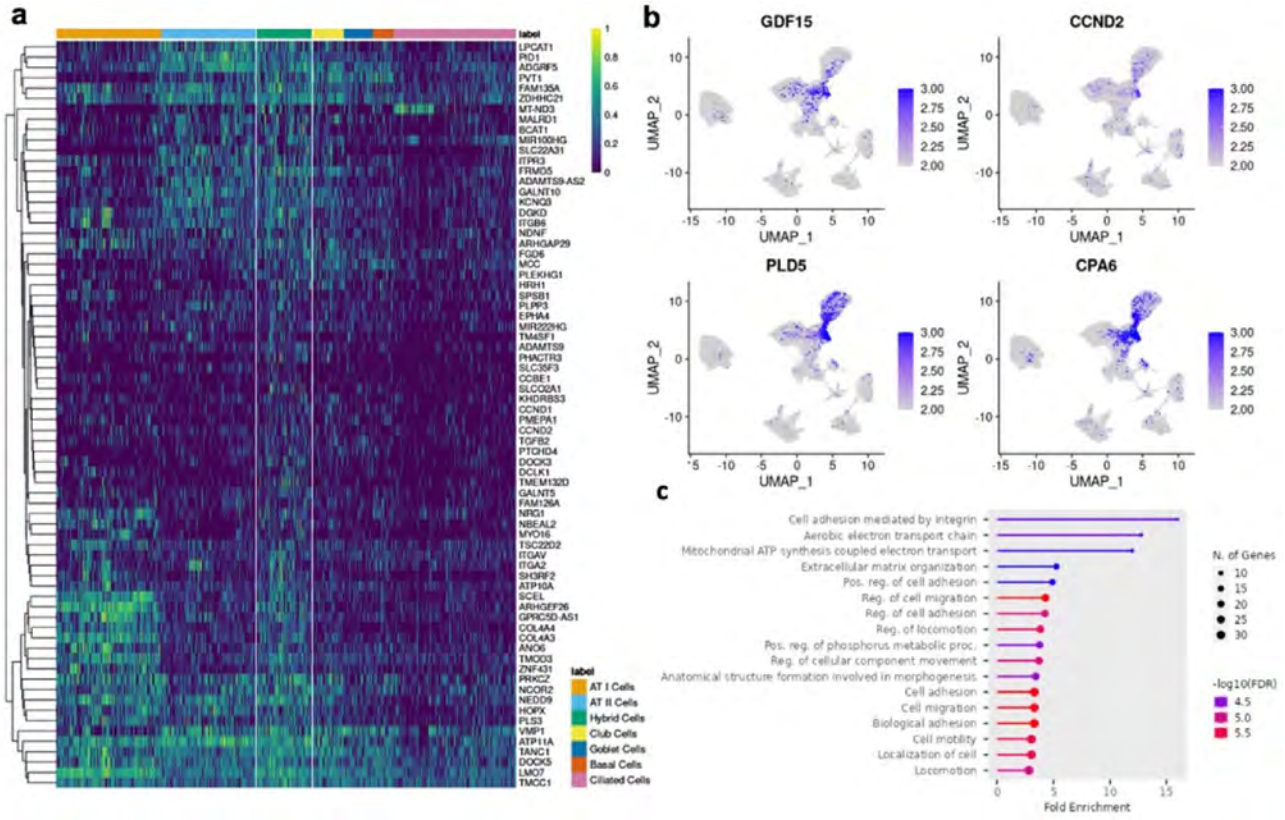

Figure 2: Identification of 'Hybrid' epithelial cell population unique to SSc-ILD and IPF. (a) Heatmap of differentially expressed genes demonstrates both shared markers across epithelial cells as well as uniquely expressed markers. (b) Feature plots of notable uniquely expressed 'Hybrid' cell markers including GDF15 and CCND2, markers of cellular senescence, and PLD5 and CPA6, markers expressed in aberrant cells in IPF. (c) Pathway analysis demonstrates enrichment of extracellular matrix organization and cell adhesion and migration.

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Infection-related Rheumatic Disease

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Sepsis is a life-threatening organ dysfunction caused by a dysregulated host response to infection. Previous studies have shown that immune dysregulation associated with severe infection persists after discharge in two-thirds of surviving patients and is associated with worse long-term outcome. Hypothesizing that persistent immune dysregulation associated with sepsis may be involved in immune-mediated inflammatory diseases **(**IMIDs), we used a nationwide database to analyze the incidence of IMIDs after sepsis. We aim to analyze the incidence of IMIDs in patients who survived sepsis.

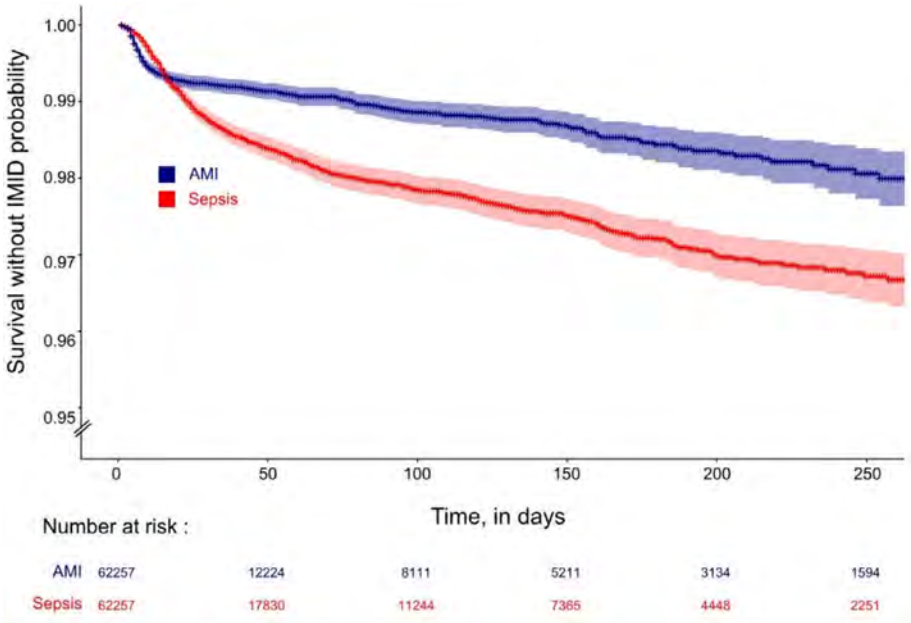

Figure 1 Survival without IMIDs among matched populations

Methods: Comprehensive data on all exposed and non-exposed patients admitted to all French hospitals from January 2011 to November 2020 were collected from the national medical-administrative database, the PMSI (*Programme de Médicalisation des Systèmes d'Information,* Information system medicalization program). The PMSI provides a summary of diagnoses, procedures, and individual medical conditions at discharge from all French healthcare facilities. All data on adult patients admitted for sepsis between January to November 2020, in any of the French healthcare facilities were retrieved from the database. Exposure was sepsis requiring hospitalization. Sepsis was defined by the combination of at least one code of infection and one code referring to an organ failure diagnosis or procedure. Patients with a first sepsis

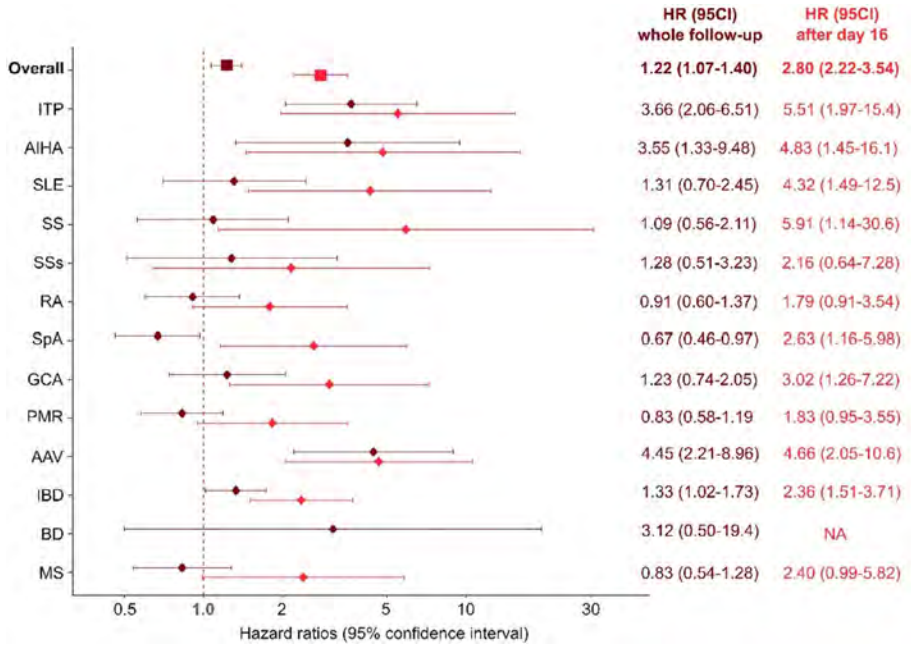

Figure 2 Risk for IMIDs onset after sepsis IMIDs, immune-mediated inflammatory diseases; ITP, immune thrombocytopenia; AIHA, autoimmune hemolytic anemia; SLE, systemic lupus erythematosus; SS, Sjögren's syndrome; SSs, systemic sclerosis; RA, rheumatoid arthritis; GCA, giant cell arteritis; PMR, polymyalgia rheumatica; AAV, ANCA-associated vasculitis; ANCA, anti-neutrophil cytoplasmic antibody; IBD, inflammatory bowel disease; UC, ulcerative colitis; MS, multiple sclerosis.

(i.e. exposed) diagnosed in a French hospital in 2020 were randomly matched (ratio 1/1) with patients admitted during the same period for acute myocardial infarction (i.e. non-exposed). An exact matching procedure taking age ±2 years, gender, and comorbidities as matching variables was performed. The main outcome was a diagnosis of IMID based on specific ICD-10 codes during a 9-month follow up. Only patients with i) a first diagnosis of sepsis (exposed) or AMI (non-exposed) in 2020 and ii) no history of IMIDs reported in PMSI between January 1, 2010 and the index stay were included.

Results: In France, the incidence rate of IMIDs after a sepsis in 2020 - analyzed in 62,257 patients – was of 7,956 [95CI 7,392-8,520] per 100,000 patient-years. As compared to the non-exposed admitted population (Table 1), the IMID-free survival analysis showed an increased risk for IMIDs of 2.80 (HR; 95%CI [2.22-3.54]) starting from day 16 after admission (Figure 1). Risk of IMIDs following severe infection differed according to the nature of the autoimmune disease and were higher for immune thrombocytopenia (5.51 [1.97-15.4]), autoimmune hemolytic anemia (4.83 [1.45-16.1]) and ANCA associated vasculitis (4.66 [2.05-10.6]) (Figure 2).

Conclusion: Our study shows an intriguing and extremely high incidence of IMIDs among survivors of severe infections.

Exacerbation of Immune-mediated Inflammatory Diseases in COVID19 Sequelae

CAMILA CAETANO[1], Tamiris Azamor[1], Nikki M. Meyer[1], Cassandra Calabrese[2], Leonard Calabrese[2], Nicolas Piuzzi[3], M. Elaine Husni[2], Suan-Sin Foo[1] and Weiqiang Chen[1], [1]Cleveland Clinic / Infection Biology Program, Global Center for Pathogen Research and Human Health, Lerner Research Institute, Cleveland, OH, [2]Cleveland Clinic / Department of Rheumatic and Immunologic Diseases, Cleveland, OH, [3]Cleveland Clinic / Department of Orthopedic Surgery, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Infection-related Rheumatic Disease
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Patients with underlying immune-mediated inflammatory diseases (IMIDs), such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), have a higher susceptibility to severe COVID19 and adverse IMID outcomes. While there is growing evidence of SARS-CoV-2 infection triggering preexisting arthritic conditions, the mechanism underlying this phenomenon remains ill-defined. Indeed, the SARS-CoV-2 accessory protein, ORF8, shares similarities with the human inflammatory cytokine IL-17. In light of the potential association between inflammatory arthritis and ORF8-mediated IL-17 signaling, our objectives are to (i) characterize immune alterations, and (ii) determine the role of ORF8 in COVID19-mediated disease exacerbation in patients with preexisting IMIDs.

Methods: Using a retrospective Cleveland Clinic COVID19 biobank cohort, we obtained 74 plasma specimens collected from four groups of patients: (i) Healthy ($COVID^{Neg}IMID^{Neg}$; n=20); (ii) IMID only ($COVID^{Neg}IMID^{Pos}$; n=20); (iii) COVID19 only ($COVID^{Pos}$ $IMID^{Neg}$; n=20) and (iv) COVID19+IMID ($COVID^{Pos}$ $IMID^{Pos}$; n=14). All $COVID^{Pos}$ samples were obtained within 10-17 days post-COVID19 diagnosis. We employed aptamer-based SomaScan technology to profile 1500 protein biomarkers in plasma, focusing on the levels of circulating plasma ORF8. Next, primary human osteoblast (OBs) cells derived

from a healthy control and an RA patient, were treated with 20ng/ml of ORF8 protein for 2 and 4 days. Supernatants and cells were collected at each time point to evaluate inflammatory (IL-17A, IL-17F, CCL2, IL-6) and bone-resorption (RANKL:OPG, CTSK, PTH1R, TPP1) markers by ELISA and real-time PCR analyses, respectively.

Results: Comparative analysis of four patient groups revealed 154 specific biomarkers associated with COVID19+IMID patients. Specifically, 74 upregulated plasma proteins were found to be indicative of augmented bone resorption process, with elevated levels of the inflammatory IL-17F and bone resorptive biomarkers – RANKL: OPG, CTSK, PTH1R and TPP1. Immunoglobulin was predicted as an upstream regulator of both the IMID only and COVID19+IMID groups, suggestive of autoimmune-dominant IMID condition. Indeed, among both groups of patients with IMIDs (n=34), RA and SLE were most commonly reported, with 15% of the IMID only patients and 17% of COVID19+IMID patients diagnosed for each condition. High circulating ORF8 levels were detected in COVID19+IMID patients, but not seen in the COVID19 only group. Intriguingly, treatment of RA OBs with ORF8 resulted in significantly higher expression of inflammatory markers (IL-17A, IL-17F, CCL2, IL-6) and bone resorption markers: (RANKL: OPG) compared to healthyOB controls, suggesting IL-17-driven inflammation and bone resorption.

Conclusion: We identified an augmented IL-17-mediated inflammatory bone resorption in COVID-19 patients with preexisting IMIDs, which is uniquely driven by SARS-CoV-2 ORF8. The predicted immune pathways identified here provide insights into unique biomarkers and potential therapeutic targets for COVID19-mediated inflammatory "flares" in IMID patients.

Abstract Number: 1671

Use of Metagenomic Microbial Plasma Cell-Free DNA Next-Generation Sequencing Assay in Outpatient Rheumatology Practice

Rachel Jenkins, Matthew Samec, Courtney Arment and Matthew Koster, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Infection-related Rheumatic Disease
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Metagenomic next-generation sequencing (mNGS) of microbial cell-free DNA (mcfDNA) allows for non-invasive broad-range pathogen detection from plasma. The Karius test (KT) is a commercially available mNGS mcfDNA technology able to evaluate over 1000 pathogens on a single blood draw. Patients presenting with inflammatory syndromes often have overlapping clinical features and in some circumstances, differentiation between autoimmune disease and indolent infection can be challenging. This is of particular importance in patients where infection needs to be excluded prior to the initiation or escalation of immunosuppression. The purpose of this study was to describe the clinical utility of KT in a tertiary outpatient rheumatology practice.

Methods: All patients for which a KT was ordered by a rheumatology provider during outpatient evaluation at Mayo Clinic, Rochester, MN between 7/1/2021 and 12/31/2022 were identified. Demographics, symptoms, and laboratory parameters at time of KT draw were abstracted. Reason for testing was categorized as fever of unknown origin (FUO), atypical

Table 1. Baseline characteristics of Karius testing groups

[a]clinical relevance was assessed based on whether the listed pathogen was considered associated with the clinical presentation for which the KT was drawn and/or resulted in initiation (or modification) of anti-microbial therapy to address the detected organism

Table 3: Organisms detected by other methodology in patients with negative Karius test

Karius Result	Clinically relevant organism	Patient ID	Organism identified by method other than Karius Test	Test/method of organism detection	Prednisone	Immuno-suppression	Antibiotic within past 1 month
Negative	Y	14	*Actinomyces odontolyticus*	Laryngeal tissue culture, surgical biopsy	No	No	No
		78	*Tropheryma whipplei*	Synovial fluid aspirate PCR	No	Methotrexate Golimumab	No
		79	*Mycobacterium marinum*	Soft tissue, tendon, culture, surgical biopsy	Yes 7.5mg/day	Methotrexate Adalimumab	No
		80	*Staphylococcus lugdunensis*	Surgical culture, joint	No	No	No
		118	*Strongyloides*	Serology	No	Certolizumab	No

presentation of possible rheumatic disease (RD) or assessment of RD flare versus infection. Results were considered negative (-) if no pathogen was listed as above KT threshold for positive. Among positive tests, determination of an organism's clinical relevance was assessed based on whether the listed pathogen was considered associated with the clinical presentation for which the KT was drawn and/or resulted in initiation (or modification) of anti-microbial therapy to address the detected organism. Records of patients with (-) KT were reviewed for a minimum of 3 months after KT draw to determine if patients with a (-) KT had subsequent identification of pathologic organism by another testing method.

Results: 150 patients with an outpatient KT were identified, 53% female, mean age of 52 years. Reasons for KT were atypical presentation of possible RD (80%), evaluation for flare of RD vs infection (16.7%) and FUO (3.3%). In total 24 (16%) patients had at least one organism listed as detected, among which 25% (6/24) were considered clinically relevant and altered final diagnosis and treatment (Table 2). 126 (84%) patients had a (-) KT of which 5 (4%) were subsequently found to have a clinically relevant infection by other testing (Table 3). Among the 121 patients with (-) KT for which alternative organism was not seen, 55 started and 11 increased immunosuppression after (-) KT; none of which were diagnosed with an infection associated with initial presentation within the subsequent 3 months after the KT test.

Conclusion: This study describes the first large series of mNGS mcfDNA in outpatient rheumatology. Six patients were found to have systemic infections which altered diagnosis and treatment. KT false (-) rate was only 4% and 3 of the 5 cases with false (-) KT required surgical biopsy for organism confirmation. Over 50% of patients with negative KT were started on immunosuppression without subsequent infection identified. Determining which patients best benefit from KT use in rheumatology practice remains to be defined. Further research is needed prior to consideration of widespread use.

Association of COVID-19 Vaccinations with Flares of Systemic Rheumatic Disease: A Case-Crossover Study

Genna Braverman[1], Medha Barbhaiya[2], Minerva Nong[1], Vivian Bykerk[3], Nathaniel Hupert[4], Colby Lewis V[4] and Lisa Mandl[2], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [3]Department of Rheumatology, Hospital for Special Surgery, New York, NY, [4]Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Infection-related Rheumatic Disease

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Fear of flare contributes to COVID-19 vaccine hesitancy in patients with systemic rheumatic diseases (SRD). Accurately ascertaining post-vaccine SRD flares and differentiating them from routine vaccine side effects is difficult. We evaluated the association of COVID-19 vaccination with SRD flares using a case-crossover design, which is ideal for studying outcomes triggered by transient within-person exposures with short windows of time-to-effect.

Methods: Adults ≥18 years enrolled in a COVID-19 Rheumatology Registry at a tertiary center were invited to participate in this study assessing SRD flares. COVID-19 vaccine dates and brands were obtained from self-report and electronic health records. International Classification of Disease-10 algorithms identified SRD diagnoses. Subjects with rheumatoid arthritis (RA), psoriatic arthritis (PsA), systemic lupus erythematosus (SLE) and scleroderma (SSc) had their diagnoses validated by classification criteria; 138 (31.8%), 55 (12.7%), 44 (10.1%) and 15 (3.5%) of 434 participants met criteria for RA, PsA, SLE and SSc, respectively. Participants self-reported both SRD flares and SRD quiescence. "Hazard periods" were defined as time before self-reported flares, and "control periods" as time before self-report of no flare. We used univariate conditional logistic regression, stratified by participant with a log likelihood equivalent Cox proportional hazards model, to evaluate for an association between flare and vaccination in the preceding 2, 7 and 14 days. (Figure 1). Subgroup analyses were performed.

Results: Of 9361 Registry participants, 1797 opted into the SRD flare study and 434 (24.2%) subjects (mean age 59 years [±13], 84.1% female, 81.9% White) contributed both hazard and control periods between 3/5/21 and 9/6/22. Most had an inflammatory arthritis or a connective tissue disease (Table 1). 96.1% of subjects received at least 1 dose of a COVID-19 vaccine and 93.1% received at least 2 doses. Of the 1316 COVID-19 immunizations received during the study, 31.7% were 1st doses, 30.7% 2nd doses and the remainder ≥ 3rd doses; 58.5% were Pfizer-BioNTech, 39.5% were Moderna and 1.4% were Johnson & Johnson. 997 flares were reported. There was no association between COVID-19 vaccination and SRD flares using lookback windows of 2, 7 or 14 days (OR 1.46 [95% CI, 0.86-2.46], OR 1.09 [95% CI, 0.76-1.55], OR 0.85 [95% CI, 0.64-1.13] respectively; p=NS for all) (Table 3). Subanalyses stratified on sex, age, SRD subtype and vaccine brand similarly showed no association with flare. Information on vaccine side effects was available for 897/1316 (68.2%) doses; 468 (52.2%) and 491 (54.7%) of 897 doses were complicated by CDC-defined local and systemic vaccine side effects, respectively. There was no association between reporting a vaccine side effect and reporting an SRD flare (p=0.09). Information on whether reported flares were consistent with a subject's "typical" flare was available for 813/997 (81.5%) flares, of which 664/813 (81.7%) were typical.

Conclusion: In this cohort of participants with SRD and high vaccine uptake, COVID-19 vaccination was not associated with SRD flares. These data are reassuring and can inform shared decision-making on COVID-19 immunization.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Infection-related Rheumatic Disease

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Given an increased risk of COVID-19 in patients with autoimmune conditions, we must better understand the immunogenicity and safety of SARS-CoV-2 vaccines in people living with rheumatic disease. We conducted the Covid VaccinE Response (COVER) trial, a multicenter, randomized controlled trial to assess the response to the SARS-CoV-2 booster in rheumatology patients on immunomodulatory therapies. A primary goal was to assess whether patients randomized to hold therapy for 2 weeks after a booster dose had improved vaccine response compared to those who continued therapy.

Methods: The COVER trial enrolled patients with rheumatoid arthritis (RA) or spondylarthritis (SpA) and was conducted in the Excellence Network in RheumatoloGY (ENRGY), a large practice-based research network (PBRN) of US rheumatologists. Participants were randomized to continue or hold current medication, abatacept (ABA) or tumor necrosis factor inhibitors (TNFi), for 2 weeks following a booster dose of COVID-19 vaccine. All patients had received primary vaccination against COVID-19 with an mRNA vaccine. LabCorp Cov2Quant IgG™ Spike assay measured levels of anti-Receptor Binding Domain (RBD) IgG antibodies prior to and following the booster dose. For each medication group (ABA or TNFi), we looked at the mean log-transformed difference pre- and post-booster and used linear regression to compare the two groups with respect to change in COVID-19 RBD antibody levels, adjusting for age, sex, BMI, methotrexate use, and number of prior vaccine doses.

Results: Within both the abatacept (n=142) and TNFi (n=121) medication groups, there were no significant baseline differences in demographics or clinical characteristics (Table 1). Combining both groups, the population was 76% female, 92% white, 17% Hispanic, with mean (SD) age of 61.1 (13.5) years, and mean (SD) BMI of 31.2 (8.2) kg/m^2. The ABA group was significantly older than the TNF group: 64.8 (11.7) vs 57.1 (14.3), p< 0.0001). Following the COVID booster vaccine, RBD antibody titers increased significantly in both ABA (p=0.0029 for holding; p=0.03604 for continuing) and TNF ($p < 0.0001$ for both arms) patients (Figure 1). Patients who continued their ABA had a numerically lower increase in anti-RBD antibody titers compared to those who held it for two weeks. However, in linear regression analysis, the mean increase in the holding arm compared to the continuing arm was not significantly different for either drug group in unadjusted analysis or after adjusting for demographic and clinical factors (a significant effect was seen for BMI (β=0.04, p=0.03) in the ABA

Anti-RBD IgG antibodies specific to SARS-CoV-2 at Post-Booster Visit, Mean (SD)	256.1 (537.7)	156.1 (213.4)	0.1710	296.9 (415.1)	195.9 (196.4)	0.09

Figure 1: Mean Pre-Booster Visit to Post-Booster Visit anti-RBD IgG Difference by Drug Group and Intervention

analysis and MTX use (β=0.63, p=0.02) in TNFs). There was no significant interaction in the effect of holding or continuing medication between the ABA and TNFi groups (interaction p-value = 0.55).

Conclusion: RA and SpA patients receiving abatacept and tumor necrosis factor inhibitors had a significant increase in antibody response after receiving a COVID-19 booster. There was a weak and non-significant trend toward improved response in the group that held ABA for up to 2 weeks post-booster that was not significant. Based on these results, briefly interrupting ABA or TNFi at the time of COVID boosting may not appear warranted.

Session Title: Abstracts: Infection-related Rheumatic Disease

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: VEXAS (Vacuoles, E1 Enzyme, X-Linked, Autoinflammatory, Somatic) syndrome is an autoinflammatory monogenic disease caused by inactivating somatic mutations in the UBA1 gene and characterized by heterogenous systemic auto-inflammation and progressive hematologic manifestations. Its management is not consensual but often include biologic DMARDs or azacytidine in case of association with myelodysplastic syndrome. Prognosis appears to be poor, with substantial morbidity and mortality mainly caused by infection. The aim of this study was to describe the spectrum of infectious complications and their risk factors in VEXAS patients.

Methods: Retrospective multicenter study including patients with genetically proven VEXAS syndrome, with at least one episode of severe infection (defined as an infection leading to hospitalization and/or intravenous infectious treatments and/or death). These patients were compared to a cohort of 50 VEXAS patients without severe infection after at least one year of follow-up since diagnosis. Risk factors of infections were assessed with multivariate Cox proportional hazard ratios models.

Results: Seventy-four patients (99% male, median [IQR] age at VEXAS onset of 68 [63-75] years) with 133 severe infections were included. Infections occurred despite anti-infective prophylaxis in 46% of cases. The main immunosuppressive drugs received at the time of infection were JAK inhibitors (29%), biologics (21%) and azacitidine (11%), while 16% of infections occurred without treatment (no immunosuppressant or corticosteroids ≤ 10 mg/d). Most frequent infection localizations

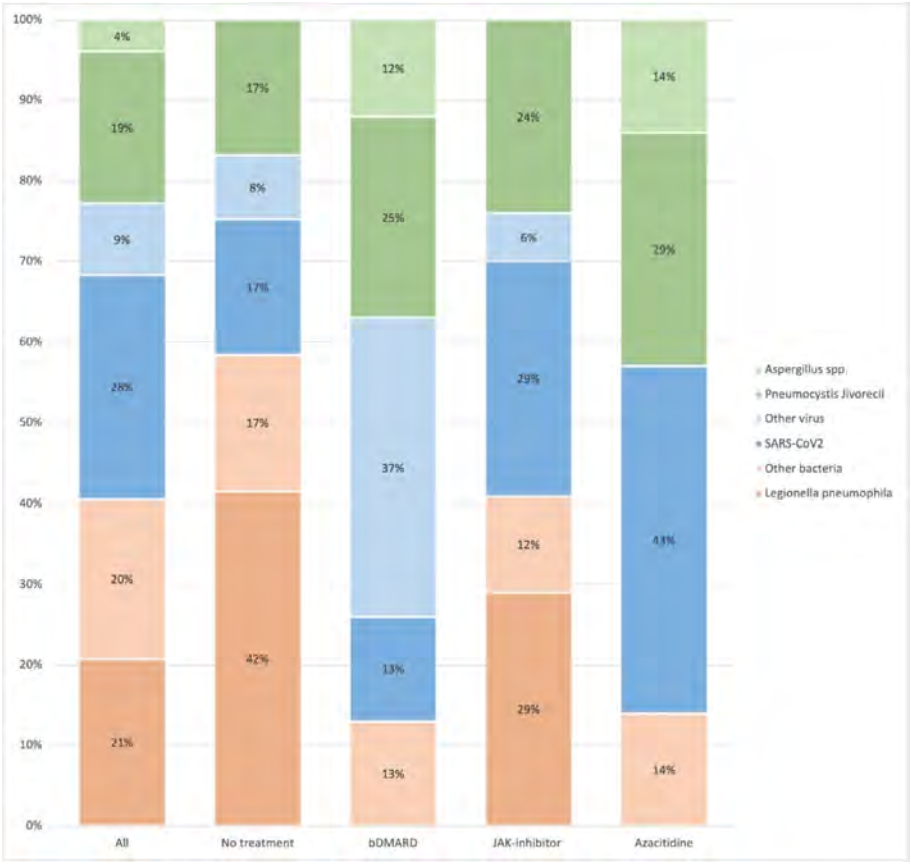

Figure 1: Distribution of infectious agents in pulmonary infections

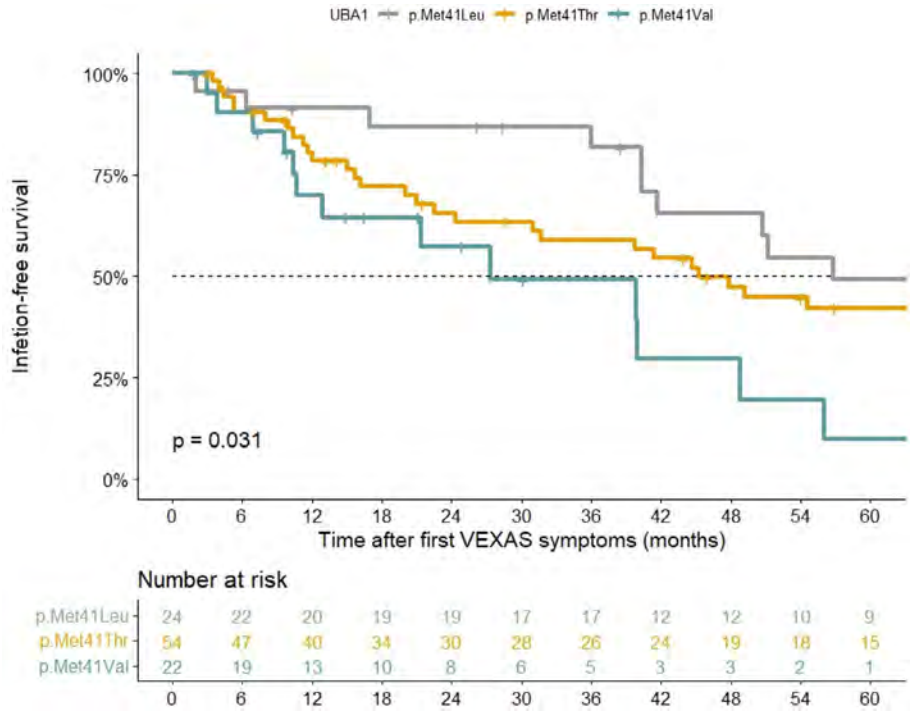

Figure 2: Kaplan-Meier curves for infection-free survival according to the type of UBA1 mutation

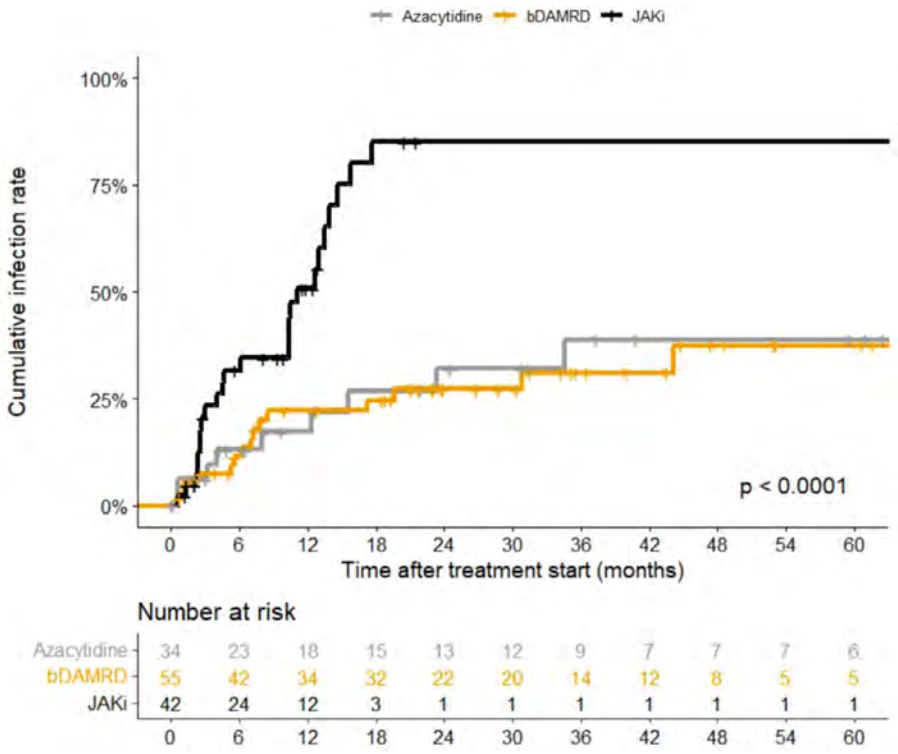

Figure 3: Cumulative incidence of severe infections according to the type of treatment received

were the lung (59%), skin (10%) and urinary tract (9%). The most commonly found infectious agents were SARS-CoV-2, Legionella pneumophila and Pneumocystis jivoreci in 28%, 21% and 19% of pulmonary infections, respectively (figure 1). Invasive fungal infections accounted for 11% of all infections. Nearly 20% of pulmonary infections occurred in the absence of treatment with a high prevalence of L. pneumophila (42%) and P. jivoreci (17%) infections.

In multivariate analysis, factors significantly associated with severe infection were p.Met41Val mutation (figure 2) (HR 2.44 [1.05-5.63], p=0.037), age at symptom onset >75 years (HR 1.91 [1.05-3.47], p=0.034) and arthralgia (HR 2.03 [1.16-3.56], p=0.013) whereas leukopenia was a protective factor (HR 0.58 [0.34-0.99], p=0.046). Among treated patients, cumulative infection rate was significantly higher with JAK inhibitors (multivariate HR 3.90 [1.78-8.55], p=0.001) compared to biologic DMARDs and azacitidine, with a median time to infection of 12 months (figure 3). After a median follow-up of 4.4 [2.5–7.7] years, 27 (36%) patients died including 15 (56%) due to severe infection.

Conclusion: VEXAS syndrome is associated with a high incidence of severe infections especially in patients carrying the p.-Met41Val mutation. The high frequency of atypical infections such as legionellosis and invasive fungal infections in patient without immunosuppressive treatment might suggest an intrinsic immunodeficiency of the disease. JAK inhibitors, used as first-line treatment, are particularly at risk of severe infections occurring early after initiation.

Survival in Patients with Rheumatoid Arthritis and Early Breast Cancer Treated with Tumor Necrosis Factor Inhibitors

Maria Suarez-Almazor[1], Juan Ruiz[2], Xiudong Lei[2], Chi-Fang Wu[2], Hui Zhao[2], Suja Rajan[3], Heather Lin[2] and Sharon Giordano[2], [1]MD Anderson Cancer Center, Houston, TX, [2]The University of Texas, MD Anderson Cancer Center, Houston, TX, [3]University of Texas School of Public Health, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Treatments II: RA Treatment Safety
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: There have been concerns about the use of tumor necrosis factor inhibitors (TNFi) in patients with rheumatoid arthritis (RA) and concomitant cancer. Few studies have examined cancer outcomes in these patients, and they have mostly included long-term survivors, rather than patients with early cancer. Therefore, the safety of TNFi in patients with recent cancer is unknown. Our aim was to examine the survival of patients with RA recently diagnosed with early-stage breast cancer (BC), who received TNFi in the first year after BC diagnosis.

Methods: We conducted a retrospective cohort study of patients with RA diagnosed with BC and RA identified in two databases from 2008 onwards: Optum's de-identified Clinformatics® Data Mart Database, and the combined Surveillance, Epidemiology, and End Results Program (SEER) and Texas Cancer Registry (TCR) – Medicare linked databases. Early BC was ascertained in Clinformatics by surgical claims codes and in SEER/TCR by stage (excluding distant BC). Use of disease modifying antirheumatic drugs (DMARDs) and glucocorticoids in the year after BC diagnosis was identified from claims and prescriptions files. Outcomes were overall survival (OS) and BC-specific survival (BCSS; only in SEER/TCR-Medicare) defined as the time from BC diagnosis to death from all causes or from BC. Survival was truncated at 5 years. We compared patients who received TNFi with those who received conventional cDMARDs, or no DMARDs, during the first year after BC diagnosis. We estimated a propensity score for use of TNFi through a logistic regression model. We conducted multivariate Cox proportional hazards regression, controlling for various covariates and for the propensity score.

Results: We identified 970 patients with RA and early-stage BC in Clinformatics (mean age 67 years, SD 10.6) and 1,246 in SEER/TCR-Medicare (mean age 74 years, SD 6). In the first year after BC diagnosis 165 (17%) received TNFi in the Clinformatics cohort, and 201 (16.1%) in the SEER/TCR-Medicare cohort. After multivariate and propensity score adjustment, no significant differences in OS were observed between patients treated with TNFi (alone or with cDMARDs) and patients treated with cDMARDs alone in Clinformatics (hazard ratio, HR=0.75 95% CI 0.41-1.37), or in SEER/TCR-Medicare (HR=0.86 95%CI 0.55-1.34). BCSS was only available for SEER/TCR-Medicare and was significantly better in patients receiving TNFi than in those receiving cDMARDs (HR=0.29 95%CI 0.09-0.98). No significant differences in OS or BCSS were observed when comparing patients who did not receive any DMARDs to those receiving TNFi. Patients receiving prednisone-equivalent doses of ^{3} 7.5mg/day had worse survival than those who did not receive glucocorticoids in Clinformatics, HR=2.51, 95%CI 1.32-4.76; in SEER/TCR-Medicare, HR=1.63, 95%CI 0.93-2.87.

Conclusion: TNFi therapy in patients with RA during the first year after early-stage BC diagnosis did not have a detrimental effect on survival. Glucocorticoids were associated with a significant increase in overall mortality in one of the databases. Additional studies are needed to determine the effects of other biologics on cancer outcomes, and of TNFi in patients with other cancer types.

Abstract Number: 1676

Tofacitinib Accelerates in Vitro Clot Formation and Delays Clot Lysis in Rheumatoid Arthritis Blood by Enhancement of Macrophage TLR4 Mediated Cytokine Responses- a New Angle on Thrombosis with JAKi in Rheumatology

Paula David[1], Thomas Macleod[2], Yu Shi[3], Payal Ganguly[1], Cedric Duval[3], Mark Harland[1], Chi Wong[1], Benazir Saleem[4] and Dennis McGonagle[5], [1]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM), Leeds, United Kingdom, [2]University of Leeds, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom, [3]Discovery and Translational Science Department, Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, Leeds, United Kingdom, [4]Leeds Teaching Hospitals NHS Trust, Rheumatology, Chapel Allerton Hospital, Leeds, United Kingdom, [5]Leeds Biomedical Research Centre, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: RA – Treatments II: RA Treatment Safety

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Rheumatoid Arthritis (RA) patients treated with Janus Kinase inhibitors (JAKi) have reportedly higher venous thromboembolism (VTE) risk and atherosclerotic-related complications including myocardial infarction (1).Although underappreciated by Rheumatologists, in certain experimental situations JAK inhibition has been linked to increased pro-inflammatory cytokine production by myeloid cells(2,3). Thus, we hypothesized that JAK inhibition-related pro-inflammatory

Figure 1: Effect of tofacitinib on immunothrombotic cytokine secretion following TLR4 stimulation.

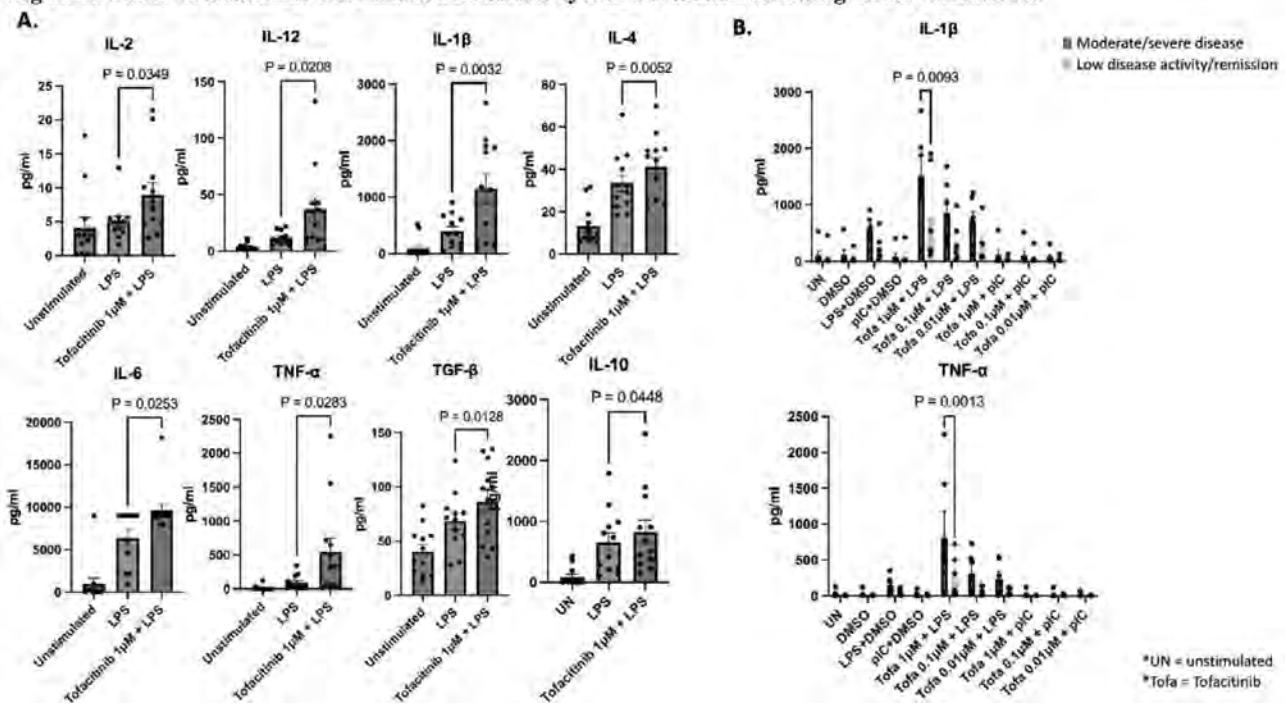

Figure 2: Fibrin turbidity and thromboelastography assays demonstrate tofacitinib accelerates in vitro clot formation and delays clot lysis.

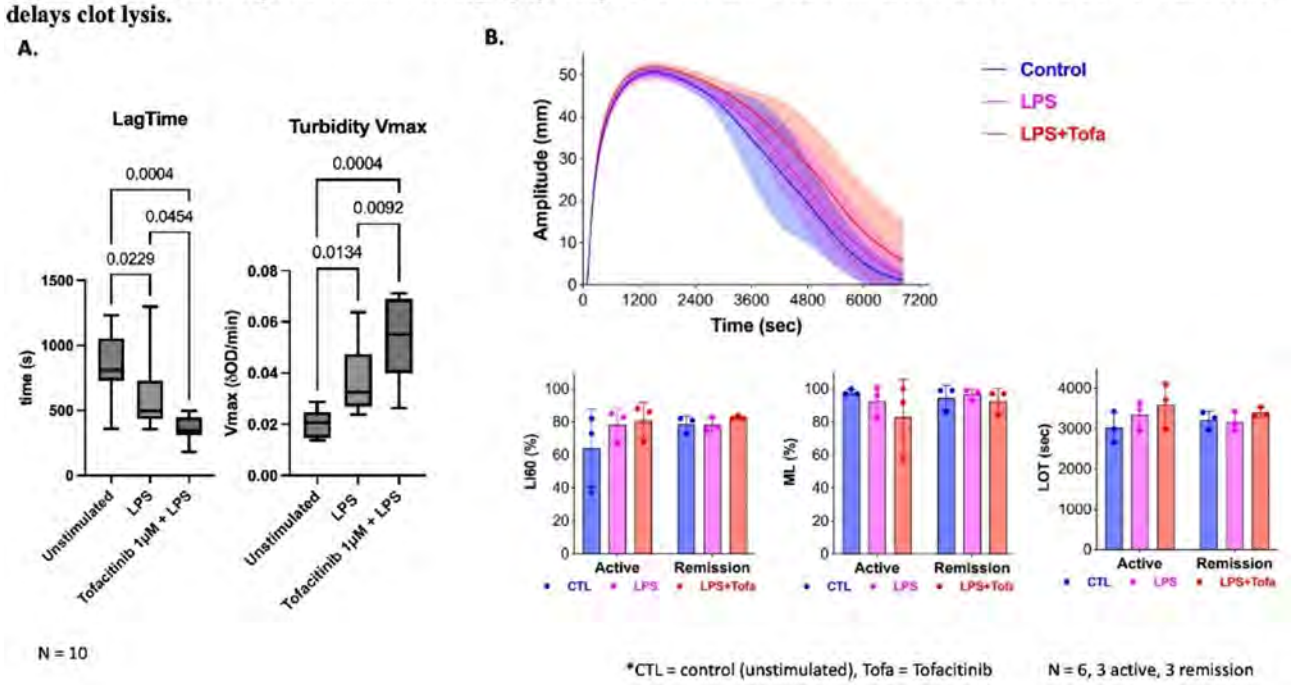

A. LagTime is the time it takes for the protofibrils to start aggregating into fibres, and Vmax is the clotting rate at the steepest point of the turbidity curve. The graphs show that the clot formation rate is faster with Tofacitinib. B. Lysis index at 60 minutes (LI60) indicates how much of the clot is remaining at 60min. So clearly there is less degradation with Tofacitinib. Maximum lysis (ML) indicates how much of the clot is lysed at the end of the run (2hrs). This shows that less clot has been lysed over the duration of the assay. Lysis onset time (LOT) represents how long it takes for the lysis to kick-in. So here, it takes longer for the lysis to start.

cytokine dysregulation with tofacitinib (JAKi) might actually drive "immunothrombosis" in both normal and RA blood.We thus investigated the circumstances where JAK inhibition may drive innate immune-mediated immunothrombosis

Methods: Blood was obtained from RA patients (n=12) under any treatment except JAKi and divided into two groups: remission/low disease activity (DAS-28-CRP < 3.2, n=6) or moderate/active disease activity (DAS-28-CRP ^{3} 3.2, n=6). Experiments were also performed on peripheral blood mononuclear cells (PBMCs) from healthy donors (n= 12) including other JAKi.Leukocytes were isolated using ammonium chloride and stimulated with TLR4 (lipopolysaccharide, LPS) and TLR3 (Polyinosinic:polycytidylic acid) agonists with and without tofacitinib at three pharmacologically relevant concentrations. Bulk RNA sequencing of stimulated cells, ELISA and Legendplex kits were used to assess cell responses to tofacitinib. Plasma turbidity assays of clot formation and fibrinolysis and thromboelastography assays were used to assess the dynamics of in-vitro clotting. Results were analyzed with GraphPad Prism software.

Results: In both RA and healthy blood, LPS-activated leukocytes treated with tofacitinib at therapeutically relevant concentrations (1 mM, 0.1 mM and 0.01 mM) further increased cytokines associated with immunothrombosis, including TNF-α, IL-1β, IL-12, IL-4, IL-6 and TGF-b (Fig 1A). This effect was absent with TLR3 agonists (not shown), and more evident in active RA when compared to remission (Fig 1B) despite similar baseline cytokine levels. Bulk RNA sequencing data showed multiple pathways whereby tofacitinib augmented LPS-treated macrophage inflammatory signatures including the NF-kB pathway, IL-12, and IL-23 pathway, and suggested disruption of immunoregulatory interferon- and IL-10-induced pathways**.**In turbidity and lysis analysis, all LPS-activated cell supernatants induced faster clot formation than the buffer control. However, clot formation rate was further increased significantly when tofacitinib was added in combination with LPS (Fig 2A).Thromboelastography showed delayed clot lysis in active RA patients' blood treated with LPS/tofacitinib, but not in remission/low disease activity subjects (Fig 2B).

Conclusion: TLR4, but not TLR3, activated myeloid cells treated with JAKi exhibited accelerated clot formation and delayed thrombolysis in RA blood samples in-vitro. This work offers novel insights into how venous and arterial immunothrombosis might occur in RA, especially in the context of bacterial challenge in active RA on JAKi therapy.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Treatments II: RA Treatment Safety
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Immunosuppressive treatments inhibit vaccine-induced immunity. We evaluated if a two-week interruption of methotrexate treatment immediately after COVID-19 booster improved antibody response against spike protein of the receptor binding domain (S1-RBD) and live virus neutralization (ancestral Wuhan and Omicron BA.1) in patients with immune mediated inflammatory diseases (IMIDs).

Methods: We conducted an open-label, prospective, parallel-group, randomized controlled, superiority trial in 26 UK hospitals. Adults attending Rheumatology and Dermatology clinics taking methotrexate (≤25mg/week) for ≥3 month for inflammatory conditions were randomly assigned 1:1 using minimization to suspend or continue methotrexate treatment for two-weeks immediately after their COVID-19 booster. Data were analyzed using an intention to treat approach.

Results: 383 participants (mean age 59.0 years, 61% female) were randomized to either suspend or continue methotrexate arms. 61.4% (n=235) were female, 54.3% (n=208) had RA, 31.9% (n=122) psoriasis with/without arthritis. The median methotrexate dose was 20 mg/week. 94.5% (n=362) received a mRNA vaccine booster, mean 178 days after the second

[1] Mixed effects model for EQ-5D, patient assessment of disease outcomes, and flares adjusted by baseline value, randomization factors (age, inflammatory condition, vaccine platform), prior infection, booster platform, and included time by treatment interaction. [2]OR for participants with at least one flare-up.

Self-reported clinical outcomes

dose of the primary vaccination. Adherence to the intervention was high with 96.3% (n=184) and 97.4% (n=187) self-reported adherence with allocation in the suspend and continue methotrexate groups respectively.

At four-weeks, the geometric mean (95% confidence interval (CI)) S1-RBD antibody level was 25,413(22,227-29,056) and 12,326(10,538-14418) U/mL in suspend and continue treatment groups respectively, with geometric mean ratio (GMR) (95%CI) 2.08(1.59-2.70), p< 0.0001, mixed-effects model. The increase in antibody response was consistent across age-groups, methotrexate doses, route, IMIDs, primary vaccination platform, and prior SARS-CoV-2 infection. Enhanced antibody responses were sustained at 12 and 26 weeks with GMR(95%CI) 1.88(1.44-2.46) and 1.50(1.12-2.01) respectively. Planned exploratory subgroup analyses suggested a greater treatment effect at higher methotrexate dose (Interaction GMR effect (95% CI) 0.67(0.47, 0.96) at 4-weeks and 0.64(0.420.96) at 12-weeks).

The Wuhan Hu-1 IC50 neutralizing antibody titer was higher in the methotrexate suspend group compared to the continue treatment group at four and 26-weeks. In a mixed-effect model, the GMR (95% CI) for Wuhan Hu-1 IC50 neutralizing antibody titer on suspending methotrexate for two-weeks was 2.56 (1.21-5.44) at 4 weeks, and 3.50 (1.34-9.18) at 26-weeks. The Omicron BA.1 IC50 cross neutralizing antibody titer was higher in the methotrexate suspend group compared to the continue treatment group at 4-weeks with GMR (95% CI) 2.42 (1.45-4.05).

There were no differences in quality of life. Self-reported disease activity deteriorated slightly at 4-weeks in the suspend methotrexate group, but normalized by week-12.

Conclusion: Two-week interruption of methotrexate treatment for IMIDs enhanced boosting of antibody responses after COVID-19 vaccination that were sustained at 12 and 26 weeks. *(Trial registration:* ISRCTN11442263)

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Treatments II: RA Treatment Safety
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: In the ORAL Surveillance trial, cancer risk was higher among patients with rheumatoid arthritis (RA) on tofacitinib, a Janus kinase inhibitor (JAKi), compared to tumor necrosis factor inhibitors (TNFi), in a population enriched for cardiovascular disease risk [1]. However, less is known regarding the comparative safety of non-TNFi biologics relative to TNFi. We assessed the comparative safety of individual non-TNFi and JAKi relative to TNFi for the risk of incident cancer in patients with RA.

Methods: We performed a cohort study using Merative MarketScan databases (2012-2021) of patients with RA identified using ≥1 ICD9/10 codes, age 18-64 years, who initiated treatment with TNFi, non-TNFi (rituximab, abatacept, tocilizumab and sarilumab), or JAKi (tofacitinib, baricitinib) on or after November 2012. Patients with past cancer diagnoses were excluded. We used Cox proportional hazard models to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for developing incident cancer (excluding non-melanoma skin cancer) within 2 years of treatment initiation in patients on non-TNFi or JAKi relative to TNFi, adjusting for potential confounders, including demographics, geographic region, year of initiating a biologic, Charlson Comorbidity Index, frailty status measured using claims-based frailty index (2), healthcare utilization within 12 months prior to starting treatment, and proxies for RA severity. Cancer diagnoses were identified using validated administrative algorithms [3]. Patients were allowed to switch from one drug class to the other, allowing a single patient to contribute person-time over different drug classes. Patients were censored if they did fill of a prescription of any of these drugs for >90 days (>180 days for rituximab), or end of study period (12/31/2021).

Table 1. Baseline characteristics of the cohort stratified by drug initiation.

Variable	TNFi n=29,286 (72%)	Rituximab n=1857 (5%)	Tocilizumab n=1279 (3%)	Sarilumab n=868 (2%)	Abatacept n=3139 (8%)	JAKi n=3991 (10%)

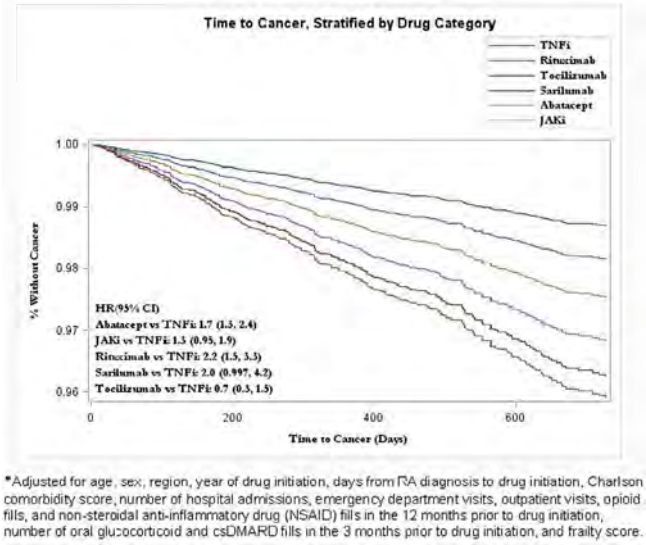
@Frailty score: 0 indicates non-frail and ≥0.2 indicates frail
Abbreviations: csDMARD: conventional synthetic disease modifying anti-rheumatic drug; IQR: Interquartile range; NSAID: Non-steroid anti-inflammatory drug; TNF: Tumor necrosis factor

Table 2. Number of cancer outcomes (95% confidence intervals) within 2 years of initiating biologic drug per 10,000 person-years at risk, stratified by drug category that the patient initiated.

	Median (IQR) days to cancer diagnosis (among those with cancer)	Raw n of cancer diagnoses	# of cancer diagnoses/10,000 person-years (95% confidence interval)
TNF alpha	173 (91, 371)	248 (0.9%)	102 (90, 115)
Rituximab	147 (37, 246)	31 (1.7%)	264 (180, 373)
Tocilizumab	212 (189, 280)	<10 (0.6%)	76 (31, 156)
Sarilumab	146 (57, 299)	<10 (0.9%)	243 (106, 474)
Abatacept	194 (98, 359)	45 (1.4%)	188 (137, 250)
JAKi	120 (52, 292)	40 (1.0%)	143 (102, 194)



*Adjusted for age, sex, region, year of drug initiation, days from RA diagnosis to drug initiation, Charlson comorbidity score, number of hospital admissions, emergency department visits, outpatient visits, opioid fills, and non-steroidal anti-inflammatory drug (NSAID) fills in the 12 months prior to drug initiation, number of oral glucocorticoid and csDMARD fills in the 3 months prior to drug initiation, and frailty score.

Figure 1. Kaplan-Meier curves showing the adjusted hazard ratio* for incident cancer per drug exposures.

Results: We included 37,026 patients involving 78% female patients with a mean age of 47.6 ± 10.3 years, of whom 72% initiated TNFi, 10% JAKi, 8% abatacept, 5% rituximab, 3% tocilizumab, and 2% sarilumab (**Table 1**). The mean follow-up time was 360 days for TNFi, 250 days for non-TNFi, and 280 days for JAKi. There were 379 incident cancers observed during follow-up (**Table 2**). In multivariable models, exposure to rituximab or abatacept had a significantly higher risk of incident cancer (HR 2.2, 95% CI 1.5, 3.3; HR 1.7, 95% CI 1.3-2.4, respectively), compared with exposure to TNFi (**Figure 1**). While the hazard ratio for incident cancer was higher with exposure to JAKi compared with TNFi, this difference was not statistically significant (HR 1.3; 95% CI 0.9-1.9).

Conclusion: While we observed a lower hazard ratio for incident cancer with exposure to TNFi compared to non-TNFi and possibly JAKi in this generally younger and predominantly female population, potential for residual confounding by indication and the small number of outcomes per drug class limit interpretation of these results. Larger studies with longer follow-up are needed for better comparison of cancer risk between these drug classes.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Treatments II: RA Treatment Safety
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: We have previously demonstrated that a combination of TNF-a and IL-6 induces mouse osteoclast-like cells with bone resorption activity both *in vitro* and *in vivo* [Arthritis & Rheumatology (A&R), 2014]. Recently, we have shown that the combination of TNF-a and IL-6 induces osteoclasts (OCs) derived from human peripheral blood monocytes (PBMs) via RANKL-independent pathways *in vitro*. In particular, the number of TNF-a and IL-6-induced OCs differentiated from peripheral blood mononuclear cells in patients with RA had a significant positive correlation with the modified total Sharp score. On the other hand, the number of RANKL-induced OCs had a significant negative correlation with whole-body bone mineral density (A&R, 2021). We undertook the present study to clarify the effects of Janus kinase (JAK) inhibitor on TNF-a and IL-6-induced OCs and RANKL-induced OCs in PBMs derived from patients with RA or healthy donors (HDs).

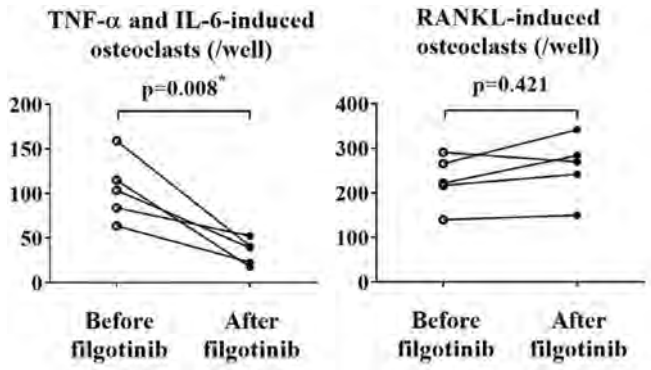

Figure. Administration of filgotinib, a JAK inhibitor, for six months inhibits the differentiation of TNF-α and IL-6-induced osteoclasts in peripheral blood monocytes from patients with RA. Left; Six months after treatment with filgotinib, the number of TNF-α and IL-6-induced osteoclasts differentiated from peripheral blood monocytes was significantly decreased compared with those of before the treatment. Right; No significant change in the number of RANKL-induced osteoclasts was observed in the same patients (each n = 5). * = $p < 0.05$ between groups, Wilcoxon's signed rank test.

Methods: PBMs derived from 5 RA patients and HDs were stimulated by TNF-α and IL-6 or RANKL with or without 100-1000 nM filgotinib, a JAK inhibitor. The number of tartrate-resistant acid phosphatase-positive multinucleated cells and bone resorption activity using a pit formation assay were assessed. Quantitative RT-PCR was used to measure the mRNA expression levels of *IL-1b* and *IL-8*. Furthermore, the number of TNF-α and IL-6-induced or RANKL-induced OCs differentiated from PBMs in RA patients before and 6 months after treatment with filgotinib was examined.

Results: The number of TNF-α and IL-6-induced OCs and RANKL-induced OCs derived from PBMs in RA patients was significantly increased compared to that in HDs (each n=5, $p< 0.05$). Filgotinib significantly inhibited the differentiation of TNF-α and IL-6-induced OCs derived from PBMs of RA patients in a dose-dependent manner (n=4, all $p< 0.05$). On the other hand, the same concentrations of filgotinib did not inhibit osteoclastogenesis induce by RANKL (n=4, all $p >0.05$). Resorption pits generated by TNF-α and IL-6-induced OCs derived from HDs in the presence of filgotinib was reduced comparing with those without filgotinib. In contrast, filgotinib did not inhibit generation of resorption pits by RANKL-induced OCs (n=4). Levels of *IL-1b* and *IL-8* mRNA expressed by TNF-α and IL-6-induced OCs from RA patients, but not RANKL-induced OCs, were significantly reduced by filgotinib (each n=3, $p< 0.05$). Six months after treatment with filgotinib, the number of TNF-α and IL-6-induced OCs differentiated from PBMs was significantly decreased compared with those of before the treatment (n=5, p=0.008) (Figure). In contrast, no significant change in the number of RANKL-induced OCs by the six-months administration of the JAK inhibitor was observed in the same patients (n = 5, p=0.421).

Conclusion: Filgotinib inhibits TNF-α and IL-6-induced osteoclast differentiation *in vitro*. Administration of filgotinib reduces differentiation potential of TNF-α and IL-6-induced OCs in PBMs from RA patients. Our results suggest that the inhibitory mechanism of filgotinib on joint destruction in RA may be related to its inhibition of TNF-α and IL-6-induced OCs, presumed pathogenic OCs.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: RA – Treatments II: RA Treatment Safety

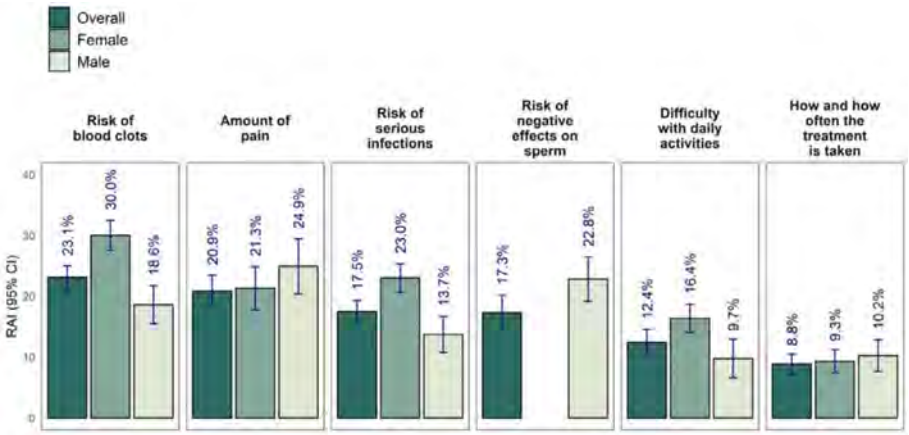
Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Multiple RA therapies are available that differ in attributes such as mode of administration and benefit-risk profile. Challenging trade-offs are made during treatment selection to accommodate patients' circumstances and ensure comprehensive disease management. EULAR recommendations for RA management emphasize the need to recognize patient preferences in shared decision-making (SDM). This study elicited trade-offs that RA patients were willing to make during treatment selection, accounting for preference heterogeneity.

Methods: An online discrete choice experiment was conducted from Sep–Oct 2021; RA patients were required to elicit their preferences for RA treatment attributes (**Figure**) and make trade-offs between them. Attributes were chosen based on literature review and qualitative patient interviews; these were tested in a quantitative pilot. Main data collection was via an online survey which asked participants to choose between hypothetical treatments. Patients were ≥18 years old, diagnosed with RA, currently received systemic DMARD therapy for RA, and resident in France, Germany, Italy, Spain, United Kingdom, or United States. Male patients were oversampled to support subgroup analysis of preferences for effects on sperm parameters. Data were analyzed using a correlated mixed logit model; differences in preferences by sex and age were explored. Relative attribute importance (RAI) scores and maximum acceptable risk (MAR) measures were derived.

Results: In total, 2,090 patients participated; 42% were female with predefined oversampling of males; mean age was 45.2 years (range 18–83). Estimated effects were significant for all attributes ($p < 0.001$), implying that they all influenced treatment choice and that preferences differed between participants. RAI scores revealed different priorities between males and females (**Figure**). Reducing pain and negative effect on semen parameters was most important to males; females were most concerned by risk of blood clots and serious infections. Remaining attributes were of lower importance. No single



Preference drivers: males – pain, blood clots; females – blood clots, infections, pain. Sperm risk data are based on male responses only.

Figure. RAI overall and by sex

Table. Benefit-risk trade-offs: willingness to accept extra risk

Attribute	Oral pill every day vs injection once a week		Reducing pain from 30% to 10%	
	Male	Female	Male	Female
Acceptable increased risk of blood clots	1.8%	0.8%	2.3%	1.2%
Acceptable increased risk of serious infections	2.5%	1.0%	3.2%	1.6%
Acceptable increased risk of negative effects on sperm (males only)	7.4%	-	10.4%	-

attribute explained treatment preferences by more than 30%. Patients aged 18-44 years placed less importance on frequency and mode of treatment administration than older patients. Patients accepted extra risks of blood clots, serious infections, or negative effects on sperm for an oral pill every day vs injection once a week, and for reducing amount of pain from 30% to 10% (**Table**). Similar observations were made for improved performance of daily activities. Acceptable trade-offs varied between patients.

Conclusion: Preferences of RA patients were driven by benefits and risks of RA treatments, with no single attribute dominating the decision making. Patients were willing to accept higher risk of serious infections and blood clots in exchange for improvements in pain, daily activities, or administration convenience. These findings emphasize the importance of considering the entire treatment profile, including benefits, risks, and administration to support SDM between providers and patients.

Tacrolimus Use in SLE Pregnancy and Its Effect on Pregnancy Outcomes: Retrospective Study in Two Japanese Tertiary Referral Centers

Takehiro Nakai[1], Nanase Honda[2], Eri Soga[2], Sho Fukui[3], Ayako Kitada[1], Naoto Yokogawa[4] and Masato Okada[1], [1]St. Luke's International Hospital, Tokyo, Japan, [2]Tokyo Metropolitan Tama Medical Center, Tama, Japan, [3]Brigham and Women's Hospital, Boston, MA, [4]Tokyo Metropolitan Tama Medical Center, Taito City, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Tacrolimus is one of the major treatment options of systemic lupus erythematosus (SLE) and is thought to be pregnancy compatible medication. Since little is known on tacrolimus use during pregnancy complicated by SLE, we conducted this study.

Methods: We included pregnant patients with SLE who were followed up at two Japanese tertiary referral centres. The pregnant patients with tacrolimus exposure and those without it were propensity score matched in a ratio of one-to-two to minimise difference in disease severity. Thereafter, we compared adverse pregnancy outcome (APO) ratio according to tacrolimus exposure.

Results: Of the 124 pregnancies, 29 were exposed to tacrolimus. The pregnant patients with tacrolimus exposure tended to suffer from lupus nephritis than did those without exposure (51.7% versus 17.9%, p< 0.01) . Moreover, they tended to be treated with hydroxychloroquine/higher dose of glucocorticoid and experienced lupus flare at conception compared with those without exposure (hydroxychloroquine: 69.9% versus 28.4%, p< 0.01; glucocorticoid dosage: 5.00 [5.00, 10.00] versus 5.00 [1.00, 7.75] mg/day, p=0.03; lupus flare: 19.2% versus 1.4%, p< 0.01).

After propensity score matching, group difference in the baseline characteristics including SLE severity diminished. In addition, no statistical differences were also noted in the APO ratio; blood pressure; and estimated glomerular filtration rate during pregnancy and after delivery between the groups. (overall APO: 47.1% versus 47.1%, p=1.0; maternal APO: 29.4% versus 26.5%, p=1.0; neonatal APO: 58.8% versus 41.2%, p=0.25; PROMISSE APO: 17.6% versus 17.6%, p=1.0; hypertensive disorders of pregnancy: 17.6% versus 14.7%, p=1.0; preeclampsia: 5.9% versus 5.9%, p=1.0)

Table 1: prevalence of adverse pregnancy outcome according to the use of tacrolimus

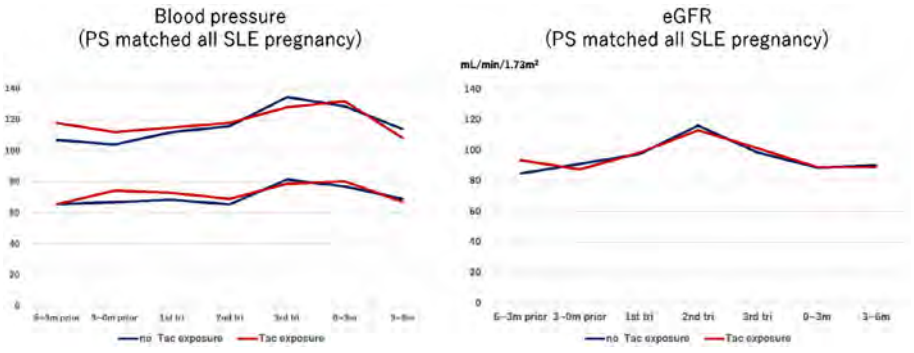

Figure 1: change in the blood pressure before and during pregnancy and after delivery

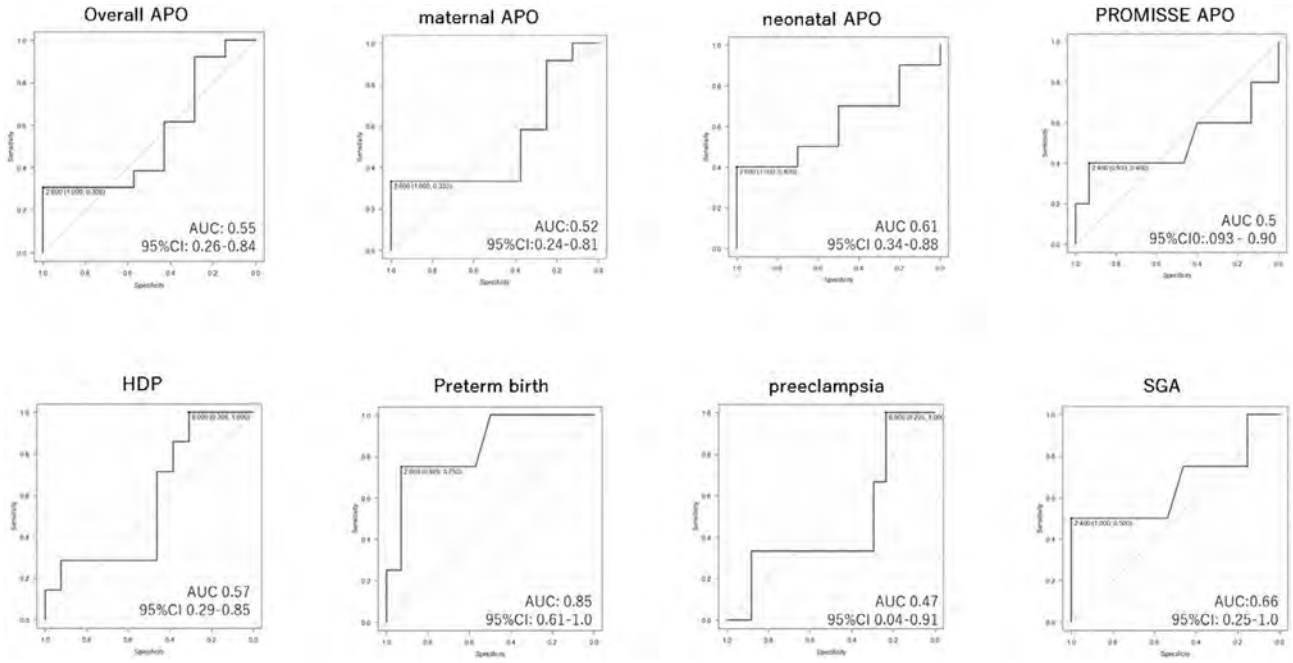

Figure 2 ROC curve for the maximum tacrolimus concentration during pregnancy and each adverse pregnancy outcome

Furthermore, receiver operating characteristic curve showed that tacrolimus concentration >2.6ng/ml was related to reduced preterm birth rate.

Conclusion: Tacrolimus use during pregnancy showed no significant impact on APO ratio, blood pressure, or renal function. Therefore, tacrolimus use might be acceptable to control lupus activity during pregnancy.

In addition, when administering tacrolimus during pregnancy, it is advisable to maintain its concentration ≥2.6 ng/ml in order to reduce the risk for preterm birth while paying careful attention to possible maternal side effects of tacrolimus.

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The management of fetuses exposed to maternal anti-SSA/Ro autoantibodies is challenging as the clinician weighs the rarity of fetal atrioventricular block (AVB) against the burden of serial surveillance. Antibody titer should be an important contributor to risk assessment and pathogenesis of disease since placental transport of maternal IgG via FcRn expressed on syncytiotrophoblast cells is less efficient during the second trimester with fetal IgG concentrations only about 10% of the maternal levels at weeks 17 – 22, the vulnerable period for AVB detection. Accordingly, we leveraged prospective data from the large multi-racial national study of pregnant women, **S**urveillance **ToP**revent AV **B**lock **L**ikely to **O**ccur **Q**uickly (STOP BLOQ), to address the impact of anti-Ro titers and utility of frequent ambulatory monitoring on outcomes in women with no previously affected children and those at risk for recurrence.

Methods: Women with positive anti-Ro autoantibodies by commercial CLIA testing from 21 sites across the U.S. were risk stratified into high and low anti-Ro60 and anti-Ro52 titers based on previous ELISA cutoff data demonstrating that women with titers < 1000 arbitrary units per mL were not at risk for fetal AVB. Those with low titers had echocardiograms only and EKGs at birth. Women exceeding this threshold for either anti-Ro60 or 52 performed fetal heart rate monitoring (FHRM)

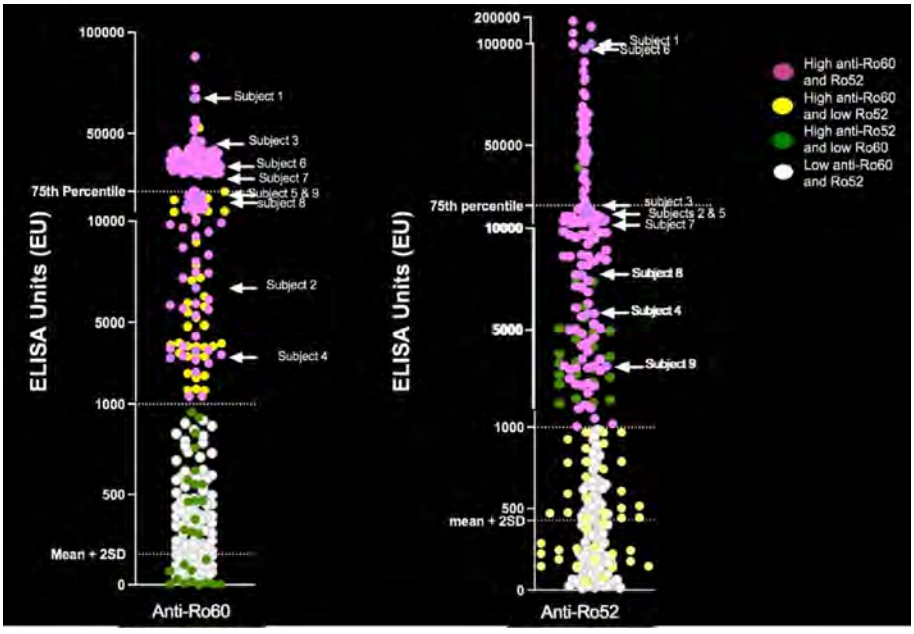

Figure 1. Titers of anti-Ro60 and Ro52 in the women enrolled in STOP BLOQ. Top quartile for anti-Ro60 > 21,336 and for anti-Ro52 > 20,420.

Table 1: Frequency of AVB in STOP BLOQ women who have completed FHRM and >26 weeks gestation.

	Overall		Previous AVB (recurrence)		No Prior AVB	
Step 1 + 2	9/381	(2.4%)	2/32	(6.3%)	7/349	(2.0%)
Step 2	9/241	(3.7%)	2/32	(6.3%)	7/209	(3.3%)
Top quartile anti-Ro60	4/58	(6.9%)	2/9	(22.2%)	2/49	(4.1%)
Top quartile anti-Ro52	2/60	(3.3%)	0/14	(0.0%)	2/46	(4.3%)
Top quartile anti-Ro60/52	2/28	(7.1%)	0/4	(0.0%)	2/24	(8.3%)

Table 2: Titers of anti-Ro60 and 52 in 4 women obtained during a prior pregnancy with AVB and a healthy pregnancy in STOP BLOQ.

	Pregnancy Outcome	Anti-Ro60	Anti-Ro52
Pair 1	AVB	5398	5116
	Healthy (STOP BLOQ)	8498	6120
Pair 2	AVB	3156	1053
	Healthy (STOP BLOQ)	3675	889
Pair 3	AVB	4406	52252
	Healthy (STOP BLOQ)	5198	49007
Pair 4	AVB	12590	102058
	Healthy (STOP BLOQ)	12003	70063

thrice daily in addition to weekly or biweekly fetal echocardiography from 18 – 26 weeks. Abnormal FHRM prompted urgent echocardiography to identify AVB.

Results: To date, 405 women have been enrolled (**Fig 1, titers**). Of these, 150 (37%) had low titers of both anti-Ro60 and 52.None of 140 pregnancies past 26 weeks resulted in AVB. Of the 255 women with titers above the threshold for either antibody, 241 completed surveillance. FHRM (performed 44,187 times) was considered abnormal in 37 audios, 9 of which were confirmed AVB by urgent echo (7 were 2nd degree AVB). Surveillance echocardiogram (performed 1871 times) detected no AVB when the FHRM was normal. Of the 9 AVB, 2/32 (6.25%) were recurrences and 7/209 (3.3%) were first time AVB (**Table 1**). Independent of previous AVB status, comparing titers for the non AVB vs AVB in the high titer group, anti-Ro60 was 16155 $\pm$ 19821 SD and 25133 $\pm$ 21494 SD (P= 0.11) and anti-Ro52 was 21194 $\pm$ 36165 SD and 32310 $\pm$ 38871 SD (P = 0.04), respectively. AVB risk increased with titers **(Table 1)**. For women within the top quartile for both anti-Ro60 and 52, the rate of AVB was 7.1% overall, and 8.3% for those never having AVB. Albeit limited numbers, having anti-Ro60 antibodies in the top quartile and a previous child with AVB conferred the highest risk of AVB, at 22%. High titer anti-Ro antibodies are necessary, but not sufficient for fetal AVB since 4 women with a prior pregnancy complicated by fetal AVB but without AVB in the current pregnancy had titers equivalent to those detected during their affected pregnancies (**Table 2**).

Conclusion: FHRM identifies early AVB, supporting this approach in the management of anti-Ro exposed pregnancies. To date, low titer anti-Ro confers no risk of AVB. While the titer of anti-Ro60 and 52 increases risk, as does previous AVB, additional factors beyond antibodies are likely.

Moving the ACR's Reproductive Health Guidelines into Practice: Assessment of a Novel Reproductive Rheumatology ECHO

Megan Clowse[1], Teresa Swezey[2], Jerome (Jeff) Federspiel[2], Catherine Sims[2], Amanda Snyderman[2], Amy Corneli[2], Sarahn Wheeler[2] and JoAnn Zell[3], [1]Duke University, Chapel Hill, NC, [2]Duke University School of Medicine, Durham, NC, [3]University of Colorado Anschutz Medical Campus, Denver, CO

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Project ECHO™ in an education model that links experts with community providers through a series of video teleconferences. Each conference involves a brief didactic session followed by a discussion of real patient cases. We piloted the first ECHO in reproductive rheumatology to increase rheumatologists' knowledge and self-efficacy in providing reproductive health care.

Methods: The Project ECHO guides informed ReproRheum ECHO curriculum development, provider recruitment, logistics, and assessment. All ACR RISE Registry providers received email invitations. The ECHO was evaluated using interviews and pre/post surveys to assess provider knowledge, self-efficacy, and to identify program strengths, weaknesses, and solicit suggestions. Self-efficacy was assessed using a modified validated Self-Efficacy 12 survey.

Results: A total of 12 providers, 8 rheumatology providers (4 MD, 2 NP, 2 fellows) and 4 experts (2 reproductive rheumatologists, 2 MFM), participated in the ReproRheum ECHO's 6, 1-hour sessions from January-March 2023. Feasibility was demonstrated: all but one provider attended all sessions.

Knowledge of the rate of birth defects after exposure to azathioprine and mycophenolate both significantly increased. Provider self-efficacy increased significantly (6.8 +/- 1.2 pre-ECHO to 8.1 +/- 0.5 post-ECHO, p=0.03). All participants 'agreed' or 'strongly agreed' that they had increased confidence in their ability to answer colleagues' questions and guide patients' choices in contraception and medication in pregnancy.

In interviews, providers described the didactic and case discussion sections as being the most valuable, noting the combination allowed them to apply the knowledge in clinical care. They expressed appreciating the diversity of perspectives and experiences of rheumatologists from across the US and the inclusion of MFM experts. Providers said they were satisfied with the amount of facts and experienced very few barriers to attendance. Providers shared they had increased knowledge, comfort and confidence in speaking with patients about reproductive health. Providers who were not recording reproductive health information routinely before the ECHO said that they had added pregnancy counseling sections to their notes. Nearly all providers viewed the LupusPregnancy.org and ReproRheum.Duke.edu handouts as useful during patient discussions. Some providers said they shared handouts with patients, while others had verbally reviewed them together. Nearly all

providers said they would definitely attend future ECHO sessions and that they would definitely recommend the ECHO to other rheumatologists and midlevel providers.

Suggestions for improvement included having patients share their perspective, role-playing patient counseling, and enhancing curricula with articles and summary sheets.

Conclusion: The pilot ReproRheum ECHO was feasible and improved knowledge and self-efficacy among rheumatologists in reproductive health. We hope to expand to multiple audiences using tailored content, including fellows, rural providers and advanced practice providers. This model is a promising approach to improving reproductive health care for women with rheumatic disease.

The Impact of Pregnancy Timing on Outcomes in SLE

Catherine Sims[1], Amanda Eudy[2], Ceshae Harding[1], Cuoghi Edens[3], Mehret Birru Talabi[4], Rosalind Ramsey-Goldman[5], Laura Neil[1] and Megan Clowse[6], [1]Duke University, Durham, NC, [2]Duke University, Raleigh, NC, [3]University of Chicago, Chicago, IL, [4]University of Pittsburgh, Pittsburgh, PA, [5]Northwestern University, Chicago, IL, [6]Duke University, Chapel Hill, NC

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: To minimize risk of poor pregnancy outcomes, the ACR Reproductive Health Guideline recommends women conceive when SLE is well controlled and treated with pregnancy-compatible medications. In addition to SLE disease activity and medications, social determinants of health can impact pregnancy outcomes. We studied the association between pregnancy timing, social determinants of health, and pregnancy outcomes.

Table 1. Patient demographics based on whether pregnancy was medically optimized, intended, or both.

	Medically Optimized Pregnancies* n=115		Intended Pregnancies° n=108		Well-Timed Pregnancies§ n=109	
	Yes n=78 (68%)	No n=37 (32%)	Yes n=68 (63%)	No n=40 (37%)	Yes n=54 (50%)	No n=55 (50%)

*Medically optimized for pregnancy if they met all three of the following criteria: urine protein:creatinine ratio (UPC) measured ≤ 6 months prior to conception or during the first trimester with < 1g proteinuria, not prescribed a teratogen at conception, and continued pregnancy compatible SLE medications after conception.
°Intended pregnancies were defined as London Measure of Unplanned Pregnancy with a score ≥ 10 at study entry.
§Well-timed pregnancies met criteria for both Medically Optimized and Intended.
[1]Comparison of data between medically optimized and not medically optimized pregnancies resulted in a p value < 0.05
[2]Comparison of data between intended and unintended pregnancies resulted in a p value < 0.05
[3]Comparison of data between well-timed and not well-timed pregnancies resulted in a p-value < 0.05
[4]All patients stopped after conception but prior to registry enrollment

Methods: All study participants met SLICC criteria for SLE, were pregnant, and enrolled in a prospective registry. At baseline, patients reported social determinants of health and SLE activity; medications, laboratory results, and physician-assessments of SLE activity were also recorded. Pregnancy timing was defined in 3 ways based on whether the woman was medically optimized, the woman intended to become pregnant, or both. "Medically optimized" pregnancies met the following criteria: no teratogen use, continued pregnancy-compatible SLE medications, and urine protein:creatinine ratio (UPC) < 1g in the 6 months prior to or during the first trimester. "Intended" pregnancies were defined using the London Measure of Unplanned Pregnancy (LMUP), a validated, 6-question self-reported survey assessing the extent that the woman intended to become pregnant. Well-timed pregnancies were both medically optimized and intended; ill-timed were either not medically optimized and/or intended. Statistical analyses compared differences in outcomes by our three definitions of pregnancy timing.

Results: A total of 115 women were enrolled, with half of pregnancies both intended and medically optimized, 20% neither intended nor medically optimized, 17% not intended but medically optimized, and 13% intended but not medically optimized. Ill-timed pregnancies were more likely to be conceived by women who were single, identify as Black or Hispanic, receive Medicaid or Medicare, have a lower income and level of education (Table 1). Additionally, women with ill-timed

Preterm Delivery (< 37 weeks)	12 (21%)	12 (41%)	14 (24%)	9 (32%)	11 (27%)	12 (32%)
Preeclampsia	8 (16%)	11 (41%)[1]	8 (17%)	11 (44%)[2]	6 (16%)	13 (37%)

*Medically optimized for pregnancy if they met all three of the following criteria: urine protein:creatinine ratio (UPC) measured ≤ 6 months prior to conception or during the first trimester with < 1g proteinuria, not prescribed a teratogen at conception, and continued pregnancy compatible SLE medications after conception.
°Intended pregnancies were defined as London Measure of Unplanned Pregnancy with a score ≥ 10 at study entry.
§Well-timed pregnancies met criteria for both Medically Optimized and Intended.
[1]Comparison of data between medically optimized and not medically optimized pregnancies resulted in a p value < 0.05
[2]Comparison of data between intended and unintended pregnancies resulted in a p value < 0.05

pregnancy had higher physician-reported SLE disease activity, were less likely to be taking pregnancy-compatible medications at their initial pregnancy visit and more likely to be taking mycophenolate at conception (Table 2). Ill-timed pregnancies were more likely to end with preeclampsia and early delivery (Table 3). In pregnancies that were not medically optimized, when adjusted for marital status, low income, Medicaid or Medicare, the risk of preterm birth and preeclampsia was three times higher than in medially optimized pregnancies (AOR: 3.33; 95% CI: 1.06, 10 for preterm birth and AOR: 3.0; 95% CI: 0.95, 10 for preeclampsia). These pregnancies were, on average, more than two weeks shorter (adjusted β: -2.38; 95% CI: -4.42, -0.34).

Conclusion: In this cohort of pregnant patients with SLE, women with ill-timed pregnancies, whether because she didn't intend to be pregnant or was not medically optimized for pregnancy, had multiple factors contributing to their higher risk for poor pregnancy outcomes, including social disadvantage, increased lupus activity, and inappropriate medication use. In order to improve outcomes in SLE, we need to target specific interventions to this particularly vulnerable population.

Abstract Number: 1685

SLE Disease Activity Is a More Important Risk Factor Than Immunosuppression for Acquiring Human Papillomavirus (HPV) Infection in Systemic Lupus Erythematosus Patients

Zehra Kazmi[1], Carlos Lorenzo[2] and Agustin Escalante[3], [1]University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]UT Heath San Antonio, Shavano Park, TX, [3]UT Health Science Center at San Antonio, San Antonio, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: SLE patients have increased rates of HPV infection and cervical cancer. Although some factors are recognized for HPV infection in SLE, the relationship with SLE disease activity is not well studied. Here, we studied the association between SLE activity and HPV infection in a time adjusted manner.

Methods: We studied patients visiting lupus clinic between May 2020 and May 2022. We included females between 21 to 65 years who had at least 1 pap smear after SLE diagnosis. Patients who had hysterectomy were excluded. We collected HPV vaccination data, HPV results, disease activity and exposure to immunosuppression since 2011.

SLE Disease Activity Index 2000 (SLEDAI-2K) and prednisone doses were recorded for each visit. Time adjusted SLEDAI (TAS) and time adjusted prednisone dose (TAP) were determined by calculating the area under the curve of over time. Data for 3 consecutive clinic visits were used.

Immunosuppressive drugs were divided into 3 groups: Conventional: Methotrexate; nonbiologic: Azathioprine, Mycophenolate mofetil, Tacrolimus, Voclosporin, Cyclophosphamide; and biologic: Belimumab, Rituximab or Abatacept.

Descriptive statistics, univariate and multivariate logistic regression were performed.

Results: We studied 74 female SLE patients (61% Hispanic, 24% African American, and 15% Caucasian) who had no history of prior HPV. Only 3 patients had received HPV vaccine. The mean ± SD age was 41 ±11 years. The mean ± SD of SLE disease duration was 7.9 ± 4.3 years. The mean number of pap smears per patient was 2.6.HPV testing was performed on 68 patients and 19 patients were HPV positive. In 6 patients, HPV testing was not performed due to HPV screening guidelines. The average time between visits was 3.7 months. The mean ± SD TAS and TAP were 4.2± 3.7 and 7.7 ± 13.1 mg, respectively.

Table 1a: Univariate factors associated with incident HPV infection

Risk factor	HPV negative (n=49)	HPV positive (n=19)	P value
Age (years)	45.6 ± 1.45	34.47 ± 2.33	0.0001
Average Number of pap smears(n)	2.45	3.47	0.03
Time Adjusted SLEDAI (months)	2.97 ±0.55	7.37 ±0.84	0.0012
Time adjusted prednisone dose (mg)	4.4	16.6	0.0023
Conventional drug exposure (%)	18.4	21.1	0.800
Non-biologic drug exposure (%)	63.3	68.4	0.689
Biologic drug exposure (%)	18.4	5.3	0.171

Table 1b: Multivariate logistic regression with acquiring HPV infection as dependent variable.

Risk factor	Odds ratio (CI)	P value
Age	0.86 (0.75-0.99)	0.032
Average Number of pap smears	2.14 (1.16-3.96)	0.015
Time adjusted prednisone dose	1.02 (0.96-1.09)	0.533
Time adjusted SLEDAI	1.43 (1.03-1.99)	0.033

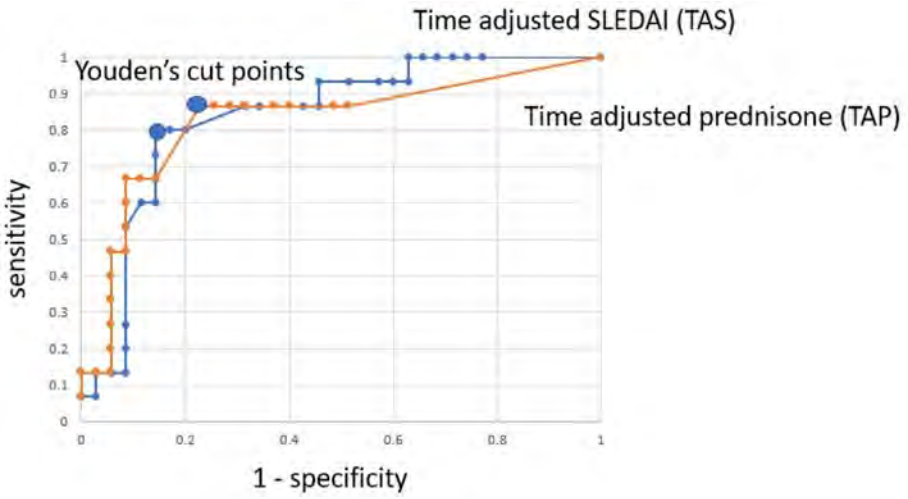

Figure 1: ROC curves of the association of HPV infection with time adjusted SLEDAI (TAS) (area under the curve 0.80) and time adjusted prednisone (TAP) (area under the curve 0.79)

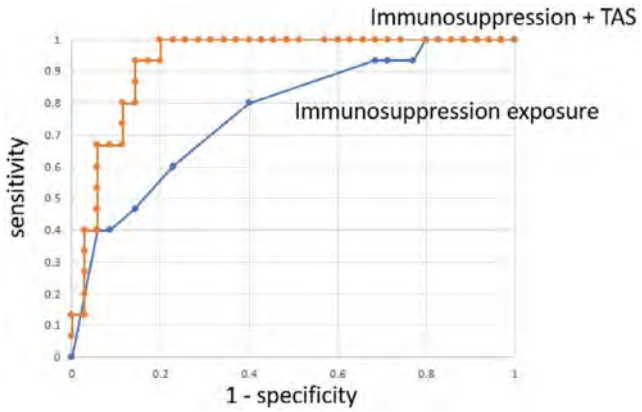

Figure 2: ROC curves of the association of HPV infection with time adjusted SLEDAI (TAS) and immunosuppression exposure (p = 0.019)

In univariate analysis, the risk of acquiring HPV was associated with younger age, higher number of pap smears, greater TAP dose, and higher TAS (Table 1a).The odds of acquiring HPV increase by 7.5% for 1 mg increase of TAP (OR 1.07, 95% CI: 1.01- 1.14). Ethnicity, SLE disease duration, alcohol use, hormonal contraception use and prior immunosuppression exposure were not associated HPV (p >0.05).

In multivariable logistic regression, age, number of pap smears and TAS were independently associated with HPV (p< 0.05 for all), but TAP was not (Table 1b). Patients were stratified into 3 TAS categories: mild < 3, moderate 3-6 and severe >6. Patients with severe SLE activity had 22.0 times higher odds of having HPV than those with mild activity (OR 22.0, 95% CI: 3.6-132.7, p 0.0007).

The cut point that better discriminated the risk of HPV infection for TAS was >5 (OR 24.0, 95% CI: 4.9-116.5) and for TAP was >15 mg (OR 16.0, 95% CI 3.5-72.6) (Figure 1). TAS increased the accuracy of immunosuppression exposure to detect HPV infection (Figure 2).

Conclusion: Our findings suggest that SLE disease activity is an independent risk factor for HPV infection, which has not been previously recognized. Reducing disease activity rather than immunosuppression may be the clinical approach to lower the risk for HPV infection. The biological basis for this association represents an important area for future study as is the role of disease activity in other infections among SLE patients.

Abstract Number: 1686

Adolescent and Young Adult Rheumatology Patient Reports of Reproductive Health Screening and Counseling in the Clinical Setting

Brittany Huynh[1], Mary Ott[1] and Stacey Tarvin[2], [1]Indiana University School of Medicine, Indianapolis, IN, [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Adolescents and young adults (AYAs) with rheumatic disease are at high risk of poor reproductive health outcomes due to disease-related risks and teratogen use. We describe patient reported counseling on sexual and reproductive health (SRH) related to rheumatic disease among an AYA population.

Methods: AYAs ages 14-26 years and assigned female at birth were recruited from pediatric rheumatology clinics at a Midwest tertiary care center. Participants completed a one-time online survey assessing SRH behaviors and counseling. Diagnosis and medication were extracted from the EMR. Data were analyzed using descriptive statistics.

Results: The 108 participants were 14-23 years old (mean 16.7 +/- 2.0). 24% reported ever having sex. 36% were on a teratogen (excluding NSAIDs). (Table 1)

Among all participants, we found low rates of reported screening for sexual activity by pediatric rheumatologists (38%). Few reported discussions regarding pregnancy prevention (17%) or emergency contraception (EC, 6%); more participants reported counseling by any provider (56% and 20% respectively, Table 2). Sexual activity screening was associated with

No		3 (8%)	6 (9%)	9.342	0.009
Unsure		12 (31%)	41 (59%)		

current teratogen use (X^2=6.539, p< 0.05). EC counseling was associated with older age (18.3+/-2.7 vs 16.6+/-2.0 years, p< 0.05) but not teratogen use or sexual activity. Pregnancy prevention counseling was associated with none of these factors.

Among AYAs on teratogens, 54% reported screening for sexual activity by pediatric rheumatologists. Only 51% reported receipt of counseling regarding the risk of their disease or medication on the health of a fetus if they were to get pregnant, and 44% regarding counseling to avoid pregnancy due to their medication. We found similar rates when asked regarding counseling by any provider. We found gaps in counseling of patients on teratogens regarding pregnancy prevention and EC, which they largely received from non-rheumatology providers. (Table 2)

Table 3. Participant rated importance of reproductive health counseling and preferences regarding education

	n (Percent)
Report to be moderately or extremely important to know*	
Effects of medication on pregnancy	100 (93%)
Birth control	92 (85%)
Emergency contraception	91 (84%)
Report personal concern about topic in the 3 months prior to survey	
Effects of medication on pregnancy	34 (32%)
Birth control	41 (38%)
Emergency contraception	15 (14%)
Preferred method of receiving information on these topics	
Talk to a healthcare provider**	62 (57%)
Rheumatologist	52/62 (84%)
Primary care provider	41/62 (66%)
OB/GYN or Adolescent medicine	41/62 (66%)
Email	50 (46%)
Website	42 (39%)
Report it is important to talk to their rheumatologist about these topics	
Yes	88 (82%)
No	5 (5%)
Unsure	15 (14%)

*For people their age with a rheumatic disease

**Select all that apply

Notably, among those on teratogens only 62% knew their medication was teratogenic. Those not on teratogens were largely unsure of the teratogenicity of their medications, and 9% inappropriately reported that their medications were teratogenic. (Table 2)

AYAs reported these topics of high importance for young people with rheumatic disease to know, and many reported recent concerns on these topics. They preferred to receive information in person from their rheumatologist, and 82% agreed it is important to talk to their rheumatologist regarding these topics. (Table 3)

Conclusion: AYAs with rheumatic disease report low levels of reproductive health screening and counseling by their rheumatologist yet report these topics are important and want to discuss them. Gaps in knowledge were identified among teratogen users. This study identifies a need for improved communication with AYAs regarding their sexual and reproductive health.

Sex of the Patient Affects Response to Advanced Therapies in Psoriatic Arthritis: Meta-analysis of Data from Randomized Controlled Trials

Lihi Eder[1], Sivakami Mylvaganam[2], Jordi Pardo Pardo[3], Jennifer Petkovic[4], Vibeke Strand[5], Philip J. Mease[6] and Keith Colaco[7], [1]Women's College Research Institute, Division of Rheumatology, University of Toronto, Toronto, ON, Canada, [2]Department of Biochemistry, University of Toronto, Toronto, ON, Canada, [3]Cochrane Musculoskeletal, University of Ottawa, Ottawa, ON, Canada, [4]Cochrane Equity Methods Group, University of Ottawa, Ottawa, ON, Canada, [5]Stanford University, Portola Valley, CA, [6]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA, [7]Women's College Research Institute / Department of Health and Society, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: PsA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Limited information exists on participation and study outcomes by sex in randomized controlled trials (RCTs) among patients with psoriatic arthritis (PsA). Through a systematic literature review and meta-analysis, we aimed to compare patient characteristics and efficacy and safety of advanced therapies between male and female patients with PsA participating in RCT.

Methods: We performed a systematic literature search of Medline, Embase and Central databases, and conference abstract archives from January 1, 2000 to June 30, 2022. RCTs that assessed the efficacy of an advanced therapy (biologic or targeted synthetic) in adult participants with PsA were included. Among studies that reported sex-disaggregated results, we extracted information on participants' baseline characteristics and proportion of participants achieving minimal disease activity (MDA), or meeting the American College of Rheumatology 20 (ACR20) and ACR50 response criteria at the primary endpoint of the study by sex. Random-effect models were used to calculate pooled effects for response in males vs. females for the different classes of advanced therapies.

Results: A total of 52 trials (21,769 participants) were included. The average percentage of male and female participants enrolled was 50.2% and 49.8%, respectively. Only 9 studies (17.3%) reported sex-disaggregated baseline characteristics, 16 studies (30.7%) reported sex-disaggregated efficacy endpoints and 2 studies (3.8%) reported sex-disaggregated safety endpoints.

Female patients had significantly higher baseline tender joint count, Health Assessment Questionnaire Disability Index, physician and patient global assessment and pain scores. Male patients had significantly higher baseline psoriasis area and severity index and CRP [**Table 1**].

Differences in pooled estimates of efficacy endpoints were seen for male and female patients across the different classes of advanced therapies. The probability of achieving MDA was significantly higher in males in the following classes of advanced therapies [**Fig. 1**]: IL-17 inhibitors (i) (OR 1.99), IL-23i (OR 1.79), TNFi (OR 2.62) and JAKi (OR 1.77). The probability was also higher in IL-12/23i and methotrexate, but not statistically significant.

Table 1 - Summary results of random effects meta-analysis of baseline patient characteristics by sex

Table 1 – Summary results of random effects meta-analysis of baseline patient characteristics by sex

Variable	Number of trials	Number of Males/Females	Mean difference (Male-Female) (95% CI)	Heterogeneity (I^2)
Tender joint count (0-68)	9	2156/2312	-3.01 (-3.83, -2.18)	0%
Swollen joint count (0-66)	9	2156/2312	-0.30 (-0.80, 0.20)	0%
PASI (0-72)	6	900/1004	1.95 (0.78, 3.11)	48%
CRP (mg/L)	5	1498/1704	2.57 (0.40, 4.74)	58%
Physician global assessment (0-100)	8	2034/2189	-1.34 (-2.08, -0.08)	16%
Patient global assessment (0-100)	9	2156/2312	-3.22 (-5.27, -1.17)	62%
Pain score (0-100)	9	2154/2312	-4.58 (-6.86, -2.30)	70%
HAQ-DI (0-3)	9	2156/2312	-0.28 (-0.33, -0.24)	61%
Variable	**Number of trials**	**Number of Males/Females**	**Odds Ratio (Male vs. Female) (95% CI)**	**Heterogeneity (I^2)**
Presence of dactylitis (yes)	3	470/512	1.92 (1.00, 3.70)	58%
Presence of enthesitis (yes)	5	1029/1051	0.67 (0.55, 0.83)	12%

CRP-C-reactive protein; HAQ-DI – health assessment questionnaire disability index; PASI- psoriasis area and severity index;

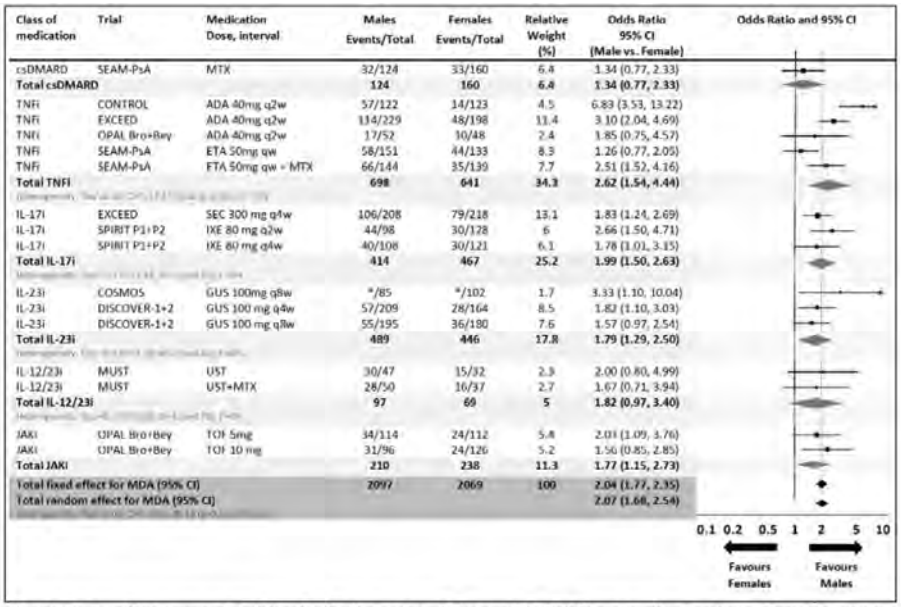

Figure 1. Random-effects meta-analysis of the odds of achieving **minimal disease activity (MDA)** in male vs. female patients with psoriatic arthritis.
CI, confidence interval; ADA, Adalimumab; DEUC, Deucravacitinib; CER, Certolizumab; csDMARD, conventional synthetic disease-modifying anti-rheumatic drug; ETA, etanercept; GUS, Guselkumab; IL-17i, interleukin-17 inhibitor; IL-12/23i, interleukin-12/23 inhibitor; IL-23i, interleukin-23 inhibitor; IXE, Ixekizumab; JAKi, janus kinase inhibitor; MTX, methotrexate; QW, weekly; Q2W, every 2 weeks; Q4W, every 4 weeks; Q8W, every 8 weeks; RIS, Risankizumab; SEC, secukinumab; TOF, Tofacitinib, TNFi, tumour necrosis factor inhibitor; UPA, Upadacitinib; UST, Ustekinumab.

Figure 1. Random-effects meta-analysis of the odds of achieving minimal disease activity (MDA) in male vs. female patients with psoriatic arthritis.

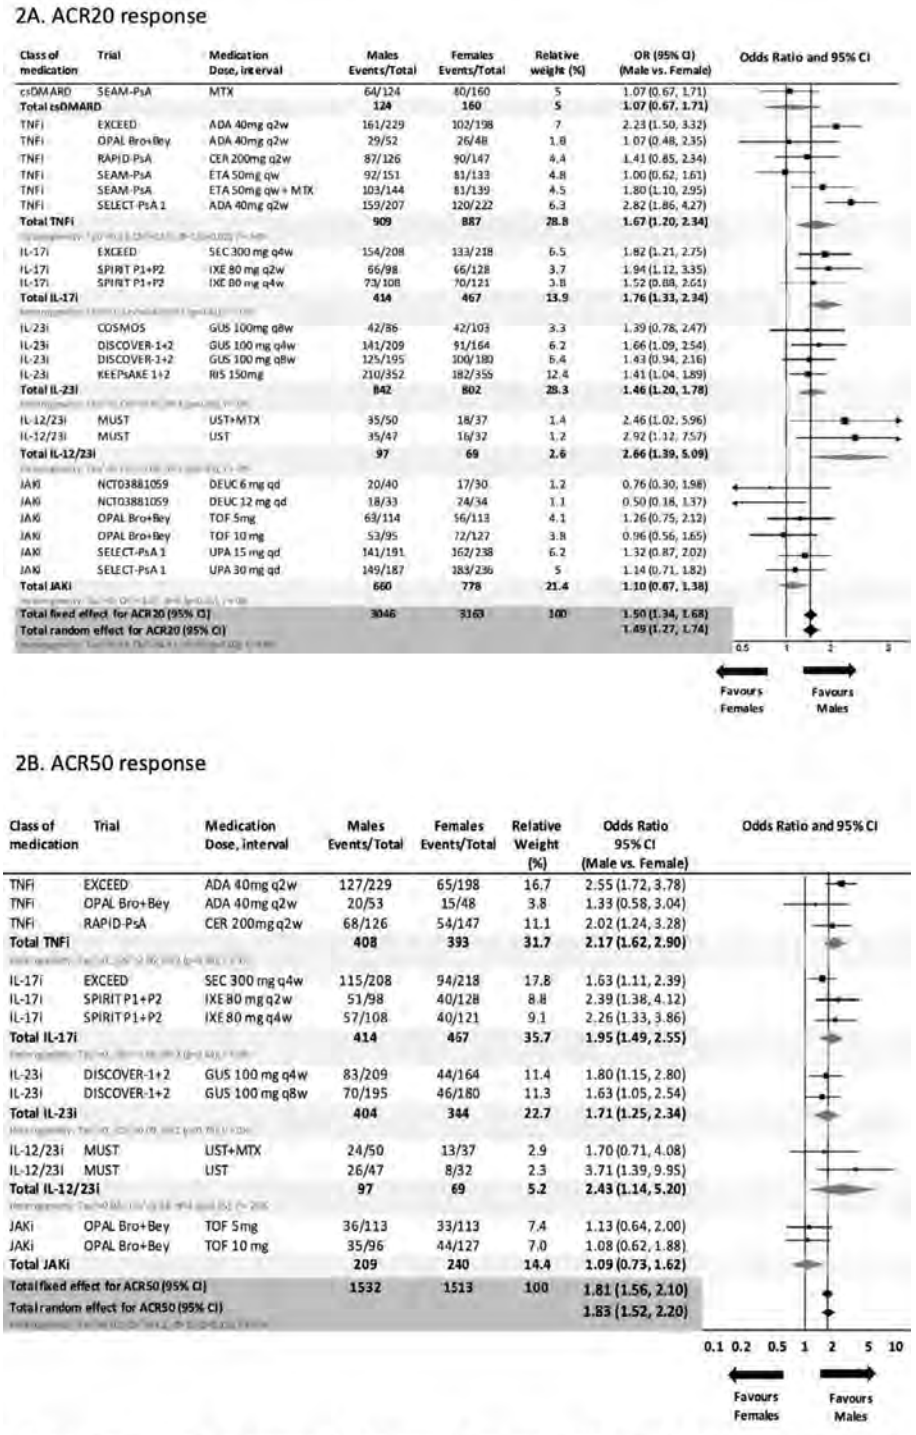

Figure 2. Random-effects meta-analysis of the efficacy of advanced therapies, by **(A) ACR20, (B) ACR50 response** between male and female patients with psoriatic arthritis.

CI, confidence interval; ACR, American College of Rheumatology; ADA, Adalimumab; DEUC, Deucravacitinib; CER, Certolizumab; csDMARD, conventional synthetic disease-modifying anti-rheumatic drug; ETA, etacercept; GUS, Guselkumab; IL-17i, interleukin-17 inhibitor; IL-12/23i, interleukin-12/23 inhibitor; IL-23i, interleukin-23 inhibitor; IXE, Ixekizumab; JAKi, janus kinase inhibitor; MTX, methotrexate; QW, weekly; Q2W, every 2 weeks; Q4W, every 4 weeks; Q8W, every 8 weeks; RIS, Risankizumab; SEC, secukinumab; TOF, Tofacitinib, TNFi, tumour necrosis factor inhibitor; UPA, Upadacitinib; UST, Ustekinumab.

Figure 2. Random-effects meta-analysis of the efficacy of advanced therapies, by (A) ACR20, (B) ACR50 response between male and female patients with psoriatic arthritis.

In contrast, variability was seen in the probability of achieving ACR response by sex across classes of advanced therapies. The probability of achieving ACR20 response was significantly higher in male vs. female patients for IL-17i (OR 1.76), IL-23i (OR 1.46), IL-12/23i (OR 2.66) and TNFi (OR 1.67), but significantly different for JAKi (OR 1.10). [**Fig. 2A**]. Similarly, the probability of achieving ACR50 response was significantly higher in males vs. females in all advanced therapies, and not significantly different for JAKi (OR 1.09) **[Fig 2B]**. Male and female patients had a similar probability of achieving ACR20 response when using placebo (OR 1.04, 95% CI 0.86, 1.27).

Conclusion: Female patients participating in RCTs are less likely to achieve efficacy end points for most classes of advanced therapies. Some differences in response outcomes were found across classes of advanced therapies. Future studies should report disaggregated sex data for baseline and end-points.

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: PsA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: IL-17 inhibition demonstrates efficacy in multiple disease domains in psoriatic arthritis. Izokibep is a unique IL-17A inhibitor with high IL-17A binding affinity (K_D= 0.3 pM), small molecular size (18.6 kDa), and an albumin attachment site. Week 16 data showed ACR50 of 52% and enthesitis resolution rates of 88%. We report data from baseline to 46 weeks in this phase 2 PsA trial[1] on arthritis and skin composite efficacy endpoints and longer-term safety.

Week 46 N=58/59	71	53	65	67	29	57

FAS, observed data by visit *post-hoc analysis
IZO=izokibep, N=number of patients, PLB=placebo

Methods: Izokibep doses of 80 mg Q2W or 40 mg Q2W were evaluated to 46 weeks or study termination. The original placebo arm switched to 80 mg Q2W at week 16 in this multicenter trial (NCT04713072). Once week 16 data were available, this trial was terminated to further examine the effective dose range of izokibep in a next P2b/3 trial. The results include as observed analysis. Eligible patients met CASPAR criteria, with ≥3 swollen and ≥3 tender joints, and prior failure/insufficient response to NSAIDs, csDMARDs or TNF inhibitors.

Results: 135 patients were randomized 1:1:1: 44 to 40 mg Q2W, 47 to 80 mg Q2W, 44 to placebo later switched to 80 mg Q2W at week 16. At week 32, 96 of 102 eligible patients had measured results and at week 46, 59 of 62 patients did. Baseline mean age was 49 (SD 12), BMI 29 (5), PsA duration 7 (8) years, SJC 10 (7) and TJC 17 (10), DAPSA 47 (22), and PsAID-9 5.9 (1.8). Mean PASI was 10 (6) in those patients with BSA >3%, and in those with enthesitis, mean LEI was 1.5 (0.5) and SPARCC was 3.4 (2.8). 13% used prior TNF inhibitors.

Beyond week 16, the 80 mg groups continued to improve, while the 40 mg group remained largely stable (Figure 1).

Most patients in the 80 mg group and the placebo/80 mg switchers achieved DAPSA low disease activity/remission and minimal disease activity (MDA) thresholds through week 46 (Table).

High LEI enthesitis resolution rates on 80 mg until week 16 were maintained while SPARCC enthesitis resolution progressed through week 46 (Figure 2). Mean PsAID-9 scores improved to week 46, to a mean 2.3 (2.0) on 80 mg, 2.2 (2.1) in the placebo/80 mg switchers and remained largely stable on 40 mg after 16 weeks, with mean 3.2 (2.5).

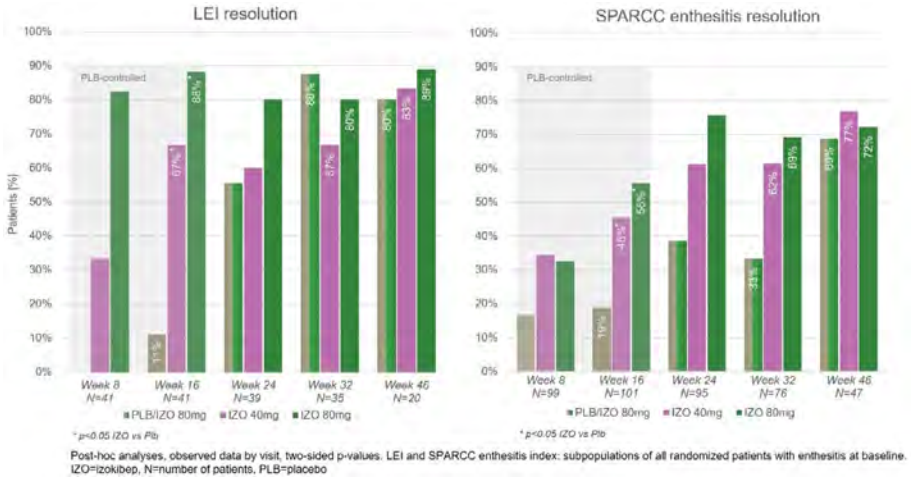

Figure 2. High Rates of LEI and SPARCC Enthesitis Complete Resolution to Week 46

Safety over the interval from week 16 to 46 remained unchanged. The most frequent adverse events were injection site reactions (14.5%) and injection site erythema (12.2%), with 1 patient discontinuing for ISR. Nasopharyngitis occurred in 6.9%, and headache and backpain occurred in 5.3% each. AEs were mostly mild and balanced across treatment groups. No Candida or fungal infections were observed from weeks 16 to 46.

Conclusion: Izokibep 80 mg demonstrated high levels of disease control with ACR70 in 52%, PASI100 in 71% and enthesitis complete resolution in 89% at week 46. Izokibep remained well tolerated, with no dose related adverse events and a safety profile generally consistent with approved IL-17A inhibitors.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: PsA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: To characterize the relationships between peripheral blood immune cell profiles in patients with psoriatic arthritis (PsA) and (1) baseline clinical and imaging disease features; (2) response to targeted advanced therapies at 3 months.

Methods: Patients with PsA who were initiating treatment with advanced therapies for active peripheral musculoskeletal disease were recruited. Patients were examined and ultrasound was performed to assess the level of inflammation in various PsA domains at baseline and after 3 months of treatment. Mass cytometry (CyTOF) was performed to characterize immune cell populations in whole blood. The frequencies of 16 immune cell populations (among CD3+ positive cells) were

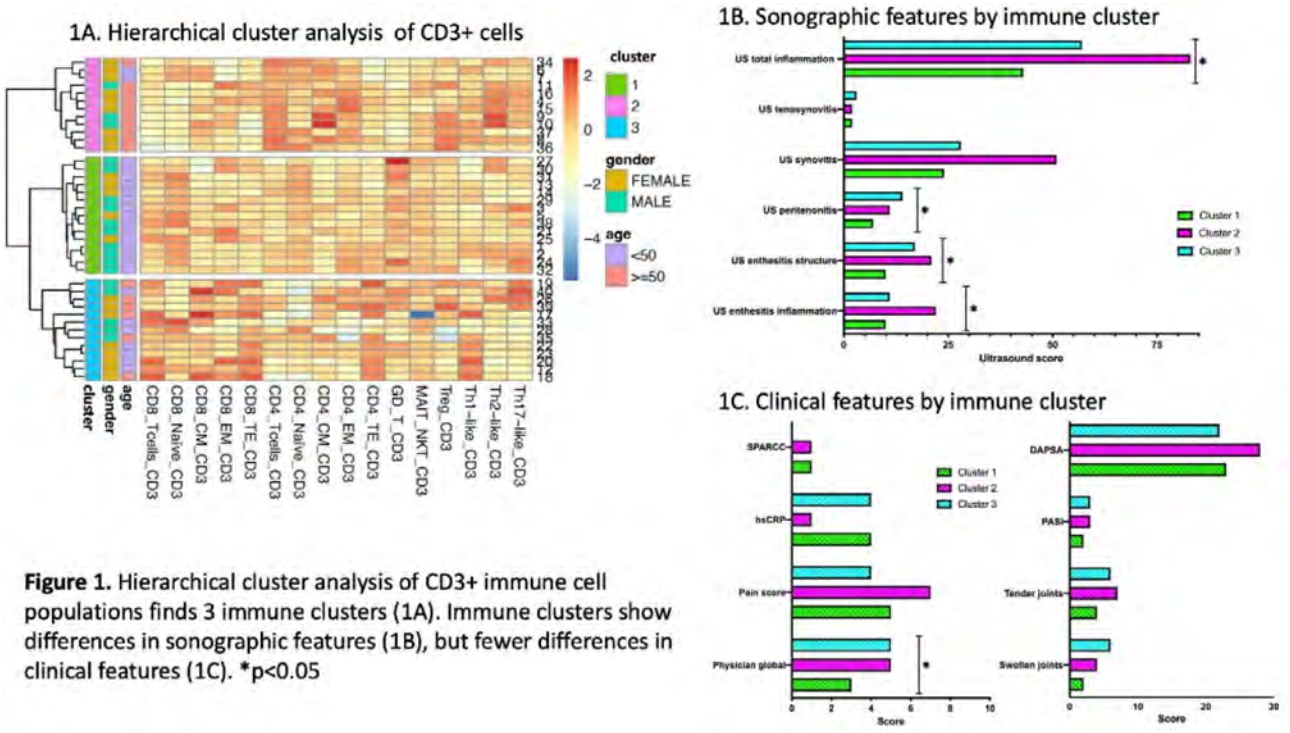

Figure 1. Hierarchical cluster analysis of CD3+ immune cell populations finds 3 immune clusters (1A). Immune clusters show differences in sonographic features (1B), but fewer differences in clinical features (1C). *p<0.05

*cell count/CD3+ cells; **difference in baseline-follow up DAPSA score adjusted for DAPSA score at baseline; CM- central memory; DAPSA – disease activity in psoriatic arthritis; EM – effector memory; MAIT NKT – mucosal associated T and Natural Killer T; TE-terminal effector; Th – T helper

automatically quantified using Probability State Modelling algorithms. Hierarchical clustering was performed using immune cell population data. The association between the 3 identified immune cell clusters and baseline characteristics, as well as clinical and sonographic response to treatment, was assessed using GEE regression models.

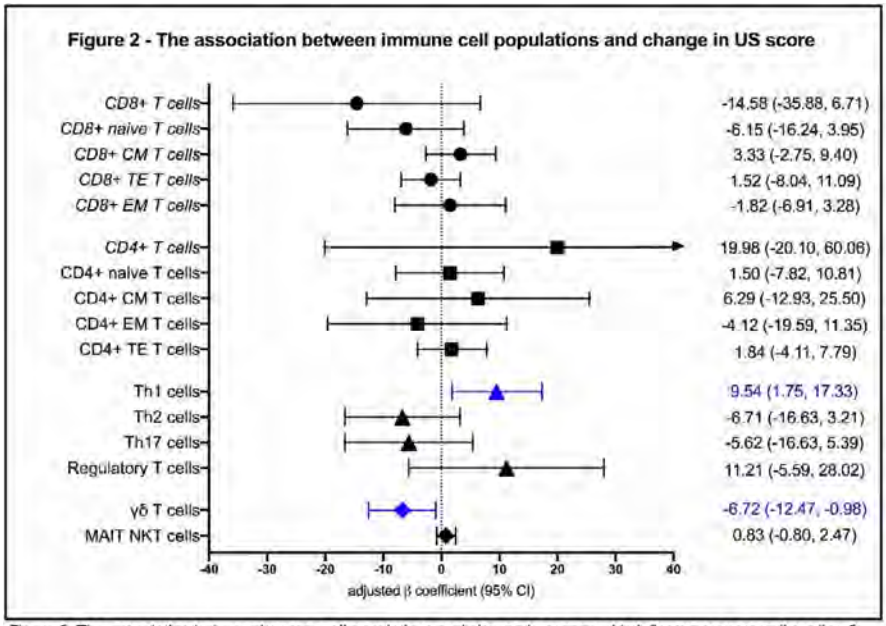

Figure 2: The association between immune cell populations and change in sonographic inflammatory score (baseline-3 months) adjusted for baseline sonographic score by GEE linear regression models. Blue lines=significant association (p<0.05)

Figure 2 - The association between immune cell populations and change in sonographic inflammation score by GEE model adjusted for baseline sonographic score

Results: 40 treatment periods involving 34 patients were analyzed (21 IL-17i; 16 TNFi; 3 JAKi). 60% of patients achieved ACR20 response. Cluster analysis identified 3 immune clusters (Figure 1). **Cluster 1** (γδT cells and CD8+ naïve predominant) was associated with lower sonographic inflammation, lower physician global assessment and younger age. **Cluster 2** (Central Memory (CM) and Effector Memory (EM) CD4+ T cells predominant) was associated with the highest levels of sonographic inflammation, in particular synovitis and enthesitis scores, and older age. **Cluster 3** (CD4+ and CD8+ Terminal Effector (TE) T cells and Th1 predominant) was associated with highest levels of peritenon inflammation (Figure 1B-C). Immune cell profiles were associated with clinical and sonographic response to therapy. Being in Cluster 2 was associated with a lower probability of achieving ACR20 response and with an increase in Disease Activity index for PsA (DAPSA) score compared to clusters 1 and 3 (Table 1). Among individual cell populations, higher levels of CD8+ cells, in particular naïve cells, was associated with reduction in DAPSA. Higher levels of γδT cells was associated with higher chances of achieving ACR20 response, while higher levels of naïve EM and CM CD4+ and Th1 cells were associated with lower treatment response (Table 1). The levels of Th1 and γδT cells also predicted change in sonographic inflammatory score (Figure 2).

Conclusion: Immune cell profiling can improve PsA phenotyping. CD4+ memory and Th1cells correlated with more severe synovitis and enthesitis and poor response to advanced therapies, while γδT cells and CD8+ naïve cells were associated with milder disease phenotype and improved treatment response.

SESSION INFORMATION

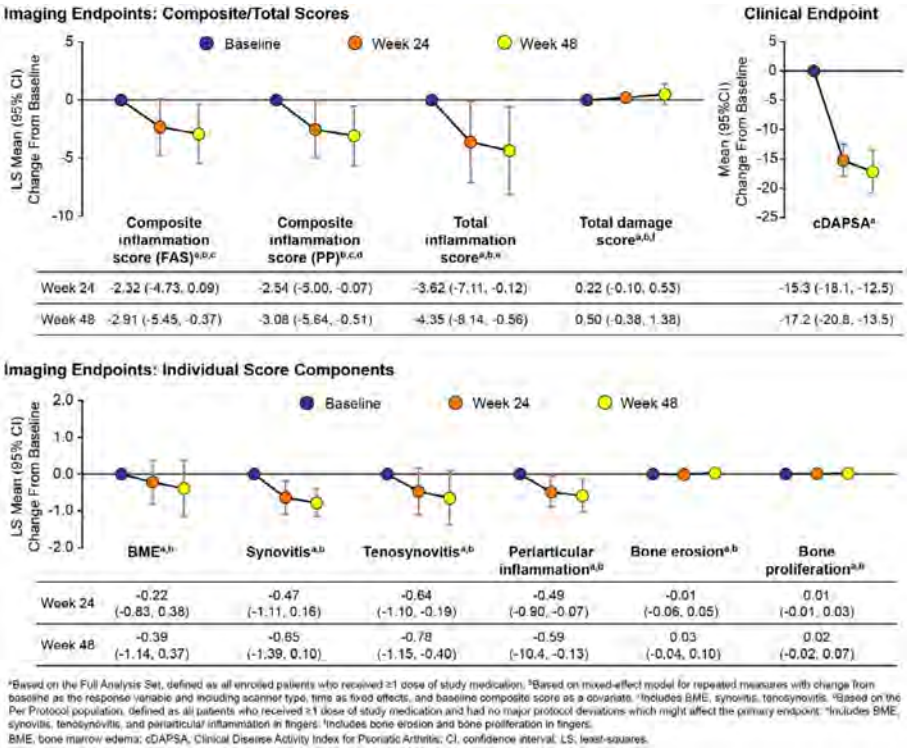
Session Date: Monday, November 13, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: PsA

Session Type: Abstract Session

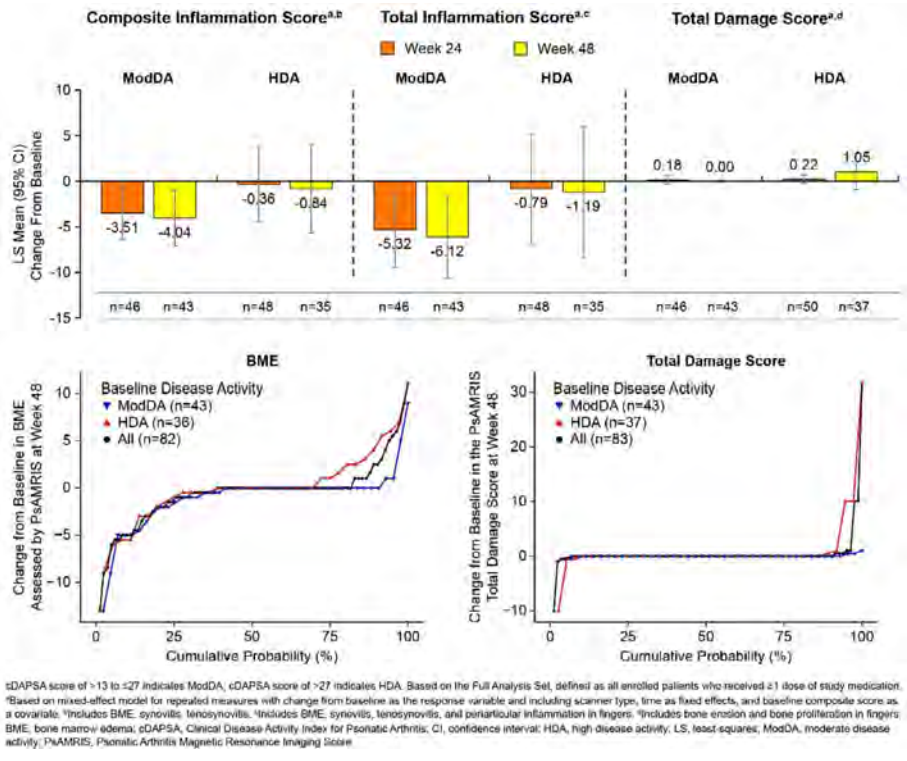
Session Time: 4:00PM–5:30PM

Background/Purpose: PsA is characterized by inflammatory arthritis, enthesitis, dactylitis, and spondylitis. Apremilast (APR) is an oral immunomodulating phosphodiesterase-4 inhibitor approved for the treatment of PsA. Here, we evaluate the efficacy of APR 30 mg BID on inflammation measured by a dedicated MRI of the hand.



Change From Baseline in Imaging and Clinical Efficacy Endpoints Following Treatment With Apremilast

Methods: MOSAIC (NCT03783026) was a phase 4, multicenter, single-arm, open-label study in patients (pts) with active PsA (≥3 months but ≤5 years since diagnosis, meeting CASPAR criteria) evaluating APR as monotherapy or in combination with stable MTX. Pts were treated with APR for 48 weeks (wk) and had contrast-enhanced MRI of the hand performed at



cDAPSA score of >13 to ≤27 indicates ModDA, cDAPSA score of >27 indicates HDA. Based on the Full Analysis Set, defined as all enrolled patients who received ≥1 dose of study medication. [a]Based on mixed-effect model for repeated measures with change from baseline as the response variable and including scanner type, time as fixed effects, and baseline composite score as a covariate. [b]Includes BME, synovitis, tenosynovitis. [c]Includes BME, synovitis, tenosynovitis, and periarticular inflammation in fingers. [d]Includes bone erosion and bone proliferation in fingers.
BME, bone marrow edema; cDAPSA, Clinical Disease Activity Index for Psoriatic Arthritis; CI, confidence interval; HDA, high disease activity; LS, least-squares; ModDA, moderate disease activity; PsAMRIS, Psoriatic Arthritis Magnetic Resonance Imaging Score.

Change From Baseline in Imaging Endpoints by Disease Activity Status at Baseline (Subgroup Analyses)

baseline (BL), Wk 24, and Wk 48. All images were read and adjudicated by 2 experienced readers blinded to clinical information and time of acquisition. The primary endpoint was change from BL in the composite score of hand bone marrow edema (BME), synovitis, and tenosynovitis in fingers 2–5, as assessed by the PsA MRI Score (PsAMRIS) at Wk 24. Total inflammation score, comprised of BME, synovitis, tenosynovitis, and periarticular inflammation in fingers, was also assessed. Structural progression determined by bone erosion and proliferation in fingers 2–5 was assessed by the total hand damage score. Subgroup analyses based on BL disease activity as measured by Clinical Disease Activity Index for PsA (cDAPSA) were performed for key endpoints.

Results: A total of 122 pts enrolled and received APR (mean age, 47 y; 55% female; and mean PsA duration, 1.9 y). The Full Analysis Set (FAS) included 98 pts evaluable for the primary endpoint and 94 were included in the per protocol (PP) set. The least-squares (LS) mean (95% CI) change from BL in the PsAMRIS (FAS) was -2.32 (-4.73, 0.09) at Wk 24 and -2.91 (-5.45, -0.37) at Wk 48 (**Figure 1**). In the PP set, the LS mean (95% CI) change from BL in the PsAMRIS at Wks 24 and 48 showed a significant reduction of disease activity (**Figure 1**). Significant improvements from BL were seen in total inflammation scores in the FAS (**Figure 1**). The total hand damage score showed no significant change from BL to Wk 48 (**Figure 1**). Pts also experienced significant improvements from BL in cDAPSA at Wks 24 and 48 (**Figure 1**). Subgroup analyses based on BL disease activity showed significant improvements from BL in inflammation in pts with moderate disease activity (ModDA; cDAPSA >13 to ≤27) and no significant change from BL in total damage. Though it was insignificant, pts with high disease activity (HDA; cDAPSA >27) did have improvement from BL in inflammation indices (**Figure 2**). No new safety signals were identified.

Conclusion: Pts with PsA treated with APR had improvements in both clinical indices and objective MRI indices of inflammation assessed by PsAMRIS in the target hand at Wk 24 and Wk 48, confirming an effect of APR on clinical and inflammatory manifestations of PsA. Pts with ModDA seemed to have greater improvement from BL in MRI inflammation scores than pts with HDA. No significant structural progression was observed. These results offer important insights on the effect of APR in PsA and highlight the value of using MRI and PsAMRIS as measures of inflammatory disease activity and change following treatment.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: PsA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Oligoarticular PsA can be associated with significant impact on quality of life, despite limited joint involvement. The phase 4 FOREMOST study evaluated the efficacy of apremilast (APR) in patients (pts) with limited joint involvement (defined as 2–4 swollen and 2–4 tender joints [2–8 active joints]) using a modified minimal disease activity score (MDA-Joints).

Table 1. Clinical and Quality-of-Life Outcomes at Week 16

	Sentinel[a] Joints			All Joints (Exploratory Analysis)		
	PBO n=105	APR n=203	Difference (95% CI)	PBO n=105	APR n=203	Difference (95% CI)
Primary endpoint						
MDA-Joints[b], n (%)	16.8 (16.0)	68.8 (33.9)	18.5% (8.9, 28.1) *P*=0.0008	8.3 (7.9)	43.2 (21.3)	13.6% (5.9, 21.4) *P*=0.0028[d]

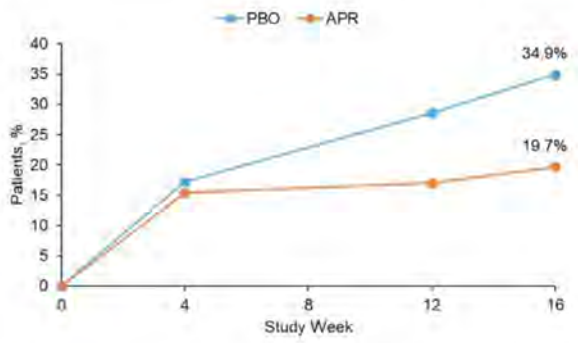
[a]In patients with pre-existing enthesopathy.
APR, apremilast; BSA, body surface area; cDAPSA, clinical disease activity index for psoriatic arthritis; HAQ-DI, health assessment questionnaire disability index; LEI, Leeds enthesitis index; PASDAS (0–10), PsA Disease Activity Score; PBO, placebo; PsAID-12 (0–10), PsA Impact of Disease; PtGA, Pt Global Assessment of Disease activity (0–100 mm VAS); SJC, swollen joint count; TJC, tender joint count; VAS, visual analog scale.

Methods: FOREMOST (NCT03747939) is a phase 4, multicenter, randomized, double-blind, placebo (PBO)-controlled, parallel-group study. Eligible pts had early disease (PsA duration ≤5 years) and limited joint involvement (>1 but ≤4 swollen and >1 but ≤4 tender joint count [SJC and TJC] of 66–68 joints assessed). Joints affected at baseline (BL) were defined as sentinel joints. Pts were randomized 2:1 to APR or PBO for 24 weeks, with an early escape at Week 16. The primary

Figure 1. Percentage of Patients Shifting From Baseline Joint Count ≤4 to Joint Count >4 Through Week 16



Percentages are calculated based on non-missing observed data at each timepoint. APR, apremilast; BL, baseline; PBO, placebo.

endpoint was the proportion of pts at Week 16 who achieved MDA-Joints (mandating SJC ≤1 and TJC ≤1 and 3/5 alternate items). Secondary endpoints assessed at Week 16 included the proportion of pts achieving Clinical Disease Activity in Psoriatic Arthritis (cDAPSA) remission (REM, ≤4) or low disease activity (LDA, >4 to ≤13), Patient's Global Assessment of Disease Activity (PtGA) ≤20, patient assessment of pain ≤15, Psoriatic Arthritis Disease Activity Score (PASDAS) good or moderate response, and change from BL in Psoriatic Arthritis Impact of Disease 12-item (PsAID-12). Exploratory analyses were performed for all joints and posthoc analyses were conducted in pts with 2–4 sentinel joints. The proportions of pts with SJC or TJC >4 over time were also assessed by pts with a BL joint count of 2–4.

Results: Of 308 pts randomized (APR: n=203; PBO: n=105), mean PsA duration was 9.9 (SD 10.2) months, mean age was 50.9 (SD 12.5) years, and 39.9% of pts were using a csDMARD. In the overall population, MDA-Joints response (primary endpoint, based on sentinel joints) was achieved by significantly more pts with APR (33.9%) vs PBO (16.0%) at Week 16 (P=0.0008) (**Table 1**). Additionally, significantly greater proportions of pts achieved secondary endpoints with APR vs PBO at Week 16 (**Table 1**). Clinical characteristics were similar between pts with ≤4 joints and >4 joints involved at BL (**-Table 2**). A total of 268 (87%) patients had ≤4 active joints at BL. In a post hoc analysis, similar MDA-Joints response rates were seen in pts with 2–4 joints (APR: 34.4%, PBO: 17.2%) vs the overall study population at Week 16. In pts with 2–4 joints involved at BL, there was an increase in the proportions of pts who switched to a joint count >4 through Week 16 among those receiving PBO but not among those receiving APR (**Figure 1**). No new safety signals were identified.

Conclusion: FOREMOST is the first global randomized controlled trial studying early oligoarticular PsA. In this study, better disease control is achievable with APR, with twice the MDA-Joint response compared with PBO at 16 weeks. A higher percentage of pts with BL joint count ≤4 shifted to a joint count of >4 with PBO vs APR.

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment II: PsA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: JAK-inhibitors (JAKi) are increasingly being prescribed to treat various inflammatory conditions, including psoriatic arthritis (PsA). While the understanding of JAKi efficacy and safety in rheumatoid arthritis is progressing, it remains less developed for PsA. The purpose of this study was to evaluate the profile of PsA patients to whom JAKi are prescribed, in a large multi-country real-world collaboration (JAK-pot).

Methods: Patients with a diagnosis of PsA, treated with either JAKi, TNF-inhibitors (TNFi) or bDMARDs with other modes of action (OMA) were included from 10 registers in which JAKi were prescribed for PsA. Treatment-courses were included only since JAKi became available in each country. We used standard descriptive statistics to evaluate patient-, disease-, and treatment characteristics across treatment groups, and across registers for JAKi only. We plotted crude retention rates for each treatment group.

Results: Among the 11,939 treatment courses considered (Table 1), 582 were JAKi, mainly tofacitinib (67%) and upadacitinib (27%), and to a lesser extent baricitinib (6%). Patients initiating JAKi tended to have more difficult to treat disease, defined as longer disease duration (> 9 years), older age, more prior bDMARD experience (52% with 3 or more previous bDMARDs), and more concomitant glucocorticoids. JAKi patient characteristics were consistent across countries (Table 2), despite varying use of specific JAKi agents, tofacitinib use ranging from 36 to 100% and upadacitinib from 0 to 64%. Crude drug retention at 1 year was 65% for JAKi was (Figure 1), which was significantly lower than for OMA (74%) and TNFi (77%).

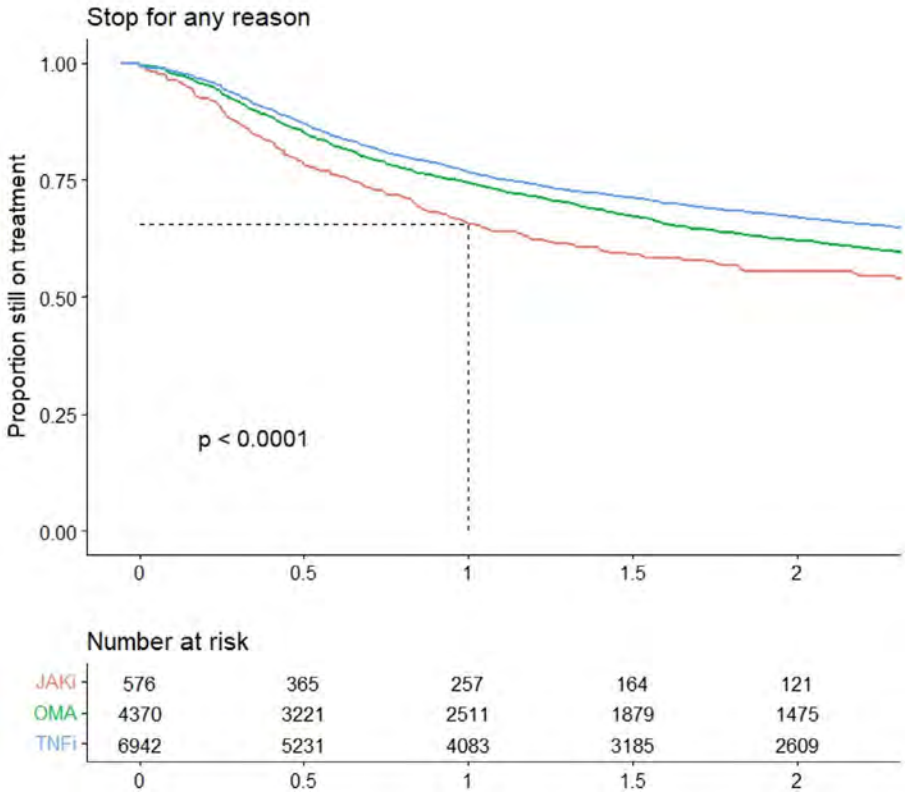

Figure 1: Crude drug retention rates

Conclusion: Unadjusted drug retention rates for second line therapies in PsA patients suggest lower drug maintenance of JAKi compared to OMA and TNFi. However, it is likely that these results are largely driven by the severity of the disease of patients on JAKi compared to patients on other treatments. Adjusted analyses are needed when evaluating the real-life effectiveness and safety of JAKi for PsA patients.

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Omics

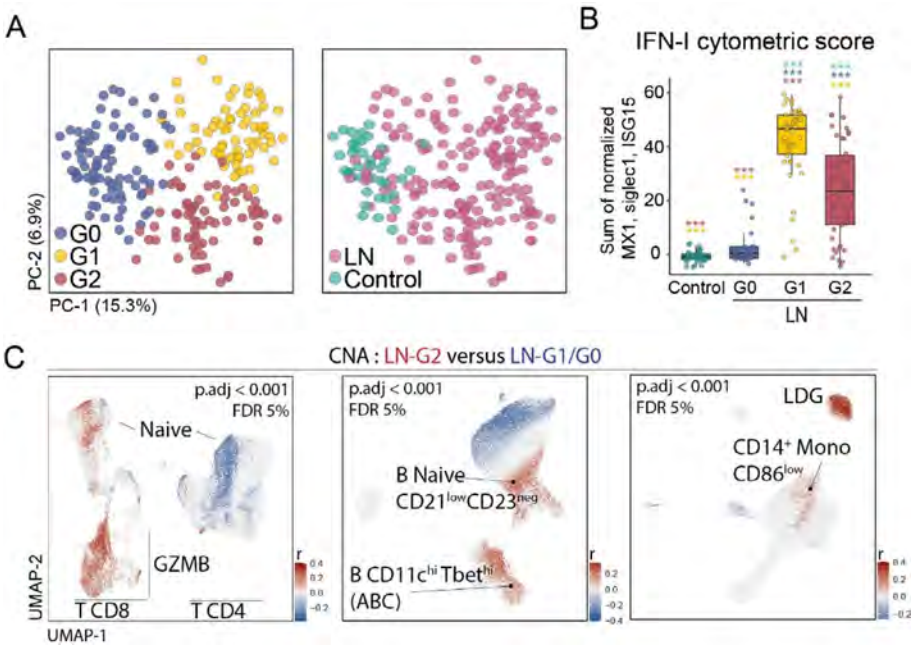
Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

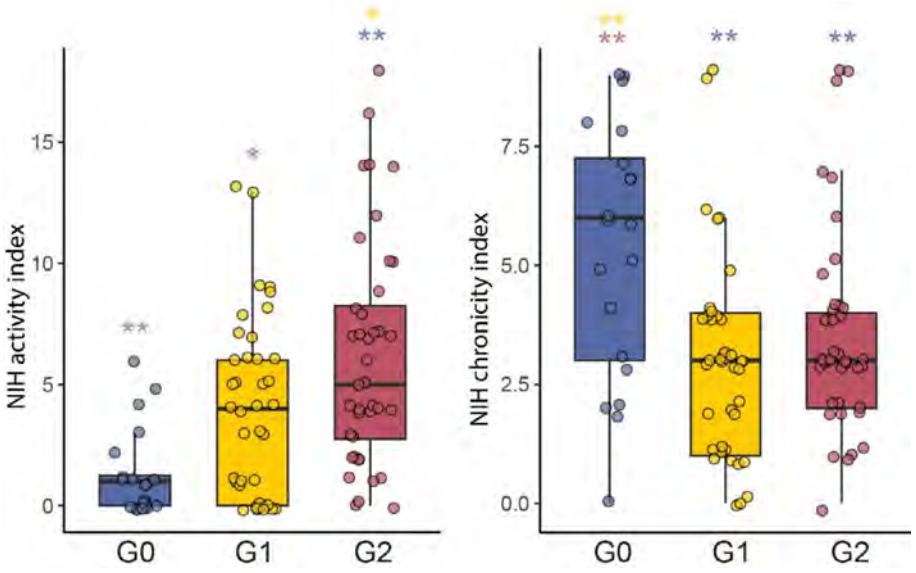
Background/Purpose: Patients with lupus nephritis (LN) have variable responses to standard-of-care therapy, and a third of patients with class III, IV, or V show a progressive decline in kidney function. Identifying distinct inflammatory processes associated with LN using non-invasive tools may improve treatment targeting. Here, we aimed to identify subgroups of LN patients that differ in systemic immune activity and to evaluate their relationship to kidney pathology.

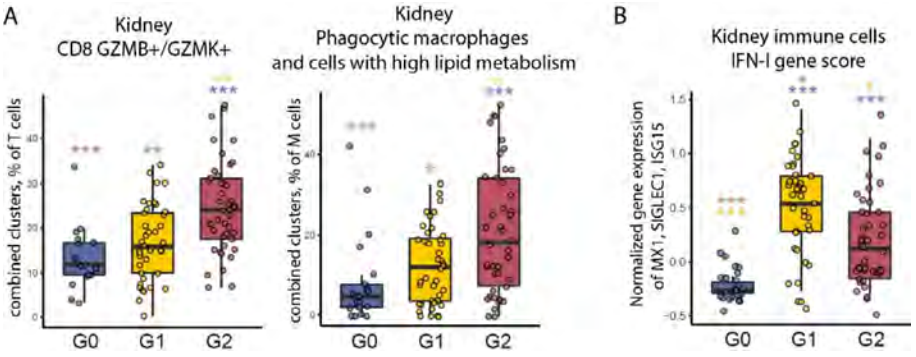
Methods: Mass cytometry using four 48-marker panels was applied to characterize peripheral blood mononuclear cells from 140 patients with active, biopsy-proven proliferative (class III or IV +/- V, n=98) or membranous (class V, n=42) nephritis and 40 healthy controls in the Accelerated Medicine Partnership RA/SLE Network Phase II study. K-means clustering was used to stratify patients based on the proportions of 55 immune cell subsets defined using B cell-, T cell-, myeloid cell-, and NK cell-focused panels.

Results: Unsupervised analysis of all samples identified 3 patient subgroups based on blood immunophenotypes (Figure 1A). The first group (G0) included all controls and 20% LN patients; the two others (G1, G2) included only LN patients. A cytometric IFN-I score, based on MX1, siglec1 and ISG15 expression, was significantly different between the three groups; G0-LN patients had comparable scores to controls and G1 displayed the highest values (Figure 1B). G2 membership was driven by an increased proportion of $GZMB^{+}$ $GZMK^{+/-}$ CD8 T cells, plus increased $CD86^{dim}$ monocytes and



activated B cells including CD11c^{hi} cells (Figure 1C). G2 was associated with higher histologic activity scores, whereas G0 had higher chronicity scores, even after controlling for race, corticoid dose, immunosuppressant use, and previous history of renal biopsy (Figure 2). Complete renal response (CR), determined at 1 year in patients with baseline urine protein-creatinine ratio $\geq$ 1, was more frequent in G2 than in G0/G1 LN patients, independently of history of previous renal biopsy (CR in G2 = 15 [41%] vs others = 9 [18%]; OR [95%CI] = 3.9 [1.3,12.5]; p.adj = 0.02). Finally, we asked whether the composition of immune cell infiltrates in the kidney, evaluated by scRNA-seq of kidney biopsies, differed between the 3 blood-defined subgroups. G2 patients had kidney T cell infiltrates enriched in GZMB^{+}/GZMK^{+} CD8 T cell subsets and in myeloid cells with an activated and phagocytic profile compared to G0/G1 patients. In contrast, G1 patients showed the highest expression of IFN-I gene signature across the groups, consistent with the pattern seen in blood (Figure 3).





Conclusion: Blood immunophenotyping identified 3 groups of LN patients with different patterns of immune cell infiltration and likelihood of response to treatment. Cytometric profiles distinguished patients with a signature involving activated CD8 T cells, CD11c^{hi} B cells and activated myeloid cells (G2) from those with the highest IFN scores (G1). Patients with increased blood and kidney CD8 GZMB^{+}GZMK$^{+/-}$ cells (G2) had increased renal activity scores at baseline and a higher likelihood of response at 1 year.

Transcriptomic Analysis of the Impact of Iberdomide on Patients with SLE

Prathyusha Bachali[1], Shimon Korish[2], Yanhua Hu[3], Peter Schafer[4], Amrie Grammer[1] and **Peter Lipsky**[1], [1]AMPEL BioSolutions, Charlottesville, VA, [2]Bristol Myers Squibb, Summit, NJ, [3]Bristol Myers Squibb, Princeton, NJ, [4]Bristol Myers Squibb, Belle Mead, NJ

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Omics
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Iberdomide is a high affinity cereblon ligand that promotes ubiquitylation and proteasomal degradation of Ikaros (IKZF1) and Aiolos (IKZF3) transcription factors and, thereby altering specific aspects of immune responsiveness. Iberdomide has been shown to be efficacious in a randomized controlled trial in patients with generalized SLE (NCT03161483) and to be specifically effective in patients with high baseline expression of the interferon gene signature (IGS)[1,2]. The current analysis sought to identify the profile of gene expression abnormalities in SLE patients responsive to iberdomide and the impact of the agent on gene expression abnormalities.

Methods: Baseline whole blood samples from 276 female SLE patients from the phase 2b iberdomide trial were utilized for this analysis. These patients had a >/= 6 month history of SLE and disease activity determined by SLEDAI-2K >/=6. Patients were randomized to placebo, or one of three doses of iberdomide (0.15, 0.3 or 0.45 mg once daily). Clinical response was determined by the SLE Responder Index 4 (SRI-4) at 24 weeks. RNAseq was performed and analyzed by Gene Set Variation Analysis (GSVA) using 32 informative gene modules and K-means clustering.

Results: Whole blood K-means clustering of the GSVA scores yielded 5 subsets of patients (Figure 1). Subset A had the fewest molecular abnormalities, whereas Subset E had the most disturbances in immune function, including enrichments in the IGS, immunoproteasome, IL-1/ inflammasome pathway, and neutrophil/granulocyte genes and lymphopenia. Clusters B-D had intermediate degrees of abnormal enrichment in specific gene modules. Cluster C had high IGS, immunoproteasome, plasma cells/Ig chains, and IL-23 complex genes, but no lymphopenia. No differences were noted between the

Figure1: KMeans clustering of GSVA scores from baseline gene expression profiles effectively identifies 5 subsets of SLE patients.

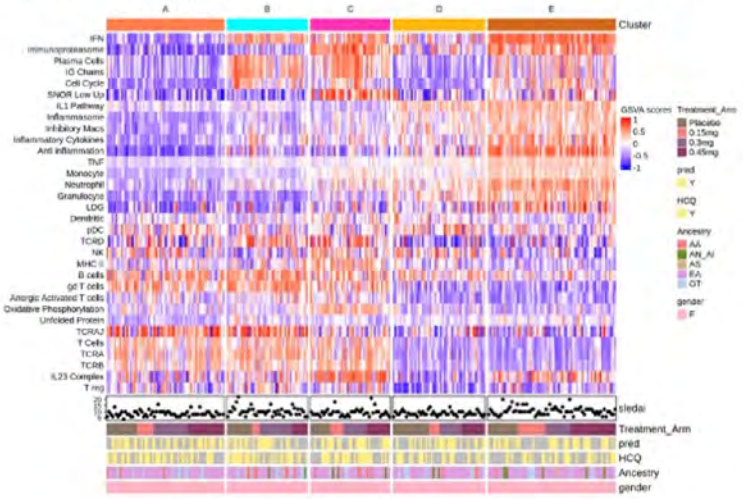

Figure 2. Clinical responses of patients in subsets defined by gene expression profiles. Responses to Iberdomide are significantly different from those to placebo in subsets C and E (p=0.002, Fishers Exact test).

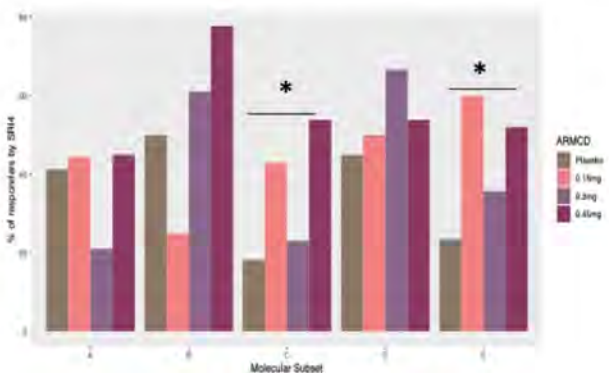

subsets with regard to steroid or hydroxychloroquine use, and differed only modestly in disease activity as measured by SLEDAI-2K, anti-DNA and Compelemnt C3and C4. Significant clinical responses to iberdomide were confined to subsets C and E (Figure 2). Effect sizes of responses in these groups ranged between 20-30%. Other subsets had higher placebo responses and no additional response to iberdomide. Treatment with iberdomide resulted in significant decreases in the B cell, plasma cell and interferon signatures and increases in the Treg signature (Figure 3).

Conclusion: K-means clustering of GSVA scores from baseline samples of the iberdomide trial successfully clustered patients into subsets that exhibited differences in response to iberdomide treatment, with the greatest responses observed in patients with the highest IGS, immunoproteasome, plasma cell, inflammasome, and IL-23 pathways. Treatment with iberdomide altered gene expression profiles in a manner consistent with the known action of the agent. Gene expression based subsetting may be useful to enrich trials for responsive patients and monitor the impact of therapy.

Figure3. Longitudinal analysis of lupus samples in subset C reveals significant decrease in IFN, B cells, Immunoproteasome and an increase in T reg and Unfolded Protein Response signatures. 3a) GSVA scores of lupus samples from subset C across baseline, week4, week12, and week24 were visualized using ComplexHeatmap in R.3b) Hedges' g effect sizes of process and cellular gene modules for week4, week12, and week24 compared to baseline in patients treated with Placebo, and three doses of Iberdomide were calculated. The heatmap visualizes the increased gene expression (> 0) in red and decreased gene expression (< 0) in blue. Welch's t-test p values are referred by * p < 0.05, ** p < 0.01, *** p < 0.001, **** p < 0.0001

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Omics

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The G1 and G2 risk variants (RVs) in Apolipoprotein L1 (APOL1) associate with CKD and may contribute to poorer outcomes for African American (AA) patients with lupus nephritis (LN). While the pathogenetic mechanism for APOL1 related CKD remains unknown, most studies focus on glomerular injury. This study leveraged the multi-center LN AMP to evaluate APOL1 RV associated clinical phenotypes and identify whether these genetic variants influence the transcriptomic landscape in kidney cells.

Methods: LN patients were consecutively enrolled in AMP at the time of a clinically indicated renal biopsy and followed for one year. Dissociated biopsies were passed through a droplet-based single-cell RNA sequencing (scRNAseq) pipeline that included quality control of sequenced libraries. Genotypes for APOL1 RVs were identified by sanger sequencing for all AA patients enrolled with available DNA.

Results: In total, 104 AA patients were genotyped; 47 (45.2%) carried zero APOL1 RVs, 45 (43.3%) one RV, and 12 (11.5%) two RVs. RVs did not associate with baseline anti-dsDNA or complement levels, biopsy class/activity/chronicity, GFR or proteinuria (Fig. 1A-G). While there was a trend toward decreased GFR at one year by gene variant dosage, there was no association with changes in proteinuria (Fig. 1F-H). ScRNAseq yielded 88383 high quality cells in patients with zero RVs (n=30), 72288 one RV (n=28), and 28694 two RVs (n=11) spanning nine parenchymal cluster types (Fig. 2A). Independent of

genotype, APOL1 expression was highest in podocyte, endothelial and ascending thin limb (ATL) cells (Fig. 2B). Median APOL1 expression was significantly higher in cells with one or two RVs in the ATL cluster but this association was not seen in podocytes or endothelial cells (Fig. 2C). Single cell pathway analysis revealed that the ATL cluster demonstrated greater pathway level variation between cells with two RVs vs zero than any other cluster, with the most distinguishing related to interferon signaling (increased), antigen presentation (increased), and mitochondrial function (decreased) (Fig. 2D). The ATL damage associated gene, lipocalin-2 (LCN2), was expressed at significantly higher levels in cells carrying two RVs (Fig. 2E). Likewise, the proportion of ATL cells double positive for APOL1 and LCN2 was higher in patients with two RVs (Fig. 2F). While it did not reach significance, the percentage of ATL cells expressing APOL1 more strongly correlated with eGFR and tubular atrophy on biopsy histology among patients with two RVs compared to those carrying zero or one RV (Fig. 3A-F).

A

Genetic Risk	Lupus Nephritis N (%)
G1/G2 Risk Variant Number	
0	47 (45.2)
1	45 (43.3)
2	12 (11.5)
APOL1 Genotype	
G0G0	47 (45.2)
G0G1	30 (28.8)
G0G2	15 (14.4)
G1G1	1 (0.96)
G1G2	10 (9.6)
G2G2	1 (0.96)

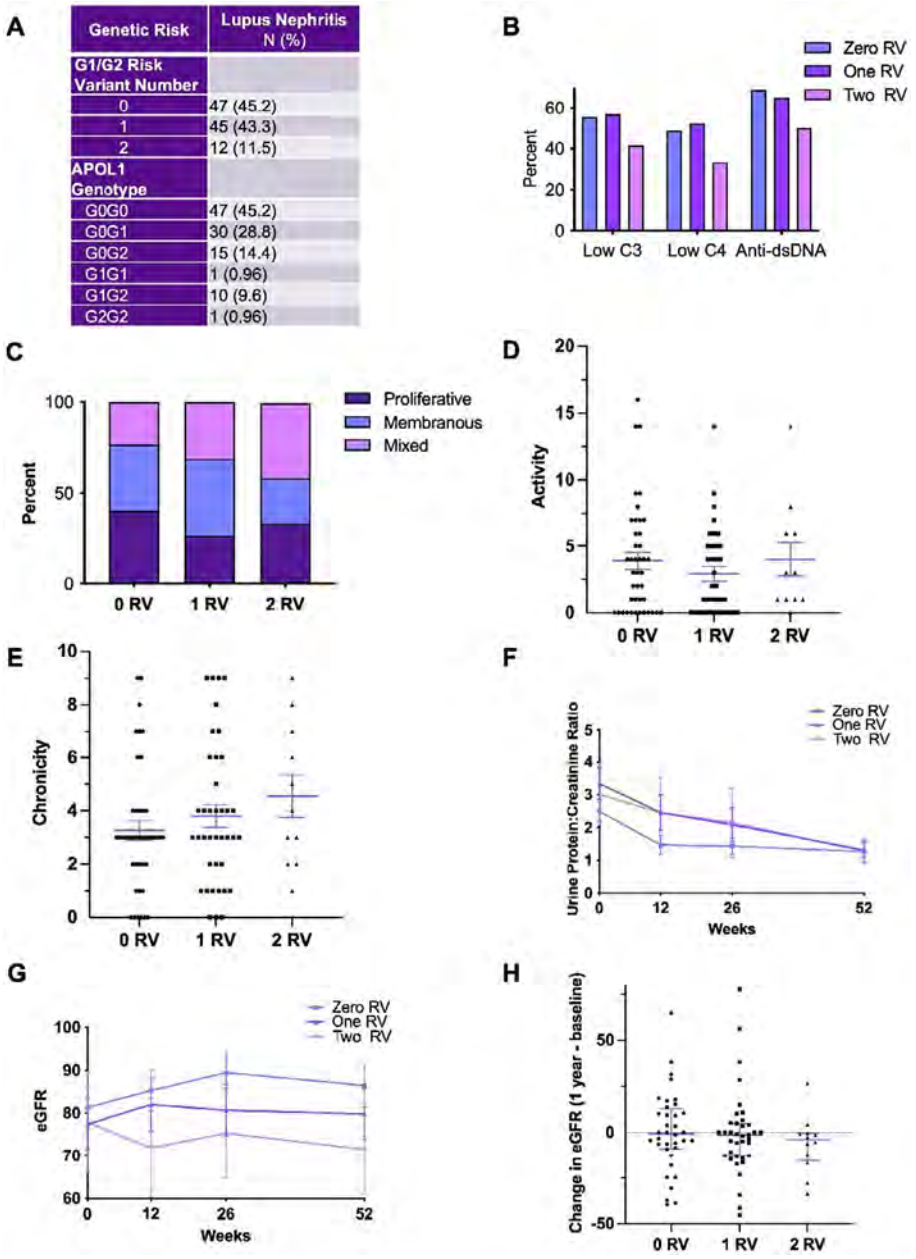

Figure 1: (A) Frequency of patients with zero, one, or two APOL1 risk variants and APOL1 genotypes. (B) Percent of patients with low C3, low C4, and positive anti-dsDNA by RV number. (C) Stacked barplot showing percent of patients with proliferative, membranous, or mixed biopsy class by RV number. (D) NIH biopsy activity index by RV number. (E) NIH biopsy chronicity index by RV number. (F) Urine protein:creatinine ratio by RV number at 0, 12, 26, and 52 weeks. (G) Estimated glomerular filtration rate (eGFR) by RV number at 0, 12, 26 and 52 weeks. (H) Change in eGFR (1 year -baseline) by RV number.

Conclusion: APOL1 RVs associated with decreased GFR but not proteinuria suggesting that current clinical indicators of LN severity may not appropriately prognosticate patients carrying APOL1 RVs and that the use of routine genotyping in the clinical setting may better risk stratify AA patients with LN. The scRNAseq data revealed that ATL cells likely express APOL1 and that this may be relevant to progressive kidney dysfunction over time. This highlights the potential for a previously unrecognized extraglomerular injury in AA SLE patients carrying APOL1 RVs providing a novel future direction for understanding APOL1 toxicity and translation to clinical trials.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Omics

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Much of our understanding of systemic lupus erythematosus (SLE) immunopathogenesis is derived from gene profiling studies, where core pathways such as neutrophil dysregulation and uncontrolled type I interferon (IFN) production by plasmacytoid dendritic cells (pDCs) have been identified. However, gene signatures found in whole blood may not reflect those in the tissues, thus potentially overlooking key drivers of disease activity and pathogenesis. While gene expression is commonly used as a proxy for protein abundance, significant discordance can exist between transcript and protein levels. We hypothesized that multidimensional blood profiling could identify new biology and reveal key molecular signatures that underlie distinct SLE pathologies.

Methods: Whole blood samples from 87 patients with mild to moderate SLE and 48 matched healthy controls were analyzed (discovery cohort). To ensure robustness of data, samples from an independent cohort of 43 patients and 52 healthy cohorts were also analyzed (validation cohort). All samples and data were collected after obtaining informed consent. Whole blood gene expression, serum proteins, autoantibodies, and immune cell assessments were collected with longitudinal clinical data. Statistical analyses were carried out in R v. 3.5.1. All data were made available in an interactive SLE Immune Atlas.

Results: We identified three protein signatures relating to interferon (IFN) signaling, granulocyte activation, and immune cell priming (IAI, GRN, and ICP) that significantly associated with disease status and unique organ-specific manifestations in SLE patients. Type I IFN activity (21-IFNGS) was present in 69.0% of patients, the IAI, GRN, and ICP signatures were present in 52.9%, 35.6%, and 42.5% of patients, respectively. While the IAI and GRN signatures correlated with transcripts, no strong gene correlates of the ICP signature were found. The ICP signature featured proteins associated with antigen presenting cells and kidney injury and correlated with proteinuria ($p=1.1E^{-3}$), decreased GFR (p=5.0E–7), and active nephritis (p=0.044). The ICP signature was predictive of damage accrual as measured by the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) over a 6-year follow-up (RR= 1.92, 95% CI 1.41–2.67). The ICP-positive patients were more likely to exhibit worsening in the renal, pulmonary, ocular and skin domains of SDI.

Conclusion: Our analyses identified a previously uncharacterized ICP protein signature enriched in patients with renal involvement, predictive of disease worsening and organ damage over time. Prospective studies would be useful to confirm the ability of the ICP signature to identify patients in need of therapeutic intervention to prevent increased risk for damage accrual.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Omics

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

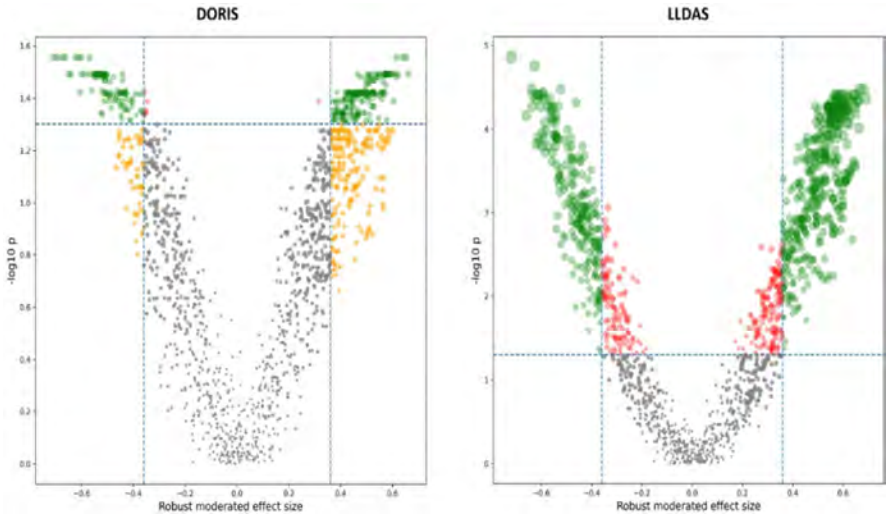

Figure 1. Volcano plot in DORIS and LLDAS subjects. Volcano plot of Reactome pathways in DORIS (left panel) or LLDAS patients (right panel). The horizontal dashed line indicates the log-transformed false-discovery rate probability threshold (q=0.05) for the moderated t-test statistic; the vertical dashed lines indicate the moderated robust effect size threshold (|dr|=0.36). Significant pathways for both conditions are highlighted in green. DORIS, definition of remission in systemic lupus erythematosus; LLDAS, lupus low disease activity state.

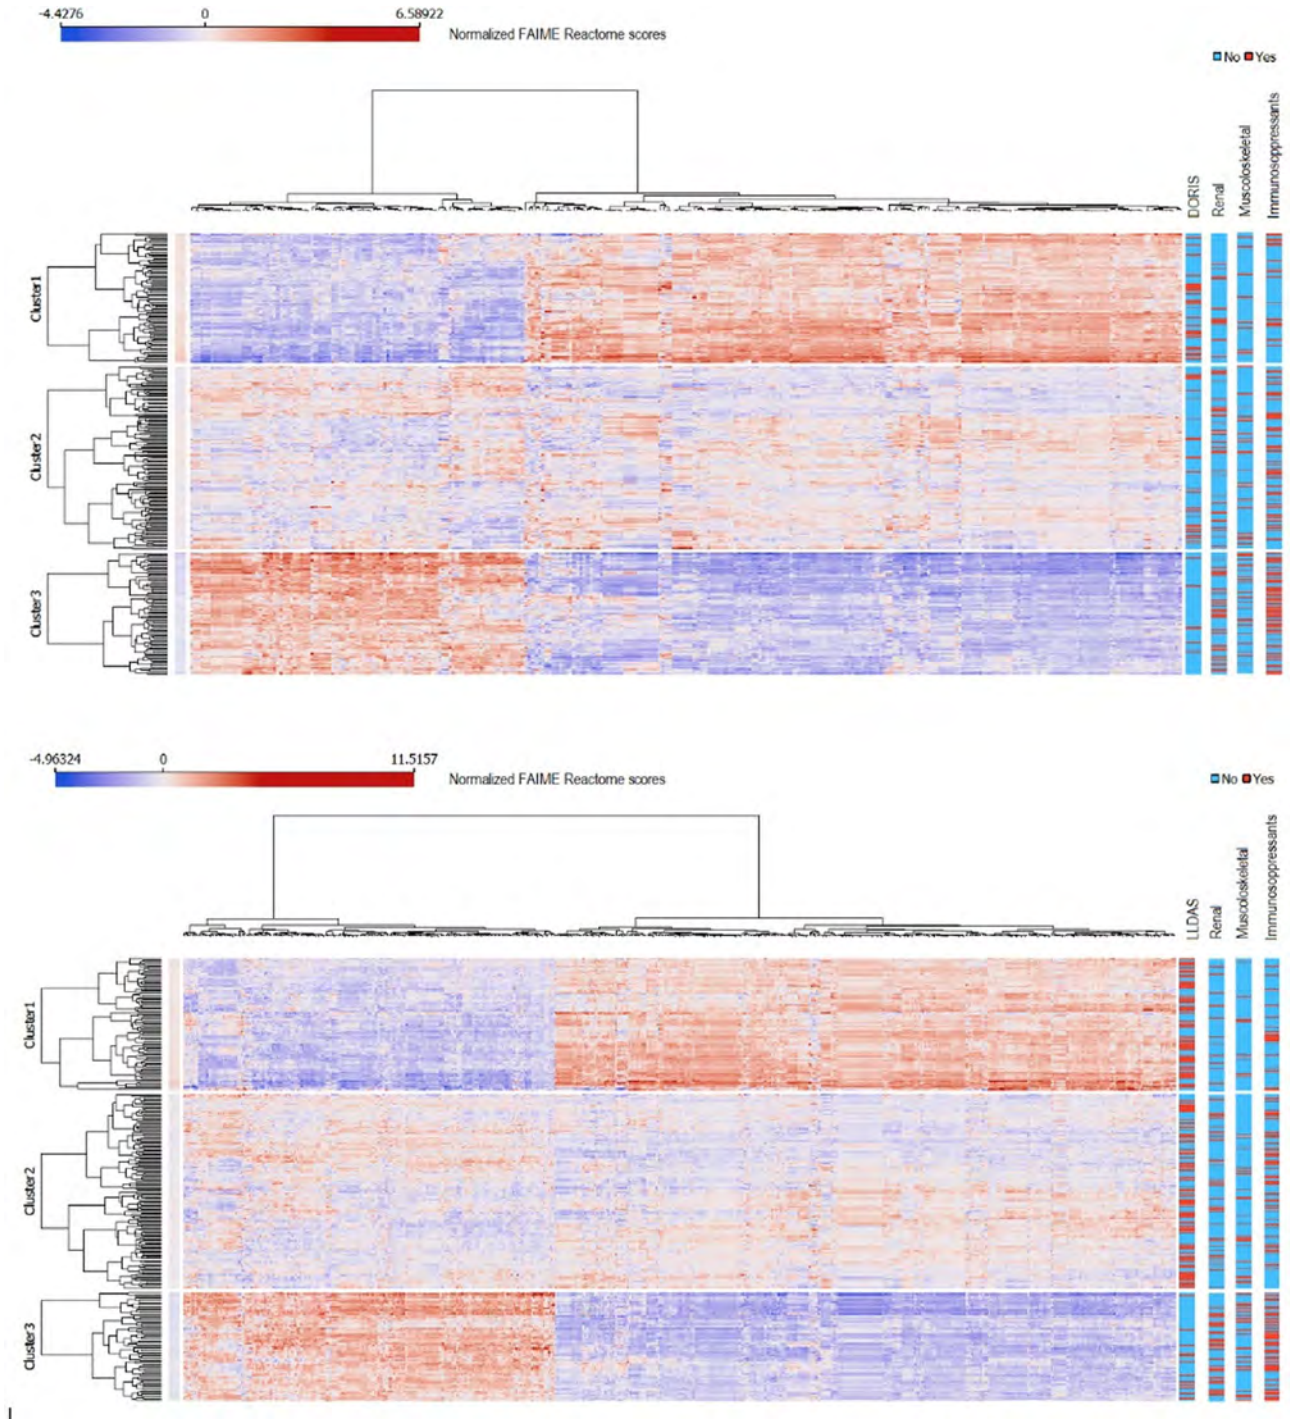

Figure 2. Clusters of Reactome individualized pathways. Individualized Reactome pathways after clustering of selected features associated with DORIS remission (top panel) or LLDAS (bottom panel). The bars to the right illustrate the distribution of relevant clinical features across clusters. DORIS, definitions of remission in systemic lupus erythematosus; LLDAS, lupus low disease activity state. Cluster1, DORIS/LLDAS cluster; Cluster2, mixed cluster; Cluster3, non-remission/non-LLDAS cluster.

Background/Purpose: Treating to remission or lupus low disease activity state (LLDAS) are conceptual frameworks for the management of SLE, but the biological milieus underlying these states have yet to be explored. We aimed at determining differentially expressed pathways (DEPs) between remission and non-remission state as well as between LLDAS and non-LLDAS.

Methods: Patients with SLE from the PRECISESADS project (NTC02890121) were stratified into patients fulfilling and not fulfilling the criteria of (i) DORIS remission, (ii) LLDAS, and (iii) LLDAS after exclusion of remission attainers. None of the patients had been treated with cyclophosphamide within 6 months or depletive therapies within 12 months from baseline.

Results: We had available data from 321 patients; 17.4% were in DORIS remission and 40.8% were in LLDAS; 28.3% of non-remission patients were in LLDAS. A total of 1465 unique Reactome pathways were selected for analysis. Overall, 288 pathways differed significantly between DORIS remitters and non-remitters with an FDR-corrected p (q)< 0.05 and a

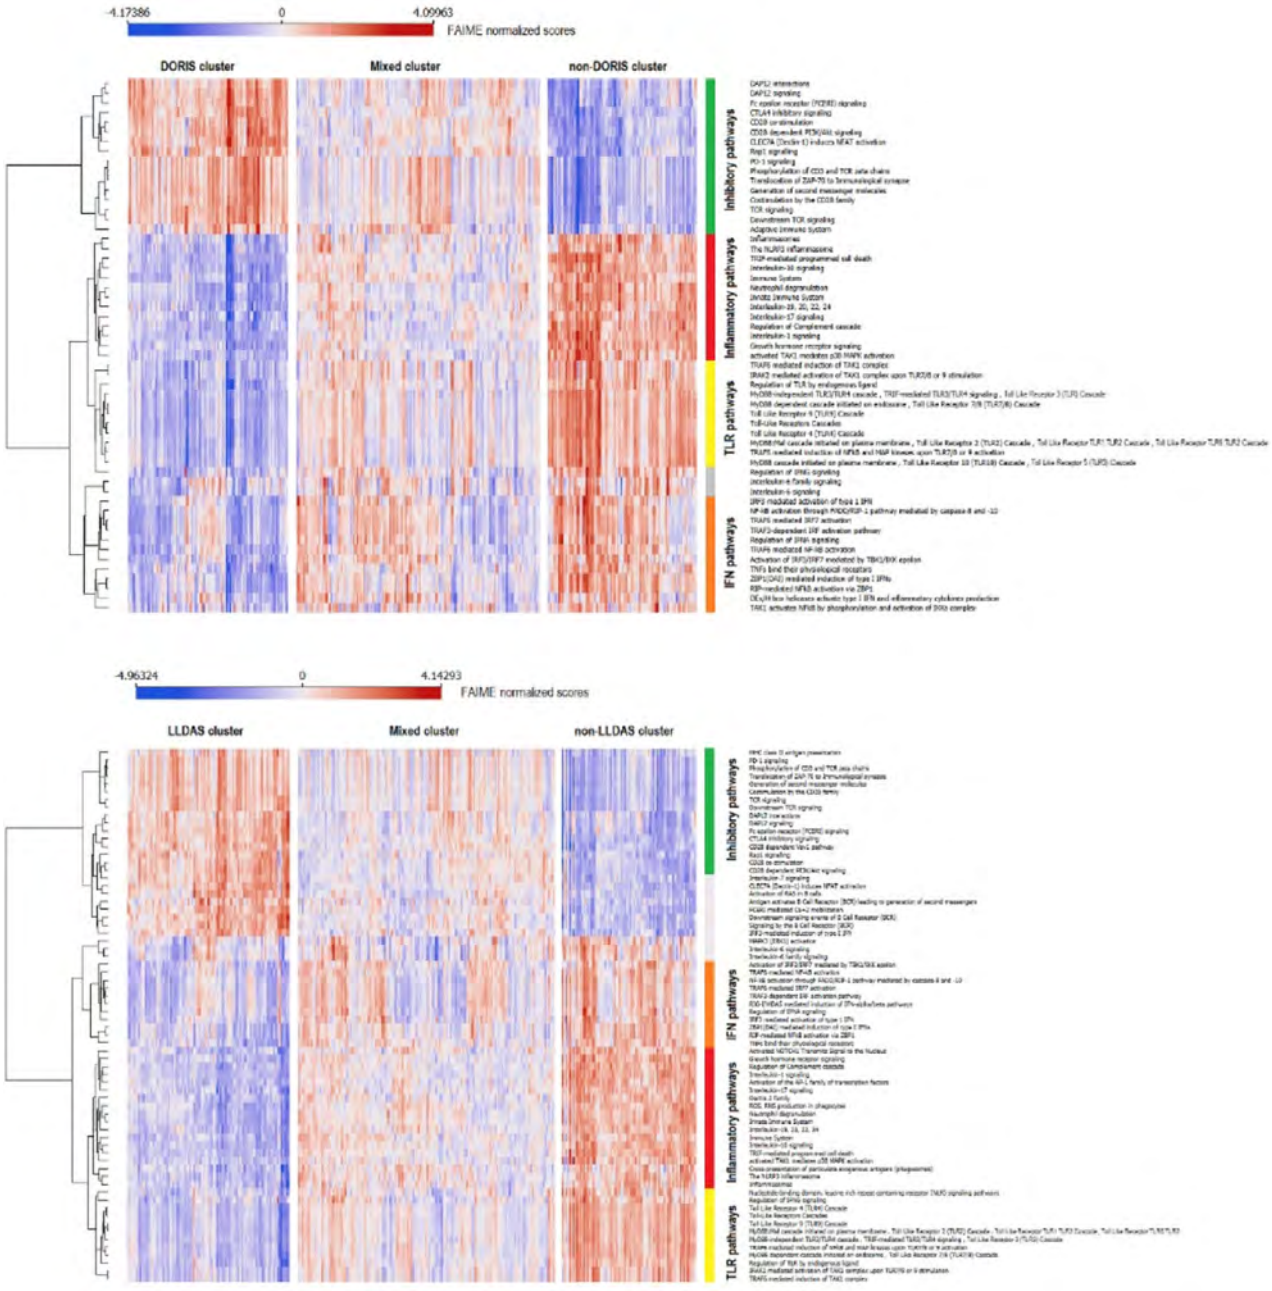

Figure 3. Immune system Rectome pathways according to biological clusters and main function. Distribution of individualized immune system Rectome pathways in DORIS (top panel) and LLDAS (bottom panel). The colored bars represent manual annotation according to the main functions of each pathway cluster, with green denoting pathways with inhibitory function on the immune system, red denoting inflammasome/inflammatory pathways enriched in cytokines, yellow denoting toll-like receptor (TLR) and related functions, orange denoting interferon (IFN) pathways, and grey denoting mixed, interleukin (IL)-6, B cells, or other pathways. DORIS, definitions of remission in systemic lupus erythematosus; LLDAS, lupus low disease activity state.

robust effect size (*dr*)≥0.36; of those, 97 were downregulated and 191 upregulated in DORIS remitters. Clustering of significant pathways yielded 3 distinct groups of patients. Accordingly, 604 pathways differed significantly ($q< 0.05$ and $dr\geq 0.36$) in LLDAS vs. non-LLDAS patients; 226 pathways were downregulated and 378 upregulated in patients in LLDAS. After clustering, 3 distinct groups could be identified (separation of classes among clusters, $\chi^2=25.3$; $p< 0.001$). In both cases, the 3 clusters were characterized by differential serological, musculoskeletal and renal activity, as well as use of immunosuppressants. Analysis of adjacent levels of disease activity using forward difference coding in linear regression models showed no DEPs between patients in DORIS remission compared with patients in LLDAS after suppression of the remitting patients. By contrast, 662 DEPs were documented between patients in LLDAS after suppression of the remitting patients and non-LLDAS patients.

Conclusion: We demonstrated for the first time molecular signaling pathways distinguishing remission/LLDAS from active SLE. Remission/LLDAS was associated with reversal of biological processes related to SLE pathogenesis, and processes linked to specific clinical manifestations. While DEP clustering by DORIS remission better grouped patients than clustering by LLDAS, substantiating the conceptual testimonial of remission being the ultimate treatment goal in SLE, the lack of substantial pathway differentiation between the two states justifies LLDAS as an acceptable goal from a biological perspective when remission is not achievable. The study revealed potentiality of existing drugs that could be repurposed to treat SLE and important pathways underlying active SLE whose modulation could aid attainment of remission. Among those, TLR cascades, BTK activity, the CTLA-4-related inhibitory signaling, and the NLRP3 inflammasome pathway were of particular interest.

High-throughput Proteomics Identities a Spectrum of Novel Serum Biomarkers of Lupus Nephritis

Huihua Ding, Yiwei Shen, Min Dai and Nan Shen, Shanghai Jiao Tong University School of Medicine, Shanghai, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Omics
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Navigating the molecular complexity of lupus nephritis (LN), a heterogeneous autoimmune disorder, poses challenges to biomarker discovery. This study addresses these challenges through an integrative approach, combining high-throughput proteomics and curated clinical samples from diverse LN states and subtypes. Our goal is to identify novel biomarkers, enhancing our understanding of LN and informing personalized treatments.

Methods: Proximity extension immunoassay (PEA, Olink) was used to evaluate the serum levels of inflammation related proteins using Explore 384-plex panel in the cohort of 80 SLE patients, including 64 active LN patients with concurrent renal biopsies and 16 active SLE patients without renal involvement at the baseline, as well as 8 age-and sex- matched healthy

controls (HCs) (Table 1). Ontological and interrelationship analyses between proteins were performed by GEO, KEGG and String analyses, to interpret the high-throughput proteomic data.

Results: Among the 368 molecules analyzed, 193 differentially expressed serum protein signatures were identified by the comparative analysis between SLE patients and HCs including 144 increased and 49 decreased molecules in SLE patients compared to HCs **(Figure 1A-E)**. The Gene Ontology (GO) analysis was performed to enrich the primary biological processes **(Figure 1F)**. Further comparative analysis was performed in the 80 SLE patients to identify novel biomarkers for kidney damage. There were 130 differentially expressed proteins between LN patients and non-LN SLE patients **(Figure 1G-I)**. The top biological processes were enriched in cytokine-mediated signaling pathway, cellular response to cytokine stimulus, response to cytokine and cell surface receptor signaling pathway **(Figure 1J)**. MCODE module screening using String software identified two clusters among the differential expressed proteins **(Figure 1K)**. Importantly, for the 64 biopsy-proven LN patients, 30 circulating proteins were found significantly altered between proliferative LN (III±V and IV±V) and membranous LN (V) patients **(Figure 1L-N)**. The GO analysis demonstrated osteoclast differentiation, collagen-activated signaling pathway, myeloid cell differentiation and hemopoiesis were enriched in the differential proteins **(Figure 1O)**. Venn diagram was performed to illustrate the distribution of total differential expressed proteins of the three comparasion sets **(Figure 1P)**.

Table 1. Demographic and clinical characteristics of study subjects (n=88).

Session Title: Abstracts: Systemic Sclerosis & Related Disorders II: Clinical Research

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Systemic sclerosis (SSc) associated pre-capillary pulmonary hypertension (precapPH) is a severe condition that requires prompt treatment. Although immunosuppressants (IMS) are standard of care for treating interstitial lung disease (ILD) and diffuse skin fibrosis (dcSSc), their effect on SSc-precapPH remains unclear. We aimed to test whether IMS affect morbidity and mortality in SSc-precapPH in the EUSTAR cohort.

Table 1. Characteristics of the study population and divided according to exposure to immunosuppressants (IMS)

Death, n(%)	307 (41)	148 (39)	159 (42)
PrecapPH worsening, n(%)	387 (54)	177 (48)	210 (58)

Methods: SSc-precapPH patients (mPAP≥ 21 mmHg, PWP≤15 mmHg, PVR≥2 WU) with at least 3 months follow-up were eligible. IMS included csDMARDS (prednisone ≥10 mg/day, cyclophosphamide, mycophenolate mofetil, azathioprine, methotrexate) and targeted therapies (abatacept, rituximab, tocilizumab, TNFi, JAKi), administered after the diagnostic right heart catheterization. The WHO precapPH class was categorized into WHO group 1 (no ILD), mild WHO group 3 (ILD and forced vital capacity – FVC ≥70%) and severe WHO group 3 (ILD and FVC< 70%).

The morbidity-mortality outcome was defined by the occurrence of either death or precapPH worsening (one of 6MWD decrease≥15%, worsening of NYHA class, onset of right heart failure, additional PAH medication, starting iv/sc prostanoids, lung transplantation, atrial septostomy). Death and precapPH worsening were also separate secondary outcomes.

We evaluated the association between IMS and time to first event with a multiple Cox regression model. Baseline covariates were chosen by expert opinion, including the WHO precapPH class, SSc-related risk factors for mortality (e.g., sex, age, dcSSc, renal crisis, digital ulcers), reasons for IMS use (e.g., muscle weakness, joint synovitis), and PAH parameters for risk

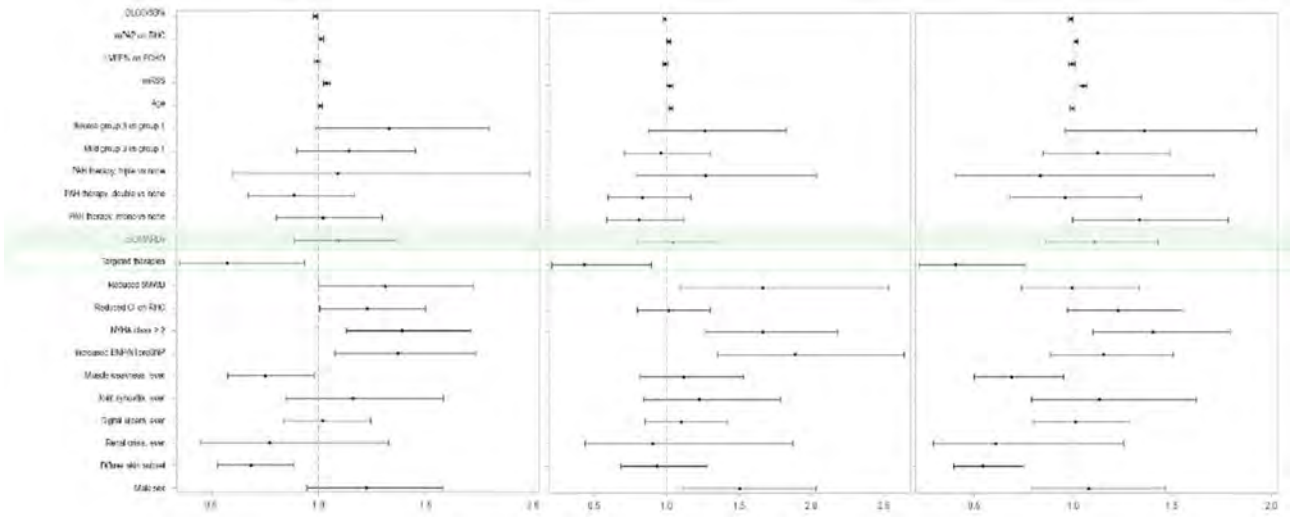

Figure 1. Effect of targeted therapies and csDMARDS on risk of morbidity-mortaliy (left panel), only death (central panel) and only worsening of precapPH (right panel).

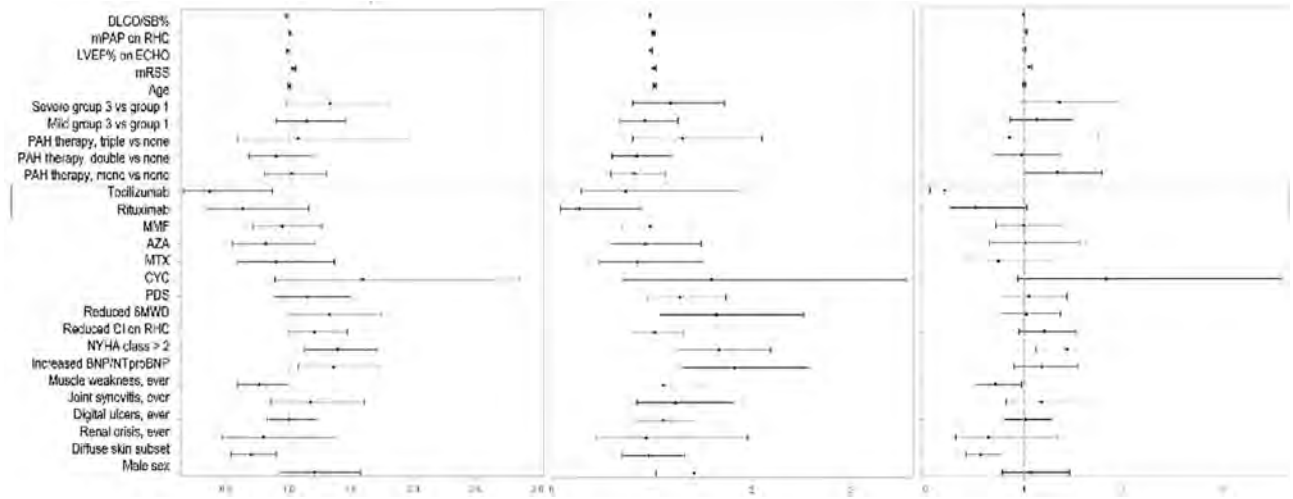

Figure 1. Effect of specific immunosuppressive compounds on risk of morbidity-mortaliy (left panel), only death (central panel) and only worsening of precapPH (right panel).

stratification (mPAP, BNP/NTproBNP, NYHA class, cardiac index, 6MWD). IMS and pulmonary arterial hypertension (PAH) drugs were treated as time-dependent variables.

Results: 755 SSc-precapPH patients were included (18% males, age 63±11 years, disease duration 11±9 years, 29% dcSSc, 60% ILD on HRCT). 377 (50%) received IMS [365 (47%) csDMARDs, 68 (9%) targeted therapies]. Patients receiving IMS had more frequently ILD, dcSSc, joint and muscle involvement (Table 1).

In median follow-up of 2.9 years, 70% of patients developed a morbidity-mortality event. While overall IMS exposure did not associate with outcomes, targeted therapies were associated with reduced risk of morbidity-mortality [HR 0.58, 95% CI 0.35-0.95, p=0.03] and both secondary outcomes [death, HR 0.43, 95% CI 0.21-0.89, p=0.02; precapPH worsening, HR 0.41, 95% CI 0.22-0.78, p< 0.01] – Figure 1.

When looking at specific targeted therapies, tocilizumab showed a risk reduction for morbidity-mortality and precapPH worsening (HR 0.37, 95% CI 0.17-0.81, p=0.02 and HR 0.19, 95% CI 0.05-0.78, p=0.02, respectively), while rituximab for death (HR 0.28, 95% CI 0.08-0.93, p=0.04) with a trend for precapPH worsening (HR 0.51, 95% CI 0.25-1.04, p=0.06) – Figure 2.

Conclusion: In this large EUSTAR SSc-precapPH cohort, targeted therapies are associated with reduced risk of mortality and precapPH worsening, which is independent from WHO group and other confounders. The impact of targeted therapies on long-term outcomes should be further explored in RCTs.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders II: Clinical Research
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Although prevalence of interstitial lung disease (ILD) in systemic sclerosis (SSc) and associated risk factors are established, less is known about its incidence and the risk factors associated with new onset of ILD following a negative baseline. We aimed to (1) estimate the annual incidence of ILD and (2) identify risk factors for new onset of ILD in baseline negative patients.

Methods: SSc patients classified according to the 2013 ACR/EULAR criteria from the EUSTAR database, with absence of ILD on high resolution computed tomography (HRCT) at baseline and having at least 1 follow-up visit were included. Patients with pulmonary arterial hypertension diagnosed by right heart catheterization were excluded. Based on follow-up HRCT, our population was divided into patients with new onset of ILD (incident group) and patients who remained ILD negative (negative group). Incidence of SSc-ILD was calculated as rate per 1000 person-years and presented starting from the first visit at the center. Prediction models were built to identify risk factors for ILD onset, with logistic regression for the 1-year and Cox regression for the long-term observation. Known predictors of new onset of ILD were chosen as covariates from previous literature and based on expert opinion.

Results: We identified 5336 ILD negative patients at baseline. New onset of ILD occurred in 1080 (20.2%) cases with median of 3.8 (IQR 1.6-7.3) years follow-up.

Table 1. Baseline characteristics of SSc patients according to the ILD onset at follow up.

	Incident ILD group (n=1080)	Negative ILD group (n=4256)	P value between groups
Age, years, mean±SD	52±14	53±14	**<0.01**
Male sex, n (%)	194 (18.1)	546 (12.8)	**<0.01**
Disease duration, years, mean±SD	6±7	7±7	**<0.01**
Caucasian, n (%)	1013 (93.8)	4057 (95.3)	**<0.05**
Smoking, ever, n (%)	68 (6.3)	409 (9.6)	**<0.01**
Diffuse SSc, n (%)	486 (45)	1023 (24)	**<0.01**
Modified Rodnan skin score, median (IQR)	7 (4-13)	4 (2-9)	**<0.01**
Digital ulcers, ever, n (%)	180 (16.7)	577 (13.6)	0.17
Pitting scars on fingertips, n (%)	351 (32.5)	1184 (27.8)	**<0.01**
Arthritis, ever, n (%)	19 (1.8)	133 (3.1)	**<0.01**
Tendon friction rubs, n (%)	74 (6.9)	192 (4.5)	**<0.01**
Muscle weakness, n (%)	167 (15.5)	503 (11.8)	**<0.01**
Esophageal symptoms, n (%)	650 (60.2)	2521 (59.2)	0.21
Dyspnea NYHA stage≥2, n (%)	357 (33.1)	1258 (29.6)	**0.02**
Scleroderma pattern on NVC, n (%)	1020 (94.6)	3915 (92)	**0.06**
DLCO/SB, % predicted, mean±SD	71±18	75±17	**<0.01**
FVC, % predicted, mean±SD	94±18	99±18	**<0.01**
Anticentromere/ Anti-topoisomerase I/ Anti-RNApolymerase III/ Anti-Pm-Scl / none of above or other, n (%)	339 (31.4) / 497 (46.0) / 32 (3) / 12 (1.1) 200 (18.5)	2459 (57.8) / 780 (18.3) / 170 (4) / 40 (0.9) / 807 (19)	**<0.01**
Increased inflammatory markers, n (%)	186 (17.2)	495 (11.6)	**<0.01**
Haemoglobin, g/dl, mean±SD	12.3±1.5	12.5±2.5	0.61
Immunosuppressants ever, n (%)	267/373 (71.6)	796/1221 (65.2)	**0.02**

The overall ILD incidence rate was 74.0 (95% CI: 68.5-79.5) per 1000 person-years. There was a continuous detection of new onset of ILD during the longitudinal observation, up to 10 years from baseline (incidence rate 54.5-82.9 per 1000 person-years; Figure 1). The baseline characteristics of incident and negative groups are shown in Table 1.

In the analysis of long-term incidence, new onset of ILD was independently predicted by dyspnea NYHA stage≥2 (HR 1.23, 95% CI1.08-1.40), male sex (HR 1.28, 95% CI1.10-1.50), age (HR 1.02, 95% CI 1.01-1.02), DLCO/SB% (HR 0.99, 95% CI 0.98-0.99), elevated inflammatory markers (HR 1.59, 95% CI 1.35-1.87), haemoglobin level (HR 0.94, 95% CI: 0.90-0.98), anti-topoisomerase I antibody (HR 2.15, 95% CI 1.82-2.53), anti-centromere antibody (HR 0.47, 95% CI0.39-0.56,) and digital ulcers ever (HR1.77, 95% CI: 1.49-2.08) (Figure 2 A). Surprisingly, the incidence of new onset of ILD was independent from disease duration.

The analysis for 1-year incidence included 13339 yearly follow-ups from 4067 baseline negative patients. All risk factors of new onset of ILD identified in the analysis of long-term incidence analysis, except for digital ulcers ever, were confirmed (Figure 2B).

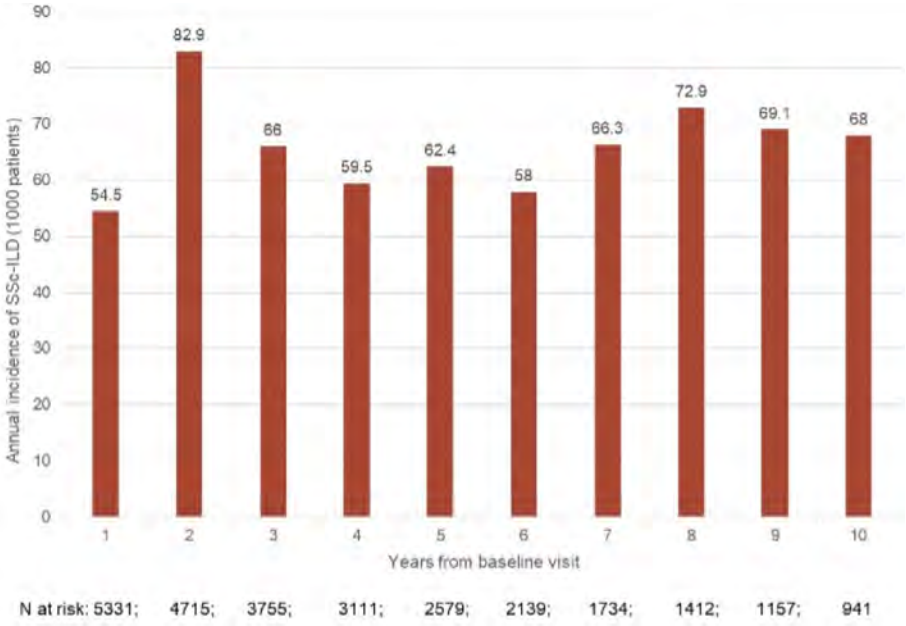

Figure 1. Annual incidence rate of new onset of ILD per 1000 patients from the baseline visit.

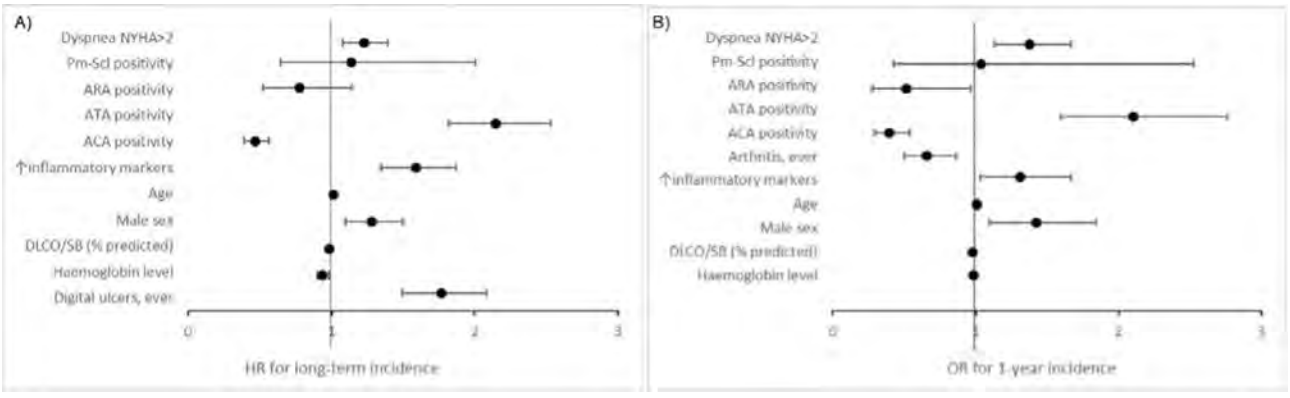

Figure 2. Prediction models of new onset of ILD for long-term (A) and 1-year observation (B).

When exposure to immunosuppressants was forced into the two models, this was not retained as a protective factor.

Conclusion: ILD can appear at any time after SSc diagnosis, with similar incidence during the disease course. We identified risk factors for new onset of ILD both at 1-year and long-term follow-up. Therefore, SSc patients should be screened following a negative baseline HRCT.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Systemic Sclerosis & Related Disorders II: Clinical Research

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The 2022 ESC/ERS Guidelines recommend upfront combination therapy for low- and intermediate-risk, and triple therapy for high-risk patients with systemic sclerosis (SSc)-associated pulmonary arterial hypertension (PAH).[1] There is no treatment recommendation for patients with mean pulmonary arterial pressure (mPAP) 21-24 mmHg and pulmonary vascular resistance (PVR) 2-3 WU. We aimed to assess treatment regimens, risk stratification, and mortality according to mPAP and PVR thresholds.

Table: Demographic and clinical characteristics by mPAP and PVR thresholds

	All PAH, n=367	mPAP 21-24 mmHg and/or PVR 2-3 WU, n=109	mPAP ≥25 mmHg and PVR ≥3 WU, n=258
Age, years (SD)	66±11	66±11	65±11
Female sex, n (%)	318 (87)	95 (87)	223 (86)
Time non-Raynaud to RHC, years (Q1-Q3)	9.5 (3.3-16.3)	12.5 (4.3-20.4)	8.5 (2.7-14.9)
Limited cutaneous subtype, n (%)	297 (83)	83 (77)	214 (86)
Anti-centromere Ab,n (%)	234 (64)	63 (58)	171 (67)
Digital ulcers, n (%)	146 (40)	45 (42)	101 (31)
Limited ILD<20%, n (%)	164 (45)	44 (40)	120 (47)
WHO-FC III and IV, n (%)	180 (50)	30 (28)	150 (59)
6MWD, meters (SD)	343±128	400±110	321±128
NT-proBNP, ng/L (Q1-Q3)	567 (207-1485)	275 (136-569)	880 (286-2120)
FVC, % (SD)	91±21	95±20	89±21
DLCO, % (SD)	45±15	53±15	42±13
mPAP, mmHg (SD)	35±12	24±3	40±11
PAWP, mmHg (SD)	9±3	10±3	9±3
PVR, WU (SD)	6.3±4.3	2.9±1.2	7.7±4.4
Risk groups			
• Low risk, n (%)	62 (24)	34 (44)	28 (16)
• Intermediate-low risk, n (%)	82 (32)	30 (38)	52 (29)
• Intermediate-high risk, n (%)	78 (31)	11 (14)	67 (38)
• High risk, n (%)	33 (13)	3 (4)	30 (17)
Treatment-naïve status, n (%)	306 (86)	87 (87)	219 (86)
Upfront therapy			
1) Monotherapy	140 (39)	28 (27)	112 (44)
2) Combination therapy	77 (21)	5 (5)	72 (28)
• Dual	67 (18)	4 (4)	63 (25)
• Triple	10 (3)	1 (1)	9 (3)
3) None	143 (40)	70 (68)	73 (28)
1-, 3- and 5-year survival	92% / 79% / 66%	98% / 91% / 83%	90% / 74% / 60%

Methods: We included SSc patients from the EUSTAR database who were diagnosed with PAH by right heart catheterization (RHC) between 2001-2021 (Project Number: CP122). PAH was defined as mPAP >20 mmHg, pulmonary artery wedge pressure ≤15 mmHg, and PVR >2 WU. We excluded patients with previous PAH-specific treatment and meaningful interstitial lung disease (ILD), defined as an extent of ILD >20% on HRCT or FVC < 70% in patients with missing quantification. We stratified patients into four risk groups based on WHO-functional class (FC), six-minute walk distance (6MWD), and NT-proBNP applying the COMPERA 2.0 risk stratification.[2] Initial treatment regimens were defined as (1) upfront monotherapy with endothelin receptor antagonists, phosphodiesterase-5 inhibitors, or prostanoids; (2) upfront combination therapy; or (3) no therapy.

Survival was evaluated using Kaplan–Meier analysis and log-rank test. We assessed treatment regimens segregated by mPAP and PVR thresholds (lower thresholds: mPAP 21-24 mmHg and/or PVR 2-3 WU vs. higher thresholds: mPAP ≥25 mmHg and PVR ≥3 WU) and by risk stratification. We assessed the impact of initial treatment regimens on mortality using Cox regression adjusted for age, male sex, DLCO, mPAP and PVR thresholds, treatment-naïve status, and risk stratification.

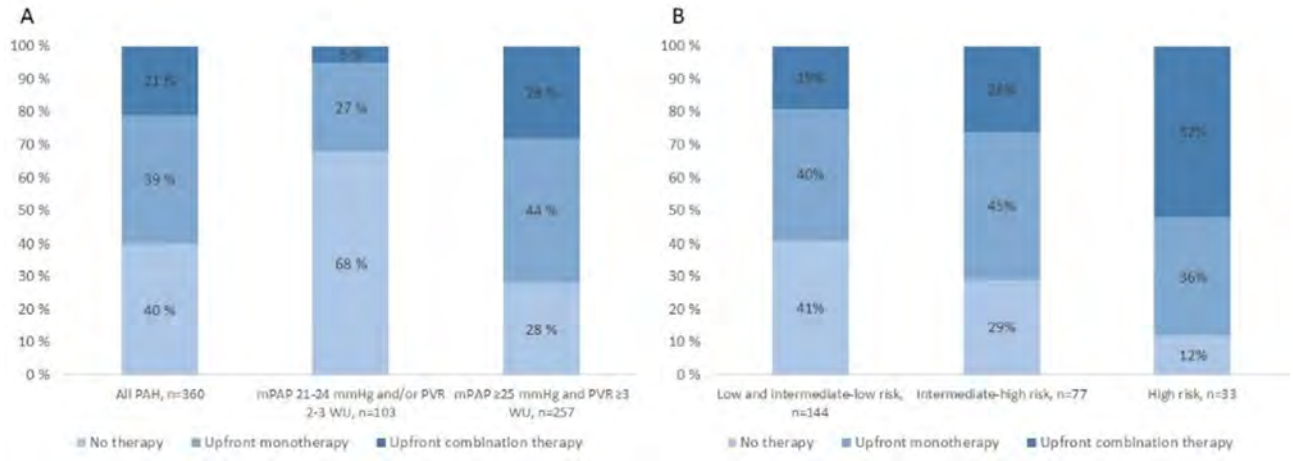

Figure 1: Proportion of patients starting upfront monotherapy, upfront combination therapy or none segregated by (A) mPAP and PVR thresholds, and (B) risk stratification

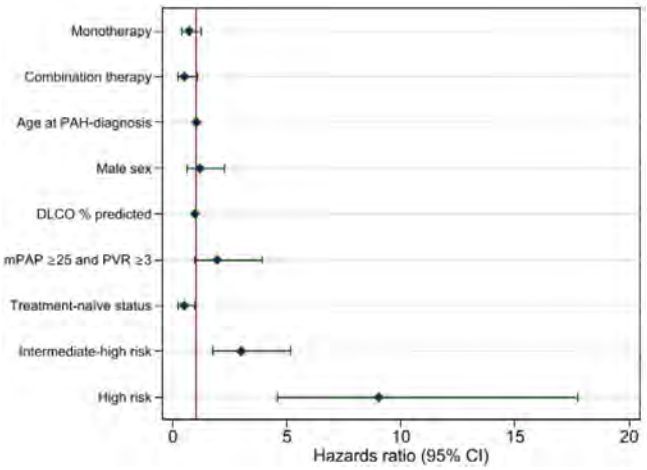

Figure 2: Impact of upfront mono- or combination therapy on mortality compared with no treatment adjusted for other risk factors in multivariable Cox regression model

Results: Of 890 patients who had RHC, 367 were eligible (table). Survival was significantly lower in the group with higher mPAP and PVR thresholds (p< 0.001) (table). The 5-year survival according to risk stratification for low-, intermediate-low, intermediate-high, and high risk was 85%, 86%, 60% and 25%, respectively.

Upfront combination therapy was used more frequently in patients with mPAP ≥25 mmHg and PVR ≥3 WU (p< 0.001) and in patients in the high-risk group (p=0.002) (fig. 1 a-b). Despite at high risk and higher thresholds, 40% of these patients did not receive any treatment (fig. 1a). In multivariable Cox regression analysis, upfront combination therapy was numerically associated with reduced mortality compared with no treatment (HR 0.50, 95% CI (0.23 - 1.09), p=0.08) (fig. 2).

