2.48–4.85) and lower in JAKi-treated patients (aHR, 0.65; 95% CI, 0.44–0.96). Other significant predictors for 5-year mortality included male gender (aHR, 1.90; 95% CI, 1.61–2.24), age (aHR, 1.08; 95% CI, 1.07–1.09), low income (aHR, 1.47; 95% CI, 1.21–1.78), comorbidities within one year before the index date (heart failure: aHR, 1.72; 95% CI, 1.14–2.59; diabetes mellitus: aHR, 1.50; 95% CI, 1.22–1.84; chronic obstructive pulmonary disease: aHR, 1.29; 95% CI, 1.02–1.63; renal disease: aHR, 1.38; 95% CI, 1.02–1.85), a history of sepsis within prior one year (aHR, 2.61; 95% CI, 1.73–3.92), and use of medications within prior one year (methotrexate: aHR, 0.65; 95% CI, 0.51–0.83; prednisolone dose > 5mg/day: aHR, 1.89; 95% CI, 1.33–2.70). Table 1 showed the top 4 causes of death in all and each group of b/tsDMARD-treated patients.

Conclusion: This study showed that among patients with RA initiating b/tsDMARDs, the 5-year mortality risk was higher in rituximab-treated patients and lower in tsDMARD-treated patients compared with TNFi-treated patients.

Assessing the Value of Comorbidity Clusters in Predicting Clinical Outcomes in Rheumatoid Arthritis: A Machine Learning Approach Using a Very Large US Registry

Daniel Solomon[1], Fredrik Johansson[2], Hongshu Guan[3], Leah Santacroce[4], Lin Guo[5], Wendi Malley[5] and Heather Litman[5], [1]Brigham and Women's Hospital, Newton, MA, [2]Chalmers University of Technology, Goteborg, Sweden, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital, Boston, MA, [5]CorEvitas, LLC, Waltham, MA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Comorbid conditions are very common in rheumatoid arthritis (RA) and several prior studies have derived comorbidity clusters using machine learning (ML). Clustering using ML is straightforward, but clusters only have value if they better explain clinical outcomes. We applied various ML algorithms to compare the clusters of comorbidities derived and to assess the value of the clusters for predicting clinical disease activity (CDAI) and function.

Methods: A large US-based RA registry, CorEvitas, was used to identify patients for the analysis. We assessed the presence of 24 comorbidities, and ML was used to derive comorbidity clusters. K-mode, K-mean, regression-based, and hierarchical clustering was used. To assess the value of the clusters, we compared them in clinical outcome models predicting clinical disease activity index (CDAI) and health assessment questionnaire (HAQ). We used data from the first three years of the six-year study period to derive clusters and assess time-averaged values for CDAI and HAQ during the latter three years. Model fit was assessed via adjusted R^2 and Root Mean Square Error for a series of models that included clusters from K-mode and each of the 24 comorbidities separately. K-mode was selected as it was representative of the ML-based clustering algorithms.

Results: 11,883 patients with RA were included who had longitudinal data over 6 years. At baseline, patients were on average 59 (SD 8) years of age, 77% were women, CDAI was 11.1 (SD 3.4, moderate disease activity), HAQ was 0.32 (SD 0.11), and disease duration was 10.9 (SD 4.3) years. During the six years of follow-up, the percentage of patients with various comorbidities increased (**Table 1**). Using five clusters produced by the K-mode ML algorithm, multivariable regression models with time-averaged CDAI as an outcome found that entering K-mode comorbidity clusters produced similarly strong models as models with each of the 24 separate comorbidities entered individually (**Table 2**). The same patterns were observed for HAQ (**Table3**). The other ML-based clustering algorithms produced very similar model results.

Table 1: Comorbidities Among 11,833 Patients with Rheumatoid Arthritis from the CorEvitas Registry Included in the Analyses, at Baseline and During Follow-Up.

	Baseline	Year 2	Year 4	Year 6
	Percentages			
Coronary artery disease	7.1	9.6	11.1	12.7
Heart failure	0.9	1.4	2.0	2.8
Hypertension	36.4	51.8	56.4	60.4
DVT/PE	1.7	2.1	2.4	2.9
Stroke/TIA	2.2	2.9	3.9	4.8
Arrhythmia	0.4	0.5	0.6	0.9

Root Mean Square Error	0.22	0.22	0.22

Conclusion: Clustering comorbidities using ML algorithms is not computationally complex but often results in clusters that are difficult to interpret from a clinical standpoint. While ML clustering is very useful for biologic modeling, using clusters to predict outcomes produces models with similar fit as those with individual comorbidities. Other use cases for comorbidity clusters might help demonstrate underlying biology.

Abstract Number: 0986

Medication Use Patterns and Factors Associated with Abnormal Pregnancy Outcomes in Patients with Rheumatoid Arthritis in Korea

Yeo-Jin Song[1], Soo-Kyung Cho[1], Yu-Seon Jung[2], Jihyun Keum[3], Sun-Young Jung[2], Dae Hyun Yoo[4] and Yoon-Kyoung Sung[1], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]College of Pharmacy, Chung-Ang University, Seoul, South Korea, [3]Department of Obstetrics and Gynecology, College of Medicine, Hanyang University, Seoul, South Korea, [4]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

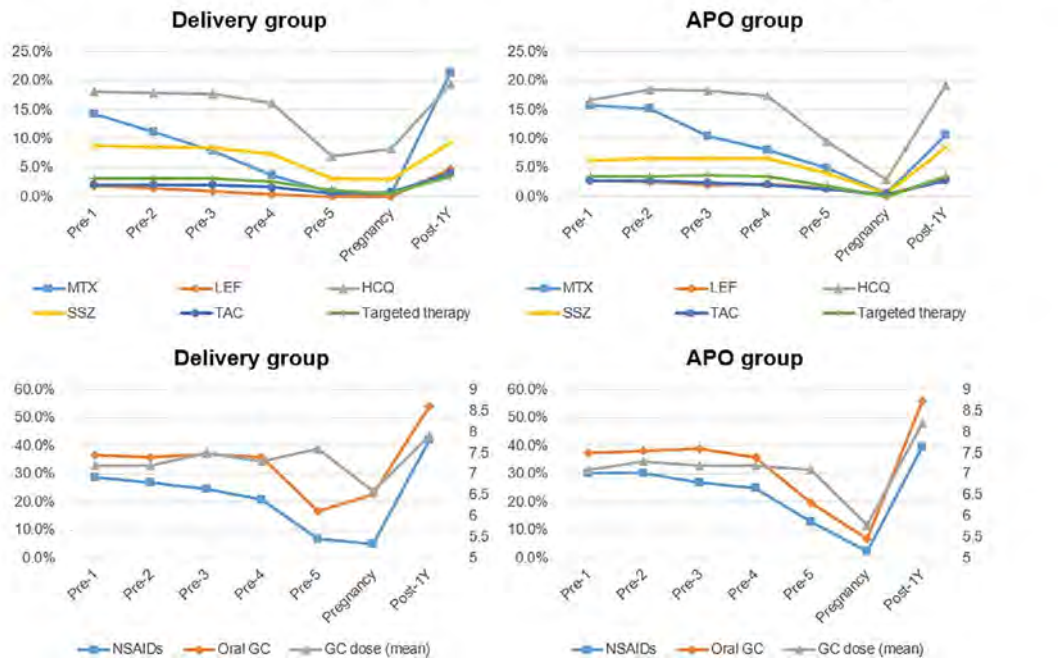
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: As female patients constitute a significant proportion of rheumatoid arthritis (RA) cases, pregnancy management is crucial for women with RA. This study aimed to investigate medication use patterns according to pregnancy outcomes and identify factors associated with abnormal pregnancy outcomes (APO) in female RA patients in Korea.

Methods: Using the Korean national health insurance database, female RA patients aged between 20 and 50 were identified based on the presence of both RA diagnostic codes and prescriptions for any disease-modifying anti-rheumatic drug (DMARD). Pregnancy episodes were selected using diagnostic or procedure codes and divided into two groups: the delivery group and the APO group (including abortion and stillbirth). Characteristics were compared between the two groups, and medication use patterns were analyzed during the preconception period, pregnancy, and one year after delivery. A multivariable logistic regression analysis was conducted to identify factors associated with APO.

Results: A total of 5,728 pregnancy episodes were included, with 4,576 in the delivery group and 1,152 in the APO group. The mean maternal age for all pregnancy episodes was 33.7 years, which was higher in the APO group. Comorbidities such as chronic pulmonary disease and diabetes mellitus were more frequent in the APO group. Hydroxychloroquine was the most commonly used conventional synthetic DMARD during the preconception period and pregnancy in both groups. Except for sulfasalazine and targeted therapies, all DMARDs were more frequently used in the APO group during the preconception period. Methotrexate and leflunomide prescriptions during pregnancy were nearly nonexistent in the delivery group. Within one year after delivery or termination of pregnancy, there was a rapid increase in the use of all DMARDs and oral glucocorticoids. In the multivariable analysis, patients aged 30-39 (adjusted odds ratio [aOR] 1.36, 95% confidence interval [CI] 1.09-1.68) and 40-49 (aOR 5.41, 95% CI 4.21-6.95) had a higher risk of APO compared to those aged 20-29. Methotrexate use (aOR 2.19, 95% CI 1.60-2.99) and leflunomide use (aOR 2.87, 95% CI 1.49-5.54) within three months before conception were associated with APO. Hospital visits for RA during pregnancy were associated with a lower risk of APO (aOR 0.67, 95% CI 0.55-0.82).

Figure. Pattern of medication use according to pregnancy outcome



GC doses are presented as prednisolone-equivalent dose (mg). APO, abnormal pregnancy outcome; MTX, methotrexate; LEF, leflunomide; HCQ, hydroxychloroquine; SSZ, sulfasalazine; TAC, tacrolimus; NSAID, nonsteroidal anti-inflammatory drug; GC, glucocorticoid. (Pre-1: from 12 months to 9 months before conception, Pre-2: from 9 months to 6 months before conception, Pre-3: from 6 months to 3 months before conception, Pre-4: during 3 months before conception, Pre-5: from conception to pregnancy recognization, Pregnancy: during pregnancy, Post-1Y: during 1 year after pregnancy outcome)

Conclusion: Medication use patterns differed between the delivery and APO groups. Methotrexate and leflunomide were associated with a higher risk of APO, emphasizing the importance of appropriate medication adjustment when planning for pregnancy. Regular hospital visits for RA treatment during pregnancy are also crucial in reducing the risk of APO.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Genetic, demographic, clinical, and immunological factors have been related with the response to treatment in inflammatory rheumatic diseases, such as rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Among them, obesity and smoking are two potentially modifiable risk factors. Obesity has been associated with persistent activity of the disease and a lower response to TNF inhibitors. Active smoking is associated with disease severity and lower response to conventional treatment. The aim of this study is to evaluate the association of baseline characteristics, particularly obesity, smoking and disease activity in patients with RA and psoriatic PsA using data from the Mexican Adverse Events Registry (BIOBADAMEX).

Methods: In this case-control study from an inception cohort from BIOBADAMEX we included all patients with RA and PsA diagnosis registered from 2016 to April 2023. We compared the clinical characteristics between RA and PsA. Patients were divided in 2 groups: those with remission/low disease activity and those with moderate/high disease activity, patients without disease activity registered were excluded. Sociodemographic, clinical, and treatment characteristics were compared between groups. Chi square and Mann Whitney U tests to analyze differences between the groups. Multivariate model was used to analyze disease activity associated variables.

Table 1: Basal characteristics of RA an PsA patients from BIOBADAMEX

	Patients with rheumatoid arthritis (n = 748)	Patients with psoriatic arthritis (n = 70)	p
Gender, female n(%)	687 (91.8)	38 (54.3)	0.3

Results: A total of 818 patients were included, 748 with RA and 70 with PsA. When comparing both groups, we found that PsA patients had higher BMI (29.4 vs 26.7, p = 0.001), lower disease duration (9.7 vs 14.2, p = 0.001) and lower use of steroids (17.1 vs 39.6, p = 0.001). Variables like gender, age, smoking, disease activity, comorbidities were similar (Table 1). When we compared RA patients with remission/low activity and moderate/high activity (Table 2), we found that moderate/high activity patients had lower smoking habit (6.1 vs 9.4, p = 0.007), lower disease duration (13.2 vs 16.1, p = 0.002), and lower use of previous biologic (36.1 vs 62.3, p = 0.001). Comparison between PsA patients with remission/low activity and moderate/high activity (Table 3) showed lower smoking frequency in moderate/high activity (5.3 vs 28, p = 0.03). For the adjusted multivariable analysis, we included age, sex, BMI, smoking, disease duration and previous use of biologic therapy. In RA patients we found that longer disease duration (p = 0.03) and previous use of biologic (p = 0.001) were associated with lower risk of disease activity. In PsA patients we found that smoking habit (p = 0.007) was associated with lower risk of disease activity.

Conclusion: In Mexican RA and PsA patients enrolled in BIOBADAMEX, we found that most of the patients have BMI >25. However, higher BMI did not show an association with disease activity. Further studies comparing BMI levels and activity, as well as comparing Mexican BMI with other regions will be conducted. On the other hand, we found that smoking was associated with lower disease activity, especially in PsA patients. This finding correlates with the Choi HK study where smokers had slower radiographic progression. This finding needs further investigation.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The approach to elderly patients (≥60 years) with rheumatic diseases offers certain difficulties and uncertainties. Older adults are a particularly vulnerable group who often have multimorbidity and polypharmacy. In addition, geriatric syndromes, such as malnutrition, sarcopenia, and frailty, significantly affect the quality of life, which is already compromised by rheumatic diseases. Furthermore, the use of antirheumatic drugs (synthetic or biological) in this group of patients is a major concern due to their potential adverse events. The aim of this study is to Determine if drug discontinuation of bDMARDs differs in elderly patients compared to younger patients with rheumatic diseases registered in the Mexican Adverse Events Registry (BIOBADAMEX).

Methods: In this case-control study from an inception cohort from BIOBADAMEX we included all patients registered from 2016 to April 2023 with at least two assessments. We divided the patients in 2 groups: younger than 60 years and older than 60 years. Survival on similar or originator bDMARDs was estimated using Kaplan-Meier analysis. Predictors of discontinuation, including use of biosimilar drugs were investigated by Cox regression analysis.

Results: Among 1041 patients in the registry, 630 had at least two assessments. Of patients analyzed, 128 (20.3%) were older than 60 years old and 512 (81.3%) were women. The most common diagnoses were RA in 407 (64.6%), ankylosing spondylitis in 83 (13.2%) patients and psoriatic arthritis in 44 (6.9%). At baseline, patients had a median (IQR) age of 50.5 (40.1-58.1) years old, median disease duration of 6.9 (2.7-13.9) years. The most common bDMARDs received were adalimumab 122 (19.4%), certolizumab 96 (15.2), tocilizumab 95 (15.1), abatacept 82 (13.0) and rituximab 67 (10.6). At the time of analysis, the median bDMARDs treatment duration was 58.8(38.6-70.7) months, 264 (41.9%) had discontinued treatment, 135 for inefficacy, 108 for adverse events and 21 for others. Fig 1 shows discontinuation rate curves in patients younger and older than 60 years old.Cox proportional-hazards demonstrated no significant differences regarding age older than 60 years old (HR 1.0, 95% CI 0.8-1.2, p=0.7), age as continuous variable (HR 0.9, 95% CI 0.9-1.0, p=0.07), use of corticosteroids (HR 1.2, 95% CI 0.9-1.4, p=0.05) or comorbidities (HR 0.9, 95% 0.6-1.5, p=0.78). To have a disease duration shorter than the median (≤6.9 years) (HR 1.2, 1.1-1.4 p=0.03), history of an adverse event (HR 2.4, 1.1-4.8, p=0.02) and high disease activity (HR 1.5,95%CI 1.2-1.7, p< 0.001) were characteristics associated with discontinuation. In the multivariable Cox regression analysis history of adverse event and high disease activity were the only variables that remained associated.

Conclusion: This analysis did not show a role of elderly age on discontinuation of bDMARDs in Mexican patients with rheumatic diseases. Survival analysis showed that in our population high disease activity and history of adverse events are associated with the discontinuation of bDMARDs.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Migraine is the second most prevalent neurologic disorder and is known to be associated with neurogenic inflammation. Previous studies suggest an association between migraine and chronic inflammatory rheumatic diseases. However, the relationship between rheumatoid arthritis (RA) and migraine has yet to be determined. This study aimed to evaluate the association between RA and subsequent migraine risk specifically in the Korean population.

Methods: This was a retrospective cohort study using the Korean National Health Insurance Service database. Participants were enrolled from 2010 to 2017 and followed up until 2019 (median follow up 4.4 years after a 1-year lag period). RA was defined using ICD-10 codes, prescription of any disease modifying anti-rheumatic drug, and enrollment in the Rare and Intractable Disease program. A total of 42,674 patients who had undergone a health checkup within 2 years prior to the initial diagnosis of RA were included in the study, after applying the exclusion criteria (previous migraine, other rheumatic disease, missing variables that were of interest). Among them, there were 29,744 patients with seropositive RA (SPRA) and 12,900 patients with seronegative RA (SNRA). A non-RA control was obtained by age- and sex- matching (1:5), resulting in the inclusion of 213,370 non-RA participants as controls. Primary outcome was the occurrence of incident migraine, defined using the ICD-10 code of migraine (G43) in the claim database. Cox proportional hazards regression analyses and Kaplan Meier curve were used for analysis.

Results: A total of 22,294 migraine cases (17,912 control and 4,382 RA) had developed. RA participants had a 1.2-fold higher risk of migraine compared with controls (adjusted hazard ratio [aHR] 1.2, 95% confidence interval [CI] 1.17-1.26). Increased risk of migraine was found in both patients with SNRA and SPRA compared with controls (aHR 1.20, CI 1.15-1.24 in SPRA; aHR 1.26, CI 1.20-1.33 in SNRA). Compared to the SNRA group, those with SPRA did not demonstrate

a heightened risk (aHR 0.94, CI 0.88-1.01). The association between RA and incident migraine was statistically significant in males (aHR 1.3 in male, 1.2 in female, p for interaction 0.04), current smokers (aHR 1.35 in current smoker, 1.31 in ex-smoker, 1.2 in never smoker, p for interaction 0.02), those with diabetes mellitus (aHR 1.33 in DM, 1.2 in non-DM, p for interaction 0.04,) and those with hyperlipidemia (aHR 1.31 in hyperlipidemia, 1.17 in non-hyperlipidemia, P for interaction 0.002).

Conclusion: RA was associated with increased risk of migraine. There was no difference in the risk of developing migraine based on seropositivity for rheumatoid arthritis.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Infections are a major contributor to morbidity and mortality in patients (pts) with rheumatoid arthritis (RA). Little is known about the risk of non-serious infections, however, which are much more common than serious infections. This study aimed to use baseline data from an ongoing longitudinal study to identify factors associated with both serious infection in the past year and recent non-serious infection.

Methods: Pts with RA from a national rheumatology community practice-based research network, the Excellence Network in RheumatoloGY (ENRGY), were remotely recruited July 2022 to May 2023 to join a prospective 6-month study. Results of baseline surveys are reported, with longitudinal data collection ongoing. Interested pts were asked to join the ArthritisPower research registry to complete monthly assessments about their physical, mental, and social health, physical function, infections, and medication use. At baseline, pts reported recent antibiotic use in the preceding 3 months and hospitalization due to infection in the preceding year, as proxies for non-serious and serious infection, respectively. We hypothesized that older age, glucocorticoid use, DMARD type, comorbidities, and measures of more severe disease would be associated with greater frequency of both serious and non-serious infection.

Results: At time of analysis, 307 pts with RA completed the baseline assessments. The mean (SD) age was 59 (14), 84% female, 86% non-Hispanic white (Table 1). TNF inhibitors were used by 47% of pts and 23% of pts were taking glucocorticoids, most commonly at doses ≤5 mg/day. Thirty-one pts (10%) reported permanently stopping RA medication in the past because of an infection. A total of 85 pts (28%) reported antibiotic use in the preceding 3 months and 17 (6%) reported

‡ PROMIS measures are T scores with range 1-100, general US population mean 50 with standard deviation of 10

^ Patient Global Assessment of disease activity score range from 0 to 10 with higher scores indicating more severe disease activity

ϕ Patient reported flare in past 30 days

hospitalization for infection in the preceding year (Table 2). Antibiotic use was associated with current glucocorticoids [OR 2.2 (95% CI, 1.2, 3.8)], recent RA disease flare [2.0 (1.2, 3.3)], worse PROMIS physical function < 40 [OR 2.5 (1.5, 4.1)], worse patient global ≥4 [1.9 (1.1, 3.2)], and asthma/COPD [OR 2.1 (1.2, 3.7)]. These factors were similarly associated with hospitalization although differences were not statistically significant (Table 2). Associations between DMARD type and both outcomes were modest and not statistically significant (Table 2).

Conclusion: Patients with RA with glucocorticoid use, recent disease flares, and poorer physical function and disease severity measures were more likely to report recent antibiotic use in the preceding 3 months and hospitalization in the past year. Both disease activity and treatment, particularly glucocorticoids, may affect both risk of serious infections and more common non-serious infections. Infections also influence treatment decisions, however, and pts not infrequently reported stopping medications because of infections. Accounting for disease activity and the potential that certain medications may

Trends in Arthroplasty Utilization for Inflammatory Arthritis Including Rheumatoid Arthritis and Spondyloarthritis in China: Analysis of a Large National Database

Dongxing Xie[1], Qiao Jiang[2], Yuqing Wang[2], Huizhong Long[2], Hu Chen[3], Jie Wei[4], Xiaoxiao Li[5], Haibo Wang[6], Chao Zeng[7] and Guanghua Lei[7], [1]Xiangya Hospital, Central South University, Changsha, China, [2]Xiangya Hospital, Changsha, China, [3]Tibet Autonomous Region People's Hospital, Lhasa, China, [4]Health Management Center, Xiangya Hospital Central South University, Changsha, China, [5]Key Laboratory of Aging-related Bone and Joint Diseases Prevention and Treatment, Ministry of Education, Xiangya Hospital, Central South University, Changsha, China, [6]China Standard Medical Information Research Center, Shenzhen, China, [7]Department of Orthopaedics, Xiangya Hospital, Central South University, Changsha, China

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Epidemiology & Public Health Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: For end-stage inflammatory arthritis (IA) including rheumatoid arthritis (RA) and spondyloarthritis (SpA), joint arthroplasty is the only treatment option, but is considered to be a failure of medical treatment. Country-level socioeconomic factors play an important role in treatment options and long-term outcomes of IA. Though trends in arthroplasty utilization for RA and SpA have been well-studied in high-income countries, the data are still scarce in low- or middle-income countries. Understanding the trends in arthroplasty utilization in low- or intermediate-income countries would add epidemiological data on this topic and have important implications for health policy in these countries. Using the Chinese national inpatient database (i.e., the Hospital Quality Monitoring System), we aimed to examine trends in arthroplasty utilization among patients with RA, SpA, and a composite group of the IA, compared with these trends among those without IA.

Methods: Patients receiving elective primary total knee arthroplasty and total hip arthroplasty for IA or non-inflammatory conditions between 2013 and 2019 were included. The International Classification of Diseases, Tenth Revision codes were used to identify RA and SpA. Comparisons between groups were performed using the Student's t-test for continuous

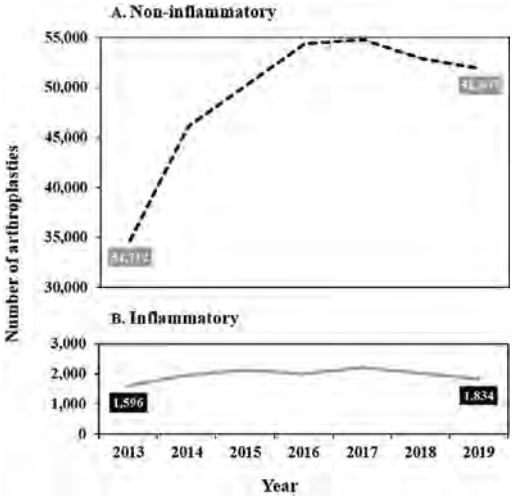

Figure 1. Trends in the number of arthroplasties in the non-inflammatory group (A) and the IA group (B).

variables and chi-square test for categorical variables. A generalized estimating equation model was used to examine trends over time.

Results: Of 358,891 arthroplasties performed between 2013 and 2019, 3.8% (13,747) were performed for IA **(Table 1)**. From 2013 to 2019, the number of arthroplasties for IA slightly increased from 1,596 to 1,834 (average yearly increase rate, 2.0%), and the number of arthroplasties for non-inflammatory conditions significantly increased from 34,712 to 51,907 (average yearly increase rate, 5.9%) ($P < 0.001$) **(Figure 1)**. The proportion of arthroplasty for IA declined from 4.4% to 3.4%. In the IA group, the mean age at arthroplasty increased from 55.8 years to 59.5 years ($P < 0.001$), and a similar result was also found in the non-inflammatory group. The number of arthroplasties for RA increased from 1,366 to 1,701 (average yearly increase rate, 3.2%) ($P < 0.001$). This contrasted with the findings of SpA (average yearly decrease rate, 7.5%) ($P < 0.001$) **(Figure 2)**. Age at arthroplasty increased from 58.5 years to 60.5 years in the RA group ($P < 0.001$) and from 39.5 years to 47.2 years in the SpA group ($P < 0.001$). In addition, a decrease in the proportion of arthroplasty before 50 years among RA and SpA patients was observed.

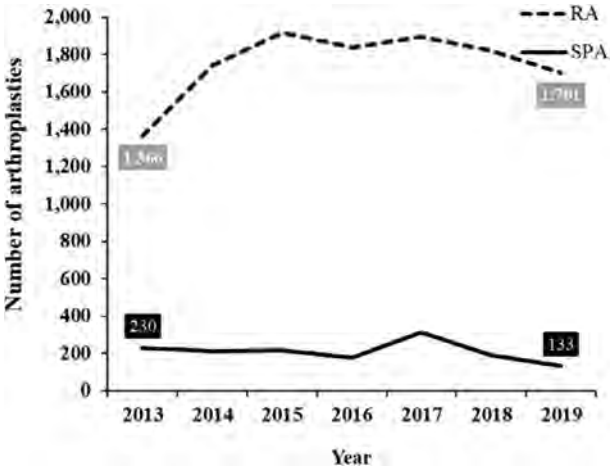

Figure 2. Trends in the number of arthroplasties in the RA group and the SpA group.

IA: inflammatory arthritis; TKA: total knee arthroplasty; THA: total hip arthroplasty; RA: rheumatoid arthritis; SpA: spondyloarthritis; IA: inflammatory arthritis; SD: standard deviation.

Conclusion: This nationwide inpatient-based study found that arthroplasty utilization slightly increased in RA, but significantly decreased in SpA in China. The increase in arthroplasty utilization for RA may be driven by the popularity of arthroplasty because a significant decrease in the proportion of arthroplasty for RA was observed. The decrease in arthroplasty utilization for SpA is conceivable given that economic development expanded the access to medical resource. Additionally, an increase in age at arthroplasty for RA and SpA was also found, suggesting long-term outcomes of RA and SpA are improving.

Abstract Number: 0992

Association Between Metabolic Syndrome and the Presence of Enthesophytes on Musculoskeletal Ultrasound Compared to Joint X-ray

Sean Brown[1], John Hardin[2] and Shereen Mahmood[3], [1]Montefiore Medical Center, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine / Montefiore Medical Center, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Epidemiology & Public Health Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesophytes consist of calcium deposition on tendons or ligaments that are proposed to form in response to localized inflammation of the enthesis, either idiopathic or in response to repetitive strain. The exact etiology of these deposits is unknown, but it has been proposed that they form as a result of tendon degeneration or a cell-mediated reactive process, and one working theory postulates that enthesophyte formation could be correlated with metabolic disorders. It is suggested that metabolic syndromes contribute to enthesopathy through tendon degeneration, aging and overuse. While joint X-ray is known to identify enthesophytes, musculoskeletal ultrasound (MSUS) offers dynamic testing due to its non-invasive nature, decreased radiation burden, affordability and versatility. There is limited research that focuses on ultrasound identification of enthesophytes in relation to metabolic syndrome and compared to other imaging modalities.

Methods: This pilot study compared the prevalence of metabolic syndrome, (characterized as hypertension, hyperlipidemia, diabetes mellitus, elevated Body Mass Index (BMI)) and enthesophytes identified on imaging between MSUS examinations and joint X-rays. The patients were identified through retrospective data collection taken from General Rheumatology Clinic and Rheumatology MSUS Clinic. 49 joints evaluated for joint pain by X-ray demonstrated enthesophytes and 5 joints evaluated for joint pain by MSUS demonstrated enthesophytes. We aimed to evaluate how many patients with joint pain found to have enthesophytes also had comorbid metabolic syndrome.

Results: Of the 49 joints demonstrating enthesophytes on X-ray, this population showed a prevalence of comorbid metabolic syndrome per joint as follows: pelvis - 17/18, knee - 9/10, and ankle - 21/21. The joint X-ray population showed evidence of enthesophytes according to age range per joint as follows: pelvis - < 40yo: 0/8, 40-70yo: 15/71, and >70yo: 3/11, knee - < 40yo: 0/8, 40-70yo: 6/71, >70yo: 4/11, and ankle - < 40yo: 0/8, 40-70yo: 16/71, and >70yo: 5/11.

Of the 5 joints demonstrating enthesophytes with MSUS, this population showed a similar prevalence of comorbid metabolic syndrome in isolated studies of the hip/pelvis (n=1), ankle (n=3).

Conclusion: As a pilot study, we found that X-ray is useful in detecting enthesophytes as a pathologic cause of pain in patients with metabolic syndrome. This highlights the need to investigate further the mechanism that drives this force. Joint X-ray showed a correlation of metabolic syndrome and age with the presence of enthesophytes. In our early MSUS evaluations, detection is achievable as well and demonstrates the high prevalence metabolic syndrome and the presence of enthesophytes, which indicates that there may be a safer, faster, more affordable way to evaluate for this underlying comorbid condition.

Abstract Number: 0993

Successful Implementation of a New Patient Video Triage Program

Dr Tarun Sharma[1], **Adam Dore**[2], Caitlin Rossi[3] and Jessica Heintzinger[3], [1]West Penn Hospital, New Delhi, India, [2]Allegheny Health Network, Pittsburgh, PA, [3]AHN, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Many factors contribute to long wait times for new patient rheumatology visits including the increasing number of rheumatology referrals and new patient visits. Through a separate retrospective analysis, we found that many new patients (32%) in our rheumatology clinics likely did not need to see rheumatology and could have been evaluated via e-Consult (72%). In addition, with the expansion and acceptance of telemedicine, we postulated a new patient video triage program could facilitate appropriate care while also avoiding unnecessary in-person rheumatology appointments.

Table 1: Comparison of referral reason and referral source between rheumatology follow-up needed vs not needed groups

No Rheum Follow up needed (n=103)				Rheum Follow up needed (n=57)		
Referral source:						
Primary care	60%			60%		
Self-referred	24%			26%		
Specialist referral	16%			14%		
Referral reason:						
Joint pain	39	37.9%		Joint pain	25	43.9%
ANA+	20	19.4%		Rheumatoid arthritis	10	17.5%
Fibromyalgia	8	7.8%		ANA+	7	12.3%
Rash	4	3.9%		Gout	3	5.3%
Rheumatoid arthritis	3	2.9%		Psoriatic arthritis	2	3.5%
elevated ESR or CRP	3	2.9%		Osteoporosis	2	3.5%
Osteoarthritis	3	2.9%		Other	8	14.0%
Fatigue	3	2.9%				
Back pain	2	1.9%				
Numbness/paresthesia	2	1.9%				
myalgia	2	1.9%				
chronic pain	2	1.9%				
Autoimmune disease	2	1.9%				
Other	10	9.7%				

Methods: New patients scheduling a rheumatology appointment from December 2022 through May 2023 were offered a video triage appointment option with a rheumatology provider at our tertiary academic medical center. Patients were advised this appointment would determine whether they would need subsequent evaluation or follow-up with rheumatology. If appropriate after evaluation, they were scheduled for an in-person appointment (average of 2 weeks later). Subsequently, a chart review was completed to validate our primary outcome of interest: need of in-person rheumatology follow-up. We also compared the 2 groups of patients: those that needed in-person rheumatology follow up vs. those that did not need follow-up to evaluate for differences in terms of visit reason and referral source. Lastly, we measured the difference in median wait times for video vs in-person new appointments.

Results: A total of 225 patients were included in the rheumatology new patient video triage program. Of these, 103 (46%) patients were found to not require an in-person rheumatology follow up and were referred back to their primary care provider or another specialty for follow-up. Only 57 (25%) patients required a subsequent in-person rheumatology follow up. A total of 26 (12%) patients did not show to or cancelled their appointments. 14 (6%) patients did not complete follow-up testing after the video appointment. The remaining 25 patients are currently being assessed to determine if ongoing rheumatology care is needed. Referral sources were similar between patients who required rheumatology follow-up and those who did not (Table 1). Reasons for initial visit are shown in Table 1. The top diagnoses that did require rheumatology follow-up were joint pain, rheumatoid arthritis (RA), and +ANA, whereas those that did not require an in-person follow-up were joint pain, +ANA, and fibromyalgia. The current median wait for a new in-person rheumatology appointment in our division is 80 days compared to a 30 day wait time for a new patient video triage appointment.

Conclusion: Through a new patient video triage program for rheumatology patients, we have shown that only 25% of the video patients needed a subsequent in-person rheumatology follow up. The referral sources and most common reason for visit were similar between the 2 groups. Of note, the average wait time for a video triage appointment is less than half of an in-person new patient appointment. Given these findings, we plan to continue this successful new patient video program to help facilitate more timely initial rheumatology evaluation and facilitate more appropriate in-person rheumatology visits.

Abstract Number: 0994

Narrative Medicine and Pediatric Rheumatology: Addressing Burnout and Bias

Aviya Lanis, Natalie Rosenwasser and Esi Morgan, Seattle Children's Hospital, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Burnout, a syndrome of emotional exhaustion and depersonalization, adversely impacts healthcare and results in mood disturbances, poor patient and provider satisfaction and high turnover. Studies have shown burnout also plays a critical role in physician bias, with increased bias among those with higher rates of burnout. The SARS-CoV-2 pandemic increased levels of burnout and exposed the high prevalence of racial bias in healthcare. There is a critical need

for methods to address burnout and bias in healthcare. Narrative medicine (NM) incorporates the stories of human experience into the medical realm and has been proven to strengthen relationships and increase empathy. To date, limited data investigating narrative medicine's impact on burnout and bias has been promising. This pilot study aims to investigate the use of NM as a tool to address burnout and explore bias amongst a pediatric rheumatology division.

Methods: Physicians, nurses, medical assistants and staff at a single center enrolled in a series of six monthly 1-hour video-based sessions lead by co-facilitators (AL, and a NM-trained facilitator) after informed consent. Sessions utilized poetry, photography, paintings, and spoken word to inspire writing prompts around the medical experience. A Plan-Do-Study-Act approach was used to guide intervention adjustments based on participant post-session feedback. Demographics were collected, and standard surveys were administered at baseline, and after the third and sixth sessions, specifically: Mini Z Burnout, Copenhagen Burnout Inventory (CBI), Provider Health Questionnaire-9 (PHQ-9) as well as Implicit Association Testing (IAT) and explicit bias Feeling Thermometer (FT).Survey data were assessed for differences with a Wilcoxon signed rank test.

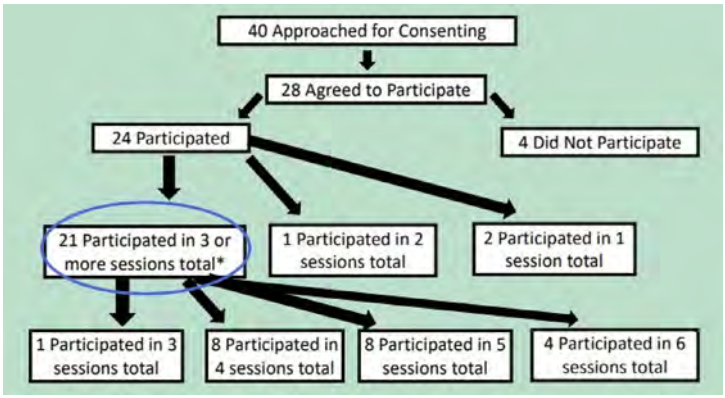

Figure 1: Breakdown of individuals consented compared to those who participated.

Table 1: Pre-, intra- and post-participation questionnaire results including observations, mean, standard deviation (SD), median, range, and Wilcoxon signed-rank test p-values. For Mini Z Burnout, a score of 20 or higher is considered to be a joyful work environment. For the CBI, a score of 50-74 is concerning for moderate burnout, 75-99 with high burnout, and a score of 100 shows severe burnout. For the PHQ-9, a score of 1-4 demonstrates minimal depression, 5-9 demonstrates mild depression, 10-14 demonstrates moderate depression and 20-27 demonstrates severe depression.

	Mini Z Burnout			Copenhagen Burnout Index (CBI)			Patient Health Questionnaire-9 (PHQ-9)		
	Pre	Intra	Post	Pre	Intra	Post	Pre	Intra	Post
Observations	21	20	16	21	19	17	21	18	17
Mean	29.2	29.5	31.4	42.8	38.4	34.5	6.0	4.6	4.2
SD	6.4	6.2	5.2	13.2	16.7	17.2	5.0	3.8	3.9
Median	30	30	32	39.5	34.2	28.9	5.0	3.5	3.0
Range	15-38	18-38	23-39	25-75	17.1-84.2	5.26-81.58	0-17	0-13	0-13
Wilcoxon Signed Rank Test P-value Pre/Intra	0.775			0.258			0.727		
Wilcoxon Signed Rank Test P-value Intra/Post		0.703			0.185			0.858	
Wilcoxon Signed Rank Test P-value Pre/Post	0.375			0.052			0.680		

Results: Twenty-four participants with 21 females, 2 males and one non-binary were divided amongst 6 narrative medicine groups for the 6 total sessions. Data analysis was completed for those who attended 3 or more sessions (n=21) (See Figure 1). Self-identified race included 18 White, 4 Asian, 1 Black, and 1 who preferred not to answer. Participants included 8 attendings, 4 fellows, 2 nurses, 2 medical assistants, and 8 staff members. While no statistical significance was seen when evaluating questionnaires for the Mini Z Burnout, CBI, or PHQ-9 when comparing questionnaires from baseline and after 6 months into participation, there was a trend toward improvement with median CBI improved from 39.5 to 28.9, and median PHQ-9 score improved from 5 to 3. (Table 1). IAT showed a statistically significant shift towards positive association with African Americans following participation (p-value= 0.012), while FT showed a non-statistically significant explicit bias shift away from positive association with European Americans (p=0.096).

Conclusion: Narrative medicine is a feasible intervention that warrants further study as a means to address bias. Additional long-term analysis is needed to understand if these changes are durable.

Rheumatoid Arthritis Early Diagnostic Clinic: A Web-based Referral Tool Serving Ethnic Minority Patients

Mercedes Quinones[1], Sharon Dowell[2], Ilona Jileaeva[3], Oshoze Kadiri[3], Christopher Swearingen[4] and Gail Kerr[5], [1]Washington DC VA Medical Center, Bethesda, MD, [2]NEA Baptist Memorial Hospital, Jonesboro, AR, [3]Howard University, Washington, DC, [4]Biosplice Therapeutics, Inc., San Diego, CA, [5]Washington DC VAMC/Georgetown and Howard Universities, Washington, DC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) data indicate a "window of opportunity" during which DMARD therapy is most effective in achieving early and sustained remission, hence expedited access and early diagnosis is essential. Health status disparities exist in ethnic minority (EM) patients with rheumatic disease, inclusive of RA, particularly with early access and referral to specialty care. RA early referral tools have led to decreased wait times and increased numbers with the diagnosis. Therefore expedited referral in EM RA populations would be advantageous for early diagnosis and intervention. We evaluated a web-based referral tool developed to facilitate referrals of EM patients with symptoms of inflammatory arthritis to specialty care.

Methods: We designed an online referral tool, RHEUMATOID ARTHRITIS EARLY DIAGNOSTIC CLINIC [RAEDC], for primary care physicians (PCPs) at clinics serving EM patients. Based on the 4 domains of the ACR/EULAR 2010 RA Classification Criteria, the tool included a joint homunculus for PCP input of swollen and tender joints. PCPs received a RA educational lecture emphasizing the importance of early referral as well as joint exam techniques. Patients who received a score of ≥6 were scheduled for a RAEDC visit within 2 weeks. PCPs received feedback within 48 hours of the visit regarding RA diagnosis and accuracy of joint exam. Demographic data, RA disease status (Anti-CCP, RF), tender and swollen joint counts (TJC, SJC), ESR, CRP, and disease activity measures (RAPID-3, CDAI) were collected at baseline and compared to Ethnic Minority RA Consortium (EMRAC), an established disease cohort. Treatment patterns for the RAEDC cohort RA patients were assessed at baseline and at 3, 6, and 12 months. PCPs completed a 10-point Likert scale assessing utility of the referral tool.

Baseline Data for RAEDC patients vs. EMRAC cohort

	RAEDC referrals (N=35)		RA diagnosis (N=11)		Non-RA diagnosis (N=24)		EMRAC (N=97)		RA vs. EMRAC

Medication Use for RAEDC Referrals Diagnosed with RA

Results: Of 51 referrals, 35 were evaluated, and 16 did not keep their appointment. Of the 35 patients seen, 11 met ACR/EULAR RA Classification Criteria (31%). Whereas RAEDC patients were evaluated within 2-4 weeks of referral, the average time to diagnosis for the EMRAC cohort was 4 months. Compared to EMRAC, RAEDC patients were mostly Hispanic, with lower educational levels, higher pain/fatigue/patient global scores, TJC, SJC, ESR, CRP, and disease activity scores RAPID-3 (17.3 [6.0] vs. 9.8 [7.6], p=0.003) and CDAI (30.9 [13.5] vs. 12.3 [9.9], $p < 0.0001$) (Table 1). At initial visit, 72.7% received a DMARD (45.4% MTX, 27.3 % other DMARD), with 100% on a DMARD within a year (Table 2). Only 20% remained on Prednisone at 12 months. Alternate inflammatory diagnoses included Gout, PMR, and SS, despite ~50% of the referral cohort with a positive RA serology. PCPs indicated favorable utility of the online tool (Likert 7.8).

Conclusion: An online referral tool accompanied by initial teaching of PCP end-users served to increase RA awareness and early referral. The early access to specialty care led to initiation of DMARDs in all patients, with limited Prednisone use by one year. Our tool served to advocate for EM patients with low education status and emphasized the importance of joint exam by PCPs in the presence of RA serologies. Evaluations of improved accuracy in joint exam by PCPs and patient opinion in use of the online tool are planned.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Health Services Research Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

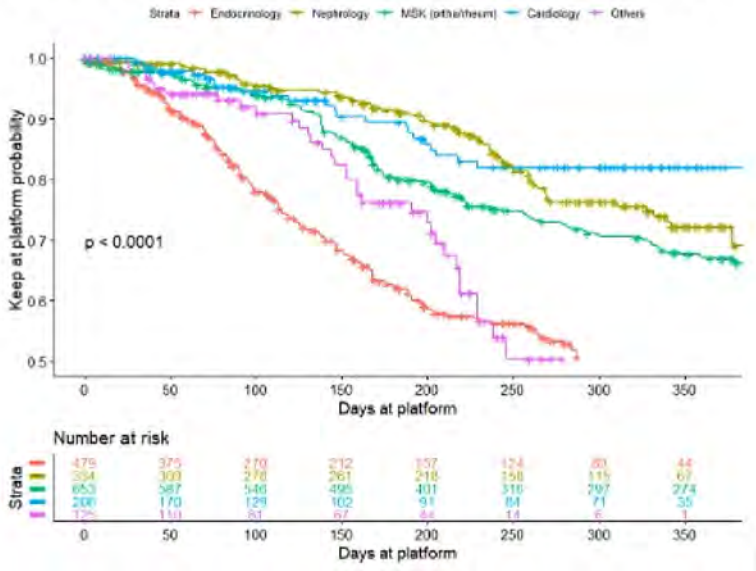
Background/Purpose: Remote Physiologic Monitoring (RPM) and Remote Therapeutic Monitoring (RTM) are new care delivery options by which patients can provide data to their provider via a biosensor device and/or smartphone app in an insurance reimbursable fashion. However, patients' willingness and persistence to engage in RPM/RTM over time is unclear.

Table 1: Characteristics of Patients Enrolled in RPM/RTM

	Endocrinology	Nephrology	MSK (ortho/rheum)	Cardiology	Other
N	479	334	653	206	125
Age, years (Mean (SD))	58.6 (15.3)	75.1 (11.7)	70.4 (10.9)	77.6 (8.8)	67.8 (14.2)
Women, %	296 (62.8%)	171 (54.6%)	429 (66.7%)	136 (66.0%)	78 (62.9%)
Median National Area Deprivation Index (ADI) ADI >=80 (deprived)*, %	50 (10.5%)	0 (0.0%)	24 (3.9%)	29 (14.2%)	14 (11.2%)

RPM = remote physiologic monitoring; RTM = remote therapeutic monitoring; MSK = musculoskeletal
**proportions shown of those with data available*

Figure 2: Persistence with RPM and RTM Over Time, Stratified by Specialty



Methods: Using data from 9/2020 - 5/2023, we examined characteristics of patients who enrolled in a national RPM/RTM program as part of routine care, stratified by medical specialty. Time on the program began at the time patients were first enrolled in the program and contributed data and continued until they voluntarily withdrew from the program, were lost to follow up (i.e. became inactive) or were censored. Kaplan Meier curves described persistence over time, stratified by medical specialty, combining musculoskeletal (orthopedics and rheumatology) and Others (e.g. pulmonology, primary care) into a single group. Cox proportional hazards models evaluated the time to discontinuation by medical specialty, adjusting for age and sex.

Results: A total of 1797 patients were enrolled, with characteristics as described in table 1.Mean age was greater than 70 years for all cohorts except endocrinology. Persistence with RPM/RTM significantly differed by specialty (Figure). Approximately 80% of patients being monitored for musculoskeletal conditions were approximately 80% adherent at 6 months. Referent to patients being monitored for musculoskeletal conditions (e.g. rheumatology), persistence with RPM/RTM was worse for patients being monitored for endocrinology conditions (age-sex-adjusted hazard ratio for non-persistence=2.3, 95% CI 1.8-2.8) and was not different for other specialties.

Conclusion: Most patients with musculoskeletal or other chronic health conditions are persistent with digital health care delivery systems such as remote physiologic and remote therapeutic monitoring. Strategies to optimize patient engagement with such programs are important to maximize the health benefits of these new digital healthcare delivery mechanisms.

Abstract Number: 0997

Impact of Depression on Healthcare Utilization in Members with Underlying Rheumatoid Arthritis, Psoriatic Arthritis and Systemic Lupus Erythematosus

W. Cliff Rutter, Jean Park, Elisea Avalos-Reyes, Chen Liu, Will Cavers, Dorothea Verbrugge and Kjel Johnson, CVS Health, Woonsocket, RI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE) have higher rates of psychiatric comorbidities, particularly depression and anxiety. Comorbid depression has been associated with increased disease activity in patients with rheumatic conditions. What isn't known, is how comorbid depression impacts healthcare utilization in these patients. The objective of this study was to assess the impact of depression on healthcare utilization in patients with RA, PsA and SLE.

Methods: This cohort study included fully insured commercial or Medicare members of a large national health plan between 1/1/2018 and 1/1/2023. Members ≥ 18 years old were included if they had at least 2 visits for RA (ICD-10 code: M05 or M06), PsA (L40.5), or SLE (M32) during the study period. Members were excluded if they did not maintain continuous

eligibility for 6 months before or after entrance into the study, had multiple conditions of interest, or had missing socioeconomic status (SES) data. Members were stratified by presence of a visit for depression and anxiety (MDD). Healthcare utilization metrics were examined as use of telemedicine, emergency department (ER), or inpatient services and were identified by place of service codes on medical claims. Telemedicine utilization included both medical and behavioral health visits. ER and inpatient claims were aggregated by day and are presented by days utilizing the service. Utilization rates were calculated based on total person years observed in each cohort and the sum of telemedicine claims. ER days and inpatient days are presented as claims or days per 100 person years observed. Rate differences and rate ratios (RR) were calculated with 95% confidence intervals (CI). Continuous variables were assessed utilizing t-tests; categorical variables were assessed with the Chi^2 test. P-values < 0.05 are significant.

Results: Of the 109,006 members included, 32,209 (29.5%) had a visit for depression (MDD). Table 1 demonstrates significant differences in baseline demographics between disease states, with MDD members being older (mean age (standard deviation (SD)): 58.2 (15.5) vs. 57.5 (15.4) years; p< 0.001) and having more comorbidities at baseline (mean Charlson Comorbidity Index (SD): 3.8 (3.1) vs. 2.8 (2.6); p< 0.001). Table 2 demonstrates the differences in healthcare utilization between cohorts. Members in the MDD group had significantly higher telemedicine (RR [95% CI]: 2.85 [2.83 – 2.86]; p< 0.0001), ER (RR [95%CI]: 2.27 [2.25-2.29]; p< 0.0001), and inpatient (RR [95% CI]: 2.94 [2.92-2.97]; p< 0.0001) utilization.

Conclusion: Members diagnosed with RA, PsA, or SLE with visits for depression and anxiety utilized significantly more healthcare services than those that did not have depression. These findings highlight the importance of managing depression and anxiety when treating patients with RA, PsA and SLE.

Barriers and Facilitators for Osteoporosis and Sarcopenia Care for Persons Living with HIV in Peru: HIV Physician and Coordinator Perspectives

Rebecca Slotkin[1], Daniel Granda Calderón[2], Joselito Malca Hernandez[2], Diego Cabrera[3], Carlos Manuel Benites Villafane[4], Patricia Jannet García[5] and Evelyn Hsieh[6], [1]Yale University, Department of Medicine, Section of Rheumatology; Yale School of Public Health, New Haven, CT, [2]Facultad de Medicina Alberto Hurtado de la Universidad Peruana Cayetano Heredia, Lima, Peru, [3]Yale University, Department of Medicine, Section of Rheumatology; Department of Internal Medicine, Waterbury Hospital, New Haven, CT, [4]Ministerio de Salud, Peru, Lima, Peru, [5]Epidemiology, STD, and HIV Unit, School of Public Health, Universidad Peruana Cayetano Heredia, Lima, Peru, [6]Yale University, Department of Medicine, Section of Rheumatology; Yale School of Public Health; Section of Rheumatology, VA Connecticut Healthcare System, Westport, CT

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Health Services Research Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Persons living with HIV (PLWH) have a higher risk of developing age-related non-communicable diseases (NCDs), such as osteoporosis and sarcopenia. In Peru, HIV providers are the primary point of medical care for PLWH. Using a qualitative approach, we examined health system barriers and facilitators for osteoporosis and sarcopenia care for PLWH in Peru from the perspective of HIV physicians and coordinators.

Methods: HIV regional program coordinators and physicians affiliated with Peru's National HIV, STI and Hepatitis Program were recruited from the Program's physician and coordinator registry and by peer referral. All coordinators (N=31) were contacted for a semi-structured in-depth interview over Zoom by a trained Peruvian research assistant. Physicians were purposefully sampled to ensure adequate regional representation. Interviews continued until thematic saturation was reached in both groups. The interviews were recorded and transcribed using Sonix.ai and checked for accuracy. Transcripts were translated to English following a standardized protocol by a team of bilingual translators, and then coded in English by two

Table 1. Interviewee Demographics

	Coordinators N=25	Physicians N=14
Age (mean) +/- SD [range]	46 +/- 9.1 [31-65]	46 +/- 9.5 [32-59]
Sex N (%) Male Female	 7 (28%) 18 (72%)	 9 (64%) 5 (35%)
Region N (%) Coast Highlands Jungle	 13 (52%) 8 (32%) 4 (16%)	 7 (50%) 4 (29%) 3 (21%)
Professional Training N (%)	RN/Midwife 23 (92%) MD 2 (8%)	Infectious Disease 12 (86%) Generalist/Internist 2 (14%)

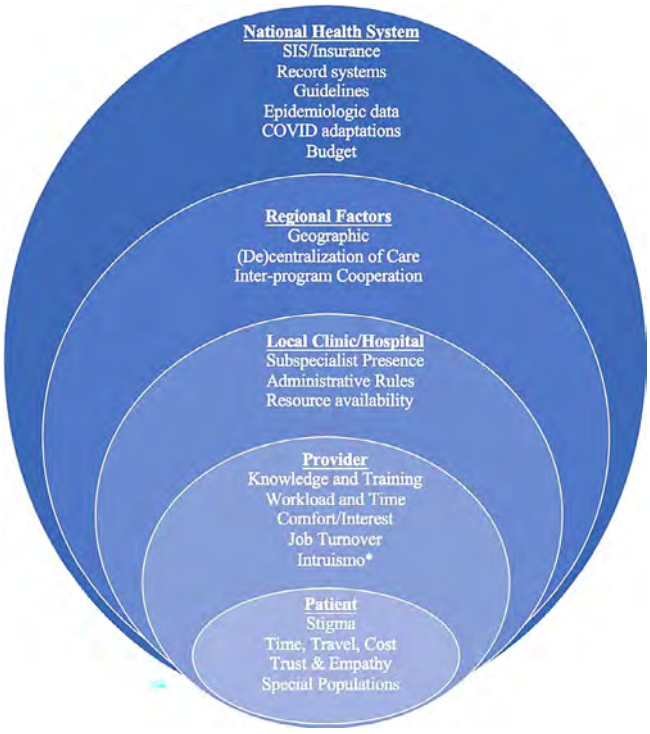

Figure 1. Socioecological Model Applied to Barriers and Facilitators of Osteoporosis and Sarcopenia Care for Persons Living with HIV. Emerging themes and sub-themes from physician and coordinator interviews were visualized using this adapted socioecological model. *Translates to the idea that one should not overstep the boundaries of their specialty.

independent coders, one of which was Peruvian to ensure culturally appropriate codes. All codes were discussed, and discrepancies were resolved by consensus. The emerging themes and sub-themes were visualized using an adapted socioecological framework.

Results: Twenty-five regional coordinators and 14 physicians were interviewed to reach thematic saturation (Table 1). Barriers and facilitators discussed by both groups were organized into major themes following a socioecological model: patient, provider, local clinic/hospital, regional, and national health system (Figure 1). Coordinators highlighted health system components such as budget, resources, the impact of the pandemic, existing NCD programs, lack of epidemiologic data on NCDs, and a motivation to improve care for PLWH. While some physicians were enthusiastic about learning more and providing osteoporosis/sarcopenia care themselves or were already providing some direct management, others felt that the patient was better served by referral to a specialist. Physicians noted barriers of knowledge/training, interest, time, workload, lack of guidelines, available medications and DXA, and an inclination to stay within the scope of their specialty, which is encouraged by their health system at the local and national levels. Physicians reported that they were aware of the growing burden of NCDs in patients aging with HIV. They described a unique position of trust with their patients, who preferred their HIV provider to manage their NCDs to simplify their care and avoid stigma, especially in areas lacking access to NCD-trained specialists.

Conclusion: This study highlights the complex interplay between patient, provider, local, regional, and national factors that influence care delivery to PLWH in Peru. Addressing the barriers of osteoporosis and sarcopenia management in PLWH will require support from HIV physicians and coordinators as well as health system level interventions such as national guidelines, training, and increased access to screening resources.

Race, Payer, and Hospital Factors Are Associated with Post-primary Total Hip Arthroplasty Healthcare Utilization

Kranti Rumalla[1], Sumanth Chandrupatla[2] and Jasvinder Singh[2], [1]Northwestern School of Medicine, Chicago, IL, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Over 450,000 primary total hip arthroplasties (THA) are performed each year. One major indication for primary THA is the presence of osteoarthritis (OA). Patient characteristics, insurance payer status, and regional and hospital level factors can lead to disparities in outcomes and costs of primary THA in patients with OA. We aimed to examine the association of these factors to extended lengths of stay and increased hospital costs after primary THA.

Methods: We utilized the National Inpatient Sample (NIS) to identify patients with OA who underwent primary THA in 2019. Diagnoses and procedures were identified using the International Classification of Disease (ICD-10) codes. We stratified healthcare/resource utilization by the occurrence of an extended length of stay (eLOS) and the presence of an increased

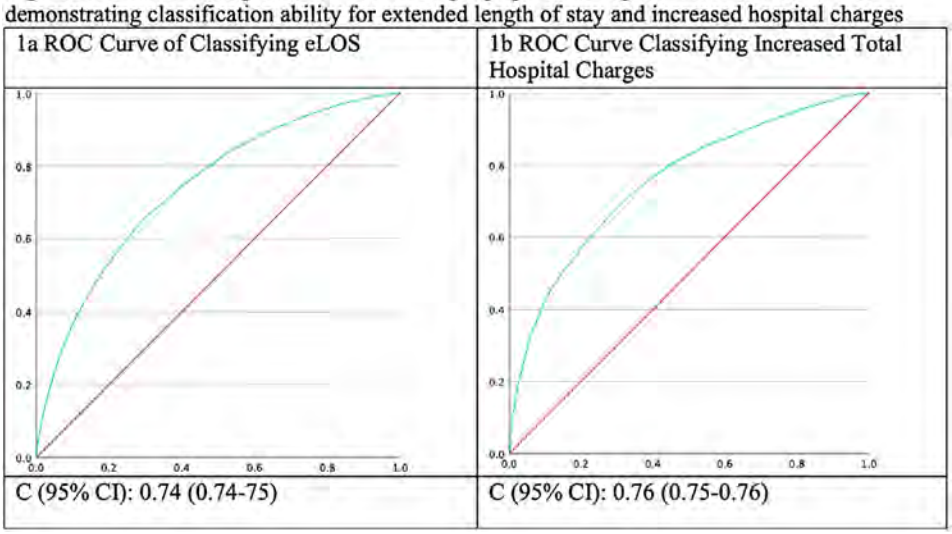
Figure-1: Multivariable prediction models of geographic and regional level characteristics demonstrating classification ability for extended length of stay and increased hospital charges



hospital charge (IHC), i.e., the upper quartile each outcome. Univariate and multivariable analyses compared patient-level, regional, and hospital characteristics associated with an eLOS or IHC. Predictive probabilities from multivariable analyses were used in Area Under the Curve (AUC) analysis.

Results: There were 424,555 patients with OA who underwent primary THA in 2019. Patient race/ethnicity, Medicaid or Medicare payer status, income, age/sex and nearly all regional, and hospital, characteristics were independently associated with eLOS (ROC C-statistic = 0.74). Significant independent predictors for IHC were race & ethnicity ($p < 0.001$), hospital region ($p < 0.001$), hospital location & teaching status ($p < 0.001$), and hospital control ($p < 0.001$). The ROC curve classifying IHC had a C-statistic of 0.76.

Conclusion: Patient race/ethnicity and insurance payer status are important determinants of longer LOS for primary THA hospitalizations in the US. Well-known geographical and hospital-level disparities are negatively associated with the outcomes and costs of primary THA in patients with OA. Policy and other interventions targeting these factors may help reduce utilization for elective THA.

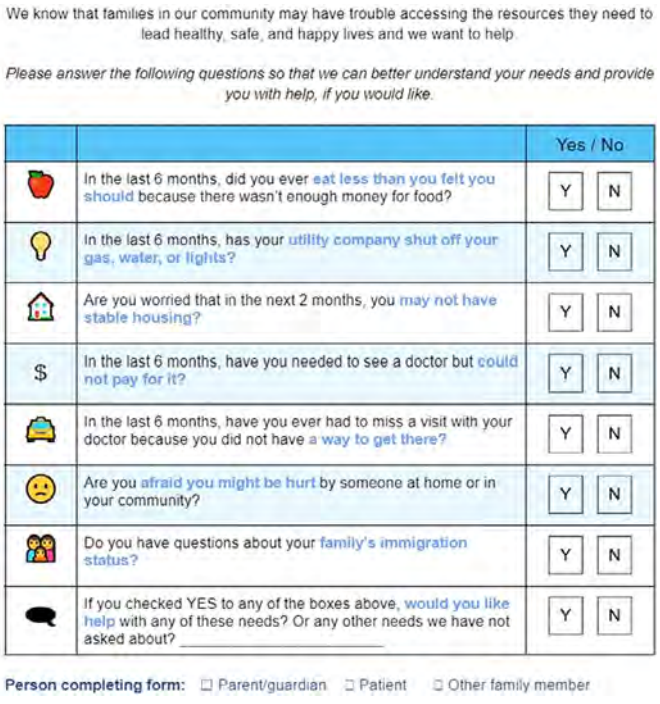
Incorporation of Social Drivers of Health Screening into a Structured Healthcare Transition Program for Adolescents and Young Adults with Chronic Rheumatic Disease

Morayah Ciprien[1], Sarah Barrientos[2], Cori Christenholz[2], Elinore Benett[2] and Rosemary Peterson[1], [1]Dell Medical School at UT Austin, Austin, TX, [2]Dell Children's Medical Center, Division of Rheumatology, Austin, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Social drivers of health (SDoH) such as access to housing and food, may significantly influence safe and timely transition to adult healthcare, yet routine screening for psychosocial barriers is uncommon in the pediatric setting. This study aims to successfully implement SDoH screening and proactive social work support into an existing standardized transition program and to assess correlations between positive SDoH screening and transition readiness among pediatric rheumatology patients.

Methods: As part of the clinic's transition program, established patients aged 14 and older with chronic rheumatic disease complete the transition readiness assessment questionnaire (TRAQ) and meet with a child life specialist every 6 months to learn healthcare self-management skills. A physician associate helps the patient schedule their first adult rheumatology visit. Starting August 2022, the SDoH screener, adapted from the Health Leads Screening Toolkit, was given to this same group of eligible patients, or legal guardians if under age 18 (Figure 1). The primary process measure was the percentage of eligible patients who completed the SDoH screener each month and the primary outcome measure was the percentage of positive



We know that families in our community may have trouble accessing the resources they need to lead healthy, safe, and happy lives and we want to help.

Please answer the following questions so that we can better understand your needs and provide you with help, if you would like.

		Yes / No
🍎	In the last 6 months, did you ever eat less than you felt you should because there wasn't enough money for food?	Y N
💡	In the last 6 months, has your utility company shut off your gas, water, or lights?	Y N
🏠	Are you worried that in the next 2 months, you may not have stable housing?	Y N
$	In the last 6 months, have you needed to see a doctor but could not pay for it?	Y N
🚗	In the last 6 months, have you ever had to miss a visit with your doctor because you did not have a way to get there?	Y N
😟	Are you afraid you might be hurt by someone at home or in your community?	Y N
👨‍👩‍👧	Do you have questions about your family's immigration status?	Y N
🗨️	If you checked YES to any of the boxes above, would you like help with any of these needs? Or any other needs we have not asked about? _____	Y N

Person completing form: ☐ Parent/guardian ☐ Patient ☐ Other family member

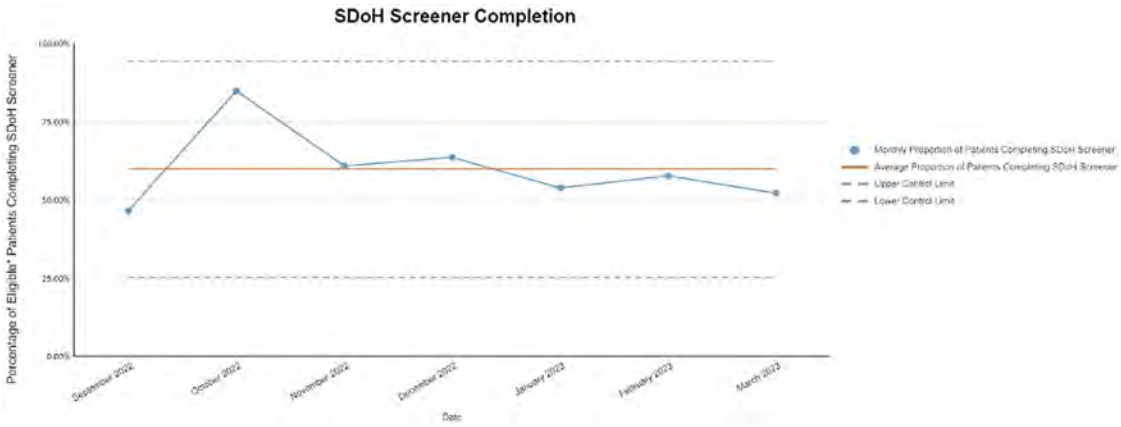

Figure 2. Statistical process control chart of percentage of eligible patients (>= 14 years, established patient, chronic rheumatic disease, present with legal guardian) completing SDoH screener each month.

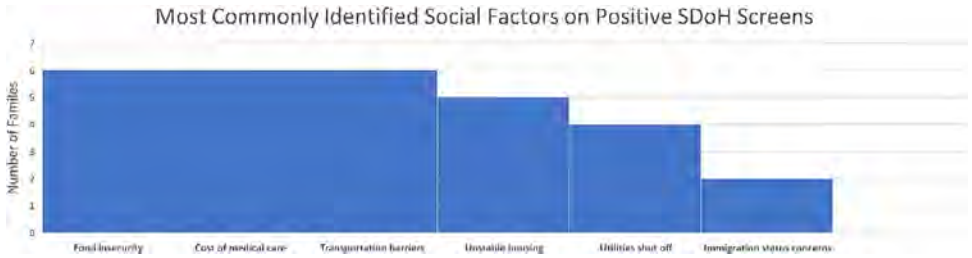

Figure 3. Frequency count of most commonly identified social factors on positive SDoH screeners

SDoH screens. A secure daily message was sent to providers, social work and medical assistants to confirm patient and family suitability to receive screeners. Results of SDoH screening were shared in the same morning text thread at time of rooming and families with positive screens were offered a meeting with the social worker. Two-sample t-test was used to determine the correlation between TRAQ scores and SDoH positivity.

Results: A total of 94 patients/families (median patient age 17 years, IQR 16-18.0) completed the SDoH screener from August 2022 through March 2023 with an average of 59.9% eligible patients per month (Figure 2). Of the completed SDoH screeners, 14.9% (n=14) were positive and 64.2% (n=9) of those families met with social work. Most common social needs included transportation issues (n = 6), food insecurity (n = 6) and financial barriers (n = 6) (Figure 3). Average TRAQ score was 3.43/5 (SD = 0.76) for all patients. There was not a significant difference in mean TRAQ score for patients with positive SDoH screen (mean 3.23 +/- 0.66) and negative SDOH screen (mean 3.52 +/- 0.77; p = 0.2). There was not an association between primary rheumatologic diagnosis and SDoH screen positivity. Since implementation of SDoH screening, only 11 patients have completed their final pediatric rheumatology visit, limiting further analysis of correlation between transition success and SDoH screening.

Conclusion: Implementation of an SDoH screener facilitated proactive social work support for a vulnerable population at risk for an unstable transition to adult care. Transportation, food insecurity, and financial barriers were the most commonly identified needs, informing clinic resource preparation. Next steps include continued long-term follow up of patient cohort, addressing barriers to social work interface with families and collecting patient-facing data regarding SDoH screening acceptability and process to explore possible underreporting bias in our patient population.

Abstract Number: 1001

Distance Not Travelled in a Tele-Rheumatology Shared Care Model: Leveraging the Expertise of an Advanced Clinician Practitioner in Arthritis Care (ACPAC)-trained Extended Role Practitioner (ERP) in Rural-remote Ontario

Amanda Steiman[1], Jocelyne Murdoch[2], Rachel Shupak[3], Taucha Inrig[4] and **Katie Lundon**[5], [1]Sinai Health System, Toronto, ON, Canada, [2]Arthritis Society, Toronto, ON, Canada, [3]St. Michael's Hospital/University of Toronto, Toronto, ON, Canada, [4]St. Michael's Hospital, Toronto, ON, Canada, [5]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A shortage of Rheumatologists has led to gaps in inflammatory arthritis (IA) care in Canada. Amplified in rural-remote communities, the number of Rheumatologists practicing rurally cannot be meaningfully increased. Alternate care strategies must be adopted. The economic impact of a shared-care Telerheumatology model, utilizing a community-embedded Advanced Clinician Practitioner in Arthritis Care (ACPAC)-ERP and an urban-based Rheumatologist, is described in terms of the estimated travel cost-savings (distance not traveled) for both patients and the healthcare system.

Methods: A Rheumatologist and an ACPAC-ERP located 463 kilometers distally, established a monthly half-day Hub-and-Spoke-Telerheumatology clinic to care for patients with suspected IA, triaged by the ACPAC-ERP. Subsequent collaborative visits occurred with the Rheumatologist (Hub-St. Michael's Hospital, Toronto) attending virtually. Geospatial information for individual patients was obtained using regional postal codes collected through demographic data. Calculations of hypothetical distances between these locations and St. Michael's Hospital were based on the most efficient and cost-effective driving route utilizing Google Maps©. Aggregate data were used to calculate distances not travelled due to the virtual care delivery model. An estimation of further cost-savings of this Telerheumatology shared model of care was based on Ministry of Health (MOH) travel grants that would have been reimbursed to these patients should they have traveled for in-person care.

Results: Data from 124 patients seen between January 2013-January 2022 were collected: 98.0% (n=496/504 visits) were virtual. An estimated 493,470 km of patient-related travel was avoided (basedon 494 Telerheumatology visits). The loci where more than 5 patients resided is represented in Figure 1.A theoretical estimate of the MOH travel grant cost was $276,428, calculated based on the total number of patient visits that would have been incurred should these patients have been followed by the Rheumatologist in-person.

Conclusion: Half of a million kilometers (493,470 km) of travel was avoided for the patients involved in this Telerheumatology study, significantly reducing the carbon footprint and environmental impact by not travelling to access specialist rheumatology care. The estimated $276,428 cost-savings in this study represents a minimal base fiscal value of the ACPAC-trained ERP working within a Telerheumatology model of care. Other indirect costs need to be further captured

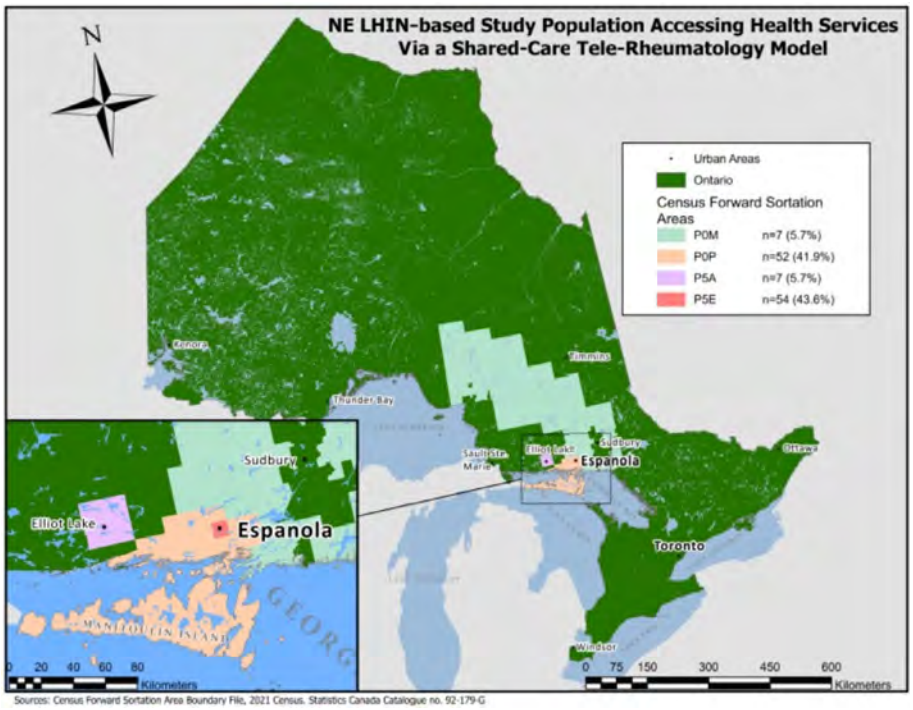

Figure 1.

in a more robust economic analysis. There is a compelling fiscal argument to support scaling-upof this model to deliver comprehensive and cost-effective virtual rheumatologic care in underserved communities provincially and beyond.

Optimizing Rural Rheumatology Access: Collaborative Tele-Health Clinic Between University of North Carolina and Piedmont Health 1 Year Extension and Opportunities for Improvement

Prarthana Jain[1], Eli Tiller[2], John Doughton[3], Rumey Ishizawar[4] and Alfredo Rivadeneira[4], [1]University of North Carolina at Chapel Hill, Division of Rheumatology, Allergy and Immunology, Thurston Arthritis Research Center, Pittsboro, NC, [2]University of North Carolina Department of Family Medicine, Piedmont Health Services, Siler City, NC, [3]University of North Carolina Department of Family Medicine, Piedmont Health Services, Prospect Hill, NC, [4]University of North Carolina at Chapel Hill, School of Medicine, Division of Rheumatology, Allergy, and Immunology, Thurston Arthritis Research Center, Chapel Hill, NC

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Health Services Research Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Access to healthcare is challenging for racial and ethnic minorities, especially in medically underserved rural areas.[1] This issue is particularly prevalent in North Carolina where 40% live in rural counties.[2] To address this disparity, a pilot project supported by the Arthritis Foundation was initiated in January 2022, to enhance access to rheumatology specialty care. The project focused on shared telehealth visits between the University of North Carolina (UNC) Rheumatology Clinic and Piedmont Health Services (PHS), a federally qualified health center catering to rural NC patients. This extension of the pilot project evaluates the follow-up data from the past year with expansion to 81 patient encounters and assess limitations of the pilot.

Telehealth Access	
Computer, Tablet, or Smartphone Access at Home, n (%)	62 (82.7)
Internet Access at home, n (%)	54 (81.8)

Methods: Patients eligible for the rheumatology telehealth clinic were established patients with a history of rheumatic disease who had been lost to follow up or new patients requiring rheumatology evaluation who faced transportation and/or financial barriers. Monthly clinic sessions were conducted between the on-site PHS provider and the off-site UNC

Table 2: Patient Satisfaction Response (n=71)

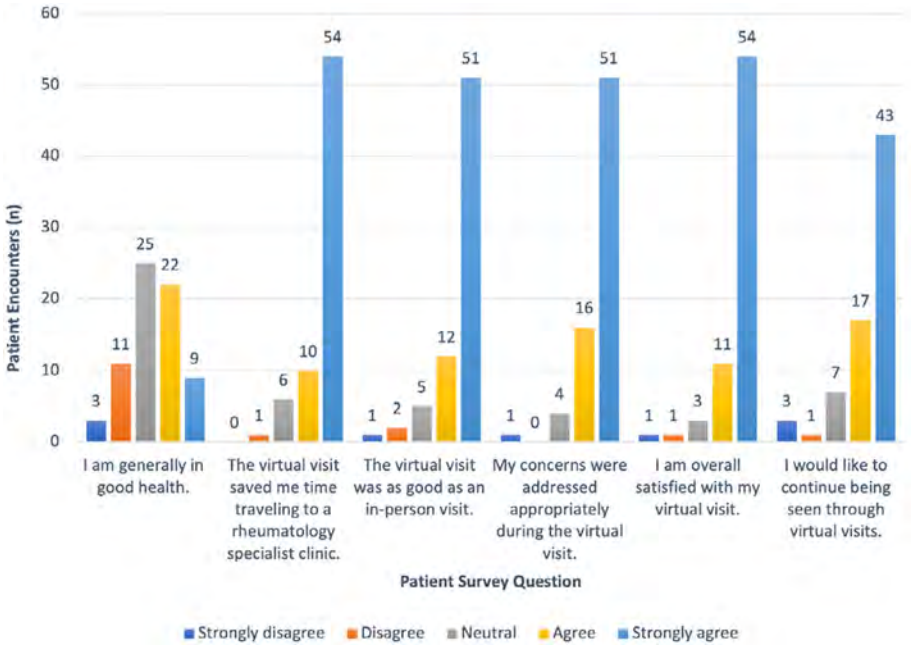

Table 3. PHS Provider Post-Didactic Survey

Table 3. PHS Provider Post-Didactic Survey	
Average Attendees Per Session	
n (%)	3.5 (7.7)
Questions	**Average score**
1. The didactic session enhanced my knowledge of evaluating and managing/co-managing rheumatological illnesses.	4.5
2. I feel comfortable applying the knowledge learned through didactics to patients with similar diseases in my clinic.	4.3
3. Participating in didactics and open forums for patient management questions is an effective way to enhance rheumatology expertise.	4.5
4. I am overall satisfied with the didactic session.	4.5

Scores are calculated from responses on a Likert scale where 1 = Strongly Disagree, 2 = Disagree, 3 = Neutral, 4 = Agree, and 5 = Strongly Agree.

rheumatologist. The PHS provider facilitated the physical examination and relayed objective data while receiving rheumatology guidance over video. The rheumatologist assisted real time with workup and management. Non-identifying patient demographics were also collected. Monthly virtual didactic sessions on core topics in rheumatology were conducted by UNC rheumatologists. PHS provider satisfaction after didactic sessions was evaluated using 5-point Likert surveys.

Results: Between January 2022 and March 2023, a total of 81 encounters (new and return) were completed. Majority of patients identified as female (84%), Hispanic (75.6%), and Spanish-speaking (67.1%). Most patients reported being uninsured (70.3%). The most encountered rheumatic conditions were RA (57.3%), SLE (14.6%), undifferentiated arthritis (5.6%), and other (21.7%). Wait time from referral to visit completion was short, with 92.1% of patients reporting less than a 1-month wait. In contrast, average wait times for new patient visits at UNC was 6 months or greater. Patient satisfaction scores were high and there was a strong interest in continuing to use this telehealth clinic for future visits. Didactic sessions received high satisfaction scores from providers, but attendance was low with an average of 4-5 community providers present per session out of the 45 invited.

Conclusion: This project supported by the Arthritis Foundation employs a unique model connecting an on-site primary care provider with a virtual rheumatologist to address barriers related to transportation, medical costs, internet access and time. Patients reported high satisfaction with this model. This project entailed educational sessions to empower the local community workforce to manage rheumatic conditions. While didactic sessions were rated favorably, provider attendance was low. Future directions include a needs assessment to evaluate barriers faced by community providers to expand rheumatology knowledge and ability to manage basic rheumatic conditions; and therefore, enhance the local community workforce serving the rural medically underserved.

A Multidisciplinary Obstetric-Medicine/Rheumatology Specialty Clinic in the United States: A Five Year Analysis

Griffin Reed[1], Joyce Mathew[1], Kelsey Rigby[2], **Mery Deeb**[3], Elena Cravens[1], Anthony Reginato[4], Gofran Tarabulsi[5] and Joanne Cunha[6], [1]Brown University, Providence, RI, [2]Dartmouth Hitchcock Medical Center, Falmouth, MA, [3]Brown University, Warwick, RI, [4]The Warren Alpert Medical School of Brown University, Providence, RI, [5]Women and Infants Hospital, The Warren Alpert Medical School of Brown University, Providence, RI, [6]The Warren Alpert Medical School of Brown University, Riverside, RI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic disorders frequently affect women of childbearing age. These diseases and medications used to treat them can have adverse effects on fertility and fetuses. At The Women and Infant's Hospital in Providence, Rhode Island, the Specialty Care in Pregnancy (SCIP) clinic provides a multidisciplinary patient care team consisting of obstetric-medicine internists collaborating with rheumatologists to care for women with rheumatologic conditions who are pregnant or hoping to become pregnant. At a national level, clinics combining these specialties are scarce with an internet search revealing only three other programs in the United States (The Brigham and Women's Hospital, Tufts Hospital, and

The Hospital for Special Surgery). The purpose of this study was to characterize the population cared for in this unique clinic, identify interventions provided by this clinic, and analyze pregnancy outcomes for the mother and child.

Methods: We performed a 5-year retrospective chart review of patients seen in the multidisciplinary obstetric-medicine/rheumatology clinic at The Women and Infants Hospital in Providence, Rhode Island, from January 1, 2016 through December 31, 2021. Outcomes extracted from the charts included: age, change to diagnosis, changes to medications, medical comorbidities, laboratory results, birth outcomes and complications, and services provided by the clinic.

Table 1. Maternal characteristics of the 87 patients seen in the shared obstetric-medicine/rheumatology shared clinic at Women and Infants Hospital in Providence, Rhode Island.

Characteristic	n=87
Age, median (IQR), years	35 (32-39)
Ethnicity, n (%)	
White	50 (58%)
Black or African American	7 (8%)
Asian	4 (5%)
Multiracial	6 (7%)
Unknown / Not Reported	19 (22%)
Ethnicity, n (%)	
Hispanic / Latino	28 (33%)
Not Hispanic / Latino	51 (59%)
Unknown/ Not Reported	7 (8%)
Non-rheumatologic conditions, n (%)	
Asthma	10 (12%)
Hypertension	6 (7%)
Obesity	5 (6%)
Diabetes	2 (2%)
Tobacco Use	2 (2%)
Alcohol Use	2 (2%)
Rheumatologic diagnosis, n (%)	
Systemic lupus erythematosus	15 (17%)
Rheumatoid arthritis	16 (18%)
ANA abnormality (≥1:160), undifferentiated	11 (13%)
Psoriatic arthritis	5 (6%)
Ankylosing spondylitis	5 (6%)
Antiphospholipid syndrome	4 (5%)
Panuveitis	2 (2%)
Drug induced lupus	2 (2%)
Discoid lupus	1 (2%)
Behcet's disease	1 (1%)
Mixed connective tissue disease	1 (1%)
Other	24 (28%)

Table 2. Frequency of medications initiated, changed, or discontinued at the shared obstetric-medicine/rheumatology shared clinic in 87 women at Women and Infants Hospital in Providence, Rhode Island.

Medications **initiated** at shared visit, n (%)	
Hydroxychloroquine	12 (14%)
Prednisone	8 (9%)
Aspirin	6 (7%)
Sulfasalazine	5 (6%)
Amitriptyline	3 (3%)
Azathioprine	2 (2%)
Medications **changed** or **discontinued** at shared visit, n (%)	
Prednisone	5 (6%)
Hydroxychloroquine	4 (5%)
Adalimumab	2 (2%)

Table 3. Outcomes from 87 pregnant women seen in the shared obstetric-medicine/rheumatology clinic at Women and Infants Hospital in Providence, Rhode Island

Pregnancy outcome, n (%)	
Live Birth	47 (54%)
Miscarriage	9 (10%)
Unknown	31 (36%)
Mode of delivery, n (%)	
Cesarean section	16 (18%)
Normal vaginal delivery	13 (15%)
Assisted vaginal delivery	2 (2%)
Unknown	51 (59%)
Fetal complications, n (%)	
Prematurity (<37 weeks)	9 (10%)
Intrauterine growth restriction	4 (5%)
Respiratory complications	2 (2%)
Infection	1 (3%)
Fetal demise	1 (3%)

Results: *Demographics* The data from 87 patients were extracted (**Table 1**). Additionally, the median gestational age at first visit was 17 weeks (IQR 11-26 weeks). 47% of patients had a primary rheumatologist prior to evaluation in clinic. *Interventions* 38 patients (44%) had a medication initiated at the clinic, 9 (10%) had a medication discontinued, and 7 (8%) had a change in dose of a medication (**Table 2**). 18 patients (21%) were referred to another specialist from the shared clinic, and 3 (3%) received fertility counseling and were referred to a fertility specialist. 8 patients (9%) were diagnosed with a new autoimmune condition. *Outcomes* Pregnancy outcomes are listed in **Table 3**. Additionally, 5 patients (6%) developed preeclampsia.

Conclusion: The Specialty Care in Pregnancy (SCIP) clinic is among the first obstetric-medicine/rheumatology multidisciplinary clinics in the United States (US) and the first to publish analysis of their data. Interventions were made in the majority of patients despite nearly half already having established care with a primary rheumatologist, which highlights the critical importance of this clinic. The most commonly initiated medications were hydroxychloroquine and prednisone, which underscores the safety and efficacy of these medications in preventing and treating flares during pregnancy. Compared with a similar clinic in the United Kingdom, our preeclampsia incidence was 6 times higher (6% vs 1%) and miscarriage incidence was 8 times higher (16% vs 2%) (1). These discrepancies may be attributed to differences in socioeconomic and racial diversity. Multidisciplinary clinics of this type are needed in the US to provide further care and research to this patient population.

Telerheumatology model, utilizing a community-embedded Advanced Clinician Practitioner in Arthritis Care (ACPAC)-ERP and an urban-based academic Rheumatologist.

Methods: A Rheumatologist and an ACPAC-ERP established a monthly half-day Hub-and-Spoke-Telerheumatology clinic to care for patients with suspected IA, triaged by the ACPAC-ERP. Comprehensive initial assessments were conducted in-person by the ACPAC-ERP (Spoke);investigations were completed prior to the Telerheumatology visit. Retrospective analysis of demographics, time-to-key-care-indicies, patient-reported outcomes, clinical data, and estimated travel savings was performed.

Table 2: referral, Assessment and Follow-up visits Some patients presented at first clinic visit alrady on DMARDS; of 21 who were eligible for new DMARD thrapy, treatment commenced on average in 52 days.

Referral, Assessment, and Follow Up Visits	
Visits	**n=124**
Range All Visits	1-20
Mean (SD)	4.0 (4.0)
Range Telerheumatology Visits	1-20
Mean Telerheumatology Visits (SD)	4.0 (3.0)
Range In-person Visits	n=10 (0-1)
Mean In-person Visits (SD)	0.1 (0.25)
T1 (Days from PCP Referral to ERP Assessment)	**n=119**
Range	0-513 days
Mean (SD)	68.9 days (81.4)
75th Percentile	84 days
T2 (Days from ERP Assessment to Telerheumatology Visit)	**n=95**
Range	0-658 days
Mean (SD)	79.7 days (103.2)
75th Percentile	92 days
T3 (Days from Telerheumatology Visit to DMARD)*	**n=21**
Range	0-371 days
Mean (SD)	52.0 days (87.8)
75th Percentile	70 days

*Some patients presented at the first clinic visit already on DMARD; of the 21 who were eligible for new DMARD therapy, treatment commenced on average in 52 days.

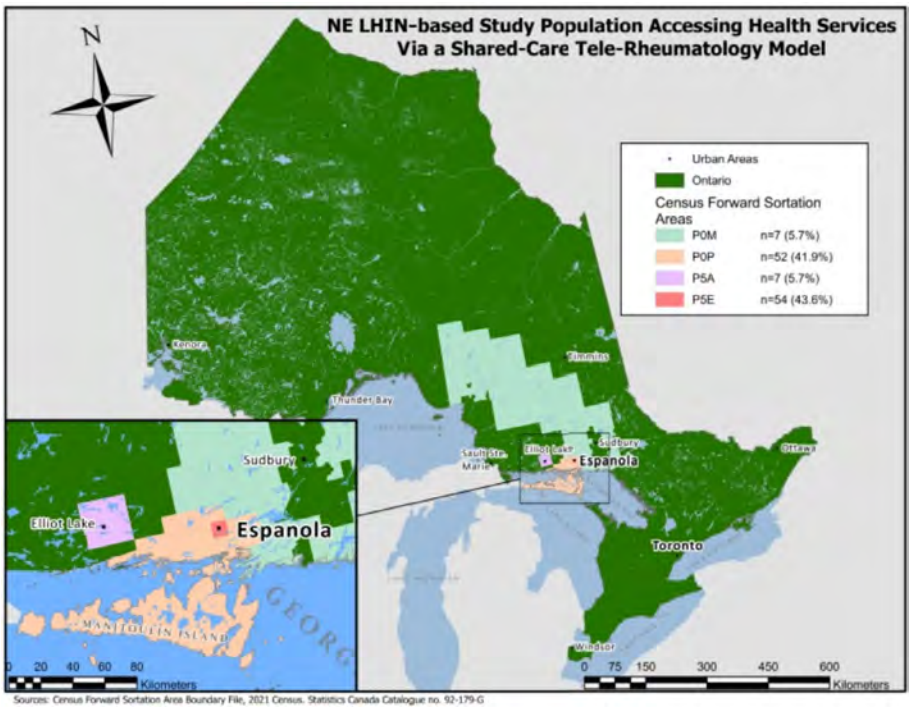

Figure 1: North East LHIN-based Study Population Accessing Health Services via Shared-Care Telerheumatology Model

Results: Data from 124 patients seen between January 2013-January 2022 were collected: 98% (n=496/504 visits) were virtual. Average age at first visit was 55.6 years, 75% were female. IA/Connective Tissue Disease (CTD) disease was confirmed in 80/124 (64.5%) patients. Mean time from primary care referral to ACPAC-ERP assessment was52.5 days and mean time from ACPAC-ERP assessment to the Telerheumatology visit was 64.5 days. An estimated 493,470 kilometers of patient-related travel was avoided.

Conclusion: A feasible, equitable, and effective ACPAC-ERP (Spoke) and Rheumatologist (Hub) Telerheumatology model of care assessing and managing patients with suspected IA in rural/remote Ontario was described. This model can be leveraged to increase capacity to deliver comprehensive virtual rheumatologic care in underserviced communities.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In the wake of the COVID-19 pandemic, telemedicine rapidly became standard of care for people with rheumatic diseases. Observational data on effectiveness and acceptability of telemedicine for rheumatology care is mixed. We aimed to determine whether satisfaction with telemedicine visits was noninferior to in-person visits for delivery of rheumatologic care.

Methods: We conducted a parallel group, randomized, single-blind, noninferiority trial in rheumatology clinics at a tertiary academic medical center. Eligible patients were age ≥ 18 years with one of several rheumatic diseases, and completed ≥ 2 clinic visits in ≤ 18 months (telemedicine or in-person) including ≥ 1 prior visit in-person in ≤ 18 months. The primary outcome was high post-visit satisfaction rate (9 or 10 on a 0 – 10 satisfaction scale). Using an administered survey, we also collected date on preference for the next visit type, self-efficacy for managing medications, and medication adherence. Preference for the next visit type was defined as: same as the group allocation, different than the group allocation or no preference. Success was determined if the satisfaction rate with telemedicine versus in-person visits was non-inferior, using a noninferiority margin of -10%. We performed modified intent-to-treat (mITT), and per protocol (PP) analyses to account for those that crossed over, with age adjustment on the PP population.

Results: Out of 599 randomized participants, 451, 38.9% Black, 84.3% women, mean age 55.6 completed surveys. In the mITT analysis, telemedicine visits were not non-inferior to in-person visits for the proportion of people that were highly satisfied, 77.4% vs. 90.5%, difference -13.1% (95% CI, -19.8% to -6.5%). 35 participants crossed over in the in-person group and 55 in the telemedicine group. In the PP analysis, the satisfaction rate for telemedicine visits was also not non-inferior to in-person visits, age-adjusted difference -16.2% (95% CI, -23.8% to -8.6%). In the mITT analysis, most participants in both arms preferred an in-person visit for their next visit. The proportion of participants who indicated they preferred the same type of visit for their next visit compared to a different visit type and no preference

Table 1. Demographic characteristics of participants who completed phone surveys and were included in the modified intent to treat analysis; p < 0.05 in bold font.

	In-person (N=221)	Telemedicine (N=230)	p

Missed work for appointment, No (%)	39 (18.0)	33 (14.7)	0.4	37 (20.2)	15 (8.9)	**0.002**
Expenses incurred related to visit, No (%)						
Meals	72 (32.6)	28 (12.2)	**<0.0001**	70 (37.6)	10 (5.7)	**<0.0001**
Lodging	0 (0)	0 (0)	-	0 (0.0)	0 (0.0)	-
Childcare	1 (0.5)	2 (0.9)	1.0	1 (0.5)	0 (0.0)	1.0
Transportation	142 (64.3)	62 (27.0)	**<0.0001**	139 (74.7)	15 (8.6)	**<0.0001**

IQR, Interquartile range; SD, standard deviation. *PROMIS self-efficacy for managing medication/treatment, reported as the T-score that represents a standardized score with mean of 50 and a standard deviation of 10, and higher scores associated with higher self-efficacy; **from the Medication Adherence Questionnaire. Self-efficacy for managing medications missing for 15 participants, medication adherence missing for 14 participants.

was significantly greater for those who had in-person visits (55.2% vs 20.0% in-person vs telemedicine, $p < 0.0001$). There were no differences between groups in self-efficacy for managing medications or medication adherence in either the mITT or PP analyses. Significantly more individuals in the in-person group vs. the telemedicine group reported expenses related to meals and transportation.

Conclusion: Among a large group of diverse, established rheumatology patients, who uniquely were randomized to visit type, high satisfaction rate with rheumatology clinic visits was significantly lower for telemedicine than for in-person visits. A meaningful minority of patients (about 20%) preferred that their next visit be telemedicine. Future studies should focus on factors associated with optimal visit type and how to achieve best outcomes for people with rheumatic diseases, including identifying subgroups that may prefer or benefit most from telemedicine.

*Inadequate health literacy grouped the following answers: ''Somewhat'', ''A little bit'', and ''Not at all''; $Employed is full-time, part-time, or temporary work; #State decile from 1 (least disadvantaged) to 10 (most disadvantaged); ##National percentile from 1 (least disadvantaged) to 100 (most disadvantaged). Race missing for 1 participant; education missing for 28 individuals; health literacy missing for 16 individuals; income missing for 205 participants; ADI missing for 132 participants.

Abstract Number: 1006

Use of Implementation Strategies to Promote Adherence of Knee Osteoarthritis Guidelines and Improve Patient Outcomes: A Systematic Review

Michelle Ramirez[1], Rebecca Fillipo[1], Connor Drake[1], Lesley Skalla[2], Kelli Allen[3], Amanda Nelson[4] and Maggie Horn[1], [1]Duke University School of Medicine, Durham, NC, [2]Duke University Medical Center Library & Archives, Durham, NC, [3]University of North Carolina, Durham, NC, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the development of care models and practice guidelines the translation of knee osteoarthritis guidelines to practice remains suboptimal. Theoretically informed implementation strategies may facilitate the translation of guidelines to practice however their selection and use present challenges for clinicians and health systems aiming to improve patient quality of care for patients with knee osteoarthritis. Therefore, the purpose of this systematic review was to describe the use of implementation strategies to promote knee osteoarthritis guideline recommendations and evaluate their impact on guideline adherent care and patient-reported outcomes.

Methods: An electronic search was performed using MEDLINE (via PubMed), Embase (Elsevier), CINAHL(EBSCO), and Web of Science (Clarivate) databases to identify studies that included the use implementation strategies to improve knee osteoarthritis guideline recommendations and or patient reported outcomes. Implementation strategies were categorized based on the nine implementation domains and 73 implementation strategies as described by the Expert Recommendations for Implementing change (ERIC) taxonomy. Risk of bias was assessed using the Cochrane Effective Practice and Organization of Care(EPOC) criteria.

Results: Twenty-one studies were included in the final review. Eight implementation domains and 36 implementation strategies were represented within the twenty one studies with six strategies represented in ten or more studies. Seventy-one percent of implementation interventions were theoretical informed with an average of ten strategies used per study. "Develop educational materials", "Conduct educational meetings", "Make training dynamic", "Distribute educational material" and "Prepare patients/consumers to be active participants" were the top represented strategies. "Utilize financial strategies" and "Provide interactive assistance" domains were the least represented of the included studies. Eight implementation domains demonstrated a positive effect on clinician adherence to knee osteoarthritis guidelines, quality of life(3 domains), disability(8 domains), and reduction of pain intensity(3 domains). "Train and educate stakeholders" and "Engage consumers" had positive effects on both clinician adherence to guidelines and patient reported outcomes. The majority of studies had a low to moderate risk of bias.

Conclusion: This review highlights the use of strategies to improve the quality of care and outcomes for patients with knee osteoarthritis. The findings suggests that using multifaceted implementation strategies appear to be effective for improving knee osteoarthritis clinical practice guideline adherence and patient-reported outcomes. The findings also suggest only 50% of the 73 strategies recommended by the ERIC taxonomy have been used in improving guideline adherence and outcomes in the context of knee osteoarthritis care management, demonstrating a need for further research. In general, the use of implementation strategies in the context of knee osteoarthritis management, may guide future initiatives to improve quality of care and patient outcomes.

Telehealth Conversion: A Strategy for Optimizing Ambulatory Access

Sancia Ferguson[1], Amanda Nanes[2], Lori Zemlicka[2] and Christie M. Bartels[3], [1]University of Wisconsin, Madison, WI, [2]UW Health, Madison, WI, [3]University of Wisconsin, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: With the rapid uptake of telehealth at the beginning of the pandemic, our group operationalized a simple strategy to convert appointments for patients who were not present at the time of their in-person visit to a telehealth visit in order to provide timely access to care amid constrained access.

Methods: Patients with late cancellations or impending no-show visits were asked if they'd like to convert their visit to telehealth. If enrolled in the electronic patient portal a video visit was offered, and if not enrolled, a telephone visit was offered. The project was piloted at 1 clinic site through 8/31/2021 before broader implementation to 2 clinics. Procedure visits were excluded. Demographics including age, gender, race/ethnicity, insurance status, and language, were analyzed using Chi-square and Fischer's exact tests to examine variations in telehealth visit type by group.

Results: Between 9/1/2023 and 3/31/2023, we successfully contacted patients across 624 visits eligible for telehealth conversion (554 unique patients) converting 83% (516/624). Of the 516 telehealth visits completed, 56% were by telephone (n= 282) and 46.2% by video (n = 234). Patients who were older or with Medicare and Medicaid public insurance were more likely to select phone visits (72.1%, 59.3%), while patients with commercial insurance were more likely to choose video visits (56%) ($p < 0.001$). Younger and urban patients were more likely to have video visits, while older and rural patients were more likely to have phone visits (Table 1) . There was no difference in the video vs telehealth visit selection by race, ethnicity, or sex. The intervention resulted in at least 258 additional hours of patient care, avoided reschedules and zero payment clinic time, with a modest revenue loss reduction

Table 1: Sociodemographics of no-show or late cancellation visits converted to telehealth n=516

Limited English Proficiency	5 (100)	0 (0)	

[1] 5 patients with limited English proficiency all choose phone and not video system data shows lower portal enrollment in this population

Sociodemographics of no-show or late cancellation visits converted to Telehealth

Figure 1: Telehealth conversion visit volume across time

for telemedicine of $7298 ($39.19 per appointment). Figure 1 shows overall gains and seasonal variation with higher winter demand. Monthly variability may also reflect clinic staff shortages during this period impacting outreach capacity.

Conclusion: Our simple, targeted strategy of converting appointments to telehealth when an in-person appointment is identified as at-risk resulted in significant access gains and modest revenue loss reduction. Clinic patients who are older, on Medicare or Medicaid, or rural preferred phone visits. Per literature, those with limited English proficiency are less likely to be actively enrolled in patient portals, which may impact their ability to convert to a video visit, a potential area to optimize in the future. Higher rates of telephone visits for rural patients, who may have less access to high-speed internet, highlight the equity considerations in offering telehealth modalities to patients.

: Telehealth conversion visit volume across time

Identifying Inflammatory Arthritis Ambulatory Care Service Model Enhancements Needed to Reduce Avoidable Emergency Department Use

Emilie Pianarosa[1], Pamela Roach[1], Patrick McLane[2], Meghan Elliott[1], Brian Holroyd[3], Shanon McQuitty[4], Steven Katz[3], Nazret Russon[2], Katie Lin[1], Claire Barber[1] and Cheryl Barnabe[1], [1]University of Calgary, Calgary, AB, Canada, [2]Alberta Health Services, Edmonton, AB, Canada, [3]University of Alberta, Edmonton, AB, Canada, [4]Arthritis Research Canada, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Emergency departments (ED) become a location for non-urgent care when ambulatory care systems are not sufficient. We aim to describe contributing factors to the decision taken by persons with inflammatory arthritis (IA) to present to the ED, their experiences of ED care, and propose enhancements in ambulatory models of care to better support patients and improve system efficiency.

Methods: An invitation to complete an online survey was distributed by the health authority in October 2021 and March 2022 to a sample of individuals with an IA condition who had visited an ED within the previous year. Descriptive statistics were used to summarize quantitative data. Thematic analysis of free text responses was conducted

to contextualize decision making and experiences of ED care, and generate system-level recommendations to reduce avoidable ED use.

Results: 82 persons (48% RA, 12% PsA, 6% SpA, 34% Gout; 63% aged 16-55 years; 48% female; 50% urban residents) completed the survey. Over 1/3 (37%) of visits were for arthritis flare or other musculoskeletal symptoms, with other primary symptoms being chest pain (15%), injury (12%) and infection (11%). Of all visits, 28% of persons reported they proceeded directly to the ED, 32% made a return visit, and 36% were completed after accessing ambulatory care, primarily a primary care provider. For visits specific to arthritis flare or other musculoskeletal symptoms, 19% of patients proceeded directly to the ED as they could not access ambulatory care (after business hours, or call to provider not returned), 36% were a return visit of which 64% were for symptoms being unresolved or worsening and with 27% not being able to follow-up with their rheumatologist. For 39% they had accessed primary or specialty care for assessment and management first but then presented to the ED anyways. The rheumatology service was contacted by the ED provider in 9% of events of patients presenting with arthritis flare. Challenges in healthcare system coordination, system processes and pressures, and communication and relationality between IA patients and healthcare providers led to negative experiences of ED care (Table 1). After an ED visit patients had remaining concerns about not having been assessed comprehensively, and not having the cause of their symptoms being explained to them. They felt they were being discharged too soon, did not have a symptom management plan, and had the responsibility to coordinate multiple further assessments with different ambulatory providers. They perceived symptoms were not being appropriately attributed to their arthritis condition, Recommendations to reduce avoidable ED use include improving access to rheumatology care for both initial visits and urgent concerns, introducing initiatives for improved ambulatory care coordination and service delivery, resourcing EDs at appropriate levels to provide quality care, and to enhance provider education about arthritis condition assessment and management.

Conclusion: We present initial recommendations to develop systems and procedures to reduce the need for ED use by IA patients. Modifying current models of care may improve patient outcomes while simultaneously decreasing utilization and cost to the healthcare system.

Main Theme	*Subtheme*	*Description*	*Quotes*
Continuity & Coordination of Care	Lack of coordination in the healthcare system	It becomes the patient's responsibility to navigate the healthcare system for their arthritis condition.	"It's a hopeless feeling to be told that there is nothing that can be done. Medications are not changed at the hospital because the rheumatologist makes that decision. Pain meds are only assessed by your personal physician. It's endless rounds of medical visits which never really end up addressing the base causation. You learn to try to handle it by yourself." "I've been in the ER plenty of times, and it's always the same thing. You're EXTREMELY lucky if you see a Rheum, instead they [referring to the ED provider] just give you pain meds and send you home and expect you to deal with it on your own time."
	Expectations of being discharged only when safe to do so	The patient needs to mobilize safely, access necessary prescriptions, and have transportation home, however they experience being discharged quickly.	"I was still very unwell however they felt there was nothing more they could do. I was unsteady and was not escorted out or asked how I was getting home. Then had to wait at the pharmacy for 45 until the prescriptions were filled. It was not ideal so I sat in the hospital reception for one hour until I felt like I could drive." "It was after 7:00 PM I believe and didn't feel I was well enough from the drugs they had given me. I told them I lived alone."
	Expectations of having a symptom management plan and follow up arranged	The patient wants to understand how they should self manage symptoms after discharge, and have any necessary follow-up arranged.	"No reassurance was given that I would be okay until I saw rheumatology. The best suggestion was ibuprofen." "They would just send me home with more pain medication and no follow up plan." "[I knew that follow up in the community with specialists would not happen/ would not happen in a timely manner."
System Process & Pressures	Long wait times for both ambulatory and acute care assessment	Patients experience prolonged wait times for assessment in the ED, yet this is accepted as there is a need for reassurance about symptoms while awaiting a rheumatology assessment.	"I spent over 95 percent of the time waiting [in the ED] for who knows what." "I was waiting to see a rheumatologist and was in a great deal of pain and was scared. I wanted reassurance I wasn't becoming more ill while waiting on rheumatology."
	Expectations of a comprehensive assessment to determine the cause for their symptoms	Patients with complex conditions and treatment anticipate having a complete history taken, with appropriate investigations completed and interpreted. However, the focus during an ED visit is on acute symptoms and/or issues only rather than being chronic disease oriented. The patients feel that the cause of their symptom onset is not explored nor explained to them. Symptoms that seem severe to the patient are not explained.	"They were unsure what was happening but sent me home and told me to come back when/if it started again so I returned 3 times for the same issues with chest pain before a doctor figured it out." "I left with NO answers to my abdominal pain, feeling just as ill as I did when I went in." "No results, communication was lacking, no answers or investigation to why I flared up." "There was still no explanation for why I was experiencing severe stomach pains, chest pains and brain fog, and no further inquiry into why I have an assortment of other symptoms that don't fully correlate to my Rheumatoid Arthritis diagnosis."
Communication & Relationality	Expectations of a respectful interaction with healthcare providers	Patients experience interactions that are short in duration, and they feel ignored and rushed out.	"Gone are the days of hospitals actually treating anyone, it's all just temporary bandaids, so you can get out of there fast enough so they can see the next person." "The doctors are always rushing and make you feel like you on an assembly line not an actual person."
	Attitudes and knowledge about arthritis	Patients experience that either every symptom they present with is attributed to arthritis by the healthcare provider even when the patient doesn't think this to be true, or that they are not believed when they indicate their symptoms are arthritis related. They feel there is a negative perception when the ED is used as a resource for chronic disease management.	"Didn't feel like they were listening to me about my symptoms not feeling like my RA and I really felt that something else was wrong." "Doctor said interesting interesting that I suggested a "rheumatoid perspective" and said I must have just over worked it. Did not make any sense which left me extremely confused and upset." "I do struggle if I go to different ER where my doctor doesn't work as sometimes they don't treat me well due to my chronic illness."

More Implementation Strategies Are Not Associated with Better Implementation Outcomes: Implementing the Lupus Patient Decision Aid

larry hearld, **Jasvinder Singh** and Mark Beasley, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess the association of the number of implementation strategies for a patient lupus decision aid (DA) with perceived implementation outcomes, and the moderating effect of the organizational climate on this relationship.

Methods: We implemented a lupus patient DA across 15 U.S. rheumatology clinics made available during a regular patient clinic visit. In addition to the standardized implementation strategies provided uniformly by the research team to each site (e.g., training on DA use, designation of a clinic champion and refresher training course), each clinic could choose from a 'menu' of implementation strategies directed to both clinic personnel and patients, customized to their clinic. We examined the effect of the number of implementation strategies with clinic-personnel-reported implementation outcomes (acceptability, appropriateness, feasibility), and the extent of impact of the organizational climate (e.g., learning environment, readiness for change) on this relationship.

Results: At the 4-month post-implementation period, the average perceptions of the lupus DA were as follows: acceptability, 3.49; appropriateness, 3.37; and feasibility, 3.40. The mean number of total strategies implemented by the participating clinics was 3.37, with 2.07 clinic-focused strategies and 1.29 patient focused strategies, that remained stable during follow-up. Adjusted for clinic and clinic personnel characteristics, and time since implementation, we found the following associations for implementation strategies: (1) total strategies not significantly associated with lupus DA acceptability, appropriateness, feasibility, success, or permanence; (2) the number of clinic-focused strategies associated positively and significantly with lupus DA acceptability, appropriateness, and feasibility; and (c) the number of patient-focused strategies was negatively significantly associated with lupus DA acceptability and feasibility but not appropriateness. We found significant moderation of the relationship between implementation strategies and implementation outcomes by the learning environment and readiness for change.

Conclusion: We found that the overall number of implementation strategies was not associated with perceptions of DA acceptability, appropriateness, and feasibility; however, these relationships did differ for different implementation targets and under different organizational conditions. Our findings highlight the importance of the context but suggest that a very nuanced consideration of contextual characteristics is needed as aggregated factors such as organizational readiness for change and its learning climate contribute to implementation success in different ways and for different implementation outcomes.

Abstract Number: 1010

Advanced Clinician Practitioners in Arthritis Care: A Workforce Profile

Laura Passalent[1], Soever Leslie[1], Amanda Steiman[2], Christopher Nielsen[1], Deborah Levy[3] and Robert Inman[4], [1]Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada, [2]Sinai Health System, Toronto, ON, Canada, [3]The Hospital for Sick Children, Toronto, ON, Canada, [4]University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The Advanced Clinician Practitioner in Arthritis Care (ACPAC) Program is a post-licensure, competency-based academic and clinical educational program that prepares physiotherapists, occupational therapists, nurses, and chiropractors for extended practice roles in the diagnosis and management of patients with arthritis, autoimmune and other musculoskeletal (MSK) conditions. Since 2005, the program has graduated extended role providers (ERPs) to manage a growing population of patients with MSK conditions; address a progressive decline in MSK specialists and better utilize health professionals to improve access to care. The objective of this study was to profile the current ACPAC workforce with respect to 1) demographics, including aspects of ethnicity, diversity and inclusion; 2) practice setting and clinical roles; 3) health system integration and 4) remuneration.

Methods: ACPAC graduates from 2006 to 2022 were sent an electronic questionnaire from February to April 2023 using Research Electronic Data CAPture software. The questionnaire was developed based on review of workforce literature and was reviewed by the investigative team for face and content validity, clarity, relevance and format. Univariate statistics were used to summarize data. All analyses were conducted in SAS v9.4.

Results: Seventy-two of 103 graduates completed the questionnaire (response rate 69.9%). *Demographics*: Most respondents were from Ontario, Canada (95.8%) and were physiotherapists (78.8%). Mean age was 49.4 (SD 9.2) years. The majority identified as women (77.8%) and White-North American/European ethnicity (71.8%). No respondents identified as North American Indigenous. *Practice setting and clinical roles:*Most reported current employment in an ERP role (76.4%). There were inconsistencies regarding ERP title. The majority (80%) were working in hospital-based settings (80%). Across all settings, 89.1% worked with adult populations, and provided either orthopaedic (54.5%) or rheumatology (40%) care. Only 12.2% reported working in rural or remote settings. *Health system integration:* Respondents reported working in various orthopaedic and rheumatology models of care including triage, interprofessional collaborative care programs and transition clinics from paediatric to adult care. *Remuneration*: Most funding models were from government sources (90.9%) with almost half (47.2%) reporting an annual salary of at least $100,000 CAD.

Conclusion: Most ACPAC ERPs are physiotherapists working in urban publicly-funded, hospital-based practices providing adult orthopaedic and rheumatology care. Opportunity exists to maximize employment of existing graduates and further expand ERP roles beyond hospital-based settings, and in rural and remote areas. Examples include family medicine clinics, community-based clinics, geriatric care, and emergency departments. A small proportion of respondents identified as non-white, with Indigenous individuals not represented in this workforce. There is value in targeting recruitment strategies to attract program candidates representative of diverse ethnic backgrounds and inclusive of Indigenous populations.

A Rheumatology Model of Care Re-design: Integrating the Advanced Practice Provider

Lisa Carnago[1], Kristin Holbrook[2], David Leverenz[3], Natalie Rivera[4] and Allison Dimsdale[5], [1]Duke Health, Hillsborough, NC, [2]Duke Health, Raleigh, NC, [3]Duke University School of Medicine, Durham, NC, [4]Children's National Hospital, Washington, DC, [5]PDC Advanced Practice, Duke School of Nursing, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a lack of guidance surrounding integration of Advanced Practice Providers (APPs) into specialty practices utilizing interprofessional Models of Care (MoC). Due to current and projected workforce shortages combined with rising patient need in the field of Rheumatology, multiple methods were utilized to engage both APP and physician perspectives to develop a MoC specific to an academic Rheumatology practice. Initial goals included understanding the current and desired MoC, as well as integration of APPs into optimized models.

Figure 1
Blueprint for Model of Care Re-Design

Methods: Utilizing a mixed methods sequential-exploratory design through a quality improvement lens, a blueprint for a MOC re-design was developed and will be presented here. Quality Improvement (QI) strategies planned: 1. Needs assessment 2. Baseline data collection 3. Dissemination 4. Team building 5. Implementation 6. Evaluation with ongoing improvements as needed (Figure 1). Phases one through four were completed as part of this project with divisional consideration for implementation of phases five and six in the future.

Results: In the needs assessment phase, we interviewed key stakeholders (divisional leadership) to develop shared goals for the optimal MoC. These goals included quality of patient care, access, and addressing barriers at the patient, physician, APP, environmental, and organizational levels. In the next phase, data collection, we distributed a survey to 12 physicians and 8 APPs in our practice addressing eleven domains: 1. Models of Care 2. Physician 3. Appropriateness of an APP to see 17 common Rheumatological diagnoses as a new or return visit 4. Logistical Considerations 5. Staff Utilization

Figure 2
Model of Care: Team Blueprint and Strategies for Formation

No	**3 (25)**	0 (0)
Interest in structured MoC incorporating the APP		
	MD (n=10)	APP (n=7)
Yes	**6 (60)**	6 (85.7)
No	**4 (40)**	1 (14.3)

MD (Medical Doctors), APP (Advanced Practice Provider), MoC (Model of Care), RVU (Relative Value Unit), Staff (Registered Nurse, Licensed Practical Nurse, Medical Assistant)

6. Provider Satisfaction 7. Telehealth Preferences 8. Patient Impact 9. Burnout Inventory 10. Work Life Balance and 11. Joy in Work. During phase three, key findings were communicated with divisional leadership and then with clinicians and staff followed by an iterative process for team building and design in phase four. Surveys showed low satisfaction with the current MoC. These findings suggest that the APP is being utilized in variable MoC and that many physicians are dissatisfied with current MoC. Additionally, strong preferences for parallel and independent practice, standardization of MoC, and a formal structure that integrates the APP was preferred by both APPs and Physicians (Table 1). The top two clinician foci for the MoC included quality of care and prevention of burnout. Clinicians agreed that the main barriers to implementing a MoC were a lack of a well-defined and documented MoC, clinic space and communication. Based upon these findings, a proposed team-based MoC was developed (Figure 2).

Conclusion: Using a mixed methods QI approach is effective to elicit clinical needs and barriers with significant clinician buy-in. Improved understanding of clinicians' desired MoC and what this MoC should focus on impacts team-based structures, for which the APP is a critical component. As the role of the APP is predominantly geared towards the clinical mission, improving full scope integration of the APP via MoC re-design in specialty practices, including Rheumatology, is pivotal to improve the quality of patient care and access.

Leveraging Cues and Rewards to Form Habits to Improve Medication Adherence in Gout: An Adaptive Behavioral Pilot Trial

Candace Feldman[1], Katherine Crum[2], Kaitlin Hanken[3], Constance Fontanet[4], Ellen Sears[2], Theresa Oduol[2], Seanna Vine[2], Juliana Mastrorilli[2], Gauri Bhatkhande[2], Julie Lauffenburger[2], Rebecca Oran[5], Ted Robertson[6], Wendy Wood[7] and Niteesh Choudhry[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, [3]Center for Healthcare Delivery Sciences and Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Boston, MA, [4]Darmouth Geisel School of Medicine, Hanover, NH, [5]BCBS, Boston, MA, [6]Ideas42, San Francisco, CA, [7]USC, Los Angelos, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Health Services Research Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Adherence to urate-lowering therapy (ULT) reduces the incidence of debilitating gout flares. Providing a cue for a behavior, reinforcing the behavior with a reward, and then repeating this process is known as the cue-reward-repetition principle. Over time, cues become more important and rewards less because the activity becomes automatic (a habit). We conducted a randomized, adaptive pilot trial to test whether leveraging cues and rewards to establish medication taking as a habit improves adherence to ULT.

Methods: We enrolled adults 18 with gout and a uric acid level of >6mg/dL within 6 months, on a stable dose of ULT (allopurinol or febuxostat), who received rheumatology and/or primary care at a multisite medical center. Participants received electronic pill caps and were randomized to 3 arms: 1) the nonadaptive intervention where they received assistance selecting a cue (e.g., "place your medication near your toothbrush") and a reward (charitable donation of $0.50/ULT adherent day) with text message reminders about their cue and the amount donated every 4 days, 2) the adaptive intervention with the

Change in automaticity – mean (SD)	0.62 (0.96)	0 (0.85)	-0.13 (0.50)	**<0.001**/0.45*
Change in medication taking routine – mean (SD)	0 (0.86)	0.14 (0.65)	-0.22 (0.86)	0.43/0.18
*Non-adaptive vs. control/Adaptive vs. control #Adherence measured using pill caps as the number of times the pill cap was opened divided by the number of doses prescribed per day				

same strategy but the reward started at $0.25/ULT adherent day and was doubled at 6 weeks if adherence was 75% 3) the control arm (pill cap monitoring only) (**Fig. 1**). The intervention ended at 12 weeks and adherence was monitored for the next 6 weeks. The primary outcome was adherence (number of times the pill cap was opened/number of doses prescribed per day) at 18 weeks. Secondary outcomes included adherence at 12 weeks, changes in automaticity, medication-taking routines and intentions, and uric acid level from baseline. We interviewed 14 patients who completed the trial to understand their experiences.

Results: Fifty-six individuals were randomized (non-adaptive arm (N=18), adaptive arm (N=20), and control arm (N=18)) (**Fig. 1**). Participants were 21% female, 81% White, 15% Black, 8% Latinx with similar demographics across arms (**Table 1**). The mean (SD) baseline uric acid was 7.47 (1.55) mg/dL. We did not observe statistically significant improvement in ULT adherence across intervention arms at 18 weeks (primary outcome) or at 12 weeks (secondary outcome) (**Table 2**). Mean (SD) adherence at 18 weeks was 0.79 (0.23) in the nonadaptive arm, 0.83 (0.18) in the adaptive arm, and 0.76 (0.26) in the control arm. Compared to the control arm, automaticity scores were higher post vs. pre intervention for the non-adaptive arm ($p< 0.001$) but not the adaptive arm ($p=0.45$); changes in other secondary outcomes were not significant. Exit interviews revealed limited intervention impact due to preestablished medication-taking habits, independent reasons to take ULT (e.g., prevention of painful gout flares) and ineffective reward (charity donation). Participants in all groups noted awareness of being monitored with the pill caps.

Conclusion: We did not observe significantly improved adherence to ULT among individuals enrolled in this habit formation intervention. High adherence in all arms and small sample size limited power. Larger studies over longer time frames are needed in diverse patient populations with varied baseline adherence to understand whether leveraging automaticity can enhance medication-taking behaviors.

Implementation of a Rheumatology-Based Social Determinants of Health Screening Program to Uncover and Address Needs in a Multihospital Health Care System

Candace Feldman[1], Rebecca Summit[1], Karli Retzel[1], Haelynn Gim[2], Leah Santacroce[1], Shalina Patel[1], Sarah Wilkie[3], Virginia Bills[1], Siobhan Case[1], Caitlyn Wasserman[3], Derrick Todd[1], Nancy Sadick[1] and Sara Schoenfeld[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA, [3]Mass General Brigham, Boston, MA, [4]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Social determinants of health (SDoH) contribute to inequities in rheumatic disease care and outcomes. Most SDoH screening occurs in primary care where resources may exist to meet related needs. Individuals with rheumatic conditions receive extensive care in the subspecialty setting where SDoH are infrequently documented and infrastructure to address needs is often lacking. We implemented SDoH screening in 9 rheumatology clinics to determine feasibility, associated factors, and the ability to address SDoH needs in a subspecialty setting.

Methods: We implemented an electronic health record-based SDoH questionnaire at e-check in, or on arrival with an iPad, at 3 hospital-based adult rheumatology clinics and 6 satellite clinics. To ensure sufficient resources to meet needs uncovered, we first focused on visits for RA, then expanded to other rheumatic conditions. Patients screened within the year in primary care were not rescreened, however our team responded to incompletely addressed needs. Patients who indicated SDoH needs received resource sheets in their primary language and those requesting assistance received outreach from the rheumatology-based community resource specialist (rCRS). Rheumatologists and primary care physicians were informed of their patients' needs and actions taken to address them. We assessed prevalence of SDoH needs, used multivariable logistic regression to examine factors associated with ≥1 SDoH need (vs. 0), and used multilevel, multivariable logistic regression to examine the association between census tract social vulnerability index (SVI) quartile and presence of needs, adjusting for demographics. We categorized actions taken by the rCRS.

Results: From 6/23/22-4/18/23, 7,146 adults (≥18 years) completed the SDoH questionnaire. 6,309 (88%) were associated with rheumatology visits and 837 (12%) with primary care and re-reviewed in rheumatology. There were 2,015 SDoH needs among 1,143 (16%) patients; 120 others requested resources without specifying needs. SDoH needs varied by demographic factors and insurance status (**Table 1**). 417 (36% of patients with needs) indicated food insecurity, 340 (30%) had difficulty paying utility bills, 297 (26%) had difficulty paying for medications (**Fig. 1**). We observed significantly higher odds of ≥1 SDoH need vs. no needs among Black (vs. White) and Hispanic (vs. non-Hispanic) individuals, Medicaid and Medicare beneficiaries (vs. Commercially insured) and Spanish speakers (vs. English) (**Table 1**). While SDoH needs were present among individuals in all neighborhoods, living in the most vulnerable SVI quartile (vs. the least) was associated with 4.92 times higher odds (95% CI 1.43-16.92) of SDoH needs. The rCRS connected patients to varied resources to address needs (**Table 2**).

Conclusion: Screening and addressing SDoH in rheumatology clinics is feasible and has revealed a significant burden of needs not being met elsewhere. While needs were concentrated among individuals living in more vulnerable neighborhoods and among historically marginalized populations, they were not limited to these groups suggesting the importance of inclusive screening and connections to resources to improve care for all patients.

Table 1. Characteristics of patients screened and odds ratios (OR, 95% CI) for presence of one or more SDoH need vs. no needs from multivariable logistic regression models

Characteristics*	Overall screened (N=7,146)	≥1 SDoH need (N=1,143)	No SDoH needs (N=6,003)	OR# (95% CI)

#Primary multivariable logistic regression model includes age, gender, race, ethnicity, primary language, insurance, and rheumatic condition. Odds ratios (ORs) for the social vulnerability index are from a separate multilevel, multivariable logistic regression model adjusted for age, gender, race, and ethnicity.

*Overall percentages are by column, SDoH percentages are by row within overall characteristic-specific Ns; all categories except rheumatic condition demonstrate statistically significant differences (p<0.01) between ≥1 SDoH need vs. no need using descriptive statistics

**Other includes Native Hawaiian and other Pacific Islander and American Indian/Alaska Native due to small sample size and individuals who indicated Other or declined to answer

*Mutually exclusive categories for analyses (i.e., if a person had a systemic rheumatic condition and osteoarthritis, they were identified as having the systemic rheumatic condition)

**Social vulnerability index quartiles restricted to addresses in MA (N=6,087) and uses MA-based references

Figure 1. Percentage of Rheumatology Patients with Specific SDoH Needs among those Indicating Any Need (N=1,143)

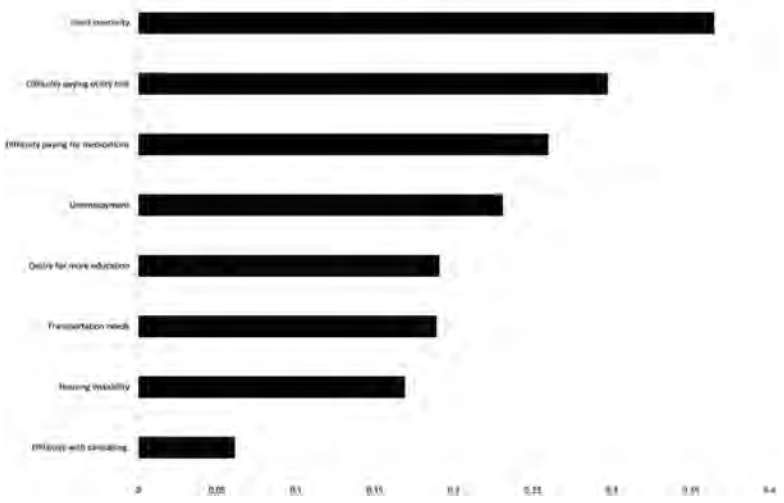

Table 2. Rheumatology-based Community Resource Specialist (rCRS) Activities to Address Social Determinants of Health (SDoH) Needs

SDoH Need	# Reached by rCRS*	Categories of Services Provided by rCRS
Food insecurity	81	• Determined eligibility for state and federal programs • Assisted with SNAP and patient assistance program applications • Assisted with packaged meal delivery application to community-based organization • Connected patients with local food pantries
Difficulty paying utility bills	76	• Facilitated access to utility payment assistance programs (e.g., Low Income Home Energy Assistance Program) • Reviewed finances and monthly bills to plan payments
Difficulty paying for medications	72	• Connected patients with organizations such as GoodRx and NeedyMeds for copayment assistance • Connected patients with multihospital-based specialty pharmacy program staff members • Connected patients with pharmaceutical company patient assistance programs when indicated • Aided in determining whether certain over the counter medications could be more affordable with prescriptions and conveying this to providers
Transportation needs	49	• Assisted with PT-1 applications • Connected patients with local public transportation ADA services • Provided information on other transportation assistance programs including Age Strong Commission Shuttle, The RIDE/RIDE Flex and planning ways to help them get to rheumatology or other subspecialty appointments
Housing instability	34	• Consulted with Harvard Center for Health Law and Policy Innovation housing legal expert for guidance regarding tenants' rights in MA • Aided with CHAMP, RAFT and Section 8 housing applications • Provided contact information for organizations offering volunteer legal services • Obtained housing letters from rheumatologists and primary care providers
Unemployment	38	• Connected patients with local hiring offices in their respective towns and with job listing websites
Desire for more education	39	• Investigated training programs based on patients' needs and loan/payment assistant programs for these programs
Difficulty with child/family-caretaking responsibilities	17	• Referred patients to elder services/Council on Aging • Assisted with SSDI application • Researched local early education resources (e.g., HeadStart, YMCA, private preschools) and provided them to patients

*Patients who indicated having ≥1 SDoH need and asked for assistance addressing needs were referred to the rCRS

Rheumatic Immune-Related Adverse Events Following Immune Checkpoint Inhibitor Therapy and Subsequent Referrals to Rheumatologists at a Private vs Public Medical Center in Los Angeles: Ramifications for Health Disparities

Laura Kobashigawa[1], Nicole Zagelbaum[2], Katherine Ruddy[3], Martha Delgado[1], Baljeet Rai[4], Victoria Gevorgyan[5], Kiana Mortezaei[6], William Stohl[7] and Elizabeth Taylor-Albert MD[8], [1]LAC+USC Internal Medicine Residency, Los Angeles, CA, [2]Beverly Hills Arthritis Associates, Beverly Hills, CA, [3]LAC+USC Internal Medicine Residency, Los Angeles, MD, [4]University of California San Francisco, San Francisco, CA, [5]Los Angeles County Hospital, Los Angeles, CA, [6]Keck Medical Center of USC, Los Angeles, CA, [7]University of Southern California Keck School of Medicine, Division of Rheumatology, Los Angeles, CA, [8]University of Southern California, Santa Monica, CA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) represent a breakthrough in cancer therapies. However, ICIs may be associated with significant immune-related adverse events (irAEs), including rheumatic irAEs. The frequency, severity, and treatment of rheumatic irAEs are not well characterized among racial and ethnic minorities. Accordingly, we

Table 1. Characteristics Among Patients at LAG and KMC with irAEs vs. No irAEs

investigated the nature of rheumatic irAEs among patients treated with ICIs and subsequent referrals to rheumatologists at 2 medical centers located in the same geographic region of Los Angeles, both staffed by faculty from the same medical school: Los Angeles General Medical Center (LAG), a safety-net public hospital, and Keck Medical Center (KMC), a private hospital.

Methods: The electronic medical records of patients 18+ years of age seen at LAG and KMC from May 2015 through May 2021 were screened for treatment with ICIs (nivolumab, pembrolizumab, and/or atezolizumab) by ICD-10 codes, and 613 individual patients (136 at LAG and 477 at KMC) were identified. Of these patients, 30 (22.1%) and 74 (15.5%) developed irAEs at LAG and KMC, respectively. We compared patient demographics, type of iRAEs, and cancer outcomes between the irAE and no-irAE groups at each institution. Among the 30 + 74 patients with irAEs, we identified 23 patients (n=8, 5.9% at LAG; and n=15, 3.1% at KMC) who developed rheumatic irAEs. We compared referral rates to a rheumatologist and management of rheumatic iRAEs between these 2 groups.

Results: No significant differences in demographics and comorbidities were detected between the irAE and no-irAE groups at either institution (Table 1). Across both medical centers, the most common rheumatic irAEs were arthritis (70.0%) followed by myositis (13.0%). Compared to patients at KMC, patients at LAG with rheumatic iRAEs were more likely to be of Hispanic ethnicity (62.5% vs. 13.3%, p=0.068), less likely to be referred to a rheumatologist (12.5% vs. 62.5%, p=0.013) and more likely to be treated with steroid monotherapy for management of rheumatic iRAEs (37.5% vs. 12.5%, p=0.466). There were no significant differences in cancer outcomes between patients with rheumatic iRAEs at each institution (Table 2).

Conclusion: While ICIs have revolutionized therapy for many different types of cancers, they may lead to the development of significant iRAEs, including rheumatic irAEs. To our knowledge, this is the first study to investigate differences in rheumatic irAEs between a public and a private institution located in the same geographic region and staffed by the same group of physicians. The significantly lower rate of referral to rheumatologists among patients with rheumatic irAEs at a public medical center compared to patients at a neighboring private institution raises concern for health care disparities between patients seeking care at a private vs public institution. Studies with larger cohorts of racially and ethnically diverse patient populations are necessary to enhance our understanding of rheumatic irAEs and to ensure equitable care for all patients.

Health Care Access in an Indigenous North American Population of Rheumatoid Arthritis Patients and Their At-risk First-Degree Relatives

Dana Wiens[1], David Robinson[1], Irene Smolik[1], Cheryl Barnabe[2], Hani El-Gabalawy[1] and **Liam O'Neil**[1], [1]University of Manitoba, Winnipeg, MB, Canada, [2]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disease that requires access to subspecialty care. Although Canada has a universal healthcare system, there are complex and interrelated factors that lead to inequitable healthcare access and delivery. These factors are particularly relevant to Canada's geographically dispersed First Nations People (FN), who bear a disproportionate burden of RA and its complications. In the context of a longitudinal study of RA onset in a FN population, we sought to identify factors that influence access to healthcare in a cohort of FN RA patients and their First-Degree Relatives (FDR).

Methods: A longitudinal cohort of FN RA patients (n = 214) and their FDR (n = 617) was recruited between 2005 and 2017 to participate in a prospective study of RA risk in the FDR (total n = 831). Study participants were recruited in both urban and rural locations in Manitoba, Canada. The study enrollment visit included a healthcare access survey which measured access on a Likert scale (Figure 1). Overall access difficulty was determined using a binary variable, where if *any* of the 7 questions scored moderate or higher, the individual was deemed to have 'access difficulty', otherwise they were classified as 'adequate access'. Modified health assessment questionnaire (mHAQ) and disease duration were collected for RA patients. Data were analyzed using chi-square test and logistic regression.

Have any of the following been a problem for you with respect to healthcare? (Please check the best answer for you.)	No problem	A bit of a problem	A moderate problem	A big problem
Wait Domain	❑	❑	❑	❑
Q1: Waiting to be seen at your nursing station?	❑	❑	❑	❑
Q2 Waiting list to be seen by a family doctor?	❑	❑	❑	❑
Q3: Waiting list to be seen by a specialist?	❑	❑	❑	❑
Travel Domain	❑	❑	❑	❑
Q4: Traveling to see a family doctor?	❑	❑	❑	❑
Q5: Traveling to see a specialist?	❑	❑	❑	❑
Medication Domain	❑	❑	❑	❑
Q6: Cost of medications?	❑	❑	❑	❑
Q7: Access to medications?	❑	❑	❑	❑
Q8: Cost of medical devices? (e.g., braces, wheelchairs, etc.)	❑	❑	❑	❑

Figure 1: Access to care questionnaire.

Results: Overall, RA and FDR participants living in rural communities reported more difficulties with healthcare access compared to urban dwellers (overall access difficulty, 53.5% vs 33.5%, p< 0.0001), and rural RA patients reported more access difficulty than unaffected rural FDR (Figure 1A, 66.9% vs 50.5%, p=0.002). In contrast, there were no differences reported between RA patients and FDR living in urban locations (Figure 2B). In the entire RA cohort, no differences in access were reported based on disease duration, age, or sex, although those with higher mHAQ scores tended to report worse access. A logistic regression model of the entire RA and FDR cohort suggested that variables which independently associated with healthcare access difficulty were *female sex* (Figure 2A, OR 1.47, 1.07-2.01), *older age* (OR 1.51, 1.12-2.04) and *living in a rural community* (OR 1.99, 1.45-2.71). The model suggested that females living in rural locations, irrespective of an RA diagnosis, were particularly disadvantaged for healthcare access, but also that males with an RA diagnosis experienced substantially more access difficulty compared to FDR males (Figure 2B).

Conclusion: Perceived difficulties in accessing healthcare were reported more frequently in FN RA patients as well as their unaffected at-risk FDR who were living in rural locations compared to those living in urban locations. We also identified sex, age and location of residence-based differences in perceived healthcare access for FN persons irrespective of disease state. In order to achieve equitable healthcare delivery in the context of a universal healthcare system, interventions to address geographic factors, such as transportation and availability of healthcare providers, need to also incorporate complex factors related to sex, gender and age.

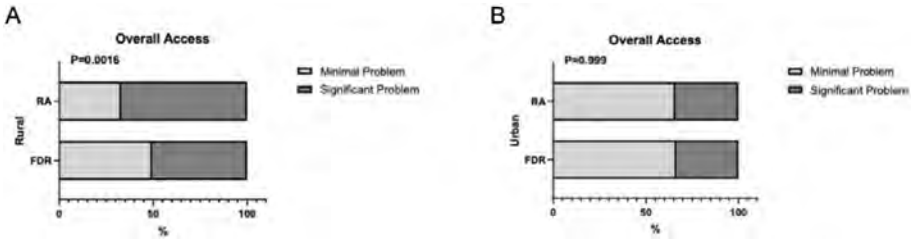

Figure 2: Poor access to care in First Nation RA patients is restricted to rural communities. (A) Overall access difficulty in RA patients compared to first-degree relatives (FDR) in rural communities. (B) Overall access difficulty in RA patients compared to first-degree relatives (FDR) in the urban setting. Differences calculated by chi-square test.

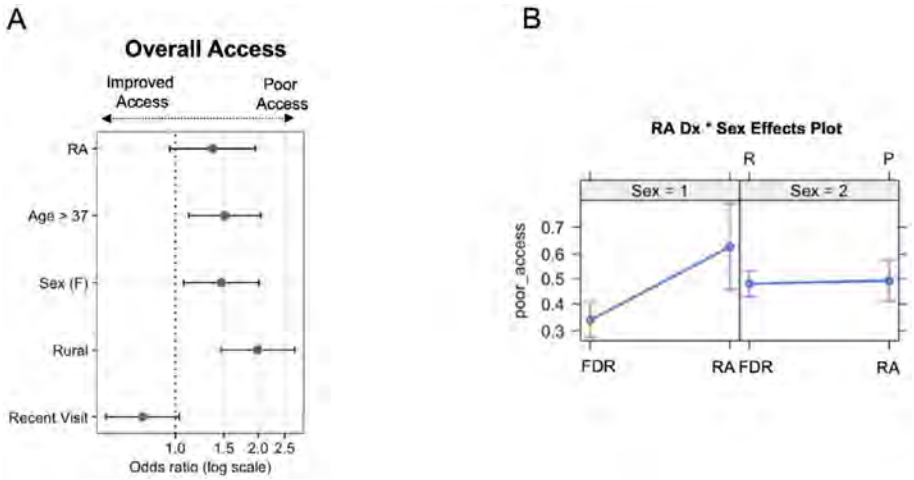

Figure 3: Poor access to care in First Nations RA patients and first-degree relatives is predominantly mediated by older age, female sex and living in a rural community. (A) Results of a logistic regression analysis that included the variables Age, Sex, RA diagnosis, and timing of the visit displaying OR with 95% confidence interval. Statistically significant OR were observed for age, sex and rural. (B) Effects plots for logistic regression interaction term between Sex and RA diagnosis. Differentially poor access was observed for males with RA, while females with RA and FDR displayed similar access.

Cost-related Medication Burden for Patients with and Without Systemic Autoimmune Rheumatic Diseases

Jeong Yee[1], Candace Feldman[1], Emily G. Oakes[1], Jack Ellrodt[1], May Choi[2], Elizabeth Karlson[1] and Karen Costenbader[3], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Calgary, Calgary, AB, Canada, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication nonadherence is a challenging issue in the management of systemic autoimmune rheumatic diseases (SARDs), leading to poor clinical outcomes. Although it is complex and multifaceted, cost is a significant barrier to medication adherence. We investigated cost-related medication burden in patients with SARDs, compared to that in patients without SARDs in a large diverse cohort across the U.S..

Methods: Among the participants with baseline survey and electronic health records in the All of Us (AoU) research program v7, we identified patients with SARDs who had ≥2 International Classification of Diseases (ICD)-9/10 and Systematized Nomenclature of Medicine (SNOMED) codes ≥ 60 days apart within two years.Cost-related medication burden was assessed in 3 ways using self-reported questionnaire data collected at enrollment: 1) unaffordability of prescription medicines, 2) cost-related medication nonadherence—skipping medications, taking less medicines, or delaying filling a prescription, and 3) cost-reducing strategies—asking for a lower cost medication, buying prescription drugs from another country, or using alternative therapies. Self-reported responses to each question were compared between patients with and without SARDs using Chi-squared tests. Logistic regression analyses calculated odds ratios (ORs), adjusting demographic, socioeconomic, and multiple clinical factors.

Results: Among respondents who fully answered these questionnaires, a total of 4,428 SARDs patients and 110,109 participants without SARDs were analyzed (**Table 1**). Patients with SARDs had lower socioeconomic status than those without SARDs. Among those with SARDs, 18.2% did not get prescription medicines due to cost, whereas this was 11.6% of those without SARDs (**Figure 1**). 18.7% of those with SARDs vs. 12.8% without SARDs reported cost-related medication nonadherence, while 29.9% with vs. 25.2% without SARDs reported using medication cost-reducing strategies. After adjusting for multiple demographic and clinical factors, patients with SARDs had 1.6-fold (95% CI 1.4-1.7) odds of reporting unaffordability of prescription medicines, 1.5-fold (95% CI 1.3-1.6) odds of reporting cost-related medication nonadherence, and 1.2-fold (95% CI 1.1-1.3) odds of reporting using cost-reducing strategies, than those without SARDs (**Figure 2**). Full adjustment reduced the odds of all 3 cost-reducing behaviors the most for those with SLE, likely as this is a younger, more diverse population of lower socioeconomic status than other SARDs groups.

Conclusion: Higher proportions of patients with SARDs self-reported unaffordability of prescription medicines, cost-related medication nonadherence, and cost-reducing strategies than did patients without SARDs in the large AoU research program, even after adjusting for multiple demographic and clinical factors. Ongoing research is investigating how cost-related

[c]Charlson comorbidity index calculated using 16 comorbidities, excluding rheumatic disease.

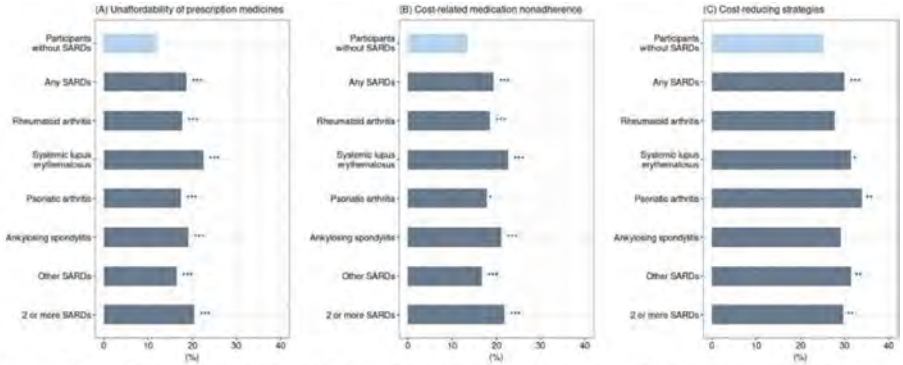

Figure 1. Prevalence (%) of cost-related medication burden reported by patients with and without systemic autoimmune rheumatic diseases (SARDs) in All of Us (v7). (A) Unaffordability of prescription medicines. (B) Cost-related medication nonadherence. (C) Cost-reducing strategies. *p<0.05, **p<0.01, *p<0.001 compared to general population.

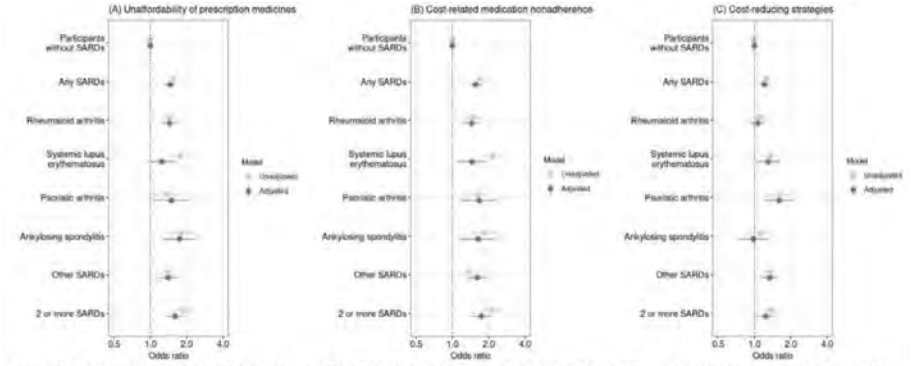

Figure 2. Unadjusted and adjusted odds ratio (95% CI) for cost-related medication burden in patients with systemic autoimmune rheumatic diseases (SARDs) compared to patients without SARDs in All of Us (v7). (A) Unaffordability of prescription medicines. (B) Cost-related medication nonadherence. (C) Cost-reducing strategies. Adjusted model included age, sex, race/ethnicity, index year, annual household income, education level, insurance type, employment status, geographical region, area deprivation index, smoking status, obesity, Charlson comorbidity index, calculated using 16 comorbidities excluding rheumatic diseases, and number of medications.

medication burden influences adherence and clinical outcomes for patients with SARDs. Clinicians and other stakeholders should consider the financial burden of medications faced by patients with SARDs to improve medication adherence and thus clinical outcomes.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The development of biologic and targeted synthetic (b/ts)DMARDs contributed to improved treatment outcomes in rheumatoid arthritis (RA). However, high medication costs may limit their use. Previously we showed less b/tsDMARD use in countries with a lower socioeconomic status (SES), than in countries with higher SES. Here we take a more detailed look at b/tsDMARD use across countries and explore cross-country relationships between Gross Domestic Product (GDP)-per-capita, indicators of b/tsDMARD use and disease outcomes in RA-patients

Methods: This multinational, observational study included countries contributing ≥100 patients using b/tsDMARDs, with available follow-up, to one of two registries: METEOR, an international registry capturing daily practice data of patients with a clinical diagnosis of RA, and JAK-POT, an investigator-initiated collaboration between national registries aiming to evaluate clinical aspects of b/tsDMARDs in RA. On a per-country basis, mean DAS28 was calculated from the last available follow-up visit per patient. B/tsDMARD usage was determined as mean time to start b/tsDMARD therapy since date of diagnosis, number of b/tsDMARDs tried per patient and duration of b/tsDMARD therapy. To calculate the time to start a first b/tsDMARD per country included from JAK-POT, only bionaïve patients were included. Possible associations between GDP per capita, indicators of b/tsDMARD use and DAS28 were tested using univariable linear regression. Regression coefficients (β) are interpreted as the numerical increase in the outcome per one point increase in the predictor.

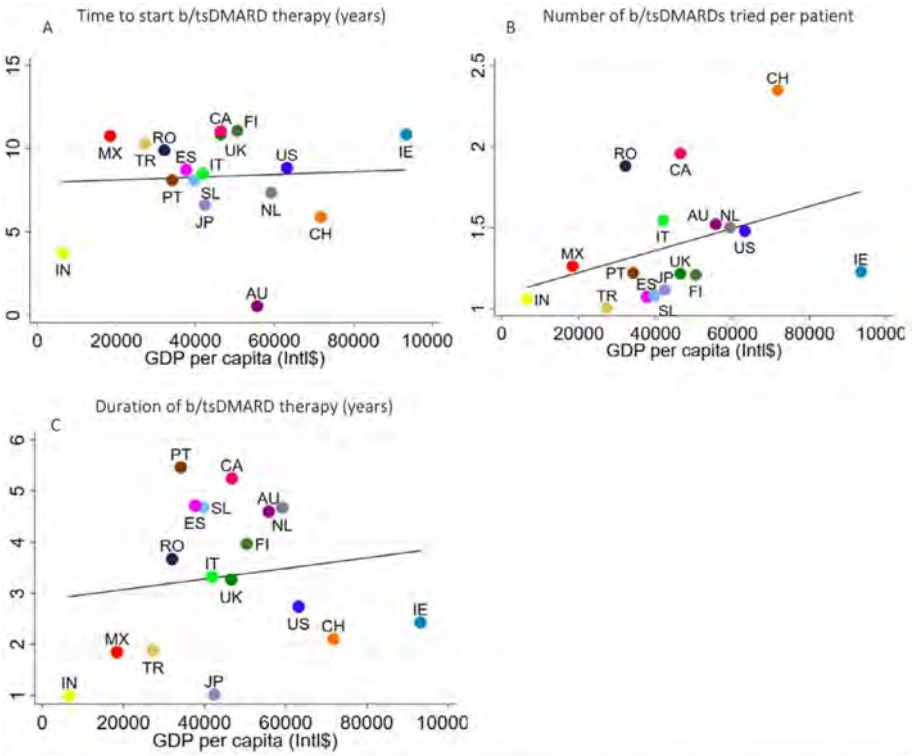

Figure 1. Associations between 'GDP per capita (Intl$)' and the 'Time to start b/tsDMARD therapy (years)' (A), 'Number of b/tsDMARDs tried per patient' (B) and 'Duration of b/tsDMARD therapy (years)' (C)

AU, Austria; CA, Canada; CH, Switzerland; ES, Spain; FI, Finland; GB, United Kingdom; IE, Ireland; IN, India; IT, Italy; JP, Japan; MX, Mexico; NL, Netherlands; PT, Portugal; RO, Romania; SL, Slovenia; TR, Turkey; US, United States

Results: Data from 25,832 patients from 17 different countries showed varying b/tsDMARD prescriptions. GDP-per-capita ranged from 6505 (India) to 93350 Intl$ (Ireland). Time to start b/tsDMARD therapy ranged from 0.5(Austria) to 11.1 (Finland) years. Mean number of b/tsDMARDs tried per patient ranged from 1.0 (Turkey) to 2.4 (Switzerland). Duration of b/tsDMARD therapy ranged from 0.9 (India) to 5.5 (Portugal) years (fig 1). Baseline DAS28 ranged between 3.7 and 6.1, but was not related to any of the indicators of b/tsDMARD use: time to start a b/tsDMARD β 0.08 (95% CI -0.7; 0.9), number of prescribed b/tsDMARDs β 0.06 (95% CI -0.03; 0.2), duration of b/tsDMARD treatment β 0.1 (95% CI -0.3; 0.5).No statistically significant associations were observed between GDP-per-capita and time to start b/tsDMARD therapy (fig 1A, β 0.09 CI 95% -0.7; 0.9), number of b/tsDMARDs tried per patient (fig 1B, β 0.07 CI 95% -0.02; 0.2) or duration of b/tsDMARD therapy (fig 1C, β 0.1 CI 95% -0.3; 0.5). None of the indicators of b/tsDMARD prescription were significantly related to DAS28 at the end of follow up: time to start a b/tsDMARD β 0.02 (95% CI -0.05; 0.1), duration of b/tsDMARD therapy β -0.03 (95% CI -0.2; 0.1) and number of b/tsDMARDsβ -0.03 (95% CI -0.6; 0.6).

Conclusion: This study showed varying b/tsDMARD prescription behavior and disease activity across 17 countries worldwide. Overall, differences in b/tsDMARD prescription behavior was not related to socioeconomic welfare and disease activity at a country level. This seems to indicate that once patients start a b/tsDMARD, socioeconomic welfare has less impact on b/tsDMARD use.

Abstract Number: 1018

Recognizing Rural Healthcare Disparities in Pain Assessment for Autoimmune Rheumatologic Diseases

Lydia Yang[1], Bharat Kumar[2] and Melissa Swee[1], [1]University of Iowa Carver College of Medicine, Iowa City, IA, [2]University of Iowa Hospitals and Clinics, Iowa City, IA

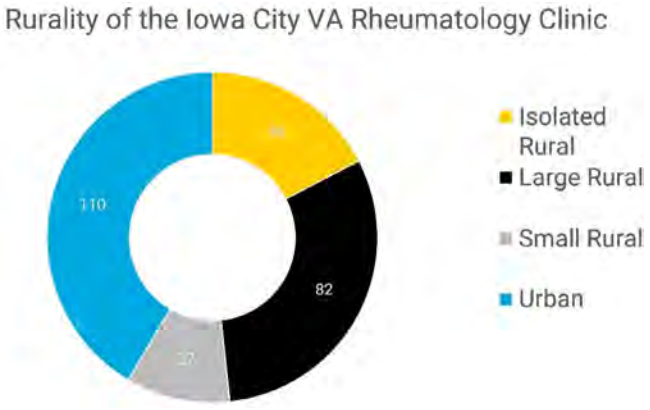
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a common complaint seen in many autoimmune rheumatologic conditions, along with decreased function and decreased sense of well-being. Pain is a highly person-specific symptom without well-validated biomarkers, making it difficult to assess and use as a standardized metric in guiding immune modulatory therapy. Multiple lines of evidence suggest that rural-dwelling patients may conceptualize and relay pain differently than non-rural-dwelling patients, which may complicate the delivery of optimal care and further healthcare disparities. Within a clinic that serves predominantly rural-dwelling patients, we aim to determine if rural-dwelling status correlates with self-reported levels of pain,

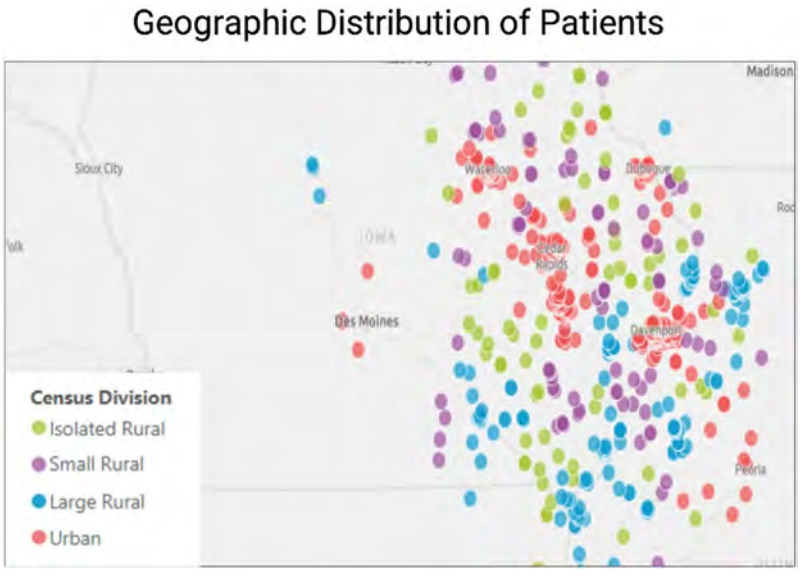
function, and sense of well-being in patients with autoimmune rheumatologic diseases. We additionally aim to determine if there is a statistically significant difference in functional activity, pain levels, and sense of well-being between rural-dwelling patients and non-rural-dwelling patients. These correlations will empower quality improvement initiatives within our clinic.

Methods: We correlate rurality with elements of the RAPID-3 form. Rurality is determined by RUC (Rural-Urban Commuting) Codes based on the patient's home address. Using RUC, patients were classified into four categories: (1) urban, (2) large rural town, (3) small rural town, and (4) isolated small rural town. The RAPID-3 is a validated questionnaire consisting of three parts: (1) functional status, (2) pain level, and (3) global well-being. All items are self-reported by patients.

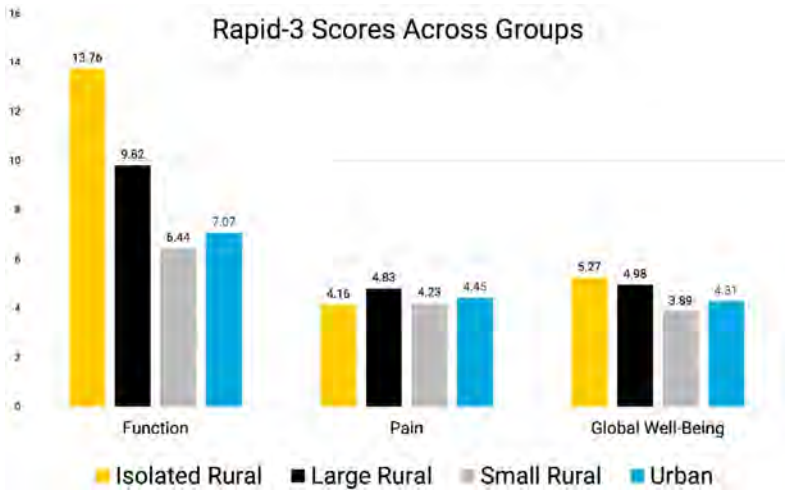
Results: Among the 265 rheumatology patients seen between May 1, 2022, to November 1, 2022, 110 were urban-dwelling and 155 were rural-dwelling (large [82], small [27], or isolated [46]).Percentages of self-reported gender and ethnicity/race (Non-Hispanic White, Hispanic, Black) were comparable as well as average age. Isolated rural-dwelling patients had the highest degree of dysfunction (13.76/20) and sense of poor well-being (5.27/10) compared to small rural-dwelling patients (6.44/20 and 3.89/10, respectively), who had the lowest degree of dysfunction and poor sense of well-being, and



Pie chart displaying the proportion of patients in each rurality classification.



Dot plot displaying the geographic distribution of patients' homes seen at the VA Rheumatology Clinic in Iowa City, IA



Bar graphs depicting differences in self-reported function, pain, and global well-being across groups.

urban-dwelling patients (7.07/20 and 4.31/10, respectively) [p-value< 0.01).In contrast, dwellers of large rural towns report the highest levels of pain (4.84/10) compared to those in isolated rural communities, who had the lowest (4.16/10).However, differences in levels of pain were not statistically significant.

Conclusion: In this clinic, there exist healthcare disparities in measuring pain, dysfunction, and sense of well-being among rural-dwelling patients with autoimmune rheumatologic diseases. Those that live in isolated rural communities tend to report lower amounts of pain despite having higher levels of poor well-being and dysfunction, compared to those living in larger rural and urban settings. These findings suggest that we may be systematically underestimating the burden of pain in patients living in isolated rural communities that obtain care through our clinic. These results empower quality improvement initiatives to better solicit pain and dysfunction among rural-dwelling patients.

Association of Historical Redlining and Present-Day Neighborhood Inequities with Missed Outpatient Appointments Among Individuals with Rheumatic Conditions

Sherry Yang[1], Leah Santacroce[2] and Candace Feldman[2], [1]Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Structural racism pervades U.S. history with continued effects on health inequities. Residential segregation serves as an example, where redlining maps outlined areas with high concentrations of Black and immigrant residents as hazardous for investment, which precluded access to mortgages and home ownership. This exclusionary

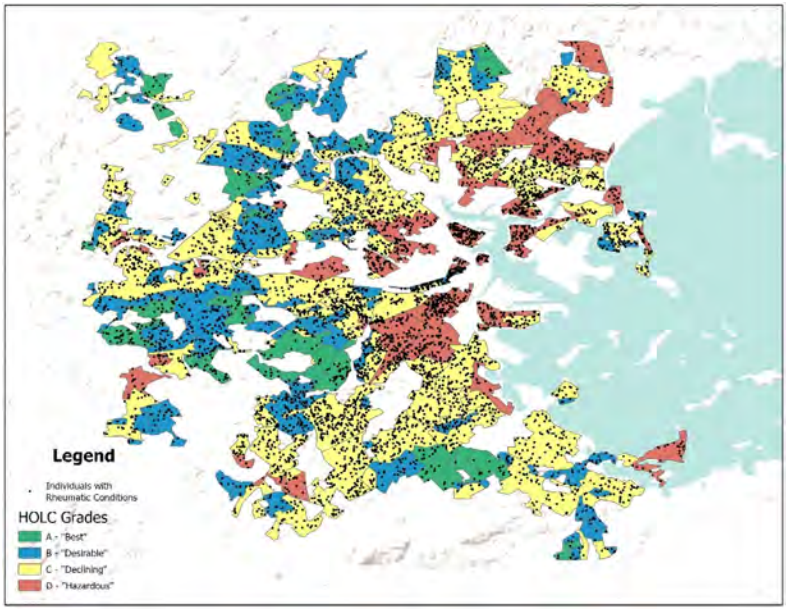

Figure 1. Current distribution of individuals with rheumatic conditions receiving care in a Massachusetts-based multihospital medical system on a 1930s Home Owners' Loan Corporation redlining map

Model 1: Adjusted for age, Asian and other/unknown race, and ethnicity, includes HOLC grades; **Model 2**: Adjusted for age, Asian and other/unknown race, and ethnicity, includes ICE for racialized economic segregation; Multilevel models account for clustering of individuals by census tract; Bolded values indicate statistically significance.

disinvestment in communities of color has led to the racial wealth gap. We studied the effects of historical redlining policies and present-day racialized economic segregation, measured by the Index of Concentration at the Extremes (ICE), on missed outpatient appointments, an indicator of access to sustained care, among individuals with rheumatic conditions.

Methods: Using a multihospital clinical data repository, we identified adults 18 years with New England addresses and 1 ICD-10 code for a rheumatic condition who received rheumatology care within 3 years of 1/2023. We defined the index date as the date of the third code for the same rheumatic condition and the baseline period as one year prior to the index date. Home addresses were geocoded and overlaid with 1930s Home Owners' Loan Corporation (HOLC) redlining vector files. The ICE for extreme high vs. low combined racial and income polarization at the census tract level was constructed using 2021 American Community Survey data. We used multilevel, multinomial logistic regression models to examine the odds of 1-3 and 4 missed outpatient appointments (Ref.=0) over 2 years post index date separately by historical HOLC

grade (A "best" to D "hazardous") and ICE quintile (most deprived (Q1) to most privileged (Q5) area for combined race and income), adjusting for demographics, insurance, and comorbidities.

Results: Among 5,598 individuals with rheumatic conditions, 1,935 had SLE/connective tissue disease, 2,800 inflammatory arthritis, 1,152 crystalline arthritis, and 3,009 osteoarthritis. The mean age was 63 (SD 16) years, 70% were female, 12% Black, and 4% Hispanic **(Table 1)**. 23% lived in the most historically redlined areas **(Figure 1)**, and 33% in areas with the most extreme present-day racialized economic deprivation (ICE Q1). Among 1,780 individuals living in ICE Q1 areas, 96% were in areas that were historically deemed hazardous (HOLC D) or declining (HOLC C). 1,915 (34%) individuals had 0 missed appointments, 1,783 (32%) had 1-3, and 1,900 (34%) had 4. Accounting for individual-level factors, patients living in the most historically redlined areas vs. the least had 1.79 times greater odds (95% CI 1.22-2.62) of 4 missed appointments. Individuals living in areas with the greatest concentration of lowest-income Black households vs. highest-income White households had 2.27 times greater odds (95% CI 1.77-2.90) of 4 missed appointments **(Table 2)**.

Conclusion: Individuals with rheumatic conditions living in historically redlined areas and current areas with highly concentrated racialized economic deprivation had significantly greater odds of repeated missed appointments. Legacies of residential segregation persist and contribute to rheumatic disease disparities. Policy interventions that dismantle structural racism are needed to address inequities in consistent access to care for patients with rheumatic conditions.

An Increase in Safety Outcome Trials and the Issue of Informed Consent

Ayse Ozdede[1], Sinem Nihal Esatoglu[2] and Hasan Yazici[3], [1]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology, İstanbul, Turkey, [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [3]Academic Hospital, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The randomized controlled trial (RCT remains a most important research tool and a necessary document for drug licensing. Informed consent is an integral component of this tool. Its exact wording is not currently in the public domain as we and others had previously voiced (1, 2). Such transparency is important not only from the point of maintaining the public trust but also for an organized skepticism, an essential element of scientific inquiry (3). Moreover,

	1990-1991 (n=309)	2019-2020 (n=581)	OR; 95% CI
Total number of RCTs	309	581	
A trial	284 (91.9%)	501 (86.2%)	0.6; 0.3-1.0
B trial	9 (2.9%)	39 (6.7%)	2.4; 1.1-5.0
Non-A trial*	25 (8.1%)	80 (13.8%)	2.0; 1.1-2.1
ICU trial	12 (3.8%)	52 (8.9%)	2.4; 1.3-4.6

* B + C trials

we had also indicated that this transparency was even more important in safety outcome trials (SOTs) (4). We have the impression that such SOTs are becoming more frequent and, in some, the outcome measure can be as severe as stroke or death. We aimed to tabulate the temporal frequency of RCTs with the primary outcome of primarily safety versus primarily efficacy, in 4 mainline general medicine journals.

Methods: RCTs published in 1990-1991 vs 2019-2020 in NEJM, JAMA, LANCET and BMJ were surveyed by 2 independent reviewers (AO, SNE). Phase 1-2 RCTs, post-hoc analyses of RCTs and RCTs reporting long term follow-up data were excluded. RCTs with an undisputable study aim and a primary endpoint of efficacy with no appreciable risk of harm to the patients were defined as an 'A trial'. Those trials in which we unanimously considered the presence of serious harm to the enrolled patients were defined as a 'B trial'. The trials that we could not unanimously decide whether to designate as an A or B, were called a 'C trial'. Discrepancies were resolved after discussion with HY and if there was no consensus, the trial was designated as 'non-A'. We compared the frequencies of the types of RCTs published in 1990-1991 vs 2019-2020. Other salient features of these RCTs were also tabulated. Of these, only data related to the intensive care unit (ICU) settings are presented in this abstract.

Results: There were 309 RCTs published in 1990-1991 and 600 RCTs published in 2019-2020. 19 RCTs on COVID-19 infection were excluded for fair comparisons. As seen in the Table there was a significant increase in the number SOTs in the later years. Moreover, the number of ICU trials, a setting in which obtaining informed consents can often be problematic, evento the degree of being *post-hoc*, were significantly increased.

Conclusion: There is a significant increase in the number of SOTs. Moreover, more RCTs are conducted in the ICUs. We re-emphasize that the informed consents of all RCTs, particularly those related to the SOTs should be in the public domain. We strongly consider that such action is necessary a. to continue receiving the necessary public trust for scientific inquiry and b. for adequately addressing the organized skepticism of our peers.

Racial Disparities Between Black and White Patients in Joint Replacement Surgery: A Systematic Review

Max Krall[1], Samuel Good[1], Collin Brantner[2], Diyu Pearce-Fisher[2], Susan Goodman[2], Michael Parks[2], Peter Sculco[2], Cynthia Kahlenberg[2], Ajay Premkumar[2], Michelle Demetres[3] and John FitzGerald[1], [1]University of California Los Angeles, Los Angeles, CA, [2]Hospital for Special Surgery, New York, NY, [3]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the documented efficacy of joint replacement surgery (JRS) for the management of refractory hip or knee osteoarthritis (OA), multiple studies have documented lower rates of JRS among Black patients with refractory hip or knee OA. The purpose of this research is to investigate how differences in patient characteristics, cultural characteristics, outcomes after joint replacement surgery (JRS), and structural barriers between Black and White patients may affect the decision to undergo JRS and how those decisions contribute to differences in utilization in JRS.

Methods: Original searches ran on April 8, 2019, April 7, 2020 and updated October 11, 2022 in the following databases: Ovid MEDLINE (ALL - 1946 to Present); Ovid EMBASE (1974 to present); and The Cochrane Library (Wiley). Our population of interest was black patients with hip and/or knee OA, our comparator was white patients with hip and/or knee OA, and our primary outcome was disparities in decisions regarding JRS. We registered the protocol under the PROSPERO international

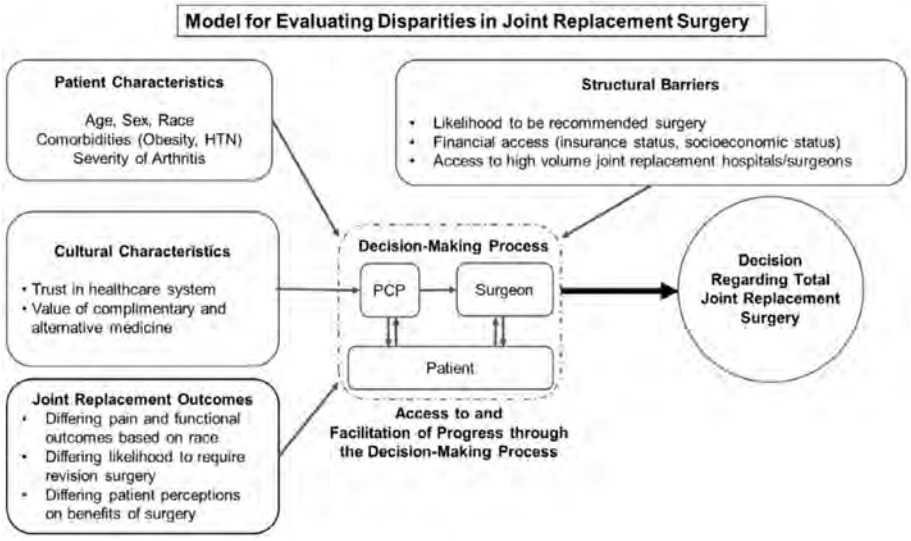

Figure 1: model for evaluating disparities in joint replacement surgery.

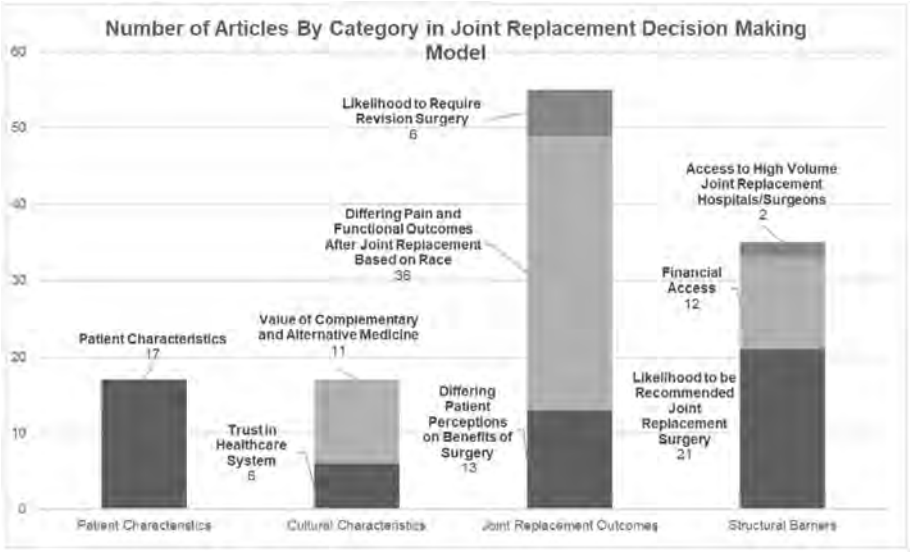

Figure 2: number of articles by category in joint replacement decision making model.

register and followed the Preferred Reporting Items of Systematic reviews and Meta-Analyses (PRISMA) guidelines. We included any articles which fit within our model (Figure 1).

Results: Searches across the chosen databases retrieved 21,390 results, 14,252 after results after de-duplication, 351 pulled for full text, and 96 selected for inclusion in this review. We then categorized these articles using our conceptual model (Figure 1): 17 in patient characteristics, 17 in cultural characteristics, 55 in joint replacement outcomes and 35 in structural barriers. We further subclassified articles within each category, as outlined in Figure 2.

Relative to white patients, Black patients had higher levels of pain catastrophizing, disability, lower levels of physical function, longer length of stay post total knee arthroplasty (TKA) and total hip arthroplasty (THA), increased ED visits post THA and TKA, decreased proportions of JRS performed as outpatients, higher rates of discharge to post-acute care facilities, and higher risk of revision after TKA. In certain analyses, the effect of race was shown to be mediated by socioeconomic disadvantage and comorbidity burden.

Conclusion: Preliminary review of the data finds that Black patients undergo JRS at lower rates than White patients. While some of this difference can be explained by lower preference for JRS vs. other arthritis treatments among Black patients, there are significant structural, financial, provider and patient factors that contribute to this difference. Some of these factors could be targeted for intervention to improve access to JRS for Black patients. The articles included for review primarily investigated differences in joint replacement outcomes and structural barriers, with less research studying baseline patient and cultural characteristics.

Lower Rates of Statin Therapy Initiation in Dermatomyositis/ Polymyositis vs. Rheumatoid Arthritis Patients with Hyperlipidemia: A Multicenter USA-Based Study (2018-2023)

Joseph Fares[1], ross Summer[1] and **Giorgos Loizidis**[2], [1]The Jane and Leonard Korman Respiratory Institute, Thomas Jefferson University Hospital, Philadelphia, PA, [2]Division of Rheumatology, Thomas Jefferson University Hospital, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the proven cardioprotective benefits of statin therapy in RA, concern for statin-associated muscle symptoms (SAMS) might deter clinicians from prescribing them to DM/PM patients with Hyperlipidemia (HLD), particularly those with disease-derived myopathy. This analysis aims to quantify and compare the initiation rates of statin therapy in patients with RA-HLD and DM/PM-HLD, with a focus on whether a diagnosis of DM/PM leads to the underutilization of these drugs.

Methods: Utilizing the TriNetX Research Network, we analyzed de-identified electronic health records from U.S.-based entities over the last five years. Inclusion criteria required the HLD diagnosis to follow the initial RA or DM/PM diagnosis by one day to five years. All patients included were on immunosuppressive medications, and we excluded patients with a second autoimmune disease diagnosis or on treatment with lipid-lowering medications other than statins. The detection of NormRx code for HMG CoA reductase inhibitors identified statin initiation. The analysis considered the HLD diagnosis (Index Event) point following RA or DM/PM diagnosis and the succeeding one month to five years (Time Window). Propensity score matching was employed for age, race, sex, ethnicity, cardiovascular risk factors, and cardiovascular diseases. TriNetX

Distribution of statin NormRX codes among RA-HLD and DM/PM-HLD cohorts

software aided in cohort matching and statistical computations. The measure of association was the Risk Ratio of statin initiation post the Index Event. A confidence interval of 95% was used, with a significance level of $p < 0.05$ (2-sided).

Results: The study included 16,590 RA-HLD and 576 DM/PM-HLD patients from 2018-2023, with average ages at HLD diagnosis being 62 (RA-HLD) and 58 (DM/PM-HLD). Both groups were predominately female and of White race (75% RA-HLD and 71% DM/PM-HLD), with a higher proportion of Black and Asian patients in the DM/PM-HLD cohort (Table 1). Statin initiation therapy was significantly higher among the RA-HLD cohort (20.6%) compared to the DM/PM-HLD cohort (12.4%) [CI 4.96%,11.46%, $p < 0.0001$], excluding those already on statin therapy. This trend persisted even with propensity score matching, with initiation rates of 19.6% for the RA-HLD groups and 12%, for the DM/PM-HLD groups [CI 2.51%, 12.61%, p 0.003] (Table 2). Regarding specific statin therapy, Atorvastatin was more commonly detected in the RA-HLD group (13% vs 8.5%), while Fluvastatin was more prevalent in the DM/PM-HLD cohort (1.73% vs 0.6%). Notably, Simvastatin nor Pitavastatin were not detected to DM/PM-HLD patients, whereas rates of Pravastatin, Rosuvastatin, and Lovastatin were similar among both groups (Table 3).

Conclusion: Despite the inherent limitations of an electronic health records-based database this study shows a concerning signal of disparity in statin initiation rates in DM/PM-HLD compared to RA-HLD patients. These results emphasize the urgent need for improved cardiovascular disease risk assessment and the development of guidelines for targeting DM/PM-HLD patients. Future research should explore factors contributing to this under-treatment and evaluate the potential risks and benefits of utilizing statins in this unique patient population.

Abstract Number: 1023

Characterization of Phenotypic Differences in IgG4-Related Disease Across the Sexes

Grace McMahon[1], **Isha Jha**[1], Aubree McMahon[1], Ana Fernandes[1], Zachary Wallace[2], Guy Katz[1], Cory Perugino[1] and John Stone[3], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Newton, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Concord, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a multi-organ fibroinflammatory disease with an autoimmune basis that can affect essentially any organ. Differences in phenotypic expression between males and females have been observed in case series features of individual organ involvement. We aimed to characterize sex differences in IgG4-RD using baseline data from the Massachusetts General Hospital (MGH) IgG4-RD cohort.

Methods: Subjects were recruited between 2008 and 2023 and classified by ACR/EULAR Classification Criteria. Age at diagnosis, disease activity, treatment status, organ involvement, pre-treatment laboratory values, and blood plasmablast concentrations were collected at baseline. Active disease was defined as IgG4-RD-associated inflammation in at least one organ, such that the IgG4-RD Responder Index score was > 0. Laboratory values are reported only on patients who had active IgG4-RD and were untreated at baseline. The study was approved by the MassGeneral Brigham IRB.

Results: Of the 564 participants enrolled in the MGH Registry for IgG4-RD, 328 fulfilled ACR/EULAR Classification Criteria and were included. There was a strong male predominance: 226 males (69%) versus 102 (31%) females [**Table 1**]. This M:F ratio of 2.2:1.0 contrasts markedly with both that of the general population (1:1) ($P < 0.001$) and our general clinic population (0.4:1.0) ($P < 0.001$). Male patients were five years older on average at the time of diagnosis (61.6 vs 56.6; $P < 0.01$) and disproportionately more likely to have involvement of the pancreas, kidneys, lymph node, aorta, large blood vessels, coronary arteries, and retroperitoneum. Females had higher involvement in the lacrimal and submandibular glands than males (for all organ involvement comparisons, $P < 0.05$) [**Figure 1**]. We examined laboratory values in 127 (39%) subjects who had active IgG4-RD and were untreated at baseline. Males were more likely to be serologically active at baseline as defined by serum IgG4, IgG1, and IgE concentrations. The mean serum IgG4 concentration in males was 620 mg/dl (±684) versus 412 mg/dl (±543) for females ($P = 0.095$). Forty-seven percent of males had serum IgG4 concentrations 5 times the upper limit of normal (ULN), compared with 29% of the female subjects. Male subjects also had higher mean concentrations of IgE and IgG1 [**Table 1**]. Mean serum lipase values were lower among the male subjects ($P = 0.020$). A greater degree of plasmablast expansion was observed in males [**Figure 2**].

Conclusion: In its predilection for affecting males more often than females, IgG4-RD bears a striking contrast to most other forms of autoimmune disease, which typically have strong female predilections. Male patients with IgG4-RD also appear more likely than females to have multi-organ involvement, to have disease affecting major organs, and to be serologically active as defined by immunoglobulin concentrations in the blood. The lower lipase levels observed in males are consistent with greater degrees of pancreatic damage. Further study is required to understand these sex differences.

Relationship Between Race and Ethnicity, Time to Diagnosis, and Disease Activity for Children with Juvenile Idiopathic Arthritis in the CARRA Registry

Sarah McGuire[1], Tania Atanassova[2], Joanna Madej[2], Manuel Jimenez[2], Daniel Horton[1] and for the CARRA TMJ Arthritis Workgroup[3], [1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]Rutgers, Robert Wood Johnson Medical School, New Brunswick, NJ, [3]Childhood Arthritis and Rheumatology Research Alliance, Washington, DC

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Compared to non-Hispanic White children, Black children diagnosed with juvenile idiopathic arthritis (JIA) have more severe disease at diagnosis and worse outcomes, such as long-term disability. We aimed to determine if time to JIA diagnosis was longer in Black and Hispanic/Latinx populations and helped explain higher disease activity scores in minoritized populations.

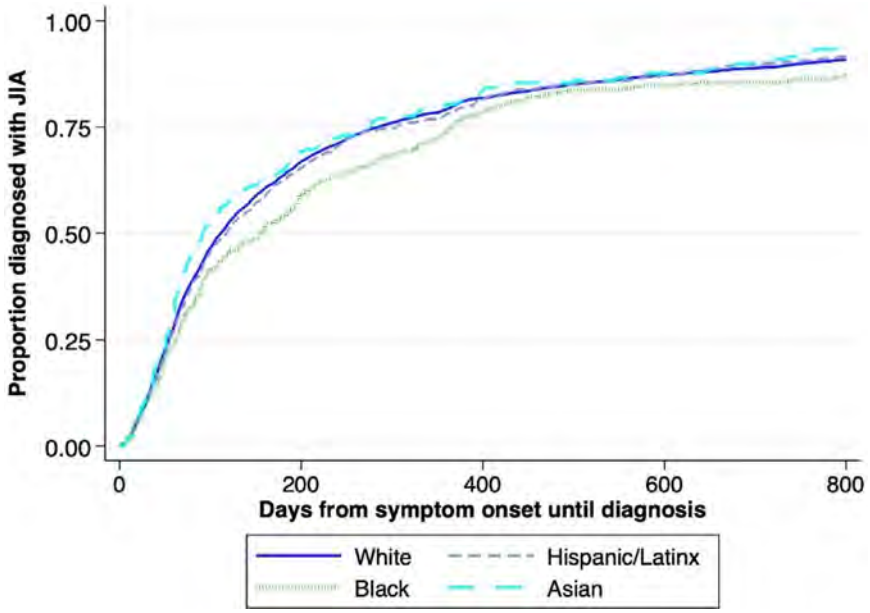

Figure. Time to JIA diagnosis in the CARRA Registry by race and ethnicity. Kaplan-Meier curves were generated to represent days from symptom onset to JIA diagnosis among US participants of the CARRA Registry, stratified by Non-Hispanic White children (blue), Hispanic/Latinx children (light purple dash), Non-Hispanic Black children (green dots), and Non-Hispanic Asian (cyan dash and dots).

Table 1. Select characteristics of the study population. Table 2. Comparison of times to diagnosis between racial and ethnic groups. aHR, adjusted hazard ratio; CI, confidence interval; IQR, interquartile range; uHR, unadjusted hazard ratio. 1 p-values from Wilcoxon rank-sum testing; 2 Cox proportional hazards model adjusted for age, sex, household income, highest educational level attained in household, insurance type, JIA type, calendar year of diagnosis, diagnosis of uveitis, Area Deprivation Index quintile (measure of local socioeconomic disadvantage), local population density, and time from date of JIA diagnosis to date of enrollment in the CARRA Registry. Missing data were imputed using multiple imputation.

Race/Ethnicity	Days to JIA diagnosis, median (IQR)	p-value[1]	uHR (95% CI)	aHR[2] (95% CI)	p-value
Non-Hispanic White (ref)	112 (54, 286)				
Hispanic/Latinx	119 (56, 305)	0.46	1.01 (0.93, 1.09)	0.99 (0.92, 1.08)	0.88
Non-Hispanic Black	158 (63, 365)	0.006	0.87 (0.77, 0.97)	0.87 (0.77, 0.98)	0.02
Non-Hispanic Asian	91.5 (51, 266)	0.21	1.07 (0.92, 1.25)	1.04 (0.89, 1.22)	0.59

Methods: We performed a retrospective cohort study using the CARRA registry, which contains sociodemographic, clinical, and patient/caregiver-reported data on children with pediatric-onset rheumatic diseases across the US and Canada. Eligible participants needed to have JIA, live in the US, and have complete data on self-reported race, ethnicity, and dates of symptom onset and diagnosis. We compared time to diagnosis among children in different racial and ethnic groups using Wilcoxon rank-sum testing, Kaplan-Meier curves, and multivariable Cox regression adjusted for age, sex, insurance type, self-reported household income and parental education, JIA type, calendar year of diagnosis, presence of uveitis, and local area-linked urban-rural status and socioeconomic disadvantage (Area Deprivation Index). To examine whether time to diagnosis mediated the relationship between race/ethnicity and disease activity at enrollment, we used a product of coefficients model, adjusting for the above covariates and time since JIA diagnosis, with bootstrapping to create bias-corrected 95% confidence intervals (CIs). Disease activity was assessed by Clinical Juvenile Arthritis Disease Activity Score 10 (cJADAS10). Missing data was imputed in 10 datasets using multiple imputation by chained equations.

Results: Of 9,037 US Registry participants with JIA, 6,558 (73%) were included. Groups differed in baseline characteristics, including age, income, education, insurance status, and JIA type (Table 1). Compared to non-Hispanic White participants, non-Hispanic Black participants had higher median times to JIA diagnosis (156 days [interquartile range (IQR) 62, 365] vs. 112 days [IQR 54, 286], p=0.006) while times to diagnosis among other racial/ethnic groups were similar (Figure, Table 2). In adjusted models, non-Hispanic Black participants had a significantly longer time to diagnosis than non-Hispanic White participants (aHR 0.87, 95% CI 0.77, 0.98) (Table 2). Time to diagnosis partially mediated the association between Black race and cJADAS10 at enrollment (indirect coefficient = 0.08, bias-corrected 95% CI 0.03, 0.17), but this effect was considerably smaller than the direct relationship between Black race and cJADAS10 (direct coefficient = 1.67, 95% CI 1.50, 1.84).

Conclusion: In a large US cohort, Black children with JIA were more likely to experience delays in diagnosis independent of clinical, geographic, and socioeconomic factors. Higher disease activity scores in Black children at enrollment were modestly explained by longer times from symptom onset to diagnosis, but other factors appeared to contribute more substantially to these disparities. Future research should examine the role of systemic racism and other factors driving racial disparities in JIA diagnosis and disease activity as well as ways to address these factors.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: A successful treat to target (T2T) strategy in ethnic minority (EM) patients with rheumatoid arthritis (RA) could improve patient outcomes and help reduce healthcare disparity but requires patient engagement. In one prospective EM RA database, a low rate of meaningful clinical response was due in part to decreased biologic DMARD (bDMARD) utilization. Other known contributors include distrust of the medical system and medication hesitancy embedded in cultural norms. Education is a critical factor in encouraging self-active participation, medication adherence, and commitment to healthcare goals, but often requires lengthy one-on-one sessions with a provider. The aim of this study was to observe the effect of a Rheumatology Care Coordinator (RCC)-led education program on patient outcomes before and after a targeted education program focused on the T2T paradigm in RA.

Methods: Participants with RA and moderate-to-high disease activity (CDAI >10, RAPID3 >6) were enrolled. Each participant completed 5 T2T-focused education sessions scheduled with routine rheumatology office visits and facilitated by a RCC who completed 6 weeks of training on RA patient education. Translation services were utilized for non-English speaking participants. Demographic and clinical characteristics were recorded, as well as race and ethnicity of providers. Disease activity measures (CDAI and RAPID3), the Arthritis Community Research Evaluation Unit (ACREU) Patient Knowledge Questionnaire (PKQ), Compliance questionnaire and Trust in Physician Scale scores were recorded at Visit 1 and Visit 5. Meaningful clinical reduction in RAPID3 (-3.8) and CDAI (- 6) at Visit 5 was calculated. Descriptive statistics were used for demographic and clinical characteristics. Student's t-test was used to assess RA-related knowledge acquisition, change in compliance, and change in disease activity.

Results: Over a mean study enrollment period of 10 (±3.4) months, there were 29 participants of mean age 57.52 ± 13.81 years, predominantly of African descent and female sex (83%) (Table 1). Most had at least high school education, one with a post graduate degree. The 4 participating providers were non-White. There was a high level of physician trust, which remained stable at the end of the study. There was no significant difference in ACREU scores ($t = -0.07$, p-value = 0.94), and although compliance scores improved, the difference was not significant ($t = -1.94$, p-value = 0.06). A significant decrease in RAPID3 ($t = 2.70$, p-value < 0.05, mean difference -3.98) and CDAI ($t = 4.36$, p-value < 0.05, mean difference -8.60) was seen, with meaningful clinical reduction in disease activity in 48% and 58% of patients, respectively. Almost 50% of participants had a change in DMARD, with 5 patients starting a new biologic therapy.

Conclusion: In a small urban cohort of predominantly African American patients with high school education, a successful T2T regimen was independent of educational level and targeted patient education. Achieving meaningful reduction in disease activity can be achieved in a setting where high physician trust enables shared decisions. The role of patient-provider race and ethnicity in achieving disease remission needs further evaluation.

**p-value represents the statistical significance of the differences observed in values between groups*

Background/Purpose: While racial/ethnic disparities in total joint arthroplasty (TJA) utilization are well-documented, the impact of orthopedic specialists on patients' perceptions of TJA is poorly understood. We aimed to assess the relationship between orthopedic consultation and patients' perspectives on TJA barriers.

Table 2: Odds ratios with 95% Confidence intervals of orthopedic consultation on rated importance of barriers to TJA ††

*††Statistical significance markers . p<0.10; * p<0.05; ** p<0.01; *** p<0.001*

Methods: This multi-institutional prospective cohort study was conducted from 2/2020 to 7/2022. We surveyed patients at 2 large urban academic institutions (Hospital for Special Surgery; New York Presbyterian-Brooklyn Methodist Hospital) and 2 national arthritis cohorts (ArthritisPower; CreakyJoints Español). The electronic questionnaire was developed through thematic analysis of semi-structured interviews conducted with minority patients experiencing advanced osteoarthritis. The questionnaire assessed participants' barriers to TJA were using a 5-level Likert scale. Responses were categorized through a top-2 box analysis: "Highly important" (very or extremely important) and "Not as important" (bottom 3 levels). We evaluated differences in characteristics between those who had and those who had not consulted an orthopedist. Multiple logistic regression models were used to analyze the adjusted odds ratios (aOR) of orthopedic consultation on patients' ratings of barriers to TJA. Models controlled for patient factors, including race, age, HOOS, JR/KOOS, JR, insurance, education, and prior discussion of TJA with any doctor.

Results: 696 participants who completed the survey were included in the analysis (94% of respondents; 24% of total queried). Most were female (88%), average age 59.3 years, 77% White participants, 11% Black, and 9% Hispanic. 49% reported having had an orthopedic consultation. The questionnaire examined five TJA barriers: 1. *Trust in surgeon*, including factors like finding a qualified surgeon; 2. *Cost/insurance*, such as challenges related to co-pays and insurance coverage; 3. *Recovery concerns*, such as insufficient social support; 4. *Surgical outcome*, such as the potential need for additional TJA due to young age; and 5. *Timing of surgery*, whereby other health concerns take precedence over TJA. Participants who had consulted with an orthopedist were older ($p< 0.05$), more likely to be college graduates ($p< 0.01$), Medicare beneficiaries ($p< 0.05$), have consulted with a primary care physician ($p< 0.01$), and have attempted arthritis treatments, such as joint injections ($p< 0.01$), braces ($p< 0.01$), and physical therapy ($p< 0.01$) **(Table 1**). After adjusting for patient factors, orthopedic consultation was a significant predictor of lower barriers relating to *cost/insurance* (aOR (95% CI): 0.52 (0.36, 0.76)) and *timing of surgery* (aOR (95% CI): 0.49 (0.31, 0.79)). (**Table 2**) Patient factors, including race and insurance, did not have significant interaction with orthopedic consultation (all $p >0.05$).

Conclusion: While those with an orthopedic consultation were able to overcome *cost/insurance* and *timing* barriers to consider TJA, significant barriers persisted. Developing strategies to identify and address the TJA barriers among minority groups may help increase utilization within these groups.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Access to care varies across health systems. Countries with universal health insurance are thought to have less wealth-based health disparities, but it is unclear if this applies to total hip arthroplasty (THA) utilization and outcomes. The purpose of this study was to determine whether a single-payer healthcare system would mitigate income-based disparities in THA utilization and outcomes.

Methods: We retrospectively compared all patients undergoing THA from 1/2012 to 9/2018 in Ontario (ON), Canada and Pennsylvania (PA), United States. We obtained PA patient data from Pennsylvania Health Care Cost Containment Council and ON patient data from Ontario's Institute for Clinical Evaluative Sciences. Patient-level data were linked to Census data of median household income of the ZIP code or postal code of patients' residence. We then analyzed whether community income-based differences in THA utilization were reduced in Ontario compared to Pennsylvania due to Canada's single-payer healthcare system. We used logistic regression to examine the relative risks for lowest community income of outcomes such as rates of 1-year revision, 90-day mortality, and 90-day readmission in the two regions.

Results: Among all THAs, 13,280 patients (15.8%) and 16,850 patients (16.0%) lived in communities within the lowest income quintile in Ontario and Pennsylvania, respectively (**Table 1).** Overall THA utilization was lower in Ontario compared to Pennsylvania across income groups **(Figure 1)**. In Ontario, patients in the highest income quintile utilized THA 43.2% more than those in the lowest income quintile (12.6 vs 8.8); this difference in utilization was slightly greater than the difference in Pennsylvania, where patients in the highest income quintile utilized THA 41.7% more than patients in the lowest income quintile (21.4 vs. 15.1) ($p < 0.001$). Patients in the lowest community income quintile in Pennsylvania had a greater rate of 1-year revision, 90-day mortality, and 90-day readmission compared to patients in the lowest income quintile of Ontario. However, after adjusting for age, sex, hospital volume, and rural vs. urban hospital, the odds for patients in the lower-income group compared to the higher-income group of 1-year revision (ON: OR 1.70, 95% CI: [1.34, 2.15]. PA: 1.30 [1.12, 1.52]), 90-day mortality (ON: 1.92 [1.24, 2.98]. PA: 1.66 [1.18, 2.33]), and 90-day readmission (ON: 1.48 [1.34, 1.62]. PA: 1.43 [1.34, 1.54] were greater in Ontario compared to Pennsylvania **(Figure 2)**.

Conclusion: Income-based differences in THA utilization were greater in Ontario than in Pennsylvania. Additionally, patients in low-income communities in Ontario were at greater risk relative to higher community income patients for adverse outcomes. These findings suggest that a single-payer insurance system may not be sufficient to eliminate income-based differences in utilization and complications of THA.

Barriers to Total Joint Arthroplasty for Patients Residing in High-Poverty Communities

J. Alex Gibbons[1], Insa Mannstadt[2], Troy Amen[2], Mangala Rajan[3], Sarah Young[4], Michael Parks[2], Mark Figgie[2], Anne Bass[5], Linda Russell[2], Bella Mehta[5], Iris Navarro-Millán[6] and Susan Goodman[2], [1]Columbia University Vagelos College of Physicians & Surgeons, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Weill Cornell Medicine, New York, NY, [4]Binghamton University, Binghamton, NY, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [6]Weill Cornell Medicine, Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients from lower socioeconomic status (SES) backgrounds have low access to total joint arthroplasty (TJA), delays in undergoing TJA, and a higher risk of adverse outcomes compared to those from high-SES backgrounds. The specific barriers to care perceived by patients from lower-SES backgrounds are not well understood, despite the significance of addressing these barriers in reducing disparities in TJA utilization and outcomes. We aimed to assess differences in patient-reported barriers to TJA by patient community poverty level.

Methods: We developed a survey by analyzing interviews with underrepresented minority patients with symptomatic osteoarthritis regarding their concerns about TJA. The 21-question survey assessed five barriers to TJA: 1) trust in surgeon (such as finding a qualified surgeon), 2) recovery (such as lack of social support), 3) cost / insurance (such as concerns about co-

Table 1. Demographic and clinical characteristics by proportion of community residents living below the national poverty line Note: Figures represent N (%) unless stated otherwise. SD = standard deviation. HOOS, JR = Hip Disability and Osteoarthritis Outcome Score. KOOS, JR = Knee Injury and Osteoarthritis Outcome Score. VAS = visual analogue scale.

Variable, N (%)	Participants from low-poverty (<20%) communities	Participants from high-poverty (≥20%) communities
	N = 584	N = 118
Age, mean (SD)	59 (11)	59 (13)
Sex: female	511 (88%)	106 (90%)
Race / Ethnicity

% of census tract living below poverty line, mean (SD)	6 (5.1)	32 (10)

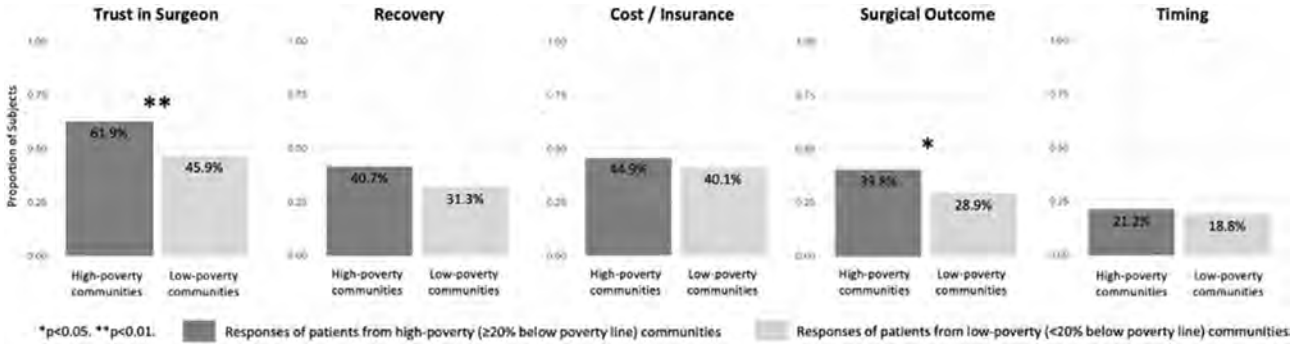

Figure 1. Proportion of participants indicating each barrier to arthroplasty as "highly important" stratified by proportion of community residents living below the national poverty line

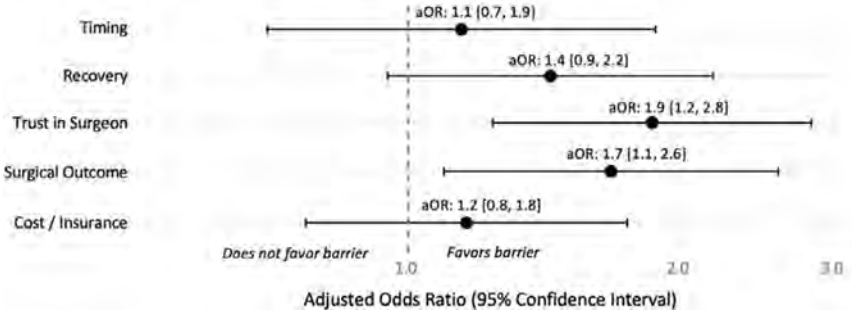

Figure 2. Adjusted odd ratios with 95% confidence intervals of participants from high-poverty communities indicating each barrier as "highly important" Note: Models adjust for age, sex, and HOOS, JR / KOOS, JR.

pay), 4) fear of poor surgical outcome (such as fear of a future revision), and 5) timing (such as not having severe enough joint pain). Participants indicated whether a barrier was important on a 5-point Likert scale, which we then dichotomized so that "Extremely" and "Very" important were defined as "*highly important,*" and other responses were "*not as important*." The survey was distributed to patients at New York City hospitals and nationally via an arthritis support group. Home addresses were geocoded and linked to census tracts; "high-poverty community" was defined as ≥20% of residents in a community living below the poverty level (American Community Survey data). Multiple logistic regression models were used to evaluate adjusted odds ratios (aOR) of community poverty to rating barriers as "*highly important*", adjusted for age, sex, Hip Disability and Osteoarthritis Outcome Score (HOOS, JR) and Knee Injury and Osteoarthritis Outcome Score (KOOS, JR).

Results: Of the 702 participants who provided an address that could be geocoded, 118 (16.8%) were residents of high-poverty communities **(Table 1**). Participants from 46 states and Puerto Rico were represented across 658 unique census tracts. All five barriers were more frequently considered "*highly important*" by residents of high-poverty communities compared to those from low-poverty communities, with differences in surgeon- and outcome-related barriers being the most pronounced (**Figure 1**). After adjusting for age, sex, and HOOS, JR / KOOS, JR, residents of high-poverty communities had a higher risk of perceiving barriers related to limited or lack of trust in a surgeon (aOR: 1.9, 95% CI: [1.2, 2.8]) and fear of poor surgical outcome (aOR: 1.7, 95% CI: [1.1, 2.6]) as "*highly important*" (**Figure 2**).

Conclusion: Residents from high-poverty communities prioritized lack of trust in surgeon and fear of poor surgical outcomes as more significant barriers to TJA compared to residents from low-poverty communities. Our work suggests that facilitating the selection of a trustworthy surgeon and providing education about the process of recovery from TJA among residents from low-income communities could be effective strategies for increasing the uptake of TJA in these communities.

