use or treatment outcomes for conventional disease-modifying agents or biologics between the two groups. In IIM patients with an infection, the infection had a median time of diagnosis 2 months prior to the IIM diagnosis.

Conclusion: While the type of IIM may be associated with infection, particularly IBM as has been reported in other literature, the presence of a infectious myopathy in IIM patients does not lead to a difference in organ involvement or treatment outcomes. The initial presentation of IIM is a crucial time for patients to be diagnosed with a concomitant infection. Further studies are needed to elucidate the link between IBM and specific infectious processes.

Abstract Number: 1968

Pregnancy Outcomes in Idiopathic Inflammatory Myopathies: A Comparison to the General American Population

Ana Valle[1], Melissa Fazzari[2] and Shereen Mahmood[3], [1]Montefiore Medical Center, Bronx, NY, [2]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine / Montefiore Medical Center, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are rare autoimmune conditions which cause multi-organ inflammation, particularly in the skin, lungs, and muscles. It is known that many autoimmune conditions affect a women's ability to become pregnant and may lead to adverse pregnancy outcomes. Studying pregnancy within IIM has been difficult due to limited cases, yet there is increasing evidence that women with IIM have increased risk of pregnancy adverse outcomes, including pre-eclampsia and low birth weight. However, few studies have evaluated the spectrum of pregnancy outcomes in IIM or compared how these outcomes compare to the general population. Our aim was to evaluate the rate of term

Table 1. Comparison of demographics and pregnancy outcomes of women with a history of IIM and a sample of women in the general American population.

Variables	National Survey (n = 6141)	IIM Patients (n = 86)
Race and Ethnicity, n (%)		
Hispanic	1230 (20.03)	34 (39.5)
White, Non-Hispanic	3648 (59.40)	9 (10.5)
Black, Non-Hispanic	902 (14.68)	39 (45.3)
Other	361 (5.88)	2 (2.3)
Unknown	0 (0)	2 (2.3)
Pregnancy Outcomes, Mean (SD)		
Living Children	1.20 (0.039)	2.13 (1.58)
Elective Abortion	0.152 (0.0.014)	0.140 (0.381)
Spontaneous Abortion	0.306 (0.017)	0.198 (0.429)
Ectopic Abortion	0.018 (0.003)	0.0349 (0.185)

pregnancies, preterm pregnancies, abortions, and living children in women with a history of IIM and to compare these with a sample of American women.

Methods: The Montefiore Medical Center Myositis registry was created from patients that met 2017 EULAR/ACR classification criteria for IIM. Demographics, including age, race, ethnicity were documented. IIM subtype and date of diagnosis were also recorded. Patients who did not identify as female and lacked an obstetrics history recorded by a physician were excluded. Pregnancy outcomes, including number of term and preterm pregnancies, abortions, and living children were recorded. A preterm birth was defined as < 37 while term birth was considered >37 weeks. Abortions were further classified into elective, spontaneous, therapeutic, ectopic, or reason unknown. These same pregnancy outcomes were extracted from Section B of the CDC's 2017-2019 National Survey of Family Group for comparison.

Results: Of 153 patients with IIM, 86 of them were female patients with an obstetrics history. The mean age of IIM diagnosis was 51.7 years old, and majority of women were of Latinx ethnicity (Table 1). There were a total number of 224 pregnancies; 185 were live births with 6 (3%) preterm births.The average number of live births was 2.13 per patient. There were 39 abortions, of which 17 (44%) were spontaneous, 12 (31%) were elective, 6 (15%) were therapeutic, 3 (8%) were ectopic and one was unknown. In comparison, the majority of women participated in the national survey were white and younger, with a mean of 32 years of age. The mean number of children was 1.2 per woman. The mean number of elective abortions were similar between the two groups (0.14 vs 0.152) and the mean number of spontaneous abortions was lower in women with a history of IIM in comparison to the general population (0.198 vs 0.306) (Table 1).

Conclusion: Female patients with a history of IIM did not confer higher frequencies of poor pregnancy outcomes, including spontaneous or elective abortions. Rate of preterm pregnancies were similar, if not lower, to national averages. Differences between our patient demographics and birth rates in comparison to the national sample may be due to cultural and socioeconomic factors. Lastly, our cohort was limited by its inability to differentiate pregnancy prior to or during active IIM disease.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Comorbidities have a profound impact on the quality of life (QoL), though global data on the burden of comorbidities and its impact on health outcomes and QoL in vulnerable groups such as Idiopathic inflammatory myopathies (IIMs) is scarce.

Methods: We studied the prevalence, distribution and clustering of comorbidities and multimorbidity among patients with IIM, AIRDs and healthy controls (HCs) and its impact on health outcomes, utilizing data from the COVAD 2 study, a global patient-reported e-survey consisting of 167 collaborators from 110 countries. Basic multimorbidity (BM) /Complex multimorbidity (CM) were defined as the co-occurrence of ≥2 non-rheumatic comorbidities & ≥3 non-rheumatic chronic conditions affecting ≥3 different organ systems1 respectively. Human Development Index (HDI) of their country was taken as a surrogate marker for socioeconomic status (SES). PROMIS global physical health (PGP), mental health (PGM), fatigue 4a (F4a) and physical function short form (SF10) were analysed using descriptive statistics and linear regression models. Hierarchical Clustering on Principal Components was performed to outline the grouping.

Results: Among 10740 respondents, 1558 IIMs (15.9%), 4591 other AIRDs (46.8%) and 3652 HCs (37.3%) were analysed. IIMs comprised mainly of DM (30.2%) and IBM (24.1%) whilst AIRDs comprised 2450 inflammatory arthritis (53.4%), 2050 CTDs (44.6%) and 235 systemic vasculitis (5.1%).

FIGURE 3 A, B, C: Clusters in IIM C: Each superscript letter indicates a subset of the 4 groups analyzed for which the means or proportions showed no difference at a significance level of .05.

Individuals with IIMs exhibited high burden of any comorbidity (OR: 1.62 vs AIRDs and 2.95 vs HCs,$p < 0.01$), BM (OR 1.66 vs AIRDs and 3.52 vs HCs,$p < 0.01$), CM (OR: 1.69 vs AIRDs and 6.23 vs HCs,$p < 0.01$), and mental health disorders (MHDs) (OR 1.33 vs AIRDs and 2.63 vs HCs,$p < 0.01$)(FIG 1A, global distribution depicted as FIG 2)

IIM patients with comorbidities (and MHDs) had worse physical function (low PGP, PGM, SF10 and higher F4a scores, all *$p < 0.001$). Worse physical function (PGP, SF10a, F4a) and mental health (PGM) was predicted by age, active disease, BM, and MHDs. Worse SF10a and F4a scores were also associated with female gender and country HDI respectively. (FIG 1B)

4 distinct clusters were identified among IIMs: Cluster 0: lower comorbidity burden and good health status Cluster 1: older patients with higher comorbidity burden and poorer health status Cluster 2: patients with higher prevalence of MHDs, lower PGP, PGM and higher F4a scores Cluster 3: older patients with average comorbidity burden and good health status.

DM, Anti-synthetase syndrome and necrotizing autoimmune myopathy were similarly represented in all clusters, while IBM and PM were more pre-dominant in clusters 1 (61.7% and 45.3%) and 3(36.4 and 34.6), while overlap myositis was more represented in clusters 2 (45.4%). (FIG 3)

Conclusion: Patients with IIMs have a higher burden of comorbidities with identifiable syndemic clusters that adversely impact physical and mental health, calling for optimized approaches for holistic patient management.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The significance of Health-related quality of life (HRQoL) in patients with autoimmune diseases is well acknowledged. Unfortunately, there is dearth of data on the HRQoL in patients with idiopathic inflammatory myopathies (IIMs)and factors adversely impacting it.

Methods: HRQoL was measured in patients classifiable as IIMs and compared with non-IIM autoimmune inflammatory rheumatic diseases (AIRDs), non-rheumatic autoimmune inflammatory diseases (NRAIDs), and healthy controls, using Patient-Reported Outcome Measurement Information System (PROMIS) instrument data obtained through the 2nd COVID-19 vaccination in autoimmune disease (COVAD-2), a global patient reported e-survey that was extensively validated and pilot tested by a team of experts (160 collaborators, 100 countries).

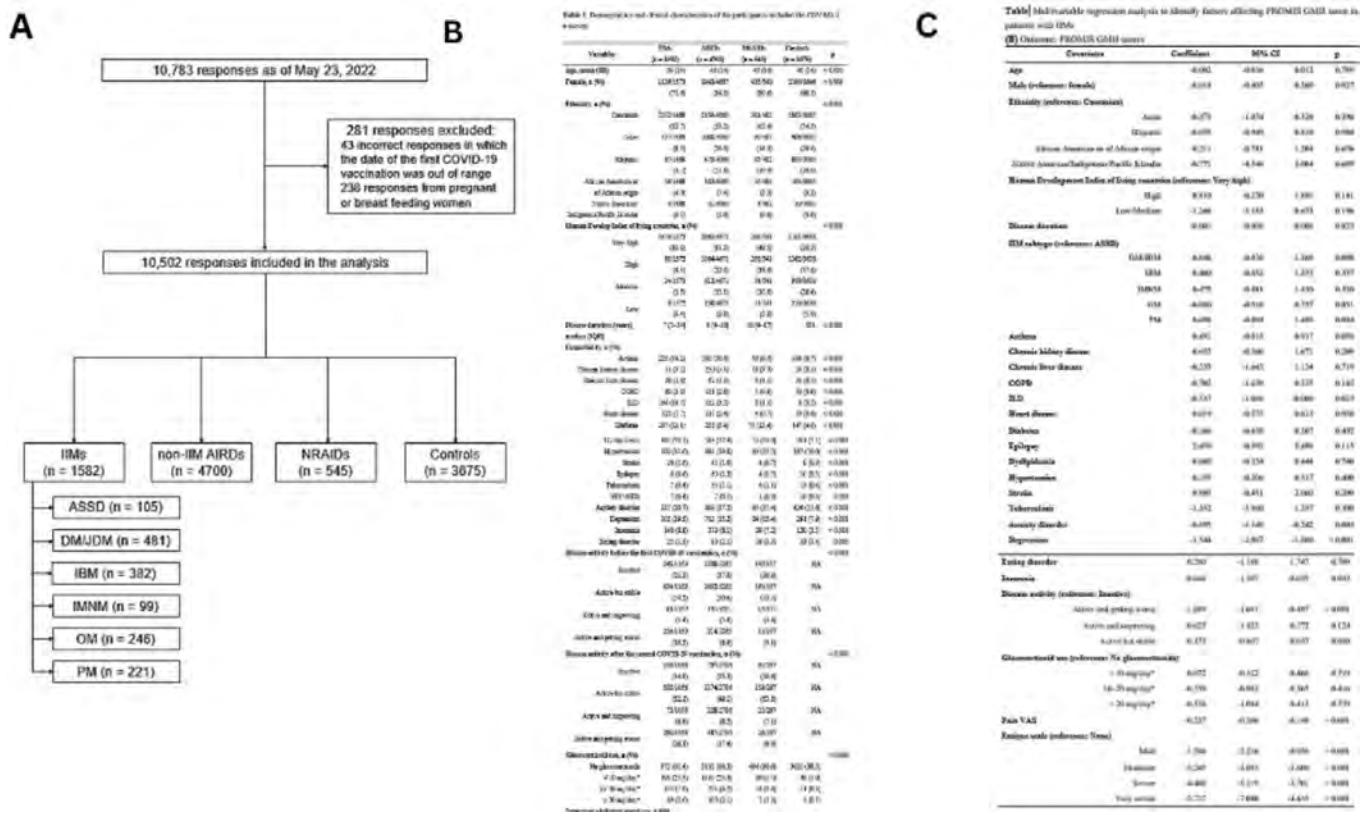

Figure 1 (A) A flow diagram of participant selection (B) Demographics and clinical characteristics of the participants included the COVAD-2 e-survey (C) Multivariable regression analysis to identify factors affecting PROMIS GMH score in patients with IIMs

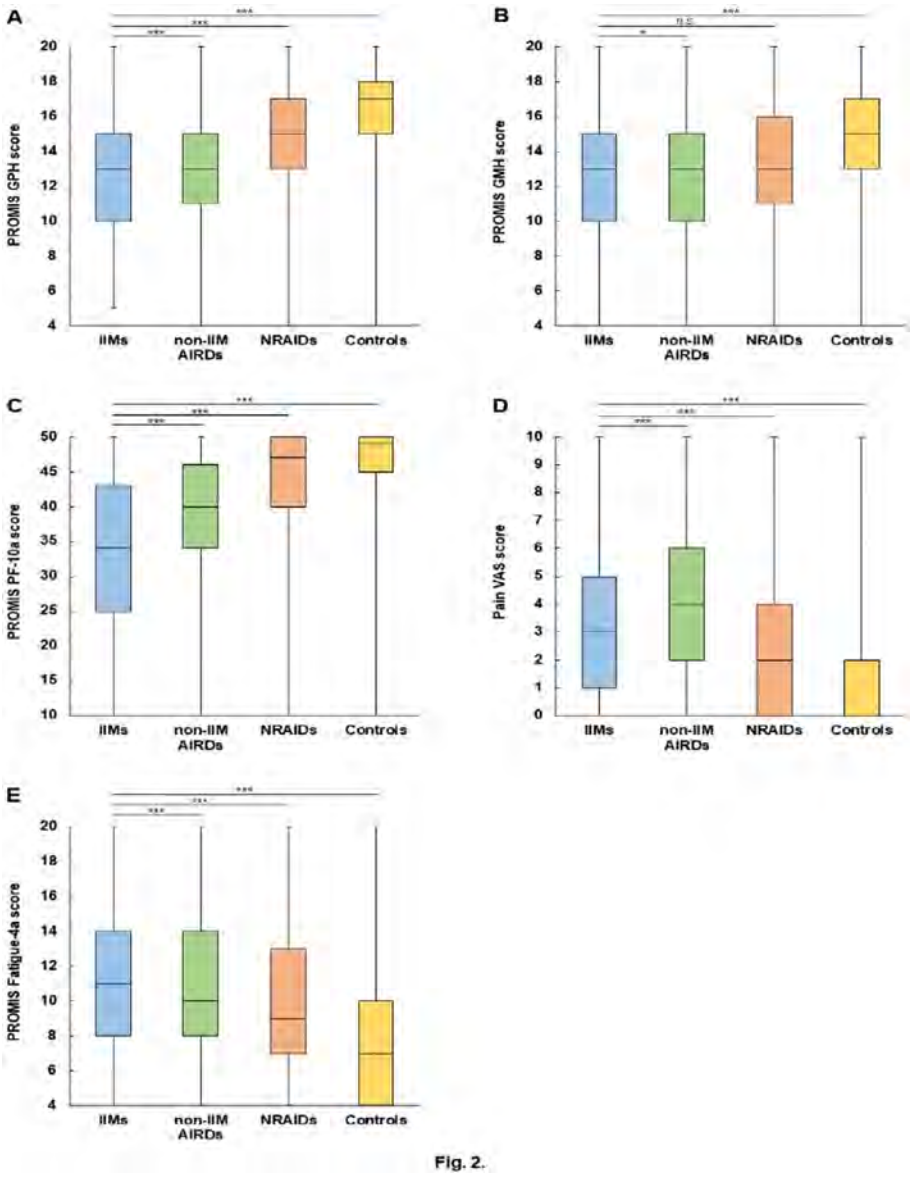

Fig. 2.

Figure 2: HRQoL in IIM patients, in comparison with non-IIM AIRDs, NRAIDs and Controls (A): PROMIS GPH scores (B): PROMIS GMH scores (C): PROMIS PH-10a score (D): Pain VAS score (E): PROMIS Fatigue-4a score

Demographics, diagnoses, comorbidities, disease activity, treatments, and PROMIS instrument data were extracted from the COVAD-2 database. (Fig. 1D) Primary outcomes were PROMIS Global Physical Health (GPH) and Mental Health (GMH). Secondary outcomes were PROMIS Physical Function 10a (PF-10a), Fatigue-4a scores, and Pain Visual Analog Scores (VAS).

Independent factors affecting GPH and GMH scores in IIMs, also in the whole population were identified using multivariable regression analysis (Fig. 2) Each PROM was stratified by IIM subgroups. (Fig. 3)

Results: Complete responses from 1582 IIMs, 4700 non-IIM AIRDs, 545 NRAIDs, and 3675 controls as of May 22 were analysed. (Fig. 1A)

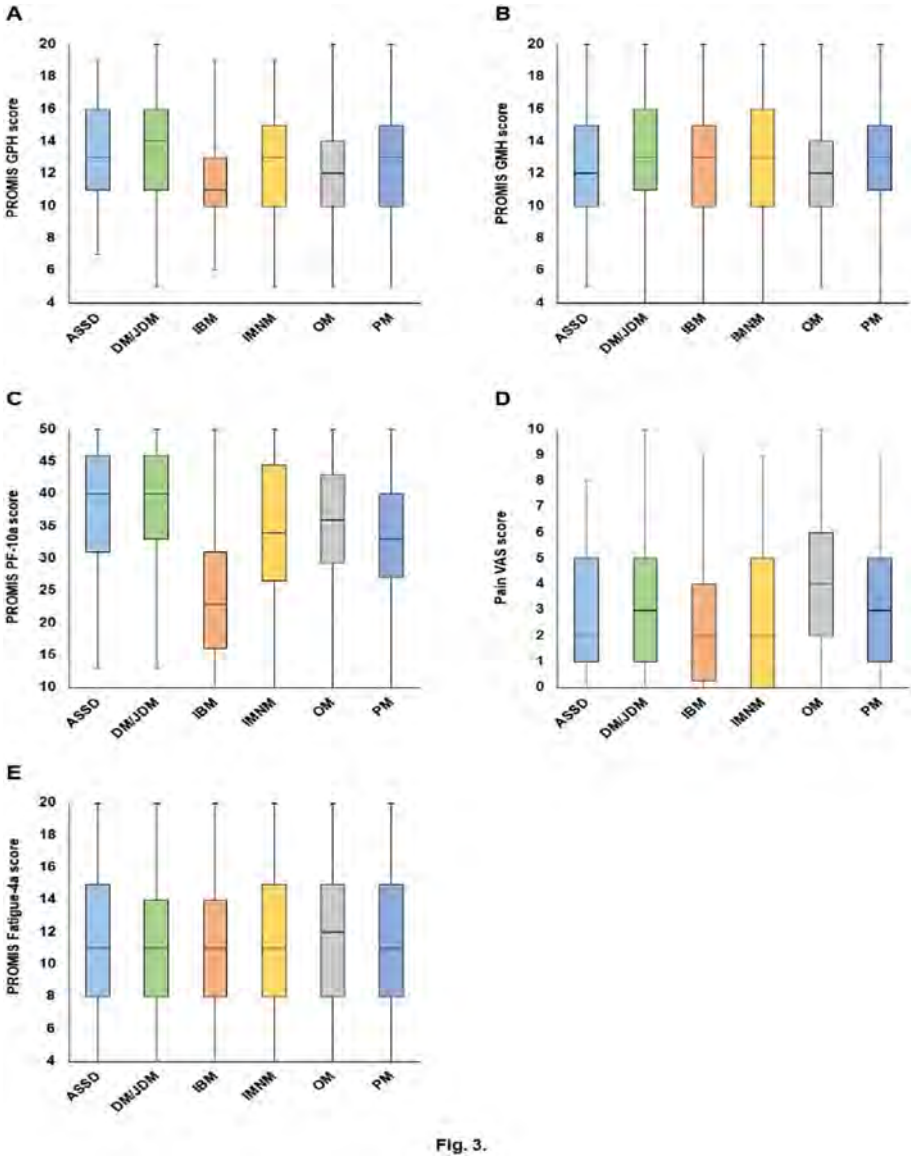

Figure 3: HRQoL in patients with IIMs subtypes (A): PROMIS GPH scores (B): PROMIS GMH scores (C): PROMIS PH-10a score (D): Pain VAS score (E): PROMIS Fatigue-4a score

Notably GPH scores were the lowest in IIMs (Fig. 2A). GMH scores in IIMs were also substantially lower than in controls (Fig. 2B) PROMIS PF-10a scores were the lowest in IIMs. (Fig. 2C) pain VAS scores were the highest in patients with non-IIM AIRDs (Fig. 2D) PROMIS Fatigue-4a scores were the highest in IIMs (Fig. 2E) indicating increased fatigue in patients with IIMs.

Among IIM subsets, PROMIS GPH and PF-10a scores were the lowest in patients with IBM. (Fig. 3A & 3C) PROMIS GMH scores were lower in patients with ASSD or OM compared to other subtypes (Fig. 3B). Pain VAS (Fig. 3D) andPROMIS Fatigue-4a scores were the highest in patients with OM (Fig. 3E).

Older age, IBM, hypertension, diabetes, active disease, glucocorticoid use, and higher fatigue scores were the factors for lower GPH scores in IIMs (Fig. 1B), whereas interstitial lung disease, mental disorders, active disease, higher pain VAS, and fatigue scores were independently associated with lower GMH scores in IIMs (Fig. 1C).

Multivariable regression analysis in the overall population identified older age, women, longer disease duration, diagnosis of autoimmune inflammatory diseases including IIMs, and comorbidities as independent factors for lower PROMIS GPH scores. (Fig. 1E) On the contrary, younger age, women, Asian ethnicity, diagnosis of autoimmune inflammatory diseases including IIMs, and comorbidities were independently associated with lower PROMIS GMH scores (Fig. 1F)

Conclusion: Both physical and mental health are significantly impaired in patients with IIMs particularly the elderly, IBM and those with specific comorbidities, calling for greater attention and optimized multidisciplinary care to enhance patient-reported experience and global well-being in this population.

Muscle Pathology in Patients with Primary Biliary Cholangitis

Jose Cesar Milisenda[1], Iago Pinal-Fernandez[2], Katherine Pak[2], Maria Casal-Dominguez[3], Yaiza Duque-Jaimez[4], Gloria Garrabou[1], Sandra Muñoz-Braceras[5], Mariona Guitart-Manpel[1], Jose Jiram Torres-Ruiz[5], Ester Tobias[4], Maria Dolores Cano[4], Iban Aldecoa[4], Josep Maria Grau[1] and Andrew Mammen[3], [1]Muscle Research Unit, Internal Medicine Service, Hospital Clinic, Barcelona, Spain, [2]National Institutes of Health, Bethesda, MD, [3]NIH, Bethesda, MD, [4]Hospital Clínic de Barcelona, Barcelona, Spain, [5]Muscle Disease Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD

SESSION INFORMATION

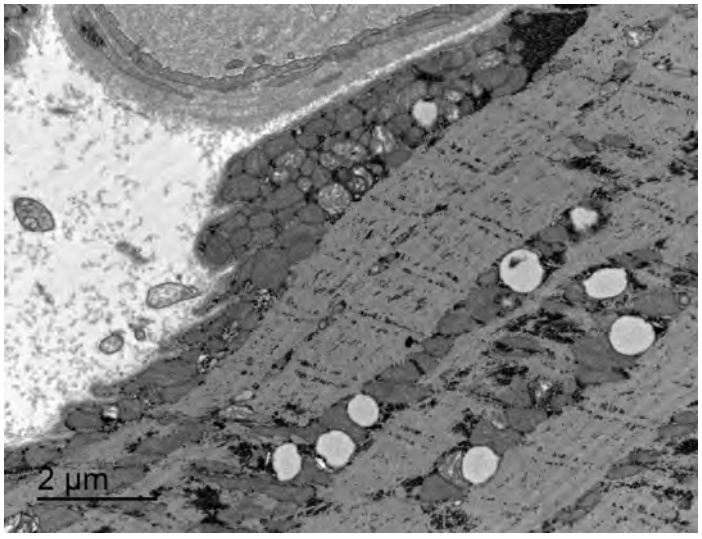
Session Date: Tuesday, November 14, 2023

Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III

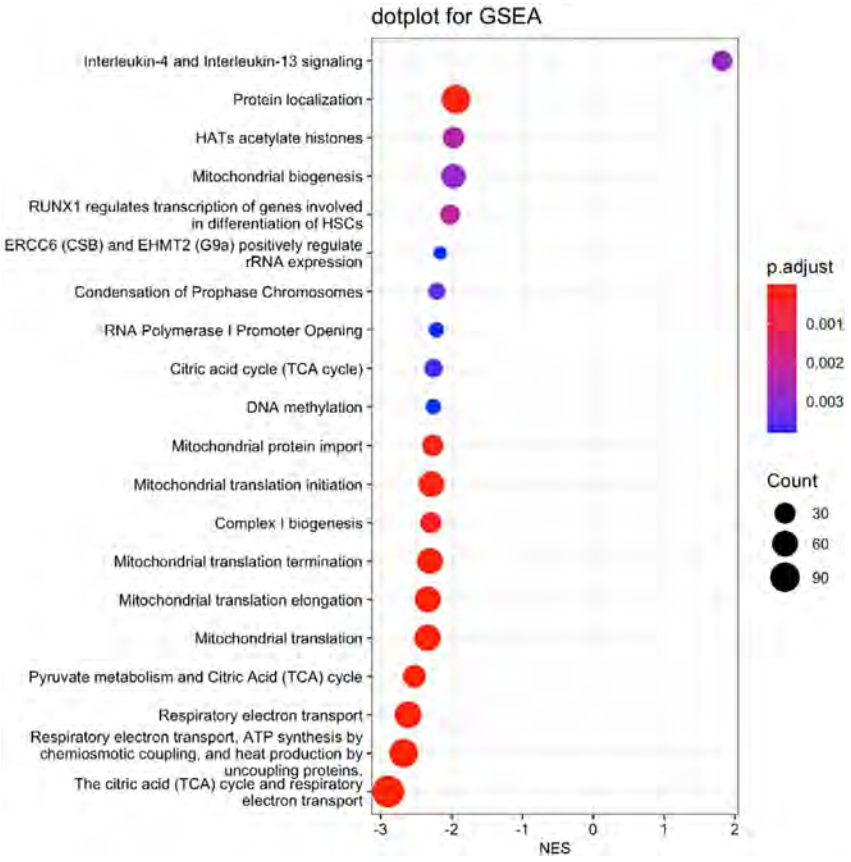
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease that primarily affects middle-aged women. It is characterized by elevated serum alkaline phosphatase levels, the presence of antimitochondrial antibodies (AMAs), and cholangiopathy on liver pathology. Fatigue is a common symptom experienced by up to 80% of patients at



ME. Mitochondrial accumulation at subsarcolemmal region



Dotplot for GSEA (PBC cases)

the time of diagnosis and during follow-up. Unfortunately, current treatments have not been effective in alleviating fatigue. The objective of this study is to evaluate fatigue and investigate any potential muscle involvement in PBC patients.

Methods: We conducted a single-center, cross-sectional study involving 50 patients who suffered from both PBC and fatigue. Muscle biopsies were performed to whom presented muscle weakness. Histopathological analysis was made and also RNA sequencing was performed on muscle biopsies (n=10) as well as 33 normal muscle biopsies. Muscle biopsies were stained for human immunoglobulin and PDC-E2.

Results: Abnormal accumulation of mitochondria in the subsarcolemal region was observed in both optical and electron microscopy. A significant set of immunoglobulin genes was specifically found to be overexpressed in CBP, while over 50 genes related to mitochondrial function were predominantly underexpressed. In muscle biopsies positive for AMA-M2, immunoglobulins were localized in the cytoplasm and colocalized with PDC-E2.

Conclusion: Based on these findings, we can conclude that there is muscular involvement in PBC, and we hypothesise it is likely mediated by AMA-M2 antibodies.

Evaluation of Myositis Autoantibodies as Predictors of Response to IVIG: Post-hoc Analysis of a Large Randomized, Double-Blind, Placebo-Controlled Phase III Trial

Christina Charles-Schoeman[1], Joachim Schessl[2], Rohit Aggarwal[3] and and the ProDERM investigators[4], [1]UCLA Medical Center, Santa Monica, CA, [2]Friedrich-Baur-Institute, Ludwig-Maximilians University of Munich, Munich, Germany, [3]University of Pittsburgh, Pittsburgh, PA, [4]Institutions in Europe and North America, Vienna, Austria

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1945–1972) Muscle Biology, Myositis & Myopathies – Basic & Clinical Science Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is an immune-mediated inflammatory myopathy (IIM). Two subsets ofautoantibodies have been identified in patients with IIM: Myositis-specific antibodies (MSA) and myositis-associated antibodies (MAA). Whereas MSA are highly specific for IIMs and represent unique clinical phenotypes and prognosis, MAA are also found in other autoimmune diseases. The ProDERM study recently demonstrated the efficacy and safety of IVIG in DM patients (1) but the potential effect of autoantibodies on treatment response has not yet been determined. This post-hoc analysis of the randomized, placebo-controlled ProDERM study investigated autoantibody status at baseline and its relationship to treatment response to IVIG.

Methods: DM patients received 2 g/kg IVIg treatment (n=47) or placebo (n=48) every 4 weeks for 16 weeks. From week 16 onwards eligible patients (N=91) received IVIG for a further 24 weeks. The primary endpoint was a Total Improvement Score (TIS) of at least 20 (= at least minimal improvement) at week 16 and no confirmed deterioration up to week 16. Serum

samples were taken at baseline and analysed for MSA (Jo-1, PL-7, PL-12, OJ, EJ, SRP, Mi-2, TIF-1, MDA5, NXP2, MJ, SUMO) and MAA (PM-SCL, Ku, U1RNP, U2RNP, U3RNP, Ro/SSA) by RNA and protein immunoprecipitations performed by the Oklahoma Medical Research Foundation. Patients were stratified according to their antibody (Ab) status as MSA-positive (including those also MAA+), MAA-positive only, or no Ab detected (Ab -ve) at baseline. Proportion of patients with minimal (TIS≥20), or moderate/major (≥ 40) response were evaluated for all patients (IVIG & placebo group) as well as separately at week 16 and 40.

Results: At baseline, a total of 49 (52%) patients were MSA-positive, 13 (14%) were MAA-positive, and in 33(35%) no Ab were detected. Demographics of patients in each group are shown in Table 1. Ten MSA+ patients were also MAA+. Figure 1 shows numbers of patients with each specific Ab. In the MSA+group (both IVIG & placebo arms), 71% (35/49) of patients had minimal response at week 16, compared to 55% (18/33) in the Ab -ve group (p= 0.12) and 38% (5/13) in the MAA+ group (p = 0.03). Of the 24 MSA+ patients randomized to IVIG 83% showed TIS response at week 16 compared to 60% of MSA+ patients receiving placebo (p= 0.07). In the AB -ve group significantly more patients responded in the IVIG

Table 1 Patient demographics and baseline characteristics

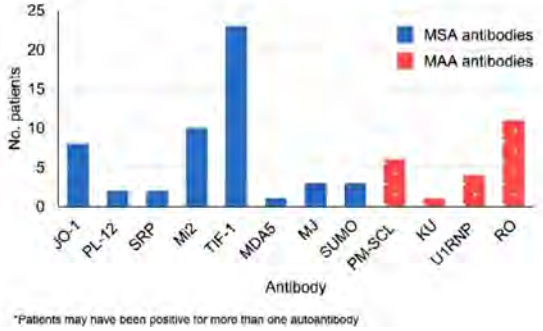
	MSA-positive* (N=49)	MAA-positive** (N=13)	No antibody detected (N=33)
Mean (range) age, years	51 (22–79)	54 (33–70)	54 (28–77)
Mean (range) time since diagnosis, years	3.66 (0.16–15.6)	5.04 (0.39–18.4)	5.8 (0.09–48.7)
Sex, n (% female)	39 (79.6)	11 (84.6)	12 (63.6)
Race, n (% White)	42 (85.7)	13 (100.0)	32 (97.0)
Mean BMI, kg/m^2	29.8	27.0	26.5
Disease severity, n (%)			
Mild	10 (20.4)	4 (30.8)	12 (36.4)
Moderate	31 (63.3)	8 (61.5)	17 (51.5)
Severe	8 (16.3)	1 (7.7)	4 (12.1)
CDASI score			
≤14	19 (38.8)	5 (38.5)	20 (60.6)
>14	30 (61.2)	8 (61.5)	13 (39.4)
Randomised treatment			
IVIg	24	4	19
Placebo	25	9	14

BMI, body mass index; CDASI, Cutaneous Disease Area and Severity Index; IVIg, intravenous immunoglobulin; MAA, myositis-associated antibodies; MSA, myositis-specific antibodies.

*10 patients positive for MSA were also positive for MAA.

**MAA-positive group contains only patients with MAA (no MSA).

Figure 1. Numbers of dermatomyositis patients with myositis-specific antibodies (MSA) and myositis-associated antibodies (MAA) in the ProDERM trial*



*Patients may have been positive for more than one autoantibody

arm than in the placebo arm (p= 0.001). For all patients no significant difference between the 3 Ab groups was seen in percentage of patients with 'moderate/major improvement' at either Week 16 or Week 40. A subanalysis of individual Ab showed no significant difference in response rates of Ab+ vs. Ab -ve patients at week 16 or 40 for anti-synthetase Ab (N=10, Jo-1, PL-12) nor for anti-Mi2 Ab (N=10). However, significantly more anti-TIF-1 + patients (N=21) had minimal response compared to anti-TIF-1 -ve patients at week 16 and 40 (p=0.02 and p=0.03 respectively).

Conclusion: MSA positive patients showed a trend of higher frequency of minimal improvement but not of moderate to major improvement when compared to MAA+ or Ab negative patients. However, the response to IVIG was similar to placebo across the 3 antibody groups, suggesting that IVIG is effective irrespective of myositis autoantibody status.

Abstract Number: 1973

Work-related Impact in Young Patients with Chronic Back Pain Awaiting a Magnetic Resonance Imaging

Diego Benavent[1], Mar Tapia[2], Daniel Bernabeu[2], Victor muley[2], Chamaida Plasencia-Rodríguez[3], Alejandro Balsa[3] and Victoria Navarro-Compán[4], [1]Hospital la Paz, Madrid, Spain, [2]Radiology Department, Hospital La Paz, Madrid, Spain, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Department of Rheumatology, La Paz University Hospital, IdiPaz, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1973–1976) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic back pain (CBP) is one of the major causes for medical consultation among young people. Given the limited sources, it is relevant knowing the characteristics associated with a higher burden in order to prioritize the performance of imaging exams. We aimed to identify factors associated with sick leave in a cohort of young patients with CBP awaiting an MRI of the spine.

Methods: The project "Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis" (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with CBP that are requested an MRI of the spine by other specialists different than rheumatologists in a tertiary hospital. The study period started in September 2021, and the dataset for this interim analysis was locked in October 2022. Patients completed a questionnaire concerning work status, including sick leave due to CBP (at-visit or prior to this). Besides, socio-demographic and clinical characteristics were collected. Patient-reported outcomes (PROs) for fatigue, Patient Global Assessment (PGA), physical function (Bath Ankylosing Spondylitis Functional Index -BASFI), and overall health (Assessment of Spondyloarthritis international Society Health Index -ASAS HI) were also evaluated. A logistic regression analysis was performed to evaluate the association of patients' characteristics with sick leave.

Table. Characteristics of employed patients by work status

		Total employed n=123	No sick leave n=58	Ever sick leave n=65	p-value
Demographics	Age	33.8 (4.8)	33.6 (5)	34.1 (4.8)	0.6
	Symptoms (months)	57.0 (54.0)	54.8 (54.1)	59.0 (54.3)	0.7
	BMI	25.4 (4)	25.4 (4.2)	25.4 (3.7)	0.9
	Female	65 (52.8)	33 (56.9)	32 (49.2)	0.5
	Education				
	Primary/secondary	66 (52.8)	27 (46.5)	38 (58.4)	0.2
	University	56 (45.5)	30 (51.7)	26 (40.0)	
	Type of work				
	Sendentary/ not active	33 (26.8)	19 (32.8)	14 (21.5)	0.5
	Physically active	76 (61.8)	38 (65.5)	38 (58.5)	
Characteristics of back pain	Buttock pain	42 (34.2)	17 (29.3)	25 (38.4)	0.4
	Night pain	58 (47.1)	21 (36.2)	37 (56.9)	0.02
	Inflammatory pain	29 (23.6)	14 (24.1)	15 (23.1)	1
	Flares of back pain	87 (70.7)	42 (72.4)	45 (69.2)	0.8
	Sudden onset	72 (58.5)	29 (50.0)	43 (66.1)	0.1
	Morning stiffness	76 (61.8)	32 (55.1)	44 (67.7)	0.2
PROs	Fatigue (0-10)	4.9 (3)	4 (3.1)	5.7 (2.7)	0.002
	PGA (0-10)	4.7 (2.9)	3.7 (2.9)	5.7 (2.6)	<0.001
	Physical function (BASFI)	3.2 (2.6)	2.4 (2.3)	4 (2.6)	<0.001
	Overall health (ASAS-HI)	6.7 (3.8)	5.6 (3.6)	7.8 (3.8)	0.002
Treatments	NSAIDs	109 (88.6)	52 (89.6)	57 (87.7)	0.2
	Muscular relaxants	88 (71.5)	33 (56.9)	55 (84.6)	<0.001
	Opioids	45 (36.6)	11 (18.9)	34 (52.3)	<0.001
	Antidepresants	19 (15.5)	4 (6.9)	15 (23.1)	0.01

Results: Of 152 recruited patients, 123 (80.9%) were actively employed, 22 (14.5%) were unemployed and 7 (4.6%) were students. Among the employed patients (52.8% female; mean age 33.8(4.8) years; 57.0 (54.0) months CBP duration), 65 (52.8%) patients had been on sick leave at some point (50 prior to visit and 15 at the study visit). Baseline characteristics are shown in **Table**. Night pain was more frequent in patients on sick leave (56.9 % vs 36.2%, p=0.02), and PROs on fatigue, PGA, physical function and overall health and functioning showed worse results in these patients, as compared to patients who had never been in sick leave. Additionally, patients with on sick leave had more frequently pharmacological treatment. After multivariable analysis, being male (OR 2.3, 95%CI 1.0-5.6), having night pain (OR=2.4, 95%CI 1.0-5.8) and reporting higher PGA (OR=1.1, 95%CI 1.0-1.4) were associated independently with being on sick leave.

Conclusion: One out of two young patients with CBP awaiting an MRI of the spine are on sick leave at some point. These patients have poorer quality of life and use more pharmacological treatment than active patients with CBP. Male sex and night pain are associated with being on sick leave due to CBP and therefore could be used to prioritize the use of spinal MRI aiming to optimize health resources.

Abstract Number: 1974

Comparison of Gait Spatiotemporal Measures Between Patients with Insertional Achilles Tendinopathy or Midportion Achilles Tendinopathy

Hayley Smitheman[1], Kayla Seymore[1], Andy Smith[1], Morgan Potter[1], Nabeel Alghamdi[1] and Karin Silbernagel[2], [1]University of Delaware, Newark, DE, [2]University of Delaware, Avondale, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1973–1976) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Insertional and midportion Achilles tendinopathy (AT) are painful injuries affecting both active and sedentary populations. Patients with AT present with pain with loading, often reporting pain with walking. Compared to midportion AT, insertional AT is more frequently associated with pain in positions of dorsiflexion, experienced during walking, due to compression of the distal tendon on the calcaneus. It is unknown however, if differences exist in gait spatiotemporal measures between AT subtypes and further, if these measures relate to pain. Therefore, the purpose of this analysis is to compare spatiotemporal measures of gait between patients with midportion AT and patients with insertional AT. We also aimed to assess the relationship between pain and spatiotemporal measures within each subtype.

Methods: Patients with insertional AT and midportion AT ambulated at their self-selected pace for 10m. Gait speed and percent of time spent in swing, stance, load response, flat foot, and pre-swing on the most symptomatic limb were measured with inertial measurement units (MuscleLab). Patient Reported Outcomes Measurement Information System (PROMIS) pain interference was used to assess pain. Independent t-tests were used to assess for differences in outcome variables between AT subtypes. Pearson correlations were used to assess for relationship between PROMIS pain interference and gait measures in patients with insertional AT and patients with midportion AT.

Results: 42 patients with insertional AT (24 F; 51.8±9 years; 32.4±7 kg/m^2) and 178 patients with midportion AT (100 F; 47.1±13 years; 28.7±6 kg/m^2) were included. No significant differences were observed between AT subtypes in any gait spatiotemporal measures or PROMIS pain interference ($p > 0.05$). In patients with midportion AT, there was a significant negative relationship between PROMIS pain interference and gait speed ($r=-0.153$, $p=0.048$) but no significant relationship with all other gait measures (p's >0.05). In patients with insertional AT, there was a significant negative relationship between PROMIS pain interference and gait speed ($r=-0.387$, $p=0.012$) and a significant negative relationship between PROMIS pain interference and percent time in load response phase ($r=-0.489$, $p< 0.001$). There were no other significant relationships with remaining analysis in patients with insertional AT.

Conclusion: No differences were observed between gait parameters or pain interference between AT subtypes. In patients with midportion AT, increased pain interference was weakly correlated with slower gait speed. The same pattern was observed in patients with insertional AT, however, the relationship was moderate between increased pain interference and reduced gait speed. Further, in patients with insertional AT, increased pain interference was moderately related to percent of time in the load response phase. Therefore, gait in patients with insertional AT may be more associated with pain than in midportion AT.

Abstract Number: 1975

Do You Believe in Exercise for Osteoarthritis? Exploring Differences in Participant Characteristics with Treatment Beliefs in Exercise for Knee Osteoarthritis

Sydney Liles[1], Jason Jakiela[2], Thomas Bye[2], Jennifer Copson[2] and Daniel White[2], [1]University of Delaware, Elkton, MD, [2]University of Delaware, Newark, DE

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1973–1976) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Knee osteoarthritis (OA) is a leading cause of disability and functional limitation in older adults. Treatments for knee OA focus on symptom management, with physical activity, e.g., exercise, receiving high recommendations. However, misconceptions about exercise are common, affecting an individual's beliefs about the benefits of exercise. Currently, little is known about the characteristics of those who have high positive and high negative beliefs about exercise. This study aims to explore how demographic factors, baseline physical activity (steps/day), and knee related outcomes differ between those with positive and negative treatment beliefs related to exercise in adults with knee OA.

Methods: We conducted a secondary analysis of baseline data from a clinical trial examining a telehealth physical therapy intervention for adults with knee OA. Included were adults within the United States who met the National Institute of Health and Clinical Excellence criteria for knee OA (> 45 years, activity related knee pain, and < 30 min of morning stiffness) and did not regularly exercise. Positive and Negative treatment beliefs were measured using the Treatment Beliefs in Knee and Hip OA (TOA) Physical Exercise (PE) questionnaire which include positive and negative subscales. High positive beliefs were defined as scores greater than 14 on the positive subscale while high negative scores were defined as scores greater than 8 on the negative subscale. These represent more than neutral agreement to positive/negative beliefs. We reported subject characteristics stratified by High Positive and High Negative Beliefs, which included age, sex, BMI, race, Visual Analog Scale (VAS) pain, steps/day, Knee Osteoarthritis Outcome Survey Activities of Daily living subscale score (KOOS ADL), and Western Ontario and McMaster Universities Osteoarthritis Index Function subscale score (WOMAC Function).

Results: 126 participants (mean age = 59.9 years old, 82% female, mean BMI = 36.2 kg/m^2) were included in the analysis (Table 1). Of those included, 73% (92/126) of the sample had high positive treatment beliefs and 26% (33/126) had high negative treatment beliefs. The high positive belief sample had a smaller proportion of females (77.1% vs 94.1%) than the low positive belief sample. Participants with high negative beliefs tended to be younger (56.4 years vs 61.2 years), had a higher

Table 1: Baseline Characteristics of Overall Sample

	Total Sample (n = 126)
Age (mean ± SD, in years)	59.9 ± 8.8
Sex (n, % female)	103, 81.8%
BMI (mean ± SD, kg/m^2)	36.2 ± 9.1
Race (n, % not white)	21, 16.7%
Steps/day (mean ± SD)	3686.3 ± 1856.5
VAS pain	66.0 ± 17.8
KOOS ADL (mean ± SD)	63.3 ± 16.5
WOMAC Function (mean ± SD)	25.0 ± 11.2

	High Positive (n=92)	Low Positive (n = 34)	High Negative (n = 33)	Low Negative (n = 93)
Age (mean ± SD, in years)	60.9 ± 9.0	57.4 ± 7.8	56.4 ± 8.0	61.2 ± 8.8
Sex (n, % female)	71, 77.1%	32, 94.1%	27, 81.8%	76, 81.7%
BMI (mean ± SD, kg/m^2)	35.7 ± 9.1	37.8 ± 9.0	39.1 ± 9.8	35.2 ± 8.6
Race (n, % not white)	14, 15.2%	7, 20.6%	3, 9.1%	18, 19.4%
Steps/day (mean ± SD)	3765.0 ± 1938.4	3506.7 ± 1669.5	4028.4 ± 1858.5	3567.9 ± 1852.9
VAS pain	64.4 ± 17.9	70.1 ± 17.1	72.6 ± 16.1	63.6 ±17.9
KOOS ADL (mean ± SD)	64.6 ± 15.3	59.8 ±19.0	58.4 ± 19.0	65.0 ± 15.2
WOMAC Function (mean ± SD)	24.1 ± 10.4	27.4 ± 12.9	28.3 ± 12.9	23.8 ± 10.3

BMI (39.1 kg/m^2 vs 35.2 kg/m^2), had higher pain (72.6 vs 63.6), had higher daily step count (4028.4 steps/day vs 3567.9 steps/day), and worse WOMAC physical function scores (28.3 vs 23.8) than those with low negative beliefs. (Table 2).

Conclusion: While the demographic makeup of individuals with high versus low positive treatment beliefs were relatively similar outside of sex, there may be some differences for high versus low negative treatment beliefs. A limitation to this study is that these differences were not formally tested due to relatively small sample size. This exploratory examination of group characteristics suggests that differences in treatment beliefs may be related to some patient characteristics, pain, and functional outcomes, however further research is needed to formally study these potential differences.

Abstract Number: 1976

Distribution and Validity of Proposed Disability Categories from the Short-Valued Life Activities Questionnaire

Louise Thoma[1], Kelli Allen[2], Beth Jonas[3] and Patti Katz[4], [1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina, Durham, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of California San Francisco, San Rafael, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1973–1976) Orthopedics, Low Back Pain, & Rehabilitation Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rehabilitation (i.e., physical therapy and occupational therapy) is indicated to improve function and participation in life activities. Rehabilitation utilization is low among adults with rheumatoid arthritis (RA) despite high rates of functional limitation. A screening tool implemented at routine rheumatology visits may facilitate appropriate referral and utilization. The Short-Valued Life Activities (SVLA) questionnaire is a validated patient-reported outcome measure that uniquely assesses accommodation use with each activity (e.g., extra time, tools, assistance). This is important because individuals who report no difficulty with a task, but use an accommodation, are at increased risk for future disability, which may be amenable to rehabilitation. We propose categorizing disability status using responses on the SVLA, as these categories could guide meaningful referral. As a first step, the purpose of this study was to determine the distribution and construct validity of the proposed disability categories among adults with RA.

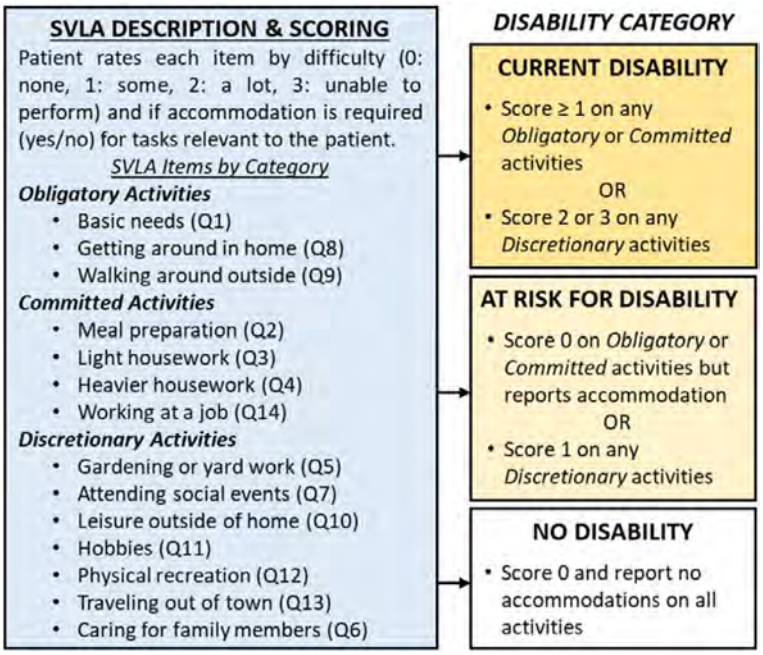

Figure 1. Proposed Disability Cat based on the SVLA

Table 1. Distribution of disability, functional limitation, and disease activity and associated correlations

	Proportion of the sample % (n)	Correlation with disability categories from the SVLA
Disability (Proposed categories from SVLA)		
No Disability	9% (27)	*n/a*
At-risk for Disability	10% (30)	
Current Disability	81% (236)	
Functional limitation (categories from PROMIS)		
No limitation (t-score > 50)	17% (51)	Rho = 0.57
Minimal limitation (50 ≥ t-score > 40)	37% (110)	p < 0.001
Moderate limitation (40 ≥ t-score > 30)	33% (97)	
Severe limitation (t-score ≤ 30)	12% (36)	
Disease activity (categories from RAPID3)		
Remission (score ≤ 3)	20% (58)	Rho = 0.56
Low severity (3 < score ≤ 6)	18% (52)	p < 0.001
Moderate severity (6 < score ≤ 12)	26% (75)	
High severity (score > 12)	36% (105)	

Methods: We conducted a cross-sectional survey study. We recruited adults with RA with at least two visits to UNC Health rheumatology clinics for RA, with at least one visit in 2020 or 2021. The survey was available electronically or verbally and included items regarding demographics, clinical information, and patient-reported outcomes. Our primary outcome was disability category (no disability, at-risk for disability, current disability) determined using responses regarding difficulty and accommodation use during 14 valued life activities in the SVLA (Figure 1). Functional limitations were assessed with the PROMIS PF10a, and categorized as no limitations, minimal limitations, moderate limitations, and severe limitations based on established t-score cutoffs. Disease activity severity was assessed with the RAPID3 and categorized as remission, low severity, moderate disease severity, and high severity based on established cutoffs. We used descriptive statistics to describe the distribution of disability categories. To assess construct validity, we calculated the correlation of the SVLA disability categories with the categories of physical function (PROMIS categories) and disease activity (RAPID3 categories) using Spearman rank test. Correlations were interpreted as moderate if $0.40 \leq \text{rho} < 0.60$ and strong if $\text{rho} \geq 0.60$.

Results: Of 1506 potential participants, 294 adults with RA completed the survey (age 56 ± 14 years, disease duration 10 ± 11 years, 82% women). The distribution of the sample in each disability category, functional limitation category, and disease activity category are detailed in Table 1. The disability categories were moderately correlated with functional limitation and disease activity categories (rho = 0.56-0.57; Table 1).

Conclusion: The proposed disability categories had good construct validity with established measures of functional limitation and disease activity in adults with RA. However, over 90% of the sample were categorized as at-risk or current disability with the proposed methods. Further research is needed to develop feasible methods to identify patients for whom rehabilitation referral should be prioritized.

Abstract Number: 1977

Combined Datasets for CNTX-4975 Osteoarthritis Knee Pain (OAKP) Phase 3 Trials (OAKP 301 and 304) to Assess Overall Efficacy and Safety of an Intra-articular Injection (IAI) of CNTX-4975-05 (CNTX) in Subjects with Chronic, Moderate-to-severe Osteoarthritis Knee Pain (MSOAKP)

James Connolly, James N Campbell, **Randall Stevens** and Colleen Newman, Centrexion Therapeutics Corporation, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: 30+ million US adults have OAKP, (13% women / 10% men). After years of using NSAIDs, analgesics, surgery and IAI, many patients remain with OAKP. CNTX is a 1 mg dose of capsaicin for IAI to reduce OAKP.

Methods: The phase 3 trials powering was based on the phase 2 trial showing a standard effect size (SES) of 0.55. Although each phase 3 trial (OAKP 301 and 304) was powered at >95% on the primary outcome measure, to allow for sufficient power for the key secondary outcome measures. The phase 3 trials were likely underpowered. The two nearly identical phase 3 trials did not meet the primary endpoint but nevertheless showed numerical superiority of CNTX over placebo. Given that the trials were nearly identical (except for a second injection in the OA-304), the results were combined for an integrated analysis. The analysis assessed the primary time point at Week 12 with the numeric pain rating scale (Primary OA-301) between (NPRS [0 – 10; 0 = no pain, 10 worst pain possible]) and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) A (Primary OA-304) (pain subscale; [0-50] -lower values have greater pain), WOMAC B (Knee stiffness [0-20]), WOMAC C (Function; [0-170]) and Patient Global Assessment of Change (PGIC;[0-7]).

Results: Between the two trials, 650 subjects received 1 dose of study drug (276 placebo, 373 CNTX). The analysis of the primary and key secondary endpoints was conducted. With the combined data sets, CNTX-separated from placebo at all time points for 6 months after a single injection. (Figure 1). The Week 12 primary endpoint reached statistical significance across all endpoints (NPRS P=0.030, WOMAC A P = 0.005, WOMAC B P=0.004, WOMAC C P=0.006 and PGIC P=0.004), as shown in Table 1 and Figure 1.Significant differences between placebo and CNTX were also evident at multiple other timepoints through Week 26.

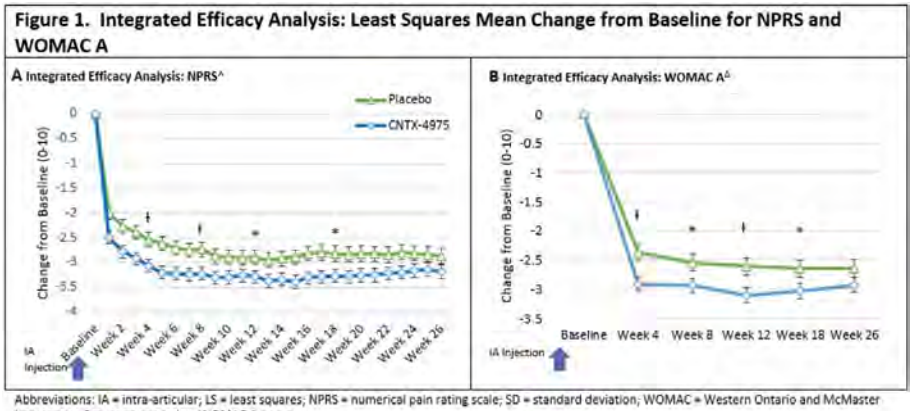
Figure 1. Integrated Efficacy Analysis: Least Squares Mean Change from Baseline for NPRS and WOMAC A



Abbreviations: IA = intra-articular; LS = least squares; NPRS = numerical pain rating scale; SD = standard deviation; WOMAC = Western Ontario and McMaster Universities Osteoarthritis Index; WOMAC A (pain)
Error bars represent standard error
Baseline NPRS Scores (mean [SD]): Placebo = 7.01 (1.09); CNTX-4975 = 7.04 (1.04)
Baseline Normalized WOMAC A scores (mean [SD]): Placebo = 6.21 (1.54); CNTX-4975 = 6.35 (1.48)
^ Due to visual spacing limits, only p values for weeks 4, 8, 12, 18, and 26 are represented
Δ Scale normalized to a 0-10 scale
* p value <0.05
† p value <0.01

Overall safety was acceptable with CNTX. Knee radiographs from Baseline to Week 52 showed no difference in KOA progression between placebo and CNTX in both trials, with no rapidly progressive osteoarthritis.

Conclusion: The separate Phase 3 trials did not meet their primary endpoints, suggesting that each trial by itself was underpowered. Combining the two trials demonstrated statistical separation and clinically meaningful benefit, and safety was acceptable. The safety database satisfies the International Conference on Harmonization (ICH) guideline for safety assessments.

Infrapatellar Fat Pad Size and Subcutaneous Fat in Knee Osteoarthritis Radiographic Progression: Data from the Osteoarthritis Initiative

Kwanghoon Lee[1], Marina Banuls-Mirete[2], Alecio Lombardi[3], Alexander Posis[3], Eric Chang[3], Nancy Lane[4] and Monica Guma[5], [1]Dongguk University ilsan Hospital, San Diego, CA, [2]Department of Medicine, University of California San Diego, San Diego, CA, [3]University of California San Diego, San Diego, CA, [4]University of California, Hillsborough, CA, [5]University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Adipose tissue is associated with knee osteoarthritis (KOA) progression. This study aimed to determine the association of infrapatellar fat pad (IPFP) size and subcutaneous adipose tissue around the distal thigh (SCAT*thigh*) on KOA progression.

Methods: This case-control study used data from the Osteoarthritis Initiative (OAI) that included 315 cases (defined as right knees with an increase of ≥1 Kellgren-Lawrence score (KL) from baseline to 48 months) and controls that were matched by age, sex, race, and baseline KL. Cross sectional area (CSA) of IPFP and SCAT*thigh* were measured using MRI images at baseline and 24 months. Multivariable conditional logistic regression models were used to estimate associations between IPFP and SCAT*thigh* with KOA progression. Mediation analysis was used to assess whether IPFP CSA or SCAT*thigh* mediates the relationships between KOA progression and obesity measures (body mass index [BMI] or abdominal circumference).

Results: IPFP CSA and SCAT*thigh* measurements were significantly increased in cases compared to controls at 24 months, but not at baseline, and were not associated with a significant increase in obesity measures. Adjusted ORs (95% CI) for KOA radiographic progression 9.299 (5.357 – 16.141) for ΔIPFP CSA, 1.646 (1.288-2.103) for ΔSCAT*thigh*, 1.286 (1.073-1.542) for baseline BMI, and 1.297 (1.091-1.541) for baseline abdominal circumference.ΔIPFP CSA significantly mediated the association between ΔSCAT*thigh* and KOA progression (39.5%), but not between obesity markers and KOA progression.

Conclusion: KOA radiographic progression was associated with IPFP size and SCAT*thigh* changes at 24 months, unrelated to an increase of BMI or abdominal circumference, suggesting that other factors trigger the worsening of local adipose tissue.

Baseline values	Case (n=315, mean±SD)	Control (n=315, mean±SD)	*P*
BMI (kg/m^2)	29.09±4.69	28.1±4.83	0.014

Weight Loss Induced by Anti-obesity Medications and All-cause Mortality Among Patients with Knee or Hip Osteoarthritis

Jie Wei[1], david Hunter[2], Nancy Lane[3], Jing Wu[4], Chao Zeng[5], Guanghua Lei[5] and Yuqing Zhang[6], [1]Health Management Center, Xiangya Hospital Central South University, Changsha, China, [2]Sydney Musculoskeletal Health, University of Sydney, St. Leonards, Australia, [3]University of California, Hillsborough, CA, [4]Key Laboratory of Aging-related Bone and Joint Diseases Prevention and Treatment, Ministry of Education, Xiangya Hospital, Central South University, Changsha, China, [5]Department of Orthopaedics, Xiangya Hospital, Central South University, Changsha, China, [6]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The current international guidelines recommend weight loss for pain relief and functional improvement in overweight or obese patients with knee or hip osteoarthritis; however, there is a paucity of data on the relation of weight loss to all-cause mortality among patients with osteoarthritis. We aimed to examine the relation of the rate of weight loss induced by anti-obesity medications over 1-year to all-cause mortality among overweight/obese patients with knee or hip osteoarthritis.

Methods: Using IQVIA Medical Research Database in the United Kingdom, we identified overweight/obese people aged 40 years or older with knee or hip osteoarthritis. We emulated analyses of a hypothetical target trial using a "cloning, censoring, and weighting" approach to assess the effect of slow-to-moderate (2-10%) or fast (≥10%) weight loss induced by the initiation of anti-obesity medications (i.e., orlistat, sibutramine, and rimonabant) within 1-year on all-cause mortality and several secondary outcomes (i.e., incident hypertension, type 2 diabetes, venous thromboembolism, cardiovascular disease, and any cancer) over 5-year follow-up, respectively (Figure 1).

Results: Among 6,524 participants initiating anti-obesity medications, the 5-year all-cause mortality was 5.3%, 4.0%, and 5.4% for "weight gain/stable", "slow-to-moderate weight loss" and "fast weight loss" arms, respectively. Compared with the "weight gain/stable" arm, hazard ratios (HRs) of all-cause mortality were 0.72 (95% confidence interval [CI]: 0.56-0.92) for the "slow-to-moderate weight loss" arm and 0.99 (95%CI: 0.67-1.44) for the "fast weight loss" arm, respectively. In addition, we found dose-response protective effects of weight loss on incident hypertension, type 2 diabetes, and venous thromboembolism. However, a slightly higher risk of cardiovascular disease, albeit non-statistically significant, was observed in the "fast rate of weight loss" arm compared with the "weight gain/stable" arm (HR=1.20, 95%CI: 0.81-1.78). No apparent difference in the risk of cancer was observed between the "fast rate of weight loss" arm and the "weight gain/stable" arm (HR=1.04, 95%CI: 0.74-1.45) (Table 1).

Conclusion: In this population-based study, a slow-to-moderate, but not fast, rate of weight loss induced by anti-obesity medications within 1-year is associated with a lower risk of all-cause mortality in overweight/obese people with knee or hip osteoarthritis. Our findings that gradual weight loss by anti-obesity medications lower all-cause mortality, if confirmed by future studies, could guide policy-making, and improve the well-being of overweight/obese patients with knee or hip OA.

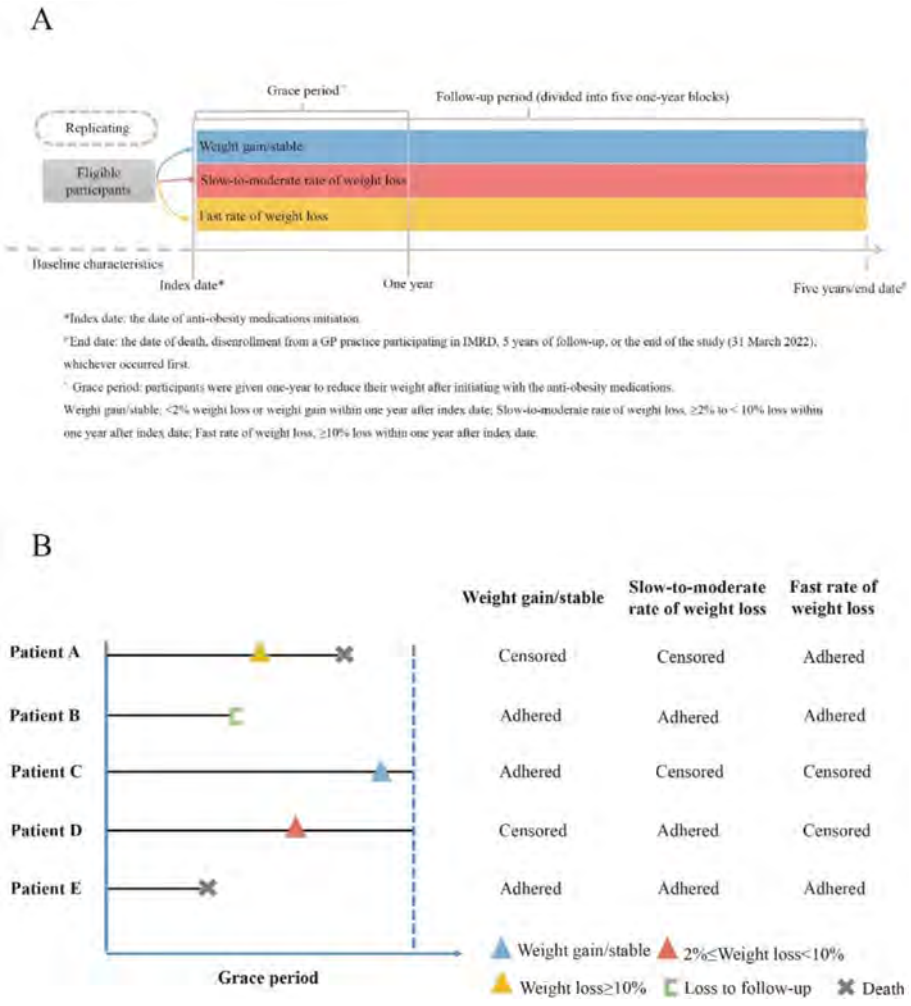

Figure 1. Study design of a hypothetical randomized controlled trial (“target trial”) on which we modeled our observational data analysis (A); Cloning and censoring in five hypothetical patients (B). Patient A lost ≥ 10% weight within one year after anti-obesity medications initiation. At time zero, 3 copies of the patient are made and they are randomly allocated to three groups. Patient A lost ≥ 10% weight within one year after anti-obesity medications initiation. The copy assigned to the “fast rate of weight loss” group is adhered with his/her assignment and will not be censored. However, the other two copies assigned to the “weight gain/stable” group and “slow-to-moderate rate of weight loss” group are violated with their assignment, and thus be censored at the time.

Table 1. Relations of weight reduction induced by anti-obesity medications within 1-year to all-cause mortality, incident hypertension, T2DM, VTE, CVD and cancer in overweight or obese knee or hip OA patients

	Weight gain/stable#	Slow-to-moderate rate of weight loss#	Fast rate of weight loss#

Movement Evoked Pain as an Outcome Measure in Patients with Knee Osteoarthritis

Leila Bagherzadeh[1], Schnitzer Thomas[2], Santiago Espinosa-Salas[1] and **Joana Barroso**[3], [1]Northwestern Physical Medicine and Rehabilitation Department, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Anesthesiology; Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain, being one of the most crucial symptoms associated with knee OA, serves as a significant outcome measure for the increasing number of studies focusing on pain management strategies. Many people with OA have no or minimal pain at rest. Therefore, identifying procedures to evoke the pain associated with OA would be of value in evaluating both neurosensory pathways important for pain perception as well as possible acute interventions focused on relieving

pain. We believe there is potential clinical value in differentiating and measuring pain during physical activity as a separate construct from pain at rest. In this study, we aimed to evaluate a novel method for inducing knee pain using a stair-stepper machine.

Methods: This study was part of a randomized, double-blind, cross-over trial to evaluate the efficacy of a topical treatment for patients with knee OA (NCT01654302). In this trial, 40 patients were assessed in 2 visits at least one week apart. In each visit, two exercise sessions were conducted, one before treatment and one after treatment. In this abstract, we focus on the findings of the first exercise session. After providing consent, patients reported their baseline pain level using a Numerical Rating Scale (NRS) from 0 to 10, with 0 meaning no pain and 10 meaning worst imaginable pain. Patients were instructed to use a commercially available stair-stepper machine (STAMINA, Springfield, MO) for a maximum of 2 minutes or until they reached maximum bearable pain. After completion of the exercise, participants assessed their knee pain intensity at 1, 5, and 60 minutes after stopping. The primary outcome measure was a change in pain intensity after exercise. To evaluate if exercise caused a significant increase in pain, we conducted a repeated measures ANOVA model to compare the NRS levels before exercise with those at 1 minute, 5 minutes, and 60 minutes after stopping exercise for two visits. Subsequently, we performed pairwise comparisons using Tukey's Honestly Significant Difference (HSD) test to further examine specific differences between the time points.

Results: Participants included 24 females and 16 males with an average age of 58 ± 7.7 years; The average pain level is presented in Table 1 and Figure 1. The analysis revealed a significant effect ($F(3,df) = 31.52$, $p < 0.001$) for visit 1 and ($F(3,df) = 3.95$, $p < 0.01$) for visit 2, indicating differences among time points for both visits. Further analysis of multiple comparisons for visit 1 showed a statistically significant increase in NRS after 1, 5, and 60 minutes compared to the baseline. However, for visit 2, the only significant difference was observed for 1 minute compared to 60 minutes. This finding could potentially be attributed to the patients' prior experience with the exercise method.