Conclusion: Our study shows that survival is impaired in SSc-PAH regardless mPAP and PVR thresholds, particularly in patients at intermediate-high and high risk. Current results show a trend toward reduced mortality for upfront combination therapy, and that many patients are not treated according to guideline recommendations. We suggest considering treatment in patients with lower mPAP and PVR thresholds and a more aggressive treatment approach in patients at intermediate-high risk to increase survival over time.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Systemic Sclerosis & Related Disorders II: Clinical Research

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Autologous hematological stem cell transplantation (AHSCT) is a grade A therapy for early diffuse progressive systemic sclerosis (SSc), that has been validated in three randomized controlled trials (RCT) compared to cyclophosphamide (CYC). CYC, however, is no longer considered the gold standard therapy for SSc and does not provide long-term benefit. The efficacy of rituximab on skin and lung involvement in SSc has recently been demonstrated in an RCT, the DESIRES study. The combination of rituximab with mycophenolate mofetil (MMF) is a potential potent regimen for progressive SSc, that has not been evaluated compared to AHSCT. We retrospectively compared the outcomes of SSc patients in our cohort, fulfilling eligibility criteria for AHSCT studies, who received a combination therapy of MMF and rituximab, with patients who underwent AHSCT.

Methods: Repeated longitudinal assessments at baseline and every 6 months for 24 months, including modified Rodnan Skin Score (mRSS), forced vital capacity (FVC), and diffusing capacity of the lung for carbon monoxide (DLCO) values, were compared between groups using a linear mixed model regression. Clinical improvement (CI) was defined as a decrease in mRSS by more than 25% or an increase in FVC by more than 10%. Event-free survival (EFS) was defined as the occurrence of death or the development of persistent major organ failure (heart, lung, kidney). Hazard ratios (HRs) and 95% CIs were calculated by Cox regression.

Results: Twenty-one SSc patients in the combination group were compared to sixteen in the AHSCT group. There were no significant differences in the demographic or clinical variables, except for Nintedanib treatment (Table 1). CI at 12 months was seen in 86% of patients in the combination group, compared to 81% in the AHSCT group (p=0.7). The hazard ratio (HR) for EFS at 24 months favored the combination group (HR=0.09, 95% CI 0.009 to 0.9; P =0.04). In both groups, a statistically significant and similar increase in FVC values, but not in DLCO, was demonstrated at each time point during follow-up. The inclusion of Nintedanib usage in the mixed model did not influence these results. In both groups, there was a significant and similar reduction in mRSS at 12 and 24 months compared to baseline (figure 1).

Conclusion: In our cohort, combination therapy of MMF and rituximab compared to AHSCT in SSc patients eligible for AHSCT, resulted in similar skin and lung clinical improvement with a better safety profile after 24 months.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Systemic Sclerosis & Related Disorders II: Clinical Research

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Systemic sclerosis (SSc) is less frequent in males, but the risk of severe outcomes is higher in males than in females(1). Seven to 30% of SSc patients have cardiovascular involvement, which is associated with poor prognosis. Cardiovascular events are reported to be more frequent in male SSc patients(2). However, the cause of this sex-specific cardiovascular risk in SSc is unknown, and commonly available screening tools including echocardiography and ECG are not sensitive to detect early cardiac dysfunction in SSc(3). Objective of this longitudinal prospective study was to assess sex differences in echocardiographic characteristics. We specifically analysed whether a difference in left ventricular global longitudinal strain (LV GLS) can explain sex difference in cardiovascular outcomes in SSc, and can be applied as prognostic screening tool for cardiovascular events in SSc.

Methods: A total of 746 SSc patients from four SSc expert centers, including 628 (84%,54±13 years) women and 118 (16%,55±15 years) men, were evaluated with standard and advanced echocardiographic examinations. The independent association of the echocardiographic parameters with the combined endpoint of cardiovascular events-hospitalization/death was evaluated.

Results: Men and women with SSc showed significant differences in disease characteristics and cardiac function. After adjusting for the most important clinical characteristics (age, disease duration since Raynaud, skin involvement, interstitial lung disease (ILD), DLCO-SB % predicted, smoking), LV ejection fraction (LVEF) and diastolic function were not significantly different anymore. However, men still presented with more impaired LV GLS as compared to women (-19% (IQR-20%-[-17%]) vs.-21%(IQR:-22%-[-19%]),p< 0.001). After median follow-up of 48 months (IQR:26–80), the combined endpoint occurred in 182 patients (24%). Kaplan-Meier survival curves showed that men experienced higher cumulative rates of

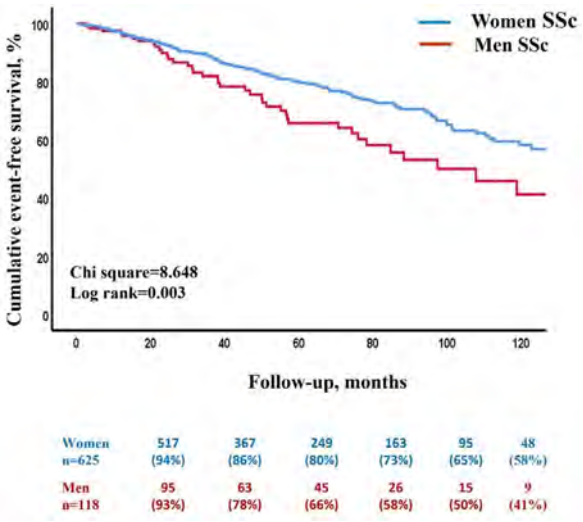

Figure 1. Survival function (for cardiovascular hospitalization/death) in women and men patients with systemic sclerosis (SSc).

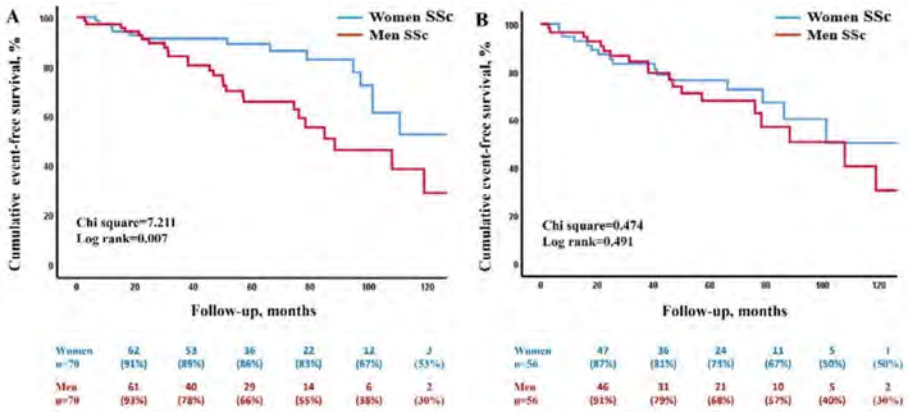

Figure 2. Survival function in women and men patients with SSc in Panel A after adjusting for age, disease duration (since Raynaud), type of SSc, lung fibrosis, DLCO-SB and NT-proBNP, in Panel B after adjusting for age, disease duration (since Raynaud), type of SSc, lung fibrosis, DLCO-SB, NT-proBNP and LV GLS.

cardiovascular events-hospitalization/death as compared to women (Chi-square 8.648; Log rank 0.003. Figure 1). When using propensity score matching to match men and women according to clinical characteristics (age, disease duration since Raynaud, subtype of SSc, ILD, DLCO-SB% predicted and NT-proBNP, n=140 patients), men still experienced higher cumulative rates of cardiovascular events/death as compared to women (Chi-square 7.211; Log rank 0.007. Figure 2A). Sex-difference in outcome disappeared when matching the groups according to the LV GLS on top of the abovementioned clinical characteristics (n=112 patients, Chi-square 0.474; Log rank 0.491, Figure 2B).

Conclusion: In SSc patients, male sex is associated with worse cardiovascular outcomes after adjusting for important clinical characteristics. LV GLS was more impaired in men as compared to women and potentially explains the sex difference in cardiovascular outcomes. Using LV GLS for early assessment of myocardial involvement may improve risk stratification and surveillance in SSc patients for both sexes.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Systemic Sclerosis & Related Disorders II: Clinical Research

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Interstitial lung disease (ILD) is a major cause of morbidity and disease-related death in systemic sclerosis (SSc). Esophageal disease is common in SSc, and micro-aspiration of gastroesophageal reflux may contribute to the pathogenesis of ILD. The aim of this study is to explore the association of erosive esophagitis (EE) determined by esophagogastroduodenoscopy (EGD) with lung function deterioration and survival in patients with SSc.

Methods: Consecutive patients presenting with symptoms of gastro-esophageal involvement who underwent EGD from 2005 to 2015 were characterized based on the occurrence of EE, following the Los Angeles criteria[1], and longitudinally evaluated. Patients with SSc-ILD were assessed over a 48-month period for pulmonary function test deterioration according to OMERACT criteria[2]. Both raw and SSc-associated mortality were documented over a ten-year period for the entire cohort. SSc patients, with or without EE, were compared though survival analysis. A competing risk survival analysis was specifically performed to investigate the association of EE with SSc-related mortality with death due to alternative causes as competing event.

Results: Of the 214 SSc patients studied, 9.8% were male, the mean age was 58.8±13.5 years, the median disease duration was 5.0 years (IQR 1.0-9.0), and the diffuse variant was present in 36.9%. Out of these patients, 33.6% had EE and 59.8% had ILD and no association was found between these two disease characteristics. Forty-nine SSc-ILD patients experienced OMERACT deterioration. EE was associated with a reduced OMERACT progression-free survival (Log-Rank p=0.015) (Fig.A) and an independently doubled risk of progression (HR 1.97, 95% CI 1.09-3.55 adjusted for age, gender, digital ulcers, disease duration, p=0.025). In the overall cohort, fifty-one deaths were reported, 37 of which were SSc-related. In the ILD group, there were a total of 27 deaths due to any cause, with 23 specifically due to SSc. EE was associated with the risk of SSc-related death in the ILD group (HR 2.08, 95% CI 1.05-5.28, Fine-Gray p=0.038) (Fig.B), but not in SSc patients without ILD.

Conclusion: In our cohort, EE represents a risk factor for functional deterioration and SSc-related long-term mortality specifically in SSc patients with ILD, supporting a detrimental role of gastro-esophageal micro-aspiration in exacerbating lung fibrosis.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Pediatric systemic lupus erythematosus (pSLE) is a multisystemic chronic autoimmune disease with high renal involvement. In SLE, neutrophil extracellular traps (NETs) are considered a potential source of antigen, leading to autoantibody production. NETs activate plasmacytoid dendritic cells to produce high levels of interferon-α, a known driver of lupus pathogenesis. NETs have also been shown to play a role in kidney pathology leading to lupus nephritis (LN).Also, low DNase activity and mutations in *DNASEIL3* have been associated with lupus. We hypothesized that NETs will be elevated in pediatric lupus and our study aims to investigate levels of circulating NETs in pSLE as compared to healthy children (pHC) and further elucidate mechanisms contributing to NET accumulation.

Methods: Plasma was obtained from 13 pSLE patients who were either treatment-naïve or not on corticosteroids at the time of enrollment and 12 pHC. Lupus disease activity was measured using SELENA-SLEDAI. ELISA and smear assay were used to detect NETs in plasma samples. DNASE1L3 concentration was measured using ELISA and DNase1L3 enzymatic activity was assayed by digestion of chromatin in purified nuclei. The ability of plasma to degrade NETs was measured using NET degradation assay.

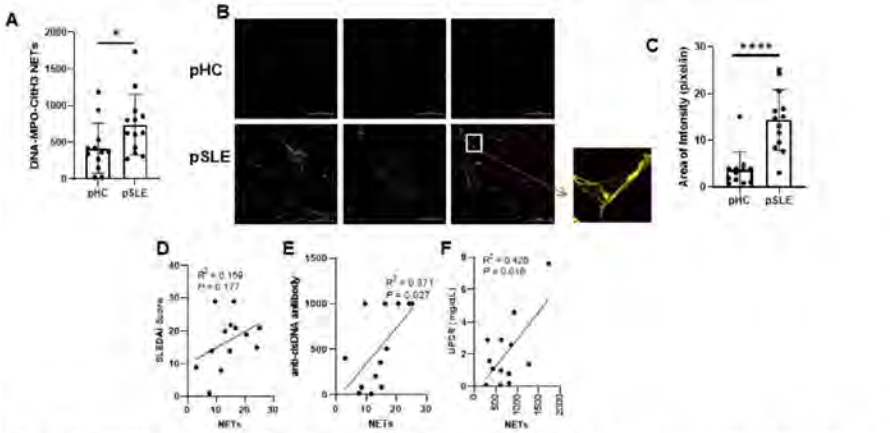

Figure 1. Increased NETs in pSLE plasma correlate with markers of disease activity. (A) ELISA detecting higher MPO-CitH3-DNA NETs in plasma of pSLE (n=13) compared to pHC (n=12). **(B)** Representative images of 3 healthy children and 3 pSLE patient plasma smears stained for MPO (green, AF488), CitH3 (red, AF594) and DAPI (blue) showing higher NETs in pSLE. **(C)** Plasma smear quantification of pHC (N=12) and pSLE (N=13) samples using ImageJ. **(D)** SELENA-SLEDAI scores demonstrated a positive slope with level of circulating NETs as detected by smear assay. Other makers of disease activity including anti-dsDNA antibody level **(E)** and UPCR **(F)** showed a strong positive correlation with circulating NETs in pSLE patients (n=13) detected by ELISA. Data are presented as mean ±SD. Statistical significance tested by unpaired parametric t test (A,C). Individual merged images represent separate donors (B). All images were taken on ZEISS Confocal M880 at 20x objective. Set scale 200 µm (B). A two-tailed correlation analysis was performed using Pearson correlation coefficients assuming Gaussian distribution (D-F).

Results: 10/13 of pSLE patients were female, with a mean of 13±4.4years, and a mean SLEDAI score of 13.8±8.1. 7/13 patients had biopsy-proven proliferative LN. Significantly higher levels of circulating NETs were found in pSLE plasma which positively correlated with measures of disease activity and anti-ds DNA titers (Figure 1). Plasma from pSLE failed to degrade NETs efficiently. Although DNASE1L3 levels were higher in pSLE patients, DNASE1L3 activity was reduced, as compared to healthy children. Moreover, higher anti-NET protective antibodies were found in pSLE plasma.

Conclusion: These data suggest that defective functional DNASE1L3 activity and increased anti-NET protective antibodies could lead to delayed clearance and accumulation of NETs in pSLE plasma.

Autoreactive B Cell Responses Are Enriched in Early-onset Oligoarticular Juvenile Idiopathic Arthritis

Claudia Harris[1], Maria Taylor[2], Ki Pui Lam[2], Indu Raman[3], Chengsong Zhu[3], Pui Lee[1], Peter Nigrovic[4], Erin Janssen[5], Jing Cui[6] and Lauren Henderson[4], [1]Division of Immunology, Boston Children's Hospital, Boston, MA, [2]Division of Immunology, Boston Children's Hospital, Boston, MA, [3]Department of Immunology, Microarray & Immune Phenotyping Core Facility, University of Texas, Southwestern Medical Center, Dallas, TX, [4]Boston Children's Hospital, Boston, MA, [5]Department of Pediatrics, Michigan Medicine, Ann Arbor, MI, [6]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A subset of children with oligoarticular juvenile idiopathic arthritis (oligo JIA) who are anti-nuclear antibody (ANA) positive are known to have dysregulated T cell-B cell interactions in affected joints. In these patients, clonally expanded T peripheral helper (Tph) cells are enriched in the synovial fluid (SF), overexpress factors associated with B cell help, and promote the differentiation of antibody-producing plasmablasts. To further evaluate B cell responses in oligo JIA, we characterized the autoantibody profile of these patients.

Methods: Paired blood and SF samples were obtained from oligo JIA patients, defined by ILAR criteria. Blood samples were also collected from pediatric controls. Plasma and SF supernatant were inputted into an autoantigen microarray platform to screen for 120 IgG and IgA autoantibodies. The net fluorescence intensity (NFI) for each antigen was calculated by subtracting the background signal. The NFI was normalized to control antibodies spiked into the arrays. Autoantigens with low signal-to-noise ratio (SNR) were excluded. The autoantibody score (Ab-score) for each autoantigen was generated by a log2 transformation using NFI and SNR. Oligo JIA patients were stratified into 3 groups based on age of disease onset and ANA status: ≤6 years, ANA+; ≤6 years, ANA-; and >6 years. ANOVA with correction for multiple comparisons was used to compare the Ab-score for each autoantigen across the study groups. R was used to generate heat maps, and statistical analysis software (SAS) was used for the statistical analysis.

Results: 23 oligo JIA and 15 pediatric controls were studied (Table 1). After quality control, results from 97 and 88 autoantigens on the IgG and IgA arrays, respectively, were retained for analysis. Compared to the plasma of controls, 57 IgG and 49 IgA autoantibodies were significantly elevated in the SF of all 3 strata of oligo JIA patients. An additional 19 IgG and

Table 1. Clinical Characteristics of the Study Subjects

Asian	1, 11%	1, 14%	0, 0%	0, 0%
Black	0, 0%	0, 0%	0, 0%	0, 0%
Other	2, 22%	0, 0%	0, 0%	0, 0%
Undisclosed	1, 11%	2, 29%	2, 29%	12, 80%
White	5, 56%	4, 57%	5, 71%	3, 20%
Hispanic Ethnicity (n, %)				
Hispanic	3, 33%	1, 14%	0, 0%	0, 0%
Non-hispanic	5, 56%	4, 57%	5, 71%	3, 20%
Undisclosed	1, 11%	2, 29%	2, 29%	12, 80%
Immunomodulatory Treatment (n, %)	0, 0%	0, 0%	0, 0%	0, 0%

32 IgA autoantibodies were significantly increased in the SF of oligo JIA patients with disease onset ≤6 years, regardless of ANA status. Fewer autoantibodies were significantly elevated in oligo JIA plasma vs. control plasma (14 IgG; 8 IgA autoantibodies), most in the ≤6 year groups. After setting a false discovery rate (FDR) of 5% to account for testing multiple autoantigens, 72 IgG and 82 IgA autoantibodies remained significantly different across the study groups. Heat maps showed that autoantibody reactivity was highest in the SF of children with early-onset disease (Figures 1-2). Directly comparing oligo JIA patients with disease onset ≤6 years (regardless of ANA status) to those who were older at initial presentation confirmed that all differentially expressed autoantibodies were higher in the patients with early-onset disease (35 IgG; 53 IgA autoantibodies in SF and 8 IgG; 36 IgA autoantibodies in plasma).

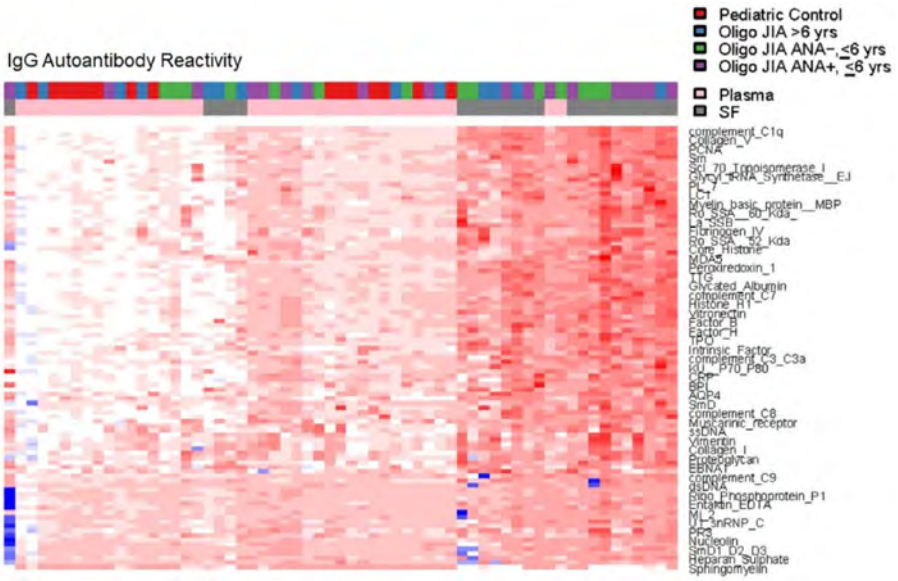

Figure 1. Heat map showing IgG Autoantibody Reactivity. Plasma and SF samples from pediatric controls and oligo JIA patients were evaluated with an autoantigen microarray. The most differentially expressed autoantibodies are depicted in the heat map. The color represents distance in standard deviations from the mean of the controls with red indicating an increase in reactivity above controls and blue indicating a decrease in reactivity compared to controls. Oligo JIA, oligoarticular juvenile idiopathic arthritis; ANA, anti-nuclear antibody; yrs, years

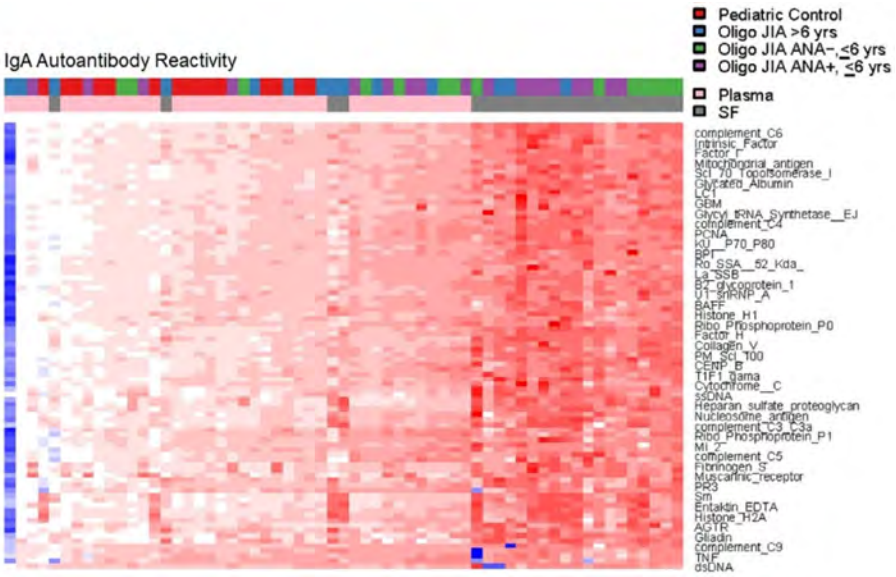

Figure 2. Heat map showing IgA Autoantibody Reactivity. Plasma and SF samples from pediatric controls and oligo JIA patients were evaluated with an autoantigen microarray. The most differentially expressed autoantibodies are depicted in the heat map. The color represents distance in standard deviations from the mean of the controls with red indicating an increase in reactivity above controls and blue indicating a decrease in reactivity compared to controls. Oligo JIA, oligoarticular juvenile idiopathic arthritis; ANA, anti-nuclear antibody; yrs, years

Conclusion: A broad array of autoantibodies were detected in the SF of oligo JIA patients. Early age at disease onset, not ANA status, was the factor most associated with the high levels of autoantibodies in SF. These findings suggest that dysregulated B cell responses in the arthritic joint are particularly prominent in oligo JIA patients who develop disease at a young age.

SF, synovial fluid; ANA, anti-nuclear antibody; JIA, juvenile idiopathic arthritis; HC, healthy control.

Background/Purpose: T peripheral helper (Tph) cells promote B cell maturation and the generation of antibodies in the inflamed joints of adults with seropositive rheumatoid arthritis (RA) and children withanti-nuclear antibody(ANA) positive oligoarticular juvenile idiopathic arthritis (oligo JIA). We recently identified a population of T cells in the synovial fluid (SF) of patients with oligo JIA that express both regulatory T (Treg) cell (FOXP3, CTLA4, GITR) and B cell-helper T cell factors (PD1, ICOS, CXCL13), which we term T peripheral regulatory (Tpr cells). We sought to determine if Tpr cells are a suppressive T cell population that may have the capacity to restrain Tph cell-B cell interactions in peripheral tissues.

Methods: Children with oligo or the closely related seronegative polyarticular JIA (ILAR criteria) provided SF samples. Healthy adults provided peripheral blood (PB) samples. PB mononuclear cells (MCs) and SFMCs were isolated by Ficoll density gradient centrifugation. Cells were stained for surface markers and then fixed and permeabilized for FOXP3 staining. Flow cytometry was used to measure FOXP3 expression in various T cell populations. For T cell-B cell co-cultures, memory B cells (Bmem; $CD19^{+}CD27^{+}IgD^{-}$) were sorted from leukocollars obtained from controls. Bmem were co-cultured with various effector T cell populations from ANA^{+}JIA patients at a ratio of 10:1 for 5 days in the presence of staphylococcal enterotoxin B (SEB). These T cell-B cell co-cultures were also performed with the addition of PB Treg cells from controls ($CD4^{+}CD25^{+}CD127^{lo}$) or autologous Tpr cells from SF ($CD4^{+}$ $CD25^{+}CD127^{lo}PD1^{int}CXCR5^{-}$) at a ratio of 1:1. After 5 days of incubation, cells were harvested and stained to determine the frequency of plasmablasts ($CD19^{+}CD27^{+}CD38^{hi}$) in the co-cultures. Study subjects with co-cultures of Tph cells and Bmem cells with less than 10% of cells in the lymphocyte gate and/or without visible lymphocyte proliferation in the FSC/SSC gate were excluded. GraphPad Prism was used for statistical analysis.

Results: 10 JIA and 10 healthy controls were studied (Table 1). FOXP3, the Treg lineage defining transcription factor, was measured in $PD1^{+}$ T cells from JIA SF by flow cytometry (Figure 1). FOXP3 levels were highest in $CD4^{+}CD25^{+}CD127^{lo}$ Treg cells with intermediate PD1 ($PD1^{int}$) expression. Thus, we identified cell surface markers to isolate viable Tpr cells ($CD4^{+}CD25^{+}CD127^{lo}PD1^{int}CXCR5^{-}$) for functional assays. To evaluate T cell-B cell interactions, we used our co-culture system to study SF samples from 5 ANA^{+} JIA patients (Figure 2). As expected, co-culture of Bmem with Tph cells ($CD4^{+}CD25^{-}PD1^{hi}CXCR5^{-}$) from JIA SF induced the production of plasmablasts. In contrast, co-culture of Bmem with Tpr cells resulted in essentially no plasmablast differentiation. Once Tpr cells were added to co-cultures of Tph and Bmem cells, they significantly reduced the frequency of plasmablasts while bulk Treg cells from control blood did not.

Conclusion: We identified a novel Treg population present in inflamed joints that expresses B cell-help factors and restrains Tph cell-B cell interactions. Further work is needed to define the effector functions of Tpr cells and determine their role in regulating inflammation in tissues.

*PBMCs from 5/10 healthy adult controls were isolated from leukocollars obtained at our institution's blood bank. Per IRB regulations, no clinical information on these individuals could be shared. In Cis SOCS1 Variants Illustrate the Precise Regulation of Interferon Signaling Needed to Prevent Autoimmunity

Yan Du[1], Evan Hsu[2], Kailey Brodeur[3], Meng Liu[4], Mindy Lo[5], Craig Platt[3] and Pui Lee[5], [1]Harvard medical school, Boston, MA, [2]Wesleyan University, Newton, MA, [3]Boston Children's Hospital, Boston, MA, [4]Southern Medical University, Boston, MA, [5]Division of Immunology, Boston Children's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic autoimmunity can be driven by monogenic or polygenic risk variants. We aimed to characterize the genetic basis of disease in a family with early-onset autoimmune manifestations including systemic lupus erythematosus (SLE), discoid lupus, and immune thrombocytopenia.

Methods: Whole exome sequencing (WES) was conducted to identify candidate variants. The impact of the identified variants was analyzed by flow cytometry, immunoprecipitation, and luciferase reporter assay in transfected 293T cells. Gene expression in peripheral blood mononuclear cells was profiled by bulk RNA sequencing and plasma cytokines were measured by proximity extension assay.

Results: We studied two siblings with early-onset systemic lupus erythematosus and immune thrombocytopenia. Mother of the probands had a history of discoid lupus and positive antinuclear antibody test. WES identified maternally inherited in cis variants (p. Pro50Leu and p.Ala76Gly) in *Suppressor of cytokine signaling 1 (SOCS1)* flanking the kinase inhibitory domain (Figure 1A). Both variants are predicted to be benign by in silico algorithms and neither variant alone affected the ability of SOCS1 to inhibit JAK-STAT1 signaling by luciferase reporter assay and flow cytometry quantification of STAT1 phosphorylation (Figure 1B,C). Immunoprecipitation studies showed that when both variants were expressed in cis, the mutant SOCS1 protein displayed decreased binding to JAK1 and reduced capacity to inhibit IFN-I signaling by ~25% compared to wildtype protein (Figure 1D,E).

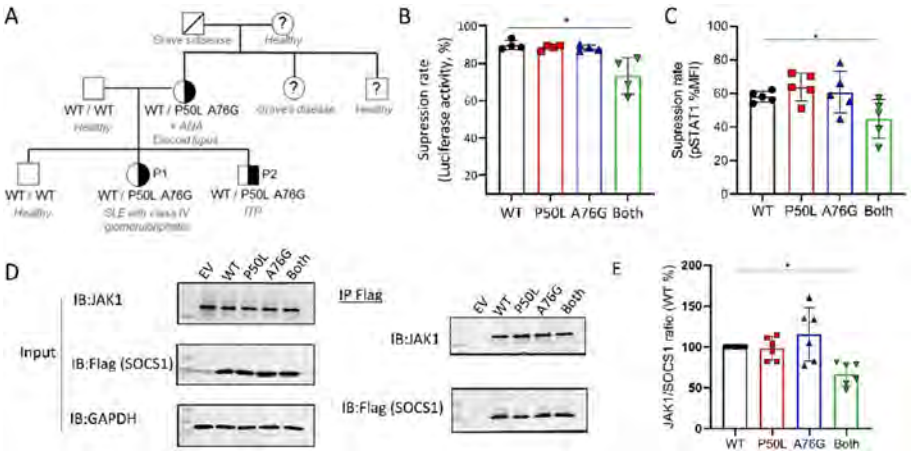

Figure 1. A) in cis SOCS1 variants in a family with multiple autoimmune manifestations. B). Suppression of IFNα2-induced luciferase activity in ISRE-luc reporter cells by ectopic expression of wildtype and mutant SOCS1. Luciferase was measured 24 hours after IFN stimulation. C) Suppression of IFNα2-induced STAT1 phosphorylation in 293T cells by ectopic expression of wildtype and mutant SOCS1. Flow cytometry for phospho-STAT1 was performed 5 minutes after IFN stimulation. D) Assessment of SOCS1-JAK1 interaction by immunoprecipitation of Flag-tagged SOCS1 and JAK1. E) Densitometry analysis of JAK1/SOCS1 ratio from 6 independent immunoprecipitation studies. * $p < 0.05$.

Supporting defective regulation of IFN-I, transcriptomic and cytokine analysis of both siblings and their mother showed increased expression of interferon-inducible genes compared to healthy controls, but less striking compared to patients with SOCS1 haploinsufficiency due to loss-of-function variants (Figure 2A,B). Peripheral blood monocytes from all three subjects further displayed increased CD169 expression and STAT1 phosphorylation upon IFN-I stimulation (Figure 2C,D).

Conclusion: Our work illustrates the critical fine-turning of IFN-I signaling by SOCS1 to prevent autoimmunity and demonstrates that a combination of variants that are individually benign may have deleterious consequences.

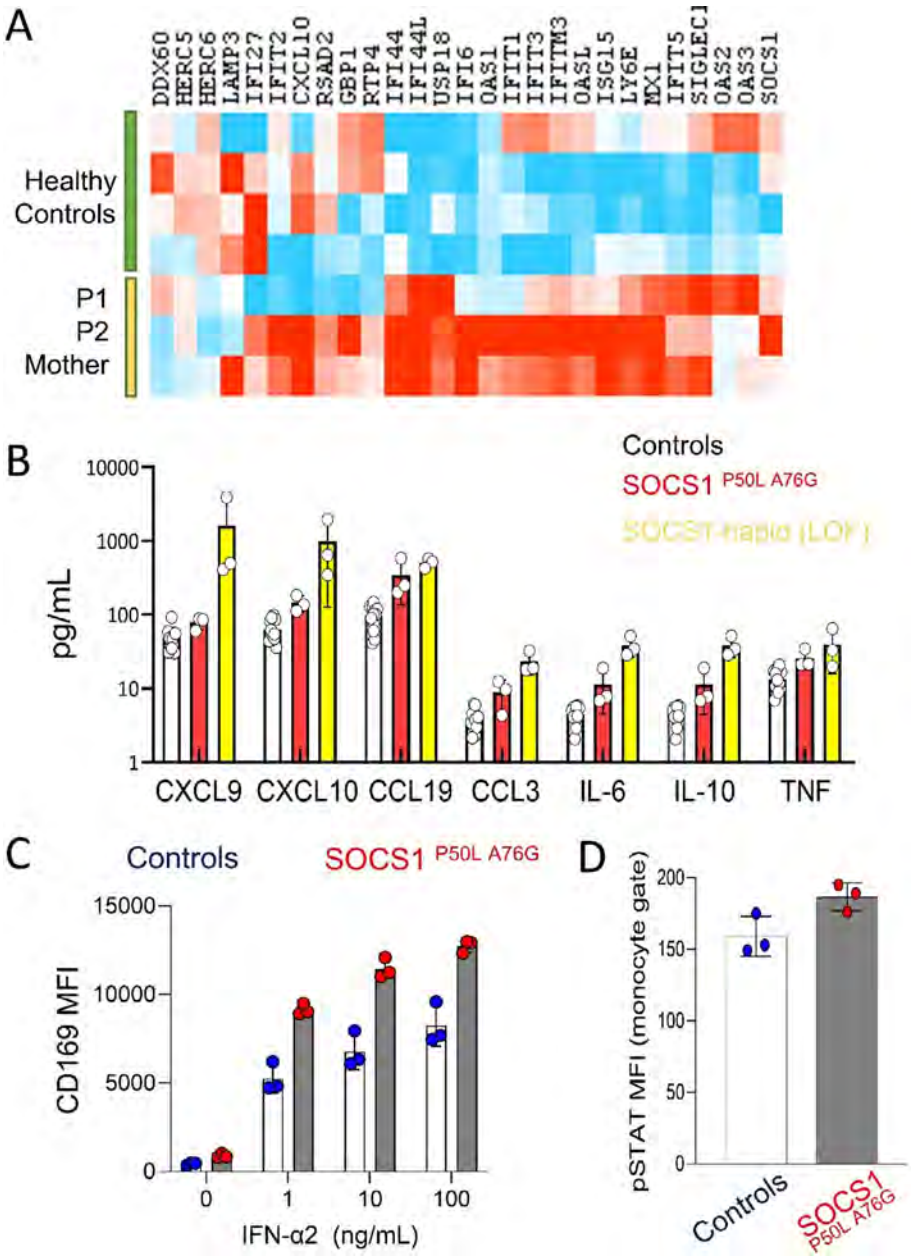

Figure 2. A) Heatmap display of IFN-inducible genes from bulk RNAseq of PBMCs from the healthy controls, probands and their mother. B) Quantification of cytokine and chemokine levels in the plasma of healthy controls, SOCS1 mutant family and SOCS1-haplosufficiency patient by Olink proximity extension assay. C) CD169 expression on CD14+ monocytes 24 hours after stimulation with IFN-2. Three individuals with SOCS1 haploinsufficiency with confirmed loss-of-function variants were included as controls. D) Flow cytometry quantification of phospho-STAT1 in CD14+ monocytes 5 minutes after IFN-2 stimulation.

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Skin inflammation in juvenile dermatomyositis (JDM) can signal disease onset or flare and prevent complete disease remission. The study of cutaneous expression signatures holds the potential to reveal novel mechanisms underlying disease heterogeneity and organ-specific inflammation. The objectives in this study were to 1) analyze skin tape stripping (TS) transcriptional profiles to identify JDM disease endotypes and 2) compare skin and blood expression signatures.

Methods: We performed TS on non-lesional +/- lesional skin in a JDM cohort (n=28, n=16 with longitudinal sampling, n=77 TS samples). All JDM patients met 2017 EULAR/ACR classification criteria and had standardized clinical disease activity assessments. Paired blood was collected in PAXgene tubes. mRNA was isolated from TS and blood followed by RNAseq. Unsupervised hierarchical clustering was performed to determine molecular JDM subgroups. Differentially expressed genes (DEGs; q-value< 0.01 and absolute log2 fold-change ≥ 1) between subgroups were extracted using TIGR-MeV. Literature-based pathways were explored using Ingenuity Pathway Analysis (IPA). Pathway-based expression scores in skin and blood

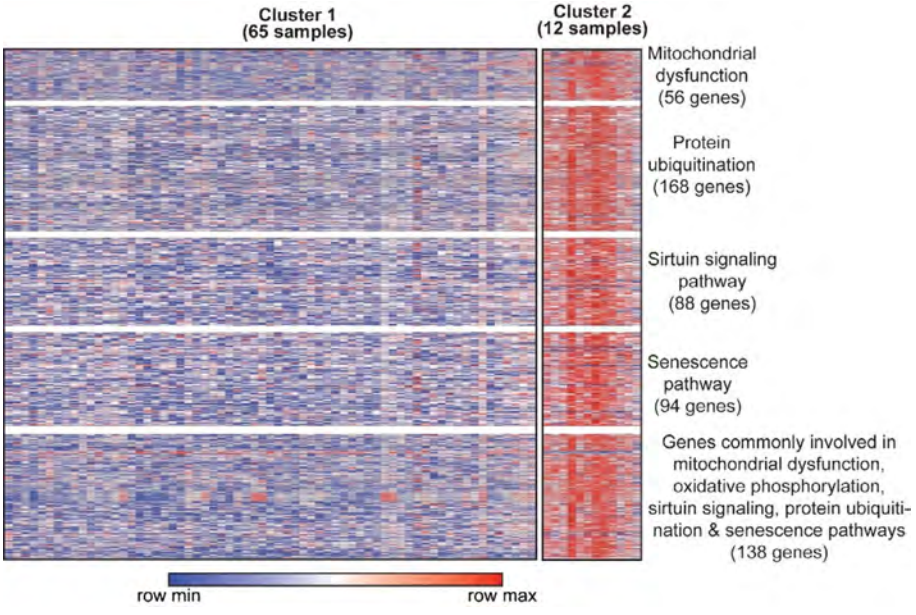

Figure 1. Heatmap of DEGs from top pathways differentiating the two JDM subgroups upon clustering of tape stripping expression profiles.

were calculated (PMID ref: 16947629) and compared between subgroups (t-test; p-value< 0.05). Cell type enrichment analysis was performed using xCell.

Results: We identified two JDM subgroups with distinct TS expression profiles (corresponding to 65 samples (28 patients) in cluster 1 and 12 samples (8 patients) in cluster 2). The two subgroups did not separate by lesional/non-lesional skin, disease duration or activity. However, subgroup 2 represented patients with a higher frequency of chronic disease and more likely to be on steroids. The 6,773 DEGs distinguishing the two subgroups represented pathways involving mitochondrial dysfunction, sirtuin signaling, oxidative phosphorylation, protein ubiquitination and senescence (p-value< 0.0001) (**Figure 1**). *NFE2L2*, a transcription factor involved in response to oxidative stress and innate immune signaling, was the top upstream regulator activated in subgroup 2 (IPA Z-score = 10.74, enrichment p-value = 6.1 E-14). Subgroup 2 demonstrated higher skin-directed interferon, mitochondrial/oxidative phosphorylation dysfunction, angiogenesis and innate immune scores in skin compared to subgroup 1 and controls (**Figure 2, top panel**). Blood as compared to skin-derived pathway scores did not as effectively highlight biological differences in subgroup 2 (**Figure 2, lower panel**). Subgroup 2 also differed from subgroup 1 in potential immune cell populations present in skin, notably with higher xCell scores from CD4 T-cells in subgroup 2 and from B-cells in subgroup 1.

Conclusion: We identified a unique JDM subgroup based on TS expression signatures, with upregulation of genes involved in mitochondrial dysfunction, sirtuin signaling and protein ubiquitination. Interestingly, TS JDM subgroups were distinguished by metabolic in addition to traditional inflammatory pathways. TS performed better than blood in differentiating

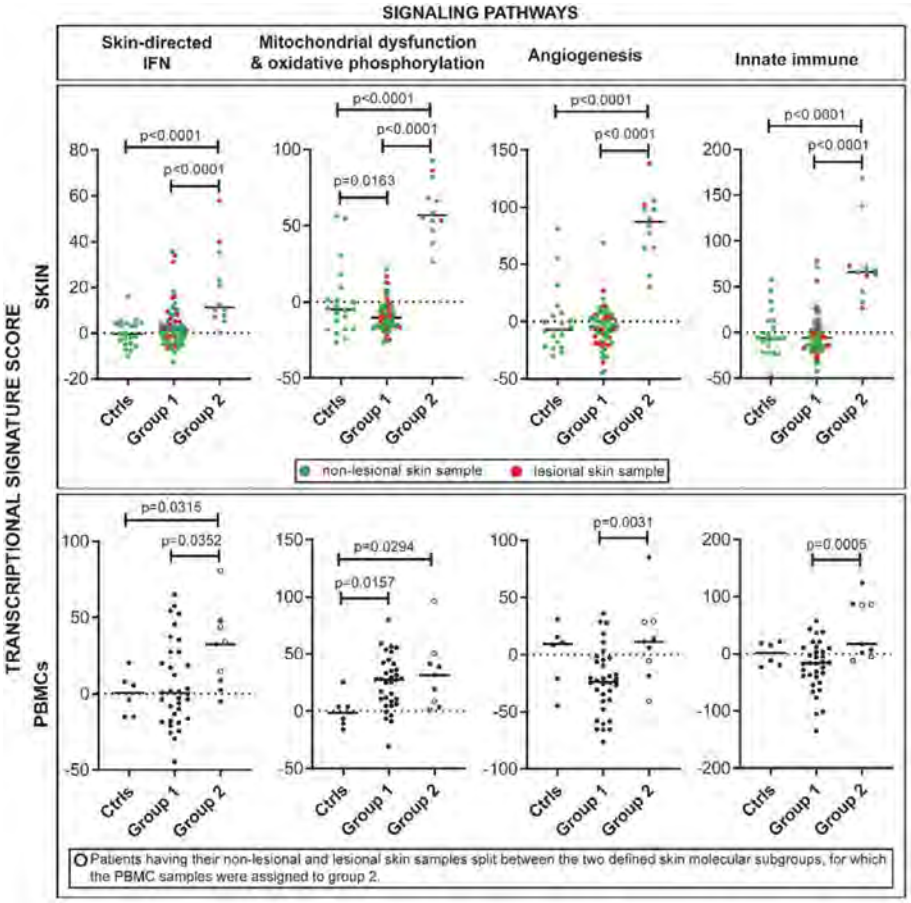

Figure 2. Skin tape stripping (top panel) and blood (lower panel) gene expression scores from selected pathways. Filled green circles represent non-lesional skin samples; filled red circles represent lesional skin samples (top panel); black open circles represent patients with non-lesional and lesional skin samples split between the two defined skin molecular subgroups, for which blood samples were assigned to group 2 (lower panel).

possible mechanisms underlying JDM disease endotypes. Skin-specific transcriptomic signatures may be able to lend insight into precision medicine care in JDM.

Genetic Associations in Juvenile Idiopathic Arthritis Determined with an Electronic Health Record Based Approach

Elizabeth Jasper, Srushti Gangireddy, Henry Ong, Jacklyn Hellwege, Todd Edwards, Digna Velez Edwards, Wei-Qi Wei and **Anna Patrick**, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) encompasses multiple forms of pediatric autoimmune arthritis. Research studies in JIA are complicated by disease heterogeneity and difficulties gathering large numbers of patients for longitudinal studies. Electronic health records (EHRs) store nearly all clinical data in one central location, are used widely across institutions, and are becoming a major source of data for studying diseases in a real-world population with longitudinal data. In this study, we use an algorithm to accurately identify a JIA cohort from an EHR linked to a DNA biobank and perform genetic studies. The goal of this work is to establish a cost-effective method for performing JIA studies in a cohort with longitudinal clinical data.

Methods: A portable algorithm was used to identify JIA patients using a combination of ICD-9-CM and ICD-10-CM codes, age criteria, and exclusion of ICD codes associated with connective tissue disease. Classification of JIA status by the algorithm was compared to true cases as determined by a rheumatology clinic note documenting JIA before 20 years old. Individuals with ICD-9-CM and ICD-10-CM codes for well child visits and without JIA-associated ICD codes or use of disease-modifying and biologic medications used to treat JIA were classified as controls. Identified cases and controls with existing genotype data from a Multi-Ethnic Genotyping Array (MEGA-ex) were included. A genome-wide association study (GWAS), adjusted for 10 principal components, was performed. S-PrediXcan was used to assess associations between JIA and genetically predicted gene expression in placenta and 48 GTEx (v7) tissues. Functional Mapping and Annotation (FUMA) of GWAS was used for annotation of single-nucleotide polymorphisms (SNPs) and to test for enrichment of predefined biological pathways. Significance was determined by a Bonferroni corrected p-value.

Results: The JIA algorithm identified 1,379 cases with a positive predictive value of 0.98 from a cohort of over 3.5 million records. There were 229 cases and 2,798 controls with genotype data. Cases were 68% female and 84% white while controls were 58% female and 48% white. GWAS identified numerous significant SNPs, the majority of which were on chromosome 6. Significant results of note include SNPs previously associated with JIA (rs2395148, rs7775055) (Figure 1). FUMA

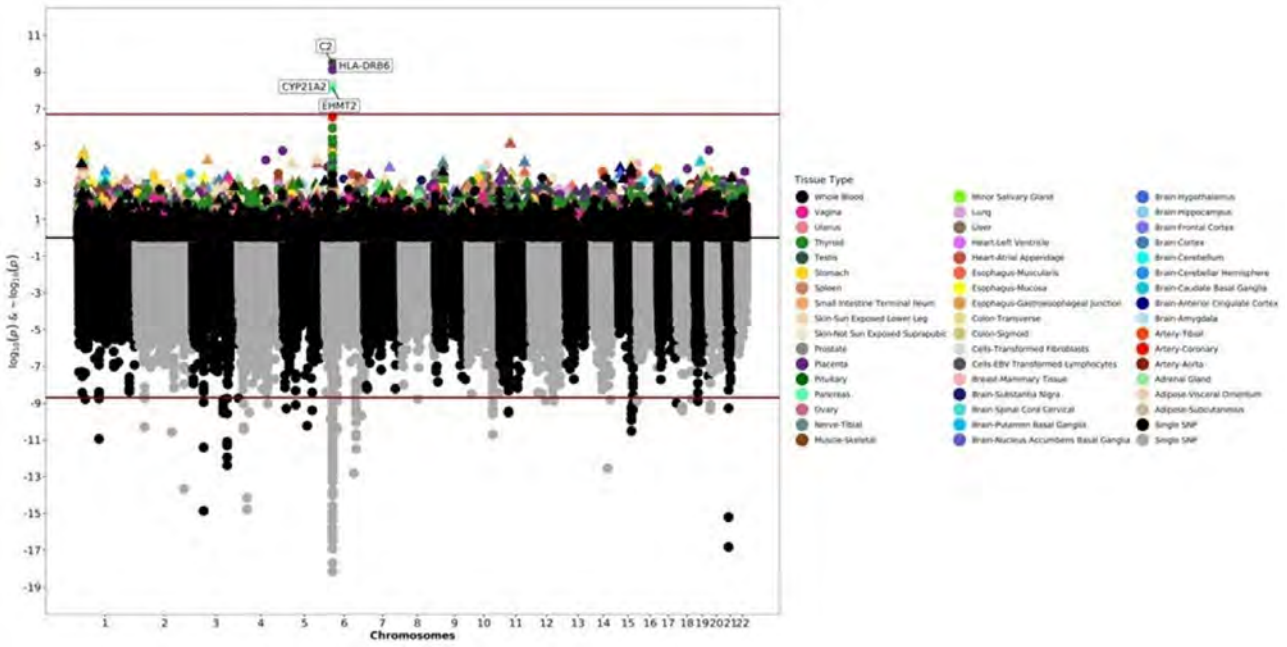

Figure 1. Juvenile Idiopathic Arthritis Miami Plot. The bottom of the graphic is a Manhattan plot which displays significant SNPs from GWAS. The top of the graphic is the results from S-PrediXcan, with symbols now representing entire genes and their genetically determined expression levels. The x-axis are chromosomes. The y-axis is log and negative log p-values from the GWAS and S-PrediXcan analyses. Colors correspond to specific tissues.

analysis identified 29 genomic risk loci and 33 lead SNPs. Canonical pathways, GO biological processes, and GO molecular functions were enriched for important processes in the immune system. S-PrediXcan identified 4 genes (*C2*, *HLA-DRB6*, *CYP21A2*, and *EHMT2*) predicted to be differentially expressed in JIA (Figure 1).

Conclusion: A portable algorithm can identify JIA patients in a real-world cohort with longitudinal clinical data. This phenotype is highly accurate and leads to biologically plausible genetic associations with JIA. This is a cost-effective method for studying JIA and its genetic associations. This approach can be expanded to generate larger cohorts across multiple institutions.

CD14+ Monocytes Demonstrate a Unique Transcriptional Signature in Macrophage Activation Syndrome, Highlighting a Role for Interferons and Identifying Putative Hemophagocytes in Circulation

Susan Canny[1], Hannah DeBerg[2], Griffin Gessay[2], Ailing Lu[3], Mary Eckert[4], Andrea La Bella[5], Susan Shenoi[6], Joyce Hui-Yuen[7], Betsy Barnes[8] and Jessica Hamerman[2], [1]Seattle Children's Hospital/University of Washington, Seattle, WA, [2]Benaroya Research Institute, Seattle, WA, [3]Feinstein Institutes for Medical Research, Manhasset, NY, [4]Seattle Children's Hospital, Seattle, WA, [5]Cohen Children's Medical Center, Queens, NY, [6]Seattle Childrens Hospital, Mercer Island, WA, [7]Division of Pediatric Rheumatology, Cohen Children's Medical Center, Lake Success, NY, [8]Northwell Health, Manhasset, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophage activation syndrome (MAS) is a potentially fatal complication of rheumatic diseases. MAS is characterized by a dysfunctional hyperinflammatory response in which there is abnormal activation of lymphocytes and phagocytes, leading to an overproduction of inflammatory cytokines and damage to host tissues. Circulating monocytes are highly responsive to their surrounding environment, are known to exhibit phenotypic and functional changes during inflammation, and can give rise to macrophages that phagocytose immune cells. However, monocytes and macrophages have not been well-studied in MAS. MAS is most commonly associated with systemic juvenile idiopathic arthritis (sJIA). At least 10% of sJIA patients will experience an overt episode of MAS with up to 50% exhibiting signs of subclinical inflammation.

Methods: We analyzed classical CD14+ monocytes from children with active MAS (6 subjects) compared to individuals with sJIA without MAS (4 subjects) and age/sex/race-matched healthy children (8 subjects) by flow cytometry and RNA sequencing (RNA-Seq). Seven MAS subjects and four age/sex/race-matched healthy controls were analyzed by single cell RNA sequencing (scRNA-Seq). Subjects with MAS were defined based on the 2016 classification criteria by Ravelli and colleagues as well as the ratio of ferritin to ESR.

Results: We found significant upregulation of CD16 surface expression during active MAS using flow cytometry (n=4-8 per group, $p < 0.001$). Our bulk RNA-Seq data show broad transcriptional changes in CD14+ monocytes from children with active MAS, including upregulation of RNase 2 (involved in processing RNAs for the innate immune sensor TLR8) and SLAMF7 (associated with monocyte/macrophage hyperinflammation in response to interferon gamma). scRNA-Seq analyses of myeloid cells from subjects with active MAS revealed a strong interferon signature in MAS monocytes with enrichment of interferon stimulated genes and alarmins. We identified hemoglobin transcripts in monocytes cells from MAS subjects by scRNA-Seq. Cells containing hemoglobin transcripts were also enriched for platelet associated genes (PF4, PPBP, GP9) and genes involved in motility, suggesting the detection of hemophagocytes in circulation.

Conclusion: These data confirm an important role for cytokines, specifically interferons, in driving gene expression in monocytes during MAS and suggest potential targets for future therapies. Together, our data show that CD14+ monocytes have a unique transcriptional signature in MAS and identify putative hemophagocytes in circulation during MAS.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Basic Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Mutations in genes coding for 20S proteasome subunits or proteasome assembly helpers cause chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperatures (CANDLE) or proteasome-associated autoinflammatory syndromes (PRAAS). Patients with CANDLE/PRAAS present with chronically elevated type I interferon scores as consequence of increased proteotoxic stress by mechanisms that are only partially characterized. The purpose of this study is to report and functionally characterize eight disease-causing variants, six of which are novel variants, in four proteasome genes (*PSMA5, PSMC5,PSMB10* and *PSMB8*) in five unrelated patients with CANDLE/PRAAS.

Methods: All patients (Pts) were enrolled into an IRB-approved protocol (NCT02974595). Whole exome sequencing was performed in all patients. Peripheral blood interferon response gene signature was determined by NanoString. The effects of the proteasome variants were investigated by transfection studies in HeLa cells.

Results: The five Pts presented in the first month of life with fever, systemic inflammation, and nodular or annular rash. Skin biopsies showed a neutrophilic dermatosis (Pts1, 2, 4 and 5) or a perivascular lymphocytic infiltrate (Pt3). One patient (Pt1) had additive loss-of-function variants in *PSMB8/*β5i (c.224C >T, p.T75M), and in 2 previously not disease-associated genes, *PSMA5/*α5 (c.502C >T, p.R168*, de novo), and *PSMC5/*Rtp6 (c.1080+1_1080+10del). Four patients had novel compound heterozygous variants in 2 known CANDLE/PRAAS-associated genes, *PSMB8/*β5i *and PSMB10/*β2i. Three Brazilian patients, Pts2-4, had the same *PSMB10/*β2i variant,c.40_42del, p.F14del, in combination with a different variant, c.500G >A p.G167D (Pt2); c.247_248insT, p.C83Lfs*123 (Pt3), and c.710+1G >C (Pt4). Pt5 was compound heterozygous for *PSMB8/*β5i variants c.163C >T, p.Q55* and c.352T >C, p.S118P. Pt1 is in clinical remission on treatment with tofacitinib in combination with tocilizumab; Pt2 responded partially and Pt5 responded fully to tofacitinib; and Pts3 and 4 are in clinical remission on baricitinib. All five patients had a high type I interferon signature in peripheral blood. Transient transfection of mutant constructs *PSMA5/*α5 p.R168*, *PSMB8/*β5i p.Q55* or *PSMB10/*β2i p.C83Lfs*123 into HeLa cells result in mRNA nonsense mediated decay and no protein production, and mutant constructs *PSMB10/*β2i p.G167AD and p.F14del, and *PSMB8/*β5i p.S118P impair cleavage of the pro-peptide and prevent incorporation of the mutant proteasome component. *PSMB10/*β2i c.710+1G >C leads to exon skipping with no incorporation of the mutant protein. All but the *PSMC5/*Rtp6 variant were shown to substantially impact the steady-state expression of the affected proteasome subunits and/or their incorporation into mature 20S and/or 26S proteasomes.

Conclusion: Our observations expand the spectrum of CANDLE/PRAAS-causing genetic variants and will improve molecular diagnosis and genetic counseling of patients with autoinflammation.

This study was supported in part by the Intramural Research Program of NIAID, NIH.

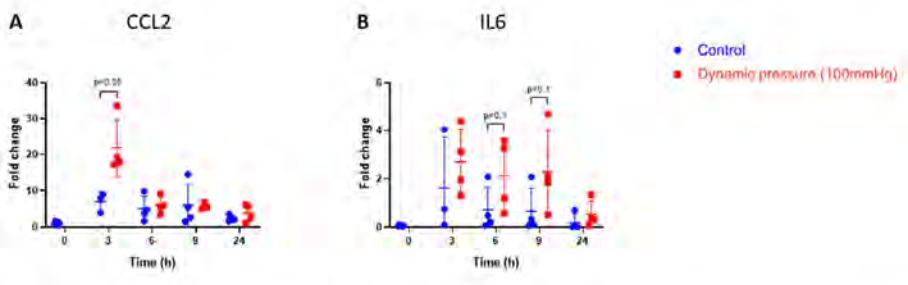
Session Title: RA – Animal Models Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

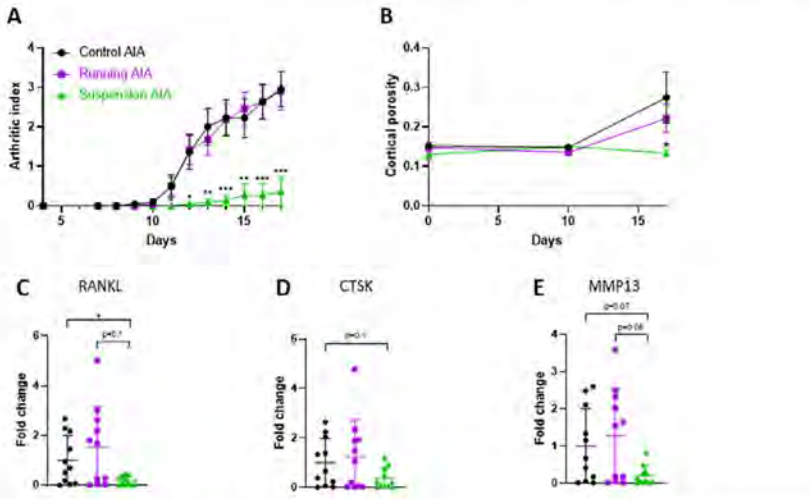
Background/Purpose: Rheumatoid arthritis (RA) is the most common chronic inflammatory rheumatic disease, characterized by synovitis associated with progressive bone loss and joint degradation. The adjuvant-induced arthritis (AIA) model mimics the pathophysiological features of RA, with high prevalence and reproducibility. Yes-associated protein (YAP) is a transcription factor involved in inflammatory signaling and arthritis progression, especially by driving the RA fibroblast-like synoviocyte (FLS) phenotype. Beyond inflammation sensing, YAP responds to mechanical stimuli. The inhibition of YAP transcriptional activity decreases arthritis in the AIA model. The objective of this study was then to investigate the effect of mechanical loading or unloading on arthritis.

Figure 1. Mechanical stress induced expression of pro-inflammatory mediators in RA organoids.



RA organoids (n=3-4 patients) were submitted to a continuous dynamic compressive force (100 mmHg) or not (control) at different times (0, 3, 6, 9 and 24h). CCL2 (A) and IL6 (B) expression were normalized by HPRT and by average of control group at 0h. Wilcoxon's tests showed no significant difference between control and dynamic pressure groups.

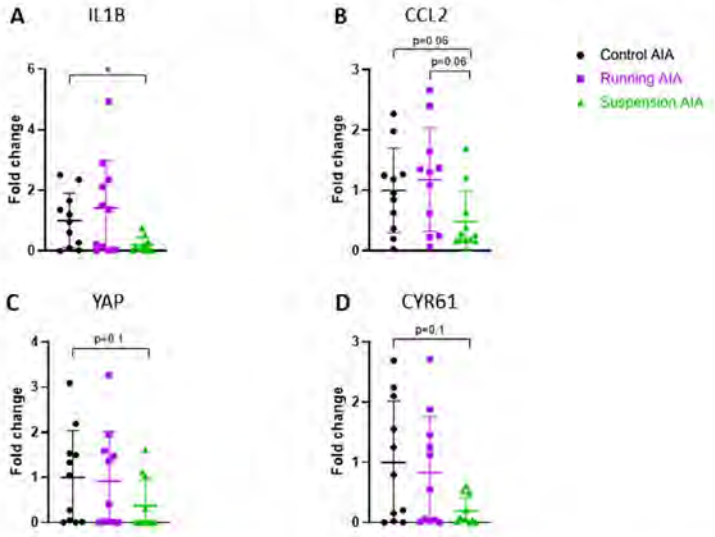
Figure 2. Mechanical unloading decreased arthritis severity and bone loss in AIA model.



Progression of arthritic index (A) and cortical porosity of the navicular bone (B) over time. Expression of RANKL (C), CTSK (D) and MMP13 (E) in the ankle of control, running and suspended AIA rats at day 17. Wilcoxon's tests were performed: *p<0.05 **p<0.01,***p<0.001. *RANKL: RANK ligand, CTSK: Cathepsin K.*

Methods: For *in vitro* studies, a compressive dynamic pressure (100mmHg) was applied on RA FLS organoids. For *in vivo* studies, mechanical loading (voluntary running), unloading (tail suspension) or no mechanical stress (control) was applied in AIA rats (n=11/group), from arthritis induction (day[D]0) until D17. Running rats only ran (1.5km/day) from D0 to D10, which is the arthritis onset in the AIA model. Daily clinical monitoring was assessed to follow the severity of arthritis. *In vivo* μ-computed tomography was realized to follow arthritis-induced bone loss.At D10 or D17, the ankles of the rats were collected to perform RT-qPCR. At D17, blood samples were collected to perform protein dosages.

Figure 3. Mechanical unloading decreased inflammation and YAP activity in AIA model.



Expression of IL1B (A), CCL2 (B), YAP (C), and CYR61 (D) in the ankle of control, running and suspended rats at day 17. were normalized by HPRT and by average of control group. Wilcoxon's tests were performed. *YAP: Yes-associated protein.*

Results: In RA organoids, mechanical stress was able to induce inflammation by increasing IL6 and CCL2 expression (Figure 1). Surprisingly, YAP transcriptional activity remained unchanged in response to mechanical stress in RA organoids. In AIA rats, CCL2 expression is increased before arthritis onset, but also during and after the peak of inflammation (D17), independently from YAP activity. In AIA rats, the control and running groups displayed the same disease onset (D10) and progression, with similar arthritis index and ankle circumference over time (Figure 2). No difference in expression of bone degradation markers (RANK ligand, Cathepsin K, MMP9, and MMP13) was observed in joint at D17 between the control and running groups (Figure 2) and pro-inflammatory mediators (IL6, IL1B, TNF, and CCL2) (Figure 3). However, the expression of pro-inflammatory mediators and bone degradation markers trended to increase in the running AIA rats joint at D10. The suspension prevented arthritis development with a decreased expression of bone degradation markers (Figure 2) and pro-inflammatory mediators in the joint at D17 (Figure 3). Moreover, arthritis-induced bone loss was inhibited in the suspension group, where cortical porosity and trabecular volume remained similar to baseline.YAP transcriptional activity also trended to decrease.

Conclusion: In conclusion, two independent mechanisms could be involved in arthritis in response to mechanical stress, one mediated by YAP and the other involving CCL2. Mechanical unloading might then prevent arthritis by decreasing YAP activity and CCL2 production. A high level of CCL2 might then increase arthritis severity by inducing inflammation at arthritis onset, leading to an increase in YAP activity and joint degradation.

Abstract Number: 1714

Aberrant Myeloid Populations in the TNF-Transgenic Model of Pulmonary Hypertension Overexpress Interferon Pathways and Are Driven by TNFR1 Signaling

Gaochan Wang[1], Qingfu Xu[2], Stacey Duemmel[1] and Benjamin Korman[1], [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary hypertension (PH) is a severe, progressive disorder characterized by elevated pulmonary artery pressures, right ventricular hypertrophy, and increased mortality. We previously demonstrated that TNF-transgenic (TNF-Tg) mice develop a severe PH phenotype and that deficiency of TNFR1 reversed this pathology. To explore the roles of immune cells contributing to PAH in TNF-Tg mouse model, we assessed single-cell RNA expression of immune cells in TNF-Tg mice crossed with mice lacking TNFR1 or TNFR2.Because we saw dramatic shifts in myeloid populations, we focused on characterizing the abnormal monocytes and macrophages present in TNF lungs.

Methods: TNF-Tg mice were crossed with mice deficient in either TNFR1(TNFR1KO) or TNFR2 (TNFR2KO). Lungs from wild type, TNF-Tg, TNF-Tg-TNFR1KO and TNF-Tg-TNFR2KO mice (n = 5–6) at 4.5 months of age were harvested and digested to a single cell suspension for single cell RNA sequencing (scRNAseq). The library was prepared using 10X Genomics Chromium instrument and sequencing was performed on Illumina NovaSeq6000. scRNAseq reads were examined for

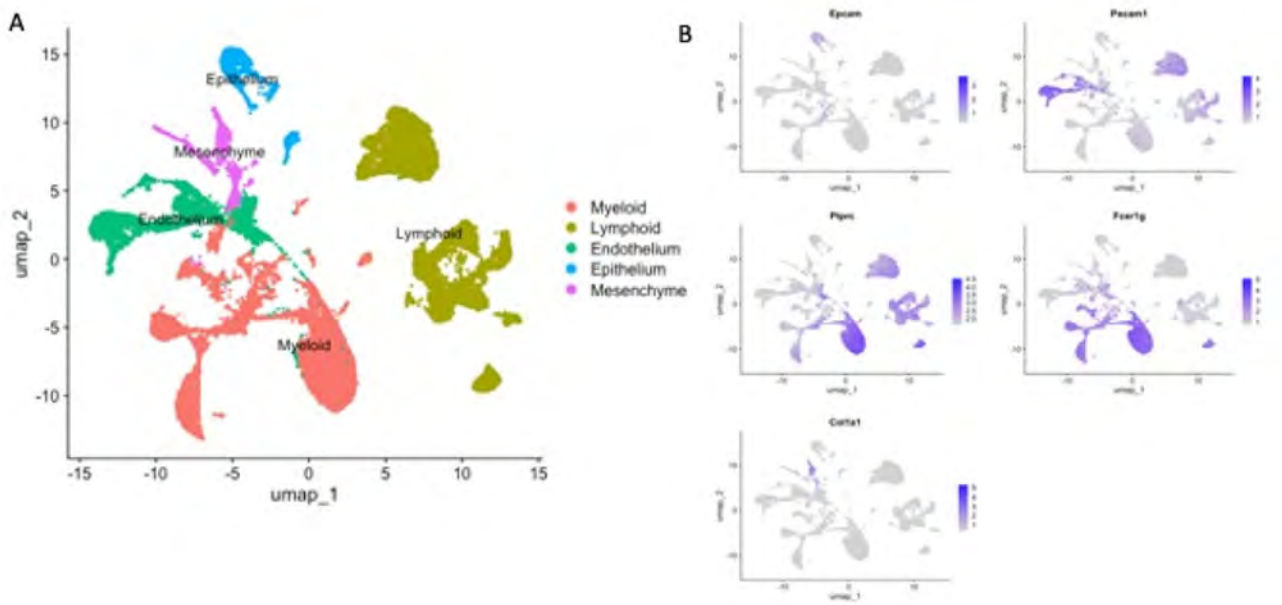

Figure 1. Cellular composition of major cell types in mouse lung. A. UMAP projection of all scRNA-seq data, showing 5 major cell groups that were identified. B. Feature plots identifying canonical markers of epithelial (Epcam), endothelial (Pecam1), mesenchymal (Col1a1), myeloid (Ptprc, Fcer1g) and lymphoid (Ptprc+, Fcer1g-) cells populations.

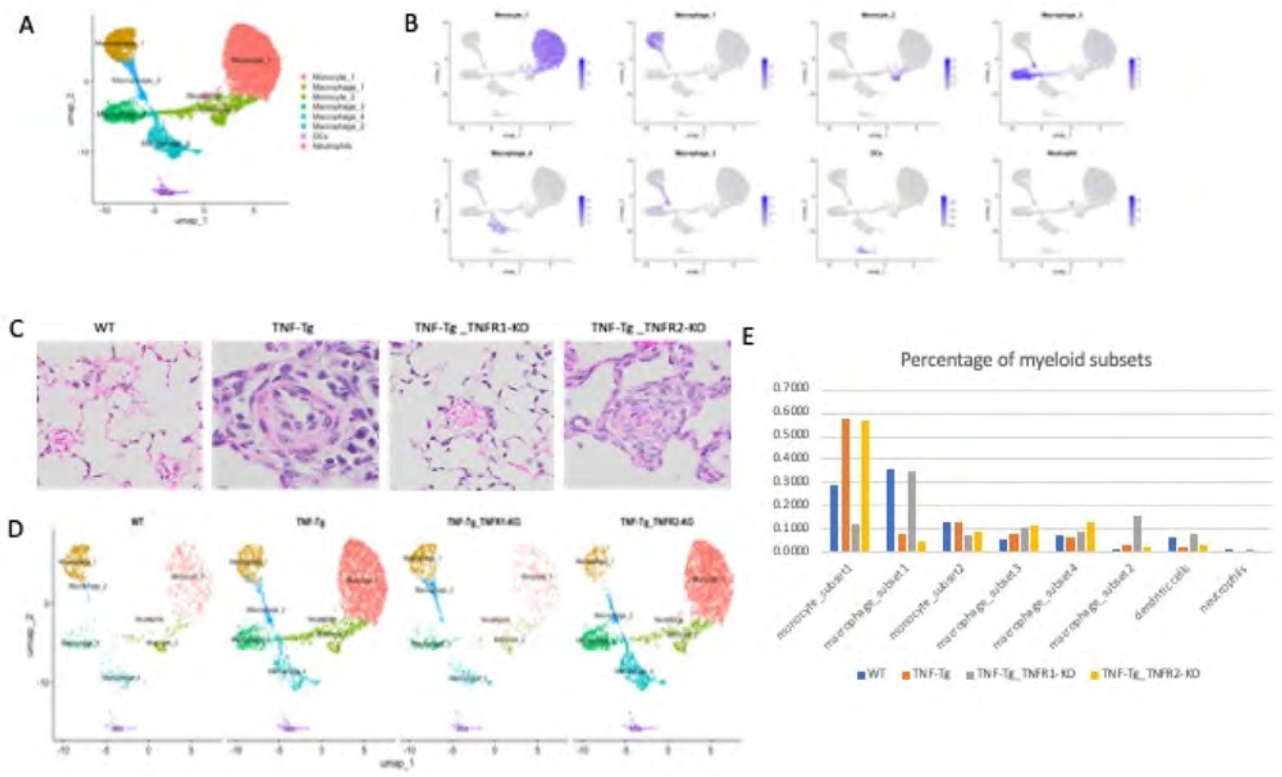

Figure 2. Cellular composition of myeloid cells identified in mouse lung from TNF-Tg and TNF receptor deficient mice. A. A total of eight clusters of myeloid cells were identified from mice across all genotypes. Cell populations are colored as indicated by legend. B. Feature plots showing expression of principal identifiers of different myeloid cell types. C. Lung histology images demonstrated that TNF-Tg and TNF-Tg_TNFR2-KO mice, but not WT and TNF-Tg_TNFR1-KO mice have pulmonary inflammation and vascular occlusion. D. UMAP plots myeloid subsets in TNF-Tg mice with and without TNF receptor deficiency. Cell populations are colored as indicated by legend. E. Proportion of myeloid subsets across genotypes.

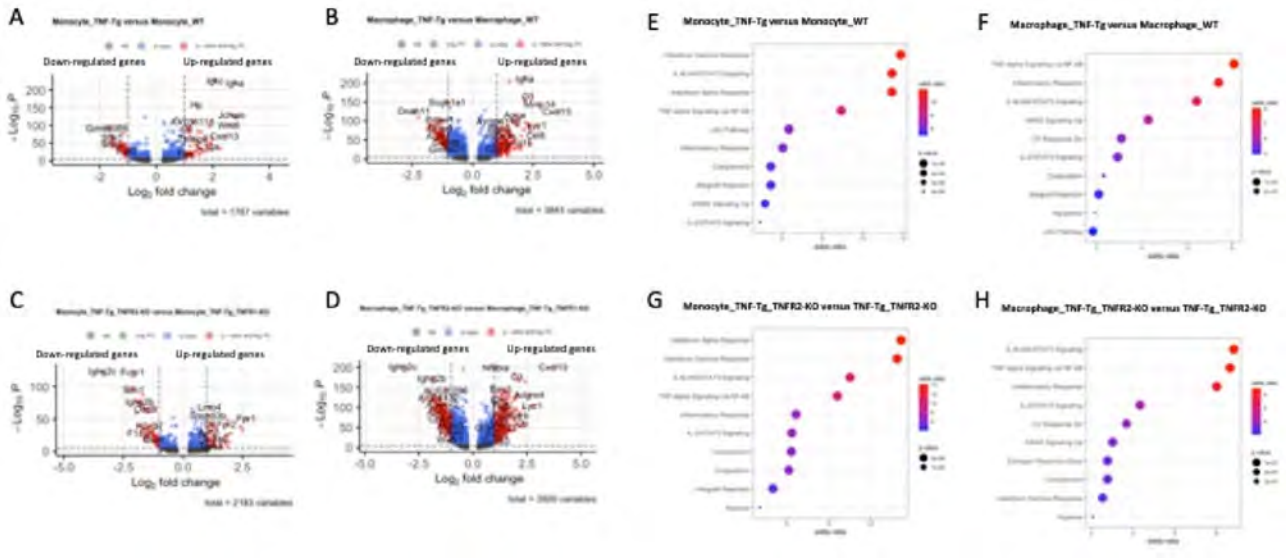

Figure 3. Differential expression (DE) analysis of genes and pathways in monocytes and macrophages. A-B. Volcano plot showing the differentially expressed genes in monocytes and macrophage between TNF-Tg and WT mice. C-D. Volcano plot showing the differentially expressed genes in monocytes and macrophage between TNF-Tg_TNFR2-KO and TNF-Tg_TNFR1-KO mice. E-F. Pathway analysis in monocytes. G-H. Pathway analysis in macrophages. MSigDB_Hallmark_2020 database was used for analysis. Dot plots identify pathways in descending significance of p-value (dot size) and odds-ration (color).

quality and mapped to reference mouse genome. The resulting scRNAseq data was analyzed with Seurat v.4.9. Differential expression and pathways analysis were performed and visualized using Seurat and R packages enrichR and Enhanced Volcano.

Results: Cells were clustered based on their expression profiles and cell types were annotated based on established cell markers from Lung Map and the published literature. A total of 40 clusters were identified, corresponding to 5 major cell groups (Fig 1.A-B): epithelial (*Epcam*$^{+}$), endothelial (*Pecam1*$^{+}$), mesenchymal (*Col1a1*$^{+}$), lymphoid (*Ptprc*$^{+}$), and myeloid (*Ptprc*$^{+}$ and *Fcer1g*$^{+}$). We observed dramatic changes in cellular composition of myeloid cells between WT and TNF-Tg, and TNF-Tg_TNFR1-KO and TNF-Tg_TNFR2-KO. We focused on myeloid cells and re-clustered these cells to identify 7 myeloid cell types (2 monocytes subsets, 4 macrophage subsets, neutrophils, and dendritic cells) were identified (Fig 2. A-B). Among the myeloid cells, monocytes and macrophages account for the dramatic changes in cellular composition. Moreover, WT and TNF-Tg-TNFR1KO mice shared the similar cellular composition, and TNF-Tg and TNF-Tg-TNFR2KO mice shared the similar cellular composition (Fig 2.D), which was consistent with the whole cellular composition in 4 mouse groups and lung histology (Fig 2.C). We next performed differential expression analysis in monocytes and macrophages (Fig 3. A-D). In monocytes, interferon responses and complement signaling were significantly differentially expressed in both TNF-Tg and TNF-Tg_TNFR2-KO mice. In macrophages, a majority of pathways related to TNF-mediated NK-kB signaling pathways and JAK/STAT signaling in TNF-Tg and TNF-Tg_TNFR2-KO mice (Fig 3. E-H).

Conclusion: Overexpression of TNF results in significant shifts in cellular composition of pulmonary myeloid cells. TNFR1 signaling is primarily responsible for these changes. Pathway analysis suggests that lung monocyte-mediated interferon responses contribute to the pathogenesis of PH.

Androgen Treatment Exhibits a Protective Role Against Focal Erosions in TNF-Induced Inflammatory Arthritis in Mice

Kiana Chen[1], Adelaide Weidner[2], Olga Astapova[2], Edward Schwarz[2] and Homaira Rahimi[2], [1]University of Rochester School of Medicine and Dentistry, Rochester, NY, [2]University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by chronic joint inflammation and bone erosion and is female predominant. The TNF-transgenic (TNF-Tg) murine model of RA develops inflammatory erosive arthritis and displays a sex difference in disease severity, with females having worse disease than males (1). Studies suggest androgens provide a protective effect against joint disease and TNF-mediated bone erosion (2). We have previously shown that the removal of endogenous sex hormones in TNF-Tg males significantly worsens their inflammatory erosive disease. Here, we investigated whether treatment of TNF-Tg mice with exogenous androgen ameliorates erosive disease.

Methods: TNF-Tg male mice were orchiectomized followed by subcutaneous implantation of either 5α-dihydrotestosterone (DHT) or placebo pellet at 1-month old (n = 3/group). Pellets released 1.5mg of DHT or placebo for 60 days (0.025mg/day). Micro-computed tomography (μCT) scans of hindpaws were taken at 3-months old and compared with μCT data of same age intact TNF-Tg males (n = 4-6 paws/group). The total bone volumes (mm^3) of the cuboid, talus, navicular and lateral intermediate cuneiform, and periarticular metatarsals were compared between groups. Deformation scores of the paws and weights were taken weekly from 1 to 3 months old. Same age sham TNF-Tg male mice weekly weights were compared between orchiectomized groups. Serum and paws were obtained for analysis and histology. Values are reported as the mean +/- standard deviation.

Results: Segmented hindpaw images showed bone erosion occurring in the periarticular regions of the metatarsals (Fig 1 A-C). Placebo-treated orchiectomized mice had significantly more bone volume loss than DHT-treated orchiectomized mice and intact mice in the cuboid (0.34 ± 0.03 Orchiectomized + Placebo; 0.43 ± 0.02 Orchiectomized + DHT; 0.43 ± 0.06 Intact), talus (0.97 ± 0.09 Orchiectomized + Placebo; 1.10 ±0.06 Orchiectomized + DHT; 1.21 ± 0.07 Intact), navicular and lateral intermediate cuneiform (0.78 ± 0.04 Orchiectomized + Placebo; 0.87 ± 0.03 Orchiectomized + DHT; 0.94 ± 0.04 Intact), and distal metatarsals (0.23 ± 0.05 Orchiectomized + Placebo; 0.28 ± 0.07 Orchiectomized + DHT; 0.27 ±0.07 Intact) (Fig 1D-H). Orchiectomized mice with placebo had significantly higher mean deformation scores at 4 weeks post-surgery (p = 0.03) (Fig 2A). Orchiectomized mice also gained significantly less weight than sham TNF-Tg mice by 6 weeks post-surgery (p = 0.03). DHT treatment of orchiectomized mice resolves that weight loss over time (Fig 2B).

Conclusion: Androgen treated orchiectomized arthritic mice had significantly improved bone volumes, limiting bone erosion even in the presence of ongoing inflammation**.** Clinical measures of weight loss and arthritis also improve with androgen treatment. These finding suggests sex hormones have a relationship with the immune system in inflammatory-erosive disease that warrants further study. Histological analysis of the paws and osteoclastogenic cultures of bone marrow are ongoing to delineate the mechanism of androgen effects on inflammation.

1. Bell R.D. et al. *Arthritis Rheumatol* 71(9): 1512-1523. 2019. 2. Traish A et al. *J Clin Med* 7(12): 549. 2018.

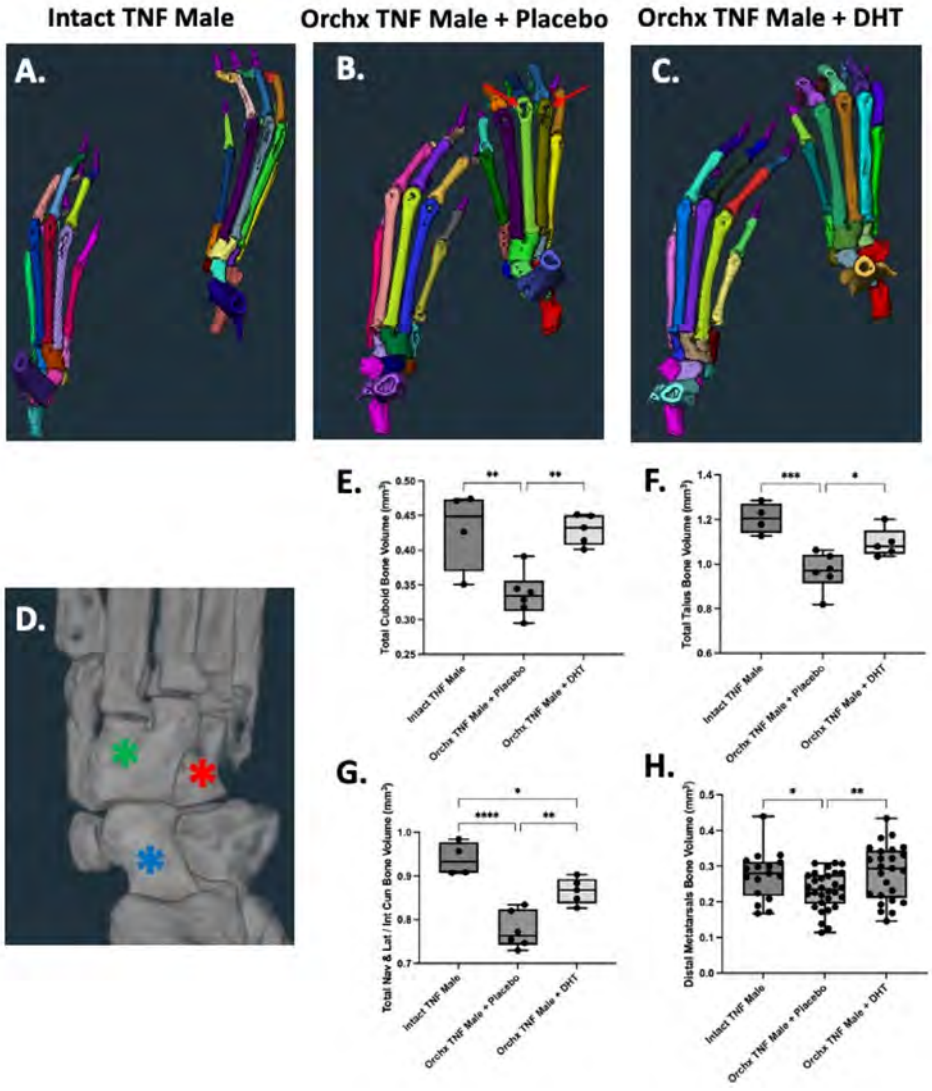

Figure 1. DHT Decreases Bone Erosions in Orchiectomized TNF-Tg Mice. μCT imaged hindpaw bones were segmented using Amira to determine total bone volume (mm3). Mice were divided into three groups (n = 4-6 paws/group), intact mice (A), orchiectomized (orchx) mice treated with placebo (B) and orchx mice treated with DHT (C). The cuboid (D, red asterisk), talus (D, blue asterisk), and navicular and lateral intermediate cuneiform (D, green asterisk) bone volumes were compared between groups. Orchiectomized mice treated with placebo were found to have significantly greater bone loss due to bone erosion in the cuboid (E), talus (F), navicular and lateral intermediate cuneiform (G) compared to the other cohorts. Placebo treated orchiectomized mice also had significantly less bone volume in the distal ends of the metatarsals that showed periarticular erosions reminiscent of erosions seen in RA patients (B, arrows; H). Orchiectomized mice treated with DHT had significantly greater bone volumes than orchiectomized mice treated with placebo, exhibiting that DHT treatment decreases bone erosion. Mid-hindpaw bone volume analysis was performed using a one-way ANOVA with Tukey's multiple comparisons. Metatarsal bone volume analysis was performed using a one-way ANOVA with Fisher's LSD test. * = $p<0.05$; ** = $p<0.01$; *** = $p<0.001$; **** = $p<0.0001$.

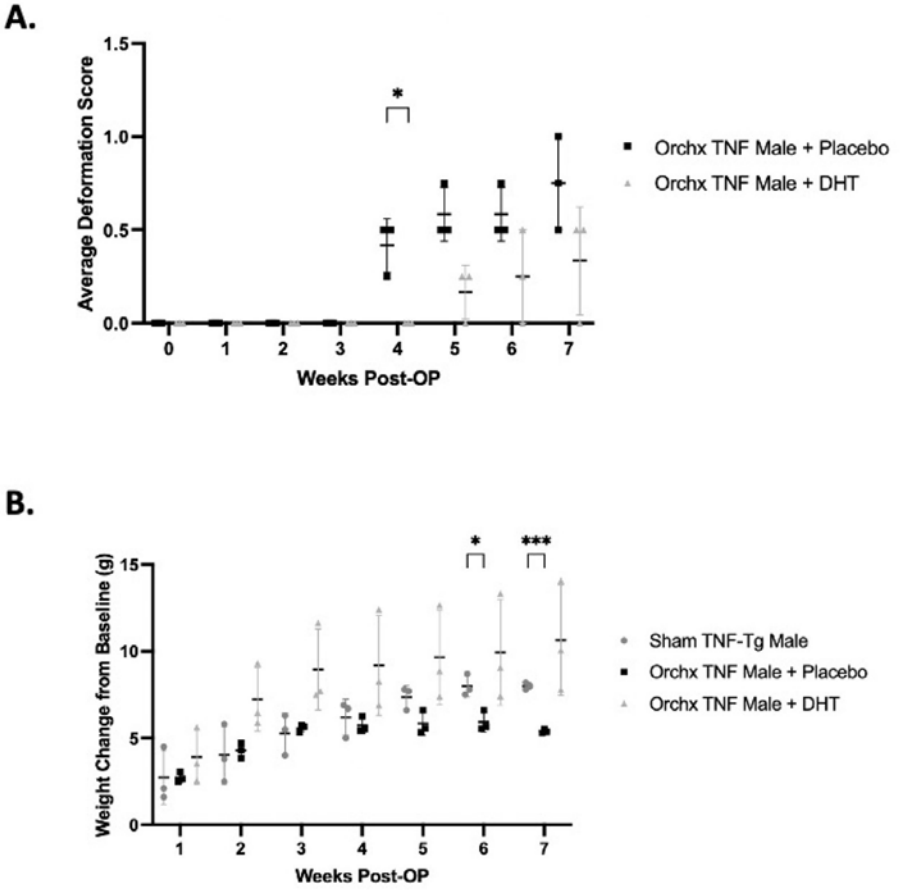

Figure 2. DHT-Treated Orchiectomized TNF-Tg Mice have Improved Clinical Measures of Disease. Orchiectomized mice treated with placebo and orchiectomized mice treated with DHT had weekly deformation scoring of their paws after surgery (n = 3 mice/cohort) (A). There was a significant difference in the average deformation score at week 4 post-op, signifying that orchiectomized mice treated with placebo displayed paw inflammation earlier than mice treated with DHT. Orchiectomized TNF-Tg mice treated with placebo, orchiectomized TNF-Tg mice treated with DHT, and sham TNF-Tg mice were also weighed weekly after surgery. The weight change from the baseline week (week 0) was compared between cohorts (B). Orchiectomized mice has significantly less weight gain than sham TNF-Tg mice by week 6 post-op. DHT treatment of orchiectomized mice ameliorates this weight loss over time. Average deformation score analysis was performed with multiple unpaired t-tests. Weight analysis was performed with a two-way ANOVA with Tukey's multiple comparisons. * = $p<0.05$, *** = $p<0.001$.

Mark Kenney[1], Kiana Chen[2], Lindsay Schnur[3], Jeffrey Fox[3], Ronald Wood[3], Lianping Xing[4], Christopher T Ritchlin[5], Homaira Rahimi[6], Edward Schwarz[6] and Hani Awad[3], [1]University of Rochester School of Medicine and Dentistry, Henrietta, NY, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY, [3]University of Rochester Medical Center, Rochester, NY, [4]University of Rochester Medical Center, Webster, NY, [5]University of Rochester Medical School, Allergy, Immunology & Rheumatology Division, Canandaigua, NY, [6]University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Development of reliable disease activity biomarkers is critical for diagnostics, prognostics, and novel drug development. In the case of preclinical models of inflammatory-erosive arthritis, such as sexually dimorphic tumor necrosis factor transgenic (TNF-Tg) mice (1), disease severity is routinely quantified in the ankle through manual segmentation of the talus or small regions of adjacent bones primarily due to the ease in measurement (2,3). Herein, we sought to determine the particular hindpaw bones that represent reliable biomarkers of sex-dependent disease progression to guide future investigation and analysis.

Methods: Hindpaw micro-computed tomography (μCT) was performed on wild-type (n=4 male, n=4 female) and TNF-Tg (n=4 male, n=7 female) mice at monthly intervals from 2-5 (females) and 2-8-months (males) of age, where female TNF-Tg mice exhibit early mortality from cardiopulmonary disease at approximately 5-6-months (1). For image analysis, we utilized our recently developed high-throughput and semi-automated segmentation strategy in Amira software (v2020.2) (4). Synovial (H&E-OG) and osteoclast (TRAP) areas of ankle joints were quantified using Visiopharm (v2021.07).

Results: First, we demonstrated our analysis method had comparable automated segmentation accuracy in wild-type and TNF-Tg hindpaws before correction (79.2±8.9% vs 80.1±5.1%, *p=0.52*), determined through analysis of ~9000 individual bones by a single user, with representative μCT (left) and bone segmentation (right) provided **(Fig. 1A-D)**. Compared to other bone compartments, the tarsal region demonstrated a sudden, specific, and significant bone volume reduction in female TNF-Tg mice by 5-months **(Fig. 1E-J)**. This sexual dimorphism was associated with unique bone-specific changes across time, as the cuboid at 4-months of age showed significantly reduced bone volumes compared to all other tarsals. In contrast, TNF-Tg male mice exhibited no difference between individual bone volumes at this timepoint **(Fig. 2A-F)**. Compared to bones with limited erosions (i.e., tibiale), the cuboid showed a corresponding increased synovial and TRAP area **(Fig. 2G-P)**. At 5-months of age, additional bones localized to the antero-lateral region of the ankle were also responsible for the dramatic erosions in the tarsal region of females **(Fig. 3A-F**, red stars), coinciding with increased $TRAP^{+}$ osteoclasts in female vs male TNF-Tg mice **(Fig. 3G-K)**.

Conclusion: Taken together, here we demonstrated that sexual dimorphism of arthritis in TNF-Tg mice is bone-specific, where the cuboid serves as a reliable biomarker of erosive arthritis with the greatest sensitivity to early and consistent bone loss related to enhanced osteoclast numbers. Ongoing work will further investigate the cellular mechanisms of these bone-specific erosions in mice and evaluate the translational potential of these biomarkers in arthritis patients through our segmentation model. 1. Bell et al. *Arthritis Rheumatol*. 71(9):1512-1523. 2019. 2. Proulx et al. *Arthritis Rheumatol*. 56(12):4024-4037. 2007. 3. Cambre et al. *Nat Commun*. 9(1):4613. 2018. 4. Kenney et al. *Bone Rep*. 16(101167). 2022.

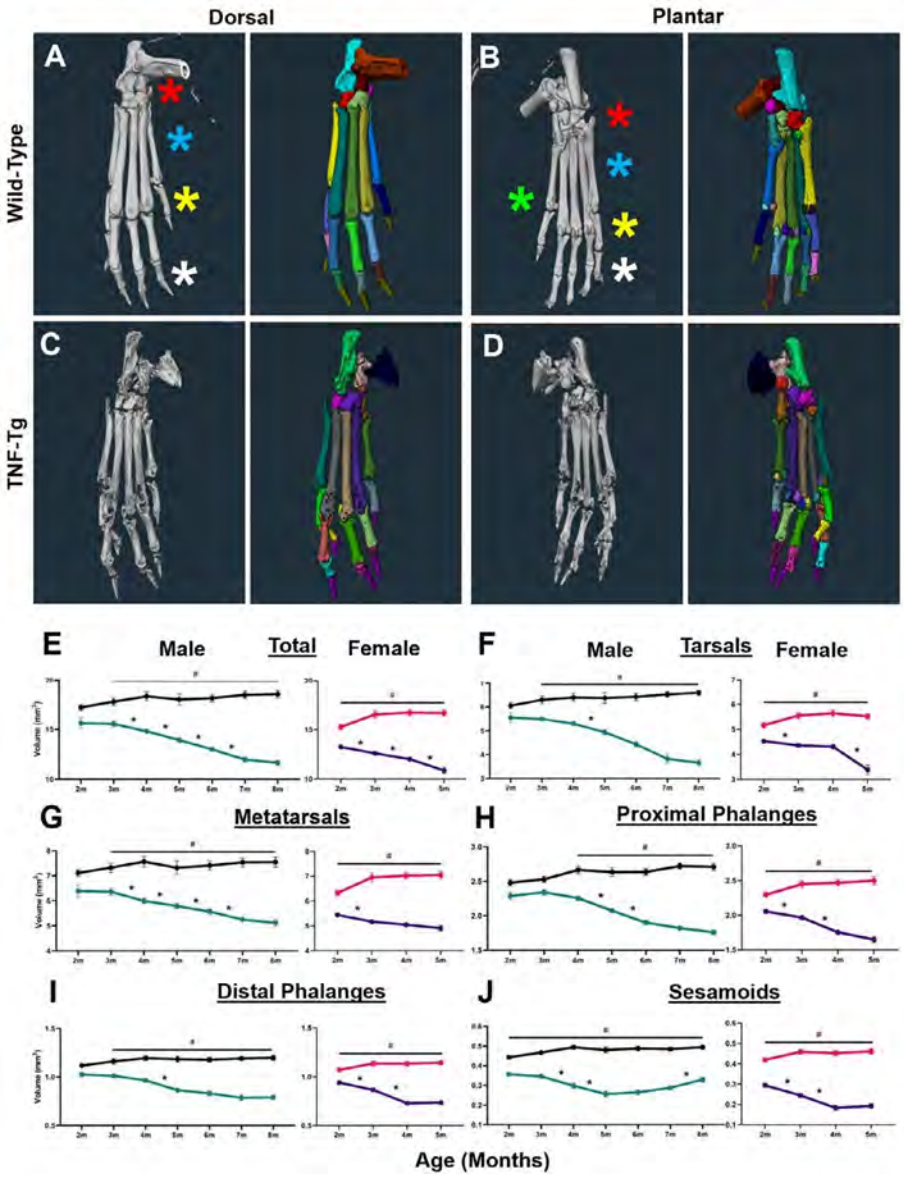

Figure 1. Semi-automated segmentation of TNF-Tg hindpaws reveals unique temporal patterns of erosions by bone compartment in female mice. To evaluate bone-specific erosions in the TNF-Tg mouse model of inflammatory-erosive arthritis, we utilized our recently published high-throughput semi-automated hindpaw segmentation protocol (4). Representative images of the dorsal and plantar surfaces of hindpaw micro-CT images (left) and the segmentation of each bone indicated by unique colors (right) are provided for wild-type (A, B) and TNF-Tg (C, D) male mice at 8-months of age. Without user intervention, the semi-automated protocol produced accurate segmentations of approximately 80% of bones in wild-type datasets (error rate ~20%), which remarkably remains consistent, and potentially improved due to reduced variance, for TNF-Tg mice with bone erosions. Patterns of bone loss in hindpaw compartments (shown in A, B: tarsals, red star; metatarsals, blue; proximal phalanges, yellow; distal phalanges, white; and sesamoids, green) were analyzed for temporal and genotype effects. Although both TNF-Tg males and females exhibited consistent bone loss across time (E, *$p<0.05$), TNF-Tg females showed unique time-dependent erosions by particular compartments. For TNF-Tg females, there was a dramatic decrease in the bone volume of the tarsals between 4-5-months of age (F) that was preceded by early erosions starting at 2-months of age in the bones associated with the phalanges that was not sustained past 4-months (G-J). In contrast, males showed relatively slow progression of erosions with limited statistical change for particular compartments at monthly intervals, except for the metatarsals (F-J). Also note the "U"-shaped progression of bone volumes in the TNF-Tg male sesamoids, likely representing reactive bone remodeling following an initial period of erosions (J). Compared to wild-type, both TNF-Tg male and female mice showed significantly reduced bone volumes in all compartments starting at 3-months and 2-months of age, respectively (#$p<0.05$). Statistics: 2-way ANOVA (males) and mixed-effects analysis (females) with Tukey's multiple comparisons (E-J).

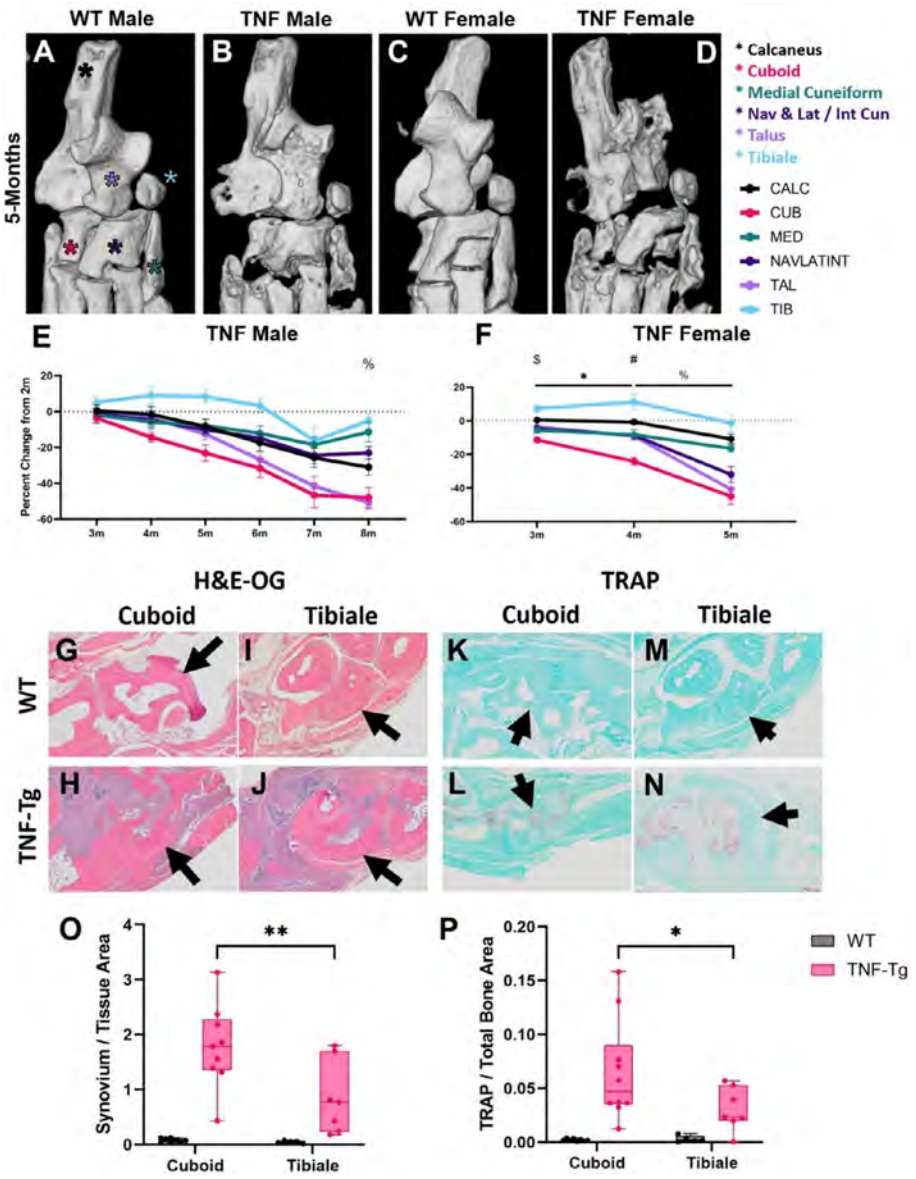

Figure 2. The cuboid is an early biomarker of erosive arthritis in TNF-Tg female mice. To further elucidate the dynamic sex-dependent, bone-specific, and temporal changes in the tarsals of TNF-Tg mice, we directly compared erosive activity between each tarsal bone to determine their biomarker potential during progression of inflammatory arthritis. High-magnification images of the tarsal compartment at 5-months of age, with the individual bones indicated by stars (calcaneus, black; cuboid, pink; medial cuneiform, green; fused navicular, lateral and intermediate cuneiform [a known C57BL/6 murine variant (4)], dark purple; talus, light purple; and tibiale, blue), are shown for each group (A-D). In order to compare the individual bones, percent change in bone volume from their baseline at 2-months was calculated to control for the differences in bone size. TNF-Tg males exhibited no significant difference in erosions between individual bones in the tarsal region, except for the tibiale, which showed a resistance to erosions compared to all other bones, except the medial cuneiform (% $p<0.05$) (E). In contrast, TNF-Tg females exhibited early erosive activity localized specifically to the cuboid bone with significantly reduced bone volumes compared to the other bones in the tarsal region by 3- and 4-months of age ($ cuboid vs all bones except medial cuneiform, # cuboid vs all bones, $p<0.05$). In addition, significant decreases in bone volume over time from 3- to 4-months of age were noted only in the cuboid and fused navicular, lateral cuneiform and intermediate cuneiform (* $p<0.05$). All bones, except for the tibiale, showed significantly reduced bone volumes from 4- to 5-months of age (% $p<0.05$), explaining the time-dependent erosions of the tarsal compartment during this timeframe, noted in Fig. 1 (F). To understand the cellular mechanisms mediating resistance (i.e., tibiale) and susceptibility (i.e., cuboid) to erosions, we histologically assessed and quantified the amount of synovium (H&E-OG) and osteoclasts (TRAP) surrounding these particular bones (arrows). Compared to the tibiale, the cuboid exhibited both increased synovial infiltrate (G-J, purple) and TRAP+ osteoclasts (K-N, red), likely involved in mediating the bone-specific erosions (G-P). Statistics: 2-way ANOVA (E, O, P) and mixed effects analysis (F) with Tukey's multiple comparisons.

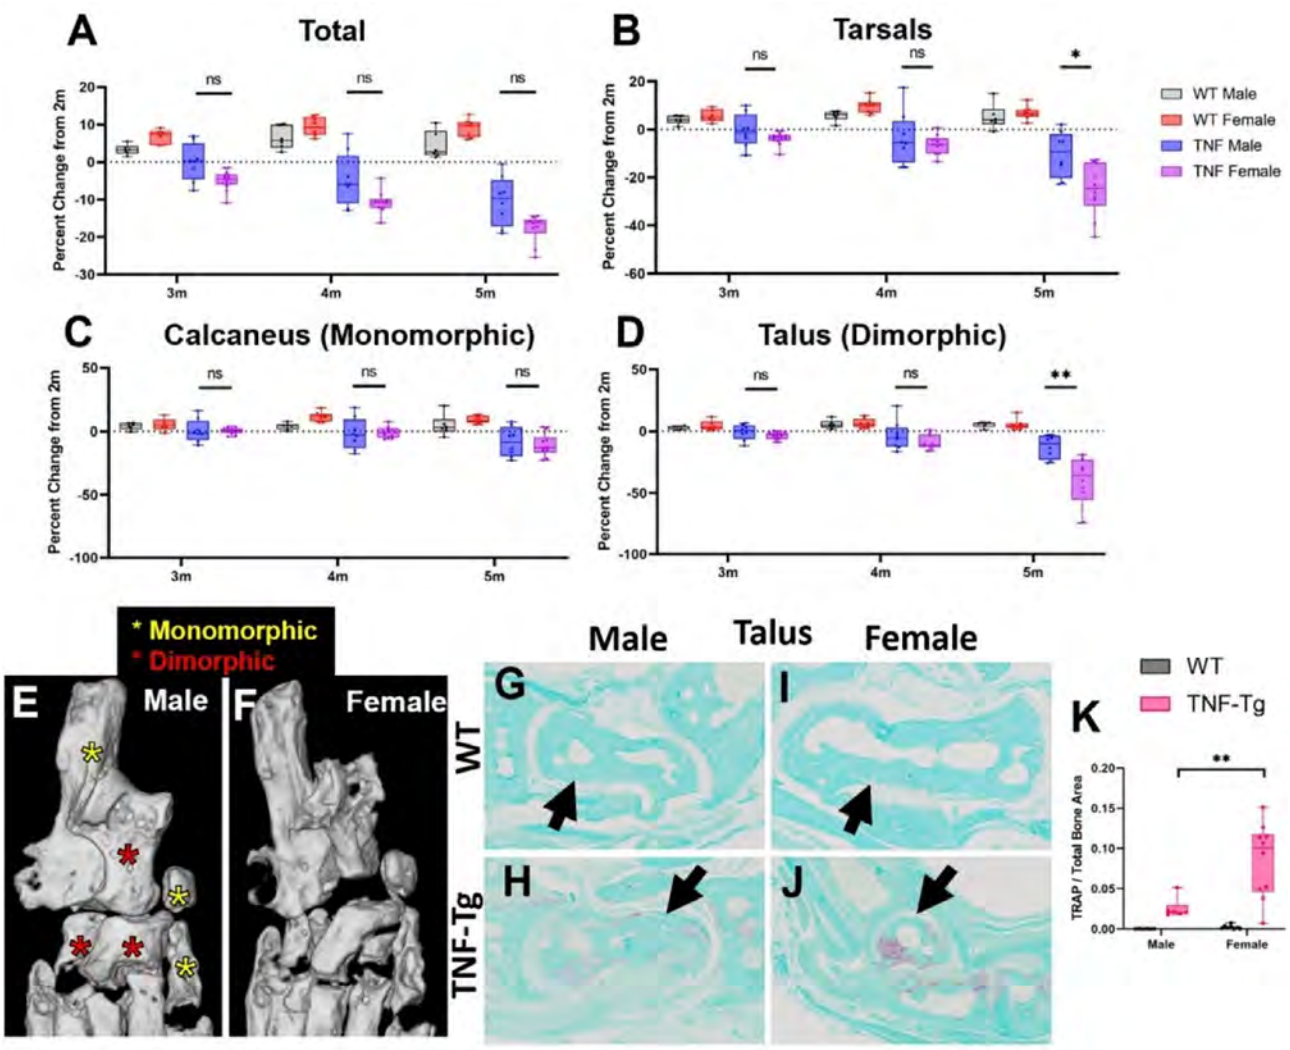

Figure 3. Anterolateral tarsal bones show severe female-specific erosions in TNF-Tg mice. Sex-dependent differences in bone erosions within the tarsal compartment were evaluated using percent change in bone volumes to normalize for animal size between groups. While total bone volume showed no significant changes between TNF-Tg males and females (A), the tarsal compartment exhibited reduced bone volumes in females compared to males at 5-months of age (B). Interestingly, for bones such as the calcaneus (C), there were no changes noted between the sexes. The significant reduction in tarsal bone volume in females was instead driven by sex-specific erosive activity in bones such as the talus (D). The particular bones associated with erosion of the tarsals in females are notably localized to the anterolateral region of the ankle (red stars), while those without sexual dimorphism are oriented posteromedially (yellow stars). Representative micro-CT images of male (E) and female (F) TNF-Tg mice at 5-months of age exhibit the lateralization of the sexually dimorphic effects (reproduced from Fig. 2 for convenience). Corresponding with these bone-specific changes, histologic evaluation revealed significantly increased TRAP+ osteoclasts (red) around the talus in TNF-Tg females vs males at 5-months of age (G-K). Statistics: Mixed effects analysis (A-D) and 2-way ANOVA (K) with Tukey's multiple comparisons; *p<0.05, **p<0.01.

Endothelial Cell Sphingosine 1-Phophate Receptor 1 Restrains VE-cadherin Cleavage and Attenuates Experimental Inflammatory Arthritis

Nathalie Burg[1], Miles Tran[2], Kevin Wei[3], Carl Blobel[1] and Jane Salmon[1], [1]Hospital for Special Surgery, New York, NY, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis, inflammatory mediators extravasate from blood into joints via gaps between endothelial cells (EC), but the contribution of ECs to inflammatory arthritis is not known. Sphingosine 1-phosphate receptor-1 (S1PR1), widely expressed on ECs, plays critical roles in EC barrier function and vascular health. Mice with an inducible EC-specific KO of S1PR1 (S1PR1 ECKO) had increased injury in response to SIA. Blockade of EC S1PR1 induced metalloproteinase-dependent cleavage of VE-cadherin in vitro. These data suggested that vascular leakage associated with S1PR1 inhibition, potentially a consequence of shedding of VE-cadherin, contributed to inflammatory injury. Therefore, we studied mice with highly stabilized EC junctions (VE-cad-α-cat mice) to test whether they resisted vascular permeability in the face of S1PR1 blockade and whether they would resist SIA. We also asked whether patients with active RA have dysregulated S1P/S1PR1 axis favoring vascular leakage.

Methods: VE-cad-α-cat mice were treated with the S1PR1 antagonist NIBR-0213 (30 mg/kg IM) for 3 hours. We measured vascular leak and sVE-cad in bronchoalveolar fluids (BAL) with BCA assay and ELISA, respectively.VE-cad-α-cat, S1PR1 ECKO, and control mice were subjected to SIA (75 ul on days 0 and 2) and clinical scores were measured in a blinded fashion. For human studies, sera from 20 patients with RA and 20 age and sex matched patients with OA were analyzed for S1P and Sa1P by mass spectroscopy. Synovial EC S1PR1 was analyzed by single cell RNA seq in 3 data sets: (1) RA subjects in Accelerating Medicines Partnership Rheumatoid Arthritis / Systemic Lupus Erythematosus (AMP RA/SLE) Network, https://www.biorxiv.org/content/10.1101/2022.02.25.481990v1, (2) RA subjects from the The Roche Network for RA, and (3) healthy controls from Faust et al (https://doi.org/10.1101/2023.05.16.540975). Data sets were integrated and clusters of endothelial subtypes were identified using the top 10 marker genes for each cluster. Capillaries were subsetted for downstream visualization of S1PR1 expression. P-values were calculated using Wilcoxon rank-sum tests across RA statuses.

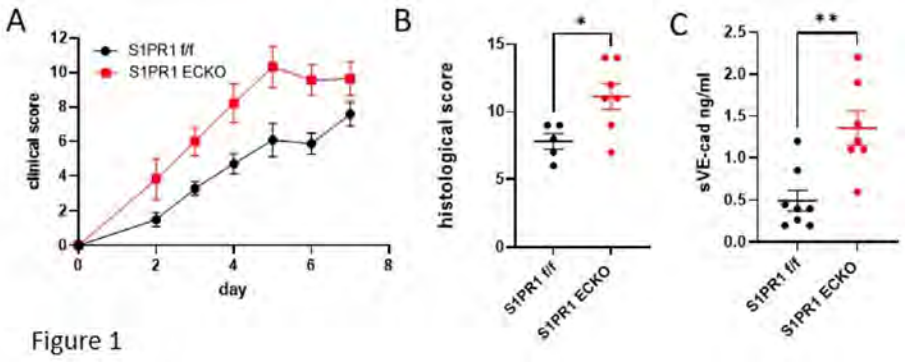

Figure 1

S1PR1 ECKO mice have increased K/BxN serum induced arthritis with evidence of increased soluble VE-cadherin (sVE-cad) in synovial fluids (SF) in early disease. (A) Clinical scores, (B) Histological scores, (C) sVE-cad in SFs on day 2-3 after SIA. *p<0.05; **p<0.01

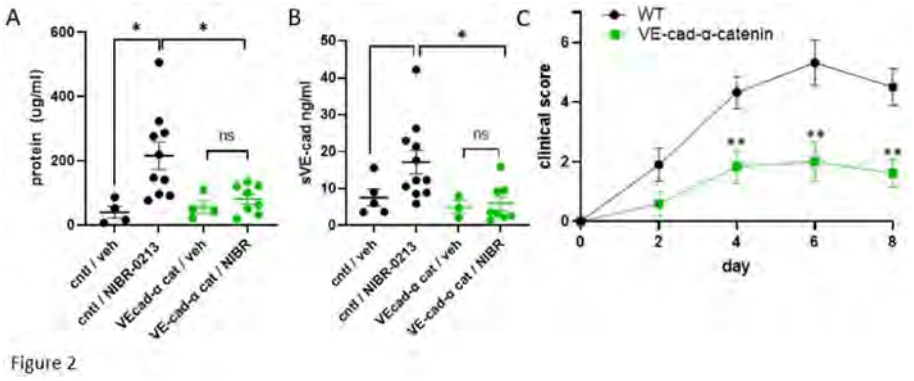

Figure 2

VE-cad-alpha-cat mice demonstrate decreased vascular leakage and soluble VE-cadherin in BAL fluids after challenge with S1PR1 antagonist NIBR-0213 and they resist SIA. Mice were treated with NIBR-0213 for 3 hours before isolation of BAL fluids. (A) BAL protein concentrations, (B) BAL sVE-cad, and (C) clinical scores after SIA. *p<0.05; **p<0.01

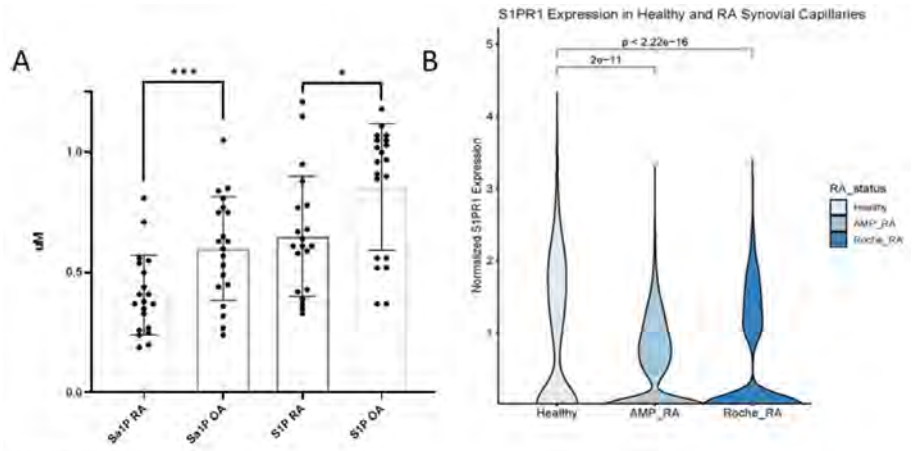

Figure 3

Patients with RA have decreased serum S1P and Sa1P and decreased S1PR1 expression in synovial capillaries compared to controls. (A) S1P and Sa1P levels in active RA vs age and sex matched OA controls. (B) Violin plots indicating S1PR1 expression in capillary ECs from RA and healthy synovial tissues as determined by single cell RNA seq; * p≤ 0.05; *** p≤ 0.001 or as indicated on graph.

Results: S1PR1 ECKO mice had more severe SIA than littermate controls (Fig 1 A,B) along with increased extravascular sVE-cadherin in synovial tissues (Fig 1C). S1PR1 blockade induced less vascular leakage and extravascular VE-cadherin in the BAL in VE-cad-α cat mice compared to controls (Fig 2 A,B).VE-cad-α-cat mice were significantly protected from SIA (Fig 2C). Patients with active rheumatoid arthritis have decreased circulating S1P and Sa1P (Fig 3A), and their synovial microvascular ECs showed decreased expression of S1PR1 (Fig 3B) suggesting dysregulated S1P/S1PR1 axis in favor of vascular permeability and vulnerability.

Conclusion: We present a model in which EC S1PR1 signaling restrains the shedding of VE-cadherin to maintain homeostatic vascular barrier function and curb inflammation in experimental arthritis. Our hypothesis that vascular permeability is a clinical target in RA is supported by evidence that patients have dysregulated S1P/ S1PR1. We identify the microvascular barrier as a potential therapeutic target in inflammatory arthritis.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Animal Models Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by pain, swelling, and joint destruction that decreases mobility.RA patients also suffer from pulmonary disease (PD) and sarcopenia, which decrease strength and endurance for physical activity (PA).Remarkably, the ACR just released its first guidelines on exercises in conjunction with medications as an integrative management approach for RA.[1]However, the risk:benefit ratio of exercise on inflamed joints remains a major concern, although the most recent clinical studies demonstrate long-term benefits.[2]In the tumor necrosis factor transgenic (TNF-Tg) mouse model of RA, which displays joint and extra-articular sequelae of RA in a sexually dimorphic manner, we showed that voluntary wheel running is effective in improving PD, but also exacerbated joint degeneration, correlating with activity output.[3, 4]Coinciding with the multifactorial disease phenotype in TNF-Tg mice, running activity (distance, rate, length, and number of run bouts) significantly declined during disease progression vs. WT littermates through multiple potential contributing features, including joint degeneration, PD, pain, gait deficiency, and sarcopenia, which have not been holistically studied in RA mouse models.

Methods: To address this deficiency, we developed an automated, *ad libitum* wheel running tracking system to examine disease outcomes related to PA and the relationship with features of RA disease outcomes in TNF-Tg mice.To holistically quantify the independent disease variables associated with PA outcomes, we developed longitudinal outcome measures of bone erosion and PD (micro-CT),[3] pain (semiautomated von Frey with the Topcat EVF system), gait (TreadScan^{Tm}), and sarcopenia (DEXA), and evaluated 8 groups of mice: male and female TNF-Tg running vs. sedentary controls, and their WT littermates.

Results: Evaluation of PD revealed that running males and females increased their aerated lung volumes, which was positively correlated with running distance and rate in WT and TNF-Tg female mice,[3] confirming the known efficacy of exercise on cardiopulmonary disease.[5] In contrast, talus bone volumes were significantly reduced in running vs. sedentary males, and negatively correlated with running distance and rate in both male and female TNF-Tg mice.[3]We also found that TNF-Tg mice have reduced sensitivity thresholds indicative of pain (**Figure 1**, $p< 0.05$), decreased stride length, and reduced lean mass (**Figure 2**, $p< 0.05$) vs. WT littermates.

Conclusion: Taken together, these results demonstrate the feasibility of holistically assessing the relationship between PA and independent disease variables in murine models of arthritis. Ongoing studies will evaluate the effects of regimented exercise on the onset and progression of these various manifestations in RA towards strategic refinement and integration of non-

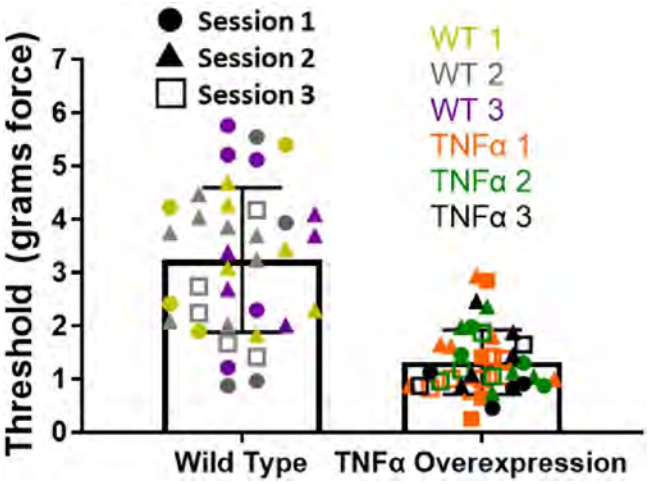

Figure 1. Automated pain assessment of mice with chronic arthritis. 4-month-old male WT and TNF-Tg mice, denoted by color, were evaluated for touch sensitivity in the modified Topcat EVF system. Values were averaged from 3 testing sessions 3 days apart denoted by symbol (n=3; p=0.0002 via t-test).

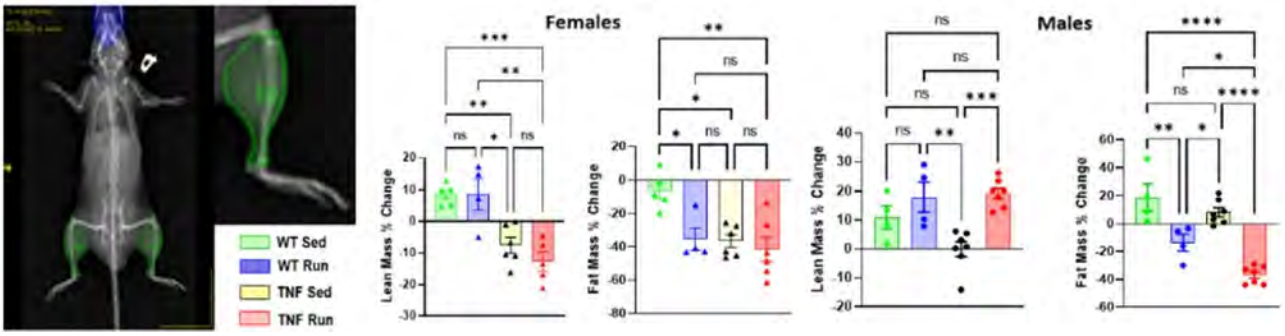

Figure 2. Ad libitum wheel running alters body composition of mice in a sexually dimorphic manner. A representative scout view of a DEXA scan of a mouse is shown to illustrate segmentation of the lower hind-limb soft tissue region of interest (ROI) used for body composition studies. DEXA analyses of the % change in lean mass (muscle) and fat mass composition of WT and TNF-Tg mice from 2 to 5.5 months of age ± ad libitum wheel running are shown. Data are presented for each mouse with mean ± SD (*p<0.05, **p<0.01, ***p<0.001, ****p<0.0001, two-way ANOVA with Tukey's multiple comparisons).

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Animal Models Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteitis on MRI and bone microstructure changes (BMC) on high-resolution peripheral quantitative CT are the earliest signs of arthritis, preceding the development of bone erosion in rheumatoid arthritis (RA). Recently, a JAK inhibitor, Baricitinib (BAR), was shown to inhibit these early changes. This study aimed to elucidate the underlying molecular mechanism of osteitis and BMC, including the role of JAK-STAT cytokines, using SKG mice, an animal model of RA with a ZAP70 gene point mutation.

Methods: Osteitis was assessed by an increase in the femur/gastrocnemius muscle (F/G) ratio in fat-suppressed T2-weighted images on MRI. BMC was evaluated by a decrease in bone volume/tissue volume (BV/TV) ratio on micro CT. Arthritis was induced by intraperitoneal injection of zymosan. BAR or a vehicle was orally administered in the early or late phases during arthritis development. Flow cytometry was used to analyze the bone marrow (BM) cells, including granulocyte-monocyte (GM) progenitor cells, granulocytes, and monocytes. Immunohistochemistry (IHC) was performed

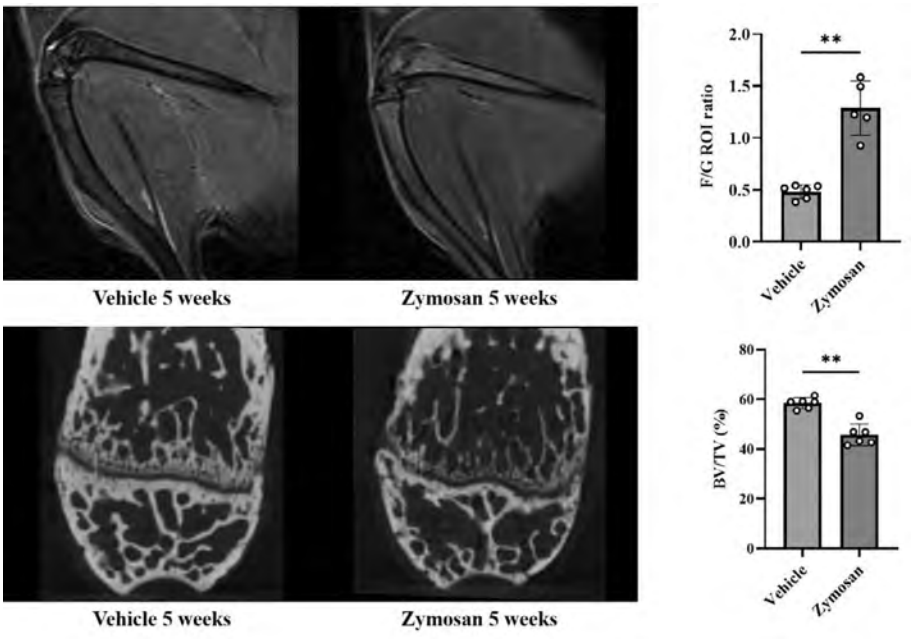

Figure: Osteitis and bone microstructure changes after arthritis induction in SKG mice BV/TV: Bone volume/Tissue volume, F/G: Femur/Gastrocnemius muscle Mann-Whitney test, ** $p < 0.01$

to identify the distribution of tartrate-resistant acid phosphatase (TRAP)-positive cells in the BM. The role of JAK-STAT cytokines was investigated by examining the expression of JAK-STAT cytokines in the BM or by supplementing recombinant (r-) GM-CSF or IL-6 to *in vivo* arthritis model or *in vitro* RANKL-mediated osteoclast differentiation assay.

Results: Osteitis developed earlier (at 2 weeks) than BMC (at 5 weeks) during arthritis development. Osteitis scores on MRI well correlated with BMC scores on micro CT (ρ=-0.58, p=0.03). Following zymosan injection, GM progenitor cells, granulocytes, and monocytes were increased in the BM. The number of monocytes significantly correlated with osteitis scores (ρ=0.77, p=0.0008). Monocytes were further subdivided into three populations (Ly6C high CD11b low, Ly6C high CD11b high, and Ly6C mid CD11b+), and TRAP-positive osteoclasts were preferentially differentiated from the Ly6C high CD11b low population (osteoclast precursor cells) *in vitro*. IHC revealed increased TRAP-positive cells at the edges of bone surfaces in the BM where BMC was observed. BAR effectively suppressed osteitis (F/G ratio: 1.44 in vehicle group vs. 1.17 in BAR group, p=0.0379) and BMC (BV/TV ratio: 37.3 % in vehicle group vs. 46.3 % in BAR group, p=0.0052). BAR reduced the number of GM progenitor cells, monocytes, and osteoclast precursor cells. Among JAK-STAT cytokines, GM-CSF and IL-6 were highly expressed in the BM after zymosan injection. *In vivo* administration of rGM-CSF to SKG mice promoted osteitis, especially when administered in the late phase of arthritis. *In vitro* addition of rGM-CSF to osteoclast differentiation assay markedly increased the number and size of osteoclasts, especially when added in the late phase of osteoclast differentiation, which was inhibited by further addition of BAR.

Conclusion: During arthritis progression, osteitis precedes BMC. The increase of GM-lineage cells in the BM induces osteitis, while proliferation and subsequent differentiation of osteoclast precursors contribute to BMC. JAK-STAT cytokines, especially GM-CSF, play a crucial role in these processes.

Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Discovery of the essential role of S1P signaling in regulating lymphocyte trafficking led to the development of S1P receptor modulators for the treatment of autoimmune disorders such as multiple sclerosis and ulcerative colitis. Cenerimod, a selective S1P1 receptor modulator, has shown positive results in preclinical models of SLE, systemic sclerosis, and Sjögren's syndrome[1-3] and two phase 2 trials in SLE. Recruitment is ongoing for two Phase 3 clinical trials

investigating 4 mg cenerimod for the treatment of adults with SLE (OPUS; NCT05648500 & NCT05672576). We examined the potential of cenerimod to modulate the progression of rheumatoid arthritis (RA) in multiple preclinical murine models.[4]

Methods: Cenerimod was orally administered as therapeutic or prophylactic treatment in RA rodent models. In the mBSA-DTH model, C57BL6/J mice were immunized with mBSA/CFA before antigen challenge. Pristane-induced arthritis (PIA) and adjuvant-induced arthritis (AIA) were induced in rats by CFA or pristane challenge, respectively. Disease development was monitored by measuring edema formation. Relevant biomarkers such as cellular changes, autoantibody development, and chemokine secretion were measured in plasma, inflamed tissue, and draining lymph nodes.

Results: In the mBSA-DTH model, cenerimod significantly reduced joint swelling and limited the production of autoantibodies and pro-inflammatory chemokines in the joints. Furthermore, analysis of the draining lymph nodes revealed a novel effect of cenerimod treatment in mitigating the migration of dendritic cells. Similarly, proliferation and cytokine secretion by effector T cells were blunted by S1P1 receptor modulation, which may be a direct consequence of reduced dendritic cell lymph node homing and hence, antigen presentation. In the rat PIA model, therapeutic cenerimod treatment decreased paw inflammation by inhibiting leukocyte influx to the site of inflammation. In the AIA model, low-dose cenerimod treatment limited joint inflammation to the same degree as low-dose corticosteroid treatment with dexamethasone, without displaying negative effects on body weight.

Conclusion: Cenerimod is highly efficacious in several murine RA models by preventing antigen transport, by reducing the release of pro-inflammatory cytokines & chemokines, and by inhibiting lymphocyte egress to the circulation. In particular, the reduction of dendritic cell migration suggests cenerimod may modulate antigen presentation, which could have implications for the treatment of autoimmune diseases. Our findings suggest that cenerimod can effectively disrupt multiple nodes of a vicious circle of pathogenesis associated with rheumatic diseases like RA. Combining these novel results with published data, we propose that S1P1 receptor modulation has potential to provide clinical benefit to patients with arthritis who currently lack satisfactory treatment options.

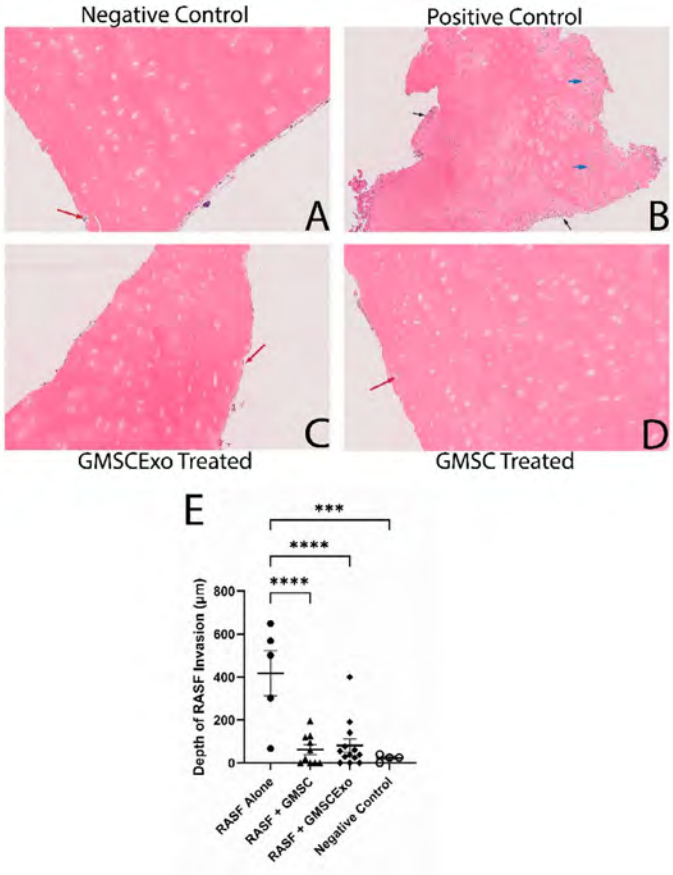
The Therapeutic Effects of Gingival Mesenchymal Stem Cells and Their Exosomes in a Chimeric Model of Rheumatoid Arthritis

shane Bruckner[1], Braden Zeno[2], Vittoria Capria[1], William Willis[3], Latha Prabha Ganesan[1] and wael Jarjour[1], [1]Ohio State University, Columbus, OH, [2]Ohio State University, Upper Arlington, OH, [3]Ohio State University, Reynoldsburg, OH

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that leads to progressive joint destruction involving multiple joints. There is a large body of evidence that suggests a crucial role for activated synovial fibroblasts in mediating both direct tissue injury and perpetuation of the complex disease process in RA (1). Synovial fibroblasts derived from RA patients (RASF) are able to attach to articular cartilage and deeply invade and degrade the cartilage matrix (2) and have been shown to migrate to secondary joint locations *in vivo* and invade and degrade cartilage similarly to the primary site (3). Human gingival-derived mesenchymal stem cells (GMSC) are promising therapeutic cell treatments for autoimmune diseases due to their immunomodulatory capacity (4). Others have demonstrated the ability of GMSC, and exosomes derived from GMSCs (GMSCExo) to suppress the deleterious *in vivo* effects of the collagen induced arthritis model in mice (5). Our aim was to test whether the destructive invasive effects of RASF in an *in vivo* chimeric mouse model of RA could be modulated by the presence of GMSC or GMSCExo. In addition, we analyzed the effects of both GMSC and GMSCExo on the ability of RASF to migrate to secondary locations. Mechanistic studies were done to understand how the GMSC were inhibiting the invasiveness of the RASF.

Methods: A chimeric human/mouse model of synovitis was created by surgically implanting SCID mice with a small piece of human articular cartilage surrounded by RASF. Each mouse received two implants; the primary implant on the right flank of the mouse contained RASF, the secondary implant contained no RASF. Mice were retro-orbitally injected once with either GMSC or GMSCExo at 5-7 days post-implantation. The implants were removed after 60 days for evaluation. Histology and IHC were used to assess RASF invasion of the cartilage. Flow cytometry was used to understand the homing ability of GMSC *in vivo,* the incidence of apoptosis of RASF and the exchange of exosomes *in vitro*.



GMSC and GMSC Derived Exosomes Block RASF Cartilage Degradation. (A) Untreated cartilage showing no RASF invasion (B) RASF treated cartilage showing perichondrocytic invasion, blue arrows, and pannus like invasive structures degrading the cartilage (C) RASF treated followed by GMSCExo treatment blocks RASF invasion and degradation (D) RASF treated followed by GMSC treatment blocks RASF invasion and degradation (E) GMSCExo and GMSC both block RASF cartilage invasion

Results: We demonstrate that both GMSC and GMSCExo are potent inhibitors of the deleterious effects of RASF. Both treatments were effective in inhibiting the invasive destructive properties of RASF as well as the potential of these cells to migrate to secondary locations and attack the cartilage there. We also present evidence that GMSC home to the site of the implant and induce programmed cell death of the RASF through the direct transfer of exosomes.

Conclusion: Our results indicate that both GMSC and GMSCExo can block the pathological effects of RASF in this chimeric model of RA. A single dose of either GMSC or GMSCExo can inhibit the deleterious effects of RASF. These treatments can also block the invasive migration of the RASF, suggesting that they can inhibit the spread of RA to other joints. Because the gingival tissue is harvested with little difficulty, relatively small amounts of tissue are required to expand the cells, the fairly simple *in vitro* expansion process, and the increasing technological advances in the production of therapeutic exosomes, we believe that GMSC and GMSCExo are excellent candidates as a treatment for RA.

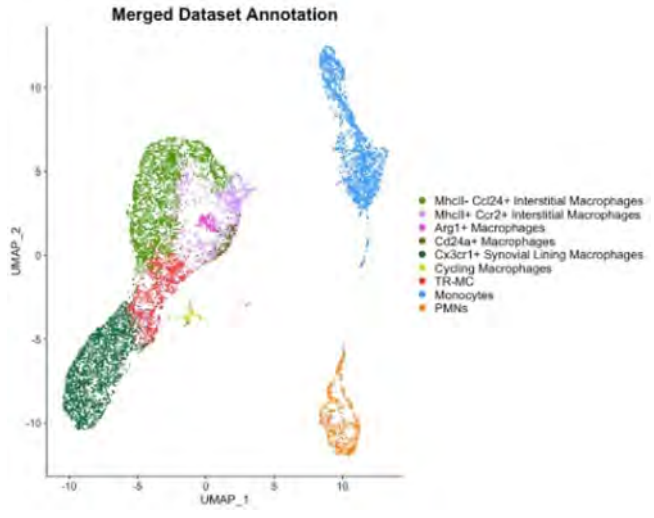
Abstract Number: 1722

Fate-mapping of Synovial Monocytes and Macrophages

Yidan Wang[1], Carla Cuda[1], Deborah Winter[2] and Harris Perlman[1], [1]Northwestern University, Chicago, IL, [2]Northwestern University, Skokie, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Synovial monocytes and macrophages are heterogenous populations. These populations play diverse roles in the development of arthritis in humans and mice. In recent years, our laboratory identified a new synovial cell type we named tissue-resident monocyte-lineage cells (TR-MCs), which are are necessary for the development of



The annotation of the merged CITE-seq datasets of synovial macrophages and monocytes.

inflammatory arthritis in mice. Although TR-MCs are CD64 negative and transcriptionally distinct from circulating monocytes and DCs, the current lack of targeted mouse models limit our ability to study this critical population and differentiate from other synovial monocyte and macrophage populations.

Methods: To study each synovial monocyte and macrophage population, we performed fate-mapping with 7 reporter models including *Cx3cr1*-ERcre-Ai3-YFP, *Cx3cr1*-Cre-Ai3-YFP, *Ms4a3*-cre-*Ai3*-YFP, *P2ry12*-ERcre-*Ai3*-YFP, *Tmem119*-GFP, *Cd68*-eGFP, and *Csf1r*-cre-*Ai3*-YFP in 8–12-week-old C57BL/6 mice. We also further characterized synovial monocyte and macrophage cells by performing cellular indexing of transcriptomes and epitopes (CITE-seq) on synovial macrophages (CD45+CD11b+CD4-CD8-Ly6G-SiglecF-NK1.1-CD64+) and monocytes (CD45+CD11b+CD4-CD8-Ly6G-SiglecF-NK1.1-MHCII-CD64-).

Results: Although 90% of synovial macrophages, 82% NCM and 76% TR-MC are derived from *Cx3cr1*-positive progenitor cells, only 41%, 91%, 27% of them express *Cx3cr1 at 8-12 week-old*. Although high percentages of Csf1r-expression were found in almost all synovial cell types, synovial macrophages express the highest intensity of *Csf1r*. Similarly, *Ms4a3* was expressed at a high percentage in both granulocytes and monocyte-lineage cell, but the intensity of Ms4a3 is more than 2 times higher in macrophages than other cell types. *P2ry12* was expressed in synovial macrophages and TR-MC with 20% positivity. The expression of CD68 and Tmem119 are same in all synovial myeloid cell types. To develop specific reporter models of synovial monocyte and macrophage subpopulations, we characterize them by merging the 2 CITE-seq datasets and identified 5 synovial macrophages subpopulations - MHCII+ CCL24+ interstitial macrophages, MHCII-CCR2+ interstitial macrophages, Arg1+ macrophages, CD24a+ macrophages and CX3CR1+ synovial lining macrophages as well as TR-MCs, monocyte-lineage cells and polymorphonuclear leukocytes (PMNs). MHCII- CCL24+ interstitial macrophages specifically expressed Cd209d and Ccl24 genes. Arg1+ macrophages exclusively expressed Arg1 and Flt1 genes. The differentially expressed genes of CX3CR1+ synovial lining macrophages are aligned with the CX3XR1+ lining macrophages published by Culemann S, et. al. CD24a+ macrophages highly expressed Tnip3 and Anxa8 genes as well as CD11c surface marker.

Conclusion: Our results currently showed that Cx3cr1, Csf1r, Ms4a3 and P2ry12 may have the ability of tracing one or more synovial monocyte and macrophage populations. The gene and surface markers identified in each synovial monocyte, macrophage and TR-MC population will help develop better tools to trace and delete them. Future studies will also focus on determining the spatial topology of each synovial monocyte and macrophage population to better define their role in joint health.

3,3-dimethyl-1-butanol and Its Metabolite 3,3-dimethylbutyrate Ameliorate Arthritis Severity in CIA Independent of Choline TMA Lyase Activity

Brendan Allen[1], Sabrina Fechtner[2], Meagan Chriswell[3], Widian Jubair[1], M. Aaron Vrolijk[1], V. Michael Holers[4] and kristine Kuhn[1], [1]University of Colorado School of Medicine, Aurora, CO, [2]University of Colorado Anschutz Medical Campus, Aurora, CO, [3]University of Colorado Anschutz SOM, Denver, CO, [4]University of Colorado, Denver, CO

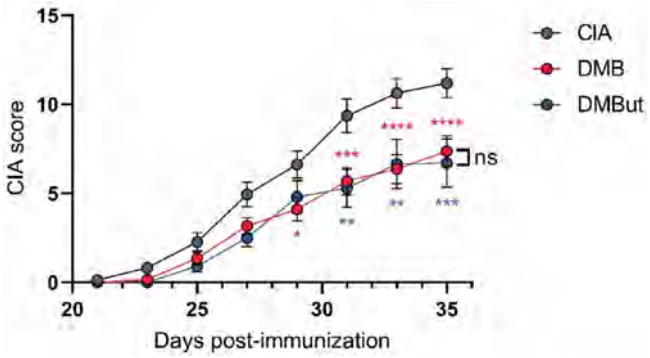
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Both human and animal studies associate specific microbiota and microbial metabolic pathways with the development of RA and autoimmune arthritis, thereby providing a novel target for next-generation therapeutic development. Notably, carnitine and choline metabolism are associated with RA in humans and autoimmune arthritis in the collagen-induced arthritis (CIA) mouse model. Further, specific bacteria linked to disease in RA and CIA can metabolize dietary carnitine and choline to drive production of trimethylamine-N-oxide (TMAO). TMAO is implicated in the pathogenesis of inflammatory diseases, such as atherosclerosis, whose underlying disease processes mirror that of RA and CIA. Thus, we investigated modulation of TMAO production as a therapeutic target in CIA using the choline TMA lyase inhibitors 3,3-diemthyl-1-butanol (DMB) and fluoromethylcholine (FMC).

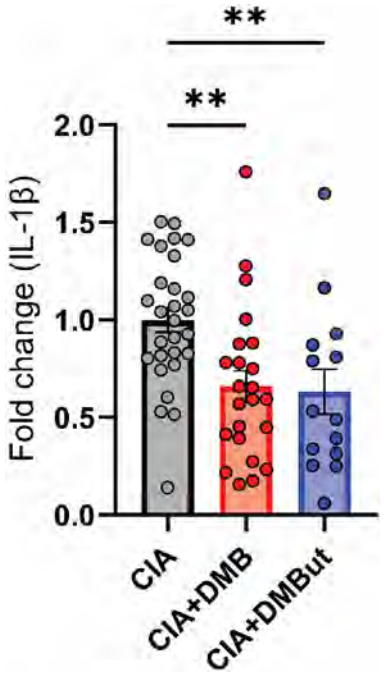
Methods: 6-week-old male DBA/1j mice were immunized at days 0 and 21 with bovine type II collagen (CII) in complete Freund's adjuvant and either left untreated or treated with 1% (vol/vol) DMB, 1% (vol/vol) 3,3-dimethylbutyrate (DMBut), or 100mg/kg FMC. Mice were assessed for disease severity using established metrics until 35 days post-initial immunization. On day 35, mice were sacrificed and tissues were harvested for analysis. Multiplex serum cytokine immunoassays; serum anti-CII ELISAs; fecal 16S sequencing; serum and liver metabolomics; flow cytometry of splenocytes and inguinal lymph node lymphocytes; and cytokine ELISAs of bone marrow-derived macrophage (BMDM) supernatants were performed.

Results: Mice given DMB showed significant reduction (>50%) in disease severity relative to untreated mice with CIA, while mice given FMC did not show reduced disease. FMC but not DMB significantly reduced cecal TMA and serum TMAO concentrations compared to untreated CIA mice. Fecal bacterial communities were not significantly altered by treatment with either FMC or DMB. DMB and its predicted metabolite, DMBut, were detected in the liver and serum, suggesting systemic effects, and both significantly reduced arthritis severity and circulating IL-1β and IL-6, but not circulating anti-CII antibodies, compared to untreated CIA mice. Splenic Th17 populations were significantly increased with DMBut treatment, but Th1, Tfh, and Treg populations were unchanged with DMB and DMBut treatment. Stimulation of BMDMs with LPS in the presence of DMB or DMBut significantly reduced secretion of IL-1β and IL-6.

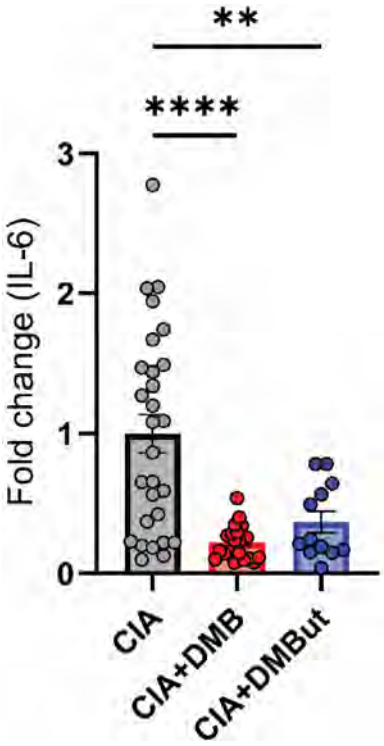
Conclusion: We found that inhibition of microbial TMA/TMAO production using FMC does not reduce arthritis severity in CIA, while treatment with DMB ameliorates CIA seemingly independent of TMA/TMAO production or microbiome effects. Moreover, DMB and a product of its metabolism in the host, DMBut, both significantly reduce disease severity and pro-inflammatory cytokines in CIA and stimulated BMDMs, suggesting that DMB and/or its metabolites have anti-inflammatory effects on monocytes. Elucidating the mechanism by which these small molecules modulate disease may provide directions for developing future RA therapies.



CIA was induced in 6-week-old male DBA/1j mice. On day 21 post-initial immunization, mice were left untreated (CIA), treated with 1% (v/v) DMB in drinking water (DMB), or treated with 1% (v/v) DMBut in drinking water (DMBut). N=24 (CIA), N=23-25 (DMB), and N=10 (DMBut) per group pooled from 5 individual experiments. Data are reported as mean ± SEM. *, p<0.05; **, p<0.01; ***, p<0.001; ****, p<0.0001; ns, non-significant as determined by two-way ANOVA with Bonferroni correction for multiple comparisons.



Serum was harvested from male DBA/1j mice at day 35 post-initial immunization and analyzed for IL-1B by a 6-plex immunoassay (Mesoscale). N=24-29 (CIA), N=27 (CIA+DMB), and N=14 (CIA+DMBut) per group pooled from 6 individual experiments. Data are reported as fold change normalized to the cytokine concentrations in the CIA group (symbols) and group mean ± SEM. **, p<0.01 as determined by one-way ANOVA with Dunnett's correction for multiple comparisons.



Serum was harvested from male DBA/1j mice at day 35 post-initial immunization and analyzed for IL-6 by a 6-plex immunoassay (Mesoscale). Human Embryonic Stem Cell-derived Mesenchymal Stem Cells Attenuates Experimental Pulmonary Fibrosis Through Mitochondria Transfer Mediated Anti-apoptotic and Immunomodulatory Effects

Hanna Lee[1], Suhee Kim[2], Mingyo Kim[2], Ok-Yi Jeong[3] and **Sang-Il Lee**[2], [1]Department of Internal Medicine, Gyeongsang National University Changwon Hospital, Changwon, South Korea, [2]Department of Internal Medicine and Institute of Health Science, Gyeongsang National University School of Medicine and Hospital, JinJu, South Korea, [3]Division of Rheumatology, Department of Internal Medicine and Institute of Health Science, Gyeongsang National University School of Medicine and Gyeongsang National University Hospital, Jinju, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a serious condition characterized by inflammation and fibrosis in the lung interstitium. The important subtypes of ILD include idiopathic pulmonary fibrosis (IPF) and connective tissue disease-associated ILD (CTD-ILD). The main histopathological pattern observed in IPF and Rheumatoid arthritis-ILD (RA-ILD) is usual interstitial pneumonia (UIP), and if left untreated, the prognosis is unfavorable. Recently, cell-based mesenchymal stem cells (MSCs) can improve lung fibrosis through anti-apoptotic effect by immunomodulation, protein expression regulation, and mitochondria transfer. However, this ability decreases with passage in adult tissue-derived MSC. But Embryonic stem cell, called DW-MSCs, maintains a constant their ability even after repeated passage culture. Therefore, we evaluated whether DW-MSC can improve lung fibrosis in IPF and RA-ILD, and to identify the mechanism of improvement.

Methods: A total of 1.0 x 10^6 DW-MSCs were injected into mice via the tail vein either 4 or 7 days after intratracheal administration of bleomycin and collagen induction. The therapeutic effect was analyzed by evaluation the lung tissue fibrosis scores, and α-SMA expression through western blot and immunohistochemistry. The immune cell modulation of DW-MSCs was evaluated by analyzing immune cells in lung tissue using flow cytometry analysis. The Damaged AECs protection of DW-MSCs was investigated by inducing apoptosis in A549 cells with $CoCl_2$ and confirming trough TUNEL assay, cell viability and the expression level of Bcl-2 and Bcl-2 associated X (Bax) through western blot. Lastly, we co-cultured DW-MSCs and hypoxia-induced AECs to confirm the transfer of mitochondria through tunneling nanotubes (TNTs) of DW-MSCs using fluorescence microscopy.

Results: DW-MSCs attenuates Bleomycin-induced and Collagen-induced pulmonary fibrosis. The therapeutic efficacy of DW-MSCs was found to be comparable to Nintedanib. DW-MSCs showed improvements in the fibrosis score, reduced α-SMA expression, and regulated fibrosis relate gene expression. Furthermore, DW-MSCs exhibited immunomodulatory effects by influencing B cells during the early phase and promoting an increase in regulatory T cells while decreasing Th17 cells during the late phase. Additionally, DW-MSCs demonstrated the ability to inhibit apoptosis in damaged AECs and down-regulate apoptosis-related proteins. Moreover, DW-MSCs enhanced cell viability and mitochondrial respiration in damaged epithelial cells by facilitating the transfer of mitochondria through tunneling nanotubes.

Conclusion: Our study provides compelling evidence for the therapeutic potential of DW-MSCs in improving IPF and RA-ILD. A single administration, DW-MSCs exhibit beneficial effects on AECs injury, inflammation, and fibrosis. These effects are achieved through the protection of AECs by inhibiting apoptosis, facilitating mitochondrial transfer, and exerting

immunomodulatory and anti-fibrotic effects. Additionally, their high clinical applicability is an added advantage as their efficacy remains constant across various passages. Therefore, DW-MSCs can be considered an ideal candidate for ILD treatment in the future.

Distinct Perivascular and Intravascular Lymphatic Mast Cells and Their Role in Lymphatic Clearance, Joint Inflammation, and Bone Erosion in the TNF-Transgenic Murine Arthritis Model

Yue Peng[1], H. Mark Kenney[2], Karen Bentley[3], Lianping Xing[4], Christopher T Ritchlin[5] and Edward Schwarz[3], [1]University of Rochester Medical Center, Rochester, NY, [2]University of Rochester School of Medicine and Dentistry, Henrietta, NY, [3]University of Rochester, Rochester, NY, [4]University of Rochester Medical Center, Webster, NY, [5]University of Rochester Medical School, Allergy, Immunology & Rheumatology Division, Canandaigua, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory-erosive arthritis is exacerbated by lymphatic dysfunction (1), and mast cells (MCs) regulate lymphatic vessel contractions via release of inflammatory and vasoactive mediators (2). In studies to directly assess this relationship, we identified a novel population of intravascular MCs embedded in the cellular architecture of murine joint-draining popliteal lymphatic vessels (PLVs) (3), along with perivascular MCs surrounding the PLV. Here, we investigated the phenotypic differences between PLV perivascular and intravascular MCs to elucidate their respective roles in regulating lymphatic function and inflammatory-erosive arthritis through genetic ablation and pharmacologic inhibition of MCs.

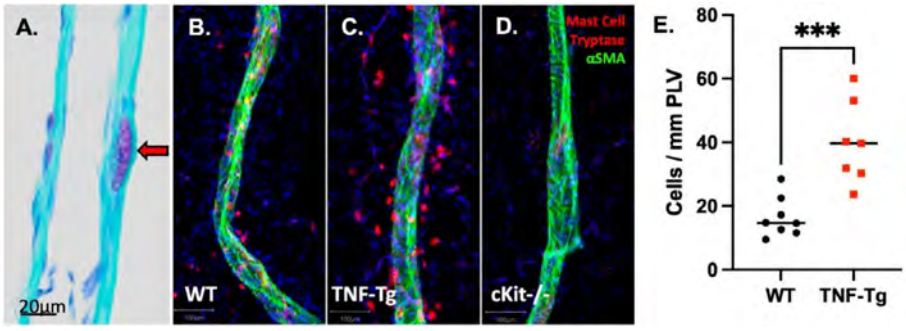

Figure 1. Identification of intravascular MCs and increased numbers of MCT+ perivascular MCs in TNF-Tg mice. Longitudinal sections of PLVs obtained from WT mice were subjected to toluidine blue staining, and a 200x micrograph is shown highlighting a novel intravascular MC embedded within the lymphatic vessel wall (red arrow), situated between the layers of lymphatic endothelial and lymphatic muscle cells (A) (3). PLVs were harvested for WMIFM of αSMA (green) and MCT (red), and representative 200x images are shown for WT (B),TNF-Tg (C), cKit-/-(D) mice, which demonstrated a complete absence of MCT+ MCs in cKit-/- as confirmation of the genetic ablation in this model. Quantification of perivascular MCT+ cells showed a significant increase in MCs surrounding inflamed TNF-Tg PLVs, normalized to vessel length (E, n=8). Statistics: Unpaired Mann Whitney test (E); ***$p < 0.001$.

Methods: PLVs from WT, TNF-Tg, and *Kit*$^{W\text{-}sh/W\text{-}sh}$ (cKit$^{-/-}$) mice (4), which have a selective hematopoietic deficit in MCs, were harvested for whole mount immunofluorescent microscopy (WMIFM) and toluidine blue histochemistry to identify MCs. *In silico* analyses were performed on single-cell RNA sequencing (scRNAseq) datasets of PLV MCs (5) vs MC populations identified in the Mouse Cell Atlas (6). Near-infrared indocyanine green (NIR-ICG) imaging quantified lymphatic clearance function. Longitudinal micro-computed tomography (μCT) assessed bone erosions, while H&E and TRAP histology evaluated synovitis and osteoclasts of the afferent ankle. MC deficiency was studied in cKit$^{-/-}$ x TNF-Tg mice (n=3), while MC inhibition was investigated in TNF-Tg mice treated with cromolyn sodium (CS; 3.15mg/g/day/i.p., n=6) vssaline (n=5) for 3 weeks.

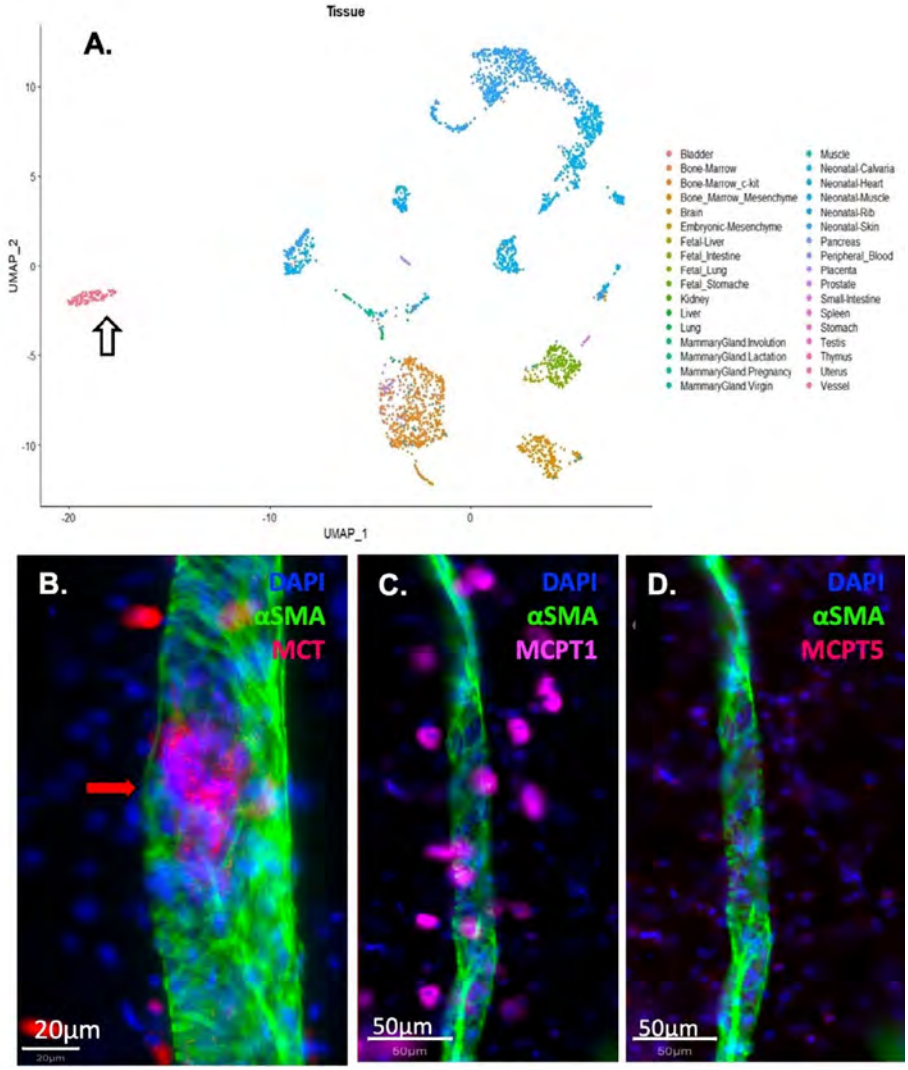

Figure 2. Identification of a unique MCT+/MCTP1-/MCPT5- PLV intravascular MC population. In silico datasets were used to extract MCs from a comprehensive scRNAseq dataset of 242k cells encompassing various organs in the Mouse Cell Atlas (6). The extraction was performed based on the expression of MC marker genes (Mcpt4, Cma1, Cpa3, Tpsb2, Kit, Fcer1a, Gata2) to subset MCs from other cell types. These MCs were subsequently integrated with the MCs from our previously published scRNAseq dataset of PLV tissue (5), reclustered, and shown as a UMAP. Notably, the PLV MCs (arrow) exhibited a distinct transcriptional pattern distinct from other MCs identified in the Mouse Cell Atlas (A). WMIFM was performed on PLVs for αSMA, MCT, MCPT1, and MCPT5, as described in Figure 1. A 400x image highlights the MCT+ intravascular MC (B, red arrow) embedded in gaps between αSMA+ lymphatic muscle cells, while a 200x image with 400x inset (white box) exhibits the MCPT1+ perivascular MC (pink arrow) and MCPT1- intravascular MC (white arrow) that exists within the αSMA- void (C). A 200x image with 400x inset (white box) demonstrates that both perivascular (red arrow) and intravascular (white arrow) MCs are MCPT5-negative (D).

Results: WMIFM of MC-tryptase (MCT) confirmed increased numbers of perivascular MCs in TNF-Tg mice, and their complete absence in cKit$^{-/-}$mice **(Fig. 1).** *In silico* scRNAseq analysis revealed a distinct population of PLV MCs vs known MCs in other mouse organs. WMIFM further demonstrated unique molecular signatures of perivascular (MCT^{+}/MCTP1^{+}/MCTP5^{-}) vs intravascular (MCT^{+}/MCTP1^{-}/MCPT5^{-}) MCs **(Fig. 2).** Remarkably, both CS treatment and cKit$^{-/-}$ x TNF-Tg mice exhibited decreased ICG clearance corresponding with increased bone erosions and synovitis vs their TNF-Tg controls **(Fig. 3)**.

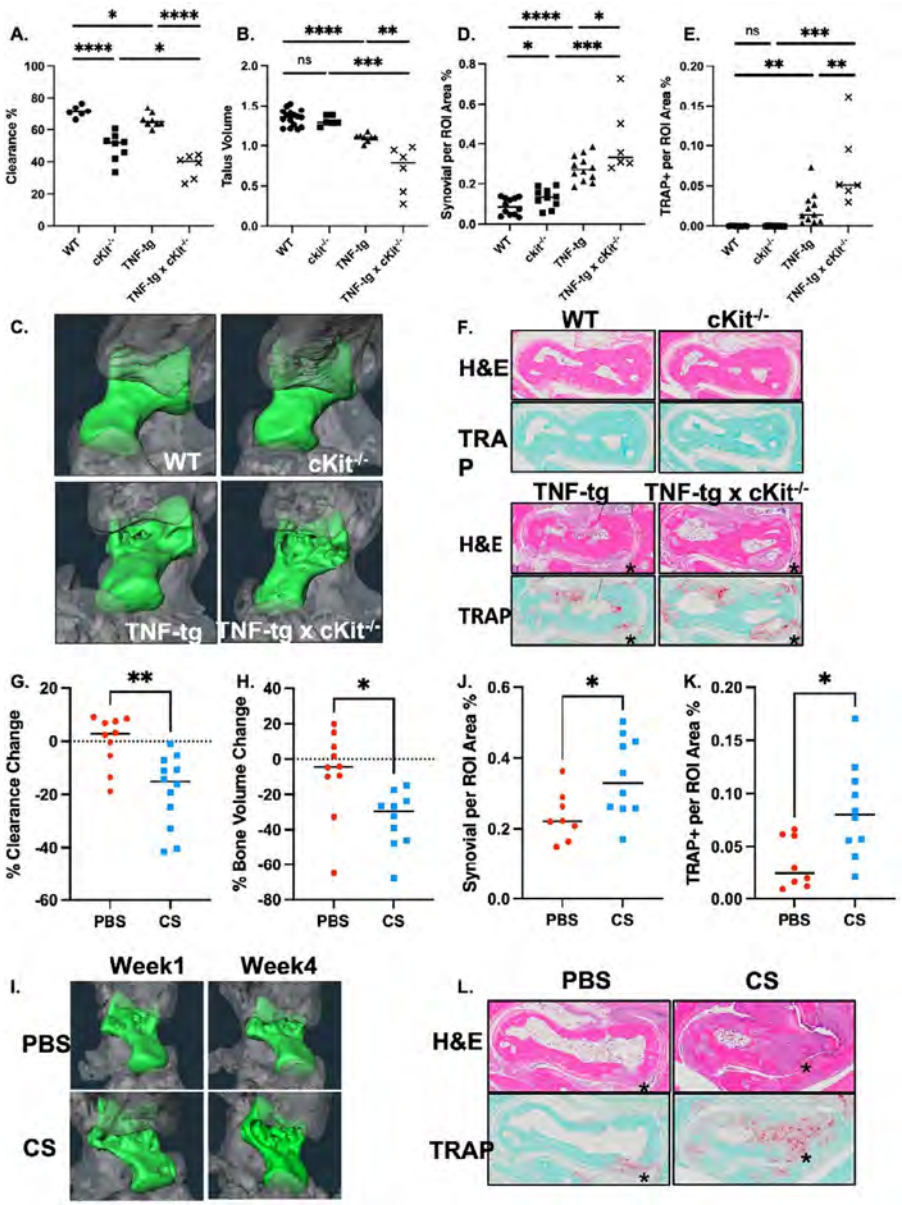

Figure 3. Global MC deletion and inhibition with cromolyn sodium decrease lymphatic clearance and exacerbate inflammatory-erosive arthritis in TNF-Tg mice. KitW-sh/W-sh (cKit-/-) and TNF-Tg mice were crossed to generate TNF-Tg x cKit-/- cohorts (both C57BL/6 background). Male mice at 4.5 months of age underwent NIR-ICG imaging, which demonstrated a combinatorial reduction of lymphatic function in the setting of inflammation (TNF-Tg) and MC ablation (cKit-/-) (A). In TNF-Tg mice, the enhanced lymphatic deficiency with MC deletion was associated with increased bone erosions in the talus (green bone) of the afferent ankle joint, quantified by micro-CT with represented images provided (B, C). Histomorphometric analysis revealed a corresponding increase in synovial inflammation (D, H&E) and number of osteoclasts (E, TRAP) in the talus region of MC deficient TNF-Tg x cKit-/- mice, as shown by representative images (F). To evaluate the effects of MC inhibition, 4-month-old female TNF-Tg mice (n=10) were randomized to 3-weeks of placebo (PBS) or cromolyn sodium (CS) treatment (n = 5 mice/group; 10 limbs) based on baseline lymphatic clearance by NIR-ICG imaging. Terminal NIR-ICG and micro-CT imaging revealed significantly reduced lymphatic clearance (G) and midfoot bone volumes (H, I; green talus as representative image) with CS, respectively. Coinciding with the increased bone erosions, histomorphometry also showed increased synovial (J) and TRAP+ osteoclast area (K) with representative images provided (L). Statistics: unpaired t-test; *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

Conclusion: In this work, we characterized unique intravascular MCTP1$^-$ MCs in a cellular niche within the tissue structure [BK1] of murine joint-draining PLVs. These intravascular MCs are distinct from known MC subtypes, including perivascular MCTP1$^+$ MCs, which are increased in TNF-Tg and absent in cKit$^{-/-}$ mice. Interestingly, both global MC deletion and inhibition decreased lymphatic function and exacerbated joint disease in TNF-Tg mice. These findings suggest subtype-specific MC regulation of lymphatic function through distinct cellular phenotypes, where MCTP1$^-$ intravascular MCs provide a protective role and selective deletion of MCTP1$^+$ perivascular MCs restored lymphatic drainage and ameliorated inflammatory-erosive arthritis.

Therapeutic Effect of ICAM-1 Mimic on Experimental Axial Spondyloarthritis

Melissa Lim[1], Shaghayegh Foroozan[2], Zoya Qaiyum[3], Michael Tang[1], Enoch Yau[4] and Robert Inman[1], [1]University Health Network, Toronto, ON, Canada, [2]University Health Network/University of Toronto, Toronto, ON, Canada, [3]Krembil Research Institute, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial Spondyloarthritis (AxSpA) is a chronic inflammatory arthritis primarily affecting the axial skeleton and commonly coexists with gut and skin inflammation. Currently, patients with axSpA require lifelong treatment. Current biologics (TNFi, IL-17i, JAKi)improve symptoms but are not curative and cannot prevent disease progression.

With the help of AI technology highlighting several unique small molecules with the potential efficacy in axSpA, it was possible to identify a potential small molecule that acts on the binding site of lymphocyte function-associated antigen-1 (LFA-1) and intercellular adhesion molecule-1 (ICAM-1). The LFA-1/ICAM-1 interaction is known to enable both T-cell activation and pro-inflammatory cytokine release. Through previously associated work with computational science and a preclinical in vivo model using DBA/1 collagen induced arthritis model, we have seen significant effects, resulting in decreased arthritis score and paw thickness. It is with this ICAM-1-mimicing small molecule compound that this study reports on the effect blocking this interaction has on an axSpA murine model.

Table 1:

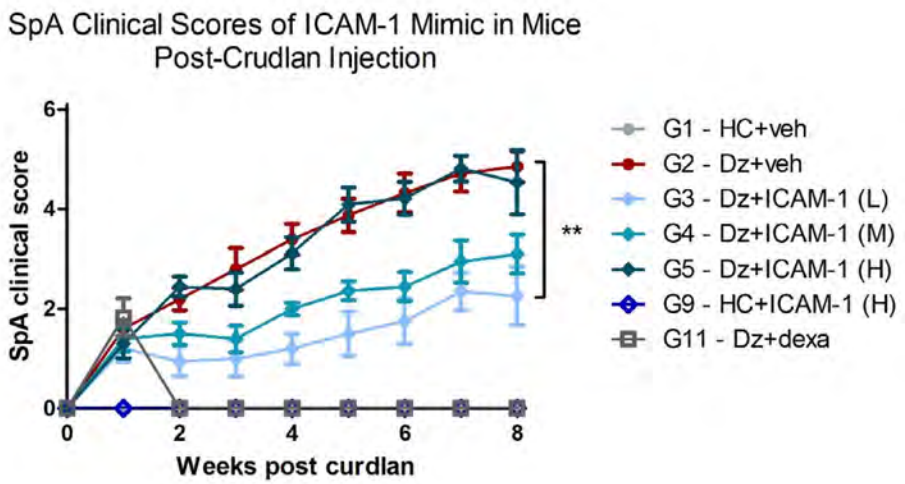
Group	Treatment	Dose (mg/kg)
G1	Healthy, no disease	0
G2	Disease + vehicle	0
G3	Disease + ICAM-1 mimic (low dose)	3
G4	Disease + ICAM-1 mimic (mid)	10
G5	Disease + ICAM-1 mimic (high)	20
G9	Healthy + ICAM-1 mimic (high)	20
G11	Disease + Dexamethasone	10

Breakdown of the treatment groups of the SKG mice for the experiment. Three different treatment doses were examined, along with control groups (healthy, diseased, dexamethasone-treated)

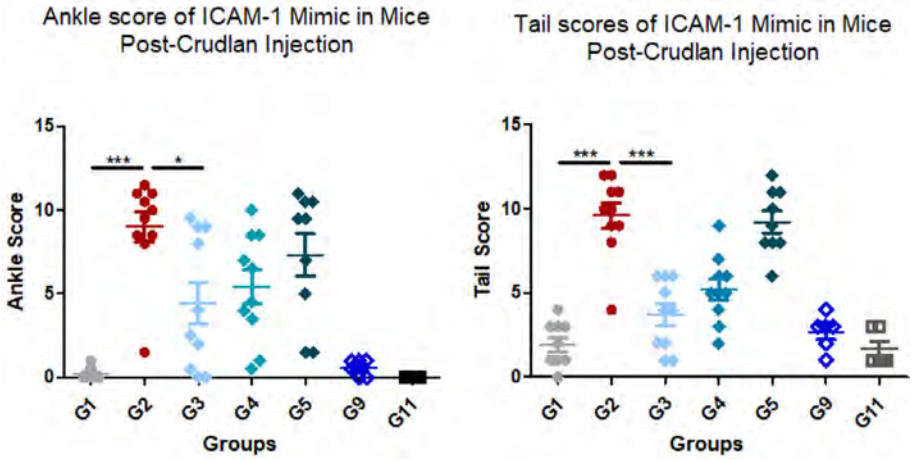
Methods: We employed the use of the SKG mouse, an IL-23- and IL17-dependent model leading to disease resembling human axSpA. SKG mice given a single dose 3mg curdlan (intraperitoneal) developed skin inflammation in ears and tail, blepharitis, and swelling of ankles and wrists and digits. Therapeutic intervention began one week post-curdlan disease induction. These mice were treated with varying doses of the ICAM-1 mimic via daily intraperitoneal (IP) injections and monitored for 8weeks.

Results: With the SKG mice, theICAM-1 mimic showed excellent tolerability and showed a significant decrease in clinical scores, which was most pronounced in the low dose treatment group (G3 in Fig 1). Histological analysis with H&E staining indicated that animals treated with the compound had significantly reduced histological scores of tails, skin, ankle, and gut for the low dose treatment group (G3).

Conclusion: This small molecule ICAM-1 mimic, identified by an axSpA drug discovery approach, shows efficacy in this preclinical model. Follow-up studies will examine pharmacokinetics and pharmacodynamics of the compound. This is promising data for application of this ICAM-1 mimic as a new therapeutic option for axSpA.



Clinical scores of the treatment groups with significance seen between the disease group (G2) and low dose (G3) treatment group.



Histological analysis H&E staining of joints. Left panel shows the ankle scores with significance seen between the disease (G2) and low dose (G3) groups. Right panel shows the ankle score with significance seen between the same two groups.

Arthritogenicity of Homocitrullinated Peptides in HLA-DRB1 Transgenic Mice

Sheri Saunders, Garth Blackler, Patti Kiser, Ewa Cairns and **Lillian Barra**, Western University, London, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Most rheumatoid arthritis (RA) patients express autoantibodies to post-translationally modified antigens, including citrullinated and homocitrullinated (also known as carbamylated) peptides. Homocitrulline and citrulline are structurally similar and immune responses to peptides containing either of these modifications are cross-reactive. Citrullinated peptides bind strongly to MHCII molecules containing a consensus sequence called the Shared Epitope (encoded by HLA-DRB1 alleles, the strongest genetic risk factor for RA). The relationship between homocitrullinated peptides and the Shared Epitope remains unclear. The aim of this study is to determine whether homocitrullinated peptides induce arthritis in a humanized mouse model of RA expressing the Shared Epitope.

Methods: Male and female HLA-DRB1*04:01-transgenic (DR4tg) mice and wild-type C57Bl/6 (B6) mice were immunized with a synthetic homocitrullinated peptide (HomoCitJED) or PBS and then received intra-articular (i.a.) HomoCitJED in one knee and PBS in the other knee. Immune responses in these mice were measured serially for serum autoantibody production by ELISA to the following antigens: HomoCitJED, CitJED (a synthetic citrullinated peptide that contains the same backbone as HomoCitJED), homocitrullinated fibrinogen (HomoCitFib), citrullinated fibrinogen (CitFib), fibrinogen (Fib) and cyclic citrullinated protein/peptide 2 (CCP2).Arthritis was assessed by serial measurements of joint swelling with calipers and by histopathology at sacrifice (day 137 post-primary immunization) using a standardized scoring system.

Results: After immunization with HomoCitJED, all DR4tg mice (14/14) developed IgG anti-HomoCitJED and anti-HomoCitFib antibodies, compared to 4/6 and 3/6 B6 mice, respectively. A small number of mice developed antibodies to CitJED (4/14 DR4tg and 1/6 B6). Anti-CCP2 was detected in 8/14 DR4tg and 4/6 B6 mice. None of the mice had detectable antibodies to Fib or CitFib. Antibody levels did not change significantly after i.a. injections and over time. PBS immunized mice did not have detectable immune responses or arthritis. After day 78 post-immunization, significant joint swelling was observed in the knees of HomoCitJED injected DR4tg mice with an arthritis score of 3.92 (SD 2.90)/12 versus 1.18 (SD 1.08)/12 in HomoCitJED-injected B6 wild-type mice; p=0.0016. Histopathologic findings included synovial thickening and pannus, hypervascularity, cartilage destruction and bone erosions.

Conclusion: Mice expressing human Shared Epitope developed immune responses to homocitrullinated and citrullinated antigens and RA-like arthritis. These findings support an arthritogenic role for homocitrullinated antigens that is enhanced by the Shared Epitope.

Abstract Number: 1728

A Novel Animal Model for Investigating the Effect of HLA-DRB1 on Atherosclerosis

Garth Blackler, James Akingbasote, Patti Kiser, Christopher Howlett, Ewa Cairns and **Lillian Barra**, Western University, London, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: HLA-DRB1 alleles are associated with various autoimmune and inflammatory conditions, including rheumatoid arthritis, polymyalgia rheumatica, giant cell arteritis, systemic lupus erythematosus, diabetes and atherosclerotic cardiovascular disease. In rheumatoid arthritis, patients expressing HLA-DRB1 have a high risk for cardiovascular mortality. This study aimed to create and characterize a novel animal model to better understand the role of HLA-DRB1 in the pathogenesis of atherosclerosis.

Methods: Mice transgenic for HLA-DRB1*04:01 (DR4tg) were crossed with an established mouse model of atherosclerosis, low density lipoprotein receptor knock-out (*Ldlr*-/-) mice. DR4tg*Ldlr*-/- (n=48), *Ldlr*-/- (n=24), DR4tg (n=24), and C57Bl/6 (B6) background (n=24) mice were fed a high fat, high cholesterol (HFHC) or regular diet (RD) for 12 weeks. Serum lipoproteins were measured using a colorimetric assay. C-reactive protein (CRP), anti-cyclic citrullinated protein/peptide antibodies2 (anti-CCP2) and oxidized LDL (OxLDL) were measured using ELISA. Atherosclerosis in whole aortas was assessed using the lipid stain, Sudan IV. The presence of citrulline in atherosclerotic plaque from aortic sinus sections was determined by immunohistochemistry. Mice were monitored for arthritis by measuring knee and ankle swelling and by histopathology.

Results: DR4tg*Ldlr*-/- had a similar degree of atherosclerotic plaque burden compared to *Ldlr*-/-, despite having lower sera low-density lipoprotein cholesterol (LDL-C) levels; p=0.0056. Levels of the more pro-atherogenic lipoprotein, OxLDL was higher in DR4tg*Ldlr*-/- than *Ldlr*-/-mice; p=0.0017. Male *Ldlr*-/- mice had worse atherosclerosis than females, but there were no sex differences in DR4tg*Ldlr*-/-. CRP was elevated in all mice fed a HFHC diet, most pronounced for DR4tg*Ldlr*-/-; p=0.0009. B6 and DR4tg mice did not have significant elevations in serum cholesterol levels and did not develop atherosclerosis. None of the mice developed antibodies to citrullinated antigens or spontaneous inflammatory arthritis.

Conclusion: HLA-DRB1 expression in a mouse model of atherosclerosis resulted in an elevation of oxidized LDL and a reduction in the male bias for atherosclerosis, mimicking what is observed in rheumatoid arthritis.

Abstract Number: 1729

An Antibody-drug Conjugate of Anti-TNFα Antibody and a Novel Glucocorticoid Molecule Exerts Synergistic Anti-inflammatory Effects for Treatment of Autoimmune Diseases

Yuhao Qin[1], **Wenming Ren**[2], Liangqin Tong[3], lu su[3] and cheng liao[3], [1]Jiangsu Hengrui Pharmaceuticals Co., Ltd, Shanghai, China, [2]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Pudong New District, China, [3]Jiangsu Hengrui Pharmaceuticals Co., Ltd., Shanghai, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor α (TNFα) is a pivotal pro-inflammatory cytokine. And TNF inhibitors are the most successful anti-rheumatic drugs for the treatment of autoimmune diseases such as rheumatic arthritis. However, many patients respond poorly or lose response gradually to anti-TNF therapies. Glucocorticoids (GCs), which exert extensive immunosuppressive effects by inhibiting the nuclear factor kappa-B signaling pathway, have been the most powerful and basic/standard treatment for many autoimmune diseases, while their long-term usage is strictly limited due to the adverse effects. Here, we describe the preclinical characterization of an anti-TNF conjugate which is consisted of an anti-TNFα antibody and a novel GC molecule with high potency.

Methods: The glucocorticoid receptor (GR) binding activity of the GC molecule was measured in a GR biochemical assay. The binding affinity of the anti-TNF conjugate with TNFα were assessed by surface plasmon resonance assay. The TNF inhibitory activities of the anti-TNF conjugate were evaluated in LPS-induced monocyte IL-6 release assay and TNFα-induced L929 cytotoxicity assay. And the *in vivo* efficacy of the anti-TNF conjugate was determined in dinitrofluorobenzene-induced delayed-type hypersensitivity (DTH) mouse model and the collagen antibody-induced arthritis (CAIA) mouse model. In addition, a 4-week GLP repeated-dose toxicity study in cynomolgus monkeys was conducted to evaluate the safety profiles.

Results: The novel GC molecule was a high potent short-acting glucocorticoid. And the anti-TNF conjugate showed similar TNFα binding affinity and TNFα-induced cytotoxic inhibitory activity to the anti-TNFα antibody. The anti-TNF conjugate could block the pro-inflammatory pathways by neutralizing soluble TNFα, and deliver the GC molecule specifically to pathogenic immune cells by binding to the transmembrane TNFα, which exerts synergistic anti-inflammatory effects and reduces the systemic exposure and side effects of GC. We proved that the anti-TNF conjugate inhibited LPS-induced IL-6 secretion in monocytes more potently than the anti-TNFα antibody. In DTH mouse model, the anti-TNF conjugate demonstrated better ear swelling remission than anti-TNFα antibody. In hTNFα-transgenic CAIA mice model, the disease severity score and histopathology were also significantly improved at a relatively low dose of the anti-TNF conjugate. Furthermore, the GLP repeated-dose toxicity study in cynomolgus monkeys showed the anti-TNF conjugate was well tolerated and no changes in cortisol were observed at doses up to 50 mg/kg. Our results showed the anti-TNF conjugate has a better efficacy than anti-TNFα antibody and has superiority in safety and tolerance compared to GCs.

Conclusion: Our data provides strong evidence that the anti-TNF conjugate is a potent anti-rheumatic drug with good safety profile, which support its further clinical application in autoimmune diseases including rheumatic arthritis and ulcerative enteritis.

Gut Microbiota Dysbiosis Impact Autonomic Function in Rheumatoid Arthritis Patients

Rachel AUDO[1], Jérome Thireau[2], Louis Rauzier[3], Marie Barozet[1], JACQUES MOREL[4], Patrice Bideaux[3], alain Lacampagne[2] and **Claire Daien**[5], [1]CHU Montpellier, Montpellier, France, [2]PhyMedExp INSERM U1046, Montpellier, France, [3]PhyMedExp U1046, Montpellier, France, [4]Protocole thérapeutique immuno-rhumatologie, Montpellier, France, [5]University Hospital, Montpellier, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with a high risk of cardiovascular (CV) risks, including accelerated atherosclerosis, left ventricular hypertrophy and decreased heart rate variability (HRV). HRV decrease reflects the inability of the autonomic nervous system (ANS) to adapt cardiac function and lower HRV is associated with a higher risk of CV events. Autonomic dysfunction is observed in RA with a prevalence as high as 60–80% and precedes apparition of symptoms. Given that gut microbiota (GM) dysbiosis also occurs before disease and inflammation in subjects who will develop RA, and that activity of vagus nerve can be modulated by the GM, we hypothesized that GM impairs the ANS balance in RA.

Methods: we investigated whether fecal microbiota transplantation (FMT) of RA patients modulates the electrocardiographic profile, the HRV and cardiac function (echocardiography) compared to FMT of healthy subjects (age-and-sex-matched controls). Using electrocardiogram (ECG) acquired by telemetry, we characterized the impact of FMT on sympathetic and/or vagal outflow using temporal- and spectral-domain analyses of HRV. High resolution echocardiography allowed us to assess both cardiac structural and contractile function. In parallel, FMT consequences on intestinal barrier permeability, the pro- or anti-inflammatory immune cells and early markers of atherosclerosis were evaluated to related potential modification to inflammatory profile.

Results: Heart Rate Variability (HRV) analysis showed that FMT from RA patients altered the ANS activity in mice, reproducing a defect of vagal tone. Indeed, in mice with fecal transfer of RA microbiota (RA-FMT), we observed an increase of heart rate, only during resting time (444.82(±20.07) bpm vs 477.12(±30), p=0.0001, n=34/group). This tachycardia results from a reduction of HRV reflecting altered ANS activity with a decrease in SDNN index (SDNN 23.88±9.97 vs 10.22±4.05 ms, p< 0.0001, n=34/group). Time domain and spectral domain analyses of HRV confirmed a decrease in the parasympathetic activity resulting in a drop of sympathovagal balance. These alterations are independent of cardiac structural, of contractile modifications and of any remodeling of cardiac muscarinic or adrenergic signaling pathway. In addition, this vagal tone dysfunction was independent of inflammation as RA FMT did not induce major immune dysfunction or change in the aortic expression of early markers of atherosclerosis (VCAM and ICAM).

Conclusion: We demonstrated that for the first time that the MI of RA patients contributes to autonomic dysfunction, independently of the inflammatory status, and without structural or contractile modification of the heart. This opens new therapeutic perspectives, such as dietary modifications, for example with the addition of fibre or the use of probiotics, to prevent autonomic dysfunction and CV risk in RA.

A Competitive Inhibitor of MOART Showed Potent Therapeutic Effects in a Mouse Model of Collagen-induced Arthritis

Sujin Park[1], DongWoo Kang[2], Haein An[1], Eunji Hong[1], Kwiyeom Yoon[2], MinWoo Kim[2], Hwajung Kim[2] and **Seong Jin Kim**[2], [1]GILO Institute, GILO Foundation, Seoul, South Korea, [2]Medpacto Inc., Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite tumor necrosis factor (TNF) inhibitors and Jak kinase inhibitors (JKI) have shown a significant advance in the treatment of rheumatoid arthritis (RA) however, only 20 to 30% of patients experience remission. Recently, we identified that *moart*, whose expression is markedly elevated at a late phase of osteoclast differentiation, is a keymembrane organizer of osteoclast multinucleation. Knockout mice lacking the entire *moart* gene dramatically reduced a bone loss in an ovariectomized mouse model. In this study, we investigated the therapeutic effects of MP2021, a competitive inhibitor of MOART, in a mouse model of collagen-induced arthritis (CIA).

Methods: To induce CIA, DBA/1J mice (n = 10 per group) were immunized subcutaneously at the tail with chicken type II collagen on days 0 and 14. Mouse MP2021, human MP2021, control IgG-Fc or TNFR2-Fc fusion protein (etanercept) were injected subcutaneously twice a week after the onset of CIA (therapeutic treatment). Clinical arthritis scores were measured by summing the scores of all four paws. Disease progression was monitored daily, and cytokines and histologic analysis (synovial inflammation, joint damage, and bone loss) were measured by ELISA, IHC, and microCT at the end of the study.

Results: Clinical arthritis scores and morphological signs of bone destruction improved in the mMP2021-treated group compared to IgG-Fc. Expression levels of IL-1b, IL-6, TNFa, COMP, MMP-3, and MMP-13 were significantly reduced in the articular bones of mice treated with mMP2021. Histologic analysis also showed that mMP2021 inhibited bone damage by inhibiting synovitis, synovial formation, and chondrolysis, and significantly reduced the number of tartrate-resistant acid phosphatase (TRAP)-positive osteoclasts. hMP2021 administered subcutaneously to CIA mice also showed more inhibitory effects on clinical arthritis scores than etanercept. The hMP2021 showed equivalent effects when administered intravenously or subcutaneously, which is a promising result for the clinical application of this molecule.

Conclusion: We found that human MP2021 as well as mouse MP2021 significantly inhibited cartilage damage and bone erosion in established mouse CIA models, along with a reduction in multinucleated osteoclasts. These findings suggest that MP2021 has potential as a novel therapeutic agent that can be effectively applied to various bone and joint diseases, including rheumatoid arthritis.

Immunopathogenesis and Preclinical Trials in a Humanized Mouse Model of Rheumatoid Arthritis(RA)

Huiyi Wang[1], Kangkang Luo[1], Shuxin Xu[1], Jiayin Zhou[1], Santi Chen[2], Jun wang[2], Wenzhao Li[2], Jing Zhao[1] and Cunxiang Ju[1], [1]GemPharmatech CO., Ltd., Nanjing, China, [2]GemPharmatech LLC, La Jolla, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The differences between human and mouse immune systems make it challenging to accurately reflect the immunopathogenesis of autoimmune diseases in patients. Therefore, translational research needs to shift focus from mouse immunology to human immunology. In addressing these challenges, the HSC-NCG-M mice have emerged as a valuable model. Gempharmatech developed the HSC-NCG-M mouse model to support the development of human T, B, NK, and myeloid cells more effectively. The HSC-NCG-M mouse model is genetically engineered on the severe immunodeficient NCG strain and produces human granulocyte/macrophage colony-stimulating factor 2 (GM-CSF, also known as CSF2), interleukin-3 (IL-3), and stem cell factor (SCF, also known as KITLG).

Methods: This study describes the construction process of the RA model in HSC-NCG-M mice. Female NCG-M mice (4-6 weeks old) were engrafted with $CD34^+$ HSC after irradiation. The RA model was induced by injecting Complete Freund's Adjuvant (CFA) into the foot pads of the hind limbs. The body weight, graft-versus-host disease (GvHD) score and the development of arthritis in the hind limbs of the mice were monitored three times a week. The arthritis score for each mouse was obtained by summing the scores for both hind limbs. The volume of the left and right hind limbs, including the joint of the paw and ankle, was measured three times a week using a claw measuring instrument until the end of the experiment.

Results: In the CFA-induced RA model based on HSC-NCG-M mice, there was an increasing number of human CD4+ T lymphocytes, Th17, Treg, and monocytes in peripheral blood, along with elevated IL-6 levels, which closely resembled clinical phenotypes of RA patients. Compared to the control group, HSC-NCG-M mice injected with CFA in the foot pads showed increased arthritis scores and swelling thickness in the hind limbs.

Conclusion: This model develop a fully functional human immune system capable of innate and adaptive immune responses. The CFA-induced RA model primarily involves the human immune system and closely resembles human RA patients. Therefore, the HSC-NCG-M mouse model is an appropriate model for studying RA, as it involves the engagement of the human immune system.

Platelet-Derived Growth Factor Is a Mediator of Disease in an Animal Model of Rheumatoid-Associated Interstitial Lung Disease

Nozima Aripova[1], Michael Duryee[1], Amy Nelson[1], Carlos Hunter[1], Breanna Butler[1], Bryant England[1], Jill Poole[1], Geoffrey Thiele[1] and Ted R Mikuls[2], [1]University of Nebraska Medical Center, Omaha, NE, [2]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Animal Models Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is a leading cause of mortality in RA with limited treatment options as well as lack of available animal modeling systems for preclinical investigations. We previously demonstrated that co-exposure of the collagen induced arthritis (CIA) with repetitive airborne lipopolysaccharide (LPS) exposure leads to increased autoimmunity, arthritis, and pro-fibrotic/pro-inflammatory lung disease. In addition to recapitulating important histopathologic features of RA-ILD, this model demonstrates more severe arthritis and lung manifestations in male mice. Platelet-derived growth factor (PDGF)-BB and its receptor (PDGFR) are important cellular proliferation and growth with dysregulation associated with cancers and tissue fibrosis, with limited and conflicting studies in RA. In the present study, we leveraged our novel mouse preclinical animal modeling system to investigate the potential role of PDGF-BB/PDGFR, in RA-associated lung disease.

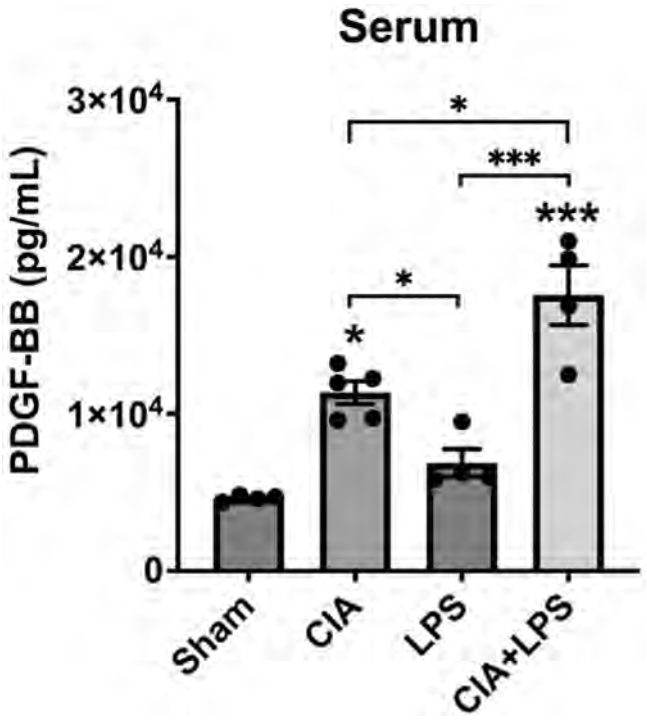

Figure 1. PDGF-BB levels in the serum of DBA mice. Mice were treated with/without CIA and with/without LPS inhalation. Scatter dot plots represent mean±SEM of platelet-derived growth factor (PDGF) levels (pg/mL). Comparisons made to Sham are illustrated above each bar: ***p<0.001, *p<0.05, n=4. Tukey's post-hoc test comparisons are illustrated between treatment groups, and only significant differences are illustrated: ***p<0.001, *p<0.05. Abbreviations: CIA, collagen-induced arthritis; LPS, lipopolysaccharide.

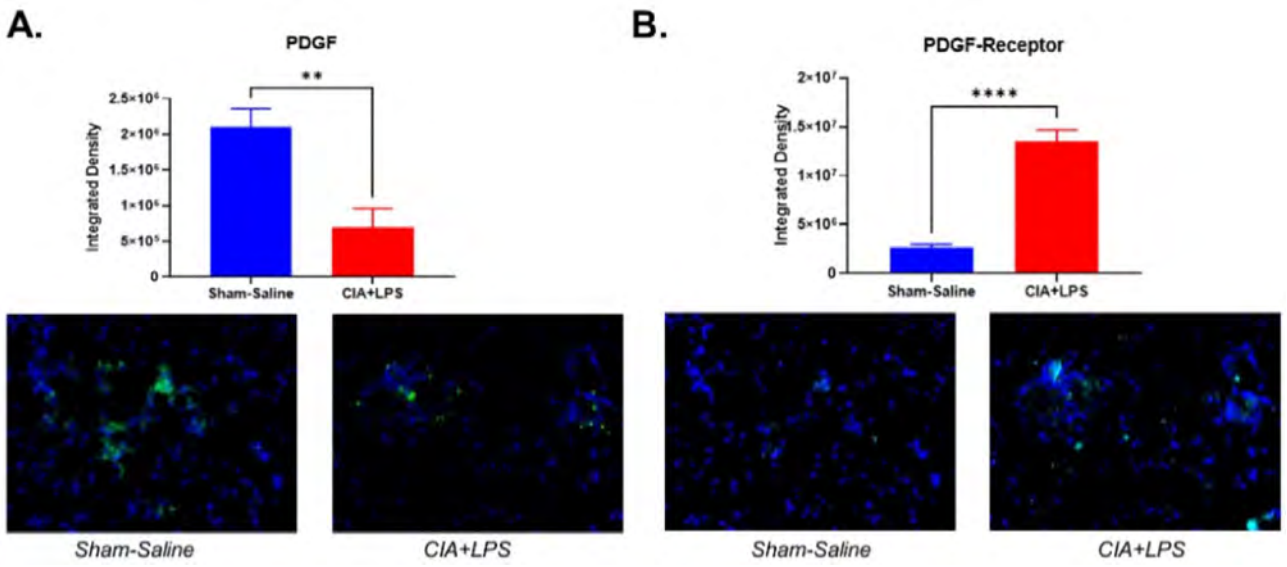

Figure 2. IHC Staining of Lung Tissue from DBA mice. Mice were treated with CIA+LPS or Sham-Saline. Lung tissues were stained for: (A) PDGF; and (B) PDGF-receptor. The data is represented as a mean of integrated density with SEM. Comparisons between the two groups were made using t-test: **p<0.01. Abbreviations: CIA, collagen-induced arthritis; LPS, lipopolysaccharide; PDGF, platelet-derived growth factor.

Methods: Arthritis-prone male (DBA/1J) mice (n=5/group) received either: Sham (saline injection/inhalation), CIA (CIA on day 1 and 21/saline inhalation), LPS (saline injection/ LPS 100ng inhalation), or CIA+LPS (CIA injection/LPS inhalation) for 5 weeks. At week 5, serum was collected for quantification of PDGF-BB using ELISA in all 4 groups. Based on marked serum differences observed between CIA+LPS and Sham, lung tissues were isolated for quantification of PDGF-BB and PDGF-receptor expression using fluorescent immunohistochemistry (IHC) in these two treatment groups. Serum PDGF-BB levels were compared using one-way ANOVA and Bonferroni multiple comparison tests across the 4 treatment groups. Fluorescent IHC, expressed in mean pixel density, was quantified and compared in CIA+LPS vs. Sham-treated mice using a t-test.

Results: Serum PDGF-BB concentrations (pg/ml mean ± SEM) were the highest in the CIA+LPS group ($1.6x10^4 \pm 1.2x10^3$; $p< 0.05$ vs. all others) (**Figure 1**). Also, serum PDGF-BB levels were significantly increased in CIA group ($1.1x10^4 \pm 5.5x10^2$) compared to Sham ($4.7x10^3 \pm 1.1x10^2$; $p< 0.05$) and LPS ($6.9x10^3 \pm 8.8x10^2$; $p< 0.05$) groups. Staining of lung tissues demonstrated that PDGF-BB expression was decreased significantly in CIA+LPS compared to Sham ($p< 0.01$) (**Figure 2**). In contrast, PDGF-receptor expression was increased significantly in CIA+LPS ($p< 0.0001$) compared to Sham.

Conclusion: Co-exposure of mice to CIA+LPS profoundly increased circulating PDGF-BB concentrations. In the corresponding lung tissues of CIA+LPS mice, PDGF-BB expression was strikingly reduced while PDGF-receptor expression was increased. These findings imply that dual exposure modulate the PDGF-BB/PDGFR pathway that release and/or production of PDGF is altered. Moreover, these observations suggest that PDGF-BB may serve as an important mediator of the inflammatory and fibrotic processes underlying RA-ILD pathogenesis and could represent a potential novel target for treatment.

Serum PDGF-BB Levels Correlate with Lung Fibrosis in Mice Injected with Malondialdehyde-Acetaldehyde and/or Citrulline Modified Vimentin

Nozima Aripova[1], Michael Duryee[1], Carlos Hunter[1], Amy Nelson[1], Breanna Butler[1], Jill Poole[1], Bryant England[1], Geoffrey Thiele[1] and Ted R Mikuls[2], [1]University of Nebraska Medical Center, Omaha, NE, [2]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary manifestations of rheumatoid arthritis (RA), such as interstitial lung disease (RA-ILD), are a major contributor to morbidity and mortality. The mechanism of pulmonary fibrosis occurring in RA-ILD is not well understood. Lung tissues from patients with RA-ILD show increased expression of vimentin (VIM) and co-localization of citrulline (CIT) and malondialdehyde-acetaldehyde (MAA) modifications. Fibrotic lung disease such as RA-ILD involves increased cellular proliferation and excessive production of extracellular matrix proteins. Such cellular responses in fibrotic lung disease are modulated by a variety of cytokines, chemokines, and growth factors. One such growth factor, platelet-derived growth factor (PDGF)-BB has been strongly associated with tissue fibrosis but has been the subject of limited studies in RA-ILD. Therefore, the current study aimed to determine whether arthritis-prone (DBA/1J) mice immunized with MAA- and/or CIT-modified VIM develop pro-fibrotic responses in the lungs and altered PDGF-BB levels in the lungs or serum.

Methods: Arthritis-prone male (DBA/1J) mice (n=5/group) were given weekly subcutaneous injections at 25μg/mL (for VIM antigens)with a) saline, b) native VIM, c) MAA-modified VIM (VIM-MAA), d) CIT-modified VIM (VIM-CIT), or e) both (VIM-MAA-CIT) for 5 weeks. At week 6, mice were euthanized, and lung tissues were stained with trichrome for collagen deposition to assess fibrotic lung responses. Additionally, serum and lung tissue homogenates were collected for quantification of PDGF-BB levels using ELISA. Group differences were compared using one-way ANOVA and Bonferroni multiple comparison test.

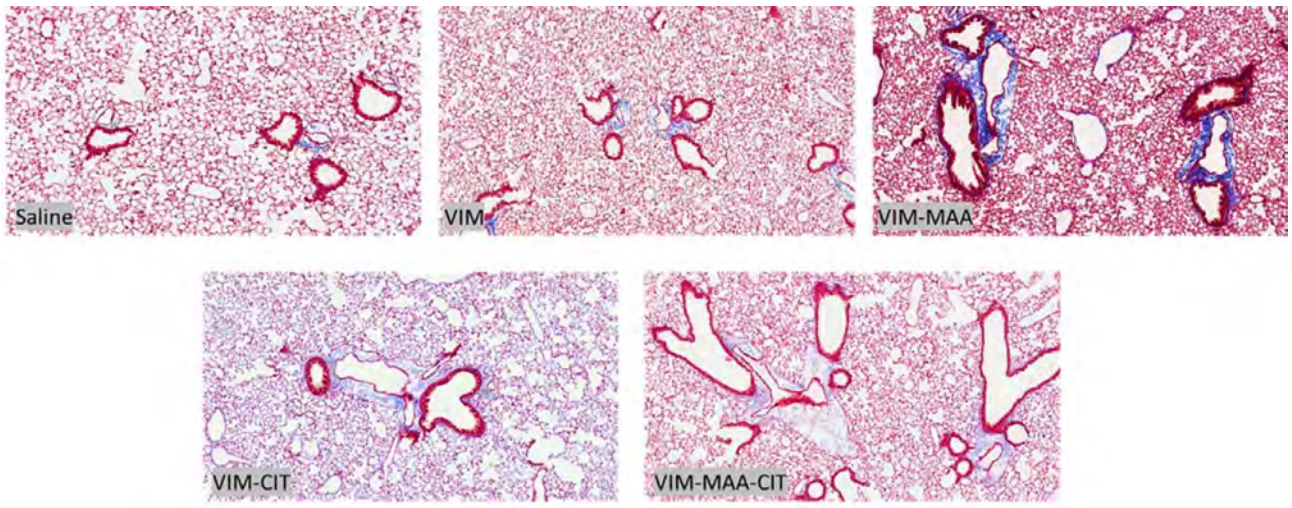

Figure 1. Trichrome staining of lung tissue in the DBA mice immunized with native and modified vimentin. Mice were immunized with saline, native VIM, VIM-MAA, VIM-CIT, and VIM-MAA-CIT.

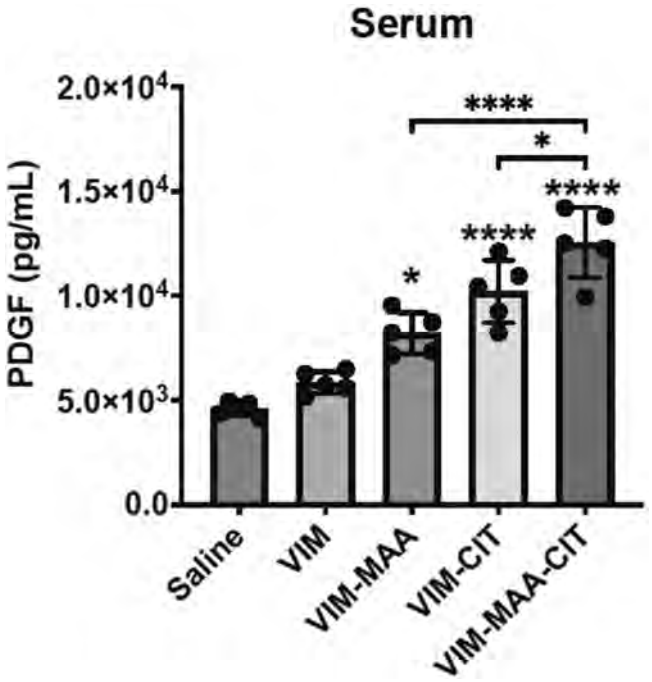

Figure 2. PDGF levels in serum of DBA mice immunized with native and modified vimentin. Mice were immunized with saline, native VIM, VIM-MAA, VIM-CIT, and VIM-MAA-CIT. The data is represented as a mean PDGF concentration (pg/mL) and reported with SEM. Comparisons made to Saline are illustrated above each bar: ****p<0.0001, *p<0.05, n≥4. Only significant differences between groups are illustrated: ****p<0.0001, *p<0.05.

Results: Trichrome staining of lungs demonstrated increased collagen deposition in mice immunized with modified VIM vs. native VIM (**Fig.1**). Serum PDGF-BB levels (mean±SEM) were highest in VIM-MAA-CIT injected group ($1.3x10^4 \pm 1.1x10^3$; $p < 0.05$ vs. others), and significantly higher than in mice immunized with VIM-CIT ($p < 0.0001$) or VIM-

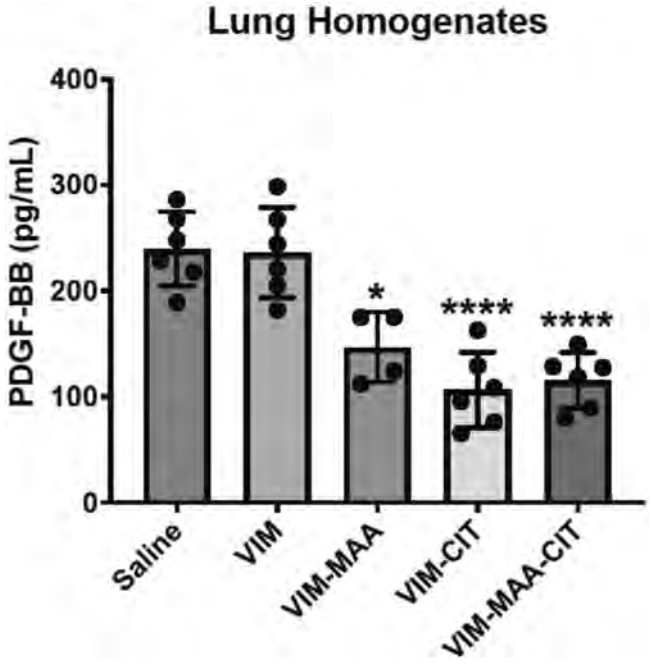

Figure 3. PDGF levels in lung homogenates of DBA mice immunized with native and modified vimentin. Mice were immunized with saline, native VIM, VIM-MAA, VIM-CIT, and VIM-MAA-CIT. The data is represented as a mean PDGF concentration (pg/mL) and reported with SEM. Comparisons made to Saline are illustrated above each bar: ****p<0.0001, *p<0.05, n≥4.

MAA ($p< 0.05$) alone (**Fig.2**). In the lung homogenates, PDGF-BB levels were decreased significantly in VIM-MAA-CIT (115.3 ±10.8; $p< 0.0001$ vs. VIM), VIM-CIT (106±14.6; $p< 0.0001$), and VIM-MAA (146.5±16.4; $p< 0.05$) compared to VIM and no significant differences between treatment groups were detected (**Fig.3**).

Conclusion: Immunization of arthritis-prone mice with modified vimentin leads to collagen deposition in lung tissues, suggesting that systemic immune reactivity to these antigens could a play in the pathogenesis of pulmonary fibrosis. In addition to generating collagen deposition, immunization of mice with dually-modified vimentin demonstrated the highest serum PDGF-BB levels compared to either single modification. In contrast, lung homogenates of mice immunized with modified vimentin showed a reduction in PDGF-BB levels compared to native vimentin. These findings suggest that PDGF-BB is either released into the circulation resulting in increased serum levels or consumed/bound by fibroblasts in the lungs of mice immunized with modified vimentin. Thus, PDGF-BB may serve as an important mediator between post-translational modifications of vimentin and fibrotic lung disease (i.e. RA-ILD).

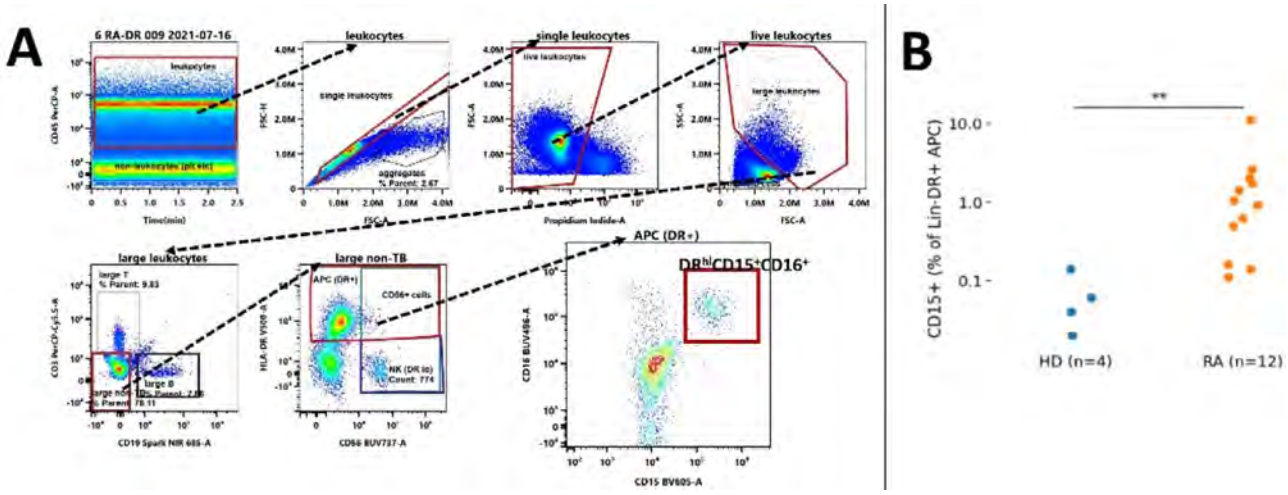
An Unorthodox HLA-DR^{hi}CD15^{+} 'Hybrid' Population in Rheumatoid Arthritis Characterized Using Spectral Cytometry

Christian Geier[1], Haani Qudsi[2], Jihad BenGabr[1], Robert Winchester[3] and Andras Perl[4], [1]SUNY Upstate Medical University, Syracuse, NY, [2]Norton College of Medicine, SUNY Upstate Medical University, Syracuse, NY, [3]Columbia University, New York, NY, [4]SUNY, Syracuse, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

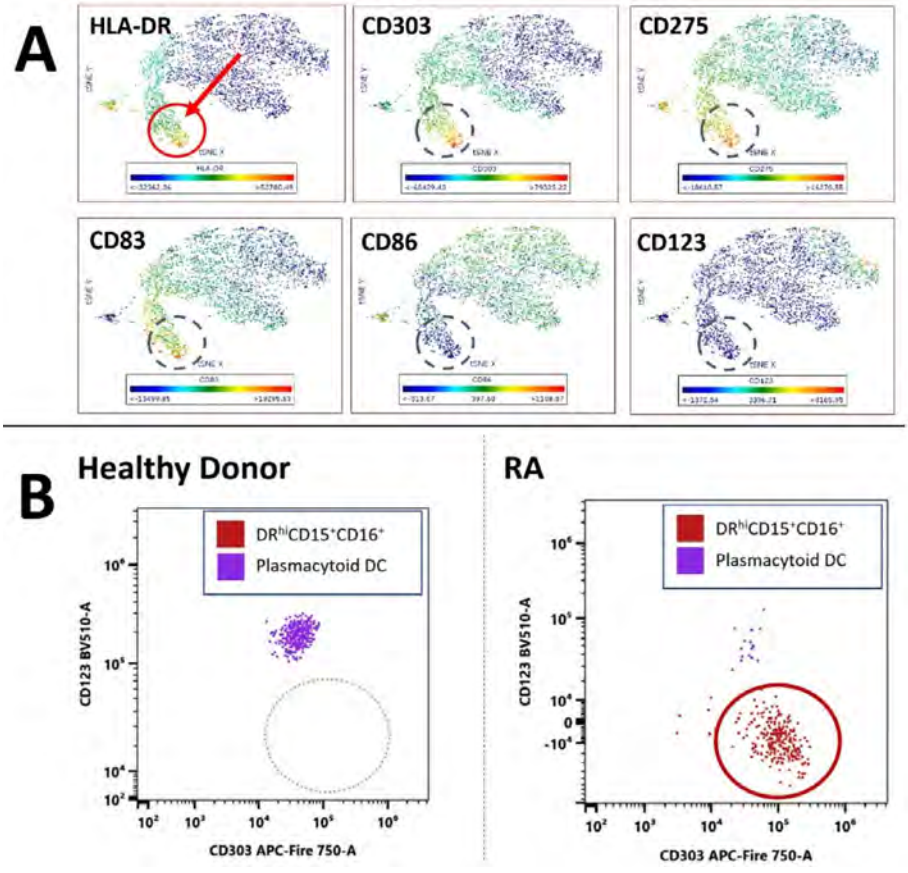
Background/Purpose: A variant of HLA-DR confers the strongest genetic risk for rheumatoid arthritis (RA) suggesting that DR^{hi} cells are important in RA. We previously found that RA blood contains 'unorthodox' DR^{hi} immune cells (non-lymphoid cells that do not conform to *bona fide* definitions of monocytesnor dendritic cells).The purpose of the study was to determine whether DR^{hi} immune cells expressing granulocyte associated molecules (CD15, CCR3)contribute to these alterations of the DR^{hi} pool in RA.