Social Determinants of Health in Children with Rheumatic Disease: A Single Center Cohort

Kristina Ciaglia[1], Elizabeth Sloan[1] and Tracey Wright[2], [1]UT Southwestern and Scottish Rite for Children, Dallas, TX, [2]UT Southwestern, Dallas, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic disease disproportionately impacts certain socioeconomic, racial, and ethnic groups frequently resulting in health care inequities. Social determinants of health (SDOH) are conditions in the environment where people exist that encompass a wide range of systems, and influence quality of life, outcomes, and risks. Aligning with health

Table 1: SDOH Survey Responses from Patients Seen in Rheumatology Clinic

Table 1: SDOH Survey Responses from Patients Seen in Rheumatology Clinic

Social Determinant of Health Survey Questions	Responses: Number of patients (%)
In the last 12 months, was there a time when you were not able to pay the mortgage or rent on time?	Yes: 109 (12.7%) No: 569 (66.1%) Refused to answer/blank: 183 (21.2%)
In the last 12 months, how many places have you lived?	1: 606 (70.4%) 2: 58 (6.7%) 3+: 6 (0.7%) Refused to answer/blank: 191 (22.2%)
In the last 12 months, was there a time when you did not have a steady place to sleep or slept in a shelter (including now)?	Yes: 19 (2.2%) No: 674 (78.3%) Refused to answer/blank: 168 (19.5%)
In the past 12 months, has lack of transportation kept you from medical appointments or from getting medications?	Yes: 39 (4.5%) No: 621 (72.2%) Refused to answer/blank: 201 (23.3%)
In the past 12 months, has lack of transportation kept you from meetings, work, or from getting things needed for daily living?	Yes: 35 (4.1%) No: 629 (73%) Refused to answer/blank: 197 (22.9%)
Within the past 12 months, you worried that your food would run out before you got the money to buy more.	Never true: 508 (59%) Sometimes true: 121 (14.1%) Often true: 19 (2.2%) Refused to answer/blank: 213 (24.7%)
Within the past 12 months, the food you bought just didn't last and you didn't have money to get more.	Never true: 542 (63%) Sometimes true: 92 (10.6%) Often true: 11 (1.3%) Refused to answer/blank: 216 (25.1%)

equity literature, children from disadvantaged socioeconomic backgrounds experience worse outcomes and delays in care.1 In adult SLE, the negative impacts of SDOH are well described with unfavorable determinants leading to more severe disease and increased mortality.2 We aimed to identify SDOH in a cohort of children with rheumatic disease followed at a single center to begin to explore risk factors for disparities in our patient population.

Methods: Patient caregivers completed a SDOH survey prior to the start of the clinic visit. Survey results from February to May 2023 were extracted from the EMR. Patient demographics, diagnosis, and survey responses were analyzed using standard descriptive statistics.

Results: We analyzed SDOH surveys (n=861) completed during the initial survey roll out. Most patients surveyed were female (70%), and the average age was 11.7 years. Seventy percent reported White race, and 38% identified their ethnicity as Hispanic/Latino. Eleven percent of respondents had no high school degree, and 7.6% reported they need help with reading materials. Approximately 4% of patients reported needing help with cost of care, utilities, food, housing, or

SDOH Responses Number (%)				
"I need help with reading materials"				
Yes	66 (7.6%)	10 (15.2%)	6 (12%)	18 (4.9%)
No	632 (73.4%)	35 (53%)	24 (48%)	240 (64.7%)
Refused to answer/blank	163 (18.9%)	21 (31.8%)	20 (40%)	113 (30.4%)
"Do you have a High School degree?"				
Yes	592 (68.8%)	32 (48.5%)	24 (48%)	228 (61.4%)
No	101 (11.7%)	11 (16.7%)	6 (12%)	31 (8.4%)
Refused to answer/blank	168 (19.5%)	23 (34.9%)	20 (40%)	112 (30.2%)

transportation. Twenty-one percent reported being often or sometimes worried about food security (Table 1). Of the patients surveyed, 66had a diagnosis of SLE,50 had JDM, and 371 had JIA(Table 2). In comparison with JIA and JDM families, SLE caregivers disclosed a statistically significant higher rate of needing help with reading materials (p=0.0136) and lack of high school degree (p=0.0355).

Conclusion: Patients seen in our center come from diverse socioeconomic, racial, and ethnic backgrounds. The SDOH survey identified critical barriers to patient care including health literacy, food security, and living costs such as transportation, housing, and utilities. Health literacy may be an essential limiting factor for our families with children who have SLE. Further study is needed to understand the impact of SDOH on outcomes for children with rheumatic disease and how it varies by diagnosis. Future efforts to improve the management and outcomes of children with rheumatic disease should focus on specific SDOH that could influence health inequities.

Patterns in the Prescription, the Denials of Coverage, and the Delays in Dispensation of Janus Kinase Inhibitors

Thomas Riley[1], Igor Dombrovsky[2], Michael George[3] and Joshua Baker[3], [1]Hopsital of the University of Pennsylvania, Springfield, PA, [2]Pennsylvania Hospital, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Janus kinase inhibitors (JAKi) have therapeutic benefits in autoimmune conditions. Access to these medications is controlled by insurance carriers through requirements for prior authorizations and the use of restricted formularies which are difficult to navigate and may lead to denials of coverage and/or delays in dispensation.This study sought to characterize the real-word coverage denials and delays in dispensation of JAKi in patients with rheumatologic diseases, hypothesizing that there would be differences in denials of prescriptions and delays in dispensation related to drug type, race, and insurance status.

Methods: A retrospective cohort was created from patients at an academic tertiary care rheumatology practice who were prescribed a JAKi between 2014 and 2023. Patients were included in this analysis if they had a documented visit with a rheumatologist documented in the electronic health record (EHR) and for the initial prescription of a JAKi (tofacitinib, baricitinib, upadacitinib) but did not include patients renewing an existing prescription. Patients were selected irrespective of underlying disease. Demographics and current/prior disease-modifying anti-rheumatic drug (DMARD) use were extracted from the EHR. To provide confirmation of insurance approval and determine the time to dispensation, pharmacy and nursing-based communications related to the processing of prior authorization and coordination with specialty pharmacies were also extracted from the EHR.

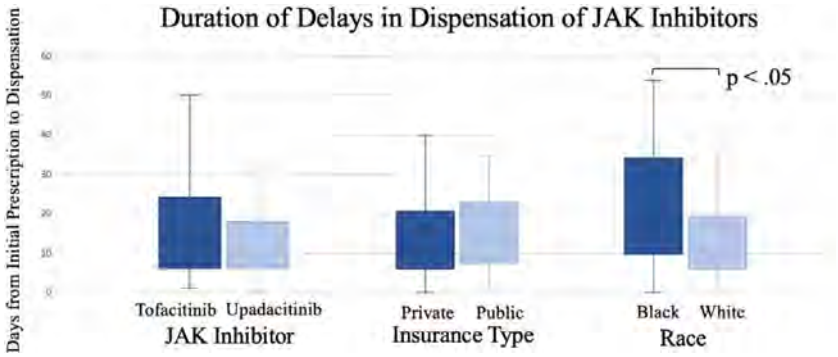

Figure 1. In evaluating the delays from time to prescription to time to dispensation, there were no significant differences comparing tofacitinib to upadacitinib (19.8 vs 15.2, p =0.34) or the insurance type the patient was enrolled in (16.7 vs 21.3, p = 0.32). However, patients who were Black experienced a longer delay in initial dispensation compared to those who were Non-Hispanic White (30.6 vs 15.8, p = 0.013)

Results: We identified a total of 118 new prescriptions for JAKi among 90 patients (81 tofacitinib, 36 upadacitinib, 1 baricitinib).Of these 118 prescriptions, 10 (8%) had coverage denied by insurance, and 5 (4%) were not dispensed for other reasons [2 were limited by co-pay, 1 changed insurance, 1 developed a severe infection, and 1 opted not to start due to personal preferences]. Patients with an approved prescription experienced, on average, an 18-day delay [IQR 6-22] between initial prescription and dispensing of a JAKi. 14 prescriptions (11%) had delays longer than 30 days. Patients who were Black experienced a longer delay in initial dispensing compared to those who were Non-Hispanic White (30.6 vs 15.8, p = 0.013). Comparing private vs public insurance, there were not differences in rates of coverage denial (10% vs 7%, p = 0.61), nor were there differences in delays in dispensation (21.3 vs 16.7, p = 0.32). There were not differences in delays in dispensation for tofactinib compared to upadacitinib (19.8 vs 15.2, p =0.34).

Conclusion: While rates of coverage denial of JAKi were low, there was an average delay in dispensing prescriptions of 18 days. Patients who were Black experienced an almost 2-fold longer delay in dispensing of JAKi compared to those who identified as Non-Hispanic White. Further evaluation is needed to identify the potential factors at play contributing to this observed disparity and the key drivers of delays in medication dispensing.

Geographic Socioeconomic Influences on Disease Activity in Rheumatoid Arthritis in an Academic and Safety-Net Hospital System

Joseph Kim[1], Song Zhang[2] and Elizabeth Blair Solow[1], [1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern, Dallas, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased morbidity and mortality, particularly if RA is poorly controlled. The effects of socioeconomic deprivation have not been well studied in the context of RA. We analyzed the impact of the Area Deprivation Index (ADI) on disease activity and cardiovascular comorbidity in RA.

Table 1. Demographics of each cohort

	Academic State ADI (n=542)	Academic National ADI (n=502)	Safety net State ADI (n=496)	Safety net National ADI (n=354)	Academic vs Safety net (n=1158)

State ADI for safety net cohort

Methods: We conducted a retrospective analysis of RA patients, defined by ICD-10 codes, seen at our academic practice and safety-net hospital system clinics in the past 5 years and are 18-89 years old. We collected age, ethnicity, race, gender, insurance plan, primary language, address, RA medications, MyChart engagement, primary care physician presence, emergency department/inpatient visits, RA disease activity and functional scores (CDAI, MDHAQ/HAQII, RAPID3), Charlson comorbidity index (CCI), and cardiovascular disease (CVD) presence. ADI was used as a proxy for socioeconomic deprivation and was assigned using 9-digit zip codes. Patients were divided by the upper ADI tertile vs lower ADI tertile and matched by gender, race/ethnicity, age, insurance and CCI using propensity score analysis. Two-sample t test and Chi-square test were conducted for final group comparisons.

Results: Patients from our academic practice (n=542) and from our safety-net hospital system (n=496) were assessed using state ADI. The mean state ADI score was 5.3 and 5.6 for academic and safety-net, respectively (range 1-10). In the academic cohort, those with high ADI scores (>8, more deprived) had higher RA disease activity (RAPID3: High 13.834±6.943 vs Low 11.166±7.370, $p< 0.0001$, CDAI: High 11.970±11.738 vs Low 9.400±7.968, $p< 0.05$) and RA functional impairment (MDHAQ: High 0.933±0.676 vs Low 0.722±0.667, $p< 0.001$) and had lower MyChart utilization ($p< .001$) compared to those with low ADI scores (< 3, less deprived). There were also statistically significant differences in smoking status ($p< .01$). In the safety-net cohort, there was a statistically significant difference in smoking status ($p< 0.05$). Otherwise, for the safety-net cohort, there were no significant differences between the high ADI and low ADI group in any of the other measured variables.

Conclusion: We found significant differences in RA disease activity and function in patients from more socioeconomically deprived areas in the academic system. The absence of these differences in safety-net patients raises important questions as to whether certain hospital specific factors influence the role ADI plays in various health outcomes. The results suggest that ADI may not be as effective at predicting RA disease activity at a safety-net hospital. Identifying the discrepancies between the two hospital systems may elucidate areas of improvement for patient care.

"Not of Your Ethnicity": A Qualitative Study Exploring Diverse Patient Experiences in Axial Spondyloarthritis (axSpA)

Bryanna Mantilla[1], K Wysham[2], Jean liew[3] and Grant Hughes[1], [1]University of Washington, Seattle, WA, [2]VA Puget Sound/University of Washington, Seattle, WA, [3]Boston University, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Healthcare Disparities in Rheumatology Poster II: Socioeconomic Determinants

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) can result in significant morbidity. Existing studies suggest functional impairment and inflammation may be worse in Black and Latine patients. However, no studies have focused on the experiences of diverse patients with axSpA. This study fills a critical knowledge gap by utilizing qualitative methods to describe the experiences of patients with axSpA from diverse racial-ethnic groups.

Methods: We identified a sampling frame of 128 adult patients with: ≥1 rheumatology visit in a university healthcare system within 3 years with a linked ICD code (spondylopathies) and patient-identification of race as Black, African American, Asian, Native American, American Indian, Alaska Native, Native Hawaiian, or Pacific Islander, or ethnicity of Hispanic or Latino. Twenty-eight patients were excluded due to not meeting diagnostic criteria or language preference other than English or Spanish. We used qualitative methods with a grounded theory approach (Figure 1). Sampling was purposive. We performed semi-structured individual interviews of 20 patients, conducted in English or Spanish. Analysis of interview transcripts was ongoing and iterative. Participants were recruited until thematic saturation was reached.

Results: Qualitative data analysis indicated six major themes (figure 2): 1) nebulous diagnostic definitions; 2) diversity and intersectionality; 3) road to rheumatology; 4) barriers to diagnosis; 5) limitations in treatment options; 6) coping with chronic illness.

Within nebulous diagnostic definitions, minor themes included: patient difficulty in understanding diagnosis, provider gaps in knowledge of axSpA, inconsistency in diagnostic language, and provider failure to query for or disbelief of inflammatory symptoms.

For diversity and intersectionality, minor themes included: the role of healthcare outside the US, provider-patient discordance, bias along age, gender and race/ethnic/cultural axes, the impact of a gendered and racialized illness script for axSpA and the importance of unique social stressors for patients.

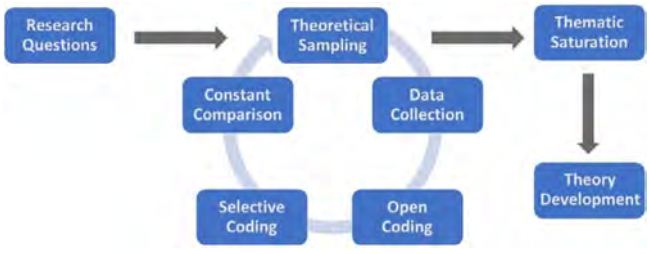

Figure 1: Schematic representation of grounded theory methodology in qualitative research

Regarding the road to rheumatology, minor themes included: reliance on positive HLA-B27 or recurrent uveitis for referral to rheumatology care, the burden of seeing multiple providers, and financial barriers to supportive diagnostic testing.

In barriers to diagnosis, minor themes included: patients' internalized communication failure, provider disbelief of symptoms or misattribution, and overall mistrust in the medical system

Within limitations in treatment, minor themes included: overreliance on physical therapy and NSAID use, difficulty understanding medication options and difficulty understanding systemic nature of disease.

About coping with chronic illness, minor themes included: chronic and incurable disease, fear and anxiety over prognosis, use of complementary therapies, protective strategies, and the importance of safety net services.

Conclusion: Our study identified six major themes of diverse patient experiences. Studying patient experiences is critical for understanding mechanisms of health disparity, targeting interventions and, ultimately, improving quality of care.

Abstract Number: 1033

The Detection of Subclinical Joint Inflammation by Thermal and Ultrasound Imaging at the Metacarpophalangeal Joints in Patients with Rheumatoid Arthritis

York Kiat Tan[1] and Gek Hsiang Lim[2], [1]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore, [2]Health Services Research Unit, Singapore General Hospital, Singapore, Singapore

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: While magnetic resonance imaging and ultrasound (US) imaging have been shown to be useful in the detection of subclinical joint inflammation in rheumatoid arthritis (RA), the literature on the use of thermal imaging (TI) in detecting subclinical disease in RA is presently lacking. The purpose of this RA study is to investigate whether there exists any correlation(s) between thermographic parameters and US-detected joint inflammation at clinically non-tender and non-swollen metacarpophalangeal joints (MCPJs).

Methods: RA patients (fulfilling the 2010 RA classification criteria) with clinically non-tender and non-swollen MCPJs underwent TI and US imaging of their 10 MCPJs on the same study visit. The thermographic parameters (maximum (Tmax), minimum (Tmin) and average (Tavg) temperatures in degree Celsius) were recorded from the dorsal surface of each MCPJ and summed up to obtain the respective Total Tmax, Total Tmin and Total Tavg per patient. Ultrasound power Doppler (PD) and grey-scale (GS) joint inflammation were scored semi-quantitatively (0-3) at the dorsal aspect of each MCPJ and summed up to obtain the respective Total PD and Total GS scores per patient. At each MCPJ, US synovitis is defined as PD ≥1 or GS ≥2 [1]. At the patient level, Pearson's correlation coefficient was used to correlate Total Tmax, Total Tmin and Total Tavg with Total PD score, Total GS score and the number of joint(s) with US synovitis (PD ≥1 or GS ≥2). Among associations which were statistically significant, simple linear regression was applied to characterise relationship between variables.

Results: A total of 340 MCPJs (clinically non-tender and non-swollen) were examined among 34 RA patients. In this cross-sectional study, the patients' baseline characteristics are as follows: age, mean (SD) 58.3 (12.5) years; Chinese (n = 25, 73.5%); female (n = 30, 88.2%); DAS28, mean (SD) 3.13 (0.84); disease duration, mean (SD) 36.9 (58.1) months. Table 1 summarises the results from the correlation analysis. Total Tmax correlated significantly (P < 0.05) with Total PD score (r = 0.38), Total GS score (r = 0.41) and the number of joint(s) with PD ≥1 or GS ≥2 (r = 0.41). Total Tmin correlated

Table 1. Results from the Pearson's correlation coefficient analysis.

Thermographic parameter	Total PD		Total GS		Number of joint(s) (PD ≥1 or GS ≥2)	
	Correlation coefficient	P-value	Correlation coefficient	P-value	Correlation coefficient	P-value
Total Tmax	0.38	0.03*	0.41	0.02*	0.41	0.02*
Total Tmin	0.33	0.06	0.40	0.02*	0.39	0.02*
Total Tavg	0.34	0.051	0.41	0.02*	0.40	0.02*

*Statistically significant at P < 0.05

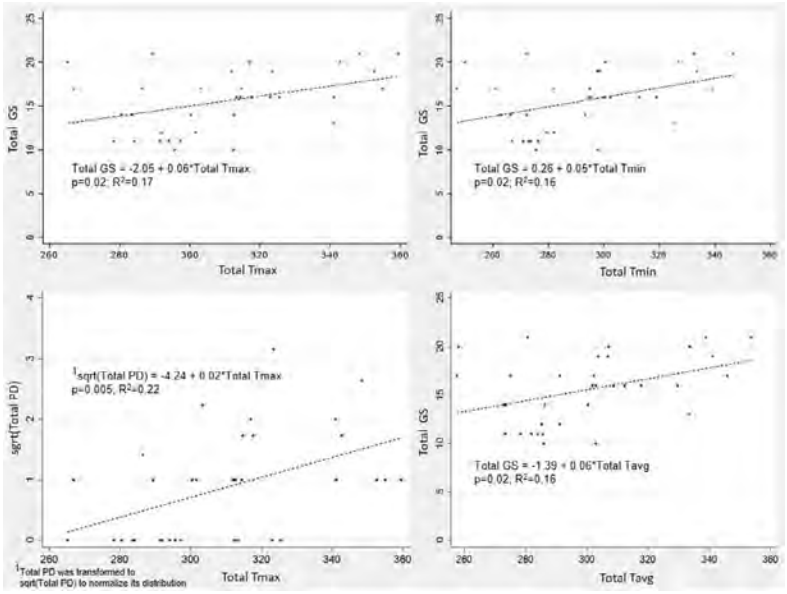

Figure 1. The relationship between thermographic parameters and ultrasound PD and GS variables.

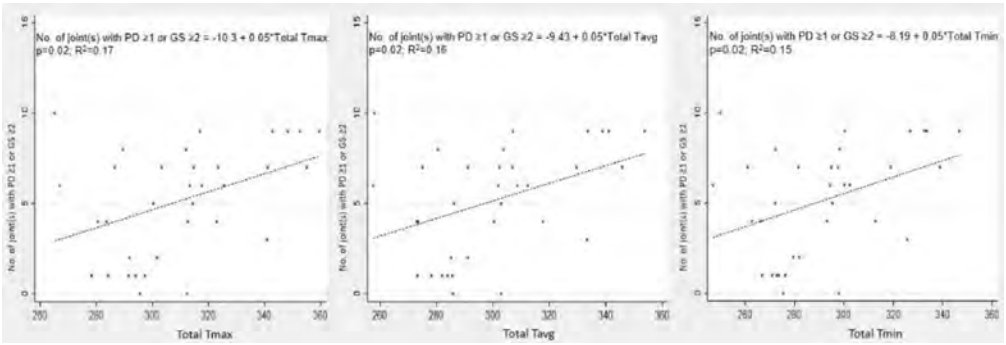

Figure 2. The relationship between thermographic parameters and number of joint(s) with PD ≥1 or GS ≥2.

significantly ($P < 0.05$) with Total GS score ($r = 0.40$) and the number of joint(s) with PD ≥1 or GS ≥2 ($r = 0.39$). Total Tavg correlated significantly ($P < 0.05$) with Total GS score ($r = 0.41$) and the number of joint(s) with PD ≥1 or GS ≥2 ($r = 0.40$). The relationship (only associations which were statistically significant are shown) of thermographic parameters with US variables and number of joint(s) with PD ≥1 or GS ≥2 are shown in Figure 1 and 2, respectively.

Conclusion: To the best of our knowledge, our RA study is the first to show that results from TI correlates significantly with US PD and GS joint inflammation as well as the number of joint(s) with ultrasound synovitis (PD ≥1 or GS ≥2) at the MCPJs. Like US imaging, TI can help detect subclinical joint inflammation at clinically non-tender and non-swollen MCPJs and further investigative work using TI in the detection of subclinical disease in RA appears warranted.

The Relationship Between the Extent of Ground Glass to Fibrosis Ratio and Treatment Response to Immunomodulatory Therapy in Three Separate Autoimmune Interstitial Lung Disease Cohorts

Scott Matson[1], Stephen Humphries[2], joyce Lee[3], Michael Roth[4], Donald Tashkin[4], Grace Kim[4], Jonathan Goldin[4], Mei Leng[4] and **Elizabeth Volkmann**[4], [1]University of Kansas School of Medicine, Kansas City, MO, [2]National Jewish Health, Denver, CO, [3]University of Colorado Anschutz Campus, Denver, CO, [4]University of California Los Angeles, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Imaging of Rheumatic Diseases Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: For patients with autoimmune interstitial lung disease (ILD), the clinician's interpretation of the extent of ground glass relative to fibrosis on imaging often influences the choice of treatment (immunomodulatory vs. antifibrotic therapy). However, it is unknown if the ground glass to fibrosis ratio affects treatment response for patients with different types of autoimmune ILDs. The purpose of this study is to examine the relationship between quantitative ground glass opacity to fibrosis ratio on baseline imaging and treatment response to immunomodulatory therapy in patients with ILD associated with systemic sclerosis (SSc) and rheumatoid arthritis (RA).

Methods: Participants of three independent cohorts were included in the present study: (1) Scleroderma Lung Study (SLS) I, which compared cyclophosphamide with placebo for SSc-ILD; SLS II, which compared cyclophosphamide with mycophenolate for SSc-ILD; and a retrospective cohort of patients with rheumatoid arthritis RA-ILD treated with immunomodulatory

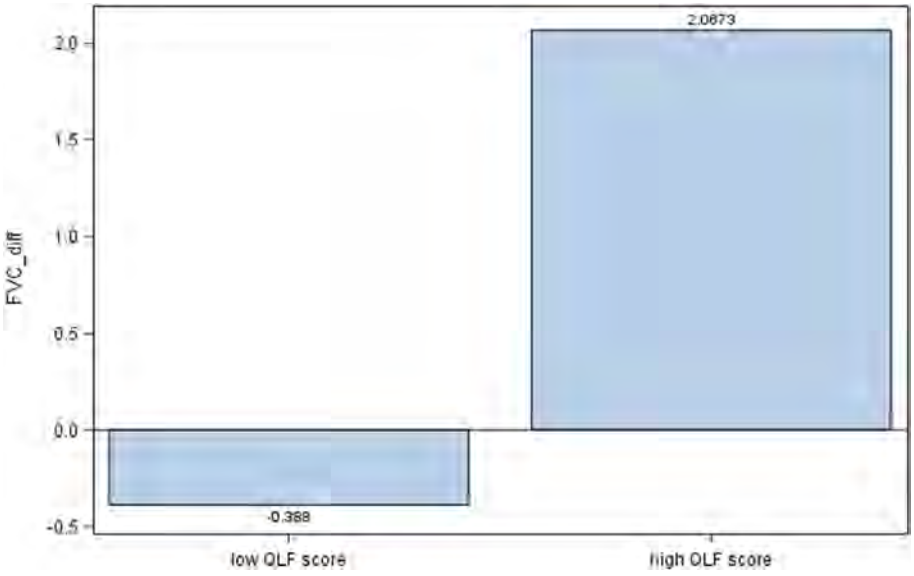

Figure 1. Bar chart that compares the mean forced vital capacity (FVC) percent predicted change at 12 months in SLS I and SLS II participants randomized to cyclophosphamide based on high versus low fibrosis (QLF) score. Patients in the high QLF score group (N=49) experienced a mean improvement in FVC%-predicted of 2.07 (SD 6.8), while patients in the low QLF group (N=53) experienced a slight mean decline in FVC %-predicted of -0.39 (SD 7.2) (P-value for between group difference [P=0.08])

therapy (azathioprine, mycophenolate mofetil or rituximab). Pretreatment high-resolution computed tomography (HRCT) scans underwent quantitative image analysis to determine whole lung ground glass and fibrosis extent. Forced vital capacity (FVC) and diffusion capacity for carbon monoxide (DLCO) percent predicted were measured at baseline and 12-months. Logistic regression analysis was used to examine the relationship between baseline ground glass to fibrosis ratio and the following outcomes: FVC improvement of 3% or greater, FVC decline of 3% or greater, and FVC decline of 5% or more or

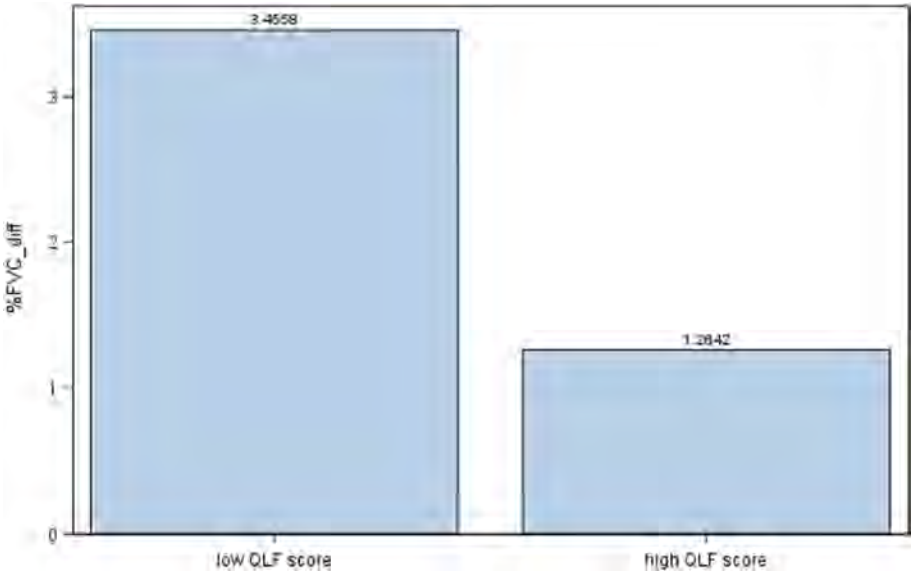

Figure 2. Bar chart that compares the mean forced vital capacity (FVC) percent predicted change at 12 months in SLS II participants randomized to mycophenolate based on high versus low fibrosis (QLF) score. Patients in the high QLF score group (N=26) experienced a mean improvement in FVC%-predicted of 1.26 (SD 7.4), while patients in the low QLF group (N=30) experienced a mean improvement in FVC%-predicted of 3.46 (SD 7.5) (P-value for between group difference [P=0.28]).

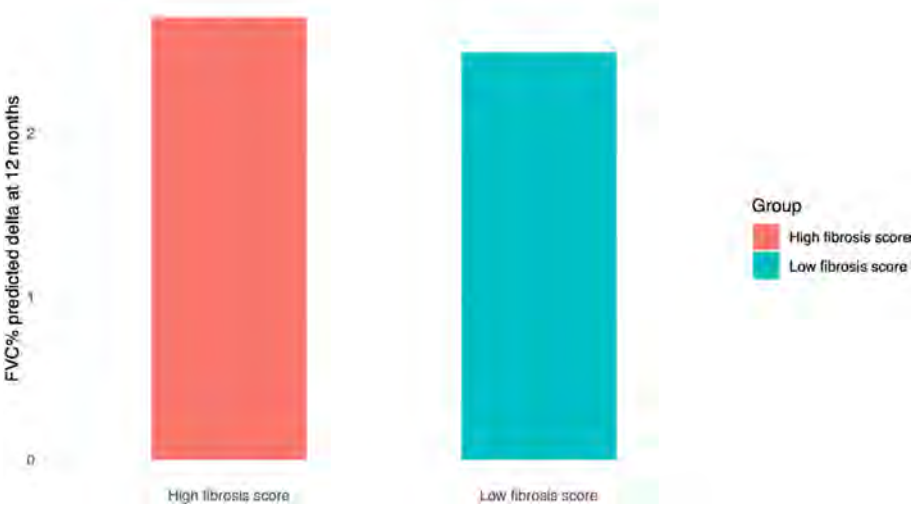

Figure 3. Bar chart that compares the mean forced vital capacity (FVC) percent predicted change at 12 months in RA-ILD participants based on high versus low fibrosis scores. Patients in the high QLF score group experienced a mean improvement in FVC%-predicted of 2.70 (SD 1.7), while patients in the low QLF group experienced a mean improvement in FVC%-predicted of 2.49 (SD 1.3) (P-value for between group difference [P=0.76]).

DLCO decline of 10% or more. Two sample t-tests were performed to compare the mean change from baseline in FVC %-predicted between patients with high versus low fibrosis scores based on the median.

Results: The total cohort included 354 patients with autoimmune ILD. The mean baseline quantitative ground glass to fibrosis ratio at baseline was higher in the SSc cohorts (SLS I: 5.3 [SD 5.5], SLS II: 5.0 [SD 5.2]) than in the RA-ILD cohort (0.62 [SD 1.2]). No significant association was observed between the quantitative ground glass to fibrosis ratio and FVC improvement ≥3% or decline ≥3%, nor the physiologic criteria for progressive pulmonary fibrosis (FVC decline of 5% or more or DLCO decline of 10% or more) at one year in any of the cohorts. Participants with high fibrosis scores demonstrated improved response to treatment with CYC in SLS I and II (Figure 1), while participants with high versus low fibrosis scores experienced a similar improvement in FVC%-predicted in the SLS II-MMF arm (Figure 2) and the RA-ILD cohort (Figure 3).

Conclusion: The extent of ground glass relative to fibrosis does not appear to affect treatment response to immunomodulatory therapy in patients with SSc-ILD and RA-ILD; whereas, higher fibrosis extent was associated with improved response to CYC in SSc-ILD. While the presence of ground glass opacity may signify an underlying inflammatory process, the etiologies of this radiological phenomenon are diverse in these two diseases and additional research is needed to understand how to predict treatment response using radiological parameters in patients with autoimmune ILD.

Abstract Number: 1035

Diagnostic and Educational Utility of an Ultrasound Protocol for Evaluation of Hand Pain in Systemic Sclerosis

Meridith Balbach, Tracy Frech, Nicholson Chadwick, Kevin Byram and Erin Chew, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hand impairment is a prevalent issue among systemic sclerosis (SSc) patients and contributes to disability and diminished quality of life. Managing hand pain can be challenging due to the coexistence of various manifestations such as inflammatory arthritis, tendinopathies, joint contractures, sclerodactyly, calcinosis, acro-osteolysis, Raynaud's phenomenon (RP), digital ulcers (DU), and chronic pain. The physical examination and radiographs are the primary methods for evaluating hand pain but are limited in scope. We hypothesized that joint ultrasound (US) is more sensitive than combined joint exam and hand radiograph for identification of acro-osteolysis, articular disease (synovitis, erosions, osteophytes), and periarticular disease (tendinopathies, calcinosis) and can assist in targeted treatment strategies.

Table 1: Patient clinical characteristics and physical exam, radiograph, and ultrasound findings. Yr= years; lcSSc= limited cutaneous systemic sclerosis; dcSSc= diffuse cutaneous systemic sclerosis; NVC= nailfold videocapillaroscopic pattern; DIP= distal interphalangeal; CMC= carpometacarpal; OA= osteoarthritis; MCP= metacarpophalangeal; CPPD= calcium pyrophosphate deposition. *Summarized ultrasound findings are displayed in Table 1 with specific pathologic features detected on ultrasound represented in Figure 1. PIP= proximal interphalangeal; MCP= metacarpophalangeal; TFCC= triangular fibrocartilage complex; DIP= distal interphalangeal

Patient	Age (yr)	SSc Disease Duration (yr)	Clinical Subset (serologies)	NVC Pattern	Fixed Contractures	Synovitis Physical Exam	Radiographic Findings & Diagnosis	Ultrasound Findings*
A	74	23	lcSSc (centromere)	Late	No	No	Non-uniform DIP and CMC joint space narrowing, osteophyte formation; OA	Flexor tendon sheath effusion
B	46	2	dcSSc (RNApol3)	Active	Yes	No	CMC degenerative change, subchondral cystic change; OA	Skin and soft tissue thickening
C	79	20	dcSSc (RNApol3, SSa52)	Late	Yes	No	MCP erosions, chondrocalcinosis	Pseudo double contour sign, fibrocartilage and hyaline calcification, calcinosis
D	37	3	dcSSc (SCL70, dsDNA)	Early	No	Yes	Normal	Inflammatory MCP synovitis, wrist tenosynovitis
E	29	2	dcSSc (SCL70)	Active	No	No	Normal	Normal

Methods: Five randomly selected SSc patients with nonspecific hand pain were referred for musculoskeletal US exam. SSc clinical features were recorded. Joint US was compared to physical exam features of synovitis, tendinopathy, digital ulcers, or calcinosis and radiographic features of erosions, osteophytes, and acro-osteolysis. A pre- and post-ultrasound survey assessed patient and provider perception of diagnostic understanding and treatment needs.

Results: Baseline characteristics, exam findings, radiographs, and ultrasound findings are noted in **Table 1**. No patients had digital ulcers or calcinosis on physical exam or acro-osteolysis on radiograph. Ultrasound exam was able to detect diverse manifestations of hand pathology (**Figure 1)**. Ultrasound review improved the referring provider's confidence in treatment decision improved in all cases (**Table 2**). Patient A was diagnosed with mechanical osteoarthritis, patient B with sclerodactyly, patient C with calcium pyrophosphate arthropathy, Patient D with inflammatory arthritis, and Patient E with chronic pain. The treatment plan was modified in all five patients. US improved patients' understanding of the cause of their joint pain in four patients. After undergoing US, all patients reported feeling that their joint problem had been more thoroughly examined and being more likely to adhere to their provider's treatment recommendations.

Conclusion: The physical exam and radiographs are not sufficient for the evaluation of hand pain in systemic sclerosis. Standardized US assessment in SSc can accurately evaluate hand pain and quantify acro-osteolysis, articular disease, and periarticular disease. Detection of these features can improve provider confidence in management decisions and advance patient understanding of disease, potentially improving treatment adherence and outcomes.

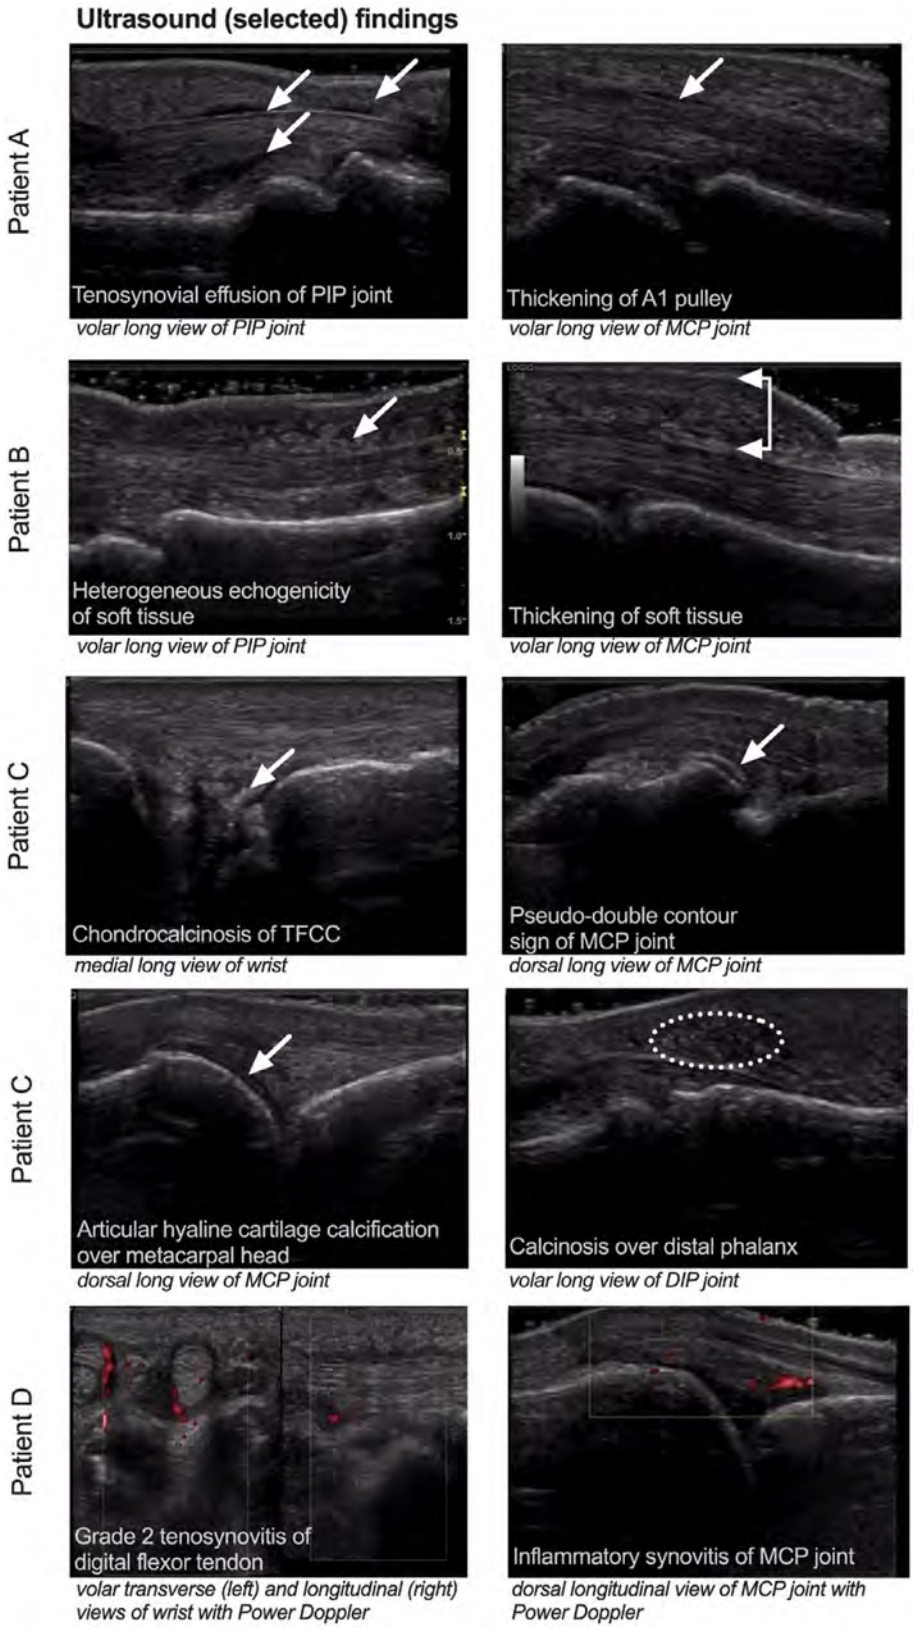

Figure 1: Selected pathologic findings on musculoskeletal ultrasound exam for patients A-D. Relevant features are indicated by white arrows or dotted oval and imaging view is labeled in italics. PIP= proximal interphalangeal; MCP= metacarpophalangeal; TFCC= triangular fibrocartilage complex; DIP= distal interphalangeal

Table 2: Patient and provider perception survey results after ultrasound exam.

Patient	Improved Patient Understanding of Hand Pain	Improved Provider Understanding of Hand Pain	Change in Care Plan Based on US Results
A	Yes	Yes	Yes
B	Yes	Yes	Yes
C	Yes	Yes	Yes

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal ultrasound (US) is a validated method for the objective assessment of the pathological changes occurring in PMR. It assists the diagnosis of the disease and increases the performance of 2012 ACR/EULAR classification criteria for PMR(1). The aim of our international multicenter study was to determine the prevalence of US findings characteristic for PMR in a cohort of newly diagnosed PMR patients.

Methods: Our PMR cohort included 390 consecutive clinically diagnosed patients from eight rheumatology centers.At diagnosis, patients underwent a bilateral US examination of shoulder and hip joints. Only patients who had no missing data were included in the analysis. The presence of joint effusion (hip, glenohumeral), bursitis (subdeltoid, trochanteric) and tenosynovitis (long biceps tendon) was recorded.

Results: A complete US examination was performed in 289 PMR patients. Mean (SD) age was 73.1 (9.7) years and 159 patients were female (55.0%). All PMR patients had at least one pathologic US finding. The presence of biceps tendosynovitis (mostly bilateral) was the most frequently recorded abnormality, disclosed in 240 patients (83.0%). The prevalence of individual pathologic US findings is reported in Table 1. The two US items included in the PMR classification criteria "at least 1 shoulder with subdeltoid bursitis and/or biceps tendosynovitis and/or glenohumeral synovitis and at least 1 hip with synovitis and/or trochanteric bursitis" (item 1) and "bilateral shoulder with subdeltoid bursitis, biceps tendosynovitis, or

Pathology	n	% (from 289)	Unilateral / Bilateral (n)
Hip effusion	137	47.4%	44 / 82
Trochanteric bursitis	55	19.0%	18 / 37
Glenohumeral joint effusion	128	44.3%	46 / 82
Subdelotid bursitis	227	78.5%	61 / 166
Biceps tenosynovitis	240	83.0%	56 / 184

n = number of cases

glenohumeral synovitis" (item 2) were fulfilled in 153 cases (52.9 %) and 269 cases (93.1%), respectively. Patients who fulfilled item 1 of US classification criteria had a higher CRP level compared to those who did not ((mean (SD) CRP 59.4 (48.1)vs 42.0 (40.7) mg/l ($p < 0.001$) for patients that not fulfilled this item, since No other associations regarding US criteria, sex, age, ESR and CRP were found.

Conclusion: At least one US abnormality of shoulder or hip joints was found in all our PMR patients, with bilateral tendosynovitis of long biceps tendon being the most common finding 83%. Ultrasound PMR classification criteria were met in 52.9% patients for item 1 and in 93.1% patients for item 2.

Dual Energy Computed Tomography (DECT) Urate Volume Predicts Fulfillment of Gout Remission After Two Years of Intensive Urate-Lowering Therapy

Adwoa Dansoa Tabi-Amponsah[1], Sarah Stewart[2], Greg Gamble[1], Anthony Doyle[3], Chang-Nam Son[4], Kieran Latto[1], Lisa Stamp[5], William Taylor[6], Anne Horne[1] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]Auckland University of Technology, Auckland, New Zealand, [3]Auckland District Health Board and University of Auckland, Auckland, New Zealand, [4]Uijeongbu Eulji Medical Center, Eulji University School of Medicine, UIJEONGBU, South Korea, [5]University of Otago, Christchurch, New Zealand, [6]University of Otago, Wellington, New Zealand

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Imaging of Rheumatic Diseases Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Preliminary gout remission criteria have been developed using OMERACT core outcome domains for long-term gout studies. This study aimed to identify variables that predict gout remission in patients receiving intensive urate-lowering therapy.

Methods: We analysed data from a 2-year, double-blind randomized controlled trial of 104 people with erosive gout. Participants were randomized to an intensive serum urate target of < 0.20mmol/L or a standard target of < 0.30mmol/L using oral urate-lowering therapies (allopurinol, probenecid, benzbromarone, and febuxostat). All participants had a dual energy CT (DECT) scan of the feet and ankles at baseline. The proportion of participants achieving gout remission according to the preliminary gout remission criteria and simplified gout remission criteria without the patient reported outcomes at Year 1 and Year 2 was calculated **(Table 1).** The simplified gout remission criteria were developed following a qualitative study examining patient perspectives of gout remission. Logistic regression models were used to evaluate independent predictors of gout remission at Year 2; these included baseline variables associated with remission in bivariate analysis and baseline values for each remission domain.

Results: The preliminary gout remission criteria were fulfilled in 11 (11%) of all participants at Year 1 and 21 (23%) of all participants at Year 2. The simplified criteria were fulfilled in 26 (27%) participants at Year 1 and 40 (44%) participants at Year 2. Similar rates of remission were observed in the two randomization groups (P >0.99). In regression models, baseline DECT urate volume was a significant predictor of gout remission at Year 2, using either criteria. Each one cm^3 increase in the baseline DECT urate volume decreased the odds of fulfilling the preliminary gout remission criteria with an odds ratio of 0.65 [95% CI 0.44-0.96], P=0.029. Likewise, each one cm^3 increase in the baseline DECT urate volume decreased the odds of fulfilling the simplified gout remission criteria with an odds ratio of 0.56 [95% CI 0.39-0.77], P< 0.001.

Conclusion: In people with erosive gout on urate-lowering therapy, high baseline MSU crystal volume measured by DECT is associated with lower odds of gout remission after two years of treatment, defined by both the preliminary gout remission criteria and simplified gout remission criteria.

Table 1. Preliminary gout remission criteria (1) and the simplified gout remission criteria used in this analysis

Preliminary gout remission criteria	Simplified gout remission criteria
Absence of gout flares in the last 12 months	Absence of gout flares in the last 12 months
Absence of tophi	Absence of tophi
Serum urate <0.36mmol/L measured at least twice in the last 12 months,	Serum urate <0.36mmol/L measured at least twice in the last 12 months
Pain due to gout <2 at least twice the last 12 months and no value 2 or more, using a 10-cm visual analogue scale or 10-point Likert scale.	
Patient global assessment <2 at least twice the last 12 months and no value 2 or more, using a 10-cm visual analogue scale or 10-point Likert scale.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Imaging of Rheumatic Diseases Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Whether a therapy has bone structure-modifying effects in the spine is crucial to determine since this is a prerequisite for a therapy to reduce development of permanent disability in patients with axial spondyloarthritis (axSpA). The current imaging modality for assessing structural progression in axSpA is conventional radiography (X-ray), using the modified Stoke Ankylosing Spondylitis Structural Score (mSASSS). However, this method is only able to show change over a minimum of two years, i.e. has a very low sensitivity to change. Alternative modalities are MRI and CT. MRI, unfortunately, cannot reliably visualize small syndesmophytes. CT is considered the gold standard but delivers substantial ionizing radiation. However, modern CT scanners allow the use of lower radiation doses (low-dose CT, ldCT).

Table 1. Occurrence, sensitivity, and specificity of new bone formation lesions, as detected by various imaging modalities, for each reader

	Number of new bone formation lesions scored (low-dose CT/synthetic CT/x-ray)					*Sensitivity/specificity for synthetic CT (low-dose CT gold standard)*					*Sensitivity/specificity for X-ray (low-dose CT gold standard)*

[1] Anterior: Anterior vertebral corners, Central: Central vertebral corners, Posterior: posterior vertebral corners, Facet joints

The purpose of this study was, with ldCT as the gold standard reference, to assess and compare the ability of a novel deep-learning MRI-based method ("synthetic CT", sCT), ldCT, and X-ray, in the assessment of structural damage in the spine in patients with axSpA.

Methods: X-ray (lumbar and cervical spine), ldCT, and sCT of the entire spine were performed in patients with axSpA (according to ASAS criteria) in a prospective observational cohort. sCT was made using the BoneMRI application (v1.6, MRIGuidance BV, Utrecht, NL) a quantitative 3D MRI technique based on a multiple gradient-echo sequence and a machine learning processing pipeline that can generate CT-like MR images. All images were scored by four readers for new bone formation (NBF; such as syndesmophytes and ankylosis). NBF was recorded as present vs. absent at the anterior, central, and posterior locations as defined by the Canada Denmark (CANDEN) MRI scoring system for the spine and at the facet joints. Images were anonymized and read blinded to information from other imaging modalities and to clinical information. Readers were trained before the exercise by mutual evaluation of 3 other ldCT and sCT image sets. Sensitivity and specificity of sCT and X-ray were calculated, with ldCT as the gold standard. Inter-reader agreement was assessed using kappa statistics.

Results: 17 patients with axSpA were included (8 women, 9 men; mean age 34.4 ± 9.5 [SD]). The mean overall number of NBF lesions scored was 186 for ldCT, 207 for sCT, and 37 for X-ray. Most findings were located at the anterior vertebral corners with a mean of 143 lesions on ldCT, 142 on sCT, and 35 on X-ray (Table 1). With ldCT as the reference, the overall sensitivity for sCT to detect NBF was 0.58, with a corresponding specificity of 0.97. sCT had the highest sensitivity (0.65) at the

Table 2. Inter-reader agreement (kappa, κ)
(Mean agreement all readers)

	All[1]	Anterior vertebral corners	Central vertebral segment	Posterior vertebral corners	Facet joints
Low-dose CT	0.64	0.68	0.04	0.39	0.50
Synthetic CT	0.39	0.51	0.08	0.13	0.24
X-ray	0.55	0.57	0	0.11	0

[1] Anterior: Anterior vertebral corners, Central: Central vertebral corners, Posterior: posterior vertebral corners, Facet joints

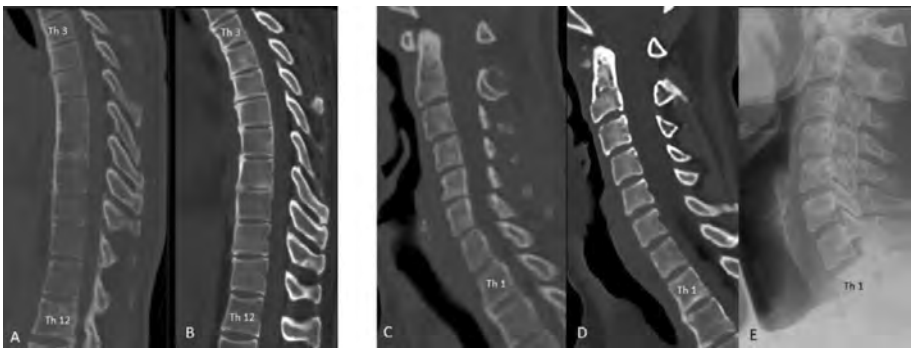

Figure 1: A-B: Low-dose CT (A) and MRI-based synthetic CT (sCT, B) of the thoracic spine. Ankylosis is seen anteriorly at several upper thoracic vertebral levels, with both modalities. C-E: Low-dose CT (C), sCT (D), and X-ray (E) of the cervical spine. Anterior ankylosis is seen at the Th1/Th2 level, both on low-dose CT and sCT, while this level is not visualized adequately by X-ray. Note: Low-dose CT versus sCT slice positioning (A-D) differ slightly at some levels. All images are from the same axSpA patient.

anterior corners (specificity 0.94). For levels that were assessable on X-ray (C2-Th1 and Th12-S1), the sensitivity was 0.47 for sCT and 0.16 for X-ray, with similar high specificities (>0.90) for both methods.

The mean inter-reader agreement for all locations was 0.64 for ldCT, 0.39 for sCT, and 0.55 for X-ray, and best for the anterior corners (Table 2).

Conclusion: MRI-based synthetic CT showed very high specificity and a sensitivity much higher than X-ray, despite limited reader training. With more training, calibration, and optimization of the scoring procedure, sCT could become highly valuable in axSpA clinical trials.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound (US) allows for visualization of many features of knee osteoarthritis (KOA) including osteophytes, meniscal extrusion, synovitis, and articular cartilage damage. Additionally, US is more sensitive than radiography and less expensive than MRI. The current analysis aimed to determine the association of features of KOA on US with patient reported symptoms and quality of life.

Methods: The Johnston County Health Study (JoCoHS) is an actively enrolling population-based study in Johnston County, North Carolina built on the infrastructure of the longstanding Johnston County Osteoarthritis Project, but with a focus on younger individuals (35-70) and a range of chronic health conditions. All JoCoHS participants provide demographic information, symptomatic and functional assessments (Knee Injury and Osteoarthritis Outcome Score (KOOS)), and imaging (knee US and multiple joint radiographs). Posteroanterior semi-flexed radiographs are read for Kellgren Lawrence Grade (KLG) by an expert musculoskeletal radiologist (JBR). Standardized knee US images are obtained by a trained sonographer (SSG). Each participant's set of images is read by 2 randomly selected expert readers (CJB, MJK, JL, JS) with disagreements adjudicated by a 3rd independent reader. For this preliminary analysis, we took the first US read for each participant (complete

Table 1. Descriptive statistics on person-level characteristics of JoCoHS sample

Knee Injury & Osteoarthritis Outcome Score (KOOS) thinking about your worst knee (N=552)	*n* or mean	*% or ±SD*

SD=standard deviation; IQR=interquartile range

reads are not yet available). The worst US feature score was defined at the person-level and negative binomial models of KOOS outcomes were used to produce adjusted odds ratios and 95% confidence intervals.

Results: The first 552 individuals (33% men, 23% Black, 9% Hispanic, mean age 55 [range 35-70] years, mean BMI 33.1 kg/m^2, 52% with less than a college degree, 33% with previous knee injury) enrolled in the JoCoHS with complete data (1083 knees with at least one US read) were included in this preliminary analysis. About one-third of the knees (330/1083) had radiographic KOA (KLG ≥ 2), while nearly half reported at least some pain, aching, or stiffness. The frequency (n, %) of each of the US features is shown in **Table 1.**

The symptoms and QOL subscales of KOOS were where participants reported the most impactful effects of KOA. Associations between each US feature with KOOS symptoms and Quality of Life subscales are shown in **Table 2.**

Except for the presence of suprapatellar power Doppler (PD), all evaluated US features were associated with worse KOOS scores. Participants with large or very large osteophytes, particularly in the medial joint, were more likely to report worse symptoms and quality of life scores. Lateral cartilage damage of any severity was associated with increased symptoms. Findings followed a similar pattern for other KOOS scales and when adjusted for KLG, although statistical significance was attenuated.

Table 2. Adjusted associations for US features for separate, KOOS outcome models, N=552, K=1083

US Knee feature main effect	KOOS symptoms subscale	KOOS QOL subscale
	IDR (95% CI)	IDR (95% CI)
GS effusion/synovitis (vs no joint capsular distension (JCD))		
1: JCD parallel to bone	1.28 (0.98, 1.67)	1.06 (0.77, 1.47)
2: JCD horizontal	**1.50 (1.12, 2.00)**	1.37 (0.96, 1.96)
3: convex or bulging JCD	1.28 (0.81, 2.03)	1.24 (0.71, 2.16)
GS synovitis (vs no synovitis)		
1: minimal recess distention by abnormal internal anechoic material	1.26 (0.97, 1.65)	1.05 (0.76, 1.46)
2: moderate distention as above, with flat/concave superficial limit	**1.50 (1.12, 2.00)**	1.36 (0.96, 1.94)
3: severe distention as above, with bulging superficial limit	1.24 (0.77, 1.97)	1.23 (0.70, 2.17)
GS effusion	**1.45 (1.18, 1.80)**	**1.38 (1.07, 1.79)**
Suprapatellar PD (vs no intra-articular signal)		
1: trace to 10% of intra-articular area with color signal	0.94 (0.74, 1.19)	0.86 (0.64, 1.15)
2-3: >10% of the intra-articular area filled with color signal	0.89 (0.54, 1.47)	0.92 (0.50, 1.71)
Osteophytes, medial (vs none)		
1: small but distinct	1.16 (0.90, 1.50)	1.14 (0.83, 1.56)
2: larger	**2.02 (1.46, 2.80)**	**1.77 (1.19, 2.63)**
3: very large	**2.11 (1.40, 3.18)**	**2.00 (1.20, 3.33)**
Osteophytes, lateral (vs none)		
1: small but distinct	1.08 (0.84, 1.41)	1.10 (0.79, 1.52)
2: larger	**1.90 (1.41, 2.58)**	**1.72 (1.18, 2.51)**
3: very large	**2.32 (1.38, 3.89)**	1.79 (0.95, 3.41)
Meniscal extrusion, medial	1.23 (0.95, 1.59)	1.07 (0.78, 1.47)
Meniscal extrusion, lateral	1.14 (0.90, 1.45)	1.09 (0.81, 1.45)
Cartilage damage, medial (vs normal cartilage)		
1: minimal thinning	1.03 (0.73, 1.47)	1.10 (0.72, 1.68)
2: mild/local thinning	1.27 (0.88, 1.84)	1.24 (0.79, 1.94)
3: complete loss of cartilage	1.26 (0.79, 2.01)	1.28 (0.72, 2.25)
Cartilage damage, lateral (vs normal cartilage)		
1: minimal thinning	**1.35 (1.01, 1.81)**	1.39 (0.98, 1.99)
2: mild/local thinning	**1.48 (1.06, 2.07)**	**1.50 (1.00, 2.24)**
3: complete loss of cartilage	**1.89 (1.22, 2.94)**	**1.72 (1.00, 2.94)**
Popliteal cyst (vs absent)		
1: small/possible	1.16 (0.92, 1.45)	1.09 (0.82, 1.44)
2: definite	**1.84 (1.21, 2.79)**	1.55 (0.93, 2.60)
Calcium crystal deposition, suprapatellar transverse	1.13 (0.72, 1.77)	1.15 (0.66, 2.00)
Calcium crystal deposition, medial	1.24 (0.82, 1.90)	1.02 (0.61, 1.71)
Calcium crystal deposition, lateral	1.00 (0.73, 1.37)	1.00 (0.69, 1.47)
Calcium crystal deposition, posterior transverse	ne	ne
Double contour sign, suprapatellar transverse	1.17 (0.70, 1.96)	0.99 (0.53, 1.87)

IDR =incidence density ratio; CI=confidence interval; ne=not estimable if <5 cells

IDR >1 indicates how many times worse the KOOS subscale outcome is for US group indicated; significant effects at alpha=0.05 shown in **BOLD**; Person-level, negative binomial models modeling KOOS outcome to produce adjusted odds ratios and 95% confidence intervals, OR (95% CI); All models include covariables for: sex, race/ethnicity, age, BMI, <College degree education, and knee injury.

Conclusion: US features of KOA, except for suprapatellar PD, are associated with worse KOOS scores. Large and very large osteophytes and lateral cartilage thinning are significantly associated with worse patient reported symptoms and decreased quality of life. Future work will provide more accurate population-based estimates for the presence of these features and their effects on patient reported outcomes.

Impact of Ultrasound Limitation to Assess Aortitis in Patients with Giant Cell Arteritis: Comparative Study with FDG-PET/CT

Juan Molina-Collada[1], Isabel Castrejon[2], Irene Monjo[3], Elisa Fernandez-Fernandez[4], Gabriela Torres[5], JULIA MARTINEZ BARRIO[6], Jose María Alvaro-Gracias[7] and Eugenio De Miguel[5], [1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Hospital Universitario Gregorio Marañón, Madrid, Spain, [3]University Hospital La Paz, Madrid, Spain, [4]La Paz University Hospital, Madrid, Spain, [5]Hospital Universitario La Paz, Madrid, Spain, [6]Rheumatology, Gregorio Marañon University Hospital, Madrid, Spain, [7]Hospital General Universitario Gregorio Marañon, Madrid, Spain

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Aortitis is a serious potential complication of patients with giant cell arteritis (GCA) and may lead to dilation, aneurysms or dissection. Since ultrasound (US) has limited access to detect aortitis, comparative studies with other imaging modalities to determine the clinical impact of this limitation and the specific situations warranting their use are needed. Our aim was to determine the impact of US intrinsic limitation to assess aortitis vs FDG-PET/CT in patients with US-proven GCA and to identify factors associated with aortic involvement.

Methods: Retrospective observational study of patients referred to US fast-track clinics at two academic centres over a four-year period. Only patients with GCA confirmed by US were included. Temporal (TA) and extracranial arteries US were performed at baseline. FDG-PET/CT was performed according to clinician's criteria. An FDG artery uptake at the aorta higher than liver uptake was considered positive for aortitis.

Table 1. Clinical, laboratory and histology findings of patients with and without aortic involvement.

	Total n=72	Patients with aortic involvement in FDG-PET/CT n=24 (33.3%)	Patients without aortic involvement in FDG-PET/CT n=48 (66.7%)	p

Table 2. US patterns of vascular involvement in patients with or without aortitis in FDG-PET/CT.

	Total n=72	Patients with aortic involvement in FDG-PET/CT n=24 (33.3%)	Patients without aortic involvement in FDG-PET/CT n=48 (66.7%)	p
Positive cranial GCA US, n (%)	50 (69.4%)	10 (41.7%)	40 (83.3%)	**<0.001**
Positive LV-GCA US, n (%)	42 (58.3%)	22 (91.7%)	20 (41.7%)	**<0.001**
Negative LV-GCA US, n (%)	30 (41.7%)	2 (8.3%)	28 (58.3%)	**<0.001**
Isolated positive LV-GCA US, n (%)	22 (30.6%)	14 (58.3%)	8 (16.7%)	**<0.001**
Positive cranial + LV-GCA US, n (%)	20 (27.8%)	8 (33.3%)	12 (25%)	0.457

GCA: giant cell arteritis; US: ultrasound; LV: large-vessel.

Results: Seventy-two of 186 patients with US-proven GCA underwent an FDG-PET/CT; 29 (40.3%) had a positive FDG-PET/CT and 24 (33.3%) presented aortitis. Only 6 (20.7%) patients with positive FDG-PET/CT had negative US findings of large vessel (LV)-GCA. Among patients with aortitis in FDG-PET/CT, only 2 (8.3%) had negative US findings of LV-GCA. Patients with aortitis were younger (68.9 *vs* 81;p< 0.001), more frequently females (79.2% *vs* 39.6%;p=0.002) and had higher platelets count (413.4 *vs* 311.1;p=0014) (Table 1). Patients with aortitis presented positive TA US less frequently (41.7% *vs* 83.3%;p< 0.001), but more LV US involvement (91.7% *vs* 41.7%; p< 0.001) versus patients without aortitis (Table 2). None of the patients with aortitis exhibited visual symptoms (0% *vs*31.2%;p=0.001).

Conclusion: FDG-PET/CT can detect aortitis in 1 out of every 3 patients with US-proven GCA. However, a negative US examination for LV-GCA suggests a low risk of aortitis. Younger and female GCA patients with thrombocytosis, absence of visual manifestations and LV-GCA on US may more frequently present aortitis by FDG-PET/CT.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Apremilast is an oral phosphodiesterase 4 inhibitor with a unique immunomodulatory mechanism of action and is approved for the treatment of psoriatic arthritis (PsA). Whole-body magnetic resonance imaging (WB-MRI) is a promising tool for inflammatory arthritis management and may provide a more thorough picture of total inflammatory burden than standard MRI or clinical assessment. Here, we evaluate the efficacy of apremilast 30 mg BID (APR) on peripheral and axial inflammation in patients with PsA.

Methods: The MOSAIC study was a phase 4, multicenter, single-arm, open-label trial that evaluated up to 48 weeks of APR treatment (monotherapy or with stable methotrexate) on MRI outcomes in patients with active PsA (≥3 months but ≤5 years since diagnosis, meeting the CASPAR criteria for PsA). Contrast-enhanced WB-MRI was performed at baseline, Week 24, and Week 48, and images were read and adjudicated by two blinded, experienced readers. Using the OMERACT MRI whole-body scoring system for inflammation in peripheral joints and entheses (MRI-WIPE), WB-MRI results were used to calculate the change from baseline in the peripheral enthesitis inflammation index (33 entheses), peripheral joint inflammation index (83 joints), and total peripheral inflammation index (enthesitis + joint inflammation). In patients deemed to have PsA spondylitis by the investigator and a baseline BASDAI Item 2 (pain) ≥4), MRI axial inflammation was assessed by calculating

Table 1. Demographics and Baseline Characteristics

Parameter	APR N=122
Age, mean (SD), y	46.6 (12.9)
Female, n (%)	67 (54.9)
Weight, mean (SD), kg	84.9 (21.2)
Duration of PsA, mean (SD), y	1.9 (1.7)
BASDAI score[a], mean (SD)	6.4 (1.5)
WB-MRI measures	—
Total peripheral inflammation index[b], mean (SD)	28.8 (22.5)
Peripheral enthesitis inflammation index[c], mean (SD)	4.7 (3.7)
Peripheral joints inflammation index[d], mean (SD)	24.1 (20.3)
CANDEN spine inflammation score[e,f], mean (SD)	5.8 (11.6)
SPARCC sacroiliac joint inflammation score[e,g], mean (SD)	2.7 (5.0)
SPARCC spine score[e,h], mean (SD)	5.4 (10.9)

APR, apremilast 30 mg BID; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BME, bone marrow edema; CANDEN, Canada-Denmark scoring system; PsA, psoriatic arthritis; SD, standard deviation; SPARCC, Spondyloarthritis Research Consortium of Canada scoring system; WB-MRI, whole-body magnetic resonance imaging.
[a]BASDAI score calculated for patients deemed to have PsA spondylitis by the investigator and a BASDAI item 2 ≥4 at baseline, n=40.
[b]Sum of the peripheral joint inflammation index (BME + synovitis in 83 joints) and peripheral enthesitis inflammation index (BME and soft tissue inflammation at 33 entheses). Score ranges from 0 to 738.
[c]Includes BME and soft tissue inflammation at 33 entheses. Score ranges from 0 to 201.
[d]Includes BME and synovitis in 83 joints. Score ranges from 0 to 537.
[e]Based on patients deemed to have PsA spondylitis by the investigator and a BASDAI item 2 ≥4 at baseline.
[f]Score ranges from 0 to 614, with higher scores reflecting greater disease activity.
[g]Score ranges from 0 to 72, with higher scores reflecting greater disease activity.
[h]Score ranges from 0 to 414, with higher scores reflecting greater disease activity.

Figure 1. Peripheral and Axial Inflammation Indices as Assessed by WB-MRI (FAS)[a]

	Peripheral joint inflammation index[a]		Peripheral enthesitis inflammation index[b]		Total peripheral inflammation index[c]		Inflammatory lesions of the spine (CANDEN)[d,e]		Inflammatory lesions of the sacroiliac joint (SPARCC)[d,f]		Inflammatory lesions of the spine (SPARCC)[d,g]	
Baseline Mean (SD)	n=117	24.1 (20.3)	n=117	4.7 (3.7)	n=117	28.8 (22.5)	n=39	5.8 (11.6)	n=39	2.7 (5.0)	n=39	5.4 (10.9)
Week 24 LS Mean Change (95% CI)	n=100	-3.4 (-5.1, -1.7)	n=100	-0.2 (-0.7, 0.3)	n=100	-3.5 (-5.5, -1.5)	n=32	-2.6 (-3.6, -1.5)	n=32	0.1 (-0.9, 1.2)	n=32	-0.5 (-1.4, 0.4)

Full analysis set, defined as all patients who received at least one dose of study medication. Based on mixed-effect model for repeated measures with change from baseline as the response variable and including scanner type, time as fixed effects, baseline composite score as a covariate.
BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BME, bone marrow edema; CANDEN, Canada-Denmark scoring system; LS, least-squares; PsA, psoriatic arthritis; SD, standard deviation; SPARCC, Spondyloarthritis Research Consortium of Canada scoring system; WB-MRI, whole-body magnetic resonance imaging.
[a]Includes BME and synovitis in 63 joints. Score ranges from 0 to 537.
[b]Includes BME and soft tissue inflammation at 33 entheses. Score ranges from 0 to 201.
[c]Sum of the peripheral joint inflammation index (BME + synovitis in 63 joints) and peripheral enthesitis inflammation index (BME and soft tissue inflammation at 33 entheses). Score ranges from 0 to 738.
[d]Based on patients deemed to have PsA spondylitis by the investigator and a BASDAI item 2 ≥4 at baseline.
[e]Score ranges from 0 to 614, with higher scores reflecting greater disease severity.
[f]Score ranges from 0 to 72, with higher scores reflecting greater disease severity.
[g]Score ranges from 0 to 414, with higher scores reflecting greater disease activity.

the change from baseline in the Canada-Denmark (CANDEN) spine score, the Spondyloarthritis Research Consortium of Canada (SPARCC) spine score, and the SPARCC sacroiliac joint (SIJ) inflammation score.

Results: A total of 122 patients were enrolled and treated with APR. Demographics and baseline disease characteristics are shown in **Table 1**. WB-MRI results showed significant reductions in peripheral joint inflammation at 24 and 48 weeks, and a significant reduction in peripheral enthesitis at 48 weeks (**Figure 1**). Taken together, a significant reduction in the total peripheral inflammation index was observed at both 24 and 48 weeks (**Figure 1**). At baseline, 40 patients were deemed by the investigator to have PsA spondylitis and a BASDAI Item 2 ≥4; 39 patients were analyzed for axial inflammation. WB-MRI using the CANDEN scoring system showed a reduction in axial inflammation at 24 and 48 weeks (**Figure 1**). There was no significant change in either SPARCC spine or SPARCC SIJ scores (**Figure 1**).

Conclusion: This is the first PsA study applying WB-MRI of both peripheral and axial joints and entheses. Patients treated with APR experienced significant improvement from baseline in peripheral joint and entheseal inflammation. These outcomes demonstrate the efficacy of APR on inflammatory manifestations of PsA and the value of using WB-MRI as an objective measure in PsA management.

B-line of Lung Ultrasound Reflects Different Morphological Features on Chest HRCT Between Interstitial Lung Disease Associated with Systemic Sclerosis and Myositis

Shinji Watanabe[1], Keina Yomono[2], Shintaro Yamamoto[1], Mikito Suzuki[3], Takahisa Gono[4] and Masataka Kuwana[4], [1]Nippon Medical School, Tokyo, Japan, [2]Nippon Medical School University, Tokyo, Japan, [3]Nippon Medical School Hospital, Tokyo, Japan, [4]Nippon Medical School Graduate School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lung ultrasound (LUS) is a non-invasive imaging tool to evaluate distribution and severity of interstitial lung disease (ILD). Utility of LUS has been examined mainly in patients with systemic sclerosis (SSc), and B-line scores assessed by LUS were shown to correlate with semiquantitative scores of chest high-resolution computed tomography (HRCT). However, little is known about performance of LUS in ILD associated with idiopathic inflammatory myopathy (IIM) or anti-synthetase syndrome (ASS). The aim of this study was to investigate utility of LUS in patients with IIM/ASS, by focusing on correlations of B-line score with morphological features on HRCT.

Methods: A total of 64 patients, including 30 with SSc-ILD and 34 with IIM/ASS-ILD were selected from a prospective LUS registry of Nippon Medical School Hospital based on fulfillment of one of classification criteria for SSc, IIM, or ASS and availability of chest HRCT and LUS images performed simultaneously. The degree of B-line was semiquantitatively scored using a 4-8 MHz microconvex transducer, and a sum of the B-line at 14 scan sites was used as a total B-line score. ILD images on HRCT were scored according to the method proposed by the Scleroderma Lung Study (SLS) by two investigators in a

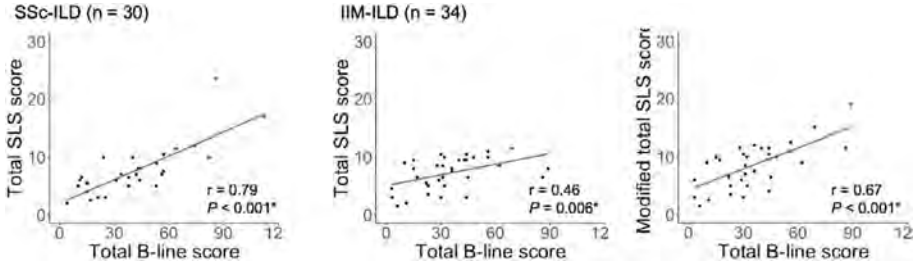

Figure 1. Single regression analysis to evaluate correlation between total B-line score and HRCT semiquantitative score. LUS: lung ultrasound; HRCT: high-resolution computed tomography; SSc systemic sclerosis; IIM: idiopathic inflammatory myopathy; ASS: anti-synthetase syndrome; ILD: interstitial lung disease; SLS: Scleroderma Lung Study. *P < 0.05

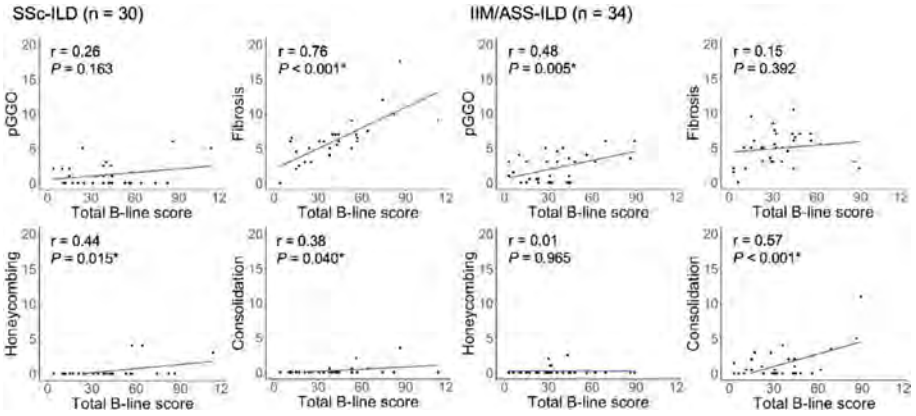

Figure 2. Single regression analysis to evaluate correlation between total B-line score and SLS scores of individual morphologies by underlying disease. SSc: systemic sclerosis; IIM: idiopathic inflammatory myopathy; ASS: anti-synthetase syndrome; ILD: interstitial lung disease; pGGO: pure ground-glass opacity; LUS: lung ultrasound; SLS: Scleroderma Lung Study. * P < 0.05

blinded fashion. The scores assessed included pure ground-glass opacity (pGGO), fibrosis, honeycombing, and consolidation, and the sum of pGGO, fibrosis, and honeycombing scores was regarded as total SLS score. In some analyses, the original SLS score was modified to include the consolidation score. Single regression analysis was used to evaluate correlations of total B-lines with SLS scores of individual morphologies and the total score. Multiple regression analysis was carried out to identify independent morphological features of HRCT contributing to total B-lines.

Results: Total B-line score correlated with total SLS score in patients with SSc-ILD (r = 0.79, P < 0.001), but the correlation was much weaker in patients with IIM/ASS-ILD (r = 0.46, P = 0.006) (Figure 1). When correlations of total B-line score with individual morphological patterns on HRCT were examined, total B-line score was significantly correlated with fibrosis (r = 0.76, P < 0.001) and weekly with honeycombing (r = 0.44, P = 0.015) and consolidation (r = 0.38, P = 0.040) in patients with SSc-ILD. On the other hand, in patients with IIM/ASS-ILD, total B-line score was correlated with pGGO (r = 0.48, P = 0.005) and consolidation (r = 0.57, P < 0.001) (Figure 2). Multiple regression analysis revealed contribution of different morphological patterns on HRCT to total B-line score: fibrosis (β = 0.743, P < 0.001) and honeycombing (β = 0.326, P = 0.007) in SSc-ILD, while consolidation (β = 0.497, P = 0.006) and fibrosis (β = 0.320, P = 0.040) in IIM/ASS-ILD. Finally, inclusion of the consolidation score in the original total SLS score resulted in improvement of correlation with total B-line score in patients with IIM/ASS-ILD (r = 0.67, P < 0.001) (Figure 1).

Conclusion: B-lines detected by LUS reflect different HRCT morphological features in patients with SSc and IIM/ASS. This difference should be considered upon interpreting total B-lines upon evaluation of ILD in clinical practice.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Almost all patients with SLE experience joint problems and arthritis, 12% suffer permanent joint damage. The wide variability in SLE arthritis and the limitations of existing assessment tools make it difficult to identify musculoskeletal involvement in clinical care and clinical trials. Identifying lupus arthritis based on physical exam remains challenging. Clinicians need a robust, easy-to-use imaging technique to diagnose and monitor arthritis in SLE. Ultrasound (US) and magnetic resonance (MRI) allow for more objective assessments but are plagued by operator dependence and high cost. With the support of a DoD award, we are developing a prototype imaging system that uses lasers and light detectors to evaluate finger joints in SLE. Here we describe preliminary data on comparisons between optical imaging and US evaluations of affected and unaffected proximal interphalangeal (PIP) joints.

Methods: Fifteen SLE patients were evaluated, 8 PIP joints (bilateral PIP 2-5)/patient were imaged, with a total of 120 images. A systematic multiplanar grey-scale (GS) and power doppler (PD) examination of PIP joints was performed using the Outcome Measures in Rheumatology (OMERACT) consensus definitions for joint pathologies, and a combined PDGS score was calculated. Immediately after the US, joints were examined using optical imaging. The instrumentation uses a 670nm, 8mW laser with a 1 mm diameter beam modulated at 300 MHz as light source. The laser beam is focused on the dorsal surface of each finger and scans across the PIP joints (as shown in Figure 1, left). The transmitted light is collected by an intensified charge-coupled device camera and the absorption and scattering distributions inside the finger are reconstructed (Fig.1 shows absorption) using a radiative transfer equation model.

Results: The PDGS scored 34 joints 0, 44 – 1, 20 – 2 and 22 – 3. The absorption and scattering data were obtained from the reconstructed images. Figure 2 shows a cross section through an unaffected joint (PDGS=0) on the left and an affected joint (PDGS=3) on the right. The average absorption coefficient of joints with PDGS = 0 or 1 was 0.52±0.19 cm^{-1}, while joints with

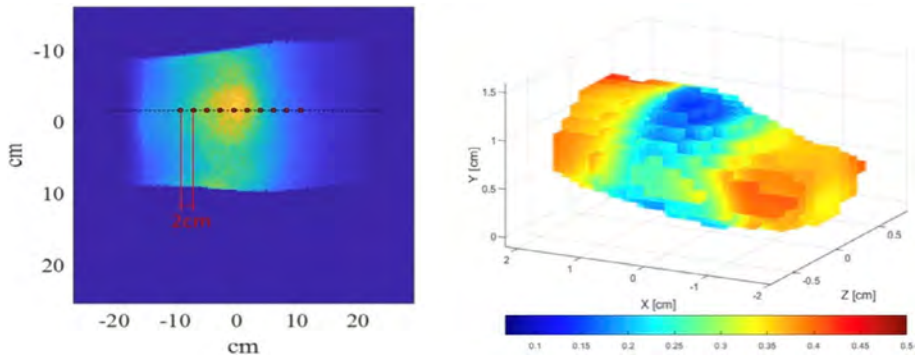

Figure 1. Left, example of the collected raw signal from the system, with the red dots indicating the different positions of the laser during the acquisition protocol. Right, example of a three-dimensional reconstruction of a joint's absorption properties.

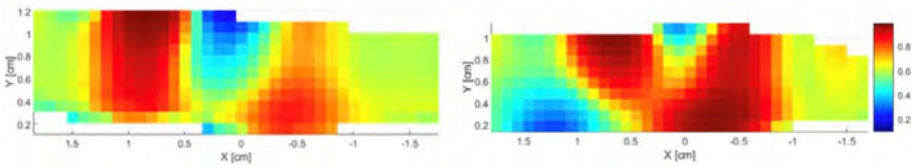

Figure 2. Representative cross-sectional images of "unaffected" (PDGS=0, left) and "affected" (PDGS=3, right) PIP joints absorption properties.

PDGS = 2 or 3 the absorption was 0.60±0.19 cm^{-1}, $p < 0.05$. Similarly, we found that the difference in the scattering coefficients between the two groups was also statistically significant (10.8±1.9 cm^{-1} versus 11.8±2.1 cm^{-1}, $p< 0.01$).

Conclusion: Optical imaging correlated with PDGS findings in 120 evaluated lupus arthritis PIP joints. Further examination of SLE arthritis using the new US OMERACT criteria that includes a tenosynovitis score and MRI will allow for better definitions of PIP arthritis and improve the correlations with optical imaging. The system, which could take the form of an ergonomic glove, will allow the investigators to image lupus arthritis, both in the office and at home, to diagnose and monitor arthritis progress. The goal is to create a portable, wearable, imaging device that permits real-time monitoring of SLE arthritis to improve patient care and outcomes.

Prevalence and Distribution of Sonographic Elementary Lesions in PsA – Results of 2 Cohorts

Ari Polachek[1], Victoria Furer[2], Sydney Thib[3], Liran Mendel[2], Ori Elkayam[2] and Lihi Eder[4], [1]Sourasky Medical Center, Tel Aviv, Israel, [2]Tel Aviv Medical Center, Tel Aviv, Israel, [3]Women's College Research Institute, Toronto, ON, Canada, [4]Women's College Research Institute, Division of Rheumatology, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) can manifest with different musculoskeletal (MSK) features. Ultrasound (US) optimizes the assessment of the different MSK features in PsA. However, there is no consensus on which MSK sonographic lesions and what locations should be evaluated by US. The group for research and assessment of psoriasis and psoriatic arthritis (GRAPPA) have set a goal of defining the most prevalent locations for the various US lesions in order to reduce the number of scanned sites.

The aim of the study was to describe the prevalence and distribution of key sonographic MSK lesions in patients with PsA.

Methods: This study analyzed data from two prospectively recruited PsA cohorts. Cohort 1 included 101 patients with active PsA (DAPSA >14) and cohort 2 included 94 patients with active PsA prior to initiation of therapy. All underwent a comprehensive US assessment, including both gray scale (GS) and power Doppler (PD) of 50 joints, 40 tendons and

14 entheses. The following sonographic lesions were assessed by two sonographers blinded to clinical data: I. Inflammatory lesions - synovitis, tenosynovitis, peritenonitis and enthesitis and II. Structural lesions – periarticular erosions and bone proliferations. Presence or Absence of these lesions was determined based on previously suggested definitions by OMERACT (when available) or other publication and their prevalence by joint/tendon site was reported.

Results: In cohort 1, mean ± SD age was 52.7 ± 13 and 55.7% were females. In cohort 2, mean ± SD age was 47.5 ± 13.2 and 48.8% were females (Table 1). The most prevalent locations of the inflammatory lesions in both cohorts were (figure 1): Synovitis (small joints) – MCP2 (cohort 1: 13.5%, cohort 2: 27%), MCP 3 (cohort 1: 11%, cohort 2: 26%), IP1 (cohort 1: 5%, cohort 2: 24.5%) PIP 3 (cohort 1:3%, cohort 2: 16%), MTP 1 (cohort 1: 35.5%, cohort 2: 35%), MTP2 (cohort 1: 24%, cohort 2: 30%), MTP3 (cohort 1: 18.5%, cohort 2: 22%); Synovitis (medium-large joints) – wrist (cohort 1: 31.5%, cohort 2: 29%)

Table 1: Baseline and clinical characteristics

	Cohort 1 (n=101)	Cohort 2 (n=94)
Age, years, mean (± SD)	52.7 (13)	47.5 (13.2)
Sex (%)	55.7	48.8
PsA duration, years, mean (± SD)	12 (12)	3.8 (17)
Tender joint count, mean (± SD)	12 (10)	7 (5)
Swollen joint count, mean (± SD)	2 (3)	5 (3)
Enthesitis (SPARCC), mean (± SD)	3.8 (4)	2 (2)
CRP mg/dl	1 (2)	0.9 (1)

Session Title: Imaging of Rheumatic Diseases Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: In recent years, the concept of D2T RA (difficult-to-treat rheumatoid arthritis) has become widespread, and D2T RA patients are defined as a state in which activity cannot be controlled even with the use of various molecular-targeted drugs. In this study, we investigated the ultrasound synovial findings in D2T RA patients. However, ultrasound findings in D2T RA patients are unknown. In this study, we investigated the ultrasound findings of D2T RA patients.

Methods: A total of 750 RA patients who underwent ultrasound examination from January 2017 to August 2020 were continuously included. Ultrasound examination was performed at the of bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and

PDUS	11.0±13.0	6.4±7.7	0.034

ulnar) and first to fifth metatarsophalangeal (MTP) joints. Both grayscale (GS) and power Doppler (PD) findings were scored to grade 0-3 by a semi-quantitative method, and the sum of GS was defined as the GSUS score and the sum of PD as the PDUS score. Of all 750 RA patients, 517 RA patients (68.9%) who treated bDMARDs/JAKi were included and devided in D2T RA patients and non-D2T RA patients. The patients' characteristics, GSUS and PDUS score were compared between D2T RA patients and non-D2T RA patients.

Results: There were 40 D2T RA patients and 477 non-D2T RA patients. Mean age was 61.2 vs. 65.0 years (p=0.133), mean disease duration of RA was 17.6 vs. 14.9 years (p=0.199), CDAI was 12.6 vs. 9.8 (0.166), and CRP level was 0.79 vs. 0.28 mg/dL (p=0.233), MMP-3 level was 295.6 vs 10.8ng/mL (p=0.057), respectively. In the D2T RA group, concomitant use ratio of MTX was low (50.0 vs 70.9 %, p=0.011), but there was no difference in the average dose of MTX (8.9 vs 9.2 mg/w, p=0.581). The concomitant use ratio of glucocorticoid (32.5 vs 12.6 %, p=0.002) and the average dose of glucocorticoid (7.7 vs 3.1 mg/d, p=0.003) were higher in D2T RA group. Regarding ultrasound findings, GSUS score (16.2 vs 9.5, p=0.011) and PDUS score (11.0 vs 6.4, p=0.034) were significantly higher in the D2T RA group.

Conclusion: The definition of D2T RA is resistant to multiple mode of bDMARDs/JAKi. Although, disease activity and inflammatory markers tended to be worse in the D2T RA group, there was no statistically significant difference in this study. However, ultrasound findings were significantly worse in D2T RA. Suppression of synovitis might be important to prevent D2T RA.

Abstract Number: 1046

The Level of RF or Anti-CCP Antibody Affect Ultrasound Synovial Findings in Patients with Rheumatoid Arthritis?

Tadashi Okano[1], Kenji Mamoto[1], Yutaro Yamada[1], Shohei Anno[2], Yuka Domae[1], Shingo Washida[1], Asami Yagami[1], Yuko Yoshida[1], Tatsuya Koike[3] and Hiroaki Nakamura[1], [1]Osaka Metropolitan University, Osaka, Japan, [2]Yodogawa Christian Hospital, Osaka, Japan, [3]Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Shirahama, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Positive for auto-antibodies such as rheumatoid factor (RF) and anti-citrullinated peptide antibodies (CCP) or having high autoantibody titers is associated with the progression of joint destruction in patients with rheumatoid arthritis (RA) (van Steenbergen HW, et al. Ann Rheum Dis. 2015;74:e3. and Hecht C, et al. Ann Rheum Dis. 2015;74:2151-6.). Therefore, we evaluated the relationship between RF or CCP levels and ultrasound synovial findings.

Methods: A total of 750 RA patients who underwent ultrasound examination from January 2017 to August 2020 were continuously included. Ultrasound examination was performed at the of bilateral first to fifth metacarpophalangeal (MCP) joints, first interphalangeal (IP) and second to fifth proximal interphalangeal (PIP) joints, wrist joints (three part of radial, medial and ulnar) and first to fifth metatarsophalangeal (MTP) joints. Both grayscale (GS) and power Doppler (PD) findings were scored to grade 0-3 by a semi-quantitative method, and the sum of GS was defined as the GS score and the sum of PD as the PD

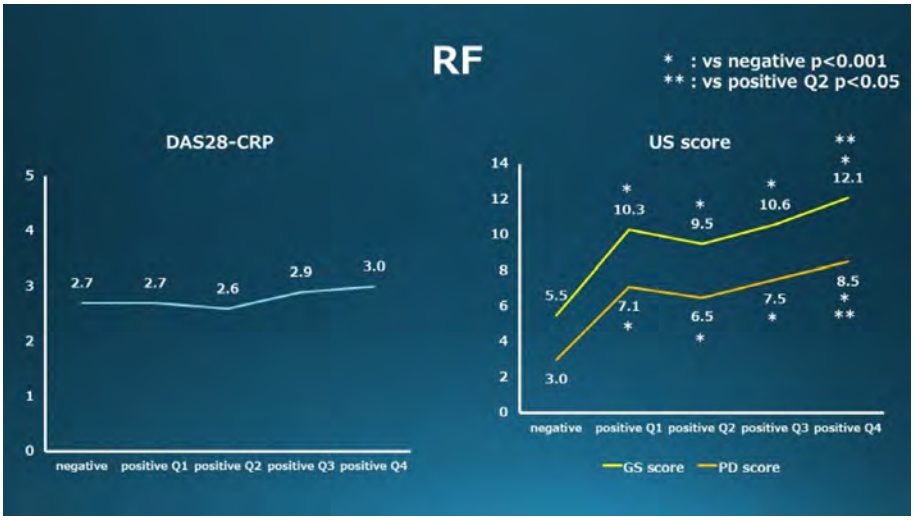

Figure 1. The relattionship between RF titer and disease activity or ultrasound findings.

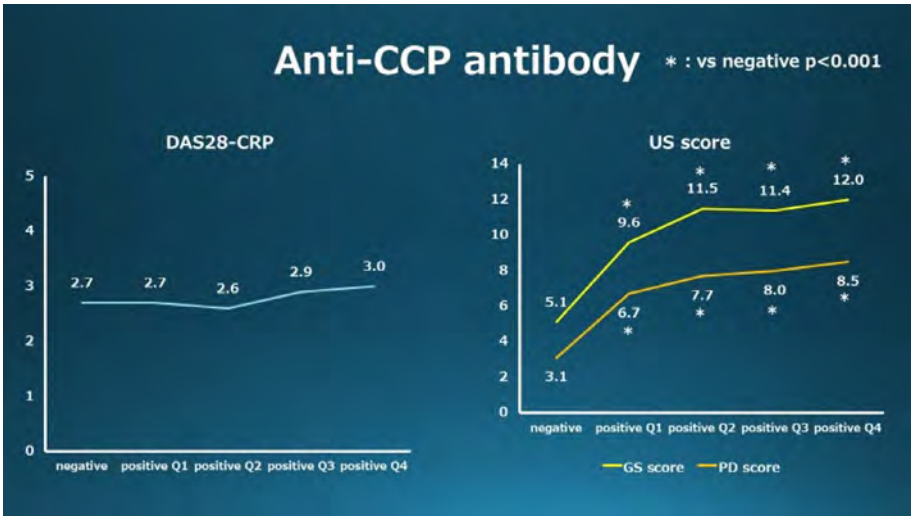

Figure 1. The relattionship between anti-CCP antibody titer and disease activity or ultrasound findings.

score. Patients were classified into a negative group and a positive group according to RF and CCP titers, and the positive group was further classified into quartiles (Q1-Q4) according to those levels, and disease activity and ultrasound synovial findings were compared.

Results: There were 655 cases in the RF positive group and 565 cases in the CCP positive group. RF positive group were divided into quartiles such as Q1: 15 < RF ≤ 72, Q2: 72 < RF ≤ 158, Q3: 72 < RF ≤ 379, Q4: 379 < RF ≤ 8160, and CCP positive group were divided into quartiles such as Q1: 4.5 ≤ CCP ≤ 36.0, Q2: 36.0 < CCP ≤ 95.6, Q3: 95.6 < CCP ≤ 308.0, Q4: 308.0 < CCP. There was no difference in disease duration or disease activity both in the RF and CCP positive group and the negative group, but the ultrasound synovitis scores were significantly worse in both GS and PD score in the positive groups. Among the RF and CCP positive groups, the ultrasound synovitis score tended to be high in the high RF and CCP group, and the highest in the Q4 group.

Conclusion: We evaluated the relationship between RF or CCP levels and ultrasound synovitis. Ultrasound synovial findings were significantly worse in positive group than negative group on both RF and CCP, regardless of disease activity. Moreover, high titer of RF or CCP levels tended to be higher ultrasound synovitis. Patients with high titer of RF or CCP levels should be considered to treat more earlier and intensively.

Infrared Thermography Imaging Discriminates Between Inflamed and Non-inflamed Joints

Maria I. (\"Maio\") Danila[1], **Giovanna Rosas**[2], Fenglong Xie[2], Jeffrey R Curtis[3], Kiara Aaron[2], Stephanie Ford[2] and Laura Hughes[4], [1]University of Alabama at Birmingham (UAB), Birmingham VA Medical Center, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Division of Clinical Immunology and Rheumatology, University of Alabama, Birmingham, AL, [4]University of Alabama at Birmingham; East Alabama Medical Center, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Infrared thermography (IRT) is an emerging technology that has the potential to rapidly assist in identifying joint inflammation in patients with joint symptoms. However, its use in clinical practice is currently limited due to the lack of a true gold standard (e.g., musculoskeletal ultrasound [MSUS]) confirming the presence of joint inflammation. We aimed to determine whether there are differences in IRT measurements between joints categorized as inflamed or not based on Power Doppler (PD) ultrasound imaging.

Methods: We conducted a cross sectional study among patients at a tertiary academic medical center. Eligible patients were age ≥ 18 years, had a rheumatologist-diagnosis of rheumatoid arthritis or a non-inflammatory joint condition (e.g. osteoarthritis) or healthy controls, and had at least one swollen joint in the hands or wrists or feet (RA patients only). IRT images were obtained using a FLIR E75 3400 camera. A manual segmentation approach was employed to place rectangular regions of interests (ROIs) over each of the 32 target joint sites. FLIR software was used to determine IRT temperature (^{0}C) parameters including ROI maximum (max), minimum (min), mean (mean), center (center) and within joint variability (STD). MSUS was obtained at the same visit by a rheumatologist with RhMSUS certification. MSKUS erosions (presence/absence), joint inflammation (PD) and synovial hypertrophy (SHT) was scored using a 0-3 severity scale (none =0, mild =1, moderate=2, and severe =3) for each wrist, metacarpophalangeal (MCP), proximal interphalangeal (PIP) and metatarsophalangeal (MTP) joint. We used mixed effects logistic regression to determine whether IRT parameters were able to discriminate between inflamed (i.e. PD score ≥ 1) and not inflamed joints (PD=0), accounting for clustering of joints within patients and adjusting for demographic factors including age, sex, and race.

Results: A total of 50 patients with RA (n=30), OA (n=10), healthy controls mean (SD) age 54.8 (14.20) years, mostly women (90.0%), 22 (44%) Black participated in the study. A total of 1598 joints were included in the analysis including 103 joints with a PD ≥ 1. A total of 248 joints had erosions. IRT measurements by PD score are presented in the Table. The c-statistic for the area under the receiver operator curve was 0.82 (Figure). After multivariable adjustment, the minimum, maximum and the within-joint variability (STD) of the thermography camera temperature readings were significantly associated with joint

Figure: Receiver Operator Curve comparing thermography with musculoskeletal ultrasound for classifying joint inflammation (PD = 1 or 2)

inflammation compared to the gold standard of PD={1,2} by MSUS. Older age, female sex, and black race also were significantly associated with the outcome.

Conclusion: We found that a commercially-available infrared thermography camera had reasonable accuracy to discriminate between inflamed versus non-inflamed joints among people with RA, OA, and healthy controls. These findings can help inform future use of IRT in clinical practice to discriminate between inflammatory and non-inflammatory joint disease in settings where a rheumatologist physical exam may not be feasible.

The Prediction of Response to Advanced Therapies on a Joint Level in Rheumatoid Arthritis: The Interpretation of Tenderness and Doppler Ultrasound

Seyyid Bilal Acikgoz[1], Ummugulsum Gazel[2], Ricardo Sabido-Sauri[2], Ozun Bayindir Tsechelidis[3], Amin Zahrai[4], Catherine Ivory[4], Elliot Hepworth[2] and sibel aydin[5], [1]University of Ottawa, Rheumatology, Ottawa, ON, Canada, [2]University of Ottawa, Ottawa, ON, Canada, [3]Ottawa University, Ottawa, ON, Canada, [4]The Ottawa Hospital Research Institute, Ottawa, ON, Canada, [5]University of Ottawa - Ottawa, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound (US) has emerged as a sensitive method, especially when compared to clinical examination, for evaluating disease activity in Rheumatoid Arthritis (RA). Several studies have shown discrepancies between the physical examination and US in detecting inflammation. In this study, we aimed to understand a) for joints that are tender at baseline, what is the response rate (same joint being non-tender at follow up), according to the presence of Doppler signal positivity at therapy initiation; b) for joints that are not tender at baseline, what is the risk of flare (being tender) at follow up, according to the presence of Doppler signal positivity at the therapy initiation.

Methods: At the ORCHESTRA (**O**ttawa **R**heumatology **C**ompre**HE**n**S**ive **TR**eatment and **A**ssessment) Clinic RA patients starting a new advanced bDMARD/tsDMARD therapy are assessed using a comprehensive screening process which includes a protocoled US scan. Patients are evaluated in the same clinic three months after new therapy initiation. For this analysis, we included all MCP, PIP and wrist joints of every patient. Analysis was performed on a joint level. Tenderness of the joint as baseline and at follow up were grouped according to having Global OMERACT-EULAR Synovitis Score (GLOESS) grade ^{3} 2 Doppler signals at baseline. Odds ratio (confidence intervals) were calculated a) for joints that were tender at baseline to understand the prediction of response; b) for joints that were not tender at baseline to understand the prediction on flare.

Results: There were 40 RA patients (70% female) included in the analysis, with 878 joints being analyzed. The median (IQR) tender and swollen joint counts were 8(11) and 7.5(5), respectively, with a DAS28 score of 3.76 (1.58). The mean (SD) age was 60.1(15.6), with a median (IQR) disease duration of 14.5 (21.3) years. Twenty-one patients (52.5%) were bionaive at baseline and 7(17.5%), 4(10%) and 8(20%) patients had failed 1, 2 or ^{3}3 biologic therapies, respectively.

TENDER at baseline	MCP, PIP and wrists		
	Good response		
	No (still tender at follow up)	Yes (not tender at follow up)	Response rate %
Baseline No Doppler	49	122	71
Doppler (+)	26	22	46

Table 1: Response rates in tender joints at baseline, according the initial Doppler positivity

Not TENDER at baseline	MCP, PIP and wrists		
	Follow up		
	Still no pain	New onset pain	Risk of flare %
Baseline No Doppler	492	59	10.1
Doppler (+)	82	26	24.1

Table 2: Flare rates in non-tender joints at baseline, according the initial Doppler positivity

219/878 joints were tender at baseline, 48 (21.9%) of whom had Doppler signals. Among the Doppler positives, the response rate was 46%. The response rate of the joints with no Doppler signals at baseline was 71%, meaning they were no longer tender at follow up. The odds of achieving response on a joint level was lower if there were Doppler signals at baseline (OR 0.34 (CI:0.18-0.66)) (table 1).

Among the 659 joints that were not tender at baseline, 108 (16.4%) had Doppler signals. Within these, 24.1% became tender at follow up. Among the 551 patients who were Doppler negative, 10.1% became symptomatic. The odds of flaring on a joint level that was previously non-tender was higher if there were Doppler signals at baseline (OR 2.64 (CI:1.58-4.44)) (table 2).

Conclusion: Our study shows that the Doppler signals at the initiation of an advanced therapy has two important meanings on a joint level: Doppler positive tender joints are more resistant to therapies (then Doppler negatives) and Doppler positive non-tender joints have a higher risk of becoming symptomatic. It is still not clear how the US should be incorporated in the treatment algorithms, but the US information suggest a different patient phenotype.

Enhanced Diagnostic Confidence with High Frequency Temporal Artery Ultrasound in Diagnosis of Cranial Giant Cell Arteritis (GCA)

Jem Ninan[1], Suellen Lyne[1], Julian McNeil[2], Joanna Tieu[3], Vidya Limaye[4], Susanna Proudman[4], Susan Lester[3] and Catherine Hill[3], [1]University of Adelaide, Adelaide, Australia, [2]Modbury Hospital, Modbury, Australia, [3]The Queen Elizabeth Hospital, Woodville, Australia, [4]Royal Adelaide Hospital, Adelaide, Australia

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A previous survey of Australian Rheumatologists indicated low confidence (60% of Australian Rheumatologists) in the use of Temporal artery ultrasound provided by their Radiology services in the diagnosis of giant cell arteritis. There is limited published information on multimodal imaging to enhance diagnostic confidence of GCA. The aim of this study was to determine the utility of standardized high-resolution temporal artery scanning protocols for diagnosis of GCA and the role of multimodal imaging in increasing the confidence of GCA diagnosis.

Methods: Consecutive patients from 2020 to 2022 with suspected GCA based on 3/5 1990 ACR classification criteria were enrolled. Patients underwent ultrasound of bilateral common superficial temporal arteries (**CSTA**) and main branches with a 22MHz linear ultrasound probe to determine the arterial intima-media thickness (**IMT**) at the CSTA and the presence of a non-compressible halo on color Doppler.Bilateral axillary artery (**AA**) IMT was measured in some patients. Additional diagnostic tests included dedicated 3Tesla MRI of scalp arteries time of flight sequence with grading of gadolinium enhancement of temporal artery (TA) wall and temporal artery biopsy (TAB) or 18FDG PET scan. Final diagnosis of GCA was determined at case-note review at 6 months by consultant rheumatologist. At least two diagnostic tests were performed on most patients. GCA diagnostic confidence was enhanced by employing multimodality imaging and biopsy. Optimal IMT cut-off measurements for GCA diagnosis were determined by Receiver Operating Characteristic analysis.

Results: 82 patients were included in the study (mean age 72 years, 66% female). Mean age was higher in the 31 (38%) patients with confirmed GCA diagnosis than those without GCA confirmation (79 vs 68 years, p=0.0002).

Of the 82 patients, 78 (95%) underwent ultrasound, 41 MRI (50%), 15 PET (18%) and 35 TAB (43%). 71% had at least two diagnostic procedures and 33% had three. The optimal IMT cut-off measurements were 0.4mm for CSTA (n=74, 86% sensitivity, 91% specificity) and 1mm for AA (n=42, 62% sensitivity,100% specificity). Sensitivity and specificity of TA halo for GCA (n=78) was 80% and 94% respectively and 63% and 95% respectively for Grade 2 Gadolinium enhancement of TA (n=41).

Conclusion: High resolution ultrasound TA Halo, and the more objective TA IMT, both performed well for cranial GCA diagnosis with excellent sensitivity and specificity.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Imaging of Rheumatic Diseases Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: *Lung ultrasound (LUS) has proven useful to detect interstitial lung disease (ILD) among patients with SSc when compared to high-resolution computerized tomography (HRCT) as the gold standard; it also exhibits advantages as a tool in clinical practice owing to its accessibility and innocuity. Nevertheless, a key drawback is currently the lack of a standardized methodology to perform LUS. Our objectives were to evaluate diagnostic accuracy of LUS for ILD by comparing the systematic evaluation of 14 intercostal spaces (ICS) against 12 postero-basal ICS; and to correlate the grade of severity of ILD assessed through LUS with findings on HRCT, both as a global score and evaluating specific concordant lung zones*.

Methods: *Patients with SSc, according to current classification criteria, were recruited from the outpatient rheumatology clinic at a referral hospital. Demographic, clinical, serological, and imaging variables were collected. LUS was performed using two scanning methods: 14 predetermined ICS and 12 postero-basal ICS. "B" lines (BL) and pleural abnormalities (PA) were documented for each ICS. HRCT was performed with a maximum 3 month-interval from the time of recruitment (before or after). Descriptive statistics, multivariate analysis, a Pearson correlation test (to compare findings between LUS and HRCT), and ROC curves (to show diagnostic accuracy) were carried out*.

Table 1. General characteristics

Variable	w/o ILD (*n*= 58)	ILD (*n*= 56)	*p*
Age	53 (43.5-60.5)	59 (50.8-66.2)	**0.007**
Gender (female)	58 (52.3)	53 (47.7)	0.07
Body Mass Index	23.8 (20.7-25.4)	23.1 (20.5-25.9)	0.97

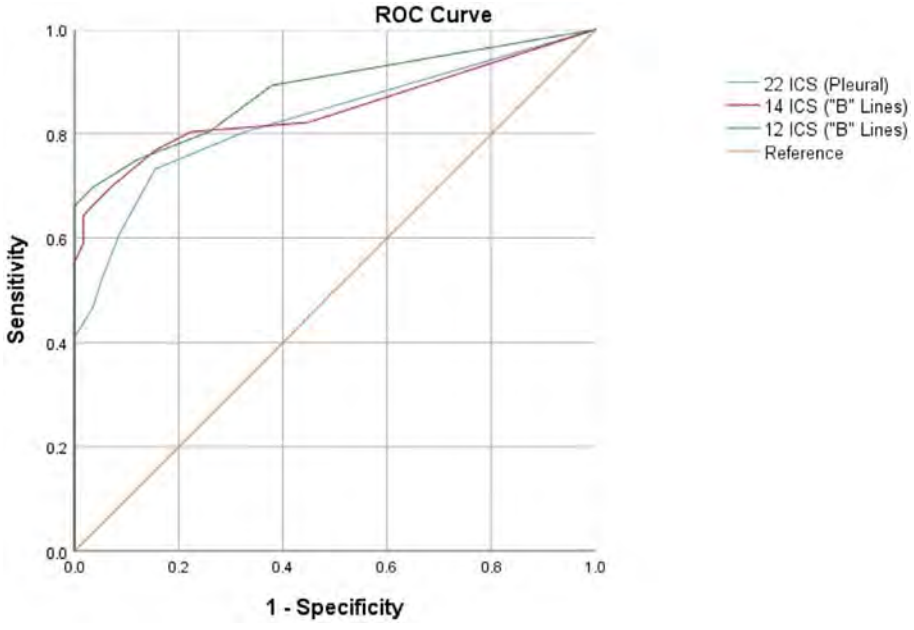
Limited	45 (57)	34 (43)	**0.008**
Diffuse	7 (26.9)	19 (73.1)	
Anti-Scl-70 (n= 92)	31 (43.1)	41 (56.9)	0.069
Anti-centromere (n= 99)	45 (52.9)	40 (47.1)	0.532
Pulmonary Hypertension (n= 70)	5 (26.3)	14 (73.7)	**0.02**
Medsger global score (n= 69)	1.5 (1-2)	2 (1-2.5)	**0.017**
Warrick score	3 (0-6)	13 (9-18)	**<0.001**
BL count in 14 ICS	0 (0-1)	7 (3-12.8)	**<0.001**
BL count in 12 ICS	0 (0-2)	6.5 (2.3-15.5)	**<0.001**
PA (22 EIC)	0 (0-1)	4 (1-9)	**<0.001**
Immunosuppresants, no. (n= 71)	1 (0-2)	1 (0-2)	0.48
Mycophenolate mophetil (n=104)	9 (36)	16 (64)	0.084

Continuous variables: Mean ± DE, Median (25-75), Categorical variables: Frequency (%)

ILD: Interstitial Lung Disease, SSc: Systemic Sclerosis.



Results: *We included 114 patients with a median age of 55 (IQR 48-63) years; 97.4% were women. Prevalence of ILD was 49.1%. Relevant baseline characteristics are shown in Table 1. Acknowledged risk factors for ILD were pulmonary hypertension (*OR 3.4, CI 95% 1.04-11.14, *p*=0.04) and diffuse SSc (OR 2.5, CI 95% 0.84-7.6 *p*= 0.10). A strong correlation was shown between the BL count in 14 ICS and the Warrick score (0.62), and the BL count in 12 ICS and Warrick score (0.61).

The AUC were 0.85 (95% CI, 0.77-0.92), 0.88 (95% CI, 0.82-0.95) and 0.83 (95% CI, 0.75-0.91) for the evaluation of the number of BL in 14 ICS, 12 ICS and the number of ICS with PA (22 EIC), respectively.

Conclusion: Our study confirms the robustness of LUS as a tool for the detection of ILD through the quantification of BL and PA when using any of two different scanning protocols (14 and 12 ICS). A reasonable diagnostic accuracy was also proven for the finding of PA, but more studies are required to elucidate their added value over BL for the diagnosis of ILD by LUS.

Session Title: Imaging of Rheumatic Diseases Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasonography (US) has experienced a rapid evolution in rheumatology. Despite many advantages being shown repeatedly, several barriers persist and stand in the way of a wider use of US in rheumatology, equipment cost being an important one. Hand-held US technology promises to take this cost down substantially. However, before it can be specifically used for rheumatology, its performance needs to be validated against gold-standard devices for key interventions. We aim to test the concurrent validity of a handheld US device versus a gold-standard device to detect characteristic features of healthy and rheumatic joints (i.e., anatomical structures and vascular flow).

Methods: Adult patients with peripheral PsA presenting with at least one tender and swollen joint were included. Each patient had consecutive US examinations using a handheld (Clarius Mobile Health Inc, HD3 L20 and L15 scanners) and a gold standard US device (GE LogicE9) for detecting synovitis, nail disease, and erosions. B mode and power Doppler images were saved for each site and lesion. Every image was given a unique identifier number at the end. Image reading was performed at least 2 weeks after the acquisition of US in all patients. A random order slide show was conducted for

scoring, irrespective of the machine used or the anatomical site or patient assessed, to ensure blindness. Scoring was done using previously validated methods. Here we present interim analysis for the first 10 patients to detect synovitis (n=240), nail disease (n=20), and erosions (n=40).

Results: Patients had a mean±SD age of 55.2±8.6, with a median (IQR) disease duration of 7(12) years. 40% were female. On the day of the US, the median (IQR tender joint count was 8.5(18.5) and swollen joint count was 4.5(5.75).At least moderate agreement was observed between the handheld and gold standard devices in all elementary lesions assessed (table). Specifically, both detecting synovitis, the L15 and L20, had a kappa of 0.499 and 0.535 compared to the GE machine, respectively, with absolute agreement rates of 76.7-77.8%. For detecting the intrasynovial Doppler signals, the L15 had a substantial agreement (kappa: 0.667, absolute agreement: 93.9%); and L20 had moderate agreement (kappa: 0.428, absolute agreement: 89.3%). The nail lesions were compared with L20, which showed a moderate agreement to detect the loss of trilaminar appearance (kappa: 0.490, absolute agreement: %75) and substantial agreement to detect nail bed vascularity (kappa: 0.732, absolute agreement: 89.5%). For erosions, there was an almost perfect agreement with the L15 (kappa: 0.876, absolute agreement: 94.1%) and moderate agreement with L20 (kappa: 0.486, absolute agreement: 77.5%). Investigating the individual discrepancies, the L20 seemed to be more sensitive to detecting erosions (fig).

Conclusion: In this interim analysis, the handheld US devices show moderate-substantial agreement to detect synovitis, nail lesions and erosions, and Doppler signals. The final analysis will be conducted after 30 PsA patients are enrolled, and enthesitis will also be analyzed. These interim results encourage testing the use of handheld US devices for wider use.

Table: The frequency, kappa and percent absolute agreement of elementary lesions on all three devices.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of anti-PD-1 (aPD-1) immunotherapy has seen significant success in clinical practice, corresponding with a continued rise in clinical indications for multiple cancer diagnoses. Immune-related adverse events (irAEs) are a type of secondary autoimmune toxicities arising in the setting of cancer immunotherapy. They can cause significant morbidity and disruption of the treatment of oncologic patients. They also offer a controlled setting for dissecting the cellular and signaling networks of autoimmunity development.

Methods: To better understand irAEs in the setting of aPD-1 immunotherapy, we established a prospective, longitudinal cohort at the University of Pennsylvania enrolling patients before immunotherapy and following them for a year. We stratified the responses in two groups: patients that developed at least one irAE event ($irAE^+$) and patients that never developed an irAE event ($irAE^-$) during that time period.

Results: Using high-dimensional cytometry, we found that $irAE^+$ patients had a larger increase in their activated CD4 T cells after PD-1 inhibition compared to $irAE^-$ patients. In addition, plasmablast generation following immunotherapy was higher for $irAE^+$ patients. Using PhIP-Seq, an autoantigen screening assay, we found that $irAE^+$ patients demonstrated robust enrichment in autoantibodies against various tissue antigens after immunotherapy with unique patterns for each patient. Finally, a large-scale proteomic analysis revealed that $irAE^+$ patients at baseline have increased levels of circulating inflammatory mediators.

Conclusion: These results indicate that there are distinct cellular and serological imprints of $irAE^+$ patients that reflect their heightened autoimmune reactivity and can be used to uncover the underlying pathogenic mechanism of irAEs and design predictive algorithms.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Data on Immune Checkpoint inhibitor (ICI) use in patients with previously diagnosed inflammatory muscle disease (IMD) is limited as these patients were excluded from clinical trials. There is a concern that use of ICIs in patients with pre-existing IMD may have flares of their disease, increased morbidity, and/or higher mortality with ICI treatment. We identified all patients diagnosed with IMD prior to ICI infusion in the Veterans Health Administration (VHA) and analyzed these patients' demographics, diagnoses, laboratory findings, clinical course, and mortality in comparison to other Veterans treated with ICIs.

Methods: This analysis used data from the VHA Corporate Data Warehouse (CDW) for demographics, ICD codes, and pharmacy information, VA cancer registry for cancer diagnosis, and all-cause mortality from the Death Ascertainment File (DAF). Veterans who received one or more ICI infusions between 6/6/2011 and 2/14/2023 were evaluated as potential IMD cases if they had two or more myositis ICD-9 or ICD-10 codes associated with a rheumatology or neurology clinic visit at least 30 days apart and both visits occurred prior to the ICI treatment. Cases meeting these criteria underwent electronic medical record review using the Compensation and Pension Record Interchange (CAPRI) to determine if the case met American College of Rheumatology (ACR) criteria for IMD. Demographic features and mortality of confirmed cases were compared to patients receiving ICI without pre-existing IMD. IMD cases were also reviewed to determine if patients developed a myositis flare.

Results: We identified 29,539 patients who received at least one ICI infusion in the VHA. Of these patients, 13 met IMD screening criteria with 8 patients having confirmed IMD by ACR criteria (dermatomyositis 3, polymyositis 2, anti-synthetase syndrome 2, and RA/myositis overlap 1). All patients were white males with an average age of 71.7 years at the time of first ICI infusion. Primary cancer diagnoses were lung - 2, melanoma - 2, head and neck - 2 kidney/other urinary - 1, and mesothelioma - 1. Four patients were treated with nivolumab and four patients with pembrolizumab (Table 1). Diagnosis of IMD was made on average 3.1 years prior to treatment with ICI. One patient with dermatomyositis had an IMD flared after two doses of ICI and was treated successfully with steroids and IVIG. No IMD flares were identified in the other seven patients. There was no difference in Kaplan Meier Survival Analysis for IMD patients in comparison to patients treated with ICI without IMD (p=0.40 by log rank test) (Figure 1).

Conclusion: Overall mortality in these 8 patients with IMD treated with an ICI was similar to other ICI treated Veterans. Among the 8 IMD patients, only one developed an IMD flare after ICI treatment that responded to glucocorticoids and IVIG therapy. These findings suggest that ICI therapy can be considered in IMD patients with close monitoring. Future research is needed to better understand the risk of IMD flare and outcomes in patients with established IMD treated with ICIs.

Immune Checkpoint Inhibitor Induced Polymyalgia Rheumatica Demonstrates a Similar Scintigraphic Appearance to Classical Polymyalgia Rheumatica on 18F-Fluorodeoxyglucose PET/CT

David Liew[1], Aurora Poon[1], Christopher McMaster[2], Russell Buchanan[1], Victor Yang[1], Andrew Scott[1] and Claire Owen[3], [1]Austin Health, Heidelberg, Australia, [2]Austin Health, Pascoe Vale South, Australia, [3]Austin Health, Malvern East, Australia

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Of the rheumatic immune-related adverse events that follow immune checkpoint inhibitor (ICI) cancer immunotherapy, de novo PMR-like episodes without inflammatory arthritis (ICI-PMR) appear to comprise a small subset, distinct from other irAEs. ICI-PMR also appear distinct from classical PMR, given they are temporally related to ICI exposure and occur at far greater incidence than expected for classical PMR alone. ICI-PMR have previously been associated with findings consistent with inflammatory morphological change on [18F] Fluorodeoxyglucose-PET/CT (FDG-PET/CT), a modality used for cancer staging. Classical PMR also has highly accurate diagnostic scintigraphic features on FDG-PET/CT. It is not known to what extent the detailed inflammatory morphological changes in ICI-PMR correlate with those in classical PMR.

Methods: A comparison was made of FDG-PET/CT images from active ICI-PMR and active classical PMR patients. Images in ICI-PMR patients were obtained from a retrospective repository of routine care FDG-PET/CT incidentally obtained for cancer staging. Images were selected where the time of image acquisition correlated with ICI-PMR active disease. Both

Table 1: Scintigraphic comparison (comparison of PMR and irAE cohorts performed by ranking 7 sites in order of average SUVmax - 5 classical PMR sites and 2 intra-articular sites)

Table 1:
Scintigraphic comparison (comparison of PMR and irAE cohorts performed by ranking 7 sites in order of average SUVmax - 5 classical PMR sites and 2 intra-articular sites)

		Rank		
Location	SUVmax (SD)	irAE	PMR	SUVmax (SD)
Ischial tuberosity	1.79 (0.49)	2	1	3.58 (1.38)
Hip capsule	1.65 (0.51)	4	2	3.39 (1.79)
Shoulder capsule	2.04 (0.53)	1	3	3.36 (1.33)
Interspinous bursa	1.60 (0.71)	5	4	2.92 (1.58)
Trochanteric bursa	1.75 (0.55)	3	5	2.50 (0.90)
Glenohumeral joint	1.48 (0.34)	6	6	1.93 (0.98)
Hip joint	1.39 (0.41)	7	7	1.84 (1.17)

diagnosis and disease activity assessment for ICI-PMR patients were determined by a rheumatologist expert in irAEs, without reference to FDG-PET/CT. Patients with clinically apparent inflammatory arthritis were excluded. Images in classical PMR were obtained from a prospective research cohort, after diagnosis and prior to glucocorticoid therapy. All patients met the 2012 ACR/EULAR PMR Classification Criteria. Seventeen sites specific to classical PMR FDG-PET/CT assessment were assessed by a nuclear medicine physician expert in assessment of PET/CT for PMR, blinded to clinical context, and were combined into seven regional sites for comparison.

Results: This analysis captured nine patients with ICI-PMR who had an incidental FDG-PET/CT when their ICI-PMR was active. The median age was 79 (69-85). The ICI indication was melanoma in 5 patients, and non-small cell lung cancer in 4 patients. The ICI agent was nivolumab in 4, pembrolizumab in 4, and durvalumab in 1; only one was receiving combination therapy with ipilimumab. There were 31 patients in the classical PMR cohort. While the overall intensity of uptake was lower in the ICI-PMR cohort, notable morphological similarities existed between both sets of patients (Table 1). Of the seven sites, shoulder capsule and ischial tuberosity ranked in the top three for both groups. For both ICI-PMR and classical PMR, intra-articular uptake at shoulder and hip joints was lower than periarticular sites classical for polymyalgia rheumatica.

Conclusion: ICI-PMR and classical PMR demonstrate similar patterns of scintigraphic uptake on FDG-PET/CT. This close similarity in inflammatory morphological change implies that classical PMR properties might inform ICI-PMR research, and that insights from ICI-PMR might prove useful for classical PMR research, as a model of induced disease.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) have revolutionized the treatment of cancer. A drawback of ICI therapy is their off-target effects known as immune-related adverse events (irAEs), including inflammatory arthritis (ICI-IA). Glucocorticoids (GC) are among the first-line treatment for most irAEs, including ICI-IA. However, given the

immunosuppressive properties of GC, there is concern that they may blunt the anti-tumor effects of ICI. There is a paucity of evidence on the safety of GC to treat ICI-IA. The aim of this study was to examine the impact of dose, timing of initiation and duration of GC on cancer outcomes in patients with ICI-IA. We hypothesized that highmaximal dose, early initiation and prolonged duration of GC exposure after onset of ICI-IA would be associated with worse outcomes.

Table 1: Baseline characteristics of subjects exposed to glucocorticoid (GC) within 90 days after onset of ICI-IA (N=76).

Female, n (%)	29 (38.2%)
Age (years), mean (SD)	68.2 (11.3)
Tumor type, n (%)

[1]p-value for comparison of progression/death between groups (≤ vs. > median).
NE=Not estimable because less than 25% or 50% of the patients failed (progressed or died).

Methods: The CanRIO retrospective cohort includes adult subjects with rheumatic irAEs after exposure to ICI, seen at one of 10 rheumatology clinics across Canada between Jan 2013 and Aug 2022, who have had standardized chart data extraction. In this sub-study, participants with *de novo* ICI-IA (without pre-existing IA), who were exposed to GC within 90 days after onset of IA, and in whom there was at least 3 months of follow up after onset of ICI-IA were analyzed. Data on maximal GC dose (max-GC dose), timing of GC initiation (time-GC) and duration of GC exposure (dur-GC) during the 90 days after the onset of ICI-IA were extracted. Median values for each were determined and used to dichotomize the exposure variables into above and below the median. Kaplan Meier analysis were used to evaluate the association between max-GC, time-GC and dur-GC with progression-free survival and overall survival.

Results: Data on 76 participants with *de novo* ICI-IA were available for analysis (Table 1). The median max-GC dose was 25 mg daily (interquartile range (IQR) 20-50 mg), median time-GC was 26.5 days (IQR 5-51 days) and median dur-GC was 59.5 days (IQR 30-82 days). Median follow up of the participants was 123.2 weeks. Max-GC dose, time-GC and dur-GC exposure had no association with progression-free and overall survival (Table 2 and Figure 1).

Conclusion: In this study of participants with *de novo* ICI-IA who were treated with GC, dose of GC, timing of initiation of GC and duration of GC exposure after onset of ICI-IA did not impact tumour outcomes. Although the confidence intervals were wide, our findings provide some reassurance about the safety of short-term GC for the management of ICI-IA. Further

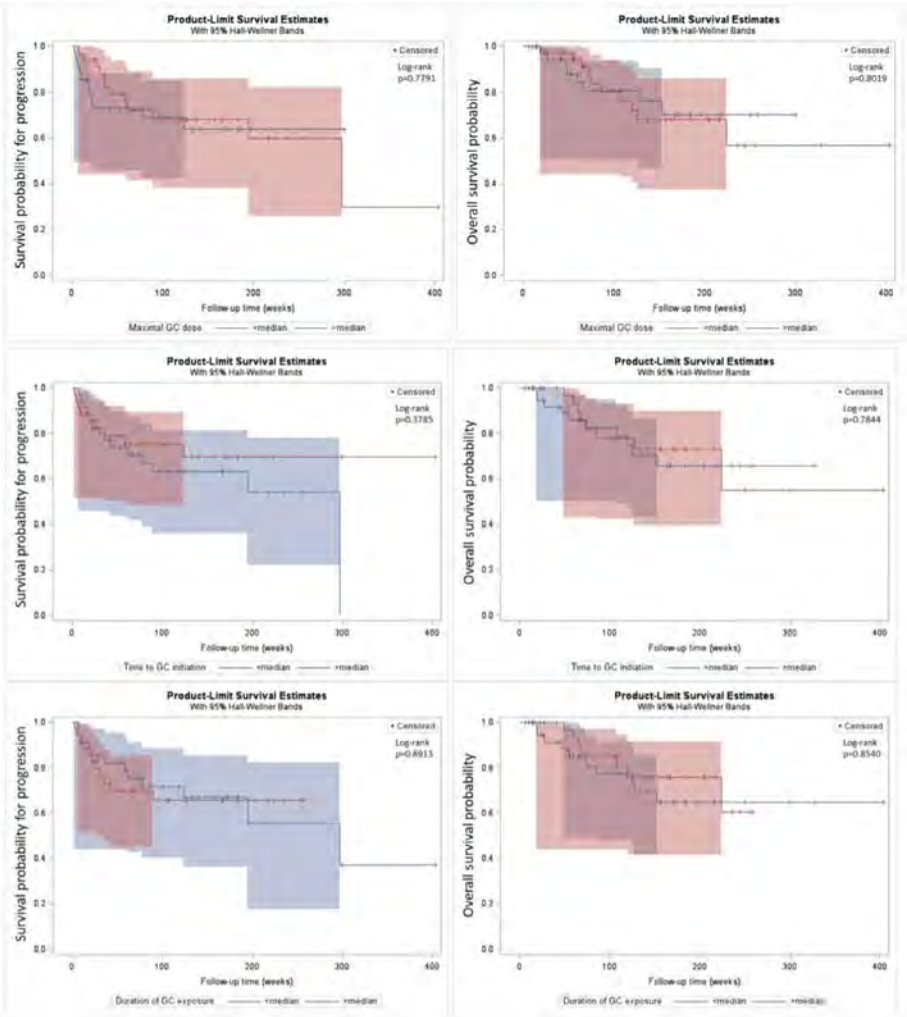

Figure 1: Progression-free and overall survival in weeks after onset of ICI-IA, stratified by the median of maximal dose, time to initiation and duration of GC within 90 days after ICI-IA onset.

studies with larger sample size and longer term follow up are needed to corroborate our results, and additional studies comparing to ICI-IA patients *unexposed* to GC are needed to optimize management.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) improve overall survival in many cancer patients by activating their immune system. However, they can cause off-target immune-related adverse events (irAEs) including inflammatory arthritis (ICI-IA), sometimes prompting ICI discontinuation. Another course of ICI is now often considered in patients with cancer progression and previous irAEs, but there are limited data regarding the safety of ICI rechallenge in this context[1]. We aimed to assess the rate and clinical features associated with ICI-IA flare/recurrence upon ICI rechallenge.

Methods: We conducted a multicenter observational study including cancer patients with ICI-IA (defined by either the presence of at least one synovitis on physical exam and/or on imaging or polymyalgia rheumatica (PMR)-like symptoms) who started a second course of ICI more than 3 months after ICI discontinuation in 4 french university hospitals. Patients with a follow-up of < 3 months after ICI rechallenge were excluded. Charts were manually reviewed to extract data on baseline characteristics, investigations, management and both ICI-IA and tumor outcomes. Patients who experienced a flare or recurrence of ICI-IA upon rechallenge were compared to those who did not.

Table 1. Clinical characteristics and outcomes of patients who flared ICI-IA upon rechallenge and those who did not flare

		ICI-IA flare after rechallenge (N=11)	No ICI-IA flare after rechallenge (N=12)
Sex	Male	7 (63.6)	6 (50)
	Female	4 (36.4)	6 (50)
Age		69.0 (8.7)	64.9 (12.9)
Tumor type	Melanoma	3 (27.2)	7 (58.3)
	Lung	5 (21.7)	2 (16.6)
	Genito-urinary	2 (18.2)	1 (8.3)
	Other	1 (9.1)	2 (16.6)
ICI	CTLA-4	0 (0.0)	1 (8.3)
	PD1/PDL-1	10 (89.9)	9 (75.0)
	Combination	1 (9.1)	2 (16.6)
Type of ICI-IA	Symmetrical polyarthritis	3 (27.3)	4 (33.3)
	Psoriatic arthritis	1 (9.1)	1 (8.3)
	Oligoarthritis	1 (9.1)	1 (8.3)
	Monoarthritis	0 (0.0)	1 (8.3)
	PMR-like	6 (54.5)	5 (41.7)
ICI-IA treatment at the moment of rechallenge	No treatment	5 (45.5)	7 (58.3)
	Prednisone	5 (45.5)	5 (41.7)
	csDMARDs	2 (18.2)	1 (8.3)
	bDMARDs	0 (0.0)	0 (0.0)
	tsDMARDs	0 (0.0)	0 (0.0)
ICI-IA disease activity at the moment of rechallenge	No symptom	9 (81.8)	9 (75.0)
	Minor symptoms	2 (18.2)	3 (25)
	Moderate/severe symptoms	0 (0.0)	0 (0.0)
Progression after ICI rechallenge		7 (63.6)	9 (75.0)
Death		3 (27.3)	1 (8.3)

Abbreviations: ICI-IA, Immune checkpoint inhibitor-induced inflammatory arthritis; ICI, Immune checkpoint inhibitors; PMR, polymyalgia rheumatica; cs DMARDS, conventional synthetic disease modifying anti-rheumatic drugs; bDMARDs, biologic DMARDs; tDMARDs, targeted DMARDs; irAE, immune-related adverse events

Results: 23 patients were included with a median follow-up duration of 7 months from ICI rechallenge. The most frequent ICI-IA presentations were PMR-like (n=11, 48%) and symmetric polyarthritis (n=7, 30.4%), which occurred after a mean time of 6.6 months during the first course of ICI. Almost all patients were treated with prednisone (n=20, 87%), 2 with csDMARDs (8.7%) and 1 with biologics (4.3%). Reason for ICI discontinuation was ICI-IA (n=8; 35%), cancer progression (n=7; 30%), other irAE (n=4; 17%) and cancer stable or in remission (n=3; 13%).

Reason for ICI rechallenge was cancer progression in all patients. At the time of ICI rechallenge, 18 patients reported no symptoms of ICI-IA (78%), 5 had minor symptoms (22%) and none had moderate or severe symptoms. Regarding baseline ICI-IA treatment, 12 patients (52%) were not receiving any ICI-IA treatment at the time of ICI rechallenge, 10 (43%) were still on prednisone and 3 (13%) were on csDMARDs. ICI-IA flare/recurrence occurred in 12 patients (52%) with a mean time of 2.2 months after ICI rechallenge. Only one patient discontinued ICI due to ICI-IA recurrence. When comparing patients who experienced ICI-IA flare/recurrence with those who did not, there was no difference in terms of baseline ICI-IA treatment or disease activity (Table 1). Laboratory and imaging data are currently being analyzed.

Conclusion: In this first observational study of ICI-IA patients rechallenged with ICI, about half of the patients experienced ICI-IA flare/recurrence which occurred earlier than the first episode of ICI-IA but allowing ICI continuation in all but one patient. Patients still on prednisone or csDMARDs to control their ICI-IA at the time of rechallenge did not seem at increased risk of flaring. Larger studies are needed to clarify risk factors of ICI-IA flare with ICI rechallenge.

evaluate whether new ICI-IA occurring in patients with a pre-existing (non-IA) autoimmune disease was associated with a greater likelihood of chronicity compared to ICI-IA occurring in patients without any pre-existing autoimmune disease.

Methods: In the MarketScan Commercial Claims, Medicare Supplemental, and Multi-State Medicaid administrative health databases, we identified all adults (18+) with at least one filled prescription for an ICI (ipilimumab, nivolumab, etc.) from Jan. 1st 2011-Dec. 31st, 2021. We excluded those without continuous health insurance coverage and those with any International Classification of Diseases (ICD) billing/hospitalization code for any IA or for DMARDs and/or biologics in the year prior to ICI initiation. The primary exposure of interest was a diagnosis of any non-IA autoimmune condition (e.g. multiple sclerosis, hypothyroidism, etc.) prior to ICI initiation. We evaluated the data between 0 and 90 days and at 180 days post-ICI-IA. Chronic ICI-IA was defined as current use of systemic glucocorticoids (GC), DMARDs and/or biologics 180 days after ICI-IA diagnosis.

Results: During the study period, 29,598 individuals were newly exposed to ICI and 395 (1.3%) of these had one or more ICD code for IA after ICI initiation. One hundred forty-nine (N=149, 38%) individuals with ICI-IA had a pre-existing autoimmune disease. The most frequent autoimmune diseases were gastrointestinal (N=56, 38%), ophthalmologic (N=28, 19%), other rheumatic diseases (N=23, 15%) and endocrine (N=17, 11%). One hundred fifty-seven (N=157, 40%) of those with ICI-IA received treatment with GC, DMARDs and/or biologics within the first 90 days after ICI-IA onset. Sixty-eight (N=68, 17% of the 395) were still under one of these treatments at 180 days post ICI-IA diagnosis. Table 1 demonstrates that men were more likely than women to receive GC, DMARDs and/or biologics treatment within the first 90 days after ICI-IA. Table 1 shows that melanoma and treatment with combination ICI (as well as a strong trend for anti-CTLA-4) were associated with chronic ICI-IA, but no pre-existing autoimmune disease was clearly associated with this outcome.

Conclusion: In univariate cross-sectional analyses of patients followed from 90 days post ICI-IA to 180 days, pre-existing autoimmune disease was not clearly associated with increased chronicity according to our definition. Melanoma, combination ICI, and possibly anti-CTLA-4 was associated with chronic ICI-IA. Multivariate hazard regression analyses are under way.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are a revolutionary treatment that boost a patient's own immune system to fight cancer. However, activation of the immune system often induces off-target immune-related adverse events (irAEs). ICI-induced inflammatory arthritis (ICI-IA) affects about 5% of ICI recipients and can lead to ICI discontinuation which might potentially negatively affect tumor outcomes. We aimed 1) to characterize the evolution of ICI-IA while ICI treatment is maintained and 2) to assess how ICI-IA influences ICI management across time.

Methods: All ICI-treated patients referred to rheumatology at Bordeaux University Hospital were identified and patients with ICI-IA defined by either the presence of at least one synovitis on physical exam and/or on imaging or polymyalgia rheumatica (PMR)-like symptoms with a follow-up of ≥ 6 months after ICI-IA onset were included. Charts were manually reviewed to extract data on baseline characteristics, investigations, management and both ICI-IA and tumor outcomes.

Results: Out of 281 referred patients, 80 fulfilled the inclusion criteria, of which 49 (61.3%) were male. The median duration follow-up after ICI-IA onset was 108 weeks [ranging from 26-330 weeks]. The most common tumor was melanoma (n=38, 47.5%), followed by lung cancer (n=16, 20.0%). The mean time from ICI-IA onset to ICI-IA treatment was 8.6 weeks and ICI was continued in 63 patients (78.8%) or temporary held in 11 (13.8%). Prednisone was prescribed in 74 patients (92.5%), csDMARDs in 22 (27.5%) and biologics in 2 (2.5%). ICI-IA resolved allowing ICI-IA treatment discontinuation in 27 patients (33.8%) while still being treated with ICI. Among those, 26 (96.3%) were treated with prednisone (median maximal dose 15 mg and median duration 52.0 weeks), 3 (11.1%) with csDMARDs and 1 (3.7%) with biologics. In patients with persistent ICI-IA while on ICI, 20 (40%) and 34 (68%) had resolved at 6 and 12 months post ICI discontinuation, respectively. During follow-up, the main reason for ICI discontinuation was a cancer stable or in remission in 31 patients (38.8%), cancer progression in 22 (27.5%), other irAE in 7 (8.8%) and ICI-IA in 4 (5.0%). Of note, ICI-IA treatment and ICI management were similar between those with active arthritis and those with resolved arthritis at 6 and 12 months post ICI discontinuation.

Conclusion: In this cohort, ICI was safely continued in most patients experiencing ICI-IA. Over one third of ICI-IA resolved despite maintaining active ICI treatment allowing arthritis treatment discontinuation. Larger studies are needed to determine predicting factors of resolving ICI-IA as this could help minimize exposure to immunosuppressive treatment.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitor (ICI) associated inflammatory arthritis (ICI-IA) has been suggested to occur in approximately 3-6% of ICI-treated patients with cancer[1] but most studies of ICI-IA are hampered by small numbers conducted at single centers. In this study, we aimed to identify cases of ICI-IA using administrative claims data to facilitate larger studies.

Methods: We used the Medicare 5% random sample from 2015-2019 to identify patients using ICIs. Cancer patients were identified by having at least 2 diagnosis codes from an oncologist for lung cancer, urothelial cancer or melanoma using ICD-9/10-CM codes. ICI-IA was defined as having two Medicare claims at least 30 days apart with combinations of ICD-9/10-CM diagnosis codes that favored specificity. Results were stratified by whether patients had i.) inflammatory arthritis after the date of ICI initiation and ii.) no diagnosis of a rheumatic disease or musculoskeletal complaint in the one year prior to the date of ICI initiation.

Table 1. Incidence rate of suspected de novo inflammatory arthritis among ICI-treated patients with cancer using various inclusion and exclusion criteria and outcome definitions.

Table 1: Incidence rate of suspected *de novo* inflammatory arthritis among ICI-treated patients with cancer using various inclusion and exclusion criteria and outcome definitions.

Inclusion	Exclusion	Outcome	Cohort size, n	Cases, n	Incidence Rate per 100 person years
2+ cancer diagnoses	Any prior evidence (using all available prior data) of a specific rheumatic disease, or evidence in the prior year of any non-specific joint symptoms	2+ visits for any specific or sensitive ICD9/10 diagnosis code for inflammatory arthritis	3119	193	6.8 (5.9-7.9)
2+ cancer diagnoses	Any prior evidence (using all available prior data) of any specific or non-specific joint symptom diagnosis	2+ visits for any specific or sensitive ICD9/10 diagnosis code for inflammatory arthritis	1515	65	4.5 (3.5-5.7)
No specific cancer diagnosis required (only ICI use)	Any prior evidence (using all available prior data) of a specific rheumatic disease, or evidence in the prior year of any non-specific joint symptoms	2+ visits for any specific or sensitive ICD9/10 diagnosis code for inflammatory arthritis	4422	264	6.9 (6.1-7.8)
No specific cancer diagnosis required (only ICI use)	Any prior evidence (using all available prior data) of any specific or non-specific joint symptom diagnosis	2+ visits for any specific or sensitive ICD9/10 diagnosis code for inflammatory arthritis	2171	96	4.9 (4.0-6.0)
2+ cancer diagnoses	No rheumatology visit in the prior year	Any visit with a rheumatologist (for any condition)	4286	70	1.9 (1.5-2.4)

Table 2: Characteristics of ICI-treated cancer patients with and without ICI-IA identified in the Medicare 5% sample

Table 2: Characteristics of ICI-treated cancer patients with and without ICI-IA identified in the Medicare 5% sample*

Variable	**ICI-IA patients*** N=193 (6%)	**Non-ICI-IA** N=2,926 (94%)	P value
Age - mean (SD) years	73.5 (7.2)	73.4 (8.0)	0.984
Sex (female) (%)	93 (48.2)	1294 (44.2)	0.283
Race			0.281
White	176 (91.2)	2576 (88.0)	
Black	12 (6.2)	203 (6.9)	
Other	5 (2.6)	147 (5.0)	0.495
Hispanic ethnicity	1 (0.5)	36 (1.2)	
Cancer type			**0.015**
Lung cancer	111 (57.5)	1,979 (67.6)	
Melanoma	42 (21.8)	417 (14.3)	
Urological cancer	38 (19.7)	494 (16.9)	
Other	2 (1.0)	36 (1.2)	
First ICI type			0.056
PD1	153 (79.3)	2,226 (76.1)	
PDL1	19 (9.8)	459 (15.7)	
CTLA4	21 (10.9)	241 (8.2)	

* ICD-9/10-CM codes for inclusion: 696.0, L405, 714, M05, M06, 720.0, M45, M46.8, M46.9, 725, M35.3, M31.5, 099.3, M02.9, 716, M13, 719.0, M25.4, 719.4, M25.5, 719.9, M25.9.

Results: We identified individuals with cancer initiating ICI 2016-2019 with a >= 12-month baseline. The incidence of ICI-IA varied modestly depending on the definition used and was generally in the range of 4-7 per 100 patient years (**Table 1**). The incidence rates were similar when all cancer were included. Patients with ICI-IA had mean (SD) age 73.5 (7.2) years, 48% women, 91% white (**Table 2**). More than half of patients (57.5%) had lung cancer, 21.8% had melanoma, and 19.7% urothelial cancer. The median (IQR) time from ICI initiation to first ICI-IA diagnosis was 147 (58, 320) days. The mean (SD) number of provider visits with an ICI-IA diagnoses was 5.3 (6.0), spanning a median (IQR) of 240 (105,461) days. Of the 193 ICI-IA patients identified using our preferred cohort definition, 14.5% used any conventional disease modifying anti-rheumatic drug (DMARD), and fewer than 5% (total) used any TNFi, IL-6Ri, JAKi, or rituximab; none used abatacept. Only 31 (16.1%) received care from a rheumatologist. Median time from ICI initiation to seeing a rheumatologist was 229 (105, 483) days and these patients had a mean (SD) of 11.7 (11.3) visits with the rheumatologist.

Conclusion: We created a simple claims-based algorithm for the preliminary identification of ICI-IA cases using national Medicare claims that results in an incidence similar to that found using registry data.[1] While validation of this algorithm using patient level clinical data linked to administrative claims may be useful to identify suspected cases of irAEs, it is likely that more sophisticated methods (e.g. natural language processing run on unstructured data) or manual medical rec

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are an increasingly used form of anti-cancer therapy, but they have been associated with a range of cardiac immune-related adverse events (iRAEs). Early detection of cardiac iRAEs may lead to prompt intervention and improved patient outcomes. In this study, we investigate the association between regular troponin monitoring and major adverse cardiac events (MACE) detection and overall survival (OS) in patients receiving ICI.

Methods: We performed a retrospective study of 825 patients receiving ICI from January 2018 to March 2022. Of these patients, 428 (52%) were evaluated via a standard troponin monitoring protocol with Troponin I measured at baseline and prior to each ICI dose. The control group included 397 (48%) patients who underwent ICI therapy prior to initiation of this

troponin monitoring protocol. We collected outcomes in all patients for nine months following their first dose of ICI. Primary outcomes included severe MACE (defined as grade ≥ 4 Cardiovascular Adverse Events (CV AEs) according to the National Cancer Institute's Common Terminology Criteria for Adverse Events version 5) and OS. To investigate whether troponin monitoring was associated with discontinuation of ICI therapy, we compared time-to-treatment-failure (TTF) between monitored and unmonitored patients in a subgroup of patients with melanoma. TTF was defined as the interval from ICI initiation to discontinuation for any reason. Additionally, we studied the relationship between troponin elevation and MACE by comparing the rates of MACE (defined as grade ≥3 CV AEs) between all patients with a positive troponin measurement during the monitoring period versus patients with negative or no troponin measurement. A positive troponin was defined as Troponin I >0.055.

Results: We found a lower rate of severe MACE in patients who underwent troponin monitoring (0.5%) compared to patients who underwent no troponin monitoring (1.8%), (HR 0.17, 95% CI 0.02-0.79). There was no difference in OS at nine months between monitored patients (81%) and unmonitored patients (82%), (HR 1.04, 95% CI 0.75-1.44). In patients with melanoma (N=89), we found no difference in TTF at nine months between patients who were monitored (54% discontinued ICI) and unmonitored (53% discontinued ICI) (p = 0.91). There were 71 patients (8.6%) with positive troponin measurement

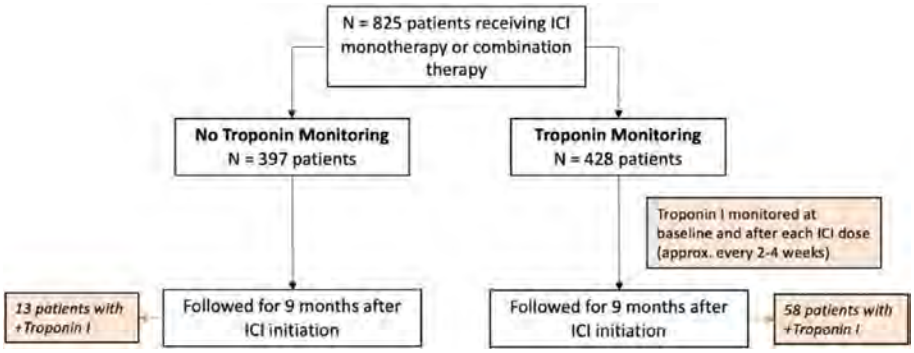

Figure 1. Troponin monitoring algorithm.

Table 1. There was a significantly lower rate of severe MACE in the troponin monitoring group compared to the unmonitored group. There was no difference in all MACE and overall survival between the two groups.

Table 1
MACE and OS within 9 Months of ICI initiation

	No Troponin Monitoring (n = 397)	Troponin Monitoring (n = 428)	Multivariable Hazard Ratio (95% CI)	P value
Death	71 (17.9%)	80 (18.7%)	1.03 (0.75 - 1.43)	0.84
Severe MACE (grade ≥ 4 CV AEs)	7 (1.8%)	2 (0.5%)	0.17 (0.02 – 0.79)	0.04
Arrhythmia	3 (0.7%)	2 (0.5%)	-	-
Myocarditis	3 (0.7%)	0 (0%)	-	-
Congestive Heart Failure	0 (0%)	0 (0%)	-	-
Acute Coronary Syndrome	0 (0%)	0 (0%)	-	-
Stroke	1 (0.2%)	0 (0%)	-	-
Pericardial Effusion	0 (0%)	0 (0%)	-	-
All MACE (grade ≥ 3 CV AEs)	11 (2.8%)	16 (3.7%)	1.34 (0.62 - 3.00)	0.47
Arrhythmia	4 (1%)	2 (0.4%)	-	-
Myocarditis	3 (0.7%)	5 (1.2%)	-	-
Congestive Heart Failure	1 (0.2%)	4 (0.9%)	-	-
Acute Coronary Syndrome	1 (0.2%)	2 (0.4%)	-	-
Stroke	1 (0.2%)	1 (0.2%)	-	-
Pericardial Effusion	1 (0.2%)	2 (0.4%)	-	-

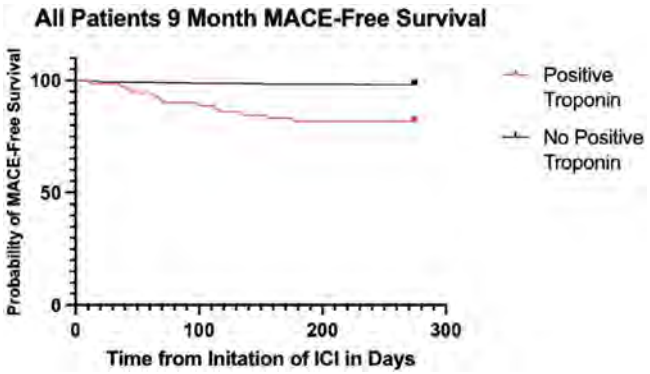

Figure 2. There was a significantly higher rate of in MACE in patients with a positive troponin compared to patients with no troponin or negative troponin within 9 months of first ICI dose ($p < 0.001$).

during the evaluated interval. Patients with positive troponin had a higher risk of MACE compared to those with negative or no troponin measurement (HR 7.20, 95% CI 2.99–17.55). This finding remained consistent when evaluated in the monitored subgroup alone (HR 4.34, 95% CI 1.578 – 12.38).

Conclusion: We found that patients undergoing regular troponin monitoring with ICI therapy had a lower rate of severe MACE compared to those without monitoring. Troponin elevation was significantly associated with MACE. Additionally, there was no difference in OS between those who were monitoring or unmonitored, and there was no difference in TTF between these two groups in patients with melanoma.

Vasculitis as an Immune-Related Adverse Event: Unraveling the Complexities at the Intersection of Immunology and Vascular Pathology

Chani-mi Lee[1], Margaret Wang[2], Aarthi Rajkumar[1], Cassandra Calabrese[3] and Leonard Calabrese[3], [1]University Hospital, Cleveland, OH, [2]Case Western Reserve University, Cleveland, OH, [3]Cleveland Clinic / Department of Rheumatic and Immunologic Diseases, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Vasculitis as an immune-related adverse event (irAE) from checkpoint inhibitor therapy (ICI) to treat cancer is a rare clinical event, and little is known regarding its nosology, clinical manifestations, or response to treatment and outcomes. In an attempt to address these gaps, we used the Preferred Reporting Items for Systemic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR) framework to further define this complication.

Methods: Two independent PUBMED searches in September and November of 2022 revealed 127 publications with 37 excluded from title by relevance, 43 excluded by article type, and 23 excluded due to lack of biopsy results, or biopsy negative for vasculitis. Twenty nine documented cases from 24 publications were included for final analysis. Basic demographics, ICI details, timing of onset of vasculitis symptoms, irAE treatment and outcomes were collected. The vasculitides were classified using 2022 ACR/EULAR Vasculitis Classification Criteria as well as 2012 Revised Chapel-Hill Nomenclature. Naidoo et al 2023 consensus definitions for irAEs were used for early versus delayed irAEs, and efforts were made to classify steroid-responsive versus unresponsive irAEs.

Results: Of the 29 cases reviewed, the average age of patients was 62.1±11.0, composed of 58.6% (17) male and 41.3% (12) female. Prominent cancer types were lung cancer (41.4%; n=12), melanoma (41.4%; n=12), and renal cancer (10.3%; n=3), with vast majority being stage 4 (75.9%, n=22) and Stage 3 (10.3%, n=3). Only 8 cases met the ACR/EULAR criteria, and by Chapel-Hill Nomenclature, approximately a third were small-vessel vasculitis (31.0%; n=9) with n=4 positive for ANCA. Most biopsies were taken from the skin (37.9%, n=11) and kidney (24.1%, n=7). Patients were either treated with single (65.5%, n=19), dual (17.2%; n=5), or sequential (17.2%; n=5) ICI regimen which included anti-PD-1 therapy in all but one case, with mean of 8.7 ± 10.5cycles received. Mean time to onset of symptoms from start ofICI was 7.2 ± 7.8 months, with delayed irAE (>3 months of initial immunotherapy) occurring in 55.2% of cases. Treatment most commonly included glucocorticoids in 96% of cases and immunotherapy was often discontinued (44.8%; n=13). Clinical improvement of irAE was documented in 86.2% (n=25). Data were missing in terms of fate of ICI (34.5%; n=10) and tumor outcomes (41.4%; n=12). Cancer progressed in 20.7% (n=6),stable in 34.5% (n=10) cases, and 6 patients died of all-causes.

Conclusion: Vasculitis as an irAE appears clinically heterogeneous and rare. Among reported cases with adequate documentation, vasculitis is of delayed onset following the initiation of immunotherapy. Outcomes of ICI-vasculitis were generally favorable, responding to glucocorticoids and immunotherapy withdrawal. There is an urgent need for more standardized reporting of rare irAEs such as vasculitis to clarify clinical risks,classification, relationship to immunotherapy and outcomes.

CAII	35.7% (10)	27.4% (66)	ns	15%

Background/Purpose: Autoimmune retinopathy (AIR) is a disease process in which circulating autoantibodies (AAbs) against retina-specific antigens cause local inflammation and can lead to blindness. Hydroxychloroquine (HCQ), likewise, can cause retinal toxicity, typically in a dose-dependent manner, for which routine screening is recommended in systemic lupus erythematosus (SLE) patients. AIR has been reported in patients with SLE but the frequency of antiretinal AAbs in SLE patients is not well described. Furthermore, the role of antiretinal AAbs in HCQ related eye toxicity has not been described. The objective of this study is to determine whether patients diagnosed with HCQ retinal toxicity are more likely to have circulating antiretinal AAbs compared to controls.

Methods: This study was conducted at two academic institutions within the United States. Patients in this study were enrolled in a longitudinal cohort study of cardiovascular risk factors. We performed antiretinal AAbs testing on 269 SLE plasma samples collected at baseline. We retrospectively reviewed charts of these patients for the presence of HCQ retinal toxicity, as well as the baseline presence of risk factors for HCQ toxicity. Our primary goal was to determine frequency of specific antiretinal AAbs in SLE patients with HCQ retinal toxicity compared to SLE patients without retinal toxicity.

Results: Patients with a diagnosis of HCQ retinal toxicity had a higher likelihood of testing positive for anti-arrestin AAbs (60.7% of patients vs. 30.7% of patients, p=0.001) and PKM2 antibodies (46.4% of patients vs. 28.2% of patients, p=0.047) compared to patients without a diagnosis of retinal toxicity (see table 1). Patients with a history of HCQ eye toxicity also had a trend towards a higher number of AAbs, with a mean of 2.96 ± 2.40 vs. 2.05 ± 1.74 in the group with no history of toxicity. In multivariate analysis accounting for risk factors associated for HCQ eye toxicity, including renal disease, BMI, average HCQ dose per year of disease duration, and disease severity using the Lupus Severity Index (LSI), we found that the presence of arrestin AAbs was associated with OR 3.2 for developing HCQ eye toxicity.

Conclusion: Antiretinal AAbs, especially arrestin and PKM2, were more common in SLE patients with HCQ retinal toxicity compared to patients without HCQ retinal toxicity. The pathogenesis and clinical significance of these autoantibodies is not clear. However, even when controlling for other risk factors associated with HCQ eye toxicity, anti-arrestin AAbs were associated with increased odds for the development of eye toxicity, suggesting a potential role for antiretinal AAbs as a biomarker of HCQ eye toxicity risk. Further prospective studies are needed to evaluate the risk of developing HCQ retinal toxicity in patients with known circulating antiretinal AAbs.

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) have revolutionized cancer therapy. Their use is complicated by development of immune-related adverse effects (irAEs), including rheumatic irAEs (Rh-irAE). Aging is known to be associated with an increase in chronic inflammation, likely driven by age-related changes in inflammatory networks and proinflammatory pathways, referred to as "inflammaging". Older age has been implicated with the development of more frequent and severe irAEs. In this study, we aim to examine whether older patients with Rh-irAEs develop more severe Rh-irAEs or greater number of irAEs compared to younger patients.

Table 1: Baseline characteristics of patient cohort

Characteristics	Younger Group < 65 years (n = 58)	Older Group ≥ 65 years (n = 81)
Age median (range)	58.5	72
Sex (% female)	30 (52%)	31 (38%)
Cancer Type, n (%)

ICI = immune checkpoint inhibitor

Methods: Adults who develop new Rh-irAEs after ICI exposure are prospectively followed at 9 academic sites across Canada as part of the CanRIO prospective cohort. We compared the severity and number of irAE between patients ≥65 years and < 65 years, using logistic regression and Poisson regression, respectively. As part of secondary analysis, we compared the immunosuppression and cancer treatment received in both groups.

Table 2: Characteristics of Rh-irAE stratified by age

• 1 to 2	15 (88%)	11 (73%)	
• 3 to 4	2 (12%)	4 (26%)	

a. Three people in each of the younger and older group have 2 Rh-irAEs each. b. Eleven people from the younger group and 10 people from the older group have ≥2 non-Rh-irAEs each. IrAE = immune-related adverse event; Rh-irAE = rheumatic immune-related adverse event; Ir = immune-related; CTCAE = Common Terminology Criteria for Adverse Events; ICI = immune checkpoint inhibitor

Results: 139 Patients with de novo Rh-irAEs recruited between Jan 2020 and March 2023 were included, 58 in the "younger" (< 65 years) and 81 in the "older" (≥65 years) group (Table 1).There was no significant difference in severity of Rh-irAE (p =0.86) or number of irAEs in each group (p = 0.283) (Table 2). Treatment of irAEs was similar between the two groups, with most patients receiving prednisone monotherapy, conventional synthetic DMARD (csDMARD) monotherapy, or combinations of prednisone/csDMARDs. Biologic DMARDs were infrequently used in both groups. ICI use was similar in both groups. There was a trend towards more severe joint-related Rh-irAEs in the younger group (32% vs 24%, p-value = 0.400), and more severe non-joint related Rh-irAEs (12% vs. 26%, p-value = 0.292) in the older group.

Conclusion: There is growing literature on the role of aging and autoimmunity, but limited data on the relationship between aging and autoimmune reactions, especially after exposure to ICI. In this prospective cohort study, we found similar numbers of overall irAE and severity of Rh-irAE in older and younger patients and similar treatment in both groups. As the role of immunotherapy continues to expand, further investigations in this area can provide insight on whether age-related changes in the immune system influence the development, severity, and clinical course of irAE, which may impact patient counselling and underlying cancer therapy.

Abstract Number: 1064

Seroconversion Rates in Rituximab-Treated Rheumatic Patients Receiving COVID-19 Vaccination

Ryan Wilson[1], Junaid Awan[2], Mary Brady[2], Ciara Hunt[2], Fahd Adeeb[3] and alexander fraser[4], [1]University of Limerick, Buncrana, Ireland, [2]University of Limerick, Limerick, Ireland, [3]RCSI & UCD (Ireland) Malaysia Campus (RUMC), Malaysia, Malaysia, [4]HSE, Limerick, Ireland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

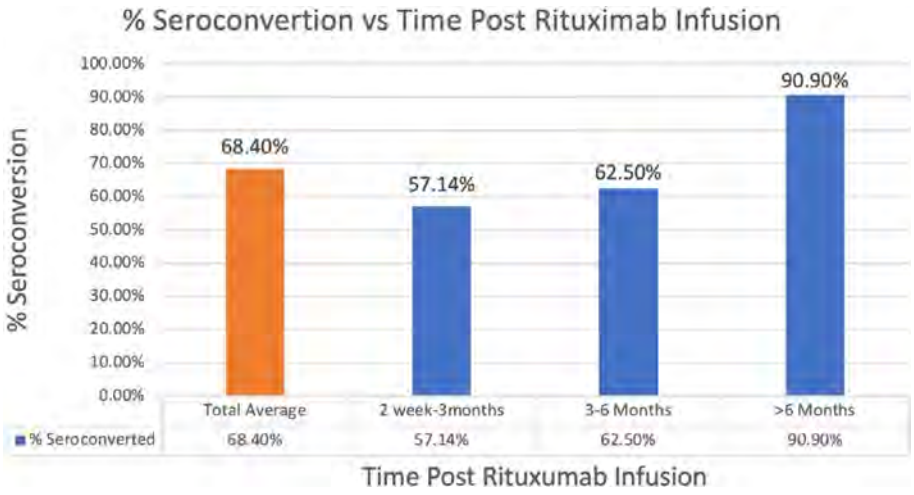
Background/Purpose: COVID-19 has increased the mortality rates among rheumatic patients, mainly those immunocompromised or with underlying comorbidities. During the COVID-19 vaccine development, patients on immunomodulatory drugs such as rituximab (RTX) were excluded from the trials due to their “high risk” categorization.

Aim: Assess the seroconversion rate of RTX-treated rheumatic patients on the COVID-19 vaccine.

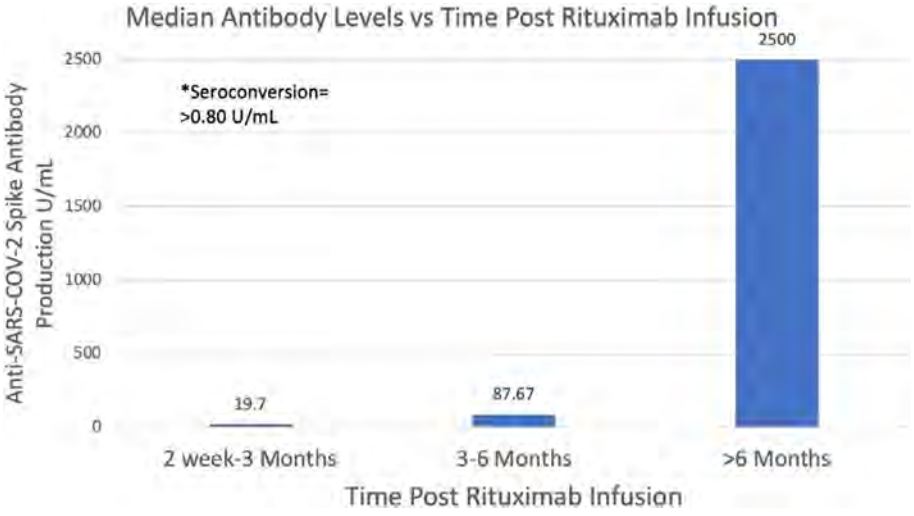
Methods: An observational cohort study on adult patients with various established inflammatory rheumatic diseases at UL Hospitals Group, Limerick receiving ≥2 COVID-19 vaccination and on scheduled RTX infusion (received ≥1 dose). Patients were stratified based on time post-immunization (< 1 month, 1-3 months, 3-6 months, and >6 months post-vaccination).

Samples (taken ≥14 days after the latest vaccination) were analyzed using the Elecsys anti-SARS-CoV-2 immunoassay for in vitro qualitative detection of IgG antibodies to SARS-COV-2, and screened for quantitative detection of anti-SARS-COV-2 nucleocapsid antigen (for previous COVID-19 infection) and anti-SARS-COV-2 spike protein (for immune response to the vaccine). The control group included patients on anti-TNF and tocilizumab (TOC). Seroconversion in response to the SARs-COV-2 is determined at >0.80 U/mL based on the manufacturer's guidelines.

Results: 49 patients were included (38 on RTX, 8 anti-TNFs, 3 TOC). Seroconversion rates were higher in the 1-3-month (75%) and 3-6-month (77%) RTX timelines; however, rates at 1 and 6 months were equal (60%) indicating antibody waning over this time period may not be significant in affecting seroconversion rates (levels remained ≥0.80 U/mL threshold). Whilst average seroconversion for the entire RTX cohort is 68.4%, the highest rates were seen in patients with a 6-month gap (90.9%). The lowest rates were seen in patients receiving immunization in the 2 week-3 months following RTX (57.14%), while the 3-6 months group showed slight improvement (62.5%). The patient population receiving anti-TNFs and TOC showed a 100% seroconversion rate.



Analysis of rates of seroconversion in rituximab patients from the time of infusion to vaccination.



Analysis of median antibody levels in rituximab patients from the time of infusion to vaccination.

Conclusion: Our data shows that a third of RTX patients treated didn't achieve seroconversion following immunization against SARS-COV-2 while the highest rates were seen in patients who had a 6-month gap. This data suggests benefit for delaying RTX infusion greater than the standard 6-month interval in suitable patients, prior to vaccination, to allow patients to reach adequate seroconversion against COVID-19 before reinitiating treatment.

	No	286 (61.5)	368 (79.3)		654 (70.4)

Table 3. Admission-associated variables. G1 (prior to admission DMARD use), G2 (no prior to admission DMARD use).

Results: In total, 929 pts were included; 44.8% were female, and 55.2%, male. Most were Caucasian(93.6%); 4.0% were Black, 0.9% Asian. Most were non-Hispanic (91.2%). Mean age was 61.6(standard deviation(s) 12.5). G1 composed 50.1% and G2 49.9%. No differences existed between groups(grps) when age (p 0.928), sex (p 0.671), race (p 0.140) or ethnicity (p 0.118) were compared. Mean BMI was 34.4 (s 9.1); greater in G1(35.1(s 9.2)) than G2(33.8 (s 8.9)) (p 0.025). Smoking history was seen in 49.9%; of these, 86.0% were former smokers and 14.0% were current smokers. Never-smokers composed 49.2% and 0.9% had unknown smoking status. G1 had more never-smokers (51.6%) than G2 (46.8%); G1 had fewer current smokers (4.7%) than G2(9.3%) (p 0.037). Prevalence of chronic kidney disease (21.4%, p 0.237), diabetes (37.2% , p 0.665), hypertension (48.2%, p 0.578), and heart failure (12.1%, p 0.155) were similar between grps. Chronic lung disease(CLD) in 12.5%; more G2 pts had CLD(15.5%) than G1(9.5%) (p 0.005). Mean Charlson Comorbidity Index (CCI) was 3.9(s 3.2) and was similar between grps (p 0.357). Mean hospital stay length(HSL): 14.8 days(s 13.9); HSL was longer in G1(17.4(s 16.7)) than G2(12.2 (s 9.6)) p< 0.001. ICU admission occurred in 50.7%; mean duration of ICU stay: 12.0 days(s 10.2); mean admission-to-ICU(ATI) interval: 67.2 hours(s 96.5). G1 had more ICU admissions (67.3% vs 34.1%, p< 0.001), and longer ICU stays (12.7 days, s 10.3) than G2 (10.7, s 10.0), p 0.0413; the ATI was similar between grps(p 0.231). Intubation and mechanical ventilation (IMV) occurred in 33.8%; more G1 pts had IMV(47.5%) than G2(20.0%), p< 0.001. Mean admission-to-ventilation interval(IAV) was 115.6 hours(s 124.5) and was similar between grps(p 0.911). Mean vent duration was 13.3 days (s 15.7) and was similar between grps(p 0.299). Non-invasive ventilation(NIV) occurred in 53.3%; more G1 pts (70.1%) received NIV than G2(36.4%), p< 0.001. Mean admission-to-NIV duration was 70.7 hours(s 118.9) and was similar between grps(p 0.322). Mean admission respiratory rate(RR) was 23.3 (s 6.6), and similar between grps (p 0.385). Mean RR during admission was 21.8(s 3.3); G1 was greater (22.6, s 3.4) than G2(21.0, s 3.0), p< 0.001. Mean maximum RR was 38.5(s 14.6); G1 was greater (40.5, s 13.2). than G2(36.5, s 15.6), p< 0.001. In-hospital mortality occurred in 29.6%. G1 was greater (38.5%) than G2 (20.7%); p< 0.001

Conclusion: Comorbidity burden was similar between grps. Although more G2 pts had CLD, G1 pts had worse respiratory outcomes including greater RR, longer HSL, greater IMV and NIV, and overall greater mortality. Our study suggests that BA DMARD exposure may predispose to worse respiratory outcomes and survival outcomes in pts hospitalized with C19 and this subset of pts may require closer monitoring when hospitalized.

Abstract Number: 1066

Biologic Drug and Anti-Drug Antibody Monitoring: All 5 TNF-Inhibitors, Infliximab, Adalimumab, Golimumab, Etanercept, Certolizumab Pegol, in 63,930 Patient Samples

Kelly Chun and Jane Yang, Labcorp, Calabasas, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic therapeutic drug monitoring (TDM) of TNF-inhibitor drug and anti-drug antibody provides patient-specific pharmacokinetic and immunogenic assessment. In suboptimal response, drug and anti-drug antibody concentrations discern the underlying mechanism of failure as: 1) *Pharmacokinetic Insufficiency*, not enough drug (low drug) 2)

Mechanistic Mismatch, wrong type of drug (as evidenced by sufficiently high drug) or 3) *immunogenicity* (anti-drug antibodies) As such, biologic TDM informs the very different medication decisions of whether to increase the same biologic or to switch drug, in- or out-of class.

Methods: Drug (in µg/mL) and anti-drug antibody (in ng/mL) were measured by lab developed chemiluminescent immunoassays (Table 1). Of note, all drug assays measure the antibody-unbound fraction of drug when serum anti-drug antibodies are present. All anti-drug antibody assays are drug-tolerant and drug-specific as verified by a confirmatory test. Blood

Table 1. Biologic TNF-Inhibitor Drug and Anti-Drug Antibody Assays: Performance Characteristics and Interpretation

Table 1: Biologic Anti-TNF Drug and Anti-Drug Antibody Assays: Performance and Interpretation

Performance of Biologic Drug Assays					
	IFX	**ADL**	**GOL**	**CTZ**	**ETN**
Assay Sensitivity LLOQ (µg/mL)	0.4	0.6	0.5	1.0	0.2
Inter-Assay Precision %CV	<8.5	<7.1	<7.4	<8.0	<13.8
Inter-Assay Accuracy % Bias	<4.9	<9.5	<6.8	<8.3	<13.7
Interpretive Comment	This drug assays measures the antibody-unbound fraction of drug that is pharmacodynamically active when anti-drug antibodies are present in serum.				
Performance of Anti-Drug Antibody Assays					
	Anti-IFX	**Anti-ADL**	**Anti-GOL**	**Anti-CTZ**	**Anti-ETN**
Assay Sensitivity LLOQ (ng/mL)	22	25	20	40	75
Inter-Assay Precision %CV	<9.7	<11.5	<5.9	<8.4	<9.5
Inter-Assay Accuracy % Bias	<4.1	<7.9	<8.1	<10.7	<14.3
Inverse Relationship with Drug?	Yes	Yes	Likely	Yes	No
Observed Immunogenicity Rate	45.2%	39.4%	4.4%	67.6%	72.3%
Proposed Titer Designation Cut-points	Low: <200 High: >1000	Low: <100 High: >800	Insufficient data to determine	Low: <1000 High: >5000	Low: <1000 High: >1000 *But no inverse relationship
Interpretive Comments	Anti-drug antibody levels should be interpreted in the context of the concomitant trough free drug concentration. Low titer anti-drug antibodies may be transient while high titers are likely to be more consequential.				
	Some immunogenicity is reversible. Elimination of intermediate titer some high titer Abs has been achieved with dose escalation and/or methotrexate or thiopurine.		Mean GOL with low (<50) or high (>50) anti-GOL were 0.51 and 0.36, respectively.	Non-neutralizing anti-pegol Abs cannot be ruled out.	Mean ETN with low (<1000) or high (>1000) anti-ETN were 2.11 and 1.97, respectively.

Figure 1: Distribution of Drug Concentrations in Anti-Drug Antibody-Negative Samples

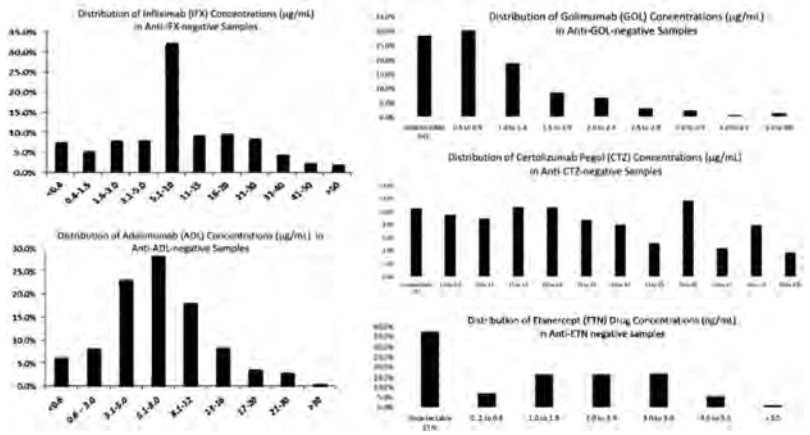

Figure 1. Distribution of Biologic Drug Concentrations in Anti-Drug Antibody-Negative Samples

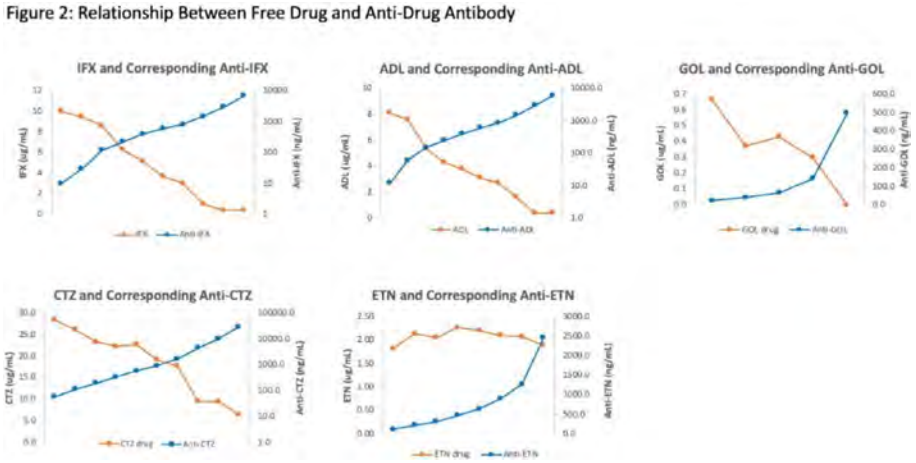

Figure 2. The Relationship between Biologic Drug and Anti-Drug Antibody Concentrations

collection just prior to next infusion/injection is recommended because target ranges have been set by studies using trough concentrations.

Results: Serum samples from 37,165, 22,412, 1032, 2587, and 734 patients were analyzed for IFX, ADL, GOL, CTZ or ETN and corresponding anti-drug antibodies. Distribution of drug levels (Figure 1) demonstrates that even in the absence of immunogenicity, many patients may be subtherapeutic when using reasonable, if not well-established, therapeutic targets of 3 for IFX, 5 for ADL, 3 for GOL, 20 for CTZ, and 3 for ETN. Immunogenicity rates were 45.2%, 39.4%, 4.4%, 67.6% and 72.3% for IFX, ADL, GOL, CTZ and ETN, respectively (Table 1). High immunogenicity of ETN and CTZ may be explained by their uniqueness as fusion and pegylated molecules, respectively. Figure 2 demonstrates the relationship between free drug and anti-drug antibody. Analysis of this inverse relationship yielded cut-points for titer designations of low, intermediate, and high for anti-IFX, anti-ADL, and anti-CTZ (Table 1). Of note, ETN alone lacked this inverse relationship. Anti-ETN, even in high titer, had no effect on concomitant ETN. Anti-CTZ were the highest numerically, but many may be non-neutralizing antibodies against pegol where only >5000 appears to be impactful. As a good rule, anti-drug antibodies should be interpreted in the context of the concomitant free drug trough concentration.

Conclusion: Here, we report TNF-inhibitor and their anti-drug antibody levels in >60,000 patients. Though clinical histories and blood collection timing are not known, Figure 1 showed that many patients may have insufficient drug levels. Observed immunogenicity rates to IFX, ADL, CTZ and ETN were high and all anti-drug antibodies except anti-ETN adversely affect free drug levels. Numeric antibody results should be interpreted with the help of titer designations (low/high) by the laboratory because low titer antibodies have less impact on drug levels and may be transient or reversible whereas high titers with nil or very low drug indicate refractory immunogenicity. In this way, biologic TDM elucidates the mechanism of suboptimal response and should be used to optimize drug efficacy and longevity by informing and expediting adjustments to medication.

A Comparison of Joint Involvement Patterns in Immune Checkpoint Inhibitor-Induced Inflammatory Arthritis and Rheumatoid Arthritis

Carlos Aude[1], Deanna Jannat-Khah[2], Karmela Kim Chan[2], Nilasha Ghosh[1], Clifton Bingham[3], Vivian Bykerk[2] and Anne Bass[1], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [2]Hospital For Special Surgery, New York, NY, [3]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have transformed cancer treatment but may trigger immune-related adverse events (irAEs) such as ICI-induced inflammatory arthritis (ICI-IA). Although ICI-IA and rheumatoid arthritis (RA) exhibit clinical similarities, it remains uncertain if ICI-IA represents an early form of RA or a distinct disease. Our study aimed to elucidate their relationship by comparing joint involvement patterns in patients with ICI-IA and early RA.

Table 1. Demographic and Clinical Characteristics of Early RA and ICI-IA Patients

Characteristic	Early RA n=163[1]	ICI-IA n=89[1]	p-value[2]
Age	43.8 (33.5 - 56.4)	67.9 (60.7 - 77.0)	**<0.001**

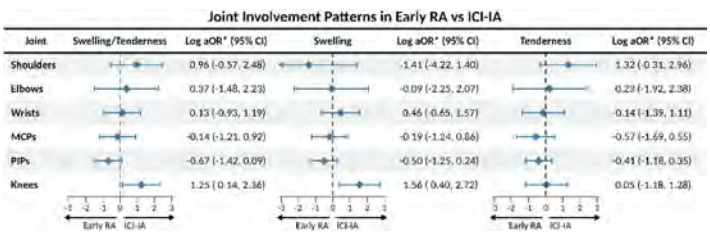

Figure 1. Forest Plot and Log Adjusted Odds Ratios (aOR) with 95% Confidence Intervals for Joint Swelling and Tenderness Comparing Early RA and ICI-IA Patients (*Adjusted for demographics, BMI, seropositivity, steroid use, DMARD use, and time from arthritis onset to study inclusion)

Methods: Clinical data from 89 ICI-IA patients in our institutional rheumatic irAE registry and 163 early RA patients from the Consortium of early ArThritis CoHorts-USA (CATCH-US) cohort were analyzed. Rheumatologists recorded the Swollen and Tender Joint Counts (SJC, TJC) at the patients' baseline visit. A multivariable logistic regression model was first utilized to identify variables associated with specific joint swelling and/or tenderness in the ICI-IA cohort. Separately, we compared the overall joint involvement pattern of ICI-IA and early RA using Fisher's exact test, while SJC, TJC, and joint symmetry were compared using multivariable linear and logistic regressions, correspondingly. Specific joint comparisons were compared with multivariable logistic regression models. All models were adjusted for demographics, BMI, seropositivity, steroid use, DMARD use, and time from symptom onset to study inclusion; ICI-IA-exclusive models were additionally adjusted for cancer type, ICI regimen, and time from ICI initiation to study inclusion.

Results: ICI-IA patients were older, more likely to be male, and less frequently seropositive than early RA patients (Table 1). In the ICI-IA-exclusive analysis, female patients exhibited a higher probability of knee tenderness (aOR=9.02, p=0.03) and a lower probability of PIP swelling (aOR=0.11, p=0.005) relative to male patients. Additionally, younger patients showed an increased likelihood of knee swelling (aOR=0.93, p=0.03) compared to their older counterparts. Notably, no other variables, including the ICI treatment regimen, were associated with specific joint involvement among ICI-IA patients. Comparative analysis between ICI-IA and early RA patients revealed higher odds of symmetrical swelling in early RA (aOR=2.44, p=0.02), despite no substantial differences in either SJC or TJC. There was a significant difference in the overall swollen joint distribution between the two cohorts (p=0.008), particularly with regard to PIP (45% vs. 60%, p=0.02) and knee involvement (54% vs. 27%, p=0.03) (Table 2). After adjusting for confounding variables, ICI-IA patients continued to exhibit higher odds of knee swelling (aOR=4.76, p=0.007), though PIP involvement did not significantly differ (p=0.08) (Figure 1). A subanalysis comparing ICI-IA and seronegative early RA patients yielded similar results.

Conclusion: We demonstrated distinct joint involvement patterns between ICI-IA and early RA patients, with more frequent knee swelling in ICI-IA and more PIP and symmetrical joint involvement in early RA. These results could inform the development of ICI-IA classification criteria, thereby enhancing differential diagnosis and treatment strategies.

Multidisciplinary Prospective Study of Patients Treated with Immune Checkpoint Inhibitors Who Developed Rheumatic Immune-related Adverse Events

Mª Carmen López-González[1], Natividad Martínez Banaclocha[2], Montserrat García Araque[2], Yoel Montoyo Pujol[2] and Mariano Andrés[3], [1]General University Hospital Dr. Balmis, Alacante, Spain, [2]General University Hospital Dr. Balmis, Alicante, Spain, [3]Dr Balmis Alicante General University Hospital-ISABIAL, Alicante, Spain

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs), by activating the immune system (specifically, T-cells), foster the reaction against tumor cells. However, parallelly, autoimmune phenomena, known as immune- related adverse effects (ir-AEs) (PMID 33902919, 29442540), can be triggered and manifest in any organ or tissue. The most common rheumatic manifestations are inflammatory arthritis, polymyalgia rheumatica, and myositis, but other inflammatory cases have also been described (PMID 32403289). More data on their frequency and characterization are needed.

Our objective was to prospectively evaluate the incidence of rheumatic ir-AEs during ICIs treatment, along with clinical characterization, management required, and outcomes.

Methods: An observational, prospective study was conducted at a tertiary center in Spain, led by the oncology department with the participation of several specialties, to evaluate the occurrence of ir-AEs in patients starting ICIs between January 2019 and April 2022. Participants were routinely followed at oncology clinics to detect ir-AEs through pre-specified clinical and laboratory assessments. For rheumatic symptoms, ir-AEs were studied by records review and evaluated in person at rheumatology clinics for those with a degree of involvement of ≥2, according to the ASCO guidelines (3). The incidence - with a 95% confidence interval (CI) - and characterization of defined rheumatic ir- AEs are presented here.

Results: Of 181 patients, 21 (11.6%, 95%CI 7.7-17.1%) developed rheumatic ir-AEs, 13 men (61.9%) with a median age of 62.3 years (p25-75 51.8-75.0). The median time from the start of ICIs to the development of rheumatic ir-AEs was 85 days (p25-75 51.5-165).The incidence rate was 0.92 cases per 100 patient-months. Blood tests for autoimmunity were positive in 69.2% of available cases (9/13), but all at a low titer (table). According to ASCO guidelines, most patients had a toxicity grade 1-2, but 3 (14.3%) patients presented with severe manifestations (grade 3): 1 (4.8%) case of inflammatory arthritis, 1 (4.8%) of xerostomia, and 1 (4.8%) of Raynaud's phenomenon with ulcers. 9 (42.9%) patients also presented with concurrent ir-AEs of different types. Rheumatic ir-AEs were successfully settled, though infliximab and intravenous vasodilators were required for some cases. While discontinuing ICIs was mostly due to neoplasm progression (47.6%), in 3 cases (14.3%) it was due to grade-3 rheumatic manifestations. 7 (33.3%) patients died during follow-up due to the oncological disease, no case due to rheumatic toxicity.

Type of tumor n (%)	Drug n (%)	Clinical presentation (%)	Antibodies n (%)	Treatment n (%)	Outcome n (%)
Lung 9 (42.9)	Pembrolizumab 8 (38.1)	Inflammatory arthritis 7 (33.3)	ANA 8 (38.1)	No rheumatological treatment 10 (47.6)	Discontinuation of ICI due to progression 10 (47.6)
Melanoma 4 (19.0)	Nivolumab 7 (33.3)	Xerostomia 5 (23.8)	Anti-centromere 1 (4.8)	Glucocorticoids 8 (38.1)	Discontinuation of ICI due to severe ir-AEs 3 (14.3)
Hodgkin's lymphoma 2 (9.5)	Nivolumab + Ipilimumab 3 (14.3)	Polymyalgia-like syndrome 5 (23.8)	Rheumatoid factor 1 (4.8)	Hydroxychloroquine 3 (14.3)	ICI is currently ongoing 4 (19.0)
Kidney 2 (9.5)	Atezolizumab 3 (14.3)	Myositis 4 (19.0)	ACPA 1 (4.8)	Pilocarpine 2 (9.5)	Completed ICI regimen 2 (9.5)
Esophagus 1 (4.8)		Raynaud's phenomenon with ulcers 1 (4.8)	Anti-TIF1γ 1 (4.8)	NSAIDs 2 (9.5)	Lost to follow-up 1 (4.8)
Bladder 1 (4.8)				Infliximab 1 (4.8)	
Mesothelioma 1 (4.8)				Vasodilators 1 (4.8)	

Conclusion: In this prospective and multidisciplinary study, 11.6% of patients treated with ICIs developed rheumatic ir-AEs. We estimated an incidence rate of 0.92 cases per patient-month. The majority experienced mild or moderate involvements, although severe cases were also observed. Therefore, a coordinated approach with oncologists is essential for patients treated with ICIs who are at risk of developing rheumatic ir-AES.

Abstract Number: 1069

Exploring the Risk of Demyelination Associated with TNF Alpha Inhibitors: Analysis of the FDA Adverse Event Reporting System (FAERS)

Manush Sondhi[1], Rahul Vyas[2], Anuj Thakre[2] and Samina Hayat[1], [1]Louisiana State University, Shreveport, LA, [2]LSU Health Science Center, Shreveport, LA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

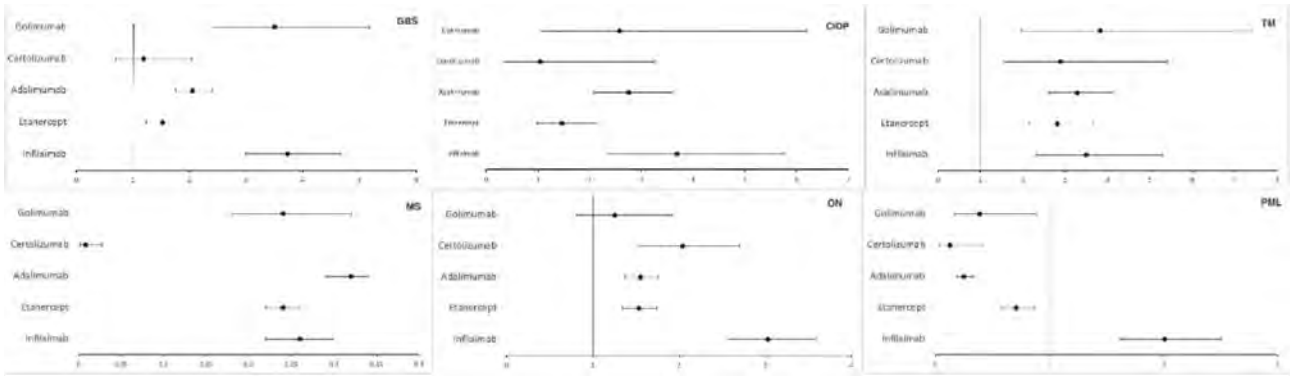
Background/Purpose: Tumor necrosis factor-alpha (TNF-α) inhibitors, a widely used class of biological immunomodulating agents targeting TNF-α, have revolutionized the treatment of various autoimmune and inflammatory conditions. However, emerging evidence suggests a potential association between TNF-α inhibitors and demyelination, a critical factor in the development and progression of neurological disorders. This abstract analyzes data from the FDA Adverse Event Reporting System (FAERS) and helps understand the potential risks underlying this association.

Methods: We performed a retrospective pharmacovigilance study that analyzed the FAERS database from 2009-2023 to investigate the association of demyelinating adverse events (AE), namely Guillain-Barre syndrome (GBS), chronic inflammatory demyelinating polyneuropathy (CIDP), transverse myelitis (TM), multiple sclerosis (MS), optic neuritis (ON), and progressive multifocal leukoencephalopathy (PML) in patients treated with FDA-approved TNF-α inhibitors (infliximab, adalimumab, etanercept, golimumab, and certolizumab). Disproportionality analysis was performed using reporting odds ratio (ROR).

Results: A total of 1,372,262 AEs were reported with TNF-α inhibitors, of which 170,109 were neurological AEs. Most AEs were among patients in the 18-64 age group (38-64%). The death rate was 4-7 % for all demyelinating categories except PML, in which the death rate was 18-22% with infliximab, etanercept, and adalimumab. GBS, CIDP, ON, and PML were

Table depicting the calculated RORs of various demyelinating adverse events associated with TNF-α inhibitors

Adverse Event	Infliximab	Etanercept	Adalimumab	Certolizumab	Golimumab
GBS	3.73(2.98-4.68)	1.52(1.24-1.85)	2.05(1.75-2.40)	1.19(0.69-2.05)	3.5(2.39-5.17)
CIDP	3.69(2.37-5.76)	1.46(0.98-2.15)	2.75(2.09-3.61)	1.04(0.33-3.25)	2.57(1.06-6.19)
TM	3.49(2.31-5.28)	2.81(2.16-3.66)	3.28(2.61-4.12)	2.89(1.55-5.39)	3.82(1.98-7.37)
MS	0.26(0.22-0.30)	0.24(0.22-0.26)	0.32(0.29-0.34)	0.008 (0.002-0.027)	0.24(0.18-0.32)
ON	3.03(2.56-3.58)	1.53(1.34-1.74)	1.55(1.37-1.75)	2.04(1.54-2.70)	1.25(0.81-1.92)
PML	2.01(1.62-2.50)	0.71(0.58-0.87)	0.25(0.19-0.34)	0.13(0.04-0.42)	0.39(0.17-0.88)



Forest plot depicting the association of demyelinating adverse events with TNF-α inhibitors

disproportionately associated with the use of infliximab with a ROR (95% CI) of 3.73 (2.98-4.68), 3.69 (2.37-5.76), 3.03 (2.56-3.58) and 2.01 (1.62-2.50) respectively. Golimumab had the highest reported association with TM, with a ROR of 3.82 (1.98-7.37). We observed a negative association of all TNF-α inhibitors with MS (ROR< 1).

Conclusion: Our study found that using certain biologic agents is associated with an increased risk of specific demyelinating disorders. While a temporal relationship between anti-TNF-α treatment and demyelinating events is suggested, the overall number of published cases is small compared to the total number of treated patients. In most cases, demyelination either progressed slowly or resolved after discontinuing anti-TNF-α therapy, indicating a potential protective effect or short-lasting harmful impact in patients already suffering from latent MS. Genetic predisposition and overlapping syndromes in autoimmune diseases also cast doubt on a direct relationship. We suggest a thorough neurological assessment of candidates considered for TNF-α blockers before initiation and periodically during treatment and avoiding the use in patients with a history or family history of demyelinating diseases. Limitations of the study include reporting bias, confounding of the observed associations, and the observational nature of the study that prevents establishing causal relationships. Further controlled studies, such as randomized clinical trials or prospective cohort studies, are needed to confirm our findings and establish causality.

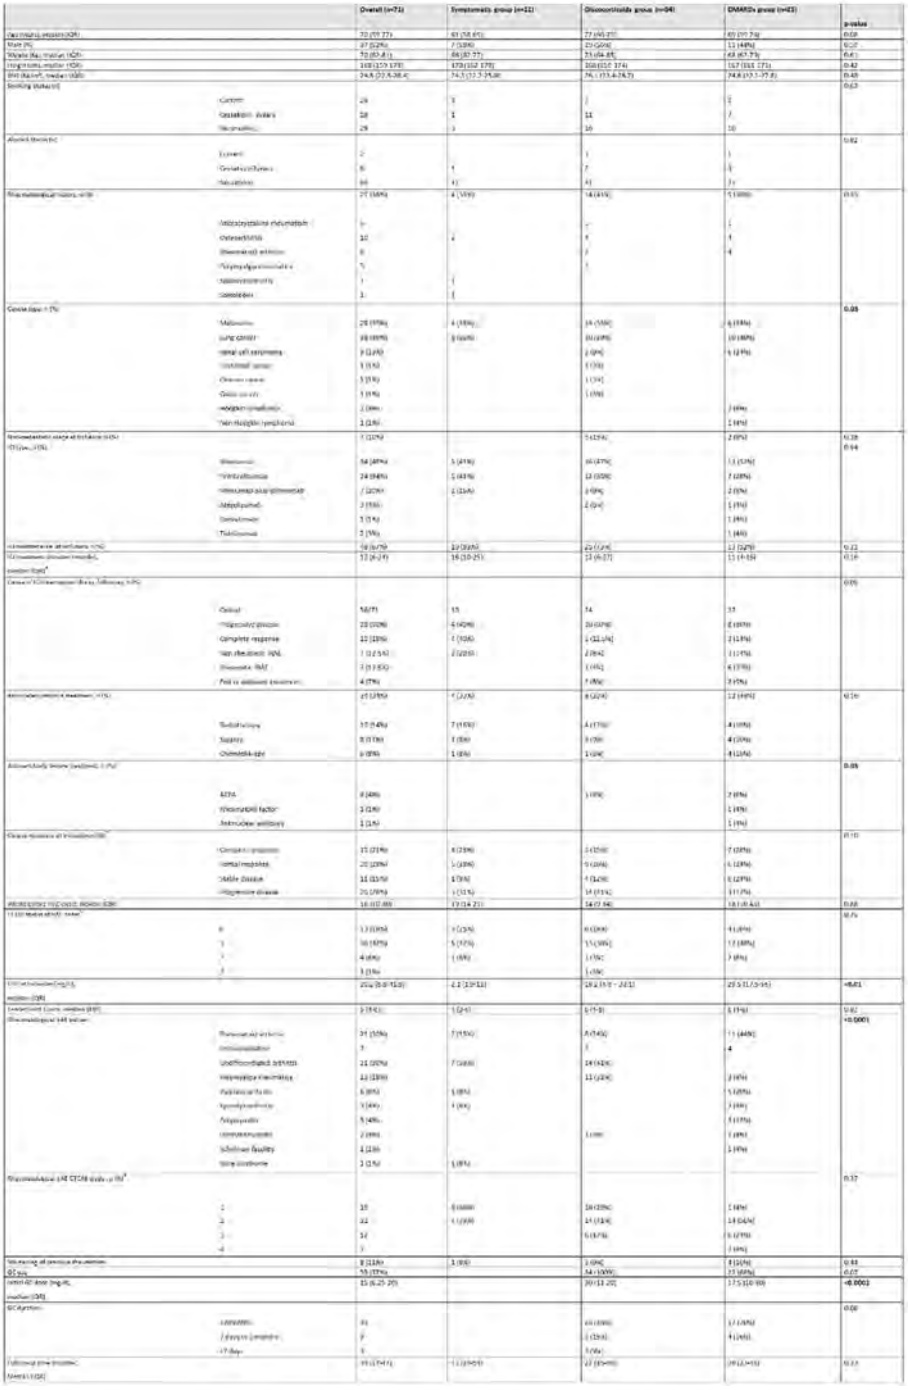
Safety of DMARDs in Rheumatologic Immune-related Adverse Events Associated with Immune Checkpoint Inhibitors: Data from a Monocentric Cohort in Hospices Civils De Lyon

Julien Seiller[1], Emmanuel Massy[2], Julien Peron[3] and Cyrille Confavreux[2], [1]Centre Expert des Métastases Osseuses (CEMOS) - Service de Rhumatologie, Centre Hospitalier Lyon-Sud, Hospices Civils de Lyon, Université de Lyon, Lyon, France, [2]Centre Expert des Métastases Osseuses (CEMOS) - Service de Rhumatologie, Centre Hospitalier Lyon-Sud, Hospices Civils de Lyon, Université de Lyon, INSERM UMR 1033-LYOS, Lyon, France, [3]Service d'oncologie médicale. Institut de Cancérologie des Hospices Civils de Lyon (IC-HCL), Université de Lyon, INSERM U1290, Lyon, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Since Immune Checkpoint Inhibitors (ICI) revolution, oncologists face immune-related adverse events (irAEs) including rheumatologic irAEs with inflammatory arthritis. Treatment of rheumatologic irAE can be challenging, using glucocorticosteroids (GC), conventional synthetic (cs-) or biological (b-) DMARDs without impeding ICI antitumoral efficiency. The objective of our study was to assess the safety of current rheumatologic irAE treatments.

Table 1 – Patients characteristics. a. 1 missing data. b. 5 missing data. c. 23 missing data. d. 6 missing data. Results are presented with median and interquartile range.



Methods: We conducted a monocentric retrospective observational study at the Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, Lyon, France. Eligible patients were adult patients treated with ICI presenting rheumatologic irAE. Patients with active inflammatory rheumatologic disease and who were not assessed by a rheumatologist were excluded. Data were obtained from medical charts using a standardized data collection. Kruskal-Wallis and Wilcoxon tests were used for comparing continuous variables. Fisher's exact test was used for comparison between categorical variables. Spearman coefficient was used for correlation test. Survival analysis was performed using Kaplan Meier method.

Results: Between July 2016 to October 2022, 71 patients were included **(Table 1)**. Patients were allocated to 3 groups regarding the treatment of their rheumatologic irAE: symptomatic group when treated with analgesics or NSAIDs (n=12), GC group when treated with systemic corticosteroids (n=34) and DMARD group when treated with csDMARD and/or bDMARD (n=25). Eighteen (72%) patients were treated with methotrexate. Ten patients were treated with bDMARD: 5 with infliximab (20%), 4 with tocilizumab (16%), 1 with etanercept (4%). No significant difference was found between different groups **(Figure 1)** regarding overall survival (OS, p=0.43), and progression free survival (PFS, p=0.46). We realized subset survival analysis including GC group, patients treated csDMARD alone (n=15) and patients treated with csDMARD and/or bDMARD (n=10), with no difference for OS and PFS. However, OS was positively correlated with time between irAE and bDMARD onset (R=0.88, p< 0.0001) unlike other groups. Based on this result, we compared patients treated with early

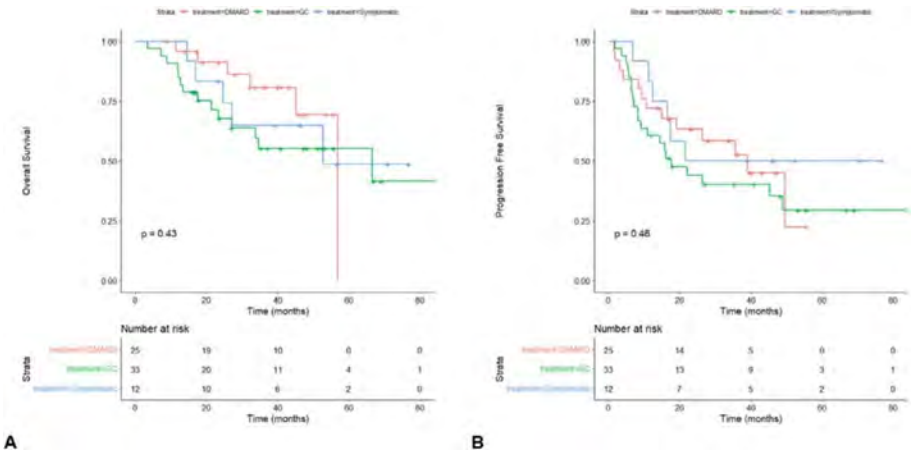


Figure 1 – Kaplan-Meier plots for A. Overall Survival and B. Progression Free Survival for types of rheumatological IRAE treatment. Corresponding risk tables are outlined below the plots.

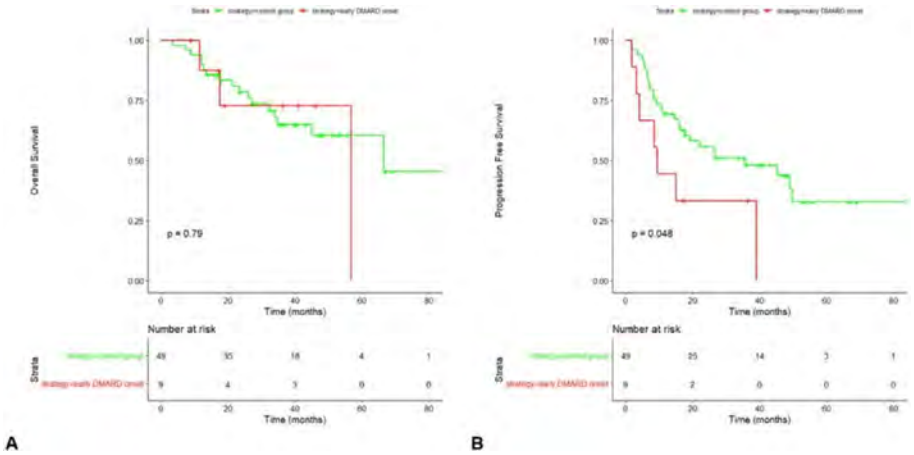

Figure 2 – Kaplan-Meier plots for A. Overall Survival and B. Progression Free Survival between early DMARD onset (<6 weeks) and control group. Corresponding risk tables are outlined below the plots.

DMARD onset (< 6 weeks after irAE onset, n=9) with a control group composed of patients with later DMARD onset after irAE and patients treated with GC (n=50). Patients in early DMARD group were mostly treated with csDMARD: 5 with methotrexate, 2 with immunoglobulins, 1 with hydroxychlororquine. One patient was treated with tocilizumab alone. Survival analysis realized between early DMARD group and control group **(Figure 2)** did not show significant difference for overall survival (p=0.79), but progression free survival was lower in early DMARD group than in control group (p=0.048).