Table 1. Pain NRS scores for visit 1 and visit 2

	Visit 1		Visit 2	
Time	Mean	SD	Mean	SD
Before exercise	6.10	±1.32	6.13	±2.07
1 minute after stopping exercise	7.80	±1.34	6.82	±1.64
5 minutes after stopping exercise	7.13	±1.40	6.11	±2.11
60 minutes hour after stopping exercise	6.63	±1.43	5.89	±2.05

Conclusion: The ability to reliably and reproducibly generate movement-evoked pain in patients with knee OA holds promise for assessing acute treatment interventions as well as evaluating neurosensory pathways, e.g., brain MRI which can help define the basis for pain perception in OA. Further studies with larger sample sizes are warranted to validate this approach and assess its sensitivity to treatment-induced pain changes.

Abstract Number: 1981

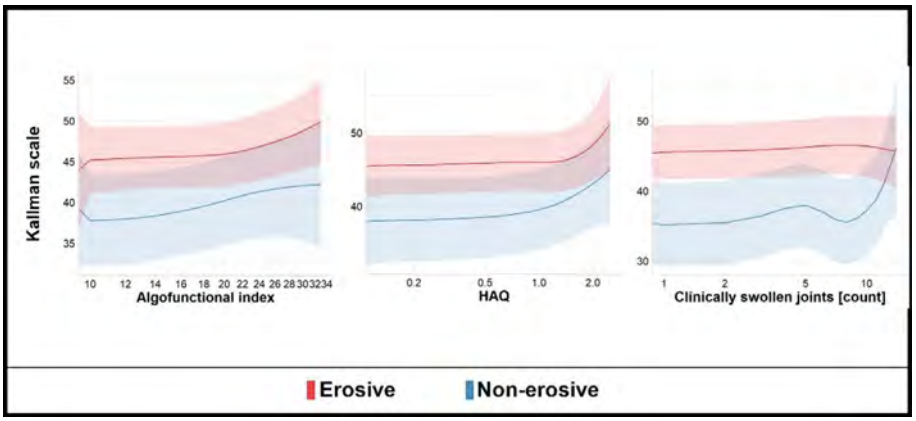
The Association Between X-ray Progression and Clinical Outcomes in Patients with Hand Osteoarthritis with 5-year Follow-up

Olga Sleglova[1], Jiri Baloun[2], Jindriska Gatterova[1], Xiao Svec[1], Olga Ruzickova[1], Karel Pavelka[3] and Ladislav Senolt[4], [1]Rheumatology Institute, Prague, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic, [3]Institut of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Praha, Czech Republic, [4]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Praha, Czech Republic

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Hand osteoarthritis (HOA) is a heterogeneous disorder with two main subtypes, non-erosive and erosive. The progression of HOA is assessed by various radiographic scoring methods, including the Kallmann scale, and the understanding of the association between radiographic changes and clinical symptoms might help improve the monitoring of disease progression.This study aimed to investigate the association of the Kallman scale with clinical assessment parameters and the erosive subtype in a Czech population of HOA patients over 5 years.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. All patients were evaluated at baseline and follow-up examinations over 2 and 5 years. Clinical examinations were performed by qualified rheumatologists. The number of clinically tender and swollen joints was recorded. Pain,



Associations of the Kallman scale with the Algofunctional index, HAQ, and the number of clinically swollen joints in patients with erosive and non-erosive HOA.

stiffness, and function were assessed. Hand disability was evaluated based on the Algofunctional index. The visual analog scale (VAS-pain) and the health assessment questionnaire (HAQ) was used for the assessment of pain and function/disability. Postero-anterior plain radiographs of both hands were examined, and radiographs were scored by two trained readers (rheumatologists) according to the Kallman scale.

Results: Of 154 patients enrolled in this study, 129 subjects (89.3% females; mean age at baseline = 64.6±8.0 years) met the ACR classification criteria for HOA and were followed up over 5 years at the outpatient department of the Institute of Rheumatology in Prague. Out of these patients, 57 were diagnosed with the non-erosive form (87.7% females; mean age at baseline = 63.8±7.7 years) and 72 with the erosive form (90.3% females; mean age at baseline = 65.7±8.1 years), where erosive HOA was defined by at least one interphalangeal joint with radiographic signs of erosion. Firstly, we analyzed each examination separately and found that the Kallman scale was both significantly increased in patients with the erosive subtype (2.95 – 3.12-fold, $p< 0.001$ for all) and associated with age in all examinations ($\beta = 1.27 – 1.57$; $p< 0.001$ for all). Next, we used generalized additive modeling (GAM) to analyze data collected over five years and discovered the association of the scale with HOA subtypes and age ($p < 0.01$ for both). GAM also revealed associations of the Kallman scale with HAQ (edf=2.5, p=0.016) in all patients and patients with non-erosive HOA (edf=1.7, p=0.027). Similarly, the scale was associated with the number of clinically swollen joints in all HOA patients (edf = 1, p = 0.041) and patients with non-erosive HOA (edf=4, p=0.046). Eventually, the Algofunctionalindex (edf=1.9, p=0.02) was only associated with the scale in all HOA patients. Other parameters (e.g., AUSCANs) were insignificant.

Conclusion: Our 5-year longitudinal study revealed the associations of structural progressions with both subtypes and age at each time point. In contrast, functional impairments were only associated with progression in the non-erosive subset and all HOA patients. Further studies in a larger cohort of patients are needed to validate these data.

Effect of Denosumab on Knee Pain and Bone Marrow Lesions in Symptomatic Knee Osteoarthritis

Terence O'Neill[1], Matthew Parkes[1], Michael Bowes[2], Richard Hodgson[1] and **David Felson**[3], [1]University of Manchester, Manchester, United Kingdom, [2]Imorphics, Manchester, United Kingdom, [3]Boston University, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There are currently no licensed therapies which reduce progression of knee OA. Current therapies focus on reducing pain, have limited effect, and some have significant adverse effects. Bone marrow lesions (BMLs) - ill-defined areas of high signal intensity in subchondral bone MRIs - are present in ~80% of patients with symptomatic knee OA and are associated with knee pain and structural progression. Denosumab is a potent antiresorptive monoclonal

antibody targeted at RANK Ligand (RANKL). We hypothesised that in patients with symptomatic knee OA, and evidence of a BML on MRI, treatment with a subcutaneous injection of denosumab would reduce BML size, thus reducing knee symptoms.

Methods: The DISKO Trial (ISRCTN96920058) was a single centre, double-blind randomised placebo-controlled trial. Adults with symptomatic knee OA were randomly allocated 1:1 to a single injection of subcutaneous Denosumab (60mg), or matched placebo. All subjects received calcium and vitamin D supplements. Eligibility criteria: age ≥40 years; x-ray changes of tibio- or patella-femoral OA based on knee x-rays within previous 24 months; knee pain in past week ≥3 on a 0-10 numerical rating scale (NRS). Knee must have evidence of BMLs on screening knee MRI (Phillips 3T), plus Kellgren and Lawrence grade 2 or 3 disease in the painful knee and 25-OH vitamin D level > 50nmol/l. Symptoms were assessed at 3 and 6 months, repeat MRI at 6 months. Primary outcome: BML area at 6 months (mm^2), from sagittal PDFS pulse sequence. Secondary outcomes: imaging parameters (BML volume), severity of knee pain (10-point NRS), other knee symptoms, and quality of life (KOOS; SF-12v2; EQ-5D-5L questionnaires).

Results: 145 men and women were assessed for eligibility. Of these, 87 were excluded, 58 taking part in the trial (30 randomised to denosumab, 28 to placebo). Mean age of randomised subjects was 64.2 years, mean BMI 29.3 Kg/m^2; mean baseline pain in the past week (0-10 NRS) was 6.0 (SD 1.7); median BML area was 787.5mm^2 (IQR 370.0mm^2 to 1150.0mm^2). A complete case mixed-effects model (N=46) adjusting for baseline found little difference in BML area between groups at 6 months (marginal mean difference = 52.0mm^2; 95% CI -151.9 to 255.9; p = 0.62). Six months between-groups differences in BML volume (marginal mean difference = 278.0mm^3; 95% CI -1877.4 to 2433.4; p = 0.80) and synovitis-effusion volume (-582.9mm^3; 95% CI -3011.3 to 1845.6; p = 0.64) were also small. At 6 months, the denosumab group had slightly greater pain in the past week NRS (0-10) (marginal mean difference = -0.25 points; 95% CI -1.6 to 1.1; p = 0.75) and the KOOS pain (100-0) (marginal mean difference = 5.0 points; CI -5.4 to 15.3; p = 0.35) compared to placebo. There were no significant between-group differences in non-pain KOOS subscales or EQ-5D-5L subscales at 3 or 6 months. Sensitivity analyses using additional covariates and multiple imputation were concordant. There were 57 adverse effects (30 Denosumab; 27 placebo), 40 mild, and 1 serious adverse event, unrelated to the intervention.

Conclusion: We found no signal to suggest a beneficial effect of denosumab on symptoms or structure. These findings do not support use of subcutaneous Denosumab for symptomatic knee OA.

WITHDRAWN

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Hand Osteoarthritis (OA) is common and causes pain and disability. Heat is anecdotally known to moderate symptoms and is conditionally recommended as a treatment for Hand OA by the American College of Rheumatology.

The purpose was to assess change in function after 6 weeks treatment with electrically heated mittens compared to sham mittens (electrical heating disabled) in participants with hand OA.

Methods: We performed a randomized superiority trial evaluating the potential benefit of heated mittens vs sham mittens during a 6-week trial period. We included participants diagnosed with hand OA according to the American College of Rheumatology classification criteria who had an AUSCAN (Australian/Canadian Osteoarthritis Hand Index) function of ≥ 40 on a 0-100 scale (higher scores indicate worse function). Participants were recruited from October 2020 to January 2023 and participated during the winter season (October to April 2020/21, 2021/22, 2022/23) in Denmark. Participants were randomly allocated (1:1) to heated mittens or sham mittens. The mittens appeared identically, including LED-lights that led when the heat function was activated. In the sham mittens, the heating was disabled. Participants were instructed to wear the mittens at least 15 minutes per day for 6 weeks. The primary outcome was change in AUSCAN function at week 6. Key secondary outcomes included AUSCAN pain, visual analog scale (VAS) global assessment of hand related problems, and grip strength. All analyses were based on the Intention-to-treat population, with continuous data modelled using repeated measures, mixed effects models adjusted for baseline variables.

Results: Two hundred participants were randomized to heated mittens (n = 100) or sham mittens (n = 100); 91 (Heat) and 95 (Sham) participants, completed the trial. The mean age was 71 years, 87 % were women, and median disease duration was 10 years (see Table 1). The mean (SE) change from baseline to week 6 in the AUSCAN function was -6.3 points (1.2) in the Heat group, and -3.3 points (1.2) in the Sham group, corresponding to a group difference of -3.0 points (95%CI, -6.3 to 0.4; $P = 0.085$; see Figure 1 and Table 2). Key secondary outcomes showed a statistically significant difference in AUSCAN pain of -5.9 points (95%CI, -9.5 to -2.2; $P = 0.002$), while no significant differences were found for VAS global assessment of hand related problems (0-100 VAS score) or grip strength.

Conclusion: Heated mittens were not superior to sham-heated mittens after 6 weeks regarding AUSCAN function but improvement in hand pain was observed.

Therapeutic Effects of Pentosan Polysulfate Sodium on Clinical and Disease Modifying Outcomes in Subjects with Knee Osteoarthritis

Mukesh Ahuja[1], Donna Skerrett[2], Curtis Gravance[3], Divya Navuru[4], Ravi Krishnan[5], Charles Inderjeeth[6], Philip Bloom[7] and Schnitzer Thomas[8], [1]Paradigm Biopharmaceuticals, Oak Brook, IL, [2]Paradigm Biopharmaceuticals, New York, NY, [3]Paradigm Biopharmaceuticals, Melba, ID, [4]Paradigm Biopharmaceuticals, Melbourne, Australia, [5]Paradigm Biopharmaceuticals, Adelaide, Australia, [6]University of Western Australia / Linear Clinical Research, Perth, Australia, [7]Sportsmed Biologic, Melbourne, Australia, [8]Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is an inflammatory joint disease, causing chronic pain, disability, and reduced quality of life. Affected joints may include the knee, hip, and hands. This study evaluated clinical and disease modifying biomarker and structural changes in subjects with knee OA pain treated with injectable pentosan polysulfate sodium (iPPS) or placebo.

Methods: In this phase 2, double-blind study, subjects were randomized to iPPS 2.0 mg/kg ideal body weight (IBW) twice weekly, 2.0 mg/kg IBW PPS once weekly + placebo once weekly, or placebo twice weekly for 6 weeks, followed by a 46-week follow-up. Subjects were evaluated at baseline, days 56 and 168 for clinical outcomes using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and synovial fluid (SF), serum and urine samples were obtained for biomarker assays. Magnetic resonance imaging (MRI) was performed at Day 168 to assess joint structure changes.

Safety was evaluated by assessing adverse events (AEs).

All comparisons were exploratory at 5% significance. The percentage change from baseline to Day 56 and Day 168 were compared between treatment groups using a mixed model for repeated measures (MMRM) analysis. Biomarkers were quantitated using verified ELISA kits. Whole-Organ MRI Scoring (WORMS) was used to assess changes in the joint structures.

Results: 61 subjects were randomized (17, 15 and 21 to twice weekly iPPS, once weekly iPPS and placebo respectively. Median age was 60 years; 57% were male; median BMI was 28.8 and KL 3-4 was 78% overall. Baseline clinical values were similar among groups. At Day 56, significant improvements in WOMAC pain (p=0.05), function (p=0.017) and overall (p=0.022) scores were observed in subjects treated with iPPS twice weekly vs placebo and all improvements continued through Day 168. Once weekly iPPS showed improvement but differences from placebo did not reach statistical significance. At Day 56 favorable changes were observed in 6 SF biomarkers (IL-6, TNF-α, βNGF, COMP, ARGS [p=0.036], TIMP-1) in iPPS-treated subjects vs placebo. At Day 168, SF biomarkers ARGS and COMP, serum biomarker ARGS (p=0.024), COMP and C2C (p=0.024), and urine biomarker CTX II demonstrated favorable changes in iPPS-treated subjects vs placebo.

MRI results showed improvements in structural disease features, most apparent in the once-weekly iPPS treated subjects: a 21% improvement in cartilage loss score in the medial femur vs 4% worsening in placebo (p=0.065), and a 17% decrease of bone marrow edema lesions in the lateral tibiofemoral compartment with an increase of 56% in the placebo (p=0.028).

Related AEs occurred in 55.0%, 73.7% and 36.4% of subjects in the iPPS once weekly, iPPS twice weekly, and placebo-treated subjects, respectively. There were no serious AEs or AEs of special interest. The majority of AEs were mild to moderate in severity. The most common related AEs were headache and injection site reactions.

Conclusion: These findings show promising effects of iPPS for pain relief and improved function while changes in biomarkers and MRI assessments show potential DMOAD effects of iPPS in patients with knee OA. Paradigm is conducting larger global studies to confirm the observed clinical and DMOAD effects of iPPS.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 30% of patients with primary knee osteoarthritis (KOA) who have undergone Total Knee Replacement (TKR) continue to experience knee pain after surgery.High levels of anxiety and/or depression before TKR have been identified as predictors of post-TKR painand are barriers to engaging in post-TKR rehabilitation. The Moving Well is a pre- and post-TKR intervention thatcombinesprinciples of cognitive behavioral therapy (CBT) and home exercisesalongside a peer coach with the goal of reducing anxiety, depression, and knee pain post-TKR.A peer coach is a person with KOA who had undergone TKR and is guiding another person with KOA in the Moving Well interventionto prepare and recover from TKR. The goal of this abstract is to present the preliminary results of this pilot study regardingthe effectiveness and feasibility of Moving Well.

Methods: We included patients with KOA scheduled for TKR 8 weeks in advance between 50-89 years, had access to a computer, internet, and spoke English. Exclusion criteria were prior joint replacement surgery,unable to exercise, or any-rheumatic diseases. Participants were randomized to either Moving Well intervention or Staying Well attention control arm. Each group received weekly 1-hour phone sessions, 7 sessions pre-TKR and 5 sessions post-TKR. The Staying Well arm covered topics on nutrition and preventive medicine anddid not receive information on TKR, exercise, or CBT principles. We used one sided t-test to determine differences in mean Generalized Anxiety Disorder (GAD)-7, Patient Health Questionnaire (PHQ)-8 scores and mean changes in Knee Injury Osteoarthritis Outcome Score (KOOS)scoresbetween arms and between baseline (8 weeks pre-TKR) and 6 weeks after TKR.

Results: Thereare 38 participants enrolled out of a target of 74 individuals for this pilot, with 22 in the Moving Well arm and 16 in the Staying Well arm. The meanage of participants is 68 years, and the population is mostly white and highly educated (Table 1). While there was no significant differencein depression (PHQ-8) or anxiety (GAD-7)scoresbetween arms (Figure 1), participants in the Moving Well program experienceda large improvement in KOOS scores 6-weeks post-TKR (Figure 2). None of the values were significant given the small sample. No participant from Moving Well dropped out while 3 dropped out from Staying Well, which suggests that the intervention is feasible and engaging for completion.

Conclusion: There were no significant changes in depression or anxiety levels between Moving Well and control groups. However, the Moving Well group demonstrated a noteworthy improvement in KOOS scorespost-TKR. These findings emphasize the potential benefits of a holistic approach in managing the challenges faced by KOA patients undergoing TKR, highlighting the importance of incorporating psychological support and exercise programs into pre- and post-

Deep Immunophenotyping of Osteoarthritis Patients Demonstrates Baseline Alterations in Monocyte Populations in OA, Dendritic Cell Subpopulations Among Radiographic Progressors, and Th17 Cells Among Pain Progressors

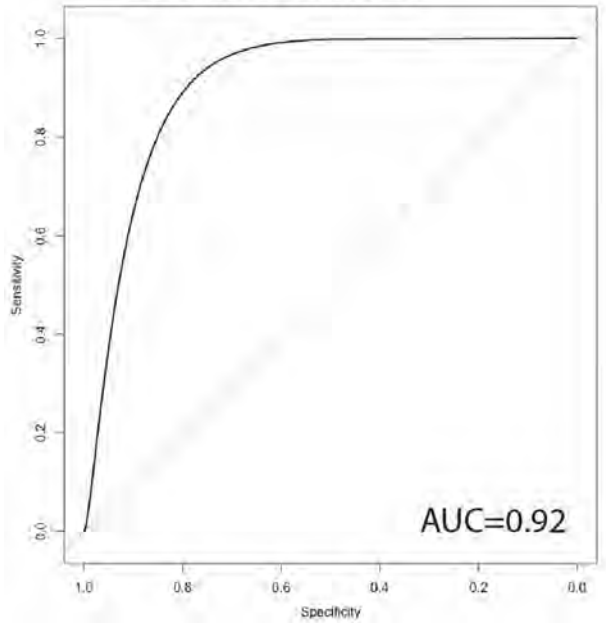
Gabby Dyson[1], Montana Barrett[2] and **Matlock Jeffries**[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma State University, Guthrie, OK

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have suggested low-level chronic inflammation plays a key role in knee osteoarthritis (OA) development and progression. In the present study, we set out to investigate, via mass cytometry, differences in circulating blood immunophenotypes in moderate-stage OA patients compared to controls, and to investigate differences in baseline immunophenotypes in OA patients who later experienced radiographic or pain progression within the subsequent 2 years.

Methods: Early OA patient samples were obtained from the Oklahoma SOONER OA cohort, defined as baseline K/L grade 0-3 and knee pain on most days for the past 6 months. Fixed-flexion radiographs and WOMAC information from visits every 6 months was analyzed. Radiographic progressors were defined as having mean medial TF joint space narrowing of ≥0.7mm within 24 months. Pain progressors were defined as having a WOMAC pain subscale worsening of at least

Figure 1: Receiver operator characteristic (ROC) curve for OA vs. control classification model



10 points on a 0-100 normalized scale within 24 months. Matched controls were obtained from the Oklahoma Immune Cohort. The final analysis included 13 OA patients and 13 controls. Among OA patients, 4/13 were radiographic progressors and 5/13 were pain progressors. Baseline blood samples were stained with Maxpar Direct immune profiling assay kit (Fluidigm), then subjected to mass cytometry analysis. Quantitative analysis of 37 immune cell populations was then performed and group differences defined with a student T-test. Generalized logistic models were then developed to classify patients into the above groups.

Results: Comparing all OA patients to controls, there were increases in MAIT/NK T cells (OA: 3.3±0.6 vs. healthy: 1.5±0.2, mean % of parent cell population±SEM, P=0.02) (Table 1) and eosinophils (4.2±0.7 vs. 1.6±0.5, P=0.01), as well as decreases in classical- (91.6±0.7 vs. 94.3±0.7, P=0.03) and transitional-monocytes (6.8±0.5 vs. 4.8±0.6, P=0.03) noted. Radiographic progressors were characterized by baseline decreases plasmacytoid- (35.8±2.5 vs. 32.6±3.2, P=0.03) and increases in myeloid-dendritic cells (64.2±2.5 vs. 67.5±3.2, P=0.03). Pain progressors were found to have increases in Th17 T-cells (13.0±2 vs. 7.4±0.6, P=0.02). A machine learning logistic model was then trained to differentiate OA patients from healthy controls and underwent 3-fold cross-validation with internal tuning. The model demonstrated 84% accuracy with a receiver operator characteristic area under the curve (ROC-AUC) of 0.92 (Figure 1).

Conclusion: Our study is the first to perform deep immunophenotyping of peripheral blood on a small group of OA patients and well-matched controls. The results suggest that significant alterations in certain immune cell subpopulations are present among OA patients and at baseline prior to future radiographic or pain progression, and provide additional support for the hypothesis that OA represents a systemic disease characterized by low-level immune dysregulation. Future research should confirm our findings and investigate the pathophysiological consequences of these variations.

Clinical and Imaging Characteristics of Individuals Who Underwent Knee Replacement During Years 3 to 5 in the FORWARD Study: A Post Hoc Analysis

Philip Conaghan[1], Felix Eckstein[2], Wolfgang Wirth[3], Marc Hochberg[4], Ali Guermazi[5], Luping Zhao[6] and Niti Goel[7], [1]University of Leeds, Leeds, United Kingdom, [2]Paracelsus Medical University, Institute of Anatomy & Ludwig Boltzmann Institute, and Chondrometrics GmbH, Salzburg, Austria, [3]Paracelsus Medical University, Institute of Anatomy & Ludwig Boltzmann Institute, and Chondrometrics GmbH, Freilassing, Germany, [4]University of Maryland School of Medicine, Baltimore, MD, [5]Boston University, Boston, MA, [6]TrialSpark, New York, NY, [7]TrialSpark, Duke University, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sprifermin is an investigational intra-articular (IA) recombinant human truncated fibroblast growth factor-18 (rhFGF-18) therapy evaluated to date in three knee osteoarthritis (KOA) trials (NCT00911469 [first-in-human {FIH} study]; NCT01033994; NCT01919164 [Phase 2 'FORWARD' study]) as a potential disease modifying OA drug. One of the treatment goals related to slowing OA structural progression is to significantly delay/prevent joint failure. In the FIH study, which enrolled a population planned to undergo knee replacement (KR), and in FORWARD, which enrolled those not planning to undergo KR for at least 2 years, a numeric reduction in KR incidence was seen within the study follow-up

period of 6 months or years (Y) 3 to 5, respectively, for the highest doses of sprifermin. This post hoc analysis explores clinical and structural data on FORWARD study participants (pts) who underwent KR in Y3-5.

Methods: Pts with KOA were randomized 1:1:1:1:1 in FORWARD to receive cycles (one IA injection weekly x 3 weeks) of placebo (PBO) or sprifermin at 30 or 100 μg IA every 6 or 12 months (Q6M, Q12M) through month 18, and were followed through to Y2 (treatment period) and Y5 (post-treatment period). Baseline (BL) and week 104 (W104) clinical and imaging data were analyzed post hoc for the population with a BL and ≥1 post-BL MRI (modified intent-to-treat [mITT]) who completed the treatment period by KR receipt in Y3-5. The Q6M and Q12M data for the sprifermin 30 μg and 100 μg arms were combined for analysis and reported descriptively. No imputation for missing data and no statistical tests were performed.

Δ=change; cLF=central lateral femur; cMF=central medial femur; FTJ=femorotibial joint; KR=knee replacement; LFTC=lateral femorotibial compartment; MFTC=medial femorotibial compartment; mITT=modified intent-to-treat; N=total sample size; n=sample evaluated; SD=standard deviation; W104=Week 104.

Results: In the PBO and sprifermin 30 μg Q12M, 30 μg Q6M, 100 μg Q12M, and 100 μg Q6M arms, the overall incidence of KR during Y3-5 was 5%, 4%, 5%, 2%, and 0% (n=4/87, 4/99, 5/92, 2/98, and 0/96), respectively. Study pts who received KR were younger than those without (Table 1). Most KRs (67%) occurred in Kellgren-Lawrence grade 3 knees at BL. The total KR population at BL had slightly greater pain, slightly more functional impairment, thinner total femorotibial compartment (TFTC) cartilage, and more denuded cartilage area of subchondral bone (dAB) than the non-KR population (Tables 1 and 2). At W104, the total KR population had numerically less improvement in pain and function, more cartilage thickness loss, and more medial femorotibial compartment (MFTC) dAB than the non-KR population (Tables 1 and 2), more so in the weight-bearing central medial femur [cMF] than in the medial tibia. These changes appeared more pronounced in the PBO group than the sprifermin 30 μg and 100 μg combined groups. Changes in dAB at W104 in the lateral femorotibial compartment (LFTC) were less marked than those in the MFTC.

Conclusion: Pts treated with IA sprifermin 100 μg had a lower incidence of KR than those receiving PBO or sprifermin 30 μg, with the incidence of KR being similar in the latter groups. Although the overall incidence of KR was low, differences in clinical and structural features (especially in the medial compartment) of KOA were apparent at BL and W104, with less symptomatic improvement and more structural worsening at W104, in those who received KR compared to those who did not. These findings need to be confirmed in a prospective study.

Extended-Release versus Immediate-Release Triamcinolone Acetonide for Osteoarthritis of the Knee with Comorbid Diabetes Type 2 Diabetes Mellitus: A Post Hoc Analysis

Andrew Spitzer[1], Helena Rodbard[2], Sheikh Usman Iqbal[3], Masato Nakazawa[3], Mary DiGiorgi[3] and Roy Winston[3], [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Endocrine and Metabolic Consultants, Rockville, MD, [3]Pacira BioSciences, Inc., Tampa, FL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Intraarticular (IA) corticosteroids are generally considered safe and effective to treat osteoarthritis of the knee (OAK) but may cause hyperglycemia that may last for weeks and can be particularly severe for up to 72 hours after injection; this hyperglycemia can have adverse implications for patients who have comorbid type 2 diabetes mellitus (T2D). A phase 2 study of 33 patients with OAK and T2D (NCT02762370) found that there were minimal blood glucose disruptions when patients were administered extended-release triamcinolone acetonide (TA-ER) compared with immediate-release triamcinolone acetonide (TA-IR). The purpose of this post hoc analysis is to characterize the clinical meaningfulness and relevance of the results of the phase 2 study.

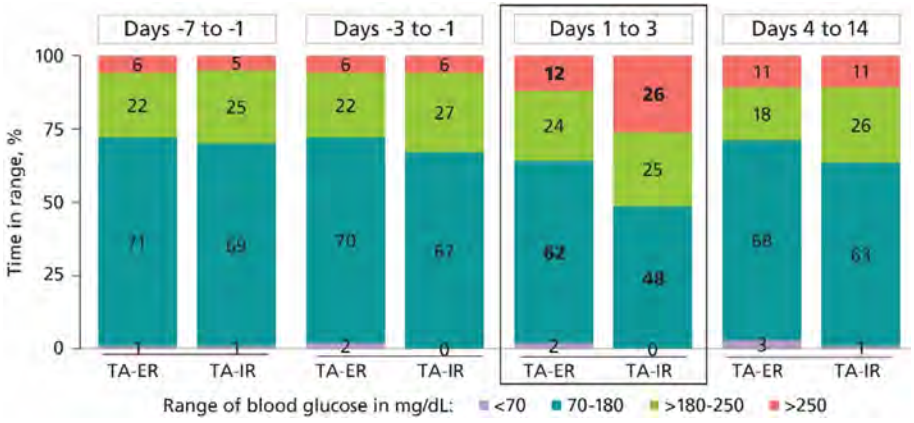

Figure 1: Percentage of time in specific blood glucose ranges. Black box indicates the critical 72-hour window. TA-ER, triamcinolone acetonide extended-release; TA-IR, triamcinolone acetonide immediate-release.

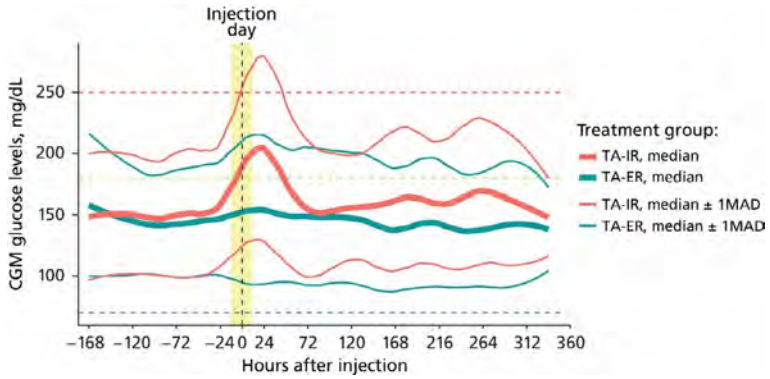

Figure 2. CGM levels over time. Median glucose levels (thick lines), median glucose levels ± 1MAD (think lines), injection day (yellow shading), and target range limits (horizontal dashed lines) are indicated. The red dashed line indicates the severe hyperglycemia threshold, while the green and blue dashed lines indicate the >180- and ≥70-mg/dL thresholds, respectively. CGM, continuous glucose monitoring; 1MAD, 1 mean absolute deviation; TA-ER, triamcinolone acetonide extended-release; TA-IR, triamcinolone acetonide immediate-release.

Methods: Patients who had T2D for ≥1 year, symptomatic OAK for ≥6 months (as defined by the American College of Rheumatology criteria for the Classification of OA of the Knee), and glycated hemoglobin ≥6.5% and < 9.0% were considered eligible and randomized to IA TA-ER or TA-IR. Before IA injection and throughout the subsequent 14 days, continuous glucose monitoring (CGM) provided an ambulatory glucose profile that summarized blood glucose levels (BGLs). Percentage of time in target range (70-180 mg/dL) and percentage of time above range (TAR; including >250 mg/dL) as defined by internationally recognized thresholds, changes from baseline in daily average BGL, and glycemic variability were compared between groups. Kaplan-Meier analysis was used to determine the time to reach 250 mg/dL and maximum BGL.

Results: Across days 1-3, IA TA-ER versus TA-IR resulted in an increased percentage of time in the target range (62% vs 48%; *P*=0.123) and a significant 2-fold lower percentage of TAR >250 mg/dL (12% vs 26%; *P*=0.047) (Figure 1). IA TA-ER had a smaller percentage of patients with maximum CGM BGL >250 mg/dL versus TA-IR (50% vs 93%). The ambulatory glucose profile analyses demonstrated more controlled BGLs and lower glucose spikes for patients receiving IA TA-ER compared with TA-IR (Figure 2). IA TA-ER had significantly higher time to maximum BGL versus TA-IR (34 vs 13 hours; *P*=0.007) and median time to 250 mg/dL (44 vs 6 hours; *P*=0.003).

Conclusion: This post hoc analysis suggests that IA TA-ER provides a clinically meaningful reduction in hyperglycemia versus TA-IR in patients with OAK and T2D. Glucose management is expected to improve with TA-ER compared with TA-IR because of the increased percentage of time in the target range. Lower and more controlled glucose spikes may lead to

fewer short-term hyperglycemia-related adverse events for patients receiving TA-ER versus TA-IR. Overall, TA-IR may reduce adverse events and healthcare utilization while improving long-term glucose control and patient well-being, particularly with repeat injections.

Shared Variation Among Cartilage Thickness Change Maps and Baseline Clinical Features at the Initiation of Structural Knee Osteoarthritis

Thomas Keefe[1], Marc Niethammer[1], Boqi Chen[1], Zhengyang Shen[1], Daniel Nissman[1], Mary Catherine Minnig[2], Yvonne Golightly[3], J.S. Marron[1] and **Amanda Nelson**[1], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Durham, NC, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To identify features of cartilage thickness change and baseline clinical indicators associated with the transition from normal to mildly reduced joint space as an early indicator of structural knee osteoarthritis (KOA).

Methods: We identified knees with radiographic medial joint space narrowing (JSN) grade 0 that transitioned to JSN grade ≥1 between any two timepoints during 96 months of follow-up in the Osteoarthritis Initiative (OAI, n=349) and selected cartilage maps (using a 3D U-Net as described in 10.1016/j.ocarto.2023.100334) from the last visit with JSN=0 and the first visit with JSN≥1. Difference maps reflecting the change in cartilage thickness at this transition for the femur and for the tibia were generated and used as data blocks. Angle-based Joint and Individual Variation Explained (AJIVE) was applied to identify the modes of variation expressed in 3 data blocks: (i) femoral cartilage change maps (ii) tibial cartilage change maps, and (iii) baseline clinical and demographic features. We examined how these blocks (different data types) varied together (shared, or "joint" variation), that may reflect features of early OA (at the transition from JSN=0 to JSN≥1). The modes of variation are visualized using loadings plots, which show the contribution of each cartilage pixel and of each OAI variable to the mode of variation (**Figure**).

Results: This analysis includes n=198 knees (from individuals with a mean age of 63 years, mean BMI of 30 kg/m^2, about ¼ with pain, after excluding outliers and those with missing data), each with (i) 57,117-pixel femoral cartilage change map, (ii) 56,204-pixel tibial cartilage change map, and (iii) 86 clinical measurements. The top three directions of shared/joint variation between the three data blocks are discussed below. **Shared direction 1** (Column 1 in **Figure**) reflects overall cartilage thinning between the transition time points (JSN=0 to JSN≥1). This pattern of overall cartilage loss is associated with poorer physical health, greater stiffness and disability, more depression, and higher BMI. **Shared direction 2** demonstrates an association with medial-predominant thinning in those with more stiffness (indicated by both WOMAC and force speeds), higher BMI, poorer physical function and mental health, greater baseline symptoms and disability, alignment, and taking

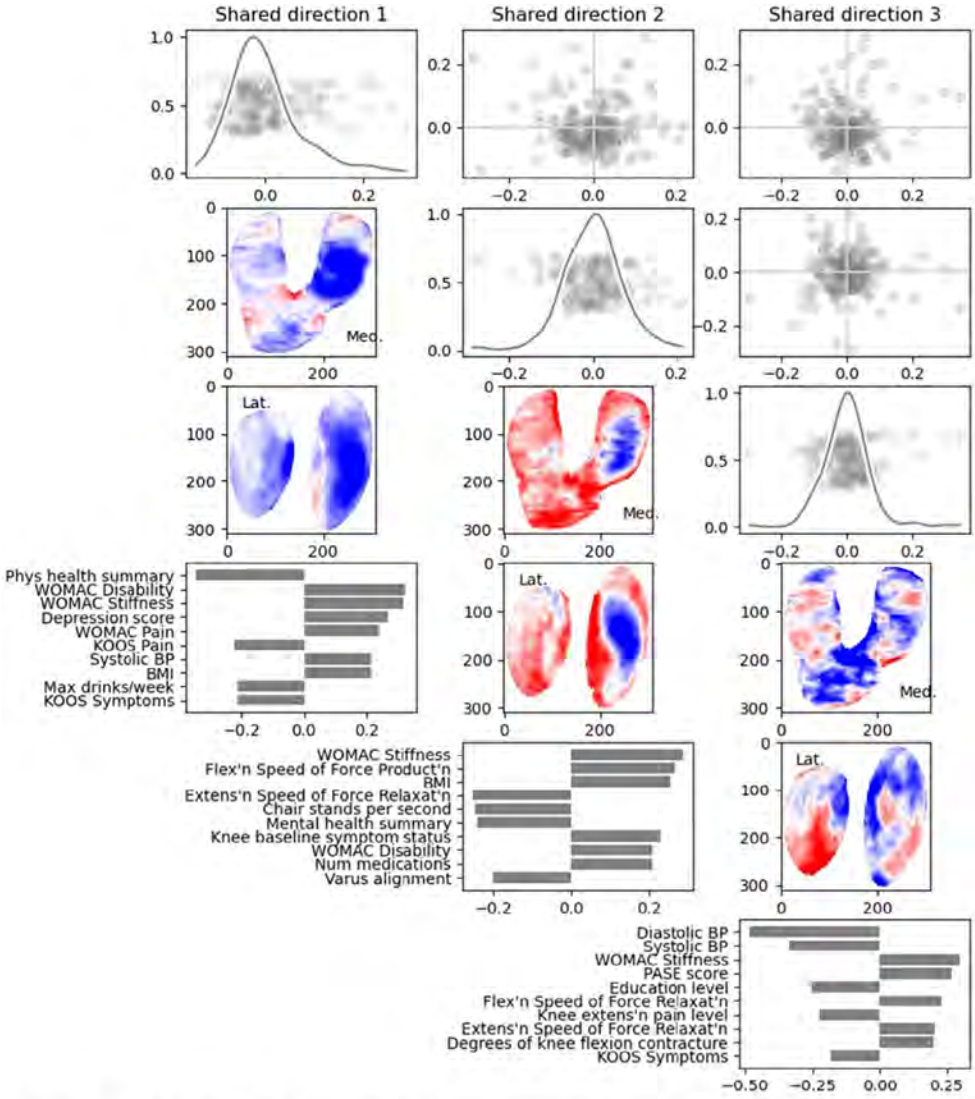

Figure. First 3 directions (columns 1-3) representing joint variation in femoral cartilage thickness change, tibial cartilage thickness change, and baseline clinical features based on AJIVE analysis using OAI baseline data. Blue=thinner and red=thicker cartilage.

more medications. **Shared direction 3** shows thinning over the femur with anterior/posterior differential loss in the tibia that is associated with lower blood pressure, education level, and extension pain but higher stiffness, physical activity, and flexion contracture.

Conclusion: These results utilize the OAI data in a novel analysis which provides directions of shared variations. There was a strong association with self-reported (via WOMAC) and functional (via force measures) stiffness in knees that subsequently transitioned from JSN=0 to JSN≥1, suggesting that stiffness (which is often overlooked or even removed from analyses) may be an important feature in early structural KOA.

Session Date: Tuesday, November 14, 2023

Session Title: (1977–1995) Osteoarthritis – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Movement-evoked pain (MEP), i.e., pain that appears with or is made worse by movement, is a common complaint in people with knee osteoarthritis (OA). MEP is more intense and bothersome than spontaneous pain and is related to greater disability. However, little is known about whether exercise, the first-line recommendation for managing chronic pain due to knee OA, can reduce MEP and factors that may predict treatment response. The objectives of this study were: (1) to investigate the effect of a 12-week exercise-based physical therapy intervention on MEP in people with knee OA and (2) to examine whether baseline psychological factors and nociceptive dysfunction predict change in MEP.

Δ in MEP from week 12 - baseline			
PainNA	-2.4 ± 2.0	-2.6 ± 2.5	-2.4 ± 1.9
Functional MEP	-0.5 ± 0.6	-0.8 ± 0.5	-0.1 ± 0.5
Exercise MEP	-0.7 ± 1.0	-0.7 ± 1.0	-0.8 ± 1.0

Abbreviations. CCI, Charlson Comorbidity Index; CES-D, Center for Epidemiological Studies-Depression; CSI, Central Sensitization Inventory; KOOS, Knee Injury and Osteoarthritis Outcome Score; MEP, movement-evoked pain; PCS, Pain Catastrophizing Scale; QST, quantitative sensory testing; SD, standard deviation; TS, temporal summation.

*Lower scores indicate greater pain.
†Higher scores indicate higher probability of central sensitization.
‡Higher scores indicate greater symptomology.

Table 1. Cohort characteristics

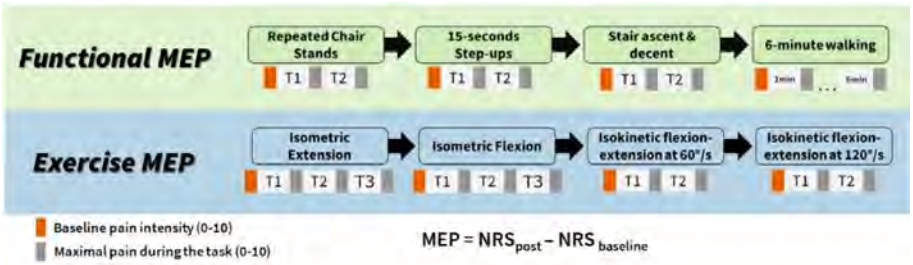

Figure 1. Assessment of functional MEP and exercise MEP. Functional MEP was assessed as the average increase in knee pain (0-10 scale) during a series of functional tasks, including repeated chair stands (x2), 15-seconds step-ups (x2), stair ascent and descent (x2), and 6-minute walk. Exercise MEP was assessed as the average increase in knee pain (0-10 scale) during a series of knee exercises including isometric extension (x3), isometric flexion (x3), and isokinetic flexion-extension at 60°/s (x2) and 120°/s (x2).

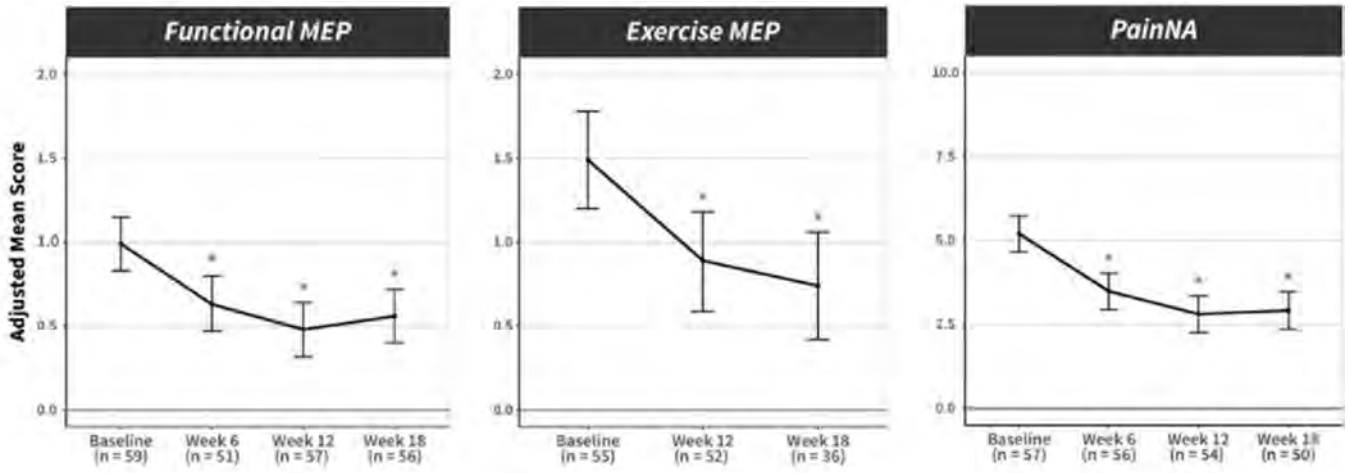

Figure 2. Adjusted means and 95% confidence intervals for measures of MEP at each study visit.
* denotes a significant change compared to baseline.

Methods: For this study, we used data from a single-arm clinical trial (#NCT04243096) of a 12-week exercise intervention in people with symptomatic knee OA (n = 60, **Table 1**) with age ≥ 50 and BMI ≤ 40 kg/m^2. Participants received 18 sessions (8 via telehealth) of an exercise intervention with a physical therapist over 12 weeks. Our primary outcome was MEP during functional activities (functional MEP), and secondary outcomes included exercise MEP and knee pain during nominated activity (PainNA, 0-10 scale) (**Figure 1**). These outcomes were assessed at baseline, and weeks 6, 12, and 18. At baseline, nociceptive functioning was assessed using quantitative sensory testing that included pressure pain threshold (PPT), mechanical temporal summation (TS), and conditioned pain modulation (CPM). At baseline, participants also completed Center for Epidemiologic Studies Depression Scale (CES-D), Central Sensitization Inventory (CSI), and pain catastrophizing scale (PCS; 3-items). Responders were individuals with ≥ 50% improvement in functional MEP from baseline to week 12. The effect of an exercise intervention on MEP from baseline to follow-up was evaluated with mixed model repeated measures (MMRM) adjusting for age, sex, BMI, and presence of comorbidities. Log-binomial regression was used to determine whether any baseline measures predicted treatment response based on functional MEP while adjusting for sex and BMI.

Results: We observed a significant improvement in all MEP outcomes with exercise at week 6 and week 12 with the improvements being sustained at week 18 (**Figure 2**). In our cohort, 63.2% of participants met our definition of responders based on functional MEP. None of the baseline measures were predictive of treatment response based on functional MEP.

Conclusion: Participants with symptomatic knee OA undergoing a 12-week exercise intervention demonstrated reductions in MEP, supporting the use of exercise as a core treatment for this population. Given the lack of a control group, it is possible that regression to the mean or other factors may have contributed to observed improvements in MEP. While minimal important change for functional MEP and exercise MEP is not known, the improvements in PainNA at week 12 were clinically meaningful. The lack of associations between baseline psychological factors as well as measures of nociceptive function suggests that exercise may be an effective intervention for MEP, irrespective of alterations in these measures in people with knee OA.

Therapeutic Efficacy of Intra Articular Injection of Human Bone Marrow Derived Mesenchymal Stem Cells in Knee Osteoarthritis; Randomized, Double-blind, Placebo-controlled Clinical Trial

Ji Won Yang, Bong-Woo Lee, Jennifer Lee and Ji Hyeon Ju, Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is severe and intractable musculoskeletal disease that eventually leads to joint failure and pain due to inflammation and joint injury. Mesenchymal stem cells (MSCs) are expected to repair damaged tissues due to their multipotency for differentiation and immunomodulatory properties. MSCs have been the promising treatment source for osteoarthritis. However, few studies reported about outcomes of an intra-articular (IA) injection of allogenic bone marrow derived MSCs (BM-MSCs). This study aimed to assess the efficacy and safety of a single IA injection of BM-MSCs for patients with knee OA.

Methods: We performed a randomized, double-blind, placebo-controlled study. Twenty-four knee OA patients were randomized to receive single IA injection of MSCs ($1x10^8$ cells/ 2 mL) or normal saline (2 mL). The change of patient reported outcome measures (PROMs) including the visual analogue scale (VAS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Knee Injury and Osteoarthritis Outcome Score (KOOS) after IA injection were assessed at serial 3, 6, 9, and 12 months from baseline. Furthermore, we performed imaging studies using magnetic resonance (MR) with T2 mapping sequences to analyze knee cartilage in all patients at baseline, 3 months, and 12 months.

Results: A total of twenty-three patients entered the final analysis, with eleven in MSCs treatment group and twelve in control group. Within group improvement of pain, measured by KOOS and WOMAC, when compared with baseline was statistically significant throughout all time points only in treatment group. Comparison between group differences revealed that treatment group had significantly more improvement of KOOS pain (23.9±18.3 vs 7.2±15.9, p=0.03) and WOMAC pain (-5.0±3.6 vs -0.1±5.5, p=0.02) at 9 months compared with control group. However, the superiority was not sustained until 12 months. In comparison of percentage change from baseline, total KOOS in treatment group had improved significantly compared with control group at 3 and 9 months. The analysis of knee cartilage using MR T2 mapping revealed that the treatment group exhibited a less sharply increase in mean T2 value compared to the control group. Specifically, the mean difference of T2 values between baseline and 12 months was found to be significantly different between treatment group and control group (2.7 ± 13.2 and 5.1 ± 12.8, respectively. p=0.009). Nine patients of treatment group experienced the acute knee pain and swelling relieved by medical treatment, but there were no serious adverse events in all patients.

Conclusion: An intra-articular injection of allogenic BM-MSCs provided satisfactory pain relief for patients with knee OA compared to control group at 9 months' follow-up. Also, comparison of T2 values from MR T2 mapping for cartilage between two groups showed that IA BM-MSCs could have a preventive effect of OA progression. Further studies with larger sample size, repetitive injections, and long-term MR follow-up are required.

Table 1. Difference between values in pain index of patient-reported outcome from the baseline to each follow-up visit.

Variables	Placebo (N=12)	MSCs-group (N=11)	p-value#

Association Between Knee Osteoarthritis Pain and Concomitant Drug Use: A Post-hoc Analysis of Two Phase 3 Clinical Trials

Claire Miller[1], Matthew Baker[2], Peter Alexandersen[3], Alejandro Mondragón[1], Ida Sofie Adrian[1], Morten Karsdal[4], Jeppe Andersen[5] and Asger Bihlet[1], [1]NBCD, Soeborg, Denmark, [2]Stanford University, Menlo Park, CA, [3]Sanos Clinics, Gandrup, Denmark, [4]Nordic Bioscience, Herlev, Denmark, [5]Sanos Group, Soeborg, Denmark

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1977–1995) Osteoarthritis – Clinical Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with knee osteoarthritis are often overweight and suffer from comorbidities, which are frequently treated pharmacologically. Our understanding of the potential disease-modifying and/or symptom-modifying effects of commonly used pharmacological treatments is scarce, but recent studies have indicated beneficial effects of metformin, antihistamines, and vitamin D. The objective of this analysis was to investigate the effects of commonly used medications on changes in structural outcomes and WOMAC pain over a two-year period.

Table: Concomitant use and associations with change in WOMAC pain/JSW over 2 year (adjusted for baseline variables)

	Treatment duration group, days	Mean ΔWOMAC pain (0-500 mm), mm (SE), *n*				Mean ΔJSW, mm (SE), *n*

Methods: This is a post-hoc analysis of two large phase III trials investigating oral salmon calcitonin in knee OA (NCT00486434 and NCT00704847). The main inclusion criteria included American College of Rheumatology (ACR) criteria for diagnosis of knee OA and at least 150 out of 500 mm Western Ontario and McMaster Universities Osteoarthritis (WOMAC) knee pain at baseline. Eligible participants for the current study had knee x-rays with joint space width (JSW) and WOMAC pain questionnaires completed at baseline and two-year follow-up. Reported use of concomitant medication was grouped according to 3rd level ATC codes, and the duration of use was divided into the following categories: 1) no use, 2) 1-49 days, 3) 50-299 days, or 4) more than 300 days. The effects of the 13 most used medications on change in WOMAC pain and change in JSW from baseline to two years was evaluated using ANCOVA analysis, adjusting for baseline variables of age, sex, body mass index (BMI), and WOMAC pain/JSW.

Results: A total of 2,206 participants were randomized in the trials. A reduction in target knee pain was associated with the use of metformin, with changes in the WOMAC pain score of -114, -72, -86, and -149 respectively for groups 1-4 (p=0.02), as well as ACE inhibitors, with changes in the WOMAC pain score of -111, -170, -104, and -136 respectively for groups 1-4 (p=0.001) (**Table**). Non-steroidal anti-inflammatory drug (NSAID) use was associated with a reduced improvement in pain over time (p=0.02). As previously reported, associations between the use of vitamin D, antihistamines, and thiazides with delayed structural progression were significant (p=0.002, p=0.03, and p=0.005, respectively). These findings, however, did not translate into a significant association with change in pain. Finally, paracetamol use was associated with a significant reduction in pain in the non-target knee (p=0.03).

Conclusion: Based on this exploratory analysis, commonly used medications in the OA knee population, such as metformin, NSAIDs, antihistamines, ACE inhibitors, vitamin D, and thiazides, may significantly impact structural and symptomatic changes over time. Further research is needed to substantiate the observed findings and to evaluate the underlying pathways that may mediate these associations.

Impact of Metabolic Syndrome on Ultrasonographic Findings and Quality of Life in Patients with Early Osteoarthritis

Maria Fernanda Gonzalez-Hernandez[1], Rolando Espinosa-Morales[2], Carlos Pineda[2], Angelica Peña[3], Araceli Bernal[1] and Alejandra Alabarda[1], [1]Instituto Nacional de Rehabilitación "Luis Guillermo Ibarra Ibarra", Mexico City, Mexico, [2]Instituto Nacional de Rehabilitacion, Mexico City, Mexico, [3]Instituto Mexicano del Seguro Social, Querétaro, Mexico

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a common disorder with increased incidence with age. Metabolic syndrome (MS) is frequently associated with OA, although other factors are considered the primary cause of the development of OA, such as: genetic, inflammatory, neuroendocrine, and mechanical stress. Conventional radiography (CR) is used to diagnose the changes of knee OA (KOA) (joint space, osteophytes, sclerosis); however early changes are difficult to assess, and few articles report these abnormalities. Previous research demonstrated a higher sensibility in ultrasonography (US) in detecting

early abnormalities compared to CR in early knee OA (eKOA). The objective of this study is to estimate the impact of metabolic syndrome in relation to prevalence of US findings and quality of life in patients with eKOA.

Methods: We included patients with eKOA diagnosis from out-patients clinical of rheumatology department, eKOA was describe as grade I and II by Kellgren and Lawrence scale. We evaluated for presence of metabolic syndrome based of ATP-III. Using a structured clinical questionnaire, we recorded epidemiologic data. Quality of life and joint functionality was evaluated with Lequesne index, EQ-5D and WOMAC. Patients were divided in two groups: eKOA with and without MS. An US was performed in each patient, structural changes in eKOA we evaluated was based in the OMERACT definitions. The structures evaluated include medial superior and lateral recess, anserine and infrapatellar bursitis, medial and lateral meniscus extrusion were scanned in each knee.

Statistical Analysis. Descriptive analysis of variables was done. In order to compare two variables, we used bivariate analysis, using t-student, Wilcoxon test, chi2

Results: We include 154 patients, female 132 patients (85.7%) vs. 22 men (14.3%). 51 (33%) patients with MS vs. 108 (67 %) without MS; of MS patients there were 9 (41%) men vs. 42 (59%) women (p=0.402). Median age of females was 47.03 ± 6.85 vs. 46 ± 7.43 in males (p=0.519). The patient with MS realized less physical activity compared with

Grade III	1 (1.96)	0 (0)	

Ultrasound findings on metabolic syndrome and OA patients

patients without MS. 78.2 % without MS vs. 21.8% (p=0.02). The patient with MS reported some comorbidities: Diabetes Mellitus 38.46%, hypertension 42.1%, hypothyroidism 7.69% and others 13.73% vs patients without MS: Diabetes Mellitus 10.71%, hypertension 17.86 %, dyslipidemia 7.14, venous insufficiency 46.43%, other 17.86 (p=0.003). We found statistical significance in the metabolic syndrome group finding synovitis in medial superior recess of the right knee (p =0.031) and Doppler activity in lateral recess of right knee (p=0.05), without significance in the presence of osteophytes. Quality of life and functionality we did not find statistical significance. (Table 1)

Conclusion: Patients with eKOA have a good QofL. The ultrasound could have an important role in eKOA to find risk factors of progression and phenotypes. There are increased prevalence of risk factors in MS patients.

How Is Paracetamol Prescribed in Low Back Pain and Osteoarthritis in France? Paracetamol Prescription Patterns in the Real-World General Practice

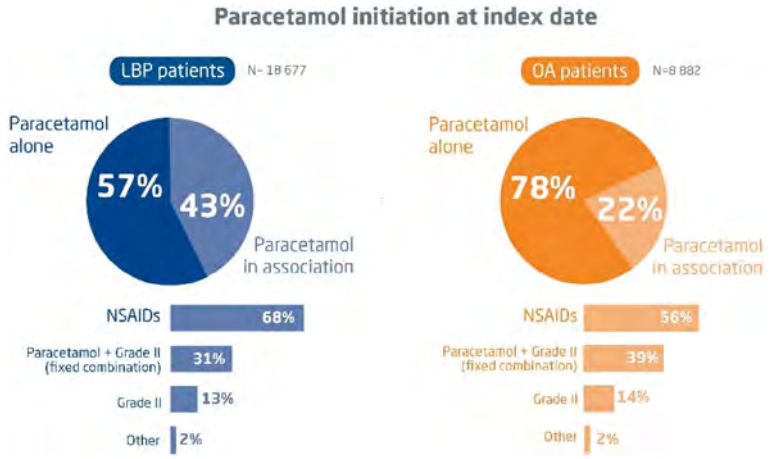
Jasque Cittée[1], Pierre Lemire[2], **Anna Annenkova**[3], Jean-Yves Milon[3] and Serge Perrot[4], [1]University Paris-Est Créteil Val de Marne Department of General Medicine, Paris, France, [2]IQVIA, Paris, France, [3]UPSA, Rueil-Malmaison, France, [4]Cochin Hospital, Université Paris Cité, INSERM U987, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lower back pain (LBP) and osteoarthritis (OA) are the most frequent musculoskeletal disorders in the general population significantly impacting patients' quality of life. An adequate pain management is key. General practitioners (GPs) are the front-line decision-makers in the French primary care system. In France, paracetamol remains a first-line analgesic in LBP and OA, according to the national guidelines. Few data on the real-world paracetamol prescriptions in LBP and OA are available.

Methods: This observational retrospective cohort study using the IQVIA electronic medical records database aimed to identify the paracetamol prescription patterns in patients with LBP and OA in real-world GP practice. Prescription data of approximately 1,200 GPs and27,559 patients were analyzed. Patients aged more than 18 years old with a registered diagnosis of LBP and OA and a paracetamol prescription during a GP consultation over a 10-month period were included in the analyses.

Results: A total of 18,677 LBP and 8,882 OA patients were included. In more than 90% of these patients, the paracetamol prescriptions were not preceded by any other analgesic for the same diagnosis within the previous month. Paracetamol was mainly prescribed alone (57% LBP, 78% OA). The most frequent associations were NSAIDs and grade II analgesics. Fewer NSAID prescriptions were observed in older patients and in patients with hypertension, heart failure and renal insufficiency in both LBP and OA. Treatment discontinuation at Month 1 was the most frequent event (67% LBP and 52% OA). In case of treatment restart, paracetamol was prescribed again in 57% LBP and 81% OA patients. At Month 3, 78% LBP and 71% OA patients discontinued treatment.



Paracetamol initiation at index date in patients with common low back pain and osteoarthritis

Conclusion: Paracetamol remains a pivotal analgesic prescribed first line in both LBP and OA from the time of initiation and during follow-up. It is the treatment of a given acute painful episode, with high proportion of treatment discontinuations after a short treatment duration. It is the analgesic of choice for recurrent pain and a satisfactory option for physicians in managing older patients and patients with comorbidities and risk factors.

Cross-cultural Adaptation, Reduction, and Validation of the Turkish Versions of the Flare-OA Questionnaire for Hip and Knee Osteoarthritis

Mehmet Tuncay Duruöz[1], Halise Hande Gezer[1], Jonathan Epstein[2], Marc Soudant[2] and Francis Guillemin[3], [1]Marmara University Medical School PMR Department, Rheumatology Division, Istanbul, Turkey, [2]Université de Lorraine, Epidémiologie clinique, Nancy, France, [3]Université de Lorraine, EA 4360 Apemac, Nancy, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1977–1995) Osteoarthritis – Clinical Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The Flare-OA is a recently developed self-reported questionnaire to assess the occurrence and severity of flares in knee and hip osteoarthritis (OA). It evaluates five aspects (pain, swelling, stiffness, consequences of symptoms, and psychological) of flare. This study aimed to translate and cross-culturally adapt the Flare-OA and its short forms using classical psychometric analysis methods in a Turkish population.

Methods: The French/English version of the questionnaire was cross-culturally adapted and translated into Turkish following an established forward–backward translation procedure. The Turkish version was checked by an expert committee for translation understandability, interpretation, and cultural relevance with ten patients (Face validity). Patients who were≥45 -years of age with clinical and radiological OA of the knee or hip, according to ACR criteria were included. The Flare OA scale consists of 33 items and has been reduced to 19 items by factor analysis and content approach. Further work with the Rasch analysis allowed to refine and shorten the questionnaire to a 16-item version with a satisfactory interval scale. The reliability of Flare-OA was assessed by internal consistency (Cronbach's alpha coefficient) and test-retest reliability at 15 days in patients without change. The sensitivity to change was assessed by standardized response mean (SRM) in those reporting change over the period. The convergent validity was assessed by the correlation of the Flare-OA with the Hip Disability and Osteoarthritis Outcome score (HOOS), Knee Injury and Osteoarthritis Outcome Score (KOOS), and the Mini Osteoarthritis Knee and Hip Quality of Life Questionnaire (Mini-OAKHQOL).

Results: A total of 185 (71.9% females) patients with a mean age of 63.2 (SD:9.1) years participated. One hundred-sixty (86.5%) of the patients had knee OA, 25(13.5%) had hip OA, and 70 (37.8%) had experienced worsening of the knee or hip OA during the last four weeks. The confirmatory factor analysis found the model with 19 items acceptable (RMSEA=0.08; SRMR=0.05; and CFI=0.95). Cronbach's alpha coefficient was 0.987 (95% CI:0.984-0.990) for 33-item,

Table. Pearson's correlation coefficients of the Flare-OA questionnaire with the other parameters for construct validity

Parameters	r	p	r	p	r	p
	33-item		19-item		16-item	
HOOS (0-100) (n=25)	0.69	0.565	0.68	0.603	0.67	0.646

The activity of daily living	-0.83	<.001	-0.83	<.001	-0.83	<.001
Other symptoms	-0.79	0.006	-0.78	0.01	-0.78	0.01
Pain KOOS	-0.83	<.001	-0.83	<.001	-0.83	<.001
Quality of life	-0.78	<.001	-0.78	<.001	-0.78	<.001
Sport and recreation	-0.69	<.001	-0.69	<.001	-0.70	<.001
Mini-OAKHQOL (0-100) (n=185)						
Mental health	-0.82	<.001	-0.81	<.001	-0.81	<.001
Pain OAKHQOL	-0.86	<.001	-0.87	<.001	-0.87	<.001
Physical activities	-0.84	<.001	-0.84	<.001	-0.85	<.001
Social functioning	-0.07	1	-0.07	1	-0.07	1
Social support	0.05	1	0.05	1	0.05	1

0.978 (95% CI:0.973-0.982) for 19-item, and 0.972 (95% CI:0.966-0.978) for 16-item. The intraclass correlation coefficient was 0.913 (95% CI:0.868-0.943), 0.915 (95% CI:0.870-0.944), and 0.912 (95% CI:0.866-0.943) in 79 patients for the test–retest reliability of the 33, 19, and 16 items, respectively. Sensitivity to change (n=89) was good in 9 patients with flare improvement [SRM 1.2 (95% CI:0.6–1.7), 1 (95% CI:0.5–1.4, and 1 (95% CI:0.5–1.5); 33, 19, and 16 items, respectively] over the period. The discriminant validity was evidenced by a significant score difference [36.2 (95% CI:29.9-42.6), 36.6 (95% CI:30.2-43.0), and 36.7 (95% CI:30.3-43.0)]for 33, 19, and 16 items, respectively between patients with and without flare. Pearson's correlation coefficients of the questionnaire with the other parameters for construct validity are represented in Table.

Conclusion: This study demonstrated that all the 33, 19, and 16-items Turkish versions of the Flare OA questionnaire are reliable and valid tools for assessing flaring in patients with knee and hip OA.

Variation in Dual-energy X-ray Absorptiometry Reporting: A National Survey of Veterans Health Administration Clinics

Karla Miller[1], Melissa Steffen[2], Kimberly McCoy[2], Michelle Mengeling[2], Heather Davila[2], Shylo Wardyn[2] and Samantha Solimeo[2], [1]University of Utah School of Medicine, Salt Lake City, UT, [2]Department of Veterans Affairs, Iowa City VA HCS, Iowa City, IA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1996–2018) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Dual-energy x-ray absorptiometry (DXA) is an important tool to identify Veterans with osteoporosis, assess fracture risk, and monitor treatment response. Variability in DXA acquisition, analysis, interpretation, and reporting is common despite existing best practice guidelines, and can adversely impact the information communicated to the ordering provider. The purpose of this quality improvement study was to evaluate the processes for national VA DXA reporting. This project was part of a larger evaluation to understand access to and quality of DXA services in the VA.

Methods: A work group of radiologists, nuclear medicine physicians, social scientists, endocrinologists, and rheumatologists were convened to develop a national bone densitometry survey. Through an iterative process, the group drafted domains, then identified topics and developed questions for each domain. The DXA reporting domain evaluated information typically included on DXA reports received by the ordering VA provider and time spent creating the reports. This study was reviewed by the Iowa City VA Research and Development Office. Survey invitations were emailed to personnel involved in DXA acquisition and interpretation at 178 facilities. Staff were given 60 days to complete the survey.

Results: Fifty-six of 178 sites (31%) completed information on data elements included in a standard DXA report. Most reports provided information on age (n=43,77%), DXA manufacturer and model (n=39,70%), and indication for DXA (n=37, 66%), while few routinely reported study limitations (n=28,50%), acquisition errors (n=22,39%), menopausal status (n=18,32%), and relevant medications (n=17,30%).DXA report elements used in clinical decision-making varied with most sites reporting T-scores at all measured sites (n=46,82%), impression (n=46,82%), bone mineral density (BMD) in g/cm2 (n=43,77%), and FRAX® (n=38,68%).Some sites reported Z-scores (n=34,61%), percent change in BMD on repeat DXA (n=31,55%), and least significant change (n=22,39%), while few reported trabecular bone score (n=11,20%), lowest T-score only (n=11,20%), and Osteoporosis Self-assessment Tool scores (n=9,16%).Few sites provided guiding recommendations beyond the DXA impression such as considering medications to reduce bone loss (n=7,13%), evaluation for

	Frequency	(%)

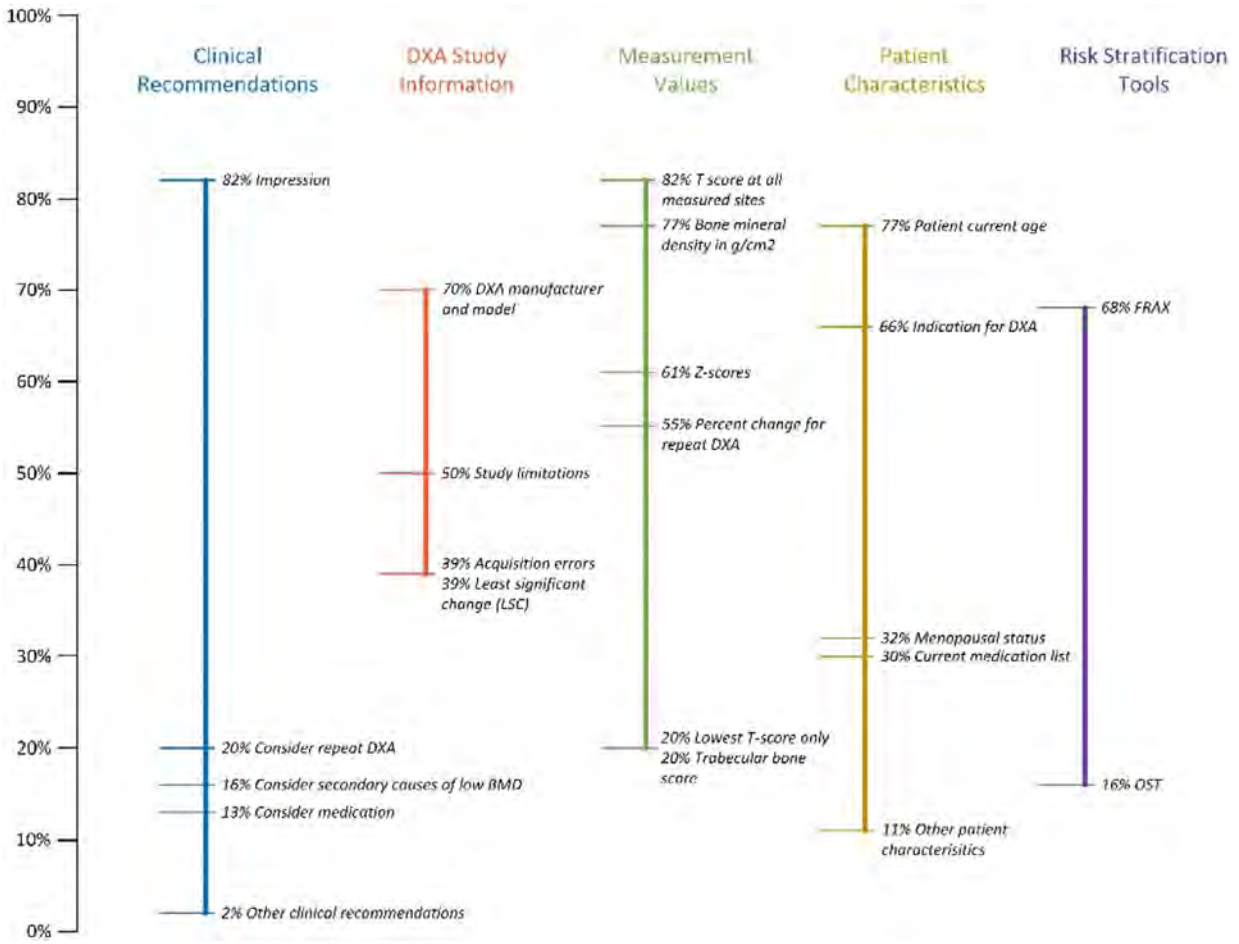
† Other patient characteristics include patient date of birth, height, weight, patient sex, patient ID, treatment medications, date of exam, and pertinent current and past medical history

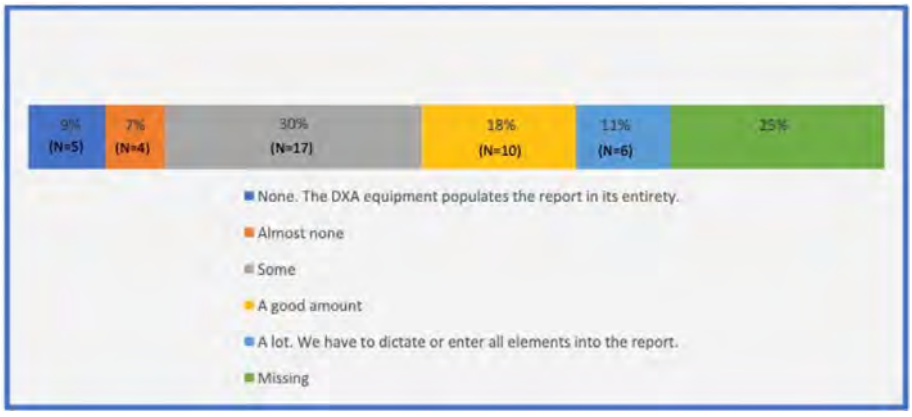
Information Routinely Included on DXA Reports (n=56)



Information Routinely Included on DXA Reports

secondary causes of osteoporosis (n=9,16%), or when to repeat DXA (n=11,20%).Nearly a third of sites (n=16,29%) indicated that DXA reports requires a "good amount" or "a lot" of time to prepare.