Methods: We studied RA patients (n=12) satisfying the 2010 ACR classification criteria and matched healthy donors by flow cytometry. PBMC and other low-density cells were isolated from blood by Ficoll density gradient centrifugation. To gate non-lymphoid DR^{hi} cells we excluded lymphocytes and non-viable cells based onforward and side scatter, CD3/CD19 dump and viability gates (Fig. 1A). We quantified the contribution of CD15^{+} cells to the non-lymphoid DR^{hi} pool and their expression (MFI) of co-stimulatory and co-inhibitory molecules. We used t-SNE on index patients (debilitating polyarticular synovitis)to clarify the higher-dimensional structure of the CD15positive DR^{hi} subpopulation followed by bi-axial gating to validate anyt-SNE guided observation and quantify distinctive features of DR^{hi}CD15^{+}. Kruskal-Wallis testing with a threshold of $p< 0.05$ was performed to assess for significant differences.



Flow cytometry and quantification of non-lymphoid DRhiCD15+ in RA. A) Gating strategy, patient with severe RA shown. B) DRhiCD15+ quantification in healthy donors (HD; blue) and RA (orange) and as percentage of non-lymphoid DRhi, logarithmic scale. Kruskal-Wallis Test ** p=0.0063

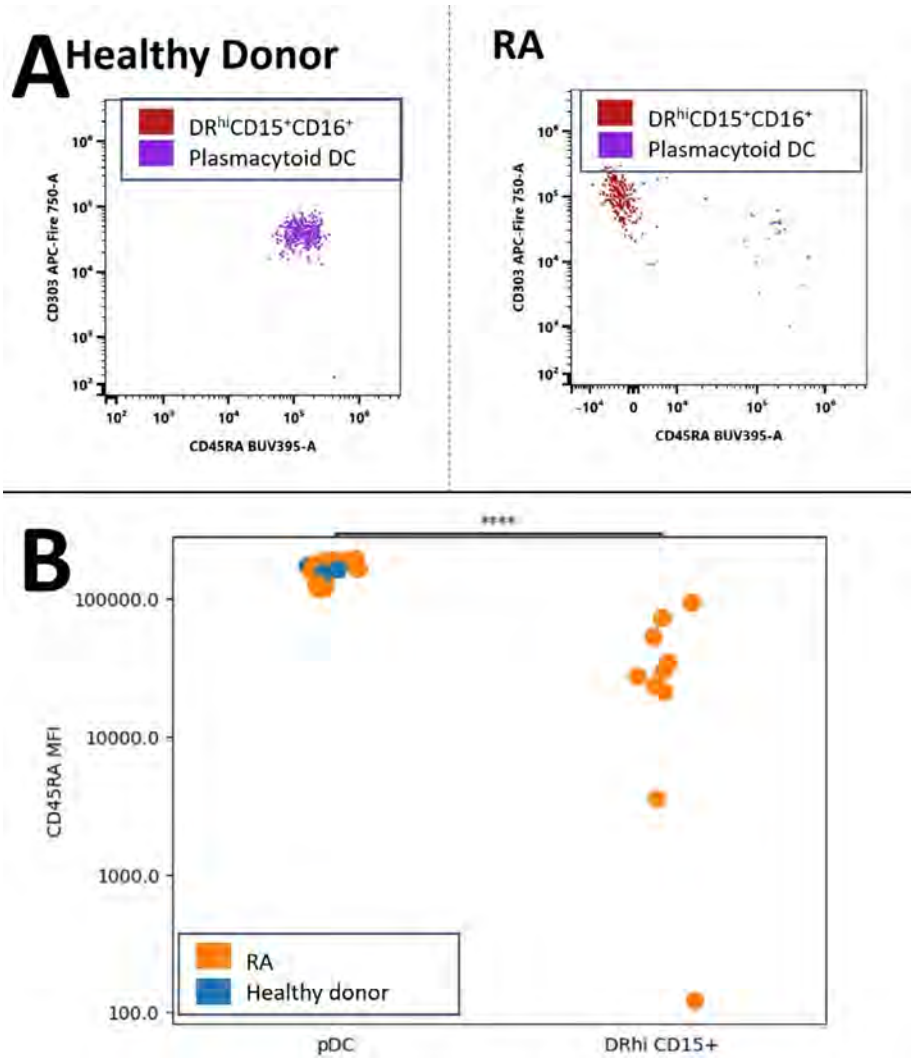
Results: In RA we found a non-lymphoid DR^{hi} $CD15^{+}$ population that was virtually absent in healthy donors (HD)(RA 0.98% vs. HD 0.05% of non-lymphoid DR^{hi}; p<0.01, Fig. 1B, 2B); these cells have near uniform CD16 co-expression (Fig 1A, gated in last plot).DR^{hi} $CD15^{+}$ showed—as expected from granulocytic cells — high side scatter but differed from granulocytes by a striking co-expression of plasma cytoid (pDC) marker CD303 (Fig. 2A, B; circled);CD123, highly expressed by pDC, was



Non-lymphoid DRhiCD15+CD16+. A) t-SNE from an RA patient with debilitating polyarthritis population (red circle and arrow) highlighting co-expression of CD303, CD83, CD275; lack of CD123. Red: high expression. Blue: low expression. B) Bi-axial gating of DRhiCD15+CD16+ and pDC reference populations. CD303 x-axis, CD123 y-axis. Left plot: healthy donor Right plot: RA patient.

not expressed. Given the shared features with both granulocytes and pDC we refer to this population as DR^{hi} 'Hybrid' cells. DR^{hi} Hybrids formed a separate cluster in RA which, along with CD303, co-expressed CD83 and CD275 (ICOS-L) (Fig. 2A, circled population).Lack of CD45RAseparatedCD303^{+}DR^{hi} Hybrids from their apparent *bone fide* CD303^{+} CD45RA^{int} pDC counterparts (Fig. 3A and B, p< 0.001), CD45RA expression of RA pDC and HD pDC did not differ (Fig 3B, left). CCR3 expression within non-lymphoid DR^{hi} was negligible (not shown).

Conclusion: RA blood contains DR^{hi}CD15^{+} cells, contributing to the non-lymphoid DR^{hi} pool in RA. Because these low-density cells share features with both granulocytes and pDCs we refer to them as DR^{hi} Hybrids; their expression of CD303 challenges the notion that this molecule is specific for plasmacytoid DC. Co-expression of CD83, CD275 suggests an inflammatory potential whereas their lack of CD45RA (as opposed to CD303^{+}pDCs) is reminiscent of the altered CD45RA expression we found previously in a DC2-like DR^{hi} subset. Joint expression of CD303 and DR suggests that DR^{hi} Hybrids maybe functionally involved in the capture and ultimate presentation of RA self-peptides to T lymphocytes. These apparently new DR^{hi} Hybrids and other unorthodox DR^{hi} populations are potential treatment targets in RA.



Comparison of CD303+ DRhiHybrids with CD303+ plasmacytoid DC. A) CD45RA and CD303 expression in healthy donor plasmacytoid DC (left; purple) and RA (with presence of DRhi hybrids) B) Quantification of CD45RA MFI of CD303+ pDC from RA (orange) and HD (blue) and CD303+ DRhi Hybrids. logarithmic scale. Kruskal-Wallis Test **** p=0.0008324

The Effect of Resolvin E1 and Resolvin D1 Specialised Pro-resolving Mediators on the Inhibition of Osteoclastogenesis

Patricia Riedlova[1], Kieran Woolcock[2], Cecilia Ansalone[2] and Carl Goodyear[2], [1]University of Glasgow - School of Infection & Immunity, Glasgow, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoclasts (OCs) are multinucleated bone-resorbing cells playing a key role in rheumatoid arthritis (RA). Under physiological conditions, OCs are in balance with bone-forming osteoblasts, whilst in RA homeostasis is disrupted, leading to excessive bone resorption. Specialised pro-resolving mediators (SPMs), a group of lipids biosynthesised from fatty acids, have been shown to resolve inflammation and play a role in bone remodelling. Notably, the SPM Resolvin E1 (RvE1) was shown to inhibit OC differentiation and bone resorption using the RAW264.7 cell line and murine models. However, the effect of RvE1 on primary human cells and its mechanism-of-action in OCs remain unknown. Another SPM, Resolvin D1 (RvD1), has also been associated with reduced bone resorption in human OCs. Thus, this study aimed to evaluate the effects of SPMs on OCs (and their pre-cursors) differentiated from primary human cells derived from healthy individuals and those with RA; while also investigating the expression of proposed SPM receptors.

Methods: Peripheral blood mononuclear cells (PBMCs) were obtained from RA patients with active disease (DAS28 >2.8) and treated with conventional DMARDs or healthy controls (HC). $CD14^+$ monocytes were isolated from PBMCs and differentiated either into macrophages with 25 ng/ml of M-CSF or into OCs with 25 ng/ml of M-CSF and RANKL. The effect of various SPMs, namely RvD1, RvE1, 17-HDHA, Maresin 1, and their combination was tested in the presence or absence of TNF to mimic inflammatory environment. The impact of SPMs on osteoclastogenesis, bone resorption, ATP production, and mitochondrial superoxide levels was assessed. SPM receptor expression was analysed by RNA sequencing and protein expression was determined by western blot (WB).

Results: Exposure of TNF-stimulated OC pre-cursors to RvE1 resulted in inhibition of osteoclastogenesis in HC individuals (15±6.7% inhibition) but not in RA. In contrast, RvD1 inhibited osteoclastogenesis under the same conditions in RA patients (16±2.4% inhibition) but not in HC. Notably, OC inhibition was associated with the presence of numerous mono- and binuclear pre-cursors, which failed to differentiate into multinucleated mature OCs. The inhibition of OC differentiation by RvE1 and RvD1 was associated with reduced superoxide production in HC and RA OCs, respectively. Transcriptional profiling of human monocytes and OCs revealed that LTB4R, CMKLR1, FPR2, and GPR18 SPM receptors were expressed in both cell types. Validation of the selected SPM receptors via WB, demonstrated that LTB4R was significantly higher in HC monocytes and OCs than in RA, while CMKLR1 and FPR2 were similarly expressed.

Conclusion: In summary, this study highlights the capacity of RvE1 and RvD1 to specifically modulate OC differentiation in primary human cells in either health or RA. Combined, these findings suggest a potential for SPMs as novel treatment for RA.

ACPA, Anti-CarP and AAPA Can Be Detected in Saliva, but Not in Feces of Seropositive Rheumatoid Arthritis Patients – Support for Mucosal Involvement in Specific Locations in RA

Veerle Derksen[1], Klara Martinsson[2], René Toes[1], Daniel Sjöberg[3], Thomas Huizinga[1], Alf Kastbom[4], Anna Svärd[3] and Diane van der Woude[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Linköping University, Linköping, Sweden, [3]Centre for Clinical Research Dalarna, Uppsala, Sweden, [4]Linköping University, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients harbor antibodies against several post-translational modifications (AMPA), for example anti-citrullinated protein antibodies (ACPA), anti-carbamylated antibodies (anti-CarP) and anti-acetylated protein antibodies (AAPA). The exact mechanism underlying the development of these autoantibodies is currently unclear. Remarkably, ACPA IgA have been detected in sputum and saliva of seropositive RA patients, suggesting local production of autoantibodies. This raises two questions: 1) Can other AMPA besides ACPA also be produced at mucosal surfaces and 2) Which mucosal sites can be involved in AMPA production? The intestines are an interesting site to investigate, as microbiome dysbiosis has been described in RA patients, and intestinal content may represent a source of post-translationally modified antigens which could trigger autoantibody formation.

Methods: Paired feces, saliva and serum samples of 36 ACPA IgG-positive RA patients, 11 ACPA IgG-negative RA patients and 21 healthy volunteers were collected. Saliva was collected via passive drooling. Feces was self-collected by participants and immediately frozen. To substantiate our findings regarding the lower intestinal tract, ileal wash fluid samples were used of 20 ACPA IgG-positive RA patients and 10 healthy donors, collected in an independent cohortvia colonoscopy. All patients fulfilled the ACR/EULAR 2010 criteria. Total IgA, anti-E. Coli IgA and ACPA, anti-CarP and AAPA IgA (serum, saliva) or Ig (feces) were detected using in-house ELISA. Samples were considered AMPA positive when the value of the modified peptide was above the cut-off (mean + 2 times SD of healthy donors) and the signal measured on the modified peptide was >2 times higher than on the unmodified peptide.

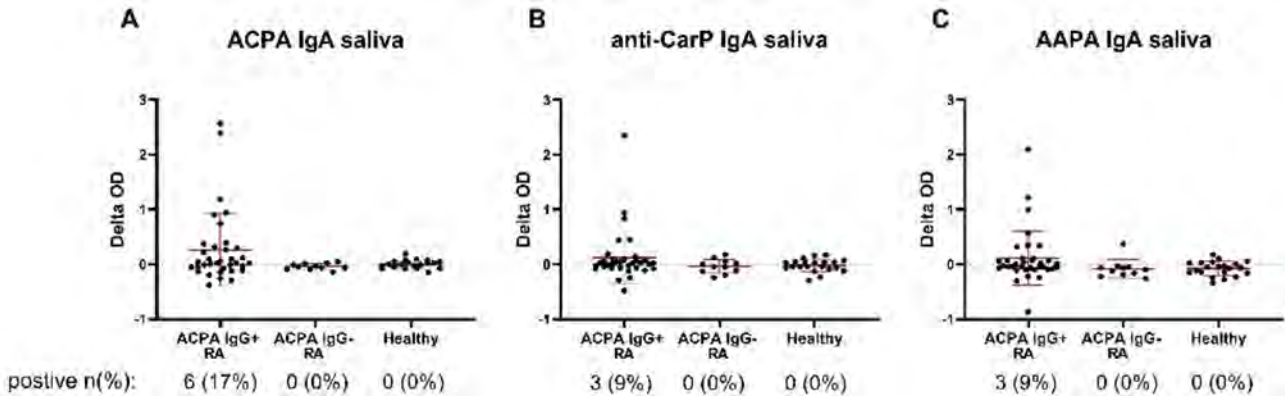

Figure 1: Autoantibody measurements in saliva. Delta OD (optical density): difference in OD between the modified peptide and the unmodified peptide. The groups on the X-axis are based on seropositivity. The number (%) of positive patients for that specific autoantibody is given. Red bars depict mean with standard deviation.

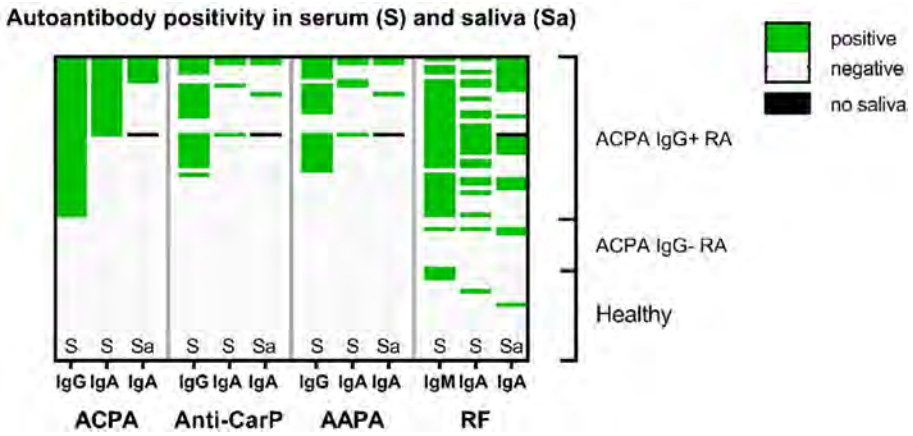

Figure 2: Positivity for the different AMPA in serum (S) and saliva (Sa). Each row depicts a study participant. The black box means no saliva available due to hyposalivation.

Results: ACPA, anti-CarP and AAPA IgA can all be detected in saliva of seropositive RA patients with differences in optical density (OD) between the modified and the unmodified peptide being clearly higher than in ACPA-negative patients and healthy controls, although the number of positive patients was low (Figure 1). When present, the saliva autoantibody profile reflects the breadth of the serum autoantibody response (Figure 2). However, AMPA Ig could not be detected in any of the fecal supernatants (Figure 3). Also in the ileal wash fluid samples no ACPA was found. Even in ACPA-positive RA patients OD-differences between the modified and unmodified peptide were consistently close to 0. Other intact IgA was present in feces, since the samples contained on average 76 μg/ml total IgA and anti-E.Coli IgA was detectable in feces of 12/36 ACPA-positive RA patients (Figure 3).

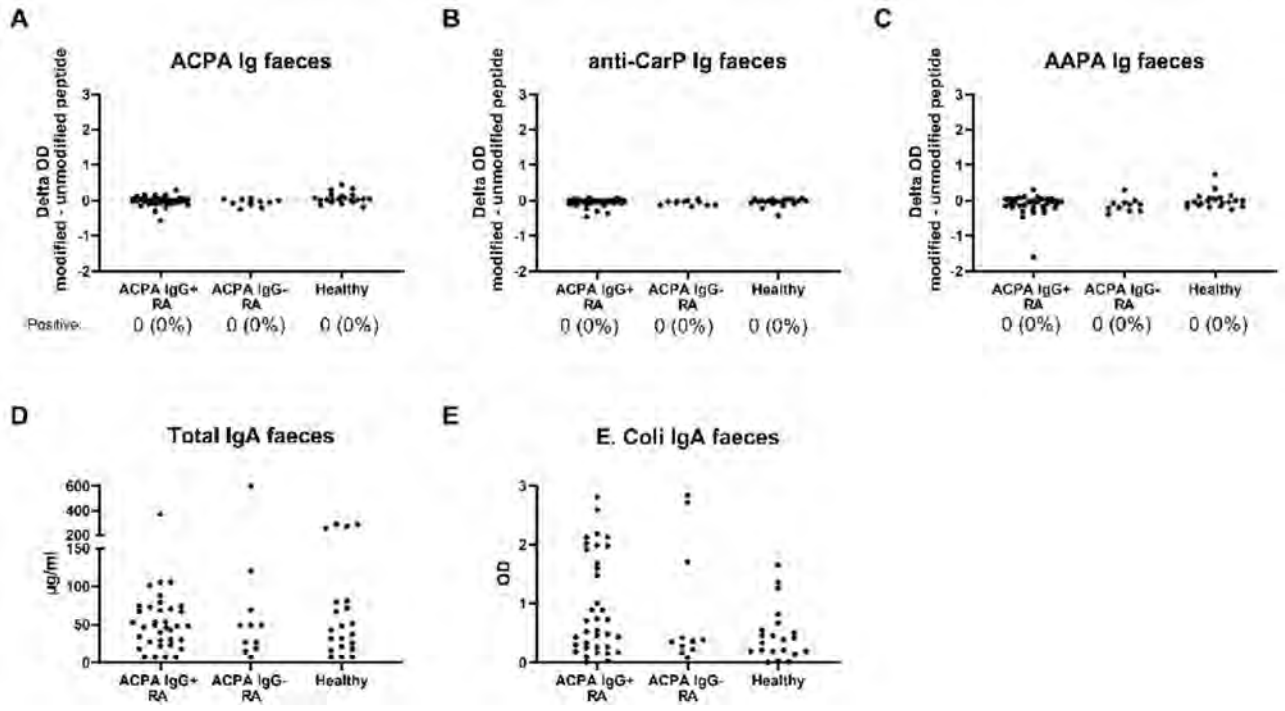

Figure 3: AMPA in feces of RA patients. A-C) ACPA, anti-CarP and AAPA Ig respectively. The groups on the X-axis are based on seropositivity. For AMPA, the number (%) of positive patients is given. On the Y-axis the difference in OD between the modified and unmodified peptide is depicted. D) Total IgA levels in μg/ml, E) OD on the anti-E. Coli IgA ELISA in the same feces samples.

Conclusion: ACPA, anti-CarP and AAPA can all be present in saliva of ACPA-positive RA patients. However, AMPA could not be detected in feces of these patients. Also in ileal wash fluid, collected in an independent cohort of ACPA-positive RA patients, no ACPA was present. Other (antigen-specific) antibodies were present in feces, indicating that the absence of an AMPA signal is not due to methodological issues. These findings suggest that the lower gastro-intestinal tract is not a main site of AMPA production in RA patients, but the oral mucosa might play a role in the AMPA response.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent literature has identified different synovial fibroblast (FLS) populations within RA synovium with distinct inflammatory profiles. Despite current advances in classifying heterogeneity of FLS subsets, understanding of the FLS landscape in healthy synovial tissue is limited. We aim to identify homeostatic vs pro-inflammatory FLS signatures in synovial tissue biopsies obtained from healthy controls (HC) and RA patients and identify conversion triggers and activated signalling pathways.

Methods: Single cell (Sc) RNAseq was performed on 21,759 FLS derived from intact synovial biopsies from 5 HC and 4 RA. Subsequently, multiparametric flow cytometric analysis (22 markers) was performed on digested synovial biopsies from HC subjects and RA patients (further stratified between ACPA+/-) to identify FLS subsets and characterize functional phenotypes.

Results: ScRNAseq identified 14 FLS clusters which broadly aligned to 4 main subsets: CD55+THY1(CD90)-FAP+, CD55-THY1+FAP+, CD55+THY1+FAP+, and CD55-THY1-FAP+. Subsequent analysis showed clusters generally fall into lining/sublining layer, immunoregulatory, and regulatory/homeostatic functional FLS subsets. Six clusters showed higher frequency in RA synovium and eight had higher frequencies in HC. Three of the clusters had lining layer markers including

THY1-, CD55+, etc. and were enriched for invasive genes (MMP1, MMP3) and chemokines (CXCL1, CXCL8). Five clusters compose the THY1+ sublining layer fibroblasts and included a perivascular subset expressing NOTCH3, TAGLN, and ACTA2, in addition to enrichment of collagen and ECM genes. Two additional clusters sharing lining layer markers are immunoregulatory demonstrating enrichment of HLA-DR genes and genes involved in a chronic inflammatory response (IL7R, IL32, TGFB1). Of the homeostatic/regulatory subsets, two were enriched with transcription factors (TF), specifically those in the AP-1 TF family and mRNA splicing/ lipid homeostasis genes, while the two other clusters showed enrichment of genes involved in metabolic regulation and angiogenic function.

Flow cytometric analysis showed significantly higher frequencies of CD45-CD146-CD31-PDPN+ FLS in RA synovium compared to HC synovium. PDPN+ populations, both lining and sublining (based on the markers of the 4 main populations observed in the ScRNAseq) displayed higher frequency in RA synovium compared to HC. When stratified for ACPA positivity an increased frequency in sublining FLS population was demonstrated in ACPA+ RA compared to ACPA-, in contrast ACPA- RA had higher frequency of lining layer FLS. This suggests that differential FLS subsets are associated with the RA synovium vs with HC, in addition to possibly differentiating between ACPA status.

Conclusion: Identification of differential FLS subsets and their associated function in the RA vs HC synovium will better facilitate our understanding of their contribution to disease pathogenesis in RA. Furthermore, by stratifying RA patients between ACPA+ and ACPA- we can understand differences of these disease states and better tailor treatments.

Mass Spectrometry Identified Rheumatoid Arthritis-Specific Modified Proteins and the Discovery of Antigen-Specific Hidden Autoantibodies

Khetam Ghannam[1], Marieluise Kirchner[2], Holger Bang[3], Thomas Häupl[4], Sarah Ohrndorf[1], Jan Zernicke[1], Ulrike Kuckelkorn[5], Philipp Mertins[6], Eugen Feist[7] and **Gerd Burmester**[8], [1]Department of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Berlin, Germany, [2]Proteomics Platform at Max Delbrück Center for Molecular Medicine and Berlin Institute of Health (BIH), Berlin, Germany, [3]Orgentec Diagnostika GmbH, Mainz, Germany, [4]Helios Department of Rheumatology, Vogelsang-Gommern, Germany, [5]Institute of Biochemistry, Berlin, Germany, [6]Proteomics Platform at Max Delbrück Center for Molecular Medicine and Berlin Institute of Health (BIH), Berlin, Germany, [7]Helios Department of Rheumatology and Clinical Immunology, Vogelsang-Gommern, Germany, [8]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic and systemic autoimmune disease characterized by synovial inflammation and progressive joint destruction. Given the presumed pathophysiologic role of anti-modified protein autoantibodies (AMPAs) in RA, it is important to obtain a comprehensive overview of the post-translational modified (PTM) proteins present in SF and serum of RA in order to reveal those autoantigens that might promote the expansion of autoreactive B cells. Therefore, mass spectrometry was used to identify citrullinated, carbamylated and acetylated proteins present within monomeric and IC (immune complexes) of synovial fluid (SF) and serum of RA, and serum of healthy donors (HD), which served as a control.

Methods: This study included 42 RA patients fulfilling the 2010 ACR/EULAR classification criteria, 44 patients with other arthritic diseases who served as the control group, and 47 HD. Proteins isolated from SF and serum were fractionated by sucrose gradient centrifugation and monomeric and IC IgG were isolated from the respective fractions according to protein markers. Mass spectrometry was used to identify PTMs within monomeric and IC IgG fractions. Rheumatoid factor (RF), anti-citrullinated, anti-carbamylated, and anti-acetylated antigen antibodies were analyzed by ELISA.

Results: In SF and serum of RA, positivity to anti-acetylated and anti-carbamylated IgG was restricted to samples positive for anti-cyclic citrullinated peptide (CCP) IgG. Anti- citrullinated IgG antibodies differentiated between RA and CG in serum and SF, while anti-acetylated IgG reactivities were significantly increased in RA-SF compared with CG. Monomeric and IC IgG isolated from formally seronegative RA patients showed very strong reactivity mainly against citrullinated peptides, indicating a "hidden" antibody response. Although mass spectrometry analysis identified citrullinated, carbamylated and acetylated proteins in all samples tested - SF from RA and serum from RA and HD - quality analysis revealed modified autoantigens unique to RA, and many were found in double or even triple modified isoforms. The frequency of modified carbamylated and acetylated proteins was significantly higher in RA than in HD.

Conclusion: Many RA-related autoantigens underwent single as well as multifold-modifications were identified within monomeric and IC of RA patients. Carbamylated and acetylated proteins distinguish between RA and HD. Monomers and IC isolated from formally seronegative patients showed hidden anti-citrullinated reactivities undetectable by conventional assays.

Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The etiology of rheumatoid arthritis (RA) is not fully understood. It is accepted that RA results from the interplay of genetic and environmental factors. Epigenetic modifications could serve as a bridge between genetic and environmental factors, potentially influencing the onset and progression of RA.

Purpose:to identify differential DNA methylation patterns across the entire genome in patients with RA compared to healthy controls, and to explore epigenetic alterations that couldbe predictors of increased disease severity.

Methods: In a cross-sectional study of a prospective cohort, we examined 64 subjects, including 16 with severe RA, 16 with non-severe RA, and 32 healthy controls. The severity phenotype was determined based on the average of moderate-to-high inflammatory activity, defined by an accumulated Disease Activity Score(DAS28-ESR) ≥3.2, positivity for rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA), as well as elevated levels of *Collinsella aerofaciens* (OTU ≥0.15). DNA methylation analysis was performed using the Infinium Methylation EPIC BeadChip (Illumina, San Diego, CA, USA), and the methylation level of each cytosine was expressed as a β-value. Descriptive analysis, ANOVA, and bivariate analysis were conducted for statistical comparisons among groups. Additionally, two multivariate logistic regression models were employed to identify factors associated with RA and the severe RA phenotype.

Model 1: Dependent variable: Patients (1) vs. Controls (0). Model 2: Dependent variable: severe RA (1) vs. Non-severe RA (0). Age and sex were variables included in both models.

Results: Table 1 shows the main demographic characteristics. The majority (75%) were female, with a mean age of 57.6 ± 9.4 years. RA patients, in comparison with the controls, presented higher smoking habits (62.5% vs 40.7%; p=0.015) and obesity (53.1% vs 28.1%; p=0.012). Among patients, subjects with severe RA compared with non-severe had a higher mean DAS28-ESR (3.9 ± 0.6 vs. 3.3 ± 0.2 mg/L, p=0.001), higher median (IQR) abundance in *Collinsella*(0.3 [0.1-1.7] vs. 0.1[0.0-0.4] mg/L, p=0.003), higher frequency of erosions (93.8% vs 50.0%; p=0.006), elevated ACPA (68.8% vs 31.1%; p=0.034) and treatment with biological therapy (56.3% vs 12.5%, p=0.009). Regarding the methylation analysis, among all the differentially methylated CpGs, only those CpGs associated with genes or pseudogenes, exhibiting a minimum β value change of ± 0.10 between groups and a p-value ≤ 0.01, were selected;thus, 7 CpG sites differentially methylated between RA and controls and 14 CpG sites differentially methylated between severe RA and non-severe RA were selected (Figure 1). The CpG sites described in each gene, located in differentially methylated regions, together with other CpGs, were proposed as possible biomarkers (Table 1). In addition, cg06166490 was considered since it is located in a differentially methylated region (adjusted$p$-value < 0.00001). Of these CpGs, 5 CpG sites were associated with the presence of RA in multivariate model 1 and 2 CpG sites with disease severity in multivariate model 2 (Table 2).

Conclusion: DNA methylation levels at specific CpG sites are associated with RA. The present study identified epigenome marks related to RA and possible disease severity, which warrant further investigation and could be useful in the diagnosis and management of the disease.

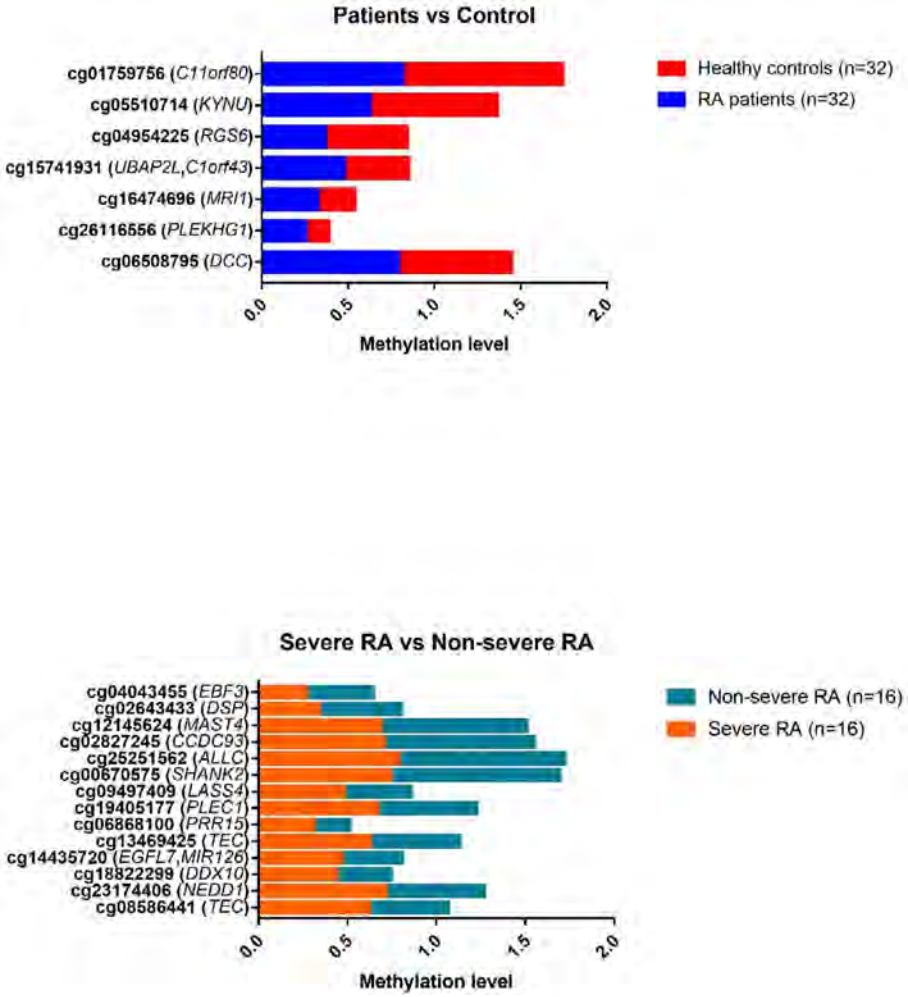

Figure 1: CpG sites with significantly differential methylation between patients with rheumatoid arthritis (RA) and healthy controls (upper panel), as well as between severe and non-severe RA patients (lower panel). The gene symbol is indicated in parentheses for each CpG site.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: CD4+ T cells recognizing citrullinated epitopes are present in peripheral blood of anti-citrulline protein antibody (ACPA) positive rheumatoid arthritis (RA) patients at time of diagnosis and during the disease course. However, it has not priorly been known if these rare cells also can be found preceding disease onset. The aim of this study was thus to investigate the presence of such autoreactive CD4+ T cells, in the at-risk phase of RA, in combination with deep T cell phenotyping.

Methods: Twenty individuals from the Karolinska Risk-RA cohort carrying the genetic risk allele, HLA-DRB1*04:01, were included in the study. At baseline, all individuals had musculoskeletal symptoms, concomitant anti-CCP-positivity, but no clinical or ultrasound signs of synovitis. Ten of these individuals progressed to arthritis (over a median period of 13 months following inclusion) and were matched to individuals that had not progressed during a median follow-up period of 53 months. Peripheral blood mononuclear cells (PBMC), from up to three sample timepoints during one year of risk phase, were assessed using HLA-class II tetramers with twelve different citrullinated candidate autoantigens (originating from tenascin-C, α-enolase, fibrinogen-β, vimentin and cartilage intermediate layer protein) and a viral influenza peptide as positive control, combined with multiparameter phenotyping using a 20-color spectral flow-cytometry panel.

Results: Overall, the baseline CD4+ phenotype was similar in individuals who progressed to arthritis and those who did not when studying markers associated with Th1, Th17, T-peripheral helper and T-regulatory cells as well as with cell activation. The memory T cell compartment was predominantly of effector memory phenotype. When looking at antigen specific T cells, all individuals had similar levels of influenza specific CD4+ T cells irrespectively of disease progression status. CD4+ T cells recognizing pools of citrullinated antigens were also present in both groups but at significantly higher frequency in the non-progressors, particularly those with reactivity towards citrullinated fibrinogen-β/vimentin. Within the arthritis progressor group, CD4+ T cells specific for citrullinated tenascin-C were the most frequently observed, with their frequencies diminishing during follow-up time points leading up to arthritis onset. These cit-tenascin-C reactive CD4+ T cells displayed phenotypes of both activation and regulatory function.

Conclusion: Autoreactive CD4+ T cells recognizing citrullinated antigens are present in the circulation before disease onset in ACPA-positive individuals with arthralgia carrying HLA-DRB1*04:01. Lower frequency of circulating citrulline specific cells in arthritis progressor individuals may suggest an ongoing homing of these cells to the joints.

Sputum Citrullinated Proteins and Sputum Anti-Cit-S100A8/A9 IgG Antibodies Are Increased in Serum Anti-CCP-IgG Positive Individuals Who Developed RA

Rachna Talluri[1], Sudeshna Sen[2], Timothy Wilson[3], Adam Savage[4], Mark Gillespie[4], Tom Bumol[4], Marie Feser[1], Jill Norri[5], Michael Holer[1], kevin Deane[1], Paul Thompson[2] and Kristen Demoruelle[1], [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Massachusetts Chan Medical School, Worcester, MA, [3]Thomas Jefferson University, Philadelphia, PA, [4]Allen Institute for Immunology, Seattle, WA, [5]Colorado School of Public Health, Denver, CO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of anti-CCP-IgG in the blood identifies individuals who are "at-risk" of developing RA. Our group has reported that in a cohort of serum anti-CCP-IgG positive at-risk individuals, 27% developed RA within 3 years. Remarkably, the rate of incident RA increased to 57% in at-risk individuals who were also sputum anti-CCP positive. Because anti-CCP detects ACPA directed to joint-based citrullinated (cit) proteins/peptides, we explored the presence of lung-based cit-proteins and associated ACPA in sputum from at-risk individuals who did or did not later develop RA.

Methods: We performed a two-step study using stored baseline sputum from a cohort of serum anti-CCP-IgGpositive at-risk individuals categorized as having 'developed RA' or 'did not develop RA' within 3 years of longitudinal follow-up. In Step 1, we determined presence of cit-proteins using pooled sputum from nine at-risk individuals who developed RA and nine

Table 1. Baseline characteristics of study participant*

	Step 1 – Characterization of sputum citrullinome		Step 2- Sputum ACPA responses to cit-proteins identified in Step 1	
	At-Risk Developed RA (N=9)	At-Risk Did not develop RA (N=9)	At-Risk Developed RA (N=16)**	At-Risk Did not develop RA (N=49)**
Age	63 (43-70)	63 (36-73)	55 (44-65)	64 (49-71)
Female sex	7 (78%)	7 (78%)	12 (75%)	33 (67%)
Ever smoker	3 (33%)	2 (22%)	9 (56%)	15 (31%)
≥1 Shared epitope allele***	6 (67%)	6 (67%)	7 (44%)	19 (41%)
Sputum anti-CCP-IgG or sputum anti-CCP-IgA positive****	5 (56%)	0 (0%)	9 (56%)	12 (24%)
Median time to RA (month)	17 (9-30)	-	19 (10-24)	-
Median time of follow-up	-	33 (22-35)	-	32 (20-39)

Results are reported in median (IQR) or N (%)
* All at-risk participants were serum anti-CCP-IgG based on CCP3 ELISA (Werfern) at baseline
** Includes 6 of 9 from Step 1 who develop RA and 8 of 9 from Step 1 who did not develop RA. Samples included in Step 1 that were not included in Step 2 were not included due to lack of remaining sputum sample available to test
*** SE tested available on 46/49 who did not develop RA
**** As previously reported, serum anti-CCP-IgG+ individuals who later developed RA were more likely to have sputum anti-CCP positivity (In Step 2 cohort, 56% vs. 24%, p=0.02).

Log2 fold change between those who developed incident RA (n=9) and those who did not (n=9) (i.e., Developed RA/Did Not Develop RA; positive values = higher in those who developed incident RA; negative values = lower in those who developed incident RA).
Bold = significantly different between groups after accounting for multiple comparisons (Bonferroni correction, p<0.0007 significant)
* Citrullinated proteins included in antigen microarray testing

matched individuals who did not develop RA. Cit-proteins were enriched using biotin labeled phenylglyoxal (chemically binds all citrulline) followed by streptavidin enrichment. Three replicates were tested for each group and cit-protein levels were compared between groups using Reductive Dimethylation based quantitative proteomics. In Step 2, we quantified ACPAs

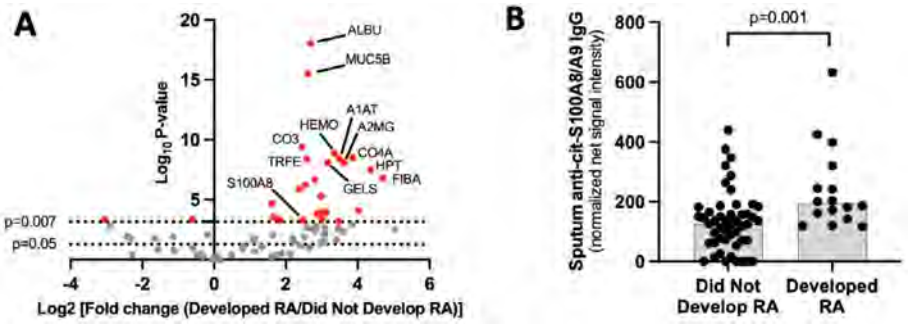

Figure 1. Sputum citrullinated proteins and sputum anti-cit-S100A8/A9 IgG antibody levels in serum an-ti-CCP-IgG positive at-risk individuals. Panel A depicts a volcano plot with the log2 (fold change) for ratios in (developed RA/did not develop RA) on the x-axis and log10 p-values on the y-axis. As such, cit-proteins to the right are increased in individuals who developed RA compared to individuals who did not develop RA. Lines correspond to a p-value of 0.05 and 0.007 (p<0.007 was significant after accounting for multiple com-parisons). Panel B depicts sputum anti-cit-S100A8/A9 IgG levels stratified by those who developed RA and those who did not develop RA within 3 years. P-values calculated based on Wilcoxon rank sum test and ac-counting for multiple comparisons (Bonferroni correction, p<0.002 significant). Abbreviations for selected proteins in Panel A: ALBU=serum albumin, MUC5B=mucin 5B, S100A8=S100-A8 protein, TRFE=lactotransferrin, CO3=complement C3, HEMO=-Hemopexin, A1AT=alpha-1 antitrypsin, A2MG=alpha-2 macroglobulin, CO4A=complement C4A, HPT=haptoglobin, FIBA=fibrinogen alpha chain, GELS=gelsolin.

directed to a subset of the cit-proteins identified in Step 1 using baseline sputum from an expanded cohort (n=65, 16 who developed RA and 49 who did not develop RA) and using a customized antigen microarray containing native and citrullinated whole proteins (GeneCopoeia OmicsArray). Cit-specific IgG and IgA reactivity was quantified by net signal intensity (background signal subtracted) normalized to internal Ig controls and subtracting native protein from cit-protein reactivity. Sputum anti-CCP-IgG and anti-CCP-IgA were quantified by ELISA and positive cut-off level established in a non-diseased control group.

Results: The cohort characteristics are described in Table 1. In Step 1, we identified 74 distinct cit-proteins in sputum (Table 2, Figure 1). Of those, 23 were significantly increased in those who developed incident RA (Table 2). In step 2, 27 of the 74 cit-proteins identified in Step 1 were tested for sputum antibody reactivity. Only sputum levels of anti-cit-S100A8/A9 IgG were significantly higher in individuals who developed RA (Figure 1). Within individuals who developed RA, sputum anti-cit-S100A8/A9 IgG correlated with sputum anti-CCP-IgG (r=0.53, p=0.03) but not sputum anti-CCP-IgA levels (p=0.12).

Conclusion: Our findings demonstrate the sputum citrullinome in serum anti-CCP-IgG positive at-risk individuals for the first time. We identified 23 sputum cit-proteins that were increased in at-risk individuals who later developed RA. Of note, multiple cit-proteins were present in sputum, and sputum antibody reactivity was detectable at some level to many of these cit-proteins. However, only sputum anti-cit-S100A8/A9 (i.e. calprotectin) IgG was significantly higher in at-risk individuals who later developed RA. This supports future studies to understand the effect of this ACPA in RA development and to understand the effects of citrullination on protein function in the lung during RA development.

Abstract Number: 1743

Individuals At-risk for and with Rheumatoid Arthritis Have Elevated Fecal Concentrations of Arthritogenic *Subdoligranulum didolesgii* Correlating with CCP3 Antibodies

Lyndsey Cole[1], Sucai Liu[2], Brendan Allen[2], Marie Feser[3], Kristen Demoruelle[3], kevin Deane[3], Michael Holer[3] and kristine Kuhn[2], [1]University of Colorado School of Medicine, Centennial, CO, [2]University of Colorado School of Medicine, Aurora, CO, [3]University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Our prior investigation identified a specific strain of *Subdoligranulum didolesgii*, *S. dido*7, to which dual IgA/IgG family plasmablast-derived monoclonal autoantibodies from individuals at-risk for RA show cross-reactivity with RA-relevant autoantigens. *S. dido*7 stimulated CD4+ T cell activation in individuals with RA. Also, it led to inflammatory arthritis (IA) in mono-colonized germ-free mice and Th17 cell expansion, RA-relevant IgG autoantibody production and colon-isolated lymphoid follicle abundance [1]. In this study, we sought to assess the prevalence and compare the fecal concentration of *S. dido*7 among healthy controls vs. individuals at-risk and with early RA and its association with CCP3 antibodies and biomarkers of intestinal permeability, zonulin and soluble CD14.

Methods: Stool and sera were prospectively collected from 3 groups: 1) 'At-Risk' individuals, defined as those with positive CCP3 with no history of nor current IA (n=54), 2) individuals with CCP3(+) RA based on 2010 ACR/EULAR criteria within 12 months of diagnosis (n=5) and 3) controls without IA or RF/CCP3 positivity (n=32). Exclusion criteria included antibiotics in the 3 months prior to sample collection. Fecal DNA was extracted using a commercial kit (Qiagen). Quantitative PCR was used to create a standard curve using known concentrations of *S. dido*7 to allow for calculation of strain-specific fecal levels in individual samples. Serum CCP3 ELISA (Werfen) was used to measure CCP IgG. Serum ELISAs (Cusabio) were used to quantitate serum zonulin and soluble CD14.

Results: Demographics are summarized in Table 1. There were no significant differences across the groups apart from age. Fecal concentration of *S. dido*7 was 2.5-fold higher in At-Risk individuals and 3.1-fold higher in early RA compared to controls (p=0.02; Figure 1). Higher serum CCP3 levels significantly correlated with higher fecal *S. dido* 7 concentration (p=0.005; Table 2). Serum CD14 but not zonulin was significantly lower in At-Risk individuals and early RA (p=0.008; Table 1). Higher zonulin significantly correlated with lower fecal *S. dido*7 concentration (p=0.002; Table 2). There was no significant correlation between fecal *S. dido*7 and serum soluble CD14 or age (Table 2).

Table 1: Characteristics and Comparisons Among Healthy Controls, Individuals At-Risk for RA, and Individuals with Early RA

Variable[a]	Healthy Controls	At-Risk CCP+	CCP+ RA	P-value (All 3)	P-value (Controls vs At-Risk)
N	32	54	5		
Age (years)	49 (35.25, 60.75)	62.5 (48.25, 72.25)	57 (48, 67)	0.007	0.002
Sex (% female)	62.5	75.9	100	0.15	0.22

Serum soluble CD14 (ng/mL)	405.8 (291.8, 506.1)	292.8 (209.3, 386.6)	248.2 (88.24, 580.9)	0.008	0.004

[a] Continuous variables presented as median (interquartile range)
[b] Defined as 1 or more HLA-DR4 alleles
[c] NHW, Non-Hispanic White

Kruskal-Wallis and Mann-Whitney tests were used for 3- and 2-way comparisons of continuous data, respectively. Categorical data comparisons were performed using Chi-square or Fisher's exact test. Correlations were performed using Spearman's rank correlation coefficient.

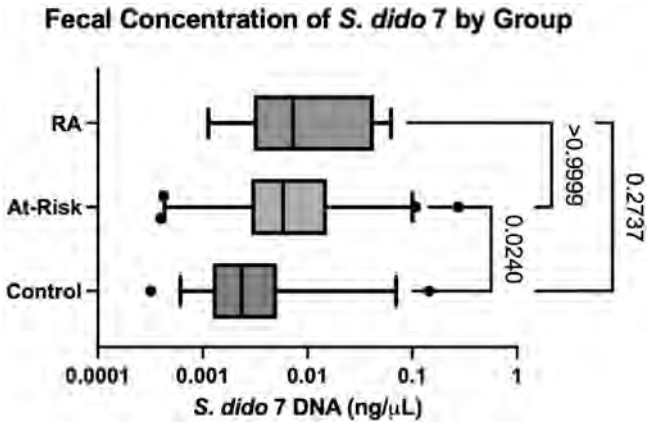

Figure 1: Fecal concentration of S. dido 7 in ng/L significantly differed across the three groups by Kruskal-Wallis test (p=0.02). After adjustment for multiple comparisons, the At-Risk group had a significantly higher fecal concentration of S. dido 7 compared to the control group by Mann-Whitney test (p=0.024).

Table 2: Spearman correlations with fecal concentration of *S. dido* 7		
Variable	**Spearman r (95% CI)**	**P value**
Serum CCP3	0.2921 (0.08551, 0.4746)	0.005
Serum zonulin	-0.3204 (-0.4984, -0.1165)	0.002
Serum soluble CD14	-0.1837 (-0.3807, 0.02933)	0.0814
Age	-0.03834 (-0.4018, 0.1555)	0.7183
BMI	-0.1310 (-0.3405, 0.09079)	0.2319

Conclusion: These data, along with prior data demonstrating arthritogenic potential of this bacterial strain, suggest*S. dido*7 may play an important mechanistic role in a subset of individuals during development of CCP autoantibodies and subsequent RA. Our data do not agree with others' findings of impaired intestinal permeability that we hypothesized as a potential mechanism by which*S. dido*7 may trigger autoimmunity. Future study is needed to address limitations, including validation of intestinal permeability studies and improvement in age- and sex-matching, as well as to evaluate*S. dido*7 in seronegative RA and its associations with clinical and biomarker features before and after arthritis development.

Histological and Molecular Comparison in the Synovial Tissue of Patients with Active Rheumatoid Arthritis to Remission

Selina Ohl[1], Klaus Frommer[1], Markus Rickert[2], Stefan Rehart[3], **Ulf Müller-Ladner**[1] and Elena Neumann[1], [1]Justus Liebig University Gießen, Campus Kerckhoff, Bad Nauheim, Germany, [2]Dept. of Orthopaedics and Orthopaedic Surgery, University Hospital Giessen and Marburg, Giessen, Germany, [3]Dept. of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital Frankfurt, Frankfurt, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease which leads to local and systemic manifestations. Subsequently, the inflamed synovium drives the destruction of cartilage and bone in the affected joints. Until now, remission has been considered the therapeutic goal of the disease, as RA cannot be cured. However, as the prognostic outcomes of patients vary significantly, a better understanding of remission is required.

Objectives: To characterize remission in RA comparing histological and molecular features of active RA patients to those in remission in the synovium.

Methods: RA patients (35-82 years) were classified as active or remission after joint replacement surgery based on clinical (e.g. painful joints, pain degree, medication) and laboratory (e.g. ESR, CRP, leucocytes) parameters. To characterize synovitis, the Krenn score was used, and immunofluorescence with CD90 and podoplanin antibodies was performed. On RNA

level, RNA sequencing of RA synovial fibroblasts (RASF) was performed, which were previously stimulated with IL-1ß for 24 hours. Differentially expressed genes (DEGs) were analysed based on a combination of absolute expression, divergence and significance. To identify enriched gene sets and pathways, a gene set enrichment analysis of DEGs was performed.

Results: 64 RA patients (29 active, 35 in remission) were included in the Krenn score analysis. Reduced values especially for hyperplasia (p=0.001) as well as for infiltrates (p=0.0001) and the general degree of inflammation (p < 0.0001) was observed in the remission group. Subanalyses of medication (e.g. biologicals, DMARDs, NSAIDs, glucocorticoids) confirmed differences between remission and active RA for all drugs and indicated an overall reduction of hyperplasia observed most strongly in the biologics group (p=0.0008). The fibroblast markers podoplanin (marker for fibroblasts located mainly in the lining) and CD90 (marker for fibroblasts located mainly in the sublining) showed the greatest differences indicating patients in remission have fewer numbers of fibroblasts in both, the lining and the sublining layer. Patients in remission showed several differentially expressed genes that were lower in remission compared to active RA patients, including e.g. IL-36ß and its corresponding receptor antagonist. As those cytokines play a role in chronic inflammatory processes and the progression of RA, the impact of these factors on RASF of patients in remission compared to active RA are of especial interest.

Conclusion: The characterization of synovium after joint replacement surgery was used to compare histological and molecular differences that may help to characterize remission in RA. The histology showed a lower degree of inflammation and, most prominent, hyperplasia for patients in remission, specifically in patients receiving biologics. RNAseq identified several genes showing altered expression pattern related to the pro-inflammatory and destructive processes during RA which gives insight into the molecular characteristics.

Chronic Inflammation and Collagen IV Fragment Canstatin Influence Rheumatoid Arthritis Synovial Fibroblast and Endothelial Cell Interactions in Vitro and in Vivo

Corinna Heck[1], Sophie Haun[1], Daria Kürsammer[1], Klaus Frommer[1], Mona Arnold[1], Markus Rickert[2], Katrin Susanne Lips[3], Stefan Rehart[4], **Ulf Müller-Ladner**[1] and Elena Neumann[1], [1]Justus Liebig University Gießen, Campus Kerckhoff, Bad Nauheim, Germany, [2]Dept. of Orthopaedics and Orthopaedic Surgery, University Hospital Giessen and Marburg, Giessen, Germany, [3]Justus Liebig University Gießen, Department of Experimental Trauma Surgery, Giessen, Germany, [4]Dept. of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital Frankfurt, Frankfurt, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In the inflamed synovium of RA patients, increased and altered angiogenesis is a pathological feature. Key players are chronically activated RA synovial fibroblasts (RASF), which promote synovial angiogenesis and matrix degradation. Canstatin is a matrix-derived anti-angiogenic collagen IV fragment that blocks the angiopoietin (ANGPT)/Tie2 pathway in endothelial cells (EC).

Objective: To analyse the effects of repetitively stimulated RASF and canstatin on vessel formation in the tube formation assay, the SCID-mouse model of RA and synovial tissue of RA patients with respect to ANGPT2 expression and RASF-EC interactions.

Methods: RASF were repetitively stimulated thrice every 24h with 0.05ng/ml IL-1ß. 2D tube formation assay was performed using HUVEC (+/- prestimulation with 0.2µg/ml canstatin for 20h) and 15%RASF seeded on Matrigel®. RASF/HUVEC were treated with 0.5µg/ml canstatin. Tube thickness and the area covered by the formed cellular network were measured. Supernatants were measured by ELISA. Cartilage was subcutaneously co-implanted with RASF alone or with 0.5µg/ml canstatin into SCID mice. Contralaterally, cartilage without RASF but with canstatin was implanted. Vessel formation and RASF-invasion were evaluated after 3-45 days.

Results: RASF or HUVEC stimulated once showed a significant IL-6 increase compared to unstimulated controls. Subsequent repetitive stimulation resulted in a significant IL-6 decrease compared to 1st stimulation in RASF (1st vs. 3rd: $p< 0.0001$) or HUVEC (1st vs. 3rd: $p=0.041$). The same effect was observed for IL-11 and CXCL2 in RASF (1st: vs. 3rd: $p< 0.0001$). In contrast, repetitive stimulation of HUVEC+15%RASF resulted in a significant IL-6 increase for each subsequent stimulation (1st vs. 3rd: $p=0.02$). Regarding tube formation, RASF significantly reduced tube thickness ($p=0.01$) and cell network area ($p < 0.0001$). RASF stimulated only once further reduced the network area ($p=0.04$), while repetitive stimulation significantly attenuated the proinflammatory effect ($p=0.03$). Stimulation of pre-treated HUVEC and unstimulated RASF with canstatin led to disturbed tube formation with reduced tube thickness ($p=0.01$). Co-culture of RASF with pre-treated HUVEC with canstatin further increased the RASF-mediated effect by reducing tube thickness ($p < 0.001$). In SCID mice, RASF-mediated helix-like vessel formation started at day 3. Number of helix-like vessels was significantly increased ipsilaterally compared to contralateral implants on day 3 and 30 ($p=0.04$). In contrast, number of helix-like vessels was significantly reduced ipsilaterally in implants containing canstatin on day 3 and 30 ($p=0.03$ both). In human RA synovium, the pathological vessel regulator ANGPT2 was significantly upregulated in vessels compared to OA tissue.

Conclusion: RASF-mediated effects on EC were detectable in the tube formation assay, since RASF and canstatin both specifically reduced tube thickness. RASF specifically altered neovascularization in SCID mice by promoting the formation of helix-like vessels. Human synovial tissue of RA patients showed significantly upregulated ANGPT2 expression compared to OA patients showing the effects on vessel formation in RA.

Smoking as a Risk Factor for Rheumatoid Arthritis: Exclusive Association with IgA Autoantibodies

Tineke van Wesemael[1], Anna Svärd[2], Annemarie Dorjee[1], Thomas Huizinga[1], René Toes[1] and **Diane van der Woude**[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Centre for Clinical Research Dalarna, Uppsala, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by autoantibodies to anti-modified protein autoantibodies (AMPAs) like anti-citrullinated protein antibodies (ACPA) and anti-acetylated protein antibodies (AAPA). Smoking is the most important environmental risk factor in autoantibody-positive RA and has been described to be specifically associated with AMPA-IgG. However, although smoking exerts its effect in the lungs, it is unknown whether smoking is preferentially associated with specific autoantibody isotypes, such as IgA, which would suggest a mucosal origin. Therefore, we set out to investigate if smoking is associated with AMPA of the IgA isotype in RA.

Methods: 618 RA patients from the Leiden Early Arthritis Cohort, of whom data were available on the presence of ACPA and AAPA -IgG and -IgA, and smoking were included. Current versus ever smoking data were collected at baseline using a questionnaire. The association between smoking and autoantibodies was assessed by logistic regression analysis. Next, a meta-analyses on results from systemic literature review on the association of smoking with ACPA-IgG and ACPA-IgA was performed.

Results: In univariate analysis, smoking was associated with various autoantibodies of different isotypes (ACPA-IgG, ACPA-IgA, AAPA-IgA, RF-IgM and RF-IgA), but since isotypes often co-occur, this precluded firm conclusions. Upon examining the exact autoantibody isotype composition, smoking was only associated with AMPA-positive RA in double-positive patients, i.e. patients who harbored both IgG ánd IgA-AMPA (figure 1A and 1B). Since smoking is also associated with autoantibody levels, we then corrected the isotype-smoking associations for these levels. Strikingly, after correction for IgA, the association between AMPA-IgG and smoking was lost (Figure 1C and 1D). However, after correction for IgG, AMPA-IgA were still associated with smoking (Figure 1C and 1D).Next, a meta-analysis was performed of all publications investigating the association of smoking with ACPA-IgG and ACPA-IgA and the current data. This confirmed that smoking was associated with ACPA-IgA but not with ACPA-IgG (figure 2). Interaction analysis of shared epitope and smoking revealed that interaction was only seen in patients that were ACPA-IgG and ACPA-IgA positive, but not in patients that were only positive for ACPA-IgG (figure 3A and 3B). This indicates that the presence of ACPA-IgA is necessary for the interaction effect.

Conclusion: In RA, smoking is exclusively associated with IgA autoantibodies against post-translationally modified proteins (AMPA), and not with AMPA IgG (figure 3C). Interaction between shared epitope and smoking is also solely found in patients positive for both IgG and IgA-ACPA. These findings support the hypothesis that smoking may exert its effect by the induction of local (auto)immune responses at mucosal sites.

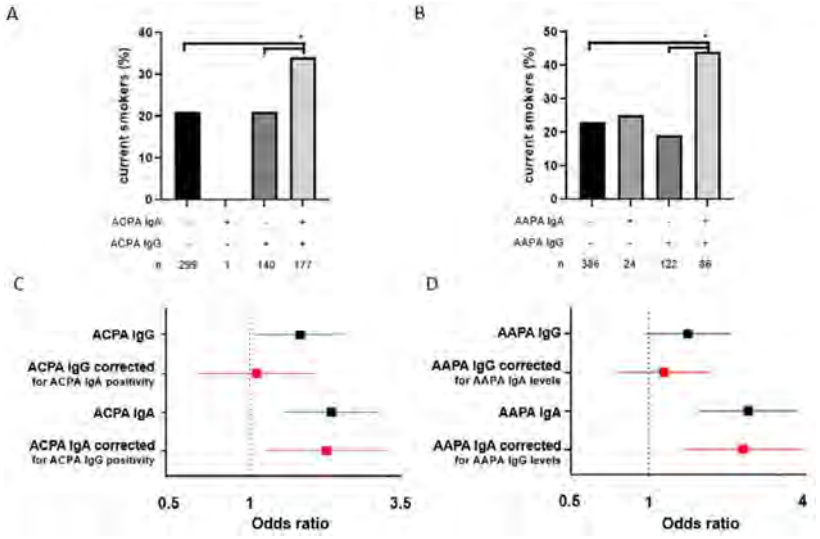

Figure 1. Association of smoking with anti-citrullinated protein antibodies (ACPA) and anti-acetylated protein antibodies (AAPA). A. Association of smoking with ACPA IgA & ACPA IgG. B Association of smoking with AAPA IgA & AAPA IgG. C. Association of smoking with ACPA IgA and ACPA IgG corrected for respectively ACPA IgG levels and ACPA IgA levels D. Association of smoking with AAPA IgA and AAPA IgG corrected for respectively AAPA IgG positivity and AAPA IgA positivity

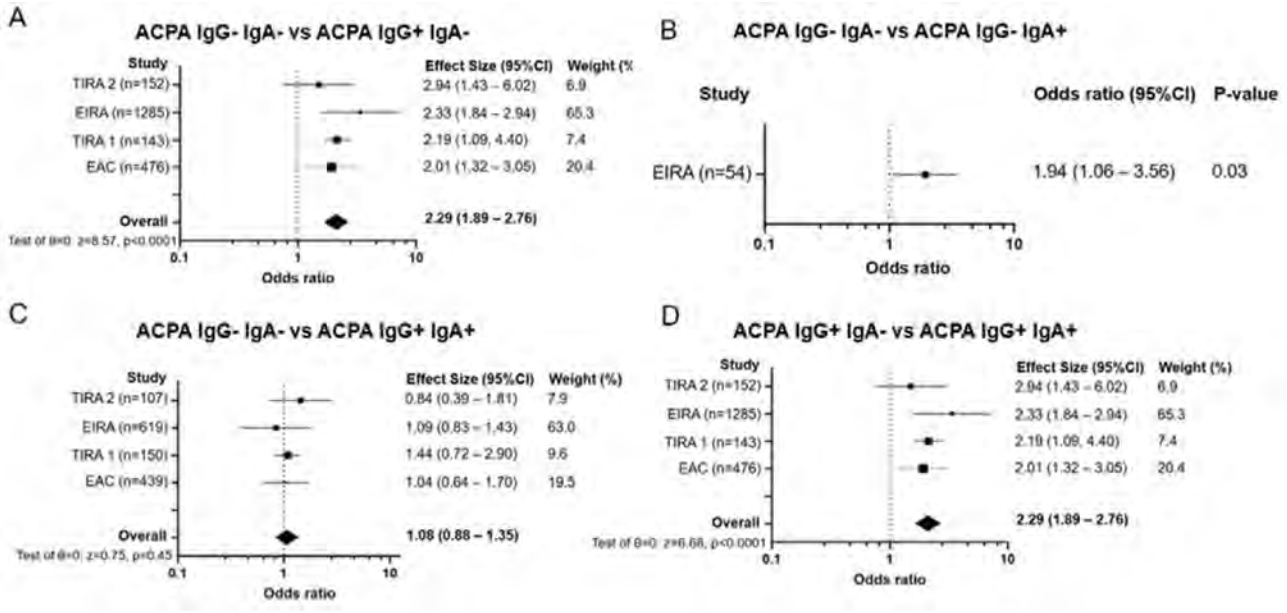

Figure 2. Meta-analysis for the association of smoking with anti-citrullinated protein antibodies (ACPA) IgG and ACPA IgA A. Meta-analysis for the association of smoking: ACPA IgG- ACPA IgA- versus ACPA IgG+ ACPA IgA- B. Association of smoking: ACPA IgG- ACPA IgA- versus ACPA IgG- ACPA IgA+ (no meta-analysis possible since this was examined in one study) C Meta-analysis for the association of smoking: ACPA IgG- ACPA IgA- versus ACPA IgG+ ACPA IgA+ D Meta-analysis for the association of smoking: ACPA IgG+ ACPA IgA- versus ACPA IgG+ ACPA IgA+

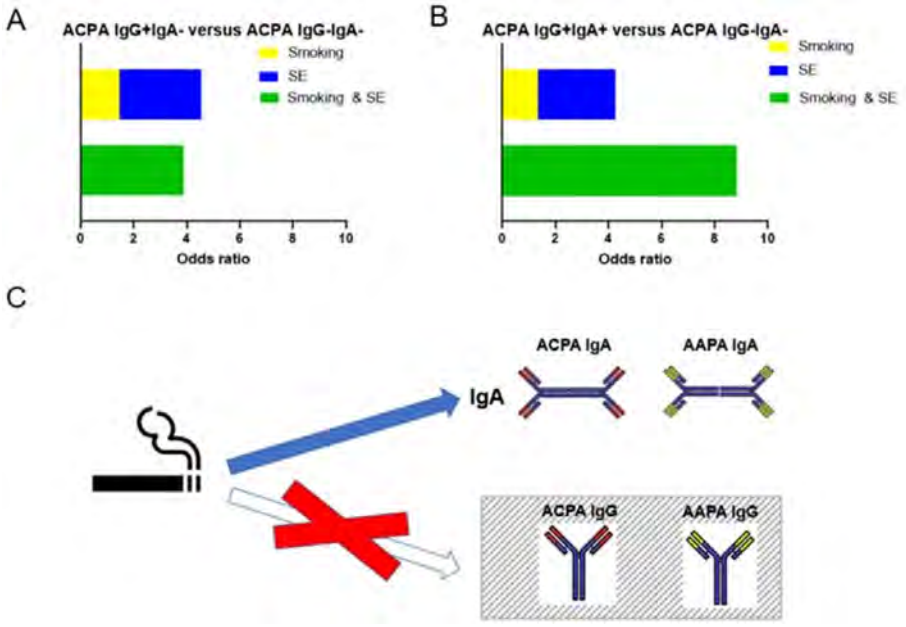

Figure 3. Interaction of shared epitiope (SE) and smoking with ACPA A. Interaction of smoking and SE in ACPA IgG+IGA- versus ACPA IgG-IgA- patients B. A Newly Described Cytokine interleukin-40 Is Increased in the Serum of Individuals At-risk of Rheumatoid Arthritis and Induces an Inflammatory Response in Mononuclear Cells

Adela Navratilova[1], Klára Prajzlerová[2], Nora Růžičková[3], Karel Pavelka[4], Jiri Vencovsky[5], Ladislav Senolt[6], Maria Filkova[3] and Lucie Andrés Cerezo[3], [1]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Hlavní město Praha, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic, [3]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic, [4]Institut of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Praha, Czech Republic, [5]Institute of Rheumatology, Prague, Czech Republic, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [6]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Praha, Czech Republic

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interleukin-40 (IL-40) is a newly described cytokine related to malignancies and immunity function. We have previously shown that IL-40 is up-regulated in early stages of rheumatoid arthritis (RA) and associates with processes that are thought to fuel the immune response. As the period preceding clinically apparent RA has not yet been fully described with respect to clinical biomarkers, we aimed to investigate IL-40 in individuals at-risk of RA development and its involvement in immune regulation in peripheral blood mononuclear cells (PBMCs).

Methods: IL-40 was analysed in the serum of individuals at-risk of RA (n=179, defined as patients with arthralgia with no clinical arthritis who are either carriers of anti-citrullinated protein antibodies, ACPA, or meeting the EULAR definition of clinically suspect arthralgia at baseline) and at the time of arthritis manifestation in patients who progressed to clinical arthritis (n=25). IL-40 was determined in the serum of age and sex-matched healthy controls (n=60). *In vitro* experiments were performed on PBMCs from at-risk individuals (n=10). Levels of IL-40 and IL-6 were measured by commercially available ELISA kits.

Results: IL-40 is up-regulated in at-risk individuals compared to healthy controls($p< 0.0001$) and the levels of IL-40 are higher in the serum of double-positive (ACPA/rheumatoid factor) compared to double-negative at-risk individuals ($p< 0.05$). Out of 175 at-risk individuals, 25 developed clinical arthritis (with median 8.17 months of follow up); however, we have not found a significant difference in the levels of IL-40 at baseline, and at the time of arthritis manifestation. *In vitro*, PBMCs from at-risk individuals exposed to recombinant IL-40 strongly enhance the secretion of IL-6 in a dose-dependent manner when compared to unstimulated cells (IL-40: 10 ng/ml, $p< 0.05$; 50, 100, 250 ng/ml, $p< 0.01$). Furthermore, the application of NFkB inhibitor to the PBMCs prior to the exposure to IL-40 significantly reduced the secretion of IL-6 when compared to IL-40 treated cells without inhibition ($p=0.004$).

Conclusion: Here we show for the first time that IL-40 is elevated in the serum of individuals at-risk of RA. Moreover, results imply that systemically elevated IL-40 induces the pro-inflammatory response in PBMCs at-risk individuals via NFkB dependent pathway.

Macrophage Extracellular Traps Require Peptidylarginine Deiminase 2 and 4 and Are a Source of Citrullinated Antigens Bound by Rheumatoid Arthritis Autoantibodies

S Janna Bashar, Caitlyn Holmes and Miriam Shelef, University of Wisconsin, Madison, WI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPAs) are a hallmark of rheumatoid arthritis, but the sources of citrullinated antigens as well as which peptidylarginine deiminases (PADs) are required for their production remain incompletely defined. Neutrophil extracellular traps (NETs) appear to be a source of citrullinated antigens bound by ACPAs, but they may not be the only source. Macrophages also generate extracellular traps (METs), but their role in rheumatoid arthritis is still emerging. The purpose of this study was to determine if METs could be a source of citrullinated proteins bound by ACPAs, and if their formation requires PAD2 or PAD4.

Methods: Thioglycolate-elicited peritoneal macrophages were isolated from wildtype, PAD2$^{-/-}$, and PAD4$^{-/-}$ mice and were left untreated or were treated with ionomycin, monosodium urate (MSU) crystals, platelet activation factor, tumor necrosis factor alpha, lipopolysaccharide, phorbol myristate acetate, or heat killed *Candida albicans*. Macrophages were fixed and incubated with DAPI and either anti-citrullinated histone H4 antibody or sera from five ACPA+ or ACPA- rheumatoid arthritis subjects. Five predetermined areas of each coverslip were visualized by immunofluorescence at 400x, and METs (decondensed structures determined to be extracellular by DNase degradation studies) were counted by eye in a blinded manner. The percentage of macrophages that were METs, citrullinated METs, and ACPA-bound METs were compared between wildtype and PAD-deficient macrophages by paired t-test with $p< 0.05$ considered significant.

Results: Ionomycin and MSU crystals reliably induced METs with citrullinated histones. In the absence of PAD2 or PAD4, citrullinated METs were reduced, with a complete absence of citrullinated METs in PAD4-deficient macrophages. Also, IgG from ACPA+, but not ACPA- sera, bound METs. Finally, in the absence of PAD2 or PAD4, ACPA-bound METs were lost.

Conclusion: In response to ionomycin and MSU, macrophages generate citrullinated extracellular traps in a PAD4- and PAD2-dependent manner.Furthermore, ACPA+ sera can bind METs, suggesting that METs may contribute to the generation of citrullinated antigens targeted by ACPAs in rheumatoid arthritis in a PAD2- and PAD4-dependent manner.

Fatty Acid Synthase Is a Critical Repressor of Ferroptosis in Rheumatoid Arthritis

Qi Cheng, Mo chen, Xin chen, Yifan Xie, Yan Du and Huaxiang wu, The Second Affiliated Hospital Of Zhejiang University School Of Medicine, Hangzhou, China

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease with synovial inflammation as the main pathological feature, and can eventually lead to irreversible joint or organ damage. Recently, several studies have reported that ferroptosis was involved in the pathogenesis of RA. However, the role of ferroptosis in abnormal activation of RA synovial fibroblasts (RASFs) is poorly understood. The purpose of our study was to explore the effect of fatty acid synthase (FASN) on ferroptosis in RASFs.

Methods: FASN expression was assessed by quantitative polymerase chain reaction (qPCR), western blotting and immunohistochemistry in synovial tissues and SFs from RA patients, osteoarthritis (OA) patients and collagen induced arthritis (CIA) mice. SF activation was evaluated by qPCR, CCK-8 and wound healing assay. Lipid peroxidation was detected by MDA levels and C11-BODIPY 581/591 fluorescence intensity. and transient small interfering RNA knockdown were performed to examine expression of SLC7A11 and signaling pathway protein.

Results: FASN was found to be significantly higher expressed in synovial tissue and SF from RA patients and CIA mice (Figure 1). Silencing of FASN by siRNA in RASFs reduced expression of FASN, SLC7A11, inflammatory cytokines (IL-1β, TNF-α and SDF-1), level of lipid and cell viability, and enhanced the expression of PTGS2 and level of lipid peroxidation,

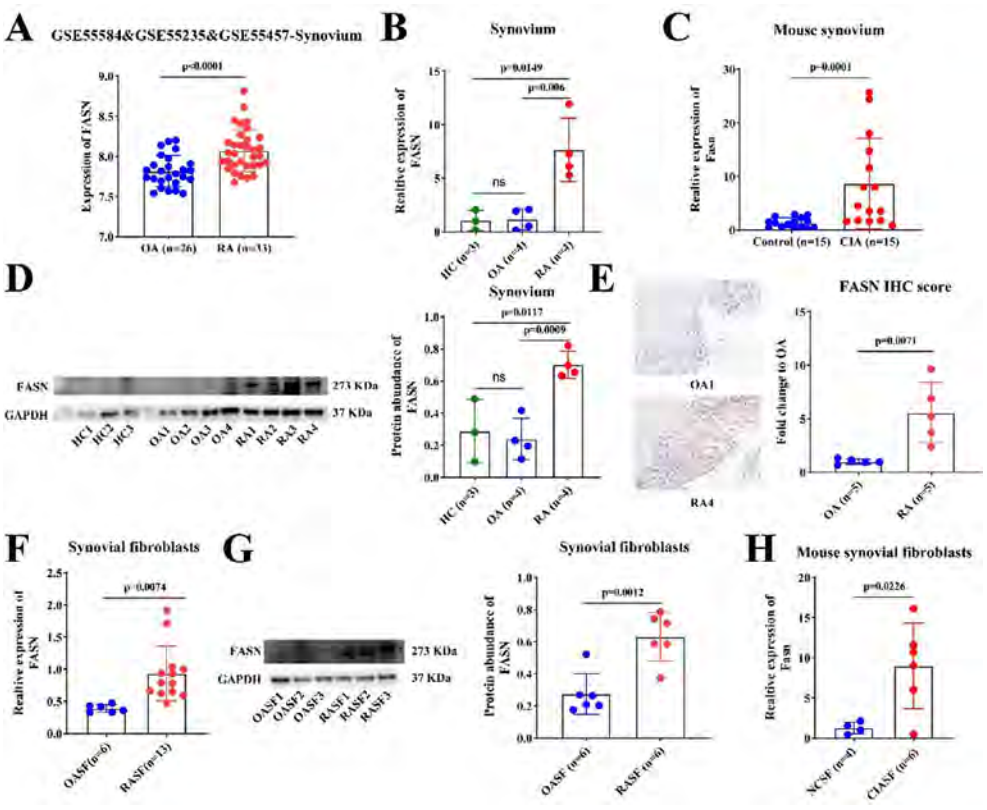

Figure 1 Expression of FASN in synovial tissues and synovial fibroblasts extracted from RA patients and CIA model mice. A. Expression of FASN in 33 RA and 26 OA synovial tissues from GSE55584&GSE55325&GSE55457 dataset. B-C. Expression of FASN in synovial tissues extracted from RA patients (B) and CIA model mice (C). D. FASN was detected by western blot in synovial tissues from 3 HC, 4 OA and 4 RA patients. E. FASN was detected by immunohistochemistry in synovial tissues from 5 OA and 5 RA patients. F-G, FASN was detected by PCR (F) and western blot (G) in SFs. H. Fasn was detected by PCR in mouse SFs. Values of $P < 0.05$ were considered significant. SFs, synovial fibroblasts. RA, rheumatoid arthritis; OA, osteoarthritis; SFs, synovial fibroblasts.

but not affected the expression of other ferroptosis (SLC40A1, FSP1 and GPX4) and lipid (ACACA, ACLY and CD36) genes (Figure 2A-2J). Moreover, treatment with the ferroptosis inhibitor, Ferrostatin-1 (Fer-1) could reverse the effect of FASN knockdown on lipid synthesis, cell viability and ferroptosis in RASFs (Figure 2E-2J). Mechanistically, FASN may promote inflammatory cytokines expression by TLR4/MYD88/NF-κ B signaling pathway, and enhance SLC7A11 expression by phosphorylating the STAT3 signal to suppress ferroptosis of RASFs (Figure 2K).

Conclusion: Our study found that FASN was a ferroptosis suppressor in RASFs. Silencing of FASN inhibited the abnormal activation of RASFs by suppressing STAT3/SLC7A11 axis and the TLR4/MYD88/NF-κB signaling pathway. Target FASN and ferroptosis may serve as a promising novel therapeutic strategy for RA.

Session Title: RA – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Fibroblast-like synoviocytes (FLS) contribute to the pathogenesis of rheumatoid arthritis (RA), especially cartilage damage and cytokine production. These cells display an aggressive phenotype in RA. Activation of the transcription factor NF-κB, which is mediated by proteasome degradation of its inhibitor IκB, is a hallmark of RA. We evaluated gene expression and the epigenetic marks of genes involved with ubiquitination in RA FLS. This process is, in part, regulated by neddylation, which conjugates NEDD8 to the cullin (CUL)-ring E3 ubiquitin ligases (CRLs). We hypothesized that dysregulated neddylation in RA FLS contributes to the RA FLS behavior.

Methods: RA or osteoarthritis (OA) FLS lines were obtained from synovial tissues at arthroplasty and used at passage 4-8. Analysis of ubiquitination pathway epigenetic marks in RA and OA FLS was performed using public ChIPseq data. RT-qPCR and Western blot analysis were used to assess gene and protein expression, respectively. NUB1 was overexpressed using an expression vector encoding *NUB1* isoform 2 with a CMV promoter. NF-κB activation was assessed *in vitro* by stimulating FLS with IL-1β (IκBα degradation, NF-κB (p65) translocation, NF-κBreporter assay and *IL6* gene expression). MLN4924 (a neddylation inhibitor) and bortezomib (a proteasome inhibitor) were used to evaluate the neddylation, NF-κB activation in RA FLS and its migration (wound healing assay). *In vivo* effect of MLN4924 was evaluated in the K/BxN serum transfer arthritis model.

Results: Epigenetic analysis identified an enhanced H3K27ac and H3K27me3 peaks in the promoter region of *NUB1,* a protein that inhibits neddylation, in OA FLS vs RA FLS, which indicates a poised region in the former. NUB1 was constitutively expressed by FLS and induction by IL-1β was greater in OA than RA FLS (6.6±0.5 fold and 3.4±0.8-fold increase for OA and RA, respectively; $p< 0.0001$). We then explored the neddylation pathway in FLS. The ratio of neddylated CUL1 (N8-CUL1) to non-neddylated CUL1 was lower in OA FLS than RA FLS in non-stimulated condition (0.30±0.04 and 0.40±0.09, respectively, $p=0.02$). NUB1 overexpression (NUB1 OE) decreased the neddylation ratio in non-stimulated RA FLS (56% decrease, $p=0.02$), decreased NF-κB nuclear translocation (30% inhibition, $p=0.04$), and IL-6 mRNA (58% inhibition, $p=0.0007$) in IL-1β stimulated RA FLS. MLN4924 decreased the neddylation ratio of CUL1 (55% inhibition, $p=0.03$), NF-κB nuclear translocation (65% inhibition, $p=0.04$) and IL-6 mRNA (99 % inhibition, $p=0.002$) in IL-1β stimulated RA FLS. Administration of MLN4924 (20 mg/kg) decreased the arthritis scores in K/BxN serum-transfer arthritis by 34% compared to vehicle alone ($p\leq0.0002$).

Conclusion: We identified differential regulation of a novel gene, NUB1, in RA FLS after cytokine stimulation. Resultant abnormalities in ubiquitination, NF-κB activation, and cytokine expression in RA FLS suggest that neddylation system contributes to the pathogenesis of RA and regulation of neddylation could be a novel therapeutic approach.

Session Title: RA – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: A hallmark of rheumatoid arthritis (RA) is the presence of anti-citrullinated protein antibodies (ACPA) targeting neoantigens which are generated by a family of enzymes called protein-arginine deiminases (PAD). Among the five members of the PAD family (PAD1, PAD2, PAD3, PAD4 and PAD6), PAD4 has been reported to play a key role in RA pathogenesis. Besides ACPA, about 25-35% of RA patients express anti-PAD4 IgG of which about 20-40% cross-react between PAD3/PAD4 and have the potential to enhance PAD4 activity leading to more erosive disease. Although several studies have been published on cross-sectional RA cohorts and controls, limited data is available from controlled clinical trials. Consequently, the aim of this study was to evaluate the prevalence of anti-PAD2, anti-PAD3 and anti-PAD4 IgG and IgA in a cohort of established RA patients, and the impact of treatment on antibody (Ab) levels, in the adalimumab vs. abatacept head-to-head active RA AMPLE study (NCT00929864).

Methods: Sera from RA patients enrolled in the AMPLE trial [at baseline (n=498), and 1 year after treatment initiation (n=218)] and from age- and sex-matched healthy controls (n=129) were tested for ACPA IgG (ImmunoscanCCPlus, Svar, Malmö, Sweden), anti-PAD2, anti-PAD3 and anti-PAD4 IgG/IgA by a novel particle-based multi-analyte technology [PMAT, research use only (RUO), Werfen, San Diego, US]. The manufacturer cut-off was used for ACPA, and preliminary cut-offs determined with internal disease and healthy controls were used for the anti-PAD Abs. Joint erosion (JE) data as measured by van der Heijde modified Total Sharp Score were compared with the Ab levels by Spearman's correlation. Anti-PAD4 IgG results were normalized to total IgG levels for analysis of changes with treatment by t-test.

Results: Profiling of Abs to PAD2, PAD3 and PAD4 using the preliminary cut-offs identified both IgG and IgA in RA patients (Table 1). Except for anti-PAD2 and anti-PAD3 IgA, all other PAD autoantibodies were more prevalent in RA patients vs. the matched controls. At baseline, the highest prevalence of Abs was found for PAD4 IgA followed by PAD4 IgG, PAD2 IgG, PAD3 IgA, PAD3 IgG and PAD2 IgA. Twenty nine percent (145/498) of RA patients were anti-PAD4 IgG+ *vs*. 2/129 (1.6%) of controls ($p < 0.0001$). The presence of anti-PAD4 IgG was significantly higher in ACPA+ RA patients [139/387 (35.9%)] compared to the ACPA- group [6/117 (5.1%)] ($p < 0.001$, Fisher exact test). A weak correlation was observed when comparing anti-PAD4 IgG titers with JE and disease duration ($\rho = 0.13$ and 0.18, $p=0.0045$ and 5.1×10^{-5}, respectively). Positivity for anti-PAD2, anti-PAD3 or anti-PAD4 IgG or IgA did not predict response to either adalimumab or abatacept. Anti-PAD4 IgG levels were generally stable at 1 year of both treatments, with a slight observed reduction in the adalimumab group when normalized to total IgG.

Table 1. Frequency of anti-PAD IgG/IgA antibodies on the RA AMPLE trial cohort and healthy controls. * Fisher exact test, A p-value of <0.05 is considered significant; n.s.: not significant

Antibody	Number (%) positive in RA patients at baseline (n=498)	Number (%) positive in RA patients at 1 year follow-up (n=218)	Number (%) positive in controls (n=129)	RA baseline vs. controls *p* values *
PAD2 IgG	75 (15.1)	20 (9.2)	2 (1.6)	p<0.0001
PAD2 IgA	29 (5.8)	15 (6.9)	4 (3.1)	n.s.
PAD3 IgG	35 (7.0)	12 (5.5)	0 (0.0)	p=0.0004
PAD3 IgA	40 (8.0)	14 (6.4)	9 (7.0)	n.s.
PAD4 IgG	145 (29.1)	52 (23.9)	2 (1.6)	p<0.0001
PAD4 IgA	154 (30.9)	63 (28.9)	9 (7.0)	p<0.0001

Conclusion: In the head-to-head adalimumab vs abatacept trial, anti-PAD4 IgG were weakly associated with JE and longer disease duration in active RA patients, which is consistent with previous reports. Anti-PAD IgG or IgA status did not predict response to treatment, and treatments had little to no impact on titers after 1 year.

Fibroblast Expression of Neurotransmitter Receptor HTR2A Associates with Inflammation in Rheumatoid Arthritis Joint

Chunyan Xiang[1], Soomin Hong[1], Bingjiao Zhao[2], Hui Pi[3], Fang Du[4], Xingyu Lu[5], Yuanjia Tang[1], Nan Shen[6], Chunxi Yang[7] and Runci Wang[8], [1]Shanghai Institute of Rheumatology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University (SJTUSM), Shanghai, China, [2]Department of Orthodontics, Shanghai Stomatological Hospital & School of Stomatology, Fudan University, Shanghai, China, [3]Jiangxi Provincial People's Hospital, The First Affiliated Hospital of Nanchang Medical College, Nanchang, China, [4]Department of Rheumatology, Renji Hospital, School of Medicine, Shanghai Jiao Tong University (SJTUSM), Shanghai, China, [5]Department of Endocrinology, Xinhua Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China, [6]Shanghai Jiao Tong University School of Medicine, Shanghai, China, [7]Department of Orthopedics, Renji Hospital, School of Medicine, Shanghai Jiao Tong University (SJTUSM), Shanghai, China, [8]Renji hospital, Shanghai Jiaotong University, Pudong Xinqu, China

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Peripheral neuroimmune crosstalk plays a crucial role in the inflammatory process and bone metabolism in joint. Serotonin receptor HTR2A was reported to be expressed on immune cells, of which gene polymorphisms are associated with an increased risk of developing RA and other autoimmune disease. However, the expression and regulation of HTR2A in arthritis synovium remain poorly understood.

Methods: Differential expression of neurotransmitter receptors (NTRs) and their correlated inflammatory molecules was identified in RA and OA synovium from public scRNA-seq dataset[1]. IHC staining of synovial tissue from RA and OA patients was performed for validation. Expression of miRNAs potentially targeting HTR2A carried by synovial fluid extracellular vesicles (EVs) was screened in low- and high-grade inflammation RA from public dataset[2] and validated by qPCR.

Results: HTR2A was expressed by 34.3% and 42.1% of fibroblasts in OA and RA synovium, while barely expressed by synovial leukocytes. Higher level of IL-6, IFN-γ, IFN stimulated genes, chemokines including CCL2, CCL8, CCL13, CXCL9, and CXCL12, and MMPs and VEGFB were observed on all cell types in RA joint, indicating a highly inflammatory microenvironment in RA. (Fig.1).

Correlation analysis showed positive correlation of HTR2A with IL6, CCL5, CXCL12, TNFSF11 and VEGFC expression in fibroblast specifically as well as in all synovial cells. The strongest correlation was found between HTR2A and CXCL12 (R=0.45). Transcriptomic findings above were confirmed on the protein level with IHC staining of RA and OA synovial tissue

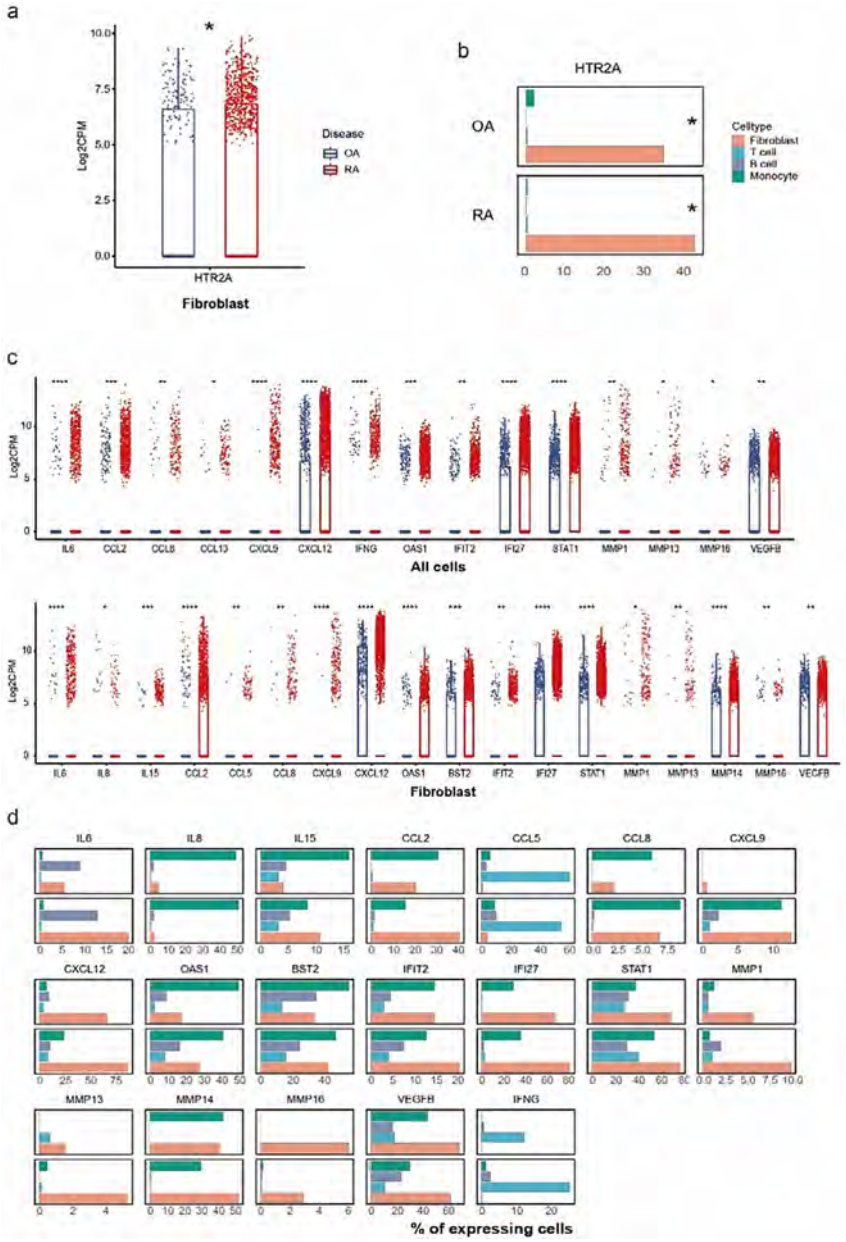

Figure 1. HTR2A and effectors expression pattern in joint synovial tissue of RA and OA patients. (a) Expression level and (b) positive percentage of HTR2A in RA and OA synovial fibroblast, (c) expression level and (d) positive percentage of inflammatory molecules in RA and OA synovium. Statistical test by Mann–Whitney U test in (a) and (c), *p < 0.05, **p < 0.01, ***p < 0.001, ****p < 0.0001. Statistical test by Chi-square or Fisher's exact test in (b) and (d), *p < 0.05.

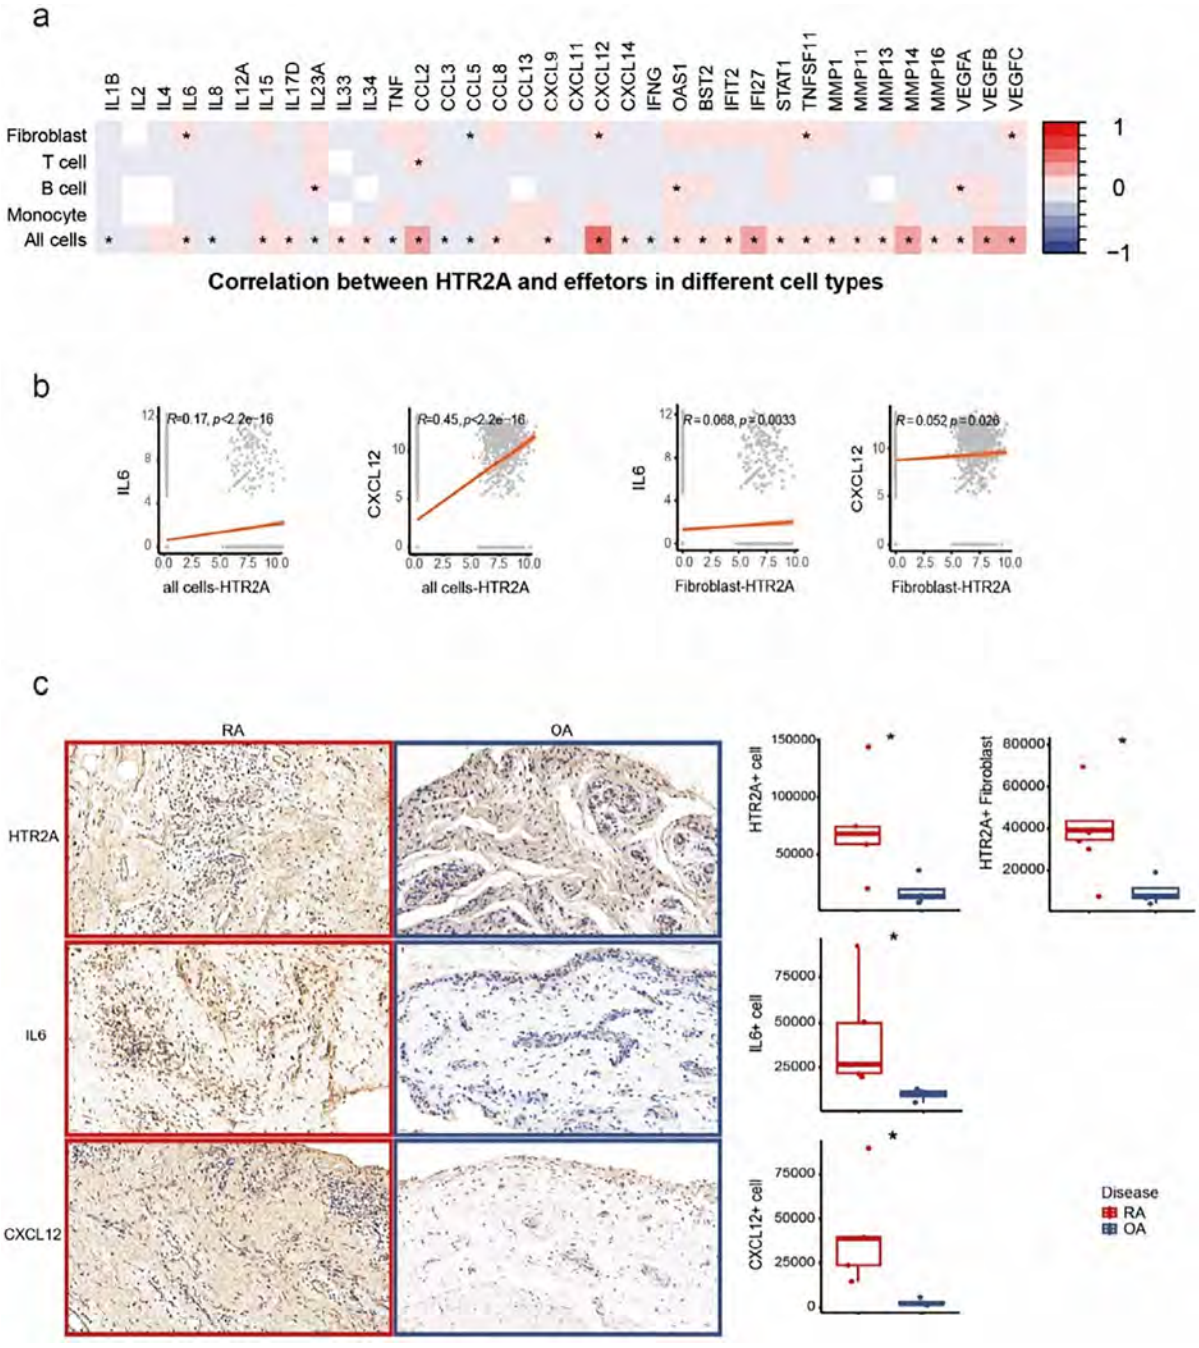

Figure 2. Inflammatory correlation and miRNA regulation of HTR2A in arthritis joints. (a) Heatmap showing correlation between HTR2A and inflammatory molecules using Pearson correlation. (b) Significant correlation plot between HTR2A and representative inflammatory molecules in fibroblast or all synovial cells. (c) 40x field view and quantification of immunohistochemical staining of HTR2A, IL6 and CXCL12 in synovial tissue of RA (n=5) and OA (n=4) patients, p values were calculated by Mann–Whitney U test, *p < 0.05, **p < 0.01, ***p < 0.001, ****p < 0.0001.

from patients. There was significantly upregulated expression of HTR2A on RA whole synovial tissue level and fibroblast level. Increased expression of IL-6 and CXCL12 was also found in RA synovial tissue (Fig.2).

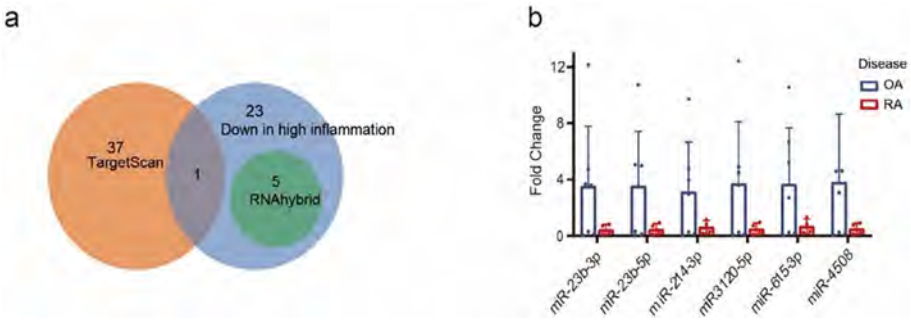

Figure 3. miRNAs targeting HTR2A carried by synovial fluid EVs. (a) Venn diagram of miRNAs targeting HTR2A. miRNAs predicted by TargetScan (orange) and RNAhybrid (green) databases, and miRNAs lowly expressed in high-inflammation RA synovial fluid EVs (blue). (b) miRNAs were extracted from OA(n=7) and RA(n=4) synovial fluid EVs, and the expression of 6 miRNAs targeting for HTR2A were validated by qPCR. p values were calculated by t-test. *p < 0.05, **p < 0.01, ***p < 0.001.

To investigate what could regulate the different HTR2A expression in RA and OA, we examined the content of EVs derived from RA and OA synovial fluid. Integrated with public RNAseq data, TargetScan and RNAhybrid prediction, 6 miRNAs predicted to regulate HTR2A expression, miRNA-23b-3p, miR-23b-5p, miR-214-3p, miR-3120-5P, miR-615-3p, and miR-4508, were significantly lower in RA EVs. A trend of lower expression of these 6 miRNAs was demonstrated by qPCR (Fig.3).

Conclusion: A neurotransmitter receptor of serotonin, HTR2A, was enriched in rheumatoid arthritis (RA) synovial fibroblast and positively correlated with inflammation. 6 miRNAs targeting HTR2A were decreased in RA synovial fluid EVs comparing to osteoarthritis. HTR2A may contribute to inflammation and RA pathogenesis, and miRNAs targeting HTR2A might offer new therapeutic strategies to alleviate inflammation in RA.

Acylcarnitine Enrichment Is a Characteristic of Rheumatoid Arthritis Fibroblast-Like Synoviocyte Metabolic Fingerprint

Georgios Vasileiadis[1], Anna-Karin Hultgård Ekwall[2], Reshmi Sureshkumar[1], Monica Guma[3], Anna Rudin[4], Yuan Zhang[1] and Cristina Maglio[1], [1]Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [2]Department of Rheumatology and Inflammation research, Sahlgrenska Academy, University of Gothenburg, Kullavik, Sweden, [3]San Diego VA Healthcare Service, La Jolla, CA, [4]Department of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Several metabolic pathways have been implicated in rheumatoid arthritis fibroblast-like synoviocytes (RA FLS) aggressive phenotype[1,2]. Here, we aimed to analyse the full spectrum of metabolic alterations associated with RA by performing untargeted metabolomics using mass spectrometry in RA FLS vs. non-inflamed (NI) FLS.

Methods: Ten RA FLS were obtained from synovial tissue specimens from patients with RA undergoing joint replacement surgery. Seven NI FLS were obtained from patients with no previous history of arthritis, undergoing diagnostic arthroscopy due to previous injury that occurred over 2 months prior to the operation. We collected primary RA and NI FLS culture extracts and untargeted annotated metabolomics were performed using liquid chromatography coupled to quadrupole time-of-flight mass spectrometry (Figure 1A).

Results: Peak intensities of 138 annotated metabolites were acquired. Metabolomics analysis revealed a distinct metabolic fingerprint between RA and NI FLS as illustrated by hierarchical clustering shown as heatmap, and partial least squares - discriminant analysis (Figure 1B, C). A volcano plot combining fold change analysis and Mann-Whitney test revealed

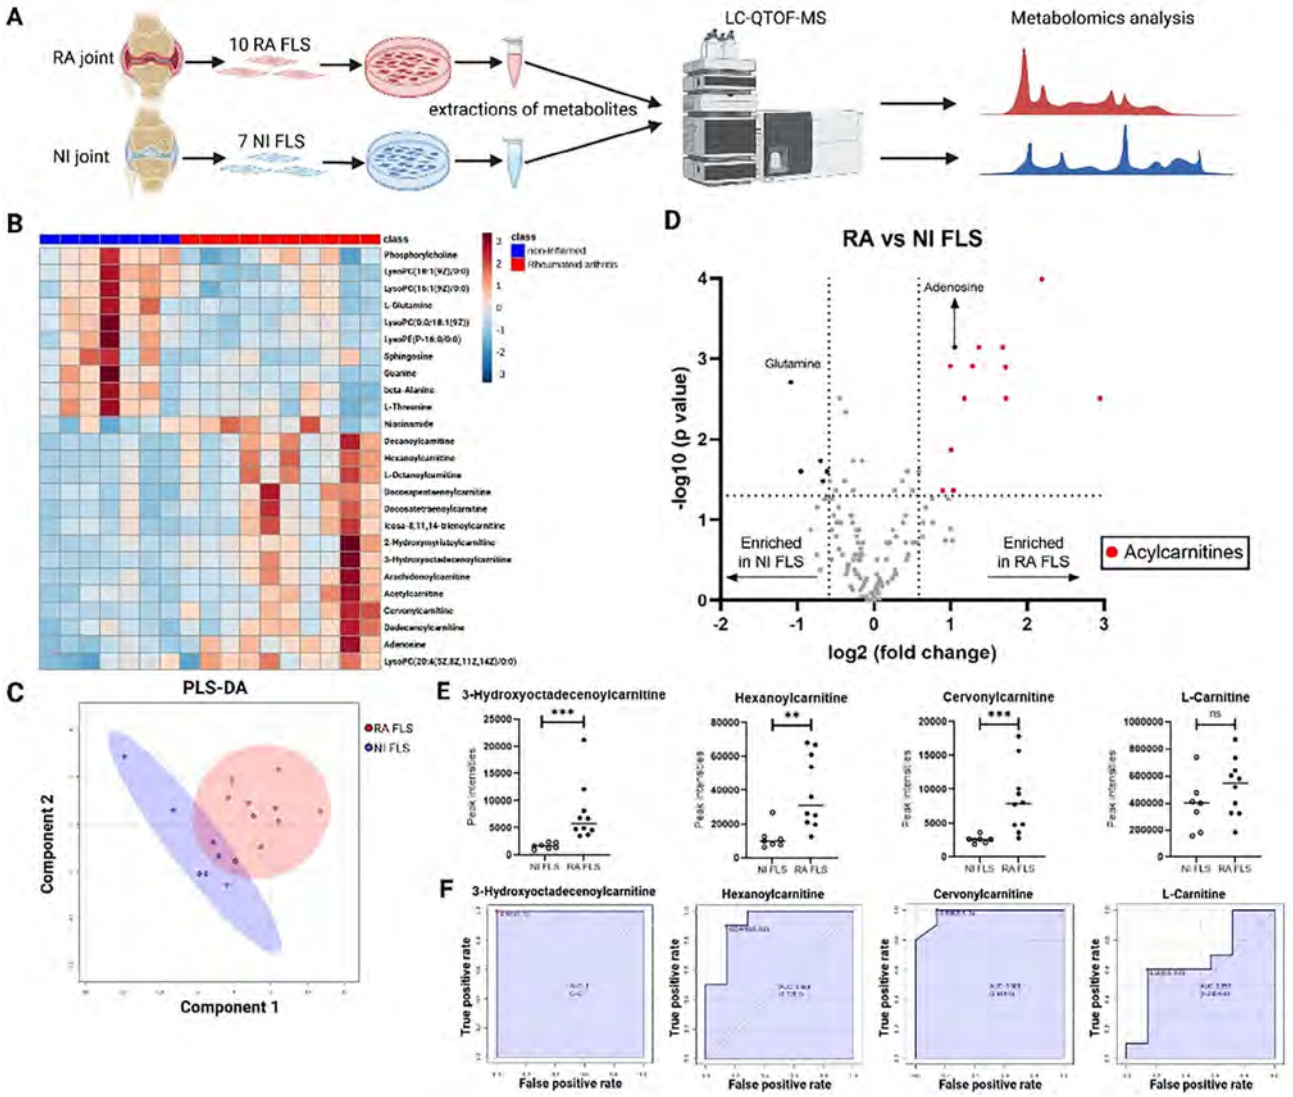

Figure 1: FLS metabolomics analysis. A. Experimental set up overview. B. Clustering result shown as heatmap. Distance measure using Euclidean distance, and clustering algorithm using Ward's linkage. Samples are shown on the x axis, while metabolites are shown on the y axis. C. Partial least squares - discriminant analysis showing the 2-D scores plot between principal component 1 and 2. Each dot represents a sample. The cycles show the 95% confidence interval. D. Enriched metabolites by volcano plot defined as fold change (x) ≥1.5 and Mann-Whitney test p-value (y) <0.05. The red dots represent acylcarnitines. E. Dot plots of the peak intensities of three selected acylcarnitines and L-carnitine in NI RA FLS. Mann-Whitney test was performed. $p<0.05$ was signified with *, $p<0.01$ with **, and $p<0.001$ with ***. F. ROC curves of three selected acylcarnitines and L-carnitine. Sensitivity is on the y-axis, and the specificity on the x-axis. Abbreviations: RA, rheumatoid arthritis; NI, non-inflamed; FLS, fibroblast-like synoviocytes; LC-QTOF-MS, liquid chromatography coupled to quadrupole time-of-flight mass spectrometry; PLS-DA, partial least squares - discriminant analysis; AUC, area-under-the-curve.

18 metabolites having different levels in RA and NI FLS; 13 were enriched in RA FLS, while five were enriched in NI FLS (Figure 1D). Of the 13 metabolites enriched in RA FLS, 12 were acylcarnitines (Figure 1E, F).

Conclusion: RA FLS show an accumulation of acylcarnitines compared to NI FLS, which suggests an involvement of lipid metabolism in RA pathophysiology. Further studies are needed to understand this phenomenon and to determine if acylcarnitine accumulation in FLS contributes to FLS dysfunction in RA.

Novel and Unique Rheumatoid Factors Cross-React with Viral Epitopes in COVID-19

Maya Amjadi[1], Maxwell Parker[2], Zihao Zheng[1], **Alex Robbins**[1], Michael Denny[1], Sara McCoy[3], Irene Ong[1] and Miriam Shelef[1], [1]University of Wisconsin, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, [3]University of Wisconsin School of Medicine and Public Health, Middleton, WI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid factors (RFs), polyreactive antibodies canonically known to bind two conformational epitopes of IgG, are a hallmark of rheumatoid arthritis but also can arise in other inflammatory conditions and infections. In turn, infections, such as respiratory infections, correlate with rheumatoid arthritis development, but the mechanisms are unclear. Recently, RF reactivity in rheumatoid arthritis, and not in other autoimmune diseases, was found to include citrullinated and homocitrullinated IgG epitopes as well as thousands of citrullinated and homocitrullinated antigens targeted by anti-citrullinated protein antibodies. Specific epitopes recognized by infection-induced RFs remain undefined. The purpose of this study was to evaluate the reactivity of RFs induced in a primary immune response in adults to better understand how a viral infection might lead to loss of immune tolerance and rheumatoid arthritis.

Methods: Clinical data and sera were obtained from adults five weeks post-COVID-19 (positive SARS-CoV-2 test in the spring of 2020) or the following subjects with no past COVID-19: rheumatoid arthritis, Sjögren's disease, lupus, smokers, and age- and sex-matched controls. Sera were used in a high density peptide array to evaluate IgA, IgM, and IgG binding to all possible 16 amino acid peptides derived from human IgG1-4 and the proteomes and proteins of several viruses including SARS-CoV-2 with results confirmed by ELISA. Antibodies were purified to evaluate cross-reactivity by ELISA. Data were analyzed by Kruskal-Wallis with Dunn's multiple comparisons tests, Mann-Whitney test, Wilcoxon matched-pairs signed rank test, and MixTwice.

Results: We identified three novel IgG epitopes (IgG1-131, IgG1-238, IgG1-293) bound by antibodies in COVID-19 but not rheumatoid arthritis, Sjögren's disease, lupus, smokers, or controls. In contrast, a hinge peptide, IgG1-104, was recognized by rheumatoid arthritis and Sjögren's disease antibodies. A polyreactive IgM-RF bound IgG1-131, IgG1-238, and many viral peptides with a tripeptide motif, as well as IgG Fc and SARS-CoV-2 spike proteins. In contrast, a previously identified rheumatoid arthritis-specific RF that binds homocitrullinated IgG1-219 recognized IgG Fc, but not motif-containing peptides or spike.

Conclusion: RFs are not a single entity in multiple diseases, but rather have disease-specific IgG reactivity and unique polyreactivities that reflect the broader immune response. Moreover, virus-induced, motif-driven polyreactivity, as opposed to molecular mimicry among a small number of antigens, can drive autoreactivity against IgG. These findings provide new insights into how viral infection may trigger immune tolerance loss with potential implications for rheumatoid arthritis and millions of people post-COVID-19.

Unique Pattern of Cadherin 6 Localization in Fibroblast-Like Synoviocytes

Camilla R. L. Machado[1], David Boyle[1], Narayanan B. Perumal[2], Robert J. Benschop[3] and Gary Firestein[1], [1]University of California San Diego, San Diego, CA, [2]Eli Lilly and Company, San Diego, CA, [3]Eli Lilly and Company, Indianapolis, IN

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The synovial lining of rheumatoid arthritis (RA) is formed by a network of fibroblast-like synoviocytes (FLS). Cadherins are type I transmembrane proteins and participate in FLS cell-to-cell contacts, particularly cadherin 11. Unbiased profiling of cadherin expression in FLS using epigenetic data identified cadherin 6 (CDH6) as a gene of interest in RA FLS. CDH6, which is a type II cadherin, has mainly been studied in oncology where high expression is associated with cancer progression and invasion. CDH6 in FLS could regulate similar functions in RA. To understand the diverse functions of CDH6 in FLS, we analyzed its cellular distribution in synovial tissue.

Methods: RA and osteoarthritis (OA) synovial tissue (n=6 each) were obtained at arthroplasty. RA FLS and OA FLS lines (n=6 each) were derived from enzymatically dispersed synovial tissue and used from passages 5-7. Western blot analysis was used for protein quantification with anti-CDH6 antibody and was normalized to GAPDH. The distribution of CDH6 in FLS and synovial tissue was evaluated by immunofluorescence and confocal microscopy.

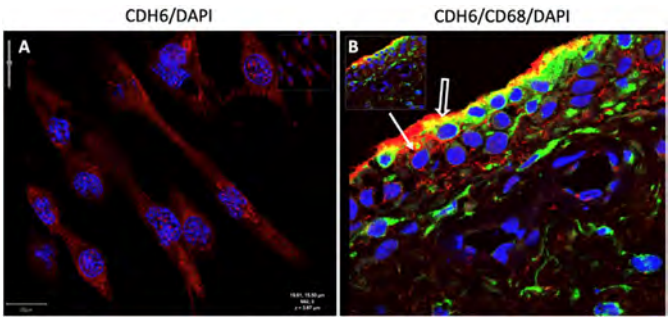

Figure 1. CDH6 expression in RA FLS and RA synovium. We performed confocal microscopy to determine if CDH6 is present in the synovial lining and its distribution in RA FLS. A) Representative image of RA FLS with anti-CDH6 (red) and DAPI (blue). CDH6 is found in the cytoplasm, perinuclear regions, nucleus, and the cell membrane. B) Representative image of RA synovium with anti-CDH6 (red) and -CD68 (green) (macrophage) antibodies show lining and sublining expression of CDH6, most likely in FLS (solid white arrow) and lining macrophages (open white arrow).

Results: Initial immunofluorescence studies of RA synovial tissue revealed abundant CDH6 in the intimal lining. Using anti-CD68 and anti-CDH6 antibodies in double stained tissues, we observed CDH6 expression in lining macrophages and fibroblasts. CDH6 was also expressed to a lesser degree in the sublining, particularly in the perivascular regions and included macrophages and non-macrophages (Figure 1). A similar distribution of CDH6 protein was observed in OA synovium and suggests that CDH6 is an important component in the synovial architecture. Because FLS reside in the intimal lining and were strongly CDH6 positive, we explored the expression and distribution of CDH6 in cultured FLS. Western blots showed that expression is higher in RA than OA FLS (1.2±0.01 vs 0.1±0.01 OD, p=0.03; n=4 each). Using immunostaining, expression was higher in FLS cultured at higher cell density and was ~2-fold higher in confluent vs. non-confluent cultures. Thus, CDH6 might be regulated, in part, by cell-cell contact. More intriguing, confocal microscopy showed significant expression of CDH6 protein in the cytoplasm, peri-nuclear regions, and nucleus in addition to the cell membrane.

Conclusion: CDH6 is expressed in synovial lining and sublining fibroblasts and macrophages. The striking intracellular distribution suggests additional functions beyond adhesion and homotypic aggregation, such as signalling and regulation of gene transcription. Thus, CDH6 has similarities to E-Cadherin, which also localizes to intracellular structures and participates in biologic functions. Our data suggest for the first time that CDH6 might have multiple functions in FLS that contribute to its pathogenic behaviour.

Circulating CD4+CD25+CD127-FoxP3+CD39+ T Cells Predict the Response to Methotrexate Across Basal Disease Activity Strata in Early Rheumatoid Arthritis

Maria-Eugenia Miranda-Carus[1], Beatriz Nieto-Carvalhal[1], Alejandro Villalba[2], Laura Nuño[1], Marta Benito-Miguel[3], Marta Novella-Navarro[4], Irene Monjo[5], Diana Peiteado[1], Sara García-Carazo[1] and Alejandro Balsa[4], [1]Hospital Universitario La Paz - IdiPAZ, Madrid, Spain, [2]Rheumatology Department, La Paz University Hospital, Madrid, Spain, [3]Universidad Nebrija, Physiology, Madrid, Spain, [4]Hospital Universitario La Paz, Madrid, Spain, [5]University Hospital La Paz, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A subset of human FoxP3+ regulatory T (Treg) cells expresses CD39 (Treg39+) and hydrolyses pro-inflammatory adenine nucleotides released at inflammatory foci, rendering the antiinflamatory adenosine. Methotrexate (MTX), inhibiting AICAR transformylase, enhances the extracellular release of adenine nucleotides and may cooperate with Treg39+ cells to control inflammation. Therefore we examined whether Treg cells may help predict the response to MTX independently of clinical parameters.

Methods: PBMCs from 82 ERA patients (duration < 24 weeks) and 82 healthy controls (HCs) were examined by cytometry to assess the frequency of CD4+CD25+CD127-FopxP3+ [total circulating Treg (cTreg)] and CD4+CD27+CD127-FoxP3+-CD39+ Treg [circulating Treg39+ (cTreg39+)]. PBMCs from 40 patients were reexamined 12 months (12m) after initiating

MTX. Disease activity was assessed by DAS28-ESR. High, moderate or low disease activity (HDA, MDA, LDA) were defined as a DAS28>5.1, >3.2 and ≤ 5.1, or DAS28 ≤ 3.2, respectively.

Results: As compared with HC, ERA patients showed an increased baseline (0 months, 0m) frequency (fr.) of cTreg with increased proportions of cTreg39+ cells. Patients who attained LDA 12m after initiating MTX had significantly higher 0m fr. of cTreg [logistic regression OR 7.18 (95% CI, 3.26-21.75); ROC AUC 0.93 (0.87-0.99), p< 0.0001] and cTreg39+ cells [OR 1.55 (1.29-2.10); AUC 0.97 (0.95-1.0), p< 0.0001], as compared with those who did not; multiple regression indicated that this was independent of age, 0m disease activity, RF or ACPA titres. The baseline cutoff fr. for 12m LDA was cTreg >7.8% [sensitivity (S) 0.82, specificity (Sp) 0.91%] and cTreg39+ > 42.0% (S 90.4, Sp 96.8%). We next analyzed separately patients who had presented with 0m-HDA (n=44), 0m-MDA (n=34) or 0m-LDA (n=4). The number of patients who attained 12m LDA was 23 (52%) in the 0m-HDA, 24 (71%) in the 0m-MDA and 4 (100%) in the 0m-LDA group. Interestingly, in either the 0m-HDA or the 0m-MDA group, the basal Treg and Treg39+ cell fr. significantly correlated with the ΔDAS28, and were good predictors of 12m-LDA [Treg OR for 0m-HDA = 2.60 (1.50-5.35), AUC 0.81 (0.68-0.94), p< 0.0005; Treg OR for 0m-MDA = 3.03 (1.55-8.50), AUC 0.88 (0.77-0.99), p< 0.0005; Treg39+ OR for 0m-HDA = 1.79 (1.27-3.90), AUC 0.97 (0.91-1.0), p< 0.0001; Treg39+ OR for 0m-MDA = 1.49 (1.18-2.31), AUC 0.95 (0.87-1.0), p< 0.0001]. After removing the seronegative patients from the 0m-HDA (n=9, 20%) or the 0m-MDA (n=6, 18%) groups, the relation of the basal Treg or Treg39+ cell fr. with the response to MTX did not vary. The small number of patients who presented with 0m-LDA (n=4) did not allow further analysis of this group. At 12m, patients demonstrated a significant reduction of cTreg and cTreg39+ with no variation observed in HC, and differences between HC and ERA were no longer apparent, likely reflecting the 0m upregulation of the genetically determined CD39 expression levels; of note, the 12m cTreg [OR 3.19 (1.68-8.0)] and cTreg39+ [OR 1.31 (1.13-1.80)] cell fr. remained associated with LDA.

Conclusion: The baseline cTreg39+ fr. in untreated ERA predicts the clinical response to MTX across baseline disease activity strata, and facilitates the development of precision medicine strategies.

Quantitative Assessment of Synovial Vascularity Using Power Doppler Index in Rheumatoid Arthritis and Psoriatic Arthritis Patients with High Disease Activity

Michał Jakubaszek, Maria Maślińska and Brygida Kwiatkowska, National Institute of Geriatrics Rheumatology and Rehabilitation, Warsaw, Poland

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Usefulness of quantitative assessment of synovial vascularity in ultrasound (US) imaging in patients with active RA and PsA (peripheral arthritis). Additionally the assessment of vascularity index (INDEX%) dependency on immunological markers such as rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) were assessed.The last aim of the study was to examine whether patients with high active peripheral PsA differ in the severity of synovial congestion from patients with high RA activity.

Methods: A total of n=80 patients were included into the study, n=60 with RA and n=20 PsA. Majority of them (for both group) were female (n=53.66.25%). Laboratory variables were assessed: RF (IU/ML units), ACPA (U/ML), ESR (mm/hour) and C-reactive protein (CRP;MG/L); disease activity were assessed by DAS 28(ESR) and simplified disease activity score (SDAI). The power doppler US (PDUS) was performed with assessment of a) the degree of the synovial membrane vascularization (from 0 to 4 grade); the following scores were used in the assessment: 0- no signs of synovial flow, 1- isolated signals in hypertrophied synovium, 2-vessels occupy less than 50% of hypertrophied membrane area synovitis, 3- inflammation affects over 50% of the examined area; b) vascularity index measured by PDUS index (INDEX%) in the ROI (region of interest) frame (figure 1). All patients underwent examination using the same US machine and by the same specialist in radiology and imaging diagnostics.

Results: Disease activity for RA and PsA patients was between 4.8- 8.3 with DAS28 and 23-183 with SDAI. The hypothesis of a positive correlation between the concentration of ACPA and INDEX% in RA group was confirmed however it was a week positivity(r=0.26) but such correlation between RF and INDEX% was not confirmed (r=0.03). ESR, CRP, DAS 28(ESR) and SDAI did not correlate significantly with the value of INDEX%. What was expected the strong positivity (r=0.56) was between SDAI and DAS28 results. Interestingly there was no correlation between DAS 28, SDAI and INDEX %, probably because all of patients from both groups had high disease activity.

Conclusion: Positive correlation between the concentration of ACPA and INDEX% value indicating that ACPA may be a prognostic factor for vascularization of the synovial membrane in patients with RA. No such correlation was confirmed for RF. Taken together obtained results pointed to ACPA as more important for synovial inflammatory activity in RA. Vascularity of synovial membrane assesed by INDEX %compared between RA and PsA group was equally high, despite the difference in RF and ACPA indicating that the presence of other cytokines is more involved in the development of synovial inflammation in PsA. The quantitative US assessment of synovial vascularity is a useful tool in comparative studies and may have a significant advantage over a qualitative study after expanding the study groups with different degrees of inflammatory activity in the synovium.

Synovial membrane with active inflammation (vascularization) and region of interest frame indicated.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with the presence of autoantibodies being the anti-citrullinated protein antibodies (ACPAs) the hallmark as they are present in almost 70% of patients with established RA. However, despite the high diagnostic value of ACPA, the sensitivity in early RA of the most common tests used in clinics is between 60-70% in newly diagnosed RA. Besides, ACPA-negative patients, who constitute up to one-third of patients with RA, entails a challenge for early diagnosis. The fact that not all RA patients are ACPA-positive means that there is a need for additional biomarkers including autoantibodies that may help to diagnose RA patients at an early stage.

Interestingly, ACPA-positive RA patients also display a different etiology and disease course compared to ACPA-negative patients. Therefore, an increased knowledge about the presence of other circulating autoantibodies related with early RA is needed to improve its diagnosis, specifically for ACPA-negative patients, and to better understand the pathogenic mechanisms underlying the different RA subsets.

Herein we aimed to search for plasma autoantibodies associated with ACPA status that could be useful to define clinical phenotypes in early RA.

Methods: The autoantibody repertoire of 80 ACPA-negative and 80 ACPA-positive early RA subjects from the Swedish population-based Epidemiological Investigation of RA (EIRA) cohort was screened using a targeted suspension bead array built on protein fragments earlier described as autoimmunity targets. Four autoantibodies were validated in another set of EIRA samples containing 317 ACPA-positive, 302 ACPA-negative and 372 age- and sex-matched controls. The relationship between the four autoantibodies and lung abnormalities on high-resolution computed tomography was also examined in 93 early RA patients. Association between the autoantibodies and clinical features was assessed by logistic regression analysis.

Results: IgG autoantibody levels towards anosmin-1 (ANOS-1) and towards muscle related coiled-coil protein (MURC) were significantly increased in ACPA-positive subjects compared to ACPA-negative and controls, and associated with ACPA status (OR=3.02; 95% CI 1.86 to 4.89; and OR=1.86; 95% CI 1.16 to 2.97, respectively). IgG autoantibody levels towards dual

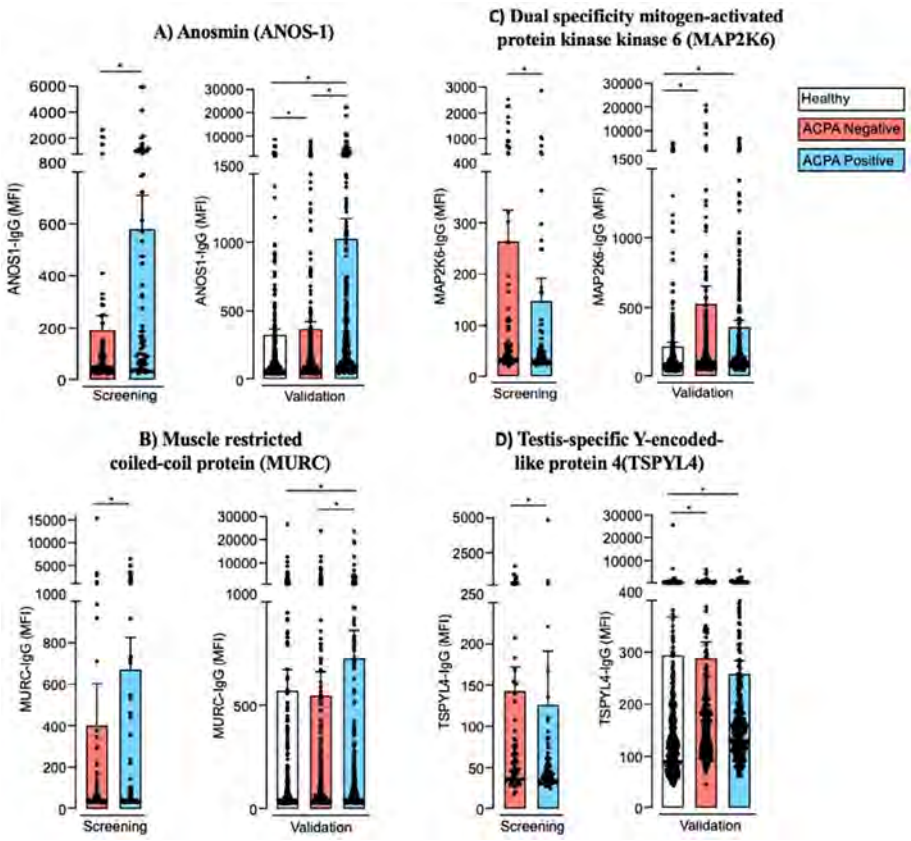

Figure 1. IgG immunoreactivity to Anosmin-1 (panel A), Muscle restricted coiled-coil protein (MURC) (panel B), Dual specificity mitogen-activated protein kinase kinase 6 (MAP2K6) (panel C) and Testis-specific Y-encoded-like protein 4 (TSPYL4) (panel D) in the screening sample set and in the validation sample set. Bar plots represent mean and standard deviation of the levels of autoantibodies measured in median fluorescence intensity (MFI).

specificity mitogen-activated protein kinase kinase 6 (MAP2K6), and testis-specific Y-encoded-like protein 4 (TSPYL4) were increased in the ACPA-negative subjects compared to ACPA-positive and controls. IgG anti-TSPYL4 was also significantly associated with ACPA-negative status (OR=0.41;95%CI 0.19 to 0.89). IgG anti-ANOS1 was associated with the smoking habit (OR=2.11;95% CI 1.22 to 3.67) and IgG anti-MURC with the presence of the shared-epitope (OR=1.95;95% CI 1.11 to 3.46). Regarding lung abnormalities, the presence of IgG anti-TSPYL4 was associated with a less prevalence of infiltrates (OR=0.11;95% CI 0.01 to 0.86), and IgG anti-MAP2K6 with less fibrosis (RR=0.85;95% CI 0.77 to 0.94).

Conclusion: Our data suggest that these four autoantibodies may be potentially useful to define clinical phenotypes of RA. Validation in other early RA sample cohorts is needed.

Runx1 Is a Key Transcription Factor That Drives Synovial Fibroblast Pathogenicity in Rheumatoid Arthritis

Christopher Mahony[1], Samuel Kemble[2], Paulynn Chin[1], Cesar Prada[3], Annie Hackland[1], Patricia Reis-Nisa[1], Lucy-Jayne Marsh[1], Peter Keane[1], Constanze Bonifer[1], Christopher Buckley[4], Stevephen Sansom[5], Mark Coles[4] and Adam Croft[1], [1]University of Birmingham, Birmingham, United Kingdom, [2]University Birmingham, Rugeley, United Kingdom, [3]The Kennedy Institute, Oxford, United Kingdom, [4]University of Oxford, Oxford, United Kingdom, [5]Kennedy Institute of Rheumatology, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Fibroblasts are key effector cells in rheumatoid arthritis (RA) underpinning joint inflammation and damage. Synovial tissue fibroblasts are heterogenous and acquire pathogenic cell states that either drive inflammation or tissue damage. However, the molecular mechanisms underpinning fibroblast heterogeneity and pathogenicity are poorly understood.

Methods: To identify key regulators of fibroblast behaviour, we performed combined scRNAseq and scATACseq analysis of synovial fibroblasts from the serum transfer induced arthritis model in mice and compared these data to additional scRNA-seq data from collagen induced arthritis and antigen induces arthritis models. Ongoing validation is being performed using multiplex imaging, spatial transcriptomics (10x Visium platform), conditionally inactivating *Runx1* in murine fibroblasts, lentiviral gain of function, pharmacologicalinhibition and ChIP-Seq.

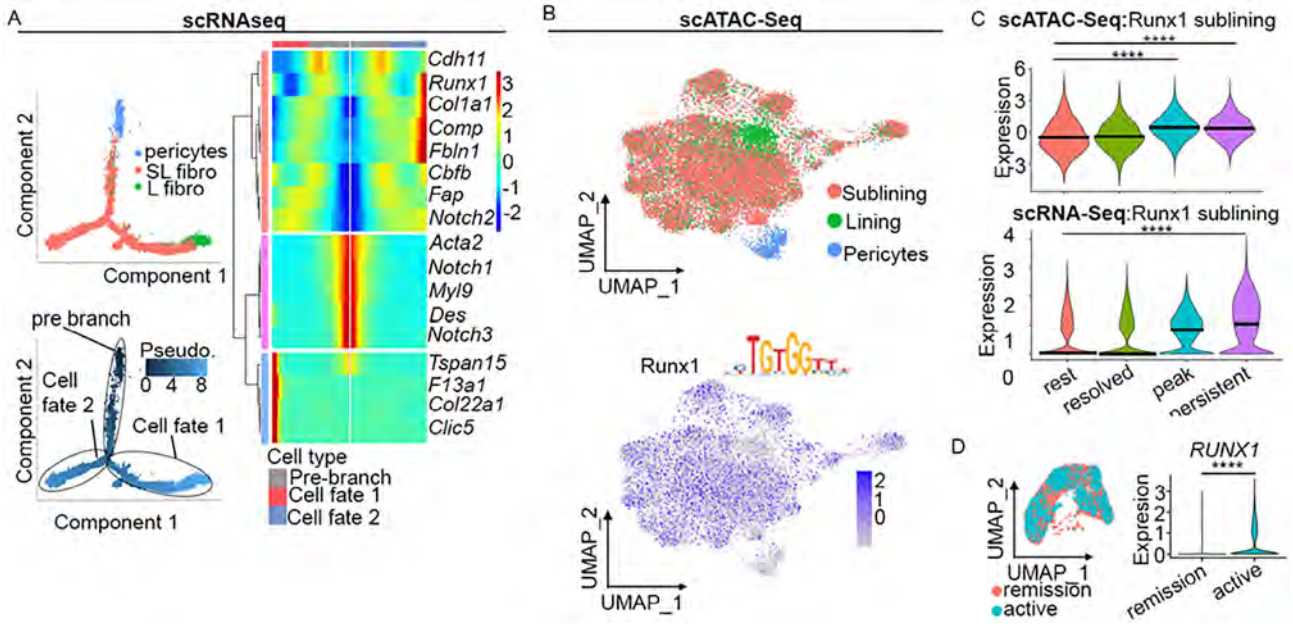

Figure 1. Runx1 expression is associated with sublining synovial fibroblast pathogenicity. (A) scRNAseq pseudotime trajectory of murine synovial fibroblasts (pericytes, sublining fibroblasts and lining layer fibroblasts). (B) scATACseq annotation and Runx1 motif activity in synovial fibroblasts. (C) scATACseq Runx1 motif activity and scRNAseq Runx1 expression across STIA (serum transfer induced arthritis) timepoints. (D) Runx1 expression in remission and active RA patients (Data from Alivernini et al., 2020).

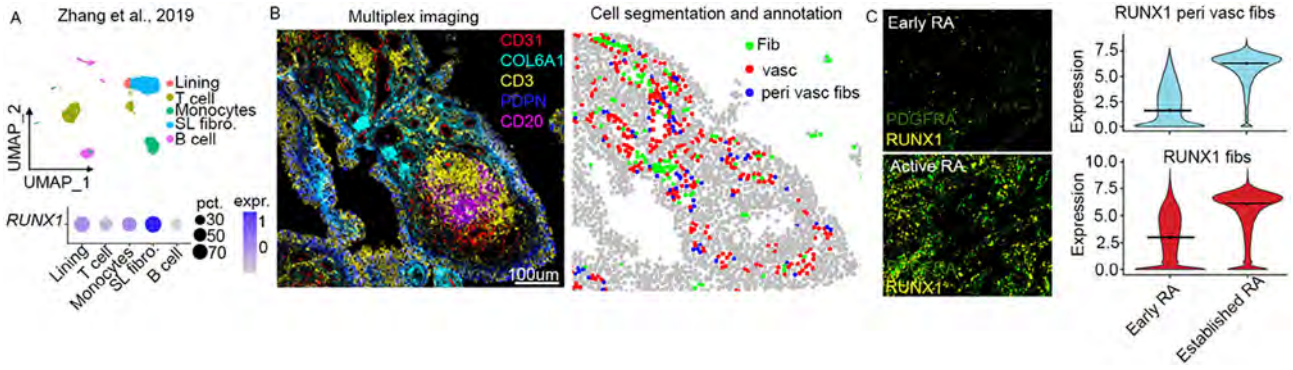

Figure 2. RUNX1 expression is associated with sublining synovial fibroblasts and is increased in active RA. (A) RUNX1 expression across synovial cells (Data from Zhang et al., 2019). SL fibro: sublining fibroblast. (B) Examples of multiplexed immunofluorescence images of synovial tissue and cellular segmentation to quantify fluorescence. Fib: fibroblasts; vasc: vasculature; peri vasc fibroblasts: perivascular fibroblasts. (C) Immunofluorescence staining and quantification of PDGFRA and RUNX1 expression on synovial tissue from early and established RA patients in perivascular and interstitial fibroblasts.

Results: We identified**Runt-related transcription factor 1**(*Runx1)* expression (scRNAseq) and motif activity (scATACseq) to be highly specific to sub-lining synovial fibroblasts which have been implicated in driving synovial inflammation (Fig. 1A, B). *Runx1* motif activity and gene expression were also found to be upregulated during joint inflammation in mice and in patients with RA and active joint inflammation, compared to those patients in clinical remission (Fig. 1C, D). Further analysis of publicly available data from RA synovium showed robust *RUNX1* expression in synovial fibroblasts (Fig. 2A). Multiplex imaging showed *RUNX1* to be enriched in perivascular fibroblasts compared to interstitial fibroblasts. Furthermore, *RUNX1* expression was increased in perivascular fibroblasts in active RA compared to early RA (Fig. 2B, C). We next confirmed that *RUNX1* expression in synovial fibroblasts is controlled by inflammatory stimuli using confocal imaging and analysis of publicly available Hi-C data. Examining publicly available ATAC-Seq data as well as coexpression analysis using spatial transcriptomics and scRNAseq data from murine models of arthritis highlighted several direct *RUNX1* target genes. We are now performing functional experiments to validate *RUNX1* targets to explore how *RUNX1* regulates fibroblast pathogenicity.

Conclusion: Our analysis identifies *RUNX1* as a novel regulator of disease associated, synovial fibroblast behaviour in inflammatory arthritis and a potential novel therapeutic target to modulate fibroblast-driven pathology in RA.

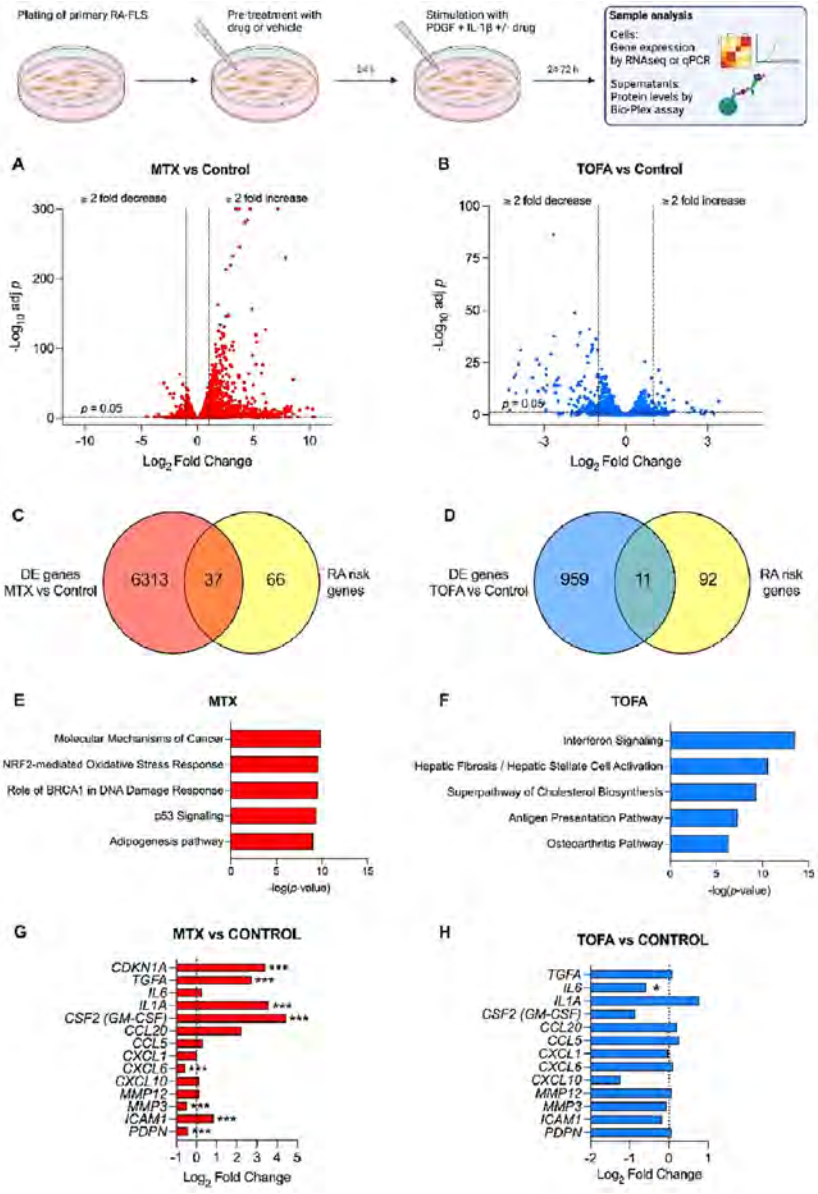
Methotrexate Augments the Release of Granulocyte-macrophage Colony-stimulating Factor from Activated Rheumatoid Arthritis Fibroblast-like Synoviocytes - Possible Consequences for Persistence of Joint Inflammation

Beatrice Bergström[1], Tilia Selldén[1], Miriam Bollmann[2], Mattias N.D Svensson[1] and **Anna-Karin Hultgård Ekwall**[3], [1]University of Gothenburg, Gothenburg, Sweden, [2]Department of Rheumatology and Inflammation research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]University of Gothenburg, Kullavik, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Activated fibroblast-like synoviocytes (FLS) are important mediators of synovitis and structural damage in rheumatoid arthritis (RA)[1]. Granulocyte-macrophage colony-stimulating factor (GM-CSF, encoded by the *CSF2* gene) is released from activated RA-FLS and promotes the production of pro-inflammatory cytokines from macrophages,

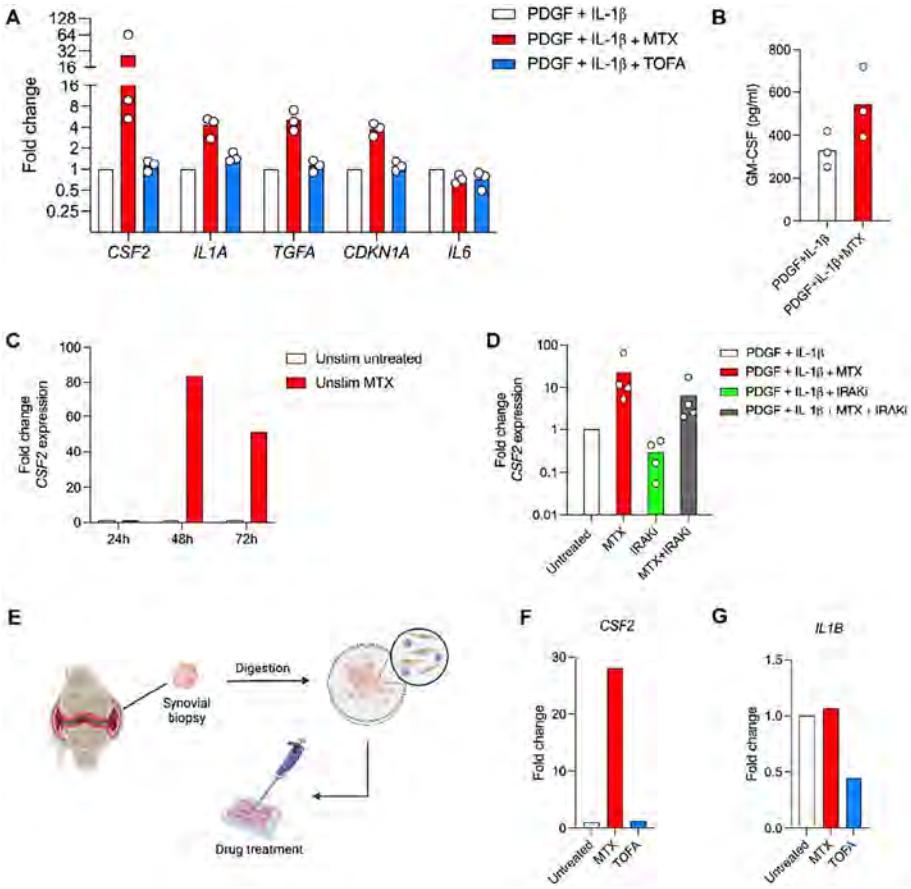


Primary RA-FLS were pre-treated with MTX, TOFA, or vehicle at 1-2,5 uM for 24 hours followed by stimulation with 20 ng/mL PDGF-BB and 2 ng/mL IL-1beta in medium with the drug or vehicle for 48 hours and finally processed for RNAseq. Vulcano plots show significantly DE genes by DESeq2 ($p \leq 0.05$) for MTX (A) and TOFA (B) vs untreated control. Venn diagram demonstrate effects of MTX (C) and TOFA (D) on RA risk genes identified by Genome wide association studies. Ingenuity Pathway Analysis revealed the five most significant pathways for MTX (E) and TOFA (F). Effects of MTX and TOFA on a core set of RA-associated FLS-expressed genes are demonstrated in G and H respectively. *Adjusted $p \leq 0.05$, **$p \leq 0.01$, ***$p \leq 0.001$ (Benjamini-Hochberg).

which in turn activates FLS creating a viscous cycle[2]. We investigated the effects of anti-rheumatic drugs on gene expression, in particular RA risk genes such as *CSF2*, in activated RA-FLS, and on cytokine release from RA synoviocyte cultures.

Methods: Primary FLS were established from synovial tissue collected from patients with RA undergoing arthroplasty or synovial biopsy. FLS were pre-treated with methotrexate (MTX), tofacitinib (TOFA, janus kinase inhibitor), zimlovisertib (IRAK4 inhibitor) or vehicle followed by stimulation with platelet-derived growth factor (PDGF) and interleukin-1β (IL-1β) for 24-72 hours (Fig.1, top). An RA *ex-vivo* synovial bioassay was performed according to Kuo et al.[3]. Cells were collected for RNAseq or qPCR, and supernatants were analyzed for protein concentrations using Bio-Plex assay.

Results: MTX demonstrated an overall activation of gene expression in PDGF+IL-1β stimulated RA-FLS compared to untreated (6350 differentially expressed (DE) genes), and to TOFA treated (970 DE genes) samples (Fig. 1A-B). MTX had a greater effect on RA risk genes (35 % DE in MTX vs CON) compared to TOFA (10 % DE in TOFA vs CON) (Fig.1C-D). Pathway analysis showed largest effects on *Molecular mechanisms of cancer* (MTX) and *Interferon signaling* (TOFA) respectively (Fig. 1E-F). Targeted analysis revealed that MTX in addition to the known induction of *CDKN1A* (p21)[4], profoundly increased *CSF2*, *IL1A* and *TGFA* expression compared to control treated activated FLS (Fig.1G). TOFA reduced *IL6* and *CXCL10* expression as expected (Fig.1H). RNAseq data were confirmed by qPCR and on protein level in FLS supernatants (Fig.2A-B). Furthermore, MTX induced *CSF2* expression also in unstimulated RA-FLS (Fig.2C). IRAK4i could not prevent the



Primary RA-FLS were pre-treated, stimulated and treated as outlined according to experimental design in figure 1. Graphs show fold change to untreated control by qPCR. A) Expression of RA-associated genes in stimulated RA-FLS treated with MTX (red bars) and TOFA (blue bars). B) GM-CSF concentration by Bio-Plex assay in supernatants of cells in A). C) Time course of CSF2 expression in MTX treated unstimulated RA-FLS. D) CSF2 expression in MTX, zimlovisertib (IRAK4i) or combination treated stimulated RA-FLS. E) Work flow of RA ex-vivo synovial bioassay. F) Induction of CSF2 expression by MTX and G) expression of IL-1beta in synoviocyte cultures (Bio-Assay) treated with MTX (red) and TOFA (blue).

increased GM-CSF expression by MTX in stimulated RA-FLS (Fig.2D). MTX induced *CSF2* expression in RA *ex-vivo* synovial cultures (Fig. 2E-F) and failed to reduce IL-1β expression as opposed to TOFA (Fig.2G).

Conclusion: Methotrexate treatment augments the release of GM-CSF from RA-FLS and leads to sustained cytokine production from synoviocytes. This off-target effect might contribute to the persistence of synovitis.

JAK/STAT Inhibition Modifies the Innate Lymphoid Cells 1 Immune Response in Patients with Rheumatoid Arthritis

Lidia La Barbera[1], Marianna Lo Pizzo[1], Chiara Rizzo[1], Leila Mohammadnezhad[1], federica Camarda[1], Francesco Ciccia[2] and Giuliana Guggino[1], [1]University of Palermo, Palermo, Italy, [2]University of Campania - Luigi Vanvitelli, Naples, Italy

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent evidence suggests that innate lymphoid cells (ILCs) might be involved in rheumatoid arthritis (RA) pathogenesis and individuals at risk of RA exhibited an increased frequency of ILC1 (Rodríguez-Carrio J, Arthritis Rheumatol. 2017). JAK3 participates in ILC1 and ILC3 differentiation. Tofacitinib and JAK3 inhibitor, PF-06651600, impair the ability of human intraepithelial ILC1 to produce IFN-γ and the proliferation of ILC1 and ILC3 (Robinette ML, Mucosal immunology. 2018). Our study aims to evaluate the effects of tofacitinib on ILC1 and ILC3 expansion and function in RA.

Methods: Twenty RA patients, who fulfilled the ACR/EULAR RA classification criteria, with active disease, naive to biological agents, were enrolled and started tofacitinib. The study was complied with the Declaration of Helsinki and was approved by the local Ethical Committee. Ten healthy donors (HD) matched for age and sex were also enrolled. Peripheral blood

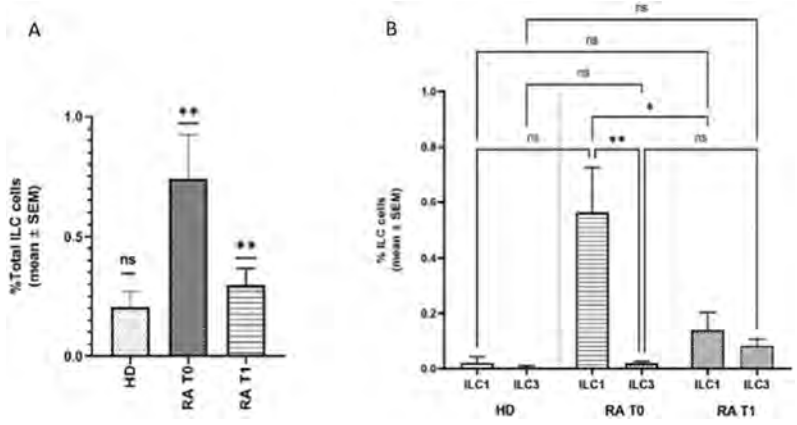

Figure 1: ILCs, ILC1, ILC3 frequencies at T0 and T1 A. Peripheral total ILCs frequency in HD and RA patients at T0 and T1; **p <0,01. B. Frequency of ILC1 and ILC3 in HD and RA patients at T0 and T1; **p <0,01, *p <0,05.

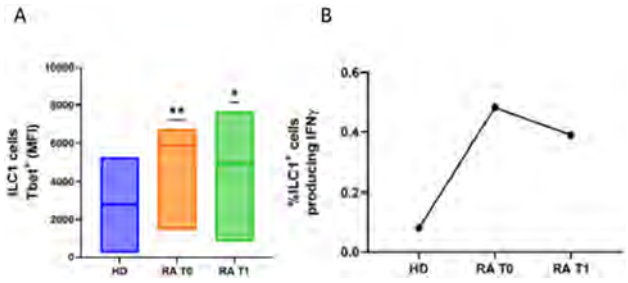

Figure 2: ILC1 functional activity at T0 and T1 A. Box plot showing comparison between median values of T-bet MFI for HD and RA patients at T0 and T1; **p <0,01, *p <0,05. B. IFNγ production by ILC1s in HD and RA patients at T0 and T1.

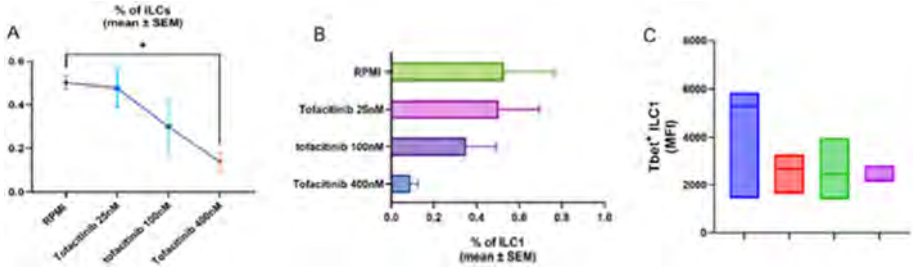

Figure 3: Effects on ILCs frequency of in vitro tofacitinib treatment A. Total ILCs frequency B. Frequency of ILC1 C. Box plot showing MFI expression of Tbet on ILC1s

mononuclear cells (PBMCs) collected before (T0) and three months after therapy (T1), were cultured to evaluate ILC1 and ILC3 frequencies and the respective production of IFN-γ and IL-17 by flow cytometry analysis. PBMCs of RA patients were *in vitro* cultured for 48 hours with tofacitinib at increasing concentrations (25nM, 100nMand 400nM) to evaluate the dose effects of tofacitinib on ILCs frequencies. Role of the Study Sponsor: Research was supported by an unrestricted grant by Pfizer.

Results: At T0, RA patients showed a significant expansion of peripheral total ILCs and ILC1 (Lin^-, $CD127^+$, $CD117^-$, $Tbet^+$) but not ILC3 (Lin^-, $CD127^+$, $CD117^+$, RoR γt^+), compared to HD. After three months of therapy the overall ILCsfrequency was significantly reduced in RA (Figure 1). Specifically, ILC1 frequency was significantly decreased in association with the reduction of transcriptional factor T-bet expression as well as the ILC1 ability to release IFN-γ (Figure 2). Instead, for ILC3 not significant modifications in frequency, RoR γt expression andIL-17 production were detected at T1. *In vitro* treatment of PBMCs with increasing concentrations of tofacitinib demonstrated a dose-dependent reduction in the frequency of ILCs compared to untreated cells. In particular, ILC1s resulted more affected, by the *in vitro* treatment, both in terms of frequency and transcription factors expressioncompared to ILC3, supporting our *ex vivo* results (Figure 3).

Conclusion: Our preliminary results demonstrate that tofacitinib modulates the innate immune response by reducing the frequency of ILC1 cells and their production of IFN- γ.

Single-cell RNA Sequencing Analysis and Immune Profiling of Antigen-specific T Cells in Patients with Rheumatoid Arthritis and Healthy Controls

JING SONG[1], Cliff Rims[1], Matthew Dufort[1], Peter Linsley[1], Eddie James[2] and Jane Buckner[2], [1]Benaroya Research Institute, Seattle, WA, [2]Benaroya Research Institute at Virginia Mason, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Single-cell analysis has emerged as a powerful tool for investigating the transcriptomics and T-cell receptor (TCR) diversity in patients with rheumatoid arthritis (RA). However, there is limited information on the specificities, immunophenotype, and TCR diversity of antigen-specific T cells in RA using single-cell RNA sequencing (scRNA-seq). To address this knowledge gap, we conducted a pilot study to demonstrate the applicability of 10x single-cell sequencing for studying antigen-specific T cells.

Methods: Peripheral blood mononuclear cells (PBMC) were from patients with seropositive RA (n=3) and healthy control (HC) subjects (n=2). All individuals were HLA DRB1*0401 or 0404. Using an activation-induced marker (AIM) assay, PBMC were stimulated overnight with a pool of peptides derived from RA antigens (Table 1) or a peptide pool for viral antigens (CFEX). CD4+CD154+ and CD8+CD137+ cells were isolated to obtain paired scRNA-seq, cellular indexing of transcriptomes and epitopes by sequencing (CITE-seq), and TCR repertoire data. Specifically, we isolated RA antigen-specific T

cells, CEFX antigen-specific T cells, and general CD3 T cells from the same subjects (Figure 1). The sorted cells were stained with the TotalSeq Human Universal Cocktail (BioLegend), hashtagged, and the captured single cells sequenced using the droplet-based 10x Chromium platform. Cell projection and graph-based clustering were performed using the Seurat package.

Results: A total of 11,053 cells, 6464 from RA and 4589 from HC subjects, were subjected to high-quality scRNA-seq analysis. Utilizing a graph-based clustering approach, we identified seven distinct clusters of cells, representing both RA and HC, which were visualized through integrated UMAPs< ![if !supportAnnotations] >[VG1]< ![endif] > combining multimodal data. Overlaying hashtags to the UMAP suggests that RA and CEFX T cells mostly mapped to cluster 4. Differential gene expression analysis and antibody expression of established lineage markers revealed that cells in cluster 4 express high levels of activation markers including CD71, CD28, CD38, HLA-DR and KLRG1, transcription factors including NR4A1, HLA-A, HLA-B and IFNG, and translation initiation factorEIF5A and EIF1. We applied a similar graph-based clustering method to RA and CEFX antigen-reactive T cells, leading to the identification of four major clusters: a cytotoxic CD8+ T cells (cluster 0), exhausted CD8+ T cells (cluster 1), activated CD4+ T cells (cluster 2), and IFN I signature CD4+ T cells (cluster 3). We observed high-quality TCR sequences in over 90% of the captured cells from each subject and significant private clonal expansions, with CD8 RA antigen-specific T cells displaying a higher degree of clonotypic expansion compared to CD4 populations. We also identified clonal sharing between RA antigen-specific T cells and the non-selected CD3 T cells in each subject.

Conclusion: Our findings highlight the power of multimodal single cell analysis to identify clonally expanded T cells in RA, characterize their phenotypic features at rest and upon activation, which may provide valuable insights into the antigen-specific T-cell responses and TCR dynamics associated with RA pathology.

Asthma Severity Is Associated Increased Serum Anti-cyclic Antibody Level at Baseline and in Increase During Longitudinal Follow-up

Drayton Rorah[1], Linh Ngo[2], Mario Castro[2], Kristen Demoruelle[3] and Scott Matson[4], [1]University of Kansas Medical Center, Kansas City, KS, [2]University of Kansas School of Medicine, Kansas City, KS, [3]University of Colorado Anschutz Medical Campus, Aurora, CO, [4]University of Kansas School of Medicine, Kansas City, MO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The lung airways have been implicated in the pathogenesis of RA. RA-associated autoantibodies, including anti-cyclic citrullinated peptide (anti-CCP) antibodies are found to be generated in the lung using induced sputum. Epidemiologic studies have identified that the presence of airways diseases, such as asthma, increase incident RA compared to healthy cohorts. However, it remains unclear how this relationship between asthma and RAdevelops. The aim of our study was to investigate the relationship between asthma severity and serumanti-CCP in cross-section andover time.

Methods: Our prospective cohort study included patients with mild, moderate, and severe asthma. One-hundred forty-four patients were included in this study. Serum anti-CCP-IgG (CCP3, Werfen) and anti-CCP-IgA (research modification of CCP3.1, Werfen) levels were measured in by ELISA in banked serum obtained at baseline and at a longitudinal visit, which was separated by four years. Cut off levels for anti-CCP positivity was determined based on 3 standard deviations above the mean level in a separate cohort of 100 non-RA controls. Comparison between anti-CCP titers across asthma severity groups were carried out via t-test where appropriate. Each participant was determined to have mild, moderate or severe asthma at their baseline visit based on previously published expert guidelines (1).

Results: Thirty-four of 144 (23.6%) were positive for anti-CCP-IgA and 2 were positive for anti-CCP-IgG (1.3%). Baseline serum anti-CCP-IgA levels were higher in patients with moderate or severe asthma compared to the mild asthma group (p=0.022, Figure 1), which remained significantly different at follow-up (p = 0.01).Both groups had an increase in mean anti-CCP-IgA levels at follow-up, although the moderate or severe group had a numerically higher increase that did not reach

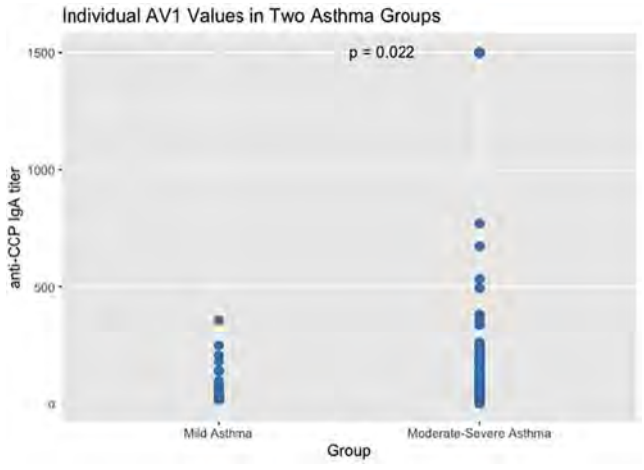

Fig1: Anti-CCP-IgA levels for each subject represented by each dot separated by asthma severity (mild vs moderate or severe)

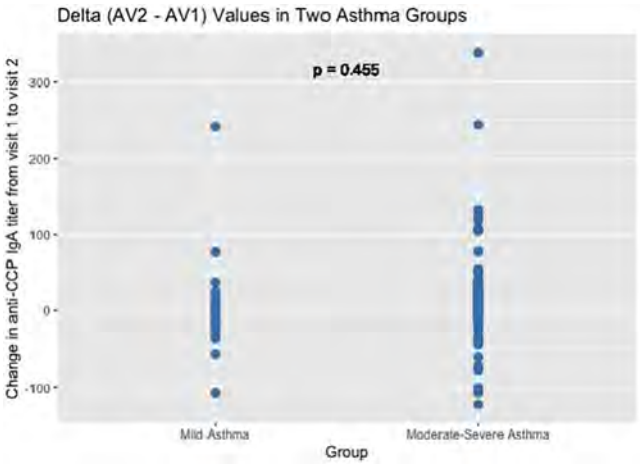

Fig 2: Each dot represents the delta in anti-CCP-IgA level from baseline to the longitudinal visit at year 4. Dots below zero represent subjects whose anti-CCP level decreased at follow-up, groups are separated by asthma severity level

statistical significance (p = 0.46, Figure 2) There was no difference in serum anti-CCP-IgG levels based on asthma disease severity at baseline or follow-up (p = 0.69 and p = 0.18 respectively).

Conclusion: We found serumanti-CCP-IgA antibodies in a modest number of asthma patients. Interestingly, there was a significant association between asthma severity and anti-CCP-IgA level, suggesting a potential relationship between airways inflammation and development of anti-CCP antibodies in these individuals. Additionally, worse baseline asthma severity (mild vs moderate/severe) had a numerically higher anti-CCP increase which did not reach statistical significance but may support the role of airway disease severity in anti-CCP generation. There was no association with anti-CCP-IgG titers which supports the role of lung mucosa in the development of this relationship.

Antibody Responses to Citrullinated Type II Collagen and Vimentin Modified with Malondialdehyde-Acetaldehyde Differ in Rheumatoid Arthritis and Rheumatoid Arthritis-Interstitial Lung Disease

Breanna Butler[1], Jill Poole[1], Michael Duryee[1], Nozima Aripova[1], Carlos Hunter[1], Bridget Kramer[1], James O'Dell[1], Geoffrey Thiele[1], Bryant England[1] and Ted R Mikuls[2], [1]University of Nebraska Medical Center, Omaha, NE, [2]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) causes significant complications and mortality in patients with rheumatoid arthritis (RA). We have previously shown that patients with RA-ILD had increased levels of serum IgA and IgM antibodies against human serum albumin modified with malondialdehyde-acetaldehyde (MAA) in addition to having higher levels of

ACPA. Moreover, lung tissues from RA-ILD patients demonstrated increased levels of MAA antigen that co-localized with citrullinated (CIT) proteins, Type II Collagen (CII) and Vimentin (VIM), suggesting that MAA may act as a cofactor that increases the immunogenicity of CIT proteins in RA-ILD patients. Therefore, antibody responses to dually modified (MAA and CIT) VIM or CII were evaluated as biomarker(s) to differentiate RA-ILD from RA and idiopathic pulmonary fibrosis (IPF), a condition with marked histopathologic similarities to RA-ILD.

Methods: Serum was collected from patients with RA, RA-ILD, or IPF (n=15 for each group). All patients with RA fulfilled the 1987 ACR classification criteria. The presence of RA-ILD was confirmed by a board-certified subspecialist (pulmonologist or rheumatologist) and the presence of supportive chest computed tomography (CT) findings. Patients were defined as having RA without ILD in the absence of a clinical diagnosis of ILD or past chest imaging findings suggestive of ILD. All patients with IPF without underlying autoimmune disease were diagnosed by a board-certified pulmonologist and had confirmatory findings of usual interstitial pneumonia (UIP) by chest CT imaging. Samples were assessed for CCP and relative units of IgG, IgM, and IgA antibody levels to CII-MAA-CIT and VIM-MAA-CIT via ELISA. Data was analyzed using a one-way ANOVA with Tukey's multiple comparison test.

Results: Participant characteristics were similar across groups: overall mean age 73 years, 90% male, 87% reporting White race and 68.9% current or former smokers. There was no difference in CCP positivity between RA and RA-ILD patients. Serum IgG antibodies to CII-MAA-CIT were significantly increased in RA-ILD patients compared to RA patients (4-fold higher, $p<0.05$) and IPF patients (42.5-fold higher, $p<0.01$) (**Fig. 1A**). Serum IgM (**Fig. 1B**) and IgA (**Fig. 1C**) antibodies to CII-MAA-CIT showed similar trends with IgG anti-CII-MAA-CIT, but only differences in RA-ILD vs. IPF reached statistical significance ($p<0.05$). In contrast, serum IgG antibodies to VIM-MAA-CIT were significantly increased in patients with RA patients when compared to those with RA-ILD (2-fold higher, $p<0.05$) and 2 IPF patients (2.1-fold higher, $p<0.05$) (**Fig. 1D**).Serum IgM (**Fig. 1E**) and IgA (**Fig. 1F**) antibodies to VIM-MAA-CIT showed a similar pattern to IgG anti-VIM-MAA-CIT, but again only differences between RA and IPF reached significance ($p<0.05$).

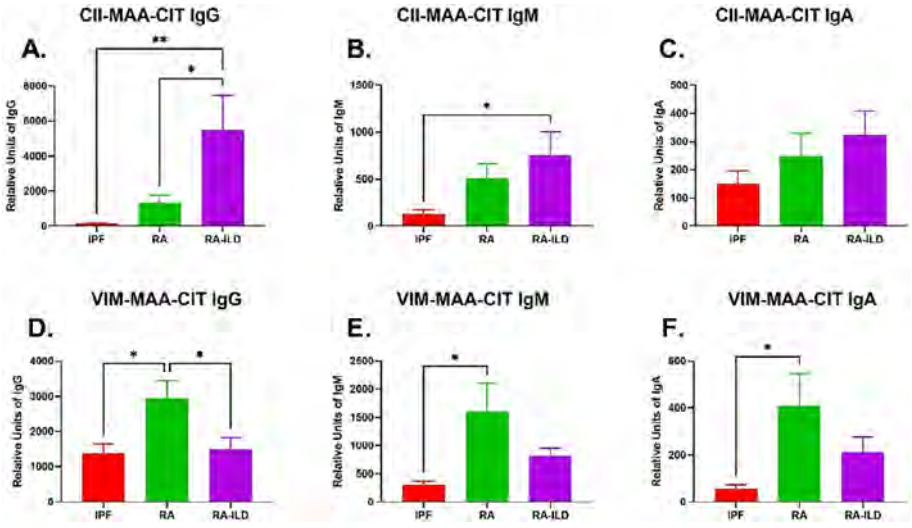

Figure 1. Serum IgG Antibody Levels to Dually Modified Type II Collagen or Vimentin. Serum samples from RA, RA-ILD, and IPF patients were incubated with native Type II Collagen and Collagen dually modified with MAA and CIT or native Vimentin and Vimentin dually modified with MAA and CIT. These samples were assayed by ELISA for (A,D) human IgG (B,E) human IgM (C,F) human IgA. Antibodies to native Collagen and Vimentin were subtracted from MAA-CIT responses. Serum IgG antibodies to CII-MAA-CIT were significantly increased in RA-ILD patients compared to RA patients (*$p<0.05$) and IPF patients (**$p<0.01$). Similar trends were observed with IgM and IgA antibodies to CII-MAA-CIT, but only IgM in RA-ILD compared to IPF was significantly increased (*$p<0.05$). Serum IgG antibodies to VIM-MAA-CIT were significantly increased in RA patients compared to both RA-ILD and IPF patients (*$p<0.05$). Similar trends were observed with IgM and IgA antibodies to VIM-MAA-CIT, but only RA compared to IPF patients had significantly increased IgM and IgA antibodies (*$p<0.05$). N=15 for IPF patients, N=15 for RA patients, and N=15 for RA-ILD patients.

Conclusion: Serum IgG antibody levels to dually-modified CII-MAA-CIT and VIM-MAA-CIT differ between patients with RA and RA-ILD. These findings suggest that dual modifications of type II collagen, but not vimentin, generate autoimmune responses that are substantially enhanced in RA-ILD and that could play a role in the pathogenesis of this extra-articular complication.

Abstract Number: 1765

Persistent Cigarette Smoking Is Associated with Rheumatoid Arthritis Onset and Neutrophil Activation in a Prospective Study of At-risk First-Degree Relatives

Jeba Maisha, Xiaobo Meng, Hani El-Gabalawy and Liam O'Neil, University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cigarette smoking (CS) is a major environmental risk factor for the development of Rheumatoid Arthritis (RA), and is associated with the development of RA autoantibodies, such as anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF). However, it remains unclear what role(s) smoking has in the pathogenesis of RA, particularly during the pre-clinical stage. Using clinical, proteomic and in-vitro approaches, we sought to better understand the relationship between CS and RA onset in a large, prospective cohort of unaffected First-Degree Relatives (FDR) of RA patients, some of whom progressed to develop RA (Progressors).

Methods: Over the past 15 years, we established a longitudinal cohort of FDR of RA patients with a view to detect and predict incident RA. At baseline, and at each subsequent study visit, a CS questionnaire was administered, which included questions regarding past and current CS, and CS intensity. Based on these data, longitudinal CS patterns were extracted and related to demographics and autoantibody profiles. A previously published (32770634) discovery serum proteomic dataset (SOMAscan, 1288 proteins) was analyzed to explore the potential effect of smoking on the proteome of FDR. Neutrophils from healthy donors were stimulated with CS extract (CSE) and analyzed by flow cytometry, enzymatic profiling, immunofluorescence, protein citrullination and extracellular DNA release (SYTOX green).

Results: In total, we were able to analyze CS patterns on 569 FDR, 19 of whom were Progressors. At baseline, current (79.6%) and ever (85.0%) CS rates were high in the study population, though neither was clearly associated with ACPA and/or RF seropositivity. Furthermore, baseline CS parameters did not predict future development of RA in the Progressors (n = 19). However, longitudinal CS patterns were strongly associated with Progression (Figure 1A, p = 0.009), with higher rates of persistent smoking in Progressors (90.0% vs 60.2%). In a logistic regression model, both persistent smoking (OR 8.0, 1.7 - 37.7) and ACPA positivity (15.9, 5.7 - 44.5) were independently associated with Progression (Figure 1B, C). Proteomic analysis and pathway enrichment suggested an upregulation of neutrophil proteins (Figure 2A) and *neutrophil degranulation* ($p=5.2E^{-18}$, Figure 2B) in active smokers. Neutrophils cultured *in-vitro* with CSE (20%) skewed neutrophils

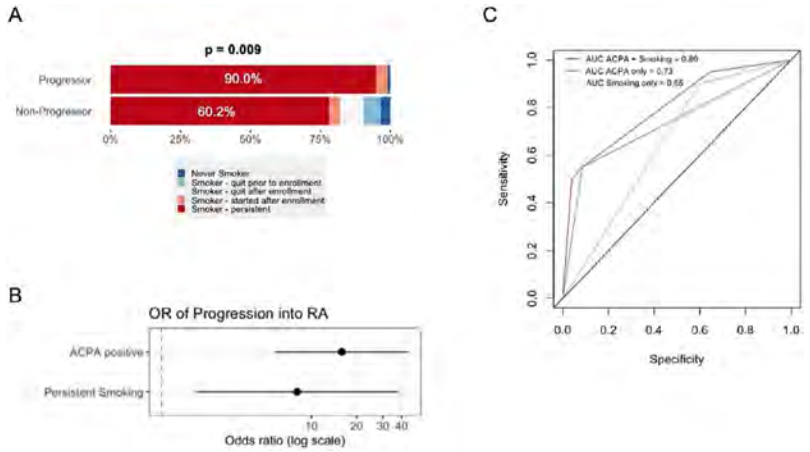

Figure 1: Persistent cigarette smoking is associated with Rheumatoid Arthritis (RA) development in at-risk First-Degree Relatives (FDR). (A) Longitudinal rates of smoking persistence, cessation and abstinence in Progressor and Non-Progressor FDR. Analyzed as an ordinal variable with Wilcoxon Rank-Sum test. (B) Odds Ratio (OR) of anti-citrullinated protein antibody positivity (ACPA) and smoking persistence for Progression into RA. (C) Area under the curve (AUC) for Smoking (teal), ACPA (blue) and Both (red) for RA Progression.

away from degranulation (Figure 3A, B) and toward neutrophil extracellular trap (NET) formation, leading to the release of neutrophil proteases, extracellular DNA and citrullinated proteins (Figure 3C, D, E).

Conclusion: We show that persistent CS rather than incident CS was associated with RA development in a cohort of at-risk FDR of RA patients. Serum proteomics suggested that neutrophils are activated in smokers and neutrophils treated with CSE release NETs, but do not degranulate. These data suggest a potential mechanism by which smoking may stimulate

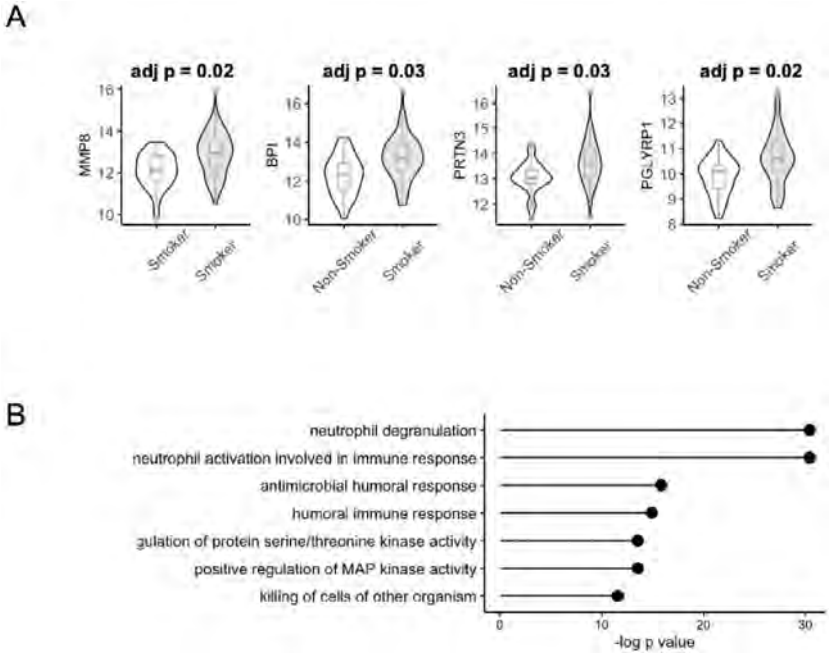

Figure 2: Smoking in at-risk First-Degree Relatives (FDR) of Rheumatoid Arthritis (RA) patients is associated with neutrophil activation. (A) Serum protein expression (SOMAscan) of matrix metalloproteinase-8 (MMP8 aka. neutrophil collagenase), bactericidal/permeability-increasing protein (BPI), proteinase-3 (PRTN3), and peptidoglycan recognition protein 1 (PGLYRP1). (B) Gene ontology enrichment scores ordered by -log p-value for significant ($p < 0.05$) upregulated proteins in smokers (FC > 1) compared to non-smokers.

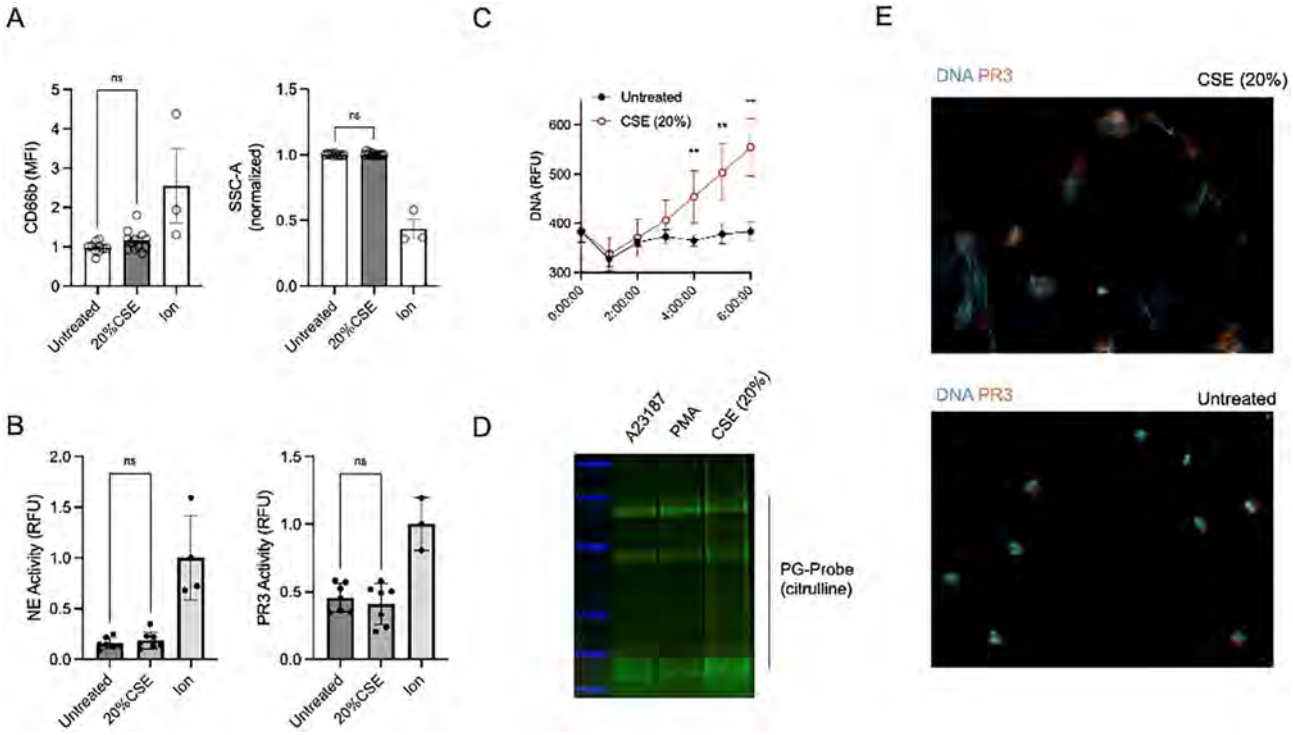

Figure 3: Neutrophils treated with cigarette smoke extract (CSE) skew towards neutrophil extracellular trap (NET) formation. (A) Neutrophils treated with CSE (20%) for 60 minutes do not upregulate CD66b (left, normalized) or display reduced side scatter (SSC, right), both surrogate markers of degranulation. Ion = A23187 (B) Protease activity for Proteinase-3 (PR3) and neutrophil elastase (NE) measured by enzyme kinetics by fluorescence in cell culture supernatant (60 minutes). Measured by Wilcox Rank-Sum Test (C) Cell-free DNA release over time measured by fluorescence (SYTOX green 0.2 μM), analyzed by multiple Mann-Whitney tests (** $p < 0.01$). (D) Protein citrullination in NETs (isolated after 4 hours in culture) measured by labeling with a Phenylglyoxal probe (PG) and in-gel fluorescent imaging. A23187 = Calcium Ionophore, PMA = phorbol myristate acetate (E) Immunofluorescence of images of CSE and untreated cells (4 hours) and stained for DNA (Hoescht, blue) and PR3 (orange).

neutrophils to undergo NET formation, and release citrullinated antigens and inflammatory proteins, which may in turn increase the risk of progression to clinically detectable RA.

Session Title: RA – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously shown that certain malondialdehyde/acetaldehyde modified protein binding autoantibodies (anti-MAA), obtained from the inflamed joints of rheumatoid arthritis (RA) patients, induced osteoclast differentiation *in vitro* and bone loss *in vivo* via an FcγR-mediated mechanism (1). In the present work we studied the effect of these antibodies on joint inflammation and, more specifically, on the function of macrophages.

Methods: We analysed global gene expression, by RNAseq, in the ankle joints of mice injected with patient-derived anti-MAA monoclonal antibodies, in the presence or absence of intraperitoneally injected LPS, which mimicked systemic inflammation. We have also analysed gene expression changes and cytokine production in anti-MAA treated macrophage cultures.

Results: Intravenous injection of anti-MAA antibodies led to subtle changes in the gene expression of the joints, with altered expression of several genes involved in immune responses and cell signalling. Intraperitoneally injected LPS induced robust gene expression changes in the ankles, with several cytokine and other immune mediators expressed at slightly higher level in the anti-MAA pretreated group. Anti-MAA pretreatment could also induce a more inflammatory macrophage phenotype *in vitro*, in response to a subsequent LPS activation. Similarly to the previously described osteoclast stimulatory effect, the inflammatory priming of macrophages was induced by several but not all of the tested anti-MAA monoclonal antibodies, and the effect was mediated via FcγR-transmitted signals.

Conclusion: Class-switched anti-MAA autoantibodies are typically associated with high disease activity in RA, but such antibodies have also been detected in some of the healthy donors and in individuals at risk of RA (2 and our unpublished data). Our results indicated that certain anti-MAA IgG autoantibody clones may contribute to an inflammatory priming of the joint tissues prior to the onset of systemic inflammation. FcγR-mediated pre-activation of macrophages could play an important role in this effect, by setting the stage for augmented responses to subsequent inflammatory stimuli.

TNF-α Utilizes the TWEAK/Fn-14 Axis in Human Rheumatoid Arthritis Synovial Fibroblasts to Induce Inflammation

Farheen Sultan Shaikh[1], Anil Singh[1], Paul Panipinto[2] and Salahuddin Ahmed[1], [1]Washington State University, Spokane, WA, [2]Washington State University College of Pharmaceutical Science and Molecular Medicine, Spokane, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor-alpha (TNF)-α is a proinflammatory cytokine in rheumatoid arthritis that transduces intracellular signal transduction pathways through specific receptors, TNF-R1, and TNF-R2. The anti-TNF therapy has been a primary approach in the management of RA, yet most of the patients fall into low- and non-responder groups with unclear reasons. TNF-like weak inducer of apoptosis (TWEAK), another TNF-superfamily member, is a pleiotropic cytokine that similar to TNF-α regulates inflammatory activity, angiogenesis, cell proliferation, and tissue remodeling by binding to its receptor, fibroblast growth factor-inducible 14 (Fn-14). As TNF-α and TWEAK activate common signaling pathways, we

investigated the crosstalk between TWEAK and TNF-α in human rheumatoid arthritis synovial fibroblasts (RASFs) and studied the role of Fn-14 receptor knockdown on TNF-α-mediated inflammation.

Methods: Human RASFs were serum-starved overnight followed by treatment with different concentrations of TWEAK (50, 100, 200, 400, and 800 ng/mL) and TNF-α (5, 10, 20, 40, and 80 ng/mL) alone and in combination for 24 hrs. The secretion of chemokines MCP-1/CCL2, RANTES/CCL5, and MMP-1 was analyzed using ELISA, and synergy was studied using CompuSyn Software. Fn-14 siRNA knockdown in RASFs was done followed by TNF-α stimulation for 24 hrs. Global effects of Fn-14 gene knockdown were studied using an RNA sequencing (RNA-seq) array. Differentially expressed genes (DEGs) were analyzed using GraphPad and Metascape tools. Interactions between Fn-14 and TNF-R1 receptors were studied using the immunoprecipitation (IP) method followed by Western blot analysis. The experiments were performed in at least three patient cell lines and the statistical value of $p< 0.05$ was considered significant.

Results: TNF-α in combination with TWEAK resulted in greater secretion of both MCP-1 and RANTES compared to each cytokine alone. The synergy was more remarkable at the low combinations of cytokines (5 ng/mL of TNF-α + 50 ng/mL of TWEAK) for MCP-1, RANTES, and MMP-1 with a combination index < 1. RNA-seq data showed that one-third of the genes were differentially expressed in RASFs when stimulated with TNF-α. Out of the 1,389 genes that were 2-fold upregulated by TNF-α, the knockdown of Fn-14 significantly suppressed 168 genes when compared to TNF-α with NCsi treatment. In addition, out of the 2,186 genes 2-fold downregulated by TNF-α, 32 genes were restored in the absence of Fn-14. Gene Ontology analysis of the RNA-seq data suggests that Fn-14-knockdown-associated genes are involved in processes like-regulation of intrinsic apoptosis, regulation of innate immunity, and sensory perception of pain. Furthermore, our IP results with TNF-R1 pull-down showed the presence of Fn-14 indicating the interaction between these two receptors, which requires further experimental investigation.

Conclusion: Our findings suggest that low-dose TNF-α synergizes with TWEAK to induce inflammation and also demonstrate the ability of TNF-α to potentially exploit the Fn-14 receptor to transduce non-canonical signaling in RASFs. This indicates that the pharmacological inhibition of Fn-14 may provide an effective adjunct therapy to anti-TNF therapy.

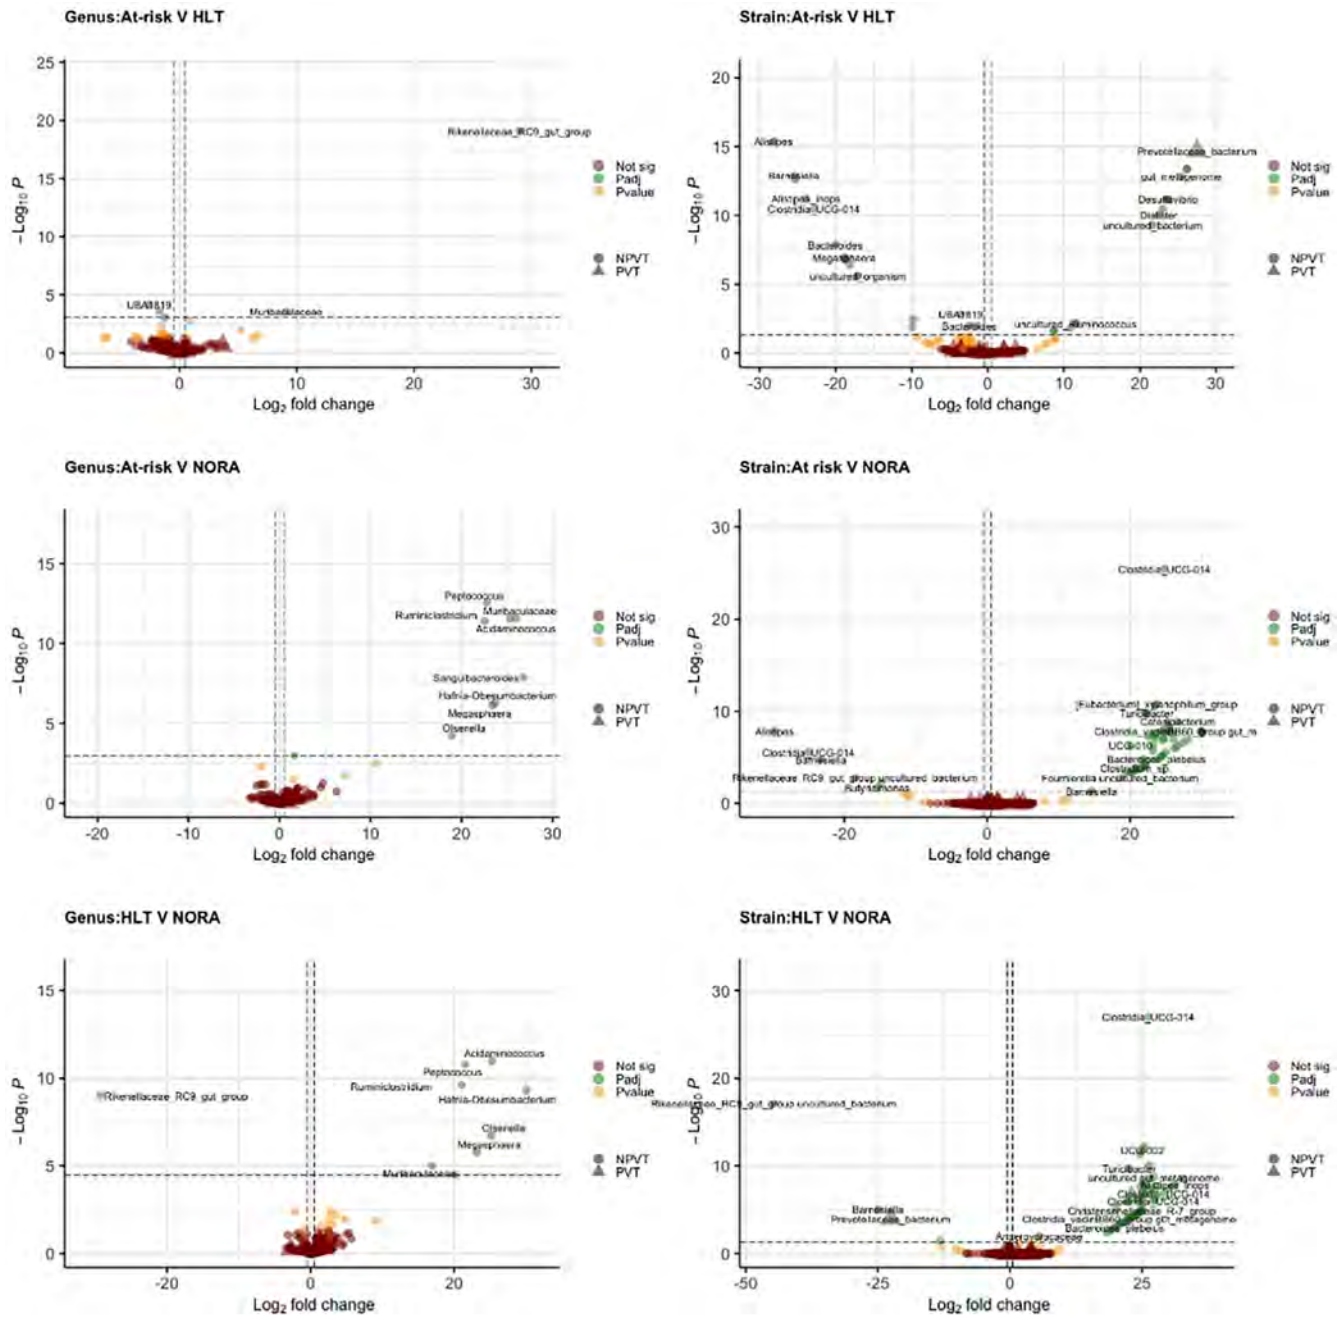
The Dynamics of the Gut Microbiome in Rheumatoid Arthritis Susceptibility: A Cross-Sectional and Longitudinal Observational Study

Christopher Rooney[1], Ian Jeffery[2], Kulveer Mankia[3], Mark Wilcox[1] and Paul Emery[4], [1]University of Leeds, Leeds, United Kingdom, [2]4D Pharma plc, Cork, Ireland, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

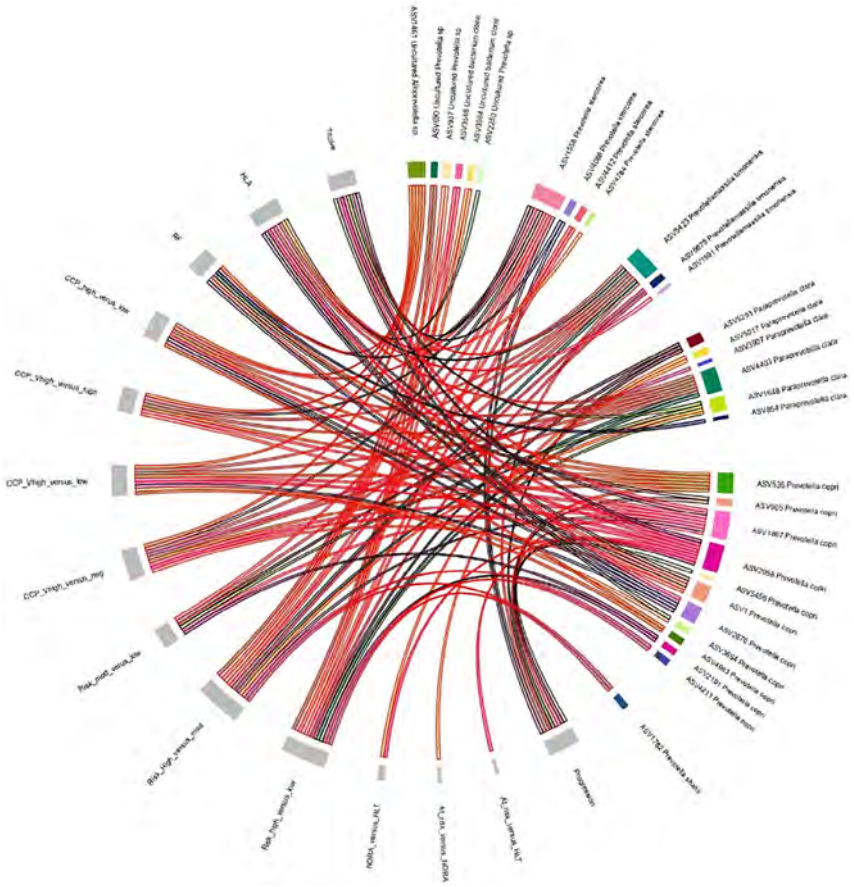
Background/Purpose: Multiple compositional shifts of gut microbiota have been identified within the rheumatoid arthritis (RA) disease continuum, encompassing both established RA and at-risk individuals (including those with pre-clinical RA). Subsequently, a variety of gut bacteria have been implicated as a potential impetus in the development of RA, none more



Differentially abundant taxa between groups. Pairwise volcano plots of at-risk individuals, NORA and healthy controls, plotting Log2 fold change against -Log10 P value, coloured according to significance. Vertical line denotes adjusted P value threshold, horizontal line denotes 0.5 Log2 fold change. Shape denotes Prevotellaceae (PVT) or not Prevotellaceae (NPVT) taxa.

so than Prevotella copri. Using a comprehensively phenotyped prospective cohort of individuals at-risk of RA this work investigates whether P. copri overabundance is ubiquitous within the pre-clinical phases of RA, establishes microbiota associations with traditional RA risk factors and hypothesizes a timeline for microbial action within RA development.

Methods: Individuals at-risk of RA were defined by the presence of anti-cyclic citrullinated protein (anti-CCP) antibodies and new musculoskeletal symptoms without clinical synovitis. Individuals were sampled at baseline (n =124 participants, 30 of whom progressed to RA), and longitudinally (n = 19 participants, 5 RA progressors) at 5 time points over 15 months. At-risk



Prevotellaceae chord plot. Associations of Prevotellaceae strains reaching nominal significant from adjusted DESeq2 models. Metadata variables in grey and strains designated by colour. Outer border denotes direction of association, increased abundance in red or decreased abundance in black.

individuals were compared to healthy controls (n = 22) and to individuals with new onset RA (n = 7). Taxonomic alterations of the gut microbiome were investigated using 16S rRNA amplicon sequencing, at both strain and genus level and confirmed using shotgun metagenomic DNA sequencing.

Results: RA progression at genus level was associated with modest changes in the gut microbiome, mainly affecting the Firmicutes and Proteobacteria phyla. A single Prevotellaceae strain was enriched in at-risk individuals compared to healthy controls (fig 1). P. copri strains demonstrate overall increased abundance with increasing anti-CCP levels and risk of progression (score based on symptomatology, HLA status, anti-CCP level and ultrasound findings), but display strain specific fluctuations with respect to early immune dysregulation, intestinal permeability, genetic risk and rheumatoid factor positivity (fig 2). Time series analysis suggests RA progression involves the development of an unstable low diversity microbiome that is characterised by the accumulation of RA associated pathobionts within the 10 months preceding RA (fig 3), which includes, but is not limited to P. copri. Functional analysis shows the NORA gut microbiome has increased abundance of pathways associated with amino acid metabolism. Healthy controls had decreased ornithine production, a precursor for citrulline.

Conclusion: These results confirm and expand the bacterial associations linked to RA progression, which involves multiple taxa at both genus and strain level and is associated with the underlying risk profile of an individual. As with previous literature, an overabundance of Prevotellaceae was identified in those at-risk of RA compared to healthy controls. Strain specific fluctuations appears to be the hallmark of Prevotellaceae associations within the RA at-risk phase. Future work will investigate how niche bacterial specialisation to the underlying risk profile may subsequently affect the abundance threshold required for a bacterial impetus in RA related autoimmunity.

TNF-Stimulated Production of IL-15 by Fibroblast-Like Synoviocytes Mediates Human Resident Memory T Cells Development in Synovial Organoid Model

Margaret Chang[1], Maryrose Hahn[2], Madison Mangin[1], Brian Wauford[1], Rachel Blaustein[3], Lauren Henderson[1], Kevin Wei[4] and Peter Nigrovic[1], [1]Boston Children's Hospital, Boston, MA, [2]Division of Immunology, Boston Children's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA) are chronic autoimmune diseases that tend to flare repeatedly in the same joints, displaying joint-specific memory. We have identified CD8+ tissue resident memory T cells (TRM) in human arthritic joints and demonstrated in murine models that these long-lived TRM remain in synovium

during remission and act as key mediators of arthritis flares. However, the factors that drive TRM formation in the synovium have not been characterized. IL-15 supports CD8 T cell activation and TRM development in other tissues. It is also elevated in synovial fluid and is expressed in the synovium in RA. Here, we explored the inflammatory drivers of IL-15 production by synovial stromal cells and investigated the role of IL-15 in synovial TRM development.

Methods: Fibroblast-like synoviocytes (FLS) isolated from human RA synovium and human umbilical vein endothelial cells (HUVEC) were grown in tissue culture and stimulated with TNF, IL-1beta, IL-6 or IFNgamma for 48 hours. Cells were collected, and IL-15 mRNA expression was assessed by quantitative PCR. To study human synovial TRM development, we developed a 3D synovial organoid that recapitulates the synovial stromal structure utilizing FLS and HUVEC encapsulated in Matrigel. CD8 memory T cells were isolated from peripheral blood of healthy donors and co-cultured with the synovial organoid for 2-3 weeks to generate TRM. TRM development was validated by cell surface markers, gene expression profile, free fatty acid uptake and migratory response to tissue egress signals. TNF was added to the culture media for 3-5 days to simulate inflammation, then removed for the duration in culture. IL-15 receptor alpha (IL-15Ra) or CD122 blocking antibodies were added to T cells 30 minutes prior to the formation of organoids, and they were replenished twice a week to inhibit IL-15 activity. After 3 weeks, cells were dissociated from the organoids and assayed for TRM surface phenotype by flow cytometry.

Results: TNF stimulation dramatically increased IL-15 gene expression in FLS by 30-fold, while it had a smaller effect on HUVEC (5-fold). IL-1beta also induced a 6-fold change in IL-15 expression in FLS, but IL-6 and IFNgamma did not. Culturing CD8 memory T cells in synovial organoids, particularly with TNF, supported the development of cells with TRM surface phenotype (CD45RO+CD62L-CCR7-HLADR-CD25-CD103+CD49a+) and TRM gene expression patterns. These TRM also had enhanced free fatty acid uptake, and they did not migrate across a transwell membrane in response to CCL21, further confirming TRM functionality. Inhibition of IL-15 activity with IL-15Ra or CD122 blocking antibodies reduced TRM development.

Conclusion: We developed a novel model for studying human synovial TRM by differentiating TRM within 3D synovial organoids composed of stromal cells from human RA synovium. We show that TNF preferentially induces FLS to produce IL-15 and demonstrate that IL-15 activity mediates TRM development in this synovial organoid system. As synovial TRM facilitate arthritis flares, effective methods to impede synovial TRM development may be valuable for durable disease control.

Dual Inhibition of TNF-α and OX40L on Synovial Inflammation and Osteoclastogenesis in Rheumatoid Arthritis

Hee Sung Kwon[1], Mi Hyeon Kim[2], Jeoung Yeon Kim[2], Seon Uk Kim[2], Hae Rim Kang[1], Seo Yoon Ban[3], Gyong Sik Ha[4], Chung Min Lee[4], Jeong Seok Lee[5] and Eun Young Lee[2], [1]Interdisciplinary Program in Cancer Biology, Integrated Major in Innovative Medical Science, Seoul National University, Seoul, South Korea, [2]Seoul National University College of Medicine, Seoul, South Korea, [3]Department of Cancer biology, Graduate School of College of Medicine, Seoul National University, Seoul, South Korea, [4]Research institute, IMBiologics Corp, Suwon, South Korea, [5]Graduate School of Medical Science and Engineering, Korea Advanced Institute of Science and Technology, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory disease that leads to progressive cartilage and bone destruction. TNF superfamily member OX40 ligand (OX40L; CD252) is expressed specifically to synovial tissue and OX40/OX40L interaction is contributed to the development of T-cell mediated immunity in RA. In collagen-induced arthritis mouse model, it was demonstrated that blockade of TNF-α or OX40L significantly ameliorated disease activity. We present targeting both TNF-α and OX40L is superior to single treatment in fibroblast-like synoviocytes (FLS) invasiveness and osteoclast activation which are crucial RA pathology.

Methods: RA FLS were used from passage 4-6. FLS were stimulated with TNF-α (10ng/ml) for 2h and then treated with single TNF-α inhibitor (50nM), OX40L inhibitor (50nM) or IMB-101, a TNF-α/OX40L bispecific antibody (50nM) for 24hrs. Differential expression of RA FLS genes were analyzed by RT-PCR. For osteoclast differentiation assay, FLS were stimulated with TNF-α (10ng/ml) for 3 days, after which CD14+ monocytes were co-cultured with the IMB-101 (50nM) in the presence of M-CSF (20ng/ml) for 3 weeks. Osteoclasts were evaluated by tartrate-resistant acid phosphatase (TRAP) staining.

Results: OX40L was increased in TNF- α induced RA FLS compared to unstimulated RA FLS ($p< 0.05$) (n=7). RT-PCR analysis revealed significant reduction of IL-6, IL-1β, CCL2, CX3CL1, MMP-1, MMP-3, ICAM-1, RANKL, VEGF and HIF1-α in TNF-α stimulated RA FLS after IMB-101 or anti TNF treatment (n=4). Among these genes, MMP-3, RANKL and VEGF were significantly reduced in dual inhibition of TNF-α and OX40L than single target therapies. In co-culture system of RA FLS and CD14+ monocytes for osteoclast formation, IMB-101 decrease the number of TRAP-positive multinucleated cells over TNF-α inhibitor.

Conclusion: These results indicated that dual inhibition of TNF-α and OX40L axis simultaneously are associated with reduction of invasiveness in synovial fibroblast and joint destruction in RA.

Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Periostin is an extracellular matrix protein that contributes to the development and repair of lung tissue [1]. Previous works have described periostin as a key factor in the aberrant evolution of the airways and parenchymal fibrosis, being involved in the pathophysiology of different chronic lung diseases such as interstitial lung diseases (ILD)

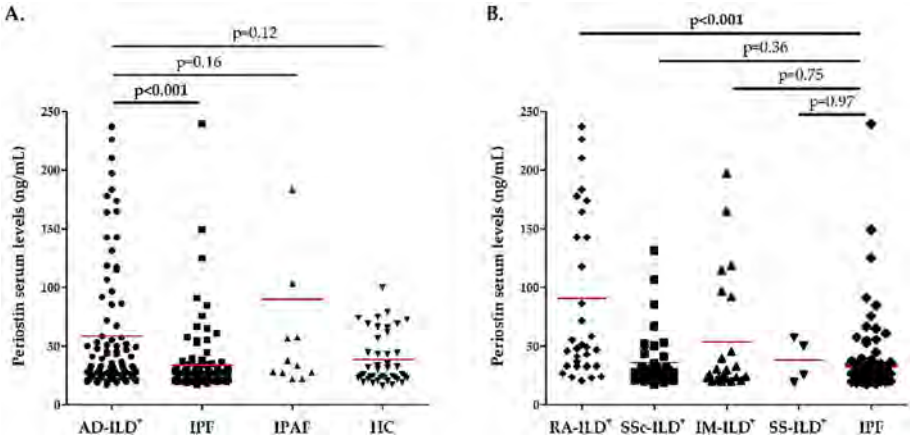

Figure 1. Role of periostin in the accurate diagnosis of AD-ILD+. A. Differences in periostin serum levels between patients with AD-ILD+ and those with IPF and IPAF, as well as HC; B. Differences in periostin serum levels between patients with AD-ILD+ stratified by the underlying AD and those with IPF. AD: autoimmune diseases; ILD: interstitial lung disease; IPF: idiopathic pulmonary fibrosis; IPAF: interstitial pneumonia with autoimmune features; HC: healthy controls; RA: rheumatoid arthritis; SSc: systemic sclerosis; IM: inflammatory myopathies; SS: sjögren syndrome. Significant results are highlighted in bold.

[1-3]. In this sense, ILD is one of the most frequent manifestations and the main cause of death in patients with autoimmune disease (AD), particularly in rheumatoid arthritis (RA), systemic sclerosis (SSc), inflammatory myopathies (IM) and Sjogren's syndrome (SS) [4]. However, the accurate diagnosis of AD-ILD$^+$ often remains a challenge due partially to the similarity with other diseases such as idiopathic pulmonary fibrosis (IPF) and interstitial pneumonia with autoimmune features (IPAF) [4]. Accordingly, this work aimed to elucidate the role of periostin in the accurate diagnosis of AD-ILD$^+$, as well as its relationship with molecules involved in the pathological process of vasculopathy and fibrosis typical of AD-ILD$^+$.

Methods: Peripheral venous blood was collected from a total of 98 patients with AD-ILD$^+$, a group composed of patients with RA-ILD$^+$ (n=33), SSc-ILD$^+$ (n=38), IM- ILD$^+$ (n=23) and SS-ILD$^+$ (n=4). Moreover, we recruited different comparative groups: 105 IPF patients, 11 IPAF patients and 43 healthy controls (HC). Serum levels of periostin were measured by enzyme-linked immunosorbent assay (ELISA). Additionally, serum levels of Krebs von den Lungen 6 (KL-6); interleukin 6 (IL-6); endothelin-1 (ET-1); vascular endothelial growth factor (VEGF) and intercellular adhesion molecule 1 (ICAM-1) were measured by ELISA.

Table 1. Relationship in AD-ILD$^+$ patients of serum levels of periostin with other relevant molecules involved in AD-ILD$^+$ pathophysiology.

	Periostin (ng/mL)	
Variable	*r*	*p*
KL-6 (U/mL)	0.10	0.55
IL-6 (pg/mL)	0.05	0.65
ET-1 (pg/mL)	0.13	0.31
VEGF (pg/mL)	**0.28**	**0.01**
ICAM-1 (ng/mL)	-0.07	0.57

AD: autoimmune diseases; ILD: interstitial lung disease; KL-6: Krebs von den Lungen 6; IL-6: interleukin 6; ET-1: endothelin-1; vascular endothelial growth factor; ICAM-1: intercellular adhesion molecule 1. Significant results are highlighted in **bold**.

Results: Patients with AD-ILD$^+$ exhibited significantly higher periostin serum levels than IPF patients ($p< 0.001$, **Figure 1A**), whereas no difference was observed in relation to IPAF patients and HC (**Figure 1A**). Specifically, RA-ILD$^+$ patients showed increased levels of periostin in relation to IPF patients ($p< 0.001$, **Figure 1B**). However, similar levels of periostin were found in patients with SSc-ILD$^+$, IM-ILD$^+$ as well as SS-ILD$^+$ and those with IPF (**Figure 1B**). Furthermore, a positive correlation was discovered between periostin serum levels and VEGF serum concentrations in AD-ILD$^+$ patients ($p=0.01$, **Table 1**). Nevertheless, periostin serum levels did not correlate with KL-6, IL-6, ET-1 and ICAM-1 levels in AD-ILD$^+$ patients (**Table 1**).

Conclusion: Our findings suggest that circulating periostin could be considered a useful biomarker to discriminate RA-ILD$^+$ from IPF, contributing to the accurate diagnosis of RA-ILD$^+$. Furthermore, this work indicates a relationship of periostin with vascular dysfunction in AD-ILD$^+$. **References**: [1] Cell Mol Life Sci.2017;74(23):4305-4314; [2] Respir Investig.2015;53 (2):73-81; [3] PLoS One.2017;12(3):e0174547; [4] Expert Rev Clin Immunol.2018;14(1):69-82. *Personal funds, VP-C: PI18/00042(ISCIII-ERDF); JB-L:FI22/00020(ISCIII-ESF); MSM-G:TRANSVAL22/01(IDIVAL); RL-M: CPII21/00004 (ISCIII-ESF)*.

Rheumatoid Arthritis-Specific Rheumatoid Factors Develop in Some COVID-19 Patients

Adam Titi[1], Ryan Adyniec[2], Nat Murren[1] and Miriam Shelef[1], [1]University of Wisconsin, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid factors (RFs), antibodies canonically known to bind two conformational epitopes of IgG Fc, are a hallmark of rheumatoid arthritis (RA) but also can arise in other inflammatory conditions and infections. In turn, infections, such as respiratory infections, correlate with RA development. Recently, RFs with reactivity to citrullinated and homocitrullinated IgG peptides were discovered in RA, but were not found in other autoimmune diseases. Similar to other infections, RFs have been reported in COVID-19, but RA-specific RFs, which perhaps could suggest a greater risk for RA, have not been evaluated. The purpose of this study was to determine if RA-specific RFs develop post-COVID-19.

Methods: Sera from adults with COVID-19 (~5 weeks post-symptom resolution), with seropositive RA, and age- and sex-matched controls (n=20) were used in ELISA to evaluate IgA, IgM, and IgG binding to the native, citrullinated (B), and homocitrullinated (J) forms of peptides beginning at amino acid positions 11, 80, 167, 202, 219, and 289 of IgG1 (Uniprot P01857) with results compared to controls by Kruskal-Wallis with Dunn's multiple comparisons tests. Also, using a threshold based on the highest control subject Ig binding signal, the percent positive for each antibody/peptide combination was compared by Fisher's exact test for RA and COVID-19 versus controls. $P< 0.05$ was considered significant.

Results: As expected, IgG binding to 75% of the citrulline- or homocitrulline-containing peptides and IgA binding to 50% of these peptides was increased in RA compared to controls. No peptides had increased IgM binding in RA. Also, no peptides had increased IgA, IgM, or IgG binding in COVID-19, although there was a trend towards increased IgG binding to IgG1-80J in COVID-19 (p=0.056). When analyzed based on percent positivity, significantly more COVID-19 subjects were positive for IgG binding to IgG1-80J and IgG1-219J compared to controls (45% and 30% vs. 0%, respectively). Also, significantly more COVID-19 subjects were positive for IgA binding to IgG1-11, IgG1-167, and IgG1-167J compared to controls (30%, 25%, and 25% vs 0% respectively). Many of these IgA and IgG binding values were minimally elevated in COVID-19, but some COVID-19 subjects had Ig binding >10x higher than controls for these peptides.