Conclusion: Our data support concerns previously raised about cancer progression in irAE treated with bDMARD and suggest precautions for using DMARD during the first 6 weeks after rheumatologic irAE onset.

No Increase in Mortality in US Veterans with Rheumatoid Arthritis Treated with Immune Checkpoint Inhibitors (ICIs)

Madeline O'Sullivan[1], Grant Cannon[1], Brian Sauer[2], Jorge Rojas Jr[3], Gary Kunkel[4], Jessica A Walsh[5], Punyasha Roul[6], Bryant England[6], Ted R Mikuls[7], Joshua Baker[8] and Tawnie Braaten[4], [1]University of Utah and Salt Lake City VA, Salt Lake City, UT, [2]Salt Lake City VA/University of Utah, Salt Lake City, UT, [3]Puget Sound VA and University of Utah, Seattle, WA, [4]University of Utah, Salt Lake City, UT, [5]Salt Lake City Veterans Affairs Health and University of Utah Health, Division of Rheumatology, Salt Lake City, UT, [6]University of Nebraska Medical Center, Omaha, NE, [7]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE, [8]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are used to treat multiple cancers with increasing frequency and have led to improved survival. However, there is limited data on the use of ICIs in patients with pre-existing autoimmune disease, specifically rheumatoid arthritis (RA), as these patients were excluded from most clinical trials. There is concern that RA patients may experience higher mortality with ICI treatment. The objective of this investigation was to compare all-cause and cause-specific mortality following ICI treatment in patients with and without pre-existing RA in the Veterans Health Administration (VHA).

Methods: This analysis employed data from the VHA Corporate Data Warehouse (CDW) for demographic and pharmacy information, VA Central Cancer Registry for cancer diagnosis, Death Ascertainment File (DAF) for all-cause mortality rates, and National Death Index (NDI) for cause of death. We identified Veterans with RA in the VHA with two ICD codes at least 30 days apart, at least one ICD code from a rheumatologist, and treatment with a disease modifying anti-rheumatic drug. Each RA case was matched up to 10:1 based on year of birth, sex, and year of VHA enrollment to Veterans without RA. RA and non-RA patients receiving ICI therapy between 6/6/2011 and 2/14/2023 were identified.All-cause mortality up to 4/30/2023 was obtained from the DAF and cause specific mortality from NDI through 12/31/2019. Demographic, ICI treatment, and cancer type were compared using student t-test or Chi square. Survival from the time of ICI initiation was evaluated using Kaplan-Meier curves and log rank testing.

Results: The cohort of Veterans with RA included 73,677 patients matched to 727,627 controls. There were 301 (0.41%) among the RA patients and 2,114 (0.29%) among the non-RA controls treated with an ICI. There were no differences in demographics, smoking status, first ICI drug, or cancer diagnosis between these groups at the time of initial ICI infusion

(Table 1). The Veterans were majority white, non-Hispanic, male, and current or former smokers. Lung cancer was the most common malignancy type and pembrolizumab was used most frequently as the first ICI in both groups. Both groups had high mortality with one-year survival 51.2% [45.2% - 56.7%] vs. 54.5% [45.3% - 56.7%] and two-year survival 35.0% [29.3% - 40.7%] vs. 37.5% [35.2% - 39.7%] in the RA and non-RA groups, respectively. There was no significant survival difference between the groups (p=0.29)(Figure 1). The NDI cause of death was similar in both groups (p=0.96) with the most common being neoplasm in 91.9% and 91.2% of patients, respectively (Table 2). Deaths due to infection were rare in both groups (1.2%).

Figure 1. Kaplan-Meier Survival Analysis After First ICI Infusion

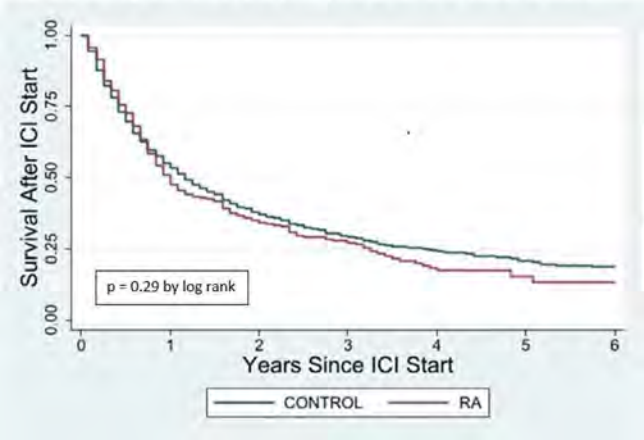

Figure 1. Kaplan-Meier survival analysis after first ICI infusion

Conclusion: Veterans with pre-existing RA who received ICIs for cancer did not experience excess mortality or differences in cause of death compared to Veterans without RA receiving ICI treatment. These preliminary data suggest that a diagnosis of RA alone should not serve as a contraindication to ICI therapy in the context of comorbid cancer.

Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) have revolutionized the treatment of cancer. Despite their efficacy on tumor outcomes they can cause severe and sometimes long-standing immune-related adverse events (irAE). Enhanced immune activation from ICI can conceivably induce expression of the receptor activator of nuclear factor kappa-B ligand (RANK-L) resulting in osteoclast activation, bone loss and fracture. Our objective was to determine the incidence rates of major osteoporotic fractures (MOF) in patients with melanoma treated with ICI, before and after initiation of ICI treatment.

Methods: We analyzed 2011-2022 data from the Optum's de-identified Clinformatics® Data Mart Database (a large commercial healthcare claims dataset from the United States). We identified patients who received one or more ICI currently approved by the Food and Drug Administration (FDA), on at least one occasion. We excluded off-label drug regimens (e.g. non approved combinations). We required that patients have a minimum of 12 months of observable data before receiving the ICI therapy. We used International Classification of Diseases (ICD 9/10) diagnostic codes to identify a diagnosis of melanoma, and we also required a minimum of 90 days follow-up after ICI initiation. We identified MOF which included fractures of the hip, forearm, humerus or vertebrae using ICD 9/10 diagnostic codes. To define a fracture event, we required at least 2 codes for a fracture in the same anatomical site within 90 days. We compared MOF rates in the year before ICI initiation with rates in the year after initiation of ICI, using proportional hazard models with robust sandwich estimate of the covariance matrix to account for correlated outcomes between the pre- and post- ICI treatment periods in the same patient. Patients were censored at last follow-up or death.

Results: We identified 34,864 patients who had received ICI and had continuous enrollment of at least 12 months prior to ICI initiation. Of these, 3,362 had a diagnosis of melanoma and had a minimum of 90 days follow-up after treatment initiation. Of the 3,362 patients with melanoma, 2,143 (64%) were male, mean age was 67 years (SD:14), 2,315 received monotherapy, 176 received combination therapy, and 871 received both therapeutic regimens in sequence. Forty-eight (1.4%) patients had a fracture in the year before ICI initiation, and 57 (1.7%) had a fracture in the year after initiation of treatment. The hazard ratio (HR) for fracture over the year after versus the year before the first ICI dose was 1.69 [95% CI 1.14 – 2.41].

Conclusion: Our findings suggest that patients who receive ICI are at increased risk of MOF during the first year after receiving therapy. Further research is needed to determine whether there are additional risk modifiers, such as concomitant treatment with steroids for irAE or metastatic bone disease, and to develop strategies for risk reduction.

Risk of Inflammatory Central Nervous System Diseases Among New Users of Biologic and Targeted Synthetic Disease-Modifying Antirheumatic Drugs

Maximilian Casey[1], Sonia Pannu[2], Saffia Bajwa[3], Ali Duarte-Garcia[4] and Mike Putman[5], [1]Medical College of Wisconsin, Milwaukee, WI, [2]University School of Milwaukee, River Hills, WI, [3]Medical College of Wisconsin, Wauwatosa, WI, [4]Mayo Clinic, Rochester, MN, [5]Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory and demyelinating central nervous system (CNS) adverse events have been observed among new users of tumor necrosis factor (TNF) inhibitors. No studies to date have defined the risk of these adverse events after initiation of TNF inhibitors as compared to other biologic and synthetic disease-modifying antirheumatic drugs (b/tsDMARD).

Methods: Data were derived from the US-based TriNetX electronic health records database. Patients were included if they had a disease for which TNF inhibitors are indicated (rheumatoid arthritis, psoriasis, psoriatic arthritis, ankylosing spondylitis, Crohn's disease, ulcerative colitis) and received a b/tsDMARD with regulatory approval for one of those diseases. Inflammatory CNS events were identified using ICD9-CM/ICD10-CM codes and unadjusted incidences were calculated. The adjusted risk among new users of TNF inhibitors was compared to other b/tsDMARDs using weighted Cox proportional hazards models.

Table 1: Characteristics of Included Patients, n = 132,015

Patient Characteristics	**n (%)**
Age at Diagnosis, mean (SD)	51.6 (16.1)
Sex	-
Male	47,387 (35.9%)
Female	84,628 (64.1%)

Hispanic or Latino	8,748 (6.6%)
Asian	2,459 (1.9%)
Other / NA	12,824 (9.7%)
Years with Disease, mean (SD)	3.5 (4.3)
Admissions during Prior Year, mean (SD)	0.4 (1.7)
Comorbidities at Diagnosis	-
Charlson Comorbidity Index	0.8 (1.7)
Chronic Obstructive Pulmonary Disease	18,017 (13.6%)
Diabetes	16,448 (12.5%)
Obesity	15,397 (11.7%)
Renal Disease	8,416 (6.4%)
Liver Disease	8,302 (6.3%)
Congestive Heart Failure	5,271 (4.0%)
Autoimmune Disease	-

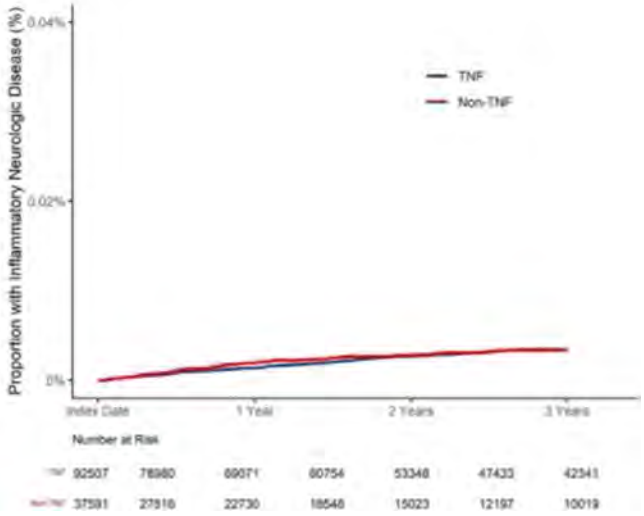
Results: Among 132,015 patients included in the analysis (84,628 female [64.1%]; mean age 51.6 [standard deviation{SD}, 16.1]), the most common first biologic agent was a TNF inhibitor (93,661, [70.9%]) followed by IL 12/23 inhibitor (7,949, [6.0%]) and Janus kinase inhibitors (6,900, [5.2%]). Patients were followed for an average of 1.85 years (SD 1.17) and contributed 244,038 patient-years of exposure time. In the primary analysis, there were 348 patients who had an inflammatory CNS event (mean time to event 388 days [SD 285 days]). The unadjusted incidence of inflammatory CNS events was numerically lower among new users of TNF inhibitors (185,909 total exposure years; 250 events, incidence 1.34 per 1,000

Table 2: Incidence of inflammatory neurologic lesions among patients who received targeted synthetic or biologic DMARDs

Class	Exposure (py)	Events	Incidence (per 1,000 py)
TNF	185,909	250	1.3
IL1223	12,094	15	1.2
CD20	10,913	36	3.3
JAK	9,439	9	1.0
Integrin	8,481	9	1.1
CTLA4	7,564	14	1.9
IL6	4,191	7	1.7
IL17	2,601	2	0.8
IL23	2,205	2	0.9
IL1	625	4	6.4
S1PR	18	0	0

Abbreviations: **TNF** = tumor necrosis factor; **IL** = interleukin; **JAK** = Janus kinase; **CD 20** = Cluster of differentiation 20; **CTLA4** = cytotoxic T lymphocyte associated protein 4; **S1PR** = sphingosine 1-phosphate receptor modulator

Figure 1: Proportion of Patients with Inflammatory Neurologic Events over Time, Stratified by TNF or non-TNF Exposure



patient-years) as compared to the combined non-TNF group (58,130 exposure years, 98 events, incidence 1.69 per 1,000 patient-years).The incidence per 1,000 person-years varied by drug class (Table 2). In a weighted Cox proportional hazards regression with TNF exposure as the referent, there was no association between TNF exposure and inflammatory CNS events as compared to the combined non-TNF b/tsDMARDs (hazard ratio [HR] 1.01, 95% confidence interval [CI] 0.75-1.36). These results persisted in subset analyses of patients with rheumatoid arthritis (HR 1.03, 95% CI 0.67-1.59), psoriasis, psoriatic arthritis, and ankylosing spondylitis (HR 1.02, 95% CI 0.47-2.19), and Crohn's disease or ulcerative colitis (HR 1.02, 95% CI 0.41-2.57).

Conclusion: This large real-world analysis of patients initiating b/tsDMARDs did not identify an increased risk of inflammatory CNS events among new users of TNF inhibitors compared to other b/tsDMARDs. Meta-analyses of randomized trials should be conducted to corroborate these findings, which may be affected by channeling bias.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) can cause inflammatory arthritis (IA) of varying severity. Many patients with ICI-IA require immunosuppression beyond corticosteroids, but there is no way to identify these patients at initial presentation. We determined baseline risk factors for requiring immunosuppression and having persistent arthritis in ICI-IA.

Methods: participants were adults with rheumatologist diagnosed ICI-IA. The primary outcome was requirement of conventional synthetic (cs) or biologic (b) DMARDs; other outcomes were persistence of IA >6 months after ICI cessation and requirement of corticosteroids. Logistic regression models evaluated associations between clinical/genetic features and primary and secondary outcomes, with adjustment for potential confounders, as appropriate. Finally, we evaluated the relationship between maximum prior dose of steroids and primary and secondary outcomes with simple logistic regression.

Results: 126 patients with ICI-IA were included; 53 patients (42%) required a csDMARD/bDMARD (demographic and clinical features by DMARD group in Table 1).In univariate logistic regressions, higher CDAI, tenosynovitis, longer symptom duration before first rheumatology visit, and longer ICI duration were significantly associated with a higher likelihood of requiring DMARDs; there was a trend toward those treated with prior chemotherapy being less likely to need DMARDs (Table 2). After adjustment, tenosynovitis, longer symptom duration, and higher CDAI remained associated with requiring DMARDs, while those with prior chemotherapy were significantly less likely to require DMARDs (Table 2). Combination anti-CTLA-4/

Symptom duration	**1.06 (1.02, 1.11)**	**0.004**	**1.06 (1.01, 1.12)**	**0.027**
Secondary Outcome: Persistent IA >6 months after ICI cessation				
	Unadjusted OR	p-value	Adjusted OR	p-value
Age	0.99 (0.96, 1.03)	0.593	0.98 (0.93, 1.02)	0.277
Female sex	1.27 (0.52, 3.08)	0.600	0.61 (0.18, 2.03)	0.419
Already on steroids at baseline visit	**5.28 (1.16, 23.96)**	**0.031**	**5.51 (1.02, 29.90)**	**0.048**
Combination ICI therapy	**5.28 (1.16, 23.96)**	**0.031**	**5.43 (1.04, 28.43)**	**0.045**
Presence of tenosynovitis	6.43 (0.81, 50.71)	0.078	7.09 (0.77, 65.16)	0.083
ICI duration	1.07 (0.99, 1.14)	0.065	1.08 (0.99, 1.18)	0.068
Symptom duration	**1.13 (1.03, 1.24)**	**0.009**	1.11 (0.99, 1.24)	0.067

PD-1 therapy and steroid use at baseline were associated with a higher risk of persistent IA (Table 2). For 98 patients with HLA typing data, there was no significant association with HLA DRB1 shared epitope alleles or HLA B27 and primary or secondary outcomes. For 62 patients reporting systemic steroid use after starting ICI therapy, but prior to their baseline visit with rheumatology, there were no differences between those treated with low dose (prednisone or equivalent ≤ 10 mg/daily), moderate dose (10 mg< prednisone daily ≤60 mg), or high dose (prednisone daily > 60 mg) corticosteroids in either requiring a csDMARD/biologic or having persistent ICI-IA.

Conclusion: Higher levels of disease activity, tenosynovitis, and longer symptom duration prior to baseline were associated with requiring DMARDs for ICI-IA, while those treated previously with chemotherapy were less likely to require DMARDs. Known genetic risk factors for traditional forms of IA were not predictive. The presence of risk factors for severe disease at baseline may indicate a role for higher initial steroid dose, earlier rheumatology referral, and adoption of immunosuppression beyond steroids to improve outcomes.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICI) have changed the landscape of treatment for many cancers. However, most cancer clinical trials for ICI excluded patients with pre-existing autoimmune diseases (PAD). Efficacy and safety data on the use of ICI in patients with rheumatic PAD (Rh-PAD) is limited to retrospective case series and reports, and many do not differentiate between Rh-PAD and non-rheumatic PAD. In one study of a large French retrospective cohort, patients on immunosuppression (IS) at baseline had poorer tumor outcomes (1).

Objectives: To explore the impact of baseline IS on the safety and efficacy of ICI in patients with Rh-PAD using data from the CanRIO retrospective and prospective cohorts.

Table 1. Summary of demographic, pre-existing rheumatic autoimmune disease, cancer and outcomes data a 3 patients who were on baseline IS had more than one Rh-PAD; 1 patient who was not on baseline IS had more than one Rh-PAD b Missing data for 3 patients in the baseline IS group and 1 patient in the no baseline IS group c 13 patients on baseline IS experienced a flare of their Rh-PAD and a de-novo irAE; 3 patients not on baseline IS experienced a flare of Rh.PAD and de-novo irAEs d 5 patients on baseline IS experienced both de-novo Rh-irAE and other irAEs; 12 patients not on baseline IS experienced de-novo Rh-irAE and other irAEs e Including skin, endocrinological (other than thyroid), heart and eyes f Missing tumor response information for 7 patients on baseline IS and 5 in no baseline IS

Favorable response (stabilization, partial or complete)	22 (44.0%)	21 (40.4%)

Methods: We evaluated patients with Rh-PAD treated with at least one dose of ICI, including CTLA-4, PD-1, or PDL-1 inhibitors. 45 patients were recruited prospectively between Jan 2020 and Apr 2023 across 9 Canadian academic sites and followed at regular intervals as per a standardized study protocol. 57 patients were retrospectively recruited using data extracted from patients referred to rheumatology specialists between Jan 2013 and Jun 2022 across 10 Canadian sites. We used logistic regression to compare the occurrence and severity of flares and de-novo immune-related adverse events (irAE), as well as tumor response, between patients on baseline IS and not on baseline IS.

Results: One hundred and two patients with Rh-PADs were followed for a median of 32 months; 50 were on baseline IS prior to ICI start, and 52 were not. The most common Rh-PADs were rheumatoid arthritis and psoriasis/psoriatic arthritis (Table 1).

Cancer type, cancer stage, ICI type, and ICI exposure time were similar in both groups (Table 1). The flare rate of patients on baseline IS was 58%, compared to only 38% in the group without baseline IS (adjusted OR=2.1; 95% CI = 0.9-5.0; p=0.09). There were no statistically significant differences in the risk of a severe flare (CTCAE grade ≥3) (p = 0.3), development of a de-novo Rh-irAE (p = 0.4) or a severe de-novo Rh-irAE (p = 0.4) (Tables 1 & 2). Tumor follow-up data was available for 38 of the 50 patients on baseline IS and 37 of the 52 patients without baseline IS. The rate of tumor progression was 42% (16 of 38) in the IS group and 27% (10 of 37) in the no IS group (HR=1.4; 95% CI = 0.6-3.1; p=0.437) but there was no difference in progression free survival between groups.

Conclusion: Early data from patients with Rh-PAD in the multicenter prospective and retrospective CanRIO cohorts suggest that 1) ICI can be effective for cancer treatment in patients with Rh-PAD, and should be offered as indicated; 2) Baseline IS does not seem to protect from flares of Rh-PAD; 3) Baseline IS does not seem to change the risk of developing de-novo irAE, nor the severity of flares/de-novo irAEs; 4) There was a non-significant trend towards baseline IS increasing the hazard of tumor progression but no difference in progression free survival between groups.

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX) is a murine/human chimeric monoclonal antibody directed against the CD20 receptor expressed on pre-B and mature B cells. Rituximab is used effectively in the treatment of different rheumatic diseases, but it can induce hypogammaglobulinemia as a side effect. The purpose of our study was to analyze the prevalence of hypogammaglobulinemia and its association with infections in patients with rheumatic diseases treated with RTX.

Methods: Multicenter, retrospective, observational study. Patients with rheumatic diseases treated with RTX in 4 centers in Madrid, in which serum immunoglobulin counts were available were included. Demographic and clinical variables of the sample were analyzed, changes in immunoglobulin G concentrations during treatment from baseline were assessed. The

Table 1. Hypogammaglobulinemia and infections in patients with rheumatic diseases treated with Rituximab.

Table 1. Hypogammaglobulinemia and infections in patients with rheumatic diseases treated with Rituximab.

	No infection(N, %)	Mild infection(N, %)	Serious infection(N, %)
Patients **without** hypogammaglobulinemia	55 (58.51)	24 (25.53)	15 (15.96)
Patients **with** hypogammaglobulinemia	7 (58.33)	3 (25)	2 (16.67)
p value		p=0.991	p=0.950

chi-square test was used to examine the relationship between variables, considering a p value < 0.05 as statistically significant. Logistic regression models were used to analyze the association between hypogammaglobulinemia and sample characteristics.

Results: One hundred and seven patients were included: 18 men (16.8%) and 89 women (83.2%), with a mean age of 55.9 (±13.9) years, a mean disease duration of 13.1 (±0.8) years, and a mean age of 51 (±14.4) years at the start of treatment. The most prevalent diagnoses were rheumatoid arthritis (RA) (50.5%), primary Sjogren's syndrome (pSS) (10.3%), and systemic lupus erythematosus (SLE) (10.3%). Fourteen (13%) patients were treated with RTX monotherapy. The rest of the patients received concomitant treatment with other immunomodulators such as corticosteroids (64.5%), methotrexate (29%), hydroxychloroquine (27%), leflunomide (9.3%), sulfasalazine (1.9%), or mycophenolate mofetil (2.8%). Twelve (11.21%) patients developed hypogammaglobulinemia (IgG< 600 mg/dl): 6 (50%) had RA, 1 (8.3%) SLE, 1 (8.3%) ANCA vasculitis, 1 (8.3%) leukocytoclastic vasculitis, 1 (8.3%) IgG4-related disease, 1 (8.3%) dermatomyositis, and 1 (8.3%) pSS. Patients with hypogammaglobulinemia had significantly lower mean serum IgG concentrations at the start of treatment (876.3 vs 1249.4 mg/dl; p=0.05). In the multivariate analysis no variable related to hypogammaglobulinemia was found. Fifty-three (49.5%) patients presented infection, of which 17 (15.9%) were serious infections (those that required admission). The distribution of infection by groups (patients with and without hypogammaglobulinemia) is shown in Table 1. No significant differences were found in the development of infections or serious infections between patients with and without hypogammaglobulinemia. Only corticosteroid doses equivalent to ≥7.5 mg/day of prednisone were found as a risk factor for the development of infections (OR 3.48, 95% CI: 1.20-0.11; p=0.02).

Conclusion: Patients with hypogammaglobulinemia had significantly lower mean IgG concentrations at the start of treatment with RTX than those who did not develop it. No greater frequency or severity of infections was observed between patients with and without hypogammaglobulinemia. Prednisone equivalent daily dose ≥7.5 mg/day was a risk factor for occurrence of infections. Larger sample size studies are needed to confirm these findings.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Due to better effectiveness and longer drug survival, a TNF inhibitor (TNFi) should preferably be combined with methotrexate (MTX). MTX has been found to reduce the development of anti-drug antibodies (ADAs), which decreases the risk of treatment failure. ADA formation, however, predominately occurs during treatment initiation. To our knowledge, the effect of tapering or stopping MTX on the formation of ADAs after longstanding treatment with TNFi is not yet known. Therefore, the aim of this study was to assess the effect of tapering and stopping MTX on the formation of ADA in rheumatoid arthritis (RA) patients with longstanding use of adalimumab (ADL).

Methods: For this study we used data from the TApering strategies in Rheumatoid Arthritis (TARA) trial. The TARA trial was a multicenter, single-blinded randomized trial that included established RA patients with a well-controlled disease, defined as a disease activity score (DAS) ≤2.4 and a swollen joint count ≤1, which was achieved with conventional synthetic (cs) DMARDs and a TNFi. Eligible patients were randomized into gradual tapering csDMARD (mainly methotrexate) followed by the TNFi, or vice versa. Tapering of MTX was realized by cutting the dosage into half, a quarter and thereafter it was stopped. The TNF inhibitor was tapered by doubling the dose interval, followed by cutting the dosage into half, and thereafter it was stopped. The total tapering schedule took 6 months, with dose adjustments every 3 months as long as there was still a controlled disease. ADA and ADL serum levels were measured at each 3-monthly visit, if serum samples were available, by a drug tolerant enzyme-linked immunosorbent assay.

Results: Of the 46 included RA patients, 21 patients did not experience a disease flare. Among patients who did not experience a flare, 10 patients tapered ADL first, while 11 patients tapered their csDMARD first. Patients had an average symptom duration of 6,5 years and were predominantly female 71% with an average age of 54 years. At baseline, the DAS (standard deviation) was 1,0 (0,6) and the mean MTX dosage before tapering was 16.5 mg/week. In the group tapering ADL first, detectable ADA prevalence remained unchanged between 10 to 20 % (Figure 1A). On the other hand ADA detection in serum increased from 18% to 68% in the RA patients who were tapering and stopping the MTX first (Figure 1B). Despite the increase in ADA formation, the mean ADL concentration showed a minor decrease from 8.3 (T0) to 7,8 (T9) ug/mL (Figure 1B). In the second year, when also ADL is tapered, patients with detectable ADA seems to have faster clearance of ADL (figure 1B).

Conclusion: Our data shows that there is an increase in detectable ADA after tapering and stopping MTX in patients with longstanding use of ADL, but this seems not to have a major effect on the clearance of ADL in the standard dose.

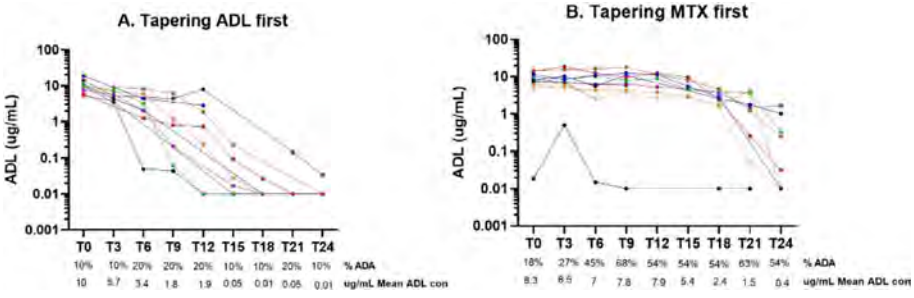

Figure 1: Anti-Drug Antibodies formation during tapering of treatment in RA patients with a well-controlled disease who did not experienced a disease flare"Each dot represents an ADL drug level measurement per individual RA patient. Measurements within each individual patient are connected by a coloured line. Abbreviations: ADL, adalimumab; con., concentration; ADA, anti-drug antibodies

Outcomes of COVID-19 Infection in Hospitalized Autoimmune Patients and Transplant Patients on Immunosuppression

Yashswee KC[1] and Rochella Ostrowski[2], [1]Loyola University, Oakpark, IL, [2]Loyola University Medical Center, Maywood, IL

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Coronavirus disease 2019 (COVID-19) can have varying outcomes. Patients with chronic conditions or immunosuppression experience more severe illness. Both organ transplant recipients and patients with certain autoimmune rheumatic diseases (ARD) require immunosuppressive therapy. We investigated the outcome of COVID-19 infections in hospitalized transplant patients and autoimmune immunosuppressed patients.

	Autoimmune Patients (n=49)		Transplant Patients (n=119)

Baseline Characteristics of Patients with Autoimmune diseases versus Transplant Patients

Methods: This is a retrospective chart review of outcomes for adult patients admitted to our institution with COVID-19 infection from March 2020 to September 2021 on immunosuppressive drugs. Patients were categorized into either a transplant or ARD group. Baseline characteristics, comorbidities, and severe outcomes during admissions were evaluated. Chi2 tests were used to compare outcomes. Odds ratios were adjusted for age, sex, and race.

Results: Of 2,140 cases reviewed, 49 patients with ARD requiring immunosuppression and 119 transplant patients were identified. The ARD group had a higher proportion of females than the transplant group (Table 1). More transplant patients had hypertension, diabetes mellitus, or chronic kidney disease (CKD). In the ARD group, 4.1% were current smokers, but seven patients (43.8%) with any history of smoking died compared with 2 (6.0%) non-smokers, although the adjusted odds ratio did not reach significance. The most common ARD was RA. Among 9 ARD patients who died, 3 had RA and SLE each. The mean age of ARD patients who died was 65.2 years. ARD patients with renal and respiratory failure were more likely to die than those without these adverse events (Table 2). Comorbidities with significantly increased risk of death in ARD patients were hypertension, CKD, and heart failure (Table 2). A history of heart failure or transplant was also associated with respiratory and renal failure. In the transplant group, a history of heart failure was associated with death, and patients with a history of CKD or heart failure were more likely to develop renal failure (Table 3). When comparing death, renal or, respiratory failure and thromboembolic events between transplant and ARD patients, there was an increase in renal failure for transplant patients compared to ARD patients (17.0 versus 4.8%, p= .017). While 14.3% of ARD patients and 16.9% of transplant

Table 3. *there was no distinction between patients with CKD and those who were already on dialysis prior to admission. 16.4% of transplant patients who experienced renal failure were renal transplant recipients (versus 20.7% who were non-renal transplant recipients).

Proportion of Transplant Patients Who Experienced an Adverse Outcome During COVID-19 Infection

patients died, and 21.8% of transplant patients required intubation, compared to 14.3% of ARD patients, these trends did not reach statistical significance. In transplant patients who died during their admission, the most common organ transplant was heart (22.7%) followed by kidney and lung (18 and 15%).

Conclusion: Studies have evaluated risk factors for severe COVID-19 outcomes in immunosuppressed patients, but there is limited literature comparing autoimmune disease and transplant patients that also evaluate severe outcomes such as renal failure and thromboembolic events. Besides renal failure, severe outcomes from COVID-19 were not significantly different between ARD and transplant patients. Risk factors for death, however, did differ between these groups. This study gives further insight into similarities and differences of immunosuppression's impact on COVID-19 outcomes in autoimmune and transplant patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Immunological Complications of Medical Therapy Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune Checkpoint Inhibitor (ICI)-induced myositis (ICI-myositis) is a rare, but potentially fatal complication of ICI therapy.Electronic health record (EHR) databases are essential to accrue sufficient patients for clinical investigations regarding phenotypical presentations, associated risks, prognosis, and management and have not yet been fully employed in this area of research.To meet this critical need, this study assessed the factors most effective in identifying ICI-myositis in the Veterans Health Administration (VHA) with the goal of developing an algorithm to accurately identify these patients.

Table 1: Sensitivity, Positive Predictive Value, and F1 Score for Individual Factors Involved in ICI-Induced Myositis Identification

Table 1: Sensitivity, Positive Predictive Value, and F1 Score for Individual Factors Involved in ICI-Induced Myositis Identification

Factors involved in ICI myositis identification	Patients Meeting Criteria	Cases meeting Criteria	Sensitivity % (95% CI)	Positive Predictive Value % (95% CI)	F1 Score

* Note = Clinic Note with term "myositis" in text
** Dis Sum = Discharge summary with "myositis" in text
*** CK 10xULN = Creatinine Kinase value at least 10 x Upper Limit of Normal
**** CK tested = Creatinine Kinase test with value either within or over the normal range
***** CK 1xULN = Creatinine Kinase value at least 1 x Upper Limit of Normal

Methods: The VA Corporate Data Warehouse (CDW) containing clinical, laboratory, pharmacy, and administrative records from the VHA's EHR, identified Veterans treated with an ICI between 6/2011 and 2/2023.Patients at high risk for ICI-myositis underwent electronic medical record review.High risk was defined by having one or more of the following: creatine kinase (CK) over 10 times the upper limit of normal (ULN) (312 U/L) within 6 months after the first ICI, the term "myositis" in a discharge summary text any time after first ICI, and/or the term "myositis" in a progress note text within six months after ICI treatment. Criteria for diagnosis of ICI-myositis were a provider ICI-myositis diagnosis in clinical notes and laboratory evidence of myositis without alternate etiologies.Levels of CK, aldolase, troponin, and Anti-Jo1 antibodies during 6 months after first ICI infusion were extracted from the CDW.Sensitivity, positive predictive value (PPV), and F1 score for individual variables and combinations of variables were calculated in comparison to the gold standard chart review diagnosis.

Results: In the 29,562 Veterans receiving an ICI, 60 (0.2%) patients were identified with ICI-myositis.In the 60 patients with CK 10xULN, 33 had ICI-myositis with a sensitivity of 55% and PPV of 55% with F1 score of 55% which was the highest F1 score of any single variable.In the 176 patients with a discharge summary with "myositis" and 477 patients with "myositis" in a clinic note the sensitivities were 76.7% and 66.7% and the PPVs were 26.1% and 8.4% with F1 score of 39.0% and 14.9% respectively.There was a wide range of sensitivity, PPV, and F1 score with the individual lab values (Table 1).The combination of factors demonstrated increased sensitivity, PPV, and F1 score with five combinations having an F1 score greater than 60% which was much higher than the F1-scores seen with individual elements (Table 2).

Conclusion: The multiple factors evaluated for the identification of ICI-myositis had varying degrees of performance with factor combinations performing best. Building on this foundational work, future work will detect and include additional clinical and laboratory factors to enhance the effectiveness of an algorithm to identify ICI-myositis patients in large databases. This work suggests that similar methods may be used to identify other immune related adverse events which can be used for further epidemiological studies.

Abstract Number: 1080

Prevalence and Incidence of Paradoxical Side-effects of TNF-α Inhibitors: A Cross-sectional Study

Antoine Minier[1], Gilles Boire[1], Sophie ROUX[1], Nathalie Carrier[2] and Hugues Allard-Chamard[1], [1]Université de Sherbrooke, Sherbrooke, QC, Canada, [2]CIUSSS de l'Estrie - CHUS, Sherbrooke, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor alpha inhibitors (TNFi) are used to treat a variety of inflammatory conditions ranging from rheumatoid arthritis to sarcoidosis. Paradoxical side-effects (PSE) of TNFi include the development of conditions normally treated by the therapeutic agent, such as psoriasis and uveitis. Most prevalent among these adverse effects is paradoxical psoriasis, described as having a prevalence of 4.6%[1] in patients with inflammatory bowel disease (IBD). Our objective was to validate the prevalence and incidence of PSE in TNFi treatment of rheumatic diseases (RD) patients and to identify risk factors.

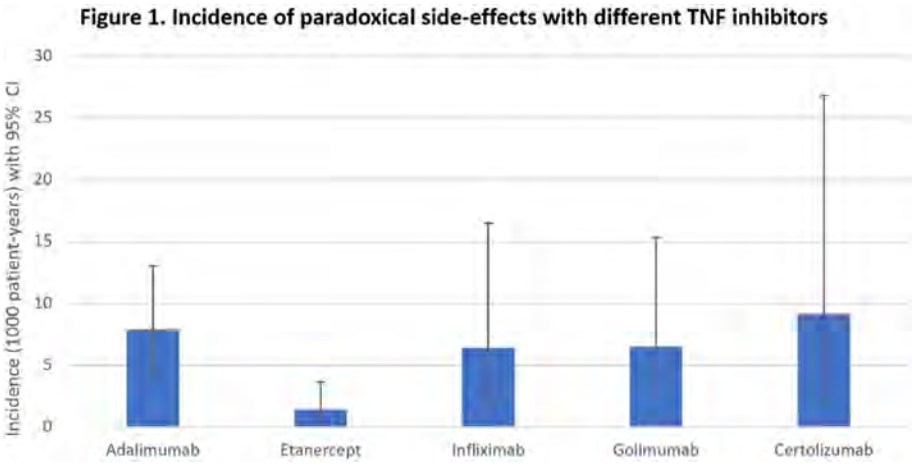
Methods: Using our institution's database on biologic agents in RD, patients that used TNFi were identified. Chart review was performed to identify PSE, which were either documented by the treating clinician or defined as the onset of a condition treatable by the biologic agent (psoriasis, uveitis, hidradenitis suppurativa (HS) or IBD). To identify risk factors, demographic information, diagnosis, and duration of treatment were recorded.

Results: From 2003 to 2023, 1184 patients used at least one TNFi. Median age at diagnosis was 46.1 years old, and females made up 55% of the population. 39% of patients had rheumatoid arthritis while 61% of patients had spondyloarthritides (37% psoriatic arthritis; 63% with other spondylarthropathies). 35 PSE were identified, including 23 cases of psoriasis, 4 cases of Crohn's disease, 3 psoriasis exacerbations , 2 palmoplantar pustulosis, 2 uveitis and 1 HS. The prevalence of PSE across our population was 3.0% (95% CI 2.1 – 4.1). Patients in the SpA group were three times more likely to experience a PSE when compared to RA with a prevalence of 5.1% vs 1.7% (OR (95% CI) = 3.06 (1.36 – 6.92), p< 0.01). A

Table 1. Demographic and clinical patient characteristics (n=1184)

Age at diagnosis (years) - med. (IQR)	46.1 (32.8-56.7)
Female sex - no. (%)	651 (55)
Smoking - no. (%)	
• Current smoker	267 (23)
• Former smoker	218 (18)
• Never smoker	492 (42)
• Unknown	207 (17)
Rheumatoid arthritis - no. (%)	464 (39)
• Rheumatoid factor positive	204 (44)
• Rheumatoid factor negative	177 (38)
• Unknown	83 (18)
Spondylarthritis - no. (%)	451 (38)
• HLA-B27 positive	205 (45)
• HLA-B27 negative	115 (26)
• Unknown	131 (29)
Psoriatic arthritis - no. (%)	269 (23)

Med.: Median, IQR: Interquartile range (25th-75th percentiles)



difference was also observed when comparing prevalence in SpA versus PsA (OR=3.56 (1.22 – 10.41), p=0.02) , while patients younger than 50 years old were more likely to experience PSE (OR=2.34 (1.16 – 2.75), p=0.02).Smoking was a risk factor (OR=2.19 (1.02 – 4.83), p=0.05). Etanercept was less likely to be used in the SpA group compared to the RA group (OR=0.27 (0.20 – 0.36), p< 0.01). Incidence of PSE per 1000 patient-years was 7.9 (95% CI : 4.4 – 13.1) for adalimumab, 2.9 (1.2 – 5.7) for etanercept, 6.4 (1.8 – 16.5) for infliximab, 6.5 (2.1 – 15.3) for golimumab and 9.2 (1.9 – 26.8) for certolizumab. The incidence rate ratio between adalimumab and etanercept was statistically significant (IRR=2.76 (1.10 – 7.52), p=0.02).

Conclusion: Our results identify an overall prevalence of 3.0% for PSE, with a prevalence of 5.1% in SpA, closely matching the prevalence previously reported in IBD. Our results suggest a higher prevalence of PSE in SpA compared to RA. Predisposition to psoriasis in SpA or cutaneous psoriasis appearing after diagnosis of PsA are likely explanations for these results. The use of the decoy receptor, etanercept, compared to monoclonal antibodies was an important protective factor, explained in part by its lesser use in the SpA group. 1. SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Immunological Complications of Medical Therapy Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Formation of anti-drug antibodies (ADAb) to biological drugs is a clinical problem. Proactive therapeutic drug monitoring (TDM) allows for timely detection of ADAb and may reduce the negative clinical consequences. The aim of the study was to explore the relation between ADAb and treatment outcomes and adverse events, and to assess the impact of proactive TDM.

Methods: Patients (n=615) with spondyloarthritis (n=181), rheumatoid arthritis (n=120), psoriatic arthritis (n=72), ulcerative colitis (n=114), Crohns disease (n=83) and psoriasis (n=45) on infliximab therapy were included in the Norwegian Drug Monitoring (NOR-DRUM) trials[1,2] and randomised to TDM or standard infliximab therapy. Patients were followed for 30/52 weeks in the NOR-DRUM A (induction therapy) and NOR-DRUM B (maintenance therapy) trials, respectively. Neutralising ADAb were assessed with a drug-sensitive assay at each infusion. The outcomes of this study were: remission 30 weeks after initiation of infliximab, having a disease worsening during 52 weeks of maintenance therapy, having an infusion reaction and infliximab treatment discontinuation. Regression and Kaplan-Meier survival analyses were used to assess the association between ADAb and the outcomes, and the impact of proactive TDM. Remission and disease worsening were defined by disease specific composite scores[1,2].

Results: ADAb were detected in 147/615 (24 %) patients. A lower proportion with ADAb achieved remission at week 30 (odds ratio (OR) 0.4, 95 % confidence interval (CI) 0.2-0.7, P< 0.01) (Table, Figure 1A) compared to ADAb negative. The risk of having a disease worsening was increased in ADAb positive (hazard ratio (HR) 2.0, CI 1.3-3.7, P< 0.01) (Table, Figure 1B) or an infusion reaction (HR 17, CI 7-41, P< 0.001) (Table, Figure 1C) was increased in patients with ADAb as compared to ADAb negative. The risk of infliximab treatment discontinuation was increased in ADAb positive patients (HR 6.6, CI 4.8-9.1, P< 0.001) (Table, Figure 1D). Patients developing ADAb in the TDM group had lower risk of having a disease worsening (HR 0.4, CI 0.3-0.6, P< 0.001) or an infusion reaction (HR 0.3, CI 0.1-0.7, P< 0.01) compared to patients with ADAb in the standard therapy group (Table, Figure 1B and C). Patients with ADAb discontinued infliximab treatment more often in the TDM group than in the control group (HR 1.4, CI 1.0-1.8, P=0.04) (Table, Figure 1D).

Conclusion: Formation of ADAb led to poorer clinical outcomes during infliximab treatment and increased the risk of infusion reactions. Early detection of ADAb by proactive TDM reduced the negative consequences of ADAb, both on infliximab effectiveness and safety. Our results highlight the role of proactive TDM in optimising TNFi therapy.

Table. Treatment and safety outcomes related to ADAb formation and TDM

Outcome: Remission week 30	**OR (CI)**	**P**
ADAb	0.4 (0.2-0.7)	<0.001
TDM	1.0 (0.7-1.5)	0.9
Outcome: Disease worsening	**HR (CI)**	**P**
ADAb	2.0 (1.3,3.1)	<0.01
TDM	0.4 (0.3-0.6)	<0.001
Outcome: Infusion reaction	**HR (CI)**	**P**
ADAb	17 (CI 7.0-41)	<0.001
TDM	0.3 (0.1-0.7)	<0.01
Outcome: Treatment discontinuation	**HR (CI)**	**P**
ADAb	6.6 (4.8-9.1)	<0.001
TDM	1.4 (1.0-1.8)	0.04

Results from multivariable logistic- or cox regression models including the covariates: ADAb, TDM, age, sex, diagnosis, comedication. Only results for ADAb and TDM are shown.
ADAb=Anti-drug antibodies; TDM=therapeutic drug monitoring

Reducing No-shows and Late Cancellations at an Academic Medical Center Subspecialty Clinic

Nicola Jackson[1], Meg James[2], **Kim Nguyen**[3], Priyanka Vashisht[2] and Avis Ware[4], [1]University of Cincinnati, Rheumatology, Blue Ash, OH, [2]University of Cincinnati Medical Center, Cincinnati, OH, [3]University of Cincinnati Medical Center, Loveland, OH, [4]University of Cincinnati College of Medicine, Loveland, OH

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient no-shows and late cancellations, defined as less than 24 hours from the visit, reduce operational efficiency, revenue generation, and lead to negative clinical outcomes. There has been an increasing trend in no-show and late cancellation rates at the University of Cincinnati Hoxworth rheumatology clinic. For fiscal year 2021, monthly rates ranged from 6.2-32.7%. Since each unused slot is not reimbursable, this has resulted in a negative financial impact. When extrapolated to all of Internal Medicine, this has led to a $2 million revenue loss. Previously, reminders for visits involved automated calls and mailing letters. Using Vizient clinical database to identify performance gaps, our smart aim was to integrate phone call reminders to decrease median benchmark for no-shows and late cancellation rates from 18.47% to 14.6% from October 31, 2022 to February 1, 2023.

Methods: The 1st Plan-Do-Study-Act (PDSA) involved identifying the optimal lead time to call and was from October 31, 2022 to December 31, 2022. The 2nd aimed to refine phone call and messaging scripts and was from January 1 to February 1, 2023. Patients were called from 1 to 6 days prior to the visit. Alternate numbers or patient portals were used if they could not be reached. Conversations and barriers were documented in the medical record. To assess for common and special cause variations, baseline rates were plotted on a run chart starting from November 22, 2021 to April 14, 2023 (Figure 1).

Results: Monthly attendance ranged from 64.3-96.3% from October 31, 2022 to February 1, 2023 (N=11-30 patients per visit). The lowest rates were during Thanksgiving at 72.7% (N=22) and Christmas at 64.3% (N=14). Data for Thanksgiving and Christmas for 2021 were similarly low with median attendance of 74.55% (N=33-66). When excluding these holidays, the median rate was above the set benchmark of 85%. We concluded that low rates during holidays are special cause variations and can show positive shift if project is of a longer duration. After the project ended on February 1, 2023, rates dropped again below the benchmark to median of 80.6%. During PDSA #1 the optimal time to call was 5 to 6 days prior allowing for identification of barriers, some of which included transportation or work obligations. If barriers could not be resolved, patients on wait lists filled the open slots. During PDSA #2, late cancellations became increasingly higher than no-shows since they were unaware of the policy. There was a positive trend in attendance once scripts were refined to explicitly inform all patients of the policy. Also, phone calls were more effective than mailed letters or patient portal messaging due to the lead time and ability to identify barriers.

Conclusion: Monthly attendance ranged from 64.3-96.3% from October 31, 2022 to February 1, 2023. When excluding no-shows and late cancellations during Thanksgiving and Christmas, the median attendance rate was above the set benchmark of 85%. Low rates during holidays are special cause variations and can show positive shift if the next phase of the

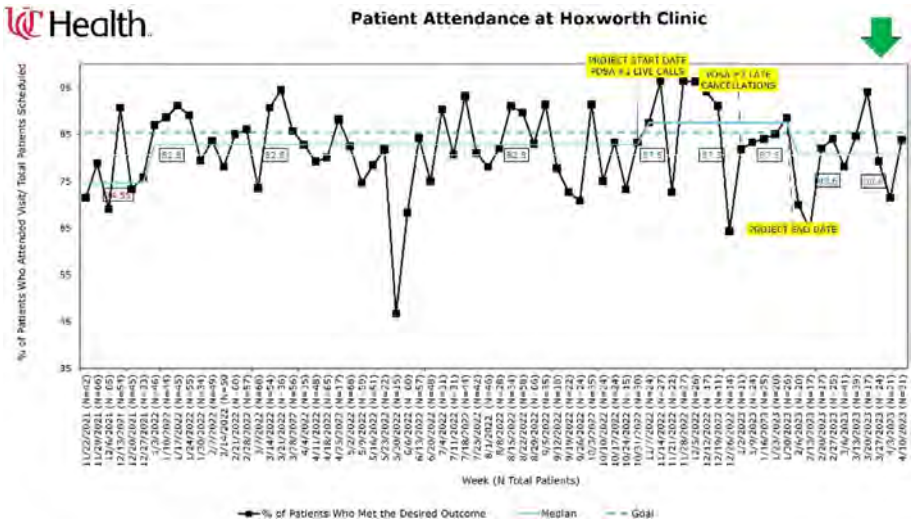

Figure 1. Monthly Attendance Rates Run Chart

project is longer. The optimal time to call is 5 to 6 days prior and are opportunities to identify barriers and to fill open slots. There was a positive trend once scripts included explanation of the policy.

SESSION INFORMATION

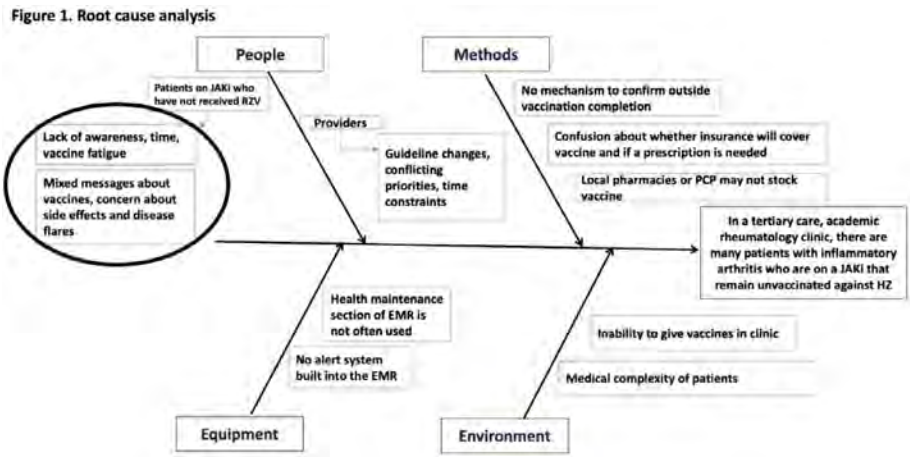
Session Date: Monday, November 13, 2023

Session Title: Measures & Measurement of Healthcare Quality Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: People with systemic rheumatologic diseases are more susceptible to herpes zoster (HZ) infection and its complications due to their underlying diseases and the medications used to treat them. Janus kinase inhibitors (JAKi) confer a substantial risk for HZ, resulting in morbidity and cost to the healthcare system. The Division of Rheumatology at the study site recognized the rate of recombinant zoster vaccine (RZV) uptake among people receiving JAKi was unacceptably low. The goal of this quality improvement study was to increase the number of RZV prescriptions written for patients on JAKi via a streamlined patient outreach campaign.



A fishbone diagram was created to assist in performing a root cause analysis of the low rate of recombinant zoster vaccine (RZV) uptake in patients on janus kinase inhibitors (JAKi). This figure depicts the several barriers to vaccination, including the barriers targeted in this quality improvement study (circled).

Methods: In September 2022, patients in a tertiary care, academic rheumatology clinic with inflammatory arthritis and a current prescription for a JAKi were identified using a query of the electronic medical record (EMR). A process map and root cause analysis were created to understand why there was a low rate of RZV uptake. Lack of awareness and vaccine fatigue were the main barriers identified (Figure 1). On January 10, 2023, a customized EMR message or letter was sent to the identified patients outlining the importance of RZV, including efficacy and safety, and requesting a reply from those interested in a prescription for RZV (Figure 2). A standardized nursing protocol was used to process responses. The outcome measure was the percentage of patients who received a RZV prescription by April 10, 2023 (goal >10%, starting from 5%).

Results: There were 194 patients identified as being on a JAKi for inflammatory arthritis. Seventy-five (39%) had documentation of RZV, and 119 (61%) did not have documentation of RZV. A message was sent via the EMR to 113 patients and via mailed letter to 6 patients without EMR access. Thirteen of 119 patients (11%) responded with a request for RZV vaccination and received a prescription for RZV between January 10, 2023 and April 10, 2023, which met the outcome measure. A total of 90 patients (46%) had documentation of RZV following the intervention (Figure 3). Fifty-one patients (43%) had a rheumatology follow-up appointment by April 9, 2023. Three patients expressed vaccine hesitancy when discussed with the provider at their appointment. One patient was concerned about side effects of RZV. Twenty-two patients (18%) had a recommendation for RZV documented in follow-up clinic notes.

Conclusion: Utilizing a targeted EMR message is a low-cost intervention that helps address barriers to recombinant zoster vaccination in patients on janus kinase inhibitors without increasing provider burden. This intervention helps empower patients who are motivated to improve their health, allowing vaccination between clinic visits or prompting discussions with providers at subsequent visits. These results will inform a broader multi-modality, patient- and provider-facing program to increase vaccination rates at the study institution, including offering in-clinic vaccinations.

Figure 2. Quality improvement study profile

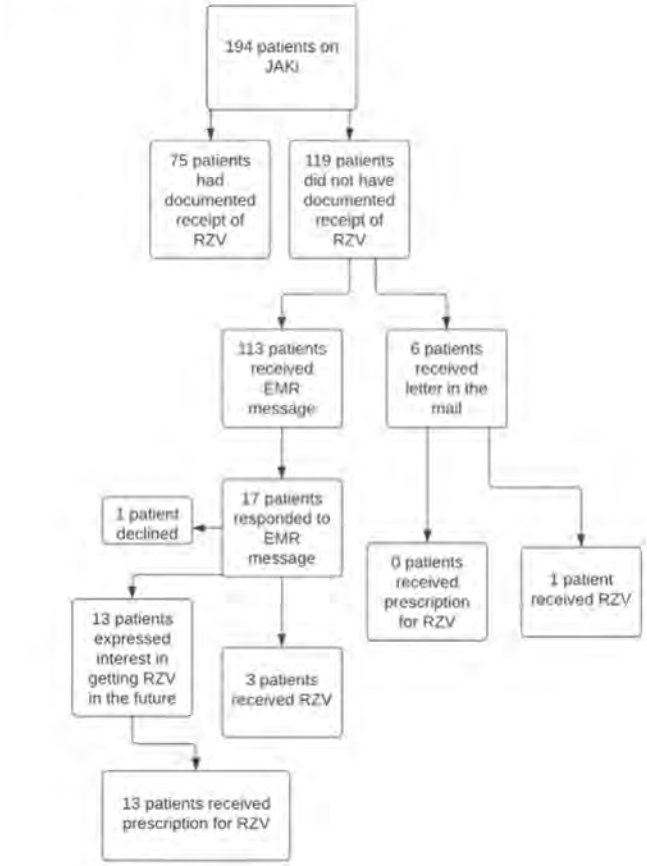


Figure 3. Recombinant Zoster Vaccine (RZV) both pre and post intervention

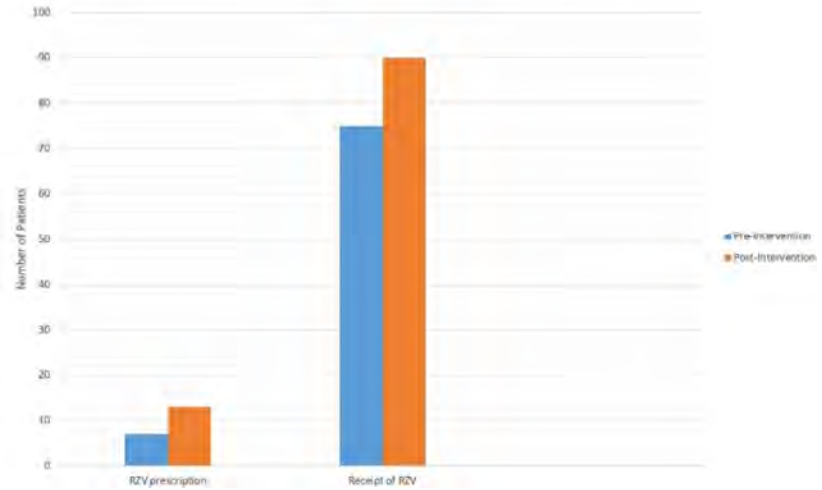

This figure shows the increase in number of patients who received RZV after the intervention (receipt of RZV). Not every patient who received RZV was given a prescription.

Identifying and Addressing Disparities in Health Literacy in Patients with Rheumatic Diseases Through Point of Care Distribution of Patient Education Materials

Kelly Corbitt[1], Abhimanyu Amarnani[2], Jammie Law[3], Cristina Sorrento[3], Nicole Leung[4], Catherine Howe[3], Tasneem Ahmed[3], Meghan Anderson[3] and Sara Stream[3], [1]New York University, El Portal, FL, [2]NYU Langone Medical Center, New York, NY, [3]New York University, New York, NY, [4]New York University Langone Hospital, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Improving health literacy in patients with rheumatic diseases is important as many have chronic, complex diagnoses treated with high-risk medications. Poor health literacy may be due to education level, language barriers, socioeconomic status, and/or inadequate access to health education material. Many of these factors are non-modifiable, putting patients at risk for healthcare disparity. We aimed to create a quality improvement initiative to (1) better characterize those with poor health literacy and (2) improve their diagnosis and medication understanding via physician provided education material.

Methods: Patients from three distinct healthcare systems in New York City (Bellevue, NYU, the VA; Table 1) with documented rheumatologic diagnoses were administered health literacy surveys during rheumatology clinic visits from September 2022 to May 2023. A baseline survey assessed the patient's ability to identify their diagnosis and medication

from a list of options, as well as self-reported level of health literacy, desire for more printed education material, primary language, and education level. Printed patient education materials, in English or Spanish, were provided in real-time with counseling on knowledge gaps. Repeat surveys are being administered at follow-up visits to assess the effectiveness of education materials. Those completed during the study period are included for preliminary analysis.

Results: 116 patients completed the baseline survey. There were fewer native English speakers and fewer patients with higher education at Bellevue. Overall, 20% of patients incorrectly selected their diagnosis and medication from the provided list. While incorrect diagnosis selection did not vary by site, incorrect medication selection differed with 5% incorrect at the VA, 14.7% at NYU, and 27.6% at Bellevue (Table 1). Across sites, medication literacy significantly differed by education level and primary language (Table 2). 38.9% of all patients reported being unsure about holding medication during infection. On average, patients from all sites self-rated their health literacy at least a 4, on a 1-5 scale (higher=better). At baseline, 54.5%

Table 1: Comparisons amongst three diverse healthcare systems in New York City. Bellevue is a public service teaching hospital. The VA is a government run hospital serving veterans and their families. New York University (NYU) Hospital is a private, not-for profit, teaching hospital. All values are represented as n (%). N is specified where it differs from the overall sample. All p-values represent chi-square analyses. For perceived level of diagnosis and medication understanding, chi-square testing compared response levels 1-3, 4, vs, 5 to ensure statistical testing validity where all expected values are greater than 1.0 and at least 20% of the expected values are greater than 5.

	Bellevue n=60	Veterans Affairs (VA) Hospital n=22	NYU n=34	p-value (Bellevue v. VA)	p-value (Bellevue v. NYU)	p-value (VA v. NYU)
Wrong Diagnosis	11 (18.3)	4 (18.2)	8 (23.5)	1	0.55	0.63
Wrong Medication	16 (26.7)	1 (5) n=20	5 (14.7)	0.03	0.14	0.27
Native English Speaker	26 (43.3)	21 (95.5)	26 (81.3) n=32	<0.001	<0.001	0.13
Any higher education	19 (35.2) n=54	17 (85) n=20	19 (59.4) n=32	<0.001	0.03	0.05
Self-reported level of diagnosis understanding (mean)	4.0 n=55	4.0 n=20	4.3 n=33	0.76	0.01	0.22
Self-reported level of medication understanding (mean)	4.2 n=55	4.2 n=21	4.4 n=33	0.68	0.1	0.63
Wants more diagnosis education material	39 (69.6) n=56	8 (38.1) n=21	13 (39.4) n=33	0.02	0.004	0.88
Wants more medication education material	43 (76.8) n=56	9 (47.4) n=19	14 (43.8) n=32	0.008	<0.001	0.68

Table 2. Results of correct medication result, organized by language and education level. All statistics Chi-square analyses.

		Correct, n (%)		Incorrect, n (%)	Significance (p)
Total	N	Count (%)	N	Count (%)	
English – Primary Language	74		15		<0.05
Yes		53 (71.6)		9 (60)	
No		21 (28.4)		6 (40)	
Education – Greater than HS	79		26		<0.01
Yes		33 (41.8)		3 (11.5)	
No		46 (58.2)		23 (88.5)	

wanted more diagnosis education and 61.7% wanted more medication education; percentages were significantly higher among patients at Bellevue than other sites (Table 1). Of those who completed the repeat survey (n=27), 74.1% found the diagnosis education materials helpful and 63% found the medication education materials helpful. Those with higher education found these more helpful overall.

Conclusion: There is a discrepancy between perceived and actual health literacy in patients with rheumatic diseases, as there were notable knowledge gaps in the survey results and uncertainty about medication use during infection, despite reports of adequate understanding. This highlights the importance of providing consistent education to all patients. Medication literacy may be a particular area for improvement, as this varied by factors that engender healthcare disparity, including lower education level and primary language. The optimal way to improve patient literacy in varied settings is an important topic for future study.

Utilizing a Maintenance of Certification (MOC) Part 4 Quality Improvement Project to Improve Data Completeness in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry

Hemalatha Srinivasalu[1], anne dennos[2], alan Russell[3], Mary Beth Son[4] and Mara Becker[2], [1]Children's National Hospital, Washington, DC, [2]Duke University, Durham, NC, [3]Duke Clinical Research Institute, Duke, NC, [4]Division of Immunology, Boston Children's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Minimizing missing data in research registries is a universal challenge. Enrolling patients into a research registry with poor data quality is wasteful and potentially unethical, as it incurs risks and cost with minimal to no benefit. Data quality is a central focus for the CARRA Registry, and we aimed to improve data completion rates for the Registry's critical variables using quality improvement (QI) methodology and obtained approval for a large group MOC Part 4 QI project through the American Board of Pediatrics to obtain credit for maintenance of board certification.

Methods: The *CARRA Registry Critical Variable MOC 4 Improvement Project* is designed to improve data completion rates for critical variables in the CARRA Registry that are required to calculate disease activity outcomes in JIA (Physician Global and Patient/Parent Global scores) and SLE (Calculable SLEDAI Score and SLE Physician & Patient/Parent Global scores). The goal is to close the gap in data completion by 50% over a 12-month period (9/1/2022-8/31/2023).Participation in each project earns 25 MOC part 4 points. Outcome Measures are data completion rates at the Registry level; Process Measures are data completion rates at the site level in addition to completion rates of monthly site engagement surveys where site-specific Plan-Do-Study-Act (PDSA) cycles are documented. At the Registry level, two PDSA cycles were completed thus far: 1) development of site-specific critical variable reports with graphs to illustrate change over time and 2) initiation of monthly office hours/Q&A sessions. Participation is voluntary and each site can choose to participate in one or both projects. The final analysis will include run charts for each sub-project to display improvement over time, and data reflecting overall improvement will be analyzed by chi-square analysis. Data reported herein is an interim analysis as of May 2023.

Figure 1: Key Driver Diagram depicting the drivers and the site-specific interventions

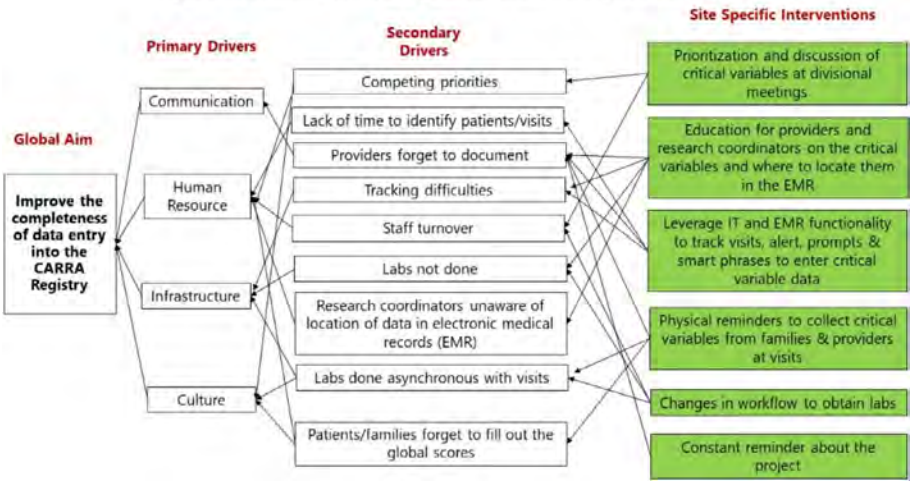

Figure 2A-2E: Run charts showing the trend in the completion rates of the critical variables from September 2022 to May 2023.

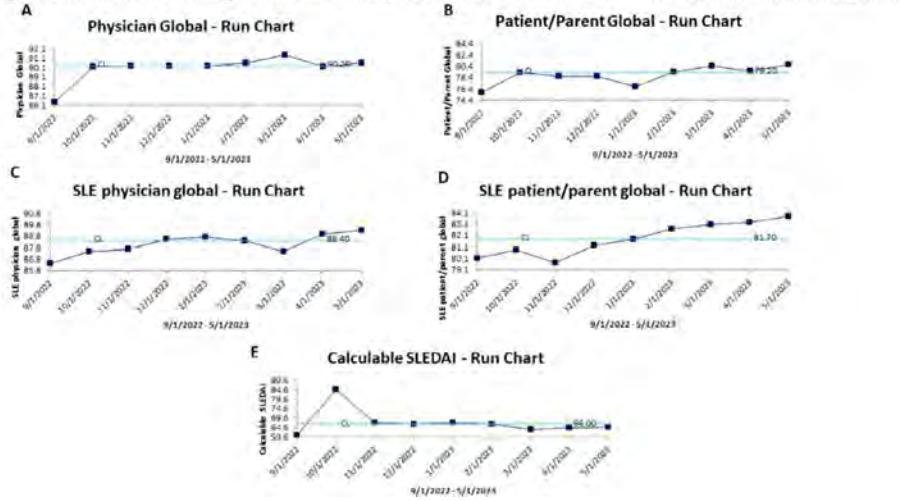

Table 1: Overall critical variable completion rates

Critical Variable	Baseline completion rate (Prior to Sep 2022) %	Interim completion rate (As of May 2023) %
Physician Global	86.4	90.5
Patient/Parent Global	75.7	80.7
SLE Physician Global	86.4	89.3
SLE Patient/Parent Global	80.1	83.7
Calculable SLEDAI	60.5	64.7

Results: Out of 71 active CARRA Registry sites, 42 (59%) are participating. Baseline completion rates were calculated from approximately 38,000 visits across participating sites. There have been 5,067 follow up visits entered into the Registry (13% of total) since MOC project initiation. Key drivers and examples of site-specific PDSA interventions are indicated in **Fig 1**. Interim run charts for each critical variable show a trend towards improvement (**Fig 2A-2E**). Averaged critical variable completion rates at baseline and May 2023 are noted in **Table 1.**

Conclusion: Interim analysis reveals a trend towards improvement in completion rates of all targeted critical variables, but the rate of improvement is slower than originally anticipated. This is likely due to the limited cross-section of new visits occurring during the 8-month project period compared to the aggregated visits accumulated from Registry inception to September 2022. As sites accrue additional follow-up visits, and continue to trial site specific interventions, we hope to observe sustained improvement in critical variable completion rates within the CARRA Registry.

Abstract Number: 1086

Increase Shingrix Vaccination Rate in Patients on JAK Inhibitors: A Quality Improvement Project at the Rheumatology Practice of an Urban Institution

Jin Feng[1] and Kristaq Koci[2], [1]Icahn School of Medicine at Mount Sinai Morningside and West, New York, NY, [2]Icahn School of Medicine at Mount Sinai Morningside and West, Bronx, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2022 ACR guidelines for vaccination strongly recommend recombinant VZV vaccination for all patients > 18 years old who are taking immunosuppressive medication. Studies have shown that there is a higher risk of shingles in patients on JAK inhibitors. To assess the Shingrix vaccination rate at the rheumatology outpatient practice of an urban academic institution and improve adherence, we initiated a quality improvement project in patients who are on JAK inhibitors.

Methods: The primary aim of our QI project was to increase the Shingrix vaccination rate by 10%. We also attempted to identify the risk factors for eligible patients not receiving Shingrix despite guideline recommendations. We acquired data quarterly from electronic health records, including patients' MRN, age, sex, race, Shingrix vaccination status, and last visit dates. Vaccination status was further validated with manual chart review. Data obtained from 4/1/2022 to 6/30/2022 were considered the baseline. We implemented interventions via Plan-Do-Study-Act (PDSA) method: 1) provide posters at clinics to improve awareness, 2) remind eligible patients during the encounter 3) notify patients' primary rheumatologists quarterly. Data were obtained from 9/1/2022-11/30/2022 and 12/1/2022-2/28/2023 respectively. We used descriptive statistics and analyzed the data via Stata/SE 17.0, stratified by Shingrix vaccination status. We also studied the trend of the Shingrix vaccination rate.

Results: From 4/1/2022 to 2/28/2023, the Shingrix vaccination rate raised from 22.22% (14/63) to 39.19% (29/74) after two cycles of PDSA, meeting our goal of a 10% increase. (Figure 1) After PDSA #1 in 9/2022, the overall vaccination rate slightly declined to 19.67%. After PDSA #2 in 12/2022, it significantly improved. Among all the patients (N = 198) seen from

4/1/2022 - 2/28/2023, 55.56% (110) of them were ≥ 50 years old while 44.44% (88) were < 50 years old. 14.14% (28) were male, while 85.86% (170) were female. 41.41% (82) of the patients were Caucasian, 10.61% (21) were African American, and 9.09% (18) of the patients identified as AAPI.

Patients ≥ 50 years old had higher vaccination rate than patients < 50 years old. (Figure 1) From 4/1/2022 to 2/28/2023, patients ≥ 50 years old had a significant increase in vaccination rate from 29.73% to 56.41%. Male and female patients had similar vaccination rates, with 41.67% male and 38.71% female vaccinated. Despite the improvement in the 12/2022 – 2/2023 period, patients who identified as African American had a lower vaccination rate than their Caucasian counterparts. 25% (2/8) African American patients were vaccinated compared to 46.97% (15/32) Caucasian patients. (Figure 2)

Conclusion: Our interventions improved the Shingrix vaccination rate. Congress's new bill eliminating the cost of vaccines covered by Medicare Part D may have also played a role. Besides achieving our goal of a 10% increase, we identified the risk factors for lower vaccination rates: patients < 50 years old and African American patients. As the PDSA cycle continues, targeted interventions will be implemented to address disparities and improve adherence to Shingrix vaccination.

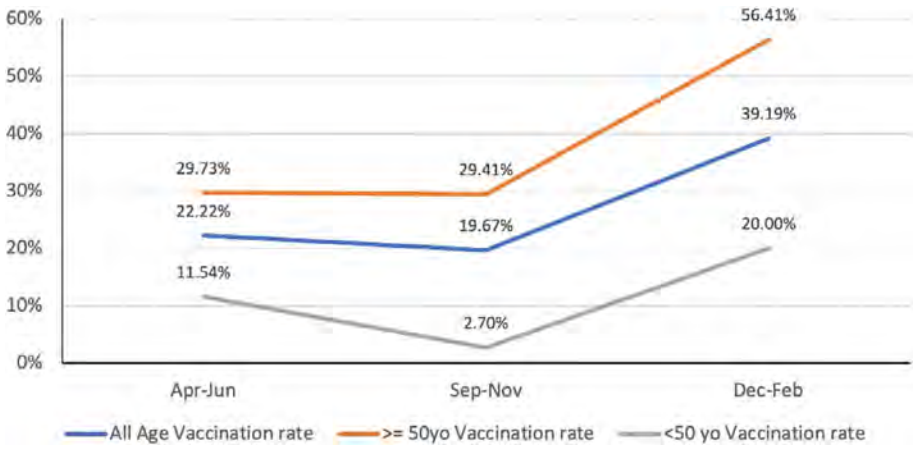

Figure 1. The trend of Shingrix vaccination rate stratified by age

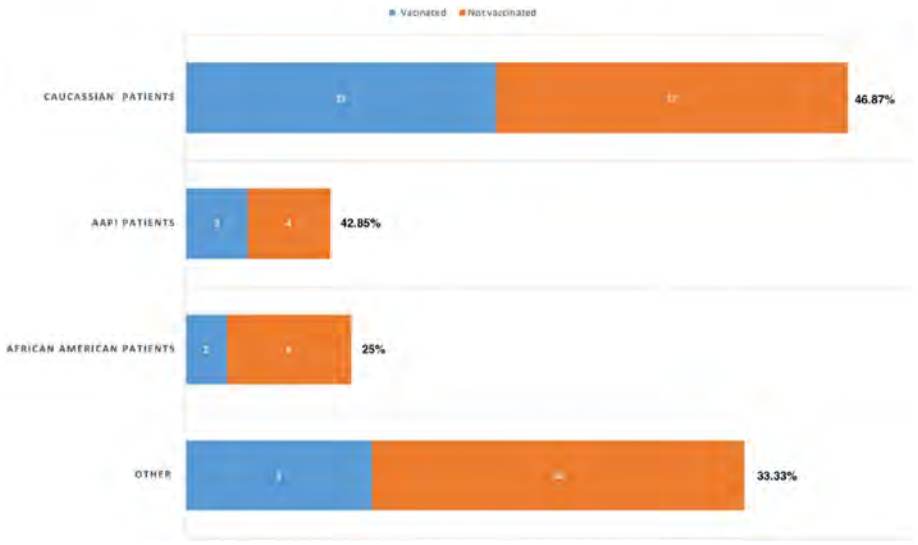

Figure 2. Shingrix vaccination rates by race/ethnicity in PDSA #2 (12/2022 - 2/2023)

Abstract Number: 1087

Characterizing Herpes Zoster Vaccination Patterns in Rheumatoid Arthritis Patients in a Tertiary Care Clinic: A Quality Improvement Approach

Sara Faghihi-Kashani, Arooj Babar and Janice Lin, Stanford University, Palo Alto, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) face an increased risk of herpes zoster (HZ) infection, notably those on immunosuppressive therapy. Herpes zoster infection is associated with comorbidities and a significant economic burden. The American College of Rheumatology recommends the recombinant herpes zoster vaccine for all immunocompromised adults above 18. We aimed to assess the current state of herpes zoster vaccination rates among RA patients at the Stanford Rheumatology Clinic and identify barriers to vaccination.

Methods: We retrospectively collected data from 1,449 consecutive RA patients seen at the Stanford Rheumatology Clinic from October 2017 to October 2022. We reviewed electronic medical records (EMR) to determine patients' characteristics and HZ vaccination status. We categorized medication history based on ever being prescribed; 1) Janus Kinase inhibitor (JAKi), 2) biologic DMARDs (bDMARD), including anti-TNF, anti-IL6, anti-IL1, and anti-CD20, 3) conventional synthetic DMARDs (csDMARD) and 4) Hydroxychloroquine. We surveyed 19 current physicians (attendings and fellows) in the Rheumatology clinic to evaluate their practice patterns on vaccine discussions.

Results: Seventeen providers responded to the physician survey. We found that 61% "sometimes" discuss HZ vaccination with their RA patients, and 46% depend on primary care providers for vaccine discussions. Figure 1 shows the physician-reported HZ vaccination discussion rate based on the medication group. Our RA patient population were mostly female (82%) and 50 years old or older (71%). Among the 1,449 RA patients, only 547 (37.7%) have had HZ vaccination. Among

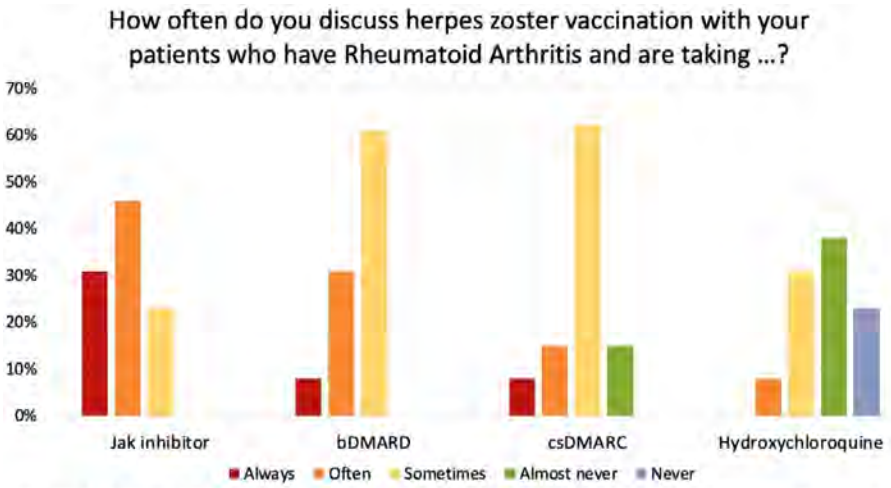

Figure 1. Frequency of herpes zoster vaccination discussion reported by physicians (n=17)

Figure 2. Shingrix vaccination rates by race/ethnicity in PDSA #2 (12/2022 - 2/2023)

those aged below 50 years, only 23 (5.5%) were vaccinated. Among the 178 patients who had ever been prescribed a JAKi, only 79 (44.4%) had the HZ vaccine, and most (90%) were aged 50 years or older (Table 1). The rate of Herpes Zoster vaccination was statistically different based on gender, ethnicity, primary language (English, Spanish, other), insurance type (Medicare, MediCal, Other/Commercial), PCP type (internal, external), and history of Herpes Zoster infection. We did not observe a statistically significant association between vaccination rate and specific immunosuppressive medication.

Conclusion: We identified a suboptimal herpes zoster vaccination rate among RA patients in our clinic, particularly those younger than 50 years on immunosuppressive therapy, including JAKi. We initiated an intervention to improve vaccine awareness by having the medical assistants inquire about the patient's herpes zoster vaccine history during the clinic pre-calls. Patients were also encouraged to have further discussions with their rheumatologists. In addition to promoting patient education and physician awareness, potential future strategies to improve the vaccination rate include fostering collaboration with primary care providers, engaging with pharmacies on campus to make the HZ vaccine readily accessible, and developing automatic reminders in the electronic medical system. Additional efforts, e.g., overcoming insurance barriers, may be needed for at-risk patients younger than 50.

Table 1. Demographic of patients with rheumatoid arthritis based on herpes zoster vaccination status.

Improving JIA Outcomes Assessments in a Large Pediatric Rheumatology Practice: A Fellow Quality Improvement Project

Anna Costello[1], Hallie Carol[1], Dori Abel[2], Sarah Bayefsky[3], Sarah Capponi[1], Adam Mayer[1], Julia Rood[1], Kirsten Spichiger[1], Joshua Madas[1], Lynsey Cecere[1], Megan Roman[1], Beth Rutstein[4] and Jon Burnham[2], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]University of Pennsylvania/ Children's Hospital of Philadelphia, Philadelphia, PA, [4]Division of Rheumatology at Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a chronic autoimmune disease that can result in long-term joint damage if inadequately treated. Collecting validated outcomes data at the point of care can facilitate a "Treat to Target" approach and allow for pre-visit planning and population management. The clinical Juvenile Arthritis Disease Activity Score (cJADAS) is a validated outcome measure that helps rheumatologists assess disease activity. It is a score that is calculated based on three inputs: provider global assessment of disease activity, patient/parent global assessment of wellbeing, and active joint count. We identified a baseline cJADAS completion rate of only 55% in our practice. Our goal was to increase the proportion of JIA visits with cJADAS completion from 55% to 70% by February 2023.

Methods: Through process mapping (Figure 1) and a Pareto analysis (Figure 2),we found that provider cJADAS components were the most common contributor to incomplete scores. Several technical elements within the electronic health record (EHR) were also noted to be limiting cJADAS completion. Through discussions with key divisional stakeholders, we identified methods to engage clinicians in the project, including education, data distribution (monthly reports), inclusion of cJADAS completion as ongoing professional practice evaluation metric, and incorporating the metric in providers' yearly incentive. Our process measure was the proportion of clinic visits with a visit-specific diagnostic code for JIA in which documentation of a cJADAS was completed.

Results: Beginning in September2022, we began educational interventions to promote cJADAS completion. The education included technical components required to complete the scores. Additionally, providers were informed that these outcome measures are critical for ongoing high-quality care and assessment of health disparities. Providers began receiving reports on monthly performance and were allowed to backfill cJADAS scores based on existing documentation. We noted a significant shift in the cJADAS metric beginning in August 2022 from a median of 56% to 79% that has been sustained through February 2023 (Figure 3).

Conclusion: Utilization of multiple change management techniques led to a rapid increase in completion of the cJADASin our patients with JIA. Moving forward, we will continue to monitor the rate of cJADAS completion to assess the sustainability of these changes. We plan to operationalize the scheduling workflow to ensure that patients with elevated cJADAS values remain engaged in rheumatology care and hope that this may help mitigate health disparities.

Improving Recombinant Zoster Vaccination Rates Among Immunosuppressed Veterans in an Academic Rheumatology Clinic

Nagendra Pokala[1], Benjamin Gardner[2], Avni Amratia[1], Daniel Emesiani[3], Jiby Mathew[4], Rashmi Arora[5], Una Makris[6] and Swathi Reddy[7], [1]Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX, [2]Department of Internal Medicine, Baylor University Medical Center, Dallas, TX, [3]Baylor Scott and White Medical Center McKinney, Dallas, TX, [4]VA North Texas Healthcare System, Dallas, TX, [5]Department of Internal Medicine, UT Southwestern Medical Center; VA North Texas Healthcare System, Dallas, TX, [6]UT Southwestern Medical Center and Dallas VA, Dallas, TX, [7]UT Southwestern Medical Center / Dallas VA Medical Center, Colleyville, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Due in part to immunosuppressant medications, patients with rheumatic diseases not only carry a higher risk of herpes zoster reactivation but also worse outcomes. In July 2021 the FDA extended the indication for the recombinant zoster vaccine (Shingrix) to include immunosuppressed adults aged 18 years or older. Shingrix vaccination rates among eligible patients in our rheumatology clinic at the Veterans Affairs (VA) Medical Center remained low. The goal of this quality improvement project is to increase vaccination rates to at least 30% fully vaccinated over a period of 12 months in immunosuppressed patients seen in our rheumatology clinic.

Methods: Patients above the age of 18 seen in the VA Dallas rheumatology clinic and on disease-modifying antirheumatic drugs (DMARDs), excluding hydroxychloroquine, were eligible for inclusion. Patients were considered due for vaccination if they were unvaccinated or partially vaccinated (one vaccine dose received at least two months prior to clinic visit). Shingrix vaccination rate was defined as the percentage of patients due for vaccination at time of clinic visit who received a Shingrix vaccine

within one week after clinic visit. Baseline data were obtained via chart review of patients seen in our rheumatology clinic during the month of October 2021. We implemented three interventions: a) educating rheumatology fellows and attendings regarding the project and the expanded FDA indication in April 2022, b) attaching a Shingrix vaccination patient information sheet to intake forms from May 2022 to October 2022 and c) providing patients with a detailed map with directions to the separate vaccine clinic. Post-intervention data were collected during the months of June, September, October, and November 2022.

Results: For the baseline month of October 2021, our population sampled (n = 100) was on average 61.7 years old (median 64), 79% were men, 53% white, and 43% had rheumatoid arthritis. At baseline, 12% of eligible patients were fully vaccinated and 77% were unvaccinated at time of clinic visit. The Shingrix vaccination rate of due patients within one week after clinic

Table 1. Patient demographics for pre-intervention and post-intervention groups

	Pre-Intervention (n = 100)	Post-Intervention (n = 405)
Patient Characteristics		
Average age (years)	61.7	61.5
Men n (%)	79 (79.0%)	333 (82.2%)
Race		
White n (%)	53 (53.0%)	228 (56.3%)
Black n (%)	34 (34.0%)	124 (30.6%)
Hispanic n (%)	7 (7.0%)	16 (4.0%)
Rheumatic Disease		
Rheumatoid Arthritis n (%)	43 (43.0%)	176 (43.5%)
Seronegative Spondyloarthritis n (%)	34 (34.0%)	133 (32.8%)
Polymyalgia Rheumatica/Giant Cell Arteritis n (%)	6 (6.0%)	25 (6.2%)

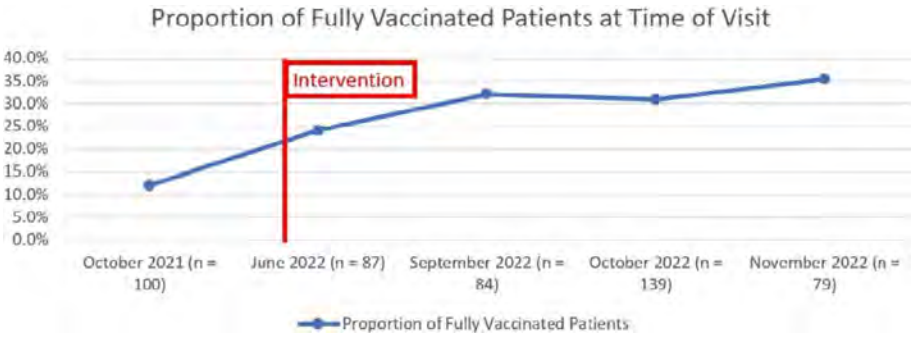

Figure 1. Proportion of fully vaccinated patients at time of visit during pre-intervention (October 2021) and post-intervention (June, September, October, November 2022) months.

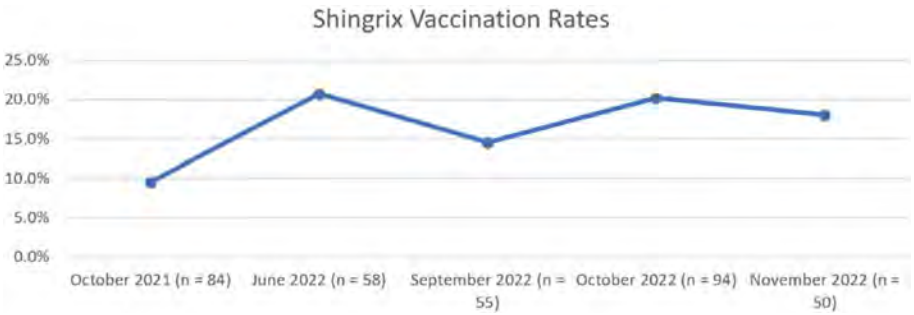

Figure 2. Percentage of patients due for vaccination at time of clinic visit who received a Shingrix vaccine within one week during pre-intervention (October 2021) and post-intervention (June, September, October, November 2022) months.

visit was 9.5% (n = 84). During post-intervention, our population sampled (n = 405) had similar demographics to the baseline (Table 1). For the post-intervention months of June, September, October, and November 2022, the proportion of fully vaccinated patients at time of clinic visit increased from baseline (Figure 1). Vaccination rates also increased during the post-intervention months (Figure 2).

Conclusion: The baseline proportion of fully vaccinated patients and vaccination rates were low among immunosuppressed patients seen in our rheumatology clinic. While our post-intervention evaluation showed an increase in the proportion of fully vaccinated patients as well as vaccination rates, overall post-intervention vaccination rates remained low at < 50%, leaving room for improvement. Our next steps will include streamlining our vaccination processes, and considering alternative communication approaches to educate our patients, especially those with vaccine hesitancy.

Improved Patient and Team Satisfaction and Pharmacy Outcomes After Implementing a Rheumatology Clinical Pharmacist in a Large Academic Medical Center

Shelby Gomez[1], Trisha Ludwig[1], Katherine Hartkopf[2], Sancia Ferguson[3], Lori Zemlicka[4], Mindy Jones[5] and Christie M. Bartels[6], [1]UW Health Pharmacy, Madison, WI, [2]Pharmacy Society of Wisconsin, Madison, WI, [3]University of Wisconsin, Madison, WI, [4]UW Health, Madison, WI, [5]Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, [6]University of Wisconsin, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: We embedded a clinical pharmacist into our university rheumatology clinics beginning in June 2022 to improve patient experience and reduce provider burden based on projected improved medication access and improved organizational financial health. The objective was to demonstrate how implementing a rheumatology clinical pharmacist with a medication access team can impact patient, provider, staff, and pharmacy outcomes.

Methods: In this mixed methods study at two academic clinics in 2022-23, we employed pre-post surveys and electronic health record (EHR) data review. We conducted a pre-implementation pharmacy services satisfaction survey and baseline needs assessment with providers and clinical staff to set priorities and leveraged existing patient surveys pre-post. Based on survey results, we categorized outcome measures of clinical pharmacist and medication access team impact into four groups: patient, provider, clinic staff, and pharmacy. EHR data included prior authorization quantity and turnaround time, manufacturer assistance referrals, time to infusion, and number of new patient enrollments, and prescriptions captured within the organizational specialty pharmacy. At six-months post-implementation, providers and clinic staff were asked to complete a post-implementation survey to assess the impact of the embedded clinical pharmacist.

Results: Patient and EHR data showed improvement after the clinical pharmacist joined the rheumatology clinic team. When asked "How well the staff worked together to care for you?" 83.3% after vs. 77.2% baseline (Q2 2022 n=298 vs. Q2 2023, n = 277) responded "extremely well" (p=0.047). The time from order to infusion decreased 9-13 days for infusions of 4 hours

or less (Table 1). Prior authorizations with a turnaround time greater than 5 days decreased by 27% (from 40 to 29/month); prior authorizations resulting in appeal decreased by 86% (from 7 to 1/month, Table 1). Our medication assistance program assisted many more patients (n=55 over 6 months) in obtaining medications through free drug programs. Prescription capture rate increased by 15% and patients enrolled in our specialty pharmacy increased from 27.8% (204/734) in Q1 2022, to 31.8% (228/718) in Q1 2023 (Figure 1).

Table 1. Medication Access

Table 1. Medication Access

Infusion Therapy- Mean Time from Order to Administration			
Treatment Duration	Pre-Implementation	Post-Implementation	Mean Improvement
2-hour infusions	20 days	7 days	13 d
4-hour infusions	21 days	12 days	9 d
6-hour infusions	32 days	34 days; Urgent spots now avail.	NA
Prior Authorization (PA) Turnaround Time and Appeals			
	Pre-Implementation	Post-Implementation	Improvement
PAs with turnaround > 5 days	40 per month	29 per month	27%
Number of Appeals	7 per month	1 per month	86%

Figure 1. Specialty Pharmacy Outcomes

Table 2. Provider and Clinic Staff Satisfaction Mean Response Pre-Post Pharmacist Implementation

Table 2. Provider and Clinic Staff Satisfaction Mean Response Pre-Post Pharmacist Implementation

Staff	Domain	Pre-Implementation	Post-Implementation	p-value t-test of means
Provider n=9/15		n=9/15	N=8/15	p<0.001
	Availability	5.89	9.8	
	Prior Authorization	5.67	9.6	
	Support for Appeals	5.11	9	
	Support for Infusions	7.61	9	
Clinic Staff/ Nurses n=5/5		n=5/5	n=5/5	p=0.015
	Support for Infusions	5.7	9.5	
	Prior Authorization	6.75	9.5	
	Confidence on Lab Monitoring for Anti-Rheumatic Medications	8.4	9.6	

Provider and staff satisfaction also significantly improved. All provider items on medication communication, prior authorization assistance, and support for appeals and infusions rose (Table 2, p< 0.001). Clinic staff satisfaction also improved in the prior authorization process (mean 9.5 vs 6.75 on scale of 1-10 best) and support for infusions (5.7 vs 9.5; pooled p=0.015,). Nurses also reported being more comfortable on anti-rheumatic medication lab monitoring after education from our clinical pharmacist.

Conclusion: The addition of an embedded rheumatology clinical pharmacist with direct support from a medication access team has improved patient, provider, and clinical staff satisfaction and outcomes. Specialty pharmacy prescription capture improved, and the cost to support the position was covered by improved financial outcomes.

Abstract Number: 1091

Prevalence of Loss to Follow up of Systemic Lupus Erythematosus Patients and Its Effect on Quality of Care

Raphael Kirou, Cesar Avalos and Ellen Ginzler, SUNY Downstate Health Sciences University, Brooklyn, NY

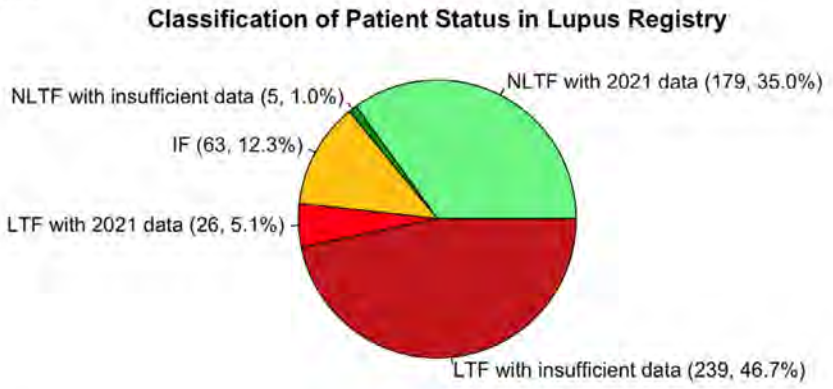
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Quality of care (QoC) in SLE patients has been studied by Schmajuk et al. (*Arthritis Care Res*2022), who developed six quality measures assessing blood pressure, lupus nephritis screening, hydroxychloroquine prescription, and corticosteroid dosing. In this study, prompted by the increased loss to follow up and disruption in care associated with the COVID-19 pandemic, we quantify the effect of loss to follow up from the rheumatology clinic at University Hospital Brooklyn (UHB) on QoC of our SLE patients.

Methods: Using the Lupus Registry at UHB rheumatology clinic, we identified all SLE patients who had any rheumatology visits between 2007 and 2019, excluding patients reported dead in 2021 or earlier. We stratified these patients into three groups based on their follow-up status: lost to follow up (all-LTF; no rheumatology visits in 2020 and 2021), not lost to follow up (all-NLTF; ≥1 rheumatology visits in each year 2019, 2020, and 2021), and inconsistently followed (IF; remaining patients). Within all-LTF, we selected all patients who had ≥2 outpatient visits to UHB at least 30 days apart in 2021 (LTF; n=26). We then matched these patients 1:2 by age and sex to all-NLTF patients with ≥2 outpatient visits to UHB at least 30 days apart in 2021 (NLTF; n=52). Finally, we completed a chart review to identify whether the six SLE quality measures outlined by Schmajuk et al. were met for these patients. To compare LTF and NLTF patients, we used chi-square analyses and a two-sample t-test ($\alpha = 0.05$).

Results: We determined that of 512 eligible patients in the registry, all of whom satisfied either the 1995 ACR or SLICC criteria for SLE, 265 (52%) were all-LTF and 184 (36%) were all-NLTF [Figure 1]. As expected, the average age (49) and the female prevalence (89%) did not differ between LTF and matched NLTF [Table 1]. Notably, 50% of LTF patients had ESRD (47% with renal transplant), compared to 2% of NLTF patients (2% with renal transplant). NLTF patients received blood pressure measurements and hydroxychloroquine prescriptions at significantly greater rates (96% and 96% respectively) than LTF patients (81% and 36% respectively) [Table 2]. Although not statistically significant, they also tended to receive more urine studies (88%) than LTF patients (76%), but also higher frequency of high dose corticosteroids (27%) than LTF patients (12%). Overall, NLTF patients received a greater proportion of eligible quality measures (0.81) than did LTF patients (0.66).

Figure 1



Notes: all-LTF comprises "LTF with 2021 data" and "LTF with insufficient data". All-NLTF comprises "NLTF with 2021 data" and "NLTF with insufficient data". Matched NLTF (n=52) taken from "NLTF with 2021 data" (n=179).

Table 1

	LTF (n = 26)	Matched NLTF (n = 52)
Sex	• Male: 3 (11.5%) • Female: 23 (88.5%)	• Male: 6 (11.5%) • Female: 46 (88.5%)
Race	• Black/African-American: 26 (100.0%)	• Black/African-American: 47 (90.4%) • White: 3 (5.8%) • Undisclosed: 2 (3.8%)
Age (Mean ± SD)	49.39 ± 15.74	49.09 ± 16.03
ESRD	13 (50.0%)	1 (1.9%)
Renal Transplant	12 (46.2%)	1 (1.9%)
Total Number of visits in 2021 (Mean ± SD)	8.73 ± 6.50	11.52 ± 8.09

Table 2

Quality Measures (2021)	LTF (n = 26)	Matched NLTF (n = 52)	p-value
BP Measurement [≥2 BP measurements ≥30 days apart]	21/26 (80.77%)	50/52 (96.15%)	0.025[1]
BP Control [Not having ≥2 blood pressure measurements ≥30 days apart with SBP>140 or DBP>90][3]	11/21 (52.38%)	30/50 (60.00%)	0.553[1]
Lupus Nephritis Screening [≥1 documented urine study (urinalysis, urine protein, or urine protein:creatinine ratio)][4]	19/25 (76.00%)	46/52 (88.46%)	0.158[1]
HCQ Prescription [At least one HCQ prescription][5]	9/25 (36.00%)	45/47 (95.74%)	<0.001[1]
HCQ Safe Dosing [HCQ dose ≤5 mg/kg/day at last visit][6]	8/9 (88.89%)	37/45 (82.2%)	0.624[1]
Corticosteroid Safe Dosing [No more than 90 days of >7.5 mg/day of prednisone]	23/26 (88.46%)	38/52 (73.08%)	0.121[1]
All eligible quality measures met	3/26 (11.54%)	14/52 (26.92%)	0.121[1]
Proportion of eligible quality measures met (Mean ± SD)	0.66 ± 0.23	0.81 ± 0.16	0.005[2]

Notes:
Quality measures adapted from Schmajuk et al. (2022) and measured for the calendar year 2021.
SBP = systolic blood pressure; DBP = diastolic blood pressure; HCQ = hydroxychloroquine.

[1]Chi-squared test
[2]Two sample t-test (unequal variances)
[3]Only patients that met "BP Measurement" measure were eligible for "BP Control" measure
[4]Patients on hemodialysis were excluded from "Lupus Nephritis Screening" measure
[5]Patients with HCQ toxicity were excluded from "HCQ Prescription" measure
[6]Only patients that met "HCQ Prescription" measure were eligible for "HCQ Safe Dosing" measure

Conclusion: Only 36% of SLE patients at UHB were consistently followed from 2019-2021. This by itself is an indicator of poor QoC, and may portend poor outcomes. In addition, LTF patients met fewer quality measures than NLTF patients. Conversely, LTF patients tended to have lower corticosteroid doses than NLTF patients, which may be indicative of fewer symptoms, another explanation for their loss to follow up. However, the possibility of subclinical SLE progression, such as lupus nephritis, means that loss to follow up can still be detrimental to these patients. We conclude that loss to follow up is a significant threat to QoC in SLE patients, and that efforts to address follow-up barriers should be made by rheumatologists in collaboration with other health care providers.

Disclosure: R. Kirou: None; **C. Avalos**: None; **E. Ginzler**: None.

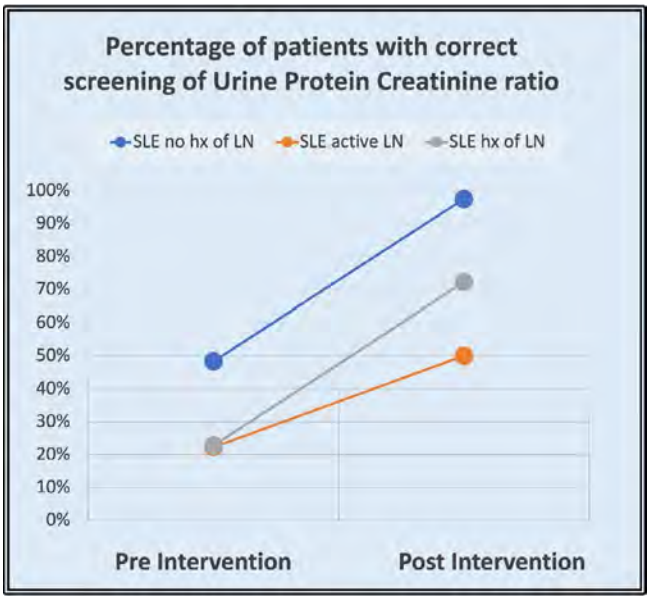
Improving Screening of Lupus Nephritis in Patients with Systemic Lupus Erythematous

Lilian Otalora Rojas[1], Gurjit S Kaeley[2] and Myint Thway[3], [1]University of Florida, Ponte Vedra Beach, FL, [2]University of Florida College of Medicine – Jacksonville, Ponte Vedra Beach, FL, [3]UF Jacksonville, Ponte Vedra, FL

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Nephritis remains one of the most devastating complications of Systemic lupus erythematosus (SLE). Lupus nephritis (LN) significantly reduces overall survival to approximately 88% at 10 years. The ACR guideline suggests that the frequency of follow-up visits is determined by the activity and severity of the disease and its complications. Current recommendations for monitoring lupus nephritis include UA (urine analysis with microscopy) and urine Protein/creatinine ratio (UPCR). This test should be obtained every 6 months for patients with SLE without active LN, every 3 months



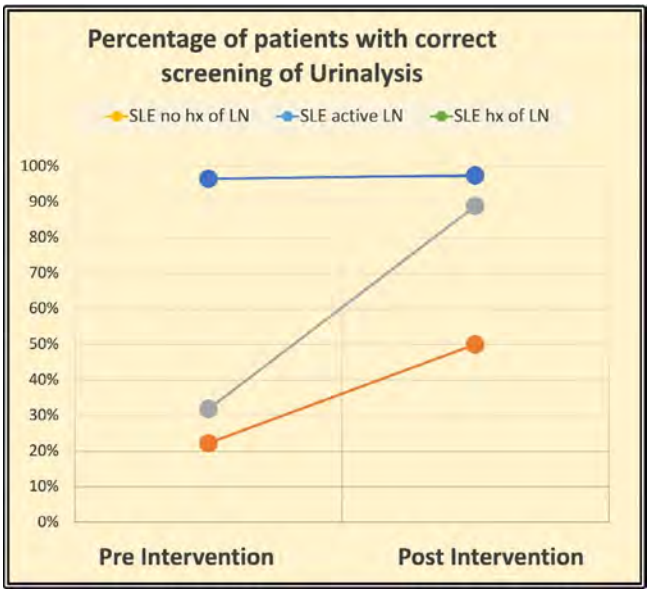
Improvement on screening rate of proteinuria

in patients with non-active LN, and every month in patients with active LN. Our overall goal was to increase the appropriate monitoring of LN in patients with SLE in our rheumatology clinic.

Methods: This quality improvement project retrospectively analyzed the medical records of 60 patients diagnosed with SLE who were seen at the rheumatology clinic at the University of Florida in Jacksonville, FL, from January 2019 to December 2019. Patients were classified as SLE without LN, non-active LN, and with active LN. The frequency of performed UA and UPCR, were recorded in each subject. After identifying baseline values, we worked with clinicians and clinic support staff on intervention. Interventions included educating fellows, faculty, and staff about current guidelines for LN screening and monitoring, creating flyers, and generating a panel order in the electronic health system (EPIC) for SLE, including UA and UPCR tests. A subsequent retrospective chart review of 60 patients was performed after 12 months to analyze the impact of interventions.

Results: Initial data showed the need for improvement in monitoring/screening laboratory parameters (UPCR and UA) for LN in our patients with SLE. Preintervention analysis showed that less than 50% of patients were correctly monitored for UPCR in the three groups, and less than 40% were monitored for UA in patients with active LN and with a history of LN as recommended per ACR guidelines. Just one group of patients: SLE patients with no LN history had a high UA monitoring rate (97%). After the intervention, monitoring/screening for LN in patients with SLE improved: Regarding UPCR, preintervention results were 48% (no history of LN), 23% (history of LN), and 22% (active LN), and it increased to 97%, 72% and 50% respectively. Adequate monitoring of UA preintervention results were 97% (no history of LN), 32% (history of LN), and 22% (active LN, and postintervention 97%, 89%, 50%. A separate chart review of those patients suggested that compliance of patients is the major issue of proper testing intervals.

Conclusion: LN is associated with increased mortality and morbidity in SLE patients. Survival of SLE has improved in the past few decades with advanced treatment, including early diagnosis of LN. ACR developed recommendations for screening LN and follow-up tests. Adherence to proper screening may help renal survival by treating exacerbations on a timely basis. This study employed various interventional methods to increase the screening of Urinalysis and proteinuria. However, patient compliance remains a challenge.



Improvement on screening rate of Urine analysis

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Measures & Measurement of Healthcare Quality Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Even though individuals with inflammatory rheumatic diseases (IRDs) were excluded from the SARS-CoV-2 vaccine trails, studies have shown that these individuals at risk of a severe course of infection do show an immune response after vaccination. The goal of our study was to show the development of the adaptive immunity over time and its activity towards different variants of concern (VoC).

Methods: For this retrospective study, patients with IRDs and a healthy control group were recruited. To evaluate the immunity induced by SARS-CoV-2 vaccination the antibody titres against the S1-domain of the spike protein of SARS-CoV-2 (BAU/ml) and the IC_{50} neutralization of different VoCs (EU1, Delta, Omicron-BA.5, BQ1.1, BF.7) were quantified at different time points before and after each vaccination. The study period started before the first and ended 26 weeks after the third vaccination.

Results: In total 187 patients with IRDs [mean age (standard deviation (SD)) 54.5 (±14.8) years, 65.8% female] and 84 healthy controls [46.7 (±13.2) years, 78.7% female] were included into the study (Table 1). Even though both patients and controls showed high antibody titres after the first two vaccinations [median (interquartile range (IQR)) 1600 BAU/ml (378.2-3468); 4446 BAU/ml (1943-7200)] the titres of the patients were significantly lower ($P< 0.0001$). After declining over the next 24 weeks, the titres showed another significant rise after the third vaccination in both groups [patients: 4344 BAU/ml (933.2-8023); controls: 5795 BAU/ml (3779-12209)]. However, the levels reached by the patients were still significantly lower compared to the controls ($P=0.04$). The decline of titres after the third vaccination was not as operand as after the second in either group (Fig. 1). Both groups displayed robust neutralization activities after the first two vaccinations for EU1, Delta and BA.5 that increased after the third dose of the mRNA vaccine. However, the controls showed a rise in neutralization capacity until 16 weeks after the second vaccination while it already started declining after the 2-week measurement in patients resulting in a significant difference. Notably, neutralization of Delta and BA.5 were significantly lower compared to the ancestral EU1. Good neutralization capacity of BQ1.1 in both groups were only reached after the third vaccination, while neither group presented reliable neutralization of the highly immunoevasive BF.7 after any vaccination. (Fig. 2) Individuals treated with rituximab were not able to mount a reliable humoral immune response after any vaccination. However, they did show adaptive T-cell responses which were comparable to the controls.

Table 1: Study population

	IRD[1] patients	Healthy control group
n	187	84
Age mean (SD[2])	54,5 (±14,8)	46,7 (±13,2)
Sex % (n)	65,8 (123)	78,7 (66)
IRDs: % (n)		
Arthritis	62,0 (116)	
Soft connective tissue disorders	15,5 (29)	
Vasculitis	16,0 (30)	
Other	7,5 (14)

Ixekizumab	2,7 (5)	
MMF	3,2 (6)	
Glucocorticoids	19,3 (36)	
Infections % (n)	21,9 (41)	25,0 (21)

[1]inflammatory rheumatic diseases
[2]standard deviation

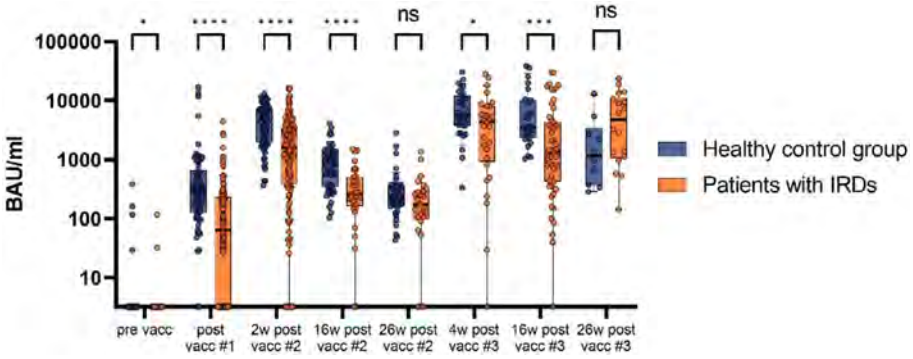

Figure 1: Antibody titres against the S1-domain of the spikeprotein of SARS-CoV-2 over time

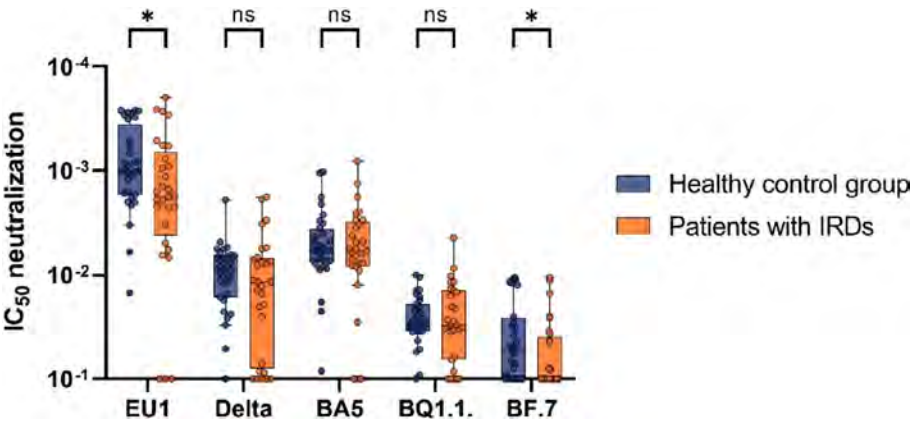

Figure 2: Neutralization capacity for different SARS-CoV-2 variants of concern four weeks after the third vaccination

Conclusion: Although patients with IRDs show lower anti-SARS-CoV-2 spike antibody titres and partly lower IC_{50} neutralization compared to healthy controls, most of them mount a robust immune response against SARS-CoV-2, indicating some level of protection from a severe course of infection. However, the original vaccines did not induce a robust neutralization capacity for the recently emerged BF.7 variant in patients or controls. Thus, variant-adapted vaccines should be considered, in particular, in high-risk patient groups, including individuals with IRDs.

"Lupus Doesn't Have Me, I Have Lupus" a Patient Centered Quality Improvement Project to Increase Medication Adherence for Patients with Lupus Nephritis

Christopher Macko[1], Patty Chen[2], Roger Santos[3], Nirmala Ramalingam[4], Nicole Tran[5] and Sijie Zheng[6], [1]Kaiser Oakland Internal Medicine Residency, Piedmont, CA, [2]Kaiser Oakland Medical Center Department of Rheumatology, Orinda, CA, [3]Kaiser East Bay Department of Pharmacy, Oakland, CA, [4]Kaiser Oakland Medical Center Department of Graduate Medical Education, Oakland, CA, [5]Kaiser Oakland Department of Adult and Family Medicine, Oakland, CA, [6]Kaiser Oakland Medical Center Department of Nephrology, Oakland, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is the most common cause of kidney injury in patients with systemic lupus erythematous (SLE) and is associated with higher morbidity and mortality. Low adherence to treatment regimens is common amongst patients with LN and is correlated with high rates of relapse, increased hospitalizations, and poor renal outcomes. Our objective was to assess and identify barriers to medication adherence for our patients with LNon mycophenolate mofetil (MMF).We used this data to design targeted interventions aimed at improving medication adherence for our patients with LN on MMF in our large integrated health system at Kaiser Permanente Oakland Medical Center, California.

Methods: We identified patients with a diagnosis of LN, who were taking MMF between 11/30/21 and 11/30/22. We collected demographic information including age, gender, 30-day copay, ethnicity, requirement of renal replacement therapy, and proportion of days covered (PDC) for MMF. We identified patients with a PDC of less than80% and surveyed them for barriers to medication adherence. Our survey questions sought to elucidate barriers such as medication side effects, cost, refill processes, and lab draws. We also asked open-ended questions to gain insight into how SLE has affected their lives.

Results: Of 37 patients with LNon MMF, almost a third (12/37) had PDC less than 80%. More than half (7/12) of these patients agreed to be interviewed. They identified the following barriers to medication adherence: forgetfulness57% (4/7), incompletelabwork28% (2/7),medication cost 14% (1/7),and intentionally missed doses 14% (1/7). No patients identified

Table 1: Characteristics of patients with LN on MMF

	Patients on MMF (N=37)	Patient on MMF with PDC <80% (N=12)	Patients on MMF with PDC <80% who agreed to be interviewed (N=7)
Median age (yrs)	47	44.5	40
Female sex %	89%	84%	100%
RRT %	3%	0%	0%
Ethnicity %			
Asian	46%	25%	14%
Black	22%	25%	43%
Hispanic	32%	50%	43%
NHW	0%	0%	0%
30-day co-pay range:	$0-$14.63	$0-$14.63	$0-$14.63
Median 30-day co-pay:	$3.33	$3.94	$4.55

Abbreviations: RRT- renal replacement therapy, MMF- Mycophenolate Mofetil, LN- Lupus Nephritis

Figure 1: Proportion of days covered (PDC) for patients with LN on MMF

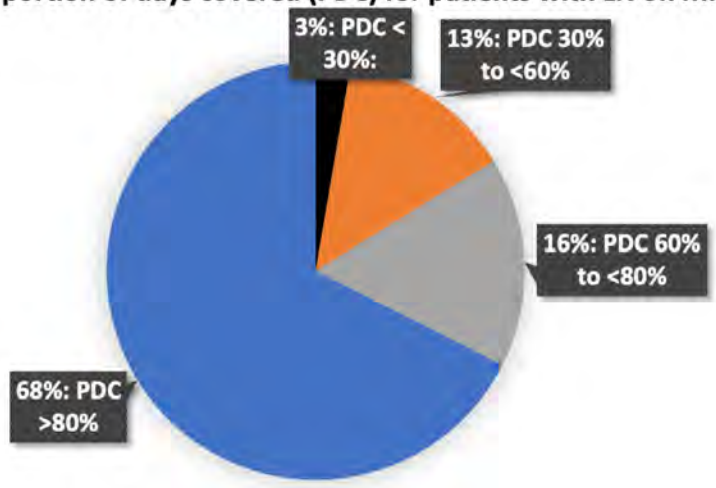

Figure 2: Patient reported barriers to medication adherence

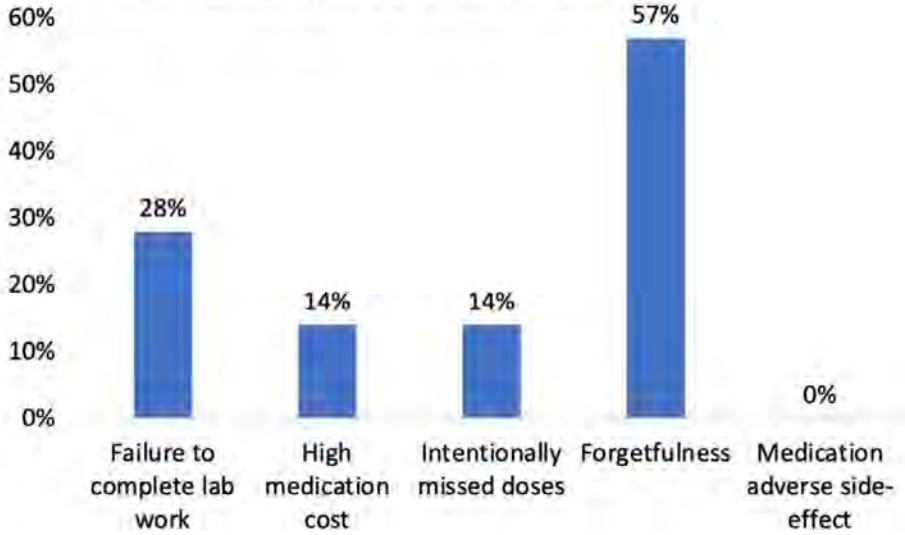

medication side effects as a barrier. More than two thirds (5/7) reported no issues with obtaining new prescriptions from the pharmacy. The median 100-day co-pay for MMF was $13.13 and 2/7 (28%) patients paid $0 for their medications.

Conclusion: At KP Oakland, two thirds of our patients with LNare adherent to their MMF; forgetfulness appears to be a challenge for our non-adherent patients. The next steps to our quality improvement initiatives will focus on the following: 1) patient and provider education about tools (medication and lab reminder apps) to promote medication adherence and 2) creating a multidisciplinary rheumatology and nephrology committee to identify and discuss patients with LN who are at risk of disease progression.

Abstract Number: 1095

Engagement with the RISE Registry Clinician Dashboard Is Associated with Higher Performance on Rheumatology Quality Measures

Emma Kersey[1], Jing Li[1], Julia Kay[1], Julia Adler-Milstein[1], Jinoos Yazdany[2] and Gabriela Schmajuk[3], [1]University of California San Francisco, San Francisco, CA, [2]University of California, General Department of Medicine, Division of Rheumatology, San Francisco, CA, [3]UCSF / SFVA, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The American College of Rheumatology's Rheumatology Informatics System for Effectiveness (RISE) EHR-based registry facilitates quality measure calculation and reporting for rheumatology practices in national pay-for-performance programs. Participating practices can leverage RISE's web-based clinician dashboard to monitor performance on quality measures, benchmark performance against registry means, and explore patient-level data to identify gaps in care. Despite substantial investment in these dashboards, the extent to which they help improve performance on quality measures remains unclear. We investigated the relationship between practice engagement with the RISE web-based dashboard and performance on rheumatology-specific measures in 2021.

Methods: Eligible practices were categorized into 3 engagement groups based on practice personnel's dashboard interactions (number of sessions and actions performed, such as drilldowns and exports) during the study period: no engagement (0 sessions), some engagement (≤ median actions), high engagement (> median actions) (**Table**). Practice performance was assessed on both individual and composite measures, utilizing all available rheumatology-specific measures (range 1 to 8) per practice that had ≥20 eligible patients. The composite measure incorporated all rheumatology-specific measures per practice and was denominator-weighted, i.e., based on the number of patients included in each individual measure denominator. Individual measure performance analysis was restricted to measures with data from ≥5 practices per engagement group. Linear regression models were used to calculate predictive margins and 95% confidence intervals for quality performance for each engagement group. Differences in performance across engagement groups were assessed via pairwise comparisons; linear trends were evaluated using orthogonal polynomial contrasts (**Figure**).

Results: Most of the 204 included practices were single-specialty (59.8%) or solo practices (29.4%), with a median of 2 providers and 4970 patients (**Table**). Among these practices, 11% had no dashboard engagement, 76% had some engagement, and 12% were highly engaged. Performance on individual rheumatology-specific measures ranged from 28%-72%

(median (IQR) 60% (47-66%)). The majority of practices' (75%) composite scores included ≥3 out of 8 possible rheumatology-specific measures with a median (IQR) performance of 65% (40-79%). We observed a pattern of higher measure performance with more dashboard engagement: 3 out of 5 individual rheumatology-specific measures and the composite measure exhibited a significant linear trend at the 5% level (**Figure**).

Table. RISE registry Practice Characteristics by Level of RISE Dashboard Engagement

	Total Practices (N)	Dashboard Engagement (N(%))		
		None	*Some*	*High*
	204	23 (11.2)	156 (76.4)	25 (12.3)
Dashboard Interactions (median (IQR))				
Total Sessions	9.0 (3.0 - 20.0)	0.0 (0.0 - 0.0)	9.0 (5.0 - 17.0)	43.0 (33.0 - 56.0)
Total Actions[1]	3.0 (0.0 - 18.0)	0.0 (0.0 - 0.0)	3.0 (0.0 - 12.5)	86.0 (58.0 - 116.0)
Practice Characteristics				
Practice Type (N(%))				
Single-Specialty	122 (59.8)	12 (52.2)	94 (60.3)	16 (64.0)
Solo Practitioner	60 (29.4)	8 (34.8)	46 (29.5)	6 (24.0)
Multi-Specialty	22 (10.7)	3 (13.0)	16 (10.3)	3 (12.0)
Practice Size (median (IQR))				
Total Patients	4970 (2710 - 9035)	5682 (1318 - 8225)	4673 (2678 - 8923)	7217 (3788 - 12906)
Total Providers	2 (1 - 5)	2 (1 - 4)	2 (1 - 5)	4 (1 - 8)
Patient Casemix (median (IQR))				
Age, median	62.0 (60.0 - 65.0)	63.0 (60.0 - 64.0)	63.0 (61.0 - 66.0)	61.0 (59.0 - 63.0)
Female, %	75.1 (73.1 - 77.3)	74.6 (73.6 - 79.1)	75.1 (72.5 - 77.1)	75.2 (73.3 - 77.2)
Medicare Insurance, %	33.2 (25.9 - 41.9)	27.1 (23.3 - 40.1)	33.5 (25.8 - 42.3)	34.3 (29.4 - 39.5)
National ADI[2], median	45.5 (29.5 - 59.3)	41.0 (30.0 - 65.0)	46.0 (29.0 - 59.5)	45.0 (39.0 - 58.0)

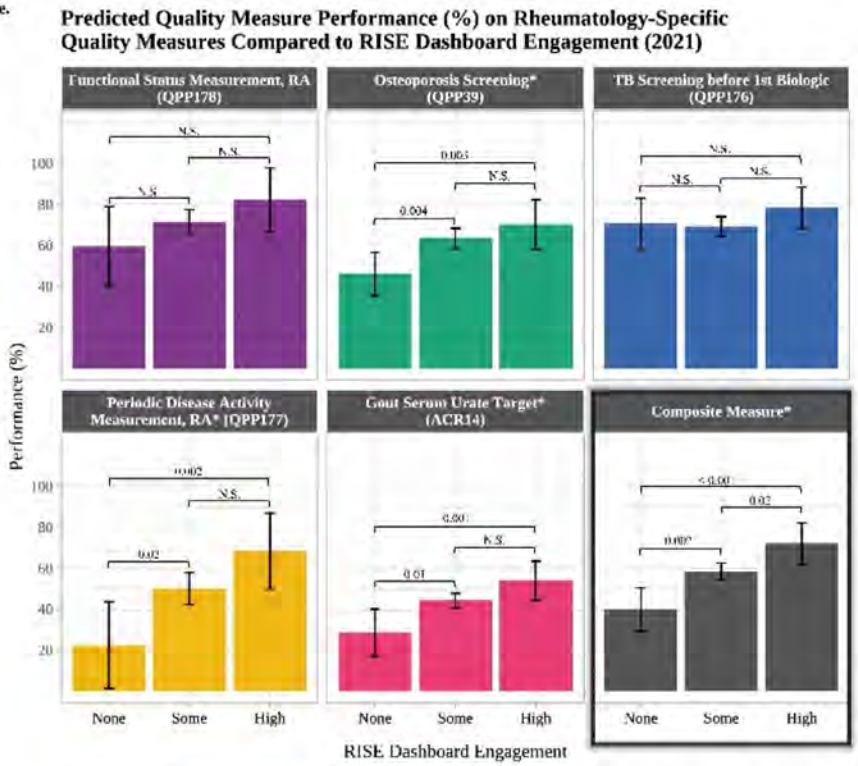
Table. summarizes dashboard interactions (total logins and actions) and practice characteristics of the affiliated RISE web-dashboard users stratified by level of engagement. Median and interquartile range (IQR), and frequency (N) and percent (%) are displayed for continuous and categorical variables, respectively.

[1]Total actions completed on the RISE dashboard during a login session included the following: total views of quality performance on selected measures at the patient-level, total exports of quality performance on selected measures at the patient-level, and total exports of a summary-level report of selected quality measures.

[2]National ADI (Area Deprivation Index) is a proxy for socioeconomic status (SES) and is derived from the University of Wisconsin School of Medicine and Public Health, Neighborhood Atlas. A higher ADI indicates lower SES (more neighborhood-level disadvantage).

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Figure.



*Significant linear trend at the 5% level between RISE dashboard engagement and quality measure performance. **Rheumatology-specific measures** were defined as measures that aligned with care routinely provided by rheumatologists. The **composite measure** included the following measures, if reported by practices: QPP178 (Functional Status Screening for RA), QPP39 (Osteoporosis Screening for patients 65–), QPP176 (TB Screening before first Biologic), QPP177 (Periodic Disease Activity Measurement for RA), ACR14 (Gout Serum Urate < 6mg/dL), ACR10 (Hepatitis B screening), ACR12 (PsA Periodic Disease Activity Assessment), and ACR15 (Hydroxychloroquine Dosing).

Conclusion: This cross-sectional analysis revealed a dose-response between degree of dashboard engagement and practice-level quality performance: RISE practices with higher levels of dashboard engagement exhibited better quality performance. Further investigation is needed to determine whether more dashboard engagement yields meaningful quality improvement over time, and whether performance is determined by engagement or vice versa.

Abstract Number: 1096

A Quality Improvement Project About Medication Adherence to Understand What Questions Rheumatology Patients Have About Their Medications, and How They Answer Them

Lena Eder[1], Kai Sun[2], Sonali Bracken[3], Ann Cameron Barr[4], Jeffrey Shen[4], Dahima Cintron[4], Mithu Maheswaranathan[4], Catherine Sims[2], Poorva Apte[4], Megan Milne[5], Nathaniel Harris[4] and David Leverenz[6], [1]Duke University, Chapel Hill, NC, [2]Duke University, Durham, NC, [3]Duke University Hospital, Apex, NC, [4]Duke University Hospital, Durham, NC, [5]Costal Carolina Health Care, New Bern, NC, [6]Duke University School of Medicine, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication non-adherence remains high among rheumatology patients, yet little is known about adherence barriers faced by patients or interventions that improve adherence. As part of a quality improvement initiative, we aimed to better understand questions rheumatology patients have about their medications, how they seek answers, and factors associated with self-reported medication adherence.

Methods: Patient surveys were administered at a fellows; continuity clinic at periodic intervals between 5/5/2022 – 4/26/2023. The survey consisted of 5 items assessing length of time taking rheumatic medications, self-reported confidence with taking medications correctly, what patients would like to learn about their medications, how patients find answers to questions about their rheumatic medications, and adherence to rheumatic medications over the past month. Survey responses were analyzed to determine differences in patient needs based on their years of experience taking rheumatic medications (0-5 years vs. >5 years) and their self-reported adherence with rheumatic medications (< 80% adherence vs. >=80%). Comparisons were performed with Fisher's exact test.

Results: Of the 88 surveys that were administered, 80 patients answered at least one question (response rate 91%). Of all respondents, 74% reported taking rheumatic medications for five years or less, 82% reported feeling "very confident" in taking their medications, and 80% reported adherence over the past month (Table 1). The top categories of information that patients wanted to learn about were "side effects I could experience" (46%) and "how the medications work" (37%). To answer questions about rheumatic medications, most respondents "ask [their] rheumatology provider directly" (83%) or turn to "Google or other internet search engine" (59%). There were no significant differences in confidence, questions about medications, or methods of answering questions according to experience taking rheumatic medications (Table 2). Patients reporting non-adherence were significantly less likely than those reporting adherence to ask their provider directly about their rheumatic medications (57% vs. 88%, p=0.01) and more likely to turn to internet searches (86% vs. 52%, p=0.03) and social media (29% vs. 5%, p=0.02) for information (Table 3).

Table 1: Overall survey results among 80 respondents.

	n (%)
How long have you been taking medications that treat a rheumatology disease?	
Total number of respondents to this question*	n=78
Less than 1 year, n (%)	32 (41%)
Between 1 to 5 years, n (%)	26 (33%)

I ask my family or friends for advice, n (%)	0 (0%)	5 (8%)	0.6
Google or another internet search engine, n (%)	12 (86%)	32 (52%)	**0.03**
Social media, n (%)	4 (29%)	3 (5%)	**0.02**
Support groups, n (%)	2 (14%)	2 (3%)	0.2
Other, n (%)	0 (0%)	2 (3%)	1

*Not all respondents answered every question. Percentages reflect the proportion of respondents who answered that individual question (blank answers are excluded).

Survey responses based on self-reported medication adherence (>80% adherent vs. <80% adherent).

Conclusion: The majority of patients taking rheumatic medications are primarily interested in learning about how their medications work and potential side effects, regardless of how long they have been taking rheumatic medications or how adherent they are to their rheumatic medications. Non-adherent patients are more likely to seek out this information through internet searches and social media, rather than asking their rheumatologist directly. These data are crucial for designing quality improvement initiatives to improve patients' knowledge and adherence when taking rheumatic medications.

Abstract Number: 1097

Improving Vaccine Uptake of the Pneumococcal 20-valent Conjugate Vaccine (PCV20) in Young Rheumatic Disease Patients Using a Brief Intense Partnership Program

Kelsey Pasch[1], Stephen Lindsey[2] and Takeda Ferguson[3], [1]Louisiana State University -- New Orleans, Baton Rouge, LA, [2]LSU Health Science Center, New Orleans, LA, [3]LSU Health Science Center School of Public Health, New Orleans, LA

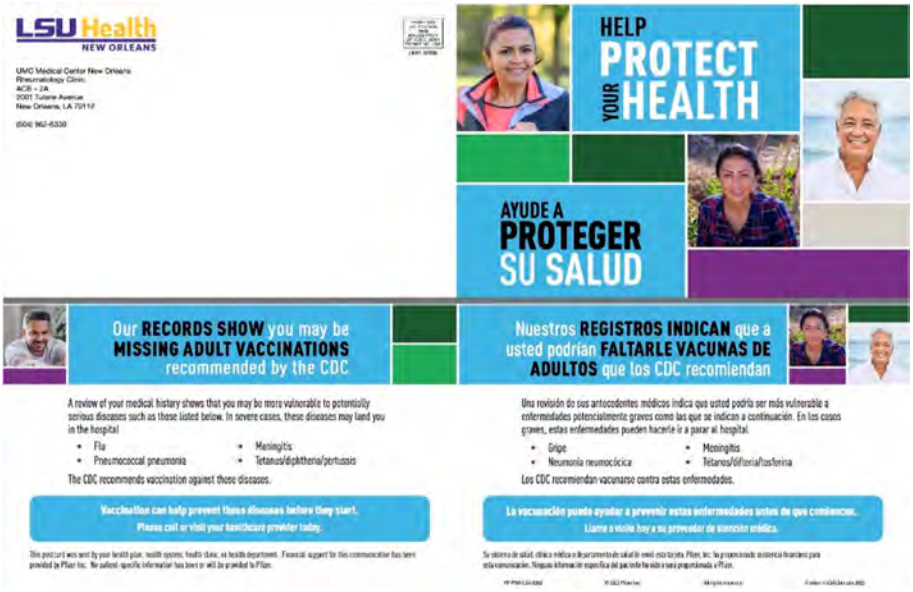
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with inflammatory rheumatic diseases (IRDs) are at increased risk of infection. The Centers for Disease Control and Prevention (CDC) and the ACR strongly recommend vaccination to decrease risk of invasive Streptococcus pneumoniae infections. Vaccine hesitancy is common, has multiple causes, and made more evident by the recent pandemic. Younger adults ages 19-64, including those with IRDs, have reduced pneumococcal vaccine uptake even though it has been recommended for them since 2012. Recent CDC data from 2020 shows 67% of patients 65 years of age and older have the pneumococcal vaccination, but only 23.9% of patients ages 19-64. The objective of this project was to increase pneumococcal vaccination uptake in our high-risk patients in the 19-64 age range, in accordance with recommendations regarding the newer PCV20 vaccine. We hypothesized that using a targeted intense outreach strategy would increase vaccine uptake compared to the current standard of care.

Methods: The Vaccine Brief Intense Partnership (V-BIP) Program was created and started in January 2023. The program included a partnership between our clinic and industry. The target intervention population was identified by electronic health records. We identified unvaccinated patients seen in the University Medical Center- New Orleans Rheumatology Clinic January 2022- January 2023, ages 19-64. All patients without vaccination documentation were contacted using an automated call system and post cards were sent to their homes alerting them of their need to update their vaccinations. Post cards were mailed February and patient calls started March 2023. Number of calls and patient's responses to call attempts are tracked, along with vaccination uptake in the original cohort from January- June 2023.

Results: Of the 1,464 rheumatology patients seen in that year ages 19-64, 580 or 39.6% were unvaccinated. Of the 580 unvaccinated patients, 138 or 26% have been successfully vaccinated within the first 4 months of the V-BIP quality improvement program. This represents a 10% increase in the receipt of the PCV20 vaccine in our 19-64 cohort. The entire automated vaccine promotion message was listened to by 65% of patients. Of postcards mailed, few were returned undeliverable. Increased awareness was discussed with providers, but no changes to the ongoing Epic Best Practice Advisory were made.



Conclusion: Our data demonstrates a significant increase in pneumococcal vaccination after a 4-month intervention of the V-BIP quality improvement project. The V-BIP program provided multi-point patient contact and information delivery, providing additional interaction with patients to increase awareness and the opportunity to schedule a vaccination appointment. The program will extend to the end of 2023. The project supports that partnerships with other entities, in addition to industry, such as specialty pharmacies, PBMs, and other organizations should be explored as ways to improve quality of care.

Improving Osteoporosis Screening in Patients with Polymyalgia Rheumatica and Giant Cell Arteritis

Kelly Tran[1], Ellen Ann Sockman[1], Rachel Salyer[1], Megan Young[1], Aisha Abbasi[1] and Devanshu Verma[2], [1]West Virginia University Hospital, Morgantown, WV, [2]West Virginia University, Morgantown, WV

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is a medical condition associated with decreased bone mass and bone architecture, which increases incidence of fragility fractures(4). It is associated with 1.5 million fractures in the United States annually and thus a major public health concern(1). Osteoporosis most often occurs in post-menopausal women; however autoimmune diseases and glucocorticoid treatment are also independent risk factors(2). Glucocorticoids remain the main treatment for giant cell arteritis (GCA) and polymyalgia rheumatica (PMR), and typically at high doses with an extended period of exposure.

Table 1.

Variables	Pre n=87	Post n=34	p-value
Age: mean (range)	72.6 (51-91)	71.4 (50-90)	0.512
Gender: n (%) Female Male	 51 (58.6) 36 (41.4)	 22 (64.7) 12 (35.3)	 0.680
Diagnosis: n (%) GCA PMR GCA/PMR	 12 (13.8) 9 (10.3) 66 (75.9)	 9 (26.5) 2 (5.9) 23 (67.6)	 0.235
Appropriate screening with DEXA scan: n (%)	50 (57.5)	24 (70.6)	0.217
Tobacco Use History: n (%)	33 (37.9)	9 (26.5)	0.291
Alcohol Use History: n (%)	25 (28.7)	2 (5.9)	0.003
Inclusion criteria*	Patients with GCA/PMR or both, those on prednisone treatment of at least 7.5 mg/day for duration of greater than 3 months		
Exclusion criteria *	Patients with GCA/PMR or both, those on prednisone treatment of less than or equal to 7.5 mg/day or duration less than or equal to 3 months		

Prolonged use of glucocorticoids induces a low bone turnover state causing more pronounced impact on the synthesis rather than the resorption, leading to net loss of bone strength(5). Thus, high and prolonged doses of glucocorticoid treatment in GCA/PMR substantially increases the risk of fractures (3,5). Current guidelines for osteoporosis screening for patients on glucocorticoid treatment were published by the American College of Rheumatology (ACR). Nevertheless, rheumatologists and primary care providers often defer responsibility to one another or to other parties, leading to a lack of osteoporosis screening in GCA/PMR patients(5).This project aimed to increase the rate of ordering recommended screening for osteoporosis by at least 10% in patients diagnosed with GCA/PMR within the West Virginia University hospital system who have been treated with high dose glucocorticoids.

Methods: Patients (n=87) diagnosed with GCA/PMR and treated with high dose of glucocorticoids (≥ 7.5 mg of prednisone for greater than 3 months) were identified via chart review from 06/24/2020 to 12/13/2021. All patients with GCA/PMR included in our study met ACR diagnostic criteria. The number of DEXA scans ordered for patients diagnosed with GCA/PMR was measured pre-intervention. The PDSA (plan-do-study-act) model was then used to implement a quality improvement (QI) initiative at the provider level, which included provider education (email and verbal) coupled with an EPIC best practice alert for this specific patient population. The number of DEXA scans ordered was assessed two months after QI implementation in post-intervention patients (n=34).

Results: Only 57.5% of pre-intervention patients (n = 87, 72.6 ± 8.4 years old) had an appropriate screening completed with a DEXA scan. Within two months after QI implementation, the screening rate in post-intervention patients (n=34, 71.4 ± 9.2 years old) increased to 70.6% (p = 0.217).

Conclusion: Screening for osteoporosis is an important preventive measure for GCA/PMR patients, especially those on high doses of glucocorticoids. Our study demonstrates an improvement in DEXA screening rates by 13.1% over a period of two months by implementing reminders and education for providers in both rheumatology clinics and primary care clinics settings. Future implementation could be expanded at the patient level, through education and sending reminders to discuss the appropriateness of osteoporosis screening with their providers.

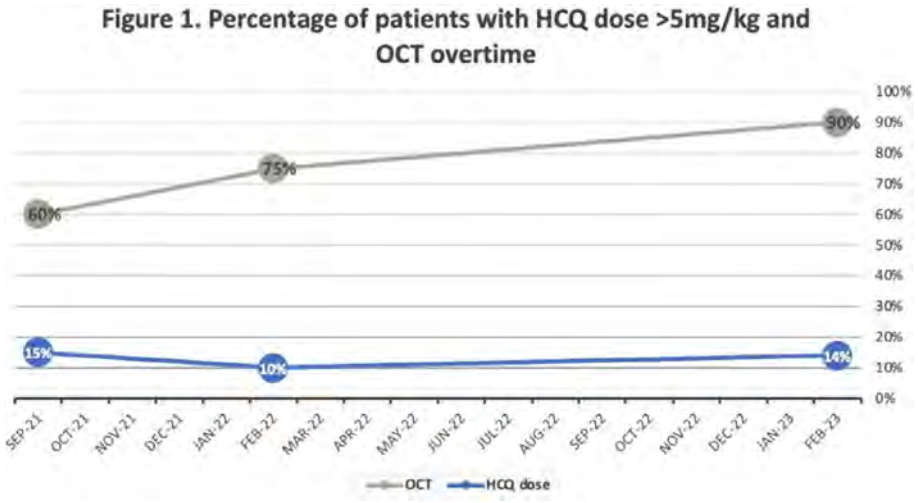
Abstract Number: 1099

Improving Hydroxychloroquine Dosing and Eye Screening Compliance in Patients with Connective Tissue Disorder

Maria Salgado Guerrero[1] and Angelo Gaffo[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, AL; Birmingham VA Medical Center, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Measures & Measurement of Healthcare Quality Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a key treatment for patients with lupus and other rheumatic diseases. To minimize the risk of retinal toxicity, the American College of Ophthalmology (ACO) guidelines published in 2016 recommends using a maximum HCQ daily dose of ≤5mg/kg of actual body weight and to begin annual retinopathy screening after 5 years of HCQ use with automated visual fields plus optical coherence tomography (OCT). The aim of this quality



Percentage of patients with HCQ dose >5mg/kg and OCT overtime

improvement project was to assess if an educational intervention could improve the adherence to ACO dosing recommendations and retinal toxicity monitoring in a large VA Medical Center.

Methods: Patients above 18 years old with a connective tissue disorder diagnosis and who were actively using HCQ were evaluated. HCQ dosing above 5 mg/kg, and eye screening status were reviewed. Two different interventions were implemented twelve months apart: 1) An educational intervention using a personal email with the ACO guidelines was sent to each provider with patients requiring screening testing or HCQ dose adjustment. 2) Second intervention using a "system alert" in the medical record with the correct HCQ dosing and annual OCT was created as a reminder when prescribing or renewing HCQ. Changes in compliance from pre- to post-interventions were assessed.

Results: A total of 258 patients with an active HCQ prescription were included. Forty patients (15%) had a HCQ dose above 5mg/kg. Among this group, HCQ was mainly prescribed by a Rheumatologist (35/40).From the forty patients with HCQ dose above 5mg/kg, 24 (60%) had at least one OCT screening. After the first intervention, the number of patients who required HCQ dose adjustment went down by 5% (15% vs 10%). Most of the patients who required HCQ dose adjustment were receiving a HCQ dose between 5-5.9 mg/kg (60%). More patients had an updated OCT (75% post vs 60% pre). After the second intervention, the number of patients who required HCQ dose adjustment went up by 4%. However, more patients had an updated OCT (90% post vs 75% pre) (Figure).

Conclusion: Educational interventions, including the review of guidelines, or system alerts on different medical records were associated with a notable improvement in retinal toxicity screening but had modest or no effect on adherence to ACO HCQ dosing recommendations.

A Comparison of Characteristics of Patients with Crystalline and Septic Arthritis Confirmed by Synovial Fluid Analysis: Towards the Development of a Diagnostic Rule

Maria Salgado Guerrero[1], Mariana Urquiaga[1], Nishah Panchani[2] and Angelo Gaffo[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Tinsley Harrison Internal Medicine Residency Program, University of Alabama at Birmingham, Arlington, TX, [3]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, AL; Birmingham VA Medical Center, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Distinguishing crystalline from septic arthritis is a common challenge in patients admitted with acute joint inflammation. Arthrocentesis for synovial fluid analysis is considered the gold standard for both entities, but it is not always available. The aim of this study was to compare the demographic, clinical, and laboratory characteristics of patients admitted with septic and crystalline arthritis confirmed by synovial fluid analysis to identify factors to develop a diagnostic rule.

Methods: Our study population consisted of patients admitted to our institution between 1999-2020 with the diagnosis of gout, pseudogout and septic arthritis identified using ICD9 and 10 codes. We reviewed medical records and included those with diagnoses confirmed by synovial fluid analysis. Demographic data including sex, race, body mass index, comorbidities, distribution of affected joints, physical exam characteristics, medications, and laboratories including estimated glomerular filtration rate, white cell and neutrophil count, inflammatory markers, and serum urate were recorded. We summarized continuous variables with medians and interquartile ranges (IQR) and categorical variables with frequencies and proportions. We used Wilcoxon rank sum and Fisher's exact test to analyze for differences between the septic and crystalline groups. We considered significant a p value of < 0.05, but we further adjusted the assessment of significance for multiple comparisons using the Bonferroni correction. All analysis was completed using R studio.

Results: Of the 256 patients identified, 51 had a diagnosis of septic arthritis and 205 a diagnosis of crystalline arthritis. Two hundred and fifty-four (99%) were men, one hundred forty-four (60%) were African-American, and ninety-six (40%) self-identified as White. The median duration of symptoms was 4 days. Compared to patients with crystalline arthritis, septic arthritis patients were more commonly of White race (Table) (54 vs 36% p=0.02), had longer symptom duration (median of 5 versus 3 days, p=0.002), tended to have fewer joints affected (p=0.001), had higher proportion of involvement of elbows (24 vs 12%) and hips (8 versus 1%), and lower proportion of knee involvement (55 versus 76%). Patient with septic arthritis had more joint erythema (47 versus 29%) but less joint swelling (84 versus 96%) and had higher proportions of history of prior surgery in the affected joint (29% vs. 3%, $p< 0.001$), and involvement of a prosthetic joint (22% vs. 0%, $p= < 0.001$). Absolute leukocyte counts and neutrophil counts were higher in patients with septic arthritis. After adjustment for multiple comparisons only the proportion of prior surgery and involvement of a prosthetic joint met the more stringent significance threshold.

Conclusion: History of prior surgical intervention in the affected joint, and prosthetic joint were strongly associated with septic arthritis. Many other demographic, clinical, and laboratory factors were also different between patients with septic and crystalline arthritis. Future steps will include the development of a prediction model for septic and crystalline arthritis when synovial fluid analysis is not available.

Table 1. Demographic and Clinical Characteristics of Patient with Acute Crystalline Arthritis and Septic Arthritis in the Inpatient Setting Prior to Joint Fluid Analysis

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Whether the presence of subclinical monosodium urate (MSU) crystal deposition leads to a pro-inflammatory state in asymptomatic hyperuricemia (AH) is unknown. We aimed to compare the inflammatory state in peripheral blood between AH patients with and without sonographic deposits.

Methods: Observational, cross-sectional study. Patients with current serum urate ≥7 mg/dl and no history of acute arthritis were consecutively recruited from internal medicine, cardiology, nephrology, endocrinology, rheumatology, and primary care. We excluded those on urate-lowering treatment or colchicine, another inflammatory rheumatic disease, or being under immunosuppressive therapy (including transplants).

Two comparative groups were predefined. ***Group 1***: **AH without deposits**; and ***Group 2***: **AH with deposits**. As sonographic deposits, we considered grade 2-3 double-contour sign and/or tophus according to 2021 OMERACT definitions[1], after a 10-location scanning (knees, tibiotalar joints, 1st and 2nd metatarsophalangeal joints, patellar and Achilles tendons) by a trained sonographer blinded to clinical and laboratory data. We measured serum levels of high-sensitivity C-reactive protein (hsCRP) in mg/dl (by immunoturbidimetry), serum amyloid-A in ng/ml (by nephelometry), and erythrocyte sedimentation rate (ESR) in mm/1h, as acute phase reactants. Later, using commercial ELISA kits, we analyzed: ***i)*** inflammasome

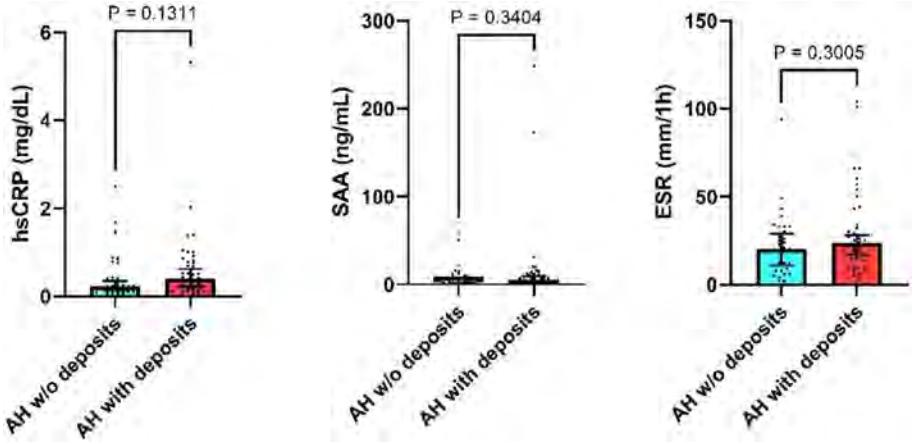

Figure 1. Comparison of acute phase reactants between groups of asymptomatic hyperuricemia. Bars show medians with their 95% confidence intervals. hsCRP: high-sensitivity C reactive protein; SAA: serum A-amyloid protein; ESR: erythrocyte sedimentation rate.

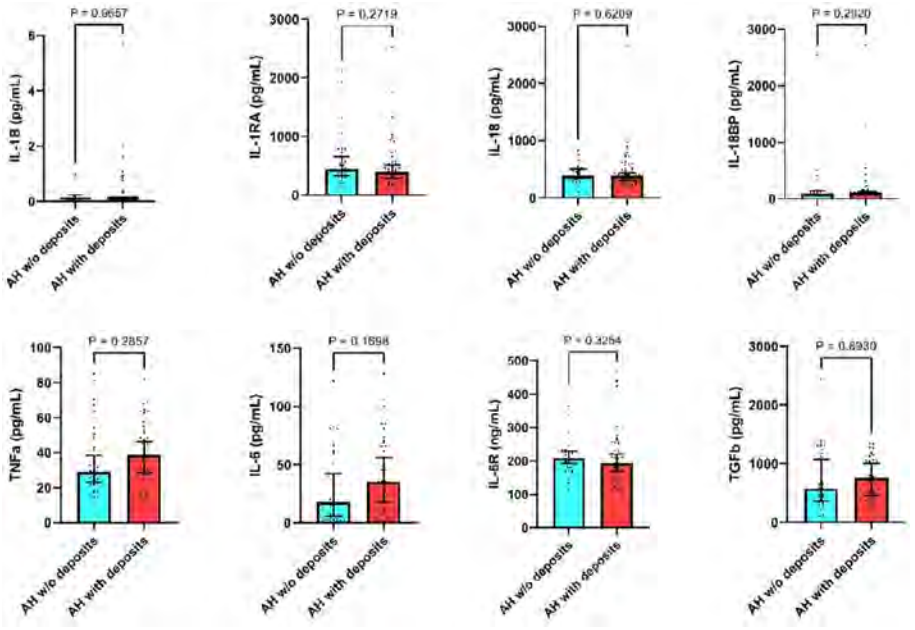

Figure 2. Comparison of cytokines between groups of asymptomatic hyperuricemia. Bars show medians with their 95% confidence intervals. IL-1β: interleukin-1β; IL1-1RA: IL-1 receptor antagonist; IL-18: interleukin-18; IL-18BP: IL-18 binding protein; TNF-α: tumor necrosis factor-α; IL-6: interleukin-6; sIL-6R: soluble IL-6 receptor; TGF-β: transforming growth factor-β.

NLRP3-related cytokines: interleukin **(IL)-1β**, IL-1 receptor antagonist (**IL-1RA**), **IL-18**, IL-18 binding protein (**IL-18BP**); and ***ii)*** general pro-inflammatory and anti-inflammatory cytokines: tumor necrosis factor **(TNF)-α**, **IL-6**, soluble IL-6 receptor (**sIL-6R**), and transforming growth factor **(TGF)-β.**

GraphPad Prism (version 9.5.1) was used to compare AH groups, through Mann-Whitney U's and Chi^2 tests.

Results: 77 subjects with AH were recruited, 71.4% men, with a mean age of 59.8 years (SD 17.3) and body mass index (BMI) of 31.2 kg/m^2 (SD 5.2). 37.7% and 29.9% had cardiovascular (CVD) and renal disease, respectively. Their mean uric acid was 7.6 mg/dl (SD 1.6).

Patients were classified into **group 1** (n=35, 45.5%) or **group 2** (n=42, 54.5%). There were no differences (group 2 vs. group 1) in age (67 vs. 56 years), men (69% vs.74.3%), BMI (31.7 vs. 29.9 kg/m^2), CVD (38.1% vs. 37.1%), estimated glomerular filtration rate (73.42 vs. 75.03 ml/min/1.73m^2), or current serum urate levels (7.35 vs. 7.40 mg/dl). The results of inflammatory markers and cytokines are presented in ***Figures 1 and 2***. There were no differences between groups, but we observed numerical differences for hsCRP, IL-6, and TNF-α.

Conclusion: The inflammatory state was comparable in AH between those with and without sonographic deposits. Some hints were noted for hsCRP, IL-6, and TNF-α that further studies with larger sizes must confirm to establish the relevance of subclinical crystal deposition in AH.

Finding Lost-to-Care Gout Patients in a Large Community Rheumatology Network: Patient Re-engagement Initiative with Metrics (PRIME)

Amy S. Mudano[1], Jessica Ryan[1], Emily Holladay[2], Kathleen Methric[3], Danielle Grauer[4], Brian LaMoreaux[3], Fenglong Xie[1] and **Jeffrey R Curtis**[5], [1]Illumination Health, Hoover, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Horizon Therapeutics, Deerfield, IL, [4]Illumination Health, Boca Raton, FL, [5]Division of Clinical Immunology and Rheumatology, University of Alabama, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of patients with gout can be complex and, given the episodic nature of gout attacks, gout patients may not always return for regular appointments, making long-term management and fostering medication adherence more difficult.We sought to identify and describe patients with gout who were lost-to-care in the Excellence Network in RheumatoloGY (ENRGY), a large community rheumatologist practice-based research network,as preparatory to an intervention to re-engage these patients in care.

Methods: We conducted a retrospective analysis of gout patients who had at least one rheumatology visit from 01/01/2020 to 05/31/2022 using electronic health records (EHRs). Eligible patients meeting our definition of presumed lost-to-follow-up must have >1 ICD10 gout diagnosis (M10* or M1A*), previous use of gout medications (e.g.allopurinol and febuxostat), most recent rheumatology visit >365 daysprior,and no future visit scheduled. We analyzed demographics for the eligible cohort and stratified by the most recent serum urate (SU) value (if available) using descriptive statistics. Serum urate value of ≤6 mg/dL indicated that the gout treatment target was achieved. A scatter plot shows the distribution of patients by rheumatology office and last SUvalue.

Results: From a total of 52,504 gout patients who had a specialist gout visit since 1/1/2020, we identified 25,421(48%) gout patients from 201 sites nationwide (Figure 1) who had not been seen in a year or more. After limiting to patients without a future appointment scheduled (98%) and those who had been on therapy (80%), there were 19,883 (38% of the overall cohort) patients that met all inclusion criteria for being lost-to-care. Patients were mostly male (74%), white (66%), with a

Lesinurad	22 (0.1)	12 (0.1)	5 (0.1)	5 (0.1)	0.76
Serum Urate, mg/dL, Mean (SD)	6.1 (9.7)	4.6 (9.8)	8.6 (15.4)	NA	<.0001
Days since last visit, Median (IQR)	749 (529, 964)	728 (502, 944)	740.0 (537, 964)	781 (560, 999)	<.0001

SD = standard deviation, BMI = body mass index, IQR = interquartile range.

mean (SD) age of 65(14.2) (Table 1). In patients where structured SU lab data was available (73% of the lost-to-care cohort), 38% were poorly controlled at their last visit (SU >6). The median (IQR) days since the most recent rheumatology provider visit was 749 (529, 964) days. Gout with tophi was coded in about 5% of patients and was slightly higher in the SUA >6 group. The scatter plot (Figure 2) shows the difference in distribution patterns among practices of patients who may have met their treatment target (SU<6) compared to those whose last SU was greater than 6.

Figure 1: Attrition Flowchart describing gout patients potentially lost to follow-up

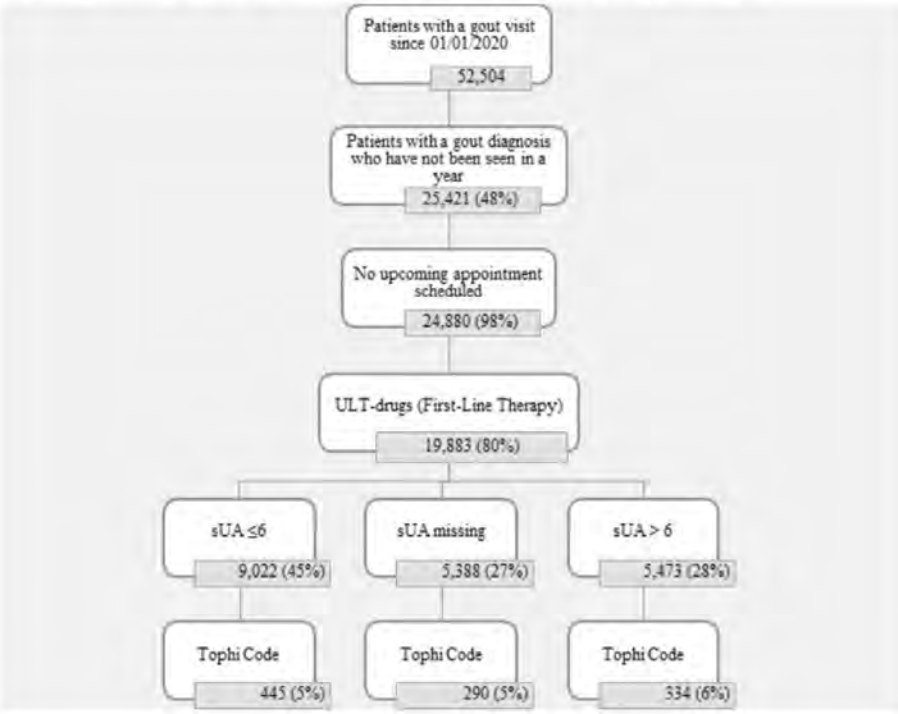

Figure 2: Clustering of gout patients by provider describing proportion who were well controlled (sUA <=6 vs. >6) at the time of their last lab test (n=192 providers). Each rheumatology provider contributed 2 dots to the scatterplot, one for the proportion of patients with the most recent sUA >6mg/dL, and a second for the proportion of their patients <=6mg/dL.

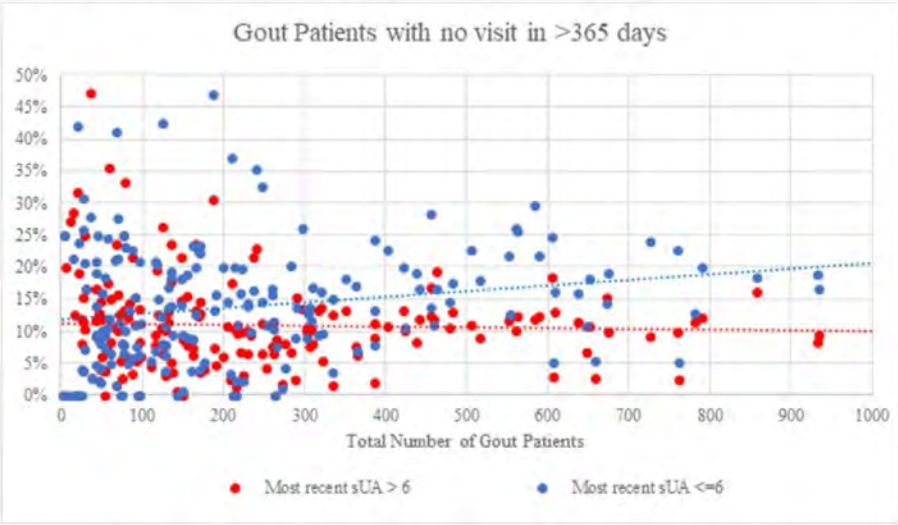

Conclusion: In this large community practice-based rheumatology network, a meaningfully large proportion of gout patients appeared lost to care. Many of these patients were sub-optimally controlled (SU >6 mg/dL) at their last rheumatologist visit, suggesting that they may benefit from further rheumatology involvement. A quality improvement initiative is in development to better understand these patients' gout care needs and offer them an expedited visit with their rheumatology provider to re-engage them in care and potentially improve outcomes.

Evaluation of Outcomes Following Discontinuation of Pegloticase Therapy

Emily Holladay[1], Amy S. Mudano[2], Fenglong Xie[2], Jingyi Zhang[1], Ted R Mikuls[3], Brian LaMoreaux[4], Lissa Padnick-Silver[4] and Jeffrey Curtis[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Illumination Health, Hoover, AL, [3]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE, [4]Horizon Therapeutics, Deerfield, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Little is known about the long-term effects of pegloticase therapy or what urate-lowering therapy (ULT) patients subsequently receive when they discontinue pegloticase. This analysis examined alternative ULT use, serum urate (SU) changes, systemic inflammatory measures, and renal function following pegloticase discontinuation.

Methods: We conducted a retrospective analysis of gout patients discontinuing pegloticase using the ACR's Rheumatology Informatics System for Effectiveness (RISE) registry from 01/2016 through 06/2022. We defined pegloticase discontinuation as a gap ≥12 weeks after a pegloticase infusion. We examined outcomes beginning two weeks after the last dose of pegloticase (defined as the 'index date'), an interval selected based on its typical every other week dosing schedule. Changes in lab values (treatment effect) following pegloticase discontinuation were examined by comparing measurements obtained within 15 days of the second pegloticase dose and those obtained after pegloticase discontinuation. We analyzed changes in SU, eGFR, CRP, and ESR using descriptive statistics. A Sankey plot was used to describe ULT medication use after the index date, and Kaplan Meier curves assessed the probability of starting post-pegloticase ULT over time.

Results: We identified 375 patients with gout who discontinued pegloticase and had paired labs. We observed lab changes in patients who discontinued pegloticase with median (IQR) differences of SU: 2.4 mg/dL (0.0, 6.3); eGFR: -1.9 mL/min (-8.7, 3.7); CRP: -0.8 mg/L (-12.8, 0.0); and ESR: -4.0 mm/hr (-13.0, 0.0), compared to pre-discontinuation values.

Of those who discontinued pegloticase, 83% started other ULTs (Figure 1), and 8% restarted pegloticase. Of those that started oral ULTs, 63% began allopurinol and 34% began febuxostat. The time to starting (or restarting) ULT is shown in Figure 2. With SU measured at least >=30 days following ULT start, 53% of patients had an SU ≤6 mg/dL with a median SU of 5.8 mg/dL (IQR: 3.6, 8.4).

After starting a new ULT, post-ULT median (IQR) SU values were 5.8 (4.7, 7.0) and,5.8 (4.5, 7.9) mg/dL for users of allopurinol and febuxostat, respectively. In contrast, patients who restarted pegloticase achieved a median SU of 0.9 mg/dL (IQR: 0.2, 9.7) after a median of 156 days (IQR: 131.0, 609.0) since prior discontinuation.

Figure 1: ULT Initiation Over Time After Pegloticase Discontinuation

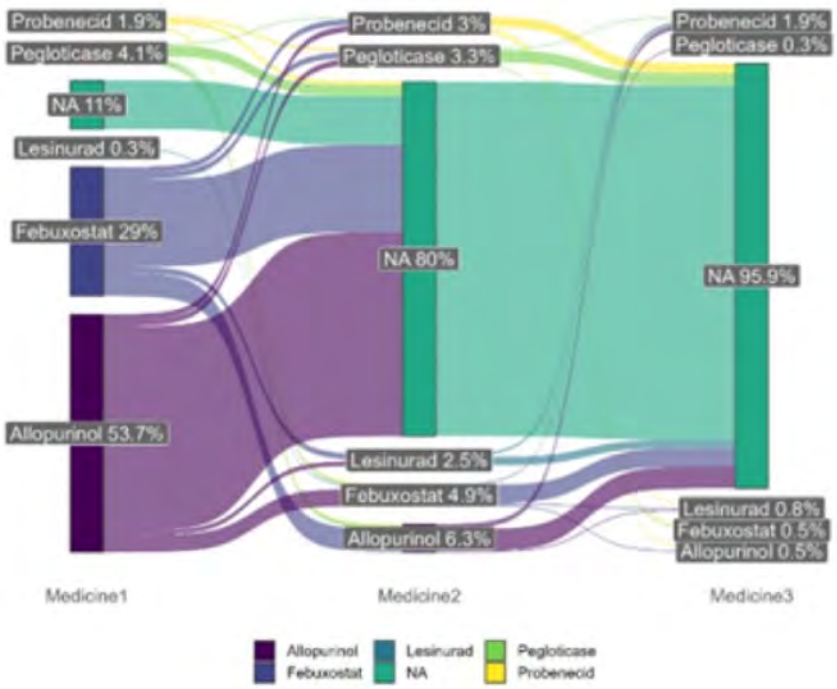

Figure 2: Probability of Not Restarting a ULT* after Pegloticase Discontinuation

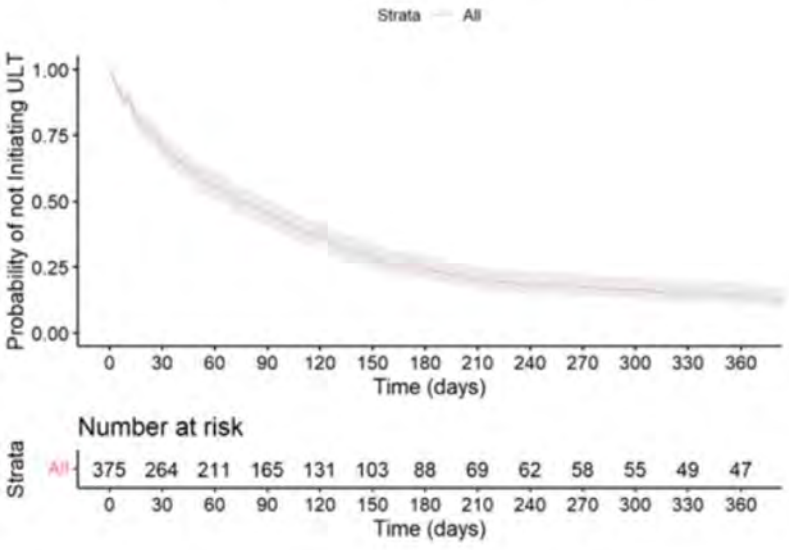

*ULT includes pegloticase

Conclusion: Pegloticase treats uncontrolled gout in patients who fail to respond to xanthine oxidase inhibitors, but the development of anti-drug antibodies, and subsequent loss of urate-lowering response may require pegloticase discontinuation. An important minority of patients fail to receive any ULT after cessation of pegloticase. Additionally, many patients who were able to restart restarting pegloticase after a prolonged gap in therapy achieved had its expected resulting SU-lowering effect with therapy even after a gap in therapy, although the context for the interruption needs to be further explored. Future studies should focus on the optimal management of gout patients who discontinue or have meaningful gaps in pegloticase treatment.

Dotinurad, a Potent and Selective Uricosuric Agent, Exhibited Promising Pharmacokinetics and Pharmacodynamic Profiles to Significantly Reduce Serum Urate Levels Following Once Daily Dosing in Healthy U.S. Subjects in a Phase 1 Clinical Trial

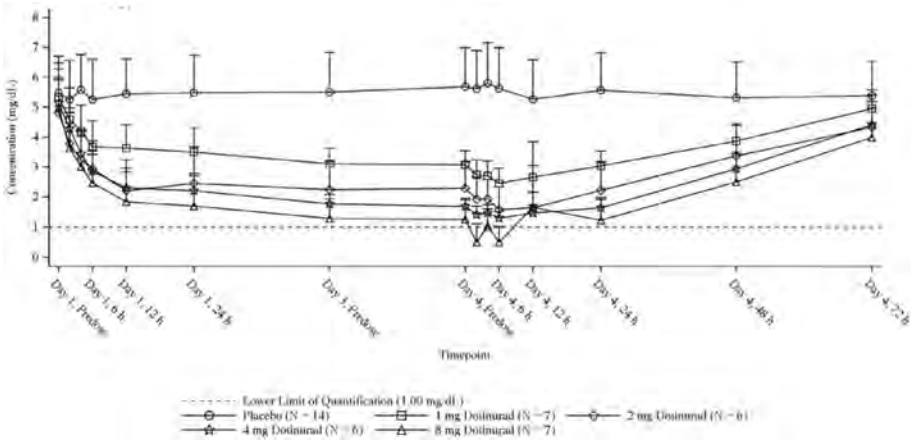
Scott Baumgartner, Raymond Zheng, Mark Harnett and **Jay Kranzler**, Urica Therapeutics Inc., New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Dotinurad is a potent and selective URAT1 inhibitor that has been approved as a once-daily drug for the treatment of hyperuricemia with or without gout in Japan since 2020, based on results of 17 clinical trials conducted in Japan with more than 1000 patients exposed with up to 58 weeks in treatment duration. In the Japanese dossier, 4mg dotinurad reduced serum urate to < 6 mg/dL in 100% of patients after long-term treatment. No significant cardiovascular, renal or hepatic adverse events were observed with dotinurad at approved doses in the Japanese studies. This Phase 1 study is the first performed in a 'western' population, initiating the development of dotinurad for eventual use in North America and EU.

Methods: Randomized, double-blind, placebo-controlled, three-period crossover multiple-dose in 15 healthy male and female volunteers (age 18 to 55 years), doses included placebo, 1, 2, 4, and 8 mg once-daily in the morning for 4 days. Serial blood samples were collected to measure pharmacokinetic concentrations of dotinurad as well as serum and urine uric acid levels.Maximum concentration (C_{max}), area under the curve ($AUC_{0-\tau}$), half-life ($t_{1/2}$) were determined.Study drug accumulation from Day 1 to Day 4 was assessed. Safety monitoring was performed throughout.

Results: Dotinurad concentrations exhibited an increase in dotinurad exposure for AUC and C_{max} that was proportional to dose.Plasma-concentration time profiles following multiple oral doses of dotinurad were characterized by a rapid absorption phase, with median T_{max} of 2.5 to 3 hours. When normalized for dose, C_{max} was consistent across the dose range. The rate of elimination appeared to be consistent across the dose groups on Day 4, with geometric mean $T_{1/2}$ values ranging from



Mean serum urate concentrations across all days in the pharmacodynamic population

7.73 to 8.82 hours. The range of accumulation ratios for $AUC_{0-\tau}$ and C_{max} were also found to be similar across all doses administered (1.18 to 1.26 and 1.07 to 1.21, respectively), demonstrating that dotinurad shows little to no accumulation in the plasma following multiple daily dosing.

As dotinurad dose increased, a respective reduction in serum urate concentrations and overall exposure to urate was observed. Steady state of reduced serum urate levels was achieved in day 3. Up to 90% sUA reduction from baseline was observed with dotinurad treatment.

Dotinurad was well tolerated with no observed serious adverse event. No treatment related adverse event was observed with 1-4 mg of dotinurad.

Conclusion: Following 4 consecutive once-daily treatments, dotinurad has exhibited a pharmacokinetic profile, in western healthy subjects, comparable to that from Japanese healthy men. All tested doses of dotinurad (1, 2, 4 & 8 mg QD) significantly reduced serum urate levels. These results support the potential application of dotinurad as a once-daily treatment for hyperuricemia in western population. Another clinical study is currently underway to further establish the safety, efficacy and drug interaction of dotinurad in U.S. gout patients.

Abstract Number: 1105

Effects of Uric Acid Lowering Treatment on Vascular Stiffness in Gout Patients

Jinseok kim, Division of Rheumatology, Department of Internal Medicine, Jeju National University Hospital, Jeju National University School of Medicine, Jeju, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Many studies have reported that gout and hyperuricemia are associated with an increase in all-cause mortality and cardiovascular mortality.Increased vascular stiffness is closely related to the occurrence of cardiovascular disease. Many studies have shown a significant correlation between uric acid levels and arterial stiffness. However, there is no study on whether vascular stiffness is improved by uric acid-lowering treatment in gout patients. Few studies have reported that uric acid-lowering treatment reduces vascular stiffness in chronic kidney disease patients. The aim of this study is to evaluate the effect of uric acid lowering treatment on vascular stiffness in gout patients.

Methods: Between June 2017 and June 2019, patients who visited Jeju National University Hospital for treatment of gout were measured for augmentation index (AIx) and follow-up to evaluate changes in vascular stiffness by uric acid lowering treatment.

Results: One hundred twenty patients participated in the study and AI was measured. At the time of the enrollment, the average age of patients was 55.1 ± 12.9 years, the mean duration of gout was 7.0 ± 6.4 years, the mean duration of uric acid lowering treatment was 27.8 ± 34.0 months, the average of uric acid level was 5.8 ± 1.9, the average of initial AIx was 22.5 ± 10.1 and the average of follow-up duration of AIx was 19.1 ± 2.1 months. When compared with the AIx improved and non-improved groups, there was a higher percentage of smokers in the improved group (16.7% vs 45.5%, p=0.007), and there was no significant difference in age, duration, and uric acid value between the two groups. However, in the group with improved AIx, the initial AIx level was significantly higher (20.6 ± 7.6 vs 26.9 ± 7.2, p< 0.001) and more people (63.6% vs 40.5%, p=0.046) had higher AIx than predicted AIx. When multivariate logistic regression analysis was performed, disease duration (b=0.714, 95% CI 0.528-0.965, p=0.029), ULT duration (b=1.059, 95% CI 1.003-1.118), smoking (109.972, 95% CI 3.693-3274.940, p=0.007) are predictor of improvement of vascular stiffness.

Conclusion: Our results show that long-term uric acid lowering treatment in patients with long gout disease duration can improve vascular stiffness.

Monosodium Urate and Calcium Pyrophosphate Crystal-induced Inflammation Relies on Cell Volume Regulation and LRRC8/VRAC Channel Activation

Twinu Wilson Chirayath[1], mete kayatekin[2], Isabelle Rubera[3], Nghia Pham[4], FREDERIC LIOTE[4], Pascal Richette[5], Vincent COMPAN[6], François Rassendren[7], Christophe Duranton[3] and Hang Korng EA[4], [1]INSERM, Paris, France, [2]CNRS-UMR7370, Nice, France, [3]CNRS-UMR 7370, Nice, France, [4]INSERM-BIOSCAR, Paris, France, [5]Lariboisière Hospital, Paris, France, [6]CNRS-IGF, Montpellier, France, [7]CNRS UMR 5203, Montpellier, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Monosodium urate (MSU) and calcium pyrophosphate (CPP) crystals are responsible for interleukin (IL)-1β dependent acute arthritis. The release of mature IL-1β is dependent on the NLRP3 inflammasome, which can be activated by other sterile stimuli such as hypo-osmolarity and ATP. During extracellular hypotonic stress, there is cellular swelling secondary to water influx. The cell sets up a defence mechanism, called regulatory volume decrease (RVD), allowing it to

return to its initial volume. RVD depends on the anion channel VRAC, a hetero-hexamer composed of members of the LRRC8 family. LRRC8A is the obligatory key protein required to form active VRAC channel. Activation of LRRC8/VRAC channel results in an efflux of anions (mainly chloride) and **osmolytes** leading to water efflux and cell volume reduction. We evaluate the role of the LRRC8/VRAC channel in cell volume regulation and IL-1β release induced by MSU and CPP crystals.

Methods: In-vitro, primed THP-1 monocytes were stimulated by synthetic sterile MSU and CPP and cytokine production was quantified by ELISA. Cell volume variations were visualized by live video recording and cell surface was measured using ImageJ software. The role of the LRRC8/VRAC channel was evaluated using a pharmacological inhibitor DCPIB or by silencing the LRRC8A subunit (shLRRC8A RNA) in these cells. In vivo, MSU and CPP crystals were injected into air pouches created subcutaneously (mimicking synovial cavity) in wild-type mice and conditional LRRC8A Knock-out mice in the macrophage lineage (Cxcr3Cre_Lrrc8aflox/flox). Supernatants and pouch lavages were used to measure cytokine production by ELISA.

Results: MSU-and CPP-induced NF-κB activation was reduced in WT THP-1 cells treated with DCPIB and in THP-1 cells where *LRRC8A* expression was silenced. Similarly, IL-1β production induced by MSU and CPP crystals was substantially decreased in WT THP-1 treated with DCPIB (MSU 5200 vs 1080 pg/ml; CPP 11500 vs 4980, $p< 0.0001$) and in shLRRC8A THP-1 cells compared to crystal-treated WT cells. MSU and CPP crystals exposure induced a biphasic cell volume change characterised by a significant increase followed by a RVD-like phenomenon. These cell volume changes were abolished in the presence of DCPIB and not observed in shLRRC8A THP-1 cells. In vivo, inflammation induced by MSU and CPP crystals assessed in lavage fluid and conventional histology was lower in Cxcr3Cre_Lrrc8aflox/flox mice as compared with wild-type mice in terms of IL-1β production and cell infiltrate.

Conclusion: These results suggested that MSU and CPP crystal-induced inflammation involves cell volume variation regulated by VRAC/LRRC8 channel.

Predictors of Pegloticase Urate-lowering Response in the Presence and Absence of Methotrexate Co-therapy

James Mossell[1], Mai Duong[2], Katie Obermeyer[2], Lissa Padnick-Silver[2], **Brian LaMoreaux**[2] and Sanjay Chabra[3], [1]Arthritis and Osteoporosis Center of South Georgia, Tifton, GA, [2]Horizon Therapeutics, Deerfield, IL, [3]Texas Arthritis Center, El Paso, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pegloticase can lower serum urate (SU) in patients with uncontrolled gout who are refractory to/intolerant of oral urate-lowering therapies. However, antidrug antibodies (ADAs) can limit pegloticase treatment response and put patients at risk for infusion reactions (IRs).[1,2] Co-administering methotrexate (MTX) with pegloticase attenuates ADAs, resulting in improved response rates (71% vs. 39% during Month 6) and decreased IR risk (4% vs. 31%).[3] Here we examine potential baseline factors that may influence urate-lowering response to pegloticase.

Methods: These analyses included uncontrolled gout patients who received biweekly pegloticase (8 mg) in the Phase 3 pegloticase registration[1] and MIRROR RCT[2] trials. Patients were included if they had received ≥1 pegloticase infusion. Treatment response was defined as SU < 6 mg/dL for at least 80% of Month 6. A classification and regression tree (CART) analysis was performed in patients who did (MIRROR RCT MTX arm) and did not (Phase 3, MIRROR RCT PBO arm) receive MTX co-therapy with pegloticase. CART analyses split datasets based on data homogeneity, providing insight on outcome prediction factors. The following pre-treatment factors were considered: patient age, sex, weight, BMI, SU, and ADA status (positive/negative).

Results: Baseline characteristics in pegloticase monotherapy (N=134; age: 54.9±14.5 years, 82.1% men, BMI: 33.0±7.5 kg/m^2, weight: 99.2±23.3 kg) and pegloticase+MTX (N=96; age: 56.0±12.5 years, 91.7% men, BMI: 32.8±5.6 kg/m^2, weight: 102.6±19.4 kg) groups were similar. 57 monotherapy (42.5%) and 71 MTX (74.0%) patients were treatment responders. For the pegloticase monotherapy group, CART analysis selected an age cut-off of 46 years (< 46 years: 14.7% response, ≥46 years: 59.0% response) as a first-level predictor and a body weight cut-off of 85 kg as a second level predictor (**Figure, Part A**). For the pegloticase+MTX group, CART analysis returned no decision tree. This finding indicates that no examined factors predicted pegloticase treatment response in the presence of MTX co-therapy. Although age did

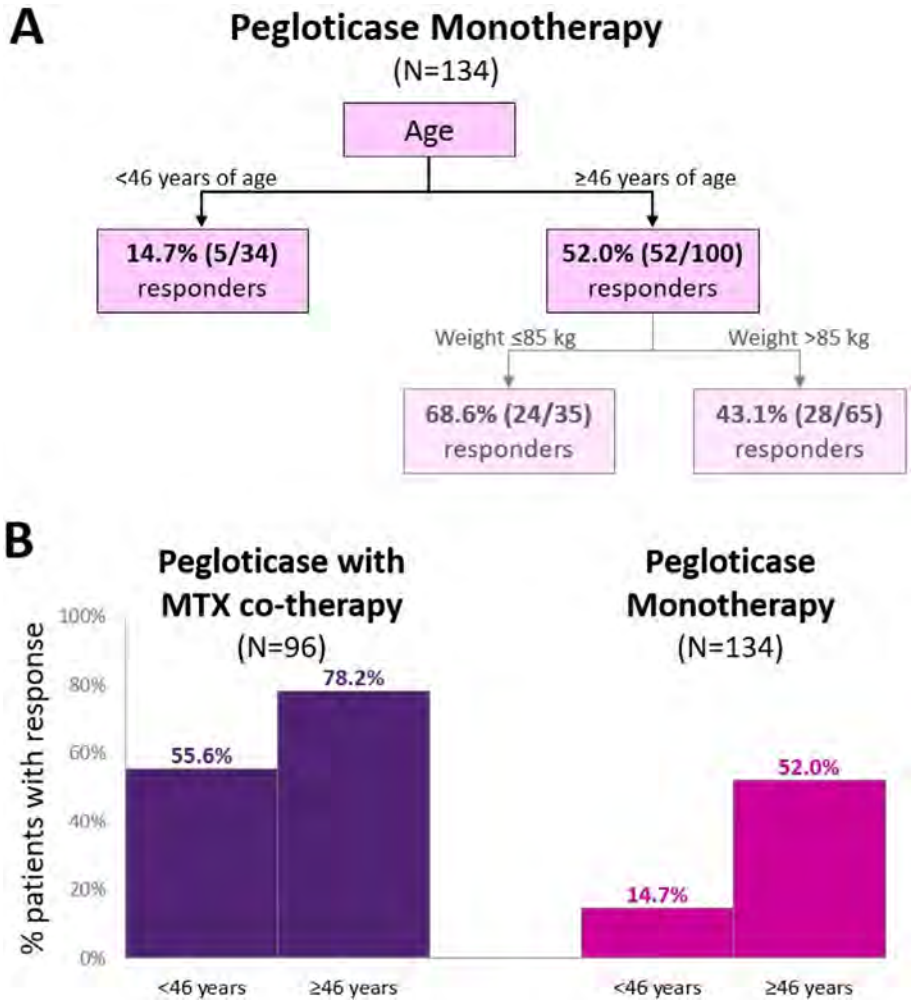

Figure. A. CART decision tree for treatment response in patients receiving pegloticase monotherapy. Pre-treatment factors examined included patient age, sex, weight, BMI, serum urate, and anti-drug antibody status (positive/negative). No decision tree was formed for patients receiving pegloticase+MTX (no examined pre-treatment factor predicted treatment response). B. Proportion of pegloticase treatment responders during Month 6 in pegloticase monotherapy CART age groupings (≥46 years, <46 years). MTX co-therapy led to increased response rate during Month 6 in both age groups.

not predict treatment response in patients receiving MTX co-therapy, those ≥46 years of age had a higher response rate than those < 46 years of age (cutoff identified in the monotherapy group, 78% vs. 56%; **Figure, Part B**).

Conclusion: With pegloticase monotherapy, younger patient age and higher body weight were predictors of treatment failure. These findings are in agreement with pharmacokinetic studies showing an influence of ADAs and body surface area on serum pegloticase concentrations. However, in the presence of MTX-co-therapy, neither patient age nor body weight predicted response to pegloticase. These findings further support the importance of MTX co-administration with pegloticase to maximize the number of patients who may benefit from this often last-line therapy.

Minimal Clinically Important Difference (MCID) of Quality of Life Assessments in Patients with Uncontrolled Gout

Brian LaMoreaux[1], Chelsea McKibbon[2], Katie Obermeyer[1], Lissa Padnick-Silver[1], Gerald Smith[2], Jiaxuan Wang[2] and Haridarshan Patel[1], [1]Horizon Therapeutics, Deerfield, IL, [2]Cytel Inc., Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is an inflammatory arthritis that results in severe joint inflammation, pain, disability, and lower quality of life (QoL). Determining minimal clinically important differences (MCIDs) for QoL metrics is essential for effectively evaluating gout patient QoL and the impact of therapy. Here, we determine and examine potential predictors of MCID for Health Assessment Questionnaire (HAQ)-Disability Index (DI), -Pain, and -Health using data from adult uncontrolled gout patients treated with pegloticase during the MIRROR Randomized Controlled Trial(RCT)[1].

Methods: MIRROR RCT participants received ≤52 weeks of pegloticase+methotrexate (MTX) orpegloticase+placebo (PBO) co-therapy[1].The change from baseline in HAQ scores were obtained at prespecified time points, including Weeks 24 and 52. HAQ scores range from 0-3 for DI, 0-100 for Pain, and 0-100 for Health, with a higher score indicating worse

Table 1. Determined MCID values for HAQ-DI, -Pain, and -Health and the proportion of patients reaching MCID at Week 24 and 52 using a distribution-based approach (0.5SD) for patients with uncontrolled gout.

	MCID Threshold	Pegloticase+MTX, n (%)	Pegloticase+PBO, n (%)
Week 24	(N=120)	(N=80)	(N=40)
HAQ-DI	-0.232	37 (46.3%)	20 (50.0%)
HAQ-Pain	-15.619	41 (51.3%)	13 (32.5%)
HAQ-Health	-14.863	46 (57.5%)	15 (37.5%)
Week 52	(N=110)	(N=76)	(N=34)
HAQ-DI	-0.278	34 (44.7%)	15 (44.1%)
HAQ-Pain	-15.596	50 (65.8%)	19 (55.9%)
HAQ-Health	-16.569	48 (63.2%)	16 (47.1%)

HAQ score range (higher score indicates worse quality of life): DI: 0-3, Pain: 0-100, Health: 0-100. HAQ, Health Assessment Questionnaire; DI, Disability Index; MTX, Methotrexate; PBO, placebo; MCID, Minimal Clinically Important Difference; SD, Standard deviation.

Table 2. Influence of examined baseline parameters on the likelihood of reaching MCID in uncontrolled gout patients receiving pegloticase therapy (MTX and PBO groups combined).

Baseline parameter	HAQ-DI OR* (p-value)	HAQ-Health OR* (p-value)	HAQ-Pain OR* (p-value)

*OR <1 denotes a lower chance of meeting MCID in the test group for categorial parameters and a lower chance of meeting MCID with lower baseline values for continuous parameters by multivariate adjusted analysis. †Time from first gout diagnosis. ‡Baseline HAQ score of the category being examined. BMI, Body mass index; HAQ, Health Assessment Questionnaire; DI, Disability Index; OR, odds ratio; MCID, minimal clinically important difference; PhGA, Physician Global Assessment.

QoL. MCIDs were calculated using two distribution-(0.5 standard deviation[SD], standard error of the mean)and two anchor-based (change difference, receiver operator curve) approaches, with physician global assessment(PhGA), serum urate response, and number of gout flares considered as anchors. Time-to-MCID was evaluated by treatment group using Kaplan-Meier curves. A logistic model and a multicollinearity test including seven covariates were used to assess baseline factors that potentially influenced reaching MCID.

Results: A total of 80 and 76 patients in the MTX group and 40 and 34 patients in the PBO group had Week 24 and 52 HAQ data, respectively. Across analysis methods, MCID values were similar. Herein, results for the0.5SDapproach are presented. MCID thresholds for all HAQ measures were established, with notable differences in the proportion of MTX and PBO patients achieving -Health and -Pain MCID at Week 24 and 52 (Table 1). Time-to-MCID for HAQ-DI and -Pain did not differ between treatment groups but was shorter for -Health in the MTX group through Week 52 (median: 20 vs. 24 weeks).Worse baseline QoL was a significant predictor of reaching MCID during therapy for all HAQ measures(Table 2). Additionally, patients with tophi at baseline were significantly less likely to reach MCID for HAQ-Pain at Week 24, but not Week 52.

Conclusion: For the first time, MCID values for HAQ-DI, -Pain, and -Health scores in an uncontrolled gout population were established. Pegloticase administered as monotherapy or with MTX co-therapy resulted in 33-66%ofpatients achieving MCID in all HAQ measures. Both treatment groups had similar median times-to-MCID ,further supporting the effect of pegloticase on QoL measures. Few assessed parameters were predictive of achieving HAQ MCIDs, but worse baseline QoL was associated with an increased likelihood of reaching all HAQ MCIDs at Week 24 and 52 and the presence of tophi at baseline was associated with a decreased likelihood of reaching HAQ-Pain MCID at Week 24. Further exploration is needed on how tophi influence levels of and changes in patient pain. These analyses are of importance for assessing potential QoL benefits during pegloticase and other urate-lowering therapies in both the clinical trial and practice settings.

Genetic Risk Variants in Hyperuricemia and Gout: Common Disease, Multiple Common and Rare Variant Hypothesis

Blanka Stiburkova[1], Katerina Pavelcova[2], Jana Masinova[1], Marketa Pavlikova[3] and Karel Pavelka[4], [1]Institute of Rheumatology, Prague, Czech Republic, [2]Institute of Rheumatology, Praha 2, Czech Republic, [3]Department of Probability and Mathematical Statistics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic, [4]Institut of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Praha, Czech Republic

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Hyperuricemia is a central feature in the pathogenesis of gout. Hyperuricemia results from an imbalance between endogenous production and excretion of urate; however, the main cause of hyperuricemia is reduced renal excretion of urate. Accumulating evidence suggests that the net amount of excreted uric acid is regulated mainly by urate transporters, such as urate transporter 1 (URAT1, a renal urate re-absorber), solute carrier family 2 member 9 (SLC2A9, also known as glucose transporter member 9), and ATP-binding cassette subfamily G member 2 (ABCG2, which is high capacity urate exporter expressed in the kidneys and intestines). Decreased extra-renal urate excretion caused by ABCG2 dysfunction is a common mechanism of hyperuricemia.

Methods: In both the hyperuricemia and gout Czech subcohort, partly previously described (1, 2) we analyzed genetic variants that are strongly associated with the transition from asymptomatic hyperuricemia to gout (3). 13 independent single nucleotide polymorphisms in *ABCG2* (rs2231142, rs131204000, rs7672194), *SLC2A9* (rs16890979, rs16891234), *SLC22A11* (rs2078267), *GCKR* (rs1260326), *MEPE* (rs114580333), *PPM1K-DT* (rs4693211, rs28793136, rs1545207), *LOC105377323* (rs114791459) and *ADH1B* (rs1229984) were genotyped using direct DNA sequencing with generic sequencing primers by ABI 3130 automated sequencer. The frequencies of polymorphisms were evaluated using Lasergene software and results were compared between a group of patients with primary hyperuricemia and patients with gout and data of the European population from the 1000 Genomes Project.

Results: We are currently completing a genetic analysis of patients with primary hyperuricemia and gout, consisting of more than 450 patients (60% gout patients). Most of the examined variants occur with significantly different frequencies in our cohort of patients with primary hyperuricemia and gout compared to the European population. Variants rs13120400, rs16890979, rs2078267, rs1260326,rs114791459, and rs1229984 showed a significantly lower frequency ($p \leq 0.0001$) in our cohort compared to the European. On the contrary, variants rs2231142, rs7672194, rs4693211 ($p \leq 0.0001$), rs28793136 ($p = 0.0021$), and rs114580333 ($p = 0.0286$) showed a significantly higher frequency in our cohort compared to the European. There was no significant difference in the frequency of these SNPs between the subcohort of patients with primary hyperuricemia and those with gout.

Conclusion: The preliminary results of our study are not entirely consistent with the findings of the GWAS study, which looked for loci associated with asymptomatic hyperuricemia to gout transition and described 13 such SNPs (3). We confirmed only a significantly higher incidence of 5 of these variants in a cohort of patients with primary hyperuricemia/gout, and the frequency of none of the 13 variants differed between subcohorts.

Pharmacokinetics and Pharmacodynamics of AR882 Following 12-Week Treatment in Patients with Gout

Roy Fleischmann[1], James Cheng-Chung Wei[2], **Zancong Shen**[3], sarah Morris[4], Elizabeth Polvent[5], Andrea Clouser-Roche[4], Vijay Hingorani[6], Rongzi Yan[7], Shunqi Yan[8], Robert Keenan[9] and Li-Tain Yeh[10], [1]Division of Rheumatology, University of Texas Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX, [2]Chung Shan Medical University Hospital, Department of Rheumatology, Taichung, Taiwan, [3]Arthrosi Therapeutics, San Diego, CA, [4]Arthrosi Therapeutics Inc, San Diego, CA, [5]Arthrosi Therapeutics, Inc., Roseville, CA, [6]Vanguard Healthsciences, Inc., San Diego, CA, [7]Arthrosi Therapeutics, Inc, Irvine, CA, [8]Arthrosi Therapeutics, Inc., Laguna Hills, CA, [9]Arthrosi Therapeutics, Chapel Hill, NC, [10]Arthrosi Therapeutics, Inc., Irvine, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In early phase studies AR882 exhibited good dose proportionality, long half-life and dose-dependent serum urate (sUA) lowering effect in a broad range of doses in healthy subjects and gout patients. In a phase 2b study, following once-daily dosing up to 3 months, the pharmacokinetics (PK) and pharmacodynamics (PD), including sUA lowering effect of AR882, were evaluated in all patients; in a subset of these patients more frequent laboratory monitoring was done.

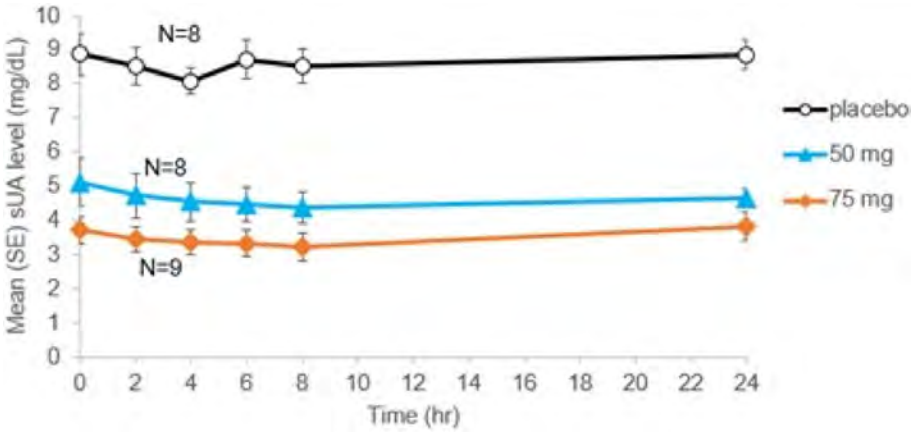

Figure 1. Mean (SE) sUA levels following 8-week dosing of AR882

Table 1. Similar response in sUA lowering between gout patients in phase 2b PKPD subset and phase 2a studies.

Study	Group	N	Mean (SD) value			sUA response, %			
			Baseline (mg/dL)	lowest sUA (mg/dL)	% change	< 6 mg/dL	< 5 mg/dL	< 4 mg/dL	< 3 mg/dL
Phase 2b	50 mg	8	8.7 (1.1)	4.1 (1.0)	-52.5 (9.3)	100	88	38	13
	75 mg	9	8.2 (1.2)	3.2 (1.1)	-62.2 (9.9)	100	89	78	67
	Placebo	8	8.4 (1.1)	8.2 (1.3)	-0.65 (12)	0	0	0	0
Phase 2a	50 mg	28	8.9 (1.1)	4.2 (0.9)	-52.7 (8.8)	96%	93%	39%	0%
	75 mg	8		3.2 (0.9)	-61.5 (7.9)	100%	100%	88%	50%

Methods: In the phase 2b, 12-week study, 140 subjects were enrolled into three treatment groups: placebo (n=47), AR882 50 mg (n=46) and AR882 75 mg (n=47) at approximately 1:1:1 ratio. A single blood sample was collected for PK/PD assessment at each clinical visit (every 2 weeks) through Week 12. In addition, a total of 25 gout patients participated in an optional sub-study with more frequent sampling occurring on baseline, Week 2, and Week 8 visits.Serial blood samples were collected up to 24 hours post-dose for AR882 and sUA measurements.

Results: Following long-term treatment, AR882 showed stable exposure across the entire treatment period. At steady-state, AR882 was readily absorbed with median T_{max} of 1.50 to 3.50 hours post-dose. AR882 demonstrated dose-dependent increase in plasma exposure. Average half-life of AR882 ranged between approximately 14 and 22 hours. Its active metabolite AR896 was formed with median T_{max} between 5- and 8-hours post-dose. Consistent with observations in the early phase studies, AR896 constituted of approximately 9% of C_{max} and 10-12% of AUC exposures with longer half-life (29-36 hours) than the parent drug.

In the sub-study group with more frequent sampling, sUA lowering effect in both AR882 treatment groups showed a smooth, consistent and flat profile across 24 hours with the lowest mean sUA reduced from baseline 8.6 mg/dL to 4.1 mg/dL (-53%) in the 50 mg group and to 3.2 mg/dL (-62%) in the 75 mg group (**Figure 1**). sUA lowering effects and the response rates in these patients were similar to those observed in an earlier, well-controlled, 3-week, cross-over design phase 2a study (**Table 1**). Mild or moderate adverse events including gout flares, diarrhea, headache, and upper respiratory infection were observed. None of the AEs led to discontinuation of investigational product.

Conclusion: In a subset of patients with full PK/PD collection, AR882 showed potent sUA lowering effect with similar exposures to those observed in closely monitored early-phase studies. AR882 50 mg and 75 mg doses were well tolerated during the entire study with an unremarkable safety profile.

Urate-Lowering Therapy Is Associated with a Reduced Risk of Arrhythmias: A Systematic Review and Meta-analysis

Palapun Waitayangkoon[1], Tatchaya Kanthajan[2] and Thiratest Leesutipornchai[3], [1]MetroWest Medical Center, Framingham, MA, [2]Srinakharinwirot University, Bangkok, Thailand, [3]University of Hawaii, Honolulu, HI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent studies have suggested that hyperuricemia is significantly associated with an increased prevalence of atrial and ventricular arrhythmias and urate-lowering therapy (ULT) may provide cardioprotective effects by lowering uric acid level and via drug's direct effects. However, research on the effects of ULT and arrhythmia risk is limited. We aim to conduct a systematic review and meta-analysis exploring the relationship between ULT and incident arrhythmias.

Methods: Potentially eligible studies were identified from PubMed and Embase databases from inception to May 2023. Search terms were derived from terms related to "Arrhythmias" and "Urate-lowering therapy". The eligible study must be cohort study that consists of one cohort of patients with ULT use and another cohort of comparators without ULT use. The study must compare the prevalence of cardiac arrhythmias in each group and report effect size with 95% confidence intervals (95% CIs). The Newcastle-Ottawa quality assessment scale was used to evaluate the quality of the included studies. We performed the meta-analysis by using a random-effects model. The heterogeneity of effect size estimates was assessed using forest plots and the Q and I^2 statistics.

Results: Six studies were included in the analysis with a total of12,435 subjects (7,404 subjects in ULT group and 5,031 in non-ULT group). Our results showed that ULT users had significant reductions in the risk of arrhythmias (pooled RR 0.79, 95% CI: 0.67–0.93, p = 0.004, I^2= 8.4%) compared to non-ULT users (Figure 1). Subgroup analysis showed that ULT users had a reduced risk of atrial fibrillation (pooled RR 0.76, 95% CI: 0.59–0.98, p = 0.034 with I^2 =12.2%) compared to non-ULT users (Figure 2), and that allopurinol users had a reduced risk of arrhythmia (pooled RR 0.66, 95% CI: 0.46–0.95, p = 0.024 with I^2= 39.6%) compared to non-allopurinol users (Figure 3).