Conclusion: There is significant variability in the degree to which DXA facilities follow best practice standards for DXA reports, even in an integrated healthcare system. Most VA DXA reports include basic information for clinical decision-making, but many do not routinely provide elements important to interpretation of the report and clinical care guidance.



Perceived Effort Associated with Preparing a DXA Report

Many DXA sites report substantial effort is needed by diagnosticians to prepare DXA reports. This study uses self-reported data and is limited by number of respondents. Our results will be used to facilitate improvement in DXA reporting quality across radiology and specialty care services in the VA.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1996–2018) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: SB16 is a human monoclonal antibody to the receptor activator of nuclear factor κB ligand that has been developed as a proposed biosimilar to reference denosumab (brand name: Prolia, DEN hereafter). This Phase III study was a randomized double-blind study to compare efficacy, safety, pharmacokinetics (PK), pharmacodynamics (PD) and immunogenicity of SB16 with DEN in postmenopausal osteoporosis (PMO) patients (NCT04664959). Results up to Month 12 are presented here.

Methods: PMO patients were randomized in a 1:1 ratio to receive either 60 mg of SB16 or DEN subcutaneously at Month 0, Month 6, and Month 12. At Month 12, patients in DEN were re-randomized in a 1:1 ratio to switch to SB16 or maintain DEN. The primary endpoint was percent (%) change from baseline in lumbar spine bone mineral density (BMD) at Month 12. Equivalence between SB16 and DEN was declared if the 95% confidence interval (CI) of Least Squares Means (LSMeans) difference of % change in lumbar spine BMD at Month 12 was within the pre-defined equivalence margin. Other secondary efficacy, PD (serum C-telopeptide of type I collagen [CTX] and procollagen type I N-terminal propeptide [P1NP]), PK and safety endpoints were also measured.

Results: Among 457 patients, 225 patients were randomized to SB16 and 232 patients to DEN. Baseline characteristics were comparable between SB16 and DEN. The mean % change from baseline in lumbar spine BMD at Month 12 was5.6% and 5.3% in SB16 and DEN, respectively (Figure 1), and the difference in LSMeans % was 0.39, 95%CI [–0.36, 1.13] for the per-protocol set, and 0.33, 90%CI [–0.25, 0.91] for the full analysis set, both within the pre-defined equivalence margin. The mean % change from baseline in total hip BMD at Month 12 was 3.5% and 3.2% in SB16 and DEN, respectively. The mean % change from baseline in femoral neck BMD at Month 12 was 2.8% and 2.3% in SB16

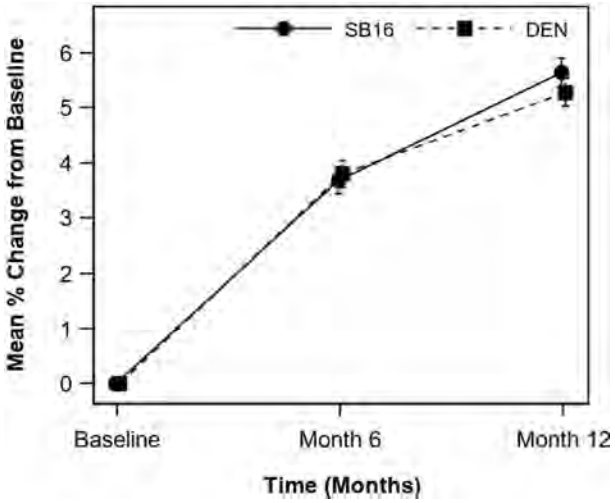

Figure 1. Mean Percent (%) Change from Baseline in Lumbar Spine BMD up to Month 12 (Full Analysis Set)

and DEN, respectively. The incidence and distribution of adverse events were comparable between SB16 and DEN up to Month 12. Serum CTX, P1NP and denosumab concentrations were comparable between SB16 and DEN up to Month 12. The median % change from baseline in serum CTX concentration over time was a decrease of at least 50% at all time points. Only 3 subjects (1 in SB16 and 2 in DEN) had non-neutralizing anti-drug antibodies.

Conclusion: This study demonstrated biosimilarity of SB16 to DEN through equivalent efficacy and comparable PD, PK, immunogenicity and safety up to Month 12.

How to Tailor Osteoporosis Therapies in Patients with Advanced Liver Disease? Variations of Renal Function by Creatinine and Cystatin C

Cristina Rodríguez-Alvear[1], Mª Carmen López-González[2], Elisabet Perea-Martínez[3], Antonio Avilés-Hernández[3], Eduardo Garín Cascales[3], Nuria Buendía Sánchez[3], Irene Calabuig-Sais[1], Pilar Bernabeu-Gonzálvez[3], Agustín Martínez-Sanchís[1], Joaquim Esteve-Vives[3], PALOMA VELA[4], Cayetano Miralles Maciá[3], Vega Jovani[5] and Mariano Andrés[1], [1]Dr Balmis Alicante General University Hospital-ISABIAL, Alicante, Spain, [2]General University Hospital Dr. Balmis, Alacante, Spain, [3]General University Hospital Dr. Balmis, Alicante, Spain, [4]Rheumatology, Hospital General Universitario Alicante, Alicante, Spain, [5]Department of Rheumatology, Hospital General Universitario Dr. Balmis, Alicante, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: (1996–2018) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rapid bone loss and increased fractures have been described after liver transplantation. Bisphosphonates are restricted in patients with significant kidney disease, as the drugs are excreted by the urine. Evaluating renal function in patients with advanced liver cirrhosis can be challenging and underestimated by standard methods, and this issue may impact the choice of the anti-osteoporosis (OP) agent.

This study analyses variations in renal function across different glomerular filtration rate (GFR) equations in patients with advanced liver disease included in a pre-transplantation assessment to tailor the use of anti-OP agents.

Methods: A descriptive cross-sectional study of patients from a tertiary center selected for a assessment before liver transplantation from February 2019 to December 2022. Sex, age, ethnicity, and serum creatinine and cystatin C (a more sensitive marker than creatinine for estimating GFR in patients with cirrhosis) levels are collected. The indication for anti-OP treatment is established in the presence of T< -1.0 by densitometry (DXA), vertebral radiographic wedging, or a history of a fragility fracture. GFR adjusted by creatinine, cystatin C, and creatinine-cystatin C was calculated using the online calculation tool MediCalc. Results are later categorized as below or above 30ml/min^2 (usual cut-off to contraindicate the use of bisphosphonates), finally comparing the rate of patients with GFR < 30 ml/min across three methods. A descriptive study is presented. Comparisons of variables are performed by Fisher's exact test, and P-values of < 0.05 are considered statistically significant.

Results: A total of 162 patients (75.9% men) were included, all Caucasian, with a mean age of 60 years (SD 7.6) and a mean BMI of 27.9 (SD 4.9). Seventy-six percent (n=120) were candidates for anti-OP therapy, and 68.5% (n=111) ultimately received it (88% bisphosphonates, 11% denosumab, and 1% teriparatide). Three percent (n=5) presented a fragility fracture, and 9.5% (n=17) showed a radiographic vertebral fracture. Fifty-one percent (n=80) had osteopenia, and 22.9% (n=36) had osteoporosis at DXA scans. Regarding renal function, mean serum creatinine and cystatin C levels were 0.99 mg/dl (SD 1) and 1.7 mg/L (SD 1), respectively. The mean estimated GFR levels using creatinine, cystatin C and creatinine-cystatin were 87 ml/min (SD 24.8), 49.3 (SD 23.4), and 63.9 (SD 23.3), respectively. The percentage of patients with GFR < 30ml/min was 1.9% if measured by creatinine, 20.5% by cystatin, and 5.6% by creatinine-cystatin (figure 1). Differences between rates were statistically significant. In this sense, anti-OP therapy was tailored accordingly in 12 patients (10.9%) with treatment indication, using denosumab instead of bisphosphonates.

Conclusion: In a setting of advanced liver disease eligible for transplantation, renal function estimates significantly varied depending on the GFR equation used, thus largely modifying the rates of patients with a contraindication for using bisphosphonates, despite the high fracture risk. Further studies are necessary to establish the best method to assess renal function in advanced liver disease patients to tailor anti-OP strategies.

Abstract Number: 1999

One-year Incidence of Clinical Fragility Fractures After Implementing an Osteoporosis Care Protocol in Patients Eligible for Liver Transplantation

Cristina Rodríguez-Alvear[1], Mª Carmen López-González[2], Elisabet Perea-Martínez[3], Antonio Avilés-Hernández[3], Irene Calabuig-Sais[1], Maria-Luisa Peral-Garrido[4], Pilar Bernabeu-Gonzálvez[3], Agustín Martínez-Sanchís[1], Joaquim Esteve-Vives[3], PALOMA VELA[5], Cayetano Miralles Maciá[3], Vega Jovani[6] and Mariano Andrés[1], [1]Dr Balmis Alicante General University Hospital-ISABIAL, Alicante, Spain, [2]General University Hospital Dr. Balmis, Alacante, Spain, [3]General University Hospital Dr. Balmis, Alicante, Spain, [4]Vinalopó University Hospital, Novelda, Spain, [5]Rheumatology, Hospital General Universitario Alicante, Alicante, Spain, [6]Department of Rheumatology, Hospital General Universitario Dr. Balmis, Alicante, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: (1996–2018) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In solid organ transplantation, liver transplants are among those most frequently associated with the development of low bone mass, which occurs in up to 85% of patients. The estimated incidence of fractures in the post-transplant period, especially in the first six months, ranges from 17% to 65%. However, this can drop to as low as 3.5% after establishing a fracture prevention protocol. In 2019, our center developed an action plan for preventing osteoporotic fractures in the post-transplant period. In a previous report, we observed that 77.3% of liver transplant recipients were candidates to start anti-osteoporosis treatment at the baseline evaluation.

The aim is to estimate the incidence of clinical fragility fractures in patients included in the pre-liver transplant study one year after the baseline evaluation of their bone health.

Methods: In this prospective cohort study, the incidence of clinical fragility fractures was analyzed one year after a multidisciplinary pre-liver transplant assessment in a tertiary academic center in Spain. The study included patients who underwent an initial study from February 2019 to December 2021, underwent liver transplantation and had complete follow-up at one

Table 1. Characteristics of patients with clinical fragility fractures in the year following liver transplant

		Patient			
Characteristics		**1**	**2**	**3**	**4**
Type of fracture		L2 vertebra	L1 vertebra	Hip	Distal radius
Time (months) between transplant and fracture		7	6	9	11
Sex		Male	Male	Male	Male
Age (years) at baseline		63	66	62	61
Bone densitometry at baseline	*Femoral neck*	−2.6	−0.8	−1.3	−1.2
	Total hip	−2.7	−1.2	−0.8	−0.9
	Lumbar spine	−4.5	−1.8	0.3	−2.8
Previous fracture		—	—	—	T12, L2
Treatment received		Zoledronate	—	Zoledronate	Zoledronate

year. The indication for anti-osteoporotic treatment at baseline was defined as bone densitometry with a T SCORE value of less than –1, vertebral wedging assessed by X-ray, or fragility fracture. During the annual follow-up visits, patients were examined for clinical fragility fracture. This descriptive study shows the cumulative incidence at one year and its 95% confidence interval (CI).

Results: Of the 162 patients who underwent the initial evaluation, 79 (48.8%) received a liver transplant and had a full follow-up at one year. Three-quarters of the sample were men, with a mean age of 60 years (standard deviation [SD] 7.5) and a mean body mass index (BMI) of 28.24 kg/m^2 (SD 4.35). Most (73.4%) were smokers, and 67% were moderate or heavy drinkers. At baseline, 2.5% (n=2) presented a fragility fracture, and 7.6% (n=6) a vertebral fracture as assessed by X-ray. Half (50.6%, n=40) presented osteopenia, and 21.5% (n=17) osteoporosis. Anti-osteoporosis therapy was indicated in 74.7% (n=59) and administered in 69.7% (n=55), consisting of bisphosphonates (92.7%) or denosumab (7.3%). Of the total liver transplant recipients with follow-up at one year, 4 experienced a clinical fracture (cumulative incidence 5%, 95% CI 1.9-12.3%; Table 1).

Conclusion: After establishing a protocol for preventing fractures in patients who are candidates for liver transplantation, the rate of post-transplant fractures was lower than in the historical series and comparable to another series with pre-transplant care.

Efficacy of Romosozumab for Glucocorticoid-induced Osteoporosis in Patients with Rheumatic Diseases; A Prospective Study

Mai Kawazoe[1], Kaichi Kaneko[2], Shotaro Masuoka[3], Soichi yamada[3], Zento Yamada[3], Sei Muraoka[3], Karin Furukawa[1], Hiroshi Sato[3], Eri Watanabe[3], Keiko Koshiba[3], Izumi Irita[3], Miwa Kanaji[3] and Toshihiro Nanki[1], [1]Division of Rheumatology, Department of Internal Medicine, Toho University School of Medicine, Ota-ku, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Toho University Sakura Medical Center, Sakura, Japan, [3]Division of Rheumatology, Department of Internal Medicine, Toho University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: (1996–2018) Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids are widely used to treat a variety of diseases, including rheumatic diseases. Although glucocorticoids improve the outcome for these diseases, various side effects of long-term treatment, such as osteoporosis, have become an important problem. Although the effects of glucocorticoids on bone metabolism remain unclear, Wnt signaling is now known to be involved in bone formation and resorption. We previously found that glucocorticoid therapy caused increase serum sclerostin, which inhibits Wnt signaling, and decrease Wnt3a, suggesting that suppression of Wnt/β-catenin signaling pathway might contribute glucocorticoid-induced osteoporosis (GIO). Therefore, inhibition of sclerostin could be a treatment for GIO. Romosozumab (ROMO) is a monoclonal antibody against sclerostin. Efficacy of ROMO in patients with postmenopausal osteoporosis and men with osteoporosis has been demonstrated in clinical trials. However, the effectiveness of ROMO in GIO is not clear. The purpose of this study was to evaluate the efficacy of ROMO compared to existing therapy by measuring bone mineral density (BMD) in patients recently initiated on glucocorticoid therapy.

Methods: This is a randomized, prospective, interventional study. Patients with rheumatic diseases who had not previously received osteoporosis treatment and were newly treated with prednisolone (PSL) 15 mg/day or more were randomly assigned to receive either ROMO, denosumab (DMAb), or bisphosphonate (BP). They were stratified at randomization according to age, sex, dose of PSL and T-scores of the lumbar spine or femoral neck. We measured BMD of the lumbar spine (L2-L4) and femoral neck at 0, 6, 12 months and serum bone turnover markers at 0, 3, 6, 9 and 12 months after initiation of glucocorticoid therapy.

Results: Ten patients were assigned to the ROMO group, 14 to the DMAb group, and 14 to the BP group. Base line data were shown in Table 1. The mean percent change of lumbar spine BMD from baseline at 12 months was greatest for the ROMO group among the three groups (ROMO; 5.7 ± 9.8%, DMAb; 5.2 ± 6.0%, BP; 0.5 ± 5.1%) (Figure 1). The mean change of femoral neck BMD at 12 months was greatest for the DMAb group (ROMO; -2.2 ± 6.0%, DMAb; 2.1 ± 3.7%, BP; -2.9 ± 5.8%). Serum bone alkaline phosphatase (BAP) level, a marker of bone formation, slightly increased in the ROMO group, but decreased in the DMAb group (Figure 2). Serum N-terminal propeptide of type I procollagen (P1NP) and osteocalcin (OC), other bone formation markers, decreased in all three groups, but the change was smaller in the ROMO group. Serum bone resorption markers, N-telopeptide crosslinked of type I collagen (NTX) and tartrate-resistant acid phosphatase isoform 5b (TRACP-5b) decreased in all groups. Urine pentosidine, bone matrix-related marker, decreased in all groups.

Conclusion: Even under treatment with PSL, patients treated with ROMO had increased lumbar spine BMD, but not femoral neck BMD, compared to patients receiving existing osteoporosis treatment with DMAb or BP. This is the first study to analyze the effect of ROMO on GIO, but further validation in a large number of cases is needed.

Table 1. Demographics and clinical data at baseline of the study population

	ROMO group (n=10)	DMAb group (n=14)	BP group (n=14)

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Metabolic bone disease (MBD), including osteopenia and osteoporosis, is common in patients with inflammatory disorders, due to disease factors and glucocorticoid (GC) use, and in those with chronic pancreatitis, due to exocrine pancreatic insufficiency (EPI). IgG4-related disease (IgG4-RD) is a systemic immune-mediated disease that commonly causes autoimmune pancreatitis (AIP) and resultant EPI. We aimed to evaluate the screening frequency and prevalence of MBD in a large single-center cohort of patients with IgG4-RD, comparing those with and without AIP.

Methods: We retrospectively assessed for the presence of MBD and associated risk factors and treatments in all patients who met ACR/EULAR Classification Criteria for IgG4-RD in our cohort using two parallel study designs. First, we conducted a chart review and extracted details on risk factors, screening frequencies, prevalence, and treatment of MBD. We limited the chart review to patients who have close follow-up in our system, defined as 1) primary care provider (PCP) in the system with ≥ 1 visit with the PCP in the previous year; or 2) ≥ 2 years of follow-up, ≥ 3 total visits in our system in the last year, and ≥ 1 visit with a non-rheumatology provider in our system in the last year. Second, we sent surveys to all living subjects in our cohort with up-to-date contact information and collected patient-reported data on MBD prevalence, risk factors, screening, and treatment. Unpaired T tests and Chi-square tests were used to compare continuous and categorical variables, respectively, between patients with and without AIP.

Results: 70 subjects (n=17 with AIP and n=53 without) met inclusion criteria for the chart review. Demographics and data on MBD, extracted from chart review, are summarized in **Table 1**. Subjects with AIP had a significantly lower mean BMI than those without. Otherwise, risk factors and MBD characteristics were similar between the two groups. Mean age was 66 years. Dual-energy X-ray absorptiometry (DXA) scans were performed in 24 (34%), and 21 subjects (30%) met World Health Organization criteria for osteoporosis or osteopenia.

Of 278 patient surveys distributed, 117 (42%) were completed (49 with AIP and 68 without). In the patient-reported data, weight was significantly lower in subjects with AIP, but other demographics and MBD risk factors were similar (**Table 2**). 73 subjects (62%) reported ≥ 3 months of cumulative GC exposure, yet only 44 (38%) had a DXA recorded. Moreover, 20 subjects (17%) reported receiving a diagnosis of MBD requiring pharmacologic intervention, yet 10 (9%) reported taking medication for MBD.

Conclusion: MBD and associated risk factors are common in patients with IgG4-RD. Although our study was underpowered to detect between-group differences, patients with AIP had lower weight and BMI than those without, emphasizing that this population may be at higher risk for MBD due to EPI. Despite high rates of MBD risk factors, DXA screening frequency

Cost-Effectiveness Analysis of Sequential Treatment with Abaloparatide Followed by Alendronate in US Women and Men with Multiple Previous Fractures

Mickael Hiligsmann[1], **Stuart Silverman**[2], Andrea J Singer[3], Yamei Wang[4], Leny Pearman[4], John Caminis[4] and Jean-Yves Reginster[5], [1]Maastricht University, Maastricht, Netherlands, [2]Cedars-Sinai Medical Center and UCLA School of Medicine, Los Angeles, CA, [3]MedStar Georgetown University Hospital, Washington, DC, [4]Radius Health, Inc., Boston, MA, [5]University of Liège, Liège, Belgium

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with multiple previous fractures are at very high risk of subsequent fractures. Common treatment strategies for these patients include generic alendronate (ALN) monotherapy or sequential therapy with an anabolic agent first (such as abaloparatide [ABL] or teriparatide [TPTD]) followed by generic ALN. Due to mounting pressure on healthcare systems, cost-effectiveness analyses are increasingly important to support decision makers in efficient healthcare resource allocation. This study was designed to evaluate the cost-effectiveness of sequential treatment with ABL followed by ALN compared to relevant alternative strategies in women and men with two previous fractures in the United States (US).

Methods: A lifetime microsimulation model estimated the US healthcare costs (in 2022 dollars) and quality-adjusted life years (QALYs) associated with sequential ABL/ALN and three relevant comparators: (1) a similar sequence beginning with unbranded TPTD; (2) generic ALN monotherapy; and (3) no treatment, which must be included as a comparator as many patients at very high fracture risk do not receive an osteoporosis medication. The analyses were conducted in men and women aged 50 to 90 years with two previous fractures and densitometric osteoporosis (bone mineral density T-score ≤–2.5). Sequential ABL/ALN is considered dominant if it is associated with more QALYs for lower costs than the comparator strategy, and is cost-effective if the cost per QALY gained falls below the US cost-effectiveness threshold of $150,000 per QALY gained. Various scenarios and sensitivity analyses were conducted to investigate uncertainty, including analyses on gender, age (50-90 years), and site of previous fractures.

Results: In both US women and men aged 50-90 years, sequential ABL/ALN was dominant compared to sequential unbranded TPTD/ALN. The costs per QALY gained of sequential ABL/ALN compared to no treatment were below the cost-effectiveness threshold in men aged ≥50 years with two previous fractures, in women aged ≥55 years with two previous fractures, and those aged ≥50 years with history of hip or vertebral fracture. When compared to ALN monotherapy, the costs per QALY gained of sequential ABL/ALN were estimated at $82,288 and $111,584 in men and women aged 70 years with two previous fractures, respectively. These numbers decreased to $35,283 and $66,707 with history of hip fracture. Sequential ABL/ALN was further cost-effective in men ≥50 years with two previous fractures, in women ≥55 years with two previous fractures including a hip or vertebral fracture, and in women ≥65 years for other types of fractures.

Conclusion: Sequential ABL/ALN is dominant in all analyses completed compared to unbranded TPTD/ALN and is cost-effective compared to generic ALN monotherapy in men aged ≥50 years, in women aged ≥55 years with history of hip or vertebral fracture, and in women aged ≥65 years with other fracture types.

Abstract Number: 2003

Effects of Abaloparatide on Cortical and Trabecular Compartments by 3D-DXA in Men with Osteoporosis

Ruban Dhaliwal[1], John Boxberger[2], Yamei Wang[2], Bruce Mitlak[2], Ludovic Humbert[3] and Neil Binkley[4], [1]Massachusetts General Hospital, Boston, MA, [2]Radius Health, Inc., Boston, MA, [3]3D-Shaper Medical, Barcelona, Spain, [4]University of Wisconsin Osteoporosis Clinical Research Program, Madison, WI

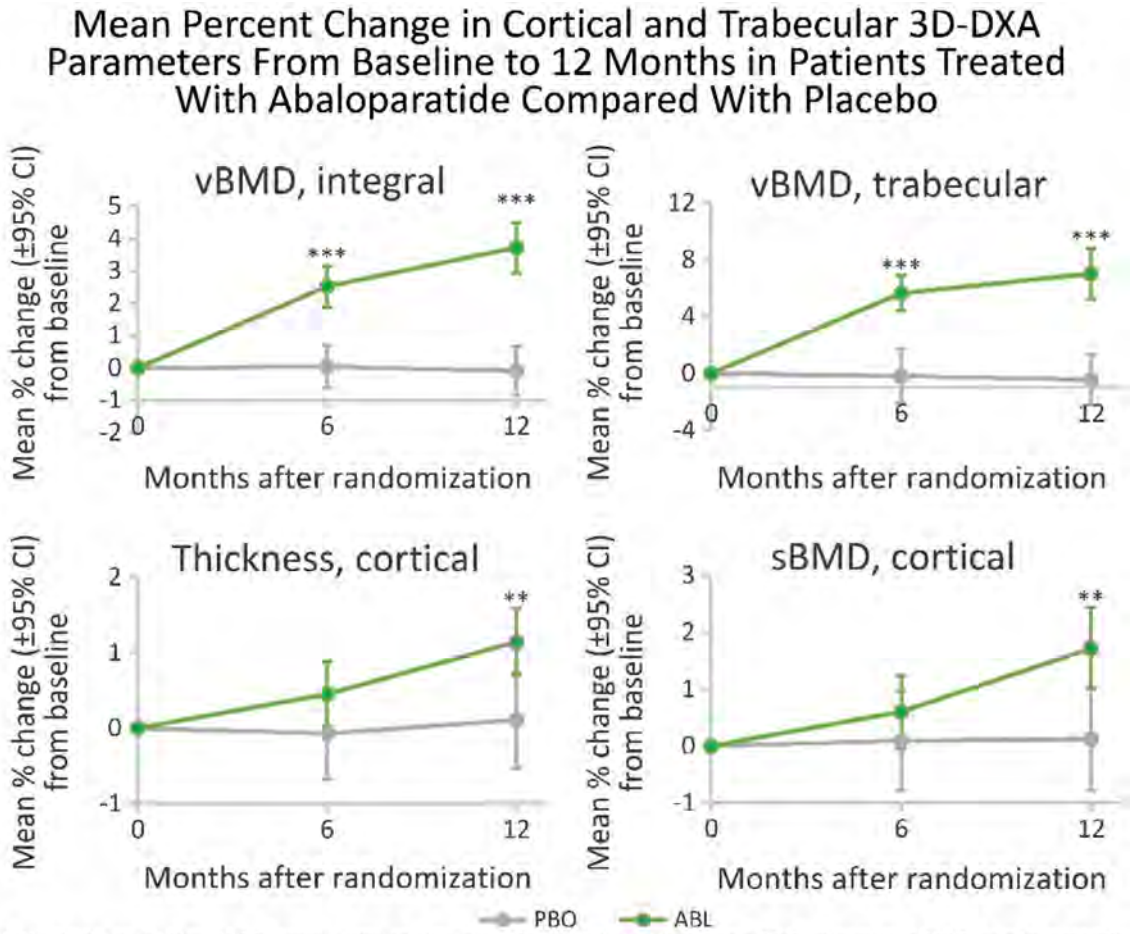
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Abaloparatide (ABL) increases BMD in men with osteoporosis. In the Abaloparatide for the Treatment of Men with Osteoporosis (ATOM) trial, DXA-measured BMD change with ABL 80 μg/day was greater than placebo (PBO) at the lumbar spine, total hip, and femoral neck. The purpose of this study was to evaluate the effects of ABL on cortical and trabecular compartments of the proximal femur in men with osteoporosis using 3D-DXA modeling.

Methods: Blinded hip DXA images from all randomized men in the ATOM trial (n=149 ABL; n=79 PBO) were retrospectively analyzed by 3D-DXA (3D-Shaper software v2.12.0, 3D-Shaper Medical) to evaluate changes from baseline at months 6 and 12 at the total hip. The ATOM trial included men with T-scores ≤–2.5 at the lumbar spine or hip. Men with T-scores ≤–1.5 with a history of radiologic vertebral fracture or low trauma nonvertebral fracture in the past 5 years or ≤–2.0 if >65 years of age were also eligible. Comparisons from baseline were made using paired *t* tests. Between-group comparisons were made for percent change from baseline data based on a mixed-effect repeated-measure model with treatment, visit, treatment-by-visit interaction and DXA scanner as fixed effects. Other covariates include BMI, age, and value at baseline.

Results: At 12 months, significant within group increases from baseline ($P < 0.0001$) in integral volumetric BMD (vBMD) (3.7%), trabecular vBMD (7.0%), cortical thickness (1.1%), and cortical surface BMD (sBMD; 1.7%) were observed with ABL. Mean percent change from baseline was greater for ABL compared to PBO ($P < 0.01$) for all 4 variables (integral vBMD, trabecular vBMD, cortical thickness, cortical sBMD) at 12 months (**Figure**).Greater increases ($P < 0.0001$) were also observed at 6 months between ABL and placebo for integral vBMD (2.5% vs 0.04%) and trabecular vBMD (5.7% vs –0.2%).

Conclusion: In men with osteoporosis in ATOM, 6 months of ABL improved trabecular 3D-DXA parameters at the total hip; 12 months of treatment improved cortical and trabecular 3D-DXA parameters at the total hip. These results are broadly consistent with those in postmenopausal women in the ACTIVE study.



ABL, abaloparatide; BMD, bone mineral density; CI, confidence interval; PBO, placebo; sBMD, surface BMD; vBMD, volumetric BMD.

Abstract Number: 2004

Bone Health Following Bariatric Surgery: A Single Center Quality Improvement Study

Andrew Benck, Haley Zimmerman, Amy Trang, Najia Shakoor and Sonali Khandelwal, Rush University, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis related fractures cause significant morbidity and mortality. Bariatric weight loss surgery is an independent risk factor for osteoporosis. Post-surgery dual energy X-Ray absorptiometry (DEXA) scans as well as close monitoring for calcium and vitamin D are suggested by current Bariatric surgery guidelines. This retrospective study

Table 1

Mean Age + STD	39.41+/- 6 years

Mean Calcium Level Post-surgery	9.22 ng/mL +/- 0.48

of bariatric surgery patients was conducted to determine if current guidelines for osteoporosis screening are being adhered to. In addition, educational seminars were provided to increase bone health education to bariatric surgery providers and patients.

Methods: This was a single-center, retrospective study of patients who had bariatric surgery from 2018 through 2020. Qualifying surgeries were Roux-en-Y gastric bypass, sleeve gastrectomy, Lap band and biliopancreatic diversion with duodenal switch. Patients aged 18-49 were included. Excluded were patients with any history of steroid use, autoimmune disease, primary hyperparathyroidism and malabsorption disorders or those already being treated for bone loss. Demographics, type of surgery, pre and post-surgical vitamin D calcium levels and BMI were collected. Descriptive statistics and paired samples t-tests were used for comparisons. Two educational interventions were completed after the results of the retrospective data. One included an educational lecture on bone health guidelines for this population delivered to bariatric surgeons. Another lecture was directed towards patients who were planning or had completed surgery. Pre and post educational surveys were delivered.

Results: 348 charts were reviewed. Demographic data and results are in Table 1. Calcium levels statistically decreased post-surgically while vitamin D levels increased . The decrease in calcium was most pronounced with Roux-en-Y gastric bypass as compared to sleeve gastrectomy 9.13 ng/ml vs. 9.27 ng/ml ($P< 0.01$). Only one patient in the study period had a post-surgical DEXA scan which revealed low bone mineral density for chronological age (Z score -2.7). Surveys following educational intervention revealed very positive results using Likert scale (Image1 and 2) but did not increase DEXA scans in the study period.

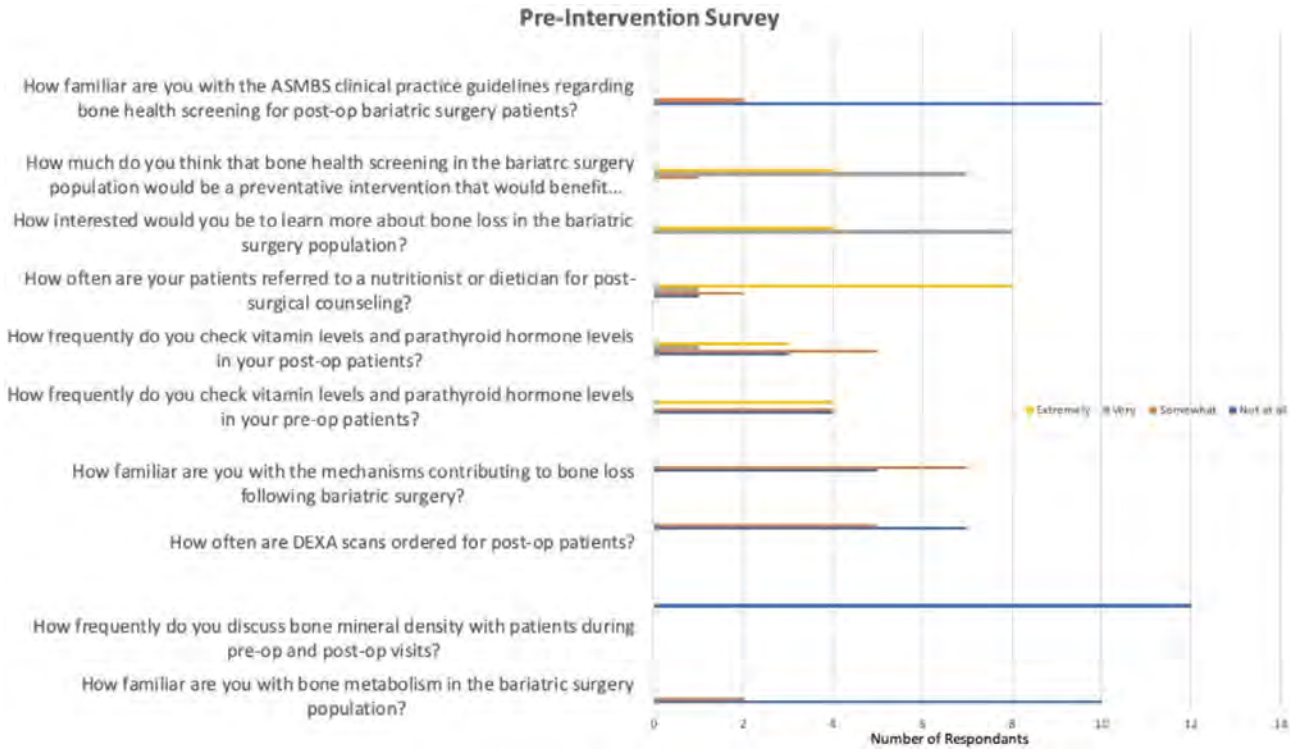

Image 1- Pre-education Survey Results

Conclusion: Screening with DEXA scans after bariatric surgery is not being done based on this brief retrospective study. This may be due to poor follow-up after surgery or the short study period following the interventions. Continued educational interventions may be successful if expanded to target primary care providers in addition to bariatric surgeons given the poor rate of patient follow-up. Our educational interventions were positively surveyed. Moreover this study found, post-surgically,

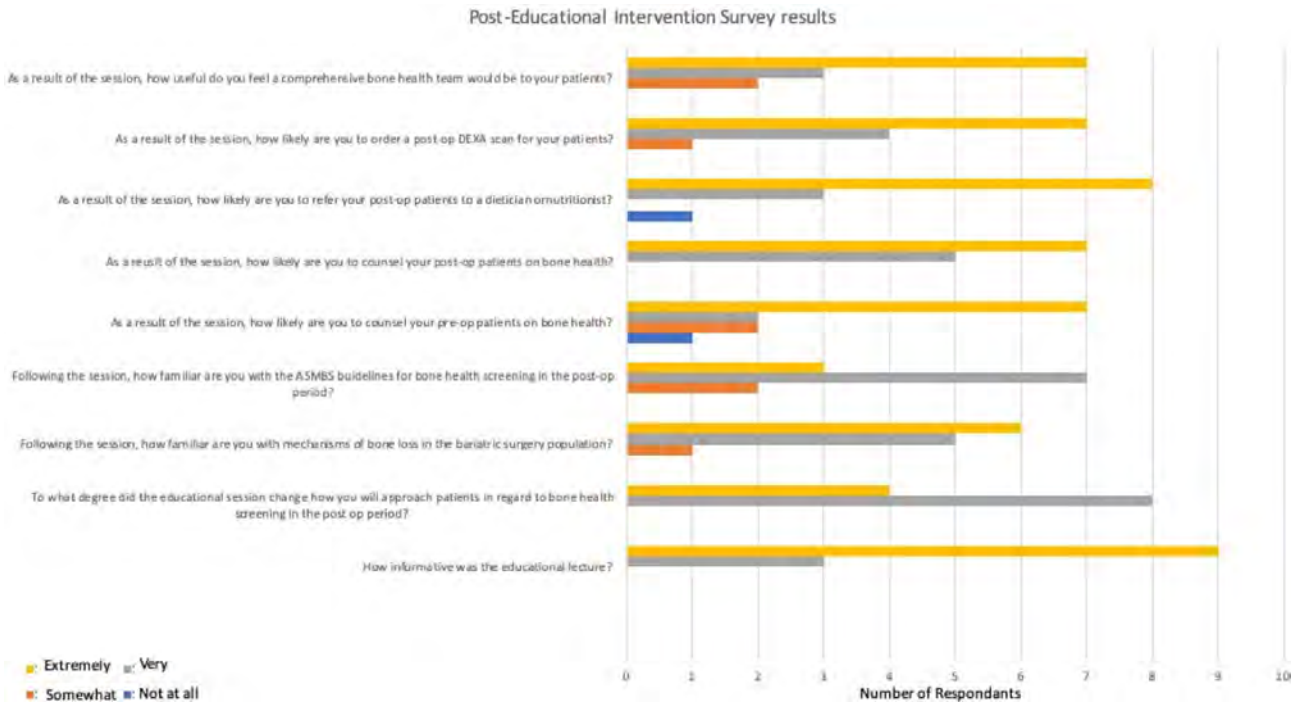

Image 2- Post-education Survey Results

calcium levels decreased and vitamin D level increased. In addition, calcium levels decreased more with Roux-en-Y gastric bypass. The inverse relationship of Vitamin D with weight loss has been reported elsewhere presumed to be related to redistribution of adipose stored vitamin D. These findings raise another potential area for modification of practice. Perhaps in addition to guided Vitamin D management and supplementation more dedicated calcium supplementation management should also be considered for these patients.

Secondary Prevention of Osteoporosis in Hip Fracture Care for Elderly Patients. Clinical and Functional Profile of Users

Belén Miguel Ibáñez, Alfonso González Ramírez, Olga Martínez González, Ana Isabel Turrión Nieves, Marta Ibáñez Martínez, Carolina Cristina Chacón Vélez, Laura Blanco Ramis, Manuel Cipriano Martín Martínez, Cristina Hidalgo Calleja, Carlos Alberto Montilla Morales, Susana Gómez Castro, Juan Francisco Blanco Blanco and Carmen Pablos Hernández, University Healthcare Complex of Salamanca, Salamanca, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is a first-rate problem in an increasingly ageing population. Falls among the elderly are a severe geriatric syndrome with relevant secondary effects. Fractures associated with both entities among the elderly are a cause of high costs and high morbidity and mortality rates. An adequate treatment of osteoporosis and fall prevention are essential factors to safeguard their well-being. The objective of this study is to analyze the clinical characteristics and circumstances of hip fractures, as well as previous fractures and anti-osteoporotic treatments in 239 elderly patients who were admitted with hip fractures in the year 2022 in the Department of Geriatric Care and Traumatology.

Methods: A descriptive, retrospective, observational and longitudinal study was conducted by analyzing the geriatric indexes, and demographic and clinical characteristics of 239 patients aged 66-99 years old who presented with low-impact hip fracture in 2022. The data analysis was carried out with SPSS.

Results: The average age of the patients was 86.79 years, with a range of 66-99 years and a predominance of women (180). During admission, a comprehensive geriatric evaluation of the situation prior to the fracture was completed. At a functional level (Table 1), the Barthel Index revealed that 182 patients had slight dependency in their daily life activities. Regarding their instrumental activities, 55 patients showed a score ≥5 out of 8. After their hip fracture, 229 patients received physical therapy in hospital and 108 patients required social interventions for their subsequent recovery. All the hip fractures were the consequence of low-impact trauma. 168 patients had suffered falls over the last year. However, according to the Downton scale, all of them (239) presented at least one risk factor for falls. These factors are detailed in Table 2. Prior to their hip fracture, 110 patients had suffered a previous low-impact fracture. The most common location was the lower limbs (46). Table 2 shows the different types of fractures. More than one previous fracture was found in 14 cases. None of the patients with previous fractures were being monitored by the Rheumatology Department. Only 22 out of the 110 patients with previous fractures were receiving or had received antiresorptive or bone-forming therapy with bisphosphonates (16), denosumab (3), denosumab after bisphosphonates (2) or teriparatide after bisphosphonates (1). All the patients received anti-

osteoporotic treatment as secondary prevention upon discharge, together with denosumab (165), bisphosphonates (66) or teriparatide (8), after ruling out the scenarios included in Table 1 which could advise against their use.

Conclusion: Osteoporosis is an underdiagnosed and undertreated condition. Previous fractures often go untreated, which leads to new fractures that compromise the patients' independence and quality of life. Hip fractures show the highest rates of morbidity and mortality. Falls play a major role in fractures among the elderly population. Their primary prevention and an adequate osteoporotic treatment must be a priority in elderly care.

Improvement of Care: Osteoporosis Screening in a Resident-led Primary Care Clinic

Massiel Jimenez Artiles[1], Roshan Subedi[2], Qi Wang[3], Bishara Jahshan[4], Khalid Gadir[4] and Waleed Quwatli[5], [1]Unity Hospital, Rochester Regional Health, Greece, NY, [2]Rochester Regional Health/Unity Hospital, Greece, NY, [3]Rochester Regional Health/Unity Hospital, Rochester, NY, [4]Unity Hospital, Rochester Regional Health, Rochester, NY, [5]Unity Hospital/ Rochester Regional Health, Rochester, NM

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

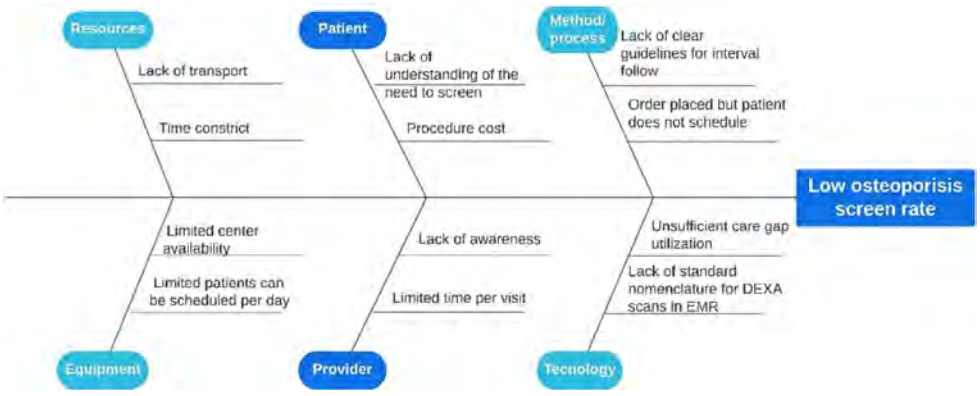
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

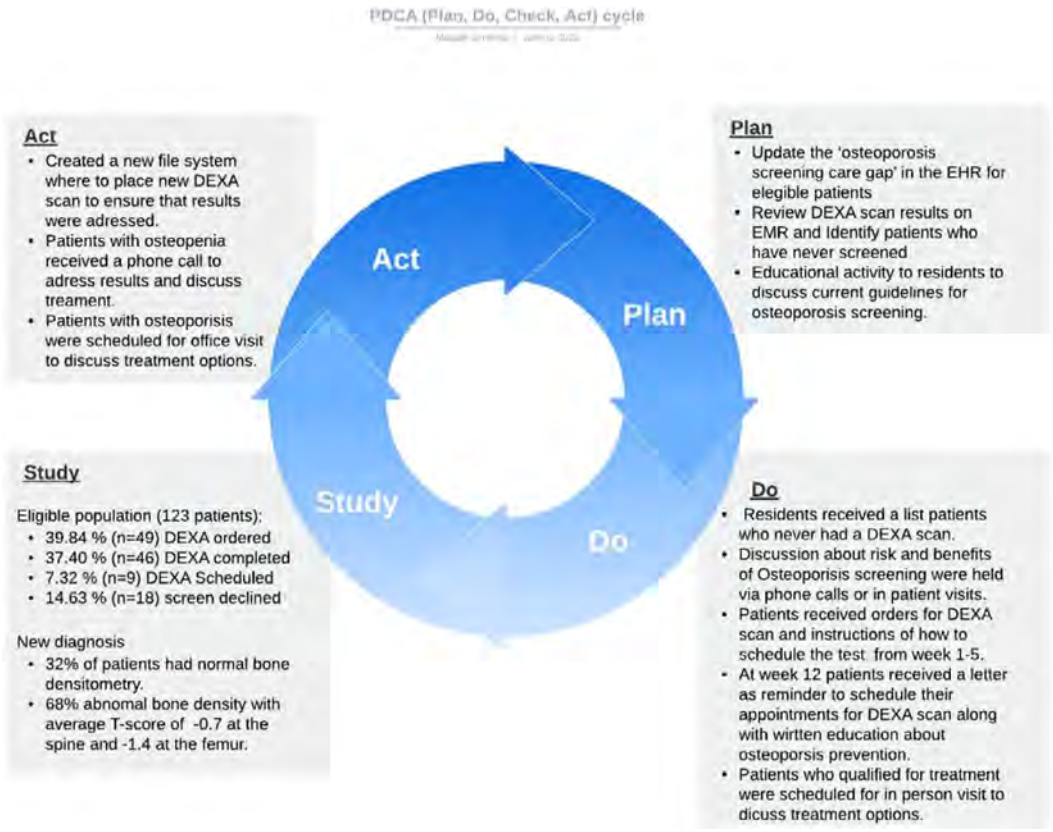
Background/Purpose: Osteoporotic fractures, especially hip fractures, are associated with significant morbidity, including limitations in ambulation, disability, and decreased quality of life. The aim of this quality improvement project was to increase the percentage of woman aged 65 or older screened for Osteoporosis in a resident-led primary care clinic and subsequently identify a population that would benefit from treatment to reduce the risk of fragility fracture.

Methods: Per the U.S. Preventive Services Task Force (USPSTF) osteoporosis screening guidelines, all female patients aged 65 or above followed by the resident primary care clinic who had not yet received osteoporosis screening by December 31st, 2022, were included. A list of eligible patients was generated through the Electronic Health Record (EHR) using patient's age, sex, and primary care physician location. A team of residents and faculty along with the associate director of quality identified possible barriers that limited the osteoporosis screening in a fishbone diagram (figure 1). A package of interventions, based on a Pareto analysis of factors in the fishbone, were prepared, completed, and analyzed through a Plan-Do-Study-Act cycle (figure 2).

Results: For the eligible group of patients (n=123), the risks and benefits of screening for osteoporosis with DEXA scan were discussed via phone call or during in person office visits. At week 12, the patients who were unable to be reached despite multiple attempts received a letter from the office with educational material about fragility fractures and benefits of undergoing osteoporosis screening. In 4 months, 37.40 % (n=46) of identified patients had their DEXA scan completed and 7.32 % (n=9) were scheduled for the upcoming weeks. 39.84% (n=49) of patients had a DEXA scan ordered without a documented scheduled date. 14.63% (n=18) of patient declined DEXA scan. The most common reason for declining screening was reluctance to start treatment. Out of the 46 patients who completed the initial screening, 68% were diagnosed with abnormal bone mass, of



Identified barriers that limit the osteoporosis screening



Plan-Do-Study-Act cycle

which 32% met osteoporosis criteria. At the 4-month mark, the overall rate of screening for all females aged 65 or older in our clinic increased from 75 to 85% and is expected to continue to improve in the upcoming months.

Conclusion: The use of osteoporosis screening reminder in the EHR along with continued provider and patient education resulted in a 10% increase over 4 months in the osteoporosis screening rate in a resident clinic.

Abstract Number: 2007

Effects of IL-17 Blockade on Skeletal Microarchitecture in Patients with Axial Spondyloarthritis: An HR-pQCT Study

Insa Mannstadt, Donald McMahon, Douglas Mintz, Weija Yuan, Linda Russell, Susan Goodman, Emily Stein and Dalit Ashany, Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (AxSpA), a chronic inflammatory rheumatic disease causes abnormal bone growth at the spine and paradoxically has been linked to osteoporosis and fragility fractures. While tumor necrosis factor alpha inhibitors have been shown to improve skeletal health in patients with AxSpA, the effect of newer medications that block interleukin-17 (IL17) on bone metabolism remains unclear. This prospective study investigated the impact of IL17 blockade on bone density (BMD) and microarchitecture in AxSpA. We hypothesized that treatment initiation would be associated with improved BMD and microarchitecture.

Methods: Skeletal assessments included areal BMD (aBMD) and trabecular bone score (TBS) by DXA, volumetric BMD (vBMD) and microarchitecture by high-resolution peripheral quantitative computed tomography (HRpQCT2) at baseline and 12-months. DXA and HRpQCT measurements from patients were compared to those of age-matched individuals in reference cohorts. Changes in imaging parameters were compared using Wilcoxon and paired t-tests, and predictors of change in HRpQCT were analyzed using multivariate linear regression.

Results: Of the 22 AxSpA participants, 55% were female (33% postmenopausal), mean age 40 years, and mean BMI 30 kg/m^2. 55% were HLA-B27 positive, mean symptom duration was 10 years, and C-reactive protein (CRP) was elevated in 32% of participants, respectively. At baseline, mean DXA and HRpQCT Z-scores were within 1 standard deviation of sex and age matched controls. At 12-months, >80% of participants reported 100% medication adherence. Standardized assessments of disease activity improved, with a decrease in Bath Ankylosing Spondylitis Disease Activity (BASDAI -33%, $p< 0.01$) and Metrology Index (BASMI -22%, $p=0.01$). In contrast, there was no significant improvement in aBMD, TBS, or microarchitecture by HRpQCT. In fact, decreases were observed in radial total vBMD (-2%, $p=0.04$) and trabecular vBMD (-2%, $p=0.04$). Radial trabecular separation tended to increase (4%, $p=0.06$). Elevated CRP tended to be associated with decrease in total vBMD (tibia $R^2=0.2$, $p=0.06$; radius $R^2=0.3$, $p=0.09$).

Conclusion: In summary, participants with AxSpA who began IL17 blockade had significant improvements in clinical symptoms, but no change or small declines in BMD and microarchitecture. Our uncontrolled study lacks data regarding whether treatment attenuated skeletal declines. Larger controlled studies are needed to investigate the long-term skeletal effects of IL-17 blockade.

Comparative Effectiveness of Denosumab versus Alendronate Among Postmenopausal Women with Osteoporosis in the U.S. Medicare Program

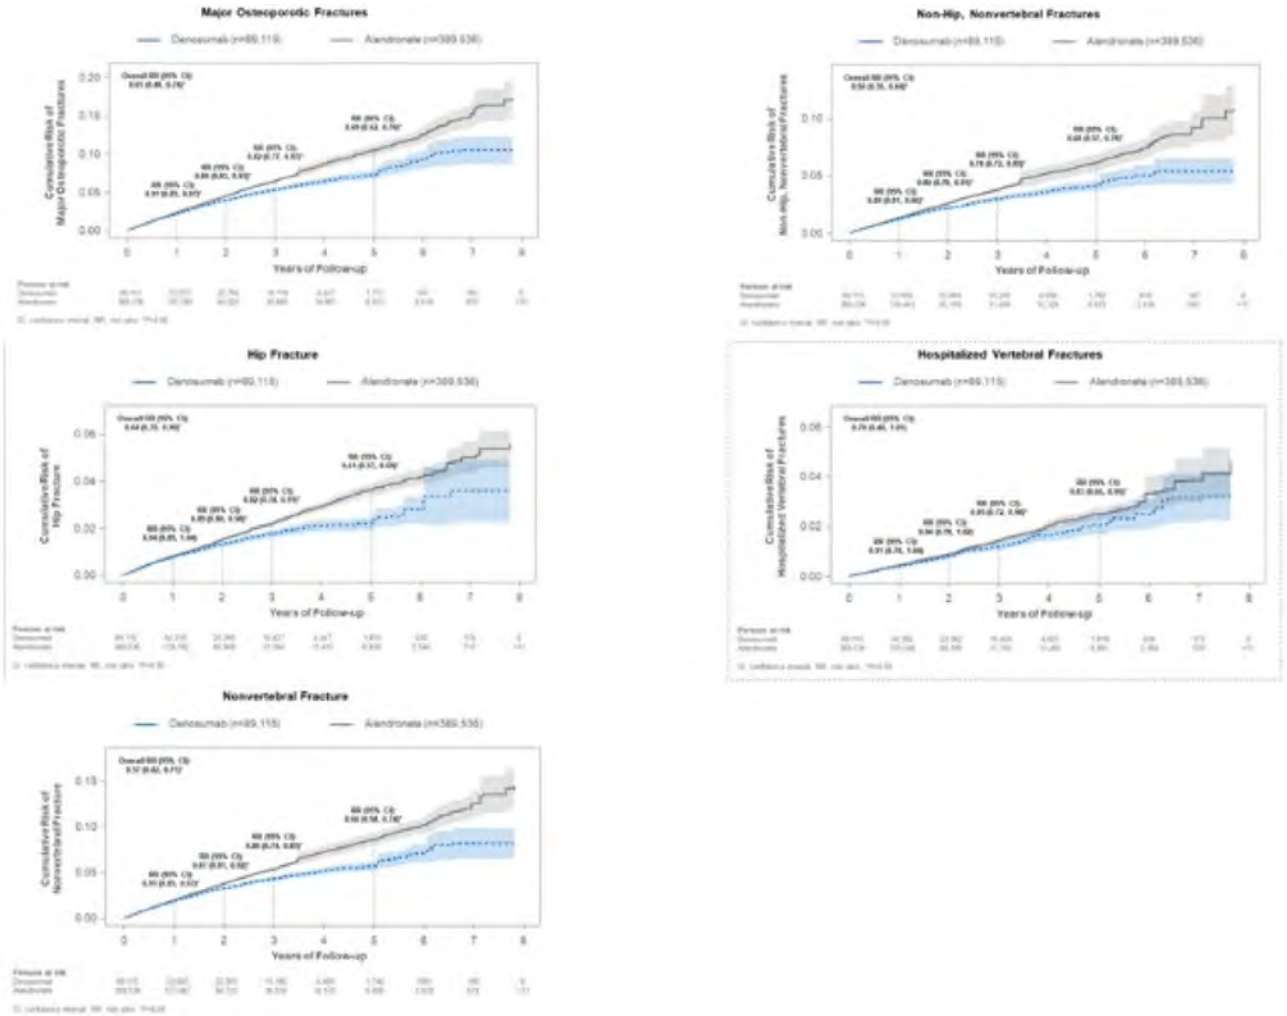
Jeffrey Curtis[1], Tarun Arora[2], Ye Liu[1], Tzu-Chieh Lin[3], Leslie Spangler[3], Vanessa C. Brunetti[3], Robert K. Stad[3], Michele McDermott[3], Brian D. Bradbury[3] and Min Kim[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Foundation for Advancing Science, Technology, Education, and Research, Birmingham, AL, [3]Amgen, Inc., Thousand Oaks, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Although clinical trials have shown that denosumab (Dmab) significantly increases bone mineral density at key skeletal sites more than oral bisphosphonates, evidence is lacking from head-to-head randomized trials evaluating fracture outcomes. This retrospective observational study evaluated the comparative effectiveness of Dmab versus alendronate (Aln) in reducing fracture risk among postmenopausal women with osteoporosis (PMO) in the U.S.

Methods: Female Medicare fee-for-service beneficiaries ≥ 66 years of age who newly initiated Dmab (n=89,115) or Aln (n=389,536) between January 1, 2012 to December 31, 2018 with no prior history of osteoporosis treatment, were followed from treatment initiation until the first instance of a specific fracture outcome, treatment discontinuation (defined as the end of treatment supply + 60-day allowable gap) or switch, Medicare disenrollment, death, or end of available data (December 31, 2019). A doubly robust inverse-probability of treatment (weights estimated from multivariate logistic regression models) and censoring (weights estimated from multivariate Cox Proportional Hazards regression models) weighted function was used to estimate the relative risk (RR) associated with the use of Dmab compared with Aln for hip, nonvertebral (NV; includes hip, humerus, pelvis, radius/ulna, other femur), non-hip, nonvertebral (NHNV), hospitalized vertebral (HV), and major osteoporotic (MOP; nonvertebral and hospitalized vertebral) fractures.

Results: Overall, Dmab reduced the risk of MOP by 39% (RR=0.61; 95% CI: 0.48-0.74), hip by 36% (0.64; 0.39-0.90), NV by 43% (0.57; 0.42-0.71), NHNV by 50% (0.50; 0.35-0.64), and HV fractures by 30% (0.70; 0.40-1.01) compared with Aln. Dmab reduced the risk of MOP fractures by 9% (0.91; 0.85-0.97) at year 1, 12% (0.88; 0.83-0.93) at year 2, 18% (0.82;



0.77-0.87) at year 3, and 31% (0.69; 0.62-0.76) at year 5.An increase in the magnitude of fracture risk reduction with increasing duration of exposure was also observed for other NV outcomes(Figure).

Conclusion: In a cohort of almost a half million, treatment-naive PMO, we observed robust and significant reductions in the risk of MOP, hip, NV, NHNV, and HV fractures for patients on Dmab compared to Aln. Patients who remained on Dmab for longer periods of time experienced greater reductions in fracture risk.

Abstract Number: 2009

Screening and Treatment of Low Bone Mineral Density in Allogeneic Hematopoietic Cell Transplant Patients

Perry Fuchs, Christina Ferraro, Chao Zhang, Chad Deal, Betty Hamilton and Sarah Keller, Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

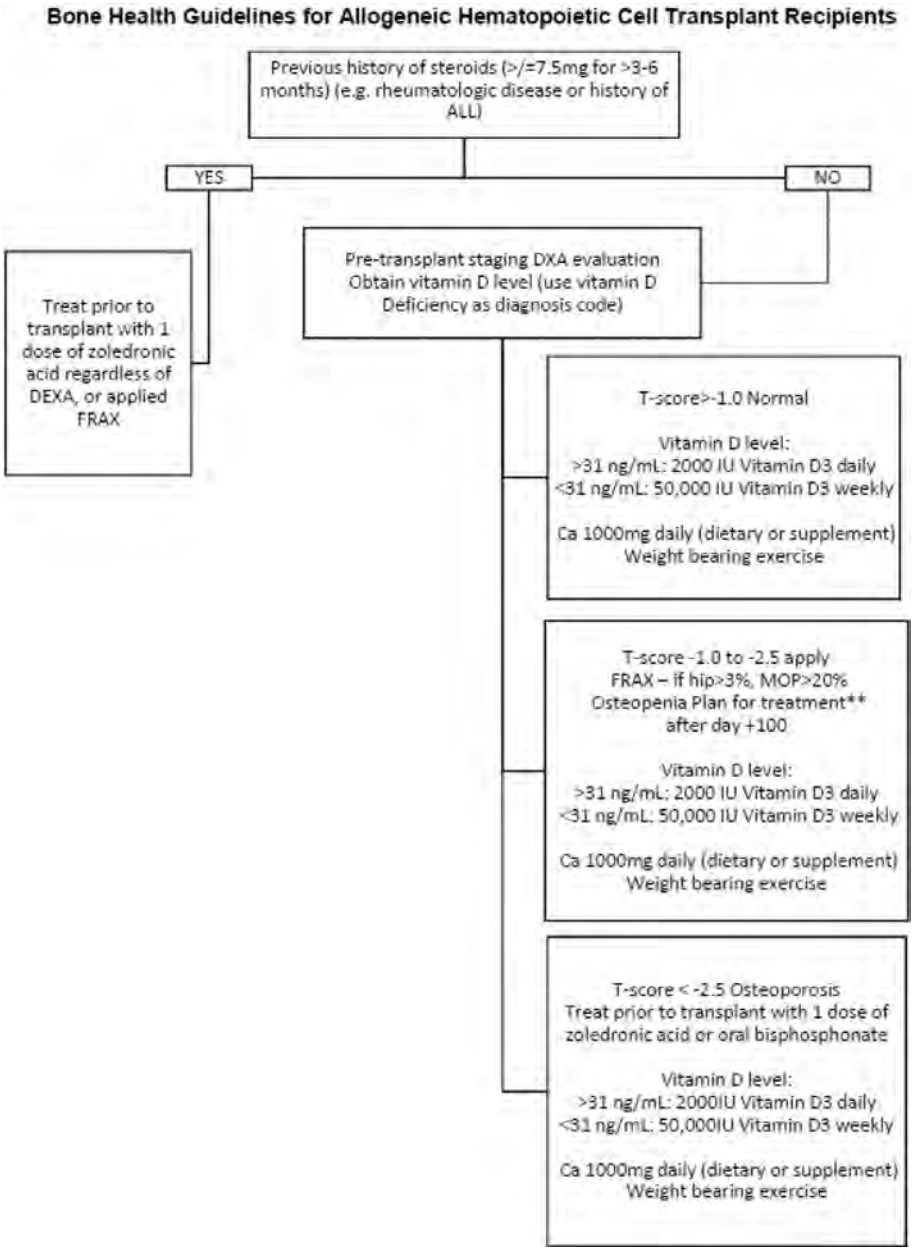
Background/Purpose: Bone mineral density (BMD) loss and fracture are important causes of increased morbidity following allogeneic hematopoietic stem cell transplant (allo-HCT).Recent societal recommendations support screeningDual X-ray Absorptiometry (DXA) both before and within 1 year after allo-HCT. Our institutionimplemented a new management algorithm that emphasized pre-transplant screening for allo-HCT patients and contained guidance on use of bone strengthening agentstoimproveBMDrelated outcomes in this population. This study evaluatedthe rate of screening and treatment of low BMD and fracture in allo-HCT patients and determined the effect that the quality improvement intervention had on these measures.

Methods: This was a retrospective chart review ofallo-HCT recipients at the Cleveland Clinic Foundationfrom April 2016 toMarch 2022. 244 patients with at least 1-year of follow up from allo-HCT were identified for analysis.The BMD management algorithm was implemented in 10/2019, and we compared rates of DXA screen (pre- and post-HCT), treatment, and fragility fractures between allo-HCT recipients before and after this time point.We also analyzed available T-scores at the spine, femoral neck, and total hip and FRAX risk scores before and after allo-HCT. Treatment was guided by National Osteoporosis Foundation (NOF) recommendations (T-score of –2.5 or less, or T-score of –1 to –2.4 and a 10-year probability of hip fracture >/= 3% or any major fracture >/= 20% as calculated by FRAX).

Results: After intervention, thepre-transplant DXA screening increased from 0% to 95%, though post-transplant DXA screening (≤13 months from HCT) decreased from 67% to 36% ($p < 0.001$). Rate of treatment indecreased from 67.23% to 35.58% ($p < 0.001$).Rate of treatment in patients meeting NOF criteria was similar pre- and post-intervention (62% vs 62%). Subgroup analysis showed treatment of osteoporosisalso remained similar between groups (75% vs 72%),however

the rate of treatment of osteopenia with a high FRAX score was improved in the post-intervention group (0% vs 38%, p = 0.204). The fracture rate was significantly lower in the post-intervention group (7.7% vs 19.3%, p = 0.004).

Conclusion: Implementation of analgorithm for screening and treatment of low BMD in allo-HCT recipientswith a focus on pre-transplant DXA screening resulted in an expected increase in pre-transplant screening, but anunexpected decreased rate of follow-up DXA within the 13 months post-transplant. This intervention alsoledto an increased rate of treatment of patients with osteopenia and elevated FRAX. The intervention led to a significantly decreased rate of fractures, which may be related to the increased awareness of low BMD and potentially due to the timing of treatment initiation, which was not directly assessed in this analysis.Allo-HCT patients are a complex population of patients that are prone to low BMD and focusing on the detection and management of this important cause of morbidity is correlated with improved outcomes.



Guidance Algorithm for Management of Low BMD in Allogeneic Hematopoietic Stem Cell Transplant Patients

Table 1. Results with p-values of screening, treatment, and fracture pre- and post-intervention

Outcome Measure	Pre-Intervention	Post-Intervention	P-Value
Pre-Transplant Screening DXA	0 (0%)	101 (95.28%)	<0.001
Screening DXA within 13 months Post-Transplant	80 (67.23%)	37 (35.58%)	<0.001
Treatment of T-score </= -2.5, OR T-score between -1 and -2.4 with FRAX Hip > 3% OR FRAX MOP > 20%	18 (62.07%)	16 (61.54%)	1
Treatment of T </= -2.5	18 (75%)	13 (72.22%)	1
Treatment of T-score between -1 and -2.4 with FRAX Hip > 3% OR FRAX MOP > 20%	0 (0%)	3 (37.5%)	0.204
Fragility Fracture Post-Transplant	23 (19.33%)	8 (7.69%)	0.004

B-FROST: Chronic OBstructive Pulmonary Disease and Vertebral FRacture of OSTeoporotic Origin: Results of a Real-life Cohort

Amine Mouamnia, Armentieres Hospital Center, Armentieres, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic obstructive pulmonary disease (COPD) is a chronic disease of the airways. It is mainly caused by smoking. Active smoking is a risk factor for osteoporosis. The occurrence of thoracic vertebral fractures can lead to additional deformities and ventilatory disorders. Moreover, little is known about the consequences of VF in COPD.

The objective is to determine the occurrence of vertebral fractures in a real-life COPD population hospitalized for exacerbation, and the risk factors involved.

Methods: The clinical characteristics of patients hospitalized in the pulmonology department from January 1 to December 31, 2022 were assessed. The diagnosis of vertebral fracture (VF) was assessed on standard chest X-rays.