Conclusion: While RFs that bind to citrulline- and homocitrulline-containing IgG epitopes are primarily restricted to RA, some COVID-19 patients generate antibodies that bind to a few of these epitopes in the native or homocitrullinated form. Longitudinally evaluating reactivity against these IgG and related epitopes, as well as joint symptoms, could provide important insights into how immune tolerance is regained or further lost on a path towards RA following a viral infection.

Integrated Analysis of Rheumatoid Arthritis (RA) Fibroblast-like Synoviocytes (FLS) Transcriptome and Chromatin Accessibility Identifies Mechanisms Associated with Location-specific Disease Severity

Eunice Choi[1], Camilla R. L. Machado[2], David Boyle[1], Wei Wang[1] and Gary Firestein[2], [1]University of California San Diego, La Jolla, CA, [2]University of California San Diego, San Diego, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Mechanisms responsible for the distribution and severity of joint involvement in RA are not known. To explore whether site-specific FLS biology might contribute to location-specific synovitis and explain the predilection for hand (wrist/metacarpal phalangeal joints) in RA, we generated transcriptomic and chromatin accessibility data from FLS to define the transcription factors (TFs) and pathways unique to each location.

Methods: FLS were derived from hand, knee and hip surgical samples. Whole genome ATAC-seq and RNA-seq were obtained from 10 hand, 10 hip, and 10 knee FLS under unstimulated (unstim) or stimulated conditions (TNF [50 ng/ml for 6 h]). Differentially expressed genes (DEGs) were identified using the Wilcoxon test. TF motifs were queried within promoter/enhancer open chromatin. The assays were integrated using Taiji (Nat Commun 2022;13:6221) and Personalized PageRanks were quantified. Cell growth was assayed using MTT in medium and PDGF-stimulated FLS on day 7.

Results: Multiple DEGs between joints were identified in their respective FLS (Table 1A). Hand vs knee or hand vs hip FLS comparisons revealed increased expression of genes associated with proliferation/inflammation (eg, *TLR2, VCAM1, MMP13*) and decreased cell-cycle inhibitors (eg, *CDKN1A, CDKN1C, CDKN2D*) in hand. Pathway analysis revealed greatest enrichment for hand vs hip and included proinflammatory (eg, TNFs bind physiological receptors) and proliferative (eg, Integrin cell surface interactions) pathways (Table 1A). Taiji distinguished joint-specific TFs and identified greater PageRanks

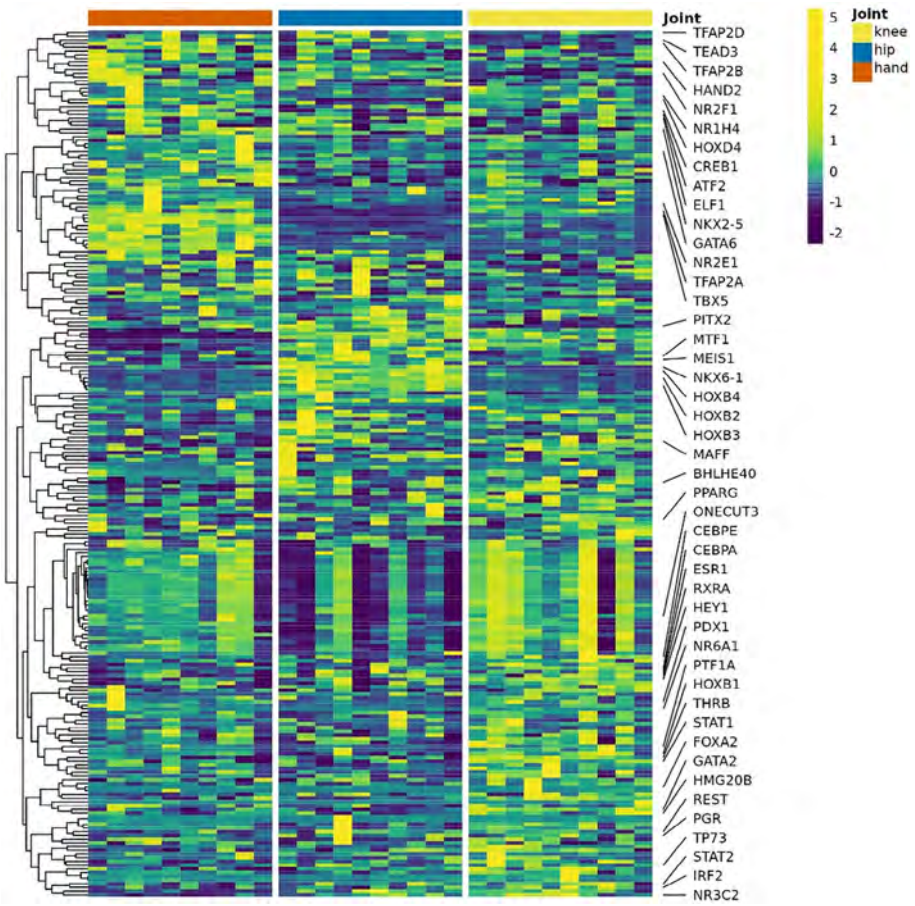

Fig 1. PageRanks of top differential TFs (Wilcoxon, top TFs selected by p-value for each pairwise comparison) for hand, knee and hip joint-derived FLS cultured in medium. Columns are colored by joint annotation. TF PageRank patterns are distinct for the 3 joint locations and involve key regulators of growth, differentiation and inflammation. Labeled TFs are TFs enriched in Reactome or Gene Ontology (GO) pathways. Unlabeled rows are not pathway enriched.

for key TFs (eg, *ATF2, CREB1*) in hand (Fig 1, Table 1A). Pathway analysis revealed greatest enrichment for hand vs hip and included proliferation/inflammation pathways (eg, MAPK activation, PIP3 activates AKT signaling) (Table 1A). The predicted differences in proliferation were confirmed in a cell growth assay showing that hand FLS proliferation was greater than hip or knee after PDGF-stim (Hand/knee or hip ratio=1.4; P< 0.001). The joint-specific transcriptome differences for hand vs hip

Table 1 A. Pairwise (hand vs hip, hand vs knee, hip vs knee) DEGs (Wilcoxon, p<0.05, abs log2FC > 0.58) were identified. Reactome and GO identified significantly enriched pathways using differentially expressed genes (p<0.05). Pairwise differential TFs were identified using the TF PageRank scores (Wilcoxon, p<0.05). Pathway enrichment for differential TFs were conducted as for the transcriptome. B. Responses to TNF stimulation were evaluated for each joint location and compared TNF-stim to unstim. DEGs between unstim and TNF-stim FLS for a particular joint location were identified (Wilcoxon, p<0.05, abs log2FC > 0.58). A similar process identified TNF-stim vs unstim differential TFs using the TF PageRank scores (Wilcoxon, p<0.05). Pathway enrichment for DEGs and differential TFs were conducted as part A.

A.	Between joint location comparisons (unstim)				B.	Within joint location comparisons (unstim vs TNF-stim)			
	#DEGs	#DEG-pathways	#TFs	#TF-pathways		#DEGs	#DEG-pathways	#TFs	#TF-pathways
Hand vs Hip	868	53	115	40	Hand	2171	103	107	89
Hand vs Knee	1539	36	73	13	Knee	2902	82	127	85
Hip vs Knee	973	3	140	13	Hip	2289	70	102	52

and knee were enhanced by TNF-stim. DEGs within a particular joint between unstim vs TNF-stim revealed greatest pathway enrichment in hand (Table 1B). TNF-stim hand FLS had unique induction of proliferation/inflammation genes (eg, *TANK, KSR1, CDC14A*) and pathways (eg, Diseases of signal transduction by growth factor receptors/second messengers, Regulation of necroptotic cell death), and these pathways were not observed in TNF-stim hip or knee. TNF-stim in hand FLS had increased PageRanks of key inflammatory TFs (eg, *RELA, STAT3*) and pathways (eg, MAPK activation, Signaling by ALK in cancer) that were not observed for hip/knee.

Conclusion: Integrated analysis of FLS identified joint-specific patterns of gene expression and TFs, including pathway enrichment in hand FLS associated with inflammation and proliferation. These differences are more prominent after TNF stimulation. Hand joints are commonly earlier and are more severe in RA. Distinctive joint-specific FLS biology associated with hand-specific pathways might explain the distribution and severity of joints involved in RA.

Gut Microbiota and Permeability Biomarkers for Diagnosis and Prognosis in Rheumatoid Arthritis Associated Interstitial Lung Disease

José Lisbona-Montañez[1], Patricia Ruiz-Limon[2], Arkaitz Mucientes[3], Natalia Mena Vazquez[4], Isabel Moreno-Indias[3], SARA MANRIQUE[5], Laura Cano-García[6], Rocío Redondo-Rodríguez[6], Francisco J tinahones[3] and Antonio Fernandez-Nebro[7], [1]Universidad de Málaga, Departamento de Medicina y Dermatología, Moclinejo, Spain, [2]IBIMA Plataforma BIONAND, Cordoba, Spain, [3]IBIMA Plataforma BIONAND, Málaga, Spain, [4]IBIMA, Málaga, Spain, [5]Division of Rheumatology, Hospital Regional Universitario Carlos Haya, Malaga, Spain, [6]Division of Rheumatology, Hospital Regional Universitario Carlos Haya, Málaga, Spain, [7]Hospital Regional Universitario de Málaga, Malaga, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Etiology and Pathogenesis Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Gut microbiota has been related to rheumatoid arthritis (RA), inflammation, and it's severity. Interstitial lung disease (ILD) is the most frequent non-pleural pulmonary manifestation and causes high morbidity and mortality in RA patients. However, the association between gut microbiota and RA associated ILD (RA-ILD) is still unknown. In the same way, there are currently no useful biomarkers for the diagnosis and prognosis of RA-ILD. Therefore, the objective of the present study is to analyze gut microbiota and permeability in RA-ILD patients and evaluate it´s association with RA-ILD and pulmonary progression.

Methods: Nested case-cohort study of 2 prospective cohorts of patients with RA with and without ILD. The cohorts were matched for age, sex, and time of RA evolution. All cases systematically underwent high-resolution computed tomography (HRCT) and pulmonary function testing (PFT) on the diagnosis of ILD. ILD was defined according to lung biopsy or HRCT based on the standard criteria of the American Thoracic Society/European Respiratory Society. Pulmonary progression was defined as the worsening of the FVC > 10% or DLCO > 15%. Gut microbiota was measured by the 16S rRNA gene and the sequences were processed using the Quantitative Insights into Microbial Ecology (QIIME2). Serum lipopolysaccharide-binding protein (LBP) and lipopolysaccharide (LPS) were measured as markers of gut permeability. Demographic, clinical, laboratory, and treatment-related data were recorded. Disease activity was measured by Disease

VARIABLE	RA-ILD n=35	RA without ILD n=35	P-value
Age in years, mean (SD)	69.7 (9.3)	66.6 (7.0)	0.130

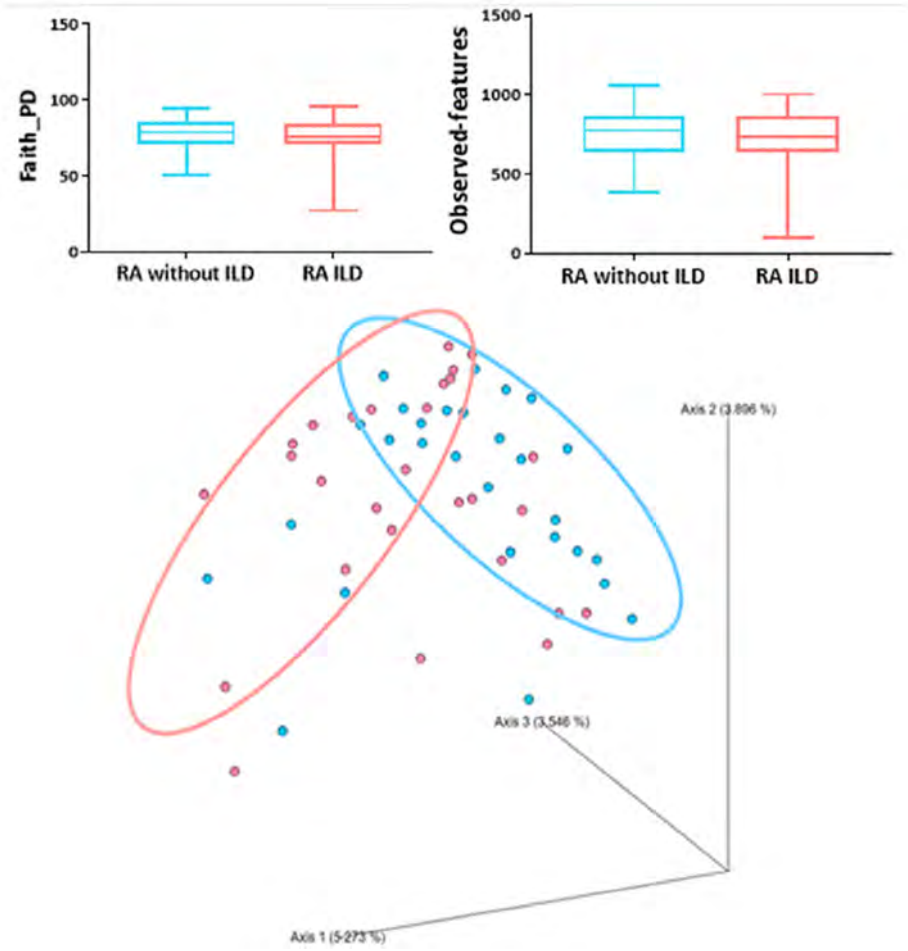
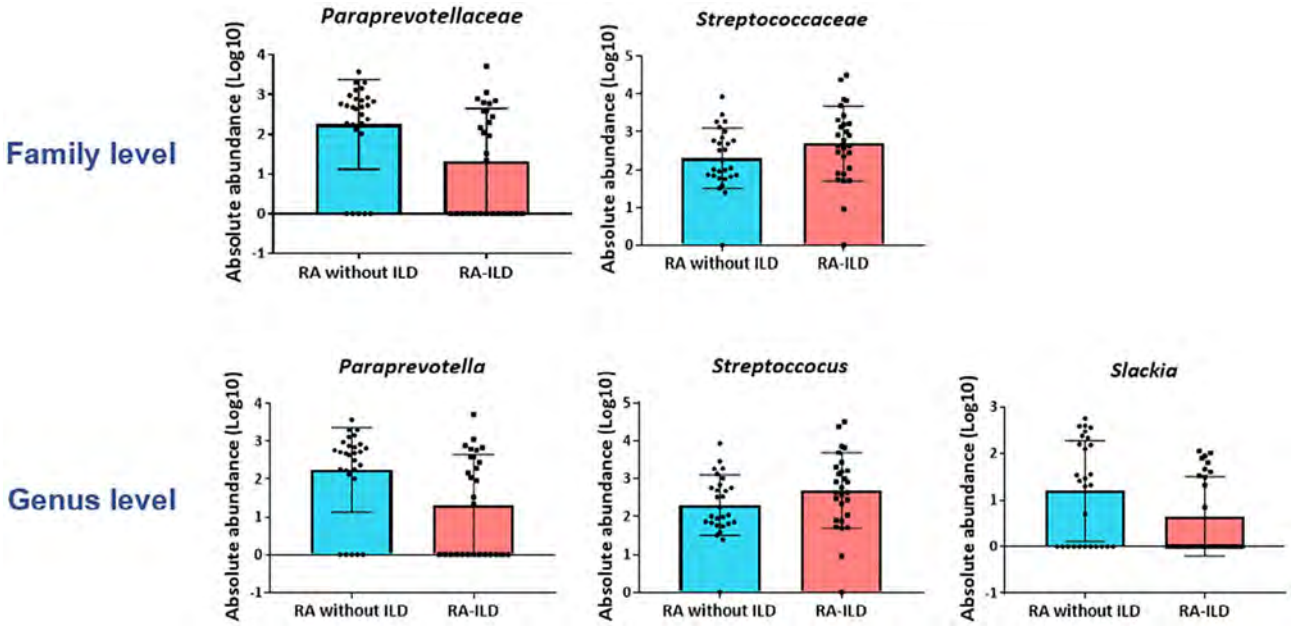
Smoking			0.760
Never smoked, n (%)	17 (48.6)	18 (51.4)	
Ex-smoker, n (%)	10 (28.6)	8 (22.9)	
Active smoker, n (%)	8 (22.9)	9 (25.7)	
Time since diagnosis RA, months, median (IQR)	149.8 (93.3-245.5)	133.7 (67.8-204.2)	0.384
Time since diagnosis of ILD, mean (SD)	66.1 (47.2)	-	-
FR+ (>10), n (%)	33 (94.3)	31 (88.6)	0.393
ACPA+ (>20), n (%)	32 (91.4)	31 (88.6)	0.690
Erosions, n (%)	21 (60.0)	19 (55.6)	0.705
DAS28-ESR, mean (SD)	3.1 (0.9)	2.6 (0.9)	**0.032**
HAQ, mean (SD)	1.2 (0.6)	0.8 (0.6)	**0.003**
FVC mean (SD)	63.0 (17.1)	83.4 (4.4)	**<0.001**
DLCO, mean (SD)	61.0 (15.2)	85.9 (7.9)	**<0.001**
UIP, n (%)	29 (82.9)	0 (0.0)	**<0.001**
NSIP, n (%)	6 (17.1)	0 (0.0)	**<0.001**

Clinical and demographic characteristics: Abbreviations. ACPA: anticitrullinated peptide antibody; DAS28: Disease activity score; DLCO: diffusing capacity of the lung for carbon monoxide; DMARDs: disease-modifying antirheumatic drug; ESR: erythrocyte sedimentation rate; FEV1: forced expiratory volume in the first second; FVC: forced vital capacity; HAQ: Health Assessment Questionnaire; HCRT: high-resolution computed tomography; NSIP: nonspecific interstitial pneumonia; RF: rheumatoid factor; SD: standard deviation; UIP: usual interstitial pneumonia.



Microbiota analysis: Alpha diversity (above) and Beta diversity (bottom). To compare the populations of both groups, the Jaccard similarity index was used and significant differences (p=0.017) were observed between both groups. Blue dots: RA without ILD; Pink dots: RA-ILD.



Gut microbiota profile: Graphs represent the families and genera with statistically significant differences. At the family level, Paraprevotellaceae (p=0.007) was significantly decreased, while Streptococcaceae (p=0.050) was significantly increased in RA-ILD patients compared to RA patients without ILD. At the genus level, Paraprevotella (p=0.007) and Slackia (p=0.041) were significantly decreased, while Streptococcus (p=0.050) was significantly increased in RA-ILD patients compared to RA patients without ILD.

Activity Score-28 with Erythrocyte Sedimentation Rate (DAS28-ESR), and the function using the Health Assessment Questionnaire (HAQ). We performed a descriptive analysis and Cox regression analysis to identify factors associated with ILD.

Results: 35 RA-ILD and 35 RA without ILD patients were included. After a mean (SD) period of 66,1 (47,2) months, pulmonary progression criteria was observed in 13 patients (37.1%). Compared with controls, RA-ILD had greater values of DAS28-ESR (p=0.032) and higher HAQ scores (p=0.003). They also had higher levels of serum LPS (p = 0.007) and more abundance of *Streptococcus* genus (p = 0.087), as well as a lower abundance of *Slackia* (p = 0.022) and *Paraprevotella* genera (p = 0.082*)*. RA-ILD patients with pulmonary progression had a higher abundance of *Streptococcus* genus (p = 0.090) and a lower abundance of *Slackia* genus. In Cox regression analysis, the moderate-high activity of DAS28-ESR (HR [IC 95%], 3.53 [1.20-6.98]; p=0.017), LPS (HR [IC 95%], 1.12 [1.02-1.23]; p=0.018) and the *Slackia* genus (HR [IC 95%], 0.98 [0.97-0.99]; p=0.010) were associated with RA-ILD.

Conclusion: RA-ILD patients showed increased gut permeability and also displayed a different pattern of gut microbiota associated with ILD diagnosis and prognosis. These findings may enable the discovery of potential RA-ILD biomarkers.

The Peptidyl Arginine Deiminase Inhibitor BB-CLA Decreases the Inflammatory and Fibrotic Responses in Macrophages and Rheumatoid Arthritis Synovial Fibroblasts Exposed to Fibrinogen Modified with Malondialdehyde-Acetaldehyde Adduct and Citrulline

Jack Mordeson[1], Nozima Aripova[1], Michael Duryee[1], James O'Dell[1], Bryant England[1], Daniel Anderson[1], Ted R Mikuls[2] and Geoffrey Thiele[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Etiology and Pathogenesis Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Peptide citrullination and adduction with malondialdehyde-acetaldehyde adduct (MAA) are post-translational modifications involved in the pathogenesis of rheumatoid arthritis (RA). Anti-cyclic-citrullinated peptide antibodies are >90% specific for the diagnosis of RA. Our laboratory has shown co-localization of MAA with citrullinated proteins in RA synovial fluid, elevated anti-MAA antibodies in RA patients, and pro-inflammatory and pro-fibrotic responses to MAA-modified antigens by macrophages *in vitro*. In addition, macrophages demonstrate increased expression of peptidyl arginine deiminase-2 (PAD2), an isozyme of PAD, in response to these MAA-adducted and citrullinated proteins. PAD catalyzes protein citrullination and may mediate the immunogenic transformation of synovial proteins and subsequent auto-antibody formation in

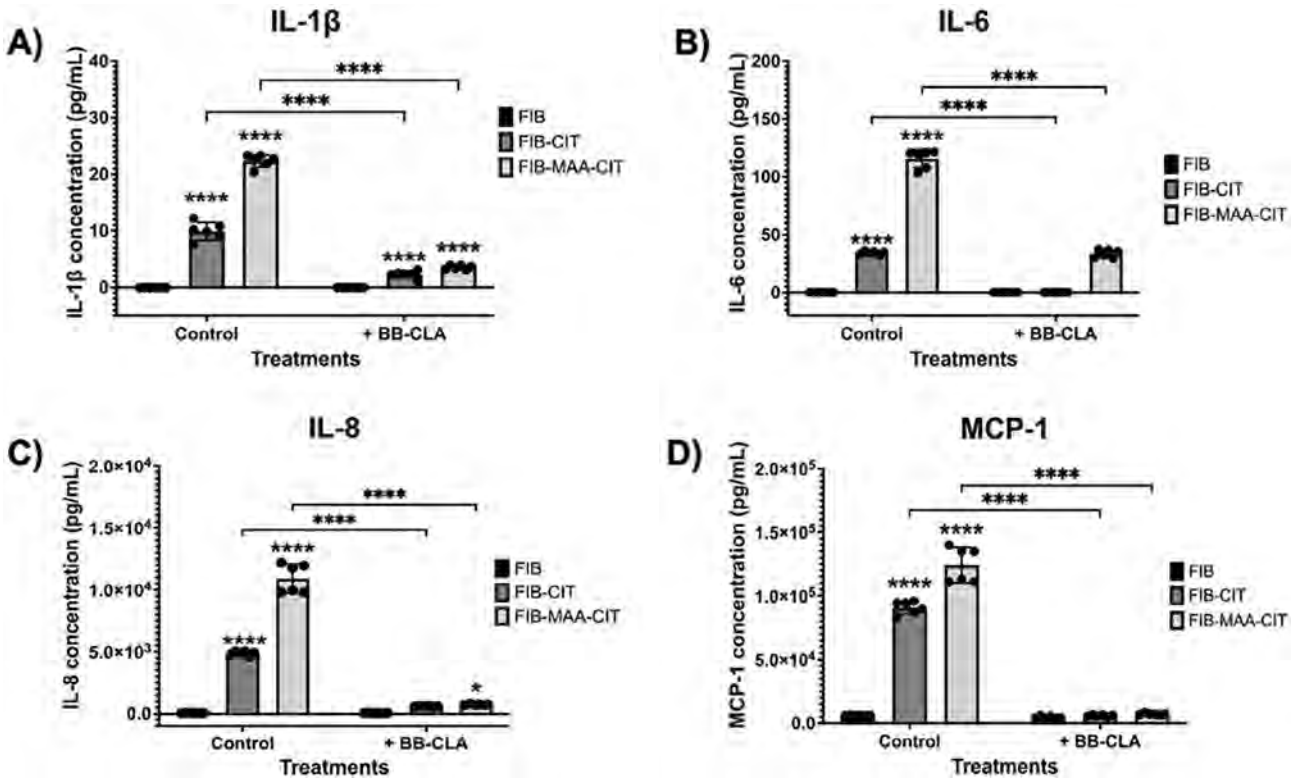

Figure 1. Inflammatory cytokines from stimulated U-937 cells. U-937 cells were stimulated with native and modified fibrinogen for 48 hours in the presence and absence of BB-CLA. IL-1β (A), IL-6 (B), IL-8 (C), and MCP-1 (D) levels were measured via ELISA. ****p<0.001.

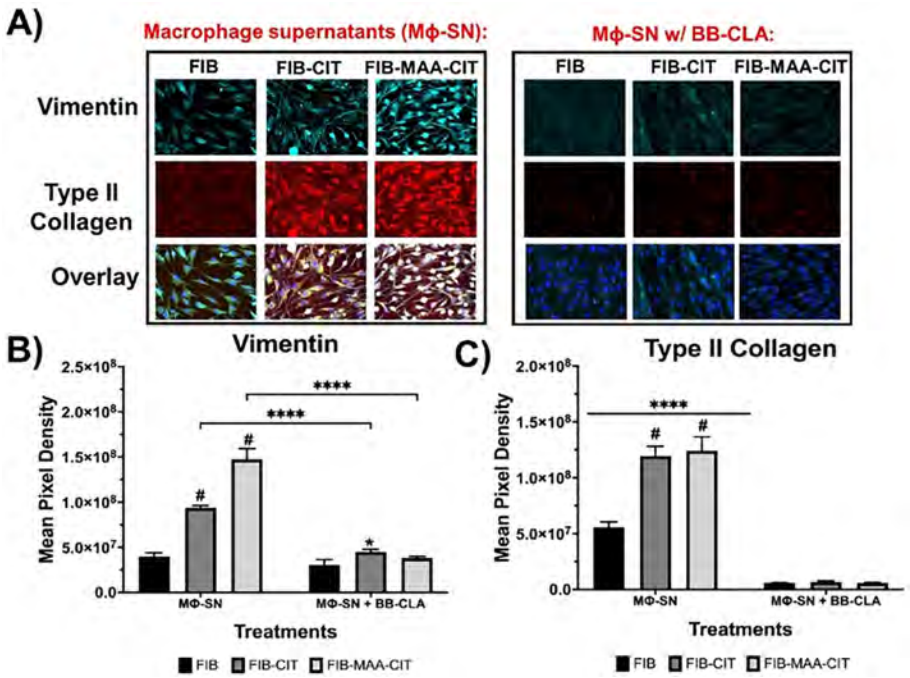

Figure 2. Fibrotic markers from stimulated HFLS-RA cells. U-937 supernatants were utilized for stimulation of HFLS-RA cells. Images were recorded following immunofluorescent staining with anti-vimentin and anti-type II collagen antibodies. ****p<0.001, #p<0.05.

RA. Here, we determine whether inhibition of PAD effects inflammatory and fibrotic markers in macrophages and RA human fibroblast-like synoviocytes (HFLS-RA) in response to stimulation with MAA and citrulline (CIT)-modified fibrinogen (FIB).

Methods: U-937 monocyte cell line was differentiated into activated macrophages by exposure to LPS, and subsequently stimulated with; unmodified FIB, FIB-CIT, or FIB-MAA-CIT in the presence (treatment group) and absence (control group) of BB-CLA (a general PAD inhibitor; PADi) for 48 hours. Supernatants collected from the media were assessed by ELISA for the pro-inflammatory cytokines; interleukin-1b (IL-1b), interleukin-6 (IL-6), interleukin-8 (IL-8), and monocyte chemoattractant protein-1 (MCP-1). HFLS from RA patients were stimulated with treatment and control supernatants from the antigen-stimulated macrophage cultures and assessed via immunofluorescent staining for the fibrotic markers vimentin and type II collagen.

Results: As previously reported, the modification of FIB with CIT and or MAA-CIT statistically increases the concentrations of the pro-inflammatory cytokines measured (Figure 1 A-D, Control). The effect of PAD inhibition on the inflammatory cytokine levels was a decrease in the secretion by stimulated macrophages of these cytokines (Figure 1 A-D, +BB-CLA) back to almost baseline levels. Examination of the HFLS cells stimulated with supernatants from macrophages activated with FIB-CIT or FIB-MAA-CIT showed an increase in both vimentin and Type II Collagen production that was significantly elevated when compared to FIB supernatant stimulation (Figure 2 A-C).

Conclusion: This study provides insight into the degree to which inflammatory and fibrotic responses from macrophages and HFLS to CIT and MAA-CIT modified fibrinogen may be PAD-mediated. Therefore, these observations strongly suggest that CIT and MAA-CIT modification of proteins play a role in the inflammatory and fibrotic responses observed in cells associated with RA development and/or progression. Additionally, they suggest that PAD inhibition is an obvious target for therapeutic intervention.

Macrophage Migration Inhibitory Factor May Help Maintain Tight Junctions in the Gut by Enhancing Occludin Expression

Shaghayegh Foroozan[1] and Nigil Haroon[2], [1]University Health Network/University of Toronto, Toronto, ON, Canada, [2]University of Toronto, University Health Network, Schroeder Arthritis Institute, Department of Medicine/Rheumatology, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial Spondyloarthritis (AxSpA) is a chronic inflammatory disease with multifactorial origins, primarily affecting the musculoskeletal system. Gut inflammation is seen in the majority of AxSpA patients, with 60% having microscopic changes and 10% with overt Inflammatory Bowel Disease (IBD). Over the years many pathways and cell populations have been linked to the pathogenesis of gut inflammation in AxSpA. Macrophage migration inhibitory factor (MIF) plays a critical role in the pathogenesis of AxSpA. Over-expression of MIF in a mouse model of SpA (SKG mice) causes major clinical features of AxSpA while blocking or depletion of MIF significantly suppresses these symptoms. However, the role of MIF in gut inflammation in AxSpA is unknown. We hypothesized that MIF is a key player driving gut inflammation in AxSPA.

To study the effect of MIF on gut homeostasis and inflammation in the SKG mouse model of spondyloarthritis

Methods: A total of 12 SKG control mice, 11 SKG mice treated with curdlan, 9 SKG-MIF Knock Out (KO), and 6 SKG-MIFKO mice treated with curdlan that were all 16 weeks old were used for this study. H&E slides were prepared for histopathology assessment on formalin-fixed paraffin-embedded (FFPE) blocks of ileum tissue (2 individuals scored the samples independently and were blinded to the group). Immunohistochemistry (IHC) was performed for occludin and MPO antibody was used to assess neutrophil (a major source of MIF) infiltration. Kruskal–Wallis test was used to analyze the difference between the 4 groups.

Results: We observed significantly increased inflammation levels in the ileum of SKG+curdlan mice compared to SKG control mice (Fig1a). SKG-MIFKO+curdlan mice did not have a significant benefit of reduction in inflammation levels. Interestingly, even without curdlan treatment, MIFKO mice showed inflammation in the gut. SKG-MIFKO mice (with and without curdlan) developed a disruption of ileal epithelium. There was a significant reduction in occludin expression compared to SKG control mice, suggesting a disruption of tight junctions (Fig1b). MPO expression was significantly elevated in SKG+curdlan and SKG-MIFKO+curdlan groups. However, although not significant, it seems that the MPO expression is lower in the SKG-MIFKO+curdlan compared to SKG+curdlan mice.

Conclusion: Knocking out MIF in SKG mice has shown improvement in AxSpA symptoms. However, based on our findings, MIF seems to have a protective role in the gut of SKG mice unlike what we see in joints. The absence of MIF leads to decreased expression of occludin. These findings together suggest that MIF is essential for the integrity of the gut epithelial barrier in the SKG mouse model of SpA. If this effect on the tight junction is directly related to MIF or through changes in type 3 immune response needs to be investigated.

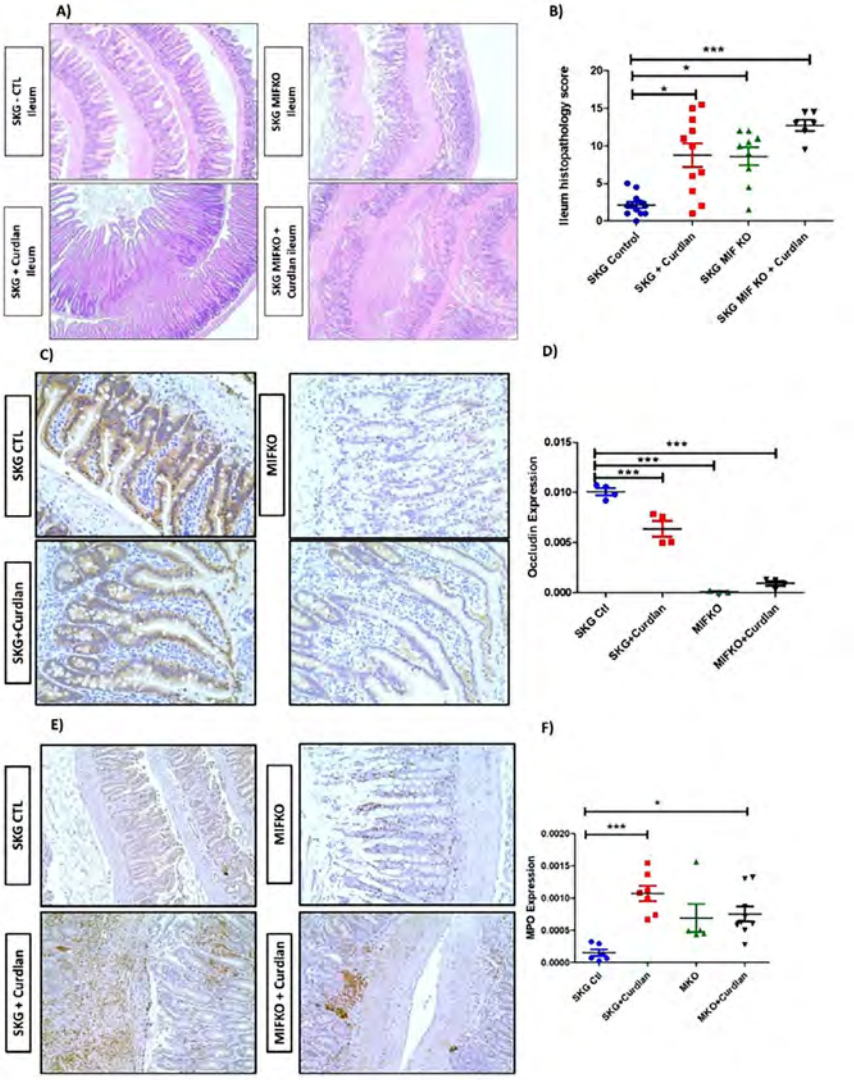

Figure1. A&B) Histopathology of ileum from SKG, SKG+Curdlan, SKG-MIFKO and SKG-MIFKO+Curdlan. C&D) IHC staining for occludin. E&F) IHC staining for MPO.

The Effect of the Inflamed Joint Microenvironment on Endothelial Cell Function

Aenea Brugman[1], Órla Tynan[2], Dumitru Anton[3], Carl Orr[4], Viviana Marzaioli[5], Douglas Veale[6] and Ursula Fearon[7], [1]Molecular Rheumatology Department, Trinity Biomedical Sciences Institute, Trinity College Dublin; EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland, [2]Molecular Rheumatology Department, Trinity Biomedical Sciences Institute, Trinity College Dublin, Ireland, EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland, [3]Molecular Rheumatology Department, Trinity Biomedical Sciences Institute, Trinity College Dublin, EULAR Centre for Arthritis and Rheumatic Diseases, St Vincent University Hospital, University College Dublin, Dublin, Ireland, [4]Saint Vincent's University Hospital, Dublin, Ireland, [5]Trinity College Dublin and University College Dublin, Dublin, Ireland, [6]St.Vincent's University Hosp, Dublin, Ireland, [7]Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: While common pathogenic mechanisms exist between PsA and RA, distinct vascular morphology has been observed, with PsA displaying a tortuous, dilated, irregular shaped morphology compared to a straight regular branching pattern observed in RA. The aim of this study is to examine the effect of the PsA and RA joint microenvironment on endothelial cell function.

Methods: PsA and RA patients underwent key-hole joint arthroscopy and synovial biopsies were obtained. PsA and RA synovial fibroblasts (FLS) were isolated and grown to passage 1-5. PsA and RA FLS supernatants were harvested and referred to as conditioned media (CM). Endothelial cells (EC) were cocultured with PsA FLS/RA FLS or PsA CM/RA CM, and pro-inflammatory mediators (cytokines, matrix-metalloproteinases, angiogenic growth factors, chemokines and adhesion molecules) were quantified by ELISA, real-time PCR and flow cytometry.

Results: Co-culture of PsA and RA FLS with EC induced IL-6 secretion, with no effect observed for MCP-1 or Ang2. PsA FLS CM induced MCP-1, Ang2, ICAM-1, MMP2 and MMP3 expression in EC, with only MMP-2 increasing in response to RA FLS CM. Both PsA FLS CM and RA FLS CM decreased VCAM-1 expression, an effect that was more pronounced for RA FLS CM. Either co-culture of PsA FLS/RA FLS or PsA FLS CM/RA FLS CM with EC induced the frequency and/or MFI of key chemokine receptors CXCR3 and CXCR4 on EC, an effect that was more pronounced for FLS CM vs FLS co-culture, particularly for PsA CM. Both PsA FLS/RA FLS coculture or PsA/RA CM decreased the frequency of CXCR5, however induced CXCR5 MFI. Only co-culture with PsA FLS and RA FLS induced the expression of ICAM-1, with no effect observed for PsA or RA FLS CM. No effect was observed for VCAM-1 expression. In contrast, the effect of coculture on FLS led to a reduction in the expression of ICAM-1 on both PsA and RA FLS, with increased expression of VCAM-1 observed for PsA FLS. No effect was observed for chemokine receptor expression on either PsA FLS or RA FLS when co-cultured with EC.

Conclusion: PsA and RA FLS/CM induce angiogenic, chemokine and adhesion molecule expression on EC, with differential effects for some mediators observed in response to PsA vs RA joint microenvironments. Furthermore, differences were observed between EC-FLS cocultures vs EC FLS CM co-cultures, suggesting cell-cell contact and soluble mediators both influence the EC pathogenic phenotype.

Role of GITR/GITRL Interaction in Modulating T Helper 9, T Helper 17 and T Regulatory Response in Psoriatic Arthritis

Chiara Rizzo[1], Lidia La Barbera[1], Marianna Lo Pizzo[1], Leila Mohammadnezhad[1], federica Camarda[1], Francesco Dieli[1], Francesco Ciccia[2] and Giuliana Guggino[1], [1]University of Palermo, Palermo, Italy, [2]University of Campania - Luigi Vanvitelli, Naples, Italy

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The inflammatory process characterizing Psoriatic Arthritis (PsA) is mainly driven by interleukin (IL)-23/IL-17 axis and IL-9 overexpression, in presence of T helper (Th)17 and Th9 expansion (Veale DJ, The Lancet. 2018). Recently, a correlation between IL-9 and Glucocorticoid-induced Tumor Necrosis Factor-related receptor (GITR), whose ligand (GITRL) is expressed on antigen presenting cells, was described. Specifically, the activation of GITR/GITRL promotes Th9 and Th17 differentiation and alters Treg functions fueling inflammation (Tian J, Front Immunol. 2020). Considering the role of Th9 and Th17 in PsA and the proinflammatory function of GITR, we aimed to study the effects of GITR/GITRL interaction in PsA.

Methods: Eighteen patients fulfilling the 2006 classification criteria for PsA (CASPAR) and 10 healthy controls (HC) were enrolled in this study; all gave their informed written consent to participate. The study complied with the Declaration of Helsinki and was approved by the local Ethics Committee. Patients had an active disease and were naïve to biologicdisease modifying antirheumatic drug (bDMARDs). Blood samples were collected from all participants. Peripheral blood mononuclear cells were isolated and GITR/GITRL expression was determined by flow-cytometry in different cell subsets. An *in vitro* functional assay with a recombinant GITR agonist was performed to assess the effect of GITR activation on Th9 and Th17 expansion and Treg functions. Cells were stimulated with anti-CD3-CD28 monoclonal antibodies (mAb) too. The frequency of T cells was studied by flow-cytometry while the expression of cytokines and transcription factors was

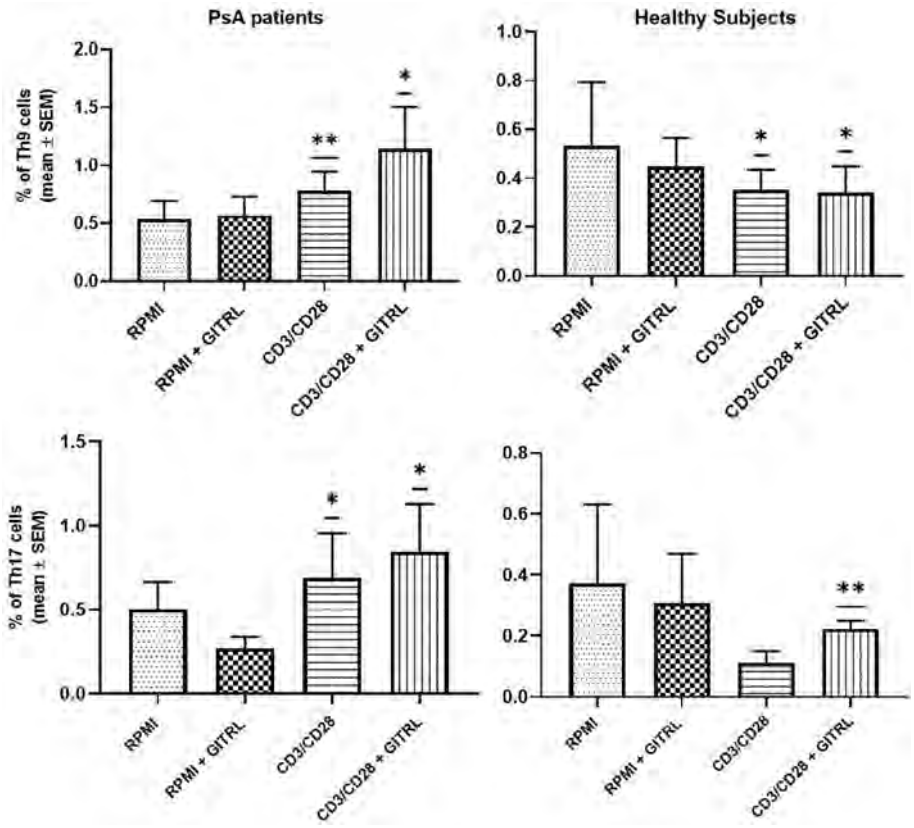

Figure 1. Recombinant GITRL effect on Th9 and Th17 frequency. Frequency of Th9 and Th17 analysed in four different conditions: RPMI, RPMI + GITRL, CD23/CD28 activation beads, CD3/CD28 + GITRL in PsA patients (left panel of the figure) and in healthy controls (right panel of the figure), respectively. *p<0.05

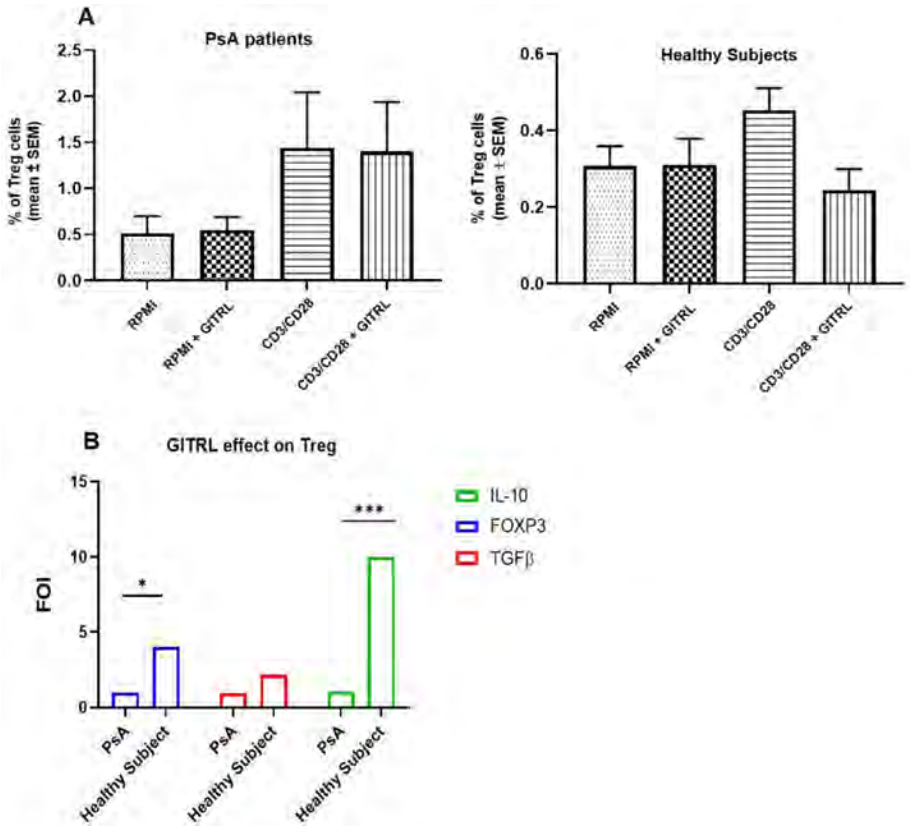

Figure 2. Recombinant GITRL effect on Treg frequency and function. A. Frequency of Treg analysed in four different conditions: RPMI, RPMI + GITRL, CD23/CD28 activation beads, CD3/CD28 + GITRL in PsA patients (on the left) and in healthy controls (on the right), respectively. B. mRNA expression of IL-10, FOXP3 and TGFβ after GITRL stimulation in PsA patients and healthy subjects analyzed by qRT-PCR. *p<0.05

assessed by qRT-PCR. Data were analyzed using GraphPad Prism version 8.0.1; p values < 0.05 were considered statistically significant.

Results: An enhanced expression of GITR among $CD4^+$ T cells was detected both pre and after *in vitro* stimulation with anti-CD3-CD28 mAb. In particular, although not statistically significant, Th17 and Th9 demonstrated an increased GITR expression after stimulation. GITRL was found upregulated on monocytes ($CD14^+$), dendritic cells ($CD11c^+$) and B cells ($CD19^+$) in PsA patients, even if no differences in cell frequency were detected between PsA and HC. The expression of HLA-DR was assessed as a positive control without evidencing any difference between PsA and HC. An expansion of both Th9 and Th17 was found after stimulation with anti-CD3-CD28 ($p< 0.05$); the proliferation of these subsets was further increased in presence of recombinant GITR agonist ($p< 0.05$) (Figure 1). Treg from PsA were expanded compared with HC after stimulation with anti-CD3-CD28 mAb. The addition of GITRL did not further modulate Treg proliferation. However, in presence of GITR agonist the mRNA expression of NF-kB, FOXP3, TGFb and IL-10 was reduced in Treg from PsA patients, with a statistically significant difference for both IL-10 and FOXP3 ($p< 0.05$) (Figure 2).

Conclusion: Our data support a novel role for GITR/GITRL axis in modulating the inflammatory process behind PsA through the expansion of Th9 and Th17 and the simultaneous suppression of Treg functions, unravelling a possible future target of therapy in PsA.

A Novel Inhibitory Pathway of Synovial Inflammation Exerted by Glucocorticoids and TNF Inhibitors Through LAG-3 Up-Regulation

Smadar Gertel[1], Victoria Furer[1], Ari Polachek[1] and Ori Elkayam[2], [1]Tel Aviv Sourasky Medical center, Tel Aviv, Israel, [2]Tel Aviv Medical Center, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic immune-mediated condition that results in systemic musculoskeletal (MSK) inflammation, including peripheral synovitis, enthesitis and axial involvement. Glucocorticoids (GCs) are indicated for local control of synovitis by intra articular injection. We hypothesized that GCs may promote suppressive activity through up-regulation of lymphocyte-activation gene-3 (LAG-3), a regulatory molecule that can be modulated by different drugs. In this study, we investigated the effects of GCs and other anti-rheumatic drugs on modulation of LAG-3 and of an additional regulatory molecule co-expressed with LAG-3, programmed cell death receptor-1 (PD-1), in synovial cells ex-vivo.

Methods: Synovial fluid mononuclear cells (SFMCs) derived from PsA patients were co-cultured with GCs [betamethasone (BET) and methylprednisolone acetate (MPA))], TNF inhibitor (i) (infliximab, IFX), IL-17Ai (secukinumab, SEC), IL-12/23i (ustekinumab, UST)] and methotrexate (MTX) or with medium alone for 5 days. Cells were analyzed for CD45 and LAG-3 by flow cytometry and all drugs were used in their therapeutic concentrations. To identify the drugs' impact on cell growth and regulatory molecules, total SFMCs cell growth and expression of LAG-3 and PD-1 on CD3 and CD14 cells were analyzed.

Results: SFMCs derived from 11 PsA patients co-cultured with GCs showed a significant increase in %LAG-3$^+$CD45$^+$ cells (BET 1mg/ml, 6.8±1.3; BET 10mg/ml, 7.1±1.4; MPA 1mg/ml, 6.7±1.3; and MPA 10mg/ml, 9.4±2.0, $p< 0.001$, respectively) as compared to medium (1.0±0.3). Likewise, IFX also increased this cell population (2.0±0.3, $p= 0.005$) as compared to the medium (1.0±0.3), but to a lesser extent than GCs. In contrast, SEC, UST, and MTX had no effect on %LAG-3$^+$CD45$^+$ cells as compared to the medium, (1.0±0.2, 0.8±0.2, and 0.9±0.2, respectively) (Figure 1A). GCs (MPA) and IFX reduced the total SFMCs cell count/well but this change was statistically significant only for GCs (21±5.1X10^5/well, $p< 0.01$ and 41±5.1X10^5/well, respectively), while MTX had no effect compared to the medium (49±4.8X10^5/well and 51±5.1X10^5/well, respectively) (Figure 1B). In the same co-culture setting, the proportion of LAG-3$^+$CD3$^+$ T cells was low for all experimental groups (Figure 1C), whereas %LAG-3$^+$CD14$^+$ monocytes were markedly up-regulated by GCs (12.8±2.1, $p< 0.001$) compared to the medium (0.9±0.4) (Figure 1 D and F). The proportion of PD-1$^+$CD14$^+$ monocyteswas not significantly increased by GCs and other drugs (Figure 1E).

Conclusion: Our data show that GCs immunosuppressive activity is mediated through up-regulation of LAG-3 in SFMCs. Within the tested anti-rheumatic drugs, this activity was exclusively mediated by GCs and to a lesser extent by a TNF inhibitor. GCs reduced the total SFMCs cell growth in culture and concomitantly up-regulated LAG-3, mainly on monocytes. This study proposes that synovial monocytes expressing LAG-3 are potential mediators of the GCs immunosuppressive effect. Further investigation into the precise involvement of LAG-3 in inhibition of synovial inflammation is required.

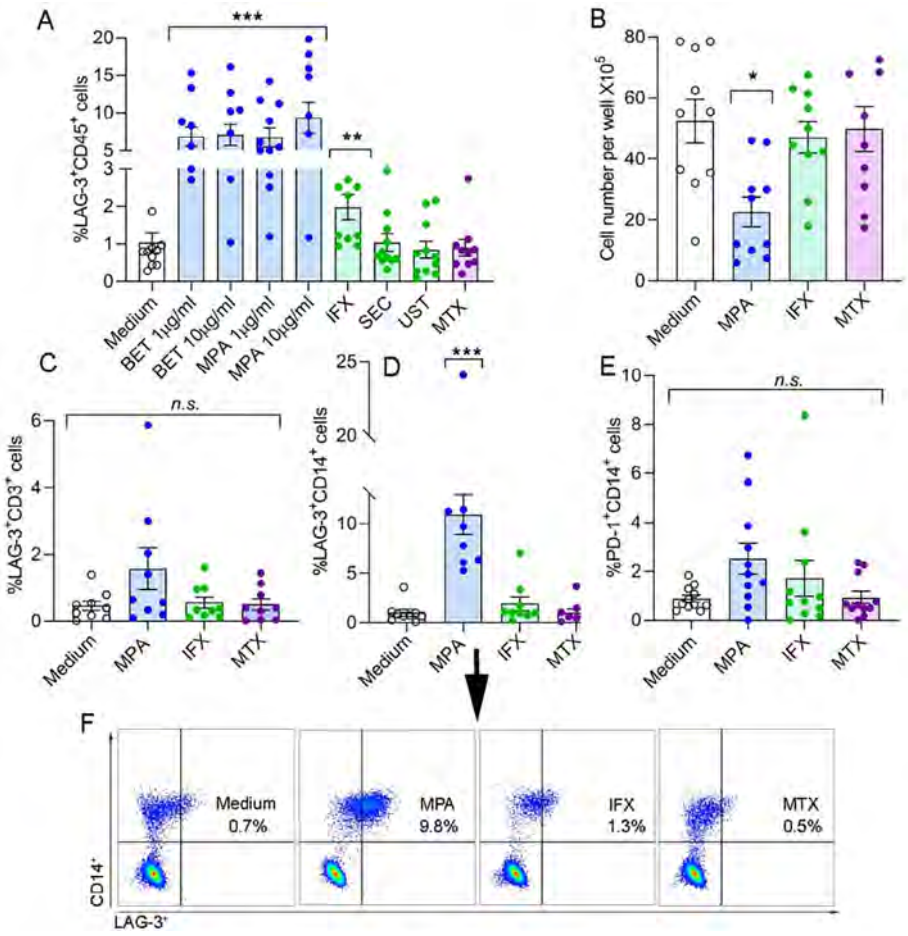

Figure 1. GCs and to a lesser extent TNF inhibitor up-regulate LAG-3 in SFMCs ex-vivo. (A) SFMCs derived from PsA patients (n=11) were cultured ex-vivo with betamethasone (BET), methylprednisolone acetate (MPA), infliximab (IFX), secukinumab (SEC), ustekinumab (UST), and methotrexate (MTX) and analyzed for %LAG-3+CD45+ cells using flow cytometry. (B) Total SFMCs cell count/well analysis was performed after 5 days in culture with the indicated drugs: MPA, IFX and MTX. In same co-culture setting: (C) %LAG-3+CD3+, (D) %+LAG-3+CD14+ and (E) %PD-1+CD14+ cells were analyzed using flow cytometry (F) Representative images of SFMCs derived from PsA patient stained for CD14 and LAG-3 after 5 days in culture with medium or with the therapeutics indicated. Positive staining is presented in the right upper quadrant of each plot with the percentage indicated. Statistical analysis calculated by the non-parametric one-way ANOVA Kruskal-Wallis test and Dunn's multiple comparison test, *$p < 0.01$, **$p < 0.005$, ***$p < 0.001$, n.s., non-significant.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (AxSpA) is a frequent inflammatory disease with a significant impact on a patient's quality of life. Therefore, early diagnosis and recognition of patients with rapid structural progression are of great importance. This pilot study aimed to profile the plasma proteome and disclose candidate biomarkers differentiating patients with structural radiographic progression after two years.

Methods: Twenty patients with ax-SpA fulfilling the ASAS classification criteria were selected according to an increase in the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) after a 2-year follow-up into radiographic progressors (ΔmSASSS ≥2) and non-progressors (ΔmSASSS = 0). Patients' disease activity was determined using C-reactive protein (CRP), Erythrocyte Sedimentation Rate (ESR), Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Activity Disease Activity Index (BASDAI) and physician global assessment (MDGA). The plasma proteome was profiled using the mass spectrometry method and statistical analysis was adjusted for CRP. All patients were naïve to b/ts DMARDs during the 2-year follow-up.

Results: Our cohort included ten patients without radiographic spinal progression (non-progressors) and ten patients who developed significant progression after two years (progressors) (mean±SD ΔmSASSS 9.88±5.1). All demographic and clinical characteristics are provided in Table 1. The profiling of plasma proteome revealed 489 quantifiable proteins, out of which 21 proteins were different between patient groups (ANOVA-computed $p < 0.05$ for all). The follow-up pairwise comparison revealed five promising biomarkers, out of which clusterin (1.20-fold, p=0.011), serum amyloid P-component (SAP) (1.43-fold, $p < 0.004$), retinol-binding protein 4 (RPB4) (1.28-fold, p=0.027), and fetuin-B (1.52-fold, p=0.051) were upregulated, while gelsolin (1.16-fold, p = 0.015) was downregulated in patients with mSASSS progression compared to those without progression (Fig. 1). Out of these proteins, gelsolin, RBP4, fetuin-B, and SAP significantly correlated with mSASSS, CRP or ASDAS (Fig. 2). All candidate proteins have previously been associated with rheumatic diseases.

Table 1 – Demographic and clinical characteristics of patients with axSpA at baseline. CRP - C-reactive protein, ESR - Erythrocyte Sedimentation Rate, ASDAS - Ankylosing Spondylitis Disease Activity Score, BASFI -Bath Ankylosing Spondylitis Functional Index, BASDAI - Bath Ankylosing Spondylitis Activity Disease Activity Index, MDGA - physician global assessment, mSASSS - modified Stoke Ankylosing Spondylitis Spinal Score, csDMARDs - conventional synthetic Disease-Modifying AntiRheumatic Drugs, MASES - Maastricht Ankylosing Spondylitis Enthesitis Score

	Non-progressors N = 10	Progressors N = 10	p-value[3]

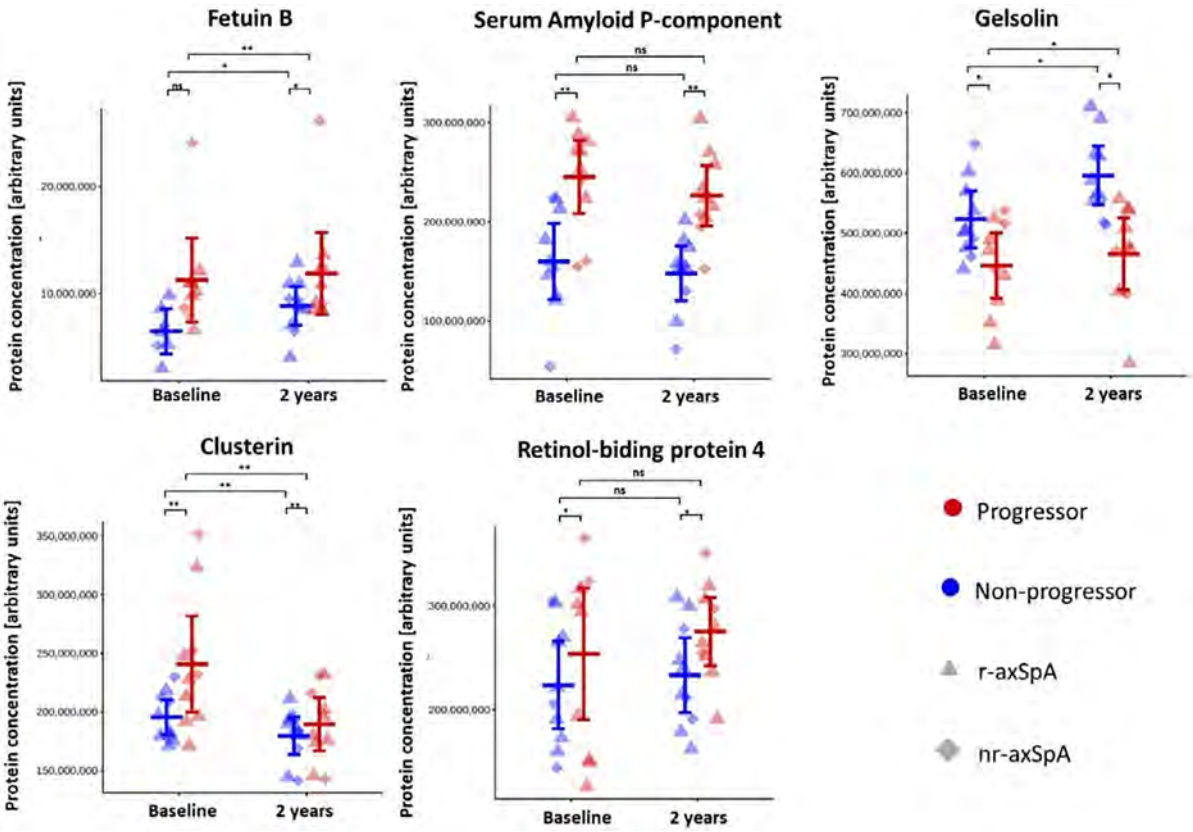

Figure 1 – Five candidate proteins with the potential to predict radiographic progression in axSpA. The error bars represent 95% confidence intervals with the mean for patients with or without mSASSS progression. p-values show statistical significance between depicted pairwise comparisons computed from linear mixed-effect models and adjusted for CRP. (***, $p < 0.001$; *, $p < 0.05$; ns, non-significant). Patients with and without mSASSS progression are coloured in red and blue, respectively, and radiographic (r-) and non-radiographic (nr-) axSpA patients are depicted as triangles and diamonds, respectively.

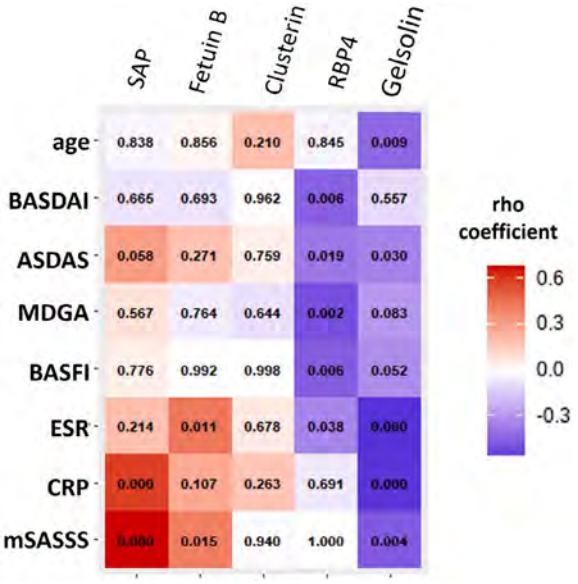

Figure 2 – Correlation matrix of five candidate proteins and selected clinical parameters. The matrix includes p-values and the colour indicates the strength and direction of Spearman's coefficient (rho).

Conclusion: This pilot study revealed five plasma proteins, which are likely to predict the structural progression of axSpA after two years. These data will be validated in an extended larger cohort.

TNF Induces Neutrophil Elastase/Gasdermin D-mediated Neutrophil Extracellular Traps in Axial Spondyloarthritis

Yehao Li and Xiang Peng, Department of Rheumatology and Immunology, The Sixth Affiliated Hospital of Guangzhou Medical University, Qingyuan People's Hospital, Qingyuan, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Emerging studies have shown that neutrophil extracellular traps (NETs) are increased and associated with the disease activity in patients with axial spondyloarthritis (axSpA). However, the molecular mechanism underlying the release of NETs remains unclear in axSpA. In this study, we aimed to investigate the role of TNF/neutrophil elastase (NE)/Gasdermin D (GSDMD) in the release of NETs in axSpA.

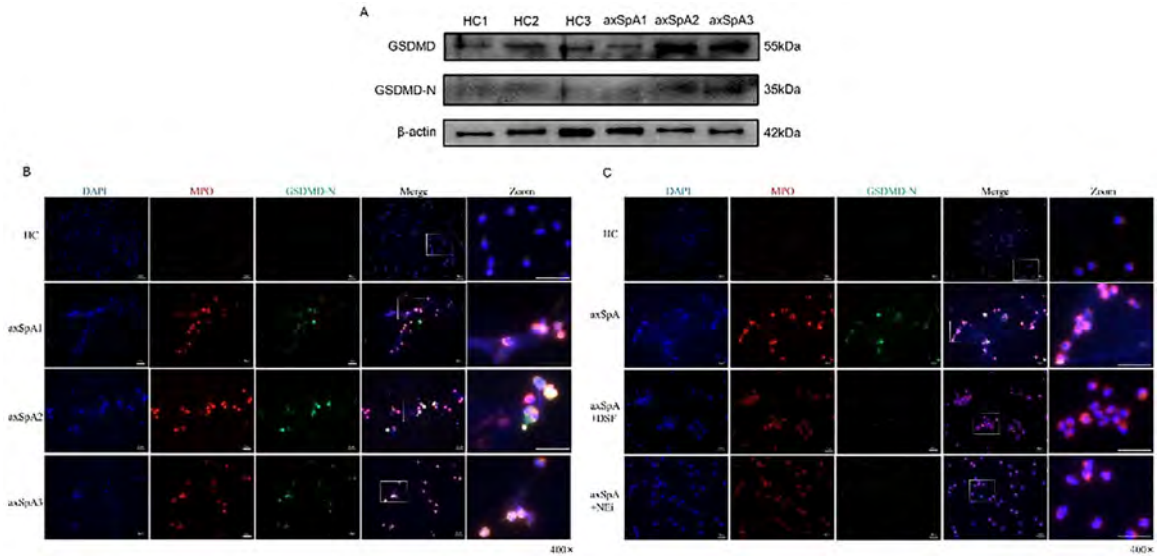

Figure 1 Increased expression of GSDMD in the neutrophils of axSpA patients and associates with NETs release. A. Western blot shows that the expressions of GSDMD and GSDMD-N were increased in the neutrophils of axSpA patients. B. Immunofluorescence images show that higher expression of GSDMD-N was found to be associated with the increased NETs structures in axSpA patients. C. Immunofluorescence images show that GSDMD inhibitor (disulfiram, DSF) or NE inhibitor (NEi) inhibited the NETs release and NEi inhibited the expression of GSDMD-N in axSpA patients.

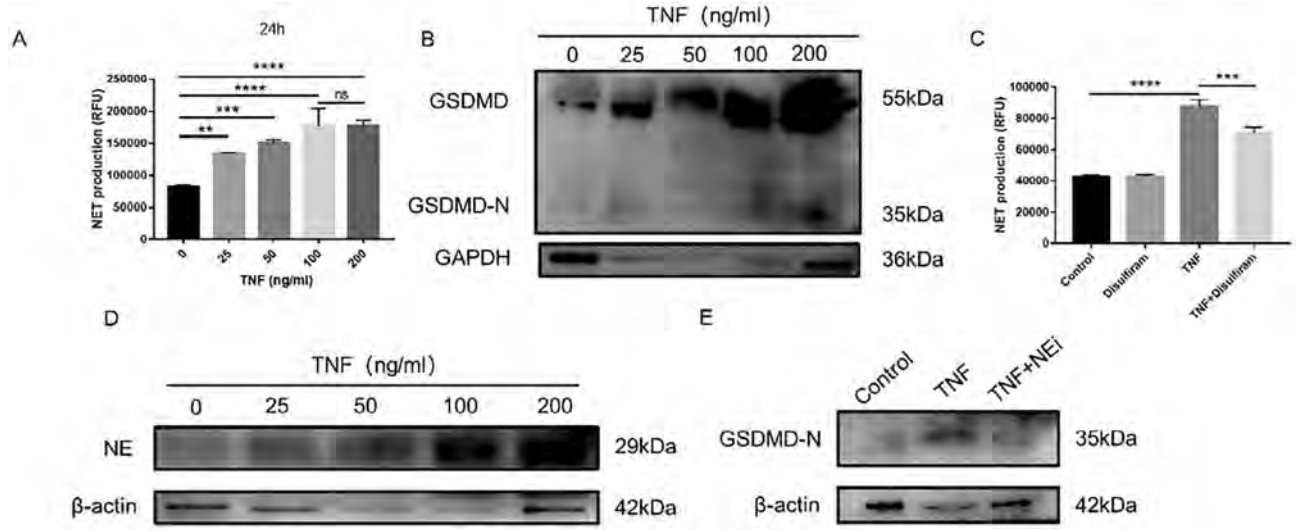

Figure 2 TNF induced the release of NETs through the NE/GSDMD pathway. A. Western blot shows that TNF induced the NETs release dose-dependently. B. Western blot shows that TNF stimulation increased the expression of GSDMD and GSDMD-N. C. GSDMD inhibitor disulfiram inhibited TNF-induced NETs release. D. Western blot shows that TNF stimulation increased the expression of NE. E. Western blot shows that NE inhibitor (NEi) inhibited TNF-induced GSDMD-N expression.

Methods: The expression of GSDMD in the neutrophils of axSpA patients was analyzed by Western blot and immunofluorescence. The role of NE/GSDMD in the NETs release of axSpA patients was tested. Furthermore, the effect of TNF on NE/GSDMD-mediated NETs was analyzed.

Results: Compared with the healthy controls, increased expression of GSDMD and the N-terminal fragment of GSDMD (GSDMD-N) were detected in the neutrophils of axSpA patients. In addition, higher expression of GSDMD-N was found to be associated with the increased NETs structures in axSpA, which was blocked by either GSDMD or NE inhibitor. Furthermore, TNF induced the release of NETs through the NE/GSDMD pathway.

Conclusion: These results demonstrated that TNF/NE/GSDMD pathway plays a critical role in the NETs release in axSpA, which reveals that NE/GSDMD may serve as novel potential targets for inhibiting NETs to treat axSpA.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The interleukin-17 (IL-17) family of cytokines consists of 6 evolutionarily conserved cytokines, IL-17A-F. Of these, IL-17A, B, C, and F play diverse roles in homeostasis and inflammation. IL-17A plays a critical pro-inflammatory role in inflammatory arthritis, particularly in the spondyloarthritis (SpA) spectrum of disease. IL-17D is an understudied member of the IL-17 family of cytokines and its function appears to be context dependent. We sought to identify the role of IL-17D in inflammatory arthritis.

Methods: We utilized two models of inflammatory arthritis: the SKG model and the serum transfer arthritis (STA) model. We tested the effect of recombinant IL-17D treatment on arthritis development in both the STA and SKG models of arthritis and assessed clinical inflammation and expression of pro-inflammatory factors in the paws by qPCR. We induced STA in *Il17d-deficient* mice and controls, performed histology and assessed cytokines by Luminex.

To identify the cell types expressing IL-17D in inflamed synovial tissues from patients with SpA and RA, we analyzed single-cell sequencing data from the Accelerating Medicines Partnership (AMP I) database, and performed RNAscope and immunofluorescence (IF). Finally, we performed *in vitro* stimulation experiments using primary human cells and cell lines.

Results: We have previously reported that IL-17D is the most highly expressed IL-17 family member in synovial tissue at the transcriptional level in patients with SpA and its expression correlates inversely with inflammation. *Il17d*-deficient mice develop more severe arthritis than littermate controls. We now show that treatment of arthritic mice with recombinant IL-17D protein attenuates inflammation in both the STA and SKG murine models of inflammatory arthritis, accompanied by downregulation of pro-inflammatory cytokines. In inflamed human synovial tissues, *IL-17D* mRNA is most highly expressed in CD34+ Fibroblast-like synoviocytes (FLS) that also express markers of stromal cell progenitors. Single-cell analysis and IF revealed the presence of one previously identified receptor for IL-17D, CD93, in inflamed synovial tissues.

Conclusion: IL-17D and the CD93 receptor are expressed in inflamed synovial tissues. IL-17D expression is localized to CD34+ FLS. In contrast to other IL-17 family cytokines that are pro-inflammatory, IL-17D attenuates inflammation in two animal models of arthritis. This finding is confirmed in the IL-17D-deficient setting. These data support an anti-inflammatory role for IL-17D in inflammatory arthritis. Further studies are ongoing to define the mechanism by which the IL-17D pathway impacts inflammation.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple lines of evidence indicate that ankylosing spondylitis (AS) is a lymphocyte-driven disease. However, which lymphocyte populations are critical in AS pathogenesis is not known. AS is a highly heritable disease, with estimates of the genetic contribution to AS ranging from 69 to 90%. Genome-wide association studies (GWAS) have identified >100 loci associated with AS, with the vast majority of likely causal variants being non-coding. In this study, we aimed to identify the key cell types mediating the genetic risk in AS using an unbiased multi-omics approach.

Methods: We integrated GWAS data with epigenomic and transcriptomic datasets in human lymphocytes to identify key cell subsets mediating genetic susceptibility to AS. We used public ATAC-seq on sorted peripheral immune cell subsets of healthy subjects, low-input RNA-seq on 7 sorted lymphocyte populations of healthy subjects, and single-cell RNA-seq from the human gut single-cell atlas. To link cell type-specific open chromatin regions or gene expression with GWAS we used 3 published methods: Linkage Disequilibrium Score-regression in Specifically Expressed Genes (LDSC-seg), SNPsea, and single-cell disease-relevance score (scDRS). We validated that these methods could identify T-cells as the main drivers of Rheumatoid Arthritis. Additionally, we performed co-localization analyses between GWAS loci and genetic variants associated with gene expression (eQTL) to find putative target genes of AS risk variants.

Results: LDSC-seg revealed that NK-specific open chromatin regions are significantly enriched in heritability for AS, while this was not the case for other cell types such as T cells, B cells, and monocytes. This finding was consistent between two AS GWAS, one using the ImmunoChip, and the other (UK biobank) using a genome-wide chip. Applying SNPsea to RNA-seq data, we validated that genes in AS risk loci are enriched in NK cell-specific gene expression, compared to 6 T cell subsets (CD4+ T, CD8+ T, MAIT, iNKT, and two gamma delta T cell subsets). Gene expression levels of AS-associated genes, such as RUNX3, TNFRSF1A, and NPEPPS, were found to be highest in NK cells. Additionally, scDRS analysis using the human gut single-cell atlas revealed significant upregulation of AS-associated genes predominantly in NK cells. With co-localization analyses using a large-scale NK cell transcriptomic study with genotyped subjects, we found putative target genes for AS risk variants, including the widely studied ERAP1, previously reported as likely target gene TNFRSF1A and two new understudied target genes.

Conclusion: Using a variety of published datasets and complementary analytical approaches, we consistently identified NK cells as the primary cell type with gene expression and open chromatin enriched in genetic risk variants for AS. These findings point to NK cells as key mediators of the genetic susceptibility to AS.

Dendritic Cell-specific TNFR2 Depletion Reduces Psoriatic Arthritis-like Disease in a Mouse Model

Raminderjit Kaur[1], M. Elaine Husni[2], Unnikrishnan Chandrasekharan[3] and Roberta Brambilla[4], [1]Cleveland Clinic, Cleveland,, OH, [2]Cleveland Clinic / Department of Rheumatic and Immunologic Diseases, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH, [4]University of Miami Miller School of Medicine, Miami,, FL

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic, progressive autoimmune condition that affects both the skin and joints. It is characterized by increased levels of the proinflammatory cytokine tumor necrosis factor-alpha (TNF-α) (Guttman-Yassky et al., 2011). TNF signals via two receptors, TNFR1 and TNFR2. Recently, our lab discovered that globally deleting the TNFR2 gene, while keeping TNFR1 intact, can reduce psoriasis-like inflammation in mice (Chandrasekharan et al., 2022). Mechanistically, we found that TNFR2 plays a crucial role in the dendritic cell (DC)-dependent production of IL-23 and polarization of TH17 cells. In psoriasis, DCs are known to be involved in capturing self-antigens from abnormal skin cell growth, presenting them to T cells, and initiating an immune response (Kamata and Tada, 2022). The current research sheds light on the critical role of TNFR2 in DC activation and the development of PsA, offering potential avenues for targeted therapeutic therapies. In this study, we are testing if targeting TNFR2 specifically in DCs using conditional knock-out mice can alleviate PsA.

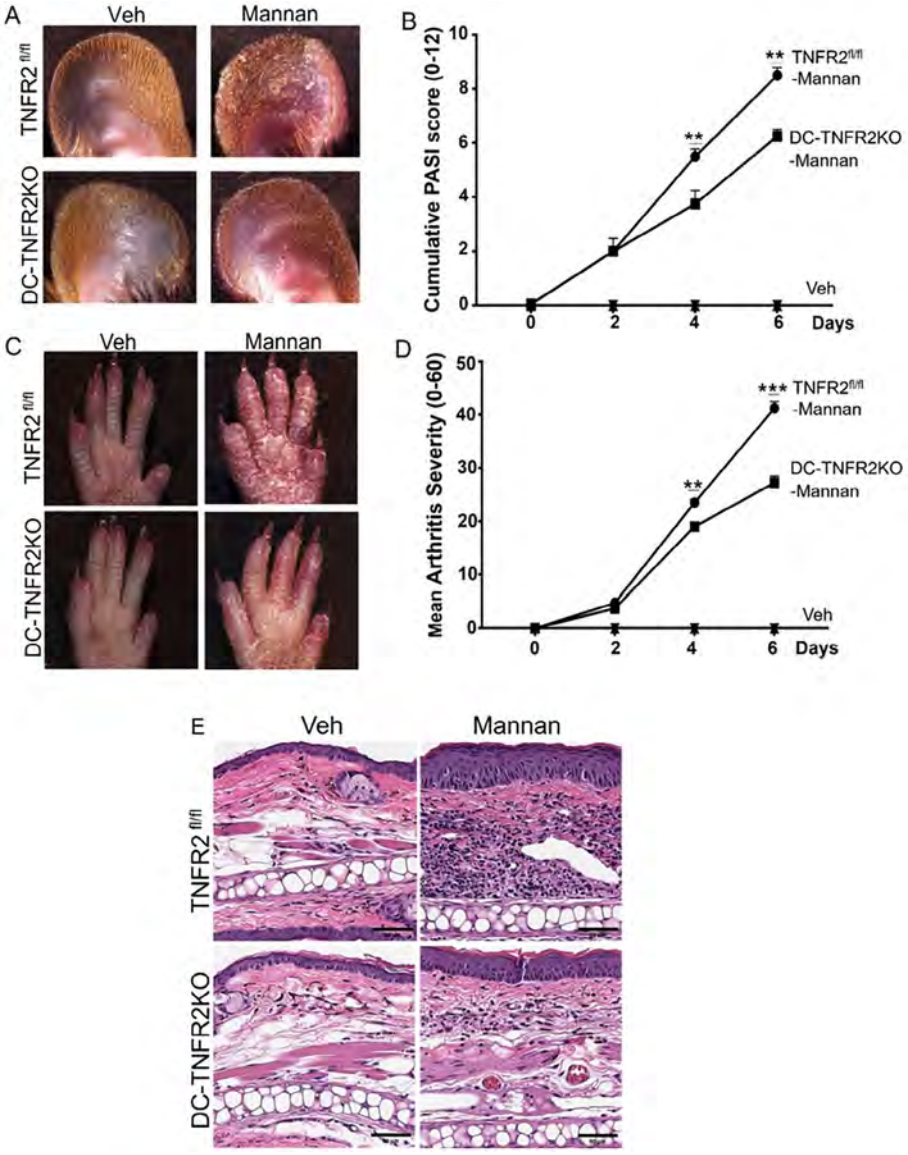

Figure 1: DC-TNFR2KO mice show reduced PsA-like disease development induced by Mannan: A. Psoriasis-like skin scaling in diseased TNFR2 fl/fl and DC-TNFR2KO mice compared with vehicle-treated mouse ear; B. PASI score of the ear; C. The arthritic phenotype (swelling and redness) and Psoriasis-like skin lesions in the hind paws of TNFR2 fl/fl and DC-TNFR2KO mice; D. Mean arthritis severity score of paws; E. Representative H &E staining of ear tissue from control and diseased TNFR2 fl/fl and DC-TNFR2KO mice; (n=6 each, ** represents p value <0.01; *** represents p value <0.001).

Methods: We investigated the impact of DC-specific TNFR2 knockout (DC-TNFR2KO) on skin lesions and joint inflammation in a mouse model of psoriatic arthritis induced by Mannan (Khmaladze et al., 2014). Psoriasis Area and Severity Index (PASI) Score and arthritis severity score calculations were performed on $TNFR2^{fl/fl}$ (control) and DC-TNFR2KO mice ($TNFR2^{fl/fl}$-CD11cCre). Histological evaluations were performed on ear skin and paw samples using H&E staining and safranin staining, respectively. Histopathological analyses and scoring were conducted in a blinded manner by independent investigators. Additionally, ELISA was used to determine whether DC-dependent cytokine production was altered in DC-TNFR2KO mice in response to Mannan treatment. Statistical analyses were performed with the SPSS version and Prism (GraphPad Software, San Diego, CA).

Results: Following Mannan injection $TNFR2^{fl/fl}$ mice developed PsA-like skin lesions and joint inflammation, while DC-TNFR2KO mice exhibited minimal symptoms (**Figure 1A-B**). The cumulative PASI score was significantly lower in DC-TNFR2KO mice compared to $TNFR2^{fl/fl}$ mice at days 4 and 6 after Mannan injection ($p < 0.01$, each). The mean arthritis severity score was also lower in DC-TNFR2KO mice ($p < 0.01$; $p < 0.001$) (**Figure 1 C-D**). Histological examination revealed that $TNFR2^{fl/fl}$ mice had significantly increased epidermal thickness (**Figure 1E**) and leukocyte infiltration compared to DC-TNFR2KO mice after Mannan injection ($p < 0.001$; $p < 0.01$). Safranin O staining showed cartilage loss in both $TNFR2^{fl/fl}$ and DC-TNFR2KO mice, however, it was less in TNFR2KO compared to $TNFR2^{fl/fl}$ mice ($p< 0.05$). Furthermore, we found diminished levels of IL-12, IFN-γ and TNF-α in the serum of DC-TNFR2KO mice compared to $TNFR2^{fl/fl}$ mice, post Mannan treatment ($p< 0.0001$; $p< 0.001$; $p< 0.01$ respectively).

Conclusion: Targeting TNFR2 specifically in dendritic cells can alleviate skin and joint inflammation in a mouse model of PsA. This study provides insights into the mechanistic role of TNFR2 in PsA pathogenesis and may contribute to the development of novel therapies for this debilitating disease.

Machine Learning Models Identify Gut Microbiota That Predict Chronicity in Reactive Arthritis

Prakashini MV[1], Soumendu Mahapatra[2], Krushna Chandra Murmu[2], Rasmita Mishra[2], Prasanta Padhan[1], Punit Prasad[2], Ramnath Misra[3] and Sakir Ahmed[4], [1]Kalinga Institute of Medical Sciences, KIIT University, Bhubaneswar, India, [2]Institute of Life Sciences, Bhubaneswar, India, [3]Kalinga Institute of Medical Sciences, KIIT University, Lucknow, India, [4]Kalinga Institute of Medical Sciences, Bhubaneswar, India

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Reactive arthritis (ReA) is the unique infection-triggered spondyloarthritis (SpA). Undifferentiated peripheral SpA (UpSpA) is similar but without previous infection, or psoriasis or inflammatory bowel disease. Around 50-70% of these remit spontaneously while the rest become chronic. There are no known markers of chronicity. We have previously described novel gut-microbiota associated with ReA/UpSpA[1]. Now, we have attempted to use these microbiota to predict which of these patients would develop chronicity.

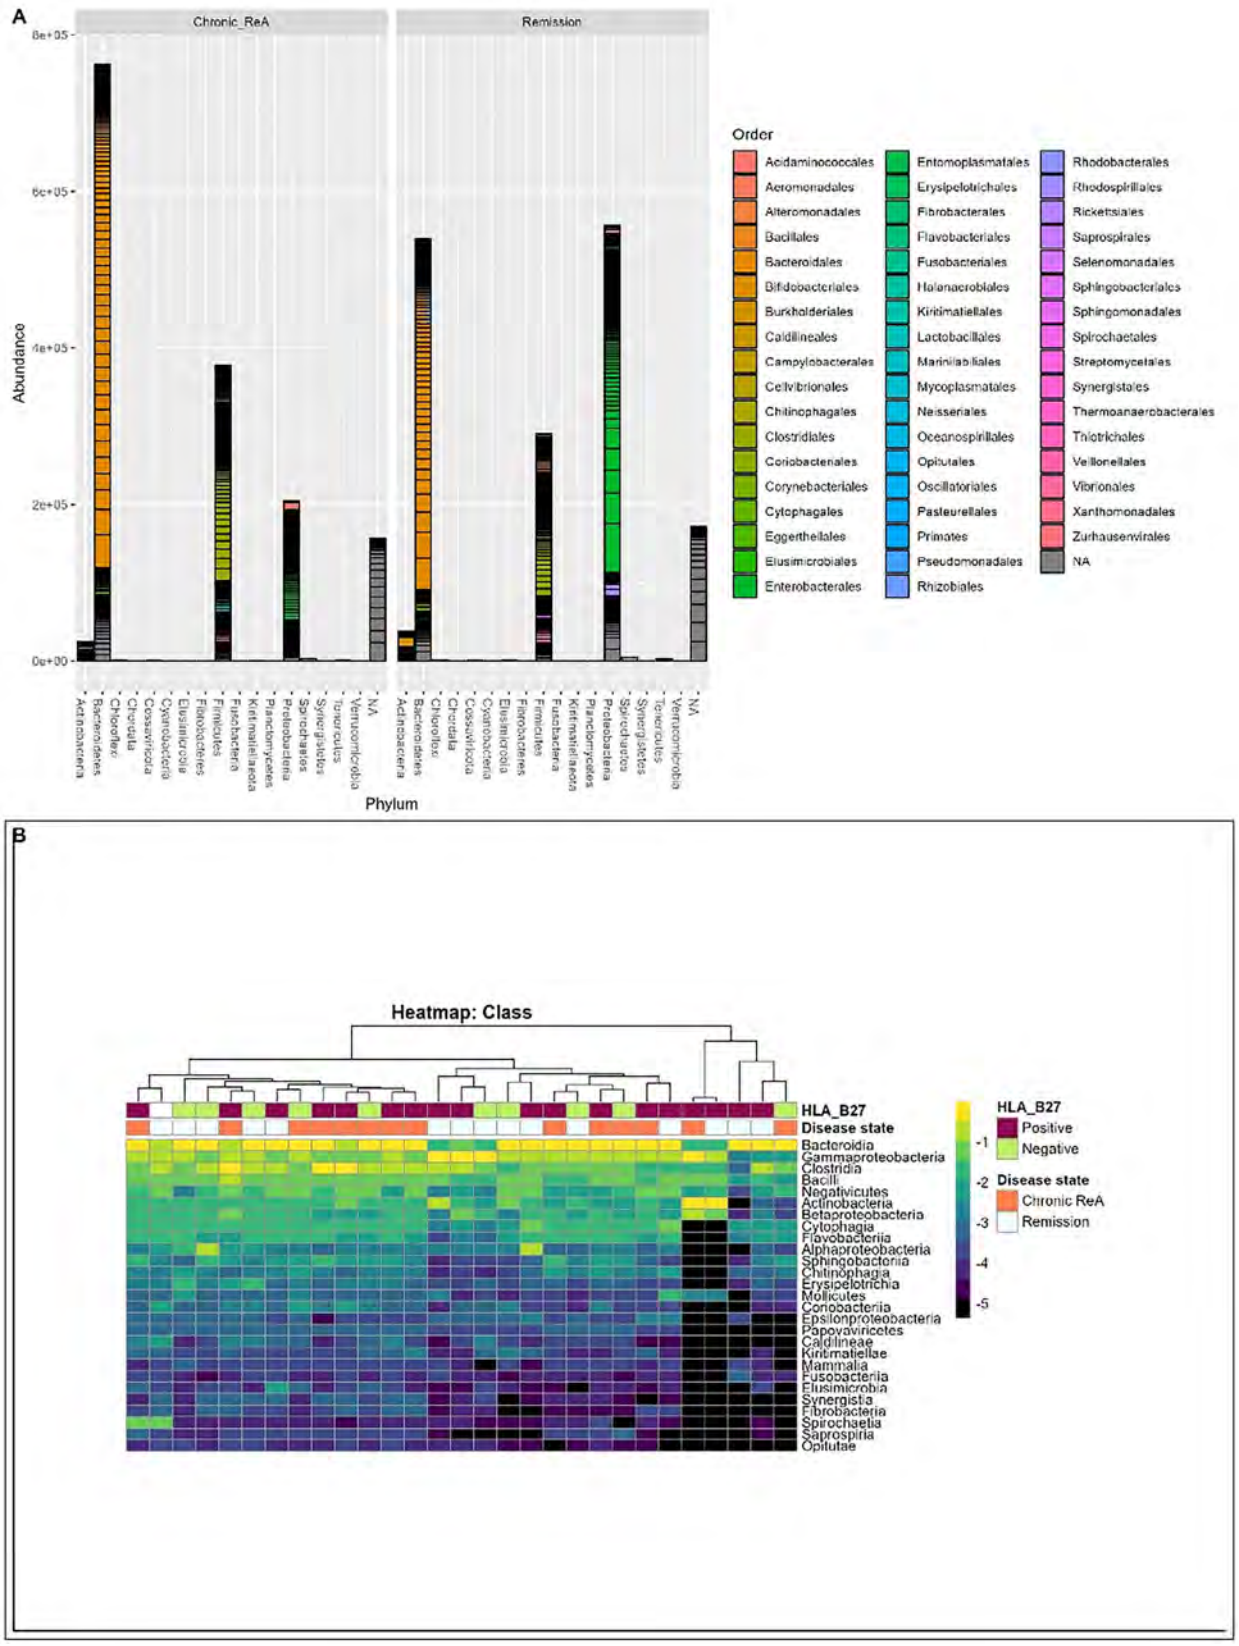

Figure 1: A – Differential abundance shown at phylum level. The Bacteroidetes to Firmicutes ratio is higher in the Chronic ReA group, as compared to Remission group; B – Heatmap visualizing the differential abundance at class level with dendrogram showing the phylogenetic relationship between different samples.

Methods: ReA and UpSpA recruited in the previous study[1] were followed up at 3 years after the initial recruitment. They were classified as having "Chronic ReA" (still on DMARDs or having symptoms of SpA) or in "Remission" (drug-free and without any symptoms in the last 12 months). A standard pipeline was used to analyze differentially abundant microbiota

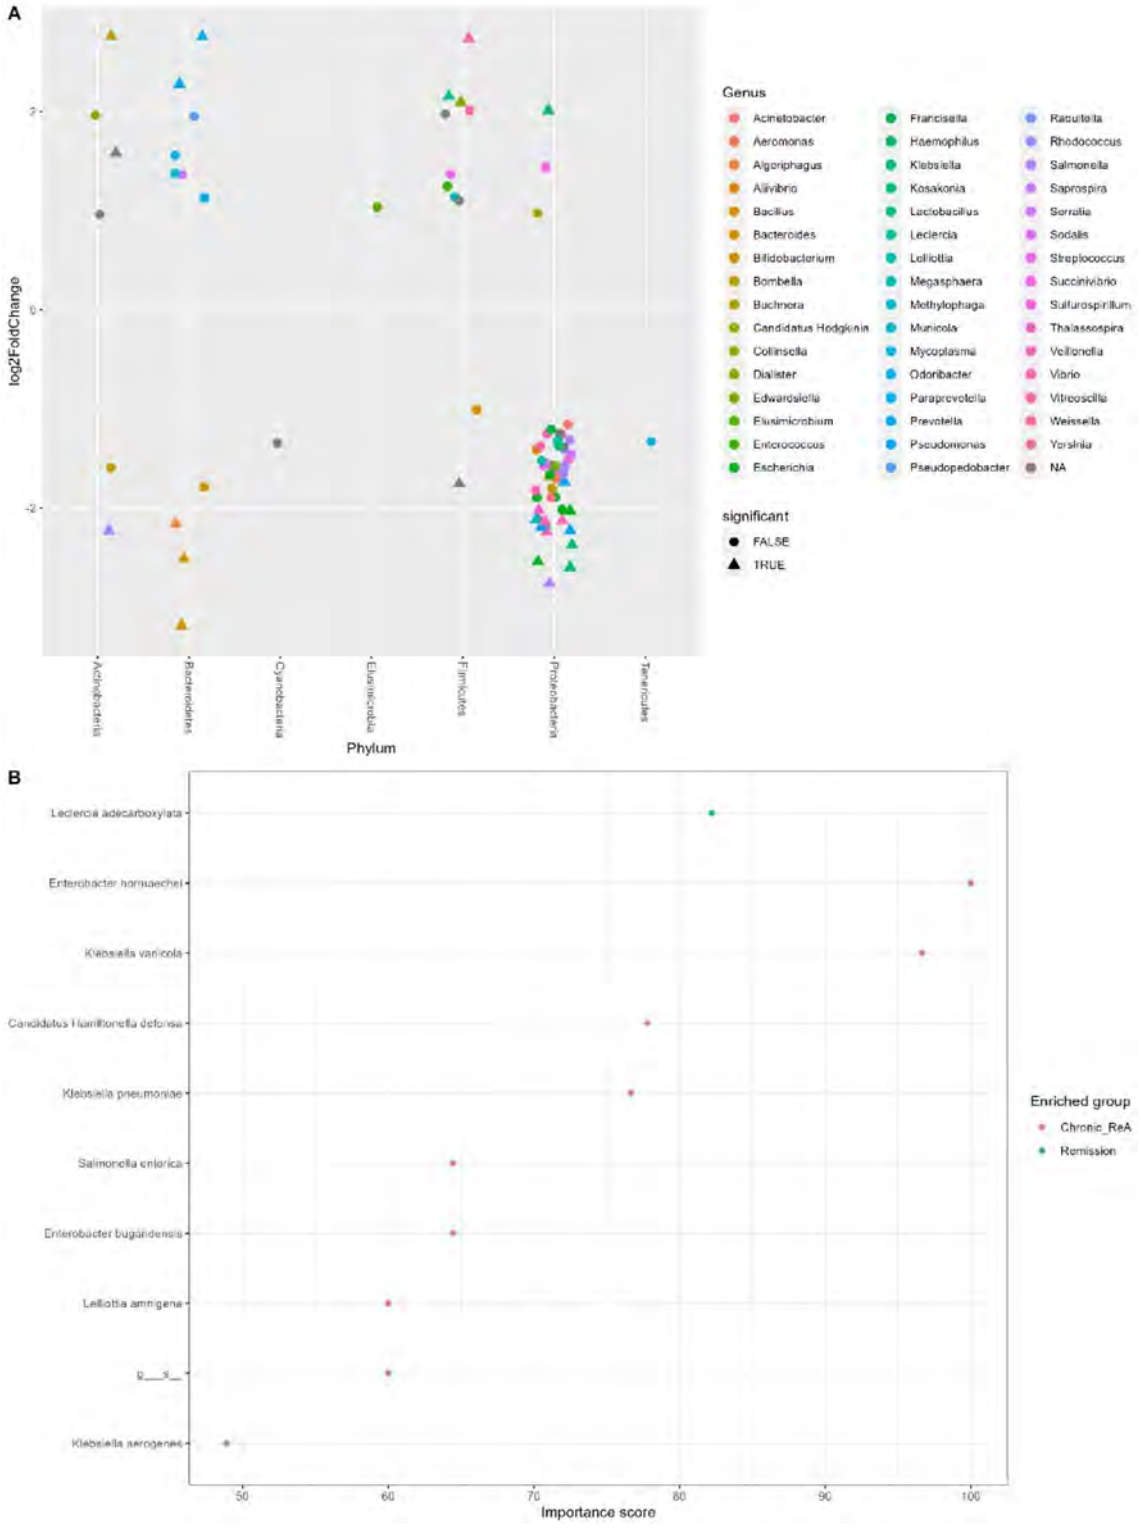

Figure 2: A – Microbiota that are at least 2-log-fold change different between chronic reactive arthritis and remission groups, stratified by Phylum. Statistically different genera (False Discovery Rate <0.05) are shown as triangles. B – Species that are most important for predicting chronicity of Reactive Arthritis as per Linear Regression Machine learning model.

between Chronic ReA and Remission groups. Further, the groups were randomly divided into training (80% data) and validation (20% data) sets. Clinical features (disease duration, DMARD use, HLA-B27 status) and microbiota of differential abundant families were analyzed by supervised machine learning algorithms (Support Vector Machine: SVM and Linear Regression: LR) to build models that could predict the development of chronicity of ReA.

Table 1: Clinical characteristics ReA – Reactive Arthritis; IQR – Interquartile range; NA – Not applicable; DMARD – Disease modifying anti-rheumatic drugs; VAS – Visual analogue score; HAQ-DI – Health assessment questionnaire-disability index; HLA – Human leukocyte antigen. *p<0.05

Table 1: Clinical characteristics

Characteristics	Chronic ReA (N=14)	Remission (N=15)	p-value
Male: Female	9:5	10:5	0.9
Median age (IQR) in years	29.5 (25.7-37.2)	29 (24-35)	0.62
Axial involvement	4 (28.5%)	0	NA
Uveitis	1	0	NA
Duration of DMARD exposure (IQR) in weeks	170 (147.7-183.4)	27 (24-35.7)	0.01*
Number of patients who received DMARDs ever	7 (50%)	4 (26.7%)	0.2
DMARDs used (ever):			NA
Methotrexate	0	2	
Sulfasalazine	5	0	
Tofacitinib	2	0	
Etanercept	0	1	
HLA-B27	10 (71.4%)	4 (26.7%)	0.015*
Pain-VAS at baseline (Median with IQR)	7.4 (5.5-9.1)	7.6 (4.4-8.4)	0.47
HAQ-DI at baseline (Median with IQR)	0.5 (0.38-0.8)	0.5 (0.3-0.5)	0.58

ReA – Reactive Arthritis; IQR – Interquartile range; NA – Not applicable; DMARD – Disease modifying anti-rheumatic drugs; VAS – Visual analogue score; HAQ-DI – Health assessment questionnaire-disability index; HLA – Human leukocyte antigen.

*p<0.05

Results: Out of the initial 55 cohort, 29 patients consented for the follow-up. 14 (48.3%) patients had chronic ReA. The clinical features are summarized in Table 1. The baseline microbiome data showed that alpha diversity (Observed, Shannon, Simpson, Fisher, InvSimpson) as well as Beta diversity (Bray-Curtis and Unweighted UniFrac) was similar between the two groups. After applying stringency filters (excluding OTUs that did not appear more than 5 times in least half the samples), the differential abundance is shown at the Phylum (Figure 1A) and Class levels (Figure 1B). Amongst microbiota whose abundance was at least log-2-fold different between Chronic ReA and Remission groups, we could identify 29 OTUs (Figure 2A) that were significantly different (FDR< 0.05). The maximum difference was seen for *Bacteroides ovatus* (log2fd=3.19), *Salmonella sp*. HNK130(2.76), *Escherichia coli* (2.54), *Bacteroides fragilis* (2.51) that were more abundant in the Chronic ReA group while *Veillonella parvula* (-2.74), *Prevotella dentalis* (-2.76), and *Bifidobacterium adolescentis* (-2.76) were more abundant in the Remission group. In the SVM model, the most accurate model was the one incorporating HLA-B27, the use of methotrexate and of sulfasalazine, and the families Enterobacteriaceae and Bifidobacteriaceae. The validation cohort showed an accuracy of 83% (95% CI: 0.36-0.99). Figure 2B summarizes the species most important for prediction in the LR model.

Conclusion: We have identified microbiota that can predict the chronicity of ReA. However, the accuracy of the prediction can be improved upon with larger cohorts with prospective validation. **Reference:** < 1. Newly Identified Gut Commensal *Clostridium Fessum* AM100 for Treating Ankylosing Spondylitis

Lu Bai[1], Chengkai Zhu[1], Yihong Xu[2], Kunhai Tang[1], Dachun Zhuo[1], Qing Zhang[1], Chengchun Geng[1], Weidong Xu[2], Hao Wu[1], Xingdong Chen[1] and Jiucun Wang[1], [1]Fudan University, Shanghai, China, [2]Changhai Hospital, Shanghai, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is an inflammatory disease of the spinal joints leading to progressive loss of spinal mobility and chronic pain. Gutdysbiosis has been reported implicated in the pathogenesis of AS, however,the functionally relevant microbial changes and the underlying molecular mechanisms remain unclear. The object of this study is to determine the key microbes in AS by meta-analysis of the metagenomic data and to examine the underlying mechanism in a proteoglycan-induced spondylitis (PGISp) mouse model of AS.

Methods: For human cohorts, meta-analysis of the fecal metagenomic data from three published cohorts was performed. Raw FASTQ files were downloaded from the ENA and NCBI Sequence Read Archive. Taxonomic profiles were generated with the mOTU profiler v.2.5.1. *Clostridium fessum*AM100 was isolated from the fecal sample of a healthy donor. The PGISp model was established to examine the effect of the strain. PGISp mice were orally inoculated daily with 10^8CFU of live AM100 diluted in 200ul PBS. The administration of AM100 was sustained across the entire time course of the experiment.

Clinical and histological analysis were performed based on the standard scoring system. Plasma IL-17A and colon lamina propria Th17 levels were assessed using ELISA and flow cytometry, respectively. New bone formation of the mouse spine was examined by micro-CT at week 20.

Results: We foundan as-yet-uncharacterized species *Clostridialesspecies*[meta_12476] with the most pronounced change between AS and the control group (FDR_{Total}= 6.95×10^{-7}), whichwas decreased in the fecalsamples from AS patients. The downregulation ofthe specieswas only found in AS patients, but not in RA patients. Next, we isolated this bacterial strain from the stool sample of a healthy male and named it*Clostridium fessum*AM100 (Figure 1).

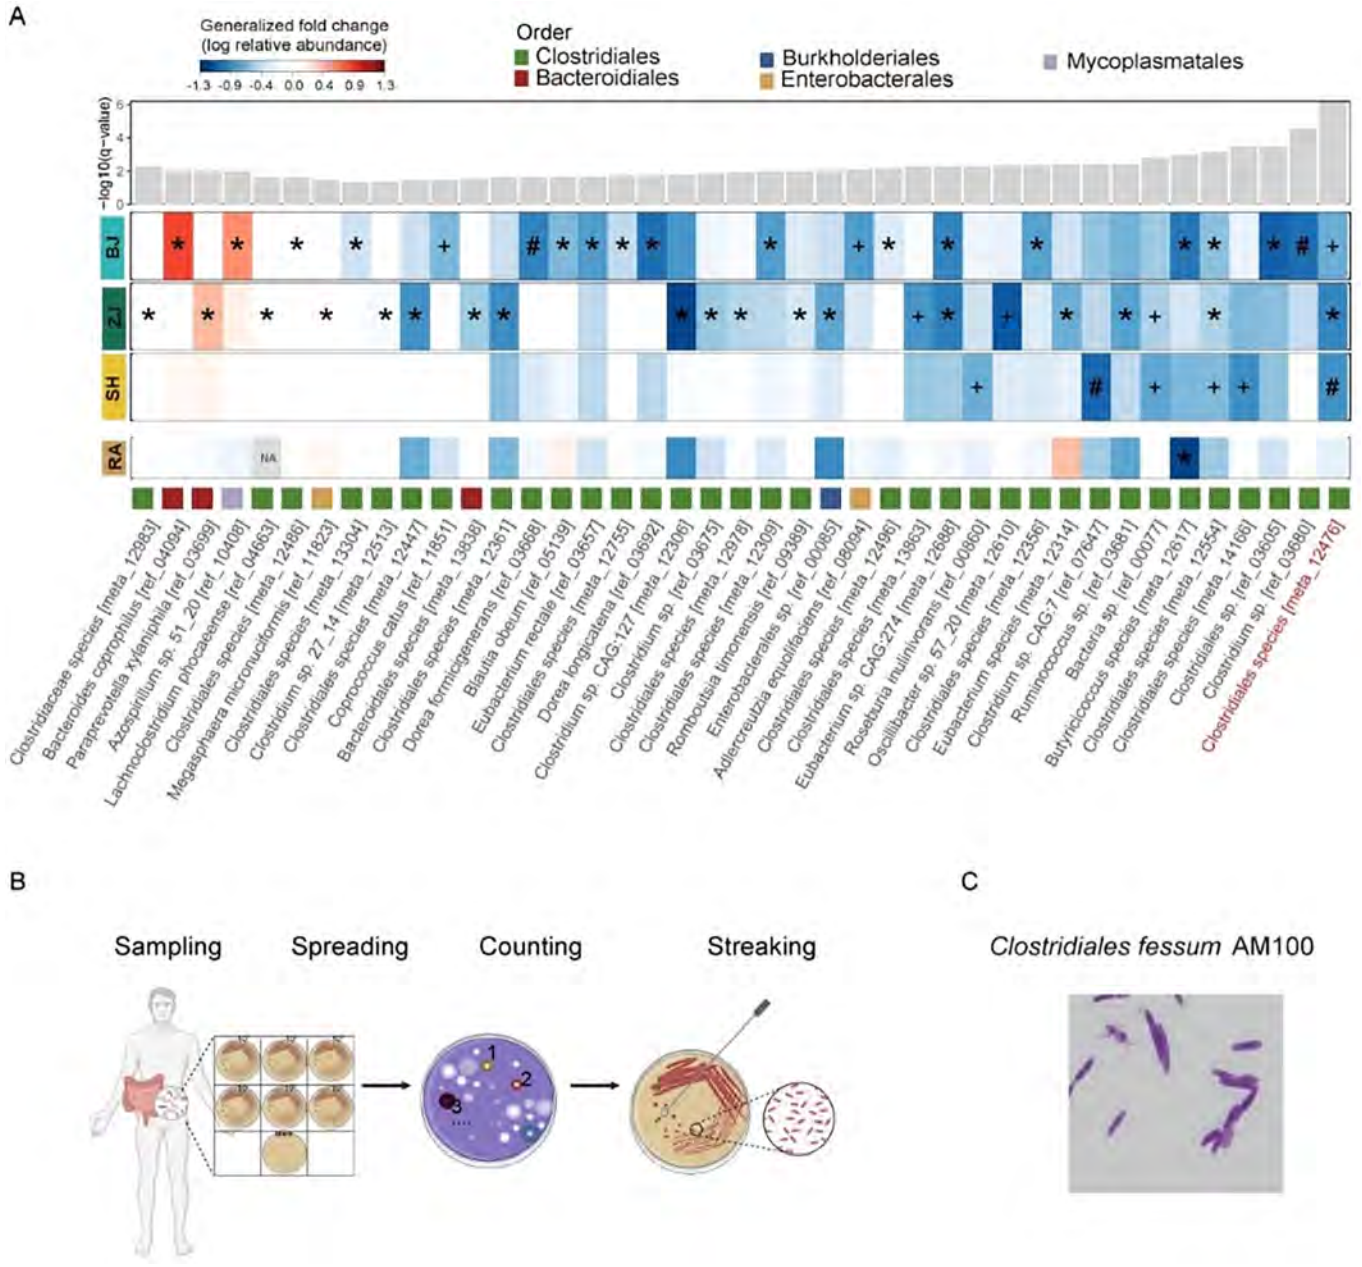

Figure 1. Gut microbial differences between AS patients and controls. (A) Heatmaps in gray and in colors showing the species-level significance, as calculated with a two-sided Wilcoxon test (FDR corrected P value), and the generalized fold change within individual studies. (B) The workflow of isolating C.fessum AM100 from male human feces. (C) Micrograph showing strain C.fessum AM100 after gram staining.

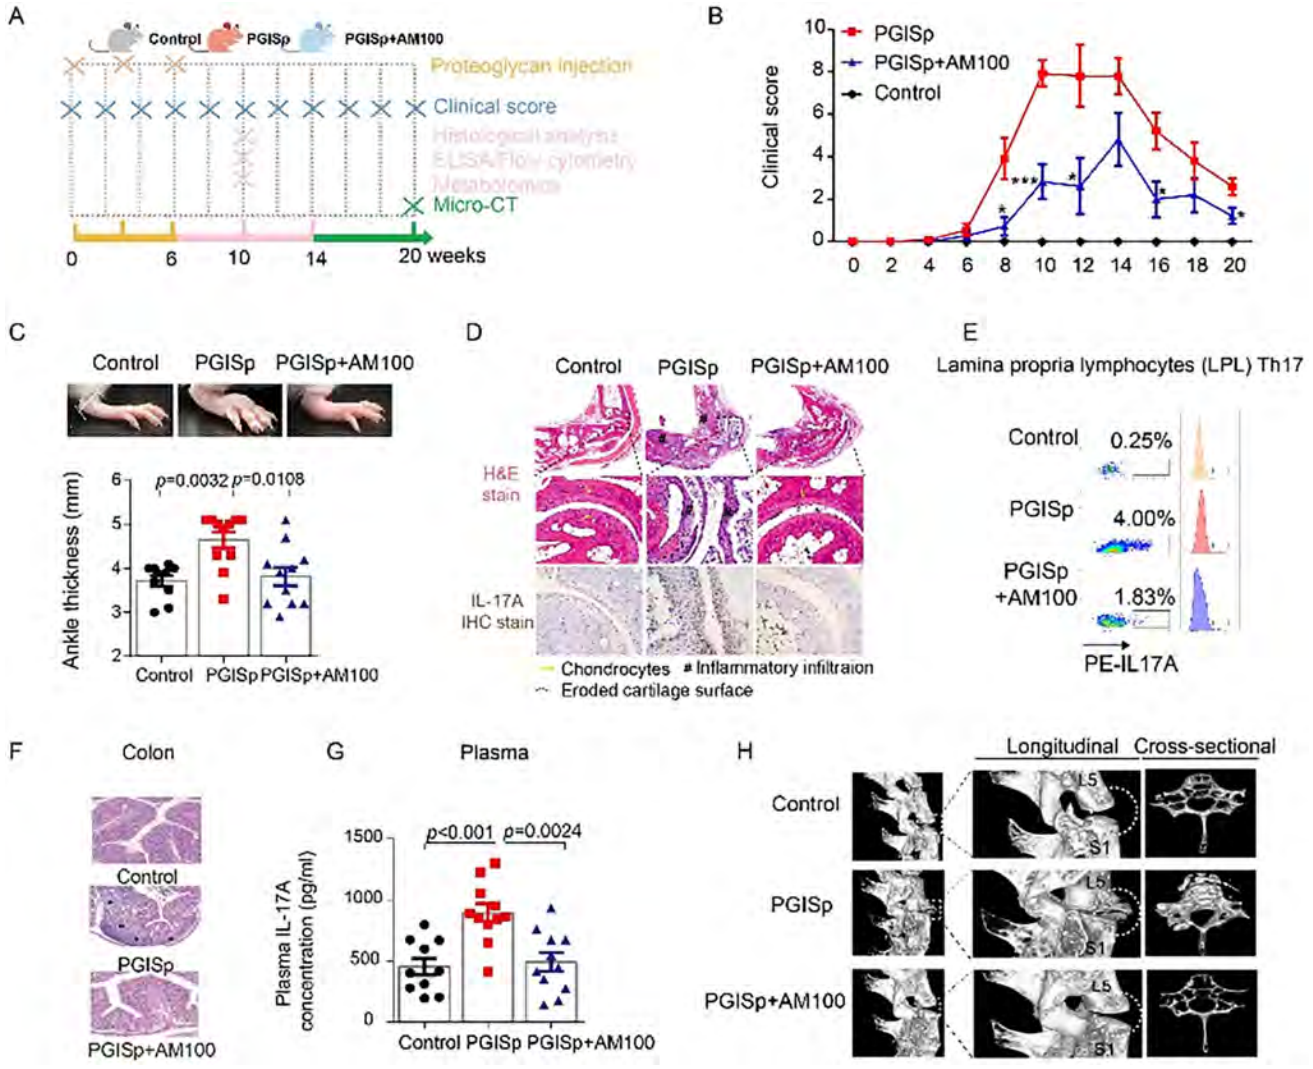

Figure 2. C.fessum AM100 ameliorates proteoglycan-induced spondyloarthritis (PGISp) in mice. (A) Schematic diagram showing the experimental design. (B) Clinical scores in control (n=10), PGISp (n=11), and PGISp mice with AM100 treatment (n=11). (C) Representative photographs of hind paws and ankle thickness. (D) Hematoxylin-eosin staining (H&E), and IL-17A immunochemistry staining images. (E) Flow cytometry analysis of Th17 cells in the LPLs. (F) Histological analysis of distal colon of mice. (G) Serum concentration of IL-17A. (H) Representative micro-CT images showing the lumbar spines and sacroiliac joints (L5-S1) at week 20.

Oral administration of *C.fessum*AM100 alleviated the AS symptoms in PGISp mice in terms of arthritis clinical score and hind paw ankle thickness. The inflammatory infiltration and synovial erosion were improved by *C.fessum*AM100. Compared with PGISp mice, AM100 treatment considerably decreased the percentage of Th17 cells among colonic lamina propria lymphocytes (cLPL), accompanied by the alleviation of colitis. AM100 significantly suppressed the cytokine production of IL17A in the plasma at week 10. At the advanced phase, AM100 delayed syndesmophyte formation in the PGISp mice (Figure 2). Metabolome analysis revealed that putrescine and γ-aminobutyric acid (GABA) were enriched in AM100 fermentation supernatant. Also, putrescine and GABA displayed anti-inflammatory effectsin vivo (Figure 3).

Conclusion: We demonstrated the key microbe *Clostridium fessum*AM100, significantly depleted in the feces of AS patients, can suppress the IL-17A-related inflammation and delay new syndesmophytes formation in the PGISp model of AS. Putrescine and GABA can mimic the beneficial effects of *C.fessum* AM100. This study suggests that *C. fessum*AM100 might serve as an attractive probiotic for the treatment of AS patients.

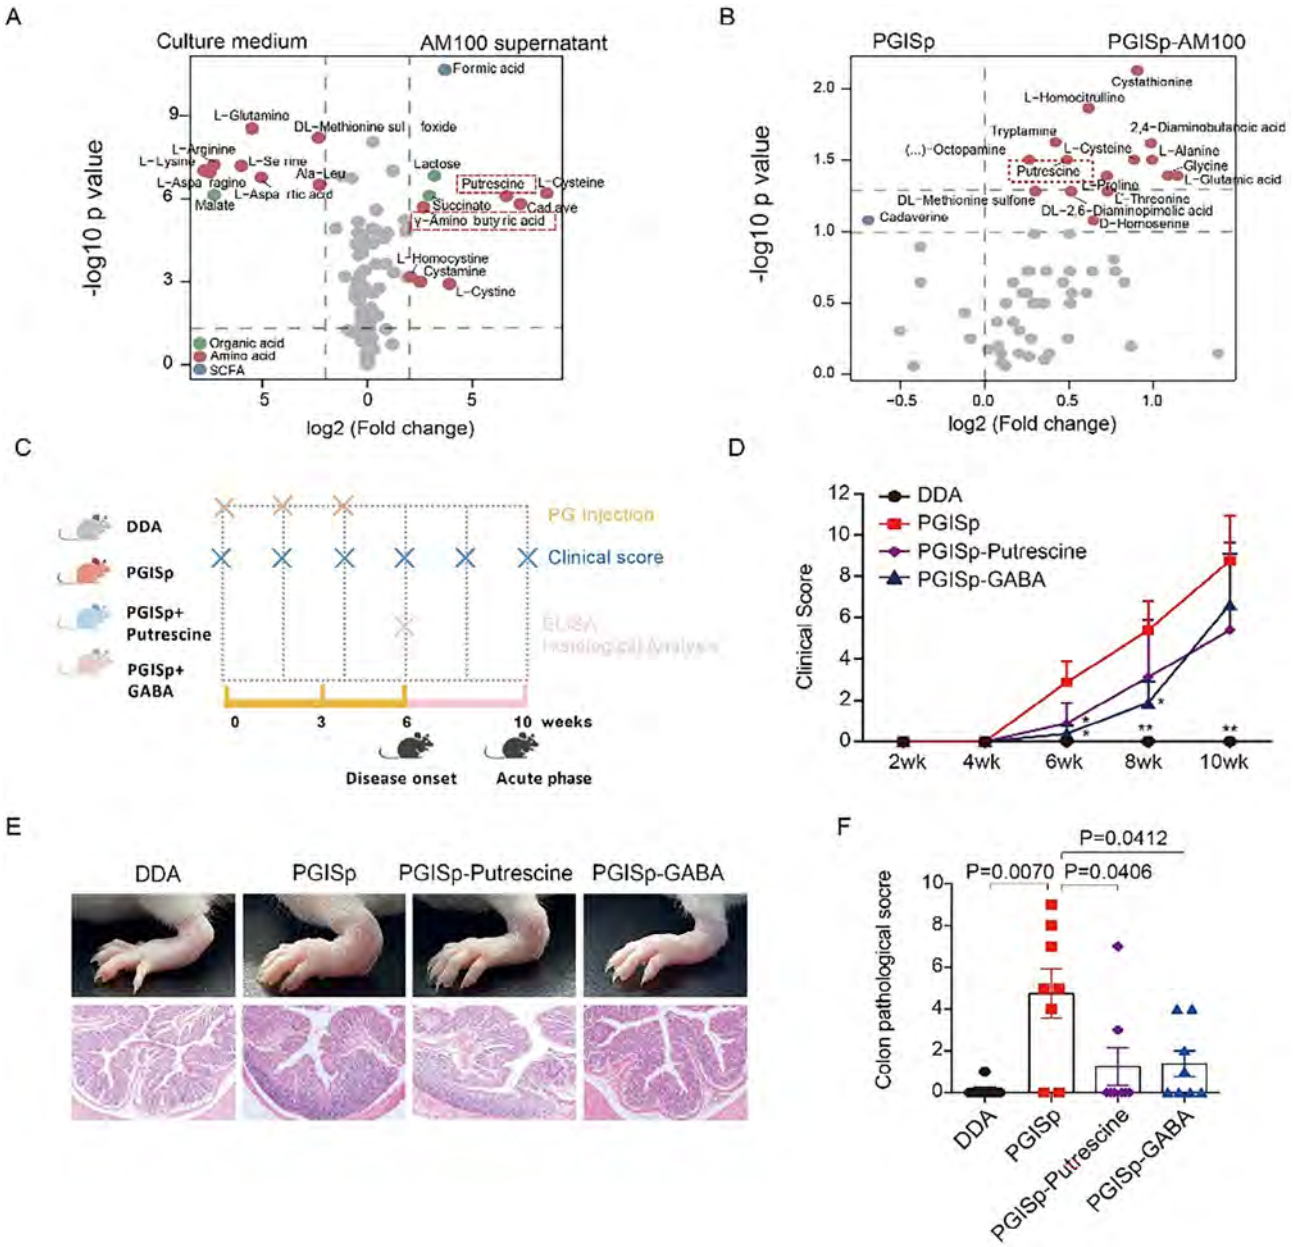

Figure 3. C.fessum AM100 ameliorates disease symptoms in mice by producing putrescine and GABA. (A) Targeted Metabolomics analysis revealed the significantly altered metabolites in AM100 fermentation supernatant vs. Culture medium, and (B) the feces of AM100-treated PGISp mice vs. PGISp mice. (C) Schematic diagram showing the experimental design. (D) Clinical scores in control, PGISp, and PGISp mice with putrescine and GABA treatment (n=8 for each group). (E) Representative photographs of hind paws and Hematoxylin-eosin (H&E) staining of the distal colon of mice. (F) Pathological severity of the colon was scored based on the severity of inflammation, damage of the crypt, and extension of lesions.

Regulatory Role of JAK-1/TYK2 Signaling on the Pannus Formation: Novel Mechanisms for JAK Inhibitors in Psoriatic Disease

Siba Raychaudhuri[1], Christine Abria[2] and Smriti K Raychaudhuri[2], [1]UC Davis, School of Medicine/ VA Medical Center, Sacramento, Davis, CA, [2]VA Sacramento Medical Center, Mather, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In psoriatic arthritis (PsA) aberrant activation/migration of specific T cell subpopulations (Th17/Th9/MAIT cells) in the joint synovium induce synovial inflammation and pannus formation. Several T cell cytokines such as IL-9, IL-17A/IL-17F, IL-22 and IL-23 play critical roles in the pathogenesis of PsA. IL-23 does not have any biological effect on synovial cells (FLS) and IL-17 does not activate the JAK/STAT signaling system. IL-9 and IL-22 have regulatory roles on proliferation of FLS; and as well JAK-1 and 3 are activated by IL-9; and JAK1/TYK2 by IL-22. Here to determine the functional significance of these signaling proteins on pannus formation we hypothesized that IL-9/IL22 induced JAK/STAT signaling regulates the proliferative cascades of FLS in PsA. We studied the regulatory role IL-9 induced JAK-1,3 and IL-22 induced JAK1/TYK2 on FLS biology.

Methods: FLS from PsA (n=10) were cultured as per our standardized protocol (Cytokine.2012;60:38-42) with rIL-9 (10ng/ml) and rIL-22 (100ng/ml). Proliferation was measured by MTT assay and CFSE dilution assay. IL-6, IL-8 and MMP3 levels were determined by ELISA. Immunoblot studies were done to assess JAK1/pJAK1, TYK2/pTYK2, STAT1/pSTAT1, STAT3/pSTAT3. Further to determine the molecular mechanisms of JAK inhibitors (JAKi) these experiments were done in the presence or absence of specific JAKi (JAK-inhibitor, Upadacitinib).

Figure 1

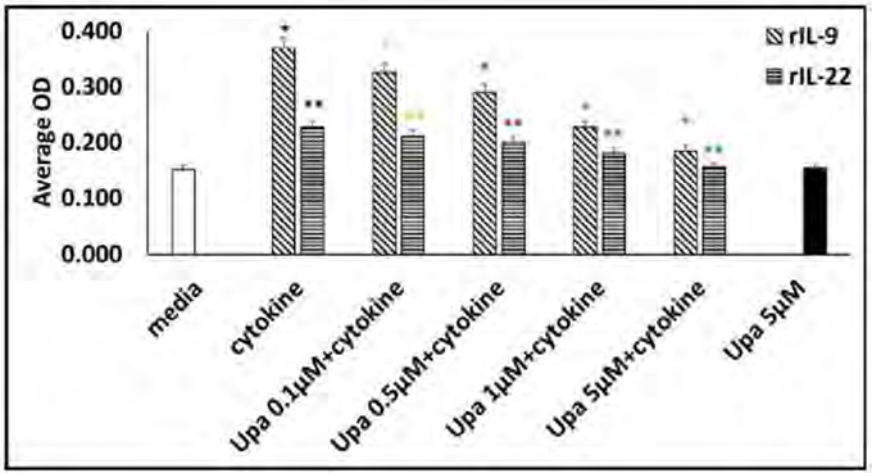

Figure 1: JAK-1 regulates rIL-9/rIL-22 induced proliferation of FLS. MTT assay results show that rIL-9/rIL-22 induced proliferation of FLS is inhibited by a specific JAK-1 inhibitor (upadacitinib). IL-9 and IL-22 increases FLS proliferation significantly compared to culture media ($p<.001$, t-test). Upadacitinib at several concentrations show significant inhibition of IL-9/IL-22 induced FLS proliferation compared to IL-9/IL-22 induced proliferation ($p<.001$).

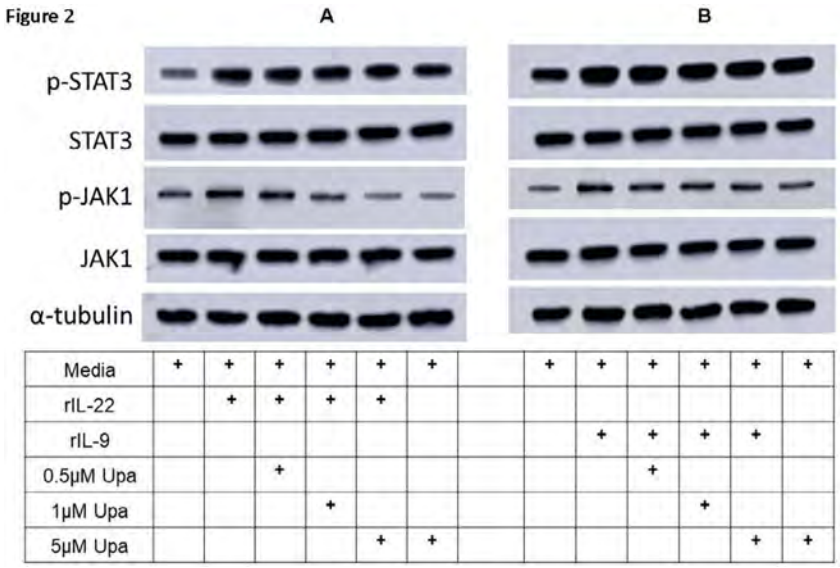

Figure-2: (A) immunoblot study of FLS demonstrates that rIL-22 induced phosphorylation of JAK-1 and STAT-3 were inhibited by specific JAK-1 inhibitor, upadacitinib. (B) immunoblot study of FLS demonstrates that rIL-9 induced phosphorylation of JAK-1 and STAT-3 were inhibited by specific JAK-1 inhibitor, upadacitinib.

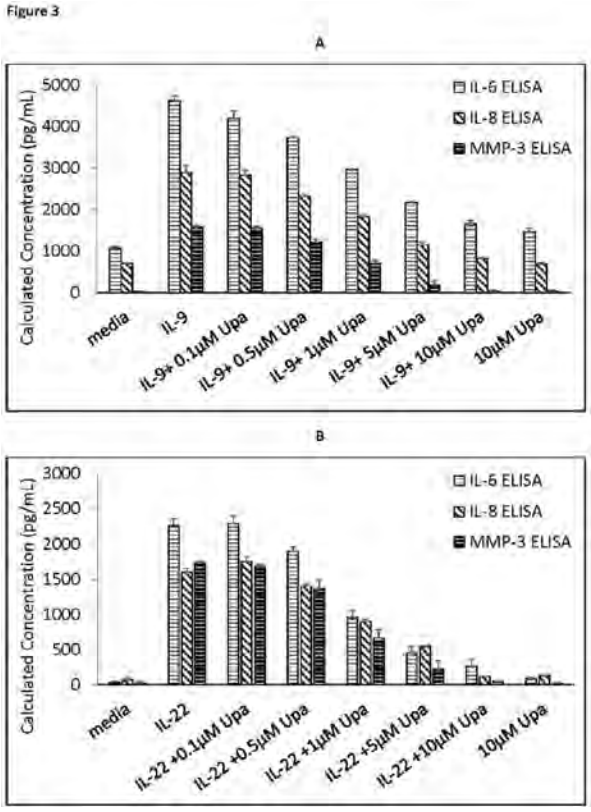

Figure 3: (A) rIL-9 induced IL-6, IL-8, MMP3 secretion by FLS was inhibited by JAK-1 inhibitor, upadacitinib. FLS were cultured with rIL-9 and several doses of upadacitinib. ELISA assay of culture supernatants showed significant inhibition of IL-6, IL-8 and MMP3 levels. (B) rIL-22 induced IL-6, IL-8, MMP3 secretion by FLS was inhibited by JAK-1 inhibitor, upadacitinib. FLS were cultured with rIL-22 and several doses of upadacitinib. ELISA assay of culture supernatants showed significant inhibition of IL-6, IL-8 and MMP3 levels.

Results: In cultured FLS we observed that rIL-22 and rIL-9 induced increased phosphorylation of JAK1/TYK2 and JAK1/JAK3 respectively compared to the culture media only, ($p< 0.01$). rIL9/rIL22 also phosphorylated STAT3/RORγt. We observed that the critical events in PsA such as (i) proliferation of FLS (ii) IL-6, IL-8 and MMP-3 production by FLS are induced by rIL-22 and rIL-9 and those were regulated by JAK1/TYK2 and JAK-1,3 respectively. Further pan-JAK inhibitors and other specific JAK-1 and TYK2 inhibitors blocked these effects significantly ($p< 0.01$). Details of some these observations on the regulatory role of JAK-1 are shown in the Figure 1. Figure-1 demonstrates that rIL-9r/rIL-22 induced proliferation of FLS could be inhibited by blocking JAK-1 with JAKi (upadacitinib) by MTT assay; Figure-2 shows the regulatory role of rIL-22 on JAK/STAT phosphorylation in FLS and Figure-3 demonstrates regulatory role of JAK-1 on FLS in respect to local cytokine and metalloproteinase production.

Conclusion: JAK/STAT signaling system of T cells and its regulatory role in the pathogenesis of psoriatic disease is well established.This study provides a novel insight about the role for JAK-1 and TYK2 signaling on pannus formation and demonstrates novel therapeutic targets for treatment of psoriatic disease.

The Emerging Mechanism of TNF&IL-17A/WNT5a/ROR2 Axis in Pathological Bone Formation of Ankylosing Spondylitis

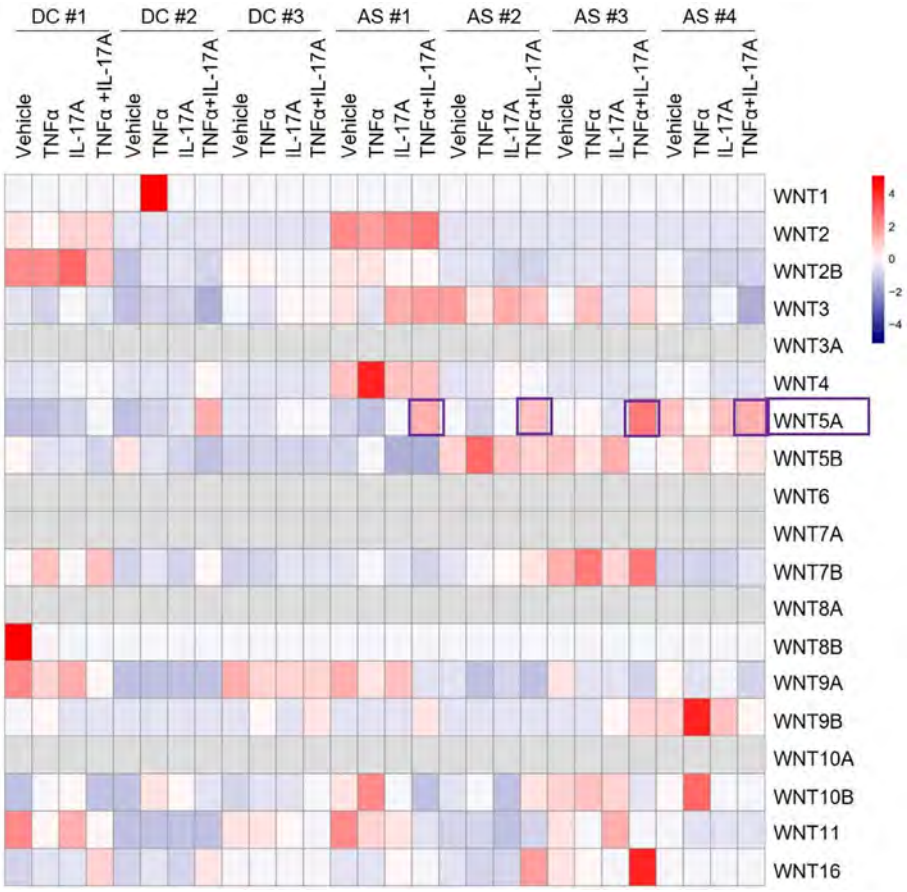
Sungsin Jo[1], Seung Hoon Lee[1], Chanhyeok Jeon[1], Sung Hoon Choi[2], Ye-Soo Park[3] and Tae-Hwan Kim[4], [1]Hanyang University Institute for Rheumatology Research, Seoul, South Korea, [2]Hanyang University Seoul Hospital, Seoul, South Korea, [3]Hanyang University College of Medicine, Guri, South Korea, [4]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

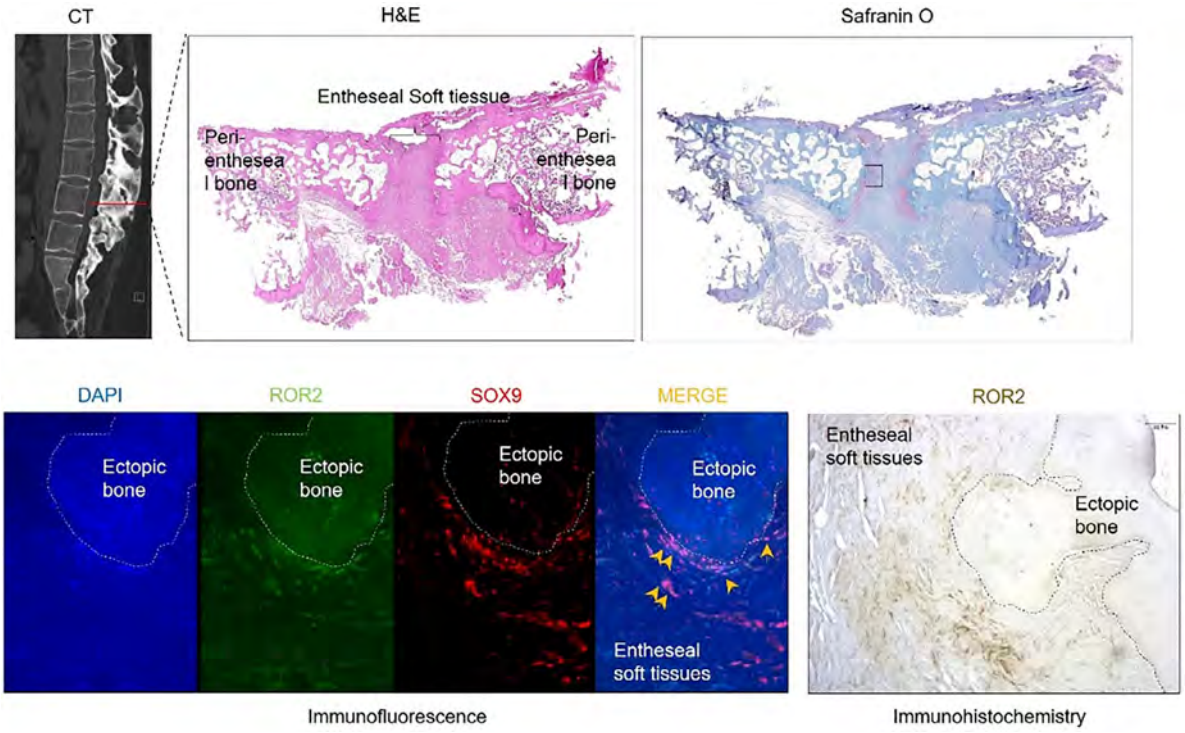
Background/Purpose: Enthesitis is one of the most distinctive features and signs of ectopic bone formation in ankylosing spondylitis (AS). The Wnt/β-catenin pathway and Th17 cells are closely associated with pathological bone formation in AS, but their association has not been fully understood.

Methods: Twenty-five healthy control (HC) and seventy AS sera was subjected to ELISA for human TNF, IL-17A, and WNT5a. Ten PBMC (three HC and seven AS) and seven enthesis cells (three control- and four AS-enthesis) were conducted to RNA-sequencing. WNT5a and Receptor tyrosine kinase like orphan receptor 2 (ROR2) expression in enthesis were validated by immunohistochemistry analysis in five diseases control and seven AS patients. Next, overexpression or knockdown of ROR2 in primary enthesis was assessed bone-forming activity in the presence or absence of WNT5a treatment. Finally, enthesitis and ectopic bone formation at the ankle were evaluated in treatment with Ror2 mouse shRNA lentiviral particle in curdlan-injected SKG mice.

Results: TNF, IL-17A and Wnt5a in AS sera were significantly increased and positively correlated with mSASSS. Co-treatment with TNF and IL-17A dramatically increased WNT5a expression in AS-enthesis cells, as evaluated by RNA-sequencing, RT-qPCR, immunoblotting, and ELISA. Also, co-treatment with TNF and IL-17A augmented the bone-forming



We found that co-treatment with TNF and IL-17A dramatically increased WNT5 expression in AS-enthesis.



We found that ROR2 is highly expressed in the ectopic bone of the human AS spinous process.

activity, bone-related gene expressions (ALP, RUNX2, and OCN), and WNT5A in AS-enthesis cells accompanied as compared to diseases control. Moreover, WNT5A treatment not only upregulated RUNX2 and CTCF expression in AS-enthesis cells via ROR2, but also showed excessive bone-forming activity under osteogenic stimulation. Intriguingly, an increase ROR2 expression in AS enthesis was revealed by RNA sequencing and validated at ectopic bone in spinal enthesis tissues from AS patients. Overexpression of ROR2 in enthesis had an accelerating bone-forming effect in Wnt5a treatment, whereas the knockdown of ROR2 in enthesis had shown the delaying bone-forming activity of AS enthesis in WNT5a treatment. Finally, treatment of Ror2 mouse shRNA lentiviral particle in curdlan-injected SKG mice exhibited a significant decrease in enthesitis and ectopic bone formation at the ankle.

Conclusion: We found that synergism of TNF and IL-17A triggers acceleration of bone mineralization and new bone formation in enthesis via WNT5/ROR2 axis. TNF&IL-17A/WNT5a/ROR2 axis may play a crucial role in pathological new bone formation in AS.

Microtrauma Exacerbates Arthritis and Enthesitis in Curdlan-administered SKG Mice by Inducing FGF16 Expresssion

Seung Hoon Lee[1], Chanhyeok Jeon[1], Sungsin Jo[1] and Tae-Hwan Kim[2], [1]Hanyang University Institute for Rheumatology Research, Seoul, South Korea, [2]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Microtrauma might be considered a crucial of various environmental factors in AS, but there is still unknown whether microtrauma has a direct/indirect role in the pathogenesis of AS.

Methods: To induce microtrauma injuries, right hindlimb of male SKG mouse was immobilized by a surgical sticking plaster and pipette tip for a week. After this period, the fixed tip was removed from ankle and the mouse was intraperitoneally injected with 3 mg curdlan. Left and Right ankles were considered microtraumatized and non-microtraumatized group, respectively. We monitored clinical arthritis to score it every week for 5 weeks. At 6 weeks, the physical changes in ankles and sacroiliac joints were evaluated by histological and micro-CT analysis. Primary muscle cells were induced by shear stress for a day to mimic microtrauma and conducted RNA-sequencing.

Results: After curdlan injection in SKG mice, the left ankle was microtraumatized and showed an increase in frequency and severity of arthritis and enthesitis when compared to the non-microtraumatized right ankle. Also, as revealed by micro-CT analysis, the inflamed bone volume was decreased in the heel of non-microtraumatized right ankle, whereas dramatically increased in heel of microtraumatized left ankle. Moreover, TNFa expression in enthesis and arthritis of ankle using IHC were much higher in microtraumatized left ankle than non-microtraumatized right ankle. Intriguingly, the SI joints of the left hip were shown cartilage fusion in the microtraumatized left as compared to the non-microtraumatized right. When RNA-sequencing data of shear stress was compared to non-stress groups, we found that the FGF16 gene is a top rank in the stress group. The expression of FGF16 was significantly elevated in the femur muscle of microtraumatized left ankle.

Conclusion: Here we showed that microtrauma at ankle using immobilization contributes to severity arthritis and enthesitis at ankle and induction of FGF16 in muscle of curdlan-injected SKG mice.

Expansion of CD8+ TCRVβ9+ T Cells in the Peripheral Blood of HLA-B27+ Patients with Axial Spondyloarthritis

Caroline Bauchiero[1], Micah Lefton[1], Stephanie Sinnappan[2], Jeffrey Sparks[3] and Joerg Ermann[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Columbia University, New York, NY, [3]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

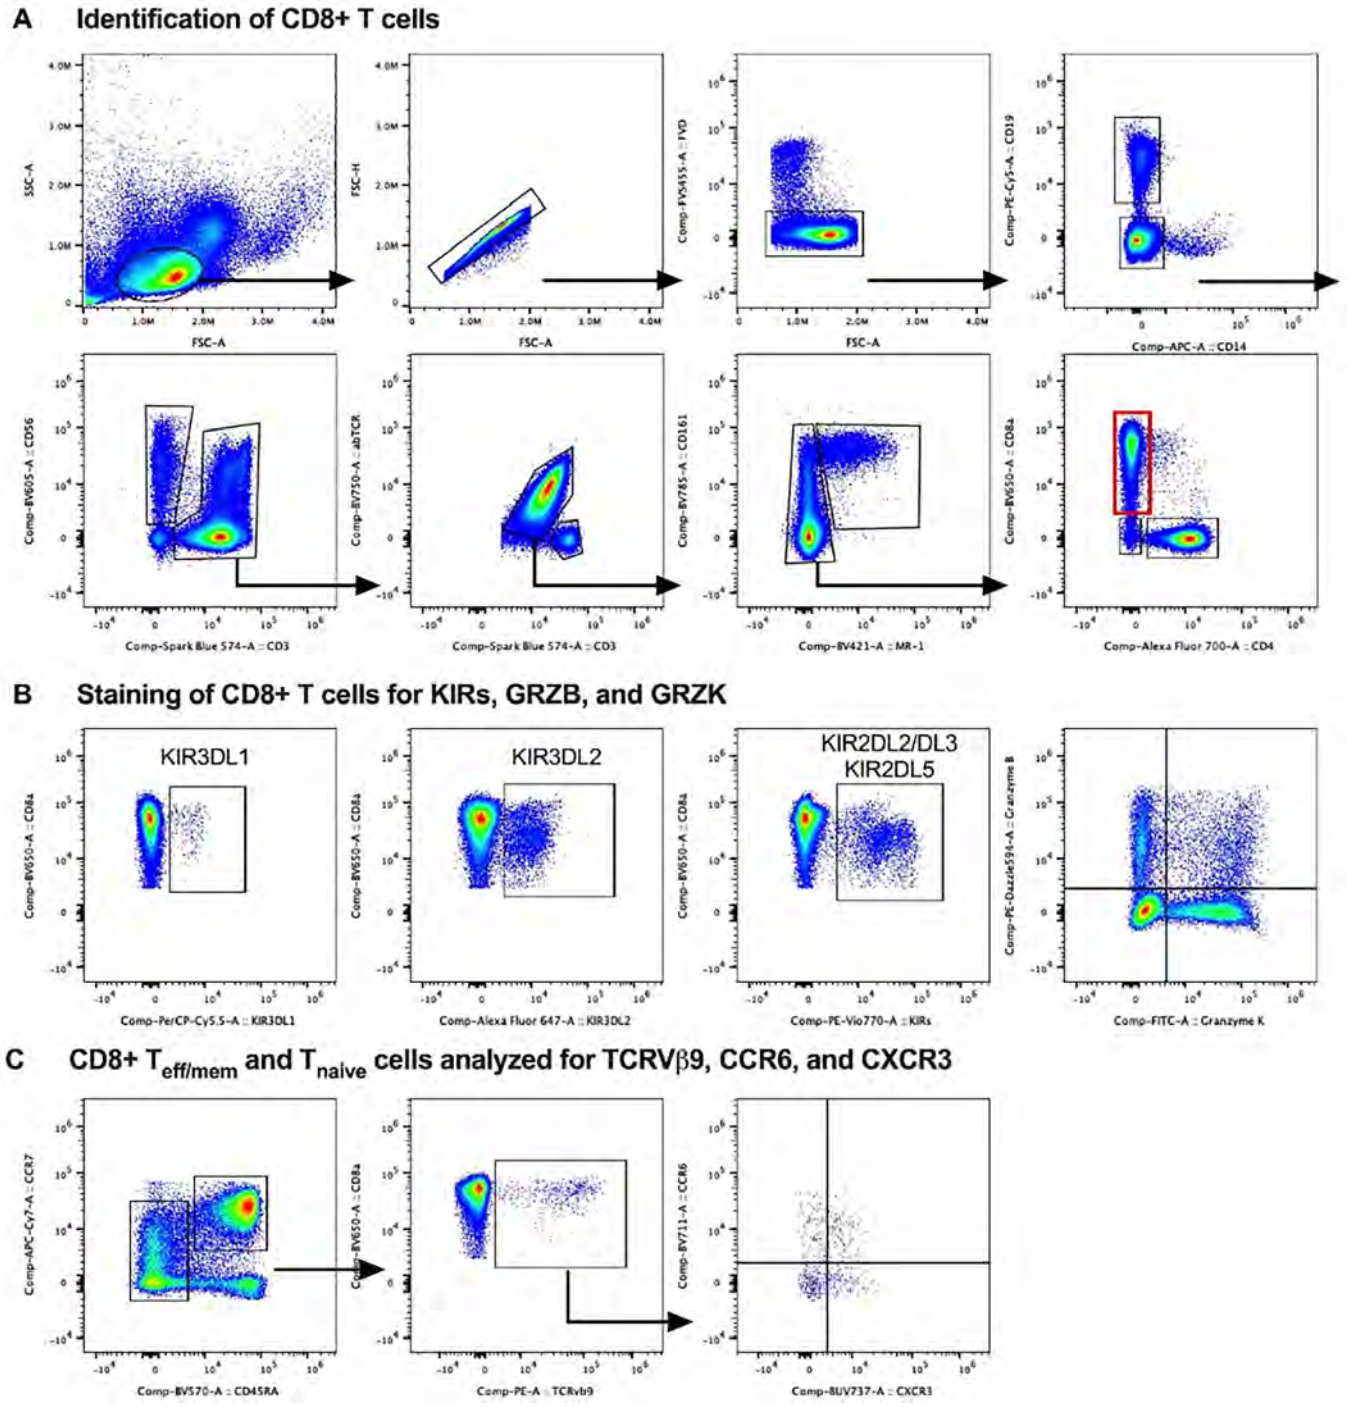
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies in human HLA-B27 transgenic rats largely discredited the idea that CD8+ T cells are key drivers of disease in axial spondyloarthritis (axSpA). However, recent studies in humans have revived interest in the role of CD8+ T cells in axSpA including the description of relevant CD8+ T cell subsets in a number of rheumatic disease settings (CD103+CD49a+ InEx cells, regulatory CD8+KIR+ T cells, Granzyme B and K expressing CD8+ T cell subsets) and the demonstration of expanded TCR clonotypes in the joints and eyes of HLA-B27+ SpA patients. In this study, we used state-of-the-art flow cytometry to search for diagnostic cellular biomarkers in axSpA reporting results for CD8+ T cells.

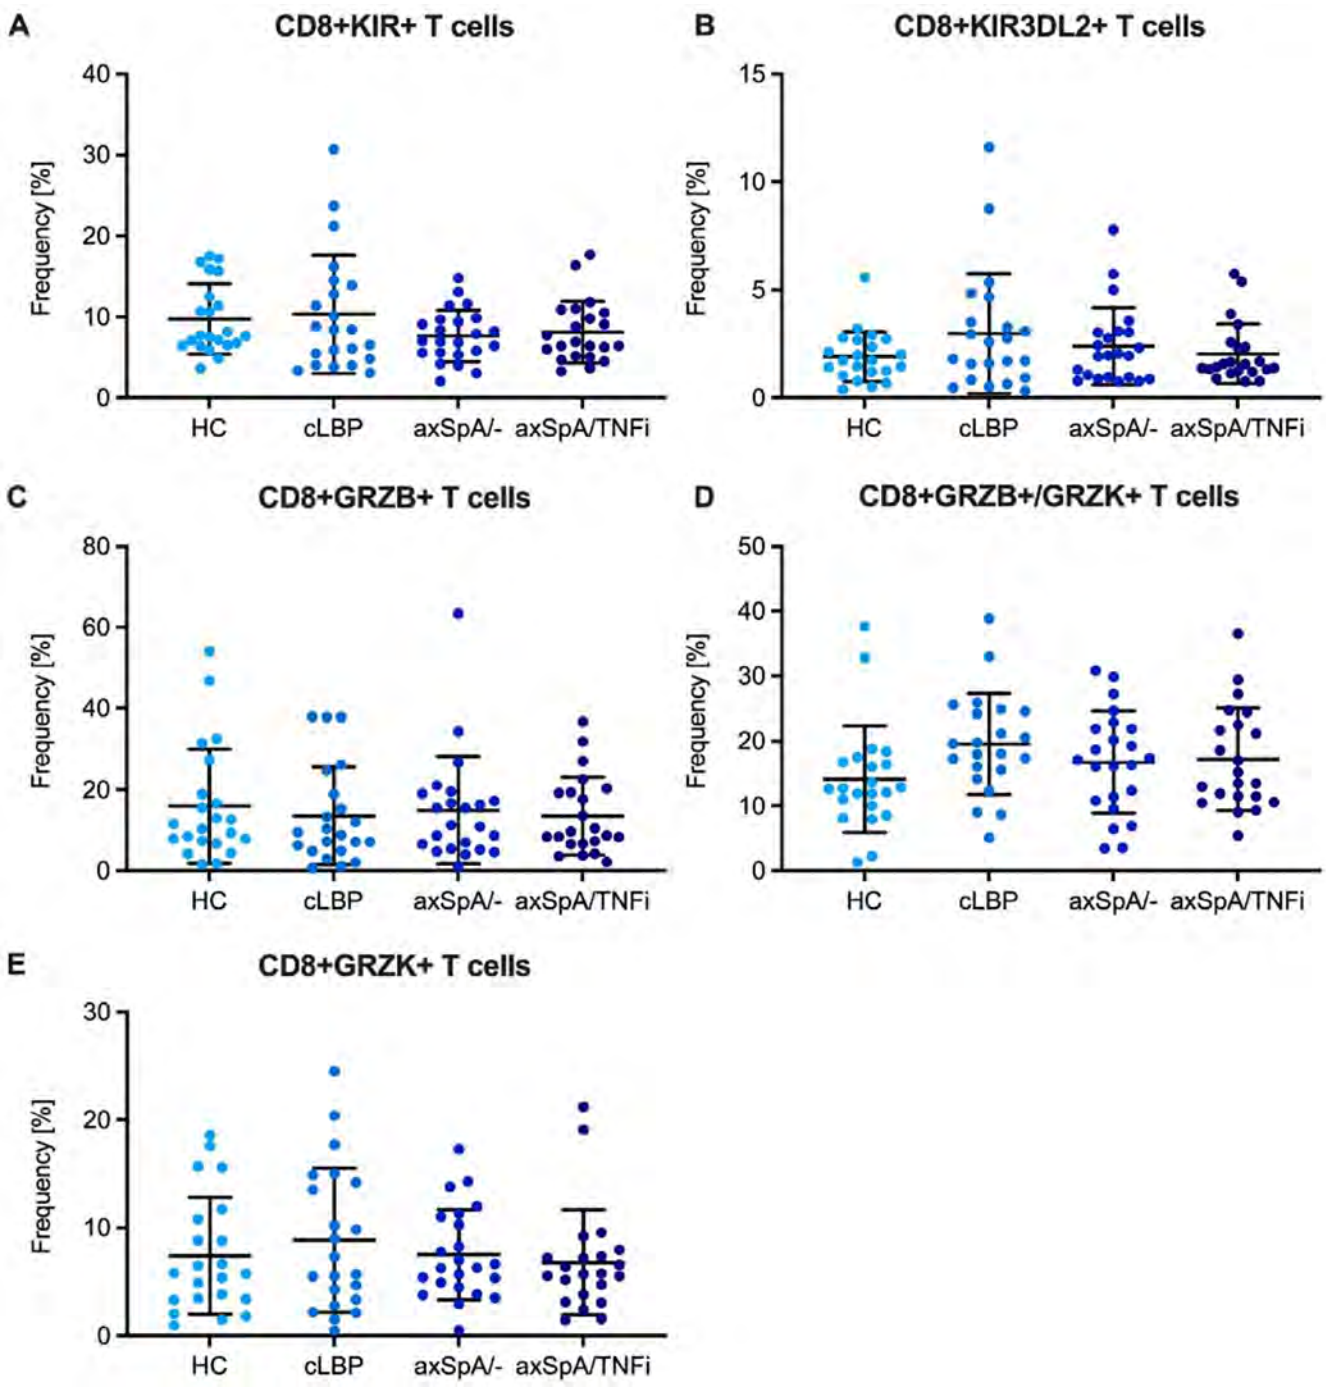
Methods: Study subjects were recruited from our hospital's Orthopedic and Arthritis Center. Four groups were compared: healthy controls (HC), patients with chronic low back pain without axSpA (cLBP), axSpA patients not on a biologic (axSpA/-), and axSpA patients treated with a TNF inhibitor (axSpA/TNFi). Groups (n=22-23 each) were matched for age, sex and genotyped for HLA-B27. All axSpA patients fulfilled modified New York criteria for ankylosing spondylitis or the 2009 ASAS criteria for axSpA. PBMCs were analyzed in two batches on a CYTEK Aurora spectral flow cytometer. Our customized 30-parameter staining panel included major lineage markers, lymphocyte differentiation and activation markers and functional markers for cytotoxicity, homing, and cytokine production potential. We included antibodies for KIR3DL1 (DX9), KIR3DL2 (DX31), KIR2DL2/L3 (DX27) and KIR2DL5 (UP-R1) as well as TCRVβ9+ (MKB1). Cells were further stained intracellularly for GRZB (GB11) and GRZK (GM26E7). FlowJo was used for quality control and analysis (see gating strategy in Fig. 1).

Results: There were no differences in the frequency of CD8+ T cells expressing any KIR or CD8+ T cells expressing the HLA-B27 binding KIR3DL2 between HC, cLBP, axSpA/- and axSpA/TNFi subjects (Fig. 2A,B). There were also no differences in the frequency of CD8+ T cell subsets distinguished by expression of GRZB and GRZK (Fig. 2C-E). About 2% of CD8+CD45RA^{lo}T$_{eff/mem}$ and CD8+CD45RA^{hi}CCR7+ T$_{naive}$ cells were TCRVβ9 positive without differences between groups. However, when only HLA-B27+ individuals were analyzed, we noticed an expansion of TCRVβ9+ cells amongst CD8+ T$_{eff/mem}$ cells in axSpA/- and axSpA/TNFi subjects, which was not seen in CD8+ T$_{naïve}$ cells or in the respective CD4+ T cell subsets (Fig. 3). Compared with control subjects, CD8+TCRVβ9+ T$_{eff/mem}$ cells in axSpA patients showed increased expression of CCR6 suggesting a Tc17 phenotype.

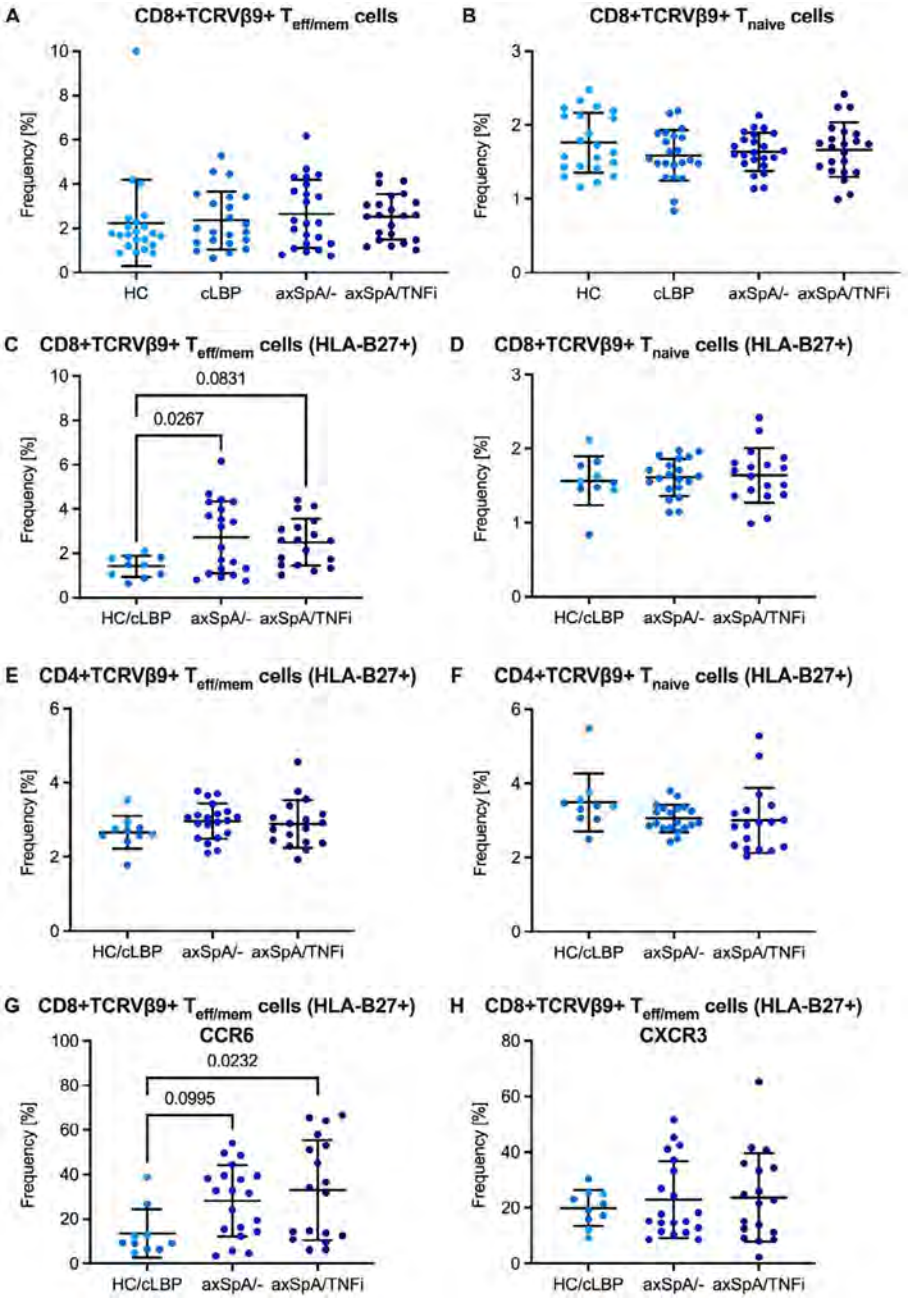
Conclusion: The observed expansion of CD8+Vβ9+ $T_{eff/mem}$ cells in the peripheral blood of HLA-B27+ patients with axSpA is consistent with the previously reported expansion of TRBV9–CDR3–TRBJ2.3 clonotypes in tissues and supports the peptide hypothesis for the HLA-B27 association with axSpA. The in-depth characterization of the CD8+TCRVβ9+ $T_{eff/mem}$ population using additional markers included in the staining panel is ongoing.



Gating strategy. (A) Identification of CD8+ T cells by hierarchical gating. (B) Staining of CD8+ T cells for expression of KIR3DL1, KIR3DL2, KIR2DL2/L3+KIR2DL5, and GRZB vs. GRZK. CD8+ T cells expressing any KIR were identified by Boolean gating (logic OR gate) in FlowJo. (C) CD45RA and CCR7 were used to identify CD8+ Teff/mem and Tnaive cells, which were then analyzed for expression of TCRVb9, CCR6 and CXCR3



(A) Expression of KIRs on total CD8+ T cells. Depicted is the fraction of CD8+ T cells that express any of the following KIRs: KIR3DL1, KIR3DL2, KIR2DL2/L3, KIR2DL5 (B) Fraction of KIR3DL2+ CD8+ T cells. (C-E) Fraction of CD8+ T cells expressing GRZB alone, GRZB and GRZK, or GRZK alone. Bars represent means and SD deviation. There were no significant differences between groups by one-way ANOVA.



(A, B) Fraction of TCRVb9+ cells amongst CD8+ Teff/mem cells and CD8+ Tnaive cells, respectively. (C, D) Fraction of TCRVb9+ cells amongst CD8+ Teff/mem cells and CD8+ Tnaive cells in HLA-B27+ individuals. HC (n=4) and cLBP (n=6) were pooled. (E, F) Fraction of TCRVb9+ cells amongst CD4+ Teff/mem cells and CD4+ Tnaive cells in HLA-B27+ individuals. (G, H) Fraction of CCR6+ and CXCR3+ cells amongst CD8+-TCRVb9+ Teff/mem cells in HLA-B27+ individuals. Bars represent means and SD deviation. P values were calculated by one-way ANOVA with post hoc Tukey's.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the widespread use of anti-TNFα therapy in psoriatic arthritis (PsA), a significant proportion of patients fail to achieve a complete treatment response. There are no predictive markers for response to TNFα blockade. Rs1061622 polymorphisms (T/T, T/G, or G/G genotypes) corresponds to a methionine with T allele or arginine with G allele at amino acid position 196 of TNFα receptor 2 (TNFR2). These polymorphisms in TNFR2 have been associated with treatment response in rheumatoid arthritis and PsA, with the G/G genotype being less likely to respond to anti-TNFα therapy compared to the T/T genotype. However, the underlying molecular mechanism explaining this association remains unknown. This study aimed to investigate the signaling differences between TNFR2 variants associated with rs1061622 polymorphisms carrying the T allele (TNFR2-196M) and G allele (TNFR2-196R), which could potentially elucidate the differential responsiveness to anti-TNFα therapy in PsA patients.

Methods: Gene expression studies were conducted in Jurkat T cells and primary human endothelial cells. Recombinant TNFR2-196M or TNFR2-196R were expressed in both cell types using a lentiviral approach. Cells were treated with TNFα alone (2 ng/mL) or TNFα in the presence of a TNFα neutralizing antibody. The expression of, ICAM-1, a TNFR2-dependent proinflammatory gene, was assessed using quantitative RT-PCR. These findings were further validated using human umbilical vein endothelial cells (HUVEC) with rs1061622 polymorphisms. The polymorphisms were determined

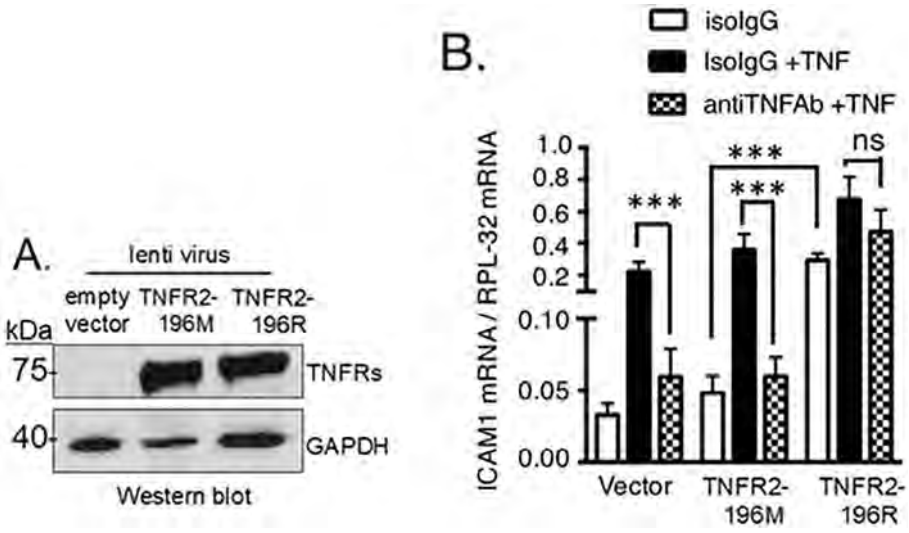

Figure 1. TNFR2-196R expressing Jurkat T cells show increased expression of ICAM-1 in the absence of TNFα. A) Western blot showing TNFR2-196M or TNFR2-196R protein expression using lentiviral approach. B) Using RTqPCR basal ICAM-1 mRNA abundance is significantly increased in TNFR2-196R over-expressing cells using lentiviral approach compared to control (vector) or TNFR2-196M over-expressing cells via lentiviral approach (white bars). This constitutive TNFR2-196R activity is not inhibited after treatment with anti-TNFα monoclonal antibody.

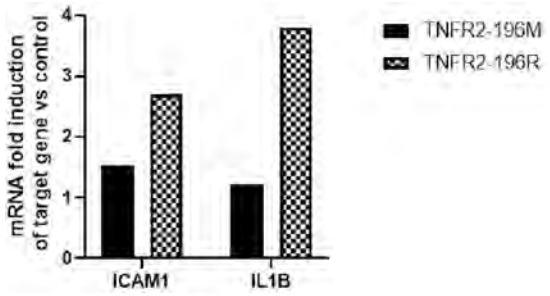

Figure 2. TNFR2-196R expressing HUVEC show increased expression of ICAM-1 and IL-1β in the absence of TNFα. Using RTqPCR basal ICAM-1 and IL-1β mRNA abundance is significantly increased in TNFR2-196R over-expressing cells via lentiviral approach (checkered) compared to uninfected HUVEC (normalized) or TNFR2-196M over-expressing cells via lentiviral approach (grey bars). Results are the average of two independent experiments.

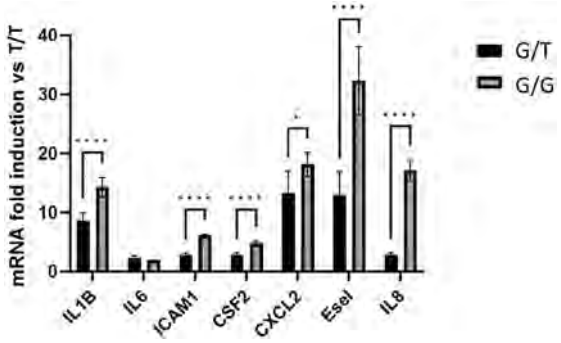

Figure 3. TNFα independent constitutive inflammatory activity in HUVEC expressing at least one G allele. Total RNA was extracted from HUVEC with T/T, T/G, or G/G genotypes. mRNA of indicated genes were quantified using RTqPCR after normalizing with mRNA levels of RPL-32, a housekeeping gene not induced by cytokines, including TNFα.

by genotyping (T/T, T/G, and G/G) discarded umbilical cord tissues prior to isolating and culturing the endothelial cells. Signaling pathways through TNFR2 were assessed using RTqPCR and Western blot analysis.

Results: In Jurkat T cells, successful expression of TNFR2-196M and TNFR2-196R was achieved (Figure 1A). Cells expressing TNFR2-196R exhibited increased basal expression of ICAM-1 compared to TNFR2-196M (Figure 1B). Importantly, treatment with a TNFα neutralizing antibody did not affect basal ICAM-1. Similarly, HUVEC cells over TNFR2-196R expressing (by lentiviral approach) showed increased ICAM-1 and IL-1β mRNA levels, while TNFR2-196M did not exhibit this effect (Figure 2). Furthermore, HUVEC isolated from subjects with G allele demonstrated higher basal expression of pro-inflammatory genes (IL-1β, IL-6, ICAM-1, GM-CSF2, CXCL2, E-selectin, Il-8) in the absence of TNFα (Figure 3). Notably, the TNFR2-independent gene P-selectin, did not show an increase in basal activity in cells expressing TNFR2-196R.

Conclusion: Our findings suggest that at least one G allele for the TNFR2 rs1061622 polymorphisms (TNFR-196R) confers a TNFα independent proinflammatory activity. These results may provide insights into a potential underlying mechanism for the association between rs1061622 polymorphisms and likelihood of response to anti-TNFα treatment in PsA. Further understanding of these signaling differences may contribute to the development of personalized treatment strategies for PsA patients based on their genetic profiles.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic Arthritis (PsA) is an inflammatory arthritis and shares several clinical features with Osteoarthritis (OA), the most common form of arthritis. This often leads to challenges in correctly diagnosing these diseases. Synovial Fluid (SF) from joints of arthritis patients contain a rich population of pathogenic modulators, such as microRNAs (miRNAs), making it a good source to study disease biomarkers. In this study, we aimed to 1) identify differentially expressed miRNA in SF of PsA and OA patients, and 2) identify differentially expressed miRNA driven pathways.

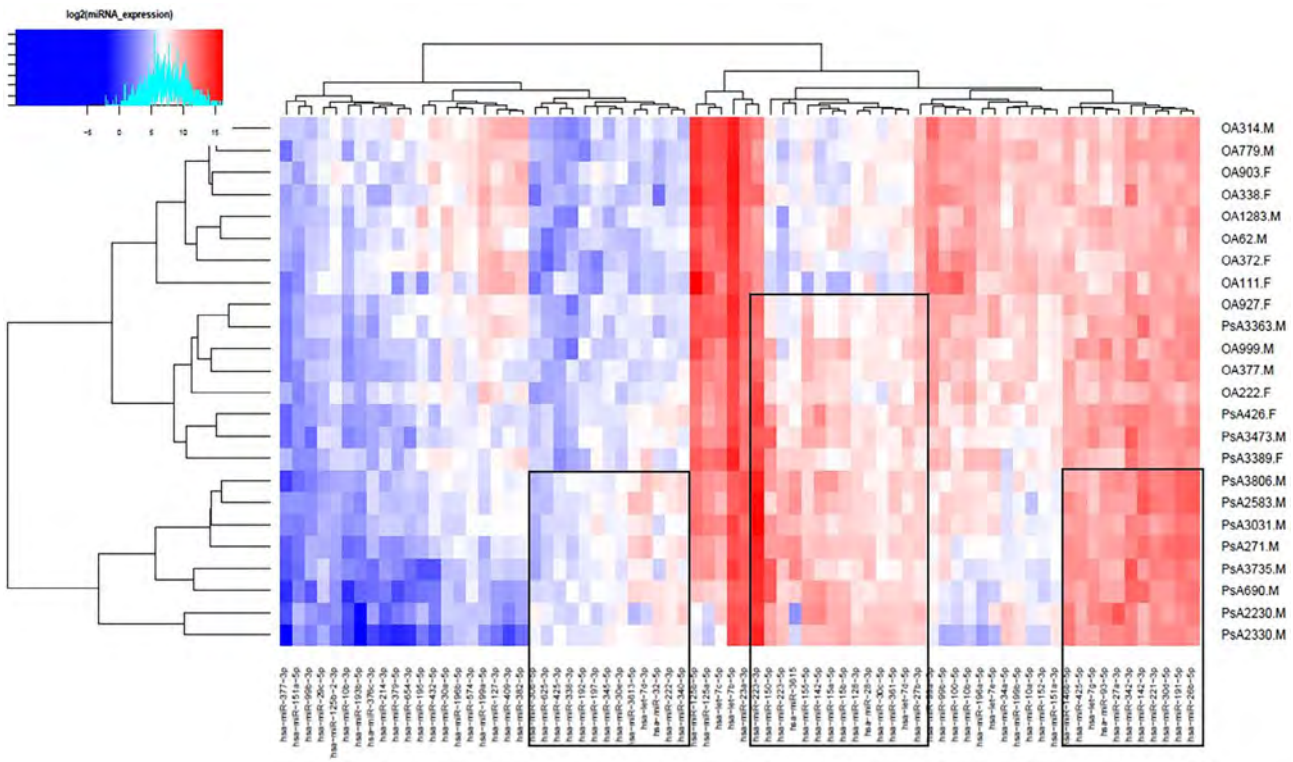

Figure. 1. Heatmap showing expression of miRNAs with Q<0.05 and fold change >1.5 in PsA and OA samples. Clusters of miRNAs that were relatively upregulated in PsA samples are indicated by the black rectangles.

Figure 2. Signaling cascades that include genes targeted by miRNAs upregulated in PsA and OA. Contextually relevant pathways were selected by applying filters for the synovium. Larger texts corresponds to highly enriched pathways.

Methods: Synovial fluid aspirated from knees of 12 PsA (sex: 8M, 4F; age (years): (median, range) = (45 (19-64)) and 12 OA patients (sex: 6M, 6F, age: (median, range) = (60 (43-74)) was used for miRNA sequencing using Illumina NextSeq 550. Linear modelling with empirical Bayes moderation (using the Limma R package) was used for assessing differential expression of miRNAs. Gene targets and enriched pathways targeted by significant miRNAs were identified by using integrative tools miRDIP and pathDIP set to a very high confidence class. For validation, SF samples from additional 35 PsA and 37 OA patients were retrieved. Total RNA including miRNA was extracted from these samples, and 5 selected candidate miRNAs were validated using quantitative RT-PCR. $\Delta\Delta$Ct method was used to calculate fold change. Differentially expressed miRNAs were defined as those with a two-fold change in expression ($-1.0 \geq \log2FC \geq 1.0$; p-value < 0.05).

Results: After miRNA sequencing, 51 miRNAs were found to be significantly differentially expressed between PsA and OA (FDR adjusted p-value less than 0.05) (Fig. 1). *QKI* (RNA binding protein), *OTUD4* (TLR signalling regulator), and *NFAT5* (osmotic stress response regulator) in PsA, and, *CELF2* (mRNA processor), *NFAT5*, and *ACVR2B* (TGFβ receptor) in OA, were the highest ranked gene targets of significant miRNAs.Figure 2 shows the signalling cascade that include genes targeted by miRNAs upregulated in PsA and OA. Pathways such as mitogen-activated protein kinase (MAPK), and WNT

Table 1. Enriched Pathways of gene targets of significant miRNAs with very high confidence of 1% and q-value <0.05. a) Enriched pathways of genes targeted by miR-27b-3p, b) Enriched pathways of genes targeted by miR-223-3p

Table 1a. Enriched Pathways of gene targets of miR-27b-3p with very high confidence of 1% and q-value <0.05 (9 of 114 shown)

Pathway	P-value	Q-value
Acute Myeloid Leukemia (AML)	4.40974e-06	2.24309e-03
Nuclear Receptors	4.39932e-06	3.35668e-03

Adipogenesis	1.27126e-05	4.84986e-03
PI3K/AKT/mTOR Signaling	4.04984e-05	5.15005e-03
BDNF-TrkB signaling	3.53413e-05	5.39308e-03
IL-6 signaling	1.30613e-04	8.66589e-03
Mitogen-Activated Protein Kinase (MAPK) Pathway	1.28515e-04	8.91427e-03

Table 1b. Enriched Pathways of gene targets of miR-223-3p with very high confidence of 1% and q-value <0.05

Pathway	P-value	Q-value
Adenoid Cystic Carcinoma	1.91224e-05	1.12121e-02
Epithelial-Mesenchymal Transition (EMT) Regulators	1.49086e-05	1.31121e-02
Signaling pathways regulating pluripotency of stem cells	1.13908e-05	2.00364e-02
Regulation of nuclear SMAD2/3 signaling	5.80453e-05	2.04203e-02
Copper Homeostasis	5.76724e-05	2.53614e-02
RUNX1 Interaction with cofactors	9.05970e-05	2.65600e-02
Cholecystokinin Receptor (CCKR) Signaling	1.17513e-04	2.95293e-02
Longevity Regulating Pathway	1.40378e-04	3.08656e-02
Leptin	1.40378e-04	3.08656e-02

signalling were included which have also been previously demonstrated to be associated with PsA and OA. On qRT-PCR, 2 out of 5 miRNAs; miR-27b-3p (log2FC= -2.391, p-value < 0.05), and miR-223-3p (log2FC= 2.830, p-value < 0.05), were significantly dysregulated in SF of PsA patients compared to OA patients. Analysis using miRDIP and pathDIP revealed 195 gene targets and 114 enriched pathways for miR-27b-3p (Table 1a), and 223 gene targets and 9 enriched pathways for miR-223-3p (Table 1b).

Conclusion: Several miRNAs are deregulated between PsA and OA. miR-27b-3p, and miR-223-3p were validated in an independent cohort of patients. Identification of gene targets and enriched pathways further support the validated findings. Additional analysis of the remaining significant miRNAs will provide valuable pathogenetic insights and may identify diagnostic signature of PsA vs OA.

Goblet Cell Specific Anti-Apoptotic Role of Interleukin-24 in Spondyloarthritis-Associated Ileitis

Amy Cameron[1], Rabina Giri[2], Jakob Begun[2], Timothy Wells[1], Ranjeny Thomas[3] and Anne-Sophie Bergot[1], [1]Frazer Institute, The University of Queensland, Woolloongabba, Australia, [2]Mater Research Institute-UQ, Woolloongabba, Australia, [3]Frazer Institute, The University of Queensland, Brisbane, Australia

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The loss of intestinal barrier integrity is a key contributor to gut inflammation, however the mechanism behind this dysregulation is not well understood. The ZAP-70^{W163C} BALB/c (SKG) mouse model of Spondyloarthritis (SpA) develops IL-23-dependent Crohn's-like ileitis after systemic curdlan administration, with fecal dysbiosis, ileal goblet cell depletion and ER stress. IL-24 is associated with ER stress and apoptosis and increased levels were observed in inflammatory bowel disease (IBD) and SpA. To help elucidate the mechanism behind intestinal barrier dysfunction and goblet cell depletion in IBD, we assessed the role of IL-24 in ileal ER stress-mediated apoptosis in SKG mice.

Methods: SKG and control BALB/c ileum was analysed by histology and immunofluorescence (IF). Ileal epithelial cells were analysed by flow cytometry. ER stress was induced with thapsigargin in the MUC2^{hi} human colonic epithelial cell line LS174T in the presence of IL-24 or control siRNA. Gene expression was analysed by RT-qPCR and protein by flow cytometry.

Results: Naïve SKG ileum has fecal dysbiosis. In SKG ileum, expression of Il24 and ER stress marker transcripts were increased relative to BALB/c ileum. By IF, IL-24 localised to the ileal goblet cells. UEA-1 expression in Ep-CAM+ intestinal epithelial cells was significantly increased, indicating increased mucin production in SKG mice compared to BALB/c. IL-24 knockdown in LS174T epithelial cells *in vitro* increased ER stress and apoptosis including increased *CHOP*, *DR5* and active caspase-3 expression.

Conclusion: IL-24, a goblet cell-specific cytokine in small intestine mitigates ER stress-induced apoptosis in mucin-producing epithelial cells. This suggests that ER stress-associated IL-24 in SKG ileum is insufficient to prevent the cascade to IBD that commences with goblet cell apoptosis and epithelial barrier breakdown.

The Role of the Deubiquitinase *ZRANB1*/TRABID in Inflammation and Bone Formation in Spondyloarthritis

Archita Srinath[1], Daniele Mauro[2], Francesco Ciccia[3] and Nigil Haroon[4], [1]University of Toronto, Toronto, ON, Canada, [2]University of Campania, Naples, Italy, [3]University of Campania - Luigi Vanvitelli, Naples, Italy, [4]University of Toronto, University Health Network, Schroeder Arthritis Institute, Department of Medicine/Rheumatology, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation and new bone formation are important disease mediators in ankylosing spondylitis (AS). Recent studies in mice show that the deubiquitinase molecule TRABID epigenetically controls the expression of IL12/23 through JMJD2D (Jumonji Domain-Containing Protein 2D). Furthermore, TRABID also upregulates EZH2 (Enhancer of zeste homolog 2), a molecule that has been implicated in pro-osteogenic pathways. This study aims to study the functional and clinical relevance of TRABID in AS pathogenesis.

Methods:

1. TRABID, EZH2 and JMJD2D protein and gene expression was evaluated in AS and healthy control tissue by immunohistochemistry/immunofluorescence and qPCR respectively.
2. THP-1 cells (monocyte cell line) and splenocytes from 16-week-old SKG mice were incubated with lipopolysaccharide (LPS) to stimulate cytokine production and varying concentrations of NSC112200, a small molecule inhibitor of TRABID. Enzyme-linked immunosorbent assay (ELISA) was used to detect IL23, TNFa and IL1b production after 24 hours in the supernatant. Finally, western blot was used to evaluate expression of EZH2 and JMJD2D.
3. TRABID was knocked down in Saos-2 cells (osteoblast cell line) using siRNAs. Cells were then incubated in an osteogenic induction media for 14 days. RNA was extracted every 3 days to evaluate osteogenic gene expression by qPCR and RNA sequencing. At day 14, calcium mineralization levels were evaluated by Alizarin Red staining.

Results:

1. Our results showed that TRABID is significantly upregulated in human and mouse AS tissue (Figure 3). TRABID+ cells and gene expression were found to be upregulated in AS gut (n=20/group, $p< 0.0001$), bone marrow (n=5/group, $p< 0.0001$) and synovium (n=10/group, $p< 0.0001$). TRABID was found to be preferentially expressed by CD68+ macrophages in the synovial lining. EZH2 and JMJD2D were also found to be significantly upregulated in the inflamed synovium.
2. THP-1 cells treated with NSC112200 and LPS together showed a marked dose dependent inhibition of IL23 production when compared with cells treated with only LPS (n=6, $p >0.0001$). Furthermore, TRABID inhibition showed a significant downregulation of both JMJD2D and EZH2 protein levels (Figure 2).

3. SKG mouse splenocytes incubated with NSC112200 dose dependently showed decreased levels of TNFa when compared with cells treated with LPS alone after 24 hours (n=3, p=0.0043).
4. TRABID knockdown by siRNA showed significant suppression of pro-osteogenic genes like SP7, Runx2 and alkaline phosphatase. Moreover, osteoblasts knocked down for TRABID failed to mineralize as evidenced by diminished alizarin red staining. RNA sequencing confirmed pathways related to TGFb signaling, bone remodeling and endochondral ossification were suppressed while negative regulation of the immune system was upregulated (Figure 1). Lastly, osteogenic induction media significantly upregulated TRABID expression over time, compared with cells treated with unconditioned growth media (p=0.0027)

Conclusion: Our results show a role for TRABID in both cytokine production and osteogenesis. Future work will address both downstream mechanisms of TRABID in these processes and evaluate TRABID inhibition in animal models of AS.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a form of inflammatory arthritis that occurs in patients with cutaneous psoriasis. Due to the lack of clinically useful diagnostic biomarkers or full understanding of pathways distinguishing PsA from psoriasis without PsA (PsC), we aimed to conduct integrated multiomics analyses using data from previously identified panel of SNPs and proteins, peripheral blood bulk RNA sequencing, miRNA sequencing and serum metabolomics obtained from carefully phenotyped individuals with psoriatic disease to identify pathways that differentiate PsA from PsC.

Methods: Serum, RNA and DNA from 102 PsA and 100 PsC patients were retrieved from a biobank of patients with psoriatic disease. Serum samples were used for miRNA sequencing, ELISA of 15 proteins (TNFSF14, S100A8/9, COMP, CRP, M2BP, OPG, DEFA, ITGB5, RANKL, CXCL10, Leptin, MMP3, OPN, Periostin, and SOST) and liquid chromatography-high resolution mass spectrometry (LC-HRMS) for metabolites, RNA for RNAseq and DNA for genotyping 42 SNPs of 19 'PsA weighted' genes. Resulting molecular data were combined with clinical data to identify the best set of biomarkers able to discriminate between PsA and PsC. A random forest model was developed to identify the best combination of diagnostic biomarkers. Further bioinformatics analysis was conducted using mirDIP 4.1[1] with threshold "very high" to identify biomarker

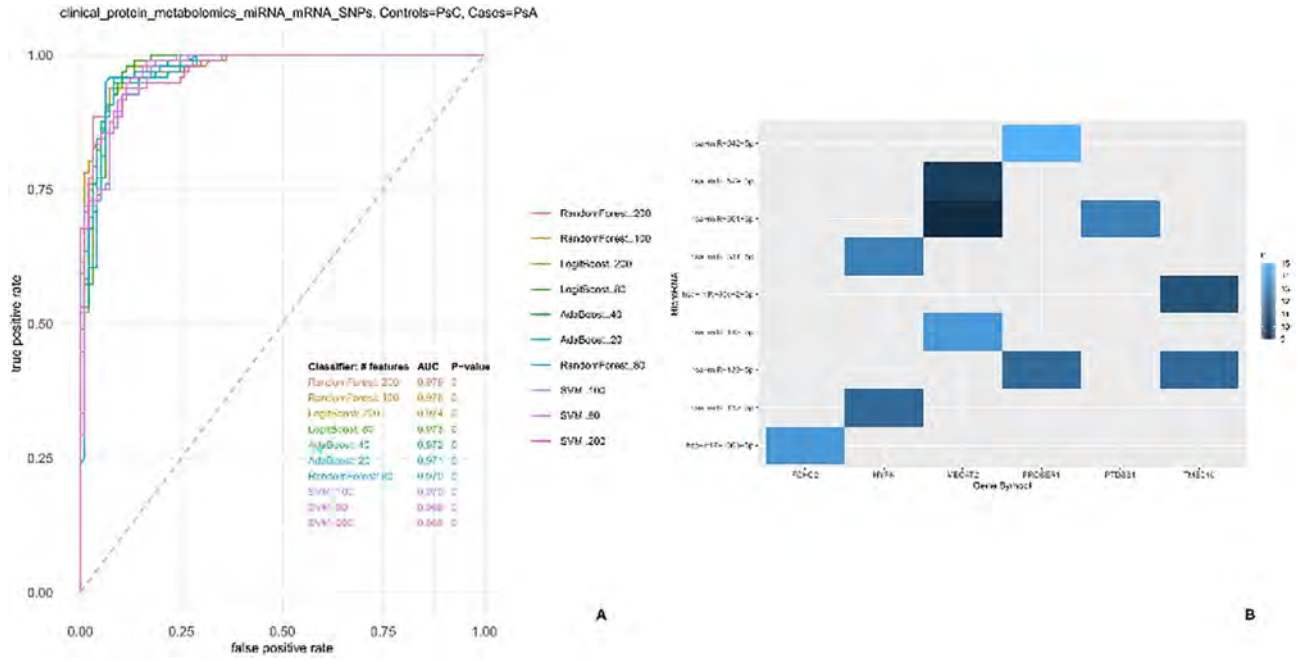

Figure 1. A) Analysis of the molecular and clinical features to identify the best biomarkers for PsA discrimination. B) miRNA to mRNA targeting using molecules from the 200 biomarkers and threshold "very high" from mirDIP 4.1.

mRNAs targeted by biomarker miRNA, and pathDIP 4[2] was used to perform pathway enrichment analysis for such mRNAs, while clusterProfiler 4.8.0[3] was used to perform Gene Ontology enrichment analysis. Analyses and visualization were performed in R 4.3.0.

Results: The random forest model identified 200 biomarkers, comprising 97 metabolites, 77 miRNAs, and 26 mRNAs, as the best performers to discriminate between PsA and PsC (Figure 1A, AUROC of 0.979, p-value < 0.001).Among the 77 miRNAs, 9 target 6 of the 26 mRNAs present in the 200 biomarkers (Figure 1B).Pathway and Gene Ontology enrichment analyses performed on the 6 genes identified several terms linked to phospho- and glycerophospholipid metabolism (Figure 2).Interestingly, of the 97 biomarker metabolites, 40 were mapped to known metabolites. Of these, 12 (30%) were either glycero- or phospholipids. Differences in phospholipid profiles between PsA and PsC have been described in [4], where a link to the immune system has also been proposed. Further validation is undergoing to confirm the diagnostic value of the 200 biomarkers and the role of the phospholipidic pathways in PsC progression to PsA.

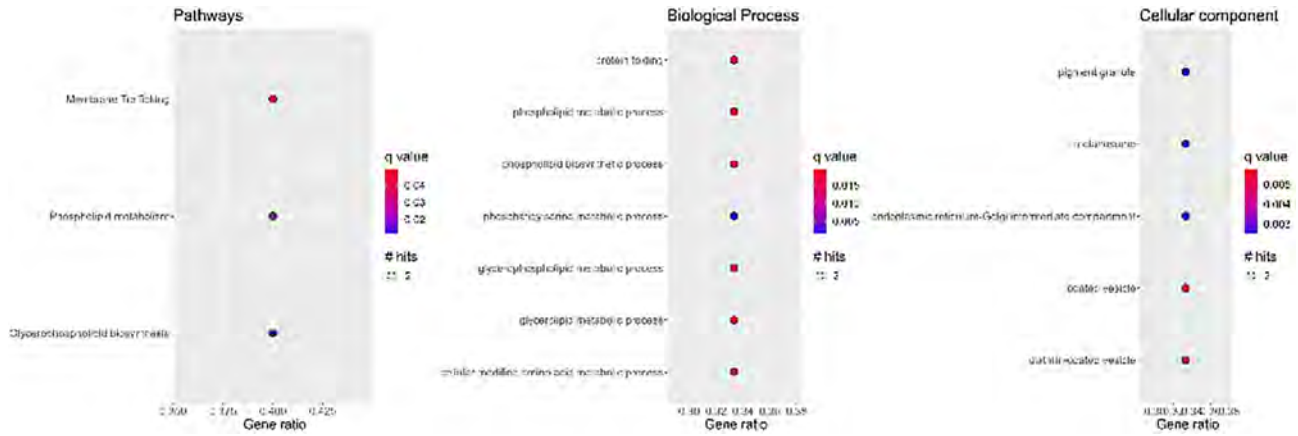

Figure 2. Pathway and Gene Ontology enrichment analysis results for the 6 genes from the 200 biomarkers identified as targets of 9 miRNAs from the same 200 biomarkers.

Conclusion: Our study highlights the importance of integrating multiple types of data to characterize different and complementary pieces of the molecular landscape that differentiate PsA and PsC. Our preliminary analysis shows that metabolic pathways can have a central role in the development and differentiation of PsA, a signal identified at the genetic level and confirmed through metabolomics analysis.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The Canadian government's COVID Immunity Task Force funded SUCCEED to study COVID vaccination responses in immune-mediated inflammatory disease(IMID). We describe how drugs, clinical factors, and vaccine history influence serological response to vaccination, summarize safety, and describe breakthrough infections.

Methods: From Vancouver, Calgary, Winnipeg, Montreal, Quebec City, Sherbrooke, Toronto, and Hamilton, data and dried blood spots/sera post-COVID vaccination were collected from adults with rheumatoid arthritis, inflammatory bowel disease, SLE, ankylosing spondylitis/spondyloarthritis and psoriasis/psoriatic arthritis, with the first sample at enrolment and then 3, 6, and 12 months after latest vaccine dose. We evaluated anti-spike(S) trimer and anti-receptor-binding domain(RBD) IgG (indicating successful serologic response to vaccine) and anti-nucleocapsid (N) IgG (indicating recent infection, cross-referenced with self-report). Multivariate generalized estimating equation regressions (accounting for repeated measures) were used to evaluate serologic response, based on log-transformed anti-RBD titres.

Results: Baseline characteristics of 1556 participants are shown in Table 1. Table 2 shows crude and adjusted odds ratios(OR). Positive associations for anti-RBD/anti-S serologic responses were seenwithfemale sex, number of vaccine doses and infections in 2021-2022. Negative associations were seen with prednisone, anti-TNF agents and rituximab. Diminution of response was clearly seen even for daily prednisone doses of 1-10 mg (adjusted OR 0.73 95%CI 0.58-0.91) and 11-20 mg (aOR 0.62 95%CI 0.43-0.90). Methotrexate and other immunosuppressants were associated with reduced response only in univariate analyses. Time since last vaccination was negatively associated with serologic response; rate of decrease was similar during the period 15-120 days since last vaccine (OR 0.75 95%CI 0.64,0.87) and 121-210 days post-last vaccine (OR 0.79 95%CI 0.67,0.92) but worse after >210 days (OR 0.53 95%CI 0.43,0.66).

[a] Adjusted for all variables shown

Self-reported post-vaccine adverse events leading to emergency department(ED) visits or hospitalizations occurred in only 1.5% of participants. Bell's Palsy represented one ED visit, with no confirmed Guillain-Barre or transverse myelitis in our preliminary analyses. Over 2021-2022, anti-N positivity (indicating recent infection) was present in 9.8% of samples; most (85%) were associated with a self-reported infection. Anti-N positivity was lowest in the summer of 2021 and highest post-Omicron (fall 2022).

Conclusion: Past infections and number of COVID-19 vaccine doses were positively associated with serologic response. Time since vaccination, particularly >210 days, was negatively associated with response. Anti-TNF agents, rituximab, and prednisone were associated with less immunogenicity. Few vaccine-related adverse events led to ED or hospitalization. Ours is the first assessment of drugs, vaccine history, and other factors on serologic COVID vaccine response in a large, pan-Canadian IMID sample. These findings may help patients, clinicians, and other stakeholders make personalized decisions about vaccination in 2023-2024 and beyond.

Factors Associated with Distress Related to Perceived Dignity in Patients with Rheumatic Diseases

Virginia Pascual Ramos[1], Guillermo Guaracha Basañez[2], Irazú Contreras Yañez[2], Maximiliano Cuevas Montoya[2], Mario García Alanís[2], Oscar Rodríguez Mayoral[3] and Harvey Max Chochinov[4], [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [3]Servicio de Cuidados Paliativos, Instituto Nacional de Cancerología, Cuidad de Mexico, Mexico, [4]Department of Psychiatry, University of Manitoba, Cancer Care Manitoba, Manitoba, MB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: From the Human rights approach, dignity is accepted as a universal need, required for the well-being of every individual. It is an irrevocable feature of personhood that does not depend on or varies according to circumstances. However, in the medical context, what dignity entails in practice will also depend on patients´ perception of themselves, how others see them, and how the nature of the illness in question affects the person's life and identity. It evokes the patient's sense of autonomy and control. The loss of perceived dignity is an existential source of Human suffering rarely explored among patients with rheumatic diseases (RMDs), which contrasts with their observations that dignity, identity, and Quality of Life (QoL) are essential areas for research focus. We recently observed that distress related to perceived dignity (DPD) was present in 26.9% of Mexican outpatients with different RMDs.

The current study complements the research on the topic and investigates the factors associated with DPD in primary outpatients with different RMDs.

Methods: This cross-sectional study was performed in February-September 2022. Consecutive primarily outpatients with RMDs completed patient-reported outcomes (PROs) (to assess mental health [DASS-21], disease activity/severity [RAPID3], disability [HAQ-DI], fatigue [FACIT], QoL [WHOQOL-BREF], satisfaction with medical care [locally adapted questionnaire], resilience [brief-resilient coping scale] and family function [family APGAR]) and had a rheumatic evaluation to assess disease activity status and comorbidity (Rheumatic Disease Comorbidity Index). Sociodemographic variables and disease-related and treatment-related variables were retrieved with standardized formats. DPD was defined based on a score ≥ 54.5 (min 25-max 125) on the previously adapted and validated Mexican version of the Patient Dignity Inventory (PDI-Mx). Multivariate regression analysis was used to identify factors associated with DPD (the dependent variable). We estimated a sample size of 334 patients (considering 20% of losses for non-analyzable data) to achieve the objective described.

Table. Description of the population's characteristics and the comparison between patients with DPD and their counterparts.

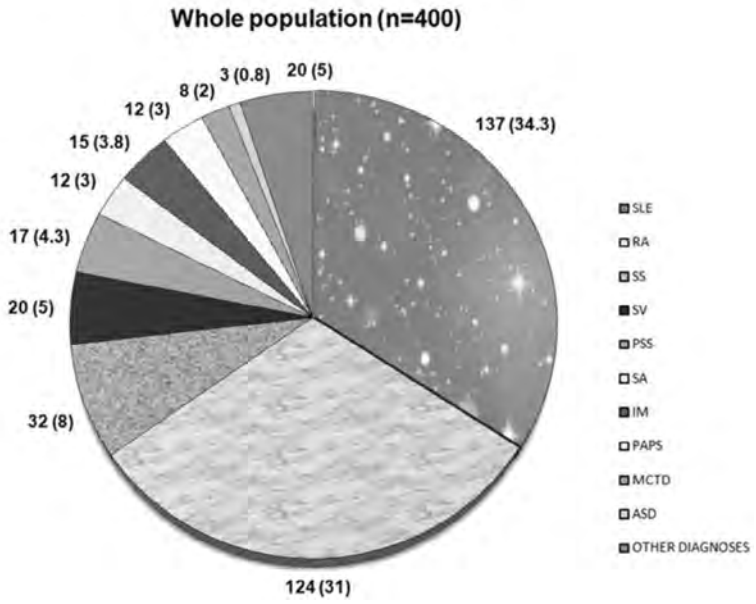
Figure 1. Diagnoses distribution.



Data presented as number (%). SLE=Systemic Lupus Erythematosus. RA=Rheumatoid Arthritis. SS=Systemic Sclerosis. SV= Systemic Vasculitis. PSS=Primary Sjögren Syndrome. SA=Spondyloartrhitis. IM= Inflammatory Myopathies. PAPS= Primary Anti-phospholopid Syndrome. MCTD= Mixed Connective Tissue Disease. ASD= Adult Onset-Still Disease.

Results: Four hundred patients were included (February-September 2022), representing patients with RMDs and the most frequent rheumatic diagnoses in our outpatient clinic (**Figure 1**). One hundred and seven patients (26.8%) had DPD. They differed from their counterparts (less educated, with intensive treatment, mental health comorbidity, and worse PROMs) (**Table**). Past mental health-related comorbidity, the number of immunosuppressive drugs/patient, the physical health dimension score of the WHOLQOL-BREF, and the emotional health dimension score of the WHOLQOL-BREF were associated with DPD (**Figure 2**).

Conclusion: We observed that DRPD was present in a substantial proportion of patients with RMDs and was associated with previous mental health comorbidity, intensive treatment of the underlying RMD, and the patient QoL. Recognizing factors associated with DPD is an essential step in the right direction toward understanding the impact of RMDs in patients' lives and preventing poorer prognoses.

Figure 2. Results from multivariate regression analysis to identify factors associated with DPD.

Association Between Knee Osteoarthritis and Mortality: A Serial Propensity Score-matched Cohort Study

Sunggun Lee[1], Minkyoung Oh[2], Mi-Yeong Kim[3], Minyoung Her[1] and Seong-Ho Kim[1], [1]Department of Internal Medicine, Haeundae Paik Hospital, Inje University College of Medicine, Busan, South Korea, [2]Department of pharmacology, Inje University College of Medicine, Busan, South Korea, [3]Department of Internal Medicine, Busan Paik Hospital, Inje University College of Medicine, Busan, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The association between symptomatic knee osteoarthritis (OA) and higher cardiovascular disease (CVD) mortality is well established; however, findings from previous studies that utilized regression analysis were limited, attributed to the strong association between OA and metabolic risk factors. This study aimed to evaluate the association between knee OA and mortality through propensity score matching.

Methods: This was a cohort study including Korean National Health and Nutrition Examination Survey (2010–2013) participants aged ≥50 years who had undergone screening knee radiographs (N=13087). By linking the survey data to Cause of Death data (through 2019) from Statistics Korea, mortality and cause-specific mortality data were obtained. Radiographic knee OA (ROA) was defined as bilateral Kellgren-Lawrence grade ≥2.Propensity score matching (1:1) was conducted between asymptomatic ROA, knee pain (without ROA), and symptomatic ROA groups and normal groups, balancing

Table 1 Risk for all-cause and cause-specific death in knee state groups[a]

	Normal	Asymptomatic ROA	Normal	Knee pain	Normal	Symptomatic ROA
All-cause mortality						
N of deaths	229	234	59	71	140	160
Rate of death (per 1000 person-years)	1.06	1.09	0.72	0.87	1.14	1.29
HR (95% CI)	Ref.	1.03 (0.86–1.24)	Ref.	1.21 (0.86–1.71)	Ref.	1.13 (0.90–1.42)
HR (95% CI)[b]	Ref.	1.04 (0.86-1.25)	Ref.	1.22 (0.86-1.74)	Ref.	1.19 (0.94-1.50)
Cardiovascular disease mortality						
N of deaths	50	56	15	9	33	47
Rate of death (per 1000 person-years)	0.23	0.26	0.18	0.11	0.27	0.38
HR (95% CI)	Ref.	1.12 (0.77–1.65)	Ref.	0.61 (0.27–1.38)	Ref.	1.39 (0.89–2.17)
HR (95% CI)[b]	Ref.	1.13 (0.76-1.68)	Ref.	0.58 (0.24-1.38)	Ref.	1.48 (0.94-2.33)
Cancer mortality						
N of deaths	89	85	21	27	52	54
Rate of death (per 1000 person-years)	0.41	0.40	0.26	0.33	0.42	0.44
HR (95% CI)	Ref.	0.96 (0.72–1.30)	Ref.	1.30 (0.73–2.29)	Ref.	1.03 (0.70–1.51)
HR (95% CI)[b]	Ref.	0.96 (0.71-1.31)	Ref.	1.30 (0.73-2.29)	Ref.	1.09 (0.74-1.62)

a. ROA radiographic knee osteoarthritis defined as bilateral Kellgren-Lawrence grade of 2 or higher.

b. Results of the sensitivity analysis in which death in a year after observation was excluded.

confounding factors (age, sex, obesity, hypertension, diabetes, total cholesterol, household income, history of stroke, history of MI). Time to death was analyzed using Cox Proportional hazard modeling. Sensitivity analysis was performed excluding those who died in a year of the observation period.

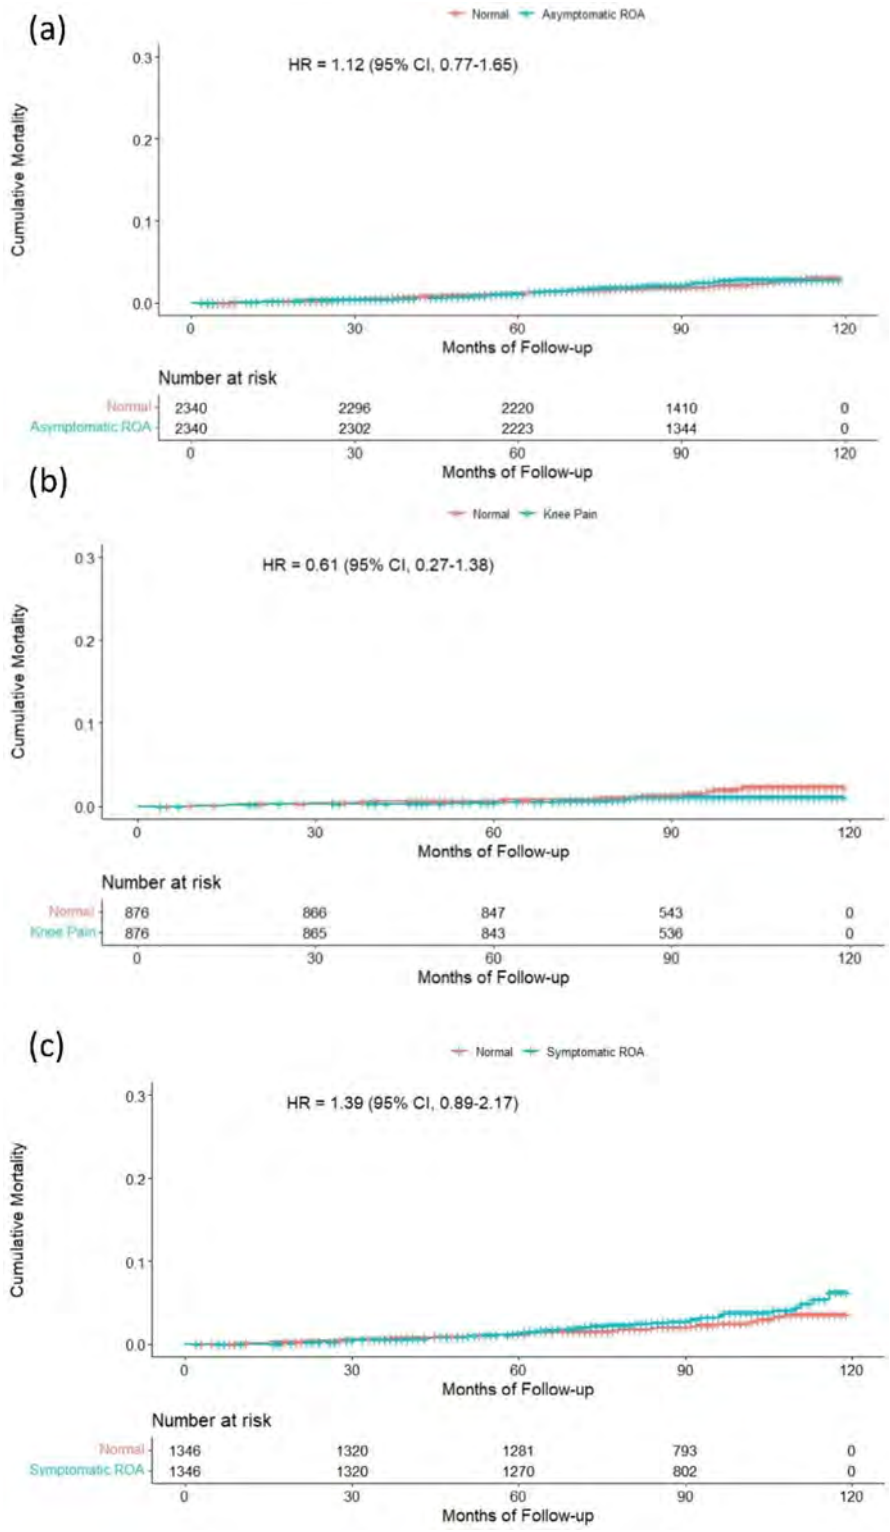

Figure 1. Kaplan–Meier plot of cumulative mortality from cardiovascular disease up to 10 years for propensity score-matched participants with (a) asymptomatic ROA, (b) knee pain without ROA, and (c) symptomatic ROA. ROA, radiographic knee osteoarthritis.

Results: The median and range of follow-up duration was 95 (0-124) months, and the total observation period was 103,330 person-years. There were 1128 deaths in the observation period. Crude mortality rates were higher in the ROA groups. All-cause mortality rate was 0.87, 1.32, 1.08, and 1.48 per 1000 patient-year in the reference, asymptomatic ROA, knee pain, and symptomatic ROA group, respectively. After matching there was a trend for higher CVD mortality in symptomatic ROA group, but not in other groups (Table 1 and Figure 1); the risk estimates were asymptomatic ROA HR 1.12 (95% CI 0.77–1.65), knee pain 0.61 (0.27–1.38), and symptomatic ROA 1.39 (0.89–2.17). There was no association between all-cause/cancer mortality and any group. In sensitivity analysis, there was a closer trend for higher CVD mortality in symptomatic ROA group (Table 1). The risk estimate was HR 1.48 (0.94–2.33).

Conclusion: When propensity score matching controls risk factor imbalances, the association between symptomatic knee OA and higher CVD-mortality was weaker compared with results of prior studies that used regression adjustment, and knee pain without radiographic OA was not associated with CVD mortality. Assuming that matching is a stronger method to control confounding variables and bias, the results may be more precise estimates of the total risk of knee OA for mortality, especially in East Asian population. Mediating effects by metabolic dysregulation merits further research.

Association of Pregabalin vs Gabapentin with Incident Congestive Heart Failure in Patients with Non-Cancer Pain

Elizabeth Park[1], Laura Daniel[2], Alyson Dickson[3], Meghan Corriere[4], Puran Nepal[5], Kathi Hall[4], Dale Plummer[4], William Dupont[4], Katherine Murray[4], C. Michael Stein[3], Wayne Ray[4] and Cecilia Chung[6], [1]Columbia University Irving Medical Center, New York, NY, [2]University of Miami, Nashville, TN, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Vanderbilt University, Nashville, TN, [5]University of Miami Health System and Miller School of Medicine, Miami, FL, [6]University of Miami, Miami, FL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic pain affects 30% of all patients in developed countries, accounting for up to 35% of prescriptions in acute care settings. Non-opioid pain medications are widely utilized for treatment of non-cancer chronic pain. Among these, pregabalin is a commonly prescribed anticonvulsant, which works by antagonizing L-type calcium channels, decreasing the release of neurotransmitters . Pregabalin use has been associated with reports of congestive heart failure (CHF), including peripheral and pulmonary edema. However, the relationship between CHF incidence and pregabalin use among patients at the highest risk of adverse reactions (i.e., senior patients with various co-morbidities) remains unclear. The purpose of this study was to compare incident CHF among new users of pregabalin versus gabapentin (the active comparator) in Medicare beneficiaries treated for non-cancer chronic pain.

Methods: This was a retrospective cohort study among Medicare beneficiaries aged 65-89 years old with chronic non-cancer pain, without prior history of CHF. Patients who were newly prescribed users of pregabalin or gabapentin were followed up between 2015-2018. The outcome was incident CHF, ascertained by hospital admissions or emergency room visits with ICD 9 and 10 codes in the first position codes. Inverse probability of treatment weighting was used to account for differences between pregabalin and gabapentin users in a time-dependent analysis (i.e., Cox proportional-hazards

Table 1. Participant Demographics, Medical History/Diagnoses, and Medications

Table 1. Participant Demographics, Medical History/Diagnoses, and Medications

Characteristic/Covariates	Weighted		
	Gabapentin	Pregabalin	Standardized Difference

regressions). A total of 318 covariates were selected for propensity scoring based on prior knowledge and literature review, and included categories such as concurrent baseline cardiovascular, neurologic, pain, and psychiatric diagnoses and corresponding medications including opioids and antipsychotics. Non-diagnostic covariates were included, as well as demographics, socioeconomic status, and indicators/metrics of health care utilization.

Results: Patient demographics and characteristics are summarized in *Table 1*. A total of 17,756 new users of pregabalin and 221,053 new users of gabapentin were included. The cohort was predominantly female sex (66.7%) and non-Hispanic White (79.9%), with a median age of 73 years. During 110,439 person-years (PY) of follow-up, 1,428 patients were hospitalized for CHF. The rate for CHF hospitalization was 18.7 per 1000 PY for pregabalin vs 12.6 per 1000 PY for gabapentin (adjusted HR 1.48 (95% CI 1.20-1.81)) (*Figure 1*). Stratified by cardiovascular disease (CVD), the rate of CHF hospitalization was 42.9 for pregabalin vs 23.4 for gabapentin (adjusted HR 1.87 (95% CI 1.40-2.60)) (*Figure 1*).

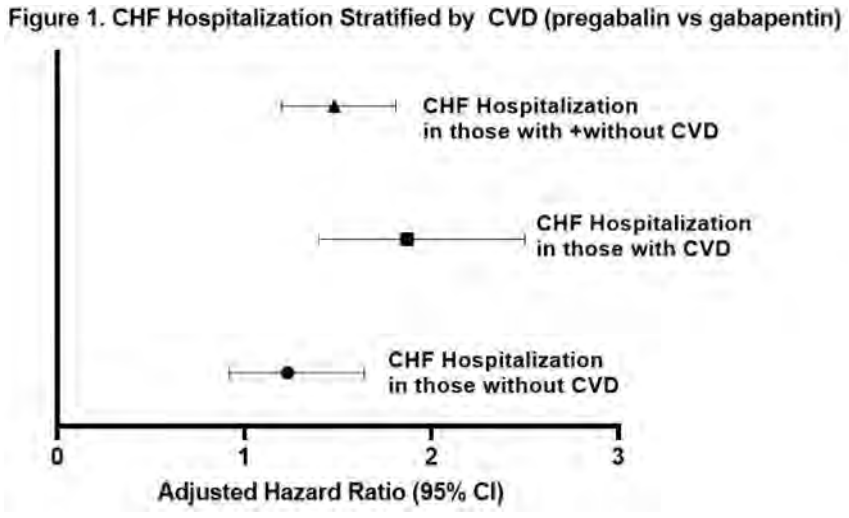

Figure 1. CHF Hospitalization Stratified by CVD (pregabalin vs gabapentin)

Conclusion: In this retrospective study of Medicare beneficiaries aged 65-89 years with chronic non-cancer pain, new users of pregabalin had higher rates of incident CHF hospitalizations or emergency room visits compared to new users of gabapentin.