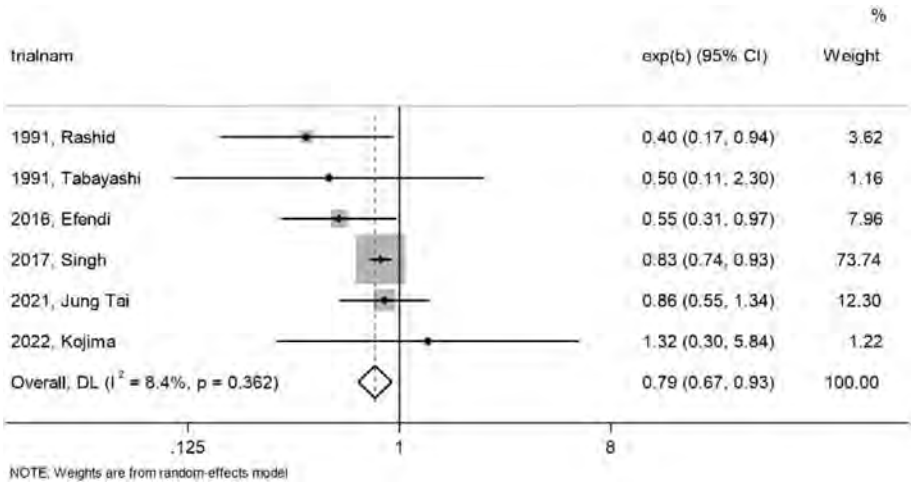

Figure 1. Forest plot of the meta-analysis for urate-lowering therapy and risk of arrhythmias

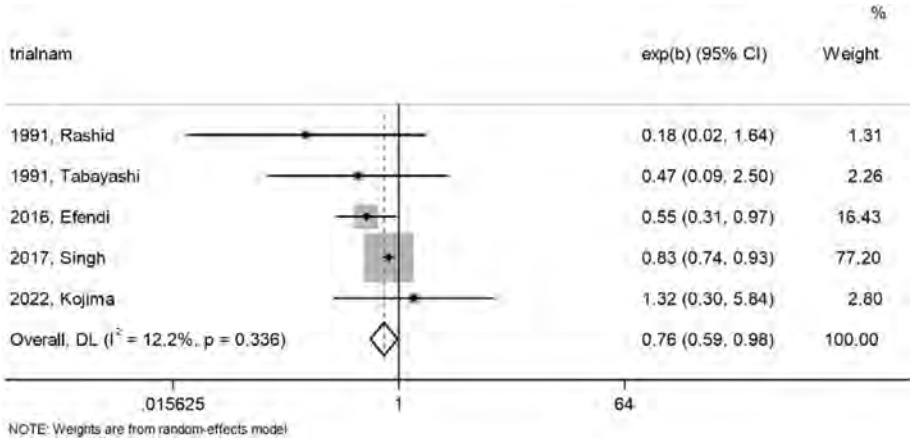

Figure 2. Forest plot of the meta-analysis for urate-lowering therapy and atrial fibrillation

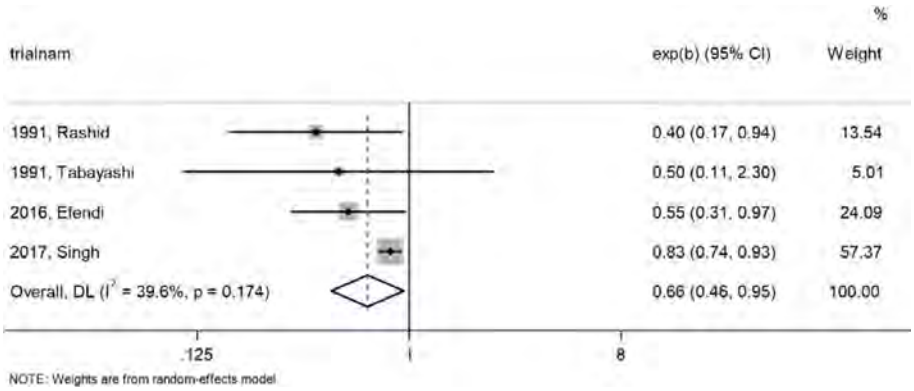

Figure 3. Forest plot of the meta-analysis for allopurinol and arrhythmias

Conclusion: Our results indicate that ULT may play a potential role in protecting arrythmias in addition to lowering uric acid level. Further investigation is needed to elucidate our results and explore the detailed mechanisms.

AR882, a Potent Uricosuric Agent, Shows Favorable Uric Acid Excretion Profile Following Multiple Doses

Zancong Shen[1], Elizabeth Polvent[2], sarah Morris[3], Rongzi Yan[4], Shunqi Yan[5], Robert Keenan[6] and **Li-Tain Yeh**[7], [1]Arthrosi Therapeutics, San Diego, CA, [2]Arthrosi Therapeutics, Inc., Roseville, CA, [3]Arthrosi Therapeutics Inc, San Diego, CA, [4]Arthrosi Therapeutics, Inc, Irvine, CA, [5]Arthrosi Therapeutics, Inc., Laguna Hills, CA, [6]Arthrosi Therapeutics, Chapel Hill, NC, [7]Arthrosi Therapeutics, Inc., Irvine, CA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The uric acid transporter inhibitor (URAT1) is responsible for the reabsorption of filtered uric acid from the renal tubular lumen. Uricosuric agents inhibit URAT1 consequently lowers serum urate (sUA). With previous uricosurics, bolus dumping of drug to the target site caused spontaneous accumulation of uric acid in renal tubules, which posed a potential influx of uric acid at high concentration leading to renal toxicity.[1] AR882 is a potent and selective URAT1 transporter inhibitor in late-phase clinical development. To illustrate the renal safety of AR882 the uric acid excretion profiles across multiple studies were collected to assess the uric acid excretion amount and rate following once-daily dosing.

Methods: In phase 1 healthy subject studies, uric acid excretion profiles were collected following 25, 50 and 75 mg once-daily doses for 10 days in a multiple-ascending dose study (n=24) and following 75 mg once-daily for 14 days (n=16) with every 2-hour collection intervals in a renal impairment study. In a phase 2b study, urine samples were collected at every 2-hour intervals up to 8 hours post-dose from 25 gout patients to evaluate the excretion amount, rate and fractional excretion of uric acid following 8 weeks of once-daily dosing at 50 and 75 mg.

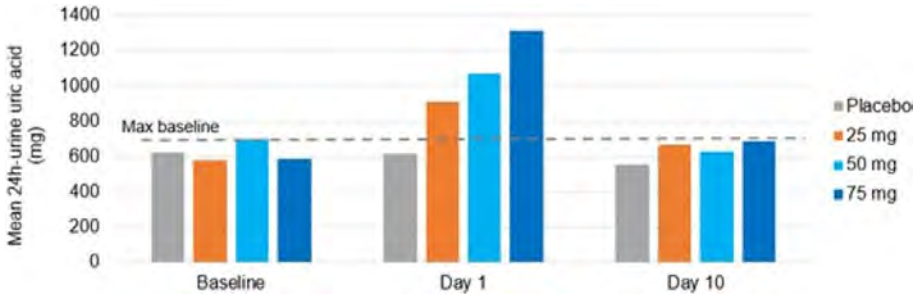

Figure 1. Mean 24-h urine uric acid excretion amount (mg) following AR882 once-daily doses for 10 days in phase 1 subjects

Figure 2. Mean urine uric acid excretion rate (mg/h) following 75-mg AR882 once-daily doses for 14 days in healthy and albuminuria phase 1 subjects

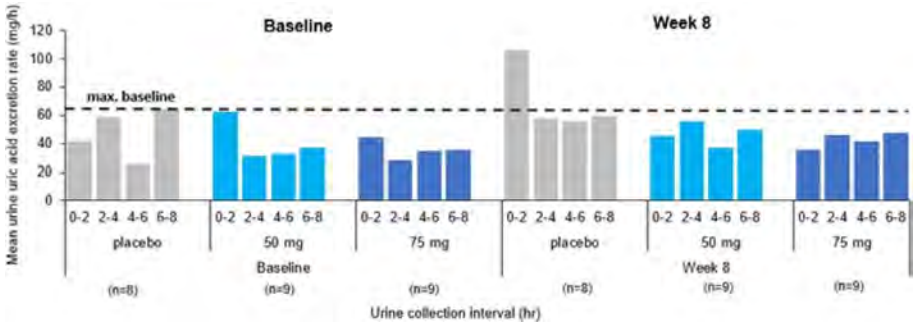

Figure 3. Mean urine uric acid excretion rate (mg/h) following 50 or 75-mg AR882 once-daily doses for 8 weeks in phase 2b gout patients

Results: In phase 1 studies, AR882 showed a relatively flat exposure profile with a slow rise to peak concentrations and slow decline over time. The fraction of dose excreted into tubules was evenly distributed across the day, mirroring the PK profile and supported its sustained sUA reduction and long-lasting URAT1 inhibitory pattern. Following 10 or 14 days of dosing, AR882 showed similar excretion amount to baseline (**Figure 1**) and similar intra-day excretion rate (**Figure 2**). In gout patients, the maximum uric acid excretion rate at baseline was under approximately 60 mg/hr. After 8-week treatment, AR882 at either 50 mg or 75 mg showed consistently low excretion rate across 8 hours post-dose which was similar to baseline or under the maximum baseline value (**Figure 3**) while maintaining significant uric acid lowering effect.

Conclusion: With its unique, slower elimination in PK, AR882 maintains a smooth intra-day uric acid excretion profile that was similar to baseline or to that in placebo patients, resulting in a lasting inhibitory effect without any high concentration of uric acid influx in the kidney tubules. The lack of daily transient increase in uric acid excretion confirms AR882, as a new uricosuric agent, possessing a favorable and safe renal profile over existing and other approved uricosuric agents.

Comparing a Capillary Urate Point-Of-Care Device to Standard Laboratory-based Serum Urate Test for Dose Titration in Gout Patients

Amanuel Kehasse[1], **Sayali Dhamne**[2], Michael LaValley[3], Jean Liew[2] and Tuhina Neogi[4], [1]Boston Medical Center, Boston, MA, [2]Boston University, Boston, MA, [3]Boston University School of Public Health, Arlington, MA, [4]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The management of gout remains poor despite the availability of effective medications and recommendation of a treat-to-target treatment strategy using of urate-lowering therapy (ULT). A serum urate level is required to make ULT dose adjustments. However, requiring lab work prior to a clinic visit can be burdensome for patients, while waiting for laboratory test results after the visit makes face-to-face counseling regarding any medication dose changes at the time of the visit impossible. Introducing a point-of-care (POC) device, much like a glucometer, would allow providers to perform serum urate testing during the clinic visit and make therapy adjustments as needed in real-time. Our purpose was to assess the accuracy, reliability, and acceptability of a POC device as compared to standard laboratory-based serum urate tests.

Methods: We measured serum urate levels in patients with gout using both a capillary POC device (Nova Max Uric Acid Monitoring System) that is FDA-approved for home use (but not approved for use in the clinic) and a standard laboratory-based test on the same day. A Bland-Altman analysis was conducted to identify whether the variability of the difference between tests was affected by the level of serum urate and to identify the limits of agreement between the two tests. We plotted the difference of the two values against the average value for each participant. Correlation between the two

measurements of serum urate was evaluated using intraclass correlation coefficients with 95% confidence intervals (CI). In addition, we assessed the patient acceptability and convenience of device use through a self-reported standard Likert scale questionnaire.

Table 1. Participants characteristics

Sample Characteristics (n=30)	Mean (SD), n (%)
Demographics	
Age	61.3 (± 12.3)
Sex	
Male	25 (83.3%)
Female	5 (16.7%)
Race	
Asian	2 (6.7%)
Black/African American	14 (46.7%)
White	7 (23.3 %)
Unknown/Not reported	7 (23.3%)
Ethnicity	
Hispanic or Latino	6 (20.0%)
Not Hispanic or Latino	23 (76.7%)
Unknown/Not reported	1 (3.3%)
Clinical characteristics	
Chronic kidney disease or end stage kidney disease	12 (40.0%)
Type 2 diabetes	7 (23.3%)
Coronary heart disease	2 (6.7%)
Heart failure	7 (23.3%)
Outcomes	
SUA on POC device	5.6 (± 2.3)
SUA from lab	7.2 (± 2.5)
Acceptability Questionnaire Completed	30 (100%)

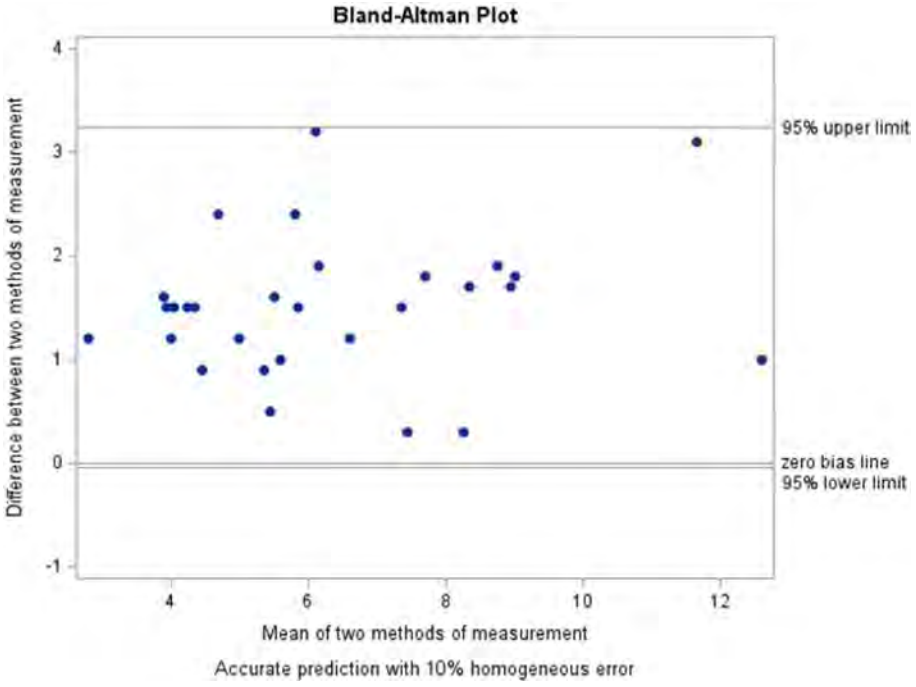

Figure 1. Bland-Altman Plot – Difference in Serum Urate Plotted Against the Average.

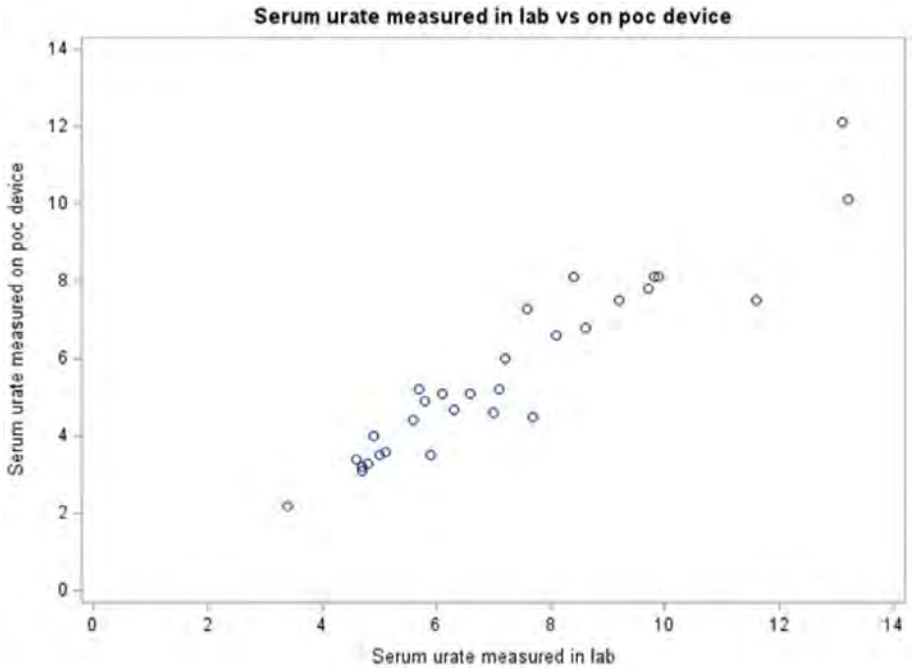

Figure 2. Scatter plot of POC and Laboratory Measures of Serum Urate

Results: We enrolled 30 patients with gout (mean age 61 ± 12.32, 83% male and 17% female; Table 1). The mean ± SD serum urate measured on the POC device was 5.65 ± 2.30 mg/dL and in the laboratory was 7.25 ± 2.52 mg/dL. The Bland-Altman plot (Figure 1) shows limits of agreement close to 0 and 3 indicating consistently lower measurements with the POC device. The intraclass correlation coefficient was 0.75 (95% CI 0.55 - 0.87), indicating moderate agreement (Figure 2). The results from the acceptability questionnaire suggest that the device was acceptable and liked by 97% of the participants. All the participants found it comfortable and 80% preferred the POC device over standard lab tests.

Conclusion: In this small pilot study, the POC device and the standard laboratory tests for serum urate were moderately correlated, though the POC device values were generally >1mg/dL lower than the laboratory values. This discrepancy in serum urate values indicates that this POC device is not suitable at the present time for making treatment decisions in the clinical setting for real-time dose titrations in patients with gout. Nonetheless, patients generally preferred a POC approach; thus, with improved accuracy, POC urate measurements could benefit real-time treat-to-target gout management.

Abstract Number: 1114

Role of Dual-energy Computed Tomography (DECT) in Detection of Carotid Artery Monosodium Urate Deposition in Patients with Gout

Muhammad Danish Sarfraz, Lee Treanor, Savvas Nicolaou and Adnan Sheikh, University of British Columbia, Vancouver, BC, Canada

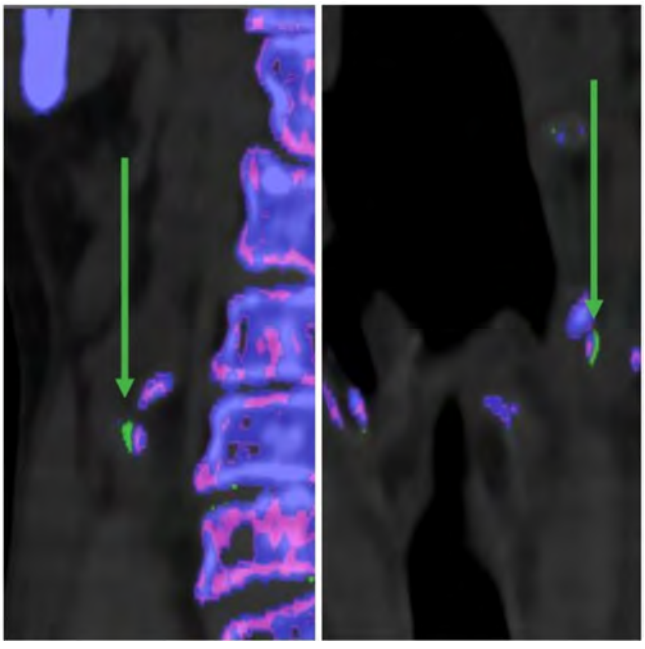
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To find out if a Dual energy CT can detect monosodium urate deposition in carotid arteries and whether the presence of monosodium urate crystals has any effect on atherosclerotic disease in terms of plaque volume.

Methods: This is a retrospective study. All patients who underwent any Dual energy neck imaging (like carotid angiogram, neck soft tissues or cervical spine) from January 2015 to December 2022 were included. All patients' charts were reviewed to determine to find gout patients with clinical and laboratory evidence. Charts were also rigorously reviewed to find potential confounding variables like hypertension, dyslipidemia, CKD and smoking as these may have effect on plaque volume. Patients with a smoking history were excluded as it has a well-established role in atherosclerotic disease. Non-smokers with either hypertension, dyslipidemia, CKD or either of two were included as most of the patients have similar comorbidities. Comprehensive data extraction was done to allow multivariable regression analysis for confounding variables. Same number of healthy controls (without a clinical history of gout or other rheumatic diseases) were included during same study period which were then age (within 5 years), sex and confounders-matched to gout patients using MedCalc. Patients with any extensive artefacts, spinal metal implants, carotid stents, carotid endarterectomy prior to scan date or prior radiotherapy to the head and neck were excluded. DECT datasets were post-processed using Syngo.ViaVB30 with gout application class at default factory settings including a DECT iodine ratio of 1.27, minimum HU at 130, resolution of 3mm, and air distance 5. Volumetric analysis of atherosclerotic plaque was performed using Syngo.ViaVB30 with Calcium scoring application in matched gout patients with carotid monosodium deposition, gout patients without carotid monosodium deposition and control/non-gout patients.

Results: Out of total 2157 patients who underwent dual energy neck imaging during study period, 85 were established gout cases with confirmed clinical and laboratory evidence. Of 85 gout cases, 2 were excluded due to presence of streak artefacts from dentures hence, n=83. Out of 83, Monosodium urate deposition was detected in carotid arteries of 10 patients (12%). None of the matched control patient demonstrated monosodium crystal deposition. Volumetric analysis of atherosclerotic plaque demonstrated larger plaque volumes in gout patients with monosodium urate deposition (n=10) than matched gout patients without monosodium urate deposition (n=10) and matched control/non-gout patients (n=10) (p value of 0.03).



Positive MSU carotid plaque on DECT

Conclusion:

1. Dual energy CT is an effective tool to detect monosodium urate deposition in carotid arteries.
2. Carotid arteries are not a common site for monosodium urate deposition but if present, can lead to increased atherosclerosis in the involved vessel.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The multifaceted clinical presentation in crystal-induced arthropathies (CiA) poses challenges to imaging. Our goal was to formulate evidence-based recommendations on the use of imaging in the diagnosis and management of CiA.

Methods: An international task force of 25 rheumatologists, radiologists, methodologists, health care professionals and patient research partners from 11 countries was formed according to the EULAR standard operating procedures. Fourteen key questions on the role of imaging in the most common forms of CiA were generated (Table 1). The CiA assessed included gout, calcium pyrophosphate dihydrate deposition and basic calcium phosphate deposition. Imaging modalities included conventional radiography, ultrasound, magnetic resonance imaging and computed tomography. Experts applied research

evidence obtained from 4 systematic literature reviews using MEDLINE, EMBASE and CENTRAL after assessing for risk of bias. Task force members provided level of agreement (LoA) anonymously by using a numeric scale.

Table 1. Research questions. BCPD: basic calcium-phosphate deposition; CiA: crystal-induced arthropathy; CPPD: calcium-pyrophosphate deposition; RQ: research question

RQ 1	What is the diagnostic value, above other diagnostic tests of individual imaging modalities in gout?
RQ 2	What is the ability and added value of individual imaging modalities for monitoring inflammation, damage or crystal deposition in gout? In case there is additional value, how frequently and at which timepoints should imaging be applied to monitor inflammation, damage or crystal deposition in gout?
RQ 3	What is the ability and added value above other measures of individual imaging modalities to predict outcome (severity) in gout?
RQ 4	What is the ability and added value above other measures of individual imaging modalities to predict treatment effect in gout?
RQ 5	What is the diagnostic value, including differential diagnosis above other diagnostic tests of individual imaging modalities in CPPD?
RQ 6	What is the ability and added value of individual imaging modalities for monitoring inflammation and damage (including crystal deposition) in CPPD? In case there is additional value, how frequently and at which timepoints should imaging be applied to monitor inflammation and damage in CPPD?
RQ 7	What is the ability and added value above other diagnostic measures of individual imaging modalities to predict outcome (severity) in CPPD?
RQ 8	What is the ability and added value above other measures of individual imaging modalities to predict treatment effect in CPPD?
RQ 9	What is the diagnostic value, including differential diagnosis, above clinical criteria of individual imaging modalities in BCPD (including calcific tendonitis of the supraspinatus tendon, calcific tendonitis of the Achilles tendon, Milwaukee shoulder syndrome and knee, etc.)?
RQ 10	What is the ability and added value of individual imaging modalities for monitoring inflammation and damage (including crystal deposition) in BCPD? In case there is additional value, how frequently and at which timepoints should imaging be applied to monitor inflammation and damage in BCPD?
RQ 11	What is the ability and added value above other diagnostic measures of individual imaging modalities to predict outcome (severity) in BCPD?
RQ 12	What is the ability and added value above other measures of individual imaging modalities to predict treatment effect in BCPD?
RQ 13	What is the ability and added value above conventional measures of individual imaging modalities in guiding diagnostic aspiration and guiding delivery of drugs in CiA?
RQ 14	What is the ability and added value above standard care of individual imaging modalities to facilitate patient education & understanding of disease in CiA?

Table 2. EULAR Recommendations for the use of imaging in crystal-induced arthropathies in clinical practice. *1a for gout, 1a for CPPD, 5 for BCPD; $1a for US, 1a for CR, 1b for CT; #A for gout, A for CPPD, C for BCPD; §A for CR, A for US, B for CT Numbers in column 'LoA' indicate the mean and SD (in parenthesis) of the LoA (range 0–10 with 0='completely disagree' to 10='completely agree'), BCPD: basic calcium phosphate deposition; CPPD: calcium pyrophosphate dihydrate deposition; DECT: dual-energy computed tomography; GoR: grades of recommendation; LoA: level of agreement; LoE: level of evidence; MTP1: first metatarsophalangeal; n.a., not applicable;

Overarching principles	**LoE**	**GoR**	**LoA**
A. Crystal-induced arthropathies are typically characterized by intermittent, acute episodes of inflammation, but may also exhibit a persistent disease course with or without superimposed flares.	n.a.	n.a.	9.83 (0.48)
B. Imaging in crystal-induced arthropathies provides useful information on crystal deposition, inflammation and structural damage.	n.a.	n.a.	9.83 (0.48)
C. The presence of imaging abnormalities, in particular, those related to crystal deposition may not always be related to clinical manifestations.	n.a.	n.a.	9.79 (0.51)
D. Patient information (medical history, physical/ laboratory examination, synovial fluid/tissue analysis, etc.) should be taken into account when imaging is considered in crystal-induced arthropathies.	n.a.	n.a.	9.75 (0.74)
E. Imaging in crystal-induced arthropathies should be performed and interpreted by trained health care professionals.	n.a.	n.a.	9.92 (0.41)
Recommendations			
1. When performing imaging in crystal-induced arthropathies, both symptomatic areas and disease-specific target sites (i.e., MTP1 joint in gout, knee and wrist in CPPD, shoulder in BCPD) should be considered.	1a*	A[§]	9.71 (0.55)
2. In the diagnostic assessment of gout, ultrasound and DECT are both recommended imaging modalities.	1a	A	9.75 (0.61)
3. When characteristic features of monosodium urate crystal deposition on ultrasound (i.e., double contour sign or tophi) or on DECT are identified, synovial fluid analysis is not needed to confirm a diagnosis of gout.	1a	A	8.79 (1.82)
4. In the diagnostic assessment of CPPD, conventional radiography and ultrasound (or computed tomography if axial involvement is suspected) are recommended imaging modalities.	1a[#]	A[$]	9.63 (0.92)
5. In the diagnostic assessment of BCPD, imaging is necessary; conventional radiography or ultrasound are the recommended modalities.	2b	C	9.08 (1.69)
6. In gout, ultrasound and DECT can be used to monitor crystal deposition and in case of ultrasound, also inflammation. Both modalities provide additional information on top of clinical and biochemical assessment. In case ultrasound/DECT are not available conventional radiography can be used to assess structural damage due to gout. The decision on when to repeat imaging depends on the clinical circumstances.	2b	B	9.33 (1.17)
7. In CPPD and BCPD serial imaging is not recommended, unless there is an unexpected change in clinical characteristics.	2a	B	9.42 (1.21)
8. In gout, assessing the amount of monosodium urate crystal deposition by ultrasound or DECT may be used to predict future flares.	2b	B	8.46 (1.67)
9. If synovial fluid analysis is required in the assessment of crystal-induced arthropathies, ultrasound guidance should be used in cases where aspiration based on anatomical landmarks is challenging.	5	D	9.71 (0.55)
10. Showing and explaining imaging findings of crystal-induced arthropathies to people with such conditions may help them understand their condition and improve treatment adherence in gout.	2b	C	9.38 (0.92)

Results: Five overarching principles and 10 recommendations were produced on the role of imaging in making a diagnosis, monitoring inflammation, structural damage and crystal deposition, predicting severity and treatment effect, guiding intervention, and patient education in CiA (Table 2). Level of evidence and grade of recommendation was evaluated. Overall, the LoA for the recommendations was very high (8.5-9.9).

Conclusion: These are the first recommendations that encompass all common forms of CiA and guide the use of established imaging modalities in this disease group.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: A substantial proportion of gout patients have type 2 diabetes (T2DM), heart failure (HF), and chronic kidney disease (CKD), for which SGLT2i treatment is recommended. Proactive use of SGLT2i among gout patients would have multiple benefits, including lowering the risk of HF and CKD progression, major adverse cardiovascular events (MACE), cardiovascular and all-cause mortality, in addition to their potential to lower serum urate and the risk of recurrent gout flares. We sought to examine the current state of SGLT2i use among gout patients with existing FDA-approved indications.

Methods: Using the Mass General Brigham (MGB) electronic health record, we identified two cohorts of gout patients with >1 gout-related encounter from 1/1/2021 to 1/4/2023 in the 1) Mass General Hospital rheumatology clinic (MGH rheum) or 2) anywhere within the MGB system (MGB gout). We used a combination of ICD codes, clinical variables, and laboratory values (**Table 1**) to determine the prevalence of FDA-approved indications for SGLT2i treatment: 1) T2DM and atherosclerotic cardiovascular disease (ASCVD); 2) T2DM and ASCVD risk factors; 3) T2DM and CKD; 4) CKD, defined as eGFR 20-44 mL/min/1.73m^2 or 45-89 mL/min/1.73m^2 with urinary albumin-to-creatinine ratio (UACR) ≥200 mg/g (regardless of T2DM); and 5) HF. We then determined the proportion of those patients with indications who were prescribed an SGLT2i.

Results: The MGH rheum and MGB gout cohorts included 1,212 and 21,301 gout patients, respectively (**Table 2**). The mean age was 64.9 and 68.1 years, respectively, and both groups were predominantly male. Of the patients in the MGH rheum and MGB gout cohorts, 41.8% and 45.6% had ≥1 FDA-approved indication for SGLT2i, respectively. However, only 10.7% and 9.7% of the patients with an SGLT2i indication (or 4.5% and 4.4% of the entire cohort) were actually prescribed one in the MGH rheum and MGB gout cohorts, respectively. The prevalence of SGLT2i indications was largely similar between the two cohorts. In both cohorts, CKD was the least prevalent indication at 16.2% and 16.0%, respectively. T2DM with ASCVD risk factors was the most prevalent indication in the MGB gout cohort at 28.4%, whereas T2DM with

Table 1. Definitions Used to Identify Indications for SGLT2i Treatment

Comorbidity	Definition
T2DM	≥2 ICD codes ever and/or hemoglobin A1c ≥6.5 ever
ASCVD	≥2 ICD codes for ASCVD ever
ASCVD risk factors	Age ≥55 and two or more of the following: obesity, hypertension, smoking, hyperlipidemia, UACR 30-300 mg/g
Obesity	Body mass index ≥30 kg/m^2
Hypertension	≥2 ICD codes for hypertension ever
Smoking	Variable available in clinical data warehouse
Hyperlipidemia	≥2 ICD codes for hyperlipidemia ever
CKD	eGFR 20-44 mL/min/1.73m^2 or eGFR 45-89 mL/min/1.73m^2 and UACR ≥200 mg/g
HF	≥2 ICD codes for HF ever

UACR = urinary albumin-to-creatinine ratio
eGFR = estimated glomerular filtration rate

Table 2. Cohort Characteristics and Indications for SGLT2i Treatment

	MGH rheum	MGB gout
N	1,212	21,301
Age, years	64.9 (14.5)	68.1 (13.7)
Male, n (%)	975 (80.5)	17076 (80.2)
Urate-lowering therapy use	659 (54.4)	7659 (36.0)
SGLT2i use	57 (4.7)	972 (4.6)
At least 1 indication for SGLT2i	507 (41.8)	9706 (45.6)
On SGLT2i‡	10.7%	9.7%
T2DM with ASCVD	244 (20.1)	4537 (21.3)
On SGLT2i‡	16.0%	13.1%
T2DM with ASCVD risk factors	287 (23.7)	6057 (28.4)
On SGLT2i‡	12.9%	11.5%
T2DM with CKD*	208 (17.2)	4134 (19.4)
On SGLT2i‡	16.8%	14.0%
CKD†	196 (16.2)	3404 (16.0)
On SGLT2i‡	16.3%	11.5%
HF	288 (23.8)	4670 (21.9)
On SGLT2i‡	14.6%	13.0%

*CKD defined as eGFR 20-59 and/or UACR ≥30 mg/g
†CKD defined as eGFR 20-44 or 45-89 with UACR ≥200 mg/g
‡Indicates proportion among those with indication listed immediately above

ASCVD risk factors and HF were similarly prevalent in the MGH rheum cohort at 23.7% and 23.8%, respectively. In both cohorts, T2DM with CKD was the indication for which the highest proportions of patients were appropriately prescribed an SGLT2i, although it still represented a minority of patients at 16.8% and 14.0%, respectively.

Conclusion: In this retrospective study from a large tertiary academic healthcare system, >40% of gout patients had ≥1 indication for SGLT2i. However, only about 10% of those with an indication for SGLT2i (or approximately 4.5% of the entire cohort) were prescribed one. Because SGLT2i have a myriad of proven cardiometabolic-kidney benefits, more proactive use of SGLT2i among patients with gout with an existing indication could improve their comorbidity outcomes and prevent premature mortality, while simultaneously yielding potential gout-related benefits. Future studies on the use of SGLT2i among gout patients are required, given the rapidly expanding indications for SGLT2i in cardiometabolic-kidney comorbidity care.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sodium-glucose cotransporter type 2 inhibitors (SGLT2i) are currently indicated as second-line therapy for type 2 diabetes and are also approved for the treatment of heart failure and chronic kidney disease, all comorbidities prevalent among gout patients. SGLT2i have also been found to reduce serum urate (SU), the causal mediator of gout, by up to 1.8 mg/dL among those with hyperuricemia (Doehner et al., Eur Heart J, 2022). However, no data are available specifically among patients with gout. We sought to determine the SU change among gout patients treated with SGLT2i or sulfonylurea (SFU, another second-line diabetes agent).

Methods: Using the Mass General Brigham electronic health record database, we identified all gout patients initiating SGLT2i or SFU who had SU measured within 3 months before and after the initiation through 2/2/2023. Gout patients were identified using an algorithm with a positive predictive value of 0.9 against the 2015 ACR/EULAR gout criteria and were required to have baseline SU ≥6 mg/dL. A rheumatologist reviewed all identified patient records to confirm their gout diagnosis and the initiation and continuation of SGLT2i or SFU treatment during the study period (up to 6 months). Patients who had SU measured < 7 days after the initial prescription or in the setting of an acute gout flare were excluded, as were patients who initiated or changed the dose of urate-lowering therapy (ULT) just prior to or during the study period. We first

calculated the within-group SU change. Then, we compared the two groups for SU change using multivariable linear regression adjusting for age, sex, baseline SU, and ULT use. We additionally adjusted for each of the other covariates for robustness and conducted subgroup analyses per ULT use and key comorbidities.

Results: There were 23 patients with gout who initiated SGLT2i and 24 patients who initiated SFU. The SGLT2i-initiators were slightly older, while the SFU-initiators included more females and had higher baseline SU (**Table 1**). Among SGLT2i-initiators, the mean SU change was -1.6 mg/dL (95% CI, -2.2 to -0.9), compared with 0.3 mg/dL (95% CI, -0.5 to 1.0) among SFU-initiators (**Figure 1**). During the study period, 43.5% of SGLT2i-initiators reached target SU < 6 mg/dL compared to 4.2% of SFU-initiators. The adjusted SU change associated with SGLT2i initiation was -1.6 mg/dL (95% CI, -2.6 to -0.7)

Table 1. Baseline Characteristics of Initiators of SGLT2i vs. Sulfonylurea

	SGLT2i (n=23)	Sulfonylurea (n=24)
Age, years, mean (SD)	66.7 (9.0)	61.6 (13.9)
Female, n (%)	1 (4.3)	4 (16.7)
Race, n (%)		
White	16 (69.6)	12 (50.0)
Other	7 (30.4)	12 (50.0)
BMI, mean (SD)	34.9 (6.7)	33.6 (5.5)
Serum urate, mg/dL, mean (SD)	7.8 (1.4)	8.3 (1.4)
Hemoglobin A1c, %, mean (SD)	7.5 (1.7)	8.6 (1.7)
eGFR, mL/min/1.73m^2, mean (SD)	47.5 (22.5)	48.8 (16.4)
Hypertension, n (%)	8 (34.8)	11 (45.8)
Type 2 diabetes, n (%)	16 (69.6)	24 (100.0)
Chronic kidney disease stage ≥3, n (%)	16 (69.6)	17 (70.8)
Heart failure, n (%)	13 (56.5)	4 (16.7)
Medications, n (%)		
Diuretics	19 (82.6)	15 (62.5)
Urate-lowering therapy (with no recent change)	17 (73.9)	9 (37.5)
Aspirin	10 (43.5)	8 (33.3)
Losartan	1 (4.3)	3 (12.5)
Colchicine	9 (39.1)	8 (33.3)
NSAIDs	7 (30.4)	10 (41.7)
DPP4i	2 (8.7)	0 (0.0)
GLP1-RA	5 (21.7)	0 (0.0)
Insulin	10 (43.5)	7 (29.2)

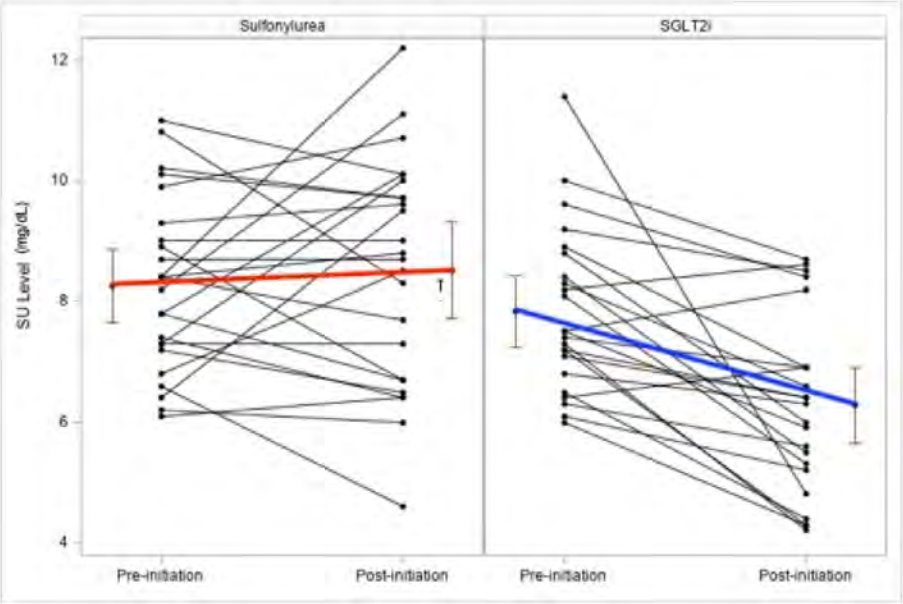
DPP4i = dipeptidyl peptidase 4 inhibitors; GLP1-RA = glucagon-like peptide-1 receptor agonists

Table 2. Adjusted Serum Urate Change Among Initiators of SGLT2i vs. Sulfonylurea

	Age, Sex adjusted	Multivariable 1*	Multivariable 2*
Overall	-1.7 mg/dL (-2.7 to -0.7)	-1.9 mg/dL (-2.8 to -0.9)	-1.6 mg/dL (-2.6 to -0.7)
ULT Use	-1.7 mg/dL (-3.1 to -0.2)	-1.7 mg/dL (-3.1 to -0.3)	—
No ULT Use	-1.6 mg/dL (-3.0 to -0.1)	-1.7 mg/dL (-3.1 to -0.4)	—
Diuretic Use	-1.9 mg/dL (-3.1 to -0.8)	-2.2 mg/dL (-3.3 to -1.1)	-1.8 mg/dL (-2.9 to -0.8)
Type 2 Diabetes	-1.2 mg/dL (-2.2 to -0.2)	-1.3 mg/dL (-2.3 to -0.3)	-1.1 mg/dL (-2.1 to -0.1)
CKD	-1.3 mg/dL (-2.2 to -0.3)	-1.6 mg/dL (-2.6 to -0.6)	-1.4 mg/dL (-2.4 to -0.4)
Prescriptions after March 2013†	-2.1 mg/dL (-3.4 to -0.8)	-2.1 mg/dL (-3.3 to -1.0)	-1.8 mg/dL (-2.9 to -0.7)

Multivariable 1: age, sex, and baseline SU
Multivariable 2: age, sex, baseline SU, and ULT use
†FDA-approval of first SGLT2i in the US

Figure 1. Serum Urate Change Among Initiators of SGLT2i vs. Sulfonylurea



compared with SFU initiation, and remained similar when stratified by ULT use (**Table 2**). These results did not change materially with additional adjustments for other covariates but were slightly attenuated but still significant among those with diabetes.

Conclusion: In this comparative effectiveness analysis of gout patients, SGLT2i use was associated with a notable reduction in SU over several months, whereas SFU use was not. With their proven multiple cardiometabolic-kidney benefits, these results suggest that SGLT2i could be a much-needed multi-purpose medication for the synergistic treatment of gout and its comorbidities, regardless of ULT use, and call for randomized clinical trials to test this hypothesis.

The Nomenclature of Calcium Pyrophosphate Deposition (CPPD) Disease – Results of a Systematic Literature Review for the Gout, Hyperuricemia and Crystal-Associated Disease Network (G-CAN) CPPD Nomenclature Project

Silvia Sirotti[1], Charlotte Jauffret[2], Edoardo Cipolletta[3], Daniele Cirillo[4], Luca Ingrao[4], Alessandro Lucia[4], Antonella Adinolfi[5], Debora Pireddu[4], Emilio Filippucci[6], Tristan Pascart[2], Sara Tedeschi[7], Robert Terkeltaub[8], Nicola Dalbeth[9] and Georgios Filippou[1], [1]IRCCS Galeazzi - Sant'Ambrogio Hospital, Milan, Italy, [2]Saint-Philibert Hospital, Lille Catholic University, Lille, France, [3]Polytechnic University of Marche, Ancona, Italy, [4]Department of Clinical Sciences and Community Health, Università degli Studi di Milano, Milan, Italy, [5]Rheumatology Unit, Grande Ospedale Metropolitano Niguarda, Milano, Italy, [6]Polytechnic University of Marche, Jesi, Italy, [7]Brigham and Women's Hospital, Boston, MA, [8]University of California San Diego, San Diego, CA, [9]University of Auckland, Auckland, New Zealand

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite prior attempts at standardising terminology of calcium pyrophosphate deposition (CPPD) disease (including the 2011 EULAR recommendations for CPPD terminology and diagnosis), many different terms are still used interchangeably to describe the disease, its elements, and its states. This confusing nomenclature has important implications for research and for patient care. The Gout, Hyperuricemia and Crystal-Associated Disease Network (G-CAN) has developed a CPPD Nomenclature Project which aims to achieve international consensus about the nomenclature of CPPD. In this first step of the project, the aim was to identify the definitions, the disease elements and the clinical states of CPPD and their corresponding labels in the scientific literature.

Methods: A systematic literature search was performed in the PubMed database starting from 01/01/2000 to 31/01/2022. The search was restricted to studies on humans and in the English language. Eight reviewers independently extracted terms related to disease definition, aetiology, pathogenesis, clinical presentation, imaging features and clinical states of CPPD. An *a priori* list of disease elements and clinical states was generated by the authors and further elements were added during data collection as appropriate. Labels for each identified disease element and clinical state were extracted and analysed to determine their frequency.

Results: A total of 2392 articles were identified using the search criteria, 1028 articles were included. The complete list of evaluated elements is showed in **Figure 1**. There was great inconsistency in the terminology used for the disease, its elements and its states. The 3 most common labels used to identify the disease were "pseudogout", "calcium pyrophosphate deposition disease" and "chondrocalcinosis". The most common acronym used was "CPPD", mostly with the meaning of "calcium pyrophosphate deposition disease" or "calcium pyrophosphate deposition" (**Table 1**). The 2 most commonly used labels describing "an episode of acute CPPD arthritis" were "pseudogout" (31%), and "acute calcium pyrophosphate crystal arthritis" (10%). For "more than one episode of acute CPPD arthritis", "recurrent pseudogout" (17%) or "recurrent

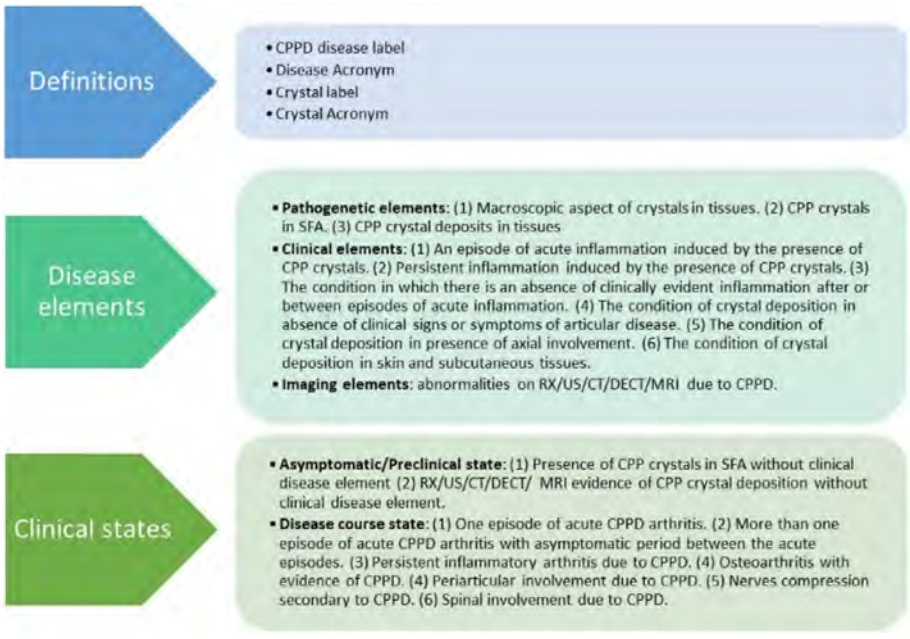

Figure 1: List of definitions, disease elements and clinical states

Table 1: Example of labels extracted for calcium pyrophosphate deposition disease

Element	More frequent labels	Frequency
Disease label	**Pseudogout**	**43.4%**
	Calcium pyrophosphate deposition disease	22.3%
	Chondrocalcinosis	21.5%
	Calcium pyrophosphate dihydrate deposition disease	12.8%
	Calcium pyrophosphate dihydrate crystal deposition disease	12.7%
	Other	57%
Acronym	**CPPD**	**63.9%**
	CC	8.4%
	CPDD	8.1%
	CPPDD	1.9%
	CPPD-CDD	1.6%
	Other	24%
Acronym meaning	**Calcium pyrophosphate deposition disease**	**24.1%**
	Calcium pyrophosphate deposition	16.1%
	Calcium pyrophosphate dihydrate deposition disease	7.1%
	Chondrocalcinosis	5.6%
	Calcium pyrophosphate crystal deposition	5%
	Other	47.3%

arthritis'' (10%) were the most used labels. ''Chronic calcium pyrophosphate crystal arthritis'' (13%) and ''pseudo-rheumatoid arthritis'' (11%) were the most commonly used labels to describe ''persistent inflammatory arthritis due to CPPD''. The most used labels used to identify ''osteoarthritis with evidence of CPPD'' were ''pseudo-osteoarthritis'' (11%) and ''calcium pyrophosphate crystal deposition with osteoarthritis'' (9%).

Conclusion: These results demonstrate the variability and lack of precision in the labels used to describe CPPD disease. The next steps of the project will be to achieve agreement about CPPD disease nomenclature through a Delphi exercise and consensus meeting, and to develop an easily understandable common language definition to increase scientific understanding and awareness of this condition and to facilitate communication with patients.

Preliminary Descriptive Analysis of the RADIAL Cohort Study About the Prevalence and the Clinical Characteristics of Patients with CPPD in Daily Clinical Practice

Silvia Sirotti[1], Joao Madruga-Dias[2], Antonella Adinolfi[3], Garifallia Sakellariou[4], Davide Rozza[5], Greta Carrara[5], Gianpiero Landolfi[5], Carlo Alberto Scire[5], Annamaria Iagnocco[6] and Georgios Filippou[1], [1]IRCCS Galeazzi - Sant'Ambrogio Hospital, Milan, Italy, [2]Centro Hospitalar do Médio Tejo, NOVA Medical School, Lisbon, Portugal, [3]Rheumatology Unit, Grande Ospedale Metropolitano Niguarda, Milano, Italy, [4]Department of Internal Medicine and Therapeutics, Università di Pavia, Istituti Clinici Scientifici Maugeri IRCCS, Pavia, Italy, [5]Società Italiana di Reumatologia, Epidemiology Research Unit, Milan, Italy, [6]University of Turin, Roma, Italy

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The RADIAL study is aimed to evaluate the performance of a composite approach, based on clinical, laboratory and ultrasound (US) data in the differential diagnosis among the main inflammatory arthropathies and Osteoarthritis (OA). In this preliminary analysis, based on partial data, we present the prevalence and the clinical characteristics of the patients affected by Calcium Pyrophosphate Deposition (CPPD) as diagnosed by US.

Methods: The RADIAL study is a multicenter, international, mixed design (retrospective, cross-sectional, prospective) diagnostic accuracy study. Consecutive patients reaching the rheumatology outpatients clinic for the first time, with suspicion of an inflammatory arthropathy, aged 18 or older and with recent standard blood exams were enrolled in the study. All patients underwent a US examination of an extended set of target joints for the assessment of specific lesions for Rheumatoid Arthritis, Psoriatic Arthritis, Gout, CPPD, Polymyalgia Rheumatica and OA. Demographic and clinical data were also collected. The presence of typical deposits in at least one joint classified patient as affected by CPPD for this preliminary analysis. After the first visit, all patients entered in routine follow up and treatment strategies were adopted according to guidelines after the diagnosis was made. To increase certainty of the diagnosis, patients will be classified after one year of follow-up (ongoing at the time of submission). In this analysis, we assessed the prevalence of CPPD in the cohort of the RADIAL study, stratified by age and US findings.

Results: 550 patients were enrolled, 58.9% female with a mean age of 60.1 yo (±14.4). 57.8% of the patients were affected by CPPD (318/550) considering the entire cohort, with a mean age of 63 yo (±13.1), significantly higher when compared to no CPPD patients [mean age 56.2 yo (±15.3)]. Stratifying by ageing, the prevalence increases to 66.2% considering the patients older than 60 (188/284) and 73% considering 80 yo or older subjects (30/41). From the US point of view, patients with CPPD had a significantly higher inflammatory involvement of wrists and knees at US (both in grey scale and power Doppler assessment - $p < 0.001$) compared to patients with any other disease and no CPPD, while no differences have been emerged between CPPD and the other arthropathies about the comorbidities and the general clinical profile.

Conclusion: CPPD is commonly encountered in a routine rheumatological setting, reaching a prevalence of more than 65% in patients older than 60. Symptom attribution is challenging as many conditions may be associated and even a higher presence of synovitis in patients with CPPD cannot be unequivocally attributed to it. There is an impellent need to raise awareness on CPPD and its possible implications. We expect RADIAL study to supply additional data on these findings.

gout flares associated with these target levels, including those requiring hospitalization, are unknown. We quantified associations of target SU with recurrent flares, including gout-primary hospitalizations, among gout patients nested in a prospective nationwide cohort.

Methods: This was a prospective cohort study of UK adults recruited over 2006-2010 and followed-up through primary care medical record linkage. As done previously [Cipolletta *et al. JAMA* 2022], flares among prevalent gout patients were ascertained by (1) hospitalization with gout (ICD-10 M10) as primary discharge diagnosis; (2) diagnosis of gout flare in primary care records; or (3) diagnosis of gout in primary care records and prescription issued on the same day for corticosteroids, colchicine, or non-steroidal anti-inflammatory drugs (NSAIDs).We also investigated flares requiring hospitalisation. Poisson regression was used to assess the relation between baseline SU levels and rates of recurrent gout flares over 1, 2, 5, and 10 years of follow-up.

Results: We followed 3,613 prevalent gout patients (86% male, mean age 60 years), among whom we documented 1,770 gout flare events over 10 years.95% (1,676/1,770) and 98% (1,728/1,770) of flares occurred in baseline SU ≥6 and ≥5 mg/dL, respectively. Rate ratio (RR) for flares with SU levels of < 6.0, 6.0-6.9, 7.0-7.9, 8.0-8.9, 9.0-9.9, and ≥10 mg/dL were

8 to 9	609	6450	14	2.2	12.15 (2.76 to 53.47)	10.58 (2.38 to 47.04)
9 to 10	212	2229	15	6.7	37.68 (8.62 to 164.76)	34.36 (7.79 to 151.67)
≥10 mg/dL	82	825	8	9.7	54.30 (11.53 to 255.72)	46.43 (9.77 to 220.78)
Per mg/dL	3613	38,142	64	1.7	1.78 (1.55 to 2.05)	1.77 (1.53 to 2.05)

No, number; PY, person years; 95% CI, 95% confidence interval. Hospitalizations were ascertained through March 5, 2020 (max 12.8 years follow-up).

1.0, 5.03, 11.64, 11.81, 18.95, and 29.13, respectively during first year of follow-up (1.59 [1.48-1.71] per mg/dL), and 1.0, 3.38, 6.93, 8.57, 10.93, and 11.40, respectively, over whole 10-year follow-up (1.49 [1.45-1.53] per mg/dL) (**Table 1**).Associations persisted irrespective of sex, race, age group, chronic kidney disease status, and diuretic and urate-lowering therapy use (all P for interaction >0.17) (**Table 2**). 97% (62/64) and 100% (64/64) of flares requiring hospitalization occurred in baseline SU ≥6 and ≥5 mg/dL, respectively (**Table 3**); corresponding RR were 1.0, 4.77, 9.02, 10.58, 34.36, and 46.43, respectively (1.77 [1.53-2.05] per mg/dL).

Conclusion: In this prospective cohort of gout patients treated in primary care, 95% and 98% of flares occurred in baseline SU ≥6 and ≥5 mg/dL, respectively. Associations were more prominent for hospitalized flares, with no cases among those with SU < 5mg/dL; higher serum urate levels are strongly associated with frequency of recurrent flares in a graded manner. These findings support the utility of these target urate levels for gout patient care, consistent with a treat-to-target approach recommended by rheumatology societies in the US and Europe, but not the American College of Physicians.

Cardiovascular Safety of Febuxostat in Patients with Gout or Hyperuricemia: A Systematic Review of Randomized Controlled Trials

Roba Ghossan[1], Ouidade Aitisha Tabesh[2], Fouad Fayad[2], Pascal Richette[3] and Thomas Bardin[4], [1]COCHIN HOSPITAL, Paris, France, [2]Hotel Dieu de France, Beirut, Lebanon, [3]Lariboisière Hospital, Paris, France, [4]Université de Paris Cité, Paris, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To this date, a causal relationship between febuxostat and cardiovascular disease remains controversial as comparison between trials can be challenging and may lead to misleading conclusions especially when facing heterogeneous cardiovascular outcomes. We aimed to compare the cardiovascular outcomes in the most pertinent trials of Febuxostat compared to controls.

Methods: We searched electronic databases using a PICOS-style approach search strategy of randomized controlled trials on cardiovascular outcomes of Febuxostat in patients with gout or hyperuricemia. We conducted a quality and risk of bias assessment of the included clinical trials. The definition of MACE as well as all reported cardiovascular outcomes were retrieved from every involved trial.

Results: Of the 1173 records identified from all sources, 20 RCTs were included in the analysis. Mean duration of follow-up was 69.7 ± 81.5 weeks and Febuxostat dose ranged from 10 to 240 mg with 80 mg being the most commonly used dosage. Overall, the quality of evidence deriving from all RCTs showed concerns in most studies (65%). Major cardiovascular event (MACE) was defined in 7 of the 20 RCTs (35%) and cardiovascular outcome reporting was very heterogeneous. Overall, data of cardiovascular safety of Febuxostat were reassuring.

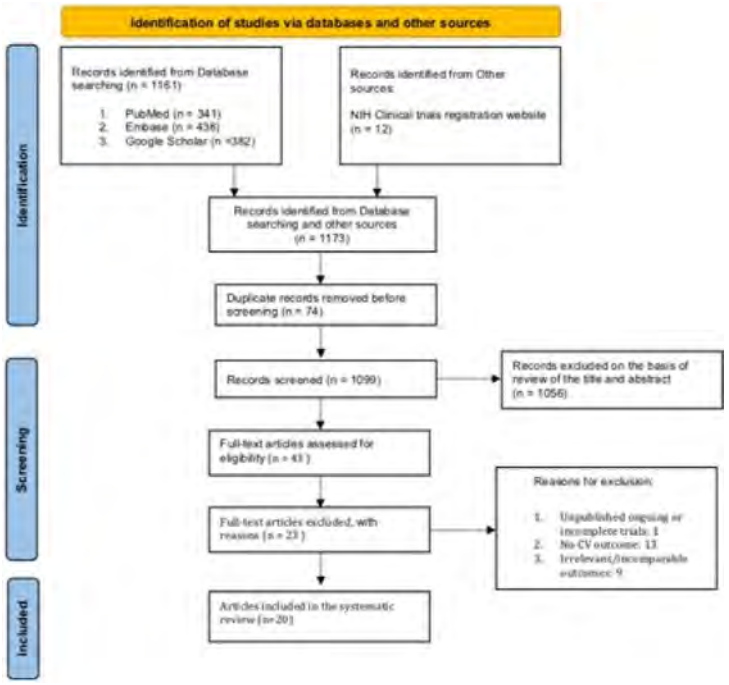

Figure 1: Flowchart of the included studies NIH: National Institutes of Health; CV: Cardiovascular

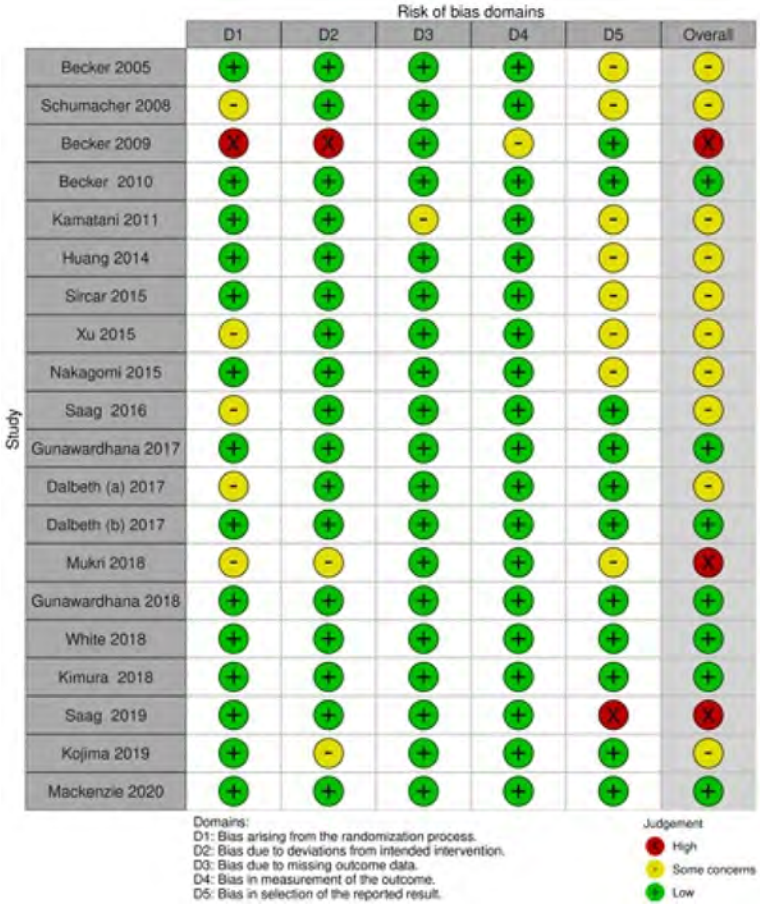

Figure 2: Risk of bias of included randomized trials

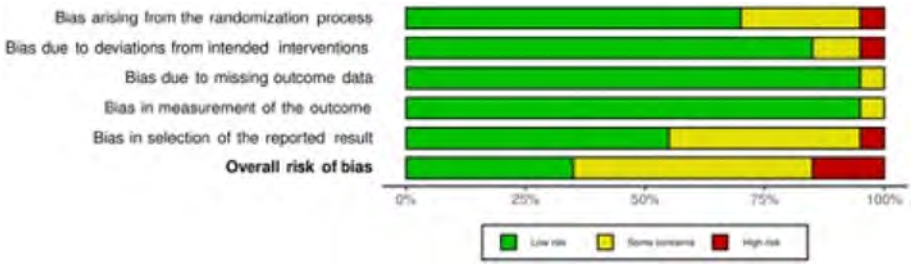

Figure 2: Risk of bias of included randomized trials

Conclusion: Our systematic review showed no alarming increase of cardiovascular mortality and outcomes in Febuxostat treated patients except for the CARES trial in which the credibility of the results is biased by the high rate of drug discontinuation and of most importantly, withdrawal from follow-up. FAST trial results, backed up with real-world data cohort studies, were robust and reassuring with regard to the cardiovascular safety of Febuxostat in most white males with gout including elderly patients. This should lead the regulatory agencies to reconsider the limitations imposed on the use of Febuxostat in patients with non-severe CV burden

The Tophus Impact Questionnaire (TIQ-20): Responsiveness to Change During Urate-Lowering Therapy

Cindy Cao[1], Greg Gamble[1], Anne Horne[1], Opetaia Aati[1], Anthony Doyle[1], Jill Drake[2], Lisa Stamp[3] and **Nicola Dalbeth**[1], [1]University of Auckland, Auckland, New Zealand, [2]Te Whatu Ora Waitaha, Christchurch, New Zealand, [3]University of Otago, Christchurch, New Zealand

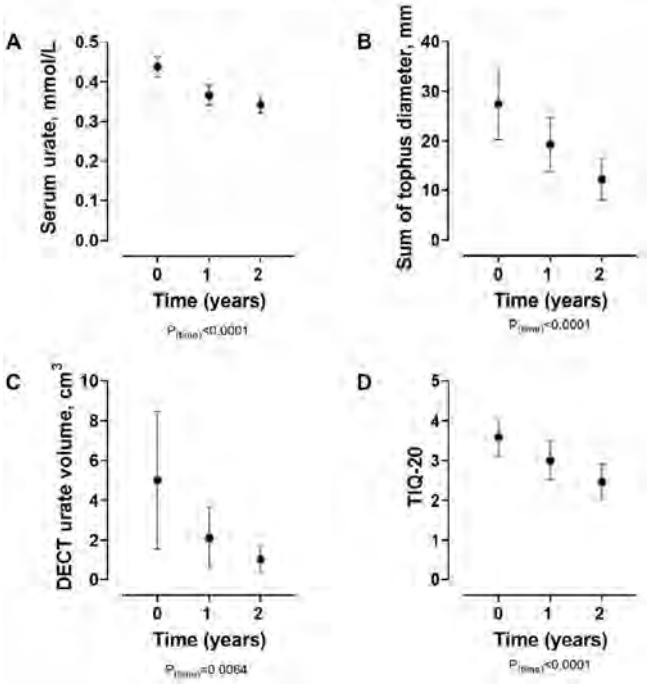
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2015, the 20-item Tophus Impact Questionnaire (TIQ-20) was developed as a tophus-specific patient reported outcome measure (Aati et al., 2015). Initial analysis of the TIQ-20 showed good psychometric properties, with high internal, face and construct validity, reproducibility, and feasibility. To date, responsiveness over time has not been reported. The aim of this study was to determine whether the TIQ-20 changes during urate-lowering therapy.

Methods: We analysed data from a two-year randomized controlled trial of allopurinol dose escalation (Stamp et al, 2017). Briefly, participants with gout on allopurinol with serum urate ≥0.36mmol/L (6mg/dL) were randomised to immediate allopurinol dose escalation to achieve a serum urate of < 0.36mmol/L, or a control group with no change in allopurinol dose. After one year, participants in the control group also had allopurinol dose escalation to achieve a serum urate of < 6mg/dL.

For participants with tophaceous gout, the longest diameter of up to three index tophi was measured using Vernier calipers and the TIQ-20 was recorded at study visits. Participants at the one site were invited into an imaging sub-study with dual energy CT (DECT) of the feet at baseline, Year 1, and Year 2.

Figure. Mean (95% CI) values for A. serum urate, B. sum of index tophus diameter, C. DECT urate volume, D. TIQ-20.



Participants were included in this analysis if they had tophaceous gout and TIQ-20 scores available at baseline, Year 1, and Year 2 (n=58, 39 with DECT data). Data from these visits were analysed using mixed model analysis. Cohen's d was calculated as a standardized effect size for assessing the difference between the baseline and Year 2 tophus mean values. Rasch modelled TIQ-20 scores were used throughout the analysis.

Results: The mean (SD) serum urate reduced over the two-year period from 0.44 (0.10) to 0.34 (0.08) mmol/L, P< 0.001 (Figure). Improvements were observed in all tophus measures including the TIQ-20 over the two-year period, with no difference between the two treatment groups (P >0.34 for treatment allocation). For the entire group, the mean (SD) sum of the index tophi diameter reduced from 27.4 (27.2) to 12.2 (16.4) mm, P< 0.0001, and the DECT urate volume reduced from 5.01 (9.85) to 1.04 (2.03) cm^3, P=0.006 (Figure). The TIQ-20 scores also reduced over two years from 3.59 (1.77) to 2.46 (1.73), P< 0.0001 (Figure), and the mean (95% CI) TIQ-20 change over the two years was -1.13 (-1.54, -0.71). Cohen's d for the sum of the index tophi diameter was 0.68, for DECT urate volume was 0.5, and for the TIQ-20 was 0.71.

Conclusion: For people with tophaceous gout treated with allopurinol using a treat to target serum urate approach, improvements in TIQ-20 occur, as well as improvements in physical and imaging tophus measures. These findings demonstrate that the TIQ-20 is a responsive instrument of tophus burden.

Real-world Trends in the Use of Immunomodulation as Co-therapy to Pegloticase: Claims-based Findings Since 2016

John Botson[1], Qianhong Fu[2], Kaiding Zhu[2], Lissa Padnick-Silver[2] and Brian LaMoreaux[2], [1]Orthopedic Physicians Alaska, Anchorage, AK, [2]Horizon Therapeutics, Deerfield, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pegloticase can treat uncontrolled gout but anti-drug antibodies limit urate-lowering response and put patients at risk for infusion reactions (IRs).[1, 2] The first case series of pegloticase+methotrexate (MTX) co-administration was presented in Nov 2018, showing a 100% response rate with no IRs.[3, 4] Real-world[5] and clinical trial data[6-8] have continued to support pegloticase+immunomodulation (IMM) co-therapy, with MIRROR RCT confirming pegloticase+MTX superiority (month 6 response rate: 71% vs. 39%; IR rate: 4% vs. 31%).[9] The pegloticase label was updated to include MTX co-therapy in July 2022.[10] Here, we examine real-world IMM co-therapy adoption through Nov 2022 using a large insurance claims database.

Methods: The Merative™ MarketScan® Research Databases (closed claims data, commercially-insured patients) were searched for patients with ≥1 pegloticase infusion code (J2507) between Jan 2016 and Nov 2022. Patients who had data within 180 days before and within 60 days after first J-code were included (not all patients who received pegloticase included). The use of IMM co-therapy (≥1 pharmacy claim [based on NDC code] for MTX, mycophenolate mofetil [MMF], azathioprine, leflunomide and/or cyclosporin ≤60 days before/after first J-code) was examined. Data are presented as mean(±SD) or n(%) as appropriate.

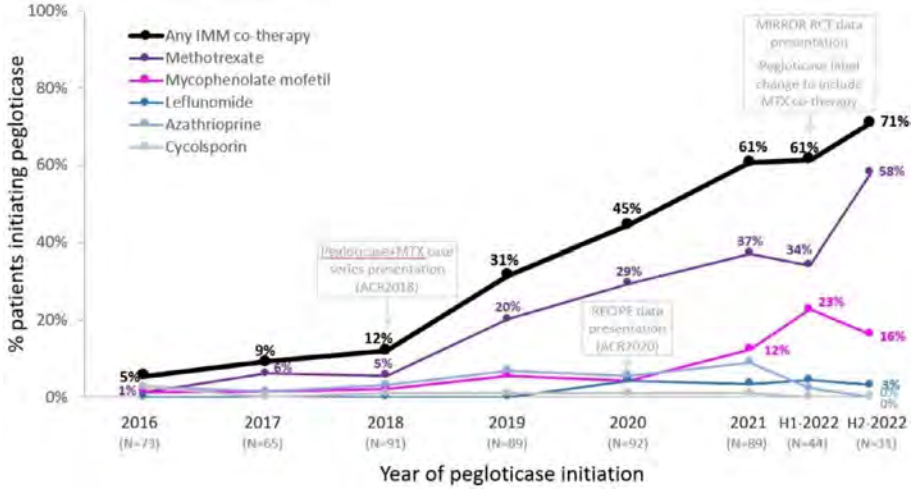

Figure. Proportion of patients with ≥1 pharmacy claim for an IMM agent within 60 days before or after initiating pegloticase therapy (a small proportion of patients received >1 IMM agent). All patients had claims in database within 180 days before and within 60 days after first pegloticase infusion (data do not include all patients who received pegloticase). MIRROR RCT, randomized controlled trial of pegloticase+MTX vs. pegloticase +placebo (N=152) [9]; RECIPE, randomized controlled trial of pegloticase+mycophenolate mofetil vs. pegloticase+placebo (N=32) [12]; IMM, immunomodulation; MTX, methotrexate; ACR, American College of Rheumatology

Results: 574 patients (91% men, 53.0±11.5 years old) met inclusion criteria. Diagnosis codes for hypertension, CKD, and cardiovascular disease were identified in 73%, 38%, and 32% of patients. Few patients (≤12%) received IMM co-therapy through 2018, but rates began to rise in 2019, presumably due to initial pegloticase+MTX case series (MTX use: 5% in 2018, 20% in 2019) and subsequent pegloticase+IMM data presentations; **Figure**). The proportion receiving IMM co-therapy continued to rise through 2022, with notable increases in MMF use following RECIPE presentation in Nov 2020 (ACR) and MTX use following MIRROR RCT presentation in Jun 2022 (EULAR) and pegloticase label update to include MTX in Jul 2022. After 2018, the majority of patients receiving IMM co-therapy had received MTX, followed by MMF and leflunomide (**Figure**).

Conclusion: Compelling real-world[5, 11] and clinical trial[9] efficacy/safety data has led to wide-spread awareness and adoption of IMM co-administration with pegloticase, often a last-hope therapy for patients suffering from uncontrolled gout. In the last part of 2022, over 70% of patients beginning pegloticase were co-administered IMM, with the majority of these patients receiving MTX.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Hemay005 is an orally active selective PDE4 inhibitor under clinical development for treating chronic inflammatory diseases. Hemay005 significantly inhibits the activation of T lymphocytes, which play a vital role in the pathogenesis of psoriatic diseases. It also inhibits Th1-type pro-inflammatory cytokines TNF-α, IFN-γ, IL-2, IL-12, and IL-23. Improvements in the side effect /efficacy ratio vs Apremilast are anticipated to improve the efficacy of Apremilast, which was side effect limited at doses >30mg.

Methods: This phase III, multicenter, double-blind, placebo-controlled study randomized adults (2:1) to Hemay005 or placebo according to the Study Design Fig 1 with the primary efficacy endpoint at 16 weeks.

Results: Efficacy: Based on FAS, the proportion of subjects with sPGA score of cleared (0) or almost cleared (1) with a decrease ≥2 points (i.e., sPGA improved) at Week 16 Efficacy Results are shown in Table 1.

Safety: During the double-blind core treatment, drug-related AEs were reported in 141 (66.8%) in the test group and 37 (39.4%) in placebo, respectively (P< 0.0001). Drug-related AEs with an incidence ≥10% in either the test or placebo group includednausea (test group vs placebo group: 23.2% vs 1.1%), diarrhea (11.4% vs. 1.1%), and vomiting (10.0% vs 0). The incidences of all these events had statistically significant differences between groups (P< 0.05), being significantly higher in the test group than in the placebo group. The severity of drug-related AEs reported during double-blind treatment phase was primarily Grade 1 or 2. Drug-related AEs ≥Grade 3 reported in the test group included hypertriglyceridemia (0.5% each for Grades 3 and 4) and hypokalemia (0.5%, Grade 3); drug-related AEs ≥Grade 3 reported in the placebo group

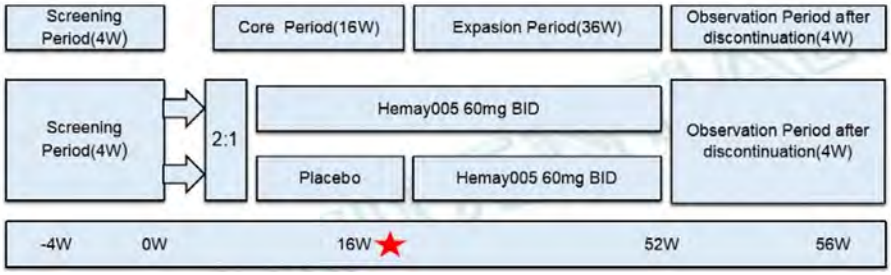

Fig 1 Study Design

At week 16	Hemay005 60mg BID (N=211)	Placebo (N=94)	P	The differernce in the response rate
PASI-75,n(%)	113(53.6)	15(16.0)	<0.0001	37.6% (95%IC:26.42%-47.15%)
sPGA0/1,n(%)	66(31.3)	6(6.4)	<0.0001	24.9% (95%IC:15.29%-32.73%)

Primary Endpoint (Efficacy) at 16 Weeks PASI75

Efficacy response (E-R)	PASI-75Efficacy prediction (%)	95% CI
15mgBID	24.77	21.12~31.91
30mg BID	33.58	25.35~51.27
60mg BID	54.38	33.86~83.52

Efficacy Model predicted response rates (PASI 75)

included soft tissue infection (1.1%, Grade 3). A population pharmacokinetics model was developed from the combined PK Phase II and Phase III data sets. The model was consistent with a one-compartment first-order absorption and linear elimination model, with an estimated elimination half-life of 12.28h.

The results showed that the PASI-75 rate at 16 weeks increased with exposure, and the efficacy signal in the 60 mg BID group was greater than in the placebo or low dose groups Table 2. In the safety analysis, the frequency of defecation and vomiting increased significantly with increasing exposure. However, there was no significant correlation between exposure and the incidences of headache, dizziness, or occult blood positive.

Conclusion: Hemay005 has the potential to be the best-in-class oral PDE4 in the management of psoriasis. The results from this study showed that Hemay005 significantly reduced the severity of moderate to severe plaque psoriasis over 16 weeks. Most AEs were mild. The severity of drug-related AEs reported during the double-blind treatment phase was primarily Grade 1 or 2. The most common drug-related AE was gastrointestinal reactions, and E-R analysis showed that the optimal dose of Hemay005 was 60 mg.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The newly described VEXAS syndrome is a very heterogenous disease with rheumatologic and hematologic manifestations, caused by somatic mutations affecting UBA1 gene, that still requires a precise definition. Our objective was to describe the clinical profile of VEXAS patients (VP) diagnosed and monitored in rheumatologic units in Spain.

Methods: A comprehensive survey covering the whole country, which included 126 Spanish hospitals with rheumatologic units, was performed to identify all the VP observed in those units. VP were defined as compatible clinical picture plus characteristic BMB and/or confirmed UBA1 gene mutations. Demographic, clinical, laboratory and outcome data were collected from medical records. Descriptive analyses were performed employing standard tests.

Results: A total of 28 VP were identified. All of them were men and had a Caucasian origin, with a mean age at diagnosis of 70.96 (±SD 8.92) years. Constitutional symptoms and fever were detected in 26 (92.85%) patients, while arthritis was present in 23 (82.14%) of them, and chondritis (including nasal chondritis, perichondritis and epiglottis' chondritis) was found in

Table 1. Baseline clinical characteristics.

CLINICAL MANIFESTATIONS	Total number and percentage
Constitutional symptoms	23 (82.14%)
Fever	22 (78.57%)
Arthritis	23 (82.14%)
Chondritis	16 (57.14%)
Skin	26 (92.85%)
Pulmonary involvement	10 (35.71%)
Renal involvement	5 (17.85%)
Periorbital edema	10 (35.7%)
Ocular manifestations	12 (42.9%)
Cardiac manifestations	1 (3.6%)
Hepatomegaly	1 (3.6%)
Splenomegaly	6 (21.4%)
Thromboembolic disease attributed to VEXAS syndrome	8 (28.6%)
Hearing loss	6 (21.4%)
Medium vessel vasculitis	4 (14.3%)

Table 2. Laboratory tests.

LABORATORY	Median and standard deviation (SD)
Haemoglobin gr/dL	10.45 (±SD 2.3)
Medium corpuscular volume fL	106.85 (±SD 10.14)
Platelets 10^3/ µL	116 (±SD 78.72)
Leukocytes / µL	5265 (±SD 2265)
CRP mg/dL	6.25 (±SD 6.44)
ESR mm/h	73 (±SD 42)

16 (57.14%) cases. Twenty-six (92.85%) patients presented 1 or more skin manifestations, being the most frequent ones: Sweet syndrome (n=18, 64.28%), leukocytoclastic vasculitis (n=8, 28.57%), erythema nodosum (n=3, 10.71%), Jessner's lymphocytic infiltration of the skin (n=2, 7.14%), and lupus-like skin lesions (n=2, 7.14%). Pulmonary involvement was found in 10 (35.71%) cases; patients presented 1 or more findings, including lung infiltrates (n=5), interstitial lung disease (n=5), pleurisy (n=2), and alveolar hemorrhage (n=1). It is worth remarking the finding of renal involvement (acute renal failure n=3, IgA nephropathy n=1, nephrotic syndrome n=1) attributed to VEXAS syndrome in 5 patients out of 28 (17.85%), complication which has not been previously described in other studies to our knowledge at the time of this publication. Other clinical manifestations are included in Table 1. Anaemia was found in 27 (96.42%) cases, being macrocytic in 22 of them; 19 (67.85%) presented thrombocytopenia as well; furthermore, 18 (64.28%) met criteria for MDS. Other laboratory findings are included in Table 2.

Conclusion: The clinical manifestations identified within our cohort of VEXAS syndrome, focusing on the rheumatologic aspect, exhibit similarities to those previously documented in this condition. However, a noteworthy observation in our study is the presence of renal involvement attributed to VEXAS syndrome in nearly 20% of our patients. This complication has not been reported in previous studies, as far as our knowledge extends at the time of this publication.

Abstract Number: 1126

Identification of Clinical Phenotypes in Behçet's Disease Using a Cluster Analysis

Ana Serrano-Combarro[1], Jose Luis Martin-Varillas[2], Raul Fernandez-Ramon[3], Lara Sanchez-Bilbao[4], Carmen Alvarez Reguera[3], ELENA Aurrecoechea[5] and Ricardo Blanco[6], [1]Hospital Universitario Marques de Valdecilla, IDIVAL, Santander, Spain, [2]Hospital de Laredo, Laredo, Spain, [3]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [4]Hospital Universitario Marques de Valdecilla, Santander, Spain, [5]HOSPITAL SIERRALLANA, Cantabria, Spain, [6]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Behcet's disease (BD) is a variable-vessel vasculitis with a high variability of clinical manifestations. The objective of our study was to identify clinical phenotypes using cluster analysis.

Methods: A model-based clustering relaying on 16 clinical variables was performed in a retrospective cohort of 120 BD patients, diagnosed and follow-up from January 1, 1980 to December 31, 2019 in 3 hospital at Northern Spain (Cantabria). Chi-square test and ANOVA were used to compare categorical and continuous variables among groups. Two-sample t-tests and the partition of Pearson's chi-square statistic were used in pairwise comparisons.

Results: Cluster analysis identified four groups: C1 (n=47; 39.2%), C2 (n=33; 27.5%), C3 (n=33; 27.5%) and C4 (n=7; 5.8%). The clusters were defined as follows: C1 as mucosal involvement, C2 as joint involvement and pseudofolliculitis, C3 as neurological and vascular involvement and C4 as uveitis and erythema nodosum. There were no baseline demographic differences between clusters and no differences in the application of classification criteria were observed (**TABLE**

Table 1: Characteristics of patients with Behçet's syndrome after clustering on clinical manifestations.

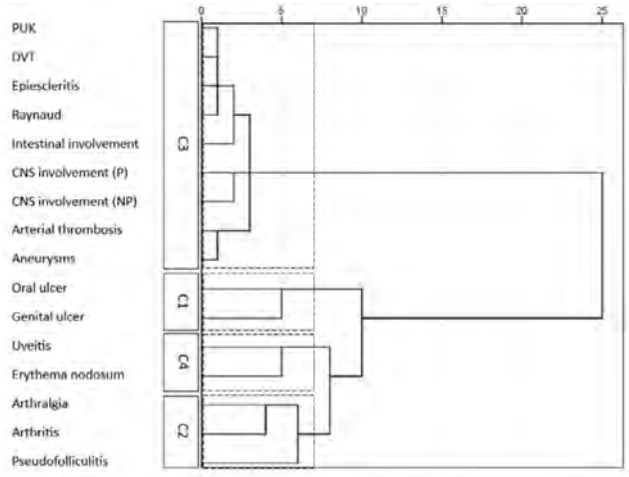
SD: standard deviation; ISG: International Study Group; ITR-ICBD: International Team For The Revision of The International Criteria; DVT: Deep venous thrombosis.



PUK: peripheral ulcerative keratitis; DVT: deep venous thrombosis; CNS: central nervous system; NP: non-parenchymal; P: parenchymal

FIGURE 1: Dendrogram of the hierarchical clustering leading to four clusters.

1). The presence of oral ulcers was predominant in all clusters, ranging from 85.7% (C4) to 95-97% (C1-C2), with no significant differences. However, a higher frequency of genital ulcers was observed in C1 compared to the other clusters. Similarly, a significantly higher frequency of erythema nodosum was observed in C4 (85.7%) and of pseudofolliculitis in C2 (93.9%) ($p< 0.001$). In addition, arterial involvement was more prevalent in C4 (100%, $p< 0.001$) but there were no differences in venous thrombotic involvement. Aneurysms were only observed in the C4 cluster (**FIGURE 2**).

Conclusion: We have defined 4 BD phenotypes in our study. This cluster approach may be useful for better patient management due to early identification of clinical patterns.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-infectious uveitis (NIU) are characterized by inflammation of the middle layer of the eye wall and have a significant impact on patients' visual-related quality of life (VRQoL). Objective measures of vision, such as visual acuity, do not fully account for the impact of these diseases on the patients' perceived QoL, as it includes other relevant and important aspects not evaluated in routine clinical practice. The assessment of the patient's QoL through standardized and validated questionnaires allows us to evaluate objectively the actual burden of the disease. Several cross-sectional studies have shown that the VRQoL of NIU patients is reduced. However, the evidence regarding how QoL evolves in real life clinical practice and what characteristics influence this evolution is scarce. Therefore, our objective is to describe the evolution of the VRQoL in subjects with NIU and to identify factors associated with increased or decreased VRQoL during follow-up.

Methods: Prospective longitudinal observational study including consecutive NIU patients from a tertiary uveitis clinic from Madrid (Spain). Main outcome was the composite score of the Visual Functioning Questionnaire 25 (VFQ25), measured at baseline and after 1 and 2 years of follow-up. Influence of demographic, clinical, and treatment-related variables (assessed at the same time points) in repeated measures of VRQoL was analyzed using bivariable and multivariable generalized estimating equations (GEE) models nested by patient.

Results: One hundred and forty five patients were included in the analysis, with 422 visits. In the two years of follow up, no significant changes were observed in the evolution of the VFQ25 (Figure). In the multivariate analysis, lower best corrected visual acuity, presence of permanent work disability, being unemployed, cells in anterior chamber ≥2+, previous cataract surgery, previous glaucoma surgery, other intraocular surgeries, and prescription of synthetic immunosuppressive drugs were independently associated with lower VFQ25 (Table).

Table. Multivariate analysis to assess the influence of socio-demographic and clinical related variables in the VRQoL of a cohort of NIU patients.

Variable	Coef (95% IC)	p-value
Women	1.82 (-0.98 to 4.63)	0.21
BCVA (logMAR)	-8.18 (-10.93 to -5.43)	$5.68x10^{-9}$
Baseline visit	Ref.	
1 year visit	-0.18 (-1.68 to 1.32)	0.81
2 year visit	-0.9 (-1.50 to 1.11)	0.77
BCVA X 1 year visit	4.61 (2.30 to 6.93)	$9.5x10^{-5}$
BCVA X 2 year visit	4.46 (3.03 to 5.88)	$9.18x10^{-10}$
Married	1.96 (-0.34 to 4.26)	0.09
Permanent work disability	-27.42 (-36.90 to -17.93)	$1.47x10^{-8}$
Unemployed	-7.04 (-10.82 to -3.27)	$2.6x10^{-4}$
Cells in anterior chamber ≥ 2 +	-3.85 (-7.03 to -0.67)	0.02
Cataract surgery	-4.61 (-8.15 to -1.07)	0.01
Glaucoma surgery	-14.51 (-24.72 to -4.30)	0.01

No ISD use	Ref.	
Synthetic ISDs	-5.38 (-8.19 to -2.56)	$1.9x10^{-4}$
Biological ISDs	3.11 (-0.59 to 6.81)	0.01
Synthetic and biological ISDs	-2.22 (-5.79 to 1.34)	0.22

VA: visual acuity; BCVA: best corrected visual acuity; logMAR: logarithm of the minimum angle of resolution; ISDs: immunosuppressive drugs; Coef: correlation coefficient

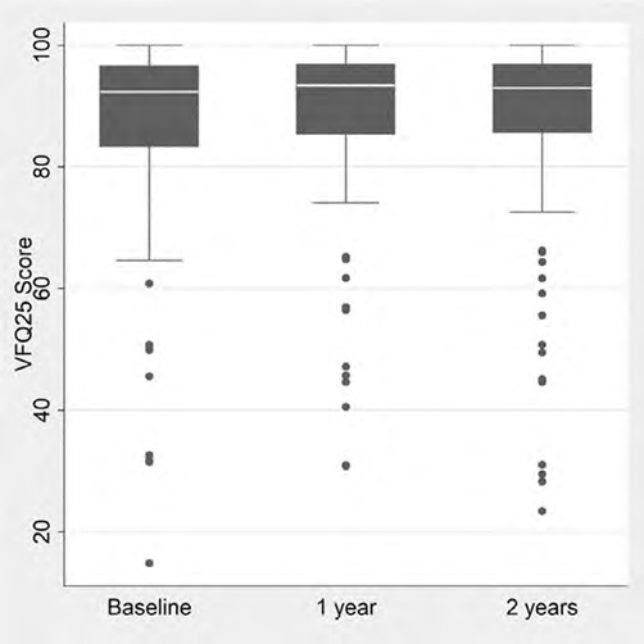

Figure. VFQ25 during follow-up

Conclusion: In the two years follow-up of our study, we did not identify significant changes in the evolution of the VRQoL in NIU patients. Nevertheless, we found some social factors that could contribute to a decreased VQ25 during follow-up. Essentially, work status and financial well-being. Clinical variables were also identified, such as lower visual acuity and factors that might reflect active disease (cells in anterior chamber ≥2+ and prescription of synthetic immunosuppressive drugs). We also detected that previous ocular surgery might contribute to a lower VQ25 score. This preliminary data allows us to evaluate other variables that contribute to the burden of the disease and the extent of the patient's suffering regarding their vision and reflect the importance of identifying them to improve our patients' quality of life.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory ocular pathology (IOP) includes internal (uveitis) and external [mainly ocular surface pathology such as epi/scleritis and peripheral ulcerative keratitis (PUK)] involvement. IOP may be severe ocular conditions refractory to conventional immunosuppressants and even biological therapy. Janus Kinase inhibitors (JAKINIB) had shown efficacy in refractory cases of different immune-mediated inflammatory diseases (IMID).

FIGURE. Therapeutical approach of refractory inflammatory ocular pathology.

In patients with refractory IOP treated with JAKINIB our aims were **a)** to assess the patients of Spanish referral centers, **b)** Literature review.

Methods: Multicenter study of 11 patients with refractory IOP treated with JAKINIB. For Literature review a search was conducted in PubMed, Embase and the Cochrane library from their inception to 1st January 2023. Original research articles studying JAKINIB treatment in patients with IOP were included. In addition, a therapeutical approach of refractory IOP is proposed.

Results: We have identified 11 cases in eight University Hospitals and 13 cases in the literature review. These 24 patients (17 women/ 7 men) (35 affected eyes), mean age 38.9±21.9 years, had different refractory IOP (uveitis=14; scleritis=5, PUK=5). Most of IOP were associated with IMID (n=19, 79.2%) while 5 cases (20.8%.), were idiopathic. The main underlying IMID were rheumatoid arthritis (n=6, 25%), juvenile idiopathic arthritis (n=5, 20.8%) and spondyloarthritis (n=4; 16.7%) **(TABLE).** Uveitis (n=14) followed by ocular surface pathology (n=10) were the most frequent subtypes of IOP. Patterns of uveitis were panuveitis (n=8), anterior uveitis (n=5; 2 of them with Cystoid macular), and posterior (n=1). Ocular surface pathology was due to scleritis (n=5) and PUK (n=5). In addition to systemic corticosteroids, before JAKINIB, conventional (n= 23; 95.8%) and biologicalimmunosuppressive drugs (n=18; 75%) were required. The JAKINIB most widely used was tofacitinib (n= 11; 45.8%) followed by baricitinib (n=8; 33.3%). In one patient with Blau Syndrome and uveitis, tofacitinib was switched to baricitinib due to severe lymphopenia.In two other patients, UPA was discontinued due to anemia and skin adverse reaction. Finally, only in one patient baricitinib was withdrawn due to lack of improvement. After starting JAKINIB treatment, 23 patients presented clinical improvement, complete (n=21, 87.5%) or partial (n= 2; 8.3%). Based on these data a therapeutical approach of refractory IOP was proposed **(FIGURE).**

Conclusion: JAKINIB may be an effective and safe therapy in IOP refractory to conventional or even biological immunosuppressive therapy.

Accuracy and Performance Characteristics of Administrative Codes for the Diagnosis of Autoinflammatory Syndromes: A Discovery and Validation Study

Saeyun Lee[1], Sujin Kim[2], Suzanne Segerstrom[2], Polly Ferguson[1] and **Aleksander Lenert**[3], [1]University of Iowa Carver College of Medicine, Iowa City, IA, [2]University of Kentucky, Lexington, KY, [3]University of Iowa, Iowa City, IA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoinflammatory syndromes (AIS), a group of rare rheumatic diseases driven by the innate immune system, remain understudied due to the lack of prospective cohorts. Electronic medical record (EMR) and administrative health databases represent an opportunity for clinical outcomes and pharmacoepidemiologic research but rely on accurate cohort building. We sought to determine and validate the accuracy and performance characteristics of administrative claims codes for the diagnosis of AIS.

Methods: Potential AIS patients were identified from the EMR at the University of Iowa Hospitals and Clinics and the Stead Family Children's Hospital from 2009 through July 2022 using a screening filter comprised of the 10th edition of the *International Classification of Diseases* (*ICD-10*) codes. We filtered based on the following ICD-10 codes for AIS subtypes: M06.1 (adult onset Sill's disease, AOSD), M08.2 (systemic juvenile idiopathic arthritis, SJIA), M35.2 (Behçet's disease, BD), M04.1 (familial Mediterranean fever, FMF), M04.2 (cryopyrin-associated periodic syndrome, CAPS); and combination of L40.3, L70.9, M65.9, M85.80 and M86.9 for SAPHO syndrome and chronic nonbacterial osteomyelitis (SAPHO-CNO). Medical records were reviewed to determine whether a patient met published criteria for AOSD, SJIA, BD, FMF, CAPS and SAPHO-CNO. Patients age < 18 at last follow-up visit or without supporting documentation to confirm their diagnoses were excluded from the analysis. Patients who did not meet AIS subtype diagnostic criteria, but who were treated for AIS by their specialist were categorized as Other AIS. Otherwise, they were categorized as non-AIS. We determined sensitivity,

Figure 1. Patient identification and screening flowchart.

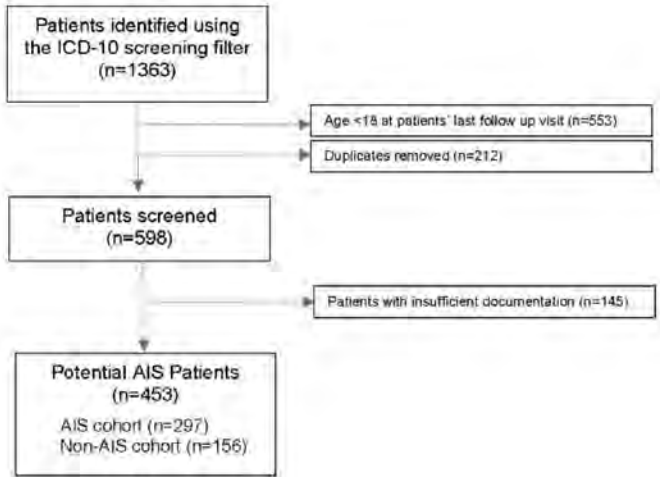

Table 1. Baseline demographics and disease characteristics of the adult AIS and non-AIS cohorts.

	AIS (n=297)	AOSD (n=56)	SJIA (n=22)	[illegible] (n=78)	BD (n=111)	FMF (n=15)	CAPS (n=9)	SAPHO-CNO (n=23)	Other AIS (n=65)	Non-AIS (n=156)
Age, median (IQR), years	39 (28-54)	41 (34-58)	27 (23-30)	36 (27-50)	45 (36-57)	30 (25-55)	37 (39-63)	42 (22-54)	31 (22-40)	47 (34-60)
Gender, female (%)	204 (69)	36 (64)	15 (68)	51 (65)	83 (75)	7 (47)	5 (56)	17 (74)	43 (66)	93 (60)
Non-Hispanic (%)	255 (86)	45 (80)	19 (86)	64 (82)	88 (79)	12 (80)	9 (100)	23 (100)	63 (97)	136 (87)
White (%)	245 (82)	38 (68)	15 (68)	53 (68)	85 (88)	8 (60)	9 (100)	20 (87)	62 (95)	132 (85)

AIS: autoinflammatory syndrome; AOSD: adult onset Still's disease; SJIA: systemic juvenile idiopathic arthritis; BD: Behçet's disease; FMF: familial Mediterranean fever; CAPS: cryopyrin-associated periodic syndrome; SAPHO: Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis; CNO: chronic nonbacterial osteomyelitis. IQR: interquartile range. Continuous variables are presented as median (IQR). Categorial variables are presented as number (percentage).

Table 2. Sensitivity, specificity, predictive values, and accuracy for identifying AIS from administrative codes (n = 453) compared with the reference standard labels (using medical chart review).

AIS Subtype (ICD-10)	True Positives	False Positives	True Negatives	False Negatives	Sensitivity, % (95% CI)	Specificity, % (95% CI)	PPV, % (95% CI)	NPV, % (95% CI)	AUC (95% CI)[a]
AOSD (M06.1)	49	20	377	7	88 (76-95)	95 (92-97)	71 (61-79)	98 (96-99)	0.91 (0.86-0.96)
SJIA (M08.2)	21	49	382	1	95 (77-100)	99 (95-91)	30 (24-36)	100 (99-100)	0.92 (0.84-1.00)
AOSD/SJIA (M06.1 or M08.2)	76	26	349	2	97 (91-100)	93 (90-95)	74 (67-81)	99 (98-100)	0.95 (0.92-0.99)
BD (M35.2)	111	36	304	0	100 (97-100)	98 (85-92)	75 (68-80)	100	0.94 (0.91-0.97)
FMF (M04.1)	15	81	357	0	100 (78-100)	82 (78-85)	16 (13-19)	100	0.81 (0.61-1.00)
CAPS (M04.2)	8	2	442	1	89 (52-100)	100 (99-100)	80 (50-94)	100 (99-100)	0.94 (0.83-1.00)
SAPHO-CNO (L40.5, L70.4, M45.1, M85.5, M86.6)	17	6	422	6	74 (53-90)	98 (96-99)	68 (51-81)	99 (97-99)	0.86 (0.76-0.96)

AIS: autoinflammatory syndrome; ICD-10: 10th edition of the International Classification of Diseases; CI: confidence interval; PPV: positive predictive value; NPV: negative predictive value; AUC: area under the receiver operating characteristic curve; AOSD: adult onset Still's disease; SJIA: systemic juvenile idiopathic arthritis; BD: Behçet's disease; FMF: familial Mediterranean fever; CAPS: cryopyrin-associated periodic syndrome; SAPHO: Synovitis, Acne, Pustulosis, Hyperostosis and Osteitis; CNO: chronic nonbacterial osteomyelitis. IQR: interquartile range. Continuous variables are presented as median (IQR). [a]For null hypothesis, area under the curve = 0.5.

specificity, positive predictive values (PPV), negative predictive values (NPV), and area under the receiver operating characteristic curve (AUC) of each ICD code or combination of codes for diagnosing each AIS.

Results: The study's screening flowchart is presented in Figure 1. Baseline demographics of the AIS and non-AIS cohorts are presented in Table 1. Out of the 453 patients with potential AIS, 297 patients had a true AIS diagnosis (AIS prevalence 66%), while 156 patients did not have AIS (non-AIS). The AIS cohort was predominantly female (68.7%) and white (82.5%) with median age of 39 (IQR, 28-54) years. Performance characteristics and accuracy of ICD codes are presented in Table 2. Sensitivity was ≥88% for AOSD, SJIA, BD, FMF and CAPS, while slightly lower for SAPHO-CNO (74%). Specificity was ≥89% for AOSD, SJIA, BD, CAPS and SAPHO-CNO, while slightly lower for FMF (82%). PPV ranged from 68% to 80% for AOSD, BD, CAPS and SAPHO-CNO; in contrast, PPVs were very poor for SJIA (30%) and FMF (16%). NPVs was excellent for all 6 AIS subtypes (≥98%). All ICD codes or a combination of ICD codes for the diagnosis of specific AIS subtypes showed excellent AUCs (≥0.86).

Conclusion: This study validated the performance characteristics and accuracy of ICD-10 administrative codes for diagnosing AOSD, BD, and FMF, and examined novel codes for diagnosing SJIA, CAPS, and SAPHO-CNO. Administrative codes have high accuracy for identifying AIS patients and can be used to construct comprehensive AIS cohorts for future clinical outcomes research.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

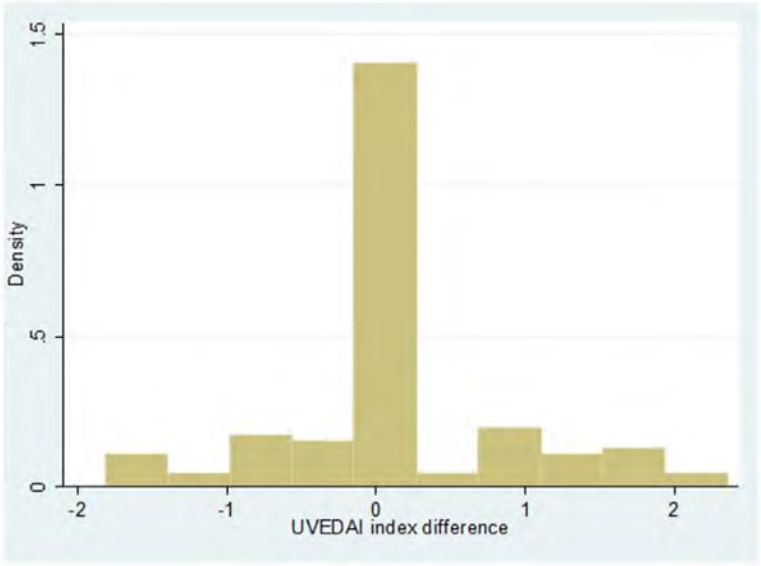
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Standardized and validated outcome measures of disease activity are lacking in the treatment and assessment of uveitis, making it difficult to compare efficacy and response to treatment. In 2014, this working group developed a composite index of ocular inflammatory activity: UVEDAI (1). The index was validated in a subsequent study conducted in 2019. The objective to this study was to determine the interobserver reliability and to demonstrate the sensitivity to change of the UVEDAI index in patients with anterior and non-anterior uveitis who undergo pharmacological treatment.

Methods: The design is an observational, longitudinal, prospective study in 7 Spanish hospitals. Patients over 18 years of age diagnosed with active uveitis were included. A complete baseline visit was performed by two ophthalmologists who determined ocular inflammatory activity with the UVEDAI index. Ophthalmologist 1 made a new visit at 4 weeks to determine



Interobserver Reliability: Differences obtained in the UVEDAI index score by ophthalmologist 1 and 2 at the baseline visit

Anatomical Location	Anterior	Intermediate / Posterior/Panuvetis	Total
UVEDAI INDEX baseline.opht.1*	1.2 ± 1.6	2.8 ± 1.8	1.9 ± 1.8
UVEDAI INDEX visit 4 wks.opht1*	0.2 ± 0.5	1.2 ± 1.5	0.6 ± 1.1
UVEDAI difference	1.04	1.54	1.25
p-value	0.00	0.00	0.00

**mean ± standard deviation*

Sensitive to Change: Mean value and difference in UVEDAI index value measured by ophthalmologist 1 in the active eye at baseline and at 4 weeks

the change in the level of uveal inflammatory activity using the UVEDAI index. The interobserver reliability analysis was performed by calculating the Intraclass Correlation Coefficient (ICC) with the values of the UVEDAI index obtained by ophthalmologist 1 and ophthalmologist 2 in the most inflamed eye at the baseline visit. Sensitivity to change in the UVEDAI index was assessed at 4 weeks from the start of pharmacological treatment by determining the Clinically Relevant Change defined as a change in UVEDAI of 0.8 points between the baseline visit and the 4-week visit.

Results: A total of 111 patients were included (54.1% male). The mean age at the time of the visit was 49.9 years. 36.9% of uveitis were idiopathic uveitis and 58.6% were anterior uveitis. The UVEDAI value was calculated from the score obtained in the 7 variables of the index. The mean value recorded in the most inflamed eye at the baseline visit by ophthalmologist 1 was 1.9 (1.2 anterior uveitis and 2.8 intermediate/posterior uveitis). The ICC for the UVEDAI value was 0.9 and when compared the mean UVEDAI values obtained by the two ophthalmologists for the most inflamed eye at the baseline visit no statistically significant differences were found (p-value >0.05), neither for the total sample nor differentiating by anatomical location. As for sensitivity of UVEDAI change, statistically significant differences (p-value=0.00) were found when comparing the mean values of the index measured by ophthalmologist 1 at the baseline visit and at 4 weeks, both in the overall sample and differentiating by anatomic location of uveitis. In all cases, the index value decreased significantly by more than 1 point at the 4-week visit after pharmacological treatment.

Conclusion: The interobserver reliability of the UVEDAI was high in the total sample and in the different variables. Furthermore, the index was sensitive in determining the change in inflammatory activity after treatment in both anterior and intermediate/posterior uveitis. We believe it is an index of activity that could be used both in routine clinical practice and in clinical studies and trials to compare results objectively

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is an immune-mediated condition that is heterogenous and can result in organ failure. To understand the disease profile of our local population better, a multi-disciplinary team was formed to review the IgG4-RD patients seen in our hospital.

Methods: A chart review was undertaken for all IgG4-RD patients seen between 1 January 2015 and 30 September 2021 at a major tertiary hospital in Singapore. All patients included fulfilled the 2020 revised comprehensive diagnostic (RCD) criteria for IgG4-RD for at least possible IgG4-RD and then scored according to the 2019 ACR/EULAR classification.

Results: Of the 58 patients included in this study, 28 scored at least 20 (i.e. completely fulfilled) for the 2019 ACR/EULAR classification criteria. 45/58 (77.6%) were male, 43/58 (74.1%) were Chinese, and median age at onset of symptoms and at diagnosis were 60.4 [inter-quartile range (IQR) 49.4-66.1] and 61.5 (IQR 50.8-67.8) years respectively. 27/58 (46.6%) were smokers, 7/58 (12.1%) had cancers, and 40/58 (69.0%) had underlying metabolic co-morbidities. Patients who completely fulfilled the ACR/EULAR classification criteria scored between 21 and 44 (median 25.5), and those who did not fulfil had a score of 4 to 19 (median 10.5). The distribution of clinical phenotypes were: 22/58 (37.9%) head and neck, 20/58 (34.5%) pancreato-biliary, 12/58 (20.7%) Mikulicz/systemic, and 4/58 (6.9%) retro-peritoneal fibrosis/aortitis. The three commonest sites of involvement were pancreato-hepato-biliary 26/58 (44.8%), ocular 17/58 (29.3%) and lymph nodes 14/58 (24.1%). The median maximum serum IgG4 level and median IgG4/total IgG ratio were 220mg/dL (IQR 98-335) and 0.149 (IQR 0.078-0.236) respectively. Patients with Mikulicz/systemic phenotype had significantly higher median total serum IgG, IgG1, IgG2 and IgG3 ($p< 0.050$). The median maximum serum IgG4 level for those who fulfilled the ACR/EULAR criteria was 280.5mg/dL (IQR 160-816.5) and those who did not fulfil was 187.5mg/dL (87-235) ($p=0.014$). Histological samples were suggestive/conclusive of IgG4-RD in 68% of patients who completely fulfilled the ACR/EULAR classification criteria and 65.4% of patients who did not ($p=0.843$). Prednisolone was the commonest treatment prescribed to patients (49/58, 84.5%). Steroid-sparing immunosuppressants were given to 32/58 (55.2%), for which azathioprine was the commonest (25/58, 43.1%) followed by rituximab (7/58, 12.1%). Surgical excision was done in 23/58 (39.7%). 44/58 (75.9%) patients achieved disease remission after first presentation and 16/58 (27.6%) were in drug-free remission. Mortality was 4/58 (6.9%) with one case attributable to complications of IgG4-RD.

Conclusion: The head and neck IgG4-RD phenotype was the commonest one in our cohort, followed by pancreato-biliary. This condition occurred more commonly in males with no gender pre-dilection in any clinical phenotype. The ACR/EULAR classification criteria appeared too restrictive and the 2020 RCD was better able to capture the full spectral of IgG4-RD patients. The overall prognosis for IgG4-RD is good and histological investigation remains important for the diagnosis of this disease.

Table 1. Description of patients

Characteristics	All patients (n=58)	Scored ≥ 20 for ACR/EULAR criteria (n=28, 48.3%)	Scored < 20 for ACR/EULAR criteria (n=30, 51.7%)	P-value
Demographics

Preclinical Profiles of FZ007-119, a Highly Potent and Selective Tyk2 Inhibitor, for the Treatment of Immune Mediated Inflammatory Diseases

Wenhe Zhong, Jielian Lu, Dong Chen, **Shiqun Zhang** and Daiguo Deng, Guangzhou Fermion Technology Co., LTD, Guangzhou, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Tyrosine Kinase 2 (TYK2) is a signaling protein within the Janus kinase (JAK) family. It plays a crucial role in transmitting signals from pro-inflammatory cytokines like IL-23, IL-12, and Type I IFN, which contribute to Immune Mediated Inflammatory Diseases (IMIDs). Here we report a novel oral TYK2 inhibitor called FZ007-119, unlike traditional kinase inhibitors that target the catalytic domain, which acts through an allosteric mechanism by binding to the pseudokinase Janus homology 2 regulatory domain (JH2) of the TYK2 enzyme. This specific mode of action allows selective inhibition of TYK2 without affecting other kinases. Current preclinical studies indicate that FZ007-119 shows promise as a treatment for IMIDs while avoiding the side effects associated with non-selective JAK inhibitors.

Methods: We employ our AI-driven structure-based drug design tool to discover selective Tyk2 inhibitors. These compounds are characterized for their drug-like properties, potency, selectivity in both enzyme and cell-based assays, DMPK in vitro and in vivo as well as in mouse models of psoriasis and atopic dermatitis.

Results: FZ007-119 exhibits high potency and specificity for binding to TYK2 JH2 (IC50=0.19nM). It does not show activity against JH1 (protein kinase domain) of JAK1, JAK2, JAK3 and TYK2 (IC50 >10μM) based on HTRF kinase assays. Cell-based assays on human PBMCs demonstrate that FZ007-119 is a potent inhibitor of IFNα stimulated TYK2 dependent signaling (IC50 = 12.2 nM) and is selective over GM-CSF induced JAK2 dependent signaling (IC50>30μM) and IL-2 induced JAK1/3 dependent signaling (IC50>30μM). FZ007-119 exhibits excellent selectivity against a panel of 207 kinases (less than 50% inhibition at 1μM) and a safety panel of 90 targets (less than 50% inhibition at 10μM). FZ007-119 demonstrates dose-dependent inhibition of ear thickness in an IL-23-induced psoriasis mice model (0.3 mg/kg, 1.0 mg/kg and 3.0 mg/kg). It also shows strong efficacy in reducing psoriasis clinical score in an imiquimod-induced mice psoriasis model (3 mg/kg, 10 mg/kg and 30 mg/kg). In a DNFB-induced Atopic Dermatitis model, FZ007-119 (1 mg/kg, 3 mg/kg and 10 mg/kg) significantly reduced lesion scores. FZ007-119 has favorable DMPK profiles, with low risk of drug-drug interactions, no significant inhibition of cytochrome P450 isozymes, and limited inhibition of BCRP or p-gp (IC50 >10μM). It is not a substrate for various transporters (OATP1B1, OATP1B3, OAT1, OAT3, OCT2, MATE1, or MATE2-K). In addition, FZ007-119 exhibits remarkable PK properties and has demonstrated good oral bioavailability in rodents and dogs.

Conclusion: Using our AI-driven drug design tools, we rapidly identified a highly potent and selective TYK2 inhibitor, FZ007-119. Preclinical data support the potential of FZ007-119 as a promising candidate for the treatment of IMIDs such as psoriasis and atopic dermatitis, offering an attractive therapeutic approach with improved efficacy and safety compared to non-selective JAK inhibitors.

Exploring the Clinical Characteristics and Correlation with Corticosteroid Dependence in Polymyalgia Rheumatica (PMR) Patients: Insights from an Academic Center

William Rigby[1], Todd Mackenzie[2], Emily Campbell[1], Joshua Skydel[3], Bryan Savage[1], Monica Dimambro[2] and **Vivekanand Tiwari**[1], [1]Dartmouth Hitchcock Medical Center, Lebanon, NH, [2]Dartmouth College, Hanover, NH, [3]Dartmouth-Hitchcock Medical Center, Lebanon, NH

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) treatment is primarily based on long-term corticosteroids, which results in significant toxicities. Studies[1,2] have shown that patients with PMR are exposed to years of corticosteroid treatment. In a single academic center cohort, we found that 76% of patients remained on steroids at the end of two years.[3] In a second cohort of PMR patients, we explored the baseline characteristics and established the success rate in discontinuing steroid treatment at years one and two after initiating the treatment.

Methods: A retrospective observational study was conducted using data collected from a rheumatology clinic at an academic Medical Center. We included patients with a primary diagnosis of PMR or PMR associated with Giant cell arteritis (GCA) and a minimum of 1-year follow-up. Patients with other rheumatological disorders were excluded. Out of 403 PMR charts reviewed from 2011 to 2021, 346 patients met the inclusion criteria.

Results: The mean age of the patient population was 71 years, with 59% being females and 41% males. Approximately 20% of the patients experienced an abrupt onset of symptoms. Among the PMR patients, 17.1% had a concurrent diagnosis of GCA, which usually developed alongside or after the PMR diagnosis. Only 2% of patients presented with Remitting Seronegative Symmetrical Synovitis with Pitting Edema (RS3PE). At the beginning of treatment (T0), the mean prednisone dose was 24 mg daily. At one year (T1), it decreased to 6.4 mg, and at two years (T2), it further reduced to 4.3 mg daily.

Table 1 Baseline characteristics (n=346)

Mean age (years)	70.8 ± 7.9
Male: Female	1:1.4
Overnight onset of symptoms (%)	19.7%
Association with GCA (%)	17.1%
Mean dose of prednisone at T0 (mg)	24 ± 15.6
Mean dose of prednisone at T1 (mg)	6.4 ± 6.5
Mean dose of prednisone at T2 (mg)	4.4 ± 6.6
% Patients off prednisone at T12 (95% CI)	17.7 (13.9-22.3)
% Patients off prednisone at T24 (95% CI)	38.2 (32.3-44.4)
% of patients with elevated CRP and elevated ESR	45.4
% of patients with normal CRP and normal ESR	14.6
% of patients with elevated CRP and normal ESR	18.3
% of patients with normal CRP and elevated ESR	15.8

*T0= Prednisone dose at the start, T1= Prednisone dose at the end of one year, T2= Prednisone dose at the end of two years, CI= Confidence interval, ESR= Erythrocyte sedimentation rate, CRP= C-reactive protein, GCA= Giant cell arteritis

Table 2. Odds Ratios of Successfully Discontinuing Prednisone as determined by Fisher's Exact Test

Characteristic	12 Months			24 Months		
	OR	95% CI	p-value	OR	95% CI	p-value
Gender*	0.71	0.38, 1.32	0.3123	1.41	0.83, 2.41	0.1994
Smoking†	1.15	0.61, 2.11	0.6576	1.14	0.66, 1.98	0.6896
ESR at Baseline	0.89	0.46, 1.75	0.7527	0.91	0.51, 1.64	0.7792
CRP at Baseline	0.84	0.43, 1.66	0.6269	0.85	0.46, 1.58	0.6605
Overnight onset of symptoms	0.89	0.39, 1.89	0.8592	1.73	0.88, 3.39	0.1029
Taking other DMARDs	0.71	0.23, 1.88	0.6587	0.57	0.22, 1.35	0.2413

* Reference group = Female

† Reference group = nonsmoker

At the end of one year, 17.7% of patients had discontinued prednisone, while only 38% had achieved discontinuation by the end of two years. The majority of patients exhibited elevated markers of inflammation (ESR or CRP), with only 14.6% presenting with normal values initially. The only patient characteristic associated with successful discontinuation was the initial steroid dose. Multivariable logistic regression analysis showed that with each unit increase in the initial prednisone dose, the odds of successfully discontinuing prednisone at 12 months decreased by 3% ($p = 0.034$). However, the significance of this association was not sustained at the 24-month mark. No other baseline characteristics were associated with successful prednisone discontinuation.

Conclusion: The clinical course of PMR is characterized by prolonged corticosteroid use, with a discouraging rate of successful prednisone discontinuation. Our study validates previous observations[3] and provides additional insights into the clinical characteristics of PMR patients. Similar to prior research[4,5], our study demonstrates that the initial corticosteroid dosage predicts the likelihood of successful discontinuation. However, the significance of this association diminishes at the 24-month mark, highlighting the need for further investigation. We acknowledge the limitations of our retrospective study, including potential selection bias due to the inclusion of patients with only one year of follow-up. Nonetheless, these findings underscore the urgency for additional research to identify and incorporate alternative disease-modifying anti-rheumatic drugs (DMARDs) into the PMR treatment regimen.

Pilot Study Investigating Adenosine Deaminase-2 as a Disease Activity Biomarker for Cardiac Sarcoidosis

Jeffrey Shen[1], Jayanth Doss[1], Ravichandra Karra Gurunath[1], Kelly Arps[1], Megan Milne[2], Rishi Rampersad[1], Kees Frelinger[1], Michael Hershfield[1] and Teresa Tarrant[1], [1]Duke University, Durham, NC, [2]Costal Carolina Health Care, New Bern, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a heterogenous granulomatous inflammatory disease that is especially dangerous when it affects the heart where it may cause fatal arrythmias and heart failure. Prompt initiation of therapy is frequently necessary, but treatment goals or targets are unclear, and there is currently no standardized approach for measuring disease activity. Imaging modalities such as PET or cardiac MRI have been used but are expensive and not always accessible. Laboratory tests such as serum calcium or serum ACE level are nonspecific. Activated macrophages are important in the pathogenesis of sarcoidosis granuloma formation and macrophages secrete adenosine deaminase 2 (ADA2) in plasma. ADA2 has been shown to correlate with disease activity in other macrophage-activated diseases such as macrophage activation syndrome and tuberculosis; however, ADA2 activity levels in systemic and cardiac sarcoidosis are not known. Total ADA levels have been shown to correlate with systemic sarcoidosis disease activity. We hope to investigate whether ADA2 may fill the gap that is needed for better diagnostics to assess disease activity and/or treatment responsiveness in cardiac and/or systemic sarcoidosis.

Methods: Patients with cardiac sarcoidosis and a control group of systemic sarcoidosis were examined.Plasma ADA2 levels for normal controls have been previously established since the ADA2 test at Duke University is CLIA certified. ADA2 activity was assessed by spectrophotometric assay and high-performance liquid chromatography. Disease activity at the time of ADA2 lab draw was retrieved by chart review for patients at our institution.

Results: Thirty-five patients with sarcoidosis have currently been studied – eleven from outside of our institution and twenty-four from within. All patients with systemic sarcoidosis had a higher mean ADA2 level (19 ± 13mU/mL) than all patients with isolated cardiac sarcoidosis (13 ± 4 mU/mL). Duke patients with untreated systemic sarcoidosis (23 ± 14 mU/mL) and those with untreated isolated cardiac sarcoidosis (16 ± 10 mU/mL) had mean ADA levels higher than controls. TNF inhibition lowered ADA2 levels in all Duke patients (mean of 16 mU/mL untreated vs. 10 mU/mL treated). All results did not reach statistical significance due to small sample size.

Conclusion: This pilot study suggests that the Duke CLIA-certified plasma ADA2 measurement could serve as a cost-effective, accessible, plasma-based biomarker for cardiac and systemic sarcoidosis that correlates with disease activity and treatment responsiveness. Our data is limited by sample size but suggest that future study in larger numbers of patients is warranted.

The Prescribing Patterns and Role of TNF-α Inhibitors in Treatment of Cardiac Sarcoidosis Patients

Alice Kwon[1], Audrey Liu[1], Sonali Narain[2], Elena Katzap[3] and Galina Marder[2], [1]Northwell Health, Manhasset, NY, [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [3]Northwell Health, Great NY, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac sarcoidosis is one of the most common causes of mortality from sarcoidosis. In this retrospective study, we describe prescribing patterns and compare outcomes between patients treated with conventional immunosuppressive therapies (IS), and tumor necrosis factor-α inhibitors (anti-TNF) therapy.

Methods: This is a retrospective analysis of cardiac sarcoidosis patients evaluated at Northwell Health Rheumatology. Diagnosis was validated by manual chart review. Clinical characteristics, echocardiogram (ECHO) and PET CT results were collected at baseline and yearly. EF was derived from ECHO and PET CT. Annualized relative percent change of EF from baseline to final year was calculated based on PET EF, or ECHO EF. Correlation between PET CT EF and ECHO EF with R = 0.56 permitted us to use ECHO as substitution when PET CT was not available. Definition of improvement (DOI) was defined as improvement of EF by > 10%, by PET CT or ECHO no new FDG uptake, and decreased standardized uptake value (SUV) when available on PET. Definition of worsening (DOW) was defined as decline in EF by > 10% on PET CT or

ECHO, new or worsening of FDG uptake, and increased SUV on PET. Descriptive statistics, T-tests, ANOVA tests, Fisher's exact and Spearman's correlation tests were used for statistical analysis.

Results: Baseline demographic and clinical characteristics of the 29 patients that met inclusion criteria are outlined in Table 1. Twenty-two patients had at least two PET/ECHO data for analysis, of whom 15 received anti-TNF. Duration of follow up was 1-3 years. Majority of patients had 2 years of follow up (11/22 patients). Four of 22 patients met DOI, and 3 of those patients had received anti-TNF (p = 0.99). 2 patients met DOW, of whom one received anti-TNF.

There was no difference in baseline EF between the two groups (p= 0.88). EF did not change from baseline to year 1 in both anti-TNF group (p = 0.2) and non-TNF group (p = 0.71). Statistically significant improvement of EF was observed at year 2 in the anti-TNF group as compared to baseline (mean EF: 46.8% vs. 51.2%, p=0.03) and the trend of improvement continued to year 3 (mean EF: 44.0% vs. 52.0%, p=0.05). The non-TNF group had improvement in mean EF, but it was not statistically

significant (41.7% vs 55.0%, p = 0.30) likely due to a small sample size. No statistically significant change was seen by calculating annualized relative EF change (Mean = 4.1, SD 11.89) in the anti-TNF group as compared to the non-TNF group (Mean = - 0.7, SD 29.38).

Conclusion: We describe clinical characteristics and prescribing patterns of cardiac sarcoidosis cohort across Northwell Health System. Interestingly, the average baseline B-type Natriuretic Peptide of patients treated with anti-TNF was lower than patients treated with conventional IS, likely due to avoidance of anti-TNF in decompensated heart failure. No significant change was seen in EF after a year, irrespective of the treatment choice. By year 2, improvement of EF was seen in the anti-TNF group and the trend continued to year 3. Further analysis is planned to compare clinical outcomes of cardiac sarcoidosis patients treated with anti-TNF versus conventional IS.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The newly described VEXAS syndrome is a very heterogenous disease with rheumatologic and hematologic manifestations, caused by somatic mutations affecting UBA1 gene, that still requires a precise definition. This report aims to address diagnostic challenges such as delays in diagnosis, misdiagnosis, and the clinical associations observed between specific genetic mutations and VEXAS patients (VP).

Methods: A comprehensive survey covering the whole country, which included 126 Spanish hospitals with rheumatologic units, was performed to identify all the VP observed in those units. VP were defined as compatible clinical picture plus characteristic BMB and/or confirmed genetic UBA1 gene mutations. Demographic and clinical data, along with the timing of

Table 1. Most frequent diagnostics prior to VEXAS.

Hepatomegaly	0%	0%

* Statistically significant differences **p<0.05.**

initial symptoms, initial and final diagnoses, and specific gene mutations identified in each case, were gathered from medical records. Descriptive analyses were conducted employing standard tests.

Results: Twenty-eight VP were identified. Mean age at onset of symptoms was 65.46 (±SD 9.44/range 40-78) years of age, while mean age at final diagnostic was 70.96 (±SD 8.92/range 46-83) years of age.Median diagnostic delay was 65.34 (±SD 41.73) months and median time from first symptom appearance to Rheumatology referral was 26.29 (±SD 41.73) months. Diagnoses prior to VEXAS syndrome are summarised in Table 1. Twenty-six (92.85%) patients underwent bone marrow biopsy; presence of at least 1 cytoplasmic vacuole was described in 23 cases. Genetic tests were performed in 23 (82.14%) patients. Within our cohort, among the three primary causative variants, 10 patients exhibited an M41L mutation, 8 patients had an M41T mutation, and 3 patients presented an M41V mutation. One patient presented a novel variation affecting c.209T >A, causing a leucine to histidine change, this alteration has not been previously described in other studies to our knowledge at the time of this publication. Finally, data regarding specific mutation was missed in a case. The mutation causing a change to leucine was associated with a phenotype more limited to the skin and joints, with absence of other manifestations as chondritis, hearing loss, or pulmonary involvement. In contrast, the threonine mutation was associated with a broader repertoire of clinical manifestations. Most of these associations were numerical rather than statistically significant (with the exceptions of negative association between hearing loss and leucine mutation and the positive one of chondritis with threonine) due to sample size limitations (Table 2). Finally, out of the 3 (10.71%) patients who died, 2 had leucine and 1 threonine mutations.

Conclusion: The VEXAS syndrome presents a significant delay in its detection as it is quite common its misdiagnosis for other multisystemic entities. Leucine mutation seems to be more associated with cutaneous and articular involvement, whereas the threonine mutation is more associated with chondritis and a more multi-organ clinical picture. These associations need further clarification through larger cohorts, which should also investigate the role of the novel mutation (c.209T >A: p.L70H) identified in this particular cohort.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

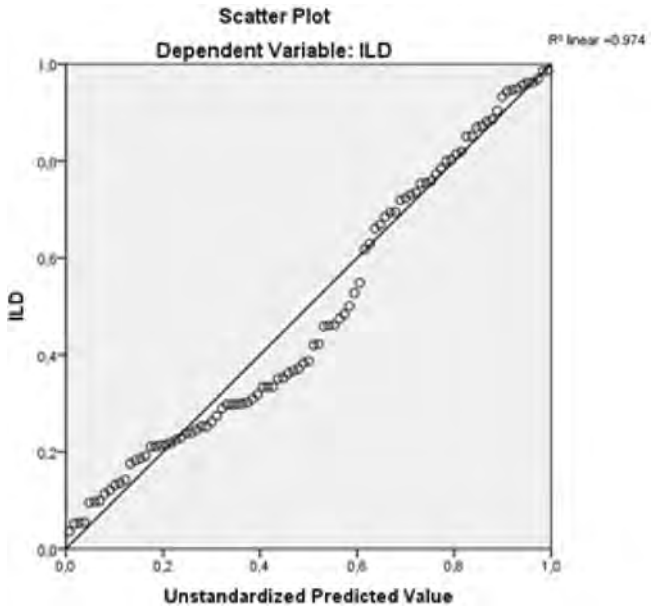
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a frequent pulmonary manifestation in idiopathic inflammatory myopathies (IIM) (IIM-ILD) and considerably influences morbidity and mortality. Krebs von den Lungen 6 (sKL-6) has been proposed as a potential biomarker reflecting the severity of ILD in connective tissue diseases. Raynaud's phenomenon is very frequent and the presence of microvascular changes in IIM have been described however, the role of nailfold videocapillaroscopy (NVC) in diagnosis and prognosis in IIM is not clearly established. We aim to determine if there is any association between NVC findings, sKL-6 levels and pulmonary involvement in patients with inflammatory myopathies.

Methods: We performed a retrospective study of IIM patients followed in a reference center and compared them according to the presence of ILD. Epidemiological, clinical and immunological data, pulmonary function tests, sKL-6 levels and NVC finding were retrieved. NVC findings including loss of capillary density, enlarged and giant capillaries, ramified capillaries, haemorrhages, thrombosis, avascular areas, disorganization of capillary architecture and subpapillary venous plexus presence were recollected, if present. Statistical analysis was performed by T-test and Fisher's exact test to compare qualitative and/or quantitative variables and multiple logistic regression modelling to identify correlation between pulmonary function tests, NVC findings and sKL-6 levels. Values of $p< 0.05$ were considered statistically significant

Table 1. Significant logistic regressions for predictors for IIM-ILD

Predictor	B value	P value
Male sex	0.186	0.036
Respiratory symptoms	0.40	0.002
%FVC	-0.322	0.01
%DLCO	-0.59	0.001
sKL-6 levels	0.53	0.002
Anti-Jo 1	0.28	0.03
Avascular areas	0.72	0.006
Enlarged capillaries	0.49	0.04



Results: 95 patients were included, 47 patients (49%) with ILD. 34% were male with a median age at inclusion of 55.3 ±24 years and a median disease duration of 6.8±7 years. Avascular areas and capillary loss showed a significant association with the presence of ILD (OR 2.43, 95% CI 1.3-5.7, p 0.004) and (OR 1.7, 95% CI 1.48-3.1, p 0.04). A negative correlation between capillary loss and enlarged capillaries was also found with FVC% (β=-0.46, p 0.001 and β=-0.57, p <0.0001) and DLCO% (β=-0.32, p 0.04 and β=-0.23, p 0.03), respectively**.** When we studied the correlation between sKL-6 levels, positive correlations with the presence of ILD (β=0.77, p 0.0004), the presence of hemorrhages (β =0.21, p 0.04) and avascular areas in NVC (β =0.64, p 0.03) and negative correlations with FVC% (β=-0.47, p 0.001) and DLCO% (β=-0.59, p, 0.005) were found. Multiple logistic regression identified as predictors for developing IIM-ILD are summarized in table 1 and represented in the scatter plot in figure 1. Male sex, respiratory symptoms, %FVC and %DLCO, sKL-6 levels, anti-Jo1 positivity and the presence of avascular areas and enlarged capillaries in NVC were identified as IIM-ILD predictors (R^2=0.974, p =0.006).

Conclusion: Capillary loss and avascular areas showed a significant association with the presence of ILD, worse FVC and DLCO values and sKL-6 levels. We identified 9 predictors for developing ILD in IIM. NVC assessment and sKL-6 levels can have a predictive role for studying pulmonary function and assessing the prognosis of IIM-ILD.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a heterogeneous group of acquired muscle diseases, which have distinct clinical, pathological and histological features. Autoantibodies are clinically useful biomarkers to help the diagnosis of IIM. Raynaud's phenomenon is very frequent and the presence of microvascular changes in IIM have been described however, the role of nailfold videocapillaroscopy NVC) for diagnosis and prognosis in IIM is not clearly established. The aim of this study was to study the relationship between clinical and immunological characteristics and nailfold videocapillaroscopy (NVC) abnormalities in patients with idiopathic inflammatory myopathies (IIMs).

Methods: We performed a retrospective study of IIM patients followed in a University Hospital. Patients underwent a NVC at 200x magnification. Epidemiological, clinical data and antibody status, including myositis and scleroderma antibody panel of all patients was retrieved. NVC findings including loss of capillary density, enlarged and giant capillaries, ramified capillaries, haemorrhages, thrombosis, avascular areas, disorganization of capillary architecture and subpapillary venous plexus

Clinical features	
Muscle weakness	79 (83%)
Skin findings	30 (32%)
ILD	47 (49%)
Dysphagia	18 (19%)
Raynaud's phenomenon	37 (39%)
CK elevation	45 (47%)
Cardiac disease	4 (4%)
NFC features	
Loss of capillary density	27 (28%)
Enlarged and giant capillaries	37 (39%)
Haemorrhages	36 (38%)
Thrombosis	19 (20%)
Avascular areas	26 (27%)
Disorganization of capillary architecture	24 (25%)
Subpapillary venous plexus	36 (38%)
Antibody status	
Disease-specific antibodies	
Anti-MDA5	8 (8%)
Anti-TIF1G	11 (12%)
Anti-MI2	11 (12%)
Anti-NXP2	6 (6%)
Anti-synthetase antibodies	
Anti-Jo1	13 (14%)
Anti-PL7	9 (9%)
Anti-PL12	5 (5%)
Disease-associated antibodies	
Anti-Ro52	27 (28%)
Anti-KU	6 (6%)
Antinuclear antibodies	61 (64%)
Others (EJ, SRP, PM-SCL75, PM-SCL100, CN1A)	22 (23%)

Table 1: Epidemiological, clinical, immunological and NFC features and autoantibody status from patients with IIM

presence were recollected, if present. For the comparison of qualitative and/or quantitative variables Fisher's exact Test or T-test was performed when necessary.

Results: 95 patients with NVC performed during the follow-up were included (66% female) with a median age at inclusion of 55.3±24 years. Median IIM duration was 6.8±7 years. 39% had Raynaud's phenomenon at first clinical evaluation and 58% of them showed NVC pathological findings. Table 1 Summarizes the epidemiological, clinical, and autoantibody status of the patients. We found an association between the presence of dysphagia and avascular areas (p=0.02) or abnormal capillary organization (p< 0.01) on NVC. ILD was associated with capillary loss (p=0.04) and avascular areas (p=0.004). Anti-MDA5+ was associated with capillary loss (p=0.03), thrombosis (p=0.02) and ramified capillaries (p=0.04). Anti-Mi2+ and anti-Th/To was associated with abnormal capillary organization (p=0.017 and p=0.001). The presence of haemorrhages was associated with anti-Ku+ (p=0.048) and anti-PL12+ (p=0.046). The presence of enlarged capillaries was associated with anti-RNA-pol III (p=0.04) and anti-NXP2 (p=0.044). A significant association between anti-Ro52 (OR 2.69, CI 95% 1.05-6.8, p 0.03) and anti-Jo1 (OR 7.03 CI 95% 1.46-33.7, p 0.01) with ILD was found. Anti-PML (OR 4.32 CI 95% 1.35-10.42, p 0.038) and anti-Th/To (OR 5.82 CI 95% 1.89-13.24, p 0.04) were associated with dysphagia. Anti-MDA5 (OR 5.85 CI 95% 1.92-14.21, p 0.044) was associated with skin involvement.

Conclusion: The presence of certain autoantibodies is related to the degree of microangiopathy in IIM and associates with capillaroscopic changes. Studying the association between capillaroscopic changes with diagnostic and pathogenic auto-antibodies in IIM can provide useful information regarding the current knowledge about pathogenesis, classification, and prognosis of the disease.

Abstract Number: 1139

From Skin to Bone Lesions: A Pioneer Study Unraveling the Underdiagnosis of SAPHO Syndrome in the Dominican Republic

Leeany Maletta[1], Diana Jimenez[2] and Rosanna de Jesus[3], [1]UNIBE School of Medicine, San Antonio, TX, [2]UNIBE School of Medicine, Miami, FL, [3]Hospital General Plaza de la Salud, Distrito Nacional, Dominican Republic

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SAPHO syndrome is a rare chronic inflammatory condition that affects the skin and osteoarticular structures. Despite being first described over 30 years ago, it remains poorly recognized in clinical practice. This study aims to comprehensively update and analyze the disease in the Dominican Republic to improve diagnosis. It dissects the socio-demographic characteristics, preferred diagnostic imaging modalities, and detailed descriptions of bone and skin lesions in the first diagnosed patients. Furthermore, this study is noteworthy for being the first to explore a correlation between dermatological and imaging findings and their interdependence.

Methods: This retrospective study reviewed electronic medical records from 2015 to 2022 to identify patients with skin conditions related to acne and psoriasis. Patients who met Kanh's and Benhamou's criteria for SAPHO syndrome, identified through imaging studies, were included in the sample population. Data on sociodemographics, comorbidities, laboratory tests, and imaging findings were collected and analyzed. Spearman correlations and chi-square tests were calculated along with their corresponding *P* values using Rstudio, with a significance level of $p< 0.05$ considered statistically significant.

Results: Among the patients reviewed, 21 of 1,340 (1.5%) met the criteria and were diagnosed with SAPHO syndrome, with a majority being females (71%). Laboratory tests, including ESR, C-reactive protein, C3, and C4, were not determining factors for diagnosis. MRI and X-ray (48%) were the preferred diagnostic tools for the disease, with sonography (10%) emerging as an alternative option for younger patients. The study identified hyperostosis (52%), osteitis (29%), and arthritis (19%) as common osteoarticular manifestations, with the dorsal column being the most commonly affected bone (82%). The most common dermatoses were severe acne (57%) and psoriasis vulgaris (29%), which commonly affected the face (62%), thorax (33%), scalp (24%), extremities (19%), back (19%), and palmoplantar region (5%). Most patients displayed one or two affected skin areas.

Conclusion: SAPHO syndrome requires a multidisciplinary approach involving rheumatologists, dermatologists, and radiologists, who rely on clinical and imaging findings for an accurate diagnosis. The disease is commonly seen in females aged 34-38, and the preferred imaging modalities for diagnosis were MRI and X-ray. This study found that severe acne exhibited

SPEARMAN CORRELATION	0.6363961	0.001925
CHI SQUARE	8.505	0.003542

Figure 3. Illustration of Spearman and chi-square correlation analysis, demonstrating for the first time a positive correlation between dermatoses in the extremities and palmoplantar region and bone lesions in long bones, revealing the interdependence between these variables.

the highest percentage of radiological findings. However, no significant correlation was observed between dermatological and radiological variables within our sample, indicating the independence of each variable from the other. We also investigated a possible correlation between affected bone areas and areas affected by dermatoses, uncovering a positive correlation between dermatoses of the extremities and palmoplantar region with radiological findings on the long bones and the pelvis. The results of this study, representing the first investigation of this topic in the Dominican Republic, hold the potential to enhance diagnostic strategies and provide valuable statistical data for both local and global understanding of SAPHO syndrome.

Inflammation Is More Prominent Than Joint Damage at Initial Visits of Patients with Inflammatory Arthritides, but Organ Damage Is More Prominent and Patient Distress Is as Prominent as Inflammation in Overall Rheumatology Care: Data from a Feasible Physician RheuMetric Checklist

Theodore Pincus[1], Tengfei Li[2] and Juan Schmukler[1], [1]Rush University Medical Center, Chicago, IL, [2]Georgetown University, Washington, DC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients consult rheumatologists for symptoms which may result from inflammatory activity or reversible problems (INF), joint or other organ damage or irreversible problems (DAM), and/or distress with neither INF nor DAM (STR), e.g., fibromyalgia. Many patients may have clinically important DAM and/or STR in addition to INF. However, quantitative assessment in routine rheumatology care is directed primarily (often exclusively) to INF, e.g., DAS28, CDAI, SLEDAI, ASDAS, and DAPSA. DAM and STR are recognized in many patients, but generally recorded only as narrative descriptions, rather than as quantitative data. INF indices are effective in clinical trials. However, measures and indices designed to assess INF may be elevated by comorbid DAM and/or STR, often despite little or no INF, particularly in routine care patients. A RheuMetric checklist includes 4 0-10 visual numeric scales (VNS) for physician global assessment (DOCGL), inflammation (DOCINF), damage (DOCDAM), and patient distress (DOCSTR), and estimates of the percent of DOCGL attributed to INF, DAM, and STR. We analyzed RheuMetric scores in routine care patients with all diagnoses at initial or return visits to recognize levels of DOCGL, INF, DAM, and STR at initial vs follow-up visits.

Methods: A retrospective cross-sectional study was performed of RheuMetric checklist 0-10 VNS estimates for DOCGL and estimates of %INF, %DAM, and %STR (total=100%) completed in routine care by the treating rheumatologist. Mean levels of these estimates were analyzed according to primary diagnosis, classified as INF (RA, SLE, SpA, vasculitis and gout), osteoarthritis (OA), primary fibromyalgia (FM), and "other," at initial or return visits, using descriptive and chi-square statistics.

Results: Highest DOCINF was in inflammatory diseases, DOCDAM in OA, and DOCSTR in primary FM (Table). The % of DOCGL attributed to INF, DAM, and STR was highest in INF diseases, OA, and primary FM, respectively ($p< 0.001$) (Table). At initial visits of patients with inflammatory diseases, mean DOCGL was 4.3, attributed 62% to INF, 24% to DAM and 14% to STR, respectively. At return visits of patients with inflammatory diseases, mean DOCGL was 3.7, attributed 33% to INF, 49% to DAM and 18% to STR (Table). In patients with all diagnoses, 36%, 36%, and 28% of DOCGL were attributed to INF, DAM, and STR, respectively, at first visits, vs 22%, 51%, and 28% at return visits (Table). RheuMetric estimates required 15-20 seconds to complete.

Conclusion: RheuMetric physician estimates for INF, DAM, and STR are feasibly recorded in 15-20 seconds in routine care, with face validity documented by significantly higher DOCINF in inflammatory diseases, DOCDAM in OA, and DOCSTR in FM. DOCINF was higher at first vs return visits, reflecting strong anti-inflammatory therapies at this time, while % DOCDAM was higher at return vs first visits. At return visits of all patients, INF accounted for 22% of DOCGL vs 50% for DAM and 28% for STR, indicating that control of inflammation is not the primary rheumatology activity after the first visit. Physician 0–10 estimates of inflammation, damage, and patient distress, in addition to DOCGL, can give a more complete quantitative patient assessment than only measures of inflammation.

Table: Cross sectional analyses of mean (standard deviation) for 0-10 physician global estimate (DOCGL) and % of DOCGL attributed to inflammation (%INF), damage (%DAM), and patient distress (%STR) (Total=100%) at 244 first visits compared to 319 return visits Δ p<0.001 at both initial and return visits. *p<0.001 vs initial visits, ◊p=0.05 vs initial visits

COVID-19 Vaccination Status and Adverse Events Following SARS-CoV-2 Vaccine in Autoimmune Inflammatory Rheumatic Disease (AIRD) Patients: A Single Center Experience

Vincent Luceño[1], Peter Paolo Daleon[1] and Sandra Navarra[2], [1]University of Santo Tomas Hospital, City of Manila, Philippines, [2]University of Santo Tomas Hospital, Joint and Bone Center, Manila, Philippines

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune inflammatory rheumatic diseases (AIRD) were associated with an increased risk for COVID-19 infection, worse clinical outcomes, and COVID-19- related deaths. Vaccines carry the potential benefit of reducing disease transmission and disease severity. Issues on vaccine safety, trigger of an autoimmune reaction or disease flares has been a long issue. Thus this study describes the COVID-19 vaccination status and adverse events following SARS-COV 2 vaccine in a tertiary hospital in Manila, Philippines.

Severity: Asymptomatic Mild Moderate Severe	 19 (86.4) 2 (9.1) 1 (4.5)

1.

Methods: This retrospective cross-sectional study included patients diagnosed with AIRD and seen in the clinics over 12 months (March 2021-March 2022).We collected data from patients' clinic records and analyzed the clinicodemographic profile, vaccination status, adverse events and development of new onset autoimmune reaction and disease flares post vaccination and those who developed COVID-19 infection even after vaccination.

Results: There were 204 respondents included in this study. Majority were female (85%). SLE, rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis were the common AIRD. The median age is 38.4 years. 100% of the respondents were fully vaccinated; 42.6% received inactivated vaccine, 30.8% viral vector vaccine and 26.4% mRNA vaccine. 65.2% reported no adverse events while 34.8% experienced constitutional, musculoskeletal, cutaneous, respiratory, gastrointestinal and cardiovascular symptoms after vaccination. There were 9 (4.4%) of the respondents who developed new onset autoimmune reaction and disease flares 7-28 days post vaccination; 1patient had new onset amyopathic dermatomyositis; 3SLE patients developed severe hematologic, cutaneous and renal flare; 2 rheumatoid arthritis, 1 spondyloarthritis, and 1 inflammatory patients in long remission had disease flares and 1 patient with henoch schonlein purpura developed flare. Twenty two of the respondents developed COVID-19 infection after 30-120 days post vaccination; of whom 86.4% developed mild symptoms, 9.1% moderate infection and 4.5% had severe infection. All of the patients recovered with no complications.

Conclusion: This study showed that patients with AIRD experienced varied organ system adverse events ranging from mild side effects to new onset autoimmune reactions and disease flares. Even after a complete vaccination, some patients still had COVID-19 infection, however preventing them from worse complications, hospitalization and death.

A Retrospective Analysis of Radiographic and Serologic Findings in Patients with Scleroderma and Interstitial Lung Disease

Nikita Jhawar, **Claire Wilson**, Andy Abril, Li Zhuo and Yaohua Ma, Mayo Clinic, Jacksonville, FL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Connective tissue diseases such as scleroderma are frequently associated with interstitial lung disease (ILD). Detection of autoantibodies is crucial in characterizing disease phenotypes, but there remains a lack of substantial data on the association of some autoantibodies present in scleroderma patients with specific ILD patterns. We sought to investigate possible association, describe the phenotypes of scleroderma seen in our study cohort, and review findings from other studies.

Methods: The cohort included adults with scleroderma and ILD who were treated at Mayo Clinic between January 2011 and December 2021. Baseline demographic, serologic, and imaging data were extracted from the electronic medical record. Continuous variables were summarized with median and range, and categorical variables were summarized with frequency and percentage (%). The Kruskal-Wallis Rank Sum test was used for continuous measures and the Chi-square test

was used for categorical measures. All tests were two-sided and p-values less than 0.95 were considered to be statistically significant. Analysis programming was performed by R-studio with R version 4.1.2.

Results: A total of 454 patients with both scleroderma and ILD were included in the study. The study cohort had a mean age of 62 years, and 103 patients (22.7%) were males. ILD patterns analyzed included NSIP (83.3%), UIP (11%), probable UIP (2.9%), indefinite UIP (2.9%), OP (1.5%) and LIP (2%). The antibody and symptoms were determined for patients with and without each of these ILD patterns. NSIP patients were more likely to have anti-Scl70 antibodies compared to patients

Supplementary table 1: Summary of demographic descriptions

without NSIP (p=0.01). OP patients were more likely to have anti-PM/Scl antibodies compared to patients without OP (p=0.006), and LIP patients were more likely to have anti-U1 snRNP antibodies compared to patients without LIP (p=0.002). LIP patients were significantly less likely to have antiScl70 antibodies than patients without LIP (p=0.025). Additionally, UIP patients were also less likely to have anti-Scl70 antibodies than patients without UIP (p=0.017). There were no clinically significant findings of anti-centromere antibodies or anti-RNA Pol III antibodies in any of the ILD patterns. No symptoms had a clinically significant association with the ILD pattern groups.

Conclusion: Our study examined associations between serologic data and ILD patterns and demonstrated a statistically significant association of anti-Scl70 antibodies with NSIP and antiPM/Scl antibodies with OP. There also appears to be an association between anti-U1 snRNP antibodies and LIP, which has not been demonstrated in the literature thus far aside from another observational study. LIP and UIP patterns were significantly less likely to have association with anti-Scl70 antibodies. We did not find any statistically significant association between anticentromere antibodies and specific ILD patterns. Finally, our study suggests that antibodies may develop in scleroderma but are not necessarily associated with development of ILD. Autoantibodies offer an invaluable tool in predicting disease outcomes and further studies are needed to elucidate this, especially with regards to scleroderma-associated ILD.

Nationwide Analysis of Adult-Onset Still's Disease with and Without Hemophagocytic Lymphohistiocytosis

Faria Sami[1], Michael Manansala[2], Shilpa Arora[1] and Augustine Manadan[2], [1]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Adult-Onset Still's Disease (AOSD) commonly manifests with fever, arthritis, rash, liver dysfunction, lymphadenopathy, and hematologic abnormalities. AOSD is also associated with Hemophagocytic Lymphohistiocytosis (HLH). We aimed to study the characteristics and outcomes of adult AOSD hospitalizations with HLH, as well as independent predictors of inpatient mortality.

Methods: We utilized the 2016 to 2019 National Inpatient Sample (NIS) database to obtain hospitalizations with a principal or secondary diagnosis of AOSD. We subdivided AOSD hospitalizations into those with and without HLH. ICD-10 codes were used to identify diagnoses. Demographics, complications of interest, total hospital charges (THC) and length of stay (LOS) were collected and compared. Variables with a p value ≤ 0.2 in the univariable screen were included in a multivariable logistic regression model for in-hospital death. Results were reported as odds ratios (OR).

Results: We identified 5,495 adult AOSD hospitalizations, of which 340 (6.2%) had HLH, and 5,155 (93.8%) did not have HLH (table 1). Relative to the non-HLH group, HLH group was younger (median age 33 vs 51 years; p< 0.001), had similar percentage of females (69.1% vs 59.4%; p=0.133), had less whites (45.6% vs 58.3%; p=0.045), similar percentage of African Americans (11.8% vs 12.2%; p=0.919), but had more Hispanics (26.5% vs 15.7%; p=0.027), had longer median LOS in days (7 vs 4; p< 0.001) and a higher median THC ($73,156 vs $41,840; p=0.001). The HLH group had higher prevalence of

Hospitalization Characteristics	AOSD without HLH (n=5,155)	AOSD with HLH (n=340)	P-value

Multivariable Analysis for In-hospital Death of AOSD Patients

for predictors of in-hospital mortality in AOSD hospitalizations are shown in table 2. Multivariable analysis showed that DIC (OR 6.13; 95% C.I. 1.002-37.499), hepatic failure (OR 7.16; 95% C.I. 1.487-34.479), infection/pneumonia/sepsis (OR 3.72; 95% CI 1.332-10.402), respiratory failure (OR 6.89; 95% C.I. 2.353-20.168) and TMA (OR 14.05; 95% CI 1.463-135.008) were associated with higher odds of in-hospital death among AOSD hospitalization (table 3).

Conclusion: We found that HLH only occurred in 6.2% of AOSD inpatients. Inpatients with both AOSD and HLH had a higher rate of concurrent AKI, DIC, hepatic failure, infections, respiratory failure, and TMA. They were also younger, had a higher proportion of Hispanics, longer LOS, greater total hospital charges, and a 9% in-hospital mortality in contrast to 1.5% in those without HLH. Despite a large difference in mortality between the groups, HLH itself was not found to be an independent risk factor for in-hospital death. Multivariable analysis in AOSD inpatients showed DIC, hepatic failure, infection/pneumonia/sepsis, respiratory failure, and TMA to be associated with higher odds of death. This information can help clinicians by improving awareness of these life-threatening complications since early recognition and prompt management may improve outcomes.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Deucravacitinib, a first-in-class, oral, selective, allosteric tyrosine kinase 2 inhibitor, is approved in multiple countries for the treatment of adults with plaque psoriasis. Deucravacitinib was superior to placebo and apremilast in the global, 52-week, phase 3 POETYK PSO-1 (NCT03624127) and PSO-2 (NCT03611751) trials in psoriasis. Deucravacitinib is being investigated in several immune-mediated diseases and has shown efficacy compared with placebo in phase 2 trials for SLE (NCT03252587) and PsA (NCT03881059). The POETYK long-term extension (LTE) trial (NCT04036435) showed that deucravacitinib maintained long-term efficacy through 2 years with no new safety signals. Here, we report clinical efficacy up to 3 years (148 weeks) in the POETYK LTE trial in a subset of patients who received continuous deucravacitinib from day 1 in the parent trials.

Table. PASI 75, PASI 90, and sPGA 0/1 response rates with continuous deucravacitinib in Week 16 (n=313) and Week 24 (n=336) PASI 75 responders[a]

	PASI 75 responders at week 16, % (95% CI, %)			PASI 75 responders at week 24, % (95% CI, %)		
Parameter	Week 16 (n = 777)	Week 52 (n = 277)	Week 148 (n = 277)	Week 24 (n = 305)	Week 52 (n = 305)	Week 148 (n = 305)
PASI 75	100 (NE–NE)	87.0 (NE–NE)	84.5 (79.8–89.2)	100 (NE–NE)	90.2 (NE–NE)	86.0 (81.6–90.3)
PASI 90	57.8 (NE–NE)	60.6 (NE–NE)	60.0 (53.9–66.1)	63.3 (NE–NE)	61.6 (NE–NE)	60.4 (54.6–66.3)
sPGA 0/1	84.1 (NE–NE)	70.8 (NE–NE)	62.8 (56.7–68.9)	83.0 (NE–NE)	74.1 (NE–NE)	64.5 (58.7–70.3)

[a]Response rate was reported using modified nonresponder imputation. The Clopper-Pearson method was used to calculate 95% CIs.
NE, nonestimable; PASI 75/90, ≥75%/90% reduction in Psoriasis Area and Severity Index; sPGA, static Physician's Global Assessment.

Methods: In POETYK PSO-1 and PSO-2, patients were randomized 1:2:1 to placebo, deucravacitinib 6 mg once daily (QD), or apremilast 30 mg twice daily. At week 52, patients could enter the POETYK LTE trial and receive open-label deucravacitinib 6 mg QD. Deucravacitinib efficacy through week 148 was evaluated in patients from pooled POETYK PSO-1 and PSO-2 populations who received continuous deucravacitinib from day 1, achieved ≥ 75% reduction from baseline in Psoriasis Area and Severity Index (PASI 75) at week 16 (primary endpoint) or week 24 (peak response), and enrolled in the POETYK LTE trial. Maintenance of response was assessed through data cutoff (June 15, 2022) and included PASI 75 and PASI 90 (≥ 90% reduction from baseline in PASI). Static Physician's Global Assessment (sPGA) score of 0 (clear) or 1 (almost clear) with a ≥ 2-point improvement from baseline was assessed.

Results: A total of 513 patients completed 52 weeks in the parent trials and received continuous deucravacitinib from day 1, including 313 (61.4%) patients (95% CI, 57.0–65.6) who achieved PASI 75 at week 16 and 336 (66.5%) patients (95% CI, 62.2–70.6) who achieved PASI 75 at week 24. Among these patients, PASI 75 response rates were maintained from week 52 to week 148 (**Table**). PASI 90 response rates were maintained in > 50% of patients from the start of the POETYK LTE trial (**Table**). Response rates for sPGA 0/1 were maintained from week 52 to week 148 (**Table**).

Conclusion: Clinical efficacy was maintained for up to 148 weeks with continuous deucravacitinib in most patients who were week 16 and week 24 PASI 75 responders from the parent trials and enrolled in the POETYK LTE trial. These findings further support the long-term use of once-daily oral deucravacitinib as an effective treatment for patients with psoriasis.

Human Cardiovascular Disease Model Provides Transcriptomic Evidence of Cardiovascular Risk Associated with Febuxostat

Ryan Feaver[1], Scott Bowers[2], Banumathi Cole[1], Steve Hoang[1], Mark Lawson[1], Justin Taylor[1], Brian LaMoreaux[2], Lin Zhao[2], Brad R Henke[1], Brian Johns[1], Andrew C Nyborg[2], Brian R Wamhoff[1] and Rob Figler[1], [1]HemoShear Therapeutics, Charlottesville, VA, [2]Horizon Therapeutics, Deerfield, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a chronic inflammatory arthritis that is undertreated and managed with the xanthine oxidase inhibitors febuxostat or allopurinol. Despite the United States Food and Drug Administration (FDA) mandating febuxostat carry its most prominent warning for serious side effects that include cardiovascular-related death, febuxostat is widely prescribed. A large, manufacturer-sponsored clinical trial (CARES) led to the febuxostat FDA warning label; however, a recent, large clinical trial (FAST) did not replicate these data in patients without pre-existing cardiovascular risk. Whether febuxostat increases cardiovascular risk remains an important question and to date there are few mechanistic studies designed to resolve this controversy.

Methods: We compared the transcriptomic signature of oral gout medications alongside 107 other clinical stage compounds, 33 of which are FDA labelled for increased cardiovascular risk, in an *in vitro* human primary cell-based cardiovascular disease model to clarify the potential risk of febuxostat.

Results: Febuxostat significantly modulated more signaling pathways associated with cell stress and cardiovascular risk than allopurinol or topiroxostat, gout medications not associated with increased cardiovascular risk. Moreover, these signaling pathways were commonly regulated by other drugs FDA labelled for cardiovascular risk. Lastly, these results were replicated with a febuxostat analog.

Conclusion: Together, these data support the FDA warning for febuxostat and suggest that cardiovascular risk associated with gout medications stems from chemical structure of the medication, itself, rather than the target, xanthine oxidase.

Gene X Environment Paradigm: Exemplified by Selected Cases of Autoinflammatory Diseases

Qingping Yao and Peter Gorevic, Stony Brook University, Stony Brook, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The current scientific opinion holds that gene and environment (G X E) interactions contribute to certain human diseases. Systemic autoinflammatory diseases (SAIDs) are usually associated with genetic variations. Unlike classic monogenic disease (Huntington's disease), some genetic mutations associated with SAIDs are of low frequency and low penetrance. In other words, a small proportion of healthy people carry these mutations. Therefore, a gene of interest or candidate gene, genetic background, and environment are hypothesized to collectively cause disease. COVID19 is an environmental factor. Herein, we report a case series of SAID patients to support the above proposition.

Methods: In this retrospective single center study, a cohort of adult patients were enrolled and fulfilled the diagnostic criteria for certain SAIDs as confirmed by molecular analysis. After extensive negative workup for systemic autoimmune and related diseases, genetic testing of periodic fever syndrome 6-gene panel and an extended SAID gene panel were performed at Commercial Diagnostic Molecular Laboratories.

Results: Of the 6 Caucasian patients, there were 4 females and 2 males with a mean age of 46.5(26 to 76). These patients were essentially healthy prior and developed autoinflammatory features following COVID19 infection (4 cases) or vaccinations (2). They experienced recurrent symptoms such as fever, rash, arthralgia and gastrointestinal symptoms among others. All patients were identified to carry *NOD2* mutations, and 3 of them carried concurrent mutations in other SAID genes, such as MEFV, NLRP3, NLRP12, TNFRSF1A, and UBA1(**Table 1** to be presented). Two of the *NOD2* mutations are rare and other mutations are of low frequency/penetrance and are known to increase susceptibility to certain SAIDs, such as Yao syndrome (NOD2), Familial Mediterranean fever (MEFV E148Q, R408Q, P369S), NLRP3-autoinflammatory disease (NLRP3 Q703K), and NLRP12-autoinflammatory disease (NLRP12 F402L). UBA1 mutation is associated with VEXAS syndrome. These SAIDs associated with the low penetrance variants are currently regarded in the new category of Genetically Transitional Disease, where mutation is necessary but not sufficient to cause disease. Genetic background refers to all other related genes that may interact with the gene of interest to potentially influence specific phenotype in concert with environment. Since all our patients carry *NOD2* variants as the denominator, the *NOD2* is considered as the gene of interest, and other SAID gene variants may be entertained as genetic background. Although most *NOD2* variants are low penetrants in this study, their penetrance could be upwardly influenced by genetic background. While these patients carry germline mutations, their disease onsets started following the COVID19 infection or vaccination. These data strongly suggest that candidate genes, genetic background and environment together may contribute to these SAIDs. Our data may also explain some patients with Long COVID Syndrome.

Conclusion: Our study supports the interactive role of genes and environment in the pathogenesis of some autoinflammatory diseases. Further study of large cohort patients is warranted.

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory musculoskeletal diseases including rheumatoid arthritis (RA) and psoriatic arthritis (PsA) are characterized by physical function impairment due to progressive inflammatory and structural changes. This becomes apparent even in the early disease stages before arthritis onset, such as in psoriasis (PsO). Chronic inflammation triggers an accelerated remodeling of the extracellular matrix (ECM), resulting in the release of specific degradation products of proinflammatory and collagen molecules that can be measured in blood. In this study, we explored whether levels of ECM biomarkers differ among patients with RA, PsA and PsO, and controls. In addition, we investigated the association between biomarkers and functional impairment by measures of hand function.

Methods: This is a secondary analysis of serum samples obtained from participants of three hand function studies with identical study conditions for sample collection and assessments (FAU ethics approval #125_16B, #357_20B). Serum samples from patients with RA, PsA, and PsO, and controls were obtained in the outpatient clinic of the Rheumatology and Dermatology Department, Universitätsklinikum Erlangen, Germany. Serum ECM catabolic markers (C1M, C2M, C3M, C4M, PRO-C4, C6M, ARG), formation markers (PRO-C1, PRO-C3, PRO-C6), and inflammation markers (VICM) were measured by immunoassay (Nordic Bioscience, Herlev, Denmark). Fine motor skills were assessed by the Moberg-Picking-Up Test (MPUT) and isometric grip strength was measured using a dynamometer. The Michigan Hand Questionnaire (MHQ) was used to evaluate patient-perceived hand function. The best out of two and three attempts was used for the analysis of MPUT and grip strength, respectively. Linear regression models with robust standard errors were used to compare biomarker levels between groups, adjusting for age and gender. Correlations between biomarker data and hand function were assessed by Spearman's rank correlation (ρ) and p-values were adjusted by false discovery rate method.

Results: 85 patients with RA, 115 with PsA, 102 with PsO and 110 controls (mean age, years: 58.4, 53.7, 45.8, 46.6; % male: 35.3, 49.6, 60.8, 45.0, respectively) were included. VICM levels were significantly higher in RA, PsA, and PsO than in controls (Figure 1, $p < 0.0001$). PsA and PsO showed significantly higher C4M levels compared to RA and controls, while C6M was lower in patients with RA and PsA than in controls (Figure 1, $p < 0.001$). C1M presented higher levels in PsO

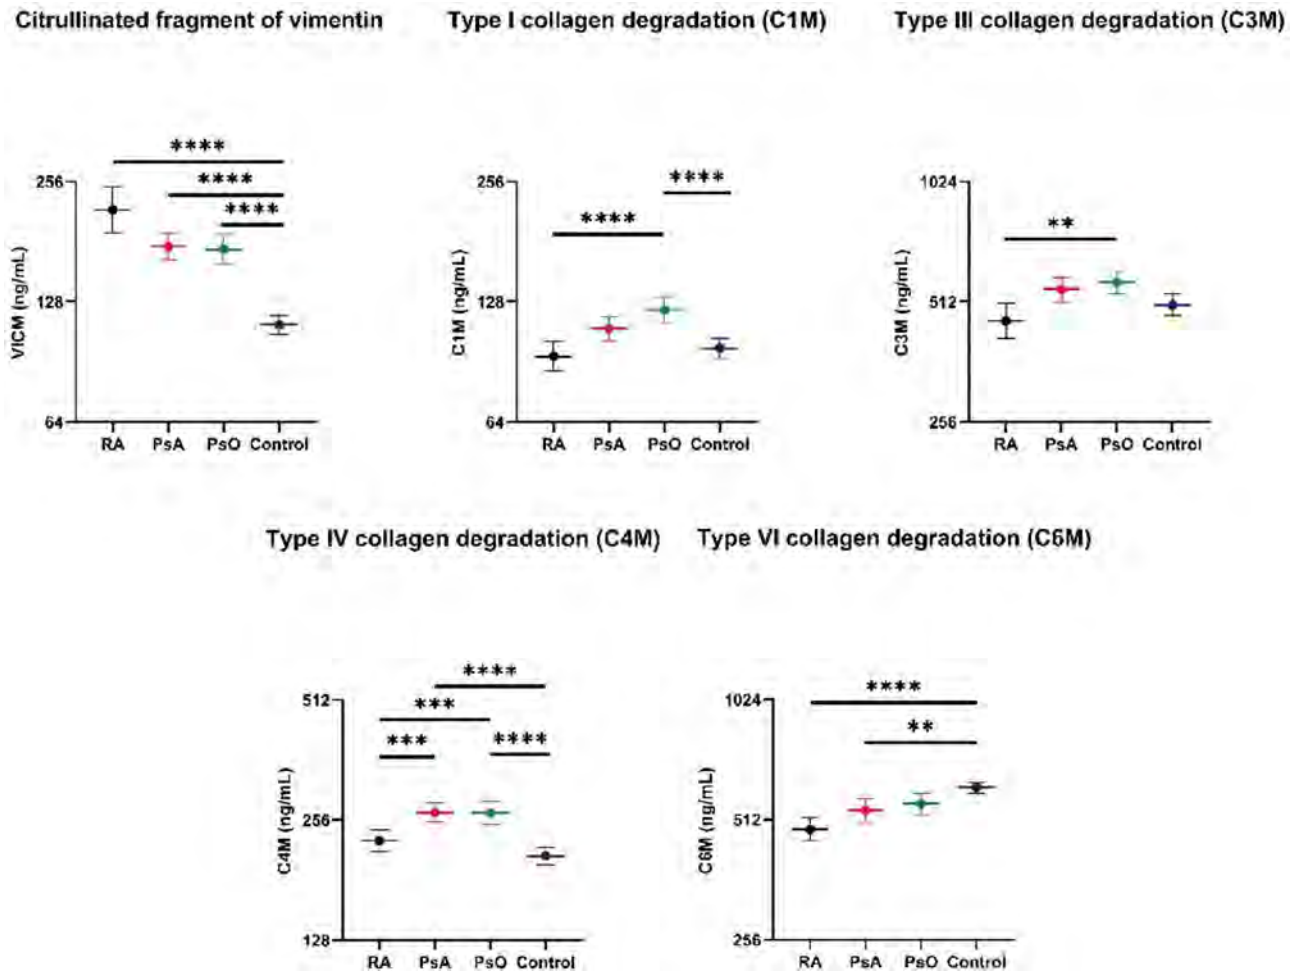

Figure 1. ECM biomarkers in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and psoriasis (PsO), and controls. Data is shown as mean ± 95% confidential intervals.Linear regression models using robust standard errors were performed to compare biomarker levels within the groups with age and gender as covariates. P-values were adjusted by Holm correction and significance threshold was set at 0.004 considering that 12 biomarkers were analyzed. Significance is shown as ** p< 0.004, ***p< 0.001 and ****p<0.0001.

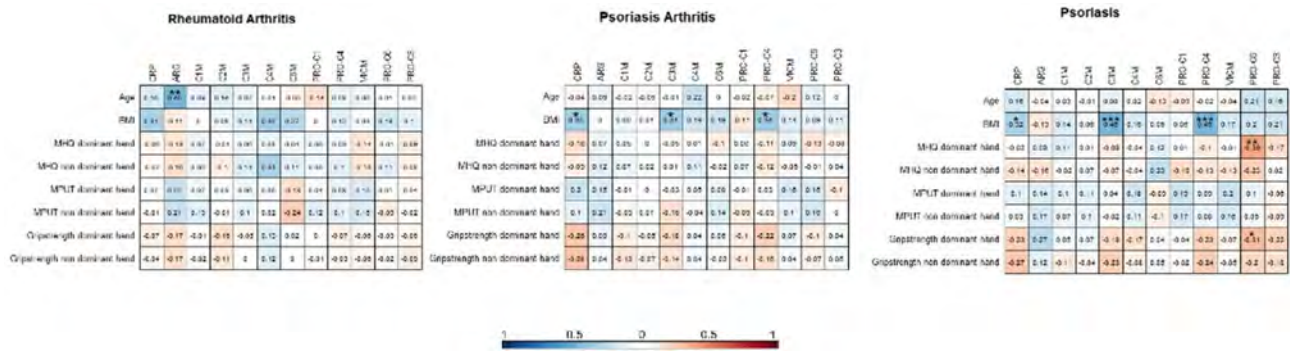

Figure 2. Spearman's correlations between serological metabolites and clinical scores were performed. Spearman's rho (ρ) is shown. The significance of correlations are shown as * p< 0.05, **p< 0.01, and ***p< 0.001. Abbreviations: BMI, body mass index; MHQ, Michigan Hand Questionnaire; MPUT, Moberg Picking-Up Test; CRP, C-reactive protein; ARG, aggrecan ADAMTS degradation; C1M, MMP-2/9/13-degraded type I collagen; C2M, MMP (multiple) -degraded type II collagen; C3M, MMP-9-degraded type III collagen; C4M, MMP (multiple)-degraded type IV collagen; C6M, MMP (multiple)-degraded type IV collagen; PRO-C1, Type I collagen N-terminal propeptide; PRO-C4, Type IV 7S domain collagen; VICM, citrullinated and MMP-degraded vimentin; PRO-C6, Type VI collagen, alpha-3 chain, C5 domain; PRO-C3, type II collagen N-terminal propeptide.

compared to controls, and together with C3M higher levels than RA (Figure 1, $p< 0.004$). The remaining biomarkers did not show any significant differences. Weak correlations were observed between the biomarkers and the hand function scores (all $\rho<\pm0.2$-0.3, Figure 2), while only PRO-C6 showed a significant negative correlation with MHQ ($\rho=-0.39$, $p< 0.01$) and grip strength ($\rho=-0.31$, $p< 0.05$) in patients with PsO.

Conclusion: Patients with RA, PsA, and PsO showed significant alterations in ECM remodeling biomarkers and specially PsA and PsO had higher levels of inflammatory biomarkers compared to RA and controls. Furthermore, predominantly in PsO, ECM formation biomarkers were associated with hand function impairment.

A Comparative Study of Clinical Phenotype in Relation to NOD2 Sub-genotypes in Yao Syndrome

Ashmia Saif[1], Hafsa Nomani[2], Frank Hwang[2], Jie Yang[2] and Qingping Yao[2], [1]Stony Brook University Hospital, Syosset, NY, [2]Stony Brook University, Stony Brook, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Yao syndrome (YAOS, OMIM 617321) is formerly designated NOD2-associated autoinflammatory disease. A spectrum of NOD2 mutations have been associated with this disease. Most patients carry compound variants and a minority carry monoallelic variant. This study aimed to compare clinical manifestations between patients with certain NOD2 sub-genotypes.

Methods: A single center retrospective study of a cohort of adult patients with YAOS was conducted.All patients underwent genetic testing for periodic fever syndrome gene panel. YAOS was diagnosed based on our published criteria, i.e., the presence of characteristic clinical phenotype and genotype with exclusion of other related diseases. This study was approved by the Institutional Review Board of Stony Brook University.

Results: There were a total of 47 patients who carried NOD2 mutations, and nearly all were Caucasian with female 74%. Mean age at diagnosis was 38±23 years and disease duration 16±25 years. All patients possessed complete or incomplete constellations of autoinflammatory features, such as recurrent fever, rash, polyarthralgia, myalgia, gastrointestinal symptoms and chest pain among others. Approximately 50% of patients had elevated acute phase reactants. Based on our prior publications and experience, most patients with YAOS carry the NOD2 variant, IVS8+158 and another concurrent NOD2 variant, such as R702W or 1007fs. In this study, 47 patients were divided into two groups:patients with carriage of NOD2 IVS8+158

Table 1. Clinical comparison of patients with monoallelic vs compound variants

*: For continuous variables, p-values were based on Wilcoxon's rank sum test; for categorical variables, p-values were based on Monte Carlo simulation from a Chi-squared test.
Note: median+/-IQR were reported for continuous variables; column percentages were reported for categorical variables.

only (N=30, 63.8%, Group1) and those with compound variants, IVS8+158/R702W or 1007fs (N=17, 36.2%, Group 2). We asked whether there would be differences of clinical manifestations between the two groups. Our study has found no statistically significant differences (**Table 1**). This study result was in agreement with our clinical observation that patients had similar clinical phenotype regardless of the sub-genotypes. Because these NOD2 variants are of low penetrance, YAOS has been recently reclassified as the new category of genetically transitional disease, where mutation is necessary but not sufficient to cause disease. The pathogenesis of YAOS may involve the interaction of the candidate gene, genetic background and environment.

Conclusion: Our study suggests that clinical phenotype is similar between YAOS patients with NOD2-subgenotypes. These variants serve as useful diagnostic markers for the disease.

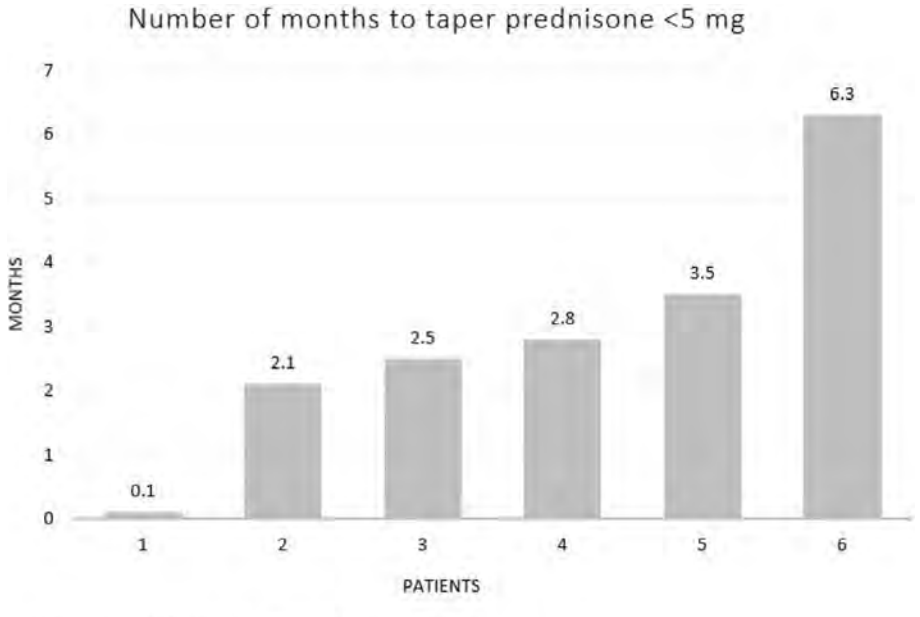
Tumor Necrosis Factor Inhibitors as First Line Steroid-Sparing Therapy for Neurosarcoidosis: A Case Series

Tessalyn Morrison[1], Taylor Lakusta-Wong[1], Chantal Roy-Hewitson[1], Jeanne Gosselin[2] and Alana Nevares[3], [1]University of Vermont, Burlington, VT, [2]University of Vermont Medical Center, Waterbury, VT, [3]University of Vermont, Essex Junction, VT

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a systemic inflammatory disease characterized by non-necrotizing granuloma formation affecting the lung, lymphatics, heart, skin, eye, kidney, and, in neurosarcoidosis, the nervous system. Neurosarcoidosis has varied manifestations, including central and peripheral neuropathies, parenchymal disease, meningitis, and myelopathy. Despite the complications of chronic steroid use, there is currently no consensus on preferred steroid-sparing treatments for



neurosarcoidosis.We aim to describe the clinical course of patients treated with tumor necrosis factor (TNF) inhibitors as the first steroid-sparing agent.

Methods: This is a case series of 8 adults with probable or definite neurosarcoidosis based on Neurosarcoid Consortium Consensus Group criteria. Patients were seen between January 1, 2010 and December 31, 2022 in our rheumatology or neurology clinic, had at least one follow up visit, and received TNF inhibitor therapy as first steroid-sparing agent. Data collected through chart review included demographics, disease characteristics, treatment course, and treatment response.

Results: Of our 8 patients, most were male (n=6) and the median age at diagnosis was 55 (IQR 23). Half were definite diagnoses (n=4), confirmed by brain biopsy. The most commonly involved neurologic tissues were parenchymal (n=7), meningeal (n=4), and spinal (n=3). Outside of neurologic involvement, most patients had lung involvement (n=6) and some had musculoskeletal (n=2) involvement. Based on available cerebrospinal fluid studies, most had elevated protein (n=6), elevated white blood cell counts (n=6), and negative angiotensin converting enzyme (n=7), IgG (n=8), and oligoclonal bands (n=8). Most patients were started on infliximab (n=7), initiated a median of 5.7 months (IQR 8.2) after sarcoidosis diagnosis, and were co-treated with methotrexate (n=7). Most patients were able to wean to < 5 mg of prednisone (n=6) in a median of 2.6 months (IQR 1.3). Most patients had one or fewer relapses (n=7) and achieved partial or complete clinical remission (n=7). A minority of patients had adverse reactions, including pulmonary infection (n=3) and skin infections (n=1); 1 patient died 12 years after diagnosis.

Conclusion: Our study provides further evidence that TNF inhibitors can be used effectively as first-line steroid sparing therapy for neurosarcoidosis. Among our neurosarcoidosis patients treated with TNF inhibitors, most were able to wean from steroids within 6 months and had significant resolution of their symptoms.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Cryofibrinogenemia (CF) is an under-recognized syndrome due to the lack of definitive criteria and the rarity of disease. CF may be primary (essential) or secondary to autoimmune, neoplastic or infections conditions. Skin manifestations, mainly ulceration, are the most common and may be a pseudovasculitic syndrome. During COVID-19 era the number of cases with skin lesions get increased. Further studies are needed to characterize this association between CF and SARS-CoV-2.

Table. Number of cases and clinical features of Cryofibrinogenemia (CF) in preCOVID-19 era and COVID-19 era.

	PRECOVID-19 (n= 5)	COVID-19 (n=14)	p
Cryofibrinogen test; positive/performed, (%positive) (N=134)	5/13 (38.5)	14/121 (11.5)	0.008
Age, years, mean±SD	60.6±11.2	43.6±21.0	0.195

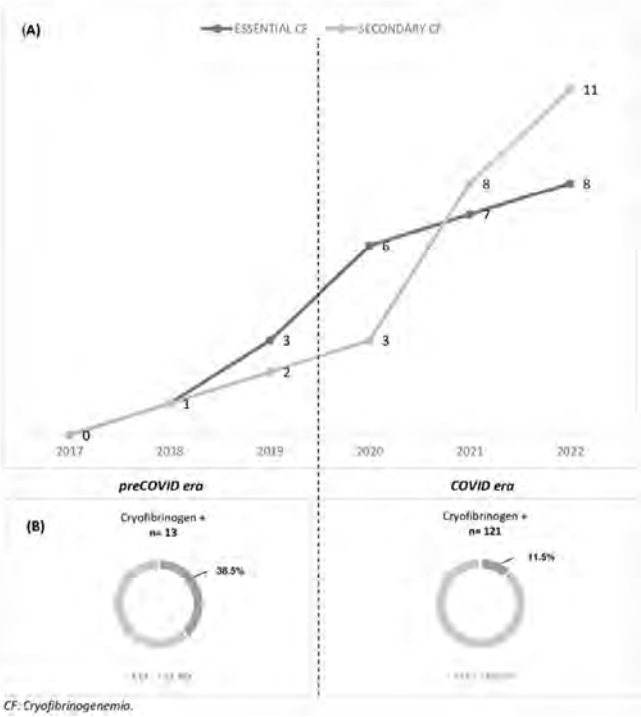
Figure. (A) Number of cases of essential CF vs secondary CF in preCOVID-19 and COVID-19 era. **(B)** Proportion of positive cryofibrinogen in both eras.



CF: Cryofibrinogenemia.

Methods: Observational single-center study in northern Spain University Hospital of 134 patients with at least one positive cryofibrinogen determination, between January 2017 and March 2020 (preCOVID era) and March 2020 and December 2022 (COVID era). CF diagnosis was confirmed accordingly to reported criteria**.**Clinical conditions, laboratory parameters, including immunological and serological analysis were collected from all patients. Blood was collected in citrated tubes for cryofibrinogen detection. Stadistical analysis was performed using SPSS software. Quantitative variables were expressed as mean±SD. Qualitative variables were compared using the Fisher's exact test or the chi-squared test, according to sample size. Quantitative variables were compared using the student's *t*.

Results: CF was confirmed in 19/134 (14.2%) patients with at least one positive cryofibrinogen test determination (preCOVID-19 era=5; COVID-19 era=14). Patients of COVID-19 era were more frequently male (64.3% vs 40%) and younger (43.6 vs 60.6). Main features are shown in **Table 1**. We observed a change in the distribution cases. In preCOVID-19 era most of cases were essential CF (60%) and in COVID-19 era most of them were secondary ones (64.3%). The 33.3% of secondary CF were mainly due to COVID-19. Cutaneous manifestations were similar in both subgroups, especially as purpuric macules (perniosis-like) in acral distributions and no significant association was noted between both eras. Antiaggregant drugs and corticosteroids were used more frequently in preCOVID-19 era. The comparative incidence after and before COVID-19 is shown in **Figure 1.** From patients with positive cryofibrinogen test, a greater proportion in preCOVID-19 had a CF.

Conclusion: CF is a rare disorder with a low prevalence. This study showed the change in the trend of CF subtypes, probably due to the influence of the COVID-19 infection. In COVID-19 era the number of positive cryofibrinogen test had envolved due to SARS-CoV2 infection, CF cases were not increased. Clinical expression of the disease has not changed in both groups.

Revised IWOS Criteria for Ocular Sarcoidosis: A 2019 Review of the 2009 Criteria in a Study of 384 Patients from a Single University Hospital

Carmen Lasa[1], Jorge Javier Gaitán[2], Lara Sanchez-Bilbao[3], David Martínez-Lopez[4], Inigo Gonzalez-Mazon[3], Jose Luis Martin-Varillas[5], Rosalía Demetrio[2], Raul Fernandez-Ramon[2] and Ricardo Blanco[6], [1]Hospital Universitario Marqués de Valdecilla, IDIVAL., La Cavada, Spain, [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [3]Hospital Universitario Marques de Valdecilla, Santander, Spain, [4]Hospital Sierrallana, Torrelavega, Spain, [5]Hospital de Laredo, Laredo, Spain, [6]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION

Session Date: Monday, November 13, 2023

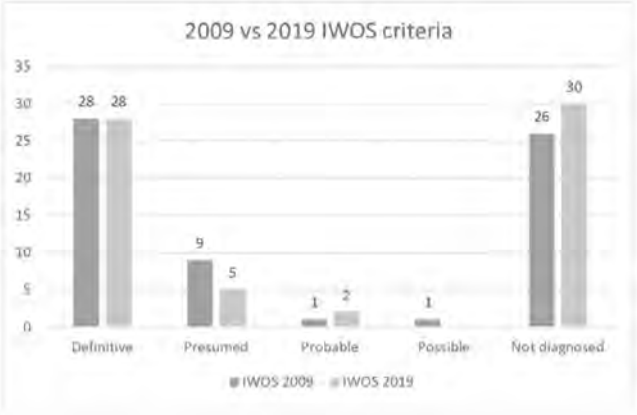
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis is a systemic inflammatory disorder which involves many organs, including eyes. Uveitis and optic neuropathy are the main manifestations. International Workshop on Ocular Sarcoidosis (IWOS) criteria for diagnosis of ocular sarcoidosis (OS) were first published in 2009 and revised in 2019. (question-based survey and panel discussion). IWOS criteria is a remarkable tool to relate uveitis to sarcoidosis, especially when ocular is the first manifestation in the systemic disease. Due to the consequences of OS, identify and initiate appropriate therapy is essential.

Figure. Results of 2009 and 2019 IWOS criteria on a defined population.



Methods: We studied a large cohort (n=384) of all consecutive patients diagnosed with sarcoidosis from January 1, 1999, to December 31, 2019. Finally, 344 patients were included according to the ATS/ERS/WASOG criteria. First (2009) and revised (2019) IWOS criteria were applied to patients diagnosed with Sarcoidosis and ocular symptoms and the results were compared in both groups for our population. Concordance between 2009 and 2019 IWOS criteria was evaluated by calculating Cohen´s kappa coefficient.

Results: 65 (51% men) of 344 patients had ocular involvement (18.9%), mean age 56.7±16.3 years. As for nationality, 92.3% were Spaniard and 7.7% were South American. A positive biopsy for sarcoidosis was obtained in 75.4% (n=49) and a negative biopsy in 6.2% (n=4). There was no statistically significative difference between diagnostic groups for IWOS 2009/IWOS 2019 in age (p=0.738/p=0.495), sex (p=0.534/p=0.459) nor nationality (p=0.529/p=0.393). When applied 2009 IWOS criteria, 60% (39 patients) met any of the diagnostic categories (43.1% *Definitive*, 13.8% *Presumed*, 1.5% *Probable*, 1.5% *Possible*). When 2019 IWOS criteria was applied, 53.8% (35 patients) met any of the new diagnostic categories (43.1% *Definitive*, 7.7% *Presumed*, 3.1% *Probable*). Sensitivity for IWOS 2009 was 0.6 and for IWOS 2019 was 0.53. There was statistically significative concordance between 2009 and 2019 IWOS criteria (p< 0.0001) with a strong consistency level (kappa = 0.824). When analyzing IWOS categories separately, we found total concordance in the *Definitive* category. *Probable* and *Possible* categories in 2009 criteria have been merged in only probable in 2019 criteria and there is a total concordance when comparing both. *Presumed* category represent the bigger change in the revised criteria. We found statistically significative concordance (p=0.000008) with a moderate consistency level (kappa = 0,524).

Conclusion: The revised 2019 IWOS criteria is less sensitive in our population; however, the main difference is in the category *Presumed*: the requirement of at least 2 intraocular signs of uveitis led to a change of 9 patients (13,8%) in 2009 IWOS down to 5 (7.7%) in 2019. In our population IWOS criteria is still has a low sensitivity.

Session Date: Monday, November 13, 2023

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a group of pathologies characterized by necrotizing inflammation that mainly affects small and medium-sized vessels. Serum anti-neutrophil cytoplasmic antibodies (ANCA), mainly anti-myeloperoxidase (anti-MPO) and anti-proteinase 3, levels may correlate to severity and prognosis of the disease. Our objective was to identify the diseases associated with positive anti-MPO antibodies detected in a single university hospital and

Group	Disease	Number (n)	Frequency (%)
Vasculitis (n=77)	Microscopic polyangiitis	34	33.7
	Granulomatosis with polyangiitis	10	8.9
	Eosinophilic granulomatosis with polyangiitis	9	9.9
	Pauci-immune glomerulonephritis	13	12.9
	Unclassified vasculitis	11	10.9
No vasculitis (n=24)	Ulcerative colitis	4	3.9
	Chron's disease	1	0.9
	Rheumatoid arthritis	2	1.9
	Sjogren's syndrome	1	0.9
	Autoimmune hepatitis	1	0.9
	Intestinal ischemia	2	1.9
	Psoriasis	1	0.9
	Lung fibrosis	1	0.9
	Pleural effusion	1	0.9
	Silicosis	1	0.9
	Infection	3	2.9
	Neoplasm	5	4.9
	Pachymeningitis	1	0.9

TABLE 1. Diseases associated with positive anti-MPO antibodies (n=101).

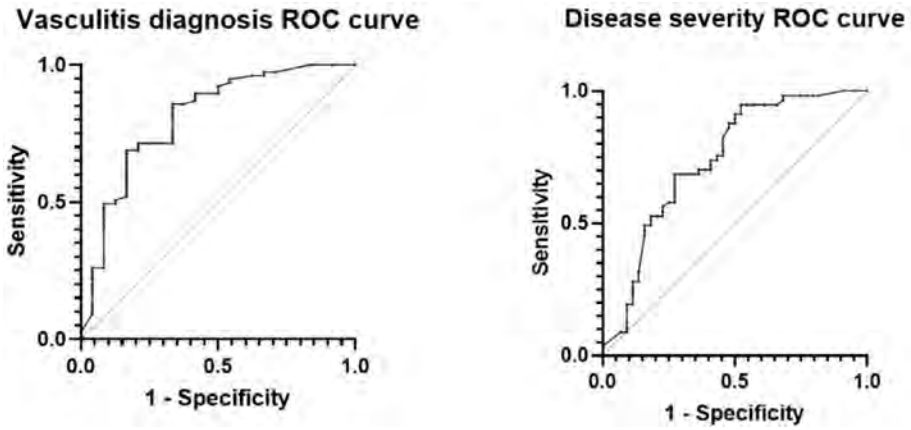

FIGURE 1. Receiver Operating Characteristic (ROC) plots for AAV and positive MPO-antibodies (AUC=0.8084) and disease severity at diagnosis (AUC=0.7160).

attempt to establish whether there is a cut-off point that correlates anti-MPO antibody levels with disease severity and prognosis.

Methods: Table 1 summarizes the frequency of positive anti-MPO antibodies, using laboratory established cut-off value, in different diseases based on a retrospective investigation of 101 positive anti-MPO antibody patients. Then, anti-MPO specificity to vasculitis was evaluated. Furthermore, data of renal disease (hematuria and/or proteinuria) and pulmonary involvement (hemoptysis, asthma and/or respiratory insufficiency) were collected at vasculitis diagnosis, as well as whether the illness progressed to the stage of requiring dialysis, transplantation, or mortality.

Results: For anti-MPO antibodies with a diagnosis of vasculitis (n=77), an area under the curve (AUC) was calculated (AUC=0.8084), and a cut-off point of 41.5 IU/ml was determined (**Figure 1**). When the analysis was restricted to exclusively microscopic polyangiitis diagnoses (n=34), the cut-off point was 36.5 IU/ml with an AUC of 0.6435. There were significant differences in anti-MPO levels between patients with renal or pulmonary dysfunction (n=65) versus those without them (n=36) (p=0.0003), and a cut-off threshold of 60 IU/ml was established. Finally, after evaluating the illness's prognosis, an AUC= 0.5546 was found, being no significant differences between those patients who had a worse disease progression (n=19) and those who did not (n=82) (p=0.4643).

Conclusion: Anti-MPO levels at the moment of vasculitis diagnosis are related with disease severity but not with disease outcome.

Abstract Number: 1153

Unmasking SAPHO: A Case Series Revealing the Clinical Spectrum and Treatment Approaches

Manush Sondhi[1], Warda Maqsood[2] and Sarwat Umer[3], [1]Louisiana State University, Shreveport, LA, [2]LSU Health Science Center, Shreveport, LA, [3]LSU Health Shreveport, Shreveport, LA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SAPHO (synovitis, acne, pustulosis, hyperostosis, and osteitis) is a relatively rare and often underdiagnosed inflammatory disorder. Its diagnosis can be challenging due to its wide range of osteoarticular and cutaneous manifestations. Managing SAPHO syndrome often necessitates a multidisciplinary approach, considering its diverse manifestations across multiple systems. Given the rarity of SAPHO syndrome, treatment approaches are primarily informed by observational studies and case reports. In this study, we present a series of five patients diagnosed with SAPHO syndrome and highlight the distribution of lesions and their response to various therapeutic agents.

Methods: In our retrospective single-center study, we examined SAPHO patients under rheumatology care from 2018 to 2023. We screened patients aged 18 or older using specific ICD-10 codes related to sacroiliitis, sternoclavicular joint pain, inflammatory spondylopathy, inflammatory arthritis, acne vulgaris, hidradenitis suppurativa, pustulosis, palmar pustulosis, and palmoplantar pustulosis. Patients with alternate diagnoses or lost to follow-up were excluded. Our analysis identified a cohort of five SAPHO patients and thoroughly characterized their articular and dermatologic manifestations. Additionally, we evaluated the treatment responses in these patients.

Results: We conducted a study on five patients (four female, one male) with SAPHO syndrome, with a mean age of 49 years (range 28-68). The average follow-up period was 56 months (range 21-130). Among the patients, three (60%) exhibited sternoclavicular joint involvement, while one (20%) had sacroiliitis. Peripheral joint involvement was reported in two patients (40%). Acne was present in three patients (60%) in the arms and legs, while one patient (20%) had hidradenitis suppurativa. One patient (20%) had comorbid Crohn's disease. All five patients (100%) were treated with methotrexate, with three patients (60%) also receiving adalimumab and one patient (20%) receiving infliximab. Four out of five patients (80%) showed improvement in bone lesions with methotrexate. Skin lesions improved in two patients (40%) with methotrexate and in two

Age/Sex/ Follow up	Bone Involvement	Skin lesions	Inflammatory Bowel disease	Treatment	Response to treatment	
					Bone lesions	Skin lesions
68/F/58 months	Knees, Feet	Hidradenitis suppurativa in the right axilla and groin	N/A	Methotrexate Adalimumab Infliximab	Improved on Adalimumab	Worsened on MTX and Adalimumab. Improved on Infliximab
54/F/26 months	Sternoclavicular Involvement	Acne in lower legs	N/A	Methotrexate	Improved on Methotrexate	Improved on Methotrexate
28/F/21 months	Lower back pain (Sacroiliitis)	Acne in arms and legs	N/A	Methotrexate Adalimumab	Improved on Methotrexate	Improved on Adalimumab
68/M/130 months	Sternoclavicular Involvement, Knees	Acne in lower legs	N/A	Methotrexate	Improved on Methotrexate	Improved on Methotrexate
29/F/47 months	Sternoclavicular Involvement	Negative	Present	Methotrexate Adalimumab	Improved on Methotrexate	Improved on Adalimumab

A cumulative table highlighting the distribution of lesions and their response to various therapeutic agents.

patients (40%) with adalimumab. In one patient, infliximab was initiated when adalimumab failed to improve the skin lesions, resulting in improvement. Three patients (60%) required treatment with two or more agents.

Conclusion: In our study, the most frequent involvement observed was in the sternoclavicular joints, followed by peripheral joints and the lower back. Acne was more commonly reported than hidradenitis suppurativa. We found that bone lesions showed favorable responses to treatment with methotrexate, while a significant proportion of skin lesions also demonstrated positive results. Adalimumab was effective in treating skin lesions, except in one case where infliximab proved to be more effective. It is important to note that the lack of validated response criteria specific to SAPHO syndrome currently hinders the objective assessment of therapeutic response. Further research is needed to develop better methods for evaluating the response to various treatment modalities in SAPHO patients.

Clinical Presentation of IgG4-Related Disease. Single Referral Hospital Experience and Literature Review

Fernando López[1], Javier Loricera[2] and Ricardo Blanco[3], [1]Rheumatology, Hospital Universitario Marqués de Valdecilla, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [3]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is an inflammatory and fibrosing entity with very heterogeneous clinical manifestations. It was recognized as a new disease entity only 12 years ago. Its pathogenesis remains unknown, clinical features are heterogeneous and unspecific, and recently released classification criteria are invaluable in early recognition

TABLE. Main features of the patients with IgG4-RD in series of more than 100 patients and in current series

Reference	Cases	Sex Female (F)/ Male (M)	Age, median [IQR] or mean±SD	Diagnosis criteria	Number of organs affected	Level of serum IgG4 (mg/dL), median [IQR]
Lanzillotta et al. Rheumatology 2020	131	F (n=36), M (n=95)	62 [53-70]	-Umehara: possible (46%), probable (2%), definitive (52%)	-1 organ (26%) -More of 1 organ (74%)	224 [115-382]
Arvel et al. Orphanet J Rare Dis 2022	127	F (n=35), M (n=92)	63 [55-69]	-Umehara: possible (82.6%), probable (2.3%), definitive (11.8%)	-1 organ (20%) -2-4 organs (66%) -More of 5 organs (9%)	980 [360-1520]
Zongke et al. Clin Rheumatol 2021	102	F (n=25), M (n=77)	62 [54.1-65.8]	-Okazaki (100%)	Median [IQR]: 2 [1-3]	399 [199-776]
Wang et al. Arthritis Res Ther 2015	215	F (n=67), M (n=148)	54 [46-62]	-Umehara: possible (47.9%), probable (4.7%), definitive (47.4%)	-1-2 organs (36%) -3-4 organs (47%) -5 or more organs (17%)	896 [350-1880]
Inoue et al. Medicine (Baltimore) 2015	235	F (n=169), M(n=46)	67	-Symptoms+laboratory+image/ Compatible histology (100%)	-1 organ (41%) -2 or more organs (59%)	470 [ND]

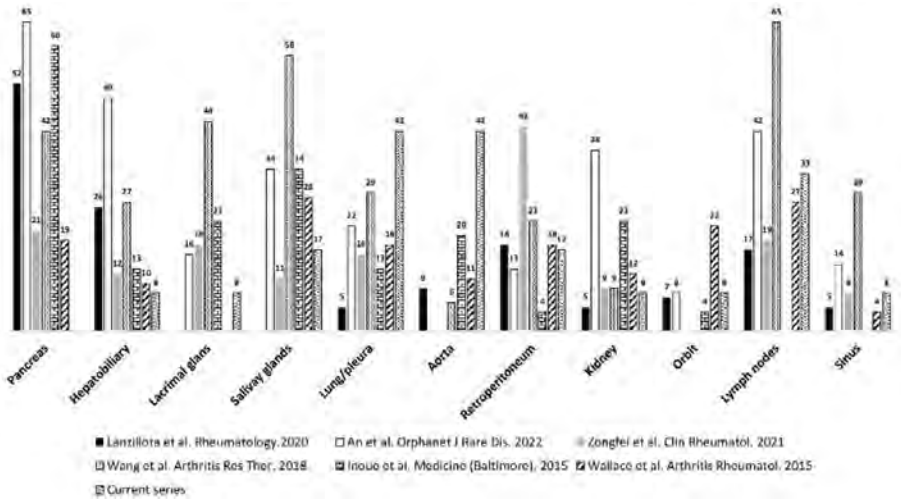
Current series	12	F (n=8), M (n=4)	61 [54.7-76]	-Okazaki: 50% -Umehara: possible (25%), probable (17%), definitive (8%) -ACR/EULAR 2020 (1%) -Symptoms+laboratory+image/ Compatible histology (50%)	-1 organ (33%) -2 organs (25%) -3 or more organs (42%)	48 [21.9-107.5]

Abbreviations: ND: no data

Main features of the patients with IgG4-RD in series of more than 100 patients and in current series



of the disease. Therefore, regrettably IgG4 related disease continues underdiagnosed. The purpose of this study is to evaluate the clinical characteristics of patients diagnosed with IgG4-RD in a single University Hospital as well as to compare it with other large series.

Methods: Study of patients from a referral hospital and literature review of cases diagnosed with IgG4-RD. Diagnosis was made accordingly to these criteria**: a)** Okazaki; **b)** Umehara; **c)** ACR/EULAR 2020; and/or **d)** clinical, laboratory and imaging suggestive findings **(ref. 1-3)**. For the literature review, we searched PubMed and the Cochrane library from its inception until 30 April 2023, selecting those series with the largest number of patients

Results: We include 12 patients (8 females/4 males) (mean±SD age; 62.4±15.5 years) diagnosed with IgG4-RD. The organs affected at diagnosis were: aorta (n=5), pleura/lung (n=5), lymph nodes (n=4), salivary glands (n=2), retroperitoneum (n=2), pericardium (n=2), lacrimal glands (n=1), bile duct (n=1), kidney (n=1), orbit (n=1), subglottis (n=1), mesentery (n=1), maxillary sinuses (n=1). IgG4 values were increased in 2 (17%) patients (median [IQR]; 250.5 [201.0-300.1] mg/dL) (normal value < 135 mg/dL). Blood plasmablasts were increased in 8 (67%) patients (median; 808 [767-1152] cells/mL) (normal values < 653 cells/mL). In the literature review, 6 series of more than 100 patients each were selected. The main data from the different series are listed in **table**. The **figure** shows the most frequently affected organs in the different series. The pancreas was one of the most frequently involved. In contrast, in our series, aortic involvement and lung/pleura were the most frequent.

Conclusion: IgG4-RD is a very heterogeneous disease with involvement of virtually every organ of the anatomy, usually presenting with involvement of more than one organ. Despite the name of the entity, serum IgG4 is not always elevated.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

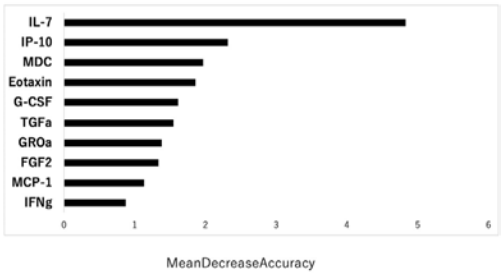
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyositis/Dermatomyositis (PM/DM) is a chronic inflammatory disease characterized by muscle weakness, and cutaneous manifestations. Although PM/DM exhibits distinct disease phenotypes based on autoantibodies, assessing the severity of muscular symptoms and predicting prognosis solely through autoantibody analysis remains challenging. The aim of this study is to identify potential biomarkers associated with muscle damage in patients with PM/DM.

Methods: This study employed a cross-sectional design to investigate a cohort of patients diagnosed with PM/DM. The initial screening involved a total of 150 PM/DM patients who had visited the Department of Immunology and Rheumatology, and the Department of Respiratory Medicine at Nagasaki University Hospital between August 2008 and June 2021, and had serum samples available for analysis. To assess muscle involvement, bilateral thigh muscles were evaluated using an MRI scoring system described by Andresson et al. Two radiologists independently conducted the scoring process. Serum cytokine levels were measured using a 43-item bead array in both the PM/DM patient group and a control group consisting of 101 healthy subjects from the residents of Saza in Nagasaki prefecture.

Exclusion criteria encompassed cases without disease activity, those complicated by rapidly progressive interstitial pneumonia, or those with underlying malignancies. Ultimately, a total of 43 patients were included in the study, as their femoral MRI images were available for analysis alongside the collected serum samples. Furthermore, an investigation involving immunostaining of muscles obtained from mice with C protein-induced myositis, as previously reported by Sugihara et al., was conducted to identify potential biomarkers.