Results: Of the 136 files analyzed, 106 patients were included. The main characteristics are shown in Table 1. The diagnosis of VF was largely underestimated (only 3.77% of VFs were described on standard chest X-rays). The prevalence of VF was 21.7%. The incidence rate was 23 cases per 106 patient-years. Lower BMI appears to be associated with the occurrence of

Table 1. Characteristics of patients

	FV	Non-FV	Significance
	Mean ± SD Median [IQR] Or Number (%)	Mean ± SD Median [IQR] Or Number (%)	
Population	23/106 (21.7)	83/106 (78.3)	
Age (years)	73.8 ± 11.5 76 [67-81]	70.4 ± 11.9 71 [63-80]	ns
Sex (F)	N=10 (43.5%)	N=39 (47.0%)	ns
BMI (kg/m2)	26.7 ± 8.6 25 [22-31]	31.2 ± 10.4 29 [23.7-37]	p<0.05
Smoking (pack-year)	33.3 ± 14.2 30 [27.5-42.5]	45.7 ± 25.3 40 [30-60]	ns
Alcohol	N=1 (4.3%)	N=16 (19.3%)	p<0.05
Inhaled steroids	N=14 (60.9%)	N=41 (49.4%)	ns
FEV1 (% of predicted)	48.0 ± 13.2 47.5 [40.5-55]	47.6 ± 20.0 45 [34-60]	ns
GOLD status	3.8 ± 0.6 4 [4-4]	3.5 ± 1.0 4 [3-4]	ns
Length of hospital stay (days)	12.0 ± 7.2 11 [7.5-14.5]	10.6 ± 9.6 8 [5.5-13.5]	ns
Number of exacerbation per year	1.4 ± 0.7 1 [1-2]	1.3 ± 0.6 1 [1-1]	ns
Intensive care admission	N=4 (17.4%)	N=15 (18.0%)	ns
Death of hospitalized patients	N=1 (4.3%)	N=6 (7.2%)	ns

SD: Standard Deviation; IQR: Interquartile Range; F: Female; BMI: Body Mass Index; kg/m2: kilogram per square meter; FEV1: Forced Expiratory Volume In 1 Second; GOLD: Global Initiative for Chronic Obstructive Lung Disease.

VF p< 0.05. Patients with VF were hospitalized longer on average and had more exacerbations during the year, but this was not significant. There was no difference in mortality between the 2 groups.

Conclusion: VF are common in COPD patients, yet they remain under-diagnosed and may contribute to increased morbidity and mortality in this population over the long terme.

Predicting Fractures in Patients with Isolated Lumbar Spine Osteoporosis Compared to Those with Isolated Hip Osteoporosis

Nicholas Rossi[1], Aamir Saeed[2], Aqib Khan[3], Hamzah Amin[2], Ummaz Nadeem[2], Zain Sultan[3] and Marwan Bukhari[2], [1]University Hospitals of Morecambe Bay Foundation Trust, Worksop, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom, [3]University Hospitals of Morecambe Bay Foundation Trust, Lancaster, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis (OP) presents with fragility fractures, which can cause significant disability and cost to health services globally. There has been extensive research looking at risk factors for osteoporosis and fractures but less into how these factors are predicted at different bony sites. We aimed to compare risk fractures for fractures in patients with isolated L1-L4 vertebrae OP compared to isolated hip OP in a large dataset.

Methods: Data were obtained from patients referred for DEXA scan in the North-West of England between 2004 and 2011. Upon attendance, demographic details, full medical history including risk factors for fracture presence of fracture were recorded. These data was retrospectively analysed using STATA(tm) , with chi squared test used for categorical data and independent sample t-test for continuous data. We then fitted logistical models reporting odds of fracture using risk factors included in the FRAX(tm) tool (age, height, weight, family history, smoking, alcohol excess, rheumatoid arthritis and steroid use) to look for predictors of fracture.

Results: The total cohort comprise 31546 patients (82% female). 2530 patients had isolated vertebral osteoporosis and 1363 had isolated hip OP. Results are shown in table 1 below. Age was significantly associated with fractures at both sites with greater fracture risk at the hips compared to the spine. Height was protective for fractures and osteoporosis at both sites. Interestingly, whilst height was less associated with fracture in patients with hip OP, it gave greater protection against fractures at the spine. Weight was more protective for fractures at the hips compared to the spine but whilst it was protective for OP at both sites, there was no significant difference between them. Smoking increased risk of OP but with no significant difference between the two sites and had no effect on fracture risk. Use of steroids was surprisingly protective of fractures at both sites, without a significant difference between them. Excess alcohol was protective against fracture in both sites with no significant difference between them and was associated with an increased risk of fractures in the spine but not in the hip. Rheumatoid arthritis (RA) increased risk of osteoporosis in the hip but not in the spine. RA also inferred greater risk of fractures at the hips but unfortunately didn't reach statistical significance in the spine.

Table 1 - Risk factors affecting neck of femurs and spinal vertebrae

Risk Factor	NOF fracture		Spine fracture	
	Odds Ratio	95% Confidence Intervals	Odds Ratio	95% Confidence Intervals
Age	1.05	1.045 - 1.056	1.045	1.041 - 1.049
Height	0.994	0.987 - 0.999	0.978	0.974 - 0.983
Weight	0.983	0.979 - 0.987	0.995	0.992 - 0.997
Current Smoker	0.911	0.772 - 1.075	1.021	0.906 - 1.151
Steroid Therapy	0.683	0.595 - 0.783	0.709	0.641 - 0.785
Excess Alcohol	0.9	0.703 - 1.153	1.384	1.203 - 1.591
Rheumatoid Arthritis	1.09	0.882 - 1.346	0.784	0.655 - 0.938

Conclusion: Our study shows that established risk factors for fractures may affect different bony sites in distinct ways. The FRAX(tm) risk factors underperform in both cohorts This suggests that isolated spinal or hip OP may be a distinct disease and might need be assessed and treated differently. Our strengths include the large numbers included, but weaknesses exist in referral bas and lack of knowledge of length of exposure to risks. Further research is needed to assess how risk factors affect different bony sites, including the forearms and ribs, as well as the pathophysiology behind the differences observed.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Denosumab and Zoledronic acid are antiresorptive drugs commonly used in the treatment of osteoporosis (OP). Zoledronic acid is a third-generation bisphosphonate that inhibits osteoclastic bone resorption through the mevalonate pathway. Denosumab is a humanized monoclonal antibody that binds to RANK-L preventing osteoclastic activation. Both can cause hypocalcemia and parathormone (PTH) elevations have been described during their use. Its prevalence, the mechanism by which it occurs, and the clinical repercussions are unknown.

The aim of our study was to analyze the prevalence of PTH elevation above the reference value in patients receiving zoledronic acid or denosumab and its relationship with other clinical-analytical parameters.

Methods: Retrospective observational study in patients with OP who have received treatment with denosumab or zoledronic at least two years. Patients were successively recruited from our service's osteoporosis database.

Patients diagnosed with primary hyperparathyroidism or with glomerular filtration rate < 30ml/min at the baseline visit were excluded from the study. Clinical and demographic data were obtained from the electronic health record. Statistical analysis was performed using R software.

Results: 91 patients with a mean age (Standard Deviation-SD) of 68 (11.3) years at the start of treatment were included.

49 (81.6% women) patients started treatment with zoledronic and 42 (61.9% women) with Denosumab.

Table 2. Logistic regression model between elevated PTH and other clinical-analytical variables.

Table 1 shows the analytical parameters throughout the follow-up.

18.4% of the patients treated with zoledronic had elevated PTH levels on some occasion compared to 35.7% of the patients treated with Denosumab (p=0.055).

Patients with persistently elevated PTH during the two visits were 3 (6%) with zoledronic and 9 (21.4%) with Denosumab (p< 0.02).

Using a logistic regression model, we analyzed the possible relationship between the elevated value of PTH (≥65pg/mL) and other clinical-analytical variables (Table 2).

Variables	Estimate	Lower 95%	Upper 95%	p.value
Antiresorptive at time of baseline visit	-0.214	-0.505	0.076	0.147
Age of onset	0.006	-0.01	0.022	0.479
Glomerular filtration rate	0.392	-0.291	1.075	0.257
Calcium corrected for albumin	-0.88	-2.674	0.914	0.332
25-OH-Vitamina D	0.11	-0.219	0.44	0.508
Normal PTH (<65pg/mL)	-0.457	-0.802	-0.113	0.01
Women gender	-0.33	-0.599	-0.061	0.017

Table 3. Linear regression model between Delta T-Score at lumbar region with other clinical-analytical variables

We found an inverse statistically significant association between corrected calcium and glomerular filtration rate compared to elevated PTH.

We calculated the progression of the T. Score between the baseline visit and the second visit in the lumbar spine, femoral neck, and total hip. We call this parameter "delta T Score".

Using a linear regression model, we analyzed the lumbar Delta T-Score against the variables listed in table 3.

Normal PTH values and female gender are associated in a statistically significant way with a worse evolution of bone mineral density at the lumbar region.

We did not find these associations in femoral neck or total hip.

Conclusion: We found a high prevalence of hyperparathyroidism in our patients, higher in those treated with Denosumab.

The elevation of PTH seems to be associated, inversely, with serum levels of ionic calcium and glomerular filtration rate. Elevated PTH levels are associated with a better evolution of bone mineral density. In this context, we believe that the elevation of PTH could act as a marker of treatment effectiveness. Other studies would be necessary to corroborate these findings.

Clinical Characteristics and Risk Factors Associated with Fragility Fractures in Patients with Primary and Idiopathic Mast Cell Activation Syndromes

Ana Isabel Ramos Lisbona[1], Karen Carpio Astudillo[1], Filip Skrabski[1], Alicia Prieto García[1], Isabel Castrejon[1], Javier Rivera[2], José María Álvaro-Gracia[1] and Teresa González[1], [1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañon, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Mast Cell Activation Syndromes (MCAS) are a group of disorders presenting with episodic multisystem symptoms, predominantly anaphylaxis, as the result of mast cell mediator release. Primary MCAS, that are those with a clonal origin such as systemic mastocytosis (SM), present a high prevalence of fragility fractures (FF), which varied from 5 to 37% of patients [1]. On the contrary, the idiopathic (non-clonal) forms of MCAS, do not appear to be associated with this risk [2]. The main objective of our study is to describe the presence of osteoporosis (OP), FF and the principal risk factors associated with FF in patients with MCAS.

Table 1. Characteristics of patients with Primary and Idiopathic MCAS.

	Primary MCAS (N=36)	Idiopathic MCAS (N=12)	p
Male, n (%)	14 (38.9)	4 (33.33)	1.00
Mean age of onset of symptoms (SD)	37.7 (17.8)	44.5 (13.1)	0.24
Mean age of diagnosis (SD)	45.4 (18.3)	51.7 (12.4)	0.27
Mean BMI (SD)	21.65 (4.25)	26.2 (5.3)	0.004
BMI <19 kg/m^2, n (%)	7 (19.44)	0 (0)	0.17
Skin symptoms, n (%)	21 (58.33)	12 (100)	0.007
Anaphylaxis, n (%)	17 (47.2)	12 (100)	0.001
Digestive symptoms, n (%)	16 (44.4)	9 (75)	0.98
Mean basal tryptase (SD)	22.60 (18.02)	5.83 (3.46)	0.003
General risk factors for OP, n (%)	19 (52.8)	3 (25)	0.18
Osteoporosis, n (%)	14 (38.9)	2 (16.67)	0.16
Fragility fractures, n (%)	9 (25)	1 (8.33)	0.22
Mean T-score in the femoral neck (SD)	-1.07 (1.18)	-0.47 (1.09)	0.12
Mean T-score in the lumbar spine (SD)	-1.39 (1.41)	-0.66 (1.43)	0.14
Mean FRAX score for overall fracture (SD)	4.06 (2.85)	4.81 (5.12)	0.56
Mean FRAX score for hip fracture (SD)	1.19 (1.63)	1.10 (2.22)	0.89

SD: standard deviation

Methods: The study population included all the patients with primary MCAS and idiopathic MCAS evaluated by the Rheumatology and Allergology departments at Hospital General Universitario Gregorio Marañón (Madrid, Spain), a tertiary-level hospital, until January 2023. The diagnosis was made according to the diagnostic and classification criteria updated in the consensus of 2021 [3]. Demographic, clinical, and analytical characteristics were collected. Bone involvement was defined as densitometric OP (T score ≤ -2.5) and/or the presence of FF on thoracic and lumbar spine X-rays. Fracture Risk Assessment Tool (FRAX) was used for estimating the risk of osteoporotic fracture with a 10-year probability. The differences between groups were tested using t-student test for continuous variables and chi-square test for categorical variables. A value of $p < 0.05$ was considered statistically significant.

Results: A total of 48 patients were included: 36 with primary MCAS (33 with mastocytosis, 5 cutaneous and 28 non-advanced systemic forms, and 3 clonal MCAS) and 12 patients with idiopathic MCAS. In the primary MCAS group, 25% of patients developed at least one FF, of which 44.4% were men with a mean age of 42 years (p=0.02); these patients also have a lower bone mineral density at the femoral neck (T-score -1.07; p=0.04) and a higher FRAX score compared to those who did not present fractures. In the group of patients with idiopathic MCAS, only one presented FF. Table 1 shows a comparison between the primary and idiopathic MCAS patients. Patients with primary MCAS have a higher prevalence OP and FF, higher tryptase levels (p=0.003) and a lower body mass index (BMI) (p=0.004). However, the risk of fracture calculated by FRAX, both for major and hip fractures, is increased in both groups.

Conclusion: The prevalence of OP and FF is higher in patients with primary MCAS compared to patients with idiopathic MCAS. A higher BMI and lower tryptase levels could explain the lower risk in the idiopathic MCAS group, although due to the small sample size the results must be handled with caution.

The Role of Orosomucoid 2 in the Regulation of Bone Remodeling by Inhibiting Osteoclastogenesis and Promoting Osteogenesis

CHONG HYUK CHUNG[1], Myeung-Su Lee[1] and **Chang-hoon Lee**[2], [1]Wonkwang University Hospital, Iksan, South Korea, [2]Wonkwang University Hospital, Iksan Jeonbuk, South Korea

SESSION INFORMATION

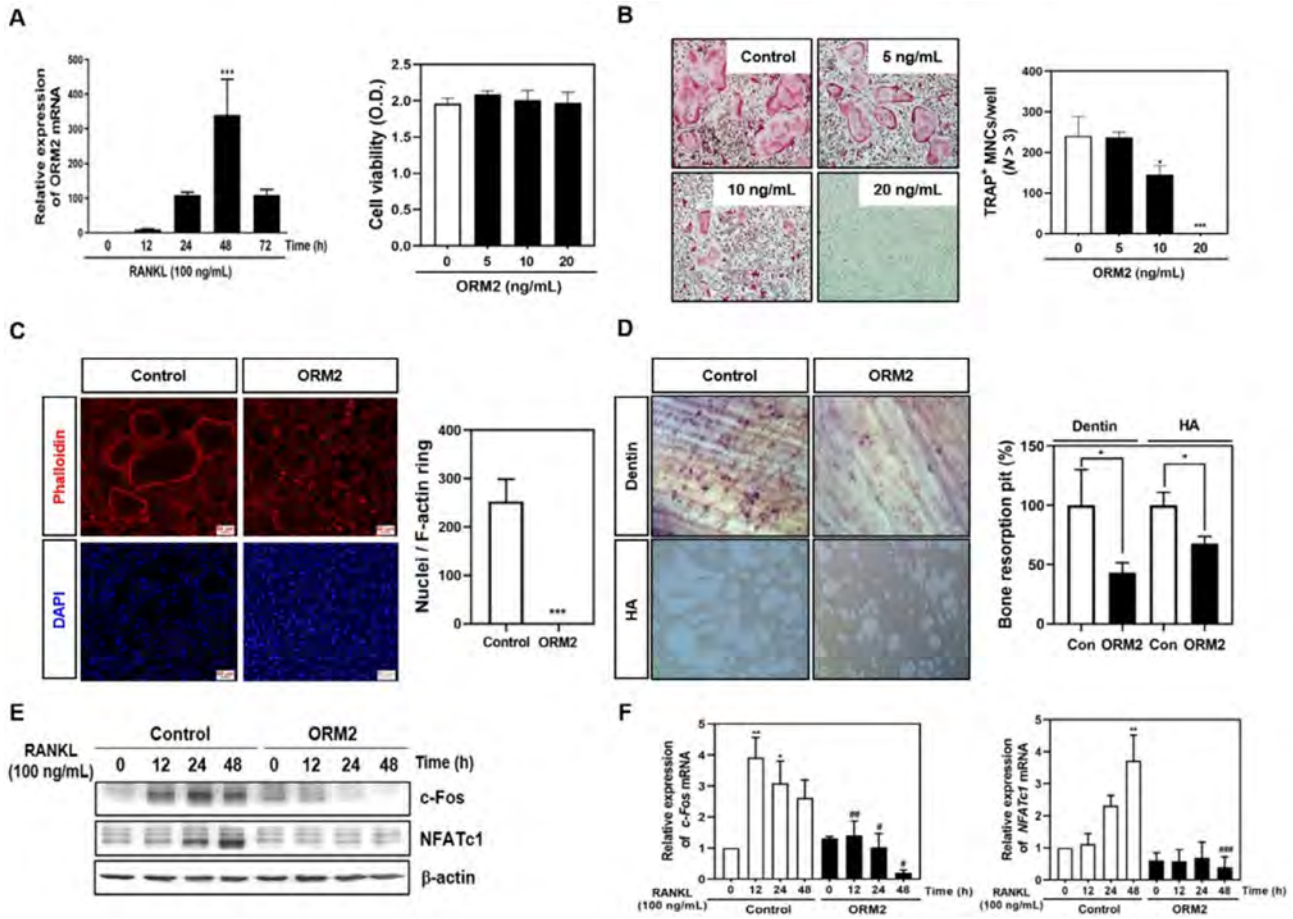
Session Date: Tuesday, November 14, 2023

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

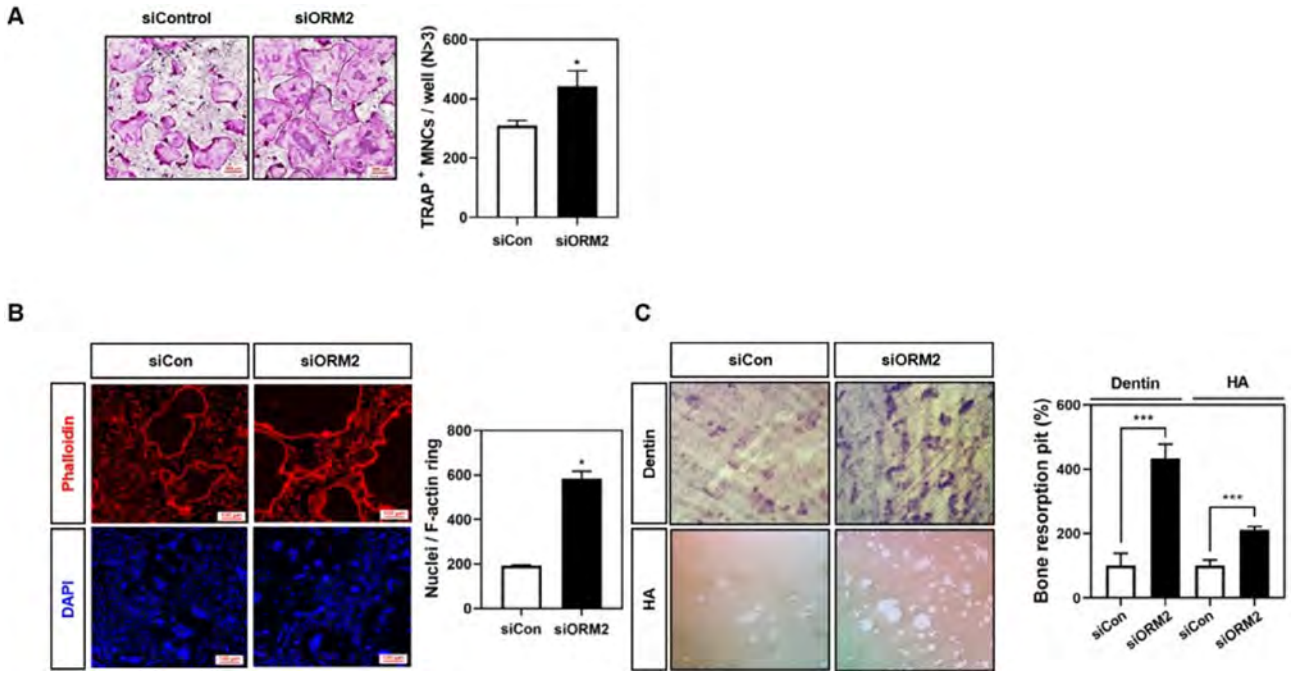
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

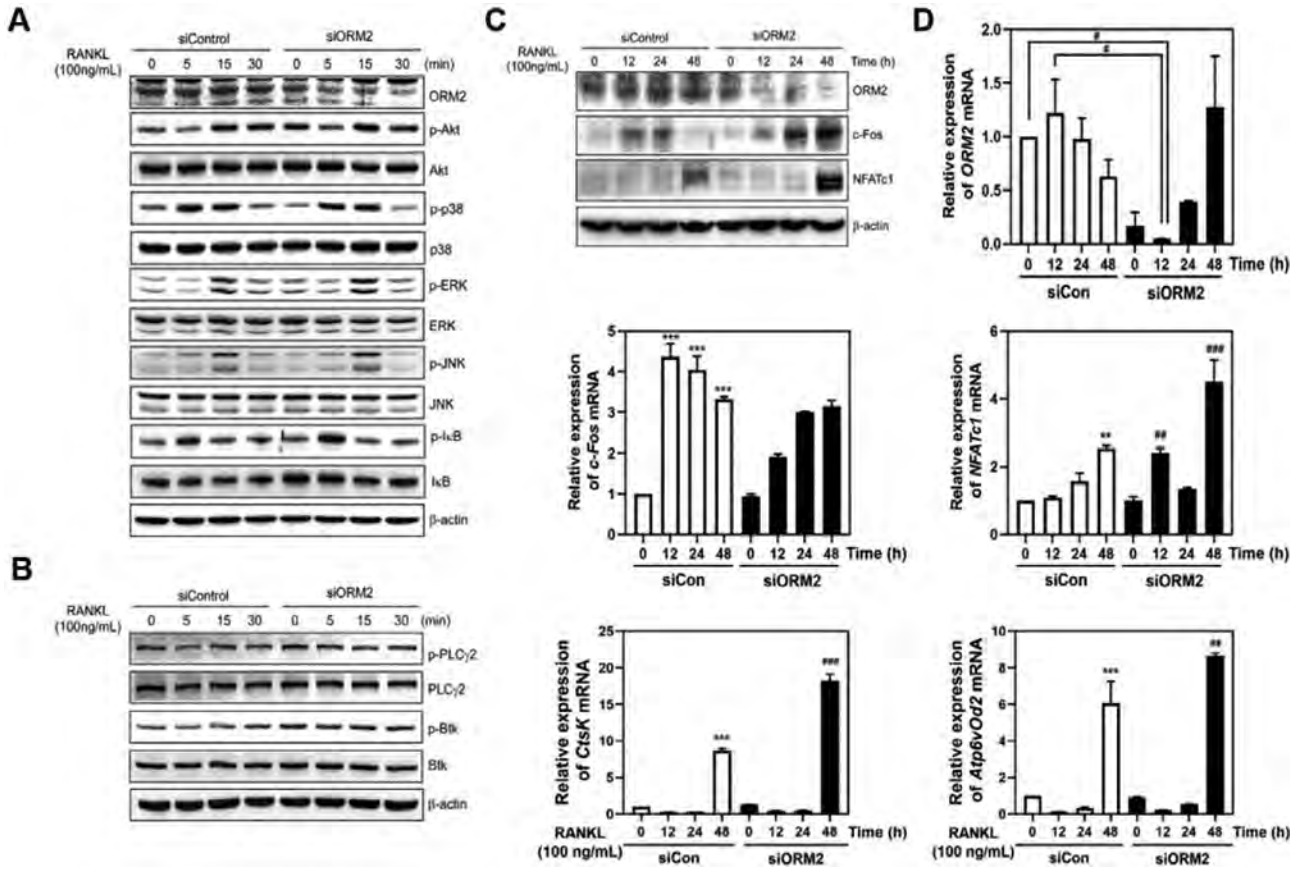
Background/Purpose: Orosomucoid (ORM) is one of the acute phase reactant protein family and is expressed in hepatocytes and secreted into plasma under stress conditions such as tissue injury, infection, and inflammation. Three types of ORM are known to date (ORM1, 2 and 3), and ORM2 is mainly expressed in bone marrow cells. ORM2 has only some studies on hepatic metabolism, inflammation and immune regulation, and no studies on bone metabolism have been reported. The aim of this study is to reveal the role of ORM2 in the differentiation and function of osteoclasts and osteoblasts



ORM2 expression was increased during RANKL-induced osteoclast differentiation and the administration of recombinant ORM2 protein restrained the formation of osteoclast and bone resorption function.



The knock down of ORM2 improved osteoclast differentiation and bone resorbing function.



The knock down of ORM2 leaded to osteoclast differentiation by increasing RANKL-mediated MAPKs (ERK, JNK), NF-KB, Akt and Btk-PLCr2 calcium signaling.

Methods: To determine the effect of ORM2 on RANKL-induced osteoclast differentiation and function, we performed TRAP staining, F-actin stating, and bone resorbing assay using ORM2 recombinant protein or ORM2 siRNA. Also, the effect of ORM2 on osteogenesis was confirmed by ALP and ARS assay. The intracellular mechanisms responsible for the dual regulation of osteoclastogenesis and osteogenesis of ORM2 were revealed by western blotting and quantitative real-time RT-PCR.

Results: We found that ORM2 is a potential target for osteoporosis therapeutics, as treatment with this agent enhances osteoblast differentiation and bone growth and suppresses osteoclast differentiation and bone resorption by performing gain- and loss-of-function studies. During ORM2-mediated regulation of osteoclastogenesis, phosphorylation of early signal transducers such as p38, JNK, Akt, IB, PLC 2, and Btk was affected, which in turn altered the mRNA and protein levels of c-Fos and NFATc1. ORM2 also increased ALP, Alizarin Red-mineralization activity, and the expression of osteoblastogenic gene markers, such as Runx2, osteocalcin (OCN), and ALP in mouse calvarial primary osteoblasts, and activated the p38-Runx2 pathway, which enhanced osteoblast differentiation.

Conclusion: we suggest that ORM2 may be a promising candidate for gene therapy for bone metabolic diseases, and further serve as a potentially important biomarker in the field of bone disease diagnosis.

Synergistic Effect Between Denosumab and Immune Checkpoint Inhibitors : A Retrospective Study of 268 Patients with Bone Metastases

Emmanuel Massy[1], Etienne Mabrut[1], Sabine Mainbourg[2] and Cyrille Confavreux[1], [1]Centre Expert des Métastases Osseuses (CEMOS) - Service de Rhumatologie, Centre Hospitalier Lyon-Sud, Hospices Civils de Lyon, Université de Lyon, INSERM UMR 1033-LYOS, Lyon, France, [2]Service de médecine interne et vasculaire, Centre Hospitalier Lyon Sud, Hospices Civils de Lyon, F-69495 Pierre-Bénite, Laboratoire de Biométrie et Biologie Evolutive, Université Lyon 1; CNRS, UMR 5558, 69622 Villeurbanne, Lyon, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Bone is the third site of metastasis. Bone metastases are associated with poorer survival of patients and impaired quality of life with the occurrence of skeletal related events. Denosumab (D-MAB), a recombinant fully monoclonal human IgG2 antibody directed against the receptor activator of nuclear factor kappa-B ligand (RANKL) is used for the prevention of skeletal related events (SRE) in advanced solid tumors with bone metastases. RANK/RANKL axis seems also essential in numerous immunological processes. Moreover, oncology had evolved last years with increasing use of Immune Checkpoint Inhibitors (ICI) that suppress tumor-induced immune system inhibition mechanisms. We hypothetized that there could be a synergistic anti-tumor effect between immunotherapy and denosumab according to case-reports, small cohorts and *in vivo* studies.

Methods: We used a retrospective database in oncology named IMMUCARE and developed in Hospices Civils de Lyon at Centre Hospitalier Lyon Sud. All patients treated with ICI from 2014 are included in this database. We analysed only patients with bone metastases and collected data in their medical file.

We analyzed overall survival (OS), progression-free survival (PFS) and switch of treatment line in different populations according to whether or not use of Denosumab. We designed three different groups, without Denosumab, ICI then Denosumab and Denosumab then ICI. We performed survival curves and Cox model for multivariate analysis.

Results: 268 patients presented with bone metastases in the whole cohort. We did not found significant difference for overall survive (OS) and progression free survival (PFS) in favor of combination of Denosumab and ICI but we have a visual impression of superiority on the survival curves in the ICI then D-MAB group. This visual impression of a beneficial effect starting around the 6th month. We identified significant difference for changing of treatment line in the ICI then D-MAB group (p = 0.022) in the conservative population, and at the limit in the corrected population (p = 0.057).

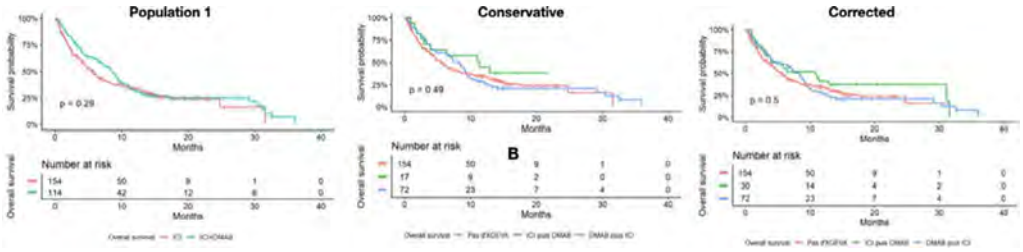

Figure 1 - Survival curves for overall survival (OS)

Conclusion: This retrospective study found no statistical benefit of association of D-MAB with ICI in the whole population but a sequence using ICI and then D-MAB seems to be beneficial to patients. It would be interesting to conduct dedicated studies in bigger cohort to confirm these latter statement.

Generation of a Human 3D *in Vitro* Bone Model That Mimics Glucocorticoid-induced Osteoporosis

Moritz Pfeiffenberger[1], Johannes Plank[1], Alexandra Damerau[1], Timo Gaber[1] and **Frank Buttgereit**[2], [1]Charité Universitatsmedizine - Berlin, Berlin, Germany, [2]Charité Universitätsmedizin, Dept. Rheumatology, Berlin, Germany

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is a bone disease characterized by low bone mass and changes in bone architecture, leading to pain and reduced mobility in patients. Glucocorticoid-induced osteoporosis (GIOP) is the best known form of secondary osteoporosis. Glucocorticoids (GC) are commonly used to treat inflammation, such as in rheumatic diseases. However, GC use can have a negative effect on the skeletal system and lead to osteoporosis.

(i) Establishing and characterizing a human *in vitro* bone model consisting of osteoblasts and osteoclasts embedded in β-TCP ("healthy" bone model), (ii) treatment with dexamethasone to induce GIOP ("osteoporotic" bone model) and (iii) using this model as a testing platform for the treatment of osteoporosis.

Methods: Our model includes osteoblasts and osteoclasts, which are mainly responsible for bone remodeling. We defined an osteoclast differentiation protocol using low-attachment plates and cultured the cells for 21 days in ∝MEM medium, 5% FCS, 5% human AB serum, 2 mmol L-glutamine, 25 ng/ml M-CSF, and 50 ng/ml RANKL. To provide the basic scaffold for the structure of the "healthy" bone model, mesenchymal stromal cells (MSCs) were seeded on β-tricalcium phosphate (β-TCP). This bone model, consisting of differentiated osteogenic cells, was fully characterized in our previous work [1].

Results: The multinuclearity, typical ß-actin ring formation, cellular activity by TRAP staining and functionality in resorption assays proved functional osteoclasts. Our protocol allowed us to passage these cells without cell loss or loss of function. To establish the previously "healthy" (i.e., untreated) bone model, we seeded osteoclasts onto a pre-seeded β-TCP

construct and cultured the co-culture for 7 days. We then analyzed the supernatant and detected marked secretion of RANKL, MMP-9, and free phosphate. This indicates the functionality of both osteoclasts and osteoblasts in our 3D model. Subsequently, the healthy model will be transferred to the osteoporosis-simulating model where treatment with dexamethasone will be applied. Once established, we plan to use the model we have developed for in vitro preclinical trials to test marketed drugs.

Conclusion: Ultimately, we will obtain an *in vitro* 3D co-culture of osteoblasts/osteoclasts simulating human native bone, which will be treated with dexamethasone to mimic key aspects of GIOP *in vitro*.

Rheumatology, Berlin, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at increased risk for osteoporosis and fragility fractures. This risk is mediated by a variety of factors such as chronic inflammation, treatment with glucocorticoids (GC), vitamin D deficiency, and others. The role of disease-specific factors of SLE has not been fully elucidated.

We aimed to identify factors associated with bone mineral density and osteoporosis including fragility fractures to better understand the interplay between disease-specific factors and general risk factors that drive bone loss in this patient population.

Methods: Rh-GIOP is a prospective observational cohort study investigating bone health in consecutive patients ≥18 years with inflammatory rheumatic diseases and current or prior GC treatment. This cross-sectional analysis assessed the baseline visits of all patients with SLE fulfilling the EULAR/ACR 2019 SLE classification criteria. Multivariable linear regressions models were fitted to identify factors associated with bone mineral density (BMD). As a second outcome, we investigated factors associated with clinical osteoporosis (OP, defined by either a T-Score of ≤ -2,5, anti-osteoporotic treatment and/or fragility fractures) by multivariable logistic regression analysis.

Results: Baseline data from 110 patients with SLE were analyzed. The mean age was 48.1±14.5 years, mean disease duration 16.3±9.9 years, and 41% of the cohort was identified as having OP. Lupus nephritis was present in 35% of the SLE patients, of whom 55% had active nephritic disease at baseline osteoporosis screening visit. Class IV and V accounted for

most nephritis cases (61%). In multivariable linear regression analysis, lupus nephritis class IV and V (reg. coefficient (95%CI): -0.745 (-1.395;-0.095)), the presence of U1-RNP antibodies (-0.750 (-1.314;-0,187)) as well as C-reactive protein (CRP, -0.015 (-0.026;-0.003)) and longer disease duration (-0.037 (-0.056;-0.018)) were significantly associated with low BMD. Conversely, clinical remission (defined as SLEDAI-2K=0 and GC dosage ≤5 mg prednisone equivalent per day) was positively associated with BMD (0.447 (0.037;0.857)), as were Siglec-1 levels on monocytes as surrogate for Type-I interferon activity (0.558 (0.150;0.967)), BMI (0.045 (0.014;0.076)), and health assessment questionnaire (HAQ, 0.307 (0.078;0.536)). In multivariable logistic regression analysis, active lupus nephritis (OR (95%CI): 7.42 (1.256;43.868)) was strongly associated with OP in patients with SLE. Additionally, age (1.06 (1.020;1.100)), HAQ (0.29 (0.120;0.682)) and complement factor 3 (1.27 (1.002;1.601)) were found to be significantly related to the presence of OP. Neither current GC use, cumulative GC dose nor GC duration were significantly associated with BMD or clinical OP.

Conclusion: In patients with SLE, indicators of disease severity, expressed by (active) lupus nephritis, high CRP, U1-RNP antibodies, and long disease duration, are related to poor bone health in addition to commonly known risk factors such as low BMI and higher age. The knowledge of these disease-specific factors helps to identify patients with SLE at particular high risk for OP and fragility fractures.

Abstract Number: 2018

Development of an Osteoporosis Treatment Gap Dashboard

Rulan Lyu[1], Patrick O'Brien[1], Tracey Wilkie[1], Yun Chang[1] and **Jonathan Cheah**[2], [1]UMass Memorial Health, Worcester, MA, [2]UMass Chan Medical School, Shrewsbury, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis and the clinical event of fragility fracture is an ever-increasing public health burden. A significant osteoporosis treatment gap remains, whereby individuals with a fragility fracture are never prescribed therapies for fracture risk reduction. In addition, recent specialty guidelines for the treatment of osteoporosis have started to risk stratify individuals for the purposes of sequential treatment strategies over time. The aim of this work is to utilize multiple sources of data within the electronic medical record (EMR) to identify individuals eligible, but who have not yet received therapies for fracture risk reduction who can then be targeted for intervention.

Methods: Within a single academic health system and focusing on the criteria distinguishing between high- and very high-risk patients as described by specialty guidelines relating to osteoporosis treatment, candidate items were identified to be incorporated into the dashboard. These included 1: demographic data such as race/ethnicity and primary insurance coverage, 2: ICD10 codes on problem lists relating to osteoporosis and fracture, 3: abstraction of T-scores from dual energy x-ray absorptiometry scans, 4: abstraction of vertebral compression fractures from CT and MRI reports and 5: information on

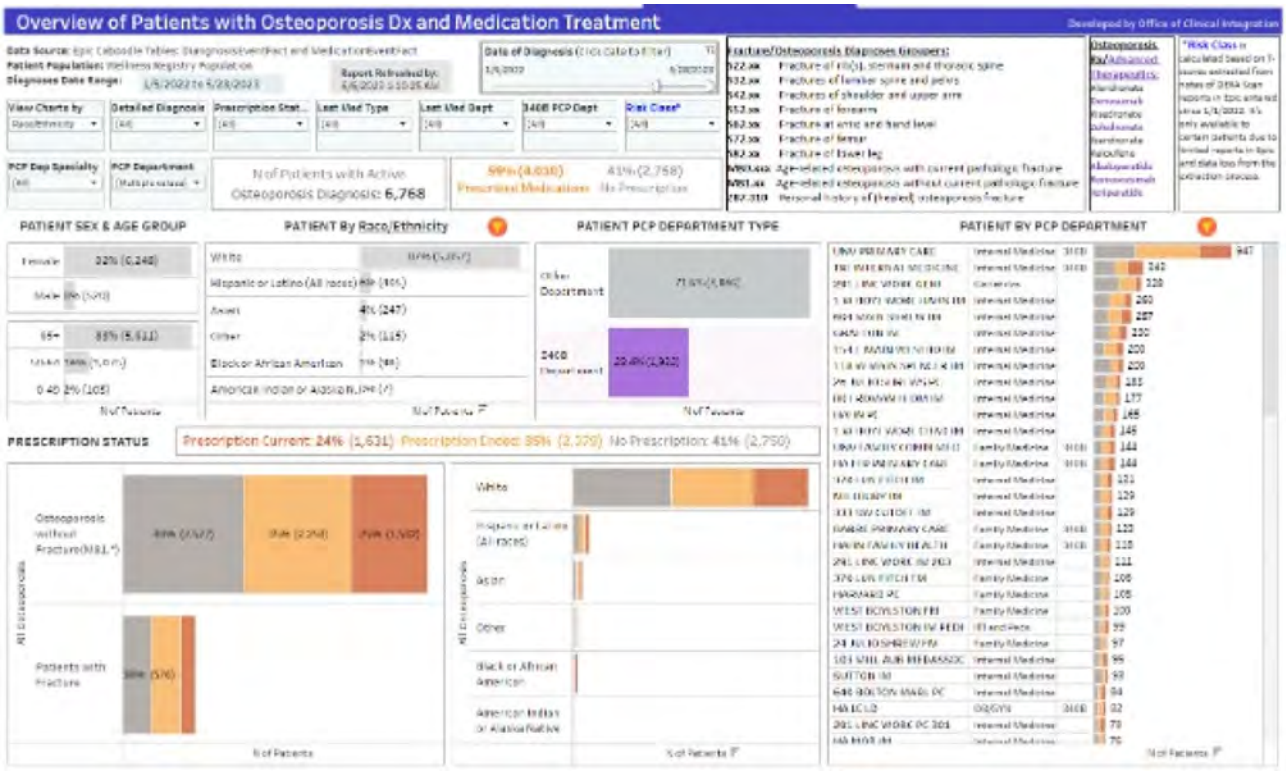

Figure 1: high level overview of osteoporosis treatment gap dashboard

prescriptions for FDA-approved medications for fracture risk reduction. The Epic Caboodle database was utilized to obtain most of the data, however, data relating to T-scores and vertebral compression fractures were abstracted separately. Once these individual pieces of data were identified, a treatment dashboard was created to present this data in an actionable format.

Results: An osteoporosis treatment gap dashboard was created (Figure 1) to identify individuals who meet diagnosis for osteoporosis by: ICD 10 code, T-score, vertebral compression fracture noted on CT or MRI reports and to stratify individuals by risk level (presence of fracture, very low t-score), as well as a number of other factors such as age, race/ethnicity, primary care provider and primary insurance coverage. Information on whether an individual has received a therapy for fracture risk reduction is also included. Specific lists of individuals can be generated accordingly, for example by primary care practice, or risk level of future fracture, to allow for locally guided interventions to address the osteoporosis treatment gap.

Conclusion: An osteoporosis treatment gap dashboard has been created which is able to identify and risk stratify individuals who per specialty guidelines would qualify for therapies for fracture risk reduction. Additional work is underway to utilize this dashboard with the aim to reduce the osteoporosis treatment gap.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is prevalent in people with inflammatory rheumatic and musculoskeletal diseases (I-RMDs) and recognized as one of the most challenging symptoms to manage (1). The existence of multiple factors that are correlated with fatigue, the lack of clarity around causal pathways and the evidence about what helps has led to a multifaceted approach to symptom management. However, there are no recommendations for fatigue management in people with I-RMDs. This lack of guidance is difficult for those living with fatigue and for healthcare professionals delivering clinical care.

Methods: A multi-disciplinary taskforce comprising 26 members from 14 European countries was convened and two systematic reviews (SRs) were conducted. The taskforce developed the recommendations based on the SR evidence and taskforce members' personal and professional experience of fatigue in I-RMDs.

Results: Four overarching principles and four recommendations were developed, which include health professionals' awareness that fatigue should be monitored and assessed, and people with I-RMDs should be offered management options. Shared decisions about fatigue management should consider the individual's needs and preferences, as well as their clinical disease activity, comorbidities and other psychosocial and contextual factors (**Table**).

Table: EULAR overarching principles and recommendations for the management of fatigue in people with inflammatory rheumatic and musculoskeletal diseases (I-RMDs)

Overarching principles			LoA Mean (SD)	LoA % with score ≥8
1. Health professionals should be aware that fatigue encompasses multiple and mutually interacting biological, psychological and social factors.			9.9 (0.3)	100
2. In people with I-RMDs, fatigue should be monitored, and management options should be offered as part of their clinical care.			9.6 (1.0)	96
3. Management of fatigue should be a shared decision between the person with an I-RMD and health and well-being professionals.			9.7 (0.7)	100
4. Management of fatigue should be based on the needs and preferences of people with I-RMDs, as well as their clinical disease activity, comorbidities and other individual psychosocial and/or contextual factors.			9.9 (0.3)	100
Recommendations	**LoE**	**GoR**	**Mean (SD)**	**% with score ≥8**
1. Health professionals should incorporate regular assessment of fatigue severity, impact and coping strategies into clinical consultations.	5	D	9.5 (1.3)	91
2. As part of their clinical care, people with I-RMDs and fatigue should be offered access to tailored physical activity interventions and encouraged to engage in long-term physical activity.	1a	A	9.6 (1.0)	96
3. As part of their clinical care, people with I-RMDs and fatigue should be offered access to structured and tailored psychoeducational interventions.	1a	A	9.5 (1.2)	96
4. The presence or worsening of fatigue should trigger evaluation of inflammatory disease activity status and consideration of immunomodulatory treatment initiation or change, if clinically indicated.	1a	A	9.4 (1.2)	82

EULAR, European Alliance of Associations of Rheumatology; LoA, Level of Agreement; LoE, Level of Evidence (1 to 5; 1=high quality RCT, and 5=expert opinion), GoR, Grade of Recommendation (A to D; A=consistent level 1 studies, and D=level 5 evidence); SD, standard deviation

Conclusion: These 2023 EULAR recommendations provide consensus and up-to-date guidance on the management of fatigue in people with I-RMDs.

Session Date: Tuesday, November 14, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: LN is a major cause of morbidity and mortality and develops in up to 60% of adult SLE patients. The experiences of patients with SLE have been explored quantitatively and qualitatively. However, we know little of the lived experiences of patients with LN. This research used a social constructionist perspective to explore patient experiences and perspectives of LN.

Methods: Patients aged≥18 years with biopsy-proven pure or mixed ISN/RPS Class III, IV, or V LN and fulfilling the ACR 1997 or SLICC 2012 Classification Criteria for SLE were purposefully recruited from a Canadian lupus cohort to participate in an innovative photovoice exercise. Over a 2-week period, participants took photos of what LN means to them, how LN impacts their daily life, and factors that impact how they manage their LN. Photos (3–5 participants) were shared and discussed in two virtual focus groups. Discussions were transcribed verbatim for subsequent thematic analysis using NVivo Software.

Table 1. Patient Characteristics

Characteristic	Total sample (N=13)
Age, mean (SD), years	41.7 (14.0)
Age at LN diagnosis, mean (SD), years	26.2 (10.1)
Age at SLE diagnosis, mean (SD), years	23.9 (10.4)
Female, %	92.3
Race & ethnicity, %	
Asian	30.8
White	61.5
Medications (ever), %	
Hydroxychloroquine	100.0
Immunosuppressants/biologics	100.0
Azathioprine	46.2
Belimumab	23.1
Cyclophosphamide	30.8
Mycophenolate mofetil/mycophenolic acid	84.6
Rituximab	23.1
Tacrolimus	23.1
LN classification, %	
Class III	33.3
Class IV	33.3
Class V	16.7
Mixed	16.7
Dialysis (ever), %	23.1
Renal transplant, %	15.4
Biopsy-proven LN within the past year and currently receiving immunosuppressants/biologic therapy, %	15.4
Biopsy-proven LN 1–5 years prior and currently receiving immunosuppressants/biologic therapy, %	23.1
Biopsy-proven LN >5 years prior and currently receiving immunosuppressants/biologic therapy, %	46.2
Biopsy-proven LN >5 years prior and no longer receiving immunosuppressants/biologic therapy, %	15.4
Women who have been pregnant or are currently pregnant and received immunosuppressants/biologic therapy during pregnancy, %	7.7

SD, standard deviation

Table 2. Results Overview

Photo Example	Primary Theme Presented in Photo	# of Photos	# of Participants	Secondary Themes Discussed	Illustrative Quote
	Wellbeing-making	n=14	n=6	-Contributing behaviours to wellbeing (e.g., rest, physical activity, listening to music, hydration, walking, diet, dogs) -Reminders of LN challenges (e.g., need for caution, symptoms, altered life trajectories)	*The mountains are also a sacred place for me, where I go to recharge and take in the fresh air and have a bath in nature... And so I believe in that, and I do find that it makes a huge difference for me. (Participant 12)*
	Participant themselves	n=13	n=6	-LN symptoms Medication side effects -Physical environment challenges -Individual management behaviours	*Sometimes they'll have a rounded doorknob, and I'm unable to enter, and they don't have the button or anything like that. Because my hands are so stiff, and I'm unable to move them, I can't open the door. One time I locked myself in a bathroom because it was a rounded doorknob. (Participant 5)*
	Healthcare experiences	n=10	n=7	-Medication challenges (e.g., number of medications required, side effects, frequency of appointments, time required, missed work, geographical distance) -Individual management behaviours	*It's a struggle sometimes, because to remember when to take them, and taking everything on time, and making sure you're taking them every day is a lot of work. As you can see there's a lot of medications that you have to take, and each of them all have different side effects. So it's hard managing some of those side effects on a daily basis. (Participant 7)*
	Home	n=5	n=4	-Reminders of LN challenges (e.g., balance of physical activity with need to be cautious) Emotional burden Reminders of responsibilities (to themselves, to family)	*This represents how it feels when you are trapped. I have called it an ice igloo, and looking out I promise myself that as soon as I'm able, I plan on taking off, but it's kind of a relief that right now I don't have to, because I feel terrible. I don't feel well, and so I have an excuse for not moving...now I live with a fairly constant fear of failure. Fear that I'm not going to be able to take off and do what I once did. (Participant 3)*
	Community	n=2	n=2	Transportation challenges LN symptoms (e.g., brain fog)	*On the train, sometimes I experience a lot of brain fog, and it's kind of holding me back right now because I want to go to school... sometimes I'll be coming home from work, and I'll be like, Wait! Where am I going? I feel confused and just lost for a few seconds. (Participant 5)*
	Friends	n=2	n=2	-Value of friendship -Reminder of physical symptoms - Individual management behaviours	*Sometimes you have to go out in the sun, to make fun with your friends. But it's a struggle to go under the sun, and after this... at the end of the day I was feverish, and having symptoms. (Participant 6)*
	Work	n=2	n=2	-Employment impacts (e.g., need for flexibility/ accommodations) Employment challenges (e.g., if flexibility/ accommodations not possible)	*Attempting to work from home just because it was a bad day, and I couldn't get out of bed. (Participant 1)*
	Other challenges	n=6	n=4	-Challenges associated with invisible illness -Financial challenges (e.g., insurance coverage for medication) -Challenges of family planning	*We were always told it was going to be harder to get pregnant. There's a lot more doctors, and medication, and appointments involved, and there's obviously a high risk of miscarriage. This is from when we had our first miscarriage, we've since had another one. Just the hardships that come with that... I've got kidney disease and it's just one of those additional complexities that you never think of. You don't realize how it's going to impact your life until it does. There's nothing you can really do about it, there's not a lot of information either. (Participant 8)*

Results: Thirteen patients withLN participated; 92.3% were female, mean (SD) age was 41.7 (14.0) years (**Table 1**). Of the 54 photos, images depicting activities/settings that contribute to wellbeing (n=14), the participants themselves (n=13), healthcare experiences (n=10), home (n=5), work (n=2), community (n=2), friends (n=2), and other challenges (n=6) were shared (**Table 2**). All participants described the physical (e.g., fatigue, joint pain, rash) and psychosocial (e.g., fear, stress, social exclusion, feeling trapped, grief, and loss) impacts of living with LN. Although twelve discussed activities that contribute to well-being (e.g., listening to music, biking, walking dogs, spending time with family/friends, spending time in nature), participants were consistently reminded of their LN during/following these activities due to physical symptoms (*There'd be days where my hands would cramp up and my knees would be stiff, but I just push through… because I love that experience of looking around at my surroundings, and the leaves falling (P5)*), the need for caution while participating (*I only rode [the bike] once, because I am always hearing my doctors very sage advice in my ear. Be careful, don't overdo it (P3)*), and altered life trajectories (*My husband and I had envisioned we'd be playing with grandchildren… but I was never able to carry… [The dogs] are affectionate, loyal, and they need us… so they are sort of the light (P3); You're always at a crossroad, you're always having to make a decision… you have to turn left or right, you can't keep going straight (P8)*). Eleven participants discussed the need for, and burden of, medications to manage their LN; side effects (n=10) and medication-related financial challenges (n=5) were highlighted.

Conclusion: Respondents reported a substantial psychosocial burden associated with their LN diagnosis. While activities that contribute to well-being were emphasized, the physical, emotional, and lifestyle impacts of LN and the associated medication journey serve as frequent reminders of the disease burden, both now and into the future. The need for flexibility (i.e., from friends, employers, and themselves) is an essential component of navigating altered life trajectories.

Beliefs, Attitudes, and Preferences of Patients with Rheumatoid Arthritis (RA) and Concomitant Cancer with Respect to RA Therapy

Juan Ruiz[1], Sheneze Madramootoo[2], Maria A. Lopez-Olivo[1], Namrata Singh[3] and Maria Suarez-Almazor[4], [1]The University of Texas, MD Anderson Cancer Center, Houston, TX, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]University of Washington, Bellevue, WA, [4]MD Anderson Cancer Center, Houston, TX

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) in patients with cancer could potentially result in poor cancer outcomes because of immunosuppression. Adequate data for shared decision-making in patients with RA and cancer is scarce, as there are uncertainties about the risk of various RA therapies on cancer progression and recurrences. The aim of this study was to identify the beliefs, preferences, and informational needs of patients with RA and cancer with respect to the harms, benefits, and risk uncertainties of RA therapy.

Methods: We conducted individual interviews of 20 patients with RA and cancer recruited consecutively at outpatient clinics in a cancer center. We used a semi-structured guide for the interviews. We explored the following themes: i) past experiences in medical encounters, ii) beliefs and attitudes about harms and benefits of RA, and iii) decision making process about RA treatment. We conducted a thematic analysis to interpret data.

Results: Fifteen (75%) patients were female, mean age was 59.4 years (SD 10.2). Median RA duration was 11 years. Four (20%) patients had breast cancer, four (20%) had melanoma, two (10%) had lymphoma, and each of the other 10 had another different cancer. (1) Past experiences. Patients reported discussing concerns with their physicians about RA symptoms, the impact of RA treatment on RA, adverse events, interactions between RA and oncologic therapies, and discontinuation of RA treatment after cancer diagnosis. Most patients felt their concerns were addressed after the discussion with their providers. (2) Beliefs and attitudes. Few patients were concerned about the risk of cancer development or recurrence with RA treatment, and some mentioned lymphoma risk with biologics. Patients were concerned about the impact of cancer treatment on RA, RA flare-ups, and suppression of their immune system. (3) Decision making process. Most patients felt decisions were shared with their providers including discontinuing, changing, or adding new drugs. Most common decision facilitators included discussions with their physicians and their own previous experiences. Most patients would consider taking a drug to improve RA even if the effect on cancer were unknown. Informational needs included the following areas: (i) adverse events and efficacy of drugs, (ii) drug interactions, (iii) impact of RA drugs on cancer, and (iv) costs. With respect to delivery of information, many patients, but not all, found other patients' testimonials helpful. Preferred types and formats for information included pictures, graphs, and numerical information (e.g. probabilities) on benefits and harms. Various modes of delivery were identified such as mailings, emails, websites, electronic medical records, videos, and through discussion with providers.

Conclusion: We identified important aspects related to the preferences, concerns, and informational needs in the treatment decision making process of patients with RA and cancer. Discussions with physicians were the most important factor to make decisions about RA treatment, but patients also identified other potential sources of information that could aid in this process.

Development of an mHealth App for Lupus: Insights from a Human-Centered Design Approach

Anna Deck[1], Kiran Singh[2], Lucas Dantas[3], Amy LeClair[2], Lisa Mandl[4], Timothy McAlindon[5], Faye Chiu[6], Monique Gore-Massy[7] and Shanthini Kasturi[2], [1]Tufts University School of Medicine, Boston, MA, [2]Tufts Medical Center, Boston, MA, [3]Ambulomics, Boston, MA, [4]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [5]Tufts Medical Center, Arlington, MA, [6]N/A, New York, NY, [7]Covid-19 GRA, West Orange, NJ

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Mobile health (mHealth) technology offers promising tools to facilitate the self-management of chronic diseases, including systemic lupus erythematosus (SLE). However, currently available mHealth applications (apps) for SLE are of limited quality and functionality, having largely been developed without the direct input of individuals living with

SLE. Human-centered design is a method of problem-solving that strives to put real people at the center of the development process and involves three steps: inspiration, ideation, and implementation. Here we describe the application of human-centered design methodology to elicit patient preferences and guide the development of an mHealth app for the management of fatigue in SLE.

Methods: Patient perspectives and preferences for an mHealth app addressing fatigue in SLE were explored in the inspiration phase through literature review, focus groups, and targeted conversations with patients. Key features for the app were identified and an initial prototype was developed in the ideation phase. Individuals with SLE reviewed the prototype in in-depth interviews and surveys. Participants were purposefully sampled around age, sex, race, ethnicity, and disease duration. They provided open-ended feedback on app functionalities and format, and rated features using a 5-point Likert scale. Interviews were conducted online using cloud-based video conferencing (Zoom) and were recorded, transcribed, and analyzed using a rapid analysis protocol and feedback capture grid. The prototype was iteratively refined in multiple cycles of feedback.

Table 1. Interview participant characteristics (n=10)

Characteristic	Value
Age Mean (SD) years	41.5 (8.6)
SLE disease duration Mean (SD) years	14.2 (7.8)
Sex	
Female	8 (80%)
Male	2 (20%)
Race	
White	4 (40%)
Black or African-American	3 (30%)
Asian	1 (10%)
More than one race	2 (20%)
Ethnicity	
Hispanic	4 (40%)
Non-Hispanic	6 (60%)
Insurance Type	
Medicaid	1 (10%)
Medicare	2 (20%)
Third party/private	6 (60%)
None	1 (10%)
Education	
High school graduate	2 (20%)
Associate degree	1 (10%)
Bachelor's degree	4 (40%)
Graduate degree	3 (30%)
Employment	
Part Time	1 (10%)
Full Time	4 (40%)
Self-Employed	2 (20%)
On Disability	3 (30%)

Table 2. Prototype Ratings [mean (standard deviation), where 1= Love it and 5= Hate it]

	Prototype 1 (n=10)	Prototype 2 (n= 7)
Features		
Education	1.6 (0.7)	Not rated
Self-Assessment Quizzes	2.1 (1.2)	Not rated
Goal setting and logs	1.6 (1.0)	Not rated
Trackers (steps/sleep/mood)	1.7 (1.0)	Not rated
Reminders	1.4 (0.7)	Not rated
Community/Social connection	1.4 (0.5)	Not rated
Format		
Color scheme	2.1 (0.8)	2.1 (1.1)
Layout	2.0 (0.9)	1.1 (0.4)
Text	2.0 (1.0)	1.9 (0.9)
Graphics/Images	1.9 (0.9)	1.9 (0.9)
Likeliness to use app	1.7 (0.9)	1.7 (0.8)

Results: Twelve patients from two academic medical centers participated in two initial focus groups and brainstormed features and functionalities for the app. Research team members, including two patient stakeholders, developed an initial app prototype based on ideas generated in the inspiration phase. Ten individuals with SLE (Table 1) provided feedback on the initial prototype and subsequent iterations in two rounds of surveys and interviews. Overall, participants rated the features and format of the prototypes highly (Table 2) and over 80% reported they were likely or highly likely to use the proposed app. Several themes around preferences for the app emerged from the interviews (Figure 1), including the importance of 1) community/social connection; 2) accessibility and inclusion, and 3) options for customization and integration of the app with existing digital health tools and health care. Participants highlighted the potential of the app to facilitate self-management and improve quality of life, but noted sustained engagement as a possible challenge.

Conclusion: A patient-engaged, human-centered design approach provided valuable insights into patient preferences and priorities for an mHealth app for the management of fatigue in SLE. Feedback from the inspiration and ideation phases will inform iterative prototype refinement and guide app pilot testing (implementation).

Abstract Number: 2023

Transition Readiness over Time in a Rheumatology Transition Clinic

SESSION INFORMATION

Session Date: **Tuesday, November 14, 2023**
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2018 we designed a Rheumatology Transition clinic to care for adolescent patients with autoimmune disease. We incorporate Health Care Transition curriculum (HCT) into our clinic to improve Transfer outcomes as patients move from a pediatric to adult healthcare model. As part of this HCT, we ask our participants to complete a Transition Readiness Assessment (TRA) that mirrors the same assessment available from the GotTransition website. This assessment quantifies a patient's preparedness to become independent in managing their own health care. This abstract presents

Table 1: Patient demographics

Variable	Summary (N=129)
Age at diagnosis: Mean (SD)	13.2 (4.3)
Median (IQR)	15.0 (11.0, 16.0)
Range	(1.4, 19.0)
Age at enrollment: Mean (SD)	18.8 (1.8)
Median (IQR)	19.0 (18.0, 20.0)
Range	(14.0, 25.0)
Sex: Female	97 (75.2%)
Male	32 (24.8%)
Gender Identity: Cis-female	46 (70.8%)
Cis-male	12 (18.5%)
Non-binary	3 (4.6%)
other	4 (6.2%)
Race: American Indian or Alaskan Native	1 (0.8%)
American Indian or Alaskan Native/Black or African American/White	1 (0.8%)
Asian	4 (3.1%)
Asian/Native Hawaiian or Other Pacific Islander	1 (0.8%)
Black or African American	4 (3.1%)
Black or African American/White	1 (0.8%)
Hawaiian or Other Pacific Islander	2 (1.6%)
Not Reported	3 (2.3%)
Other	4 (3.1%)
Unknown	3 (2.3%)
White	105 (81.4%)
Ethnicity: Hispanic or Latino	21 (16.3%)
NOT Hispanic or Latino	101 (78.3%)
Not Reported	3 (2.3%)
Unknown	4 (3.1%)
Time between surveys: Mean (SD)	358.9 (238.2)
Median (IQR)	290.5 (187.8, 401.5)
Range	(91.0, 906.0)

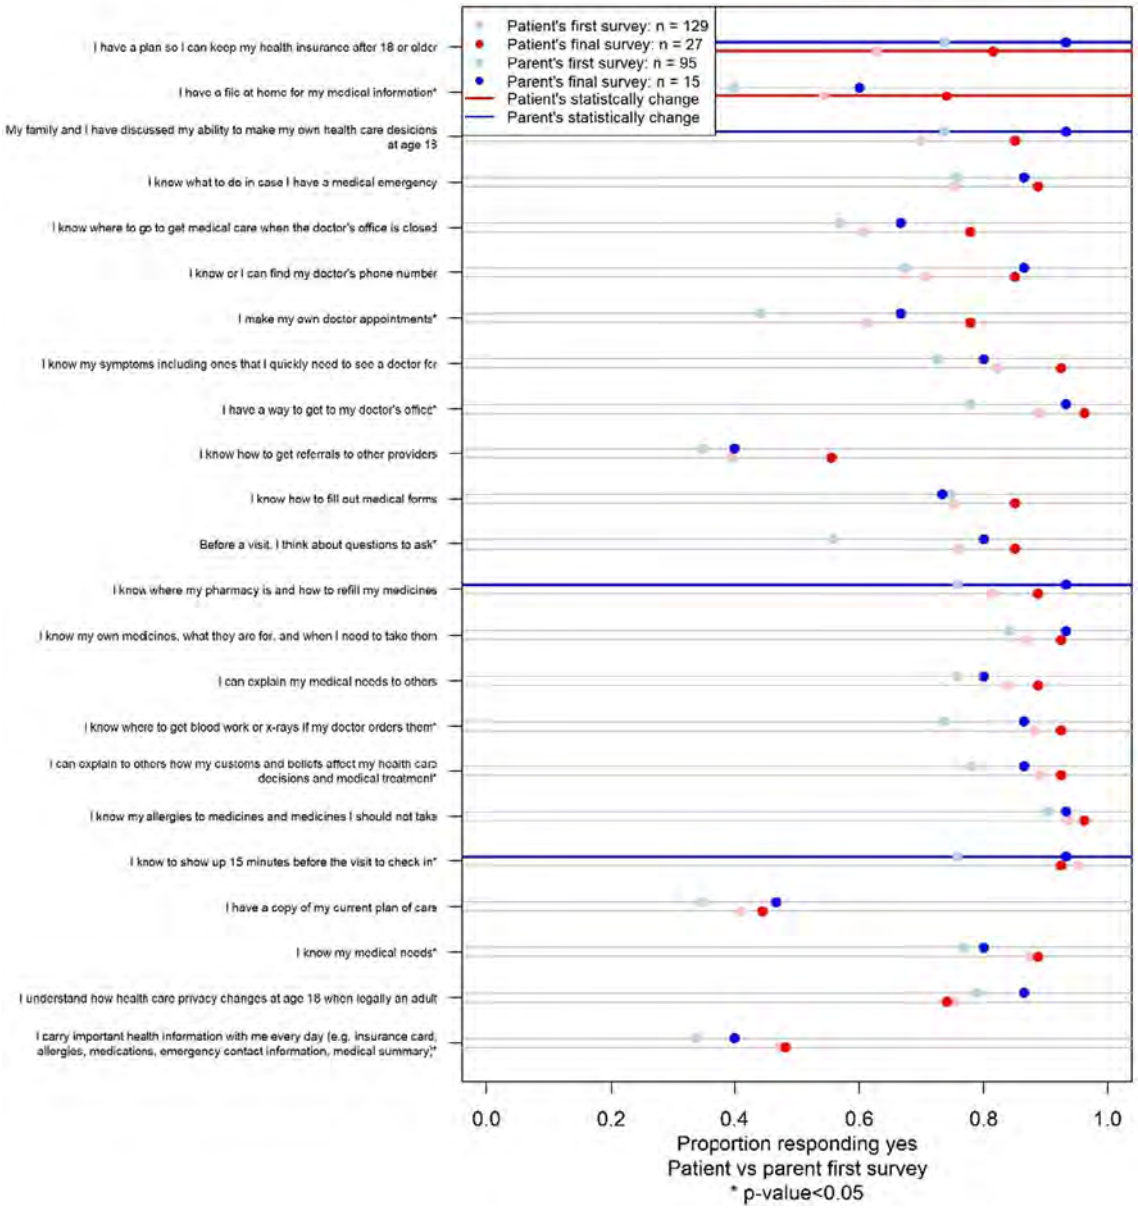
Missing values: Age at diagnosis = 3, Age at enrollment = 3, Gender Identity = 64, Time between surveys = 105.

preliminary data from the TRA, contrasting responses over time in individual patients and parents, and the responses from the patients versus their parents or legal guardians.

Methods: Participants are asked to complete the TRA. The TRA is requested at two time points. First, when patients are first evaluated. Second, just before their first clinical visit with an adult Rheumatologist in an adult Rheumatology clinic.

Responses from the patients at the two time points were evaluated and compared using appropriate statistical analyses. To assess the significance of changes in responses over time, a t-test was conducted to compare the patients' first and second answers. The mean (SD) was calculated to summarize the age at diagnosis, age at enrollment, and the number of days from the first survey to the second survey. Additionally, the median (interquartile range, IQR) and range were used to summarize the distribution of these variables. Categorical variables such as sex, gender identity, race, and ethnicity were summarized using N (%) to indicate the number and percentage of patients within each category.

Figure 1: TRA responses over time



Results: As of May 2023, we had 129 patient and 95 parent participants in the first TRA; and 27 patient and 15 parent participants in the second TRA (Table 1: Patient demographics). In all but two variables, patients and parents report improvement in Transition readiness. Patients report better Transition readiness, than do parents, when they are first enrolled into the registry. Where there is a statistically significant disparity between patients and parents in their assessment, it is patients who report better Transition readiness at registry enrollment. However, where there is a statistically significant disparity in their assessment over time, it is parents who are more likely to report a longitudinal improvement in their child's Transition readiness over time (Figure 1: TRA responses over time).

Conclusion: These findings alone do not prove a causative effect between the HCT curriculum in our Transition clinic and improved Transition readiness over time. However, this improvement in Transition readiness over time is encouraging. Potential confounders might include an independent progression in maturity and independence with age that might also improve Transition readiness. In our future research, we will work to understand patient-specific variables that influence improved Transition readiness, and if there is a correlation with Transition readiness and Transfer and medical outcomes.

Abstract Number: 2024

Patient-Reported Outcomes in Patients with Lupus Nephritis: A Post Hoc Analysis of Control Arm Data from Two Completed Phase III Randomized Clinical Trials

Christophe T. Tchakoute[1], Huiyan (Ashley) Mao[2], Gene Wallenstein[1], Jorge Ross Terres[1], Seitaro Yoshida[1] and **Lisa Lindsay**[1], [1]Genentech, Inc., South San Francisco, CA, [2]Hoffmann-La Roche Ltd, Mississauga, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a severe and common (50%) organ-threatening manifestation of systemic lupus erythematosus and is associated with a high risk of progression to chronic kidney disease and kidney failure.[1] LN treatment goals include normalization of kidney function, low disease activity and, increasingly, improvements in health-related quality of life (HRQOL). Assessment of content validity for the Short Form-36 (SF-36) and FACIT-Fatigue scales have identified fatigue, pain, vitality and physical well-being as particularly impactful in patients with LN compared with healthy controls.[2,3] Limited data exist on the relationship between renal function and HRQOL in patients with LN.