Factors Associated with an Electronic Health Record-Based Definition of Post-Acute Sequelae of COVID-19 in Patients with Systemic Autoimmune Rheumatic Diseases

Naomi Patel[1], Xiaosong Wang[2], Yumeko Kawano[2], Abigail Schiff[2], Rathnam Venkat[2], Claire Cook[1], Kathleen Vanni[2], Grace Qian[2], Katarina Bade[2], Shruthi Srivatsan[1], Krishan Guzzo[1], Zachary Williams[1], Emily Kowalski[2], Alene Saavedra[2], Jeffrey Sparks[3] and Zachary Wallace[4], [1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Massachusetts General Hospital, Newton, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunosuppression for treatment of systemic autoimmune rheumatic diseases (SARDs) is associated with increased risk of severe acute COVID-19 due to blunted vaccine responses and impaired immune response to infection. Whether immunosuppression may also alter the risk for post-acute sequelae of COVID-19 (PASC), or "long COVID," is unclear. Previous studies (Al-Aly *et al*, *Nature Medicine,* 2022) have developed electronic health record (EHR)-based definitions of PASC that have the benefit of including all COVID-19 survivors, rather than relying on prospective studies that may have selection bias, but have not been performed among SARD patients. We evaluated baseline demographic and disease factors associated with PASC in a large EHR-based cohort of patients with SARDs.

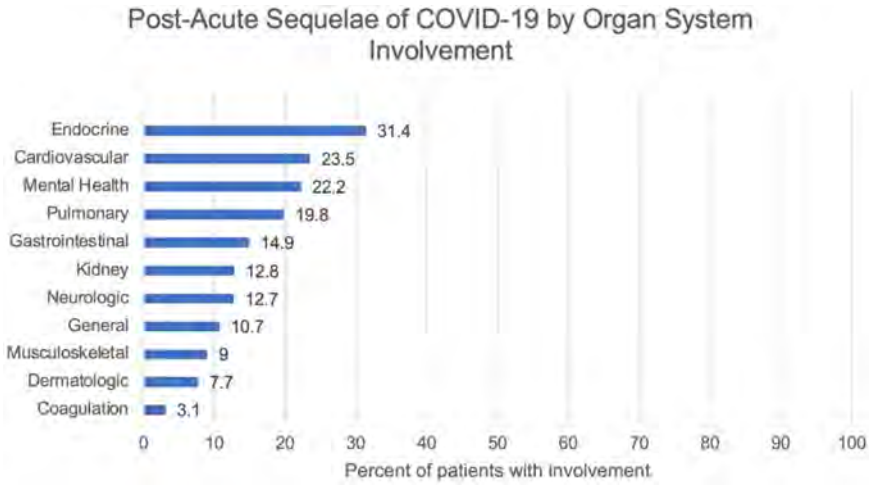

Figure. Proportion of patients who developed Post-Acute Sequelae of COVID-19 during the study period by organ system involvement

Methods: We systematically identified patients with SARDs and confirmed COVID-19 in a large healthcare system (up to 1/18/2023). We required patients to have baseline data in the EHR prior to the index date, defined as initial COVID-19 infection. Patients who survived COVID-19 were followed from 30 days after the index date until the development of any incident PASC feature, repeat COVID-19 infection, 1 year of follow-up, death, or until 4/14/2023. We evaluated the proportion with incident PASC features, defined by incident ICD codes, relevant vital signs or labs, and/or medications, extracted from the EHR. We estimated the association of baseline characteristics with the risk of PASC using multivariable Cox regression.

Table 1. Demographics and rheumatic disease characteristics of patients with history of COVID-19 infection

Characteristic	n (%) (n=2459)
Age at time of COVID-19, mean ± SD	57.38 (16.57)
Female, n (%)	1878 (76.4%)
Race, n (%)	
White	1862 (75.7%)
Black	212 (8.6%)

CD20 inhibitors	174 (7.1%)
IL-6 receptor inhibitors	96 (3.9%)
CTLA-4 Ig	58 (2.4%)
IL-17, IL-12/23, or IL-23 inhibitors	85 (3.5%)
Other biologic DMARD	
Baseline glucocorticoid use at COVID-19 diagnosis	577 (23.5%)
Dose (prednisone-equivalent, daily mg), median [IQR]	5 (4, 10)
Charlson Comorbidity Index, median (IQR)	1 (1, 3)
Calendar time of COVID-19 infection	
Mar 1, 2020 - June 30, 2021	834 (33.9%)
July 1, 2021 - December 16, 2021	179 (7.3%)
December 17, 2021 - January 18, 2023	1446 (58.8%)
Hospitalized for acute COVID-19	356 (14.5%)

Results: We identified 2,459 patients with SARDs and confirmed COVID-19 (76% female, mean age 57 years, **Table 1**)**.** The majority of patients (1566; 64%) had at least one incident feature of PASC. The most common incident PASC features were hyperlipidemia (561; 23%), anxiety (419; 17%), dyspnea (303; 12%), fatigue (263; 11%), and chest pain (246; 10%) (**Figure**). Compared to antimalarial monotherapy, TNF inhibitors were associated with lower PASC risk (aHR 0.78, 95% CI 0.64-0.94) and CD20 inhibitors were associated with higher PASC risk (aHR 1.27, 95% CI 1.02-1.59) (**Table 2**)**.** Glucocorticoid use (vs. non-use) was associated with higher PASC risk (aHR 1.15, 95% CI 1.02-1.29). Compared to those with COVID-19 infection early in the pandemic, those with infection during the Delta wave (aHR 0.59, 95% CI 0.46-0.76) and Omicron era (aHR 0.51, 95% CI 0.41-0.63) had a lower risk of PASC. Older age, Black race, increased comorbidity burden, hospitalization for acute COVID-19 infection, and diagnosis of SLE or ANCA-associated vasculitis (compared to RA) were also associated with higher PASC risk.

Table 2. Selected baseline factors at the time of COVID-19 infection and their associations with Post-Acute Sequelae of COVID-19.

*Multivariable model is adjusted for age, sex, CCI, vaccination status (unvaccinated or partially vaccinated, vaccinated with initial series, or additional vaccines), and calendar time
**DMARDs are mutually exclusive variables using hierarchical categories.

Conclusion: Among patients with SARDs, CD20 inhibitor users had a higher PASC risk while TNF inhibitor users had a lower PASC risk following COVID-19 infection, suggesting that baseline immunosuppression may alter the post-acute COVID-19 course. Other factors associated with PASC included SLE or ANCA-associated vasculitis, as well as general population risk factors including calendar time (as a marker of SARS-CoV-2 variant and available treatments), older age, race, and hospitalization for acute COVID-19. These findings emphasize the potentially large burden of PASC among patients with SARDs.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with immune-mediated inflammatory diseases (IMIDs) and particularly those treated with B-cell-depleting agents frequently fail to develop humoral responses to SARS-CoV-2 vaccinations and have an increased risk of breakthrough infections and severe COVID-19 (Simon D, Arthritis Rheum (2022); Avouac J, Lancet Rheum (2022)). Passive immunization with monoclonal antibodies such as the FDA- and EMA-approved combination tixagevimab/cilgavimab could be an alternative option for this frail population. However, despite promising results from trials on healthy individuals (Levin MJ, NEJM (2022)), efficacy data on IMIDs are scarce. With our study, we aimed to investigate the effect of a pre-exposure prophylaxis (PrEP) with tixagevimab/cilgavimab on the humoral responses and on the prevention of symptomatic COVID-19 in vaccine-refractory IMID patients.

Methods: A prospective interventional cohort study was performed on a cohort of high-risk vaccine-refractory IMID patients undergoing B-cell depletion and/or with primary immunodeficiencies that received PrEP with a single dose of subcutaneous tixagevimab/cilgavimab (150mg/150mg). COVID-19 outcomes and serum anti-SARS-CoV-2 IgG were assessed at baseline, day 1, day 14, day 28, month 3, and after at least 6 months. Standardised incidence ratios (SIR) of COVID-19 were compared to (i) a control group of other vaccine-refractory IMID and primary immunodeficiency patients who did not receive

Table 1. Demographic and clinical characteristics of the treated cohort and control group.

	Controls, N = 114	PrEP-treated, N = 38
Age (years), Mean (SD)	62.7 (13.39)	62.1 (14.17)
Sex, n / N (%)

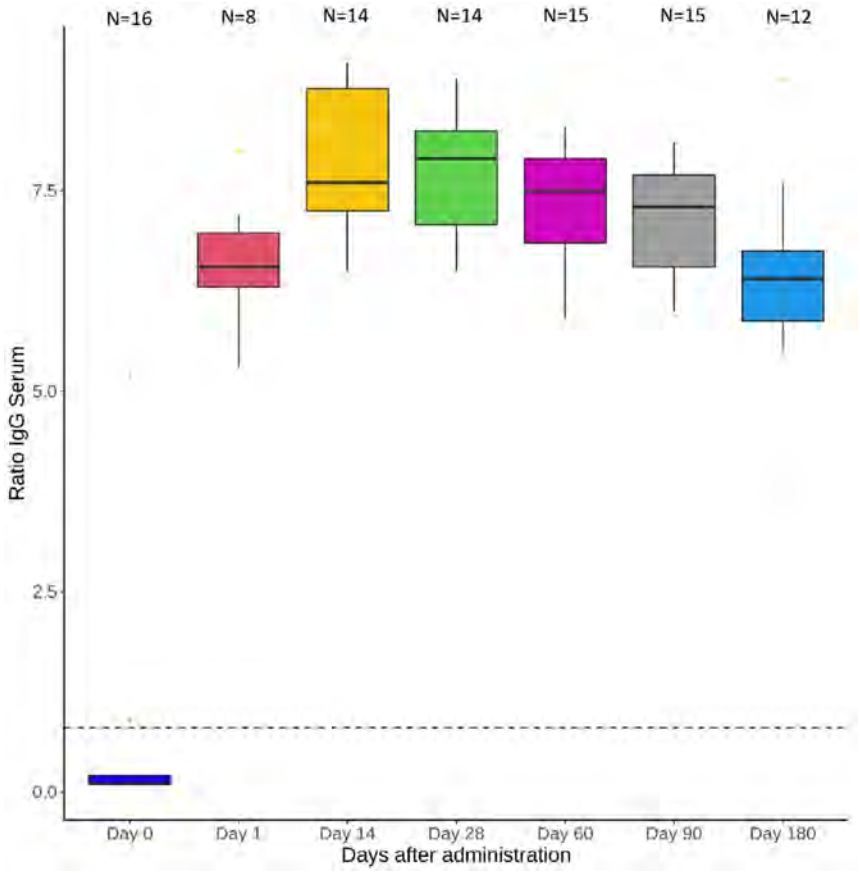

Figure 1. Box and whiskers plot of the levels of serum anti-SARS-CoV-2 spike IgG antibodies before and after 1 day, 14 days, 28 days, 60 days, and 90 days from tixagevimab/cilgavimab treatment. The dashed horizontal line represents the cut-off value of 0.8 optical density ratio (anti-SARS-CoV-2 IgG negative/positive).

prophylactic treatment with tixagevimab/cilgavimab and (ii) the local general population to assess the risk of symptomatic COVID-19. All included patients were attending the outpatient clinic of the Department of Medicine 3 (Rheumatology and Immunology) of the University Clinic Erlangen between March and September 2022. Ethical approval (#157_20 B) to conduct this analysis was granted by the institutional review board of the University Clinic of Erlangen.

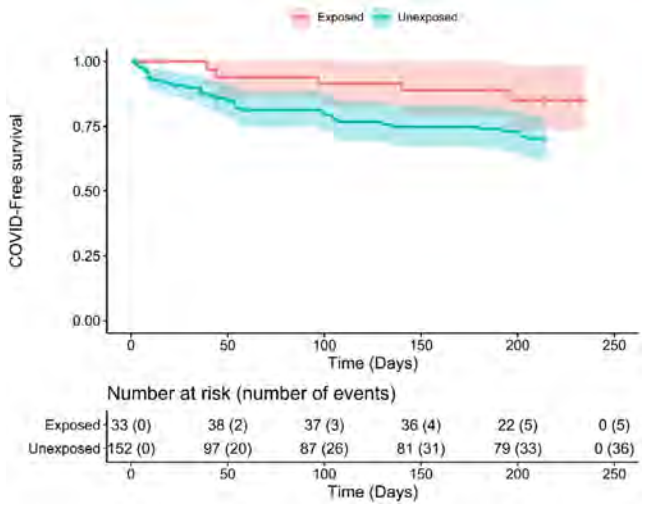

Figure 2. Kaplan-Meier curve of COVID-free survival for the treated group (red line) and the untreated vaccine-refractory controls (blue line).

Results: A total of 38 high-risk IMID patients received tixagevimab/cilgavimab and were compared with 114 untreated high-risk IMID controls. Clinical and demographic characteristics are shown in Table 1. Serum anti-Spike IgG increased to 6.6 OD (SD: ±0.8) at day one and remained positive up to month 6 (6.3±1.4 OD) (Figure 1). Compared to the general population, the SIR of COVID-19 in treated patients was 0.76 (95% CI: 0.24-1.58) despite the increased risk profile and more frequent use of B-cell-depleting therapies. The SIR of the untreated control group was 1.51 (1.07-2.02), corresponding to a significantly increased incidence of COVID-19. A Kaplan-Meyer curve of infection-free survival throughout the 6-month follow-up period is shown in figure 2.

Conclusion: Passive immunization with tixagevimab/cilgavimab is safe and effective in quicklly inducing anti-SARS-CoV-2 humoral immunity and potentially in preventing COVID-19 in high-risk vaccine-refractory IMID patients. These data provide a proof of concept for the use of monoclonal antibodies as a preventative strategy against SARS-CoV-2 in vulnerable populations such as those with inadequate vaccine responses. Thus, the development of new neutralizing antibodies to protect this frail population remains critical.

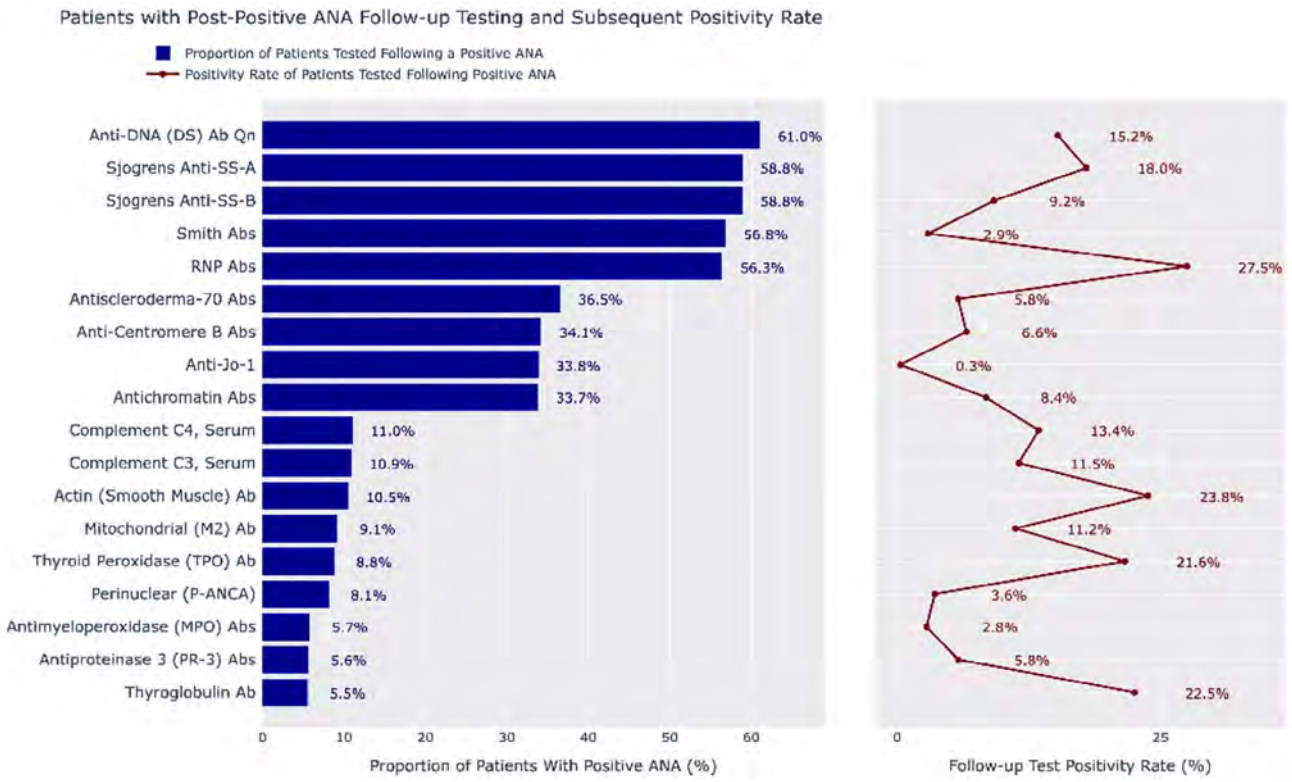
Rheumatologic Disorder Diagnostic Testing Patterns:Real World Evidence from a National Laboratory Database

David Alfego[1], Quinn Hlatky[2], Stanley Naides[3], Karis Lee[4], Jennifer Ennis[5] and Kristen Clark[6], [1]LabCorp, San Diego, CA, [2]LabCorp, Philadelphia, PA, [3]Labcorp, Dana Point, CA, [4]LabCorp, Orlando, FL, [5]LabCorp, Chicago, IL, [6]LabCorp, Raleigh, NC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatologic disorders can take years to diagnose. Diagnosis often requires a combination of specific symptoms, examination findings and laboratory testing, rather than a single test. Additionally, symptoms presenting in rheumatologic processes are often present in other common conditions, making diagnosis challenging. A common starting point is an antinuclear antibody (ANA) test, often ordered by a non-rheumatology provider, followed by a wide range of further antibody testing to narrow disorders. Here, we sought to examine patterns of post-ANA testing using real world evidence to inform order guidance opportunities and help advance diagnosis.

Methods: De-identified data from the Labcorp® testing databasewere queried for all ANA orders (both individual and panel testing) between 2011 and 2022. Any ANA order placed by a rheumatologist was excluded. Follow-up antibody testing (such as Anti-Smith, Anti-dsDNA antibodies, etc.) within 365 days post-positive ANA result (1:80 or higher) and respective positivity rates were examined. Reason for ANA ordering was evaluated via ICD-10 codes associated with the original order where the ANA was the only test run on an individual specimen to remove any conflicting ICD codes with other tests.



Patients with Post-Positive ANA Follow-up Testing and Subsequent Positivity Rate

Results: A total of 1,834,048 distinct ANA tests were ordered by a non-rheumatology provider between 2011 and 2022 and had positive results. Of these tests, 49.7% (n=910,683) were ordered by primary care and only 11.2% of the total sample (n=204,608) were associated with patients who had any order placed by a rheumatologist within a year of the ANA. Anti-dsDNA, anti-SSA, anti-SSB, Smith and RNP antibodies were the most frequently ordered autoimmune-specific follow-up tests performed by non-rheumatologists, each representing just over 50% of the sample. Of these, RNP antibodies had the highest positivity rate (27.5%), and Smith antibodies the lowest (2.9%). Thyroglobulin antibodies were the least ordered tests (5.5% of cohort) but had one of the highest positivity rates (22.5%). Of specimens with only an ANA ordered (n=148,882), M25.50 (pain in unspecified joint, 12.6% of the cohort), R76.8 (other abnormal findings in serum, 6.7%) and R53.83 (other fatigue, 5.3%), I10 (essential primary hypertension, 3.8%) and E55.9 (Vitamin D deficiency, 3.1%) were the most frequent ICD-10s ordered but together represented only 8.1% of the total cohort.

Top 10 Most Frequently Used ICD-10s with ANA orders

Conclusion: There does not appear to be a clear ordering pattern of follow-up testing within a year of a positive ANA test. While more than half of the cohort received some common antibody tests like Anti-dsDNA, positivity rates were low. Interestingly, approximately 10% of the cohort had an order from a rheumatologist within a year, suggesting the majority of diagnostic workup is being done by primary care. Ordering ICD-10 codes represent suspicion for a rheumatologic process and symptoms, such as joint pain, but the frequency of hypertension and Vitamin D deficiency codes do not readily explain a reason for ordering. Results suggest the need for a guideline approach for rheumatologic disorder testing evaluation and education in the non-rheumatologic setting.

Perceived Dignity in Patients with Rheumatic Diseases: An Unrecognized Source of Emotional Distress

Virginia Pascual Ramos[1], Guillermo Guaracha Basañez[2], Irazú Contreras Yañez[2], Maximiliano Cuevas Montoya[2], Oscar Rodríguez Mayoral[3], Harvey Max Chochinov[4] and Mario García Alanís[2], [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [3]Servicio de Cuidados Paliativos, Instituto Nacional de Cancerología, Cuidad de Mexico, Mexico, [4]Department of Psychiatry, University of Manitoba, Cancer Care Manitoba, Manitoba, MB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dignity is generally considered a fundamental feature of human individuals, related to human rationality and morality. This connotation of dignity is recognized as intrinsic dignity. However, in the clinical setting, the notion of dignity evokes how patients see themselves and are seen by others and how the nature of the illness in question affects the person's life and identity. Perceived dignity is a recognized source of multifaceted distress in cancer patients, which has been associated with the medical care environment, and patients feel a diminished sense of worth or value and a burden to others. The spectrum of rheumatic diseases' clinical expression provides evidence that a significant percentage of the patients might present with progressive health decline, disability, distressing symptoms affecting their capacity to continue with usual activities and roles, and limited autonomy, all of which threaten patients' perceived dignity.

The study's primary objective was to determine distress related to perceived dignity (DPD) among Mexican patients with RMDs. The rationale and methods for adapting and validating the Mexican version of the Patient Dignity Inventory (PDI-Mx) in the population are additionally described.

Methods: This cross-sectional study was developed in 2 phases (January 2022-July 2022). Three convenience samples of different patients were used, and quotes were considered to represent the ten most frequent local RMDs-related diagnoses (**Figure 1**). Phase 1 consisted of pilot testing and questionnaire feasibility (n=50 patients, *Sample 1*), and the PDI-Mx content validity (judgment experts' agreement), construct validity (exploratory factor analysis), criterion validity (Spearman correlations), and reliability (internal consistency and temporal stability) in 220 outpatients (*Sample 2*), among whom 30 underwent test-retest. Phase 2 consisted of DPD quantification in 290 outpatients with RMDs (*Sample 3*). Receiving Operating Curve

Table. Strength of the association between the PDI-Mx score, the DASS21 score, the HAQ-DI score, the family APGAR score, and the Brief Resilient Coping Scale score.

	DASS21 *Anxiety*	DASS21 *Depression*	DASS21 *Stress*	HAQ-DI	Family APGAR	BRCS
PDI-Mx global	0.673	0.754	0.692	0.549	-0.286	-0.285
Dimension I	0.677	0.758	0.670	0.507	-0.301	-0.292
Dimension II	0.631	0.688	0.694	0.448	-0.234	-0.253
Dimension III	0.495	0.492	0.448	0.628	NS	-0.149*
Dimension IV	0.503	0.574	0.521	0.417	-0.431	-0.173

DASS21=Depression, Anxiety, and Stress Scale. HAQ-DI=Health Assessment Questionnaire Disability Index. APGAR=Adaptation Partnership Growth Affection Resolve. BRCS= Brief Resilient Coping Scale. PDI-Mx= Perceived Dignity Inventory (Mexican version). NS=Not Significant. Dimension I=Loss of meaning in Life. Dimension II=Discomfort and uncertainty. Dimension III=Loss of Independence. Dimension IV=Loss of Social support.

was used to define the best PDI-Mx cut-off for DPD (≥54.5, min-max:25-125, higher scores indicating more DPD) with the gold standard defined according to DASS21 scores of at least moderate severity for anxiety and depression and a psychiatric interview that confirmed clinically relevant symptoms of emotional distress.

Figure 1. Diagnoses distribution in the 3 samples used.

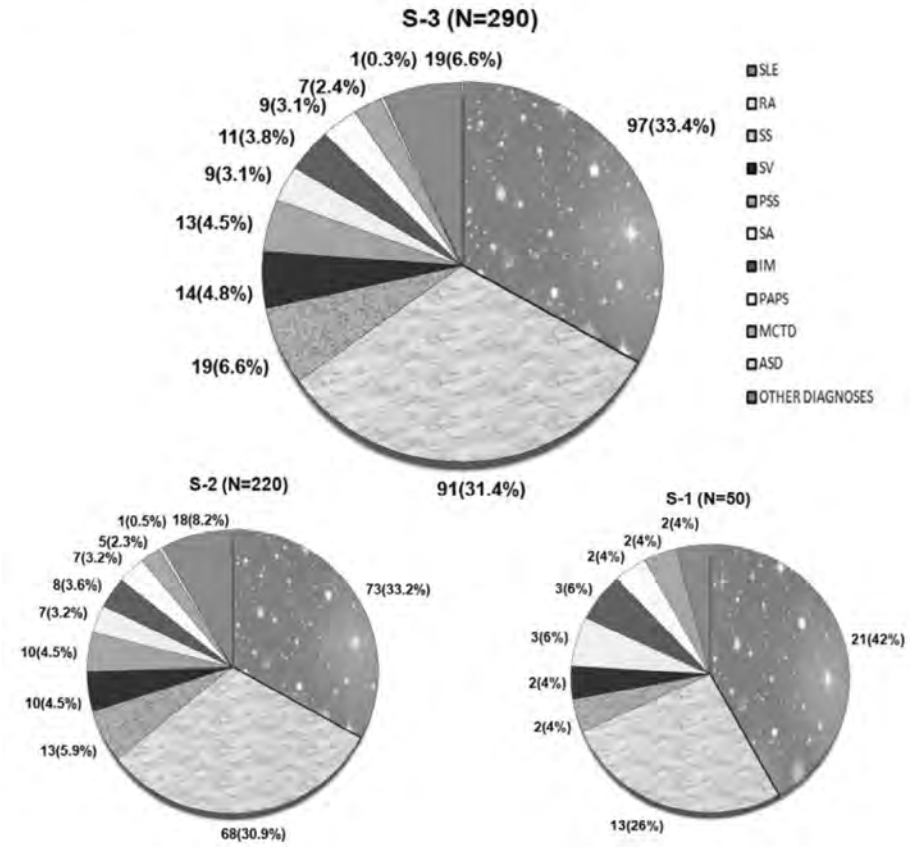

Figure 2. PDI-Mx structure pre and post-factorial analysis.

Results: Overall, patients were representative of typical outpatients with RMDs from a National tertiary care level center, and the most frequent diagnoses were Systemic Lupus Erythematosus and Rheumatoid arthritis (**Figure 1**). DPD was present in 78 patients (26.9%). The 25-item PDI-Mx was found feasible, valid (experts' agreement ≥82%; a 4-factor structure accounted for 68.7% of the total variance; moderate to high correlations between the PDI-Mx and questionnaires summarized in the **Table**) and reliable (Cronbach's α=0.962, ICC=0.939 [95%CI=0.913-0.961]). The structure of the PDI-Mx underwent mild modifications after factorial analysis (**Figure 2**).

Conclusion: DPD was homogeneously present in up to 27% of Mexican patients with different RMDs. The PDI-Mx process validation was rigorous, and its critical quality indicators were validity, reliability, and feasibility.

Plant-based Diet Quality and the Risk of Gout: Results from Two Prospective Cohort Studies of US Men and Women

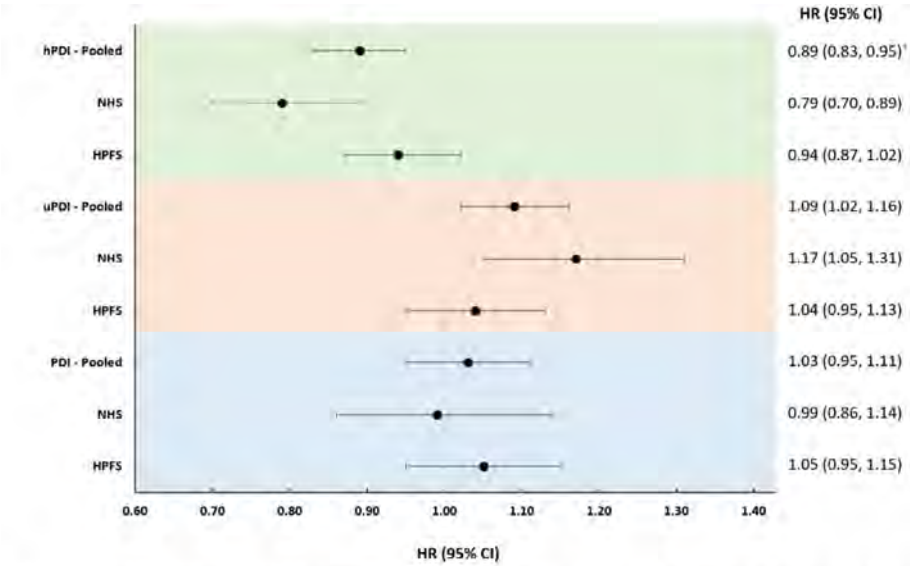
Sharan Rai[1], Frank Hu[1], Molin Wang[1], Hyon K. Choi[2] and Qi Sun[1], [1]Harvard T.H. Chan School of Public Health, Boston, MA, [2]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Plant-based diets are growing in popularity due to their health benefits for selected cardiometabolic diseases as well as favorable environmental impact. However, the limited prior studies of gout simply dichotomized plant-based diets as "vegetarian" vs. "meat-containing" and did not differentiate between the quality of plant foods. Therefore, we examined associations between adherence to a plant-based diet (including healthy and unhealthy versions of this diet), as well as its 18 individual food group components, and incident gout.

Methods: We analyzed data from 123,014 men and women in the Health Professionals Follow-up Study and Nurses' Health Study who were free of gout at baseline. We constructed an overall plant-based diet index (PDI) as well as healthy (hPDI) and unhealthy (uPDI) versions of this index that emphasize healthy and less healthy plant-based foods, respectively. These diet indices were comprised of 18 food groups which were assessed using a validated semi-quantitative food frequency questionnaire, with possible scores ranging from 18 (lowest) to 90 (highest). Participants reported a new diagnosis of gout on biennial questionnaires. We defined incident cases of gout as those that were confirmed with a supplementary questionnaire to meet the preliminary American College of Rheumatology survey criteria for gout (Wallace et al., 1977). We used Cox proportional hazards regression models to evaluate multivariable-adjusted associations between all three PDIs and incident gout.

Results: The hPDI was inversely associated with incident gout (pooled HR per 10-unit increase 0.89 [0.83, 0.95]), while the uPDI was positively associated (pooled HR per 10-unit increase 1.09 [1.02, 1.16]) **(Figure)**. Similar associations were observed in strata defined by hypertension status, overweight, dairy intake, fiber intake, and menopausal status with no evidence of statistically significant effect modification. However, for hPDI (not but uPDI), the inverse association with gout persisted among those who were less physically active (i.e., below the median level of physical activity; pooled HR comparing extreme quintiles 0.68 [0.56, 0.82]) but was no longer significant among those who were more physically active (0.94 [0.76, 1.16]) (P for interaction=0.01). Finally, the overall PDI (emphasizing intakes of all plant foods) was not associated with gout risk **(Figure)**. Among individual food groups, higher intakes of certain healthy plant foods such as whole grain foods (pooled HR per additional daily serving, 0.93 [0.89, 0.97]) and tea/coffee (0.95 [0.92, 0.97]) were independently associated with a lower risk of gout, while selected unhealthy plant foods such as fruit juice (1.07 [1.01, 1.13]) and sugar-sweetened beverages (1.17 [1.07, 1.27]) were positively associated with gout.



*Models were age and calendar time stratified and adjusted for energy intake (quintiles), body mass index (<21, 21-22.9, 23-24.9, 25-26.9, 27-28.9, 29-30.9, 31-32.9, 33-34.9, ≥35 kg/m², missing), history of hypertension, history of renal failure (men only), diuretic use, physical activity (quintiles or missing), and alcohol intake (0, 1-5, 6-10, 11-15, 16-30, >30 g/day). Among women, the model was additionally adjusted for oral contraceptive use and menopausal status/postmenopausal hormone use (premenopausal, postmenopausal never, current, or past users, or missing).
†P-value for *Q*-statistic <0.05, indicating statistically significant heterogeneity among the two cohorts.

Conclusion: In conclusion, we found evidence for an inverse association between a healthy plant-based diet and incident gout, and a positive association between an unhealthy plant-based diet and gout. Our findings support current dietary recommendations to increase consumption of healthy plant foods while lowering intake of unhealthy plant foods to mitigate gout risk.

Longitudinal Changes in Serum Urate Associate Minimally with Changes in Daily Alcohol Intake

Sho Fukui[1], Masato Okada[2], Tomohiro Shinozaki[3], Takahiro Asano[2], Takehiro Nakai[2], Hiromichi Tamaki[2], Mitsumasa Kishimoto[4], Hiroshi Hasegawa[5], Takeaki Matsuda[5], Javier Marrugo[1], Sara Tedeschi[1] and Daniel Solomon[6], [1]Brigham and Women's Hospital, Boston, MA, [2]St. Luke's International Hospital, Tokyo, Japan, [3]Tokyo University of Science, Tokyo, Japan, [4]Kyorin University School of Medicine, Yokohoma, Japan, [5]Kyorin University, Tokyo, Japan, [6]Brigham and Women's Hospital, Newton, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cross-sectional epidemiologic studies support a direct relationship between alcohol intake and serum urate (SU). These observations are parts of the basis for gout recommendations suggesting limiting alcohol intake. However, it is unknown whether reductions in alcohol intake over time are associated with reductions in SU. Hence, we evaluated the relationship between changes in daily alcohol intake and changes in SU levels.

Methods: This longitudinal observational study used prospectively collected annual medical checkup data at a large medical checkup center in Japan. At each visit, daily alcohol intake information was collected using a standardized collection tool, and SU was routinely measured. We included consecutive participants with at least two visits from Oct 2012 to Oct 2022. Participants who received treatment for hyperuricemia or gout during the study period were excluded. The outcome was a change in SU between two visits, and exposures of interest were changes in total daily alcohol intake and in specific types of alcoholic beverage intake (e.g., beer, whiskey, wine, sake, shochu, and others). We used a linear mixed-effect model with random intercepts to take longitudinal intrapersonal correlations into account. We adjusted for SU and alcohol consumption at a prior visit. In addition, age, sex, body mass index, eGFR, medication use, smoking status, daily activity level, exercise level, and results of dietary questionnaires measured at prior visits were adjusted for in primary analyses. In secondary analyses, covariates measured at subsequent visits were also included. As well, we examined the associations in people who fully discontinued alcohol consumption and in sub-groups.

Results: A total of 63,486 participants with 370,572 visits were included in the analyses. The mean (standard deviation) age was 48.0 (12.9) years, and 28,578 (45.0%) were male. 37,199 (58.6%) were regular alcohol drinkers with a median alcohol intake of 1.4 drink/day. The mean interval between visits was 1.3 years. There were 149,441 episodes of changing daily alcohol intake in 41,661 participants (Table 1). The primary analysis showed a significant but very small association between one alcoholic drink decrease and SU (SU change -0.019 [-0.021, -0.017] mg/dL; $p< 0.001$); the association varied based on the type of alcohol consumed. The extents of the associations were almost the same in secondary analyses and when we

Table 1. Baseline characteristics of participants in the medical checkup

	Total participants N=63,486

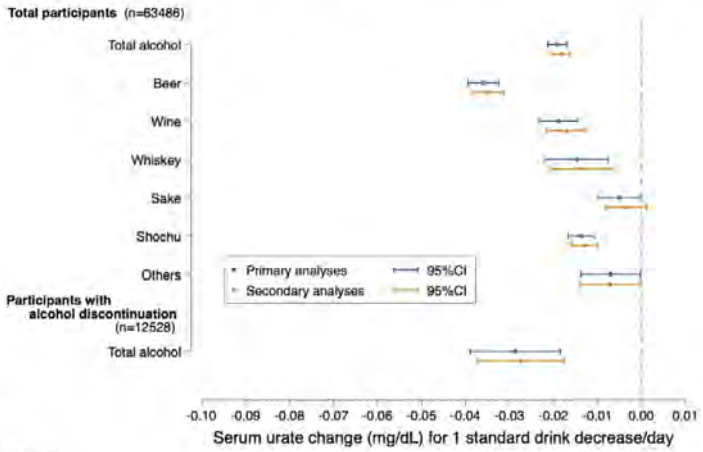
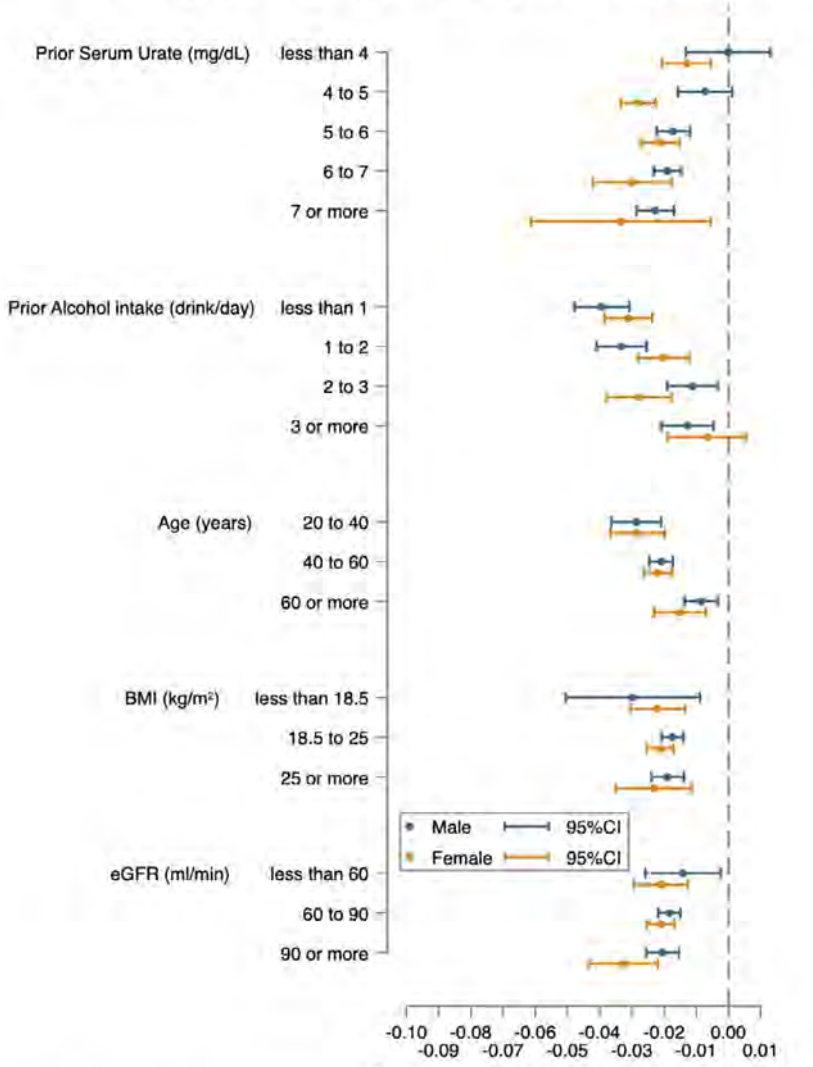
Continuous variables are presented as mean (standard deviation) or median (interquartile range) based on their distribution

Figure 1. The association of changes in serum urate levels (mg/dL) with one unit decrease in daily alcohol intake (standard drink/day)



NOTES:
Sake: Japanese rice wine, Shochu: Japanese spirit.
Total alcohol included beer, wine, whiskey, sake, shochu, and other alcoholic beverages.
SU and alcohol consumption at a prior visit were adjusted for in all analyses. In primary analyses, we adjusted for other covariates measured at prior visits. In secondary analyses, we additionally adjusted for covariates measured at subsequent visits
Other covariates included age, sex, body mass index, eGFR, medication use, smoking status, daily activity level, exercise level, and results of dietary questionnaires.

Figure 2. Results of stratified subgroup analyses for the association of changes in serum urate levels (mg/dL) with one unit decrease in daily alcohol intake (standard drink/day)



NOTES:
Results were adjusted for SU, alcohol consumption, age, body mass index, eGFR, medication use, smoking status, daily activity level, exercise level, and results of dietary questionnaires measured at prior visits.

focused on the visits where participants fully discontinued regular alcohol intake (Figure 1). In stratified sub-group analyses, larger but still small changes in SU were observed in younger participants, lighter drinkers, and those with higher initial SU levels. (Figure 2).

Conclusion: Although alcohol intake is associated with acute gout events, this study found that longitudinal changes in daily alcohol consumption did not result in clinically relevant changes in chronic SU levels. Reducing alcohol intake alone is unlikely to be a major driver of reductions in chronic SU in the general population.

The Prevalence of Cardiac Sarcoidosis – A Systemic Review and Meta-Analysis

Daming Shao[1], Jiyoung Seo[1], Shaunak Mangeshkar[1], Natalia Nazarenko[1], Stepan Esagian[1], Leonidas Palaiodimos[1] and Damianos Kokkinidis[2], [1]Albert Einstein College of Medicine/Jacobi Medical Center, Bronx, NY, [2]Yale University School of Medicine, New Haven, CT

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac sarcoidosis (CS) results from granulomatous infiltrating of the myocardium and manifests as an extended clinical spectrum from silence to conduction disturbances, ventricular tachyarrhythmias, heart failure, and sudden cardiac death. Despite the various presentations, there is a dearth of cumulative evidence of CS prevalence, and the current knowledge is mainly based on studies with small sample sizes or performed in selected countries. This study aimed to use a systematic review and meta-analysis methodology to explore the CS prevalence among population subgroups worldwide and patients with different cardiac abnormalities.

Methods: A literature search was conducted in the PubMed and EMBASE databases until September 8, 2022. Methodological quality assessment of non-randomized studies was performed with high-quality studies included. The statistical analysis included meta-analysis using a random-effects model to estimate pooled CS prevalence and accounting for variations in the study populations, the timing of CS diagnosis, and the length of follow-up between studies in the subgroup analyses.

Results: The prevalence of CS was reported in 172 studies conducted in 28 countries across five WHO regions, with a significant proportion of research originating from the United States (37%) and Japan (21%) and a cumulative total of 122,535 individuals (Figure 1). The prevalence of definite CS among patients with systemic sarcoidosis, extracardiac sarcoidosis being screened for CS, and patients with clinical signs of CS was 11% (9%-14%), 27% (18-37%), and 43% (36%-50%), respectively. Besides patients with suspicions of CS, a higher pooled prevalence was also found in patients with an initial diagnosis of giant cell myocarditis (59%) and deceased sarcoidosis patients undergoing autopsy (36%). Among the organ-specific sarcoidosis cohort, cardiac involvement was diagnosed in 20% of pulmonary sarcoidosis patients, 6% of renal sarcoidosis patients, and 4% of ocular sarcoidosis patients. Seven studies showed that the prevalence of sarcoidosis with cardiac involvement only (isolated cardiac sarcoidosis, ICS) was 13% (4%-26%). Regarding subgroups of cardiac manifestations, 11% of patients with unexplained conduction block and 6% with ventricular arrhythmia or unexplained cardiomyopathy/structural abnormalities were diagnosed with CS. In comparison, CS was identified in 2% of patients who had succumbed to sudden cardiac arrest or death and 2% of patients eligible for or undergoing heart transplantation (Figure 2).

Conclusion: This systematic review and meta-analysis is the first study to provide an overview of CS prevalence among large-scale populations worldwide and introduces important epidemiologic data at population and organ-specific levels. Essential gaps in current epidemiology research of CS were also identified. We encourage and advocate for further global research efforts with the inclusion of currently underrepresented populations to better understand CS.

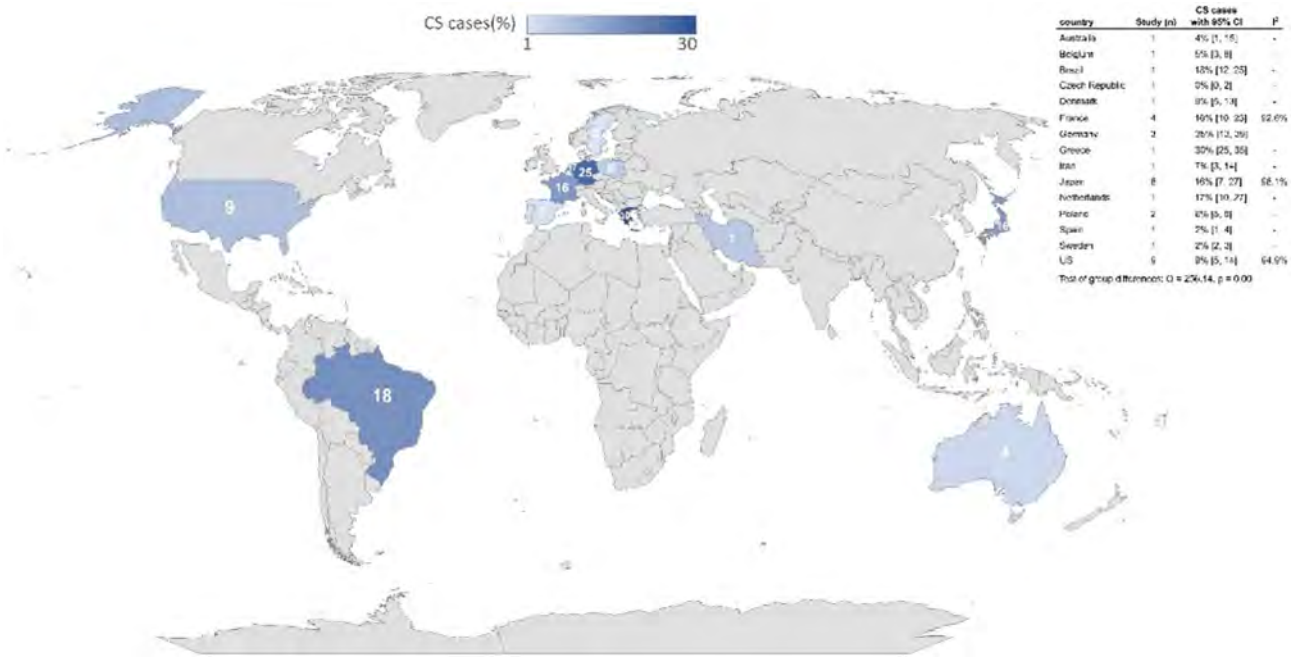

Figure 1. World map demonstrating the prevalence of cardiac sarcoidosis (CS) cases within systemic sarcoidosis subgroups by country. Country-specific studies on CS prevalence are present on the right with 95% confidence intervals (CIs), derived from meta-analysis (random-effects model). Significant differences were detected, p<0.001

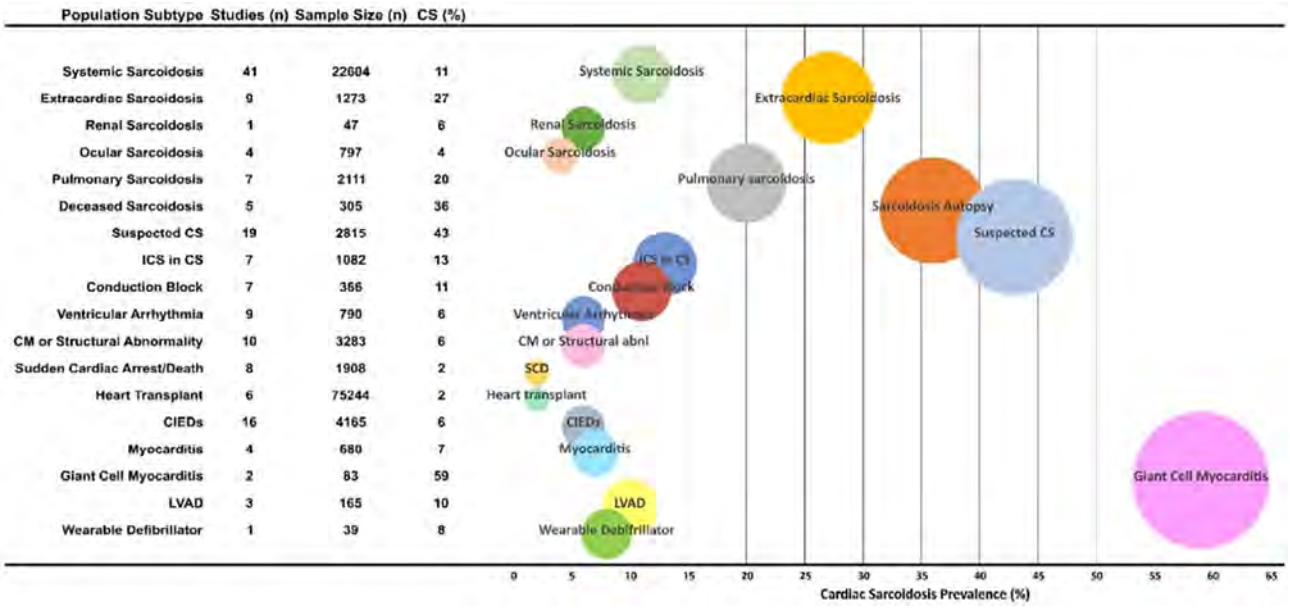

Figure 2. The prevalence of cardiac sarcoidosis (CS) in various populations. The bubble plot shows the prevalence of CS on the x-axis, with each bubble size corresponding to the CS prevalence. ICS, isolated cardiac sarcoidosis; CM, cardiomyopathy; CIED, cardiac implantable electronic device; LVAD, left ventricular assist devices; SCD, sudden cardiac death.

Abstract Number: 1807

Hypothyroidism Impacts Clinical and Healthcare Utilization Outcomes After Primary Total Hip Arthroplasty

Sumanth Chandrupatla[1], Kranti Rumalla[2] and Jasvinder Singh[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Northwestern School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Most data on the effect of comorbidities on primary total hip arthroplasty (THA) outcomes is focused on conditions that directly impact joint health, or on one underlying cause, such as osteoarthritis (OA), but there is little comparison between underlying causes of THA. This study aimed to assess the association of hypothyroidism with outcomes of primary THA, stratified by the primary underlying cause.

Methods: We identified all patients undergoing primary THA in the 2019 national inpatient sample. These patients were stratified based on primary diagnoses into hip OA (N=405691), avascular necrosis (AVN; N=17060), fracture (N=104265), inflammatory arthritis (IA; N=5720), and "other" (N=59155). We identified hypothyroidism and complications using secondary diagnoses. Complications codes were specified to be initial encounters, when possible. We performed multivariable-adjusted regression analyses adjusted for race, age, sex, hospital bed size, census region and teaching status with clinical and healthcare utilization outcomes as endpoints.

Results: Total cohort population was 591,891. Mean age was 68.8, mean length of stay (LOS) was 2.7 days, and 58.2% were female. Overall, hypothyroidism was significantly associated with increased LOS, non-routine discharge, acute renal failure (ARF), and anemia ($p \leq 0.003$ for each), and decreased risk of pneumonia ($p=0.031$). In the OA cohort, hypothyroidism was associated with increased LOS, non-routine discharge, anemia, and ARF ($p \leq 0.008$ for each). Hypothyroidism was associated with increased blood transfusion ($p=0.049$) in the AVN cohort. In the fracture cohort, hypothyroidism was associated with increased odds of non-routine discharge, and anemia ($p \leq 0.020$ for each), but decreased odds of deep veinous thrombosis ($p=0.034$).

Conclusion: Hypothyroidism was associated with clinical and healthcare utilization outcomes in a nationally representative sample of patients who underwent primary THA, especially in OA, AVN, and fracture cohorts. Interventions of tailored patient management strategies for hypothyroidism in THA peri-operative period should be tested for their efficacy to improve peri-operative outcomes.

Table-1: Baseline Hospital and Patient Characteristics with hypothyroidism who underwent primary total hip arthroplasty (THA) in the National Inpatient Sample (2019, N=591,891)

Variable	No Hypothyroidism (N=496,735; 83.9%)	Hypothyroidism (N=95,155; 16.1%)	Overall (N=591,891)	p value

Abstract Number: 1808

Tobacco Smoking Reduces the Incidence and Delays the Progression of Knee Osteoarthritis: 10-year Retrospective Cohort Study Based on Korea National Health Insurance Service-Health Screening Database

Junyong Park[1], Minkook Son[2], Sang Yeob Lee[1], Wontae Chung[1] and SungWon Lee[1], [1]Dong-A University Hospital, Busan, South Korea, [2]Dong-A University, Busan, South Korea

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: There are conflicting results about relationship between smoking and incidence of knee osteoarthritis (OA). The effect of smoking to preexisting knee OA has also not been addressed in detail. To address these issues, we designed a retrospective cohort study to investigate the relationship between smoking and knee OA, based on a large-scale claim database from Korea.

Methods: The Korea National Health Insurance Service-Health Screening database is registered with 98% of Koreans and includes all insurance claims. From this database, two retrospective cohort study were conducted. The operational definition of diagnosis of knee osteoarthritis was knee osteoarthritis code (M17) or any site of osteoarthritis code (M15 to M19) along with a knee x-ray (G720, G721). In OA incidence study, the diagnosis of knee osteoarthritis was set as a primary endpoint on OA-naïve people. In OA progression study, we hypothesized that knee replacement surgery is a surrogate marker for progression of knee OA. Thus in OA progression study, the primary endpoint was set as knee replacement surgery (N2072, N2077, N2712, N2717) among previously diagnosed knee OA patients. The study populations were followed from the day of health screening at index year to primary endpoint, the date of death, or December 31, 2019, whichever comes first.

Table 1. Baseline characteristics of knee OA incidence study population

All subjects (n = 316,387)	Non-smoker group (n = 187,116)	Ex-smoker group (n = 65,290)	Smoker group (n = 63,981)	P-value
Demographics				
Age (years)	58.8 ± 9.0	58.2 ± 8.5	56.5 ± 7.8	< 0.001
Income level (%)				< 0.001
1st quartile	28,637 (15.3)	6,903 (10.6)	8,726 (13.6)	
2nd quartile	40,708 (21.8)	11,247 (17.2)	13,650 (21.3)	
3rd quartile	53,301 (28.5)	18,643 (28.6)	19,972 (31.2)	
4th quartile	64,470 (34.5)	28,497 (43.6)	21,633 (33.8)	
Health screening

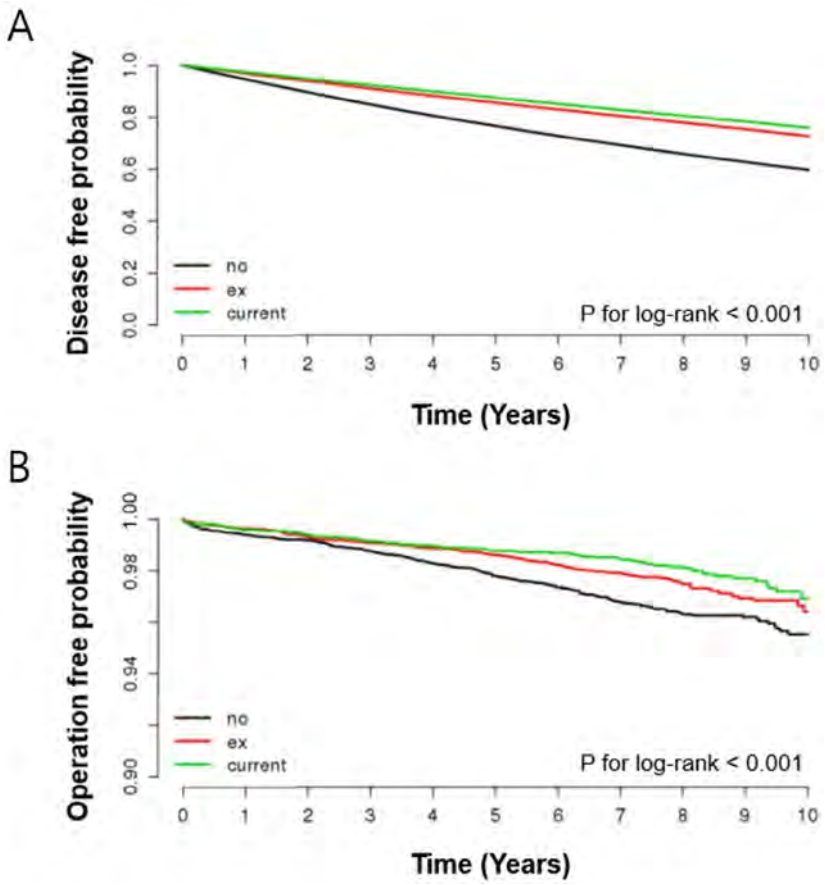

Figure 1. The Kaplan Meyer(K-M) curve of each studies. (A) K-M curve of knee OA incidence study. (B) K-M curve of knee OA progression study.

Results: The patient group was classified into non-smoker, ex-smoker, and smoker groups according to the responses to the health examination questionnaire. The baseline characteristics of each group in incidence study and progression study are included in Table 1 and Table 2. The incidence of knee OA was 38.9%, 26%, and 23% in each group of non-smoker, ex-smoker, and smoker group with statistical significance (P-value < 0.001). When the disease-free probability for knee OA was presented using the Kaplan-Meier curve, the risk of knee OA incidence was significantly different between the non-smoker group and the smoker group over time (Figure 1A). The hazard ratio of ex-smoker to non-smoker were 0.95 (0.83-0.97), and those of smoker to non-smoker were 0.89 (0.87-0.91). In knee OA progression study, the frequency of knee replacement surgery due to OA was 5.3% among non-smokers, 2.3% among ex-smokers, and 2.1% among smokers. The Kaplan-Meier curve of knee OA progression study showed that the knee replacement surgery in non-smoker group was more frequent than ex-smoker group and non-smoker group as time passed (Figure 1B). The adjusted hazard ratio of ex-smoker to non-smoker were 0.81 (0.66-0.99, p=0.04) and those of smoker to non-smoker were 0.76 (0.61-0.96, p=0.02).

Conclusion: This large-scale retrospective cohort study revealed that both incidence and frequency of knee replacement surgery, one of the indicators of progression of knee osteoarthritis, was lower in smoker group and ex-smoker group than in non-smoker group. Further studies on exact mechanism of smoking and osteoarthritis are required.

Clinical Outcome and Antibody Responses Following the Surge of SARS-CoV-2 Omicron Infection Among Patients with Systemic Autoimmune Diseases

Zhu Chen[1], nan xiang[1], Qian Wang[1], Yuwei Li[1], Huizhi Jin[1], Guosheng Wang[1], Xiaomei Li[2], Tengchuan Jin[1] and Wei Bao[1], [1]University of Science and Technology of China, Hefei, China, [2]University of Science and Technology of China, Department of Rheumatology and Immunology, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, Hefei, China

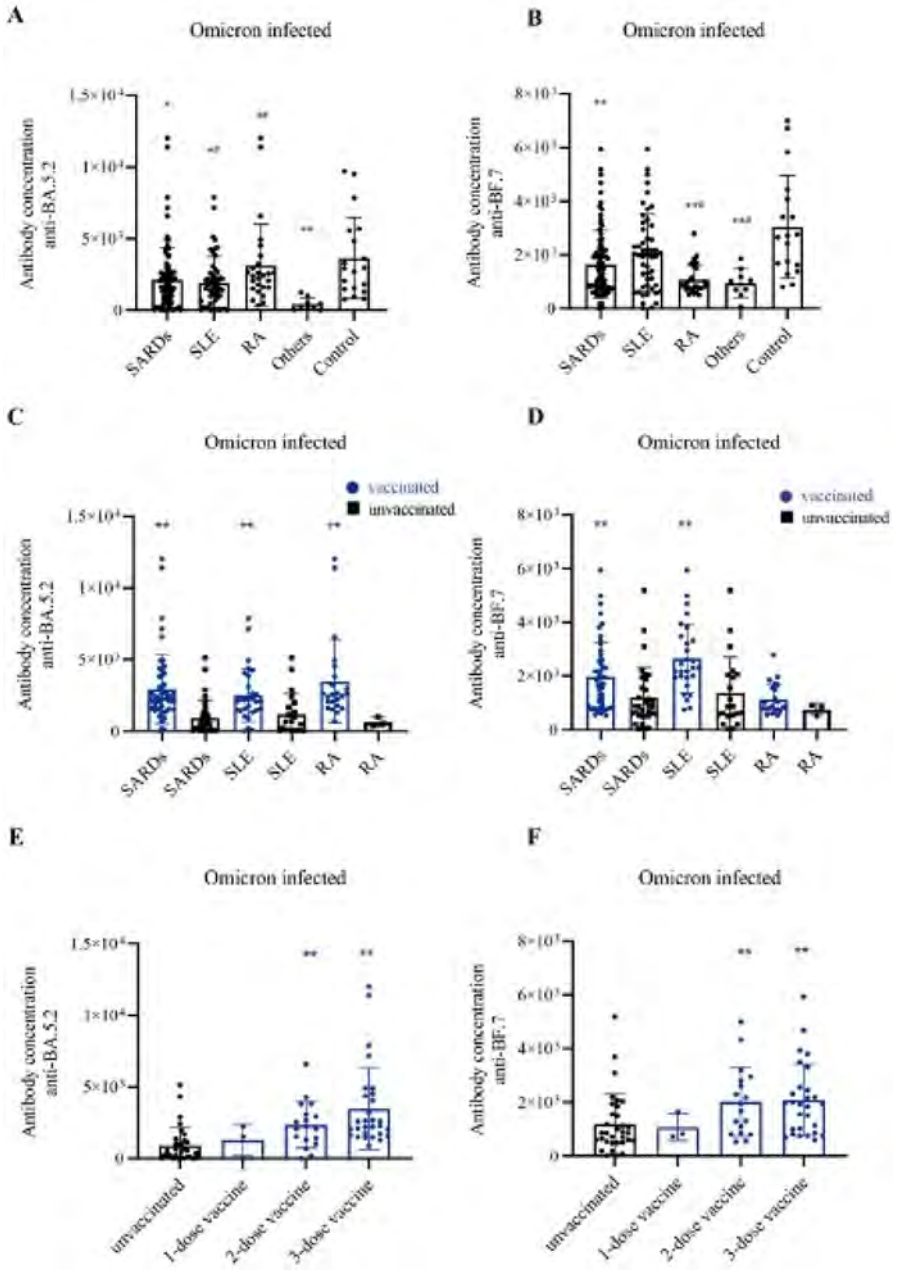
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The surge of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) variant Omicron infections has affected most Chinese residents at the end of 2022, including a number of patients with systemic autoimmune rheumatic diseases (SARDs). The aim of this study was to investigate clinical outcomes and the antibody level of the Omicron variant in SARDs patients after SARS-CoV-2 Omicron infection.

Methods: A total of 682 SARDs patients were surveyed. The type of SARDs, demographics, concurrent treatment, SARS-CoV-2 vaccination history, and clinical outcomes were recorded. Among these patients, we tested BA.5.2 and BF.7 Omicron variant IgG antibody level using enzyme-linked immunosorbent assay (ELISA) from the collected blood samples from 102 SARDs patients and 19 healthy controls (HCs).

Results: 604 (88.6%) SARD patients were infected with SARS-CoV-2 during the pandemic, with the most common symptoms including fever (79.3%), cough (70.1%), malaise (39.1%), expectoration (31.0%), sore throat (28.7%), and ageusia (25.3%). The majority of patients (78.6%) had mild symptoms after SARS-CoV-2 Omicron infection. A total of 102 SARDs

patients (mean age, 40.3 years, 89.2% female), including 60 SLE, 32 RA and 10 other SARDs, were tested for the antibodies against omicron variant IgG. We found that the BA.5.2 antibody level of infected SARDs patients was lower than that of HCs ($P< 0.05$), and a similar alteration was also observed in the antibody level of the BF.7 variant. Notably, the vaccinated SARDs group had notably higher levels of BA.5.2 and BF.7 antibodies than the unvaccinated group. Although the use of glucocorticoids (GC) does not affect the antibody levels, the level of BA.5.2 antibody was significantly decreased in SLE patients



The antibody concentrations in SARDs patients and controls infected with SARS-CoV-2 Omicron (A). Quantitative analysis of RBD antibody titers against the Omicron BA.5.2 variant calculated by ELISA. Compared with control, *P<0.05, ** P<0.01; compared with other SARDs group, #P<0.05, ## P<0.01. (B). Quantitative analysis of RBD antibody titers against the Omicron BF.7 variant calculated by ELISA. Compared with control, *P<0.05, ** P<0.01; compared with SLE group, #P<0.05. (C-D). Quantitative analysis of RBD antibody titers against the Omicron BA.5.2 (C) and BF.7 (D) variants calculated by ELISA between the vaccinated group and unvaccinated group, *P<0.05, ** P<0.01. (E-F). Quantitative analysis of RBD antibody titers against the Omicron BA.5.2 (E) and BF.7 (F) variants calculated by ELISA in SARDs patients with different vaccine doses, *P<0.05, ** P<0.01.

treated with bDMARDs compared with those treated with GCs and/or HCQ ($P< 0.05$). No significant difference in BF.7 antibody levels was found in SLE patients with different DMARDs use.

Conclusion: During the SARS-CoV-2 wave in China, in which the Omicron sublineages BA.5.2 and BF.7 were dominant, unvaccinated SARDs patients had lower antibody production, suggesting the need for valuable prevention and management strategies.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Alcohol intake has been known to be interrelated with hyperuricemia and gout. However, the results of its influence are conflicting on serum uric acid (SUA) levels in terms of the beverage types and drinking amount. The study aimed to assess the impact of alcohol on SUA levels concerning the types of beverages and the drinking amount and habits in a large number of Korean populations.

Methods: We evaluated 17,011 adults who underwent comprehensive health examinations between 2011 and 2016. A standard drink unit for alcohol intake in Korea is defined as 8g based on the WHO definition. The dominant beverage was defined as the type of alcoholic beverage that was taken up more than 75% of total alcohol intake among beer, soju (Korean traditional liquor), and wine. Drinking habits were compared using the proportion within the same group of dominant liquor. Alcohol intake was categorized into six groups: none (0), almost none (0.01–0.49), little (0.50–0.99), light (1.00–1.99), moderate (2.00–3.99) and heavy (≥4.00) in the standard drink unit. The effect of alcohol consumption on SUA levels was investigated using linear regression models. Interaction effects were investigated in the subgroup analyses of sex and BMI.

Table 1. Associations between SUA levels and alcohol intakes of dominant groups in total. † Adjusted for other alcoholic beverages, age, sex, BMI, creatinine, LDL-C, hypertension, DM, alcohol-free calorie intake, and total protein intake ‡ Adjusted for age, sex, BMI, creatinine, LDL-C, hypertension, DM, alcohol-free calorie intake, and total protein intake

	SUA levels (mg/dL) according to the category of alcohol intakes						*P* for trend
	None	Almost none	Little	Light	Moderate	Heavy

Multivariable (95% C.I.)‡	*(reference)*	-0.02 (-0.08, 0.04)	-0.01 (-0.08, 0.06)	0.05 (-0.02, 0.12)	0.15 (0.08, 0.21)	0.25 (0.18, 0.32)	< 0.0001

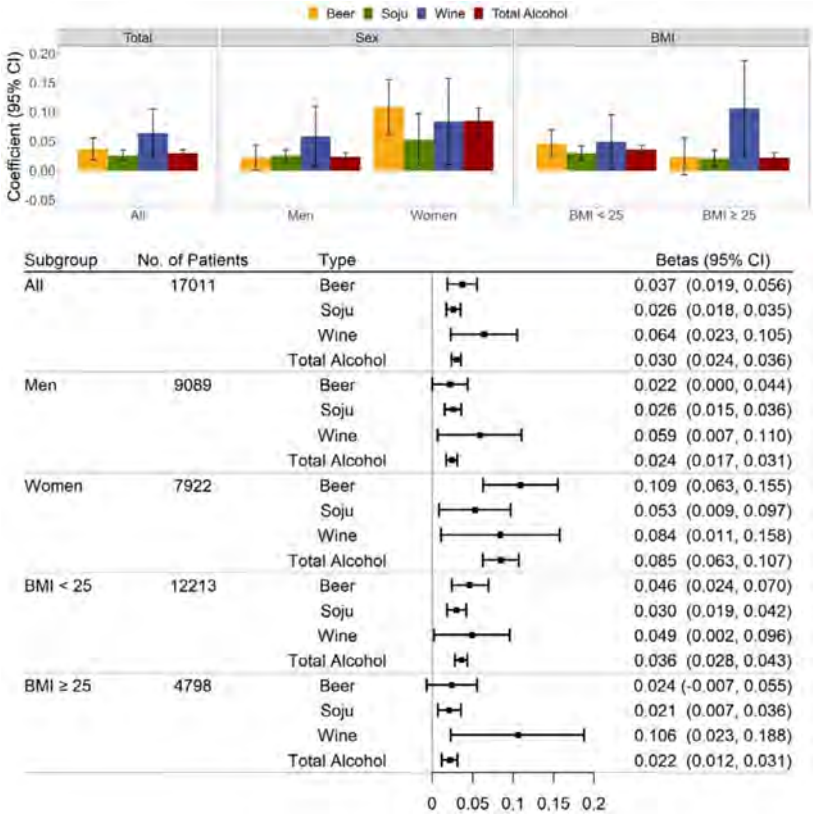

Figure 1. Associations between SUA levels and alcohol intakes in the sex and BMI subgroups. Interactions were significant for intake of beer, soju and total alcohol in the BMI subgroup, and for intake of beer and total alcohol in the sex subgroup (P values for interaction < 0.05). All other P values for interaction were greater than 0.05. Error bars represent 95% confidence intervals.

Results: The mean age of participants was 51.67±7.10 years, with 53.4% of men, and 69.6% of drinkers. The mean SUA level was 5.12±1.36 mg/dL and drinkers had significantly higher SUA, BMI, creatinine, low-density lipoprotein cholesterol, energy intake, and total protein intake ($p< 0.05$). Men's dominant beverage was soju, within which the proportion of heavy and mixed intake was noticeably higher. Women's dominant beverage was beer, within which the proportion of almost non-drinking was remarkable. SUA levels according to the six categories of alcohol intake were positively associated in a dose-dependent manner (p for trend< 0.001) irrespective of the beverage types and the association of beer and wine was weakened but still significant after adjusting in multivariable models. The total alcohol effect on SUA levels was greater in women compared to men: 0.26 [95% CI, 0.15-0.38] vs. 0.10 [0.01-0.18] mg/dL for the moderate drinking category and 0.53 [0.34-0.71] vs. 0.19 [0.11-0.27] mg/dL for the heavy drinking category (women vs. men). A significant change in SUA levels attributable to an association with alcohol intake was observed in beer, soju, and wine (0.039 [95% CI, 0.020-0.057], 0.028 [0.019-0.037], and 0.068 [0.027-0.108] mg/dL per standard drink unit per day). This effect on SUA levels differed in regard to the types of dominant beverages in men and women. Both sex and BMI had significant interactions with the alcohol effect on SUA levels. The modifying effects of alcohol intake were higher in women than those in men regardless of the beverage types. The interactions were also higher in subjects with BMI < 25 than in those with BMI ≥ 25, consistently across all types of beverages except wine.

Conclusion: Alcohol intake could have a significant dose-dependent association with SUA levels in both men and women, irrespective of the beverage types of alcohol and drinking habits. These findings may support healthcare providers to guide and educate subjects having hyperuricemia and gout in terms of alcohol intake.

Abstract Number: 1811

Strong Relationships Between Body Component Changes and Serum Uric Acid Variability

Jiwon Hwang[1], Mi Yeon Lee[2], Yeonghee Eun[3] and Joong Kyong Ahn[3], [1]Division of Rheumatology, Department of Internal Medicine, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon-si, South Korea, [2]Division of Biostatistics, Department of R&D Management, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea, [3]Division of Rheumatology, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity has a well-known relationship with higher serum uric acid (SUA) levels. Skeletal muscles are another site for producing uric acid as the endogenous pool of purine. However, the actual influence of muscle mass on SUA levels was occasionally investigated.The study aimed to evaluate the impact of changing body components on SUA levels in a large number of Korean healthy populations.

Methods: We investigated 39,505 examinees from health check-up programs between 2015 and 2017. Analysis was separately conducted in men (n = 24,623) and pre- and post-menopausal women (n = 14,810 and n = 702, respectively). Body components including waist-hip ratio (WHR) were assessed using the bioimpedance method. We adopted skeletal muscle

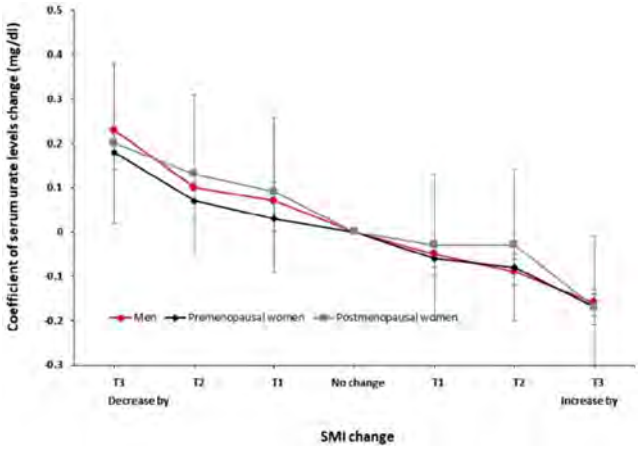

Figure 1. Association between SUA levels and SMI changes. The association was significantly strong and clearly dose-dependent along with the serial adjustment of covariates in the regression model.

mass index (SMI) and fat mass index (FMI) based on body weight (kg). Each study population was categorized into seven groups according to the changes of body components over two years as tertiles of increase and decrease: T3 (the most), T2, and T1 (the least) of increase, no change, and T3 (the most), T2, and T1 (the least) of decrease. Hyperuricemia was defined as SUA ≥ 7mg/dL in men and SUA ≥ 6 mg/dL in women. We analyzed odds ratios (ORs) for achieving the target SUA level (< 6mg/dL) and coefficients for the association with SUA level according to the changes in body components over two years.

Results: The mean age was 38.6 ± 6.5 years in men, 37.2 ± 5.4 years in premenopausal women, and 46.1 ± 8.2 years in postmenopausal women. The mean SUA level was 6.25 ± 1.21 mg/dL in men, 4.23 ± 0.88 mg/dL in premenopausal women, and 4.34 ± 0.91 mg/dL in postmenopausal women. Hyperuricemia was most common in men (26.08%), followed by postmenopausal women (4.42%) and premenopausal women (3.22%). Over two years, the change in muscle mass was mostly within ± 2.5kg and muscle mass decreased more frequently than increased in both men and women. The impact of SMI seemed dose-dependent; the ORs (95% CI) of target attainment for T1, T2, and T3 of SMI increase were 1.10 (1.00-1.20), 1.10 (1.01-1.21), and 1.45 (1.32-1.59) in men and 1.16 (0.82-1.65), 1.48 (1.02-2.15), and 1.48 (1.06-2.06) in premenopausal women whereas the ORs for T1, T2, and T3 of SMI decrease were 1.02 (0.93-1.12), 0.92 (0.84-1.00), and 0.85 (0.77-0.93) in men and 1.18 (0.84-1.65), 0.73 (0.55-0.98), and 0.67 (0.51-0.88) in premenopausal women as compared with the reference group. Of FMI and WHR, the impact seemed inverse. The relationship between the changes

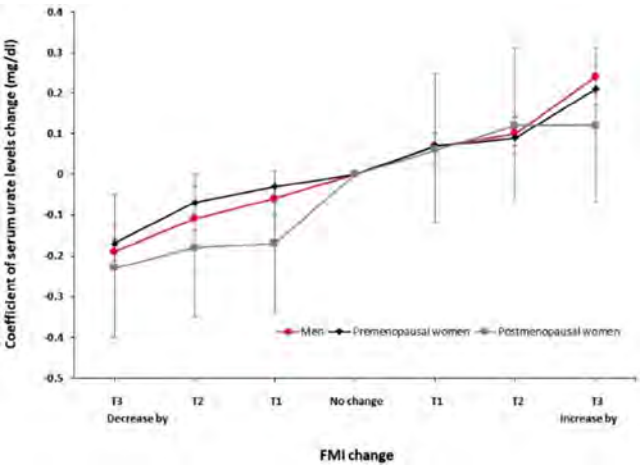

Figure 2. Association between SUA levels and FMI changes. The association was significantly strong and clearly dose-dependent along with the serial adjustment of covariates in the regression model.

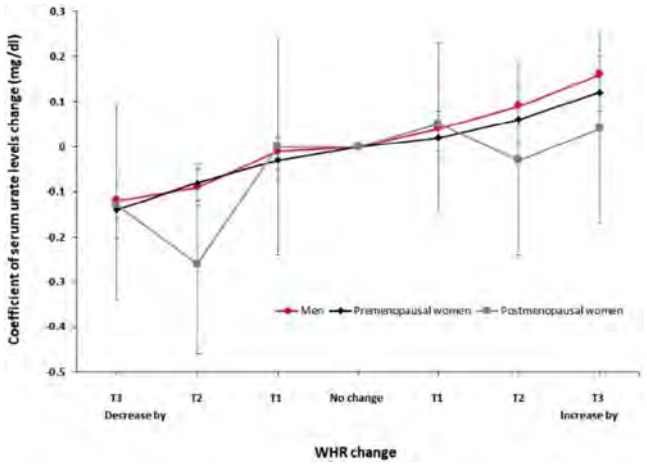

Figure 3. Association between SUA levels and WHR changes. The association was significantly strong and clearly dose-dependent along with the serial adjustment of covariates in the regression model.

in body components and SUA variability was strong and clearly dose-dependent in men and premenopausal women. However, the direction of SUA level changes was not the same among the relationship with body component changes: a positive relationship with FMI and WHR changes while a negative relationship with SMI changes.

Conclusion: We demonstrated that the changes in SMI, FMI, and WHR had a significant impact on achieving the target SUA level and the strong relationship with SUA level variability. Our results could boost the practical advice in clinics regarding physical fitness training for subjects with hyperuricemia and gout.

Duloxetine and the Risk for Cardiovascular Events in US Veterans with Non-Cancer Pain

Laura Daniel[1], Alyson Dickson[2], Puran Nepal[1], Otis Wilson[3], Adriana Hung[2], Dale Plummer[3], William Dupont[3], Katherine Murray[3], C. Michael Stein[2], Wayne Ray[3] and Cecilia Chung[4], [1]University of Miami, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Vanderbilt University, Nashville, TN, [4]University of Miami, Miami, FL

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Duloxetine is a serotonin-norepinephrine reuptake inhibitor approved by the FDA for the treatment of different forms of chronic pain. Because of its adrenergic activity, duloxetine could increase the risk for cardiovascular events, but conversely, given its antiplatelet activity, duloxetine may decrease cardiovascular risk. Therefore, there is a need to define duloxetine's comparative safety relative to other non-opioid medications used to treat chronic pain. We aimed to compare rates of a composite cardiovascular outcome among new users of duloxetine with rates among new users of the active comparator gabapentin in US Veterans with non-cancer chronic pain.

Methods: This is a retrospective cohort study among Veterans with chronic pain who received new prescriptions for one of the study drugs: duloxetine or gabapentin. The cohorts were assembled using the VA Informatics and Computing Infrastructure (VINCI). We excluded Veterans with cancer or other life-threatening diagnoses in the year prior to their first prescription of the study drugs. The primary outcome was a composite cardiovascular disease outcome including acute myocardial infarction (AMI), stroke, or out-of-hospital death. We calculated time-dependent propensity scores and used inverse probability weighting analysis to compare the risk of cardiovascular disease between the study drugs and adjust for confounding.

Results: The study included new users of duloxetine and gabapentin. At baseline, the groups had similar rates of cardiovascular comorbidities and medications. However, before inverse probability weighting, the groups differed in some baseline characteristics. In particular, fewer users of duloxetine had a diagnosis of diabetes neuropathy compared to gabapentin users (5.2% vs. 11.2%). During 288,430 person-years, the rate of cardiovascular events among new users of duloxetine was 11.5/1,000 person-years compared to 17.5/1,000 person-years among new users of gabapentin [unadjusted HR=0.66 (95% CI=0.60-0.73)]. However, after inverse probability weighting adjustment, the risk for cardiovascular events in new users of duloxetine was not statistically different than in new users of gabapentin [aHR=1.07 (95%CI: 0.94-1.21)].

Conclusion: In this large-scale retrospective study of VA patients who received treatment for non-cancer pain, new users of duloxetine and gabapentin had similar risks of cardiovascular events.

Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Data on cellular and humoral immunogenicity triggered by SARS-CoV-2 vaccines in patients with autoimmune rheumatic diseases (ARD) are limited. While current vaccine efforts have focused on the induction of neutralizing antibodies against SARS-CoV-2, T-cell immunity may also provide protection against infection. Experimental data suggest that CD8+ T cell responses may have a protective role in the presence of decreasing or sub protective antibody titers.

The aim of this project is to describe the serological and T cell responses to the third dose of vaccine (either with BNT162b2 mRNA or ChAdOx1 nCoV-19 replication-deficient adenoviral vector vaccines) in a cohort of patients with ARD (rheumatoid arthritis and spondyloarthropathies) treated with biologic therapies, to describe the impact of these treatments on vaccine

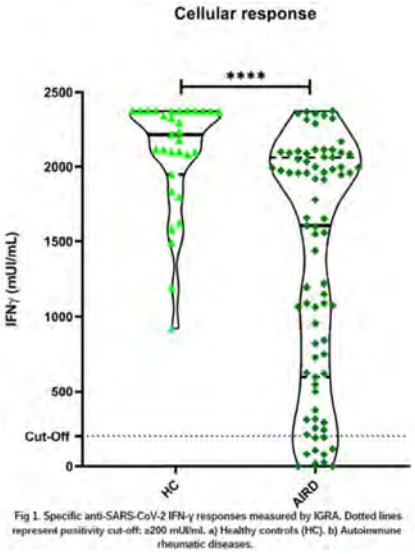

Fig 1. Specific anti-SARS-CoV-2 IFN-γ responses measured by IGRA. Dotted lines represent positivity cut-off: ≥200 mUI/ml. a) Healthy controls (HC). b) Autoimmune rheumatic diseases.

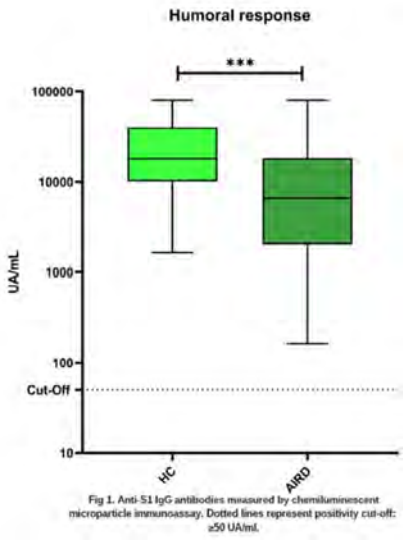

Fig 1. Anti-S1 IgG antibodies measured by chemiluminescent microparticle immunoassay. Dotted lines represent positivity cut-off: ≥50 UA/ml.

response in this patient population. As a second objective, we will describe the characteristics of patients who did not present an adequate immunogenic response.

Methods: Case-control study. We studied in 79 patients with ARD and in 31 healthy controls, anti-SARS-CoV-2 specific interferon-gamma (IFN-γ) production measured by IGRA between 8-12 weeks after the third dose of anti-SARS-CoV-2 vaccine. In addition, humoral response was measured by anti-S1 IgG antibody production measured by chemiluminescent microparticle immunoassay. Statistical comparison between categorical variables was performed by Fisher's or $\chi 2$ test. For quantitative variables by Kruskal-Wallis test or Mann-Whitney test.

Results: 79 patients with ARD (48 women, 31 men; mean age 58±11.4) 43 (54%), with rheumatoid arthritis and 36 (45.6%) with spondyloarthropathies. 32 (49.5%) of them were on glucocorticoid treatment (mean dose 4.92 mg/day), 25 (31.6%) on methotrexate and 56 (70.9%) on anti-TNF. Post-vaccination results showed positive T-cell immune responses in 68 of 79 (86.1%) ARD patients with mean IFN- γ anti-SARS-CoV-2 titers of 1,606.85 mUI/ml. 7 (8.9%) of ARD patients showed negative IFN-γ SARS-CoV-2 levels, while 4 (5%) had borderline titers. 100% of patients with previous COVID 19 disease had positive cellular responses. Within the group of negative or borderline cellular responses, 7 of 10 were men (70%), with no significant differences in terms of diagnosis, comorbidities or immunosuppressive treatments used. In the control group, 100% presented positive cellular responses. Anti-Spike IgG antibodies were detectable in all patients with ARD as in the control group.

Conclusion: Our preliminary data show that most patients with ARD were able to generate an adequate specific cellular response after vaccination against SARS-CoV-2, emphasizing the relevance of vaccination in this group. Specific antibody responses secondary to anti-SARS-CoV-2 vaccination were detected in all patients with ARD. Our data could support the relevance of these immune responses to personalize prevention, vaccination decision-making and treatment in this subgroup of patients.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Growing evidence suggests that environmental factors may contribute to disease phenotype among patients diagnosed with the idiopathic inflammatory myopathies (IIM), dermatomyositis (DM), polymyositis (PM), and inclusion body myositis (IBM), as well as the anti-synthetase syndrome (SYN)-associated lung disease (LD). Occupational exposures, includingrespirable silica dust, have been associated with some systemic autoimmune diseases and lung disease, but associations with IIM phenotype are not well understood.

Methods: We analyzed data from 1390 adult IIM patients (ages 18-65) in a national patient registry (including 658 dermatomyositis [DM], 451 polymyositis [PM], and 309 inclusion body myositis [IBM]) diagnosed through 2011. Other phenotype data included self-reported lung involvement, fever, arthritis, and reported diagnosis of other autoimmune rheumatic

*Anti-synthetase syndrome phenotype included lung disease with arthritis or fever; Autoimmune rheumatic disease includes rheumatoid arthritis/juvenile rheumatoid arthritis, systemic lupus erythematosus, scleroderma; ‡Odds ratios and 95% Confidence Intervals (CI) adjusted for age and gender; referent group for anti-synthetase syndrome phenotype excludes those with lung disease the absence of fever or arthritis (n=144).

diseases (ARD). A self-administered questionnaire asked about specific jobs, hobbies, longest held job (year started/stopped), and exposures prior to diagnosis. Responses were evaluated in a blinded expert review and rules-based assessment to assign exposure intensity with certainty ratings forrespirable silica dust (derived from quartz in rock, sand, or soil), solvents, and heavy metals prior to diagnosis. We examined exposure associations with (1) DM or PM vs. IBM, (2) LD+ fever or arthritis (SYN phenotype; N=218; 16%) vs. no LD (N=1028) and (3) comparing those with overlapping ARD (N=166; 12%) vs. no ARD (N=1224). We calculated odds ratios (OR) and 95% confidence intervals (CI) in logistic regression models adjusted for age and gender.

Results: High silica exposure was associated with increased odds of DM compared to IBM (OR 2.02; 95%CI 1.18, 3.46; p-trend=0.004 vs. unexposed), and the SYN phenotype (1.71; 1.07, 2.74; p-trend=0.005), which was also associated with high or moderate exposure to heavy metals (1.49; 1.00, 2.14; p-trend=0.026). High silica exposure was also associated with the ARD-overlap phenotype (2.07; 1.19, 3.61; p-trend=0.02) and the OR was elevated for high or moderate heavy metal exposure (1.59; 0.99, 2.55, p-trend=0.051). Associations limited to high certainty exposures were stronger for silica exposure and the DM, SYN, and ARD phenotypes, and for heavy metals and the SYN phenotype, and results were similar when limited to female participants.Solvent exposure was not associated with DM or PM (vs. IBM), or the SYN or ARD-overlap phenotypes.

Conclusion: These findings suggest that intense occupational exposure to respirable silica dust and exposure to heavy metals may contribute to distinctive disease phenotypes in adult IIM patients, including lung involvement, one of the more severe manifestations of IIM, and overlap with other ARD. Larger clinical studies, including rigorous exposure assessment, are warranted to identify high risk patients and investigate potential etiologies.

Abstract Number: 1815

The Association of Body Mass Index with SARS-CoV-2 Infection (COVID-19) in Patients with Inflammatory Arthritis on Biologic Disease Modifying Anti-Rheumatic Drugs: Results from the Singapore National Biologics Register

Preeti Dhanasekaran[1], Margaret Ma[2], Manjari Lahiri[2], Li Wearn Koh[3], Stanley Angkodjojo[4], Andrew Yu Keat Khor[5], James Jiaqi Liu[6], Stephanie Wong[7] and Siaw Ing Yeo[6], [1]National University of Singapore, Singapore, Singapore, [2]National University Hospital, Singapore, Singapore, [3]Tan Tock Seng Hospital, Braddell Heights, Singapore, [4]Sengkang General Hospital / Singhealth, Singapore, Singapore, [5]Changi General Hospital, Singapore, Singapore, [6]Singapore General Hospital, Singapore, Singapore, [7]Tan Tock Seng Hospital, Singapore, Singapore

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine the association of body mass index (BMI) with incident COVID-19 infection in patients with inflammatory arthritis (IA) using biologic disease-modifying anti-rheumatic drugs (bDMARDs) and describe the demographic and clinical characteristics of patients with severe COVID-19.

Methods: This was a prospective inception cohort study of IA patients ≥ 21 years old initiating a bDMARD after July 2016 across 6 public-sector hospitals in Singapore. Data were collected via face-to-face questionnaires and abstracted from electronic medical records. Baseline characteristics were compared using chi-square test for categorical variables; and t-test and Mann-Whitney U test for continuous variables for normal and non-normal distributions respectively. The association of BMI with COVID-19 infection was analyzed using multivariate logistic regression, adjusting for demographics and other baseline characteristics.

Results: 477 patients (60.0% female, 69.4% Chinese) with median (IQR) age of 49.0 (38.0, 58.0)years were included. 39.8% had rheumatoid arthritis, 27.0% had psoriatic arthritis and 33.1% had a spondyloarthropathy. The majority of patients (67.1%) were on tumor necrosis factor inhibitors (TNFi). 148 (31.0%) patients had incident SARS-CoV-2 infection. Compared to patients not infected with COVID-19, those who contracted COVID-19 had a higher BMI (24.9 vs 26.4 kg/m^2, p = 0.03) (Table 1). Having a BMI of ≥ 25 kg/m^2 (odds ratio [OR] 1.75; 95% CI (1.09, 2.81), p = 0.02) was independently associated with COVID-19 infection, after adjusting for age, sex, race, smoking status and co-morbidities (Table 2). Severe COVID-19 was defined as infections resulting in hospitalization and/or death. Three (2.0%) of 148 patients had severe COVID-19 infection requiring hospitalization. All were male and two were Chinese. Two had rheumatoid arthritis while one had axial spondyloarthritis. All three had co-morbidities of hypertension and hyperlipidemia, and two had diabetes mellitus. At the time of severe COVID-19 infection, the patients were respectively on golimumab, tofacitinib and adalimumab biosimilar (Amgevita®).

Anti-CD20	0.55 (0.12, 2.56)	0.45		
Others	0.79 (0.33, 1.89)	0.60		

bDMARD: biological disease modifying anti-rheumatic drug * Variables were included in the multivariable model if they were significant at P ≤ 0.2 on univariate analysis. † Included in the multivariable model despite not statistically significant in the univariable analysis due to significant correlation with BMI and need to be adjusted for. TNFi, Tumor necrosis factor inhibitors – adalimumab (Humira®), golimumab, infliximab, etanercept, adalimumab biosimilar (Amgevita®) and infliximab biosimilar (Remsima®); IL-17i, Interleukin-17 inhibitor – secukinumab, ixekizumab; JAKi, Janus kinase inhibitor – tofacitinib, baricitinib; Anti-CD20 – rituximab, rituximab biosimilar (Truxima®); Others include tocilizumab (IL-6 inhibitor), gulselkumab and ustekinumab (IL-12/23 inhibitors) and abatacept (Cytotoxic T lymphocyte-associated antigen 4-immunoglobulin (CTLA4-Ig)).

Conclusion: Higher BMI was associated with incident COVID-19 infection in this cohort. This could be due to upregulation of angiotensin-converting enzyme 2 (ACE2) receptors found in adipose tissues and impaired viral elimination as a result of disease-related and/ or obesity-induced blunted immune response and chronic inflammation [1]. Severe SARS-CoV-2 infections in this cohort were rare.Optimization of BMI may contribute to reducing risk and severity of COVID-19 infection.

Abstract Number: 1816

Hyperuricemia – Especially "Metabolic Hyperuricemia" – Is Independently Associated with Higher Risk of Fatty Liver

Janis Timsans[1], Jenni Kauppi[1], Hannu Kautiainen[2] and Markku Kauppi[3], [1]Päijät-Häme Central Hospital, Lahti, Finland, [2]University of Helsinki, Folkhälsan Research Center, Helsinki, Finland, [3]University of Helsinki, Helsinki, Finland

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated serum uric acid (SUA) level is rather prevalent in the general population, and it is associated with numerous comorbidities and mortality. Etiology of hyperuricemia seems to play a role in hyperuricemia-associated morbidity and mortality risk. Metabolic hyperuricemia (elevated SUA mainly due to urate overproduction) is found to be more dangerous than renal hyperuricemia (elevated SUA due to renal underexcretion of uric acid).[1] There has however been only few studies done on the association between hyperuricemia and fatty liver and it is not known if the different types of hyperuricemia affect the fatty liver risk differently.

Methods: We used data from GOAL (Good Ageing in Lahti region) study – a prospective, population-based study of elderly Northern European individuals (52–76 years). Data of SUA levels and other laboratory parameters, comorbidities, lifestyle habits and socioeconomic factors were collected. Persons with SUA values of >410 μmol/L (≈6.9 mg/dL; 75th percentile) are represented as clearly hyperuricemic. In those that are clearly hyperuricemia, we defined hyperuricaemia renal if estimated glomerular filtration rate (eGFR) was ≤67 ml/min (25th percentile) and metabolic if eGFR was >67 ml/min. Glomerulal filtration rate was calculated using CKD-EPI creatinine-cystatin C equation. Fatty liver index (FLI) is an accurate predictor of hepatic steatosis and it was calculated from body mass index, waist circumference, triglyceride, and gamma-glutamyl transferase data.[2] Persons with FLI ≥80 (75th percentile) are represented as having a very high probability of fatty liver. The results for mortality in the 15-year follow-up period were adjusted for age, sex, education, smoking status, alcohol consumption, body mass index, hypertension, dyslipidemia, and diabetes.

Results: There is a clear correlation between FLI and SUA in both women [r=0.47 (95% CI =0.43-0.51)]and men [r=0.37 (95% CI =0.32-0.42)], see figure 1. Mortality was higher in individuals with FLI ≥80 than in those with FLI < 80 both in clearly hyperuricemic and slightly hyperuricemic/normouricemic persons. When compared to individuals with SUA ≤410 μmol/L

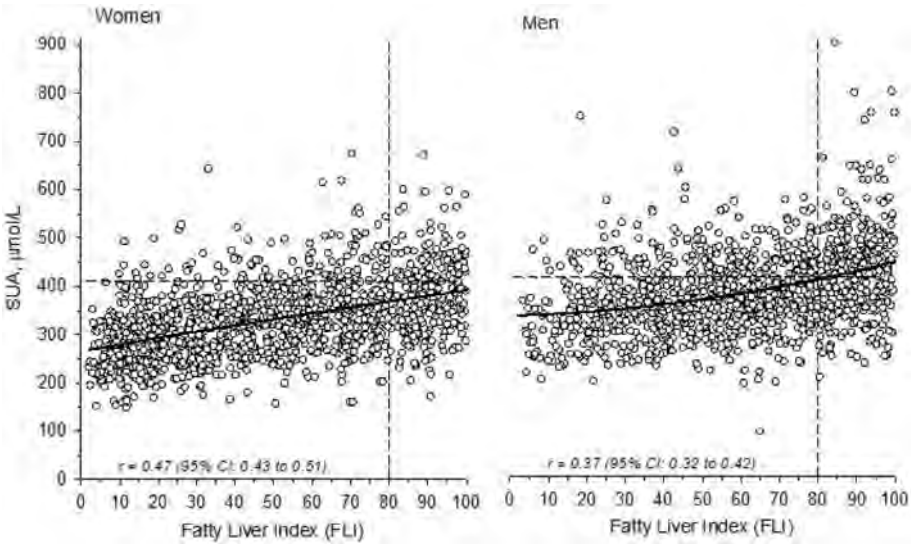

Figure 1. Correlation between fatty liver index (FLI) and serum uric acid (SUA) in women and men. The bold line indicates a trendline. Dashed lines indicate the 75th percentile of SUA (410 µmol/L (≈ 6.9 mg/dL)) and 25th percentile of estimated glomerular filtration rate (eGFR; 67 ml/min) of the study population. Models included quadratic terms for FLI.

Table 1. Adjusted hazard ratio (HR) for all-cause mortality in persons with fatty liver index (FLI) of ≥ 80 and < 80 and clearly elevated serum uric acid (SUA) level or slightly elevated/normal SUA level. Persons with FLI < 80 and SUA < 410 µmol/L (≈ 6.9 mg/dL) shown as reference.

	SUA < 410 µmol/L (≈ 6.9 mg/dL) HR (95% CI)	SUA ≥ 410 µmol/L (≈ 6.9 mg/dL) HR (95% CI)
FLI <80	1.00 (Reference)*	1.16 (0.95 to 1.40)
FLI ≥80	1.34 (1.06 to 1.70)	1.76 (1.39 to 2.23)

*Denominator of Hazard ratios.

(≈6.9 mg/dL) and FLI < 80 the hazard ratio (HR) for all-cause mortality was 1.76 (95% CI: 1.39 to 2.23) in clearly hyperuricemic persons with FLI ≥80, 1.16 (95% CI: 0.95 to 1.40) in clearly hyperuricemic persons with FLI < 80 and 1.34 (95% CI: 1.06 to 1.70) in persons with SUA ≤ 410 µmol/L (≈6.9 mg/dL) and FLI ≥80 (table 1). Individuals with metabolic hyperuricemia had a statistically significantly higher FLI than individuals with renal hyperuricemia: mean (SD)=73.4 (12.2) and 69.6 (22.5), respectively, p=0.015 after adjusting for sex and diabetes.

Conclusion: Fatty liver positively correlates with serum uric acid level. Both fatty liver and hyperuricaemia increase mortality and the most dangerous is a combination of both conditions. Regarding development of fatty liver "metabolic hyperuricemia" appears to be more hazardous than "renalhyperuricemia" since it associates with higher FLI.

Abstract Number: 1817

Geographic Variability of Inflammatory Bowel Disease Related Mortality, 1999-2019; CDC WONDER

Saleha Aziz[1], Anum Akhlaq[1], **Sana Gurz**[2] and Yousaf Zafar[1], [1]University of Mississippi Medical Center, Jackson, MS, [2]University of Nevada, Las Vegas, NV

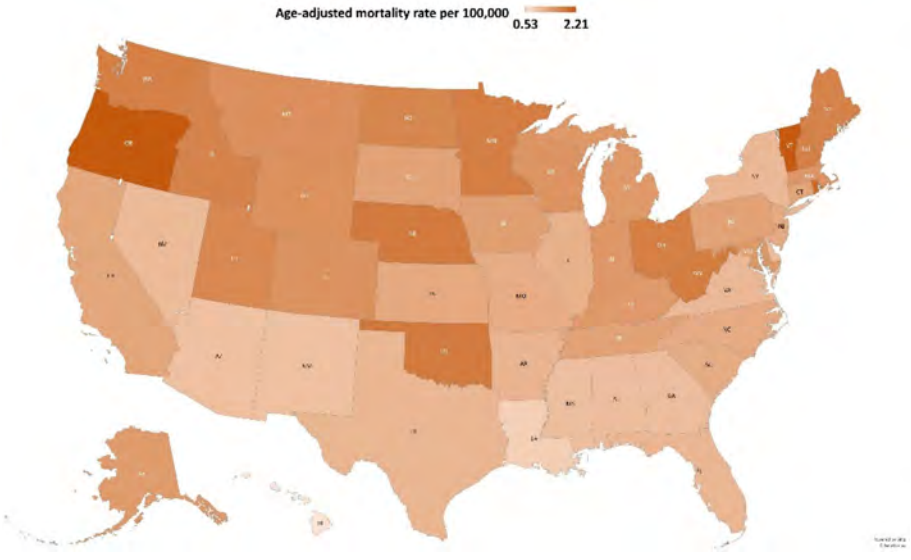
SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

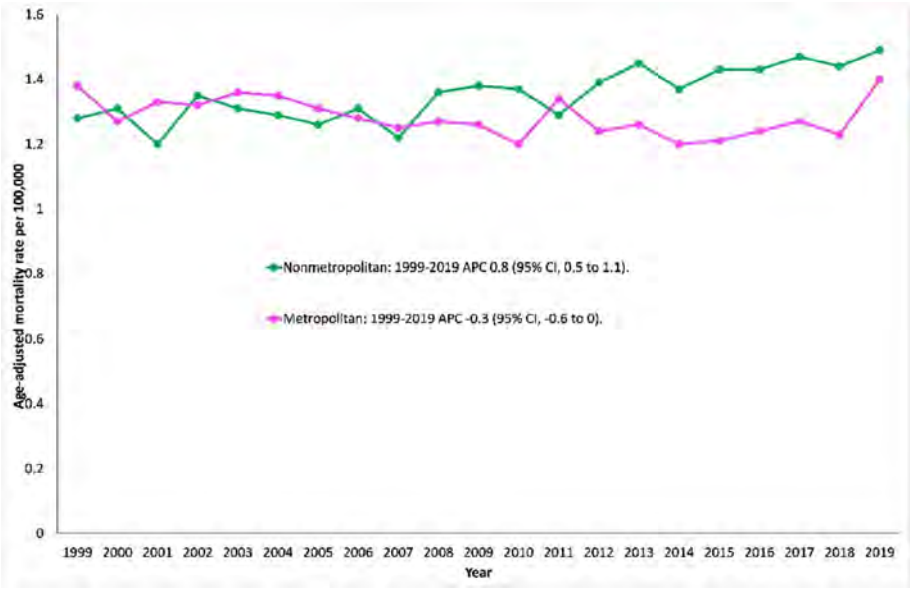
Background/Purpose: The United States makes a significant contribution to Inflammatory Bowel Disease (IBD) related disease burden worldwide. However, data on geographic variability of IBD related mortality within the United States is scarce. Our study assessed the trends in IBD related mortality stratified by geographic pattern through states and metropolitan-nonmetropolitan designation from 1999 to 2019.

Methods: We used Centers for Disease Control and Prevention Wide-Ranging OnLine Data for Epidemiologic Research (CDC WONDER) to access National Vital Statistics System data from 1999 to 2019. IBD related deaths, age >/=25 years were identified from multiple causes of death and were represented as age-adjusted mortality rates (AAMR) per 100,000 population. AAMR was stratified by states and metropolitan-nonmetropolitan designation. Annual percentage changes (APC) were calculated to examine changes in trends using joinpoint regression.

Results: The AAMR per 100,000 population from 1999 to 2019 was 1.29. Crohn's Disease had a higher AAMR compared with Ulcerative Colitis, (0.83 vs 0.53, respectively). The states with the highest AAMR included Oregon (2.21), Vermont (2.19), Rhode Island (1.98), Nebraska (1.81), and Oklahoma (1.78). The lowest AAMRs were seen in Hawaii (0.53), Louisiana (0.8), District of Columbia (0.97), New Mexico (0.98) and Arizona (0.98). Non-metropolitan areas had a higher AAMR compared with metropolitan areas from 1999 to 2019 (1.37 vs 1.28, respectively). Amongst non-metropolitan designations,



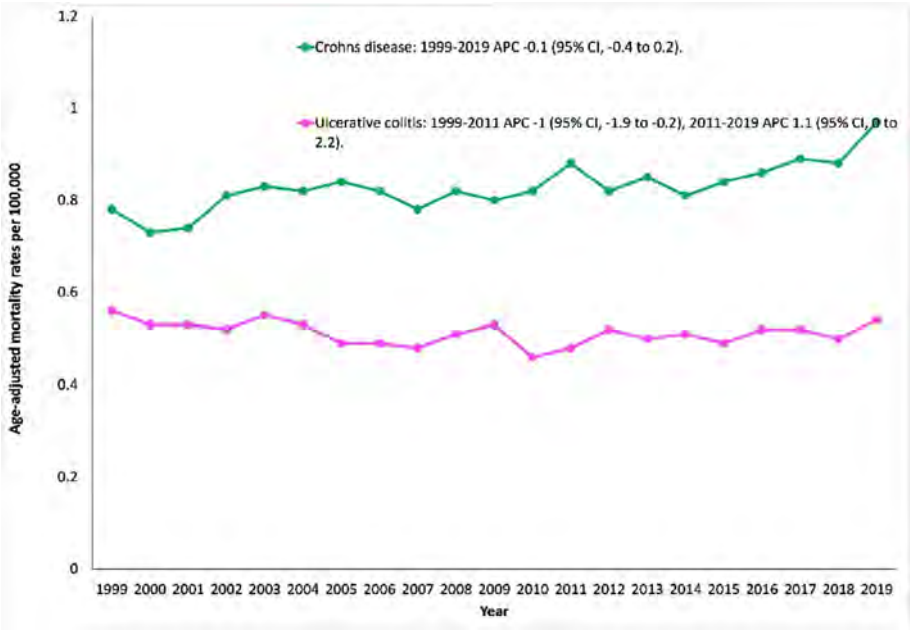
State-level Inflammatory Bowel Disease–related age-adjusted mortality rates per 100,000 people in the United States, 1999 to 2019.



Inflammatory Bowel Disease–related mortality rates stratified by Urban-Rural classification in the United States, 1999 to 2019.

there was a rise in AAMR (1.28 vs 1.49) from 1999 to 2019 (APC 0.8 [95% CI, 0.5 to 1.1]), whereas in metropolitan counties AAMR decreased from 1999 to 2019 (APC -0.3 [95% CI, -0.6 to 0.0]).

Conclusion: Our study demonstrated considerable geographic variation in regards to IBD-related mortality. Overall higher mortality rates were seen in non-metropolitan versus metropolitan areas, along with a rise in mortality trends within non-metropolitan areas. The geographic disparity in mortality determined by our study highlights the need for robust monitoring of patients in these locations, reevaluation of state level health policies, as well as investigation of risk factors leading to these discrepancies.



Inflammatory Bowel Disease–related mortality rates stratified by disease categories in the United States, 1999 to 2019.

Abstract Number: 1818

Compliance with Romosozumab and Fracture Risk Among Postmenopausal Women in the U.S

Ye Liu[1], Tarun Arora[2], **Jeffrey Curtis**[1] and Jingyi Zhang[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Foundation for Advancing Science, Technology, Education, and Research, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Romosozumab (romo) is a newly approved osteoporosis (OP) medicine for women with postmenopausal OP at high risk of fracture. The utilization pattern of romo has not been well described. This study aimed to evaluate the association between treatment compliance and baseline fracture risk among new users of romo.

Methods: Using fee-for-service Medicare data, women age ≥65 years newly initiating romo between 4/1/2019 and 6/30/2021 were identified. Claims data was linked to electronic medical record (EMR) data obtained from 9 data marts of 3 PCORNet Clinical Research Networks to obtain the needed covariates to estimate a FRAX score (with Body Mass Index).Comorbidities and medical history were identified from claims while biometric data were obtained from the EMR. The FRAX algorithm was used to calculate 10-year risk of hip and major fracture (clinical spine, forearm, hip, or shoulder) upon romo initiation. We set the median of FRAX (BMI) hip and major fracture risk as the cut-off for higher fracture risk. Treatment adherence (measured by the proportion of days covered [PDC]) and discontinuation rate (defined as gap > 30 days after the expected date of the next romo administration) were calculated. Kaplan-Meier method was used to estimate the discontinuation rate and 95% confidence interval [CI]. A Cox proportional hazard model was used to evaluate the association between baseline fracture risk and discontinuation, controlling for demographics and Charlson score.

Results: There were 12,216 romo new users identified and among them, 559 were linked with PCORNet EMR data. Across PCORNet data marts, the proportion of women who linked ranged from 82% - 98%.The median (IQR) 10-year hip and major fracture risks estimated by FRAX were 11.0 (6.4, 19.0) and 26.0 (18.0, 35.0), respectively. Romo users with higher baseline fracture risk were older, had more history of fractures, were more likely to receive prior OP treatment, compared with those with lower risk (Table 1). They also had higher rate of romo discontinuation (Table 1, Figure 1). Cox regression showed that, after adjusting for age, race, geographic region, and Charlson comorbidity score, the HR (95% CI)for discontinuation associated with higher(above the median) hip and major OP fracture risk was 1.39 (1.01 - 1.91. p=0.043) and 1.51 (1.11 - 2.06. p=0.009), respectively.

Conclusion: In this cohort of women with high fracture risk and using administrative claims data linked to EHR data, romo users who had baseline higher fracture risk had poorer treatment compliance. These data suggest that physician should focus more on improving treatment adherence when prescribing new therapy such as romo for vulnerable patients with higher fracture risk.

Table 1: Baseline characteristics and romosozumab treatment compliance for the Medicare-PCORnet linked romosozumab new user cohort.

	Higher hip fracture risk [b] (n=278)	Lower hip fracture risk (n=281)	Higher major fracture risk (n=292)	Lower major fracture risk (n=267)

Abstract Number: 1819

Clinical Indications Associated with New Opioid Use for Pain Management in the United Kingdom Using National Primary Care Data

Max Lyon, Carlos Ramirez Medina, Elinor Davies and Meghna Jani, Centre for Epidemiology Versus Arthritis, Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Prescription opioids for non-cancer pain in the UK have increased considerably over the past two decades, alongside a rise in associated harms. Despite the high prevalence of opioid use, there are limited data on the specific indications for prescribing opioids for non-cancer pain. By understanding the reasons for opioid initiation and relative contribution of systems and specific conditions, the opioid burden in patient subgroups can be assessed to develop tailored interventions, policies, and additional support as appropriate. The aim was to evaluate indications associated with new opioid initiation in non-cancer pain using nationally representative UK data.

Methods: Data from the Clinical Practice Research Datalink (CPRD) AURUM were used, a nationally representative database of anonymised electronic health records from General Practices across the UK, between 1/1/06 to 31/09/21. People ≥18 years who were new users of opioids were included. Exclusion criteria included a cancer diagnosis five years prior to first opioid prescription (index date) and methadone users. SNOMED-CT code lists were derived for conditions associated with opioid use following consultation with GPs, rheumatologists, pharmacists, and chronic pain specialists. These were applied to a period one-year prior to index date for surgical indication and five years prior for chronic conditions. Descriptive statistics were used to analyse the data using STATA v13.1, allowing for overlap between indications.

Results: A total of 3,032,185 patients classed as new opioid users over the ~15-year study window were identified. Opioids were initiated more commonly in women (60.7%), people aged 45-64 (40.0%) and ≥65 years (37.0%). We identified 9 systems associated with initiating opioids. The most common were musculoskeletal (73.2%), respiratory (53.1%), infections (25.7%), trauma/injury (16.1%), neurology (16.0%), gastrointestinal (4.2%) and post-surgical (3.9%) (Table 1). Musculoskeletal (MSK) conditions that were most frequently associated with opioid use were osteoarthritis (n=1,536,437, 50.7%), low back pain (1,094,225, 36.1%), other non-inflammatory MSK conditions (e.g. rotator cuff tears), rheumatoid arthritis (63,367, 2.2%) and fibromyalgia (56,038, 1.9%). Post-surgical indications one year prior to index date were associated with 3.9% of all prescriptions. Orthopaedic surgeries were the most common and contributed to 42.1% all post-surgical indications (Table 1). This included total knee replacements (n= 31,944; 27.6%) and total hip replacements (n=17,865; 14.5%) of all post-surgical indications.

Conclusion: This is the first study in the UK evaluating large scale national data to assess indications associated with opioid initiation. Almost three quarters of the new prescriptions of opioids for non-cancer pain were in people with a diagnosis of a MSK condition. Orthopaedic surgeries contributed to a third of all post-surgical indications. These findings could help

Table 1: Clinical indications associated with new opioid use with different look back periods (overlapping totals) – systems ordered by percentages.

System	n (%)	Indications	n (%)
Musculoskeletal	2,244,444 (74.0%)	Osteoarthritis	1,536,437 (50.7%)
		Low back pain	1,094,225 (36.1%)
		MSK (non-inflammatory) bursitis, rotator cuff, tendonitis	344,347 (11.4%)

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Epidemiology & Public Health Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a prevalent and debilitating musculoskeletal condition that has imposed a significant burden on the United States (US) healthcare system. This study aims to explore the burden and trends of osteoarthritis in the US from 1990 to 2019.

Methods: Using the Global Burden of Disease methodology, this analysis presents a comprehensive overview of the Prevalence, Incidence, Disability adjusted life year (DALYs), Years lived with Disability (YLDs) by age, sex, year across the US from 1990-2019. All estimates were presented as total counts and age-standardized rates per 100 000 population, with uncertainty intervals (UIs).

Results: The prevalence cases of total osteoarthritis in the US nearly doubled from 28,873,208 (95%UIs: 25,939,261-32,228,468) in 1990 to 51,865,888 (46,804,271-57,860,984) in 2019. Similarly, the incidence of osteoarthritis increased from 1,990,039 (1,789,372-2,247,569) in 1990 to 3,462,236 (3,060,905-3,923,793) in 2019. The YLDs due to osteoarthritis also saw an upward trend, rising from 1,087,979 (556,601-2,194,304) in 1990 to 1,986,342 (1,023,960-3,964,292) in 2019. The annual percentage change (APC) in DALYs increased by 83% (75%-91%) from 1990 to 2019, indicating a substantial rise in the burden of osteoarthritis. The APC of age-standardized incidence rate (ASIR) increased by 6% (3%-10%), suggesting a steady growth in the occurrence of new cases. Among the states, Massachusetts experienced the highest incidence APC (13%), followed by California (12%) and Minnesota (10%) from 1990 to 2019. Interestingly, North Dakota was the only state that reported a decrease in the APC of ASIR by 2%. When analyzing the age-

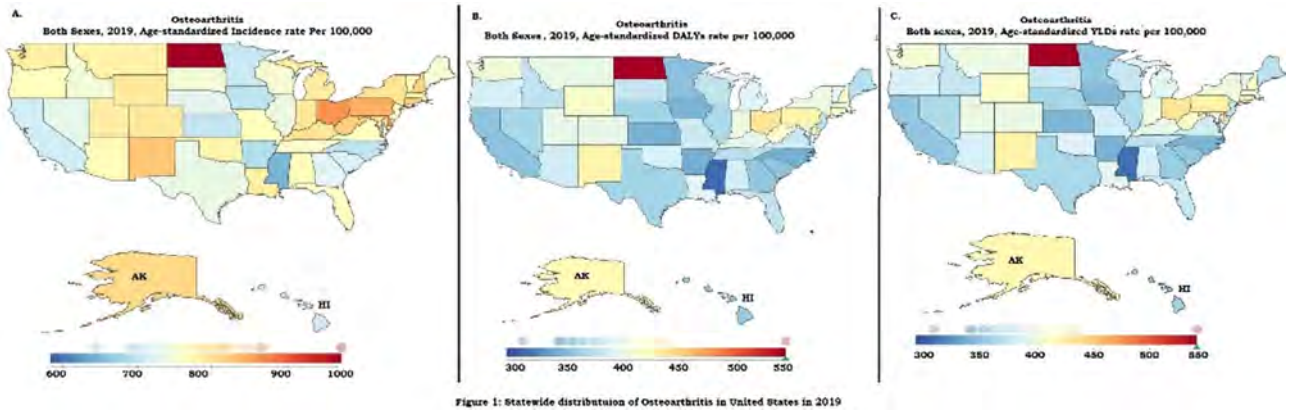

Figure 1: Statewide distribution of Osteoarthritis in United States in 2019

Statewide distribution of Osteoarthritis in United States in 2019.

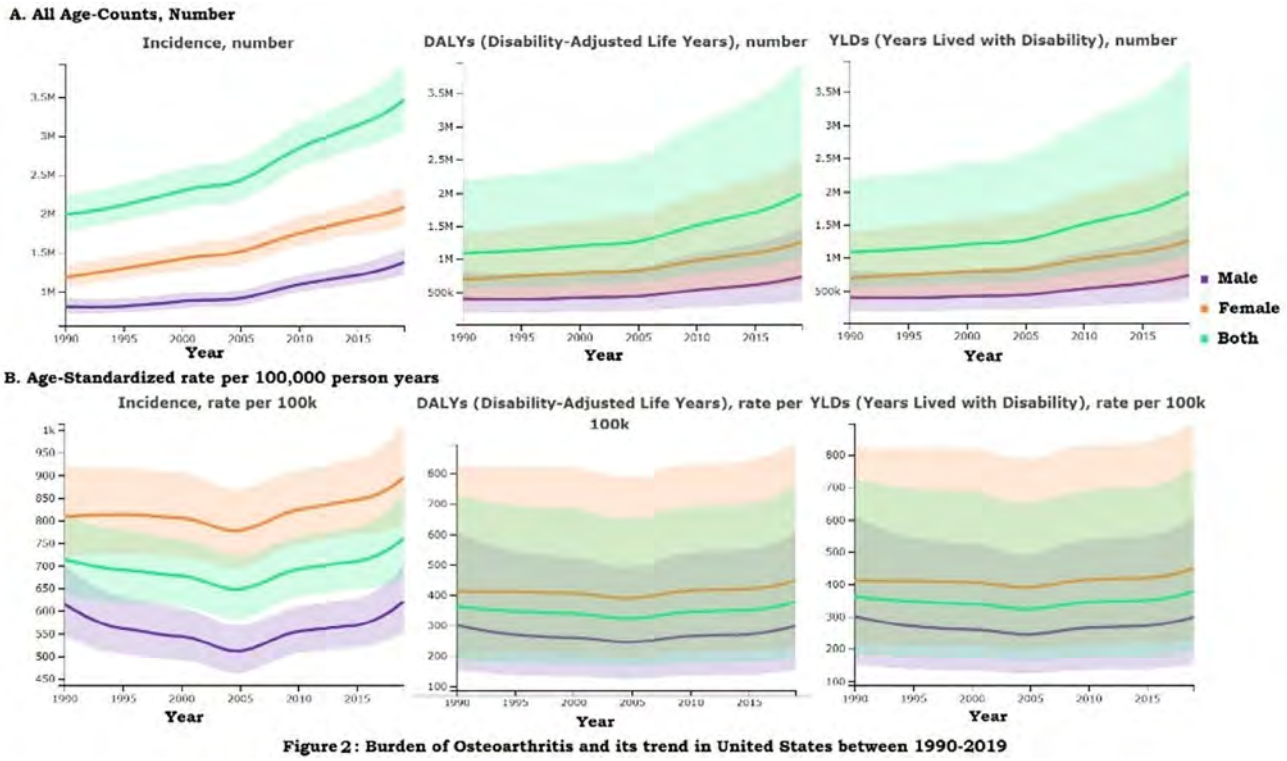

Figure 2: Burden of Osteoarthritis and its trend in United States between 1990-2019

Burden of Osteoarthritis and its trend in United States between 1990-2019.

standardized DALYs rate (ASDALR), California exhibited the highest APC (12%), followed by Massachusetts (10%). Nevada had the highest APC in total incidence cases (226%), with Arizona closely behind at 158%. In contrast, the District of Columbia had the lowest APC in total incidence cases (23%) from 1990 to 2019. Regarding gender differences, females had a higher total number of incidence cases in the APC analysis (76% vs. 70%), while the increase in DALYs was similar for both males and females. Looking at specific age groups, Nevada and Alaska had the highest APC increase in incidence among individuals aged 95 and above, while North Dakota had the lowest APC in the 40-44 age group for females. For males,

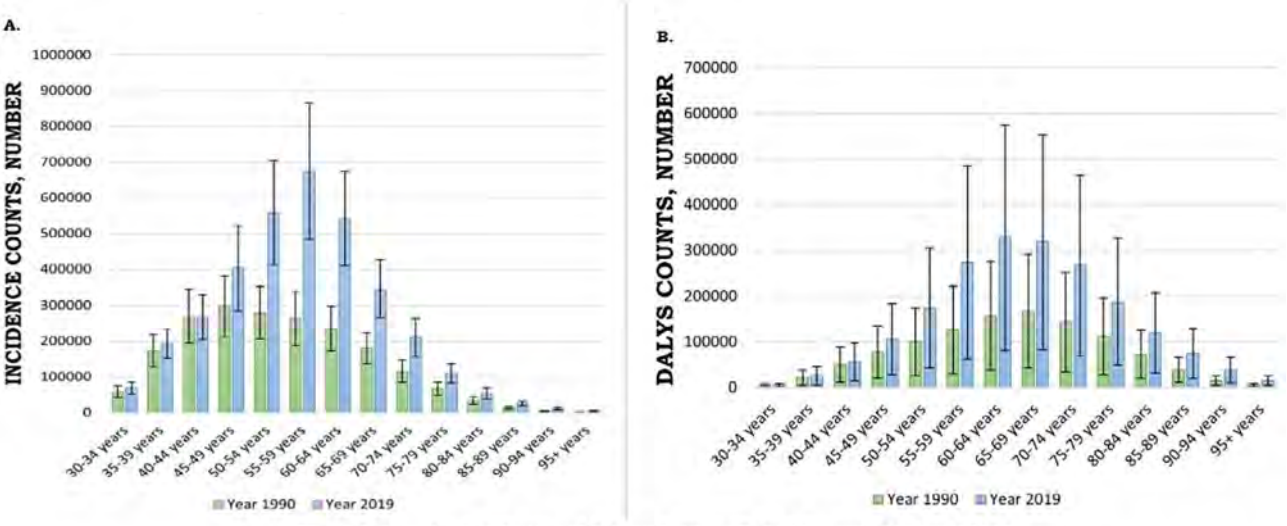

Figure 3: Age-wise distribution of Osteoarthritis in United States in 1990 and 2019.

Age-wise distribution of Osteoarthritis in United States in 1990 and 2019.

Nevada and Alaska had the highest APC increase in incidence among aged 95 and above, while Vermont had the lowest in the 40-44 age group.

Conclusion: In the US, the overall burden of osteoarthritis has steadily increased over the past three decades, with a notable variation in burden observed across different states. It is crucial to prioritize public health initiatives that promote healthy aging, early detection, and appropriate interventions. This includes raising awareness about the risk factors associated with osteoarthritis, implementing strategies to promote physical activity and healthy lifestyles, and ensuring equitable access to effective treatments and therapies.

The "Weekend Effect" and Rheumatological Association in Patients with Diffuse Alveolar Haemorrhage

Shobhit Piplani[1], Shreya Gulati[2], Vladimir Jelic[1], Asad Ahmed[3], Sung Mi Yoon[1], Donclair Brown[1], Miroslav Radulovic[1] and Beverly Johnson[4], [1]Jacobi Medical Center/North Central Bronx, Albert Einstein College of Medicine, NYC Health and Hospitals, Bronx, NY, [2]Jawahar lal Nehru Medical College, New York, NY, [3]SUNY Downstate, Brooklyn, NY, [4]Albert Einstein College of Medicine, Jacobi/NCB, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Diffuse alveolar hemorrhage (DAH) is a life-threatening pulmonary complication commonly associated with autoimmune disorders. Limited treatment options are available for DAH, and time to initiating treatment is critical. The day of admission may be an important predictor of patient outcomes. The "weekend effect", which results from low staff availability over weekends, has been reported to have a number of negative outcomes. (1) However, there is limited evidence on the weekend effect on DAH, and in particular DAH association with rheumatologic disease. This study assesses the impact of the "weekend effect" inpatient mortality and outcomes in patients with DAH) and rheumatologic conditions.

Methods: This study utilized the National Inpatient Sample (NIS) database for 2020, which contains data on over seven million unweighted hospitalizations, to identify patients with DAH and rheumatological conditions. The patients were classified based on admission on a weekday or a weekend, and confounding variables were accounted for using multivariable logistic regression models. The primary outcome was inpatient mortality, and secondary outcomes included intubation, non-invasive ventilation, bronchoscopy, invasive ventilation, length of hospital stay, and total hospitalization charges.

Results: The study included 515 patients with primary diagnosis of DAH. Patients with lupus, systemic sclerosis, sjogren's syndrome, Granulomatosis with polyangitis, vasculitis had a significance association with DAH $p< 0.0001$. Overall, DAH had 17.8% mortality on weekends vs 9.30% on weekdays with an OR 4.1(0.63-27.3), p=0.139, and greater likelihood of intubation OR 2.81(1.08-7.33) p= 0.034. Patients admitted on weekends had higher length of stay (LOS) 5.28 vs 4.52 days, p = 0.024 and higher total cost of stay; $171,101 vs $83,867 vs., p=0.026. Use on non-invasive ventilation, invasive ventilation, and bronchoscopy had similar odds in both groups. Those admitted on the weekends were more often in the lowest income quartile, 42.86% vs 23.29%.

Table 2. Primary and Secondary Outcomes				
	Total	Weekend	Weekday	P Value
Total inpatient mortality (%)	60 (11.6%)	17.80%	9.30%	0.23
Intubation (%)	24.27%	39.29%	18.67%	**0.029**

Rheumatological Associations with Diffuse Alveolar Hemorrhage

Conclusion: This study highlights the association between several rheumatological conditions and DAH. As well it illustrates the weekend effect on inpatient mortality from DAH, and other outcomes. It shows a rather large increase in mortality from DAH in patients admitted on the weekends, as well as higher cost and length of stay. Interestingly, those in the lowest income bracket were most likely to be admitted on a weekend. These findings can help inform clinical decision-making and resource allocation to improve the care of DAH patients, especially in those with rheumatologic disease.

The Food and Drug Administration's (FDA's) Safety Surveillance of Baricitinib and Tocilizumab for COVID-19 (Disclaimer: This Abstract Reflects the Views of the Authors and Not Necessarily Those of the US FDA)

Laura Kangas[1], Lisa Wolf[2], Maya Beganovic[3], Rachna Kapoor[4], James Kidd[4], Kate McCartan[4], Kim Swank[4] and Ida-Lina Diak[4], [1]Food and Drug Administration, Bethesda, MD, [2]Food and Drug Administration, Chevy Chase, MD, [3]Food and Drug Administration, Chicago, IL, [4]Food and Drug Administration, Silver Spring, MD

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib, a Janus kinase inhibitor, and tocilizumab, an interleukin-6 receptor antagonist, are two products first approved for the treatment of rheumatoid arthritis. Notably, these products were authorized for emergency use for the treatment of COVID-19 and now are FDA-approved for this use in adults. As part of FDA's mission to protect the public health, FDA performed safety surveillance of products used, authorized, or approved for the treatment or prophylaxis of COVID-19. The purpose of this descriptive study is to describe the high-level findings from FDA's surveillance of adverse event (AE) reports with baricitinib and tocilizumab used for the treatment of COVID-19.

Methods: We conducted recurring daily searches of the FDA Adverse Event Reporting System, weekly searches of the medical literature, and reviewed cases submitted to the FDA-American College of Medical Toxicology COVID-19 Toxicology Investigators Consortium (FACT) Pharmacovigilance Project Sub-registry through April 24, 2023. We performed a high-level overview of the reports, summarizing information on age, sex, country of origin, AE seriousness, and top reported AEs. We focused on reports containing AEs of interest defined as unlabeled AEs with the potential for serious outcomes, labeled AEs with unexpected characteristics, and other important findings that inform product safety.

Results: We reviewed 935 reports with baricitinib and 1,963 reports with tocilizumab. Regarding baricitinib, most reports originated from foreign countries (77%). Of those reporting sex (868) and age (837), more involved males (67%) than females (33%) and the median age was 62 years (range 8-100 years). About 30% of reports had a fatal outcome, which includes

mortality from all causes (e.g., sequelae of COVID-19, comorbidities, indeterminate) and does not imply a causal relationship to the drug. We identified the following AEs of interest: thromboembolism, acute kidney injury, major adverse cardiovascular events, gastrointestinal (GI) perforation, rhabdomyolysis, hepatitis B reactivation, drug-induced liver injury, and posterior reversible encephalopathy syndrome (PRES). Regarding tocilizumab, most reports originated from foreign countries (67%). Of those reporting sex (1,193) and age (1,090), more involved males (71%) than females (29%) and the median age was 61 years (range 7 months-98 years). About 44% of reports had a fatal outcome, which includes mortality from all causes and does not imply a causal relationship to the biologic. We identified the following AEs of interest: GI perforation, cerebrovascular accident, intestinal pneumatosis, viral-induced hepatitis, and PRES.

Conclusion: FDA identified multiple AEs of interest with use of baricitinib and tocilizumab for COVID-19 requiring continued monitoring; these AEs were few in number, confounded by concomitant medications/diseases, and/or were unassessable because of limited information. The current Emergency Use Authorization Fact Sheets for pediatrics and approved product labeling for baricitinib and tocilizumab appropriately communicate the safety profiles of these products for the COVID-19 population.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunothrombosis is a critical pathological feature of fulminant COVID-19 pneumonia in which immunosuppression with common immunomodulatory agents such as corticosteroids, IL-6 receptor blockers, and JAK inhibitors have shown benefit [1–4].The basis for the efficacy of immunomodulation in the face of potentially critical viral pneumonia remains poorly understood. This study ascertained the impact of age and obesity, both of which increase thrombotic tendencies, on survival following baricitinib therapy for severe COVID-19 in the Phase III COV-BARRIER 3 trial where baricitinib improved survival compared to placebo [4].

Methods: We performed a post-hoc analysis of the COV-BARRIER multicentre double-blind randomized study of baricitinib versus placebo with an assessment of 28-day mortality (a key secondary outcome in the trial) in 1525 hospitalized COVID-19 adult patients. Age was categorized into < 65 years and ≥65 years, and BMI was categorized d into < 25 kg/m^2 (normal), and ≥ 25 kg/m^2 (high). To assess the incidence rate ratios of mortality in the different subgroups, we employed the assumption of a Poisson distribution. All-cause mortality by day 28 was evaluated in a cox-regression analysis (adjusted to age) in three different groups according to BMI (< 25 kg/m^2, 25-30 kg/m^2, and > 30 kg/m^2).

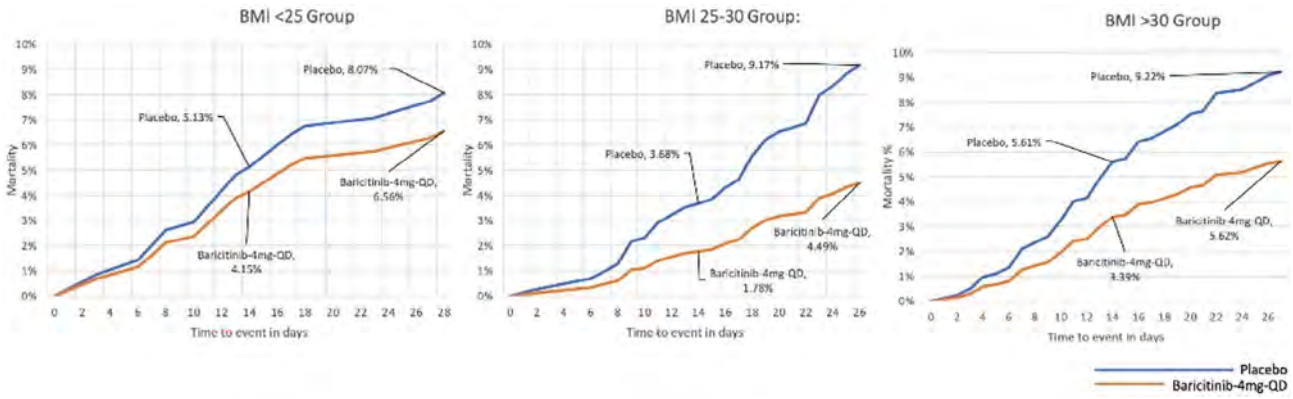

Figure 1. Twenty-eight-day-all-cause mortality in Placebo and Baricitinib arms according to different BMI groups (adjusted to age)

Results: As reported in COV-BARRIER 3 data [4], all-cause mortality by day 28, a key-secondary endpoint, was 8% (n=62) in the baricitinib arm and 13% (n=100) for placebo (PBO), HR 0.57 [95% CI 0.41-0.78].However, we found that in the normal BMI group, irrespective of age, baricitinib therapy did not show a significant survival advantage when compared to PBO [IRR of 1.89 (95% CI: 0.49 to 7.28) and 0.95 (95% CI: 0.46 to 1.99) for < 65yo and ≥ 65yo respectively]. In patients with high BMI, mortality in the baricitinib group was 5.3% (22/418) in < 65 years old (yo) and 20.0% (40/200) in ≥ 65yo. For PBO, mortality rates were 9.9% (43/435) in < 65yo and 30.5% (53/174) in ≥ 65yo. The Incidence rate ratio (IRR) was 0.53 (95% CI: 0.32 to 0.87) and 0.66 (95% CI: 0.46 to 0.94) for the respective age categories. The 28-all-cause-mortality for BMI over 30 was 9.22% for baricitinib and 5.62% for PBO [HR= 0.6, (5.6%vs 9.2%), $p< 0.05$], while for BMI < 25, the difference between 28-all-cause-mortality between baricitinib and PBO arms was not significant [(6.6% vs 8.1), $p>0.05$] (Figure 1).

Conclusion: Baricitinib was associated with significantly lower mortality in patients with high BMI and older subjects. Both BMI and age are associated with immunothrombosis, and the protective effect of JAK inhibition in such groups is remarkable given the reports of thrombosis with JAK inhibition in rheumatoid arthritis.

Background/Purpose:

Acknowledgment: Contributed on behalf of the National COVID Cohort Collaborative (N3C) Consortium

Individuals with rheumatologic diseases (RD) are at higher risk for severe COVID-19 compared to their healthy counterparts. ACR recommendations for COVID-19 vaccination of patients with RD was issued at nearly the same time as CDC recommendations for vaccination during pregnancy, in late July 2021. However, limited data to date exists on vaccination effectiveness among pregnant patients with RD. The aim of this study was to assess the incidence and severity of breakthrough COVID-19 post-vaccination in pregnant patients with RD.

Methods: Using a retrospective cohort analysis of the National Covid Cohort Collaborative (N3C), a nationally sampled and prospectively collected electronic health records repository, we analyzed incident and severe COVID-19 in pregnant patients with RD who were fully vaccinated or additionally vaccinated as defined by CDC recommendations before or during their pregnancy compared to non-vaccinated pregnant persons with RD from December 10, 2020, through May 28, 2022. Pregnant persons were identified using the HIPPS algorithm developed and validated for this purpose for N3C data. Within this group, those with RD were identified using diagnostic codes for the most prevalent RDs, namely SLE, RA, or spondyloarthritis. Incident breakthrough infection was defined as any COVID-19 positivity via laboratory or diagnostic criteria at least 14 days after full vaccination. To evaluate the severity of COVID-19, we identified incidences of hospitalization (all-cause) and hospitalization for COVID-19. We estimated adjusted hazard ratios using Cox proportional hazard models, adjusting for age, race/ethnicity, comorbidities, and data partner site.

Results: Of the 3826 pregnant persons with RD included in our cohort, 466 (12.2%) were vaccinated during and 565 (14.8%) prior to pregnancy, with the remaining 2795 (73.0%) having no reported COVID-19 vaccine. Baseline characteristics of the cohort are shown in Table 1. Compared to unvaccinated pregnant persons, we found an adjusted hazard ratio (aHR) of incident COVID-19 of 1.26 (95%CI: 0.88, 1.78) for fully vaccinated, either before or during pregnancy, pregnant persons (Table 2). Compared to unvaccinated pregnant persons, the risk of severe COVID-19 was lower for fully vaccinated, either before or during pregnancy. The aHR for COVID-19 related hospitalization was 0.31 (95%CI: 0.10, 0.93) when comparing those who were fully vaccinated prior to pregnancy with unvaccinated individuals (Table 3).

Table 2: COVID-19 incidence and breakthrough among pregnant persons with rheumatic disease by vaccination status within the N3C cohort, December 10, 2020 to May 28, 2022

Table 2: COVID-19 incidence and breakthrough among pregnant persons with rheumatic disease by vaccination status

Fully vaccinated pregnant persons vaccinated prior to pregnancy n=(562)	0.08	0.27 (0.09, 0.84)	0.28 (0.09, 0.87)	0.31 (0.10, 0.93)

*adjusted for age, race/ethnicity, and data partner site

**adjusted for age, race/ethnicity, modified CCI, and data partner site

Conclusion: While our analysis did not identify a statistically significant protection from COVID-19 initial vaccinations for incident infections among pregnant persons with RD, our data suggests a clear benefit associated with vaccination and prevention of severe COVID-19. While the overall rates of these severe COVID-19 outcomes were rare, the positive signal suggests pregnant persons with RD should continue to be prioritized for booster vaccinations.

Exploring the Health and Cannabis Use Among Young and Middle-Aged Adults with Rheumatologic Conditions in Alberta, Canada

Elaine Yacyshyn, Simran Gulati, Samuel Lowe, Allyson Jones, Tarek Turk, Shelby Yamamoto, Kali Gregg, Linda Kolewaski, Joanne Olson, Pauline Paul and Cheryl Sadowski, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interest in using cannabis for the management of pain and associated symptoms of rheumatic diseases is rapidly rising in young adults. This, in turn, has heightened the pressure on healthcare providers and scientists to provide evidence-based answers on the role of cannabis in rheumatic diseases in a timely manner. To establish a foundation for care, we aim to contextualize the demand for cannabis. In this study, we assess the health profiles and cannabis use patterns among young and middle-aged (18-45) adult rheumatology patients in Alberta, Canada.

Methods: Adults in Alberta were contacted for recruitment through Alberta Health Services, the sole provincial-level administrative health authority, if they had one or more diagnostic code for rheumatologic conditions and had at least one billing code related to health system use in the past year. Data were collected between March and November 2022 from participants using an online survey designed to capture a broad range of sociodemographic, lifetime cannabis use, and health factors. Descriptive statistics were used to explore the health and cannabis use characteristics of survey respondents. Bivariate methods were used to investigate potential differences in self-rated pain and wellbeing scores, as well as reasons for using cannabis, between cannabis use groups.

Results: Our sample included 193 respondents between the ages of 18 and 45 (mean age=36.1, SD=6.5) and consisted of largely of Caucasian (80.3%, n=155) female (60.0%, n=108) respondents. Majority of respondents had used cannabis, with 94 (48.7%) current users, 59 (38.6%) past users, and 40 (20.7%) never users. The most prevalent rheumatologic conditions reported were rheumatoid arthritis (16.6%, n=32), osteoarthritis (15.5%, n=30), and fibromyalgia (7.8%, n=15) with 27 (14.0%) respondents having reported two or more rheumatologic conditions. A 101 (52.3%) and 111 (57.5%) respondents reported experiencing mental and physical comorbidities, respectively. When comparing self-rated health profiles, the proportion of respondents with high pain scores (47.0% vs. 23.1%, p=0.007) and low wellbeing scores (55.0% vs. 27.0%) were significantly higher for cannabis users (current and past users) compared to never users. Among cannabis users (n=153), the proportion of respondents with high pain scores (53.2% vs. 36.7%, p=0.047) was significantly higher among current users versus past users, with no significant difference in low wellbeing scores between groups (58.1% vs. 50.0%, p=0.338). A higher proportion of current-cannabis users report using cannabis to address rheumatologic pain (54.3% vs. 30.5%, p=0.004) and stress (64.9% vs. 17.0%) compared to past users.

Conclusion: Young adult and middle-aged rheumatology patients experiencing high pain and poor well-being might be more likely to use cannabis, with pain and stress management being common reasons for current use. Further work is needed to determine if cannabis use relates to changes in pain and well-being over time.

Abstract Number: 1826

Investigating the Health Profiles and the Prevalence and Correlates of Cannabis Use Among Patients Accessing Rheumatologic Care in Alberta, Canada

Elaine Yacyshyn, Simran Gulati, Samuel Lowe, Allyson Jones, Tarek Turk, Shelby Yamamoto, Kali Gregg, Linda Kolewaski, Joanne Olson, Pauline Paul and Cheryl Sadowski, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Epidemiology & Public Health Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Implications of using cannabis as therapeutics in a growing number of diseases coupled with increasing public awareness are leading to an increase in patient interest to use cannabis for the treatment of rheumatic conditions. Nevertheless, its legalization and widespread availability have made it difficult for providers to attain a true understanding of its current uptake and demand. Through this study, we aim to delineate the prevalence of cannabis use as well as identify the health profiles and correlates of cannabis use among patients with rheumatic disease in Alberta.

Methods: Adults in Alberta were contacted for recruitment through Alberta Health Services, the sole provincial-level administrative health authority, if they had one or more diagnostic code for rheumatologic conditions and at least one billing code related to health system use in the past year. Data were collected between March and November 2022 from participants using an online survey designed to capture a broad range of factors including sociodemographics, rheumatologic diagnoses and therapeutics, medical history and comorbidities, patterns of cannabis use, and lifestyle factors. Descriptive statistics were used to assess the prevalence and patterns of rheumatologic conditions and cannabis use among our sample. Logistic regression modelling was used to investigate the factors associated with cannabis use among respondents that had ever used cannabis.

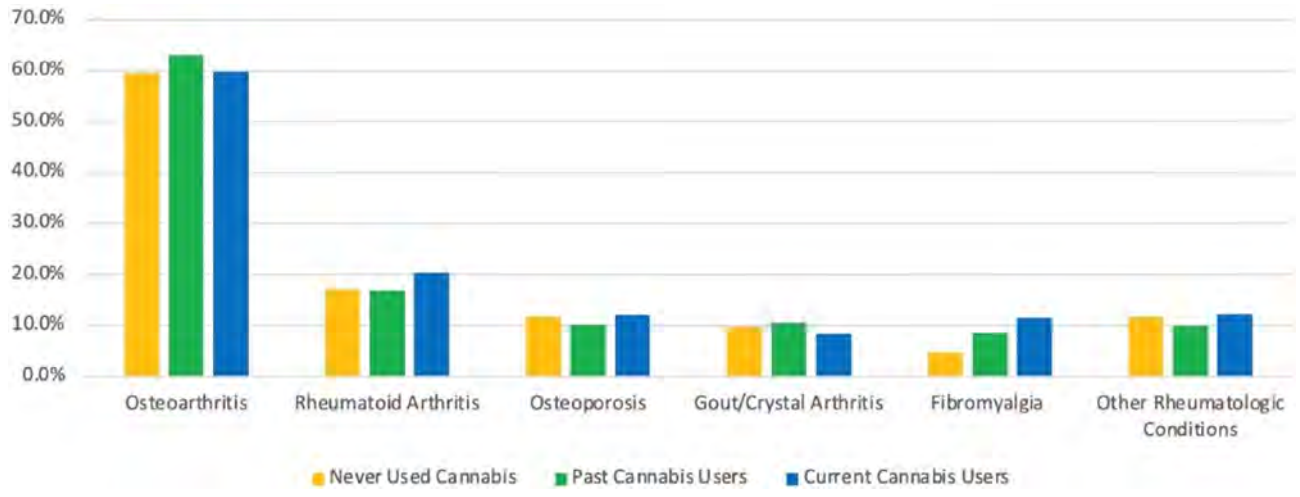

Figure 1: Distribution by percentage of current + past users of cannabis for treatment among various rheumatic conditions.

Results: Our sample of 2,932 respondents consisted largely of female (54.1%, n=1,588), Caucasian (92.5%, n=2,711), and older (mean age=66.7 years, SD=12.2 years, range=18-98 years) respondents, with 730 (24.9%) current cannabis users, 851 (29.0%) past users, and 1,351 (46.1%) never users. The most prevalent rheumatic conditions among respondents were osteoarthritis (60.6%, n=1,776), rheumatoid arthritis (17.9%, n=526), and osteoporosis (11.4%, n=335), with 614 respondents (20.9%) reporting two rheumatologic conditions and 200 respondents (6.8%) reporting three or more conditions. 535 (18.2%) and 2,334 (79.6%) respondents experienced at least one mental and physical comorbid condition, respectively. Logistic regression model estimates indicate that individuals with increased odds of using cannabis were those who were younger, male, experienced mental illness, and sleep disturbances, reported high levels of pain, lacked health insurance, were previous or current smokers, and consumed four or more alcoholic drinks per week.

Conclusion: This study highlights rheumatology patients are using cannabis and identifies factors associated with its use. Our results provide foundational context for ongoing work focused on better understanding the role of cannabis use as a therapeutic tool for rheumatology patients. Future work includes the development and implementation of a tool designed to inform the use of cannabis in managing rheumatologic conditions.

Revolutionizing Fibromyalgia Treatment: Exploring the Efficacy of a New FDA Cleared Photoceutical Device

Timothy Demchak[1], Ernesto Leal-Junior[2], Neide Ribeiro[2], Heliodora Casalechi[2], Douglas Johnson[3] and Shaiane Tomazoni[4], [1]Indiana State University, Terre Haute, IN, [2]Nove de Julho University, São Paulo, Brazil, [3]Multi Radiance Medical, Solon, OH, [4]University of Bergen, Bergen, Norway

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia syndrome effects 2-8% of the general population and is characterized by specific tender points. FM annual economic impact $12-$14 billion.Current treatments are only effective in 10% of patients.There is a need to develop alternative treatment methods. Photobiomodulation therapy (PBMT is an electrophysical agent that utilizes non-ionizing forms of light that can be used alone or associated to static magnetic field (PBMT-sMF) to promote analgesia in several health conditions. Evidence of the effects of PBMT alone and PBMT-sMF in FM patients is conflicting.We investigated the efficacy of a new PBMT-sMF device versus placebo on FM.

Methods: A randomized placebo-controlled trial, with blinded patients, therapists, and assessors was performed. 90 female (age= 46 years) patients that met ACR FM diagnostic criteria were randomized into either PBMT-sMF (n=45) or placebo (n=45) groups. Patients from both groups received 9 treatment sessions, 3 times a week, for 3 weeks. PBMT-sMF treatment consisted of 60 J per active tender point during each session, Placebo treatment was 0 J per active tender point. Clinical outcomes were collected at baseline, after the 9th treatment (PostTx) and at 4 weeks follow-up post-treatment. Outcome measures included Tender Point Count (TCP); Impact of FM on their life using Fibromyalgia Impact Questionnaire (FIQ); and Pain Intensity (PI) measured with a 0-100 Visual Analog Scale (VAS).A Fischer's Exact Test for two independent

Table 1. Mean and standard deviation (absolute values) for the outcomes of the study (n =90).

Outcomes	PBMT-sMF (n = 45)	Placebo (n = 45)
Tender Point Count (TPC)		
Baseline	15.29 (3.08)	15.20 (2.69)
End of treatment	7.29 (3.99)****	12.49 (3.92)
Follow-up	6.22 (4.25)****	10.13 (4.66)
Impact of fibromyalgia (FIQ 0-100)		
Baseline	79.68 (11.05)	77.54 (11.57)
End of treatment	43.89 (22.34)**	56.71 (18.63)
Follow-up	41.64 (25.86)*	52.61 (21.57)
Pain intensity (VAS 0-100)		
Baseline	80.64 (13.99)	74.89 (13.54)
End of treatment	37.80 (23.31)****	56.91 (20.31)
Follow-up	34.47 (26.34)**	49.58 (26.21)

Difference of placebo: ****p<0.0001; **p<0.01; *p<0.05.
PBMT-sMF, photobiomodulation therapy combined with static magnetic field.

groups was used to compare proportion of successes between groups and an Unpair T-test was used to analyze pain intensity.Patient satisfaction was measured using a Likert scale.

Results: Baseline outcomes measures were equal between groups.PBMT-sMF group reported lower TCP ((p< 0.0001), FIQ score (p< 0.01), and Pain intensity (p< 0.0001) than placebo post treatment.The lower outcomes remained at the 4-week follow-up (TCP p< 0,0001; FIQ p< 0.01; Pain Intensity (p< 0.01)).Table 1 summarizes data and significant differences.TCP decreased 52% Post Tx in PBMT-sMF group versus 18% in Placebo.Additionally, PBMT-sMF group FIQ and Pain intensity decreased 45% and 53% respectively.Placebo FIQ and Pain intensity on decreased 27% and 18% respectively.98% of PBMT-sMF group were somewhat satisfied or satisfied with their outcomes Post-treatment and 91% at the follow-up and the Placebo group were 71% and 73% at same time points.

Conclusion: PBMT-sMF is superior to placebo in decreasing TPC, improving function (decreased FIQ) and overall pain intensity.This study supports using PBMT-sMF to treat patients with fibromyalgia. PBMT-sMF might be considered an important adjuvant to the treatment of patients with fibromyalgia.

Positive Screening for Fibromyalgia or Depression on Validated MDHAQ Indices Is Seen in 56-71% of Rheumatoid Arthritis Patients with High DAS28 or CDAI, 40-47% with Moderate, 2-42% with Low, and 0-21% with DAS28 or CDAI Remission

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: DAS28 (disease activity score 28) and CDAI (clinical disease activity index) are prominent indices to assess patients with rheumatoid arthritis (RA) quantitatively, for which disease activity is classified into 4 categories of high, moderate, low, and remission. Both DAS28 and CDAI may be elevated by non-inflammatory comorbid fibromyalgia (FM) and depression (DEP), unrelated to disease activity.Prospective systematic comparison of the number of patients in different DAS28 and CDAI activity categories who screen positive for FM and/or DEP has not been reported. Feasible screening for FM and DEP is available using MDHAQ (multidimensional health assessment questionnaire) indices for FM FAST4 (FM assessment screening tool) and DEP MDS2 (MDHAQ depression screen), which agree more than 80% with reference standards and require a single MDHAQ completed by most patients in 5-10 minutes.

Methods: Across-sectional study at a routine care visit included collection of DAS28 and CDAI.Patients completed an MDHAQ to record global assessment (PaGA), pain, and fatigue on 0-10 visual numeric scales (VNS), a 0-3 DEP query, 0-54 self-report RADAI painful joint count, 60-symptom checklist including DEP, and medical history queries. A FAST4 FM screen is positive if 3/4 are met: pain VNS≥6/10, fatigue VNS≥6/10, RADAI ≥16/54, symptom checklist≥16/60. An MDS2 DEP screen is positive if 0-3.3 DEP response is ≥2.2 OR positive DEP on the symptom checklist. Patients were classified into 4 DAS28-ESR and CDAI activity categories: high (>5.1/28 & >22/76), moderate (3.2-5.1 & 10.1-22), low (2.6-3.2 & 2.9-10), and remission (≤2.6 & 2.8), respectively. The median swollen and tender joint counts (SJC and TJC) and proportions of FAST4 and MDS2 patients in each category were compared using chi-square analyses.

Table: Median (interquartile range interquartile range IQR) values for swollen joint count (SJC) and tender joint count (TJC) according to each of 4 “activity" categories for DAS28 and CDAI and and number of patients (percent) in each "activity” category

Table: Median (interquartile range interquartile range IQR) values for swollen joint count (SJC) and tender joint count (TJC) according to each of 4 “activity" categories for DAS28 and CDAI and and number of patients (percent) in each "activity” category

Measure (Range or units)	All Patients Median (IQR) or Number (%) pos	Remission Median IQR	Low Median IQR	Moderate Median IQR	High Median IQR
DAS28-ESR	2.9 (2.2-3.7)	<2.6	2.6-3.2	3.2-5.1	>5.1
Number of pts (%)	128	57	19	43	9
Median (IQR) values for swollen joint count (SJC) and tender joint count (TJC)					
SJC (0-28)	0 (0-2)	0 (0-1)	0 (0-1)	1 (0-4)	6 (3-11)
TJC (0-28)	2 (0-5)	0 (0-1)	2 (0-4)	5 (2-8)	14 (13-18)
Number of patients (% positive for FAST4 (FM screening tool) or MDS2 (MDHAQ depression screen)					
FAST4 (% pos FM)	36 (28%)	8 (14%)	4 (21%)	18 (42%)	6 (67%)
MDS2 (% pos DEP)	45 (35%)	12 (21%)	8 (42%)	20 (47%)	5 (56%)
CDAI	11.5 (5-18.5)	<2.8	2.9-10	10.1-22	>22
Number of pts (%)	140	17	44	55	24
Median (IQR) values for swollen joint count (SJC) and tender joint count (TJC) SJC and TJC					
SJC (0-28)	0 (0-2)	0 (0-0)	0 (0-1)	0 (0-3)	5 (1-8)
TJC (0-28)	2 (0-5)	0 (0-0)	1 (0-2)	3 (1-5)	13 (8-18)
Number of patients (% positive for FAST4 (FM screening tool) or MDS2 (MDHAQ depression screen)					
FAST4 (% pos FM)	40 (29%)	0 (0%)	1 (2%)	22 (40%)	17 (71%)
MDS2 (% pos DEP)	52 (37%)	1 (5.9%)	10 (23%)	24 (44%)	17 (71%)

Results: Among 128 patients for DAS28 and 140 for CDAI (12 were missing ESR), categories of remission, low, moderate, and high activity, respectively, included 44%, 15% 34%, and 7% by DAS28-ESR, and 13%, 31%, 39% and 16% by CDAI. Median SJC was 0, 0, 2 and 4 for patients in DAS28-ESR and 0, 0, 0 and 4 for patients in CDAI categories. Median TJC was 0, 2, 5 and 5 in 4 DAS28-ESR categories, and 0, 1, 3 and 14 in 4 CDAI categories, respectively (Table). Positive FAST4 FM screen was seen in 28-29% and MDS2 screen in 35-37% of all patients.Positive FAST4 screen was seen in 13%, 22%, 44% and 67% in 4 DAS28-ESR categories of remission, low, moderate, and high activity, respectively, and 0%, 2.6%, 38%, and 80% in the 4 CDAI categories, respectively. Positive MDS2 DEP was seen in 20%, 44%, 46% and 56% in 4 DAS28-ESR categories, and 6%, 24%, 40% and 70% in 4 CDAI categories, respectively.

Conclusion: Among RA patients classified as in high DAS28-ESR or CDAI activity, more than 50% screened positive for FM or DEP, compared to lower proportions for more favorable categories, including fewer than 21% for those in DAS28-ESR or CDAI remission.These phenomena may affect treat-to-target and other aspects of RA management. Feasible screening for FM and DEP is available according to valid MDHAQ FAST4 and MDS2 indices, as well as RAPID3 (routine assessment of patient index data), requiring only a single questionnaire which is completed by most patients in 5-10 minutes.

Blood-derived Extracellular Vesicles as Potential Diagnostic Biomarker in Fibromyalgia Syndrome

Gilad Halpert, Daniel Yechiali, liel Katbi, Eri Govrin, Boris Guilbord, Ori Segal and Howard AMITAL, Sheba Medical Center, Ramat Gan, Israel

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The Fibromyalgia syndrome (FMS) is a global chronic pain condition, which affects approximately 2–6% of the population. The underlying mechanism of FMS is unclear and there is no specific lab test to confirm the diagnosis of FMS. There is an unmet need regarding the development of a precise diagnostic marker for FMS. Previous studies had demonstrated that small extracellular vesicles (sEVs), are involved in: intercellular communications and in the pathogenesis of inflammatory/autoimmune diseases. Recently, an autoimmune origin had been suggested for the development of FMS. In the current study, we aimed to characterize sEVs derived from blood of FMS patients and to explore a potential change in the expression of key proteins in these vesicles as compared to healthy controls.

Methods: sEVs have been isolated from the plasma of women diagnosed with primary FMS (n=9) vs. Age matched healthy women (n=9), using size exclusion chromatography technique. Characterization of these sEVs have been conducted using nanoparticle tracking analysis, transition electron microscopy and western blot analysis. The protein profile of these sEVs have been explored using proteomics analysis.

Results: We found changes in the expression of various proteins in sEVs derived from plasma of FMS as compared to healthy controls (Figure 1), among them: immunological- (e.g. Complement component 1q), neurological- (e.g. Cofilin-1), ribosomal protein assembly- (e.g. Nucleophosmin) and oxidative stress- (e.g. Superoxide dismutase) related proteins.

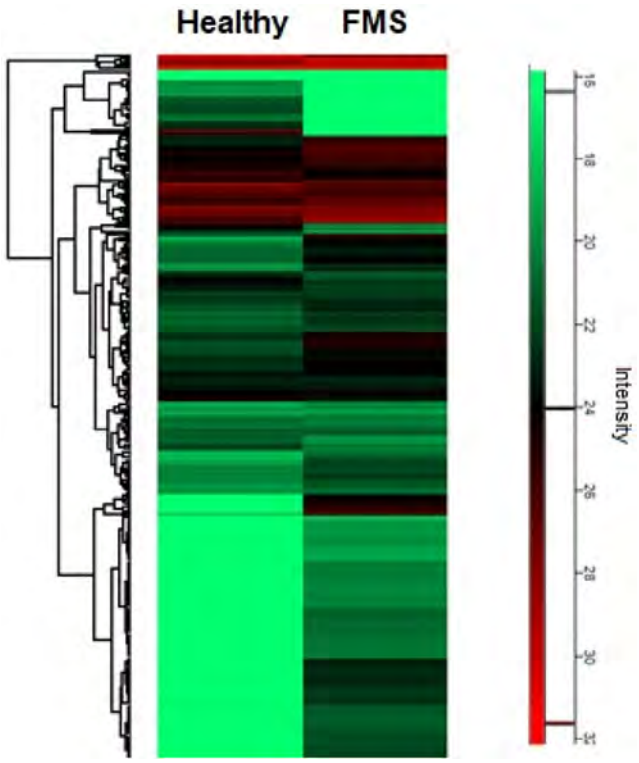

Figure 1: Heatmap visualization of protein expression profiles, in blood-derived small extracellular vesicles (sEVs) isolated from FMS patients vs. healthy controls, identified by proteomics analysis.

Conclusion: Our results potentially shed a light on the importance of sEVs in the pathophysiology of FMS and their potential to serve as a new diagnostic biomarker candidate in FMS.

Exploring Psychosocial Characteristics of Youth with Chronic Pain Across Gender Identities

Evan Mulvihill[1], Liam Courtney[2], Alora Rando[1] and Katherine Salamon[3], [1]Nemours Children's Health, Wilmington, DE, [2]Rowan-Virtua School of Osteopathic Medicine, Stratford, NJ, [3]Nemours Children's Health, Wilmingon, DE

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pediatric chronic pain is a common, significant public health concern leading to decreased quality of life for youth and burden on the healthcare system[1]. While there is research highlighting the benefit of a biopsychosocial model to treat chronic pain, there are disparities in access to evidence-based care[2]. Anecdotally, youth who identify with transgender or non-binary gender identities may not be referred to interdisciplinary pediatric chronic pain programs as often

as cis-gender youth. The current study aimed to explore baseline characteristics of youth referred to an outpatient interdisciplinary pediatric chronic pain program at an East Coast children's hospital across gender identity.

Methods: Youth completed questionnaires electronically as part of the initial evaluation within an outpatient interdisciplinary pediatric chronic pain program. From February 2020-April 2023, 335 youth completed questionnaires including the Chronic Pain Acceptance Questionnaire, PROMIS Pain Interference, and PROMIS Anxiety. Of these, 248 identified as cisgender female, 48 identified as cisgender male, 25 identified as non-binary, and 4 identified as transgender.

Results: Overall, 8.7% of the sample identified as gender diverse, which is a higher percentage as compared to national rates in the US for young adults (5.1%)[6]. Average age of the sample was 14 years old. Youth were predominately Non-Hispanic (92.7%) and White (83%). Youth who identified as transgender reported the highest pain acceptance scores. Cisgender males reported the least anxiety. Youth with non-binary gender identity reported the lowest pain acceptance, highest pain interference, and highest levels of anxiety. There were no statically significant differences in pain inference between cisgender and nonbinary youth.

Conclusion: These data represent a first look at exploring characteristics of youth and gender identity for patients entering a pediatric chronic pain program. Interestingly, youth with nonbinary gender identity did not differ in functional impairment, but appeared to experience higher levels of self-reported anxiety and lower acceptance of pain. This suggests these youth may have a decreased willingness to engage in activities in the face of pain or experience pain generally. Awareness of a patient's gender identity may be beneficial in understanding the impact of pain and highlights the need for a biopsychosocial model approach to pain management. This study was limited by relatively small numbers and does include youth already referred to a pain program. More research is needed to explore the role of gender identity as it relates to pain management, and referral patterns.

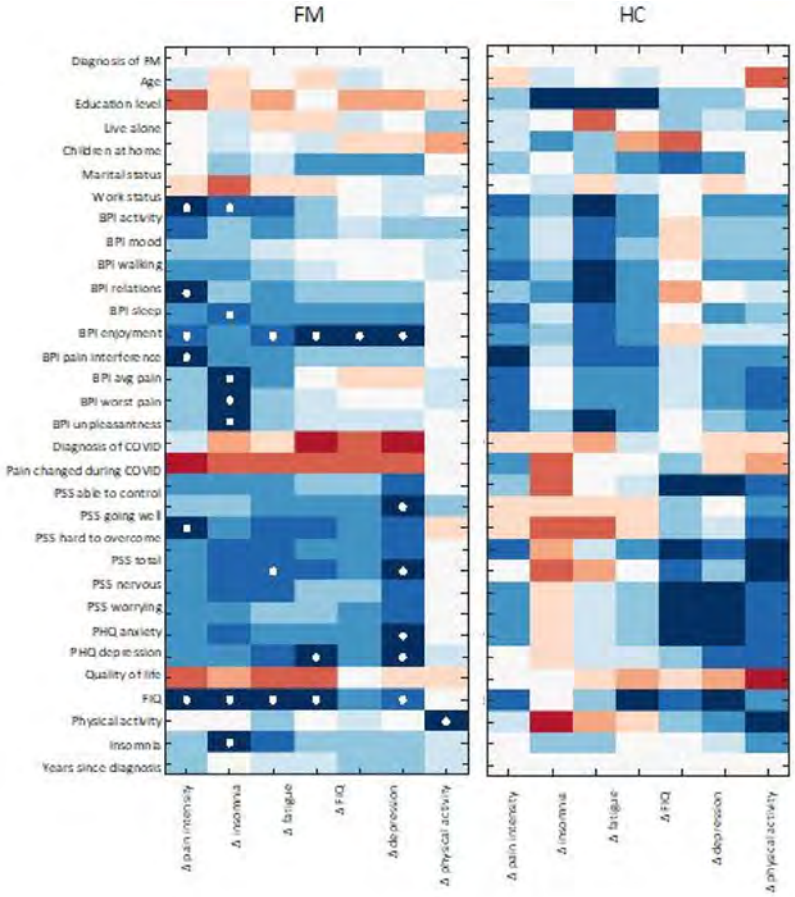
Questionnaire (AQAP), the ED-5D-5L Quality of Life Questionnaire and pandemic-related emotions using the Perceived Stress Scale (PSS). Analyses included Fischer Exact test for dichotomous variables; Wilk-Shapiro test for normality of distribution for quantitative variables; ANOVA for normally distributed variables; the non-parametric Kruskal-Wallis test for non-normally distributed variables; adjustment for multiple comparisons using Benjamini-Hochberg correction; and correlation analysis using the non-parametric Kendall Tau test. Analyses were done on IBM SPSS version 28.

Results: Participants were FM (32) and HC (21), all female, predominantly white, and with significant differences in BMI (higher in FM), living alone and work status. COVID infection occurred in FM vs HC 34% vs. 14%. Emotions related to COVID were similar for both groups (**Table 1**). Treatment modifications for FM were non-pharmacological vs pharmacological by 47% vs 25% respectively. FM patients generally perceived worsening of pain, but without change on questionnaire-based measurement and greater COVID perceived anxiety, but without differences for numbers screened positive for anxiety and depression on PHQ. Quality of life was significantly improved for FM, with other questionnaires measures unchanged for



Heat map of a univariate Kendall correlation matrix based on a hierarchical clustering of clinical measure values. Blue shades indicate positive correlations while red shades indicate negative correlations (20.5,rho,0.5). Statistically significant correlations are marked by a white dot (Benjamini–Hochberg FDR corrected P , 0.05).

Legend: BPI – Brief Pain Inventory; PSS – Perceived Stress Scale; PHQ – Patient Health Questionnaire; FIQ – Fibromyalgia Impact Questionnaire.

Figure 1: Clinical measures vs. covariates for FM and HC

both groups (**Table 2**). Physical activity remained stable for FM but decreased for HC (**Table 2**). For FM, clinical measures did not correlate with demographic variables or subjective or measured change in pain, but did correlate with function, affective status and total FIQ, with no significant correlations among HC (**Figure 1**).

Conclusion: Contrary to expectations, FM status remained either stable or improved according to standard questionnaires, although there was a perception of increased pain. These observations could be explained by several putative explanations: 1) FM patients may have a resilience to prolonged compared to acute stressors; 2) Societal factors such as slower life pace related to the pandemic 3) as FM scored significantly higher than HC in all measures, changes during COVID pandemic may represent regression to the mean.

Abstract Number: 1832

Prevalence of Musculoskeletal Manifestations in Post-acute COVID 19 Patients and Their Quality of Life at Kenyatta National Hospital

Miriam Kiyiapi, Omondi Oyoo, Peter Oyiro and Frederick Wangai, University of Nairobi, Nairobi, Kenya

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Since its discovery in Wuhan, China, severe acute respiratory syndrome coronavirus 2 (*SARS CoV 2*) has ravaged the globe on an unprecedented scale. While coronavirus disease (COVID-19) was initially thought to be an *acute* disease only, protracted symptomatology led to the characterisation of post-acute COVID-19 syndrome (PACS). PACS is now recognised as a bonafide array of multi-systemic clinical manifestations 12 weeks beyond the onset of acute symptoms that is not attributable to alternative pre-covid diagnoses. The prevalence of musculoskeletal (MSK) manifestations in PACS has been demonstrated in different populations with Fibromyalgia (FM) in post-acute COVID-19 being identified as a new facet of PACS. MSK manifestations have decreased the quality of life (QoL) of patients affecting their self-care, mental health, work ethic and livelihood.

Our study set out to determine the prevalence of MSK manifestations in post-acute COVID-19 syndrome patients and their quality of life at Kenyatta National Hospital (KNH). We also set out to determine the prevalence of Fibromyalgia as a rheumatological diagnosis of interest in PACS.

Methods: A descriptive cross-sectional study conducted at KNH, a tertiary (Level 6) regional referral hospital in Nairobi, Kenya. We recruited 101 patients, randomly sampled from the inpatient COVID-19 database. Following screening for eligibility, contact via phone was established and patients who consented verbally were scheduled for physical participation where written consent was taken. A chart review was done prior to the PI-participant physical encounter. Study tools were filled by participants and a musculoskeletal examination was conducted by the Principal Investigator (PI). MSK manifestations were recorded accordingly. Diagnosis of Fibromyalgia was done using the American College of Rheumatology (ACR) criteria and assessment of QoL was done using the 36-item short form (SF 36) questionnaire.

Results: The prevalence of MSK manifestations in PACS was 57.4% (95% CI 47.5% - 66.3%), the most common being fatigue (65.5%), arthralgia (58.6%) and myalgia (53.4%). The prevalence of Fibromyalgia was documented at 10.9% (95% CI 5.9% - 17.8%). Patients with MSK manifestations were 6.8 times more likely to have poor QoL than those without MSK manifestations. All the 8 domains of the SF 36 were adversely impaired among PACS patients with MSK manifestations; physical health (mean score 5.3+/-4.5 SD) and emotional wellness (mean score 10.4+/-5.8 SD) being the most affected categories. PACS patients with MSK manifestations were more likely to be female, who had a high BMI and long duration of hospital stay where they were treated with steroids in the acute phase of COVID-19. Smokers were also more likely to develop MSK manifestations. We did not elicit presence of comorbidity, older age and positive vaccination status as independent associated factors.

Conclusion: MSK manifestations in PACS are significant clinical features affecting 57.4% of COVID-19 survivors, who are about 7 times more likely to have poor QoL, adversely influencing their productivity for work and livelihood.

Abstract Number: 1833

Development of a Polygenic Risk Model for Therapeutic Response to Bedtime Sublingual Cyclobenzaprine (TNX-102 SL*) in Fibromyalgia Based on Polygenic Single Nucleotide Polymorphism (SNP)-Count Scores

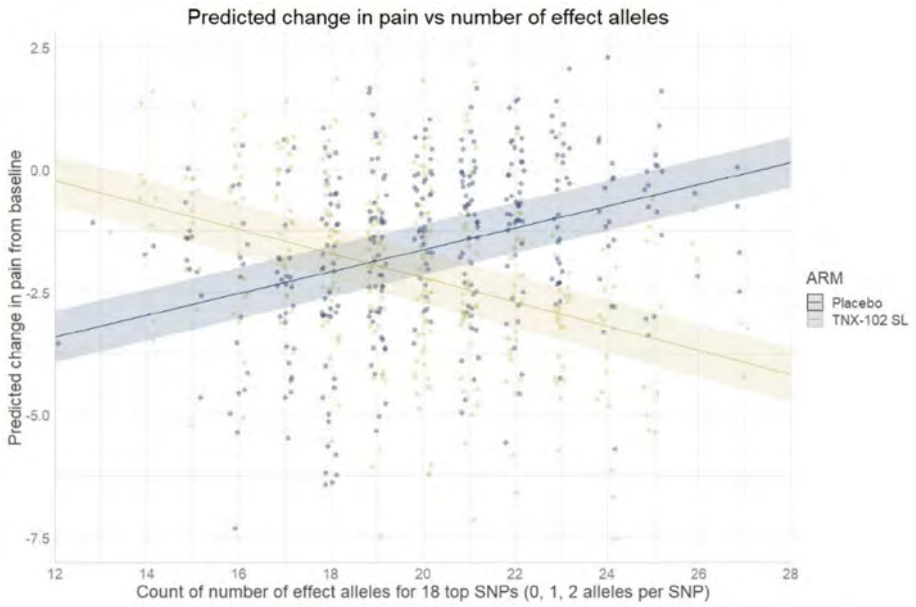
Jeffrey Rosenfeld[1], Greta Linse[2], Sally Slipher[2], Candace Flint[3], Annie Iserson[3], Herbert Harris[4], Jean Engels[3], Gregory Sullivan[5] and Seth Lederman[6], [1]Tonix Pharmaceuticals, Chatham, NJ, [2]Montana State University, Bozeman, MT, [3]Tonix Pharmaceuticals, New York, NY, [4]Tonix Pharmaceuticals, Chapel Hill, NC, [5]Tonix Pharmaceuticals Inc, Chatham, NJ, [6]Tonix Pharmaceuticals, South Dartmouth, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FM) is characterized by widespread pain, non-restorative sleep, fatigue, and cognitive dysfunction. TNX-102 SL is a sublingual cyclobenzaprine tablet designed for daily use at bedtime. SNPs from participants in two Phase 3 trials were analyzed by an iterative genome-wide association study (GWAS) method to build a set of drug-response-related alleles that correlate with improvements in pain and sleep.

Methods: Whole exome sequencing (WES) was performed on peripheral blood from participants in two Phase 3 trials of TNX-102 SL 5.6 mg in FM. Markers were identified using a multi-loci mixed model (MLMM) extended to include a genome x treatment arm (G×T) term. A GWAS was run to test for each marker. First, a model was made using only the top marker. The GWAS was then repeated using the first marker as a co-variate to find the next top marker for the model. This procedure was iterated until an optimal model was constructed and a panel of best-performing loci was identified. A scoring system was developed that counted the number of favorable alleles (0-36) present in each patient. We examined the correlation of this count score with drug response on pain and sleep across both studies.

Results: In analyzing treatment responses in two Phase 3 FM studies, we identified 18 loci of interest. All of the markers in the final model had p-values $< e^{-4}$ which are individually of interest, but not genome-wide significant. However, when used together to generate a count score, substantially improved predictive power was observed. Sub-setting patients based on the count score resulted in increased effect sizes for the change in pain score and sleep score when comparing TNX-102 SL to placebo



The predicted change in pain for individuals across the 2 clinical trials as based on the number of positive drug response alleles

in each study separately. As the count scores increase, the effect size improves while the sample size decreases. For example, if patients with at least a count score of 20 are retrospectively grouped, the effect size for pain reduction in the group increases to 0.90, as compared to 0.26 in the unselected population. Of note, all of the drug-response-related SNPs were intronic.

Conclusion: Polygenic drug-response related SNP-counts have potential to identify patients with higher effect size on pain reduction from TNX-102 SL treatment compared to placebo, as first explored in a retrospective analysis of two Phase 3 FM studies. The use of this polygenic SNP-counting method has the potential to identify patients in future studies that are likely to benefit from TNX-102 SL treatment. The Whole Genome Sequencing of study participants has been completed and may reveal additional drug-response-related SNPs. The panel will be validated on a future trial of similar design.

Evaluation of Fibromyalgia, Clinical/Serologic Activity, and Patient Reported Outcomes in a Racially/Ethnically Diverse SLE Patient Cohort

Kelly Corbitt[1], Philip Carlucci[2], Brooke Cohen[3], Mala Masson[3], H Michael Belmont[4], Amit Saxena[5], Chung-E Tseng[3], Jing Wang[3], Kamil Barbour[6], Jill Buyon[7], Peter Izmirly[2] and Heather Gold[3], [1]New York University, El Portal, FL, [2]New York University School of Medicine, New York, NY, [3]New York University, New York, NY, [4]NYU School of Medicine, New York, NY, [5]New York University Grossman School of Medicine, Rheumatology, New York, NY, [6]Centers for Disease Control and Prevention, Atlanta, GA, [7]NYU Grossman School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients have a higher prevalence of fibromyalgia (FM) than the general population. FM symptoms, such as nociplastic pain and fatigue, are known to cause discordance in how patients and physicians view well-controlled SLE, and these variables impact quality of life in ways not captured by traditional disease activity scores. There is a paucity of objective data surrounding the clinical interplay of these two diseases. Given this, and emerging evidence suggesting the contribution of autoimmunity to FM, this study evaluated FM clinically, serologically, and via patient reported outcomes in a multi-racial/ethnic SLE patient cohort.

Methods: Patients from an established lupus cohort were screened for FM using the 2016 FM classification criteria during an in-person rheumatologist visit. Hybrid SELENA-SLEDAI scores, SLE classification criteria, medications, and SLICC damage index were evaluated. A portion of the patients who reported any chronic pain also completed 8 PROMIS measures. Clinical and serologic activity was compared in patients with and without FM, as well as T-score means of PROMIS measures between FM and non-FM chronic pain patients. For T-score means significantly different between groups, linear regression models adjusting for age, race/ethnicity, SELENA-SLEDAI score, and steroid use were estimated.

Results: Of 316 SLE patients completing the FM questionnaire, 55 (17%) met criteria for FM, 57 (18%) reported chronic pain without FM, and 204 (65%) had no chronic pain. The racial/ethnic composition of the FM patients was 35% White, 27% Black, 6% Asian, and 31% Hispanic, which differed from those without FM (p=0.023), primarily due to a smaller proportion of Asian patients with FM. There was no significant difference in overall SELENA-SLEDAI score. However, there was more active arthritis in the FM group versus the non-FM group (Table 1). The widespread pain index (WPI) and symptom severity score (SSS) were not correlated with current degree of SLE activity in FM or in non-FM chronic pain patients (Figure 1). Of the SLE criteria, FM patients were less likely to have ever had lupus nephritis and more likely to have malar rash. The SLICC damage index did not differ between groups. Of the 112 patients with chronic pain (plus/minus FM), 70 completed at least one

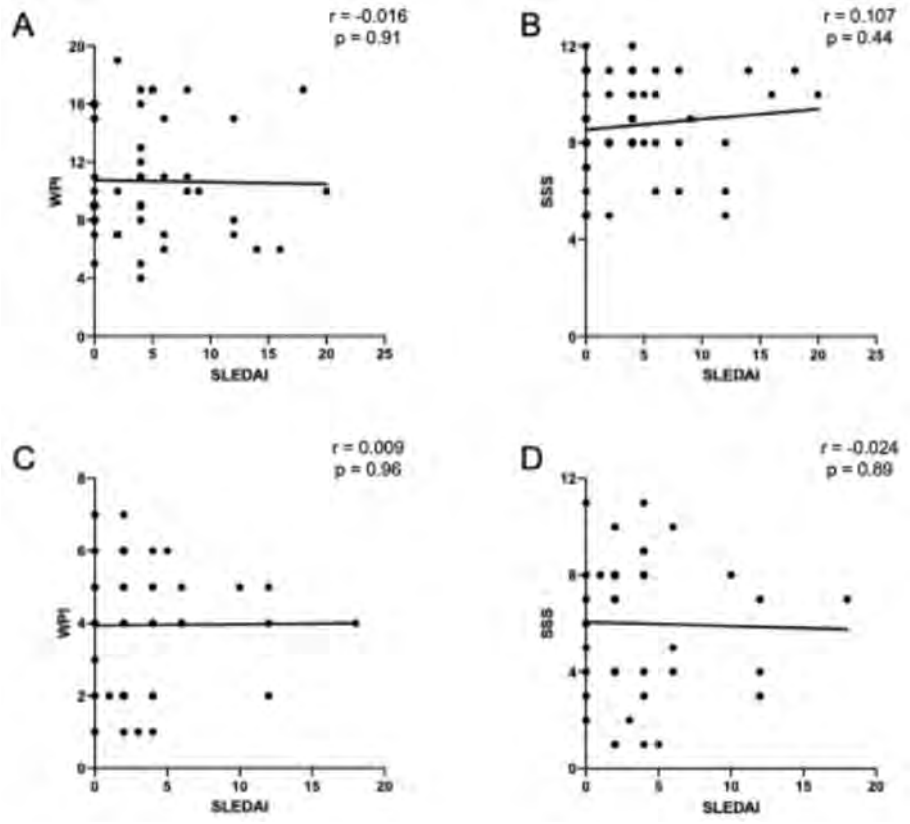

Figure 1. WPI and SSS do not correlate with SLEDAI in FM or non-FM chronic pain patients. A–B show the correlation between WPI (A) or SSS (B) and SLEDAI in FM patients and C–D show the correlation between WPI (C) or SSS (D) and SLEDAI in non-FM chronic pain patients.

PROMIS measure. Fatigue, sleep disturbance, and cognitive function were significantly worse in FM patients, whereas pain measures, depression, anxiety, and physical function did not differ between groups (Table 2). After adjusting for age, race (White/non-Hispanic), SELENA-SLEDAI score, and current steroid use, FM was associated with a 5-point increase in mean sleep disturbance and fatigue scores. Cognitive function, however, was no longer significantly associated with FM.

Table 1. Clinical and serologic profiling of SLE patients with FM compared to those without FM, n=316. Demographics, current SLE manifestations via SELENA-SLEDAI, SLE classification criteria and associated antibodies, and SLICC damage index are all shown. *N is specified where it differs from overall sample size.

Thrombocytopenia	56 (22)	7 (13)	0.193
Arthritis	174 (67)	44 (80)	0.055
Increased dsDNA binding	220 (84)	40 (73)	0.052
Low complement	188 (72)	33 (60)	0.105
Anti-Smith antibodies	115 (44)	21 (38)	0.457
Lupus Anticoagulant	49 (19)	10 (18)	1
Anticardiolipin antibodies	42 (16)	7 (13)	0.682
Anti-Beta-2 glycoprotein 1 antibodies	49 (19)	12 (22)	0.578
Anti-Ro antibodies	112 (43)	25 (46)	0.766
Anti-La antibodies	35 (13)	8 (15)	0.820
Anti-RNP antibodies	103 (40)	23 (43)	0.763
SLICC Damage Index			
Damage Index Score, median [IQR]	1 [0, 2]	1 [0,2]	0.753

Table 2. PROMIS measures assessed between groups, with "worse" quality of life represented by higher scores for symptoms and lower scores for function. PROMIS T score mean for the general United States population=50 (SD=10). Minimally important difference=2–3 for PROMIS measures in patients with lupus. Non-FM chronic pain patients had n=35 in the top 4 measures of the table and n=33 for the remaining 4 measures.

PROMIS Measure	FM (mean (SD)), n=35	Non-FM chronic pain (mean (SD)), n=35	p-value
Fatigue	67 (6.7)	61 (8.9)	0.006
Sleep disturbance 8b	62 (6.8)	57 (9.1)	0.01
Physical function	39 (5.6)	41 (6.1)	0.144
Pain intensity 3a	62 (7.1)	60 (6.0)	0.095
Pain Interference	63 (5.5)	61 (5.9)	0.054
Cognitive function abilities subset	41 (7.0)	46 (7.7)	0.005
Anxiety	62 (5.2)	61 (8.3)	0.911
Depression	58 (7.3)	55 (7.6)	0.162

Conclusion: These findings underscore that symptoms associated with FM in SLE patients can be independent of chronic pain, SLE disease activity and damage, and overall suggests the need for better understanding of the biology of this group.

Abstract Number: 1835

A Survey on Fibromyalgia-Related Knowledge Among Internal Medicine Residents

Summia Matin Afridi[1], Ahmad Raja[2] and Muhammad Daniyal[3], [1]Albany Medical Center, Albany, NY, [2]Mary Imogene Bassett Hospital, Evanston, IL, [3]Mary Imogene Bassett Hospital, Cooperstown, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia is a chronic pain syndrome that commonly presents with fatigue, widespread musculoskeletal pain, and sleep disturbances. Patients can also have accompanying somatic and cognitive symptoms. According to National Fibromyalgia Association (NFA) it is estimated to affect around 10 million people every year in the U.S. It is more common in women (75-90%) but it can be seen in men and children as well. Fibromyalgia is usually under-recognized and the patients initially present to their primary care physicians when they start to develop symptoms. We did a cross-sectional survey to assess the knowledge of fibromyalgia diagnosis and management among Internal Medicine residents so that gaps can be identified, and intervention should be done through educational programs.

Methods: A 19-item questionnaire was prepared using current ACR and EULAR guidelines. A cross-sectional survey was conducted among residents from two residency programs in Chicago and Florida. The questionnaire included around 11 questions regarding the pathogenesis, diagnosis, and management of fibromyalgia. Other questions were mainly

focused on how comfortable the residents are with diagnosing and managing fibromyalgia patients and the educational training they have received so far. Residents with 70% or more correct answers were considered to have good knowledge. The correct answers were compared to the number of teaching sessions and if the residents are familiar with recent guidelines.

Results: A total of 64 (64%) residents out of 100 completed the survey, only 34% (22) got a score of 70% or more and 41% scored 50% or less. Only 15% of the responders felt that they were adequately taught on the subject. Less than 30% of the responders felt comfortable diagnosing and managing fibromyalgia and only 18.8% of the residents have read the guidelines regarding it. Around 53% of the residents reported that they have not attended any teaching sessions on fibromyalgia. It was also found on the survey that less than 15% of the residents are familiar with FDA-approved medications for the treatment of fibromyalgia and the recent advances in the subject. About 50% of the residents who read the guidelines scored 70% or more as compared to around 30% of the residents who did not indicating that many residents need to familiarize themselves with the recent guidelines which can aid in the appropriate management of fibromyalgia. Another interesting finding in the results was that around 38% of PGY-1 residents got 70% of the questions right compared to 14.3% of PGY-2 residents and 42% of PGY-3 residents.

Conclusion: Our survey results suggest that there is a lack of knowledge among residents regarding the diagnosis and management of fibromyalgia. Therefore, teaching sessions aiming at these knowledge gaps can help in early recognition and better initial management of these patients.

Abstract Number: 1836

Embracing a Biopsychosocial Approach to Fibromyalgia-like Symptoms in People with SLE: Insights from the Type 2 SLE Consortium

Jennifer Rogers[1], Megan Clowse[2] and Amanda Eudy[3], [1]Duke University, Durham, NC, [2]Duke University, Chapel Hill, NC, [3]Duke University, Raleigh, NC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with SLE experience distressing fibromyalgia-like symptoms of fatigue, widespread pain, mood disturbance, and brain fog that negatively impact quality of life and are challenging to manage. These symptoms, termed Type 2 SLE, can be related to inflammatory and non-inflammatory etiologies. Studies of fibromyalgia suggest that addressing biopsychosocial factors can improve quality of life. A Type 2 SLE Consortium was created to bring together a multidisciplinary team of patients and clinicians to develop equitable, feasible, and potentially effective approaches to care for people living with Type 2 SLE.

Methods: The Type 2 SLE Consortium included patients meeting ACR/SLICC SLE classification criteria and clinicians who treat chronic pain, insomnia, and mood disorders. The consortium met in 3 group sessions; additionally, each consortium member was invited to complete an individual interview. The sessions were conducted virtually between August 2022-April 2023 and auto-recorded and then transcribed.

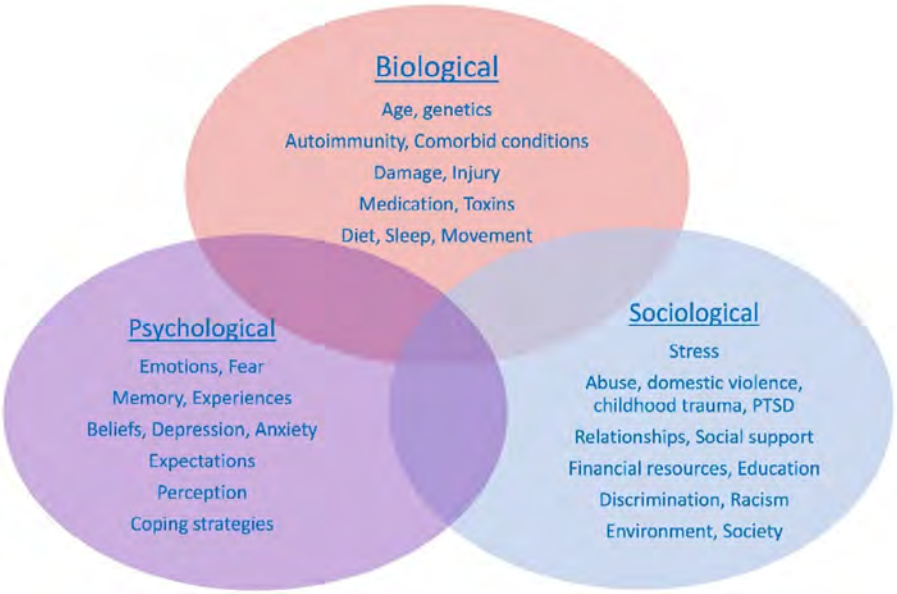

Figure 1. Biopsychosocial factors that contribute to fibromyalgia-like symptoms in SLE

Early sessions included a review of the Type 1 & 2 SLE Model, followed by suggestions from Consortium members about the possible etiology, contributing factors, and treatment approaches for fibromyalgia-like symptoms in people with SLE. Rapid qualitative evaluation identified key themes.

Table 2. Care delivery and treatment recommendations for clinicians and patients

Recommendations for clinicians	Recommendations for patients

• Meet the patient where they are
• Use motivational interviewing
• Build trust
  • "I'm here to work with you."
  • "How do we get you from here to a better place?"
• Be yourself, authentic, use humor
• Identify barriers and needs
• Set collaborative goals
• Explain symptoms and incorporate educational resources
• Set expectations
• Treat underlying mood disorders
• Refer to allied health professionals
• Minimize narcotics, benzodiazepines and sleep medications
• Explore alternative therapies and novel interventions
	• Reframe the relationship and emotions surrounding pain
	• Acceptance of situation
	• Manage expectations
	• Create personal goals
	• Pacing: adjust schedule and set limitations
	• Build self-efficacy → engage in healing
	• Practice mindfulness, distraction, relaxion techniques
	• Increase movement and exercise
	• Improve sleep hygiene
	• Use heating pads, soaks, topicals, massage
	• Plan for flares
	• Peer and social support
	• Have hope

Results: The Type 2 SLE Consortium included 2 women with SLE (both Black with SLE duration >15 years) and 18 health professionals (67% female, 89% academic). Expertise was gathered from adult and pediatric rheumatology, integrative medicine, neurology, psychiatry, psychology, palliative care, neuropsychology, medical weight management, sleep, pain, and stress management. The majority (83%) attended at least 1 group meeting and all but 1 member completed the individual session.

The Consortium identified a range of biopsychosocial factors that can predispose, precipitate, and perpetuate Type 2 symptoms such as fear, stress, and trauma (Figure 1).Two main categories of approaches to care were identified: one for providers and the other for patients (Table 2). Key themes consisted of building better therapeutic relationships, adjusting expectations, improving symptom understanding, lifestyle interventions, and multidisciplinary collaboration. Specific guidance for clinicians included active listening, validating symptoms, and using motivational interviewing. Patients with SLE would benefit from setting personal goals, building self-efficacy, pacing, identifying personal factors, and reframing their relationship with symptoms.

Conclusion: Key recommendations from this multi-disciplinary consortium were to individualize treatment based on the biopsychosocial underpinnings driving the symptom burden. The importance of communication, trust, education, and multidisciplinary collaboration was emphasized. Rheumatologists cannot be the sole providers to improve Type 2 SLE symptoms but can encourage patients to partner with others who can provide the necessary care. Our future studies will continue to develop and evaluate holistic approaches to SLE care.

Abstract Number: 1837

Depression and Suicide Attempt in Systemic Lupus Erythematosus with and Without Fibromyalgia

Irakli Tskhakaia[1], Pushti Khandwala[1] and Irene Tan[2], [1]Albert Einstein Medical Center Philadelphia, Philadelphia, PA, [2]Einstein Medical Center Philadelphia, Bala Cynwyd, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Suicide and depression represent a high burden of morbidity and mortality worldwide. It is well known that fibromyalgia (FM) is associated with mood and behavioral disorders. FM is extremely common in patients with systemic lupus erythematosus (SLE) even though FM does not correlate with SLE activity. We investigate the rate of concomitant depressive disorder and suicide attempts in patients with SLE.

Methods: TrinetX, a global federated research network that provides a dataset of electronic medical records from different healthcare organizations (HCOs) was utilized. Initial query was made on June 6, 2023 from 1/1/2010 to 6/6/2023 to identify patients aged >18 with a diagnosis of "Systemic Lupus Erythematosus" (International Classification of Diseases, 10th version (ICD-10) Code M32). Two cohorts were made, on the basis of the presence of a diagnosis of "Fibromyalgia" (ICD-10

Table 1. Major Depressive Disorder and Suicide Attempts in Patients with SLE with and without FM

	FM	No FM	OR (95% CI)
	N=53,221	N=53,221	P Value
Major Depressive Disorder	5.864	2.255	2.799 (2.662-2.943)
			p<0.0001
Suicide Attempt	625	238	2.645 (2.277-3.073)
			p<0.0001

Abbreviations: CI, confidence interval; FM, Fibromyalgia; OR, odds ratio.

Code M79.7). Propensity score matching was carried out to match age, race , and gender. Compare outcome analytic function was utilized to map the correlation with "Suicide attempt" (ICD 10 Code T14.91) and "Major Depressive Disorder (MDD)" (ICD 10 Code F33), and prevalence Odds ratios (OR) were calculate

Results: We identified cohort 1 as patients with concomitant diagnoses of SLE and FM with a total of 55,350 patients. Cohort 2 as SLE patients without FM included 219,914 patients. Using propensity score matching, patients with SLE but without FM were matched 1:1 to 53,221 patients with both SLE and FM. Data demonstrated mean age of 55.6 years (SD 14.6). Percentage of females in cohort 1 was 93.978% and 93.969% in cohort 2 with the white race being the most prevalent followed by unknown ethnicity, African-American and Asian. A total of 5,864 patients with SLE and FM also had a diagnosis of "Major Depressive Disorder" (ICD 10 Code F33), compared to 2,255 patients without FM, with a 6.781% risk difference (95% CI - 6.465%-7.097%, $p < 0.0001$), and Odds ratio of 2.799 (2.662-2.943, $p< 0.0001$). In addition, 625 patients with SLE and FM also had a diagnosis of "Suicide Attempt" (ICD 10 Code T14.91), compared to 238 patients without FM, with 0.727% risk difference (95% CI - (0.619%,0.835%), $p < 0.0001$), and Odds ratio of 2.645 (2.277-3.073, $p< 0.0001$), see table 1. Similar results were identified before propensity score matching, with OR of concomitant MDD in patients with SLE and FM compared to the cohort without FM being 3.146 (3.037-3.258, $p< 0.0001$) and OR of Suicide Attempt being 2.653 (2.396-2.938, $p < 0.0001$.

Conclusion: In this real-world, real-time study, patients with SLE and concomitant fibromyalgia have increased risk of major depressive disorder and suicide attempt when compared with SLE patients without fibromyalgia.

The Burden of Dysautonomia in Patients Suffering from Pathologies Associated with Generalized Joint Hypermobility

Alizée Perrein[1], Fabien Pontille[1], Paul Decker[2], david Attali[3], Thomas Moulinet[4] and **Roland Jaussaud**[5], [1]Département de Médecine interne et immunologie clinique, Université de Lorraine / CHRU de Nancy, Vandoeuvre-les-Nancy, France, [2]Nancy hospital, France, Nancy, France, [3]Université Paris Cité, Laboratoire Psychopathologie et Processus de Santé, Boulogne-Billancourt, France, [4]Department of Internal Medicine, Centre hospitalier universitaire de Nancy, Nancy, France, [5]Département de Médecine interne et immunologie clinique, Université de Lorraine / CHRU de Nancy, Vandoeuvre Les Nancy, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypermobility spectrum disorders (HSD) and hypermobile Ehlers Danlos syndrome (hEDS) are among the conditions associated with generalized joint hypermobility (GJH). Alongside myofascial and skeletal pain manifestations, other polymorphic co-morbid manifestations, often multiple, are linked to an autonomic dysregulation syndrome. The aim of this study was to characterize the impact of dysautonomia in patients suffering from joint hypermobility syndrome (HSD/hEDS).

Methods: Incident patients were recruited from consultations at the Center of Competence for Rare Diseases of Non-Vascular EDS. Inclusion criteria were GJH and clinical criteria for hEDS or HSD. Scores on the following questionnaires were collected : SCOPA-AUT (dysautonomia), Nijmegen (hyperventilation), HAD (anxiety, depression), Tampa (kinesiophobia), PSQI (sleep), Gastro-Intestinal Quality of Life Index (GIQLI), Pichot (fatigue), VAS physical pain and VAS psychological pain, VAS quality of life. A comparison of the 2 hEDS and HSD groups was carried out, followed by a principal component analysis (PCA). The search of homogeneous groups of patients was carried out using hierachical cluster analysis.

Results: 36 patients were included (18 hEDS, 18 HSD) with a significantly higher level of anxiety-depression in the hEDS group (25.33 vs 18.39, $p = 0.017$). The Nijmegen score was higher in the hEDS group (46.91 vs 38.94, $p = 0.016$). The mean SCOPA-AUT score was 37.08 ± 9.86 and did not differ significantly between the 2 groups; there was no statistically significant difference between the 2 groups for the other parameters studied. The level of dysautonomia was correlated with younger age, high Nijmegen score, kinesiophobia, fatigue, sleep disturbance, marked anxiety-depressive syndrome and poor GI QoL. PCA revealed a strong correlation between the level of dysautonomia and GI QoL. Two homogeneous groups of patients were identified : one of which ($n = 23$) was characterized by very high impairment of GI QoL and a high level of dysautonomia.

Conclusion: Our study illustrates the importance of dysautonomia as a major comorbidity in HSD/hEDS. Dysfunctional breathing seems almost constant, and dysautonomia is associated with a major impairment of GI QoL. An anxiety or depressive disorder is very common in these situations, and supports the recently put forward hypothesis of a neuroconnective phenotype. The polyvagal theory provides important physiological clues for understanding these pathologies and for their therapeutic management.

Value of Small Fiber Neuropathy in Fibromyalgia Patients in a Rheumatological Setting

Styliani Tsiami[1], Elena Enax-Krumova[2], Dietrich Sturm[3], Matthias Vorgerd[2], Bjoern Buehring[4], Juergen Braun[5] and **Xenofon Baraliakos**[1], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany, [2]Neurologische Klinik Universitätsklinikum Bergmannsheil Bochum, Ruhr-University Bochum, Bochum, Germany, [3]Agaplesion Bethesda - Krankenhaus, Wuppertal, Klinik für Neurologie, Wuppertal, Germany, [4]Krankenhaus St. Josef, Wuppertal, Klinik für Internistische Rheumatologie, Wuppertal, Germany, [5]Ruhr-Universität Bochum and Rheumazentrum Ruhrgebiet, Herne, Germany

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Small fiber neuropathy (SFN), a polyneuropathy (PNP) affecting A-delta and C-fibers has been described in patients with fibromyalgia (FM). Different patterns of small fiber damage may characterize distinct subtypes of FM. We aimed to investigate the value of detecting different degrees of SFN in patients diagnosed with FM.

Methods: Consecutive patients who were treated for pain exacerbation of FM at a university specialized tertiary center were included in the study after informed consent. Patients had to fulfil the 2016 ACR diagnostic criteria for FM and other inflammatory rheumatic musculoskeletal diseases (RMD) were excluded. The rheumatological therapy included pain pharmacotherapy, balneophysical treatment, physiotherapy and occupational therapy. All patients underwent a careful rheumatologic and neurologic physical clinical examination including a Schirmer-Test for dry eyes and were asked to fill out questionnaires, in which data on pain, depression, neuropathic symptoms, sleep quality, daytime sleepiness, fatigue, and quality of life were assessed. Thereafter small fiber tests were performed in the neurologic department including a skin punch biopsy on the upper and lower leg and a corneal confocal microscopy (CCM).

Results: Overall, 93 patients (86 females, 92.5%, mean age 54±10.1, mean disease duration 4.9±5.3 years) were included, 25 received anticonvulsants (26.9%) and 15 opioids (16.1%) for pain treatment. Intraepidermal nerve fiber density (IENFD) as detected by skin biopsy was reduced in 58 patients (62.4%), 43 of whom (74.1%) had reduced IENFD at both proximal and distal sites. CCM showed pathologic findings in 18 patients with reduced IENFD at any site (31%) and in 8 with normal IENFD (22.9%), with dry eyes being present in 13 (22.4%) and 6 (17.1%) of those patients, respectively. There was no difference in pain, depression, neuropathic symptoms, sleep quality, daytime sleepiness, fatigue, or quality of life scores between groups (Table).

Conclusion: In this FM population with high disease burden and indication for inpatient therapy, small fiber pathology as found by skin biopsies and CCM was present in more than two third of the FM patients suggesting that there are subgroups. However, there were no significant clinical differences between patients with and without SFN. Further analysis should explore, whether both subgroups differ in their long-term outcome after the inpatient treatment.

Value of Various Intra-Articular Injections for Knee Osteoarthritis Management

Hanna Mass[1], Jamie Collins[1], david Hunter[2], Catherine Yang[1], Morgan Jones[1], Stephen Messier[3], Tuhina Neogi[4], A. David Paltiel[5], Jeffrey Katz[1] and Elena Losina[6], [1]Brigham and Women's Hospital, Boston, MA, [2]Sydney Musculoskeletal Health, University of Sydney, St. Leonards, Australia, [3]Wake Forest University, Winston-Salem, NC, [4]Boston University School of Medicine, Boston, MA, [5]Yale School of Public health, New Haven, CT, [6]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Health Services Research Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Intra-articular injections (IAI) are commonly used to relieve pain and delay total knee replacement (TKR) in persons with knee OA. Despite higher costs and conflicting evidence of efficacy, utilization of hyaluronic acid (HA) and platelet rich plasma (PRP) IAIs have increased dramatically over the last decade.

Methods: We used the Osteoarthritis Policy (OAPol) Model, a widely published and validated microsimulation of knee OA, to assess the value of alternative IAIs. We considered 5 strategies: 1) no IAI, 2) saline (placebo), 3) corticosteroid (CS), 4) HA, and 5) PRP. We assumed that IAIs are offered to patients with inadequate pain control from NSAIDs. In the model, if and when IAIs do not provide adequate pain relief, OA care progresses to opioids and/or TKR. We used a random-effects meta-analysis to estimate IAI-specific pain reduction from high-quality (Jadad score 4+) RCTs. We analyzed data from 11 RCTs for saline, 12 for CS, 24 for HA, and 8 for PRP. We estimated pain reductions for one IAI series of -14 points for saline at 3 months, -22 for CS at 3 months, -22 for HA at 6 months, and -17 for PRP at 12 months. The cost of IAIs included the visit, IAI administration and medication costs. We derived the cost of CS ($315), HA ($795), and saline ($309) IAI from the Medicare Drug Fee Schedule and estimated the cost of PRP ($2586) from literature. In the base case analysis, based on the literature, we assumed that repeat CS injections increase the risk of OA progression (HR=3.02). We ran the model over the remaining lifetime of a cohort with average age 50 years at the start of simulation, pain 51 (WOMAC, 0-100, 100 worst), 50% KL3/50% KL2. We determined the value of specific IAIs using incremental cost-effectiveness ratios (ICERs), evaluated from the health care perspective and calculated as the ratio of the difference in lifetime costs to the difference in quality adjusted

Table 1. Costs, clinical benefits, and incremental cost effectiveness ratios for select intra-articular injections

Strategy	COST	QALYs	ICER
CS increases risk of OA progression:			
No Injection	$160,364	12.879	
Saline	$162,159	13.019	$12,900
CS	$162,626	13.033	$32,500
HA	$163,195	13.042	$62,100
PRP	$166,746	13.064	$159,400
CS does not increase risk of OA progression:			
No Injection	$160,364	12.879	
Saline	$162,159	13.019	d*
CS	$162,256	13.039	$11,800
HA	$163,195	13.042	d*
PRP	$166,746	13.064	$177,000

CS = Corticosteroid, HA = Hyaluronic Acid, PRP = Platelet Rich Plasma, QALY = Quality Adjusted Life Year, ICER = Incremental Cost-Effectiveness Ratio. ICERs were rounded to the nearest 100.

* Strategies that lead to greater ICER compared to the next strategy never represent an optimal use of resources. By convention, such strategies are labeled "extendedly dominated" and eliminated from consideration.

life years (QALYs) between two strategies. The IAI that maximizes QALYs with ICER< willingness to pay (WTP) threshold is considered the most cost-effective strategy.

Results: QALYs and costs for each strategy are presented in Table 1. Assuming CS does not increase the risk of OA progression, CS results in an ICER of $11,800/QALY compared to no injection, and PRP results in an ICER of $177,000/QALY compared to CS. Assuming CS does increase the risk of OA progression, the resultant ICERS are $12,900/QALY for saline compared to no injection, $32,500/QALY for CS compared to saline, $62,100/QALY for HA compared to CS, and $159,400/QALY for PRP compared to HA. If CS increased the risk of OA progression, PRP would achieve ICERs of $100K/QALY ($50K/QALY) at a price of $1,965 ($1,448). If CS did not increase risk of OA progression, even lower PRP prices ($1,655 and $1,086) would be required to attain these ICER thresholds.

Conclusion: For WTP thresholds between $11,800 and $62,100/QALY, CS is the preferred strategy, regardless of what we assume about their impact on OA progression. If CS has no impact on risk of OA progression, it remains the preferred strategy until WTP exceeds $177,000/QALY. If CS increases risk of OA progression, HA becomes preferred for WTP > $62,000.

Clinical Trial Perceptions Among Male Patients with Systemic Lupus Erythematosus (SLE): Georgians Organized Against Lupus (GOAL) Cohort

Hilton Mozee[1], Charmayne Dunlop-Thomas[1], Gaobin Bao[1], Kim Schofield[2], Jessica Williams[3] and S. Sam Lim[1], [1]Emory University, Atlanta, GA, [2]Georgia State Rep. HD 63, Atlanta, GA, [3]Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Minority patients are disproportionately affected by SLE. Yet, they are underrepresented in SLE clinical trials compared to White patients. Specifically, patients that identify as male and Black are significantly understudied. We explored racial and gender differences in clinical trial perceptions among a cohort of predominantly Black patients with SLE in Atlanta, Georgia.

Methods: Data from the Georgians Organized Against Lupus (GOAL) cohort were used for this analysis. The GOAL cohort consists of validated SLE patients living in Atlanta, Georgia. Since 2012, SLE patients have been surveyed annually regarding demographics, SLE natural history, treatment, healthcare utilization, and psychosocial factors. For this study, only male patients were assessed. The 2022 GOAL survey included ad-hoc questions that assessed clinical trial knowledge, willingness to participate, and hesitancy in clinical trial enrollment. The Systemic Lupus Activity Questionnaire (SLAQ), Self-administered Brief Index of Lupus Damage (SA-BILD), and self-efficacy, depression, and perceived stress measures were included in this study. Descriptive analysis was used for comparisons.

Results: A total of 47 males responded to the 2022 GOAL Survey; the majority were Black (79% Black, 19% White, 2% Asian) with a mean age 32 years (SD 11.8), mean education of 14 years (SD 2.3), and majority unemployed (59%). The mean disease duration was 16 years (SD 10.6), mean disease activity score was 11 (SD 7.3), and mean organ damage score was

			Clinical Trials-Comfortable Participating

PROMIS Depression	Mean ± SD	52.1 ± 11.6	47.0 ± 9.3	54.1 ± 12.5	51.6 ± 11.2
Perceived Stress Scale 10	Mean ± SD	16.3 ± 8.2	15.3 ± 3.9	17.6 ± 8.1	15.1 ± 9.4

PROMIS T-score rescales the raw score into a standardized score with a mean of 50 and a standard deviation of 10. Higher scores represent more of the concept measured. Values indicate the mean. Abbreviations: SA-BILD – Self-Administered-Brief Index of Lupus Damage, SLAQ – Systemic Lupus Activity Questionnaire

5 (SD 4.4). We found that 47% of male respondents (n=19 Black, n=3 White) were willing to participate in lupus clinical trials. In contrast, about 30% were unwilling to participate, and 38% were unsure if they would participate in a clinical trial. Male willingness to participate was associated with higher disease activity, living in poverty (50%), less instrumental support), and more social isolation, as compared to those unwilling or unsure (Table). Education, marital status, work status, insurance type, physical function, depression, and perceived stress were not associated with willingness to participate in clinical trials among male respondents.

Conclusion: Among a predominantly Black cohort of males with SLE**,** we found that respondents with more disease activity, fewer resources, and social support appeared more willing to participate in clinical trials. Further efforts are necessary to educate and provide social support to individuals with SLE that are unsure or resistant to clinical trial participation, especially among underrepresented groups, including males. Similar studies have found that clinical trial education, recruitment through lupus support groups, and diversity of clinical trial staff are potential ways to increase trial participation. Further studies of males with SLE are necessary to validate our study findings and provide more knowledge on factors associated with clinical trial hesitancy among this population.

Reduction in the Concomitant Ordering of Erythrocyte Sedimentation Rate and C-Reactive Protein Within the Rheumatology Clinics at an Academic Medical Center

Ruchi Desai[1], Nainesh Shah[1], Ray Zhang[1], Maria Bacalao[2], Haidy Galous[3], David Karp[1] and Puneet Bajaj[1], [1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern, Dallas, TX, [3]UT Southwestern, Southlake, TX

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ESR and CRP are two laboratory values usedto assess inflammation. There is data to support that CRPis superior to ESR to detect/monitor inflammation or infection due to its better accuracy and reproducibility.Yet, they are often ordered on patients at the same time – essentially performing two separate tests to measure one biological process. This redundant laboratory testing is leading to higher costs to patients and the health systems, and contributes to excess phlebotomy, without any significant clinical benefits. The goal of this quality improvement project was to implement best practices to reduce ESR co-ordering with CRP within the rheumatologyclinics (one clinic in the university setting, 3 satellite clinics, and one safety net clinic)at an academic medical center.

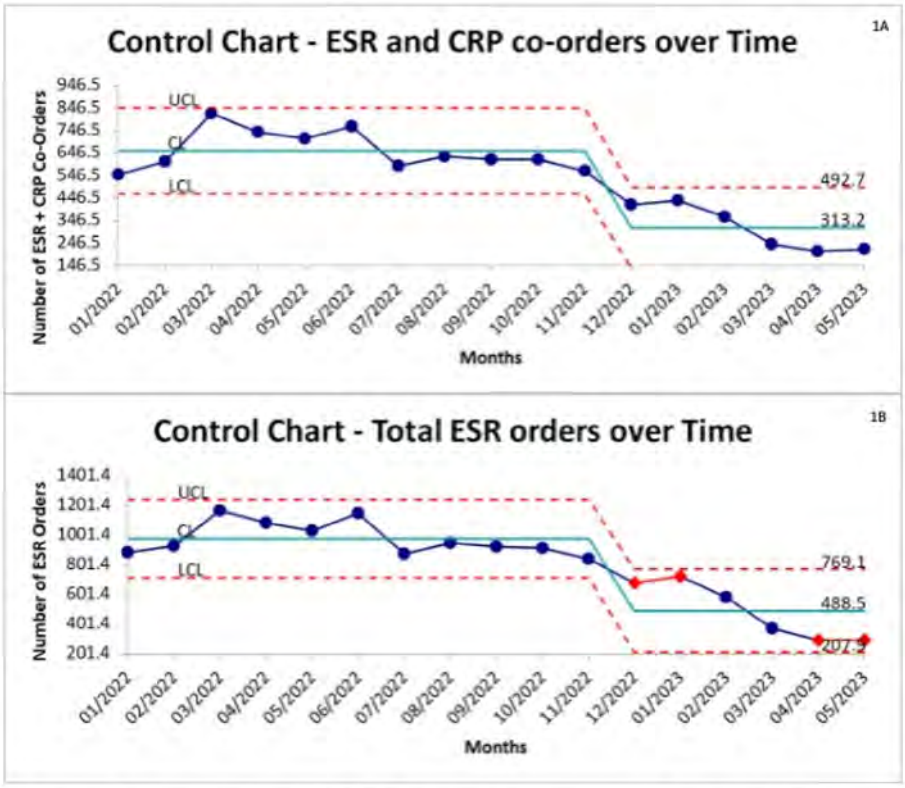

Figure 1: Control charts for ESR and CRP co-orders (1A) and Total ESR orders (1B) at university and satellite rheumatology clinics.