Figure. 1



Results: Out of the total of 43 cytokines examined, 38 cytokines were deemed appropriate for further analysis. Through RandomForest analysis, it was determined that Interleukin (IL) -7, among the cytokines studied, exhibited the highest significance in distinguishing between the two groups categorized by median MRI score (Figure 1). Moreover, patients with elevated MRI scores exhibited significantly higher levels of serum IL-7 compared to healthy individuals. Correlation analysis revealed a correlation coefficient of 0.3551 (p=0.019) between MRI score and IL-7. Immunohistochemical assessment of muscle tissues in mice with C protein-induced myositis showed the expression of IL-7 and IL-7 receptor on infiltrating mononuclear cells in the muscles.

Conclusion: Our findings indicate that IL-7 can be as a reliable indicator of muscle damage. Assessing IL-7 levels has the potential to serve as a biomarker for predicting muscle damage in patients with PM/DM, particularly when combined with the measurement of other cytokines.

Presentations and Outcomes of Idiopathic Inflammatory Myopathies in Hong Kong

Iris Tang[1], Ho So[2], Teresa Ii[3], Vivian Tang[4], Chi Ho[5] and Roy Ho[6], [1]Department of Medicine, University of Hong Kong, Hong Kong, Hong Kong, [2]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [3]Queen Mary Hospital, Hong Kong, Hong Kong, [4]North District Hospital, Hong Kong, Hong Kong, [5]Alice Ho Miu Ling Nethersole Hospital, Hong Kong, Hong Kong, [6]Queen Elizabeth Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of heterogeneous autoimmune diseases with cutaneous, musculoskeletal, and systemic involvements. The Hong Kong Myositis Registry (MyoHK) was established to collect longitudinal data on Hong Kong adult IIM patients to enhance our knowledge on the clinical courses and prognosis in IIM.

Methods: This was a retrospective multicentre cohort. Consecutive adult IIM patients followed up in 7 rheumatology centers in Hong Kong were reported voluntarily to the MyoHK registry from January 2018 to May 2023. Additional IIM patients were identified by the Clinical Data retrieval system. Electronic patient records were reviewed. Demographics, clinical data, myositis-specific antibodies (MSAs) and mortality were documented.

Results: 456 patients were included with a mean age at diagnosis of 53.9 ± 13.5 years and 71.1% were female. The median follow-up duration was 72 months (IQR 37-148.8). The most common clinical subtype was dermatomyositis (39.9%), followed by polymyositis (36.4%) and amyopathic dermatomyositis (21.9%). 330 (77.5%) had at least one positive MSA. Anti-melanoma-differentiation-associated gene 5 (Anti-MDA5) and anti-Jo1 were the most prevalent MSAs, both identified in 58 patients (12.7%), followed by anti-transcription-intermediary-factor-1-gamma (Anti-TIF1g) (12.3%) and non-Jo-1

Table 1. Frequencies of different clinical manifestations of Idiopathic Inflammatory Myopathies

Table 1. Frequencies of different clinical manifestations of Idiopathic Inflammatory Myopathies

Clinical manifestations	No of Patients (%)	Clinical manifestations	No of Patients (%)
Weakness	323 (70.8%)	Mechanic Hands	65 (14.0%)
Skin Rash	284 (62.3%)	Raynaud phenomenon	70 (15.4%)

NXP2	10 (2.2%)	/	/	ILD	0.220 (0.058 – 0.842)
SAE	7 (1.5%)	Cancer	4.739 (1.157 – 19.412)	/	/

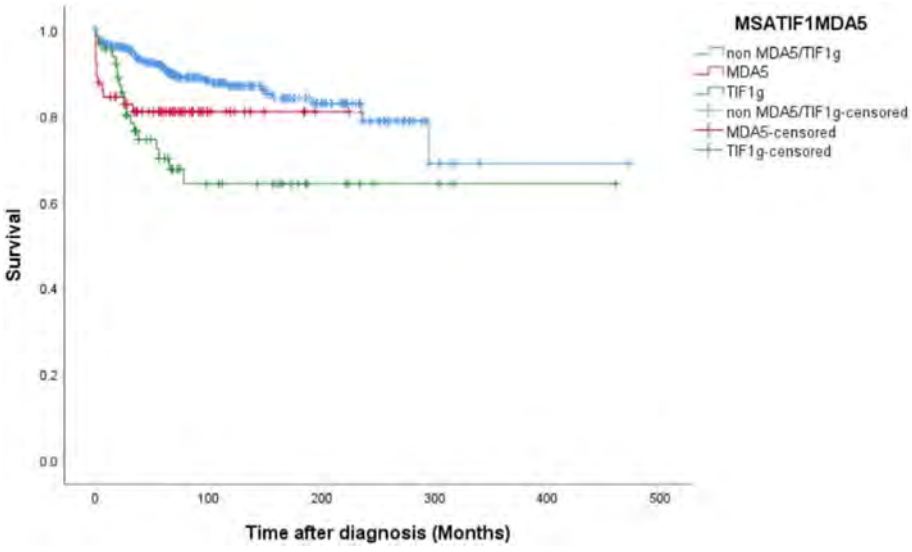

Figure 1. Kaplan-Meier curve of survival of anti-MDA5 antibody positive, anti-TIF1g antibody positive and the rest of IIM patients

anti-tRNA-synthetase antibodies (11.8%). Interstitial lung diseases (ILD) affected 55% of IIM patients, of which 39 patients (8.6%) had rapidly progressive ILD (RP-ILD). Cancer occurred in 84 patients (18.4%), with Nasopharyngeal cancer and lung cancer accounting for 22.6% and 20.2% of all malignancies respectively. Mortality was reported in 74 IIM patients (16.2%) with 22 (4.8%) reported within 6 months of IIM diagnosis. The leading causes of overall mortality were infection (25.6%), malignancies (23.0%) and respiratory failure (18.9%), whereas respiratory failure accounted for 40.9% of deaths occurring within six months of IIM diagnosis. The presence of anti-Jo1 [OR 7.92 (95% CI 2.62-23.95)] and non-Jo1 anti-synthetase MSAs [OR 4.50 (95% 2.24-9.02)] were associated with the development of ILD, whereas anti-MDA5 was associated with RP-ILD [OR 9.46 (95%CI 2.44-36.75)]. Anti-TIF1g [OR 4.16 (95%CI 1.73-9.96)] and anti-SAE [OR 4.74 (95%CI 2.25-9.02)] were associated with malignancy. Tables 1 &2 summarized the clinical manifestations and association with MSAs. Cox regression analysis confirmed older age [HR 1.09 (95% CI 1.06 – 1.11)], RP-ILD [HR 5.79 (95% CI 2.77 – 12.10)], and cancer [HR 3.85 (95% CI 2.19 – 6.77)] to be independent predictors of mortality while anti-MDA5 tended to associate with mortality [HR 1.98(95% CI 0.96 – 4.12)]. Multivariate analysis revealed RP-ILD [HR 7.59 (95% CI 1.77 – 32.53)], MDA5 positivity [HR 5.06 (95% CI 1.05 – 24.24)] and age at diagnosis [HR 1.06 (95% CI 1.00 – 1.13)] were associated with mortality within 6 months of diagnosis. Figure 1 showed the survival between anti-MDA5, anti-TIF1g and rest of IIM patients.

Conclusion: Anti-MDA5 and anti-Jo1 antibodies are the commonest MSA among Hong Kong IIM patients. Older age, presence of cancer and RP-ILD were predictors of mortality. Anti-MDA5 was associated with early mortality.

Experience of Pain in Adults with Idiopathic Inflammatory Myopathies, Myositis

Helene Alexanderson[1], Masoumeh Tasaroffi[2], Henrik Pettersson[3] and Malin Regardt[3], [1]Karolinska Institutet, Stockholm, Sweden, [2]Danderyds Hospital, Stockholm, Sweden, [3]Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Knowledge of pain in myositis is limited. Recent research suggest that pain is a common symptom in adults with myositis and deemed as one of the most important symptoms to assess in clinical trials and clinical care[1]. The aim of this study was to explore experience of pain in adults with myositis.

Methods: Informants were strategically identified to represent women and men, various age, myositis-diagnosis, diagnosis duration and self-reported pain (≥ 30 mm VAS). 10 adults with polymyositis (n=5), dermatomyositis, (n=3), and antisynthetase syndrome (n=2), 6 women, age range 24-68 years, participated in an individual interview. A semi-structured interview guide was used. Interviews were audiotaped and transcribed verbatim and analyzed by inductive qualitative content analysis. Briefly, transcripts were read by MT,HA separately, identifying meaning bearing units and discussed until consensus, developing condensates, codes and categories. Data were triangulated until consensus (HA,MR,HP).

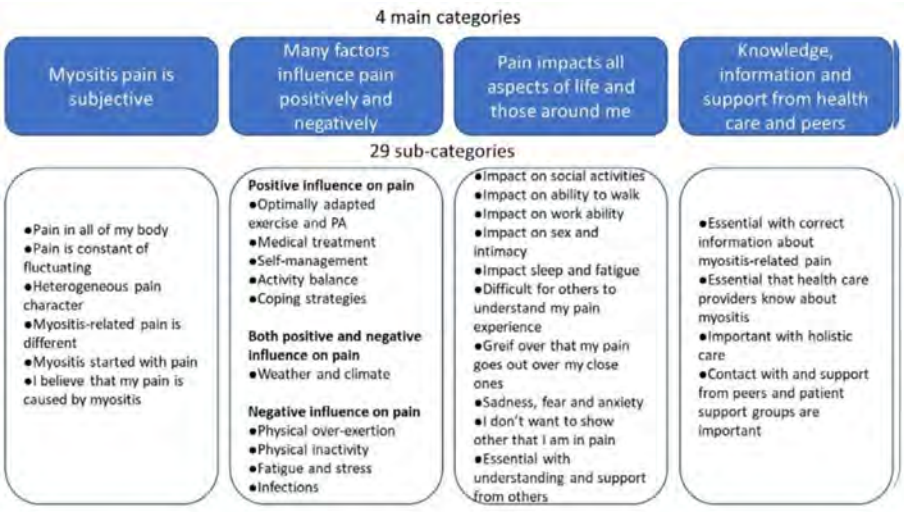

Figure 1. Main categories and sub-categories identified from qualitative content analysis.

Results: Four main categories and 29 sub-categories were identified (Figure 1). Main categories: **1. Myositis pain is subjective***(example codes: Burning pain, tenderness and tensed muscles, Constant pain in my arms, Pain was first symptom of myositis.)***2. Factors influencing myositis positively and negatively***(Exercise reduce pain, Balancing activities and rest reduce pain, Be positive and happy and not focus on the pain, Prednisolone reduce pain, but pain return with tapering of dose,increased pain when I am inactive.)***3. Pain impacts all areas of my life and those around me***(Pain hinders family activities, Difficult to accept that sex no longer is part of my life, Pain reduces sleep quality, Sad that I feel like a burden to others.)***4. Knowledge, information and support from health-care and peers***(Lost a lot of time due to incorrect information, Listen to your doctor, Meet others with myositis for support and tips)*.

Conclusion: Pain is an important symptom in myositis affecting many aspects of life and family/friends. Myositis-related pain is heterogeneous as to character, localization, and duration. Although relieved by medical treatment and adapted exercise, pain can remain as a chronic symptom. Health-care professionals should ask patients about myositis-related pain, and address pain by adequate treatment and information.

Dermatomyositis Flares After COVID-19 Vaccination and/or SARS-CoV-2 Infection

Maximiliano Diaz Menindez[1], Megan Sullivan[2], Benjamin Wang[3], Andy Abril[3], Vikas Majithia[2], Ronald Butendieck[3], Colleen T. Ball[4] and Florentina Berianu[2], [1]Mayo Clinic, Phoenix, AZ, [2]Mayo Clinic Florida, Jacksonville, FL, [3]Mayo Clinic, Jacksonville, FL, [4]Mayo Clinic Jacksonville, Jacksonville, FL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is an autoimmune disorder part of the group of idiopathic inflammatory myopathies. It is characterized by proximal muscle weakness and skin involvement. Part of the diagnosis includes clinical features, muscle biopsy, electromyography, myositis specific antibodies and laboratory findings. We have seen an association of active DM disease (either new diagnosis or relapse of previously controlled disease) after COVID-19 infection and vaccination. The first cases reported in the literature were by Gokhale et al., who reported 5 cases in India. Other studies have seen a correlation between the vaccine and the positivity of anti-MDA5 antibodies.

Our study aimed to observe the characteristics of a DM cohort after COVID-19 infection and vaccination.

Methods: A retrospective chart review was performed on patients treated between March 1, 2020, and October 31, 2022, for DM. New DM diagnosis or relapse of preexisting DM symptoms following either SARS-CoV-2 infection or COVID-19 vaccination was documented as active DM disease. Qualifying DM symptoms included characteristic rash, muscle weakness, and increased creatine kinase.

For the analysis of our primary aim, we estimated the proportion of patients who had active DM symptoms within 4 weeks after COVID-19 infection or vaccination; a two-sided 95% confidence interval for the single proportion was estimated using the score method. In an exploratory analysis we reported the number and percentage of patients who developed active DM symptoms within 4 weeks following COVID-19 infection or vaccination according to patient characteristics where continuous characteristics were categorized according to the sample median.

Results: 101 patients were treated for DM at our institution in the Division of Rheumatology. 15/101 patients (14.9%) had symptoms related to DM (relapse or new diagnosis) following SARS-COV-2 infection or vaccination. Three (3.0%) patients developed symptoms both with vaccination and infection, 10 (9.9%) patients developed symptoms post SARS-COV-2 infection and 8 (7.9%) developed symptoms post COVID-19 vaccination.

14/15 (93.3%) patients had a positive myositis antibody (see Figure 1). The ten patients who presented with symptoms post infection had a younger mean age of 50 compared to 62 in patients without a flare post infection (p=0.047) (see Table 1).

Of those who developed symptoms post-vaccination (3 patients had symptoms following both infection and vaccination), demographics and vaccine type are presented in Table 2.

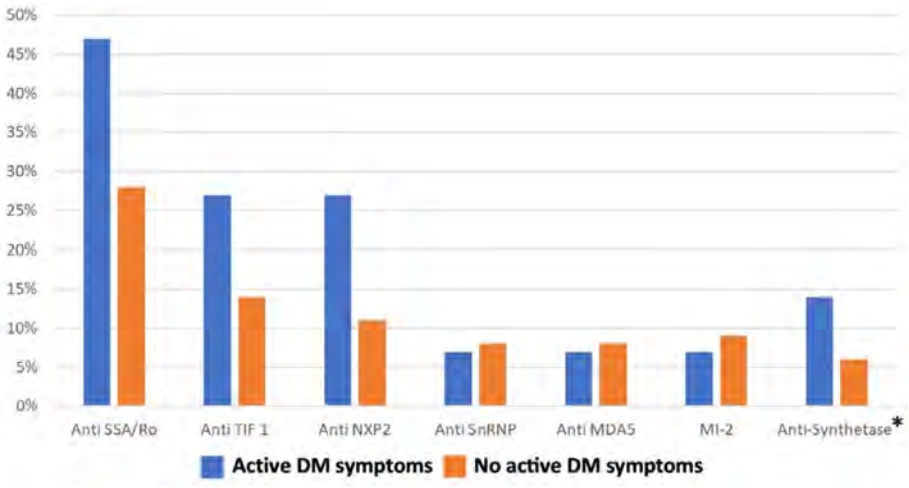

Figure 1. Percentage of positive antibodies in patients with or without active DM symptoms after infection / vaccination * Anti-Synthetase included anti-Jo-1, anti-PL-7, anti-PL-12, anti-OJ, anti-EJ, anti-KS, anti-SRP, anti-Zo, anti-HA, and anti-Ku

The mean onset of symptoms following SARS-COV-2 infection was 2.6 days with a median of 1 (Q1: 0; Q3: 5) and following COVID-19 vaccination was 1.38 days, median of 1 (Q1: 0.5; Q3: 2).

Conclusion: This retrospective study revealed a strong temporal relationship between DM symptoms and Covid-19 infection or vaccination in 14.9% of all DM patients evaluated in our clinic during the pandemic. The higher prevalence of NXP2 in our cohort is unique from prior reports. Additional studies are required to understand the possible pathophysiology behind this association.

Expanded Cytotoxic CD8+ T Cell Clones Characterize the Blood of Inclusion Body Myositis Patients

Miriam Fein[1], Laura Donlin[1], David Fernandez[1] and **Lorien Shakib**[2], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Inclusion body myositis (IBM) is an inflammatory myopathy, characterized by CD8+ T cell infiltration of muscle and patients present with progressive muscle weakness and atrophy, leading to disability due to no FDA-approved therapies. Patients with IBM have been noted to frequently exhibit aberrant expansion of circulating CD8+ T cells, even satisfying classification criteria for T cell large granular lymphocytic leukemia (T-LGL) in >50% of cases, in one study. However, high-resolution profiling of the transcriptome and TCR repertoire in IBM are lacking.

We aim to evaluate the TCR repertoire of circulatory CD8+ T cells, allowing us to simultaneously define the transcriptomes of expanded and non-expanded clonotypes in blood of IBM patients.

Methods: 12 IBM patients and 8 age-matched healthy controls were sorted for non-naïve CD8+ T cells by flow cytometry. Single-cell RNA and TCR sequencing was performed to profile the whole gene expression, coupled with paired TCRa and TCRb chains, at single-cell resolution. Additional markers during flow cytometry allowed for further identification of aberrant populations in IBM compared to age-matched healthy controls.

Results: Our results found IBM CD8+ T cell were highly expanded compared to age-matched healthy controls. These CD8+ T cells were identified in both the broad non-naïve T cell population, as well as the specific CD8+ CD57+ T cell subset. Enrichment of T-LGL leukemia genes, in addition to CD8+ effector function, cytotoxicity and inflammatory chemokines and cytokines were found in expanded clonotypes, with a higher gene expression found in hyperexpanded clones compared to minimally expanded clonotypes. Absence of common TCR clonotypes between patients in IBM was found, a pattern also seen in T-LGL leukemia. GSEA analysis also confirmed a downregulation of cell apoptosis processes in hyperexpanded clonotypes, a feature of T-LGL leukemia clones.

Conclusion: Significant clonal expansion of CD8+ T cells in the blood was found in our IBM cohort compared to our age-matched healthy controls. Additionally, these hyperexpanded clonotypes have elevated cytotoxic and T cell activation genes in comparison to their minimally expanded counterparts. These results highlight how the blood compartment of IBM, a progressive muscle disease, is important in IBM and how future studies and therapies should be targeting these aberrant CD8+ T cell clones.

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: IIM-ILD follows a varied clinical course. Serological profile can help predict clinical phenotype, but impact on ILD prognosis is less clear. This multicentre UK cohort study examines whether serological profile can predict mortality and change in lung function over time.

Methods: Patients with IIM-ILD were identified in 3 NHS trusts from local databases. Adults with ILD meeting IIM diagnostic criteria or Interstitial Pneumonia with Autoimmune Features (IPAF) with Myositis Specific Antibodies (MSA) were included. Baseline characteristics from time of presentation were compared across antibody groups and across survivors/deceased at 2 years. Survival analysis looking at time to death (or lung transplant) for duration of available follow-up was modelled by Cox-Proportional Hazards comparing each antibody individually to all others. Models were adjusted for age, gender,

Antibody	Number of patients	Number Reaching End Point	Univariate Model HR	Univariate Model p value	Multivariate Model HR	Multivariate Model p value

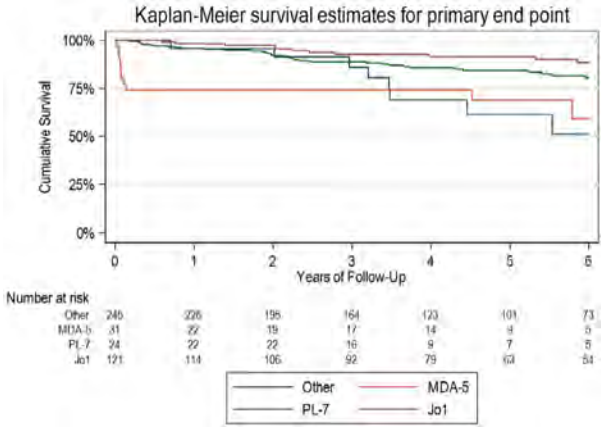
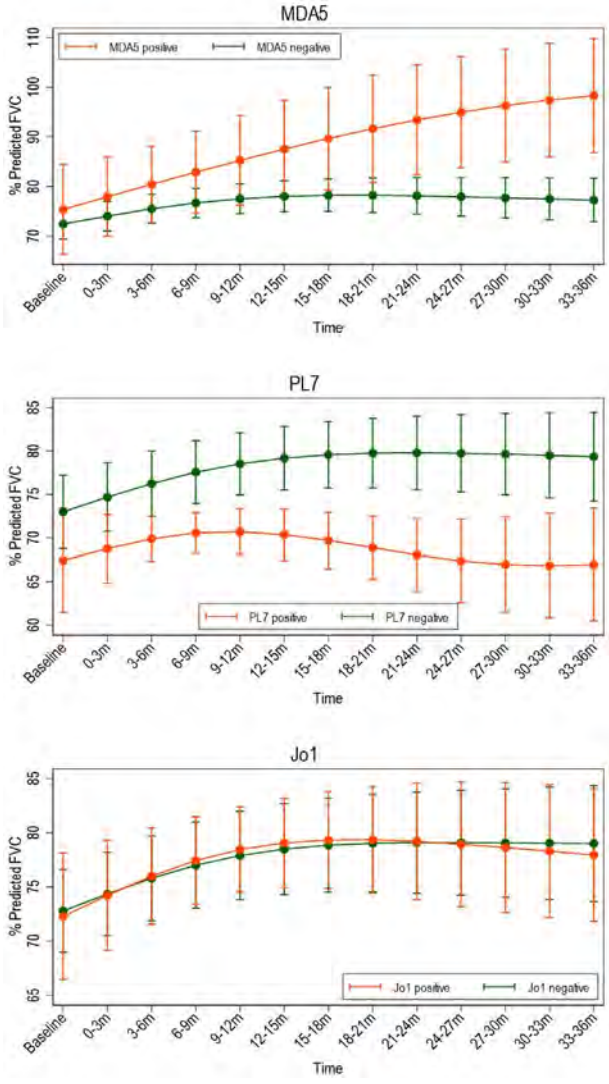
Univariate and multivariate hazard ratios for primary endpoint of death/transplant according to presence or absence of each antibody. Statistically significant results are in bold type. *Counts of <5 suppressed to maintain anonymity



Kaplan-Meier survival curves for death/transplant according to antibody for the three antibodies showing statistically significant differences in survival on both univariate and multivariate analysis



Time trends in % predicted FVC in a) MDA5, b) PL7, and c) Jo1 using multi-level mixed effects models for repeated measures over time, showing slow improvement in MDA-5 FVC, whereas PL-7 deteriorates.

ethnicity, presence of overlap CTD/malignancy, smoking and site. Regression models were also used to observe trends in lung function parameters over time.

Results: Of 430 included patients, 68% were female, 46% were of White ethnicity. 81% met IIM criteria, 19% were IPAF. Mean follow up duration was 4.3 years. Common antibodies were to Ro52, Jo1, PL12, MDA5 (n=195, 126, 44 & 32 respectively). 10% had evidence of pulmonary hypertension within 1 year of diagnosis, 4% had malignancy within 3 years. Baseline characteristics of survivors vs fatal cases at 2 years showed survivors were younger (51.4 vs 61.7 years), more likely to have never smoked (69% vs 44%), less likely to have been hospitalised at diagnosis (15% vs 52%) and had a lower Charleson Comorbidity Index. Survivors had lower CRP, higher CK & higher baseline FEV1/FVC/TLCO. Imbalance in age, BMI, CK and comorbidity status were seen across antibody groups. MDA5 had the highest adjusted hazard ratio (HR) for mortality of 4.59 (95%CI 2.10-10.01). Kaplan-Meier curve shows high early mortality in this group. Anti-synthetase antibodies (ARS) carried a reduced risk of mortality (HR 0.63), however individually Jo1 had low HR (0.61, 95%CI 0.4-0.87) and PL7 had high HR (2.07, 95%CI 1.44-2.99). RNP showed worse prognosis on adjusted analysis (HR 1.88, 95%CI 1.25-2.84) (Table 1). Regression models suggest that compared to other antibodies, %pred FVC in MDA5 improves over the first 3 years, in PL7 it drops, and in Jo1 it is no different (Figure 1). MDA5 % pred FEV1 also showed improvement, but in Ku it was lower than other antibodies from 21 months. There were no significant differences in % pred TLCO between antibodies.

Conclusion: There is strong evidence that antibody status associates with clinical outcomes, both in terms of progression of lung disease and mortality, suggesting pathogenetic differences. MDA5 predicts a high risk of death early on in disease course, whilst Jo1 associates with lower mortality. PL7 and RNP were additional antibodies associating with higher mortality. Difference between Jo1 and PL7 highlights variation within anti-synthetase syndrome. Paradoxically, if an MDA5 positive person survived the early disease phase, there was evidence that lung function can recover, which may reflect different MDA5 subpopulations.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is an autoimmune myopathy responsible for muscle weakness associated with decreased quality of life and increased mortality. DM muscular histology is characterized by specific lesions of perifascicular fibers consisting of atrophy, type I interferon (IFN-I) signature, expression of major histocompatibility complex class I (MHC-I) and mitochondrial dysfunctions (1). The origin of these lesions is not understood. Current treatments are empirical, partially effective, expose to a risk of side effects and present a high rate of relapse upon discontinuation. The objective of the study was to identify innovative therapeutic strategies for DM, based on the identification of the molecular pathways that underlie perifascicular fibers lesions and the repositioning of drugs already approved in humans.

Methods: To reveal the molecular pathways underlying DM perifascicular fibers lesions, perifascicular and endofascicular fibers from muscle biopsy of 19 patients with recent and untreated myositis (DM, other myositis) or without myopathy were microdissected by laser, their transcriptome was established by RNA sequencing and analyzed by bioinformatic methods. To identify innovative therapeutic strategies based both on DM pathophysiological mechanisms and on existing drugs, the transcriptomic signature specific to DM perifascicular fibers obtained by microdissection experiments was used for a drug repositioning analysis as described by Karatzas et al. (2). To validate the predications obtained, the effect of drug candidates already used in humans was tested in *in vitro* and *in vivo* preclinical models: in 1) cultured human muscle cells treated with IFN-β and in 2) a mouse model of myositis experimentally induced by immunization against skeletal muscle fast-type C protein.

Results: Transcriptomic analysis of patient's muscle fibers combined with topographic information (perifascicular VS endofascicular localization) revealed that a proteasome deregulation predominant in the perifascicular fibers is a hallmark of DM. The integration of 3 computer databases of drug repositioning allowed the identification of 9 molecules predicted to reverse the pathological signature of the DM perifascicular fibers. The drug with the highest therapeutic potential was a proteasome inhibitor (Ixazomib). A second proteasome inhibitor (MG-132) was also identified. 2 drugs already used for DM (prednisolone and a JAK inhibitor) was identified with a lower therapeutic score. In the cellular model (human myotubes treated with IFN-I), ixazomib reversed the atrophy, IFN-I signature, MHC-I expression and mitochondrial dysfunctions induced by IFN-β treatment. In the mouse model of myositis, ixazomib restored muscle strength and decreased blood creatine kinase level.

Conclusion: Proteasome inhibition could be a new effective therapeutic strategy for DM.

Serial Imaging Changes in Skeletal Muscle Composition and Their Association with Clinical Outcomes in Idiopathic Inflammatory Myopathies

Mamatha Gorijavolu[1], Chengappa Kavadichanda[1], Ramesh Ananthakrishnan[1], Christina Mariaselvam[1], Molly Thabah[1] and VS Negi[2], [1]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, [2]All India Institute of Medical Sciences, Bilaspur, Puducherry, India

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Muscle weakness in inflammatory myopathies (IIM) is due to muscle-edema, atrophy and fatty-infiltration among which edema is the predominant cause at baseline. Some IIM pateints do not achieve full muscle power even with immunosupressive treatment which mainly targets edema. Serial changes occuring in skeletal muscles visualized on thigh MRI can help understand the failure of complete recovery. Role of Dual energy X-ray Absorptiometry (DXA) assessed skeletal muscle compositon as outcome measure in IIM was not studied previously.

Objectives: To see the changes in skeletal muscle composition over 6 months in IIM patients using imaging and to assess the agreement of MRI and DXA scores with each other and with clinical outcome measures

Methods: Patients satisfying 2017 ACR-EULAR classification criteria for IIM were prospectively enrolled. All patients underwent thigh MRI(t-MRI) STIR and T1 weighted sequences (axial and coronal) at baseline, 3 and 6 months and DXA scan at baseline and 6 months. Manual muscle testing-8(MMT-8), Functional index-3(FI-3), 2-minute walk distance (2MWD) were

assessed at baseline, 3 and 6 months. t-MRI was scored using a semi-quantitative score for muscle edema, fascial edema, muscle atrophy and fatty infiltration. Friedman test was used to compare variables at baseline, 3 and 6 months and Spearman correlation was done for agreement of MRI and DXA scores with each other and clinical outcome measures.

Results: 17 patients (12 females) were enrolled and all of them completed 3-months follow-up while only 13 completed 6-months follow-up. Median (IQR) age was 38 (27-46) years, disease duration was 6 (2-24). The study group comprised of 10 dermatomyositis, 5 antisynthetase syndrome and 3 immune mediated necrotizing myopathy patients MRI assessed muscle-edema and fascial-edema decreased significantly and fatty-infiltration increased significantly ($p < 0.01$) from baseline to 3-months. Muscle atrophy showed no change. Improvement in MMT-8 and 2MWD was significant between baseline and 3-months($p< 0.001$) whereas FI-3 continued to improve till 6-months($p< 0.001$) (Table 1). At baseline MMT-8($r=-0.631$; $p< 0.01$), FI-3($r=-0.698$; $p< 0.01$) and 2MWD ($R=-0.485$; $p< 0.05$) negatively correlated with only muscle edema. At 3-months MMT-8 and 2MWD negatively correlated with muscle-edema ($r=-0.673$, $r=-0.591$), atrophy ($r=-0.732$, $r=-0.577$) and fatty-infiltration ($r=-0.575$, $r=-0.743$) ($p< 0.05$) respectively (table 2). MRI fatty-infiltration score and atrophy score did not correlate with DXA assessed leg fat percentage and appendicular mass/ht2 respectively at baseline but had significant correlation ($p< 0.05$) at 6- months (Figure 1).

Conclusion: In IIM, edema decreased but fatty infiltration increased significantly in first 3-months. DXA assessment of fat and lean mass did not agree with MRI atrophy and fatty infiltration at baseline probably due to concomitant muscle edema.

Anti-melanoma Differentiation Associated Gene 5 (Anti-MDA5) Antibody Dermatomyositis: Clinical Features and Outcome in a Racially Diverse Patient Cohort

Sai Koyoda[1], Dawn Wahezi[2], Xianhong Xie[3], Anand Kumthekar[4], Clement Tagoe[3] and **Bibi Ayesha**[5], [1]Essen Medical Center, Rahway, NJ, [2]Children's Hospital at Montefiore, New Rochelle, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [5]Montefiore Medical Center, Bronx, NY

SESSION INFORMATION

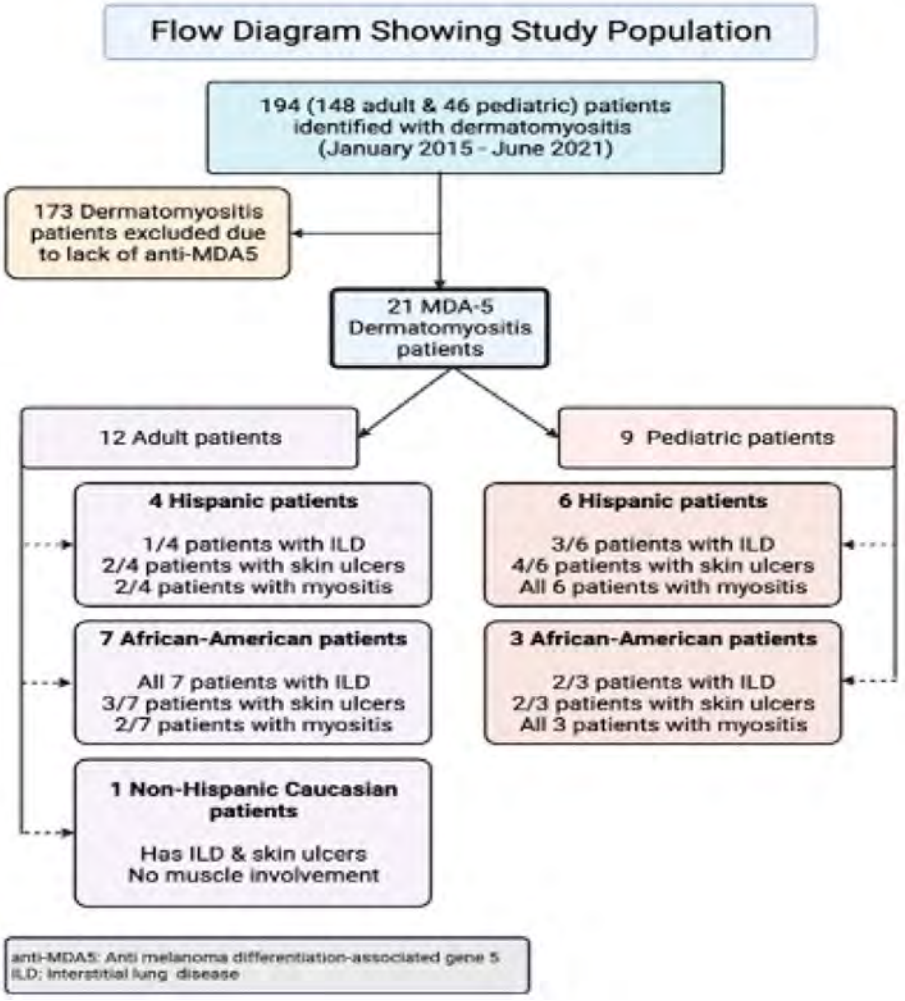
Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-melanoma differentiation-associated gene 5 (anti-MDA5) antibody dermatomyositis typically expresses rapidly progressing interstitial lung disease (RP-ILD) and ulcerative skin lesions, with or without muscle involvement. There is a lack of understanding on early diagnosis and treatment to avoid untoward outcomes. Our objective was



Flow Diagram Showing Study Population

Ulcerative Skin Lesion in MDA-5 Dermatomyositis

to identify distinguishing clinical and laboratory features to assess disease progression amongst a diverse cohort with anti-MDA5 dermatomyositis based on serologic, histopathologic, and radiographic status.

Methods: We studied the disease phenotype in a racially diverse juvenile and adult population with anti-MDA5 dermatomyositis at our institution through a retrospective chart review. We identified 194 dermatomyositis patients, 21 of whom were MDA5 antibody positive. Data were analyzed by Fischer's exact test and ANOVA.

Results: Twelve adult patients represented 8% of all adult dermatomyositis cases (12/148) and 9 represented 19 % of the pediatric dermatomyositis cases (9/46). In adult patients, the mean age of disease onset was 45.2 years (SD 14.4 years). Nine adult ILD cases were noted, of which 2 were RP-ILD. The presence of the Ro52 antibody was associated with rapid disease progression. In the pediatric group, the mean age of onset was 6.6 years (SD 4.9 years). All children had muscle weakness, and 5 had ILD. Myositis was noted to be more prevalent in the pediatric population, compared to adults respectively (9/9 Vs. 4/12 cases; p=0.05). ILD was statistically significant in the African American population (9/10 Vs. 5/11 cases, p=0.03) and of these 3 cases had fatal RP-ILD. The combined mortality rate of 14.2% was more favorable than the 40-60% reported in the literature.

Conclusion: The general disease characteristics of our cohort were similar in both adult and pediatric patients except for myositis, which was more common in the pediatric population. The incidence of ILD was higher in adults, especially in the African American population who had worse outcomes. The rapid escalation of therapy and use of rituximab may have improved our outcomes over historic controls.

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune-mediated myopathies (IMM) are a heterogeneous group of diseases characterized by inflammation and muscle weakness; among their differential diagnoses are the dysferlinopathies, which are autosomal recessive neuromuscular disorders caused by mutations in the DYSF gene that present muscle weakness and significant increase of CK, just like IMM. The aim of this research is to determine the sonographic differences between dysferlinopathies and immune-mediated myopathies and whether these allow their classification.

Methods: Observational, cross-sectional, and analytical study in which we evaluated 20 muscles from 11 patients with dysferlinopathies and 11 with IMM. They were matched for age, sex, and time of disease evolution. Clinical and laboratory variables were analyzed. GE LOGIQ^{TM}e equipment with a 4-12 MHz linear transducer was used, and the thickness of each muscle was measured. A semiquantitative scale evaluated elementary lesions: atrophy, edema, power Doppler, and the Heckmatt scale (0-4) was calculated. Descriptive statistics were performed. Finally, discriminant analysis was performed to determine which ultrasound variables best predicted the diagnoses.

Table 1. Characterization of patients with dysferlinopathies and inflammatory myopathies

	Dysferlinopathies n=11	IMM n=11	
General characteristics			*p
Women	9 (81.8%)	9 (81.8%)	
Males	2 (18.18%)	2 (18.18%)	
Ages (years)	39.54±11.24	37.36±10.62	.971
Evolution (years)	16±8.43	16.55±8.25	.852

Laborstories			
CK (mcg/L)	2785.50 (1052.75-4378.75)	162.00 (72.00-311.00)	.000
LDH (U/L)	289.00 (192.00-411.75)	170.00 (156.00-196.00)	.001
TGO (U/L)	52.75 (42.25-71.55)	25.30 (16.90-29.70)	.011
TGP (U/L)	78.30 (64.90-113.80)	20.10 (15.50-28.00)	.016
Muscle size			
BB (cm)	1.67±0.63	2.76±0.49	*<0.0001*
CD (cm)	2.70±0.84	3.45±0.87	*.040*
GC (cm)	1.88±0.42	3.16±0.42	***<0.001***
Discriminant analysis	Function	Function	**CP
BB	7.434	13.926	≤2.44
CD	-1.117	-4.250	≤2.72
GC	13.489	25.399	≤2.29
Constant	-18.051	-52.935	

- Group 1: -18.051+7.434(B/B)+1.117(CD)+13.489(GC)
- Group 2: -52.953+13.926(B/B)-4.250(CD)+25.399(GC)

Results: A total of 40 muscles were evaluated, finding a greater degree of atrophy and a higher Heckmatt scale in patients with dysferlinopathies compared to MII (Table 1). Discriminant analysis showed that the set of 3 muscles, Right biceps/brachialis (BB), Right quadriceps (CD), and Gastrocnemius/right soleus (GC), had a diagnostic accuracy of 100% (sensitivity 100%, specificity 100%, canonical coefficient 0.733 p=.000). We present a set of 2 formulas that allow classifying with the highest score according to the measurement of the muscles in group 1 (dysferlinopathy) or group 2 (MII). Finally, a COR analysis was performed to determine the cut-off points of each muscle to classify as dysferlinopathies.

Conclusion: The study of 3 muscle groups (BB, CD, GC) presents high diagnostic accuracy in differentiating dysferlinopathies from MII, especially when no genetic study or antibodies are available and diagnostic doubt exists.

Long-term Changes in Lung Function in Melanoma Differentiation-associated Protein 5 (MDA5) Antibody Positive Dermatomyositis Patients: Experience of a Single Center Longitudinal Cohort in North America

Jenice Cheah[1], Sangmee Bae[2], Tiffany De Leon[2], Yuna Lee[1] and Christina Charles-Schoeman[3], [1]University of California Los Angeles, Los Angeles, CA, [2]UCLA Rheumatology, Los Angeles, CA, [3]UCLA Medical Center, Santa Monica, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) associated with antibodies to melanoma differentiation-associated protein 5 (MDA5 ab) in patients with dermatomyositis (DM) has been associated with a rapid decline in lung function and high mortality early in disease. The current work evaluated long-term changes in lung function in a longitudinal MDA5 ab positive DM cohort in North America.

Methods: We identified DM patients with MDA5 ab in a single center longitudinal cohort of 355 adult patients with idiopathic inflammatory myopathies (IIM). Patient clinical characteristics and longitudinal pulmonary function tests (PFT), echocardiograms, and high-resolution computed tomography (HRCT) chest scan results were collected by chart review.

Results: 30 DM patients (8.5%) of the IIM cohort had confirmed positive MDA5 ab testing. The clinical characteristics of patients with ILD (n=24, 80%) and without ILD (n= 6, 20%) by HRCT are shown in Table 1. Patients without ILD were younger and more likely to present with inflammatory arthritis. Patients with ILD had an aggressive disease phenotype with 75% (22/24) requiring initial hospitalization. Two ILD patients died of rapidly progressive ILD within 3 months of cohort entry. ILD patients were treated predominantly with combination immunotherapy (Table 1) during longitudinal follow-up and remained on combination immunotherapy with 3.1 ± 1.3 (mean ± SD) individual therapies at the last follow-up visit available for this analysis. Non-ILD patients remained on a mean combination of 2.0 ± 1.3 therapies at the last follow-up visit (p =0.06 vs ILD group). 18 ILD patients had short-term (∼2 yr) follow-up PFT data available (1.8 ± 0.6 years from baseline PFT), and

10 ILD patients had both short-term (~2 yr) and long-term follow-up PFT data available (2.0 ± 0.6 and 6.8 ± 3.4 years from baseline PFT, respectively).In analysis of both cohorts, significant improvements in % predicted DLCOHg, FVC, and FEV1 were noted over time (Tables 2-3). In the long-term cohort, continued improvement in pulmonary function beyond the initial follow-up visit at ~2 years with progressive increases in % predicted DLCOHg, FEV1, and FVC at ~ 7 years were noted (Table 3).

Conclusion: A low mortality rate and significant improvements in pulmonary function over long-term follow-up were observed in a North American cohort of MDA5 ab positive patients with ILD treated predominantly with combination immunomodulatory therapy. These results emphasize the importance of early identification and aggressive treatment of MDA5 ab positive DM patients with ILD who may have reversible impairment in lung function.

Disease duration from baseline PFT to 2-year follow-up PFT = 2.0 ± 0.6 years (Mean ± SD).
Disease duration from baseline PFT to long-term follow-up PFT= 6.8 ± 3.4 years (Mean ±SD).

Patients with COVID-19 and Polymyositis Inpatient Outcomes and Hospital Cost: Nationwide Inpatient Sample 2020

Emily He[1] and Vaneet Sandhu[2], [1]Loma Linda University Health, Loma Linda, CA, [2]Loma Linda University, Loma Linda, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: During the COVID-19 pandemic, there were growing concerns regarding the impact of SARS-CoV-2 on not only patients with rheumatic diseases but also the national hospital system. Research from prior studies on rheumatic and musculoskeletal diseases have identified higher rates of COVID-19 infection and higher mortality rate on a global scale; however, there is scant information on the economic burden on patients and the hospital system. In our study, we aim to analyze the demographic trend and inpatient hospital impact in the United States among patients admitted with concomitant COVID-19 infection and polymyositis.

Methods: We used the National Inpatient Sample (NIS), which is the largest public inpatient database of community hospitals, from 2020 and extracted adult patients (age 18 years and older) with the principal diagnosis of COVID-19 and secondary diagnosis of polymyositis based on the International Classification Disease version 10 (ICD-10) codes. All diagnoses were weighted to be nationally representative. Demographic characteristics, length of stay, hospitalization cost, and co-morbidities were analyzed using STATA, version 17. Pearson chi-squared test was used to compare categorical variables and studentt-test was used to compare continuous variables. Multivariable logistic regression was used to compare mortality with p-value set at < 0.05 for statistical significance.

Results: 32,355,827 hospitalizations were included in the NIS 2020 database and 1,644,600 patients met our inclusion criteria. 365 patients with COVD-19 and polymyositis were admitted in 2020. Patients with COVID-19 as a primary diagnosis and polymyositis as a secondary diagnosis had a 1.98 times higher mortality than those with a diagnosis of COVID-19 alone (OR: 1.98, 95% CI: 1.15-3.42, p=0.01). COVID-19 cohort had average age of 63 years and 52.1% male compared to COVID-19 and polymyositis cohort who had average age of 62 years and 68.5% female. For COVID-19 patients, they were predominantly White, average hospital stay of 8days,and hospital cost $91,446. For COVID-19 and polymyositis cohort, they had a greater percentage of Black patients, predominantly female, average hospital stay of 8 days, and hospital cost $106,700. For co-morbidities, COVID-19 and polymyositis patients had a higher percentage of coronary artery disease and previous myocardial infarction (Table 1).

Conclusion: Both cohorts were predominantly treated at large teaching hospitals, approximate mean age of 60 years old, and over half of each cohort had hospital cost greater than their median household income. Despite these similarities between both groups, patients with pre-existing diagnosis of polymyositis with concomitant COVID-19 infection had almost double the inpatient mortality compared to patients who were hospitalized for COVID-19 alone. Our study highlights the importance of targeting at-risk patient demographics, particularly Black women who were more likely to be hospitalized for concomitant polymyositis and COVID-19 infection. This study not only augments prior research on inflammatory myopathy and COVID-19 infection, but also underlines the increased mortality risk and hospital cost in the American population.

Table 1: Baseline characteristics of COVID-19 patients with and without polymyositis

	COVID-19	COVID-19 and polymyositis	*p*-value

Transcriptome Analysis of Peripheral Blood Reveals Superiority of the Triple Combination of Baricitinib, Rituximab, and Tacrolimus Therapy (BRT-Tx.) for anti-MDA5 Antibody-positive Dermatomyositis (MDA5-DM)

Yoshinobu Koyama[1], Yoshiharu Sato[2], Yu Nakai[3] and Moe Tokunaga(Sakamoto)[3], [1]Japanese Red Cross Okayama Hospital, Okayama, Japan, [2]DNA Chip Research Inc, Tokyo, Japan, [3]Rheumatology, Center for Autoimmune diseases, Japanese Red Cross Okayama Hospital, Okayama, Japan

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: MDA5-DM is characterized by high mortality due to rapid progressive ILD. We reported that in MDA-5DM, (1) RIG-1-like receptor signaling is enhanced, (2) antiviral responses are also enhanced, and (3) the key for survival is suppression of RIG-I-like and IFN signaling (ACR2022, Oral 0508).Our experience with an autopsy case suggests that uncontrolled activation of macrophages may play a role in the etiology of ILD. Recently, it has been reported that tacrolimus (TAC) and cyclophosphamide (CY) combination therapy (TC-Tx) administered early in the course of the disease improved the prognosis, however, some cases could not be saved.

Therefore, we devised BRT therapy (BRT-Tx).The regimen of the treatment combines baricitinib (BAR), which inhibits GM-CSF and IFN signaling and effectively suppresses uncontrolled macrophages, with rituximab (RTX) and TAC, which rapidly inhibits B cell-T cell interaction and ultimately prevents anti-MDA5 antibody production. In this report, we determine the differences in gene expression between BRT- and TC-Tx for MDA5-DM patients in peripheral blood.

Methods: Transcriptome of peripheral blood from 6 MDA5-DM (TC: 3, BRT: 3) patients with multiple poor prognostic factors were analyzed. Differentially expressed genes (DEGs) were identified between pre- and 2-3 months after treatment. Geneontology (GO), clustering, and gene set variation analysis(GSVA) were performed for the DEGs. As one BRT case was added since our last year's presentation, we reanalyzed the difference between surviving and fatal cases. The IFN signature was scored separately for Types 1, 2, and 3, and the changes between pre- and post-treatment were investigated.

Results: Two of three cases with TC died during treatment, while all three cases on BRT recovered. Cluster analysis of DEGs separated fatal cases from survivors, not by the type of treatment. Comparing surviving and fatal cases, GO analysis revealed that the immune system via immunoglobulins and B cells was significantly suppressed in surviving cases. GO analysis of DEGs in each therapeutic group showed that expression of B cell-related genes were significantly suppressed after BRT-Tx. Meanwhile, TC-Tx significantly suppressed such pathways as cell proliferation, and was less specific for the target cells than BRT-Tx. The changes in IFN signature score after treatment showed an increase in type 2 and 3 IFN scores in all fatal cases and an increase in type 1 IFN score in one fatal case.

Conclusion: BRT-Tx significantly suppressed gene expression associated with B cells, while TC-Tx was characterized by low specificity of therapeutic targets. Comparison of surviving and fatal cases revealed that the combination of RTX was a key to success, as suppression of the immune system via immunoglobulins and B cells is the critical for survival. Analysis of the IFN signature revealed an increase in the IFN score after treatment in fatal cases, indicating that the combination of BAR is beneficial. The superiority of BRT-Tx seems clear from the fact that all patients survived while only one/three patients survived with TC therapy. This regimen is also superior to the existing TC regimen in terms of cytotoxicity and can become the standard of care in the future.

Evaluation of Agreement Between Functional and Radiological Changes in Idiopathic Inflammatory Myositis (IIM) Associated Interstitial Lung Disease (ILD)

Sonali Narain[1], Can Hu[2], Michael Liu[1], Himanshu Vashistha[1], Kourosh Shargani[3] and Galina Marder[1], [1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Fort Lee, NJ, [3]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: ILD is a major cause of morbidity and mortality in IIM. The diagnosis and progression of ILD often relies on high resolution computed tomography (HRCT) and pulmonary function tests (PFT). The goal of this study is to assess the agreement between functional and radiological changes longitudinally in patients with IIM-ILD.

Methods: This is a retrospective study on patients in the Northwell Myositis cohort. All patients met 2017 EULAR/ACR classification criteria for IIM. ILD diagnosis was identified by chart review and by presence of NSIP, COP/BOOP, UIP, and unspecified patterns on HRCT. We included 22 patients who had >2 corresponding HRCT and PFT, performed within 6 months of each other. Qualitative ILD patterns are reported using descriptive statistics.

Baseline FVC, FEV1, and DLCO values were collected, and percent changes were calculated for subsequent PFTs from baseline. Improvement or worsening was defined as ≥ 10% increase or decrease in 1 variable with no more than 5% decrease or increase in other variables. HRCT scans were categorized as improved, stable or worsened compared to the previous scan per radiologist assessment.

There were 65 matched HRCT/PFT pairs, ranging from 2 to 5 pairs per patient. Using initial HRCT and PFT as baseline, improvement, stability or worsening were assessed for 43 matched pairs using the above definition. Kappa statistics was calculated to measure the agreement between the changes seen on PFT versus HRCT.

Results: A total of 22 patients with median age of 57.5 years were included in the study. The average follow-up time was 5 years (range: 1-13years). The most common HRCT finding at baseline was bilateral groundglass opacities (77.3%, 17/22), followed by reticular opacities (36.4%, 8/22). The most common initial immunosuppressive agent in addition to steroid was mycophenolate mofetil (54.5%, 12/22), followed by methotrexate (18.2%, 4/22), azathioprine (9%, 2/22), and rituximab (9%, 2/22). Two patients received steroids alone and 1 patient declined treatment.

At baseline, mean FVC was 67% (SD:19. 3), mean FEV1 was 68.6% (SD:21.1), mean DLCO was 48.5% (SD:16.9). On PFT, 13.6% (3/22) patients worsened, 27.3% (6/22) were stable, and 59.1% (13/22) improved. On HRCT, 22.7% (5/22) patients worsened, 54.5% (12/22) were stable, 22.7% (5/22) improved.

Table 1 showed HRCT and PFT status change

		HRCT status		
		Worsened	Stable	Improved
Overall PFT status	Worsened	2	6	0
	Stable	3	10	2
	Improved	0	15	5

Agreement of improvement, stability or worsening for the follow-up pairs of HRCT and PFT is shown in Table 1. Kappa coefficient between these pairs was 0.071 (SE = 0.102, 95% CI -0.129 to 0.272), indicating poor agreement. When analysis was performed by combining improved and stable in one category, the coefficient marginally increased to 0.192 (SE = 0.181, 95% CI -0.129 to 0.272)

Conclusion: When comparing the agreement of HRCT and PFT to assess change in ILD status over time in this study, we found that more patients showed improvement on PFT than HRCT. While PFT was more likely to detect improvement, HRCT was more likely to document stability. The poor agreement between functional and radiological changes demonstrated in this study suggested the deficiency in current methods for monitoring ILD progression. More sensitive modalities are needed to detect change over time in patients with immune-mediated ILD.

All-cause Mortality and Risk Factors for Death in a Large Multi-center Prospective Registry Cohort of Idiopathic Inflammatory Myositis in China

Liying Peng[1], Peng Yin[2], Mucong Li[3], Qian Wang[4], Yanhong wang[1], Shuang Zhou[4], chanyuan wu[4], Jiuliang zhao[1], Dong xu[5], Mengtao Li[3] and xiaofeng Zeng[4], [1]Peking Union Medical College, Beijing, China, [2]Chinese Center for Disease Control and Prevention, Beijing, China, [3]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [4]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, [5]Peking Union Medical College Hospital, Beijing, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Our study depicted the mortality and independent risk factors of IIM patients in a large multi-center prospective registry cohort in China.

Methods: Patients registered before 31st, December 2021 in the Chinese Rheumatism Data Center-Myositis Registry (CRDC-MYO) were included. Juvenile patients, patients with malignancy at baseline, or patients complicated with other CTD were excluded. Baseline and follow-up data were collected from CRDC-MYO registry database. Death information was obtained from the Chinese Center for Disease Control and Prevention's disease surveillance points system. Kaplan-Meier Curves and Log-rank test was used to compare the mortality. Univariable and multivariable Cox hazards regression analysis were used to identify potential risk factors for death.

Results: 4534 IIM cases were finally enrolled, including 2902 dermatomyositis (64.0%), 592 polymyositis (13.1%), 927 anti-synthetase syndrome (20.4%), and 113 immune-mediated necrotising myopathy (2.5%). 510 deaths in total were recorded. The cumulative survival at 1, 3, 5 and 10 years were 92.6%, 88.6%, 86.2%, and 80.5% (Figure 1a). Significant differences ($P < 0.05$) in survival between different subgroups (Figure 1b) as well as different myositis-specific antibodies were confirmed by log-rank test (Figure 1c). Malignancy (18.8%), interstitial lung disease (18.8%), cardiovascular diseases (18.8%), and infections (18.6%) were the most common causes of deaths (Figure 2a). We observed a shift in the predominant causes of death from pulmonary interstitial disease and infection within the initial three-year period to tumor and cardiovascular

diseases in the subsequent years as the follow-up time extended (Figure 2b). There is significant variation in the composition of causes of death among myositis patients with different antibodies (Figure 2c). Patients with positive anti-TIF1γ antibody commonly succumb to malignancies, whereas patients with positive anti-MDA5 antibody and anti-Jo-1 antibody frequently experience mortality due to interstitial lung disease. Multivariable Cox regression analysis confirmed male (HR=1.53, 95%CI 1.27-1.83), ferritin≥420ng/ml (2.95 [1.85-4.71]), lymphocytopenia (1.89 [1.51-1.38]), ILD (1.28 [1.02-1.60]), anti-MDA-5 antibody (1.53 [1.21-2.20]), and anti-TIF1γ antibody (1.75 [1.16-2.64]) as independent risk factors, and anti-Jo-1 antibody (0.56 [0.40-0.78]) as protective factor for mortality after adjusting for age (Figure 3).

Conclusion: Patients with positive anti-MDA5 antibody exhibited the most rapid decline in survival rate during the first year, whereas patients with anti-TIF1γ antibody had a worse prognosis over a longer follow-up period. This might be attributed to the fact that causes of mortality among myositis patients vary over time, with anti-TIF1γ-positive patients being more susceptible to malignancies. In addition to interstitial lung disease, myositis-specific antibodies appeared to exert a more deci-

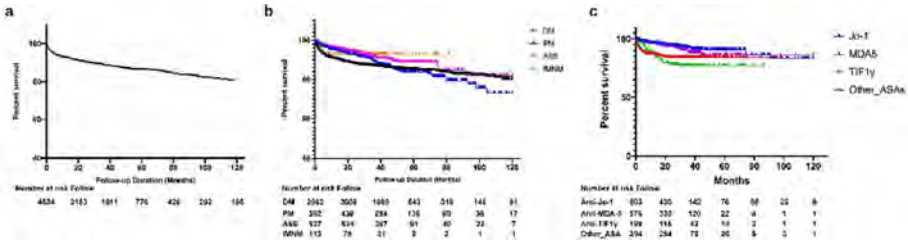

Figure 1 Kaplan-Meier curves for: a. the entire idiopathic inflammatory myositis patients in Chinese Rheumatism Data Center-Myositis Registry (CRDC-MYO); b. patients in different myositis subtypes; c. patients with different myositis-specific antibodies.

Damage Accrual in Idiopathic Inflammatory Myopathies: Data from a Monocentric Cohort and Impact on Patients' Quality of Life

Chiara Cardelli[1], Simone Barsotti[2], Elenia Laurino[1], Michele Diomedi[1], Federico Fattorini[1], Alessandra Tripoli[1], Linda Carli[1] and Marta Mosca[1], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Internal Medicine, Ospedale di Livorno, Pisa, Italy

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Although the prognosis of Idiopathic Inflammatory Myopathies (IIMs) has noticeably improved over time, their chronicity may still expose a considerable number of patients to the development of persistent damage. The purpose of the study was a retrospective analysis of damage accrual in a monocentric cohort of IIM patients, with the aim of also finding possible correlations with epidemiological and clinical data and assessing the impact of damage on patients' quality of life (QoL).

Methods: Consecutive adult patients with a diagnosis of IIM (2017 EULAR/ACR criteria) for at least one year and regularly followed at our Myositis Clinic were recruited. Demographic and clinical features were recorded. At the last follow-up, the Myositis Damage Index (MDI) was applied. IIM activity was evaluated according to the International Myositis Assessment and Clinical Studies Group Disease Activity Core Set Measures. To investigate QoL, patients were asked to fill in generic Patient Reported Outcomes (PROs). Results were reported as mean±SD or median (IQR) for continuous variables and as percentage for categorical variables. Intergroup comparisons were assessed by using chi-square and Mann-Whitney tests, as appropriate. Spearman's coefficient was used to analyse correlations between variables. P values < 0.05 were considered significant.

Results: Eighty IIM patients were enrolled. Demographic and clinical features of the cohort are shown in Table 1. Overall, 78 patients (97.5%) developed at least one item of damage. Using the MDI tool, the damage was represented as follows: global damage VAS 0.75 (0.92); MDI extent of damage score 10.8% (±6.9); MDI severity of damage score 8.2% (10.0). As expected, damage correlated positively with patients' age ($r=0.467$, $p< 0.001$) and disease duration ($r=0.302$, $p=0.007$). A greater damage was associated with cumulative muscle ($p=0.044$) and oesophageal ($p=0.005$) involvement. A positive correlation emerged between damage and the cumulative dose of glucocorticoids ($r=0.404$, $p=0.003$), even when adjusted for patients' age. Correlations were also found between a greater damage accrual and a history of treatment with mycophenolate mofetil ($p=0.039$), cyclophosphamide ($p=0.045$) and immunoglobulins ($p=0.007$). Among disease activity measures, damage correlated with Physician and Patient Global Assessment, Health Assessment Questionnaire (all $r\geq0.322$, $p\leq0.015$) and Manual Muscle Testing-8 ($r< -0.436$, $p< 0.001$) at the last follow-up. As for patients' QoL evaluated by PROs, a higher global damage correlated negatively with several domains of the Short Form-36 and with fatigue assessed by the Functional Assessment of Chronic Illness Therapy (all $r\leq-0.332$, $p\leq0.021$) and positively with the depression subscale score of the Hospital Anxiety and Depression Scale and with activity impairment assessed by the Work Productivity and Activity Impairment Questionnaire (all $r\geq0.367$, $p\leq0.023$).

Table 1. Demographic and clinical characteristics of the cohort of IIM patients.

IIMs cohort (N=80)	
Female	47 (58.8%)
Mean age	66.5 ± 13.4 years
Mean disease duration	8.2 ± 5.6 years
Disease subset	
Polymyositis	40 (50%)
Dermatomyositis	37 (46.3%)
Inclusion body myositis	3 (3.7%)
Anti-synthetase syndrome	21 (26.3%)
Cumulative organ involvement	
Muscular involvement	75 (93.8%)
Cutaneous involvement	37 (46.3%)
Oesophageal involvement	53 (66.3%)
Pulmonary involvement	39 (48.8%)
Cardiac involvement	11 (13.8%)
Microvascular involvement	37 (46.3%)
Articular involvement	16 (20.0%)
Cumulative treatments	
Glucocorticoids (GCs)	80 (100%)
Mean cumulative GCs dose (methylprednisolone equivalent)	10.4±10.3 g (min. 0.4 – max. 57.2)
Mean GCs daily dose (at the last follow-up)	4.4±3.3 mg (min. 1 – max. 20)
Methotrexate	45 (56.3%)
Azathioprine	13 (16.3%)
Cyclosporin A	29 (36.3%)
Mycophenolate mofetil	15 (18.8%)
Cyclophosphamide	30 (37.5%)
Leflunomide	1 (1.3%)
Rituximab	12 (15.0%)
Tofacitinib	1 (1.3%)
Anakinra	1 (1.3%)
Hydroxychloroquine	32 (40.0%)
Immunoglobulins (intravenous or subcutaneous)	37 (46.3%)

Conclusion: IIMs are conditions burdened by a significant damage accrual that can lead to disability and significantly impact patients' QoL, emphasising the need for appropriate strategies to reduce its accumulation, that still represents an unmet need for these patients.

Cardiac Biomarkers Are a Useful Initial Screening Tool for Myocarditis in Patients with Idiopathic Inflammatory Myopathies

Caoilfhionn M. Connolly[1], Jana Lovell[2], Melody Chung[3], Brittany Adler[2], Jemima Albayda[2], Eleni Tiniakou[2], Christopher Mecoli[1], Stefan Zimmerman[2], Lisa Christopher-Stine[2], Nisha Gilotra[2] and Julie Paik[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Kaiser Permanante, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Myocarditis in idiopathic inflammatory myopathies (IIM) is poorly understood despite its associated morbidity and mortality. As manifestations of myocarditis can be mild or subclinical in IIM, early detection is crucial to inform clinical decision-making. Currently, there is a paucity of guidance on optimal myocarditis screening among IIM patients, and there is a critical need to enhance early detection of this potentially fatal disease manifestation to improve clinical outcomes. Thus, we sought to prospectively screen newly diagnosed IIM patients in a rigorously phenotyped cohort to (i) determine the prevalence of myocarditis, (ii) identify risk factors associated with myocarditis and (iii) assess the utility of baseline serum cardiac biomarkers as initial screening to inform the need for advanced cardiac evaluation

Methods: Consecutive patients with a clinician verified new diagnosis of IIM based on either ACR/EULAR or Bohan and Peter classification criteria for IIM evaluated at a single center were recruited from 7/1/2022-3/30/2023; new diagnosis was defined as within one year of symptom onset. IIM subgroups ofpolymyositis (PM), dermatomyositis (DM), antisynthetase syndrome (ASyS), immune-mediated necrotizing myopathy (IMNM), and overlap systemic sclerosis (SSc)/myositis were included; those with inclusion body myositis were excluded. Eligible patients underwent cardiac serum biomarkers (troponin I/high-sensitivity troponin and NT-proBNP), electrocardiography, transthoracic echocardiogram (TTE) and cardiac MRI (cMR). Lake Louise Criteria was used for the diagnosis of myocarditis by cMR requiring 2 of 3 positive criteria for

Table 1. Clinical characteristics of 26 newly diagnosed IIM patients stratified by presence/absence of myocarditis

Cardiac events**	3 (50)	0 (0)	0.01

*Differences in population characteristics between those with myocarditis and those without were compared using Wilcoxon rank-sum test for continuous variables, and Fisher's exact test for binary or categorical variables. ^Therapy at the time of cardiac evaluation $More than 1 simultaneous immunomodulatory agent &1 missing value thus denominator 19 **includes heart failure event, cardiac hospitalization, arrhythmia and death

evidence of hyperemia, edema, and myocardial necrosis/fibrosis. Clinical cardiac events, including heart failure events, arrhythmia events, cardiac hospitalization and death were monitored throughout follow up to 6/7/2023.

Results: Among 26 patients, 85% were female (22/26) and the most common diagnosis was that of overlap SSc/IIM (11/26; 42%) followed by IMNM (6/26; 23.1%). 15/26 (57.7%) had elevation in at least one serum biomarker, most commonly troponin I (13/15; 86.7%). 6/26 (23.1%) patients met Lake Louise Criteria by cMR for myocarditis. When compared to patients without myocarditis, those with myocarditis had numerically higher median CK (U/L) (2075.00 [IQR 336-4206] versus1201.5 [IQR 178-8435.5], p=0.71) and more frequently had elevations in both cardiac biomarkers (100% versus 21%; p=0.01) (Table 1). Among those with myocarditis, anti-Ku was the most common autoantibody (3/6), followed by anti-Scl70, anti-PL12 and anti-Zo (1/6 each). All patients with myocarditis received escalation in immunosuppressive therapy. Three patients (all with myocarditis) experienced clinical cardiac events; two were admitted for heart failure, while the other experienced arrythmia.

Conclusion: The frequency of myocarditis in this cohort was 23%. SSc/IIM overlap was the most prevalent subgroup among patients with myocarditis, suggesting that these patients may be at greater risk. All patients with myocarditis were positive for both cardiac biomarkers, which may represent a useful initial screening tool to inform the need for advanced cardiac imaging.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Our aim was to explore whether maintenance of remission in patients with idiopathic inflammatory myopathy (IIM) depends on glucocorticoids (GCs) after achieving remission. Therefor we aimed to evaluate long-term outcomes after GC-free remissions in patients with IIM and to determine factors associated with relapses. Secondly since the IMACS criteria for remission and relapse in IIM had not been fully validated [1], we examined their compatibility with statements of physicians.

Methods: Data from prospectively followed patients with IIM in the Swedish Rheumatology Quality Register (SRQ) fulfilling the EULAR/ACR classification criteria were extracted and analyzed. For compatibilities of the definition of IMACS-remission, we investigated whether changes in IMACS core sets (CK, MMT8, extramuscular disease activity, patient-/physician-global assessment score (Pt-GA/Ph-GA), and health assessment questionnaire (HAQ)) were within 15% between 6 months before and after the physician's statements of remission/inactive [1].

Relapse was defined as either fulfilling IMACS criteria for relapse (within 20–30% changes in a month) [1] or administration of GC/immunosuppression (IS), which were validated against IMACS relapse criteria. Furthermore, to increase the sensitivity of relapse, a modified IMACS (mIMACS) criteria for relapse was defined as not only changes every month but also changes

Table 1. IMACS core sets at 6 months before and after remission and their compatibilities to IMACS remission criteria

IMACS core sets at 3 time points								
	6 months before		At remission		6 months later		6M before vs remission	6M later vs remission

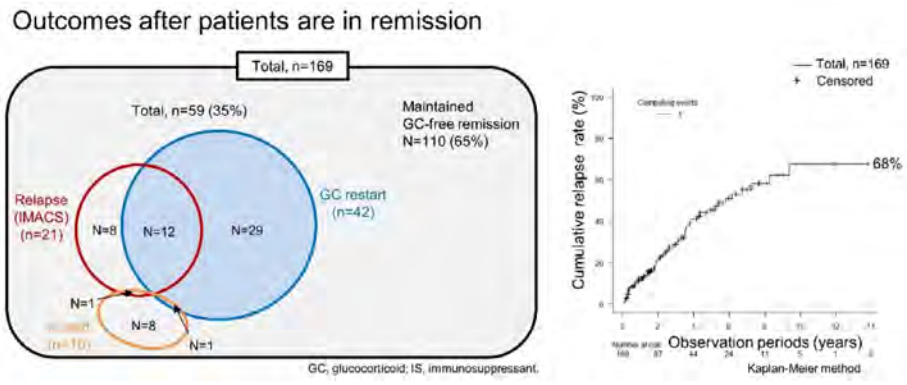
Relapse determined by monthly changes (1, IMACS criteria, blue arrows, red circle), or changes from remission to a time point (2, modified IMACS criteria [mIMACS], orange arrows, blue circle).



Relapse after glucocorticoid-free remission are shown in the left figure (red circle, relapse difined by IMACS; blue circle, glucocorticoid re-start; yellow circle, immunosuppressant admistration). Cumulateve relapse rates during 14 years are shown by Kaplan-Meier method in the right figure. GC, glucocorticoid; IS, immunosuppressant; +, censored patients.

from remission to a visit (Fig. 1). Relapses were examined for up to 14 years, and factors affecting relapses were also explored using logistic regression analyses.

Results: Of 697 patients with IIM, 192 patients were excluded because of lacking outcome data, 169 patients were identified with GC-free remission. Their IMACS core sets were not worsened over 6 months after the physician's statement of remission/inactive. Variables that fulfilled IMACS-remission over 6 months before and after remission were CK (22%, 23%, respectively), MMT8 (89%, 95%), extra-muscular data (100%, no data), Pt-GA (56%, 70%), Ph-GA (64%, 81%), and HAQ (42%, 51%) (Table 1).

After GC-free remission, relapses were observed in 59 of the 169 patients, up to 9.4 years, with a cumulative relapse rate of 68% over 14 years for the Kaplan-Meier curve (Fig. 2). Twenty-one patients (36%) fulfilled IMACS criteria for relapse, including 9 patients with original IMACS criteria and 20 patients with mIMACS criteria (Fig. 1), in which IMACS core set was not significantly different. Relapses other than IMACS-relapse were defined as administration of GC/IS (n=38, Fig. 2). Characteristics in patients with IMACS-relapse were worsened CK, HAQ, Pt-GA, and Ph-GA. In contrast, Ph-GA and CRP worsened in patients with GC/IS defined relapse. Anti-Jo1 autoantibodies were shown as a risk factor for relapses by logistic regression analyses (odds ratio: 6.3, [95%CI: 1.11, 36.0]).

Conclusion: GC free remission using standard of care was achieved in 33% of patients with IIM. Cumulative relapse rate was recorded in 68% of these patients and occurred up to 9.4 years. Especially patients with anti-Jo1 autoantibodies are at risk to relapse. In addition, our real life data suggest that the criteria for remission and relapse in IMACS may need to be modified to fully capture disease flares.

Prognostic Biomarkers and Radiological Features of Idiopathic Inflammatory Myopathy Associated Interstitial Lung Disease

Toshimasa Shimizu[1], Haruna Matsuo[2], Tomohiro Koga[3], Noriho Sakamoto[4], Hiroshi Mukae[1] and Atsushi Kawakami[1], [1]Nagasaki University, Nagasaki, Japan, [2]Nagasaki University, Nagasaki City, Japan, [3]Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki University, Nagasaki, Japan, [4]Department of Respiratory Medicine, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathy (IIM) is a chronic inflammatory disorder involved in skeletal muscles. Interstitial lung disease (ILD) as an organ lesion is a common complication of IIM and may develop into rapidly progressive interstitial lung disease (RPILD), which can be life-threatening. Several myositis-specific antibodies, such as anti-melanoma differentiation-associated gene 5 (MDA5) and anti-aminoacyl-tRNA synthetase (ARS) antibodies, have been associated with developing ILD, which are associated with different prognoses. In addition, patients with IIM-associated ILD are characterized by several radiologic patterns. However, radiological patterns and prognostic biomarkers of IIM-associated ILDs remain obscure, especially in patients with the same antibody positivity. This study aimed to identify the radiological features and specific biomarkers for predicting the short-term prognosis of IIM-associated ILD.

Methods: We enrolled 116 patients with IIM-associated ILD, in either RPILD (n = 55) or non-RPILD (n = 61), who had visited the Department of Immunology and Rheumatology and the Department of Respiratory Medicine at Nagasaki University Hospital between February 2007 and July 2020. We retrospectively obtained the patient's demographics and clinical

Figure 1.

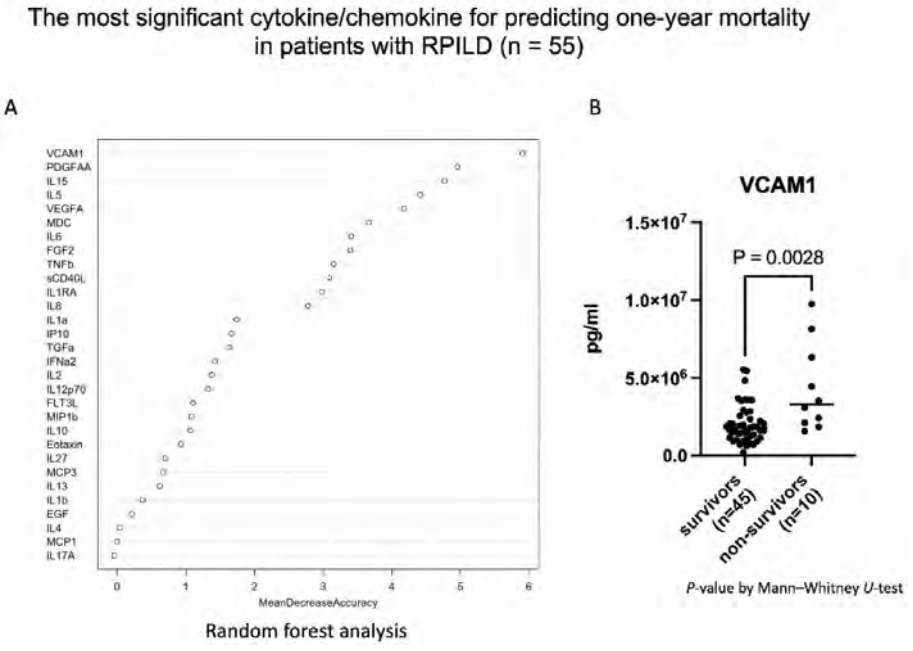

Figure 1. The most significant cytokine/chemokine for predicting one-year mortality in patients with RPILD

Figure 2.

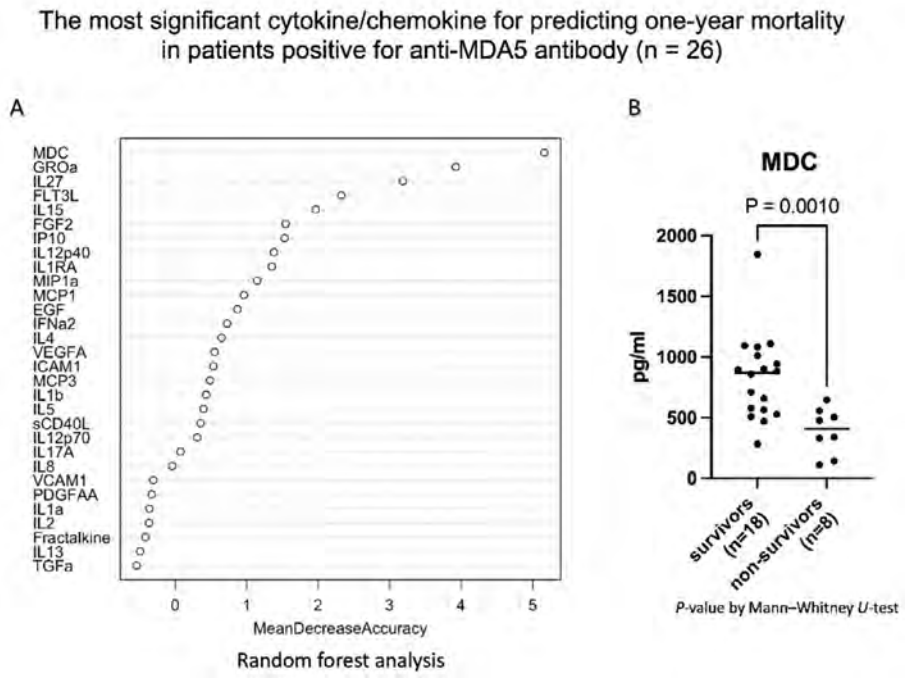

Figure 2. The most significant cytokine/chemokine for predicting one-year mortality in patients positive for anti-MDA5 antibody

characteristics using medical records. The high-resolution CT (HRCT) patterns of ILD, which included diffuse alveolar damage (DAD), nonspecific interstitial pneumonia (NSIP), organizing pneumonia (OP), NSIP with OP, and usual interstitial pneumonia (UIP) pattern, were classified by the experienced pulmonologist. Serum levels of 43 cytokines/chemokines were measured by a multi-suspension cytokine array. These serum variables were ranked by their importance by a multivariate classification algorithm termed random forest analysis.

Results: The one-year mortality rate of patients with RPILD was higher than that with non-RPILD. Within the RPILD group, the HRCT patterns were categorized as follows: NSIP (45.5%), NSIP with OP (25.5%), OP (18.2%), DAD (7.2%), and other (3.6%) patterns. We found the most important cytokine/chemokine for predicting one-year mortality in the RPILD patients was vascular cell adhesion molecule-1 (VCAM-1) using random forest analysis (Fig. 1A). The levels of VCAM-1 were significantly higher in the RPILD groups with survivors than those with non-survivors (Fig. 1B).Among the patients with anti-MDA5 positive ILD, the HRCT patterns were classified as NSIP (46.2%), NSIP with OP (38.5%), OP (11.5%), and DAD (3.8%) patterns. Our random forest analysis revealed macrophage-derived chemokine (MDC), also known as CCL22, was the most significant cytokine/chemokine for predicting one-year mortality in the patients with positive for anti-MDA5 antibody (Fig. 2A). The MDC levels were significantly lower in the patients with survivors than in those with non-survivors (Fig. 2B). In addition, MDC was also the most significant cytokine to predict death within one year in the patients with anti-MDA5 positive RPILD.

Conclusion: This study identified a unique set of serum biomarkers that could predict the short-term prognosis of IIM-associated ILD and characteristic radiological features for each phenotype.

Anti-HMGCR Immune-mediated Necrotising Myopathy: Calculation of Incidence and Confirmation of Low Malignancy Risk in Two Independent Cohorts. a Retrospective Case Review

Thomas Khoo[1], Xia Lyu[2], James Lilleker[1], Janine Lamb[1], Vidya Limaye[3] and Hector Chinoy[4], [1]University of Manchester, Manchester, United Kingdom, [2]Department of Rheumatology, Shanghai Renji Hospital, School of Medicine, Shanghai Jiaotong University, Shanghai, China, [3]Royal Adelaide Hospital, Adelaide, Australia, [4]The University of Manchester, Sale, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Immune-mediated necrotising myopathy (IMNM) is a rare complication of statin therapy, associated with the development of anti-HMGCR antibodies directed against the enzymatic target of statins (3-hydroxy-3-methylglutaryl-CoA). We sought to calculate the incidence of anti-HMGCR IMNM and determine whether there is a malignancy association in two independent cohorts of anti-HMGCR positive patients presenting to specialist rheumatology services in Greater Manchester (GM), United Kingdom, and South Australia (SA), Australia.

Methods: Patients with detected anti-HMGCR antibodies (January 2018-December 2022) were identified. Demographics, statin exposure, details of any previous or current malignancy, date of self-reported symptom onset and peak creatine kinase (CK) level were recorded. Using population data from 2021 by the Office of National Statistics (GM: 2.9 million people) and the Australian Bureau of Statistics (SA: 1.8 million people), annual incidences were calculated.

Results: The combined incidence of anti-HMGCR IMNM in our cohorts was 0.9-2.4 per million person years over the study period (Table 1). There was more than a doubling of incidence in GM from 2021 to 2022 despite stable testing practices (57-68 tests for anti-HMGCR performed annually). Twenty-four patients (50% female, 71% Caucasian, median age 63.6 years, range: 18.5-89.9 years) from GM and eight (37.5% female, 63% Caucasian, median age 70.3 years, range: 57.9-82.2 years) from SA were identified with a median follow-up of 16.3 months (range: 1.03-58.7 months). The time from first self-reported symptom to anti-HMGCR antibody testing was shorter in SA than GM (median 6.8 *vs* 22.5 months). Three patients (all female, aged 18, 28 and 60 years) were statin-naïve. Most patients (18/29) were exposed to atorvastatin (3/29 to simvastatin, 3/29 to rosuvastatin, 5/29 unknown). The median duration of statin use prior to anti-HMGCR testing was

Table 1: Annual cases of anti-HMGCR myopathy and calculated incidence in Greater Manchester and South Australia

Table 1: Annual cases of anti-HMGCR myopathy and calculated incidence in Greater Manchester and South Australia

Year	Greater Manchester		South Australia		Combined incidence*
	Cases	Incidence*	Cases	Incidence*	
2022	9	3.1	2	1.1	2.4
2021	4	1.4	1	0.6	1.1
2020	4	1.4	2	1.1	1.3
2019	3	1.0	3	1.7	1.3
2018	4	1.4	0	0	0.9

*Incidences reported per million person years. Population for the calculation of incidence derived from 2021 census data (Greater Manchester: 2.9 million people and South Australia: 1.8 million people)

36 months (range: 1-120 months). Five patients had a history of prior malignancy (hepatocellular, parotid, prostate (2), renal); notably all except one (data unavailable) occurred more than five years prior to anti-HMGCR testing. The median peak CK was 5000U/L (range: 964-39076U/L). Where data was available, CK subsequently normalised in 8/27 (29.6%) (time from treatment to stable normal CK: median 12 months, range: 2.3-69.2 months) and 8/25 (32%) had regained normal muscle power. Where data was available, more than half (10/16, 62.5%) remained on prednisolone at time of latest review (median 8 months after anti-HMGCR testing, median dose 5.5mg daily)

Conclusion: We confirm that anti-HMGCR is a rare subtype of inflammatory myopathy and report a recent apparent increase in the incidence of anti-HMGCR IMNM in the GM cohort. We found no temporal association of anti-HMGCR IMNM with malignancy within the timeframes usually defined for cancer-associated myositis. The difference between GM and SA in time from self-reported symptom onset to anti-HMGCR testing likely reflects varying pathways of specialist referral. Further multi-site collaborations will help to clarify the epidemiology of anti-HMGCR IMNM.

Inclusion of All Myositis Specific Autoantibodies or Other Rashes Leads to Better Sensitivity but Lower Specificity of 2017 EULAR/ACR Myositis Classification Criteria for Dermatomyositis

Yusra Hasan[1], Katharine Ching Chung[2], Dana Ascherman[3], Siamak Moghadam-Kia[4], Chester V. Oddis[3] and Rohit Aggarwal[3], [1]CHI Health Creighton University Medical Center, Omaha, NE, [2]University of Pittsburgh Medical Center, Mckeesport, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh Medical Center, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic Inflammatory Myopathies (IIM), collectively known as myositis, are heterogeneous disorders characterized by muscle weakness and muscle inflammation. ACR/EULAR classification criterion for IIM was published in 2016 that showed the sensitivity and specificity for probable diagnosis 87%/82% without biopsies, and 93%/88% with biopsies. The criteria is currently being used in most clinical trials and research studies. However, it has been criticized for its lack of a full panel of autoantibodies as well as the non-inclusion of other Dermatomyositis-specific rashes. The aim of our study was to evaluate if the addition of other myositis-specific antibodies (MSAs) and/or DM rashes other than Gottron papules/sign or heliotrope rash would improve the accuracy of the criteria.

Methods: Data were obtained from a prospectively collected myositis registry at a single tertiary care center but retrospectively extracted in subjects with an initial visit between 1995 to 2020. The classification criteria dataset included all variables of 2017 EULAR/ACR as well as Bohan and Peter myositis classification criteria.Additional variables were verified by chart review if/when required and all variables and scores were cross-checked by 2 physicians. Classification scores were re-calculated by adding:

a. all non-Jo1 MSA/MAA receiving the same score as Jo-1,

b. all other DM rashes except Gottron papule/sign, and heliotrope (i.e., shawl sign, V-neck, holster sign, malar rash not sparing naso-labial fold, mechanics hands, periorbital edema) receiving the same score as Gottron papules.
c. both a & b.

Psychometric properties of the 2017 EULAR/ACR classification criteria and proposed modifications were calculated using the diagnosis made by expert rheumatologist physicians as the gold standard.

Results: 798 patients with IIM including 268 with dermatomyositis, 41 with clinically amyopathic dermatomyositis (CADM). In our analysis, 2017 EULAR/ACR showed 91% accuracy, with high sensitivity (87% and 73%) and specificity (94%, and 93%), with and without muscle biopsy, respectively. Bohan and Peter showed lower sensitivity and specificity of 57% and 74% respectively.

		Sensitivity	Specificity	Positive Predictive Value	Negative Predictive value	Accuracy
Bohan & Peter		57	74	59	72	67
Eular/ACR[1]	With Biopsy	87	94	90	91	91
	Without Biopsy	73	93	88	84	85
2. Eular/ACR with the addition of other MSA/MAA	With Biopsy	88	94	91	91	91.6
	Without Biopsy	77	93	88	86	87
3. Eular/ACR with the addition of other MSA[2]	With Biopsy	88	94	91	91	91.6
	Without Biopsy	77	93	88	86	87
4. Eular/ACR with addition of other DM Rashes	With Biopsy	96	86	84	97	90,7
	Without Biopsy	79	86	79	86	83
5. Eular/ACR with addition of other DM Rashes and all MSA/MAA	With Biopsy	96	86	84	97	90.7
	Without Biopsy	83	85	78	88	84
6. Eular/ACR with addition of other Rashes and other MSA	With Biopsy	96	86	84	97	90.7
	Without Biopsy	82	85	78	88	84

[1] Eular/ACR myositis classification criteria 2017
[2] MSA includes MDA5, TIF1y, NXP2, Mi-2, SAE, PL7, PL12, EJ, OJ, SRP.

Psychometric properties of IIM classification criteria and proposed modifications.

The modification of adding other MSA/MAA along with Anti Jo1 leads to a minor improvement in sensitivity (88% and 77% with and without biopsy respectively) without loss of specificity. Adding other DM rashes with Gottron papules increases sensitivity significantly (96% and 79% with and without biopsy, respectively) but with a decrease in specificity (86%). (Table 1)

The modification of adding other MSA/MAA as well as other DM rashes together improves sensitivity the best but at the cost of specificity.

Conclusion: The addition of other skin rashes and/or MSA to the 2016 EULAR/ACR criteria improves sensitivity but at a cost of specificity. Modification of the EULAR/ACR classification criteria is required to overcome some of the shortcomings of the current criteria.

Brepocitinib Prevents Type-I Interferon Induced Damage in Cultured Myocytes and Endothelial Cells Indicating a Potential Role in the Treatment of Dermatomyositis

Jiri Vencovsky[1], Jolie Feldman[2], Lisa McConnachie[2] and Brendan M. Johnson[2], [1]Institute of Rheumatology, Prague, Czech Republic, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Priovant Therapeutics, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM), an idiopathic inflammatory myopathy, is a chronic and often debilitating condition characterized by a hallmark skin rash (e.g., Gottron's sign and heliotrope rash) with perifascicular atrophy and subsequent muscle weakness. The pathogenesis of DM involves dysregulation in signaling of Type I interferon (IFN-I), IFN-ɣ, IL-12, and IL-23. TYK2 and JAK1, are essential for the signaling pathway of these cytokines. Brepocitinib, a selective and potent dual TYK2/JAK1 inhibitor is in development for the treatment of DM and is expected to reduce signaling of these cytokines.A Phase 3 clinical trial of brepocitinib in adults with DM is ongoing (NCT05437263).

Methods: To evaluate the efficacy of brepocitinib in preventing IFN-I induced pathological changes characteristic of DM, human skeletal muscle myoblasts were cultured and differentiated into myotubes then treated with vehicle control or IFN-I to induce cellular damage. Myotubes were also preincubated for 1 hour with brepocitinib (1 μM or 130 nM, the latter represents the average free plasma concentration after brepocitinib 30 mg QD) prior to IFN-I treatment. Immunofluorescence staining followed by image analysis to determine myosin 4 surface area were conducted after 48 hours of IFN-I treatment. Human dermal microvascular endothelial cells (HMEC-1) were cultured and, once vascular networks were established, cells

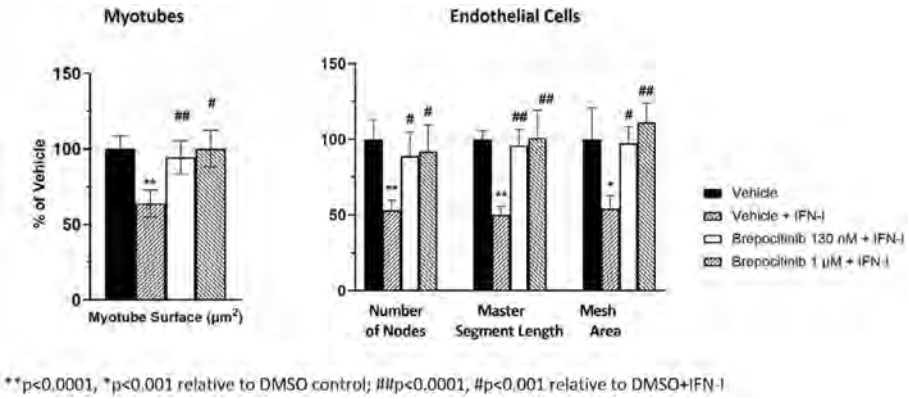

Figure 1. Brepocitinib Effects on IFN-I Induced Myotube and Endothelial Cell Damage

were treated with IFN-I or vehicle control. Cells were also preincubated for 1 hour with brepocitinib as described above. Under light microscopy 9 hours after treatment, the number of nodes, master segment length, and total mesh area were analyzed. One-way ANOVA followed by Tukey's multiple comparison post-hoc analyses were performed.

Results: Myosin surface area was reduced by ~40%, relative to vehicle treated control, in myotubes exposed to IFN-I ($p < 0.0001$). This cytokine induced damage was prevented by brepocitinib preincubation (both 130 nM and 1 μM) with mean myosin surface areas of 96% and 100% of the vehicle control, respectively. The differences between IFN-I treatment alone and brepocitinib were significant ($p < 0.0001$ [1 μM] and $P < 0.001$ [130 nM]). Similarly, HMEC-1 exposure to IFN-I significantly reduced the mean number of nodes, mean master segment length, and mean total mesh area by 47 to 50% relative to vehicle control ($p < 0.0001$ nodes and segments, $p < 0.001$ mesh area). With brepocitinib preincubation, this damage was prevented with the mean number of nodes, master segment lengths, and total mesh area ranging from 89 to 111% of vehicle control. These differences were statistically different from the IFN-I treatment at both brepocitinib concentrations and all endpoints ($p < 0.001$ for all conditions).

Conclusion: One of the most debilitating aspects of DM is muscle weakness resulting from perifascicular atrophy leading to significant impacts on quality of life for these patients. We report here the ability of brepocitinib to prevent IFN-I induced damage in both myocytes and microvasculature in culture at clinically relevant concentrations, providing further pharmacologic rationale for brepocitinib in the treatment of DM.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Statin-induced immune-mediated necrotizing myopathy (IMNM) is associated with anti-3-hydroxy-3-methylglutaryl-CoA reductase (HMGCR) autoantibodies. It is characterized by elevated creatine kinase (CK) levels, and severe muscle weakness. Measuring disease activity is problematic, since it is challenging to differentiate it from damage. The utility of the quantitative analysis of anti-HMGCR autoantibodies during the follow-up has not been thoroughly studied.

Our aum was to assess the usefulness of measuring the levels of anti-HMGCR autoantibodies in relation to response to treatment.

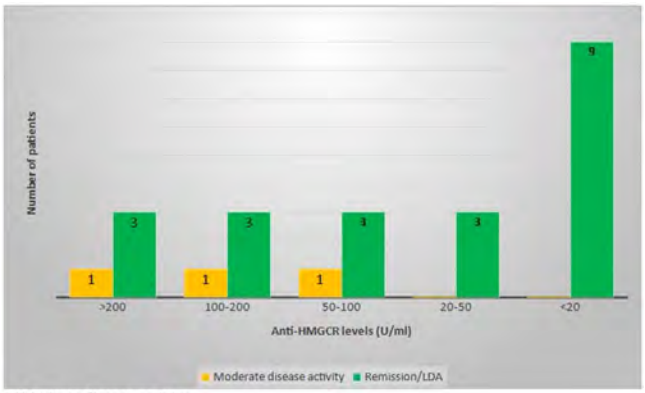
Methods: We included patients all consecutive patients diagnosed with statin-induced IMNM according to the definition of the European Neuromuscular International Workshop 2016 and positivity for anti-HMGCR autoantibodies in two centers from Spain and Sweden from January 2017 to November 2022. All patients were followed for at least 3 months to be included. Clinical data was extracted retrospectively from the patients' clinical records. Remission was defined as no disease activity assessed by expert rheumatologists according to 2016 ACR/EULAR response criteria in myositis. Moderate and high disease activity was defined when physician global activity score was higher than 2 or 3 (on a Likert scale) respectively . Anti-HMGCR autoantibodies level was measured at the time of diagnosis and at a variable period of time after treatment. Results were obtained using the chemiluminescence immunoassay (CLIA) method. Negative anti-HMGCR was considered as levels lower than 20 U/ml.

Results: Our group combined of 24 patients. Main features of the patients are summarized in the **TABLE**. 21 (87.5%) patients reached clinical remission or low disease activity. However, 3 patients (12.5%) remained with moderate activity of the disease. None of the patients had high disease activity. Anti-HMGCR levels at diagnosis were higher than 100 U/ml in 23 patients (95.8%) and above 200 in 11 patients (45.8%). However, anti-HMGCR levels after treatment were significantly lower in patients in remission (p=0.035). Numeric levels in patients at diagnosis of the disease and after treatment are shown in the **FIGURE**. Most of the patients at diagnosis (with high activity of the disease) had high anti-HMGCR levels (22 patients,

Variables	Total (n=24)	Remission / low activity (n=21)	Moderate activity (n=3)	P (remission vs no remission)
Age (years), mean ± SD	68.2 ± 7.2	67.6 ± 7.1	67.3 ± 10.1	0.95
Sex (women), n (%)	10 (42)	9 (42.9)	1 (33.3)	0.89
Analytical values, mean ±SD				
• CK (ukat/L) at diagnosis	114.3 ± 103.9	103.5 ± 100	230.7 ± 84.5	0.51
• Anti-HMGCR levels at diagnosis	214.6 ± 110.8	212.2 ± 89.7	295 ± 127.8	0.24
• Anti-HMGCR levels after treatment	83.8 ± 89	74 ± 80.4	190 ± 100.1	**0.035***
Muscle strength assessment, mean ±SD				
• MMT-8 at diagnosis	64.4 ± 12	65.4 ± 12.7	62.7 ± 13.5	0.73
• MMT-8 after treatment	77.6 ± 4.2	78.6 ± 3.1	74.3 ± 8.1	0.1

CK: Creatine kinase.
Upper limit for CK: < 4.7 ukat/L for men and 3.5 ukat/L for women.
*: p < 0.05

TABLE: General features of 24 patients diagnosed with anti-HMGCR positive IMNM



LDA: Low disease activity

FIGURE: Anti-HMGCR autoantibodies levels according to disease activity after treatment in 24 patients with IMNM.

91.7% had levels above 100 U/ml). After treatment, most patients in remission had low (n=3, 14.3%) or negative (n=9, 42.9%), while patients with moderate activity had higher levels (n=2, 66.7% with levels above 100 U/ml). However, 6 patients in remission (28.6%) still had levels above 100 U/ml.

Conclusion: Anti-HMGCR autoantibodies levels evaluation can be used in parallel with other tools to accurately measure disease activity in patients with statin-induced IMNM. However, more studies are needed to confirm these results.

Self-Perceived Knowledge of Myositis Among Social Media Respondents-a Pilot Study on Twitter

Srijan Mittal[1], Vanshita Batra[1], Parikshit Sen[2], Saadia Sasha Ali[3], Arpit Mago[4], Mark Russell[5], Eugenia Gkiaouraki[6] and Rohit Aggarwal[6], [1]Maulana Azad Medical College, New Delhi, India, [2]Maulana Azad Medical College, 2-Bahadurshah Zafar Marg, New Delhi, Delhi-110002, India., Dalhi, India, [3]King's College Hospital, Epsom, United Kingdom, [4]Jawaharlal Nehru Medical College, Belgaum, India, [5]King's College Hospital, London, United Kingdom, [6]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Myositis is a rare complex autoimmune disease that is less known and poorly understood, with increased effort required for education of practitioners, students, educators, and patients. Social media platforms offer immense potential for rare disease education, though assessment of baseline knowledge is crucial to develop a comprehensive health education program disseminated through social media. We assessed the current level of knowledge and

understanding of myositis, and explored preferred methods of learning, among social media respondents to develop a social media-based myositis education program.

Methods: A validated, pilot tested baseline self-reporting survey was circulated on Twitter, and all respondents >18 years were invited to participate. The survey collected data on demographics, country of residence, profession, and sources of health-related information used for learning. Respondents reported their perceived level of knowledge of myositis on a 5-point Likert scale from 1 (very low) to 5 (very high). Level of knowledge, pattern of twitter activity, and sources of health information used were compared between the different groups through descriptive statistics.

Results: A total of 504 participants responded to the survey, with 48.2% females, ranging from 18-20 to >70 years, with most in the 30–40-year age group (31.1%), from 66 countries across six continents, mostly from the United States (37.5%), India (15.66%) and the United Kingdom (5.79%) (Fig 1A). Respondents included patients (25.2%), trainees (26.1%) from medical student to residents and fellows, as well as faculty (27.8%) from various specialties (Figure 1B, Table 1). The overall knowledge of myositis increased with a higher level of medical training with mean (SD) score of 2.5 (0.9) in medical students, 2.8 (0.8) in residents, 3.3 (0.6) in fellows, and 3.9 (0.6) among attending rheumatologists, where 1 was 'very low' while 5 was 'very high'. Importantly, the overall knowledge of myositis amongst myositis patients and autoimmune patients were 3.1 (0.9) and 2.1 (1.0) respectively indicating a low to medium level (Fig 2A). Myositis pathogenesis was least understood followed by myositis ILD and myositis complications. Social media was reported as the most common platform to be used amongst all respondents for medical educational content, however traditional in person and online lectures remain important for medical personnel (Fig 2B). Patients clearly favored social media for their knowledge.

Conclusion: The overall knowledge of myositis remains low amongst patients. In the medical community overall myositis knowledge is low to moderate among trainees, though increases medical training progresses. Social media is commonly used by patients, students and doctors to access educational content on myositis, though traditional lectures remain important among the medical community. This provides an excellent means to educate patients and clinicians alike about this rare condition which may in turn may improve patient outcomes.

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: To assess the real-world, long-term effectiveness of rituximab (RTX) as a rescue therapy in patients with antisynthetase syndrome and interstitial lung disease (ASS-ILD).

Methods: Multicentre observational retrospective longitudinal study of a cohort of patients with ASS-ILD that started treatment with RTX due to recurrent or ongoing progressive ILD despite therapy with glucocorticoids and immunosuppressants.

Results: Twenty-eight patients were analyzed; 15 fulfilled the criteria of progressive pulmonary fibrosis. Ongoing therapy with immunosuppressants remained unchanged. Examining the entire study population, before treatment with RTX the mean decline in %pFVC and %pDLCO from the ILD diagnosis was -6.44% and -14.85%, respectively. After six months of

Mean distance covered in 6MWT (meter)	334 ± 136 (289 – 456)	418 ± 91,5 (367,5 – 528,5)	+103,54 m	0,33 (-197,17 to -9,91)

%pFVC = predicted forced vital capacity, %pDLCO = predicted diffusing capacity for carbon monoxide, corrected for hemoglobin; RTX = rituximab; 6MWT = 6-minute walking test

treatment, RTX reversed the decline in pulmonary function test (PFTs) parameters: Δ%pFVC +6.29% (95% CI: -10.07 to 2.51; p=0.002 compared to baseline) and Δ%pDLCO +6.15% (95% CI: -10.86 to -1.43; p=0.013). Twenty-four patients completed one year of therapy and 22 two years, maintaining the response in PFTs: Δ%pFVC: +9.93% (95% CI: -15.61 to -4.25; p=0.002) and Δ%pDLCO: +7.66% (95% CI: -11.67 to -3.65; p< 0.001) [Table 1]. In addition, there was a significant reduction in the median dose of prednisone, and it could be suspended in 18% of cases. In 33% of patients who required oxygen therapy at the start of treatment, it could be discontinued. The frequency of adverse events reached 28.5% of cases.

Conclusion: Based on our results, RTX appears to be effective as rescue therapy in most patients with recurrent or progressive ASSD-ILD unresponsive to conventional treatment. Use of RTX was well tolerated in the majority of patients

Machine Learning Approach for the Prediction of anti-MDA5 Positive Dermatomyositis Mortality

Xinlei Liu[1], Fumin Qi[2], Wei Wei[1] and Yin Zhao[1], [1]Tianjin Medical University General Hospital, Tianjin, China, [2]Tianjin Medical University, Tianjin, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: We describe a single-center clinical cohort of MDA5 positive dermatomyositis(DM) in China and apply a machine learning approach to predict the risk of mortality in patients.

Methods: We conducted a retrospective collection of clinical characteristics from 70 Asian patients diagnosed with MDA5+ DM between June 2017 and March 2023. The collected data encompassed various aspects, including basic information, clinical symptoms and signs, prognosis, treatment methods, imaging information, pulmonary functions, and laboratory examinations. The cohorts were divided into training and validation sets in a 4:1 ratio. Machine learning approaches (Ridge, LASSO, Elastic Net) were employed to identify the optimal variables among the 152 variables, which were used to construct a COX regression model. A Nomogram was subsequently developed to provide guidance for clinical practice.

Results: Demographic and disease characteristics of the 70 MDA5 positive DM patients can be found in Table 1. The median follow-up time was 10 months (IQR 2-40, range 0.5-71), and 29 patients (41.4%) died in our study. The deceased patients were older in age, had a shorter duration of disease, exhibited fever, respiratory symptoms, and poorer lung condition, as well as higher levels of inflammatory markers. After comparing three machine learning methods, it was found that the Partial Likelihood Deviance of the Lasso-COX regression model was 5.001, which was not the lowest. However, it was comparable to the other models in terms of deviation and showed good performance with a c-index of 0.7421. This indicates that the model has strong discriminatory power. Therefore, the Lasso-COX model was ultimately chosen to establish the risk prediction model in this study (Fig).

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Myositis-specific antibodies (MSA) represent unique phenotypes in idiopathic inflammatory myopathies (IIM). Myositis-associated antibodies (MAA) most commonly occur in IIM overlap syndromes. MSA and MAA should be assessed in all IIM patients, but their real-world frequency, distribution, and patient awareness are not well known. Given the increasing importance of MSA/MAA in IIM diagnosis and management, we examined their real-world vs. expert-center frequency, awareness, and distribution.

Myositis-associated antibodies: anti-SSA(Ro), anti-PM-Scl, anti-Ku, anti-U1RNP, anti-U2RNP

Methods: Myositis Patient-Centered Tele-Research is a multi-center observational study. Patients were enrolled remotely from anywhere in the U.S. through social media and patient organizations (Tele-Research Cohort, TRC) and traditionally through myositis centers (Center-Based Cohort, CBC). Patients completed a pre-screening questionnaire with MSA/MAA and IIM self-report, the latter being confirmed by a rheumatologist, neurologist, or dermatologist. Patients also self-reported on study disease criteria: proximal muscle weakness, muscle or skin biopsy, electromyography, muscle enzyme, and/or dermatomyositis rashes. A subset of patients had their clinical features, diagnosis, and MSA/MAA results confirmed by physician chart review.

Results: 408 participants completed the pre-screening questionnaire: 317 (77.8%) females, mean age 54.84 (SD +/- 13.8), 378 (92.6%) non-Hispanic, and 328 (80.4%) White, 49 (12%) Black, 13 (3.3%) Asian. Most patients (378, 92.6%) met study IIM criteria. The most common diagnoses were dermatomyositis (195; 51.6%), polymyositis, or necrotizing myopathy (183; 48.4%). A total of 177 (46.8%) reported a positive MSA and/or MAA while 62 (12.4%) were antibody negative and 139 (36.8%) were unsure about their antibody status. The most common MSAs were Jo-1 (31.6%), anti-SRP (11.3%), anti-HMGCR (9%), anti-TIF1-γ (9%), anti-Mi-2 (6.2%), and anti-MDA-5 (5.1%). Regarding MAA, 21 (11.8%) had a positive SSA (Ro), 9 (5.1%) anti-PM-Scl, 3 (1.74%) anti-Ku, and 2 (1.13%) anti-U1RNP. There was no difference in MSA/MAA frequency or distribution by U.S. region or enrollment method (remote vs. from myositis center). Antibody status awareness was significantly higher in the Northeast compared to other regions. Age, gender, ethnicity, and race were not associated with antibody knowledge. There was no difference in antibody awareness between enrollment methods. In a subset of patients (n=94), antibody self-report was highly consistent with physician chart-confirmed MSA/MAA positivity (96.4%) and overall negative or positive status (91.5%).

Conclusion: In a large national real-world IIM cohort, anti-Jo1, -SRP, -HMGCR, -TIF1-γ, -Mi-2, -MDA-5, -SSA, - PM-Scl were the most common MSA/MAA reported by patients. One-third of patients were unaware of their antibody status. There was no difference in antibody frequency, distribution, or awareness by patients enrolled remotely vs. by expert centers. Patients enrolled from the Northeast had significantly more autoantibody awareness. No demographic differences were seen. Patient awareness of their disease and key test results is crucial, as they are important allies in healthcare decision-making.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are rare, heterogeneous diseases characterized by chronic skeletal muscle inflammation and weakness. Initial conventional therapy is based on expert opinion and includes glucocorticoids and methotrexate, azathioprine, or mycophenolate. Second line therapy (calcineurin inhibitors or IVIG) and then escalation to third line therapy (rituximab or cyclophosphamide) is considered if initial therapy is insufficient. Adherence to these recommendations and the impact of nonconventional therapies in real-world circumstances is unclear. The aim of this study was to characterize treatment trajectories in IIM and assess changes in patient-reported outcomes (PROs) and symptom frequency among those on conventional vs nonconventional therapies.

Methods: Data were provided by adults with IIM enrolled in the FORWARD Databank. Participants with co-occurring RA, SLE, or SSc were excluded. Participant characteristics and treatment category (none, glucocorticoids alone, first line without glucocorticoid, first line, second line, third line, and other immunomodulator) were assessed at study entry (baseline) and at

PRO=patient-reported outcome; VAS=visual analog scale; HAQ=Health Assessment Questionnaire; PAS=Patient Activity Scale; RDCI=Rheumatic Disease Comorbidity Index; PSD=polysymptomatic distress.

last/most recent observation (ultimate treatment). First, second, and third line treatments were considered "conventional" and glucocorticoid alone, first line without a glucocorticoid, and other immunomodulators were considered "nonconventional." Differences in baseline characteristics between those on conventional, nonconventional, and no therapy were assessed using one-way ANOVA and Fisher's exact tests. Changes in PROs and symptom frequency from baseline to ultimate treatment were evaluated using paired t-tests and McNemar tests.

Results: Among 126 participants who met inclusion criteria, 43% were on first line therapy at baseline, while 23% received glucocorticoids alone. Only 2% were on second line therapy, and none received third line therapy. The remaining participants were on first line therapy without glucocorticoids (17%), nonconventional immunomodulators (9%) or no treatment (6%). Over 504 person-years (from baseline to ultimate treatment), 47% reported first line treatment, 10% reported second line, and 3% reported third line as the most advanced conventional therapy received. The remaining 40% reported nonconventional or no treatment throughout observation. Analyses of PROs and symptom frequencies from baseline to ultimate treatment showed significant improvements in polysymptomatic distress (PSD; 10.2 to 8.3, p=0.03) and muscle weakness (71% to 48%, p< 0.01) among those consistently on conventional therapy. Participants who switched to conventional from nonconventional therapy experienced improved PSD (14.0 to 10.9, p=0.04). No significant changes were observed in the nonconventional treatment group.

Conclusion: Despite recommendations for combination therapy in IIM, a substantial proportion of individuals do not receive concomitant immunomodulators. Our results suggest that individuals who remain on conventional therapies have improved PSD with less muscle weakness over time. The use of nonconventional treatments highlights the need for further investigation of their effectiveness.

CoLchicine for Treatment of OsteoArthritis of the Knee—Updated Data from a Double-blind, Placebo-controlled Trial

Katherine Tse[1], Roni Meidan[2], Michael Toprover[3], David Wei[2], Nicole Leung[4], Maryfe Coronel[2], Julia Cai[2], Aryan Jain[2], maria lessa[2], Renata La Rocca Vieira[2], Svetlana Krasnokutsky Samuels[2], Michael Pillinger[5] and **Jonathan Samuels**[6], [1]NYU Langone, New York, NY, [2]NYU Langone Helath, New York, NY, [3]New York University Langone Health, New York, NY, [4]New York University Langone Hospital, New York, NY, [5]New York University Grossman School of Medicine, New York, NY, [6]NYU Langone, Rye Brook, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Knee osteoarthritis (OA) has a probable inflammatory role for IL-1b. The presence of calcium and urate crystals may contribute to OA by activating the NLRP3 inflammasome, leading to IL-1b production. Colchicine is a well-tolerated anti-inflammatory drug that inhibits the inflammasome and suppresses IL-1b. Prior studies investigating the efficacy of colchicine on knee OA include some reporting pain relief, others showing improvement in inflammatory markers, but none assessing synovial effusions.

Methods: CLOAK is a randomized, double-blind, placebo-controlled trial of colchicine (0.6 mg daily for 3 months) for knee OA (Fig. 1). We are enrolling individuals ≥ 40 years of age, BMI ≤ 30 kg/m^2, with symptomatic knee OA and Kellgren-Lawrence grade 2 or 3 on radiographs, who are willing to abstain from other anti-inflammatory treatment during the trial. Clinical outcomes include the change in knee pain by visual analog scale (VAS), and in Knee injury and Osteoarthritis Outcome Scores (KOOS) in the colchicine and placebo groups. If present, synovial fluid is aspirated and analyzed. Biologic outcomes to be assessed after study completion include changes in inflammatory markers in plasma, peripheral blood leukocytes, and synovial fluid.

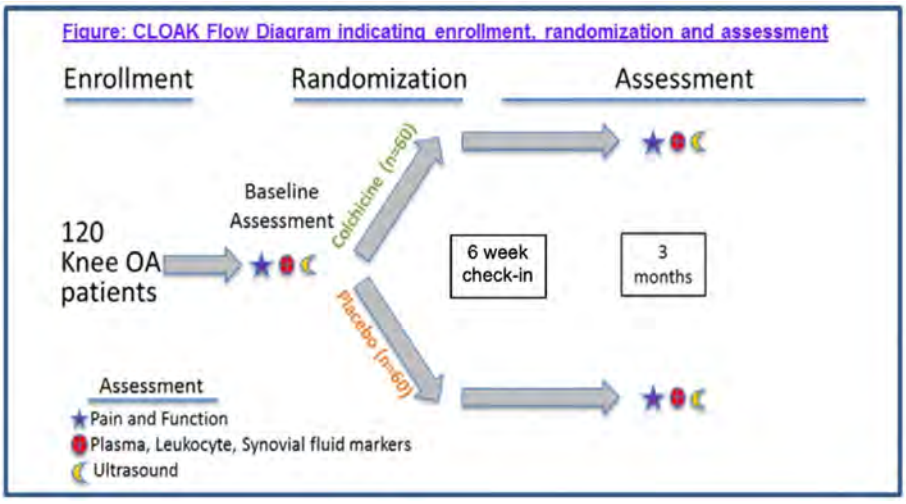

Figure 1. Flow diagram of study plan.

Results: To date, 1,105 potential subjects were contacted, 119 screened, and 97 enrolled. 69 have finished the study with data available: 32% male, 64% White, 24% Black, 4% Asian and 8% other, with mean±SD BMI 27.5±3.9 kg/m^2 and age 68.6±10.1 years. Inclusive of all completing participants (blinded to treatment vs placebo) over the 3 months, mean VAS pain improved (decreased) by -1.04 units in the index knee; 58% demonstrated VAS improvement while 42% had no change or worsened. The mean VAS improvement was concordant with improvements (increases) in all 5 KOOS component subscores (Fig. 2), including mean pain (6.99), symptoms (7.30), activities of daily living (8.01), sports activity (2.45), and quality of life (5.59). Subsets of patients with baseline VAS ≥6 and baseline KOOS ≤60 for pain (i.e., more severe) showed significantly more 3-month mean KOOS pain improvement, even with the blinded inclusion of placebo, than those with less baseline severity (by baseline VAS: 10.8 vs. 1.95, p=0.030; by baseline KOOS 12.2 vs 1.1, p=0.008) (Fig. 3). Sonography was performed on all 69 subjects pre- and post-treatment. Subjects without effusion at baseline were more likely to experience knee pain improvement post treatment than those with effusion (mean KOOS improvement 9.8 vs 1.6, p=0.046).The prevalence of effusions did not differ pre and post treatment (29 vs 26%, ns).

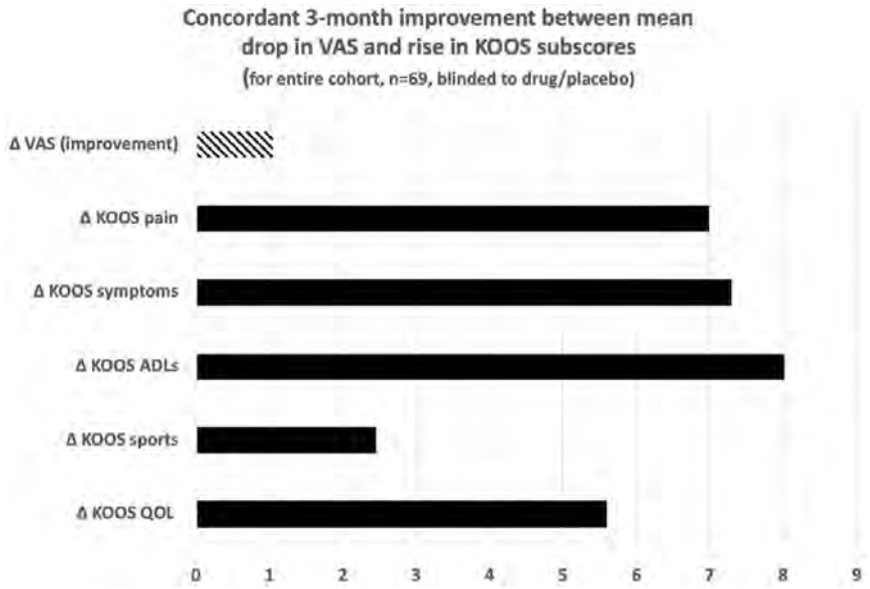

Figure 2. Concordant 3-month improvement with mean drop in VAS and rise in KOOS subscores

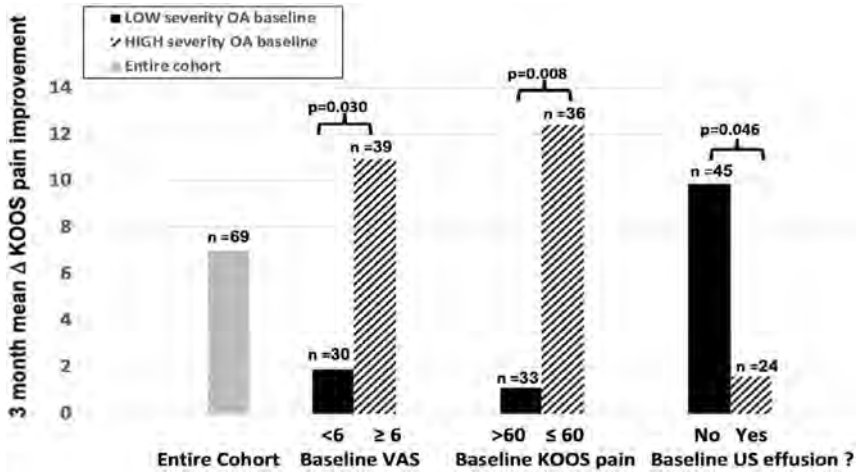

Figure 3. Subject improvement in KOOS score from beginning to end of study, according to high or low baseline severity as measured by VAS and KOOS scores and presence of synovial effusion

Conclusion: The findings of this blinded analysis are consistent with the possibility that colchicine may offer benefit in terms of pain, function, and effusion in subjects with knee OA not taking other anti-inflammatory agents. Patients with higher baseline pain severity were more likely to improve, whereas patients with effusions at baseline were less likely to improve, with regard to post-treatment VAS and KOOS pain scores. Enrollment is ongoing, and the study will be unblinded and fully analyzed upon completion. Supported by an investigator-initiated grant from Hikma Pharmaceuticals.

Abstract Number: 1184

A Wearable-Sensor for Assessment of Gait and Chair Stand Patterns in People with Knee Osteoarthritis: Validation and Responsiveness to Treatment of a Potential Digital Biomarker

Deepak Kumar[1], Lukas Adamowicz[2], Benjamin Senderling[1], Mary Gheller[1], Michael LaValley[3], Kathryn Bacon[1], Pirinka Georgiev[2], Charmaine Demanuele[2], Paul Wacnik[2] and Tuhina Neogi[4], [1]Boston University, Boston, MA, [2]Pfizer Inc., Cambridge, MA, [3]Boston University School of Public Health, Arlington, MA, [4]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The objectives of this study in people with knee osteoarthritis (OA) were to (a) examine the agreement between measures of gait and chair stand patterns derived from a wearable-sensor and those from gold-standard motion capture, (b) assess the correlation between wearable-sensor derived measures and standard functional measures, and (c) examine the responsiveness of wearable-sensor derived measures to an exercise-based physical therapy intervention.

Table 1. Agreement between sensor and motion-capture derived measures using data from baseline, week 12, and week 18 visits.

Table 1. Agreement between sensor and motion-capture derived measures using data from baseline, week 12, and week 18 visits.

	Sensor-derived (mean [standard deviation])	Motion Capture derived (mean [standard deviation])	% difference	Agreement (ICC[2,1] with 95% confidence intervals
Walking at self-selected pace				
Cadence (steps/min)	120.86 (119.29, 122.42)	123.25 (121.61, 124.88)	1.94	0.835 (0.740, 0.897)

Minimum acceleration (m/s^2)	-3.17 (-3.40, -2.94)	-2.27 (-2.41, -2.14)	-39.49	0.566 (0.363, 0.717)

Methods: We conducted a single-arm clinical trial (NCT04243096) of a 12-week exercise intervention in people with symptomatic knee OA (n = 60, age = 66.3±7.4 years; 75% women; BMI = 29.0±4.8 kg/m^2). Participants received 18 sessions of an exercise-based physical therapy intervention over 12 weeks. Spatiotemporal gait parameters and measures of chair stand mechanics (Table 2) were extracted from an inertial sensor worn on the lower back as well as from optical motion capture during walking at self-selected pace and chair stand tasks. Agreement between sensor and motion capture measures was examined using intraclass coefficients (ICC [2,1]). Participants also completed standard functional tests including a walking test (28-meters), 5 times chair stand test, and a 6-minute walk test, while wearing the inertial sensor and correlations between sensor derived measures and functional measures were assessed. The wearable sensor measures with excellent

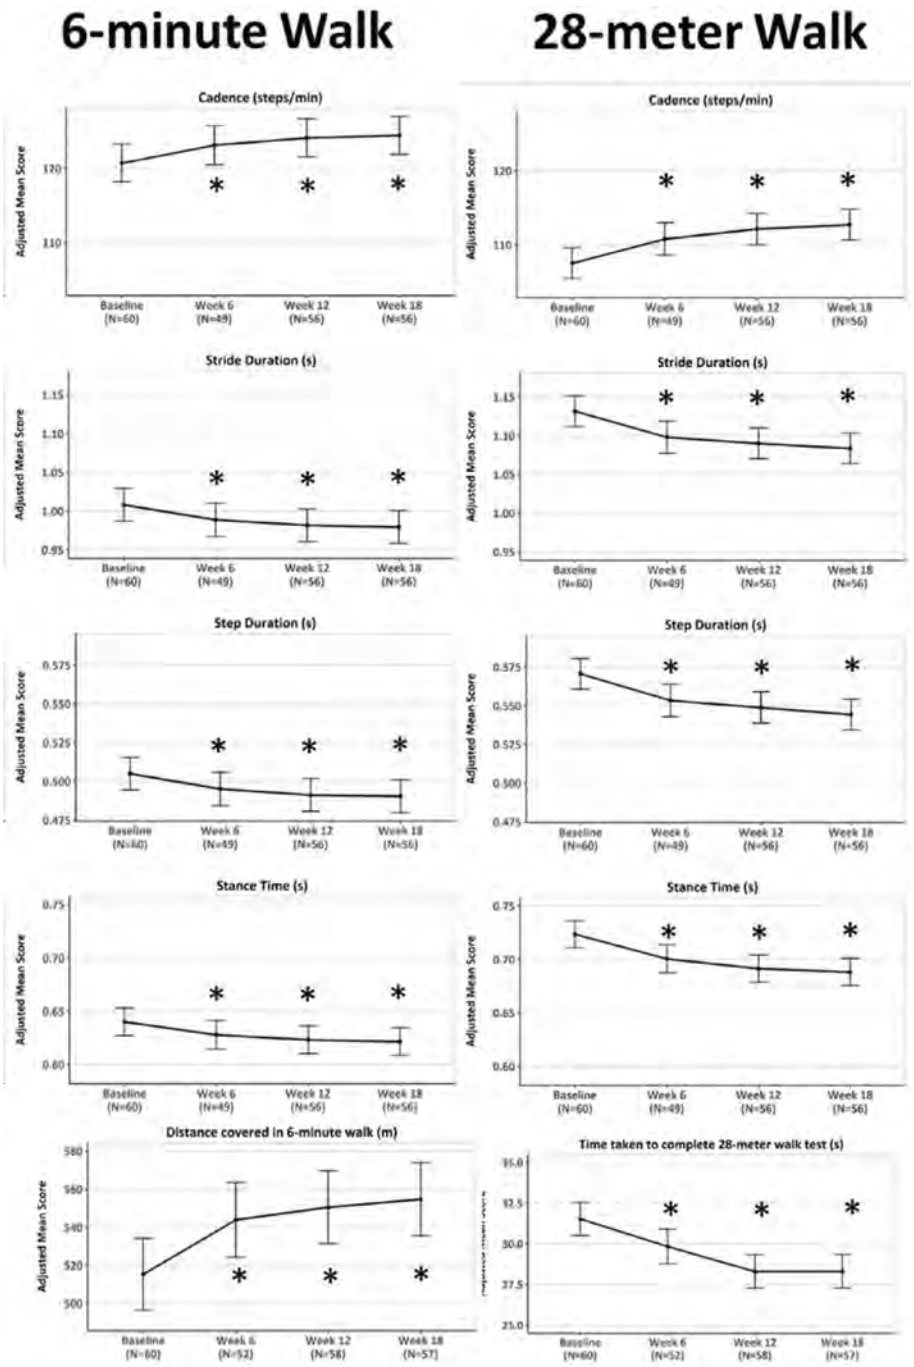

Figure 1. Adjusted means for sensor-derived measures (with excellent agreement) and standard functional measures at baseline, week 6, week 12, and week 18 during the 6-minute walk test (left) and 28-meter walk test (right). * indicates significant change compared to baseline.

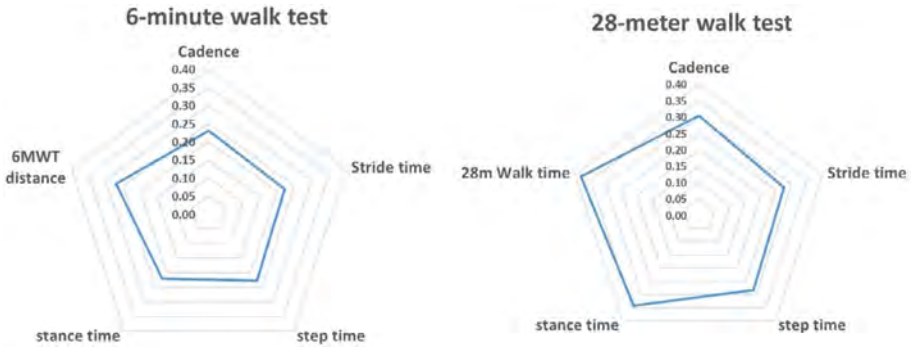

Figure 2. Standardized response means for change from baseline to week 12 in sensor-derived measures (with excellent agreement) and standard functional measures during 6-minute walk test (left) and 28-meter walk test (right)

agreement with motion capture and standard measures during functional tests were evaluated with mixed model repeated measures (MMRM) models with visit as a categorical factor adjusting for age, sex, BMI, and presence of comorbidities.

Results: The agreement between sensor and motion capture derived measures was excellent (ICC ≥ 0.75) for cadence, stride duration, step duration, and stance duration, good (0.6≤ICC≤0.74) for initial double support duration, terminal double support duration, total double support duration, and swing time, and moderate (0.4≤ICC≤0.59) for step length and gait speed (**Table 1**). Sensor derived measures and functional measures were significantly correlated in the expected directions with somewhat stronger correlations during 6-minute walk (range 0.68-0.90) vs. and 5-time chair stand (range 0.67-0.70) vs. 28-meter walk (range 0.46-0.65). With the intervention, all sensor derived measures showed significant improvements in all functional tests with the improvement maintained from 12- to 18-weeks (**Figure 1 and 2**).

Conclusion: Multiple measures of gait and chair stand patterns derived using a single inertial sensor demonstrate good agreement with gold-standard measures derived from motion capture. Spatial measures (step length, speed) performed worse than temporal measures. Sensor derived measures are moderately correlated with standard functional outcomes and may provide additional information not captured by standard measures. Sensor derived measures are responsive to change with an effective treatment and potentially could serve as digital biomarker for monitoring or treatment response.

Abstract Number: 1185

Soluble Buffered Alendronate After Denosumab Discontinuation in Erosive Hand OA Patients

Tine Vanhaverbeke[1], Dirk Elewaut[2] and Ruth Wittoek[1], [1]Dept. of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium, [2]Ghent University and VIB Center for Inflammation Research, Ghent, Belgium

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In osteoporotic patients, discontinuation of denosumab is associated with a rapid increase in bone turnover and bone loss. Denosumab was recently proven to have clear structure modifying effects in erosive hand osteoarthritis (OA) patients compared to placebo. So far, the effect of denosumab discontinuation in a non-osteoporotic population is unclear. The objective was to investigate whether buffered soluble alendronate after denosumab discontinuation, can counter potential increase in bone turnover in this non-osteoporotic population.

Methods: Patients with erosive hand OA, who participated in a RCT with denosumab, were randomized to open label treatment with oral effervescent alendronate 70 mg weekly for either 24 or 48 weeks, after discontinuating denosumab treatment. Underlying osteoporosis was excluded at baseline. Serum bone turnover markers (C-terminal telopeptide of type I collagen (CTx-I) and N-terminal propeptide of type I procollagen (PINP) were measured at baseline, week 12, week 24 and week 48. Dual energy X-ray absorptiometry was performed at baseline, week 24 and week 48. The primary end point was the number of patients maintaining serum bone turnover markers within pre-menopausal reference range. Statistical analysis was performed with an intention to treat approach. Secondary end point was change in bone mineral density (BMD). Occurrence of adverse events were recorded.

Results: Fifteen patients were randomized to each treatment group. At week 48, 5 of 15 (33%) patients from alendronate 24 weeks vs 1 of 15 (7%) from alendronate 48 weeks, showed CTx-I values above pre-menopausal ranges. For PINP, 7 of 15 (47%) from alendronate 24 weeks vs. 2 of 15 (13%) from alendronate 48 weeks, showed values exceeding pre-menopausal ranges. The amount of patients above pre-menopausal ranges was not significantly different between both groups (p=0.11 and p=0.17 for CTx-I and PINP respectively). Mean changes of CTx-I levels between baseline and week 48 were significantly lower for alendronate 48 vs 24 weeks (p=0.043). For PINP, mean changes were numerically lower in alendronate 48 weeks but not statistically significant. BMD T-scores did not differ significantly between baseline and week 48, except for T-scores at the lumbar spine in alendronate 24 weeks. No significant differences were seen in mean change BMD between treatment groups. No fractures were reported.

Conclusion: Soluble alendronate 70mg weekly after denosumab discontinuation in this non-osteoporotic population did not maintain bone turnover markers under premenopausal reference range in all patients. Clinical implications of the increase of bone turnover markers in this non osteoporotic remain doubtful, since BMD values did not change over time, except at the lumbar spine in the 24 weeks alendronate group. Longer follow-up is warranted to evaluate clinical consequences on long term.

Presence of Erosions Is Not a Risk Factor for the Development of Knee OA in a Hand OA Population: The Framingham OA Study

Tine Vanhaverbeke[1], Gabriela Rabasa[2], Ruth Wittoek[1], Ida Kristin Haugen[3] and David Felson[2], [1]Dept. of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium, [2]Boston University, Boston, MA, [3]Diakonhjemmet Hospital, Oslo, Norway

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a prevalent musculoskeletal disease and can affect multiple joint sites in one patient. Studies have shown an association between hand and knee OA (1). However, few studies have examined the association between erosive hand OA, a subtype of hand OA considered to be more inflammatory, and knee OA. The goal of this study was to assess the association between erosive hand OA and knee OA and to identify risk factors for the development of knee OA in a hand OA population.

Methods: All subjects were selected from the Offspring and Community cohorts of the Framingham OA study. Bilateral knee and hand radiographs were obtained and scored using the Kellgren-Lawrence grade (KLG). Radiographic tibiofemoral OA was defined as at least one knee having a KLG≥2. Symptomatic knee OA was defined as presence of radiographic OA, in combination with presence of frequent knee pain. Radiographic hand OA (RHOA) was defined as KLG≥2 in at least one hand joint, erosive hand OA as RHOA plus a central erosion and symptomatic hand OA as RHOA plus pain, aching or stiffness in the same joint. Crude prevalence and incidence numbers were calculated. Multivariable logistic regression analysis, adjusted for age, sex and BMI was performed.

Results: In total, 1293 participants were studied. After adjustment for age, sex and BMI, presence of radiographic hand OA was associated with the development of symptomatic knee OA (OR 1.8 [1.4,2.4]). Similar results were found for symptomatic hand OA as the predictor (OR 1.9 [1.3,2.7]). However, compared with nonerosive hand OA, erosive hand OA was not identified as a risk factor for the development of symptomatic knee OA (OR 1.3 [0.7, 2.6]). Other risk factors identified for the development of symptomatic knee OA were: presence of thumb OA (vs. no thumb OA), presence of OA at a distal

Table 1: Risk factors for the development of symptomatic knee osteoarthritis in subjects with symptomatic hand osteoarthritis

Variable	Odds Ratio (OR)	95% Confidence Interval (95% CI)
Presence of Symptomatic Hand OA	1.89	(1.34, 2.67)
Presence of Symptomatic Bilateral Hand OA	1.47	(0.84, 2.57)
Presence of Thumb Base OA	1.98	(1.36, 2.90)
Presence of DIP OA	1.73	(1.20, 2.50)
Presence of PIP OA	1.97	(1.29, 3.03)
Presence of Erosive HOA	1.18	(0.60, 2.34)
Number of Finger Joints Affected-Continuous*	1.17	(1.06, 1.29)
Number of Finger Joints Affected-Dichotomous (1 if 3 or more joints are affected for kl >=2)*	1.84	(1.15, 2.96)
>= 1 Unit Change in KL Grade in At Least One Joint*	2.09	(1.50, 2.91)
>= 1 Unit Change in KL Grade in At Least Two Joints*	2.13	(1.53, 2.97)
>= 1 Unit Change in KL Grade in At Least Three Joints*	2.29	(1.61, 3.26)

* Includes thumb

Table 2: Risk factors for the development of symptomatic knee osteoarthritis in subjects with radiographic hand osteoarthritis

Variable	Odds Ratio (OR)	95% Confidence Interval (95% CI)
Presence of Radiographic Hand OA	1.8	(1.4, 2.4)
Presence of Radiographic Bilateral Hand OA	1.9	(1.4, 2.6)
Presence of Thumb Base OA	1.9	(1.4, 2.6)
Presence of DIP OA	1.6	(1.2, 2.1)
Presence of PIP OA	1.8	(1.2, 2.7)
Presence of Erosive HOA	1.3	(0.7, 2.6)
Number of Finger Joints Affected-Continuous*	1.2	(1.1, 1.3)
Number of Finger Joints Affected-Dichotomous (1 if 3 or more joints are affected for kl >=2)*	1.8	(1.2, 2.7)
>= 1 Unit Change in KL Grade in At Least One Joint*	2.1	(1.6, 2.8)
>= 1 Unit Change in KL Grade in At Least Two Joints*	2.2	(1.7, 2.9)
>= 1 Unit Change in KL Grade in At Least Three Joints*	2.2	(1.6, 3.0)

* Includes thumb

interphalangeal (DIP) joint, presence of OA at a proximal interphalangeal (PIP) joint, the number of finger joints affected and a change of at least 1 unit in KL grade in one or more hand joints (interphalangeal and thumb joints). .

Conclusion: This study confirms presence of hand OA is a risk factor for the development of knee OA. However, in a hand OA population, presence of erosions is not an additional risk factor. Our results may suggest that erosive hand OA is unrelated to OA in the knee.

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Hand osteoarthritis (OA) is a frequently occurring form of OA characterized by symptoms including joint pain, stiffness, and swelling which affect performance of activities of daily living.The Australian/Canadian Osteoarthritis Hand Index (AUSCAN) is a key functional survey for hand OA, consisting of 15 questions organized into three subscales: pain, stiffness, and physical function.While AUSCAN results are typically reported as a total index and/or subscale scores, the individual questions are more granular endpoints which are relevant to patients' daily activities such as getting dressed, turning doorknobs and faucets, and cooking. The purpose of this post-hoc analysis was to evaluate the scores from the individual AUSCAN questions from an 8-week randomized, double-blind, placebo-controlled trial of diclofenac sodium 1% gel (DSG) vs vehicle in the treatment of hand OA (Altman RD, et al. J Rheumatol 2009;36:1991-9).

0 = no pain/stiffness/difficulty, 100 = severe pain/stiffness/difficulty

Mean scores for individual AUSCAN questions (0-100 scale)

Methods: Patients diagnosed with hand OA in the dominant hand were randomly assigned DSG (n = 198) or vehicle (n = 187) and applied 2 g to each hand 4 times daily for 8 weeks. Vehicle was identical to DSG except for the absence of diclofenac sodium.AUSCAN questions were scored using a scale of 0 (no pain/stiffness/difficulty)-100 (extreme pain/stiffness/difficulty) at baseline and at weeks 1, 2, 4, 6 and 8.Mean scores for each question were assessed and compared between treatments at each timepoint using Analysis of Covariance (ANCOVA) with baseline as a covariate in the model and with no multiplicity correction.

Results: DSG demonstrated efficacy with reduction of pain subscale question scores at week 6 by 42%-44% (33%-35% for vehicle), stiffness scores by 42% (30% for vehicle) and physical function subscale scores by 39%-45% (27%-33% for vehicle).Statistically significant differences favoring DSG over vehicle were observed at weeks 4 and 6 (the primary endpoints) in all categories and at week 8 in the stiffness and physical function questions. Specifically, the questions with the greatest separation from vehicle at week 6 involved pain when turning and squeezing objects, stiffness upon wakening, difficulty turning doorknobs and faucets, and difficulty getting dressed, all of which are important components of hand functionality in daily living. Questions that did not reach statistical significance demonstrated a trend favoring DSG.

Conclusion: The results from this analysis show that the individual AUSCAN index question scores for DSG reach statistical significance vs vehicle at week 4 and last through week 8.The DSG scores at week 6 demonstrate a 39%-45% improvement from baseline in performing daily activities including turning objects such as doorknobs and faucets, getting dressed, and cooking compared to 27%-35% reductions from baseline for vehicle. These endpoints may be more meaningful to patients than the subscale scores of pain, stiffness and physical function, and may provide healthcare providers better ways to communicate the benefit of using DSG to treat the symptoms of hand OA.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is not cure or an efficient treatment for the osteoarthritis (OA). Mitochondrial damage and dysfunction are described during OA process modulating chondrocyte function and survival contributing to its pathogenesis. As a consequence, mitochondria has proposed as a potential therapeutic target for OA.

Aim: To describe a method to isolate functional mitochondria and assess their functionality and capacity to integrate in joint tissues

Methods: Magnetic beads coupled to anti-TOM22 was used to obtain isolate mitochondria from liver of C57BL/6JOlaHsd after classical tissue digestion. Transmission Electron microscopy (TEM) images and Western blot (WB) were using to stablish the purity and the analysis of Mitotracker Red® staining and ATP were studied in the stablish of mitochondria viability. To evaluated the capacity of mitochondria to integrated in the joint tissues, cartilage and synovial membrane explants were co-incubated in presence of isolated mitochondria labeled with Iron nanoparticles or MitoTarker Red ® during 24, 48 hours (h). Mitochondria labeled with Mitotracker Red® were injected in left knee of 3 C57BL/6JOlaHsd mice and 48 h after the animals were euthanized. The ability of the injected mitochondria to cross the different joint tissues was analyzed, as well as the biological effect and safety of the intra-articular injection.

Results: Normal mitochondrial morphology was obtained when TEM images were analyzed (**Figure 1-A**). WB showed a big signal of *ATP synthase α* in mitochondrial isolated fraction while *BIP* and *Tubulin-α* were detected only in the elution fraction (**Figure 1-B**). These data reflected that isolated mitochondria were purity. The Mitochondria viability was analyzed through the evaluation of MitoTracker Red ® fluorescence and ATP production. Isolated mitochondria labeled with MitoTracker Red ® showed higher fluorescent than the same samples without label (81±6.92 vs 2.51±0.29, p=0.05) (**Figure 1-C**). ATP production in isolated mitochondria was modulated when were incubated in presence of 0.8 µM Rotenone (27.64±3.42 vs 16.76±4.62) (**Figure 1-D**). These results showed that isolated mitochondria were functional.

In vitro analysis showed the presence of isolated mitochondria embedded in the ECM of the superficial and intermedial layer of cartilage and into the ECM of synovial tissue (**Figure 2-A-B**). Morphology of chondrocytes in the different layers of the cartilage and morphology of synoviocytes did not show any change. Intrarticular injection of mitochondria caused low grade of joint inflammatory response as well as any systemic complication, no animal dead. Histologic studies of left joint showed Mitotracker Red® signal in the synovial membrane and in the superficial layer of the cartilage (**Figure 2-C**). Synovitis was not present. Histologic studies of the right knee and organs did not detect any red fluorescence stain.

Conclusion: Isolated mitochondria penetrate ECM of cartilage and synovium. In mice, intraarticular injection of functional isolated mitochondria is safety. These data give us the opportunity to continue studying the mitochondria as a treatment for OA.

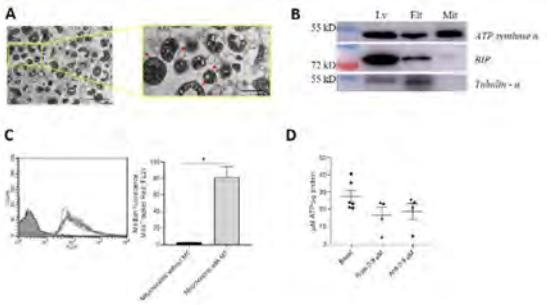

Figure 1. Purity and viability of isolated mitochondria. A Transmission electron microscopy (TEM) image of isolated mitochondria: representative image of purify mitochondria from mouse liver. mitochondria morphology was investigated by transmission electron microscopy. picture was taken at 9,000x (left panel) and the magnification area at 25,000x (right panel), black bars display 2.5 µm (left panel) and 1 µm (right panel) respectively. Black dots at the outer membrane represent anti TOM22 magnetic beads (red arrows). **B. Western blot** of preparations probed with antibodies specific for organelle-cell compartment specific marker proteins: cytosol (Tubulin-α), mitochondria (ATPsintase α) and Endoplasmic Reticulum (GRP78 -BIP). Lv: liver homogenate, Flt: elution fraction, Mit: isolated mitochondria. **C. Mitochondrial membrane potential (ψm)** of isolated mitochondria labeled with MitoTracker Red® was measured by flow cytometry .Graph. represented the the median of fluorescence showed the comparison between mitochondria without and with Mitotracker Red® (MT) (N=4). **D. ATP production** nmol/µg mitochondrial protein was determined by ATP assay in isolated mitochondria (basal) and in isolated mitochondria incubated in presence of 0.8 µM Rotenone (Rote) or 0.8 µM Antimycine A (Anti) during 2 h (N=4) *p≤0.05

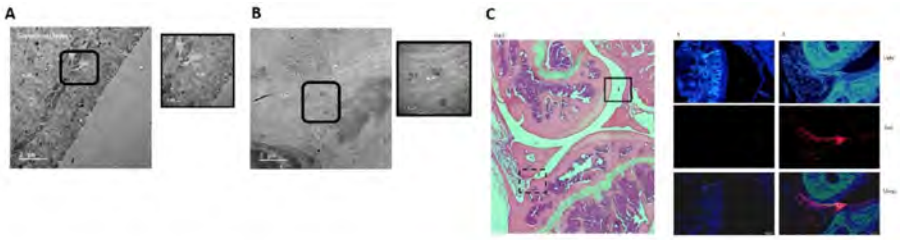

Figure 2. Mitochondria has the capacity in breaking through joint tissue and penetrate in ECM of cartilage and synovium. A. Cartilage with mitochondria injection labeled with iron during 48 h. Images showed the presence of mitochondria in the superficial layer embedded in the extracellular matrix (em), these pictures were taken at 15,000 X and 40,000 X respectively and withe bar display 2 and 1 µm respectively. **B**. Synovial membrane incubated with mitochondria labeled with iron, picture showed the presence of mitochondria embedded in the extracellular matrix (em), picture was taken at 15,000 x (left panel) and the magnification area at 50,000 x (right panel), white bars display 2 (left panel) and 0.5 µm (right panel) respectively. **C**. ***In vivo* model**. Mitochondria obtained from mouse liver were labeled with MitoTracker Red® and injected in the mouse left knee. 48 h later the animal was scarified. The red fluorescence analysis showed the presence of red mitochondria in the superficial layer of the cartilage and in the synovial membrane.

Abstract Number: 1189

Evaluating Neuropathic and Nociplastic Pain in Patients with Hip and Knee Osteoarthritis

Carly Conran[1], Larry Moreland[2], Andrew Clauw[1], Jennifer Seifert[1], Carson Keeter[3], Craig Hogan[1] and Michael Dayton[1], [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Colorado, Denver, CO, [3]University of Colorado, Aurora, CO

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic pain in patients with hip and knee osteoarthritis (OA) has been classically attributed to nociceptive pain pathways. Emerging evidence has demonstrated influence from additional pain pathways in OA (Table 1). In this study, we screened for pre-operative neuropathic and nociplastic pain in patients who subsequently underwent hip or knee arthroplasty.

Methods: Participants filled out two surveys reflecting pre-surgical pain: 1) the PainDETECT questionnaire (PD-Q) to assess neuropathic pain, and 2) the Fibromyalgia Survey Questionnaire (FSQ). The FSQ is comprised of the Widespread Pain Index (WPI) assessing widespread musculoskeletal pain and the Symptom Severity Scale (SSS) assessing comorbid symptoms (e.g., fatigue). The 2016 fibromyalgia criteria were used as inclusion criteria for fibromyalgia diagnosis.

Results: Overall, 89 participants were included in our analysis (23 hip OA, 66 knee OA). The mean age was 66.0 ± 9.01 (mean ± SD), 50 were female (56.2%), 84 were Caucasian Non-Hispanic (94.4%), the mean BMI was 30.43 ±5.56 (Table 2). Of this cohort, 18.0% had widespread pain (WPI ≥ 7), 7.9% met diagnostic criteria for fibromyalgia, 25.8% had possible neuropathic pain (PD-Q 13-18), and 12.4% had probable neuropathic pain (PD-Q ≥19) (Figure 1). This represented 34 (38.2%) unique individuals. We did not find significant differences in age, BMI, sex or site of OA among those with versus without widespread pain, fibromyalgia or neuropathic pain.

Conclusion: Among patients with hip or knee OA who underwent joint arthroplasty, more than a third had evidence of pre-operative nociplastic and/or neuropathic pain. This has clinical relevance, as nociplastic and neuropathic pain may have decreased responsiveness to peripherally directed therapies such as surgery. Given the evidence that there are multiple

Worsening of Pain as Perceived by Patients Is Not Reflected by an Annual Standardized Questionnaire

Coen van der Meulen[1], Lotte van de Stadt[2], Frits Rosendaal[1] and Margreet Kloppenburg[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Reade, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The course of pain in hand osteoarthritis (OA) is often investigated with repeated validated pain questionnaires. However, it is unknown whether these questionnaires reliably reflect patients' experience of changes in pain. This experience may be influenced by amongst others recall and a shift in the patients' perception of the pain over time. In order to improve patient outcomes, it is important to ensure that what is measured as a decrease in pain is also experienced as such. Therefore, this study aimed to compare yearly changes on a validated pain questionnaire with the pain course recalled by the patient.

Methods: Four year data of the ongoing HOSTAS (Hand OSTeoArthritis in Secondary care, patients with primary hand OA diagnosed by rheumatologist) cohort were used.

Pain was measured with the Australian/Canadian hand Osteoarthritis index (AUSCAN) pain subscale (range 0-20) annually from baseline. Change in cross-sectional AUSCAN pain scores between years were categorized using the minimal clinical important improvement (MCII, 1.6). Additionally, an anchor question asking participants whether pain had worsened, improved, remained stable or if they had never had pain, compared with the year before, was collected annually. Patients were included in the current analysis if change in AUSCAN pain and the anchor question were available for at least one year.

Changes in annual AUSCAN scores were compared to answers on the anchor questions Cohen's kappa was calculated. Annual results were comparable between years, so the years were pooled.

Results: Over 4 years, 708 annual intervals (307 patients, mean age 61.0 (SD 8.2), 82% women, mean BMI 27.3 (SD 4.8), baseline AUSCAN pain 9.1 (SD 4.2)) with change in AUSCAN and anchor questions were available. Of 307 patients, 95 provided one interval, 74 provided two, 87 provided three and 51 provided four. In 203 intervals 172 patients reported an increase in AUSCAN pain (of which in 151 intervals patients (74%) indicated their pain had worsened), in 293 intervals 199 patients reported a stable level of pain (of which in 96 intervals (33%) indicated their pain had not changed) and in 212 intervals 176 patients reported a decrease in pain (of which 39 (19%) indicated their pain had improved) (table 1). The most frequent answer was worsening pain. In 422 (60%) of intervals, the anchor question was not in concordance with the AUSCAN pain (Cohen's kappa of 0.12).

Table 1. Change in AUSCAN pain compared with change in pain on anchor question

		Change in AUSCAN pain			
		Improvement	Stable	Worsening	Total
Anchor question	Worse – more pain	98 (14)	173 (24)	**151 (21)**	422 (60)
	No change	74 (10)	**96 (14)**	41 (6)	211 (30)
	Better – less pain	**39 (6)**	20 (3)	11 (2)	70 (10)
	Never had this symptom	1 (0)	4 (1)	0 (0)	5 (1)
	Total	212 (30)	293 (41)	203 (29)	708 (100)

Table 1. Change in AUSCAN pain vs anchor questions. The number and % of concordant answers in bold.

Conclusion: Changes in yearly AUSCAN pain measured differ greatly from the course of pain over the last year perceived by the patient. The patients described deterioration more often than is reflected in the differences between AUSCAN pain measurements. Further investigations to understand pain development, how patients perceive pain development and how best to evaluate it, are warranted.

A Phase 1b, Randomized, Double-Blind, Placebo-Controlled, Multiple-Dosing, Ascending-Dose Study Evaluating the Safety, Tolerability and Pharmacokinetics of XG004 Applied Topically in Participants with Osteoarthritis of the Knee

Guang-Liang Jiang[1] and Feng Xu[2], [1]Xgene Pharmaceutical Inc., Lexington, MA, [2]Xgene Pharmaceutical Inc., Altos Hills, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Globally osteoarthritis affects about 302 million patients, knee osteoarthritis accounts for 263 million and ranks the highest in disability and pain compared to OA of other joints. Efficacious and safe therapeutics for chronic management of OA symptoms are still needed. Topical therapies remain the first line of recommendation for pharmacological management of OA. The current study was to assess a topical gel formulation of XG004, a new chemical entity inhibiting both the COX enzymes and the calcium a2d-subunit, in knee OA patients.

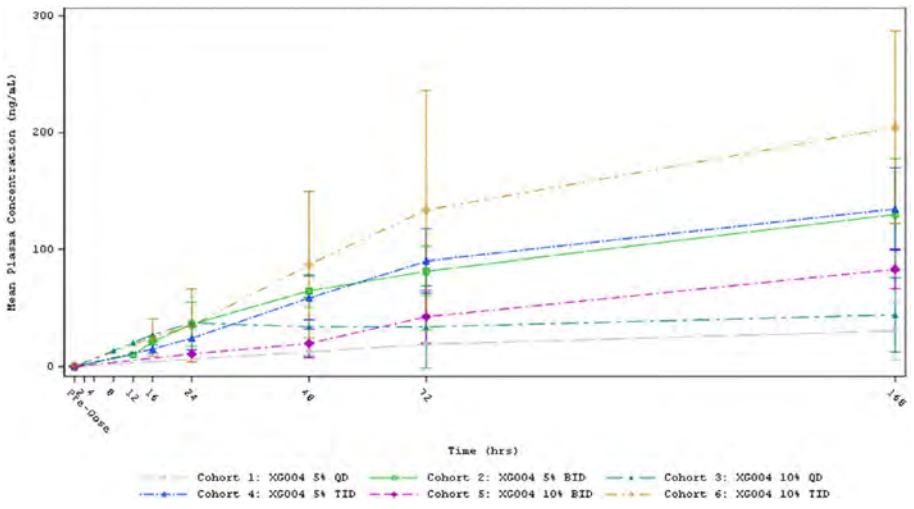

Figure 1. Plasma Concentrations (mean +/- SD) of Naproxen (linear)

Methods: The Phase 1b study (NCT054540200) was a randomized, double-blind, placebo-controlled, single-center, parallel-group trial, evaluating the safety, PK and efficacy of topical application of XG004 gel in Australian patients with OA of the knee. Patients with moderate to severe OA pain and Kellgren-Lawrence (KL) grade of II-IV were randomized in a 3:1 ratio to receive 4 mL of 5% or 10% topical gel of XG004 or placebo qd, bid, or tid over one week period. Trough plasma and synovial fluid (SF, withdrawn on day 8) PK was assessed with up to 24 hours interval from the last dosing. The exploratory efficacy was measured by changes from baseline in daily walking pain, sleep interference, the WOMAC scores, and the Patient Global Impression of Change (PGIC).

Results: 32 randomized patients had a mean baseline walking pain of 5.7 (0-10 NRS scale), 25% patients had KL grade IV, 56.2% patients had painDETECT score ≥ 13 (indicating neuropathic pain components), those and other baseline characteristics were well balanced between active and placebo arms. All reported good tolerability and safety without SAEs or discontinuation to the study drug. While pregabalin (an active metabolite) was only measurable in plasms of 10% TID dosing cohort, XG004 and another active metabolite naproxen were readily assessable in both plasma and SF. Plasma concentration increased over time in a dose-frequency- and drug-content-dependent way (Fig. 1). The magnitude of symptom improvement was greater in BID or TID dosing cohorts than in the QD cohorts. Over placebo, the BID or TID drug applications resulted in symptom relief in WOMAC pain, physical function, stiffness, total score, and daily walking pain with standard

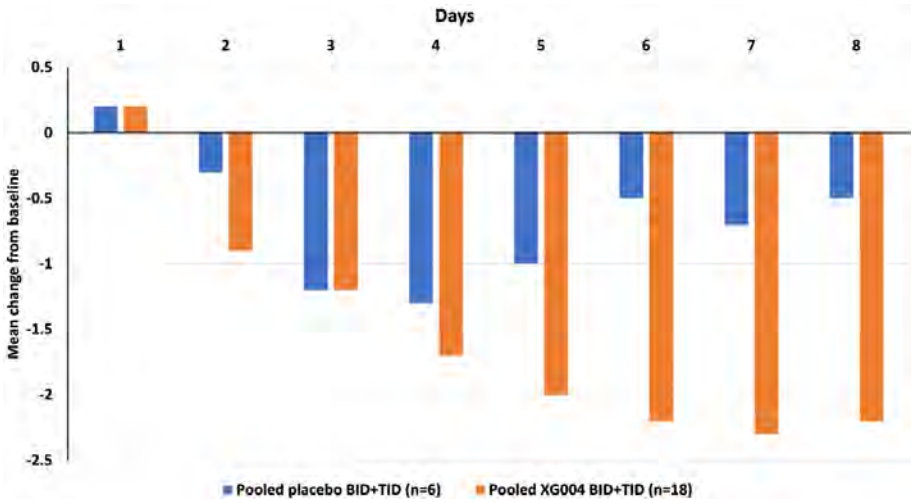

Figure 2. Sleep Interference Score Changes from Baseline in Pooled BID+TID Cohorts (0-10 NRS scale)

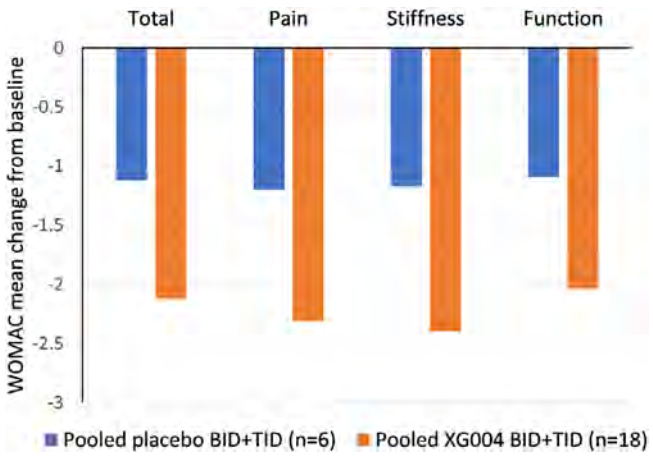

Figure 3. WOMAC Total and Subscore Changes from Baseline in Pooled BID+TID Cohorts (0-10 NRS scale)

effect sizes of 0.639, 0.444, 0.528, 0.508, and 0.343 by the end of 7 days treatment, respectively (Fig. 3). Meantime, these treatment regimens improved pain-induced sleep interference with an effect size of 0.752 (Fig. 2). 72.2% patients with XG004 BID or TID treatment reported at least "minimally improvement" and 27.8% reported "no change", while 50% reported at least "minimally improved" and 50% reported "no change" or "minimally worse" in the placebo-treated patients.

Conclusion: XG004 topical gel in knee OA patients showed good tolerability and safety. XG004 and its active metabolites were detectable in sparse plasma and/or SF samples. 5% or 10% BID or TID dosing showed substantial improvement in knee pain, stiffness, physical function, as well as sleep quality. With novel dual targeting on both nociceptive and neuropathic pain signals, XG004 topical could be a promising more efficacious and safer addition to chronic OA pain management.

Autoimmune Thyroid Disease Associates with Symptomatic Hand Osteoarthritis in Older Persons in the Third National Health and Nutrition Examination Survey

Clement Tagoe[1] and Wanyi Wang[2], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Elite Research, LLC, Irving, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) of the hand is associated with the presence of bony deformities in the proximal interphalangeal joints, distal interphalangeal joints, and first carpometacarpal joints, frequently with joint pain and stiffness (1). The factors conferring risk and determining the joint distributions in hand OA are not well understood. Due to similarities in the epidemiology of hand OA and autoimmune thyroid disease (AITD) we investigated for the first time, a possible association between the two conditions in participants representative of the US population. The purpose of the study was to examine whether the AITD autoantibodies, anti-thyroid peroxidase antibody (TPOAb) and anti-thyroglobulin antibody (TgAb), associate with hand OA and symptomatic hand OA in the Third National Health and Nutrition Examination Survey (NHANES III).

Methods: NHANES III interviewed a sample of 33,994 participants, 3128 of whom were aged 60 years and over in Phase 2 (1991 – 1994) of the study where data for osteoarthritis were collected. A total of 2429 persons ≥60 years of age had no missing data for TPOAb and TgAb. Clinical hand OA (46.6% of participants) was defined using the American College of Rheumatology Classification Criteria modified for the NHANES III data set following the experience of Dillon et al. (2). Symptomatic hand OA (8.6% of participants) was defined as hand OA with the presence of chronic hand pain recorded as the presence of a "yes" response to the question, "Have you ever had pain in your hands on most days for at least 6 weeks? This also includes aching and stiffness". Data on hand OA or symptomatic hand OA were examined with respect to their associations with TPOAb and TgAb. Log binomial and modified Poisson regression models were fit to examine the associations between the anti-thyroid autoantibodies, and hand OA or symptomatic hand OA.

Results: Higher levels of TPOAb were associated with a higher prevalence of symptomatic hand OA in the unadjusted (*PR*=1.182, *p*=0.024) and adjusted models, after controlling for age, gender, and diabetes (*PR*=1.174, *p*=0.039). The significance of the association was no longer observed when positive TPOAb was classified into four levels and was compared

with negative TPOAb. TgAb analyzed as a continuous variable showed a trend to being positively associated with symptomatic hand OA (p< 0.10) in both the unadjusted and adjusted models. When positive TgAb was stratified as a categorical variable with four levels and compared with negative TgAb the highest quartile was associated with a higher prevalence of symptomatic hand OA than negative TgAb in the unadjusted (*PR*=2.242, *p*=0.008) and adjusted models (*PR*=2.045,*p*=0.038). There was no significant association between TPOAb or TgAb and hand OA.

Conclusion: Higher levels of TPOAb may be associated with the presence of symptomatic hand OA in persons ≥60 years. Persons ≥60 years with the highest quartile levels of TgAb may be more likely to present with symptomatic hand OA. Neither TPOAb nor TgAb was significantly related to the presence of hand OA.

The Association of Peak Forces and Loading Rates During Walking with MRI-Based Structural Worsening of the Knee: The Multicenter Osteoarthritis Study

Lauren Sara[1], David Felson[1], Michael LaValley[2], Gabriela Rabasa[1], Beth Lewis[3], John Lynch[4], Neil Segal[5], Ali Guermazi[1], Frank Roemer[6], Joshua Stefanik[7] and Cara Lewis[1], [1]Boston University, Boston, MA, [2]Boston University School of Public Health, Arlington, MA, [3]University of Alabama at Birimingham, Birmingham, AL, [4]University of California San Francisco, San Francisco, CA, [5]University of Kansas, Kansas City, KS, [6]Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany, [7]Northeastern University, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Mechanical loading is an important, modifiable risk factor for knee osteoarthritis (OA). Walking loads have been previously proposed as a risk factor for developing OA; however, there is a scarcity of literature exploring the longitudinal relation of baseline walking kinetics on structural worsening in the knee joint. Thus, our purpose was to analyze peak vertical ground reaction force (GRF) and average slope of the force (i.e., average loading rate (ALR)) during walking in persons with and without knee OA, and to explore the relation of these exposure variables to changes in MRI-based structural outcomes two years later. We hypothesized that increased peak GRF and ALR would be associated with greater odds of MRI-based structural worsening.

Methods: Data from the Multicenter Osteoarthritis Study (MOST), an NIH-funded cohort study, were used. Participants were included if they had walking GRF data at baseline (i.e., year 12 of MOST) and had obtained knee MRIs at baseline and follow-up (i.e., years 12 & 14 of MOST). Participants were excluded if they underwent total knee arthroplasty of either knee, whether prior to or during the study period.

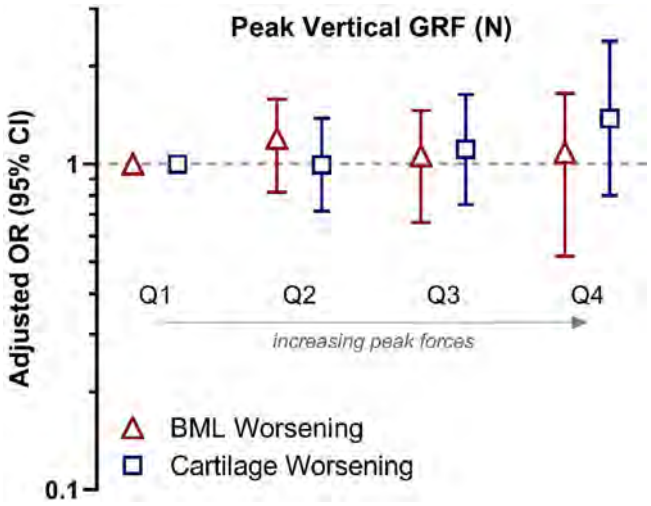

Figure 1. Adjusted odds ratios for BML and cartilage worsening across quartiles of peak vertical ground reaction force (GRF) during walking. Quartile 1 (Q1) is the reference quartile and has the lowest peak GRF, while Q4 has the highest peak GRF.

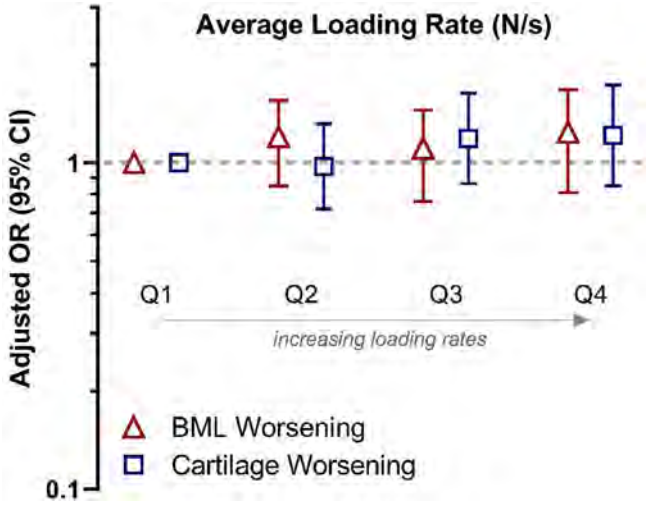

Figure 2. Adjusted odds ratios for BML and cartilage worsening across quartiles of average vertical ground reaction force loading rates during walking. Quartile 1 (Q1) is the reference quartile and has the lowest average loading rate, while Q4 has the highest average loading rate.

Peak vertical ground reaction force (GRF) and average loading rate were evaluated during the first ~10% of the gait cycle following initial contact, averaged across four trials per knee, grouped into sex-specific quartiles (Q1-Q4), and analyzed in relation to structural outcomes. MRIs were read paired by experienced musculoskeletal radiologists using the MOAKS scales. Structural worsening was operationalized in two ways: (1) increase in size of bone marrow lesions (BMLs); and (2) cartilage worsening, defined as an increase in cartilage score anywhere in the knee including incident damage. BML and cartilage worsening were separately dichotomized as Y/N (i.e., any increase in BML size or any cartilage loss) at 2-year follow-up. Analyses were conducted using logistic regression adjusting for specific covariates (gait speed, age, sex, body weight, race, and mechanical alignment). For both exposure variables, peak GRF and ALR, Quartile 1 is the reference group and represents the lowest magnitudes of force and loading rate.

Results: 1577 participants (age: 61(9) years, BMI: 28(5) kg/m^2; 56% female, 86% white) met criteria for inclusion; 8 observations were removed from analyses due to missing exposure and/or outcome data. At follow-up, 46% had BML worsening, and 45% had cartilage worsening. There were no between-quartile differences (p=0.29-0.69) or linear trends for BML worsening in either of the exposure variables (Chi Square=0.04-0.54, p=0.46-0.83). The odds of cartilage worsening were 11% higher in Q3 and 38% higher in Q4 of peak GRF (see figures) (test for linear trend: Chi Square=1.23, p=0.27). For ALR, the odds of cartilage worsening were 19% higher for Q3 and 21% higher for Q4 (test for linear trend: Chi Square=1.85, p=0.17).

Conclusion: Peak vertical GRF and GRF loading rate were not associated with worsening BMLs in the knee joint in persons with mild or no knee OA. Though not significant, the odds of cartilage worsening suggest a modestly elevated risk of cartilage worsening at higher peak GRF and higher loading rates when walking.

Abstract Number: 1194

Extent of Subregional Involvement of Subchondral Bone Marrow Lesions in Incident Knee OA Is Associated with Weight-Bearing Knee Pain

Kent Kwoh[1], Frank Roemer[2], Erin Ashbeck[3] and Ali Guermazi[4], [1]University of Arizona, Tucson, AZ, [2]Friedrich-Alexander University Erlangen-Nürnberg, Erlangen, Germany, [3]University of Arizona Arthritis Center, Tucson, AZ, [4]Boston University, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Subchondral bone marrow lesions (BMLs) have been associated with incident and progressive pain and reported to fluctuate along with concurrent fluctuations in symptoms. While associated with other structural, cellular, and biochemical features of OA that cause pain, BMLs may contribute directly to OA pain via cytokines, NGF, and altered biomechanics in knee OA, though evidence surrounding the role of BMLs and weight-bearing pain, specifically, is limited. Our objective was to estimate the effect of BML involvement on weight-bearing knee pain following radiographic KOA development, across the whole knee and by bone plate.

Methods: The OAI is a longitudinal observational study of participants with or at risk of symptomatic KOA. We identified incident cases of radiographic KOA, defined as KLG 2 or 3 on centrally graded x-rays. Participants underwent bilateral posteroanterior fixed-flexion weight-bearing knee radiography and non-contrast 3T MRI over 10 years of follow-up. MSK radiologists graded BMLs, effusion-synovitis (ES), Hoffa-synovitis (HS), cartilage and meniscal damage using the MRI Osteoarthritis Knee Score (MOAKS). BML involvement was assessed in 15 subregions (Figure 1). The WOMAC questionnaire includes pain assessment during 3 weight-bearing activities: walking on a flat surface, going up/down stairs, and standing, rated as none (0), mild (1), moderate (2), severe (3), or extreme (4). The weight-bearing knee pain score was defined as the

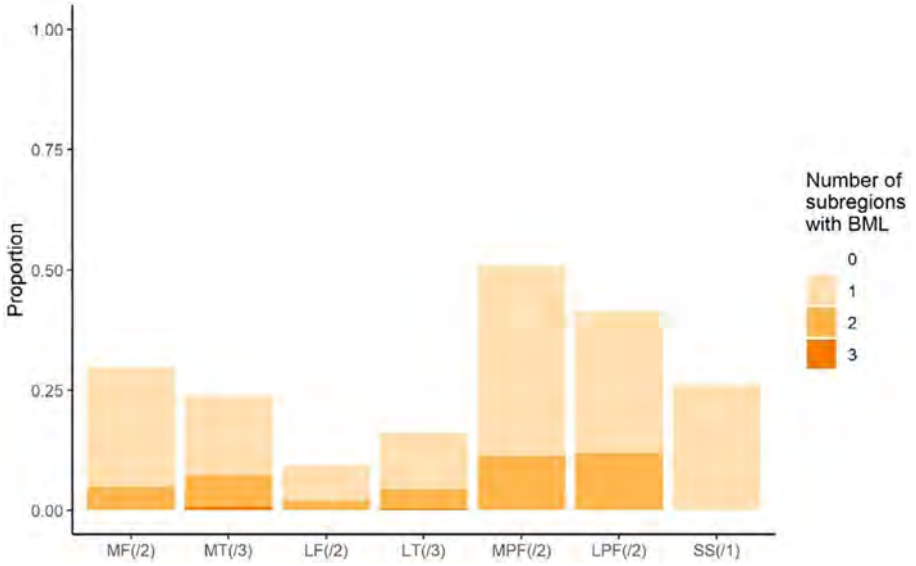

Figure 1. Prevalence of BML involvement in each bone plate, including 15 subregions: medial femur (MF) [FemCentMed, FemPostMed]; medial tibia (MT) [TibAntMed, TibCentMed, TibPostMed]; lateral femur (LF) [FemCentLat, FemPostLat]; lateral tibia (LT) [TibAntLat, TibCentLat, TibPostLat]; medial patellofemoral (MPF) [FemAntMed, PatellaMed]; lateral patellofemoral (LPF) [FemAntLat, PatellaLat]; subspinous (SS) [TibSubSpCent]

sum of reported pain scores during these activities (0-12). We fit a proportional odds logistic regression to model weight-bearing knee pain using penalized maximum likelihood estimation; predictors included the number of subregions with BML involvement, other structural damage scores, KLG, age, and BMI at the same clinic visit, as well as sex and race. We similarly fit a model with the number of subregions with BML involvement at the bone-plate level. Models were compared with and without the number of subregions with BML involvement using a likelihood ratio test (LRT). The predicted probability of weight-bearing pain score 4 or greater is reported with nonparametric bootstrap 95% confidence intervals with cluster sampling at the participant-level.

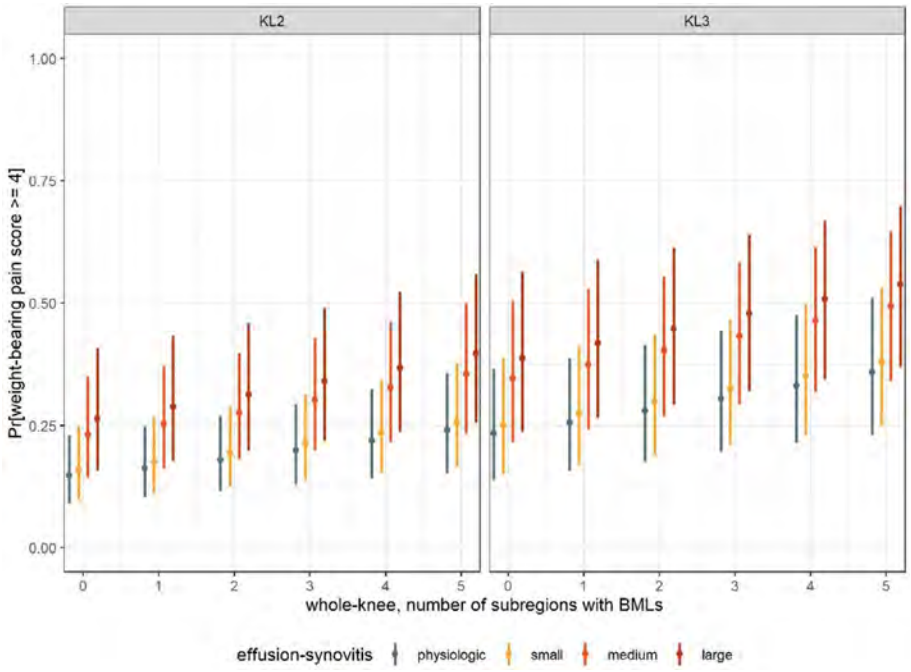

Figure 2. Weight-Bearing Knee Pain and Subregional BML Involvement By Amount of Effusion-Synovitis and Kellgren-Lawrence Grade

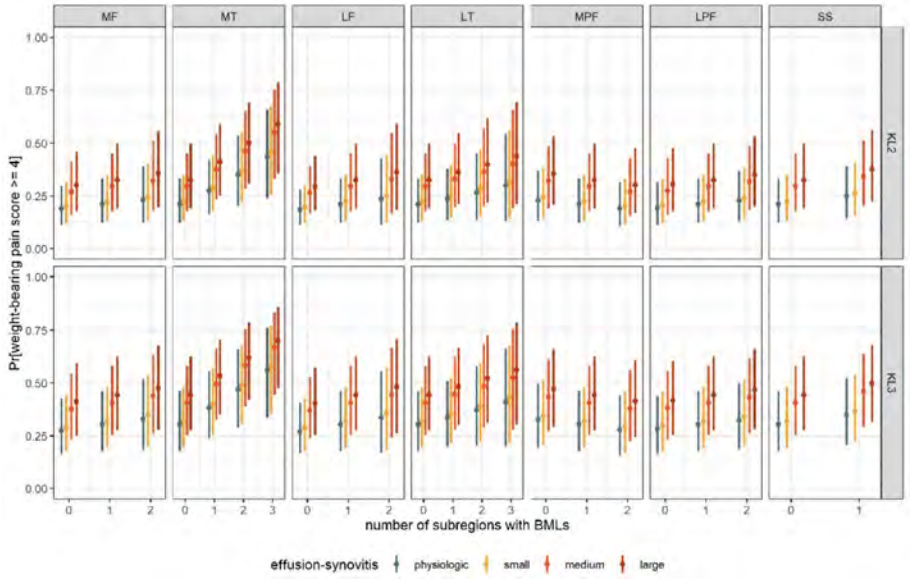

Figure 3. Weight-Bearing Knee Pain and Subregional BML Involvement within Bone Plates By Amount of Effusion-Synovitis and Kellgren-Lawrence Grade

Results: We identified 690 knees contributed by 623 participants with radiographic KOA (i.e., KL2 or KL3 at the time of MRI). The mean participant age was 65 years (SD 9), mean BMI was 29.3 (SD 4.8), 66% reported female sex, and 83% self-identified as white.The prevalence of BML involvement in our sample is shown for each bone plate (Figure 1). Predicted probability of weight-bearing pain is reported based on BML involvement, ES, and KLG, from fully adjusted models (Figures 2-3). The number of subregions in the whole knee with BML involvement was associated with weight-bearing pain (LRT p=0.006). The model that included affected subregions in each bone plate implicated BML involvement in the MT (LRT p=0.002).

Conclusion: Our findings suggest that the probability of weight-bearing knee pain increases with increasing subregional involvement of BMLs, largely driven by MT BMLs.

Abstract Number: 1195

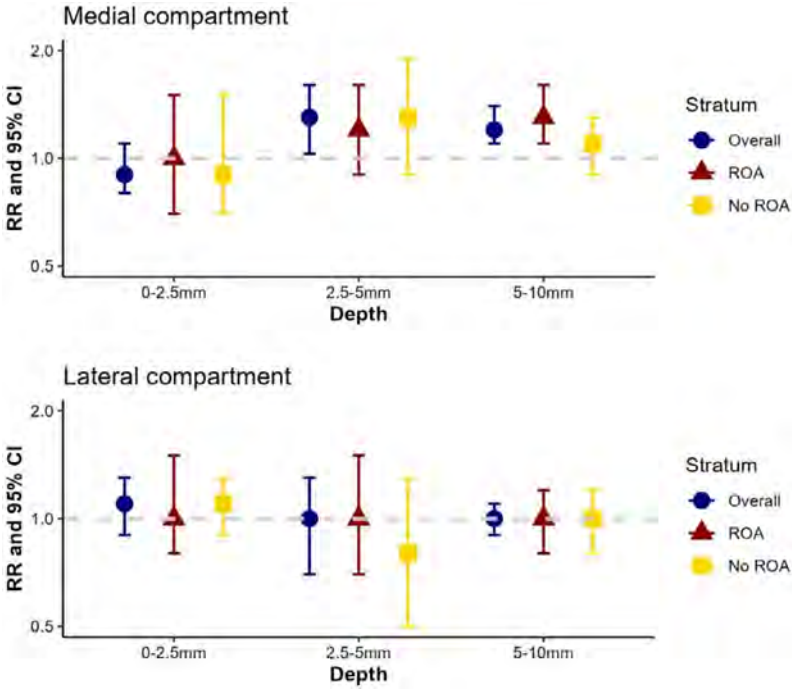
Relationship of Depth-Specific Subchondral Bone Mineral Density to MRI Cartilage Worsening: The Multicenter Osteoarthritis Study

Jean Liew[1], JD Johnston[2], Gabriela Rabasa[1], Beth Lewis[3], John Lynch[4], James Torner[5] and Tuhina Neogi[6], [1]Boston University, Boston, MA, [2]University of Saskatchewan, Saskatoon, SK, Canada, [3]University of Alabama at Birimingham, Birmingham, AL, [4]University of California San Francisco, San Francisco, CA, [5]University of Iowa, Iowa City, IA, [6]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: While OA has been considered a disease of cartilage, early subchondral bone changes may precede cartilage abnormalities. Although higher systemic BMD has a known association with radiographic OA severity, the relation of local subchondral BMD measures at the knee with structural changes on MRI is not well studied. CT topographic mapping of subchondral density is a 3D imaging tool that precisely measures subchondral cortical and trabecular BMD in relation to depth from the subchondral surface, allowing for the study of local knee BMD and its impact on important OA structural outcomes. This study aims to evaluate compartment- and depth-specific subchondral knee BMD in relation to cartilage worsening on knee MRI, with the hypothesis that higher local subchondral knee BMD will be associated with higher risk of cartilage loss in the same compartment.

Methods: Participants from the Multicenter Osteoarthritis (MOST) study, a NIH-funded longitudinal prospective cohort of older adults with or at risk of knee OA, who had knee CTs and MRIs at the 12th year study visit were included in this longitudinal analysis. A 3D imaging tool measuring BMD in relation to depth from the subchondral surface was used to assess proximal tibial subchondral BMD at depths of 0-2.5 mm, 2.5-5.0 mm, and 5-10 mm. Regional analyses of each medial and lateral plateau, at each depth were performed to calculate average BMD. Cartilage worsening on MRI was defined as any increase in the MRI OA Knee Score (MOAKS) subregion score between the 12th year visit and 2-year follow-up, considering the medial and lateral compartment separately. We evaluated the relation of subchondral BMD to compartment-specific cartilage worsening using binomial regression with generalized estimating equations to account for 2 knees within individuals,



Multivariable analyses for the association of subchondral BMD and compartment-specific cartilage worsening, overall and stratified by the presence of radiographic OA

for each compartment and depth in separate models, and adjusted for age, sex, and body mass index (BMI). We additionally stratified by radiographic OA (ROA) status in separate models.

Results: We included 1659 participants (mean age 61 years, 56% female, mean BMI 29 kg/m^2). At baseline, 90% of knees had any cartilage damage on knee MRI and 10% had any cartilage worsening at 2-year follow-up. In the medial compartment, at depths of 2.5-10mm below the subchondral surface, the risk of MRI cartilage worsening was 1.2-1.3 times higher for each standard deviation increase in the average subchondral BMD, after confounder adjustment. This association was not seen in the most superficial medial compartment depth (0-2.5mm), nor in the lateral compartment. Analyses stratified by ROA status did not differ substantially from the main results.

Conclusion: Higher subchondral tibial BMD measures were associated with higher risk of cartilage loss in the medial compartment at deeper depths of 2.5-10mm beneath the subchondral surface. These results support differential depth- and compartment-specific contributions from subchondral BMD involved in the pathogenesis of cartilage damage in knee OA.

Abstract Number: 1196

Association of Long-Term Use of Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) with Worsening Symptoms and Structural Changes of Knee Osteoarthritis: An Individual Patient Data Meta-Analysis of Cohort Studies

Zubeyir Salis[1] and Amanda Sainsbury[2], [1]The University of New South Wales, Kensington, Australia, [2]The University of Western Australia, Crawley, Australia

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) are commonly prescribed for short-term management of symptoms of knee osteoarthritis (KOA), but they are often used long-term, and the long-term effects are unclear. Therefore, we aimed to investigate the association of long-term use of NSAIDs with KOA symptoms and structural changes.

Methods: We performed individual patient data meta-analysis of three independent cohort studies: Osteoarthritis Initiative (OAI); Multicenter Osteoarthritis (MOST); and Cohort Hip and Cohort Knee (CHECK). The participants had or were at risk of developing KOA. A participant was classified as long-term user of NSAIDs if they were using them at baseline and during all follow-up visits. The follow-up visits occurred annually over 4 years in OAI, over 5 years in CHECK, and every 2.5 years over 5 years in MOST. A participant was classified as a non-user of NSAIDs if they did not use it at baseline and at any follow-up visits. There were 435 participants (with 870 knees) identified as long-term users of NSAIDs, and 3,762 participants (with 7,524 knees) identified as non-users. Outcomes included worsening pain, disability, and stiffness, assessed by the Western Ontario and McMaster Universities Arthritis Index (WOMAC) scores, structural changes assessed by Kellgren/Lawrence (K/L) grades, and incidence of total knee replacement. Generalized estimating equations were used to assess the association of long-term use of NSAIDs with the change in outcomes between baseline and the 4-to-5-year follow-up, accounting for the clustering of left and right knees within each participant. The analyses were adjusted for sex; race; baseline values of age; body mass index (BMI); smoking status; comorbidity score; walking for leisure or activity; the pain, disability, and stiffness scores on WOMAC; the severity of osteoarthritis as assessed by K/L grades; and study cohort (OAI, MOST, and CHECK).

Results: Compared to non-users, long-term users of NSAIDs had significantly increased odds of worsening pain, disability, and stiffness that was of a clinically meaningful degree. The odds ratios (OR) were 2.04 (95% confidence intervals [CI]: 1.66 to 2.49) for pain, 2.21 (95% CI: 1.74 to 2.80) for disability, and 1.58 (95% CI: 1.29 to 1.93) for stiffness. For structural changes, compared to non-users, long-term users of NSAIDs had significantly increased odds of worsening in both severity of structural changes of KOA (OR: 1.43; 95% CI: 1.15 to 1.77) and incidence of total knee replacement (OR: 3.13; 95% CI: 2.08 to 4.70).

Conclusion: Long-term use of NSAIDs may have detrimental effects on KOA, including worsening symptoms and structural changes. Although NSAIDs are useful for short-term management of KOA symptoms, our findings highlight potential adverse effects of long-term use. Therefore, healthcare providers should weigh the benefits and risks of long-term NSAID use in patients with KOA and consider alternative strategies to improve patient outcomes in the long term.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Safe and effective therapies are needed for OA pain. MM-II, a novel suspension of large, empty, multilamellar liposomes composed of dimyristoylphosphatidylcholine and dipalmitoylphosphatidylcholine, effectively reduced cartilage degeneration in OA animal models administered weekly IA injections. A single IA injection of MM-II lowered knee pain in OA patients for up to 3 months in a first-in-human study. This phase 2b study evaluated dosing, safety, and efficacy of MM-II through 26 weeks in patients with symptomatic knee OA.

Methods: Consenting patients were enrolled in a 6-arm, randomized, double-blind, placebo (PBO)-controlled, 26-week trial evaluating one IA injection of 1, 3, and 6 mL of MM-II (150 mM lipids) and corresponding volumes of PBO. Key inclusion criteria were age ≥40 years, radiographic Kellgren-Lawrence grades 2 or 3 in the index knee, ACR criteria for OA, WOMAC A pain level ≥2/4 within 24 hours of baseline (BL), index knee visual analog scale pain score of 50 to 90 mm for ≥5/7 days prior to BL, and intolerance or inadequate response to NSAIDs or acetaminophen. Patients with moderate to large effusions in the index knee

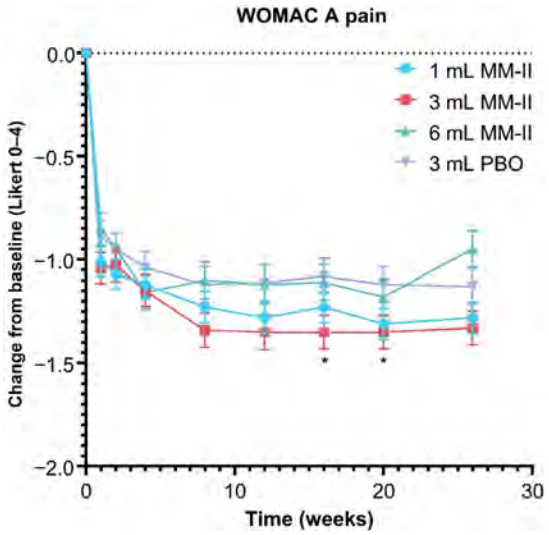

Figure 1. Change in baseline WOMAC A pain score over time. Data points represent least square means; error bars represent standard error. *P <0.05, multiplicity-unadjusted pairwise comparison of MM-II 3 mL to PBO 3 mL. PBO, placebo.

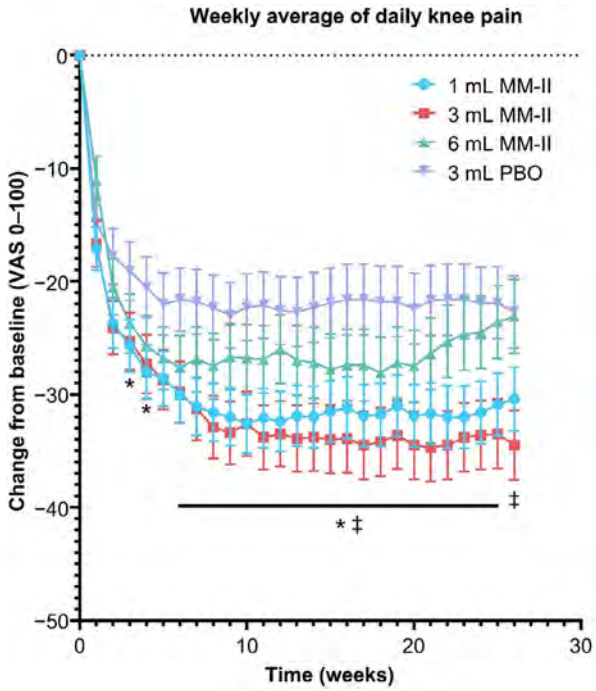

Figure 2. Change from baseline weekly average of daily pain over time. Data points represent least square means; error bars represent standard error. *P <0.05, 1 mL MM-II vs 3 mL PBO (not adjusted for multiplicity); ‡P <0.05, 3 mL MM-II vs 3 mL PBO (not adjusted for multiplicity). PBO, placebo; VAS, visual analog scale.

or with moderate to severe pain in another joint were excluded. The primary endpoint was change in WOMAC A pain score at week 12; secondary endpoints included change from BL in WOMAC A pain, weekly average daily knee pain score, and use of rescue medication. Randomization was stratified by BMI and BL index knee pain. The primary endpoint was analyzed for all patients who received MM-II or PBO (full analysis set) using mixed models for repeated measures. Treatment differences were estimated with least square means (LSM), and multiplicity-adjusted *P*-values were calculated for MM-II vs PBO 3 mL WOMAC A scores using step-down Dunnett's hierarchical testing. Nominal *P*-values were not adjusted for multiplicity.

Results: Of 397 enrolled patients, 258 (65.0%) were female and 266 (67.0%) were White. Mean age and BMI were 62.7 years (standard deviation [SD], 8.1) and 30.8 kg/m^2 (SD, 6.1), respectively. Treatment groups did not significantly differ at BL. Overall, 7.1% of patients discontinued the study. At week 12, LSM change from BL WOMAC A pain was –0.24 for the MM-II 3 mL group (95% confidence interval [CI], –0.476 to –0.004; $P = 0.085$), –0.16 for the 1 mL group (95% CI, –0.390 to 0.061; $P = 0.850$), and –0.02 for the MM-II 6 mL group (95% CI, –0.269 to 0.222; $P = 0.850$). In the 3 mL group, results were sustained until week 26 with nominal significance at 2 time points (**Figure 1**). When comparing MM-II 3 mL to the pooled PBO groups, LSM difference in change from BL of WOMAC A pain at week 12 was –0.28 (95% CI, –0.484 to –0.068; $P = 0.018$). LSM differences in weekly average daily pain scores for the MM-II 3 mL group were nominally significant from week 6 through 26 (nominal $P < 0.05$ for all; **Figure 2**). Changes in rescue medication use reflected changes in symptoms. Treatment-emergent serious adverse events (AEs) were reported in 2.67% of MM-II and 2.99% of PBO patients; incidence of injection site AEs were 1.91% and 2.99%, respectively.

Conclusion: MM-II treatment was well tolerated and may provide durable, clinically relevant pain relief. These data support phase 3 studies.

Bicycling Is Not Associated with New Knee Pain or Disease Progression over 48 Months in Those with Knee Osteoarthritis: Data from the Osteoarthritis Initiative

Colin McLaughlin[1], **Grace Lo**[1], Jeffrey Driban[2], Timothy McAlindon[3], Andrea Kriska[4], Bonnie Rockette-Wagner[4], Marc Hochberg[5], Michael Nevitt[6], Kent Kwoh[7] and Charles Eaton[8], [1]Baylor College of Medicine, Houston, TX, [2]Tufts Medical Center, Westborough, MA, [3]Tufts Medical Center, Arlington, MA, [4]University of Pittsburgh, Pittsburgh, PA, [5]University of Maryland School of Medicine, Baltimore, MD, [6]University of California San Francisco, Orinda, CA, [7]University of Arizona, Tucson, AZ, [8]Brown University, Pawtucket, RI

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Osteoarthritis – Clinical Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

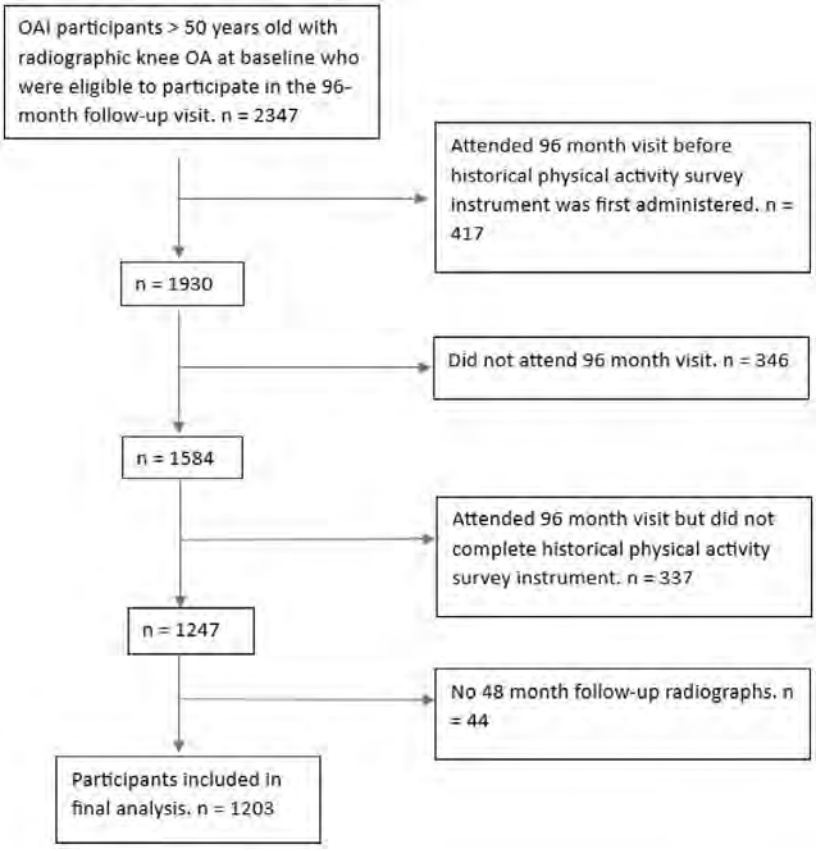

Figure 1: flow diagram indicating the selection process.

Background/Purpose: Bicycling is viewed as a non-weight bearing exercise and is often recommended as a preferred exercise for those with knee osteoarthritis (OA).However, there is no long-term epidemiologic evidence to support this recommendation.Therefore, we evaluated the relationship of bicycling with symptomatic and structural progression in those with pre-existing radiographic knee OA in the Osteoarthritis Initiative (OAI), a longitudinal observational study designed to identify biomarkers for the development and progression of symptomatic and structural knee OA.

Methods: This is a nested cohort study within the OAI, which included participants over the age of 50 years at OAI baseline who had radiographic OA in at least one knee (excluding those knees that already had undergone joint arthroplasty) at the time of OAI enrollment. Bicyclists were defined using a self-administered questionnaire completed at the 96-month visit, identifying people who had participated in the activity at least 10 times for at least 20 minutes each time. The flow diagram illustrates those who were included in the analysis. At baseline and 48-months, symptoms were assessed using the frequent knee pain question, and radiographs were scored using the Kellgren-Lawrence (KL) grade (2-4) and medial joint space narrowing (JSN) score (0-3) to determine the following outcomes of interest, including KL grade worsening (increase of KL by at least 1 grade), medial JSN worsening (any increase in medial JSN score, including within grade worsening), new knee pain

Table 1: Baseline and 48-month Characteristics of non-bicyclers and bicyclers

Baseline Characteristics	Non-bicyclers	Bicyclers	p-value

*adjusted for age, sex between OAI baseline and 48-month follow up visit			

(transitioning from no knee pain to knee pain), and improved knee pain (transitioning from knee pain to no knee pain). We evaluated the association of bicycling with the outcomes of interest using a knee-based analysis with logistic regression with generalized estimating equations to account for correlation between knees within a given person.We present crude results and those adjusted for age and sex.

Results: 1203 participants contributed 1808 knees to the study with 20% self-identifying as bicyclists. Table 1 shows the demographics of the two groups; both KL grade and JSN grade were well balanced between the groups. Notable differences were male predominance and increased number of TKR in the bicycling group compared with controls. Table 2 shows that there were no significant associations between bicycling and any of the four outcomes

Conclusion: Among individuals 50 years old and older with known radiographic knee OA, self-reported bicycling was not associated with worsening knee pain or radiographically defined structural progression. These findings support that bicycling is not harmful to knees in those with radiographic OA.

Association of Dipeptidyl Peptidase-4 Inhibitor Use for Type 2 Diabetes and Incidence of OA in Taiwan

Hsiang-Yen Lee[1], Ching-Kuei Chang[1], Tzu-Min Lin[1], Tzu-Tung Ku[2], Jin-Hua Chen[2], Yu-Hsiu Chen[3], Shu-Chuan Chen[4] and Chi-Ching Chang[2], [1]Taipei Medical University Hospital, Taipei, Taiwan, [2]Taipei Medical University, Taipei, Taiwan, [3]Tri-Service General Hospital, Taipei, Taiwan, [4]Idaho State University, Idaho State Pocatello, ID

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Osteoarthritis – Clinical Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Cellular senescence is involved in osteoarthritis (OA) development. Dipeptidyl Peptidase-4 (DPP4) is associated with senescence in OA chondrocytes. It is uncertain whether DPP4 inhibitor use is associated with reduced risk of OA in patients with type 2 diabetes mellitus. We aimed to establish whether DPP4 inhibitor use was associated with a reduced risk of OA among these patients.

Methods: We selected patients with type 2 diabetes mellitus that was diagnosed between 2008 and 2018 from the Taiwan National Health Insurance Research Database.We used Individual Matching (1:1), age ±1, same gender, same index year, same Diabetes Compilations Severity Index to balancepotential confounders between DPP4 inhibitor users and nonusers. We assessed the risks of incident OA using Cox proportional hazards regression between DPP4 inhibitor users and nonusers.

Results: We included 166,987 participants who were not treated with DPP4 inhibitor and 166,987who were treated with DPP4 inhibitor (mean age 58.60yr, standard deviation 9.53yr; 56.07% were men). In the DPP4 inhibitor use cohort, 5953 patients developed OA during a median follow-up of 3.61years (Table 1). Compared with participants who did not use DPP4 inhibitor, those who used DPP4 inhibitor had lower risks of incident OA (adjusted hazard ratio [HR] 0.43, 95% confidence interval [CI]0.42∼0.45(Table 2).Furthermore, the use of concurrent medications, such as Glucagon-like peptide-1receptor agonist (GLP-1RA; 0.22 [0.15∼0.31]) and Corticosteroid (0.66 [0.64∼0.68]), was associated with a lower OA risk (Table 3).We observed no relationship between a dose-dependent effect of DPP4 inhibitor use and OA(Table 3).

Abstract Number: 1200

Self-Reported Effectiveness of Cannabis for Arthritis-Related Pain

Kristin Wipfler[1], Joanna Zeiger[2] and Kaleb Michaud[3], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]Canna Research Foundation, Boulder, CO, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain management remains a significant challenge for individuals with rheumatic diseases (RDs), often causing patients to seek complementary or alternative treatments to traditional medications. Cannabis has been investigated as a potential option due to its immunomodulatory and analgesic effects, and arthritic pain is a commonly reported reason for cannabis use.[1] However, little is known about its safety or effectiveness in this population, and existing products are incredibly diverse and often unregulated. The objective of this study was to assess differences in self-reported effectiveness of cannabis or cannabis-derived products (hereafter simply "cannabis") for the treatment of arthritis-related pain by the presence or absence of tetrahydrocannabinol (THC).

Methods: The study population included adults in the FORWARD Databank who reported use of cannabis for treating arthritis-related pain. Participants were categorized into two groups: those who used products containing cannabidiol (CBD) but not THC, and those who used products containing THC with or without CBD. Univariate analyses were performed to examine differences between these groups, as well as between those who found cannabis effective or ineffective. Characteristics that varied significantly (chi-square or t-test $p < 0.05$) were included in a multivariable logistic regression model to assess the relationship between the presence of THC and effectiveness of cannabis in treating arthritic pain.

Results: Among 1,718 participants using cannabis for arthritis-related pain, 811 used THC-containing products while 907 used CBD-only products. In univariate analysis, THC users were significantly more likely to find cannabis effective compared to CBD-only users (62% v 39%, $p < 0.001$; Figure 1). THC users were younger, more likely to be male, more likely to live in a state where cannabis is legal, more likely to smoke, vape, or ingest cannabis, less likely to use topical cannabis, and more likely to use cannabis for other reasons in addition to pain relief (Table 1). After adjusting for confounders, logistic regression showed that participants using cannabis products with THC had significantly higher odds of finding cannabis effective for pain reduction (OR 2.2 [1.5, 3.1]; $p < 0.001$; Figure 2). Participants who used topical cannabis or who also used cannabis to treat insomnia or anxiety had significantly higher odds of finding cannabis effective, while participants with higher global VAS scores were less likely to find cannabis effective.