Methods: We conducted a post hoc descriptive analysis of data collected from the control arms of 2 global Phase III LN RCTs: LUNAR (NCT00282347)[4] and BELONG (NCT00626197).[5] We excluded active-arm patients to focus on patients receiving standard of care (SOC) therapy. These studies included adult ANA+ patients with biopsy-confirmed class III/IV LN and proteinuria. We described patients according to baseline factors and characterized HRQOL scores over study week. The LUNAR trial included the Expanded Health Survey (EHS) (Weeks 0, 12, 24 and 52), and BELONG included the SF-36, FACIT-Fatigue and modified Brief Pain Inventory (Weeks 0, 12, 24, 36 and 48). The SF-36 and EHS include information on general health, social/physical functioning, role limitations due to physical/emotional problems, vitality, emotional well-being and pain. We analyzed these tools based on recoding responses to a range of 0 to 100, with higher values representing better HRQOL. We assessed the relationship between (1) baseline proteinuria (urine protein creatinine ratio [UPCR]) and (2) complete renal response (CRR) and mean change in fatigue and general health scores using stratified analyses and Mann-Whitney test for differences.

Results: Table 1 describes baseline study-specific patient characteristics. The lowest baseline scores were identified for general health and vitality in the SF-36 and for fatigue, tiredness and energy in the FACIT-Fatigue. **Figure 1** provides SF-36 scores for general health, pain, vitality, physical functioning and fatigue by study week. HRQOL trajectories suggest consistent patterns across trials with improvements in domains such as fatigue and pain. Patients with baseline UPCR ≥3 had greater change in fatigue score at Week 52/48 than those with UPCR < 3 (**Figure 2**). We did not identify significant changes in fatigue score by CRR status, nor change in general health score at Week 52/48 according to baseline UPCR or CRR.

Table 1. Description of Study Population at Baseline: Control Arm Data From the LUNAR and BELONG LN Trials

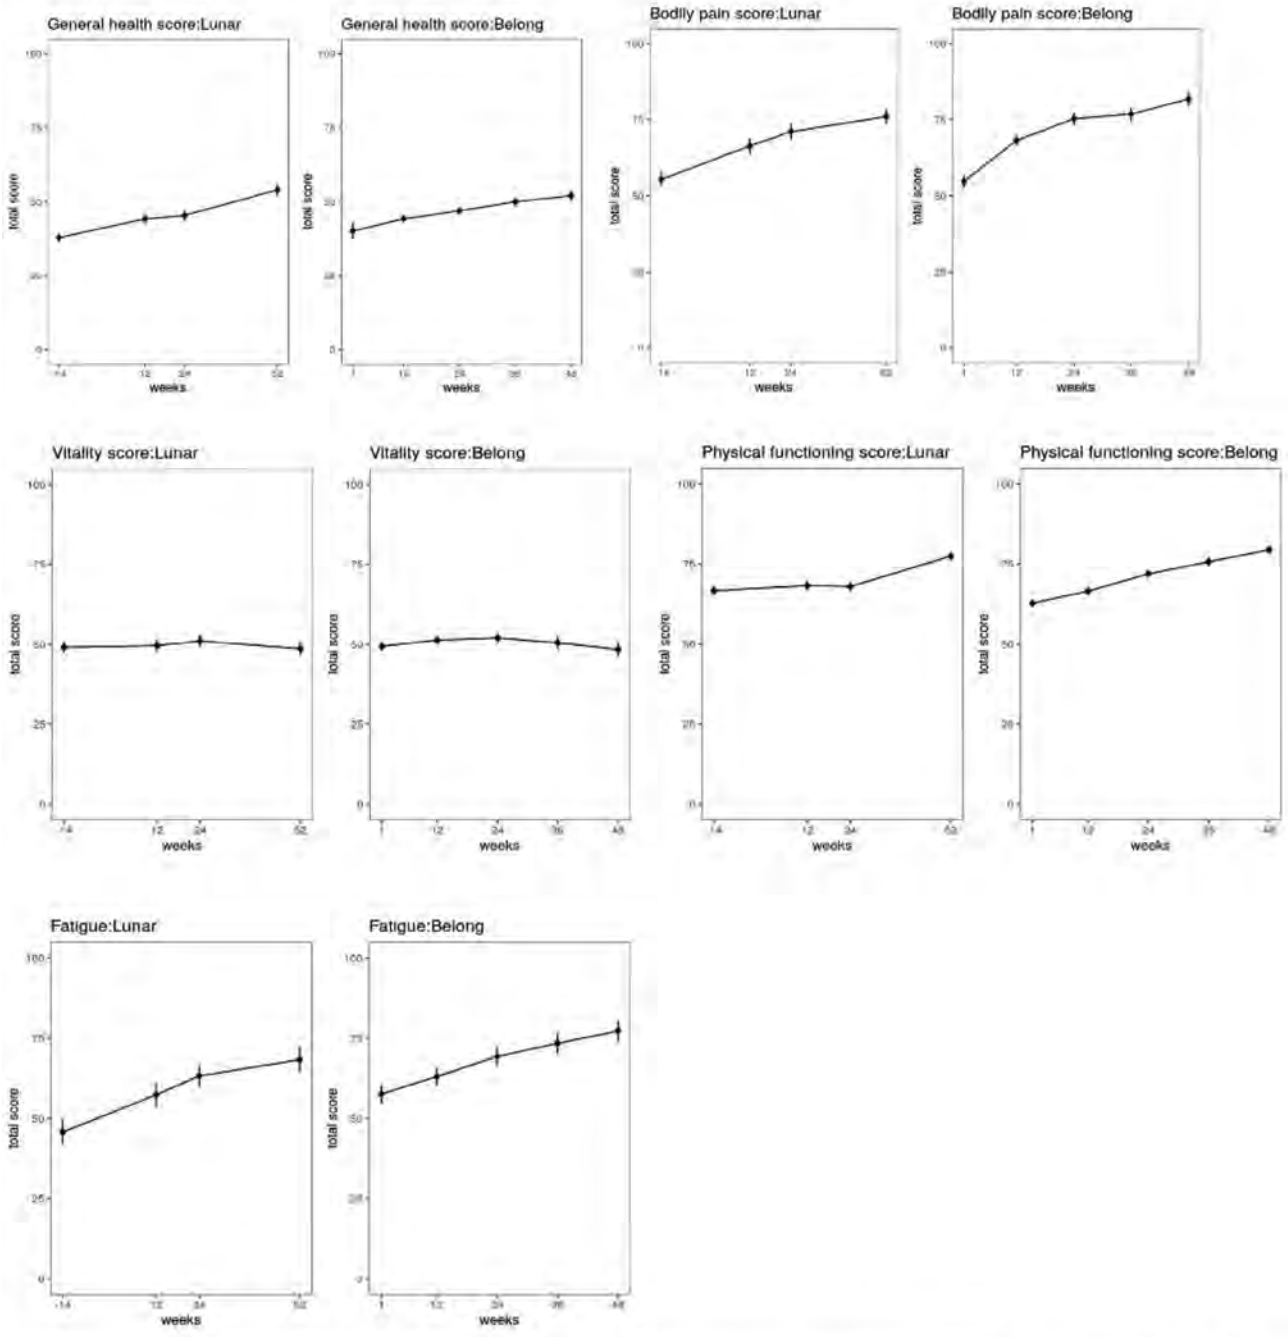
	LUNAR (N=72)*	BELONG (N=126)†
Study period	Jan 2006 – Nov 2009	Feb 2008 – Sept 2010
SOC used in control arm	MMF	MMF or CYC/AZA
Follow-up time, median (Q1, Q3), months	18.5 (17.0, 24.3)	14 (10.8, 18.0)
Age, mean (SD), years	29.4 (9.3)	31.4 (9.9)
Female sex, n (%)	67 (93.1)	107 (84.9)
Race and ethnicity, n (%)		
American Indian or Alaskan Native	0 (0)	17 (13.5)
White	26 (36.1)	58 (46.0)
Black or African American	19 (26.4)	5 (4.0)
Asian	3 (4.2)	35 (27.8)
Other	23 (31.9)	11 (8.7)
Multiple	1 (1.4)	0 (0)
Region, n (%)		
Latin America	20 (27.8)	47 (37.3)
United States	52 (72.2)	15 (11.9)
Europe	0 (0)	31 (24.6)
Asia	0 (0)	31 (24.6)
Africa	0 (0)	1 (0.8)
LN Class		
III ± V	24 (33.3)	30 (23.8)
IV ± V	48 (66.6)	96 (76.2)
Serum creatinine, mean (SD), mg/dL	1 (0.5)	0.89 (0.4)
UPCR, mean (SD), mg/mg	4.4 (3.1)	6.3 (27.2)
eGFR, mean (SD), mL/min/1.73m²	93.7 (36.6)	98.2 (29.5)
C3, mean (SD), mg/dL	74.1 (27.9)	64.7 (25.6)
C4, mean (SD), mg/dL	13.8 (9.4)	14.9 (8.5)

AZA, azathioprine; CYC, cyclophosphamide; eGFR, estimated glomerular filtration rate; LN, lupus nephritis; MMF, mycophenolate mofetil; SOC, standard of care.

*The LUNAR trial was a Phase III, randomized, double-blind, placebo-controlled, multicenter study to evaluate the efficacy and safety of rituximab in combination with MMF compared with placebo in combination with MMF in patients diagnosed with International Society of Nephrology/Renal Pathology Society (ISN/RPS) 2003 Class III or IV LN.

†The BELONG trial was a Phase III, randomized, double-blind, placebo-controlled, multicenter, parallel-group study designed to evaluate the efficacy and safety of ocrelizumab added to SOC (corticosteroid plus 1 of 2 immunosuppressant regimens) compared with placebo added to SOC in patients with WHO or ISN Class III or IV LN. The BELONG trial terminated early (October 19, 2009) due to an imbalance in infections in the active arm of the trial. Thus, the maximal follow-up for this post hoc analysis was 48 weeks.

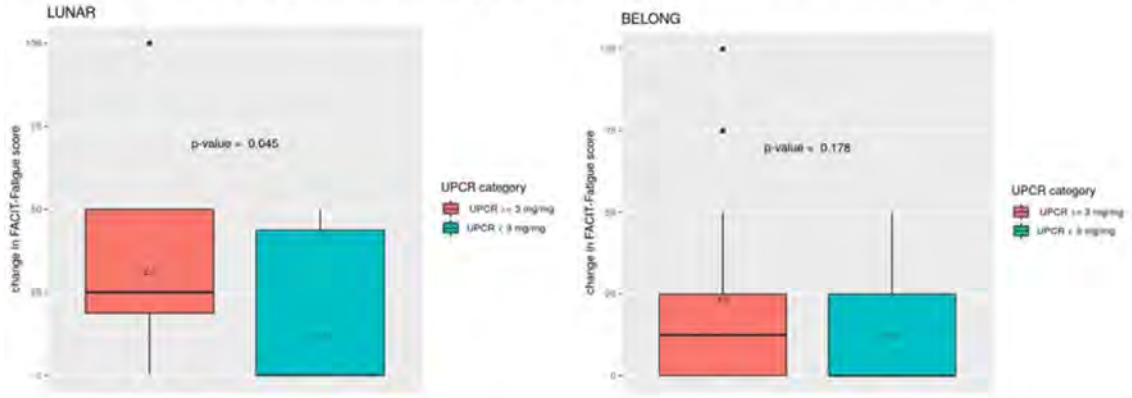
Figure 1. SF-36 Scores* According to Study Week in Control Arm Patients From the LUNAR and BELONG Trials for General Health, Pain, Vitality, Physical Well-Being and Fatigue†



*Patient responses were recoded on a range of 0 to 100, with higher values representing better HRQOL, consistent with Rand Corporation SF-36 scoring instructions. Standard errors were calculated for each score.
†The time frame for each domain was as follows: general health = now; pain, physical well-being and vitality = prior 4 weeks; fatigue = prior 4 weeks in the LUNAR trial and prior 7 days in the BELONG trial.

Conclusion: Initial post hoc analysis of patients in the control arms of the LUNAR and BELONG trials suggest greater improvements in fatigue among patients with baseline UPCR ≥3. Additional multivariate analyses will provide enhanced understanding of the relationship between renal function and HRQOL over time.

Figure 1. Mean Change in Fatigue Scores According to Baseline Proteinuria in the LUNAR and BELONG Trials



Fatigue†	LUNAR			BELONG		
	Baseline proteinuria (UPCR)*			Baseline proteinuria (UPCR)*		
	≥3 mg/mg (n=37)	<3 mg/mg (n=23)	Overall (N=72)	≥3 mg/mg (n=59)	<3 mg/mg (n=64)	Overall (N=126)
Baseline						
Mean (SD)	45.8 (30.8)	53.3 (30.4)	45.7 (31.3)	52.3 (30.4)	62.3 (27.6)	57.6 (29.1)
Median (Q1, Q3)	50.0 (25.0, 75.0)	50.0 (25.0, 75.0)	50.0 (25.0, 75.0)	50.0 (25.0, 75.0)	75.0 (50.0, 75.0)	50.0 (37.5, 75.0)

Osteoporosis Treatment Attributes and Levels for an Online Decision-Making Tool for Patients: Findings from Adaptive Choice-Based Conjoint Analysis

Jeffrey Curtis[1], **Kelly Gavigan**[2], W. Benjamin Nowell[3], David Curtis[4], Danielle Ali[5], Xiaoyu Liu[6], Katherine Makaroff[6], Christopher Almario[6], Carine Khalil[6], So Yung Choi[7] and Brennan Spiegel[6], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Global Healthy Living Foundation, Upper Nyack, NY, [3]Global Healthy Living Foundation, Nyack, NY, [4]Global Healthy Living Foundation, San Francisco, CA, [5]Global Healthy Living Foundation, Upper Nayack, NY, [6]Cedars-Sinai Center for Outcomes Research and Education (CS-CORE), Los Angeles, CA, [7]Biostatistics and Bioinformatics Research Center, Cedars-Sinai Cancer, Los Angeles, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis (OP) treatment options have different attributes based on mode of administration, frequency of administration, risks of minor and serious side effects, and effectiveness, among others. People living with OP (pts) prioritize different aspects of OP treatment based on their own preferences and on physician recommendations. The study's objective was to assess individual preferences among pts to inform an online decision-making tool for OP treatment.

Methods: An adaptive choice-based conjoint (ACBC) analysis survey was developed to quantify the relative importance of 6 OP medication attributes. Pts from Cedars-Sinai academic medical center were invited to complete the online conjoint exercises. The conjoint software determined each pt's preferences by calculating importance scores for each medication attribute (higher=more important). Results of the conjoint exercise were used to develop an online treatment decision-making tool for OP. We then tested the tool and the website it lives on with OP pts to improve functionality. User testing

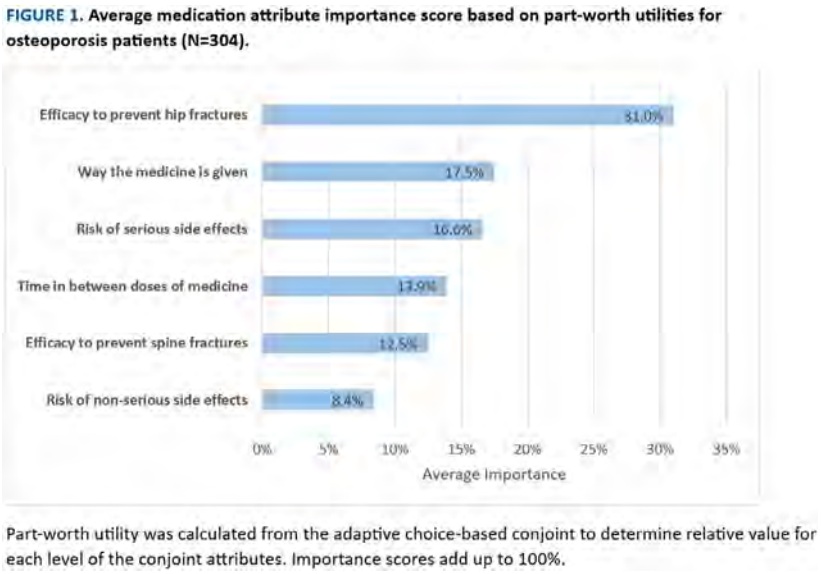

FIGURE 1. Average medication attribute importance score based on part-worth utilities for osteoporosis patients (N=304). Part-worth utility was calculated from the adaptive choice-based conjoint to determine relative value for each level of the conjoint attributes. Importance scores add up to 100%.

TABLE 1. Final attributes and levels included in the online decision tool.

Scenario attribute	Attribute levels
Way the medicine is given	• By mouth, self-administered, daily • By mouth, self-administered, weekly • By mouth, self-administered, monthly • Injection, self-administered, daily • Injection, provider-administered, monthly • Injection, provider-administered, every 6 months • Intravenous, provider-administered, yearly
Effectiveness to prevent spine fractures	• 50% • 80%
Effectiveness to prevent hip fractures	• 0% • 25% • 50%
Effectiveness to improve bone mineral density	• 4% at the hip and 9% at the spine • 9% at the hip and 18% at the spine
Risk of non-serious side effects	• No increased risk compared to not taking the medicine • 2% increased risk compared to not taking the medicine • 4% increased risk compared to not taking the medicine
Risk of serious side effects	• No increased risk compared to not taking the medicine • 1 out of 100,000 people (0.001%) • 10 out of 100,000 people (0.01%)

TABLE 1. Final attributes and levels included in the online decision tool.

involved recruiting a sample group of OP pts from the ArthritisPower research registry to review the website and use the tool while researchers remotely observed their behavior and collected feedback.

Results: A total of 304 pts completed the ACBC survey. Based on importance score, the most important attributes in the decision-making process were efficacy at preventing hip fractures (31.0%), way the medicine is given (17.5%), and risk of serious side effect (16.6%) (Figure 1). Attributes and levels for the final decision-making tool were based on results of the ACBC survey and informed by currently available treatment options, iterative feedback from providers and drug manufacturers, and user testing with 5 OP pts. Effectiveness to improve bone mineral density (BMD) was added as an attribute to reflect currently available OP treatments that demonstrate improvement in BMD but lack clinical data demonstrating effectiveness to prevent fractures. User testers encountered challenges with understanding how certain questions worked. While the question types could not be changed, as they are fundamental to the conjoint analysis exercise, the functionality of some of the questions were improved and additional directions were added at the start of the tool.The decision-making tool with final list of attributes and levels is being developed and disseminated by a patient advocacy organization (Table 1).

Conclusion: Pts with OP may benefit from identifying personal preferences using an online treatment decision-making tool developed with input from pts, providers, and researchers. A publicly available tool such as this may facilitate productive patient-provider conversations and foster shared decision-making for OP therapies in fracture liaison services and other clinical settings.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Telehealth services and, increasingly, remote therapeutic monitoring, can be used to enable the continuum of clinical care in out-of-office settings. This remotely provided care can increase personalization of healthcare by using patient-relevant data, but lack of opportunity for in-person examination may remain a barrier. Our objective was to develop and pilot a smartphone application (app)-based program to teach patients to perform guided self-examination to measure the disease activity of their rheumatoid arthritis (RA), to facilitate remote care.

Methods: An in-app tool to instruct patients with RA to conduct a self-guided 28 tender and swollen joint count (28-TJC, 28-SJC) was developed for the ArthritisPower research registry app based on previously developed videos[1]. An instructional script of on-screen messaging and animations was iteratively refined by the study team of physicians, researchers, patients, and patient advocates. A storyboard of the final script was user tested with ArthritisPower members living with RA. The tool was then piloted in the ArthritisPower app by RA patients in a community rheumatology practice to gain feedback on the user interface and user experience. Participation in the pilot consisted of registering for ArthritisPower, completing six physical and social health patient reported outcomes (PROs) (PROMIS measures for Pain Interference, Physical Function, Fatigue, and Satisfaction with Participation in Discretionary Activities; RADAI-5; and OMERACT RA Flare), and completing the guided, self-conducted 28-TJC, 28-SJC. The in-app assessment was compared to in-person assessment by a rheumatologist within 6 days of a scheduled office visit.

Results: Five RA patients participated in the pilot testing. The mean (SD) time to completion for the PROs and joint self-assessment tool was 18.3 (3.5) minutes, with the PROs taking 5.4 (0.9) minutes on average and the joint self-assessment taking 12.9 (3.5) minutes on average to complete. Based on this pilot, edits were made to the tool. These included simplifying the language in the registration process, clarifying what was required to successfully complete participation and the expected time commitment, clarifying concepts of tender and swollen joints, adding inspirational progress messaging, and refining the instructional tool. Example screens from the in-app module can be found in Figure 1.

Conclusion: Piloting in real-world settings highlighted areas for change that are hoped to increase successful participation, such as simplifying language, clarifying requirements, and adding motivational messaging. The refined tool is currently being deployed in a larger study to evaluate the accuracy and utility of patient-conducted TJC and SJC for guiding RA management decisions. [1]Grainger, et al. ACR Open Rheum. 2020;2(12):705-709.

Developing and Implementing a Pilot Educational Intervention to Improve Readiness for Self-Management Among Patients with Rheumatic Diseases in Uganda

Trina Pal[1], Auther Jjunju[2], joshua bilsborrow[3], Lillian Tugume[4], Rachel Galvao[3], Evelyn Hsieh[5] and Mark Kaddumukasa[4], [1]Section of Rheumatology, Yale School of Medicine, West Hartford, CT, [2]The Arthritis Association of Uganda, Kampala, Uganda, [3]Section of Rheumatology, Yale School of Medicine, New Haven, CT, [4]Department of Medicine, School of Medicine, College of Health Sciences, Makerere University, Kampala, Uganda, [5]Yale University, Department of Medicine, Section of Rheumatology; Yale School of Public Health; Section of Rheumatology, VA Connecticut Healthcare System, Westport, CT

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Self-management is an effective strategy for improving health outcomes among patients with chronic conditions such as rheumatic diseases. Patient education about self-management among patients with rheumatic disease in Uganda is limited. In collaboration with The Arthritis Association of Uganda (TAAU), a fully registered, patient-led NGO, this pilot study aimed to evaluate the feasibility of developing and implementing a virtual patient education series and collecting information regarding self-management.

Methods: Four virtual sessions were developed together with direct input from the Ugandan rheumatology patient perspective. Adults ≥18 years of age receiving care at the Mulago Hospital Rheumatology Clinic were invited to participate. Patients were asked to complete a survey at enrollment regarding demographic and clinical characteristics and self-management readiness via the validated 13-item Patient Activation Measure (PAM) tool (see table), and an Exit Survey to re-assess the PAM. Feasibility and acceptability metrics were collected including the ability of the study team to develop and deliver all sessions as planned, attendees per session, attendees who returned for subsequent sessions, attendees who completed each of the surveys, barriers that were faced, and patient satisfaction.

Results: The four topics selected and developed, based upon the experience and input of TAAU, encompassed: Introduction to Arthritis, Exercise & Nutrition, Women's Health & Rheumatic Disease, and Understanding My Disease & Rheumatology Medications. Sessions were delivered over Zoom from 1/2023 - 5/2023, approximately every other week prior to the start of the morning clinic. Each topic was presented twice to maximize patient participation. Local team members simultaneously interpreted content into Luganda. An average of 21 participants (range 17-24) attended each session (mean age 48 ±14 years, 72% women). Reported diagnoses included rheumatoid arthritis, osteoarthritis, systemic lupus erythematosus, crystalline arthritis, psoriatic arthritis, and "not sure". A total of 33 Enrollment Surveys and 41 Exit Surveys were collected. Mean raw PAM scores were 36.9±3.8 at enrollment and 41.5±2.2 at exit. Challenges encountered and discussed included language barriers, adapting medical terminology to health literacy levels, and administrative/logistical hurdles (internet connection reliability, preparing and managing hard copies of the surveys, accessing the meeting space, inclement weather, accommodating interest in remote participation). Patients reported sessions were useful, appropriate and engaging, and expressed a strong interest in additional future sessions.

Conclusion: In this pilot study, we demonstrated the feasibility of developing and implementing an educational series focused on self-management for patients with rheumatic diseases and collecting associated measures. Our findings will directly inform the design and delivery of future expanded interventions on this topic. Next steps will include formal cultural

Table 1: 13-Item Patient Activation Measure

	When you think about your rheumatic condition and your rheumatology care, how much do you agree or disagree with the following statements? *(Check the box that applies)*	Strongly Disagree	Disagree	Agree	Strongly Agree	Not Applicable
1	When all is said and done, I am the person who is responsible for managing my rheumatic condition					
2	Taking an active role in my own health care is the most important factor in determining my musculoskeletal health and ability to function					
3	I am confident that I can take actions that will help prevent or minimize some symptoms or problems associated with my rheumatic condition					
4	I know what each of my prescribed rheumatology medications do					
5	I am confident that I can tell when I need to go get rheumatology care and when I can handle a musculoskeletal health problem myself					
6	I am confident I can tell my rheumatology care provider concerns I have even when he or she does not ask					
7	I am confident that I can follow through on rheumatology treatments I need to do at home					
8	I understand the nature and causes of my rheumatic condition(s)					
9	I know the different treatment options available for my health condition					
10	I have been able to maintain the lifestyle changes that I have made for my musculoskeletal health					
11	I know how to prevent further problems with my health condition					
12	I am confident I can figure out solutions when new situations or problems arise with my rheumatic condition					
13	I am confident that I can maintain lifestyle changes, like diet and exercise, even during times of stress					

adaptation and validation of the 13-item PAM, incorporation of remote participation, and direct assessment of knowledge gaps, and self-management practices.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

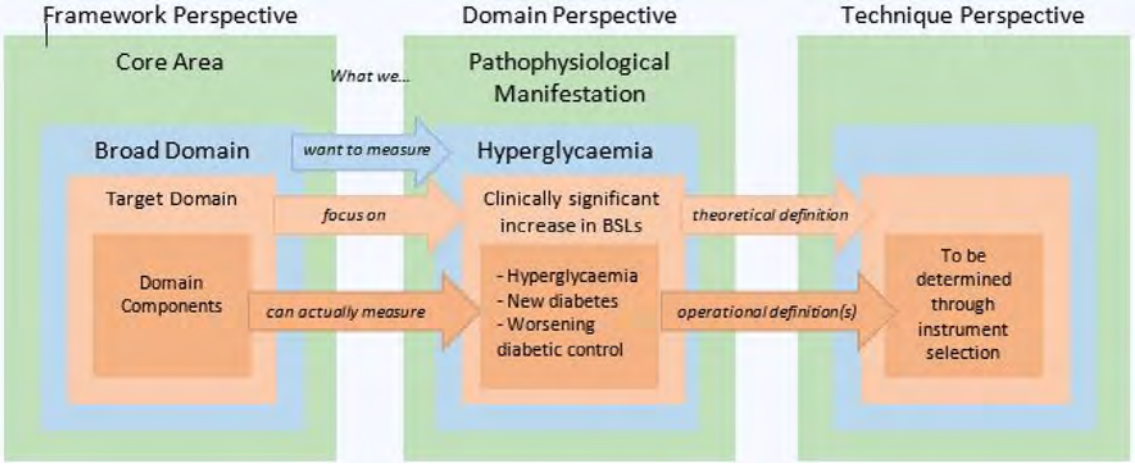
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Healthcare research has historically been medically oriented, less focused on the patients' perspective that research shows can improve the quality of care. OMERACT advocates for the development of core outcome sets to improve outcome measures in rheumatology by incorporating the patient perspective, which is often neglected in research. The OMERACT Glucocorticoid (GC) Impact Working Group has been working to develop a core domain set to measure the impact of GCs. Based on qualitative research and multiple rounds of Delphi-type exercises, the group identified mandatory domains for inclusion in all clinical trials where the effects of GCs are measured. These include infections, bone fragility, mood disorders, hypertension, diabetes, weight, fatigue, and mortality.

A fundamental aim of the GC Impact Working Group is to develop a core outcome set of measurement tools or instruments to represent and assess relevant outcomes, through application of the well-established OMERACT methodology. Before progressing to instrument selection, the Working Group sought to establish precise definitions of all mandatory domains within the core domain set to facilitate measurement.



The layered definition approach that provides a detailed definition of the domain and the elements of that domain that should be found in a suitable instrument using that technique. BSL – Blood Sugar Level, Example of mandatory domain

Methods: OMERACT methodology was applied with the use of evidence and consensus-based decision making of all stakeholder groups (patient research partners, health care professionals, clinician researchers, industry members and methodologists) to develop detailed definitions for the broad domain, target domain, and domain components, considering sources of variability that could impact the outcome measure assessed by a given instrument (fig 1). The working group synthesized prior qualitative studies, quantitative work, and results from Delphi rounds, to develop a rich definition of 'what' is to be measured.

Results: Over a 2-year period, from 2021–2023, the OMERACT Working Group on GC Impact conducted virtual meetings to establish domain definitions. The core area identified for all domains was pathophysiological, except weight, which was divided into both pathophysiological and life impact manifestations, and fatigue which has only life impact manifestations. Sources of variability were recognized, including cultural factors, age, gender, education level, socioeconomic status, personal experiences, emotional state, and language barriers. To minimize the impact of potential variability, instrument selection will require rigorous validation procedures. The domain definitions endorsed, through this consensus-based decision-making process, will form the foundation for instrument selection and the initial step of domain / concept match and content validity in the OMERACT pillar of 'truth' before moving on to feasibility, and discrimination

Conclusion: The OMERACT GC Impact Working Group have endorsed detailed domain definitions for core domains. The next step of the working group is to select instruments and develop the core outcome set for inclusion in all clinical trials where the effects of GCs are measured.

Health-Related Quality of Life in Idiopathic Inflammatory Myopathies: How to Act for Improving the Disease Burden of Patients?

Chiara Cardelli[1], Simone Barsotti[2], Elenia Laurino[1], Michele Diomedi[1], Federico Fattorini[1], Dina Zucchi[3], Alessandra Tripoli[1], Linda Carli[1] and Marta Mosca[1], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [2]Internal Medicine, Ospedale di Livorno, Pisa, Italy, [3]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Italy; Department of Medical Biotechnologies, University of Siena, Pisa, Italy

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic Inflammatory Myopathies (IIM) are rare, multisystemic and complex diseases that strongly impact the Quality of Life (QoL) of those affected. Patient Reported Outcomes (PROs) are validated tools that assess the overall health status of patients, particularly with regard to emotional and functional domains. The aim of the study was to evaluate the impact of disease clinical features and comorbidities on Health-Related (HR) QoL in a monocentric cohort of IIM patients.

Methods: Consecutive adult patients with a diagnosis of IIM (2017 EULAR/ACR criteria) followed at our Myositis Clinic were enrolled in this cross-sectional study. Demographic and clinical data were collected at enrolment. HRQoL was evaluated by administration of generic PROs: Patient Global Assessment (PGA), Health Assessment Questionnaire (HAQ), Short-Form 36 Items Health Survey (SF36), Functional Assessment of Chronic Illness Therapy Fatigue Subscale (FACIT-F), Hospital Anxiety and Depression Scale (HADS). Intergroup comparisons were assessed using t-test and Mann-Whitney tests, as appropriate. Multivariate analysis was performed by a linear regression model.

Results: We enrolled 85 patients (67.1% female; mean age 65.7±12.5 years; mean disease duration 7.9±6.5 years) with the following diagnosis: 44 dermatomyositis (51.8%), 36 polymyositis (42.3%), 5 inclusion body myositis (5.9%). Among clinical features, dysphagia and sicca symptoms were found to have the greatest impact on HRQoL: in fact, dysphagia was associated with worse outcomes in all PROs (PGA $p< 0.001$, HAQ $p< 0.001$, SF36 $p\leq0.031$, FACIT-F $p< 0.001$, HADS $p=0.023$ for anxiety and $p=0.002$ for depression), while sicca symptoms were found to be associated with worse scores in three of four SF36 domains of both mental and physical health ($p\leq0.044$ and $p\leq0.027$, respectively) and in a greater fatigue assessed by FACIT-F ($p=0.006$). As expected, HRQoL was significantly impaired by the coexistence of fibromyalgia (FM), which indeed determined worse scores of HAQ ($p=0.031$) and all SF36 domains ($p\leq0.021$), higher fatigue levels ($p=0.006$) and higher levels of anxiety and depression evaluated by HADS ($p=0.025$ and $p=0.05$, respectively); also osteoporosis (OP) was found to significantly impact on PGA ($p=0.027$) and physical functioning and general health evaluated by SF-36 ($p=0.044$ and $p=0.029$, respectively). At multivariate analysis, among clinical variables, only dysphagia maintained a significant impact on almost all PROs ($p\leq0.018$, except for pain and physical role domains of SF36); among comorbidities, FM had a significant impact on all PROs ($p\leq0.05$), whereas OP had an impact only on the SF36 domains ($p\leq0.03$).

Conclusion: Our data could help rheumatologists to focus their attention on specific clinical domains of IIMs in the perspective of preserving patients' QoL. In particular, dysphagia and FM were found to be the main determinants of HRQoL in IIM patients, thus suggesting their better control and optimized management could significantly improve patients' physical and psychological functioning. Moreover, OP prevention might further reduce the disease burden in this group of patients, thus ameliorating their quality of care.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Trauma exposures are associated with SLE onset and disease activity; perceived stress is also associated with greater SLE disease activity and worse patient-reported outcomes. However, perceptions of stress vary in response to life events and may be influenced positively and negatively by psychosocial factors. In an SLE cohort, we examined the association of stressful events with perceived stress, whether psychosocial factors affected perceived stress, and whether these relationships varied by prior trauma exposures.

Methods: Data were from a sample of adults with SLE from the California Lupus Epidemiology Study (n = 242). We first examined correlations of stressful events that occurred in the past year (Life Events Inventory: queries potentially stressful health, living situation, family, financial, and legal events) and psychosocial factors (3 positive: resilience, self-efficacy, emotional support; 1 negative: social isolation) with perceived stress (Perceived Stress Scale). Because of high correlations among positive psychosocial variables, we used principal components analyses to create a positive psychosocial factor score. We then used multivariable linear regression to examine independent associations of stressful events and psychosocial variables with perceived stress, controlling for age, sex, disease duration, and educational attainment for the total sample and stratified by lifetime trauma history (Brief Trauma Questionnaire, BTQ; any traumatic event vs none). Analyses stratified by history of adverse childhood experiences (ACEs; 0-1 events vs ≥2 events) among the subset for whom ACEs data were available (n = 180) were performed.

Results: Sample characteristics are shown in **Table 1**. Individuals who had experienced trauma (71%, BTQ) had significantly higher perceived stress scores, more stressful events, lower emotional support scores, and higher social isolation scores (**Table 2**). Overall, a greater number of stressful events over the previous year and social isolation were correlated with greater perceived stress, and positive psychosocial factors (resilience, self-efficacy, and emotional support) were

associated with lower perceived stress (**Table 2**). In analyses stratified by BTQ trauma and ACEs (38%), associations of positive and negative psychosocial factors with perceived stress were similar between groups. However, the number of recent stressful life events was significantly associated with perceived stress only for people with BTQ trauma or ACEs (**Table 3**).

Abbreviations: BTQ: Brief Trauma Questionnaire; PROMIS: Patient Reported Outcomes Measurement Information System; ACEs: adverse childhood experiences
*First eigenvalue from principal component analysis of resilience, emotional support, and self-efficacy scores
Models include Life Events Inventory, positive psychosocial factor score, PROMIS Social Isolation T-score, and age, sex, disease duration, and education ≤high school, Brief Index of Lupus Damage ≥2.

Conclusion: Perceived stress was higher in individuals with SLE with BTQ trauma and/or ACEs. Individuals with trauma history may be more vulnerable to current interpersonal, economic, or other stressful experiences that lead to higher perceived stress levels. Given demonstrated associations between perceived stress and poor health outcomes in SLE, modifiable positive psychosocial resources such as self-efficacy and emotional support may be important in managing perceptions of stress. Increased access to interventions that strengthen positive psychosocial factors and lessen negative ones to lower perceived stress is a next step towards improving outcomes in SLE.

Involving Patients Research Partners in Research in Rheumatology: Where Do We Stand? A Scoping Review of Recent Randomized Controlled Trials and Translational Science Studies

Diego Benavent[1], Muriel Elhai[2], Krystel Aouad[3], Paul Studenic[4], Maarten de Wit[5] and Laure Gossec[6], [1]Hospital la Paz, Madrid, Spain, [2]University Hospital zurich, University of Zurich, Zurich, Switzerland, [3]Saint George Hospital University Medical Center, Beirut, Lebanon, [4]Medical University of Vienna and Karolinska Institutet (sweden), Vienna, Austria, [5]Patient Research Partner, Stichting Tools, Amsterdam, Netherlands, [6]Sorbonne Université and Pitié Salpêtrière Hospital, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients bring valuable insights to research; the inclusion of patient research partners (PRPs) in research projects is increasingly recognised and recommended in medical research, also by the Food and Drug Administration. The level of involvement of PRPs in translational rheumatology research projects remains unknown, while in randomized clinical trials (RCTs) published between 2016 and 2020, it has been reported to be as low as 2%[1]. The objective of this study was to assess the involvement of PRPs in recent translational studies and RCTs in rheumatology.

Methods: In this scoping review, we analyzed the 80 most recent articles (40 for translational studies and 40 for RCTs) in each of the target diseases (rheumatoid arthritis, psoriatic arthritis, systemic lupus erythematosus and lower-extremity osteoarthritis), published up until March 1st, 2023, in rheumatology and general scientific journals with an impact factor of >5. The extent of PRP involvement was assessed, as reported in the Methods, affiliations of authors and acknowledgments sections. General data on the studies was also collected. The analysis was descriptive.

Results: Overall, 221 studies were screened; most were excluded due to wrong study design or wrong disease. Among the 40 translational studies (10 for each disease studied), half were published in rheumatological journals. Fifty percent of the studies were conducted in Asia, 30% in Europe and 20% in North America. None of the included translational studies reported PRP involvement (Figure 1). Of 40 clinical trials (10 for each disease studied), 78% were published in rheumatology journals. Fifty-two percent of the studies were conducted in North America, 25% in Europe and 23% in Asia. Among the 40 RCTs, 8 studies (20%) reported PRP involvement (Figure 1). These trials were from Europe (6/8, 75%), and North

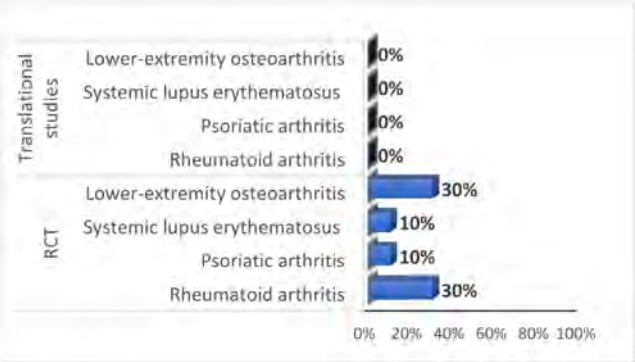

Figure 1: Involvement of patient research partners in recent translational studies and RCTs

America (2/8, 25%). Most of them (6/8, 75%) were non-industry funded. The type of PRP involvement was reported in 4/8 studies (50%); four studies reported PRP participation in the study design and two studies reported involvement in the interpretation of the results. All the trials reporting the number of PRPs (6/8, 75%), involved at least two PRPs.

Conclusion: Despite a world-wide movement advocating for increased patient involvement in research, the involvement of PRPs in translational research and RCTs in rheumatology remains low. While there has been an improvement in PRP involvement in RCTs compared to previous literature reviews (20% vs. 2%)[1], PRPs are still absent in translational research projects. This under-representation of PRP involvement in research highlights a persistent gap between recommendations and practice.

Goal Concordance in Rheumatoid Arthritis Patients with Depression – What Do Patients Prioritize?

Allison Schue[1], Rachel Matsumoto[2] and Jennifer Barton[3], [1]Providence St. Vincent Medical Center, Portland, OR, [2]VA Portland Health Care System, Portland, OR, [3]VA Portland Health Care System/OHSU, Portland, OR

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression prevalence in patients with rheumatoid arthritis (RA) is higher than the general population (~40% and 4.1%, respectively). Patients with depressive symptoms show reduced biologic therapy response. Patient-clinician goal concordance has been linked to improved outcomes in other chronic conditions including diabetes but has not been explored in RA patients with depression. Our objective was to (a) describe treatment goals for RA patients with and without depression and (b) assess whether RA patient-clinician goal concordance varies by depression status.

Methods: RA patients seen in the prior 12 months at one of two rheumatology clinics (Veterans Affairs- and university-based) were enrolled in a cross-sectional survey study. Patients and their rheumatology clinician independently ranked their top three (of eight) RA treatment goals. PHQ8 score ≥10 defined depression. Descriptive statistics were used to characterize treatment goals for both groups. Fisher's exact test was used to determine statistical significance with a Bonferroni correction to account for multiple comparisons (p= 0.006). Goal concordance, defined as a patient's top goal ranked in their clinician's top three goals, was compared between groups.

Results: 148 dyads were included in the analysis (148 patients, 14 clinicians). Patients were 51% female and 28% non-white, with mean disease duration of 12 years (SD= 9). 32 patients (22%) met depression criteria. Overall, "less pain" was identified as a treatment goal most often, regardless of depression status (81% depressed, 91% non-depressed, p= 0.21). Similarly, "fewer problems doing my daily activities" was the second-most selected treatment priority for patients with and without depression (56% and 69%, respectively, p= 0.21). However, patients with depression identified "feel less tired" as their third-most selected goal (47% depressed, 33% non-depressed, p=0.15), while those without depression identified "avoid side effects from medication" third-most frequently (41% non-depressed, 28% depressed, p=0.22). Patients with depression also identified "improve sleep" as a goal more often than patients without depression (41% depressed, 16% non-depressed, p= 0.006). Goal concordance did not differ significantly between patients with and without depression (91% and 78% meeting concordance definition, respectively, p= 0.1).

Conclusion: RA patients, regardless of concomitant depressed mood, most often prioritized "less pain," followed by "fewer problems doing my daily activities." However, differences emerged in the third-most valued goal such that patients with depression ranked "feel less tired" and patients without depression ranked "avoid side effects from medication" more often. Goal concordance did not differ significantly between groups, which may be explained by the high value placed on pain in goal ranking and our patient-centered definition of concordance. Pain is a common symptom in RA and routinely elicited at clinic visits, prompting discussions between patients and clinicians. Research to explore ways to improve goal elicitation beyond pain among all RA patients and their clinicians is warranted.

Sex Differences in Patient-Reported Outcomes in Patients with Rheumatoid Arthritis After Starting a New Disease-Modifying Antirheumatic Medication

John Davis[1], Sara Achenbach[2], Courtney Arment[1], Delamo Bekele[1], Vanessa Kronzer[1], Thomas Mason[1], Elena Myasoedova[1], Lynne Peterson[1], Kerry Wright[1] and Cynthia Crowson[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, MN, Rochester, MN

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-Reported Outcome Measurement Information System (PROMIS®) measures are valued in the assessment of health outcomes for patients with rheumatoid arthritis (RA). However, little is known about sex differences in change in key PROMIS domains following initiation of DMARD therapy. We aimed to examine sex differences in PROs among patients with RA after starting a new DMARD.

Methods: In this retrospective study, patients with RA seen at a single institution between 1/2020 and 10/2021 were included. RA patients were identified by presence of 2 diagnostic codes (ICD-10: M05.x/M06.x, excluding M06.1) and prescription of a DMARD. PROMIS computer adaptive tests for Physical Function, Pain Interference, Fatigue, Depression, and Ability to Participate in Social Roles and Activities were routinely collected at each clinical visit. Patients with available PROMIS measures at the start of a new conventional synthetic (cs), biologic (b), or targeted synthetic (ts) DMARD and at least one subsequent visit were included in the analysis. Minimum clinically important differences (MCID) and meaningful differences were defined for each PROMIS measure (ref: Bartlett et al, AC&R 2022). Generalized binomial models with logit link were used to examine sex differences in improvement or worsening of PROMIS measures over time, adjusting for age, DMARD type and duration.

Results: A total of 179 patients with RA (76% female; 93% white; mean age 56.2 years) who started 202 new DMARDs (85 csDMARDs, 88 bDMARDs and 29 tsDMARDs) were studied. Median follow-up was 5.8 (interquartile range: 3.7-9.4) months per DMARD. Mean (±SD) PROMIS measures at DMARD initiation were 38.7 (±7.0) for physical function, 44.7 (±7.8) for social participation, 62.7 (±5.8) for Pain interference, 58.6 (±9.2) for fatigue and 5.20 (±8.7) for depression. Women were 3 times more likely to have worsening of their depression score by at least 2 points after starting a new DMARD (36% of women worsened vs 18% of men; odds ratio: 3.07; 95% CI: 1.29-7.30; Table). This association persisted after adjusting for change in physical function (OR: 2.86; 95% CI: 1.16-7.01). This association also persisted (but did not reach statistical significance) in the subset of patients who experienced a meaningful improvement in physical function (OR: 4.16; 95% CI: 0.71-24.44). No statistically significant sex differences were noted in pain interference (p=0.69) or ability to participate (p=0.23). Women were somewhat more likely to experience worsening physical function (OR: 2.24; 95% CI: 0.92-5.48; p=0.08) and were somewhat less likely to experience worsening fatigue (OR: 0.56; 95% CI: 0.26-1.21; p=0.14) compared to men, but these associations did not reach statistical significance.

Conclusion: We observed that women with RA initiating a new DMARD were more likely to experience worsening depression as compared to men, even when they experienced treatment-associated improvement in physical function. The findings point to important sex differences in PRO responses to DMARD therapy and highlight the value of PROMIS measures in understanding sex differences in RA health outcomes.

Table. PROMIS measures at DMARD initiation and subsequent changes in women and men with RA.

	Women				Men			
PROMIS measure	At DMARD initiation Mean (±SD)	Improved by ≥2 points	No meaningful change	Worsened by ≥2 points	At DMARD initiation Mean (±SD)	Improved by ≥2 points	No meaningful change	Worsened by ≥2 points
Physical Function	38 (±7)	37%	69%	32%	40 (±6)	36%	45%	18%
Ability to Participate	45 (±8)	44%	25%	32%	45 (±7)	41%	23%	36%
Pain Interference	63 (±6)	49%	23%	28%	63 (±5)	53%	26%	21%
Fatigue	60 (±9)	45%	21%	34%	55 (±9)	29%	18%	53%
Depression	52 (±9)	39%	24%	36%	51 (±8)	36%	47%	18%

Assessment of the Immediate and Short-term Impact of an Information Course on Patients' Knowledge About Rheumatoid Arthritis: Evaluation Using a Self-prepared and Validated Assessment Questionnaire

Ranjan Gupta[1], Rudra Prosad Goswami[2], Manshi Yadav[1], Sandhya Saini[1], Anju Mohan[1] and Vanamail Perumal[1], [1]All India Institute of Medical Sciences, New Delhi, India, [2]Department of Rheumatology, All India Institute of Medical Sciences, New Delhi, India

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term outcomes in rheumatic diseases can be improved by improving patients' knowledge, beliefs and perception about their disease which can help them in coping with the disease better. However, there is a lack of tools/instruments in rheumatoid arthritis (RA) to 1. objectively assess patients' knowledge in various domains & 2. To assess the impact of a patient education program. The aim of the study is to develop, validate and assess the performance of a self-prepared questionnaire for assessing patients' knowledge about their disease and to use this tool to assess the impact of an information course in improving the above-mentioned elements among patient.

Table – 1 Question-wise assessment of responses before and after the information course and the statistical significance of the change

*change with respect to the correct responses before and after the information course (Assessed by McNemar test)

Methods: A self-prepared questionnaire (Hindi/English) containing 24 multiple choice or true-false type questions with single correct answer assessing patients' knowledge about RA in 3 domains (a. etiology, disease process, signs & symptoms b. drug therapy & monitoring c. joint protection, exercise, coping) was prepared. All questions had an item-level content validity index (I-CVI) of at least 0.9. The scale-level content validity index based on the universal agreement method (S-CVI/UA) was 0.8 for the whole questionnaire as assessed by 6 experts. All questions had an option of 'I don't know' which would prevent patients from guessing the answer from the available options. Each question was given a score of 1 if answered correctly. The questionnaire was applied 3 times: at baseline, immediately after an information course to see the immediate impact and after 4 months to see the retention of the information. Information on demographic features and socio-economic status was also collected. Frequency data were compared using McNemar test for paired nominal data & kappa statistics for ordinal data. Student's paired t-test was used for comparison of mean scores to see the impact.

Results: At baseline, the questionnaire was applied to 274 patients with RA (F:M=248:26; mean age 44±11.9 years) and the median(range) score was poor 5(0-21) (Table–1). Among them, 141 patients attended the information course. The option 'I don't know' was exercised 3186 times (48.24%) before the information course which reduced to 469 (13.86%) times after the course. After the information course, all the questions recorded a higher number of correct responses as compared to before the course. Twenty-one questions had significantly higher correct response rate (Table–1). Median score for increased from 5(0-21) to 17(0-24) ($p< 0.001$) which was irrespective of the socio-economic classes and education status of the patients (Figure-1). Upon re-administering the questionnaire after 4 months, the median score 13(0-24) of the questionnaire (n=78) remained significantly higher ($p< 0.001$) as compared to baseline score (Figure 1) with 21 out of 24 questions achieving statistical significance (Table–2).

Conclusion: Indian patients with RA have a poor knowledge base about their disease which one may strive to improve by implementing short information courses. The information course was found to be effective across the socio-economic classes and educational status. The provided information was retained at 4th month of follow up months without any reinforcement course.

Table – 2 Question-wise assessment of responses before the information course and after 4 months with the statistical significance of the change

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an inflammatory, multisystemic, chronic disease more prevalent in women and can significantly impact health-related quality of life (HRQoL).[1] Sociodemographic factors have been associated with reduced HRQoL in patients with SLE such as experiencing violence particularly intimate partner violence

(IPV). IPV includes physical violence, sexual violence, and psychological aggression by a romantic or sexual partner.[2] Women with SLE are at risk for IPV and should be evaluated to recognize this problem. The aim of this study was to evaluate the impact of IPV in HRQoL in women with SLE.

Methods: We performed a cross-sectional study from September 2022 to April 2023 in an outpatient rheumatology clinic at Hospital Universitario "Dr. José Eleuterio González" in Northeast Mexico. We included female patients who were ≥ 18 years, met EULAR/ACR 2019 SLE classification criteria for at least 24 weeks, had ≥ 2 in the last 12 months, and had one of the following statuses: romantic relationship, divorced/separated or widowed and single/never married.[2]

At first, we performed consultations and assessments of the following: disease activity measured by Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), response to treatment measured by Physician Global Assessment (PhGA), and cumulative damage measured by Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index (SDI). After consultation, patients were invited to participate, those who accepted were located in a private room to hand a written consent. Patients answered the following questionnaires: IPV,

Table 1. Baseline demographic characteristics

	n = 24
Age in years, mean ± SD	34.33 ± 10.26
Marital status, n (%)	
o Single	8 (33.33)
o Married	5 (20.83)
o Never married	9 (37.50)
o Widow	2 (8.33)
Number of romantic partners, mean ± SD	2.1 ± 1.04
Current romantic partner, n (%)	
o Yes	15 (62.50)
o No	9 (37.50)
Educational level, n (%)	
o Elementary school	3 (12.50)
o Junior High School	8 (33.33)
o Senior high school	11 (45.83)
o College	2 (8.33)
Employment status, n (%)	
o Paid employment	9 (37.50)
o Not employed	15 (62.50)
Monthly income in dollars	
o Less than 290	3 (33.33)
o 290 – 600	4 (44.44)
o 600 – 1, 150	2 (22.22)
o More than 1, 1150	0
Housework, n (%)	
o Yes	22 (91.66)
o No	2 (8.33)
Health insurance, n (%)	
o Yes	22 (91.66)

SLEDAI-2K, mean ± SD	4.8 ± 1.7
LupusQoL, mean ± SD	
Physical domain	84.93 +-13.34
Emotional domain	80.81 + -18.06
Body image domain	81.08 +-21.05
Burden to others	73.02 +- 29.38
Sexual domain	74.41 +- 28.79
Total	78.85 +- 16.23

SD, standard deviation; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; LupusQoL, Lupus Quality of Life

chronic pain syndromes, and quality of life. Participants were required to answer the Spanish version of the following questionnaires: Hurt, Insulted, Threatened with harm, and Screamed at (HITS), Index of Spouse Abuse Physical Scale (ISA-P) and Lupus Quality of Life (LupusQoL).

Results: From October 2022 to April 2023, 24 patients were included. The baseline demographic characteristics are listed in Table 1. Six patients had experienced IPV. IPV, HITS and ISA-P results are seen in table 2 and 3.

Conclusion: Data about IPV in women with SLE in our country are missing. IPV prevalence in our study was 33.33% higher than reported by Sardinha L. et al 2018 which evaluated violence in women without autoimmune diseases at 16%. The analysis performed between patients who were victims of IPV and quality of life showed a statistical trend in patients having experienced IPV in the last year in the emotional domain of Lupus QoL, but this was not observed in women who experienced IPV in their lifetime. With these results, we concluded that IPV in women with SLE has an impact in the emotional domain on the quality of life of Lupus (HR-QoL).

Switch or Stay the Same? Preferences of People with Autoimmune Disease on Rituximab for Different Types of COVID-19 Vaccine Boosters

Todd Wilson[1], **Paul R. Fortin**[2], Ines Colmegna[3], Sonia Theriault[4], Nathalie Amiable[5], Alexandra Godbout[5] and Glen Hazlewood[1], [1]University of Calgary, Calgary, AB, Canada, [2]Centre ARThrite - CHU de Québec - Université Laval, Quebec City, QC, Canada, [3]The Research Institute of the McGill University Health Centre, Montréal, QC, Canada, [4]The Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [5]Centre ARThrite - CHU de Quebec - Universite Laval, Quebec City, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19 vaccines are now being offered as regular boosters every 6-12 months for people with autoimmune rheumatic diseases, particularly for people on rituximab, where serological responses to vaccination are poor. We were interested in understanding the preferences of patients taking rituximab for a booster with the same messenger RNA (mRNA) vaccine, versus a switch to a protein subunit vaccine.

Methods: We conducted a discrete-choice experiment (DCE) within a clinical trial comparing vaccine types for 4th (Trajectory A) and 5th (Trajectory B) doses in people with autoimmune rheumatic diseases, all of whom had received prior mRNA vaccines. In this open label, non-randomized, comparative trial, people could choose between an mRNA or protein subunit vaccine. In the DCE, people were asked to choose between two different vaccine types or "no vaccine" in a series of ten hypothetical questions, where the vaccine choices varied in terms of their effectiveness, likelihood of a flare, and type of vaccine (same (mRNA) versus switch to a protein subunit vaccine). The DCE was administered by computer in French and English at the two trial sites in Quebec, Canada. We used a hierarchal Bayes model with continuous levels to estimate average and individual part-worth utilities and attribute importance across the range of levels presented for the three attributes. We compared the preferences of people who chose the different vaccine types through a Wilcoxon rank-sum test on the median individual part-utility values.

Results: Among 78 people who agreed to participate, 69 (88%) completed the survey.Participants had an average age of 58 years, 78% were female, and 58% had above high school education. The type of autoimmune disease was rheumatoid arthritis (43%), ANCA associated vasculitis (32%), systemic lupus erythematosus (9%) and other (16%), with a median disease duration of 9 years. 65% of respondents had a prior COVID-19 infection at study entry. Of the 69 participants, 36 (52%) people chose an mRNA vaccine and 33 (48%) people chose a protein subunit vaccine. On average, people preferred to stay with the same vaccine type, rather than switch to a protein subunit vaccine. However, people would accept a protein subunit vaccine if it was associated with an 18% absolute increase in effectiveness, or a 6% absolute reduction in the risk of flare. People who chose the protein subunit vaccine placed a higher importance on vaccine effectiveness ($p < 0.001$) and lower importance on vaccine type ($p < 0.001$).

Conclusion: People with autoimmune diseases on rituximab who had received prior mRNA COVID-19 vaccines preferred to stay with mRNA vaccines for subsequent doses unless the new protein subunit vaccine was substantially more effective (~20%) or safe, although variability in preferences was found. This supports current approaches of booster immunizations with the same vaccine, and provides an estimate of what would be considered a worthwhile increase in effectiveness for high-risk patients to choose a different vaccine type.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Many studies have shown that rheumatologic conditions are associated with a higher risk of depression. The two most common methods to detect depression in these studies used DSM/ICD criteria; alternatively, self-report screening questionnaires, such as the Patient Health Questionnaire (PHQ). However, using one or the other

method to detect depression might lead to decreased sensitivity to detect depression, and the statistical analysis can be fraught with difficulty since numerous confounding variables affect depression. In this study, we aim to implement both methods to detect depression in patients with Systemic sclerosis (SSc), Dermatomyositis (DM), and Fibromyalgia(FM) using propensity-score matching in a national cohort database.

Methods: ICD 9/10 codes were used to identify SSc, DM, and FM, of which a propensity score matching (PSM) analysis was used to evaluate the effect of disease on the risk of developing depression in a cohort of 240,353 Americans enrolled in the "All of Us database." ICD 9/10 codes were used, and it can be inferred that the ACR classification criteria for the diseases were met. Covariates for matching included age, gender, race, ethnicity, income level, education level, marital status, cigarette exposure, alcohol exposure, drug exposure, and comorbidities. The control groups were matched with a ratio of 1 to each patient group based on propensity scores. The PSM reduces any confounding factors between the case and control cohorts. A logistic regression analysis determined the association between each disorder and depression. Global Mental Health Scores (GMHS) were compared between control and disease groups using a t-test or Mann-Whitney U test. GMHS is a patient-reported perspective of their mental health, with a score range of 0-20, with the maximum score representing optimum health status.

Results: Out of 240,353 individuals, 638 patients with SSc, 358 patients with DM, and 21,263 FM patients were identified. Control groups for each disease were statistically not different ($p \geq 0.05$) from the case groups for age, gender, race, ethnicity, income level, education level, marital status, cigarette exposure, alcohol exposure, drug exposure, and Charlson comorbidity scores. Only FM was associated with increased risk of depression (OR 2.32 [95% CI: 2.23-2.41], $p < 0.001$), which was in line with the lower average GMHS of FM patients (13.1) compared to control (13.8) ($p < 0.001$). SSc (OR 0.94, 95% CI: 0.75-1.17, p=0.571) and DM (OR 1.07, 95% CI: 0.80-1.44, p=0.649) were not associated with an increased risk of depression. The average GMHS of SSc (13.6) and DM (13.4) patients were statistically not different from their respective control groups.

Conclusion: When used concurrently, diagnostic codes for depression and self-reported screening questionnaires were congruent in assessing the association of depression with common rheumatologic disorders. In addition, the use of propensity score matching helped eliminate confounding variables.

Impact of COVID-19 Pandemic on Preventative Health Screenings in Rheumatology Outpatients

Minerva Nong[1], Medha Barbhaiya[2], Jonah Levine[3], Vivian Bykerk[4], Rachel Heise[5] and Lisa Mandl[2], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [3]NYU Grossman School of Medicine, New York, NY, [4]Department of Rheumatology, Hospital for Special Surgery, New York, NY, [5]Department of Population Health Sciences, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic created significant barriers to accessing recommended preventative health screening. Patients already managing a chronic disease, particularly those using immunosuppressive medications, may have been disproportionately impacted due to heightened concerns about nosocomial COVID-19 infection risks. The goal of this study was to identify delays in preventative health screening among rheumatology outpatients and assess risk factors associated with delays.

Methods: Between 03/09/2022 and 06/15/2022, 9918 adults enrolled in a single center COVID-19 Rheumatology Registry in New York City were asked whether they skipped or delayed pap smears, mammograms and/or colonoscopy screenings due to the COVID-19 pandemic. Participants living in NY, NJ, or CT were also assigned a census tract-based Social Vulnerability Index (SVI). ICD-10 algorithms identified systemic rheumatic diseases (SRDs). We compared differences between those who did or did not delay screenings using Chi-square, Fisher's exact, or Wilcoxon rank-sum tests as appropriate. We used multivariable models to assess risk factors associated with delay of each screening test in both the whole cohort and separately in the subgroup with SVI scores.

Results: 2735/9918 (27.6%) participants responded. Mean age was 65.4 years (SD=12.7), 90.6% White, 4.6% Hispanic/LatinX. 2000 were recommended to have regular preventive health screens. Delays were reported in 286/1093 pap smears (26.2%); 350/1426 mammograms (24.5%); and 306/1551 colonoscopies (19.7%). More Hispanic/LatinX vs. non-Hispanic/LatinX participants delayed pap smears (37% vs. 25%, p=.04) and mammograms (36% vs. 24%, p=.02). Fewer White participants delayed pap smears (25% of White participants delayed, 32% Black, 52% Asian, 33% Other; p=.01). Mammogram delays also differed by race (24% of White participants delayed, 20% Black, 47% Asian, and 33% Other; p=.02). More females than males delayed colonoscopies (22% vs. 13%, $p < .001$). Younger age was associated with delaying all three screens (all $p< 0.05$). Participants living in census tracts with the worst socioeconomic vulnerability had higher proportions of delayed mammograms (35% vs. 24%, p=.01). Participants using any immunomodulatory/immunosuppressive medication at registry enrollment were more likely to report delaying all three screens (p=.03). Having an SRD was not associated with delays. In multivariable models, adjusting for all other covariates, those on immunomodulatory/immunosuppressive medications were more likely to delay pap smears (OR 1.55, 95% CI: 1.14, 2.12) and colonoscopies (OR 1.33, 95% CI: 1.01, 1.77), but not mammograms (OR 1.22, 95% CI: 0.93-1.59). Males were less likely to delay colonoscopies (OR 0.55, 95% CI: 0.39, 0.78). For every one-year increase in age, the odds of delaying a mammogram decrease by 1.7% (OR 0.98, 95% CI: 0.97, 0.996).

Conclusion: Immunomodulatory/immunosuppressive medications but not SRD diagnosis was associated with preventive screening delays. These data can help identify rheumatology patients at risk for preventative screening delays. The impact of race, ethnicity, and SES on delaying health screening should be explored in more diverse populations.

Clinical, Immunologic, and Genetic Characteristics in Patients with Syndrome of Undifferentiated Recurrent Fevers (SURF)

Marci Macaraeg, Michael Matt, Elizabeth Handorf, Elizabeth Baker and Grant Schulert, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

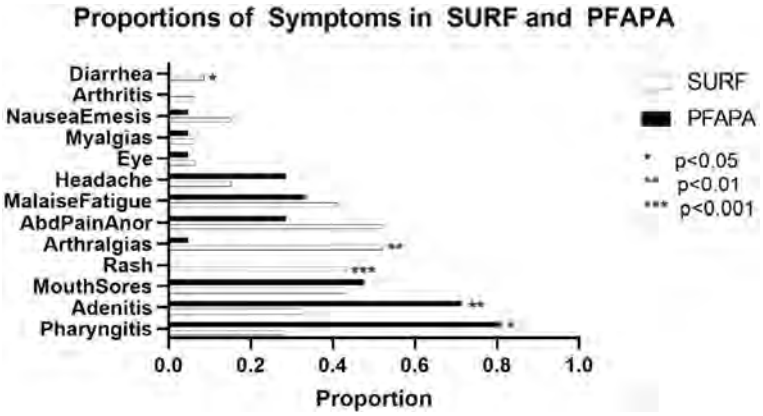
SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

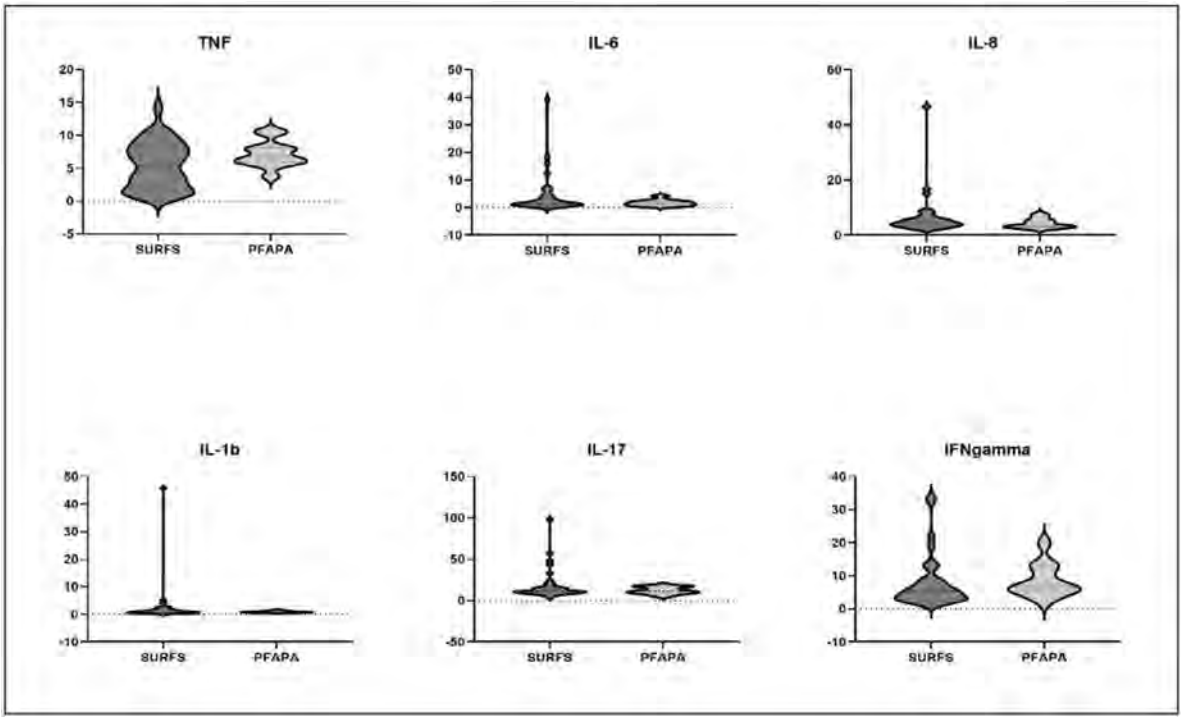
Session Time: 9:00AM–11:00AM



Proportion of symptoms in patients with SURF versus PFAPA. Symptoms that were significantly different between the two groups are noted with an asterisk.

Background/Purpose: Unexplained recurrent fevers are a common presentation to pediatric rheumatology and a significant burden to affected families due to missed daycare or school days for the child and missed work days for the parent. Syndrome of Undifferentiated Recurrent Fevers (SURF) represents a group of disorders characterized by self-limited recurrent fevers and systemic autoinflammation without confirmed molecular diagnosis of a Hereditary Recurrent Fever syndrome (HRF) as well as not fulfilling criteria for Periodic Fever, Adenitis, Pharyngitis, Aphthous stomatitis syndrome (PFAPA). This study aims to differentiate the clinical and chemical findings between SURF and PFAPA; to characterize the clinical, chemical, and genetic findings; and to describe treatment responses of SURF patients.

Methods: We enrolled 47 patients followed at the Cincinnati Children's Hospital (CCHMC) Autoinflammatory Treatment and Research Center who met criteria for SURF based on history of recurrent fevers, genetic testing negative for HRF, and did not meet EULAR/PRINTO classification criteria for PFAPA. Baseline data was collected at enrollment, including their



Violin plot of pro-inflammatory cytokines where SURF patients were found to have very elevated, outlier measurements.

	On Demand Steroids *n (%)*	T&A *n (%)*	Colchicine *n (%)*	Cimetidine *n (%)*	Anti-IL1 *n (%)*
Complete response	11 (64.7)	7 (58.3)	8 (42.1)	1 (25)	8 (47)

Treatment response table showing total number of patients who were trialed on a therapy, as well as the number and percentage of patients who who had a complete, incomplete, or no response.

symptoms during episodes, family history, genetic testing, and inflammatory markers/cytokines. Cytokines were run using a cytokine multiplex assay. In some patients, exome sequencing was performed with focused analysis of 394 genes implicated in known inflammatory disorders as well as primary immunodeficiency syndromes. Clinical symptoms between SURF and PFAPA were compared using Welch's T-Test and two-tailed Fisher's exact test. Cytokines for SURF and PFAPA were compared using Mann-Whitney U Test and hierarchical clustering.