Control Charts for ESR and CRP co-orders and Total ESR orders at university and satellite rheumatology clinics.

Methods: We utilized the Plan, Do, Study, Act (PDSA) iterative methodology for continuous improvement.We collected and analyzed baseline information on CRP and ESR ordering at all 5 rheumatology clinics. Several interventions were implemented including general education to all rheumatology providers and clinic staff(February 2023), targeted education to a few providers with high ESR/CRP co-orders (March 2023), and removal of the ESR order from the rheumatology order set (March 2023) within the Electronic Health Record (EHR).At the safety net clinic, the ESR order had been deselected as a default order on their order set in March 2021. We monitored ESR and CRP co-ordersand total ESR orders to evaluate the impact of our interventions.

Results: Pre-intervention data analysis of CRP and ESR co-orders within the rheumatologyclinics showed that over 12 months, there were 2,392co-orders at the safety net clinic and 7,250co-orders at university clinics between 1/1/22-11/22/22.The primary reason for co-orders was high-risk medication monitoring for RA and SLE.At the university and satelliterheumatology clinics,the average number of total ESR orders decreased by 50% and the average number of ESR and CRP co-orders decreased by 52% between the time frames of 1/2022-11/2022 and 12/2022-5/2023with major changes in process seen around December 2022 and January 2023 (Figure 1).At the safety net clinic, the average number of ESR and CRP co-orders decreased by 65% and the average number of total ESR orders decreased by 64% between the time frames of 1/2022-9/2022 and 10/2022-5/2023 with major changes in process seen around October 2022 (Figure 2). Orders for CRP alone remained stable at all clinics.

Conclusion: It is feasible to reduce the unnecessary ordering of ESR tests through a systematic approach within the clinics in an academic setting.Educational and EHR interventions can be particularly effective interventions as demonstrated by the significant decrease in both ESR and CRP co-orders as well as total ESR orders.Changes seen prior to February 2023 may

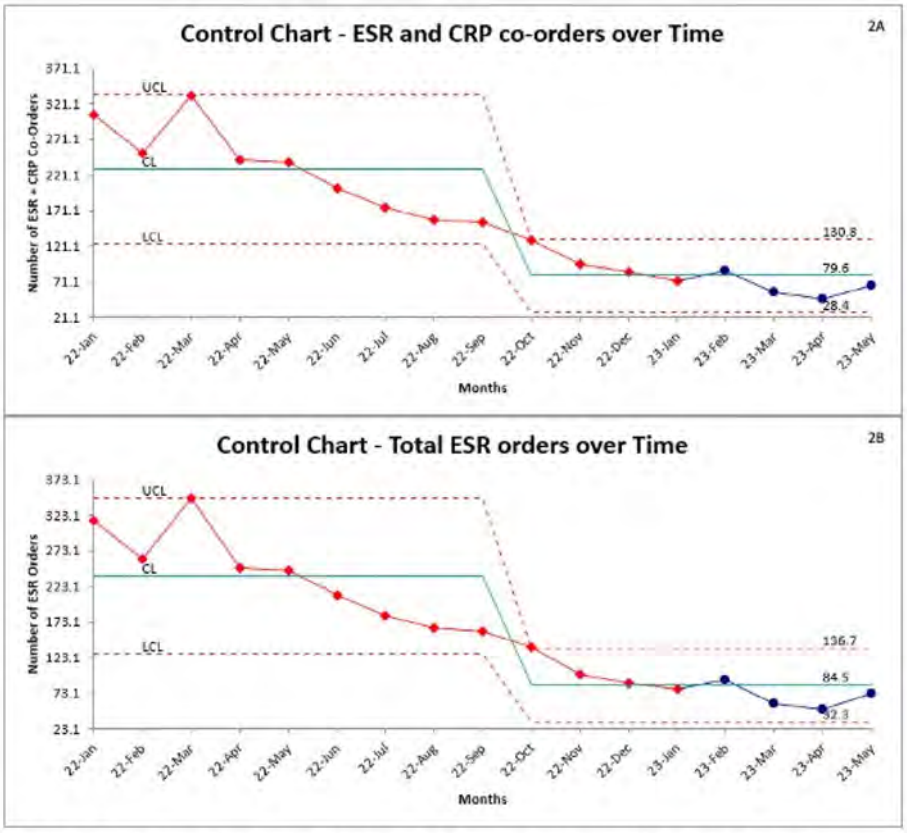

Figure 2: Control charts for ESR and CRP co-orders (2A) and Total ESR orders (2B) at the safety net clinic.

Control Charts for ESR and CRP co-orders and Total ESR orders at the safety net rheumatology clinic.

be due to the Hawthorne effect as rheumatology providers were aware that the department was investigating this topic. In the future, we plan to modify the ESR order with our EHR to implement changes throughout the health system covering all specialties.

Detection of Clinically Relevant Subgroups in Patients Undergoing Knee Replacement Using Machine Learning

Brooke McGinley[1], Gabriela Rabasa[1], Jean Liew[1], Tuhina Neogi[2], David Felson[1] and Michael LaValley[3], [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University School of Public Health, Arlington, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In the US the lifetime risk for Knee Replacement surgery (KR) is 7% for men and 9.5% for women, and this accounts for substantial health care costs. The detection of distinct subgroups of patients among those who undergo KR would have substantial clinical benefits as the subgroups may help identify clinical phenotypes allowing more finely targeted treatment, potentially reducing costs and surgical burden. The purpose of this study is to use machine learning approaches to detect subgroups among the KR patients from the combined Osteoarthritis Initiative (OAI) and the Multi-Center Osteoarthritis Study (MOST) to determine clinical phenotypes.

Methods: We used data from the Osteoarthritis Initiative (OAI) and the Multicenter Osteoarthritis Study (MOST) for analysis. We took participants that underwent KR during follow-up and extracted demographic and clinical characteristics from the exam before a participant's first KR. These characteristics included age, sex, race and ethnicity, weight, height, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) scales, Physical Activity Scale for the Elderly (PASE) score, Kellgren & Lawrence (KL) grade, education, depression status, Non-Steroidal Anti-inflammatory Drug (NSAID) use, opioid use and Charlson comorbidity index. For clustering, we used random forests analysis to determine nonparametric pairwise distances between participants, Principal Coordinates Analysis (PCoA) to place participants on a 2-dimensional grid best preserving pairwise distances, and Partitioning Around the Medoids (PAM) to group nearby participants on the grid into clusters. We prespecified use of the five cluster results to allow interpretability and clinical utility of resulting phenotypes. Continuous characteristics are compared between clusters by ANOVA F-tests and categorical characteristics by chi-square tests.

Results: We identified 1108 KR subjects; 412 (37%) from OAI and 696 (63%) from MOST. The 5-cluster results with participant positions on the 2-dimensional PCoA grid are shown in Figure 1 with plotting symbols indicating cohort (MOST vs. OAI) and color indicating cluster. Table 1 shows key characteristics by cluster membership. Cluster 1 is largest and most diverse, is majority female, with the highest percentage of depression and the greatest amount of WOMAC disability. Cluster 2 suggests post-traumatic osteoarthritis with physically active, younger men with a history of knee surgery or injury. Cluster 3 is older men with severe radiographic osteoarthritis. Cluster 4 is women with moderate levels of pain, activity and radiographic

Table 1: Key Characteristics by Cluster Membership

Table 1: Random Forest 5 Cluster Summary

	1 (N = 521)	2 (N = 154)	3 (N = 169)	4 (N = 159)	5 (N = 105)	P-value

MOST Cohort, %	62.0	79.2	68.6	59.7	38.1	<0.001

Continous variables are summarized using the mean ± SD, while categorical variables are summarized using percentages.

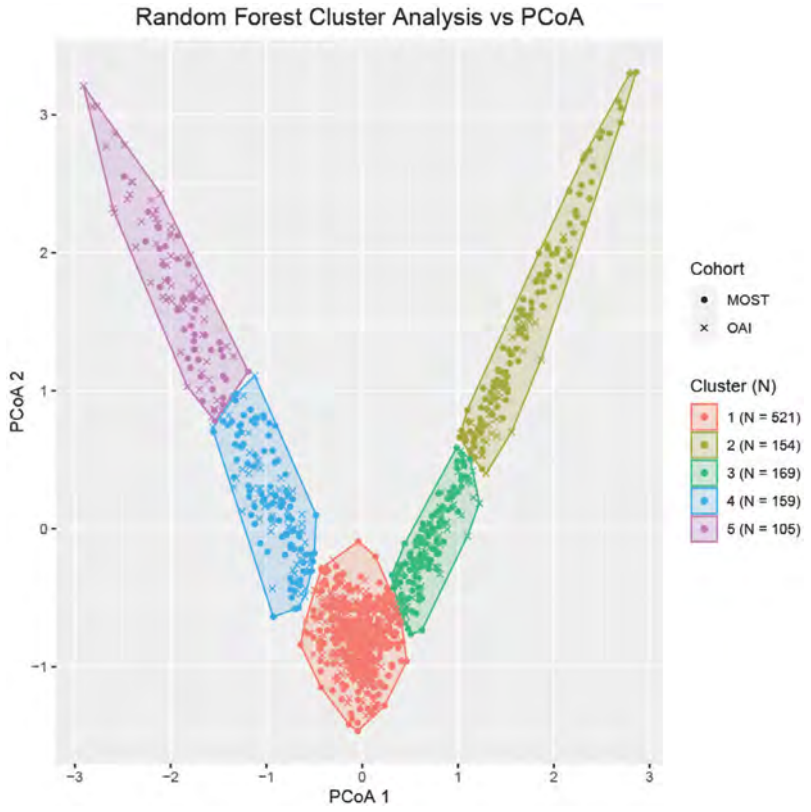

Figure 1: Participant Positions on PCoA Grid with Symbols for Cohort and Colors Indicating Clusters

involvement. Cluster 5 is older women with low levels of weight and physical activity, high NSAID and opioid use and severe radiographic osteoarthritis.

Conclusion: We found distinct clusters with differences in sex, age, radiographic OA severity, race, activity, disability, and depression among clusters. These clusters will be further validated and refined by comparison to sets of clusters generated using only participants from the Multicenter Osteoarthritis Study and only those from the Osteoarthritis Initiative.

Are Patients with Inflammatory Rheumatic Diseases Ready for Studies with Medical Cannabis? – Results from a Digital Survey

Jutta Richter[1], Aurelia Beichert[2], Tim Filla[2], Matthias Schneider[3], Joerg Distler[4] and Inna Frohne[2], [1]Clinic for Rheumatology and Hiller Research Unit, Heinrich-Heine-University Duesseldorf, Medical Faculty, Düsseldorf, Germany, [2]Clinic for Rheumatology and Hiller Research Unit University Clinic Duesseldorf, Düsseldorf, Germany, [3]Heinrich-Heine-Universitaet Duesseldorf, Duesseldorf, Germany, [4]Clinic for Rheumatology University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany; Hiller Research Center, University Hospital Düsseldorf, Medical Faculty of Heinrich Heine University, Düsseldorf, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There is an increasing demand from patients for medical cannabis in the German population [1]. Although medical cannabis might be used to treat pain and reduce inflammation in patients with inflammatory rheumatic diseases (IRD) in addition to the immunomodulatory therapy data regarding the prevalent use of and the interest in the treatment with medical cannabis is scarce. We investigated the knowledge of patients with IRD about medical cannabis and to evaluate patients' attitudes towards the use of medical cannabis in a clinical trial (CT). The analysis included whether attitudes towards medical cannabis depend e.g. on medication, treatment satisfaction, pain levels and health status.

Methods: A digital survey was conducted via an App from Asepha [2]. Our outpatients either filled out the questionnaire in the clinic using a clinic owned iPad (Version 9) or participated using a QR code handed out leading to the survey via their mobile device. Patients answered the questions anonymously. The survey included sociodemographic data, and current pain and immunosuppressive medication. Patients' willingness to consume medical cannabis in a CT was inquired. Concerns (e.g. fear of side effects, dependence on medical cannabis) that might prevent patients' from participating in a CT were assessed. Descriptive data and a penalized ordinal regression (POR) were performed using R. Ethical approval was obtained, DRKS registration number is DRKS00030875.

Results: Data were collected from 192 patients with IRD. Table 1 lists sociodemographic and clinical data. 70% were interested in the participation in a CT although of these 83% were satisfied with their current treatment. Mean number (± standard deviation) of taken pain medication was 0.8 (±0.9), mean number of taken herbal drugs was 0.6 (±1.0). Former recreational cannabis use increases the readiness to participate in a CT. Among those still undecided about taking medicinal cannabis in a CT, the main reason was the lack of sufficient information about cannabis (63%). Another relevant reason was

fear of side effects (40%) and fear of cannabis (16%). The POR depicted that current cs- resp. bDMARD therapy, former recreational cannabis use, number of already taken herbal drugs, lack of information on cannabis, and fear of cannabis but not pain or satisfaction with the current medication significantly influence patients' willingness to participate in a cannabis CT. Limitations in performing daily activities and patients global health status increase the willingness to participate in a cannabis CT, other OR are depicted in table2.

Conclusion: One third of IRD patients were interested in the participation in a CT with medical cannabis and additional 39% were potentially interested. Apart from current medication especially lack of information on cannabis and fear of cannabis were limiting factors. This demonstrates that patients' education about medical cannabis is highly necessary to increase its acceptance and thus willingness to participate in a related CT. Cannabis trials are widely and significantly accepted by patients with a history of recreational use.

Table 1: Sociodemographic and clinical data and willingness to take medical cannabis in a clinical trial (n.a. not applicable)

		Willing to take medical cannabis in a clinical trial		
	Total cohort n (%)	Yes n (%)	Undecided n (%)	No n (%)

Abstract Number: 1845

Development of a Scoring System for Accurate Lupus Nephritis Case Identification in Real-World Databases

Zara Izadi[1], Alfredo Aguirre[1], Christine Anastasiou[1], Julia Kay[1], Gabriela Schmajuk[2] and Jinoos Yazdany[3], [1]University of California San Francisco, San Francisco, CA, [2]UCSF / SFVA, San Francisco, CA, [3]University of California, General Department of Medicine, Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Accurate identification of prevalent cases of lupus nephritis (LN) is essential for timely patient monitoring and treatment, advancing research, and informing public health initiatives for the management of LN. However, diagnosis codes for LN are generally underutilized, making identification of this patient population in real-world databases challenging. We developed a scoring system to quantify the probability of accurate LN case identification.

Table 1. Characteristics of the underlying population.

		Health system A N = 4,152	Health system B N = 370
Age, Mean (SD)		50.4 (18.6)	49.5 (15.5)
Sex, N (%)	Female	3,629 (87.4)	313 (84.6)
	Male	520 (12.5)	56 (15.1)
	Other or Unknown	3 (0.1)	1 (0.3)
Race/ethnicity, N (%)	Non-Hispanic White	1,534 (37.0)	35 (9.5)
	Non-Hispanic Black	473 (11.4)	76 (20.5)
	Asian	688 (16.6)	94 (25.4)
	Hispanic or Latino	802 (19.3)	122 (33.0)
	Other or Mixed	413 (10.0)	41 (11.1)
	Unknown	242 (5.8)	2 (0.5)

Methods: We used data from EHRs of two large health systems and included patients with ≥1 ICD9/10 codes for SLE from June 2012 to Jan 2022. Prevalent LN was defined as current active LN or a history of LN. We used regular expressions with negation to loosely tag LN within EHR notes, in a training set consisting of a balanced sample of 2038 patients from the larger health system. Testing sets included 100 patients randomly selected from each health system and were manually chart reviewed to classify patients as having 'no LN', 'definite LN' (biopsy report of Class III, IV or V LN), 'potential LN' (no biopsy report but physician diagnosed LN), and 'diagnostic uncertainty' (physician states LN is possible). A gradient boosting model (GBM) including 42 predictors that covered demographics, encounters, diagnosis and procedure codes, comorbidities, medications, and laboratory test results (e.g., serologies, urine studies, chemistries) was used for predictor selection. Predictive performance of a logit regression model (LRM) including key predictors from GBM was evaluated for identifying patients with a "strict" (definite LN) or an "inclusive" (definite LN, potential LN, or diagnostic uncertainty) definition of LN. A LRM-based scoring system was developed and calibrated.

Results: Table 1 includes demographics of the 4,522 patients meeting the eligibility criteria from both health systems. In addition to more specific diagnosis codes for LN, presence of diagnosis codes for acute or chronic kidney disease or proteinuria, younger age at first SLE diagnosis code, and use of mycophenolate mofetil or mycophenolic acid were identified as key predictors and included in the final LRM. Urine protein creatinine ratios (UPCR) >0.5, abnormal complement

Table 2. Performance of the final logit regression model including key predictors. LN: Lupus nephritis; AUC: area under the curve; PPV: positive predictive value; NPV: negative predictive value; Strict definition of LN: definite LN; Inclusive definition of LN: definite LN, potential LN, or diagnostic uncertainty.

Test set	Definition of LN	AUC	Sensitivity	Specificity	PPV	NPV	Accuracy
Health system A	Strict	0.91	0.88	0.80	0.70	0.93	0.83
	Inclusive	0.93	0.88	0.88	0.84	0.91	0.88
Health system B (External set)	Strict	0.88	0.80	0.85	0.78	0.86	0.83
	Inclusive	0.87	0.74	0.87	0.83	0.80	0.81
Calibration							
Predicted probabilities		<50%	50-60%	60-70%	70-80%	80-90%	>90%
Observed probabilities (95% CI)		19% (17-21)	49% (40-58)	69% (55-81)	79% (69-86)	85% (81-89)	91% (86-95)

Table 3. The scoring system and interpretation. Diagnosis codes for lupus nephritis included ICD10 codes: M32.14 or M32.15, or ICD9 code 710.0 in combination with ICD9 codes 583.81, 581.81, or 583.89. Diagnosis codes for acute or chronic kidney disease or proteinuria included ICD10: N00-N08, N17-N19, and R80, or ICD9 codes 580-586, and 791.0.

Patient characteristic	Points *(add unless stated)*
One diagnosis code (ICD10) for lupus nephritis	35
Or	
Two or more diagnosis codes (ICD9 or ICD10) for lupus nephritis	115
One diagnosis code for acute or chronic kidney disease or proteinuria	70
Or	
Two or more diagnosis codes for acute or chronic kidney disease or proteinuria	95
Any use of mycophenolate mofetil or mycophenolic acid	45
Age (in years) at first systemic lupus erythematosus diagnosis code	Subtract age

Total Score	Predicted Probability
<80	<50%
80-110	50-60%
110-140	60-70%
140-175	70-80%
175-230	80-90%
>230	>90%

component 3 (C3) levels, any use of hydroxychloroquine, azathioprine, or rituximab, and glucocorticoid dose were also identified as important predictors but were omitted from the final LRM as their inclusion did not further improve performance. The final LRM had an area under the curve, sensitivity, and positive predictive value of 0.93, 0.88, and 0.84, respectively, for identifying LN using the inclusive definition, performed similarly with a strict LN definition, and had good external validity when tested in the second health system (Table 2). Predicted and observed probabilities had good calibration (Table 2).The scoring system was derived from this model (Table 3).

Conclusion: Prediction of prevalent LN using data elements available in EHR or claims data was feasible, had good accuracy and was validated externally. The scoring system has the potential to identify prevalent LN accurately across health systems.

Abstract Number: 1846

A Longitudinal Study: The Benefits of Non-Pharmacological Approaches to Improve Self-Reported Pain, Stiffness, and Fatigue in Individuals with Musculoskeletal Disorders

Titilayo Adeniran, Bertilia Trieu, Claudia Zurlini, Bonnie McGrath, Linda Roberts, Pamela Sanchez-Villagomez, Vilma Briones, Robyn Wiesel, Sandra Goldsmith and Laura Robbins, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal disorders are a leading cause of disability worldwide, with low back pain being one of the primary causes. The World Health Organization (WHO) reports that chronic musculoskeletal pain affects 20-33% of the global population, which amounts to a staggering 1.75 billion people. Chronic pain is often accompanied by persistent fatigue, a common complaint among individuals with musculoskeletal disorders such as osteoarthritis, rheumatoid arthritis, fibromyalgia, and low back pain. Stiffness is also a debilitating symptom that affects about half of those with chronic pain and musculoskeletal disorders. While medications can provide symptomatic relief to these conditions, non-pharmacological approaches reduce reliance on medications and address the underlying causes of musculoskeletal disorders. To optimize the quality of life of individuals with musculoskeletal disorders, the Education Institute at Hospital for Special Surgery (HSS) implemented non-pharmacological interventions.

Methods: These non-pharmacological interventions include 6-week virtual exercise classes, which encompass a variety of activities such as Pilates, Yoga, T'ai Chi Chih, mindfulness-based therapy, and relaxation techniques. These exercises are designed to be low-intensity, performed safely at home, and tailored to accommodate participants' diverse mobility levels. The virtual classes are led by certified instructors who specialize in working with individuals affected by musculoskeletal disorders. Moreover, these interventions are accessible to patients and the public using Zoom and phone as the platforms for delivery. Program effectiveness is measured using pre/post-online surveys assessing pain intensity, pain interference with seven aspects of daily living (ADL), stiffness, and fatigue. A longitudinal analysis is conducted using regression models.

Results: Since 2020, 366 participants have participated in our non-pharmacological interventions. Of those assessed (n=190), 70 participants self-reported having at least one musculoskeletal condition. Most were females (98%), ages ≥60 years (90%), Caucasian (91%), and non-Hispanic (98%). For every 6-week virtual physical activity program, participants reporting at least one musculoskeletal condition experienced statistically significant decreases in pain intensity ($p \leq 0.01$), stiffness ($p \leq 0.01$), and fatigue ($p \leq 0.05$). Decreased pain interference with seven ADL were seen but not at statistically significant levels. Also, most participants reported gaining knowledge (93%) and self-management skills (90%) to manage their condition.

Conclusion: Our findings support the benefits of non-pharmacological approaches in managing musculoskeletal disorders and their debilitating symptoms, offering a comprehensive approach that empowers individuals and promotes quality of life. Future research is needed in longitudinal studies to assess these interventions' sustainable benefits and long-term functional outcomes and examine the challenges and strategies for implementing these approaches within various healthcare settings, including community-based programs, which would help bridge the gap between research and practice.

Abstract Number: 1847

Influence of Seasonal Changes on Adherence in Rheumatoid Arthritis Patients

Cody Schmidt, Kunal Patel, **Samantha Delgado**, Guy Cozzi, Elisea Avalos-Reyes, W. Cliff Rutter, Rashmi Grover, Lucia Feczko, Will Cavers and Kjel Johnson, CVS Health, Woonsocket, RI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) symptoms are suspected to be linked with exposure to colder environments. Previous studies on RA and seasonality have focused on RA activity; however, none assess medication adherence. The objective of this study was to assess the impact of seasonal changes on medication adherence among patients beginning subcutaneous or oral RA treatment.

Methods: This is a retrospective cohort study of adult RA patients throughout the United States enrolled in a large health plan taking subcutaneous or oral RA medications between 3/1/2019 and 2/28/2021. Patients were included if they were newly diagnosed with RA (ICD-10 codes M05.X and M06.X). Medication adherence for these patients was tracked for 12 months after starting therapy. Medication classes included: TNF-αinhibitors, Janus Kinase inhibitors (JAK), Interleukin-6 (IL-6) inhibitors, a T-cell blocker, and folate analogs. Medication history was stratified into meteorological seasons for the northern hemisphere: spring (3/1-5/31), summer (6/1-8/31), fall (9/1-11/30), and winter (12/1-2/28). Monthly medication adherence was measured using proportion of days covered (PDC) between the first and last fill of the year. The effect of seasonality on monthly adherence was estimated using linear regression, controlling for age, gender, and other patient demographics. Predicted PDC was calculated using resultant equations; p-values < 0.05 were significant.

Results: In total, 3,710 patients were included in this study; adherence was captured for 39,628 member-months. The average age of the cohort was 56 years (standard deviation (sd) = 14); 2,797 (75%) identified as female. The average monthly PDC was 0.84. Predicted monthly PDC was highest in summer (0.85), followed by spring (0.85), fall (0.84) and lowest in the winter (0.83). Significant differences in PDC by season were found in winter ($p < 0.01$). Seasonality effects differed by drug class. For TNF-α inhibitors, spring ($p < 0.01$) and winter ($p < 0.01$) were associated with lower mean PDCs. None of the season coefficients were statistically significant for JAK inhibitors. Adherence for IL-6 inhibitors (p=0.04), T-Cell blockers ($p < 0.01$) and folate analog (p=0.01) were the most sensitive to winter seasonal changes. Subsampling by climate region revealed the negative impact of winter on medication adherence was limited to members residing in humid (p=0.00) or cold climates (p=0.01).

Conclusion: Medication adherence decreased in winter months, but the effect of seasonality depended on class and was drug specific. Seasonality influences adherence, but only for specific seasons.

Demographic and Clinical Factors Associated with HPV Vaccination in Young Adults with Rheumatic Disease

Caroline Siegel[1], Lauren Robinson[1], Deanna Jannat-Khah[1], Avi Mikhaylov[1], Nancy Pan[1] and Lisa Sammaritano[2], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Health Services Research Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The HPV vaccine is safe and immunogenic in RD patients but uptake is suboptimal. We aimed to evaluate factors associated with HPV vaccination in individuals with RDs, including RD diagnosis and age at diagnosis. We hypothesized that being diagnosed with an RD around the age when HPV vaccine initiation is recommended could pose a barrier to vaccination.

Table 1. Demographic and Clinical Characteristics of Patients Aged 16-22 with Rheumatic Disease Stratified by HPV Vaccination Status

Variable	Unvaccinated (N=161)	Vaccinated (N=160)	p-value
Demographics			
Age, yrs – mean (SD)	19.5 (2.0)	19.6 (2.2)	0.66
Age at RD diagnosis, yrs – mean (SD)	14.9 (4.8)	15.0 (4.7)	0.92
Female	110 (68.3)	123 (76.9)	0.09
Race			*0.001*
• Asian	7 (4.3)	15 (9.4)	
• Black	7 (4.3)	22 (13.8)	
• White	114 (70.8)	81 (50.6)	
• Other	21 (13.0)	31 (19.4)	
• *Patient declined/Unavailable*	*12 (7.5)*	*11 (6.9)*	
Ethnicity			*0.005*
• Hispanic/Latino	30 (18.6)	45 (28.1)	
• Not Hispanic/Latino	121 (75.2)	114 (71.3)	
• *Patient refused/Unknown*	*10 (6.2)*	*1 (0.6)*	
Insurance type			*<0.001*
• Medicaid and/or Medicare	22 (13.7)	48 (30.0)	
• Private	134 (83.2)	112 (70.0)	
• *Unspecified*	*5 (3.1)*	*0 (0)*	
Clinical Information			
Rheumatic disease diagnosis			*0.007*
• Inflammatory arthritis	98 (60.9)	87 (54.4)	
• Connective tissue disease	34 (21.1)	60 (37.5)	
• Vasculitis	6 (3.7)	6 (3.8)	
• Chronic recurrent multifocal osteomyelitis	9 (5.6)	1 (0.6)	
• Localized scleroderma	6 (3.7)	2 (1.3)	
• Autoinflammatory disease	4 (2.5)	2 (1.3)	
• Other inflammatory disease	4 (2.5)	2 (1.3)	
Immunosuppressive medication use (at most recent visit)	95 (59.0)	106 (66.3)	0.26
Influenza vaccination (ever)	97 (60.2)	155 (96.9)	*<0.001*
COVID-19 vaccination			*<0.001*
• 0 doses	58 (36.0)	12 (7.5)	
• 1-2 doses	54 (33.5)	50 (31.2)	
• ≥3 doses	49 (30.4)	98 (61.3)	

Values are reported as N (%) unless otherwise indicated. A p-value <0.05 was considered statistically significant.

Methods: This retrospective study included individuals aged 16-22 seen by a rheumatologist in our academic center ≥2 times (2020-2022) who had an RD diagnosis and New York State (NYS) residence. We used chart review to ascertain demographics, immunization information (automatically pulled from the NYS Immunization Information System), RD diagnosis, and medications. We descriptively compared demographic and clinical variables between patients who had received 0-1 HPV vaccine doses ("unvaccinated") and those who had received 2-3 doses ("vaccinated") and performed multivariable logistic regression to assess the association between RD-related factors and HPV vaccination after adjusting for relevant demographic and clinical variables.

Results: Of 671 patients aged 16-22 seen by a rheumatologist ≥2 times in the study timeframe, 321 (47.8%) had an RD diagnosis and NYS residence. Mean age at most recent visit was 20 ± 2.1 years and at diagnosis was 14.9 ± 4.7 years, 233 (72.6%) were female, and 161 (50.2%) were unvaccinated. Compared to those who were vaccinated, unvaccinated individuals were more frequently White (70.8% vs 50.6%, p=0.001), non-Hispanic/Latino (75.2% vs. 71.3%, p=0.005), and privately insured (83.2% vs. 70.0%, p< 0.001). HPV vaccinated patients more frequently had received an influenza vaccine (96.9% vs. 60.2%, p< 0.001) or ≥3 COVID-19 vaccine doses (61.9% vs. 30.4%, p=0.003) compared to unvaccinated patients. RD diagnosis differed by HPV vaccine status (p=0.007): inflammatory arthritis (IA) was more common in unvaccinated vs. vaccinated patients (60.9% vs. 54.4%) and CTD was more common in vaccinated vs. unvaccinated patients (37.5% vs. 21.1%) [**Table 1**]. In multivariable analysis, Black vs. White patients with RD were more likely HPV vaccinated (OR 5.74, 95% CI [1.61-20.54], p=0.007) as well as those who had ever received an influenza vaccine vs. those who had not (OR 11.47, 95% CI [4.31-30-.51], p< 0.001); patients with "other" RD vs. IA were less likely HPV vaccinated (OR 0.20, 95% CI [0.08-0.52], p=0.001) [**Table 2**]. Age at RD diagnosis did not differ between groups and was not associated with HPV vaccination after adjustment.

Table 2. Logistic Regression Model Evaluating the Association Between Demographic and Clinical Characteristics and HPV Vaccination in Patients Aged 16-22 with Rheumatic Disease

Variable	Odds Ratio	95% Confidence Interval	p-value
Demographics			
Age	1.04	0.89 – 1.22	0.59
Sex			
• Male	*Referent*		
• Female	1.64	0.85 – 3.20	0.14
Race			
• White	*Referent*		
• Black	5.7	1.61 – 20.54	*0.01*
• Asian	2.76	0.79 – 9.62	0.11
• Other	2.62	1.02 – 6.78	0.05
Ethnicity			
• Hispanic/Latino	*Referent*		
• Not Hispanic/Latino	1.00	0.45 – 2.23	1.00
Insurance

Clinical Information			
Rheumatic disease diagnosis			
• Inflammatory arthritis	*Referent*		
• Connective tissue disease	0.64	0.30 – 1.36	0.25
• Other[1]	0.20	0.08 – 0.52	*0.001*
Age at diagnosis			
• <17 years	*Referent*		
• 17-22 years	1.34	0.65 – 2.73	0.43
Influenza vaccination (ever)			
• No	*Referent*		
• Yes	11.47	4.31 – 30.51	*<0.001*
COVID-19 vaccination			
• 0 doses	*Referent*		
• 1-2 doses	4.36	1.81 – 10.52	*0.001*
• ≥3 doses	8.00	3.37 – 19.00	*<0.001*

A p-value <0.05 was considered statistically significant.
1. Vasculitis, chronic recurrent multifocal osteomyelitis, localized scleroderma, autoinflammatory disease, and other inflammatory disease.

Conclusion: In a large sample of patients aged 16-22 with RD, half had not received ≥2 HPV vaccine doses. As has been demonstrated in the general population, White race, non-Hispanic/Latino ethnicity, and having private insurance were associated with decreased HPV vaccine uptake. HPV vaccination was associated with influenza and COVID-19 vaccination, suggesting that some factors driving elective vaccine uptake are independent of vaccine type. Unvaccinated individuals more commonly had IA whereas vaccinated individuals more commonly had CTD; age at diagnosis was not associated with HPV vaccination after adjustment. Further research is needed to identify and mitigate barriers to HPV vaccination in this high-risk group.

Background/Purpose: The Covid-19 pandemic constituted major challenges for health-care services worldwide. We aimed to compare Covid-19 restrictions across Europe during the first three waves of the pandemic, as well as the consultation and follow-up practices of patients with spondyloarthritis before and during the pandemic.

Methods: Rheumatologists completed a Research Electronic Data Capture (REDCap) survey in 13 observational registries in the European Spondyloarthritis Research Collaboration Network (EuroSpA) between July 1st and October 27,th 2022: ATTRA (Czech Republic), DANBIO (Denmark), ESRBTR (Estonia), ROB-FIN (Finland), ICEBIO (Iceland), GISEA (Italy), ARC (Netherlands), NOR-DMARD (Norway), Reuma.pt (Portugal), RRBR (Romania), biorx.si (Slovenia), BIOBADASER (Spain), and SCQM (Switzerland), answering questions on Covid-19 restrictions in their individual countries and the impact of Covid-19 on consultation and follow-up of routine care patients with spondyloarthritis in their registries. The survey covered the period from the start of the pandemic in the different countries, until 1st of March, 2022.

Results: The first case of Covid-19 in each country was reported between 31st of January 2020 in Spain and 4th of March 2020 in Slovenia. Use of facemask in public was mandatory in all countries during the peak of the pandemic, but use of filtering facemask (type P2 or P3) only in four countries (Table 1). All countries except for Iceland had a

*The new modalities of consultation referred to are listed in Table 2. §For Estonia and Romania this applied to routine care patients but not patients included in the respective registries +, Yes; -, No; FU, follow-up patients; NA, not applicable; NP, new patients

nationwide total lockdown. Most countries had nationwide curfews, which occasionally applied to specific periods throughout the day. All countries had social distancing varying between one and two meters from others in public. This was mandatory at some time-point during the pandemic in all countries, except in Finland and Portugal, where it was recommended.

Before the pandemic, only four countries/registries had alternative modes of consultation in addition to the usual routine care physical consultations (Table 2). However, during the pandemic, nine registries initiated other modes of routine care consultations, the most common being phone consultations. The new modalities of consultations were not mandatory in any registry, except for mandatory non-urgent remote consultations in Switzerland during the first wave of the pandemic (phone or video, Table 3). In addition, in Spain, phone consultations and consultations between primary care physicians and rheumatologists were mandatory at some hospitals.

In every registry, rheumatologists reported an increased patient relocation from physical to remote consultations during the pandemic. At the peak of the pandemic, most of the patients were assessed remotely; however, this mainly applied to follow-up patients. More patients and healthcare providers canceled appointments during the pandemic than before. Furthermore, in all registries, staff was translocated to other duties and patients had fewer follow-up consultations than usual.

Conclusion: The Covid-19 pandemic had far-reaching consequences across Europe, not only due to nationwide restrictions, but also as a result of its negative impact on the accessibility of rheumatological care and follow-up.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1840–1861) Health Services Research Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: According to recent ACR and EULAR rheumatoid arthritis (RA) guidelines, glucocorticoids (GCs) should only be used for brief periods or not at all. Our aim was to investigate U.S. real-world GC usage patterns in elderly early RA patients, who are especially likely to suffer from adverse events, and assess the relationship between GC initiation, entrance into rheumatologic care, and subsequent, long-term GC use.

Methods: We joined data from the Rheumatology Informatics System for Effectiveness (RISE) with Medicare claims (2016-2018). Early RA patients were identified with a first RA ICD code in RISE between 01/01/2017 and 09/01/2018 (index date) plus a second code ≥30 days later. To ensure observability, we required continuous enrollment in Medicare in the year of their first RA code and the preceding year. To identify early RA patients, we required ≥18 months of observation in Medicare prior to the index date and no RA code for >12 months before the index date. Patients who received GCs before the index date from rheumatologists not participating in RISE were excluded. Patient characteristics were assessed during the six months following the index date. GC initiation for early RA was defined by a GC claim in Medicare between 3 months before to 6 months after the index date (**Figure**). Chronic use at 3, 6 and 12 months after initiation was defined by an active GC claim at each time point without a medication gap of >6 months. We used standardized mean differences to compare patient characteristics among GC initiators vs. non-initiators. Time between GC initiation and the start of rheumatology care was calculated as the difference between the GC initiation date and the index date. Mean GC doses during follow-up were

GC, glucocorticoid; RA, rheumatoid arthritis.

*Mg/d prednisone equivalent. Average daily dose estimated by summing all GC claims during follow-up divided by the number of days covered. Chronic use at 3, 6 and 12 months after initiation was defined by an active GC claim at each time point without a medication gap of >6 months.

estimated by summing total GC dose dispensed over total number of days covered. ANOVA was used to test differences in GC doses and time of GC initiation between patients with different durations of use.

Results: 1854 patients (68% female; mean [SD] age of 75 [8]) with early RA were included, of which 41% initiated GCs. GC initiators and non-initiators were similar in most baseline characteristics (**Table 1**), although data on disease activity was scarce. 65.1% of GC initiators had their first GC claim before the index date (mean [SD] time from first GC claim to index date: -16.2 [58.3] days). Of 497 patients with a GC claim before the index date, 63.6% received their first prescription from a non-rheumatologist. Among 763 GC initiators, 69.7%, 49.9%, and 20.5% became chronic GC users at 3, 6 and 12 months after their first GC claim. Longer duration of GC use was associated with a longer time between the first GC claim and the index date (**Table 2**). Mean GC doses during follow-up were less than 5 mg/d prednisone equivalent for chronic 6- and 12-month users.

Conclusion: Almost half of elderly early RA patients received GCs for their RA, most often prior to the first visit with a rheumatologist. Among patients who initiated GCs, 20% continued to receive them 12 months later. Most of the time doses were low. Initiatives to reduce GC exposure among patients with early RA will likely require close collaboration between rheumatologists and primary care to expedite referrals to rheumatology care.

Abstract Number: 1851

Healthcare Providers' Experiences of a Mandatory Nationwide Transition to an Adalimumab Biosimilar

Chiara Gasteiger[1], Maria Lobo[2], Lun Shen Wong[1], Rachel Murdoch[1] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]Department of Rheumatology, Te Toka Tumai Auckland, Auckland, New Zealand

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Transitioning patients with rheumatic diseases to biosimilars has become common to reduce healthcare costs and improve patient access to biologic therapies. However, it is unclear how the transition process impacts healthcare providers at the frontline of the brand change. This study explores providers' experiences of a nationwide mandatory brand change to an adalimumab biosimilar.

Methods: A nationwide online survey was conducted in Aotearoa New Zealand with rheumatologists, rheumatology nurses, and pharmacists. The transition was the first large-scale nationwide brand change for biosimilars and was anticipated to benefit >700 patients in the first year and reduce administrative burdens by extending authorization renewal durations. The transition occurred between March and September 2022, with data collected between November 2022 and February 2023. Survey items assessed satisfaction with logistics and supply, information and education, support, and administrative workload, on a 0-10 scale, with 10 indicating high satisfaction. Open-ended questions explored changes to workload and what did and did not go well during the transition.

Results: The sample (N = 164) consisted of rheumatologists (n = 39), rheumatology nurses (n = 16), and pharmacists (n = 109), yielding a response rate of 61%, 62%, and 3% for each practicing workforce. The mean [SD] overall satisfaction score with the transition was 5.7 [2.6]. Providers were the least satisfied with training for the biosimilar device (mean [SD] 3.7 [2.8]), information from government agencies (4.4 [2.7]), and administrative workload (4.6 [2.9]) during the transition. Satisfaction with adalimumab safety, efficacy, quality of the device, and the provision of sharps bins, alcohol wipes, and patient support was lower following the transition ($p < .05$ for all). Satisfaction with administrative workload (B = .37, $p < .001$) and training for the device (B = .20, $p = .020$) predicted overall satisfaction. Providers' workload increased during the transition period due to additional patient counseling needs, navigating the initial authorization process, and sourcing resources and information. Participants reported that the transition was complicated by poorly implemented initial authorization processes and loss of the bio-originator patient support program. The citrate-free preservative and longer authorization duration after the transition were viewed positively.

Conclusion: Providers reported increased workload during the transition and less satisfaction with the biosimilar following the adalimumab transition. Provider experiences may be improved by ensuring training for the biosimilar device, maintaining a high-quality patient support program, and ensuring authorization processes function well throughout the transition period.

Human Papillomavirus Vaccine Uptakes in Ethnically Diverse Women Living with Systemic Lupus Erythematosus

Sebastian Bruera[1], Yinan Huang[2], Savannah Bowman[1], Maria Suarez-Almazor[3], Grace Lo[1], Maria A. Lopez-Olivo[4] and Sandeep Agarwal[1], [1]Baylor College of Medicine, Houston, TX, [2]Department of Pharmacy Administration, University of Mississippi School of Pharmacy, Oxford, MS, [3]MD Anderson Cancer Center, Houston, TX, [4]The University of Texas, MD Anderson Cancer Center, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with systemic lupus erythematosus are at an increased risk of infections from the human papillomavirus (HPV) and subsequently HPV-mediated malignancies and genital warts. The HPV vaccine is an effective preventative strategy for these complications; however, the HPV vaccination rate has not been well described in a racially and ethnically diverse patient population in the United States.Furthermore, the attitudes, knowledge, and beliefs of patients towards HPV vaccination has not been described in women with SLE.

Methods: We performed a cross-sectional study in which we enrolled consecutive women with a diagnosis of SLE by 2019 ACR criteria. Eligible women were aged 21-45 years of age without a prior history of cervical cancer or hysterectomy. The Centers for Disease Control (CDC) recommends vaccination up to ages 45 for patients that are high risk for HPV infections. We collected demographics, clinical characteristics, constructs of the Health Belief Model (HBM) (susceptibility, severity, perceived barriers, benefits, cues to action, and self-efficacy). Patients answered questions according to the 5-point Likert Scale (1 – Strongly Agree to 5- Strongly Disagree). Answers were reversely coded when necessary and means with standard deviations were generated. Higher means showed an increased perception of an individual construct (i.e. a higher mean for barriers indicates women had perceived barriers for why they did not obtain the HPV vaccine, whereas a higher mean for severity indicates beliefs that there are less consequences from HPV infection). Our primary outcome was self-reported HPV vaccination, as there is currently no approved laboratory study to confirm vaccination status.

Results: We enrolled 75 women. The mean age was 33. Most patients were either black (27%) or Hispanic (44%). Our results showed that only 27% of patients had received HPV vaccination, whereas the remaining 73% either had not received the vaccine or were unsure. There were no associations between HPV vaccination and demographic variables (including race, ethnicity, marital status, insurance, education, and smoking status). With respect to HBM constructs where a value of 3 is neutral, women with SLE had increased perceived barriers (mean 4.0, SD 0.83) and decreased perceived severity (mean 3.25, SD 0.90). Women did not have an increase in the perceived susceptibility (mean 2.4, SD 0.63), benefits (mean 1.9, SD 0.81), self-efficacy (mean 1.96, SD 0.66), and cues to action (mean 1.9, SD 0.43). There were no statistically significant differences in the HBM constructs between vaccinated and non-vaccinated women.

Conclusion: Women with SLE that should consider HPV vaccination by the CDC guidelines are vaccinated at a low rate of 27%. Our HBM model shows that women had increased perceiver barriers to vaccination and had decreased perceived severity about HPV infection. This model suggests that strategies to target the constructs can be used to increase screening in this vulnerable patient population.

Each Joint in a 28 Joint Count Is More Likely to Be Affected by Deformity/Limited Motion Than by Swelling in Rheumatoid Arthritis Patients with Long Disease Duration: Deformity/Limited Motion Should Be Included in Joint Counts Performed in Routine Care

Rahel Hunter[1], Nicholas Rodwell[2] and Theodore Pincus[1], [1]Rush University Medical Center, Chicago, IL, [2]Liverpool Hospital, Liverpool, Australia

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The 28 joint count for rheumatoid arthritis (RA) was designed to recognize 3 abnormalities: swelling, (SWL), tenderness/pain on motion (TEN), and deformity/limited motion (DEF), recorded as total swollen joint count (SJC), tender/pain on motion joint count (TJC), and deformed/limited motion joint count (DJC). In clinical trials over 6-12 months, DJC generally is omitted, appropriately, as the aim is to assess reduction of inflammation by active vs control treatments in groups of selected patients. However, omission of DJC has been extended to most long-term routine care and longitudinal

Number of patients (total=104) with involvement of specific joints or joint groups included in the 28 joint count with swelling (SJC), tenderness/pain on motion (TJC), and/or deformity/limited motion (DJC)

Joint or joint group	SJC positive	TJC positive	DJC positive
Total mean	1.8	3.9	**5.5**
Total median	0	2	**4**

R knee	6	**37**	24
TOTAL			

Highest total in bold
*=Median of 5 joints

Number of patients (total=104) with involvement of specific joints or joint groups included in the 28 joint count with swelling (SJC), tenderness/pain on motion (TJC), and/or deformity/limited motion (DJC) Highest total in bold *=Median of 5 joints

databases, potentially underestimating the severity of patient status. We compared the likelihood of SWL, TEN and DEF in individual joints in 28 joint counts which were assessed in RA patients who had been treated over long periods.

Methods: A standard 28 joint count was performed at a routine care visit of 104 RA patients who had been treated over long periods, in which SWL, TEN and DEF were recorded for each joint. The total SJC, TJC, and DJC was recorded as totals of SWL, TEN and DEF in each of the 28 joints. The numbers of SWL, TEN and DEF of wrists, elbows, shoulders and knees were calculated for individual joints. Median values for 5 each of left (L) and right (R) interphalangeal (PIP) joints and metacarpophalangeal joints (MCP) were calculated to represent these joints.

Results: The study included 104 patients with mean and median age of 59.9 and 61.3 years and mean and median disease duration of 11.6 and 10.0 years, respectively. The mean and median total SJC was 1.8 and 0, TJC 3.9 and 2, and DJC 5.5 and 4, respectively (Table). The highest levels for all joint abnormalities were seen in wrists and lowest in elbows, although differences were not large. DEF was higher than SWL for all joints and joint groups included in the 28 joint count (Table). DEF was also higher than TEN for all 20 PIP and MCP joints (only 4 medians are included in the table) and wrists; TEN was marginally higher than DEF for shoulder, elbow, and knee joints.

Conclusion: Patients treated in the biological era with median disease duration of 10 years have low total SJC, reflecting excellent control of inflammation. However, joint deformity (and tenderness) are considerably more prevalent than swelling. Omission of deformity/limited motion, as is appropriately usual in clinical trials, in long-term care and longitudinal databases may give inappropriately favorable impressions of long-term RA outcomes. It is suggested that DJC be included in all formal joint counts in routine clinical care and long-term databases.

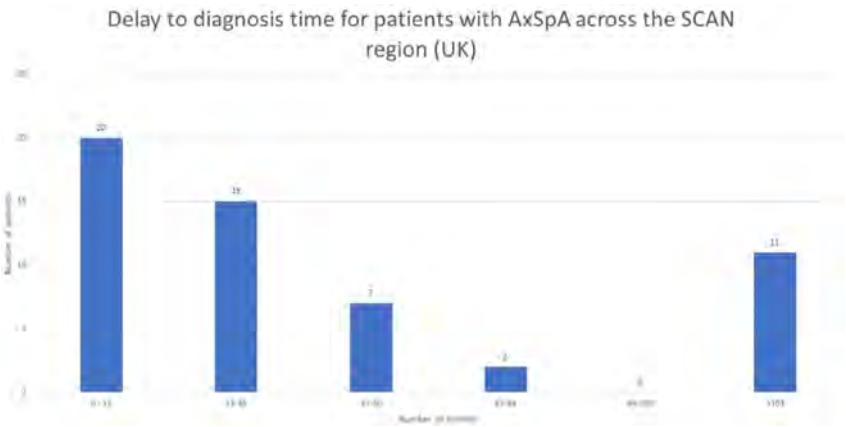
What Is Our Regional Delay to Diagnosis in Patients with Axial Spondyloarthropathy - Are We Hitting the Target? Data from a Multi-centre UK Patient Cohort

Gurdeep Dulay[1], Antoni Chan[2], Catherine Boys[3], Aisling Coy[4], Mary Devin[5], Leslie Goh[6], Arran McDougall[2], Kathryn Rigler[2], Jacqui Tomkins[7], Dinny Wallis[7] and Emma Williams[8], [1]Portsmouth Hospitals University NHS Trust, Portsmouth, United Kingdom, [2]Royal Berkshire NHS Foundation Trust, Reading, United Kingdom, [3]NHS, Basingstoke, United Kingdom, [4]Salisbury NHS Foundation Trust, Salisbury, United Kingdom, [5]Dorset County Hospital NHS, Dorchester, United Kingdom, [6]NHS, Portsmouth, United Kingdom, [7]NHS, Southampton, United Kingdom, [8]NHS, Winchester, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Due to the insidious onset of axial spondyloarthritis (AxSpA), there is often a significant delay to diagnosis. The average delay to diagnosis in the UK is 8.5 years. This is associated with several adverse sequelae including poor disease-related quality of life and worse overall health outcomes. In addition, there are substantial health-economic costs associated with this. Recent modelling data in the UK, commissioned by the National Axial Spondyloarthritis Society (NASS), demonstrated the average financial cost of this delay to be £196,000 ($243,000 US) per person affected. There is now a focus on reducing diagnostic delay for patients with AxSpA. The South Central Axial Spondyloarthritis Network



A summary of the length of time taken for patients to receive a diagnosis of AxSpA. 55 patients from 6 different hospitals across the SCAN region (UK).

(SCAN) is a network of NHS (National Health Service) Rheumatology departments in hospitals across south-central UK. The group is multidisciplinary.

Methods: We undertook a retrospective data collection of 5-10 sequential cases of newly diagnosed AxSpA from 6 different regional hospitals within the SCAN network. A total of 55 patient cases was included in this cohort. We categorised data in terms of length of delay to diagnosis from first symptom onset. A primary aim was to establish what proportion of our regional patient cohort received a diagnosis within 1 year of first symptom onset. This target aligns with the target set by NASS (UK) and represents the world's first gold standard time to diagnosis of 1 year. Data was also collected about gender and age at diagnosis.

Results: Based on this representative sample from our region, the gold standard time to diagnosis (within 1 year) is being acheived in 36% of our patient cohort. A further significant proportion of patients (27%) received a diagnosis between 13-36 months following first symptom onset. However, 20% of patients in our cohort are waiting longer than the national average of 8.5 years (or 103 weeks) before receiving a diagnosis of AxSpA.

One-third of our patient cohort (33%) were female. The average age of the patients at the time of diagnosis was 36.8 years.

Conclusion: Whilst acknowledging the relatively modest size of the sample, this regional multicentre dataset has allowed us to establish that 36% of our patient cohort achieved a gold standard time to diagnosis (within 1 year of first symptom onset). The majority of patients (63%) received a diagnosis within 36 months of first symptoms onset. it is important to also highlight that 20% of patients endured a longer than UK national average delay to diagnosis (>103 months/ >8.5 years).

We are aiming to improve our delay to diagnosis by introducing a standardised regional referral proforma for patients with suspected AxSpA. This can be used in primary care to guide clinicians and facilitate earlier referral to Rheumatology. The aims of this intervention would be to increase the proportion of patients achieving a gold standard time to diagnosis and reduce the proportion of patients in all the other time categories, especially those patients with the longest delay to diagnosis. By sharing this work we hope that other global colleagues may also review their own local data and consider service improvement initiatives to reduce delay to diagnosis for patients with AxSpA.

Using a Whole-population Approach to Help Design More Effective and Efficient Healthcare Services for People with Fibromyalgia

Gary Macfarlane[1], Roxanne Cooksey[2], Ernest Choy[3] and Rosemary Hollick[4], [1]Aberdeen Centre for Arthritis and Musculoskeletal Health (Epidemiology Group), University of Aberdeen, Aberdeen, United Kingdom, [2]Cardiff University, Cardiff, United Kingdom, [3]Section of Rheumatology, Cardiff University, Cardiff, United Kingdom, [4]University of Aberdeen, Aberdeen, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A large body of evidence has informed, internationally, management recommendations for people with fibromyalgia. However there are very few studies which have examined how best to design services to deliver effective care. Much of the available evidence characterising the health and use of health services for people with fibromyalgia comes from small studies or in highly-selected groups. The use of routinely collected health data offers the possibility of large and unselected samples to better quantify the characteristics of people with fibromyalgia and their use of health services.

Methods: A case-control study of patients with fibromyalgia using deidentified National Health Service health and care data held in the Secured Anonymised Information Linkage (SAIL) databank for the whole population of Wales. Individuals ≥18 years and with a code present for fibromyalgia in their primary care records between 2004-18 formed the case group. Each case was matched with up to four controls: by sex, age; socio-economic status and with a code for any health care use within 30 days of the code date of the case. We analysed past events in their primary care record for cases and controls.

Results: 19,742 cases and 76,746 controls were included in this analysis. The vast majority of cases were female (89%) and had a median age of 48 years. The mean BMI was higher in cases (30.3 v. 28.8 kgm^{-2}) who were also more likely to have smoked (73 v. 68%), and have comorbidities (with the exception of cancer) (Table 1), specifically Inflammatory Arthritis (5.4 v. 2.2%) and Inflammatory Bowel Disease (1.9 v. 1.1%) . Depression/anxiety was recorded in 74% of cases, while sleep disorders were also common (24.8%). The use of anti-depressants was near universal in people with fibromyalgia (95%), opiates prescription common (82%), while gabapentin was used by 51% and steroids by 44%. Codes for tress and

Pain management	13.4%	2.1%	11.3 (10.7 to 11.7)
Physiotherapy	2.4%	1.6%	0.8 (0.5 to 1.0)
Psychotherapy	0.3%	0.1%	0.2 (0.1 to 0.3)
Radiology	1.5%	0.8%	0.7 (0.6 to 1.0)
Respiratory Medicine	10.3%	4.8%	5.5 (5.1 to 6.0)
Rehabilitation	6.6%	1.5%	5.1 (4.7 to 5.5)
Rheumatology	5.6 %	1.7%	3.9 (3.6 to 4.3)
General Surgery	47.0%	27.3%	19.7 (18.9 to 20.5)
Orthopaedics & trauma	49.2%	26.8%	22.4 (21.7 to 23.2)
Gynaecology (female patients)	46.8%	28.7%	18.1 (17.4 to 19.0)

bereavement (27.2 v. 17.6%) and specifically adverse life events (10.7% v. 8.8%) were significantly more common in cases. In the year prior to diagnosis referrals to 17 out of the 20 specialties examined were more common in cases – particularly for Gastroenterology, Neurology, Pain Management, General Surgery and Orthopaedics (Table 2). Only 1 in 20 of cases have been referred to Rheumatology prior to the first recording of fibromyalgia in their records, however almost half had been referred to each of General Surgery, Orthopaedics and Gynaecology.

Conclusion: This whole population approach has quantified the burden of comorbidities in people diagnosed with fibromyalgia, and highlighted the very common use of opiates whose use is recommended against. The previously reported role of adversity in the aetiology of the condition is replicated. This large unselected-sample approach offers potential for understanding interactions with healthcare of people before and after diagnosis of fibromyalgia (and relating to these to patient characteristics); investigating the opportunities for harm; and the design of more efficient and effective approaches to their care.

Abstract Number: 1856

Improving Recombinant Zoster Vaccination Rates in Patients Receiving Immunosuppressive Therapy in the Rheumatology Clinic at the Orlando VA Healthcare System – a Quality Improvement Project

Kathlyn Camargo Macias[1], Ravi Shahu Khal[1], Ariail Schmitz[2], Kathleen McCabe[1], Taylor Kann[1], Marilyn Mosquera[3] and Ashwini Komarla[4], [1]University of Central Florida, Orlando, FL, [2]University of Central Florida, St. Cloud, FL, [3]University of Central Florida, Casselberry, FL, [4]ORLANDO VAMC, Orlando, FL

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Herpes zoster is a painful rash that involves one to three adjacent dermatomes, secondary to reactivation of latent varicella-zoster virus (VZV). About 95% of the U.S population has been exposed to VZV, and therefore are at risk of developing herpes zoster. Many patients with rheumatologic conditions are at higher risk for herpes zoster and related complications.

Since 2017, The Centers for Disease Control and Prevention has recommended the 2-dose series recombinant zoster vaccination (RZV) in all immunocompetent adults aged ≥50 years. In 2021, this recommendation was expanded to include adults aged ≥18 years who are or will be immunodeficient or immunosuppressed because of disease or therapy. This recommendation includes patients with rheumatologic conditions or patients on immunosuppressive medications. This Quality Improvement project was designed to increase the RZV vaccination rate to 50% in patients receiving immunosuppressive therapy in the rheumatology clinic at the Orlando VA Healthcare System.

Methods: We identified patients aged ≥18 years who were prescribed biologics, Janus Kinase (JAK) inhibitors and/or conventional synthetic disease modifying antirrheumatic drugs (csDMARDs), from 2/2021 until 2/2022, who had not received RZV vaccination. We conducted a root cause analysis to identify barriers for RZV vaccination. Our interventions included a visual aid in patient rooms encouraging patients to ask about RZV vaccination, pre-visit screening for RZV vaccination done by nurses and providers, set up a process on how to order RZV vaccine in satellite clinics, presentation to rheumatology faculty about baseline metrics, and providing education on the RZV vaccine at each clinic visit. We then obtained follow-up data from 5/2022 until 4/2023.

Results: A total of 808 patients aged ≥18 years who were prescribed immunosuppressive medications in the rheumatology clinics from 2/2021 until 2/2022 were identified. Of these patients, 67% (n=540) had not received RZV vaccination, and 418 of these patients were ≥50 years of age. Therefore, only 33% of our patients on immunosuppressive therapy have been appropriately vaccinated against VZV.

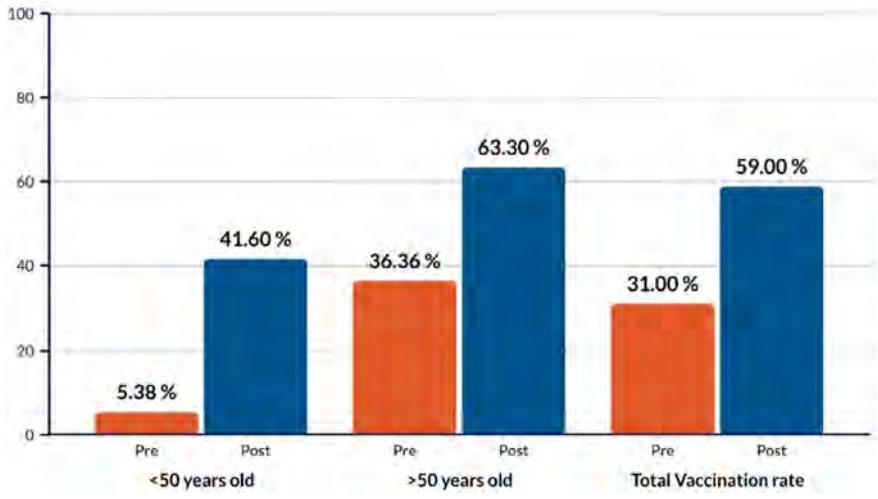

Figure 1. Percentage of RZV vaccination rate

After our intervention, we identified 761 patients aged ≥18 years who were prescribed biologics or JAK inhibitors from 5/2022 until 4/2023. Of these patients, 41% (n=309) had not received RZV vaccination and 229 of these patients were ≥50 years of age. Therefore, RZV vaccination rate increased from 33% to 59% (Figure 1).

There is a numerically increase of the percentage of immunosuppressed patients who have been appropriately vaccinated against VZV. The total of patients in the pre-intervention group is higher than post-intervention, and this could be related to changes in medication regimen or geographic relocation.

Conclusion: Results from our quality improvement project showed increase in the RZV vaccination rate in the rheumatology clinics at the Orlando VA Healthcare System. This initiative requires continuous awareness from the rheumatology providers and nurses to capture those patients that have not been vaccinated against RZV. Future directions include expanding this initiative to other departments that prescribe immunosuppressive therapy.

More Than 50% of Rheumatoid Arthritis (RA) Patients with High or Moderate CDAI (clinical Disease Activity Index) Screen Positive on MDHAQ (multidimensional Health Assessment Questionnaire) Indices for FAST4 (fibromyalgia Assessment Screening Tool) And/or MDS2 (MDHAQ Depression Screen)

Juan Schmukler and Theodore Pincus, Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Treat to target in rheumatoid arthritis (RA) suggests escalation of therapy in patients whose scores are high or moderate on a disease activity index such as the Clinical Disease Activity index (CDAI), although exceptions are recognized according to shared decisions. Individual RA clinical core data set measures and indices may be elevated by non-inflammatory comorbidities such as fibromyalgia (FM) and depression (DEP), independent of disease activity (ACR Open Rheum. 2022. Semin Arth Rheum. 2023;58:152151).Most studies are retrospective using various patient questionnaires to recognize DEP or FM. A Multidimensional Health Assessment Questionnaire (MDHAQ) contains indices to screen for FM, Fibromyalgia Assessment Screening Tool (FAST4) and DEP, MDHAQ Depression Screen (MDS2-) on a single questionnaire, in addition to RAPID3 to assess clinial status. We performed a cross sectional study to analyze the prevalence of FM and DEP in RA patients in different CDAI categories.

Methods: A cross-sectional study was performed in unselected RA patients at a routine care visit. All patients completed an MDHAQ, which includes the FAST4 and MDS2 indices.A 28 swollen joint count (SJC), 28 tender joint count (TJC), 0-10 global assessments of patient (PaGA) and physician (PhGA) were assessed to calculate a 0-76 CDAI. The proportion of patients who screened positive (+) or negative (-) for FM on FAST4 and/or DEP on MDS2 were analyzed according to CDAI remission/low (R/L) vs moderate/high (M/H) categories. Chi-square tests were used to assess statistical significance.

CDAI n=104	FAST4 FM- MDS2 Dep- n (row%)	FAST4 FM+ and/or MDS2 Dep+ n (row%)	Total
Total	79	25	104
Remission/Low (R./L)	49 (96%)	2 (4%)	51
Moderate/High (M/L)	30 (57%)	23 (43%)	53
	p <0.0001		
Remission/Low SJC <2	47 (96%)	2 (4%)	49
Remission/Low SJC ≥2	2 (100%)	0	2
Moderate/High SJC <2	15 (52%)	14 (48%)	29
Moderate/High SJC ≥2	15 (63%)	9 (37%)	24
	p <0.0001	p=0.27	

Demographic and MDHAQ index data for anxiety, depression, fibromyalgia, and RAPID3 in routine care patients with osteoarthritis or rheumatoid arthritis

Results: The study included 104 RA patients, with median CDAI of 10.5 and interquartile range (IQR) 11.6, classified as moderate disease activity. Among the 104 patients 17 (16%) were FAST4+, 17 (16%) MDS2+, 9 (9%) were FAST4+ & MDS+ (8 each were FAST4+, MDS2- or FAST4-, MDS2+), and 79 (76%) were FAST4-,MDS2-.CDAI R/L activity was seen in 51 (49%) and M/H in 53 (51%) patients. Among the 51 in R/L, 49 (96%, 47% of all patients) were FAST4-,MDS2-, while 2 (4%, 2% of all patients) were FAST4-,MDS2+. Conversely, among the 53 patients in M/H activity, 30 (57%, 29% of all patients) were FAST4-,MDS2-, while 23 (43%, 22% of all patients) were FAST4+ or MDS2+ (or both FAST4+,MDS2+) ($p < 0.0001$) (Table). Further stratification of patients according to CDAI category, SJC of < 2 vs ≥2, and FAST4 and MDS2 status indicated that CDAI R/L patients included 47 FAST4-,MDS2- and with SJC< 2 vs 2 with SJC ≥2, compared to 15 CDAI M/H patients each with FAST4-,MDS2- or FAST4 or MDS2+ ($p < 0.0001$) (Table). By contrast, no significant differences in SJC vs CDAI categories were seen in FAST4+ or MDS2+ patients (p-0.27), although numbers are small.

Conclusion: About half of unselected RA patients seen in routine care who were in M/H CDAI activity screened positive for FM, DEP or both, in contrast to only 4% of those in R/L activity.FM or DEP were screened for on MDHAQ indices FAST4 and MDS2, with minimal extra time required for the physician.Patients in M/H CDAI activity did not differ significantly for SJC < 2 vs ≥2, regardless of FM or DEP status. These findings extend prior evidence that non-inflammatory comorbidities may elevate RA index levels, with implications for treat to target and general rheumatology care.

How Did a Mandatory Switch Policy Influence the Uptake of Adalimumab Biosimilar and Other TNF Inhibitors?

Nick Bansback[1], Michael law[1], Fiona Clemont[2], Mina Tadrous[3], Sandra Blitz[1] and Mark Harrison[1], [1]University of British Columbia, Vancouver, BC, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]University of Toronto, Toronto, ON, Canada

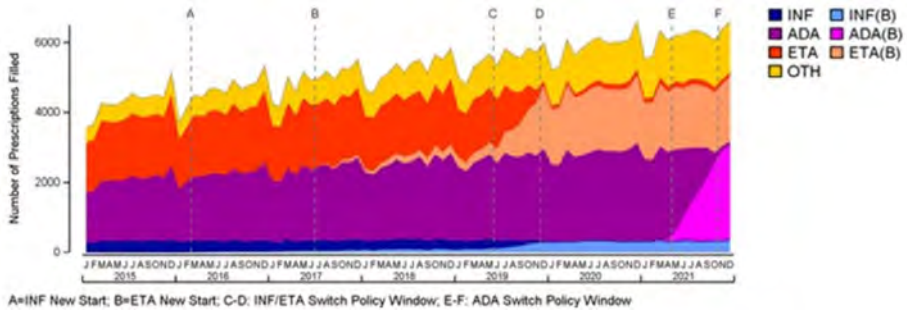
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In response to the low uptake of biosimilars, British Columbia (BC) in Canada became the first jurisdiction in North America to require patients with inflammatory arthritis to switch to a biosimilar in order to maintain coverage. While the impact of this policy on etanercept (ETA) and infliximab (INF) has been previously reported, this study considered the impact of the policy on adalimumab (ADA) when the biosimilar became available in 2021.

Methods: We used administrative data from British Columbia (Population Data BC) to derive a cohort of patients with inflammatory arthritis being prescribed TNF inhibitor therapy before the policies were introduced. Previously established case definitions including ICD codes were used to establish patients with different inflammatory diseases. The data included both public and private coverage since commercial insurers providing supplementary drug coverage also aligned their policies with the BC Provincial government. Exceptional coverage for reference products was permitted under both biosimilar switching policies if medically necessary. We used descriptive statistics to analyze the trend of uptake pre and post the policy period, and a quasi-experimental interrupted time series analysis to consider the change in trends. We used interrupted time series analysis to estimate biosimilar uptake.

Results: The study identified 11,171 BC residents aged 18 years or older who were using a TNF inhibitor during the study period (01/2015-12/2021). The mean age of the cohort was 54 years and 59% were female. During the first switch policy that included mandatory switches for ETA and INF in 2019, biosimilar prescriptions increased from 7.9% to 35.0% of all TNF prescriptions. After the first switch period, there was a small but consistent decline in overall biosimilar use, with an increase in golimumab and certolizumab prescriptions. During the second switch policy in 2021 which focused on adalimumab, overall biosimilar prescriptions increased from 34% to 72% of all TNF inhibitor prescriptions. In December 2021, 96.4%, 93.0% and 92.0% of prescriptions for ADA, ETA and INF respectively were biosimilar products.

Conclusion: The study findings indicate that a mandatory switch policy for biosimilar adalimumab has been as successful as the policy for infliximab and etanercept achieving high biosimilar use in British Columbia. Prior to the policy, uptake was low indicating the need for such a policy to influence change. Further analysis will explore changes in other healthcare utilization and assess the long-term effects of these policies. These findings are particularly relevant to regions with concentrated insurance systems, as mandatory switching policies could yield greater cost savings.



Utilization of TNF inhibitors - originators and biosimilars - in patients with inflammatory disease over time

Session Date: Tuesday, November 14, 2023

Session Title: (1840–1861) Health Services Research Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous disease that disproportionately affects women, racially and ethnically minoritized populations, and people of lower socioeconomic status (SES). Though SLE diagnosis and treatment have improved, United States health disparities persist. Our prior urban center study showed that living in disadvantaged neighborhoods was one of the strongest factors associated with fewer SLE visits and labs. The current study aimed to expand upon findings by examining SLE across rural, urban and suburban academic institutions in the state to identify care gaps and damage.

Methods: Our cohort included patients with prevalent SLE and at least one rheumatology and one primary care visit at one of three tertiary care centers in a Midwest state: urban, suburban, and rural populations. Process measures included receipt of any hydroxychloroquine (HCQ) (or documented contraindication or intolerance) and HCQ adherence defined as prescriptions covering >/=80% of calendar days (2014). Primary outcomes were time to new SLICC damage index (SDI) events or death 1/1/2015-12/31/2020. Processes and outcomes were reported by race, ethnicity, and Area Deprivation Index (ADI), a composite of 17 variables depicting neighborhood disadvantage. Data were analyzed using descriptive statistics and Cox proportional-hazards models.

Results: A total of 954 SLE patients were identified. Most were female (90.58%) and White (73.06% vs 21.28% Black; Table 1). Average age at SLE diagnosis was 43.38 (SD 14.92). Patients of Black race were diagnosed at an earlier age (38.23, SD 12.26 vs 45.37, 15.22 White). Most patients of Black race were from the urban site (73.89%). Black patients also had a much higher representation in the most disadvantaged ADI neighborhood quintile (42.25% vs 3.44% White). Antiphospholipid syndrome was more prevalent in White patients (15.20% vs. 9.5% Black); renal disease more prevalent in Black patients (59.61% vs. 29.12% White).

No statistically significant differences in HCQ use were noted by ADI or ethnicity, but compared to White patients, those of Black race had higher rates of prescription or contraindication for HCQ (97.38% vs 92.64 White%, p=0.002). Black patients had 9.37% lower adherence defined by prescriptions covering >/=80% of days (56.45% v. 65.82%, p=0.023). Yet, HCQ adherence did not predict SDI damage (38% with vs 33% without >/=80% HCQ days). Table 2 shows more damage in White and less disadvantaged. Limits include possible selection or follow up bias, and adherence by prescribing data.

Conclusion: SLE patients of Black race were much more likely to live in the most disadvantaged ADI quintile in this cohort. Black patients were more likely prescribed HCQ but less likely to have >/= 80% of days prescribed than White patients. In sum, data showed no significant disparities in HCQ use by neighborhood ADI or ethnicity at these tertiary centers, but did

Table 1. Statewide lupus cohort description (n=954 with complete data)

		Prevalent SLE (n=954) (%)	Black (n=203, 21.28%) (%)	White (n=697, 73.06%) (%)
SLE by ACR Criteria		93.29	93.10	93.26

Abstract Number: 1860

Evaluation of the Receipt of Adequate Pharmacological and Psychological Treatment for Incident Depression and Anxiety in Individuals Living with Inflammatory Arthritis

Alyssa Howren[1], Eric Sayre[2], J. Antonio Avina-Zubieta[3], Joseph Puyat[1], Deborah Da Costa[4], Hui Xie[5], Amit Gupta[1] and Mary De Vera[1], [1]University of British Columbia, Vancouver, BC, Canada, [2]British Columbia Centre on Substance Use, Vancouver, BC, Canada, [3]Arthritis Research Canada, Vancouver, BC, Canada, [4]McGill University, Pointe-Claire, QC, Canada, [5]Simon Fraser University, Richmond, BC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To describe patterns of pharmacological and psychological treatment and evaluate the receipt of minimally adequate treatment for incident depression and anxiety in individuals with inflammatory arthritis (IA), specifically ankylosing spondylitis (AS), psoriatic arthritis (PsA), and rheumatoid arthritis (RA).

Methods: Our cohort study used population-based linked administrative health databases from Population Data BC to identify individuals (≥18 years)with IA and IA-free controls matched on age, sex, and incident depression or anxiety. We assessed mental health treatment in the first year following incident depression or anxiety and pharmacological treatments were identified using Anatomical Therapeutic Chemical codes for antidepressants and anxiolytics. Psychological treatments were identified using fee-item codes that included publicly funded counselling, psychotherapy, and psychiatrist visits. We defined minimally adequate pharmacological treatment as antidepressant prescriptions filled with ≥84 days of supply. We defined minimally adequate psychological treatment as the receipt of ≥4 counselling/psychotherapy services. Multivariable logistic regression models, adjusted for age, sex, comorbidities, income, and residence, were used to evaluate the odds of individuals with IA receiving minimally adequate pharmacological or psychological care for their incident depression or anxiety as compared to IA-free controls.

Results: Cases of incident depression were identified in 6,951 individuals with IA (mean age 54.8 ± 18.3 years, 65.5% female) and 6,951 IA-free controls (mean age 54.8 ± 18.3 years, 65.5% female). Incident anxiety was identified among 3,701 with IA (mean age 52.9 ± 16.8 years, 74.3% female) and 3,701 IA-free controls (mean age 52.9 ± 16.8 years, 74.3% female) (**Table 1**). More than half of the IA and control study sample with depression had ≥1 antidepressant prescription filled (IA 64.3%; controls 61.4%). Fewer individuals with IA and comorbid anxiety had ≥1 antidepressant (IA 58.5%, controls 54.2%) or ≥1 anxiolytic (IA 46.8%, controls 40.1%) prescription dispensed. The receipt of minimally adequate pharmacological and psychological treatment for depression was observed in 50.5% and 19.6% of those with IA, respectively, with no significant difference compared to controls (pharmacological: adjusted odds ratio [aOR] 1.01, 95% confidence interval [CI] 0.90 to 1.13; psychological: aOR 0.96, 95% CI 0.88 to 1.05). The proportion receiving minimally adequate pharmacological (IA 46.9%, controls 44.1%) and psychological (IA 20.2%, controls 19.0%) treatment for anxiety was also similar between individuals with IA and controls (pharmacological: aOR 0.91, 95% CI 0.77 to 1.08; psychological: aOR 1.04, 95% CI 0.92 to 1.18).

Table 1. Characteristics of individuals with inflammatory arthritis (IA) and IA-free controls with incident depression or anxiety.

	Depression		Anxiety	
Characteristic	**IA (n=6,951)**	**IA-free Controls (n=6,951)**	**IA (n=3,701)**	**IA-free Controls (n=3,701)**

Descriptive statistics were determined for the year prior to IA index date.
Abbreviations: IA – inflammatory arthritis; SD – standard deviation

Conclusion: A large proportion of individuals with depression or anxiety were not receiving adequate care by means of medications and publicly funded mental health services, regardless of a comorbid IA diagnosis. Exploring methods for rheumatology to facilitate greater access to mental health care is imperative given the increased prevalence and negative impacts of depression and anxiety in this patient population.

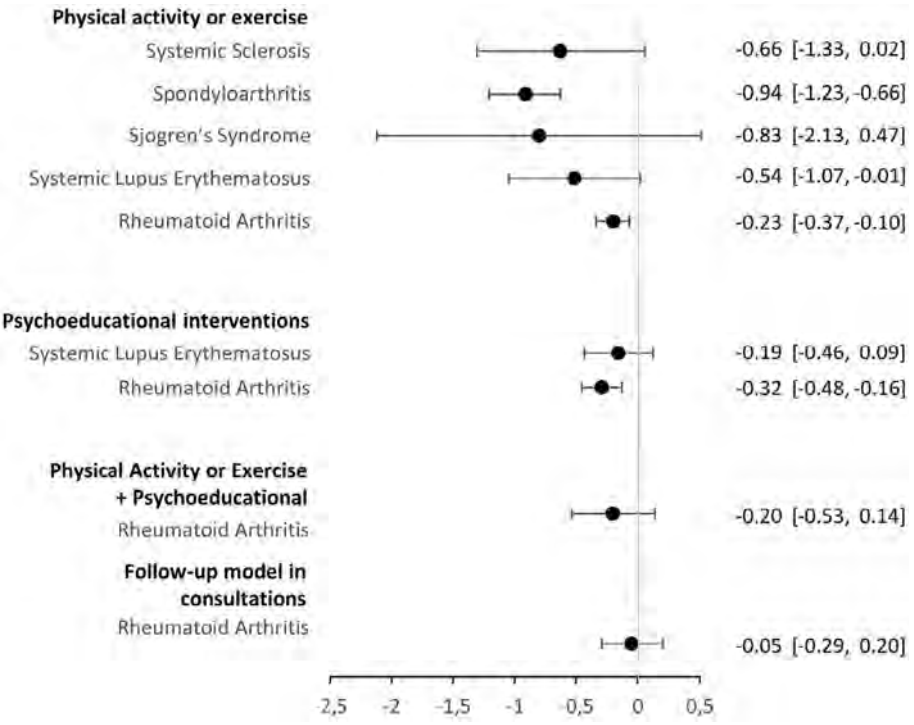
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1840–1861) Health Services Research Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To identify the best evidence on the efficacy of non-pharmacological interventions in reducing fatigue in people with I-RMDs and to summarise their safety in the identified studies to inform EULAR recommendations for the management of fatigue in people with inflammatory rheumatic and musculoskeletal disease (I-RMD).

Methods: Systematic review of adults with I-RMD conducted according to the Cochrane Handbook. Search strategy ran in Medline, Embase, Cochrane Library, CINAHL Complete, PEDro, OTseeker and PsycINFO. Assessment of risk of bias, data extraction, and synthesis performed by two reviewers independently. Data pooled in statistical meta-analyses.

Results: From a total of 4,150 records, 454 were selected for full-text review, 82 fulfilled the inclusion criteria, and 55 RCTs were included in meta-analyses. Physical activity or exercise were efficacious in reducing fatigue in rheumatoid arthritis (RA) (SMD=-0.23, $p< 0.001$), systemic lupus erythematosus (SLE) (SMD=-0.54, $p=0.04$) and spondyloarthritis (SpA) (SMD=-0.94, $p< 0.001$). A reduction in fatigue was also observed in Sjögren's syndrome and systemic sclerosis, although not statistically significant (SMD=-0.83, $p=0.21$; SMD=-0.66, $p=0.06$, respectively). Psychoeducational interventions were efficacious in reducing fatigue in RA (SMD=-0.32, $p< 0.001$), but not in SLE (SMD=-0.19, $p=0.18$). Follow-up models in consultations and multicomponent interventions reduced fatigue in RA, although the effect was not statistically significant (SMD=-0.05, $p=0.71$; SMD=-0.20, $p=0.24$, respectively) (**Figure**). The narrative results of the RCTs not included in the meta-analysis indicated that several other non-pharmacological interventions were efficacious in reducing fatigue, with reassuring safety results.



Conclusion: Non-pharmacological interventions are efficacious and safe for the management of fatigue in people with I-RMD.

Session Date: Tuesday, November 14, 2023

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Table. Thoracic and Lumbar Spinal Imaging features in a cohort of 136 patients referred for low back pain.

	DISH	DEGENERATIVE	AS	All	p-value
Total number of patients	**38**	**71**	**27**	**136**	
Thoracic Spine Xray					
Presence of SpA changes, N patients/ All patients in the group (%)	10/36 (27.8)	5/66 (7.6)	3/26 (11.5)	18/128 (14.1)	0.024
Presence of degenerative changes, N patients/ All patients in the group (%)	36/36 (100)	58/66 (87.9)	25/26 (96.1)	119/128 (93.0)	0.055
Lumbar Spine Xray					
Presence of SpA changes, N patients/ All patients in the group (%)	7/32 (21.9)	14/62 (22.6)	11/22 (50.0)	32/116 (27.6)	0.034
Presence of degenerative changes, N patients/ All patients in the group (%)	30/32 (93.8)	58/62 (93.5)	21/22 (95.5)	109/116 (93.9)	1.000

Background/Purpose: Degenerative changes of the spine (DC), diffuse idiopathic skeletal hyperostosis (DISH) and radiographic axial Spondyloarthritis (r-axSpA) may present with overlapping inflammatory and degenerative findings on imaging, which, next to the general symptom of chronic back pain might, represent a challenge for an accurate diagnosis. We aimed to evaluate the distribution of spinal imaging features in a real-life cohort of patients with chronic back pain referred to a tertiary university rheumatology center and identify those associated with DC, DISH or r-axSpA.

Methods: In a cross-sectional analysis of patients with chronic low back pain, demographic and disease data were collected. Imaging of the spine (thoracic or lumbar) and sacroiliac joints was performed per the clinical indication. All images were evaluated by two independent trained readers including erosions, sclerosis, squaring, osteophytes and syndesmophytes on conventional radiographs (CR) and bone marrow edema (BME) or degenerative changes on magnetic resonance imaging (MRI). The final diagnosis made by the rheumatologist at discharge was the gold standard. Data were presented descriptively and compared among the three diagnosis groups (DC, DISH and axSpA).

Results: Among 136 referred patients, 71 had DC, 38 DISH, and 27 r-axSpA. Mean age was 63.2±11.4 (p=0.135 among the three groups), and 86 (63.2%) were males (88.9% in axSpA, p=0.003). Patients had high levels of comorbidities: 91 (72.8%) had hypertension (higher in the DC group, 52 (82.8%), p=0.04), 37 (27.6%) had diabetes (higher in DISH, 39.5%, p=0.012) and 31 (23.3%) were current smokers (higher in axSpA, 53.8%, p< 0.001). Although axSpA-related spinal changes on CR were expectedly more prevalent in the axSpA group (thoracic 14.1%, p=0.024; lumbar 93.9%, p=0.034), they were also present in DISH (27.8% and 21.9%) and DC (7.6% and 22.6%, respectively). DC were present in the three groups in 93.0% in the thoracic and in 93.9% in the lumbar spine, without a statistically significant differences (Table). Similarly, on thoracic and lumbar spine MRI, BME was present in DISH in 33.3% and 41.7% and in DC in 20.4% and 32.7% lumbar spines, respectively.

Conclusion: A significant overlap of inflammatory and degenerative features on spinal imaging among patients with DC, DISH or axSpA was found in this older group of patients. Particularly, r-axSpA-related spinal CR features were found in a fourth of patients with DISH, while MRI BME was found in a third of them.

Immune-mediated Hypertrophic Pachymeningitis: Focusing on the Localization and Volume of Thickened Dura Mater Lesion

Yasuhiro Shimojima[1], Junji Ikeda[2] and Yoshiki Sekijima[1], [1]Department of Medicine (Neurology and Rheumatology), Shinshu University School of Medicine, Matsumoto, Japan, [2]Department of Medicine (Neurologu and Rheumatology), Shinshu University School of Medicine, Matsumoto, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypertrophic pachymeningitis (HP) is a rare inflammatory neurological disorder characterized by the thickened dura mater with extensive tissue fibrosis and immune-mediated inflammation. Notably, headaches and cranial neuropathies are frequently observed in immune-mediated HP, which is attributed to antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis or IgG4-related disease as the common underlying diseases. However, it is still obscure how the volume and localization of HP lesions affect the development of the relevant neurological impairments. This study evaluated the quantification and localization of the thickened dura mater and analyzed their impact on clinical findings in immune-mediated HP.

Methods: We evaluated the volume of the contrast-enhanced dura mater on magnetic resonance imaging in 19 patients with HP, including 12 with ANCA-related, 4 with IgG4-related, and 3 with idiopathic HP, by the imaging feature quantification system. We enrolled 10 patients with multiple sclerosis (MS) as controls. In patients with HP, the impacts of HP volume on neurological symptoms and cerebrospinal fluid (CSF) laboratory markers were statistically analyzed. The receiver operating characteristic (ROC) curve analyses were also performed to detect the cut-off volume of the contrast-enhanced dura mater.

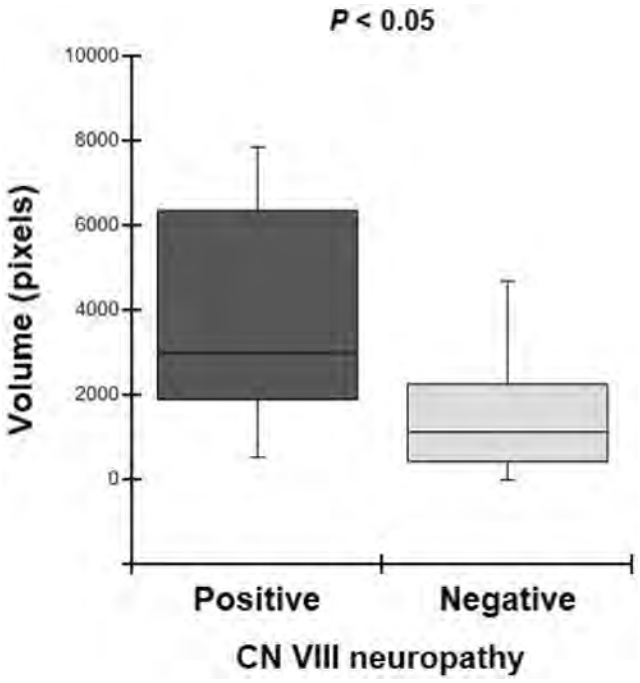

Figure 1: The volume of the thickened dura mater in the cranial fossa between patients with and without cranial nerve (CN) VIII neuropathy

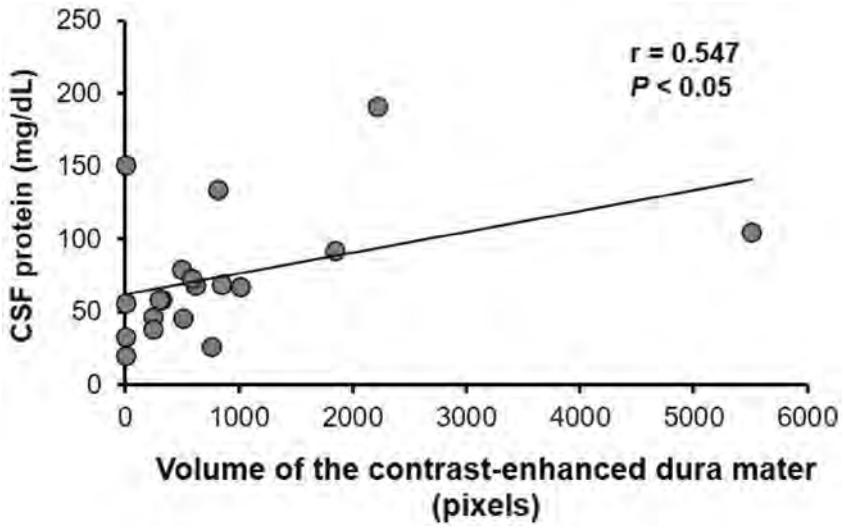

Figure 2: Correlation between the volume of the thickened dura mater in the tentorium cerebelli and cerebrospinal fluid (CSF) protein levels

Results: Patients with HP demonstrated significantly higher volumes of the contrast-enhanced dura mater in the convexity, cranial fossa, and tentorium cerebelli than those with MS ($P < 0.01$). Of the 19 patients with HP, more than the cut-off volume in the convexity, cranial fossa, and tentorium cerebelli was observed in 16 (84%), 12 (63%), and 15 (79%) patients, respectively. Meanwhile, the volume of the contrast-enhanced dura mater was not significantly different among patients with ANCA-related, IgG4-related, and idiopathic HP. In patients with HP, those with cranial nerve (CN) VIII neuropathy had a significantly higher volume of the contrast-enhanced dura mater in the cranial fossa than those without CN VIII neuropathy ($P < 0.05$) (**Fig. 1**). The cut-off volume in the cranial fossa was more frequently exceeded in patients with CN VIII neuropathy than in those without CN VIII neuropathy. A positive correlation between the volume of the contrast-enhanced dura mater in the tentorium cerebelli and CSF protein levels was significantly observed in patients with HP ($P < 0.05$) (**Fig. 2**).

Conclusion: HP lesions in the cranial fossa may be robustly implicated in impairing CN VIII. The enlargement of HP lesions in the tentorium cerebelli can increase CSF protein levels. This study suggests that quantification of the thickened dura mater is useful for elucidating the relationship with the clinical findings in immune-mediated HP.

Quantifying Inflammation: A Novel *In-Vivo* Total Body PET Imaging Tool to Determine the Kinetics of the Degree of Changes in Inflammation in Different Time Points

Siba Raychaudhuri[1], Sanchita Raychaudhuri[2], Naveen Chandrasekar[3], Christine Abria[3], Sneha Banerjee[3], Smriti K Raychaudhuri[3] and Abhijit Chaudhari[2], [1]UC Davis, School of Medicine/ VA Medical Center, Sacramento, Davis, CA, [2]UC Davis School of Medicine, Sacramento, CA, [3]VA Sacramento Medical Center, Mather, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Collagen-induced arthritis (CIA) mouse model is one of the best recognized animal model for autoimmune diseases. In this model clinical methods of evaluating inflammation and its severity are flawed due to observer bias; for histological studies mice need to be sacrificed so longitudinal studies in the same mouse cannot be performed. The hypothesis of our study was that as by PET imaging the degree of inflammation can be quantified so in a CIA mouse model by total body PET (TB-PET) imaging (i) we should be able to quantify the total inflammatory burden (SUVmax) to determine the kinetics of the degree of changes in inflammation with the progress of the disease (ii) this will allow to perform longitudinal studies to determine the efficacy of novel drugs within days.

Methods: Arthritis was induced using bovine type II collagen in DBA/1J mice (n=40) as per the standard protocol; mice developed arthritis around Day 28. The mice (n=10) had weekly PET imaging that is on day 28, day 35, day 42, and day 56. The maximum ^{18}F-FDG uptake (SUV score) was determined for the most severe joint in each mouse to generate a comprehensive**PET score (PS).** To further evaluate about applications of this model for quantitative longitudinal studies for therapeutic response 15 mice were treated with mouse anti-IL-23 mab; these mice received anti-IL23 mab weekly injections of 100ug/mouse for 4 weeks (Day35, Day42, Day49and Day56). Mice were scored clinically and scanned on these days and on day 63 one week after completion of the 4th dose. Mice (n=5) were additionally scanned on "day 5" and on "day 10" to determine early clinical response of IL-23p19 antibody.

Results: The clinical scores (CS) as well the **PET scores (PS)** for arthritis in the untreated mice gradually increased with time. The median clinical score**(CS)**increased with time to 2, 2.5, 3, 3.5 and 3 respectively on day 28, 35, 42 and 56. The PS SUV score (SUVmax) on Day 0 was 1.02. PS median values compared to the Day "0" increased to 1.52 on day 28 ($p< 0.05$), 3.5 on day 35 ($p< 0.05$),4.5 on day 42 ($p< 0.05$) and 3.5 on day 56 ($p< 0.05$). Our results confirm that the kinetics of the total inflammatory load can be quantified at different time points. The murine anti-IL-23 mAb treatment provided expected results, with time CS reduced from 7.3±1.8 (n=12) on day 35 to 2.8±1.1 (n=12) on day 63 ($p< 0.001$). Quantified *in vivo* PS median values as well showed improvement, PS (SUVmax) median values compared to the day 35 (before treatment) in this longitudinal study decreased with time: 2.0 on day 35 (before treatment), 1.8 on Day 40, 1.5 on Day 45 ($p< 0.05$), and 1.3 on day

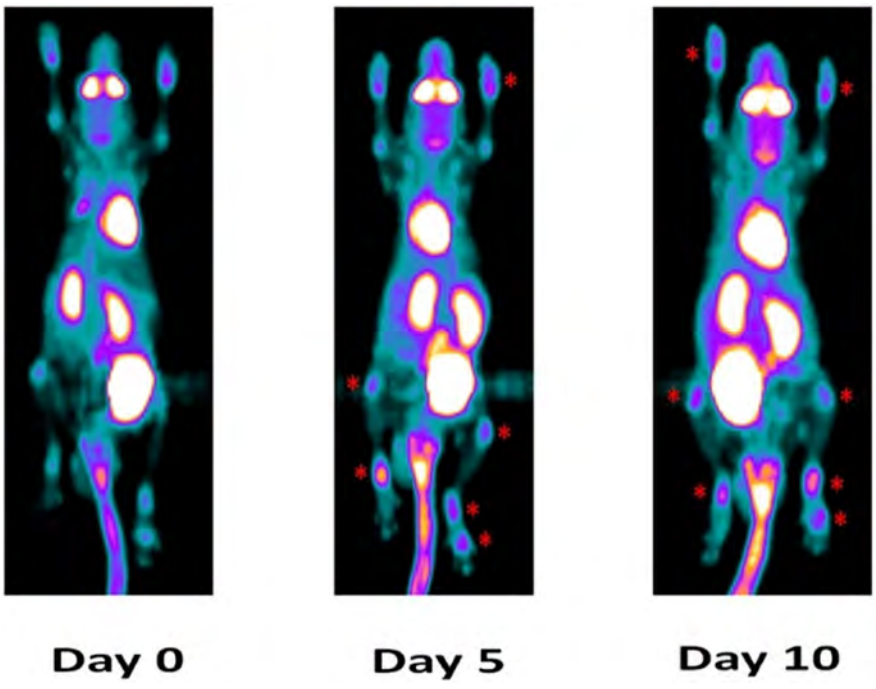

Figure 1. Untreated mice displayed increased inflammation on limb joints with increased PET signaling as marked by the red stars. This mouse not treated with anti-IL-23p19 mAb in longitudinal study by PET imaging demonstrated a progressive increase of PET signaling that is higher degree of inflammation on both fore and hind limb joints on Day 5 and Day 10.

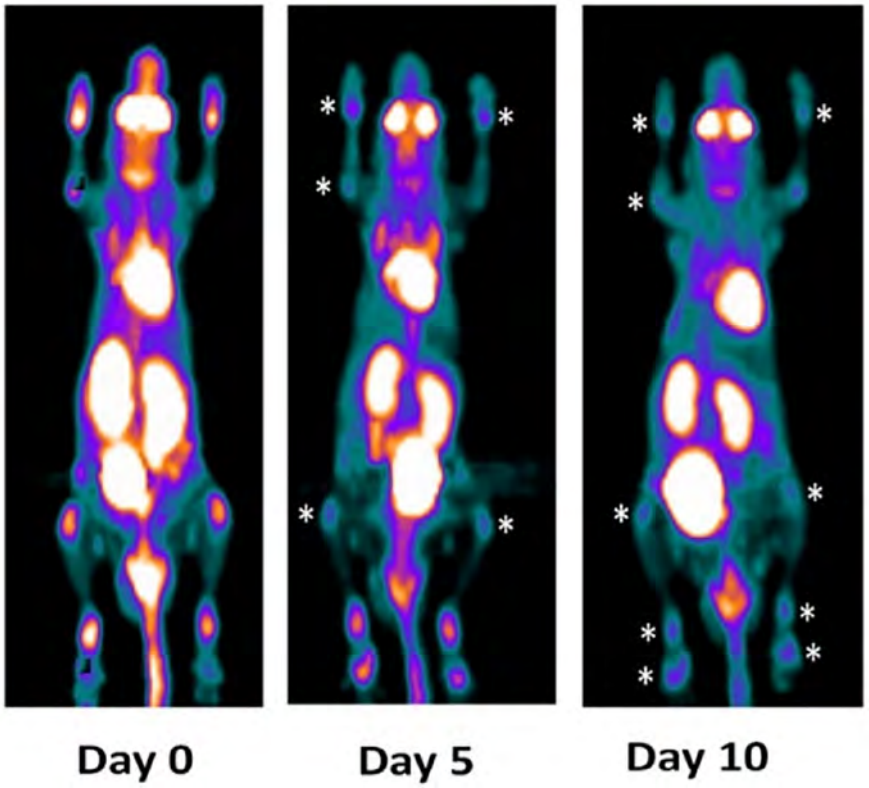

Figure 2. Efficacy of anti-IL23 mab could be identified as early as on the day 5 as identified by the white stars. This mouse treated with anti-IL-23 mAb in longitudinal study by PET imaging demonstrated progressive reduction of PET signaling that is the degree of inflammation on both fore and hind limb joints on Day 5 and Day 10.

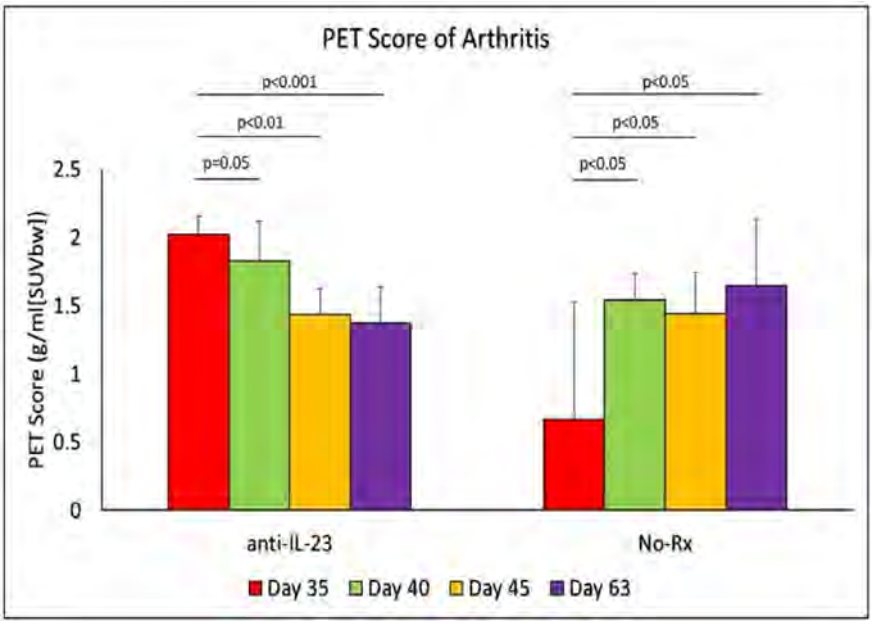

Figure 3. PET Score (SUVmax) of Arthritis with and without treatment: Change in PET Score (SUVmax) over the study to demonstrate the change in inflammation in treatment against the control group. Day 35 was the beginning of anti-IL23 antibody treatment and imaging, with further imaging on days 40, 45, and 63. Mice without any treatment showed significant increase in inflammation, while mice with anti-IL-23 antibody treatment demonstrated significant decrease of inflammation.

63 ($p < 0.05$) (Figure 1,2,3). These results demonstrated the unique quantifiable measures of therapeutic efficacy of anti-IL-23 mAb.

Conclusion: Our results demonstrate the quantification of the kinetics of degree of change in inflammation provided by the PET-CIA model; while the mice treated with mAb showed therapeutic efficacy as early as on the Day 5 (Figure 2,3). Thus, this model will be a novel tool for monitoring inflammatory load and a unique tool to evaluate efficacy or resistance to therapies during early stages of treatment. With time we are transferring these observations to quantify the degree of inflammation in human with RA and PsA.

Abstract Number: 1865

Is Flexion Contracture in Knee Osteoarthritis Associated with MRI Pathologies over Time? Data from the Osteoarthritis Initiative

Daniel Chan Chun Kong[1], Philip Conaghan[2] and Mark Campbell[3], [1]University of Ottawa, Ottawa, ON, Canada, [2]University of Leeds, Leeds, United Kingdom, [3]Elisabeth Bruyere Hospital, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Knee flexion contracture (FC) is associated with worse clinical outcomes in those with knee OA. Cross sectional data demonstrated that knee FC was associated with non-specific widespread MRI degenerative changes[1]. To our knowledge, there have been no longitudinal studies evaluating the association between knee FC and MRI-visualized OA-associated structural changes.

The purpose of this study is to determine whether baseline knee extension is associated with longitudinal knee structural changes on MRI, using data from the Osteoarthritis Initiative.

Methods: Retrospective cohort analysis using data from all 596 participants of the Foundation for the National Institutes of Health subset for whom knee extension and years 1 and 2 MRI data were available (1 knee/participant). MRIs were scored using the semi-quantitative MRI OA Knee Score (MOAKS). Participant demographics, body mass index (BMI), recruitment site, and baseline knee alignment and maximal extension were obtained. Baseline Kellgren Lawrence (KL) grade, and Western Ontario McMaster Osteoarthritis (WOMAC) Index score were also collected.

Univariate general linear model with analysis of covariance (ANCOVA) was performed to assess the association between baseline clinical knee extension (degrees) and MOAKS structural scoring at years 1 and 2, correcting for relevant clinical factors.

Results: Participant mean age was 61.5±8.9 years, BMI 30.7±4.9, mean KL grade 2.24 valgus 0.65, WOMAC total 12.7, with 58.7% being female. Max knee extension was 0.25±3.97°, alignment 0.34 valgus±3.68°.

Table 1. Associations between knee loss of extension and MOAKS ranked by effect size

Year 1		
Knee structure	**B [95% CI]**	**p-value[a]**
% BML - tibia medial posterior	-0.011 [-0.02,-0.002]	0.013
Osteophyte size - tibia medial	0.01 [0.002,0.018]	0.011
Osteophyte size - femur lateral anterior (trochlear)	0.009 [0.001,0.0017]	0.036
Osteophyte size - femur medial posterior	0.009 [0.001,0.017]	0.024
# BML lesions - tibia medial posterior	-0.004 [-0.007,-0.001]	0.02

Posterior	*% BML* *# BMLs* *Meniscal hypertrophy*		*Osteophyte size*	
Year 2				
Region	***Tibia***		***Femur***	
	Medial	*Lateral*	*Medial*	*Lateral*
Anterior				*Osteophyte size*
Central		*Meniscal extrusion*		
Posterior	*Meniscal hypertrophy* *Meniscal Tear*			*%BML* *BML size* *#BML*

[a] for knee extension association between MOAKS structure controlling for age, sex, BMI, recruitment site, knee alignment, baseline MOAKS for structure and site of interest, WOMAC score, and KL grade
CI: confidence interval
%BML: percent of bone marrow lesion comprised of edema
#BML: number of bone marrow lesions

Tables 1 and 2 summarize the associations between knee extension and MOAKSs pathologies by effect size and region at years 1 and 2.

Conclusion: Knee FC is associated with multiple OA structural pathologies at 1 and 2 years, with an anatomic predisposition to the posterior knee. At both years 1 and 2, osteophyte size at the lateral femur trochlea, lateral meniscal extrusion and medial meniscal posterior horn hypertrophy were consistently associated with baseline loss of knee extension. Further studies evaluating structural change mechanisms and potential early therapeutic interventions once a knee FC is detected are needed.

MRI Confirms MRE Evidence of Sacroiliitis in Many with Crohn's Disease: A Prospective Study for the Screening of axSpA in High-risk Populations

Fardina Malik[1], Soterios Gyftopoulos[1], Jordan Axelrad[1], Shannon Chang[1], Simon Hong[1], Maia McAllister[2], Morayo Kendra Olateru Olagbegi[3], Erin Alaia[1], William Walter[1], Accelerating Medicines Partnership Program RA SLE Network[4], David Hudesman[1] and Jose Scher[5], [1]NYU Grossman School of Medicine, New York, NY, [2]NYU, New York, NY, [3]New York University, New York, NY, [4]Cedars-Sinai Medical Center, Los Angeles, CA, [5]New York University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sacroiliitis can be detected incidentally on magnetic resonance enterography (MRE) scans in Crohn's disease (CD) patients, obtained for CD assessment during clinical practice. However, the diagnostic accuracy of MRE-based sacroiliitis has not been studied for clinical relevance and applicability. The purpose of this study was to prospectively enroll CD patients with previously positive MRE-based sacroiliitis and examine them for signs of spondyloarthritis (SpA), undergo standardized MRI of sacroiliac joints (MRI-SIJ) and determine clinical significance of this finding by rheumatological assessment.

Methods: CD patients with evidence of sacroiliitis on routine MRE were prospectively enrolled from the NYU Inflammatory Bowel Disease (IBD) Center. All subjects underwent standard MRI-SIJ at time of follow-up. Data collected included history-related CD, joint symptoms, back pain, 66-68 joint count, enthesitis scores and Harvey Bradshaw Index (HBI, a measure of CD activity). Use of tumor necrosis factor-alpha inhibitors (TNFi) and non-TNFi therapies were recorded at the

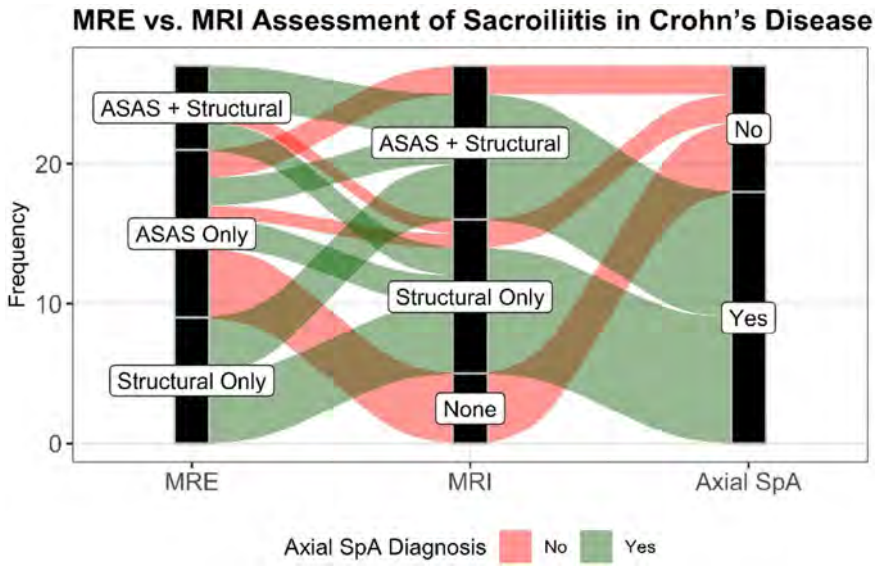

Figure: Alluvial plot showing evolution of sacroiliitis lesions between baseline MRE and follow up MRI and their relationship with axSpA diagnosis

time of MRE and MRI. MRI-SIJs were read by a blinded board-certified musculoskeletal radiologist. MRI was considered positive for sacroiliitis based on radiologist's global impression, Assessment of SpondyloArthritis International Society (ASAS) positivity and presence of structural lesions.

Results: 27 CD subjects with evidence of sacroiliitis on MRE were enrolled. 59.3% (n=16) were female, 88.9% (n=24) were white with a median age of 30 years [IQR: 27 – 43.5]. The median duration of CD was 3.2 years [IQR: 1.06 – 10.1] at the time MRE with a median HBI score of 4 [IQR: 1.5 – 7] consistent with mild CD activity. 37% of subjects were on TNFi and 14.8% were on non-TNFi therapy at the time of MRE. 66.6% (n=18) fulfilled ASAS positivity and 55.5% (n=15) with at least 1 structural lesion on MRE. The median duration between MRE and follow-up MRI was 2.13 years [IQR: 0.57 – 3.42]. 81.5% (n=22) of MRE-positive patients had evidence of sacroiliitis on the follow-up MRI, with 40.7% (n=11) fulfilling ASAS positivity. 23 subjects had back pain, and 15 subjects had inflammatory back pain (IBP) at the time of MRI. Of those with IBP, 93.3% (n=14) had MRI evidence of sacroiliitis. 66.7% (n=18) were determined to have Axial SpA (axSpA) by the assessing rheumatologist at the time of MRI. Median HBI was 3 [IQR: 2-6] at the time of MRI, suggesting remission. 48.1% and 33.3% of CD subjects were on TNFi and non-TNFi, respectively at the time of MRI. CD patients with structural lesions on the initial MRE were significantly more likely to have axSpA diagnosis on rheumatological assessment compared to those without (93.3% vs. 33.3%, p=0.003) (Figure 1).

Conclusion: Sequentially examined positive MRE scans in CD patients, obtained for standard of care, revealed a surprisingly high percentage of MRI-confirmed cases of sacroiliitis, many associated with clinical findings of axSpA. This study emphasizes the importance of MRE as a valuable screening tool to detect "hidden" sacroiliitis in CD patients, prompting rheumatological evaluation, which can impact therapeutic decision-making since only some of the currently available therapies for CD are effective in axSpA.

Abstract Number: 1867

Peripheral Volumetric Bone Mineral Density and Erosive Disease in Patients with Established Rheumatoid Arthritis: A Cross-Sectional Study Using High-Resolution Peripheral Quantitative Computed Tomography

Mathias Hänel[1], Rasmus Klose-Jensen[2], Josephine Therkildsen[3], Anne-Birgitte Garm Blavnsfeldt[3], Bente Langdahl[3], Stinus Gadegaard Hansen[4], Kresten Keller[5] and Ellen Margrethe Hauge[3], [1]Rheumatollogy, Aarhus University Hospital, Aarhus, Denmark, [2]Rheumatology, Aarhus University Hospital, Aarhus, Denmark, [3]Aarhus University Hospital, Aarhus, Denmark, [4]Odense University Hospital, Svendborg Sygehus, Svendborg, Denmark, [5]Department of Rheumatology, Aarhus University Hospital; Department of Clinical Medicine, Aarhus University, Aarhus, Denmark

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: High resolution peripheral quantitative computed tomography (HR-pQCT) is a promising imaging modality for assessing volumetric bone mineral density (BMD) in rheumatoid arthritis (RA), and has shown potential for use as an alternative to X-ray for detecting erosions in patients with RA. However, knowledge about the association between erosions and peripheral volumetric BMD is lacking. Thus, the aim of this study was to investigate the association between erosions and volumetric BMD in patients with RA.

Methods: In this cross-sectional study, 301 patients with established RA (disease duration > 5 years) according to the ACR/EULAR (2010) classification criteria were included. In total, 184 patients were imaged at the distal radius and 117 patients were imaged at the ultra-distal radius by HR-pQCT. All patients underwent radiographic examinations of the hands, wrists, and feet and were scored using the Sharp/Van der Heijde (SvH) method. Furthermore, the patients with RA imaged at the distal radius was matched by sex and age with a cohort of healthy controls (HC) with HR-pQCT of the distal radius (n =169).

Results: 301 patients with RA (median age 63.7 [55.1;70.8] years, 71 % women) were included in the study. The median disease duration was 14 [8;21] years. Compared with healthy controls, patients with RA had significantly lower total and cortical BMD at the distal radius (26.1%, $p < 0.0001$ & 13.0%, $p < 0.0001$), with no statistically significant difference in

Table 1: Results from HR-pQCT of the distal radius in patients with rheumatoid arthritis and healthy controls, matched by sex and age

	RA (n = 169)	HC (n = 169)	p
Tt. BMD (mg HA/cm³)	244.98 [63.35]	318.50 [76.43]	**<0.0001**
Ct. BMD (mg HA/cm³)	764.43 [104.34]	870.46 [68.31]	**<0.0001**
Tb. BMD (mg HA/cm³)	142.97 [44.04]	147.87 [46.17]	0.32
Ct. Th. (mm)	0.48 [0.20]	0.84 [0.23]	**<0.0001**
Tb. N. (1/mm)	2.03 [1.65;2.24]	1.95 [1.65;2.19]	0.28
Tb. Th. (mm)	0.060 [0.055;0.069]	0.063 [0.056;0.073]	**0.03**
Tb. Sp. (mm)	0.433 [0.374;0.533]	0.447 [0.389;0.547]	0.19
BV/TV	0.12 [0.04]	0.12 [0.04]	0.32

Tt. BMD = Total BMD, Ct. BMD = Cortical BMD, Ct. Th. = Cortical thickness, Tb. BMD = Trabecular BMD, Tb. N. = Trabecular number, Tb. Th. = Trabecular thickness, Tb. Sp. = Trabecular spacing, BV/TV = Bone volume/trabecular volume, HA = Hydroxyapatite.

Results are displayed as mean [SD] or median [IQR] and p-values are calculated according to distribution.

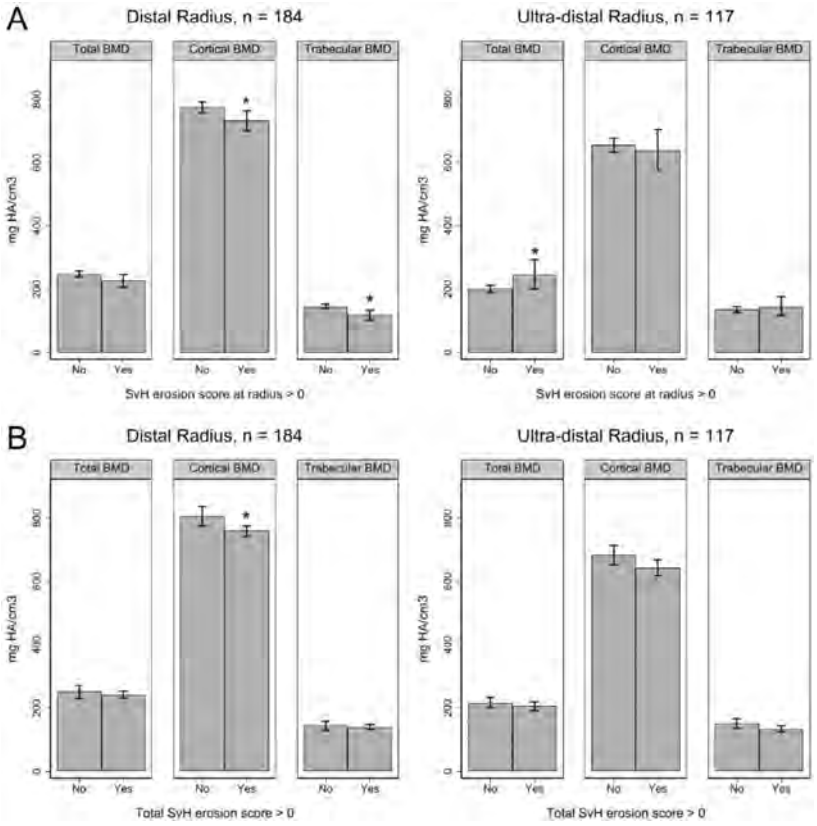

Figure 1: Mean and 95% confidence intervals for total, cortical and trabecular BMD at the distal and ultra-distal radius imaged by HR-pQCT (A): Stratified by Sharp/Van der Heijde erosion score at the radius. (B): Stratified by total Sharp/Van der Heijde erosion score. * = $p < 0.05$.

trabecular BMD. Furthermore, cortical and trabecular thickness was significantly lower in patients with RA compared to healthy controls (54.5%, $p < 0.0001$ & 4.9%, $p = 0.03$) (Table 1). Local erosions were associated with significantly decreased cortical and trabecular BMD at the distal radius ($p = 0.03$ & $p = 0.0008$), while at the ultra-distal radius, local erosions were associated with significantly higher total BMD ($p = 0.005$). Erosive disease in general was associated with significantly decreased cortical BMD at the distal radius ($p = 0.02$) with no statistically significant difference between the groups at the ultra-distal radius (Figure 1). At the distal radius, multivariate linear regression analyses showed a significant negative association between total SvH erosion score and trabecular BMD (coefficient = -0.28, $p = 0.001$) with no statistically significant associations between total and cortical BMD after adjusting for disease activity, sex, age, height, weight and tobacco pack years. At the ultra-distal radius, multivariate linear regression analyses showed a significant positive association between total SvH erosion score and total BMD (coefficient = 0.49, $p = 0.001$) with no statistically significant associations between total SvH erosion score and cortical and trabecular BMD.

Conclusion: Our results suggest that erosive disease in RA causes systemic bone changes resulting in decreased BMD at the cortical and/or trabecular bone compartment. This indicates that evaluation of erosive disease likely adds value to the assessment of systemic bone changes in patients with RA. Furthermore, it underlines the need for longitudinal studies investigating the changes in erosive status and BMD over time.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Radiographic joint damage progresses in 20-30% of rheumatoid arthritis (RA) patients despite fulfilling clinical remission criteria (1). Osteitis assessed on MRI is a well known predictor of subsequent radiographic bone damage progression (2). Therefore, targeting absence of osteitis combined with clinical remission may improve long-term radiographic outcomes. The purpose of the study was therefore: To investigate whether a 2-year MRI treat-to-target (MRI T2T) strategy targeting absence of osteitis combined with clinical remission, compared to a conventional T2T strategy targeting clinical remission only, could reduce radiographic joint damage progression over 5 years in RA patients.

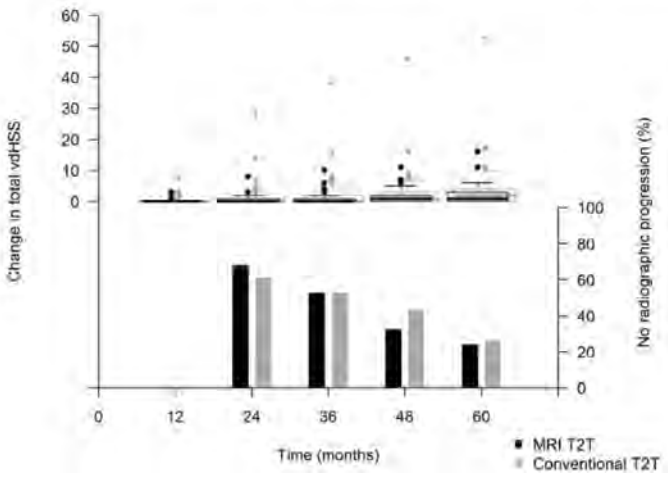
Methods: IMAGINE-more was designed as a 3-year observational extension study of the 2-year IMAGINE-RA randomized clinical trial (3). IMAGINE-RA included 200 RA patients in clinical remission (DAS28-CRP< 3.2 and no swollen joints), with erosive disease (bone erosion on conventional radiography),and treated with conventional synthetic DMARDs (csDMARDs).

TABLE: RADIOGRAPHIC ENDPOINTS AT 5 YEARS (CHANGE FROM BASELINE - YEAR 0)*

		MRI T2T		Conventional T2T	Difference between groups	P value
	n		n			
Primary endpoint						
No radiographic progression, No. (%)	59	14 (24%)	72	19 (26%)	OR=0.70 (0.28 to 1.71)	0.431
Key secondary endpoint						
Change in total vdHSS (0-448)	47	1.0 [0.0-3.0]	56	2.0 [0.0-4.0]	0.0 (-1.0 to 0.0)	0.515
Other secondary endpoints						
Change in erosion (0-280)	47	1.0 [0.0-2.0]	56	1.0 [0.0-3.0]	0.0 (0.0 to 0.0)	0.967
Change in JSN (0-168)	47	0.0 [0.0-0.5]	56	0.0 [0.0-1.3]	0.0 (0.0 to 0.0)	0.565

Group contrasts are presented as No. (%) for dichotomous data and medians [IQR] for continuous data. OR (95%CI) were estimated from logistic regression adjusted for a propensity score and with non-responder imputation. For endpoints with continuous data median differences (95%CI) were calculated based on the ITT population (no manual imputation) *In addition to the radiographic endpoints, the full IMAGINE-more study includes a clinical co-primary endpoint, and several secondary endpoints.

Figure: Changes from baseline to 5 years in total vdHSS (top) and proportions with no radiographic progression (bottom)



Illustrates the change in total vdHSS from baseline to 60 months (i.e., 5 years) based on the ITT population (no manual imputation done), as well as the proportions with no radiographic progression (delta total vdHSS<0) in each group from baseline to 60 months, with non-responder imputation.

The objective was to investigate whether a 2-year MRI T2T strategy targeting absence of osteitis combined with clinical remission (DAS28-CRP≤3.2 and no swollen joints) as compared to a conventional T2T strategy, targeting clinical remission only, could improve remission rates and prevent radiographic joint damage progression. If treatment target was not met, treatment was intensified stepwise starting with increment in csDMARDs and subsequently adding biologics. Participants in the IMAGINE-more extension study were managed in routine clinical practice in outpatient clinics. Clinical examinations and radiographs of hands and feet (also obtained at baseline, year 1 and 2 in IMAGINE-RA) were done year 3, 4 and 5. The primary endpoint was the proportion of patients with no radiographic progression (increase in total van der Heijde-modified Sharp score (vdHSS) ≤0) from baseline to year 5. Secondary endpoints were changes from baseline to 5 years in total vdHSS, vdHSS erosion and joint space narrowing (JSN) scores. Dichotomous endpoints were estimated by logistic regression, while median differences were calculated for the continuous outcome measures.

Results: Informed consent to participation in IMAGINE-more was obtained from 131 patients (59 from the originalMRI T2T group). Of these, 14 patients (24%) in the MRI T2T group and 19 patients (26%) in the conventional T2T group had no radiographic progression from baseline to year 5 (OR 0.70 [0.28 to 1.71]). As illustrated in the Table and Figure, the median progression in total vdHSS from baseline to 5 years was low, with no differences between treatment groups.

Conclusion: A 2-year combined MRI T2T and clinical T2T strategy, compared with a conventional clinical T2T strategy alone, did not result in reduced radiographic progression in the long term over 5 years in RA patients with erosive disease in clinical remission. In accordance with the primary results from the IMAGINE-RA trial, these findings do not support systematic use of MRI to guide treatment in RA patients in remission.

FDG-PET/CT for Diagnosing Polymyalgia Rheumatica Before, During and After a Short-term Prednisolone Cessation – a Prospective Study of 101 Patients

Andreas Wiggers Nielsen[1], Ib Tønder Hansen[2], Berit Dalsgaard Nielsen[3], Søren Geill Kjær[4], Jesper Blegvad-Nissen[4], Christian Møller Sørensen[3], Ellen-Margrethe Hauge[1], Lars Christian Gormsen[2] and Kresten Krarup Keller[1], [1]Aarhus University Hospital, Aarhus, Denmark, [2]Aarhus University Hospital, Aarhus N, Denmark, [3]Department of Internal Medicine, Horsens, Denmark, [4]Diagnostic Centre, Silkeborg, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) can be challenging to diagnose since other diseases may present with similar symptoms. As a result, a significant number of patients are referred to rheumatologists for a second opinion. However, a notable proportion of patients are administered prednisolone prior to rheumatologic assessment, which can obscure the symptoms of PMR and important differential diagnoses. ^{18}F-fluorodeoxyglucose(FDG) positron emission tomography and computed tomography (PET/CT) has been suggested as a potential tool to aid the clinician diagnosing PMR, but it is unclear whether PET/CT can be used after the initiation of prednisolone. This study aimed to investigate the diagnostic utility of FDG-PET/CT in patients suspected of PMR, specifically evaluating the diagnostic accuracy before, during, and after a short-term taper of prednisolone.

Methods: This study included 101 patients who were suspected of having PMR. All patients were clinically diagnosed with PMR or non-PMR at a baseline visit and subsequently had a PET/CT performed. Patients diagnosed with PMR were administered prednisolone with a starting dose of 15 mg following the first PET/CT. After 8 weeks of treatment a second PET/CT was performed when prednisolone had been tapered to 10 mg, according to an algorithm reflecting routine care. Afterwards, prednisolone was tapered with complete cessation at week 9 followed by a third PET/CT at week 10. A PET/CT assessment of PMR or non-PMR was given utilizing the validated Leuven score (Figure 1) [1]. The final diagnosis for all patients was confirmed at a 1-year follow-up visit.

Results: Preliminary results of the first 79 patients have been obtained, and the baseline characteristics of the PMR and non-PMR group are outlined in table 1. A baseline PET/CT diagnosis showed a sensitivity of 88.7% and a specificity of 61.5% using a clinical diagnosis at 1 year as the reference standard (Figure 1). The low specificity was partially explained by a high rate of false positive patients with a final diagnosis of other inflammatory diseases, since 8 out of 10 non-PMR patients with a final diagnosis of rheumatoid arthritis or reactive diseases had a PET/CT indicating PMR according to the Leuven score. After 8 weeks of prednisolone treatment the Leuven score decreased significantly, but in 14/46 patients the PET/CT diagnosis remained positive for PMR (Figure 2). After prednisolone cessation the Leuven score increased significantly, with a positive PET/CT diagnosis of PMR in 25/37.

Table 1 – Baseline data of patients with a final diagnosis of PMR and non-PMR (control group) based on 1-year follow-up visit

Baseline characteristics	PMR group n=53	Control group n=26
Age, mean ±SD	72 ±7.3	69 ±8.8
Female sex, n(%)	25 (47%)	13 (50%)
Symptoms at diagnosis:		
Bilateral shoulder pain	50 (94%)	18 (69%)
Limited range of shoulder movement	42 (79%)	5 (19%)
Bilateral hip girdle pain	45 (85%)	17 (65%)
Limited range of hip movement	29 (55%)	8 (31%)
Absence of other joint pain	28 (53%)	11 (42%)
Morning stiffness >45 min	36 (69%)	11 (44%)
Weight loss >2 kg	10 (19%)	4 (15%)
Lab work		
C-reactive protein (mg/L), median (IQR)	39 (25-57)	12 (4-35)
Erythrocyte sedimentation rate, mm, median (IQR)	49 (30-64)	29 (18-42)
PMR activity		
Treating physician global VAS-score, mean ±SD	6.2 ±1.9	2.9 ±2.6
Patient reported pain VAS-score, mean ±SD	7.2 ±1.6	5.8 ±2.0
PMR activity score, mean ±SD	26.1 ±21.6	13.7 ±7.6

Conclusion: Initiation of prednisolone treatment prior to PET/CT significantly reduces the diagnostic accuracy for a PMR diagnosis. Therefore, a short-term prednisolone taper is advisable before using PET/CT to diagnose PMR in patients treated with a medium dosage of prednisolone. Furthermore, PET/CT utilizing the Leuven score may not be reliable for differentiating PMR from other inflammatory disorders during the initial evaluation.

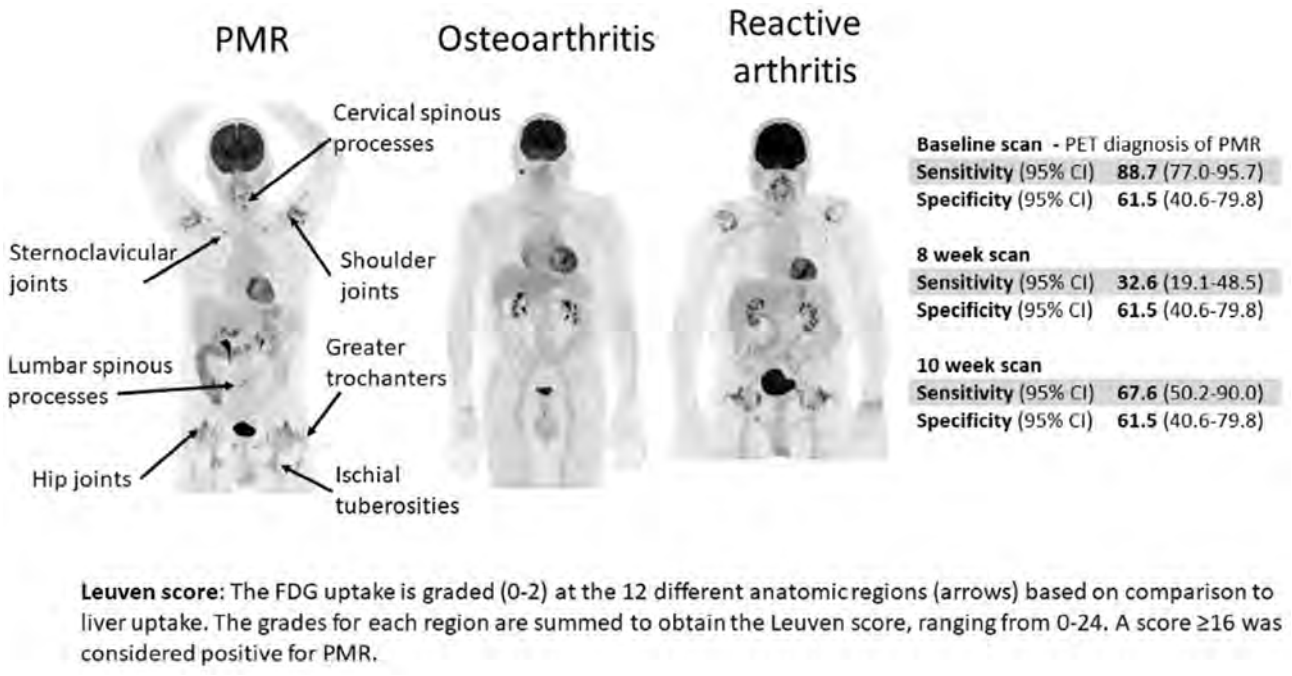

Figure 1 – PET/CT diagnosis of PMR at baseline, 8 weeks and 10 weeks using the Leuven score.

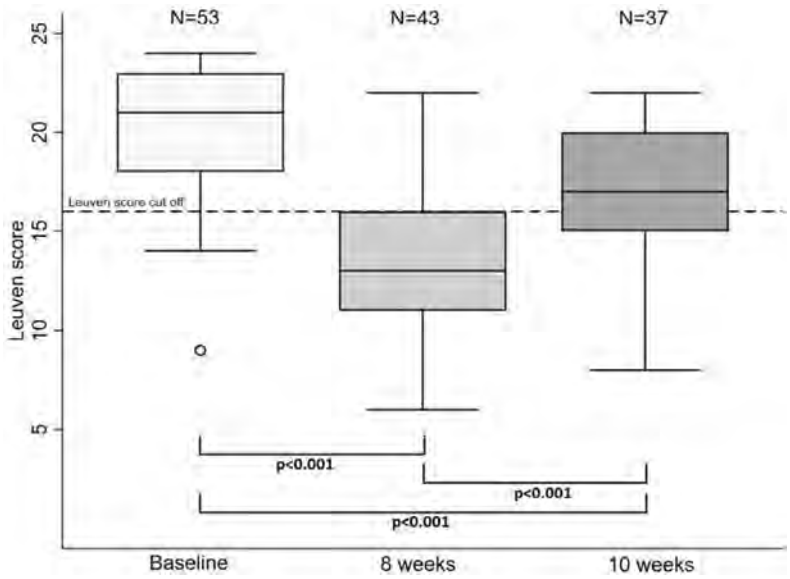

Figure 2 – Box plot of Leuven score at baseline, after 8 weeks of prednisolone treatment and at 10 weeks after a 2 week prednisolone taper.

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Low back pain (LBP) is a leading cause of doctor visits and disability. The annual direct expenditures for LBP management exceed $80 billion, not including indirect costs associated with prolonged disability and lost worker productivity. Despite increasing expenses over time, patient outcomes have not improved, which may be due to overutilization of diagnostic imaging, invasive procedures, and unnecessary specialty referrals. Many providers investigate anatomic structures as an underlying etiology for back pain, which can lead to inappropriate, and even harmful low-validity

Table 1. Demographics

tests. Therefore, evidence-based clinical practice guidelines for optimal utilization of imaging are highly recommended. This study identifies our current practice for utilization of lumbar spine imaging in patients with LBP in our outpatient clinic and outcomes based on imaging findings.

Methods: We used the electronic medical record to generate a patient list, including those 18 years and older who were managed for LBP and referred for lumbar spine imaging between January 1, 2022, and December 31, 2022. Patient demographics, baseline clinical characteristics, and subsequent interventions, such as referrals, counseling, physical therapy, pain management, spinal procedures, opioid prescription, and disability application, were recorded and analyzed using descriptive statistics.

Results: 170 patients were diagnosed with LBP during the study period. Of these, 49% received imaging, with 49% having plain radiography, 9% CT scans, and 40% MRI. 17% of patients had more than one imaging study done, from which 71% had plain radiography followed by MRI. Notably, 82% of those who had plain radiography followed by MRI were done during the chronic course of LBP. Among patients who received imaging, 26% had acute pain, 7% had subacute pain, and 67% had chronic pain. Imaging showed that 43% of the X-ray group had normal or nonspecific results, 73% of the MRI group had degenerative diseases, 44% had herniated discs, and 32% had spinal stenosis. Overall, only 3% of patients had serious diagnoses. Sixty six percent (66%) had lifestyle counseling and referral to physical therapy, 25% of patients were referred to spine specialists, 9% to rheumatologists, and 21% to pain specialists. Half of patients with chronic LBP were treated with muscle relaxants. Only 3% were prescribed opioids and 10% had spinal procedures. Interestingly, 5 patients were referred to rheumatologists for sacroiliac (SI) joint changes.

Conclusion: Majority of LBP in the outpatient setting have an uncomplicated, nonspecific course that require no further diagnostic evaluation. MRI of the lumbar spine is the modality of choice for the majority of patients requiring imaging per ACR appropriateness criteria. Lumbar spine radiographs are of limited utility and are generally only indicated when fracture is a concern. Complete history and careful physical and neurologic examinations are always the cornerstones of LBP management. Our study identifies the current clinical practice for utilization of imaging for patients with LBP among providers in our outpatient clinic. The study recommends further projects to optimize LBP management in our clinic based on evidence-based guidelines.

Abstract Number: 1871

Utility of Infrared Thermography in Patients with Digital Gangrene

Nidhish Chandra M, Puneet Kumar, Urmila Dhakad, Shweta Bhardwaj, Sanjay Pruthviraj Buddha, Parag Vijayvergia and Lily Singh, King George Medical University, Lucknow, India

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

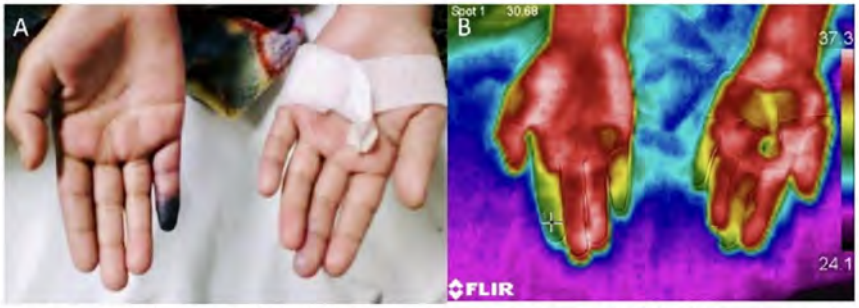
Background/Purpose: Digital gangrene has been described as a complication of several Autoimmune Inflammatory Rheumatic Diseases(AIIRD). Due to multiple underlying mechanisms causing digital gangrene in AIIRD patients, it is difficult clinically to determine the aetiology. Moreover, it is difficult to clinically assess and determine the progression of pregangrenous changes daily. In this study, we would like to assess the utility of infrared thermography in identifying the

Table 1: Baseline characteristics of patients with digital gangrene

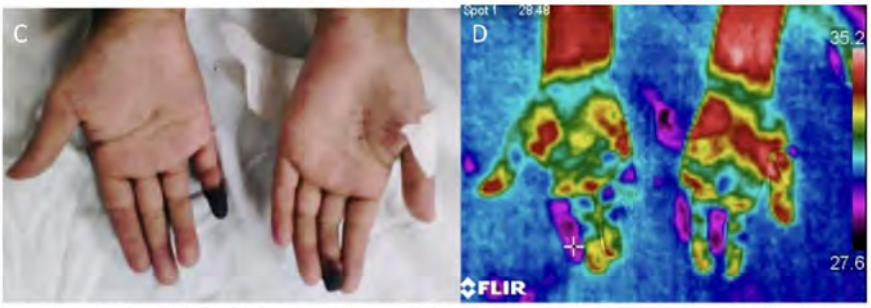
	All Patients (n=22)
Age (years)	29 ± 13.9
Females	16 (72.7%)
Etiology of gangrene at enrollment	
SLE vasculitis	9
RA vasculitis	2
Scleroderma	7
SLE vasculopathy	1
Mixed connective tissue disorder (MCTD)	1
Atherosclerosis	1
Buerger disease	1

aetiology of digital gangrene as well as assessing the daily progression of pregangrenous areas using infrared thermography principle.

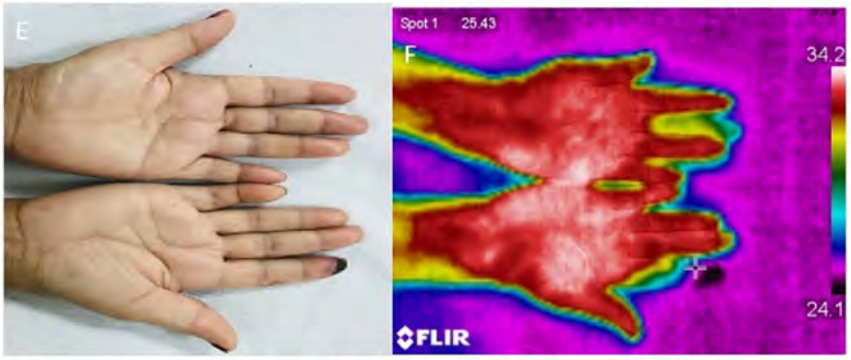
Methods: 22 patients with digital gangrene were included. Infrared thermography was done using compact thermal camera FLIR C5 which has a resolution of 19,200 pixels and an infrared sensor of 160*120 with thermal sensitivity of < 70 mK. Baseline thermography images will be taken on day 1 and will be repeated on daily basis till discharge to assess for daily



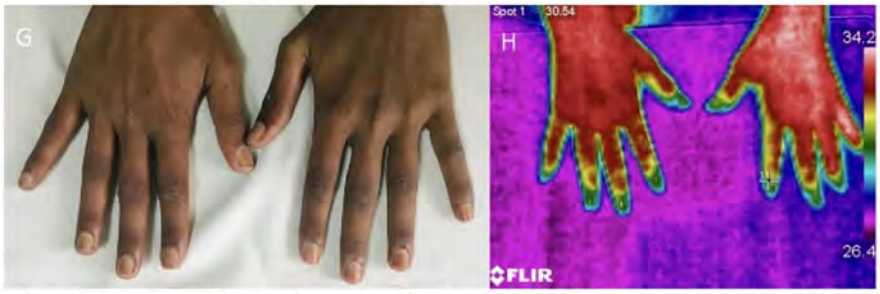
Panel A shows clinical image of a patient with gangrenous changes over right little finger. Panel B shows infrared thermography image of the same patient with reduced temperature over right index finger, little finger and left little finger and middle finger.



Panel C shows clinical image of the same patient on day 3 with new gangrenous change over left middle finger. Panel D shows infrared thermography image with reduced temperature over right index finger, little finger and left middle finger and little finger



Panel E shows clinical image of a patient with RA vasculitis with gangrenous change in right index finger. Panel F shows infrared thermography image of the same patient with reduced temperature in right index finger and left middle finger



Panel G shows clinical image of a patient with scleroderma with pregangrenous change in left index finger. Panel H shows infrared thermography image of the same patient with reduced temperature in all the fingers

progression of gangrene. Thermography images were correlated with clinical aetiology of gangrene to see for any specific pattern. Daily thermographic images were compared with clinical progression of gangrene to see if thermography could predict gangrene evolution.

Results: We found that infrared thermography was a useful tool for assessing pregangrenous lesion in patients presenting with digital gangrene. Out of 22 patients enrolled with digital gangrene, 3 had progressive gangrene in which infrared thermography image on day 1 showed reduced temperature of pregangrenous fingers which later became gangrenous. It was found that the mean temperature detected by using infrared thermography in gangrene due to vasculitis was 31.3 ±1.4°C whereas the mean temperature due to vasculopathic lesion was 27.8±1.6°C indicating that vasculopathic gangrene tend to be colder than vasculitic gangrene. Out of 9 patients who had vasculopathic gangrene, 7 had symmetrical reduction in temperature in both limbs which was clinically inapparent, indicating that infrared thermography could be used as a potential tool to detect vasculopathy. On monthly follow up of these patients, it was found that patients with vasculitic gangrene tend to have a better temperature response after treatment with immunosuppression when compared to vasculopathic gangrene indicating that infrared thermography could be utilised as a potential tool to assess treatment response in patients with vasculitis and vasculopathic gangrene.

Conclusion: Infrared thermography could be a utilized as a potential tool in assessing patients with digital gangrene especially in identifying pregangrenous lesions early, differentiating vasculitis and vasculopathic lesions and for assessing treatment response. Further studies are required to validate the use of infrared thermography in patients with digital gangrene.

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) is an essential tool in the evaluation of patients with axial spondyloarthritis (axSpA). In-depth knowledge of characteristic MRI lesions and their definitions, as well as reliability of identification and scoring, varies amongst general radiologists and rheumatologists.[1] A deep learning algorithm was developed to detect the presence of inflammation in SIJ MRI (MRI+) scans with promising results.[2] The aim of this diagnostic performance study was to assess the ability of a deep learning algorithm to identify MRI+ scans in a study cohort of axSpA patients.

Methods: 731 baseline SIJ MRI scans were collected from two prospective randomized controlled trial cohorts in patients with non-radiographic (nr-) and radiographic (r-) axSpA (RAPID-axSpA [NCT01087762] and C-OPTIMISE [NCT02505542])[3,4] and were centrally evaluated by two expert readers (and adjudicator in case of disagreement) for the presence of inflammation by the 2009 Assessment in SpondyloArthritis international Society (ASAS) definition.[5] The MRI scans were processed by the previously trained deep learning algorithm,[2] blinded to clinical information and central expert

Table. Performance results comparing the algorithm and the human readers for the classification of MRI-SIJ scans. The metric values are point estimate (95% CI)

	All (N=731)	RAPID-axSpA (n=152)	C-OPTIMISE (n=579)
Central reading, MRI+; n (%)	436 (59.6%)	99 (65.1%)	337 (58.2%)
Sensitivity	0.70 (95% CI: 0.66–0.73)	0.66 (95% CI: 0.58–0.73)	0.71 (95% CI: 0.67–0.75)
Specificity	0.81 (95% CI: 0.78–0.84)	0.89 (95% CI: 0.82–0.95)	0.79 (95% CI: 0.75–0.83)
PPV	0.84 (95% CI: 0.82–0.87)	0.92 (95% CI: 0.87–0.96)	0.83 (95% CI: 0.79–0.86)
NPV	0.64 (95% CI: 0.61–0.68)	0.58 (95% CI: 0.50–0.67)	0.66 (95% CI: 0.62–0.70)
Cohen's kappa	0.49 (95% CI: 0.43–0.55)	0.48 (95% CI: 0.36–0.61)	0.49 (95% CI: 0.42–0.56)
Absolute agreement	0.74 (95% CI: 0.72–0.77)	0.74 (95% CI: 0.68–0.79)	0.74 (95% CI: 0.72–0.77)

CI: confidence interval; MRI: magnetic resonance imaging; NPV: negative predictive value; PPV: positive predictive value; SIJ: sacroiliac joints.

readings. Performance evaluation included sensitivity, specificity, positive and negative predictive values (PPV and NPV), Cohen's Kappa and the absolute agreement to assess the agreement between the deep learning algorithm and the human readers for the classification of MRI-SIJ scans. Bootstrapping was used to construct the 95% confidence interval (CI).

Results: Pooling the patients from RAPID-axSpA (n=152) and C-OPTIMISE (n=579) yielded a validation set of 731 patients (mean age: 34.2 years, SD: 8.6; 69.1% male) of which 44.6% were patients with nr-axSpA and 59.6% were MRI+ as per central readings. Comparing the trained algorithm with the human central readings for the classification of MRI+/MRI– on the pooled validation set yielded a sensitivity of 70% (95% CI: 66–73%), specificity of 81% (95% CI: 78–84%), PPV of 84% (95% CI: 82–87%), NPV of 64% (95% CI: 61–68%), Cohen's kappa of 0.49 (95% CI: 0.43–0.55), and absolute agreement of 74% (95% CI: 72–77%; **Table**).

Conclusion: A previously trained deep learning algorithm enabled acceptable detection of the presence of inflammation according to the 2009 ASAS MRI definition in axSpA patients from two clinical trials. This suggests that an MRI+ detection algorithm has the potential to support clinicians in identifying axSpA patients.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The study of the cervical spine (CS) in axial spondyloarthritis (axSpA) and its radiographic characteristics including the zygapophyseal joints (ZJ) may be helpful for early diagnosis, establishing a prognosis and sharpening treatment choices.

The aim of this study is to describe the prevalence and characteristics of CS involvement in a cohort of patients with axSpA and its associated factors, who have been followed up in the Rheumatology Department of a third level university hospital.

Table 1. Characteristics of the CS and no CS group.

n=340			NoCS group (n=158)	CS group (n=182)	p-value
Sex	n (%)	Men	91 (57.6)	153 (84.1)	<0.001

Methods: Descriptive, retrospective and unicentric study. Patients with an axSpA diagnosis based on the ASAS classification criteria, from March 2011 to December 2022, retrieved from a dedicated axSpA database were included. Sociodemographic, clinical, radiographic and therapeutic variables were gathered. They were separated into two groups according to CS involvement; "CS group" as patients with BASRI≥2 in CS and/or a score ≥3 in ZJ measured by De Vlam method (1); and "no CS group" as controls.

Results: A total of 340 patients were included (71.8% men; mean age 57,4 ± 14,9 years). CS involvement is common among axSpA (n=182; 53,5%). ZJ involvement was observed in 99 patients (29,1%), and of those, 21 did not show concomitant structural damage in the vertebral bodies. A total of 83 patients (24,4%) had damage in the vertebral bodies

Schober 10	Mean (SD)		4.3 (1.2)	2.7 (1.7)	<0.001

BMI: Body Mass Index; SpA: Spondyloarthritis; CRP: C-Reactive Protein; IBD: Inflammatory Bowel Disease; r-axSpA: radiographic axial Spondyloarthritis; AS: Ankylosing Spondylitis; EnA: Entheropatic Arhtritis (IBD-Associated Spondyloarthritis); Ps SpA: Psoriasic Spondyloarthritis; nr-axSpA: non-radiographic Spondyloarthritis; NSAID: Non-steroidal anti-inflammatory drugs; bDMARD: *Biologic Disease-modifying Antirheumatic Drug*

exclusively, and 37 (10,9%) had CS involvement without radiographic involvement of the lumbar spine (LS) (29,7% women). Patients from the CS group were predominantly men, older, had a higher BMI and a higher prevalence of smoking (table 1). They also showed a higher disease activity (BASDAI and ASDAS-CRP), worse function (BASFI), worse mobility in CS and LS (Schober test), as well as more structural damage in both LS and sacroiliac joints. No differences were found between groups for HLA B27 positive, age at diagnosis, familiar history, presence of arthritis, enthesitis, dactylitis or extra musculo-skeletal manifestations (uveitis, psoriasis or IBD).

Conclusion: The radiographic evaluation of the CS is relevant in axSpA, and it should be performed routinely, as well as the evaluation of the ZJ, as they are commonly involved in axSpA and related to higher disease activity and worse function.

Abstract Number: 1874

Cartilage Thickness Measures Are More Responsive Than Cartilage Area Loss Measures: A Comparison of Quantitative and Semi-quantitative Cartilage Assessments from the Osteoarthritis Initiative

Aaron Ray[1], **Alan Brett**[2], Bright Dube[3], Michael Bowes[4] and Philip Conaghan[3], [1]York and Scarborough Teaching Hospitals: NHS Foundation Trust, York, United Kingdom, [2]Stryker, Austin, TX, [3]University of Leeds, Leeds, United Kingdom, [4]Imorphics Ltd, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cartilage loss in 1-2 year osteoarthritis clinical trials is often small, but a critical outcome measure. The aim of this study was to compare the cross-sectional relationship and longitudinal responsiveness of the semi-quantitative MRI Osteoarthritis Knee Score (MOAKS) with quantitative cartilage thickness measures.

Methods: Images and MOAKS scores from 297 participants with radiographic progression (groups 1 and 2) from the OAI FNIH sub-cohort were included. To facilitate direct comparison with MOAKS, novel quantitative measures of cartilage loss were matched to MOAKS regions (Q-MOAKS).Mean normative cartilage thickness was computed for each subregion (Figure 1) using FNIH controls (group 4). Q-MOAKS thickness loss score (tQCM) was based on the proportion of cartilage thickness over a subregion that was < 95% normative thickness and denudation score (dQCM) was based on < 5% normative thickness. Q-MOAKS area proportions (tQCMr) were compared for responsiveness. These were categorised into scores as for MOAKS for cross-sectional analysis. Quantitative cartilage thickness (ThCtAB) was also measured in the MOAKS subregions. We compared MOAKS against Q-MOAKS and ThCtAB. Cross-sectional relationships between measures were assessed using Spearman's rank correlation. Responsiveness was assessed at 1 and 2 years using standardised response means (SRM).

Results: Cross-sectionally, there was moderate correlation between MOAKS and Q-MOAKS denudation in the central medial femur (cMF *r*=0.42, (95%CI:0.32, 0.51)) and tibia (cMT *r*=0.51, (0.42, 0.59)). There was a poor correlation between MOAKS and Q-MOAKS thickness loss and denudation scores in all other regions. In the cMT region, 61% (96/159) of knees with MOAKS thickness loss tMCM = 2 (the 10-75% score) were also tQMC = 2 and 66% of MOAKS denudation dMCM = 2 were also dQCM = 2 (Figure 2). In the cMF region, the figures were 56% and 23%.MOAKS tMCM and dMCM were less responsive than Q-MOAKS tQCM and dQCM in most subregions (Table 1). MOAKS tMCM in cMT demonstrated the most

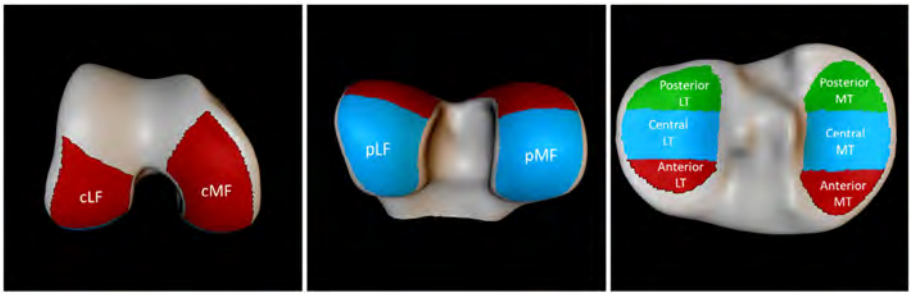

Figure 1: Cartilage regions defined for Q-MOAKS and ThCtAB. Cartilage regions definitions consisting of the medial and lateral central and posterior femur (cMF, cLF, pMF, pLF) subregions and the medial and lateral tibial anterior, central, posterior (aMT, cMT, pMT, aLT, cLT, pLT) subregions.

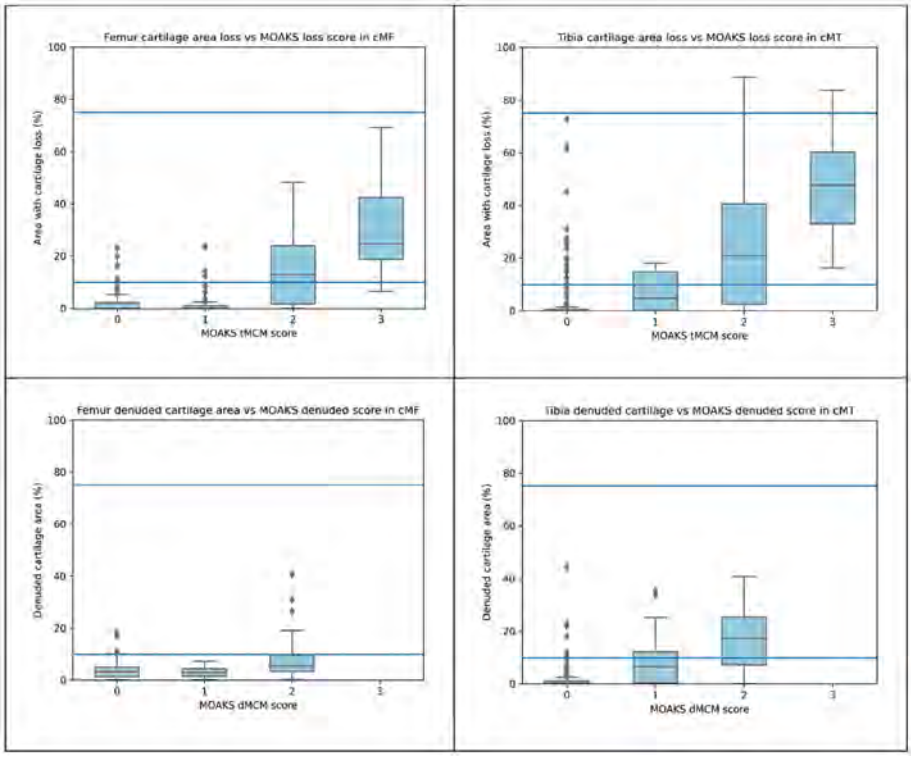

Figure 2: The association between 3D quantitative cartilage area percentage measures and MOAKS scores in the central medial femur and tibia. Top: comparison of cartilage thickness loss. Bottom: comparison of cartilage denudation. There were no MOAKS dMCM = 3 scores in this cohort. Horizontal blue lines indicate the MOAKS score definition thresholds (0: 0%, 1: 0-10%, 2: 10-75%, 3: >75%).

responsiveness for all the thickness loss scores (SRM=0.47, (95%CI:0.41, 0.54)). Quantitative cartilage thickness (ThCtAB) measures were most responsive.

Table 1: Responsiveness (SRM) of standard cartilage MOAKS scores, Q-MOAKS ratios and quantitative cartilage thickness at one-year and two-year follow-up.

	YEAR ONE			YEAR TWO		
			FEMUR			
	MOAKS tMCM	Q-MOAKS tQCMr	Thickness ThCtAB	MOAKS tMCM	Q-MOAKS tQCMr	Thickness ThCtAB
	0.15	0.36	-0.32	0.47	0.73	-0.84
	(0.02, 0.27)	(0.25, 0.47)	(-0.44, -0.20)	(0.41, 0.54)	(0.64, 0.83)	(-0.96, -0.73)
	0.00	0.09	-0.03	0.11	0.24	-0.22
	(-0.11, 0.12)	(-0.04, 0.18)	(-0.14, 0.08)	(0.00, 0.18)	(0.17, 0.31)	(-0.32, -0.11)
			TIBIA			
	MOAKS tMCM	Q-MOAKS tQCMr	Thickness ThCtAB	MOAKS tMCM	Q-MOAKS tQCMr	Thickness ThCtAB
	0.16	0.28	-0.40	0.39	0.49	-0.73
	(0.05, 0.26)	(0.18, 0.38)	(-0.52, -0.30)	(0.33, 0.45)	(0.38, 0.60)	(-0.85, -0.62)
	0.03	0.14	-0.23	0.19	0.22	-0.47
	(-0.07, 0.16)	(0.04, 0.24)	(-0.34, -0.13)	(0.14, 0.25)	(0.12, 0.32)	(-0.59, -0.36)

Conclusion: In the cross-sectional analysis, the concordance between MOAKS scores and the actual ratio of cartilage loss to subregion area was poor. MOAKS appeared to overestimate grades 2 and 3. Quantitative measures of thickness loss were almost twice as responsive as MOAKS, likely because thickness loss is a more responsive construct than area loss for cartilage assessment.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the consistency of rheumatologists' assessment of nailfold capillaroscopy images of patients with Raynaud's phenomenon (RP).

Methods: Nailfold video capillaroscopy(NVC), with a 200x magnification, was used to acquire images from6 digits (the second, third and fourth fingers of both hands) of patients with RP. According to the European League Against Rheumatism Study Group on Microcirculation in Rheumatic Diseases (EULAR SG MC/RD) standardized capillaroscopy evaluation chart, 5 trained rheumatologists classified all NVC images into five patterns: "normal", "non-specific", "early", "active" and "late", and their majority votes derived the gold standard. Two months later, one-fifth of these images were randomly selected for a second assessment by the same rheumatologists. Intra-class correlation coefficient (ICC) was used to analyze inter and intra-observer reliability, and Student's *t* test was used to compare ICC scores.

from

Results: We enrolled 302 participants with RP, 15 of them with primary and 287 with secondary RP. A total of 3805 high-resolution NVC images were obtained, with an average of 13.3 images per patient. The intra-observer reliability of assessment was higher than the inter- (ICC0.894 within and 0.645 between observers, p=0.001). There was poor reliability among rheumatologists for the evaluation of normal and non-specific patterns (inter-observer ICC 0.480 and 0.428 respectively). Agreement for the identification of active and late patterns (inter-observer ICC 0.508 and 0.513, respectively) is higher than for the early pattern (0.387, p=0.001).

Conclusion: Relatively low reliability between observers is one of the major problems in manual assessment of nailfold capillaries of RP patients. Methods to improve the consistency need to be proposed.

A Deep Learning System for Automated Assessing Microcirculation Abnormalities in Nailfold Capillaroscopy Images of Systemic Sclerosis

Yue Zhuang[1], Zipeng Wang[2], Jing Zhu[3], Yongbin Yu[2] and Yi Liu[4], [1]Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China, [2]School of information and software engineering, University of Electronic Science and Technology of China, Chengdu, China, [3]Department of Rheumatology and Immunology, Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China, [4]Department of Rheumatology and Immunology, West China Hospital, Sichuan University, Chengdu, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Detection of specific abnormalities in capillaries, named scleroderma patterns, by nailfold capillaroscopy (NFC) is one of the most important means to diagnose systemic sclerosis (SSc). In addition, different stages of the scleroderma pattern (the early, active, late stage) reflect the activity and severity of the disease. However, the reliability of the NFC images evaluated by rheumatologists was unsatisfactory. We aim to develop and validate a deep learning system for identifying scleroderma pattern from non-scleroderma patternand further classifying different stages of scleroderma pattern.

Methods: NFC with a 200x magnification was used to acquire images from the second, third and fourth fingers of both hands. Majority votes of three rheumatologists to judge the five NFC patterns (normal, non-specific, early, active and late pattern)derived ground-truth labels. NFC-captured images were randomly assigned to the train and validation sets in a 8:2

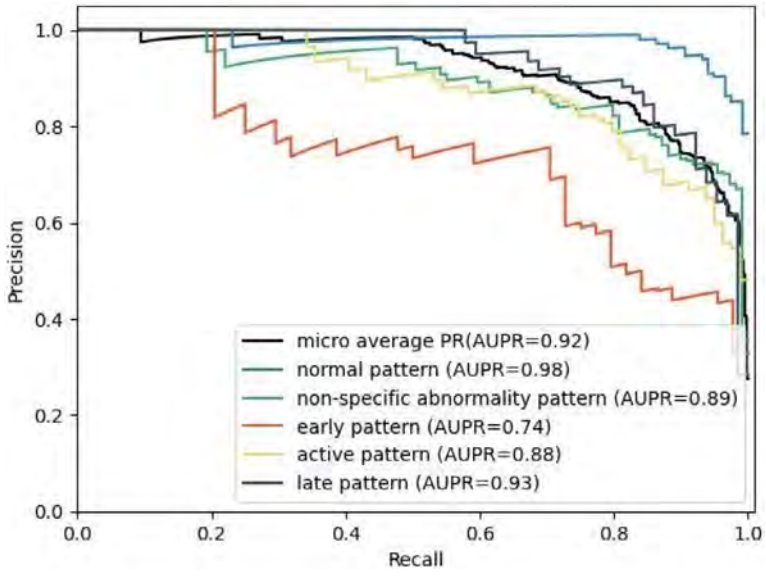

Figure 1. Precision Recall Curves on Validation Set. AUPR: Areas under the precision recall curve.

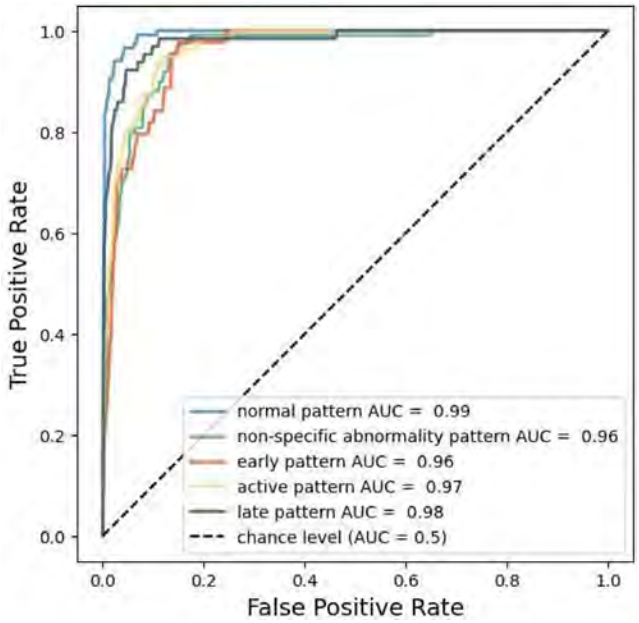

Figure 2. ROC Curves on Validation Set. AUC: Areas under the receiver operating characteristics curve.

ratio. Images analyzed using *ResNeXt*, a deep learning technique. The outcome investigated was the *ResNeXt*'s ability to identify different stages of NFC patterns. The performance of the model was assessed by estimating areas under the precision recall curvesand the receiver operating characteristics curves (ROCs).

Results: Nailfold capillaroscopy (NFC) was performed in 274 adult participants from two clinic medical centers, including 140 SSc and 134 controls (74 healthy controls, 27 with primary Raynaud's phenomenon, 48 with metabolic syndrome). A total of 2893 high-resolution NFC images were obtained, with an average of 10.6 images per participant. In the validation set, *ResNeXt* had good performance in identifying the different patterns in NFC images with areas under theprecision recall curves (AUPR) from 0.74 to 0.98, and with areas under the ROCs (AUC) from 0.96 to 0.99.

Conclusion: The *ResNeXt* is a well-performing tool for identifying scleroderma patterns in SSc from controls, and it may assist rheumatologistsin generating consistent and high-quality assessment of microcirculation abnormalities.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Every effort should be made to confirm a suspected diagnosis of giant cell arteritis (GCA). According to the 2018 update of the EULAR recommendations for the management of large vessel vasculitis, objective confirmation of the presence of vasculitis should always be obtained by histology (temporal artery biopsy [TAB]) or imaging, with color Doppler ultrasound (CDUS) of the temporal arteries being the most commonly used imaging method. However, in clinical practice, it is not uncommon to encounter patients with negative cranial studies, and this subgroup, remains the most challenging to diagnosis. The present study aimed to investigate the diagnostic performance of ^{18}F-FDG PET-CT for assessing large vessel involvement in patients with suspected GCA and a negative TAB.

Methods: We retrospectively reviewed our hospital databases to identify all patients with suspected GCA and a negative TAB who underwent an ^{18}F-FDG PET-CT in an attempt to confirm the diagnosis. The gold standard for GCA diagnosis was clinical confirmation after a follow-up period of at least 12 months.

Results: One hundred and twenty-seven patients were included. After a detailed review of the medical records, 73 patients were finally diagnosed has having GCA. Three of the remaining 54 subjects were diagnosed with other types of vasculitis, and 51 had other diagnoses. Among the 73 patients diagnosed with GCA, ^{18}F-FDG PET-CT was considered positive in 61 cases (83.5%). Nine of the 12 GCA patients with negative PET-CT had undergone previous glucocorticoid treatment. Of the 54 patients without ACG, FDG-PET was considered positive in only 8 (14.8%) (1 case of Erdheim-Chester disease, 3 IgG4-related disease, 1 case of sarcoidosis, and 3 clinically isolated aortitis). Overall, the diagnostic performance of ^{18}F-FDG PET-CT in assessing large vessel involvement in patients with suspected GCA and negative TAB yielded 83.5% sensitivity, 85.1% specificity, and a diagnostic accuracy of 84% with an area under the ROC curve of 0.844 (95% CI:0.752 to 0.936).

Conclusion: Our study confirms the usefulness of ^{18}F-FDG PET-CT when the GCA diagnosis is uncertain following a negative TAB result, by demonstrating the presence of large vessel vasculitis.

MRI-determined Intramuscular Fat Changes During Oral Glucocorticoid Treatment: Findings from a Feasibility Study

Thurkka Rajeswaran[1], Emma Harris[2], hannah Mathieson[1], John Biglands[3], Paul Stewart[1], Ai Lyn Tan[1] and Sarah Mackie[4], [1]University of Leeds, Leeds, United Kingdom, [2]The Open University, Milton Keynes, United Kingdom, [3]NIHR Leeds Biomedical Research Centre and Medical Physics and Engineering , Leeds Teaching Hospitals NHS Trust Leeds, Leeds, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Oral glucocorticoid therapy has many adverse effects including insulin resistance and myopathy. Long-term glucocorticoid therapy causes a "sarcopenic obesity" phenotype of adiposity with muscle wasting. The type IIb ("fast twitch") muscle fibres affected by glucocorticoid myopathy make up a greater proportion of hamstrings than of quadriceps. Hamstring muscles also contains a higher proportion of intramuscular fat than quadriceps. In population studies intramuscular fat is a marker of "unhealthy aging" and is associated with elevated morbidity and mortality. We performed a study to determine the feasibility and sensitivity to change of various assessments of muscle for future research studies.

Methods: Modalities for assessment of muscles included MRI (using Siemens MAGNETOM Verio 3T MR Scanner) of proximal leg muscles(hamstrings; semitendinosus, semimembranosus, biceps femoris and quadriceps;rectus femoris, vastus lateralis, vastus medialis,vastus intermedius). A 40 slice volume interpolated breath-hold examination (VIBE), 2-point Dixon, image series was acquired with the inferior slice located at the insertion point of the distal rectus femoris muscle into the tendon. Muscle volume, and single slice intramuscular fat fraction estimates, were acquired from the same VIBE Dixon acquisition. Muscle strength was assessed by biodex/isokinetic dynamometry.Physical performance was assessed via an extended timed get up and go test. Feasibility was assessed in a group of patients treated with oral glucocorticoid therapy for various rheumatological indications and compared to data from age matched controls. Sensitivity to change was

A) Muscle Evaluation comparing baseline cases to controls (n=34 for cases and controls)			
	Case Mean (SD)	Control Mean (SD)	Unpaired T-test P-value
Muscle Imaging			
Muscle Volume [cm^3]	1130 (308)	1210 (298)	0.335
* Muscle Quality - Hamstring Fat Fraction [%]	8.93 (3.5)	7.26 (2.68)	0.028
Muscle Quality - Quadricep Fat Fraction [%]	4.57 (1.75)	4.84 (2.1)	0.559
Muscle Strength			
Time needed to complete extended time get up and go [s]	19.7 (10.8)	17.6 (3.64)	0.0845
* Hamstrings (Peak knee flexion [N.m])	31.2 (12.7)	47.0(21.8)	0.00155
Quadriceps (Peak knee extension [N.m])	89.1 (37.2)	77.1(34.4)	0.249
B) Longitudinal Muscle Evaluation comparing subset of baseline cases, to after 4-6 months of glucocorticoid use			
	Baseline Case Mean (SD)	Longitudinal Case Mean (SD)	Paired T-Test
Muscle Imaging (n=10)			
Muscle Volume [cm^3]	1130 (141)	1790 (158)	$t(9) = -2.09$, $p = 0.066$
*Muscle Quality - Hamstring Fat Fraction [%]	9.35 (4.81)	10.35 (5.65)	$t(9) = -2.97$, $p = 0.0157$
Muscle Quality - Quadricep Fat Fraction [%]	3.69 (1.07)	3.99 (1.36)	$t(9) = -1.92$, $p = 0.0868$
Muscle Strength (n=8)			
Time needed to complete extended time get up and go [s]	18.3 (3.94)	19.5 (6.37)	$t(7) = -1.04$, $p = 0.333$
Hamstrings (Peak knee flexion [N.m])	31.4(10.2)	31.0 (7.34)	$t(7) = 0.117$, $p = 0.910$
Quadriceps (Peak knee extension [N.m])	94.8 (31.5)	84.1(34.1)	$t(7) = 1.60$, $p = 0.154$

1a) Muscle Evaluation comparing baseline cases to controls (n=34 for cases and controls) 1b) Longitudinal Muscle Evaluation comparing subset of baseline cases, to after 4-6 months of glucocorticoid use

assessed in a subset of patients taking < 4 weeks glucocorticoid therapy at first assessment, by repeating the feasible measures after 4-6 months of glucocorticoid therapy.

Results: 34 glucocorticoid-treated patients (19 cases of polymyalgia rheumatica (PMR), 4 of giant cell arteritis (GCA), 5 of PMR and GCA, and 6 of other inflammatory conditions) were matched for age (range 45 to 86yrs) and sex (26/34 female) to 34 healthy controls. Compared to controls, patients treated with glucocorticoids had lower hamstring muscle strength and higher fat fraction, but similar muscle volume and physical performance (Table 1A). After 4-6 months of oral glucocorticoid therapy, there was a significant increase in hamstrings fat fraction compared to visit 1, and no significant change in the other measured variables (Table 1B).

Conclusion: Patients taking oral glucocorticoids for rheumatic diseases had greater hamstrings intramuscular fat than matched controls, and reduced hamstrings strength. These differences could have been due to the drug and/or the disease being treated. With increasing duration of glucocorticoid therapy there was a further increase in hamstring fat fraction despite no significant change in muscle strength. Intramuscular fat infiltration could be a sensitive modality for detecting metabolic alterations resulting from long-term glucocorticoid therapy. Further studies are needed to investigate the potential of MRI as a potential endpoint for clinical trials of glucocorticoid-sparing treatments.

Artificial Intelligence for the Detection of Sacroiliitis on Magnetic Resonance Imaging in Patients with Axial Spondyloarthritis

Seulkee Lee[1], Uju Jeon[2], Ji Hyun Lee[3], Seonyoung Kang[1], Hyungjin Kim[1], Jaejoon Lee[1], Myung Jin Chung[2], Jinseok Kim[4], Eun-Mi Koh[5] and Hoon-Suk Cha[1], [1]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [2]Medical AI Research Center, Samsung Medical Center, Seoul, South Korea, [3]Department of Radiology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, South Korea, [4]Department of Rheumatology, Jeju National University Hospital, Jeju National University School of Medicine, Jeju-si, Jeju-do, South Korea, La Jolla, CA, South Korea, [5]Health Insurance Review and Assessment Service, Seoul, South Korea

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

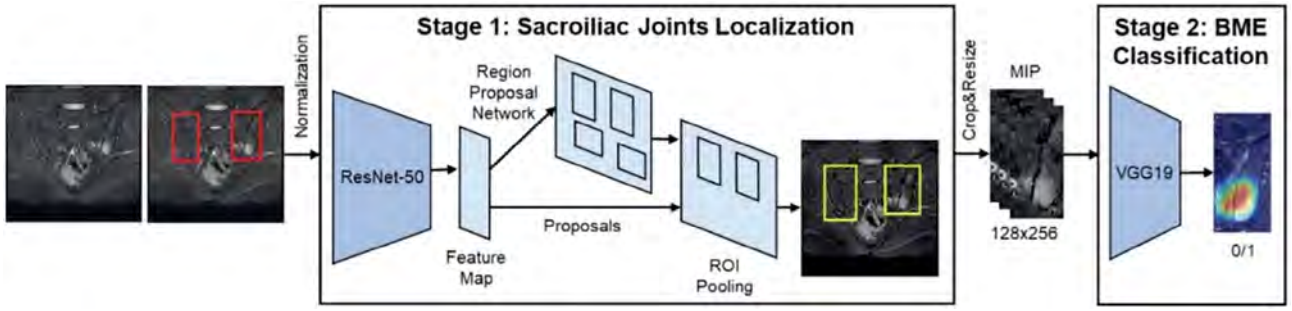
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

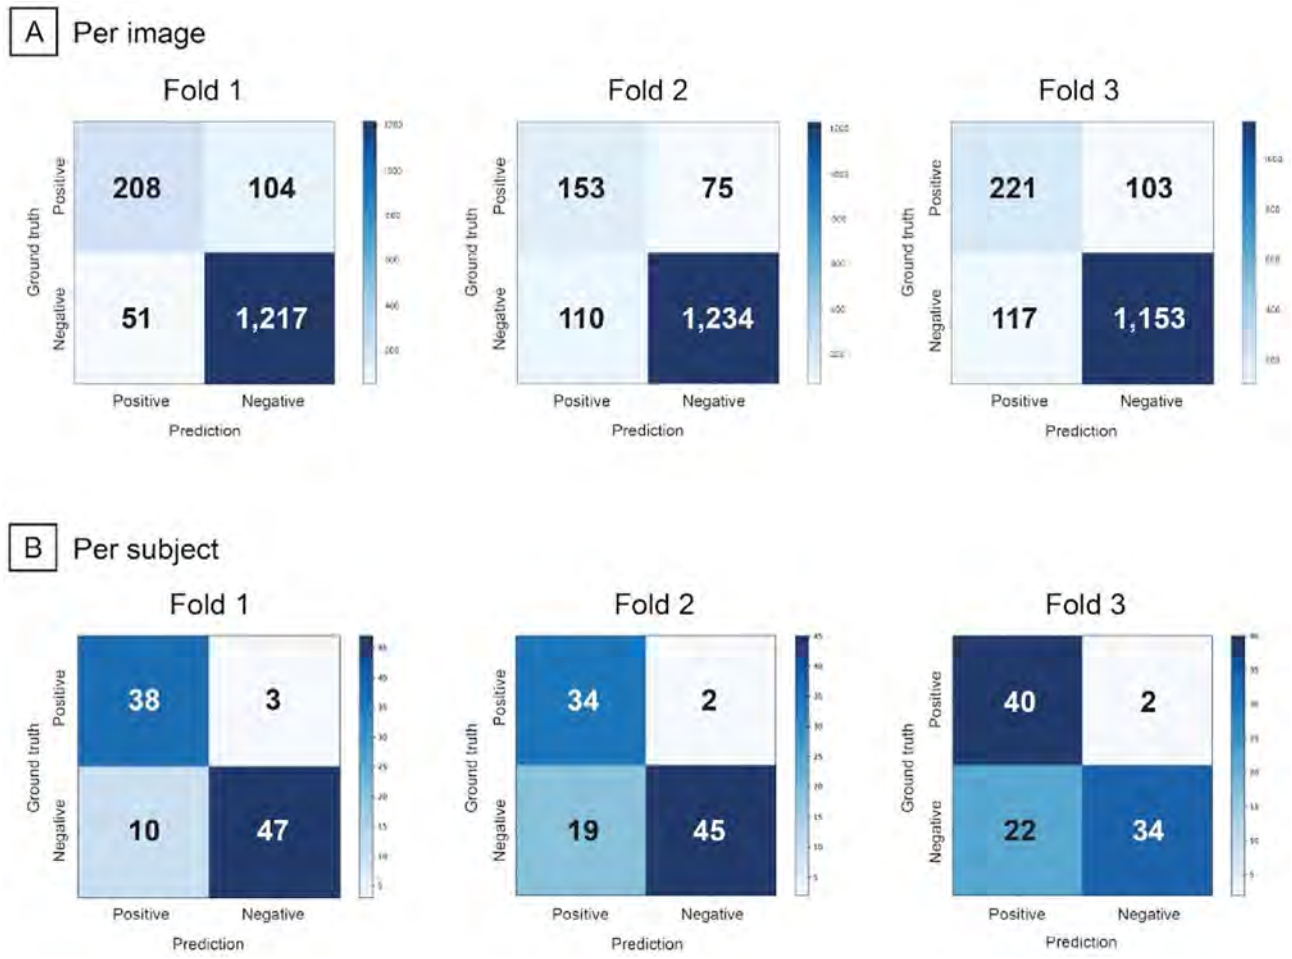
Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) is important for the early detection of axial spondyloarthritis (axSpA). However, evaluation of sacroiliitis on MRI requires expertise because degenerative changes can mimic axSpA, and semiquantitative diagnosis remains subject to significant variation. Artificial intelligence (AI) has previously been applied to various MRI data including that of musculoskeletal system. Therefore, we developed an AI model for detecting in patients with axSpA, on MRI.

Methods: This study included MRI examinations of patients who underwent semi-coronal MRI scans of the sacroiliac joints owing to chronic back pain with short tau inversion recovery sequences between January 2010 and December 2021. Sacroiliitis was defined as a positive MRI finding according to the Assessment of Spondylo Arthritis international Society (ASAS) classification criteria for axSpA. The pipeline for the proposed automatic sacroiliitis classification method is shown in Figure 1. We developed a two-stage framework. First, the Faster R-CNN network extracted regions of interest (ROIs) to localize the sacroiliac joints. Maximum intensity projection (MIP) of three consecutive slices was used to mimic the reading



Artificial intelligence framework to detect sacroiliitis in accordance with the Assessment of SpondyloArthritis International Society criteria for axial spondyloarthritis.



Confusion matrices of the first-round cross-validation using the proposed method (Method C) for detecting sacroiliitis (A) for individual MRI slices; (B) for each subject.

Performances by individual MRI slices		
	Accuracy (95% CI), %	AUROC (95% CI)
Method A[a]	86.6 (85.4 to 87.8)	0.731 (0.681 to 0.780)
Method B[b]	86.5 (85.3 to 87.7)	0.747 (0.699 to 0.796)
Method C[c]	89.8 (88.8 to 90.8)	0.830 (0.792 to 0.868)
Performances by each patient		
	Accuracy	AUROC
Method A[a]	69.2 (62.7 to 75.6)	0.711 (0.660 to 0.763)
Method B[b]	69.9 (63.7 to 76.1)	0.722 (0.671 to 0.774)
Method C[c]	79.4 (73.9 to 84.9)	0.816 (0.776 to 0.856)

Abbreviation: AUROC, area under the receiver operating characteristic curve.

[a] Artificial intelligence model for the detection of sacroiliitis without augmentation and maximum intensity projection.

[b] Artificial intelligence model for the detection of sacroiliitis using augmentation without maximum intensity projection.

[c] Artificial intelligence model for the detection of sacroiliitis using both augmentation and maximum intensity projection.

Performances of artificial intelligence models for the detection of sacroiliitis compatible with the Assessment of SpondyloArthritis international Society definition.

of two adjacent slices. Second, the VGG-19 network determined the presence of sacroiliitis in localized ROIs. We augmented the positive dataset six-fold because of the smaller number of data points compared with the negative dataset. The sacroiliitis classification performance was measured using the accuracy and area under the receiver operating characteristic curve (AUROC). The prediction models were evaluated using three-round three-fold cross-validation.

Results: A total of 296 participants with 4,746 MRI slices were included. Sacroiliitis was identified in 864 MRI slices from 119 participants. The mean accuracy and AUROC for the detection of sacroiliitis were 89.8% (95% CI, 88.8%–90.8%) and 0.830 (95% CI, 0.792–0.868), respectively, at the image level and 79.4% (95% CI, 73.9%–84.9%) and 0.816 (95% CI, 0.776–0.856), respectively, at the patient level. The confusion matrices for the detection of sacroiliitis per image and subject are shown in Figure 2. In the original model, without using MIP and dataset augmentation, the mean accuracy and AUROC were 86.6% (95% CI, 85.4%–87.8%) and 0.731 (95% CI, 0.681–0.780), respectively, at the image level and 69.2% (95% CI, 62.7%–75.6%) and 0.711 (95% CI, 0.660–0.763), respectively, at the individual level (Table 1). Improved performances were observed compared with the original model.

Conclusion: An AI model was developed for the detection of sacroiliitis using MRI, compatible with the ASAS criteria for axSpA, with the potential to aid MRI application in a wider clinical setting.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

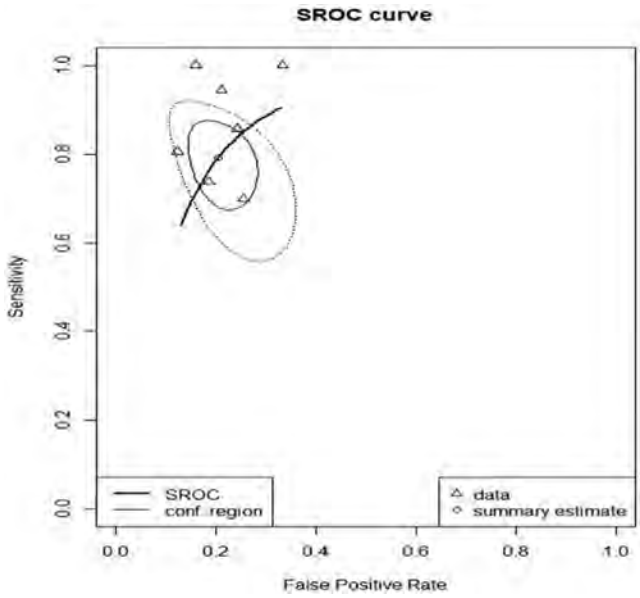
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The diagnostic role of Magnetic Resonance Imaging (MRI) for axial spondyloarthritis(axSpA) has grown since introducing the ASAS criteria for axSpA. Recent advances in machine learning (ML) haveshown promisein MRI interpretation for sacroiliitis detection in axSpA. Thisstudy aims to provide a systemic review and a summary estimate ofperformance indices of MLalgorithms in discriminating sacroiliitis in accordance with axSpAon MRI.

Methods: Embase, MEDLINE, CINAHL Complete, Web of Science, and IEEE Xplore Digital Library databases were used. The search was performed on 5 June 2023. Screening and extraction were performed independently by two authors according to the Checklist for Artificial Intelligence in Medical Imaging (CLAIM). To summarize sensitivity and specificity, a bivariate random effects model was employed. The Summary Receiver Operating Characteristics (SROC) curve derived from parameters extracted from a given model is presented with summary points defined by 95% confidence and prediction regions. This graph can also derive the partial Area Under the Curve (pAUC). Risk of bias was assessed by the checklist for



Summary Receiver Operating Characteristics (SROC) of seven studies, presented with the summary point of sensitivity and specificity defined by 95% confidence and 95% prediction regions

critical Appraisal and data extraction for systematic Reviews of prediction Modelling Studies (PROBAST). The protocol was registered before the review started (CRD42023415446).

Results: A total of 1,986 studies were searched. Following the selection process, ten and seven studies were used for qualitative assessment and meta-analysis, respectively. The majority of studies were original articles, predominantly from European and Asian regions, and based on hospital cohorts. Also, half of the 10 studiesutilized deep learning, and three studiesconducted external validation. Nine studies used the discrimination of radiologic SpA features of ASAS as the ground truth. Seven validation or test datasets (274 positive and 375 negative sacroiliitis patients) were included in the meta-analysis. Its pooled sensitivity, specificity, and pAUC were 79% (95% CI: 70-86%), 80% (73-85%), and 0.79 respectively (Figure 1). Two studies conducted external validation and comparison between machine and human doctors. The

	Non-expert radiologist 3	81% (58% - 95%)	91% (83% - 96%)	89% (82% - 94%)
	Average of non-experts	79% (56% - 93%)	87% (79% - 93%)	86% (79% - 92%)

Sensitivity, specificity and accuracy of two studies performed external validation and comparison between machine and human rater(s).

Ensembling Mask regions with convolutional neural network algorithm's accuracy achieved 92% (88-100%), and that of expert radiologists' showed a range of 92-98%. The deep neural network algorithm's accuracy from the other study showed 78% (69-85%), and that of expert and non-expert radiologists' were an average of 94% (87-97%) and 86% (79-92%) respectability (Table). The summary of the quality appraisal tool (PROBAST) showed that more than half of the studies (six of 10 studies) were unclear and had a high risk of bias in the analysis domain (Figure 2).

Conclusion: ML algorithms for discriminating SpAfeatures in MRI have acceptable pooled sensitivity and specificity (around 80%). However, there are potential bias concerns in the validation process, and the number of studies comparing the accuracy of human experts and machines was small, limiting interpretation. An accuracy issue of machine leaning algorithms inSpA can be concluded in the future if well-designed and transparent reports that follow a guideline become more widely available.

Deep Learning Approaches to Rheumatoid Arthritis Severity Prognosis

Zhong-Yuan Lai[1], Aditya Varna Iyer[2], Isaac Zachary To[1], Ivano Lodato[1], Simran Hiranandani[1], Tommy LAM[3], Ho So[4] and Lai-Shan Tam[5], [1]Allos AI, London, United Kingdom, [2]Allos AI, University of Oxford, Oxford, United Kingdom, [3]Medicine and Therapeutics, Prince of Wales Hospital, Hong Kong, Hong Kong, [4]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [5]The Chinese University of Hong Kong, New Territories, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is the most common form of inflammatory arthritis affecting a large sector of the global population. The disease is associated with a high socio-economic burden owing to disability caused and costs of treatment. Conventional diagnostic methods rely on the skill of trained clinicians in interpreting and prognosing the severity of RA from X-ray images. This is slow, costly, and often error prone. We propose novel AI models that can perform an automatic quantification of X-Ray damage.

Methods: Data is retrieved from the Prince of Wales Hospital in Hong Kong. Patients diagnosed with RA were recruited with physician's diagnoses are recorded at the first clinic visit according to ICD9-CM. Inclusion criteria are 1) patients who carried the diagnosis code of RA (ICD9-CM: 714), 2) >= 1 follow up visit after disease onset, 3) serial XR hands available (>= 1 set) after disease onset, 4) age >=18 at disease onset, and 5) DAS28 < 5.1. The final dataset consists of a cohort of ∼600 X-ray images of hands and feet. Each X-ray image is labeled with a corresponding value for the van der Heijde Modified Sharp score (vdH score). Our trained deep learning model analyzes a typical X-ray image in two distinct ways:

1. Classification: we partition the dataset according to the vdH value into 11 disjoint sets. Each set corresponds to images with vdH score within a specific range. The classifier is then tasked with deciding the range of vdH values to be assigned to a typical X-ray image;

2. Regression: our trained model directly outputs a numerical value of the vdH score based on its analysis of a typical X-ray image. This task is computationally harder than classification as the model predicts continuous values and therefore can be used in disease progression analysis of X-rays collected over time.

These approaches are prefaced by preprocessing pipelines designed to take the intricacies of images into account. Our deep learning frameworks are based on the Visual Transformer (ViT) architecture. For regression, our framework can take prior information regarding RA severity into account, much in the same way that a physician performs annotation on an image. Prior information is integrated into the regression framework in the form of a trained shape model.

Results: We obtained accuracies between 70-75% on the validation dataset, for the 11-bin classification problem. We also computed the Area-Under-Curve score (AUC), which is a more accurate reflection on the robustness of our classification in the presence of imbalanced data. We obtained an AUC of 0.8. For the regression problem, we obtain relational errors of 0.25-0.3 (computed as fractional deviation of prediction from truths), competitive with a clinician.

Conclusion: We implement deep learning frameworks to automatically assign severity scores to X-rays of bones via classification or regression. With both frameworks we show that it is possible for deep learning prognostic pipelines to be robustly implemented and deployed for use in a conventional clinical workflow, thus paving the way for expedited prognosis and increased quality of care for RA patients.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Since the development of the EULAR recommendations for the use of imaging in large vessel vasculitis (LVV) in 2017, new data has emerged in the field of imaging techniques and their application in the diagnosis and follow-up of patients with giant cell arteritis (GCA) and Takayasu arteritis (TAK).The objective of this review was to summarize

Table 1. Pooled sensitivities and specificities of diagnostic studies on GCA with clinical diagnosis as reference standard GCA, giant cell arteritis; MRI, magnetic resonance imaging; PET-CT, positron emission tomography – computed tomography; US, ultrasound

	Index test	Number of studies	Pooled sensitivity (95%CI)	Pooled specificity (95%CI)
All studies	US	23	0.76 (0.66,0.83)	0.91 (0.86,0.94)
	MRI	8	0.82 (0.76,0.86)	0.92 (0.84,0.97)
	PET-CT	5	0.80 (0.70,0.87)	0.91 (0.67,0.98)
Low risk of bias studies	US	8	0.88 (0.83,0.92)	0.96 (0.86,0.99)
	MRI	3	0.81 (0.71,0.89)	0.98 (0.89,1.00)
	PET-CT	4	0.76 (0.67,0.83)	0.95 (0.71,0.99)

the evidence on different imaging techniques for diagnosis, monitoring, and outcome prediction in LVV in order to inform a EULAR task force updating the recommendations for imaging in LVV.

Methods: Systematic literature review (SLR) on studies published between 2017-2022 on ultrasound (US), magnetic resonance imaging (MRI), computed tomography (CT), positron emission tomography (PET)-CT/MRI and fluorescein angiography in patients with LVV (PROSPERO registration CRD42022360545). Eligible study designs included randomized controlled trials and observational studies but excluded case-controlled studies. Two reviewers independently performed data extraction, synthesis, and risk of bias assessment. For studies on diagnosis, meta-analyses were performed using data from both the original and updated SLR whenever possible. Pooled sensitivities and specificities were obtained by fitting random effects models for all studies and for studies with low risk of bias separately. Meta-analyses were performed in R version 4.2.1. using the "lme4" package. The description of observations without inferences and the heterogeneity of reported data precluded any meta-analysis for outcome prediction or monitoring.

Results: A total of 4696 references were identified. Thirty-eight studies on GCA (n=32), TAK (n=2), and GCA and TAK (n=4) were included through the update, adding up to eighty-one studies from both SLRs. Pooled sensitivities and specificities for US, MRI and PET-CT using a clinical diagnosis of GCA as the reference standard are depicted in table 1. No studies on the diagnostic value of imaging techniques were found for TAK. The US evaluation of patients with suspected GCA, including the assessment of both cranial and extracranial vessels, showed a higher pooled sensitivity (95%CI) (89% [73%-96%] vs 70% [59%-79%]) and similar specificity (95%CI) (91% [83%-95%] vs 91% [84%-94%]) compared to only including cranial vessels. Studies on outcome prediction (n=5) and monitoring (n=10) reported change of signs of vasculitis along with disease activity and proposed composite scores comprising several vessel territories for US, MRI and PET-CT.

Conclusion: US, MRI and PET-CT revealed a good performance for the diagnosis of GCA. Assessing both cranial and extracranial vessels with US leads to a higher pooled sensitivity with a similar pooled specificity compared to an assessment limited to cranial vessels.

Abstract Number: 1883

Thalamocortical Mechanisms of a Remote Mind-body Intervention for Knee Osteoarthritis Pain

Jian Kong[1], Valeria Sacca[1] and **Chenchen Wang**[2], [1]Massachusetts General Hospital, Boston, MA, [2]Center of Integrative Medicine and Division of Rheumatology, Tufts Medical Center, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies found that individuals with pain exhibit altered thalamocortical rhythm, abnormal function, and structural connectivity within the network. Effective treatment may relieve pain by modulating the thalamocortical circuits. We examine how remote Tai Chi mind-body exercise modulates the static and dynamic resting state functional connectivity (rsFC) of thalamus subregions associated with movement, sensory and limbic systems.

Methods: Patients ≥ 50 years of age who met ACR criteria for symptomatic KOA were randomized to either a Tai Chi or Wellness Education and attended 12 weeks of biweekly remote sessions. The clinical outcomes included WOMAC, Anxiety and Depression, Self-efficacy and quality of life. Resting-state Functional magnetic resonance imaging (fMRI, using simultaneously multi-slice sequences) and high-resolution structure MRI scans were applied with a 3.0T Siemens scanner at baseline and after intervention. We applied theCONN toolbox for seed-based static and dynamic rsFC analysis. Three thalamus subregions (motor thalamus subregion, ventral posterolateral thalamus and mediodorsal thalamus) were used as seeds based on parcellation of the thalamic nuclei of AAL3. A threshold of $p < 0.005$ voxel-wise and $p < 0.05$ False Discovery Rate corrected at cluster level was applied for whole-brain analysis. Small volume correction was applied for pre-defined regions of interest (limbic system and prefrontal cortex).

Results: Thirty-four patients were randomized and 31 completed pre- and post-MRI scans. Mean age was 66 years, 65% female. At 12 weeks, compared to education, a significantly greater improvement in WOMAC pain score was found in the Tai Chi group ($p < 0.05$). No significant differences between groups were found for other clinical outcomes. *Static rsFC analysis* showed that compared to Wellness education, remote Tai Chi exercise increased 1) motor thalamus subregion static rsFC at the right cerebellum (lateral hemisphere); 2) ventral posterolateral thalamusstatic rsFC at the right cerebellum (medial and lateral hemisphere); 3) mediodorsal thalamus static rsFC at the bilateral cerebellum (medial and lateral hemisphere). Tai-Chi decreased 1) motor thalamus subregion static rsFC at the bilateral dorsal anterior cingulate cortex (dACC) and right amygdala/hippocampus; 2) ventral posterolateral thalamus static rsFC at the right lateral and orbital prefrontal cortex, bilateral dACC/mid-cingulate cortex, and right hippocampus; 3) mediodorsal thalamus static rsFC at bilateral temporal gyrus/uncus/amygdala/hippocampus. *Dynamic rsFC analysis* showed that compared to Wellness education, remote Tai Chi decreased 1) motor thalamus subregion dynamic rsFC at the left rACC/medial prefrontal cortex (mPFC), and bilateral cerebellum; 2) ventral posterolateral thalamus dynamic rsFC at the bilateral rACC/mPFC, primary motor and premotor cortex and middle temporal gyrus. No significant findings when using the mediodorsal thalamus as a seed.

Conclusion: Our results suggest that remote Tai Chi can modulate the functional connections between the thalamus-cerebellum and thalamus-limbic systems in individuals with KOA, and can reduce theconnectivityvariability betweenthese regions.

Which Cell Pattern in Immunological Bronchoalveolar Lavage (BAL) Is Associated with a High-resolution Computer Tomography (HRCT) Pattern at the Onset of Inflammatory Rheumatic Disease with Interstitial Lung Disease?

tobias Hoffmann[1], Martin Förster[2], Peter Oelzner[1], Claus Kroegel[2], Ulf Teichgräber[3], Diane Renz[4], Joachim Böttcher[1], Christian Schulze[2], Gunter Wolf[1], Marcus Franz[2] and **Alexander Pfeil**[1], [1]Department of Internal Medicine III, Jena University Hospital – Friedrich Schiller University Jena, Jena, Germany, [2]Department of Internal Medicine I, Jena University Hospital – Friedrich Schiller University Jena, Jena, Germany, [3]Institute of Diagnostic and Interventional Radiology, Jena University Hospital – Friedrich Schiller University Jena, Jena, Germany, [4]Institute of Diagnostic and Interventional Radiology, Department of Pediatric Radiology, Hannover Medical School, Hannover, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory rheumatic diseases (IRD) are associated with interstitial lung disease (ILD). High-resolution Computer Tomography (HRCT) is recommended as goldstandard in the detection of IRD-ILD. The main HRCT-pattern included ground-glass opacities (GGO), non-specific interstitial pneumonia (NSIP), usual interstitial pneumonia (UIP), granuloma and cryptogenic organizing pneumonia (COP). Further, bronchoalveolar lavage (BAL) can be used to evaluate pulmonal cell pattern. The aim of this study was to evaluate HRCT pattern at the onset of IRD-ILD and to correlate the HRCT pattern to immunological BAL pattern.

Methods: The study includes 61 patients (connective tissue disease n=39, myositis n=9, vasculitis n=10 and rheumatoid arthritis n=3) with newly diagnosed IRD and evidence of ILD on HRCT. In addition to HRCT, immunological BAL was performed. The American Thoracic Society Clinical Practice Guideline were used to define BAL pattern with lymphocytic cellular pattern (>15% lymphocytes), neutrophilic cellular pattern (> 3% neutrophils), eosinophilic cellular pattern (>1% eosinophils) and unspecific cellular pattern. No patient received any immunosuppressive therapy.

Results: For the total study cohort, the main HRCT pattern were NSIP (44.3%) and GGO (31.3%), followed by UIP (14.8%), granuloma (4.9%) and COP (3.3%). BAL pattern showed the following distribution: 37.7% lymphocytic cellular pattern, 27.9% neutrophilic cellular pattern, 18.0% eosinophilic cellular pattern and 16.4% unspecific cellular pattern. Concerning GGO, the main BAL pattern was lymphocytic cellular pattern (47.4%), whereas neutrophilic cellular pattern (37.0%) and lymphocytic cellular pattern (25.9%) were the dominant pattern in NSIP. UIP revealed the following BAL pattern: lymphocytic cellular pattern 55.6%, neutrophilic cellular pattern 33.3% and unspecific cellular pattern 11.1%.

Conclusion: GGO in HRCT is associated with the occurrence of a lymphocytic pattern in BAL, whereas in NSIP and UIP pattern the lymphocytic and neutophilic pattern is equally expressed. Based on the data, a further leading evaluation should be made with regard to the therapeutic options (anti-inflammatory and / or anti-fibrotic therapy) as well as the prognosis of IRD-ILD.

Abstract Number: 1885

The Frequency and Importance of Subchondral Radius Cysts in Rheumatoid Arthritis Patients Under B/tsDMARDs

Umut Kalyoncu[1] and Gizem Ayan[2], [1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey, [2]Hacettepe University Faculty of Medicine Division of Rheumatology, Ankara, Turkey

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of subchondral cysts in patients with rheumatoid arthritis (RA) has long been recognised. The concept of geodes used in geology would be the best terminology used to name the latter. In this asessment, we aimed to determine the frequency, distribution and characteristics of geodes in the radius in RA patients in a biologic disease modifying anti-rheumatic drug (bDMARD) cohort.

Methods: The HUR-BIO database was established in 2005, 2355 RA patients were registered as of January 2023. Anterior-posterior standard hand X-rays of the first 500 patients in HUR-BIO who had at least one hand X-ray were evaluated. The most recent hand X-ray of the patients was evaluated. From 500 patients in 28 (5.6%) patients, the presence or absence of subchondral cysts on radiographs could not be determined. 24 (4.8%) patients had cystic-erosive changes in the radius, but these patients were not included in the analysis because the bone integrity of the radius cortex was compromised. The localisation and size of the geodes, the distance from the distal part of the radius, the distance from the geodes to the radius, and the distance between the radius and the carpal bone were measured. The distance between the radius and scaphoid and the distance between the radius and lunate bone were measured at the narrowest point (Figure 1). Involvement of the carpal bones was evaluated according to the modified Larsen score. Demographic, clinic characteristtics were assessed and compared between patients with and without goedes.

Results: Goedes were found in 63/448(14.1%) of these patients. Mean (SD) years of age at the time of hand x-ray was 54.4 (12.4) and 51.1 (12.9) in with/out goedes, respectively In the comparison of patients with/out goedes, there were differences in terms of male gender and anti-CCP positivity and disease duration. Larsen score in carpal bones was worse in patients with subchondral cysts (Table 1). A total of 98 cysts were found in 63 patients; 8 (12.6%) unilateral single cyst 37 (58.7%), unilateral double cyst 14 (22.2%), bilateral 12 (19.0%). The dominant cyst on the right was found in 40 patients and the second cyst in 14 patients, while the dominant cyst on the left was found in 35 patients and the second cyst in 9 patients. The distribution of sclerosis around these cysts was as follows; absent 4 (4.1%), mild 59 (60.2%), moderate 33 (33.7%), marked 2 (2.0%). The mean (SD) distance between the upper end of the cyst and the radius was 1.7 (0.67) mm. In 26 patients with multiple cysts, anti-CCP antibody positivity was more frequent (90.0% vs 64.3%, p=0.043), and Larsen score of grade 2 or higher was more frequent (92.3% vs 67.6%, p=0.020) Patients with subchondral cysts larger than 50 mm2 were more frequently male (64.7% vs 21.7%, p=0.001), smoking was more frequent (76.5% vs 43.2%, p=0.020).(Table 2).

Conclusion: In a cohort of RA patients who were required to use bDMARD, geodes were found in the radius in 14% of patients. These cysts were, usually single but bilateral in one-fifth of the patients. The relation between the diameter and number of geodes, anti-CCP positivity and gender suggests that these patients may represent a subgroup with a more erosive course.

Costotransverse Joint Ankylosis and Association with Syndesmophyte Progression in Patients with Radiographic Axial Spondyloarthritis

Hong Ki Min[1], Se Hee Kim[2], Hae-Rim Kim[3], Sang-Heon Lee[1] and Sang-Hoon Lee[2], [1]Konkuk University School of Medicine, Seoul, South Korea, [2]Kyung Hee University Hospital at Gangdong, Seoul, South Korea, [3]Rheumatology, Konkuk University Medical Center, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Costotransverse joint ankylosis in radiographic axial spondyloarthritis (r-axSpA) patients was measured. Furthermore, the association between syndesmophyte progression assessed by CT syndesmophyte score (CTSS) and facet, costovertebral, and costotransverse joints ankylosis were evaluated.

Methods: Whole spine CT images taken at baseline and at 2-year follow-up were used to calculate the CTSS of vertebral body. In addition, ankylosis of the facet/costovertebral/costotransverse joints was scored. CTSS (range, 0–552) and facet joint ankylosis (range, 0–46) were assessed at 23 vertebral units. Costovertebral joints at T1–T12 (range, 0–48) and costotransverse joints at T1–T10 (range, 0–20) were also assessed. Intraclass correlation coefficients (ICC) were calculated to determine inter-reader reliability. Odds ratios (OR) was calculated to identify associations between syndesmophyte progression and baseline status of other joints.

Results: Fifty patients with r-axSpA were included. Reader 1 identified C7–T3 (facet joints), T5–T7 and T12 (costovertebral joints), and T8–T9 (costotransverse joints), as common sites of ankylosis at baseline and at 2-year follow-up. The ICCs for facet, costovertebral, and costotransverse joints at baseline were 0.876 (95% confidence interval [CI] 0.782–0.930), 0.952 (95% CI, 0.915–0.973), and 0.753 (95% CI, 0.564–0.860), respectively. Multivariate logistic regression analysis revealed that the OR of baseline costovertebral and costotransverse joint ankylosis for predicting CTSS progression was 4.644 (95% CI, 2.295–9.398) and 1.524 (95% CI, 1.036–2.244), respectively.

Conclusion: Costotransverse joint ankylosis in r-axSpA patients can be measured semi-quantitatively on whole spine CT, and ankylosis of the costotransverse joints predicts progression of syndesmophytes.

Total-body PET Quantitative Biomarkers Reveal Key Differences in Enthesitis Between Rheumatoid and Psoriatic Arthritis Patients

Dario Mazza[1], Siba Raychaudhuri[2], Yasser Abdelhafez[1] and Abhijit Chaudhari[3], [1]University of California Davis, Sacramento, CA, [2]UC Davis, School of Medicine/ VA Medical Center, Sacramento, Davis, CA, [3]UC Davis School of Medicine, Sacramento, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the ability of total-body PET (TB-PET) biomarkers to quantify enthesitis in Psoriatic (PsA) and Rheumatoid Arthritis (RA). We hypothesize that objective characterization of specific disease domains will allow PET to reliably distinguish between these two conditions and add to current understanding of their in-vivo pathologies.

Methods: As part of an ongoing study using TB-PET to study autoimmune inflammatory arthritis, we present results of 39 patients (N = 15 with RA and N = 24 with PsA). Participants underwent an ultra-low dose TB-PET/CT scan using the [18F]FDG radiotracer at a single timepoint. Thirty-eight entheses per participant were evaluated on PET images, matching those from the Leeds Enthesitis Index (LEI), Maastricht Ankylosing Spondylitis Enthesis Score (MASES), Spondyloarthritis Research Consortium of Canada (SPARCC), Berlin (Major), San Francisco, and 4-point enthesitis measures1.

Each enthesis was graded on a Likert scale (0-3) and the maximum Standardized Uptake Value (SUVmax) was recorded. Summed Likert scale scores and summed SUVmax across all entheses assessed and their average was used to compare between groups. The number of active entheses (scored 2 or more) were counted and compared between groups. Differences between groups were assessed via Mann Whitney U-tests. Receiver operating characteristic (ROC) curves were produced to assess the diagnostic potential of these metrics.

Results: The total number of PET-positive entheses was higher in participants with PsA (8.83 ± 5.1) compared to RA (4.25 ± 2.7, $p < 0.05$). Across all the 38 entheses sites, there was a significant difference in both summed Likert scale scores and summed SUVmax between groups ($p < 0.01$), as can be seen in Figure 1. The same metrics assessed for the LEI subset showed no difference between the groups. They did show significant differences for the MASES and SPARCC groupings of entheses ($p < 0.05$) (Table 1). ROC analysis showed that both summed scores for entheses can perform acceptably as binary classifiers. The best performing measures were those utilizing the San Francisco entheses sites and achieved AUC

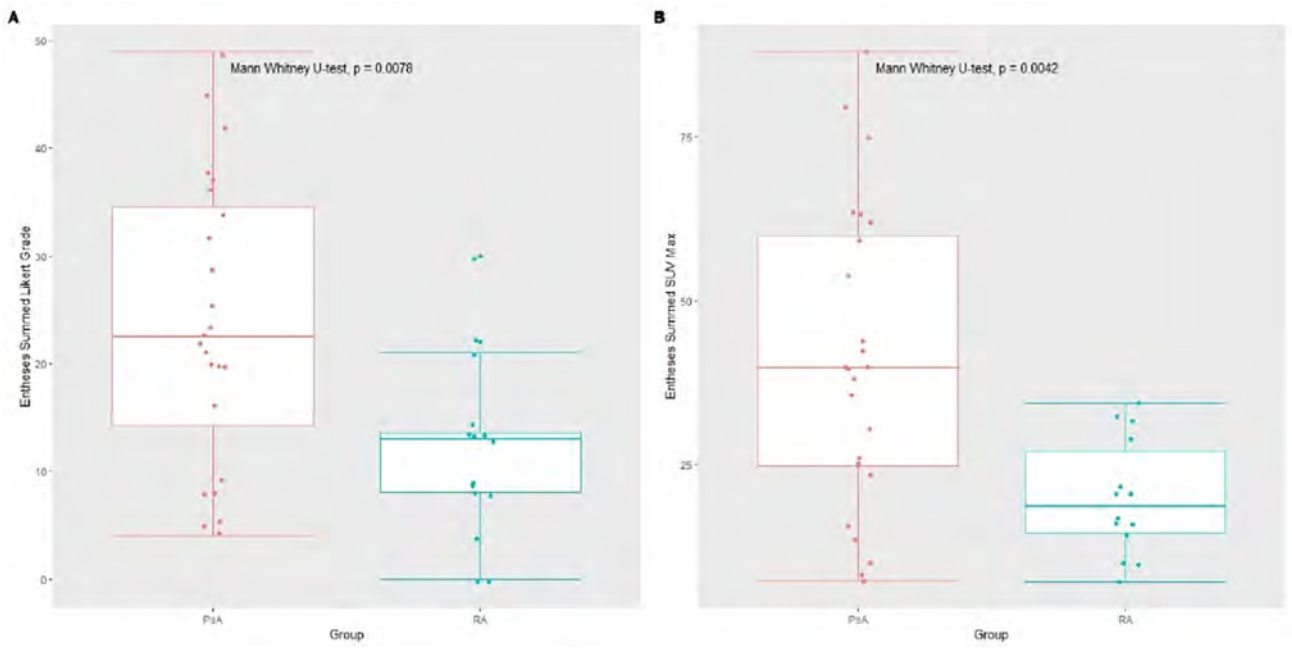

Figure 1: (A) Summed Likert grading of active entheses sites for PsA and RA participants; (B) Summed SUV max of active sites in PsA and RA participants.

Table 1: Summary of the differences in PET metrics between RA and PsA participants for each subset of entheses assessed. In all cases, PsA patients had higher average scores. Statistically significant results are shown in bold.

	Difference in PET positivity (p-value)	Difference in summed Likert score (p-value)	Difference in summed SUV max (p-value)
All 38 entheses sites	Yes **(0.01)**	Yes **(0.008)**	Yes **(0.004)**
LEI	Yes **(0.049)**	No (0.31)	No (0.39)
MASES	Yes **(0.02)**	Yes **(0.01)**	Yes **(0.01)**
SPARCC	No (0.07)	Yes **(0.03)**	Yes **(0.03)**
MAJOR	Yes **(0.04)**	Yes **(0.04)**	Yes **(0.02)**
San Francisco	Yes **(0.02)**	Yes **(0.007)**	Yes **(0.003)**
4-Point	Yes **(0.02)**	Yes **(0.04)**	Yes **(0.04)**

values of 0.76 (95% CI 0.63-0.90)and 0.79 (95% CI 0.63-0.91) for summed scores and summed SUV max, respectively, followed closely by all entheses sites (0.76, 0.78), MASES (0.74, 0.75), and SPARCC (0.71, 0.72). Summed Likert grades and summed SUVmax performed less well and poorly on the 4-point (0.69, 0.69) and LEI (0.56, 0.58) subsets, respectively.

Conclusion: Our results demonstrate that PET measures can be used to quantify and characterize specific disease domains in autoimmune arthritis. Higher and more frequent uptake in the entheses of PsA patients confirms enthesitis as a core feature of PsA that can potentially distinguish it from RA. Different performance of the various site groupings according to the established enthesitis measures highlight the need for in-depth evaluation of these measures against the standard clinical evaluation and possibly other imaging modalities.

Solving the Final Puzzle of Gout Detection in DECT via Machine Learning-Based Mitigation of Pseudolesion-Related Challenges: Enhancing Diagnostic Accuracy

Wan-Hee Yoo[1], Eun Hae Park[1], Dae-Woo Lee[1], Riel Casto-Zunti[2] and **Yunjung Choi**[1], [1]Jeonbuk National University Medical School, Jeonju, South Korea, [2]University of Saskatchewan, Saskatoon, SK, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In a recent study, the low specificity of Dual-Energy CT (DECT) has raised concerns due to the frequent occurrence of pseudo lesions, also referred to as clumpy artifacts, result in inaccurate discrimination from true monosodium urate (MSU) crystals due to their small size and overlapping image findings. This clinical impact is significant since a

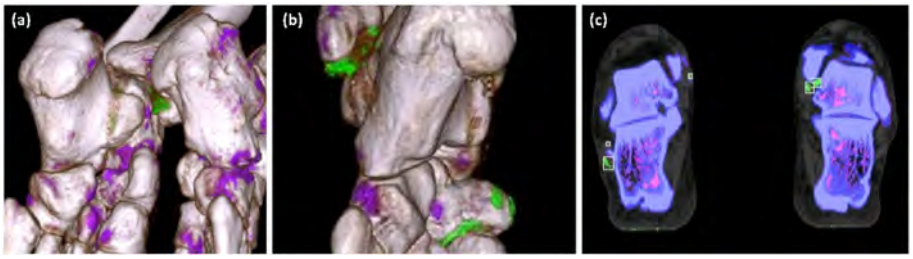

Figure 1. Applying deep learning to distinguish pseudo lesion and true monosodium urate (MSU) deposit. (a) In 3D DECT, there are pseudo lesions that appear as scattered green color foci at the hindfoot. Note that this patient obtains CT for fracture evaluation. (b) 3D DECT from gouty patients shows multiple patches of green color foci at the mid and hind foot. The green color from (a) and (b) are difficult to distinguish. (c) Final ROI labeling for deep learning.