Conclusion: This study provides valuable insights into the use of cannabis for pain management in individuals with RDs. Our findings suggest that cannabis products containing THC and/or that are applied topically are more likely to be perceived by patients as effective. These results highlight the importance of considering the specific formulation of cannabis products as

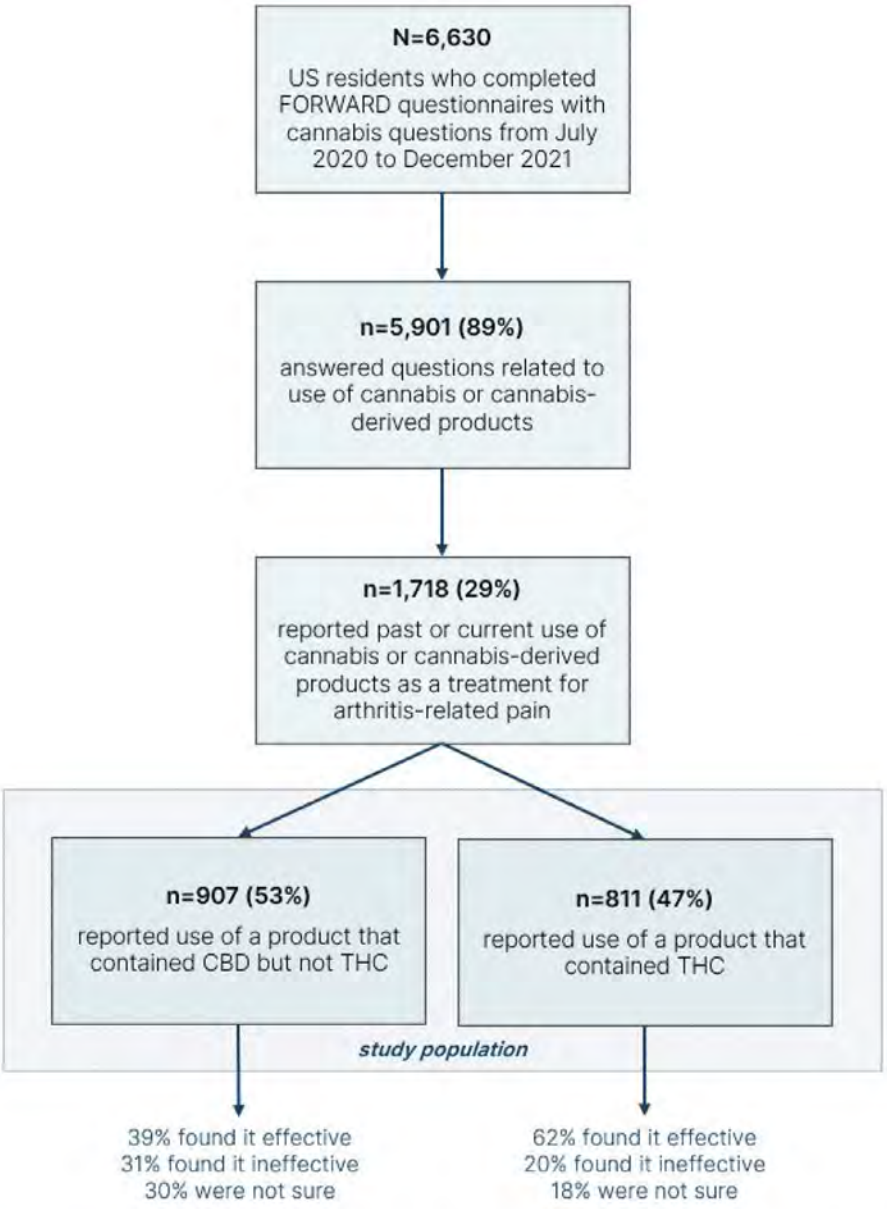

Figure 1. Inclusion criteria and study population selection. The final study population included FORWARD participants living in the US who completed questionnaires from July 2020 to December 2021 and reported using cannabis or cannabis-derived products for the treatment of arthritis-related pain. Participants who reported use of products containing THC were significantly more likely to find the product effective compared to participants who reported the use of CBD-containing products that did not contain THC (chi-square $p<0.001$).

well as their route of administration when evaluating their therapeutic potential. Prospective studies, particularly randomized controlled clinical trials, are needed to better understand efficacy and potential risks of cannabis use in this population.

1. Wipfler, K. *et al*. *Arthritis Care & Research***74**, 2091–2099 (2022)

Table 1. Characteristics of FORWARD participants who have reported using cannabis or cannabis-derived products to treat arthritis-related pain. Summary statistics are presented by whether the product did or did not contain THC, and by whether the participant reported finding the product effective or not. Significance testing was performed with Student's t-tests or chi-square tests, as appropriate.

Cannabis legality categories were determined as of January 2020. Cannabis use may have been decriminalized and/or available in certain formulations in states in the "not legal" category. CBD=cannabidiol; THC=tetrahydrocannabinol; BMI=Body Mass Index; RDCI=Rheumatic Disease Comorbidity Index; DMARD=disease-modifying antirheumatic drug; csDMARD=conventional synthetic DMARD; TNFi=tumor necrosis factor inhibitor; bDMARD=biologic DMARD; nTNFi=non-TNFi; JAKi=Janus kinase inhibitor; PRO=patient-reported outcome; VAS=visual analog scale; HAQ-II=Health Assessment Questionnaire II; PAS-II=Patient Activity Scale II.

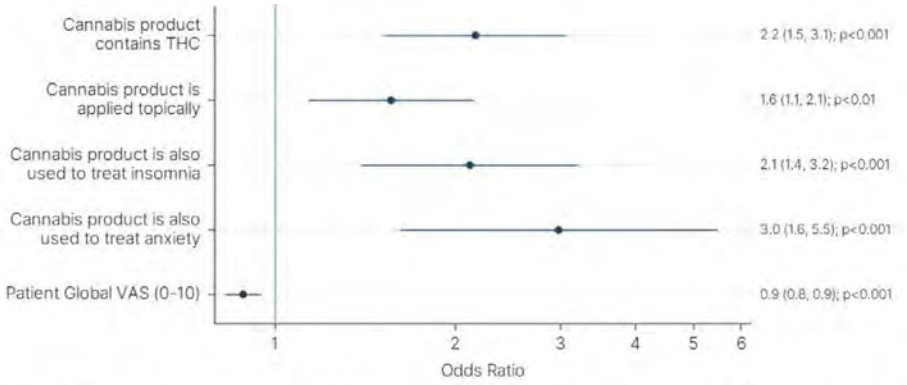

Figure 2. Factors associated with self-reported effectiveness of cannabis products in treating arthritis-related pain from multivariable analysis. The phrase "cannabis product" is used to describe cannabis or cannabis derived products that may or may not include tetrahydrocannabinol (THC). The multivariable logistic regression model included all covariates from Table 1 with p<0.05 (age, sex, race, history of smoking, state cannabis legality, routes of administration, additional reasons for use, fatigue, and global severity). Statistically significant (p<0.05) covariates are presented with their associated odds ratio (95% confidence interval) and p-value.

Frailty and Its Impact on Patient Reported Outcomes in Polymyalgia Rheumatica

Patricia Harkins[1], Sharon Cowley[2], David Kane[3] and Richard Conway[4], [1]St James's Hospital, Dublin, Ireland, [2]Tallaght University Hospital, Dublin, Dublin, Ireland, [3]Tallaght University Hospital & Trinity College Dublin, Dublin, Ireland, [4]Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty is an increasingly important construct in the field of rheumatology, aiding the identification of individuals with increased vulnerability to accelerated clinical decline and overall worse disease outcomes.

The aim of this research was to explore the prevalence of frailty, and its potential associated impact on patient reported outcomes (PRO's) in a cohort of patients with Polymyalgia Rheumatica (PMR).

Methods: Patients with a diagnosis of PMR (fulfilling the 2012 EULAR/ACR Classification Criteria), who were in clinical remission and on active treatment with glucocorticoids were recruited from two centres. Patients were ≥3 months and ≤12 months from diagnosis.

Frailty was defined by the 5 criteria of the widely validated Fried Phenotypic Frailty Index.

Patient reported outcomes included anxiety, using the Generalised Anxiety Disorder Assessment (GAD-7), mood, using the Patient Health Questionnaire (PHQ-9), fatigue using the Functional Assessment of Chronic Illness Therapy - Fatigue Scale (FACIT-F), pain, using the Visual Analogue Scale (VAS) and overall health related quality of life, using the Health Assessment

Table 1: Baseline characteristics by frailty classification according to Fried Phenotypic Frailty Index.

Table1. Baseline characteristics by frailty classification according to Fried Phenotypic Frailty Index				
Characteristic	**Robust (n=33)**	**Pre-frail (n=14)**	**Frail (n=4)**	**p-value**
Sex, female, n(%)	18(54.5%)	7 (50%)	4 (100%)	
Age, median (IQR)	72 (69-76)	67 (59- 71.8)	66.5 (63-73.2)	0.049
Body Mass Index, median (IQR)	25.4 (23.8-28.4)	30.8(26.4-32.2)	34.1 (25.8-36.1)	0.040
Rheumatic disease comorbidity index (RDCI), median (IQR)	2.0 (1-3)	1.5 (0.2-2.8)	3.5 (2.5-4.2)	0.262
GAD-7 score, median (IQR)	0 (0-2)	0 (0-4.8)	11.5 (9-14.2)	0.003
PHQ-9 score, median (IQR)	1 (0-3)	3.5 (2.2-7.8)	1.45 (12.2-17.5)	0.001
HAQ-DI score, median (IQR)	0 (0-0)	0.6 (0-0.8)	1.4 (1.1-1.8)	<0.001
VAS pain score, median (IQR)	0 (0-0)	4 (2-4)	2 (2-2.5)	<0.001
FACIT-F score, median (IQR)	48 (45-50)	40.5(36.8-43.8)	18.5 (16-24.8)	0.001

Questionnaire-Disability Index (HAQ-DI). The associations between categorical variables were compared using chi-squared or Fishers exact test where appropriate. The association between continuous variables and categorical variables were assessed using the Kruskal-Wallis test. Correlations were calculated using Pearson's r. All analyses were conducted using R (R Core Team, 2022). A p-value of < 0.05 was considered as statistically significant.

Results: 51 consecutive patients were recruited, of which 56.9% (n=29) were female. Using the Fried Phenotypic index, 64.7% (n=33) were classified as robust, 27.5% (n=14) as pre-frail, and 7.8% (n=4) as frail. All patients classified as frail were female, and had a statistically significant higher BMI (p=0.040) than those in the robust and pre-frail categories. Compared to robust individuals, those who were frail had statistically significant higher median GAD-7 (p=0.003), PHQ-9 (p=0.001), VAS (p=< 0.001) and HAQ-DI (p< 0.001) scores. FACIT-F scores were also worse in those who were frail versus robust (p=0.001).

Conclusion: Over one third of patients with PMR in this cohort were classified as pre-frail or frail. Increased frailty status was significantly correlated with worse PRO's, including mood, pain, fatigue and overall quality of life. As frailty is a potentially reversible state, accurately identifying frailty, and implementing appropriate interventions is of utmost importance to ensure improved clinical outcomes in those with PMR.

Goal Concordant Patient-clinician Dyads Have Higher Odds of Communication Around Rheumatoid Arthritis Goals

Jennifer Barton[1], Danielle ZuZero[2], Diego Molina Ochoa[3], Rachel Matsumoto[4] and Edward Yelin[5], [1]VA Portland Health Care System/OHSU, Portland, OR, [2]National University of Natural Medicine, Portland, OR, [3]University of Maryland School of Medicine, Baltimore, MD, [4]VA Portland Health Care System, Portland, OR, [5]University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Goal concordance between patients with chronic disease and their clinicians is linked to improved outcomes, however, less is known about goal concordance and goal communication in rheumatoid arthritis (RA). Our objective was to explore the relationship between goal concordance and actual conversation of patient goals during the clinic visit.

Methods: Patients with RA seen at one of two rheumatology clinics were enrolled in a cross-sectional survey study. Prior to the visit, enrolled patients and their clinicians independently ranked their top 3 goals for RA treatment. After the visit, patients completed a survey question that asked if any of their goals were discussed during the visit. Concordance was defined as the patient's #1 goal being among any of the top 3 listed by the clinician. Additional survey items included a measure of health literacy, demographics, and self-reported adherence. Goal concordance and number of goals discussed were analyzed using both descriptive statistics and statistical analysis using a Chi^2 test, in which we compared rates of communication between concordant and non-concordant patient-clinician dyads.

Results: 178 patient-clinician dyads included 15 clinicians. Of the 178 patients, 58% were female, 16% Spanish speaking, and 29% with limited health literacy. The majority of dyads (79%) were goal concordant. Among goal-concordant dyads, 33% did not discuss any goals during the visit, while 19% discussed 1 goal, 27% discussed 2 goals, and 21% discussed 3 goals. In contrast, 57% of non-goal concordant dyads did not discuss any goals during the visit, compared with 19% who discussed one goal, 16% discussed 2 goals, and 8% discussed 3 goals. Goal concordant dyads were more likely to discuss at least one goal during the visit (OR 2.63, p-value 0.009).

Conclusion: Goal concordant dyads were more likely to discuss RA patient goals during the clinic visit compared with discordant dyads. Tools to elicit RA patient goals prior to a clinic visit that can be incorporated into real-time discussions with clinicians have potential to improve patient engagement in care and RA outcomes.

Vaccination Against SARS-CoV-2 in Inflammatory Arthritis and Factors Determining Its Decision

Olivier FAKIH[1], Charlotte Bourgoin[2], Violette Benier[1], Thomas Lohse[1], Cerise Guillochon[1], Elodie Bouvier[2], Jean-Charles Balblanc[1], Thierry Conrozier[1] and Anne Lohse[1], [1]Service de rhumatologie, Hôpital Nord Franche-Comté, Trévenans, France, [2]Unité de recherche clinique, Hôpital Nord Franche-Comté, Trévenans, France

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: DMARDs, which are essential for controlling the progression of inflammatory arthritis (IA), are mostly immunomodulators that significantly increase the risk of severe infections. Therefore, several vaccinations are recommended for patients receiving these treatments. In the recent pandemic context of Covid-19, vaccination of these patients against SARS-Cov2 seems to be a major issue in their management and is recommended by scientific societies. Better identification of patients reluctant to receive this vaccination would make it possible to adapt the information to encourage their adherence.

Methods: An observational cross-sectional monocentric study in current practice was conducted to include 150 adult patients treated with DMARDs for IA at the rheumatology outpatient clinic of the Hôpital Nord Franche-Comté between June and December 2021. The main objective of this study was to determine the factors associated with refusal of vaccination against SARS-CoV-2. During routine visits, a questionnaire was administered to the patients after obtaining their consent. This questionnaire contained demographic and pathology-related data (type of IA, activity level, disease duration), treatment-related data (type of DMARD, use of corticosteroids, number of targeted therapies, number of DMARD lines), other vaccinations, and recommended follow-ups during IA (gynecological, oral, etc.), as well as diets (vegetarian, vegan, etc.). Patients who did not wish to be vaccinated answered questions regarding the reasons for their refusal. The primary endpoint was willingness to be vaccinated against SARS-CoV-2. The factors associated with willingness or refusal were also studied. Statistical analyses were performed using R++ software (ClinicalTrials.gov Identifier: NCT04970550).

Results: 100 women and 49 men, mean age of 57.9 years, with a mean BMI of 27.0 were included. The percentage of vaccinated patients was 72.5%. There was no difference between vaccinated and non-vaccinated patients in terms of sex, type of current DMARD, number of lines of DMARDs, level of education, other vaccinations (hepatitis, pneumococcus), recommended follow-up (gynecological, dermatological, oral), diet, or use of alternative medicines. The non-vaccinated patients were significantly younger (p=0.03), more worried about adverse effects (among others, cancer, and vaccine-related Covid contamination), and that it triggered a flare-up of IA (all p=0.0004). They had less confidence in the pharmaceutical industry and in new technologies (p=0.0004). They were less likely to be vaccinated against influenza (p=0.003). Their partners were less frequently vaccinated against Covid-19 (p=0.002).

Conclusion: Slightly less than 75% of patients were vaccinated against Covid-19. The factors associated with refusal of vaccination were younger age, unvaccinated spouse, fear of adverse events, and refusal of the influenza vaccination. The type of DMARD or IA (RA, AS, PsA, or other SpA) did not influence the decision to vaccinate. However, non-vaccinated patients were not less compliant with other vaccinations (except for influenza) and follow-up recommendations inherent to their treatment.

Understanding Community Perspectives on Disease Management: A Social Media Analysis of Gout Care Strategies

Maurice Flurie[1], Monica Converse[1], Christopher Parker[2], Brian LaMoreaux[3], Daniel Hernandez[4], N. Lawrence Edwards[5], Gary Ho[1], Kristina Davidson[6], E. Robert Wassman[1], Christopher DeFelice[1] and **Maria Picone**[1], [1]TREND Community, Philadelphia, PA, [2]TREND Community, Austin, TX, [3]Horizon Therapeutics, Deerfield, IL, [4]Global Healthy Living Foundation, St. Johns, FL, [5]University of Florida College of Medicine, Gainesville, FL, [6]Horizon Therapeutics, Dublin, Ireland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To comprehensively understand the impact of disease management strategies, it is essential to understand the patient perspective. Gout is a chronic inflammatory arthritis characterized by painful joint flare-ups secondary to uric acid accumulation. Virtually all subspecialty groups recommend a proactive "treat-to-target" strategy to reduce serum urate levels, but many individuals living with gout adhere to a "treat-to-no symptoms" strategy. Here, we aimed to characterize gout community perspectives on various management approaches to gout care.

Methods: We evaluated 2 online social media communities using a proprietary analytics engine that evaluates social media conversations using natural language processing. Sources included a private Facebook group, The Gout Support Group of America (15,000+ members), which had 50,000 posts/comments from 2021 to 2023; and a public subreddit, r/gout (9,000+ members), with 125,000 posts/comments from 2011 to 2023. The engine used a topic modeling approach to identify the most frequent conversation themes across groups. Topics related to disease management were then tagged. All management topics were subject to sentiment analysis in which posts/comments were scored from −1 (most negative) to 1 (most positive) using a pretrained sentiment tagger. A final exploratory analysis identified the number of questions in each topic.

Results: Topic modeling yielded more than 30 topics that had at least 300 total posts/comments. Fourteen topics related to disease management (others related to disease burden, etc.). Polarity analysis showed the most positive management topics, in rank order, to be *uric acid monitoring*, *weight loss*, *cbd/thc*, *allopurinol*, and *prednisone*. Statistically significant differences were found between topic polarities as determined by 1-way ANOVA [$F(4,10543) = 16.74$, $P = .0001$]. A Tukey post hoc test revealed that *uric acid monitoring* conversation polarity was significantly higher [0.15 (0.24), $P = .008$] than *cbd/thc* conversations, as well as *allopurinol* and *prednisone* conversations but not *weight loss* conversations. Exploratory analysis showed that about 40% of all posts/comments in *diseasemanagement* topics included questions, compared with 20% in *disease burden* topics.

Conclusion: Using a proprietary analytics engine, we identified the most prevalent topics of conversation across 2 online gout communities. In comparing the top 5 most positive management topics, *uric acid monitoring* achieved the highest mean sentiment. Though the functional impact of sentiment differences is not easily appraised, these contrasts could suggest that gout community members tend to prefer uric acid monitoring over reactive management approaches such as prednisone. *Disease management* topics were composed of about 40% questions (vs 20% for *disease burden* topics),

suggesting that increased awareness of various management strategies could benefit community members. Further work is needed to continue investigation of the patient perspective on gout management, which could be an important factor for patients having greater autonomy and participation in controlling their disease.

Universal Social Determinants of Health Screening in a Pediatric Rheumatology Specialty Clinic: A Feasibility Study

Mia Chandler[1], Margart Taggart[2], Maria Alfieri[2], Olha Halyabar[3], Joyce Chang[2], Mary Beth Son[4] and Melissa Hazen[2], [1]Boston Children's Hospital, Milton, MA, [2]Boston Children's Hospital, Boston, MA, [3]Children's Hospital/Boston Medical Center, Newton, MA, [4]Division of Immunology, Boston Children's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Social determinants of health (SDoH) significantly impact health outcomes. Practice guidelines from a national pediatric organization and federal agencies recommend routine assessment of SDoH. Screening is increasingly prevalent in the pediatric primary care setting. However, little evidence exists to suggest that pediatric specialty clinics can successfully screen for and address SDoH needs routinely. This study aimed to 1) test the feasibility of universal SDoH

1.	Do you/your child have frequent emotional or behavior concerns?	Yes	No
2.	Do you worry about your/your child's adjustment to illness?	Yes	No
3.	Do you worry about school attendance or school performance related to medical issues?	Yes	No
4.	Do you worry about where you live being unaffordable or unstable?	Yes	No
5.	Do you worry about your living conditions affecting you/your child's health (i.e. mold, bugs)?	Yes	No
6.	Do you worry about your heat or electricity being shut off where you live?	Yes	No
7.	Do you worry that your/your child's food supply will run out?	Yes	No
8.	Do you/your child have trouble with transportation for medical appointments?	Yes	No
9.	Do you worry about work attendance or work performance related to medical issues?	Yes	No
10.	Do you worry about paying for your/your child's health care? Do you need assistance obtaining health insurance coverage? ***Please circle cost, coverage, or both***	Yes	No

Figure 1: Needs Assessment Questionnaire – English Version

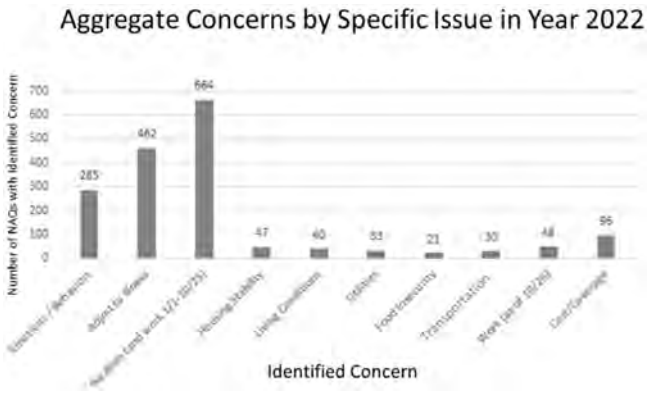

Figure 2: Identified Concerns from the Needs Assessment Questionnaire in Year 2022

screening and 2) understand the burden of SDoH-related needs in a large academic pediatric rheumatology subspecialty clinic.

Methods: As part of a quality improvement project to understand the burden of and address unmet social needs at a large pediatric academic medical center, the study team developed a SDoH needs assessment questionnaire (NAQ) via the nominal group technique. The study team included a full-time social worker and pediatric rheumatologists, including a SDoH/health equity physician researcher. The NAQ and the process outlining the distribution and return of the NAQ to the social worker were piloted. Iterative changes to the NAQ and to the process map were made to optimize the return rate. The brightly colored paper-based NAQ, translated into English and Spanish, was distributed by front desk staff to every patient/family at each in-person visit conducted in the main campus of a pediatric rheumatology outpatient clinic. Completed surveys were returned by the rheumatology providers to a single designated receptacle and then collected by the social worker within 1-2 business days. The responses from all NAQs were analyzed to understand the burden of unmet SDoH-related needs. The social worker addressed any non-urgent unmet needs identified on returned NAQs by way of the electronic health record patient portal or phone call. Acute needs identified in the clinic prompted a direct page or message to the social worker for urgent follow-up.

Results: The NAQ consists of 10 questions assessing the presence or absence of family/patient concernsabout SDoH-related needs: emotional/behavioral, adjustment to illness, school attendance or performance, housing insecurity, living conditions, utilities (heat and electric) insecurity, food insecurity, transportation access, work attendance or performance, and health care insurance/health care costs (Figure 1). Nearly 2/3 of rheumatology outpatient clinic visits between January 1-December 31, 2022, resulted in a completed NAQ (2355/3738). At least 1 unmet SDoH-related need was identified on 903 (38%) of the completed NAQs. School attendance/performance was the most frequently identified concern (Figure 2). The social worker responded to all 903 (100%) NAQs that identified unmet needs.

Conclusion: There is a significant burden of SDoH-related needs among patients presenting to a large academic outpatient pediatric rheumatology specialty clinic. Universal screening of social and behavioral determinants of health with subsequent follow-up to address unmet needs is feasible with a dedicated, full-time social worker on staff.Given the high burden of SDoH-related needs, further studies are needed to assess the effectiveness and impact of social work interventions over time.

Abstract Number: 1206

Self-Perceptions of Aging and Physical Activity in Older Adults with Arthritis: Does General Health Matter?

Sarah Lieber[1], Jerad Moxley[2], Lisa Mandl[1], M. Carrington Reid[2] and Sara Czaja[2], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Negative self-perceptions of aging are generally associated with decreased physical function in older adults. Whether self-perceptions of aging (i.e., "awareness of age-related change" including gains and losses) impact physical activity (PA) in older adults with arthritis, for whom activity is particularly important, is not well understood [1]. We examined associations between self-reported PA and awareness of age-related change, self-reported general health, and individual characteristics (e.g., sociodemographic features and comorbidity) among older adults with self-reported arthritis. We also explored whether self-reported general health mediated the relationship between awareness of age-related change losses and self-reported PA.

Methods: This cross-sectional study analyzed baseline data from a randomized controlled trial of a digitally delivered intervention designed to enhance PA versus an educational control. Adults ≥60 years of age enrolled at 2 sites. Participants with arthritis of any type were included. Sociodemographic characteristics and comorbid conditions were self-reported. PA levels

[e]Global Physical Activity Questionnaire

quantified as MET-minutes/week, awareness of age-related change gains and losses, general health, pain level and interference, and social support were assessed using validated questionnaires. Pearson correlations were used to evaluate relationships between PA and sociodemographic characteristics, multimorbidity, awareness of age-related changes, general health, pain level and interference, and social support. Awareness of age-related change losses (independent variable), general health (mediator), and PA (dependent variable) were included in a mediation model.

Results: Significant correlations were observed between PA and general health ($r = -0.29$; $p < 0.01$), social support ($r = 0.27$; $p < 0.01$), and awareness of age-related change losses ($r = -0.27$; $p < 0.01$). General health significantly mediated the negative effect of greater awareness of age-related change losses on PA, i.e., for each 1-unit increase in awareness of age-related change losses, physical activity is expected to decrease by 582.61 MET-minutes/week when mediated by general

Table 3

Table 3. Mediation model relating awareness of age-related change losses[a] and self-reported general health[b] to self-reported physical activity[c] (N=99)

Model domain	Standardized ß coefficient	Unstandardized ß coefficient [95% confidence interval]
Direct effects on general health		
Awareness of age-related change losses	0.29	0.25 [0.05, 0.45]
Race and ethnicity		
Black or African American	0.17	0.3 [-0.05, 0.65]
Other	0.09	0.24 [-0.34, 0.83]
Hispanic or Latino	0.09	0.17 [-0.23, 0.56]
Social support[d]	-0.14	-0.01 [-0.04, 0.01]
Direct effects on physical activity		
Awareness of age-related change losses	-0.06	-471.06 [-2320.80, 1378.69]
General health	-0.25	-2315.12 [-4184.8, -445.44]
Race and ethnicity		
Black or African American	0.27	4318.67 [1132.69, 7504.66]
Other	-0.01	-285.35 [-5527.6, 4956.89]
Hispanic or Latino	0.01	159.46 [-3356.69, 3675.6]
Social support	0.15	129.8 [-67.71, 327.3]
Indirect effect of age-related change losses on physical activity mediated by general health	-0.07	-582.61 [-1502.88, -24.82]

[a]Awareness of age-related change
[b]36-Item Short Form Survey General Health Scale
[c]Global Physical Activity Questionnaire
[d]12-Item Interpersonal Support Evaluation List

health (indirect effect of general health on PA unstandardized ß = -582.61; 95% confidence interval [-1502.88, -24.82]).

Conclusion: Negative self-perceptions of aging were associated with less PA in older adults with arthritis, but the impact of these negative self-perceptions was attenuated by general health. Interventions to improve PA in arthritis patients may need to target self-perceptions of aging, as well as general health.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases such as rheumatoid arthritis (RA) and Systemic lupus erythematosus (SLE) were known for increased prevalence and risk of death from cardiovascular disease (CVD) due to systemic inflammation in conjunction with other environmental risk factors and genetic predispositions. [1] The COVID-19 pandemic is of the leading causes for the increased age-adjusted mortality rate in 2020 due to various unforeseeable conditions including unequitable healthcare resource distribution, decrease access to medical treatment other than for COVID-19 infection. [2]

To investigate if the presence of the COVID-19 had an impact on the mortality outcome of acute myocardial infraction (AMI) and acute heart failure (AHF) in rheumatic diseases (RDs) including patients with RA, SLE, scleroderma, psoriasis/psoriatic arthritis, gout, myositis and vasculitis, and sarcoidosis in the United States using the NIS inpatient database from 2016-2020.

Methods: Using NIS database from 2016-2020, which stratifies 20% of the total national hospital admissions, we identified patients with a primary admission diagnosis (s) of AMI or AHF (with concurrent COVID-19 infection for 2020 data) using ICD-10 codes. (Table.1) For each admission, we calculated the baseline characteristics including mortality risk with independent variable for present or absence of RDs' ICD10 codes as the secondary diagnosis. The association of RDs with inpatient mortality was calculated using multivariable logistic regression.

Results: For 2016-2019, there were 484,775 AMI admissions without underlying RDs comparing to 23,538 AMI with RDs. During this pre-COVID-19 pandemic time, the inpatient mortality was significantly higher in the non-RDs (4.6% vs. 3.8%, $p< 0.001$). For AHF hospitalizations, 204,848 admissions were non-RDs compared to 15,799 RDs. There was no

significance in term of mortality between these two groups. (2.8% vs. 2.7%, p=0.3) The odd of dying from AMI and AHF in patients with RDs was less compared to patients in the non-RDs group after adjusting for age, race, gender, regions and other confounders. (OR=0.76, p< 0.001) (Table.2A) For the pandemic year, there were 26,313 total AMI/COVID-19 infection hospitalizations, whereas 1,164 of these admissions were from patients with RDs. The mortality was still more significant in the non-RDs group. (5.6% vs. 4.2%, p=0.042) For the AHF/COVID-19 infection hospitalization, total of 4,405 with 204 of them were from the non RDs group. Due to smaller sample size, the mortality was not significant higher in the non-RDs group. (3.2% vs. 1.0%, p=0.073) In terms of the combined mortality OR of AMI/AHF/COVID-19 infection for 2020, the non-RDs group was still having lower odd compared to RDs group (Table.2B).

Conclusion: Based on our analysis, the presence of co-morbid RDs was not associated with increase mortality in patients hospitalized with AMI even with coexisting COVID-19 infection. For the AHF cohort, there was no significance in mortality in both groups. A detailed cardiovascular review of systemic during each rheumatology clinic visit may have helped to implement early intervention on CVD complications in RDs by early referral to cardiology.

Investigating the Experiences of Patients Living with Antiphospholipid Antibodies: A Qualitative Study

Francesca Cardwell[1], Alexandra Kobza[2], Susan Elliott[1], paul Gibson[2], Nancy Soliman[2], leslie skeith[2], Ann Clarke[3] and Megan R.W. Barber[2], [1]University of Waterloo, Waterloo, ON, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]University of Calgary, Division of Rheumatology, Cumming School of Medicine, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Substantial morbidity and mortality affect those with aPLs and APS, yet the patient experience remains poorly understood. This research investigated patient experiences of aPL/APS 1) diagnosis; 2) effects on daily life; and 3) healthcare and treatment.

Methods: Patients aged ≥18 years with ≥1 positive aPL on ≥2 occasions or those meeting the Revised Sapporo criteria for APS were purposefully recruited from a Canadian multidisciplinary APS clinic to participate in semi-structured in-depth interviews. Interviews were conducted virtually and transcribed verbatim for subsequent thematic analysis using NVivo software.

Results: Twelve patients with aPLs/APS were interviewed; 91.7% were female, mean (SD) age was 47.1 (16.1) years, 66.7% had aPLs/APS with SLE (per 1997 ACR or 2012 SLICC criteria), and 33.3% had aPLs/APS without SLE (Table 1). Patients experienced a range of challenges (e.g., obstetric and thrombotic complications) and emotional impacts (e.g., relief, anxiety) around the time of aPL/APS diagnosis (*It's been a traumatic experience (Participant #050)*) (Figure 1). In addition to the physical and psychosocial impacts of living with aPLs/APS, patients reported modified leisure activities, altered employment trajectories, and both positive and negative impacts on relationships (*My relationship with my family has become stronger, my relationship with the family that I'm potentially marrying into has become weaker (#040)*). The past and future impacts on family planning were critical to how patients experienced living with aPLs/APS; specifically, they shared experiences of miscarriage and other pregnancy complications, fear of future impacts on pregnancy, and

medication-related challenges, such as with low-molecular-weight heparin injections (*I would have these bruises, it made it awkward when I would go for ultrasounds (#029)*). Challenging aspects of aPL/APS healthcare and treatment were also discussed (Figure 1), particularly related to the lifestyle impacts, side effects, and emotional burden associated with medication use (*I hate it, I hate it. It's awful (#059)*). Although a lack of aPL/APS resources was described, participants expressed trust in

Table 1: Patient characteristics

Characteristic	Total sample
All aPLs/APS, n (%)	12 (100%)
APS with SLE, n (%)	5 (41.7%)
aPLs with SLE, n (%)	3 (25.0%)
APS only, without SLE, n (%)	4 (33.3%)
aPLs only, without SLE, n (%)	0 (0.0%)
Age (years) at time of interview, mean (SD)	47.1 (15.1)
aPLs/APS disease duration (years) at time of interview, mean (SD)	8.9 (7.4)
Female, %	91.7%
SLE + aPLs/APS: medications taken in the past year[a], % (n = 8)	
Antimalarials, n (%)	8 (66.7%)
Anticoagulants, n (%)	5 (41.7%)
Antiplatelets, n (%)	5 (41.7%)
Immunosuppressants/steroids[b], n (%)	4 (33.3%)
aPLs/APS only, without SLE: medications taken in the past year[a], % (n = 4)	
Antimalarials, n (%)	1 (8.3%)
Anticoagulants, n (%)	2 (25.0%)
Antiplatelets, n (%)	2 (25.0%)
Immunosuppressants/steroids[b], n (%)	0 (0.0%)

[a]*Categories are not mutually exclusive.*
[b]*Immunosuppressants/steroids include: belimumab, mycophenolate mofetil or mycophenolic acid, and steroids.*

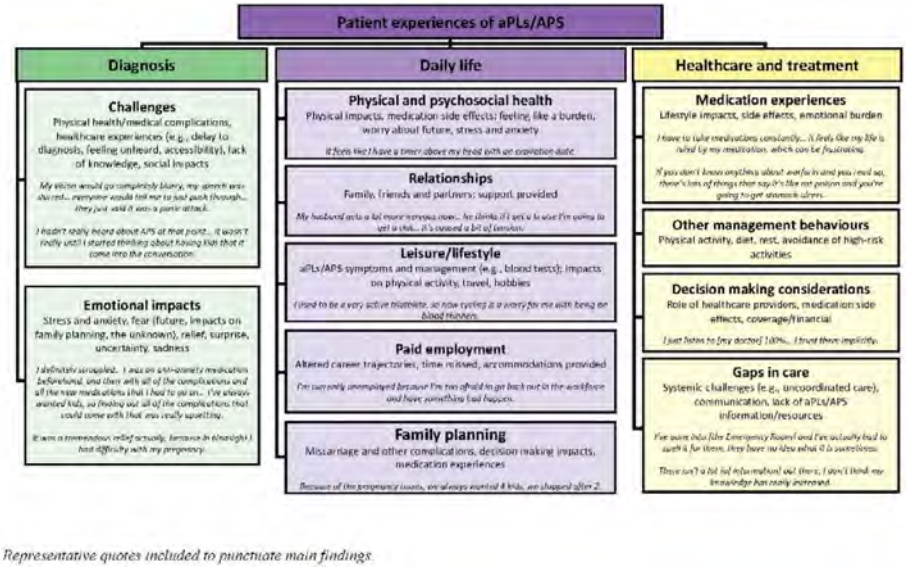

Figure 1: Overview of themes emerging through qualitative analysis

healthcare providers when making management decisions or when seeking information. Suggestions for resources included the need for additional medication-related information (long-term risks, dietary requirements; *Being able to speak with somebody who knows how warfarin works in relation to Vitamin K… that was my biggest battle (#059)*), examples to help contextualize management behaviours (*Can I sit on the couch and watch a movie? Do I have to be constantly moving around? I think more situational examples would have been helpful (#041)*), and additional information for those with aPLs/APS without SLE (*There might be a whole different resource instead of just always focusing on the lupus patients (#050)*).

Conclusion: Patients highlighted how the diverse manifestations of aPLs/APS, accentuated by management-related challenges, impose considerable physical and psychosocial burdens. Results will inform the development of patient resources and decision aids aligned with patient priorities.

Abstract Number: 1209

The Role of Kinesiophobia on Ankylosing Spondylitis Disease Activity, Exercise Habits, and Quality of Life

Joel Thompson, University of North Carolina at Chapel Hill, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Ankylosing Spondylitis (AS) consistently report exercise frequencies that are lower than healthy controls and ACSM/EULAR recommended frequencies; even though exercise has consistently been demonstrated to improve function and disease activity in patients with AS. This study explored the presence of kinesiophobia in populations with AS, specifically exploring if kinesiophobia has any correlation with disease activity, functionality, quality of life, and exercise habits of individuals with AS.

Methods: This study recruited 182 participants with AS via digital AS support groups and social media organizations. Recruited participants responded to a survey via Qualtrics that included the following validated patient reported outcome measures (PROMs): Tampa Scale of Kinesiophobia 11 (TSK-11), Baths Ankylosing Spondylitis Functional Index (BASFI), Baths Ankylosing Spondylitis Disease Activity Index (BASDAI), Ankylosing Spondylitis Quality of Life Questionnaire (AS QoL), and a modified National Health Interview Survey (NHIS) to assess exercise habits.

Results: The results of this study suggest a high level of kinesiophobia in this population with a mean TSK-11 score of 29.45 ± 6.18, with 20% reporting "severe" (>35/44) scores for kinesiophobia. Participants with high kinesiophobia also demonstrated more active disease (r=.419, p >0.001), more functional limitations (r=.532, p >0.001), and more Quality-of-Life limitations (r=.611, p >0.001).Participants with high kinesiophobia also demonstrated less activity frequency for vigorous, moderate, and strengthening activities (r=-.279, r=-.256, r=.400; p >0.001).Patients that did report engaging in moderate activity 3 or more times a week also reported significantly better results in all 4 outcome measures versus patients who did

not.A similar significant improvement in outcome measures was found for patients who reported engaging in strengthening activity 2 or more times per week versus patients who did not.

Conclusion: This study shows a significant correlation of TSK-11 scores with other clinical measures in AS patients and self-reported exercise habits. Thus, kinesiophobia may play a role in the clinical presentation of AS and so tests such as the TSK-11 may be a valuable screening tool for AS treatment.

Conservative treatment with physical therapy and regular activity is an important aspect of management of autoinflammatory disorders such as AS. Studies in populations with general low back pain (LBP) have showed success in treating chronic LBP by treating the biopsychosocial aspects associated with kinesiophobia when patients demonstrate kinesiophobia and fear-avoidant behaviors. Understanding the presence and characteristics of kinesiophobia in populations with AS can help shape and drive effective intervention models for clinicians and so the TSK-11 can be a valuable tool in screening and evaluating patients in the AS population.

Assessing Patient-Reported Drug Efficacy and Adherence Among IL-23 Inhibitors for Psoriasis and Psoriatic Arthritis

Fahad Ahmed[1], Syed M. Rahman[2], Sarah Trent[3], Lap Pham[3], Nashwah Memon[4], Hannah Chung[3] and Adel Haque[5], [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]University of Rochester School of Medicine and Dentistry, Rochester, NY, [3]PA Dermatology Partners, Philadelphia, PA, [4]Lake Erie College of Osteopathic Medicine, Bradenton, FL, [5]Jefferson Health - Northeast, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Data suggest that patient satisfaction with drug therapy in psoriasis (Pso) and psoriatic arthritis (PsA) is associated with treatment compliance and, ultimately, disease response. Biologics, including IL-23 inhibitors such as risankizumab and guselkumab, have shown efficacy for both plaque psoriasis and psoriatic arthritis. However, meta-analyses reporting patient adherence to prescribed biologic therapy range from 61% to 70%, with limited data elucidating patients' reasons for non-adherence. The objective of this study was to characterize patient-reported factors associated with adherence and efficacy among IL-23 inhibitors for psoriasis and psoriatic arthritis.

Methods: Data were collected from 37 consecutive adult patients with Pso and PsA treated with an IL-23 inhibitor (either risankizumab or guselkumab) from a single clinic at our institution from 2019 onwards. Patient-reported therapy satisfaction was assessed using an adapted Treatment Satisfaction Questionnaire for Medication (TSQM-9). The TSQM-9 is a validated instrument used to assess patient satisfaction with medication across three domains: effectiveness, convenience, and global satisfaction. TSQM-9 domain scores are calculated as recommended by the instrument authors and range from 0 to 100, with higher scores indicating increased satisfaction in that domain. Medication non-adherence was defined as at least one missed injection over the study period. Exploratory factor loading was conducted to identify specific attributes of therapy associated with adherence. Statistical analysis was performed using logistic regression.

Results: Our cohort consisted of 37 patients with a mean age of 49.7 ± 15.9 (standard deviation) years, of whom 54.1% were male. The mean treatment duration from drug initiation to the study period was 14.1 months ± 10.0, with 22 patients prescribed risankizumab and 15 patients prescribed guselkumab. In our cohort, 32% of patients reported at least one missed dose, and 5% of patients reported multiple missed doses. The overall TSQM-9 scores by domain were as follows: effectiveness 93.4 ± 7.9, convenience 93.4 ± 9.1, and global satisfaction 89.6 ± 15.9. Mean scores for TSQM-9 statistically differed ($p < 0.05$) between fully compliant patients and non-compliant patients for convenience (96.5 ± 5.4 vs. 87.6 ± 11.8). There were no intra-drug differences in satisfaction or adherence within our cohort despite variations in dosing regimens. Factor loading revealed medication planning, medication administration, and side effects as the top three variables responsible for satisfaction variance between groups.

Conclusion: This study suggests that differences in biologic therapy adherence among patients with psoriasis and psoriatic arthritis may be influenced by patient therapy convenience and satisfaction as defined by medication planning, administration, and side effects. Larger studies should further attempt to characterize and address specific barriers identified.

Description of Self-Efficacy for Managing Symptoms and Emotions in a Large Rheumatology Clinic Population

Rachel Dayno[1], Michael George[1], Kimberly DeQuattro[2], Marissa Blum[3], Sharon Kolasinski[4] and Dana DiRenzo[5], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Media, PA, [3]University of Pennsylvania, Cherry Hill, NJ, [4]University of Pennsylvania, Philadephia, PA, [5]University of Pennsylvania, Bala Cynwyd, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Self-efficacy (SE) is the inner belief in one's ability to succeed in specific situations and tasks. SE for managing the symptoms and emotions associated with chronic disease has considerable impact on health-related quality of life (HRQoL) and health outcomes. The goal of this study was to describe SE for people living with various rheumatologic diseases with comparison across insurance type and clinic setting and correlation with HRQoL.

Methods: This study was a retrospective, cross-sectional analysis of patients in the rheumatology division at a large academic medical center who had office visits and completed self-efficacy PROMIS questionnaires from July 1, 2022 to January 1, 2023. Outpatient clinic locations were urban and suburban. Questionnaires included the Patient Reported Outcome Measurement Information System (PROMIS)-29 V2.1 collection of short, fixed forms (physical function, anxiety, depression, fatigue, sleep disturbance, ability to participate in social roles and activities, pain interference) and PROMIS Self-Efficacy for Managing Symptoms (SE Symptoms) and Emotions (SE Emotions) Computer Adaptive Tests. PROMIS T-scores are based on United States (US) population normative values with a mean (SD) T-score of 50 (10). Rheumatologic diagnosis was confirmed by the treating rheumatologist at the time of the encounter. Mean PROMIS T-scores were compared across gender, race, ethnicity, clinic location, rheumatologic diagnosis and insurance type using t-tests vs ANOVA or Kruskal-Wallis, where applicable.

Depression	50.4 (8.2)	51.7 (9.3)	60.0 (9.4)	<0.001
Pain Interference	57.6 (9.0)	59.7 (9.4)	66.6 (7.0)	<0.001
Physical Function	43.7(8.3)	40.9 (10.0)	37.7 (6.5)	<0.001
Social Participation	47.8 (8.0)	45.7 (10.1)	41.7 (7.1)	<0.001
Self-Efficacy Symptoms	44.4 (7.0)	45.7 (9.0)	37.1 (7.8)	<0.001
Self-Efficacy Emotions	47.6 (7.2)	47.8 (9.0)	40.7 (7.0)	<0.001

Results shown are mean (SD) of PROMIS T-scores. Excludes patients with self-pay. *Significance determined by ANOVA. #Higher PROMIS measures reflect more of a concept, and lower PROMIS measures reflect less of a concept (ex., higher PROMIS physical function T-scores denote better physical function).

Results: There were 1,619 patients who completed office visits during the study timeframe and 647 patients (40%) completed PROMIS measures. Mean age, sex, race, disease duration, and comorbidities varied significantly between diagnoses and patients with osteoarthritis were significantly older (Table 1). The median (IQR) T-score for SE Emotions was 46 (43, 52) and the median (IQR) T-score for SE Symptoms was 43 (39, 48) for those with rheumatologic disease, below US population normative values. All PROMIS domains statistically differed between disease groups except for SE Symptoms (p=0.065) (Table 1). Compared to those with high SE for managing symptoms and high SE for managing emotions (T-scores >43 and 46, respectively) those with low SE had significantly worse HRQoL in all PROMIS domains by 5-10 mean T-score units (p< 0.001) (Figure 1). Specifically, patients with low SE Emotions had more mood disturbance and patients with low SE Symptoms had worse pain and fatigue. Patients who had low SE Emotions/low SE Symptoms had the worst HRQoL profiles overall. HRQoL including SE domains were significantly worse for individuals with Medicaid (Table 2) but not by clinic location.

Conclusion: Self-efficacy (SE) for managing symptoms and emotions was lower than expected for people living with rheumatologic disease and especially lower for those with Medicaid insurance. This suggests that SE may be impacted by socioeconomic status but needs to be explored further. SE can be measured as part of routine rheumatology clinical care, and physician awareness and interventions to strengthen SE have the potential to improve patient outcomes.

Racial Disparities in Comorbidities and Perception of Physical Health in Systemic Lupus Erythematosus

OKEOGHENE AKPOIGBE[1], YONG EUN[2], COMFORT ANIM-KORANTENG[2] and AMANDA SAMMUT[2], [1]NYCHH- HARLEM, Bronx, NY, [2]NYCHH- HARLEM, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic multisystemic immune-mediated disease with often nonspecific symptoms, associated with recurrent flares that can be life threatening. Prevalence of SLE in women and minorities especially African Americans (AA) are higher with a higher disease severity index [(1)]. Studies have shown that higher morbidity scores correlate with lower perceived physical health score [(2)]. Our study aims to assess racial disparities in perception of health using morbidity index scores and perceived physical health in SLE patients.

Methods: We included 258,188 patients from *All of Us* dataset 6 from May 6, 2018 to January 1, 2022 who had available electronic health records data. SLE patients were identified with ICD 9/10 codes. We calculated average Charlson Comorbidity Index (CCI) for SLE patients and prevalence of the following common comorbidities by race: chronic pulmonary disease (CPD), peripheral vascular disease (PVD), renal disease (RD), diabetes (DM), and congestive heart failure (CHF). From the survey data, we calculated average PROMIS-PH scores to assess the degree of self-reported physical health, with responses ranging from 2 to 10. Analysis was performed in the web-based platform Jupyter Notebook using the programming language R.

Results: Of 4,959 patients with SLE, Whites (N=1,430) had the highest average CCI of 5.44, followed by 5.34 in AA (N=857) and 4.55 in Asians (N=85). AA showed the lowest average PROMIS-PH score of 5.82, representing worse perception of physical health, compared to Whites (6.32) and Asians (6.45). Asians had the lowest prevalence of CPD (30.6%) compared to AA (45.3%) and Whites (46.8%). PVD prevalence was similar in Asians (24.6%) and in AA (25.6%) but higher in Whites (29.8%). Of note, RD in Whites was the lowest with 23.9%, higher in AA (34.2%) and Asians (40%). For DM, AA had the highest prevalence at 37.1%, followed by 20.7% in Whites and 20% in Asians. Prevalence of CHF was notably high in AA (25.9%), 15.1% in Whites and less than 15% in Asians.

Conclusion: Despite similarity in average CCI between AA and White SLE patients, self-perception of physical health was significantly lower in AA. Our study shows that morbidity indices do not always correlate with perception of health. Differences in the types of comorbidities, such as CHF and DM in African Americans could be responsible for the disparities in perceived health.

Using Patient-Reported Disease Activity in a Population-Based Cohort to Predict Systemic Lupus Erythematous Hospitalization and Emergency Room Visits

S. Sam Lim[1], Sandra Wu[2], Ryan Ross[3], Gaobin Bao[1], Megan Richards[3], Liisa Palmer[3] and Gary Bryant[4], [1]Emory University, Atlanta, GA, [2]AstraZeneca, Hockessin, DE, [3]Merative, Cambridge, MA, [4]AstraZeneca, New Castle, DE

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease that has a large range of clinical manifestations, some of which can be severe. Reducing SLE flares leading to emergency room (ER) visits and hospitalizations is often difficult for clinicians given the heterogeneity of symptoms that can identify at-risk patients. The SLE Activity Questionnaire (SLAQ), a validated patient-reported instrument designed to screen disease activities in the clinical settings, may be a novel way to predict SLE-related healthcare utilization; but such association and application has not been studied and there have been few data to support its use in the clinical setting. The purpose of this analysis was to assess the patient-reported disease activity symptoms using SLAQ components in a population-based lupus cohort and develop a predictive model to identify patients at a higher risk for SLE-related hospitalization and ER visits.

Table 1 SLAQ components by SLE-related hospitalization or ER visit

	Overall N = 1,456	No SLE-related hospitalization/ER N = 1,350	≥ 1 SLE-related hospitalization/ER N = 106

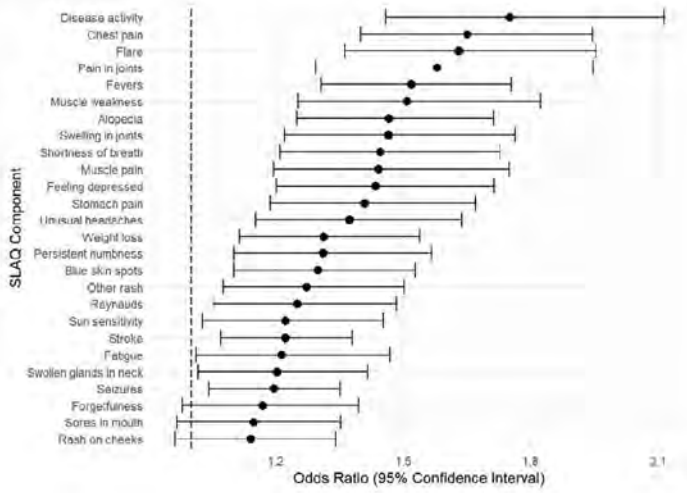
Self-report disease activity† (Mean, SD)	4.0 (3.4)	3.8 (3.3)	5.7 (3.4)

*SLAQ score is a composite variable calculated using the individual SLAQ components. Disease activity scores can range from 0-47, with 47 indicating the highest disease activity.
†Self-reported disease activity is collected on a scale from 0 (no/low activity) to 10 (severe/high activity).

Figure 1. Unadjusted association between SLAQ components and SLE-related hospitalizations/ER visits



Estimated odds ratio (and 95% CI) for each SLAQ component from unadjusted logistic regression model predicting SLE-hospitalization or ER visits. All components were standardized to the same numeric scale of 0-3 of increasing severity.

Methods: This study used data from two surveys (2011-2013) of the Georgians Organized Against Lupus (GOAL) cohort, a Centers for Disease Control and Prevention supported population-based cohort of validated SLE patients in Atlanta who complete annual surveys, including sociodemographic and the SLAQ. This database was linked with the Georgia Hospital Discharge Database to obtain ER visits and hospitalizations within 6 months of each survey. An SLE-related hospitalization or ER visit is defined based on diagnosis of SLE-related condition in the primary position within 6 months of GOAL survey completion. The unadjusted association between SLAQ components and SLE-hospitalizations or ER visits was assessed using logistic regression to identify the strongest SLAQ predictors. A classification and regression tree (CART) model generated a decision tree for predicting SLE-hospitalization or ER risk based on the SLAQ components.

Results: Of the 1,486 GOAL participants, 136 (9.2%) had an SLE-related hospitalization or ER visit within 6-months of survey completion. The mean age at survey completion was 47 (SD: 13) years, 94% of patients were female, 78% of patients were Black, and had SLE for 14 (9) years. Patients with ≥1 SLE-related hospitalizations or ER visits had higher SLAQ scores than those without hospitalization (22 vs. 17; Table 1). The risk of SLE-related hospitalization or ER visit was higher among patients with higher disease activity scores, chest pain with deep breath, and those with more SLE flares (Figure 1). CART modeling suggests patients who had chest pain with deep breath and fevers as the high-risk group with 18.8% likelihood of an SLE-related hospitalization or ER visit in the next 6 months. The high-risk group have a 2-fold increased risk than the average patients (Pr=9.2%), and a 4-to-6-fold risk than those identified as low-risk (Pr=3.2-4.5%).

Conclusion: Patients who reported chest pain with deep breath and fevers were at the highest risk of having anSLE-related hospitalization or ER visit within 6 months. The inclusion of the SLAQ in routine care may provide physicians and patients with valuable information that could help mitigate healthcare utilization and improve outcomes.

Using Patient Self-Reported Measures to Predict All-Cause Hospitalization in a Population-Based Lupus Cohort

S. Sam Lim[1], Sandra Wu[2], Ryan Ross[3], Gaobin Bao[1], Megan Richards[3], Liisa Palmer[3] and Gary Bryant[4], [1]Emory University, Atlanta, GA, [2]AstraZeneca, Hockessin, DE, [3]Merative, Cambridge, MA, [4]AstraZeneca, New Castle, DE

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease that affects the skin, joints, kidneys, lungs, central nervous system, and hematopoietic system. As a result of disease activity, patients with SLE have a 2- to 3-fold increased risk of hospitalization compared with the general population. Previous research has aimed to identify potential biomarkers or clinical factors that could be used to predict SLE flares that correlate with hospitalizations, but to date there has been little consistency. The purpose of this study was to develop a patient-centric predictive model that can be easily integrated into the clinical setting to identify patients that are at a higher risk for hospitalization.

Methods: Georgians Organized Against Lupus (GOAL) is a Centers for Disease Control and Prevention supported population-based cohort of validated SLE patients in Atlanta who complete annual surveys. From two surveys (2011-13), demographic, social-economic, clinical information and self-reported outcomes including Short-Form Survey (SF-12) and the SLE Activity Questionnaire (SLAQ) were obtained. This database was linked with the Georgia Hospital Discharge Database to obtain all-cause hospitalizations within 6 months of each survey. Those who died during a hospitalization were censored at the time of death.

Following descriptive analyses, a multivariable model examined the predictors of interest and all-cause hospitalization. Automated variable selection methods, the lowest Akaike Information Criterion (AIC) and selection through penalized regression (LASSO), were used. Variables of low importance across methods were excluded from further analysis. A classification and

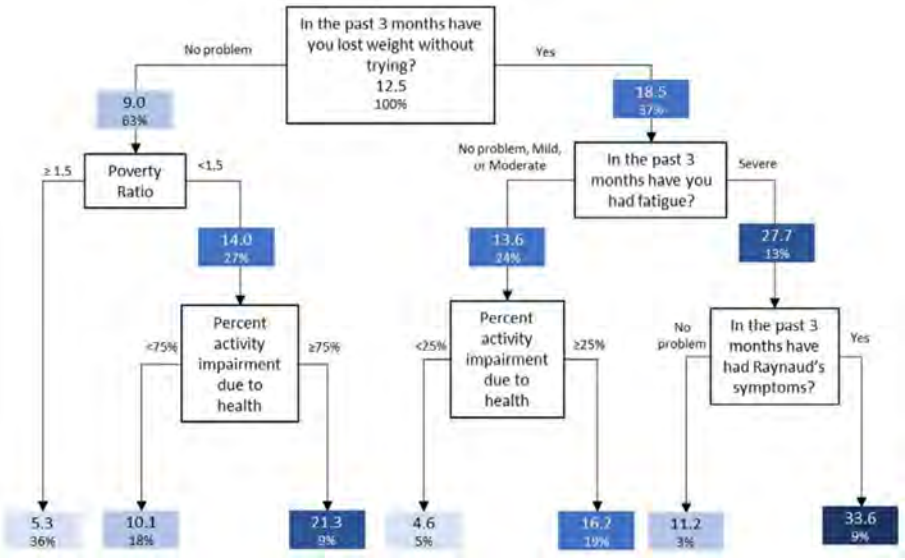
None/Unknown	249 (17%)	224 (17%)	25 (13%)



regression tree (CART) model generated a decision tree for predicting hospitalization risk based on a combination of components from SLAQ, SF-12, and sociodemographic characteristics.

Results: Of the 1,486 GOAL responses, 186 (12.5%) had an all-cause hospitalization within 6-months after survey completion. The mean age at survey completion was 47 (SD: 13), 94% of patients were female, 78% of patients were Black, and had SLE for 14 (9) years (Table 1). CART modeling identified patients with weight loss, fatigue, and Raynaud's symptoms as having the highest probability of having a hospitalization within 6 months (Pr=33.6%) (Figure1). Among those without weight loss, an increased probability of hospitalization was seen among those that had a poverty ratio < 1.5 and had more than 75% activity impairment due to health (Pr=21.3%).

Conclusion: In a population-based SLE cohort with a large proportion of Black patients, those who had weight loss, fatigue, and Raynaud's symptoms in the previous 3 months were at high risk of being hospitalized within the next 6 months. Collection of these symptoms that may not often be deemed clinically significant can be utilized in the clinical setting to identify SLE patients at higher risk of hospitalization and guide providers and patients accordingly.

Efficacy of Pharmacological Interventions: A Systematic Review Informing the 2023 EULAR Recommendations for the Management of Fatigue in People with Inflammatory Rheumatic and Musculoskeletal Diseases

Bayram Farisogullari[1], Eduardo Santos[2], Emma Dures[3], Rinie Geenen[4] and Pedro Machado[5], [1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey, [2]Health Sciences Research Unit: Nursing (UICISA: E), Nursing School of Coimbra (ESEnfC), Coimbra, Portugal, [3]Academic Rheumatology, Bristol Royal Infirmary; and Faculty of Health and Applied Sciences, University of the West of England, Bristol, United Kingdom, [4]Utrecht University, Vorstenbosch, Netherlands, [5]Centre for Rheumatology & Department of

Neuromuscular Diseases, University College London, London, UK. Department of Rheumatology, Northwick Park Hospital, London North West University Healthcare NHS trust, London, UK., London, United Kingdom

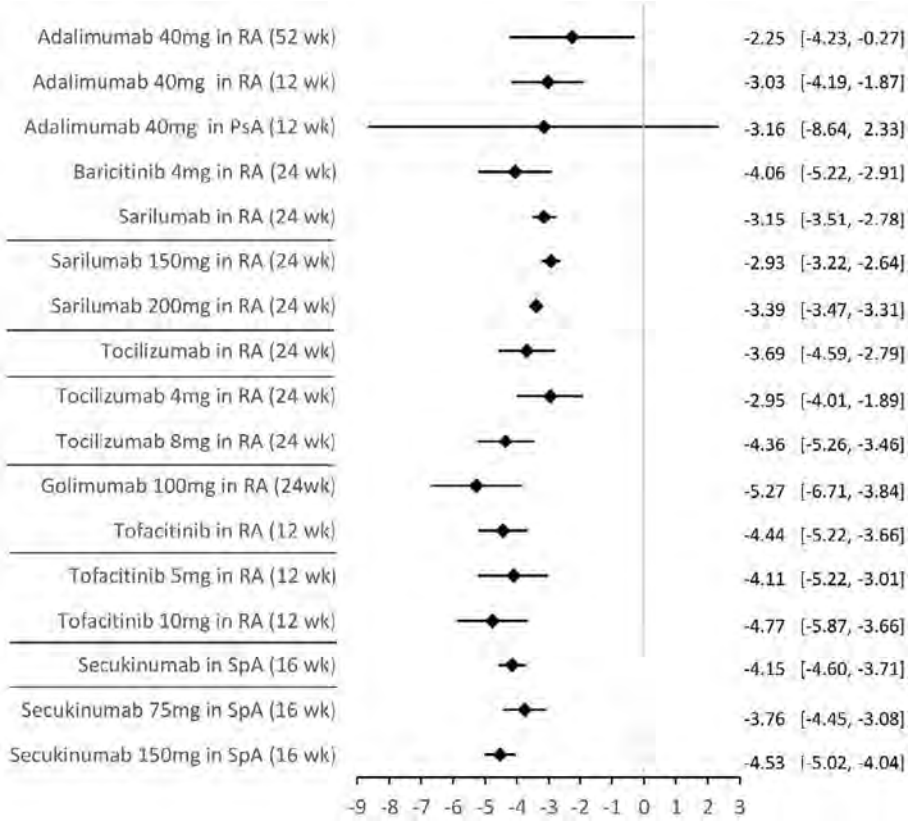
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To identify the best evidence on the efficacy of pharmacological interventions in reducing fatigue in people with I-RMDs and to summarise their safety in the identified studies to inform EULAR recommendations for the management of fatigue in people with inflammatory rheumatic and musculoskeletal disease (I-RMD).

Methods: Systematic review of adults with I-RMD conducted according to the Cochrane Handbook. Search strategy ran in Medline, Embase, Cochrane Library, CINAHL Complete, PEDro, OTseeker and PsycINFO. Assessment of risk of bias, data extraction, and synthesis performed by two reviewers independently. Data pooled in statistical meta-analyses.

Results: From a total of 4,150 records, 454 were selected for full-text review, 105 fulfilled the inclusion criteria, and 19 RCTs were included in meta-analyses. Adalimumab was superior to placebo in reducing fatigue at 52 and 12 weeks (wk) in rheumatoid arthritis (RA) (mean difference [MD]=-2.25, p=0.03; MD=-3.03, p< 0.001; respectively) and psoriatic arthritis (MD=-3.16, p=0.26). Golimumab (24wk: MD=-5.27, p< 0.001), baricitinib (24wk: MD=-4.06, p< 0.001), sarilumab (24wk: MD=-3.15, p< 0.001), tocilizumab (24wk: MD=-3.69, p< 0.001) and tofacitinib (12wk: MD=-4.44, p< 0.001) were also superior to placebo in reducing fatigue in RA. A dose/effect relationship was observed for sarilumab, tocilizumab and tofacitinib. In spondyloarthritis, secukinumab was superior to placebo in reducing fatigue at 16wk (MD=-4.15, p< 0.001), with a dose/



effect relationship also observed (**Figure**). The narrative results of the RCTs not included in the meta-analysis indicated that several other pharmacological interventions were efficacious in reducing fatigue, with reassuring safety results.

Conclusion: Pharmacological interventions are efficacious and safe for the management of fatigue in people with I-RMD.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a multisystem autoimmune rheumatic disease with heterogeneous manifestations, including common symptoms such as pain, fatigue, dyspnea, and Raynaud's phenomenon. It can also include rare but life-threatening complications such as renal failure and pulmonary hypertension. While the ACR Composite Response Index in Systemic Sclerosis (ACR CRISS), an existing clinical outcome assessment (COA), has shown favorable

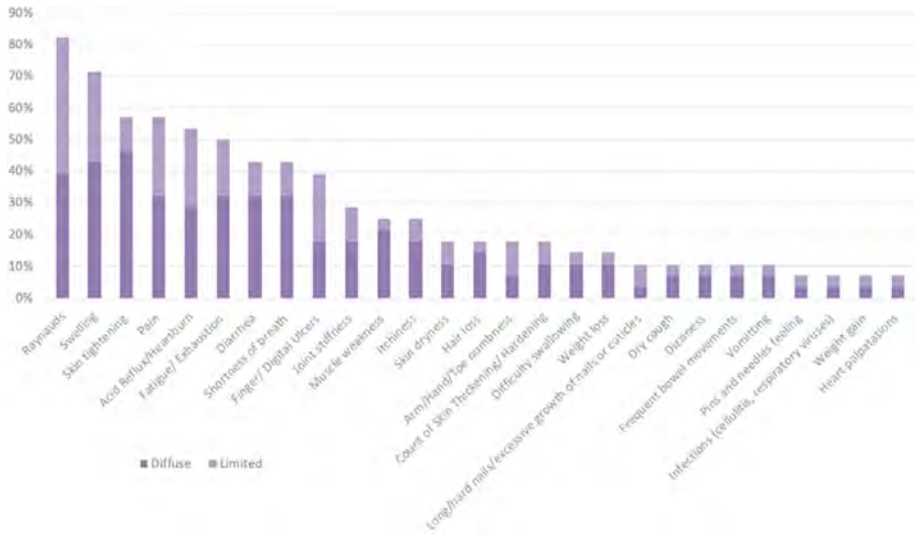

Figure 1. Disease Symptoms and Treatment Side Effects Reported by Participants with Both Subtypes of Systemic Sclerosis (N=27)

Table 1. Frequently Reported Disease Symptoms, Treatment Side Effects, and Bother Ratings by Participants with Both Subtypes of Systemic Sclerosis

Disease symptom/Treatment side effect	Number (%) who mentioned DS/TSE during interview	Mean Bother rating and range (0-10)	
Raynaud's disease	23 (82.1%)	6.1	1-10
Swelling[1]	20 (71.4%)	6.1	1-10
Pain[2]	16 (57.1%)	6.8	0-10
Skin tightening	16 (57.1%)	5.4	1-10
Acid reflux/heartburn/GERD	15 (53.6%)	5.6	0-10
Fatigue/exhaustion	14 (50.0%)	7.8	2-10

[1]Swelling includes hands, fingers, face, ankles, feet, joints.
[2]Pain includes abdominal, joint, jaw, hips, feet, ankles, hand, skin, whole body aches, nerve, muscle aches/soreness/cramps, generalized.

performance in SSc clinical trials, research is needed to develop a COA to more fully assess the way a patient feels, functions, and/or survives, per the FDA guidance. The purpose of this research is to comprehensively identify the disease symptoms (DS) and treatment side effects (TSE) that are most bothersome for patients with SSc toward the development a new and robust COA.

Methods: Concept elicitation interviews were conducted from February 2023 to May 2023 with 28 participants with SSc (15 participants with diffuse cutaneous SSc and 13 participants with limited cutaneous SSc). The 90-minute interviews focused on DS and TSE, how bothersome they were (0 = not at all bothersome to 10 = extremely bothersome), and their impacts on participants' lives. Interview data were summarized and results were analyzed thematically.

Results: The sample had a mean age of 54 years (range: 34-69) and was primarily women (82.1%), consistent with the broader gender distribution of SSc. The sample was diverse, including White (75.0%), Black (17.8%), Hispanic (7.1%), and American Indian (3.6%) participants. Overall, the sample reported 76 unique concepts (DS/TSE). After combining similar concepts for analytic purposes (e.g., sleep disturbances combined insomnia, hypersomnia) participants reported 66 DS/TSE. Participants with diffuse SSc reported an average of 13 DS/TSEs, while participants with limited SSc reported an average of 7 DS/TSEs. As presented in Figure 1, the most described DS/TSE across all participants was Raynaud's disease (82.1%), followed by swelling (71.4%), pain (57.1%), skin tightening (57.1%), acid reflux/heartburn/GERD (53.6%), and fatigue/exhaustion (50%). Of those DS/TSEs, fatigue was described as the most bothersome (M=7.8), followed by pain (M=6.8), swelling (M=6.1), Raynaud's (M=6.1), acid reflux/heartburn/GERD (M=5.6), and skin tightening (M=5.4). See Table 1 for more detail. Fatigue was the top bothersome DS/TSE for both diffuse and limited groups (M=7.8 and M=7.6 respectively). Both groups reported DS/TSE unique to their respective groups. Participants in the diffuse group uniquely reported contractures (46.7%), headaches (33.3%), skin discoloration (26.7%), and bloating/cramping (26.7%). Participants in the limited group uniquely reported eczema/red dots/blood vessels on skin (30.8%), and facial rash (15.4%).

Conclusion: These findings were consistent with symptoms described in the "Voice of the Patient" report for systemic sclerosis (2021) developed for the FDA's Patient-Focused Drug Development Initiative. This research will aid the creation of a new SSc COA measure using existing FACIT, PROMIS, and Neuro-QoL measurement systems, and new SSc-specific items, which will be capable of assessing multiple patient-centered domains.

Session Date: Monday, November 13, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II

Session Type: Poster Session B

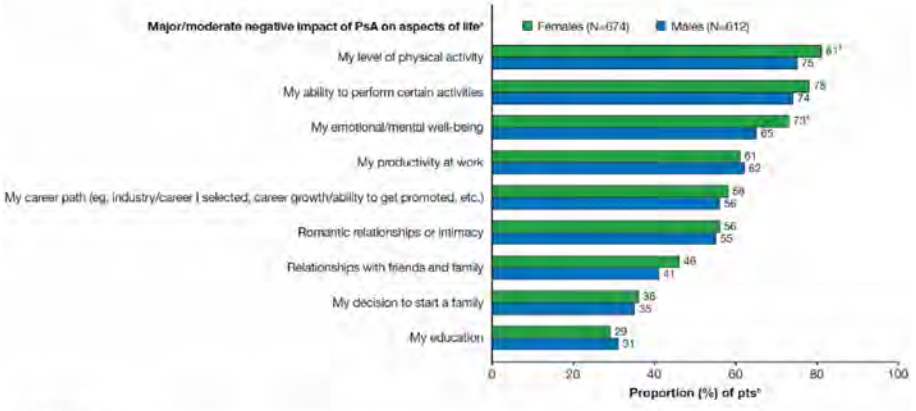
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with PsA have more severe disease activity and lower health-related quality of life vs men.[1] This post hoc analysis assessed sex differences in disease impact perceptions and physician interactions with patients (pts) with PsA using global survey data.

Methods: An online survey by The Harris Poll (Nov 2, 2017–Mar 12, 2018) included 1,286 pts from 8 countries, aged ≥ 18 years, who had PsA for > 1 year, visited a rheumatologist/dermatologist in the past 12 months, and had used ≥ 1 DMARD for PsA.[2] Results were stratified post hoc by sex; analyzed descriptively and by binomial (chi-squared) tests. Percentages/binomial tests of the final global data were adjusted for size of each country's adult population. Statistically significant differences ($p < 0.05$) were described as more/higher.

Results: 52% of pts were female; 24% from Europe (France/Spain/UK). Mean age of females/males (41.3/41.0 years) and time since diagnosis (9.2/8.8 years) were similar. More females had anxiety (32% vs 24%), osteoarthritis (17% vs 9%), had taken a steroid (57% vs 43%), and were taking any DMARD (biologic and oral DMARDs; 20% vs 15%). More females vs males reported a major/moderate negative PsA impact on physical activity (81% vs 75%) and emotional/mental well-being

Fig. Major/moderate negative impacts of PsA for female vs male pts



*p < 0.05 for females vs males
†How much of a negative impact, if any, has PsA had on each of the following aspects of your life?
‡% based on weighted n (adjusted for size of each country's adult population)
N, number of pts that answered question; pts, patients

Table. Communication satisfaction[a] with rheumatologist, and discussion topics[b] between pts and their rheumatologist

n, yes, (%)[c]	Female (N=620)	Male (N=552)
Satisfaction[a]		
Very satisfied	371 (60)*	281 (51)
Somewhat satisfied	174 (28)*	214 (39)
Somewhat dissatisfied	40 (6)	33 (6)
Very dissatisfied	36 (6)	24 (4)
Discussion topics[b]		
Treatment goals	515 (83)*	428 (78)
Overall health	507 (82)	444 (80)
Physical exam of musculoskeletal symptoms	509 (82)	432 (78)
Impact on ability to conduct daily activities	510 (82)*	403 (73)
Response to and/or satisfaction with treatment regimen	500 (81)*	396 (72)
Impact on physical activity	491 (79)	413 (75)
Physical exam of skin/nail symptoms	469 (76)	406 (74)
Back pain (pain/stiffness)	467 (75)	411 (74)
Disease management plan	448 (72)	411 (74)
Unusual fatigue	430 (69)	370 (67)

*$p < 0.05$ for females vs males

[a]How satisfied are you with the communication you currently have with your rheumatologist regarding PsA? (Among pts who visited a rheumatologist in the past 12 months

[b]In the last 12 months, have you discussed/conducted the following with your rheumatologist regarding PsA?

[c]% and binomial tests based on weighted data (adjusted for size of each country's adult population)

N, number of pts that answered question; n, number of pts with satisfaction level or who participated in each discussion topic; pts, patients

(73% vs 65%); major/moderate impact on other life aspects, such as work productivity, was similar between sexes (Fig). More females vs males reported the following because of PsA: emotional distress (65% vs 50%), stopped social activities (49% vs 41%), and went on permanent work disability (14% vs 9%); more males vs females reported lower work productivity (47% vs 38%) because of PsA. Switching treatment due to joint symptoms (41% vs 28%) and side effects (35% vs 22%) were higher in females vs males; switching due to potential serious side effect concerns (29% vs 16%) and symptoms being under control (18% vs 9%) were higher in males vs females. More females vs males were very satisfied with their rheumatologist's communication (60% vs 51%), and discussed treatment goals (83% vs 78%), impact on ability to conduct daily activities (82% vs 73%), and response to and/or satisfaction with treatment regimen (81% vs 72%; Table). Pt ability to describe their PsA diagnosis/recall symptoms may limit the study.

Conclusion: More women vs men reported a major/moderate PsA impact on physical and emotional/mental well-being. More women were very satisfied with communication and discussed treatment goals with their rheumatologist. It is important to consider how sex impacts a pt's experience with PsA.

SESSION INFORMATION

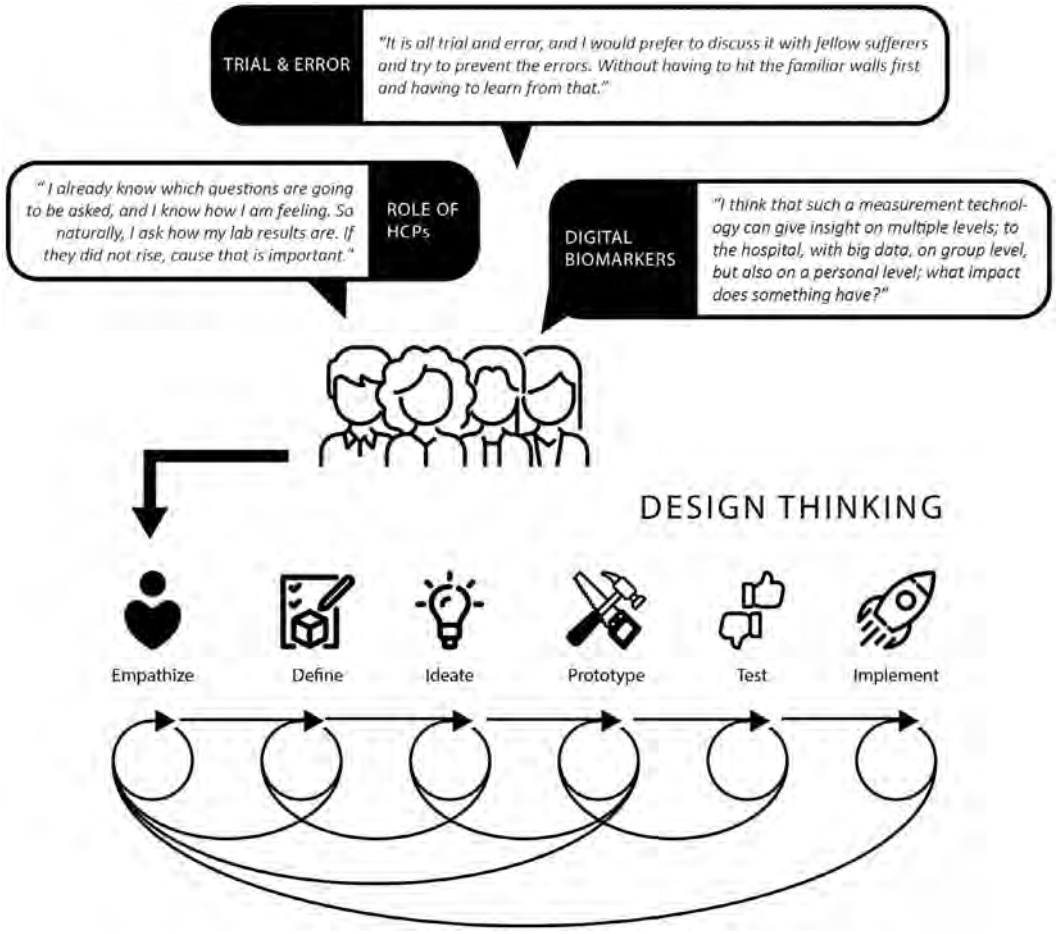
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The Inflammatory Arthritis (IA) patient population is growing, whilst facing a shortage of health care professionals (HCPs). It is impossible to meet the future care demand. *Digital Biomarkers (DBs)* are objective, quantifiable, physiological and behavioural data that are collected and measured with digital devices. They can support continuous measurements outside the physical confines of clinical environments and help close the gap in healthcare demands.

This study aims to obtain the patients' insights on disease activity, disease management and care needs; and to empathise with their attitude towards DBs in order to obtain future directions for DB development.

Methods: Design Thinking is followed for the development of DBs in rheumatology. It is a human-centered problem-solving approach that leverages empathy and collective idea generation to tackle complex challenges. Sixty minute online semi-structured focus group discussions, based on the Common Sense Model of Self-Regulation were conducted (Leventhal et al. 2016). All interviews were audio-recorded, transcribed to verbatim, coded and discussed with our patient partners.

Results: Six focus groups were organised, with a total of 30 IA patients (22 PsA; 8 RA, age 51± 11 years, 48% male, time since diagnosis 7 (3:12,5) years). The main findings were: *Trial and error;* life after diagnosis is marked by trial and error. Learning how and when to listen to their bodies, uncovering potential inflammation-triggers and developing appropriate disease management. Needs are discussions on lifestyle adjustments, career choices and life adaptations with their HCPs and fellow patients. T*he HCPs role;* patients visited their HCP for affirmation, reflection and future directions. They often doubted whether their symptoms were rheumatic. Secondly, they wanted assurance adverse drug reactions are absent, blood tests



Quotes from patient focus groups and the design thinking process

brought peace of mind. Furthermore, consultations were indicated as obligatory self-reflection. Conversing with their HCP was seen as a reality check and a conversation about (new) options. *DBs;* attitudes towards DBs varied. Some patients thought it could provide them with deeper insights and reminders before crossing a line. Some patients thought it relevant only for their HCP. They did not want a constant disease reminder. Others did not see any additional value. They knew themselves well enough, no device should tell them whether their feelings are justified.

Conclusion: The following problem statement from the patients' perspective can be formulated; "we suffer from a disease that turned our lives upside down, we have to cope with it daily. Our learning is by trial and error. We must know which activities to avoid and how to predict flares. It is difficult to discriminate ordinary pain, from pain preceding a flare. Affirmation from our HCPs and our blood results bring peace of mind. Perhaps, by applying technology, we can speed up our learning process and triggers of flare could be identified. However, one should be mindful of the purpose, the amount of notifications and the data representation." In general there is no strong resistance to DBs. However, for future uptake the recorded data should be of clear benefit for the patient.

Patient Experience of Brain Fog to Inform the Development of a De Novo Patient Reported Outcome (PRO) in Patients with Sjögren's Disease

Denise Kruzikas[1], Ann Eldred[2], Shelly Kafka[3], Janet Church[4], Katherine Hammitt[4], Patricia Koochaki[5] and Christina O'Donnell[6], [1]AbbVie, Inc., North Chicago, IL, [2]AbbVie, Inc., Lake Bluff, IL, [3]AbbVie, Inc., Norristown, PA, [4]Sjögren's Foundation, Reston, VA, [5]ICON Clinical Research LLC, Raleigh, NC, [6]ICON plc, Raleigh, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Brain fog is commonly reported by SJD patients, though limited evidence exists to understand patient experiences. Various terms may be used to describe brain fog, including mental or cognitive fatigue and cognitive dysfunction. While cognitive difficulties are typically assessed via battery testing, there is no brain fog PRO to assess related patient symptoms and impacts experienced by patients. The purpose of this study was to explore concepts related to brain fog among SJD patients, and attempt to discern whether brain fog is related to fatigue or may be a separate manifestation as experienced by SJD patients.

Methods: A cross-sectional qualitative study among adults with clinician-confirmed SJD consisted of 30-minute semi-structured concept elicitation (CE) interviews and a pile-sort exercise. A thematic approach, a codebook, and MAXQDA software were used to organize, code, and analyze anonymized CE interview transcripts. In the sorting exercise, patients ranked all items from the Neuro-QoL-Cognitive Function and PROMIS-Cognitive Fatigue item banks as most, somewhat, or not relevant to their brain fog experience. Cultural consensus analysis (CCA) was used to determine whether there were items that participants agreed were most relevant (consensus) that may be considered for a de novo PRO instrument.

Figure 1. Patient-Reported Symptoms of Brain Fog in SJD by Cognitive Domain

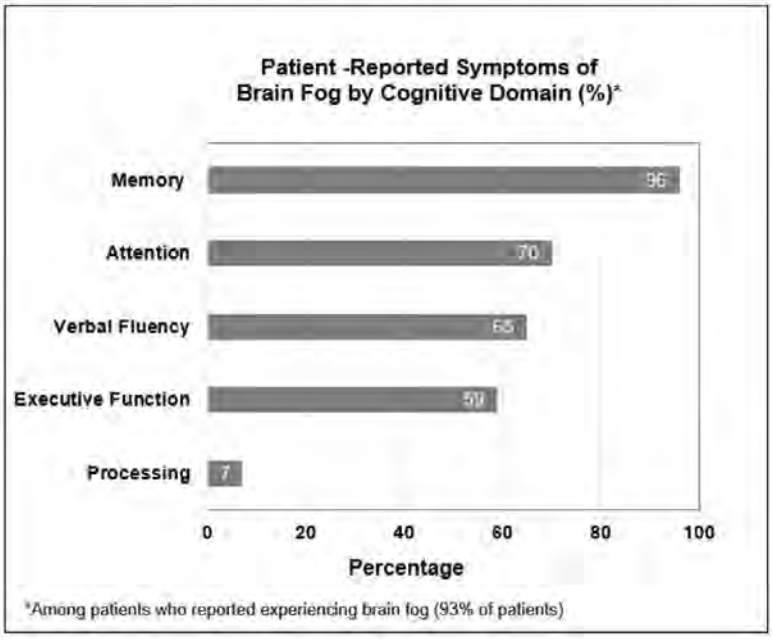

Table 1. Selected Patient Descriptions of Brain Fog Symptoms by Cognitive Domain

Memory	*"[…] and brain fog, brain fog is another one. […]* ***Forgetting—forgetting what I [laughs] was going to say constantly****. So, I'm not sure, I forgot where I was going with all this. We were talking about dry mouth?" (Patient 001)*
Attention	*"I basically check out or* ***I can't focus*** *on what I'm doing. That's what I consider brain fog, anyway, is* ***lack of focus****. Just feeling maybe not physically tired but just* ***tired of concentrating****. It's just a lot of work." (Patient 015)*
Verbal Fluency	*"So, there are sometimes, yes, the speech doesn't want to come out properly or* ***I'll stumble over words or it's like I'm not speaking clearly****." (P001)*
Executive Function	*"If there are multiple things going on, I do. If I* ***can focus on one thing*** *then I'm fine, but I* ***can't multitask anymore****." (Patient 040)*

Results: Of N=29 SJD patients interviewed (mean age, 63 yrs; 97% female; 79% Caucasian; mean length of time since diagnosis, 13.6 yrs), 75% spontaneously used the term "brain fog" to describe their cognitive difficulties. Symptoms included deficits in memory (96%), concentration (70%), verbalizing (65%), and executive function (59%) (Figure 1, Table 1). Patients reported experiencing brain fog all the time (12%), daily (24%), weekly (36%), monthly (20%) or annually (8%). Results indicated patients generally do not associate brain fog directly with fatigue; of 11 (44%) patients describing brain fog and fatigue as somewhat related, 9 (82%) stated brain fog and fatigue can occur separately while 5 felt fatigue was triggering or causing their brain fog (45%). CCA results from the pile sort exercise indicated that consensus, defined as an Eigenvalue ratio of >3.1, existed among a participant subset (n=10; ER 4.05). Comparing results based on this subset and all patients demonstrated a nearly identical overlap in highly ranked items between the two groups. Neuro-QoL items consistently ranked higher than PROMIS items; 17 of the top 20 highest ranked items were based on the Neuro-QoL, indicating items of cognitive dysfunction were more relevant than those of cognitive fatigue for SJD patients.

Conclusion: Brain fog commonly affects SJD patients with symptoms impacting memory, concentration, verbalization and executive function. Participant endorsement of items from the Neuro-QoL suggests brain fog may be attributable to independent cognitive dysfunction rather than cognitive fatigue. The results support exploring the use of highly ranked Neuro-QoL items to develop a draft de-novo Brain Fog PRO for further research in SJD patients.

Sjögren's Patients' Experiences and Content Validity of the Dry Eye Disease Symptom Questionnaire (DED-SQ)

Denise Kruzikas[1], Ann Eldred[2], Shelly Kafka[3], Janet Church[4], Katherine Hammitt[4], Patricia Koochaki[5] and Christina O'Donnell[6], [1]AbbVie, Inc., North Chicago, IL, [2]AbbVie, Inc., Lake Bluff, IL, [3]AbbVie, Inc., Norristown, PA, [4]Sjögren's Foundation, Reston, VA, [5]ICON Clinical Research LLC, Raleigh, NC, [6]ICON plc, Raleigh, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Dry eye is one of the most important and prevalent symptoms experienced by patients with Sjögren's Disease (SJD). The DED-SQ is a 12-item patient reported outcome (PRO) measure developed to assess dry eye disease. The purpose of this study was to identify the most important dry eye concepts to SJD patients and assess content validity of the DED-SQ for use in SJD populations.

Methods: Recruitment was conducted in partnership with the Sjögren's Foundation, with patients self-selecting for participation. US patients with physician-confirmed diagnosis of SJD and symptoms of dry eye were recruited. Combined concept elicitation (CE) and cognitive interviews (CI) were conducted by phone or online platform with 29 adult SJD patients. During CE, patients reported the most important dry eye symptoms and the impact of dry eye on their daily lives and ability to function. During CI, patients completed the DED-SQ followed by discussion of the relevancy of items, clarity of wording, ease of completion, selection of response options, comprehensiveness, and appropriateness of the recall period. Interviews

Table 1. Selected Patient Descriptions of Dry Eye

*"It feels like, at its best it feels as if **your eyes are really tired** and it also means that you're **struggling sometimes to focus on things**." (Patient 006)*
*"Well, in the beginning it felt like there was **sand in your eye**, and now it feels, it's a **burn** that is beyond, and yet I, it's very difficult to get relief anymore." (Patient 009)*
*"It's **painful** if I don't medicate—it can be so painful that I **can't read**, can't keep my eyes open." (Patient 040)*
*"They're going to get irritated; I end up having **blurry vision**, and then they'll get **swollen**, they'll get **red and irritated**." (Patient 001)*
*"My eyes would become so dry that I **could not remove the contacts**, they would **stick to my eyeballs**, even using the rewetting solution." (Patient 038)*
*"It feels like your lids are sticking closed. It looks like you're **looking through a fog**. You could read an eye chart and blink and get a totally different response five seconds later, because the **dry eyes just distorts your vision** to that degree. It also **feels like gritty and itchy**, yeah." (Patient 016)*

were audio recorded, transcribed, and anonymized. Thematic analysis of the CE data was conducted using MAXQDA, software designed to organize and facilitate qualitative data analysis, and a codebook, developed from the interview guide and supplemented with additional codes derived from patient comments. An item tracking matrix was used to facilitate a systematic evaluation of the individual items, instructions, recall period and response options to make recommendations for revision.

Results: The study participants were predominantly female (96%), White (79%), and held a bachelor's degree or higher (90%). On average, participants were 62.8 years of age. Patients reported multiple symptoms of dry eye (Table 1), including general dryness (100%), pain, soreness, or an ache in their eyes (41%), as well as a gritty and/or sandy feeling in their eyes (45%). Patients also reported that dry eye caused their vision to be blurry, distorted, foggy, or fuzzy making it difficult to read text (38%). The reported dry eye symptom descriptions mapped well onto concepts/items in DED-SQ and patients found most items in the DED-SQ relevant to their experiences. Some patients suggested concepts that may be less relevant to SJD ("red eyes" (56%), "itchy eyes" (31%), or "crustiness" (52%) or that may be difficult to distinguish from causes other than SJD ("stinging/sharp feeling", "burning" (28%)). Apart from items on stinging and burning, patients interpreted the items as intended (≥93%) and found the items easy to answer (≥81%). Patients felt the past 24-hour recall period was appropriate (82%).No additional dry eye symptoms beyond those included in the DED-SQ were identified.

Conclusion: These results reveal dry eye consists of a constellation of symptoms. A PRO covering the multifaceted concept of dry eye may be needed to appropriately assess SJD patients' experiences. These findings suggest a revised DED-SQ may be fit-for-purpose for assessing dry eye in SJD. Further research can help assess the content validity of a revised DED-SQ in SJD patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: JDM is a rare immune-mediated disease of childhood that is thought to result from genetic predisposition and environmental drivers, with documented links to microbial exposures. In this multi-center, prospective, observational cohort study, we evaluated whether JDM is associated with discrete oral and gut microbiome signatures using siblings to control for family-associated microbial communities.

Methods: We generated 16S rRNA sequence data from fecal, saliva, supragingival, and subgingival plaque samples from JDM probands (*n*=28, age range 3-18 years, mean age 10 years, 46% female). To control for genetic and environmental determinants of microbiome community structure, we also profiled microbiomes of their unaffected family members (*n*=27 siblings, *n*=26 mothers, and *n*=17 fathers). We performed paired within-family comparisons as well as unpaired analyses of different cohorts.

Results: Family unit was the predominant factor explaining variance in both weighted and unweighted UniFrac distances between samples for each sample type ($p< 0.001$ in fecal, saliva, supragingival swab, and posterior subgingival dental plaque samples; $p< 0.01$ in anterior subgingival dental plaque samples, permutational multivariate analysis of variance. Unweighted UniFrac distances between siblings was significantly smaller than the distances between JDM probands in our cohort ($p< 0.002$, two-tailed Student's *t*-test).

In fecal samples, 4% of bacterial amplicon sequence variants (ASVs) were differentially abundant in microbiomes between JDM probands and their siblings (**Figure 1A, Table 1**). In the case where ASVs that were initially classified as unannotated bacteria during the analyses, taxonomy was assigned based on BLAST results.Approximately 8% of ASVs identified in the ***anterior*** subgingival dental plaque were significantly different between JDM probands and their healthy siblings (**Figure 1B).** In ***posterior*** subgingival dental plaque samples, approximately 7% of identified ASVs were significantly differentially

Table 1. Differential 16s rRNA Microbial amplicon sequence variants (ASVs) in children with JDM compared to healthy siblings (Percent ± SEM).

[*] Multiple ASVs were identified for these species
[#] Significantly different between JDM and siblings

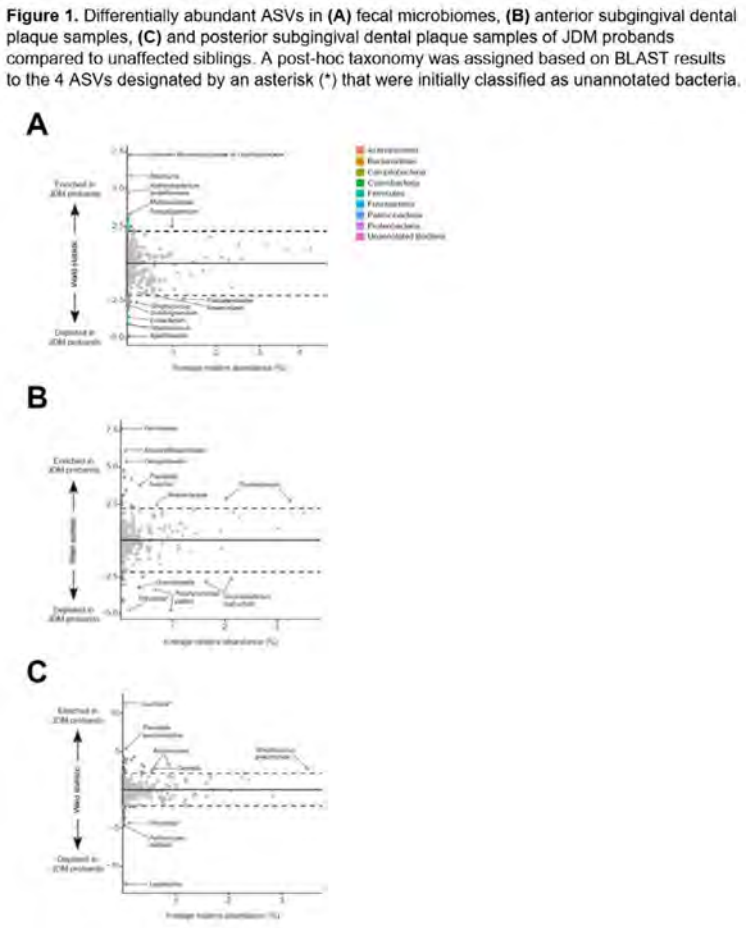

Figure 1. Differentially abundant ASVs in (A) fecal microbiomes, (B) anterior subgingival dental plaque samples, (C) and posterior subgingival dental plaque samples of JDM probands compared to unaffected siblings. A post-hoc taxonomy was assigned based on BLAST results to the 4 ASVs designated by an asterisk (*) that were initially classified as unannotated bacteria.

abundant between JDM probands and their siblings (**Figure 1C)**. We also observed differentially abundant ASVs in the saliva and supragingival swab samples from JDM probands, all of which were found in very low abundances, including salivary enrichment of *Veillonella* and *Prevotella shahii* and depletion of *Prevotellamelaninogenica*.

Conclusion: The oral and gut microbiomes of JDM probands were more similar to their own unaffected siblings than they were to the microbiomes of other JDM probands, suggesting family unit has a significant effect on microbiome community structure. Nonetheless, in a sibling-paired analysis, several potentially immunomodulatory bacterial taxa were differentially abundant in the microbiomes of JDM probands, including *Faecalibacterium* in the gut and *Streptococcus* in the oral cavity. The loss or gain of specific fecal and oral bacteria may potentially play a role in disease pathogenesis and/or be secondary to immune dysfunction in susceptible individuals.

The Association Between Gingival Inflammation and Clinical Signs of Active Juvenile Dermatomyositis (JDM)

Albert Chow[1], Hyun Song[2], Laurie Brenchley[3], Nastaran Bayat[4], Mary Eckert[5], Sean Koester[6], adam Schiffenbauer[7], Rita Volochayev[7], Pamela Gardner[3], Peggy Lee[8], Jeffrey McLean[9], Susan Shenoi[10], Lisa Rider[11], Anne Stevens[12] and Neelendu Dey[13], [1]Loma Linda University, Loma Linda, CA, [2]Department of Dentistry, Seattle Children's Hospital, Seattle, WA, [3]Office of the Clinical Director, NIDCR, National Institutes of Health, Bethesda, MD, [4]Social Scientific Systems, DLH Holdings Corp, Silver Spring, MD, [5]Center for Clinical and Translational Research, Seattle Children's Research Institute, Seattle, WA, [6]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA, [7]Environmental Autoimmunity Group, Clinical Research Branch, National Institute of Environmental Health Sciences, National Institutes of Health, Bethesda, MD, [8]Department of Oral Medicine, School of Dentistry, University of Washington, Seattle, WA, [9]Department of Periodontics, University of Washington, Seattle, WA, [10]Seattle Childrens Hospital, Mercer Island, WA, [11]NIEHS, NIH, Bethesda, MD, [12]Janssen, Hansville, WA, [13]Department of Medicine, Division of Gastroenterology, University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

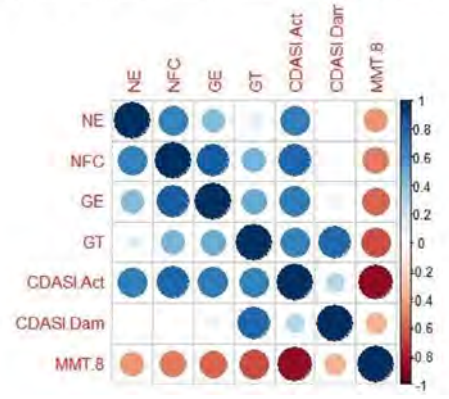
Session Time: 9:00AM–11:00AM

Background/Purpose: JDM is a rare vasculopathy of unknown etiology characterized by typical rashes and proximal weakness. JDM has been associated with gingivitis, which can be triggered by microbial dysbiosis and has been implicated in the etiology of systemic autoimmune disease. This study aimed to characterize the relationship between oral inflammation and vasculopathy with JDM disease activity.

Methods: A prospective pilot observational study was conducted at two centers. Patients met probable or definite Bohan and Peter criteria for JDM, and were excluded for co-existing autoimmune diagnoses, antibiotics within 3 months of enrollment, or gingival erythema secondary to tooth eruption or orthodontic appliances. Gingival erythema, telangiectasias, gingival index, and plaque index were scored by dentists and dental hygienists. Myositis disease activity measures such as manual muscle testing of 8 core groups (MMT8), Cutaneous DM Disease Area and Severity Index (CDASI), and nailfold

Figure 1: Associations of nailfold and gingival capillary scores in patients with JDM.

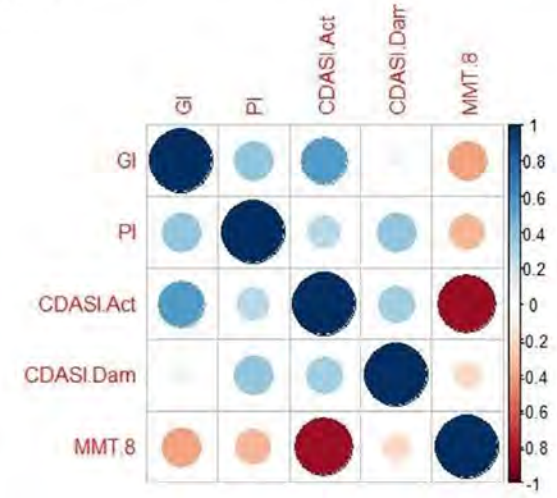
Central readings of nailfold and gingival capillary scores were conducted in patients with JDM via photographs (N=14). NFC, nailfold capillary abnormalities; NE, nailfold erythema; GE, gingival erythema; GT, gingival telangiectasis; CDASI.Act, CDASI total activity score; CDASI.Dam, CDASI total damage score; MMT.8, manual muscle testing of 8 core groups. Diagonal dark blue circles indicate 1:1 Spearman correlation. Color intensity, effect size; circle radii, statistical significance; Blue, positive effect; Red, negative effect. Note the red (negative) correlation between MMT8 and other clinical findings.



Associations of nailfold and gingival capillary scores in patients with JDM.

Figure 2: Associations of Gingival Index and Plaque Index in patients with JDM.

Associations of Gingival Index, Plaque Index with JDM disease outcomes in 17 patients with JDM evaluated during clinical examinations and N=17. GI, gingival index; PI, plaque Index; CDASI.Act, CDASI total activity score; CDASI.Dam, CDASI total damage score; MMT.8, manual muscle testing of 8 core groups.



Associations of Gingival Index and Plaque Index in patients with JDM.

capillaroscopy (NFC) were assessed by pediatric rheumatologists. To conduct parallel evaluations of vasculopathy in nailfolds and gingiva, we developed a central dichotomous scoring system averaging the presence or absence of erythema and telangiectasias from photographs over 6 anterior teeth and 10 fingers. With uncertain distribution and variance patterns in JDM, we elected to use Spearman's correlation despite small sample size.

Results: Seventeen subjects ages 3.8-15.5 (mean 8.9) years, with 9 females were included. The mean MMT8 was 140; eleven met PRINTO criteria for clinically inactive disease. The mean CDASI activity score was 6.5 and mean CDASI damage score 1.8.In evaluation of photographs, reliability was good: with Cohen's Kappa k=0.860 and 0.940 for NFC telangiectasia and erythema and k=0.840 and 0.814 for gingival telangiectasias and erythema. Excellent correlation was found between gingival erythema and presence of NFC abnormalities (r=0.85, p=0.003) and between the presence of gingival telangiectasias and CDASI Damage (r=0.74, p=0.009), with moderate correlation between gingival erythema and MMT8 (r=-0.36, p=0.012) (Figure 1).There was a moderate correlation between Gingival Index and CDASI Activity (r=-0.56, P=0.02) (Figure 2).

Conclusion: We systematically quantified gingival and NFC vasculopathy in JDM and found correlations between signs of oral vasculopathy and both skin and muscle disease, suggesting related pathogenic processes. Future mechanistic studies are needed to elucidate mechanisms, including whether gingival vasculopathy remains an underrecognized primary vasculopathic manifestation of JDM.

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a heterogeneous multisystemic autoimmune disorder that can cause life-threatening complications. There is a paucity of data on the utility of extracorporeal membrane oxygenation (ECMO) in children with SLE. The Extracorporeal Life Support Organization (ELSO) 2023 International summary reported an overall pediatric survival to discharge for 61% pulmonary support, 55% cardiac support, and 41% extracorporeal cardio-pulmonary resuscitation (eCPR). A recent systematic analysis on the use of ECMO in children with immune-mediated

Table 1: Demographics by Survival at Discharge

SLE Primary Diagnosis*	8	(34.8)		5	(20.0)		0.335

disorders showed a 50% survival to discharge, including 53% pulmonary support, 55% cardiac support, and 34% eCPR. We aim to describe the use and outcomes of ECMO in childhood-onset SLE.

Methods: After approval by the ELSO Registry Committee, a retrospective cohort study from the registry database included patients < 18 years of age who had International Classification of Diseases Ninth Revision (ICD9) and Tenth Revision (ICD10) codes consistent with SLE from 2012-2022. The decision to use ECMO was made independently at each center. The primary outcome was survival to hospital discharge. Descriptive analysis on demographic information, pre-ECMO variables, ECMO mode and support indications, complications, and survival was performed using Stata v 15.1 (StataCorp, College Station, TX, USA). ECMO patient and mechanical complications were predefined by ELSO. Data on severity of illness or immunosuppression therapy was not included as it is not available in the registry.

No		17	(73.90)		18	(72.00)	
Yes		6	(26.10)		7	(28.00)	

Results: During the study period, 48 children with SLE received ECMO. Table 1 show the demographics and patients comorbidities. Table 2 show ECMO characteristics for patients by survival status at discharge. Overall, 52% survived to discharge, 50% received ECMO for respiratory support (40% survival), 31% received cardiac support (44% survival), and 18% received eCPR (16% survival). The most common complications were renal dysfunction (61% non-survivors vs 64% survivors), followed by hemorrhagic (26% non-survivors vs 20%), and mechanical (26% non-survivors vs 28% survivors) complications. No ECMO parameters or patient characteristics differentiated survivors from non-survivors.

Conclusion: ECMO can be used as a life supporting therapy in children with SLE, with similar outcomes to the experience in children with immune-mediated disorders. The decision to use ECMO in this population remains challenging due to the nature of the systemic disease and potential complications related to immunosuppression. Additional analyses comparing survival rates in children and adults with lupus are underway.

*Comorbid and SLE primary diagnoses were entered via ICD9/10 coding. Pulmonary involvement was defined using codes for pulmonary hemorrhage, hemoptysis, acute respiratory distress syndrome, pulmonary hypertension. Renal involvement was defined using codes for acute kidney injury, chronic kidney disease, end-stage renal disease, glomerulonephritis. Cardiac disease was defined using codes for pericarditis, pericardial effusion, endocarditis, myocarditis.

*ECMO patient and mechanical complications were predefined by ELSO. Mechanical defined as those requiring interventions such as change of equipment or circuit components. MAP: mean airway pressure, PEEP: positive end-expiratory pressure, ECPR: extracorporeal cardiopulmonary resuscitation, VA: veno-arterial, VV: venous-venous.

Abstract Number: 1224

Mental Health Screening Follow-Up in the Childhood-Onset Systemic Lupus Clinic

Audrea Chen[1], Tala El Tal[2], Asha Jeyanathan[1], Holly Convery[1], Stephanie Wong[1], Linda Hiraki[1], Deborah Levy[1] and Andrea Knight[1], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]Children's Hospital of Eastern Ontario (CHEO), Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Common barriers to conducting mental health (MH) screening in pediatric clinics include provider uncertainty with follow-up after screening, and concern with increasing burden of referrals to MH services. However, regular MH screens help identify patients who need MH care and engage them in follow-up. In the childhood-onset systemic lupus erythematosus (cSLE) clinic at The Hospital for Sick Children, a new MH screening and referral system was recently implemented. This project aims to describe MH screening results and assess patient satisfaction with their MH care in the cSLE clinic.

Methods: Patients followed in the cSLE clinic aged ≥12 received a MH screen with validated assessment tools for depression (PHQ-9) and anxiety (GAD-7). Referral to MH services (psychology, social work, psychiatry and adolescent medicine) was based on symptom severity (Fig.1) and discussion with the patient. All patients who completed the MH screen received

a handout with free online MH resources. An anonymous survey to assess patient satisfaction with their MH care was sent to patients ≥8 weeks after their initial screen. Repeat screens were performed for patients after 6 months. 66 surveys were distributed to 100 eligible patients. Data were collected from January 2022 to May 2023.

Results: 153 MH screens were completed, 37 patients were screened twice and 2 patients were screened 3 times. Most patients (60%) had minimal or no symptoms of depression and anxiety (Fig. 2). About a third of patients had mild symptoms, 14% of patients had moderate to severe symptoms and 8 patients (5%) reported suicidal ideation (primarily passive) (Fig.2). 12 patients (11%) were referred to adolescent medicine, 4 (4%) to social work and 1 (1%) to psychiatry. 28 satisfaction surveys were completed for a response rate of 42%. While 21% of patients felt that the MH screen brought up unwanted feelings, 100% found the MH screen to be a positive experience. 71% of patients were interested in follow-up or resources after their screen. 8 (28%) patients who completed the survey were referred to MH providers and were all satisfied with the services received. 5 patients had their appointment >4 weeks after referral, 2 patients had an appointment < 4 weeks after their referral and 1 patient had their appointment the same day as cSLE clinic. 2 patients seen >4 weeks after the referral felt that

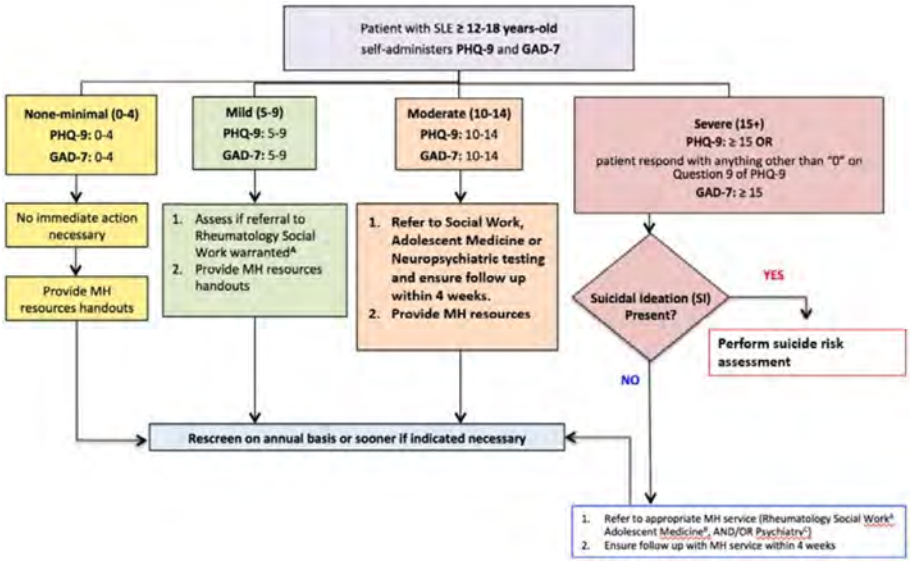

Figure 1. Pediatric rheumatology MH screen referral algorithm based on PHQ-9 and GAD-7 screening scores.

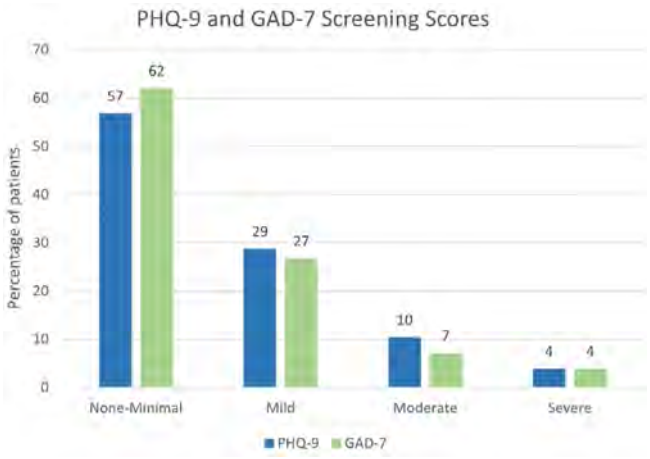

Figure 2. PHQ-9 and GAD-7 scores for depression and anxiety symptoms among the screened cSLE patients. Categories: None-minimal represents a score of 0-4, Mild 5-9, Moderate 10-14, Severe >15.

time to their MH appointment was too long. Suggested improvements to the MH process included making the physical space more welcoming and private, and asking about MH at every clinic visit.

Conclusion: While most patients had mild or no symptoms of depression and anxiety, MH screens detected 14% of patients with moderate to severe symptoms, and 16% were referred to MH services. MH screening was a positive experience and receiving MH resources was important to patients. Patients' MH concerns were adequately addressed with MH services, although time to follow-up could be improved. Overall, the new MH screening process has identified important concerns for patients with cSLE and initiated appropriate referral to MH services with high rates of patient satisfaction. We hope to further improve this process based on patient feedback by changing the physical space and increasing the frequency of screens.

Nailfold Video Capillaroscopy and Its Association with Autoantibodies and Rheumatic Diseases in Pediatric Patients

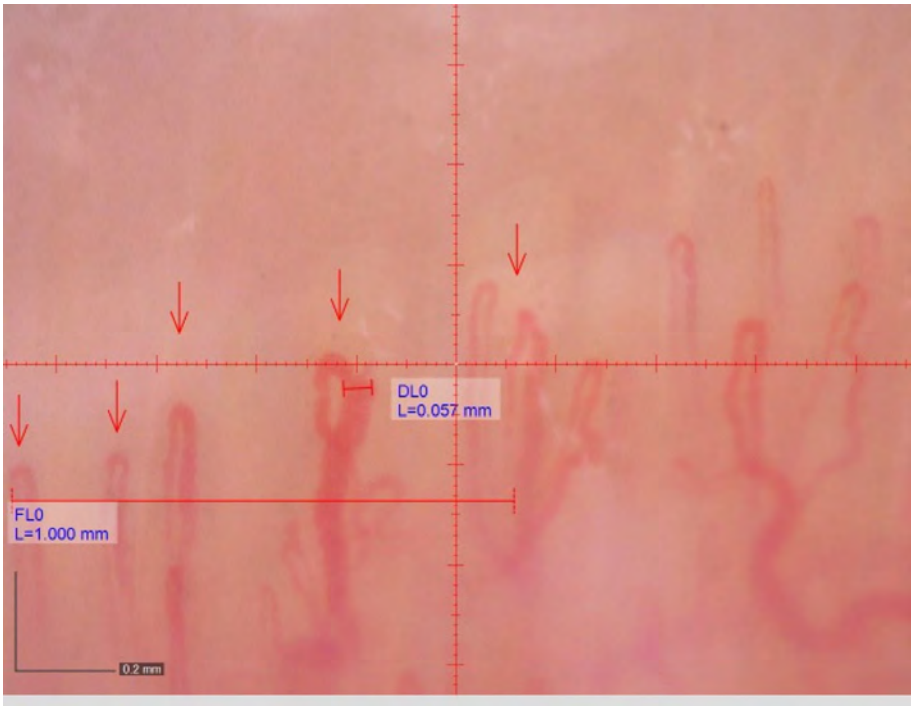
Yazmin Espinosa[1], Sara Concha[1], Clara Schulze[1] and **Antonia Valenzuela**[2], [1]Pontificia Universidad Católica de Chile, Santiago de Chile, Chile, [2]Pontificia Universidad Católica de Chile, Santiago, Chile

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Nailfold video capillaroscopy (NVC) is useful in diagnosing secondary Raynaud's phenomenon (RP) and predicting systemic sclerosis (SSc) and other CTD in adults. Recent studies indicate its potential application in children with positive antinuclear autoantibodies (ANA), irrespective of the presence of RP. We aimed to evaluate microvascular abnormalities in children using NVC in a cohort of pediatric Chilean patients.

Methods: This cross-sectional study included children between 5 to 18 years with diagnosis of CTD, RP and/or positive ANA. Using a 200 magnification DinoLite microscope, NVC findings were according to the standardized international consensus definitions from the EULAR Study Group on Microcirculation in Rheumatic Diseases into normal, non-specific and SSc patterns. ANA were detected through routine clinical care by indirect immunofluorescence techniques on HEp-2 substrate and/or immunoblotting ANA Profile 23 Ag. Extractable nuclear antibodies (ENA) were detected by Enzyme-Linked Immunosorbent Assay.

Results: 28 children were consecutively included. Median age was 12 years (interquartile range (ICR) 8-14), and 79% were female (n=22). 57% of the patients had CTD/RP (n=16) and 43% (n=12) had a positive ANA without features of CTD/RP. Non-specific abnormalities were the most frequent pattern (n=25, 89%). The SSc pattern was found in 2 patients, and 1 patient had a normal NVC pattern. The patient with normal pattern was a healthy child without CTD and with high titers of DFS70 antibody on ANA immunoblotting. The 2 patients with SScPattern had a clinical diagnosis of MCTD with RP and high titers of RNP/Sm antibody, and exhibit an active SSc pattern on NVC. Patients with positive ANA without CTD/RP had a median of 6.5 capillaries/mm (ICR 6-7) and a median apical diameter of 21,5 μm (ICR 17-24) . Most of them had a non-specific NVC pattern (n=11, 92%), and dilated capillaries were present in 50% (n=6), without microhemorrhages or giant capillaries. Patients with CTD/RP had a median apical diameter of 22.5 μm (ICR 17.5-24). Most of them had dilated capillaries (75%, n=12), and 88% (n=14)



had a non-specific pattern. Patients with a positive ANA without CTD/RP had significantly lower median apical diameters than those with CTD/RP (p=0.0091). In univariate analysis, CTD/RP (p=0.0091), and the presence of RP (p=0.0048) were associated with higher median apical diameters. High titers of RNP/Sm antibodies on ENA panel (p=0.0376), positive Sm (p=0.0376), and positive La autoantibodies (p=0.0376) were associated with higher apical diameters. In the ENA panel, high titles of RNP/Sm (p=0.0211), positive Sm (p=0.0211) and positive La (p=0.0211) were associated with fewer capillaries.

Conclusion: This study adds further knowledge of NVC technique and methodology in children and adolescents. Our results highlight the potential utility of regular use of NVC in pediatric patients with positive ANA, RP and CTD.

Examining the Relationship Between Socioenvironmental Factors and Cognitive Functioning in Youth with Childhood-Onset Systemic Lupus Erythematosus

Ashley Danguecan[1], Ibrahim Mohamed[2], Sarah Mossad[1], Tala El Tal[3], Adrienne Davis[1], Asha Jeyanathan[1], Sona Sandhu[1], Lawrence Ng[1], Paris Moaf[1], Deborah Levy[1], Linda Hiraki[1] and Andrea Knight[1], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]The Hospital for Sick Children, Brampton, ON, Canada, [3]Children's Hospital of Eastern Ontario (CHEO), Ottawa, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Problems with cognitive functioning are common in childhood-onset systemic lupus erythematosus (cSLE); these may be attributed to many factors including underlying brain inflammation. Socioenvironmental factors are known to impact disease outcomes, with poorer outcomes associated with those from disadvantaged groups. However, little is known about how socioenvironmental disadvantage may be related to cognition in cSLE. We examined the associations between socioenvironmental disadvantage, disease factors, and cognitive functioning in a pediatric cSLE cohort.

Methods: We examined a cross-sectional sample of youth with cSLE aged 10-17 years from a major tertiary hospital SLE outpatient clinic between January 2020 and April 2023. All patients met ACR or SLICC classification criteria for SLE. Area-level indicators of socioenvironmental disadvantage were obtained using the Ontario Marginalization Index, which measures levels of poverty (material deprivation) and proportion of immigrants or minoritized ethnic groups within a region (ethnic concentration). Cognition was evaluated using standardized measures of sustained attention (Conners Continuous Performance Test – Third Edition), working memory (Digit Span subtest from the age-appropriate Wechsler intelligence Scale), and inhibitory control (Color-Word Interference test from the Delis Kaplan Executive Function System).The associations between cognitive function scores, disease activity (SLEDAI-2K), disease damage (SDI) and each socioenvironmental factor were examined using separate multivariable linear regression models. P-values < .05 were considered statistically significant.

Results: A total of 49 youth with cSLE (86% female) with a mean age of 15.3 years (SD=1.7) were included in the study; mean disease duration was 22.6 months (SD=25.9), 33% had active disease (SLEDAI-2K >4) and 8% had disease damage (SDI >0). 28.6% of patients lived in the highest quintile of material deprivation, and 61.2% lived in the highest quintile of ethnic concentration (Table 1, Figure 1).

In multivariable analysis, higher material deprivation was associated with poorer working memory (β = -0.415, 95% CI -0.69, -0.14, p=0.004) (Table 2).Ethnic concentration was not associated with the cognitive outcomes. The covariate for presence of disease damage showed independent statistically significant associations with worse attention and poorer inhibitory control in both of the models for material deprivation and ethnic concentration (Table 2).

Conclusion: In keeping with known health disparities in cSLE, our data shows that higher levels of material deprivation were associated with poorer working memory performance, even when adjusting for current disease activity, damage and duration of disease. In our small cohort, disease damage was associated with worse attention and inhibitory control; replication

Table 1. Demographic and Clinical Characteristics of the Total Sample (n=49)

[1]CPT-3 detectability T score with mean = 50, SD=10; Higher scores are indicative of worse attention.
[2]WISC/WAIS Digit Span subtest scaled score with mean=10, SD=3; Higher scores are indicative of better working memory.
[3]DKEFS Color-Word Interference trial 3 scaled score with mean =10, SD=3; Higher scores are indicative of better inhibitory control.
Statistically significant results with *p*<0.05 are in bold font.

of this finding is needed with larger samples. Continued examination of the range of disparate outcomes in cSLE over time is essential for better understanding how we can best provide care for all youth with cSLE, and mitigate both disease-related and socioenvironmental risk factors.

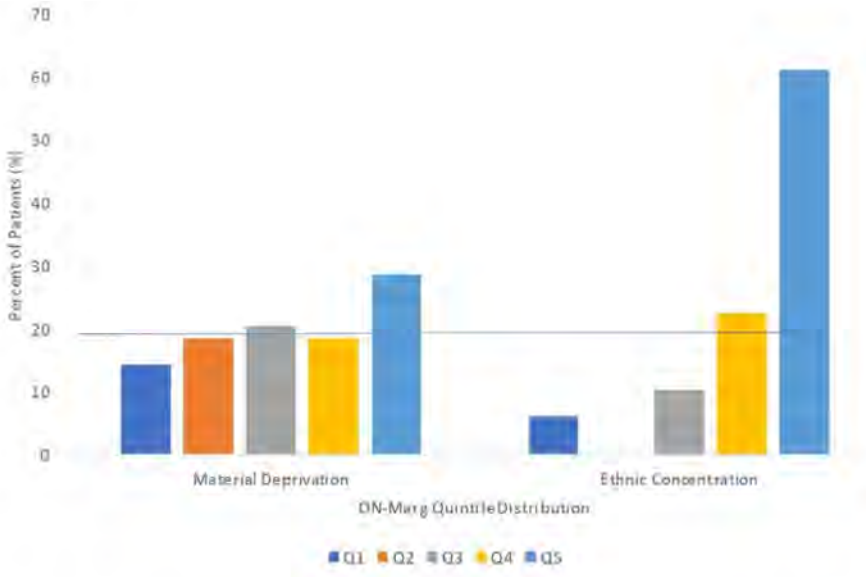

Figure 1. Quintile distribution of the Ontario Marginalization Index dimension z-scores[1] for the cSLE cohort (n=49). Ontario Marginalization Index z-scores represent the number of standard deviations from the expected mean of 0 on a given dimension, with higher scores indicating that the patient resides in an area of greater than average material deprivation or ethnic concentration. The blue line indicates the expected proportion of patients that should belong in each quintile (Q1-Q5) based on provincial census data.

Abstract Number: 1227

Serious Infections Following Rituximab Administration in Children with Systemic Lupus Erythematosus

Jordan Roberts[1], Anna Faino[2], Mersine Bryan[1], Jonathan Cogen[1] and Esi Morgan[1], [1]Seattle Children's Hospital, Seattle, WA, [2]Seattle Children's Research Institute, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab has been associated with high rates of infection among adults with systemic lupus erythematosus. However, studies of infection risk following rituximab among children with pediatric lupus (pSLE) are lacking. We conducted a retrospective study to assess incidence of hospitalized serious infections following rituximab among children with pSLE, and to assess changes in rituximab use over time.

Table 1: Characteristics of Children with pSLE who Received Rituximab and were Hospitalized with Serious Infection

Variable	Total Rituximab Cohort (2,708 hospitalizations with rituximab administered among 1,567 children)	Serious Infection Following Rituximab (339 hospitalizations with infection among 219 children in first year after rituximab)
Age at Admission (years)	16 [13 - 17] median [IQR]	16 [14 - 18]
Female	2243 (83%)	281 (83%)
Race/Ethnicity		
Asian	166 (6%)	11 (3%)
Hispanic	779 (29%)	127 (37%)
Multiracial	34 (1%)	3 (1%)
Non-Hispanic Black	1089 (40%)	123 (36%)
Non-Hispanic White	435 (16%)	55 (16%)
Other	168 (6%)	18 (5%)
Unknown	37 (1%)	2 (1%)
Insurance Status		
Private	850 (33%)	97 (29%)
Public (non-military)	1633 (60%)	220 (65%)
Military	71 (3%)	9 (3%)
Self-pay/Uninsured	51 (2%)	1 (0%)
Other/Unknown	63 (2%)	12 (4%)
Household Income		
<25k	237 (9%)	19 (6%)
25 to 50k	1611 (61%)	213 (64%)
50 to 75k	672 (25%)	85 (26%)
75 to 100k	92 (3%)	14 (4%)
100k or more	25 (1%)	1 (0%)
Lupus Nephritis	1634 (60%)	225 (66%)
End Stage Renal Disease	131 (5%)	38 (11%)
ICU admission during hospitalization	446 (16%)	88 (26%)

Methods: Children and adolescents ages 2-21 years with an ICD-9 or ICD-10 code for SLE (710.0, M32*) and who received at least one dose of rituximab during admission to a Pediatric Health Information System (PHIS)-participating hospital from 2009-2020 were included. The PHIS includes in-hospital administrative data from >50 freestanding U.S. children's hospitals. Serious infections were defined by ICD-9 and ICD-10 codes for infections during an inpatient, observation or admission encounter. Antimicrobial medication use was also required for bacterial or fungal infections. The study period for infections was 12 months following the index hospitalization when rituximab was administered. Summary statistics were used to describe children with pSLE who received rituximab, and the subset who developed a serious infection. Incidence rates for infections requiring hospitalization over the 12 months following first rituximab administration were calculated using exposure time truncated at time of death, first hospitalized infection, or 12 months after index hospitalization for rituximab administration. Rituximab use by year of hospital discharge was assessed from 2009-2021.

Table 2: Hospitalization Outcome by Type of Infection

Variable	**All Hospitalized Infections (n=339)**	**ICU Stay (n=88)**	**Death during Hospitalization (n=7)**
	N (% of total hospitalization)	*N (% of hospitalization with ICU)*	*N (% of total deaths)*
Type of Infection			
>1 serious infection code	61 (18%)	31 (35%)	5 (71%)
Bacterial			
Bacterial pneumonia	78 (23%)	26 (30%)	2 (29%)
Sepsis	69 (20%)	45 (51%)	5 (71%)
Cellulitis	66 (19%)	14 (16%)	2 (29%)
Urinary Tract Infection	43 (13%)	4 (5%)	0 (0%)

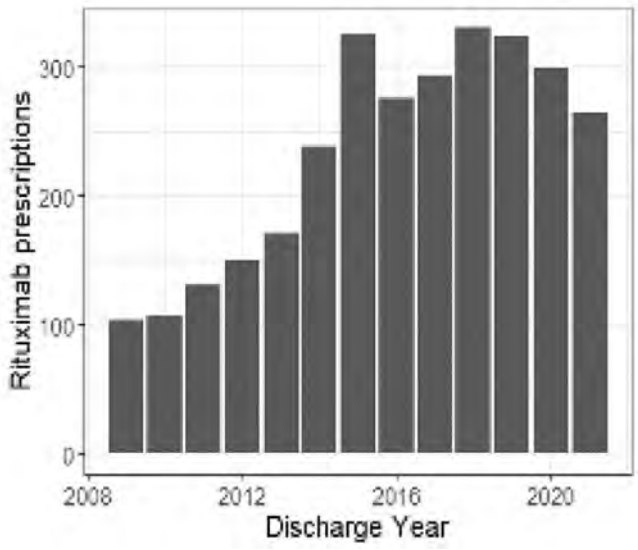

Figure 1: Hospitalizations with Rituximab Administered by Discharge Year

Results: We identified 1,567 children with pSLE who received rituximab. Demographic and clinical characteristics of the study cohort are presented in Table 1. 624 (40%) children with pSLE received cyclophosphamide in the 3 months prior to, and up to 1 year after index hospitalization. Hospitalizations with rituximab administered decreased from 2019 to 2020 and 2021 (Figure 1). Among 1,567 rituximab-treated children with pSLE, 219 (representing 339 hospitalizations) were admitted with a serious infection within 1 year after the first rituximab administration (exclusive of index hospitalization) for an incidence rate of 140 cases per 1,000 patient-years. Median [IQR] time to hospitalization with serious infection following rituximab was 1.83 [0.61, 5.84] months. 7 children with pSLE (0.44%) died during a hospitalization with an infection in the year following rituximab administration. The most common serious infections were bacterial pneumonia, sepsis and cellulitis (Table 2). There were 12 children with pSLE hospitalized with COVID-19 (4% of hospitalizations) and no in-hospital deaths with COVID-19.

Conclusion: We observed high rates of serious infection in the year following first rituximab administration in a large multi-center cohort of youth with pSLE. Rituximab use declined during the COVID-19 pandemic, though no fatalities during hospitalizations with COVID-19 were observed. Concomitant use of other highly immunosuppressive medications was common in our cohort. Further research is needed to identify risk factors for serious infection following rituximab among children with pSLE.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD) is an autoinflammatory disease characterized by a variable vessel vasculitis. In the past, several criteria have been created for adult BD classification. In 2015, the first set of BD paediatric classification criteria, the PEDBD, was proposed by an international Expert consensus. The aim of the study was to perform an external validation of the PEDBD classification criteria in a cohort of internationally validated pediatric BD, through an international Expert-based consensus process.

Methods: 210 patients (70BD, 40 PFAPA (Periodic Fever-Apthous stomatitis-Pharingytis-Adenopathies), 35 FMF, 26 HyperIgD syndrome, 22 TNF-receptor associated periodic fever syndrome, 17 undefined recurrent fevers) were randomly selected from the Eurofever Registry (patients excluded if disease onset > 16 years and if included in the first PEDBD study). A set of 11 Experts blinded to the original diagnosis, were chosen to evaluate the patients: in the 1st round, clinical and serological data were evaluated; in the 2nd round genetic data were added; in the 3rd round the other Experts' votes and comments were shown. Using the expert consensus as gold standard (agreement >80%), the PEDBD, the ISG and the ICBD criteria were applied to BD patients and to confounding diseases with a consensus, in order to define their sensitivity, specificity and accuracy.

Results: At the end of the 3rd round, a consensus on the initial diagnosis was reached in 66.2% of patients. The BD patients with an agreement (24) were classified as confirmed-BD, and those with an agreement of 60-70% (10) as probable-BD.In confirmed-BD patients, oral ulcers were present in all the patients, genital ulcers in 77%, skin manifestations in 50%, a positive pathergy reaction in 39%, ocular manifestations in 54%, with a reesulting impaired vision in 17%, venous thrombosis in 8%, neurological manifestations in 21%, gastrointestinal manifestations in 38%, articular manifestations in 33% and fever in 50% of patients. The patients with ocular and vascular involvement were all males. HLA-B51 was positive in 69% of patients. When comparing these patients with the confounding diseases, an older age at disease onset, the presence of oral and genital ulcers, skin papulo-pustular lesions, a positive pathergy test and posterior uveitis were BD distinctive elements.

The ISG, ICBD and PEDBD criteria were applied to confirmed-BD and to the confounding disease controls, resulting in the following test characteristics (Table).

Criteria	Sensitivity	Specificity	Accuracy
ISG	0.50	1.0	0.91
ICBD	0.79	0.97	0.94
PEDBD	0.58	0.99	0.92

Conclusion: the PEDBD were very specific in classifying BD patients, while the ICBD had a better sensitivity, especially for patients with only bipolar aphtosis. One limitation is that specific monogenetic BS mimics were not included as disease controls, thus the true accuracy of all these criteria may be lower in practice. The complexity of childhood BD suggests larger prospective international cohorts to foster the performance of the criteria, and to understand if BD clusters and ethnic variables should be added to the criteria.

Table 2: BRIEF-2 Executive Function Scores Over Time for cSLE Participants and Controls

BRIEF-2 Executive Function (EF)	Mild elevated T-Score*, n (%)	Potentially/ Clinically elevated T-Score*, n (%)	Baseline T-score, mean (SD)	1 year T-score, mean (SD)	Within-group comparisons Test Statistic, p-value
cSLE Participants (n=22)					
GEC	4 (18)	9 (41)	58.5 (13)	55.9 (10.3)	0.72, p=0.47
BRI	2 (9)	6 (27)	55 (12.6)	53.4 (9.3)	0.46, p=0.64
CRI	5 (22)	8 (36)	60 (14.1)	56.1 (10.2)	0.98, p=0.33
ERI	4 (18)	5 (22)	55.7 (10.4)	56.7 (10.2)	- 0.29, p=0.77
Controls (n=10)					
GEC	1 (10)	3 (30)	57.8 (8.9)	56.1 (11.8)	0.16, p=0.88
BRI	3 (30)	3 (30)	54.7 (11.6)	53.4 (10)	0.19, p=0.85
CRI	0 (0)	3 (30)	55.3 (10.3)	55.7 (12.5)	0, p=1
ERI	1 (10)	4 (40)	57.1 (12.4)	55.3 (14.8)	0.25, p=0.80

*Patients with elevated scores include those occurring at either the baseline or 1-year timepoints according to the following categories for Behavior Rating Inventory of Executive Function 2 (BRIEF-2) T-scores: 60-64 = mildly elevated, 65-69= potentially clinically elevated; ≥ 70 = clinically elevated. A higher T-score indicates a greater degree of difficulty in executive functioning.

function (EF) over time have not been well-studied in cSLE compared to typically developing children. We aimed to characterize the course of EF over time in cSLE patients matched to healthy controls.

Methods: We examined a prospective longitudinal sample of patients with cSLE (ages 12-17, met ACR or SLICC classification criteria for SLE), along with age and sex-matched healthy controls over two time points (baseline and 1 year later) collected from January 2020 to May 2023. Participants completed the self-report Behavior Rating Inventory of Executive Function 2 (BRIEF-2) that generated overall EF difficulties index score (global executive composite (GEC)), and three subindices – behavioral regulation index (BRI), cognitive regulation index (CRI), and emotion regulation index (ERI)). T-scores are transformations of raw scores based on age and sex norms. A higher T-score indicates a greater degree of difficulty in executive functioning. Disease measures including SLE Disease Activity Index 2000 (SLEDAI-2K), SLICC/ACR damage index (SDI), glucocorticoid use at visit and cumulative use, and disease duration were collected. The primary outcome was EF measured by GEC, BRI, CRI, and ERI T-scores, with a focus on GEC. T-tests were performed to examine within-group and between-group comparisons of mean scores at baseline and 1-year, and of change in mean scores (1 year minus baseline) respectively, for cSLE participants and controls.

Results: Twenty-two patients with cSLE and 10 controls were included. For cSLE, the mean age was 15.7 ± SD 1.5 years, 86% were female, median SLEDAI-2K score was 2 (IQR 2-4) and median disease duration was 2 years (IQR 1.2-4.3) (Table1). In cSLE patients compared to controls, mildly elevated GEC T-scores were present in 18% (n=4) vs. 1 (10%); potentially and/or clinically elevated GEC T-scores were present in 41% (n=9) vs 30 %(n=3) (Table2) at baseline or 1-year timepoints. While the mean CRI T-score showed a small improvement from baseline and 1 year later (60 vs 56.1), there were no statistically significant differences for within-group comparisons of any of the BRIEF-T scores over time for both cSLE and controls (Table 2). There were also no significant differences between the cSLE and control groups for mean change in the BRIEF-T scores over time (GEC, t-value=0.78, p=0.43; BRI t-value= -0.28, p=0.77, CRI t-value= -1.2, p=0.20, ERI t-value 0.99, p=0.32).

Conclusion: Self-reported EF was stable over a one-year period in this small cohort of patients with cSLE and controls. Although no significant differences in mean scores for EF were found between cSLE and controls, 59% (versus 40% of HC) had at least mild difficulties in EF. More longitudinal research is needed with longer follow up to identify cognitive function trajectories and at-risk groups for executive dysfunction in cSLE.

Abstract Number: 1230

Differences in Nailfold Capillary Morphology Distinguish Juvenile Dermatomyositis Patients That Are Myositis-Specific Autoantibody Positive

Nicholas McClellan, Sarah Vandenbergen, Sophia Matossian, J. Michelle Kahlenberg and Jessica Turnier, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is characterized by multiorgan vasculopathy, and degree of vasculopathy can indicate more severe disease. Nailfold capillaroscopy is a non-invasive method to directly evaluate abnormalities in the microvasculature. While the majority of children with JDM present with nailfold capillary (NFC) abnormalities, we do not fully understand whether NFC patterns and characteristics might differentiate JDM from other pediatric autoimmune diseases or lend insight into distinct JDM subgroups. In this study, we utilized high-resolution nailfold video capillaroscopy paired with a machine learning approach to (1) generate patient subgroups based on NFC features and (2) characterize clinical features defining each patient subgroup.

Methods: We utilized nailfold video capillaroscopy at 200x to obtain images from JDM (n=23), childhood systemic lupus erythematosus (SLE) (n=9), mixed connective tissue disease (MCTD) (n=5) and healthy control (n=17) patients at the University of Michigan Pediatric Rheumatology Clinic (1/1/23 – 5/31/23). We quantified NFC features from images using a convolutional neural network via an automated method, including density of normal and giant capillaries, microhemorrhages, and

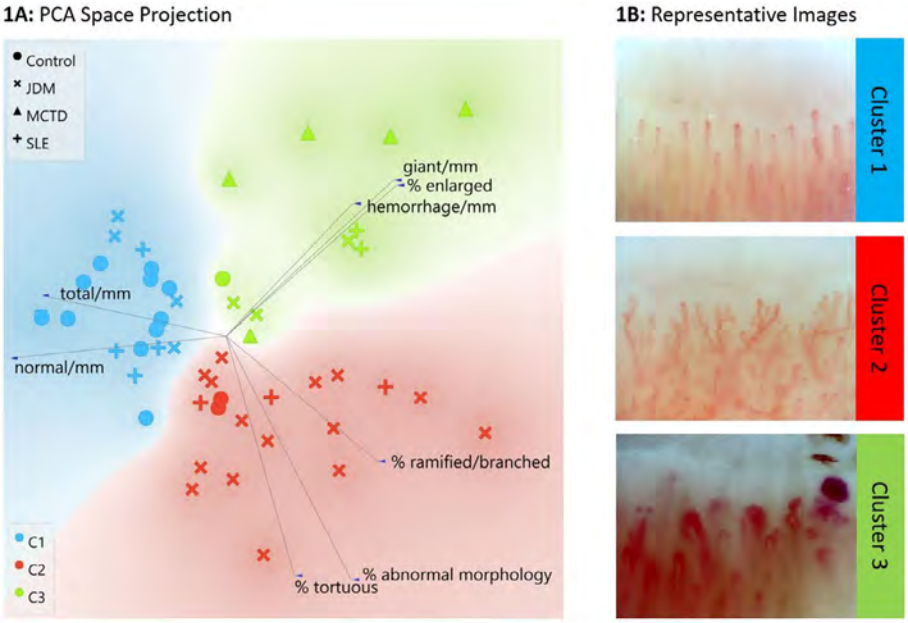

Figure 1: (1A) Principal Component Analysis (PCA) plot from Louvain cluster analysis visualized by linear projection. Symbols represent each patient, localized by alignment toward or away from each feature along its axis. (1B) Representative images demonstrating predominant NFC pattern and features from patients in each cluster.

percentage of enlarged, tortuous or ramified capillaries. We then performed unsupervised cluster analysis to identify patients with similar NFC features. Following this, clinical variables were grouped by cluster with differences between means assessed for significance by ANOVA ($p \leq 0.05$).

Results: We identified 3 patient clusters distinguished by a predominant NFC pattern of either higher relative capillary density (cluster 1 (C1)), abnormal morphology (C2) or enlarged capillaries (C3) (**Figure 1**). Upon review of JDM clinical features by cluster, we found JDM patients were primarily assigned to C2 (65%), with the remainder in C1 (22%) and C3 (13%). MCTD patients were entirely assigned to C3 (100%). Patients with SLE were distributed more evenly, with 44%, 33%, and 22% in C1, 2, and 3, respectively. The majority of control patients were assigned to C1 (82%) (**Figure 2A**). Interestingly, we found that all JDM patients with presence of a positive MSA (TIF-1γ, MDA5, NXP2, Mi-2, Ku) were assigned to C2, while those with negative MSAs were spread between C1, 2 and 3 (**Figure 2B**). We assessed CK values by cluster, revealing a trend toward higher CK in C3 (mean 550.8 u/L) than C2 (mean 201.2 u/L) or C1 (mean 83.6) (**Figure 3A**, p=0.073). Aldolase and LDH levels were similar between clusters (p=0.65 and p=0.77, respectively). Skin disease activity as assessed by Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) scores trended toward higher values in C3 (mean 5.7) as compared to C2 (mean 1.5) and C1 (mean 2.5) (**Figure 3B**, p=0.124).

Conclusion: We demonstrate 3 distinct groupings of NFC patterns that align with clinical diagnosis and MSA positivity. A predominant pattern of tortuosity and ramification is most pronounced in JDM as compared to MCTD, SLE and control patients. Further investigation into NFC morphology and patterns within a larger JDM cohort may hold the potential to assist in diagnosis, disease subtyping, monitoring and prognostication.

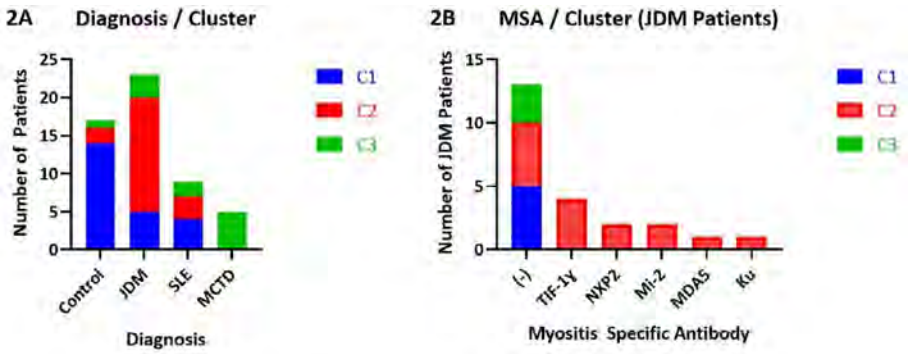

Figure 2: Stacked columns representing patients in each assigned cluster, separated by diagnosis (2A, left) and by myositis specific antibody (2B, right).

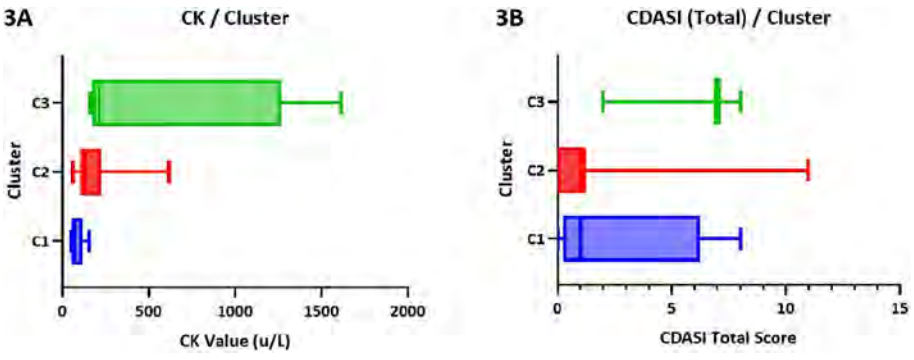

Figure 3: Box-and-whisker plots of CK values by cluster (3A, left) and total CDASI score (3B, right)

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: High levels of emotional distress have been reported in children with juvenile myositis (JM). Inadequate recognition of mental health concerns by healthcare providers (HCPs) can contribute to poor disease outcomes. A recent multicenter study confirmed the feasibility and acceptability of mental health screening (MHS) in patients with JM. The global aim of this quality improvement project was to implement MHS with referrals to an integrated social worker as standard of care for patients ≥5 years of age seen in the SickKids JM clinic. The specific aims were to 1) increase the rate of MHS from 0 to ≥50% in a 90-day period, and 2) ensure that all patients with moderate or severe screening results received referrals for social work assessment.

Table 1. MHS Implementation in Juvenile Myositis Clinic: Results Across PDSA Cycles Over a 3-Month Period

Table 1. MHS Implementation in Juvenile Myositis Clinic: Results Across PDSA Cycles Over a 3-Month Period

PDSA Cycle	Patients Completing MHS	Number with Completed AVS Documentation	Number with Completed EHR Documentation	Number Receiving Handout	Number of Positive Screens Referred to Social Work	Barriers to Implementation and Post-Cycle Changes
#1 (Mar 7 - Apr 4)	12 (100%)	4 (25%)	12 (100%)	12 (100%)	2/3 (66.7%)	Limited HCP time → Speed buttons in EHR Rotating trainees HCPs not knowing the process → Educational infographic for rotating trainees Need for interpreter → Obtain screener in other languages HCPs not sure which format of handouts to distribute → Patients receive both digital (in AVS) and physical copies of the handout
#2 (Apr 18)	7 (100%)	4 (57.1%)	5 (71.4%)	7 (100%)	2 of 2 (100%)	HCPs needing a reminder to complete documentation → Pre-clinic dot phrase → HCPs with incomplete documentation receive reminder emails
#3 (May 16 - May 30)	13 (100%)	12 (92.3%)	13 (100%)	13 (100%)	2 of 2 (100%)	In progress

Methods: A multidisciplinary stakeholder team (rheumatologists, physical therapists, nurse, social worker, research coordinators, and patient/caregiver advisors) iteratively developed screening and referral workflows, and educational resources for HCPs and families. Patients attending the JM clinic were to be screened for anxiety and depression [12-18 years old: Generalized Anxiety Disorder-7 (GAD-7) and Patient Health Questionnaire (PHQ-9); caregivers of patients 5 to < 12 years old: Pediatric Symptom Checklist (PSC-17)]. All patients were to receive a mental health resource handout and patients with positive screens were to be reviewed by physicians who decided whether to refer to the social worker. HCPs were to document MHS in patients' After Visit Summary (AVS) and electronic health record (EHR). Feedback was sought from HCPs and patients/caregivers who agreed to participate in surveys, which informed successive plan, do, study, and act (PDSA) cycles.

Results: Prior to implementation we did not perform MHS as standard care in JM clinic. We conducted three PDSA cycles from March 7 to May 30, 2023. All 32 patients (100%) seen in the clinic received MHS and the resource handout (Table 1). Documentation of MHS in the AVS and EHR rose from 25% to 92.3% and 71.4% to 100%, respectively. There were seven positive screens (22%), of which, six(86%) were referred to the integrated social worker and one was not as they were being seen at our clinic for a secondary opinion. All patient/caregiver survey participants (n=16) indicated that they were satisfied with the MHS process.

Conclusion: The JM clinic has successfully implemented MHS for all its patients within 90days and achieved timely referral to integrated social work. Additional PDSA cycles are needed to support its sustainability as well as build a robust culture of documentation. Future work will include development of tailored mental health resources to address the needs of patients with JM, caregivers, and siblings.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1, 000, 000 children. The Juvenile Systemic Scleroderma Inception cohort (jSScC) is the largest cohort of jSSc patients in the world. The jSScC collects longitudinal data prospectively in jSSc, allowing the evaluation of the development of organ involvement and patients and physician reported outcomes in jSSc over time.

Table 1. Clinical characteristics and patient and physician related outcome over time

	0 month N=74	36-month follow-up N=74	P Value
Female/Male	3.6:1 (58/16)		
Cutaneous subtype			
Diffuse subtype	74% (55/74)		
Limited subtype	26% (19/74)		
Median Disease duration (years), IQR	2.3 (0.8 – 4.2)		
Median age at onset of Raynaud´s (years), IQR	9.3 (5.7 – 12.5)		
Median age at onset of non-Raynaud´s (years), IQR	10.3 (6.7 – 13.3)		
Disease modifying drugs	90% (64/71)	90% (66/73)	
MRSS, median (IQR)	10 (3 – 20)	7 (2 – 20)	0.041
Presence of Swollen joints	16% (12/74)	4% (3/74)	0.014
Muscle Weakness	16% (10/62)	3% (2/69)	0.009
Elevated CK	25% (13/52)	9% (4/44)	0.042
Patient Reported Outcome (median, IQR)			
Patient global disease activity	40 (20 – 50) n=52	20 (10 – 30) n=61	0.014
Patient global disease damage	40 (20 – 60) n=52	20 (10 – 30) n=61	0.005
Patient Raynaud activity	20 (10 – 50) n=65	10 (0 – 20) n=64	0.034
Physician Reported Outcome (median, IQR)			
Physician global disease activity	30 (20 – 45) n=58	15 (5 – 25) n=69	0.001
Organ involvement with nonsignificant change			
History of ulceration	49% (36/74)	64% (47/73)	0.054
Pulmonary Hypertension (Ultrasound)	4% (3/71)	7% (4/57)	0.490
Only Cardiac involvement	3% (2/74)	3% (2/74)	-
Hypertension assessed by RR	0% (0/74)	0% (0/74)	-
Renal Crisis	0% (0/74)	0% (0/74)	-
Gastrointestinal Involvement			
Overall	38% (28/74)	39% (29/74)	0.866
BMI ≤ - 2 z score	17% (12/71)	20% (13/65)	0.641

Methods: The jSScC enrolls jSSc patients who developed the first non-Raynaud´s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion. We reviewed jSScC patient clinical data and patient and physician reported outcomes of those with 36 months follow up from the time of inclusion until 1st of April 2023.

Results: We could extract data of 74 patients, 74% with diffuse cutaneous subtype. The female/male ratio was 3.6:1. 89% of the patients were Caucasian. Median age of onset of Raynaud symptom was 9.3 years and the median age of onset of non-Raynaud symptom was 10.3 years. Median disease duration was 2.3 years at the time of inclusion in the cohort (T0). Ninety percent of the patients were treated with disease modifying anti-rheumatic drugs at T0 and 90% after 36months (T36). Four clinical parameters improved significantly over time: the median modified Rodnan skin score decreased from 10 to 7 (p=0.041), the number of patients with swollen joints decreased from 16% to 4% (p=0.014), the number of patients with elevated CK value decreased from 25% to 9% (p=0.042) and the number of patients with muscle weakness decreased from 16% to 3% (p=0.009). All other organ involvement did not show any statistically significant change from T0 to T36.

Three of the four patient reported outcomes improved significantly from T0 to T36: patient reported disease activity (VAS 0 – 100) from 40 to 20 (p=0.014), patient reported disease damage (VAS 0 – 100) from 40 to 20 (p=0.005), patient reported Raynaud activity (VAS 0 – 100) from 20 to 10 (p=0.034). One of the three physician reported outcomes improved significantly: the physician global disease activity (VAS 0 – 100) from 30 to 15 (p=0.001).

Conclusion: Skin and musculoskeletal clinical features improved significantly over 36 months. It is reassuring that major internal organ manifestations, such as cardiac, pulmonary and gastrointestinal were stable. No renal crisis occurred over the 36-month time period. The patient and physician-reported outcomes had the most positive impact over the 36 months period in this large international cohort.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1,000,000 children. Currently no medications are licensed for the treatment of jSSc. Due to its rarity, only recently the first management and treatment guidelines have been published, the jSSc SHARE (Single Hub and Access point for paediatric Rheumatology in Europe) recommendations, reflecting consensus opinion upon pediatric rheumatologists(1). We reviewed the applied medication in the treatment of the patients in the juvenile systemic scleroderma inception cohort (jSScC) up to April 2023.

Methods: We reviewed the change of the applied medication in the treatment of jSSc patients over 36 months in the jSScC. The frequency of medications was calculated across the cohort at timepoint 0 (enrollment), and 36 months. jSScC is a prospective cohort of jSSc patients, who developed the first non-Raynaud́ s symptom before the age of 16 years and are under the age of 18 years at the time of inclusion.

Results: We extracted data from 71 patients from the jSScC who were followed for 36 months, 75% had diffuse subtype. At the time of inclusion in the cohort the median disease duration was 2.4 years, median age of the first non-Raynaud symptom was 10.3 years. We captured the recorded medications at 0 months and 36 months. 64/71(90%) received any kind of Disease modifying drug (DMARD).

MEDICATIONS	Time point 0 N =71	T36 months N=71	P value
Any Medication	90% (64/71)	90% (64/71)	
Vascular medications			
Endothelin receptor antagonist	17% (11/64)	22% (14/64)	0.504
PDE-5-Blocker	3% (2/64)	9% (6/64)	0.144
Immunomodulators			
Glucocorticoids	56% (36/64)	31% (20/64)	0.004
All csDMARDs:			
Methotrexate	53% (34/64)	25% (16/64)	0.001
Mycophenolate Mofetil	22% (14/64)	67% (43/64)	<0.001
Hydroxychloroquine	13% (8/64)	20% (13/64)	0.233
Cyclophosphamide	14% (9/64)	0% (0/64)	0.002
Azathioprine	3% (2/64)	3% (2/64)	
All bDMARDs:			
Tocilizumab	0% (0/64)	17% (11/64)	0.001
Rituximab	0% (0/64)	0% (0/64)	
Adalimumab	2% (1/64)	0% (0/64)	0.315
Autologous Stem cell transplantation	0% (0)	1% (1)	

csDMARDs: Conventional synthetic disease-modifying antirheumatic drugs
bDMARDs: Biological disease-modifying antirheumatic drugs

The glucocorticoid use decreased from month 0 to 36 months from 56% to 31% (p=0.004).The methotrexate use decreased from 53% to 25% (p=0.001), in opposite the mycophenolate use increased from 22% to 67% (p< 0.001). The cyclophosphamide use decreased from 14% to 0% (p=0.002). Tocilizumab use increased from 0% to 17% (p=0.001). All other medication use showed no significant changes. Endothelin receptor antagonist was used in 17% patients at time point 0 and 22% at 36 months. PDE-5 blocker use increased from 3% to 9%.

Conclusion: At baseline half of the patients were on glucocorticoids. This is more frequent than typical adult SSc practice but coincides with jSSc SHARE treatment recommendations (#1) (1). After 36 months observation in the cohort over 90% of patients received a DMARD therapy. Methotrexate and mycophenolate mofetil were the most commonly prescribed DMARDs, which also reflects the SHARE treatment recommendations (#2 and #3).At 36 months the use of glucocorticoids, methotrexate and cyclophosphamide decreased, and the use of mycophenolate and tocilizumab increased. In general, biological DMARDs are typically considered in severe or refractory disease (SHARE recommendation #7), reflecting the lower percentage compared to csDMARDs. Endothelial receptor antagonists, such as bosentan, were used over time in approximately 20% of the patients, reflecting SHARE recommendation #6 for pulmonary hypertension and/or digital tip ulcers. This is the first evaluation looking at clinical medication practice pattern in jSSc over 36 months, and its comparison to recently published consensus guidelines.

Abstract Number: 1234

Cognitive Performance Score of the Pediatric Automated Neuropsychological Assessment Metrics Software in a Brazilian Cohort and Its Association with Disease Activity

Jaqueline de amorim[1], Simone Kishimoto[1], Paula Fernandes[1], Roberto Marini[2], Zahi Touma[3], Hermine Brunner[4] and **Simone Appenzeller**[1], [1]UNICAMP, Campinas, Brazil, [2]Revista Brasileira de Reumatologia, Campinas, Brazil, [3]University of Toronto, Toronto, ON, Canada, [4]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The PedAnam (Pediatric Automated Neuropsychological Assessment Metrics) is an automatic software to evaluate cognitive performance that has recently been validated into Portugues (Brazil). The purpose of this study was to (1) Explore and test Cognitive Performance Score (CPS) in childhood-onset systemic lupus erythematosus (cSLE). (2) Compare different CPS scores between cSLE and to determine if there is an association with disease activity.

Methods: Consecutive cSLE and healthy controls responded to the PedAnam. We performed the calculation of four scores: (1) PedANAM-CPSUWA using unweighted averages of the accuracy score; (2) PedANAM-CPSPCA principal component analysis; (3) PedANAM-CPSlogit used logistic regression; (4)PedANAM-CPSmultiscore logistic models based on performance parameters with selected subtests. After these calculations, we observed the correlation between the CPS indices and compared the performance of patients and healthy controls. Cognitive impairment was determined by z-scores and considered present if ≤2 SD from healthy controls. Disease activity was evaluated through SLE disease activity score and cutoff of 3 was considered active disease.

Results: We included a total of 50 consecutive cSLE (45 [90%] women; median age = 14 years; age range = 9–18 years) and 50 healthy controls (44 [88 %] women; median age = 15; age range = 9-18 years). We observed a correlation between the PedANAM-CPSUWA and the PedANAM-CPSPCA (r = 0.99), PedANAM-CPSPCA and PedANAM-CPSmultiscore (r = -0.60) logit and PedANAM-CPSUWA (r = -0.56). We observed statistically significant differences between patients and healthy controls in the PedANAM-CPSUWA and PedANAM-CPSPCA scores (P = 0.001). Cognitive impairment was observed in12 (24%) cSLE patients and 1 (2%) healthy controls (p < 0.001) by the PedANAM-CPSUWA index and using the PedANAM-CPSPCA index. An association between disease activity and PedANAM-CPSUWA index (p=0.01) and PedANAM-CPSPCA index (p=0.002) was observed**.**

Conclusion: After the translation and validation process, this is the first study using the CPS in Brazilian version of PedANAM and we identified two of the metrics that were able to differentiate between cSLE and healthy controls. Worse performance with disease activity was observed. Funding FAPESP (CEPID BRAINN 13/07559-3)

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a critical need for tools to distinguish between maturational changes mimicking subchondral edema from pathologic inflammation within the SI joints on MRI. We aimed to establish standards for interpretation of diffusion weighted imaging (DWI) in healthy children.

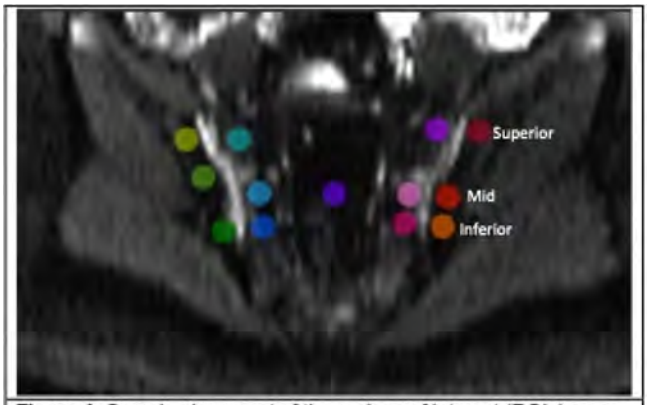

Figure 1. Sample placement of the regions of interest (ROIs) on a control patient in the mid SI joint. Analogous ROI placement performed on 1 anterior and 1 posterior slice of the SI joint.

Table 1. Apparent diffusion coefficient (ADC) values by region of interest (ROI) on anterior, mid, and posterior slices in superior, mid, and inferior locations of the ilium and sacrum. Each subject contributed data from right and left sacroiliac joints.

			Anterior Median (IQR)	Mid Median (IQR)	Posterior Median (IQR)
Type I	Iliac	***Superior Mid***		335.3 (210.6-533.4)	
		Inferior		630 (491.1-879.5)	
	Sacrum	***Superior Mid Inferior***	845.4 (751.9-985.6)	710.9 (655.9-803.9)	728.6 (560.2-804.0)
Type II	Iliac	Superior		366.6 (291.9-459.4)	
		Mid		340.5 (230.5-380.0)	
		Inferior		577.8 (454.0-670.3)	
	Sacrum	***Superior Mid Inferior***	837.0 (764.2-1073.0)	749.5 (621.2-773.5)	684.7 (499.3-769.4)
Type III	Iliac	***Superior Mid***		320.7 (225.5-403.0)	
		Inferior		518.3 (336.8-665.7)	
	Sacrum	***Superior***	489.1 (315.5-727.8)		556.0 (280.4-794.9)
		Mid	672.5 (375.4-784.6)		795.7 (425.7-1008.8)
		Inferior	489.1 (315.5-727.8)		556.0 (280.4-794.9)
Type IV	Iliac	***Superior Mid***	291.3 (65.7-412.1)		435.9 (210.6-495.3)
		Inferior	517.1 (344.8-593.1)		418.5 (375.0-569.0)
	Sacrum	***Superior Mid Inferior***		497.3 (381.0-514.8)	

Legend. Regions of interest (ROIs) that were not significantly different across slices (anterior/mid/posterior) or across joint sites (superior/mid/inferior) were combined to create a representative value of those regions. The combinations are shown in the table through merged columns across anterior, mid, and posterior slices and by bold and italicized region names across superior, mid, and inferior locations for each bone and maturational type.

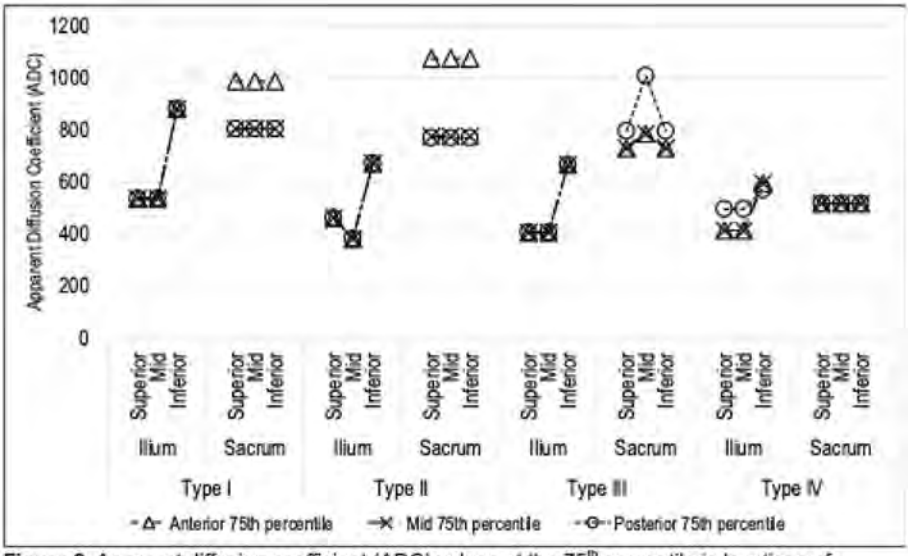

Figure 2. Apparent diffusion coefficient (ADC) values at the 75th percentile in locations of interest among patients with normal MRI scans of the sacroiliac joints.

Methods: This was a retrospective cross-sectional study of MRI scans of healthy controls identified from a prior study that evaluated the appearance of MRI in healthy children (Chauvin et. al, 2019) and through query of the digital archiving system at a single center across a range of bone maturation. DWI and short-tau inversion recovery (STIR) images were analyzed independently by 2 pediatric radiologists using custom software (Parametric MRI, Philadelphia, PA; https://www.parametricmri.com/). DWI series performed in the axial plane were reformatted by the software into a semi-coronal plane. To establish normative ranges of apparent diffusion coefficient (ADC) in controls, circular regions of interest (ROIs) of 0.15-0.22 cm^2 were placed at the superior, mid, and inferior portions of the anterior, mid, and posterior ilium and sacrum along the cartilaginous SI joint (Figure 1), avoiding sclerosis. ADC was calculated using a linear log model and all available b values. The type (I-IV) of sacral apophyseal/periarticular maturational signal was recorded. Mixed effects regression models with subject-specific random effect to account for clustering were used to determine if the ROIs (average ADC from the 2 raters) for the superior, mid, and inferior locations for the anterior, mid, posterior portions of the sacrum and ilium differed significantly for each maturational type.

Results: DWI and STIR sequences from 63 healthy children were assessed. Table 1 lists the ADC for each part of the SI joint for maturational types I-IV. Figure 2 shows the 75th percentile of normative values. ADC at the superior, mid, and inferior portions of the anterior, mid, and posterior of the sacrum were not significantly different for type I, II, and IV maturation; for type III, ADC from the posterior sacrum was significantly higher than the anterior and mid slices. The median ADC values in the sacrum were significantly different between maturational types ($p < 0.001$) and decreased from type I to type IV. ADC values were significantly different in the ilium between the inferior, mid, and superior parts of the SI joint ($p < 0.001$) with higher ADC values observed in the inferior locations compared to the superior or mid portion of the joint in anterior, mid, and posterior slices for all 4 maturational types.

Conclusion: We established ADC normative values for the superior, mid, and inferior portions of the anterior, mid, and posterior sacrum and ilium along the cartilaginous SI joint by maturational type. Observed trends with more variable ADC in the ilium and higher ADC at the inferior aspect of the ilium are in accordance with prior observations on STIR in the maturing SI joint; however, the ADC from DWI goes beyond prior STIR observations by quantifying the difference(s). Next steps are to establish empirical cut-offs to distinguish normal maturational changes from pathologic inflammation to improve the specificity and confidence in the diagnostic interpretation of the MRI.

Melanoma Differentiation-Associated Protein-5 in Juvenile Dermatomyositis: A Single Center Cohort

Dawn Gist[1], Sarah Molina[2], Maria Pereira[3], Andrea Ramirez[3], Cagri Yildirim-Toruner[4] and Marietta De Guzman[3], [1]Baylor College of Medicine Pediatrics Residency, Houston, TX, [2]Baylor College of Medicine - Pediatrics Residency Program, Houston, TX, [3]Baylor College of Medicine, Houston, TX, [4]Baylor College of Medicine, Texas Children's Hospital, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is an idiopathic inflammatory myopathy that causes muscle weakness, rash, vascular changes, or other organ involvement. The phenotypes may vary, and studies suggest a correlation between myositis-specific antibodies (MSA), clinical presentation, and course. This is thought to be due to specific cytokine profiles activated by these antibodies. Melanoma Differentiation-Associated Protein-5 (MDA5) is an MSA associated with clinically amyopathic dermatomyositis and lung disease with high risk for rapidly progressive interstitial lung disease. This study aims to highlight the clinical manifestations of MDA5+ JDM and disease course in a racially and ethnically diverse population. We also aim to assess racial disparities in time-to-diagnosis from cutaneous symptom onset.

Methods: After Institutional Review Board approval was obtained, we conducted a retrospective chart review of patients diagnosed with MDA5-positive JDM at Texas Children's Hospital.Clinical characteristics at the time of diagnosis, 6-month, 12-month, and most recent visits were recorded.

Results: Nineteen patients were included, with a mean age of 9.9 years (range 3-18), 68% female, 21% Black, 79% White, and 68% Hispanic. Figure 1 shows the clinical findings at presentation. All had cutaneous and vascular features, 78% had muscle disease, 74% had interstitial lung disease, and 47% had gastrointestinal (GI) symptoms. Most common skin findings were Gottron's papules (95%), palmar papules (47%), and heliotrope rash (47%). Median time in months from onset of cutaneous symptoms to diagnosis was 5.5 among Black patients, 5 among Hispanic, and 3 among White Non-Hispanic. Three

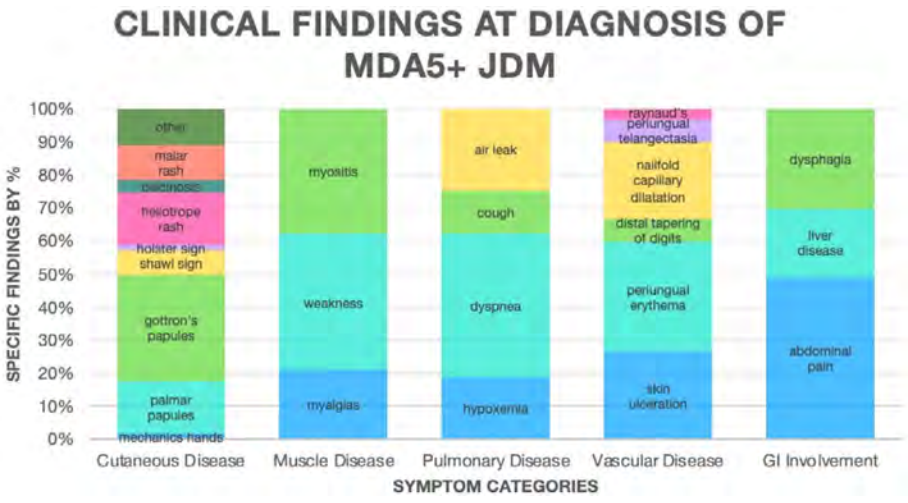

Figure 1: Clinical Findings at Diagnosis of MDA5+ JDM

patients had a lung biopsy, with the most common findings of organizing pneumonia and diffuse alveolar damage. Figure 2 summarizes induction treatment given. 8% of patients had clinical remission at 6-month follow-up, 30% at 12 months, and 50% at last visit (mean of 31.1 months, range: 6-70).Two patients diagnosed at age 3 years had progressive, diffuse alveolar damage resulting in death shortly after diagnosis. At last follow up, 20% still required corticosteroids, 30% required intravenous immunoglobulin (IVIG), and 20% required rituximab. While arthritis, cutaneous symptoms, and GI symptoms improved over time, vascular, muscular, and lung disease were persistent at last visit (Figure 3).

Conclusion: MDA5+ JDM patients in this cohort presented with prominent cutaneous and vascular disease. Lung disease was present early and persisted late in disease course. Half of patients had not reached remission at the last visit, and several continued to require steroids, IVIG, and B-cell depletion. Further studies comparing these patients to non-MDA5 controls may help characterize the role of MDA5 in these findings. While this study does not show a significant difference in time to

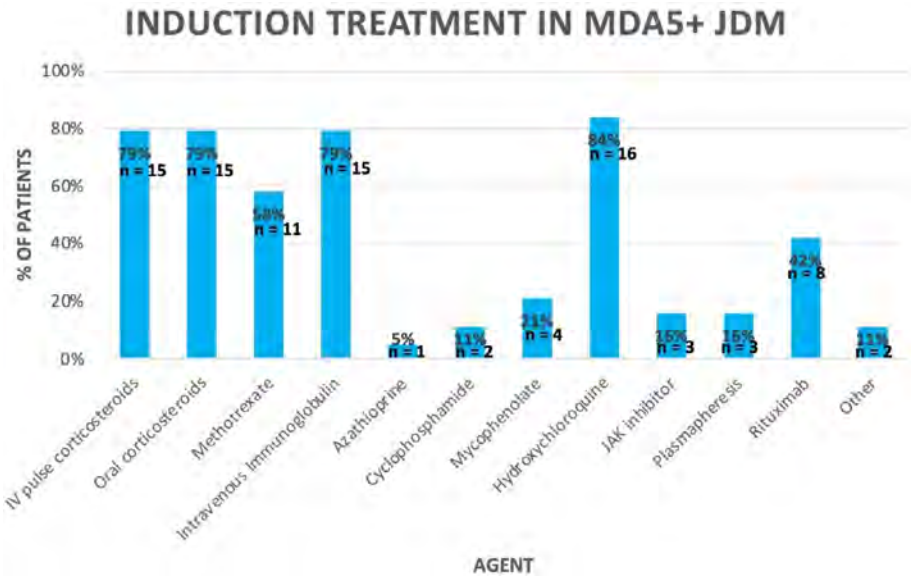

Figure 2: Induction Treatment in MDA5+ JDM

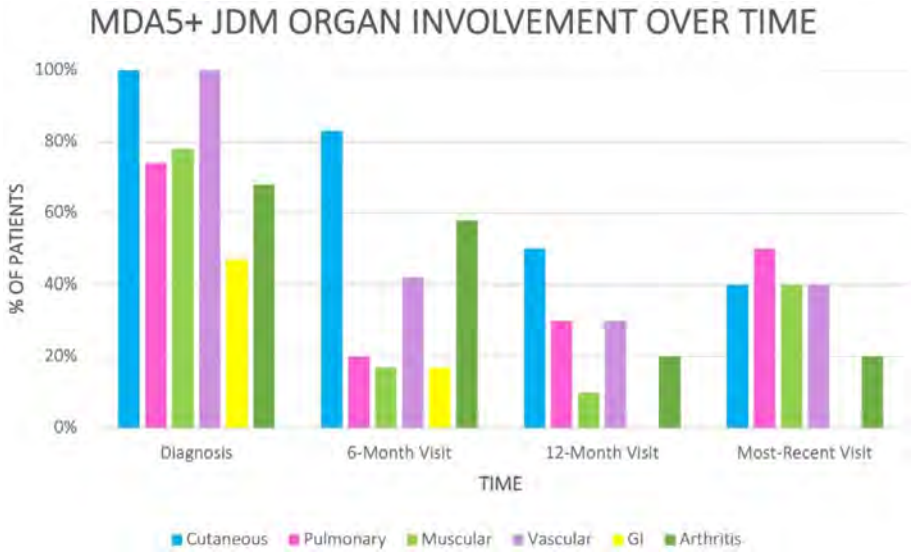

Figure 3: MDA5+ JDM Organ Involvement Over Time

diagnosis from onset of cutaneous symptoms between racial and ethnic groups, the sample sizes were small. More data on time to diagnosis, especially in Black and Hispanic patients, is needed to assess for delays in diagnosis, as there continues to be a need for education and recognition of cutaneous features in dark skin tones.

The Associations Between Depressive Symptoms and Executive Function and Academic Outcomes in Children with SLE

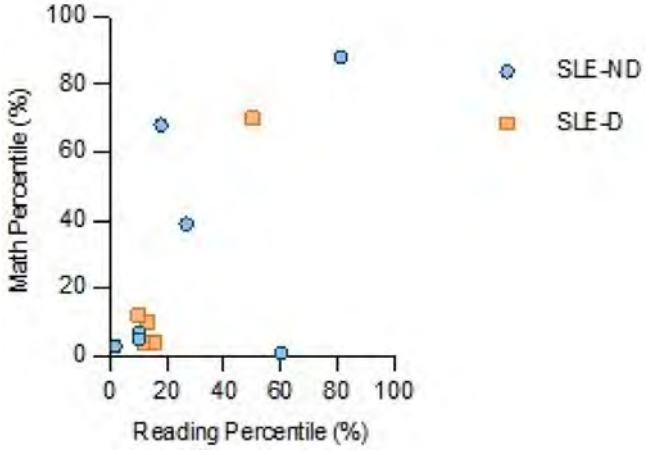
Hannah Bradfield[1], Paola Sparagana[2], Elizabeth Sloan[1], Chanhee Jo[3], Tracey Wright[1] and Sheryl Frierson[2], [1]UT Southwestern, Dallas, TX, [2]Scottish Rite for Children, Dallas, TX, [3]Texas Scottish Rite Hospital, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Children with juvenile-onset SLE (jSLE) have high rates of depression.[1-2] Adolescents with depression, but without a chronic illness, have lower academic engagement, efficacy, and school functioning.[3] While academic outcomes have been studied in children with jSLE, no studies have explored the associations between depression and academic outcomes in this population. [4] This pilot study aimed to evaluate the relationship between depressive symptoms and executive function and academic outcomes in jSLE.The study also explored the relationship of depressive symptoms to other disease/patient-specific variables, including age at onset, disease duration, and disease activity.

Methods: jSLEpatients, 9-18 years of age, completed the Wide Range Achievement Test 5th Edition (WRAT5) and the Center for Epidemiological Studies – Depression Scale (CESD). Their parent completed the Behavior Rating Inventory of Executive Function 2nd Edition (BRIEF2) and a questionnaire gathering demographics and academic performance. The SLEDAI

Figure 2



and SLICC/ACR Damage Index, were obtained. Two-sample T-test was used to identify associations between depressive symptoms and academic outcomes, including WRAT5 and BRIEF scores, and disease/patient-specific variables.

Results: Of the 12 patients enrolled, 42% screened positive for significant depressive symptoms.Forty percent of patients who screened positive for depressive symptoms reported receiving mental health treatment. The WRAT5 mean math computation and reading composite percentile ranks were higher for participants without significant depressive symptoms (SLE-ND) compared to those with significant depressive symptoms (SLE-D), but this difference was not significant (see figure 1). The mean BRIEF Initiate scale percentile was higher for participants with significant depressive symptoms compared

to those without, but this difference was also not significant. Patients with significant depressive symptoms tended to be older at disease onset and have shorter disease duration (see figures 2A-B).

Conclusion: Depressive symptoms, often untreated, were common in this cohort with jSLE. While there may be clinically meaningful differences in academic outcomes in jSLE patients with significant depressive symptoms, the small sample size precluded us from detecting significant differences. However, this pilot study demonstrated the feasibility of administering tools to assess depressive symptoms, executive function, and academic outcomes in jSLE. Larger studies are needed to better understand these trends.

Prevalence of Celiac Disease Among Children and Adolescents with Systemic Lupus Erythematosus (SLE)

Oscar Mwizerwa[1], Andrea Knight[2], Daniela Dominguez[2], Deborah Levy[2], Holly Convery[2], Kendal Thompson[2], Nicholas Gold[2], Catherine M Walsh[2] and Linda Hiraki[2], [1]University of Toronto, The Hospital for Sick Children, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) and celiac disease (CD) are autoimmune diseases characterized by the presence of specific autoantibodies. We aimed to investigate the prevalence of CD in a multiethnic cohort of children and adolescents with SLE.

Methods: We completed a retrospective cohort study of patients under 18 years of age who were diagnosed and followed for SLE at The Hospital for Sick Children between January 2010 and June 2022. We restricted to patients screened for CD with immunoglobulin A antibodies against tissue transglutaminase (tTG-IgA) within one year of SLE diagnosis. We recorded tTG-IgA titers and reviewed medical records for additional investigations, including pathology reports of duodenal biopsies. CD was confirmed by duodenal histology based on the modified Marsh-Oberhuber classification (Marsh ≥3). Demographic and SLE disease features were extracted from the dedicated Lupus database. We calculated the prevalence of clinical features, positive tTG-IgA results, and biopsy-confirmed CD, and compared SLE features between CD and non-CD groups with Fisher's exact tests.

Results: CD screening was completed in 74% (300/404) of children diagnosed with SLE. Thirteen (4%) had positive tTG-IgA serology (ranging from 38 to >100 U/ml [positive >8U/ml] for Enzyme-linked immunoassay testing and 34 to >4965 CU [positive >30 CU] using the Chemiluminescent Immunoassay). Ten of 13 (77%) patients with positive anti-tTG autoantibodies

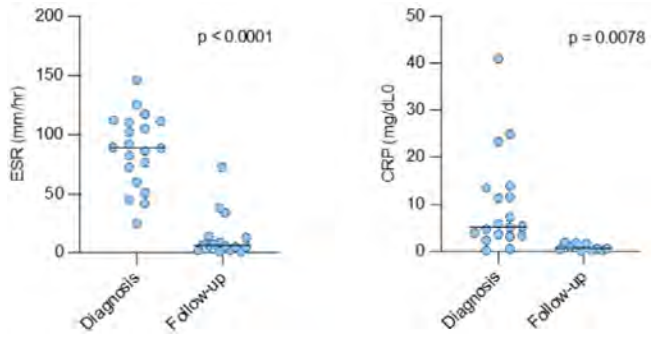

Figure 2. Differences in ESR and CRP from diagnosis to last follow-up visit compared by Wilcoxon signed-rank test.

had an endoscopy and duodenal biopsy. Of those biopsied, eight had histopathologic evidence of CD which represents 62% of patients with positive serology, and 2.6% of the screened SLE population. Among patients with CD, only 50% had GI symptoms and 62% (8/13) had positive anti-endomysial antibodies. All patients with biopsy-proven CD were diagnosed within one year of SLE diagnosis. There were no significant differences in SLE features observed between those with and without CD.

Conclusion: Biopsy-proven CD was diagnosed in 2.6% of children and adolescents with SLE, which is higher than the reported prevalence in the general population of 1.4% by seroprevalence and 0.7% by biopsy. Only half of the patients with biopsy-proven CD had GI symptoms, highlighting the utility of screening in the childhood SLE population.

Clinical Manifestations and Management of Takayasu Arteritis: A Multicenter Pediatric Cohort

Ana Luiza Altaffer[1], Kristina Ciaglia[2], Elizabeth Sloan[3] and Marietta De Guzman[4], [1]Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [2]UT Southwestern and Scottish Rite for Children, Dallas, TX, [3]UT Southwestern, Dallas, TX, [4]Baylor College of Medicine, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TA) is a rare granulomatous vasculitis that affects large vessels, including the aorta, its major branches, and the pulmonary artery. Data on the presentation and clinical course of pediatric TA are limited, and children present with different clinical features than their adult counterparts.

Methods: With institutional review board approval, a retrospective cohort study of children who were diagnosed with TA at two large pediatric centers between 2005-2022 and 2016-2023 was performed. Data were abstracted from the electronic medical record. Patient demographics, presenting symptoms and signs, imaging findings, and management data were evaluated using standard descriptive statistics.

Results: Twenty-one patients were included. The majority were female (90.45%), with a mean age at diagnosis of 13.5 years (range 9-17). Most were Hispanic or Latino (71.4%). Diagnosis occurred a median of 4 months following symptoms onset (IQR 1-15), and the mean follow-up period was 38 months (range 5-112). The most prevalent symptoms at initial presentation were constitutional (95.5%), with fatigue being almost universally present (Table 1). A history of claudication was only elicited from one patient at presentation. Over half (54.5%) presented with hypertension, BP differential, and/or decreased pulses. All but one patient had an elevated ESR (mean 82.5 mm/hr, range 25-146), and all but four had an elevated CRP (mean 5.2, range 0.2-13.6) (Table 1). All patients had imaging evidence of aortic involvement, including the abdominal (76.2%), ascending thoracic (71.4%), and descending thoracic (66.7%) segments. Seven patients (33.3%) had renal artery stenosis. All patients were initiated on systemic corticosteroids at diagnosis. The most common initial steroid-sparing immunomodulatory regimen included a combination of methotrexate and infliximab (42.9%). Eighty-one percent were treated with a biologic DMARD (bDMARD) at some point (Figure 1). Many patients switched steroid-sparing agents throughout their disease course. Reasons for addition or change of therapy included poor disease control or flare, inability to wean steroids, new disease manifestations, adverse effects, and patient preference. Five patients (23.8%) required surgical management. At the most recent follow-up visit, 10 patients remained on steroids. Five patients were still symptomatic. One patient achieved drug-free clinical remission. There was a statistically significant decrease in ESR ($p< 0.0001$) and CRP ($p=0.0078$) from the initial to final visit (Figure 2).

Conclusion: Like prior pediatric studies, patients in our cohort presented predominantly with constitutional symptoms, musculoskeletal involvement, hypertension, and elevated inflammatory markers. bDMARDs were introduced earlier than in previously reported cohorts. Our cohort was demographically different from other pediatric case series as we report majority Hispanic/Latino patients. While many patients were asymptomatic at the last follow-up, approximately half still required steroids for disease control.

Obvious Only in Retrospect: A Cohort of STING Associated Vasculopathy in Infancy (SAVI) Without Typical Rash

Ilaria Maccora[1], Patricia Vega-Fernandez[2], Kimberly Risma[3] and Grant Schulert[4], [1]PhD student, in the Area of Drugs and Innovative Treatments, NeuroFARBA Department, University of Florence. Meyer Children's Hospital, Firenze, Italy, [2]Division of Rheumatology, Cincinnati Children's Hospital, Medical Centre, Cincinnati, OH, [3]Division of Allergy and Immunology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: STING-associated vasculopathy with onset in infancy (SAVI) is characterized by systemic inflammation, skin vasculopathy and interstitial lung disease. However, since the initial description knowledge and clinical spectrum of this disease has substantially broadened. Here we present the clinical and laboratory characteristics of 2 families with SAVI presenting with autoimmunity and lung disease without significant cutaneous vasculopathy

Methods: We performed a retrospective chart review of patients with a genetic diagnosis of SAVI followed at the Rheumatology division of Cincinnati Children's Hospital Medical Center (CCHMC). We collected demographic, clinical, laboratory and radiological information.

Results: We identified 9 patients from 2 families. *Family A* consisted of 7 individuals (the father (patient G), 3 sons and 3 daughters) carrying the heterozygous variant in STING1 c.463G >A, previously reported as cohort with undiagnosed interstitial lung disease, arthritis, and atopic dermatitis. The diagnosis was confirmed reviewing their medical records and performing genetic testing for SAVI. *Family B* consisted of 2 individuals (father (patient I) and daughter (patient H)), carrying the c.842G >A variant (see table 1). The median age at onset of symptoms in these 9 patients was 18 months (range 1-adulthood). The first symptom was eczema in 5 (55.5%), lung disease in 3 (33.3%), failure to thrive in 2 (22.2%), and arthritis in 1 (11.1%). Eight patients showed skin involvement (7 eczema and alopecia and 1 blistering rash), 7/9 lung involvement, 5/9 arthritis, 7/9 arthralgia and 1/9 increased liver enzymes. Seven patients underwent to lung CT that showed an interstitial lung disease of different severity characterized by minimal ground glass or nodular lesion up to diffuse cystic lesions to

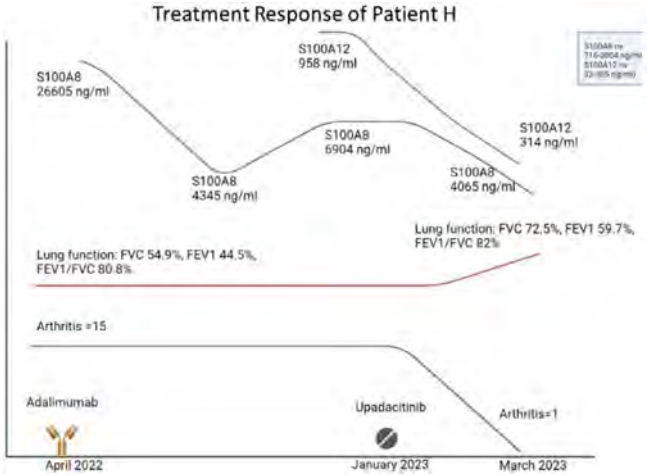

Figure1: visual presentation of response to treatment of patient H (adalimumab and Upadacitinib) in terms of articular response, lung response and some inflammatory biomarkers.

complete disruption of parenchyma. Lung biopsy performed in 5 patients showed chronic inflammatory bronchiolitis. Laboratory tests were available in 8 patients: all had increased ESR, 75% ANA and rheumatoid factor positivity, and 62.5% hypergammaglobulinemia. Lymphocyte subset showed expanded B cells in 75% (median 38.5% Range 31-53%), with decreased CD8+T in 71% (median 14%, R 10-38%) and 57% with increased CD4+/CD8. Plasma cytokines performed in 7 patients, showed increased value of IL1b (1/7), IL2 (2/7), IL4 (2/7), IL5 (4/7), IL8 (3/7) IL6 (5/7), TNFa (4/7). One patient of *Family A* died at age 9 years because of lung disease. The daughter of *family B (patient H),* after failing anti-TNF, received a JAK-inhibitor upadacitinib, with resolution of arthritis and improvement of lung function (spirometry) after 1.5 months of treatment.

Conclusion: The phenotype of SAVI may be extremely variable even within the same family. It is essential to reconsider prior cases with familial ILD and autoimmunity in order to identify the correct diagnosis and tailored treatment.

Adverse Childhood Experiences in a Paediatric Systemic Lupus Erythematosus Cohort

Stephanie Fevrier[1], Olivia Hendrikx[1], Ashley Danguecan[1], Asha Jeyanathan[1], Lawrence Ng[1], Ibrahim Mohamed[2], Paris Moaf[1], Sondos Ayyash[1], Chelsea DeCoste[3], Deborah Levy[1], Linda Hiraki[1] and Andrea Knight[1], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]The Hospital for Sick Children, Brampton, ON, Canada, [3]IWK Health Centre, Halifax, NS, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, multiorgan autoimmune disease in which 20% of cases are diagnosed in childhood. Adverse childhood experiences (ACEs) are traumatic events or experiences occurring in childhood. While adult SLE patients with a history of ACEs report higher levels of depression, ACEs' more immediate impact on adolescents with childhood-onset SLE (cSLE) is unknown. Research posits that ACEs and cSLE can be detrimental to the rapidly developing adolescent brain as they are both associated with an increased risk of cognitive impairment and mood disorders. This study aims to: 1) determine the prevalence of ACEs and 2) examine the relationship between ACEs and cognitive performance and mood disorder symptoms in cSLE.

Methods: We conducted a retrospective cohort study of participants ages 10-18 years who met the ACR or SLICC classification criteria for SLE. We identified 18 types of ACEs according to the CDC-Kaiser and Philadelphia ACEs frameworks through electronic medical records and responses from the PTSD section of the Kiddie-Schedule for Affective Disorders and Schizophrenia (K-SADS). Outcomes of interest were: i) executive function (EF, measured by the Delis-Kaplan Executive Function System (D-KEFS)), ii) depression (Beck Depression Inventory-II (BDI-II), Children's Depression Inventory-II (CDI-II) and Center for Epidemiological Studies Depression Scale for Children (CES-DC)), and iii) anxiety (Screen for Childhood Anxiety and Related Emotional Disorders (SCARED)), each available for subsets of the cohort. We tabulated the prevalence, types, and timing of ACEs. Multivariable regression analyses examined the relationship between binary ACEs exposure and EF (D-KEFS scaled scores) and the presence of clinically elevated depression and anxiety symptoms; all models were adjusted for sex and age at cSLE diagnosis.

Results: The study involved 224 patients; 85% were female, and 83% identified as non-white, with a median age at diagnosis of 13.2 (IQR 4.4) years and a median disease duration of 2.7 (IQR 5.9) years. Forty-one percent (n=92) of the cohort had at least one documented ACE, of which 60% (n=37) had ≥2 ACEs; 55% of these ACEs occurred before cSLE diagnosis. Of all ACEs types, parental separation/divorce, bullying, and parental mental illness were the most frequent (Figure 1).

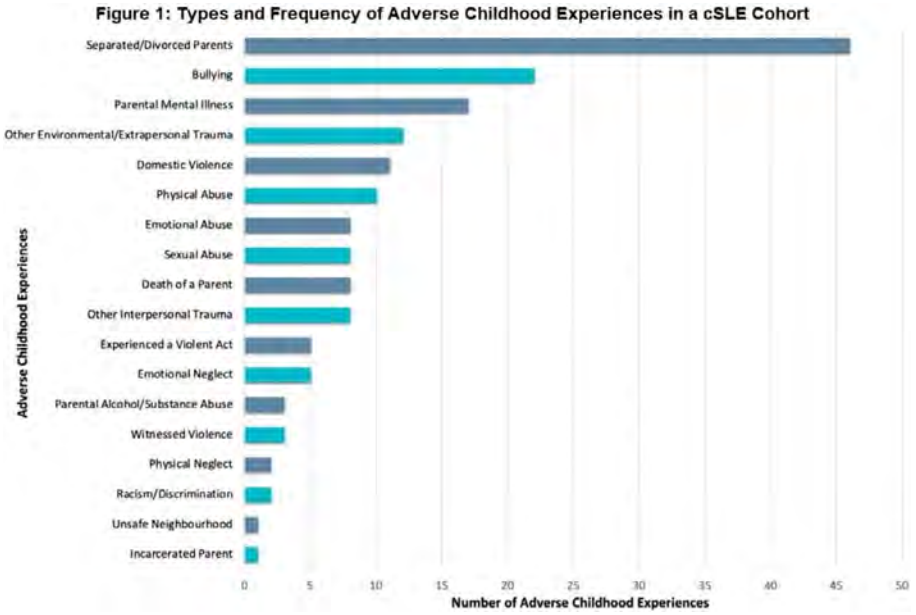

Figure 1. Bar chart showing the 18 ACEs types (adopted from the CDC-Kaiser and Philadelphia ACEs frameworks) and the frequency of each ACE among participants with documented ACEs. A total of n=172 ACEs events were identified among n=224 patients with cSLE.

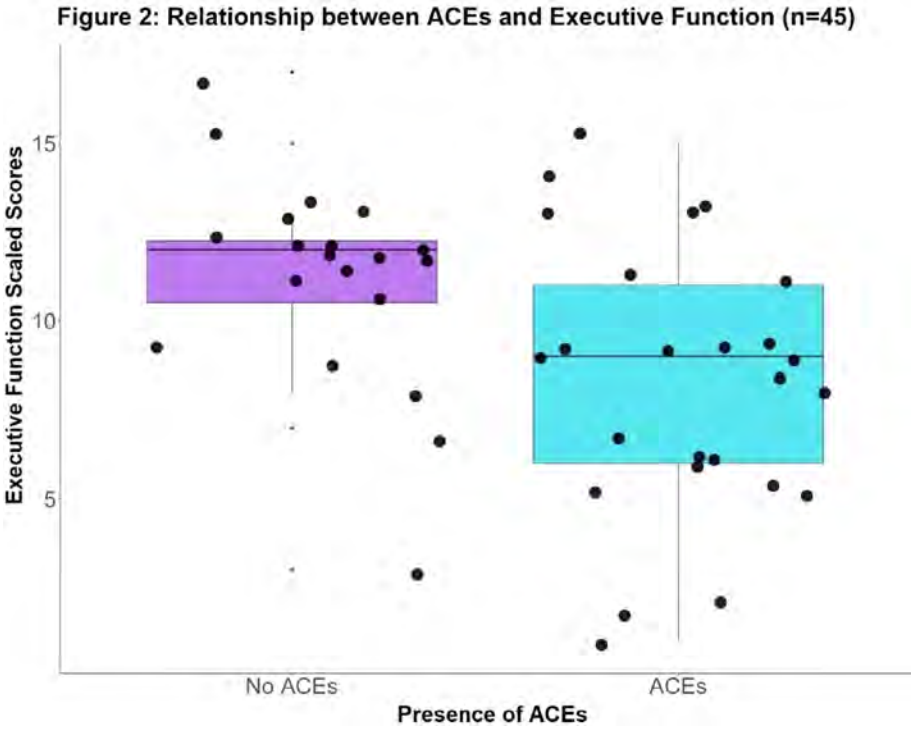

Figure 2. Box plot showing findings from a multivariable linear regression model examining the associations between ACEs exposure and EF scores, adjusting for sex and age at cSLE. Scaled scores from the D-KEFS Colour-Word Interference Test (CWIT) were measured as a continuous variable (scores of ≤7 indicate below-average performance). EF data were available for a subset of 45 participants.

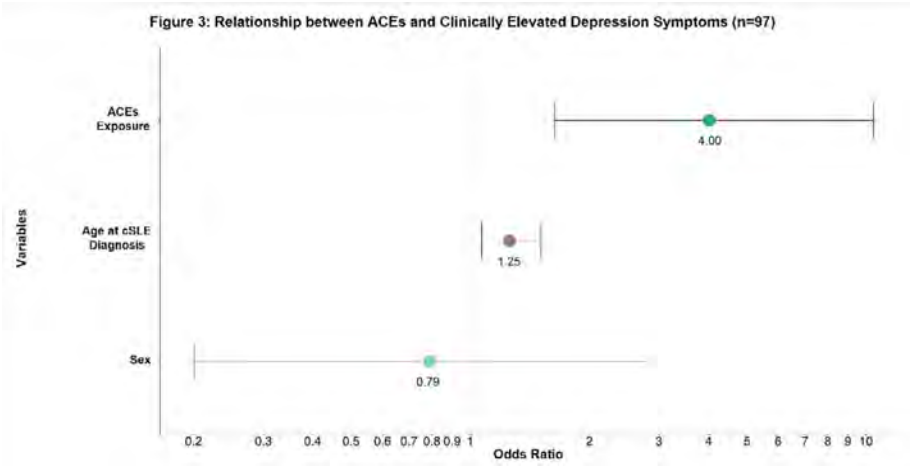

Figure 3. Odds plot showing findings from a multivariable logistic regression model examining the associations between ACEs exposure and the presence of clinically elevated depression symptoms, adjusting for sex and age at cSLE. Depression scores based on the BDI-II, CDI-II and CES-DC score classifications were measured as a binary variable and categorized as clinically elevated depression symptoms or not clinically elevated depression symptoms. Depression data were available for a subset of 97 participants.

Multivariable linear regression analysis (sample n=45) showed a significant association between ACEs exposure and worse EF performance on D-KEFS (β = -2.93, 95% CI [-5.04, -0.82], p = 0.008) (Figure 2). ACEs exposure was significantly associated with clinically elevated depression symptoms (OR = 4.00, 95% CI [1.63, 10.43], p = 0.003, sample n=97) (Figure 3). No association was found between ACEs exposure and clinically elevated anxiety symptoms (OR = 1.07, 95% CI [0.47, 2.46], p = 0.868, sample n=99).

Conclusion: ACEs negatively impact EF performance and mental health in children and adolescents with SLE. Further investigation is required into the neuropsychiatric consequences of ACEs and potential biological pathways that enable these deleterious outcomes in youth with cSLE and other chronic illnesses.

Agreement Between Parent- and Self-Report of Executive Function in Adolescents with Childhood-Onset Systemic Lupus Erythematosus

justine ledochowski[1], Sarah Mossad[2], Tala El Tal[3], Victoria Lishak[2], Ibrahim Mohamed[4], Joanna Law[2], Lawrence Ng[2], Paris Moaf[2], Asha Jeyanathan[2], Adrienne Davis[2], Linda Hiraki[2], Deborah Levy[2], Ashley Danguecan[2] and Andrea Knight[2], [1]Department of Psychology, The Hospital for Sick Children, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada, [3]Children's Hospital of Eastern Ontario (CHEO), Ottawa, ON, Canada, [4]The Hospital for Sick Children, Brampton, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Executive functions (EFs) are a set of cognitive skills that enable successful problem solving and goal-directed behavior. EFs are predictive of academic success, mental and physical health, self-care, medical adherence, and transition from the pediatric to adult medical system, thereby impacting capacity for disease self-management and quality of life. One method of measuring EF is standardized questionnaires, completed by parents or youth. Agreement between raters is not yet well known in childhood-onset systemic lupus erythematosus (cSLE) and would provide clinically valuable information about parental concern and youth's self-awareness. Questionnaires could inform which patients may require follow-up for cognitive concerns, but it is not yet established whether these should be collected from parents, youth, or both. The aim of this study was to examine the agreement between parent and self-report ratings of EF.

Methods: Participants were youth aged 12-17 who met the ACR or SLICC criteria for SLE, and their parents. The Behavior Rating Inventory of Executive Function, Second Edition (BRIEF-2) parent- and self-report versions were collected. The BRIEF-2 is a standardized questionnaire assessing EFs in daily life with parent- and self-report versions (Figure 1). Intraclass correlation coefficients (ICCs) were calculated for the General Executive Composite (GEC), Behavior Regulation Index (BRI), Emotion Regulation Index (ERI), Cognitive Regulation Index (CRI), and six subscales. Mean T-scores between patients and parents were compared with paired-sample t-tests.