Results: Rash and arthralgias were each more likely to occur in SURF, while pharyngitis was more in PFAPA. Symptoms in SURF and PFAPA patients are shown in Figure 1. Our analysis showed similar cytokine levels between PFAPA and SURF, however SURF patients had more outliers including IL-1beta, IL-6, IL-8, and IL-17A (Figure 2). Hierarchical clustering showed a distinct subgroup of SURF patients with elevated IFNg, IL17a, IL12p70, and IL23. Treatment response for SURF patients ranged from self-resolution to the use of biologics and are further detailed in Table 1. Genetic variants of unknown clinical significance (VUCS) were frequently found in patients with SURF. Several patients had mutations in genes that are implicated in B cell development, immunodeficiencies, granulocyte/monocyte development, and inflammatory bowel disease risk.

Conclusion: SURF is a group of patients with recurrent fevers but without a known monogenic cause. Our preliminary findings suggest SURF has distinct clinical features from PFAPA, with a subgroup that is chemically different. They also suggest SURF is heterogeneous in clinical, chemical, and genetic findings, and in treatment responses. We find frequent VUCS in pathways which may have relevance to disease pathogenesis, and possible associations to SURF endotypes. Further research is necessary to understand these SURF endotypes, what drives the disorder, and how physicians can better predict which treatment will be most successful for each patient.

Distinguishing Multisystem Inflammatory Syndrome in Children from Typhus Using Artificial Intelligence: MISC vs. Endemic Typhus (AI-MET)

Angela Chun[1], Abraham Bautista-Castillo[2], Isabella Osuna[1], Kristiana Nasto[1], Flor Munoz[3], Gordon Schutze[1], Sridevi Devaraj[1], Eyal Muscal[4], Marietta De Guzman[5], Kristen Sexson Tejtel[1], Ioannis Kakadiaris[2] and Tiphanie Vogel[1], [1]Baylor College of Medicine / Texas Children's Hospital, Houston, TX, [2]Computational Biomedicine Lab University of Houston, Houston, TX, [3]Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [4]Division of Rheumatology, Department of Pediatrics, Baylor College of Medicine, Houston, TX, [5]Baylor College of Medicine, Houston, TX

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Multisystem inflammatory syndrome in children (MIS-C) following SARS-CoV2infection is a recognized mimic of other inflammatory disorders, including Kawasaki Disease and macrophage activation syndrome. However, MIS-C can also mimic acute infections, such as endemic typhus, presenting a diagnostic challenge with discordant treatments. We aimed to use artificial intelligence (AI) to develop a clinical decision support system that rapidly and accurately distinguishes **M**IS-C versus **E**ndemic **T**yphus (MET).

Methods: With local IRB approval, 49 demographic, clinical, and laboratory features (21 categorical and 28 continuous) available within 6 hours of presentation were retrospectively extracted from the electronic medical records of 133 MIS-C and 87 typhus patients admitted to a single quaternary pediatric system between January 1, 2020 and December 31, 2021. Laboratory values were considered high, low or normal based on institutional norms. Using the attention module of a deep learning model and prioritizing accuracy, during training and testing we iteratively narrowed down to the 30 features necessary to maintain complete accuracy in classification. The AI-MET clinical decision support system was built to use these 30 clinical features, combined with the importance assigned to them by the attention module, to assist providers in distinguishing between MIS-C and typhus manually (i.e., without software) as often as possible.

Results: AI-MET is a two-phase clinical decision support system. In phase 1 of AI-MET, a provider uses 17 features to manually calculate a score (MET-17) to arrive at a diagnostic classification (Table I). If the MET-17 score does not surpass a predetermined confidence level, 13 additional features are added and the MET-30 score is calculated using a recurrent neural network. While 24 of the 30 features (80%) were statistically different between patients with MIS-C and typhus, values for

Epidemiologic Link to COVID-19		(-)5	(−)5
Antecedent Illness		(-)2	(−)2
Conjunctivitis		(-)4	(−)4
Rash		(−)3	(-)3
The patient is classified as typhus if the total score is ≥62. The patient is classified as MIS-C if the total score is ≤ (-)35. If the total score falls between (-)35 and 62, proceed to MET-30.			

Abbreviations: ALC, absolute lymphocyte count; ALT, alanine aminotransferase; ANC, absolute neutrophil count; AST, aspartate aminotransferase; BNP, B-type natriuretic peptide; bpm, beats per minute; °F, degree Fahrenheit; NLR, neutrophil to lymphocyte ratio, Tmax, maximum temperature; WNL, within normal limits

each feature alone were so overlapping between the two patient groups that the features were irrelevant distinguishers as individual parameters. However, AI-MET successfully classified all 220 typhus and MIS-C patients with 100% accuracy. Approximately half of the patients were classified manually with sufficient confidence during phase I using MET-17 that MET-30 (i.e., software) was not needed. A validation cohort of 111 additional MIS-C patients with all 30 AI-MET features available was also classified as MIS-C with 99% accuracy (110/111).

Conclusion: There is significant diagnostic overlap between MIS-C and endemic typhus. Artificial intelligence can successfully distinguish these diagnoses using features typically available within the first 6 hours of patient presentation. As a clinical decision support system, AI-MET will be a valuable tool for front-line providers facing the difficulty of timely diagnosis of a febrile child in endemic areas.

Abstract Number: 2041

An Analysis of Recurrent Parotitis Patients Referred to Rheumatology Clinic

Yiressy Pina[1], Elton Lambert[2], Maria Pereira[2] and Marietta De Guzman[2], [1]Baylor College of Medicine, Richmond, TX, [2]Baylor College of Medicine, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile recurrent parotitis (JRP) is characterized by non-obstructive, non-suppurative inflammation of the parotid glands of unknown etiology. The onset of symptoms occurs typically between ages 3-6 and there is a tendency for spontaneous resolution after puberty. Patients are primarily managed by Otolaryngology and approximately 2/3 of patients respond to sialadenoscopy after failing conservative measures, however additional medical therapies are sometimes required. The purpose of this study was to analyze the subset of patients who are referred to rheumatology and to describe the immunosuppressive treatment utilized.

Methods: With approval from our Institutional Review Board, patients were identified via our electronic medical records (EMR) using the ICD-9 and ICD-10 codes for "recurrent parotitis" and "parotitis" between 2013 and 2023 who were seen by rheumatology. Patients 21 years and younger, with at least 3 episodes of parotitis per year or 2 within 6 months, were included. Demographic and clinical information was obtained. Treatment response was determined as complete remission (no episodes in 12 months) or partial response (less than 3 episodes per year or less than 2 episodes per 6 months). Data were evaluated using standard descriptive statistics.

Results: A total of 26 patients met inclusion criteria. Average age was 7 (range 3-21), majority were female (73%), white (77%), and non-Hispanic (62%). Average total episodes of parotitis were 7 (range 2-42), with 4 episodes per year on average. Bilateral parotitis was noted in 81%. Average duration of symptoms prior to referral to rheumatology was 20 months (range 2-84). The more common referral reasons included recurrence (35%) and concern for autoimmune etiology based

Table 1: Comparison of Patients with Idiopathic JRP and Patients with Rheumatologic Diagnoses

SSB Antibody	Positive 0 Negative (95%) Not Done (5%)	Positive (40%) Negative (60%)
Rheumatoid Factor	Positive 0 Negative 84% Not Checked 16%	Positive 20% Negative 40% Not Checked 40%
Accompanying Symptoms at Presentation	Facial pain (89%) Fever (42%) Arthralgia (21%) Dry eyes (21%) Dry mouth (16%) Caries (21%) Arthritis (5%)	Facial Pain (60%) Fever (40%) Arthralgia (40%) Dry eyes (40%) Dry mouth (5%) Caries (40%) Arthritis (0)
Salivary Gland Biopsy	N=8 -Lymphoplasmacytic infiltrate/sialadenitis: 50% -Granulomatous Inflammation: 12.5% -Nonspecific inflammation: 12.5% -Inadequate sample: 25%	N=3 -Non necrotizing granulomatous inflammation (67%) -Granulomatous parotiditis (33%)
Treatment	NSAIDS (37%) Antibiotics (26%) Oral steroids (26%) IV steroids (5%) MTX (16%) HCQ (11%)	NSAIDS (60%) Antibiotics (40%) Oral steroids (60%) IV steroids (0) MTX (40%) HCQ (40%) Other: Colchicine (20%), Humira (20%)
Patients achieving remission	N=12 Complete response: 36% Partial response: 9% No response: 27% Not enough information: 27%	N=5 Complete response: 40% Partial response: 40% No response: 20%

Table 2: Rheumatologic Therapy for patients with idiopathic JRP				
Patient	Age	Rheumatologic Treatment	Outcome	Notes
Patient 1	4	Oral corticosteroids	No response	Did improve per rheumatology provider but did not meet partial or complete remission criteria
Patient 2	5	Oral corticosteroids	Not enough information	First episode of parotitis did improve but did not meet partial or complete remission criteria.
Patient 3	5	Oral corticosteroids	No response	
Patient 4	5	Hydroxychloroquine	Not enough information	Started on medication early this year without documented relapses but has not had a follow up visit.
Patient 5	10	Oral corticosteroids, hydroxychloroquine, methotrexate	Complete response	
Patient 6	16	Oral/IV corticosteroids methotrexate	No response	Radiologic improvement of parotitis but still with frequent pain episodes.
Patient 7	6	Methotrexate	Complete response	

on laboratory evaluation or biopsy (27%). Five (18.6%) patients had a rheumatologic diagnosis: 2 with Sjogren's syndrome, 2 with sarcoidosis and 1 with unspecified granulomatous parotitis. Among patients referred, ANA was checked in 23 of 26 patients of which 57% were positive. Fifty percent of patients in the group underwent biopsy. Ten out of 26 patients underwent sialadenoscopy with steroid injection, 6 with Kenalog (60%), 3 with ciprofloxacin/dexamethasone (30%), and one with both (10%). Patients were followed for a mean of 25.7 months (range 0.5 -97).Of those without rheumatologic or infectious diagnosis, 7 (37%) patients received immunomodulatory treatment of which 2 achieved complete remission (29%). Treatment included corticosteroids, NSAID, methotrexate, and hydroxychloroquine (Table 2). Among the 12 patients without therapy, 2 (17%) had complete remission.

Conclusion: Patients with JRP were referred to rheumatology clinic due to suspicion for autoimmune conditions or refractory course. In this cohort only a small number of patients had a rheumatologic diagnosis and few idiopathic JRP received immunomodulatory therapy. A subset of children with recurrent parotitis may benefit from rheumatologic consultation and possible treatment with anti-inflammatory and immunomodulatory therapy. Limitation of this study include its retrospective nature, small number of patients and short follow up periods.

Intraocular Cytokine Profiling of Autoimmune Uveitis

Maryrose Hahn[1], Madison Mangin[2], Marc Todd[1], Pui Lee[1], Mindy Lo[1], Bharti Gangwani[3], Ankoor Shah[3], Amanda Colombo[4], Jessica Scott[4], Stephen Anesi[4], C. Stephen Foster[4], Peter Chang[4], Peter Nigrovic[2] and Margaret Chang[2], [1]Division of Immunology, Boston Children's Hospital, Boston, MA, [2]Boston Children's Hospital, Boston, MA, [3]Department of Ophthalmology, Boston Children's Hospital, Boston, MA, [4]Massachusetts Eye Research and Surgery Institution, Waltham, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune uveitis is an inflammatory disorder of the eye that is associated with significant morbidity, including vision-threatening complications and chronic reliance on immunosuppressive therapies. Each uveitis subtype is categorized by the affected region of the eye and is associated with different autoimmune disorders with distinct immunopathology (i.e. juvenile arthritis, sarcoidosis and Behcet's disease). However, it is unclear how these differences translate into differences in intraocular pathology. Here, we sought to evaluate the intraocular cytokine profile within each uveitis subtype.

Methods: We obtained intraocular fluid samples from patients at Boston Children's Hospital and Massachusetts Eye Research & Surgery Institution with uveitis or non-inflammatory controls undergoing eye surgery. We also collected clinical information such as slit-lamp examinations and medications at the time of surgery. Cytokine content in the aqueous humor was assessed through the Olink proteomics platform, which utilizes proximity extension assay technology to detect 45 cytokines through a multiplex immunoassay. To identify differences in the presence of specific cytokines, we used generalized linear models (LIMMA) on $\log_2$ transformed data. Each uveitis subtype was compared to the controls using Bayesian post-hoc testing. Thresholds for differential cytokine levels were adjusted $p< 0.05$ and fold change >1.

Results: We collected aqueous humor samples from control patients (n=10) and patients with anterior uveitis (n=13), intermediate uveitis (n=2), posterior uveitis (n=4), and panuveitis (n=7). At the time of sample collection, all patients had near-quiet disease activity on slit-lamp examination with anterior chamber cells grades between 0 and 0.5+ by SUN criteria. As expected, non-inflammatory control patients displayed low cytokine levels in their aqueous humor. Anterior uveitis and panuveitis had elevated cytokine expression, while intermediate uveitis and posterior uveitis showed cytokine levels comparable to controls, reflecting the anatomical regions affected by each uveitis subtype. Patients with anterior uveitis segregated into two groups, those with increased inflammatory cytokines (n=6) and those without (n=7). However, there were no significant differences in examination findings or medication usage between these two groups. Among the inflamed anterior uveitis samples, there was significant upregulation of TNF, IL-17, IL-10, IL-6, CXCL9 and IL-15, as well as several chemokines and matrix metalloproteinases compared to controls. Panuveitis also displayed a similar pattern of cytokine upregulation with no significant differences in expression between inflamed anterior uveitis and panuveitis.

Conclusion: While ophthalmic examinations indicated near-quiet clinical disease activity at the time of surgery, panuveitis patients and a subset of anterior uveitis patients displayed persistent inflammation within their intraocular fluid. Further, the similarities in the intraocular cytokine profile between anterior uveitis and panuveitis suggest convergence in inflammatory pathways.

Phenotype of Musculoskeletal Manifestations in a Canadian Inception Cohort of Pediatric Patients with Inflammatory Bowel Disease

Emily Dzongowski[1], Michael Miller[1], Melanie Schmidt[1], Nidhi Rashmikant Suthar[1], Thomas D Walters[2], Anne Griffiths[2], Wael El-Matary[3], Eric Benchimol[2], Jennifer deBruyn[4], **Roberta A Berard**[1] and Eileen Crowley[1], [1]Children's Hospital - London Health Sciences Centre, London, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada, [3]University of Manitoba, Winnipeg, MB, Canada, [4]Alberta Children's Hospital, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal (MSK) manifestations, including arthritis and arthralgia, are among the most common extraintestinal manifestations (EIMs) of inflammatory bowel disease (IBD), reported in 20-30% of adult patients. While patterns of MSK EIMs have been well-characterized in the adult population, there remains a paucity of data in pediatrics. The purpose of this study was to determine the frequency of MSK EIMs in a contemporary cohort of Canadian pIBD patients and describe the phenotype of MSK EIMs in this population.

Methods: This was a prospective longitudinal cohort study using data from the inception cohort of CIDsCaNN (Canadian Children IBD Network). This is a national network involving 12 academic pediatric centers in Canada. The inception cohort is comprised of patients aged 2 to 17 enrolled at diagnosis and followed prospectively. The study included data from creation of the inception cohort (01-04-2014) to the end of the previous calendar year (31-12-2021). Frequency of MSK EIMs was calculated for the entire inception cohort, as well as for subgroups based on age (< 5, 5 to 12, and 12 to 17), sex, and IBD type. For patients with MSK EIMs, phenotype was described by analyzing case report forms for specific EIM features as reported by treating physician. Variables were compared with Pearson Chi-square or Fisher's exact test, where cell counts were < 5. Statistical significance was defined as two-tailed p-value < 0.05. For patients without MSK EIM at time of IBD diagnosis, a Cox regression survival analysis was used to examine differences in age, sex, and ethnicity in terms of time to MSK EIM development, with right censoring for patients who never reported MSK EIMs over the course of follow up.

Results: A total of 1330 pIBD patients were included. 81 patients (6.1%) were reported to have MSK EIMs at IBD diagnosis or any point during follow up. There was no significant difference in overall MSK EIM frequency between sex or age groups. MSK EIMs were present in 63 CD (7.6%), 10 UC (2.6%), and 8 IBD-U (6.4%) patients. Patients with CD were more likely to have MSK EIMs than those with UC or IBD-U (7.6% vs 3.6%, p=0.002). 47 patients (58.0%) had MSK EIMs at or prior to IBD diagnosis while 34 patients developed MSK EIMs >4 weeks after IBD diagnosis. There was no difference in time to MSK EIM development by age or ethnicity. Females were more likely to develop MSK EIMs after IBD diagnosis than males, with odds of MSK EIM development increasing by factor of 4.68 for each year after IBD diagnosis (p=0.047). Of MSK EIM patients, 59 (74.7%) were evaluated by a rheumatologist. Peripheral MSK disease (arthritis, enthesitis, and dactylitis) was reported in 51 patients (63%). Data regarding axial disease (sacroiliitis and ankylosing spondylitis) were only available in 37 patients, 19 of whom reported axial distribution. Peripheral and axial MSK symptoms followed the course of bowel disease in 40.3% and 28.1% of patients respectively, which were not significantly different.

Conclusion: MSK EIMs affect 6.1% of a contemporary cohort of Canadian pIBD patients. This is less than reported in literature, which may be related to physician-reported nature of our data. Their phenotype is variable, with peripheral disease more frequent than axial disease across IBD types.

Abstract Number: 2044

Monogenic Interferon Mediated Diseases: Novel Phenotype and Genotype Characteristics from Saudi Population

Alhanouf Alsaleem, Sulaiman Al-Mayouf and Shahad Alansari, King Faisal Specialist Hospital & Research Centre, Riyadh, Saudi Arabia

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: IFN-mediated diseases are mendelian innate immunodysregulatory disorders that present early in life with fevers, sterile organ inflammation, and a high type-I IFN-response gene signature in peripheral blood cells. To date, monumental discoveries of novel genetic variants with various phenotypic features have been recognized. We sought to describe novel genotype and phenotype findings in Saudi children with a final diagnosis of autoinflammatory interferonopathy and compare our data to previous studies.

Methods: This is a descriptive retrospective cohort study of pediatric patients with final genetically confirmed type I interferonopathies. Medical records were reviewed for demographic, family history, clinical and genetic data.

Results: Total of 17 patients (11 female) were included in the study. Eight patients (47%) presented within the first six months. Median age of disease onset was nine months (IQR: 3-36), and the median age of diagnosis was four years (IQR: 2-9). The rates of consanguinity and family history of affected members were high (88% and 47%, respectively). Whole exome sequencing was performed in 13 patients, two had a Leukoencephalopathy genetic panel and two target gene tests. six patients with Aicardi-Goutières syndrome (RNASEH2A, RNASEH2C, IFIH1), two patients with STING-associated vasculopathy with onset in infancy (TMEM173), 1 patient with chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (PSMB8), one patient with DNASE2. seven patients had rare interferonopathy conditions (3=ISG15, 2=ZNFX1, 1=SOCS1, 1=STAT1). Of 17 patients, 11 (64%) had novel genetic variants. The most frequent features were fever (76%), neurology (70%), mucocutaneous (59%), gastrointestinal (53%), and pulmonary (47%). Hypogammaglobinemia and recurrent infections were seen in (47%) and (23%) respectively. Thirteen patients (76%) had elevated inflammatory markers. More than half patients treated aggressively; corticosteroids (59%), Jak inhibitor (35%), IVIG (29%), and various immunosuppressive agents in (23%) patients. Most of the patients had partial response to treatment. The majority had features of disease damage: growth failure (70%) followed by developmental delay (159%) and zero death.

Conclusion: This Saudi monogenic interferonopathies cohort represents the largest single center study from the Arab population. Our findings support the previous reports; early-onset fever, neurology and respiratory features should raise the suspicion of interferonopathies. However, there is eminent evidence of novel phenotypic variability. Our data expands the spectrum of clinical finding in relation to novel genetic variants.

Disclosure: A. Alsaleem: None; **S. Al-Mayouf**: None; **S. Alansari**: None.

Treatment Response in a Cohort of Pediatric Patients with Autosomal Dominant Neovascular Inflammatory Vitreoretinopathy (ADNIV)

Ilaria Maccora[1], Arjun Sood[2], Grant Schulert[3], Alexandra Duell[3], Preston Land[4], Cameron C Sapp[2], Jennifer Huggins[3], Tiffany Nguyen[2], Megan Quilan-Waters[3], Sumit Sharma[5], Sunil Srivastava[2] and Sheila Angeles-Han[6], [1]PhD student, in the Area of Drugs and Innovative Treatments, NeuroFARBA Department, University of Florence. Meyer Children's Hospital, Firenze, Italy, [2]Cincinnati Eye Institute, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [4]Cincinnati Children's Hospital, Medical Center, Cincinnati, OH, [5]Cleveland Clinic, Cleveland, OH, [6]Cincinnati Children's Hospital, Cincinnati, OH

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pediatric uveitis often requires systemic immunomodulatory therapy (IMT) to prevent sight-threatening complications. Autosomal dominant neovascular inflammatory vitreoretinopathy (ADNIV) is a rare autoimmune condition caused by variants in CAPN5, diagnosed in adulthood, and characterized by intermediate uveitis, retinal degeneration and neovascularization. It is asymptomatic in early stages but inevitably leads to permanent blindness despite treatment. Proteomic studies report elevated IL6 and VEGF in the vitreous, suggesting a role for targeted therapy to alter disease trajectory. Our aim is to present the visual outcomes of a pediatric ADNIV cohort after systemic IMT.

Methods: Cohort study of patients ≤18 years old with a genetic diagnosis of ADNIV, (+) CAPN5 variants (p.Leu244Pro), ultra-widefield fluorescein angiography (UWFA) and optical coherence tomography (OCT) imaging, and a minimum follow-up of 6 months (m) of systemic IMT. Treatment response was defined as a decrease in 1) vitreous cells on clinical examination, 2) retinal vascular leakage on UWFA, and/or 3) macular edema on OCT.

Results: 8 children (16 eyes) met inclusion criteria (Table 1). Five were female, median age at diagnosis was 14 (range [R] 9-16) years and 4 were asymptomatic. Median follow-up was 18 m (R 6-20). On initial exam, visual acuity in the worse eye was 20/100 or better, 0 had anterior uveitis, while 7 patients had vitreous cells, 8 vascular leakage (UWFA), 2 neovascularization (UWFA), 3 macular oedema (OCT) and 1 cataract. Five patients were initially treated with oral (n=5) or local/injected corticosteroids (n=4), and anti-VEGF therapy (n=2). Due to persistent inflammation, systemic IMT was started in 7/8 patients

response. Only 1/5 was able to increase the interval of administration of intraocular corticosteroids. Four/five patients discontinued TCZ for inefficacy. The single patient discontinued ADA due to inefficacy. Outcomes at the last available follow-up are reported in Table 3. Of 6 patients, 2 switched to tofacitinib and 5 received steroid implants.

Conclusion: We report the visual outcomes of the largest series of children with ADNIV treated with systemic IMT. Early testing for CAPN5 gene in at risk children, and regular screening for uveitis and vasculitis will lead to prompt intervention. MTX, IFX and TCZ were ineffective. However, we observed that TCZ was able to decrease the need of intraocular corticosteroids in one patient. Further studies are needed to determine optimal treatment in terms of molecules chosen but also of route of administration in these children.

Abstract Number: 2046

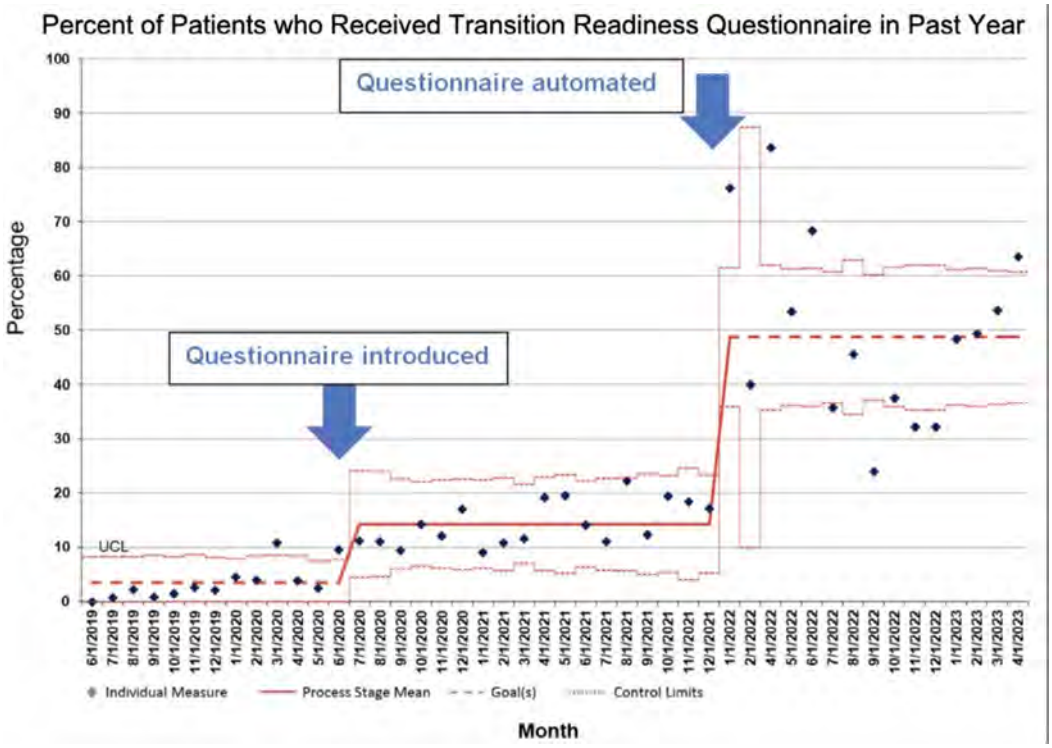
Implementation of an Automated Transition Readiness Assessment in a Pediatric Rheumatology Clinic

Elizabeth Murray[1], Melissa Argraves[1], Alysha Taxter[2], Kelly Wise[3], Paul Jensen[4], Alana Goldstein-Leever[1], Bethanne Thomas[1], Alexa Scott[1], Jonnie Lee Hughes[1], James Gallup[1], Diana Sumano Vicente[1], Stacy Ardoin[1] and Vidya Sivaraman[1], [1]Nationwide Children's Hospital, Columbus, OH, [2]Nationwide Children's, Columbus, OH, [3]Nationwide Children's Hospital, Hilliard, OH, [4]Intermountain Southwest Rheumatology Associates, St. George, UT

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Many pediatric patients are inadequately prepared for the transition from pediatric to adult subspecialty healthcare, and patients who fail to transition successfully are more vulnerable to poor health outcomes.Frequently, pediatric rheumatology clinics do not provide formal training or resources to develop skills related to this transition. Interventions to improve the transition process include implementing a transition policy andperiodically assessing patient and parent or caregiver readiness to transition.

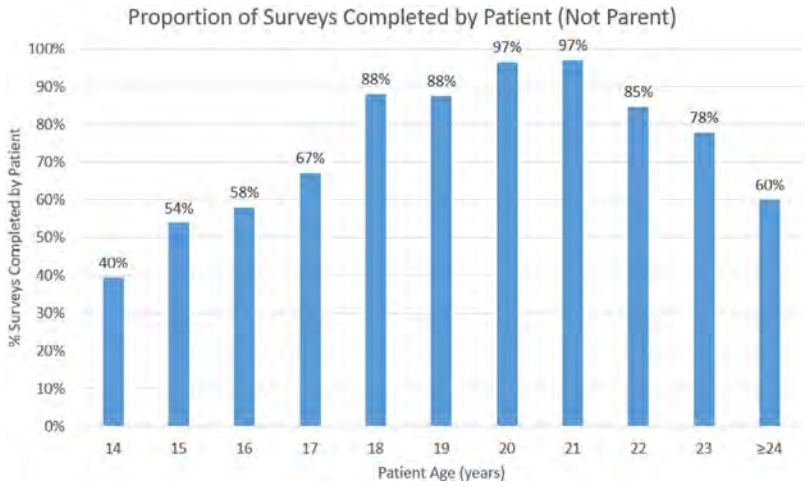
Methods: A multidisciplinary transition team formed to improve processes related to transition to adult care by using quality improvement (QI) methodology. Beginning in July 2020, a modified Transition Readiness Assessment Questionnaire (TRAQ) was delivered through the electronic health record (EHR) for patients aged ≥ 14 years with ≥2 visits in the prior 3 years. Beginning in December 2021, questionnaires were automatically assigned annually during routine care. Questionnaires asked about patients' interest in and perceived readiness for moving to an adult rheumatology setting by age 21, as well as need for education on skills required to navigate the medical system and advocate for one's own needs. Questionnaires could be completed by either the patient or a parent or caregiver. Data was extracted via EHR reporting tools. QI methodology and descriptive statistics were used.



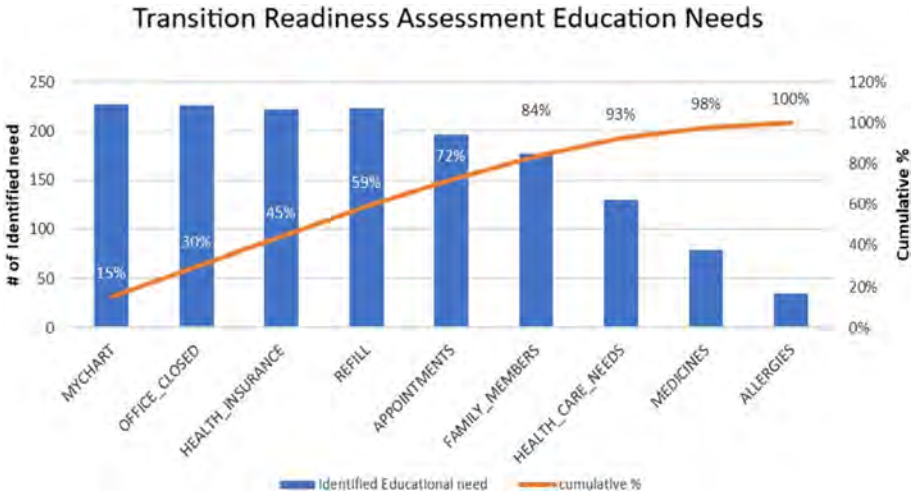
Integrating automated questionnaires within the EHR significantly increased the proportion of patients aged ≥ 14 years who received a questionnaire (p<0.001)

Results: Integrating automated questionnaires within the EHR significantly increased the proportion of patients aged ≥ 14 years who received a questionnaire from less than 20% to nearly 50% of patients (p< 0.001). This increase was sustained over the 16 months following the introduction of automated questionnaires (Figure 1).

From January 2022 to April 2023, 1091 questionnaires were administered. Of these, 862 (79%) were fully completed and 918 (84%) had at least one question answered by 868 unique patients. The median age was 16 years [interquartile range 15, 18]. Fewer than half of 14-year-old patients completed the questionnaire themselves; the patient completion rate increased up to age 20-21, then decreased (Figure 2).



The patient completion rate increased up to age 20-21, then decreased.



The most frequently identified educational needs related to EHR messaging, obtaining care if the office is closed, health insurance, refilling medications, making appointments, and awareness of family history.

The most frequently identified educational needs related to EHR messaging, obtaining care if the office is closed, health insurance, refilling medications, making appointments, and awareness of family history. Together, these six factors accounted for over 80% of the identified needs (Figure 3).

Unsurprisingly, older patients reported less need for education on each skill assessed. Patients aged 14-17 were about twice as likely to report they could not complete each skill independently.

Conclusion: Integrating a transition readiness assessment in the EHR is feasible and can identify population-wide knowledge gaps as well as facilitate targeted individual education. In our population, the most perceived educational needs include EHR messaging, emergency care, health insurance, and refilling medications. Older patients are generally more likely to report competence at each skill assessed. This process can be implemented at other sites to help streamline transition readiness assessment and increase response rates.

Abstract Number: 2047

Safety of Baricitinib for COVID-19 Related Hyperinflammation in Pediatric Patients: A Large Tertiary Care Center Experience

Meredith Rae[1], Jessica Nguyen[2], Marietta DeGuzman[3], Catherine Foster[1], Flor Munoz[1] and Eyal Muscal[4], [1]Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [2]Baylor College of Medicine, Manvel, TX, [3]Baylor College of Medicine / Texas Children's Hospital, Houston, TX, [4]Division of Rheumatology, Department of Pediatrics, Baylor College of Medicine, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A small proportion of children with acute COVID-19 experienced life-threatening hyperinflammation. It has been proposed that an innate immune recognition of viral RNA triggers excessive cytokine and interferon production. Adult studies have shown baricitinib usage (as part of an emergency use authorization) to be associated with stabilization of severe disease and reduced mortality. There is a paucity of pediatric data regarding COVID-19-associated JAK inhibition. We collected data on inflammation, disease progression, and safety of baricitinib in children hospitalized with COVID-19.

Methods: Retrospective medical record review was conducted of children admitted with COVID-19. Demographics, laboratory, and clinical features were collected from all children treated with baritcitinib for COVID-19 pneumonia and secondary hyperinflammation throughout all major surges of the pandemic under the auspices of an IRB approval.

Results: The demographics and clinical features of 10 patients treated with a JAK inhibitor are shown in Table 1. Nine (90%) were Hispanic, and 7 (70%) were male. All patients were obese (BMI >95th percentile) but were otherwise healthy. All children treated with baricitinib were infected during Delta strain predominance. All had fever and respiratory distress as presenting symptoms, and 60% had GI symptoms. Median onset of symptoms was 7 days prior to admission (IQR 7-11 d). No patients met criteria for MIS-C. Baricitnib was initiated on median hospital day 2 (IQR 1.5-2 d) and administered for a median of 10 days (IQR 6-14 d). All patients were on dexamethasone and remdesivir and had improvements in their inflammatory markers during their course. Two children required escalation to ECMO after initiation of baricitinib. One of these

Table 1. Patient characteristics, N=10

Median age (years)	15.5 (IQR 14-19)
Sex	
Male	70%
Female	30%
Race/ethnicity	
Hispanic	90%
White	10%
Median BMI (kg/m^2)	37.7 (IQR 30.2-46.5)
Comorbid conditions	
Obesity	100%
Autism Spectrum Disorder	10%
Asthma	10%
Obstructive sleep apnea	10%
History of seizures	10%

children passed away. Of the surviving patients, median time to clinical recovery, assessed by a score of 1 on NIAID-OS, was 10 days (IQR 8-16 d). Median ICU stay was 9.5 days (IQR 5.8-18.5 d), and length of hospital stay was 11 days (IQR 11-23.5 d). Baricitinib was stopped in only one patient due to clinical concern of pulmonary embolism (unable to be imaged). Three patients developed secondary infections followingbaricitinib initiation (MSSA and culture-negative pneumonia in two). One critically ill patient developed numerous infections during the hospital stay (UTIs [*E.coli* and *Klebsiella*], MSSA pneumonia/ bacteremia, *Proteus mirabilis* and *E. faecalis* wound infections). Baricitinib was safely continued with mild-moderate increased transaminases in 7 patients (Table 3). One patient developed neutropenia, and two lymphopenia. Hematologic events were transient and did not require cessation of baricitinib.

Conclusion: Children with Delta-variant associated hyperinflammation tolerated adjunctive treatment with baricitinib with a lower-than-expected adverse event and cessation rate. Additional data from other centers may be necessary to understand the role of JAK inhibition in enhancing the survival of children with severe COVID pneumonias and inflammation.

Table 2. Clinical course, N=10

Presenting symptoms on admission	
Fever	100%
Respiratory symptoms	100%
GI symptoms	60%

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The ChRonic nonbacterial Osteomyelitis Magnetic Resonance Imaging Scoring (CROMRIS) tool was developed but it was not digitized yet. Our objectives are: 1) to adapt the CROMRIS tool to a web-based platform and 2) assess the usability of this system among radiologists.

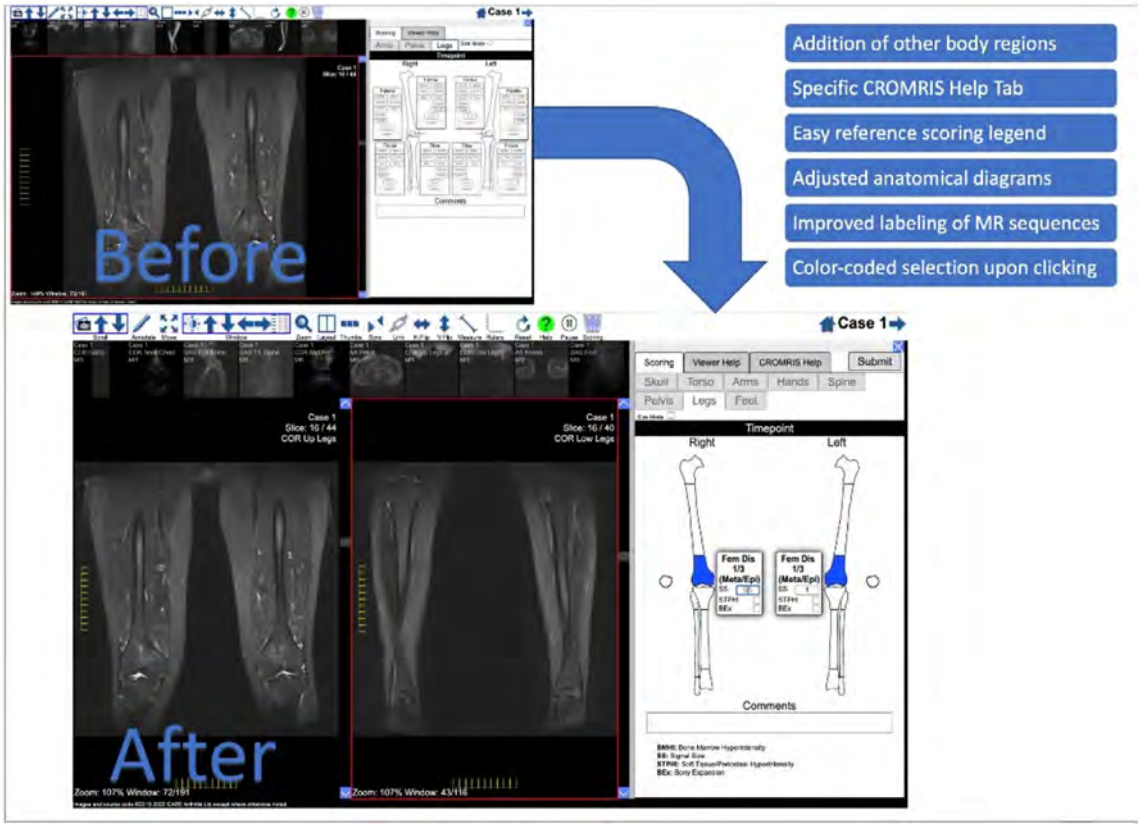

Figure 1. Screenshot of Web-based CROMRIS Portal on Tab for Long Bones of Lower Extremity Before and After Feedback Sessions/Usability Testing

Methods: A prototype web-based CROMRIS tool was developed by CARRA's CNO Workgroup and CARE-Arthritis in 2019. Since then, monthly meetings between software developers, rheumatologists, radiologists and an illustrator led to a beta version that included the whole skeleton. A group of radiologists (n=7) provided feedback on the beta version in a demo

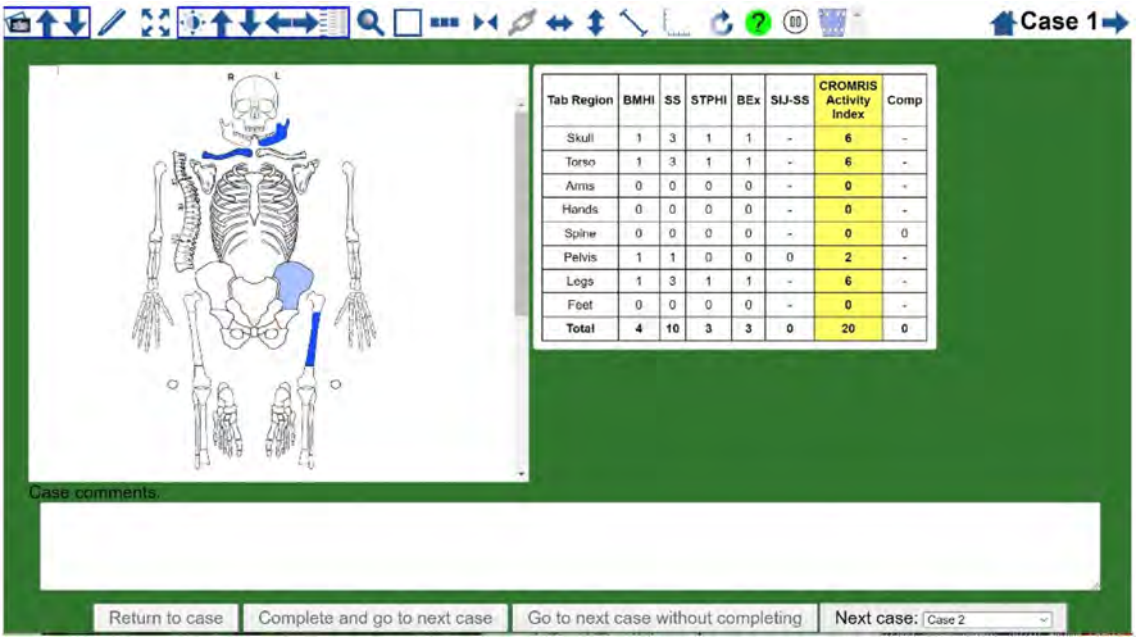

Figure 2. Screenshot of Summary Page for Final Web-based CROMRIS Portal

Table 1. Scoring of Active CNO Lesions in General Bone Units in the Web-Based CROMRIS

CNO Lesion Characteristic		SCORE
Bone marrow hyperintensity (BMHI)	Absent	0
	Present	1
Signal Size (SS)	< 25%	1
	25–50%	2
	> 50%	3
Soft tissue hyperintensity/periosteal reaction (ST/PHI)	Absent	0
	Present	1
Bony expansion (BEx)	Absent	0
	Present	1

1.The characteristics included and score assigned to each variable for active CNO lesions within bone units as described in the Atlas for the web-based CROMRIS portal in general. Adding up all parameters for a maximum score of six for each bone unit, except sacroiliac joints, which is scored separately. Bone units are defined in the Atlas.
2.The sum of individual bone unit scores is the CROMRIS Activity Index.

session on 4/11/22 via semi-structured surveys (#IRB2021-00033). Usability was assessed by surveys using the System Usability Scale (SUS), a Likert scale in which respondents indicate their level of agreement or disagreement on a scale of 1 to 5 for 10 statements on ease of use, effectiveness, and satisfaction in content of use. Feedback was reported with descriptive content analysis, continuous variables as means and categorical variables as percentages.

Results: A clickable-schematic-based CROMRIS was developed to include all body regions [Figure 1]. Notable features are the ability to immediately highlight a schematic region upon selection to directly input scores. Suggested changes included labeling of individual spine and rib segments, insertion of scoring legend on each tab for reference and creation of a summary page with a composite diagram where one can visualize the location and size of lesions by color as well as a numerical CROMRIS activity index [Figure 2]. The general scoring on the portal is indicated by clicking on a bone unit to indicate the presence of bone marrow hyperintensity consistent with an active CNO lesion, which is qualified by other lesion parameters [Table 1]. A video tutorial and MRI Atlas is on the platform for training (https://www.carearthritis.com/mriportal/crmo/index/). Visual factors and anatomical diagrams were among the features "liked best" by the survey respondents. Mean SUS scores increased from 64.5 (below average) to 75 (above average). All respondents agreed that the final version of the web-based CROMRIS was "easy to learn" and found that the "various functions of the web-based CROMRIS were well integrated, and "would like to use the web-based CROMRIS in future clinical trials."

Conclusion: The web-based CROMRIS portal shows good usability amongst radiologists. Studies of interrater reliability among experienced pediatric radiologists are underway. Once validated, this tool can be used as a semi-quantitative MRI scoring tool to allow for standardization of reporting output of radiological interpretations of MRI in CNO. The authors wish to acknowledge CARRA and the ongoing Arthritis Foundation financial support of CARRA.

Vaccination Coverage and Caregiver Perspectives for Children with Rheumatic Diseases Compared to Healthy Controls

Shine Vazhappilly[1], Racheal Githumbi[2], Nicole Johnson[2], Otto G Vanderkooi[2] and Heinrike Schmeling[2], [1]Saba University, Blue Ash, OH, [2]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Children with rheumatic diseases (RD) have an increased incidence of infections and their complications, both from underlying disease activity and immunosuppressive treatments. Vaccines have been well-established as effective intervention in combating these. Studies assessing vaccination barriers remain limited.

To assess the vaccination status of children with RD and identify immunization facilitators and barriers of families compared to healthy controls (HC)

Methods: A cross-sectional study of children with RD and HC (fracture clinic) at a single tertiary care center was performed. Demographics, diagnosis, and current treatments were obtained from health records. Children with RD were considered immunosuppressed, if they were currently received corticosteroids, nonbiologic or biologic disease-modifying agent. A unique provincial electronic database that records accurate vaccine history was used to obtain actual patient vaccination history. Perceived immunization barriers, concerns, factors promoting vaccination, and satisfaction with information received were captured from a caregiver questionnaire. Descriptive statistical methods were used to analyze the data.

Results: A total of 144 children with RD (76% considered immunosuppressed) and 111 HC were recruited into the study. Vaccination database: Both, children with RD and HC received most of the provincial recommended vaccines at rates of 85% or above, except for Influenza. Influenza vaccine had the lowest adherence rate at 34% RD vs 21% HC: 25% vs 43% in the 1 – 4 years old group, 32% vs 24% in the 5 – 11 years old group, and 38% vs 10% in the 12+ years old group. Caregiver questionnaire: In 31% of children with RD at least one vaccination was withheld, most commonly for active disease (27%), recommendation against receiving vaccinations by health care provider (25%), concerns about side effects post vaccination (18%) and/or disease flare (14%). In 27% of HC at least one vaccination was withheld, most commonly for concerns about side effects post vaccination (13%). Several sources of information were utilized. Both groups listed the primary vaccination information source as the family doctor (66% in RD vs 69% in HC). At least 85% of survey respondents in each group felt satisfied by the amount of information received. The following information gaps were identified: 1) risks and contraindications of vaccinations in general and in children with rheumatic diseases, 2) age-appropriate vaccination schedules and modalities, 3) best practice of vaccination documentation. Vaccination reminders were identified as useful, with several comments indicating that e-mail alerts, reminders, and a method to track this information would be useful.

Conclusion: Most children with RD and HC equally received the recommended vaccines. Immunization gaps were identified for Influenza in both groups and presents an area of improvement. Knowledge regarding contraindications to vaccination is well understood. Concerns about perceived safety limit vaccination completeness in both groups.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

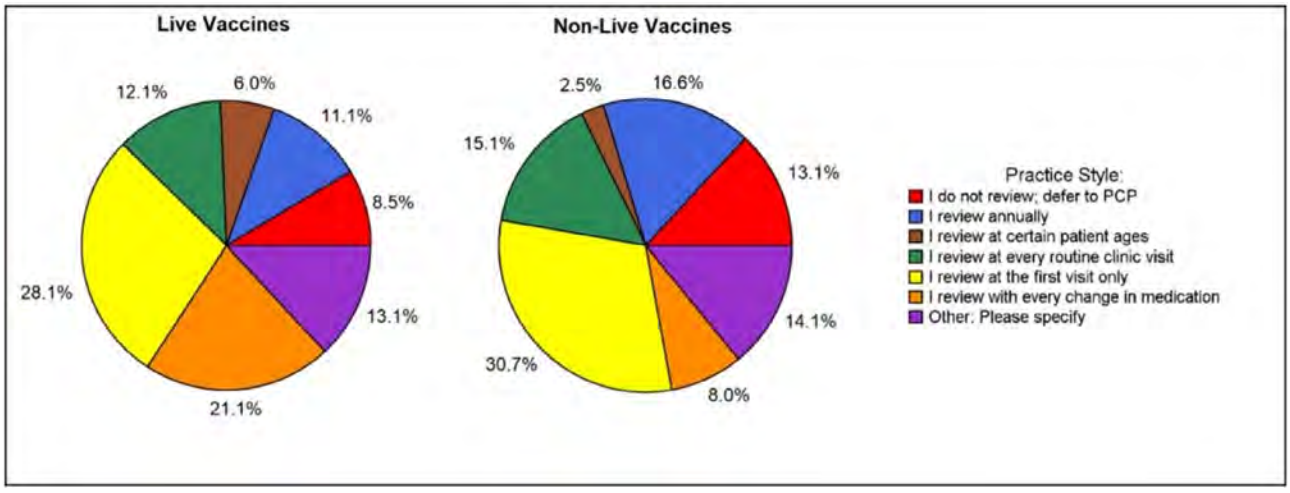
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunocompromised children (ICC), including children with rheumatic diseases receiving immunosuppressive therapies (IST) are at increased risk of morbidity from vaccine-preventable infections. The 2022 American College of Rheumatology (ACR) Vaccination Guidelines emphasize the need to vaccinate ICC and minimize missed opportunities for immunizations. Children with rheumatic diseases receiving IST are eligible to receive inactivated vaccines, however vaccination rates remain unacceptably low in these children. The CARRA Vaccination Workgroup (WG) surveyed North American pediatric rheumatologists about their vaccination practices when caring for children receiving IST.

Methods: The CARRA Vaccination WG developed and electronically distributed a REDCap survey to CARRA member healthcare professionals from March-May 2022.

Results: The survey was completed by 219 pediatric rheumatology providers with a response rate of 60% (74% attendings, 21% fellows). More than 90% of rheumatology providers reviewed their patients' vaccinations, with most reviewing live (28%) and non-live vaccines (31%) at the first visit only (Figure 1). Several providers used comments to clarify their vaccine review practices, most commonly reporting reviewing influenza and COVID vaccines alone, or in combination with other vaccines. Thirty-nine percent of providers reviewed conjugate (PCV-13) and polysaccharide (PPSV 23) pneumococcal vaccine status, especially in patients with childhood-onset SLE (c-SLE). Twenty-six percent reviewed vaccination status based on initiation or type of IST, and age, whereas half of respondents reported used a disease-specific review approach, focused primarily on c-SLE (89%), followed by systemic vasculitis (42%), juvenile dermatomyositis (39%) and juvenile idiopathic arthritis (28%). Forty-two percent of providers reported medication-specific review, including prior to Rituximab initiation (57%), initiation of any IST (20%), IVIG (10%), or cyclophosphamide (7%). There was also variability in communication about vaccines between rheumatology provider and primary care pediatricians (PCPs), with 41% of rheumatologists indicating they did not contact the PCP, 22% contacting the PCP regarding live vaccines only, 30% for live and non-live vaccines, 19% for pneumococcal vaccines, and 18% for 'Other', of which more than half of those who wrote narrative comments stated vaccine recommendations were included in the clinic note to the PCP.

Conclusion: This survey demonstrated significant variability in rheumatology provider approaches to vaccinations in ICC. While 90% of rheumatology providers reviewed vaccinations, less than half reviewed seasonal vaccines or pneumococcal vaccines, and those who did, mainly reviewed vaccinations in the setting of specific diseases, specific medications, or



Provider Practices for Review of Patient Vaccinations

new patient visits. Our results highlight opportunities for improvement in the care of ICC by increasing awareness of the need for vaccination against vaccine-preventable infections. This study underscores the need for standardized vaccination practices in ICC and improved communication between providers to maximize immunization opportunities for ICC.

Screening Multisystem Inflammatory Syndrome in Children: Accuracy of SickKids Screening Pathway Compared to ACR Algorithm

Greta Mastrangelo[1], Paul Tsoukas[1], Trent Mizzi[2], Beth Gamulka[3], Amy Xu[1], Arthur Hoi Hin Cheng[1] and Rae Yeung[4], [1]Division of Rheumatology, Department of Paediatrics, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [2]Department of Emergency Medicine, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [3]Department of Paediatrics, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada, [4]The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Multisystem Inflammatory Syndrome in Children (MIS-C), also known as Pediatric Inflammatory Multisystem Syndrome temporally associated with COVID-19 (PIMS), is one of the most serious complications associated with COVID-19.The clinical features of MIS-C are not unique and are commonly seen in childhood febrile conditions. Thus, there is a need to identify those febrile children with MIS-C to enable early diagnosis and treatment. In response to the health care emergency, a multidisciplinary team from The Hospital for Sick Children (SickKids) of Toronto developed a preliminary screening pathway for the evaluation of possible MIS-C. The primary objective is to determine if the SickKids screening

pathway is sensitive and specific to identify patients with MIS-C from other febrile children with suspected but not confirmed diagnosis of MIS-C. The secondary objective of this study is to determine how the ACR MIS-C algorithm performs compared to the SickKids screening pathway in differentiating children with MIS-C from the febrile controls.

Methods: Retrospective case-controlled, cross-sectional study including children who have been assessed at SickKids with suspected or confirmed MIS-C from March 2020 to March 2022. The MIS-C group included all children meeting the most permissive case definition as per international MIS-C and PIMS definitionsand adjudicated by our multi-disciplinary MIS-C working group; the febrile control group consisted of all patients with a history of three or more days of fever who were suspected of MIS-C and qualified for the SickKids MIS-C screening pathway, but did not fulfill criteria for MIS-C after adjudication by our multi-disciplinary group. SickKids and ACR pathways were retrospectively applied to both groups.The diagnosis result obtained using the pathways was compared with the final clinical diagnosis made using the WHO definition criteria, used as the gold standard. From the contingency table, sensitivity and specificity have been calculated along with a 95% confidence interval.

Results: 402 children (241 with MIS-C and 161 febrile controls) were included in the study. The median age was 4.18 years (IQR: 1.9 to 9.0) and 237 (60%) were male. For the SickKids screening pathway, the sensitivity was 62% (95%CI, 54.2% to 70.4%), and specificity was 91% (95%CI, 86.9% to 94.2%). The positive predictive value (PPV) was 79% and the negative predictive value (NPV) was 81%. Overall, the balanced accuracy was equal to 76%. The ACR screening pathway had 74% sensitivity (95%CI, 67.3% to 81.4%), and 99% specificity (95%CI, 98.1% to 100%), with PPV of 98% and NPV of 87%. The balanced accuracy was 87%.

Conclusion: The SickKids MIS-C screening pathway has a high specificity, but a low sensitivity and accuracy in capturing children with MIS-C at the onset of the disease. Overall, the ACR algorithm performs better at differentiating children with MIS-C from febrile controls.

Risk Factors for Hospitalization for SARS-CoV-2 in Pediatric Patients with Rheumatic Diseases: A Systematic Review and Meta-analysis

Qianzi Zhao[1], Beth Wallace[2], Lawrence Jung[3] and Tova Ronis[4], [1]Trinity Health Ann Arbor, Ann Arbor, MI, [2]Michigan Medicine, VA Ann Arbor Healthcare System, Ann Arbor, MI, [3]Jung Medical, Cedar Falls, IA, [4]Children's National Hospital, Chevy Chase, MD

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Among adults who develop SARS-CoV-2 infection, those with rheumatic diseases (RDs) have similar hospitalization rates compared to those without RDs. Similar comparisons are lacking in children, due to the overall rarity of hospitalization due to SARS-CoV-2 in this population. We aimed to examine hospitalization risk for SARS-CoV-2 in pediatric patients with rheumatic diseases and its associated risk factors.

Author	Year	Country	Type	Study design	Calendar period	Total number	Rheumatic diseases included	Newcastle-Ottawa scale

AID, autoinflammatory disease; CARRA, Childhood Arthritis and Rheumatology Research Alliance; CTD, connective tissue disease; EULAR, European Alliance of Associations for Rheumatology; JIA, juvenile idiopathic arthritis; RA, rheumatoid arthritis; RD, rheumatic disease; SLE, systemic lupus erythematosus.

Methods: We conducted a systemic literature search in MEDLINE, EMBASE, Web of Science, and China National Knowledge Infrastructure from December 1, 2019 through April 20, 2023. We included observational studies of pediatric rheumatic disease populations with sufficient data to calculate at least one odds ratio (ORs) for the primary outcome of COVID-19-related hospitalization(Fig 1). We assessed risk of bias using the Newcastle-Ottawa Scale for cohort studies.

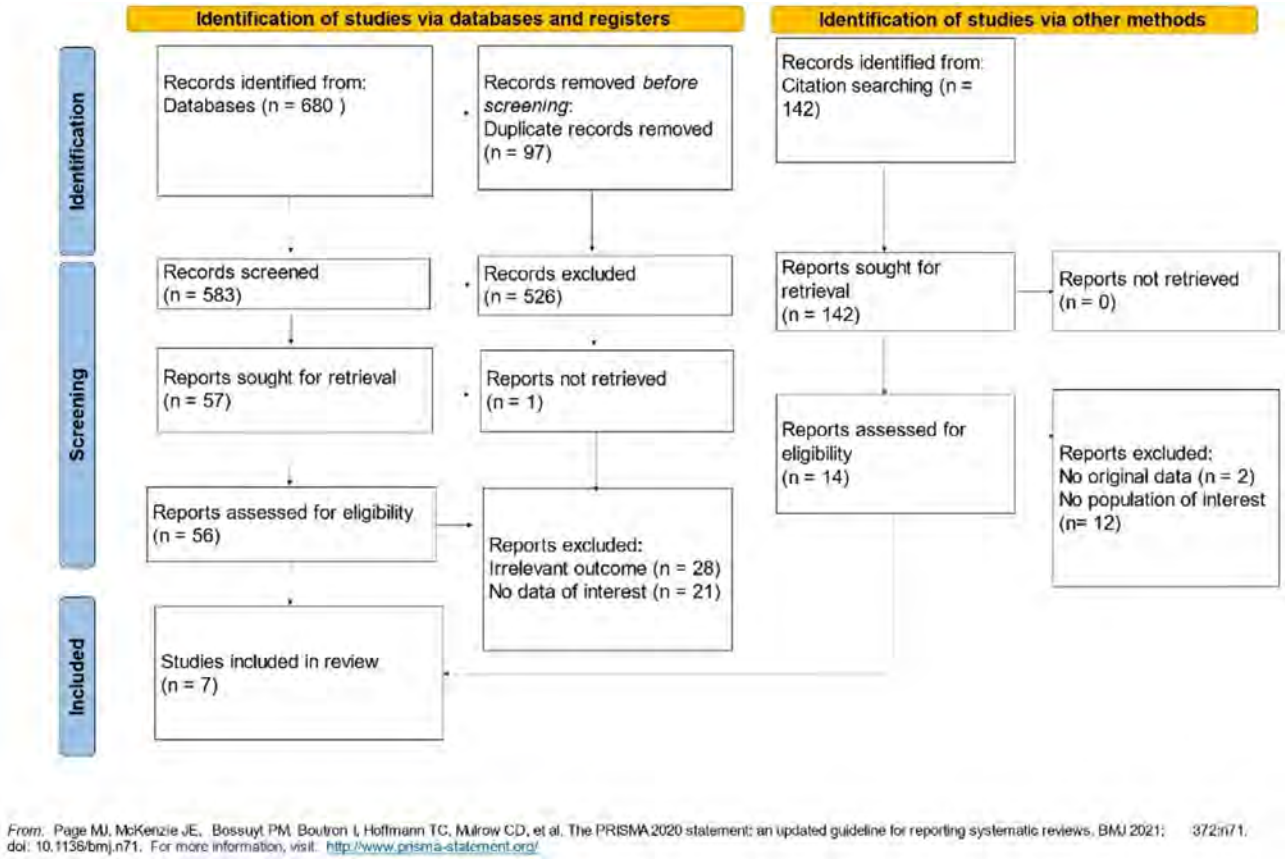

Figure 1. PRISMA Flow chart of the methods used for identification of studies.

Study heterogeneity was assessed by Q statistics and I^2 statistic. ORs with 95% confidence intervals (95% CIs) were calculated using fixed-effect models based on the Mantel-Haenszel method if $I^2 < 50\%$.

Results: Sevencohort studies capturing 1,019 pediatric RD patients with confirmed SARS-CoV-2 were included (Table 1, Fig 1). Odds of hospitalization was increased in children with RD compared to healthy children ((OR 2.31; [95% CI, 1.17-4.58]), Fig. 2A). The diagnoses of systemic lupus erythematosus/connective tissue disease (SLE/CTD) ((OR 2.83; [95% CI 1.25, 6.40), Fig. 2B) and systemic juvenile idiopathic arthritis (JIA) ((OR 2.54, [95% CI, 1.01-6.40]), Fig. 2D) were associated with increased odds of hospitalization, while total JIA was associated with reduced odds ((OR 0.42, [95% CI, 0.26-0.67]), Fig. 2C). Use of rituximab ((OR 4.62, [95% CI, 1.87-11.4], Fig. 2E)), glucocorticoids ((OR 3.75; 95% CI [2.17-6.48]), Fig. 2F) or IL-1 inhibitors ((OR 2.28, [95% CI, 1.09-4.78], Fig. 2G) was associated with increased odds of hospitalization; use of TNF inhibitors was associated with reduced odds ((OR 0.35, [95% CI, 0.19-0.65], Fig. 2H). Use of tocilizumab (OR 0.99, [95% CI, 0.34-2.87]), tofacitinib (OR 3.01, [95% CI, 0.69-13.12]) and traditional DMARDs (OR 0.71, [95% CI, 0.43-1.17] were not associated with a change in odds of hospitalization. A limitation of the study was the predominantly Caucasian population, with no data for patients from China, India, Korea or Japan.

Conclusion: Pediatric patients with RDs have higher oddsof SARS-CoV-2 related hospitalization than healthy children, especially those with SLE/CTD and those using Rituximab, glucocorticoids and IL-1 inhibitor.In contrast, JIA and anti-TNF inhibitor use was associated with a reduced odds of hospitalization.

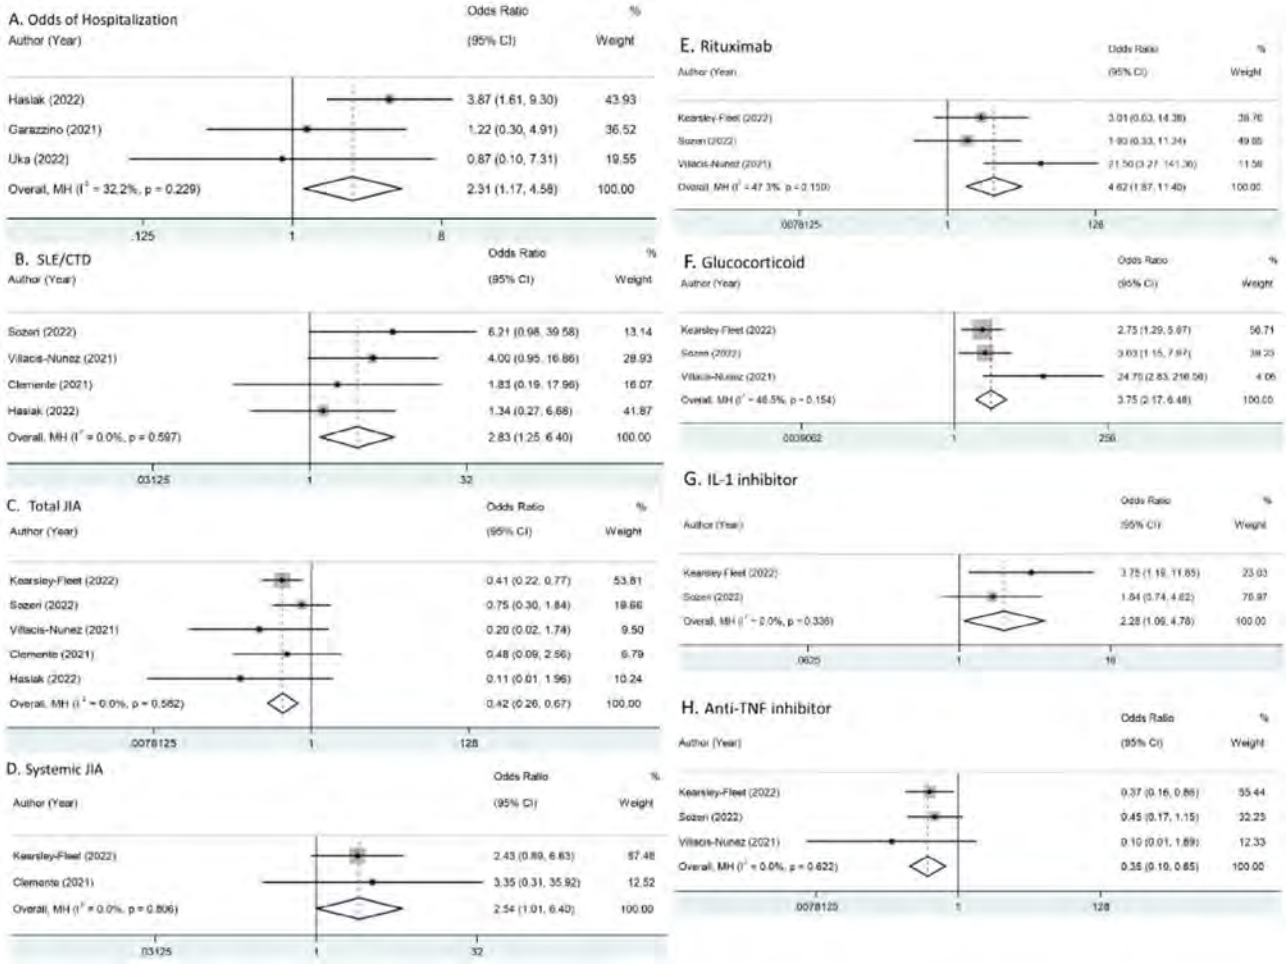

Figure 2. Forest plots demonstrating odds ratio of hospitalization in children with rheumatic diseases and associated risk factors of hospitalization: A. odds of hospitalization, B. SLE/CTD, C. total JIA, D. systemic JIA, E. Rituximab, F. Glucocorticoid, G. IL-1 inhibitor, H. anti-TNF inhibitor

Predictive Factors Associated with Treatment Response in Chronic Nonbacterial Osteomyelitis

Katherine Nowicki[1], Nathan Rogers[2], Carson Keeter[2], Nathan Donaldson[2], Jennifer Soep[2] and Yongdong (Dan) Zhao[3], [1]University of Colorado, Lakewood, CO, [2]University of Colorado, Aurora, CO, [3]University of Washington, Redmond, WA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic nonbacterial osteomyelitis (CNO) is characterized by sterile inflammatory bone lesions and most commonly affects skeletally immature children. Non-steroidal anti-inflammatory drugs (NSAIDs) are the first-line treatment, but in some cases second-line treatments including methotrexate, TNF-alpha inhibitors, and bisphosphonates are required. It remains unclear which patients are most likely to respond to NSAIDs or require a second-line treatment based on their initial presentation. In this study, we sought to describe our CNO cohort and to determine which pre-treatment clinical variables are associated with response to NSAID monotherapy versus requiring a second-line medication.

Methods: A retrospective chart review of patients with a diagnosis of CNO made before 18 years of age who attended the CNO clinic at Children's Hospital Colorado between 1/1/05 and 1/31/22 was performed. The standardized treatment approach involved 6 months of NSAIDs, followed by a trial of discontinuation in responders. Patients who failed the discontinuation trial were given a longer NSAID course. Patients with spinal involvement, patients with comorbidities such as psoriasis or inflammatory bowel disease, and NSAID-non-responderswere treated with second-line therapies. Clinical characteristics were recorded,including which of 6 regions (head and face, neck and back, upper torso,upper extremities, lower torso, lower extremities) were affected by CNO. Patients were divided into three groups: NSAID-short (NSAID monotherapy for 3 to < 7 months), NSAID-long (NSAID monotherapy for ≥7 months), or second-line treatment. A multiple linear regression model was constructed to determine the relationship between total NSAID monotherapy days and relevant predictors. Multiple logistic regression was used to determine the odds of needing second-line treatment when considering those same predictors. Both models contained combinations of variables which minimized the Akaike Information Criteria (AIC), resulting in models with low multicollinearity and high predictive power.