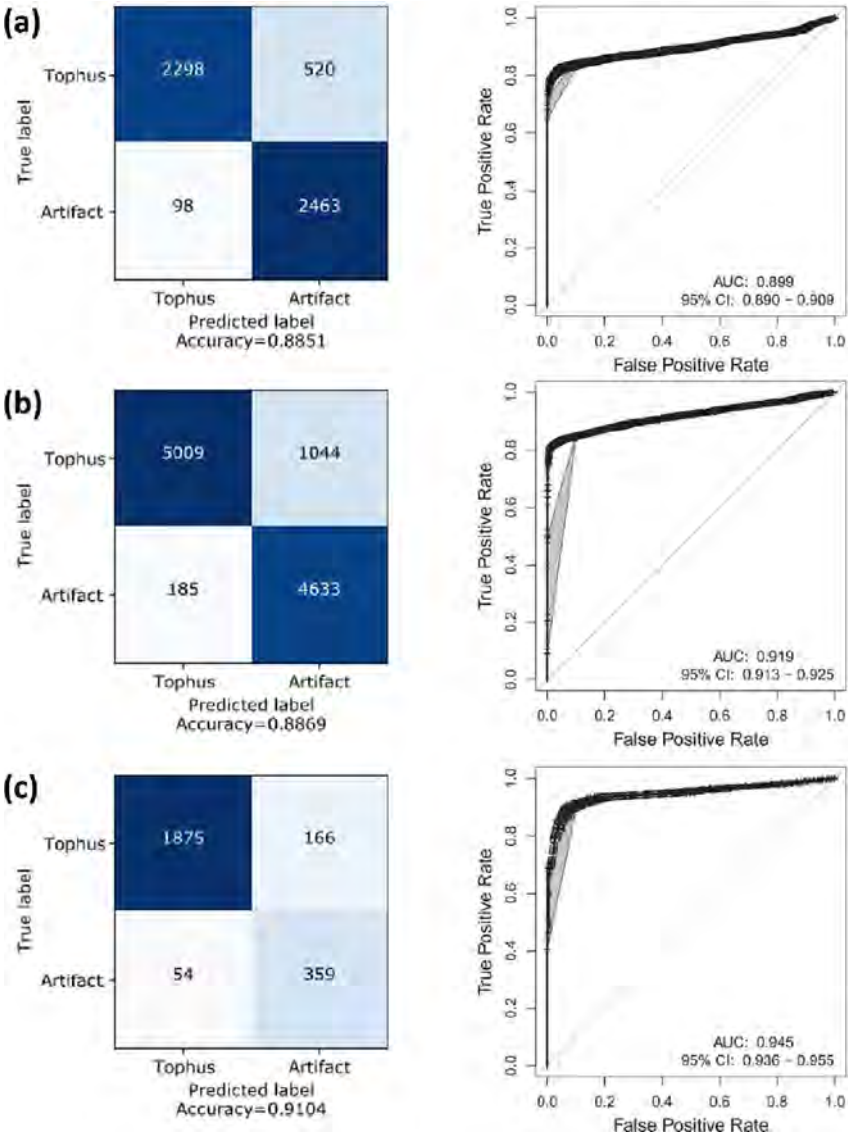

Figure 2. Confusion matrices and ROC curves of VGG16 architecture with Global Average Pooling (GAP) for differentiating between tophus and artifact instances on a per-region of interest (RoI) basis. The top pair (a) of matrices and curves corresponds to the classification model trained on the small-area dataset. The middle pair (b) represents the results for the medium-area dataset, while the bottom pair (c) displays the outcomes for the large-area dataset.

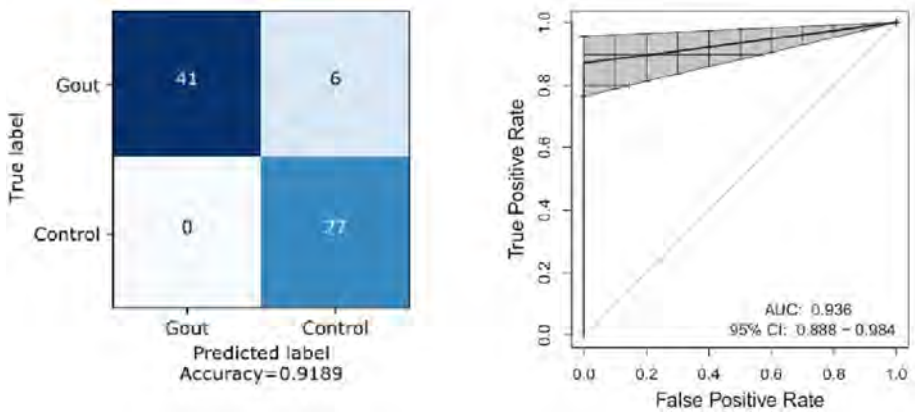

Figure 3. Confusion Matrix and ROC curve of Support Vector Machine (SVM) or distinguishing between gout and control cases on a per-patient basis

positive image finding on DECT is assigned a score of four, which accounts for half of the threshold according to the 2015 EULAR/ACR classification guideline.

The objective of this study is to assess the efficacy and accuracy of machine learning algorithms in distinguishing pseudo lesion from true MSU crystals in DECT imaging.

Methods: This study presents a comprehensive analysis of 18,958 regions of interest (ROIs) extracted from the green color foci of Dual-energy CT (DECT) scans obtained from 47 individuals diagnosed with gout and 27 gout-free controls. The ROIs were meticulously categorized into three size groups: small (n=4,911), medium (n=11,419), and large (n=2,628). As we conducted our analysis, we employed a two-step approach for the classification of tophus/artifacts, both on a per-lesion basis and on a per-patient basis. For the per-lesion classification, a convolutional neural network (CNN) model based on the VGG16 architecture with Global Average Pooling (GAP) was utilized. This model was trained using a 6-fold cross-validation scheme, where the dataset was divided into six subsets. To perform the classification on a per-patient basis, a Support Vector Machine (SVM) approach was employed and trained five times using cross-validation training folds. The performance of the models was evaluated using area under the receiver operating characteristic curve, sensitivity, specificity, positive predictive value, and negative predictive value.

Results: The sensitivity and specificity of the deep learning algorithm, VGG16 with GAP, for different sizes of ROIs were as follows: for small-sized ROIs, the sensitivity was 81.5% (95% CI, 95.3-96.8%) with a specificity of 96.1% (95% CI, 95.3-96.8%); for medium-sized ROIs, the sensitivity was 82.7% (95% CI, 81.7-83.7%) with a specificity of 96.1% (95% CI, 95.5-96.6%); and for large-sized ROIs, the sensitivity was 91.8% (95% CI, 90.6-93.0%) with a specificity of 86.9% (95% CI, 83.2-90.0%). The DL algorithm exhibited accuracies of 88.5% for small-sized ROIs, 88.6% for medium-sized ROIs, and 91.0% for large-sized ROIs. In the per-patient analysis, the SVM approach demonstrated a sensitivity of 87.2%, a specificity of 100%, and an accuracy of 91.8% (95% CI, 83.1-96.9%) in distinguishing between patients with gout and gout-free controls.

Conclusion: By applying deep learning algorithms, DECT shows impressive diagnostic performance by distinguishing the green color foci of DECT scans from pseudo lesions and tophi, leading to enhanced specificity even with small-sized green color lesions. Deep learning algorithms offer comprehensible and unequivocal approaches in DECT, allowing for precise and unmistakable diagnoses of gout.

Utility of a Diagnostic Algorithm in the Assessment of Large Vessel Vasculitis

HUGO AVALOS BOGADO[1], GUSTAVO AÑEZ STURCHIO[2], Ernesto Trallero-Araguas[3], Esther Espartal López[4], sebastián Sandoval Moreno[1], daniela Ulloa Navas[5] and Juan José De Agustín De Oro[2], [1]Rheumatology Department Vall d'Hebrón University Hospital, Barcelona, Spain, [2]Vall d'Hebron University Hospital, Barcelona, Spain, [3]Systemic Autoimmune Disease Unit, Vall d'Hebron Institute of Research, Barcelona, Spain, [4]Vall Hebron University Hospital, Rheumatology Department, Barcelona, Spain, [5]Rheumatology Department, Vall Hebron University Hospital, Barcelona, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most prevalent type of primary systemic vasculitis among individuals aged 50 and above. Imaging techniques such as ultrasound (US), magnetic resonance imaging (MRI), and {18F}-fluorodeoxyglucose positron emission tomography (PET-CT) have emerged as crucial diagnostic tools due to their non-invasive nature, higher sensitivity and availability compared to temporal artery biopsy (TAB) and angiography.

The purpose of this study is to evaluate the effectiveness of an algorithm based on imaging techniques in the diagnosis of GCA. Additionally, it seeks to assess the potential reduction in costs and unnecessary investigations during the diagnostic process.

Methods: The project consists of two phases. The first phase involved a retrospective analysis of a cohort suspected of having GCA, derived from outpatient consultations (OC) and hospitalizations in a tertiary hospital's Rheumatology department (February 2021-December 2022). A diagnostic evaluation was conducted using clinical criteria and imaging techniques

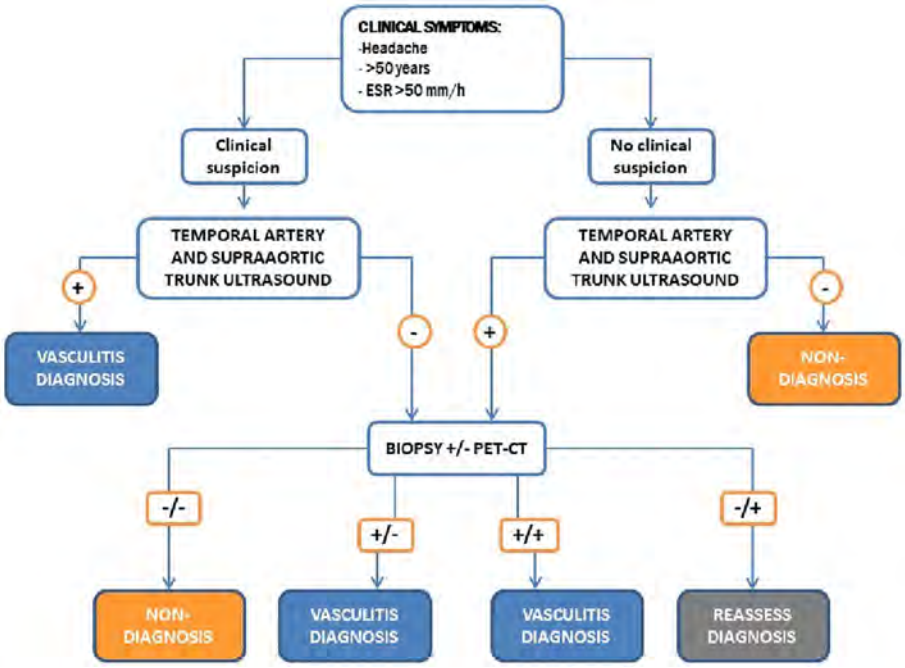

Figure 1. Proposed algorithm for the study of large vessels vasculitis

Table. Clinical variables, complementary tests, diagnosis and treatment. AION= Anterior ischemic optic neuritis; PET-CT= positron emission tomography; TAB= Temporal artery biopsy; US=ultrasound; GC=glucocorticoids

Oral GC mean starting dose 50mg/day	0	11/34	11

(US, PET-CT, TAB). US examinations were performed according to a standardized protocol within the Rheumatology service. In the second phase, the proposed diagnostic algorithm (Figure) was retrospectively applied, and the results were compared with the pre-algorithm phase. All patients provided their consent for participation.

Results: The study included 40 patients (80% women, n=32; 20% men, n=8), with a mean age of 72.55. All patients had clinical suspicion and 100% underwent US examinations with findings suggestive of GCA in 10 individuals (25%). TAB was performed in 9 patients (22.5%) and 3 of them (7.5%) had compatible results. PET-CT was conducted in 30 (75%) with conclusive results observed in 13 cases (32.5%). A final diagnosis of GCA was established in 16 patients (40%): clinical criteria + US in 1 patient (6.25%); clinical criteria + US + PET-CT in 8 (50%); clinical criteria + US + PET-CT + TAB in 7 (43.75%) (Table). Notably, among the 6 patients admitted to the hospital, 5 presented with initial clinical manifestations of anterior ischemic optic neuritis (AION). Within the diagnosed group, 10 individuals received corticosteroid treatment for at least 5 days prior to undergoing imaging techniques. Retrospective application of the algorithm to 8 patients (20%) with compatible US findings indicated that no further investigations would have been necessary (TAB + PET-CT in 5 patients and PET-CT alone in 3). Consequently, a total of 13 unnecessary supplementary tests could have been avoided. The maximum cost per patient amounted to €1117 (PET-CT €997, US €70, TAB €50). Implementation of the algorithm could have resulted in cost savings of €8176 and reduced iatrogenesis in this subgroup.

Conclusion: The utilization of an algorithm represents a practical and applicable tool in the diagnostic process of GCA. US serves as a valuable screening method in the initial evaluation, effectively reducing costs and redundant investigations in patients with compatible results and a high clinical suspicion. In cases where both clinical criteria and US findings are negative, it aids in excluding GCA as a diagnosis.

Use of Artificial Intelligence to Diagnose Polymyalgia Rheumatica on ^{18}F-FDG Whole Body PET/CT in Patients with Atypical Clinical Features

Emily Martin[1], Christopher McMaster[1], Saskia Rowson[1], Victor Yang[1], Aurora Poon[1], Bonnia Liu[1], Jessica Leung[2], Andrew Scott[1], David Liew[1] and **Claire Owen**[3], [1]Austin Health, Heidelberg, Australia, [2]Austin Health, Preston, Australia, [3]Austin Health, Malvern East, Australia

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: PET/CT is a highly sensitive and specific test for diagnosing PMR.(1) This study investigated the utility of ^{18}F-FDG whole body PET/CT in patients presenting with atypical clinical features and tested the performance of a novel artificial intelligence (AI) algorithm to simplify PMR diagnosis.

Methods: PET/CT reports from January 2015 to current were searched for findings suggestive of PMR using natural language processing. The scanned medical record of each identified case was reviewed to determine the final clinical diagnosis. Required criteria per the 2012 EULAR/ACR PMR Classification Criteria(2) (age ≥50 years, bilateral shoulder aching and abnormal CRP +/ ESR) were recorded, with patients not meeting these considered "atypical". Qualitative and semi-

Table 1: Frequency and 18F-FDG avidity of key musculoskeletal site abnormalities in atypical compared with typical PMR patients.

Site	Atypical Frequency	Typical Frequency	Mean Atypical SUV_{max}	Mean Typical SUV_{max}
Peri-Articular Shoulder	17/17 (100%)	34/35 (97.1%)	2.44±0.76	3.27±1.34 *p=0.01*
Peri-Articular Hip	15/17 (88.2%)	33/35 (94.3%)	1.79±1.02	3.27±1.81 *p=0.001*
Interspinous Region	14/17 (82.3%)	31/35 (88.6%)	1.58±1.04	2.82±1.58 *p=0.003*
Adjacent to Ischial Tuberosities	17/17 (100%)	34/35 (97.1%)	2.32±0.63	3.48±1.42 *p=0.001*
Posteromedial Knee	12/15 (80%)	25/34 (73.5%)	1.59±1.03	2.70±1.04 *p=0.001*
Volar Hand	7/16 (43.7%)	12/34 (35.3%)	0.95±1.24	2.38±1.06 *p=0.001*

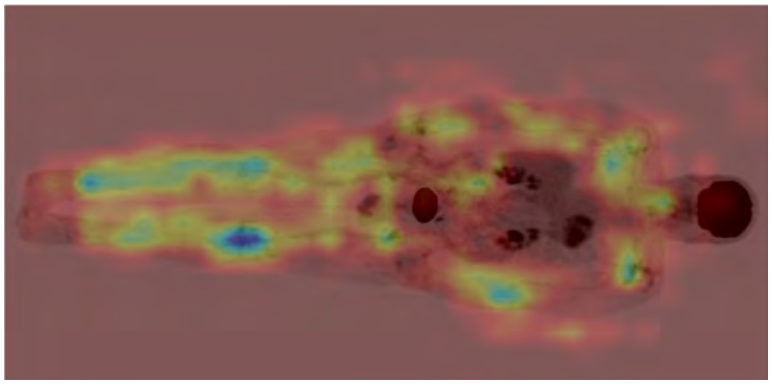

Figure 1: An example GradCam map highlights areas of the PET/CT image that contributed to a positive PMR diagnosis. This patient had bilateral shoulder and posteromedial knee symptoms – the GradCam map shows high intensity in these regions.

quantitative (SUV_{max}) PET/CT scores of steroid-naïve atypical PMR patients were compared with an existing typical steroid-naïve PMR population. Differences in ^{18}F-FDG avidity (mean SUV_{max}) were examined at key musculoskeletal sites. The performance of a ResNet50 AI model trained on PET/CT images of typical PMR and large joint arthritis patients was tested on the atypical PMR cohort. GradCam maps were employed to cross-check the AI's focus on characteristic PMR-involved anatomical regions.

Results: 225 PET/CT reports were retrieved from >38,000 scans, with 121 patients possessing a final clinical PMR diagnosis. 17 steroid-naïve atypical patients were compared with 35 steroid-naïve typical cases. Mean CRP (10.1±20.9 cf. 44.0 ±32.9 [p=0.0002]) and ESR (11.5±7.2 cf. 49.3±29.6 [p=0.0001]) were lower in the atypical group, but the frequency of abnormalities at key musculoskeletal sites was similar (Table 1). A statistically significant difference ($p < 0.05$) in mean SUV_{max} was detected between the groups at every musculoskeletal site analyzed. When the novel AI-trained model was tested on PET/CT images of atypical patients, 16/17 were identified as positive for a PMR diagnosis. Figure 1 provides a GradCam map example in an atypical PMR case.

Conclusion: PMR patients with atypical clinical features exhibit the same PET/CT abnormalities as typical cases, but affected musculoskeletal sites are less ^{18}F-FDG avid. This distinctive imaging pattern can be harnessed by AI technology to facilitate PMR diagnosis in challenging clinical scenarios.

Methods: Epos (Early PsA on treatment strategy) is a prospective, single-arm, interventional, open-label, single-center phase 4 trial (EUDRACT 2018-000335-27) in psoriasis patients with an increased risk of transition to psoriatic arthritis (PsA). Participants had to have (i) mild to moderate psoriasis, (ii) arthralgia and (iii) subclinical inflammatory changes assessed by hand MRI and/or high-resolution CT. Patients with any present or past signs of PsA (arthritis, dactylitis, enthesitis, axial involvement) as well as previous treatment with biological or targeted-synthetic DMARDs were not allowed to participate. Participants received apremilast 30 mg twice daily over 24 weeks. To assess the effect of apremilast on entheseal bone changes high-resolution CT scans of the entheseal areas of metacarpal finger joints were conducted at baseline and week 24. At the entheseal areas, peripheral volumetric bone mineral density (vBMD), bone microstructure and structural entheseal lesions were assessed. Clinical response and safety were monitored.

Results: 20 patients (50 [SD 11.6] years; 9 women) with a duration of skin psoriasis of 18.6 [SD 12.8] years were included (table 1). At week 24, skin disease significantly improved (Psoriasis Area and Severity Index: from 10.9±6.7 at baseline to 5.2±6.6 at week 24) as well as arthralgia (VAS: from 30.1±23.3 at baseline to 22.4±26.7 at week 24) (table 2). Tender joint count 68 and tender enthesis count also declined over 24 weeks of treatment (3.2±3.4 at baseline vs. 0.8±1.8 at week 24 and 1.6±2.7 at baseline vs. 0.5±0.9 at week 24, respectively) (table 2). No significant progress was found for entheseal cortical vBMD (baseline: 699.3±92.7 mg HA/cm^{3}vs. week 24: 701.8±97.6 mg HA/cm^3, p=0.523) and entheseal cortical thickness (0.4±0.1 mm vs. 0.4±0.1 mm, p=0.323) (table 2). Accordingly, no progression was detected in structural entheseal lesions. No new safety signals with apremilast treatment were observed.

Conclusion: Apremilast leads to early disease interception by improving skin disease and arthralgia and halting progression of entheseal bone changes in psoriasis patients at risk for the transition to PsA. Larger studies with longer follow-up periods are needed to validate these findings.

Sacroiliac Bone Marrow Oedema on Postpartum MRI Does Not Result in Significant SpA-like Structural Lesions: Results of a 5-year Follow-up Study

De Meester Liesbet[1], **Gaelle Varkas**[2], Manouk de Hooge[3], Ann-Sophie De Craemer[4], Nele Herregods[5], Lennart Jans[5], Philippe Carron[6], Dirk Elewaut[7] and Filip Van den Bosch[8], [1]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [2]Dept. of Rheumatology, Ghent University Hospital, Ghent, Belgium, [3]Ghent University Hospital, Hesperange, Luxembourg, [4]Ghent University Hospital, Gent, Belgium, [5]Department of Radiology, Ghent University Hospital, Ghent, Belgium, [6]UZ Gent, Gent, Belgium, [7]Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [8]Department of Internal Medicine and Pediatrics, Ghent University and VIB Center for Inflammation Research, Ghent, Belgium

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sacroiliac bone marrow oedema (BMO) on MRI, immediately after childbirth, has been observed in a large proportion of postpartum women and appears to be a transient phenomenon. Although generally attributed to mechanical stress, these postpartum BMO lesions bear a striking resemblance to the inflammatory lesions seen in axial spondyloarthritis (axSpA). In axSpA, active inflammatory lesions are likely to progress to structural lesions, particularly fat metaplasia and erosions. It is not known whether the same is true for mechanical stress-induced BMO. To assess the long-term evolution of postpartum BMO and the potential development of axSpA-like structural lesions, we performed a 5-year follow-up ofour prospective study on sacroiliac MRI lesions in healthy women following an uncomplicated vaginal delivery.

Methods: Seventeen (48.6%) of the original 35 participants underwent a new MRI of the sacroiliac joints (MRI-SIJ) approximately 5 years after delivery. Structural lesions (fat metaplasia, erosions, sclerosis, (partial) ankylosis) and BMO were scored by three well-trained, calibrated readers using the Spondyloarthritis Research Consortium of Canada (SPARCC) scoring system. Agreement with the Assessment of SpondyloArthritis international Society (ASAS) MRI definition of sacroiliitis was assessed. Baseline MRI images were re-evaluated, and compared with the 5-year follow-up MRI data. Demographic, clinical, and obstetric data were updated.

Results: The overall prevalence of fat metaplasia, erosions and sclerosis on baseline and 5-year MRI images was low. No ankylosis was found. Scores for fat metaplasia and erosions did not change significantly between the two time points. A numerical increase in sclerosis score at year 5 was seen in only3 of 17 subjects, all of whom had BMO after delivery. As expected, there was a significant decrease in BMO from baseline to year 5. Six of the 17 subjects (35%) still had BMO at the 5-year follow-up MRI-SIJ,3 of whom met the ASAS definition of sacroiliitis. No deep or intense BMO lesions were observed.

Conclusion: In postpartum women, nosignificant development of axSpA-like structural MRI lesions was observed 5 years after delivery. These results support the hypothesis that transient mechanical stress-induced sacroiliac BMO, while resembling axSpA on MRI,does not evolve into chronic structural lesions.

Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: VEXAS syndrome (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) is anautoinflammatory syndrome caused by somatic mosaicism in the *UBA1* gene. [^{18}F]-FDG-PET/CT is often performed during the diagnostic workup of patients with VEXAS syndrome, but the abnormalities that may be detected with this imaging examination are not well described.

Methods: We performed a retrospective multicenter study in France and Belgium. Patients with confirmed VEXAS syndrome, defined by the presence of an autoinflammatory syndrome and detection of a pathogenic *UBA1*mutation, who underwent at least one [^{18}F]-FDG-PET/CT were considered eligible. Data on the clinical presentation, laboratory results, genetic analyses, and [^{18}F]-FDG-PET/CT imaging results were collected using a standardized form. In an exploratory analysis, the observed abnormalities were compared according to the clinical disease activity status and the VEXAS syndrome clusters as previously defined by Georgin-Lavialle et al. (Br J Dermatol 2022;186:564–74).

Results: A total of 106 [^{18}F]-FDG-PET/CT scans were performed in 57 VEXAS patients. All patients were male and had a median age of 71 (IQR, 66-76) years at symptom onset and 75 (IQR 69-79) years at diagnosis. The most frequent clinical manifestations included cutaneous lesions (86%), fever (79%), arthralgia or arthritis (68%), pulmonary manifestations (46%), ear or nose chondritis (37%), and venous thrombo-embolism (33%). Only 29% of scans were performed before treatment for VEXAS, as the majority of patients received corticosteroids (66%) and/or other immunosuppressive treatments (40%) at the time of imaging. Patients most commonly had increased FDG uptake in the bone marrow (82%), lymph nodes

(54%), lungs (37%), and spleen (30%). Less frequently, patients had hypermetabolism in the pleura (18%), nose or ear cartilage (9%), joints (5%), and pericardium (2%). Increased arterial FDG uptake was identified in 12% of patients, including aortic involvement (5%) and asymmetric artery involvement (9%). Significantly more abnormalities were detected by [^{18}F]-FDG-PET/CT in VEXAS patients with active disease (median 3 [IQR 2-4]) compared to those in clinical remission (median 1 [IQR 1-2]) ($P < 0.001$). However, abnormal FDG uptake often remained present in patients who were considered to be in clinical remission, particularly in the bone marrow (70%), lymph nodes (35%), lungs (20%), and arteries (10%). When comparing those with active disease according to the VEXAS syndrome clusters, we observed a trend towards more abnormalities in the inflammatory cluster (n=17; median 3 [IQR 2-5]) and the hematological/myelodysplasia cluster (n=24; median 3 [IQR 2-4]), compared to the mild-to-moderate cluster (n=7; median 1 [IQR 1-4]) (P=0.09).

Conclusion: We report on [^{18}F]-FDG-PET/CT imaging results among patients with VEXAS syndrome. Although zones of abnormal FDG uptake occurred frequently in VEXAS syndrome, the abnormalities were mostly non-specific. More abnormalities were detected among those with active disease, but bone marrow hypermetabolism in particular often persisted in those considered to be in remission, suggesting subclinical disease activity.

3-Dimensional Regional Variation in Inter-rater Reliability of Bone Marrow Lesion Scoring in the Knee

Stephanie Wichuk[1], Walter P. Maksymowych[1], Joel Paschke[2], Abhilash Hareendranathan[3] and Jacob Jaremko[1], [1]University of Alberta, Edmonton, AB, Canada, [2]CARE Arthritis, Edmonton, AB, Canada, [3]Radiology and Diagnostic Imaging, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1862–1894) Imaging of Rheumatic Diseases Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Bone marrow lesions (BML) are an important scoring feature on magnetic resonance imaging (MRI) of knee osteoarthritis (OA), and their presence in certain anatomical locations may be more closely related to various clinical measures than in others. At the same time, anatomical location may impact BML scoring reliability. The Knee Inflammation MRI Scoring System (KIMRISS) scores BML from fluid-sensitive sagittal MRI[1]. Readers place ready-made overlays onto scorable portions of the femur, tibia, and patella, demarcating medial, intercondylar, and lateral knee compartments. These overlays divide each scorable region into smaller grid squares which are evaluated for presence of BML on each slice. We aimed to evaluate 3-dimensional patterns of regional variation in inter-rater reliability for BML within these sagittally-placed KIMRISS grid elements when divided into subsections across the coronal plane. This granular analysis serves as a precursor to further study of the relationship of precise BML location to clinical measures and outcomes, as reliable data is required to ensure validity of such analyses.

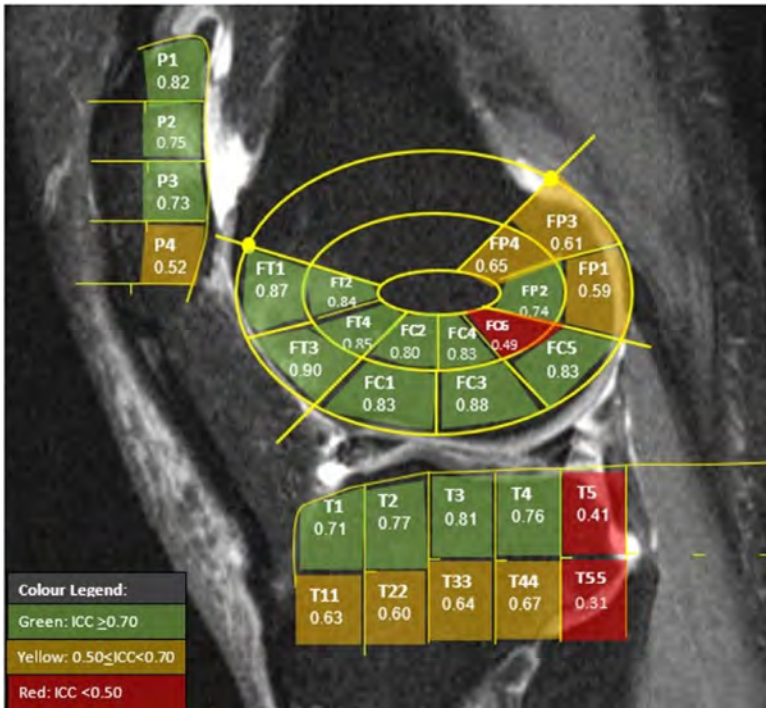

Figure 1. KIMRISS grid region labels with 8-reader mean ICC from baseline knee MRIs from the Osteoarthritis Initiative dataset (n=61).

Methods: MRI from 61 patients in the Osteoarthritis Initiative (OAI) dataset were scored by 8 trained readers using KIMRISS. Each grid overlay region in the femur and tibia (14 and 10 regions, respectively) was divided into 6 equal subregions medially to laterally, excluding the intercondylar region.We calculated an overall 8-reader interclass correlation coefficient (ICC) for each subregion and generated a 3D segmentation model of the knee to visualize variation in ICCs.

Results: Before any subdivision in the coronal plane, ICCs ≥ 0.70 were achieved in 61% of grid regions (Figure 1). Highest reliability was found trochlear region of the femur (ICCs 0.84-0.90), while lowest ICCs occurred in a small interior region of the femur [mean (SD) ICC=0.49 (0.26)] and the two posteriormost tibial regions [mean (SD) ICC=0.41 (0.26) and 0.31 (0.33)]. After further subdividing regions medially to laterally, highest overall reliability amongst all KIMRISS grid squares occurred in the central slices of the lateral compartment of the femur (median ICC=0.72) and the innermost slices of the medial compartment of the tibia (median ICC=0.42). (Figure 2, Table 1). Lowest overall reliability occurred in the central slices of the medial compartment of the femur (median ICC=0.15) and the medialmost slices of the medial compartment of the tibia (median ICC= 0.28)

Conclusion: While reduced ICCs are to be expected across the board in subdivided scoring regions compared to larger summed regions, this analysis highlights differences in inter-rater reliability over 3 dimensions of the knee. Any analysis of the relationship of clinical variables to precise BML location should consider the degree of scoring reliability at the scoring locations entered into the model. Certain regions may need to be excluded or enlarged to achieve inter-rater consistency.

Comparative Analysis of Existing Tools in Assessing Cardiovascular Risk in Patients with Rheumatoid Arthritis: Exploring the Inadequacies

Pritee Shrestha[1], Peter Larsen[1] and Pablo Weilg Espejo[2], [1]Mercy One North Iowa Medical Center, Mason City, IA, [2]Boston Medical Center, Chelsea, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Rheumatoid Arthritis (RA) are at increased risk of cardiovascular disease (CVD). Despite multiple CVD risk tools available, reliability to RA population is limited as they might not fully incorporate the unique risk factors faced by this population cohort. Studies have shown a direct correlation between RA disease severity and increased prevalence of CVD risk factors like diabetes and arthrosclerosis. [1,2] Based on these findings, we can expect an adequate tool designed to assess the burden of cardiovascular disease risk should reflect the disease severity in patients

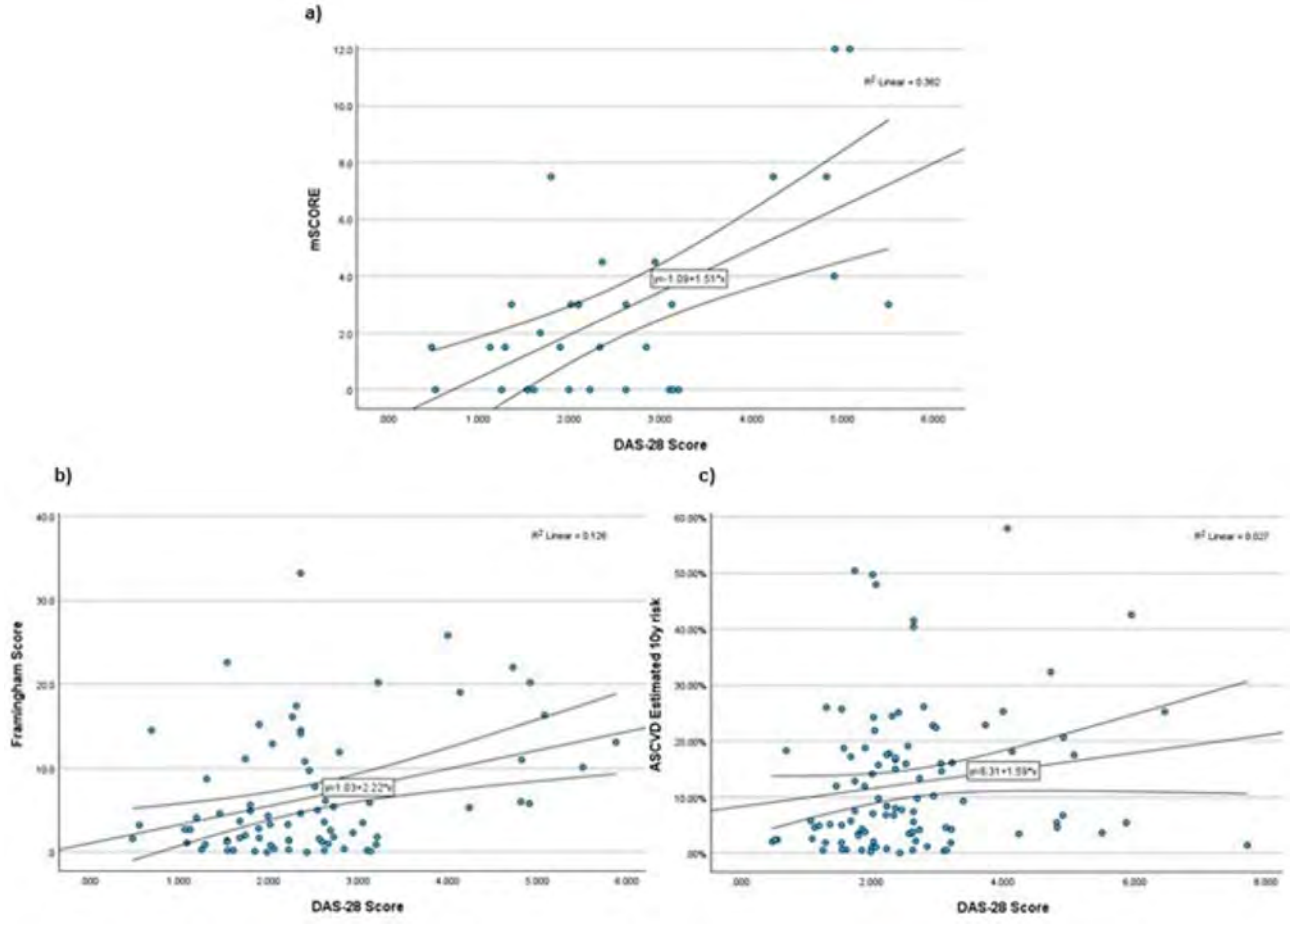

Figure 1. Scattered plot illustrating a) strongest correlation between mSCORE and DAS-28 scores suggesting that as RA disease activity increases, the cardiovascular risk per mSCORE calculation also increases. On the other hand, the b)Framingham score and c) ASCVD score shows weaker correlations with the DAS-28 score.

with RA. We aim to assess the reliability of current CVD assessment tools used in patients with RA by comparing the strength of correlation between these tools with the RA disease severity.

Methods: A single centered retrospective observational analysis was conducted. Medical records of 102 patients all of whom met 2010 ACR/EULAR criteria were included including the DAS-28 score calculated per rheumatologist. SPSS was utilized to assess the strength and direction of the relationship between each CVD assessment tool and RA disease activity. For the former, we employed ASCVD, Framingham and mSCORE. The mSCORE risk assessment tool was recommended by EULAR to access CVD risk in patients with RA. [1] Correlational analysis between CVD assessment tools and DAS-28 score was performed to evaluate the relationship between CVD risk and disease activity. Statin use in patients at risk as recommended by the AHA were reviewed.

Results: Results revealed the correlational coefficient for mSCORE, Framingham score and ASCVD score with DAS-28 score where 0.618, 0.355, 0.165 with P value of < 0.001, 0.001 and 0.098 respectively (Table 1). These findings suggest that mSCORE shows the strongest correlation with DAS-28 scores compared to ASCVD and Framingham score (Figure 1). Further, we identified the number of patients with moderate to high disease activity that are calculated to have a low CVD risk. Increased variability among the tools raises questions about the accuracy of these tools in reflecting the true risk. We found that 42% (n=8) patients and 21% (n=4) who had moderate to high risk were classified as low risk in ASCVD and Framingham score respectively. At the same time, for the mSCORE, none of the patients with moderate to high disease activity was classified as low risk(Table 2). These findings reinforce our previous result.

Table 1. Correlational analysis between the mSCORE, ASCVD score, Framingham score with DAS-28 score performed to evaluate the relationship between CVD risk and RA disease activity. The statistical significance for ASCVD likely impacted by a small sample size along with confounding variables such as age, sex, and other patient demographics. Overall, the higher correlational coefficient for mSCORE suggests that it may be a better predictor of cardiovascular risk in relation to disease activity in RA patients, compared to the Framingham and ASCVD scores.

Correlations				
		ASCVD Estimated 10y risk	Framingham Score of Individual (%)	mSCORE
DAS28	Pearson Correlation	.165	.355	.618
	Sig. (2-tailed)	.098	.001	< .001
	N	102	78	33

Table 2. Comparative analysis using crosstabulation to assess if the risk stratification categories calculated by each tool aligns with the severity category of the disease. 8 patients in ASCVD and 4 patients in Framingham score system who had moderate to high RA disease activity were classified to have a low risk of CVD using these risk assessment tools. Whereas none of the patients with moderate to high disease activities were classified to have a low CVD risk in mSCORE system.

		DAS-28 Severity Category	
Scoring Tool	Risk Category	high	moderate
ASCVD scale	High risk	2	5
	Intermediate risk	0	4
	Low risk	3	5
Framingham severity scale	*	3	3
	High risk	0	4
	Intermediate risk	2	3
	Low risk	0	4
mSCORE severity scale	*	4	9
	High risk	0	4
	Intermediate risk	1	1
	Low risk	0	0

* Population who did not meet criteria for the calculation of the associated CVD risk score

Conclusion: Being explicitly designed for RA patients, mSCORE is likely to capture the cardiovascular risk profile of these individuals better as it incorporates RA-specific factors. Although such RA-specific tools offer some improvement over general population-based tools, their practical application remains challenging due to several experimental limitations. As a result, providers often rely on general tools leaving a concern that these patients are not being appropriately treated. Moreover, we are observing treatment failures even with currently used general risk assessment tools. Approximately 32% (n=20) in our study, who warranted statin therapy based on their ASCVD risk were not receiving it. These findings draw attention to a significant gap in adequate management of cardiovascular health in this population.

Systematic Review and Analysis of Mobile Apps for Rheumatoid Arthritis Using the Mobile Application Rating Scale

Pamela Gonzalez Manrique[1], Vinit Gilvaz[2], Ravinder Kaler[3], Neha Batra[3] and Anthony Reginato[2], [1]Roger Williams Medical Center, North Providence, RI, [2]The Warren Alpert Medical School of Brown University, Providence, RI, [3]Roger Williams Medical Center, Providence, RI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a systemic autoimmune disease characterized by inflammatory polyarthritis with infrequent extra-articular involvement. The management of RA typically requires frequent clinic visits (approximately 7.2 visits/ year) to manage disease activity, as well as to monitor for the toxic effects of the medications prescribed. Evidence shows that mobile health (mHealth) apps, when implemented along with clinic visits, improve medication adherence, patient outcomes, in addition to decreasing health care costs in chronic diseases. The purpose of our study is to evaluate individual mHealth apps for RA from both the Android and Apple store. In addition to rating each app using the Mobile Application Rating Scale (MARS), we aim to assess the factual accuracy of the information provided, as well as the amount of medical and personal data collected by each app. We will also evaluate the 10 EULAR recommendations provided by the task force.

Methods: Each app will be rated by two physicians from the division of Rheumatology. The app searches will be done using Apple Store, and Google Play Store. The search will include the keywords: "arthritis", "RA", "rheumatoid arthritis". Inclusion criteria: 1) available for Android and iOS operating systems 2) in English 3) targets RA as subject matter 4) downloadable in the USA. Exclusion criteria: 1) not directed towards RA 2) explicitly only for physician use 3) inactive app 4) Duplicates 5) only available with an additional device. 6) All information with no data input option. Each mobile app will be rated on the MARS scale. The two physicians were trained prior. Additionally, we will evaluate if applications meet EULAR recommendations. We will compare and contrast the information gathered including demographic, insurance, provider information, and prescription data, as well as evaluate whether it is a pharmaceutical vs traditional app (Figure 1).

Results: Upon initial search, 133 applications were retrieved in the Apple Store and 178 in the Google App Store. Only 121 of the apps were in both stores, and only 10/121 met our inclusion and exclusion criteria. The mean score for MARS rating scare of our apps was 3.5 which indicates an acceptable quality. The lowest scores were found to be in the engagement sections with mean of 3.3, and the highest in functionality with mean of 3.87 (Fig 2a and 2b). Overall, it was found that the

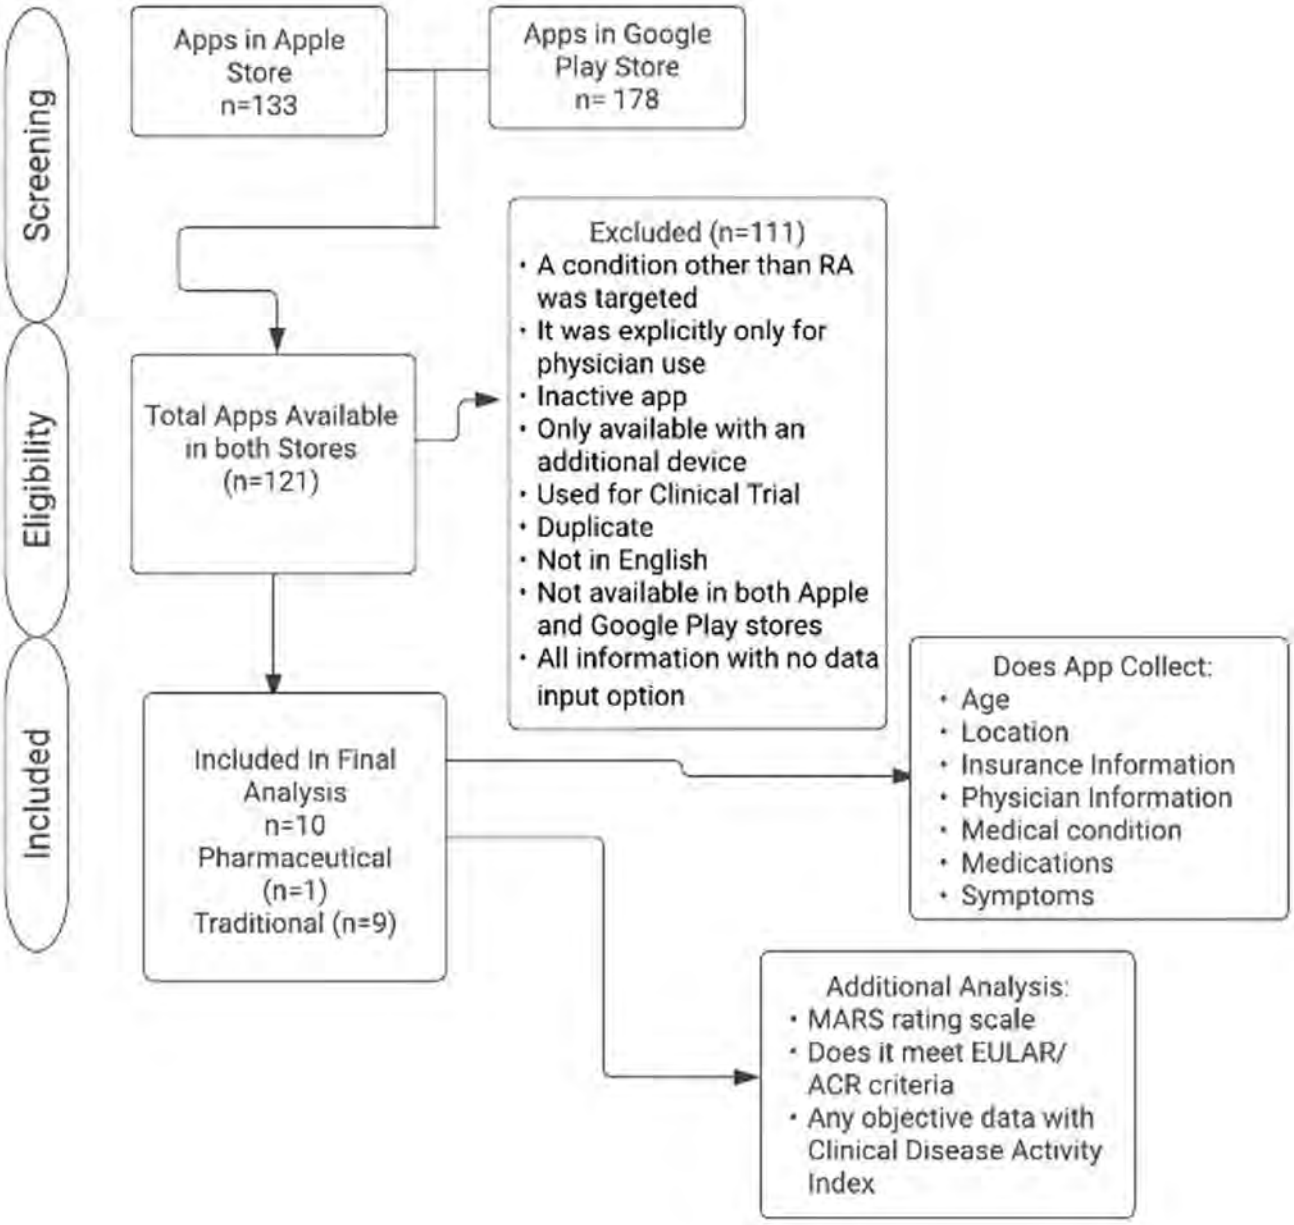

Figure 1: App Selection Process Flow Chart

best rated apps were those few that were designed by rheumatologists, and had arthritic patients involved. When looking at EULAR criteria, no application met all of them.

Conclusion: To our knowledge, this is the first study using both EULAR recommendations and MARS to systematically analyze RA apps. Mobile apps when used along with traditional visits can help foster compliance to medication, help disease modification and improve morbidity and mortality. Our study further illustrates that the applications that were designed by physicians did the best, which strengthen EULAR's recommendation. Overall, there are many applications in the app stores, however there are very few that are acceptable. More work and standardization needs to be done with these applications and we should look closer to EULAR guidelines to further optimize these applications.

Table 1: Characteristics of included rheumatology apps

App Name	Technical Aspects/Content	Privacy Policy Available	Ask for Insurance	Ask for Provider Information	Pharmaceutical Drug App	Price
Abbvie - Complete: Includes Humira, Skyrizi, Rinvoq	Injection reminder/ notification, nurse support, log symptoms/ medication side effects, Write down medications, Discounts/ savings, Age, sex, location; rheumatology condition but no other past medical history documented	Yes	Yes	No	Yes	Free
RA Monitor	Medication and symptoms tracker Daily functionality, mood and stress, Anonymous social networking with other people with RA. Can message provider. Updated news with rheumatology advancements, can share PDF files and upload. Location, age, sex	Yes	No	Yes	No	Free
RA Manager	Can upload pictures and share with provider, up-to date info on RA with reputable sources, HIPPA protected info, meds with reminders, sx, specific to RA, can share data with healthcare team, manage	Yes	No	Yes	No	Free
	medications, age, location, sex.					
Rheumatoid Arthritis Storylines	Medication, symptom and mood tracking. Health journal. Sync vital signs with wearable devices. Age, Sex.	Yes	No	No	No	Free
Rheumatoid Arthritis Diary	Symptom tracking. Gives you statistical % of triggers, including food, stress location, activity, weather patterns and sleep patterns. Keep track of your appointments, lab analyses, and medical records. how likely triggers are by finding patterns. Age, sex.	Yes	No	Yes	No	$4.99
Arthritis Tracker	Application mostly intended for teens and young adults with arthritis. Symptom tracking. Can track sleep, emotions, energy levels, medication side effects. There is an information section for advice and information. Age, Sex.	Yes	No	No	No	Free
ConnectPlus	For RA and other rheum conditions. Developed with pts and clinical teams across the NHS. Information about condition, symptom tracker, connect with specialists in	Yes	No	Yes	No	Free
	rheumatology. Medicine tracking, healthy lifestyle tips, they ask for sex, age, location.					
Arthritis + Patient	Made by rheumatologists and reviewed by a network of rheumatology peers. Development of the app was also done with consultation with arthritis patients. Information requested is past medical history, social history, age, sex, location, meds, homunculus, BASDAI, HAQ, BASFI. App also provides educational material. Also has features like speech to text widgets. Can take pictures to show progression or flares.	Yes	No	Yes	No	Free
My Arthritis	Ampersand Health in collaboration with King's College Hospital NHS Foundation and the National Rheumatoid Arthritis Society; sx tracking, courses for pts, connect to hospital, access medical records. Can also participate in research.	Yes	No	Yes	No	Free

Abstract Number: 1897

In Pursuit of Excellence: Improving Systemic Sclerosis Quality of Care

Aos Aboabat[1], Samar Aboulenain[1], Zareen Ahmad[2], Medha Soowamber[3] and Sindhu Johnson[4], [1]University of Toronto, Toronto, ON, Canada, [2]Toronto Scleroderma Program, Mount Sinai Hospital, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [3]Toronto Scleroderma Program, Mount Sinai Hospital, Toronto Western Hospital, University of Toronto, Woodbridge, ON, Canada, [4]Division of Rheumatology, Department of Medicine, Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western and Mount Sinai Hospitals; Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a complex autoimmune disease with significant morbidity and mortality. Quality indicators (QIs) for SSc care, previously published, are essential tools to enhance patient outcomes. However, a gap in the implementation of these QIs in clinical practice has been observed. This quality improvement project was designed to enhance the application of SSc QIs. The objectives of this study were to identify the quality gap in systemic sclerosis (SSc) care through assessment of recommended QIs and to evaluate the impact of targeted interventions to improve their uptake.

Methods: We conducted an interrupted time series study at 4 Scleroderma clinics across 2 hospitals over 10 months. Using the model for improvement framework, we employed the Plan-Do-Study-Act (PDSA) methodology to implement sequential change ideas. Interventions were increasing knowledge and awareness among physicians, implementing standardized care processes, and ensuring the availability of necessary devices. Outcome measures were the rates of completion of suboptimal baseline and monitoring/treatment QIs among newly diagnosed and early SSc patients. Process measures were the rates of SpO2 documentation, completion of annual pulmonary function tests (PFTs), baseline creatinine kinase (CK) measurements, blood pressure (BP) self-measurement counseling, and referrals to a hand exercise program for patients with reduced hand function. Balancing measures were staff satisfaction (5-point Likert scale, 1-5 from strong dissatisfaction to strong satisfaction) and perceived workload related to interventions (increase in time per patient).

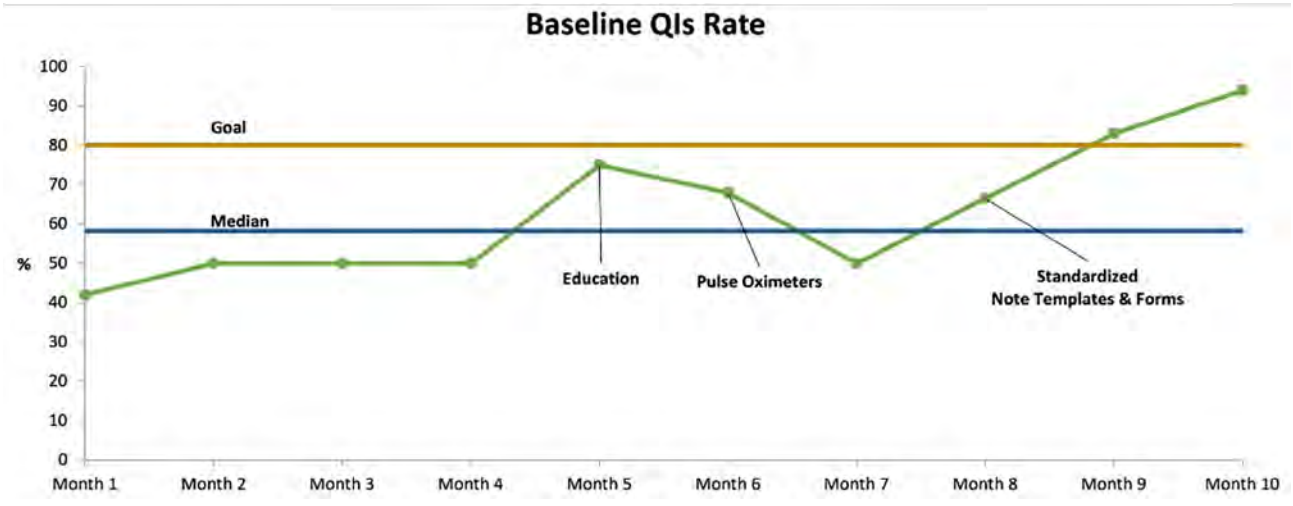

Figure 1

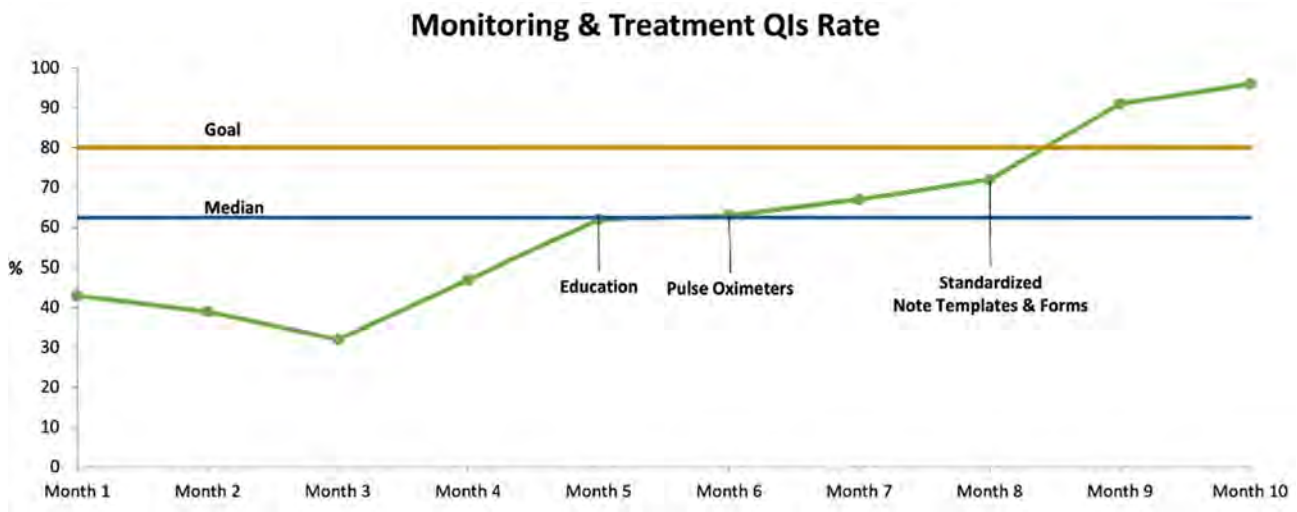

Figure 2

Results: The rate of baseline QIs among newly diagnosed SSc patients improved from 42% to 94% over 10 months (Figure. 1). The rate of monitoring and treatment QIs among early SSc patients improved from 43% to 96% (Figure. 2). Process measures including rates of SpO2 documentation during in-person visits (35.7% to 86%), completion of annual PFTs (64% to 100%), baseline CK measurements (33% to 100%), BP self-measurement counseling (0% to 100%), and referrals to a hand exercise program (33% to 100%) showed improvements. Balancing measures indicated stakeholder satisfaction (median rating 4) with the changes and no increased perceived workload (mean time increased by 2.5 minutes per patient).

Conclusion: The implementation of the interventions led to improvements in the rate of completion of QIs. Continuous monitoring through regular audits and the application of subsequent PDSA cycles as required is critical for sustaining these improvements. This initiative underscores the importance of systematic quality improvement in enhancing the management of complex autoimmune diseases like SSc.

Patient After Visit Instructions at a University Rheumatology Outpatient Clinic: Do They Make a Difference?

Dijo Joseph, Rong Hu, Robert Min, Meenakshi Jolly and Sobia Hassan, Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: As low health literacy (HL) has been linked to poor health outcomes in rheumatic diseases, it is important to optimize organizational HL. One way of doing this might be through the delivery of after visit instructions (AVI) which are personalized instructions written by a provider & given to patients in the outpatient rheumatology setting. An initial needs assessment revealed that only 25% of patients received AVI at our institution. Herein, we aimed to evaluate the

effectiveness of two after visit interventions aimed at improving the delivery, comprehension, & retention of management plans for patients in an academic rheumatology clinic.

Methods: This was a prospective, randomized, proof-of-concept study. Patients scheduled for clinic visits were randomized into three groups: control group (standard of care), standardized AVI only (templated personalized AVI), & standardized AVI plus Teach back (TB). In TB, the patient repeats management changes to the provider in their own words. Patients completed an Arthritis Rapid Estimate of Adult Literacy in Medicine (A-REALM) questionnaire, to assess rheumatology health literacy. A telephone survey was conducted 1-2 weeks after their clinic visit to assess retention & comprehension in three categories: reason for visit, medication changes, & referrals/further testing. The primary outcome of the study was correspondence between patient responses & the plan outlined in the provider management plan. Patient satisfaction was assessed as a secondary outcome. AVI readability was evaluated using Flesch-Kincaid (FK) scores.

Table 1 Baseline demographics and characteristics

	Total (N=75) (%)
Mean Age Years (SD)	56.7 (14.5)
Gender	
Female	56 (75.7%)
Ethnicity	
Hispanic	13 (17.3)
Not Hispanic	62 (82.7)
Race	
White	27 (36)
Black	34 (45.3)
Asian	2 (2.7)
Other	11 (14.7)
New Patient	30 (40)
Mean Years of Education	15.08
Mean A-REALM*	61.83
Primary Rheumatological Diagnosis	
Inflammatory/Autoimmune	35 (47.3)
Non-inflammatory Conditions	36 (48.6)
Not Applicable	4 (5.3)
Study Arm	
Control	31 (41.3)
AVI only	19 (25.3)
AVI & TB	25 (33.3)
Change in Management During Visit	64 (85.3)
AVI Provided	57 (77)
AVI Provided in Control Group	14/31 (45.2%)
AVI Provided in Control Group w/ Change in Management	13/25 (52%)

*A-REALM is a screening instrument used to assess an adult's ability to read common rheumatology words. A score of >61 indicates a high school literacy level.

Table 2 Patients with Greater Than or Equal to 75% Concordance on the post-visit retention survey

	Control (N=31)	AVI Only (N=19)	AVI & TB (N=25)	Chi Squared P-Value
Reason for visit	18 (58.1%)	16 (84.2%)	18 (72%)	0.313
Medication changes/side effects	11 (35%)	7 (36%)	17 (68%)	0.207
Imaging, Diagnostics, Referrals	12 (38.7%)	10 (52.6%)	13 (52%)	0.631

Table 3 Satisfaction Survey Results of Patients that Answered Strongly Agree

	Control (N=22)	AVI only (N=14)	AVI & TB (N=18)	Chi Squared P-Value
Easy to Understand	21 (95.4%)	7 (50%)	16 (88.8%)	**.004**
Listened Carefully	18 (81.8%)	7 (50%)	16 (88.8%)	.139
Showed Respect	21 (95.4%)	10 (71.4%)	15 (83.3%)	**.025**
Spent Enough Time	18 (81.8%)	10 (71.4%)	16 (88.8%)	.557
Confident in Providers Ability	19 (86.3%)	7 (50%)	14 (77.8%)	.168

Results: 75 patients completed the study with 31 (41.3%) in the control group, 19 (25.3%) in the AVI only group, & 25 (33.3%) in the AVI w/ TB group. Demographics are shown in Table 1. Mean age was 56.7 years. The mean A-REALM was 61.83 which equated with a high school HL. Among the patients with >75% concordance between their responses & the provider's note, there was no difference across the three AVI groups in any of the categories evaluated: reason for visit, medication changes, & referrals (Table 2). Of the 54 patients that completed the satisfaction survey, more patients in the control group responded 'strongly agree' to "the doctor was easy to understand" & "the doctor spent enough time with me" (Table 3). The mean FK readability scores were significantly better in the control group than the intervention groups ($p < 0.001$). Of the patients that were provided personalized AVI only 55% acknowledged receiving them & of those 70% endorsed reading them.

Conclusion: Presence/type of AVI had no significant impact on patient's retention or comprehension regarding their disease or management.Unexpectedly, the readability of AVI & components of satisfaction were better among controls than the other two groups. This may potentially be attributed to more direct patient engagement, & the AVI being brief & simpler in the control group. Further research addressing the limitations of this study could allow us to understand the utility of these patient education strategies to optimize after visit processes.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Collaborating with the Centers for Disease Control and Prevention (CDC), the ACR has developed new quality measures for lupus clinical care, including clinical and patient-reported outcome measures (PROMs), through a consensus-based process. Here we summarize the development of the 5 measures and introduce corresponding Healthy People with Lupus 2030 goals, which aim to guide the widespread adoption of these measures.

Methods: Two interdisciplinary workgroups, one focused on clinical process-of-care measures and one focused on PROMs, were convened. Both groups used literature reviews, modified Delphi procedures, and extensive patient input to arrive at lupus quality measures. For clinical measures, workgroup members extracted quality constructs from guidelines and rated them by importance and feasibility to generate evidence-based quality measure statements. In 3 Delphi sessions, a multidisciplinary panel voted on the importance to individual patients, feasibility of measurement, and public health impact of each statement. Measures with consensus on feasibility and importance were ranked to identify the top three. For PROMs, experts reviewed literature regarding quality-of-life domains in lupus and conducted focus groups with patients to prioritize domains and measures. A Delphi panel reviewed PROMs corresponding to priority domains for content validity, psychometric quality, feasibility of implementation, and importance for guiding patient-self management. The patient advisory panel reviewed PROMs in parallel and contributed to selecting final measures. Healthy People with Lupus 2030 goals were derived from the final clinical and PRO-based measures.

Results: For clinical process-of-care measures, review of guidelines and distillation of 57 quality constructs resulted in 15 quality measure statements. The 3 most highly ranked quality measures were 1) increasing hydroxychloroquine use, 2) avoiding glucocorticoid use >7.5 mg/day for >6 months, and 3) monitoring of kidney function and urine protein excretion at least every 6 months. For PROMs, literature review identified 12 domains. The workgroup and patient partners ranked depression, physical function, pain, cognition, and fatigue as high-priority domains. Delphi panel members and patient advisors recommended the 2 highest rated domains, physical function and depression, for annual measurement. PROMs recommended for depression were the Patient Health Questionnaire (PHQ) or Patient Reported Outcomes Measurement

Table. American College of Rheumatology/Centers for Disease Control and Prevention Quality Measures for Lupus and Corresponding Healthy People with Lupus 2030 Goals

Quality Measure	Healthy People with Lupus 2030 Goal	Potential Public Health Impact
IF a patient has lupus, THEN they should have a prescription for hydroxychloroquine on or after the date of the most recent rheumatology visit unless a contraindication or adverse event is documented in the medical record.	All eligible patients with lupus should take hydroxychloroquine	Reduce morbidity, decrease flares, reduce acute care use, and possibly improve mortality in SLE
IF a patient has lupus, THEN the glucocorticoid dose should not exceed 7.5 mg/day prednisone (or equivalent) for more than 6 months.	All people with lupus should avoid prednisone doses 7.5 mg/day (or equivalent) for longer than 6 months	Reduce glucocorticoid morbidity
IF a patient has lupus, THEN measurement of both kidney function and protein excretion (urinalysis and/or quantitative measurement) should be checked at least every 6 months.	All people with lupus should have twice yearly laboratory testing to screen for kidney disease and review these results with their lupus physician	Reduce morbidity by early identification of lupus nephritis, and reducing loss to follow-up
IF a patient has lupus, THEN functional status assessment using a standardized, validated measure (preferred: PROMIS PF10A or CAT; alternative: MDHAQ) should be performed at least once per year.	All people with lupus should complete a PROM evaluating functional status at least once per year	Reduce functional loss and disability
IF a patient has lupus, THEN depression assessment using a standardized, validated measure (preferred: PHQ-8; alternatives: PHQ-2, PHQ-9, PROMIS depression SF or CAT) should be performed at least once per year.	All people with lupus should complete a PROM evaluating depression at least once per year	Identify depression and reduce suicides

PROMIS, Patient Reported Outcomes Measurement Information System; PF10A, 10-item PROMIS physical function form; CAT, computerized adaptive testing; MDHAQ, Multi-Dimensional Health Assessment Questionnaire; PROM, patient-reported outcome measure; PHQ, Patient Health Questionnaire; SF, short form.

Healthy People with Lupus 2030: Goals to Improve the Quality of Care and Health of All People with Lupus in the United States

*The project described was supported by Grant number 1 NU58DP006908-01-00 – Component A; Developing and Disseminating Programs to Build Sustainable Lupus Awareness, Knowledge, Skills and Partnerships. Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the Department of Health and Human Services, Centers for Disease Control and Prevention.

Healthy People with Lupus 2030 Campaign

Information System (PROMIS) depression scales; PROMs recommended for physical function were the PROMIS physical function scales or the Multi-Dimensional Health Assessment Questionnaire (MDHAQ). The **Table** shows the final measures and corresponding Healthy People with Lupus 2030 goals.

Conclusion: Healthy People with Lupus 2030 provides a vision for improving clinical care for all people with lupus in the United States (**Figure**). Key priorities are increasing the use of hydroxychloroquine, reducing glucocorticoid exposure, regular monitoring for lupus nephritis (to prevent loss to follow-up and kidney failure), reducing disability, and reducing depression and suicide among people with lupus.

Abstract Number: 1900

Assessment of Hospitalist Confidence Levels in Management of Rheumatic Conditions to Identify Potential Knowledge Gaps

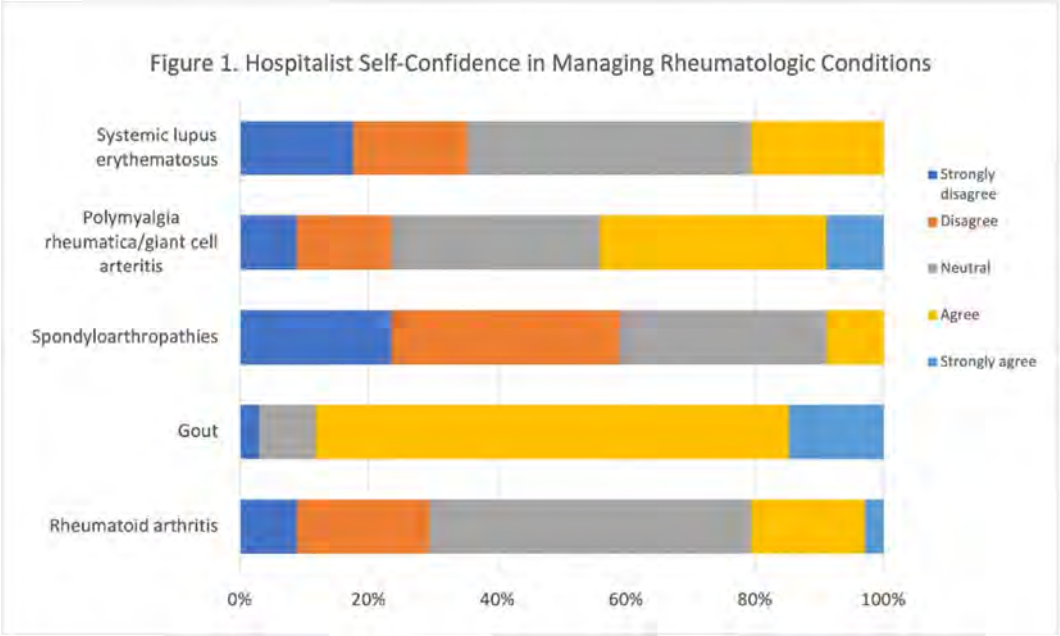
Lily Sung, Amber Young and Jiha Lee, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

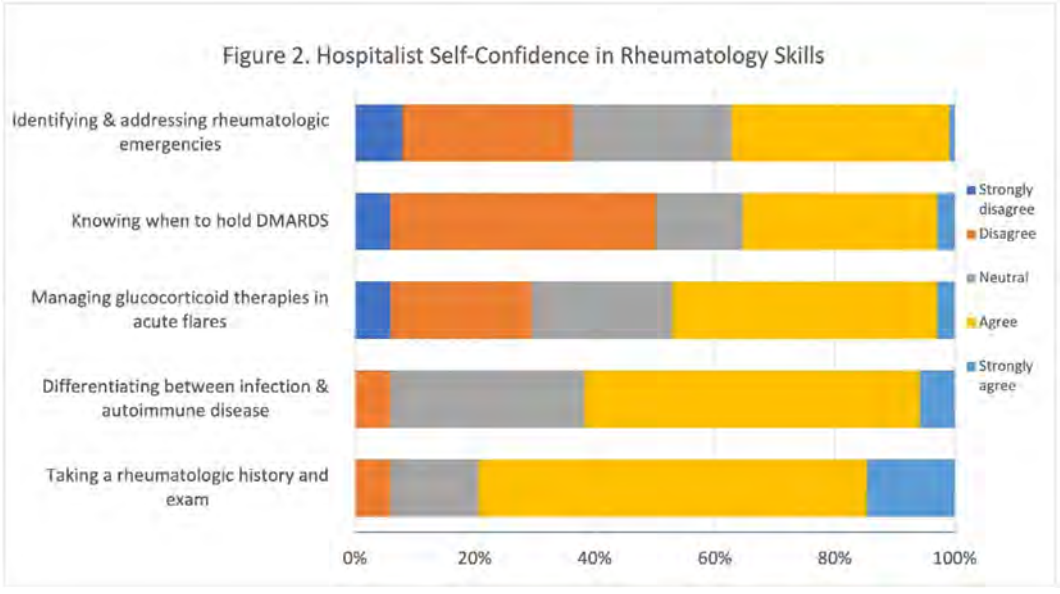
Background/Purpose: Healthcare utilization, including hospitalization, is high among patients with rheumatic musculoskeletal diseases (RMD). As the primary care providers during admission, hospitalists play a key role in improving care of RMD patients, and their role will be ever more important given the projected workforce shortage of rheumatologists, especially in resource limited and rural areas. We assessed academic hospitalists confidence levels, interests, and preferred method of learning to identify educational needs and opportunities to improve care of patients with RMD.

Methods: Hospitalists at a single large tertiary academic center participated in an online survey developed based on consensus between two rheumatologists and one hospitalist. Demographics of sex, years of experience, and exposure to rheumatology curriculum were obtained. Using a five-point Likert scale (1=strongly disagree, 5=strongly agree) hospitalists rated their level of confidence in managing five common RMD conditions: rheumatoid arthritis, gout, spondyloarthropathies, polymyalgia rheumatica/giant cell arteritis and lupus. They also rated confidence levels in five skills related to inpatient care of RMD patients: performing a rheumatologic history and exam, differentiating between acute infectious and autoimmune conditions, identifying rheumatologic emergencies, managing steroid therapy in acute rheumatic flares, and knowing when to hold DMARDs. We also asked open-ended questions to collect qualitative information on individual interest, perceived challenges, and preferred learning methods in rheumatology.

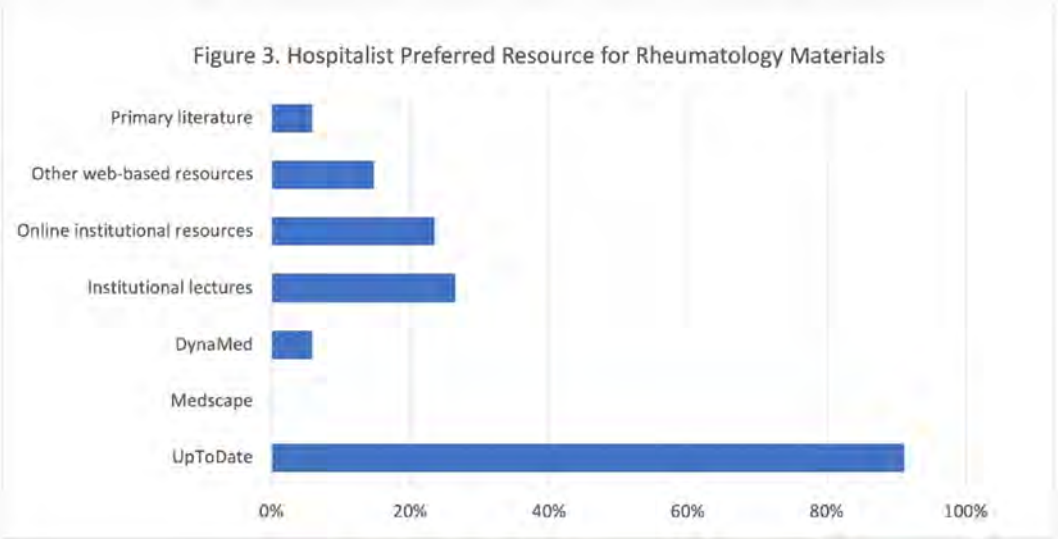
Results: This is an ongoing study, and we report preliminary data from 34 completed responses where the survey response rate was 26%. Half (53%) of the respondents had ≥ 5 years of experience working as hospitalists and 32% reported minimal training in rheumatology. Half reported caring for > 10 RMD patients on average each month. Hospitalist confidence in managing gout was highest, with 97% rating neutral or greater (Figure 1). Confidence in managing lupus and spondyloarthropathies were lowest, with 65% and 41% rating neutral or greater, respectively. Hospitalists were not confident in identifying rheumatologic emergencies or knowing when to hold DMARDs with 36% and 50% reporting less than neutral, respectively (Figure 2). Most were interested in learning about lupus and its complications, rheumatologic emergencies, and understanding appropriateness of rheumatology consultation. Almost all (n=31) hospitalists reported using UpToDate as their preferred resource for rheumatology (Figure 3).



Responses measured on a 5 point Likert scale (1: strongly disagree, 5: strongly agree), in response to statements regarding management of conditions listed.



Responses measured on a 5 point Likert scale (1: strongly disagree, 5: strongly agree), in response to statements regarding skill sets listed.



Respondents were able to select more than one option.

Conclusion: Hospitalists reported caring for a fair number of RMD patients, but they had minimal training and knowledge gaps in certain rheumatologic conditions and skills related to the care of hospitalized RMD patients. They expressed interest in rheumatologic learning opportunities and understanding how to best engage rheumatologists. Further studies are needed to develop educational resources and guide interdisciplinary collaboration between hospitalists and rheumatologists to improve the care of RMD patients in the inpatient setting.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: When assessing disease activity in patients with axial spondyloarthritis (axSpA), the Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS-CRP) is recommended over ASDAS with erythrocyte sedimentation rate (ASDAS-ESR). Although ASDAS-CRP and ASDAS-ESR are not interchangeable, the same cut-offs are

Table 1. ASDAS-ESR cut-off estimation that corresponds to established ASDAS-CRP cut-offs

	n (P+N)	AUC	Sensitivity	Specificity	ASDAS-ESR cut-off
ASDAS-CRP<1.3	4,306 (1,255+3,051)	0.95	0.91	0.86	<1.3743
ASDAS-CRP<2.1	4,306 (2,566+1,740)	0.96	0.89	0.91	<1.8923
ASDAS-CRP>3.5	4,306 (2,209+2,097)	0.93	0.85	0.86	>3.3074

Optimal cut-off estimated by maximising the Youden index (=sensitivity+specificity-1). Selection of cut-offs relied on a single treatment course per patient with available baseline and at least one follow-up timepoint per patient, prioritising earlier TNFi (among the first three treatment courses) and timepoint (for follow-up data).

ASDAS: Ankylosing Spondylitis Disease Activity Score; ASDAS-CRP: ASDAS based on C Reactive Protein; ASDAS-ESR: ASDAS based on Erythrocyte Sedimentation Rate; AUC: area under the curve; n: number of patients; N: negative; P: positive.

Table 2. Statistical measures comparing ASDAS-ESR and ASDAS-CRP cut-offs for classifying patients in different disease activity states

A. Established ASDAS-ESR vs. ASDAS-CRP cut-offs							
Cut-offs between "inactive disease" and "low disease activity" (follow-up)							
N	ASDAS-ESR<1.3	ASDAS-CRP<1.3	Proportion of Discordance	Sensitivity	Specificity	BalAcc	κ

5,850	2,633/5,303 (49.7%)	2,637/5,352 (49.3%)	757/5,296 (14.3%)	0.86	0.86	0.86	0.71

Analyses were conducted on data from all available treatment courses, including up to 3 different follow-up timepoints per treatment course for each patient included in the study.

ASDAS: Ankylosing Spondylitis Disease Activity Score; ASDAS-CRP: ASDAS based on C-Reactive Protein; ASDAS-ESR: ASDAS based on Erythrocyte Sedimentation Rate; BalAcc: balanced accuracy (i.e., the average of sensitivity and specificity); N: number of observations; κ: Cohen's kappa coefficient.

used to classify patients into four distinct disease activity states: inactive disease (ID), low disease activity (LDA), high disease activity (HDA) and very high disease activity (VHDA). These cut-offs were developed based on ASDAS-CRP. We aimed to (i) estimate optimal ASDAS-ESR values corresponding to the established ASDAS-CRP cut-offs (< 1.3, < 2.1 and > 3.5), and (ii) investigate the improvement of level of agreement between ASDAS-ESR and ASDAS-CRP disease activity states when applying the estimated ASDAS-ESR cut-offs.

Methods: Prospectively collected real-world data from axSpA patients starting a 1st, 2nd or 3rd tumor necrosis factor inhibitor (TNFi) from 9 countries participating in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were analysed. Data were collected at baseline and three follow-up visits (6, 12 and 24 months) per TNFi treatment course. To have the best representation of the disease activity states, aggregated follow-up data were used to evaluate the ASDAS-CRP cut-offs for ID and between LDA and HDA, while baseline data were used to assess the cut-off for VHDA. We performed receiver operating characteristic analyses using the Youden index to estimate the optimal ASDAS-ESR values corresponding to ASDAS-CRP cut-offs. The level of agreement between ASDAS-ESR and ASDAS-CRP disease activity states was also assessed.

Results: We analysed data from 4,306 patients with complete registration of ASDAS scores at baseline and at least one complete follow-up registration of ASDAS scores during the same TNFi treatment course. Mean (SD) ASDAS-CRP and ASDAS-ESR were 3.5 (1.0) and 2.0 (1.0) at baseline and 3.3 (1.0) and 1.9 (1.0) at follow-up, respectively. The estimated ASDAS-ESR cut-offs between ID and LDA, between LDA and HDA and between HDA and VHDA corresponding to ASDAS-CRP cut-offs were < 1.4, < 1.9 and > 3.3, respectively (Table 1). Good agreement was observed between disease activity states applying the established ASDAS-ESR and ASDAS-CRP cut-offs, although the VHDA cut-off showed slightly worse agreement than the other two cut-offs (Table 2, upper panel). The statistical measures comparing the estimated ASDAS-ESR (< 1.4, < 1.9 and > 3.3) and ASDAS-CRP (< 1.3, < 2.1 and > 3.5) cut-off values performed slightly better only for VHDA as compared to applying the same cut-offs for both ASDAS versions (Table 2, lower panel). However, the proportion of discordance for the cut-offs for ID and between LDA and HDA increased slightly with the estimated ASDAS-ESR cut-off values.

Conclusion: In a multi-national cohort, the estimated ASDAS-ESR cut-offs between disease activity states were < 1.4, < 1.9 and > 3.3. The original cut-offs overall performed similarly as the ones we estimated. Our findings did not provide sufficient evidence to reject the established ASDAS-ESR cut-offs.

Improving the Sharing of Information from Reviews of Measurement Properties: The OMERACT Summary of Measurement Properties (SOMP) Table

shawna grosskleg[1], lara maxwell[2], **Dorcas Beaton**[3], B Shea[1] and Peter Tugwell[1], [1]OMERACT, Ottawa, ON, Canada, [2]University of Ottawa, Ottawa, ON, Canada, [3]Institute for Work & Health, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systematic reviews of measurement properties of an outcome measurement instrument are fast becoming the evidence base for making decisions about the suitability of the instrument for a given application. Transparency in processes and decision-making at each step are important to allow consumers of the reviews to have a clear understanding of the results.At OMERACT (Outcome Measures in Rheumatology) we used an iterative process between methodologists and users for developing a summary of measurement properties table (SOMP) to use as a knowledge translation tool for communicating what was done, what was found, and what recommendations can be made from it.

Methods: Working with key stakeholders and end users, including patients, clinical trialists, clinicians and methodologists across several disease areas, the information that needed to be included in a SOMP was determined and initial designs laid out. Users provided feedback and revisions, which were integrated while ensuring the core elements were also being communicated.

Results: Several features emerged for inclusion in the SOMP.We wanted the SOMP to be a standalone resource so the name/version of the tool, the target population (if restricted in the review) and the target concept the reviewers are trying to measure with this instrument were all included at the top of the table. Further, we designed the SOMP to be assembled as teams moved through the review steps so that it was clear the level of detail that was going into any statement about an instrument, and it was transparent exactly which studies/primary resources were included in the review and how they were reviewed.

The SOMP (Figure 1) uses symbols (colour for critical appraisal of methods, +/- for comparison of results to psychometric standards) and algorithms (for making conclusions based on the results in the synthesis steps).Should steps not be done in a given review (i.e., no critical appraisal in a descriptive review) the absence of colours in the boxes would demonstrate this for the users. Rows within the table include evidence from each study included in decision-making.

Conclusion: The SOMP was designed to capture the measurement properties evidence and decision-making processes for the OMERACT community to agree on whether an instrument is good enough to be included to represent a domain for a core outcome set.Its iterative development within a multidisciplinary consensus-based organization has helped us develop a tool we are finding useful in the transparent communication about methods and decision-making made in a given review.Although our key target is regulatory approval and core outcome set development, we have learned about the importance of being transparent in how decisions were made about an instrument, and how to share the body of evidence with others, leading to broader applications of the evidence base.

Assessing Disparities Through Missing Race and Ethnicity Data: Results from a Juvenile Arthritis Registry

Katelyn Banschbach[1], Jade Singleton[2], Esi Morgan[2] and Xing Wang[3], [1]University of Washington, Seattle, WA, [2]Seattle Children's Hospital, Seattle, WA, [3]Biostatistics Epidemiology and Analytics in Research (BEAR), Seattle Children's Research Institute, Seattle, WA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Research databases are missing 25-50% of race and ethnicity, typically related to Black and Hispanic data.[1,2]The absence of this data can lead to inaccurate assessment of patient outcomes by race.[1,3,4] Our aim is to assess the impact of missing race and ethnicity on outcome measures in a JIA registry (Pediatric Care Outcomes Improvement Network (PR-COIN)).

Methods: Descriptive analysis of demographic and clinical data from 9 PRCOIN centers was performed. Missing race and ethnicity data was quantified by site. Relative risk (RR) of moderate to severe clinical juvenile arthritis disease activity score (cJADAS ³5) at first visit after enrollment was compared across race (Black, White, other, missing) and ethnicity (Hispanic, non-Hispanic, missing).A RED Cap survey on data collection and entry was administered to each site.

Results: A total of 1,505 JIA patients from 9 (of 23) sites were included (Table 1). Race was missing for 24% and ethnicity was missing for 23% with missing data ranging from 0-100% (Table 2).

CJADAS score at first follow-up (2-6 months after enrollment) was high (³5) for 30% of White patients and 55% of Black patients with a RR of 1.84 (p=0.0001) of higher cJADAS in Black patients (Table 3). There was no difference in risk for patients of Other races, relative to White patients, RR 1.0 (p=0.99). For patients missing race, risk of high cJADAS at first follow-up was lower than for White patients, RR 0.88 (p=0.21). There was no difference in rates of high cJADAS at first follow

Table 1 Patient Characteristics

Table 3 cJADAS Outcomes by Race and Ethnicity			
	High cJADAS[1],n (%)	Low cJADAS, n (%)	Relative Risk of High cJADAS (p value)
RACE			
White	297 (30%)	697 (70%)	Reference
Black	22 (55%)	18 (45%)	1.84 (p=0.0001)
Other	34 (30%	80 (70%)	1.0 (p=0.9904)
Missing	94 (26%)	263 (74%)	0.88 (p=0.2106)
Ethnicity			
Hispanic	48 (30%)	112 (70%)	0.94 (p=0.6459)
Non-Hispanic	319 (32%)	683 (68%)	Reference
Missing	80 (23%)	263 (77%)	0.73 (p=0.0041)

(1) High cJADAS (score ≥5) at the first follow-up (2-6 months after enrollment)

up by Hispanic vs non-Hispanic ethnicity, RR 0.94 (p=0.65). For patients with missing ethnicity, risk of high cJADAS at first follow-up was 27% lower than non-Hispanic patients, RR 0.73 (p=0.0041).

Four of 9 sites completed a survey. Two sites are missing 0% of race and < 2% of ethnicity data. One is missing 12.6% race and 14.9% ethnicity. These 3 sites enter data manually. One is missing 100% of race and ethnicity data and uploads data via electronic data transfer (EDT).

Conclusion: Amount of missing race and ethnicity data is highly variable, ranging from 0-100%. Additional survey data is needed to understand the impact of data entry method on missingness. Preliminary, unadjusted analysis suggests RR of high cJADAS at first follow up is higher for Black compared to White patients in a setting of missing data. Patients with missing race had lower RR of high cJADAS at first follow up compared to White patients. This suggests that completion of missing race could change RR assessments. Next steps include multivariate analysis to adjust for confounding factors (age, gender, site, ILAR code, insurance status).It also includes interventions to complete missing data and reassessment of RR of high cJADAS.

Treat-to-Target in RA Clinical Practice: Global Evidence of Practice Gaps and Educational Needs

Douglas White[1], **Maya Buch**[2], Suzanne Murray[3], Diane Caballero[4], Orsolya Nagy[5] and Tsutomu Takeuchi[6], [1]Waikato Clinical School, University of Auckland, Hamilton, New Zealand, [2]University of Manchester and NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom, [3]AXDEV Group Inc, Brossard, QC, Canada, [4]AbbVie, Inc., Chicago, IL, [5]AbbVie, Inc., Budapest, Hungary, [6]Keio University School of Medicine and Saitama Medical University, Tokyo, Japan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II

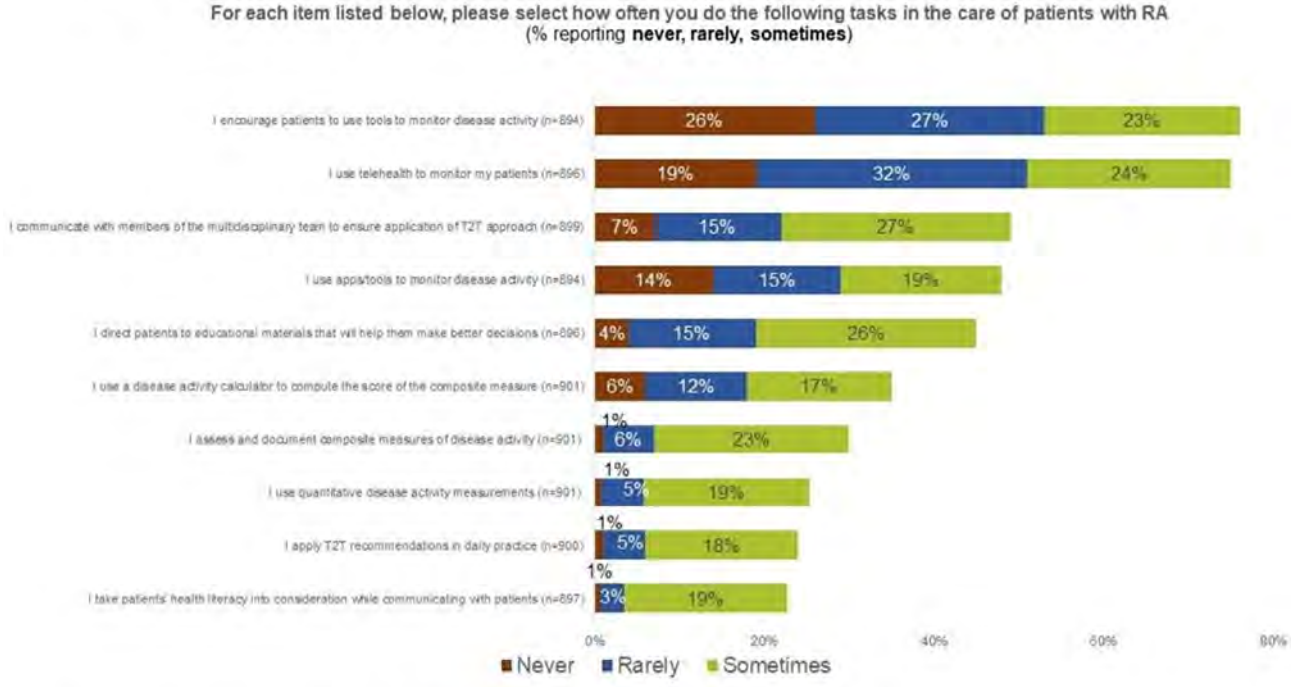
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target (T2T) is a widely established and accepted approach in RA management, but its real-world implementation is suboptimal[1]. Further primary research is required to identify the most relevant barriers to, and facilitators of, real-world T2T implementation[2]. This survey assessed perceived barriers to, and facilitators of, T2T implementation among rheumatologists globally.

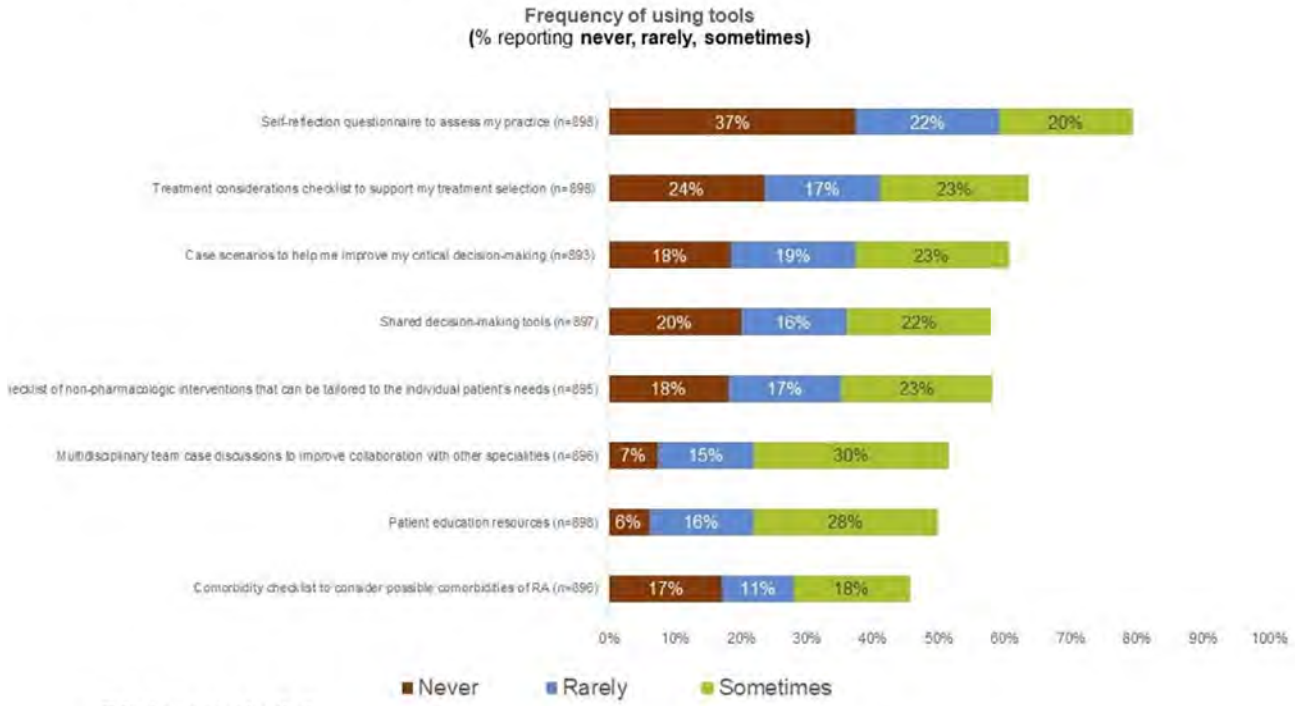
Methods: A non-remunerated quantitative survey was completed by eligible rheumatologists (≥2 years' practice experience, awareness of T2T approach, ≥10 patients with RA/year) between June 6 and Sep 30, 2022, in 35 ex-US countries. The survey was informed by a systematic literature review[2] and included 9 questions across 6 key areas of T2T

Figure 1. Least performed tasks by rheumatologists



RA, rheumatoid arthritis; T2T, treat-to-target.

Figure 2. Least frequently used tools by rheumatologists



RA, rheumatoid arthritis.

Table 1. Common gaps and barriers reported in the global survey that impact use of the T2T approach in RA

Key themes	Knowledge, skills, and confidence gaps	Clinical practice behaviors		System/contextual barriers
		Challenges/task performance	Use of tools	
Collaboration and communication with patients and colleagues	• Assessing health literacy levels of patients • Understanding patient goals and adapting language while communicating with patients	• Encouraging patients to use tools to monitor disease activity • Reconciling patient perspectives on successful treatment with their own perspectives • Directing patients to educational materials • Communicating with multidisciplinary teams to ensure application of T2T approach	• Limited use of shared decision-making tools	• Patients skipping too many appointments
Using PROs and considering patient preferences	• Using PROs to assess disease activity	• Identifying patient preferences to determine treatment target • Trusting patient-reported joint counts	• Limited use of treatment considerations checklist	• Contradictory assessments between PROs and composite measures
Adjusting treatment based on disease activity measures		• Interpretating disease activity measures, especially measures other than composite measures		• Electronic medical record not adapted to capture disease activity measures • Change in disease activity linked to patient non-adherence
Overall delivery of care		• Limited use, and confidence in use, of telehealth with patients with RA	• Limited use of self-reflection questionnaires	• Clinical processes limit full implementation of T2T approach

PRO, patient-reported outcome; RA, rheumatoid arthritis; T2T, treat-to-target.

implementation in RA: knowledge, skill, confidence, agreement (attitudes/context), contextual/systemic barriers, and behaviors. Knowledge, skill, and confidence were rated on a 5-point scale and reported as suboptimal (no/basic/intermediate knowledge or skill; not/slightly/somewhat confident) or optimal (advanced/expert knowledge or skill; confident/very confident). Agreement was rated on a 6-point scale (strongly disagree to strongly agree) and barriers on a 4-point scale (not at all to serious barrier). Behaviors were rated on a 5-point scale and reported as infrequent (never/rarely/sometimes) or frequent (often/always).

Results: Of 903 surveyed rheumatologists (Europe, n=297; Americas, n=293; Asia-Pacific, n=200; Middle East & Africa, n=113), 72% had ≥11 years of practice experience and 80% reported practicing T2T consistently or frequently. Despite awareness of the T2T approach, there was suboptimal knowledge, skill, and confidence in determining patient health literacy and adapting language while communicating with patients, considering patient goals, and using PROs to assess disease activity. At least 75% of rheumatologists never, rarely, or sometimes used telehealth or encouraged patients to use disease self-assessment tools (Figure 1). The least frequently used tools by rheumatologists were self-reflection questionnaires, treatment considerations checklists, case scenarios, and shared decision-making tools (Figure 2), primarily due to the perception these tools were time-consuming, not needed, or non-existent. Patient adherence-related issues were the top barriers to documenting disease activity, with the other barriers mostly related to healthcare system-related processes. Higher gaps were generally observed in rheumatologists who do not consistently or frequently practice T2T, or who had < 10 years of experience. Table 1 regroups the common gaps and barriers under 4 key themes.

Conclusion: These results highlight practice gaps and educational needs in rheumatologists that can inform educational programs and interventions to support T2T implementation. Based on these findings, recommended focus areas for improving T2T implementation include incorporating all components of T2T in practice, optimal use of telehealth in RA, patient education and shared decision-making, and the use of tools to enhance practice efficiency.

Implementation of the Clinical Disease Activity Index to Optimize Treat-to-Target Management of Rheumatoid Arthritis at the University of North Carolina Hospitals Rheumatology Specialty Clinic

Rumey Ishizawar[1], Thuyvan Phan[2] and Steven Takacs[3], [1]University of North Carolina at Chapel Hill, School of Medicine, Division of Rheumatology, Allergy, and Immunology, Thurston Arthritis Research Center, Chapel Hill, NC, [2]University of North Carolina Hospitals Department of Pharmacy, Apex, NC, [3]University of North Carolina Faculty Physicians, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2021 American College of Rheumatology (ACR) guidelines for the treatment of rheumatoid arthritis (RA) recommend a treat-to-target approach to optimize clinical outcomes. This approach requires frequent monitoring of disease activity using validated instruments and modification of treatment with the goal of reaching low disease activity or remission. The Centers for Medicare and Medicaid Services (CMS) and Rheumatology Informatics System for Effectiveness (RISE) registry have defined that patients with a diagnosis of RA should have an assessment using an ACR-preferred RA disease activity tool at ≥50% of encounters annually for the traditional Merit-based Incentive Payment System (MIPS). The University of North Carolina (UNC) Hospitals Rheumatology Specialty Clinic utilizes an electronic health record (EHR) with a flowsheet built to measure Clinical Disease Activity Index (CDAI); one such validated instrument. The purpose of this study was to understand use, limitations, and intervene to improve utilization of the CDAI among patients with RA.

Methods: Qualtrics™ surveys were distributed pre- and post-intervention to clinical care providers. Surveys queried knowledge of the ACR guidelines, CDAI implementation, and perceived barriers. Responses were anonymous and there was no identification if providers were trainees, faculty, or advance care partners. CDAI utilization was measured for the 6 months preceding the intervention and then 6 months post-intervention through the EHR. Interventions included 1) education to providers and care partners by a clinical pharmacist, 2) EHR daily reports for providers to capture relevant scheduled visits, 3) creation of a physical patient global assessment form, and 4) involvement of care partners in distributing and capturing the patient global assessment during patient triage. This project received IRB waiver as non-human subject research (UNC IRB 22-1967).

Results: On average, CDAI use in the 6 months prior to the intervention was 33%, improving to 58% post-intervention. We observed a slight lag for initial uptake as well as a plateau following intervention. Pre-intervention (n=17 providers) and post-intervention surveys (n=11 providers) indicated similar barriers, including: 1) lack of time during patient visit, 2) remembering

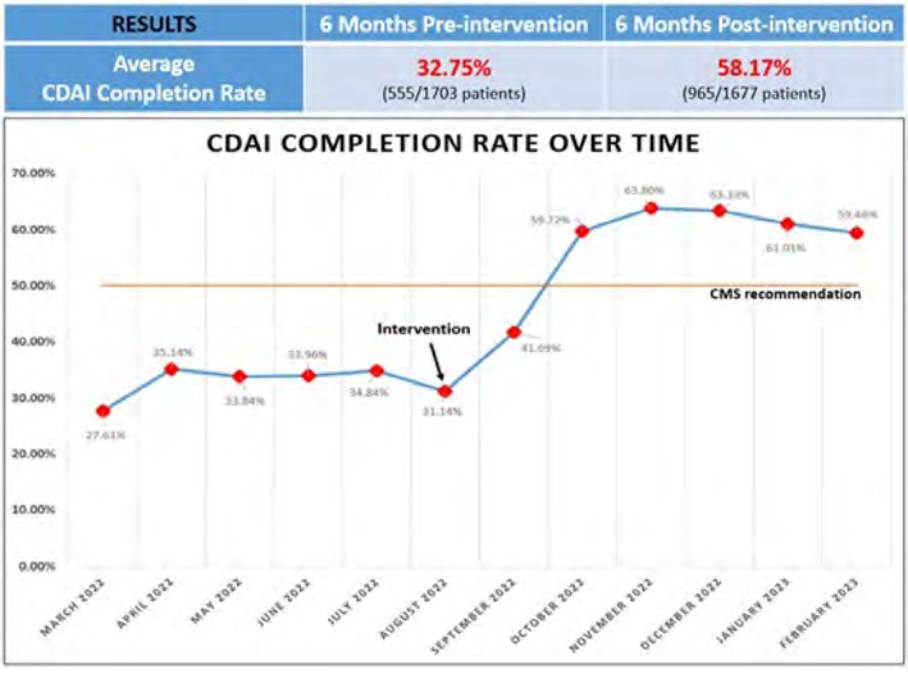

Figure 1. CDAI Completion Rate Over Time

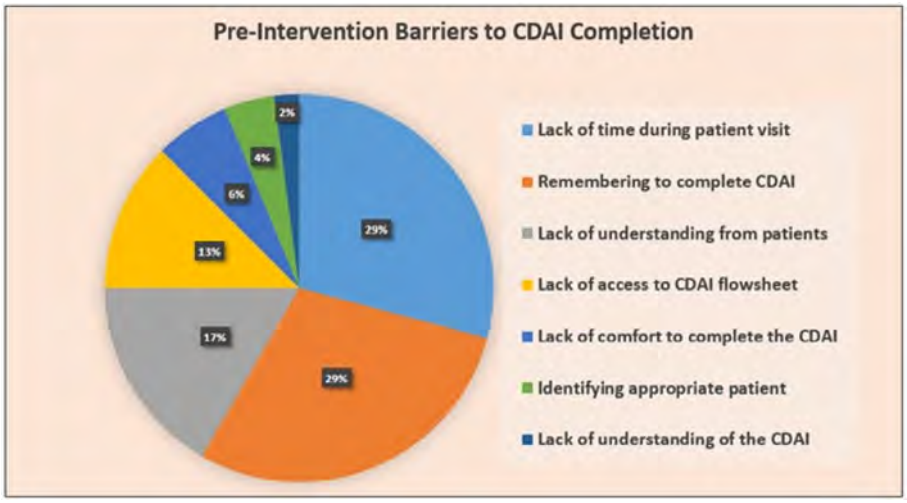

Figure 2a. Pre-Intervention Barriers to CDAI Completion

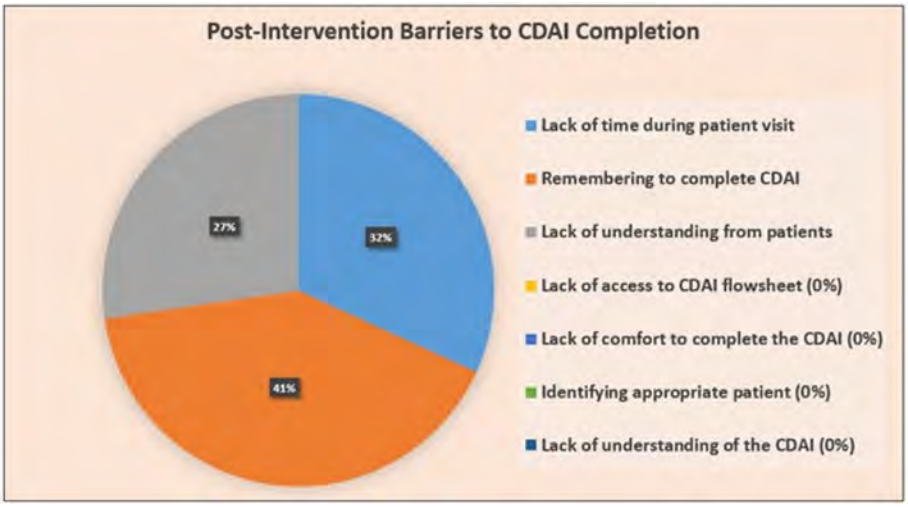

Figure 2b. Post-Intervention Barriers to CDAI Completion

to complete the CDAI, and 3) lack of understanding from patients to input CDAI global assessment. Following the intervention, provider barriers that were removed include: 1) lack of understanding of the CDAI, 2) lack of comfort in completing the CDAI, 3) access to the CDAI flowsheet in the EHR, and 4) identifying appropriate patients to complete the CDAI.

Conclusion: A simple educational intervention for both providers and care partners, as well as implementation of new workflow increased CDAI utilization in our clinic. Continuing assessment and repeated interventions are likely needed to optimize use. Identified barriers such as lack of time, remembering to complete CDAI, and patient understanding to complete global assessment are future targets for productive change.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In November 2022, the American College of Rheumatology (ACR) released the ACR Guidelines for Exercise, Rehabilitation, Diet, and Additional Integrative Interventions for Rheumatoid Arthritis with several lifestyle recommendations in dietary, exercise, rehabilitation categories as well as additional integrative and mental health guidance.Limited data on implementation practices post-guideline are published. Data were reviewed to determine rates of adherence to the guideline post-creation as well as referral patterns in the year prior to guideline release for both rheumatology and non-rheumatology clinicians.

Methods: We identified patients 18 and older with a primary diagnosis of rheumatoid arthritis seen within the rheumatology department at our institution between November 15, 2022 and February 15, 2023 utilizing an electronic medical record (EMR)-extracted report and manual chart review.Patients were excluded if they had expired within the study period or had an alternative primary rheumatologic diagnosis. IRB approval was obtained.

Results: Data were analyzed for 791 patients. Mean (SD) age was 62.3 (13.8), 77.6% of the patients were female, and 94.6% were white. Mean (SD) BMI was 31.3 (7.5) kg/m2. 394 (49.8%) were receiving biologic or synthetic targeted disease-modifying anti-rheumatic drug (DMARD) therapy (Table 1). 28 (3.5%) patients received a recommendation for an exercise regimen in the 3-month study period. 25 (3.2%), 4 (0.5%), and 4 (0.5%) patients received post-guideline referrals to physical therapy, occupational therapy, and dietary recommendation for the Mediterranean diet, respectively (Table 2). In the year prior to guideline release, 51 (6.4%) patients received physical therapy referrals from a rheumatologist and 109 (13.8%) from a non-rheumatologist. 3 (0.4%) patients received a weight loss clinic referral from a rheumatologist and 24 (3.0%) from a non-rheumatologist pre-guideline. 4 (0.5%) patients received dietician referral from a rheumatologist and 37 (4.7%) from a non-rheumatologist pre-guideline.

Conclusion: The adherence to the 2022 ACR lifestyle guidelines for RA was low. For interventions studied, there was no significant increase in referrals or recommendations post-guideline. Though there was significant obesity in the patient population with higher-than-average BMI (average BMI ∼26.5 in the United States), only a handful of patients received a dietary intervention from rheumatology.Dietary interventions were low for both rheumatology and non-rheumatology clinicians pre-guideline release. Study limitations include descriptive methods without comparisons for statistical analysis as well as short duration of follow up. Several factors such as patient preferences, workload and complex disease management, as well as the recency of the guideline release may offer explanations for low uptake of recommending lifestyle interventions. Future work is needed to create practical recommendations and measures of quality for lifestyle intervention in patients with rheumatoid arthritis that balance patient needs and provider workload.

Table 1: Patient characteristics

Total (n=791)		Value (n(%))
Age (mean)		62.3 (+/-13.8)
Sex	Female	614 (77.6)
	Male	177 (22.4)
Race	Caucasian/white	739 (94.6)
	Black/African American	6 (0.8)
	American Indian/Alaska Native	33 (4.23)
	Asian	3 (0.4)
Immunosuppressive Regimen	Biologic or Synthetic targeted DMARD	394 (49.8)
	Conventional DMARDs only	304 (38.4)
	Steroid only	18 (2.3)
	None	29 (3.7)
Disease control	Clinical remission	373 (47.2)
	Low disease activity	225 (28.4)
	Moderate to high disease activity	193 (24.4)
Comorbid conditions	Osteoarthritis	426 (53.9)
	Gout	40 (5.1)
	Psoriasis	27 (3.4)
	Type II Diabetes Mellitus	126 (15.9)
Body mass index (kg/m^2)	Mean	31.3 (+/- 7.5)
	Underweight (<18.5)	6 (0.8)
	Normal (18.5-24.9)	158 (20.0)
	Overweight (25-29.9)	207 (26.2)
	Obesity (30-39.9)	316 (39.9)
	Morbid Obesity (≥40)	92 (11.6)
	Missing	12 (1.5)

Table 2: Number and percentage of patients receiving lifestyle recommendations and referrals by rheumatology within 3 months post-guideline and referrals by rheumatology and non-rheumatology provider in the year prior to guideline release

Total=791	Rheumatology post-guideline n(%)	Rheumatology pre-guideline n(%)	Non-rheumatology pre-guideline n(%)
Exercise			
Any Exercise recommendation	28 (3.5)	N/A	N/A

Session Date: Tuesday, November 14, 2023

Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The Outcome Measures in Rheumatology group (OMERACT) developed methodological steps to select instrument(s) to assess content appropriateness of outcomes, as well as tools to accomplish this task. In this study we present the results obtained following these steps to select instrument(s) to assess flares in osteoarthritis, based on the associated domains

Methods: An update of a previous 2017 literature review was conducted in PubMed, Web of Science and Psych Info databases over the period from 2017 to 2021, with the primary goal of searching instruments associated with flare in knee and hip OA or their correlated characteristics. Using the OMERACT Handbook Filter 2.2[1], we evaluated the content of instruments included according to five core domains endorsed by OMERACT[2], and then classified into three categories: "sure match with domains of flare in OA"; "uncertain match with domains of flare in OA"; and "sure not match with domains of flare in OA". The instruments retained in the first two categories were analyzed by the experts of the working group (WG) Flares in OA, composed of patients, physicians, and researchers, in two rounds of Delphi survey using limesurvey. The goal was to identify among these five instruments which one best matches with the target domain (trust) and which one is more practical to use (feasibility). The final selection was obtained by a vote of the group.

Results: Initially 575 papers were filtered. After experts' analysis, 59 studies were included, and 44 instruments associated with flare in OA were identified. Most were studies about pain in knee or hip OA (35%), cultural adaptation of a measure (33%) or studies investigating psychometric properties of full (16%) or short form (4%) instruments. An international panel of 26 group members participated in the Delphi surveys. In Delphi Survey Round 1, we had 15 instruments flagged by experts with green, amber and red and we proposed: reject instrument with less than 50% in red flag, classify uncertain when they received between 50 and 70% in amber flag and keep instruments that received more than 70% in green flag. Five instruments were pre-selected: ICOAP, HOOS, KOOS, OAKHQOL and Flare-OA. WOMAC was clearly not focused on flare, and we decided to substitute the full length OAKHQOL with the short form Mini-OAKHQOL. For the Delphi Round 2, we set a unique threshold of 70% to make decision. The instruments obtained at least 75% in questions about trust and feasibility,which carried them all to the last phase, it means, to vote on the instrument. Only the Flare-OA questionnaire obtained 100% of votes in favor.

Conclusion: The OMERACT Handbook Filter 2.2 has proven helpful tool for selecting an instrument. The Flare-OA questionnaire was selected as the best matching and practical instrument to assess flare in lower limb osteoarthritis. References 1. Guillemin F, Ricatte C, Barcenilla-Wong A, et al. Clinic Protocol Boosts Blood Pressure Confirmatory Readings and Accuracy in an Academic Medical Center

Kubra Bugdayli[1], Amber Meyer[1], Antoinette Keith[1], Karunakar Dirisala[1], Guillermo Quiceno[1] and Puneet Bajaj[2], [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypertension is the most common modifiable risk factor for cardiovascular diseases among all adults. Studies have shown that single blood pressure (BP) measurements vary in an unpredictable way in clinics, and up to one-third of patients initially categorized with high BP were subsequently reclassified into lower BP categories upon confirmatory readings.

This quality improvement project aimed at improving the rate of checking BP a second time (confirmatory reading) if the initial BP was high (systolic ≥140 mmHg or diastolic ≥90 mmHg) by implementing a staff-driven workflow with a goal to improve accuracy of clinic BP values.

Methods: This study was conducted at a large quaternary care academic center.We included patients from internal medicine subspecialty clinics (IMSS), which includes rheumatology, seen between June 2022 and April 2023 with initial high BP (systolic BP ≥140 mmHg or diastolic BP ≥90 mmHg). We created a new workflow (Figure 1) to standardize the process of obtaining confirmatory readings for initial high BP. Nurses and medical assistants (MAs) received education on accurate BP measurement techniques, the workflow, the importance of confirmatory readings and accurate documentation within EMR. Upon check-in, medical assistants escorted patients to the exam room, where they measured BP using proper techniques and recorded in the EMR. If the initial BP was high, the MAs flagged the patient's room accordingly. After the flagged patients were evaluated by the healthcare provider, MAs or nurses repeated the BP measurement using proper techniques and documented the results in the EMR. To collect and track the BP data, we developed a Tableau software dashboard that was updated monthly. The Department of Internal Medicine sent monthly quality improvement newsletter to all clinic leadership, serving as a reminder of clinic performance, which is then shared with the clinic staff to further reinforce adherence to the established workflow.

Results: Between June and December 2022, the IMSS clinics had a total of 18,390 encounters, of which 4,009 (21.8%) were eligible for confirmatory reading due to high initial readings. The confirmatory rate increased from a baseline of 38% between June 2021 to May 2022 to 55% between June to December 2022. In the rheumatology clinics, out of a total of 4,371 encounters, 1,073 (24.5%) were eligible for confirmatory reading. The clinic's confirmatory rate improved from a baseline of 17.6% between June 2021 to May 2022 to 48% between June to December 2022 as seen in the control charts

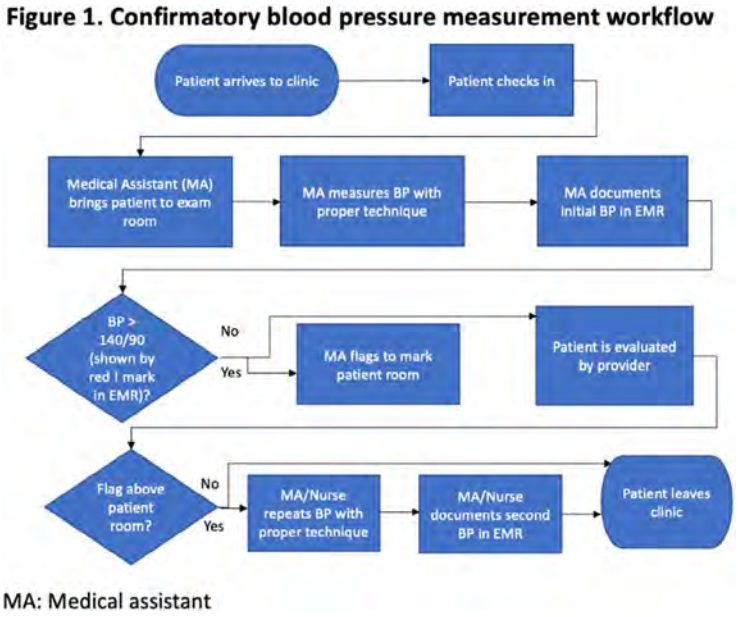

Figure 1. Confirmatory blood pressure measurement workflow

Figure 2.

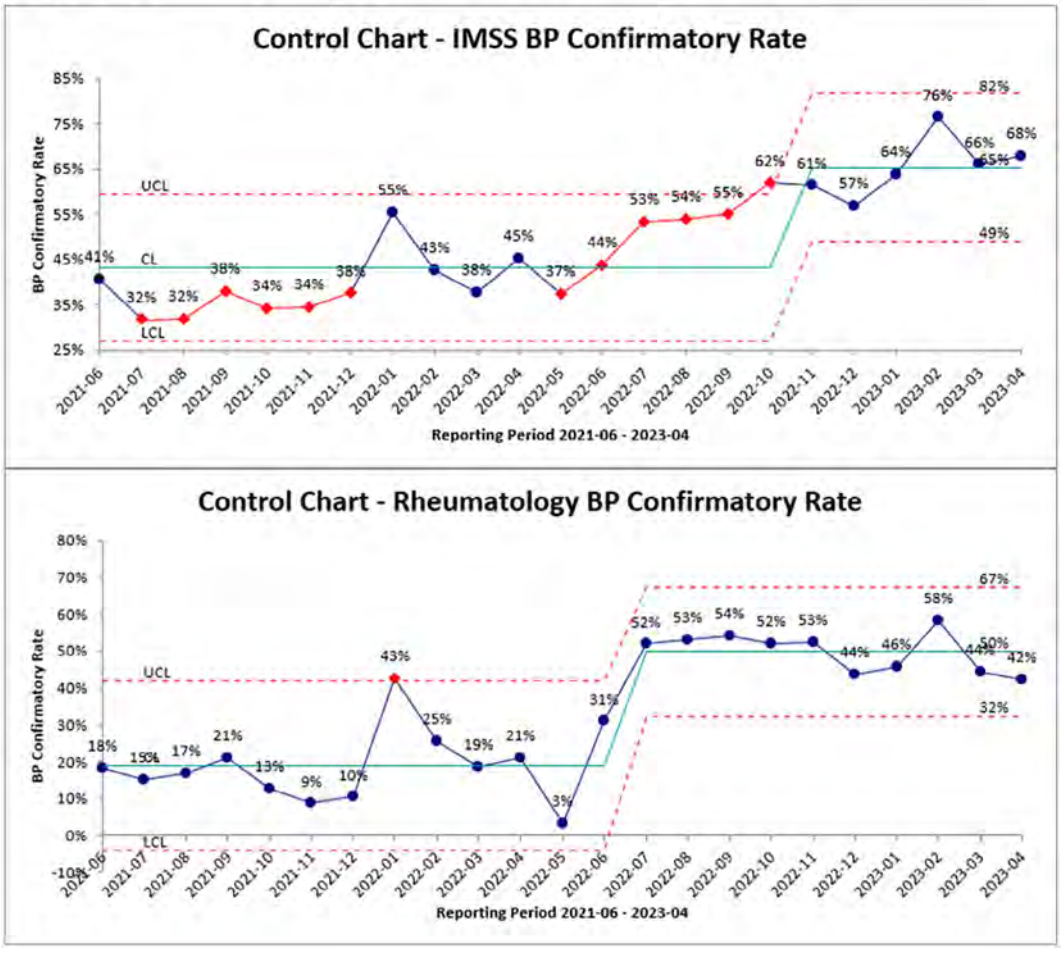

Figure 2. Control charts for confirmatory rates

Figure 3. The rate of blood pressure change from uncontrolled (≥ 140/90) to controlled (<140/90) after confirmatory reading

Figure 3. The rate of blood pressure change from uncontrolled (≥ 140/90) to controlled (<140/90) after confirmatory reading

(Figure 2). The confirmatory rate remained stable at 48% in the rheumatology clinics, while in the IMSS clinics, it improved to 60% by April 2023. Among patients who had confirmatory readings, 36% (Figure 3) showed an improvement in blood pressure to below 140/90 mmHg.

Conclusion: It is feasible to increase the rate of BP confirmatory readings within a clinic using a staff-driven workflow. We were able to improve the rate of confirmatory reading over 20% in the IMSS clinics and over 30% in the rheumatology clinics within eleven months. Additionally, 36% of the patient who underwent repeat BP checks had improved BP, underscoring the importance of confirmatory readings for accurate measurement.

Abstract Number: 1909

Identifying and Addressing Suboptimal Urate Lowering Therapy in Gout Patients with Chronic Kidney Disease

Lena Eder[1] and David Leverenz[2], [1]Duke University, Chapel Hill, NC, [2]Duke University School of Medicine, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with gout and chronic kidney disease (CKD) are often not appropriately managed with goal-directed urate-lowering therapy (ULT). To address deficits in management of gout patients with CKD, we aimed to understand how their ULT was managed by primary care within an academic health system.

Methods: We used Slicer Dicer, an analytic tool within our electronic health record (EHR), to identify patients seen within the primary care health system associated with our academic medical center between 02/01/2022 and 02/01/2023 who also had an ICD-10 diagnosis code related to gout and CKD 3, 4, or 5. 121 charts were manually reviewed to determine patient's

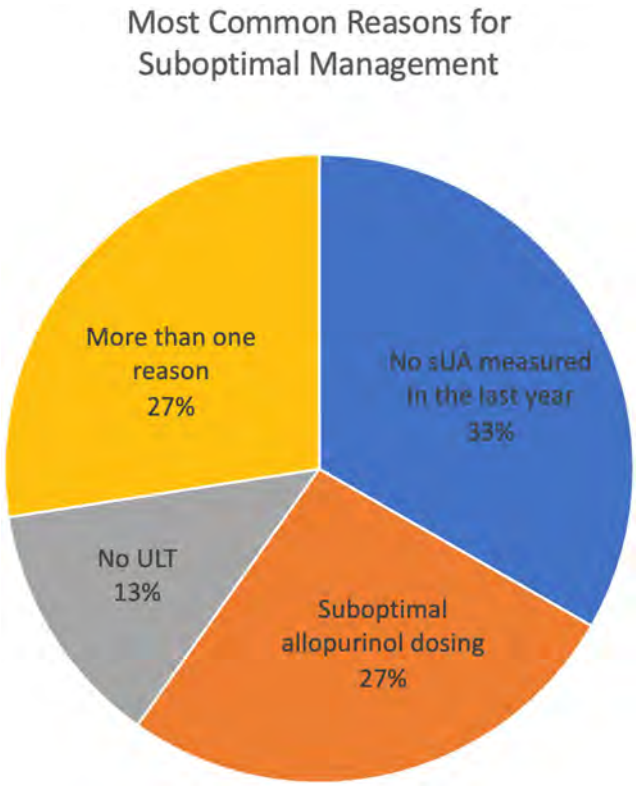

Figure 1. Most Common Reasons for Suboptimal Management of Gout Patients with CKD

glomerular filtration rate (GFR), stage of CKD, serum uric acid (and whether it was checked in the past year), urate-lowering therapy (and dose if applicable), and whether their gout was optimally managed according to the 2020 American College of Rheumatology Guideline for the Management of Gout. To address any seasonal factors, we reviewed charts of patients seen during the first weeks of April 2022, July 2022, October 2022, and January 2023.

Results: 3,371 gout patients with CKD were seen by a primary care provider between 02/01/2022 – 02/01/2023 in our health system. Of the 121 patients further analyzed, 40% had CKD 3, 35% had CKD 4, and 25% had CKD 5. The average GFR was 28.5. A total of 113 patients (93%) had a uric acid available to review. Among all patients, 52% (n = 63) had a serum uric acid checked within a year of their appointment, of which the mean serum uric acid was 7.8. 77% (n = 93) had an active prescription for allopurinol or febuxostat, and 96% (n = 116) were managed primarily by their PCP and had never seen a rheumatologist. Overall, 16% (n = 19) of all the patients reviewed had optimal management of their gout according to ACR guidelines. The most common reasons for suboptimal care were: no serum uric acid measured in the last year (33%, n = 34), suboptimal ULT dosing (27%, n = 27), no ULT prescribed (13%, n = 13), or a combination of these factors (27%, n = 28) (**Figure 1)**.

Conclusion: There are deficits in management of gout patients with a diagnosis of CKD which may lead to worsening morbidity and mortality. Many of these patients are not being treated to goal with suboptimal doses of urate-lowering therapy or no urate-lowering therapy at all. We speculate that this trend may be due to a number of reasons including gaps in knowledge by primary care regarding ULT in patients with a diagnosis of CKD and/or inaccurately in the "normal" range for serum uric acid in the EHR (abnormal is defined as 8 or above). Overall, these findings suggest the need for an educational initiative or health-systems based intervention to address the care of these patients.

Session Date: Tuesday, November 14, 2023

Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite significant interest in the scale and spread of rheumatoid arthritis (RA) outcome measures to facilitate a patient-centered, treat-to-target approach, use of these measures remains inconsistent among rheumatologists. We used the Consolidated Framework for Implementation Research (CFIR) to guide qualitative interviews with stakeholders about facilitators and barriers to RA outcome measurement in real-world rheumatology care, with the goal of disseminating best practices for implementation via an online toolkit

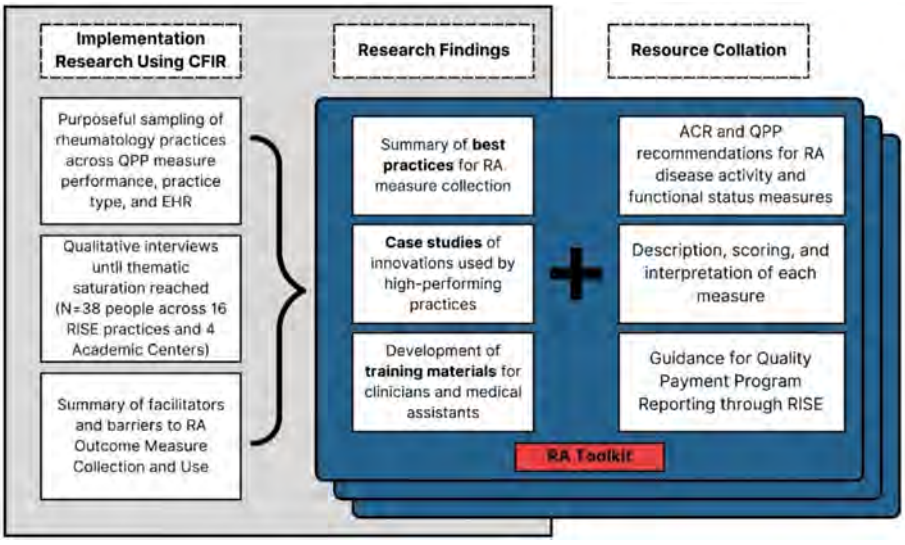

Figure 1: Methods for Developing the RA Outcome Measures Toolkit

Methods: Using RISE registry data, we invited 85 practices with high performance on RA disease activity (DA) measures (≥ 50% percentile on the Quality Payment Program (QPP) 177 periodic assessment of DA) and 54 practices with lower performance to participate. Because academic medical centers (AMCs) are under-represented in RISE, 4 AMCs were also invited to participate. Rheumatologists and key staff from each practice participated in virtual interviews. CFIR concepts were used to develop a semi-structured interview guide to understand workflows, facilitators, and barriers to RA outcome measure collection. Interview recordings were transcribed verbatim and analyzed thematically using deductive and inductive techniques to generate themes and subthemes. Collaborating with the ACR staff, we compiled information from these interviews to develop the online RA Toolkit, a comprehensive resource to facilitate RA outcome measurement in clinical practice (Figure 1).

Table 1: Summary of key findings from qualitative interviews about RA outcome measure collection with rheumatology practices

CFIR Framework Domain	Challenges Identified in Interviews	Solutions Implemented by High-Performing Practices
Outer setting	Incomplete capture of RA measure performance in RISE registry	Check performance on measures frequently. If performance measures are inaccurate, reach out to a representative of the registry for troubleshooting
Outer setting Inner setting	Financial limitations replacing older EHR systems with newer options dedicated to Rheumatology	Work within the range of capabilities in any EHR can help with the inability to migrate to a different, more expensive, system. (Example: customization and internal quality improvement techniques may result in more helpful outcomes than starting from scratch with a new EHR.
Inner setting	Challenges developing reliable workflows to administer patient-reported outcomes to only RA patients	Administer patient-reported outcomes to all rheumatology patients regardless of diagnosis
Inner setting	Time constraints with high patient volumes	Use quality improvement methods to reduce inefficiencies and optimize measure collection
Inner setting	Gaps in workflows that lead to missing RA outcome data in the EHR.	Checks and balances: Ensuring that workflows are consistent, efficient and engage practice staff and patients
Inner setting Individuals	Inadequate training for medical staff, particularly when there is high staff turnover	Ensure redundancy in workflows so that they are not dependent on a single staff member (or a limited number of staff)
Individuals	Patient survey fatigue	Review RA outcome measures regularly with patients to allow them to track their progress and facilitate shared decision-making, which motivates patients to fill out repeated RA outcome measures surveys
Individuals Characteristics	Language barriers and low health literacy	Have RA outcome measure forms available in multiple languages; visual scales for interpretation
Characteristics	Difficulty collecting RA outcome measures during telehealth visits	Administer questionnaires such as the RAPID-3 electronically through web-based applications
Implementation	Difficulty in keeping staff accountable to collect PROs, especially for in-person visits	Assign practice champions (physicians or staff) that regularly communicate importance of RA outcome measure performance and continually optimize workflows
Innovation	Difficulty collecting RA outcomes in structured data fields in the EHR	Use EHR software that facilitates RA outcome measure documentation, creating flowsheets, or investing in custom IT builds to permit reliable data capture

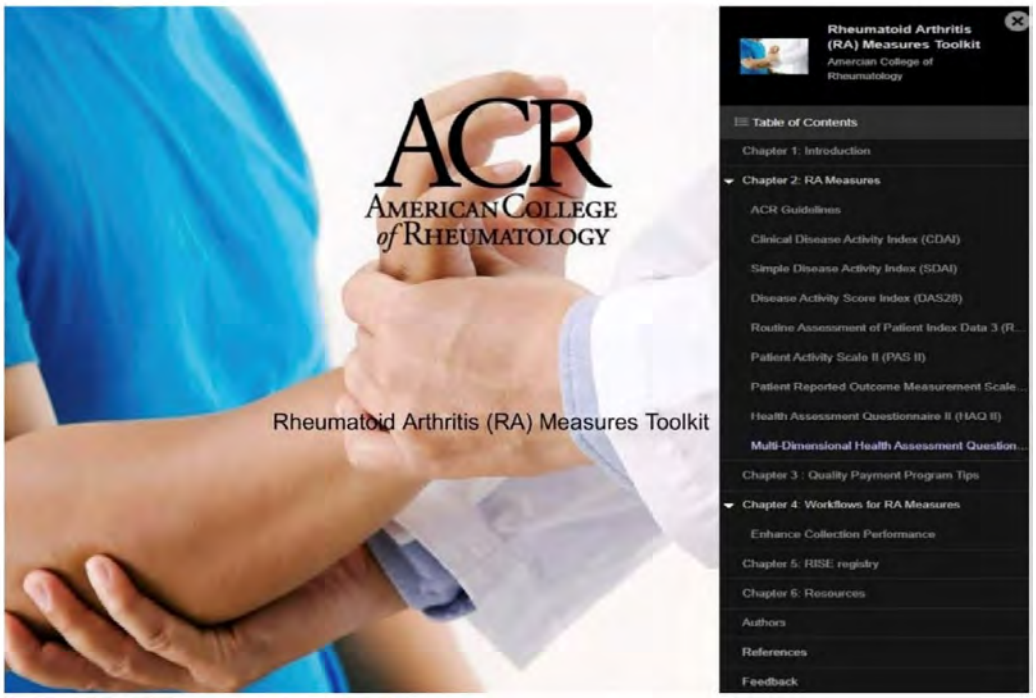

Figure 2: RA Measures toolkit: https://ratoolkit.kotobee.com/

Results: Interviews were conducted with invited practices until thematic saturation was reached (38 interviews across 16 RISE practices and 4 AMC). Participants included 21 rheumatologists, 8 medical assistants, 6 practice managers, 1 nurse practitioner, and 2 information technology specialists. Each interview highlighted unique innovations, resources, best practices, and challenges for collecting RA outcome measures (select findings summarized in Table 1). Results of the qualitative interviews, ACR guidelines regarding RA outcome measures, and other evidence-based resources were compiled in the RA Toolkit (available at RAToolkit.kotobee.com). The Toolkit is a multimedia online resource for RA outcome measure implementation geared toward use by clinicians and staff. Sections include text, videos, and downloadable forms that aid in understanding and using RA outcome measures in clinical practice, recommendations and best practices identified from high performers across diverse practice settings and EHRs, training resources for staff, and validated translations of available RA measures in Spanish and Chinese (Figure 2).

Conclusion: Qualitative interviews conducted with rheumatology teams laid the groundwork to develop a best practices implementation toolkit to disseminate innovations in RA measures collection. The ACR RA Toolkit is the first comprehensive, evidence-based, open-source resource available for rheumatologists and healthcare teams to guide effective implementation, collection, and use of RA outcome measures that promote quality and value-based patient-centered care.

Using the Technology Acceptance Model to Assess Physician Perceptions and Experiences Using the Rheumatoid Arthritis-Patient-Reported Outcomes Dashboard: Mixed-Methods Study

Catherine Nasrallah[1], Cherish Wilson[2], Alicia Hamblin[1], Lindsay Jacobsohn[1], Cammie Young[3], Cammie Young[3], Mary Nakamura[4], Andrew Gross[1], Judith Ashouri[1], Mehrdad Matloubian[1], Jinoos Yazdany[1] and Gabriela Schmajuk[2], [1]University of California San Francisco, San Francisco, CA, [2]UCSF / SFVA, San Francisco, CA, [3]University of California San Francisco, Oakland, CA, [4]UCSF/SFVAHCS, San Francisco, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Improving shared decision-making using a treat-to-target approach, including the use of patient reported outcomes (PROs), is important to providing high quality care for rheumatoid arthritis (RA). We developed an EHR-integrated, patient-facing sidecar dashboard application that displays RA outcomes (disease activity (DA), functional status, pain scores), medications, and lab results for use during clinical visits (Figure 1). The purpose of this study was to assess physician perceptions and experiences using the dashboard in a university rheumatology clinic.

Methods: Data derived from focus group (FG) discussions and surveys with physicians who had access to the dashboard as part of a randomized, stepped-wedge pragmatic trial. FGs explored physician perceptions towards the usability, acceptability, and usefulness of the dashboard. FG data were analyzed thematically using deductive and inductive techniques; emerging themes were categorized according to the Technology Acceptance Model (TAM; Figure 2). Surveys, which were collected during consecutive visits in which the dashboard was not discussed with the patient, queried physicians' reasons for non-use. Survey data were summarized as proportions.

Results: 3 FGs included 12 rheumatologists and 102 surveys were collected from 14 physicians. Major themes that emerged from the FG analysis as barriers to using the dashboard included inconsistent collection of RA outcomes leading to sparse data in the dashboard and concerns about explaining RA outcomes, especially to patients with fibromyalgia (Table). Other challenges included time constraints and technical difficulties refreshing the dashboard to display real-time data. Nevertheless, physicians were enthusiastic about the dashboard and expressed the usefulness of visualizing RA outcome trajectories in a graphical format for motivating patients, enhancing patient understanding of their RA outcomes, and improving communication about medications. Methods for integrating the dashboard into the visit varied: some physicians used the dashboard at the beginning of the visit as they documented RA outcomes; others used it at the end to justify changes to therapy; and a few shared it only with stable patients. Survey results aligned with the themes identified in the FGs: the most reported reason for not using the dashboard was an assumption that the dashboard would not be useful for the patient (32%) (often because of low DA or comorbid conditions). Other reasons included forgetting to use the dashboard (19%), lack of patient data in the dashboard (12%), and time constraints (12%). Technical difficulties accounted for a small amount of non-use (6%).

Conclusion: We used a mixed-methods approach to assess physician perceptions of a novel EHR sidecar dashboard application that aims to improve the quality of care for RA patients. Despite enthusiasm for the value of this new technology, discomfort with discussing RA outcomes, inconsistent workflows for incorporating the dashboard into the visit, and incomplete EHR data were major reasons for not using the dashboard. Future work should address these barriers to improve uptake of the dashboard.

Figure 1: Screenshot of the Rheumatoid Arthritis-Patient-Reported Outcomes Dashboard (RA-PRO)

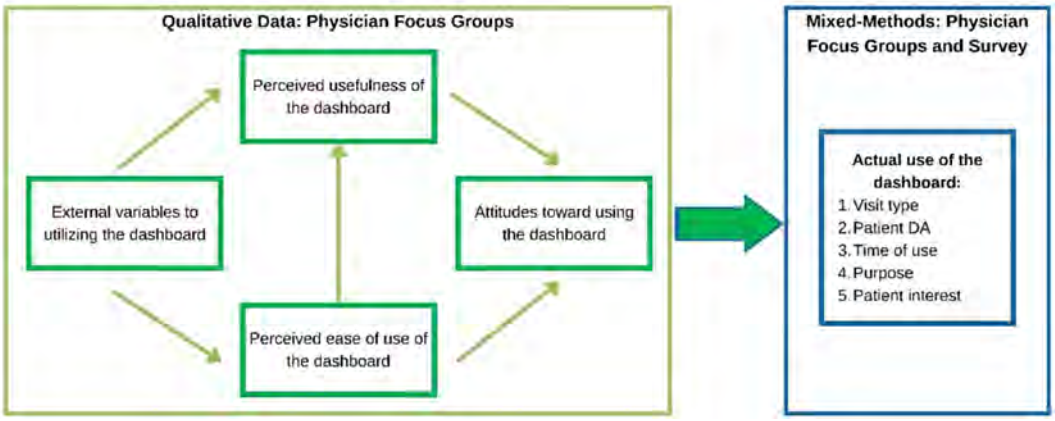

Figure 2: Physician Technology Acceptance Model (TAM) of the RA-PRO dashboard.

Table: Physician Perceptions of the RA-PRO dashboard sidecar application: Qualitative Results

TAM concept	Themes	Sample Quotes
External variables	Inconsistent collection of RA outcomes in the EHR	*"We have a lot of new staff, and they're not all up to speed with [collecting PROs] and gets dropped which I find it frustrating. But it's just all about training"*
	Patient Comorbidities	*"A patient who also has prominent fibromyalgia. There are challenges around that. How can I point out like discordance of patient global... I don't know how to use it in that context"*
	Patient interpretation of PRO questions	*"Patients don't always differentiate between the pain score and the global disease activity, some of them write different scores, [but] many of them write the same thing".*
	Limited knowledge about PRO scoring	*"I focus on the CDAI just because that's the easiest for me to explain. But I start to see the other ones like RIMIS. I'm not exactly sure how that's calculated"*
Perceived Usefulness	Initiating therapy	*"The patient had been off therapy for a long time, it was a good way to show her how severe her disease activity was, and she was open and starting treatment that day"*
	Changing medications	*"I've found it to be the most useful to convince patient to change their medications...I had a number of patients that I've been trying for several years to convince to change therapy and after a couple of visits with this dashboard they actually changed"*
	Discussing RA outcomes with patients	*"Patients asking questions about the numbers, what they are, what it means...They were surprised that we've been collecting and plotting the data for like so many years."*
	Visualizing disease trajectories	*"I think the visualization makes it easier for the patients to see as opposed to just looking at numbers across a chart and, I find that most of my patients really appreciate it"*
	Improving patient understanding of their disease	*"It's interesting to use it when patients feel like they're doing Ok, because say they're on prednisone and I don't think they're doing Ok...and when they actually see their score not being as good as it could be they actually sort of think twice."*
	Motivating patients about treat-to-target approach	*"What I find is that even in patients who are doing well, they like to see this positive feedback up during this green zone"*
Perceived Ease of Use	Lack of familiarity with dashboard content	*"I don't know how to talk about the dashboard. I just say, our goal is to get you up in the green zone, but I don't know what else to talk about"*
	Time constraints	*"I spend a lot of time listening to everything they recorded. At the end, I have to rush, explain the medications and follow up, so I think something additional is just a too much"*
	Technical difficulties	*"It just doesn't update and then you'll have their most recent CDAI, and you realize you're looking at the old CDAI, you have to refresh everything"*
	Virtual visits	*"I do a 28 joint count exam over video, and I walk the patients, through their exam."(O)* *"I have not been successful with that because I haven't figured out how to really assess the tender and swollen joint count numbers which is pretty significant for the CDAI" (C)*
	Design	*"It's a nice pictorial representation for the patients to see how they've been doing with their symptoms over time" (O)* *"I tend to discuss the DA and the PRO sort of separately, so I wish that the medications were closer to the CDAI" (C)*
	Collecting PROs	*"The best way to do it is to fill it out during the visit. It doesn't really take time and it makes the documentation and the homunculus better because I am doing it in real-time" (O)* *"it might be harder to remember to pause to do that with patients, we focus on other things" (C)*

Abstract Number: 1912

Impact of Pharmacist-Led Specialty Medication Management Service on Time-to-Dispense for Specialty Rheumatologic Medications in a University Health System

Khashayar Ahmadmehrabi[1], Navin Ravishankar[2], Diana Mekhiel[3] and Zineb Aouhab[3], [1]Loyola University Medical Center, Oak Park, IL, [2]Indiana University Health, Indianapolis, IN, [3]Loyola University Medical Center, Maywood, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1895–1912) Measures & Measurement of Healthcare Quality Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Given the progressive joint damage and physical disability associated with uncontrolled Rheumatoid arthritis (RA), a treat-to target-strategy through the early utilization of disease-modifying antirheumatic drugs (DMARD) provides patients with the best opportunity to control their disease earlier. Biologic and targeted DMARDs are specialty medications, and while there is not a single defining aspect of specialty medications, most are high cost and involve complexity in storage requirements, handling and delivery, patient management and manufacturer restrictions. While specialty medications have brought successful treatment options to diseases that previously had limited options, they have also made the prior authorization system increasingly complex, often leading to a delay in treatment. Pharmacist-led specialty medication approval programs, such as Specialty Medication Services (SMS), complete prior authorizations, appeals, and aid in financial assistance for specialty medications. This study will examine the impact of a pharmacist-led SMS on time-to-dispense for DMARDs in patients with Rheumatoid Arthritis. The primary endpoint of this study will be to compare time-to-dispense for DMARDs before and after implementation of specialty medication services.

Methods: This study was conducted in a retrospective cohort manner, evaluating the time-to-dispense of specialty rheumatologic medications before and after implementation of SMS. Data was generated from the electronic medical record (EMR). Therapy initiation orders entered through the EMR for any of the included specialty medications prescribed by Rheumatology for the same 6-month period in April 2016- October 2016 (control group, pre-SMS), compared to April 2019-October 2019 (study group, post-SMS). Each patient's EMR was reviewed to collect information on dispensing pharmacy, prior authorization, indication for treatment, and if financial assistance was needed. A total of 100 patients were included in the study, 50 of whom underwent medication approval prior to the implementation of SMS (2016), and 50 of whom underwent medication approval after implementation of SMS (2019).

Results: Among the pre-SMS implementation group (2016), the mean time-to-dispense- was 14.7 days (SD +/- 24 days), while mean time-to-medication dispense for the post-SMS establishment group (2019) was 5 days (+/- 6.7 days). There is a statistically significant difference in days until medication dispensed ($p < 0.001$) for 2016 versus 2019. The two groups demographics and insurance carriers were comparable, though more patients had private insurance in the 2019 group (68%), as compared to the 2016 group (44%, Table 1)

Table 1: Characteristics of patients by Pharmacist access year.

	2016	2019	
Race/Ethnicity, n (%)			
Caucasian	30 (60.00)	31 (62.00)

Abatacept	-	1 (2.00)	
Tofacitnib	-	2 (4.00)	
Tocilizumab	-	1 (2.00)	
Golilumab	-	2 (4.00)	
Age			
Mean (SD)	54.7 (12.3)	50.5 (13.1)	
*Significant at α = 0.05 level †Fisher's exact test p-value			

	n	Mean (SD)	n	Mean (SD)	n	Mean (SD)	P-VAL
Days until Approval	100	9.9 (18.2)	50	14.7 (24.0)	50	5.0 (6.7)	<.0001*

Conclusion: This study shows that the implementation of Pharmacist-led specialty medication approval programs, such as Specialty Medication Services, significantly reduced the number of days until specialty medications were dispensed in a university health system. While there is a difference in the average time to dispense with the utilization of Specialty Medication Services, further studies are needed to determine the impact of early medication approval and dispensing and how this corresponds to patient clinical outcomes.

Neurosarcoidosis Disease Epidemiology. University Hospital in Northern Spain 1999-2019

Ana Serrano-Combarro[1], Alba Herrero-Morant[2], Lara Sanchez-Bilbao[3], Inigo Gonzalez-Mazon[3], David Martinez-Lopez[4], Jose Luis Martin-Varillas[5], Raul Fernandez-Ramon[6] and Ricardo Blanco[7], [1]Hospital Universitario Marques de Valdecilla, IDIVAL, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla, Ontinyent, Spain, [3]Hospital Universitario Marques de Valdecilla, Santander, Spain, [4]Hospital de Sierrallana, Santander, Spain, [5]Hospital de Laredo, Laredo, Spain, [6]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [7]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Neurosarcoidosis (NS) is a serious and relative uncommon complication of sarcoidosis. Data on incidence is scarce and varies worldwide. Our objective is toestimate NS epidemiology in Northern Spain.

Methods: Patients diagnosed with sarcoidosis at a University hospital in Northern Spain, between January 1999 and December 2019 were assessed. Sarcoidosis diagnosis was established according to ATS/ERS/WASOG criteria as follows: compatible clinical and radiological presentation, histopathologic confirmation, and exclusion of other granulomatous diseases. NS was diagnosed according to the NS Consortium Consensus Group. Demographic and clinical data were collected. The incidence of sarcoidosis between 1999-2019 was estimated by gender, age, and year of diagnosis.

Results: NS was observed in 30 of 234 (12.8%) (19 women/ 11 men) (mean age: 55.0±15.8 years) patients with sarcoidosis. The underlying neurological manifestations were chronic headache (n=13, 43.4%), peripheral neuropathy (n=6, 20.0%), cranial neuropathy (n=5, 16.7%), spinal cord abnormalities (n=3, 10.0%) and aseptic meningitis (n=3, 10.0%). A comparison between different geographical areas is summarized in **Table 1**. There are wide variations in frequency (US:4.8% to France:33.9%), gender predominance and age at diagnosis (31 to 55 years) depending on the geographical area.

TABLE 1: Main clinical features and treatment of neurosarcoidosis in different geographical areas.

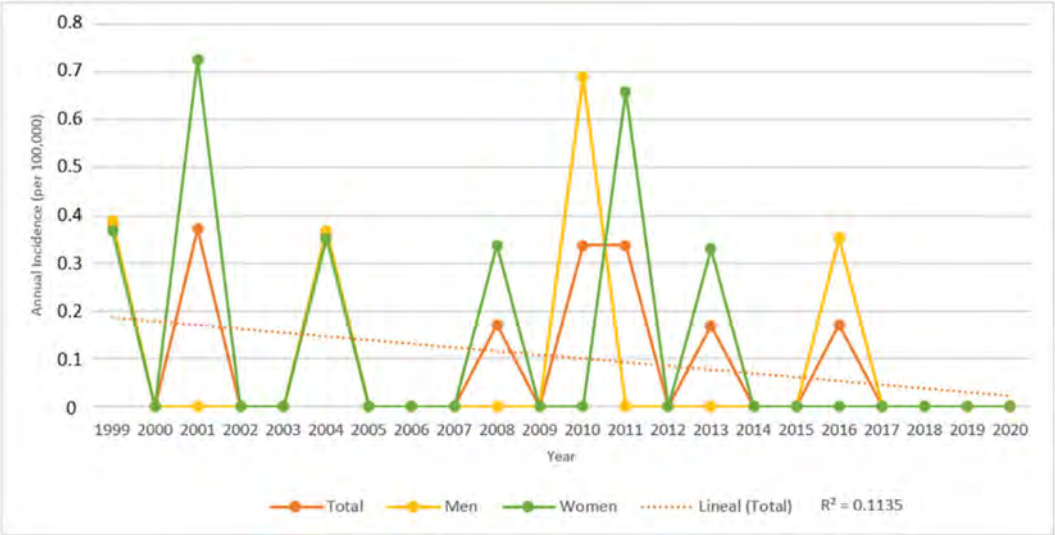

FIGURE 1: Trends in age at neurosarcoidosis diagnosis in Cantabria, Spain, in 1999-2019 by gender.

Nevertheless, most of the patients were diagnosed in the 5th decade of life. Annual incidence of NS in our population area in the 1999-2019 period was 0.11 per 100000 people, 95% (CI:0.11-0.26); 0.08 (0.07-0.24) in men, 0.13 (0.09-0.24) in women. There were variations in annual incidences, ranging from a minimum value of 0.08 in 2013-2014 to a maximum of 0.19/100000 population in 1999-2000. A downward trend in annual incidence over time was observed. Nevertheless, the correlation was weak(r^2=0.1135) (**Figure 1**).

Conclusion: The epidemiological characteristics of NS is very different in frequency. Frequency estimated in this study was similar to that of other countries.

Intravenous Immunoglobulins in the Treatment of Idiopathic Inflammatory Myopathies in a Region of Northern Spain: Analysis by Subtypes

Cristina Corrales Selaya[1], David Martínez-Lopez[2], Diana Prieto-Peña[1], Fabricio Benavides[1], Jose Luis Martin-Varillas[3] and Ricardo Blanco[4], [1]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [2]Hospital Sierrallana, Torrelavega, Spain, [3]Hospital de Laredo, Laredo, Spain, [4]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of diseases characterised mainly by the presence of inflammation and muscle weakness. The main subtypes of IIM are Dermatomyositis (DM), Polymyositis (PM), Inclusion body myositis (IBM), Immune-mediated necrotising myopathies (IMNM) and Anti-synthetase syndrome (ASS).

Currently the treatment of IIMs is not well established. Intravenous immunoglobulins (IVIG) are a therapeutic alternative for the treatment of IIM. Although their mechanism of action is not precisely known, several studies suggest that they are effective in the treatment of multiple rheumatological diseases, including IIM.

The main objective of this study is to describe the use of IVIG, as well as to determine its efficacy in different subtypes of IIM in a cohort of patients from northern Spain.

Methods: Observational study of patients with IIM who required at least one cycle of IVIG between January 2000 and December 2022. Patients with IIM who met a) EULAR/ACR 2017 criteria for DM and PM, b) European Neuromuscular International Workshop 2016 definition for MNIM and c) Connor's criteria in SAS were included.

Treatment efficacy was studied based on a) clinical variables (muscle weakness and skin involvement), b) analytical variables (Creatin Kinase CK) and c) corticosteroid sparing effect. All these factors were measured at 1 month, 3 months, 6 months, 1 year and 2 years after starting IVIG treatment.

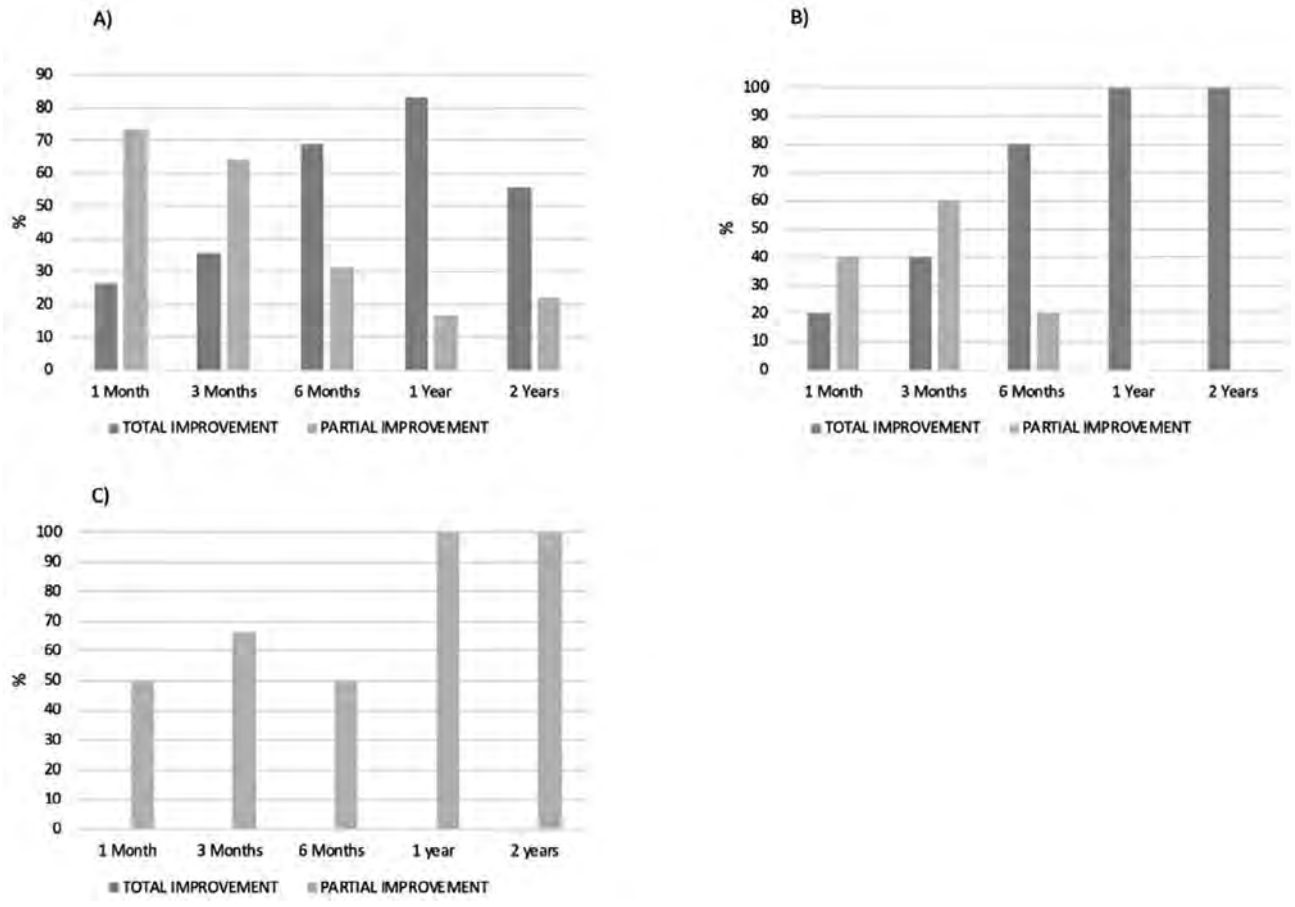

Figure 1. Muscle weakness improvement. a) Dermatomyositis b) Inmune-mediated necrotizing myopathies. c) Polymyositis

Muscle weakness was measured in 3 territories (upper limb, lower limb and neck flexor muscles) using the MRC (Medical Research Council Grading System) muscle strength scale.

The evolution of clinical parameters was classified into 3 categories: complete improvement (resolution), partial improvement and no improvement.

The IVIG treatment schedule used was 2g/kg spread over 2-5 days.

Results: A total of 37 patients with IIM were included, 29 females (78%) and 8 males (22%), with a mean age 47 ± 27 years. The most frequent group was DM (n=27; 73%), followed by IMNM (n=6; 16%), PM (n=3; 8%) and ASS (n=1; 3%).

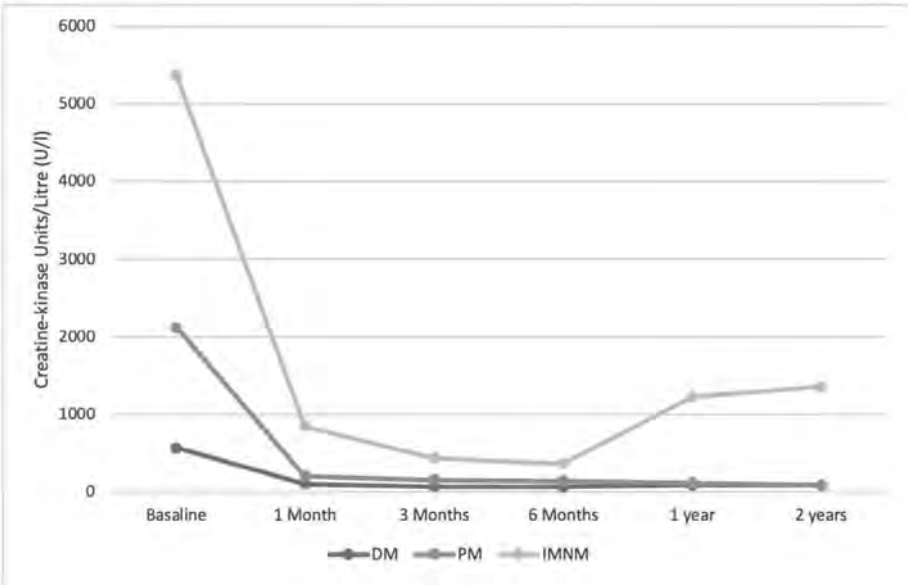

FIGURE 2. Creatine-Kinase evolution.

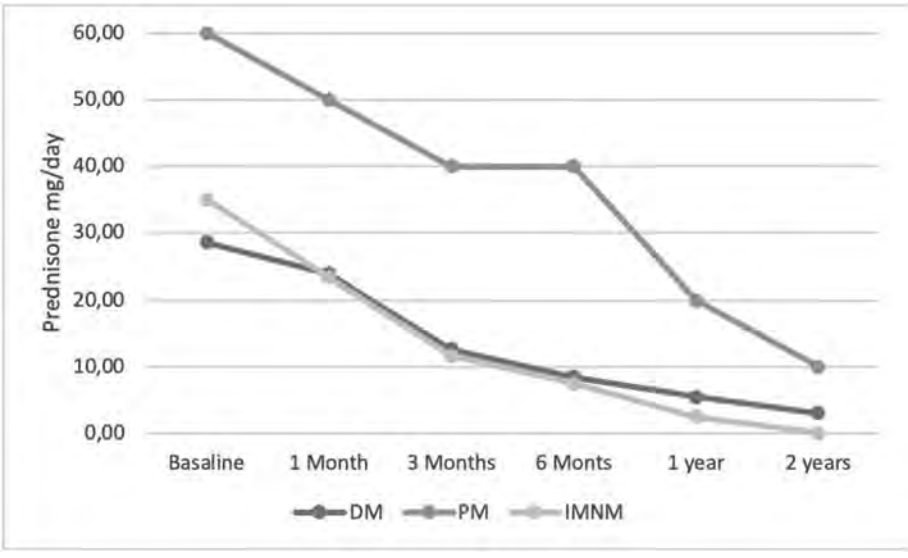

FIGURE 3. Corticosteroid sparing effect.

Eight (30%) patients with DM received IVIG as induction therapy associated with standard treatment, while 19 (70.37%) patients received IVIG after boluses of methylprednisolone (n=10; 53%), prednisone 45 mg/day (n=19; 100%), or associated with other immunosuppressants (IS) (methotrexate, azathioprine, cyclophosphamide or mycophenolate). The main indication for IVIG in this group was muscle weakness (n=19; 70%) and skin involvement (n=8; 30%). The main indication for IVIG in MD was muscle weakness (n=19; 70%) and skin involvement (n=8; 30%).

All PM patients (n=3) had received previous treatment with Prednisone 60mg/day. The main indication was muscle weakness (n=3, 100%).

Of the 6 patients with IMNM, 5 (67%) received IVIG as induction therapy and 1 patient (33%) after Prednisone 60 mg/day. In all of them the indication was muscle weakness.

Only one patient with ASS received IVIG treatment, due to interstitial lung involvement and muscle weakness.

An improvement in muscle weakness (total and/or partial) (Figure 1), CK levels (Figure 2) and a sparing glucocorticoid effectof IVIGwas observed in all IIM subtypes.(Figure 3)

Conclusion: IVIGs are effective in all 3 subtypes of IIM studied.

Scleritis and Development of Autoimmune Disease: A Case Series

Tessalyn Morrison[1], Moriah Gottman[2], Marcia Friedman[3] and Daniela Ghetie[4], [1]University of Vermont, Burlington, VT, [2]Oregon Health & Science University, Milwaukie, OR, [3]Alpine Immune Sciences, Inc., Beaverton, OR, [4]Oregon Health & Science University, Portland, OR

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleritis involves inflammation of the sclera caused by trauma, infections, or autoimmune conditions. The purpose of our study was to understand the relationship between scleritis and the presence of autoimmune disease, including the temporal relationship, treatment course, recurrence, and associated serologies.Characterizing the relationship between scleritis and autoimmunity can help clinicians identify and treat conditions effectively.

Methods: We conducted a case series of 341 scleritis patients seen between January 1, 2005 and December 20, 2020. Demographics, treatment types, treatment failures, recurrence events, and serology data were compared among patients with and without autoimmune disorders. Autoimmune disorders were described by disease and by time course. American College of Rheumatology criteria were unable to be used to verify diagnoses for this study.

Results: Most patients with scleritis had an associated autoimmune disorder (n=196, 57%), and most patients developed their disorder before scleritis (62%). There were no significant differences in age, gender, ethnicity, or race among scleritis patients with and without autoimmune disorders. Most patients had recurrence of scleritis (54%), and patients with autoimmune disorders were more likely to have a recurrence (62% vs 48%, $p< 0.05$). The most common scleritis treatments were nonsteroidal anti-inflammatory drugs, topical and systemic prednisone. There were no differences in treatment failure rates based on having an autoimmune disorder. The most common autoimmune disorders associated with scleritis were rheumatoid arthritis (39%), vasculitis (21%), and inflammatory bowel disease (14%). The incidence of autoimmune disorders developed after scleritis for any condition was 0.84/100,000 person years, with 0.33/100,000 person years for vasculitis, and 0.23/100,000 person years for RA. Based on limited data, there were no relationships between RF and ACPA serologies

and time course of developing autoimmune disorders and scleritis. Dual-seropositive patients were more likely to have an autoimmune disorder compared to seronegative patients (72% vs 35%, p< 0.001), as were RF+/ACPA- patients (70% vs 35%,p< 0.05).

Conclusion: Scleritis is associated with autoimmune diseases, most commonly developed before scleritis. Scleritis among autoimmune patients is more likely to recur. Comparative studies are needed to identify individual risk factors associated with development of autoimmune disease among scleritis patients.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Although *NLRP1* was the first identified member of the NOD-like receptors family, its role as a sensor of pathogen- or damage-associated signals and its connection with systemic autoinflammatory disorders (SAIDs) have not been clarified yet. Missense or non-sense variations of the NLRP1 gene have already been associated with some clinical phenotypes including dyskeratosis, arthritis, recurrent fever, chronic infections, recurrent acute phase response, recurrent respiratory papillomatosis, keratosis pilaris, palmoplantar wart-like hyperkeratotic papules, atrophoderma vermiculata, and familial keratosis lichenoides chronica. Some polymorphisms have also been associated with autoimmune disorders. We herein report the clinical findings of 5 patients with *NLRP1* variants.

Methods: The study group included the patients who were referred to our center with a potential diagnosis of SAID and screened for variants of 22 autoinflammatory genes. Those patients with NLRP3 variants were identified, and their clinical and laboratory findings were evaluated.

Results: A total of 146 cases with potential diagnosis of SAID were included, and their genetic analysis results were evaluated. *NLRP1* variants were identified in 5 (3.4 %) cases. All of the *NLRP1* gene variants were classified as variant of uncertain significance (VUS). All but one patients had additional variants in other autoinflammatory genes (Table 1). The most common clinical finding was recurrent urticaria (n=4). Case 1 had NLRP3-AID-like clinical phenotype in addition to Crohn's disease with sacroiliitis. Case 2 had scleritis attacks and had a combination of two gene variants. Case 3 had Behçet's disease-like phenotype with oral aphthous stomatitis, genital ulcers, and cerebrovascular event with VUS in both *NLRC4* and *NLRP1* genes. Case 4 had a TRAPS-like phenotype with serositis and periorbital edema with NLRP1 VUS and a pathogenic *MEFV*

variant. Case 5 had an FMF-like phenotype with VUS in the *NLRP1* VUS and a pathogenic variant in the *MEFV* genes along with five different gene variants. None of the patients had a family history for a phenotype compatible with SAIDs.

Table 1: Genotype and phenotypes of patients with NLRP1 variants. *: Pathogenic and likely pathogenic, †: VUS

Patient no	Sex	Current age	Age onset	Gene	Amino acid change	rs number	Frequency	Clinic	Treatment
1	F	32	4	NLRP1 †	p.Val939Met	rs61754791	0.016102	Fever attacks every two weeks with cold-induced urticarial rash, abdominal pain, nausea, elevated acute phase reactants, Crohn's disease and sacroiliitis, proteinuria (amyloidosis?)	Canakinumab

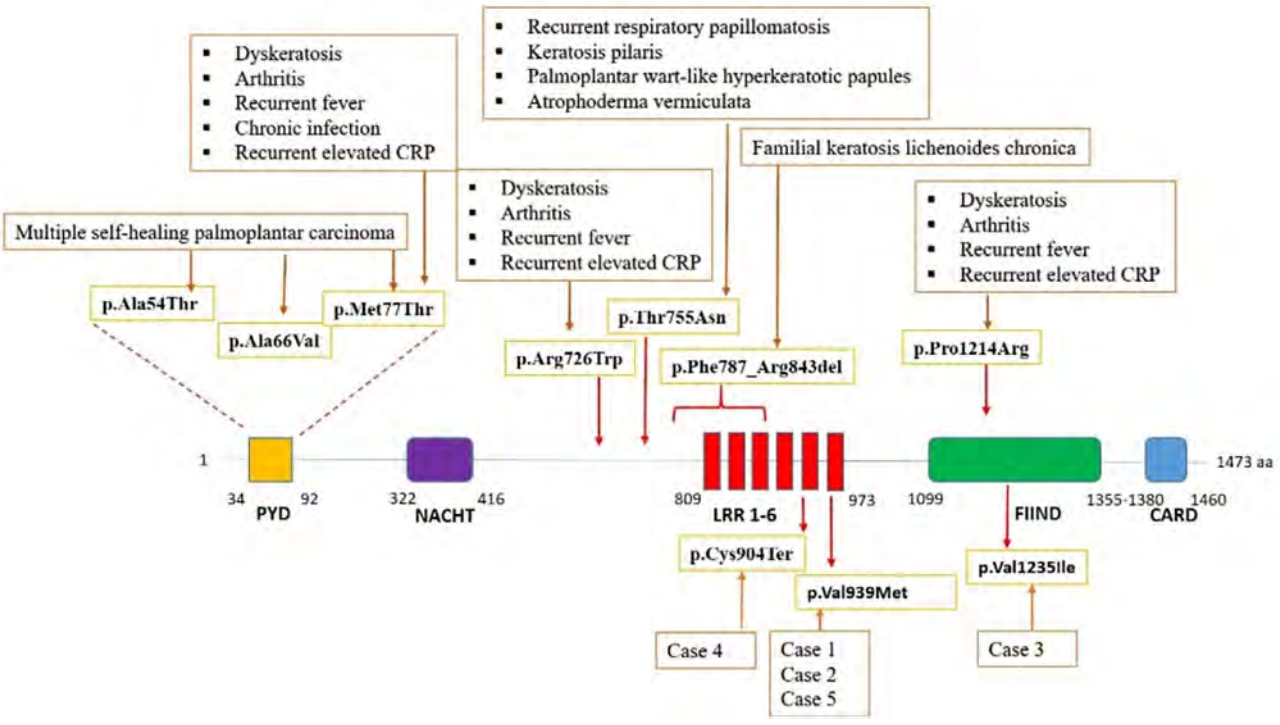

Figure 1: NLRP1 variants and phenotypic features of the reported patients (above the line) and our cases (below the line).

Conclusion: *NLRP1*-associated SAID has been emerging as a new entity, and the phenotypic features of the reported patients varied significantly according to the positions of the variants within the different domains of the gene (Figure 1). We herein report 4 patients with recurrent urticaria as the most common clinical feature in association with 3 different VUS in the *NLRP1* gene, and none of the accompanying genetic variants have not been related to urticaria below. The *NLRP1* gene p.Val939Met variant is a relatively common variant (allele frequency 0.01), but relatively frequent observation of this variant in the current patient group may suggest that it may have a functional role very similar to the relatively common variant of p.Gln703Lys in the NLRP3 gene. One of the remaining two variants (p.Val1235Ile) was not reported before, and the other one (p.Cys904Ter) was expected to have a pathogenic role due to early termination of the protein (Figure 1). Collection of more cases would help clarify the spectrum of clinical findings of the patients with NLRP1-AID.

Reducing Inadvertent Antifilarial Antibody Testing at an Academic Medical Center: A Quality Improvement Project

Khiem Vu, Justin Choi and Jon Golenbiewski, Atrium Health Wake Forest Baptist Medical Center, Winston-Salem, NC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-Related Disease (IgG4-RD) is a fibroinflammatory autoimmune disease that can present with glandular swelling, chronic pancreatitis, sclerosing cholangitis, and retroperitoneal fibrosis, amongst others. Along with a supporting clinical history, diagnosis is typically established by biopsy of affected tissue showing hallmark histopathologic findings. Many patients demonstrate elevated serum IgG4 levels and checking levels is often part of the initial workup when considering IgG4-RD. At Atrium Health Wake Forest Baptist, IgG4 levels can be checked by ordering IgG subclass levels or IgG4 levels. However, we have frequently observed the filarial IgG4 antibody test erroneously ordered instead, even though the patient's symptoms are not suggestive of filariasis or other tropical infectious disease. Inadvertent ordering of filarial IgG4 consumes healthcare dollars and may lead to delay in diagnosis of potential IgG4-RD. Our goal was to quantify how prevalent this issue is over the last 5 years (March 2017-March 2022) and institute a quality improvement (QI) intervention to significantly reduce inadvertent filarial IgG4 testing.

Methods: Using SlicerDicer on EPIC, we determined the number of patients who had ≥ 1 filarial IgG4 level ordered (date range 3/22/2017-3/21/2022). Using the patient's medical record number (MRN), we individually reviewed the charts to determine whether such testing was indicated or done inadvertently while investigating a diagnosis of IgG4-RD. We designed a pop-up reminder that appears when a provider tries to order a filarial IgG4. The pop-up contained recommendations for alternative testing for IgG Subclass 4 or IgG Subclasses instead, and officially launched on 3/22/2022. To determine the efficacy of our intervention after a 1-year observation, we determined the number of patients who had ≥ 1 filarial IgG4 ordered between the dates 3/22/2022 and 3/21/2023.

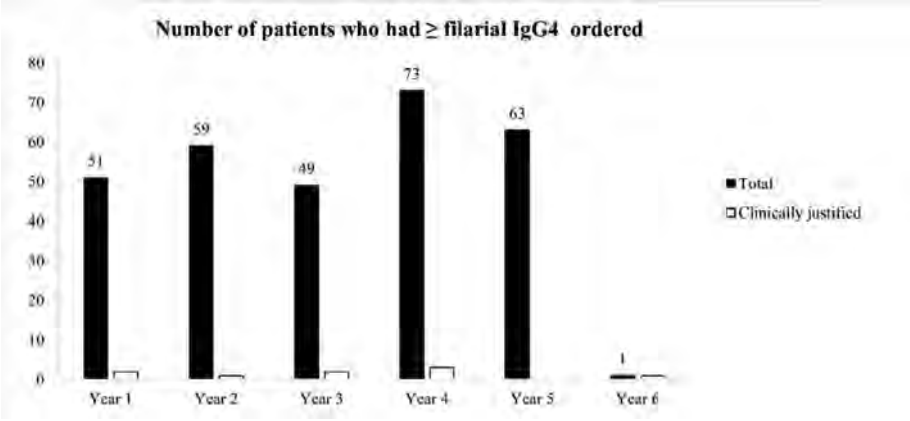

Figure 1

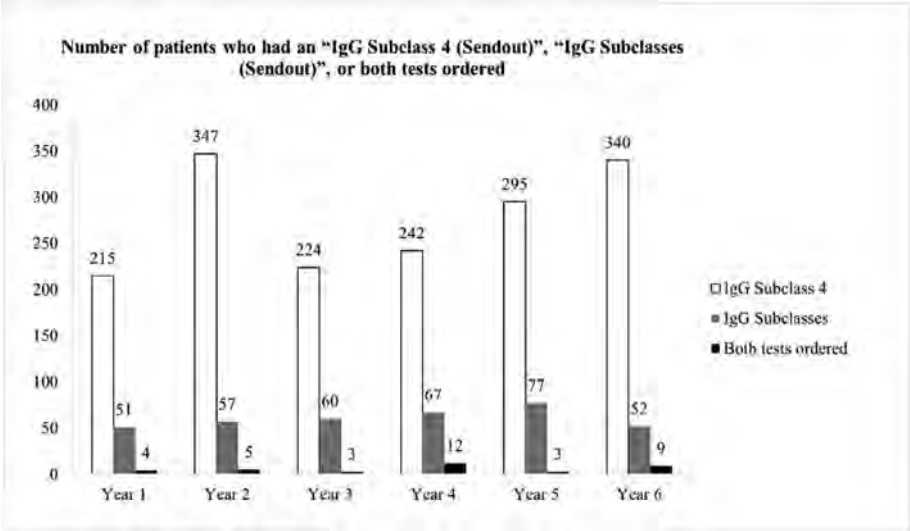

Figure 2

Results: 295 patients had ≥ 1 filarial IgG4 test ordered between 3/22/2017 and 3/21/2022 (average 59 patients per year). The vast majority of patients (97.3%) had unjustifiable reasons for ordering the test, after review of the patients' charts (**-Figure 1**) However, our pop-up intervention significantly reduced (100% reduction) inadvertent filarial IgG4 testing after a 1-year observation. Only 1 filarial IgG4 test was ordered during 3/22/2022-3/21/2023, and it was clinically indicated after chart review **(Figure 1)** Ordering of IgG4 Subclass 4 or IgG Subclasses was not negatively affected by the pop-up (**Figure 2**)

Conclusion: We instituted an effective QI intervention in the form of a pop-up reminder that effectively eliminated the inadvertent checking of filarial IgG4 when such testing was not justified.It was selective against filarial IgG4 orders, and did not create an undue burden on providers who tried to order potentially justifiable IgG4 or IgG subclass testing. Since each filarial IgG4 test costs $288.75 at Labcorp (821383), our intervention could potentially reduce health expenditures by $17,000 per year at our institution. This strategy could be applied at other medical centers if a similar problem with filarial IgG4 exists and can also be applied to other lab tests that are often checked inadvertently.

Nationwide Analysis of Predictors of Sarcoid Inpatient Mortality

Michael Manansala[1], Faria Sami[2], Shilpa Arora[3] and Augustine Manadan[1], [1]Rush University Medical Center, Chicago, IL, [2]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, [3]Cook County Hospital, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is multisystem autoimmune disease characterized by noncaseating granulomas which can result in significant morbidity and mortality. This study aims to identify variables associated with in-hospital death for sarcoid patients on a national level.

Methods: We performed a retrospective study of adult sarcoid hospitalizations from 2016-2020 National Inpatient Sample (NIS) database. Diagnoses for each hospitalization were identified by ICD-10 codes. We sought to identify predictors of in-hospital death among sarcoid patients. Variables were selected from literature review and ranking of common diagnoses among sarcoid inpatients. Variables with a p value ≤ 0.2 in the univariable screen were included in a multivariable logistic regression model. P values ≤ 0.05 were considered significant in the multivariable analysis.

Results: There were 405,450 inpatient admissions with a diagnosis of sarcoidosis in the 2016-2020 NIS database. Of those, 10,210 (2.5%) died while in the hospital (table 1). The deceased group was older (median age 67 vs 61 years; p< 0.0001), had more males (41.7% vs 38.6%; p=0.0035), had longer median LOS (6 vs 4 days; p< 0.0001), had higher median total hospital charges ($78,507vs $37,333; p< 0.0001), and higher Charlson comorbidity index (CCI) (3 vs 2; p< 0.0001). Univariable analysis showed many variables associated with in-hospital death among sarcoid patients (table 2). Multivariable analysis showed the following variables were independently associated with a higher odds of in-hospital death: Age (OR 1.03; 95% CI 1.023 -1.032), CCI (OR 1.14; 95% CI 1.102-1.170), COVID-19 (OR 2.69; 95% CI 2.133-3.384), male gender (OR 1.16; 95% CI 1.047-1.290), other race (OR 1.79; 95% CI 1.275-2.505), acidosis (OR 2.46; 95% CI 2.190-2.755), Acute kidney failure (AKF) (OR 1.89; 95% CI 1.695-2.107), arrhythmia/heart blocks (OR 1.58; 95% CI 1.414-1.767), cerebral edema/brain compression (OR 8.29; 95% CI 6.177-11.115), disseminated intravascular coagulation (DIC) (OR 11.87; 95% CI 6.417-21.948), encephalopathy (OR 1.81; 95% CI 1.574-2.082), hepatic failure (OR 4.28; 95% CI 3.446-5.319), hemophagocytic lymphohistiocytosis (OR 5.43; 95% CI 1.269-23.212), aspiration pneumonia (OR 1.89; 95% CI 1.557-2.300), pulmonary embolus (OR 2.18; 95% CI 1.697-2.793), pulmonary hypertension (OR 1.22; 95% CI 1.079-1.383), respiratory failure (OR 6.70; 95% CI 5.911-7.592), and sepsis (OR 2.81; 95% CI 2.494-3.156) (table 3).

Conclusion: Our analysis showed that 2.5% of inpatient admissions carrying a sarcoid diagnosis ended in death. Demographic factors such as age, gender, other race, and CCI were independently associated with higher odds of mortality, while African American race and income quartile were not. Several comorbidities were independently associated with higher odds of in-hospital death: acidosis, acute kidney failure, arrhythmia/heart blocks, cerebral edema/brain compression, DIC, encephalopathy, hepatic failure, HLH, aspiration pneumonia, PE, pulmonary hypertension, respiratory failure, and sepsis. Clinicians should remain vigilant for these life-threatening complications since early recognition and intervention may improve inpatient sarcoid outcomes.

Arthroplasty Outcomes in Immune Checkpoint Inhibitor-Treated Patients: A Single Center Series

Yasmine Elfarra[1], Edward DiCarlo[2], Jonathan Vigdorchik[2], Carlos Aude[3], Nilasha Ghosh[3], Anne Bass[3] and Karmela Kim Chan[2], [1]Weill Cornell, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) have changed the landscape of cancer treatment dramatically, but because of their mechanism of action they are also known to cause immune-related adverse events, including chronic inflammatory arthritis (ICI-IA) and osteoarthritis flares. Additionally, the safety of joint arthroplasty in such patients has not yet been described. We undertook this study to describe the histology and outcomes of hip and knee arthroplasty (THA and TKA) at our high-volume orthopedic hospital among patients who received ICI within one year of surgery.

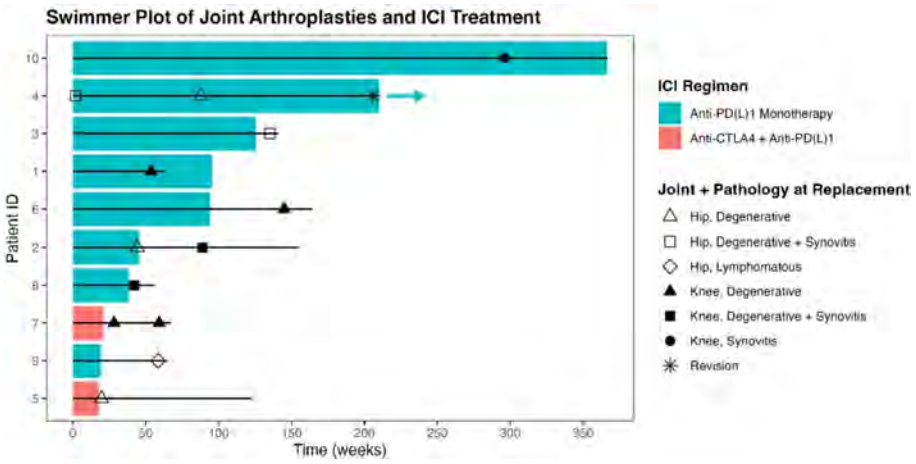

Figure 1. Swimmer's plot showing different checkpoint inhibitor regimens, joint replaced, and histology, plotted against time

Table 1. Patient characteristics. ICI = immune checkpoint inhibitor; ipi/nivo = ipilimumab/nivolumab

Patient	Age/Sex BMI	Cancer/Stage	ICI/Duration (months)	Time from last dose to surgery (days)	Joint	Charlson Comorbidity Index	Length of hospital stay (days)/discharge disposition	Complication	F/U Time (days)	Histology

9	65 M 28.2	Lymphoma	Pembrolizumab 5	334	Right hip	4	1/home with services	None	47	Degenerative with lymphomatous involvement
10	69 M 29	Urothelial IV	Nivolumab 84	7	Right knee	8	2/home with services	None	492	Marked lymphoplasmacytic synovitis consistent with rheumatoid arthritis

Methods: We identified all ICI-treated patients who underwent joint arthroplasty at Hospital for Special Surgery (HSS) from 1/1/2018 to 12/31/2022, excluding patients whose last dose of ICI was >365 days prior to surgery. Clinical information was extracted retrospectively from the electronic medical record. The study was approved by the HSS IRB.

Results: Ten patients who had received ICI treatment underwent 13 native joint arthroplasties (**Table 1)**. Mean age was 70, mean BMI 27.45. Two patients had established ICI-IA. Median duration of ICI therapy was 18 months. Median time from the last dose of ICI to surgery was 27 days. Median duration of follow up was 271 days. There were 6 TKA, 1 unicompartmental knee replacement, and 6 THA (**Figure 1**). In 12/13, joint replacement surgery was indicated after failing conservative therapy for degenerative joint disease. There were no surgical site infections, wound healing issues, 30-day readmissions, cardiovascular events, or death. All patients were discharged home, most with services. Of the 2 patients with known ICI-IA, one (with known lymphoma) was found to have lymphomatous involvement of an otherwise degenerative hip; the other patient, who had monoarticular ICI-IA and for whom TKR was meant to be curative, had knee histology that showed marked lymphoplasmacytic inflammation resembling rheumatoid arthritis. All other joint explants had degenerative disease, 3 with mild-moderate synovitis. One patient had calcium pyrophosphate crystal deposits. One patient, who has remained on treatment from the time immediately preceding her first THA in 3/2019 until the present, required a revision THA 2/2023. The primary THA used a dual mobility prosthesis and modular dual mobility liner containing cobalt/chromium. Histology of the THA explant at the time of revision showed an immune-mediated inflammatory granulomatous reaction (adverse local tissue reaction), possibly from corrosion at the dual mobility liner, or from neck/stem incompatibility. Serum cobalt level was elevated at 2.7 ucg/L (nv 0.1-0.4). These reactions are uncommon; in one systematic review of arthroplasties using similar components, only 3% of patients had elevated ion levels.[1]

Conclusion: This single-center retrospective case series demonstrates the relative safety of performing joint arthroplasty in cancer patients treated with ICI. Most patients had degenerative changes with some mild to moderate reactive synovitis. One patient had an immune-mediated reaction leading to early revision; it is plausible that ICI treatment played a role in augmenting the immune response.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: JS005 is a novel anti-IL-17A monoclonal antibody with unique patented complementarity-determining region (CDR) sequences. This Phase Ib/II study (NCT05344248) aimed to evaluate the safety, tolerability, efficacy and pharmacokinetic characteristics of JS005 in patients with moderate to severe plaque psoriasis.

Methods: This study was composed of a dose-escalation phase Ib trial and a multicenter, double-blind, placebo-controlled phase II trial. Moderate to severe plaque psoriasis patients were enrolled to receive subcutaneous JS005 60mg (n=6), 150mg (n=9), 300mg (n=9), 600mg (n=6) and placebo (n=10) in the phase Ib trial. In the phase II trial, moderate to severe plaque psoriasis patients aged 18 to 75 years were randomized in a 1:1:1 ratio to receive subcutaneous JS005 at 150mg (n=48), 300mg (n=47) or placebo (n=48) once a week (QW) from Week 0 to Week 4, and once every 4 weeks (Q4W) from Week 5 to Week 12. Follow-up period was continued for 8 weeks after the last dose. The primary endpoint was the proportion of patients with at least 75% improvement in Psoriasis Area and Severity Index (PASI 75) from baseline at Week 12.

Results: A total of 40 and 143 patients were enrolled in this phase Ib and phase II trials, respectively. In the phase Ib trial, JS005 was well tolerated in moderate to severe plaque psoriasis patients, the incidence of Treatment Emergent Adverse Events (TEAEs) was similar across groups ($p > 0.05$). Results from full analysis set (FAS) showed significantly higher response rates of PASI 75 with JS005 60mg (50%, $p < 0.0001$), 150mg (100%, $p < 0.0001$), 300mg (100%, $p < 0.0001$) and 600mg (100%, $p < 0.0001$) than with placebo (0%) at Week 12 (Fig. 1). In the phase II trial, the proportions of patients achieved PASI 75 at week 12 were significantly higher in the JS005 150mg group (95.8%, $p < 0.0001$) and 300mg group (89.4%, $p < 0.0001$) than in the placebo group (8.3%) (Fig. 2). The incidence of TEAEs was 62.5%, 63.8%, and 64.6% in the JS005 150mg, 300mg and placebo groups, respectively. The severity of TEAEs in JS005 150mg and 300mg groups were all CTCAE grade 1 and Grade 2. The most common drug related TEAEs in JS005 group were hyperuricemia (6.3%), blood uric acid increase (5.3%), and hypertriglyceridemia (5.3%). There were no AEs that led to study withdrawal and permanent treatment discontinuation, and no serious AE or death events occurred.

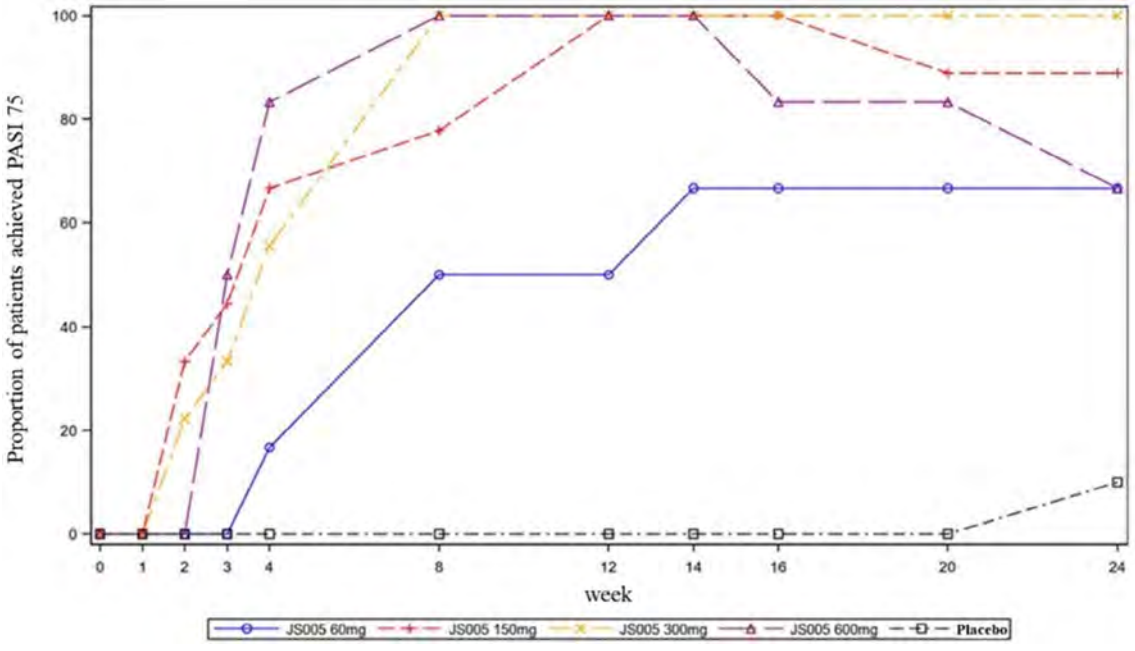

Figure 1 Proportion of patients achieving PASI 75 over 24 weeks in Phase Ib trial (full analysis set)

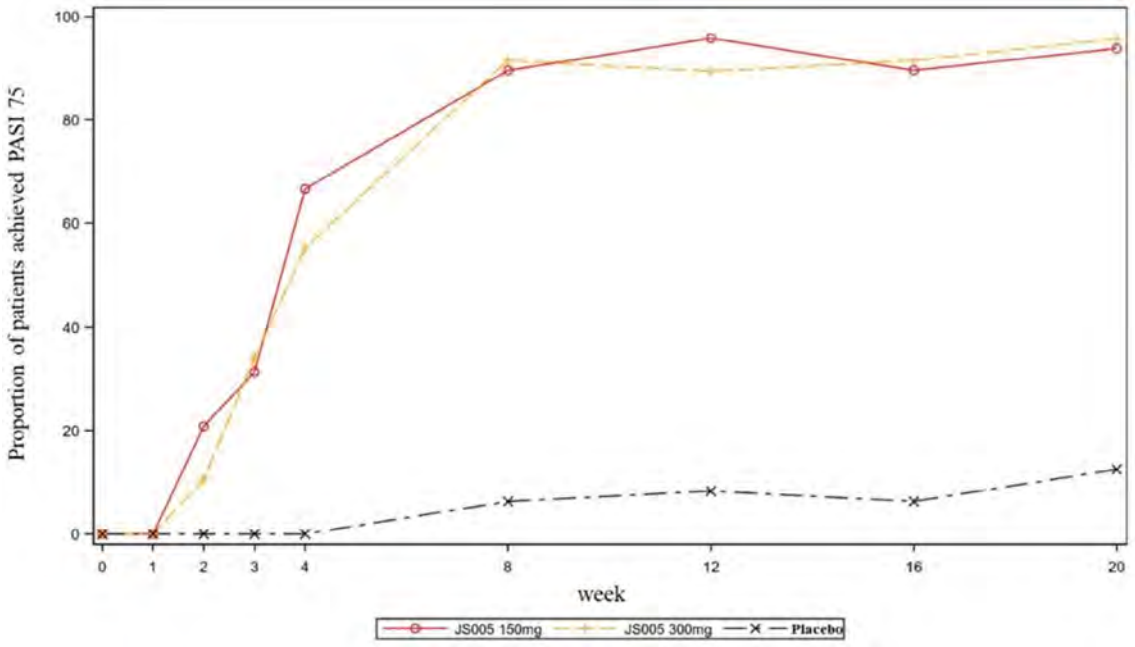

Figure 2 Proportion of patients achieving PASI 75 over 20 weeks in Phase II trial (full analysis set)

Conclusion: This phase Ib/II study demonstrated that JS005 was highly effective and well tolerated in moderate to severe plaque psoriasis.

Clinical Spectrum of VEXAS Syndrome in a Rheumatology Department

Herman Mann[1], Blanka Stiburkova[2], Katerina Pavelcova[1], Monika Belickova[3], Cyril Salek[3], Jana Juhaszova[1] and Jiri Vencovsky[4], [1]Institute of Rheumatology, Praha 2, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic, [3]Institute of Hematology and Blood Transfusion, Praha 2, Czech Republic, [4]Institute of Rheumatology, Prague, Czech Republic, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: VEXAS (vacuoles, E1 activating enzyme, X-linked, auto-inflammatory, somatic) syndrome is a clinically serious and potentially fatal adult-onset disease caused by somatic mutations in the *UBA1* (Ubiquitin-like modifier activating enzyme 1) gene in hematopoietic progenitor cells. VEXAS syndrome clinically presents with inflammatory and hematological symptoms in middle and older age, predominantly in males. Multisystem inflammation most commonly affects the skin, eyes, joints, blood vessels, cartilage, and lungs. Patients with VEXAS syndrome may meet diagnostic criteria

Table 1: Clinical characteristics of patients with VEXAS syndrome

Abbreviations: AZA: azathioprine, GC: glucocorticoids, CTD: connective tissue disease, Dg: diagnosis, GI: gastrointestinal, HCQ: hydroxychloroquine, INF: infliximab, MDS: myelodysplastic syndrome, RA-: seronegative rheumatoid arthritis, RPC: relapsing polychondritis, SAS: sulfasalazine, Sx: symptoms, TCZ: tocilizumab, TOFA: tofacitinib, Tx: treatment, VTE: venous thromboembolism

for several rheumatic diseases and/or hematological disorders. Given its heterogeneous clinical manifestations a high degree of clinical suspicion is required for pursuing the diagnosis of VEXAS syndrome; therefore, clinicians must be aware of the clinical features of VEXAS syndrome. The purpose of this study is to describe a series of cases diagnosed in a rheumatology department.

Methods: Institute of Rheumatology is the largest tertiary academic center providing care for patients with all types of inflammatory rheumatic diseases in the Czech Republic. Patients with symptom onset at age ≥40 years with undiagnosed inflammatory conditions, chondritis, unclassified vasculitis, neutrophilic dermatosis and classifiable inflammatory rheumatic diseases, which were a) resistant to standard therapy, b) associated with hematologic disorders or c)associated with atypical inflammatory manifestations for given diagnosis were considered for *UBA1* testing. Retrospective chart review was performed to obtain pertinent demographic information and clinical data for patients with detected *UBA1* somatic mutations.

Results: We have tested 22 patients (17 males and 5 females) with suspicious clinical phenotype and were able to detect previously described somatic *UBA1* mutations in five of them. One additional patient with clonal cytopenia and multi-organ inflammatory features (patient 4) harbored a previously undescribed *UBA1* variant in exon 14, which proved pathogenic in enzymatic analyses (1). Clinical features of individual patients are summarized in Table 1. All patients were males with a median age at symptom onset 66.5 years (IQR 57, 73) and median duration of symptoms prior to VEXAS syndrome diagnosis 3 years (IQR 2, 5). All patients were treated for a presumptive rheumatologic diagnosis with glucocorticoids and three patients received various other immunosupressants prior to the diagnosis of VEXAS syndrome. Myelodysplastic syndrome was diagnosed based on bone marrow biopsy in three patients, two additional patients had macrocytic anemia. Notably no cytopenia and normal MCV were present in one patient with longstanding inflammatory symptoms.

Conclusion: VEXAS syndrome presents with heterogenous clinical manifestations and should be considered in rheumatology patients with corresponding inflammatory phenotype even in the absence of hematologic abnormalities. 1) Stiburkova B, et al.Novel Somatic UBA1 Variant in a Patient With VEXAS Syndrome. Use of Plasma with High Titer Neutralizing Autoantibodies to Type I Interferons in Patients with Severe Refractory Flare-up of Hidradenitis Suppurativa as Novel Passive Immunotherapy Approach: Trial Protocol

Charline Vauchy[1], Maxime Desmarets[1], Paul Bastard[2], Anne Puel[2], Pascale Richard[3], Jean Laurent Casanova[2], Pierre Tiberghien[3], **Eric Toussirot**[4] and Francois Aubin[5], [1]INSERM CIC-1431, Besançon, France, [2]IHU Imagine, AP-HP Necker, Paris, France, [3]Etablissement Français du Sang, St. Denis, France, [4]University Hospital of Besancon, Besançon, France, [5]Dermatology, University Hospital of Besancon, Besançon, France

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Hidradenitis suppurativa (HS) is a multifactorial auto-inflammatory disorder with a prevalence of 1% in North American and European populations. HS may be associated with various systemic inflammatory conditions including arthritis. Transcriptome analyses of inflammatory pathways and single-cell RNA sequencing of injured skin found upregulation of type I interferon (IFN)-regulated genes (IFN signature). Plasma from healthy donors may contain autoantibodies (Abs) neutralizing type I IFN (alpha and/or omega). In patients with systemic lupus erythematosus (SLE), the presence of these antibodies has been associated with less severe disease. We hypothesize that these Abs provide a potential therapeutic strategy in patients with severe refractory flare-up of HS. Thus, we aim to evaluate the feasibility, safety, and to collect preliminary evidences of efficacy of plasma with neutralizing Abs to type I IFN in patients with severe refractory HS.

Methods: We propose a multicentre prospective phase I-II trial in adult patients with severe refractory flare-up of HS (Hurley stage III). This will be a two-level dose escalation (1 or 2 plasmas) trial combining safety (classic 3+3) and efficacy criteria (Fleming two-stage design), with priority given to safety. The total number of patients enrolled will range from 2 (if more than 1 severe adverse event) to 17 patients. Each patient will receive plasma from healthy donors identified as harboring high titers of neutralizing Abs against IFN. The primary endpoint will combine occurrence of serious adverse events and evidence of IFN alpha neutralization at Day 2 (D2) (> 90% neutralization of IFN alpha by the recipient's plasma). Secondary endpoints will be clinical response (defined as at least a 50% reduction in the abscess and inflammatory nodule count), disease activity score (HS-PGA, IHS4, HiSCR), pain intensity, health-related quality of Life (DLQI) and patient satisfaction (Patient Satisfaction Index and Treatment Satisfaction Questionnaire for Medication). IFN alpha neutralization will also be evaluated at hour 1 (after transfusion) and days 7, 14, 21 and 28. Other type I IFN-associated criteria, including anti-IFN alpha auto-Abs and IFN alpha levels at day 0 (pre-transfusion), hour 1 and days 2, 7 14, 21 and 28 will be part of secondary objectives and IFN signature will be assessed in biopsies of HS skin lesion, before and after transfusion.

Results: Expected results: plasma dose escalation will be based on the safety and the transient neutralization of circulating type I IFN. This neutralization is likely to impact the inflammatory response observed in these patients, as well as the associated lesions and pain.

Conclusion: To our knowledge, this will be the first trial assessing the potential for plasma with high titer neutralizing Abs to type I IFN to treat auto-inflammatory diseases. It may open opportunities for such passive immunotherapy in diseases characterized by interferon signature such as HS and SLE.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of comorbidities in rheumatic diseases may vary by disease and geographic region. This study aimed to investigate the comorbidities associated with rheumatoid arthritis (RA), ankylosing spondylitis (AS), primary Sjögren's syndrome (PSS) and systemic lupus erythematosus (SLE).

Methods: Data from consecutive patients attending a tertiary care facility between 2020 and 2021 were analyzed. Patients diagnosed with RA, AS, PSS and SLE based on established criteria were included in the study

Table 1 Prevalence of comorbidities in inflammatory rheumatic patients

	Rheumatoid Arthritis	Ankylosing spondylitis	Primary Sjogren's (PSS)	Systemic lupus Erythematosus (SLE)	Total
Total number	N=1000	N=100	N=44	N=203	N=1347
F: M	880:120 (7:1)	27:73 (1:3)	42:2 (21:1)	191:12 (16:1)	1140:207 (6:1)
Age (mean + SD) years	47.68 ±11.46	37.2 ±14.06	47 ±11.00	34.17 ±11.30	41.51
ESR (mean) mm/ Hour	52.69 ± 26.8	31.21 ±16.12	41±26 mm/hour	21±26	38.23
Hypertension	11% (109/1000)	8% (8/100)	18.2% (8/44)	9.9 % (20/203)	10.7% 145/1347
Hypothyroidism	8.5% (85/1000)	10% (10/100)	15.9% (7/44)	27.1% (55/203)	11.6% (157/1347)
Diabetes	7% 70/1000	21% 21/100	6.8% (3/44)	4.4% (9/203)	7.6% (103/1347)
Skin	0.8% 8/1000	14 % (14/100)	4.6% (2/44)	1.5% (3/203)	2% (27/1347)
Ischemic heart Disease	0.1% 1/1000	0	0 % (0/44)	0.5% (1/203)	0.15% 2/1347
Osteoporosis	0.1 % (1/1000)	0	0% (0/44)	0% (0/203)	0.08% 1/1347
Surgery	2% 20/1000	9% (9/100)	2.3% (1/44)	0%	2.2% (30/1347)
Cancer	2/100 0.02%	2/100 (2%)	0%	0%	0.03% 4/1347
Tuberculosis	10 10/1000	2 2/100	1 1/47	0	0.09% 13/1347

Results: A total of 1347 patients (Table 1) were analyzed in this study. In patients with inflammatory rheumatic diseases (N=1347), hypertension (10.7%) and hypothyroidism (11.6%) were the most common comorbidities. When individually assessed for specific diseases, patients with rheumatoid arthritis (RA) (N=1000) had hypertension as the most common comorbidity (11%), followed by hypothyroidism (8.5%). Likewise, patients with ankylosing spondylitis (AS) (N=100) showed a similar pattern, with hypertension and hypothyroidism being the most common comorbidities. Patients with Sjögren's syndrome (N=44) showed a higher prevalence of hypertension (18.2%) and hypothyroidism (15.9%). In patients with systemic lupus erythematosus (SLE) (N=203), the prevalence of hypothyroidism (27.1%) and hypertension (9.9%) was higher, while diabetes was less common The overall prevalence of hypertension ranged from 8 to 12%, with the highest prevalence being found in primary Sjögren's syndrome (18.2%). SLE had the highest prevalence of hypothyroidism (27.1%), which was two to three times higher compared to other rheumatic diseases, likely reflecting the increased incidence of autoimmune thyroiditis in this population. In contrast, the prevalence of diabetes was lower in SLE, possibly reflecting the younger age of the patients. The relatively younger age group may also explain the lower prevalence of comorbidities such as cancer, osteoporosis, and ischemic heart disease in the study population Overall, the prevalence and pattern of comorbidities in this study were relatively lower compared to internationally published studies that included populations from different ethnic backgrounds. These findings underscore the distinct patterns of comorbidities among various rheumatic diseases, likely influenced by underlying disease characteristics. Additionally, the younger age group in the study population with fewer comorbidities emphasizes the importance of early diagnosis and optimal management of rheumatic diseases to prevent the development of comorbidities.

Conclusion: Prevalence and pattern of comorbidities in rheumatic diseases vary between different diseases and populations. Understanding these differences is crucial for tailoring treatment strategies and improving patient outcomes.

Impact of the COVID-19 Pandemic on Clinical and Psychosocial Features of Patients with UCTD

Caroline Siegel[1], Lucy Masto[1], Amaya Smole[1], Bessie Stamm[1], JoAnn Vega[1], Dongmei Sun[1], Deanna Jannat-Khah[1], Michael Lockshin[2], Lisa Sammaritano[2] and Medha Barbhaiya[2], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The early COVID-19 pandemic led to physical and psychological burdens for patients with systemic rheumatic diseases, whether or not they had had COVID-19. To assess the impact of this public health crisis on people with UCTD, we compared demographic, clinical and psychosocial features between patients enrolled in our UCTD registry before versus after the initial wave of the COVID-19 pandemic in New York City.

Methods: This retrospective cohort study included patients enrolled in an academic hospital-based UCTD registry with positive ANA, ≥1 sign/symptom of a CTD, who do not meet ACR/EULAR-endorsed classification criteria for SLE, RA, SSc, Primary Sjögren's, Idiopathic Inflammatory Myopathy, or 2006 Revised Sapporo Criteria for APS. We collected demographic information from patients and clinical characteristics from chart review. Upon enrollment, participants completed the 36-Item Short Form Health Survey (SF-36) to assess health-related quality of life (HRQoL), General Anxiety Disorder-7

(GAD-7), Beck Depression Inventory (BDI), and Fatigue Severity Scale (FSS). We compared demographic, clinical, and psychosocial variables between participants enrolled April 2018-February 2020 ("pre-COVID-19") to those enrolled March 2020-May 2023 ("post-COVID-19"). We used multivariable linear regression to evaluate the association between enrollment date (before vs. after pandemic onset) and HRQoL (i.e. SF-36 physical component summary [PCS] and mental component summary [MCS] scores).

Results: There were 78 patients with UCTD: median age 49.5 years [IQR 34.3, 57.8], 96% female, 74% White race, 74% non-Hispanic/Latino ethnicity. There were no differences in demographics, CTD manifestations, comorbidities, or medications between groups [**Table 1**].

In the post-COVID-19 group, the SF-36 'social functioning' score was higher (i.e. better) than in the pre-COVID-19 group (median [IQR] 62.5 [50.0, 87.5] vs. 50.0 [37.5, 75.0], p=0.03). The post-COVID-19 PCS and MCS scores were numerically higher (PCS: 42.3 [32.3, 50.1] vs. 34.0 [27.3, 46.2], p=0.09; MCS: 45.9 [35.6, 52.8] vs. 44.1 [29.8, 46.6], p=0.06). The post-COVID-19 vs. pre-COVID-19 group had a higher frequency of BDI-defined mild depression and a lower frequency of moderate/severe depression (p=0.04); GAD-7 and FSS scores did not differ between groups [**Table 2**].

Table 1. Clinical Characteristics, COVID-19 Risk Factors, and Medication Use in "Pre-COVID-19" vs. "Post-COVID-19" UCTD Groups

Characteristic	Overall (N=78)	Pre-COVID-19 (N=41)	Post-COVID-19 (N=37)	p-values

Immunosuppressive	10 (12.8)	6 (14.6)	4 (10.8)	0.87
• Biologics, small molecules, IVIG	4 (5.1)	2 (4.9)	2 (5.4)	
• Disease-modifying antirheumatic drugs	6 (7.7)	4 (9.8)	2 (5.4)	

Data are represented by median [IQR] or n (%); p-values <0.05 was statistically significant.
1. All criteria-based manifestations defined as per 1997 ACR Classification Criteria for SLE.
2. Sub-categories not mutually exclusive.
3. Congestive heart failure, coronary artery disease, type 2 diabetes mellitus, hyperlipidemia, hypertension
4. Chronic obstructive pulmonary disease/asthma, interstitial lung disease

After adjustment, the post-COVID-19 group had slightly but not significantly increased PCS (Estimate: 3.32, 95% CI: -1.95 – 8.59, p=0.21) and MCS (Estimate:4.18, 95% CI -0.72 – 9.09, p=0.09) scores compared to the pre-COVID-19 group. BMI was inversely associated with PCS score (Estimate -0.46; 95% CI -0.87 – -0.05, p=0.03) [**Table 3**].

Conclusion: Comparing demographically and clinically similar patients with UCTD enrolled in our registry before and after March 2020, we found that those assessed after the onset of the COVID-19 pandemic had decreased moderate/severe depression and increased social functioning with a trend toward improved HRQoL. Our results suggest that circumstances

Table 2. Assessment of Health-Related Quality of Life, Anxiety, Depression, and Fatigue in "Pre-COVID-19" vs. "Post-COVID-19" UCTD Groups

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal pain is a key symptom experienced by patients with SAPHO and chronic nonbacterial osteomyelitis (SAPHO-CNO), yet its relation to disease activity assessment remains unknown. We sought to determine the relation between patient-reported outcome (PRO) measures for pain, and the physician and patient assessments of disease activity in adults with SAPHO-CNO.

Methods: Adults (≥18 years of age) with SAPHO-CNO enrolled in the SAPHO-CNO study (SCS), a prospective longitudinal observational study, completed 5 PRO instruments for the assessment of pain: 1) global pain in SAPHO-CNO by the numeric rating scale (NRS, 0-10); 2) pain scale of the Short Form 36-item survey (SF-36) (0-100); 3) Patient-Reported Outcomes Measurement Information System (PROMIS) pain interference short form (SF) (6a v1.1); 4) PROMIS nociceptive pain quality SF (5a v2.0); and 5) PROMIS neuropathic pain quality SF (5a v2.0). Subjects completed a patient global assessment (NRS, 0-10) for overall and musculoskeletal (MSK) disease activity in SAPHO-CNO. Physician-assessed disease activity was measured by the physician global scale (NRS, 0-10) for overall and MSK symptoms. Correlational analyses using Spearman's rank correlation coefficient (rho, *r*) were performed between 1) physician-assessed and patient-reported disease activity (for overall and MSK), and 2) disease activity (by physician and patient) and PRO pain measures. P-values less than 0.05 were considered significant.

Results: Fifty-eight subjects in the SCS completed their assessments at baseline and were included in this cross-sectional analysis. Baseline characteristics of the adult SAPHO-CNO cohort are summarized in Table 1. We observed weak correlation between physician-assessed and patient-reported overall ($r(56)$=0.37, p=0.005) and MSK ($r(56)$=0.34, p=0.009)

disease activity in SAPHO-CNO. Next, we observed a weak correlation for 4 out of 5 PRO pain measures and physician-assessed disease activity, except for PROMIS pain interference which showed moderate correlation (r ~0.44-0.46) with physician-assessed overall and MSK disease activity (Table 2). In contrast, there was moderate/good correlation for 3 out of 5 PRO pain measures, and strong correlation of pain by NRS with overall (r = 0.71) and MSK (r = 0.76) disease activity by the patient (Table 2). The PROMIS neuropathic scale showed weak correlation with patient-reported disease activity; additionally, this scale had a high floor effect (29.3% of subjects had the lowest score).

Conclusion: The physician global assessment of disease activity in adult SAPHO-CNO does not fully capture patient pain and likely misses important disease experiences from the patient perspective. For pain quality assessment, the PROMIS neuropathic pain scale may not be suitable. Incorporating patient-reported pain measures will be important for the development of a future composite disease activity index in adult SAPHO-CNO.

Table 1. Baseline demographics and disease characteristics of adults with SAPHO-CNO.