Table 1. Demographic and Clinical Characteristics

Variable	Mean (SD)
Current age (years)	15.4(1.7)
Sex (females; n[%])	32(88.9%)
Race/ethnicity n[%])	
American Indian or Alaskan Native	1(2.8%)
Asian	19 (50%)
Black or African-American	4 (11.1%)
White	9 (25%)
Other/Mixed	4 (11.1%
Disease duration (months)	26.6(28.5)
Disease Activity (SLEDAI-2K)	3.6(3.7)
Disease Damage (SDI)	0.2(0.6)

Table 2. Intraclass Correlation Coefficients and Mean Differences between Parent-Report and Self-Report

BRIEF-2 Index/Scale	ICC	Parent-Report M(SD)	Self-Report M(SD)	Mean Difference
General Executive Composite	.567***	50.2(11.3)	57.2(11.9)	-6.94**
Indices				
Behaviour Regulation Index	.580***	49.2(10.7)	54.5(11.3)	-5.23**
Emotion Regulation Index	.362*	52.7(11.9)	56.4(10.6)	-3.69
Cognitive Regulation Index	.566***	50.2(11.7)	58.1(13.3)	-7.89**
Scales				
Inhibit	.478***	48.8(9.8)	55.2(11.3)	-6.47***
Self-Monitor	.550***	50.1(11.9)	52.8(10.2)	-2.17
Shift	.098	52.9(12.3)	55(10)	-2.13
Emotional Control	.580***	52.1(10.9)	57.1(12.1)	-4.12**
Working Memory	.681***	53.1(12.6)	59.9(14.2)	-6.81***
Plan/Organize	.574***	49.3(11.4)	55.1(11.5)	-5.69**

Note: ICC= intraclass correlation coefficient, ICCs are classified as ≤ 0.40 poor to fair agreement, 0.41-0.60 moderate agreement, 0.61-0.80 good agreement, 0.81-1.00 excellent agreement

* p ≤ .05; **p ≤.01; ***p ≤ .001

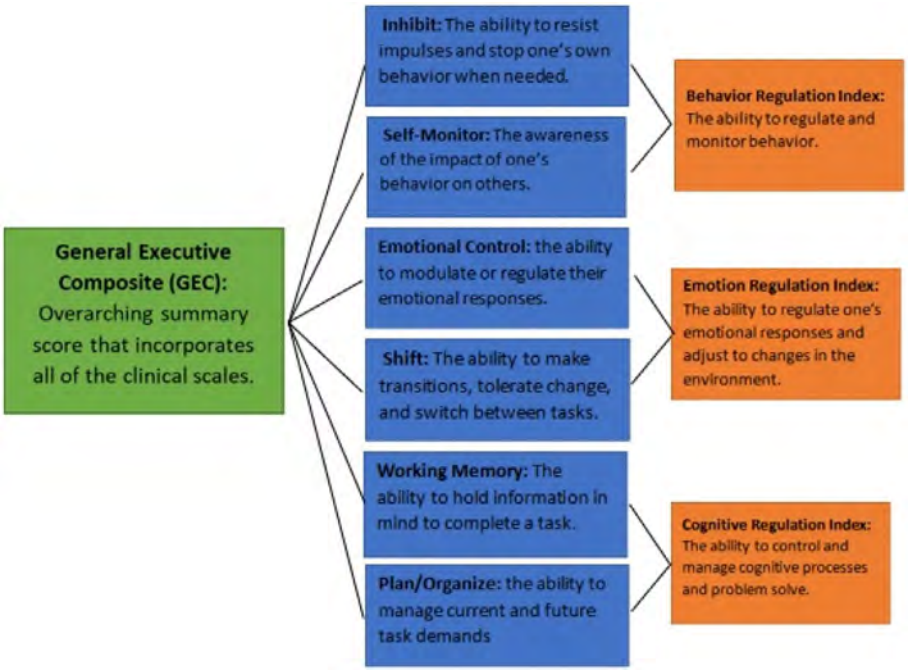

Figure 1. Structure and Definitions of the BRIEF-2 Scales and Indices

Results: Among 36 youth-parent dyads (Mean= 15.4 [SD1.7] years), ICCs between parent- and self-report (Table 2) showed moderate agreement for the overall GEC, BRI and CRI, however, the ERI showed poor agreement. For subscales, agreement was good for working memory, and moderate for inhibit, self-monitor, emotional control, and planning/organization, while ratings for the shift scale were discrepant. Mean T-score comparisons (Table 2) showed that youth rated themselves as having significantly more difficulties relative to parent-report on the GEC, BRI and CRI, as well as the inhibit, emotional control, working memory, and planning/organization subscales.

Conclusion: While ICCs indicated moderate to good consistency between most EF ratings on parent- and self-report, agreement for the ERI was poor and the shift scale was discrepant. Further analyses demonstrated that youth rated themselves as having more EF difficulties relative to parent's report across several EF domains. Our findings suggest that direct youth self-report is needed for comprehensive assessment using the BRIEF-2 and highlights the importance of considering the youth's own perspective of their cognitive functioning rather than relying on parent report alone. Future directions include comparing parent- and self-report BRIEFs with performance-based measures of EF.

Tubulointerstitial Inflammation Is Associated with End-Stage Renal Disease in Pediatric Lupus Nephritis: A Single Center Retrospective Cohort Study

Ryan Mitacek, Qiong Liu, Linda Wagner-Weiner, Shireen Hashmat and Anthony Chang, University of Chicago, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is associated with significant morbidity and mortality. The 2018 International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification criteria and the NIH chronicity activity indices are used for LN classification. Some adult studies report tubulointerstitial (TI) inflammation is an independent predictor of renal outcomes in LN. However, its impact in pediatric LN remains unexplored.

Methods: We conducted a retrospective, observational cohort study utilizing a subgroup analysis of patients with biopsy-confirmed LN. Inclusion criteria encompassed all patients with biopsy-confirmed lupus nephritis, where the renal biopsies were performed at the University of Chicago between January 1, 2006, and September 6, 2022. Patients were required to be ≤ 21 years of age at the time of their initial kidney biopsy. Exclusion criteria consisted of a follow-up duration of

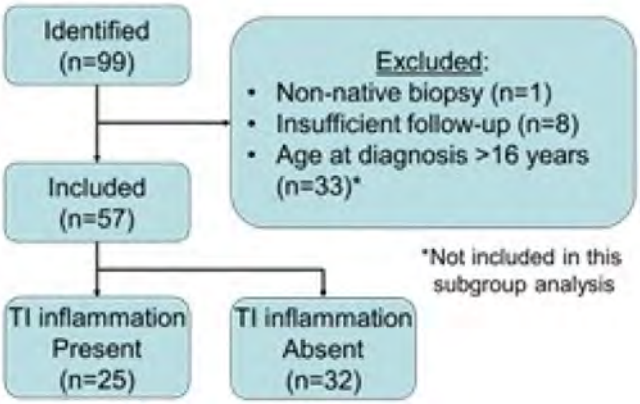

Figure 1. Study Flow Diagram

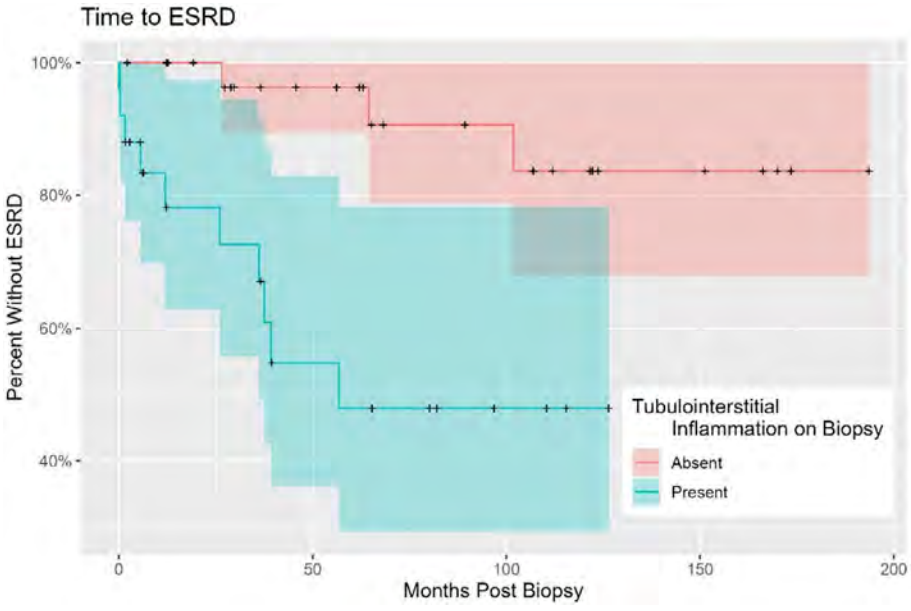

Figure 2. Time to ESRD

≤ 3 months and an age ≥ 16 years at the time of initial lupus diagnosis. Non-native renal biopsies were also excluded. The primary outcome measures were end-stage renal disease (ESRD) and/or the need for dialysis.

Results: Out of 99 identified biopsies, 42 were excluded, leaving 57 patients for analysis (see figure 1). The mean follow-up duration was 74 months (SD 26, max 210). TI inflammation was present for 25 (44%) and absent for 32 (56%). Of those with TI inflammation, 10 (40%) developed ESRD while only 3 (9.4%) without inflammation developed ESRD. Survival analysis showed a significant association with ESRD, with a positive likelihood ratio of 6.6 (95% CI 1.8, 24.3). Patients with TI inflammation experienced a shorter time to ESRD (mean 21.51 months, SD 20.32) compared to those without TI inflammation (mean 64.33 months, SD 37.65; see figure 2). ESRD was correlated with the NIH activity index (LR 1.9, 95% CI 1.1 - 1.3) and the NIH chronicity index (LR 3.1, 95% CI 1.8 - 5.4). Hemoglobin, C3 level, and proteinuria at 3 months and obesity at

	Urine Pro:Cr ratio	1639 (2732)	1062 (1862)	3877 (4300)	0.008
	C3 level	93.3 (27)	97.5 (27.7)	75.8 (15.1)	0.039

12 months was associated with ESRD. ESRD was not correlated with ISN/RPS classification, race, sex, Hispanic ethnicity, or induction treatment (see table 1). It should be noted that 35 patients (62%) had missing data for non-outcome variables at certain timepoints. This study had a considerable amount of missing data for non-outcome variables, leading to wide confidence intervals due to the high proportion of right-censored data and limited number of events.

Conclusion: Our findings indicate a significant association between tubulointerstitial (TI) inflammation and the primary endpoint of ESRD or dialysis in our pediatric lupus nephritis cohort. Further evaluation of TI inflammation may provide valuable insights into the pathogenesis, prognosis, and treatment of pediatric lupus nephritis patients. However, these conclusions are constrained by the retrospective nature of the study and the significant amount of missing data.

Characterizing Lupus in African American Children in Southern United States

Anita Dhanrajani[1], Taylor Long[2], Spencer Hagwood[2], Cynthia Karlson[2] and Cali Foreman[2], [1]University of Mississippi Medical Center, New Orleans, LA, [2]University of Mississippi Medical Center, Jackson, MS

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: African-American (AA) ethnicity is a known predisposing factor for childhood onset systemic lupus erythematosus (cSLE) and a predictor of poor outcomes. In addition to ethnicity, income and geographical location are known drivers of health care disparities in cSLE. Despite this knowledge, there is lack of literature describing demographic and clinical features of cSLE in a predominant AA cohort. This study aims to characterize demographic and clinical features of cSLE patients in the Southeast United States (US) compared to current literature describing predominantly Caucasian cohorts.

Methods: Cross sectional study of cSLE patients from 2 centers in Southeast United States – University of Mississippi Medical center (UMMC) and University of Alabama at Birmingham (UAB). Prevalent and incident patients with cSLE at UMMC were consented for the study. Demographic, social and clinical data was retrospectively collected by chart review. Similar

	Study cohort N=45 N (%)	1000 faces of lupus cohort N=213 N (%)	Chi-square test results
Female sex	37 (82)	176 (83)	0.26, p= 0.6
African American ethnicity	37 (82)	22 (11)	87.29, **p < 0.00001**
Renal involvement present	14 (31)	72 (36)	0.12, p=0.72
Neurologic involvement present	9 (20)	26 (13)	1.92, p=0.16
SDI > 0	23 (51)	32 (16)	25.79, **p < 0.00001**
SDI > 2	20 (44)	14 (7)	42.82, **p < 0.00001**
Social vulnerability grade >2	38 (84)	NA	NA

	Study cohort (N=36) Mean (+/- SD)	1000 faces of lupus cohort (N= 199) Mean (+/- SD)	Unpaired t test results
Age at diagnosis (years)	13.5 (2.8)	12.6 (3)	**p=0.04**
ACR criteria	5.1 (1.27)	NA	NA
SLEDAI baseline	13.06 (9.3)	3.1 (2.1)	**p<0.0001**
SLEDAI at 6 months	7.4 (6.81)	NA	NA
SLEDAI at 1 year	4.7 (3.94)	NA	NA
Social vulnerability index score	0.74	NA	NA

data was obtained for the cSLE UAB cohort via the CARRA registry database. Data from both cohorts was combined and analyzed using SPSS statistical software. Descriptive statistics were used for demographic and clinical features. Unpaired t test and chi square test were used to compare outcomes in this cohort with those reported in the literature.

Results: Results are described for a total cohort of 45 patients, comprising 26 from UMMC and 19 from UAB. 37/45 (82.2%) were female, 37/45 (82.2%) were of AA ethnicity, and 30/45 (66.7%) had Medicaid insurance. Mean age at diagnosis (+/- SD) of SLE for the cohort was 13.5 years (+/- 2.8). Mean ACR score at diagnosis was 5.1 (+/- 1.27), SLICC score was 8.4 (+/- 2.5). Average baseline SLEDAI score was 13.06 (+/- 9.3), while SLEDAI score at 6 months and 1 year respectively were 7.4 and 4.7. Average distance traveled to see a rheumatologist was 74.83 miles compared to a national average of 42.8 miles. 37/45 patients (82%) belonged to medium-high or high Social Vulnerability Index (SVI) group based on zip code.

Average baseline SLEDAI compared to a multiethnic Canadian cohort with 10% black population, was significantly higher: 13.06 versus 3.1 ($p < 0.0001$, $t=10.99$). 23/45 had SDI > 0 (51.11%) versus 16% reported in the literature ($p < 0.00001$, chi-square 25.79). 20/45 (44.4%) had SDI >/= 2 compared to 7% reported in the literature ($p < 0.00001$, chi-square 42.82).

Patients from UMMC were offered depression and anxiety screening by a counselor in a multi-disciplinary clinic. 15/26 (57.7%) patients were screened with Revised Children's Anxiety and Depression Scale (RCADS). 5/15 (33.3%) and 6/15 (40%) had elevated scores for depression and anxiety respectively.

Conclusion: Compared to multiethnic cohorts of cSLE from Canada, this predominantly AA patient population from two centers in the Southern United States has significantly higher disease activity and greater damage accrual. Social risk factors for this population include a higher SVI, longer distance from an academic pediatric rheumatology center and having Medicaid insurance. The effect of these factors on disparity of disease outcomes needs to be further explored with larger cohorts.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There are no widely accepted diagnostic or classification criteria for childhood Sjögren's disease (cSjD). To address the urgent need for consensus, the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Sjogren's Workgroup created a clinical diagnostic algorithm for cSjD. This study evaluates the sensitivity of the diagnostic algorithm to diagnose cSjD using an international cohort of patients.

Methods: The diagnostic algorithm was developed per expert opinion and has four distinct clinical pathway entry points: Parotitis (P), Systemic/Neurologic Manifestations (SN), Sicca symptoms (SIC) and Incidental Salivary or Lacrimal Gland Inflammation on Imaging (INC). The algorithm classifies patients as cSjD, probable cSjD, and negative for cSjD. The validation cohort was an international cohort of 300 cSjD cases, which includes extensive demographic and clinical information. De-identified clinical data from the cSjD cohort was put through the diagnostic algorithm. A response of Sjögren's disease (SjD) and probable SjD was classified as "positive" for SjD and all other responses were classified as "negative". Two analyses for the sensitivity of the algorithm for diagnosis were performed, one putting all patients through all pathways, and the other with patients only being put through the pathway they would meet criteria for entry into.

Results: The cSjD cohort (n=300) is 83% female with a mean age of diagnosis of 12 (9,15) years. Among the 300 cSjD cases, 100 (33%) were positive based on the algorithm across all pathways. 100 patients had adequate data allowing them to complete at least one of the 4 pathways, 75% of whom were positive across all pathways. Within each pathway, sensitivity of the algorithm ranged from 23-43% (all cases, Table 1) and 50-82% (limited to cases with complete data, Table 2). The proportion of patients without information for each variable is as follows: parotid biopsy (98%), ocular or oral screen (91%), minor salivary gland biopsy (65%), salivary gland ultrasound (65%) and positive SSA or SSB (2%).

Table 1: Sensitivity of the algorithm to diagnose Sjögren's Disease using the complete cohort where missing data is classified as NO

	Run all Patients through the pathways.		*Run all patients who fit specifically through that pathway*	
Pathway	**Total number of people with complete Info**	**Number with Positive Sjogren (Sensitivity out of complete Info (%))**	**Total number of people with complete Info**	**Number with Positive Sjogren (Sensitivity out of complete Info (%))**
Aggregated Diagnosis	300	100 (33.33)	-	-
Parotitis	300	71 (23.67)	140	41 (29.29)

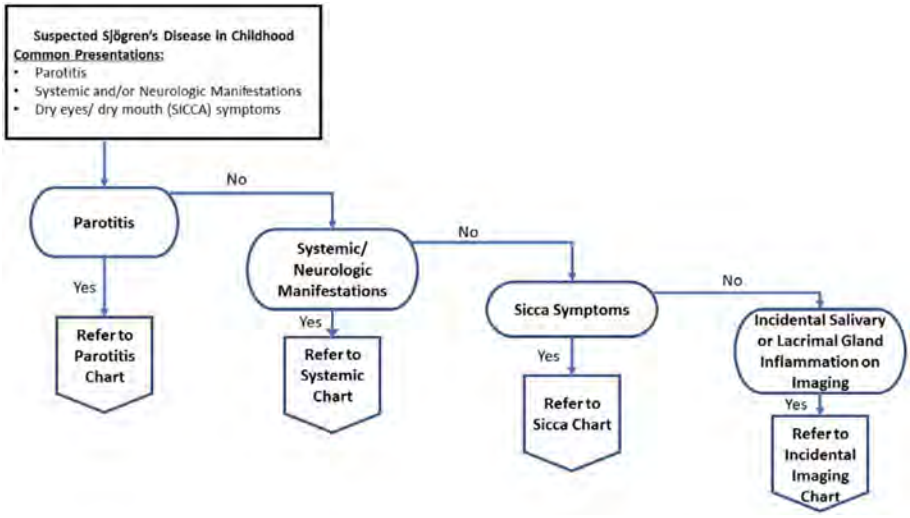
Table 2: Sensitivity of algorithm to diagnose Sjögren's Disease where cases were excluded if unable to complete pathway due to missing data

	Run all Patients through the pathways.		*Run all patients who fit specifically through that pathway*	
Pathway	**Total number of people with complete Info**	**Number with Positive Sjogren (Sensitivity out of complete Info (%))**	**Total number of people with complete Info**	**Number with Positive Sjogren (Sensitivity out of complete Info (%))**
Aggregated Diagnosis	100	75 (75)	-	-
Parotitis	83	61 (73.49)	54	38 (70.37)
Systemic Neurologic	18	10 (10)	25	13 (52)
SICCA	26	19 (73.08)	22	18 (81.82)
Incidental	68	46 (67.65)	40	26 (65)



Conclusion: The sensitivity of the algorithm was limited by the lack of completion of diagnostic studies commonly performed in adults with SjD. The P and SIC arms of the algorithm were the most sensitive arms of the algorithm. The SN arm was the least sensitive arm, possibly due to the inhomogeneous and rare presentations in cSjD. Invasive and difficult testing were the least likely to be completed. This algorithm has adequate sensitivity in the setting of complete data, suggesting it is an appropriate diagnostic algorithm for cSjD until a more sensitive, pediatric specific classification criterion can be developed.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis is a poorly understood and morbid complication of juvenile dermatomyositis (JDM). As there is no consensus treatment approach for calcinosis, and limited knowledge of outcomes, we seek to inform future treatment guidance for this significant complication of JDM. We performed a multi-institutional retrospective review of treated cases of JDM calcinosis to assess outcomes as they relate to JDM severity, myositis autoantibody, initial treatment, and calcinosis-directed treatment.

Methods: Collaborators of Childhood Arthritis and Rheumatology Research Alliance (CARRA) submitted retrospectively reviewed cases with data collected at timepoints of JDM and calcinosis diagnoses, respectively, as well as the determined outcome of each specific calcinosis treatment.All cases were sourced from electronic health record searches of clinical terms or billing codes. Only cases diagnosed and treated from 2003 to 2019 were included to capture the contemporary era of JDM treatment. Cases were required to have probable/definitive JDM by Bohan and Peter criteria and calcinosis. Outcome was assessed in univariable and multivariable analyses as time to improvement by clinician judgement utilizing all available follow-up. Proportion with improvement along with 95% confidence intervals was estimated using Kaplan-Meier analysis. Multivariable Cox models were used to assess the association between patient characteristics and time to improvement beginning at calcinosis diagnosis.

Table 1 – Patient, disease, and treatment characteristics*

	Overall (N=63)
Age at calcinosis diagnosis, years	9.4 [5.7, 13.3]
Age at JDM diagnosis, years	7.8 [4.1, 11.1]
Duration of calcinosis symptoms prior to calcinosis diagnosis, years	0.2 [0.1, 0.3]
Duration of JDM symptoms prior to JDM diagnosis, years	0.5 [0.2, 1.0]
Male sex, n (%)	18 (29.6)
Race, n (%)	
White	25 (39.7)
Hispanic, Latino or Spanish origin	17 (27.0)

Jo-1 (n=47)	3 (6.4)
MDA5 (caDM140) (n=33)	5 (15.2)
Mi-2 (n=42)	3 (7.1)
NXP2 (MJ) (n=32)	12 (37.5)
TIF1-gamma (P155/140) (n=35)	5 (14.3)
U1 RNP (n=36)	1 (2.8)
Characteristics at JDM diagnosis, n (%)	
Calcinosis present	20 (31.7)
Aggressive treatment of JDM†	38 (60.3)
Characteristics at calcinosis diagnosis, n (%)	
Active JDM (n=62)	47 (75.8)
Moderate to severe JDM	33 (52.4)
Active muscle involvement	31 (49.2)
Active skin involvement	51 (81.0)
Background medication(s)‡	41 (65.1)
Treatment at calcinosis diagnosis, n (%)	
None	11 (17.6)
Immunomodulatory agent(s)§	28 (44.4)
Immunomodulatory agent(s) plus Ca-modifying treatment(s)	19 (30.2)
Calcium modifying treatment(s)¶	5 (7.9)
Immunosuppressant(s)	30 (47.6)
Bisphosphonates	13 (20.6)
IVIG	20 (31.7)
Biologics	4 (6.3)
Surgical excision resulting from referral	7 (11.1)

* Continuous variables are summarized as median [interquartile range]. Categorical variables are summarized as frequency (percentage). Observations with complete information are presented when fewer than 63.
† Within the first 3 months of JDM diagnosis, receiving IV methylprednisolone ≥2 mg/kg/day continued for more than 1 week, and/or cyclophosphamide, and/or IVIG and/or rituximab
‡ Includes glucocorticoids, immunomodulatory drugs, IVIG, and biologics
§ Includes glucocorticoids, immunosuppressants (Methotrexate, Leflunomide, Azathioprine, Mycophenolate mofetil, Mycophenolic acid, Sirolimus, Tacrolimus, Thalidomide, Lenalidomide, Cyclosporine, Hydroxychloroquine, Sulfasalazine, Cyclophosphamide, Colchicine), non-biologic DMARDs (tofacitinib, baricitinib, ruxolitinib), IVIG, Biologic DMARDs (Rituximab, Etanercept, Infliximab, Adalimumab, Certolizumab, Golimumab, Anakinra, Canakinumab, Rilonacept, Abatacept, Tocilizumab).
¶ Includes agents that effect calcium or phosphorus (Bisphosphonates, Vitamin D, Vitamin C, Calcium-channel blocker, Sodium thiosulfate, Aluminum hydroxide, Warfarin, Minocycline, Probenecid).

Table 2 - Summary of Adjusted Univariable Analyses of Significant Improvement and Disease/Patient Characteristics*

Disease/Patient Characteristics	*HR (95% CI, adjusted)*	*P*
Female Sex	1.42 (0.68, 2.99)	*0.521*
Calcinosis at JDM diagnosis	1.21 (0.51, 2.91)	0.665
Active JDM at calcinosis diagnosis	1.42 (0.60, 3.38)	0.425
Moderate to severe JDM severity at calcinosis diagnosis	1.07 (0.52, 2.20)	0.850
Aggressive treatment of JDM at JDM diagnosis	1.45 (0.74, 2.84)	0.276
Any myositis antibody	1.36 (0.65, 2.83)	0.411
NXP2 (MJ) or MDA5 antibody	0.67 (0.26, 1.72)	0.401

*Results are from Cox proportional hazards models adjusted for age, sex, and time between initial JDM diagnosis and calcinosis diagnosis. Significant improvement was defined as moderate/significant improvement or complete/total resolution in the survey. Association between characteristics and improvement was assessed using time-dependent indicators for the given characteristics. Hazard ratios represent the multiplicative increase in hazard for improvement associated with the given treatments.

Table 3. Summary of Adjusted Univariable Analyses of Time-dependent Treatment Regimens*

Treatment Regimen	*HR (95% CI, adjusted)*	*P*
None	Ref.	
Immunomodulatory Agent(s)	2.57 (0.74, 8.96)	0.139
Calcium modifying treatment(s)	1.79 (0.38, 8.32)	0.458
Immunomodulatory Agent(s) + Ca-modifying treatment(s)	3.08 (0.90, 10.55)	0.074
Types of Immunomodulatory Agent		
Immunosuppressant(s)	1.40 (0.78, 2.49)	0.259
IVIG	1.95 (1.10, 3.45)	0.022
Biologics	1.40 (0.66, 3.00)	0.382
Bisphosphonates	1.23 (0.67, 2.24)	0.506
Surgical Excision	0.82 (0.24, 2.79)	0.751

*Results are from Cox proportional hazards models adjusted for age, sex, and time between initial JDM diagnosis and calcinosis diagnosis. Association between treatment and improvement was assessed using time-dependent indicators for the given treatments. Hazard ratios represent the multiplicative increase in hazard for improvement associated with the given treatments.

Results: Data for 63 patients were collected from 11 institutions. Median age was 7.8 years at JDM diagnosis and 9.4 years at calcinosis diagnosis. Calcinosis was present at JDM diagnosis in 32%. JDM was considered active in 76% of cases at the time of calcinosis diagnosis. Fifty percent of patients had a positive myositis autoantibody, with anti-nuclear matrix protein 2 (NXP2) antibody being the most common (38%) (Table 1). The presence of NXP2 or anti-melanoma differentiation-associated gene 5 (MDA5) antibodies did not reach statistical significance to influence outcomes but trended to lower likelihood of improvement (Table 2). Patients received multiple treatment regimens including immunomodulating agents with or without other calcium modifying treatments. Seventy nine percent of patients ultimately showed improvement. IVIG was associated with greater probability of calcinosis improvement (p=0.02) compared to treatment without IVIG (Table 3). The improvement was largely determined based on history and physical exam (93%), whereas imaging was used in a small number of cases (14%).

Conclusion: NXP2 antibody was the most common myositis antibody in our JDM calcinosis population. Those with NXP2/MDA5 antibody were less likely to respond to treatment, although not statistically significant. Our cohort received multiple treatment regimens including both immunomodulating therapies and calcium modifying agents. Reassuringly, most patients showed improvement over time, especially with IVIG; however standardized measures of defining improvement are warranted. Improved knowledge of treatment choices and outcomes can support future prospective studies.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab (BEL) is an approved treatment for SLE, in addition to standard therapy. Intravenous (IV) BEL is approved in patients (pts) ≥5 years of age, and subcutaneous (SC) BEL is approved in adults.[1] This study aimed to evaluate the pharmacokinetics (PK), pharmacodynamics (PD), and safety of SC BEL in pediatric pts with SLE.

Methods: This was a multicenter, open-label trial (GSK Study 200908; NCT04179032) of pediatric pts (5–17 years of age) with active SLE who received SC BEL, plus standard therapy, over 52 weeks (wks). A 3-weight band dosing regimen was planned to correct for higher exposure expected with low body weight (≥15–< 30 kg: 200 mg/2 wks; ≥30–< 50 kg: 200 mg/10 days; ≥50 kg: 200 mg/wk). Pts received SC BEL for the first 12 wks (Part A) and could then choose to enter a 40-wk extension (Wk 12–52; Part B). Primary outcome was PK; a population PK (popPK) model (2-compartmental with 1st order absorption, distribution, and elimination) was developed using data from the pediatric IV BEL PLUTO trial (NCT01649765)[2] and the current trial, and was informed by a previous model developed for IV BEL in pediatrics.[3] Exposures were compared with those in the adult BLISS-SC trial (NCT01484496).[4] Secondary outcomes: safety (adverse events [AEs], serious AEs [SAEs], and AEs of special interest [AESI]); PD (percentage change from baseline [BL] in biomarker levels).

Results: Of the 25 pediatric pts enrolled, 84.0% were female; mean (standard deviation, SD) age at screening was 14.0 (2.1) years. Approximately half of pts were ≥50 kg (52.0%) and 48.0% were ≥30–< 50 kg; no pts were enrolled in the < 30 kg cohort. All pts completed Part A and continued into Part B; 92.0% of pts completed Part B. Mean BEL concentrations were generally higher in pts ^{3}50 kg compared with ^{3}30 to < 50 kg (**Table 1, Figure A**). However, across a pediatric population, the

popPK analysis showed that exposures for the 3-weight band SC regimen were expected to be consistent with adult SC exposures from BLISS-SC (**Figure B**). Most pts had ≥1 AE (88.0%; **Table 2**). Nine (36.0%) pts had mild or moderate COVID-19. One (4.0%) pt had a single SAE (mild COVID-19) and was hospitalized, and 3 (12.0%) had an AESI (all post-injection systemic reaction). No infections of special interest, malignancies, depression/suicide/self-injury, or deaths were reported. From BL to Wk 52, there were median percent decreases in Ig levels (IgA: –13.1%; IgG: –12.3%; IgM: –30.8%) and anti-dsDNA antibody levels (–58.9% among those positive at BL). In pts with low complement (C) at BL, there were median percent increases in C3 (+23.5%) and C4 (+67.5%) levels at Wk 52.

Conclusion: SC BEL exposure in pediatric pts with SLE was consistent with the adult SC (200 mg/wk) population. The PD and safety profiles of SC BEL 200 mg in children 5–17 years of age with SLE were consistent with the known profiles of BEL in SLE. No new safety concerns were identified in this population.

Table 1. PopPK model-derived exposures and observed BEL concentrations at Wk 12. AUC.ss, area under the curve at steady state calculated over the dosing period; Cavg.ss, average concentration at steady state; Cavg (Wk 0–12), average concentration over the first 12 wks of treatment; Cmax.ss, maximum concentration at steady state; Cmin.ss, minimum concentration at steady state; CV, coefficient of variation.

Geometric mean (CV%), range	All pts (N=25)	Pts ≥50 kg (n=13)	Pts ≥30–<50 kg (n=12)

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Arterial and venous thrombosis occurs in 6.6 to 38.4% of pediatric Behçet disease (BD) and cerebral sinus is one of the most involved districts. The aim of our study was to report clinical features and outcomes of a pediatric BD multicentre cohort with thrombosis, to identify possible predictive factors of thrombosis

Methods: A retrospective data collection of pediatric BD patients with thrombosis (T+) included in the EUROFEVER registry was conducted. Clinical data of BD patients without thrombosis (T-), belonging to the same contributing rheumatology units have been retrieved from EUROFEVER registry. T+ and T- groups were matched in a 2:1 ratio.

Results: 37 T+ patients were compared to 74 T- patients across 13 European pediatric rheumatology centers. BD onset occurred at a median age of 153 months (IQR±57) and 156 months (IQR±51) in the T+ and T- group, respectively. At onset, ICBD criteria fulfillment was significantly higher in the T- group compared to the T+ ($p=0.015$), whereas no differences were detected in ISG and PEDBD criteria frequencies. No gender differences were observed, Caucasian ethnicity significantly recurred in T- group while Middle Eastern in T+ group ($p=0.002$). HLA-B51 haplotype positivity was significantly reported in T- patients ($p=0.04$). At onset, pustulosis was most frequently observed in the T- group ($p< 0.001$) as well as gastrointestinal symptoms ($p< 0.001$) and ocular involvement ($p=0.022$). Conversely, neurological symptoms were more often described in T+ patients ($p=0.034$). As for T+ group, thrombosis was reported at BD presentation in 8/37 patients (29.6%). For the remaining patients, who developed thrombosis later in the disease course, the comparison of symptoms revealed that oral aphtosis ($p=0.003$), genital aphtosis ($p=0.014$) and posterior uveitis ($p=0.050$) were more frequently observed at BD onset than at thrombosis presentation, while pustulosis ($p=0.02$) and fever

(p=0.019) significantly coexisted with thrombosis. Thrombosis type was mainly venous (26/37,70.3%), predominantly involving the cerebral sinuses (21/37, 56.8%). 16/29 (55.2%) T+ patients were on treatment before thrombosis onset with at least one systemic, non-steroid treatment. After thrombosis occurence, 35/37 (94.6%) T+ patients underwent or added an immunomodulatory treatment. 26/32 (81.3%) and 26/33 (21.2%) started anticoagulant and antiplatelet therapy, respectively. At a median follow up of 4 months (IQR±10), 9/28 (32.1%) T+ patients resolved thrombosis, 8/28 (28.6%) had a partial regression and 11/28 (39.3%) a persistence. A recurrence was reported in 6/31(19.4%) as venous thrombosis.

Conclusion: Middle Eastern ethnicity significantly recurred in T+ group, pustolosis and fever were more frequently concomitant to thrombosis. Neurological symptoms at onset could be related to thrombosis development in the BD course. Sinus veins were confirmed as the most frequent thrombosis site. Larger studies are required to better define predictive risk factors of thrombosis in pediatric BD.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile lupus (JSLE) and dermatomyositis (JDM) patients are at high risk for cardiovascular disease (CVD). The American Heart Association cardiovascular health (CVH) construct is the sum of protective factors against CVD. JSLE/JDM patients are at risk of premature loss of CVH that may increase lifetime risk for CVD. Emotional distress is often elevated in JSLE/JDM patients and may be a modifiable factor that adversely impacts CVH in this population. We hypothesize that emotional distress is associated with worse CVH in JSLE/JDM.

Methods: JSLE/JDM patients (5-22yo) were enrolled at Duke and UNC Children's Hospitals. PROMIS® Pediatric (self-report) and/or Parent-Proxy measures of emotional distress were administered, including Psychological Stress Experiences, Depressive Symptoms, and Anxiety (PROMIS-Str/-Depr/-Anx). CVH indicators included CVH Behaviors (diet quality screener; PROMIS Physical Activity) and CVH Factors (body mass index, blood pressure, non-HDL cholesterol, HbA1c). CVH Summary (CVH-S, all 6 indicators), Behaviors (CVH-B) and Factors (CVH-F) scores were derived (range 0-100, higher scores indicate better CVH). Spearman's correlations between PROMIS emotional distress measures and CVH scores were calculated for the overall cohort and for subgroups (race/ethnicity, age, diagnosis, gender, steroid use). Rank sum tests

Table 1: Participant Characteristics

	n (with data)	n (%) or median (IQR)
Diagnosis		
JSLE	83	48 (58%)
JDM	83	35 (42%)
Age (years)	83	16 (12-18)
Female Gender	83	66 (80%)
Race/Ethnicity	83	
White		29 (35%)
Black, African-American, African, Afro-Carribean		38 (46%)
Hispanic, Latino/Latina/Latinx, or Spanish origin		10 (12%)
Asian		8 (10%)
Native Hawaiian or Other Pacific Islander		1 (1.2%)
Other		2 (2.4%)
Medical & Psychiatric History:		
History of Any Cardiovascular Comorbidities	83	47 (56.6%)
Current Antihypertensive Medication Use	83	22 (26.5%)
Current Lipid-Lowering Therapy Use	83	2 (2.4%)
History of Any Psychiatric Comorbidity	83	45 (54.2%)
Current Psychiatric Medication Use	83	18 (21.7%)
On/off corticosteroids	83	36 (43.4%)
Disease Activity:		
Physician's Global Assessment of Disease Activity (JSLE and JDM)	83	0.5 (0-2)
Physician's Global Assessment of Disease Activity (JSLE only)	48	0.5 (0-1.5)
Physician's Global Assessment of Disease Activity (JDM only)	35	1 (0-2.2)
PROMIS Self-Report		
Psychological Stress Experiences	73	58.3 (50.6-64.3)
Moderate to Severe Stress		42 (57.5%)
Depressive Symptoms	75	51.9 (40.7-61.7)
Moderate to Severe Depressive Symptoms		36 (48%)
Anxiety	75	51.6 (38.8-59.8)
Moderate to Severe Anxiety Symptoms		37 (49.3%)
PROMIS Parent-Proxy Report		
Psychological Stress Experiences	56	58.7 (53.4-66.4)
Moderate to Severe Stress		31 (55.4%)
Depressive Symptoms	55	45.4 (36.2-58.1)
Moderate to Severe Depressive Symptoms		21 (38.2%)
Anxiety	55	49.2 (43.3-56.8)
Moderate to Severe Anxiety Symptoms		25 (45.5%)
CVH Scores:		
CVH Summary Score (CVH-S)	82	69.6 (60.2-78.1)
CVH Behaviors Subscore (CVH-B)	83	45 (30-55)
CVH Factors Subscore (CVH-F)	82	82.5 (71.2-93.8)

compared median CVH scores between patients with minimal vs moderate/severe emotional distress in the overall cohort. Rank sum tests also compared median CVH scores by subgroup among patients with moderate/severe emotional distress. Minimal vs moderate/severe emotional distress groups were based on published PROMIS T-score cutoffs. Variation of the association of PROMIS-Str/-Depr/-Anx with CVH by subgroups was assessed via interactions in regression models.

Results: Data were analyzed for 83 patients (Table 1). In the overall cohort, PROMIS-Anx modestly correlated with CVH-F (rho -0.26, p = 0.019) (Table 2) and patients with moderate/severe PROMIS-Anx scores had worse median CVH-F than those with minimal PROMIS-Anx (90 vs 77.5, p = 0.011). CVH-B scores were most strongly related to PROMIS-Str scores

Table 2: Spearman's Correlations Between CVH Scores and PROMIS T-scores, Stratified by Participant Subgroups

		No	70.8 (60.0, 80.0)		52.5 (30.0, 55.0)	

*CVH-F not displayed as all results non-significant and no trends towards significance (i.e. p >0.1)

p <0.05 | p ≤ or 0.1 but >0.05

in patients on steroids relative to those who were not, and with PROMIS-Depr scores in non-Hispanic White relative to minority race/ethnicity patients (Table 2). Among patients with moderate/severe emotional distress, CVH-S/-B scores were lower in JSLE vs JDM patients and CVH-B scores were lower in older (≥16yo) vs younger (< 16yo) JSLE/JDM patients (Table 3). Interactions indicated JSLE diagnosis and non-Hispanic White race/ethnicity were associated with stronger inverse relationships between PROMIS-Depr scores and CVH-S ($p = 0.043$) and CVH-B ($p = 0.017$) respectively.

Conclusion: Moderate/severe emotional distress is associated with worse CVH, driven by lower CVH-B, in JSLE as well as ≥16yo JSLE/JDM patients. We also noted differences by race/ethnicity in the association of emotional distress with CVH-B. Future analyses will identify social determinants of health and clinical features that influence associations of emotional distress with CVH in JSLE/JDM patients.

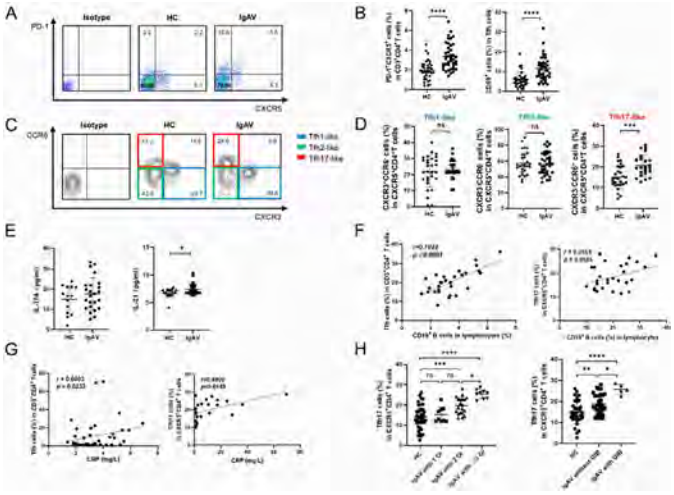
Local Inflammatory Response Mediated by the Homing of Tfh17 Cells Is Involved in Tissue Injury of Immunoglobulin a Vasculitis

Xiaoxue Ma, Qinglian Jiang and Xuyang Chi, The First Hospital of China Medical University, Shenyang, China

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM



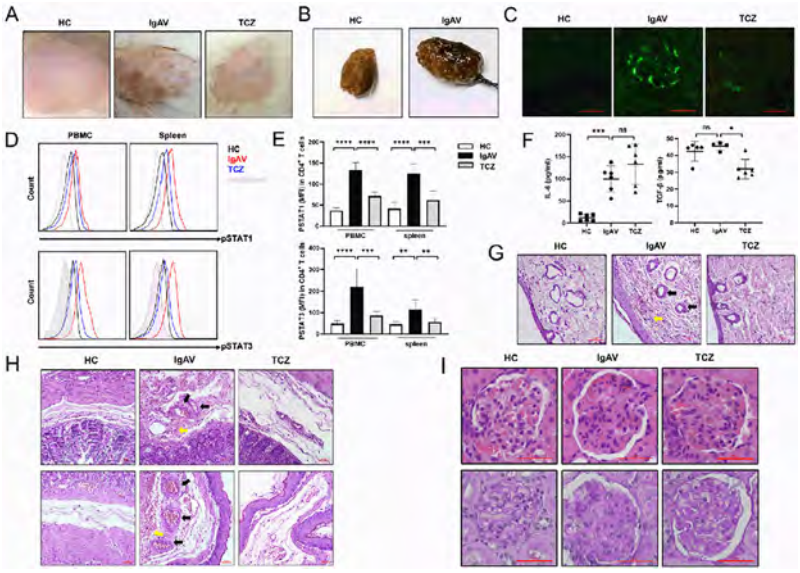
Circulating CD4+CXCR5+CCR6+ Tfh17 cells are increased and associated with IgAV disease severity. PBMCs and serum were isolated from the peripheral blood of IgAV patients and HCs without incubation. (A) Representative flow cytometry plots showing the percentage of circulating PD-1+CXCR5+ Tfh cells in CD3+CD4+ T cells. (B) Scatter plots showing the frequencies of circulating PD-1+CXCR5+ Tfh and CD69+ activated cTfh cells in CD3+CD4+ T cells. (C, D) Representative flow cytometry plots and scatter plots showing the percentages of cTfh1, cTfh2, and cTfh17 subsets in circulating CD3+CD4+CXCR5+ Tfh cells. (E) Serum levels of IL-17A and IL-21 evaluated by ELISA (25 of 40 IgAV patients were randomly selected and tested). Correlations of (F) frequencies of CD19+ B cells in lymphocytes (32 of 40 IgAV patients were randomly selected and tested) and (G) serum CRP levels with the percentages of cTfh cells and cTfh17 cells from IgAV patients. (H) Frequencies of circulating CXCR3–CCR6+ Tfh17 cells in circulating CD3+CD4+CXCR5+ Tfh cells from HC and IgAV patients grouped by the organ involvement (OI) number or the presence of gastrointestinal bleeding (GIB). ns: not significant; *p<0.05; **p<0.01; ***p<0.001; ****p<0.0001.

Background/Purpose: Immunoglobulin A vasculitis (IgAV), also named Henoch–Schönlein purpura, is a systemic vasculitis characterized by the deposition of IgA1-dominant immune complexes in small vessels that often involves the skin, joints, gastrointestinal tract, and kidney. Research indicated increased frequencies of circulating activated B cells and plasmablasts in IgAV, which may serve as the source of

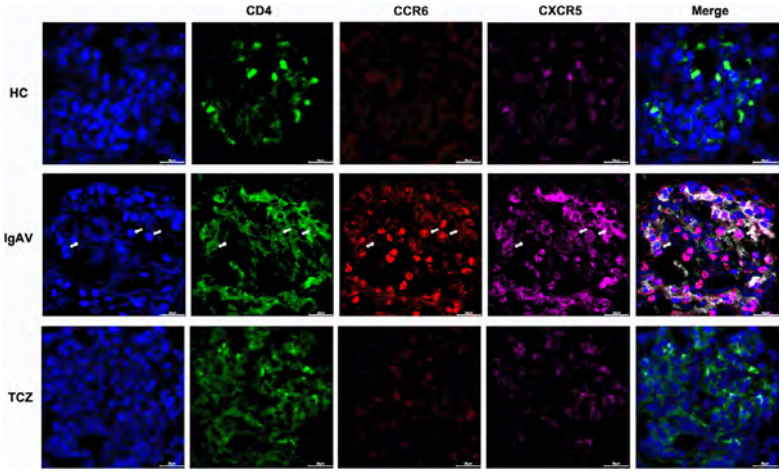
the rising IgA levels. T follicular helper (Tfh) 17 cells are considered to support B cells to switch to high-affinity IgA production. Previous study has confirmed that Tfh17 cells increase in the peripheral blood of IgAV patients. To evaluate the pathological role and the contribution in local tissue damage of Tfh17 cells in IgAV, we investigated the mechanism responsible for the differentiation of Tfh17 and the production of IgA in IgAV patients and IgAV rats respectively, and explored how to ameliorate IgAV by modulating Tfh17 generation.

Methods: Renal biopsy samples and peripheral blood mononuclear cells from IgAV patients were analyzed respectively by immunofluorescence staining and flow cytometry. In vitro culture was performed to assess the modulation of cytokine-induced phenotypes. IgAV rat model was established by intragastric administration of mixed solution, intraperitoneal injection of ovalbumin and Freund's adjuvant. IgAV rats were used to explore the therapeutic effects of regulating Tfh17 cells. Serum cytokine and IgA levels were measured by ELISA while histopathological changes were evaluated by H&E and PAS staining. Flow cytometry and immunofluorescence staining were used to detect T cell and GC B cell phenotypes and homing characteristics in circulation and tissues of IgAV rats.

Results: Frequency of CD4+CXCR5+CCR6+Tfh17 cells were increased in the circulation and organization of IgAV patients and associated with disease severity. The increased expressions of CD103, CCR6, CCR9 lead to the homing and residence characteristics of Tfh17 cells, resulting in local inflammatory response. Suppression of Tfh17 cells reduced the production of IgA and greatly ameliorated clinical symptoms and decreased IgA deposition and mesangial proliferation in the kidney in IgAV rats.



Suppressing Tfh17 using tocilizumab ameliorates symptoms in the IgAV rat. SD rats were respectively assigned to HC, IgAV, and TCZ groups. Representative photographs showing (A) hemorrhagic rash and (B) bloody stool from the three groups. Representative immunofluorescence images (C) showing renal IgA deposition from the three groups. (D, E) PBMCs and spleen cells were isolated from the three groups. Representative flow cytometry line graphs (D) and bar graphs (E) showing the expression of pSTAT1 and pSTAT3 in CD4+ T cells. (F) Serum levels of IL-6 and TGF-β in the three groups (the serum TGF-β level was tested in 5 rats from the HC group, 4 rats from the IgAV group, and 6 rats from the TCZ group). Representative photomicrographs showing H&E-stained sections of (G) skin and (H) intestinal (upper) and gastric (lower) tissues from the three groups. Black arrows indicate thickened vessel walls, hemangiectasis, and hyperemia; yellow arrows indicate extravasated erythrocytes. (I) Representative photomicrographs showing H&E-stained (upper) and PAS-stained (lower) sections of the kidney from the three groups. Scale bar = 50 μm. MFI: mean fluorescence intensity; ns: not significant; *p<0.05; **p<0.01; ***p<0.001; ****p<0.0001.



Expression of Tfh17 cells in the renal tissue of IgAV rat. Multichannel confocal immunofluorescence staining of human renal tissue for CD4, CCR6 and CXCR5 with composite multiplexed images (scale bar: 20 lm). Arrowheads indicate representative CD4+CCR6+ CXCR5+ Tfh17 cells.

Conclusion: Our findings suggest that suppression of Tfh17 differentiation can alleviate IgA-mediated vasculitis and inflammatory tissue damage, which may permit the development of tailored medicines for treating IgAV.

Neurologic Manifestations of Pediatric Sjogren's Disease Patients: Case Series from an Academic Children's Hospital

Maya Faison[1], Catherine Lavallee[2], Joseph McDonald[1] and Cuoghi Edens[1], [1]University of Chicago Medicine, Chicago, IL, [2]Virginia Tech Carilion School of Medicine, Roanoke, VA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of Sjogren's disease (SD) is becoming increasingly recognized in pediatric rheumatology. Despite fewer sicca symptoms, it has been shown that pediatric SD (pSD) patients experience neurologic manifestations at a rate higher than their adult counterparts. This case series aims to identify the neurologic manifestations and associated characteristics of pediatric patients with SD at a single academic institution.

Methods: Billing codes, age parameters, and encounter dates were used to identify patients diagnosed with SD prior to 18 years of age and seen between November 1, 2011 and August 15, 2022. 79 charts were initially identified (Figure 1). Charts were reviewed to confirm that patients had a diagnosis of pSD or connective tissue disease (CTD) with SD features. Set search terms were then applied to find patients who met inclusion criteria for neurologic manifestations. Patient demographics, serologies, neurologic manifestations, evaluation, and management were manually extracted. IRB approval was obtained for retrospective chart review.

Results: Twenty-eight pediatric patients were evaluated in the specified time frame and diagnosed with pSD/CTD. Thirteen of these patients (46%) had neurologic manifestations. Of these, 62% (8/13) had sicca symptoms and 77% (10/13) had arthralgia at diagnosis. 85% of patients with neurologic manifestations were female. 46% of patients were identified as white,

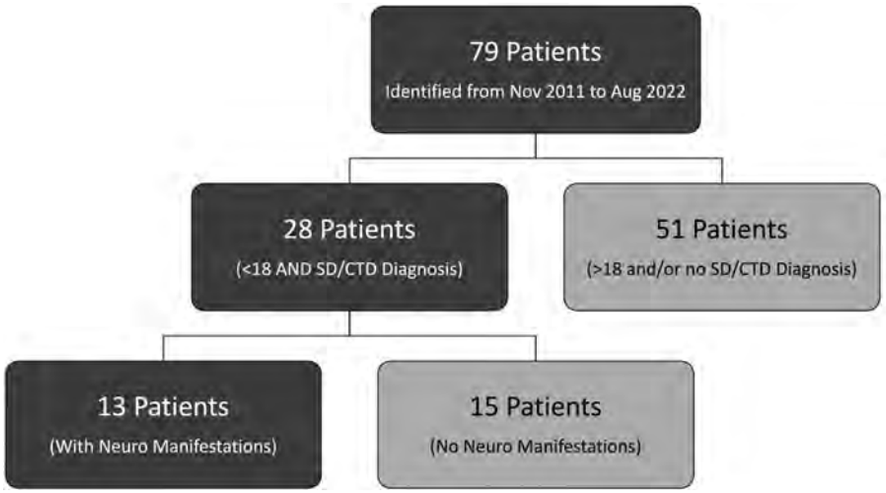

Figure 1

31% as black, and 23% as Hispanic/Latina/o/x. Additional demographic information and testing results can be found in Table 1. The most common neurologic manifestations in pSD patients were headaches and sensory changes, which occurred in eight patients (62%) and seven patients respectively (54%). Six of the eight patients with headaches were

Legend:
GC = Glucocorticoids HCQ = Hydroxychloroquine MTX = Methotrexate AZA = Azathioprine RTX = Rituximab
N → R = Neurology referral to Rheumatology R → N = Rheumatology referral to Neurology

diagnosed with migraines, and four of the seven patients affected by sensory changes were diagnosed with small fiber neuropathy. Other diagnoses included mononeuritis multiplex (1/13), aseptic meningitis (1/13), recurrent Bell's palsy (1/13), and mild neurocognitive disorder (1/13). All neurologic manifestations, timing with regard to pSD diagnosis, work-up, and treatments are in Table 2. For ~70% of patients (9/13), neurologic manifestations began prior to or at the time of their pSD diagnosis. For patients with symptoms occurring prior to pSD diagnosis, all symptoms occurred one or more years prior. Five patients (38%) had treatment regimen changes due to their neurologic manifestations. Adjustments included the addition or increase of glucocorticoids (4/13), the addition of rituximab (2/13), the addition of IVIg (1/13), and an increase in hydroxychloroquine dose (1/13).

Conclusion: Neurologic manifestations occurred in nearly half of pSD patients. Migraines and small fiber neuropathy, which are more frequently seen in SD patients, were the most common pSD neurologic manifestations. For pediatric patients with neurologic symptoms of unknown etiology and pediatric patients with other rheumatologic diagnoses, pSD should remain in the differential as a possible diagnosis to explain their neurologic symptoms.

Physician Global Assessment of Disease Activity in Childhood-Onset Systemic Lupus Erythematosus – Does the Approach Matter?

Ekemini Ogbu[1], Hermine Brunner[2], Jennifer Huggins[3], Angela Merritt[3], Megan Quilan-Waters[3], Catherine Robben[3], Chen Chen[3], Daniel J Lovell[4] and Bin Huang[3], [1]Cincinnati Children's Hospital Medical Center, University of Cincinnati School of Medicine, Johns Hopkins University, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Division of Rheumatology, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]UC Department of Pediatrics, Cincinnati Children's Hospital, University of Cincinnati, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Physician Global Assessment of Disease Activity (PhGA) are commonly used outcome measures in pediatric rheumatology. For childhood-onset systemic lupus erythematosus (cSLE), the traditional visual analog scale (range: 0 – 10; 0=inactive; 10=very active; $PhGA_{0\text{-}10}$) but also the SELENA-SLEDAI (range: 0-3; 0= none, 1=mild, 2=moderate, 3=severe; $PhGA_{0\text{-}3}$) are used to measure treatment response, flare, and Lupus Low Disease Activity Status (LLDAS) with $PhGA_{0\text{-}3} \leq 1$. Thus, the purpose of this study was to compare the measurement properties of the $PhGA_{0\text{-}10}$ and the $PhGA_{0\text{-}3}$ in cSLE and with scores of the SLEDAI-2k, and the SELENA-SLEDAI.

Methods: Secondary data analysis from a convenience sample of 100 cSLE followed every 3 months for up to 7 visits (1). Ratings of $PhGA_{0\text{-}10}$, $PhGA_{0\text{-}3}$, parent assessment of patient well-being (ParGA; range: 0= very poorly, 10=very well), SLEDAI-2k and SELENA-SLEDAI were compared. After linear transformation of $PhGA_{0\text{-}10}$ to a 0-3 range ($tPhGA_{0\text{-}10}$) frequency of $PhGA_{0\text{-}3} \leq 1$ were compared.

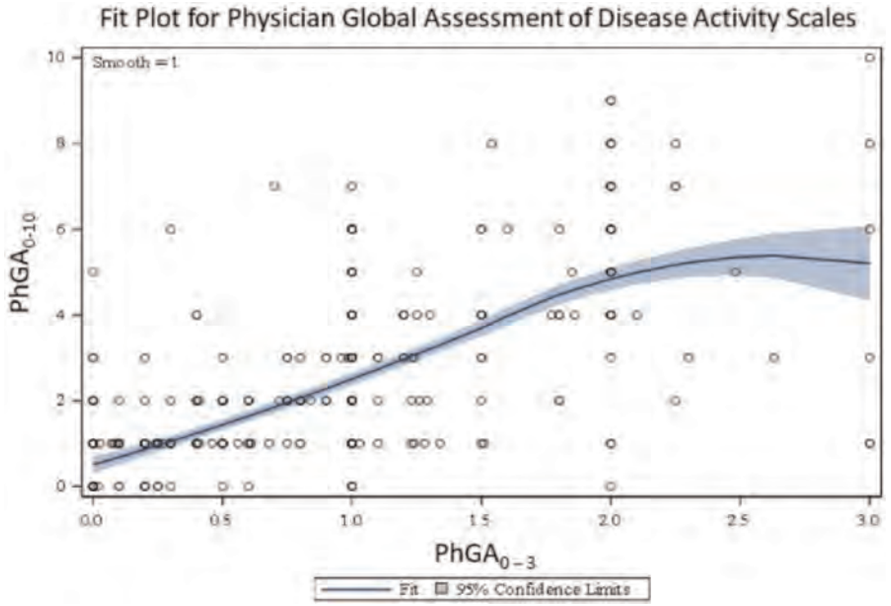

Figure 1: Relationship of Physician Global Assessment of Disease Activity traditional visual analog scale (PhGA0-10) with the SELENA-SLEDAI scale (PhGA0-3)

Results: In 601 visits, mean (SD)/median (range) of $PhGA_{0-10}$, $PhGA_{0-3}$, SLEDAI-2K and SELENA-SLEDAI were 2.13 (1.87)/2 (0-10), 0.79 (0.64)/1(0-3), 4.63 (4.14)/ 4 (0-28) and 4.51 (4.1) / 4 (0-32) respectively. $PhGA_{0-10}$ were moderately correlated with $PhGA_{0-3}$ (r=0.73; p< 0.0001; Figure 1) with more variability for $PhGA_{0-3} \geq 2$. ParGA was weakly correlated with $PhGA_{0-10}$, $PhGA_{0-3}$, SLEDAI-2k and SELENA-SLEDAI scores (r = -0.34, -0.30, -0.19 and -0.20). SELENA-SLEDAI and SLEDAI-2k scores were highly (r=0.98) correlated with each other. However, SLEDAI-2K/SELENA-SLEDAI scores were weakly correlated with $PhGA_{0-3}$ (r=0.28/0.28; p < .001) and moderately correlated with $PhGA_{0-10}$ (r= 0.56/0.54; p < .0001). There were 490/497 of 601 visits with $PhGA_{0-3} \leq 1$ / $tPhGA_{0-10} \leq 1$ [Kappa (SE) =0.59 (0.04), McNemar p=0.4].

Conclusion: Using the traditional $PhGA_{0-10}$ in cSLE yields almost identical LLDAS rates compared to the $PhGA_{0-3}$. Given its closer association with the scores of disease activity indices in cSLE, use of the $PhGA_{0-10}$ may be preferable in pediatric populations.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood Sjögren 's disease (cSjD) is a poorly defined systemic autoimmune disorder. Due to the absence of diagnostic criteria, heterogeneous presentations, and the dissimilarity between adult- and childhood-onset diseases, diagnosing and managing symptomatic children suspected of having cSjD is challenging. Currently, no clinical guidelines for these children are available. The study aims to propose a novel Florida Scoring System (FSS) for the stratification of heterogenous clinical and laboratory features of children with suspected cSjD condition.

Methods: A total of 191 clinical and laboratory variables from 217 patients enrolled between January 2018 and March 2022 were subject to our machine learning analysis. These patients with suspected cSjD were referred from Pediatric Rheumatology Clinics at the University of Florida (UF) in Gainesville and AdventHealth for Children in Orlando to the UF Center for Orphaned Autoimmune Disorders to rule out/rule in cSjD with further work-ups. In the absence of any established cSjD diagnostic criteria, the final cSjD diagnosis was made based on the 2016 ACR/EULAR criteria for adult SjD.Latent class analysis (LCA) was performed on 33 clinical/laboratory variables from 191 variables to stratify heterogeneous patient features. Artificial neural networks (ANN) and other machine learning models were constructed for internal validation and ranking of variable importance. Along with LCA and internal validations, causal graphical learning identified key variables, which became the foundation for the final FSS.

Results: Three distinct classes were defined by the LCA model. Machine learning models, including random forest, gradient-boosted decision tree, partial least square discriminatory analysis, LASSO-penalized ordinal regression, and ANN, accurately predicted three classes and ranked similar variable importance consistently. The causal graph model identified eight essential variables for inferring LCA-derived patient classes. FSS was developed using weighted points with a maximum of 24. As shown in Table 1,the final FSS score is the summation of subjective and objective features without requiring a lip biopsy, Schirmer test, SICCA ocular staining, and/or sialometry. If the FSS score >11, children with suspected cSjD are classified as Class I. Those with score >6 and ≤11 are classified as class II, and those with score < 6 are classified as class III. Out of the patients who fulfilled the 2016 criteria, the percentages in Classes I, II, and III were 70%, 18%, and 14%, respectively ($p < 0.001$). The characteristics of each class are listed in Table 2.

Table 1. Proposed Florida Scoring System (FSS) for children with clinical suspicion of cSjD using weighted points between the minimum of 0 and maximum of 24

Table 1. Proposed Florida Scoring System (FSS) for children with clinical suspicion of cSjD using weighted points between the minimum of 0 and maximum of 24.

Item	Weighted Points[†]
***Subjective score*[‡]**. *Each ESSPRI score will be multiplied by the weighted points and added together. The final sum will be divided by 10.*	
ESSPRI-Dryness	4
ESSPRI-Fatigue	3
Objective score. *Each present item will be weighted by the point below and added together.*	
Cytopenia[§]	5
Hypergammaglobulinemia[**]	4.5
Anti-SSA	3
ESSDAI Articular Domain[††]	2.5
SGUS	2
Final Classification	**Summation of subjective and objective scores**
Class I	FSS score >11
Class II	6 < FSS score ≤ 11
Class III	FSS score ≤ 6

[†] Points for weighting were generated by the coefficients from the ordinal regression model.

[‡] In the case of children who cannot report ESSPRI scores, parents can report subjective dry mouth and fatigue as "yes" or "no". If "yes", dry mouth will be weighed as "4" and fatigue as "3".

[§] Cytopenia: defined as the reduction of one or more mature blood cell types (e.g., neutropenia, lymphopenia, thrombocytopenia, and any type of anemia) in the peripheral blood.

[**] Hypergammaglobulinemia: above the reference range by age.

[††] Articular domain in ESSDAI (arthritis or arthralgia with morning stiffness) objectively evaluated by a specialist.

Conclusion: We propose the novel FSS, a physician-friendly scoring system, to stratify clinical/laboratory features of children with cSjD. Further evaluation of FSS with new cohorts will ensure the clinical usefulness of FSS for early recognition, diagnostic workup, and monitoring.

Table 2. Clinical characteristics of three classes

Table 2. Clinical characteristics of three classes

	Class I (n = 27)	Class II (n = 98)	Class III (n = 92)
FSS score			
	FSS score >11	6 < FSS score ≤ 11	FSS score ≤ 6
Patients fulfilling the 2016 criteria (%)			
	70% (n = 19/27)	18% (n = 18/98)	14% (n = 13/92)
Overall characteristics			
	Prominent glandular and systemic symptoms with high prevalence of positive labs & SGUS	Prominent sicca/systemic symptoms and low prevalence in positive labs	Low prevalence of sicca, systemic symptoms, and labs
Clinical and laboratory characteristics*			
Laboratory features	High prevalence of: anti-SSA (81.5%) anti-SSB (40.7%) low C3 (30.8%) low C4 (38.5%) high IgG (55.6%) cytopenia (40.7%)	Low prevalence of: anti-SSA (8.6%) anti-SSB (5.2%) low C3 (1.1%) low C4 (8.7%) high IgG (1.0%) cytopenia (1.0%)	Low prevalence of: anti-SSA (6.7%) anti-SSB (7.8%) low C3 (1.3%) low C4 (7.9%) high IgG (3.3%) cytopenia (1.1%)
Positive SGUS	Highest (90.9%)	Lowest (5.41%)	21.0%

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile onset SLE (jSLE) has more severe disease and has poorer outcome as compared to adults SLE. Ethnicity affects clinical course and disease outcome in SLE. There is a lack of data on outcomes from inception cohort of jSLE from South Asia.

Methods: Patients with SLE with ≥4 ACR classification criteria for SLE, who were enrolled in the Indian SLE inception cohort for research (INSPIRE) and had onset of symptoms before the age of 18 years were included. Data on their clinical features, autoantibodies, activity as well as short term outcome including death was extracted from the database at baseline and at every 6 months follow up for 24 months. Lupus low disease activity (LLDAS) was calculated. Baseline predictors of attainment of LLDAS and flare at 1 year were also studied. All variables with p=0.1 were put in multivariate analysis using binary logistic regression.

Results: Among 2503 patients enrolled in INSPIRE cohort 491(19.6%) had jSLE. Their mean age at onset of disease was 14.58+2.69 years and median duration of symptoms was 10 months. Major clinical features were : fever (84.5%). malar rash/ACLE (64.3%), oral ulcers (69%), pleural effusion (21%), Seizures (13%), Leucopenia (33%), and Class III/IV LN (17%) (Table 1), BILAG (A/B) in neuropsychiatric domain was present in 55, renal domain in 195, and gastrointestinal domain in 29 patients. Among autoantibodies, antibodies to dsDNA (71.9%), nucleosome (39%), histones (35%), RO_52 (30%), RO_60 (35%), La (11%), ribosomal P protein (38%), nRNP (51%), Sm (42%), Scl-70 (3%). The mean SLEDAI score was 13.05+ 8.19 and PGA score was 1.22+0.89. There were 47 deaths during 2-year follow-up period. The actuarial survival at 2 years was 83.6%. There was no difference in survival between patients with LN or those without it. (Figure 1). LLDAS was achieved at 1 year by 57.4% and at 2 years by 65.2% in patients who had completed that point of follow up (Table 2). Among those who achieved LLDAS at 12 months, in 78 where 24 month follow up was available, 59 (75%) had sustained remission. None of the clinical features or antibodies at baseline were major predictors of achieving LLDAS at 1 year. Presence of SCLE (p=0.049) and anti-Ro 52 antibody (p=0.049) reduced the odds of achieving LLDAS while presence of psychosis (p=0.033) and acute confusional state (p=0.022) increased the odds of achieving LLDAS at 12 months. The baseline factors associated with flare at 12 months were discoid rash (p=0.002), leucopenia (p=0.007), low C3 (p=0.027), low C4 (p=0.005) and anti-nucleosome antibodies (p=0.014). On multivariate analysis only anti-nucleosome antibodies (OR 0.503 (CI 0.270-0.935), serum C3 levels (OR 0.987 (0.976-0.998) and discoid rash (OR 2,617 (1.336-5.126) were significantly associated with flare.

Table 1: Baseline clinical features of the cohort

Feature	Value
Females: Males	433:58
Mean age (Years)	14.58+2.69
Median duration of symptoms (months)	11
Clinical features: number (%)	
Fever > 38.3 C	415 (84.5)
Oral ulcers	340 (69%)
Subacute cutaneous lupus	38(8%)
Acute cutaneous lupus	316(64.3%)
Discoid rash	90(18%)
Proteinuria>0.5g/24hr	193(39%)
Class II or V lupus nephritis	83(17%)
Class III or IV lupus nephritis	41(8 %)
Delirium	16(3%)
Psychosis	11(2%)
Seizure	65(13%)
Pleural effusion	105(21%)
Pericardial effusion	54(11%)
Leukopenia	602 (32%)
Thrombocytopenia	116 (24%)
Autoimmune hemolysis	93 (19%)
Low C3	375 (76.3%)
Low C4	296 (60.2%)

Conclusion: jSLE in India is associated with significant early mortality. Almost one-third patients do not achieve low disease activity even at 2 years of treatment. Thus, there is a need for better therapeutic options for lupus

Table 1: Baseline clinical features of the cohort

Clinical Characteristics and Disease Outcomes of anti-NXP2 Positive Juvenile Dermatomyositis: A Single Center Cohort

Sarah Molina[1], Dawn Gist[2], Marietta De Guzman[3], Eyal Muscal[4], Jamie Lai[2] and Maria Pereira[3], [1]Baylor College of Medicine - Pediatrics Residency Program, Houston, TX, [2]Baylor College of Medicine / Texas Children's Hospital, Houston, TX, [3]Baylor College of Medicine, Houston, TX, [4]Division of Rheumatology, Department of Pediatrics, Baylor College of Medicine, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Pediatric Rheumatology – Clinical Poster II: Connective Tissue Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare idiopathic inflammatory myopathy with clinically heterogeneous presentations that can be categorized by myositis-specific antibodies (MSAs). NXP2 is among the more common of MSAs, seen in approximately 20-25% of cases. It is associated with an increased risk of severe muscle weakness, dysphagia, and vasculopathy which may cause gastrointestinal ulceration and bleeding. Children with NXP2 are described to be more resistant to conventional therapies and at risk for prolonged active disease. This retrospective chart review aims to provide additional data on 18 patients at one institution regarding clinical presentation, management, and outcomes.

Methods: With approval from our IRB, we reviewed the presentation, management, and outcomes of patients with positive NXP2-antibody JDM before 18 years old between January 2012 - May 2023. Data abstracted include clinical features, diagnostic studies, therapy at initial and follow up at 6-month, 12-month, and last clinic visit. Muscle strength was measured by muscle manual testing (MMT) and Childhood Myositis Assessment Scale (CMAS). Remission defined as CMAS >48 and/or documented full strength, absence of active skin and vascular disease, and normalized muscle enzymes.

Results: A total of 18 patients were included: 66% female, 50% Hispanic, with a median age of 8 years [4-12] at presentation; median time to diagnosis was 1.5 months [1-3]. All had progressive proximal lower extremity and neck muscle weakness. Proximal upper extremity weakness was seen in 83%, with bulbar weakness in 44% (*see Figure 1*). Initial median CMAS was 12 [10-18]. All had abnormal MRIs, with 83% showing diffuse myositis. 56% of patients had a muscle biopsy, which all but 1 were diagnostic of JDM. 83% of patients presented with cutaneous manifestations, two with calcinosis. 61% had periungual vascular changes. Gastrointestinal features were seen in 61%. Median duration of follow up was 36.5 months [24 –77]. CMAS at 12 months and the last visit were 43 and 48 [43-52], respectively. 56% reported dysphagia over time. Two patients required invasive feeding methods. Two developed skin ulcerations, 1 had bowel ulceration with perforations requiring partial colectomy with end-ileostomy creation, and 2 developed SMA syndrome from excessive weight loss. No lung or cardiac disease reported. Only 2 patients had a monophasic course. Progressive calcinosis was seen in 41% (*see Figure 2*). All received steroids and methotrexate, 94% IVIG, 89% hydroxychloroquine, 50% rituximab, and 22% required other biologic therapies (*see Figure 3*). Remission achieved in 44% after a median of 44 months of therapy [25.5 - 52.5]. No malignancy or deaths reported.

Demographics	Age (years)	8 (2 - 16)		
	Sex	Female, Male	56%, 44%	
	Race	Caucasian	72%	
		Black	17%	
		Asian	6%	
		American Indian	6%	
	Ethnicity	Hispanic	50%	
Clinical Characteristics	Cutaneous findings		83%

	Gastrointestinal symptoms		61%	
	Vascular changes		67%	
Diagnostic Studies at Presentation	Muscle Enzyme Abnormalities	CK median	1304 (144 - 2487)	*(normal 55 - 215)*
		Aldolase median	19 (13 - 25)	*(normal 3.4 - 8.6)*
		AST median	116.5 (75- 184)	*(normal 12 - 32)*
	MRI Dermatomyositis	Diffuse myositis	15/18	
		Abnormal subcutaneous fat signal	11/18	
		Fascial edema / abnormality	7/18	
	Miscellaneous tests	ANA positive	17/17	
		Other antibodies positive*	2/17	
		IgG elevated	3/11	

*positive includes TIF1, anti-Jo1, Scl70, RNP

Figure 1: Clinical Presentation in NXP2+ JDM

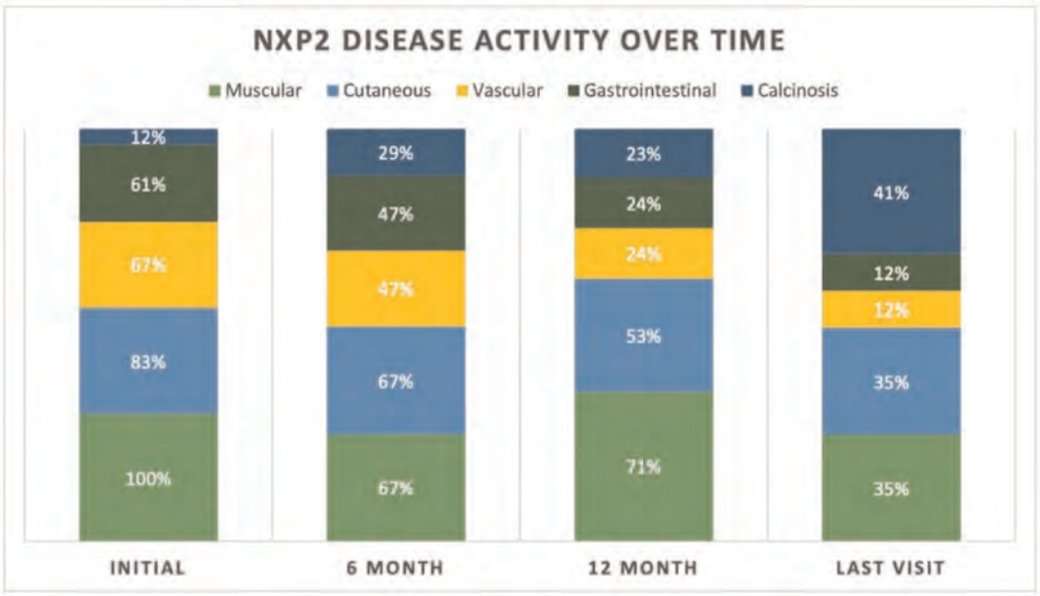

Figure 2: NXP2 Disease Activity Over Time

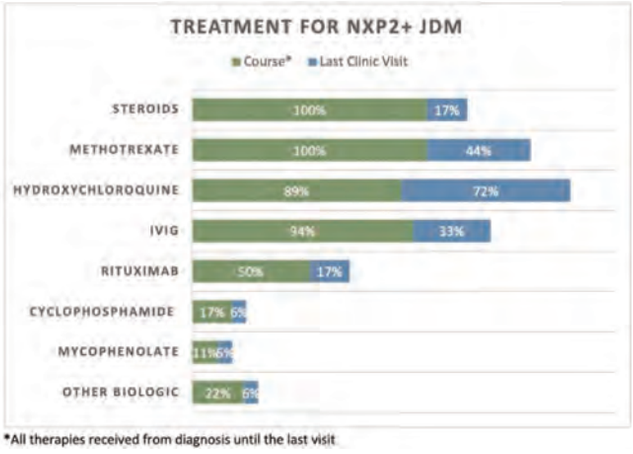

Figure 3: Treatment for NXP2+ JDM

Conclusion: Children with NXP2+ JDM in our cohort developed a chronic disease course where gastrointestinal features were common with complications that could be severe. Progressive calcinosis was seen despite aggressive therapies. Remission was achieved in 44% after prolonged therapy. Our patients provided information as to the challenges for supportive and multimodal immunotherapy. Additional large multi-center cohort studies are needed to determine the optimum treatment course with validated remission criteria.

Self-esteem and Body Image of Young People with Rheumatic Diseases: A Systematic Review

Leticia Leon[1], Daniel clemente Garulo[2], Carmen Heredia[3] and lydia Abasolo[4], [1]Fundación Investigación Biomédica Hospital Clínico San Carlos, Madrid, Spain, [2]Pediatric Rheumatology Unit, Hospital Niño Jesús, Madrid, Spain, [3]Universidad Camilo Jose Cela, Madrid, Spain, [4]Hospital Clínico San Carlos, Madrid, Spain

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Psychology/Social Science – Interprofessional Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Little is known about the self-esteem and body image impact in young people with rheumatic and musculoskeletal diseases (RMD). Studies in chronic illness suggest that chronic health conditions can develop changes in appearance, or social activities disruption, consequentially body image and self-esteem can be altered mainly in young people. The purpose of this study was to synthesize existing research related to self-esteem and body image in young people with RMD.

Methods: Databases (MEDLINE, Embase, PsycINFO, and CINAHL) were searched until April 2023. Results were limited to English-language studies. Studies were screened and evaluated for inclusion by two investigators. The systematic review included: a) All original articles reporting self-esteem or body image of young people with RMDs ; b) Qualitative studies (data obtained through individual interview and/or focus groups), quantitative studies (information obtained through questionnaires) or c) mixed designs (articles including qualitative and quantitative methods) Case studies, letters to the editor and commentaries were excluded. Additionally, a manual search was undertaken wherein reference lists of selected articles were screened for inclusion.

Results: Twelve articles were eligible for inclusion in the present review. Eligible studies were identified for juvenile idiopathic arthritis (6), lupus (3), scleroderma (2), and vasculitis (1). As main results we highlight the following: Glucocorticoids use was found to consistently associate with poor body image, in all conditions (due to visible side-effects of medication). Greater body image concerns were associated with facial lesions, and the resulting perceived stigma (this appearance concern was also related to depression). Females showed lower self-esteem than males. Anxiety and apprehension about their physical and sexual attractiveness was associated with lower self-esteem. Feeling of restrictions in their experimentation with drinking and sexual relations also impacted their self-esteem. A lower self-esteem was associated with poor QoL, and regarding DMARDs treatments, use of IL-6 treatment improved self-esteem.

Conclusion: The use of disease-specific measures and the heterogeneous group of studies complicated the synthesis of the findings. However, some factors appeared most associated with poorer self-esteem and body image across disease groups. Young people with RMD, who already face additional medical and psychosocial burden, might benefit from monitoring tools and interventions designed to improve their body image and bolster self-esteem in the ongoing context of self-care and adherence. Moreover, understanding these issues can help in treatment planning, and clinical decision-making for this population.

Session Title: Psychology/Social Science – Interprofessional Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: A large body of research reports that people with inflammatory arthritis (IA) are at increased risk for work disability, which profoundly affects all aspects of life. While researchers describe the challenges that people with IA face in maintaining employment, these studies largely focus on addressing concrete barriers and strategies and inadequately explore psychosocial factors that may influence the ability to continue working. A EULAR taskforce recently released points

Table 2. Preliminary Themes and Illustrative Quotes

Table 2: Preliminary Themes and Illustrative Quotes

Theme	Illustrative Quote
Challenges to identity and pride *(The important role work plays in sense of identity, pride in achievements, struggle coping with IA and its impact at work.)*	"I always wanted to be a cop. I worked hard for about four years to try to get into an agency. It's very competitive. So, it was a long road to get there. I worked very hard to get there, worked very hard in the academy to finish and get certified. I loved what I did. ... In the position I currently hold, I am still able to go above and beyond because there are things that I can physically and emotionally do. If I am reassigned to other positions, such as doing surveillance or sitting in a car all day long for like seven or eight hours, obviously I will not be able to do that." (Female, works full-time)
Guilt, shame and ableism *(Guilt, shame and internalized ableism about one's diminished capacity and its impact at work)*	"There are still times, though, when it was tougher to do things, especially when my hands were bad, and I would have to help move things. You would feel guilty if you didn't help move things because, here I am, a guy in my 30s, and you know: 'Can you help me move this?' 'Kind of.' You don't want to look like you are being unhelpful, and so there's that psychological component to it as well." (Male, works full-time)
Managing perceptions *(Attempts to process and cope with real or imagined perceptions of family and/or colleagues)*	"I would want people to understand that when someone has RA and they go to work, they're really working two jobs or even three. One of them is performing as well as everyone else ... and then there is another job of having to manage one's energy and having to manage the perception of others." (Female, works part-time and self-employed)
Grappling with disclosure *(Weighing decisions re: whether or not to disclose condition at work, and the potential consequences)*	"I'm going to be honest. I have lied because with early childhood education they do not want you calling out if you don't feel well, or they don't want to hire someone who is older or not physically capable, because someone else has to pick up the slack. ... I had to be honest about the skin aspect, obviously, because it's there. So, I'll be like: 'Oh, I have psoriasis and blah blah,' but I will conveniently leave out how all-encompassing it can be. It's not just this, you know." (Female, self-employed)
Pushing through *(Internal/external pressure to be productive at work, presenteeism, absenteeism)*	"I think that I would never have been able to decrease my full-time hours. I think that I would never have been able to go part-time. I would have kept pushing because I would have had to. You know, there's no one to back me up. It's just me, right? And I would have never let up. And I would have eventually, I really believe, would have been on disability at some point because I would have pushed so hard that I wouldn't have been able to walk." (Female, not currently working)
Financial security *(The imperative to maintain employment to sustain living costs, medical insurance and healthcare)*	"I'm really glad I can work, and I earn enough money, and have insurance, but I'm also kind of upset that it's such a necessity...for me, I mean, I know it's a necessity for everybody, but it just feels like I have even less of a choice than I imagine other people might have." (Female, works full-time) "So, if I ever need motivation, to get motivated to get up and go to work in the morning, that might be the thing... I enjoy working, I feel like I may be more driven because, you know, the fact that I literally cannot afford to be unemployed and uninsured. (Female, works full-time)
Mental health impact *(Stress, anxiety, anger, depression, reflected in all study themes)*	"I would cry every Sunday before I would go in on Monday. I couldn't do it, like it was impacting how I was at home. I couldn't do it." (Female, self-employed)
Personal/professional support *(Plays an important role in an individual's ability to manage their IA at work. Support is complex, variable, vital to maintaining work, and often inadequate)*	"I feel a bit more supported by my family. It's as simple as someone having dinner for me now. Like, I don't have to worry about fixing dinner for myself, or you know, laundry or household chores." (Female, works full-time)
New perspectives, transformations, meaning-making *(Evolving priorities and values, shift in perspective, privileging self-care, and turning to spiritual practices and other forms of meaning-making)*	"Actually, one of my sons said I'm 'more human.' I'm choking up a little bit because when they were growing up I was not there, I was working. I'd come home at 3 o'clock [in the morning] and when I woke up they were already gone, they were at school. Sometimes I would pick them up, but it was rare... My younger son said I used to be very angry. I feel wholeheartedly that now they see the real me because before it was the 'worker me.' Before, I was a human working, now it is a human being." (Male, works part-time and self-employed)

to consider to support people with rheumatic and musculoskeletal diseases, highlighting that "work outcomes comprise … physical and mental health … but also personal and environmental factors. These contextual factors can be barriers as well as facilitators, and are of special interest if they are modifiable." (Boonen, 2023). This study, therefore, explores the psychological experience of people with IA in their efforts to maintain sustainable work while coping with their illness. Our aim is to report key psychosocial areas of exploration to be considered in a comprehensive evaluation of IA patients.

Methods: In a mixed methods qualitative study, a clinical social work researcher conducted semi-structured interviews with MD-diagnosed IA patients (18+ years, currently employed or within the past 5 years). Interviews were conducted via Zoom, averaged 1 hour in duration, and were recorded and transcribed verbatim. Participants were recruited from an NYC academic hospital by MDs, SWs, and by a community partner.

Using thematic analysis and NVivo software, 4 reviewers conducted preliminary analysis of data of 20 interviews to identify emerging themes. We also collected demographic information (*Table 1*).

Results: While 40 IA patients participated, we include here preliminary results from 20 interviews. Nine interrelated themes emerged *(Table 2)*: **Challenges to identity and pride** (achievements, coping with illness' impact on work); **Guilt or shame** (diminished capacity, internalized ableism); **Managing perceptions** (attempts to process and cope with perceptions of others); **Grappling with disclosure** (and potential consequences); **Pushing through** (internal/external pressure to function, presenteeism); **Financial security** (living costs, healthcare); **Mental health impact** (stress, anxiety, anger, depression reflected in all study themes); **Personal/professional support** (complex, variable, vital to sustaining work, often inadequate); and **New perspectives, transformations and meaning-making** (evolving priorities and values).

Conclusion: Preliminary findings demonstrate a significant psychological impact related to IA patients' efforts to maintain employment while coping with the challenges of their illness. This nuanced perspective is an important area of inquiry for a more holistic patient assessment and can inform multidisciplinary interventions to support IA patients at work. Continued analysis will further describe the diverse needs of people with IA across job type, gender, orientation, race, ethnicity and other factors.

Abstract Number: 1258

"What Is My Risk Really?": A Qualitative Exploration and Ideal-Type Analysis of Preventive Interventions Among Individuals at Risk of Rheumatoid Arthritis

Lara S Chapman[1], Heidi J Siddle[1], Stefan Serban[2], Kulveer Mankia[1], Christopher Rooney[3], Zhain Mustufvi[4], Simon Pini[5] and Karen Vinall-Collier[4], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]Public Health Directorate, NHS England North West Region, Manchester, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]School of Dentistry, University of Leeds, Leeds, United Kingdom, [5]Leeds Institute of Health Sciences, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Psychology/Social Science – Interprofessional Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: A preclinical phase of rheumatoid arthritis (RA), in which 'at-risk' individuals develop autoantibodies and/or symptoms and progress to clinical arthritis and classifiable RA, is well established (1). Emerging evidence suggests intervention in the pre-arthritis phase could reduce the risk of RA developing, delay onset and progression of RA, or reduce the severity of the condition should it develop (2). Preventive interventions include drug therapies and lifestyle changes. It is important that potential treatments are acceptable to at-risk individuals, particularly as RA prevention trials to date have demonstrated recruitment challenges (2). This study aimed to explore factors that would influence at-risk individuals' engagement with potential preventive interventions, including RA medication, antibiotics, probiotics, oral health treatment and maintenance, dietary changes, and smoking cessation.

Methods: This was a qualitative study employing a phenomenological approach. Anti-cyclic citrullinated peptide (anti-CCP) positive at-risk individuals with musculoskeletal symptoms but no synovitis were recruited from the Leeds CCP cohort. Individual semi-structured interviews were conducted via video or telephone between March-June 2022. Interviews were audio-recorded and transcribed verbatim and data were analyzed using reflexive thematic analysis. A secondary ideal-type analysis was subsequently conducted to understand different approaches to health-related behaviors.

Results: Nineteen CCP+ at-risk individuals (ten women; age range 35-70) participated. Three overarching themes were identified (Figure 1). Participants described distress related to ongoing symptoms and a burden of uncertainty regarding disease progression. Many participants had concerns about side effects of preventive RA medication and preventive antibiotics. In contrast, most participants expressed willingness to take a probiotic, and to make oral health and dietary changes with the aim of preventing RA. Participants' perceived engagement with preventive measures was influenced by symptom severity, personal risk level, comorbidities, experiences of taking other medications or supplements, knowledge of risk factors, and perceived effort. Three 'types' of participants were identified from the data: pro-active preventers (health-conscious, seek information and act on knowledge about being at-risk); change considerers (deal with health issues as they happen, rely on direct medical advice to make changes); fearful avoiders (worry about the future, limited engagement).

Conclusion: Our study suggests that having more severe symptoms, a higher personal risk level, increased knowledge about risk factors, and positive experiences of taking other medications would increase engagement with preventive interventions among CCP+ at-risk individuals, but that an individual's overall orientation to health behaviors also impacts on their

Figure 1. Themes

attitude towards preventing RA. These findings could inform recruitment and retention in pre-RA research and promote uptake of preventive interventions in clinical practice.

Voices Unheard: Unmasking the Hidden Challenges of Youth with Rheumatic Diseases

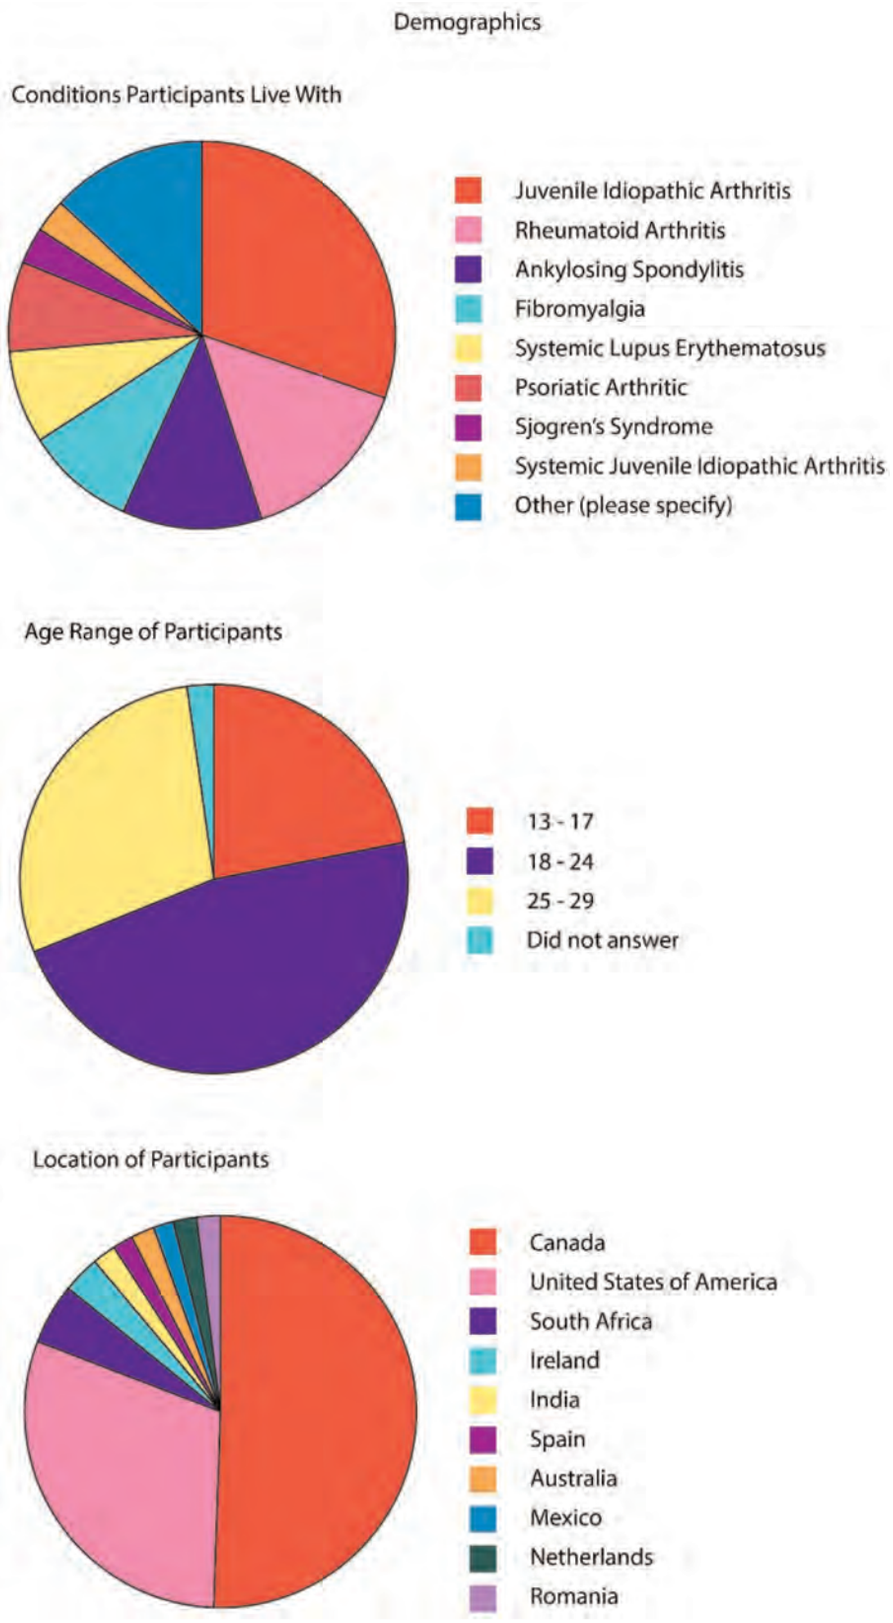
Natasha Trehan[1], Laurie Proulx[2] and Isabel Dukes[3], [1]University of Ottawa, Take a Pain Check Foundation, Toronto, ON, Canada, [2]Canadian Arthritis Patient Alliance, Ottawa, ON, Canada, [3]CAPA & TAPC, Freelance, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Psychology/Social Science – Interprofessional Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

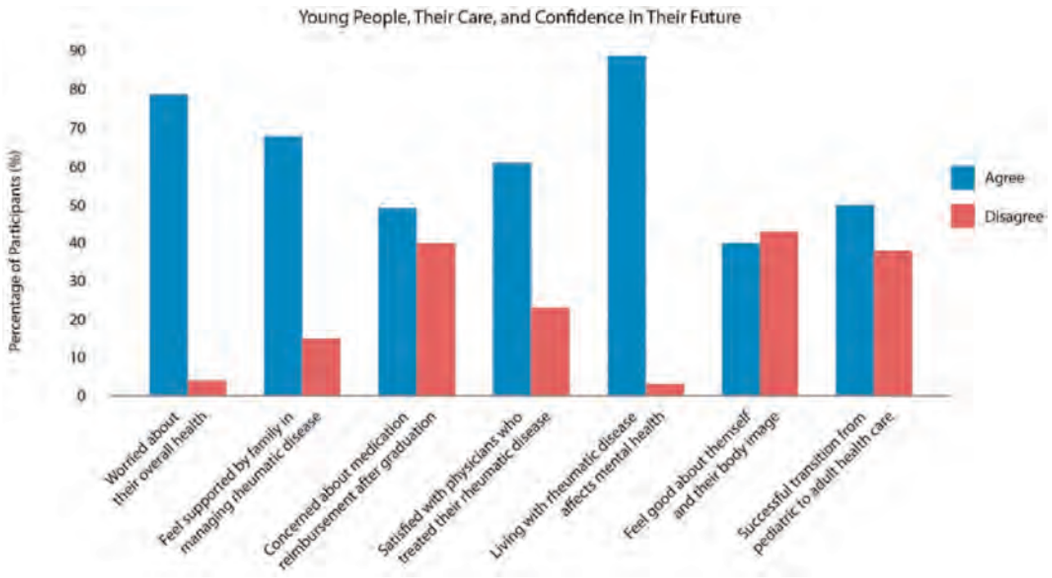
Background/Purpose: Rheumatic disease doesn't merely present physical challenges—it also significantly impacts various psychological and social aspects of one's life, often disrupting academic progress, straining friendships, and fostering a sense of social isolation for youth and young adults. Take a Pain Check Foundation (TAPC) and the Canadian Arthritis Patient Alliance (CAPA) are grassroots, patient-driven, and managed organizations. This effort illuminates the collaboration of these organizations, shining a light on their dedication to uplifting young lives and increasing awareness about the hurdles they face. The objective of this effort was to gain a comprehensive understanding of the needs of youth and young adults with rheumatic diseases to identify strategies in support of mental health and psychosocial well-being.

Methods: A survey was developed and young people with lived experience of rheumatic disease were consulted. The survey covered several domains including navigating the healthcare system, mental health and social support, self-confidence and self-image, and the transition from pediatric to adult care. The survey was opened in September 2022 and closed in January 2023. During this time, 67 participants completed the survey. Descriptive statistics were used to analyze the data per domain and sub-group analysis based on age, disease type, and geographic area (Figure 1).

Results: Over one in two participants (52%) lived with Juvenile Idiopathic Arthritis and others lived with Rheumatoid Arthritis (25%), Ankylosing Spondylitis (20%), Fibromyalgia (16%) and Systemic Lupus Erythematosus (13%) and Psoriatic Arthritis (13%). Findings revealed that a significant proportion (79%) of respondents expressed worry about their health, and 89% said their rheumatic disease affects their mental health. Self-perception and body image were reported as dissatisfactory for over 40% of youths. While a considerable number of participants (69%) felt supported by their families in managing their condition, 20% did not feel supported by romantic partners and friends. The majority of respondents (61%) expressed satisfaction with physicians who treated their rheumatic disease. Nearly half of the respondents (48%) felt ready for the transition from pediatric to adult care transition, while an equal proportion reported a successful transition experience (50%). Significant concerns were raised regarding medication reimbursement after graduating from school, as nearly half of the participants (49%) expressed unpreparedness (Figure 2).



Three pie graphs indicating demographic information gathered in the study. Demographic information includes age, location, and conditions participants live with.



A double bar graph showing how many participants agree or disagree with a variety of questions related to their care, mental health, and confidence in their future.

Conclusion: The survey provides valuable insights into the experiences and perceptions of young individuals living with rheumatic diseases and shows the need for targeted interventions and enhanced social support. Survey findings also suggest the need for innovative and tailored interventions about healthcare navigation and drug reimbursement faced by this population. Addressing this multifaceted challenge, TAPC and CAPA are creating the necessary tools and resources to aid young people with rheumatic conditions.

Abstract Number: 1260

Optimal Approaches for Reducing Depressive Symptoms in Rheumatoid Arthritis Patients Based on Psychological Interventions: A Systematic Review and Network Meta-analysis

Zhang Lijuan and Wu Beiwen, Shanghai Jiao Tong University School of Medicine, Shanghai, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Psychology/Social Science – Interprofessional Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In recent years, numerous psychological interventions for rheumatoid arthritis (RA) patients have been developed. However, it remains unclear which psychological interventions are effective and preferred for their depressive symptoms. The purpose of this study was to identify the optimal psychological interventions approach for reducing depressive symptoms in RA patients.

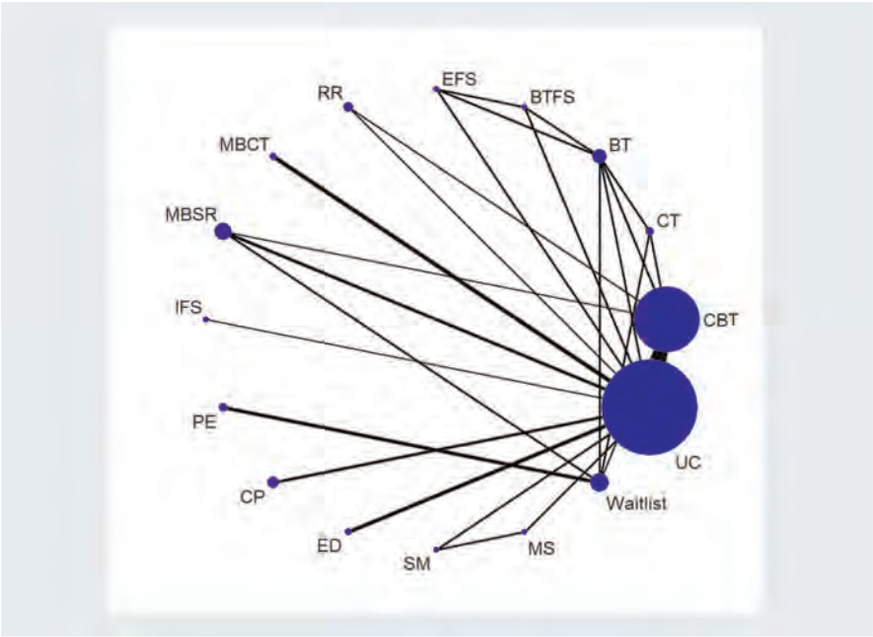

Figure 1 Network plots of depression at post-intervention. AUC: Area under curve; CBT: Cognitive behavioral Therapy; CT: the cognitive therapy; BT: the behavior therapy; BTFS: the behavior therapy with family support group; EFS: the education family support group; RR: Relaxation response training; MBCT: Mindfulness-Based Cognitive Therapy; MBSR: Mindfulness-Based Stress Reduction; IFS: Internal Family Systems; PE: Patients education; CP: Combined psychological intervention; ED: Emotional disclosure; SM: Stress Management; MS: Mutual Support; UC: Usual care.

Methods: The PubMed, Embase, PsycINFO, the Cochrane Library, China National Knowledge Infrastructure (CNKI), Wanfang databases, and grey literature were searched between inception and 31 December 2022. Pairs of reviewers screened studies, abstracted aggregate level data, and appraised risk of bias with the Cochrane risk of bias tool. The network meta-analysis was conducted using STATA software version 14.0.

Results: A total of 23 randomized controlled trials, involving 1885 participants and 16 psychological interventions were included in our analyses. In this network meta-analysis, two interventions were associated with a greater reduction in symptoms of depression compared with treatment as usual care group: mindfulness-based cognitive therapy (MBCT) (standardized mean difference –1.67, 95% credible interval -2.23 to -1.10) and combined psychological intervention (CP) (–0.72, –1.16 to –0.28). Although most psychological interventions showed non-significant effects, the surface under the cumulative ranking curve (SUCRA) values revealed that the best psychological intervention for depression was MBCT (99.9%), followed by CP (85.6%), and Internal Family Systems (IFS) psychotherapeutic intervention (69.0%).

Conclusion: MBCT was the most recommended psychological intervention to accompany the depression among RA patients according to our network meta-analysis results.

Abstract Number: 1261

Network Analysis of Depression and Anxiety Symptoms in Chinese Rheumatoid Arthritis Patients

Zhang Lijuan and Wu Beiwen, Shanghai Jiao Tong University School of Medicine, Shanghai, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Psychology/Social Science – Interprofessional Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients are susceptible to comorbid anxiety and depression. From the network model perspective, comorbidity is due to direct interactions between depression and anxiety symptoms. The objective of this study was to assess the network structure of depression and anxiety symptoms in Chinese RA patients and identify the central and bridge symptoms as well as how depression and anxiety symptoms are related to quality of life (QoL) in the network.

Methods: A total of 402 Chinese RA patients were included in this study. Depression and anxiety symptoms were measured by the Hospital Anxiety and Depression Scale (HADS).R software was used to estimate the network. Specifically, we computed the predictability, expected influence (EI) and bridge expected influence (BEI) for each symptom and showed a flow network of "QoL".

Results: Our network revealed that the strongest edge was D2 "See the bad side of things"-D3 "Not feeling cheerful" across the whole network. For centrality indices, D3 "Not feeling cheerful" and D6 "Feeling down" had the highest EI values in the network, while A4 "Trouble relaxing" and D6 "Feeling down" had the highest BEI values of their respective community. As to "QoL", the strongest direct edge related to it was A1 "Nervousness".

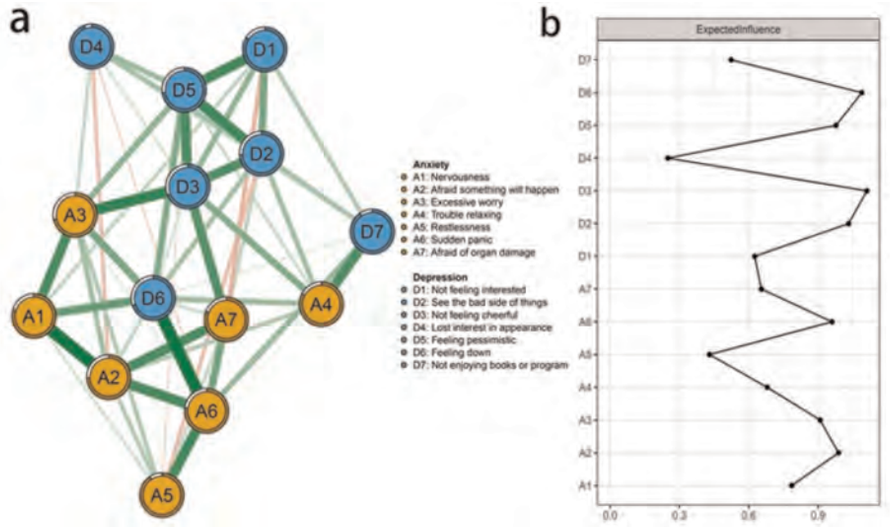

FIGURE 1 The anxiety-depression network structure and the expected influence indices in Chinese RA patients. (a) The anxiety-depression network structure of the Chinese RA patients. The nodes in the network represent symptoms of anxiety and depression, and the edges represent correlations of symptoms. Green edges and red edges represent positive and negative correlations, respectively, and thicker edges represent higher correlations. (b) The expected influence indices in the anxiety-depression network of Chinese RA patients.

Conclusion: Network analyses highlighted specific associations between symptoms of depression and anxiety in Chinese RA patients. D3 "Not feeling cheerful" and D6 "Feeling down" were the core symptoms in the network; A4 "Trouble relaxing" and D6 "Feeling down" were the most critical bridge symptoms. A1 "Nervousness" was also identified as key priority due to its significant association with QoL. Our study emphasizes the necessity of implications for clinical prevention and intervention based on these symptoms in Chinese RA patients.

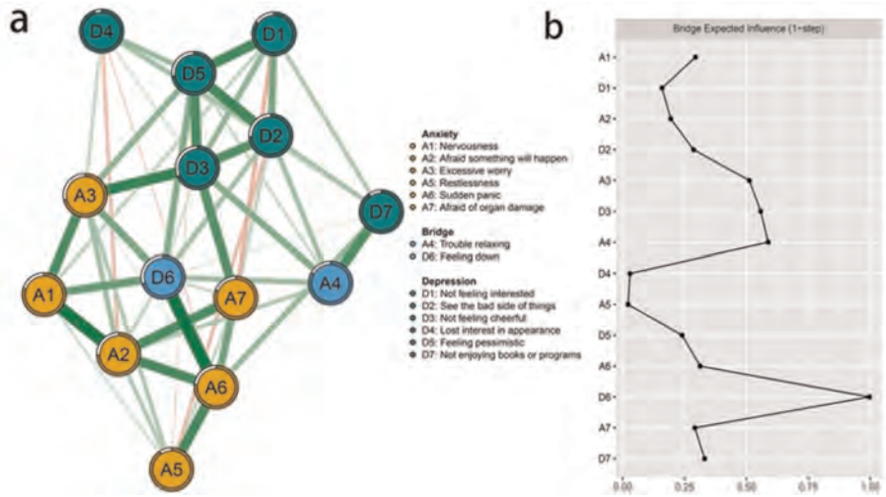

FIGURE 2 The anxiety-depression network structure highlighting the bridge symptoms and the bridge expected influence indices in Chinese RA patients. (a) The anxiety-depression network structure highlighting the bridge symptoms. The nodes in the network represent symptoms of anxiety and depression, and bridge symptoms are highlighted in blue. The edges represent correlations of symptoms, green edges and red edges represent positive and negative correlations, respectively, and thicker edges represent higher correlations. (b) The bridge expected influence indices in the anxiety-depression network of Chinese RA patients.

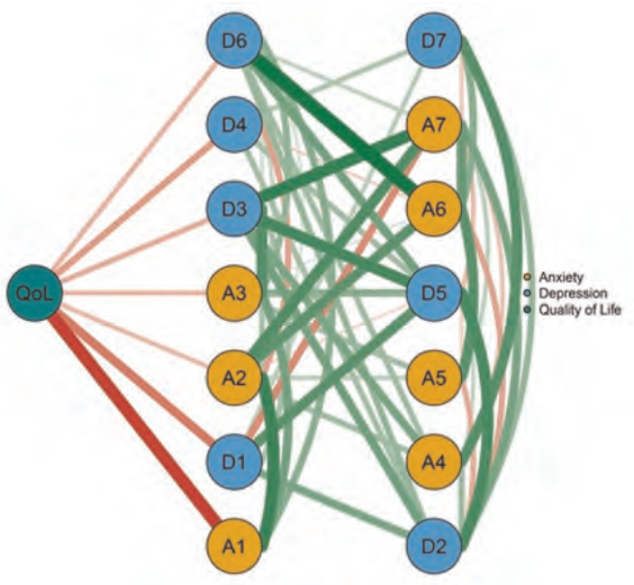

FIGURE 3 The flow network of quality of life in Chinese RA patients. The nodes in the network represent symptoms of anxiety and depression, and the edges represent correlations of symptoms. Green edges and red edges represent positive and negative correlations, respectively, and thicker edges represent higher correlations. A1-Nervousness, A2-Afraid something will happen, A3-Excessive worry, A4-Trouble relaxing, A5-Restlessness, A6-Sudden panic, A7-Afraid of organ damage, D1-Not feeling interested, D2-See the bad side of things, D3-Not feeling cheerful, D4-Lost interest in appearance, D5-Feeling pessimistic, D6-Feeling down, D7-Not enjoying books or programs, QoL-quality of life.

"Somebody Who's Been There and Can Understand the Challenges That You're Going Through": Participant Perspectives of a Resilience-Based Energy Management Online Intervention for Systemic Sclerosis with Peer Health Coaches

Yen Chen[1], Alexandra Harper[2], Tiffany Phanhdone[3], Mary Alore[1], Sheri Hicks[1], Adam Pape[1], Gina Jay[1], Shannen Bolde[1], Jennie Feldpausch[1], Dinesh Khanna[1] and Susan Murphy[4], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ypsilanti Charter Twp, MI, [3]Northwestern University, Chicago, IL, [4]University of Michigan, Plymouth, MI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Psychology/Social Science – Interprofessional Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: People with systemic sclerosis (SSc) often experience fatigue, which impacts daily life functioning and quality of life. We developed a 12-week, resilience-based energy management intervention to promote well-being (RENEW) that focuses on healthy behaviors and resilience skills. Participants worked with a trained peer health coach, who also has SSc, setting healthy goals and tracking progress. We conducted interviews to explore participant experience and the impact of RENEW on SSc symptom management.

Methods: From a clinical trial *(ClinicalTrials.gov: NCT04908943)* testing the effectiveness of the RENEW program versus a waitlist control, we purposively selected RENEW program participants who scored high or low on the Patient Global Impression of Change (PGIC) scale. We then conducted virtual interviews (N = 21). Transcripts were analyzed using the rigorous and accelerated data reduction (RADaR) technique combined with thematic content analysis. During the coding process, codes were refined collaboratively by coders, including a patient partner. Any discrepancies were resolved through discussions. Codes with similar content were merged and organized into subthemes and themes to better understand the data.

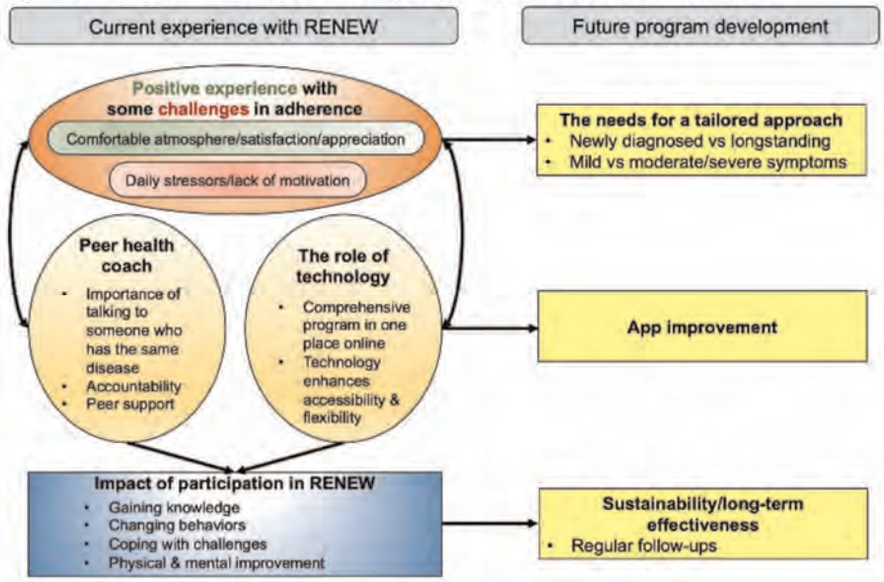
Results: Twenty-one participants (mean age = 57 ± 14 years; 18 females; 13 diffuse SSc subtype; 11 early disease duration ≤ 5 years) with 12 reported high PGIC (Table 1). Five themes were identified (Figure 1). 1) *Peer health coaches*: Participants valued support provided by peer health coaches. The coaches understood their needs and provided guidance throughout the program, helping them set achievable goals and develop strategies to overcome challenges. 2) *Impact of participation*: RENEW had a positive impact on managing fatigue. Participants reported gaining knowledge and skills in developing healthy behaviors that improved their overall physical and mental health. 3) *Program experiences*: Participants expressed overall satisfaction with comprehensiveness and relevance to SSc. However, they faced difficulties in managing everyday life stressors and obligations, which sometimes affected their motivation and/or ability to participate in RENEW. 4) *Need for a tailored approach*: Although results were generally positive, participants suggested tailoring the approach to optimize effectiveness of RENEW. They recommended tailored information for newly diagnosed patients versus those with a longer disease duration to better address specific needs. 5) *Role of technology*: Participants appreciated the convenience of Zoom and easy accessibility of the program through an online platform or app. However, some participants mentioned that the app was not user-friendly and suggested improvement.

Table 1. Participants PGIC, demographics and SSc characteristics, and change in fatigue score from baseline to 12 weeks (n = 21)

PGIC score		ID	Age	Sex	Race	SSc subtype	SSc duration	Fatigue Change[a]
Low	1	1	59	F	African American	Diffuse	11+ years	17.4
	2	2	69	F	White	Diffuse	11+ years	1.8
	3	3	72	M	White	Diffuse	11+ years	1.7
	3	4	58	F	White	Limited	11+ years	0
	3	5	44	F	White	Limited	≤ 5 years	-1.8
	3	6	63	F	White	Limited	6-10 years	-2.2
	3	7	78	F	White	Overlap	11+ years	-2.6
	3	8	56	F	White	Diffuse	11+ years	-2.8
	3	9	87	F	White	Diffuse	≤ 5 years	-3.6
High	6	10	40	F	African American	Diffuse	11+ years	5.3
	6	11	54	F	African American	Overlap	≤ 5 years	-1.6
	7	12	61	F	White	Diffuse	≤ 5 years	-8.2
	6	13	51	M	White	Diffuse	≤ 5 years	-8.9
	6	14	59	F	African American	Diffuse	≤ 5 years	-9.8
	6	15	31	F	Asian & other	Diffuse	≤ 5 years	-10.3
	6	16	35	F	African American	Diffuse	11+ years	-11.0
	6	17	63	M	White	Diffuse	≤ 5 years	-12.0
	7	18	58	F	African American	Diffuse	≤ 5 years	-12.2
	6	19	65	F	Asian & other	Limited	≤ 5 years	-12.5
	7	20	40	F	White	Limited	≤ 5 years	-14.4
	7	21	47	F	White	Limited	11+ years	-16.1

a. To assess change in fatigue, we calculated the difference between the fatigue score at baseline and the score at the 12-week. Negative values indicated a favorable change, suggesting an improvement or decreased in fatigue.
PGIC, Patient Global Impression of Change: 1= No change (or condition has gotten worse); 2 = Almost the same, hardly any change at all; 3 = A little better, but no noticeable change; 4 = Somewhat better, but the change has not made any real difference; 5 = Moderately better, and a slight but noticeable change; 6 = Better and a definite improvement that has made a real and worthwhile difference; 7 = A great deal better and a considerable improvement that has made all the difference.

Figure 1. A conceptual model representing the participants' experiences in RENEW



Conclusion: Our findings highlighted the importance of the peer health coach component to our self-management intervention. Participation in the program led to improved fatigue management and well-being for individuals with SSc. However, we identified a need to tailor RENEW based on different SSc duration groups. While the virtual program was convenient, suggestions for improving the app were noted. These findings contribute to the development and refinement of future interventions for people with SSc.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Psychology/Social Science – Interprofessional Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression is one of the most common psychiatric comorbidities in patients with rheumatic diseases. A study has shown that almost a third of patients with Rheumatoid Arthritis (RA) present symptoms of major depressive disorder, making it more prevalent than general population. (1) Early and continuous screening could help reduce the prevalence of mental health disorders. (2) The objective of this study was to evaluate and identify patients at risk of developing anxiety and/or depressive disorders.

Methods: We conducted a cross-sectional study at the outpatient rheumatology clinic of Hospital Universitario Dr. José Eleuterio González. Patients aged 18 and older with at least one rheumatic disease were included. Sociodemographic and disease activity data were collected from records. We administered the Hospital Anxiety and Depression Scale (HADS): a score of 0 is classified as no risk, 1-7 points low risk, 8-10 intermediate risk, and >11 high risk. For fatigue, we utilized The Functional Assessment of Chronic Illness Therapy scale (FACIT). Those identified as high risk were referred for psychiatric evaluation.

Results: We enrolled a total of 893 patients. Based on their scores, 42.70% (382) showed no risk of anxiety, while 57.22% (511) had a low, intermediate, or high risk (Table 1). Among the patients without anxiety symptoms, 89.3% (341) were female, with a mean disease duration of 7.2 +/- 7.9 years and a mean age of 49.9 +/- 15.1 years. Rheumatoid Arthritis (RA) was the most common diagnosis, accounting for 48.7% (186). On the other hand, only 152 patients (16.57%) were classified as high risk for anxiety, with 97.4% of them being female. The mean age in this group was 53.7 +/- 14.8 years, and mean disease duration was 6.9 +/- 7 years. Among those at high risk, RA was the most prevalent diagnosis, affecting

Yes	224 (65.9)	165 (72.1)	82 (74.5)	110 (74.3)	
No	116 (34.1)	64 (27.9)	28 (25.5)	38 (25.7)	

52.25% (80) of the patients (Table 1). Regarding risk of depression, 66.40% (593) of all patients presented no risk of depression, while 33.57% (300) had a low, intermediate, or high risk. Among those without depression symptoms, 91.6% were female, with a mean age of 50.1 +/- 15 years. RA was the most frequent diagnosis, accounting for 58.2% of the patients. In the group with a high risk of depression, we found 2.79% (25) of patients, with a mean age of 56.4 +/- 18 years and a mean disease duration of 7.7 +/- 7.8 years (Table 2). Fatigue and depression risk were more prevalent in individuals with higher anxiety scores ($p < 0.001$)

Conclusion: Our findings revealed that in our patient population, risk for anxiety and depression increases with age, and is more prevalent in women. Additionally, we observed that fatigue was associated with both anxiety and depression risk scores. Furthermore, there was a positive association between high-risk scores for anxiety and high-risk scores for depression. Based on these results, we strongly recommend the regular screening of patients who are at high risk of developing mental health problems

Nomination of Biomarkers for Self-testing Disease Activity in Rheumatoid Arthritis Using Patient Similarity Networks: A Pilot Study

Martina Skacelova[1], Ondrej Janca[2], Milos Kudelka[2], Bishu Shrestha[3], Pavel Horak[4] and Eva Kriegova[3], [1]Department of Internal Medicine III - Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, Czech Republic, [2]Department of Computer Science, Faculty of Electrical Engineering and Computer Science, VSB-Technical University of Ostrava, Ostrava, Czech Republic, [3]Department of Immunology, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Czech Republic, Olomouc, Czech Republic, [4]Department of Internal Medicine III- Nephrology, Rheumatology, Endocrinology, Faculty of Medicine and Dentistry, Palacký University, Olomouc, Czech Republic

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Although telemedicine in rheumatoid arthritis (RA) could improve disease control with lower healthcare costs, knowledge of suitable parameters for self-testing disease activity still remains limited. The alteration in lipoproteins among RA patients seems to be associated with disease activity and severity. Objective: To explore the relationship between disease activity and a set of serum inflammatory and lipid biomarkers and patient and physician evaluations in RA.

Methods: Activity markers (CRP, ESR, swollen (SJC) & tender (TJC) joint counts), serum lipids and patient health status evaluation using the visual analogous scale (VAS) completed by the patient and clinician were analysed at two-time points in a real-world cohort of patients with RA (n=22, males/females, 4/18) using patient similarity networks (PSNs). Disease activity was assessed by DAS28 at each visit, and most patients were treated with biologics (inhibitors of TNFa/JAK/IL6/others: 12/3/2/5).

Results: When comparing patient and physician evaluations, patient evaluations differed significantly from physician evaluations in ∼1/3 of patients (differences in SJC >5, TJC >3, and/or VAS >30), mainly with overestimated values of SJC and VAS health status by patients. Therefore, we constructed a PSN based only on laboratory parameters and revealed three clusters (subgroups) of patients who differed in CRP, low-density lipoprotein cholesterol (LDL-C), and apolipoprotein-AI (apoA-I) levels, all three of which have been associated with RA disease activity in previous studies. One subgroup (CI) characterised by a low CRP and high LDL-C and apoA-I included predominantly non-active patients (6/9, confidence C=67%, support S=41%). The majority of these patients changed to active after the 3-month follow-up. Two subgroups: CII) with low CRP and LDL-C (5/6, C=83%, S=27%), and CIII) with high CRP and LDL-C and low apoA-I (6/7, C=86%, S=32%) included predominantly active patients. Our data support a key role for serum apoA-I levels in activity assessment, as these levels are strongly related to disease activity at follow-up. The expansion of the study cohort is ongoing.

Conclusion: Our study shows the utility of serum biomarkers for assessing disease activity, independent of the patient and clinician evaluations. Whether the nominated biomarkers are suitable for the automated approach, clinical use and/or interpretation of cardiovascular risk or even sorting active patients in telemedicine approach, deserves future validation on a larger patient cohort.

Changes in the Endocannabinoid Tone in Rheumatoid Arthritis and Osteoarthritis – Discovery of a Novel Target for the Treatment of Pain and Inflammation?

Jost Klawitter[1], Andrew Clauw[1], Jennifer Seifert[1], Jelena Klawitter[1], Bridget Tompson[1], Cristina Sempio[1], Uwe Christians[1] and Larry Moreland[2], [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]University of Colorado, Denver, CO

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation is a complicated physiological process that results in a variety of disorders. Several inflammatory mediators are produced during this process, which is responsible for long-term inflammatory conditions like osteoarthritis (OA) and rheumatoid arthritis (RA). Endocannabinoids (ECs) and the endocannabinoid system play a pivotal role in the physiological response to pain and inflammation. A clinical study was performed to investigate changes in endocannabinoid tone and related lipid meditators in OA and RA compared to age-matched healthy participants.

Methods: A clinical study with 80 subjects (53 Female and 27 male) was performed including 25 RA and 18 OA patients and 37 healthy participants. Venous blood was drawn, plasma was generated, and one aliquot of plasma was acidified using 0.5% formic acid to preserve/stabilize endocannabinoids and related lipid mediators. An in-house developed and validated HPLC-MS/MS-based assay for the analysis of 20 ECs and congeners was performed as. Moreover, we applied a lipid mediator multiplex assay for the analysis of 131 oxylipins many of which are related to the ECs pathway. Data were analyzed using ANOVA in combination with the LSD post-hoc test (SPSS 28.0).

Results: Average age of study participants was 55.8±10.6 years with 57.2±8.3, 62.2±6.6 and 52.0±12.0 for the RA, OA and control group, respectively. The female/male ratio was 53/27 with 16/9, 15/3 and 22/15 for the RA, OA and control group, respectively. The endocannabinoid analysis revealed significantly decreased levels of 2-arachidonoylglycerol (2-AG, see Figure 1). In contrast, EC levels of the ethanolamide (EA) group (anandamide (AEA), docosahexaenoyl-EA, palmitoleoyl-EA and other EAs) were increased in the RA group and to a lesser extent in the OA group (Figure 1 lower part).This analysis of oxylipins revealed decreased levels of the inflammation resolving lipid 9-oxo-octadecadienoic acid (9-oxoODE) in RA compared to all other study groups. In contrast, proinflammatory lipids 11-hydroxy docosahexaenoic acid (11-HDHA) and 12-hydroxy-eicosatetraenoic acid (12-HETE) were significantly increased in both the RA and OA group as compared to healthy controls.

Conclusion: ECs have very short half-lives. The study design included addition of stabilizer solution to plasma that enabled us to accurately determine the EC levels, specifically 2-AG. Using this approach, we found decreased levels of the major antinociceptive and anti-inflammatory endocannabinoid 2-AG in RA and OA subjects. 2-AG is a key regulator of nociception

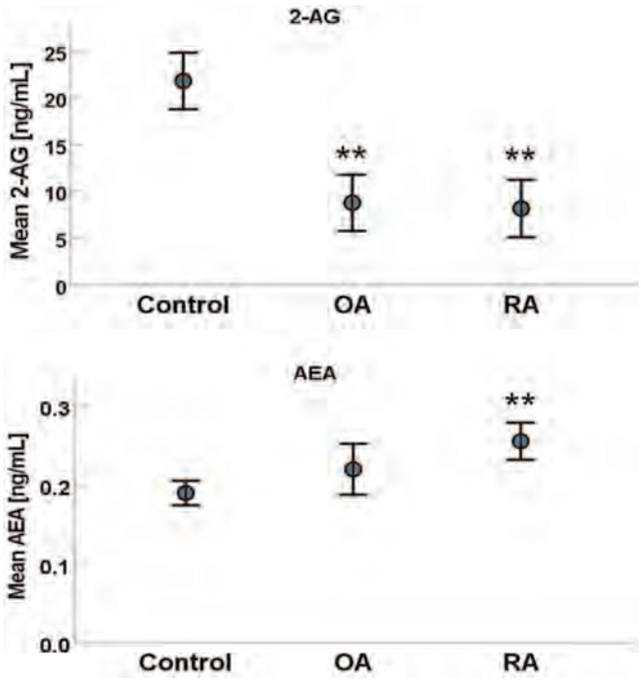

Figure 1: Mean 2-AG (upper) and AEA (lower) plasma levels in osteoarthritis (n=17), rheumatoid arthritis (n=25) and in age matched healthy controls (n=37). Data are shown as mean ± SEM.**p<0.01 post-hoc LSD.

and inflammation, and decreased levels could be a major mechanistic contributor to pain and inflammation in RA and OA. In addition, we observed increased levels of ethanolamide endocannabinoids (EA-ECs). This may be an indicator for decreased FAAH (fatty acid amide hydrolase) activity, the major EA-ECs regulating enzyme. Although anandamide (the major EA-EC) functions as a CB1 receptor agonist in the CNS, it shows vanilloid TRPV1 receptor agonism peripherally. Overall, our results suggest the involvement of ECs in inflammation and pain in patients with RA and OA and may present a potential treatment target.

The Anti-inflammatory Effect of High-density Lipoprotein Is Blunted by Delivery of Altered MicroRNA Cargo to Macrophages in Patients with Rheumatoid Arthritis

Qiong Wu, Quanhu Sheng, Danielle Michell, Marisol Ramirez-Solano, Olivia Posey, Anastasiia Phothisane, Shahensha Shaik, Kasey Vickers and **Michelle Ormseth**, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: High-density lipoprotein (HDL) has well-characterized anti-atherogenic cholesterol efflux and anti-oxidant functions. Another function of HDL uncharacterized in RA is its ability to transport microRNAs (miRNAs) between cells and thus alter cellular function. The study's purpose was to determine if HDL-miRNA cargo is altered and affects inflammation in RA.

Methods: HDL-miRNAs were characterized in 30 RA and 30 control subjects by next generation sequencing and quantitative PCR. The most abundant differentially expressed miRNA was evaluated further. The function of miR-1246 was assessed by miRNA mimics, antagomiRs, siRNA knockdown and luciferase assays. Monocyte-derived macrophages were treated with miR-1246-loaded HDL, and unmodified HDL from RA and control subjects to measure delivery of miR-1246 and its effect on IL-6.

Results: The most abundant miRNA on HDL was miR-1246; it was significantly enriched 2-fold on HDL from RA versus control subjects. HDL-mediated miR-1246 delivery to macrophages significantly increased *IL6* expression 43-fold. miR-1246 delivery significantly decreased *DUSP3* 1.5-fold and *DUSP3* siRNA knockdown increased macrophage *IL6* expression. Luciferase assay indicated *DUSP3* is a direct target of miR-1246. Unmodified HDL from RA delivered 1.6-fold more miR-1246 versus control subject HDL. Unmodified HDL from both RA and control subjects attenuated activated macrophage *IL6* expression, but this effect was significantly blunted in RA so that *IL6* expression was 3.4-fold higher after RA versus control HDL treatment.

Conclusion: HDL-miR-1246 was increased in RA versus control subjects and delivery of miR-1246 to macrophages increased *IL-6* expression by targeting *DUSP3*. The altered HDL-miRNA cargo in RA blunted HDL's anti-inflammatory effect.

Lower Herpes Zoster Rate of Tocilizumab and Tofacitinib in Patients Undergoing Treatment for Rheumatoid Arthritis

Yao fan Fang[1], Lai-Chu See[2] and Shu-Hao Chang[2], [1]Chang-Gung Memorial Hospital – Linkou, Taoyuan, Taiwan, [2]Biostatistics Core Laboratory, Molecular Medicine Research centre, Chang Gung University, Taoyuan City, Taiwan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biological disease-modifying antirheumatic drugs (bDMARDs) have become the primary treatment option for rheumatoid arthritis (RA) from 2010 in Taiwan. Tocilizumab is an interleukin-6 receptor inhibitor (IL-6Ri) and Tofacitinib is Janus kinase inhibitor (JAKi), in treating RA patients. They have much similar mechanism and efficacy. To address this concern, we conducted a comparison of the safety outcomes of Tocilizumab and Tofacitinib in RA patients in real-world clinical settings.

Table 1. Baseline characteristics of patients in the Tocilizumab and Tofacitinib.

	Tofacitinib	Tocilizumab	SMD	Tofacitinib	Tocilizumab	SMD

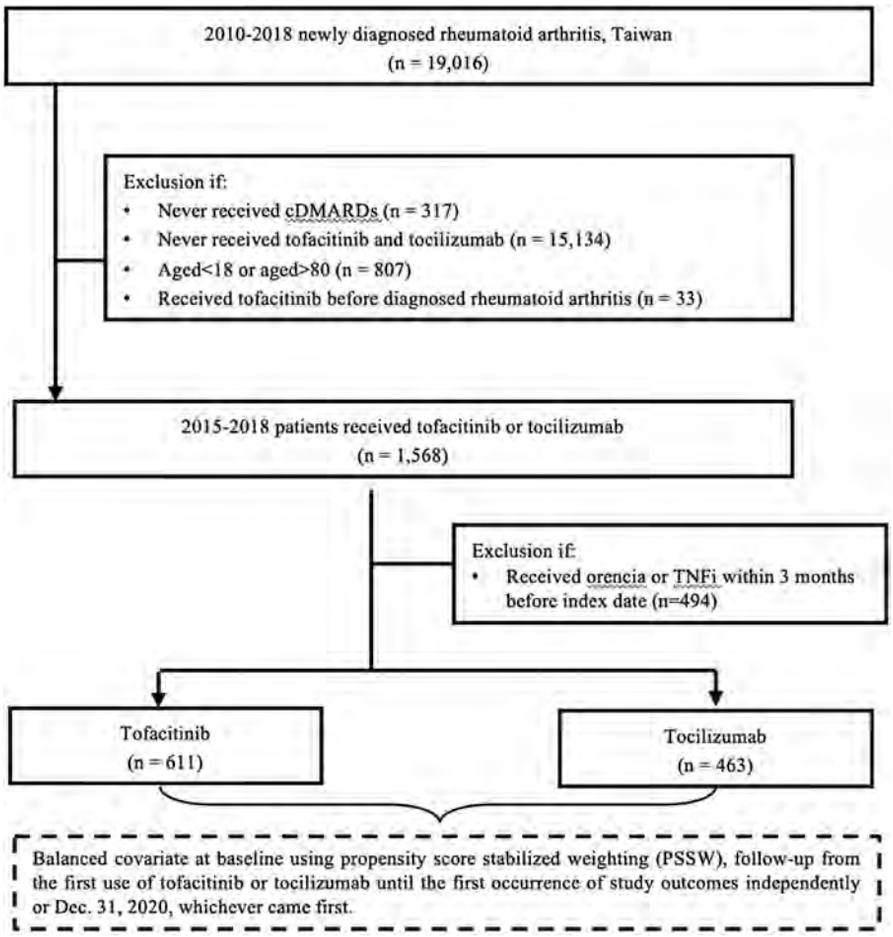

Figure 1. Flowchart for identifying patients with rheumatoid arthritis in the Taiwan National Health Insurance Research Database during the period 2010–2018.

Methods: Patients diagnosed with RA between 2010 and 2018 were identified from the Taiwan National Health Insurance Research Database and followed till 2020. Propensity score stabilized weighting (PSSW) was used to balance the baseline characteristics of the Tocilizumab and Tofacitinib groups. The incidences of safety outcomes, namely cardiovascular (CV) events, total hip replacement (THR), total knee replacement (TKR), tuberculosis (TB), herpes zoster infection, cancer and all-cause mortality, were compared between the study groups.

Results: A total of 1,074 patients with RA who were administered Tocilizumab (n = 463) and Tofacitinib (n = 611) were included in this study. The mean follow-up duration was 1.96 years in Tocilizumab group and 1.98 in the Tofacitinib group. A lower incidence rate of herpes zoster infection was observed in the Tocilizumab group than in the tofacitinib group. All-cause mortality, CV events, THR and TB infection had higher incidence rate but all without statistical significance.

Conclusion: Although, the mechanism of Tocilizumab and Tofacitinib are much similar. Lower herpes zoster incident rate was observed in Tocilizumab group compared with Tofacitinib. Other safety issues and mortality rates revealed comparable incidences in both groups with RA patients treated in real-world settings.

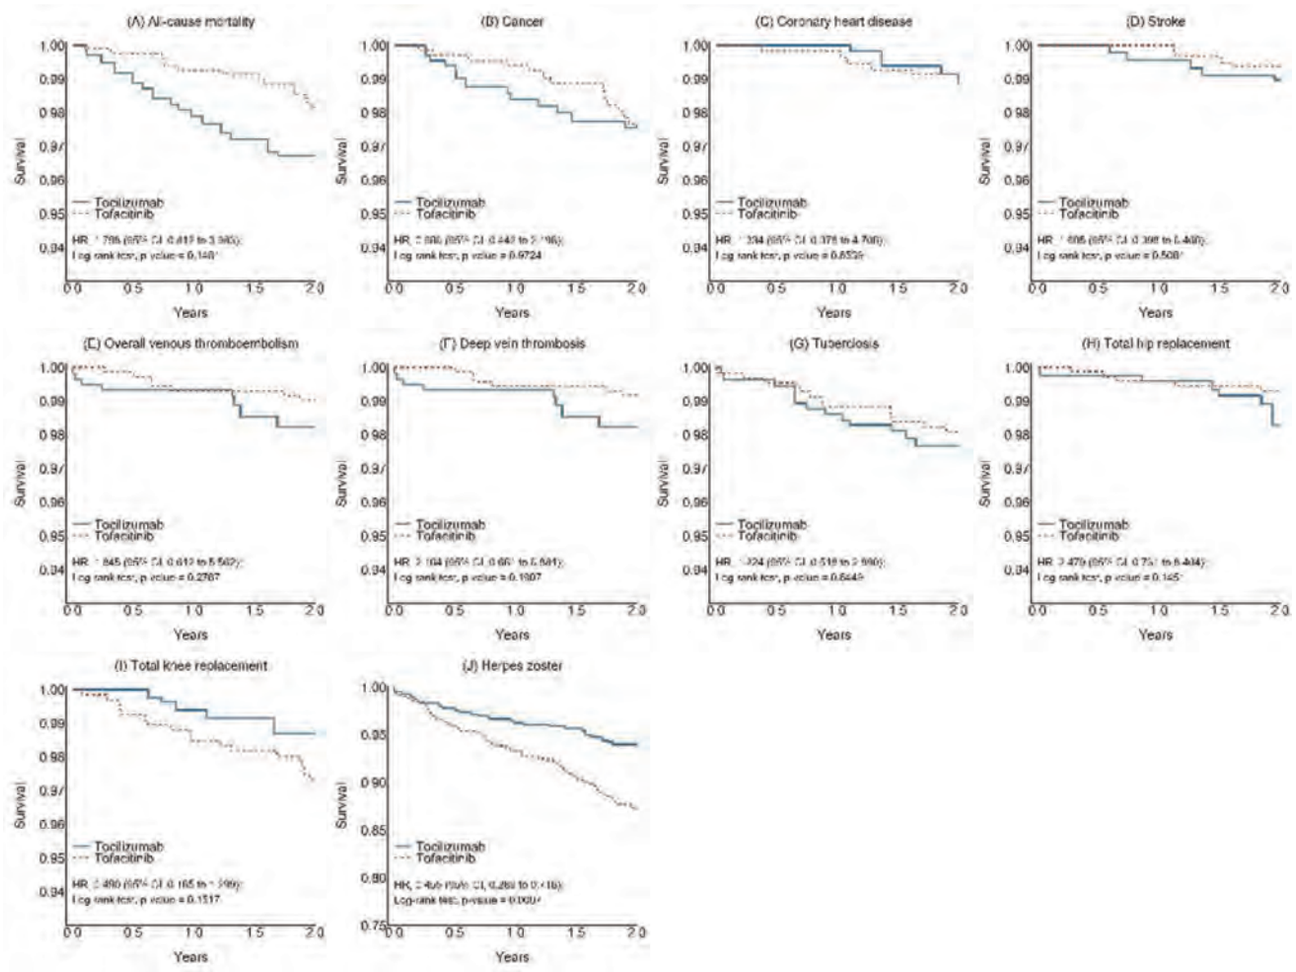

Figure 2. Survival curve of safety outcomes in the Tocilizumab and Tofacitinib groups.

Clinical Characteristics of Patients with Rheumatoid Arthritis (RA) Who Rate Their Global Assessment of Disease Activity Substantially Lower Than Their Physicians (Negative Discordance) Based on a Large RA Database in Japan: A Rare but Important Subgroup

Tetsuji Sawada[1], Susumu Nishiyama[2], Shohei Yamashita[3], Toshihiro Matsui[4] and Shigeto Tohma[5], [1]Tokyo Medical University Hospital, Shinjuku Tokyo, Japan, [2]Kurashiki Medical Center, Kurashiki, Japan, [3]Tokyo Medical University Hospital, Shinjuku, Japan, [4]NHO Sagamihara National Hospital, Kanagawa, Japan, [5]NHO Tokyo National Hospital, Dallas, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Discordance between patient global assessment (PGA) and physician global assessment (PhGA) regarding the disease activity of rheumatoid arthritis (RA) can be divided into three groups: positive discordance, concordance, and negative discordance. Several studies have demonstrated that the major determinants of positive discordance (PGA > PhGA) are pain and functional impairment. The clinical manifestations of negative discordance (PGA < PhGA) have not yet been fully elucidated. This study identifies determinants of this discordance using a nationwide RA database in Japan (*NinJa*).

Methods: The data of 13,945 patients with RA registered in *NinJa* in 2014 with available joint counts were analyzed. Data from patients with RA registered in both *NinJa* in 2014 and 2018 (n=4,923) were analyzed to study the radiographic progression of RA. The clinical variables used for the analysis included age, sex, disease duration, radiographic stage, functional class, pain visual analog scale (VAS) score, tender joint count (TJC), swollen joint count (SJC), disease activity score in 28 joints, C-reactive protein (DAS28-CRP), modified Health Assessment Questionnaire (mHAQ), and rheumatoid factor and anti-citrullinated peptide antibody (ACPA) levels. The affected joint distribution was investigated using joint indices (JI) x, y, and z, which were calculated as indices for the upper and lower joints and large joint involvement, respectively (Int J Rheum Dis 21(6):1237-45, 2018).

Results: Using a PGA-PhGA cutoff of 3 on a 10-cm scale, the numbers of patients with RA classified into positive discordance (PGA-PhGA > 3), concordance (-3 < PGA-PhGA < 3), and negative discordance (PGA-PhGA < -3) were 2,049 (14.7%), 11,785 (84.5%), and 111 (0.8%), respectively. There were no significant differences in age or disease duration between the three groups; however, the proportion of male patients was significantly higher in the negative-discordance group (19.9%, 16.5%, and 28.8%, respectively; $p< 0.01$). The TJC ($p< 0.01$), SJC ($p< 0.01$), and DAS28-CRP ($p< 0.01$) scores were higher in the negative discordance group than in the concordance group, while the PGA ($p< 0.05$) scores were lower in the negative discordance group than in the concordance group. JI x was significantly higher in the negative discordance group than in the other groups ($p< 0.01$). The proportion of patients with radiographic progression was significantly higher in the negative discordance group (33.3%) than in the concordance and positive concordance groups (13.7% and 11.5%, respectively; $p< 0.01$).

Conclusion: Negative discordance is prevalent in males and associated with higher disease activity, especially in the upper extremities, though the patients rated their disease activities substantially lower than their attending physicians. As negative discordance is associated with the progression of joint destruction, this rare but important discordance status can be regarded as a potential factor of poor prognosis.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: RA-associated interstitial lung disease (RA-ILD) is a heterogenous condition encompassing multiple subtypes with varying histopathology, prognosis, and potential treatment options. The most common RA-ILD subtypes are usual interstitial pneumonia (UIP) and nonspecific interstitial pneumonia (NSIP). RA-UIP is characterized by fibrosis and

ILD = interstitial lung disease, NSIP = nonspecific interstitial pneumonia, OR = odds ratio, RA = rheumatoid arthritis, UIP = usual interstitial pneumonia

portends the worst prognosis but may be treated with antifibrotic therapy. RA-NSIP is more likely to have inflammatory features on lung imaging. Despite these differences, most prior research studied RA-ILD as a single entity rather than examining individual subtypes. Therefore, we investigated differences in demographic, serologic, and lifestyle risk factors for RA-ILD and major RA-ILD subtypes.

Methods: We systematically identified RA-ILD cases and RA-noILD controls from two established RA cohorts. RA-ILD and subtypes (including UIP, NSIP, and other/indeterminate) were determined by clinical imaging reports and research review of clinically-indicated chest high-resolution computed tomography (HRCT) by at least two thoracic radiologists using a sequential reader method. RA-ILD cases met criteria for definite/probable RA-ILD (Bongartz, *A&R*, 2010). RA-noILD controls had no evidence of ILD on clinical review of medical records AND research HRCT review. Demographics, RA-related autoantibody testing, and smoking were extracted from study questionnaires or electronic health records. We investigated associations between RA-ILD and subtypes with demographic, serologic, and lifestyle factors using multivariable logistic regression, pooling both cohorts due to limited sample size.

Results: From 3328 RA patients, we identified 201 RA-ILD cases (mean age 51 years, 66.2% female) and 547 RA-noILD controls (mean age 49 years, 78.1% female). Of the RA-ILD cases, 69 (34.3%) had RA-UIP, 34 (16.9%) had RA-NSIP, and 98 (48.8%) had other subtypes or were indeterminate (**Table 1**). RA-ILD was associated with male sex (OR 1.63, 95%CI 1.12 to 2.37), seropositivity for RF and/or anti-CCP (OR 2.23, 95%CI 1.52 to 3.28) and ever smoking (OR 1.71, 95%CI 1.19 to 2.45, **Table 2**). Having all three risk factors (male, seropositive, smoking) was strongly associated with RA-ILD (OR 6.09, 95%CI 2.95 to 12.58, **Table 3**) and particularly with RA-UIP (OR 12.8, 95%CI 3.50 to 46.8) compared to RA-NSIP (OR 2.96 95%CI 0.77 to 11.56). RA-UIP was associated with male sex (OR 2.69, 95%CI 1.56 to 4.67) and positive

anti-CCP (OR 2.23, 95%CI 1.52 to 3.28, **Table 2**). RA-NSIP was associated with positive RF (OR 3.21 95%CI 1.46 to 7.07) but not male sex (OR 1.21, 95%CI 0.53 to 2.74).

Conclusion: In this study comparing systematically phenotyped RA-ILD cases with RA-noILD controls confirmed by HRCT, we found distinct risk factor profiles for RA-UIP and RA-NSIP. Male sex and elevated anti-CCP were strongly associated with RA-UIP, the most severe RA-ILD subtype. The combination of male sex, seropositivity, and smoking conferred nearly 13-fold increased risk of RA-UIP. These findings suggest that RA-ILD sex differences are specific to RA-UIP and may help clarify RA-ILD heterogeneity to optimize screening and treatment approaches.

Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Current EULAR recommendations for cardiovascular risk (CVR) assessment in rheumatoid arthritis (RA) patients indicate that the CVR evaluation should be performed according to national guidelines; however, there was no algorithm designed for the Mexican population until 2019, when the World Health Organization (WHO) published the CVR charts for 21 world regions, including Mexico. The aim of this study was to determine the capacity of the WHO and other five algorithms for the detection of carotid plaque in RA patients.

Methods: This was a cross-sectional study. We included 164 patients with RA diagnosis according to the 2010 ACR/EULAR classification criteria, aged 40-75 years. CVR was calculated with six algorithms: WHO, FRS-lipids, FRS-BMI, SCORE, ACC/AHA and QRISK3. The result was multiplied by 1.5, according to current guidelines. Carotid ultrasound was performed to all patients to identify the presence of carotid plaque, which was defined as a cIMT ≥ 1.2 mm or a focal thickness ≥ 0.5 mm. A ROC-curve analysis was performed, and the cutoff points to detect carotid plaque of each algorithm were determined using Youden's Index. Area under the curve (AUC), sensitivity, specificity, and likelihood ratios were calculated. A p-value < 0.05 was considered statistically significant.

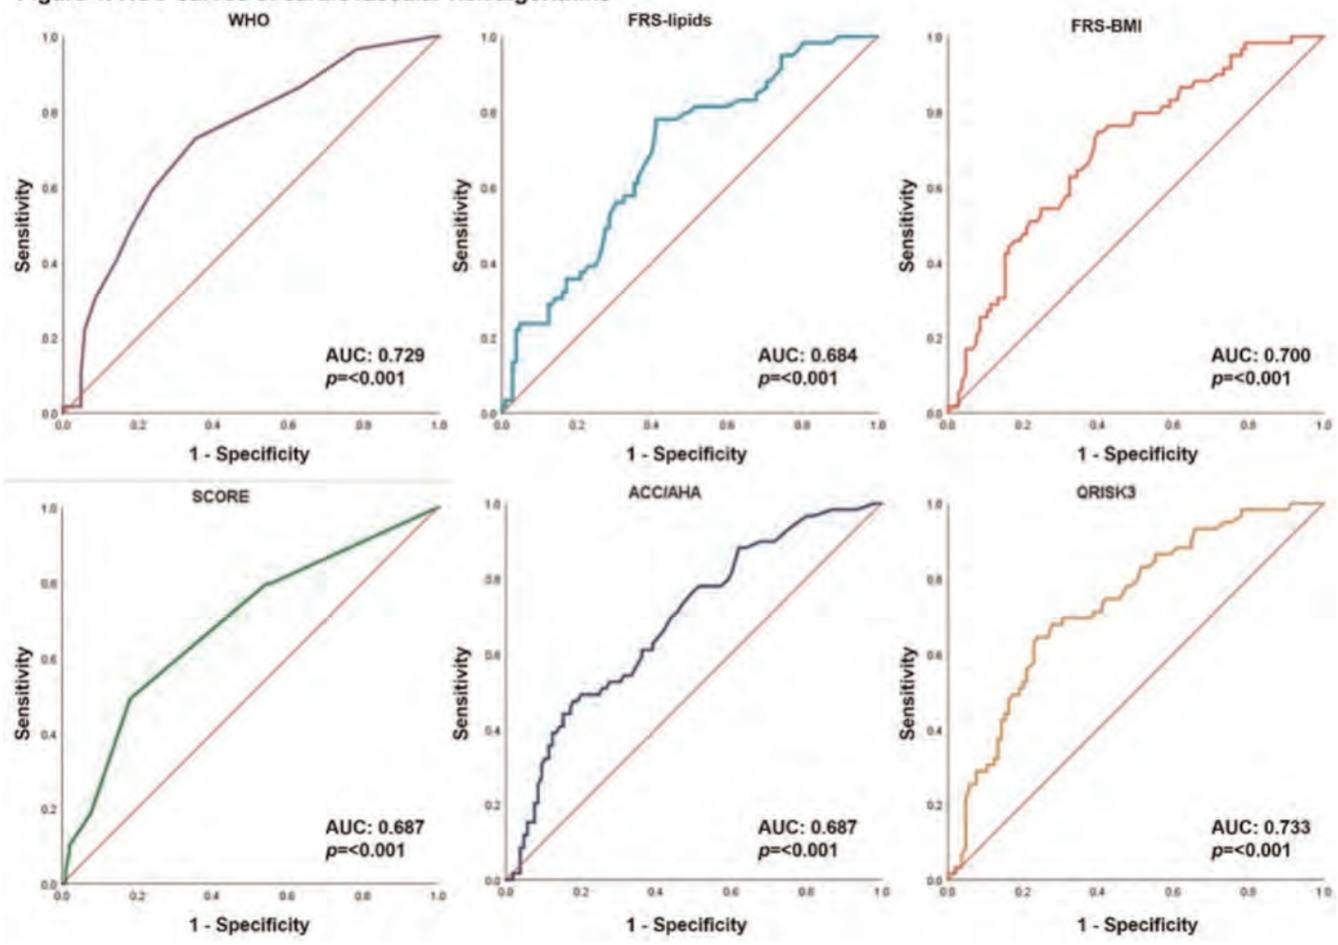
Table 1. Capacity of cardiovascular risk algorithms to detect presence of carotid plaque in rheumatoid arthritis patients.

Algorithms (cut-off points)	High risk cut-off point	AUC	CI 95%		p	Sensibility	Specificity	Likelihood ratio	
			Inferior limit	Superior limit				+	-
WHO (5.25)	≥ 10%	0.729	0.649	0.809	<0.001	72.9%	64.8%	2.07	0.42
FRS-lipids (8.62)	≥ 20%	0.684	0.601	0.767	<0.001	67.8%	61.0%	1.74	0.53
FRS-BMI (11.55)	≥ 20%	0.700	0.618	0.781	<0.001	72.9%	61.0%	1.87	0.44
SCORE (1.5)	≥ 5%	0.687	0.601	0.773	<0.001	79.7%	45.7%	1.47	0.44
ACC/AHA (3.82)	≥ 20%	0.687	0.604	0.770	<0.001	62.7%	61.0%	1.61	0.61
QRISK3 (6.05)	≥ 20%	0.733	0.654	0.811	<0.001	71.2%	61.0%	1.82	0.47

AUC, area under the curve; WHO, World Health Organization; FRS, Framingham Risk Score; BMI, body mass index.

AUC, area under the curve; WHO, World Health Organization; FRS, Framingham Risk Score; BMI, body mass index.

Figure 1. ROC-curves of cardiovascular risk algorithms



Results: The prevalence of carotid plaque was 35.9%. Mean age was 55.8 ±8.9 years, 156 (95.1%) patients were women, 27 (16.5%) patients had diagnosis of type 2 diabetes mellitus, 53 (32.3%) patients had hypertension, 58 (35.4%) had dyslipidemia, 56 (34.1%) had obesity and 15 (9.1%) were active smokers. The ROC-curve analysis of the algorithms is shown in table 1 and figure 1. All the algorithms tested in this study demonstrated significant discrimination for the presence of carotid plaque, with p-values < 0.001.

Conclusion: Among the various algorithms evaluated, the WHO calculator stood out as one of the most effective tools for detecting carotid plaque, demonstrating superior positive and negative likelihood ratios; however, similar to the other algorithms, a lower cut-off point than the one established by the official guidelines was needed to identify high-risk patients with the presence of CP who were initially classified as low-moderate risk by the CVR algorithm, even though the results were multiplied by 1.5 as established by EULAR recommendations, with the exception of QRISK-3, considering the fact that the disease itself is considered a CVR factor. The utilization of carotid ultrasound remains essential in order to accurately identify high-risk patients and provide them with timely treatment.

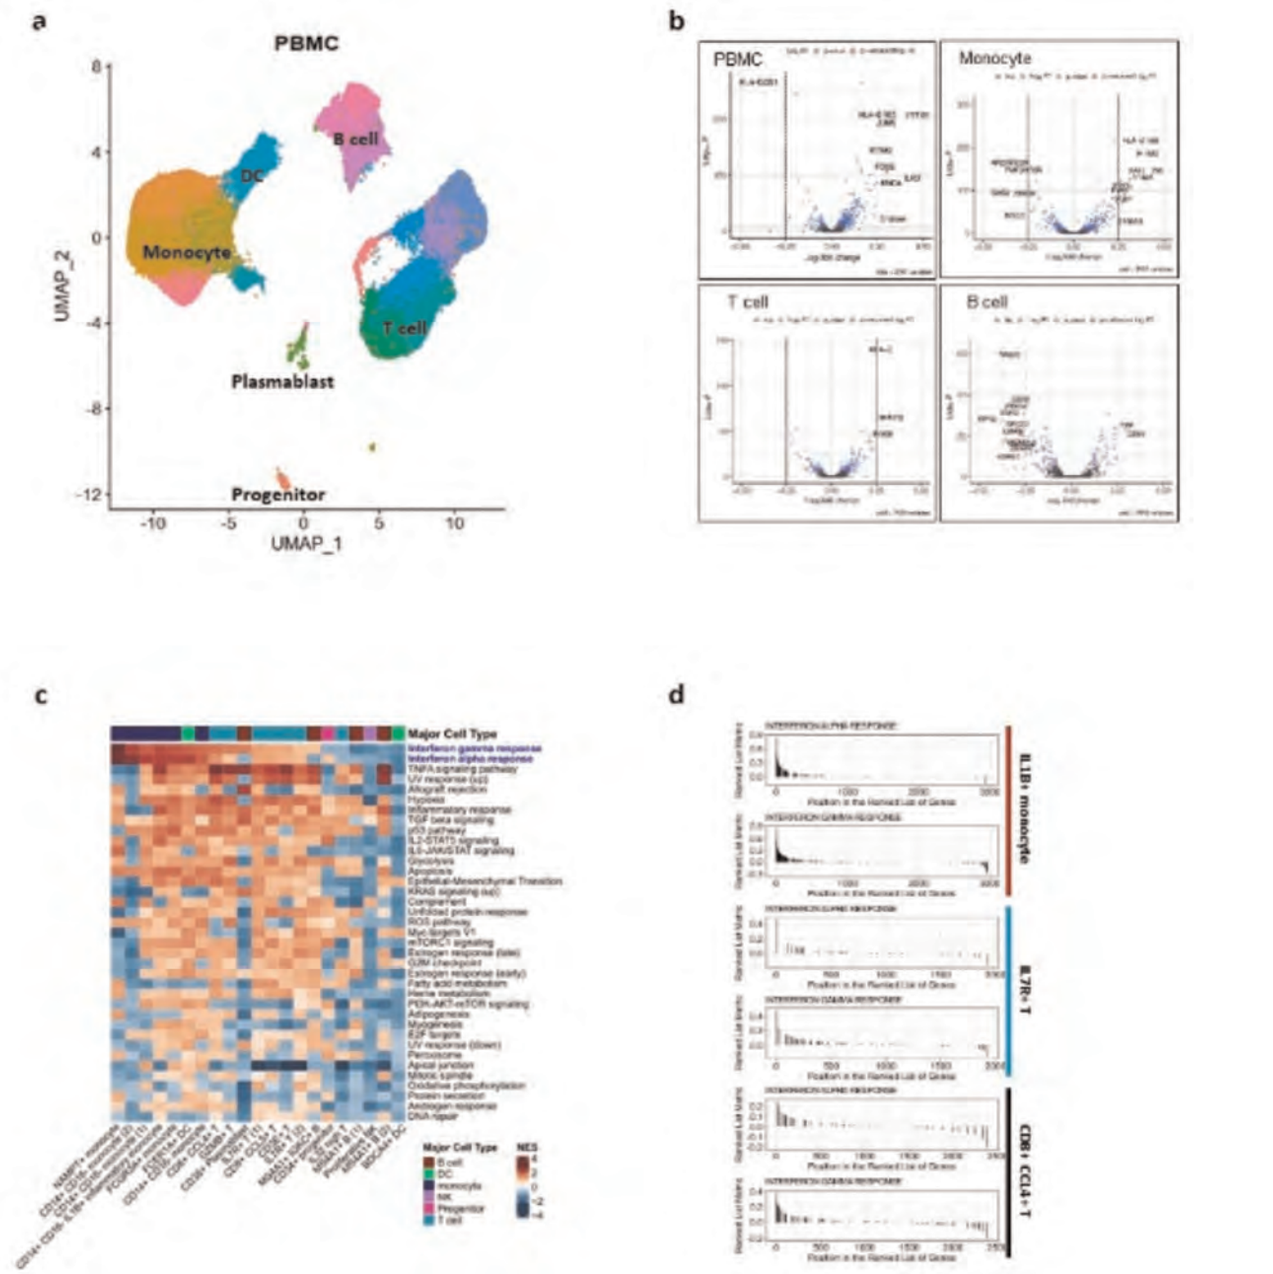
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent research has revealed a significant upregulation of IFNγ-related genes in RA patients, though the underlying mechanisms and implications are still unclear. To further investigate these gene expression alterations, we implemented single-cell RNA sequencing and performed an analysis on the peripheral blood mononuclear cells (PBMCs) of RA patients.

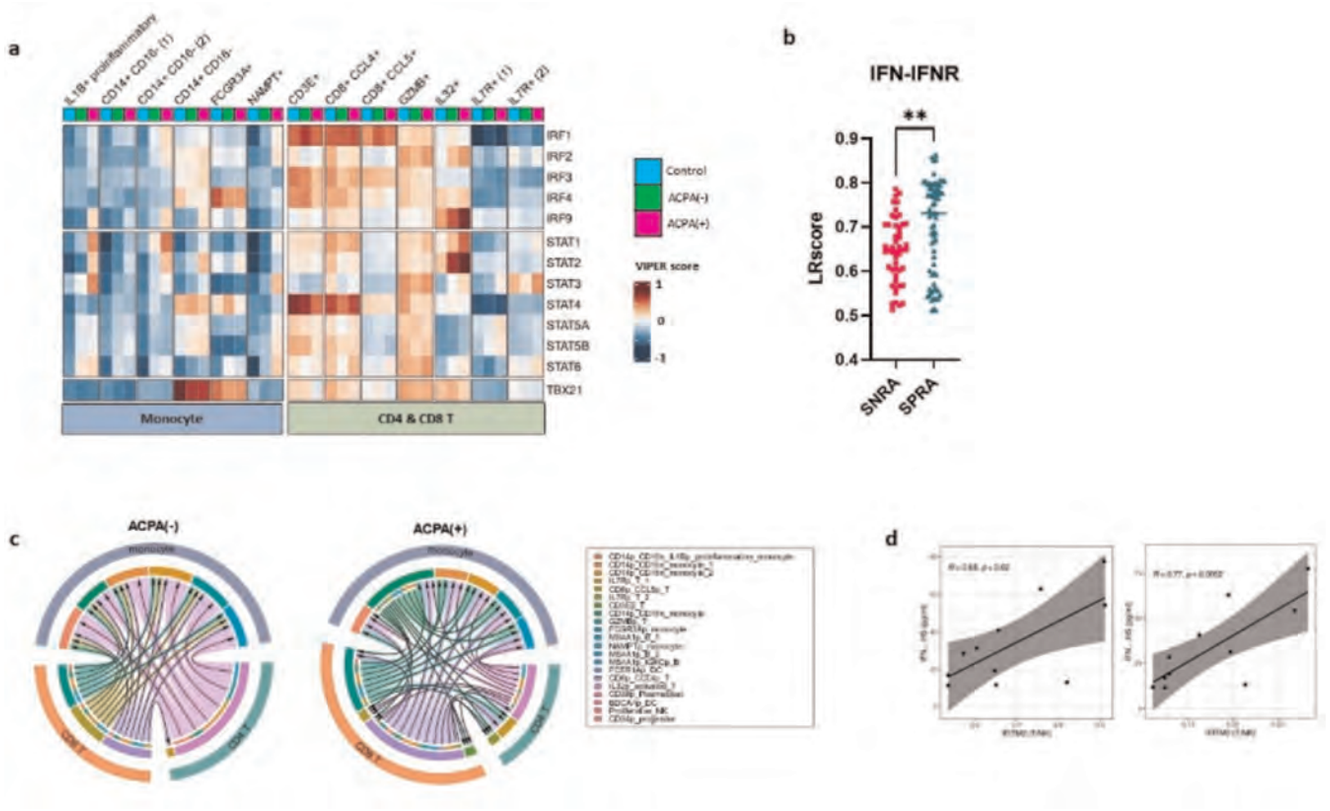
Methods: We executed a single-cell RNA sequencing study on peripheral blood samples from patients with anti-citrullinated protein antibody positive (ACPA+) and negative (ACPA-) RA. Cell subsets were identified, and their distribution and functional characteristics were compared based on ACPA presence.

Results: Our analysis identified 37,318 single cells grouped into 17 different cell types. We observed an expanded proportion of IL1B+ monocytes, IL7R+ T cells, and CD8+ CCL4+ T cells in ACPA+ RA patients. Enrichment analysis scores of interferon-gamma (IFNγ) response genes increased in nearly all monocytes and T cell subsets in ACPA+ RA. These patients exhibited heightened interactions between IFNγ and IFNγ receptors upstream of IFNγ response genes. Cell-cell interaction

was significantly amplified between monocytes and T cells in ACPA+ RA. Additionally, we discovered upregulated IFNγ-driven transcription factors (TFs) such as STATs and IRFs in ACPA+ RA. Major target genes of STATs and IRFs were identified, with IFITM3 and IFITM2 standing out as strongly associated target genes. A significant positive correlation was also found between IFITM2, IFITM3, and elevated serum levels of IFNγ, a signature cytokine of Th1 cells. This finding supports their potential clinical implications in ACPA+ RA.



Landscape of peripheral blood mononuclear cells of patients with RA and differentially expressed gene sets of each cell subset based on Gene Ontology terms (a) t-SNE map based on single-cell RNA-seq data obtained from PBMC of 16 rheumatoid arthritis (RA) patients, with or without anti-CCP antibody, showing 17 different cell types after clustering with 37,318 cells. (b) Volcano plot for PBMC, T, B, and monocyte, comparing ACPA+ vs. ACPA- groups, showing differentially expressed genes obtained by comparison. (c) The heatmap displays the results of gene set enrichment analysis for genes whose expression levels change in ACPA-compared to ACPA+ for 17 cell types. Column annotation of heatmap showing the major cell types (T, B, DC, monocyte, NK, progenitor) indicated for each cell type. (d) The GSEA graph shows the results of IFN-alpha and IFN-gamma response gene sets for three types of subcellular groups that increase in ACPA+ patient groups.



Ligand-receptor score and cell-cell interaction patterns with regard to interplays of IFN and IFN receptor (a) Heatmap representing the activity score of STAT and IRF families predicted to regulate the expression of IFITM2 and IFITM3. (b) The bar graph represents the LR score for IFN-IFNR in the ligand-receptor analysis results. (c) Chord diagram showing the difference in the interaction of IFN-IFNR between monocyte-T cells in ACPA- and ACPA+ groups. The legend on the left side of the diagram represents the subcellular types of monocyte and T cells seen in the second layer of the diagram. (d) Graph showing the correlation between the degree of mRNA expression of IFITM2/3 for each patient and Interferon concentration measured in serum.

Conclusion: Our findings offer novel insights emphasizing the critical role of IFNγ in regulating Th1 skewing in the pathogenesis of ACPA+ RA, as compared to ACPA- RA. The increased interactions between monocytes and T cells and high serum levels of IFNγ, particularly in ACPA+ RA, provide a more comprehensive understanding of the pathogenesis of ACPA+ RA.

Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In August 2021, the CDC recommended a third SARS-CoV-2 mRNA vaccine dose to complete the initial vaccine series for immunosuppressed patients who had previously received 2 mRNA doses. Despite this, some rheumatoid arthritis (RA) patients may remain at increased risk for breakthrough COVID-19 infection, due to use of immunomodulators which lead to blunted immune responses to vaccination and infection. Identifying patients at highest risk for

breakthrough infection despite 3 vaccines can prioritize resources for prevention. Therefore, we investigated the risk of breakthrough COVID-19 among RA patients with at least 3 vaccine doses using disease-modifying antirheumatic drugs (DMARDs), especially TNF inhibitors (TNFi) and CD20 inhibitors (CD20i), during the Omicron wave.

Methods: We performed a retrospective cohort study investigating DMARDs and risk for breakthrough COVID-19 among RA patients who had received 3 mRNA vaccines at a large health care system. A previously validated algorithm was used to identify RA patients using a combination of diagnosis codes and DMARD/glucocorticoid prescription (PPV 90%). COVID-19 was identified systematically from positive PCR tests or patient reports to the hospital/clinic of home rapid antigen tests. Patients were followed from the date of 3rd vaccine (index date) until breakthrough COVID-19, non-COVID death, or end of follow-up (January 18, 2023). A previously defined hierarchical algorithm was used to categorize DMARD exposures. Covariates included demographics, lifestyle, comorbidities, and prior COVID-19. We used Cox proportional hazards models to estimate the risk of COVID-19 among different DMARD users. We then used propensity scores and overlap-weighting to further account for confounding when comparing the risk among users of CD20i vs. TNFi.

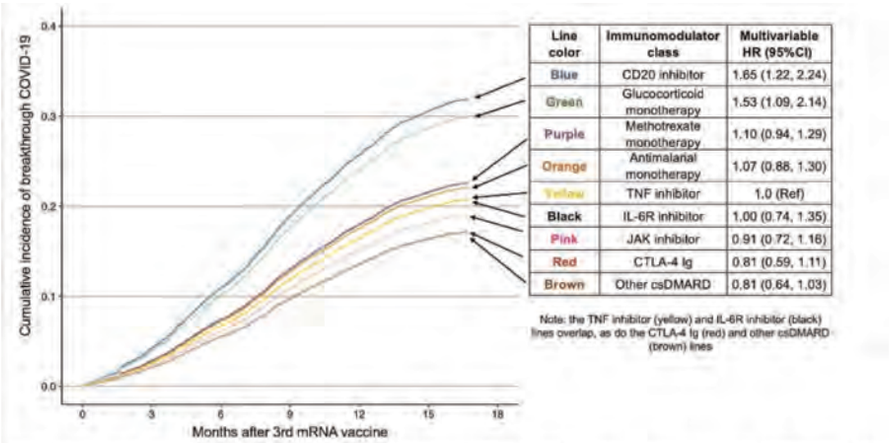

Figure 1. Cumulative incidence and hazard ratio for breakthrough COVID-19 by immunomodulator use at 3rd COVID mRNA vaccine dose.

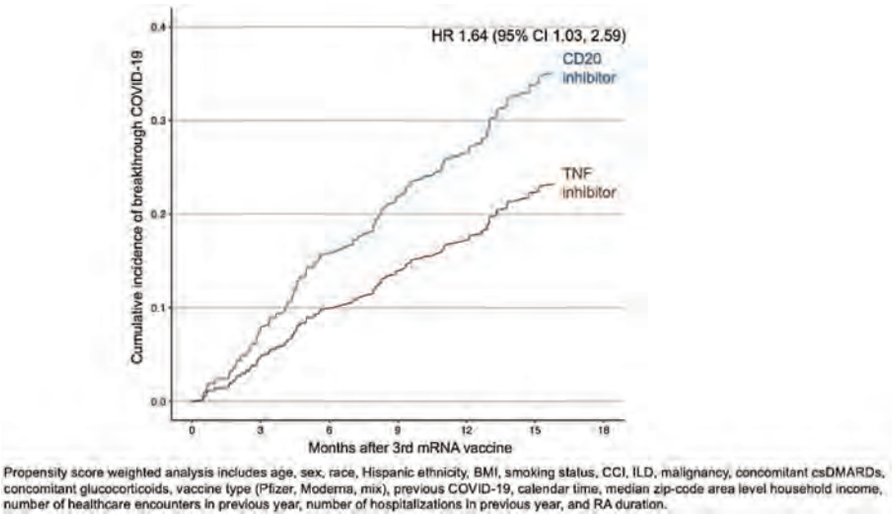

Figure 2. Propensity-score weighted cumulative incidence of COVID-19 after 3rd mRNA vaccine, comparing CD20 inhibitor users vs. TNF inhibitor users.

Results: We identified 5781 patients with RA who used DMARDs/glucocorticoids and received 3 mRNA vaccine doses (78.8% female, mean age 64.2 years). During mean follow up of 12.8 months, 1173 (20.2%) had a SARS-CoV-2 infection (incidence rate 15.7 per 1000 person-months) (**Table 1**). Users of CD20i were more likely than TNFi users to have COVID-19 after the index date (adjusted HR 1.74, 95%CI 1.30-2.33), as were users of steroid monotherapy (adjusted HR 1.47, 95%CI 1.09-1.98) (**Figure 1**). After using propensity scores for overlap weighting to account for baseline differences, CD20i users remained at higher risk for COVID-19 than TNFi users (HR 1.62, 95%CI 1.02-2.56; **Figure 2**). In a sensitivity analysis excluding patients with cancer or interstitial lung disease, the findings were similar.

Conclusion: In this RA-specific study evaluating the impact of DMARD use on the risk of COVID-19 during the Omicron phase of the pandemic, we identified CD20i and steroid monotherapy use as risk factors for breakthrough COVID-19. This contemporary study highlights the excess risk associated with glucocorticoid monotherapy or CD20 inhibitor use for RA treatment and identifies important subgroups for counseling and additional risk mitigation strategies.

Long-term Follow-up of Treated-to-target RA and UA: Results of the BeSt and IMPROVED Studies

Sascha Heckert[1], Johanna Maria Maassen[1], Isabell Nevins[2], F. Fodili[3], Margreet Steup-Beekman[4], Thomas Huizinga[1], Sytske Anne Bergstra[1] and CF Allaart[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leiden University Medical Center, Amsterdam, Netherlands, [3]Stichting ReumaZorg ZWN, Roosendaal, Netherlands, [4]Leiden University Medical Center, Den Haag, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2 trials with an original follow-up of 5-10 years, patients with early arthritis were treated to target, resulting in low disease activity or remission in the majority of patients and limited radiographic progression. We invited former participants for a long-term follow-up ('RECALL') visit.

Methods: In BeSt (inclusion 2000-2002) 508 patients with early RA were randomized to: 1. Sequential DMARD monotherapy; 2. Step-up combination therapy; 3. Initial csDMARD combination therapy with prednisone or 4. Initial combination of MTX + infliximab, and treated-to-target DAS≤2.4 for 10 years. In IMPROVED (inclusion 2007-2010) 610 patients with early RA or UA received induction therapy with MTX + prednisone, with DAS< 1.6 as a treatment target. After 4 months 67% were in DAS remission (early remission). From 2019 to 2022 patients from both trials were invited for follow-up (after 20/12 years respectively). Outcomes were functional ability (HAQ), disease activity (3-component DAS) and radiographic damage (Sharp/Van der Heijde score, SHS, based on hands/feet X-rays of BeSt/IMPROVED at baseline & RECALL study visit, assessed by one reader (intrareader coefficient 0.98)). All outcomes had < 6% missing. In BeSt, SHS was compared

CRP, mean (SD)	18.8 (23.5)	23.0 (32.4)
Health Assessment Questionnaire, mean (SD)	1.1 (0.6)	1.4 (0.7)
ACPA positive, %	66	48
RF positive, %	64	54
SHS, mean (SD)	1.9 (3.0)	2.1 (3.3)

IMPROVED baseline characteristics of RECALL participants

baseline. Compared to the other arms, SHS was lower in arm 4 (median SHS (IQR) 17 (8-58) in arm 1, 14 (3-28) in arm 2, 22 (7-42) in arm 3 and 9 (3-27) in arm 4). After adjusting for baseline differences this difference was statistically significant for arms 1 (p=0.02) and 3 (p=0.01), but not for arm 2 (p=0.16). 54% (282/523) of alive IMPROVED patients participated (table 2). Their mean age at IMPROVED baseline was 49±12 years (non-participants/deceased: 55±15 years). At 12-year follow-up, median HAQ was 0.50, IQR 0-1.0; 0.56±0.7 lower than at baseline. Mean DAS was 1.4±0.7, with 255/279 (91%) of patients with DAS≤2.4 and 189/279 (68%) in DAS remission. Overall median SHS was 8 (IQR 3-16) with a median SHS progression since baseline of 6 (IQR 3-13). Median SHS (IQR) was 10 (IQR 4-17) in the early remission group vs 6 (IQR 2-15) in patients that had not been in early remission. There was no statistically significant difference after adjusting for possible confounders (p=0.28).

Conclusion: 91% of patients who attended long term follow-up of BeSt/IMPROVED after respectively 20 and 12 years were in remission or low disease activity, with a median HAQ of 0.75/0.50 and clinically significant SHS progression of median 11/6 points.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Direct functionality of the hand is not commonly assessed in daily practice or clinical trials in patients with rheumatoid arthritis (RA). Functional dexterity test (FDT), developed to assess a patient's ability to use the hand for daily tasks and widely used in rehabilitation medicine, has also been suggested as a legitimate tool for RA patients [Aaron et al, J Hand Ther. 2003]. *Aim:* To examine the value of FDT in a cohort of RA patients and to study the correlation between the results of FDT and RA activity.

Methods: Patients with established RA were followed in the outpatient clinic of Bnai Zion Medical Center performed the FDT during their regular follow-up visits. All patients were given 100 seconds (sec) to complete the test; the performance was measured in seconds separately for the dominant and non-dominant hands. FDT results were compared among 28 patients with active RA and clinical disease activity index(CDAI) greater than 10, 20 RA patients with controlled disease activity (CDAI of less than or equal to 10), and 20 volunteers with no rheumatic disease from the hospital personnel who agreed to perform the FDT.

Table 1. Corresponding FDT results for the dominant and non-dominant hand

	FDT dominant hand mean (range) in *sec* and comparison with control group, p value		FDT non-dominant hand mean (range) in *sec* and comparison with control group, p value	
RA, CDAI>10	43 (24-100)	0.0001	50 (22-100)	0.0001
RA, CDAI≤ 10	35 (27-70)	0.001	38 (24-68)	0.013
Control group	25 (20-40)		29 (22-45)	
Normal FDT	Up to 25		Up to 27	

Results: A group of patients with active RA was younger than other groups, with a median age of 56 years (range 30-88 years) vs. 65 years (range 41-78 years) in the controlled RA group vs. 62 years (range 40-82 years) in the control group, $p < 0.03$. The mean disease duration was 11 years (range 3-26 years) in the active disease group and 11 years (range 1-47 years) in the controlled RA group, p=0.97. The gender composition of the groups was similar, with female patients comprising 70% to 82% (p=0.67). All 28 RA patients with CDAI >10 and 16 of 20 patients with CDAI< or equal to 10 were treated with biologics (p=0.02). Mean FDT for the dominant hand was 43 sec (range 24-100 sec) in the active RA group, 35 sec (range 27-70 sec) in the controlled RA group, and 25 sec (range 20-40 sec) in persons without arthritis. Corresponding FDT results for the non-dominant hand were 50 sec (range 22-100 sec), 38 sec (range 24-68 sec), and 29 sec (22-45 sec), respectively (Table 1). The difference in the FDT results between the two RA groups was non-significant for the dominant hand (p=0.28) but reached statistical significance for the non-dominant hand (p=0.02). Individuals without arthritis performed FDT either by dominant or non-dominant hand significantly better than any RA group (p values from 0.013 to 0.0001). FDT results significantly correlated with CDAI in the group of active RA only, with R=0.47/p=0.01 for the dominant hand and R=0.49/p=0.007 for the non-dominant hand vs. R=0.29/p=0.2, and R=0.4/p=0.08, respectively, in the controlled RA group. Minimally or non-functioning dominant hand, as predefined by FDT, was observed in 17 of 28 patients with active RA (61%), 11 of 20 patients (55%) with controlled disease, and 3 of 20 (15%) volunteers with no rheumatic disease.

Conclusion: FDT revealed a significant decrease in hand function in most RA patients. In patients with high or moderate RA activity, FDT correlated well with CDAI scores, while this correlation was lost in the group of patients with low disease activity or remission, where 55% of patients still demonstrated a significant loss in the dominant hand function.

Abstract Number: 1275

Prevalence of Frailty Among Individuals Living with Rheumatoid Arthritis: A Population-based Cohort Study

Alexandra Legge[1] and Diane Lacaille[2], [1]Dalhousie University, Halifax, NS, Canada, [2]Arthritis Research Canada, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies have demonstrated a link between frailty and chronic inflammation, raising the question of whether chronic inflammatory diseases like rheumatoid arthritis (RA) may be associated with increased rates of frailty. Our objective was to evaluate the prevalence of frailty among individuals living with RA compared to the general population without RA.

Methods: We conducted a population-based cohort study using administrative health data for a Canadian province from 1990 - 2018. A previously validated case definition based on physician billing data was used to assemble an incident cohort of all cases with RA onset from 1996 - 2008. To capture the health state of individuals living with RA, the baseline date was defined as 5 years after the index date for RA diagnosis. A random sample of 50% of incident RA cases was included in this analysis, none of which were used for the derivation of our frailty measure. Each RA individual was matched 2:1 by sex, birth year, and index year with randomly selected individuals from the general population with no physician visits for any type of inflammatory arthritis. For controls, the index date was defined as the date of a randomly selected health care encounter occurring in the same calendar year as the index year of the RA case to which they were matched, and the baseline date was defined as 5 years after this index date. Frailty was measured using a frailty index (FI), which we previously developed using a combination of data-driven and consensus-based methods. The FI includes 40 health deficits, the presence of which was evaluated using administrative health data for the 3 years prior to the baseline date. Each deficit was scored from 0 (absent) to 1 (present) and individual deficit scores were summed and divided by the total number of deficits to produce a baseline FI score for each individual. Frailty was defined as a baseline FI score > 0.21. We compared the prevalence of frailty among RA patients and non-RA controls using conditional logistic regression. The number of health deficits present was compared between RA patients and non-RA controls using negative binomial regression. Multivariable models were stratified by age, sex, and calendar year, and were adjusted for rurality, socioeconomic status, and baseline scores for the Romano version of the Charlson comorbidity index (CCI).

Table 1. Baseline characteristics of individuals living with rheumatoid arthritis (RA cases) versus age- and sex-matched individuals without inflammatory arthritis (non-RA controls).

Table 1. Baseline characteristics of individuals living with rheumatoid arthritis (RA cases) versus age- and sex-matched individuals without inflammatory arthritis (non-RA controls).

	RA cases n=13367	Non-RA controls n=26734
Age at baseline (years), mean (SD)	60.2 (14.4)	60.2 (14.4)
Female, n (%)	9213 (68.9%)	18420 (68.9%)
Rurality		
Urban, n (%)	11064 (82.8%)	23275 (87.1%)
Rural, n (%)	2303 (17.2%)	3458 (12.9%)
Neighbourhood income quintile		
Lowest 20%, n (%)	2878 (21.5%)	4882 (18.3%)
20-40%, n (%)	2667 (20.0%)	5104 (19.1%)
40-60%, n (%)	2922 (21.9%)	5755 (21.5%)
60-80%, n (%)	2541 (19.0%)	5411 (20.2%)
Highest 20%, n (%)	2359 (17.6%)	5582 (20.9%)
Baseline Romano CCI [a]		
Mean (SD) score	0.83 (1.60)	0.65 (1.43)
Median (IQR) score	0 (0-1)	0 (0-1)
Score ≥ 1, n (%)	4933 (36.9%)	8003 (29.9%)
Baseline frailty index (FI) [a]		
Mean (SD) score	0.078 (0.070)	0.053 (0.058)
Median (IQR) score	0.0625 (0.025-0.1125)	0.0375 (0.0125-0.075)
Frail (FI > 0.21), n (%)	744 (5.6%)	703 (2.6%)

[a] Calculated using administrative health data for the 3-year assessment period prior to the baseline date.
SD = standard deviation; IQR = interquartile range; CCI = Charlson comorbidity index.

Table 2. Conditional logistic regression models for frailty status among individuals with rheumatoid arthritis (RA cases; n=13367) versus matched individuals without inflammatory arthritis (non-RA controls; n=26734).

Table 2. Conditional logistic regression models for frailty status among individuals with rheumatoid arthritis (RA cases; n=13367) versus matched individuals without inflammatory arthritis (non-RA controls; n=26734).

	Odds ratio (95% CI)
Model 1: Unadjusted	
RA cases (versus non-RA controls)	2.29 (2.05 – 2.56)
Model 2: Adjusted for rurality, neighbourhood income quintile	
RA cases (versus non-RA controls)	2.27 (2.04 – 2.54)
Model 3: Adjusted for rurality, neighbourhood income quintile, baseline CCI score	
RA cases (versus non-RA controls)	2.30 (2.03 – 2.60)

Frailty defined as a baseline frailty index (FI) score > 0.21, calculated using administrative health data for the 3 years prior to the baseline date.
All models stratified by the matching variables (birth year, sex, and year of index date).
CCI = Charlson comorbidity index; CI = confidence interval.

Table 3. Negative binomial regression models for the number of health deficits present at baseline among individuals with rheumatoid arthritis (RA cases; n=13367) versus matched individuals without inflammatory arthritis (non-RA controls; n=26734).

Table 3. Negative binomial regression models for the number of health deficits[a] present at baseline among individuals with rheumatoid arthritis (RA cases; n=13367) versus matched individuals without inflammatory arthritis (non-RA controls; n=26734).

	Rate Ratio (95% CI)
Model 1: Unadjusted	
RA cases (versus non-RA controls)	1.52 (1.49 – 1.55)
Model 2: Adjusted for rurality, neighbourhood income quintile	
RA cases (versus non-RA controls)	1.51 (1.48 – 1.54)
Model 3: Adjusted for rurality, neighbourhood income quintile, baseline CCI score	
RA cases (versus non-RA controls)	1.47 (1.44 – 1.50)

[a] Based on 40 health deficits included in the frailty index (FI), evaluated using administrative health data for the 3 years prior to the baseline date.
All models stratified by the matching variables (birth year, sex, and year of index date).
CCI = Charlson comorbidity index; CI = confidence interval.

Results: Baseline characteristics for RA patients (n=13367) and non-RA controls (n=26734) are shown in **Table 1**. Baseline FI scores were significantly higher among RA patients compared to non-RA controls and a greater proportion of RA patients were considered frail at baseline **(Table 1)**. The odds of frailty were significantly higher among RA patients compared to non-RA controls, and this relationship was unchanged following adjustment for potential confounders **(Table 2)**. Similar results were obtained for the number of health deficits present at baseline **(Table 3)**.

Conclusion: Frailty is significantly more common among individuals living with RA when compared to age- and sex-matched individuals without inflammatory arthritis. Future work will aim to better understand the reasons for these differences and identify strategies to prevent and treat frailty in RA.

Multimorbidity Burden Predicts Lower Likelihood of Remission in Patients with Rheumatoid Arthritis

Cynthia Crowson, Chanakya Kodishala, Tina Gunderson, Atkinson Elizabeth, Vanessa Kronzer, John Davis, Courtney Arment, Delamo Bekele, Thomas Mason, Lynne Peterson, Kerry Wright and Elena Myasoedova, Mayo Clinic, Rochester, MN

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Seropositivity has historically been associated with poor disease outcomes in patients with rheumatoid arthritis (RA). Seronegative RA is on the rise and is associated with higher rates of multimorbidity (i.e., 2 or more chronic conditions). However, little is known about the association between multimorbidity and RA disease activity. We aimed to assess the association between multimorbidity and RA disease flares and remission.

Methods: This retrospective, population-based study included residents of a geographically well-defined area with incident RA in 1999-2014 who fulfilled 1987 ACR criteria for RA. Flare/remission were defined using OMERACT definitions and were manually abstracted from medical records. Flare was defined as a worsening of disease requiring initiation, change, or escalation of therapy or documentation of 'flare up' or 'active' disease. Remission was defined as an absence of disease activity (e.g., 'remission', 'quiescent', 'no activity') and/or based on ≤1 tender/swollen joints and normal inflammatory markers. Multimorbidity at RA incidence was defined using 55 chronic conditions published previously and was categorized as MM2+ (2 or more comorbidities) or MM5+ (5 or more comorbidities). Binomial mixed models with random effects accounting for multiple visits per patient adjusted for age, sex, RA duration, seropositivity, incidence year, and smoking status were used to assess the association between flare/remission and multimorbidity.

Results: The study included 625 patients with RA (mean age 55.5 years, 70% female, 88% white, 68% seropositive, 47% current/former smokers, 40% obese). Among 7841 visits over a mean follow-up of 8.7 (SD 4.3) years, 2793 were in flare (36%) and 1929 (25%) were in remission. Multimorbidity was modestly associated with flare, but these associations did not reach statistical significance (MM2+: OR 1.22;95% CI: 0.97-1.53, p=0.08; MM5+: OR 1.16; 95%CI 0.94-1.44, p=0.16). Multimorbidity was significantly associated with decreased odds of remission for both MM2+ (OR 0.63; 95%CI 0.46-0.87, p=0.0048) and MM5+ (OR 0.64 [95%CI 0.48-0.87, p=0.0046). Seropositivity was not significantly associated with flare (OR 1.13; 95%CI 0.93-1.40; p=0.21) or remission (OR 1.00; 95%CI 0.75-1.34, p=0.99). Male sex, longer RA duration, and increased age were associated with significantly greater odds of remission and smoking at baseline was associated with significantly decreased odds of remission. RA duration, increased age, and increased year of RA index were associated with significantly lower odds of flare and current smoking with significantly increased odds of flare.

Conclusion: Patients with RA and multimorbidity were less likely to achieve remission. Multimorbidity was a stronger predictor of poor prognosis than seropositivity. These results underscore the importance of considering multimorbidity and not just seropositivity when assessing prognosis for patients with RA. Further research is needed to elucidate the underlying mechanisms of these associations (e.g., whether certain morbidities are associated with poor prognosis, or the impact of patient complexity on adherence or other issues are playing a role).

Relationship Between Quality of Life and the Region of the Affected Joints in Japanese Patients with Rheumatoid Arthritis: A Cross-sectional Study

Kenichiro Tokunaga[1], Takahiro Nishino[2], Hideto Oshikawa[1], Toshihiro Matsui[3] and Shigeto Tohma[4], [1]Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan, [2]National Hospital Organization Sagamihara National Hospital, Kanagawa, Japan, [3]NHO Sagamihara National Hospital, Kanagawa, Japan, [4]NHO Tokyo National Hospital, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: This clinical study aimed to investigate the relationship between affected joints and the quality of life (QOL) in patients with rheumatoid arthritis (RA) in Japan.

Methods: We analyzed data from 15,553 RA patients registered in the NinJa database in 2020 to investigate the relationship between affected joints and the quality of life (QOL). QOL was assessed using the EuroQol 5-Dimensions (EQ-5D) questionnaire. Patients for whom EQ-5D data were acquired were included in this study. The affected joints, based on a 68-joint count, were categorized into four regions: upper/large, upper/small, lower/large, and lower/small. The presence or absence of swelling or tenderness in the joints within each region was evaluated as a binary variable. We performed multivariable regression analysis with EQ-5D scores as the dependent variable. The independent variables included demographic factors (age, sex), disease duration, pain visual analogue scale (pain VAS), C-reactive protein (CRP) levels, positivity of rheumatoid factor (RF) and anti-citrullinated peptide antibody (ACPA), scores from the hospital anxiety and depression scale (HADS-A and HADS-D), modified health assessment questionnaire (mHAQ), Steinbrocker's stage, and the presence/absence of swelling or tenderness in the affected joints within each region.

Results: The study included 11,709 RA patients, with a mean age of 67.0 years (SD = 12.9), and 79.2% were women. The mean disease duration was 14.0 years (SD = 11.2). (Table 1) After adjusting for covariates, the activity of upper/large joints region (β = -0.02, 95% CI: -0.02 to -0.01, $p < 0.01$), lower/large (β = -0.03, 95% CI: -0.04 to -0.02, $p < 0.01$), 65 to 74 years old (β = -0.03, 95% CI: -0.05 to -0.00, $p = 0.02$), 75 years old or older (β = -0.05, 95% CI: -0.07 to -0.03, $p < 0.01$), women sex (β = -0.01, 95% CI: -0.02 to -0.00, $p < 0.01$), pain VAS (β = -0.02, 95% CI: -0.02 to -0.02), CRP (β = -0.01, 95% CI: -0.01 to -0.00, $p < 0.01$), HADS-A (β = -0.01, 95% CI: -0.01 to -0.01, $p < 0.01$), HADS-D (β = -0.01, 95% CI: -0.01 to -0.00, $p < 0.01$), and mHAQ (β = -0.15, 95% CI: -0.16 to -0.14, $p < 0.01$) were found to be significantly associated with lower EQ-5D scores, indicating worse QOL. (Table 2)

Conclusion: In this study, we found significant associations between various factors and QOL of RA patients in Japan. Specifically, among the demographic factors, being aged 65 or older and female, along with higher scores on pain VAS, elevated CRP levels, increased scores on HADS-A and HADS-D, and higher mHAQ scores were all associated with decreased EQ-5D scores, indicating lower QOL. Furthermore, we observed that the presence of swelling or tenderness in the affected joints within both the upper and lower extremities, particularly in the large joints, was significantly associated with lower EQ-5D scores. By considering these factors and the specific joint distribution, healthcare professionals can tailor interventions and treatment strategies to improve the QOL of RA patients, focusing on mitigating pain, reducing inflammation, and addressing functional limitations associated with affected joints.

Nature and Severity of Activity Limitations According to the Health Assessment Questionnaire Disability Index in Patients with Rheumatoid Arthritis and Functional Disability

Manja van Wissen[1], Maaike gademan[1], Cornelia van den Ende[2], Max Teuwen[1], Wilfred Peter[1], Dirkjan van Schaardenburg[3], Alfons den Broeder[2], Thea Vliet Vlieland[4] and Salima van Weely[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Sint Maartenskliniek, Nijmegen, Netherlands, [3]Reade, Amsterdam, Netherlands, [4]Leids University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Not withstanding modern treatment, some Rheumatoid Arthritis (RA) patients have severe disability due to persistently high disease activity, joint destruction/deformities and/or comorbidities. Insight into the severity and nature of their functional limitations is important to treat this subgroup adequately. The aim of this research was to describe the severity and nature of functional limitations in RA patients with severe functional limitations, according to the Health Assessment Questionnaire Disability Index (HAQ-DI).

Methods: Baseline data from RA patients with severe functional limitations participating in a randomized controlled trial on the (cost-)effectiveness of longstanding physical therapy compared to usual care were used (Netherlands Trial Register NL8238). Participants completed the HAQ-DI, a questionnaire reflecting problems in activities of daily living and consisting of 20 items divided over eight domains (Dressing and grooming, Arising, Eating, Walking, Personal hygiene, Reaching, Gripping and Usual activities). Each item is scored on a 4-point scale (0-3, no difficulty-unable to perform), with the total HAQ-DI score ranging from 0-3 (no disability-severe disability). Demographic characteristics were administered and the EuroQol 5-Dimensions 5-Levels (EQ-5D-5L, index score (-0.446-1.000), and Visual Analogue Scale (EQ-VAS, 0-100)) were used to estimate health-related quality of life.

Results: 215 participants were included (n=194; 90% women, age 58.8 (SD 12.9) years, median disease duration 19 (IQR 9-27) years). The median EQ-5D-5L index and EQ-VAS were 0.6 (0.3-0.7) and 59 (41 -70). The median total HAQ-DI score was 1.5 (1.1-1.9) and the majority (83%, n=179) had a total HAQ-DI score ≥1, indicating moderate to severe functional limitations. Figure 1 shows the mean HAQ-DI scores per domain and the percentage of patients reporting no/some/much difficulty or inability to perform daily activities within each domain. More than half of the participants had a domain score ≥1 in all 8 domains (52%, n=111), 24% (n=52) in 7 domains, 13% (n=28) in 6 domains and 11% (n=24) in 5 or less domains. The domains Personal hygiene and Reaching had the highest percentage of participants with a maximum score of 3 (42% and 28%).

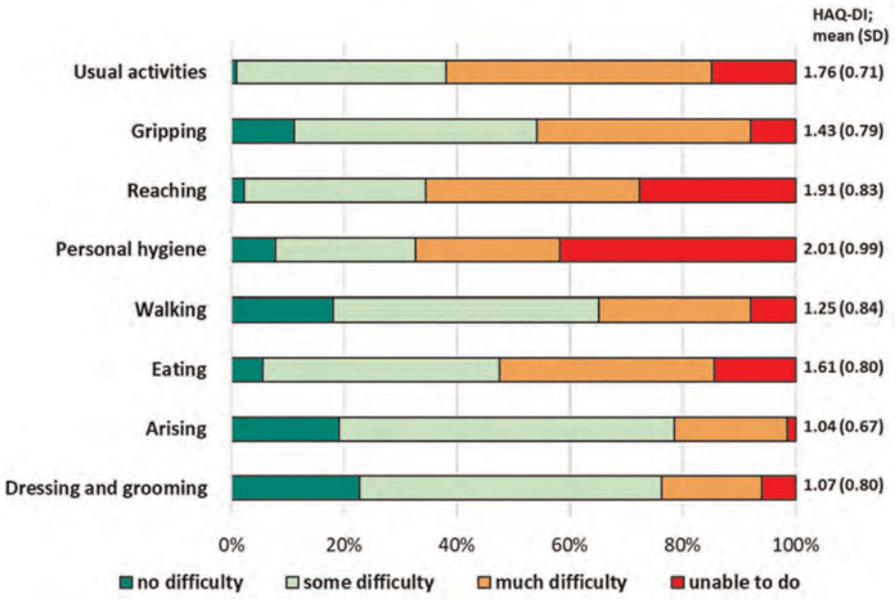

Figure 1. Mean HAQ-DI scores for each HAQ-DI domain and the percentage of patients that reported to have either no/some/much difficulty or unable to perform everyday activities represented for each domain.

Funding: This project is financially supported by the Netherlands Organization for Health Research and Development (ZonMw; 852004018), Ministry of Health, Welfare and Sport (Ministerie van Volksgezondheid, Welzijn en Sport), the Royal Dutch Society for Physical Therapy (KNGF) and the Dutch Arthritis Society (ReumaNederland).

Conclusion: In this subgroup of RA patients with severe functional limitations, the majority had limitations in almost all domains of the HAQ-DI. Mostly, limitations were seen in Personal hygiene and Reaching. In clinical practice, a comprehensive assessment of all areas of daily activities might thus be warranted, as well as shared decision-making between patients and clinicians to prioritize functional limitations and set personalized treatment goals.

What Is the Nature of Functional Problems in People with Rheumatoid Arthritis and Severe Disability; An Analysis Using the International Classification of Functioning, Disability and Health as a Reference

Max Teuwen[1], Salima van Weely[1], Thea Vliet Vlieland[2], Thom Douw[3], Manja van Wissen[1], Alfons den Broeder[4], Dirkjan van Schaardenburg[5], Cornelia van den Ende[4] and Maaike gademan[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leids University Medical Center, Leiden, Netherlands, [3]Leiden University of Applied Sciences, Leiden, Netherlands, [4]Sint Maartenskliniek, Nijmegen, Netherlands, [5]Reade, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a lack of knowledge about the limitations in activities and participation experienced by a subgroup of people with rheumatoid arthritis (RA) and severe functional disability, such as those with difficult-to-treat RA. More insight is essential to optimize their treatment, in particular non-pharmacological care, of which exercise therapy is an essential element. The International Classification of Functioning, Disability and Health (ICF) offers a common framework to classify functional limitations. Therefore, the aim of the study was to describe limitations in activities and participation of people with RA with severe functional disability using the ICF as a reference.

Methods: Baseline data from n=206 people with RA and severe disability, participating in an exercise trial were used. In that trial, the Patient Specific Complaint (PSC) was used as an instrument to identify and quantify limitations in activities and participation. For each participant, the three most limited activities as derived from the PSC were linked to the ICF. Two researchers independently identified meaningful concepts within each PSC activity and linked them to the most specific ICF category within the "Activities and Participation" component, following standardized linking rules. The frequencies of ICF categories were calculated and compared with activities and participation elements of the Comprehensive and Brief ICF Core Sets for RA.

Results: Of 206 RA patients (90.8% female, 58.7 (12.9) years of age, 1.5 (0.5) HAQ-DI score), 618 PSC activities were linked to 909 (72 unique) ICF categories. Taking into account all three activities, the five most prevalent ICF categories concerned the ICF domain Mobility (d4) and included d4501 walking long distances (n=121/909; 13.3%); d4502 walking on different

Table 1. Frequencies and nature of most prevalent limitations within the ICF component activities and participation of people with RA and severe disability (n=909 ICF categories)

Total of 3 PSC activities	N (%)	PSC activity 1	N (%)	PSC activity 2	N (%)	PSC activity 3	N (%)
d4501 walking long distances	121 (13.3)	d4501 walking long distances	75 (23.7)	d4501 walking long distances	28 (9.5)	d4103 changing basic body position from sitting	28 (9.4)
d4502 walking on different surfaces	79 (8.7)	d4502 walking on different surfaces	47 (14.9)	d451 stair climbing	25 (8.5)	d451 stair climbing	27 (9.0)
d451 stair climbing	62 (6.8)	d4500 walking short distances	33 (10.4)	d4103 changing basic body position from sitting	20 (6.8)	d4402 manipulating	20 (6.7)
d4103 changing basic body position from sitting	60 (6.6)	d4401 grasping	14 (4.4)	d4750 driving human-powered transportation	19 (6.4)	d4401 grasping	19 (6.4)
d4401 grasping	51 (5.6)	d4103 changing basic body position from sitting	12 (3.8)	d4401 grasping	18 (6.1)	d4501 walking long distances	18 (6.0)

PSC: Patient specific complaints

Funding

This project is financially supported by the Netherlands Organization for Health Research and Development (ZonMw; 852004018), Ministry of Health, Welfare and Sport (Ministerie van Volksgezondheid, Welzijn en Sport), the Royal Dutch Society for Physical Therapy (KNGF) and the Dutch Arthritis Society (ReumaNederland).

surfaces (n=79/909; 8.7%); d451 stair climbing (n=62/909; 6.8%); d4103 changing basic body position from sitting (n=60/909; 6.6%); and d4401 grasping (n=51/909, 5.6%) (Table 1). Considering the top-5 of the three individual PSC activities, three additional ICF categories (driving human-powered transportation, manipulating, walking short distances) were found to be relatively frequent. All of the most frequent ICF categories were included in the ICF RA Core Sets, except for stair climbing.

Conclusion: Most limitations of patients with RA with severe disability were seen in the ICF domain Mobility. Except for stair climbing, most of the identified ICF categories were covered by the related sections of the ICF RA Core sets. Clinicians should thus be aware that some relatively common problems in selected groups of RA patients may not be included in the Core Sets.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of aortic stenosis is increased in people with RA and valvular heart disease (VHD) is among the most over-represented causes of cardiovascular death in RA. Thus, VHD is an under-appreciated extra-articular manifestation in RA, whose risk factors in RA are largely unknown. Because aortic and mitral valve disease comprise the majority of the VHD burden in the U.S., we examined the associations of RA-related clinical variables with the risk of incident aortic and mitral valve disease in a large cohort of U.S. Veterans with RA.

Methods: We studied participants in the Veterans Affairs RA (VARA) registry, a multicenter, prospective cohort of U.S. Veterans with RA. Using diagnostic and procedural codes in linked VA, Medicare, and National Death Index data, a composite VHD outcome was defined as the development of aortic stenosis or insufficiency, non-rheumatic mitral stenosis, mitral insufficiency, aortic or mitral valve procedural intervention, or death related to aortic or mitral valve disease. Participants who experienced the VHD outcome prior to enrollment were excluded. Included participants were followed from registry enrollment to the first of the composite outcome, death, or end of study period (12/2020). RA disease activity was assessed using DAS28-CRP (DAS28-ESR if missing) and CDAI. From banked serum at enrollment, rheumatoid factor, anti-CCP, and hsCRP concentrations were measured using nephelometry or ELISA. We examined the association of these RA-related clinical variables with VHD risk in multivariable Cox regression models, adjusting for demographics, BMI, smoking status, hypertension, diabetes, coronary artery disease, and medication (methotrexate, hydroxychloroquine, TNFi, prednisone, statin) use at baseline.