Results: 164 patients fulfilled inclusion criteria and 70 patients were excluded. Cohort characteristics overall and for each of the 3 treatment groups are presented in Table 1. Comparison between the NSAID-short and NSAID-long groups showed that patients with unifocal disease at diagnosis required 47% less days of NSAID treatment than those with multifocal disease at diagnosis (Table 2). Comparison of the NSAID monotherapy groups to the second-line treatment group showed that patients with 2 or more regions affected by CNO were 1.94 times more likely to require a second-line treatment ($p < 0.05$) and that patients with symmetric bone lesions were 6.86 times more likely to require a second-line treatment ($p< 0.0001$) (Table 3).

Conclusion: Our cohort is similar to other reported CNO cohorts in terms of clinical characteristics. Patients with unifocal CNO involvement at diagnosis are more likely to require shorter NSAID treatment courses. Patients with 2 or more regions affected by CNO and those with symmetric bone lesions are more likely to require a second-line treatment. These findings may inform treatment choices for patients with CNO.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood Chronic Idiopathic Uveitis (cCIU) is a severe ocular condition that accounts for the 40% of all uveitis in children. Its timely and proper treatment is critical to prevent severe complications. Our purpose isto report the treatment response of a large cohort of cCIU.

Methods: This is a retrospective multicentre international observation study conducted at Meyer Children's Hospital IRCCS and Bristol Royal Hospital for children. The medical records of children were reviewed if they have a diagnosis of cCIU prior to 16 years old, and received a systemic treatment other than corticosteroids. We collected demographic, clinical and laboratory data. The main outcome was the achievement of response and remission on treatment according to SUN criteria.

Results: 146 cCIU (76 male, 42 ANA positive) with a median age at onset of 112months (range 20-199), 122 had a bilateral involvement (83.6%), 78 had anterior uveitis (53.4%), 17 anterior+intermediate (11.6%), 32 intermediate (21.9%) and 19 panuveitis (13%) were screened for inclusion criteria (see table 1). 115 patients received at least one systemic therapy other than corticosteroids (78.8%), 68 two different lines (46.6%), 20 three-line treatment (13.7%), and 3 four-line treatment (2.1). The median time for the first drug administered was 6 months (range 0-73). As first line-treatment 93 children received

List of abbreviations: *ADA: adalimumab, MM: mycophenolate mofetil, MTX methotrexate, IFN: infliximab, N number, IQR interquartile range, NS non significant.*

methotrexate (63.7%), 21 adalimumab (14.4%) (of whom 4 with concomitant methotrexate), and 1 mycophenolate mofetil (MMF) (0.7%). As second line treatment 6 received methotrexate, 45 adalimumab, 15 MMF, 1 azathioprine, and 1 tacrolimus. Among the first-line therapies, we observed that patients treated with adalimumab achieved more frequently ocular response (19/21 vs 55/91 χ^2 8.72 p 0.01) and ocular remission (19/21 vs 42/45 χ^2 12.2 p < 0.001), with no difference in frequency of relapse on therapy and time to first relapse on the therapy (see table 2). Additionally, cCIU with worse visual acuity (>0.4 LogMAR) were less likely to achieve disease remission with methotrexate as first-line treatment (χ^2 6.7p 0.035). Among the second-line therapy, adalimumab achieved more frequently ocular remission (38/1 (ADA) vs 5/1 (MTX) vs 9/12 (MMF), χ^2 6.29 p 0.043) (table 2).

Conclusion: Adalimumab showed better chance to achieve ocular remission, as first and second line treatment, as well as in patients with worst outcome: ANA positivity, worse visual acuity, intermediate uveitis. **Acknowledgements:** All the patients that received adalimumab as first line treatment were followed at Meyer Children's Hospital IRCCS, and the off label prescription authorization was obtained.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) and Crohn's disease (CD) are now controlled using immunosuppressive medications. However, disease control comes at the risk of increased infection. It remains unclear if immunosuppressed pediatric patients mount a blunted and/or rapidly waning immune response to the Hepatitis A virus (HAV) vaccine. We conducted a randomized controlled pilot trial to compare vaccine immunogenicity to either pediatric or adult doses of HAV seronegative adolescents, aged 12-15 years, receiving immunosuppressive medications for JIA or CD.

Methods: Participants were recruited from the outpatient Rheumatology and Gastroenterology clinics at a single center. Demographics, diagnosis, and current treatments were obtained from health records**.**19 participants, confirmed to be HAV seronegative, were randomized such that 10 were assigned to receive HAV Pediatric 80 antigen units and 9 HAV 160 antigen units. Serum samples were analyzed using the Elecsys anti-HAV assay.All serum samples were tested at 4-time points; pre-vaccine dose 1 (t1), ∼ 28 days post-vaccine dose 1 (t2), pre-vaccine dose 2 (t3) and ∼ 28 days post-

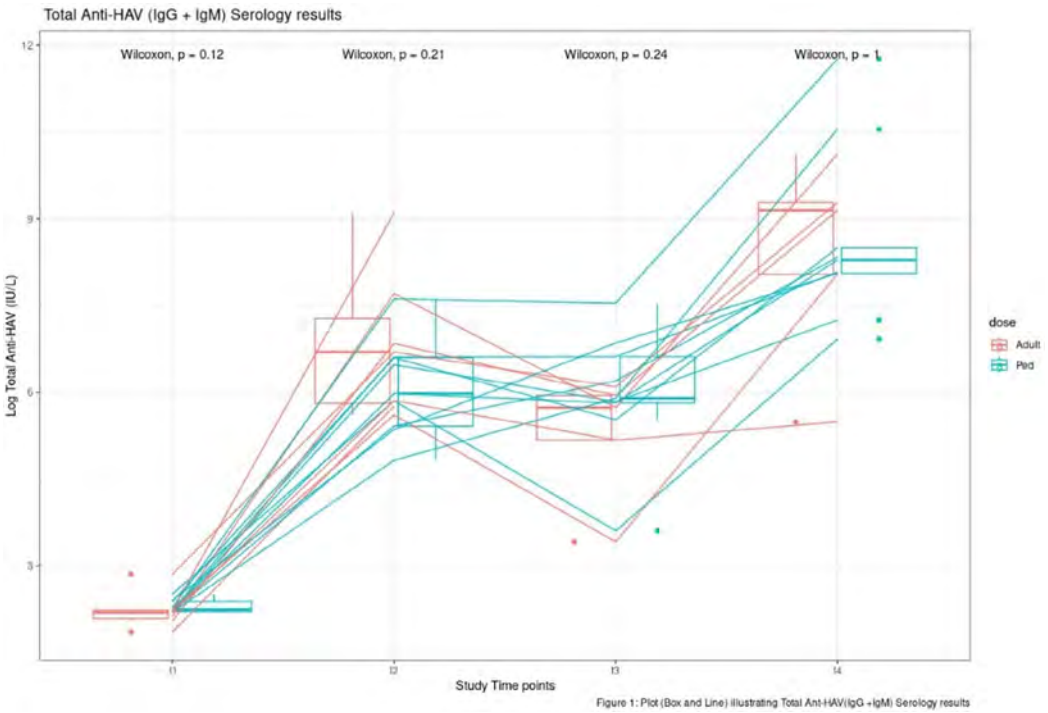

Figure 1: Plot (Box and Line) illustrating Total Ant-HAV(IgG +IgM) Serology results

vaccine dose 2 (t4).Participants were considered seropositive if they achieved a threshold of ≥ 20 IU/L anti-HAV. Descriptive statistics and a Wilcoxon rank test was used to analyze the data.

Results: 16/19 participants completed the 2-dose regimen (each dose 6 months apart). 10/6 were female/male; aged 13.32 ± 1.29 years (mean ± SD); diagnosed with CD (3/16) or JIA (13/16). Seven patients were treated with DMARDs and 2 with TNF-alpha Inhibitor monotherapy. Three patients were treated concomitantly with Methotrexate/Sulfasalazine and 4 with methotrexate/TNF-alpha Inhibitors. All participants (16/16) mounted a seropositive response ∼ 28 days after vaccine dose 1 (t2) that was maintained at t3 and t4. Figure 1 illustrates individual (lines) median, and interquartile ln transformed values (box plot) for both dose assignments over the study time points. Serological response between participant's assigned to pediatric vs adult doses were not statistically significant ($p < 0.05$) at all time points; however, participants receiving the adult vaccine appeared to have a higher median serology value 28 days post-vaccine dose 2. Adverse events were reported by 2/16 participants after the first dose. All adverse events resolved without sequelae. No serious adverse events were reported.

Conclusion: This is the first randomized controlled trial that compares the immunogenicity of pediatric vs. adult doses of HAV vaccine in immunosuppressed pediatric patients. We found no statistical difference in the serological response to Pediatric or Adult vaccine formulations. However, our results support evidence of the immunogenicity of HAV vaccine in immunosuppressed CD and JIA patients. Uniquely, this trial provides a preliminary pragmatic approach that will inform future studies and vaccination guidelines on the comparative benefits of both formulations. Future studies with longer follow up time frame, larger sample sizes and healthy controls will need to be conducted.

Pediatric Acute-onset Neuropsychiatric Syndrome: Markers of Inflammation/autoimmunity at Clinical Presentation and Eventual Development of Arthritis and Other Autoimmune Diseases

Meiqian Ma[1], Erin Masteron[2] and Jennifer Frankovich[1], [1]Stanford University School of Medicine, Palo Alto, CA, [2]University of Washington School of Public Health, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Certain psychiatric conditions are associated with systemic inflammatory processes. We aimed to evaluate whether a pediatric condition characterized by a sudden onset of severe neuropsychiatric symptoms, pediatric acute-onset neuropsychiatric syndrome (PANS), is related to inflammatory disease.

Methods: This retrospective, observational analysis is based on longitudinal clinical data from patients with PANS from the Stanford Immune Behavioral Health (IBH) Clinicfrom 2012-2021.We reviewed patient medical records since birth to evaluate immune activation markers during psychiatric flare episodes, arthritis andautoimmune disease diagnoses. We describe

laboratory, physical exam, and musculoskeletal ultrasoundresults and estimate the cumulative risk of developing arthritis and autoimmunediseases using product limit (Kaplan-Meier) survival probability.

Results: We analyzed data from 193 children who had a sudden onset of severe neuropsychiatric symptoms at approximately 7.5 ± 3.5 years of age.These patients had been followed in the IBH Clinic for an average of47.9 ± 25.5 months (mean age: 13.9 ± 4.7 yearsat data collection). Among those tested for immune activation markers, 55% had results indicative of autoimmunity, 12% of immune dysregulation, and 45% of vasculopathy (Table 1). By 14 years of age, the estimated cumulative incidence of juvenile-onset arthritis was 28% (95% CI: 21%, 36%) and of autoimmune disease was 8% (95% CI: 4%, 12%).We report novel findings among children with arthritis, including capsular thickening (55%), DIP tenderness (82%), and spinous process tenderness (80%) (Table 2).

Medical Trauma and Its Association with Pain and Disability Risk in Children with Inflammatory Arthritis

Leah Medrano[1], Brenda Bursch[1], Jennifer Weiss[2], Alice Hoftman[1], Joshua Li[3], Nicholas Jackson[3] and Deborah McCurdy[1], [1]David Geffen School of Medicine, UCLA, Los Angeles, CA, [2]Hackensack Meridian School of Medicine, Hackensack, NJ, [3]Department of Medicine Statistics Core, David Geffen School of Medicine, UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: This study aims to determine the prevalence of medical trauma and its impacts on outcomes in a sample of children with inflammatory arthritis. We hypothesize that medical trauma is an underrecognized entity in this population, and that it is associated with worse pain outcomes and disability risk.

Methods: Children aged 8-18 years with juvenile idiopathic arthritis (JIA) or juvenile lupus erythematosus (jSLE) with a history of inflammatory arthritis were recruited from a single center pediatric rheumatology clinic. Participants completed a questionnaire assessing for medical trauma related to their arthritis with an adapted Child PTSD Symptom Scale for DSM-V (CPSS-V). Further questionnaires assessed for self-efficacy to function despite pain (Child Self-Efficacy Scale), pain scores (Verbal Rating Scale, 0-10), juvenile fibromyalgia (JFM) (Pain and Symptom Assessment Tool), anxiety sensitivity (Childhood Anxiety Sensitivity Index), and other adverse childhood experiences (ACEs). Demographic and disease activity data were collected. Differences between those with and without probable medical PTSD (CPSS-V score >31 vs ≤ 31) were assessed using rank sum and exact tests. Linear regression examined continuous associations with CPSS-V.

Results: Fifty children and adolescents with JIA (n=42) or jSLE (n=8) completed the study. Twenty (40%) children had CPSS-V scores of moderate or greater severity and 7 (14%) scored in the probable medical PTSD range. Those with juvenile spondyloarthropathy and rheumatoid factor positive polyarticular JIA had the highest trauma scores, but there was no overall difference in trauma scores between JIA and jSLE. CPSS-V scores in the probable medical PTSD range were significantly associated with older age, higher pain and anxiety sensitivity scores, more ACEs and depression history, and higher JIA disease activity scores (cJADAS-10) but not jSLE activity scores (SLEDAI-2K). There was a trend towards poorer self-efficacy scores and meeting JFM criteria in the probable medical PTSD group. Poorer self-efficacy scores were significantly associated with higher CPSS-V scores when assessed as a continuous variable. Nine (18%) participants met criteria for JFM and had higher average trauma scores compared to those who did not. Trauma scores were not associated with history of hospitalization or injected medication use.

Conclusion: Medical trauma symptoms were reported by many participants in this cohort of children with inflammatory arthritis. Those who have experienced more trauma from their rheumatologic disease may be at risk for worse pain outcomes and increased disability, specifically poor self-efficacy and high anxiety sensitivity. Further studies are necessary to

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: NOMID is a severe form of cryopyrin-associated periodic syndrome characterized by systemic inflammation and CNS manifestations, including sensorineural hearing loss. IL-1 blocking agents, Anakinra and canakinumab, are standard treatment, we assessed the long-term impact of IL-1 blocking treatment on progression of hearing loss.

Methods: Pts (n=39) enrolled in NCT02974595 protocol underwent hearing tests at baseline and on treatment (n=447) Table 1. Bone conduction at four frequency (4F-PTA) (average hearing at 500, 1000, 2000, 4000 Hz) and bone conduction at 4000 Hz only (surrogate for high frequency (HF) hearing) were longitudinally evaluated. 4F-PTA >25 dB, or HF >25 dB at baseline were defined as baseline 4F-PTA or HF hearing loss respectively.

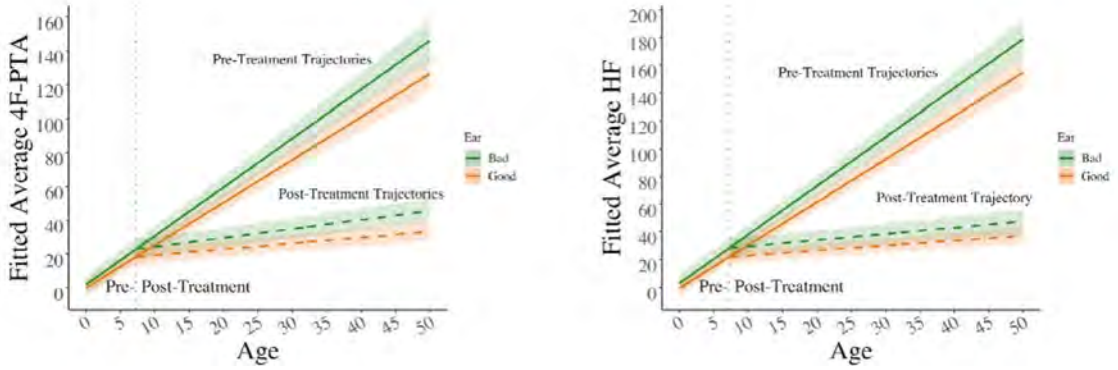
Progressive 4F-PTA hearing loss was defined as 20dB increase in one frequency or 10dB increase in two consecutive frequencies and progressive HF hearing loss as change from baseline by 10dB. Pts' ears were analyzed separately as 'good' and 'bad,' where hearing levels differed. Pts with a hearing level of >80 dB were excluded from trajectory analysis. Incidences of upper respiratory infections were extracted from records and brain MRI scored for cochlear enhancement. 36 or 39 pts. had a lumbar puncture at their last visit; 65 biomarkers were measured in CSF and compared with three healthy controls.

Linear mixed models were applied to trajectories of hearing loss before and after treatment. Multivariate and univariate logistic regression assessed the impact of baseline hearing loss and infections on progression and of CSF inflammatory cytokines on MRI cochlear enhancement and hearing loss.

Table 1: Characteristics of the NOMID cohort who underwent serial hearing assessment

Demographics		NOMID N=39
Current Age	Years Median (range) years	20 (8-43)
	Gender Female (%)	23 (59%)
	Ethnicity White (%)	26 (66%)
Genetic diagnosis	*NLRP3* mutations # (somatic, germline)	7 Somatic 32 Germline
Age at treatment initiation	Years Median (range)	7 (1, 28)
Duration of treatment	Years Median (range)	15 (7-18)
Treatment regimen	Anakinra (Canakinumab)	34 (5)

Figure 1: The trajectory of hearing loss, in both 4F-PTA and HF, significantly differed between treated and untreated patients (p<0.00001), indicating that IL-1 blockade slows down progression of the hearing loss.



Results: The trajectory of hearing loss significantly differed between treated and untreated patients, indicating that IL-1 blockade slows down progression (p< 0.00001) (Figure 1). Yearly 4F-PTA increase on treatment was 0.35 dB in the good ear and 0.5 dB in the bad ear, compared to a 2.5 dB increase in the good ear and 2.9 dB in the bad ear prior to treatment. Yearly HF hearing loss worsened by 0.36 dB in the good ear (0.5 dB bad ear), compared to 3.11 dB in the good ear and 3.5 dB in the bad ear prior to treatment (Figure 1). Cochlear enhancement, age at start of treatment and baseline hearing loss significantly contributed to hearing loss progression; recurrent infections did not reach significance. The univariate logistic regression identified elevated cytokines associated with cochlear enhancement in the corresponding MRI. In 36 pts' CSF, IL-1b, and markers of endothelial, neutrophil and macrophage activation, E-Selectin, NGAL, and CD163, were significantly associated with cochlear enhancement.

Conclusion: Hearing loss continues to progress more than expected for age despite treatment. IL-1 blocking treatment (84 % on anakinra) in NOMID patients however significantly retards progression of hearing loss. Baseline hearing loss, older age at the start of treatment, and cochlear enhancement on brain MRI were associated with faster progression of hearing loss in treated NOMID patients. Cochlear enhancement was significantly associated with CSF levels of IL-1b and markers of neutrophil and macrophage activation, suggestive of subclinical inflammation as driver of onging hearing loss.

Figure 2:

A. Multivariate regression analysis revealed that aging, cochlear enhancement in MRI, presence of hearing loss at baseline, and late treatment initiation are associated with hearing loss progression.

B. Univariate regression of revealed that cochlear enhancement was associated with abnormal biomarkers in the CSF (E-Selectin, CD163, NGAL and IL-1β)

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Neonatal-Onset Multisystem Inflammatory Disease (NOMID) often require long-term high-dose treatment with anakinra at 5-8 mg/kg daily subcutaneous injections to control CNS inflammation that includes aseptic meningitis, hydrocephalus, and sensorineural hearing loss. We recently described anakinra-associated amyloidomas that present with "fixed subcutaneous lumps" at the site of anakinra injections in patients with NOMID after 13 and 16 years of treatment [1] and screened our cohort for development of iatrogenic (Interleukin-1 receptor antagonist protein)-type amyloid (anakinra) (AIL1RAP).

Methods: Telephone screening of 41 NOMID pts enrolled in NCT02974595 identified 10 pts with fixed subcutaneous lumps at the anakinra injection site. Of those six patients underwent skin biopsies, clinical assessment of treatment response, and serum IL-1 receptor antagonist measurements by ELISA, which measures endogenous and recombinant IL-1 receptor antagonist (anakinra). Liquid chromatography-tandem mass spectrometry (LC-MS/MS) was performed to chemically characterize microdissected amyloid deposits in skin biopsies.

Results: All seven patients biopsied had amyloid deposits at the deep dermis that by mass spectrometry was identified as recombinant of anakinra-type amyloid (AIL1RAP)[2] (Figure 1). All patients had been on a median 19 yrs. of treatment and received a median dose of 320 mg (3 syringes) daily. Table 1. All were in clinical remission with normal CRPs. One patient

Table 1: Characteristics of the NOMID cohort who developed recombinant IL-1 receptor antagonist-type amyloidosis

	NOMID N=7

Gender, female (%)	4 (60%)
BMI median (range)	31.5 (26-36)
Anakinra dose median (range)	320 (300-600 mg/day) 3 (3-6 mg/kg)
Years on treatment median (range, yrs)	19 (15-19)

Figure 1: Subcutaneous nodules at the site of anakinra injections

with nephrotic range proteinuria and early satiety had kidney and gastric biopsies that showed AIL1RAP deposits in glomeruli, the tubular basement membrane, and in-between glands in the gastric mucosa. The six other patients had no clinical evidence of disseminated amyloidosis. Serum IL-1ra levels (n=6) ranged from 7500 to 18,000 ng/mL, compared levels between 100-400 pg/mL in healthy controls (n=11). Patients with the focal form of the AIL1RAP amyloidosis were switched to the combination of canakinumab injections every 4 wks and anakinra injections between 50-200 mg daily, that were required to achieve control of headache and CNS inflammation. The patient with systemic Amyloidosis only received canakinumab but developed headaches. The CSF evaluation showed a rise in the IL-6 (from 2 pg/mL on anakinra alone before the switch) to 403 pg/mL (nl< 7.5 pg/mL) on canakinumab monotherapy (300mg/month).

B) Apple-green birefringence of the Congo red-stained cutaneous amyloid under polarized light.
C) Kidney biopsy with Congophilic deposits in the mesangium and a capillary wall. D) High magnification transmission electron microscopy (TEM) image of amyloid deposits that revealed randomly oriented fibrils(X50,000).
E) Microdissection of the amyloid deposits F) liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis of CongoRed postive and Congo red-negative areas in the skin, stomach, and kidney biopsies. Proteins in the blue box indicate the amyloidogenic anakinra (dual yellow/blue star) and the three universal amyloid signature proteins (blue stars). Numbers in green boxes indicate the total number of MS/MS spectra matched to the protein in the corresponding biopsy and are a semi-quantitative measure of abundance. High spectral counts of the amyloid signature proteins (Apolipoprotein E, Apolipoprotein A-IV, and serum amyloid P-component) and the amyloidogenic IL1RA protein (anakinra) are present in CongoRed positive areas and absent in CongoRed negative areas.

Conclusion: AIL1RAP skin amyloidosis developed in 7 NOMID patients (20 % of screened patients) on high-dose long-term, anakinra treatment; one patient developed systemic AIL1RAP amyloidosis. Combination of canakinumab with lower anakinra doses, controlled CNS inflammation however "safe" serum levels that prevent the development and dissemination iatrogenic AIL1RAP amyloidosis have not been established. Screening all patients, early diagnosis of AIL1RAP-type amyloid and treatment adjustments are critical in assuring adequate treatment and in reducing the risk of developing systemic AIL1-RAP amyloidosis.

Abstract Number: 2060

Creation of a Standardized and Collaborative Transfer Process from Pediatric to Adult Rheumatology

Alana Haussmann[1], Lauren Taylor-Maloney[2], Ingrid Pan[2], Katherine Nowicki[3], JoAnn Zell[4] and Katharine Moore[5], [1]University of Colorado Internal Medicine Residency, Denver, CO, [2]Children's Hospital Colorado, Aurora, CO, [3]University of Colorado, Lakewood, CO, [4]University of Colorado Anschutz Medical Campus, Denver, CO, [5]University of Colorado / Children's Hospital Colorado, Aurora, CO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Pediatric Rheumatology – Clinical Poster III: Potpourri
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The transfer of care from pediatric to adult rheumatology (AR) is a complex process dependent on communication between medical teams within and across institutions, resource allocation, and patient factors. We outline a successful workflow for the transfer of care that optimizes clinical informatics and includes the creation of a formal collaboration between pediatric rheumatology (PR) and AR.

Methods: In January 2020 a transition-focused partnership was formed between PR and AR physicians, advanced practice providers, nurses, and pharmacists within the University of Colorado (CU)health system. Upon initiation of the transfer process in PR, a standardized electronic medical record checklist is used to guide the transfer workflow and leverage smart data elements to optimize patient tracking. A pediatric transition committee monitors each patient's transfer progress, ensuring checklist items are complete and initiating direct communication with AR. A cross-institutional transfer log is maintained using a HIPAA-compliant platform. Patients transferring to CU AR are reviewed quarterly at interdisciplinary transfer rounds attended by PR and AR members. Each patient is reviewed to identify barriers for those who have not been scheduled in AR. The records of all patients are periodically reviewed to identify correlates of success as well as risks and system barriers for transfer delays and failures.

Results: The creation of customized templates and data collection tools in the electronic medical record, a cross-institutional patient tracking system, and a collaborative PR-AR transition committee with quarterly transfer rounds have all been sustainable successes. Since the initiation of transfer rounds in January 2022, 54% of patients initially identified as lost to transfer were recaptured, with subsequent successful scheduling in AR. Of the forty-three patients reviewed to date by this committee, only four remain lost to follow-up.

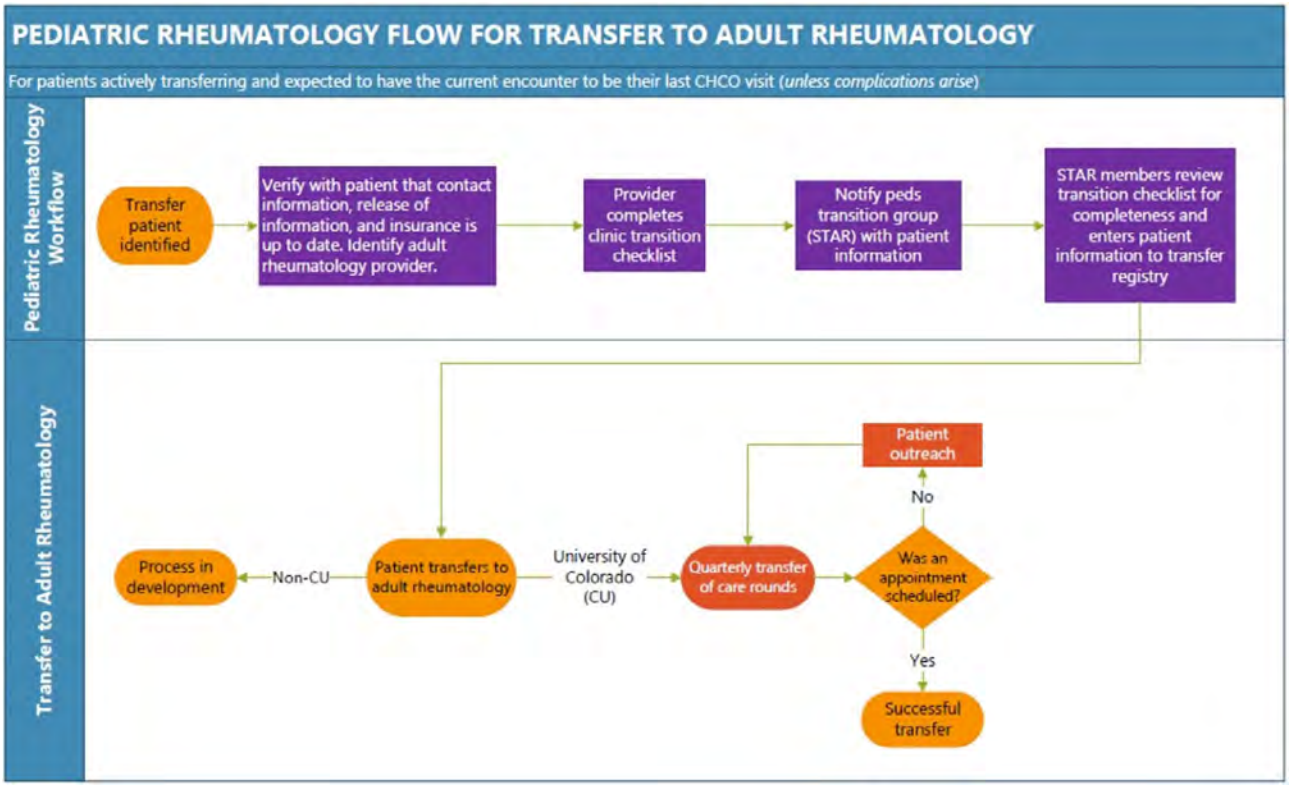

Figure 1: Transfer of Care Process

Conclusion: Pediatric and adult rheumatology team members successfully formed an interdisciplinary partnership with a standardized process for identifying and tracking patients who transfer from pediatric to adult care within one health system. Standardized electronic medical record workflows and the use of a PR-AR transfer log help centralize information and facilitate review during transfer rounds, allowing for the identification of system and patient-level barriers. Transfer rounds minimize loss of patient follow-up and facilitate opportunities for iterative changes to the rheumatology transfer process. The establishment of a pediatric and adult subspecialty committee is a sustainable intervention that could be carried out with extramural adult practices and holds promise for improving transfer of care outcomes.

Abstract Number: 2061

Evaluation of a Tool to Enhance Training of the Physical Examination of the Temporomandibular Joint (TM Joint) in Juvenile Idiopathic Arthritis (JIA)

Tova Ronis[1], Nancy Pan[2], Rebecca Sadun[3], Melissa Lerman[4], Cory Resnick[5], James Bost[6], Peter Stoustrup[7], Marinka Twilt[8] and for the CARRA TMJ Arthritis Workgroup[9], [1]Children's National Hospital, Chevy Chase, MD, [2]Hospital for Special Surgery, New York, NY, [3]Duke University, Durham, NC, [4]Children's Hospital of Philadelphia, Philadelphia, PA, [5]Harvard Medical School, Boston, MA, [6]Children's Health Center, Children's National Medical Center, Washington, DC, [7]Aarhus University, Aarhus, Denmark, [8]Alberta Children's Hospital, Calgary, AB, Canada, [9]Childhood Arthritis and Rheumatology Research Alliance, Washington, DC

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis of the TM joint is a frequent finding in patients with JIA, potentially leading to dentofacial deformities, pain, and lower quality of life.[1] Orofacial examination enables early detection of TM joint involvement.[2] The TM Joint Juvenile Arthritis Work Group published a standardized physical exam (article) to assess for JIA-induced orofacial manifestations.[2] Training programs do not routinely teach a standardized TM joint exam. The aim of the study was to demonstrate the effectiveness of a novel e-learning module in teaching the physical exam of the TM joint in JIA.

Methods: A 20-minute e-learning module consisting of instructive videos and interactive questions was created. Pediatric rheumatology fellows participated in a study to assess the module. Block randomization was performed, and fellows were stratified by post-graduate year. One group received the article while the second group received both the article and access to the e-learning module. All participants completed a written pre-test before the learning intervention andthen underwent both: an in-person objective structured clinical examination (OSCE)during the Childhood Arthritis and Rheumatology Research Alliance Scientific Meeting inMarch 2023; and a written post-test. The maximum OSCE score was 18. Crosstab tables and Chi-squared tests were used to assess categorical variables across groups. For continuous measures when comparing the two groups, Wilcoxon Rank Sum tests were used due to the small sample size.

Results: Twenty-two pediatric rheumatology fellows enrolled, with 11 in each group. Both reported an equal amount of time spent preparing for the OSCE (mean 34.8 mins). *Written test:* The two groups performed equally. There was a trend toward significance in defining maximal incisal opening (MIO) on the written test in the module group. Both groups had a trend towards improvement in recognition of patient profiles and facial asymmetry. *OSCE:* The mean OSCE score was 11.1 (SD 3.3) in the article group and 13.5 (SD 1.9) in the module group, with a trend towards significance (p=0.059). Significant differences were seen on the OSCE in learning domains related to measuring MIO, calculating maximal unassisted mouth opening (MUMO), and assessment of facial symmetry. There were no differences in other domains (see Table 1). Confidence in TM joint exam skills was increased in all fellows after the intervention with no difference between groups (Figure 1). Enjoyment scores in the module group were higher than in the article group (mean 7.7/10 vs 5.9/10, p=0.017) (Figure 2).

Table 1. OSCE scores by learning group. OSCE: objective structured clinical examination, MUMO: maximal unassisted mouth opening.

	Module Mean (SD)	Article Mean (SD)	P value (Wilcoxon Rank Sum Test)
OSCE total score	13.54 (1.91)	11.09 (3.27)	0.059
History taking	3.09 (0.94)	2.82 (1.08)	0.581
Palpation	2 (0.63)	2.27 (0.90)	0.214
Mandibular deviation	2.54 (1.13)	2.09 (1.37)	0.418
Measurements	4.09 (1.38)	2.36 (1.21)	0.005
MUMO calculation	1.45 (0.93)	0.36 (0.81)	0.012
Symmetry	1 (0)	0.63 (0.50)	0.030
Profile	0.81 (0.40)	0.91 (0.30)	0.543

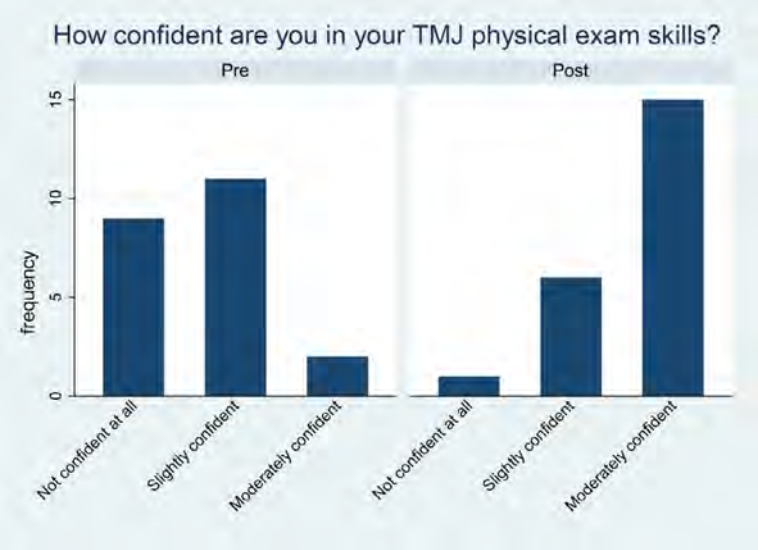

Figure 1. Self-reported confidence in TM Joint physical exam skills before and after the learning intervention for all participants. No difference was noted between groups.

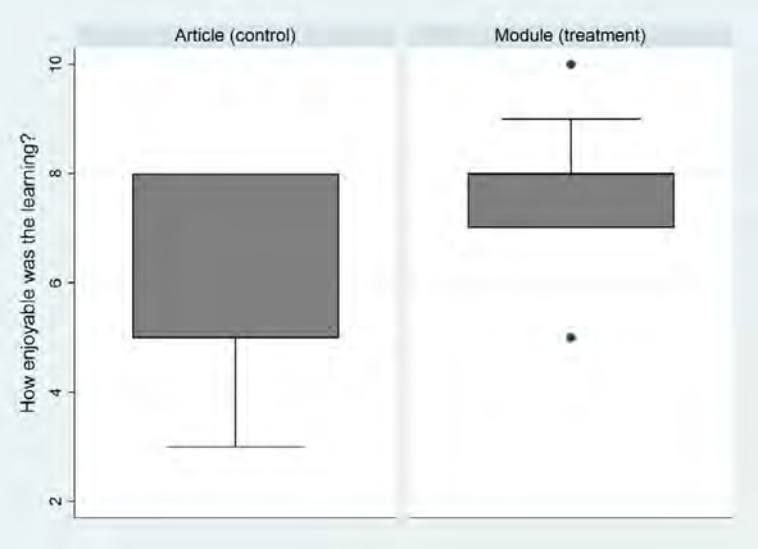

Figure 2. Participant response to "How enjoyable was the learning?"

Conclusion: This study demonstrated effectiveness of a novel e-learning module in teaching the physical exam of the TM joint in JIA. Learners who viewed the module were more adept at obtaining quantitative TM joint measurements than those who read the article. Both groups showed improvement in overall skill and confidence level, although the module group enjoyed the learning experience more.

Abstract Number: 2062

A Mental Health Workshop for Pediatric Rheumatology Fellows

Caitlan Pinotti[1], Alison Manning[2], Suzanne Edison[3] and Rebecca Sadun[1], [1]Duke University, Durham, NC, [2]Lifespan, East Providence, RI, [3]Cure JM Foundation, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Many children with a rheumatic disease have concurrent mental and behavioral health challenges, but only ~40% of these symptoms are brought to medical attention. Per an American Board of Pediatrics (ABP) survey, more than 75% of pediatric rheumatology fellows believe it is important for them to address the mental health needs of their patients, but fewer than 25% feel confident in their skills to do so. Importantly, a Childhood Arthritis and Rheumatology Research Alliance (CARRA) survey demonstrated that both rheumatology patients and their parents feel most comfortable discussing their mental health concerns with their pediatric rheumatologist.

Methods: Using the ABP Roadmap Project curriculum as a framework, a 2-hour virtual mental health workshop specifically tailored to the needs of pediatric rheumatology fellows was developed and delivered as a collaboration between a child and adolescent psychiatrist and a pediatric rheumatologist. Through the workshop, participants were instructed in a strategic approach to mental health conversations, taught to utilize validated mental health screening tools, and provided guidelines on the identification of high-risk patients who need urgent mental health services. Participant confidence in addressing 11 mental healthcare domains was assessed using a retrospective pre/post survey with a 4-point Likert scale (very low to very high confidence). Descriptive statistics and a paired t-test were used in data analysis.

Results: Twenty-six of the 37 (70%) participatingpediatric rheumatology fellows completed the workshop survey, with roughly equal distribution across the three years of fellowship training (Table 1). The retrospective pre/post survey revealed a significant increase in participants' confidence across all 11 mental health domains (Table 2). No difference was detected by postgraduate year. Pre-workshop, participants reported the least confidence in safety planning for high-risk patients (mean = 2.03), with level of confidence rising by more than 1 point post-workshop (mean = 3.13). Pre-workshop, participants reported the highest confidence in recognizing the signs and symptoms of depression and anxiety (mean = 2.93), with confidence rising to 3.37 post-workshop. Confidence scores across the 11 domains increased from 2.34 (2=low confidence) to 3.29 (3=high confidence). No participants rated their comfort level as very low for any of the 11 domains following

Table 1. Pre- and post-workshop confidence (averaged over all 11 domains) stratified by fellowship year, juxtaposed with averaged pre- and post-workshop confidence of the four participating pediatric rheumatology faculty. Confidence level measured on a 4-point Likert scale (1 = "very low" confidence, 2 = "low" confidence, 3 = "high" confidence, 4 = "very high" confidence).

	Respondent Number (%)	Pre-Workshop Mean	Post-Workshop Mean	Mean Confidence Gain
Fellows				
First year	10 (33%)	2.34	3.29	0.95
Second year	8 (27%)	2.33	3.19	0.86
Third year	8 (27%)	2.42	3.45	1.03
Faculty				
Total	4 (13%)	2.20	3.16	0.95

Table 2. Pre- and post-workshop confidence for each of the 11 domains. Confidence level measured on a 4-point Likert scale (1 = "very low" confidence, 2 = "low" confidence, 3 = "high confidence, 4 = "very high" confidence).

Domain	Pre-Workshop Mean	Post-Workshop Mean	P-value
Initiate a conversation with patients and their caregivers about mental health concerns	2.70	3.53	< 0.0001
Recognize the signs and symptoms of depression and anxiety	2.93	3.37	0.0002
Talking with caregivers about things in their lives that cause them stress related to their child's health or care	2.40	3.20	< 0.0001
Providing individual resources and guidance to improve the mental health and quality of life for patients	2.07	3.23	< 0.0001
Providing individual resources and guidance to improve the mental health and quality of life for caregivers and families	2.07	3.17	< 0.0001
Interpreting a PHQ-9	2.70	3.50	< 0.0001
Interpreting a GAD-7	2.40	3.23	< 0.0001
Discussing suicidal ideation with a patient	2.20	3.40	< 0.0001
Stratifying a patient's risk of suicide	2.17	3.27	< 0.0001
Providing safety planning to reduce the likelihood of death by suicide	2.03	3.13	< 0.0001
Explaining the risks and benefits of an SSRI to a patient and caregivers	2.07	3.17	< 0.0001
Overall	**2.34**	**3.29**	**< 0.0001**

the workshop. When asked what changes they will implement following the workshop, 60% stated they will routinely screen patients, 30% will discuss mental and emotional health with all patients, and 30% plan to explore mental health resources in their state. On a 10-point Likert scale, with 10 being extremely relevant or extremely helpful, participants rated the workshop at a relevance of 9.67 and a helpfulness of 9.33.

Conclusion: A virtual training workshop improved pediatric rheumatology fellows' confidence in addressing the mental and emotional healthcare needs of their patients. Additional training could further foster a robust and standardized approach to assessing and addressing the mental health needs of pediatric patients with rheumatic disease.

Abstract Number: 2063

Training to Increase Minority Enrollment in Lupus Clinical Trials with CommunitY Engagement (TIMELY): Assessing Behavioral Predictors of Clinical Trial Referrals Among Healthcare Providers

Saira Sheikh[1], Tessa Englund[1], Andrew Simkus[2], Nicole Wanty[3], Annie McNeill[4], Kristen Holtz[4], Tenesha Hood[5], Starla Blanks[6], Maria Allen[7] and Allen Anandarajah[7], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]KDH Research & Communication, Asheville, NC, [3]KDH Research & Communication, Marietta, GA, [4]KDH Research & Communication, Atlanta, GA, [5]ACR, Atlanta, GA, [6]American College of Rheumatology, Atlanta, GA, [7]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study is to assess outcomes among healthcare providers in the American College of Rheumatology's (ACR) Training to Increase Minority Enrollment in Lupus Clinical Trials with CommunitY Engagement (TIMELY) program. The TIMELY program was designed to improve engagement of healthcare providers and therefore promote referrals of underrepresented patients with lupus to clinical trials (LCTs). Enrolled providers participated in two components of the TIMELY program: 1) The ACR's Materials to Increase Minority Involvement in Clinical Trials (MIMICT) continuing medical education (CME) course; and 2) Roundtable meetings where providers learned about and discussed barriers, strategies, and opportunities to advance participation of underrepresented patients in LCTs.

Methods: This roundtable study used an online survey to evaluate pre-post changes in theory-based behavioral predictors of clinical trial referrals, including attitudes, self-efficacy, and intentions to refer underrepresented patients to LCTs. Research teams at two participating sites, the University of North Carolina at Chapel Hill (UNC) and University of Rochester Medical Center (URMC), began enrollment in June 2022 and implemented the TIMELY roundtables between September 2022 and April 2023. Community members, community health workers, and advisory committee members provided extensive support and guidance to facilitate TIMELY roundtable implementation. In conjunction with the ACR, sites recruited participants and hosted roundtables in-person and online with regional providers who care for patients with lupus. Providers completed a baseline survey prior to roundtable participation, and post-roundtable, and 3-month follow-up surveys. We conducted paired t-tests between baseline and follow-up to assess differences in composite scores and individual measures for each outcome.

Results: As of April 2023, the sample included 35 providers. From baseline to follow-up, composite scores for self-efficacy increased from 6.62 to 7.42 ($p< 0.01$) and composite scores for intentions increased from 7.14 to 8.21 ($p=0.001$).

Conclusion: These promising findings highlight the potential of the TIMELY program to improve theory-based behavioral predictors of provider referrals of underrepresented patients to LCTs.

Abstract Number: 2064

Perceptions of Rheumatology Fellows on Mentorship Quality After Implementation of a Formalized Mentorship Program

Sarah Capponi[1] and Rachel Hilburg[2], [1]Hospital of the University of Pennsylvania, New Hope, PA, [2]Hospital of the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the importance of mentorship, there are few formalized mentorship organizations in fellowship training programs. Rheumatology is a field with increasing popularity[1], and mentorship is suggested as one of many reasons for this trend[2], yet no formalized mentorship programs in adult Rheumatology fellowships have been described at the time of this writing. In the 2022-2023 academic year, the Hospital of the University of Pennsylvania (Penn) Rheumatology fellowship program implemented a formalized mentorship program for trainees. Trainees identified a faculty member to serve as their mentor and pairs met quarterly to discuss educational, personal, and career goals. It was hypothesized that this program would improve trainee satisfaction overall compared with fellows who had completed fellowship without formal mentorship.

Methods: Data from previously graduatedPenn Rheumatology Fellows and currentPenn Rheumatology Fellows was collected via anonymous survey.

Results: 32 fellows with graduation years from 2016 – 2024 were surveyed and 26 responded, with an 81% overall response rate of current and former Penn Rheumatology fellows.

In the group of former fellows, 28% did not identify a faculty mentor and 72% did. Cited barriers to having a mentor included lack of time, lack of faculty interest, and the absence of the establishment of a formal mentoring relationship with faculty. In the current fellow cohort, 100% identified mentors.

Fellows who graduated prior to the mentorship program reported 11.8% more satisfaction with perceived effectiveness of their mentor's ability to advance their clinical skills (p-value 0.01).

Fellows who experienced the formalized mentorship program were 12.1% more satisfied with their assigned mentor's ability to help them network and increase opportunities for professional development; they also were 12.1% more satisfied with their mentor's sponsorship and advocacy during training (p-value 0.03).

There were no differences between the two cohorts of fellows with respect to their mentor's impact on their post fellowship career planning, perceived research productivity, and guidance through handing sensitive or challenging issues that arose during fellowship.

Overall, perceptions of the fellowship program independent of mentorship were largely positive, without statistically significant differences between the two cohorts of fellows.

Conclusion: Implementation of formalized mentorship programs in fellowship leads to improved trainee perceptions of faculty investment in their careers through sponsorship and networking; however, this small, single program survey did not show the establishment of a formalized mentor-mentee relationship improved trainee perceptions of improved clinical skills, research productivity, or ability to handle challenging interactions during fellowship.

Exploring the Power of Ultrasound in Rheumatology: Insights from Young Rheumatologists in Mexico

Mario R. Garcia-Pompermayer[1], Sarah G. Ayton[2], Karina Silva Luna[3] and Mario Alberto Garza Elizondo[3], [1]Hospital San Jose, TecSalud, Tecnologico de Monterrey, Monterrey, Mexico, [2]Mailman School of Public Health, Columbia University, New York, NY, [3]Hospital Zambrano-Hellion, TecSalud, Tecnologico de Monterrey, Monterrey, Mexico

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal ultrasound (MSUS) is a valuable tool in Rheumatology as it is non-invasive, cost-effective, and useful in regular clinical practice. However, its adoption has been slow and MSUS education in Mexico is limited. Our objective is to assess MSUS knowledge, attitudes, and practices in young Rheumatologists in Mexico and identify potential barriers and facilitators to its clinical use.

Methods: An online survey was distributed to ReumaJoven, a network of young Rheumatologists in Mexico. The survey captured demographics, and general, institutional, and personal MSUS information. The need for MSUS in Rheumatology in Mexico was assessed for association with knowledge, attitudes, and practices. Multivariable analysis using elastic net and bootstrapping identified drivers of respondent attitudes.

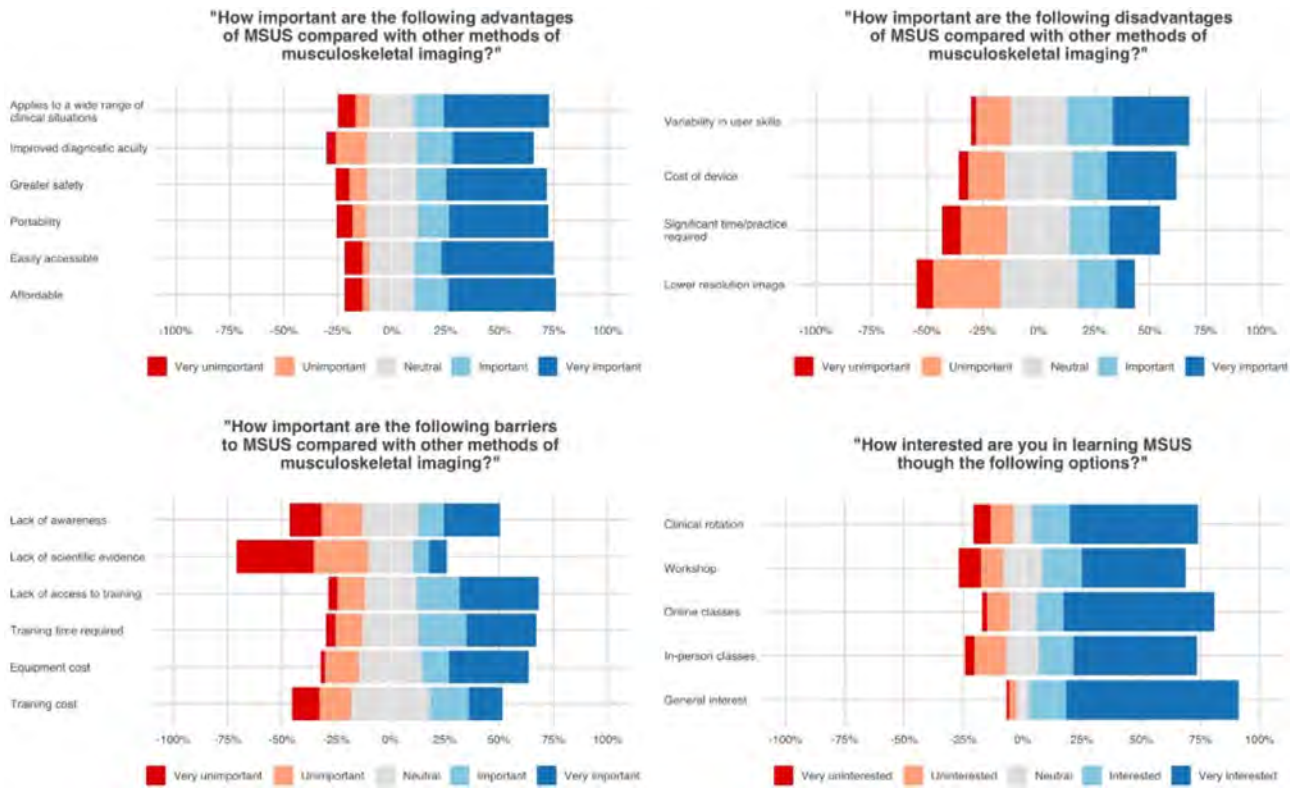

Figure 1. Responses to questions about the advantages, disadvantages, interest in learning, and barriers to implementing (clockwise from top left) MSUS among young Rheumatologists in Mexico.

Results: Rheumatologists (n=91) completed the survey (women: n=52, 54.17%, age: median=35.08, IQR: 32.79-37.73 years). Most worked in public hospitals (n=65, 67.71%) and private practices (n=80, 83.33%), including residents (n=5, 5.21%), professors (n=37, 38.54%), and non-academic clinicians (n=54, 56.25%). The most prominent barriers to MSUS were lack of access to training (important or very important: n=54, 56.25%) and training time required (n=52, 54.17%). Lack of scientific evidence was not an important barrier to MSUS use (unimportant or very unimportant: n=58, 60.42%). Most (n=78, 81.25%) reported MSUS is necessary in clinical Rheumatology practice in Mexico. This positive MSUS attitude was significantly associated with learning about MSUS from conferences (p=0.029) and colleagues (p=0.005), formal (p=0.043) and in-person training (p=0.020), use in the respondent's practice (p=0.027), and MSUS use by Radiologists in the respondent's institute (p< 0.001). Most were interested in learning MSUS (n=85, 88.54%), which was significantly increased in those reporting positive MSUS attitudes (n=74, 94.49%, p< 0.001). Elastic net identified drivers of positive MSUS attitudes, including learning about MSUS from conferences, colleagues, and in residency; use of MSUS in the respondent's practice, the respondent performing MSUS, using MSUS for diagnosis or monitoring of Synovitis/Inflammatory joint disease; and use of MSUS by Radiologists in the respondent's institute. Use of MSUS for diagnosis or monitoring of Synovitis/Inflammatory joint disease (OR=1.43, 95%CI: 1.00-2.05) and use of MSUS by Radiologists in the respondent's institute (OR=1.70, 95%CI: 1.20-2.90) were statistically significantly associated with positive MSUS attitudes in the final multivariable analysis.

Conclusion: This study assessed knowledge, attitudes, and practices of MSUS among young Rheumatologists in Mexico and identified barriers and facilitators to its implementation. Most recognized the necessity of MSUS in clinical practice, particularly those with prior training, who used MSUS in their practice, and had access to MSUS expertise. Improving MSUS

Table 1. Characteristics of MSUS knowledge, practices, and attitudes among 96 young Rheumatologists in Mexico.

	Characteristic	Overall	Need for MSUS in Rheumatology Practice in Mexico			Multivariable Analysis (Elastic Net)	
			Necessary (N = 78)	Not Necessary (N = 18)	P-value

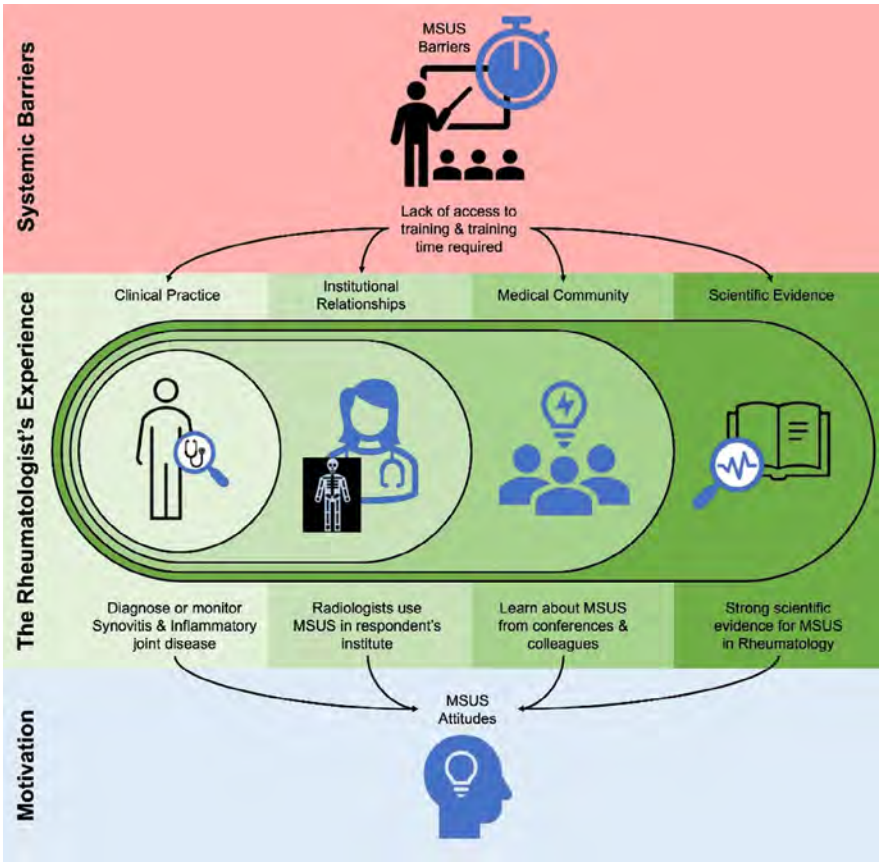

Figure 2. Overview of facilitators and barriers to implementing MSUS in clinical practice. Systemic barriers to MSUS implementation impact the Rheumatologist's experience of their clinical practice, institutional resources, knowledge shared in the medical community, and the available scientific evidence. Notably, use of MSUS for diagnosis and monitoring synovitis and inflammatory joint disease in clinical practice, having Radiologists who use MSUS in their institute, learning about MSUS from the medical community, and the strong scientific evidence surrounding MSUS all drive positive attitudes and impact motivation to implement MSUS.

education and training opportunities, and promoting collaboration between Rheumatologists and Radiologists may overcome barriers to adoption of MSUS in Mexico, ultimately improving patient care.

Ultrasound Guided Synovial Biopsy Course: Achievement of Learner Self Efficacy

Diane Horowitz[1], Darren Tabechian[2], Ami Ben-Artzi[3], Karina Torralba[4] and Arthur Mandelin[5], [1]Northwell Health, Great Neck, NY, [2]University of Rochester Medical Center, Rochester, NY, [3]Ami Ben Artzi, MD, San Diego, CA, [4]Loma Linda University, Loma Linda, CA, [5]Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Professional Education Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Ultrasound guided synovial biopsy (UGSB) is a minimally invasive, safe and effective tool to obtain synovium for clinical and research purposes. Described in Europe in 1997, UGSB was introduced to US rheumatologists in 2015 via the NIH-AMP program. Logistical barriers, learner confidence and the lack of a critical mass of trained rheumatologists to assist new learners have impeded the adaptation of UGSB in the USA. UGSBy, a collaborative group of four USA-based rheumatologists who completed the 2015 NIH-AMP program, was formed to develop a network of rheumatologists skilled in UGSB. In 2022, UGSBy partnered with the Ultrasound School of North American Rheumatologists (USSONAR) and conducted 3 courses in the USA to expand the workforce of USGB trained rheumatologists. An emphasis on patient safety was an integral feature of these courses. This study was conducted to determine the effectiveness of these courses in allowing learners to integrate knowledge with acquisition of skills in UGSB.

Methods: Three courses were conducted (1:15 students, 2:16 students, 3:14 students). Each course consisted of didactic and hands-on cadaver training. Instructor to learner ratio was 1:4. Musculoskeletal ultrasound competence was a course prerequisite which was defined as prior certification and/or documented course completion in basic-advanced musculoskeletal ultrasound. Serial surveys were deployed at the course completion (T0) and every 3 months after (T3, T6…). Learner confidence was assessed with the L-SES, a validated learning self-efficacy scale (L-SES) for Clinical Skills, consisting of 12 five-point Likert scale (strongly disagree-strongly agree) based questions to measure three domains: cognitive (Cog), affective (Aff) and psychomotor (Psy). The L-SES has been shown to directly correlate with academic achievement and effective learning strategy use.

Results: Learners from the first course reported positive mean L-SES in the cognitive domain (Cog=3.85, Aff=2.9, Psy=2.9, n=5) at T6. Learners from the second course demonstrated a positive mean LES in all three domains at T0 (Cog=4.4, Aff=3.7, Psy=3.84, n=16); at T3 the cognitive and psychomotor domains had a positive L-SES (Cog=3.9, Aff=2.9, Psy=3.25, n=4). A learner from the first course performed a first biopsy 5 months after the course.

Conclusion: Integration of knowledge with skill acquisition in UGSB is important in determining the quality of education received in these courses. Learners in these courses report a positive L-SES. Further analysis with serial data will explore (1) serial changes in L-SES, (2) the relationship between adaptation UGSB and L-SES, and (3) impact of the presence of a colleague in the same practice situation who is skilled in UGSB and time to adaptation of UGSB after training.

A New Tool Assessing Trainees' Interventional Musculoskeletal Ultrasound Skills

Stine Maya Dreier Carstensen[1], Lene Terslev[2], Søren Just[3], Mikkel Østergaard[4], Mogens Pfeiffer-Jensen[1] and Lars Konge[5], [1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, Copenhagen University Hospital – Rigshospitalet Glostrup, Copenhagen, Denmark, [2]Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark, [3]Section of Rheumatology, Department of Medicine, Odense University Hospital – Svendborg Hospital, Odense, Denmark, [4]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, Rigshospitalet; University of Copenhagen, Copenhagen, Denmark, [5]Copenhagen Academy for Medical Education and Simulation The Capital Region of Denmark, Copenhagen, Denmark

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interventional musculoskeletal ultrasound (MSUS) procedures, such as ultrasound-guided arthrocentesis and joint injections, are routinely used in rheumatology practice. However, the efficacy and safety of these procedures rely on the competence of the individual physician, and intensive training is essential before independent practice. Assessment tools play a pivotal role in providing structured feedback to the trainees and ensuring end-of-training competence. An international expert panel of radiologists developed the Interventional Ultrasound Skills Evaluation (IUSE) tool to evaluate operator competence in invasive ultrasound procedures relevant for abdominal and thoracal interventions. It is unsuitable for assessing MSUS procedures and therefore, we aimed to develop and establish valid evidence for a modified version of the IUSE assessment tool designed for evaluating trainees in interventional MSUS procedures relevant in rheumatology.

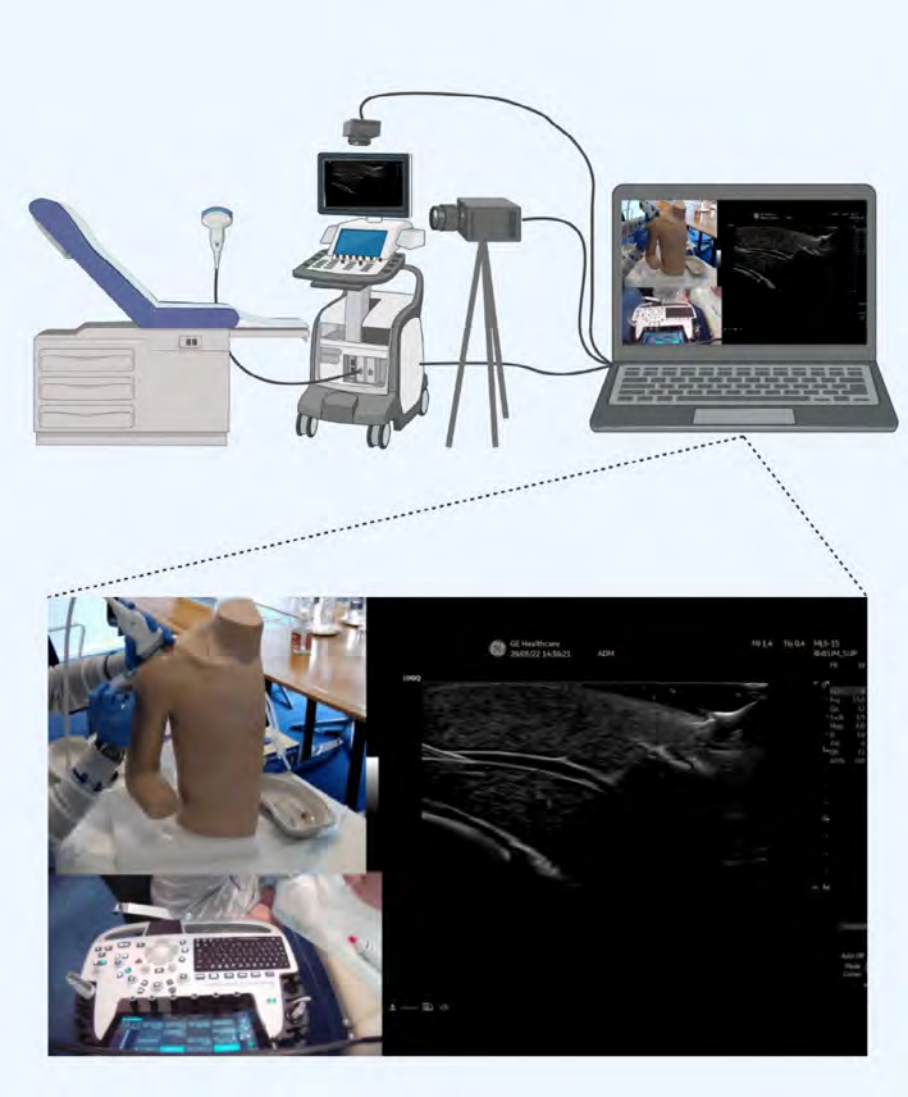

Figure 1: The setup included three different video inputs: the ultrasound image, how the participant handled the machine and adjusted the buttons, and how the participant performed the procedure on the fantom. The videos were subsequently uploaded to an online rating platform.

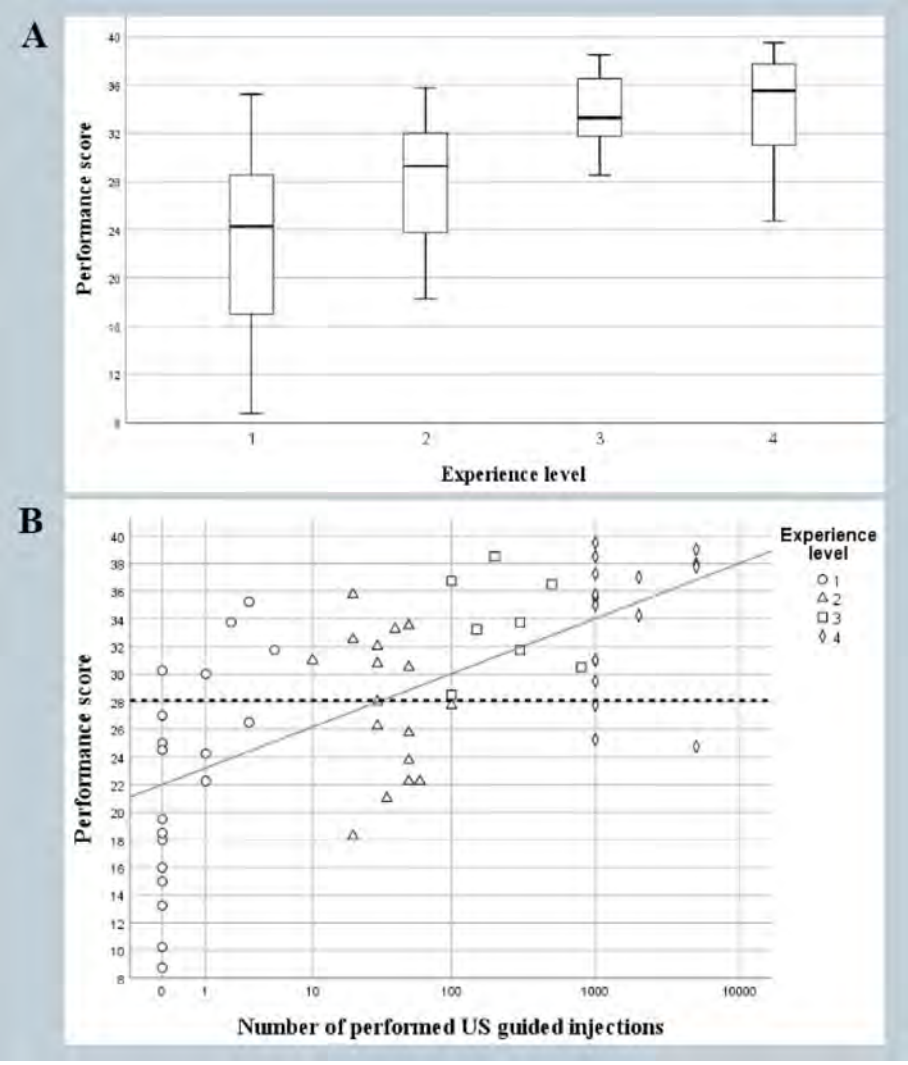

Figure 2: Experience and Performance. A) Boxplot illustration of the mean AIMUS performance score in the four different groups (1:novices, 2: intermediates, 3:experienced, and 4:experts). B) Number of previously performed interventional MSUS procedures correlated to the AIMUS performance score, divided into the same four experience levels.

Methods: An expert panel of rheumatologists modified the IUSE tool to reflect the essential steps in interventional MSUS procedures. The modified tool was named the Assessment of Interventional Musculoskeletal Ultrasound Skills (AIMUS) and included 8 items: indications, contraindications, preparation, US equipment, procedural instruments, route, hand-eye coordination and, procedure and outcome. To gather validity evidence for the AIMUS tool, physicians with different levels of interventional MSUS experience were enrolled in the study and instructed to perform two interventional MSUS procedures on simulated patient cases, i.e., subdeltoid bursitis and biceps tenosynovitis. The procedures included both ultrasound-guided aspiration and injection techniques and were performed on a shoulder rubber fantom with ultrasound capabilities, Figure 1. All examinations were video recorded (n=130), anonymized, and subsequently assessed in random order by two blinded raters using the AIMUS tool.