	Adults with SAPHO-CNO (n = 58)
Age, median (IQR), years	33 (24-49)
Gender, female (%)	52 (86.2)
Non-Hispanic (%)	56 (96.6)
White (%)	53 (91.4)
Time from diagnosis, median (IQR), years	5 (3-10)
MSK involvement, n (%)	58 (100)
Skin involvement, n (%)	
PPP	16 (27.6)
PSV	14 (24.1)
HS	6 (10.3)
Acne (severe)	7 (12.1)
Patient Global Assessment, median (IQR) (NRS, 0-10)	
Overall Disease Activity in SAPHO-CNO	3.5 (2.0-6.5)
MSK Disease Activity in SAPHO-CNO	3.5 (1.4-7.0)
Physician Global Assessment, median (IQR) (NRS, 0-10)	
Overall Disease Activity in SAPHO-CNO	3.0 (1.4-6.0)
MSK Disease Activity in SAPHO-CNO	2.8 (1.0-5.0)
Patient-reported Outcome Measures for Pain.	
Pain in SAPHO-CNO (NRS, 0-10)	5.0 (2.5-7.5)
SF-36 Pain Scale (0-100)	57.5 (45.0-71.9)
PROMIS Pain Interference	58.0 (53.3-65.1)
PROMIS Neuropathic Pain Quality	44.1 (37.2-48.2)
PROMIS Nociceptive Pain Quality	53.5 (44.6-58.0)

SAPHO: Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis; CNO: chronic nonbacterial osteomyelitis; IQR: interquartile range; MSK: musculoskeletal; PPP: palmo-plantar pustulosis, PSV: psoriasis vulgaris, HS: hidradenitis suppurativa, NRS: numeric rating scale; SF-36: Short Form 36-item survey; PROMIS: Patient-Reported Outcomes Measurement Information System. Scores are reported as median with interquartile range (IQR). For NRS, rating is from 0 (no active disease, no pain) to 10 (worst active disease, worst pain). All PROMIS measures are short forms.

Table 2. Correlations between physician- and patient-assessed disease activity with patient-reported measures of pain in adults with SAPHO-CNO.

	Physician Global Disease Activity		Patient Global Disease Activity	
	Overall	MSK	Overall	MSK
PRO Measure for Pain:	*r*	*r*	*r*	*r*
Pain in SAPHO-CNO (NRS)	0.30*	0.32*	0.71*	0.76*
SF-36 Pain Scale	-0.36*	-0.37*	-0.61*	-0.63*
PROMIS Pain Interference	0.46*	0.44*	0.61*	0.58*
PROMIS Neuropathic Pain Quality	0.23	0.14	0.30*	0.35*
PROMIS Nociceptive Pain Quality	0.30*	0.38*	0.55*	0.53*

SAPHO: Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis; CNO: chronic nonbacterial osteomyelitis; MSK: musculoskeletal; PRO: patient-reported outcome; *r*: Spearman's rank correlation coefficient; NRS: numeric rating scale; SF-36: Short Form 36-item survey; PROMIS: Patient-Reported Outcomes Measurement Information System. *p-value < 0.05.

Use of 18F-FDG PET in Assessing Response to Treatment in Adults with Pulmonary Sarcoidosis: A Systematic Literature Review

Koushan Kouranloo[1], Mathangi Krishnakumar[2] and Mrinalini Dey[3], [1]Rheumatology & Internal Medicine Trainee-Surrey, UK. Education fellow University of Liverpool, Liverpool, United Kingdom, [2]Wrexham Maelor Hospital, Wrexham, United Kingdom, [3]Queen Elizabeth Hospital, London, United Kingdom; University of Liverpool, Liverpool, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a chronic, multisystem, granulomatous disease commonly affecting the lungs. Immunosuppressants, particularly corticosteroids, are the mainstay of treatment. Symptoms, severity and response to treatment can follow a heterogenous pattern, presenting a clinical challenge. Positron Emission Tomography (PET) imaging with the use of Fludeoxyglucose F18 (18F-FDG) has been recommended by the American Thoracic Society guidelines in choosing an appropriate biopsy site.Use of 18F-FDG PET in disease monitoring remains uncertain. We undertook a systematic literature review (SLR) on the use of 18F-FDG PET in assessing response to treatment in adults with pulmonary sarcoidosis.

Methods: The protocol was registered on Prospero (CRD42023416412). All published articles discussing PET CT use in response to treatment in pulmonary sarcoidosis were included, until March 2023, in Medline, Embase, and Cochrane Databases. The search was restricted to English-language articles. All article types were eligible except opinion pieces, case reports, case series of ≤10 patients and reviews. Articles meeting inclusion criteria were examined by one author, with 20% validity screening. In addition to basic demographics, information was extracted on: Siltzbach classification of subjects; treatment; additional tests performed; time between baseline and follow-up PET CT.

Results: Initially, 1759 articles were retrieved with 8 ultimately included (4 prospective; 3 retrospective; 1 case-control). A pooled total of 260 patients with pulmonary sarcoidosis were included, 40.7% male, mean age 47.0 years (SD 3.4). Study populations were from France (n=1), China (n=1), The Netherlands (n=1), Turkey (n=1), India (n=2) and Serbia (n=2). Treatment for pulmonary sarcoidosis varied markedly amongst the included studies, including: infliximab (n=1) and systemic corticosteroids (n=3); treatment was unknown in 4 studies. All studies used 18F-FDG-PET, except one in which gallium-67 scintigraphy was also used. Time between baseline PET CT and follow-up scan ranged from 2.8 weeks to 12 months. Compared to clinical response, sensitivity of PET CT in determining response to treatment ranged from 56% to 100%, with mean sensitivity of 75.3% (SD 16.0). Additional tests performed across all studies included spirometry, chest radiograph, serum angiotensin-converting-enzyme levels, soluble interleukin-2 receptor levels. All studies concluded that PET CT correlates with clinical response to treatment and is useful for prognostication, aside from one study which concluded that metabolic response on PET CT can predict future risk of relapses but does not correlate with clinical response.

Conclusion: To our knowledge, this is the first SLR summarising the use of 18F-FDG PET in assessing response to treatment in adults with pulmonary sarcoidosis. 18F-FDG-PET is useful in determining response to treatment and prognosis in pulmonary sarcoidosis, and may have a role in predicting future response. Further work in greater patient numbers is required to confirm the utility of PET CT in the management of pulmonary sarcoidosis.

Manifestations, Management and Outcomes of Interstitial Lung Disease Associated with Anti-synthetase Syndrome: A Systematic Literature Review

Koushan Kouranloo[1], Mrinalini Dey[2], Veronica Yioe[3], Lisa G Spencer[3] and Caroline V Cotton[4], [1]Rheumatology & Internal Medicine Trainee- Surrey, UK. Education fellow University of Liverpool, Liverpool, United Kingdom, [2]Queen Elizabeth Hospital, London, United Kingdom; University of Liverpool, Liverpool, United Kingdom, [3]Liverpool Regional Lung Disease Service, Aintree Hospital, Lower Lane, Liverpool, United Kingdom, [4]Department of rheumatology, Liverpool University NHS Foundation Trust, Liverpool, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-synthetase syndrome (ASS) is a chronic autoimmune inflammatory condition, characterized by myositis, interstitial lung disease (ILD), arthritis, Raynaud's phenomenon and mechanic's hands. This systematic review (SR) aims to summarise the manifestations, management and outcomes of ILD associated with ASS (ASS-ILD).

Methods: The protocol was registered on Prospero (CRD42023416414). Articles discussing management and outcomes of ASS-ILD, published 1946 until April 2023, were included. Medline, Embase and Cochrane Databases were searched. Case reports, case series of < 10, reviews and conference abstracts were excluded. Articles meeting inclusion criteria were examined by two authors. Data on demographics, treatment, antibody serology, physiological and radiological findings at baseline and one-year were extracted.

Results: Initially, 451 articles were retrieved with 10 included (9 cohort, 1 case series; Figure 1). Risk of bias assessment established studies were of variable quality (Table 1). A total of 514 patients were included, 67.8% female, mean age 52.4 (SD 4.6) years at ILD induction therapy. Cohorts were from: Europe (n=5); North America (n=3); China (n=2). Patients had the following myositis-associated autoantibodies: Jo-1 (48%); PL7 (15.1%); PL12 (29.2%), EJ (15.9%); OJ (3.3%). In addition, 143 patients had anti-Ro52 positivity. Baseline high-resolution computed tomography (where available) showed: non-specific interstitial pneumonia (NSIP) (n=220; 42.8%); organising pneumonia (OP) (n=142; 27.6%); NSIP/OP overlap (n=51; 9.9%); nonspecific interstitial pneumonia (n=34; 6.6%). Of these, NSIP subtype was reported in 12 patients (6 fibrotic, 6 cellular). Pulmonary hypertension was discussed in 2 cohorts, with 6 patients having a confirmed diagnosis. Patients received the following drugs for induction (with glucocorticoids [GC]): cyclophosphamide (CYC) (n=136; 26.5%); rituximab (RTX) (n=88; 17.1%); calcineurin inhibitors (n=84; 16.3%); other disease-modifying anti-rheumatic drugs (n=183; 35.6%); intravenous immunoglobulin (IVIG; n=17; 3.3%); GC only (n=20; 3.9%). Overall median forced vital capacity (FVC) pre-treatment was 52.7% and 68.5% at one year. Overall median diffusion capacity of lungs for carbon monoxide (DLCO) pre-treatment was 44.5% and 49.1% at one year. Due to heterogeneity of methodology and cohorts, direct comparison was not possible for most drugs. Patients treated with RTX had an overall median 12.2% improvement in FVC and 2.9% increase in DLCO at one year. Patients treated with CYC had a 17% and 6.3% increase in FVC and DLCO respectively after one year. In patients receiving IVIG, 7/17 had >10% increase in FVC at one year. 5.4% (n=28) were reported to have died post-treatment due to: infection (n=8) including Pneumocystis [n=2, both post-rituximab]; malignancy (n=3); multiorgan failure (n=2). 15 patients had no reported cause of death.

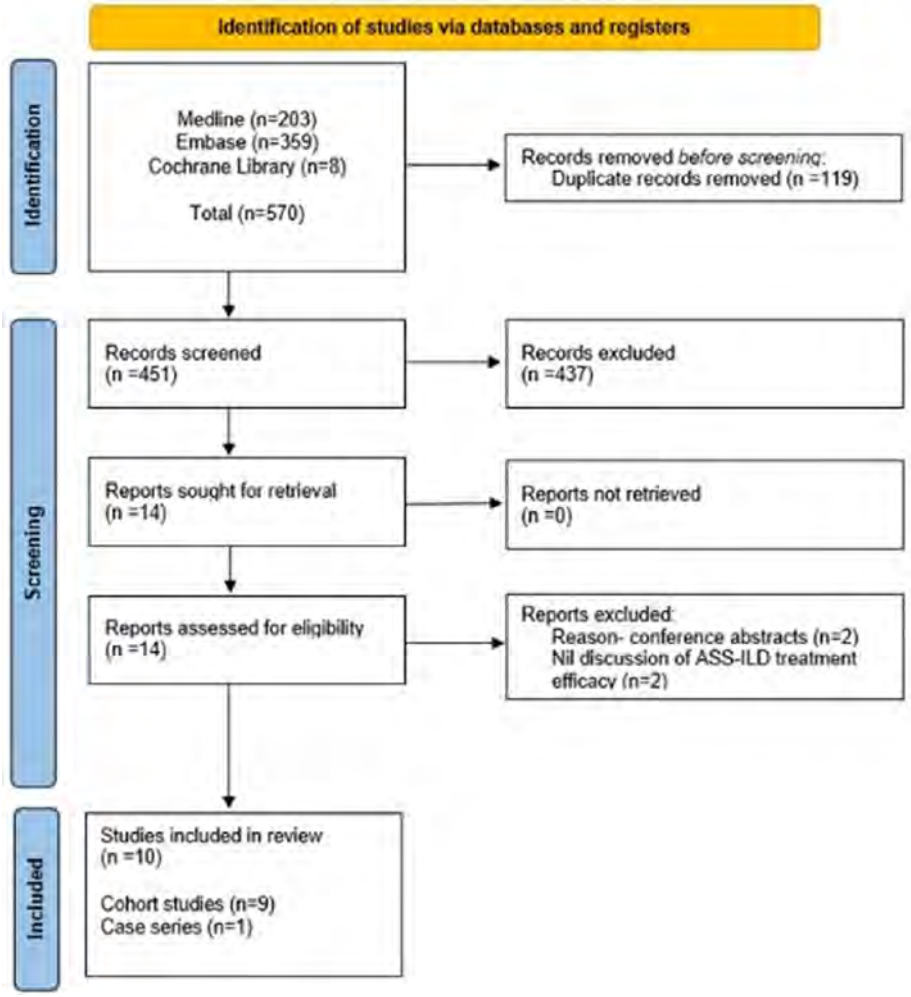

Figure 1: Flow diagram of stages of systematic literature review. Cochrane Library encompasses library of: systematic reviews; systematic review protocols; controlled clinical trials. ASS-ILD: interstitial lung disease associated with anti-synthetase syndrome.

Conclusion: This is the first SR summarising the management and outcomes of ASS-ILD. No significant difference was found between the effectiveness of treatments with regards to physiological respiratory function. More robust trials are required to reduce the morbidity and mortality resulting from ASS-ILD.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Vaccination against SARS-CoV2 has been the primary global strategy to prevent severe forms of this respiratory infection. However, multiple studies have shown that patients undergoing treatment with biological therapies, especially those targeting B lymphocytes, have a poorer response to vaccination. It should be taken into consideration that a lower IgG titer is associated with higher mortality from Covid-19. Objective: To describe the vaccine response rate in patients treated with rituximab (RTX), ocrelizumab (OCR), abatacept (ABT), belimumab (BEL), and compare the response between rheumatic and neurological patients.

Methods: Descriptive study. Rheumatic and neurological patients undergoing treatment with RTX, OCR, ABT, and BEL between January 2020 and July 2022 at the Germans Trias i Pujol Hospital were included. Immunoglobulin G (IgG) levels against the SARS-CoV2 spike protein were quantified, considering >260 BAU/mL as a positive response to vaccination. Variables such as age, vaccination schedule, recent infection, corticosteroid therapy, or synthetic DMARDs were analyzed. Additionally, clinical-demographic variables and risk factors for severe SARS-CoV2 infection were described.

Results: The study included 122 rheumatic patients, of whom 59 received RTX, 45 ABT, and 18 BEL, as well as 17 neurological patients undergoing treatment with OCR and 7 with RTX. The mean age was 51 years, and 72% were women. The most frequent rheumatic diagnoses were rheumatoid arthritis (55), systemic lupus erythematosus (31), small vessel vasculitis (8), among others. All neurological patients had demyelinating diseases such as multiple sclerosis. Concomitant DMARD therapy was received by 48% of the patients studied. 92% of the patients were fully vaccinated (3 or more doses), and 8% had experienced the infection in the previous 3 months. Corticosteroid therapy was received by 49% of the patients, with 92% receiving low-dose corticosteroids. 39% were on DMARDs, with hydroxychloroquine (27%) and methotrexate (19%) being the most common. In rheumatic patients, serology was negative in 40 patients treated with RTX (67%), and 8 with ABT (17%). No patient treated with BEL had negative serology. The median IgG level was 30 BAU/mL in patients undergoing treatment with RTX, 993 BAU/mL with ABT, and 1797 BAU/mL with BEL ($p < 0.001$) (Fig 1). Regarding negative serology, there were no differences in terms of age (RTX p=0.28, ABT p=0.71), corticosteroid use (RTX p=0.67, ABT p=0.25), or DMARDs (RTX p=0.06, ABT p=0.21). In neurological patients, the median IgG level with OCR was 504 BAU/mL, and with RTX it was 361 BAU/mL, compared to 30 BAU/mL in rheumatic patients with RTX (p 0.005) (Fig 2).

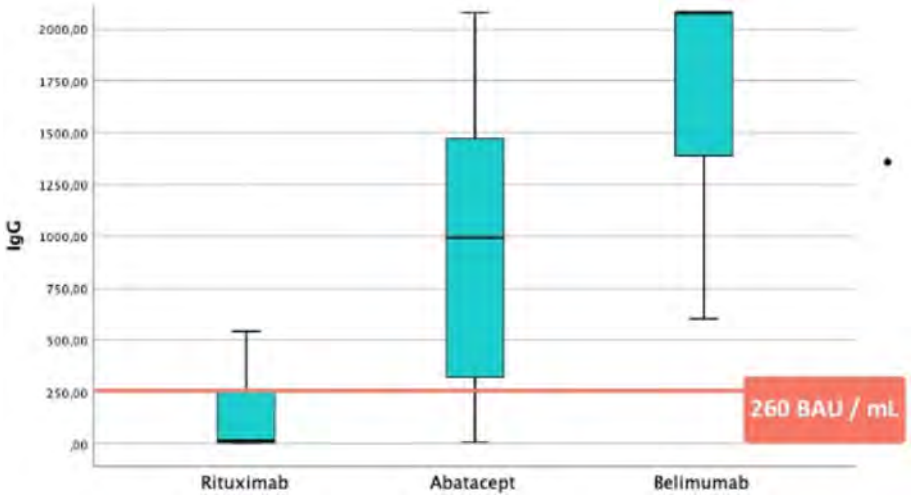

Figure 1. IgG levels aganist SARS-CoV2 spike protein in rheumatic patients treated with Rituximab, Abatacept and Belimumab.

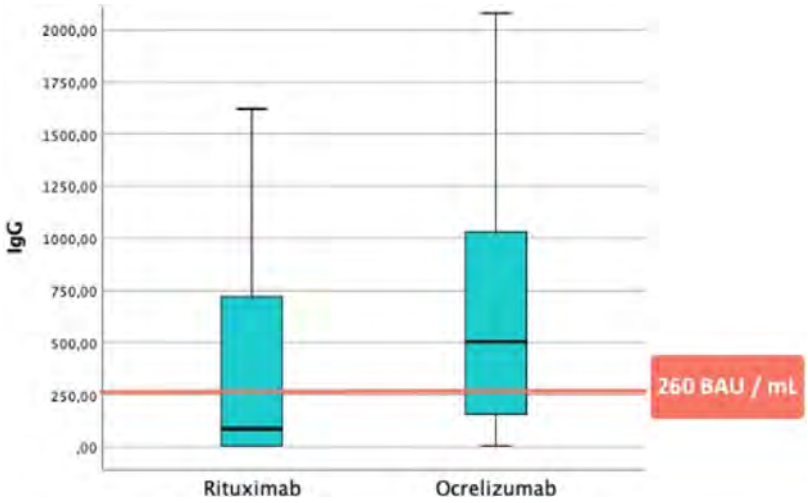

Figure 2. IgG levels aganist SARS-CoV2 spike protein in patients treated with Rituximab and Ocrelizumab.

Conclusion: In our cohort, not all patients undergoing biological treatment exhibit the same vaccine response to SARS-CoV2. Patients receiving RTX show the lowest response, followed by ABT. However, all patients treated with BEL had positive serology. Neurological patients treated with B lymphocyte-targeted therapies showed a greater vaccine response than rheumatic patients. No serological differences were observed depending on the use or non-use of DMARDs, age, or low-dose corticosteroid therapy.

Anakinra Treatment in Idiopathic Recurrent Pericarditis: A Single-center Experience

Zeynep Toker Dincer[1], Sejla Karup[2], Erkin Yilmaz[1], Osman Corbali[1] and Serdal Ugurlu[1], [1]Istanbul University-Cerrahpasa, Istanbul, Turkey, [2]Cerrahpasa Medical Faculty, Istanbul University-Cerrahpasa, Istanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic recurrent pericarditis (IRP) is defined by recurring episodes of pericardial inflammation without a known cause. This study investigates the safety and efficacy of anakinra, an interleukin-1 inhibitor, as an effective therapy for IRP in cases resistant to conventional therapy.

Methods: A retrospective evaluation of patients treated at our autoinflammatory center between 2011-2023 was conducted. Patient files were examined for demographic, clinical, and treatment response data, including non-steroid anti-inflammatory drugs (NSAIDs), corticosteroids, and colchicine. Monogenic autoinflammatory disease screening was

Table 1. Demographic data on all patients (N=21)

Female n (%)	9 (42.9%)
Male n (%)	12 (57.1%)
Age (mean ± standard deviation)	43.1±16.5
Recurrent Idiopathic Pericarditis n (%)	18 (85.7%)
Post COVID-19 Pericarditis n (%)	1 (4.8%)
Pericarditis Associated with Post COVID-19 Vaccination n (%)	2 (9.5%)

Table 2. Anakinra Treatment in IRP (N=21)

	(mean ± standard deviation)
Duration (months) of the treatment	28.1±28.1
Number of attacks before the treatment	5.57±3.49
The time (months) between the treatment and symptom onset	31,3±38.8
CRP levels before the treatment	196±67.8
CRP levels after the treatment*	2.6±3.15
Attacks during routine doses of anakinra	3 (14.3%)
	n (%)
Increased intervals between the anakinra administration	16 (76.1%)
Anakinra cessation without increasing intervals between administration	5 (23.8%)
Attacks during increasing intervals between administration	9 (56.3%)
Attempted anakinra dose reduction	14 (66.7%)
Attack after anakinra treatment reduction	8 (57.1%)
Anakinra cessation	9 (42.9%)
Side effects (injection site reaction)	4 (19.0%)

*$p<.001$

performed for MEFV, TRAPS, MVK, NLRP3, and NOD2. The study evaluated anakinra treatment in IRP patients unresponsive to conventional therapy. Patients who experienced multiple episodes of pericarditis were diagnosed with recurrent pericarditis.

Results: The study included 21 participants, with 9 (42.9%) female and 12 (57.1%) male patients. The average age of the participants was 43.1±16.5 years. Among the participants, 2 (9.5%) were diagnosed with pericarditis following the COVID-19 vaccine, 1 (4.8%) experienced pericarditis after a COVID-19 infection, and 18 (85.7%) had a diagnosis of IRP. The MEFV mutation analysis revealed that 2 (9.5%) had a mutation in Exon 10, and 4 (19.0%) had a mutation in Exon 2. MEFV mutation carriers did not exhibit typical symptoms of Familial Mediterranean Fever (FMF). Among the participants, 9 (56.3%) were classified as steroid-dependent, 5 (31.3%) were not treated with steroids, and 2 (12.5%) showed no response to steroid therapy. Successful steroid tapering was achieved in 12 (75%) out of 16 patients, and 2 (16.7%) experienced attacks after tapering. Out of 3 patients, 2 (66.6%) successfully discontinued hydroxychloroquine (HQ), while out of the 15 cases, 14 (93.3%) successfully discontinued NSAID treatment. Colchicine treatment was discontinued in 6 (28.6%) out of 21 patients. The participants experienced an average of 5.57±3.49 attacks of pericarditis before starting anakinra. The duration between symptom onset and anakinra treatment initiation was found to be an average of 31.3±38.8 months. The average duration of anakinra treatment was 28.1±28.1 months. In 16 patients (76.1%), the interval between the anakinra administration was increased, among which 9 (56.3%) experienced attacks during this period. An attempt to discontinue anakinra treatment was made in 14 (66.7%) cases, resulting in 8 (57.1%) participants experiencing attacks when anakinra was stopped, and complete discontinuation was achieved in 9 (42.9%) participants. The levels of C-reactive protein (CRP) before anakinra treatment were measured to be an average of 196±67.8, while after anakinra treatment, the average levels were 2.6±3.15. Four patients (19.0%) experienced injection site reactions.

Conclusion: In conclusion, the study adds to the growing body of evidence of the use of interleukin-1 inhibitors, such as anakinra, as a promising treatment modality for RIP in cases resistant to conventional therapy.

Blue Digit Syndrome as the Initial Presentation of Various Diseases: A Case Series

Raquel Ugena García[1], Juan José Lluch Galcerá[2], Cristina Calomarde Gomez[1], Ivette Casafont-Sole[3] and Lourdes Mateo Soria[2], [1]Rheumatology department. Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [2]Hospital Germans Trias i Pujol, Badalona, Spain, [3]Hospital Universitari Germans Trias i Pujol, Badalona, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Blue Digit Syndrome (BDS) represents the cutaneous manifestation of numerous diseases that cause blue discoloration in one or more fingers in the absence of trauma and with preserved pulses. The diagnosis of the underlying cause is crucial to preserve the affected extremity and treat the underlying disease. While it may not be the most common etiology, many systemic autoimmune and inflammatory diseases can present with cutaneous manifestations such as BDS. These conditions may include connective tissue diseases like systemic sclerosis (SSc), vasculitis, and other rheumatic disorders. Being sometimes the only exploratory finding, diagnosis may be challenging.

This study aimed to define the prevalence of different etiologies in patients with BDS. Additionally, the clinical characteristics, assessment findings, complementary investigations, and patient outcomes were described.

Methods: Ambispective cohort study. All patients admitted to the Rheumatology Department of Hospital Universitari Germans Trias i Pujol for blue digit syndrome between January 2017 and December 2022 were included.

Results: Forty-five patients (20 males and 25 females) were included with a mean age of 56.4 years. 46.7% were smokers. 48.9% had cardiovascular risk factors. The most frequent diagnoses were thromboangiitis obliterans (TAO) (22.2%) systemic sclerosis (SSc) (15.6%), severe atherosclerosis (8.9%), haematological disorder (8.9%) and cryoglobulinemia (8.9%). 10% of cases were considered idiopathic, and 12.5% were multifactorial. To be noted, a patient initially diagnosed of idiopathic blue finger syndrome was ultimately diagnosed with prostate cancer. Half of the cases presented with involvement limited to the upper extremities. 28.9% of patients had systemic symptoms. Examinations included autoimmunity tests, echocardiogram, arteriography, blood analysis among others. Skin biopsies were performed in 13 out of 40 patients, of which 2 out of 13 showed diagnostic findings of cholesterol emboli, 1 out of 13 showed calciphylaxis, 1 out of 13 showed vasculitis, and the remaining cases (9 out of 13) had no specific findings. 56% of the cases resolved with medical treatment. 8 patients (17.8) of patients required surgical amputation of the affected finger.

Conclusion: In our experience, the most common cause of BDS was TAO, followed by SSc. The differential diagnosis is broad and requires multiple complementary investigations, although some may have limited utility and carry the risk of iatrogenic harm. Therefore, a reasoned and systematic diagnostic approach based on initial suspicion is crucial.

Abstract Number: 1931

Anti-Ku Antibodies: A Case Series

Raquel Ugena García[1], Cristina Calomarde Gomez[1], Joan Climent[2] and Lourdes Mateo Soria[2], [1]Rheumatology department. Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [2]Hospital Germans Trias i Pujol, Badalona, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-Ku antibodies (Abs) were initially described in patients with polymyositis and scleroderma. Subsequently, an association has been demonstrated with other systemic autoimmune diseases (SADs), particularly overlap syndromes. However, controversies exist regarding their clinical significance and their relationship with SADs or some of their manifestations. Objective: To describe the clinical and immunological characteristics of a case series of patients with positive anti-Ku antibodies.

Methods: Descriptive study of a cohort of patients from a university hospital with positive anti-Ku antibodies between 2017 and 2022. Clinical variables (Raynaud's phenomenon, arthritis, arthralgia, myalgia, muscle weakness, dyspnea, dysphagia, diffuse interstitial lung disease (DILD)), complementary investigations (pulmonary function tests (PFTs), high-resolution computed tomography (HRCT), capillaroscopy), and autoimmune study (ANA ENA, anti-DNA, complement study, anti-PM scl 75 antibodies, anti-PM scl 100 antibodies, CENP-B, antiphospholipid antibodies, rheumatoid factor (RF), and anti-citrullinated peptide antibodies (ACPA)) were analyzed. Finally, clinical diagnostic orientation, diagnosis based on systemic autoimmune disease (SAD) criteria, or final diagnosis of non-SAD pathologies were recorded.

Results: A total of 17 patients positive for anti-Ku antibodies were identified, of whom 14 were women (82.4%) with a mean age of 57 years and a median follow-up of 43 months. The clinical manifestations presented were as follows: arthralgia (13; 76.5%), arthritis (8; 47.1%), myalgia (6; 35.3%), myositis (2; 11.8%), muscle weakness (2; 11.8%), dysphagia (1; 5.9%), dyspnea (4; 23.5%), and Raynaud's phenomenon (3; 17.6%). All patients had positive ANA, of which 8 cases (47.1%) exhibited a nucleolar pattern, 8 cases (47.1%) showed a fine speckled pattern, and only 1 case had a centromeric dot-like pattern. A total of 8 patients underwent high-resolution computed tomography (HRCT), of which 2 cases (25%) presented a ground-glass opacities pattern, 2 cases (25%) had pulmonary thromboembolism, and 2 cases (25%) had one or multiple neoplastic pulmonary nodules. Pulmonary function tests (PFTs) were performed in 7 cases, with 3 cases (42.9%) showing normal results, 2 cases (28.6%) displaying an obstructive pattern, and 2 cases (28.6%) demonstrating a restrictive pattern. Capillaroscopy was performed on 4 patients (3 normal results, 1 non-specific pattern). A diagnosis of neoplasia was established in 5 cases (29.4%). Only 6 patients (35.3%) met the criteria for systemic autoimmune disease (SAD), including 3 cases of systemic lupus erythematosus (one of them with associated antiphospholipid syndrome), 2 cases of Sjögren's syndrome, and 1 case of systemic sclerosis.

Conclusion: In our case series, the clinical and laboratory characteristics were highly heterogeneous. The presence of anti-Ku antibodies was associated with the diagnosis of a systemic autoimmune disease (SAD) in just over one-third of the cases.

The Association Between Initial Ferritin and Complications from Adults Onset Stills Disease and Intensive Care Unit Admission

Olivia Yang[1], Caroline Bui[1], Scott Kubomoto[1], Napatkamon Ayutyanont[1], Kimberly Vickery[1] and Kumar Venkat[2], [1]Riverside Community Hospital, Riverside, CA, [2]Retired, Irvine, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Adult Onset Still's Disease (AOSD) is an autoinflammatory disease characterized by quotidian fever, arthralgia, and a salmon colored rash. Due to its rarity, there is a dearth of knowledge regarding this patient population, clinical presentation, complications, and outcomes.

Methods: Data was collected retrospectively from the Hospital Corporation of America database from 2016 to 2021. Adult patients with a diagnosis of AOSD and without other autoimmune diseases were included in the study. On these subjects, characteristics such as gender and age were collected as well as clinical information such as presenting laboratory values, outcomes, and complications were analyzed.

Results: There were 185 subjects included in this study, 69.7% were women and 67.6% were white in race (Table 1). About 10% of subjects were on home biologic medications prior to presentation. Initial laboratory findings included mean white blood cell count of 12.84 +/- 6.91, ESR 55.60 +/- 39.26, CRP 16.66 +/- 42.77, ferritin 6,793.06 +/- 11,012.50, ALT 81.85 +/- 164.93, and AST 97.83 +/- 264.52 (Table 2). Forty-four subjects were admitted to the Intensive Care Unit (ICU). While there is no statistically significant difference in those who were admitted to the ICU and not admitted in initial CRP and ESR values, there is a statistically significant difference in initial ferritin. Those who had to be admitted to the ICU had an initial ferritin 5,974.597 units higher (p=0.048). Subjects who had hemophagocytic lymphohistiocytosis (HL) (p=0.001), disseminated intravascular coagulation (DIC) (p=0.013), pleural effusions (p < 0.001) had a statistically significant frequency

Table 1: Patient Demographics: including gender, race/ethnicity, and mean age.

		Number	Percentage
Gender	Male	56	30.3
	Female	129	69.7
Race/ethnicity	White	125	67.6
	Non-white*	60	32.4
Mean Age		47	

*The non-white groups were too small to further stratify

Table 2: Initial Laboratory Values: including liver enzymes, inflammatory markers, and complete blood count mean and standard deviations

		Mean	SD
Liver Enzymes	ALT	81.85	164.93
	AST	97.83	264.52
Inflammatory Markers	ESR	55.60	39.26
	CRP	16.66	42.77
	Ferritin	6,793.06	11,012.50
CBC	Hemoglobin	11.82	2.22
	WBC	12.84	6.91
	Platelet count	246.02	119.97

Table 3: Complications and Admission to ICU: list of different complications found in this sample with percent admitted to ICU. Some of the rates of admission to ICU are significant and listed below

	# of encounters	% admit to ICU
Hemophagocytic lymphohistiocytosis	9	67
Disseminated intravascular coagulation	2	100
Pleural effusion	8	75
Pulmonary hypertension	5	40
Pericardial effusion	7	43
Myocarditis	2	50
Cardiac tamponade	2	100
Hepatic failure	7	57
Significant	**P value**	**Not significant**
Hemophagocytic lymphohistiocytosis	0.001	Pericarditis
Disseminated intravascular coagulation	0.013	ARDS
Pleural effusions	<0.001	Hemolytic anemia

[a]ICU admission was used as a surrogate for mortality as mortality in this group was low
There were no patients with thrombotic thrombocytopenic purpura or interstitial pneumonitis

of being admitted to the ICU; whereas those with pericarditis, hemolytic anemia, and acute respiratory distress syndrome (ARDS) did not (Table 3).

Conclusion: The demographic results of white women being at highest risk for disease is consistent with current data. Similarly, the laboratory results of having leukocytosis, transaminitis, and elevated inflammatory markers are also consistent with prior studies. As only 6 subjects passed, admission to the intensive care unit (ICU) was used as a surrogate for morbidity from complications. Admission to the ICU was statistically associated with having a higher ferritin; however, ferritin was only collected in 92 subjects. While the average increase was about 6,000 units higher, this is likely an underestimate as the maximum laboratory value is 40,000. The complications of HL, DIC, and pleural effusions were associated with admission to the ICU, while pericarditis, hemolytic anemia, and ARDS were not. As those with AOSD tend to have delayed diagnosis and poor outcomes as a result, it is paramount that more studies are done to aid in management.

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4RD) is an immune-mediated disease characterized by dense lymphoid-lymphoplasmacytic infiltrates with high IgG4-positive plasma cells with heterogeneous clinical manifestations. The data on IgG4-RD phenotypes variation is mounting but limited to Caucasian and Asian population. In our study we describe a IgG4-RD clinical and immunosuppressive (IS) treatment in four major ethnic groups.

Table 1. Demographic and clinical phenotypic IgG4RD variations between different ethnic groups.

* IgG4 levels greater than 135 mg/dL.						

Methods: This is a retrospective analysis of IgG4-RD records from Northwell Health Rheumatology seen between 2011 and December 2023. Diagnosis of IgG4RD was confirmed by manual medical records review. Demographics data, disease characteristics, IgG4 serum level and pathology descriptors were recorded. Descriptive statistics were used for statistical analysis. We calculated the chi-square test statistic using the observed frequencies among the four ethnicities.

Results: 56 patients with diagnosis of IgG4RD were identified from the Rheumatology Northwell database. Demographic and clinical characteristics of the total cohort and ethnic subgroups in (**Table 1**). 45% (25/56) of patients were Caucasian, 27% (15/56) - Asian, 16% (9/56) - Black, and 13% (7/56) - Hispanic. 99% (51/56) met 2020 revised comprehensive diagnostic criteria for definite, probable, possible IgG4RD. 89% met pathologic criteria **(Table 1).** Clinical manifestations showed significant overlap of clinical clusters among the four ethnicities **(Figure 1).** The most prevalent manifestation was Mikulicz/systemic, observed in half of all patients, followed by 34% head and neck limited and 29% retroperitoneal. Retroperitoneal domain was more commonly recorded in Caucasians (36 % (9/25)) with 16 % of aortitis while frequency in Black patients was 11 % (1/9) and no aortitis was observed. Meningeal and ENT involvement was much more common in Asian subgroup (40%) compared to only 10 % in other ethnicities. The only case of breast IgG4RD was recorded in Asian subgroup. All patients across all ethnic groups received corticosteroids as initial therapy. 1st line immunosuppressive agent was used in more than 70% of all patients. Similar distribution was recorded for Caucasians, Asians, and Hispanics. Blacks were less likely (33%) to be on IS and none was on 2nd line IS therapy. Furthermore, 8-14% of Caucasians, Hispanics and Asian patients received rituximab, it was not used for Blacks patients (**Table 2**). No statistically significant evidence among the four ethnicities was found.

Conclusion: Significant overlap of clinical clusters was observed among the four ethnicities. Mikulicz /systemic pattern was highly predominant among entire cohort and all 4 ethnicities. Asian patients had more common ENT and meningeal involvement. The Blacks were less likely to be on IS agents and were not on rituximab. While this discrepancy with other ethnic groups could reflect more benign disease course, other factors should be investigated further. As New York is home to a highly diverse population, this study contributes important insights that can potentially be applicable to other regions with similar demographic characteristics.

Table 2. IgG4RD treatment variations between different ethnic groups

Treatment	Caucasian (n = 25)	Asian (n = 15)	Black American (n = 9)	Hispanic (n = 7)	Total (n = 56)	P-value
corticosteroids (% patients (n))	100 % (25)	100% (15)	100% (9)	100% (7)	100% (56)	-

Pooled Safety Analysis from the VOLTAIRE Trials in Patients with Rheumatoid Arthritis, Crohn's Disease, and Chronic Plaque Psoriasis

Stanley Cohen[1], Shaun Bender[2], Amy Shaberman[3], Richard Vinisko[3] and Dorothy McCabe[3], [1]University of Texas Southwestern, Dallas, TX, [2]Alnylam Pharmaceuticals, Cambridge, MA, [3]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The VOLTAIRE trials program compared the safety, efficacy, and immunogenicity of biosimilar BI 695501 with adalimumab reference product (RP) for indications including moderate-severe rheumatoid arthritis (RA), Crohn's disease (CD), and chronic plaque psoriasis (PsO),[1-4] and included a switching study to investigate interchangeability.[5] This analysis estimates the incidence of safety endpoints across 5 phase 3 randomized controlled clinical trials in patients with RA (VOLTAIRE-RA and VOLTAIRE-RAext), CD (VOLTAIRE-CD), and PsO (VOLTAIRE-PsO and VOLTAIRE-X) who received ≥1 dose of BI 695501 or adalimumab RP.

Methods: Safety endpoints included in this analysis were adverse events (AEs), serious adverse events (SAEs), discontinuations due to AEs, deaths, and adverse events of special interest (AESIs; specifically, serious infections, malignancies, and major adverse cardiovascular events [MACE; defined as non-fatal stroke, myocardial infarction, or fatal cardiovascular death]). Exposure-adjusted incidence rates (EAIR) were calculated per 100 patient-years. Incidence rates are reported by disease indication and treatment arm. For the at-risk person-years, the starting point was the first dose of BI 695501 or adalimumab RP, and the end point was 10 weeks after the last dose, the data cut-off date or the first safety event (whichever occurred first). Subgroup analyses by patient age and sex were also conducted.

Results: The mean age of patients with RA was higher than that of patients with CD or PsO, and a greater proportion of patients with RA were female. The mean length of follow up in this analysis was 62 weeks in patients with RA, 48 weeks in patients with CD, and 32 weeks in patients with PsO. Safety data are summarized in Table 1. Rates of SAEs and discontinuations due to AEs were similar among patients with RA and PsO, but slightly higher among those with CD. Overall incidence rates of AEs, SAEs, discontinuations due to AEs, deaths, and AESIs were consistent between the BI 695501 and adalimumab RP treatment arms within each indication. There were no cases of malignancies or MACE reported in patients with PsO or CD, while both were observed in patients with RA. Subgroup analyses of patients with RA by age and sex showed no between-group differences, and a similar trend was observed for patients with CD and PsO.

Conclusion: In patients with RA, CD and PsO, there were no differences between biosimilar BI 695501 or the adalimumab RP regarding the rate of AEs, SAEs, discontinuations due to AEs, deaths, or the AESIs of serious infections, cancer, or MACE. **Trial Registrations:** VOLTAIRE-RA, NCT02137226; VOLTAIRE-RAext, NCT02640612; VOLTAIRE-CD, NCT02871635; VOLTAIRE-PsO, NCT02850965

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

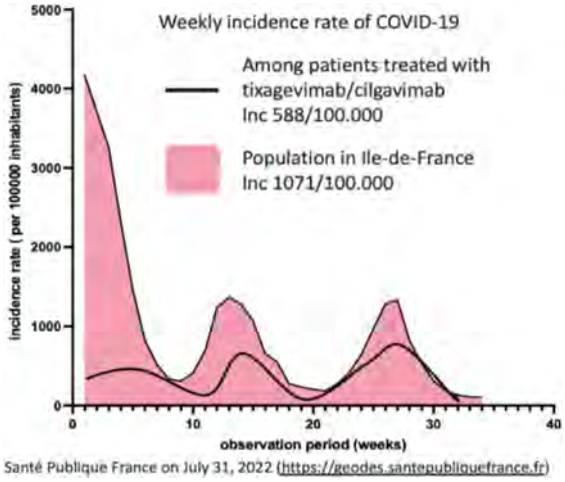
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with autoimmune or inflammatory diseases treated with immunosuppressants such as anti-CD20 are at increased risk for severe COVID-19 and have a high probability of insufficient response to vaccination. The monoclonal antibody combination tixagevimab/cilgavimab has received early access approval to reduce the frequency of symptomatic COVID-19 in immunocompromised patients at risk for severe COVID-19 and unresponsive to vaccination. We aim to evaluate the clinical efficacy of tixagevimab/cilgavimab in pre-exposure prophylaxis in patients with increased risk of severe COVID-19 in rheumatology.

Methods: In this multicenter observational study conducted between December 2021 and August 2022, we included patients with autoimmune or inflammatory diseases who received at least one intramuscular injection of tixagevimab/cilgavimab as pre-exposure prophylaxis in 3 French rheumatology units. Occurrence of COVID-19 was assessed during usual follow-up or by phone call. The endpoint was the incidence of COVID-19 and its severity.



Results: Tixagevimab/cilgavimab was administered to 115 patients, median age 62 years (52-71), with chronic arthritis (n=53), connective tissue disease (n=38) or vasculitis (n=11). The main background immunosuppressants were rituximab (n=98), methotrexate (n=48), mycophenolate mofetil (n=19), cyclophosphamide (n=15), azathioprine (n=12), and corticosteroids (n=62, median dose 5 mg, CI95% 5-8). During a median follow-up of 128 days (93-173), COVID-19 occurred in 23/115 patients (20%) with Omicron identified for the 8 genotyped patients. During the study period, the average weekly incidence was 1071 per 100.000 inhabitants in Ile-de-France vs. 588 per 100.000 in our patients. Patients who received a 2-injections regimen had a lower risk of infection than patients with a single injection (16/49, 33%, vs. 5/64, 8%, p=0.0012). The COVID-19+ patients did not differ from uninfected patients in terms of age, comorbidities, type and duration of underlying disease, extra-articular organ involvement or background immunosuppressants. All COVID-19 cases were non-severe, there were no deaths. The tolerance of injections was excellent, with no side effects observed.

Conclusion: In a population with autoimmune or inflammatory diseases at increased risk of severe COVID-19 with a poor response to vaccination, pre-exposure prophylaxis by tixagevimab/cilgavimab limited the risk of infection and the severity of COVID-19. This study supports the use of COVID-19 serological tests in this patient population in order to detect those who do not respond adequately to vaccination since pre-exposure treatments and/or early treatments are available.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pediatric patients with autoinflammatory diseases (AID) on Canakinumab (CAN) therapy have been affected by the coronavirus pandemic including SARS-CoV-2 infection, SARS-CoV-2 vaccination, and AID disease management. In the RELIANCE registry, severity of SARS-CoV-2 infection, safety of SARS-CoV-2 vaccination and comparison of disease management before and during pandemic in pediatric patients with cryopyrin-associated periodic syndromes (CAPS), familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and tumor necrosis factor receptor-associated periodic syndrome (TRAPS) on CAN therapy was investigated in clinical practice.

Methods: The RELIANCE registry is a prospective, non-interventional, observational study in Germany enrolling pediatric (age ≥2 years) and adult patients with a clinically confirmed diagnosis of AID who routinely receive CAN. Efficacy and safety parameters are recorded at baseline and assessed at 6-month intervals.

Results: The present interim analysis includes data from n=101 pediatric patients with AID enrolled in the RELIANCE registry between October 2017 and December 2022. The median duration of CAN treatment before and during the study was 3.7 years (0-13.5 years).

During the study, 29 SARS-CoV-2 infections were reported for n=27 pediatric patients. 22 infections caused mild symptoms and 7 infections caused moderate symptoms. N=25 (24.8 %) of pediatric patients received at least one SARS-CoV-2 vaccination (15 Comirnaty, 13 not specified). Vaccination reactions (not further specified) were reported in n=3 patients. No reactions were classified as serious.

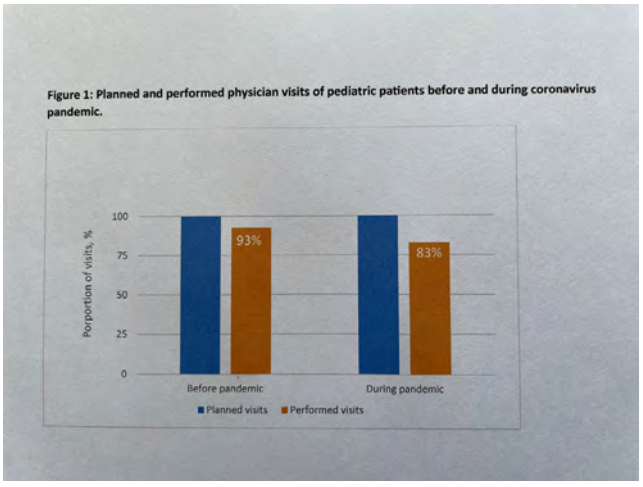

Figure 1: Planned and performed physician visits of pediatric patients before and during coronavirus pandemic.

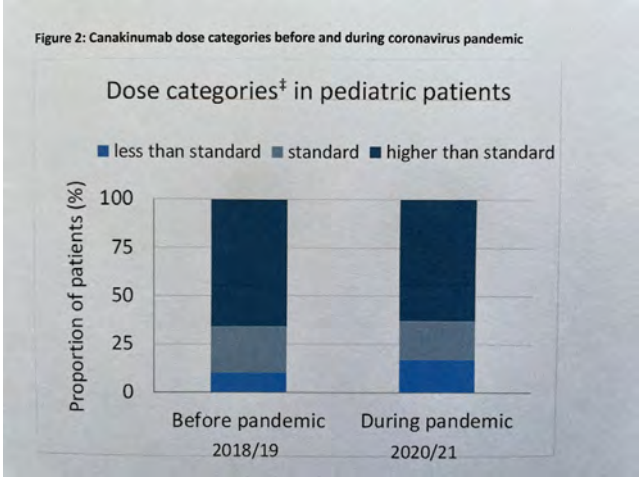

Figure 2: Canakinumab dose categories before and during coronavirus pandemic.

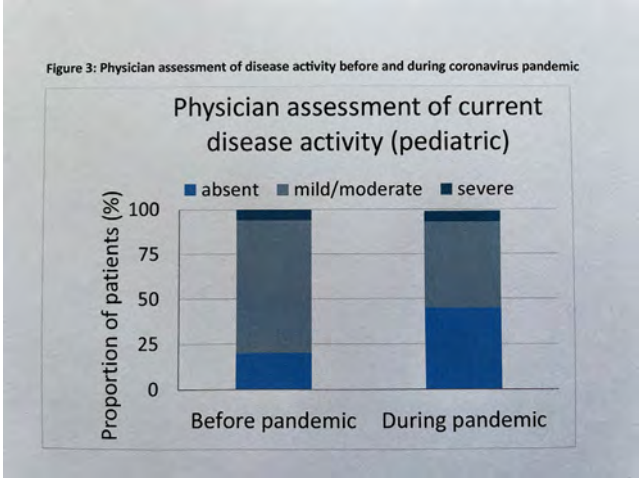

Figure 3: Physician assessment of disease activity before and during coronavirus pandemic.

During the COVID-19 pandemic in 2020 and 2021, only 83 % of regular patient visits were performed (Fig. 1). In addition, patients received slightly lower CAN dosing (20% standard dose CAN [SD], 17% lower than SD, and 63% higher than SD compared to 24% SD, 10% lower than SD, and 66% higher than SD before pandemic (Fig. 2). However, disease activity by patient rating (VAS score 1-10) improved from 3 before to 2 during the pandemic. By physician global assessment, the proportion of pediatric patients with no disease activity arose from 20% before to 45% during the pandemic (Fig. 3). In contrast: no major changes in disease activity were documented in adult patients.

Conclusion: Pediatric AID patients under long-term Canakinumab treatment experienced improved disease control during the Coronavirus pandemic.

Efficacy of Different Treatment Approaches for Cardiac Sarcoidosis

Frank Cai[1], Anisha Paulson[1], Amy Wozniak[2], Emily Gilbert[2] and Rochella Ostrowski[2], [1]Loyola University Medical Center, Oak Park, IL, [2]Loyola University Medical Center, Maywood, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There is currently a lack of a consensus standardized guideline for the treatment of cardiac sarcoidosis (CS) because of its rarity, heterogeneity of disease manifestations, and challenges of long-term management. The purpose of this study is to evaluate the efficacy of different treatment regimens, including TNF-α inhibitors, on clinical outcomes. This is the most comprehensive and up to date analysis for CS patients treated at our tertiary care institution, and the continuity of longitudinal care highlights the nuances of treatment decisions made by our physicians to contribute to the standard of practice.

Methods: A monocentric retrospective study of 50 CS patients at our institution was conducted. 31 patients (62%) met World Association of Sarcoidosis and other Granulomatous Disorders (WASOG) and Health Rhythm Society (HRS) diagnostic criteria. The other 19 patients (38%) were clinically diagnosed without biopsy proven disease but fulfilled one of the WASOG probable cardiac characteristics. For clinical outcomes, worsening was defined by the onset of a new CS manifestation[1], stabilization as absence of a new CS manifestation and stable ejection fraction (EF) or PET myocardial uptake, and improvement as absence of a new CS manifestation, but with either a ≥ 10% increase in or normalization of EF or improvement in PET myocardial uptake. Generalized estimating equations (GEE) models with independent correlation structure and identity link were used to calculate p-values for comparisons of individual treatment regimens and outcomes.

1. Ballul T, et al. *Int J Cardiol*. 2019;276:208-211.

Results: Table 1 provides patient demographics and distribution of the different treatment combinations. Of the 50, there were 48 patients treated with at least one regimen, and 34 patients with at least one follow-up treatment for a total of 124 individual treatments.

Table 2 and 3 summarize the associations of each treatment with the overall clinical outcome defined as improved, stable, or worsened. 46.3% of treatment regimens showed clinical improvement and an additional 27.4% showed stabilization. Of these, 50% had clinical improvement with the first treatment as compared to 27.6% in follow-up treatments. In terms of the different regimens, 81% of regimens with steroids only had stable or improved clinical outcomes which was the highest percentage in the treatment groups. 60% of regimens with a TNF-α inhibitor had stable or improved clinical outcomes.

Table 1. Summary of Characteristics and Treatment Regimens

Worsen	12 (9.7)	4 (8.3)	8 (10.5)
No Comparison	48 (38.7)	20 (41.7)	28 (36.8)
Arrhythmias			
Either New or Recurrent arrhythmia***	26 (21.0)	9 (18.8)	17 (22.3)
New arrhythmia	14 (11.3)	6 (12.5)	8 (10.5)
Recurrent arrhythmia	14 (11.3)	3 (6.2)	11 (14.5)

*12 out of 16 'Improve' were 'Improved to Normal'
**26 out of the 49 'Improve' were to 'Complete Resolution'
***2 of the 26 had both types of arrhythmias

Conclusion: In our study, patients were more likely to see clinical improvement with initial treatment compared to subsequent regimens. This highlights the importance of early therapy as treatment later in the disease course will less likely lead to clinical improvement, possibly a reflection of scarring or irreversible pathology in later stages of the disease. Therefore, clinicians should consider an approach that is more proactive upfront to avoid this progression. In terms of a specific regimen, although our results do not show a superior treatment, the trend does show that regardless of the regimen, the majority of patients have clinical improvement with treatment.

Table 3. Clinical Outcomes of Individual Medications and Combination Treatments

Individual Medications	All Treatments N= 112, n (%)	Worse N=33, n (%)	Stable/ Improved N= 79, n (%)	P- value

Cranial Nerve Manifestations in Sarcoidosis Associated with Lymphoma, Non-facial Paralysis, and Other Neurologic Disorders

Mary Salim, Emily Kokush, Evelyne Kalyoussef, Eugenio Capitle and Reena Khianey, Rutgers New Jersey Medical School, Newark, NJ

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a systemic granulomatous inflammatory disease that affects multiple organ systems including the including the lungs, skin, skeletal, and nervous system. Cranial neuropathies (CN) involving the optic, facial, and oculovestibular nerves can be an isolated manifestation. Here, we aim to identify comorbidities in this subset of sarcoidosis patients to raise a higher suspicion for this diagnosis; thereby, avoiding a delay in appropriate management.

Methods: The National Inpatient Sample (NIS) from 2003 to 2014 was queried to identify patients diagnosed with sarcoidosis (ICD9: 135). Patients with sarcoidosis were categorized into two groups based on whether they had comorbid CN palsies and disorders (CN I-XII palsy, multiple CN palsies, optic neuritis, trigeminal neuralgia, and sensorineural hearing loss).Univariate and multivariate analyses were conducted to compare patient and hospital characteristics as well as Elixhauser comorbidities between the two groups.

Table 1			
	CN (n=1,314)	Non-CN (n=170,589)	p-value
Age, years	52.62 ± 15.19	56.15 ± 13.85	<.001
Sex			.002
Male	29.9%	34.1%	
Female	70.1%	65.9%	
Length of Stay (days)	5.91 ± 6.56	5.50 ± 6.82	0.030
Total Charges	$41,511 ± $55,206	$38,150 ± $62,345	0.053
Comorbidities	Odds Ratio (95% CI)		
Chronic pulmonary disease	0.634 (0.544-0.738)		<0.001
Congestive Heart Failure	0.528 (0.401-0.697)		<0.001
Lymphoma	2.271 (1.518-3.398)		<0.001
Other Neurological disorders	1.425 (1.155-1.758)		0.001
Paralysis	2.682 (2.037-3.531)		<0.001
Pulmonary circulation disorders	0.609 (0.423-0.876)		0.008
Renal Failure	0.649 (0.514-0.818)		<0.001

Results: Approximately 0.8% (n=1,314) of patients with sarcoidosis (n=173,236) had CN. Patients with CN were significantly younger (52.62 years±15.19 vs 56.15±13.85, p< 0.001) and female (70.1% vs 65.9%, p=0.002) compared to their non-CN counterparts. Although length of hospital stay (5.91days ± 6.56 vs 5.50±6.82, p=0.030) was significantly longer for sarcoidosis with CN, total hospital charges($41,511±$55,206 vs $38,150±$62,345, p=0.053)did not significantly differ between the groups. Patients were at significantly lower odds to develop CN if they had comorbid chronic pulmonary disease (OR [95% CI]:0.634 [0.544-0.738], p< 0.001),congestive heart failure (0.528 [0.401-0.697], p< 0.001), pulmonary circulation disorders (0.609 [0.423-0.876], p=0.008), or renal failure (0.649 [0.514-0.818], p< 0.001).Patients with lymphoma (2.271 [1.518-3.398], p< 0.001), other neurologic disorders (1.425 [1.155-1.758], p=0.001) and non-facial paralysis (2.682 [2.037-3.531], p< 0.001) had increased likelihood of developing CN. The presence of comorbid coagulopathy, iron deficiency anemia, diabetes, liver disease, or fluid/electrolyte disorders did not significantly impact the likelihood of developing CN (table 1).

Conclusion: Our analysis demonstrates greater odds of CN in sarcoidosis patients with comorbid lymphoma, other neurologic disorders, or non-facial paralysis. However, sarcoidosis patients with cardiopulmonary comorbidities or renal failure were less likely to have CN, suggesting that sarcoidosis patients with CN may somewhat spare other organs. Sarcoidosis patients who are relatively young, have other neurological disorders, non-facial paralysis, or lymphomas require a higher index of suspicion for CN.

Abstract Number: 1939

Sinonasal Sarcoidosis Associated with Chronic Pulmonary Disease, Deficiency Anemias, and Obesity

Emily Kokush, **Mary Salim**, Eugenio Capitle, Reena Khianey and Evelyne Kalyoussef, Rutgers New Jersey Medical School, Newark, NJ

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a systemic granulomatous inflammatory disease that can involve multiple organ systems. Rarely, sarcoidosis can involve the upper respiratory tract including the sinonasal region. Symptoms easily mimic those of allergic or atrophic rhinitis, bacterial sinusitis; therefore, commonly leading to misdiagnosis. Here, we aim to identify

Table 1			
	SN (n=5,127)	Non-SN (n=168,109)	p-value
Age, years	55.09 ± 13.45	56.15 ± 13.87	<.001
Sex			<.001
Male	29.5%	34.2%	
Female	70.5%	65.8%	
Length of Stay (days)	5.42 ± 6.71	5.51 ± 6.81	.357
Total Charges	$36,400 ± $52,672	$38,229 ± $62,562	.041
Comorbidities	Odds Ratio (95% CI)		
Chronic pulmonary disease	1.168 (1.093-1.249)		<0.001
Congestive Heart Failure	0.869 (0.785-0.963)		0.008
Deficiency anemia	1.171 (1.083-1.267)		<0.001
Diabetes, uncomplicated	0.872 (0.81-0.939)		<0.001
Diabetes, complicated	0.853 (0.743-0.979)		0.024
Obesity	1.228 (1.136-1.329)		<0.001
Renal Failure	0.833 (0.752-0.923)		<0.001
Death during admission	0.603 (.457-.795)		<0.001

comorbidities in this subset of sarcoidosis patients to raise a higher clinical suspicion for this diagnosis in a higher risk population; thereby, avoiding a delay in appropriate management.

Methods: The National Inpatient Sample (NIS) from 2003 to 2014 was queried to identify patients diagnosed with sarcoidosis (ICD-9: 135). Patients with sarcoidosis were categorized into two groups based on whether they had comorbid sinonasal diagnoses (including acute or chronic sinusitis, nasal polyps, deviated nasal septum, epistaxis, or nasal mucositis). Univariate and multivariate logistic analyses were conducted to compare patient and hospital characteristics as well as Elixhauser comorbidities between the two groups.

Results: A total of 173,236 sarcoidosis patients were included, 5,127 (3.0%) of whom had a comorbid SN diagnosis. Patients with SN involvement were younger (55.09 years ± 13.45 vs 56.15 ± 13.87, p< .001), more often female (70.5% vs 65.8%) than their non-SN counterparts. After accounting for demographics, patients who developed SN diagnoses were more likely to have chronic pulmonary disease (OR [95% CI]: 1.168 [1.093-1.249], p< 0.001), deficiency anemia (1.171 [1.083-1.267], p< 0.001), and be obese (1.228 [1.136-1.329], p< 0.001). However, those with congestive heart failure (0.869 [0.785-0.963], p=0.008), diabetes (0.872 [0.810-0.939], p< 0.001), or renal failure (0.833 [0.752-0.923], p< 0.001) were less likely to have a SN comorbidity. Patients with SN involvement had decreased hospital charges ($36,400 ± $52,672 vs $38,229 ± $62,562, p=0.041), but did not significantly differ on length of stay (5.42 ± 6.71 vs 5.51 ± 6.8, p=0.357) than those without a SN diagnosis. Patients with SN involvement of sarcoidosis were also less likely to die during their hospital admission than their non-SN counterparts (0.603[.457-.795], p< 0.001) (table 1).

Conclusion: Our findings suggest that the management of sarcoidosis patients with chronic pulmonary disease, deficiency anemia, or obesity should include a high index of suspicion for comorbid SN diagnoses. However, SN involvement does not increase sarcoid patients' risk for death, prolonged stay, or increased hospital charges. Further research is warranted to investigate underlying mechanisms and clinical implications of SN involvement in sarcoidosis.

A Single-center, Observational, Retrospective, Case Control Study of Rituximab for the Treatment of Interstitial Pneumonia Associated with Autoimmune Features

Tegveer Sandhu[1], Lea Meir[2], Nicole Ng[1], Lila Klein[1], Jigna Zatakia[1], Maria Padilla[1] and Ioannis Tassiulas[1], [1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Icahn School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with interstitial lung diseases (ILD) and clinical features of autoimmunity who do not satisfy the classification criteria for a specific autoimmune rheumatic disease are diagnosed with interstitial pneumonia with autoimmune features (IPAF). The treatment approach to ILD in this setting remains undefined. We conducted an observational retrospective study to examine the use of rituximab (RTX) in IPAF.

Methods: Patients from the Mount Sinai/National Jewish Respiratory Institute Patient Registry and Biorepository were included if they met the 2015 classification criteria for IPAF and were treated with RTX. Patients who met the criteria for another autoimmune disorder were excluded. Clinical improvement was defined as improvement in four domains after the use of RTX, including: pulmonary function tests (PFTs), CT chest findings, need for respiratory related hospitalization and survival.

Results: Of the 791 patients in the registry, 14 patients met the criteria for IPAF and received at least one dose of Rituximab. 19 patients were identified who met the criteria for IPAF and did not receive Rituximab to serve as the control group. There were no differences in the baseline demographics. Five patients (45.4%) in the RTX group were improved and 4 (36.3%) remained with stable FVC and DLCO. Accordingly, HRCT scan findings improved in 3 (33%) patients and remained stable

Table 1 Showing immunosuppressive use and the outcomes in the Rituximab and the control group

Immunosuppression and antifibrotic medication use			
	IPAF with Rituxan (N=14)	IPAF without Rituxan (N=19)	
Steroids	11 (78.6)	17 (89.5)	0.3
Cellcept	12 (85.7)	7 (36.8)	0.05
Imuran	3 (21.4)	0	0.067
Tacrolimus	3 (21.4)	0	0.067
Cytoxan	1 (7.1)	0	0.6
IVIG	4 (28.6)	0	0.024
Pirfenidone	1 (7.1)	1 (5.3)	0.6

Respiratory outcomes			
	Rituximab (n=14)	**Control group (n=19)**	**P value**
Need for supplemental oxygen	5 (35.7)	9 (47.4)	0.3
Incidence of infections	6 (42.9)	5 (26.3)	0.2
Respiratory related admissions	2 (14.3)	5 (26.3)	0.3
Mortality	1 (7.1)	1 (5.3)	0.5
Pulmonary Function Tests			
	Rituximab (n=11)	**Control group (n=15)**	P value
FVC improved	5 (45.4)	4 (26.6)	0.4
FVC remained stable	4 (36.3)	7 (46.6)	0.5
FVC worsened	2 (18.1)	4 (26.6)	0.7
First percent predicted FVC	72.4 + 18.2	69.6 + 18.7	0.68
Most recent percent predicted FVC	69.6 ± 15.7	73.4 ± 28.5	0.68
Percent predicted FVC delta	-2.57 ± 24	-0.68 ± 18.9	0.8
Median years between the PFTs	3.1	3.3	0.5
	Rituximab (n=10)	**Control group (n=15)**	P value
DLCO improved	3 (30)	4 (26.6)	0.63
DLCO stable	5 (50)	8 (53.3)	0.4
DLCO worsened	2 (20)	3 (20)	0.6
First percent predicted DLCO	51 + 17.3	54.6 ± 19.4	0.9
Most recent percent predicted DLCO	53.7 + 19.3	52.7 ± 25.9	0.7
Percent predicted DLCO delta	2.6 ± 13.2	-1.47 + 14.5	0.6

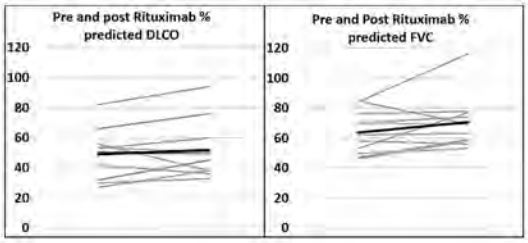

Figure 2. Line diagram showing the trend of the percent predicted DLCO and FVC before and after the Rituximab. Mean percent predicted DLCO and FVC values are represented by the solid black line.

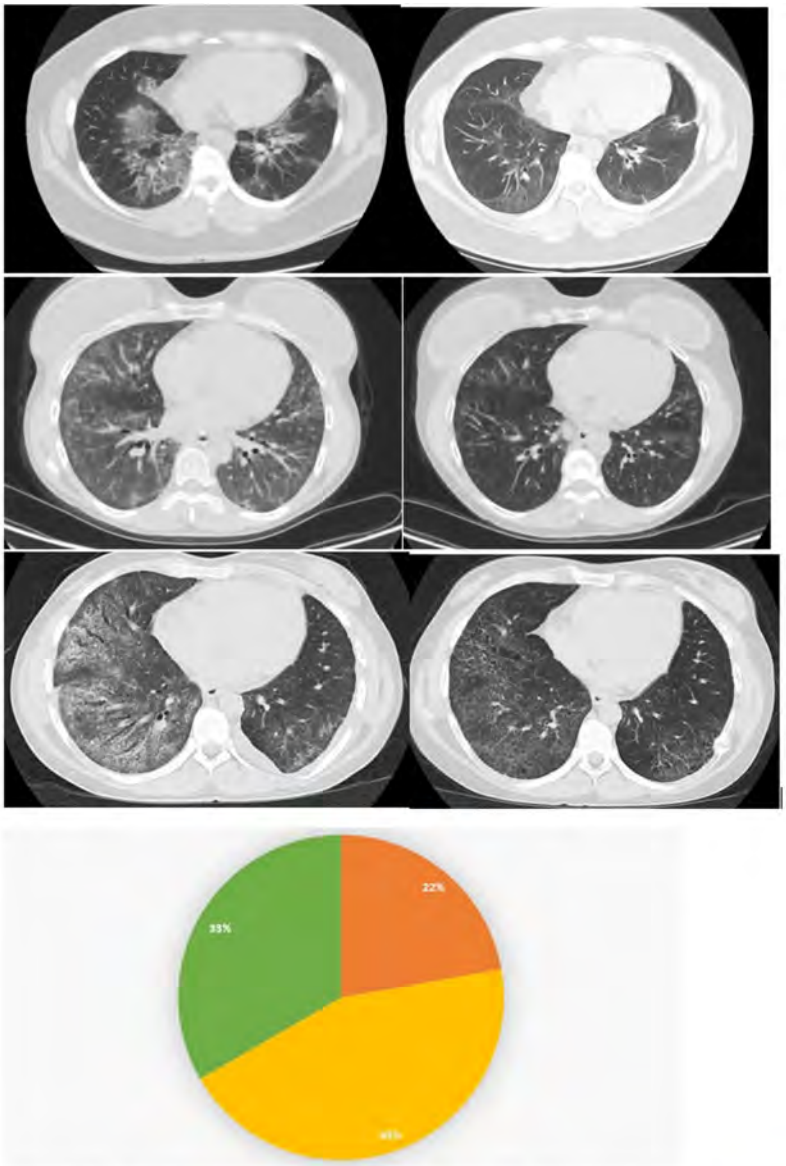

Figure 3: CT scan findings before (left) and after (right)the rituximab therapy showing improvement in three of the 9 patients who had repeat CT chests within two years of the Rituximab therapy. Pie chart (bottom) showing the percentage of patients with stable (yellow), improved (green) and worsened (orange) CT chest findings.

in 4 (45%), from 9 patients with available HRCT scans. Frequency of oxygen use, incidence of infection, respiratory related admissions and overall mortality was similar in both the groups.

Conclusion: The majority of patients with IPAF receiving rituximab showed improvement or stability in their pulmonary function. Although both the groups had similar outcomes, all patients in the RTX group had failed multiple immunosuppressive agents, suggesting refractory ILD. We propose RTX as an option for patients with moderate to severe IPAF who progress despite standard immunosuppressive therapy. Further prospective studies are needed to assess the benefit of RTX in this subset of patients with ILD.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There is limited information on VEXAS syndrome in the Latin-American population. We aimed to identify *UBA1* mutations causing VEXAS syndrome in Mexican patients presenting with inflammatory and hematologic manifestations.

Methods: We included patients who had (i) one or more inflammatory manifestations associated with VEXAS syndrome (e.g. chondritis, neutrophilic dermatoses, vasculitis, pneumonitis), and (ii) one or more chronic cytopenias, or isolated macrocytosis. Genomic DNA was extracted from peripheral blood or available biopsies (bone marrow or skin). To identify pathogenic *UBA1* mutations, Sanger sequencing of exons 3, 14, and 16 was performed. To identify variables associated with a positive result, we compared *UBA1*-positive and *UBA1*-negative patients. The *UBA1*-positive patients were compared with an external cohort comprising 20 patients with VEXAS syndrome from the USA.

Results: A total of 29 patients were tested, of whom 11 had a mutation in *UBA1* (positive detection rate: 37.9%). Eight were male (72.7%). The mean age at symptom onset was 59±17.2 years. The youngest patient was 23 y/o. Nine (81.8%) had the p.Met41Thr, and one each the p.Met41Val and p.Ser56Phe mutations. The clinical diagnoses (not mutually exclusive) were

Table 1. Clinical, genetic, and hematological characteristics of both VEXAS cohorts.

Table 1.	Mexican cohort N=11	External cohort N=20	P*
Male, n (%)	8 (72.7)	20 (100)	0.03
Age at symptom onset, years, mean (SD)	59 ± 17.2	61 ± 7	0.55
p.Met41Thr mutation, n (%)	9 (81.8)	13 (65)	0.32
p.Met41Val, mutation, n (%)	1 (9.1)	2 (10)	0.93
p.Met41Leu, mutation, n (%)	0	4 (20)	0.16
Relapsing polychondritis, n (%)	4 (36.4)	13 (65)	0.12
Sweet syndrome, n (%)	2 (18.2)	7 (35)	0.32
Undifferentiated autoinflammatory syndrome, n (%)	1 (9.1)	4 (20)	0.63
Myelodisplastic syndrome, n (%)	6 (54.5)	5 (25)	0.10
Fever, n (%)	6 (54.5)	17 (85)	0.06
Dermatological, n (%)	10 (90.9)	16 (80)	0.42
Inflammatory eye disease, n (%)	3 (27.3)	8 (40)	0.47
Periorbital edema, n (%)	2 (18.2)	12 (60)	0.02
Arthritis, n (%)	4 (36.4)	17 (85)	0.006
Pneumonitis, n (%)	2 (18.2)	13 (65)	0.01
Auricular chondritis, n (%)	5 (45.5)	14 (70)	0.17
Nasal chondritis, n (%)	3 (27.3)	11 (55)	0.13
Venous thrombosis, n (%)	2 (18.2)	10 (50)	0.08
Orchitis, n (%)	2/8 (25)	3 (15)	0.60
Macrocytic anemia, n (%)	8 (72.7)	10 (50)	0.22
Leukopenia, n (%)	6 (54.5)	4 (20)	0.04
Neutropenia, n (%)	5 (45.5)	0	0.003
Thrombocytopenia, n (%)	5 (45.5)	5 (25)	0.24
*Dichotomous variables were analysed with the Chi-square test or Fisher exact test. Comparison between means was made with Student's T-test			

myelodysplastic syndrome in 6 (54.5%), relapsing polychondritis in 4 (36.5%), Sweet syndrome in 2 (18.2%), and one each of polyarteritis nodosa, type I cryoglobulinemia, pyoderma gangrenosum, thyroid orbitopathy, undifferentiated autoinflammatory syndrome, multiple myeloma, and chronic myeloid leukemia.

Clinical and hematological manifestations are summarized in Table 1. Ten patients (90.9%) had hematological manifestations, with macrocytic anemia being the most common in 8 cases (72.7%), although most had macrocytosis (90.9%). Out of the 7 patients who underwent a bone marrow aspirate, 4 (57.1%) had vacuoles. Glucocorticoids and immunosuppressors were prescribed to 7 patients (58.3%), while chemotherapeutic regimens were used in 2 (18.2%). The median number of treatment lines was 1.5 (IQR: 1-2.5). With a median follow-up of 44 months (IQR 24-66), two patients had died.

The presence of macrocytosis (OR: 12.5, CI: 1.3-119.3) and macrocytic anemia (OR: 6.9, CI: 1.2-37.2) were associated with the presence of a pathogenic *UBA1* mutation. Conversely, having a clinical diagnosis other than the most reported in VEXAS syndrome exhibited a negative association with a positive *UBA1* mutation (OR: 0.064, CI: 0.007-0.612).

Compared to the external cohort, our patients showed higher frequencies of female patients, leukopenia, and neutropenia, but lower frequencies of fever, periorbital edema, arthritis, pneumonitis, and venous thrombosis (Table 1).

Conclusion: Patients with clinical diagnoses commonly associated with VEXAS syndrome, along with the presence of macrocytosis or macrocytic anemia, have an increased likelihood of harboring a pathogenic *UBA1* mutation. While our cohort displayed some distinct clinical and hematologic manifestations compared to the USA cohort, the type of *UBA1* mutations and clinical diagnoses were consistent. Noteworthy, our cohort included a higher proportion of female patients and one of the youngest ever reported cases of VEXAS.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatic immune-mediated inflammatory diseases (rheumatic-IMID) with latent tuberculosis infection (LTBI) requiring biologic therapy (BT) are at anincreased risk of developing active tuberculosis (TB). Screening of LTBI with tuberculin skin test (TST) and/or interferon (IFN)-γ release assays (IGRA) is recommended before startingBT.

Methods: Cross-sectional single University hospital study including all patients diagnosedwith rheumatic-IMID who underwent a TST test and/or IGRA in a five-year period (2016-2020). TST was performed by a subcutaneous injection of 0.1 ml of purified proteinderivative (PPD) with a reading after 72 hours. TST was considered positive with aninduration of more than 5 mm of diameter. If the first TST was negative, a new TST (booster)was performed between 1 and 2 weeks after the first TST. The IGRA test used wasQuantiFERON®-TB Gold Plus (QFT-Plus). LTBI was diagnosed by a positive IGRA and/orTST and absence of active TB (normal chest X-ray). Concordance between IGRA and TSTwas studied using adjusted Cohen's kappa coefficient.

Results: Booster was positive in 66 patients (7.7%) out of 857 patients with a negative simple TST.TST (+ booster) was positive in 187 patients (22.9%) out of 817 with a negative orindeterminate IGRA test. IGRA test was positive in 30 (3.8%) out of 793 patients with anegative TST (+ booster), as is shown in **Figure 1 and 2.** Adjusted Cohen's Kappa coefficient between TST (+ booster) andIGRA (QFT-plus) was 0.62.

Figure 1. Increased sensitivity in detection of LTBI in patients with negative simple TST with additional booster TST and IGRA test.

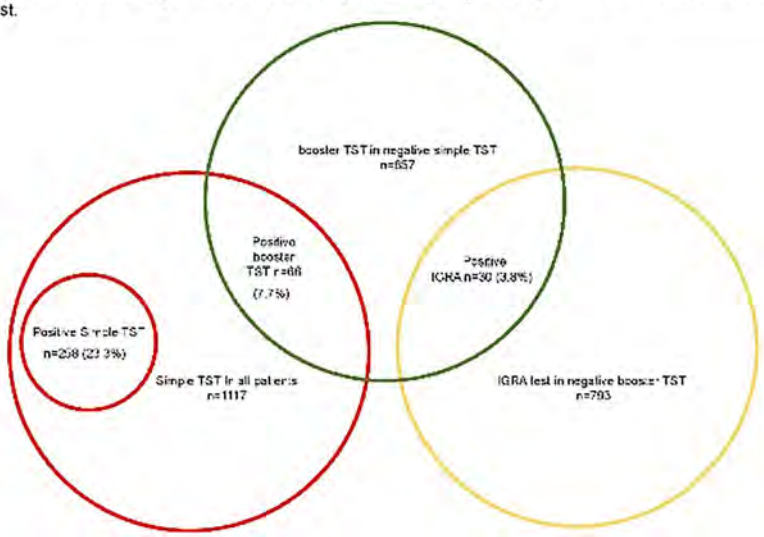

Figure 2. Increased sensitivity in detection of LTBI in patients with negative IGRA test with additional simple TST and booster TST.

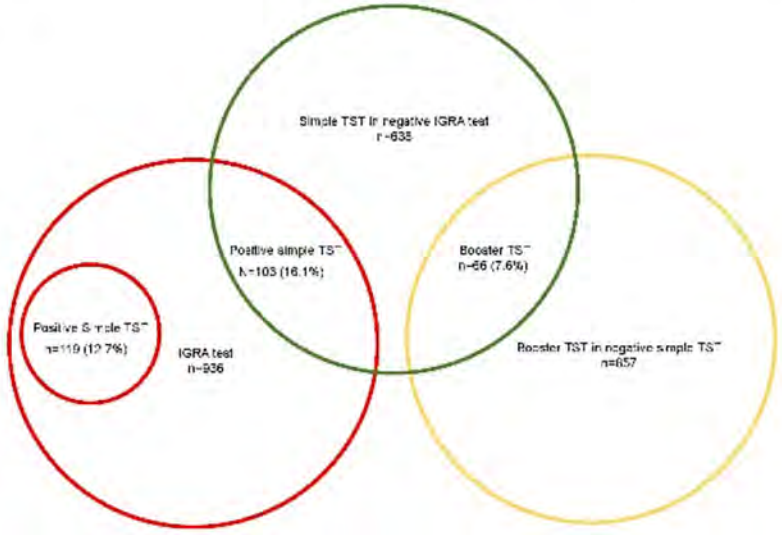

Conclusion: LTBI is frequent between patients with rheumatic-IMID. Booster after negativesimple TST may be useful, since it can detect LTBI. Furthermore, IGRA and TST (+ booster)show a moderate fair grade of agreement. In addition, some patients who had a negative orindeterminate result on IGRA or TST could have a positive result in the other examination.This highlights the importance of performing both tests in all patients. Accordingly,performing both tests in patients with rheumatic-IMID before BT may be highlyrecommended.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4 immunoglobulin-related disease (IgG4-RD) is a rare, systemic immune-mediated fibro-inflammatory process with an unclear etiology and pathophysiology with the capacity of affecting multiple organs. It exhibits common pathophysiological, serological, and clinical characteristics.

Objectives: To describe clinical presentation, evolution, and treatment heterogeneity among a series of IgG4-RD cases and to compare the accuracy of the last two most recent IgG4-RD classification and diagnostic criteria.

Methods: A single-center retrospective cross-sectional study was conducted, encompassing patients with a suspected diagnosis of IgG4-RD from various hospital departments (Rheumatology, Digestive Medicine, Internal Medicine and Pneumology). The study period lasted from January 2010 to August 2022. Exclusion criteria were applied to patients who were ultimately diagnosed with other pathologies, and for those patients who remained with a suspected diagnosis of IgG4-RD, the Umehara-Okazaki 2011 and ACR/EULAR 2019 criteria were subsequently employed.

Results: A total of 182 patients with elevated IgG4 and/or a suspected diagnosis of IgG4-RD were initially collected. After applying the exclusion criteria, 22 potential cases of IgG4-RD were described (Table 1). The Umehara and Okazaki 2011 diagnostic criteria were applied, resulting in the classification of 13 patients (mean age :60 years; 57% women); with 5 being classified as definitive disease, 3 as probable disease, and 5 as possible disease. One death was recorded in this group, which was related to heart failure. Furthermore, the ACR/EULAR 2019 classification criteria were applied to the same patient cohort (Table 1), resulting in the diagnosis of 7 patients (mean age:57 years; 71% women) with a mean follow-up of 5.3 years. In this group, 85.71% of patients had elevated IgG4 levels (mean: 176.3 mg/dL). Retroperitoneal fibrosis and aortitis were the most prevalent form of presentation for both groups (2011 and 2019 criteria) accounting for 38.5% and 28.6% respectively. Initially, 85.71% of the patients finally diagnosed with IgG4-RD received corticosteroids followed by other immunosuppressants such as Azathioprine, Methotrexate, Rituximab, surgical treatment, or maintenance doses of corticosteroids.

Conclusion: IgG4-RD is a recently recognized entity that exhibits significant heterogeneity in clinical, analytical, and histopathological presentation. Differences arise when utilizing different diagnostic criteria.

The most recent and stringent ACR/EULAR 2019 classification criteria allow for a more accurate classification of patients by emphasizing histopathology, different forms of presentation, and analytical data. Therefore, on many occasions, a multidisciplinary approach is often necessary.

Table 1. High diagnostic IgG4-RD group, Umehara and Okazaki 2011 and ACR/EULAR 2019 IgG4-RD criteria.

	High diagnostic IgG4-RD cases n=22	Umehara-Okazaki criteria 2011 n=13	ACR/EULAR criteria 2019 n=7
Age, median (IQR), years	62 (34-87)	60 (34-82)	57 (34-79)
Sex, female (%)	54,54	61,54	71,42
Follow-up, median (IQR), years	5,18 (1-28)	4,4 (1-9)	5,3 (1-9)
Death, n (%)	9,09	7,69	0
IgG4 level, median (IQR), mg/dL	152 (32,6- >194)	163,71 (56,6 ->194)	176,3 (109- >194)
Elevated IgG4, n (%)	63,63	84,62	85,71
Normal IgG4, n (%)	13,63	7,69	0
Not evaluated IgG4, n (%)	22,72	7,69	14,29
CRP, median (IQR), mg/dL	3,33 (0-10,7)	3 (0,1 -10,7)	6 (0,39 -7,8)
ESR, median (IQR), mm/h	32,89 (7-120)	42 (10 -120)	48,4 (16-120)
Available biopsy at IgG4 involvement site (%)	40,91	69,23	100
Clinical phenotypes

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1913–1944) Miscellaneous Rheumatic & Inflammatory Diseases Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) comprises a wide range of disorders categorized by clinical, radiographic and pathologic findings that is closely associated with autoimmune connective tissue diseases (CTD), requiring an investigation into a potential unknown CTD when diagnosing ILD. A significant number of patients can exhibit nonspecific signs of autoimmunity, either clinical and/or serologic, without meeting the criteria for a distinct CTD, which has led to the classification of this disease as Interstitial Pneumonia with Autoimmune Features (IPAF). In our study, we aim to characterize a cohort of patients with ILD who satisfy the IPAF criteria.

Table 1. Demographic, clinical, serologic and morphologic features of 34 patients with IPAF.

Characteristics	ILD patients with IPAF criteria
Age at ILD diagnosis (years), mean ± SD	58 ±11,84
Sex (men/women), n (%)	22/12 (65/25)
Smoking history, n (%)	27 (79)
PFTs at ILD diagnosis	
FVC (% predicted), mean ± SD	77.46 ± 23.1
DLCO (% predicted), mean ± SD	40.87 ± 15.8
Clinical domain, n (%)	
Raynaud's phenomenon	10 (29)
Inflammatory arthritis	8 (24)
Digital edema	2 (6)
Distal digital fissuring/ ulceration	1 (3)
Palmar telangiectasia	0 (0)
Gottron sign	0 (0)
Serologic domain, n (%)	
ANA >1:320 speckled, homogeneous or combined pattern	17 (50)
Rheumatoid factor	6 (18)
Anti-CCP Abs	3 (9)
Anti-B2 glicoprotein Abs	3 (9)
Anti-DNA Abs	2 (6)
Anti-Ssa Abs	2 (6)
Anti-Ku Abs	2 (6)
Anti-Ro52 Abs	1 (3)
Morphologic domain, n (%)	
HRCT pattern of UIP	11 (32)
HRCT pattern of probable UIP	7 (21)
HRCT pattern of NSIP	8 (24)
Other HRCT patterns	6 (18)
Suggestive histological patterns	17 (50)

DLCO: diffusing capacity of the lung for carbon monoxide; FVC: forced vital capacity; ILD: interstitial lung disease; PFTs: pulmonary function tests; SD: standard deviation; VA: alveolar volume; Abs: Antibodies; HRCT: high-resolution computed tomography; UIP: usual interstitial pneumonia; NSIP: non-specific interstitial pneumonia.

Methods: We collected data of patients assessed in a multidisciplinary clinic of Pneumology and Rheumatology at the Marqués de Valdecilla University Hospital (Santander, Spain). Included patients had a confirmed diagnosis of ILD, determined either through a chest high-resolution computed tomography (HRCT) or lung biopsy. Medical records were examined to assess clinical and/or serologic IPAF criteria, as well as HRCT and lung biopsy reports. Exclusion from the study took place if patients met classification criteria for a distinct CTD or if there was incomplete data to asses their case.

Results: From a cohort of 689 patients with ILD, we included a total of 34 individuals who fulfilled the criteria for IPAF. Among them, mean age at diagnosis was 58 ±11,84. 22 (65%) were male and 12 (35%) female. 27 (79%) had smoking history. 15 out of the 34 patients (44%) met the clinical criteria for IPAF, being Raynaud's phenomenon the most frequent (n=10), followed by inflammatory arthritis (n=8), digital edema (n=2) and digital ulceration (n=1). Serologic criteria for IPAF were fulfilled

by 28 out of 34 patients (84%). The most prevalent serologic criterion was the presence of an ANA higher than 1:320 (patterns: speckled, homogeneous or combined. n=17) followed by positive rheumatoid factor (n=6), anti-CCP (n=3), anti-ß2 glicoprotein (n=3), anti-DNA (n=2), anti-Ssa (n=2), anti-Ku (n=2) and anti-Ro52 (n=1). As for radiologic and morphologic criteria, 30 patients (88%) met the requirements for IPAF, being usual interstitial pneumonia (UIP) (n=11) the most frequently observed, followed by probable UIP pattern (n=7) and non-specific interstitial pneumonia (NSIP) (n=8). **Table 1** shows the demographic, clinical, serologic and morphologic features of our patients.

Conclusion: This is a single-center, retrospective study focused on patients who fulfilled IPAF criteria. Among this cohort, a majority of men was reported (65%), and a high proportion of patients presented smoking history (79%). Regarding clinical, serologic or morphologic features, even with less than half of the patients (44%) showing clinical features of CTD, serologic (84%) and radiologic-morphologic (88%) criteria were met by a majority of patients. Given the benefits of early immunosuppressive treatment in this disease, a thorough identification of findings in either clinical, serologic and/or morphologic domains must be prioritized when approaching patients when suspecting a IPAF diagnosis.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Myositis is a rare inflammatory complication associated with immune related adverse events (irAE) of immune checkpoints inhibition (ICI) immunotherapy[1]. It is characterized by musculoskeletal inflammation, resulting in significant muscle weakness and pain. Diagnosis is based on clinical evaluations, blood tests, and imaging studies. Management of myositis may involve the suspension or adjustment of immunotherapy, as well as the administration of anti-inflammatory or immunosuppressive medications[2]. Although this complication can be severe, immunotherapy remains a valuable tool in cancer treatment for these patients.

Methods: A retrospective, descriptive study of patients treated with ICIs that developed myositis as a result of said treatment, at Parc Taulí and Marqués de Valdecilla University Hospitals, between 2016 and 2022. Medical records were reviewed by a rheumatologist to identify demographic and clinic relevant data.

Table 1: Patients clinical characteristics, presentation, treatments and outcomes.

Patient information	Patient Case				
	1	2	3	4	5
Age at ICI treatment	48	83	63	72	79
Gender	M	F	M	M	F
Tumor	Melanoma	Melanoma	Renal	Colorrectal	Urothelial
Treatment	Pembrolizumab	Pembrolizumab	Nivolumab	Durvalumab	Atezolizumab
Mechanism	PD1	PD1	PD1	PDL1	PDL1
Line of treatment	3	1	2	1	2
ICI on monotherapy?	Yes	Yes	Yes	No	Yes
Time before irAE onset (weeks)	4	4	4	4	4
Rheumatological Manifestations	Myositis	Myositis	Myositis	Myositis	Myositis
Other manifestations	Asthenia	Myasthenia	Hepatitis	Myasthenia, Myocarditis, Toxicodermia, Thyroiditis, Hepatitis, Pneumonitis	Asthenia, Myocarditis, meningo-encephalitis
Treatments					
GC	x	x	x	x	x
IVIG		x	x	x	x
Rituximab	x				
Mycophenolate				x	x
Discontinuation of ICI		x	x	x	x
Due to irAE		x	x	x	
Death		x	x		x
Related to irAE		x			

Results: From a cohort of 734 patients treated with ICIs, 54 presented rheumatologic irAEs, of which 5 developed myositis, (3 male/2 female). 3 were treated with anti-PD1, 2 with anti-PDL1. Underlying cancer types included melanoma (n=2), colorectal (n=1), renal (n=1) and urothelial (n=1). Patients presented concomitant irAEs, such as myasthenia (2), hepatitis (2), pneumonitis (1), meningoencephalitis (1) and myocarditis (1). All patients required treatment with high doses of glucocorticoids and the association of either intravenous immunoglobulins (IGIV) (n=4) and/or biologic (n=1) or synthetic (n=2) immunosuppressant (IS) drugs. In 4 out of 5 cases, this irAE was the main reason for ICI treatment discontinuation, and only 1 presented permanent response to treatment. **Table 1** shows the patients' clinical characteristics, presentation, treatments and outcomes. Serologically, only 1 patient presented elevated CRP, but 4 out of 5 presented positivity for autoantibodies, which included anti-Ro52 anti-PM Scl, ANA Nucleolar pattern, anti-GAD and anti-SRP.

Conclusion: Our study highlights the significant burden of irAE myositis in patients undergoing ICI therapy. All 5 patients in our study required intensive treatment with corticosteroids, 4/5 received intravenous immunoglobulin (IVIG), and 4/5 tested positive for autoantibodies and presented other irAEs. There was only complete response to the treatment of the irAE on 1 patient, with the remaining 5 requiring maintenance treatment and experiencing relapses or little improvement. 3 patients died, at least in one of them by irAE related complications. These findings emphasize the need for increased vigilance in monitoring and early intervention to manage irAEs such as myositis effectively. Further research is needed to understand the underlying mechanisms and improve detection and treatment strategies for this complication of immunotherapy.

Zetomipzomib Demonstrates Favorable Long-term Safety and Tolerability Profile Without Signs of Immunosuppression: Results from the PRESIDIO Study and Its Open-label Extension Study in Patients with Dermatomyositis and Polymyositis

Rohit Aggarwal[1], Namita Goyal[2], Diana Lam[3], Allen Ng[3], Richard Leff[4], Kathryn Ray[3], Eunmi Park[3] and Noreen Henig[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]UCI Health, Orange, CA, [3]Kezar Life Sciences, South San Francisco, CA, [4]Kezar Life Sciences, Chadds Ford, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyositis (PM) and dermatomyositis (DM) are chronic autoimmune diseases characterized by muscle inflammation and weakness. In a collagen-induced myositis mouse model, immunoproteasome inhibition has shown to significantly revert the decreased grip strength and reduce the histopathological score of inflamed striated muscles. Zetomipzomib (KZR-616) is a first-in-class selective inhibitor of the immunoproteasome. PRESIDIO (NCT04033926) was a Phase 2 randomized, double-blind, placebo-controlled crossover study evaluating the safety, tolerability, efficacy and PK/PD of zetomipzomib 45 mg subcutaneously (SC) weekly (QW) treatment in patients (pts) with active PM and DM with an open-label extension (OLE) to evaluate the long-term efficacy and safety up to 96 weeks (NCT04628936). Results from PRESIDIO and its OLE study are reported here.

Methods: Pts were randomized to initially receive zetomipzomib 45 mg (first two doses: 30 mg) or placebo SC QW; pts received zetomipzomib or placebo treatment over 16 weeks, followed by crossover to the other arm for an additional 16 weeks (total study duration of 32 weeks). Study entry criteria included adults with probable or definite PM or DM based on the 2017 EULAR/ACR Classification Criteria with confirmed active disease (MMT-8 score of 80-136 and two other abnormal core set measures). The primary endpoint was the mean change in the Total Improvement Score (TIS). Pts completing 32 weeks of the double-blind treatment period could enroll in the OLE study up to 96 weeks.

Table 1: Zetomipzomib Treatment Demonstrated a Favorable Safety and Tolerability Profile in the PRESIDIO Study and Its OLE Study

Patients Experiencing Adverse Events, n (%)	Zetomipzomib N=25	Placebo N=22*	Zetomipzomib OLE N=18
Patients with any TEAE	22 (88.0)	15 (68.2)	16 (88.9)
Grade 1	21 (84.0)	14 (63.6)	15 (83.3)
Grade 2	8 (32.0)	8 (36.4)	10 (55.6)
Grade 3	2 (8.0)	2 (9.1)	2 (11.1)
Grade 4	0 (0)	0 (0)	0 (0)
Most common TEAE: Injection-site reaction	18 (72.0)	3 (13.6)	14 (77.8)
TEAEs leading to study discontinuation	1 (4.0)	0 (0)	3 (16.7)
Serious TEAE (all unrelated)	2 (8.0)	1 (4.5)	1 (5.6)
Infections TEAEs	7 (28.0)	6 (27.3)	7 (38.9)
Grade 1	5 (20.0)	5 (22.7)	5 (27.8)
Grade 2	2 (8.0)	3 (13.6)	3 (16.7)
Grade 3	0 (0)	1 (4.5)	0 (0)
Grade 4	0 (0)	0 (0)	0 (0)
Opportunistic Infections	0	0	0
Death	0	0	0

*Three patients withdrew prior to receiving placebo

Results: 25 pts with active DM (n=13) and PM (n=12) enrolled and 20 pts completed through end-of-treatment; 18 opted into the OLE study (4 pts received < 24 weeks of zetomipzomib dosing, 4 pts received 24-48 weeks of dosing, and 10 pts received ≥48 weeks of zetomipzomib dosing [1 pt had 96 weeks of treatment]). Overall, pts saw clinically meaningful improvements in TIS, but zetomipzomib demonstrated no significant differentiation from placebo. At Week 16, the zetomipzomib group achieved a mean TIS of 25.5 versus 25.0 in the placebo group. Following cross-over at Week 32, the pts receiving zetomipzomib beginning at Week 16 achieved a mean TIS of 34.2 versus 34.1 in those receiving placebo beginning at Week 16. Zetomipzomib treated patients also showed improvements in other efficacy endpoints. In the OLE, mean TIS generally continued to improve with reduced symptoms and improvement in strength. Treatment-emergent adverse events (TEAE) were generally mild-to-moderate (Table 1). The most common TEAEs were injection site reactions (ISRs), which were generally transient and manageable. ISRs occurred more frequently with zetomipzomib than with placebo. There was no evidence of immunosuppression observed, as measured by preserved cell counts and lack of ≥ Grade 3 infection or opportunistic infections. There were no off-target or new adverse events observed with >1-year weekly administration in the OLE.

Conclusion: Zetomipzomib demonstrated a favorable safety and tolerability profile without signs of direct immunosuppression upon prolonged exposure. Zetomipzomib did not show differentiation from placebo, but individual patients with DM or PM experienced a clinically meaningful improvement in TIS.

National Incidence, Prevalence & Mortality in Idiopathic Inflammatory Myopathies & Associated Interstitial Lung Disease in England

Jennifer Hannah[1], Fiona Pearce[2], Myron Odingo[2], Megan Rutter[2], Jeanette Aston[3], Jennifer Lai[3], Matthew Grainge[2], Sean Mcphail[3], Peter Lanyon[2], Mary Bythell[3], James Galloway[4] and Patrick Gordon[5], [1]King's College London, London, United Kingdom, [2]University of Nottingham, Nottingham, United Kingdom, [3]National Disease Registration Service, Leeds, United Kingdom, [4]King's College London, London, United Kingdom, [5]NHS, London, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

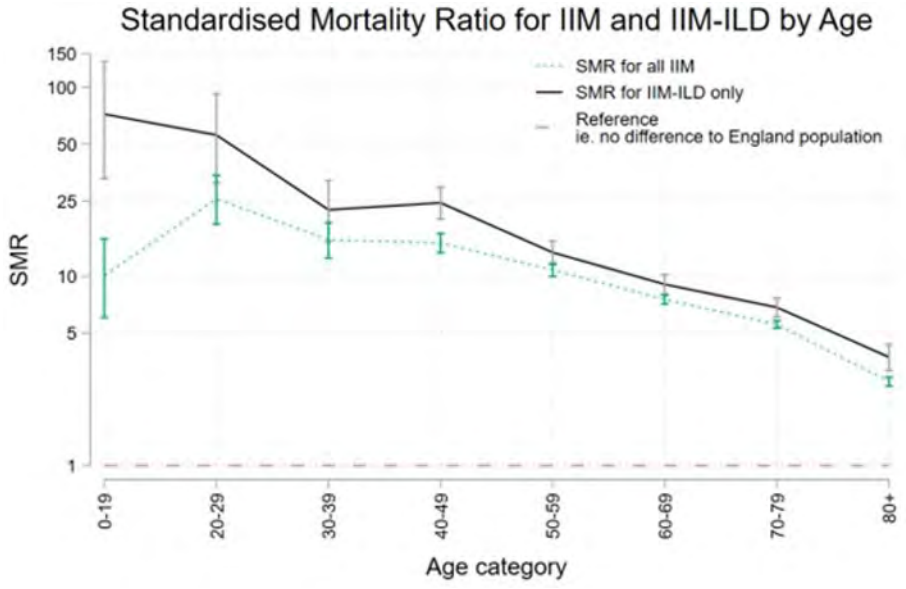
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Ethnicity, sex, age & socioeconomic deprivation can all lead to health inequity. Impact of these factors in epidemiology of Idiopathic Inflammatory Myopathies (IIM) has not been widely researched.In collaboration with National Congenital Anomaly & Rare Disease Registration Service (NCARDRS), we described national incidence, prevalence & mortality in IIM and associated Interstitial Lung Disease (IIM-ILD) according to demographics.

Methods: Hospital Episode Statistics (HES) collected at every NHS hospital admission in England, were used to create a national cohort of patients with IIM & IIM-ILD associated ICD-10 codes between 2006-2022. Cases were identified according to pre-validated methods (Hannah, 2022). Age, sex, ethnicity, Index of Multiple Deprivation (IMD) and death certification were collated. Denominator populations were extracted from Office of National Statistics publications. Incidence rates were calculated by multivariate Poisson regression, standardized mortality ratio (SMR) by indirect standardization, and survival analysis by multivariate Cox models. Incidence Rate Ratios (IRR) were mutually adjusted for age, sex & IMD (Ethnicity IRR was not adjusted for IMD due to lack of suitable denominator data). Cox models were adjusted for age, sex, ethnicity, IMD and ILD status.



SMR for IIM and subgroup of IIM-ILD compared to the population of England demonstrating increased SMR across all age categories

	Denominator population	Crude incident rates per 100,000 (95% CI)	Adjusted incidence rate ratio (95% CI)*	Mortality Rate per 1000 person years (95% CI)	Adjusted Hazard Ratio (95% CI) †

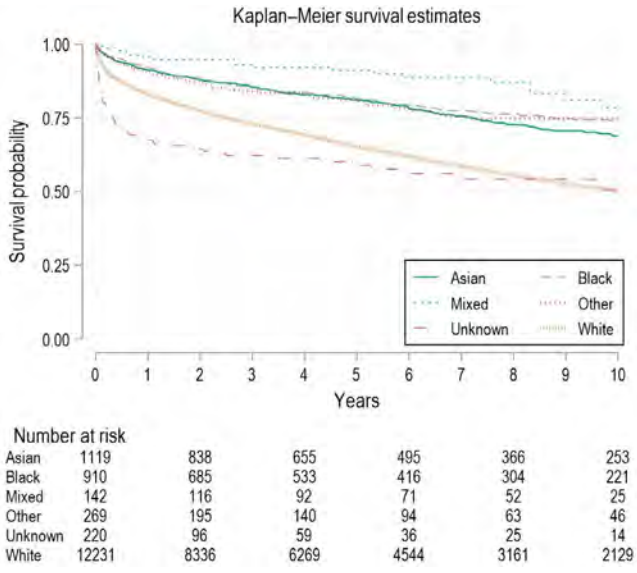
Incidence Rate Ratios and mortality Hazard Ratio according to demographics. *Incidence rate ratios are adjusted for age, sex and socioeconomic status †Adjusted hazard ratios for age, sex, socioeconomic status, ethnicity and presence of ILD are mutually adjusted.



Kaplan-Meier survival curve showing increased mortality in Unknown and White ethnicity categories

Results: 14,891 incident IIM cases were identified giving an incidence rate of 1.72/100,000 person-years. Point prevalence was 17.9/100,000 in 2022. Mean age was 59.7 years with incidence peaking at 70-80 years. Multivariate models (Table) showed IIM incidence was higher in females IRR 1.30 (95%CI 1.25, 1.34), but mortality was lower (hazard ratio (HR) 0.78 (95%CI 0.74, 0.82)). Incidence was higher in Asian and Black ethnicities than White (IRR 1.56 and 2.77 respectively). Mortality was higher in White ethnicity (Asian HR 0.80 and Black HR 0.78). The most deprived population quintile had similar incidence IRR 1.06 (95%CI 1.02, 1.11), but higher mortality HR 1.34 (95%CI 1.25, 1.44) than less deprived populations. 17.2% of IIM cases had ILD. IIM-ILD incidence did not vary largely by socioeconomic deprivation, but was substantially higher in Black, Other and Asian populations compared to White (IRR 5.11, 4.07, 2.48). Mortality of IIM-ILD was also lower in Asian HR 0.76 (95%CI 0.61, 0.95) and Black HR 0.73 (95%CI 0.57, 0.93) patients. SMR was 5.13 for IIM and 7.92 for IIM-ILD. Crude mortality increases with age, but standardized mortality is highest in younger patients with ILD. Death certification was available in 7,159 cases. IIM was recognized as a contributory factor in 39%, and ILD in 10.6%. Malignancy was the most reported 'underlying cause of death' (24.7%), then cardiovascular disease (19.9%) and respiratory disease (15.8%). Asian and Black ethnicities were less likely to have malignancy mentioned on death certificates (IRR 0.48 and 0.61 respectively).

Conclusion: We have defined national incidence, prevalence and SMR estimates for IIM and IIM-ILD. Incidence is higher in females, Black, Asian and Other ethnicities. Mortality is higher in White ethnicities, increased deprivation and males. Increased mortality in White ethnicities may partially relate to increased malignancy-associated disease.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial Lung Disease (ILD), prevalent in Idiopathic Inflammatory Myositis (IIM) patients, significantly impacts prognosis. Certain myositis-specific antibodies, including anti-MDA5 and anti-aminoacyl-tRNA synthetases (ARS), are linked to increased ILD incidence, while other myositis antibodies were rarely discussed. Recent evidence suggests survival rates among Interstitial Pneumonitis with Autoimmune Feature (IPAF) patients harboring myositis specific antibodies (MSA) parallel those with IIM-ILD [1]. Our study aims to investigate the pulmonary involvement in IIM and IPAF patients, emphasizing the role of diverse myositis antibodies, within a single center cohort.

Methods: From Jan. 2010 to Dec. 2022, patients diagnosed with IIM who underwent myositis antibody testing were identified in a Taiwan medical center. Additionally, 49 patients diagnosed with IPAF per the 2015 ERS statement with positive myositis antibody result were also enrolled for analysis.[2] The diagnosis of ILD was confirmed by a HRCT finding. The myositis antibodies were determined through line-blot multiplex assay (Autoimmune Inflammatory Myopathies 16 Ag, Euroimmun, Lübeck, Germany), encompassing 16 autoantigens.

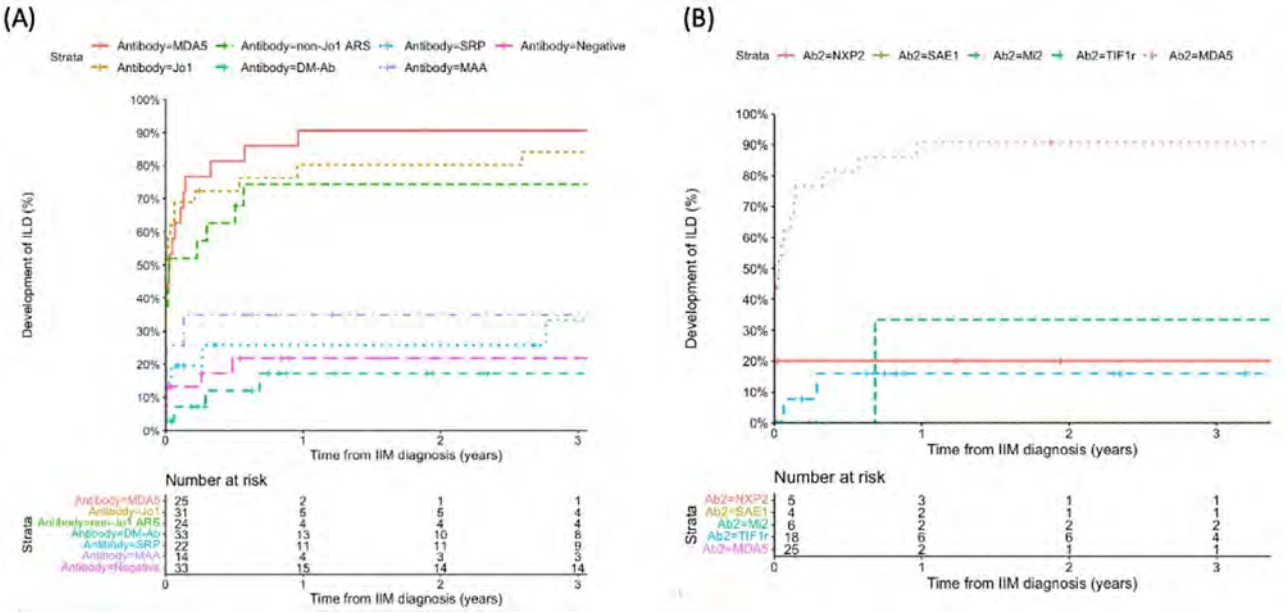

Fig.1: Cumulative incidence of ILD development stratified according to different myositis antibodies (A) and dermatomyoisits-specific antibodies (B). Anti-ARS=aminoacyl tRNA synthetase antibodies (including anti-Jo1, EJ, OJ, PL-7, PL-12), DM-Ab = dermatomyositis specific antibodies (including anti-TIF1r, NXP2, SAE, Mi2, MDA5).

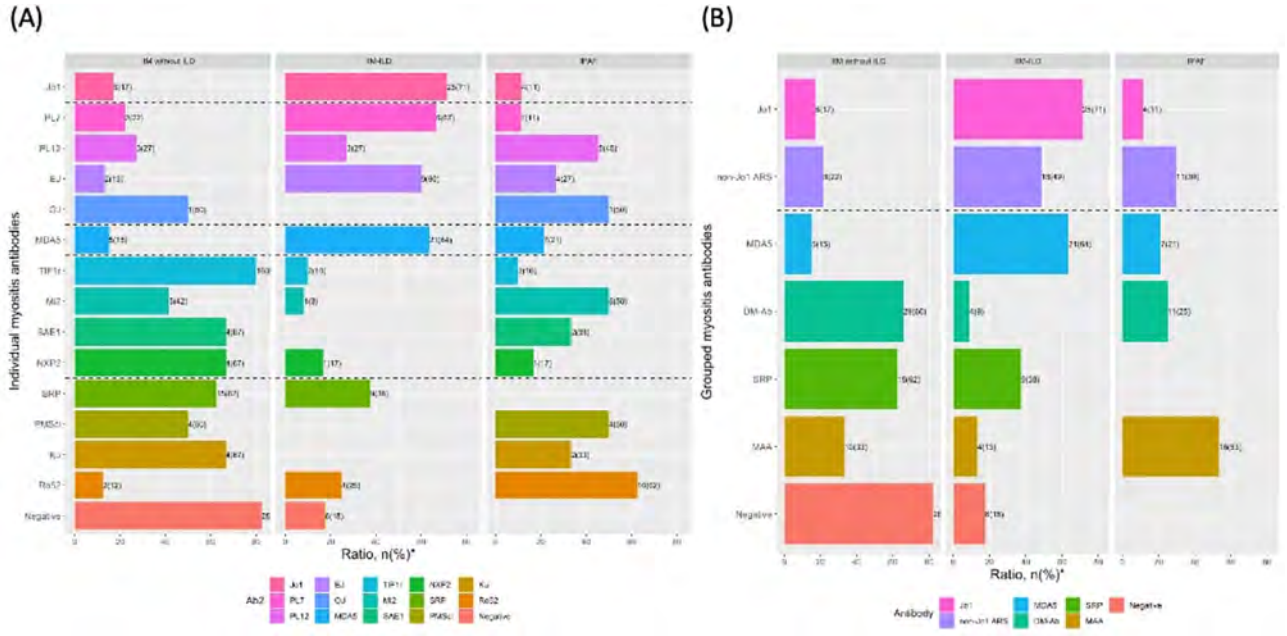
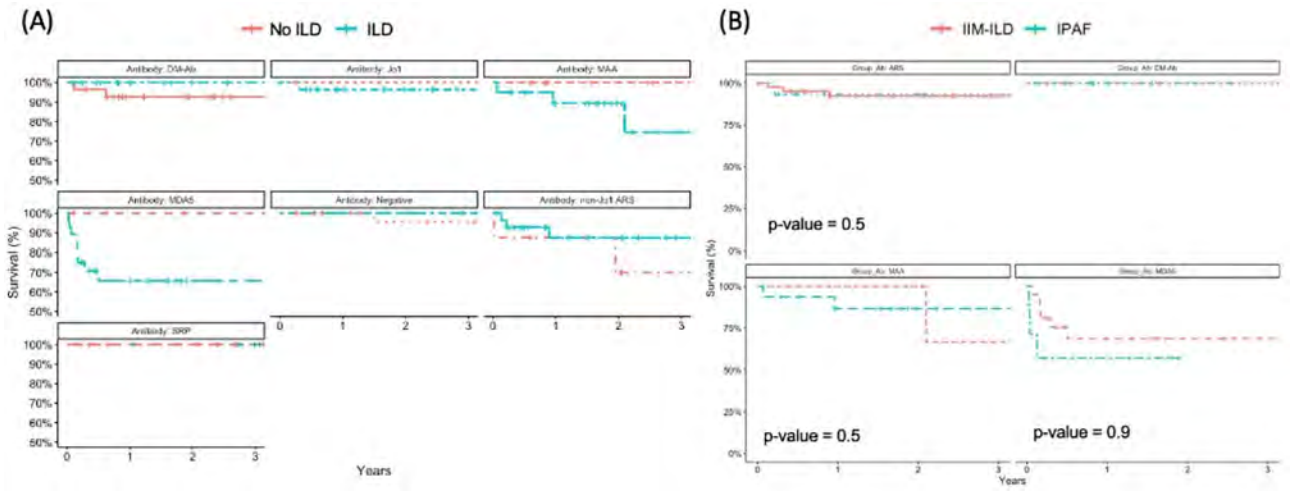


Distribution of myositis antibodies among IIM without ILD, IIM-ILD, and IPAF patient groups, stratified according to individual antibodies (A) and grouped antibodies (B). Numbers beside each bar indicate patient count and respective percentage. Anti-ARS=aminoacyl tRNA synthetase antibodies (including anti-Jo1, EJ, OJ, PL-7, PL-12), DM-Ab = dermatomyositis specific antibodies (including anti-TIF1r, NXP2, SAE, Mi2, MDA5).



Kaplan–Meier survival curve for IIM and IPAF subgroups. (A) The survival impact of ILD stratified by different myositis antibodies. (B) The survival curve of patients with IIM-ILD and IPAF stratified by selected myositis antibodies.

Results: 118 IIM patients (mean age 52, 75% female) and 49 IPAF patients (mean age 67, 49% female) were enrolled. The anti-MDA5 and ARS were significantly associated with ILD development, exhibiting the 3-year incidence exceeding 70%, with most cases presenting within the first year post-diagnosis. Approximately 40% patients with anti-SRP ultimately developed ILD (Figure 1A). In patients with DM-specific antibodies (TIF1r, Mi2, SAE1, NXP2, MDA5, as defined by ENMC 2020 consensus) except for anti-MDA5, most remained ILD-free 3 years post-diagnosis (Figure 1B). A non-negligible fraction of patients with anti-MDA5, anti-ARS, and dermatomyositis-specific antibodies presented with IPAF instead of IIM or ASS (Figure 2). However, the correlation between ILD and poor prognosis only exist for patients with anti-MDA5 and MAA (Figure 3A). Furthermore, the 3-year survival rate for IIM-ILD and IPAF patients with anti-MDA5 (68% vs 57%, p=0.9) , anti-ARS (92% vs 93%, p=0.5) and DM-specific antibodies (100% vs 100%) were similar (Figure 3B).

Conclusion: Anti-MDA5 and ARS antibodies demonstrated a strong correlation with ILD development, and prognosis was consistent among IIM-ILD and IPAF patients. Other dermatomyositis-specific antibodies and anti-SRP were also associated with ILD development, albeit to a lesser extent, and the onset of ILD did not correlate with a poorer prognosis.

Relapse of Rapidly Progressive Interstitial Lung Disease in Patients with Anti-Melanoma Differentiation-Associated Gene 5 Autoantibody-Positive Dermatomyositis

Noriko Sasaki, Toshiki Ohisa, Akira Ishii, Mai Sugiyama, Yuichiro Ota, Chiho Yamada and Shinji Sato, Tokai university School of Medicine, Isehara, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies to Melanoma Differentiation-Associated Gene 5 (MDA5) are found specifically in patients with dermatomyositis (DM). Their presence is closely associated with rapidly progressive interstitial lung disease (RP-ILD) and poor prognosis. Although RP-ILD is a life-threatening condition, relapse of RP-ILD has rarely been reported after the success of the initial treatment. Nonetheless, some patients do relapse, but the clinical features and changes in laboratory biomarkers at the time of relapse of RP-ILD in patients with anti-MDA5-positive DM remain unclear. The aim of this study was to establish the clinical features of anti-MDA5-positive RP-ILD in patients with exacerbations after remission had been achieved.

Methods: Forty-one patients with classic DM or Clinically Amyopathic (CA) DM and ILD who were seen at Tokai University from 2011 to 2021 were retrospectively evaluated for their clinical and immunological characteristics including the occurrence of relapse during the clinical course after remission induction. Anti-MDA5 antibody was assayed by protein immunoprecipitation and enzyme-linked immunosorbent assays. Comparisons between relapse and non-relapse groups were made using the chi-square test.

Results: Forty-four patients with DM or CADM were found to have anti-MDA5 antibody. Three were excluded from the analysis because of insufficient clinical/immunological information. Of 41 patients (male/female: 7/34, mean age ± SD: 55.2 ± 11.9), 13 (32%) died despite initial intensive immunosuppressive treatment at an early phase of disease. Twenty-three patients achieved remission with the initial therapy and did not relapse during follow-up (56%). The remaining 5 patients (12%) in remission on initial treatment later relapsed. Of these 5 patients (male/female: 2/3, a mean age ± SD: 49.8 ± 11.2), one had classic DM and 4 had CADM. At the time of relapse, two patients complained of respiratory symptoms and all had worsening abnormal shadow on high resolution computed tomography (HRCT). Serum CRP, KL-6 and ferritin levels tended to be increased at the time of relapse. In 3 of the 5 (60%), the anti-MDA5 antibody titer was again above the cut-off level at relapse. The number of relapsing patients with anti-MDA5 antibody titer increasing again above the cut-off level was higher than in those who did not relapse (60% vs. 0%, P=0.003).

Conclusion: These results indicate that relapse may occur even after complete remission of RP-ILD has been achieved. Increased anti-MDA5 antibody titers, as well as respiratory symptoms and HRCT findings, are potential indicators of RP-ILD relapse in patients with DM.

Thromboembolic Risk Associated with Intravenous Immune Globulin Use in Patients with Idiopathic Inflammatory Myopathy: A Large Database Study

Rohan Mehta[1], Mike Putman[2] and Didem Saygin[3], [1]Medical College of Wisconsin, Milwaukee, WI, [2]Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI, [3]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Intravenous immune globulin (IVIG) recently received regulatory approval for the treatment of dermatomyositis, one of the idiopathic inflammatory myopathies (IIM). The pivotal randomized trial informing approval observed 6 thrombotic adverse events among patients exposed to IVIG, which included both venous thromboembolism (VTE) and arterial thromboembolism (ATE). The objective of this study is to determine the real-world incidence of ATE and VTE among adults who received IVIG for IIM or other indications.

Methods: Patients from TriNetX, a large federated health records database, were included if they received ≥1 IVIG administrations. ATE and VTE were identified using ICD-9-CM/ICD-10-CM codes and patients were characterized as IIM if they received two codes separated by 30 days within 3 years of the first IVIG administration. Patients could contribute multiple IVIg exposure intervals, which could be 1 to 7 days long, depending on how many consecutive IVIg administrations a patient received. Risk periods were defined for each patient for each IVIG interval as follows: ATE (IVIg interval day 1 to 2 days after the last day of the IVIG interval), VTE (IVIg interval day 1 to 13 days after the last day of the IVIg interval), and control (14 days

Table 1: Characteristics of included patients, n = 38,230

Characteristic	Overall	IVIG	Myositis
Total Number of Patients	38,230	36,553	1,677
Total IVIG Administrations, mean (SD)	256,868	233,079	23,789
IVIG Administrations per Patient, mean (SD)	6.7 (14.3)	6.4 (13.3)	14.2 (26.5)
Age at Diagnosis, mean (SD)	55.7 (16.7)	55.7 (16.8)	54.6 (14.7)
Gender	-	-	-

Table 2: Incidence and incident rate ratios for venous and arterial thromboembolism in the overall cohort and within the subset of patients with myositis

Group	Outcome	Exposure Period	Events	Follow-up Time	Unadjusted Incident Rate Ratio IRR (95% CI)
Overall Cohort (n = 38,230)	Venous Thromboembolism	Control	153	5,233 Years	1.25 (1.01-1.55)
		IVIG-Exposure	190	5,204 Years	
	Arterial Thromboembolism	Control	96	5,233 Years	7.59 (5.51-10.4)
		IVIG-Exposure	62	445 Years	
Myositis Cohort (n = 1,677)	Venous Thromboembolism	Control	12	387 Years	0.73 (0.30-1.63)
		IVIG-Exposure	10	459 Years	
	Arterial Thromboembolism	Control	7	387 Years	1.24 (0.26-5.96)
		IVIG-Exposure	2	89 Years	

after the last day of the IVIg interval to 31 days after IVIg interval day 1). Unadjusted incident rate ratios (IRR) were calculated and adjusted analyses were performed using stratified and weighted Poisson regressions.

Results: This project included 38,230 patients who received a total of 256,868 IVIg administrations. A subset of 1,677 patients (4.4%) were categorized as IIM. The majority of IIM patients were female (71.4%) and white (61.9%). After excluding exposure time outside of the defined risk windows and censoring patients after their first event, there were 345 VTE and 158 ATE in the overall cohort. In the overall cohort, during the exposure and control periods the unadjusted incidence rates of VTE were 36.5 cases and 29.6 cases per 1,000 person-years, respectively (unadjusted IRR 1.23, 95% confidence interval (CI) 1.00-1.52) and the unadjusted incident rates of ATE were 139.0 cases and 18.3 cases per 1,000 person-years (unadjusted IRR 7.59, CI 5.51-10.40). Adjusted RR were 2.30 (95% CI 0.96-5.90) for VTE and 0.80 (95% CI 0.33-2.14) for ATE. Among patients with IIM, there were 22 VTE and 9 ATE. During exposure and control periods the unadjusted incidence rates of VTE were 21.8 cases and 31.0 cases per 1,000 person-years, respectively (unadjusted IRR 0.70, 95% CI 0.30-1.63) and the unadjusted incident rates of ATE were 22.4 cases and 18.1 cases per 1,000 person-years, respectively (IRR 1.24, CI 0.26-5.96). Adjusted rates could not be calculated for the subset with myositis given a low number of events.

Conclusion: In this study, the risk of ATE and VTE among patients exposed to IVIG was low. In unadjusted analysis, the rate of ATE and VTE was elevated after IVIG administration, but this did not persist in adjusted analyses. No increased risk was observed among patients with IIM in unadjusted analysis. Ongoing surveillance studies using randomized designs should be conducted to corroborate these findings.

Valid and Reliable Physical Function Tests in Idiopathic Inflammatory Myositis

Tanya Chandra[1], Raisa Lomanto Silva[2], shiri keret[3], Akanksha Sharma[4], Siamak Moghadam-Kia[2], Dana Ascherman[5], Chester V. Oddis[5] and Rohit Aggarwal[5], [1]Georgetown University Hospital, Washington, DC, [2]University of Pittsburgh Medical Center, Pittsburgh, PA, [3]Bnai Zion, Atlit, Israel, [4]UPMC Mercy Hospital, Pittsburgh, PA, [5]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) can cause significant impairment in physical function. Sit to Stand (STS) and Timed Up and Go (TUG) are quick and operator-independent measures of physical function. We evaluated the psychometric properties (reliability, validity, and responsiveness) of these compared to established core set measures (CSMs) of disease activity and outcome. We also assessed the feasibility of patients self-performing these tests at home remotely.

Methods: Data from a 6-month prospective observational study on IIM: Myositis Patient Centered Tele-Research Study (My PACER) was analyzed. There were 2 cohorts, a Tele-Research Cohort (TRC; remote enrollment from anywhere in US) and a Center Based Cohort (CBC; in person enrollment from myositis centers). Patient reported assessments and functional assessments (STS and TUG) were collected monthly over 6-months. STS is the number of times a patient can stand from a seated position and sit back down in 30 seconds. TUG is the time needed to rise from a chair, walk 3 meters, return to the chair and sit down. For the CBC, patients were trained in person by the coordinator, whereas for TRC training was provided by pre-recorded video instructions and patients self-performed the tests remotely. These tests were done twice at each visit, with the average of the two used in analysis. In addition, myositis core set measures (CSMs) were assessed by myositis experts at baseline and 6 month follow up (done in person for CBC patients and remotely through telemedicine visits and medical records for TRC patients). We examined test-retest reliability using Spearman correlation. To assess validity, we compared STS and TUG against all CSMs and other disease activity measures at baseline. We assessed responsiveness by assessing differences of median changes in STS and TUG in different categories of improvement according to various outcome measures and compared them using the Mann Whitney Test.

Results: 120 patients (75% female,80.8% Caucasian, mean age of55.5+/- 13.43 years,39.2 % PM, 51.7% DM, 9.1% Necrotizing Myopathy [NM]) participated in the study. There was strong test-retest reliability between baseline and month 1 for STS (r=0.8) and TUG (r=0.87); p< 0.01.Reliability was high regardless of method of recruitment and training for STS, however, TUG showed higher reliability in patients recruited and trained remotely (TRC) as compared to locally (CBC). Reliability was maintained across clinical disease subtypes (DM, PM and NM). At baseline STS and TUG showed very strong correlation with each other (r=-0.75) as well as with all CSMs except Extra-Muscular Global and CK. Strong correlations were seen with Muscle Disease Activity and a validated PRO of physical function (PROMIS-PF 20).At 6 months, STS and TUG were significantly better among patients who improved according to 2016 EULAR/ACR myositis response criteria (Total Improvement Score) compared to those who didn't.

Conclusion: STS and TUG showed good reliability including when self-performed by patients remotely using video instructions, with excellent construct validity and responsiveness. STS and TUG are feasible functional assessment in myositis that can be performed in clinic or remotely.

Table 1. Demographic characteristics of participants

Anti-MDA5 Associated Dermatomyositis: Clinical Features and Outcomes in a Predominantly African-American Case Series

David Wang[1], Arezou Khosroshahi[2] and Prateek Gandiga[2], [1]Emory University School of Medicine, Atlanta, GA, [2]Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with autoantibodies against melanoma differentiation-associated protein 5 (MDA-5) are reported to have a significant risk of developing rapidly progressive and fatal interstitial lung disease (ILD) in clinically amyopathic dermatomyositis patients (CADM). Previous cohort studies of dermatomyositis patients who have been evaluated for the presence of anti-MDA5 antibodies and associated clinical features and outcomes have been largely performed in the Asian, generally Japanese population, or Caucasian patients in North American studies. Few studies have examined MDA5 manifestations in non-Asian subjects. Available reports suggest rates of CADM and ILD may be lower in Caucasian predominant MDA5 cohorts compared to Japanese or Chinese groups. Additionally, association between rapidly progressive interstitial lung disease (RP-ILD) and MDA5 was variable in these North American studies. The goal of this study is to describe the clinical findings and outcomes of a pre-dominantly black cohort in anti-MDA5 associated ILD and the rapidly progressive variant.

Methods: This retrospective case series identified 17 patients with CADM who had anti-MDA5 autoantibodies. Clinical characteristics, high-resolution computed tomography data, lab test results, presence of additional myositis autoantibodies (MAAs), and response to therapy and treatment outcomes were compared between 2 subgroups: black and non-black patients.

Results: Among 17 patients with CADM and anti-MDA 5 autoantibodies, 15 (88%) developed ILD with 6 patients (40%) having the rapidly progressive variant. All 6 patients with RP-ILD presented in the black sub-group. Out of the pre-dominantly black cohort (11 of 17 patients), 6 (55%) patients had at least one additional MAA. Within the black cohort, 5 patients were positive for ANA, 1 for anti-CCP, 3 for anti-SSA, 5 for anti-Ro52, and 1 for anti-synthetase antibodies. Black patients exhibited a higher prevalence of MAAs when compared to the non-black cohort. Average ferritin levels in black (951±2043) and non-black (976±805) patients were both elevated. Average values of CPK, aldolase, ferritin, FVC, and TLC did not differ significantly between black and non-black patients, but the majority of patients with anti-MDA5 antibody alone (4 of 5) developed ILD but not RP-ILD. Three out of four patients who died developed RP-ILD and all four had additional MAAs.

Conclusion: Black patients with anti-MDA5 positive DM exhibited many of the key phenotypic findings in other MDA5 positive DM populations. However, in our cohort, there was a notably increased incidence of RP-ILD and mortality among Black patients compared to non-Black patients. These potential phenotypic variations should be explored further as they can have implications for appropriate evaluation and treatment. Anti-MDA5 positive patients with CADM who are black have a higher prevalence of co-existent MAAs portending a poorer prognosis and a potentially greater predilection of developing RP-ILD than their non-black counterparts. Patients with anti-MDA5 antibodies alone generally have milder forms of ILD whereas coexistent MAAs serve as a possible marker for less favorable prognoses in anti-MDA5 positive patients.

Mortality Trends in Polymyositis and Dermatomyositis in Mexico: A General Population-based Study from 2000 to 2019

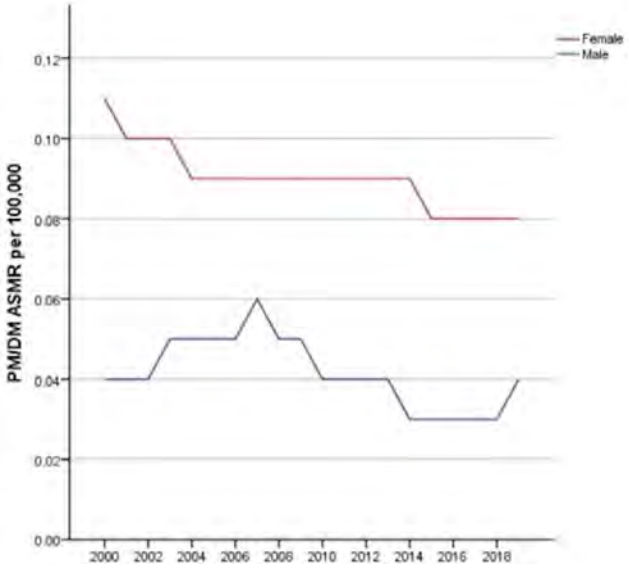
CLAUDIA MENDOZA PINTO[1], Pamela Munguía-Realpozo[1], Ivet Etchegaray-Morales[2], Mario García-Carrasco[2], Paulina Cortés-Hernández[1], Roberto Arreguín-Reyes[1], Jorge Ayón-Aguilar[1] and Gabriel Rodríguez-Castillo[2], [1]Instituto Mexicano del Seguro Socia, Puebla, Mexico, [2]Medicine School, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with polymyositis and dermatomyositis (PM/DM) present multiple complications that may lead to increased mortality rates and data on PM/DM mortality in Mexico is lacking.

The objective of this study was to assess mortality trends in PM/DM idiopathic inflammatory myopathies (IMM) in Mexico between 2000 and 2019, overall and by sex, age group, and geographic regions.

Methods: Data were acquired from the General Board of Health Information Open Access databases, and we identified deaths for PM/DM (ICD codes, 10th edition), which were recorded from 2000 to 2019 from all public hospitals nationwide. Age-standardized mortality rates (ASMR) per 100,000 persons were calculated for PM/DM and non-PM/DM overall, by sexes, and by geographic region. Annual percentage change (APC) and average annual percentage change (AAPC) in ASMR were calculated using Joinpoint regression software.



Temporal trends in age-standardized mortality in PM/DM subjects by sex.

Results: We found 1,456 deaths from PM/DM and 11,343,652 non-PM/DM in Mexico from 2000 and 2019. The ASMR (per 100,000 inhabitants) was 0.07 over the period. The gender distribution of PM/DM deaths was 69.8% in women and 30.2% in men. Compared to non-PM/DM, PM/DM individuals had a higher proportion in the younger population (younger than 45 years) (40.2% vs. 22.3%). Overall, a significantly downtrend in the ASMR was identified from 2007 to 2017 in subjects with PM/DM (APC -3.2%; 95% CI, -5.3 to -1.0; p = 0.008), while mortality trends were stable for non-PM/DM individuals. Similar trends were identified by sex in PM/DM patients (Fig 1). The Joinpoint analysis did not identify variation in temporal trends in mortality rates by geographic region; however, an increment in the proportion of deaths in the ratio of PM/DM to non-PM/DM ASMR from 2000 to 2019 was detected in the Northern and Southern regions (+17.6% and +84.9%, respectively).

Conclusion: Over a 20-year period, we observed that deaths due to PM/DM occurred predominantly in females. A notable decrease in overall mortality rates was identified between 2007 and 2017. Differences by sex, age, and geographic region were also detected.

Evaluation of Cancer Screening Methods in Patients Diagnosed with Inflammatory Muscle Disease at Kansas University Medical Center

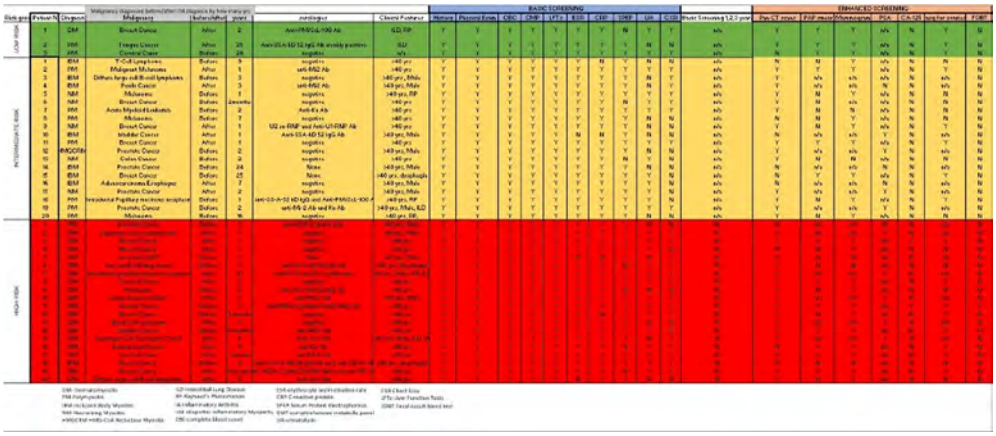
Padmini Giri[1], Amrita Bath[2] and **Pooja Bhadbhade**[2], [1]University of Kansas Medical Center, Overland Park, KS, [2]University of Kansas Medical Center, Kansas City, MO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

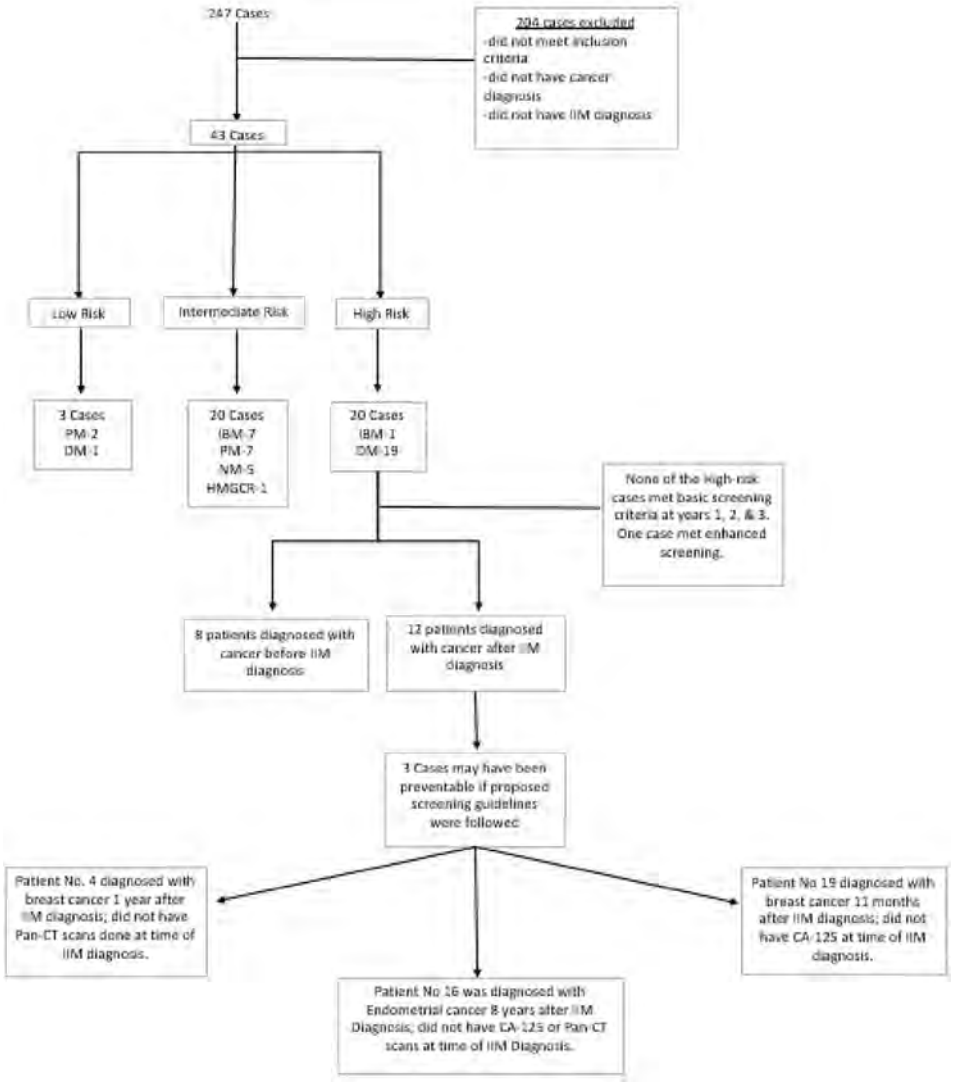
Background/Purpose: Idiopathic inflammatory myopathies (IIM) are characterized by muscle weakness and inflammation. There is an increased risk of developing cancer in patients (pts) with IIM compared to the general population. While most cancers are detected within the 1st year of IIM diagnosis, ongoing monitoring is recommended for 3-5 years post-diagnosis.

In November 2021, a systematic review and meta-analysis was conducted to inform cancer screening guidelines in IIM. The review aimed to evaluate the cancer screening investigations and develop evidence-based guidelines. These guidelines were subsequently developed in collaboration with experts from around the world, utilizing a Delphi process involving 75 participants from 22 countries. The manuscript detailing the proposed guidelines is forthcoming. The purpose of this study was to evaluate the effectiveness/appropriateness of the screening methods employed at our institution and compare them with the proposed guidelines.

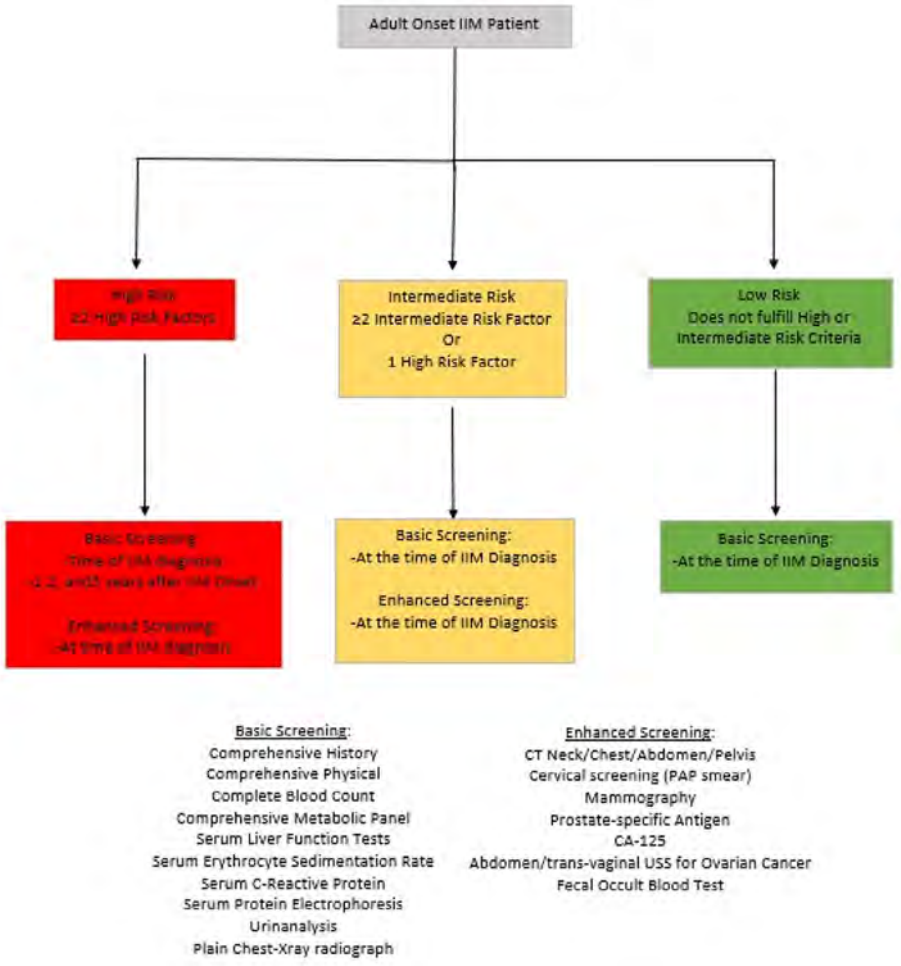
Methods: A retrospective chart review at our tertiary medical center using EMR-EPIC, Research Electronic Data Capture software, and Heron Research database, to identify pts being treated for IIM and diagnosed with malignancy between 1/2012 to 1/2022. We implemented risk stratification methods based on the proposed guidelines for malignancy screening in patients with IIM.



Data from analyzed cases organized into low, intermediate, and high risk categories. Special focus on type of IIM, malignancy, serologies, basic and enhanced screening.



Flow chart break down of cases analyzed. Special focus on 12 high-risk cases diagnosed with cancer after initial IIM diagnosis.



Flow chart explanation of how to categorize patients into low, intermediate, and high risk categories as well as what is included in basic and enhanced screening.

Results: Among the 20 high-risk cases identified, 12 pts were diagnosed with cancer after their IIM diagnosis, none met the basic screening recommendations for the first 3 years following IIM diagnosis. One patient met the criteria for enhanced screening. Among the 20 intermediate-risk cases, 7 were diagnosed with cancer after IIM diagnosis. 15 of 20 intermediate-risk cases did not undergo complete basic screening, and none met the criteria for enhanced screening. Among the 3 low-risk pts, 1 met the basic screening requirements. The most missed component of enhanced screening was fecal occult blood test, while the most frequently overlooked element of basic screening was chest x-ray. 3 high-risk pts may have had their cancers detected earlier if screening guidelines were followed.

9 of 15 female pts with gynecological and breast cancers were classified as high-risk. Among the 26 female intermediate/high-risk cases, 16 did not undergo PAP smears, 5 did not have mammograms, and 13 did not undergo abdominal/trans-vaginal ultrasounds. Additionally, there were 5 gastrointestinal malignancies, and 10 of 40 intermediate/high-risk pts did not have pan-CT scans.

Conclusion: We conclude the proposed guidelines, particularly for high-risk cases, play a vital role in detecting malignancies occurring after IIM diagnosis. Most high-risk cases were diagnosed with cancer within 1-5 years of initial IIM diagnosis. A significant proportion of malignancies observed were female-specific cancers (breast/gynecologic), many that occurred within 1-3 years of IIM diagnosis. This suggests the importance of enhanced screening up to 3-5 years beyond the initial diagnosis

of IIM in high-risk pts. It is evident that our institution did not fully adhere to the proposed guidelines; however, these results could form a quality improvement project aimed at enhancing cancer screening for pts with IIM.

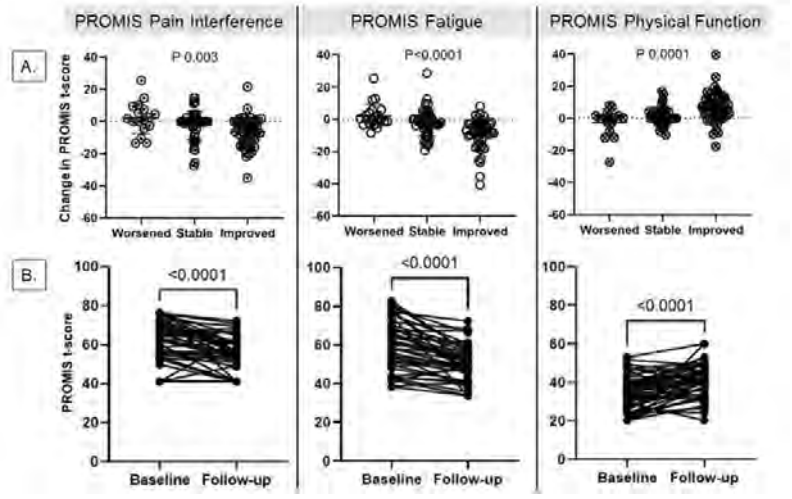
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient reported outcome measures (PROMs) are critical in assessing clinical outcomes. There is a paucity of PROMs for use in patients with adult idiopathic inflammatory myopathies (IIM). The Outcome Measures in Rheumatology (OMERACT) Myositis Working Group was established to develop validated PROMs for adult IIM. Our previous

Figure 1. PROMIS instruments across the anchor categories (A) and over time change in the PROMIS scores of patients who reported anchor-specific improvement only (B).



work has included identifying the domains of interest as pain interference, fatigue, and physical function and demonstrating the content validity, test-retest reliability, and construct validity of the PROMIS pain interference (6a), fatigue (7a), and physical function (8b) instruments. In this study, our goal was to assess the responsiveness and minimal important difference of these instruments in a prospective longitudinal cohort of adults with IIM.

Methods: Adults with IIM who were seen in the outpatient clinics in United States of America (USA), Netherlands, South Korea, Sweden, and Australia, were enrolled in this prospective observational study with two study visits. Relevant myositis core set measures (manual muscle testing [MMT8, 0-80], physician and patient global disease activity [0-10]), and the PROMIS instruments for pain interference (6a), fatigue (7a), and physical function (8b) were collected at the baseline and follow-up visits. Domain-specific anchor questions for symptoms of pain, fatigue, and physical function were asked at the follow-up visit (a lot better, a little better, stable, a little worse, a lot worse). Responsiveness of the PROMIS instruments was assessed using i) ANOVA to compare the scores across the anchor categories (worsened, stable, improved), ii) paired t

Stable	Baseline Follow-up	55.1 53.0	-2.1	8.3	-0.21	-0.25	47
Improved	Baseline Follow-up	59.7 50.5	-9.2	9.8	-0.83†	-0.93†	45
PROMIS Physical Function							
Worsened	Baseline Follow-up	39.1 36.5	-2.6	8.7	-0.27	-0.29	16
Stable	Baseline Follow-up	42.0 43.2	1.2	5.4	0.12	0.23	41
Improved	Baseline Follow-up	34.6 41.1	6.5	9.4	0.75†	0.70†	51

SD: Standard deviation

**Five anchor categories were lumped under 3 categories (worsened, stable, improved) due to small sample size in each subgroup.*

†*Large effect size and standardized response mean (interpreted as small <0.2, medium 0.2-0.5, large >0.5)*

test, effect size and standardized response mean for within-person score change, and iii) Pearson correlation with myositis outcome measures. Effect size was interpreted as small for < 0.2, medium for 0.2-0.5, and large for >0.5. Minimal important difference was calculated using the anchor-based method.

Results: 114 patients with IIM (median age of 60 [50-70], 60% female) completed two study visits at five international sites (USA [32.5%], Netherlands [23.7%], Korea [21.9%], Sweden [18.4%], Australia [3.5%])(Table 1). Changes in PROMIS pain interference, fatigue, and physical function were significantly different among anchor categories (Figure 1). Patients who reported improvement in domain-specific anchor questions had a significant improvement in their PROMIS scores with at least medium effect size (>0.5), while patients who reported worsening and stability in anchor questions did not show a significant change with weak effect size (< 0.2) (Table 2). PROMIS instruments had weak to moderate correlations with MMT, patient and physician global. Using the anchor-based method, the minimal important difference was 2.7 t-score for PROMIS pain interference, 4 for fatigue, and 3.3 for physical function.

Conclusion: This study provides evidence towards the responsiveness of the PROMIS instruments in a large international prospective cohort of adults with IIM supporting their use as PROMs in adult myositis. Further work is planned to examine responsiveness in a larger cohort of those who worsen and in clinical trials.

Rituximab Treatment in Adult Patients with Idiopathic Inflammatory Myositis (IIM): A Systematic Review and Meta-analysis

Lilian Otalora Rojas[1], Karishma Ramsubeik[2], Luis Sanchez-Ramos[2], Shastri Motilal[3], Jasvinder Singh[4] and Gurjit S Kaeley[5], [1]University of Florida, Ponte Vedra Beach, FL, [2]University of Florida, Jacksonville, FL, [3]The University of the West Indies, St. Augustine, Trinidad and Tobago, [4]University of Alabama at Birmingham, Birmingham, AL, [5]University of Florida College of Medicine – Jacksonville, Ponte Vedra Beach, FL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune myositis involves a spectrum of rare autoimmune disorders characterized by inflammation and damage to skeletal muscles. The management of these challenging conditions often requires immunosuppressive therapies. Rituximab (RTX), a monoclonal antibody targeting CD20-positive B cells, has emerged as a promising therapeutic option for patients with autoimmune myositis who are refractory to or intolerant of conventional treatments.This meta-analysis aims to evaluate the efficacy and safety of RTX treatment in patients with autoimmune myositis, encompassing polymyositis (PM), dermatomyositis (DM), juvenile dermatomyositis (JDM), antisynthetase syndrome (ASS), and immune-mediated necrotizing myositis (IMNM).

Methods: A comprehensive literature search was conducted using electronic databases:*PubMed and Embase*to identify relevant studies published up to September 2022. Studies reporting on the efficacy and safety outcomes of RTX treatment in patients with autoimmune myositis were included, case reports or series with less than 3 subjects were excluded. Data were extracted, and a random-effects model was used to calculate pooled estimates for clinical response rates, subgroup analysis, and adverse events. This study was registered withPROSPERO 2022 CRD42022353740

Results: A total of 17 studies, 1 RCT and 16 uncontrolled studies, involving 362 patients with autoimmune myositis were included in the meta-analysis. The pooled analysis demonstrated a notable overall clinical response rate of 70% (95% confidence interval [CI]: 57-82% I2=71.8%, p= < 0.001), Pooled complete remission rate after treatment with RTX was 13% (95% CI:3-25%, I2=79.5%, p=< 0.001), and partial remission rate was 48% (95% CI: 30–66%, I2=86.0%, p=< 0.001). Subgroup analyses showed high response rates in all typed of myositis PM 69% (95% CI: 42-91% I2=52.0%, p=0.04) DM 67% (95% CI: 45-86% I2=52.0%, p=0.04), ASS 70% (95% CI: 34-97% I2=79.4%, p=< 0.001), JDM 60% (95% CI: 21-94%) and NIIM (just one study) 86% (95% CI: 42-100%). Regarding RTX induction dose, subgroup analysis showed similar overall response with 1 g IV at days 0 and 14 days 68% (95% CI:47-86, I2=75.3% P=< 0.001) and 375 mg/m2 weekly for 4 weeks was 71% (95% CI:48–90, I2=24.6% P=0.80). Regarding safety, 120 adverse events were reported. The most reported adverse events from the 362 patients were infusion reactions in 67 (18.5%) and infections in 45 patients (12.4%).

Conclusion: The highly variable response and remission rates seen in this review warrant further controlled trials on RTX for autoimmune myositis. RTX demonstrates a favorable clinical response rate and muscle strength improvement. Potential adverse events, particularly infusion reactions and infections, should be considered. Further research is needed to optimize treatment protocols and assess long-term outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Vitamin D deficiency is commonly associated with sarcopenia; however, the latest International Clinical Practice Guidelines for Sarcopenia do not recommend vitamin D supplementation for sarcopenia owing to a lack of an apparent therapeutic effect on the indices of sarcopenia among participants with replete vitamin D concentration (i.e., 25[OH]D >50 nmol/L) from randomized controlled trials. While there is consensus in all vitamin D guidelines that serum levels of 25(OH)D < 25 nmol/L should be corrected, approximately 30% of the world population's 25(OH)D levels range from 25 to 50 nmol/L, and it remains unclear whether such suboptimal levels of 25(OH)D can maintain optimal health, including the risk of sarcopenia.

Methods: Among 295,489 participants of unrelated European ancestry from the UK Biobank, we examined the causal association between genetic variants for serum 25(OH)D concentration and the sarcopenia risk. The primary outcome was sarcopenia, defined by the European Working Group on Sarcopenia in Older People. The secondary outcomes

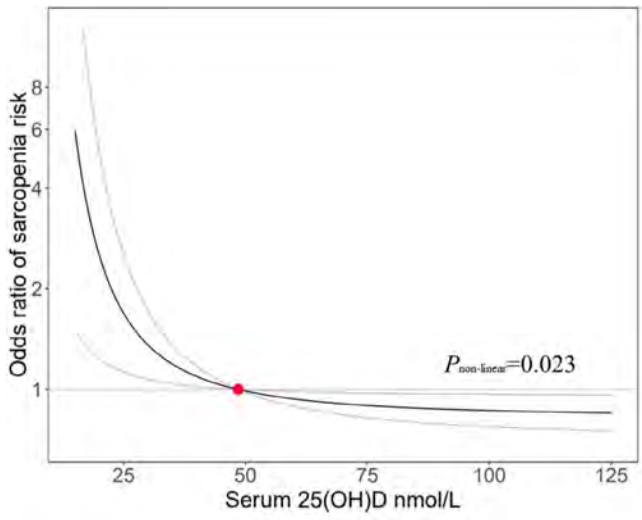

Figure 1 Genetic association of serum 25(OH)D with risk of sarcopenia using 35 SNPs to the instrument. The red dot represents the reference point of serum 25(OH)D of 50 nmol/L. The gray lines represent the 95% confidence intervals. The adjustment includes age, sex, assessment center, birth location, top 20 genetic principal components, genotyping array in both stages, and nuisance factors, which could affect serum 25(OH)D measurements, including the month in which the blood sample was taken, fasting time before the blood sample was taken, and sample aliquots for measurement.

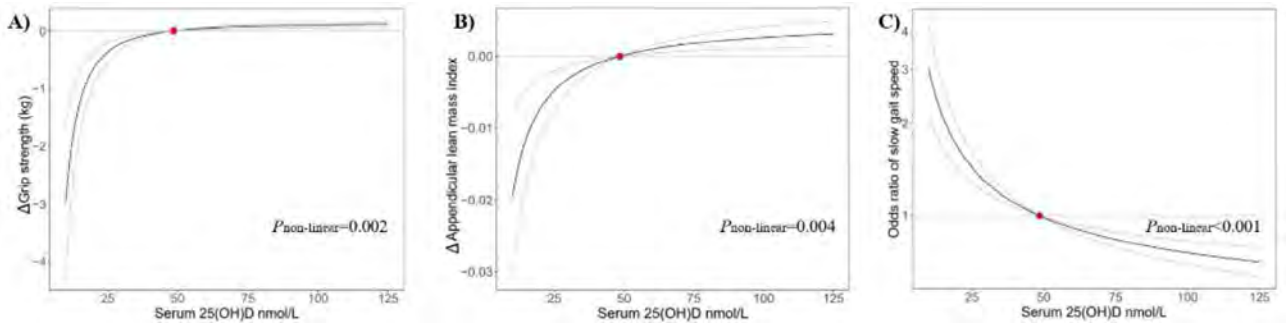

Figure 2 Genetic association of serum 25(OH)D with indices of sarcopenia using 35 SNPs to the instrument. (A) grip strength, (B) appendicular lean mass index, and (C) slow gait speed. The red dot represents the reference point of serum 25(OH)D of 50 nmol/L. The gray lines represent the 95% confidence intervals. The adjustment includes age, sex, assessment center, birth location, top 20 genetic principal components, genotyping array in both stages, and nuisance factors, which could affect serum 25(OH)D measurements, including the month in which the blood sample was taken, fasting time before the blood sample was taken, and sample aliquots for measurement.

consisted of three sarcopenia indices, i.e., grip strength, appendicular lean mass index, and gait speed. We calculated a weighted genetic score using 35 single nucleotide polymorphisms as instrumental variables for serum 25(OH)D concentration and performed non-linear Mendelian randomization to estimate the effect of serum 25(OH)D on sarcopenia risk and its indices.

Results: In the phenotypic association analyses, compared with serum 25(OH)D 50-74.9 nmol/L category, serum 25(OH)D levels below 50 nmol/L adjusted for multivariable factors were inversely associated with each of the sarcopenia indices (Table 1). There was an L-shaped ($P_{non\text{-}linear}$=0.023) association between genetically predicted serum 25(OH)D concentration and risk of sarcopenia (**Fig. 1**). The risk of sarcopenia decreased rapidly as serum 25(OH)D concentration increased until 50 nmol/L and then leveled off. The odds ratio of sarcopenia for serum 25(OH)D level of 25 nmol/L vs. 50 nmol/L was 1.69 (95% CI: 1.13 to 2.53). Similar patterns were also observed when the association between serum 25(OH)D concentration and risks of each of the sarcopenia indices were evaluated (**Fig. 2**).

Conclusion: Our study supports a causal relationship between suboptimal vitamin D levels and sarcopenia risk. These findings suggest that vitamin D supplementation needs to be considered for individuals with suboptimal vitamin D levels to reduce the burden of sarcopenia.

Validity, Responsiveness and Minimal Clinically Important Difference of EQ-5D-5L in Inflammatory Myositis: A Longitudinal Study

Chengappa Kavadichanda[1], Parthibane S[1], Mamatha Gorijavolu[1], Sai Kumar Dunga[1], Amrita Nayak[1], Sitanshu Sekhar[1] and Rohit Aggarwal[2], [1]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myositis (IIM) significantly impacts health-related quality of life (HRQoL). EQ5D-5L is a widely used and validated tool to measure HRQoL. The health utility scores (HUS) derived from EQ5D-5L are used to calculate QALY and to analyze cost effectivity. To the best of our knowledge, there are no studies that have validated EQ5D-5L in IIM. To test the validity of EQ-5D HUS in assessing HRQoL in IIM. To assess the responsiveness to change and to calculate minimal clinically important differences (MCID) of EQ-5D HUS

Table 1: Mean change in the myositis core set measures and EQ5D-5L health utility scores across all patients using HAQ-DI and TIS as anchor

Table 3: Estimation of Minimal clinically important difference (MCID) using various methods

	Anchor based			
	Estimated value for MCID	*AUC, Sensitivity and specificity*	*Spearman's Rho*	*95%CI*
Change in HAQ-DI ≥ 0.22	0.303	0.96, 96.9%, 88.5%	0.79 (<0.001)	0.90-1.0
	Distribution based method			
0.5*SD (MCID= 0.5 SD of the ΔSD score)	0.34	NA	NA	NA

Methods: This was a single centre prospective study involving patients with IIM. Patients were evaluated at 0 and 6 months with all 6 myositis core set measures and EQ5D-5L. The EQ5D-5L health states for Indian population were used to calculate HUS. Individuals with MMT8 of < 74/80 and / or those who had extra muscular disease activity of > 2/10 were considered active and the rest as inactive disease. Muscle weakness was classified as severe (MMT-8 < 54/80), mild-moderate (MMT-8 54 to 73/80) and inactive (MMT-8 ≥74). Construct validity of EQ5D-HUS (ability to differentiate different health states) was tested by comparing scores and Cohens'D effect size (ES) across disease severity. Responsiveness to change was estimated with ES for the change in scores between those with improvement and no improvement in HAQ-DI and total improvement scores (TIS). MCID was calculated using distribution-based method (0.5*SD of change) and anchor based method (ROC curve) using a change of ≥0.22 of HAQ-DI between 0 and 6 months as the anchor.

Results: Fifty-eight IIM patients with mean (SD) age of 37.6 (9.8), 76% (N=44) females were included in the study. Disease subset included 34 (58.6%) DM, 18 (31%) anti-synthetase syndrome, 3 (5.2%) immune mediated necrotizing myopathy and 3 (5.2%) PM.

Median MMT-8 (0-80) at baseline was 61.35 ±15.49 with a median (IQR) of extra-muscular disease activity (0-10) of 3 (0,5). The median (range) EQ5D-5L health utility score was 0.415 (-0.69, 0.87). Sixteen patients had severe myositis with EQ-5D HUS of -0.68, 34 mild to moderate had EQ-5DHUS of 0.42 and 8 had inactive disease EQ-5DHUS- 0.81 at baseline (p< 0.01). The changes in MMT-8, HAQ-DI, physician and patient global assessment, extra muscular diseases activity and EQ5-D HUS between 0 and 6 months in the cohort is represented in table 1.

The EQ-5D HUS increased by 0.625 (p < 0.001) in 6 months and was able to differentiate between patients with improvement based on HAQ-DI and 2016 ACR/EULAR Myositis response criteria (TIS ≥20) (Table 1). The ES of change in MMT-8, HAQ-DI, Physician and patient global assessment, extra muscular diseases activity and EQ5-D HUS between those with improvement as per HAQ-DI ≥0.22 and TIS ≥ 20 is in table 2.

Upon calculating the MCID to detect a minimal change in HAQ DI of 0.22, the best model with a sensitivity of 96.9 and specificity of 88.5 was at an EQ-5D HUS of 0.303. The distribution-based MCID calculation using the 0.5 SD method resulted in a value of 0.34 for EQ-5D HUS (Table 3).

Conclusion: Health utility scores derived from EQ5D-5L is a valid instrument for measuring the HRQoL in IIM. An MCID of 0.3- 0.34 had the highest sensitivity and specificity to detect change in clinical state among patients with IIM.

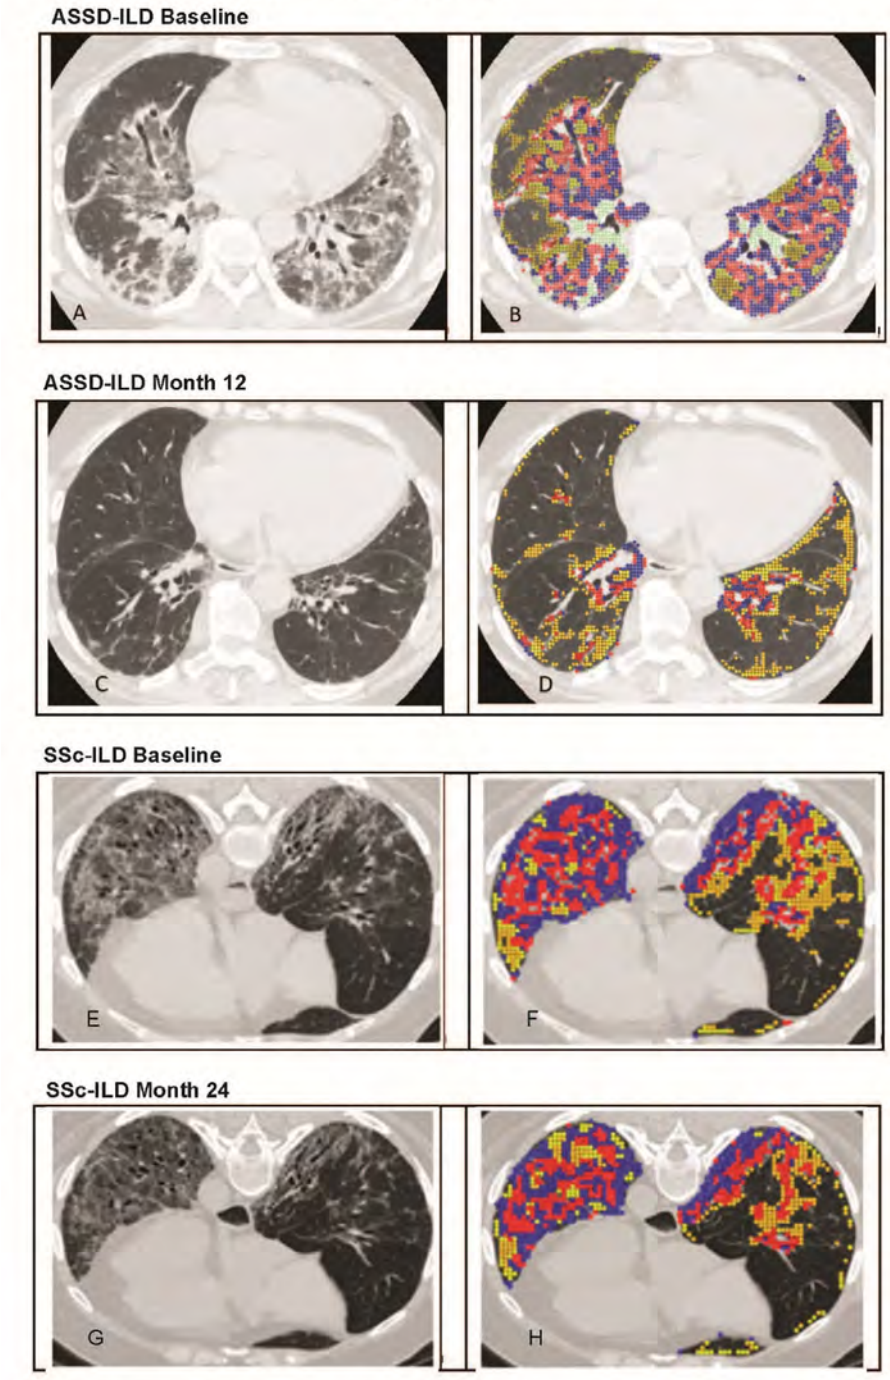
Values are in Mean±SD, Median[IQR] for skewed data, N(%) Zone of maximum involvement was defined as the lobe with the highest QLF score. Zones are defined as area-equivalent regions of the lung across the upper, middle and lower regions of each lung. Note, difference in disease duration. ASS was within 3 months or recent worsening, ssc was mean 2.6 years (0.3-7.1 years) Max lobe based on lobe with highest QILD2 *p<0.05 compared to SSc-ILD group

Figure 1. Representative subjects with favorable treatment response by HRCT in ASSD-ILD and SSc-ILD with quantitative map overlay



Representative subjects with favorable treatment response by high-resolution computed tomography (HRCT) in ASSD-ILD (A-D) and SSc-ILD (E-H). In the quantitative map overlay (right panel), the sum of the blue and red areas represents the extent of quantitative lung fibrosis (QLF), and the yellow area represents the extent of quantitative ground glass(QGG). The sum of all the colors represents quantitation of total ILD (QILD). (A,B) In ASSD-ILD, there is mixed ground glass and consolidative infiltrates in lower lobes with thick walled reticulations and mild bronchiectasis with some volume loss. The pattern of fibrosis is inconsistent with UIP and favors but not classic for organizing pneumonia. Follow up image (C,D) demonstrates significant decrease in the lung infiltrates with residual reticular lines and limited loss of volume. The quantitative overlay shows significant decrease in QLF and QGG. (E,F) In SSc-ILD, HRCT at baseline demonstrates lower lobe course ground glass opacity with reticulations and traction bronchiectasis/bronchiolectasis and relative subpleural sparing best seen on the left side. (G) After 24 months, there is subtle decrease in density of ground glass and extent and thickness of reticulations but persistent bronchiectasis/bronchiolectasis. (H) Quantitative map overlay at 24 months demonstrates decrease in QLF shaded as red and blue.

Table 2. Mean changes for study outcomes from baseline

	N	ASSD-ILD	N	SSc-ILD	P value
FVC ml change (%)	18	-0.01[-0.08,0.06]	110	0.02[0.003,0.04]	0.33

Values reported as mean change[95%CI]. Change in FVC in ml indicates (FVC in ml at 12 months – FVC in ml at baseline)/(FVC in ml at baseline) Change in DLCO in ml indicates (DLCO in ml at 12 months – DLCO in ml at baseline)/(DLCO in ml at baseline) % predicted change were absolute differences between baseline and 12 months Follow up time between quantitative CT scores were 12 months for ASSD-ILD trial and 24 months for SSc-ILD trial.

scleroderma lung study II (SLSII). The current study aims to describe quantitative CT scores in myositis and antisynthetase syndrome related ILD in comparison to scleroderma ILD (SSc-ILD).

Methods: Quantitative CT scores were performed on HRCT scans obtained from the Abatacept for the Treatment of Myositis-Associated ILD (Attack My-ILD) clinical trial which was a 12-month study including 20 adult patients with antisynthetase syndrome and active ILD (ASSD-ILD). We compared baseline scores with a subgroup of an observational cohort of myositis patients with ILD (Myositis-ILD), and the SLS II cohort which included patients with limited or diffuse scleroderma and active ILD (SSc-ILD). Quantitative CT scores were compared between the 3 ILD cohorts at baseline, and scores over time were compared between the two clinical trial cohorts (ASSD-ILD and SSc-ILD). Images were also assessed visually by thoracic radiologists.

Results: Baseline characteristics are described in Table 1. The ASSD-ILD group had lowest forced vital capacity(FVC) and diffusing capacity (DLCO) and highest quantitative scores for ground glass (QGG), fibrosis (QLF) , honeycombing (QHC) and total sum of disease (QILD) among the 3 cohorts. Zone of maximum involvement was shared throughout upper, middle and lower zones in ASSD- and Myositis-ILD, unlike SSc-ILD where 94% had maximum disease in the lower zones of the lung. Visual review of the ASSD-ILD and Myositis-ILD images revealed a pattern distinct from SSc-ILD (Figure 1). In ASSD- and Myositis-ILD, there are areas of confluent fibrosis that mimic organizing pneumonia with fibrosis and volume loss. Also, the disease extends to the periphery of the lung, unlike SSc-ILD which tends to spare the periphery. Both diseases demonstrate ground glass opacity and reticulations with bronchiectasis. In comparing subjects that showed favorable treatment response from the two clinical trials, the ASSD-ILD patient showed marked improvement in CT images (Figure 1-A to C) which was also reflected in changes in their quantitative scores (Figure 1-B to D), whereas in the SSc-ILD subject the improvement was more subtle (Figure 1 E,F to G,H). Mean changes in lung physiology and quantitative CT scores over the trial period demonstrated that QLF scores in the ASSD-ILD cohort showed greater improvement compared to the SSc-ILD cohort despite its shorter follow up time and the lack of differences in changes in FVC or DLCO between the groups (Table 2).

Conclusion: HRCT images from ASSD-ILD and Myositis-ILD demonstrate a pattern that is distinct from SSc-ILD. ASSD-ILD shows more marked improvement in HRCT images with treatment than SSc-ILD which is reflected as a significantly greater decrease in quantitative CT scores over time compared to SSc-ILD. Further studies are needed to better characterize and quantify HRCT images in myositis and antisynthetase syndrome related ILD.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

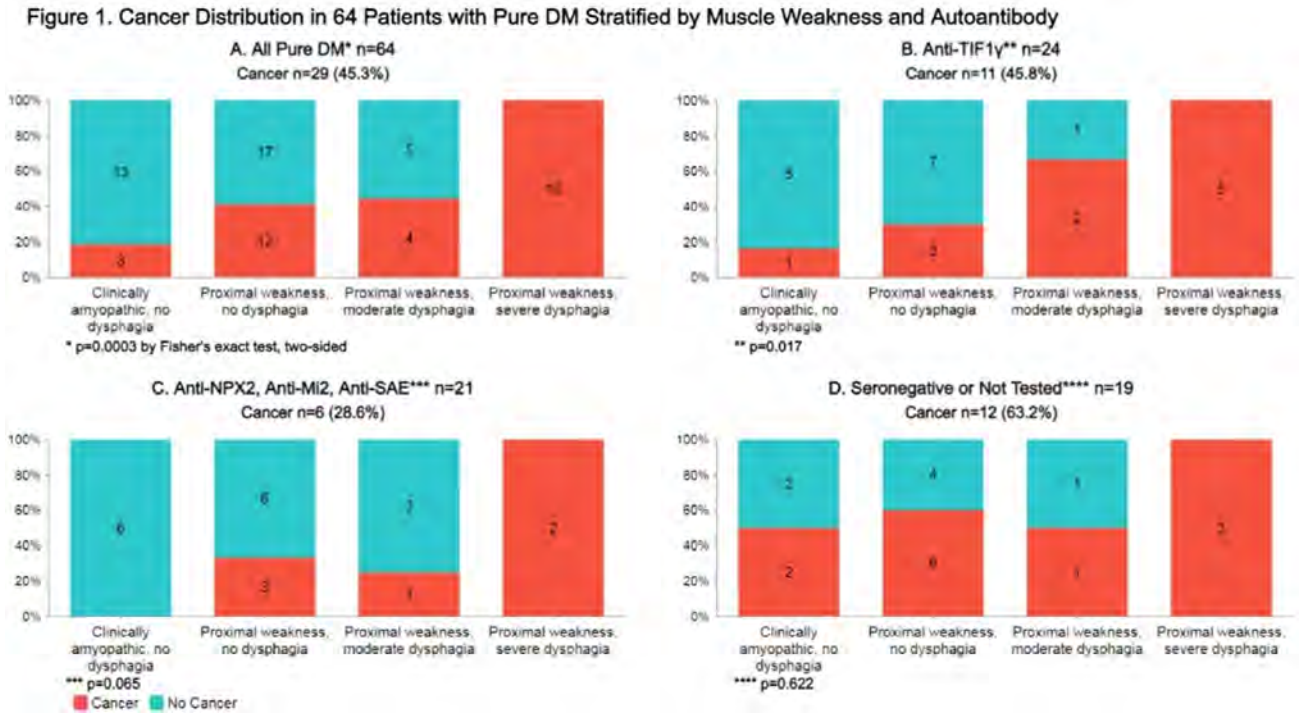
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of cancer is increased in patients with pure dermatomyositis (DM), i.e. patients with a DM rash and without an anti-MDA-5 syndrome, a suspected or confirmed anti-synthetase syndrome or scleromyositis. The aim of this study was to describe the relationship between the extent of muscle involvement and the prevalence of cancer in serologically-defined subsets of pure DM.

Methods: Patients with pure DM were selected from a retrospective cohort of incident autoimmune myositis (AIM) seen in two rheumatology academic centers between 2000 and 2021. All patients were classified by expert opinion into one of three serologically distinct groups: group 1 (anti-TIF1γ autoantibodies), group 2 (non-anti-TIF1γ autoantibodies) and group 3 (seronegative/not tested). The degree of muscle involvement was stratified in four mutually exclusive categories: clinically amyopathic (CADM), proximal muscle weakness alone, proximal muscle weakness with moderate dysphagia (no aspiration) on video fluoroscopy swallow study (VFSS) and proximal muscle weakness with severe dysphagia (by VFSS or clinical aspiration). A diagnosis of cancer within (±) three years of AIM was recorded.

Results: Of 250 patients with AIM, 64 had pure DM. Anti-TIF1γ autoantibodies were positive in 24 (37.5%) patients, anti-Mi-2 in 9 (14.1%), anti-NXP2 in 7 (10.9%) and anti-SAE in 5 (7.8%), while 9 (14.1%) patients were seronegative and 10 (15.6%) untested. Cancer occurred in 29 of 64 (45.3%) patients: 11 of 24 (45.8%) in group 1, 6 of 21 (28.6%) in group



2, and 12 of 19 (63.2%) in group 3 (Figure 1). When stratified by extent of muscle weakness, cancer was seen in 18.8% (n=3/16) of CADM, 41.4% (n=12/29) of patients with proximal muscle weakness alone, 44.4% (n=4/9) of those with moderate dysphagia and 100% (n=10/10) of patients with severe dysphagia (p=0.0003 by Fisher's Exact Test) (Figure 1, panel A). A statistically significant gradual increase in cancer frequency with incremental extent of muscle weakness was also seen in group 1 (p=0.017) (Figure 1, panel B). All 3 patients with CADM and cancer survived, whereas all 10 patients with severe dysphagia and cancer died from their cancer.

Conclusion: In pure DM, cancer prevalence within 3 years of AIM diagnosis significantly increases with increasing extent of muscle weakness. Severe oropharyngeal dysphagia combined with proximal weakness is associated with the highest prevalence of cancer and poorest prognosis. Assessing the extent of muscle involvement in pure DM may improve cancer risk stratification.

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-PM/Scl autoantibodies (Abs) are an uncommon myositis-associated autoantibody (MAA) in juvenile myositis. The clinical features and outcomes associated with anti-PM/Scl Abs in juvenile myositis are largely uncharacterized.

Characteristic	Anti-PM/Scl positive, N = 19	Anti-PM/Scl negative, N = 532	p-value
Demographics			
Female	79% (15 / 19)	70% (372 / 532)	0.4
Caucasian	79% (15 / 19)	69% (366 / 532)	0.3
Black	0% (0 / 19)	13% (70 / 532)	0.2
Hispanic	0% (0 / 19)	6.2% (33 / 532)	0.6
Asian	5.3% (1 / 19)	2.3% (12 / 532)	0.4
Other	16% (3 / 19)	9.6% (51 / 532)	0.4
Age at diagnosis (years)	11.8 (8.3, 14.2)	7.5 (5.1, 11.7)	**0.003**
Duration from diagnosis to enrollment (years)	0.3 (0.2, 3.6)	1.6 (0.5, 3.6)	0.10
Clinical Subgroups			
JDM	53% (10 / 19)	84% (447 / 532)	**0.002**
JPM	11% (2 / 19)	6.6% (35 / 532)	0.4
JCTM	37% (7 / 19)	9.4% (50 / 532)	**0.002**

Anti-NT5C1A	21% (3 / 14)	28% (98 / 356)	0.8
ANA titer	1,280 (1,040, 2,176)	320 (160, 870)	**0.006**
ANA with nucleolar pattern	92% (11 / 12)	3.4% (8 / 234)	**<0.001**

TABLE 1: Demographics and clinicoserologic subgroups of juvenile myositis patients with and without anti-PM/Scl autoantibodies. Abbreviations: ANA, antinuclear antibody; JCTM, juvenile connective tissue myositis; JDM, juvenile dermatomyositis; JPM, juvenile polymyositis; MSA, myositis-specific autoantibody; SSc, systemic sclerosis.

Methods: Patients with juvenile myositis enrolled in NIH myositis natural history studies were screened for anti-PM/Scl and other myositis Abs. Demographics, clinical manifestations, medications, and outcomes of those with and without anti-PM/Scl Abs were compared using Chi-squared, Fisher's exact test, or Wilcoxon rank-sum test. Multivariable logistic regression with adjustment for year of diagnosis and myositis autoantibodies was performed for statistically significant variables from the univariable analyses. A two-sided $p< 0.05$ was considered significant.

Results: Nineteen of 551 patients (3.4%) had anti-PM/Scl Abs by immunoprecipitation (**Table 1**). Among those with sera available for immunoblotting, 5 were positive for anti-PM/Scl-100, 1 was positive for anti-PM/Scl-75, 4 were positive for both antigens, and 3 were blot negative, likely reacting only to native protein. Patients with anti-PM/Scl Abs were older at diagnosis (11.8 vs 7.5 years, p=0.003) and more likely to have juvenile connective tissue disease myositis (37% vs 9.4%, p=0.002), frequently overlapping with systemic sclerosis (SSc) (21% vs 0.6%, $p< 0.001$). MSAs were less commonly associated with anti-PM/Scl Abs (16% vs 80%, $p< 0.001$). There was no difference in the frequency of anti-Ro52 Abs among patients with or without anti-PM/Scl Abs. ANA titer was higher (1:1280 vs 1:320, p=0.006) and a nucleolar pattern (92% vs 3.4%, $p< 0.001$) was more common among those with anti-PM/Scl Abs. Patients with anti-PM/Scl Abs had higher odds of certain clinical features (**Table 2**), including sclerodactyly (OR 22.4; 95% CI 6.74-71.5), mechanic's hands (OR 11.6; 95% CI 4.18-31.1), Raynaud's phenomenon (OR 8.11; 95% CI 3.14-21.3), and ILD (OR 7.54; 95% CI 2.19-23.9) and lower odds of malar rash (OR 0.29; 95% CI 0.11-0.73). There was also a lower odds of treatment with IV methylprednisolone (OR 0.32; 95% CI 0.10-0.91) for those with anti-PM/Scl Abs.

Characteristic	Anti-PM/Scl positive, N = 19	Anti-PM/Scl negative, N = 532	p-value	OR	95% CI
Clinical features

Mortality	11% (2 / 19)	21% (5 / 24)	0.4

TABLE 3: Comparison of demographics, clinical subgroups, myositis-associated autoantibodies, clinical features, medications received, and outcomes between juvenile myositis patients with anti-PM/Scl and anti-synthetase autoantibodies. Abbreviations: ANA, antinuclear antibody; DMARD, disease-modifying antirheumatic drug; IV, intravenous; IVIG, intravenous immunoglobulin; JCTM, juvenile connective tissue myositis; JDM, juvenile dermatomyositis; JPM, juvenile polymyositis; SSc, systemic sclerosis.

Given the similarity in clinical features to anti-synthetase syndrome, patients with anti-PM/Scl were compared to those with anti-aminoacyl tRNA synthetase (ARS) Abs (**Table 3**). Anti-ARS Abs were present in 24 (4.3%) patients, similar in frequency to anti-PM/Scl Abs. Among patients with anti-PM/Scl Abs, none was Black (0% vs 25%, p=0.027) and overlap with SSc was more common (21% vs 0%, p=0.031). Those with anti-PM/Scl Abs less often had co-occurring anti-Ro52 Abs (18% vs 64%, p=0.004) and myalgia (32% vs 78%, p=0.002). The presence of ANA with nucleolar pattern (92% vs 6.2%, p< 0.001) was more frequent in anti-PM/Scl Ab-positive patients.

Conclusion: Anti-PM/Scl Abs, unlike other MAAs, were associated with a well-defined phenotype resembling anti-synthetase syndrome. Patients with anti-PM/Scl Abs, compared to those with anti-ARS Abs, were not Black, had an ANA with nucleolar pattern, and less frequently were positive for anti-Ro52 Abs.

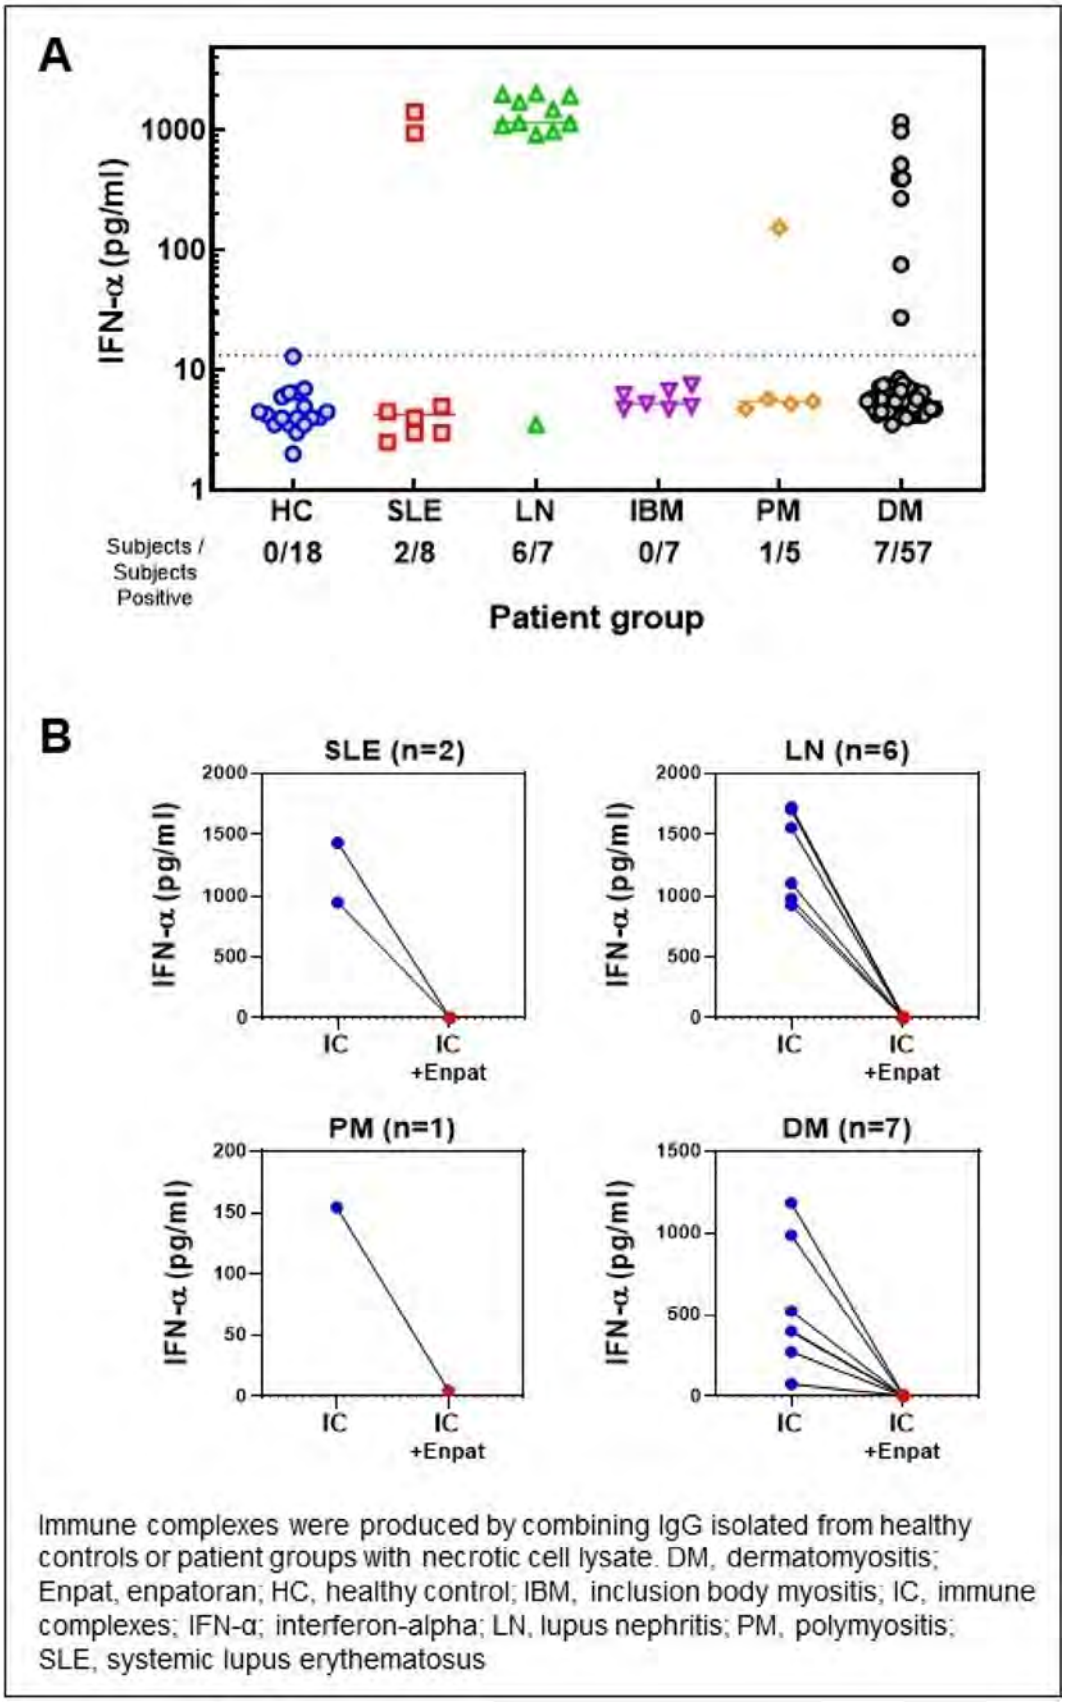
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tissue inflammation is a major disease driver in idiopathic inflammatory myopathies (IIM), leading to muscle weakness and, in the case of dermatomyositis (DM), a subtype of IIM, cutaneous manifestations. In some IIM subtypes, particularly DM, inflammation in the affected tissue is considered a major disease driver. The upstream pathways causing inflammation in IIM are poorly characterized; better understanding could lead to development of more effective treatments. Activation of endosomal toll-like receptors (TLR) is one possible driver of inflammation in IIM as hallmarks of TLR activation are observed in some patients, including high Type I interferon (IFN) and the presence of RNA-containing immune complexes. We studied the potential contribution of TLR7 and TLR8 in IIM pathogenesis.

Methods: Immune complexes from 69 patients with IIM as well as 15 lupus patients and 18 healthy controls were tested for their ability to activate healthy donor peripheral blood mononuclear cells (PBMCs) and the impact of the TLR7/8 inhibitor enpatoran on PBMC activation was evaluated in a subset of participants. Human myoblasts and satellite cells were treated with supernatants from TLR7/8-activated PBMCs and gene expression was evaluated by NanoString. Mice were dosed intramuscularly with the TLR7/8 agonist R848 and single cell RNA sequencing was run on the muscle to ascertain the cell types responding to TLR7/8 and the downstream effects.

Results: Immune complexes from patients with IIM and lupus stimulated the production of IFN-α from PBMCs and triggered significant gene expression changes, including induction of a Type I IFN-gene signature. IFN production was completely blocked by enpatoran **(Fig 1)**. DM patients, specifically those with autoantibodies targeting Jo-1, had the highest prevalence of activating immune complexes. Histidyl-transfer RNA, which is associated with the Jo-1 autoantibody, activated PBMCs in a TLR7/8-dependent manner. Myoblasts and satellite cells were activated by supernatants from TLR7/8 agonist-treated PBMCs, as determined by gene expression changes including increased expression of cytokines/chemokines and decreased expression of some muscle cell markers **(Fig 2)**. *In vivo*, monocytes/macrophages and endothelial cells in muscle were activated by R848. Both cell types produced inflammatory cytokines downstream of NF-κB and endothelial cells increased expression of adhesion molecules. There was also the appearance of an IFN-gene signature in multiple cell types.

Conclusion: TLR7/8 activation can lead to inflammation in muscle with deleterious effects. RNA in immune complexes from patients with IIM, particularly Jo-1-positive DM patients, may activate TLR7/8. These data suggest that enpatoran may reduce inflammation in myositis that is triggered by TLR7/8 activation.



Immune complexes were produced by combining IgG isolated from healthy controls or patient groups with necrotic cell lysate. DM, dermatomyositis; Enpat, enpatoran; HC, healthy control; IBM, inclusion body myositis; IC, immune complexes; IFN-α; interferon-alpha; LN, lupus nephritis; PM, polymyositis; SLE, systemic lupus erythematosus

Figure 1. Patient-derived immune complexes can induce IFN-α (A) downstream of TLR7/8 (B)

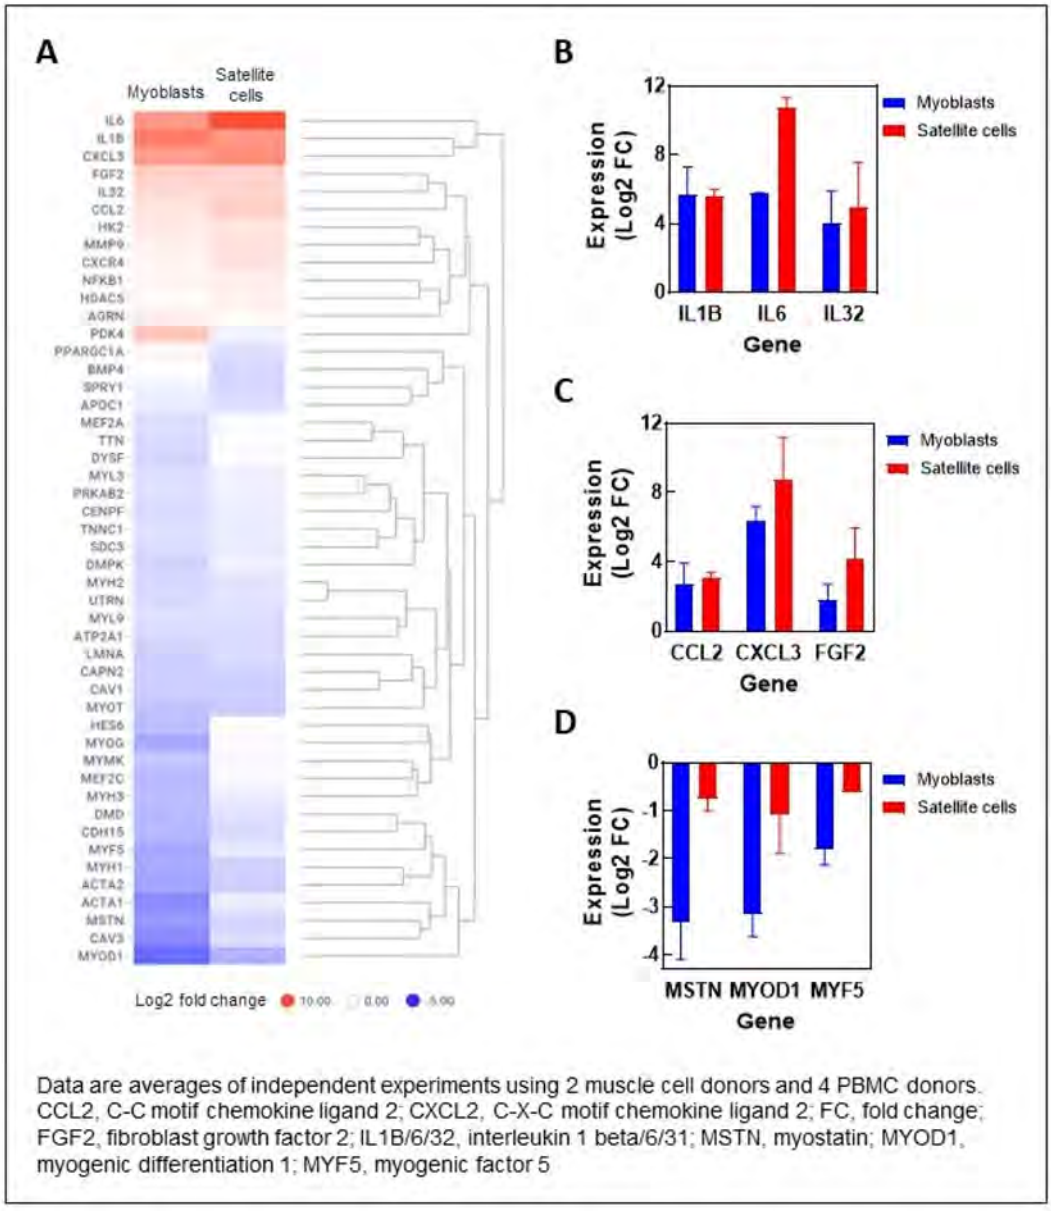


Figure 2. Myoblasts and satellite cells stimulated with supernatants from R848-activated PBMCs increase expression of muscle cell activating factors and cytokines (A, heatmap shows fold change vs control muscle cells; B, expression of selected genes shown)

Effect of JAK-STAT Inhibition by Baricitinib and Tofacitinib on Disease Phenotype in a Mouse Model of Myositis

Rita Spathis, Sabrina Narvesen, Deeva Robles Kuriplach, Karen Huang, Teja Sundar, Daniel Shulman, Elizabeth Bagley, Kanneboyina Nagaraju and Melissa Morales, Binghamton University, Johnson City, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dysregulation of the interferon (IFN) pathway plays a major role in the pathophysiology of autoimmune myositis. Upregulation of type 1 IFN stimulated genes (an IFN 'signature') is present in myositis patients and this signature is related to disease severity. The JAK family of tyrosine kinases, which mediate interferon signaling through the signal transducer and activators of transcription (STAT), have thus become therapeutic targets for treating myositis as well as other autoimmune diseases. Therefore, we investigated the effects of two JAK-STAT inhibitors, baricitinib and tofacitinib, on development of the disease process in the major histocompatibility complex (MHC) class I transgenic mouse model, which exhibits features very similar to human myositis, including an upregulation of type 1 IFN stimulated genes.

Methods: Myositis was induced in 21-day old female mice by removal of doxycycline. Mice were randomized into 4 groups (n=12/group); myositis no treatment, myositis + baricitinib, myositis + tofacitinib, and control. Baricitinib and tofacitinib were administered daily as a cherry syrup oral suspension at 10 mg/kg and 20 mg/kg body weight respectively for six weeks. Treatment groups were evaluated based on survival time, body weight, muscle strength and function (GSM, *in vitro* torque and treadmill exhaustion), histologic disease severity and expression levels of the type 1 IFN stimulated genes (ISG) Mx1, IFIT1, IRF7, and ISG15. Data were collected in a blinded fashion.

Results: Myositis mice had significantly reduced weight gain, muscle function and strength, and inflammation in the quadricep muscle compared to controls. Tofacitinib treatment resulted in significant improvement in survival of myositis mice, with 55% surviving to the end of the study compared to 27% for the myositis and baricitinib treatment groups. Expression levels of the type 1 interferon genes Mx1, IFIT1, IRF7, and ISG15, which were significantly elevated in myositis mice, were noticeably decreased in skeletal muscle of both baricitinib and tofacitinib treated mice. However, significant reductions in IFIT1 ($p = 0.03$) and IRF7 ($p = 0.04$) expression were observed only in the tofacitinib treated group. Neither tofacitinib nor baricitinib treatment resulted in significant functional improvement.

Conclusion: Overall, we observed that treatment with tofacitinib significantly improved survival and lowered the IFN signature, but this did not translate to functional improvement. Furthermore, baricitinib did not significantly improve any of the measures tested.While both tofacitinib and baricitinib interfere with the JAK1 pathway, tofacitinib additionally interferes with the JAK3 pathway which is involved in signal transduction of the γc family of cytokines. This difference could explain the increased efficacy of tofacitinib in this study.

Penn State Registry of Inflammatory Myopathies (PRIMO) Provides Insights into Disease Features and Co-Morbidity Screening Utilization

Jacob Colello[1], Kirsten Riggle[1], Galen Foulke[2], Peri Newman[1], Jamie Carter[1] and Nancy Olsen[1], [1]TE-Penn State MS Hershey Medical Center, Hershey, PA, [2]Penn State MS Hershey Medical Center, Hershey, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is a relatively rare condition with significant morbidity and mortality across the lifespan.Recent advances in diagnostics and therapeutics have significant potential to improve outcomes.We set up the Penn State Registry of Inflammatory Myopathies (PRIMO) and sought to understand the current status of DM patients seen in the relatively rural population of south-central Pennsylvania.Objectives are to determine whether our patients have had access to optimal care and to explore approaches to improving outcomes.

Methods: Records for patients seen at Hershey Medical Center with diagnosis code M33 (including all subcodes) in a 10 year period starting 1/1/2010 were extracted from the EMR.Each record was reviewed (by JC) to confirm the 2017 EULAR/ACR classification criteria for idiopathic inflammatory myopathies. Features of108 patients with DM or juvenile DM were reviewed in detail (by JC and KR) using data extraction forms and compiled in a REDCap database.Descriptive statistics were used to summarize results.

Results: Most patients (87%) had adult DM; the overall average age was 52 years (range 7 to 88 years).Other demographic features are shown (Table 1).Encounters for the first myositis-related symptoms occurred most commonly in family medicine (44%), dermatology (16.7%) and pediatrics (13.1%); only 6% had an initial myositis-related encounter in rheumatology.Common presenting symptoms were rash (94.2%) and muscle weakness (81.7%).Autoimmune comorbidities included celiac disease (14.3%) and thyroid conditions (28.4%).Familial conditions included RA (35.7%), SLE (21.4%) and Sjogren's (14.3%); no patient reported a family history of DM or polymyositis.Lab testing at presentation showed elevated muscle enzymes (CK, LDH or transaminases) in 72% and ANA positivity in 66%; 2/3 had speckled pattern.Of myositis-specific autoantibodies (MSA) measured, the most prevalent was Tif-1 gamma, positive in 15.4% of those tested (Table 2).When performed, tissue biopsies were highly diagnostic (skin:43/49 patients tested, 88% positive; muscle 38/42, 90%).Muscle MRI done in 33 individuals showed inflammation in 73% and atrophy in 9%.Prevalence of malignancy (9.6%) was relatively low; screening for malignancies was not recorded for all patients (Table 3).Other testing for comorbidities included echocardiograms, which were normal in 88% of 25 examined and HRCT which showed ILD changes in 38% of 21 tested. Less than half of individuals had PFTs completed.

Table 1: Demographic Features in 108 DM patients	
Age	52 (22) years*
Juvenile (< 18 yrs)	13%
Female	76.9%
Race: White/Black/other	78.7/6.5/14.8%
Ethnicity: Hispanic/NonHispanic/unknown	12.1/84.1/3.7%
Status: Deceased/Alive/Lost to followup	8.6/70.5/21.0%
Never smoker/Never used alcohol	77.1%/61.9%

*Mean (SD)

Table 2: Autoantibody Testing			
Autoantibody	Positive	Negative	Unknown/not done
Jo-1	6	89	9
PL-12	0	83	21
PL-7	1	83	20
EJ	1	82	21
OJ	0	82	22
SRP	2	76	26
HMGCR*	1	5	98
MDA5	6	27	71
NXP-2	5	34	65
Mi2	6	70	28
Tif-1 gamma	16	23	65
Ro/SSA	5	57	42
PM-SCl	1	48	55
Ku	1	66	37
RNP	4	55	45

*HMGR = anti-HMG Co-A Reductase

Table 3: Malignancy Screening Tests in 84 Adult DM Patients	
CT Thorax	75.0%*
CT Abdomen/Pelvis	76.2%
PET CT	11.9%
Colonoscopy	48.8%
Mammogram (females only)	51.2%
Pelvic ultrasound (females only)	29.8%

*Percent tested

Conclusion: DM outcomes may be improving in part due to improved screening for comorbidities as well as availability of new treatment options.The rate of malignancy in our patients was lower than expected, despite the high prevalence of malignancy-related autoantibodies (TIF-1g, NXP-2) among those patients with evaluation for MSA. Whether this is related to length of followup is being further investigated.Our study also demonstrates that screening for comorbidities had lower than expected utilization representing a potential practice gap.Future studies are needed to determine if this a local trend, or a population shortfall in DM management. Development of personalized medicine approaches should be prioritized.

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Disease activity assessment is key in the management of patients with idiopathic inflammatory myopathies (IIM). However, patients' perception of disease may differ from clinicians. We tried to understand what factors lead to discrepancy between patients' and physicians' perception of disease activity in IIMs from the COVID-19 Vaccination in Autoimmune Diseases (COVAD) study.

Methods: The COVAD-1 study collected global cross-sectional data from adults with autoimmune diseases and healthy controls by a team of 106 experts from 94 countries from April-December 2021, on demographics; disease characteristics, treatment and glucocorticoid (GC) dose; and validated patient reported outcomes (PROs), including PROMIS SF10 physical function, VAS-pain and VAS-fatigue. Patient-perceived active disease was self-reported. Physician-reported active disease was defined as presence of joint swelling, active rash or worsened muscle weakness and/or GC dose ≥10mg prednisolone equivalents. Discordant and concordant pairs of patient-physician reported disease activity were compared, and predictors of discordance were analysed using multivariate regression models.

Table 1. Demographics and patient reported outcome measures among the disease subgroups. 	Discordant: PA	-0.07	0.94 (0.88-0.99)	0.02
	Concordant: both active	-0.14	0.87 (0.82-0.92)	<0.001
PM[b]	Discordant: EA	-0.08	0.92 (0.84-0.99)	0.036
	Discordant: PA	-0.12	0.88 (0.82-0.95)	0.001
	Concordant: both active	-0.13	0.87 (0.82-0.94)	<0.001
ASSD[c]	Discordant: EA	-0.14	0.87(0.749-1.011)	0.07
	Discordant: PA	-0.15	1.042 (0.836-1.298)	0.009
	Concordant: both active	-0.14	1.178 (0.953-1.457)	0.011
OM[d]	Discordant: EA	-0.06	0.94 (0.85-1.05)	0.26
	Discordant: PA	-0.03	0.97 (0.89-1.05)	0.48
	Concordant: both active	-0.12	0.88 (0.82-0.96)	0.005
NAM[e]	N/D			
IBM[f]	Discordant: EA	0.07	1.07 (0.98-1.17)	0.11
	Discordant: PA	0.02	1.03 (0.97-1.08)	0.37
	Concordant: both active	0.01	1.02 (0.96-1.08)	0.59

responses. Poorest concordance was observed in inclusion body myositis (IBM), overlap myositis (OM) and necrotising autoimmune myopathy (NAM) subgroups. Among patients with DM and OM, those with higher PROMIS physical function scores (i.e. better physical function) were more likely to be concordant (DM: OR=1.03, 95% CI: 1.01-1.05, p=0.012; OM: OR=1.04, 95% CI: 1.01-1.06, p=0.012) while older patients with DM were prone to discordance (OR =0.98, 95% CI: 0.97-0.99, p=0.03) PROMIS scores varied significantly among the four groups of perceived disease activity (active or inactive by patient and/or physician) and disease subgroups except IBM (Figure 1). Pain and Fatigue VAS scores also varied significantly among the four groups. Multivariable analysis, controlling for age, gender, fatigue and pain, showed respondents with higher PROMIS physical function scores were more likely to belong to one of the active disease perception groups, compared to concordant inactive groups, for all disease subgroups except IBM (Table 2). Addition of PROMIS increased area under the curve by 8-10% in model fitting. Simple cut-off scores based on PROMIS scores could be developed to distinguish active from inactive disease.

Conclusion: Our study provides invaluable insights into the factors determining patents' perception of self-reported disease activity, and the disease groups where these measures may be less reliable for remote monitoring and virtual trials. Patient-reported assessment might be discordant in IBM while likely to be fairly concordant in DM and younger individuals irrespective of pain and fatigue.

Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-synthetase syndrome (ASS) is an idiopathic inflammatory myopathy, typically characterized from the triad interstitial lung disease (ILD), myositis and arthritis, together with anti-aminoacyl tRNA synthetase (ARS) antibodies (Ab) positivity. Recent data suggested esophageal involvement could commonly occurs, being related to a higher

risk of pulmonary complications, at first ab ingestis pneumonia, able to significantly worsen the respiratory function of ASS patients and related to a poor prognosis. Esophageal involvement can be assessed using both double-contrast conventional radiology (DCCR) and oro-pharyngeal-esophageal scintigraphy (OPES). Moreover, DCCR may show the presence of gastrointestinal (GI) pathologies, such as esophagitis, achalasia and hiatal hernia, with a prevalence in Italian population up to 33%, 0.03% and 10% respectively. The first aim of the study is to evaluate the prevalence of esophageal involvement in a monocentric cohort of patients with ASS; secondly, we aimed at comparing DCCR and OPES in highlighting swallowing dysfunctions or GI comorbidities.

Methods: We retrospectively analyzed medical records of consecutive patients with a diagnosis of ASS based on both physicians' clinical diagnosis and ARS Ab positivity, regularly followed at our Myositis Clinic from January 2018 to May 2023. Demographic and clinical data of patients, together with DCCR and OPES results were collected; moreover, patients were asked to fill in MD Anderson Dysphagia Inventory (MDADI) to evaluate their dysphagia. Intergroups comparisons were assessed by using Chi-square, t-test and ANOVA. P values < 0.05 were considered significant.

Results: We included 37 patients (21 female, 56.8%) with a mean age of 56.3±7.9 years; 12 (32.5%) reported dysphagia and, on 31 (83.7%) who filled in MDADI, 9 (29%) showed scores corresponding to a swallowing disability, significantly associated to subjective dysphagia ($p< 0.001$). Twenty patients (54.1%) performed OPES; up to 5/20 (25%) showed an increased esophageal (E) transit time (TT), oropharyngeal (OP) retention index (RI) was increased in up to 17/20 patients (85%) and E RI was increased in up to 12/20 patients (60%). DCCR was performed in 14 patients (37.8%); hypotone and hypokinesis were found in 7/14 (50%); besides, DCCR highlighted the presence of achalasia, esophagitis and hiatal hernia respectively in 7 (50%), 10 and 10 (71.4%) patients.

Conclusion: Less than one third of ASS patients perceive to have dysphagia; however, up to 85% of those who underwent OPES and up to 50% of those who performed DCCR showed a significant swallowing dysfunction. Moreover, DCCR showed a significantly higher prevalence of GI comorbidities in ASS patients than in the general population. This is the first study at our knowledge analyzing the prevalence of esophageal involvement in ASS, through 2 different methods and in comparison with patients' perception of dysphagia. Further studies are needed to confirm our data, but they already could suggest to investigate GI involvement and GI comorbidities in ASS, even in asymptomatic patients, with the aim of optimizing their quality of care, also reducing the risk of respiratory complications related to dysphagia.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Over the last few decades, it has been established that multiple infections can mimic idiopathic inflammatory myopathies (IIM). HIV, HTLV-1, and Lyme disease are all associated with chronic, progressive myopathies indistinguishable from IIM. While the similarities between IIM and these infectious myopathies have been reported, differences in disease course or treatment outcomes in this population with co-existing IIM and infectious myopathies has not been evaluated. Our aim was to compare the spectrum of organ involvement and treatment response in IIM patients with infections at risk for comorbid infectious myopathies in comparison to IIM patients without infections which may contribute to myositis.

Methods: A registry was created of Montefiore Medical Center patients that met 2017 EULAR/ACR classification criteria for IIM that included patient demographics, IIM subtype, clinical manifestations by organ system, comorbidities, and treatment history. Medication failure was defined by rheumatologist, discontinuation due to adverse effects, or medication change within 3 months. Medication control was defined by documented clinical improvement. Lyme and HTLV-1 statuses were based on confirmatory western blot testing and HIV status was confirmed by viral load. If these variables were positive, diagnosis date was also recorded. Statistical analysis was carried out with paired t-tests and signed rank tests. All p values < 0.05 were considered significant.

Results: Of our cohort of 153 IIM patients, 2 patients were found to have HIV, 9 were HTLV-1 positive, and one met criteria for active Lyme disease. Given the small number of patients with possible infectious myopathies, these were analyzed together in one group. Comparison of the IIM patients with infections and IIM patients without infectious comorbidities, we found a similar distribution of age, sex, Latinx ethnicity, and race between the two groups as shown in Table 1. When comparing IIM subtypes between the two groups, we found dermatomyositis was found more frequently in the non-infectious cohort ($p = 0.01$) and inclusion body myositis (IBM) was found more frequently in the infectious cohort ($p = 0.03$) (Table 1). There were no differences in cutaneous, gastrointestinal, or pulmonary manifestations between the two groups (Table 2). The rates of neoplasm and venous thrombosis complications were also comparable. There was no difference in steroid

Table 1: Comparison of IIM patient demographics based on presence of infectious disease.

Demographics	IIM Patient Group		P-value
	Infection (+) (n = 12)	Infection (-) (n = 141)	
Age at IIM, mean (SD)	47.89 (12.53)	52.07 (14.14)	0.34
Sex, n (%)			0.18
Female	7 (58.3)	107 (75.9)	
Male	5 (41.7)	34 (24.1)	
Latinx, n (%)			0.74
Yes	4 (33.3)	58 (41.1)	
No	8 (66.7)	77 (54.6)	
Unknown	0 (0)	6 (4.3)	
Race, n (%)			0.64
American Indian	0 (0)	2 (1.4)	
Asian	0 (0)	6 (4.3)	
Black	8 (66.7)	62 (44.0)	
White	2 (16.7)	44 (31.2)	
Unknown	2 (16.7)	27 (19.2)	
IIM Subtype, n (%)			
Polymyositis	4 (33.3)	41 (29.1)	0.75
Dermatomyositis	2 (16.7)	79 (56.0)	**0.01**
Amyopathic Dermatomyositis	2 (16.7)	9 (6.4)	0.21
Mixed Connective Tissue Disease	0 (0)	15 (10.6)	0.61
Immune-Mediated Necrotizing Myopathy	0 (0)	20 (14.2)	0.37
Inclusion Body Myositis	4 (33.3)	13 (9.2)	**0.03**

Table 2: Comparison of clinical Characteristics between IIM patients with and without infections associated with myositis.

Clinical Characteristics	IIM Patient Group		P-value
	Infection (+) (n = 12)	Infection (-) (n = 141)	
Heliotrope rash, n (%)			0.21
No	10 (83.3)	86 (61.0)	
Yes	2 (16.7)	55 (39.0)	
Grotton's papules or sign, n (%)			0.37
No	9 (75.0)	84 (59.6)	
Yes	3 (25.0)	57 (40.4)	
Dysphagia, n (%)			0.70
No	7 (58.3)	74 (52.5)	
Yes	5 (41.7)	67 (47.5)	
Interstitial lung disease, n (%)			0.76
No	8 (66.7)	83 (58.9)	
Yes	4 (33.3)	58 (41.1)	
Neoplasm, n (%)			1.00