Results: Among 2,848 eligible participants (mean age 71.6 years, 88% male, mean DAS28 3.8), we observed 128 composite VHD events over a mean follow up of 6.7 years (IR 6.67 [5.61-7.93] per 1000 person years). The incidence of aortic (IR 3.72 [2.95-4.68]) and mitral disease (IR 3.25 [2.54-4.16]) were similar. After multivariable adjustment, hsCRP concentration was significantly associated with incident VHD (**Table 1;** aHR 1.21 [1.02-1.43] per log unit increase; aHR 1.88 [1.10-3.23] for highest hsCRP quartile). Non-significant trends toward elevated VHD risk were observed in those who were RF (aHR 1.26 [0.78-2.03]) or anti-CCP positive (aHR 1.27 [0.80-2.03]), whereas higher autoantibody concentrations were not associated with VHD (**Table 2**). Referent to participants in DAS28 remission, those with higher DAS28 categories demonstrated trends toward higher VHD risk. DAS28 and CDAI scores, as well as high CDAI disease activity, similarly demonstrated non-significant trends with VHD risk.

*Adjusted hazard ratios (aHR) estimated in multivariable Cox regression models adjusting for age, sex, race, body mass index, smoking status, hypertension, diabetes, coronary artery disease, DAS28, and medications (methotrexate, hydroxychloroquine, TNFi, prednisone, statins) at enrollment. **Distribution of autoantibody concentrations skewed, thus were log-transformed prior to analysis Abbreviations: CCP, cyclic citrullinated peptide; CI, confidence interval; IU, international unit; mL, milliliter; ULN, upper limit of normal.	

Conclusion: In this prospective RA cohort, baseline systemic inflammation as assessed by hsCRP was associated with a higher risk of incident VHD. Composite clinical RA disease activity measures were not significantly associated with incident VHD, though estimates were imprecise and only baseline disease activity measures were evaluated. Continued study is warranted to identify mediators that drive VHD risk in RA.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Our study aimed to estimate the incidence and risk factors of cancer among rheumatoid arthritis (RA) patients treated with tocilizumab (TCZ) and followed for five years in the French registry (REGATE), which assessed the effectiveness and safety of TCZ.

Methods: We specifically focused on solid cancers, hematological malignancies, and skin cancers including non melanoma skin cancers (NMSC). To collect these data, we developed a pre-defined data collection form and distributed it to participating centers that reported malignancies in REGATE. To identify potential risk factors associated with cancer, we performed a univariate analysis and a multivariate analysis using logistic regression analysis.

Results: Our study included 1496 patients with RA who were treated with TCZ for a mean duration of 32.0 (±22.0) months and followed for an average of 47 (±15.2) months, resulting in a total exposure of 3990.9 patient-years (PY). Of these patients, 63 (4.2%) were diagnosed with a total of 75 cancers during the follow-up period (35 solid neoplasms, 11 hematological malignancies, 3 melanomas, and 26 NMSC). The overall incidence of cancer excluding NMSC was 8.3 /1000 PY, which was calculated after excluding patients who developed cancer more than 90 days after the last TCZ administration Our multivariate analysis revealed that high age (OR=1.06 [1.03-1.09], p=0.001) and smoking exposure (OR=2.80 [1.38-5.68], p=0.004) were independent risk factors for the group of cancers excluding NMSC.

Conclusion: Our study identified an incidence of cancer comparable to that observed in RA patients treated with other bDMARD and no other risk factor than those known in the general population

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) related lung manifestations have a significantly impact the morbidity and mortality. Male gender and RF/ACPA positivity are known risk factors but so far, no specific biomarkers, which could predict the future development of lung involvement in RA have been identified. We aimed to explore if proteome signature in peripheral blood and sputum differs in RA patients with and without lung involvement and if possible, biomarkers for RA-related lung disease could be identified.

Methods: Peripheral blood and sputum samples were obtained from RA patients with (n=33, 73% female, mean age 68 years, 94% ACPA positive) and without (n=7,100% female, mean age 69 years, 86% ACPA positive) pulmonary manifestations in a single-centre explorative and cross-sectional study. A simultaneous proteome analysis targeting 92-plex inflammatory proteins in peripheral blood and in sputum was performed using proximity extension immunoassay (PEA) (Proteomics, Uppsala, Sweden) (ref). The associations between the levels of possible biomarkers and lung involvement were studied using logistic regression analysis.

Results: Significant differences between the groups were found for the levels of eight proteins in blood and for four proteins in sputum. Separate logistic regression models revealed significantly increased levels of 4 proteins in plasma: IL8, 4EBP1, SIRT2, and ST1A1 with an OR of having RA related lung involvement of 2,9-9,9. Additional 5 proteins (IL12B and FGF19 in plasma, and IL17A, CXCL5 and DNER in sputum) were associated with significantly lower risk of lung involvement (OR 0,1-0,3) (Figure).

Conclusion: The results from this study confirm the feasibility of proximity extension immunoassay (Proteomics) for proteome analysis in peripheral blood and sputum in RA patients with or without lung involvement. The difference in proteomics signature in blood and sputum indicate the analysis may be applied in the search for effective predictors of RA related lung diseases. Despite limitations we identified a number of promising biomarkers of lung involvement in RA in blood and sputum.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The atherogenic index of plasma (AIP) is a novel marker to identify cardiovascular disease. Recently, AIP was reported to be related to long-term cardiovascular disease risk in women with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). We aimed to evaluate if RA-patients with high AIP present a higher prevalence of carotid plaque than patients with RA and low AIP.

Methods: A cross-sectional and comparative study including RA-patients aged 40 to 75 who fulfilled the ACR/EULAR 2010 classification criteria for RA. Patients with previous cardiovascular disease were excluded. Carotid ultrasound was performed on all study participants. The presence of carotid plaque (CP) was defined as diffuse carotid intima-media thickness (cIMT) ≥1.2 mm or focal thickness ≥0.5 mm. Subclinical atherosclerosis was defined as the presence of CP or an increased cIMT (≥0.8mm). Cardiovascular disease risk was evaluated using 6 algorithms: ACC/AHA 2013, FRS-Lipids, FRS-BMI,

RRS, QRISK3, and SCORE2. AIP was defined by log (TG/HDL-C) mg/dL, and levels ≥0.21 were considered as high AIP. Patients were divided into two groups according to AIP levels. The distribution between groups was assessed with the Kolmogorov-Smirnov test. Comparisons with Chi-square or Fisher's exact test and Student's t-test or Mann Whitney's U-test, accordingly. A value of $p \leq 0.05$ was considered statistically significant.

Results: A total of 144 patients with RA were included, most of which were women (n=133, 94%). There was no difference between sex, traditional cardiovascular risk factors, disease activity, or disease duration between patients with high AIP and those RA-patients with low AIP (Table 1). The prevalence of CP (37.5% vs 25.0%, p=0.106) and overall subclinical atherosclerosis (58.3% vs 62.5%, p=0.609) was similar between groups (Table 1). However, the prevalence of increased cIMT was higher in RA-patients with high AIP (29.2% vs 54.2%, p=0.002). Cardiovascular risk was increased in patients with high AIP using FRS-Lipids Score (7.6 vs 9.6, p=0.037) and RRS (1.5 vs 1.5, p=0.009) (Table 2).

Conclusion: The prevalence of increased cIMT was higher in RA-patients and had a high atherogenic index of plasma (AIP). AIP could be a helpful marker for the early identification of patients with increased cIMT.

Table 1. Demographic characteristics.

Characteristics	RA patients with low AIP (n=72)	RA patients with high AIP (n=72)	*p*-value
Age, years, ± SD	56.7 ± 9.7	55.8 ± 9.7	NS

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

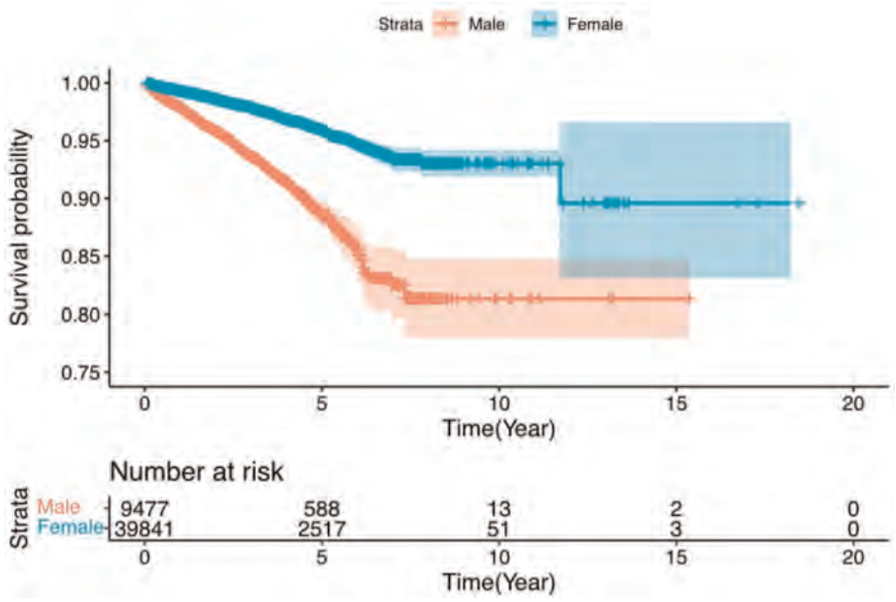

Figure 1. Kaplan-Meier analysis of sex factor. Shades of the curves shows 95% confidential intervals.

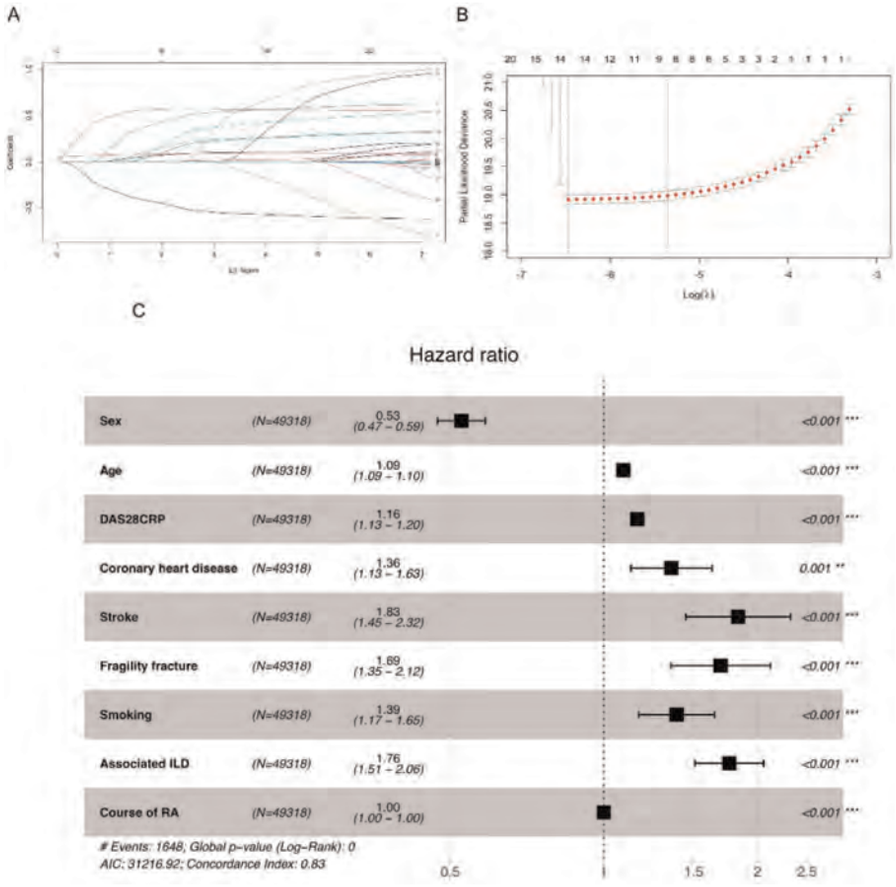

Figure 2. Variable selection using the least absolute shrinkage and selection operator (LASSO) model and results from Cox model. (A) LASSO model coefficient profiles of the 33 candidate variables. (B) Cross-validation in the LASSO model. The error bars represent the partial likelihood deviance standard error (SE). (C) Forest plot of hazard ratio according to Cox model.

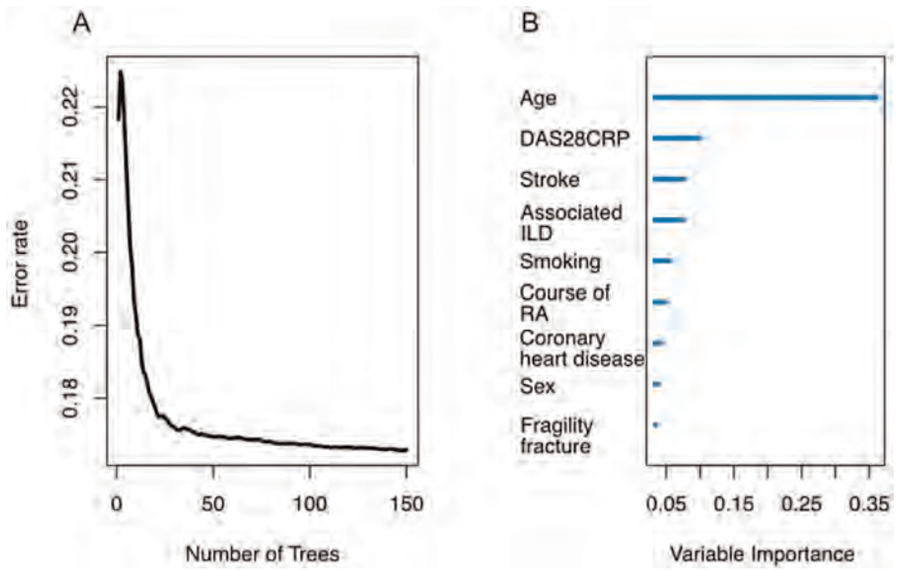

Figure 3. Random survival forest (RSF) model. (A) Out-of-bag (OOB) error rate to number of trees. (B) Bar plot of variable importance (VIMP).

Background/Purpose: Rheumatoid arthritis (RA) poses significant challenges for patients in China due to prolonged disease duration prior to a definitive diagnosis, resulting in comorbidities and increased mortality rates in RA management. Although the ACR/EULAR guideline has identified certain laboratory results as poor prognostic factors (PPFs), their availability is limited in community-based centers, particularly in rural areas. Moreover, comprehensive patient follow-up remains a challenge. Consequently, the utilization of readily accessible baseline data assumes paramount importance in the nationwide management of RA. This study seeks to predict mortality rates by leveraging baseline data obtained from a nationwide cohort of RA patients.

Methods: The clinical data utilized in this study were obtained from the database of the Chinese Registry of Rheumatoid Arthritis (CREDIT), while the survival outcome data were from the Chinese Center for Disease Control and Prevention. The datasets were linked based on the diagnosis ID, and the baseline data were extracted based on the first recorded follow-up date. Data cleaning was performed to ensure data quality. To identify the most crucial features, the least absolute shrinkage and selection operator (LASSO) technique was employed. Subsequently, two modeling approaches, the Cox proportional hazards model (Cox model) and random survival forest (RSF), were simultaneously applied to develop predictive models using the selected features. The performance of these models was evaluated by Harrell's concordance index (C-index) and compared.

Results: The registry was initiated on October 9, 2003, and is currently ongoing. Survival outcomes were collected until December 31, 2021, with no loss to follow-up observed. A total of 49,318 patients (Mean age: 51.96 (IQR: 44.00-61.00); Female sex: 39.841, 80.78%) diagnosed with RA from 125 medical centers across China were included in this study. 1,648 deaths were recorded, while 47,670 patients remained under observation (Figure 1). The LASSO technique identified 9 variables within 1 standard error, which were utilized in model construction. Notably, the variables demonstrating significant importance were sex, smoking status, stroke, and the presence of associated interstitial lung disease (ILD), as evidenced by the beta coefficients in the Cox model and the Variable Importance (VIMP) in the RSF model (Figure 2 and 3). The Cox model exhibited a C-index of 0.831 (95% confidence interval [CI]: 0.808-0.852), while the RSF model achieved a C-index of 0.879 (95% CI: 0.829-0.916).

Conclusion: This study shows that the risk of mortality in RA patients can be predicted based on demographic factors and comorbidities from baseline data. Specifically, male sex, smoking, stroke, and the presence of associated ILD were identified as factors associated with a higher risk of mortality. Both the Cox model and RSF proved to be effective methods for

mortality prediction while the RSF model exhibited higher accuracy but lower explainability. Future research could focus on exploring the prediction of comorbidities within the same cohort, further enriching our understanding of their impact on mortality risk in RA patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

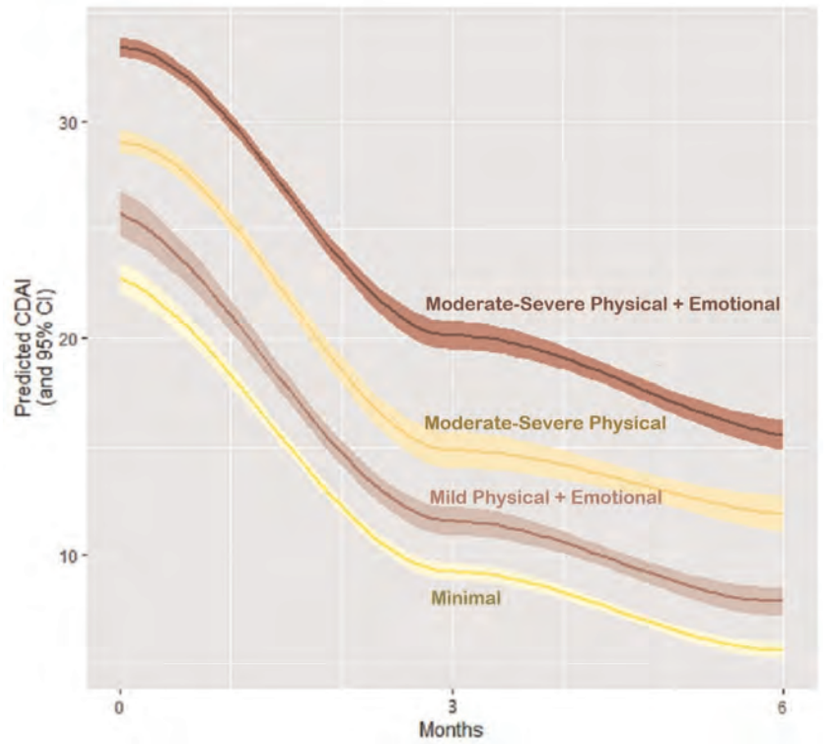
Background/Purpose: We have previously shown that PROMIS-29 physical (pain, fatigue) and emotional (depression, anxiety) symptom clusters can be used to identify 4 distinct early RA patient sub-groups, and that patient sub-groups with higher emotional symptoms experienced greater physical and emotional symptom burden despite all receiving conventional RA treatment with MTX over 6-months follow up. Here, we examine whether these 4 identified patient subgroups also follow distinct trajectories of disease activity over the first 6 months of MTX therapy.

Methods: Data were from adults with newly diagnosed early RA (symptoms < 1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) study who were initiating treatment with MTX for the first time and had complete clinical and PRO measures at baseline, 3- and 6-month follow up. PROMIS-29 anxiety, depression, fatigue, and pain scores were used to classify patients into 4 patient sub-groups using latent transition analysis: Group 1: **Minimal Sx**; Group 2: **Mild Physical + emotional Sx**; Group 3: **Moderate-Severe Physical Sx**; and Group 4: **Moderate-Severe Physical + emotional Sx**. Linear mixed effects

CDAI Disease Activity Over the First 6-Months of Methotrexate Treatment Across Early RA Patient Sub-Groups

	CDAI Mean Difference (95% CI)^
Class (reference – Group 1: Minimal Symptoms)	
Group 2:Mild Physical + Emotional	2.90 (0.19, 5.61)
Group 3:Moderate-Severe Physical	5.89 (3.44, 8.33)
Group 4: Moderate-Severe Physical and Emotional	10.74 (8.00, 13.48)

^ Adjusted for: age, sex, race, education, smoking status, obesity, comorbidities, serology status and symptom duration.



Predicted change in CDAI over the first 6 months of MTX therapy in adults with new-onset RA (n=310).

regression was used to estimate trajectories of CDAI disease activity over the first 6 months of MTX treatment across groups adjusting for age, sex, race, education, smoking status, obesity, comorbidities, serology status and symptom duration.

Results: The sample included 310 early RA patients initiating MTX treatment for the first time. Participants had a mean age of 56, CDAI of 29.3, and symptom duration of 5 months; 67% were women and 78%were White. At baseline, average disease activity was high across all 4 patient groups though mean CDAI scores were highest for patients in Group 3 (**Moderate-Severe Physical Sx**) (mean (sd) CDAI: 29.2 (12.7)) and Group 4 (**Moderate-Severe Physical + emotional Sx**) (mean (sd) CDAI: 32 (14.0). Disease activity improved for all groups over 6-months of treatment with MTX though not to the same degree across groups. Compared with patients in Group 1 (**Minimal Sx)**, mean CDAI was nearly 3 points higher for participants in Group 2 (**Mild Physical + emotional Sx)** was nearly6-points higher for Group 3 (**Moderate-Severe Physical Sx)** and nearly 11 points higher for Group 4 (**Moderate-Severe Physical + emotional sx)** (FIGURE).

Conclusion: We found that despite being treated with the same conventional RA MTX treatment, early RA patients displayed varying levels of physical (pain, fatigue) and emotional symptoms [anxiety, depression] and that these symptom clusters could be used to identify distinct patient sub-groups with substantial differences in disease activity over 6-months of follow up. Results suggest that both the presence and intensity of physical symptoms plus the levels of anxiety and depression may indicate more complex subtypes of RA with a less favorable prognosis. Evaluating both physical and emotional symptoms at the time of diagnosis may help providers better tailor RA treatment by potentially combining medications and supportive interventions that reduce overall symptom burden and improve treatment outcomes and QOL.

Abstract Number: 1286

Impact of Body Mass Index (BMI) on Upper versus Lower Extremity Joints Assessed Using Clinical and Musculoskeletal Ultrasound Measures in Rheumatoid Arthritis Patients

Nicolette Morris[1], Elena Saab[2], Lucia Chen[1], Jenny Brook[1], Gurjit S Kaeley[3], David Elashoff[1] and Veena Ranganath[1], [1]David Geffen School of Medicine, UCLA, Los Angeles, CA, [2]Wake Forest University School of Medicine, Los Angeles, CA, [3]University of Florida College of Medicine – Jacksonville, Ponte Vedra Beach, FL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Tender and swollen joints counts may be differentially affected in rheumatoid arthritis (RA) patients with obesity. A prior study demonstrated an association between increased BMI and swelling of the lower extremity joints (Ranganath et al. 2019). To our knowledge, there are no publications describing the impact BMI has on musculoskeletal ultrasound (MSUS) measures of the upper and lower extremity (UE and LE) joints. This study aimed to examine the association of BMI with clinical and MSUS joint assessments of the UE/LE joints in a large cohort of RA patients.

Methods: We examined a cross-sectional cohort of 268 patients meeting American College of Rheumatology 2010 RA classification criteria who completed screening visits for clinical trials. Patients were grouped by BMI: < 25, 25 to 30, and ≥ 30. Demographic data and DAS28/ESR were collected including 28 and 44 tender and swollen joint counts (TJC28, SJC28, TJC44, SJC44). Following the LAJAX protocol (Ben-Artzi et al. 2021), grayscale and power Doppler ultrasound (GSUS and PDUS) images were obtained from 34 joints: bilateral radioulnar joint midline of the wrists, proximal interphalangeal joints, interphalangeal joints, metacarpophalangeal joints, knees, and metatarsophalangeal joints (excluding MTP1).

Table 1. Number of upper and lower extremity joints analyzed per composite joint characteristic across BMI. BMI = body mass index, N = number, GSUS = grayscale ultrasound, PDUS = power Doppler ultrasound, TJC28 = 28 tender joint count, SJC28 = 28 swollen joint count, TJC44 = 44 tender joint count, SJC44 = 44 swollen joint count.

	Normal Weight BMI <25 N = 66		Overweight BMI 25-30 N = 62		Obese BMI >30 N = 140	
Composite Joint Characteristic Analyzed	Upper Extremity Joint N	Lower Extremity Joint N	Upper Extremity Joint N	Lower Extremity Joint N	Upper Extremity Joint N	Lower Extremity Joint N
GSUS	1584	660	1488	620	3360	1400
PDUS	1584	660	1488	620	3360	1400
TJC28	1716	132	1612	124	3640	280
SJC28	1716	132	1612	124	3640	280
TJC44	1980	924	1860	868	4200	1960
SJC44	1980	924	1860	868	4200	1960

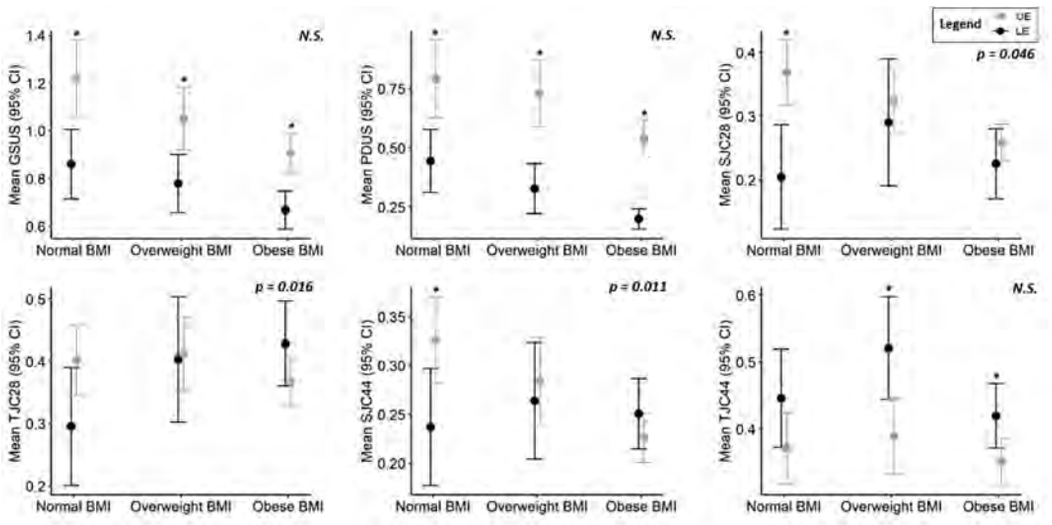

Figure 1. Upper versus lower extremity joints across BMI categories for musculoskeletal ultrasound measures and joint counts. N.S. = ANOVA not significant ($p > 0.05$), * = significant difference ($p < 0.05$), LE = lower extremity, UE = upper extremity, CI = confidence interval, BMI = body mass index, N = number, GSUS = grayscale ultrasound, PDUS = power Doppler ultrasound, TJC28 = 28 tender joint count, SJC28 = 28 swollen joint count, TJC44 = 44 tender joint count, SJC44 = 44 swollen joint count.

Each image was scored on a scale of 0-3. For joints with multiple views, the highest PDUS and GSUS score was used. Joints were categorized as either UE or LE. GSUS and PDUS scores were calculated by taking the average of all individual joint scores per UE or LE group. SJC and TJC scores were calculated using the proportion of swollen or tender joints out of all joints per UE or LE group. Differences between UE and LE joints for both ultrasound (GSUS and PDUS) and clinical joint measures (TJCs and SJCs) were calculated across BMI groups using t-tests. For each joint assessment, interaction effects were tested between UE/LE joint categories and BMI via analysis of variance (ANOVA).

Results: Within the cohort, mean age was 54.8 years, 90.2% were female, 45% Caucasian, 78.7% seropositive and mean disease duration was 11.9 years. Patients overall had moderate disease activity with an average DAS28/ESR of 4.8. A total of 11,792 joints were examined by MSUS and/or joint counts. A breakdown of the UE and LE joint distribution per measure among BMI groups is shown in Table 1. Analyses comparing UE versus LE joints demonstrated a higher MSUS burden (GSUS and PDUS) in the UEs regardless of BMI (Figure 1) ($p< 0.05$), although there was not a significant UE/LE by BMI interaction ($p>0.05$). For SJC28 and SJC44 the UE/LE difference was significantly different across BMI categories ($p< 0.05$ for interaction). Normal weight patients had significantly higher joint swelling in the UEs (both $p< 0.03$), but this was not seen for overweight or obese patients (all $p>0.05$). Significant differences in individual joints of TJC28 for UE/LE were observed across BMI groups ($p=0.02$).

Conclusion: We observed a significant differential effect of BMI in the UE versus LE comparisons for clinical joint assessments (TJC 44, SJC 28, and SJC44), which are thought to be more subjective measures. However, for more objective measurements of joints by MSUS (PDUS and GSUS), this differential effect of UE/LE across BMI was not seen.

activity measures (composite clinical measures, patient surveys, and musculoskeletal ultrasound (MSUS)) across BMI in a large RA cohort. Prior studies evaluating this question have been small with conflicting findings.

Methods: Clinical and MSUS data were obtained from 268 RA patients meeting American College of Rheumatology 2010 RA classification criteria who completed screening visits for RA clinical trials at an academic center. Patients were grouped by BMI categories: < 25, 25 to 30, and ≥ 30. Laboratory measurement of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), anti-cyclic citrullinated peptide (ACPA) and rheumatoid factor (RF) levels were performed. 28- and 44-joint count Disease Activity Scores using ESR (DAS28/ESR and DAS44/ESR), Health Assessment Questionnaire Disability Index (HAQ-DI) and Routine Assessment of Patient Index Data 3 (RAPID3) scores were calculated. Grayscale and power Doppler ultrasound (GSUS and PDUS) scores were calculated using the LAJAX 34 joint protocol (Ben-Artzi et al. 2021). Images were scored semi-quantitatively on a scale of 0–3. Total PDUS and GSUS scores were calculated via summation of all 34 joint scores (range 0–102). Demographic and clinical characteristics were categorized across BMI groups using the Kruskal-Wallis test (KW) for continuous variables and chi-square tests for categorical variables. Multiple linear regressions were used to assess factors influencing PDUS and GSUS.

Results: Demographics were similar across BMI categories except for race/ethnicity (p=0.02). GSUS and PDUS scores significantly differed across BMI groups, with obese patients showing the lowest MSUS activity (p< 0.001 and p=0.001, respectively). DAS28/ESR, DAS44/ESR, TJC28, TJC44 were not different across BMI. However, SJC28 and SJC44 were significantly different across BMI groups and numerically lower in BMI >30. RAPID3 demonstrated a significant difference across BMI where obese patients were numerically lower, while HAQ-DI did not differ. In the regression models, BMI was significantly negatively associated with PDUS and GSUS after accounting for demographic characteristics, DAS28/ESR, disease duration, and seropositivity. In these models race, sex, smoking, seropositivity and DAS28/ESR were also significantly associated with MSUS findings.

Conclusion: In this large cohort of RA patients, DAS28/ESR and DAS44/ESR were similar across BMI categories. However, active synovitis as measured by PDUS and GSUS scores were independently negatively associated with BMI, after accounting for DAS and other demographic factors. These results suggest there is less MSUS joint inflammation in obese patients, which is consistent with prior findings of reduced radiographic damage observed in obese RA patients. Further study is warranted to confirm these findings.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: With the advent of new therapies and increasing life expectancy, there is a rising number of older adults living with rheumatoid arthritis (RA). Patients with RA are at a higher risk for developing frailty[1], and frailty in RA has been linked with increased risk of hospitalization[2]. However, little is known regarding the association between frailty status and a patient's hospitalization outcomes. Our study investigated whether frailty increases risk for readmission and inpatient mortality in RA patients.

Methods: Using the 2018 Nationwide Readmissions Database, we identified adult patients (age ≥18 years) admitted with a primary or secondary diagnosis of RA (using ICD 10 codes) between January to June 2018. Utilizing validated claim-based Hospital Frailty Score[3], patients' frailty risk score was calculated at the time of index admission and individuals were categorized into frail (score ≥ 5) and non-frail (score < 5) groups. Our primary outcome of interest was risk of readmission following discharge after index hospitalization. Secondary outcomes of interest included inpatient mortality, prolonged length of

Characteristics at the time of index hospitalization	Non-frail patients (N = 69056)	Frail patients (N = 64131)	P-value

**Model adjusted for age, sex, household income, hospital characteristics (teaching status, capacity, location), and Elixhauser comorbidities index.*

Cox Proportional Hazard Analysis Evaluating Risk of Readmission by Frailty Risk Score

admission (≥ 7 days), mean days to readmission, and costs of hospitalization. We used descriptive statistics to compare patient demographics, admission characteristics, and hospital characteristics at index hospitalization in frail vs non-frail groups. Multivariable Cox proportional hazard analysis was performed to evaluate the independent effect of frailty on readmission after controlling for age, sex, household income, hospital characteristics (teaching status, capacity, location), and Elixhauser comorbidities index.

Results: 133,187 patients with RA met our inclusion criteria. Of these, 64,131 (48.15%) patients were categorized as frail, and 69,056 (51.85%) patients were non-frail. Frail patients were older, female, predominantly with Medicare coverage, and had higher Elixhauser comorbidity index (**Table 1**). Frail patients had a higher rate of readmission (56.60%) compared to the non-frail group (30.61%). After readmission, frail patients also had significantly higher inpatient mortality compared to non-frail patients (3.36% vs 0.39%, $p < 0.005$) and a longer length of stay (7.82% vs 26.24%, $p < 0.005$) (**Table 2**). On multivariate analysis, frailty was independently associated with a 9% increased risk of readmissions (adjusted hazard ratio, 1.09; 95% confidence interval, 1.08 – 1.11) (**Table 3**).

Conclusion: Frailty is associated with a higher risk of readmissions in patients with RA. In addition, frail patients with RA have higher likelihood for poorer outcomes after hospitalization (such as increased inpatient mortality) relative to non-frail patients. These findings are crucial in identifying hospitalized patients with RA who are at a higher risk of worse outcomes. Future studies should explore modifiable factors to mitigate these risks.

Increases in Serum Levels of Tartrate-Resistant Acid Phosphatase 5b Reflected Radiographic Progression of Joint Damage in Treated Rheumatoid Arthritis

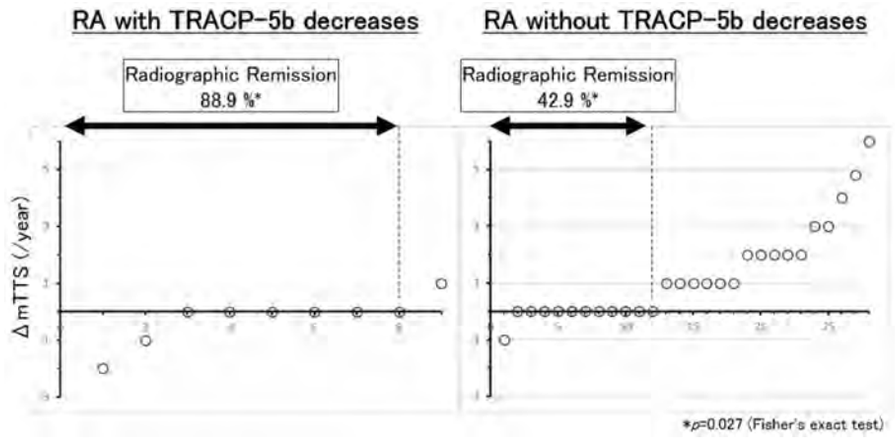
Takayoshi Owada[1], Takayuki Kobayashi[1], Ayae Tanaka[2], Kei Ikeda[2], Hirokuni Hirata[1], Masafumi Arima[3], Kazuhiro Kurasawa[2] and Yasutsugu Fukushima[1], [1]Dokkyo Medical University Saitama Medical Center, Koshigaya, Japan, [2]Dokkyo Medical University, Mibu-machi, Shimotsuga-gun, Japan, [3]Dokkyo Medical University, Koshigaya, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) is one of inflammatory arthritis, and this autoimmune-mediated polyarthritis results in structural joint destruction. Articular bone erosion leading to joint destruction in RA is caused by bone resorption of osteoclasts activated by synovial inflammation. Joint damage is usually evaluated by imaging studies, but there are few reports in which joint damage was assessed by bone resorption markers that reflect osteoclast activity. Tartrate-resistant acid phosphatase (TRACP) 5b is a bone resorption marker localized only in osteoclasts and is released during bone resorption, so it directly reflects the number and active state of osteoclasts. Recently, serum levels of TRACP-5b have been reported to correlate with the severity of radiographic damage and the number of articular bone erosion of computed tomography in RA patients. However, the relationship between TRACP-5b and joint damage progression is still unclear. Therefore, we investigated whether TRACP-5b is useful for evaluating the progression of articular damage in RA.

Methods: 37 RA patients were registered, who filled RA criteria 2010, were premenopausal women and men younger than 55 years at enrollment (M0), didn't have metabolic bone diseases or malignancies, were in the treatment with DMARDs, and were followed up until month 12 (M12). Serum TRACP-5b level measurement and radiographic joint damage assessment were performed at M0 and M12. A significant decrease in TRACP-5b titers was defined as a decrease of 12.4% (the minimum significant change; MSC) or more in one year. Radiographic remission of join damage was defined as yearly modified total Sharp score (mTSS) progression below 0.5. Their medical records were reviewed retrospectively.

Results: Subjects at M0 were 31 female, were median age 45.7 years with 5.4 years of disease duration, and were treated with MTX, glucocorticoid, biological/targeted synthetic DMARD and bisphosphonate/denosumab (n=30, 9, 12 and 6, respectively). RA disease activity of median SDAI was 3.29 at M0 and 4.09 at M12 (p=0.670), and median mTSS changed from 15 to 14 (p=0.027). Serum TRACP-5b titers (median) were 253 mU/dl at M0 and 294 at M12 (p=0.672). TRACP-5b levels at M0 and M12 didn't correlated with mTSS at M0 and M12. Increases in TRACP-5b titers between M0 and M12 were positively correlated with changes in erosion score of mTSS (ρ=0.5166; p=0.0011). 20 of 37 subjects (54.1%) achieved



remission in radiographic evaluation. In univariate analysis, increases in TRACP-5b titers were negatively associated with radiographic remission (OR=0.980; 95% confidence interval: 0.961-0.993, for each 1 mU/dl increase in TRACP-5b titers; p=0.001). Only 9 of 37 patients showed significant decreases in TRACP-5b titers. 8 of these 9 patients (88.9%) had radiographic remission, but only 42.9% of 28 cases without TRACP-5b decreases showed structural remission (p=0.027).

Conclusion: Changes in serum TRACP-5b levels were related to aggravation of joint damage in RA during treatment. TRACP-5b is useful for assessing progression of RA joint destruction. In the absence of significant TRACP-5b reduction, joint damage progresses in about 60% of RA patients.

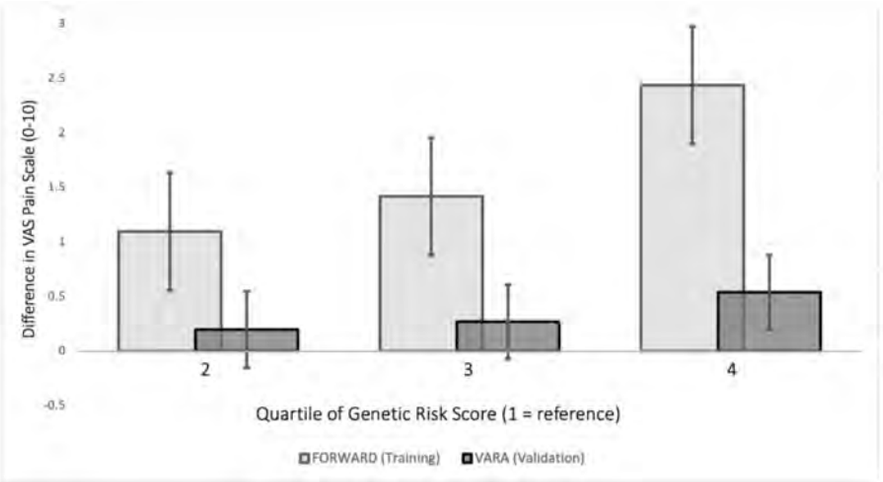
Development of a Genetic Risk Score for Pain in Rheumatoid Arthritis

Katie McMenamin[1], Kristin Wipfler[2], Austin Wheeler[3], Grant Cannon[4], K Wysham[5], Brian Sauer[6], Bryant England[3], Kaleb Michaud[3], Ted R Mikuls[7] and Joshua Baker[8], [1]Boston University, Boston, MA, [2]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [3]University of Nebraska Medical Center, Omaha, NE, [4]University of Utah and Salt Lake City VA, Salt Lake City, UT, [5]VA Puget Sound/University of Washington, Seattle, WA, [6]Salt Lake City VA/University of Utah, Salt Lake City, UT, [7]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE, [8]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain in rheumatoid arthritis (RA) is multifactorial and involves processes beyond inflammation such as peripheral and central pain processing. Several genes have been associated with pain processing through studies of fibromyalgia (FM), but it is largely unknown how genetics may affect pain in other rheumatic diseases. The aim of this study was to determine if single nucleotide polymorphisms (SNPs) associated with FM also have an impact on pain and disease activity in patients with RA.

Methods: Participants with RA with whole genome SNP data were included from two independent cohorts: 1) *FORWARD* (National Data Bank for Rheumatic Diseases) and 2) Veterans Affairs RA registry (VARA). Linear regression was used to determine the relationship between 30 individual SNPs previously associated with FM (Jannsen et al. *An Acad Bras Ciênc*. 2021) and baseline pain scores in *FORWARD* adjusting for age, sex and race. A genetic risk score (GRS) was generated using all 30 SNPs, weighted by the coefficients for each SNP from this regression. Linear regression was then used to assess the relationship between the GRS and cross-sectional (baseline) pain (visual analogue scale, range 0-10) in *FORWARD* (training dataset) and VARA (validation dataset). Similarly, the association of GRS with pain during longitudinal follow-up was determined using regression with generalized estimating equations adjusting for age, sex and race. In addition, the associations between GRS and disease activity, at enrollment and during longitudinal follow-up in each study were determined.



Difference in baseline mean VAS pain score by quartile of genetic risk score for FORWARD (training) and VARA (validation) cohorts

	Training		Validation	
	***FORWARD* (PAS-II)**		**VARA (RAPID3)**	
Baseline				
Genetic Risk Quartile	**β (95% CI)**	**P**	**β (95% CI)**	**P**
1	ref	--	ref	--
2	0.79 (0.35, 1.23)	<0.01	0.46 (-0.33, 1.26)	0.25
3	0.97 (0.54, 1.40)	<0.01	0.40 (-0.39, 1.19)	0.32
4	1.28 (1.26, 2.13)	<0.01	1.06 (0.33, 1.26)	<0.01
Longitudinal				
Genetic Risk Quartile	**β (95% CI)**	**P**	**β (95% CI)**	**P**
1	ref	--	ref	--
2	0.43 (0.07, 0.8)	0.02	0.21 (-0.36, 0.77)	0.48
3	0.78 (0.41, 1.16)	<0.01	0.17 (-0.39, 0.74)	0.54
4	1.17 (0.8, 1.55)	<0.01	0.72 (0.16, 1.28)	0.01

Genetic risk score quartile and disease activity score at baseline and throughout all observations for FORWARD (training) and VARA (validation) datasets

Results: This study included 765 patients from *FORWARD* (mean age 56.8 years, 89.4% female) and 2176 from VARA (mean age 71.7 years, 11.0% female). Several SNPs were associated with pain scores in each cohort, but no single SNP was associated in both cohorts. For example, VARA participants with the homozygous major allele of the *BDNF* rs6265 polymorphism (brain-derived neurotrophic factor) had less pain [B: -2.16 (95% CI: -4.06, -0.25, p=0.02)] compared to those with the homozygous minor allele, but a similar association was not observed in *FORWARD*.*FORWARD* participants with a higher GRS had significantly more pain, with those in the highest quartile having higher baseline pain scores [+2.44 (95% CI: (1.91, 2.97) p< 0.01 (range 0-10)] (Figure). VARA participants in the greatest quartile of GRS also had modestly higher baseline pain scores [+0.54 (95% CI: 0.20, 0.89), p< 0.01]. Participants in the highest GRS quartile from both cohorts also had significantly greater pain scores throughout follow-up. The GRS was associated with higher baseline and longitudinal patient-reported disease activity as measured by the PAS-II (*FORWARD*) and RAPID3 (VARA) (Table).

Conclusion: A genetic risk score based on previously identified pain-related SNPs modestly predicted greater pain in an external independent cohort. These observations suggest that more comprehensive genetic scores may eventually provide meaningful clinical value in understanding pain in RA patients. More accurate prediction may be possible through more advanced methods such as machine learning and with an increasing understanding of the genes involved in pain processing.

Risk Factors for Major Adverse Cardiovascular Events and Malignancies in Patients with Rheumatoid Arthritis in a Real-World Setting in Japan

Toshitaka Hirano[1], Naonobu Sugiyama[2], Masato Hoshi[1], Joo-Young Jo[3], Kichul Shin[4] and Kunihiro Yamaoka[5], [1]Pfizer Japan Inc, Tokyo, Japan, [2]Pfizer Japan Inc, Japan, Japan, [3]Pfizer Pharmaceuticals Korea Ltd, Seoul, South Korea, [4]Seoul Metropolitan Government- Seoul National University Boramae Medical Center, Seoul, South Korea, [5]Department of Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Sagamihara, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with RA are at an increased risk of major adverse cardiovascular events (MACE) and malignancies vs the general population.[1,2] However, risk factors for MACE and malignancy in pts with RA may differ by geographic location; to date, limited real-world data (RWD) assess this. Thus, this study aimed to identify risk factors for MACE and malignancy (including non-melanoma skin cancer) in pts with RA using RWD in Japan.

Methods: This was a cohort study of pts with RA using a RW database (electronic medical records, claims, and discharge abstract data) of medical institutions in Japan (maintained by the Health, Clinic, and Education Information Evaluation Institute; supported by the RWD Co. Ltd). Eligible pts from January 2013–December 2021 had ≥ 1 RA diagnosis, were aged ≥ 18 years, were prescribed ≥ 1 RA drug, had no psoriasis diagnosis, and had a record after the index date. For the MACE cohort, pts had no myocardial infarction or stroke diagnosis ≤ 31 days before index. For the malignancy cohort, pts had no

malignancy diagnosis < 1 year before index. Outcomes were the incidence of initial MACE and malignancy during follow-up (up to July 1, 2022). Known/exploratory risk factors/variables, including demographics, comorbidities, medications, administration of imaging techniques (eg X-rays), and laboratory tests, were selected using Cox regression models.A sequential variable selection technique with univariate analysis, variance inflation factors, and correlation coefficients was used to select exploratory risk factors. Sensitivity analyses were conducted with and without using laboratory tests as risk factors to identify consistent findings. Adjusted hazard ratios with 95% confidence intervals were calculated.

Results: Across MACE (16,012 pts) and malignancy (14,545 pts) cohorts, most pts were female (64.69–66.90%) and aged ≥ 65 years (69.78–68.88%); the most common comorbidities (all ≥ 29.60%) were hypertension, hyperlipidemia, and malignancies (MACE cohort only; Table). In total, there were 214 MACE over 43,964.7 pt-years (PY; incidence rate [IR] 0.49/100 PY) and 315 malignancies over 40,251.6 PY (IR 0.78/100 PY). Significant variables associated with increased MACE risk were male sex, older age, hypertension, renal disease, cerebrovascular disease, and X-ray administration (Fig 1). Significant variables for increased malignancy risk were male sex, older age, NSAID use, emphysema, serious infection, history of malignancies, and X-ray administration; steroid use and fracture diagnosis were significant for reduced malignancy risk (Fig 2).

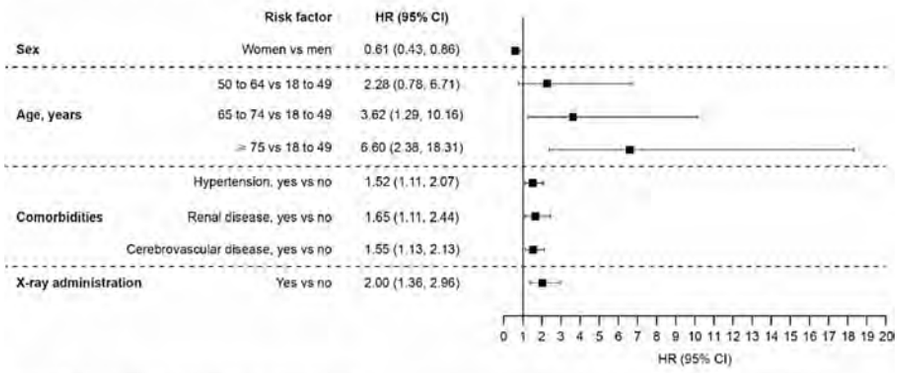
History of malignancy	4,731	29.55	3,362	23.11
X-ray administration	11,100	69.32	9,855	67.76

bDMARD, biologic DMARD; COPD, chronic obstructive pulmonary disease; csDMARD, conventional synthetic DMARD; JAK, Janus kinase; MACE, major adverse cardiovascular events; N, total number of eligible pts; n, number of pts with characteristic; NA, not applicable; pt, patient

Conclusion: In pts with RA in RW settings in Japan, male sex, older age, and X-ray administration were associated with increased risk for MACE and malignancies. Hypertension and cerebrovascular disease increased MACE risk; emphysema increased malignancy risk. Missing data may have reduced potential associations, eg BMI/smoking. 1. Aviña-Zubieta et al. Ann Rheum Dis 2012; 71: 1524–9 2. Simon et al. Arthritis Res Ther 2015; 17: 212 Study sponsored by Pfizer. Medical writing support provided by L Rodgers, CMC Connect; funded by Pfizer.

Fig 1. Statistically significant risk factors for MACE in sensitivity analyses

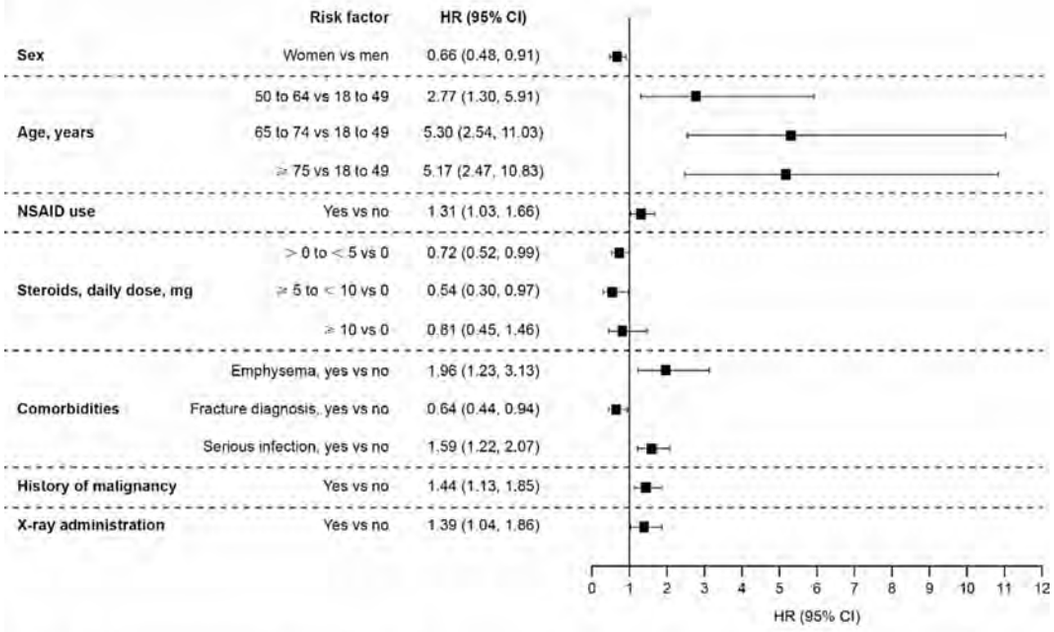


Analyses without laboratory tests included as risk factors are shown

The covariate assessment window for sex and age was the index date. For comorbidities and X-ray imaging, the covariate assessment window was the period from 1 year prior to the index date to the index date

CI, confidence interval; HR, hazard ratio; MACE, major adverse cardiovascular events

Fig 2. Statistically significant risk factors for malignancies in sensitivity analyses



Analyses without laboratory tests included as risk factors are shown

The covariate assessment window for sex and age was the index date. For NSAIDs and steroids, the covariate assessment window was the period from 3 months prior to the index date to the index date. For comorbidities and X-ray administration, the covariate assessment window was the period from 1 year prior to the index date to the index date. For history of malignancy, the covariate assessment window was the period from the initial date in the database to 1 year prior to the index date

CI, confidence interval; HR, hazard ratio

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Lipid metabolism impacts immune cell plasticity, activation, differentiation, and function, making the analysis of the lipidomic profile crucial in understanding chronic inflammatory diseases like Rheumatoid Arthritis (RA). High throughput metabolomic techniques offer a comprehensive view of lipid metabolism and can contribute to characterizing the pathogenesis of RA.

This study aimed to analyze the lipidomic profile in the serum of RA patients, examine its association with disease activity, and investigate how biological and targeted synthetic therapies modulate this profile.

Methods: A total of 250 consecutive RA patients participated, providing serum samples and clinical data (disease activity, acute phase reactants, autoimmune profile). Nightingale LTD's nuclear magnetic resonance (NMR) spectroscopy, covering over 200 lipid markers, was used to analyze the lipidomic profile. Additionally, a subgroup of active RA patients underwent prospective monitoring after receiving biologics (anti-TNF: n=50, anti-IL6R: n=15) or JAK inhibitors (JAKi: n=20). Serum samples collected before and after therapy evaluated changes in the lipid and clinical profiles. In vitro studies using an oil red staining assay examined lipid accumulation in HepG2 liver cells treated with serum from RA patients with varying disease activity.

Results: RA patients were divided into high (68), moderate (117), and low (65) disease activity groups. Approximately 100 lipid markers showed significant alterations across these groups. Interestingly, patients with high disease activity exhibited reduced levels of numerous lipid markers, including apolipoproteins, cholesterol, fatty acids (SFA, MUFA, PUFA, Omega 3 and 6, LA, DHA), triglycerides, cholines, phospholipids, lipoproteins (HDL, LDL, VLDL), and total lipid content in lipoproteins. Strong correlations were found between these lipid markers and inflammatory (CRP, ESR) and autoimmune parameters (ACPAs, RF). After six months of therapy, lipid markers significantly increased alongside clinical and analytical improvements in RA patients. Each drug demonstrated both common and distinct molecules that reversed the altered lipid metabolism. In vitro studies showed lipid accumulation in HepG2 liver cells treated with serum from RA patients with high disease activity compared to those with low disease activity, suggesting inflammation-induced altered hepatocyte metabolism as a potential contributor to reduced circulating lipid profiles.

Conclusion: Active RA patients exhibit a significantly reduced lipidomic profile directly linked to disease activity, inflammatory markers, and autoimmune parameters. Biological therapies and JAK inhibitors restore the altered lipid metabolism concurrently with clinical improvement. In vitro studies support the hypothesis that inflammation-induced lipid accumulation in the liver may partially explain the reduction in circulating lipid profiles in active patients. Ongoing studies aim to uncover the underlying mechanisms of these effects. Supported by ISCIII (PI21/0591, CD21/00187, RD21/0002/0033), RYC2021-033828-I, J. Andalucía (P20_01367) co-financed by FEDER; Fundacion Andaluza de Reumatología.

Single Camera Hand Motion Capturing as a Digital Biomarker for Disease Activity in Rheumatoid Arthritis Using Computer Vision: The Proof-of-Concept MeFisto Study

Vincenzo Venerito[1], Tobias Maningold[2], Deborah Markham[3], Marc Blanchard[4], Florenzo Iannone[1] and **Thomas Hügle**[5], [1]Rheumatology Unit, Department of Precision and Regenerative Medicine and Ionian Area, University of Bari "Aldo Moro", Bari, Italy, [2]Department of Rheumatology, University Hospital Bern (Inselspital), University Bern, Bern, Switzerland, [3]on behalf of Department Rheumatology, University Hospital Lausanne, Lausanne, Switzerland, [4]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University Lausanne, Lausanne, Switzerland, [5]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University of Lausanne, Lausanne, Switzerland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Computer vision technology offerspromising possibilities for remotely assessing disease activity in rheumatoid arthritis (RA) patients, enabling telemedicine and improving access to care. The objective of this proof-of-concept study was to investigate the association between hand motion tracking features obtained through computer vision and disease activity in RA patients.

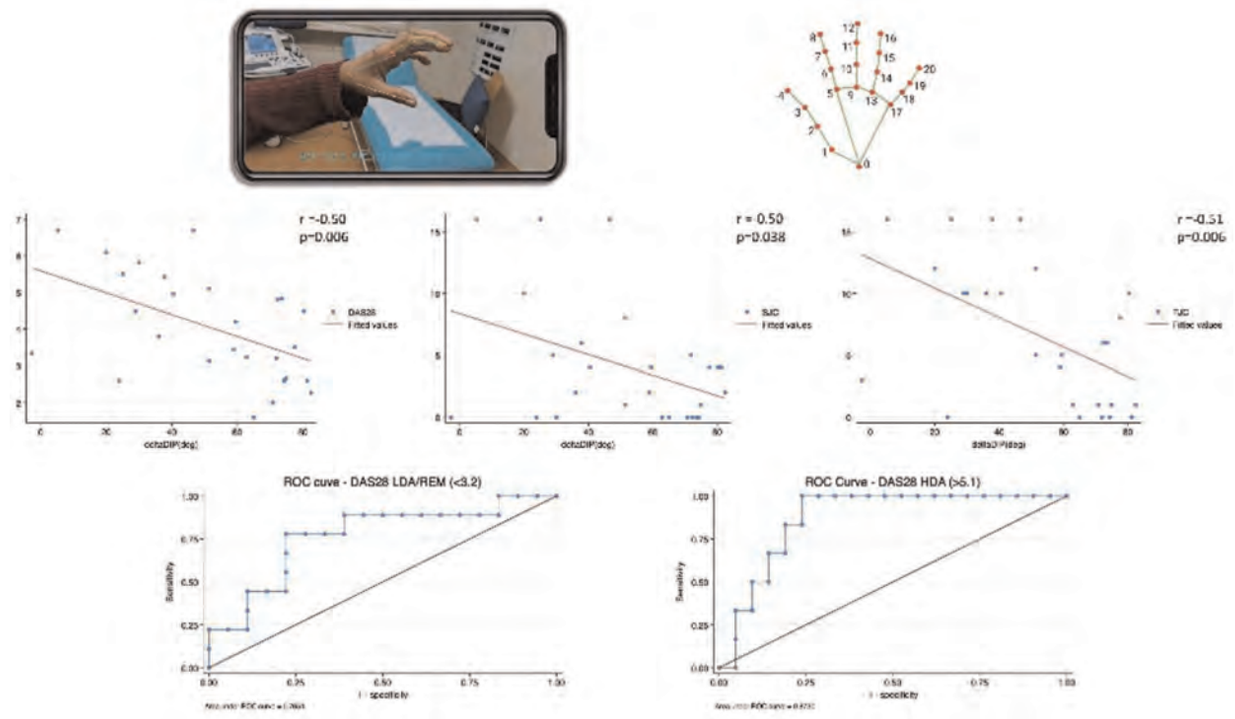

Figure 1. Single Camera algorithm for the detection of range of motion and speed. Correlation with disease activity as well as swollen and tender joint counts.

Methods: This proof-of-concept study included a total of 28 patients with classified rheumatoid arthritis (RA) from three European rheumatology centers. Disease activity was assessed using the Disease Activity Score 28 (DAS28), the Swollen Hand Joint Count (SJC), and the Tender Hand Joint Count (TJC). An ad-hoc hand motion analysis app based on the MediaPipe API was developed in a Python 3.9 environment and deployed on Windows 11, enabling computer vision inference of hand motion data. Upon smartphone single camera recording, the algorithm tracked the mean degree change of joint angle on flexion and the mean time to maximal flexion for each joint (sample video available: https://tinyurl.com/4hux35ze). The prediction performance was further analyzed using the area under the receiver operating characteristic (AUROC) curve.

Results: Among the 28 patients, 9 (32.14%) were classified as having low disease activity (LDA) or being in remission, 6 (21.42%) had high disease activity (HDA), and the remaining 13 (46.42%) fell within the moderate disease activity range. The flexion of the distal interphalangeal (DIP) joint demonstrated a strong correlation with disease activity measures, including DAS28, SJC, and TJC ($p = 0.006$, $r = -0.50$; $p = 0.03$, $r = -0.50$; $p = 0.006$, $r = -0.51$, respectively). Additionally, DIP flexion was found to be a significant predictor of LDA/remission (OR 1.05, 95% CI 1.01-1.10) and HDA (OR 0.93, 95% CI 0.89-0.99). AUROCs have been depicted in Figure 1.

Conclusion: This proof-of-concept study highlights the potential of computer vision technology for remotely assessing disease activity in RA patients. Integrating hand motion tracking into telemedicine platforms could enable rheumatologists to remotely assess disease activity, thereby improving access to care for RA patients. This approach has the potential to enhance telemedicine services, particularly in situations where in-person visits are challenging or limited.

Patient Reported Outcome Measures for Rheumatoid Arthritis Disease Activity: Using Rasch Measurement Theory and Cognitive Interviewing to Achieve More Meaningful Measurement

Tim Pickles[1], Mike Horton[2], Karl Bang Christensen[3], Rhiannon Phillips[4], David Gillespie[1], Neil Mo[5] and Ernest Choy[6], [1]Cardiff University, Cardiff, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]University of Copenhagen, Copenhagen, Denmark, [4]Cardiff Metropolitan University, Cardiff, United Kingdom, [5]Swansea Bay University Health Board, Port Talbot, United Kingdom, [6]Section of Rheumatology, Cardiff University, Cardiff, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Disease Activity (DA) monitoring is a standard of care in Rheumatoid Arthritis (RA). A systematic review of Patient Reported Outcome Measures (PROMs) for RA DA demonstrated a lack of sufficient evidence for content validity. The aim of this study was to use Rasch measurement theory (RMT) to develop a valid item pool for measurement of RA DA, and then explore patients' views on the relevance, comprehensiveness and comprehensibility of these items.

Methods: Questionnaires were sent to people aged 18 or over with RA in 2020/21, which included items from identified PROMs from a systematic review - RADAI5, RADAI, RADAI-SF, PDAS2, GAS, PAS, PAS-II, RAPID3, RAPID4, PRO-CLARA, PROM-score, RADAR, RADAI-F5, FLARE-RA and RA-FQ - and others suggested by patient feedback. Items were grouped into core domains established by OMERACT and included in exploratory factor analyses (EFA). By domain, psychometric properties were assessed by RMT analyses, which provided results on targeting, model fit, internal consistency, local dependency, unidimensionality and item threshold ordering. Sampling used a maximal variation approach across various demographics from the questionnaire-returning participants. Individual cognitive interviews took place in 2022/23. The think aloud technique was used as participants answered items, who were then asked about relevance, comprehensiveness and comprehensibility.

Results: A test dataset of n=398 and a validation dataset of n=293 were available. EFA of the test dataset showed that 30 items across the tenderness and swelling, patient global, pain, fatigue, physical functioning and stiffness domains loaded together. RMT analyses in the test dataset indicated that the patient global domain comprised two domains: general health and disease activity. In assessing the now seven domains, 12 items were discarded. Subtest analyses in the validation dataset indicated that patient global general health and fatigue could not be used to measure RA DA but the remaining five domains, containing 12 items, could. 20 participants were interviewed using a questionnaire containing the 12 identified RA DA items, six additional RA DA items, and six general health and fatigue items, which were presented to elicit views on their potential for inclusion. No consistent concerns were identified with the 12 RA DA items with regards relevance, comprehensiveness and comprehensibility. Some participants would prefer longer timeframes (> one week) for symptom reporting to fully capture their DA, a 'don't know' option, and asking about symptoms at different times of day due to diurnal patterns in symptoms. One participant noted that 'disease activity' was a confusing term.

Conclusion: Patient global items relating to general health and disease activity were two separate domains. RA DA can be measured using tenderness and swelling, patient global disease activity, pain, physical functioning and stiffness items, but not with fatigue and patient global general health items. These results provide initial evidence of content validity of the item pool in terms of relevance, comprehensiveness and comprehensibility. The next step is to develop a computer adaptive test based on anchored locations calculated using these data.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Early RA patients may present with more tender than swollen joints, which can persist during DMARD therapy. Elevated TSJD (tender-swollen joint difference) is often challenging for rheumatologists, as there may be multiple causes, and in some, it may contribute to overestimating disease activity scores and ineffective treatment decisions.Little is known about the phenotype and impact of TSJD on patient function. Our objective was to evaluate the distribution and impact of TSJD on functional outcomes in the first year following RA diagnosis, and to determine whether associations vary by joint size. A better understanding of pain patterns relating to TSJD may help identify patients who could benefit from adjunctive treatments targeted at different pain pathways.

Table: Every 1-point increase of TJSD associated with Worsening Functional Outcome*

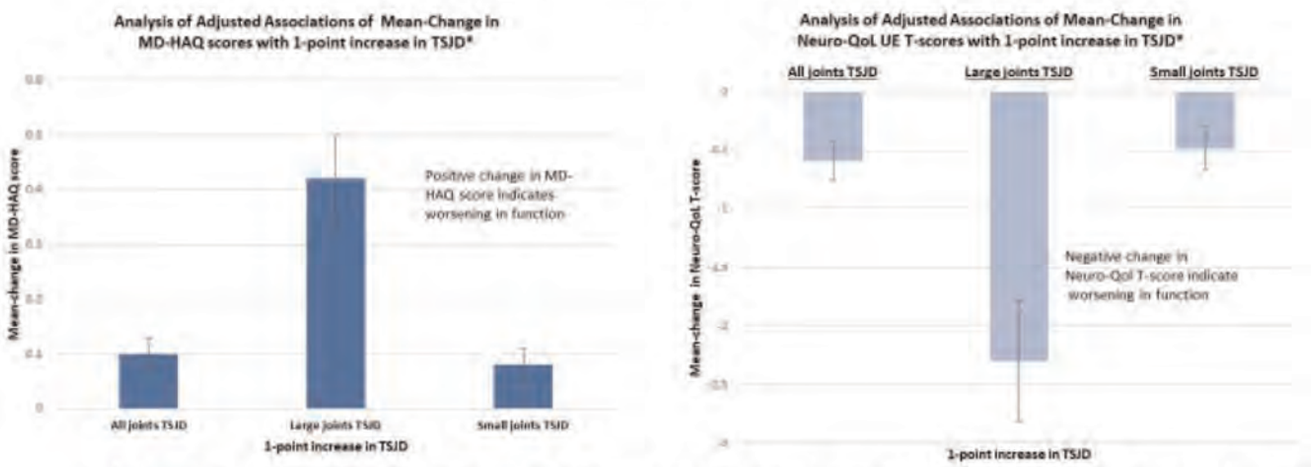
Outcome (Mean Change) for Functional Measures	All 28 joints		Large joints		Small joints	
	MC	95% CI	MC	95% CI	MC	95% CI
Function						
MDHAQ – physical function (0-10)						
TSJD (0-28)$^{\Phi}$	0.10	(0.08, 0.13)	0.42	(0.33, 0.50)	0.08	(0.05, 0.11)
NeuroQoL Upper Extremity T-score (0-100)						
TSJD (0-28)$^{\Phi}$	-0.59	(-0.76, -0.43)	-2.30	(-2.81, -1.79)	-0.49	(-0.67, -0.30)

MC - mean change for a 1-point increase in TSJD

*Multivariate mixed effects models adjusted for time, age at baseline, sex, education, current smoker at baseline, RDCI at baseline, osteoarthritis/back pain at baseline as well as time variant treatment at previous visit of oral steroids, methotrexate and advanced therapy.

$^{\Phi}$unit increase of linear TSJD of 1

Figure: Functional Outcomes in Patients with RA Worsen with Having More Tender than Swollen Joints



*Multi-variate mixed effects models adjusted for time, age at baseline, sex, education, current smoker at baseline, RDCI at baseline, osteoarthritis/back pain at baseline and time-variant treatment

Methods: Data were from patients with active, early RA enrolled in the Canadian Early Arthritis Cohort (CATCH), who completed assessments of general function (MDHAQ, range 0-10), upper extremity (UE) function of small and large joints (Neuro-QoL UE index, T-scores 0-100) over 1-year. 28 tender and swollen joint counts including 6 large joints (shoulders, elbows, knees) and 22 small joints (wrists, MCPs, PIPs) were performed. TSJDs were calculated by subtracting SJC from TJC at each visit. Adjusted associations between TSJD and functional outcomes (MD-HAQ and Neuro-QoL UE function T-score) were estimated in separate multivariable mixed effects models adjusted for age, sex, education, smoking, comorbidities, osteoarthritis/back pain and RA treatment. Separate analyses were performed for large versus small joint TSJD to examine potential differential impacts by joint size.

Results: Patients (n=549) were 70% female, mean (SD) age 56 (15) years, disease duration 5.3 (2.9) months. At baseline, 287 (52%) had TSJD >0, persisting in 32% at 12-months. 43% involved small joints and 34% had large joints, persisting at 12 months in 25% and 15% respectively. Higher TSJD was significantly associated with worse function [adjusted mean-changes (95%CI): MD-HAQ increase of 0.10 (0.08, 0.13) and decrease in Neuro-QoL UE function T-scores by -0.59 (-0.76, -0.43)] for every 1-point increase in TSJD (Table, Figure). Higher large joint TSJDs in particular were associated with the worst functional outcomes.

Conclusion: Having more tender than swollen joints is common in early RA. Higher TSJD score is associated with progressive worsening of functional outcomes, particularly when large joints are affected. Early identification and targeted intervention of predominantly tender joints may be needed to prevent long-term dysfunction.

Decline in Incidence of Extraarticular Manifestations of Rheumatoid Arthritis: A Population-Based Cohort Study

Bradly Kimbrough[1], Cynthia Crowson[1], John Davis[1], Eric Matteson[2] and Elena Myasoedova[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic College of Medicine and Science, Rochester, MN, USA, Rochester, MN

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Extraarticular manifestations of rheumatoid arthritis (ExRA) are associated with increased disease burden and mortality. They are also common, affecting about half of patients with RA. Two primary risk factors for developing ExRA include high disease activity and seropositivity.Given advancements in RA management in the last two decades,

Table 1. Baseline demographics, clinical characteristics, and comorbidities

Variable	Period of RA Incidence		
	1985-1999 (N=296)	2000-2014 (N=611)	Total (N=907)
Age (mean ± SD), years	57.6 ± 16.03	55.3 ± 15.27	56.1 ± 15.55
Female, n (%)	198 (67%)	430 (70%)	628 (69%)
Follow up, years (SD)	9.1 (3.61)	7.4 (4.06)	7.9 (4.00)
RF positive, n (%)	208 (70%)	349 (58%)	557 (62%)
Percent tested for RF	100%	98%	99%
Cigarette smoking, n (%)			
Never	127 (43%)	326 (53%)	453 (50%)
Former	113 (38%)	187 (31%)	300 (33%)
Current	56 (19%)	98 (16%)	154 (17%)
Obesity (body mass index ≥30 kg/m^2), n (%)	76 (26%)	247 (40%)	323 (36%)
Periarticular erosions, n (%)			
In the 1st year after RA diagnosis	70 (24%)	175 (29%)	245 (27%)
Percent with radiographs	93%	95%	94%
Highest ESR in the 1st year after RA incidence, mm/h (SD)	32.9 (25.2)	30.1 (24.7)	31.0 (24.9)
Medication exposure in the first year after RA incidence, n (%)			
Methotrexate	73 (25%)	319 (52%)	392 (43%)
Other DMARDs	173 (58%)	286 (47%)	459 (51%)
bDMARD	4 (1%)	68 (11%)	72 (8%)

Abbreviations: RA = rheumatoid arthritis; SD = standard deviation; RF = rheumatoid factor; ESR = erythrocyte sedimentation rate; DMARDs = disease modifying antirheumatic drugs; bDMARDs = biologic disease modifying antirheumatic drugs

epidemiologic data indicating an increasing incidence of seronegative RA, and lack of recent population-based epidemiologic studies evaluating ExRA over time, it is unclear if either the frequency of ExRA or mortality associated with ExRA has changed in recent years. This study aims to assess changes in the cumulative incidence of ExRA and associated mortality risk.

Methods: Trends in ExRA occurrence were evaluated using a population-based inception cohort. All adult patients with incident RA from 1985 through 2014 meeting the 1987 American College of Rheumatology criteria were included. Patients were divided into two cohorts based on the incidence date of RA, 1985-1999 and 2000-2014. Patients were followed until the earlier of death, migration from the region, or 12/31/2000 (for patients with incident RA from 1985-1994), 12/31/2008 (for patients with incident RA from 1995-2007), or 10/15/2022 (for patients with incident RA from 2008-2014). The occurrence of ExRA was determined by manual chart review. The 10-year cumulative incidence was estimated for each ExRA in both cohorts. Cox proportional hazard models were used to determine associations between specific demographic and RA disease characteristics and ExRA and between ExRA and mortality.

Results: A total of 907 patients were included in this study. There were 296 in the 1985-1999 cohort and 611 in the 2000-2014 cohort (table 1). The earlier cohort had a median follow up of 9.5 years (interquartile range [IQR] 6.7-12.0) and the later cohort had a median follow up of 7.4 years (IQR 4-10.3 years). The 10-year cumulative incidence of any ExRA

Table 2. Cumulative incidence of extraarticular rheumatoid arthritis at 10-year follow up

	Period of RA Incidence				
	1985-1999 (n = 296)		2000-2014 (n = 611)

Abbreviations: ExRA = extraarticular manifestation of rheumatoid arthritis, HR = hazard ratio; RA = rheumatoid arthritis, CI = confidence interval. HR reaching statistical significance in bold.
*There were no cases of retinal vasculitis, glomerulonephritis, or amyloidosis in either cohort; **Adjusted for age and sex. Must have at least 5 events in each group; ¥Included major cutaneous and internal organ vasculitis

Figure 1. Risk of developing any extraarticular manifestation of rheumatoid arthritis based on year of rheumatoid arthritis incidence.

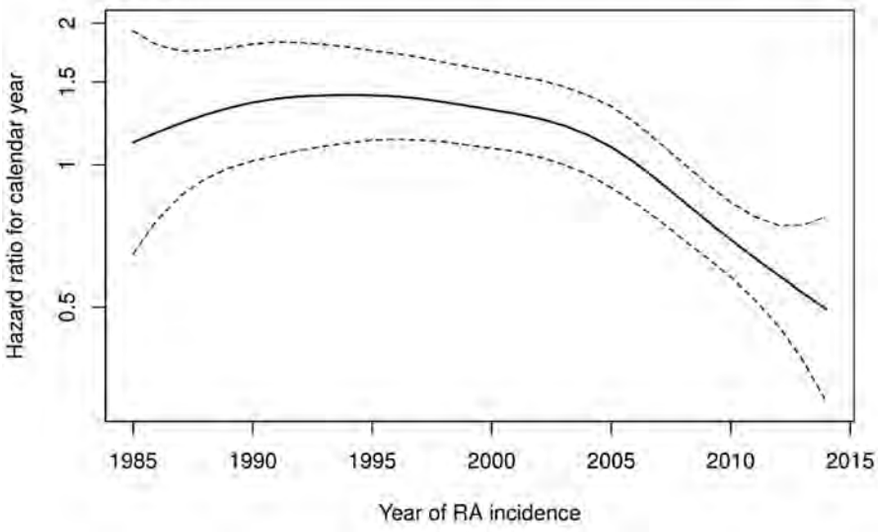

Figure demonstrating the changing hazard ratios (solid black line) and associated 95% confidence intervals (dotted lines) for the development of any extraarticular manifestation of rheumatoid arthritis as a linear trend based on year of rheumatoid arthritis incidence.

decreased significantly between the earlier and later cohorts (45.1% vs 31.6%, p< 0.001; table 2 and figure 1). This was largely driven by significant declines in subcutaneous rheumatoid nodules (30.9% vs 15.8%, p< 0.001) and non-severe ExRA (41.4% vs 28.8%, p=0.001). Several risk factors for the development of any ExRA were identified, including RF positivity (hazard ratio [HR] 2.02, 95% confidence interval [CI] 1.43-2.86), current smoking (HR 1.61, 95% CI 1.10-2.34), and erosions (HR 1.46, 95% CI 1.05-2.04). Mortality was increased in patients with either non-severe (HR 1.83, 95% CI 1.18-2.85) or severe ExRA (HR 3.05, 95% CI 1.44-6.49).

Conclusion: The incidence of ExRA has decreased over time. Despite improvements in RA therapeutics and management strategies, mortality remains increased in patients with ExRA.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19 vaccines have been proven to be safe in the healthy population. Data on longer-term AEs in people with autoimmune diseases (AIDs), including rheumatoid arthritis (RA) are lacking. COVID-19 vaccination-related AEs in patients with RA, rheumatic (rAIDs), and non-rheumatic AIDs (nrAIDs) and healthy controls (HC) greater than seven days post-vaccination were assessed in the COVID-19 Vaccination in Autoimmune Diseases (COVAD)-2 study.

Methods: The COVAD-2 study group comprised 157 collaborators across 106 countries. The study was conducted between February and June 2022. An online survey captured self-reported data related to COVID-19 vaccination-related AEs in RA, AIDs, and HCs. rAIDs included connective tissue diseases, inflammatory myopathies and inflammatory arthritis. nrAIDs comprised inflammatory bowel disease, multiple sclerosis etc. We compared COVID-19 vaccination-related delayed AEs among RA, other rAIDs, nrAIDs and HCs, adjusting for age, gender and ethnicity, using multivariable binary regression. Statistically significant results are reported.

Results: Among 7203 participants, 1423 (19.7%) RA, 2620 (36.4%) rAIDs, 426 (5.9%) nrAIDs and 2734 (38%) HCs were included from a total of 17612 respondents, with 75% female and 42.2% Caucasian (Table 1). People with RA were older [median age 51 (40-62); rAIDs, 48 (37-59); nrAIDs 43 (34-53); HC 38 (30-49)]. When compared to HCs, people with RA reported higher overall major AEs in the multivariable analyses [OR 1.3 (1.0-1.7)], especially throat

Asian	1632	22.7	322	22.6	542	20.7	57	13.4	710	26.0
Caucasian (White)	3039	42.2	784	55.1	1274	48.6	227	53.3	754	27.6
Do not wish to disclose	262	3.6	49	3.4	84	3.2	14	3.3	115	4.2
Hispanic	1200	16.7	104	7.3	293	11.2	83	19.5	720	26.3
Native American/Indigenous/Pacific Islander	53	0.7	8	0.6	21	0.8	4	0.9	20	0.7
Other	628	8.7	98	6.9	206	7.9	34	8.0	290	10.6

closure [OR 2.9 (1.1-7.3)], and increased number of several minor AEs (Table 2). People with RA had fewer reported episodes of fever [OR 0.7 (0.5-1.0)]. When compared to rAIDS, people with RA had fewer episodes of rash [OR 0.6 (0.4-1.0)], and when compared to nrAIDs, had increased reported injection site pain [OR 1.7 (1.0-2.6)], myalgia [OR 1.9 (1.1-3.4)], body ache [OR 2.2 (1.3-3.7)], joint pain [OR 2.7 (1.5-4.8)], fever [OR 1.8 (1.0-3.3)] and swelling of extremities [OR 4.9 (1.1-21.4)]. ChadOx1 nCOV-19 (Oxford/ AstraZeneca) led to significantly increased minor AEs in the RA group [OR 1.9 (1.4-2.6)], compared to other vaccines, while the Moderna vaccination was associated with increased hospitalisation in people with RA [OR 2.4 (1.3-4.3)]. People with active RA had increased major AEs [OR 1.8 (1.1 – 3.0)] and hospitalisation [OR 4.1 (1.3 – 13.3)], compared to inactive RA. RA patients without autoimmune comorbidities had significantly fewer major and minor AEs compared to those with other rAIDs (Table 3). People with RA and mental health diagnoses had increased reported chills [OR 1.8 (1.1 – 3.0)] and chest pain [OR 2.5 (1.1 – 6.0)]. Decreased incidence of hospitalisation was seen in patients taking methotrexate [OR 0.5 (0.3-0.9)] or TNF inhibitors [OR 0.1 (0.02-0.9)] compared to hydroxychloroquine, sulfasalazine and leflunomide.

Conclusion: COVID-19 vaccination is safe with minimal to no risks of delayed AEs in patients with RA compared to HCs, and fewer compared to other rAIDs. Active RA and presence of co-existent rAIDs were both associated with increased risk of delayed AEs.

Table 2: Effects of COVID-19 vaccination in patients with rheumatoid arthritis (RA) vs healthy controls (HCs). Factors included as covariates in multivariable binary logistic regression analysis included age, sex, ethnicity.

Risk Factors Associated with Venous Thromboembolism in Rheumatoid Arthritis in Clinical Practice

Fiona Oudart[1], Marion THOMAS[2], Alice Combier[3], Anna Molto[2], Yannick ALLANORE[4] and Jérôme Avouac[5], [1]Université Paris Cité, Paris, France, [2]HOPITAL COCHIN AP-HP, Service de Rhumatologie, Paris, France, [3]APHP / Cochin Hospital, Paris, France, [4]Université Paris Cité, Paris, France, [5]Service de Rhumatologie, Hôpital Cochin, AP-HP.Centre – Université Paris Cité, Paris, France

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Increased risk of venous thromboembolism (VTE) has been reported in rheumatoid arthritis (RA) compared to the general population. However, factors associated with the risk of VTE have been barely studied in RA. Our objective was to identify classical or disease-related risk factors of VTE in RA patients in clinical practice.

Methods: Retrospective observational study performed on all RA patients fulfilling the 2010 ACR/EULAR clarification criteria attending the one-day hospitalization program of the Rheumatology department, Cochin hospital, in 2021. We used the electronic medical report to identify the occurrence of VTE in 2021 and collect RA disease characteristics and risk factors for VTE. Multivariate analysis by logistic regression was performed to determine the factors independently associated with VTE.

Results: We included 405 RA patients (330 females, 81%), with a mean age of 59±14 years and a mean disease duration of 16±13 years. Positive rheumatoid factor and positive anti-CCP antibodies were detected in 331 (82%) and 347 (86%) patients respectively. 252 patients (62%) had bone erosions. The mean DAS28 was 3.5±1.4 ; 218 patients (48%) received corticosteroids (mean dose 2.6±3.3 mg/L), 247 (61%) methotrexate, and 151 (54%) targeted biologic or synthetic DMARDs (b/tsDMARDs), including 72 on TNF inhibitors, 70 on rituximab and 39 on JAK inhibitors (13 baricitinib, 7 tofacitinib 17 upadacitinib and 2 filgotinib). We identified 15 (4%) venous thromboembolic events that occurred in 2021, including 11 PVT and 8 PE (incidence of 3.7 for 100 patient/year). The mean duration between the occurrence and VTE and the visit was 3.6 ±4.8 months. Among these 15 VTE patients, 11 were women (73%, vs. 82% in patient without VTE), with a mean age of 65±12 years (vs. 59±14, p=0.11). Age >65 years was more frequent in patient with VTE (60% vs. 33%, p=0.030); 4 (27%) patients with VTE had a history of previous VTE (vs. 3%, p< 0.001), 9 (60%) were hospitalized up to 6 months before the event (vs. 6%, p< 0.001), 5 (33%) experienced surgery up to 3 months bfore the event (vs. 2%, p< 0.001) and 4 (33%) had a history of fracture (vs. 3%, p< 0.001). No difference was oberved regarding body mass index, the frequency of

Table 1: results of the logistic regression analysis including VTE as the dependent variable

Variable	Odd ratio (95% CI)	p-value
Age >65 years	1.37 (0.38-4.84)	0.63
Male sex	1.15 (0.26-5.04)	0.85
Extra-articular manifestation	2.64 (0.72-9.64)	0.14
CRP levels	4.41 (0.51-31.28)	0.39
Corticosteroids	1.31 (0.33-5.42)	0.36
JAK inhibitors	7.69, (1.21-81.15)	0.027
History of previous VTE	33.06 (3.57-96.56)	0.002
Hospitalization up to 3 months	11.62 (2.89-46.71)	0.005
Surgery up to 6 months	8.02 (1.16-55.22)	0.034
History of fracture	0.56 (0.07-4.34)	0.58

smoking, neoplasia, recent travel (up to 3 months) and estrogen/antidepressant therapies. No patient had thrombophilia. Regarding RA characteristics, patients with VTE were more likely to present extra-articular manifestations (67% vs. 35%, p=0.011) and higher CRP levels (18±35 mg/L vs. 6.3±13 mg/L, p=0.007). They also received more frequently corticosteroids (73% vs. 47%, p=0.048) and JAKi (27% vs. 9%, p=0.021). Disease duration, autoantibody status, frequency of erosions, DA28 and treatment with methotrexate or bDMARDs did not differ between these 2 groups. Logitic regression analysis identified history of previous VTE, hospitalization, surgery and treatment with JAKi as independently associated with the occurrence of VTE (**Table 1**).

Conclusion: History of VTE was identified as the strongest risk factor of the occurrence of VTE. Our results suggest a specific warning on recent hospitalization and surgery as precipitating events to VTE.As recommended by the PRAC JAKi should be used with caution in patients with risk factors for VTE.

Rheumatoid Arthritis Patients Who Never Use a Biological During Their Disease Course Represent a Subgroup of Patients Likely to Achieve Sustained DMARD-free Remission

Judith Heutz[1], Pascal de Jong[1], Annette van der Helm-van Mil[2] and Elise van Mulligen[1], [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: According to the 2022 EULAR recommendations for the management of rheumatoid arthritis (RA) complete cessation of DMARDs is not advisable due to a high risk of disease flares. On the other hand, DMARD-free remission (DFR) is proven to be achievable and sustainable in 10-20% of RA patients. This paradoxical notion can possibly be explained by the fact that the EULAR recommendations refer to evidence from RCTs investigating ACPA-positive RA-patients with high disease activity at inclusion. Generally, this subgroup is treated more often with biologicals, while in daily practice only part of RA patients use a biological (ascertainment bias). We therefore hypothesized that RA patients who are treated with biologicals are less capable of achieving sustained DFR (sDFR) than patients who are not treated with biologicals. We studied this in two different cohorts.

Methods: Patients who fulfilled the 1987 and/or 2010 criteria for RA from the Leiden Early Arthritis Clinic (EAC) and from the treatment in the Rotterdam Arthritis Cohort (tREACH) trial were selected. The EAC is a population-based inception cohort that includes early arthritis patients who are treated according to general guidelines. The tREACH was a treat-to-target strategy trial in which RA patients were treated according to protocol that included treatment intensification as well as tapering. RA patients that had been treated with a biological at any point in time during 5 (EAC) and 3 (tREACH) years of follow-up

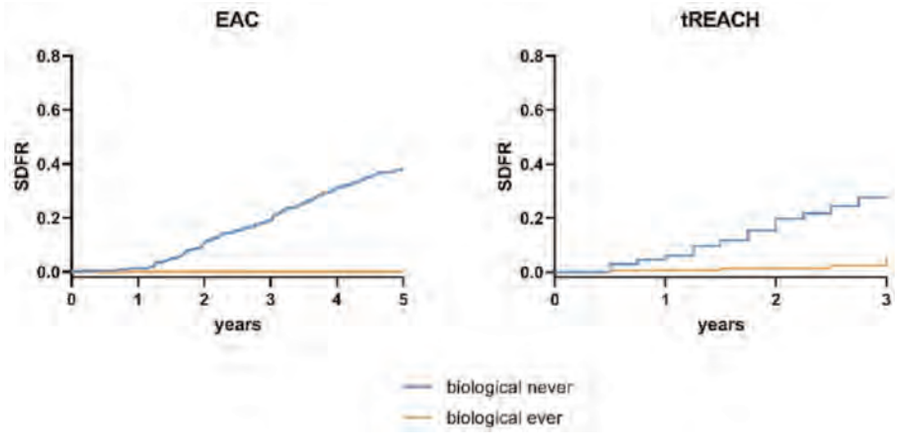

Figure 1. Kaplan Meier curves for achievement of sustained DFR in the EAC and tREACH. Orange lines indicate patients with a history of biological use. Blue lines indicate patients without a history of biological use. Follow-up time was 5 years in the EAC and 3 years in the tREACH. DFR, DMARD-free remission.

were compared to RA patients who had never used a biological in this period for the outcome of achieving sDFR. sDFR was defined as the sustained (≥12 months) absence of clinical arthritis after discontinuation of DMARD in both the EAC and tREACH. Differences in sDFR were visualised with Kaplan-Meier curves and tested with log rank tests.

Results: In the EAC 627 RA patients were followed for 5 years. None of the RA patients who ever used a biological achieved sDFR (0%), while 30% (162/538) of the patients who never used a biological achieved sDFR (p-value < 0.001; Figure 1). In the tREACH trial 425 patients were followed for 3 years; 3.2% (5/154) of patients who ever used a biological achieved sDFR, while 22% (60/271) of patients who never used a biological achieved sDFR (p-value < 0.001; Figure 1).

Conclusion: RA patients who use/used a biological have a negligible chance of achieving sDFR; in contrast to the large proportion of RA patients without biological use. Since the current RA management guidelines may suffer from ascertainment bias, future guidelines may be amended such that DMARD cessation is not discouraged in RA-patients without biologicals.

Bone Marrow Edema in MRI Is More Associated with Rapid Radiographic Progression Than Clinically Relevant Radiographic Progression

Kou Katayama[1], Takanobu Okubo[2], Toshikazu Sato[1], Kitaru Tanaka[3], Tomoki Kawahata[3], Yuichi Makino[4] and Hiroshi Ito[5], [1]Department of Orthopedic Surgery, Katayama Orthopedic Rheumatology Clinic, Asahikawa, Japan, [2]Department of Radiology, Katayama Orthopedic Rheumatology Clinic, Asahikawa, Japan, [3]Division of Metabolism and Biosystemic Science, Gastroenterology, and Hematology/Oncology, Department of Medicine, Asahikawa Medical University, Asahikawa, Japan, [4]Department of Medicine, Division of Rheumatology, Asahikawa Medical University Hospital, Asahikawa, Japan, [5]Department of orthpedic surgery, Asahikawa Medical University, Asahikawa, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rapid radiographic progression (RRP) is selected as one of the risk factors for difficult- to- treat RA, which needs to be resolved as soon as possible. On the other hand, EULAR recommendations for imaging were published, in which MRI bone oedema was an independent and strong predictor for joint destruction.

To clarify, association of BE with RRP using the clinical data in RA patients treated with conventional synthetic (cs) DMARDs. This study was undertaken for patients as post-hoc analysis of the paper (Trial Registration Number: UMIN000012200): Etiology of autoimmune diseases: Commensal bacterial pathogens overwhelming antibody defence function evoke serological marker levels and aggravate disease activity in rheumatoid arthritis. (K. Terato et al. Published: February 6, 2018, https://doi.org/10.1371/journal.pone.0190588).

Methods: All patients were mainly treated with methotrexate (MTX) or MTX +other csDMARDs combination therapy. The majority of patients did not respond to medication. None of the patients received biologics during the study. Hand and feet X-rays were taken for all patients and MRI was taken for affected hand. The modified total Sharp score (mTSS) was evaluated by KK and TO over a period of one year. MRI hand BE (rarely other large joints) were also checked by same reader by OMERACT MRI method as BE score.

Results: 1) At first, baseline data of 108 non-RRP patients and 47 Clinically relevant radiographic progression (CRRP:5 >ΔmTSS /year≥3)+RRP patients (ΔmTSS /year ≥5) were statistically compared. Short duration, high BE rate and MRI BE score (hand), high DAS28-ESR , high CRP levels, high mTSS, high yearly progression of mTSS were significantly increased in RRP+CRRP group compared with non RRP group. Secondly, background data of 13 CRRP and 34 RRP patients were compared. Only percentages of BE, MRI BE score (hand) were significantly increased in RRP group compared with CRRP group (table 1)

2)Secondly, patient data were divided into 5 groups according to rate of 1) ΔmTSS/year-- ≥10, 2)< 10 and ≥5 (both 1)2) are in RRP group), 3) < 5 and ≥3 (in CRRP group), 4) < 3 and >0.5, and 5)) ≤ 0.5(both 4)5) are in non RRP group). Mean of DAS28-ESR in the group of ΔmTSS /year ≥10 was significantly lower in the group of ΔmTSS /year < 10 and ≥5 and < 3 and >0.5, respectively(P< 0.05). No significant changes were observed in SJC (x10), CRP value (x10), RF, MMP3 (ng/ml) (figure 1A). We also compared mean BRI BE score (hand)(x10), ΔmTSS /year (x10), mTSS, age, disease duration among

Figure 1

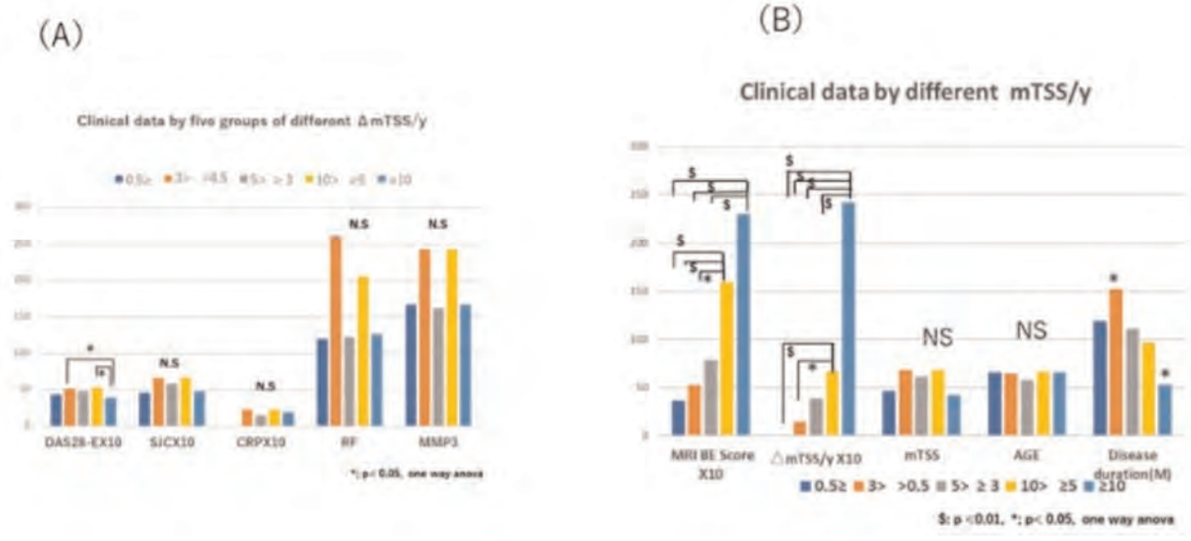

Figure 1.

5 groups. As a results, MRI BE score (hand) and and ΔmTSS /year in the group of ΔmTSS /year-≥10 or < 10 and ≥5 (both 4) 5) are in RRP group) was significantly higher than another group (figure 1B).

3) Finally, we investigated correlation between MRI BE score and ΔmTSS /year(x10). We found slight correlation between them. r = 0.57 P = 0.001(Pearson Correlation Coefficient) (Figure 2).

The Relationship Between Socioeconomic Factors and Persistent Active Rheumatoid Arthritis: Results from (NEIAA) a Large UK Cohort of Early Inflammatory Arthritis

Maryam Adas[1], Sam Norton[1], Andrew Cope[1], Maya Buch[2], James Galloway[1] and Elena Nikiphorou[1], [1]King's College London, London, United Kingdom, [2]University of Manchester and NIHR Manchester Biomedical Research Centre, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Psychosocial factors may interplay with biological factors to drive a refractory disease state in patients with inflammatory arthritis1. We aim to explore which socioeconomic, and disease related factors associated with persistent active rheumatoid arthritis (PactiveRA) in the first year, despite use of conventional synthetic DMARDs.

Methods: NEIAA is an observational cohort of adult patients with early RA patients in England and Wales. Data from May 2018 until Oct 2022 were acquired. All patients fulfilled the ACR/EULAR 2010 criteria for RA. Patients were defined as having PactiveRA based on three consecutive Disease Activity Scores (DAS28) of >3.2 at baseline, three and 12 months of follow up. Controlled RA (contRA) was defined as patients started with high DAS28 >3.2 at baseline then entered remission (DAS28 ≤ 3.2 at the three and 12 month time-points). PactiveRA status was used as the primary outcome variable.

Table. The association between PactiveRA with socioeconomic, clinical and treatment variables

Independent predictors at baseline	Univariable analysis OR (95% CI)	Multivariable analysis OR (95% CI)
Age (years)	0.99 (0.98,0.99)	0.99 (0.98,0.99)
Female gender	1.37 (1.15,1.63)	1.38 (1.16,1.64)
IMD (less social deprivation)	0.91 (0.88,0.94)	0.92 (0.89,0.95)
Ever smoked (referent never-smoked)	1.21 (1.02,1.43)	1.22 (1.02,1.47)
Depression	2.30 (1.67,3.17)	2.15 (1.54,3.01)
Lung disease	1.46 (1.14,1.86)	1.44 (1.12,1.85)
Stomach ulcer	1.71 (1.17,2.50)	1.72 (1.17,2.52)
CCP and RA seropositivity	0.80 (0.67,0.94)	0.69 (0.58,0.83)
Corticosteroids	1.52 (1.18,1.96)	1.50 (1.16,1.94)

Persistent active (pactiveRA) defined as DAS28 >3.2 at baseline, 3 and 12 moths of follow-up. CCP: cyclic citrullinated peptide; IMD: index of multiple deprivation; RF: rheumatoid factor. (p<0.05 for all predictors).

Univariable, followed by multivariable analyses stepwise forward logistic regression to explore associations with PactiveRA. Age and gender were included in the models as a priori, with socioeconomic variables handled as the main independent variables (social deprivation, smoking-status and comorbidities) of interest, followed by disease related factors.

Results: A total of 15,626 patients had a diagnosis of RA in NEIAA. Of which, 682 patients with pactiveRA and 1,026 patients with contRA were analysed. Compared to contRA, patients with PactiveRA were younger (aged 58, interquartile range (IQR): 49, 67) vs (62, IQR: 52,72), included more females 471 (69%) vs 607 (59%), were current or ex-smokers, and more likely to have depression, lung and gastrointestinal disease.

Also, patients with PactiveRA had worse scores in Patient Reported Outcomes at baseline and Patient Health Questionnaire Anxiety and Depression Screener. Logistic regression results are summarised in the table. Age, gender, living in a socially deprived area and being an ex or current smoker, were associated with PactiveRA in models controlling for markers of disease severity (seropositivity). Baseline corticosteroid use was also associated with PactiveRA ($p< 0.05$ for all) and having a concomitant diagnosis of depression, odds ratio (OR) 2.30 (95%CI: 1.67,3.17), lung disease OR 1.46 (95%CI: 1.14,1.86) and gastric ulcer OR 1.71 (95%CI: 1.17,2.50) were significantly related to PactiveRA**.**

Conclusion: Sociodemographic factors and living in socially deprived areas were all associated with PactiveRA, independent of clinical and disease characteristics. Identifying 'adverse' socioeconomic factors that could drive persistent active disease early in the disease process, can help better guide interventions that would be suitable for individual patients and their respective needs.

NOTES: All models include the baseline target to background ratios values from the most diseased segment (MDS TBR). PCE, Pooled Cohort Equation, includes age, sex, race, diabetes status, cigarette use, systolic blood pressure, treatment for hypertension, and high-density lipoprotein value. R^2 indicates better model fit when larger and Root Mean Square Error is better when smaller.

candidate biomarkers shown in prior literature to be associated with both RA and CV disease. These analyses tested a wide range of candidate biomarkers against CV risk assessed by arterial inflammation using a FDG PET/CT scan at baseline and 24 weeks.

Methods: These analyses leveraged data from TARGET trial (NCT02374021). Subjects had RA and were inadequate responders to methotrexate (MTX); they were then randomized to add a TNF inhibitor or triple therapy (MTX + sulfasalazine + hydroxychloroquine). Both treatment strategies demonstrated significant suppression of arterial inflammation, measured as the change in target to background ratio in the most diseased segment (MDS TBR) on the FDG PET/CT. However, we observed no significant differences in change in arterial inflammation between the arms. In this analysis, both arms were combined into a single cohort and candidate biomarkers (see **Table 1**) were tested at baseline and 24 weeks. First, progressively adjusted models tested baseline candidate biomarker values (per standard deviation) as predictors of change in MDS TBR between baseline and 24 weeks. Second, change (also 0 to 24 weeks) in candidate biomarker values (per standard deviation) were tested against change in MDS TBR. Models with only biomarkers, only traditional CV risk factors (Pooled Cohort Equation), and both were tested.

Table 2: Linear Regression Results Assessing Relationship Between Change in Each Candidate Biomarker from Baseline and Change in Target to Background Ratio in the TARGET Trial Cohort, with Increasing Adjustment

Model Fit Statistics			
R^2	0.64	0.21	0.63
Adjusted R^2	0.23	0.20	0.19
Root mean squared error	0.306	0.450	0.309

NOTES: All models include the baseline target to background ratios values from the most diseased segment (MDS TBR) and the baseline biomarker values. PCE, Pooled Cohort Equation, includes age, sex, race, diabetes status, cigarette use, systolic blood pressure, treatment for hypertension, and high-density lipoprotein value. R^2 indicates better model fit when larger and Root Mean Square Error is better when smaller.

Results: 115 patients had both biomarker data and FDG PET/CT data at baseline and 24 weeks. The patients in TARGET were similar to typical RA patients: 58-year median age; 71% women; 16 months median duration RA; and baseline DAS28 4.8. From the candidate biomarkers tested, we found significant adjusted associations between baseline values of SAA (b = -0.18, 95% CI -0.35, -0.01), CRP (b = 0.19, 95% CI 0.00, 0.38), and YKL-40 (b = 0.14, 95% CI 0.04, 0.25) (see **Table 1**) and change in arterial inflammation. We found significant adjusted associations between change from baseline to 24 weeks and change in MDS TBR for the following biomarkers (see **Table 2**): serum apolipoprotein A1 (b = -0.14, 95% CI -0.28, -0.01) and MMP-1 (b = 0.16, 95% CI -0.30, -0.02)**.** Model fit (R^2 and Root Mean Square Error, RMSE) was substantially improved when biomarkers were added to traditional CV risk factors.

Conclusion: A broad candidate biomarker scan among patients with RA demonstrated statistically and potentially clinically significant associations with change in arterial inflammation on FDG PET/CT. These biomarkers will be further tested in a large clinical RA cohort with confirmed CV events.

Patient's and Physician's Evaluation of Global Assessment of Disease Activity over Follow up and Across Disease Activity Levels in Recent-Onset Rheumatoid Arthritis

Audrey-Anne Couture[1], Nathalie Carrier[2], Hugues Allard-Chamard[3], Sophie ROUX[3], Patrick Liang[3] and Gilles Boire[3], [1]University of Montréal, Montréal, QC, Canada, [2]CIUSSS de l'Estrie - CHUS, Sherbrooke, QC, Canada, [3]Université de Sherbrooke, Sherbrooke, QC, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Composite measures (e.g. SDAI) to assess Rheumatoid Arthritis (RA) disease activity incorporate patient (PGA) and evaluator (EGA) global assessments. EGA and PGA are often discordant, reflecting divergent perspectives on evaluation of disease impact and potentially towards therapeutic goals. We evaluated the stability of PGA minus EGA (PGA-EGA) concordance or discordance from baseline to up to 5 years, and across all levels of disease activity in 822 patients (≥ 90% confirmed RA) from the prospective longitudinal Early Undifferentiated PolyArthritis (EUPA) cohort.

Table. Characteristics of patients according to Baseline PGA-EGA discordance (n=822)

Baseline characteristics	< -1 (n=205)	[-1 to 1] (n=224)	]1 to 3] (n=213)	> 3 (n=180)	p-value

CES-D score	15 (8-23)	15 (10-24)	18 (11-24)	18 (13-30)	**0.0033**

Variables were presented with median (IQR: Interquartile range) or with frequencies n (%). CES-D: Center for Evaluation Studies - Depression

Methods: Demographics, clinical and serological variables, radiographic damage (Sharp van der Heijde scores), treatments, comorbidities, and Patient-Reported Outcomes (pain, function, depression, sleep quality) were collected at baseline (median symptom duration 3.7 months) and at 12, 18, 30, 42 and 60 months from symptom onset. PGA and EGA were reported using a 0-10 cm visual analog scale (VAS). PGA-EGA discordance was divided in four subgroups: **negative** discordance group (< -1 cm), **concordance** group (≥-1cm and ≤+1 cm), positive **discordance group I** (>1 cm and ≤3 cm) and **group II** (>3 cm).

Results: At baseline, concordance was present in 27.3%, negative discordance in 24.9% while 47.8% expressed positive discordance (25.9 % group I and 21.9% group II). Over 60 months, concordance increased to 45.7%, negative discordance decreased to 7.7%, while positive discordant groups remained stable (still 46.4 % at 5 years). In positive discordant groups at baseline, patients were younger (median 58.6 years group I and 59.8 years group II, $p < 0.003$), had higher functional impact (M-HAQ ≥1, 46.3 % to 50.2 % $p < 0.001$), fewer tender and swollen joints ($p < 0.0001$), but rated higher for pain, fatigue, sleep disturbances ($p < 0.0001$) and depression (CES-D, median score 18 for both groups, $p < 0.005$). Only 20% (117/583) remained in the same subgroups between 18 and 60 months. The majority of those who remained stable were patients with concordance (79/117) and with positive discordance group II (25/117). Concordance was most frequent in remission, negative discordance in high disease activity, while group I positive discordance appeared independent of disease activity. Group II positive discordance was highest (35-38%) with low or moderate disease activity.

Conclusion: In this study of patients with early arthritis, almost half evaluated their global disease activity worse than the evaluator (positive discordance) and this proportion remained stable over the first 60 months of disease. Patients in positive discordant group were younger and reported higher functional impact, pain, fatigue, poor sleep and more symptoms of

Figure 1. Evolution of discordance and concordance over time

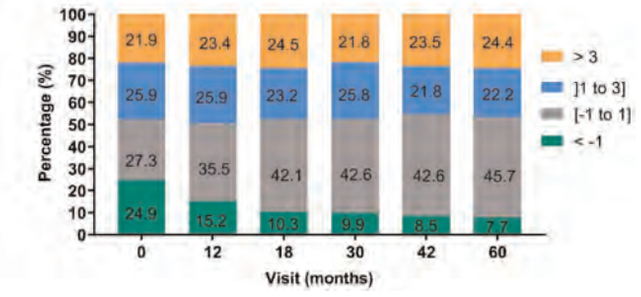

Figure 2. Distribution of concordance/discordance according to SDAI

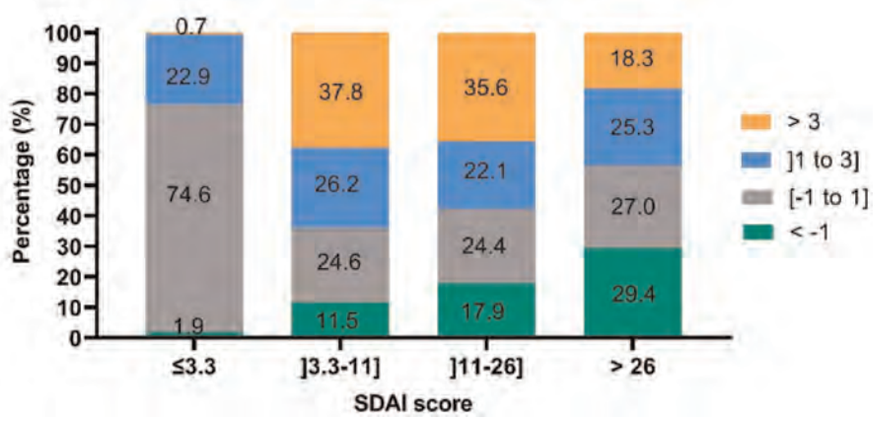

depression but had lower tender and swollen joint counts. Concordance was best when the patients were in SDAI remission. Negative discordance increased with disease activity. Over time, the relative proportions of each group remained similar, but only a small number of individual patients remained in the same group, most frequently in the concordance group but also among those who invariably rated their disease markedly more active than their physicians (group II), a subgroup important to identify early on to improve their management.

Window of Opportunity to Achieve Better Functional Outcomes in Patients with RA: Effectiveness of an Early Treatment Strategy

Vivian Bykerk[1], Isabel Castrejon[2], Vibeke Strand[3], Stephanie Dahan[4], Raul Castellanos-Moreira[5], Leo Chen[6] and Wayne Little[4], [1]Department of Rheumatology, Hospital for Special Surgery, New York, NY, [2]Hospital Universitario Gregorio Marañón, Madrid, Spain, [3]Stanford University, Palo Alto, CA, [4]Bristol Myers Squibb, Princeton, NJ, [5]Bristol Myers Squibb, Madrid, Spain, [6]Syneos Health, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: RA is a chronic disease that can lead to irreversible damage and functional decline with delayed or inadequate treatment.[1] Abatacept + MTX is effective for many patients (pts) with RA[2,3] and may better preserve functional status when introduced early in the disease course[4]. The HAQ-disability index (DI) is a pt-reported outcome delineating physical function impacted by RA.[3,5] This study assessed the relationship between baseline (BL) disease duration after initiating abatacept + MTX and improved physical function using HAQ-DI scores in RA over 8 yrs.

Methods: This pooled analysis included data from 15 randomized controlled trials (RCTs) in pts with RA (ACR/EULAR 2010 criteria[6]) treated with abatacept + MTX. Included pts had data available on BL disease duration, HAQ-DI scores (0–3 scale), and demographic characteristics. Trends in mean HAQ-DI and mean change in HAQ-DI from BL over time were modelled using mixed-effect linear regression models, fitted to BL disease duration and the log of treatment duration as fixed effects and subject identities as random effects. Analyses were repeated in subgroups categorized by age, sex, race, and BMI.

Results: Of the 6042 pts included, most had a disease duration < 2 yrs (34.5%), a normal BMI of 18.5 to < 25 kg/m^2 (29.6%), were of female sex (80.3%) and White (82.1%) (mean age: 51.2 yrs; **Table 1**). In the overall population, HAQ-DI decreases were associated with shorter disease duration (**Fig 1A**): the magnitude of changes in HAQ-DI scores decreased as disease duration increased at all time points (**Fig 2A**). A similar trend was observed for subgroups categorized by age (**Figs 1B–D, 2B–D**), sex, race, and BMI (data not shown). BL HAQ-DI scores for all disease duration categories were higher among females (95% CI: 1.6–1.7 vs 1.3–1.5 in males), and the trend in HAQ-DI reductions was more gradual in male versus female pts (data not shown). In the overall population and subgroups categorized by age, the greatest reduction in HAQ-DI

Table 1. BL demographic and disease characteristics of the pooled study population[a]

Characteristics	Overall population (N = 6042)
Disease duration, yrs, n (%)	
< 2	2083 (34.5)
2 to < 5	1109 (18.4)
5 to < 10	1143 (18.9)
≥ 10	1707 (28.3)
Age, yrs, mean (95% CI)	51.2 (50.9–51.5)
Sex, n (%)	
Male	1191 (19.7)
Female	4851 (80.3)
Race, n (%)	
White	4960 (82.1)
Black/African American	282 (4.7)

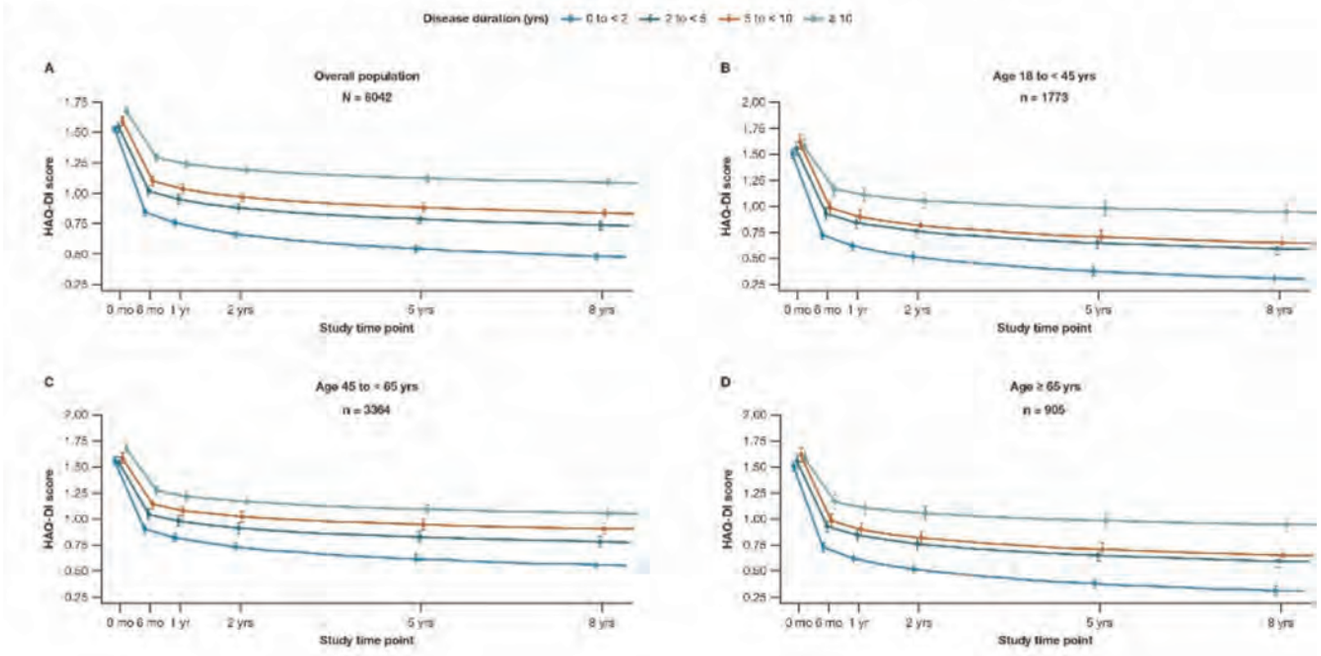
≥ 30 (obese)	1613 (26.7)

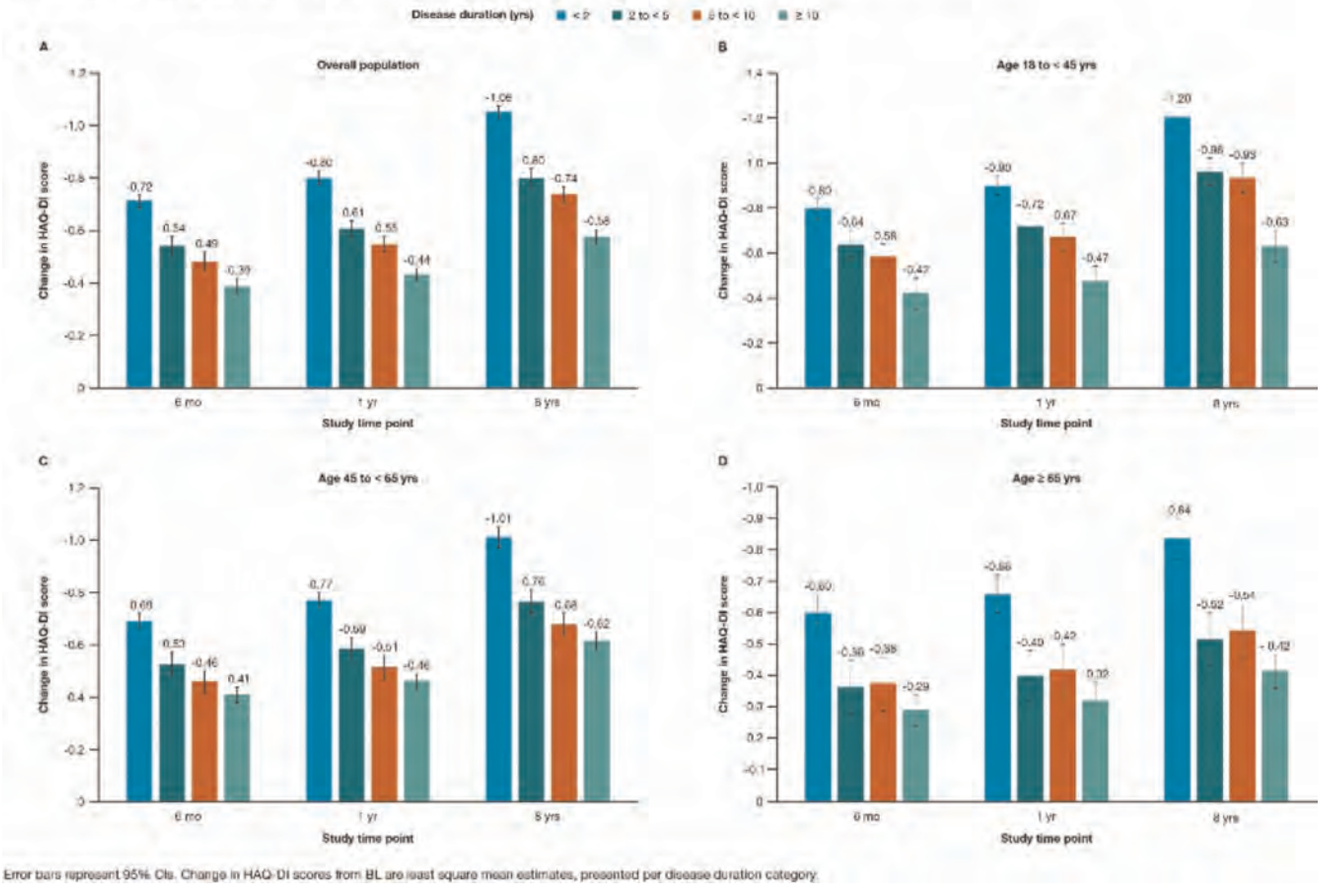
[a]Pooled data from 15 randomized controlled trials: IM101-023, IM101-029, IM101-031, IM101-043, IM101-064, IM101-100, IM101-101, IM101-102, IM101-167, IM101-173, IM101-174, IM101-226, IM101-235, IM101-550, and IM101-567.

Fig 1. Estimated mean HAQ-DI scores from BL to yr 8 by BL disease duration for (A) the overall population and population grouped by age: (B) 18 to < 45 yrs, (C) 45 to < 65 yrs, and (D) ≥ 65 yrs



Error bars represent 95% CIs. Study time points are approximated using 30-day mos and 365-day yrs. For identical time points, x-axis offset was applied to improve visibility and avoid overlap of the curves. HAQ-DI scores are least square mean estimates.

Fig 2. Change in HAQ-DI scores from BL to yr 8 for (A) the overall population and population grouped by age: (B) 18 to < 45 yrs, (C) 45 to < 65 yrs, and (D) ≥ 65 yrs



Error bars represent 95% CIs. Change in HAQ-DI scores from BL are least square mean estimates, presented per disease duration category.

scores occurred between BL and 6 mo, followed by gradual reductions until 8 yrs (**Figs 1, 2**). Differences between disease duration categories were notable from 6 mo and increased with follow-up time (**Figs 1, 2**). The largest reductions in HAQ-DI scores were reported by pts with RA disease duration < 2 yrs and the smallest reductions, by those with RA disease duration ≥ 10 yrs (**Fig 2A**).

Conclusion: Pts with RA receiving earlier abatacept treatment (within 2 yrs of diagnosis) reported greater improvements in and better maintenance of physical function over time. In all groups analyzed, pts with the shortest disease duration at BL who received abatacept + MTX had the best outcomes. Among currently available RA treatments, abatacept + MTX notably improves physical function in pts with early RA. Our findings support the need for prospective RCTs to evaluate abatacept + MTX as an early-line treatment for RA.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

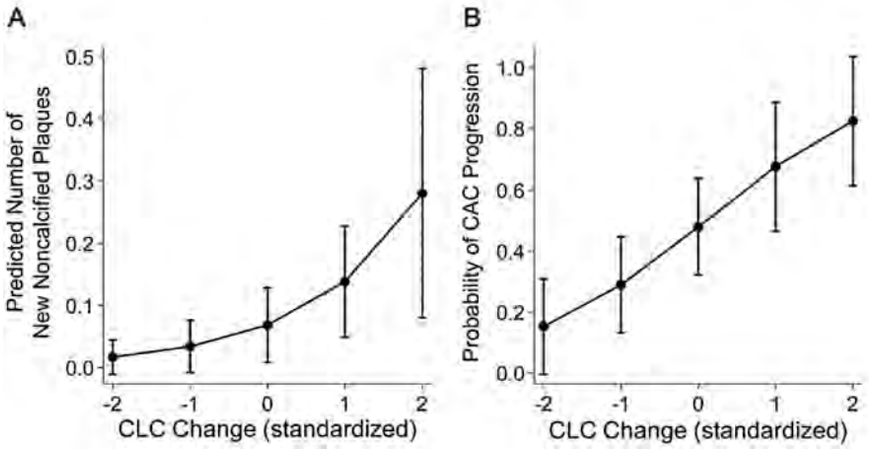
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The ability of serum to deliver cholesterol to cells is known as cholesterol loading capacity (CLC) and associates with foam cell formation. In rheumatoid arthritis (RA), CLC was linked to long-term cardiovascular risk as well as coronary atherosclerosis burden and vulnerable plaque composition, particularly in biologic nonusers[1]. The relationship between changes in CLC over time and plaque progression is unknown.

Figure 1 Noncalcified plaque increase **(A)** and probability of CAC progression (B) per standard deviation increase in CLC change from baseline to follow-up



Methods: Atherosclerosis (noncalcified, partially or fully calcified plaques and coronary artery calcium [CAC] score) was evaluated with coronary computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 100 after 6.9±0.4 years. Presence of 5 or more plaques in a patient and lesions rendering greater than 50% luminal stenosis were considered extensive and obstructive disease respectively. CLC was measured as intracellular cholesterol content in serum treated human THP-1 monocyte-derived macrophages with a fluorimetric assay during baseline and follow-up atherosclerosis assessments. Multivariable negative binomial and robust linear regression tested the associations between changes in CLC from baseline to follow-up and coronary plaque and CAC progression and new extensive or obstructive disease respectively.

Results: CLC decreased in 68% and increased in 32% of patients at follow-up. All subjects (34/34) at the highest tertile of baseline CLC showed decrease at follow-up whereas 25/33 (75.8%) of patients at the lowest CLC tertile showed increase ($p< 0.0001$). CLC change (per standard deviation) associated with noncalcified plaque increase after adjusting for atherosclerotic cardiovascular disease (ASCVD) score, baseline plaque burden, obesity and duration of prednisone exposure throughout follow-up (incident rate ratio [IRR] 2.03, 95% confidence interval [95%CI] 1.27-3.24, p=0.003); risk of CAC increase after adjustments for ASCVD, baseline CAC, time-averaged c-reactive protein (TA-CRP), weighted daily-average atorvastatin equivalent dose and obesity (odds ratio [OR] 2.26, 95%CI 1.25-3.24, p=0.007) and risk of new extensive or obstructive disease at follow-up after adjusting for ASCVD, baseline plaque and TA-CRP (OR 3.17, 95%CI 1.01-9.94, p=0.048). Incrementally higher CLC at follow-up compared to baseline associated with progressively more new noncalcified plaques, greater risk of CAC increase and new extensive or obstructive disease. In contrast, greater decreases in follow-up CLC associated with significantly fewer new noncalcified plaques (Figure 1A), gradually lower risk of CAC increase (Figure 1B) and new extensive or obstructive disease.

Conclusion: Increasing CLC and therefore rising cholesterol content in arterial wall macrophages over time associates with coronary atherosclerosis progression in a dose-dependent manner, and particularly higher burden of lipid rich noncalcified plaques and extensive or obstructive disease conveying the greatest cardiovascular risk.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Baseline and cumulative inflammation have both been associated with increased cardiovascular event (CVE) risk in patients with rheumatoid arthritis (RA). Statin therapy reduced systemic inflammation, attenuated coronary atherosclerosis progression and promoted plaque calcification and stabilization[1] both in general as well as RA patients. We here explored whether baseline statin use influenced the impact of baseline C-reactive protein (CRP) on long-term cardiovascular risk in patients with RA.

Methods: We evaluated 4,357 patients without known cardiovascular disease upon registration to *A*n Int*e*rnationa*l C*ardiovascular *C*onsortium for people with *RA* (ATACC-RA) and who were followed prospectively. The primary outcome was ischemic CVE defined as the composite endpoint of cardiovascular death, non-fatal myocardial infarction, non-fatal stroke, coronary revascularization, stable angina pectoris, transient ischemic attack, and peripheral arterial disease with or without revascularization. Missing data were imputed using multiple imputation with 10 repetitions. Multivariable Cox models stratified by center evaluated the effect of natural logarithm of CRP, statin use and their interaction on CVE risk after adjusting for age, gender, hypertension, diabetes, family history, smoking, age at RA diagnosis, and total cholesterol to high-density lipoprotein (TC/HDL)ratio. A sensitivity analysis was performed using inverse probability of treatment weights to balance differences between statin treated and untreated patients.

Results: At baseline 462 patients were treated with statins whereas 3,895 were not. Statin therapy inversely associated with low density lipoprotein cholesterol (p< 0.001), TC/HDL ratio (p< 0.001) and CRP(ln) (p=0.048). Over 26,356 patient years (PY) of follow-up, 361 total ischemic CVE were recorded, 321 over 24,235 PY in statin nonusers and 40 over 2,121 PY in statin users. Incidence of any ischemic CVE was 13.3 (95% CI 11.9-14.8)/1000PY among statin nonusers and 18.9 (95% CI 13.8-25.7)/1000PY in statin users (incidence rate difference 5.62 [95% CI -0.41 to 11.64]). In the entire cohort, baseline CRP(ln) was not associated with ischemic CVE risk, [adjusted hazards ratio- aHR 1.07 (95% CI 0.98-1.17), p=0.138]. However, higher CRP(ln) associated with greater risk of the composite outcome exclusively in statin nonusers [aHR 1.10 (95% CI

Figure 1 Cardiovascular event risk in main (unweighted) and sensitivity analyses (inverse probability-IP weighted) with increasing CRP

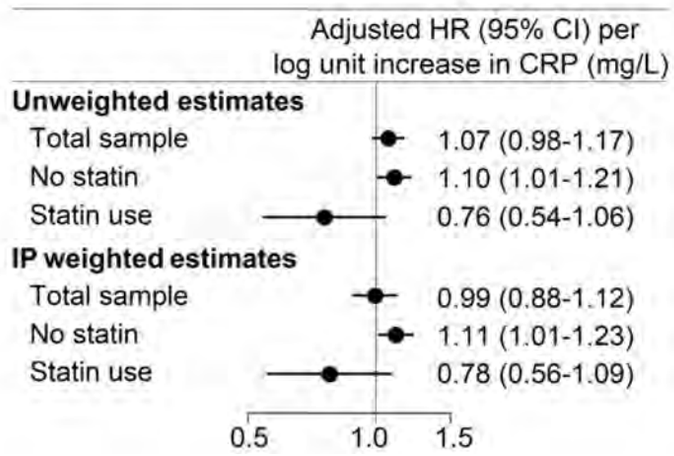

Figure 2 Cumulative probability of ischemic cardiovascular event in statin users and nonusers at high (+1-SD) and low (-1-SD) baseline CRP

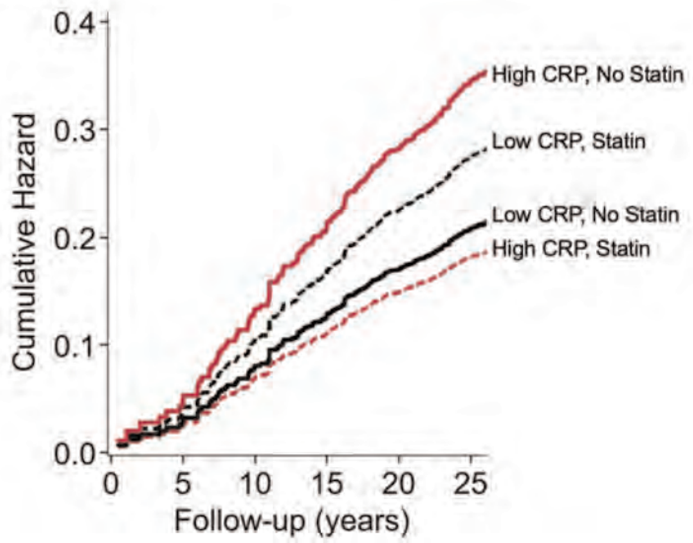

1.01-1.21), p=0.036] but not in statin users (p-interaction=0.032, Figures 1 and 2). While CRP(ln) was not different between statin groups after inverse probability weighting adjustment (p=0.333), the sensitivity analysis yielded similar results: higher CRP(ln) associated with greater ischemic CVE risk in statin nonusers [aHR 1.11 (95% CI 1.01-1.22), p=0.030] but not among statin users (p-interaction=0.046).

Conclusion: Higher inflammation at baseline associated with greater risk of any ischemic CVE among statin nonusers but not in users. This points to the potential of statin-specific effects directly on atherosclerotic plaque—such as lower progression and stabilization[1]—above and beyond effects on cholesterol metabolism and systemic inflammation.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster II

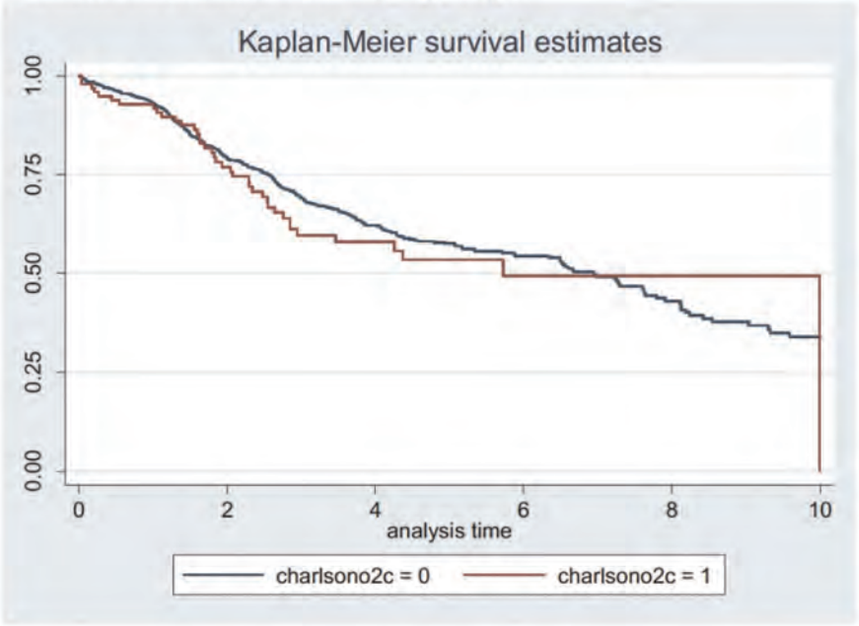
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Rheumatoid Arthritis (RA) have a higher prevalence of comorbidities, compared to the general population. The presence of such comorbidities has been directly associated with an increased disease activity. However, little is known about the impact of comorbidities in the therapeutic response and in the retention rate. *Objectives:* a) To evaluate the effect of comorbidities on the first biologic disease-modifying antirheumatic drug (bDMARD) effectiveness in patients with RA after 2 years of follow-up, and b) to determine the influence of such comorbidities on the first bDMARD retention rate.

Methods: The study population consisted of patients with a diagnosis of RA and exposed to a first bDMARDs, included in BIOBADASER. BIOBADASER is a prospective, large national drug safety registry of patients with rheumatic diseases exposed to b- or tsDMARDs. Patients were classified in two groups at baseline according to the Charlson Comorbidity index (CCI) score: < 3 and ≥3. Patients achieving remission (DAS28< 2.6) at 1 and 2-years timepoints after the anti-TNF initiation were compared between the two groups using chi-square test. The absolute DAS28 score over time was compared between both groups of patients using a linear regression model adjusted for sex and age, and considering the follow-up visit as covariate. Finally, the first bDMARD retention rate was compared between patients < 3 and ≥3 using Log-Rank test and Kaplan-Meier curve.

Figure 1. Kaplan Meier curve comparing the first bDMARD retention rate between the two groups.



Results: A total of 1253 patients initiating bDMARD were included (76.6% female and mean age 56 years at the beginning of therapy). Overall, 107 (9%) patients had a CCI ≥3, being diabetes the most frequent comorbidity (5.0%). No differences were found in DAS28< 2.6 between patients with CCI< 3 and CCI≥3 after 1 year of follow-up (48.2% vs. 44.2%, p-value=0.457), nor after 2 years (50.8% vs. 40.7%, p-value=0.135). The linear regression model showed significant higher scores in DAS28 over the two years in patients with a CCI ≥3 after adjusting for age and sex (beta coefficient 0.27, 95%CI: 0.02-0.51; p-value=0.034). Finally, no differences in the bDMARD retention rate were found between both groups (median 2.6 years [IQR: 1.5-4.1] in CCI< 3 vs. 2.1 years [IQR: 0.6-3.7] in CCI≥3; log rank test p-value 0.467) (Figure).

Conclusion: These data suggest that a higher CCI in patients with RA is associated with greater DAS28 scores during the first two years after bDMARD initiation, although no differences in remission status were found. In addition, a slightly shorter retention rate was found in patients with CCI≥3, although the difference was non-significant. These results suggest a lower probability of disease activity control in patients with comorbidities after the initiation of bDMARD.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Factor (RF) is an antibody against the Fc fragment of IgG that contributes to the Rheumatoid Arthritis (RA) development. RF can bind the Fc fragment of infliximab, suggesting the hypothesis that it can also bind other monoclonal antibodies (mAB (Adalimumab, Golimumab and Infliximab)) and fusion proteins (FP (Etanercept)), leading to a lower drug levels and potential early withdrawal. Conversely, the absence of Fc fragment in Certolizumab Pegol (PEG) may lead to a higher retention rate in comparison with other drugs in RA patients (pts) with high RF titers. Objectives: a) to compare the retention rate to PEG vs. mAB and vs. FP in AR pts with high RF titers; b) to conduct the similar analysis but stratifying in naïve and non-naïve pts.

Methods: Longitudinal, retrospective and multicentre study including pts with RA and treated with any TNFi (mAB, FP or PEG) between 2010-2022. RF levels before TNFi initiation and the dates of both initiation and treatment withdrawal were collected. Log-rank test and Kaplan-Meier curves were conducted to evaluate the retention rate to the three molecular structures according to the level of RF considering the quartiles of the baseline titres as cut-offs: < 15, >60 and >200 UI/ml (negative, high, and very high levels, respectively). A sensitivity analysis was performed using a Propensity Score (PS) matching the PEG, mAB and FP populations according to the age, sex and previous TNFi use.

Results: A total of 755 pts with RA treated with TNFi (132 PEG, 441 mAB and 182 FP) and with available titres of RF were included (mean age 53 (12) years, 80.2% female and 70.7% naïve). In the total population, a similar retention rate to PEG, mAB and FP was found (6.1y (95%CI 3.7-NA), 4.2y (95%CI 3.3-8.7) and 4.6y (95%CI 2.9-7.8), respectively, p=0.380). According to the RF levels, the retention rate to the three molecular structures were similar in seronegative pts(F.1A), and in those with high (F.1B) and very high levels (F.1C). When selecting non-naïve pts, those with negative RF titres showed similar retention rates across molecular structures (F.2A). However, in non-naïve ptswith high levels of RF, those treated with PEG showed a significant longer retention rate in comparison with mAB and FP (median 11.0y (95%CI 6.3-NA), 1.4y (95%CI 1.1-NA) and 3.1y (95%CI 0.8-8.8) respectively, p=0.017)(F.2B). Similar results were obtained in non-naïve ptswith

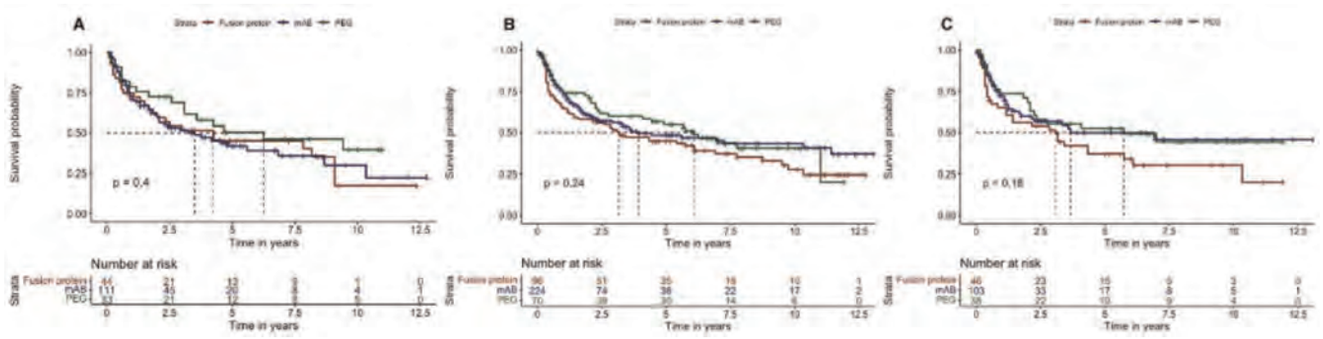

Figure 1. Retention rate to the three molecular structures according to the baseline RF titers: (A) <15 IU/ml, (B) >60 IU/ml and (C) >200 UI/ml.

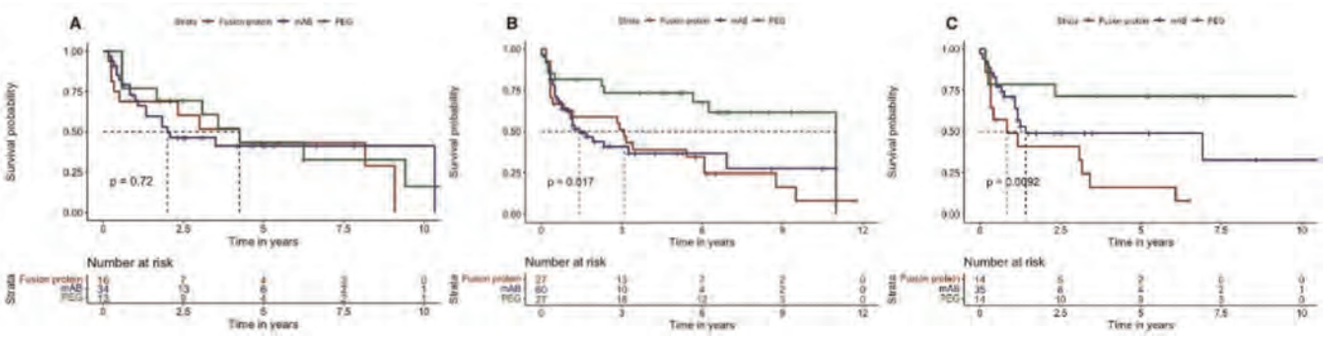

Figure 2. Retention rate to the three molecular structures according to the baseline RF titers in non-naïve patients: (A) <15 IU/ml, (B) >60 IU/ml and (C) >200 UI/ml.

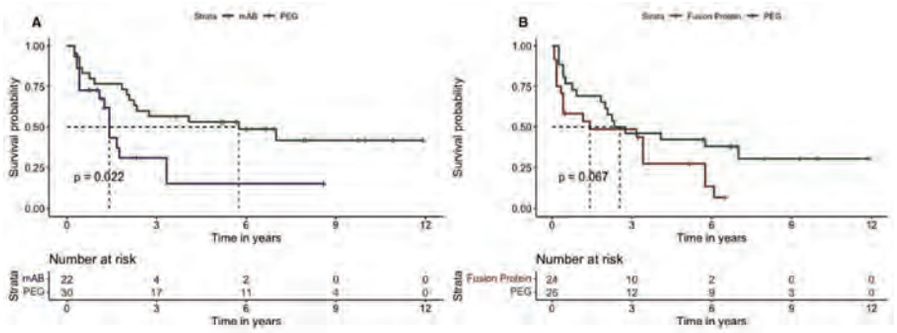

Figure 3. Sensitivity analysis in patients with very high baseline levels of RF (>200 UI/ml) using the PS: (A) PEG vs. mAB and (B) PEG vs. fusion protein.

very high titres of RF (F.2C). In ptswith very high levels of RF, the sensitivity analysis using the PS showed a significant longer retention rate to PEG vs. mAB (median 5.8y (95%CI 2.3-NA) vs. 1.4y (95%CI 1.3-NA), respectively, p=0.022) irrespectively of the previous use of TNFi (F.3A). Likewise, PEG vs. FP showed a longer retention rate, although these differences were non-significant (median 2.5y (95%CI 1.8-NA) vs. 1.4y (95%CI 0.4-5.8), p=0.067)(F.3B).

Conclusion: High or very high RF titers before TNFi initiation were associated with a longer retention rate in non-naïve pts treated with PEG in comparison with mAB and FP. When matching the population using PS, very high levels of RF were associated with longer retention rate to PEG vs. mAB irrespectively of the previous use of TNFi. These results confirm the possible effect of the RF in binding the Fc fragment of the drug.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the increasing number of available targeted therapies (TT) in rheumatoid arthritis (RA), a proportion of RA patients fail to respond to their first TT, and response decreases with increasing TTs exposures. The definition of refractory RA (refRA) patients is complex; however, recent EULAR guidance defines "difficult-to-treat RA" (D2T RA) as a failure of two or more TTs with differing mechanisms of action (TTDMA) with signs suggestive of active disease, and the management of signs and/or symptoms is perceived as difficult by the rheumatologist and/or the patient.

We aimed to determine the clinical and therapeutic profile of refRA, to describe the patterns of drug sequencing in terms of loss of response, non-response or adverse effects that are associated with RefRA.

Methods: Observational retrospective study with a single-center cohort of RA patients (ACR/EULAR 2010 criteria) exposed to TT since 2000 was performed. We defined refRA as failure of at least 2 TTDMA with moderate/high activity at the TT onset. Demographic and clinical variables were extracted from the electronic medical record, and we analyzed the different lines of treatment with TTs, its duration treatment and reasons for treatment discontinuation.

Results: 537 RA patients undergoing TTs were included, 81 from them were considered as refRA. Clinical and demographic characteristics are listed in table 1.

In a multivariate logistic regression analysis RefRA patients showed younger age at diagnosis, higher proportion of female sex and Sjögren Syndrome, and higher Das28-ESR values than non-refRA (P< 0.001). No differences in CRP and ESR levels, rheumatoid factor or anti-CCP positivity, cardiovascular events, depression, fibromyalgia or pulmonary affection were observed. A Kapplan-Meier survival analysis showed a shorter length of TT in RefRA than non-RefRA (P< 0.0001).

Anti-TNF was the treatment of choice for the 1sr and 2nd TTs, however is less likely to be administered in non-RefRA rather than RefRA (P< 0.001) (table 2), and RefRA showed more incidence of switches (P< 0.001). The absence of conventional DMARD treatment is more likely in Non-RefRA (P=0.046).

Table1

Variable	Non-D2T RA N=456	D2T RA N=81	
	Mean (SD) / n(%)	Mean (SD) / n(%)	P-value
Age at diagnosis (years)	47.6 (12.87)	41.78 (11.37)	<0.001
Age at the beginning of the 1st TT (years)	55.84 (11.99)	48.68 (10.57)	<0.001
Time of disease evolution until the 1st TT (months)	100.54 (102.12)	84.43 (96.52)	0.188
Duration of TT (months)	72.84 (69.23)	42.17 (47.41)	<0.001
Sex (female)	348 (76.32%)	72 (88.89%)	0.01216
C-Reactive Protein	17.85 (23.61)	25.6 (31.23)	0.0346
Erythrocyte sedimentation rate	35.1 (22.88)	47 (31.97)	<0.001
Das28-ESR	5.01 (1.23)	5.55 (1.13)	0.0014
Primary non-response treatment	21 (9.05%)	11 (13.58%)	0.0016
Secondary non-response treatment	91 (39.22%)	40 (49.38%)	<0.001
Discontinuation by adverse event	75 (32.33%)	28 (34.57%)	<0.001
Sjögren syndrome	75 (32.33%)	28 (34.57%)	0.1154
Raynaud's phenomenon	11 (2.41%)	1 (1.23%)	0.7677
Pulmonary affection	81 (17.76%)	18 (22.22%)	0.3681
Cardiovascular event	81 (17.76%)	17 (20.99%)	0.5193
Fibromyalgia	20 (4.39%)	6 (7.41%)	0.4195
Depression	35 (7.68%)	7 (8.64%)	0.9999
Diabetes	58 (12.89%)	7 (12.5%)	0.9886
Dyslipidemia	185 (41.11%)	21 (37.5%)	0.8636
Arterial hypertension	177 (39.33%)	19 (33.93%)	0.6803

Loss of response in 1sr and 2nd TTs were the main reason for discontinuing treatment in refRA, being the adverse event and other causes no related to TT the more frequent as cause of discontinuing TT in non-refRA (P=0.006). When we analyze the reason for discontinuing treatment and excluding the "other causes", if the cause of discontinuing treatment in refRA is a primary non-response, near of the 30% of patients discontinue in second-line by the same reason; and if the cause for discontinuation in first-line is an adverse effect, the 33% of patients discontinue in second-line by the same reason.

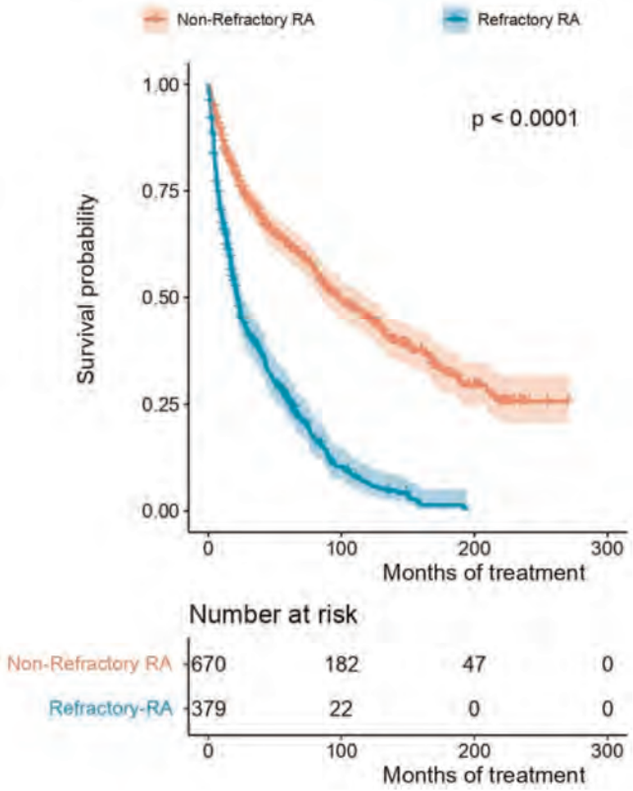

Figure1

Conclusion: RefRA patients in this study showed lower age at diagnosis, higher proportion of female sex and Sjögren Syndrome. With an exposition of 4 TTs as an average in refRA, the duration of TT is shorter and anti-TNF was the most frequent TT both in first and second line of treatment with more incidence of switching. Loss of response is the most common cause of discontinuation in refRA, with lower rate of adverse events and other causes of discontinuation than non-RefRA.

Comparison of Two Methotrexate Initiation Strategies in Rheumatoid Arthritis in Current Practice

Paola Vidal-Montal[1], Alice Combier[2], Alexia STEELANDT[2], Marion THOMAS[2], Javier Narvaez[3], Joan Miquel Nolla[1], Yannick ALLANORE[4] and Jerome AVOUAC[5], [1]Department of Rheumatology, Hospital Universitario de Bellvitge, Barcelona, Spain, [2]HOPITAL COCHIN AP-HP, Service de Rhumatologie, Paris, France, [3]Hospital Universitario de Bellvitge, Barcelona, Spain, [4]Université Paris Cité, Paris, France, [5]Rheumatology A Department, Hôpital Cochin, AP-HP Centre - Université Paris Cité, Paris, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To compare the efficacy and tolerance at 3 and 6 months of two methotrexate (MTX) initiation strategies in rheumatoid arthritis (RA).

Methods: Retrospective,monocentric,cross-sectionalstudy including patients with RA who initiated MTX as first-line therapy during the last 2 years according to one of the following 2 strategies: a "conventional" strategy (CS) defined by an initiation of oral MTX at a dose of 10-15 mg/week or an "aggressive" strategy (AS), defined by an initiation of subcutaneous (SC) MTX at a dose of 15 mg/week SC or >15 mg/week either orally or SC. Each strategy allowed the possibility to increase the doses and/or switch to the SC route at 3 months. Efficacy was assessed at 3 and 6 months using the DAS28-CRP. The tolerance of each strategy was also assessed at month 3 and 6.

Results: We included 101 patients (85 women) with a mean age of 55±12 years and disease duration of 5±6 months. The frequency of rheumatoid factors, anti-CCP antibodies and erosions was 83%, 81% and 38% respectively. 61 patients initiated MTX according to the CS, with an increase of dose and/or a switch to the SC route at 3 months for 31 patients, and 40 patients started treatment according to the AS, with an increase of dose and/or switch to the SC route at 3 months for 14 patients. There was no difference between these 2 groups in terms of age, gender, disease duration, antibody status, frequency of bone erosions, body mass index, comorbidities and disease activity at baseline. Efficacy at 3 months was significantly higher with the AS (reduction of the DAS28-CRP from 4.34±0.91 to 2.39±0.75, mean difference of 1.95±1.21, $p< 0.001$) compared to the CS (reduction of the DAS28-CRP from 4.09±0.62 to 2.88±0.73, mean difference of 1.21 ±0.90, $p=0.12$) (**Figure 1**). The improvement of tender/swollen joint counts, patient global assessment and CRP levels

was also significantly more important at 3 months with the AS (**Table 1**). At 6 months, although the DAS28-CRP was similar in the 2 groups (**Figure 1**), less patients from the AS subgroup required an escalation to a targeted biologic/synthetic therapy compared to the CS (12/40, 30% vs. 29/61, 48%, p=0.073). The frequency of digestive side effects at 3 months was significantly lower in the AS (3/40, 7,5% vs. 16/61, 26%, p=0.021). The frequency of hepatic cytolysis at 3 month was higher in the AS (4/40, 10% vs. 1/61,1,6%, p=0.057). The frequency of asthenia at 3 months was similar in both groups (7/4, 18% vs. 6/61, 10%, p=0.25). Only one infection was observed in the CS and no hematological side effect was recorded. At 6 months, the cumulative incidence of side effects was 23% with the AS compared to 46% with the CS (p=0.015). Only one treatment discontinuation was noted in the AS subgroup vs. 9 in the CS subgroup (p=0.042).

Conclusion: This study suggests that it is possible to use a more aggressive initiation strategy of MTX in RA in routine clinical practice. This strategy allows to obtain an earlier clinical response and it is associated with a better tolerance than the conventional strategy. These results need to be confirmed in prospective studies.

Table 1: Evaluation of efficacy parameter at 3 months according to the methotrexate initiation strategy

	"Conventional" strategy (n=61)	"Aggressive" strategy (n=40)	p-value
Variation of tender joint count	-2.6±3.4	-4.4±4.9	0.032
Variation of swollen joint count	-2.0±5	-4.7±4.0	0.005
Variation of PGA-VAS	-24±25	-40±35	0.009
Variation of CRP (mg/L)	-1.8±13	-15±20	<0.001

T Cell Subset Signatures Predicted Clinical Response to Etanercept-biosimilar Yisaipu in Patients with Rheumatoid Arthritis

Huaqun Zhu[1], Sumei Tang[1], Gong Cheng[1], Yingni Li[1], Yun Li[1], Feng Sun[1], Xiaolin Sun[1], Jiahui Cheng[1], Ru Li[1] and Zhanguo Li[2], [1]Peking University People's Hospital, Beijing, China, [2]Peking University Health Science Center, Department of Rheumatology and Immunology, People's Hospital, Beijing, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Our study aimed to use machine-learning approaches to characterize the immune cell profiles of patients who were inadequate responders to Etanercept-Biosimilar Yisaipu (Yisaipu-IRs) and develop an Yisaipu-IR risk model based on immune cell signatures in rheumatoid arthritis (RA).

Methods: The study included RA patients from the Department of Rheumatology and Immunology, Peking University People's Hospital between July 1, 2022 and May 3, 2023. All the patients fulfilled the 2010 American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) classification criteria for RA. All the patients received Yisaipu 25mg twice a week for 6 months. Patients who didn't achieve ACR20 improvement at 3rd month after enrollment were defined as Yisaipu-IRs and others were defined as Yisaipu adequate responders (Yisaipu-ARs). Immunophenotyping profiles (24 immune cell subsets) of peripheral blood mononuclear cell from Yisaipu-IRs and Yisaipu-ARs were determined by flow cytometry. Spearman correlation analysis was used to test the association between immune phenotypes. Sparse partial least squares-discriminant analysis (sPLS-DA) was used to assess classification and parameter selection. Univariate and multivariate logistic regression analyses were performed to identify immune cell signatures associated with Yisaipu-IRs to build a risk model. Study design and analysis plan flow diagram was shown in **figure1**.

Results: Peripheral blood was collected from 30 Yisaipu-ARs and 8 Yisaipu-IRs. The demographic data and clinical features of the patients were described in **table 1**. The mean age was 51.8±12.4 years for Yisaipu-ARs and 52.5±12.8 years for Yisaipu-IRs. In-depth immune cell phenotyping showed that Yisaipu-IRs had a disrupted immune cell profile, compared with Yisaipu-ARs, including alteration in total CD8$^+$ T-cell, regulatory T-cell (Treg), effector T-cell (Teff) and total B-cell (**figure 2**). Correlation analysis displayed significant disruption in the relationship among total CD8$^+$ T-cell, Treg and B-cell with each other in Yisaipu-IRs compared to Yisaipu-ARs (**figure 3**). The top-ranked immunological features discriminated by sPLS-DA included total CD8$^+$ T-cell, Treg and CLA$^+$ Treg and Teff (**figure 4)**. Logistic regression analysis was applied to confirm that total CD8$^+$ T-cell, CLA$^+$ Treg and foxp3$^+$Treg were significantly associated with ETN-IRs, substantiating the global immunological difference between Yisaipu-IRs and Yisaipu-ARs (**figure 5**). A multi-parametric prediction model for Yisaipu-IRs was established based on weighted immunological signatures including total CD8$^+$ T-cell, CLA$^+$ Treg and foxp3$^+$ Treg. Receiver operating characteristic curve (ROC) analysis of the model showed an area under the curve (AUC) of 0.874 (accuracy 87.4%) (**figure 6**), indicating good performance in discriminating Yisaipu-IRs from Yisaipu-ARs.

Table 1. Characteristics of the patients in the adequate and inadequate responders to Yisaipu at enrollment.

Characteristics	Adequate responders (AR, n=30)	Inadequate responders (IR, n=8)	P
Basic information			
Age, years	51.8±12.4	52.5±12.8	0.848

Abbreviations: DAS28-CRP, disease activity Score indexed by C-reactive protein; WBC, white blood cell; Hb, hemoglobin; PLT, platelet; ALT, alanine aminotransferase; AST, aspartate amino transferase. Cr, creatinine; BUN, blood urea nitrogen; ESR, erythrocyte sedimentation rate; CRP. C-reactive protein; ACPA, anti-cyclic citrullinated peptide antibody; RF, rheumatoid factor; DMARDs, disease -modifying anti-rheumatic drugs.

Conclusion: T cell signatures might promisingly predict the clinical response to Yisaipu in RA patients and facilitate better stratification of patients for optimal treatment choices in the future.

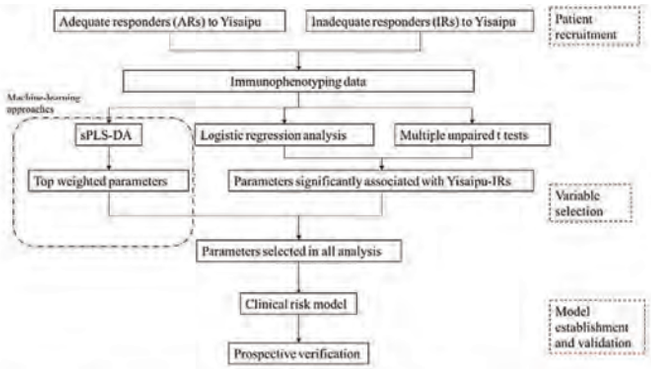

Figure 1. Study design and analysis plan flow diagram. sPLS-DA, sparse partial least squares-discriminant analysis. Yisaipu-IR, inadequate responder to Yisaipu.

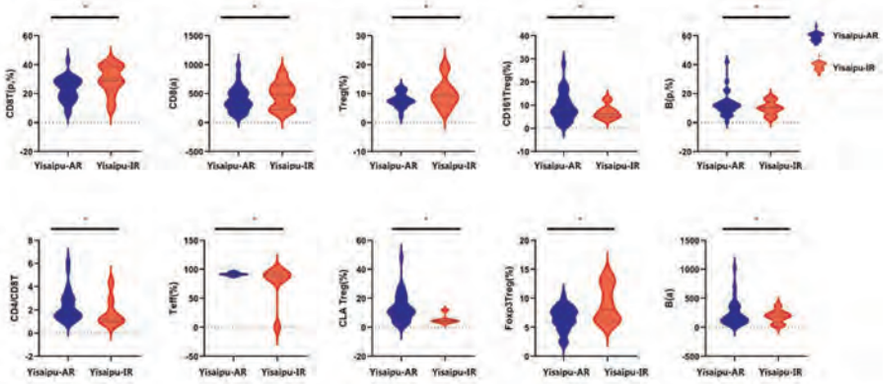

Figure 2. Comparison analyses of the peripheral cell subset profiles between Yisaipu-ARs and Yisaipu-IRs by unpaired t test. Violin plots displayed that total CD8+ T-cell, regulatory T-cell (Treg), effector T-cell (Teff) and total B-cell were significantly different between Yisaipu-ARs and Yisaipu-IRs. Asterisks indicated significant correlations, p<0.05. Yisaipu-IR, inadequate responder to Yisaipu; Yisaipu-AR, adequate responder to Yisaipu; p, percentage; a, absolute count.

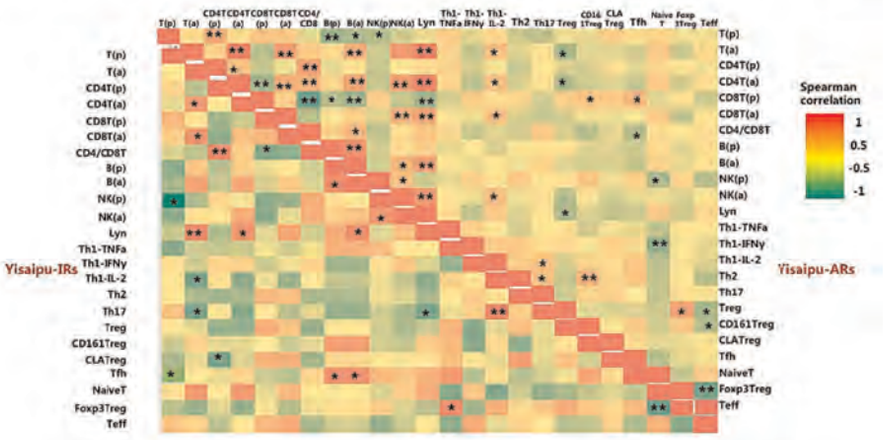

Figure 3. Correlation comparison analysis were performed on immune phenotyping data. The bottom left of the heat map showed the correlation between immune cell types in Yisaipu-IRs and the upper right of the heat map showed the correlation between immune cell types in Yisaipu-ARs. Spearman correlation coefficients for each pair of cell types were represented by colure. Asterisks indicated significant correlations, p<0.05. Yisaipu-IR, inadequate responder to Yisaipu; Yisaipu-AR, adequate responder to Yisaipu; p, percentage; a, absolute count.

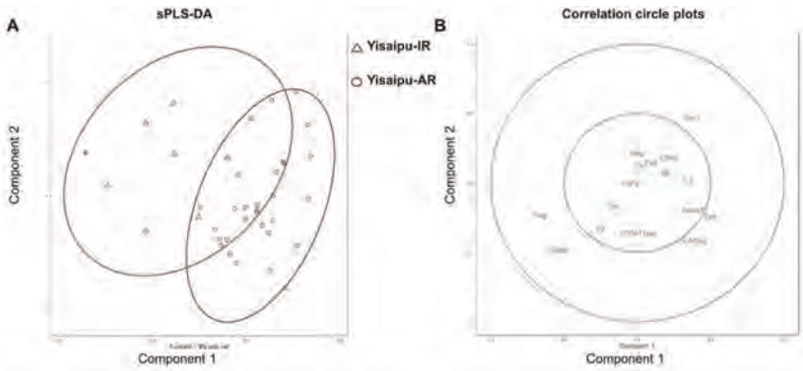

Figure 4. Top hits validated with sparse partial least squares-discriminant analysis (sPLS-DA) based on immunological parameters.**(A)** Individual distribution points and confidence ellipses (ovals) were plotted for the Yisaipu-ARs (red circle) and Yisaipu-IRs(purple triangle). **(B)** Using this analysis, the weighting of each cell type in component 1 and 2 was displayed (inner circle is the 0·5 cutoff). Yisaipu-IR, inadequate responder to Yisaipu; Yisaipu-AR, adequate responder to Yisaipu; p, percentage; a, absolute count.

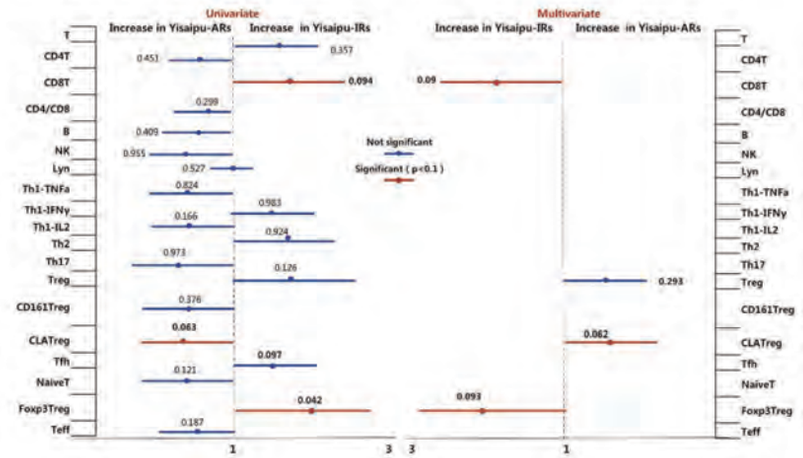

Figure 5. Odds ratios (error bars indicate 95% CIs) of 19 immunological parameters were computed with univaraite and multivariate logistic regression analysis. Yisaipu-IR, inadequate responder to Yisaipu; Yisaipu-AR, adequate responders to Yisaipu.

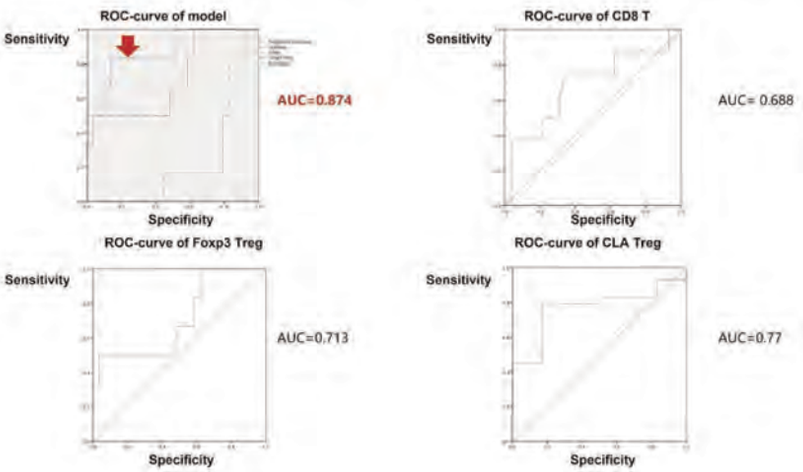

Figure 6. Receiver operating characteristic curve (ROC) with area under the curve (AUC) from univariate models showed the sensitivity and specificity of the top three markers (including total $CD8^+$ T-cell, CLA^+ Treg and $foxp3^+$Treg) identified by Yisaipu-IR risk model. Yisaipu-IR, inadequate responder to etanercept.

Uncovering Risk Factors for Adverse Events and Infections in Rheumatoid Arthritis and Rheumatoid Arthritis with Interstitial Lung Disease Under Biologics or Targeted Synthetic DMARDs: Insights from the KOBIO Registry

Ji-Won Kim[1], Ju-Yang Jung[1], Chang-Hee Suh[2] and Hyoun-Ah Kim[1], [1]Ajou University School of Medicine, Suwon, South Korea, [2]Ajou University Hospital, Suwon, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: This study aimed to identify risk factors associated with adverse events (AEs) and infections in patients with rheumatoid arthritis (RA) and comorbid interstitial lung disease (ILD) receiving biologics or targeted synthetic disease-modifying anti-rheumatic drugs (b/tsDMARDs), using data from the Korean College of Rheumatology Biologics (KOBIO) registry.

Methods: We analyzed data from a cohort of 2,266 adult RA patients who received b/tsDMARDs between December 2012 and December 2021, including 169 patients having comorbid ILD. We identified risk factors for AEs and infections in the whole RA group and RA-ILD group and investigated the impact of infections on mortality in patients with RA and comorbid ILD.

Figure 1. Kaplan-Meier curve for mortality according to ILD in total RA patients (N=2,266) (A) and for mortality according to having infection in RA-ILD patients (n=169) (B)

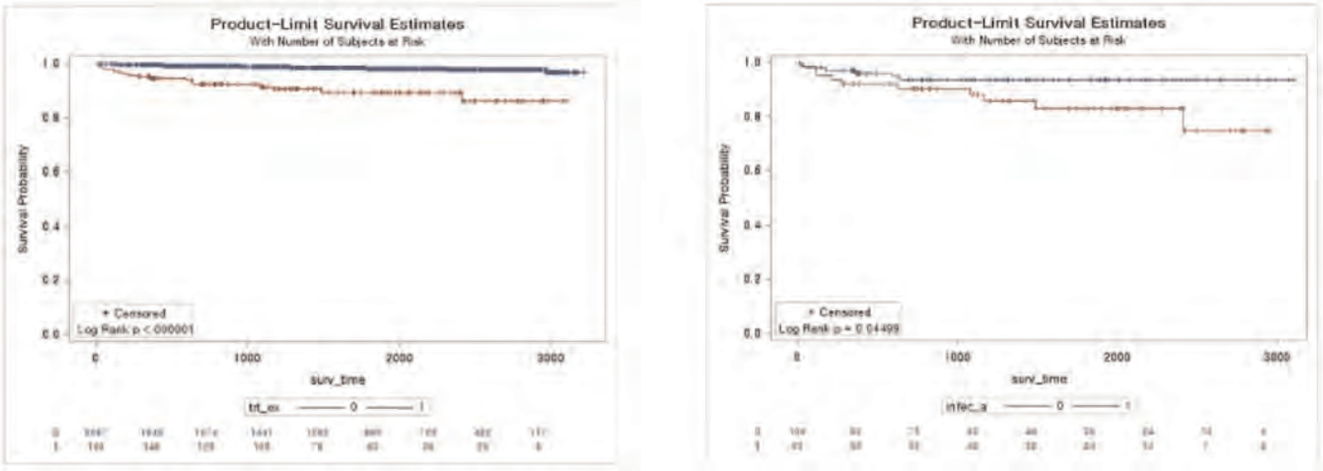

Table 1. Risk factors of infection in total RA and RA with ILD

	Total RA (N=2,266)				RA-ILD (n=169)

Concomitant sulfasalazine	0.81 (0.38, 1.75)	0.599			0.74 (0.14, 3.86)	0.725		
Concomitant leflunomide	1.02 (0.64, 1.71)	0.849			0.46 (0.11, 2.03)	0.319		
Concomitant corticosteroid	1.12 (0.87, 1.45)	0.371			1.25 (0.43, 3.79)	0.653		
Dose of corticosteroid	1.02 (0.99, 1.05)	0.227			1.02 (0.92, 1.14)	0.670		

Results: Among all RA patients, 45.7% withdrew b/tsDMARDs, while in the RA-ILD group, a higher proportion of 57.4% withdrew their regimen. The main reason for withdrawing b/tsDMARDs in the RA-ILD group was adverse events (AEs), with infections being the largest proportion among the reported AEs. In the RA without ILD group, the frequency of AEs was significantly lower compared to the RA-ILD group (ILD: 45.4%, non-ILD: 27.8%, $p < 0.001$), among the AEs, infusion-related reactions were more common than infections. In multivariate analysis of risk factors for AEs and infections in the RA-ILD group, older age was identified as a risk factor for AEs (OR, 2.65, $p = 0.024$), and only current smoking was identified as a risk factor for infections (OR, 2.214, $p = 0.023$). In the whole RA, ILD (OR = 1.97, $p < 0.001$), current smoking (OR = 1.28, $p = 0.047$), abatacept (OR = 0.71, $p = 0.026$), tocilizumab (OR = 0.79, $p = 0.046$), JAK inhibitors (OR = 0.52, $p < 0.001$), hypertension (OR = 1.42, $p = 0.001$), cardiovascular diseases (OR = 1.46, $p = 0.001$), concomitant methotrexate (OR = 0.72, $p = 0.001$), and dose of corticosteroid (OR = 1.03, $p = 0.023$) were associated with infections.

Conclusion: The patients with RA-ILD had a higher rate of withdrawal of b/tsDMARDs due to AEs and infections compared to patients with RA without ILD. In RA-ILD group, older age was identified as a risk factor for AEs, while current smoking was identified as a risk factor for infections.

Remotely Supervised Weight Loss and Exercise Training Improves Disease Activity and Patient Reported Outcomes in Older Patients with Rheumatoid Arthritis

Brian Andonian, Leanna Ross, Alyssa Sudnick, Johanna Johnson, Carl Pieper, Connie Bales, Kathryn Porter Starr, William Kraus and Kim Huffman, Duke University, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Older persons with rheumatoid arthritis (RA) are at increased risk for sarcopenic obesity, physical disability, adverse drug events, and cardiovascular disease; thus, there is a need for novel, non-pharmacologic interventions to improve clinical care in this patient population. Weight loss and exercise training have well-established benefits of improving clinical outcomes in non-RA populations; however, the effects of combined lifestyle interventions for older patients with RA are understudied. In this randomized controlled trial of older patients with RA and overweight/obesity, our goal was to identify the effects of a remotely supervised weight loss and exercise training (SWET) intervention on disease activity and patient reported outcomes.

Methods: Older (age 60-80 years), previously sedentary participants with RA and overweight/obesity (BMI 28-40 kg/m^2), who all satisfied 2010 ACR/EULAR RA classification criteria, were randomized to 16 weeks of SWET or a counseling health as treatment (CHAT) control group. The SWET intervention group completed aerobic training (150 minutes/week moderate-to-vigorous exercise), resistance training (2 days/week), and a hypocaloric diet (7% weight loss target). The CHAT control group completed 2 baseline visits of diet and exercise counseling followed by usual care. Baseline and post-intervention assessments included body composition assessment (BOD POD®), minimal waist circumference measurement, muscle strength assessment (isometric knee extension), RA disease activity (DAS-28-CRP) assessment, and Patient-Reported Outcomes Measurement Information

Table 1. Changes in outcomes pre- and post-intervention

Variable (units)	CHAT control intervention group			Remotely supervised SWET intervention group			
	Pre (0 weeks) n=10	Post (16 weeks) n=10	Within group pre-post p-value	Pre (0 weeks) n=10	Post (16 weeks) n=10	Within group pre-post p-value	Between group absolute change p-value

PROMIS-physical function (T-score)	41.7 (5.0)	41.7 (6.4)	0.90	42.3 (6.3)	48.1 (6.5)	0.01	0.01
PROMIS-mental health (T-score)	51.6 (6.6)	51.9 (6.6)	0.52	54.1 (8.8)	57.6 (8.4)	0.01	0.02
PROMIS-cognitive function (T-score)	53.6 (7.7)	51.1 (8.7)	0.25	49.3 (9.6)	52.3 (8.0)	0.12	0.16
PROMIS-pain intensity (T-score)	46.5 (6.1)	45.7 (4.0)	0.50	46.3 (5.8)	41.7 (7.9)	0.04	0.11
PROMIS-fatigue (T-score)	49.0 (9.1)	52.0 (6.0)	0.16	49.0 (6.3)	44.0 (9.9)	0.06	0.02

Values are shown as mean (SD). CHAT counseling health as treatment, SWET supervised weight loss and exercise training, DAS-28-CRP disease activity score in 28 joints with C-reactive protein, VAS visual analog scale, CRP C-reactive protein, PROMIS Patient-Reported Outcomes Measurement Information System

System (PROMIS) questionnaires. Within group pre- versus post-intervention changes were assessed using Wilcoxon signed rank tests. Between group comparisons of outcome absolute change (post – pre) were assessed using regression modeling controlling for the baseline outcome. Relationships were assessed using Spearman's correlations. Statistical significance for the primary outcome (between group changes in DAS-28-CRP) was established at $p< 0.05$.

Results: Compared to the CHAT control group (n=10, 9 female, mean age 65.6±5.4), older RA participants who completed the remotely supervised SWET intervention (n=10, 7 female, mean age 67.7±5.4) significantly improved DAS-28-CRP (p=0.03) (Table 1). SWET group participants also comparatively improved patient reported outcomes, including physical health, physical function, mental health, and fatigue ($p< 0.05$ for all) (Table 1). Decreases in DAS-28-CRP among all participants (n=20) were associated with decreases in waist circumference (rho=0.48, p=0.03) and increases in leg muscle strength (rho=-0.57, p=0.01).

Conclusion: In older participants with RA and overweight/obesity, when compared to a lifestyle counseling control intervention, a remotely supervised weight loss and exercise training intervention significantly improved RA disease activity and multiple patient-reported assessments of overall health. Results of this randomized control trial support the use of multifaceted lifestyle interventions in the usual clinical care of older patients with RA.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this study was to evaluate the safety of bone-marrow derived allogeneic mesenchymal stem cells (MSCs) as therapeutic agents in early rheumatoid arthritis (RA). Used to reduced graft-versus-host disease following bone marrow transplantation, MSCs are being clinically tested in multiple sclerosis, Crohn's disease, cystic fibrosis and other diseases for their immune regulatory properties. We designed and conducted a Phase 1 randomized double blind clinical trial (RDBCT) using MSCs in early RA. MSCs have immunomodulatory properties ex vivo and *in vivo*. We hypothesized that a "window of opportunity" would exist in early RA during which immune tolerance could be restored to a "pre-RA-like" state

Methods: We conducted a Phase 1 RDBCT in early RA patients using a single infusion of marrow derived allogeneic MSCs. Donors were pre-screened and MSCs isolated and expanded and tested in functional suppressor assays *ex vivo*. The selected MSC donor had a second bone marrow aspiration and MSCs were expanded in the Case Comprehensive Cancer Center GMP faculty and cryopreserved. MSCs underwent purity and adventitious testing in advance and endotoxin prior to release. Studies were perfumed under IND # 016906 and according to the Declaration of Helsinki. Patients enrolled had symptoms of RA for less than two years and had elevated rheumatoid factor or antibody directed against citrullinated peptides or both. Known DMSO sensitivity, active infection and history of disease modifying drugs (DMARDs) other than methotrexate, hydroxychloroquine and low dose prednisone were exclusionary.

Results: Screening lasted 42 days prior to infusion. Of the ten patients treated, five were administered MSCs at 2 million (M)/kg and three patients at 4M/kg and two received sham infusion. Patients were pre-medicated with acetaminophen and diphenhydramine. There were no dose limiting toxicity and no infusion reactions. Two SAEs were not considered to be study

Table 1 Demographics

vertigo	1	1	0	0

Tab

related: 1) acute exacerbation of chronic low back pain; 2) hip fracture in a patient on low dose steroids. Enrollment was halted after ten patients due to stalling during the pandemic. Demographics are included in Table 1. Spirometry post-infusion was discontinued with permission mid-way through the trial as no respiratory AEs occurred in conjunction with or immediately after infusion. No study related AEs related to the therapeutic agent were reported (Table 2). Secondary outcomes including Patient Reported Outcomes and DAS28CRP are under analysis.

Conclusion: Use of "off the shelf" bone marrow derived adult "mesenchymal stem cells" appear safe using dosages up to 4M/Kg. There were no dose limiting toxicities observed and patients tolerated infusion well without pre-conditioning, as is required for use of other cellular therapies. Given the safety of using MSC's, we suggest that allogeneic MSCs should be tested early in RA in a phase 2 study for their ability to induce immune quiescence and induction of host regulatory cells as well as efficacy responses.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Active rheumatoid arthritis (RA) is associated with a higher prevalence of insulin resistance (IR). Dysregulation of adipokines driven by low-level systemic inflammation plays a central role in the development of IR. Adiponectin (Adp) is an adipokine exerting anti-inflammatory and insulin-sensitizing activity. However suppression of Adp secretion by IL-6 was shown in previous studies, data on associations of Adp with serum lipid profiles and disease activity in patients with RA treated with biologic DMARDs are controversial. Here we present the changes in serum Adp levels in patients with active RA during treatment with IL-6 inhibitor olokizumab (OKZ).

Methods: Data were extracted from 3 double-blind RCTs (NCT02760368; NCT02760407; NCT02760433). Patients were randomized to receive subcutaneous (SC) injections of OKZ 64 mg every 2 weeks (q2w), OKZ 64 mg once every 4 weeks (q4w), or placebo for 24 weeks, all on background of MTX.

Demographics were assessed at baseline. Body weight and height were assessed at baseline, week 4, 8, 12, 18, and 24. Clinical and laboratory data were collected at baseline, week 4, 12, and 24. Associations with changes in Adp were evaluated by partial correlations adjusted for gender, age, BMI, and lipid-modifying therapy for lipid profiles or for gender, age; BMI; Adp; changes in BMI and cholesterol for disease activity.

Results: Serum Adp measurements were available for 1944 pts (730/765/499 pts in OKZ q2w, OKZ q4w, and placebo groups). Baseline characteristics were equally distributed across treatment groups. In total 18% of patients received lipid modifying agents, with the percentage slightly higher in OKZ groups compared to placebo. Pre-dose Adp levels were positively associated with longer disease duration, and inversely associated with BMI at baseline, however no association was observed with disease activity (Figure 1A).

Significantly elevated levels of triglycerides, total cholesterol, HDL- and LDL-cholesterol were observed at all post-dose timepoints (figure 1B, 1C). After 24 weeks of treatment, Adp increased significantly by 1590.46 (182.90) ug/L, 1743.61 (180.14) ug/L, and 687.58 (238.33) in OKZ q2w, OKZ q4w, and placebo groups. Significant difference with placebo was observed in OKZ q4w group only (difference (SE) 1056.03 (299.37) μg/L, $p = 0.02$).

Adp changes were positively correlated with changes in total and HDL-cholesterol ($r=0.134$ and $r=0.281$, $p< 0.001$), a very weak however significant correlation was seen with changes in LDL-cholesterol ($r=0.067$, $p=0.018$) and probability to reach low disease activity (DAS28-CRP < 3.2) at week 24 ($r=0.061$, $p=0.001$), but not with post-baseline changes in

Table. Demographic and other baseline characteristics of CREDO population included in the Adp analysis (ITT population)

Parameter	OKZ 64 mg q2w N=730	OKZ 64 mg q4w N=765	Placebo N=449

Mean triglycerides (SE), mmol/L	1.41 (0.02)	1.43 (0.03)	1.44 (0.03)
Lipid-lowering agents, n(%)	140 (19.2)**	152 (19.9)**	58 (12.9)

*** p <0.01 in comparison with placebo*
OKZ = olokizumab, q2w = every 2 weeks, q4w = every 4 weeks, RA = rheumatoid arthritis; BMI = body mass index; IQR = interquartile range; HDL-C = high density lipoprotein cholesterol; LDL-C = low density lipoprotein cholesterol

triglycerides or BMI. Adp levels were inversely correlated with DAS28-ESR and ESR at week 24 (r=-0.061, p=0.048, r=-0.082, p=0.004).

Conclusion: Significant elevation of serum Adp was observed after 24 weeks of OKZ treatment in patients with RA. Adp changes positively correlated with elevations of total and HDL-cholesterol, independently of post-treatment changes in BMI. Increased Adp may have protective insulin-sensitizing effects and may contribute to decreasing the risk of CV complications in RA patients.

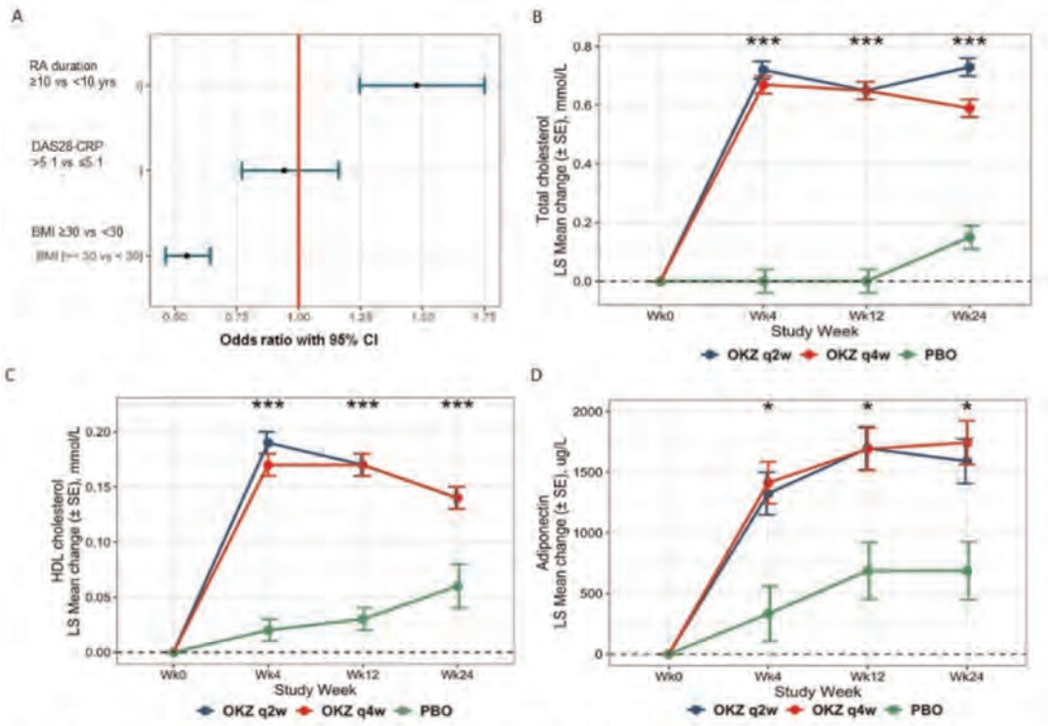

Figure 1 Baseline associations(A) and changes from baseline in lipids(B,C) and Adp (D) in adult patients with moderately to severely active RA receiving OKZ therapy on top of MTX

Comparisons to placebo: * p <0.05; *** p <0.001. Linear mixed model was used to compare change in Adp from baseline between OKZ groups and placebo with adjustments for baseline Adp, baseline BMI, post-baseline dynamic in BMI and total cholesterol. OKZ = olokizumab, q2w = every 2 weeks, q4w = every 4 weeks, PBO = placebo; RA = rheumatoid arthritis; BMI = body mass index; IQR = interquartile range; MTX = methotrexate; LS Mean = least square mean; SE = standard error

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated rheumatoid factor (RF) in patients with rheumatoid arthritis (RA) is associated with higher disease activity. A significantly lower efficacy of TNF inhibitors (TNFi) monoclonal antibodies (mAbs), Infliximab (IFX) and Adalimumab (ADL) as well as the fusion protein etanercept, in seropositive RA patients with high RF levels has been described[1,2]. Certolizumab pegol (CZP), a Fc-free pegylated mAb anti-TNF has shown comparable efficacy irrespective of baseline RF status [3]. RF binds the Fc fragment of IgG1 which is the subtype used to engineer the majority of TNFi mAbs. Augmented clearance of mAbs in the presence of high titers of FR, due to the formation of large immune complexes, may likely explain reported negative impact of RF titers in mAbs efficacy. We aim to evaluate in clinical practice whether RF and ACPA levels in RA patients influence serum drug levels of 3 TNFi with differentiated molecular structures.

Characteristics	Total (n=170)	Infliximab (n=90)	Adalimumab (n=48)	Certolizumab pegol (n=32)

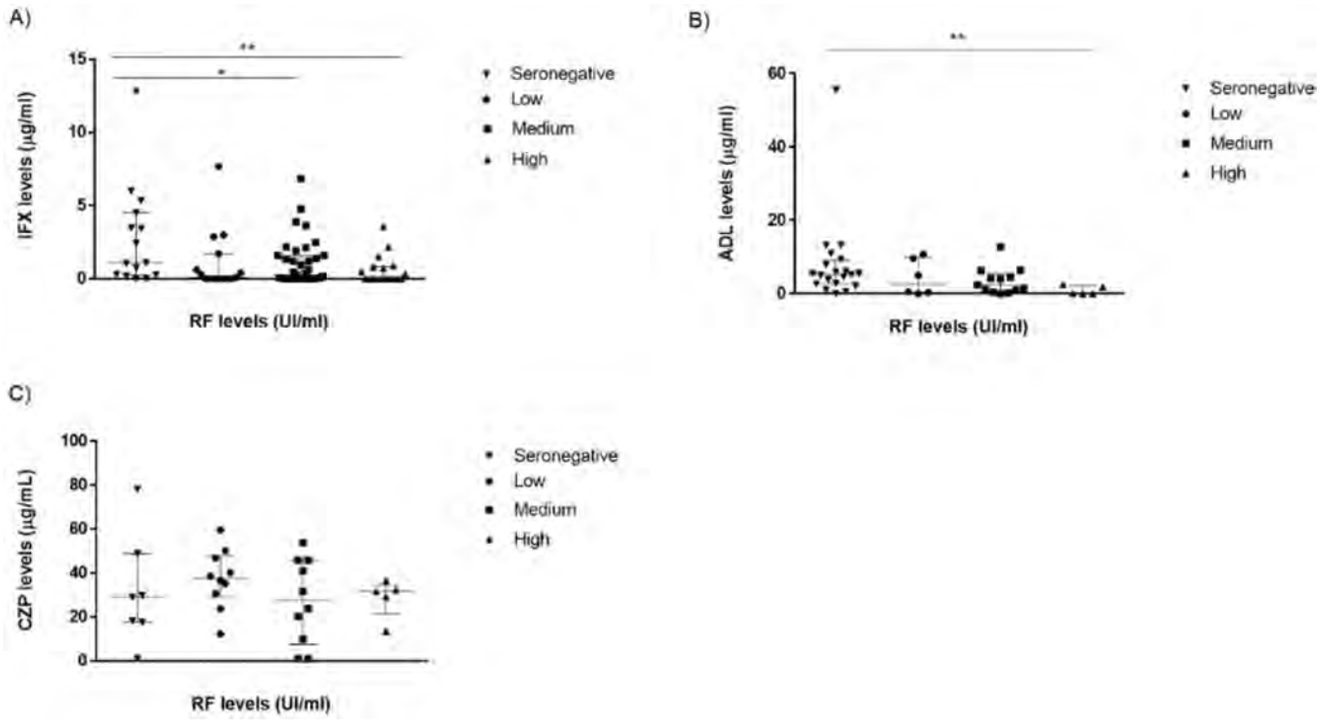
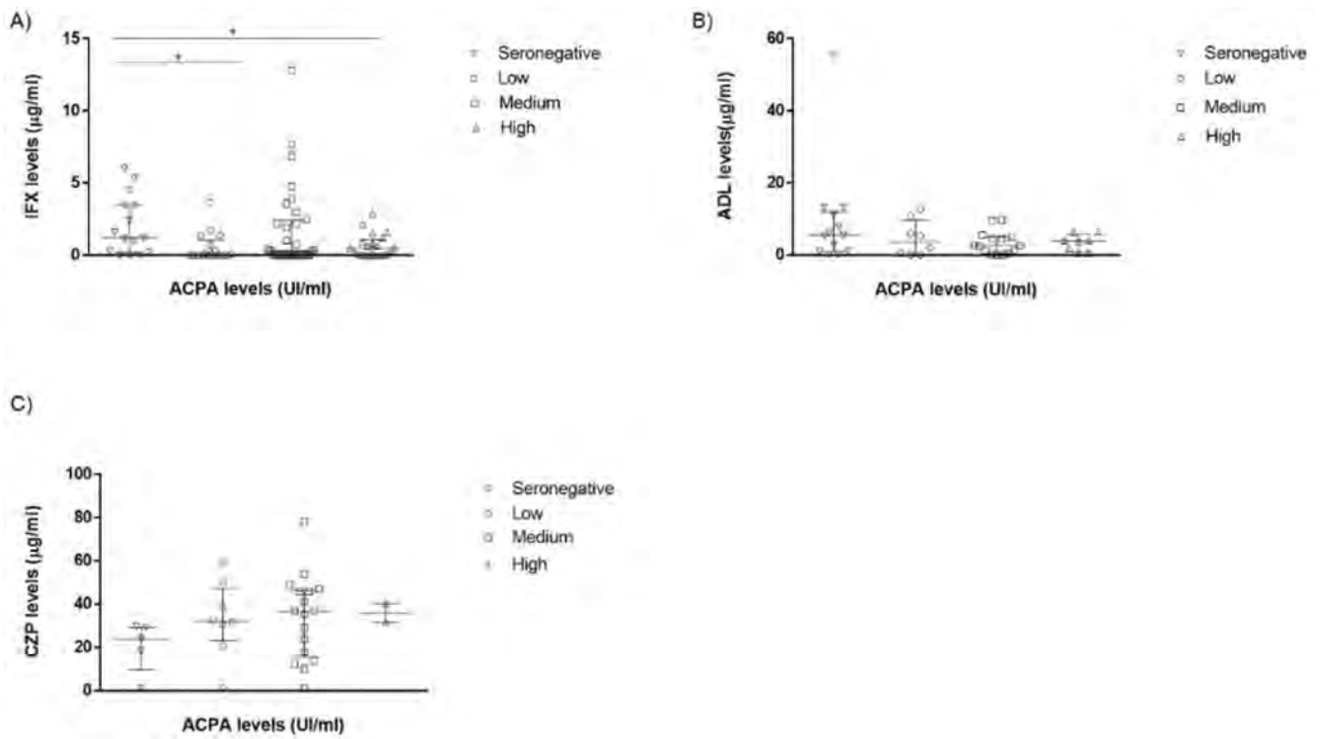
Demographics characteristics of patients with RA treated with infliximab (IFX), adalimumab (ADL) and certolizumab (CTZ) at baseline.



Median drug levels (ng/ml) at 6 months by baseline RF quartiles.



Median drug levels (ng/ml) at 6 months by baseline ACPA quartiles.

[1] Bobbio-Pallavicini F. Ann Rheum Dis 2007;66(3):302–7 [2] Potter C. Ann Rheum Dis 2009;68(1):69–74 [3] Tanaka Y. APLAR 2020. Oral Communication

Methods: We evaluated retrospectively a cohort of consecutive RA patients treated with either IFX, ADL or CZP. Clinical, laboratory and demographic data were collected for all patients at baseline (T0) and after 6 months (T6) of treatment. RF and ACPA titers, serum drug levels were measured at T0 and T6 using nephelometry and ELISA respectively. Patients were stratified into quartiles based on baseline RF [seronegative (< 20 UI/ml, low (20-57.0), medium (57.0-380), and high (> 380)] and ACPA [negative (< 25.0 IU/ml), low (25.0–167 IU/ml), medium (167–1582 IU/ml) and high (>1582 IU/ml)]. Association between baseline RF and ACPA titers and drug levels were assessed using non-parametric test (Mann-Whitney).

Results: A total of 170 patients from a tertiary hospital were evaluated: 90 (66%) received IFX, 48 (35%) ADL and 32 (22%) CZP. Demographic characteristics are shown in **Table 1**. RF and ACPA were positive in 76% and 80 % of patients, respectively. A higher proportion of patients in the IFX group (77%) had both RF+ and ACPA+ status followed by CZP (75%) and ADL (54%) groups. Serum IFX and ADL levels at T6 were significantly lower in patients with higher basal RF titers (Fig 1). In contrast, no differences between drug levels at T6 across baseline RF titers were observed in the CZP group **(Fig. 1).**For ACPA status, only IFX levels at T6 were statistically higher in basal ACPA negative patients **(Fig.2).**Most patients with high ACPA levels had also medium or high RF levels: 11/22 (50%) patients and 1/22 (32%), respectively. Anti-Drug Antibodies (ADA) were detected in 26 patients with IFX, 2 with ADL and 2 with CZP.In the case of IFX, the major percentage of patients with ADA positive had medium or high RF levels patients (39% and 38%, respectively) compared to patients with seronegative andlow RF levels (4% and 19% respectively).

Conclusion: Baseline RF titers do not impact serum drug levels of CZP (a Fc-free anti-TNF) whereas they are significantly linked to low serum drug levels of complete monoclonal antibodies (IFX and ADL) in clinical settings in RA patients. These differences might aid physicians to select suitable treatment for the management of RA.

Discontinuation of Biological Disease Modifying Drugs Due to Adverse Drug Reactions in an Inception Rheumatoid Arthritis Cohort

Zulema Rosales-Rosado[1], Maria Rodriguez Laguna[2], Cristina lajas Petisco[2], Clara De Miguel[2] and lydia Abasolo[1], [1]Hospital Clínico San Carlos, Madrid, Spain, [2]Hospital Clinico San Carlos, Madrid, Spain

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a well-known risk of developing adverse drug reactions (ADR) in rheumatic patients due, mainly, to the use of Disease Modifying Drugs (DMARD). In the last two decades, the use of biological DMARDs (bDMARDs) has increased extensively but our knowledge of the ADR to these drugs outside clinical trials setting and in the long term has not at the same rate; especially those that require drug discontinuation. **Purpose.** To describe the incidence and characteristics of ADR to bDMARD, as well as the factors associated to their discontinuation in an inception cohort of patients with RA.

Methods: We conducted an observational longitudinal retrospective study. Patients: all recent onset RA diagnosed between January 1st 2007 and December 31st 2015 followed in outpatient clinic at Hospital Clinico San Carlos until January 1st 2022, which used any bDMARD ≥ 3 months, were included. Primary outcome: development of an ADR that required drug discontinuation (moderate: discontinuation drug, severe: hospitalization or death of the patient due to the ADR). Covariables: sociodemographic, clinical and treatment. Statistical analysis: incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI]. A multivariate Cox regression analysis was used to evaluate the risk factors of discontinuation due to ADR. Results were expressed as HR with their 95% CI.

Table 1. Characteristics at baseline

Age at onset (years), mean (± SD)	52.38 (13.80)
Women %	81.72
Married %	59.24
Active workers %	65.59
Active or ex smoker %	41.80
FR %	63.98
Anti-CCP %	55.80
ESR at diagnosis mm/h (± SD)	41.56 (28.42)
Rosser at diagnosis (± SD)	0.96 (0.06)
Comorbid conditions %	
Hypercholesterolemia	26.34
Hypertension	23.66
Hypothyroidism	17.74
Diabetes Mellitus	9.68
Depression	8.60
Osteoporosis	6.99
Chronic obstructive pulmonary disease	6.99
Cancer	4.84
Fractures	4.30
Gastric ulcer	4.30
Cardiovascular disease	2.15
Liver Disease	1.08
Heart failure	0.54

Results: 186 patients were included (927.86 patient-years), 81.72% were women with a mean age at diagnosis of 52.38 ±13.80. Characteristics at baseline are shown in table 1. They received 347 courses of bDMARD treatment of which 81 were discontinued due to ADR (11.50%; IR 8.73 [7.02-10.85]). 75.30% of the ADR were moderate (IR 6.57 [5.12-8.45]) and 24.69% severe (IR 2.16 [1.39-3.34]). Infection was the most frequent cause of ADR (n=28, 35.44%), followed by allergic reactions (n=16, 20.25%); 2 patients died due to an ADR. Incidence rates are shown in table 2. After performing bivariate and multivariate analysis (table 3) we found that the risk of ADR was higher in patients with heart failure (HR 3.85 [1.48-10.04]) or osteoporosis (HR 2.57 [1.10-5.99]) at diagnosis and in posterior courses of treatment (HR 3.28 [1.92-5.59]); there was a tendency of higher risk to develop ADR with the use of JAK inhibitors (HR 2.15 [0.96-4.85]) compared to anti-TNF, but it did not reach statistical significance. Rituximab had lower risk (HR 0.41 [0.17-0.98]) for the development of ADR compared to anti-TNF.

Conclusion: Discontinuations of bDMARDs in clinical practice due to ADR are common (13.06%) with an estimated IR of 8.73%, most of them moderate. Infection was the main cause of ADR with only 2 deaths registered due to an ADR during follow-up. Higher incidences of ADR to bDMARD were found in the female sex, older patients, concomitant use of corticoids as well as with some bDMARDs (JAKi and Abatacept). We should pay special attention regarding the development of ADR

Table 2. IR of discontinuation due to ADR.

	Patients/year	N	IR	95%CI
Total	927.86	81	8.73	7.02-10.85