Results: Sixty-five physicians from 21 different countries attending the EULAR 2022 conference were included and categorized into four groups based on their experience with interventional MSUS, determined by the number of procedures performed: 19 novices (0-10), 18 intermediate (10-100), 9 experienced (100-1000), and 17 experts (>1000). Two participants were excluded from the analysis due to a lack of data on their experience. The internal consistency of the AIMUS tool was excellent, with a Cronbach alpha of 0.9. The inter-case reliability was good with a Pearson's correlation coefficient

(PCC) of 0.7 and the inter-rater reliability was moderate to good (PCC 0.6). The ability to discriminate between different levels of experience was highly significant ($p < 0.001$), with a linear correlation between the performance scores and the participant experience levels, Figure 2.

Conclusion: We have developed and established solid validity evidence for the AIMUS tool for evaluating trainees' interventional MSUS skills. The AIMUS tool can be used in daily clinical practice and implemented in training curricula for establishing competency-based training for interventional MSUS procedures in the future.

Integration of Basic Science into Virtual Patient Cases to Enhance Clinical Reasoning Skills

Karl Rombo[1], **Alexander Borg**[1] and Ioannis Parodis[2], [1]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Digital education, also known as e-learning, comprises several different learning modalities e.g. virtual patient (VP) simulations. VPs have been proposed to be an effective way of exposing health profession students to greater quantities of patient cases, also ensuring that students encounter diagnoses and presentations that serve the needs of their learning outcomes, regardless of the patients they happen to encounter during clinical rotations.

Our aim was to explore medical students' perceptions and emotions towards integration of basic science aspects in VP cases within rheumatology, and evaluate their self-perceived acquirement of clinical reasoning (CR) skills. A secondary aim was to collect information that would be utilised for the development of a model, with concepts and strategies for how to integrate basic science concepts into case-based CR training platforms.

Methods: We performed an interventional, explorative phenomenological study, with medical students recruited from a one-week long clinical placement in rheumatology. The integration was implemented in five VP scenarios. During the last day of the week, the VP cases were discussed during a seminar, together with discussion of the basic science integration. The VP cases had been created with Virtual interactive case simulator (VIC). Students' perceptions and emotions of basic science as well as CR skills were explored through thematic content analysis of transcribed interviews. Transcriptions were coded and analysed using Malterud's systematic text condensation. Transcriptions were read by the entire research team. Next, condensations and themes were presented to the research team to discuss internal validity of the material. Quotes and condensations were then translated to English. Finally, all transcriptions were re-read one last time to ensure that the themes and general concepts still corresponded to the material.

Results: A total of 14 students were tasked to complete five basic science-enhanced VP cases. After data analysis, we identified five themes, illustrating students' perceptions of basic science integration into VP cases and its possible impact on the self-perception of their CR ability: (i) appreciation of basic science knowledge and the role in future work; (ii) ambiguity towards basic science in practice as an obstacle for integration; (iii) the effect of basic science integration on self-perception of CR; (iv) an attractive design of basic science integration; (v) low knowledge of the concept of CR.

Overall, student's perceptions towards basic science were positive but their motivation for performing the integrative activity themselves was low. Students reported enhanced CR ability after having performed the activity. They also reported a value of continuous integration of basic science during rotations in the hospital environment. However, this was hindered by a fear of asking senior colleagues questions related to basic science, as they perceived that they "should have known this themselves".

Conclusion: Our results suggest that student's are positive to basic science integration within educational activities at the medical programme, accompanied by the fact that it might improve their CR abilities.

Abstract Number: 2069

Navigating the Residency-to-Fellowship Transition in Rheumatology

Lilian Otalora Rojas[1] and Gurjit S Kaeley[2], [1]University of Florida, Ponte Vedra Beach, FL, [2]University of Florida College of Medicine – Jacksonville, Ponte Vedra Beach, FL

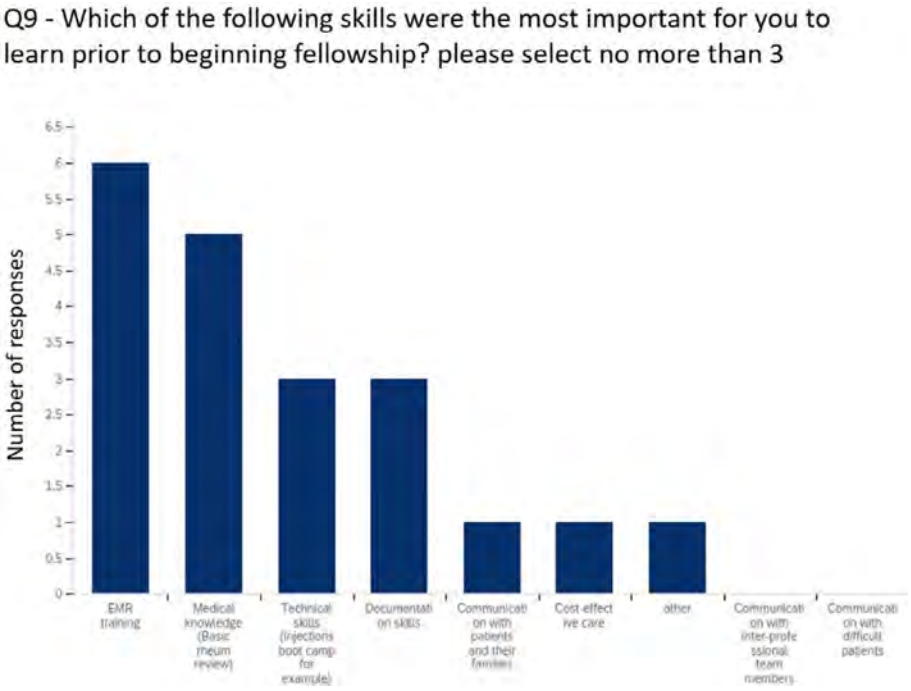
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Transitioning from residency to fellowship is a significant milestone in a medical professional's career. Physicians acquire foundational knowledge and skills during residency, while fellowship allows physicians to gain advanced expertise and specialized training in a specific area of medicine. This transition can be exciting and challenging, as fellows must adapt to a new learning environment, work with different colleagues, and take on greater responsibility in patient care. Nonetheless, with the right mindset, resources, and support, the transition from residency to fellowship can be a rewarding and fulfilling experience that prepares physicians for a successful medical career. This project assesses the transition process from internal medicine residence to rheumatology fellowship.

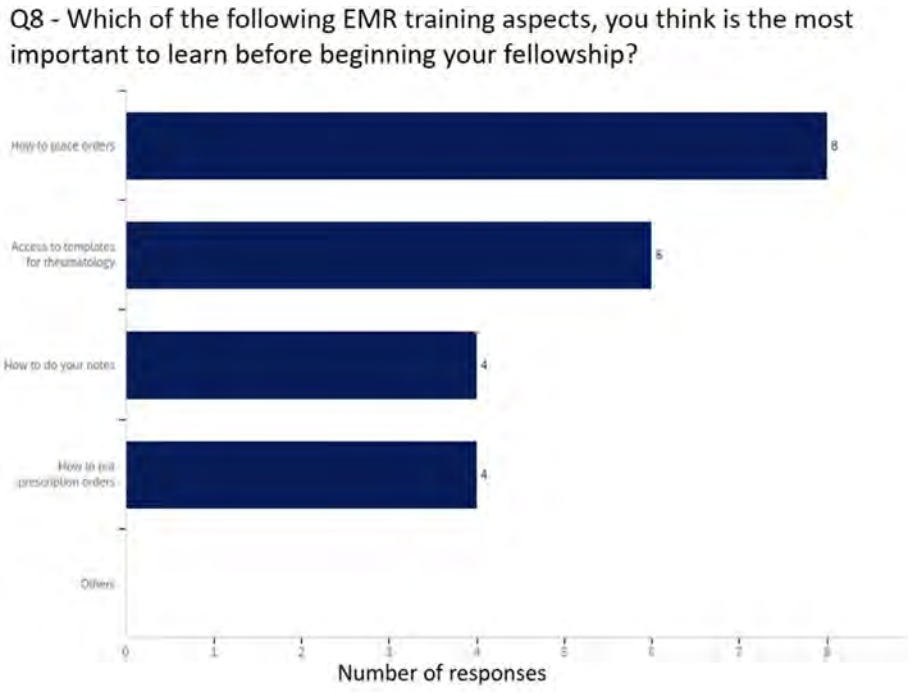
Methods: A cross-sectional survey of rheumatology fellows in Florida in April 2022 was conducted. We used a voluntary, brief, anonymous Qualtrics questionnaire to assess the transition from internal medicine residence to Rheumatology Fellowship. The survey was sent to 28 fellows. The survey assessed their perception of the transition process, including the level of preparedness, challenges encountered during the transition, and satisfaction with the support provided during the transition process, including mentorship, orientation, and institutional resources.

Results: A total of 12 fellows completed the survey, with a response rate of 43%. Age range was: 33.33%: 25-30 years, 50%: 30-35 years, and 16.67% >35 years, 91.67% were female, 33.33% were PYG 4, 50% PGY 5, and 16.67% PGY6. The majority of respondents reported feeling adequately prepared for fellowship. 41.67% (n=5) responded that the transition

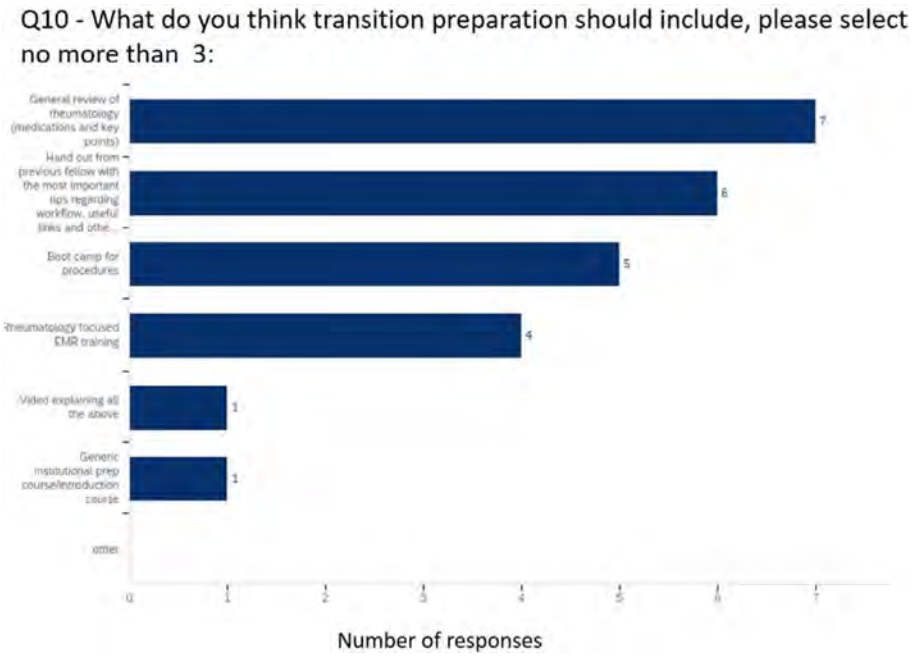
process from residence to fellowship was good, 25% excellent, 8.3% average, and 24% poor. 50% of responders did not participate in a generic institutional preparation course or specialty fellow preparation course. Most of the fellowship introductions lasted less than one week (72.73%). Fellows considered that the most important skill to learn before beginning the fellowship was EMR training (30%), followed by medical knowledge (basic rheumatology review) (25%), injections, and documentation skills. Regarding specific questions about EMR training, the most voted option was how to place orders



Report of the most important skills prior to beginning fellowship.



Report of most important EMR training aspects to learn before beginning fellowship.



(36.36%) and access to templates in rheumatology (27.27%). Most residents (29.17%) responded that transition preparation should include a general review of rheumatology, handouts from previous fellows (25%), boot camp for procedures (20.8,3%) and rheumatology-focused EMR training 16.67%.

Conclusion: Although most respondents reported being satisfied with the support provided during the transition, there are some areas of improvement during the transition process, especially in EMR training. These findings highlight the need for ongoing evaluation and improvement of the transition process from residency to fellowship. Targeted interventions, such as EMR training, general rheumatology and procedures boot camps, and handouts from previous fellows with important tips may help improve the transition experience's quality and better prepare residents for success in their fellowship programs.

Augmenting Medical Education: An Evaluation of GPT-4 and ChatGPT in Answering Rheumatology Questions from the Spanish Medical Licensing Examination

Alfredo Madrid García[1], zulema Rosales[2], Dalifer Freites[2], Inés Pérez Sancristóbal[3], Benjamin Fernandez[3] and Luis Rodríguez Rodríguez[3], [1]Fundación Investigación Biomédica Hospital Clínico San Carlos, Madrid, Spain, [2]Hospital Clínico San Carlos, Madrid, Spain, [3]Hospital Clinico San Carlos, Madrid, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

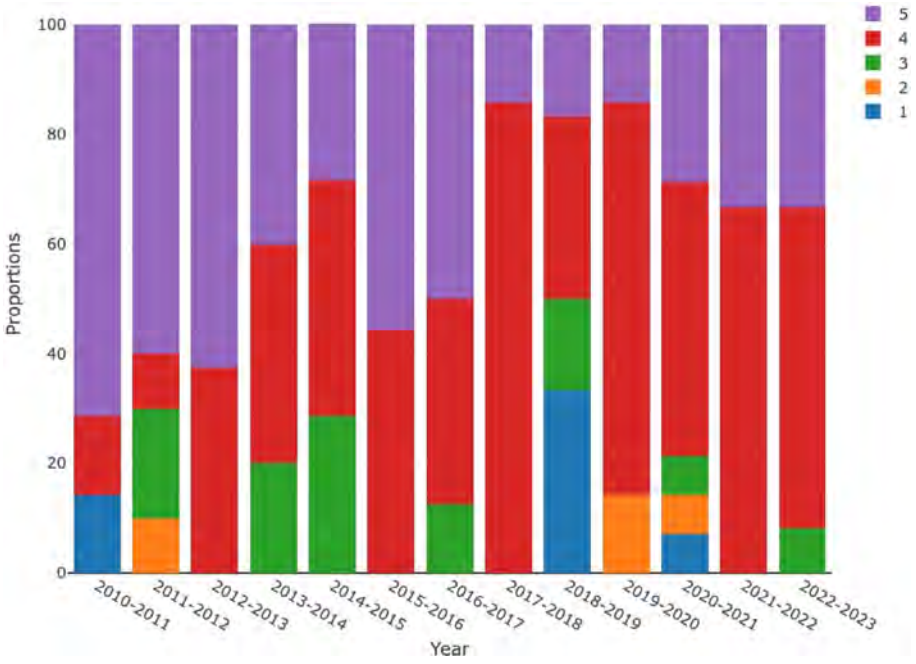
Background/Purpose: The emergence of Large Language Models (LLM) with remarkable performance such as GPT-4 and ChatGPT, has led to an unprecedented uptake in the population. One of the most promising and studied applications for these models concerns education. Their ability to understand and generate human-like text creates a multitude of opportunities for enhancing educational practices and outcomes. The objectives of this study were to assess the success rate of GPT-4/ChatGPT in answering rheumatology questions from the access exam to specialized medical training in Spain (MIR), and to evaluate the medical reasoning followed by ChatGPT/GPT-4.

Methods: Rheumatology questions from the MIR exam published from 2010 onwards were selected and used as prompts. Questions present clinical cases or factual queries, followed by four to five responses with a single correct answer. Questions containing images were excluded.

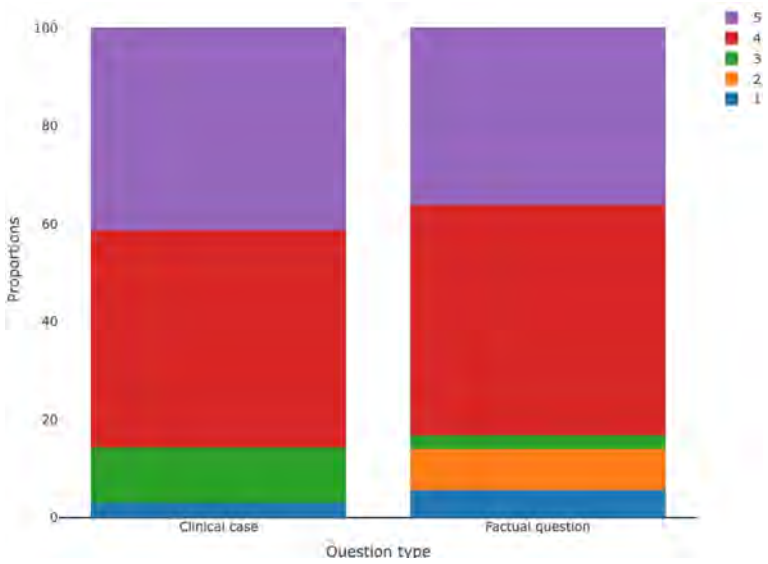
Official responses were compared with those provided by GPT-4/ChatGPT to estimate the chatbots accuracy. Differences between LLM were evaluated using McNemar's test.

A rheumatologist with teaching experience in preparing students for the MIR exam assessed the correctness of the medical reasoning of the LLM given for each of the questions, using a 5-point Likert scale, where 5 indicates that the reasoning was entirely correct. The influence in the medical reasoning score of the chatbot model used was analyzed using McNemar's test. The influence of the year of the exam question, type of question (clinical case vs. factual), patient's gender in the clinical case questions, and pathology addressed were assessed using logistic regression models, after dichotomizing the Likert scale into two groups: low score (i.e.,1,2,3) vs high score (i.e., 4, 5).

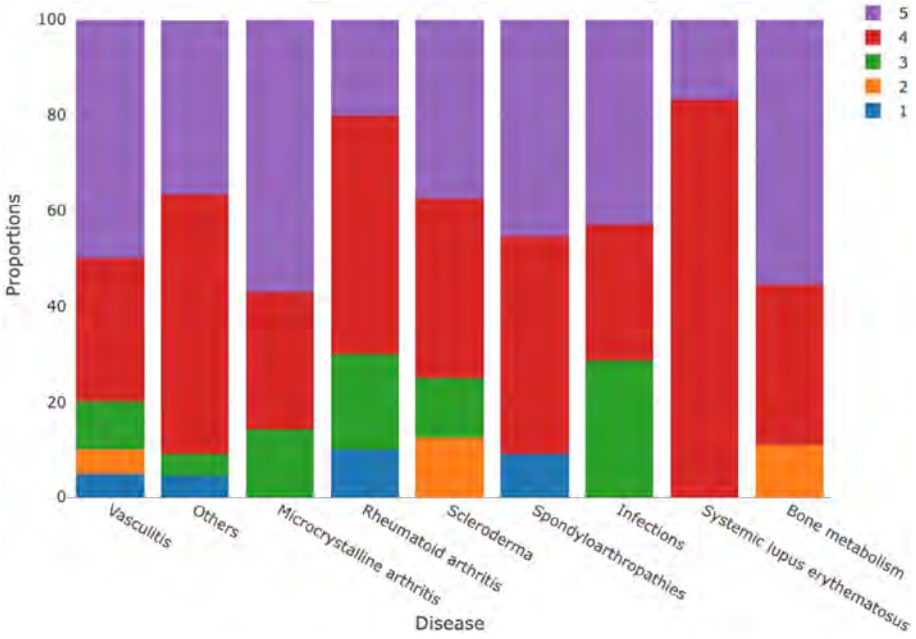
Results: After applying the inclusion criteria, 106 questions remained, including 36 (34%) factual queries and 70 (66%) clinical case questions. 99 (93.4%) and 69 (65.1%) questions were correctly answered by GPT-4 and ChatGPT, respectively. Most of the questions that GPT-4 failed were factual queries (5/7, 71.4%). We observed a significantly higher proportion of correct answers provided by GPT-4 ($p=1.2x10^{-7}$). Moreover, the clinical reasoning score of this LLM was also higher ($p=4.7x10^{-5}$). Regarding the other variables, there were no statistically significant differences in the clinical reasoning score for GPT-4/ChatGPT across the various categories studied. Figures 1, 2 and 3 show the scores given to each question, considering the year, question type and disease.



GPT-4 medical reasoning score of the questions according to the year



GPT-4 medical reasoning score of the questions according to its type



GPT-4 medical reasoning score of the questions according to the disease

Conclusion: GPT-4 showed a significantly higher accuracy and clinical reasoning score than ChatGPT.

No significant differences in the clinical reasoning correctness were observed regarding the type of question or the condition evaluated.

GPT-4 could become a valuable asset in medical education, although its precise role still has to be defined.

A Consensus Based Shoulder Examination for Rheumatology Training

Huseyin Berk Degirmenci[1], Robert Kalish[2], Ratnesh Chopra[3], Kat Gilek-Seibert[4], Fotios Koumpouras[5], Vasileios Kyttaris[6], Santhanam Lakshminarayanan[7], Bonita Libman[8], Stephanie Mathew[9], Kenneth O'Rourke[10], Anthony Reginato[11] and Eugene Kissin[12], [1]St. Elizabeth's Medical Center, Boston, MA, [2]Tufts University School of Medicine, Boston, MA, [3]UMass Chan Medical School, Shrewsbury, MA, [4]Roger Williams Medical Center, Sharon, MA, [5]Yale School of Medicine, New Haven, CT, [6]BIDMC, Boston, MA, [7]University of Connecticut School of Medicine, Farmington, CT, [8]The University of Vermont Medical Center, Burlington, VT, [9]Dartmouth-Hitchcock Medical Center, Hanover, NH, [10]Maine Medical Center, Falmouth, ME, [11]The Warren Alpert Medical School of Brown University, Providence, RI, [12]Boston University, Newton, MA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Professional Education Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Physical examination of a patient with nonspecific shoulder pain is a non-standardized teaching objective among rheumatology fellowship programs. We used the Delphi methodology to identify both variability in shoulder examination performed by rheumatology fellows and areas of consensus among rheumatology fellowship program directors (PDs) in New England.

Methods: Past or present rheumatology PDs currently working in New England were recruited. Participants taught a 5-minute shoulder examination to one of their trainees and recorded the resulting video of the shoulder examination by the trainee. We compiled a comprehensive list of all the performed maneuvers from these videos. Participants received an anonymized electronic survey instructing them to rank each maneuver into one of the three categories: *(Tier 1) Teach all fellows & should be performed routinely; (Tier 2) Teach all fellows BUT should be performed only in specific scenarios; (Tier 3) Teach only to selected fellows & should be performed only in specific scenarios*. When a significant variation in technique between trainees was observed, we surveyed PDs for the best technique (independently of the results of tier consensus). We encouraged participants to include comments explaining reasoning, and/or literature support for their choices. Participants received a compilation of anonymized comments and results of the 1st survey round. Items not meeting ≥70% consensus threshold were included in the 2nd survey. This process was repeated for a 3rd survey. A separate survey collected PD demographics.

Table 1. Demographics of the program directors

Table 1. Demographics of the program directors	Mean ± Standard Deviation (SD)	(Range)
# of years working as clinical rheumatologist	21 ± 7.7	(9-31)
# of years serving (or had served) as fellowship program director	9 ± 5.6	(3-22)
# of fellows accepted to their rheumatology fellowship program	2 ± 0.6	(1-3)
Estimated % of MSK exam knowledge fellows learn(ed) from the participant compared to total MSK exam knowledge of the fellows	39 ± 16.2	(10-70)
Estimated % of time spent for direct patient care compared to total work hours	60 ± 12.2	(33-75)
Estimated % of patient encounters for shoulder pain compared to all patient counters	14 ± 6.1	(7-25)
Estimated % of use of the US of the shoulder for shoulder pain encounters	15 ± 29.2	(0-82)
Self-rating of the MSK examination skills from 0-100 (0 being no skills, 100 being best possible skills)	75 ± 10.6	(50-95)

Neer's test**	passive motion without arm pronation (1/11)	passive motion with arm pronation (10/11)	active motion without arm pronation (0/11)
Speed's test*	with simultaneous biceps palpation (3/11)	without simultaneous biceps palpation (8/11)	N/A
Cross arm adduction test**	with passive motion (9/11)	with active motion (2/11)	N/A
Legend for Table 3: ***Consensus threshold definition: ≥70% (or ≥8/11 answers)*** *Red superscript asterisks added next to the items that met consensus threshold to represent survey rounds during which they met the consensus as following:* **: met consensus during the 1st round; **: met consensus during the 2nd round; ***: met consensus during the 3rd round*			

Results: 11 of 13 recruited PDs agreed to participate and 100% of participants completed all rounds of the study. Participants were PDs for nine years (range 3-22), 45% are/were the main teachers for the MSK examination in their fellowship programs, andrated themselves 75 (range 50-95) on a 100-point scale for prowess in physical examination (Table 1). The study addressed 65 items: 52 questions for tier designation of the exam maneuvers and 13 questions for different examination techniques. Participants achieved consensus for 40/52 tier designation items (Table 2) and for 8/13 technique items (Table 3). Consensus for tier designation items increased from 44% in round 1, to 69% in round 2, and 77% by round 3. For technique-related items, consensus increased from 31% to 54% to 61% (Tables 2 and 3).

Conclusion: This is the first study focused on shoulder examination specific to rheumatology training and practice, which may be distinct from that required for orthopedics, physiatry, or primary care. By collecting anonymized video recordings from each participant, we cataloged the range of shoulder physical exam maneuvers and techniques performed in almost all teaching programs in New England. The Delphi methodology allowed consensus building among PDs for which shoulder examination techniques to teach, which to perform routinely vs. selectively, and how to perform them. These results, in the context of "nonspecific" shoulder pain, should be generalizable and can provide guidance for all US rheumatology fellowship training programs given the similarity in the scope of practice and education.

Utility of a Novel Pediatric Rheumatology Interactive Teleconference Series: Rheum2Play

Sarah Molina[1], **Tresa Ambooken**[2], Christina Gulla[3], Miriah Gillispie-Taylor[4] and Ginger Janow[5], [1]Baylor College of Medicine - Pediatrics Residency Program, Houston, TX, [2]Hackensack Meridian Health, Hackensack, NJ, [3]HUMC pediatrics residency, Hackensack, NJ, [4]Baylor College of Medicine, Texas Children's Hospital, Houston, TX, [5]Joseph M. Sanzari Children's Hospital at Hackensack Meridian Health, Glen Rock, NJ

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Within pediatric subspecialities, pediatric rheumatology remains one of the newest and smallest, with a paucity of resources available for new trainees and those interested in learning more. It is estimated that 1 in every 250 children has juvenile arthritis, but there are only approximately 400 practicing pediatric rheumatologists nationwide. Most pediatric rheumatologists are concentrated in larger cities, leaving a significant part of the country underserved, meaning pediatric trainees often also lack exposure to pediatric rheumatology. Estimates suggest that approximately 33% of medical schools and 40% of pediatric residency programs lack access to a pediatric rheumatologist, significantly impacting training. Lack of exposure of pediatric rheumatology by learnders early in training and lack of access to pediatric rheumatology clinical experience during any part of training are likely contributing factors to delays in presentation to care of affected patients. To help bridge this gap, social media, particularly the podcast platform, has been increasingly utilized and may be a large part of the future of medical education.

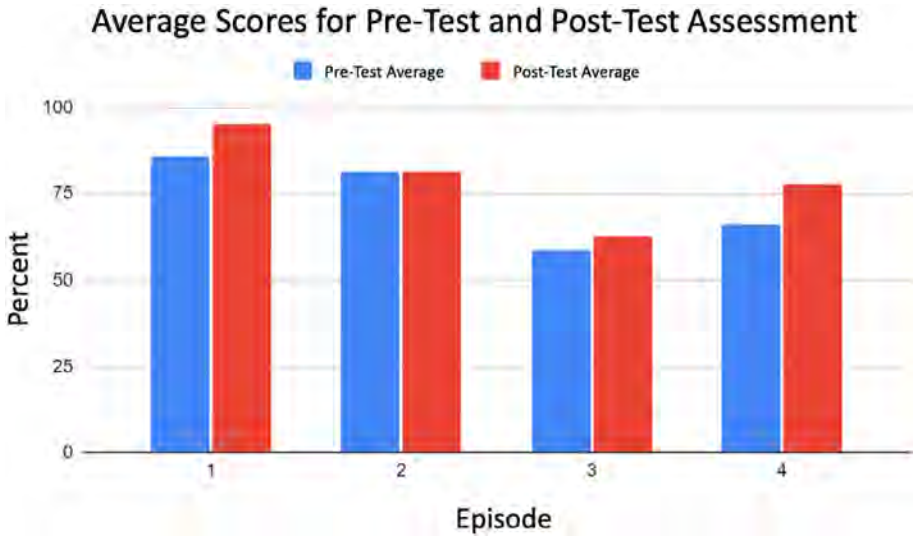

Figure 1. Pre and post-test assessment scores for four live conference sessions. Assessments included questions regarding knowledge and confidence. Scores did show improvement for three of the four sessions when combining both knowledge and confidence assessments.

Methods: Four live, interactive educational teleconferences were held for an audience of pediatric residents and pediatric rheumatology fellows. Each session focused on a different subtype of juvenile idiopathic arthritis arthritis (JIA). Recruitment was via email to pediatric residency program directors and pediatric rheumatology fellowship directors. Pre- and post-tests were developed based on learning objectives to assess specific knowledge and confidence regarding ability to recognize and workup JIA. Test scores for which there were paired pre- and post-test data were included in the analysis. Per session, average pre and post test scores were calculated and compared to assess uptake of knowledge and increase in confidence potentially attributable to the session. Given the small number of participants statistical significance could not be assessed.

Results: Number of participants per session ranged from 3-8. Average assessment averages increased in 4 of the 5 sessions (Figure 1) and average confidence increased after all sessions (Figure 2).

Conclusion: Our results suggest that a live teleconference is likely effective at increasing medical knowledge and confidence in recognition and workup of JIA. Recruitment provided some challenges and we intend to improve dissemination by converting sessions into podcasts. While knowledge scores did not show dramatic improvement. Sessions are unscripted

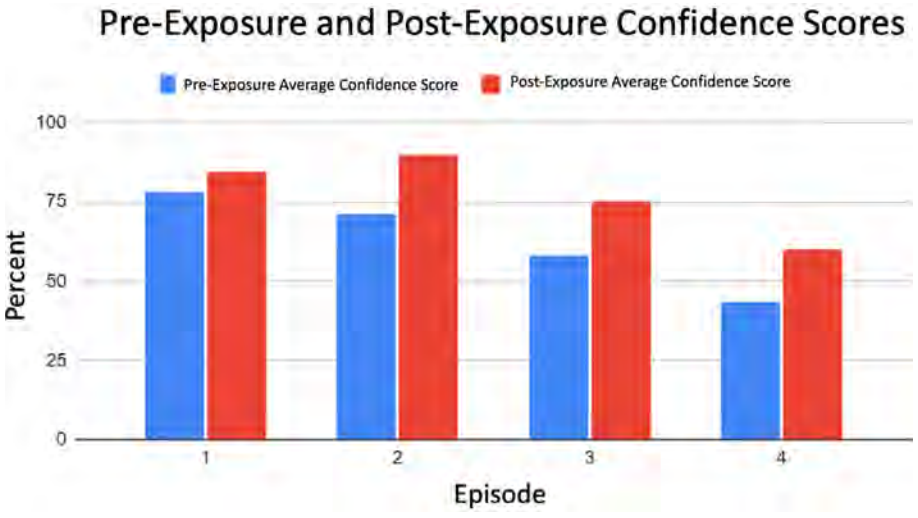

Figure 2. In all assessments, post-exposure assessment of confidence scores were higher than pre-exposure assessment scores for all episodes.

and conversational, which may prove more difficult to include the specific content in the pre-and post-tests. There was a more impressive increase in confidence scores, suggesting that the learners found the sessions useful in future diagnosis and management of conditions discussed, making this a valuable learning experience. To overcome these challenges, we plan to convert these teleconference sessions to podcasts with an associated web-based platform, and develop pre-and post-tests that are congruent with our podcast content. Overall, the tools developed provide useful and portable educational resources for a wide audience of pediatric health practitioners.

Abstract Number: 2073

Outcomes of the First Year of a Rheumatology Curriculum at Two Internal Medicine Residency Programs

Laura Arneson[1], Biana Modilevsky[2] and Anisha Dua[1], [1]Northwestern University, Chicago, IL, [2]University of Arizona - Tucson / Banner University Medical Center, Tucson, AZ

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Enhancing rheumatology education in Internal Medicine (IM) residency may encourage residents to pursue rheumatology careers, and promote familiarity with rheumatology among those entering other fields. A needs assessment of rheumatology training in IM residency was conducted at an academic program (A) and community program (B) in the same city in 2021. At baseline, all third-year residents at B rotated in a rheumatology clinic for one month; A had no required rheumatology rotation. Neither program had structured rheumatology didactics. Surveys of residents and analysis of In-Training Exam (ITE) scores guided development of a rheumatology curriculum. An assessment of curriculum outcomes after the first year is presented.

Methods: A baseline survey was sent to all IM residents at A and B in Spring 2021, with questions on amount of rheumatology training in residency, interest in learning about rheumatology, interest and confidence in specific topics, and preferred curriculum formats. Results informed the curriculum, implemented starting August 2021. Noon conferences about rheumatology labs and systemic lupus erythematosus (SLE) were delivered at A and B, including pre- and post-quizzes and reference handouts. At A, conferences were also delivered on spondyloarthropathies and vasculitis, and each intern was scheduled for one half-day in rheumatology clinic. The survey was repeated in Spring 2022. ITE scores before and after curriculum implementation were compared (Fall 2020 and 2022).

Results: Baseline surveys were completed by 46% of residents (n=53) at A and 87% (n=20) at B. Post-surveys were by completed by 19% of residents (n=22) at A and 100% (n=23) at B. From 2021 to 2022, ratings of amount of rheumatology training in residency, interest in learning about rheumatology, and confidence in topics covered in conferences increased non-significantly (Figure 1). Preference for in-person curriculum formats increased at A and remained high at B (Figure 2). During the conference on labs, average quiz score increased at A: 40% (n=17, SD 26%) to 74% (n=20, SD 20%), and at B: 27% (n=6, SD 10%) to 77% (n=5, SD 15%). For the conference on SLE, average quiz score increased at A: 42% (n=8, SD 15%) to 90% (n=6, SD 17%), and at B: 52% (n=11, SD 10%) to 93% (n=14, SD 13%). From 2020 to 2022, scores on

the rheumatology portion of the ITE increased from 65th to 89th national percentile at A, and decreased from 5th to 4thpercentile at B. Ranking ITE performance in the 11 IM subspecialties by percentile, A's rheumatology scoreincreased from 10th to 3rd (tied) subspecialty, while B's decreased from 6th (tied) to 10th (tied).

Conclusion: Implementation of a rheumatology curriculum resulted in several advances after one year; outcomes varied between two programs. Residents demonstrated knowledge gains during conference sessions at both A and B. Rheumatology ITE score percentile improved only at A, which received additional didactics. Resident-reported metrics of their rheumatology training improved slightly at both. Preferred curriculum formats shifted from virtual to in-person from 2021 to 2022. Incomplete resident participation at A was a limitation. Next steps include adding additional conferences and reference materials.

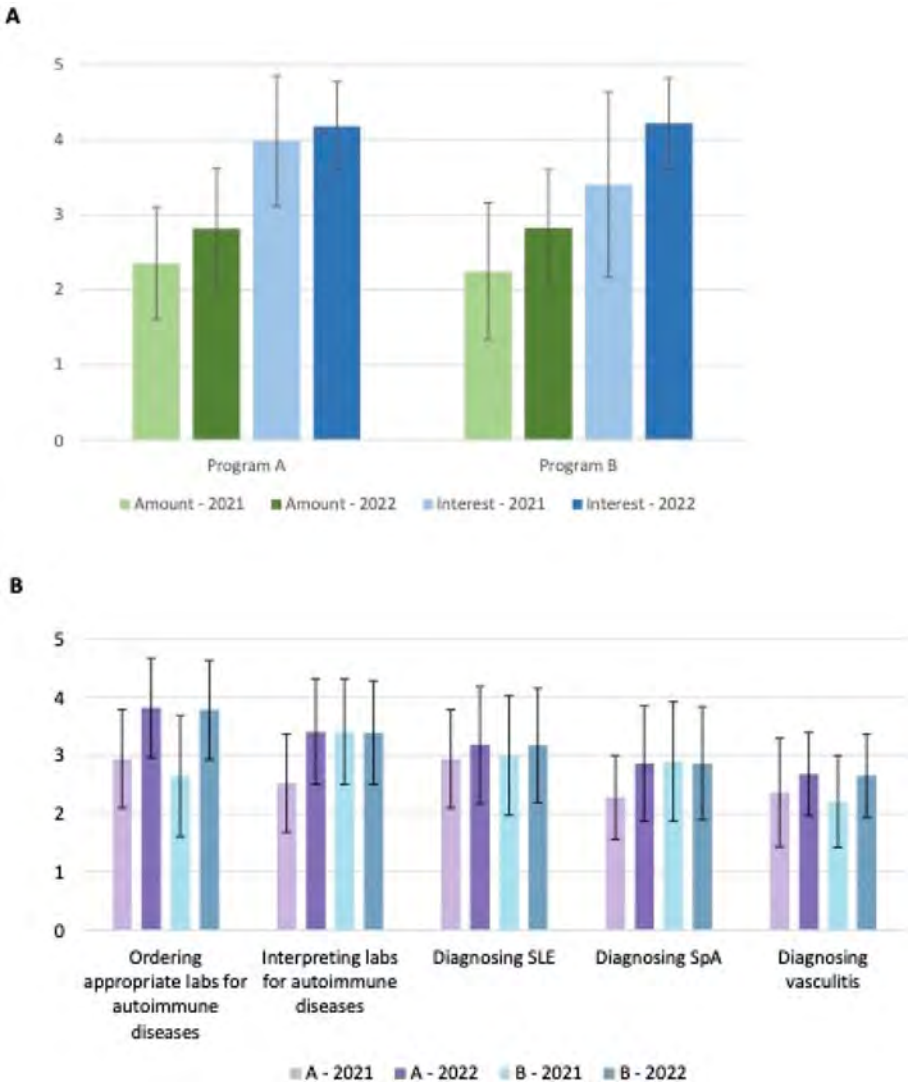

Figure 1. Resident survey responses from internal medicine programs A and B, before and after implementation of a rheumatology curriculum. Pre-surveys (lighter bars) were conducted in Spring 2021 at A (n=53, response rate 46%) and B (n=20, response rate 87%). Post-surveys (darker bars) were conducted in Spring 2022 at A (n=22, response rate 19%) and B (n=23, response rate 100%). Error bars represent standard deviations. Panel A: Rating of the amount of rheumatology training received in residency on a 5-point Likert scale (1 = very inadequate, 5 = more than adequate) is shown in green; rating of interest in learning about rheumatology on a 5-point Likert scale (1 = not at all interested, 5 = very interested) is shown in blue. Panel B: Rating of confidence in rheumatology topics on a 5-point Likert scale (1 = not at all confident, 5 = very confident) is shown in purple for A and blue for B. SLE = systemic lupus erythematosus; SpA = spondyloarthropathies.

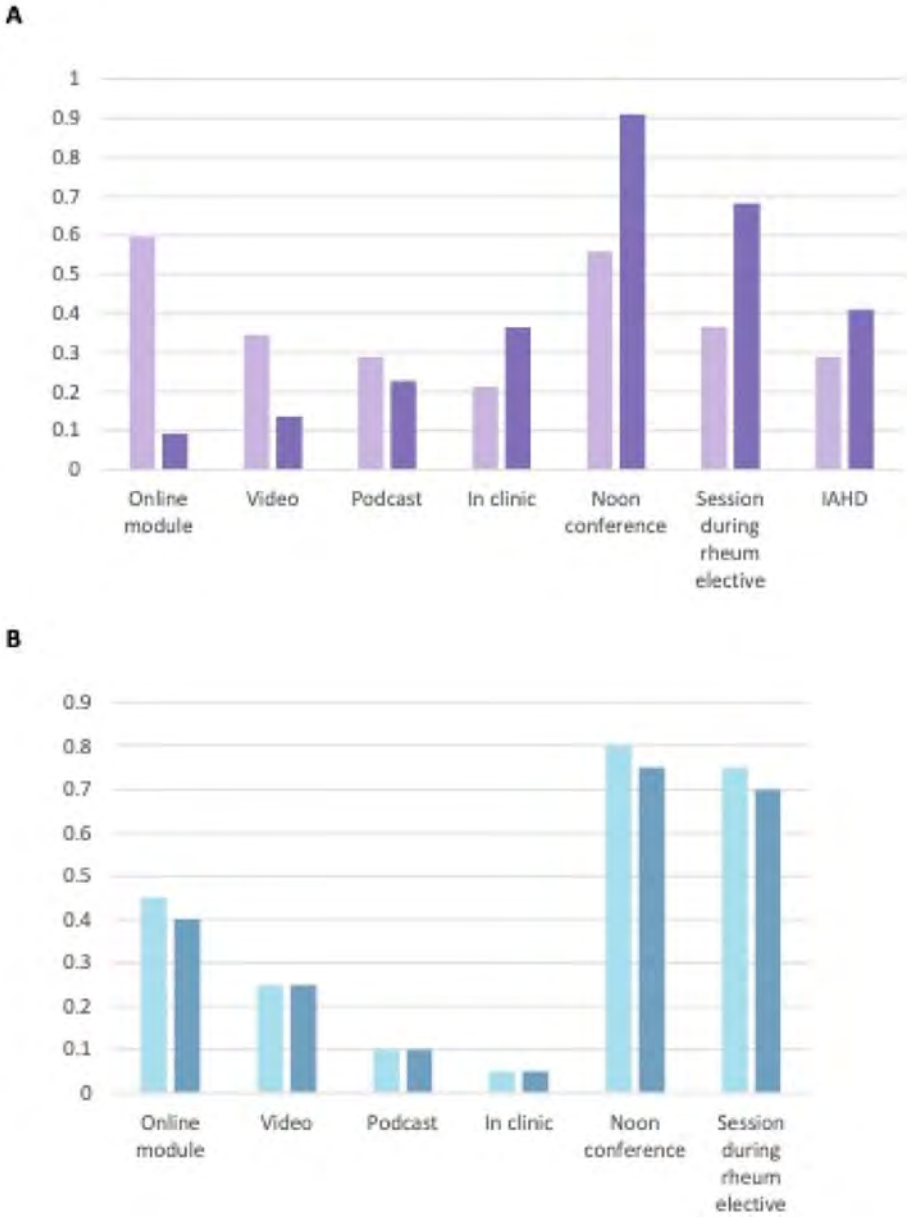

Figure 2. Resident preferences for format of a rheumatology curriculum in 2021 compared to 2022, at program A (panel A) and program B (panel B). Pre-surveys (lighter bars) were conducted in Spring 2021 at A (n=53, response rate 46%) and B (n=20, response rate 87%). Post-surveys (darker bars) were conducted in Spring 2022 at A (n=22, response rate 19%) and B (n=23, response rate 100%). Residents were asked to select 1-3 preferred formats; percent of residents selecting each format is shown. Rheum = rheumatology; IAHD = intern academic half-day, a format available only at A.

Disclosure: L. Arneson: None; **B. Modilevsky**: None; **A. Dua**: AbbVie/Abbott, 2, Amgen, 2, GlaxoSmithKlein(GSK), 2, Novartis, 2, sanofi, 2.

Abstract Number: 2074

Creation and Dissemination of a Near-Peer Rheumatology Fellowship Bootcamp

Sarah Donohue, Tiffany Lin and Justin Levinson, University of Wisconsin, Madison, WI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Transitions in medical education, such as the matriculation from residency to fellowship, can be a challenging experience with increased knowledge expectations in new clinical settings. Despite the growing number of transition courses, or "bootcamps," there remains a paucity of medical education research, a leaning towards virtual programs, and no published orientation curricula for subspecialized training in rheumatology. We compared the effect of a near-peer rheumatology fellowship bootcamp on new fellows' self-assessments before, after, and 6 months following our intervention along with fellows' clinical knowledge exam scores and performance evaluations by faculty.

Methods: We designed a 3-day intensive, interactive, multi-modality curriculum that included near-peer senior fellow led introductory sessions, workspace tour, and workflow workshops. In addition, incoming fellows were exposed to hands-on SIM center physical exam teaching skills, MSK ultrasound introduction, injection teaching, and disease specific didactic sessions. The 2 junior rheumatology fellows were then assessed with a pre-, post-, and 6-month follow-up 46 question survey. Rheumatology faculty completed a 20-question survey comparing consecutive year fellows who did not complete a bootcamp to those who did. 10 clinical knowledge questions on basic concepts in rheumatology were administered to the fellows with each survey.

Table 1. Fellow Self-Assessment Survey Results & Clinical Knowledge Exam Scores

Learning Objective (# of questions)	Pre – Bootcamp Survey Results (SD)	Post – Bootcamp Survey Results (SD)	6 Month Follow-up Survey (SD)	F-statistic value	P-value
Level of clinical knowledge (n=7)	2.0 (0.65)	3.0 (0.58)	3.5 (0.41)	13.21	<0.001
Developing Work-Up Plan (n=10)	1.9 (0.46)	2.6 (0.39)	3.1 (0.70)	12.77	<0.001
Developing Treatment Plans (n=10)	1.95 (0.37)	2.7 (0.26)	3.3 (0.75)	16.13	<0.001
Arthrocentesis Capability (n=3)	1.33 (0.58)	1.83 (0.29)	3.17 (0.29)	16.15	0.004
MSK Ultrasound (n=1)	1.00	1.50	3.50	-	-
Work-Flow/Administrative Tasks (n=9)	1.75 (1.7)	2.81 (0.88)	3.81 (0.46)	7.39	0.003
Clinical Knowledge Question Scores (n=10)	85%	90.00%	100%	-	-

Key: Likert scale of survey. 1= Not at all/Poor, 2=A little/Fair, 3=Somewhat/Good, 4= Very, 5=Extremely/Excellent.

Results: With 46 survey questions grouped into learning objectives, we compared self-assessed comfort in: Level of clinical knowledge (n=7), Developing work-up plans (n=10), Developing treatment plans (n=10), Arthrocentesis capability (n=3), MSK ultrasound (n=1), and Workflow/administrative tasks (n=9; Table 1). We found that the bootcamp increased fellow level of confidence in all proposed learning objectives, and improvement continued at the 6-month follow-up retention of knowledge survey. The pre-bootcamp clinical knowledge mean exam score was 85%, improved to 90% on the post-bootcamp exam, and ultimately 100% correct at the 6 month follow up. Post intervention, the faculty survey discovered that our junior fellows were better equipped to develop a work-up plan ($p< 0.00001$) and treatment plan ($p< 0.00001$; Table 2). Faculty assessed the success in introducing high yield concepts between "good" and "very" with a score of 3.4 on a 5-point Likert scale. A secondary objective of comparing the creation of working relationships between faculty and new fellows was graded as 3.7.

Conclusion: This innovative University of Wisconsin rheumatology fellowship bootcamp represents the first published iteration for a near-peer led rheumatology curriculum. Distinctively, this curriculum included simulation center actors, a hands-on course on arthrocentesis and dedicated senior fellow led clinical setting workshops and tour. The fellow-led teaching model further consolidates the knowledge in senior fellows. Future directions include expansion of the bootcamp to prospectively collect baseline data and increase the sample size.

Table 2. Faculty Survey Results

Learning Objective (# of questions)	Pre – Bootcamp Faculty Survey (SD)	Post – Bootcamp Faculty Survey (SD)	T- value	P-value
Level of clinical knowledge (n=7)	2.19 (0.29)	2.32 (0.15)	1.96	0.098
Developing Work-Up Plan (n=10)	1.98 (0.25)	2.62 (0.21)	12.30	< 0.00001
Developing Treatment Plans (n=10)	2.01 (0.29)	2.63 (0.25)	9.59	< 0.00001
Work-Flow/Administrative Tasks (n=7)	-	3.23	-	-
Overall Success of the Bootcamp Objectives (n=3)	-	3.50	-	-

Key: Likert scale of survey. 1= Not at all/Poor, 2=A little/Fair, 3=Somewhat/Good, 4= Very, 5=Extremely/Excellent.

Abstract Number: 2075

The Impact of Rheumatology Fellow Initiated Curriculum Design on Resident Education

Karen Kruzer[1], Vincent Vertalino[1], Nilson Tapia[1], Andrew Long[1], Amy Blatt[2], Ummara Shah[1] and Bethany Marston[1], [1]Department of Rheumatology, University of Rochester Medical Center, Rochester, NY, [2]Department of Medicine, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Professional Education Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatology fellows have a critical role as medical educators for residents and offer unique perspectives on patient care. Fellow scholarly activity is an ACGME requirement in the practice of rheumatology. The purpose of this medical education initiative was for rheumatology fellows to create a longitudinal educational curriculum for internal medicine (IM) residents, and to assess efficacy through both objective knowledge questions and subjective feedback questions.

Methods: The rheumatology fellows at the University of Rochester Medical Center (URMC) developed a needs-assessment of rheumatology core topics from the American Board of Internal Medicine Certification Examination Blueprint. Topics were selected based on IM resident feedback from a needs-assessment. Each fellow created an interactive discussion-based didactic education session for a total of four sixty-minute sessions throughout the 2022-2023 academic year. Self-assessment surveys were completed by residents before and immediately after participation in fellow-led didactics, and percent improvement between pre and post assessments was calculated. The objective knowledge assessments included questions addressing diagnosis, laboratory findings, imaging, and treatments for each topic. A subjective questionnaire soliciting resident feedback assessed effectiveness for resident academic training, applicability to inpatient rotations and residency clinics, and impact on clinical management.

Results: Curriculum topics were selected based on needs-assessment responses from IM residents (N=26), where each resident selected one topic. The most requested topics included dermatologic manifestations of rheumatologic disease (38.5%), vasculitis (30.8%), seronegative spondyloarthropathies (11.5%), and crystal arthropathy (7.7%). After implementing the longitudinal education series, there was a 35% improvement in rheumatology-dermatology knowledge questions,

Table 1. Results of needs-based assessment.

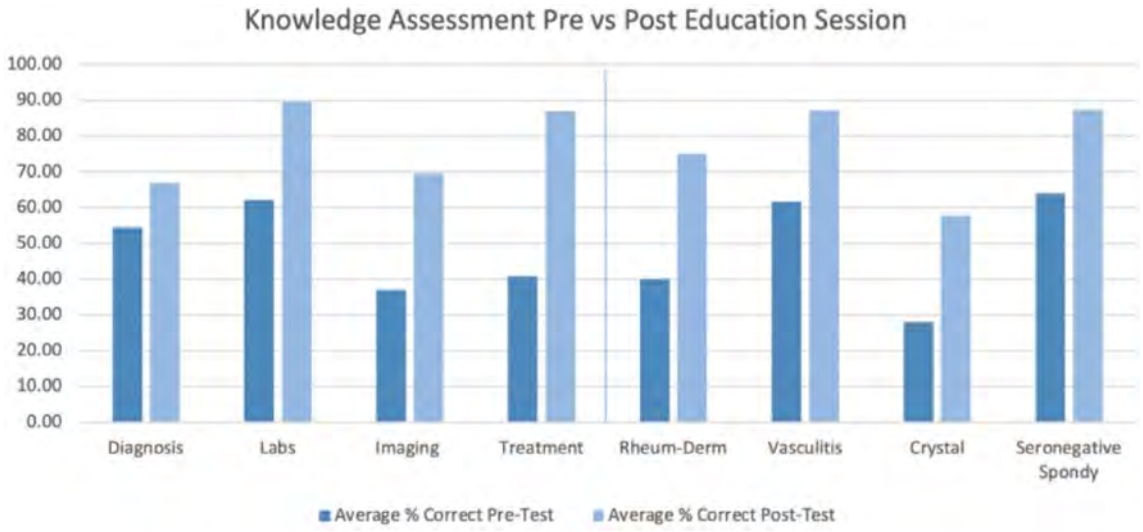
Topic	Total Responses (n=26)	Percent (%)
Crystal arthritis and septic arthritis	2	7.7
Dermatologic manifestations of rheumatologic conditions	10	38.5
Inflammatory myopathy	0	0
Lupus	1	3.8
Osteoarthritis, metabolic bone disease, osteoporosis	1	3.8
Rheumatoid Arthritis	0	0
Scleroderma	1	3.8
Seronegative Spondyloarthropathies	3	11.5
Vasculitis	8	30.8

Table 2. Results of knowledge assessment pre and post education session. Table depicts the total number of responses and percent correct responses for diagnosis, labs, imaging, and treatment specific questions.

		Diagnosis	Labs	Imaging	Treatment	Overall % Improvement
Dermatology-Rheumatology						
	Pre-Test	5 (38.5%)	7 (53.9%)	5 (38.5%)	3 (23.1%)	
	Post-Test	9 (56.3%)	11 (68.8%)	11 (68.8%)	15 (93.8%)	35
Vasculitis						
	Pre-Test	6 (50%)	9 (75%)	8 (66.7%)	7 (58.33)	
	Post-Test	6 (66.7%)	9 (90%)	9 (90%)	10 (100%)	25.7
Crystal Arthritis						
	Pre-Test	3 (30%)	2 (20%)	1 (10%)	2 (20%)	
	Post-Test	4 (44.4%)	9 (100%)	4 (44.4%)	6 (66.7%)	32
Seronegative Spondyloarthropathy						
	Pre-Test	8 (100%)	8 (100%)	3 (32.5%)	5 (62.5)	
	Post-Test	8 (100%)	8 (100%)	6 (75%)	7 (87.5%)	23.5
Improvement (%)		12.2	27.5	32.7	46	29.1

25.7% improvement in vasculitis questions, 32% improvement in crystal arthropathy questions, and 23.5% improvement in seronegative spondyloarthropathy questions. The majority of residents found the education session helpful for their academic training (96%), helpful for inpatient medicine rotations and clinic (84.4%), and felt it would change their clinical management (88.8%).

Conclusion: This innovative rheumatology fellow initiated curriculum design project was an effective way to educate resident learners on rheumatology topics, as well as for rheumatology fellows to build medical education skills. By creating a unique culture of collaboration among fellows and residents there is potential for broad positive effects and improvement in patient care. There were improvements in each disease category, which were not proportional to the percentage of students who requested these topics during the needs-assessment. This study was limited by sample size, as many residents were unable to attend the full education session. We plan to continue this education series in future years by including additional rheumatology topics, and expanding to incorporate additional IM subspecialty fellowship programs in the education sessions.



Graph 1. Results of knowledge assessment before and after the education sessions.

Abstract Number: 2076

Piloting a Rheumatology and Sports Medicine Case-Based Collaborative Learning Curriculum for Medical Students

M. Dave Dimachkie[1], Brittany Bettendorf[2] and Marion Sanders[1], [1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]University of Iowa, Iowa City, IA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Case-based collaborative learning (CBCL) is an interactive teaching method that integrates cases with key concepts. CBCL is recognized as a means for knowledge improvement for learners and consequently has become increasingly utilized in medical education. Herein, our group created a CBCL curriculum with rheumatology and sports medicine content.

Methods: All medical students on a 10-week Internal Medicine (IM) Core Clerkship were enrolled in this study measuring the efficacy of this curriculum. The 1.5-hour rheumatology and sports medicine CBCL curriculum was performed in-person once per clerkship cycle. The CBCL is led by an internal medicine resident rotating on a dedicated teaching rotation.The CBCL consists of several topics, including crystalline arthropathies, osteoarthritis, inflammatory arthritis, and sports medicine. To assess knowledge improvement, we developed a pre/post multiple-choice question knowledge assessment and analyzed score differentials. To elaborate, students completed an 8-question pretest knowledge assessment two days prior to the CBCL curriculum. Answers to the pretest questions were not provided to the students at the completion of the pretest. The questions/answers to the pretest were not explicitly discussed during the CBCL presentation. Students then completed the same 8 question quiz after the CBCL curriculum. The posttest was made available 1 day after the CBCL curriculum ended and was required to be completed within 4 days of the session. All students completed both the pre/post assessment.

Results: Institutional Review Board approval was obtained, and data was collected from January 2022-December 2022. Statistical differences were analyzed using paired t-testing and analysis of variance (ANOVA).136students completed both CBCL quizzes. The mean scores of the pre- and post-quizzes were 61.4% (SD +/- 23.0%) and 70.6% (SD +/- 19.4%), respectively. The score improvement for the overall cohort was 9.2% ($p< 0.001$). All medical student blocks had a statistically significant improvement in quiz scores except for block 3 ($p=0.354$). ANOVA testing demonstrated consistency across the four blocks regarding mean pretest ($p=0.284$), posttest ($p=0.687$) and score improvement ($p=0.565$) with no significant differences between blocks.

Conclusion: CBCL was an effective alternative to lecture-based teaching, and consequently, this curriculum was integrated into the IM Clerkship Curriculum. A limitation of this project was the inability to determine long-term retention of concepts acquired during the CBCL. Future directions of this project may include diversification of pre- and post-tests and obtaining student-centered feedback on the curriculum.

Abstract Number: 2077

A Curriculum of Online Education Significantly Improved Rheumatologists' Knowledge, Competence and Confidence in Managing Patients with Spondyloarthritis

Elaine Bell[1], Marinella Calle[2] and Iain McInnes[3], [1]Medscape Global Education, London, United Kingdom, [2]MEDSCAPE GLOBAL, London, United Kingdom, [3]University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) are challenging conditions for rheumatologists to manage. There is an increasing focus on virtual training modalities post-pandemic. We assessed whether a curriculum of online educational activities could improve rheumatologists' knowledge, competence and confidence in managing patients with spondyloarthritis.

Methods: A curriculum of virtual activities was developed on the evolving therapeutic landscape in the treatment of psoriasis (PSO) and spondyloarthritis (SpA). Data presented here are from the initial 4 activities on SpA, including 2 on line panel discussions and enduring versions of symposia from EADV 2022 and ACR 2022. Data were collected between 2022 and 2023 with n numbers for each activity ranging from 108 to 549 completing pre- and post-activity questions. Educational effect was assessed with a repeated-pairs pre-/post-assessment; 3 multiple-choice, knowledge or competence questions and 1 self-efficacy, 5-point Likert scale confidence question were analyzed. Data were subsequently combined and analyzed by 5 themes to provide a summative overview of the effect of the education across the combined activities. A McNemar's test was conducted to assess statistical significance of changes from pre- to post-assessment.

Results:

- 12,256 MD learners across the globe participated in the activities including 3,877 rheumatologists, 3,180 dermatologists and 4,104 primary care physicians
- Rheumatologists demonstrated a statistically significant improvement in knowledge or competence across 4 of the 5 learning themes (clinical data informing disease management, individualizing treatment to limit disease progression, monitoring disease activity and treatment goals for PsA and axSpA; all $P < 0.01$)
- Overall, 79% of rheumatologists gained competence and 26% gained knowledge
- Overall, 33% of rheumatologists reported increased confidence e.g. in setting appropriate treatment goals or implementing a treat-to-target strategy: for confidence questions aligned with each individual activity, the percentage of rheumatologists who gained confidence ranged from 19% to 59%

Conclusion: These results highlight the benefits of an on-line curriculum of education in challenging rheumatologists to better manage patients with PsA and axSpA. As the treatment landscape for these diseases continues to evolve, rheumatologists will likely benefit from further innovative educational modalities on key clinical data for emerging medicines and strategies for their deployment in clinical practice.

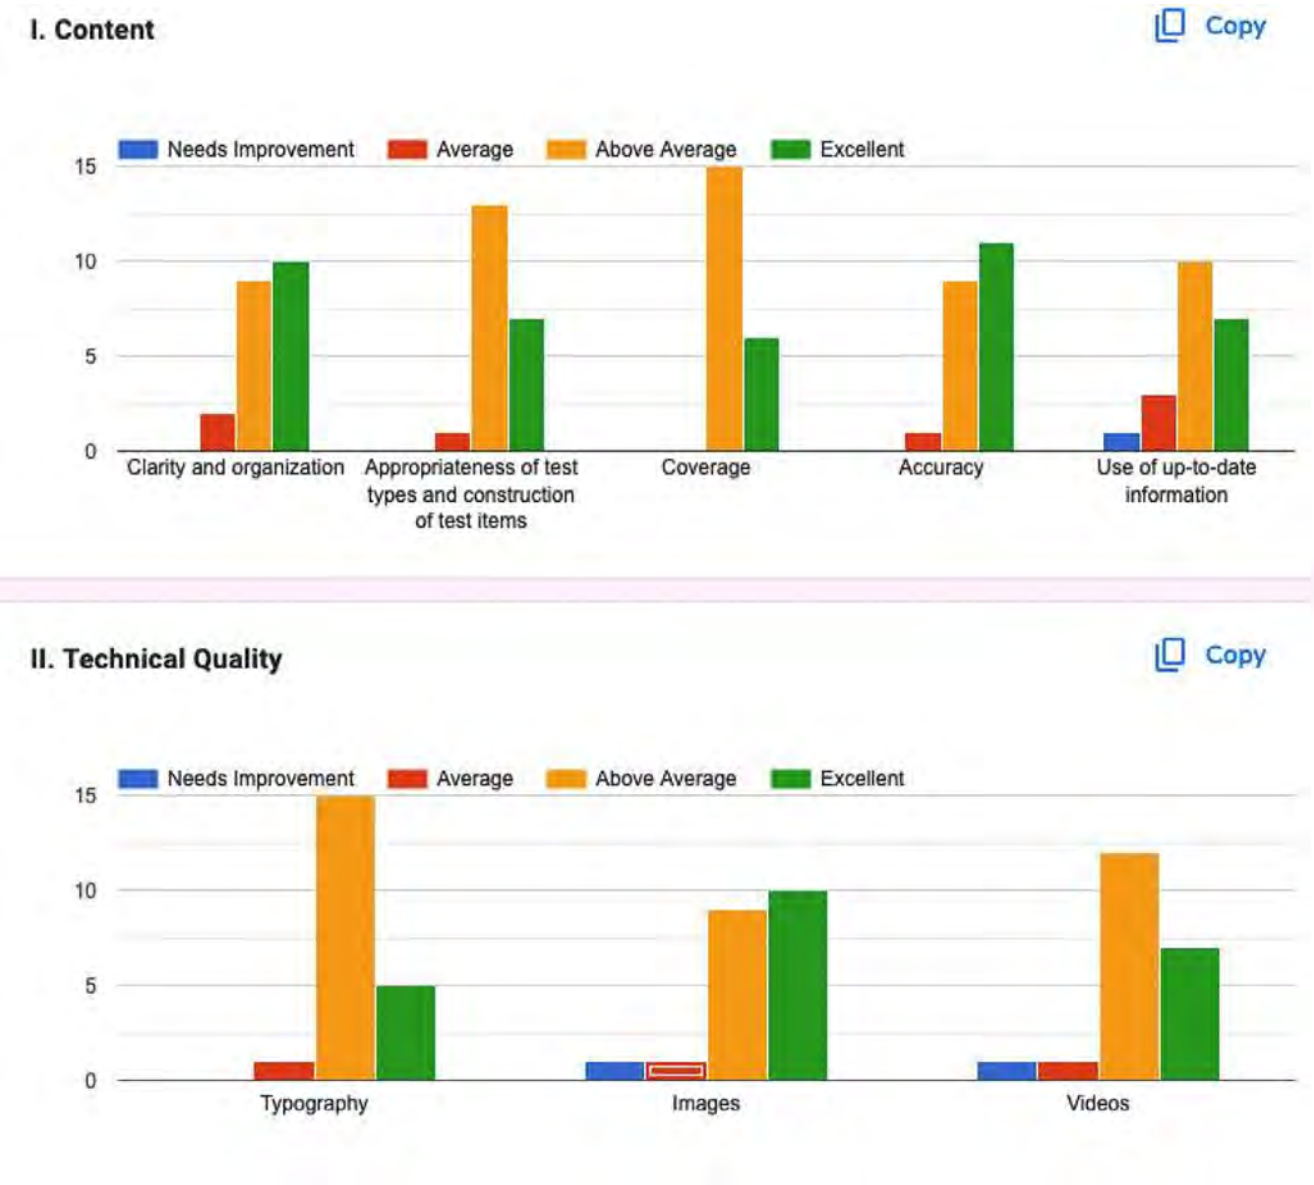
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The ARGO Project (applied rheumatology on the go) is an online learning tool in Rheumatology. It uses Cerego, an adaptive learning technology online/mobile platform. Started in 2017, by integrating distance learning (or e-learning), busy trainees or early career Rheumatologists can review or update themselves in Basic and Applied Rheumatology. The 20 modules of various rheumatology question materials are presented to the learner depending on their individual learning patterns. Items that the learner seems to have more difficulty with will be shown more frequently compared to items they find easy. There are notes, and external resources for the learner to facilitate asynchronous learning. Users and instructors can track progress and determine the difficulty of questions.

Methods: The platform is catered towards helping recently graduated fellows into reviewing prior to their board exams. Enrollment is voluntary through interest and word of mouth from past fellows. This year, instructor editors were invited to help update the content of the project.

Usability surveys on the use of the platform were sent to the society communications group. Descriptive analysis was used to analyze the results. Free text answers were categorized into themes.

Results: At the time of this interim analysis only 21 of the prior 70 past and current fellows agreed to evaluate the platform. 33% of the respondents were from the first batch of 2017, followed by 2019. 66% of the fellows did not know how to use the Spaced Repetition concept. For those who used the platform for more than 1 yr (those who did not pass the board exam the first time), only 2 out of 9 respondents used it less for the second year. When asked about the content of the modules, the majority of the respondents answered it was above average. It is expected to see some feedback about the need to upgrade the information since the module was originally started in 2017. With regards to technical quality, a few respondents recommended adding more images and videos. This is important feedback given the increase in use of musculoskeletal ultrasound in our curriculum over the last few years. Nevertheless it is reassuring to see that navigation was still easy for the users. When asked which part of the project they favored the most, the majority selected the flashcards and mnemonic notes. All respondents felt they would recommend the platform as a learning tool. For the free text comments, there appeared to be some common suggestions themes such as



Usability survey of the ARGO project: Content and Technological Quality

automation: notification messages or emails when not logging in at appropriate intervals. Another common suggestion theme was to use the platform in tandem with the examination blueprint topics.

Conclusion: The survey will continue until the next interval progress report as part of the ILAR grant requirements. It is reassuring to see that a 6 year old module retains most of it's usability for medical education. Additional images and videos may be needed for improved user experience. For the next phase of the project, a separate feedback form will be sent to the instructor-editor groups invited to update the content of the modules.

Usability survey of the ARGO project: Navigation and favorite feature

Abstract Number: 2079

Comparative Analysis of Teledidactic and On-Campus Training in Musculoskeletal Ultrasound – the TELMUS Study

Ricarda Neubauer[1], Florian Recker[2], Claus Juergen Bauer[3], Simon Petzinna[1], Pantelis Karakostas[3], Charlotte Behning[4] and **Valentin Sebastian Schäfer**[3], [1]Clinic of Internal Medicine III, Oncology, Hematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Bonn, Germany, [2]Department of Obstetrics and Prenatal Medicine, University Hospital Bonn, Bonn, Germany, [3]Clinic of Internal Medicine III, Department of Oncology, Hematology, Rheumatology and Clinical Immunology, University Hospital of Bonn, Bonn, Germany, [4]Institute of Medical Biometry, Informatics and Epidemiology, Medical Faculty, University of Bonn, Bonn, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal ultrasound (MSUS) plays a vital role as a diagnostic imaging modality in rheumatology, while also serving as an effective teaching tool to enhance medical students' comprehension of functional anatomy. Amidst the COVID-19 pandemic, the utilization of portable ultrasound equipment and telemedicine teaching methods ensured the continuity of practical skill instruction, with the potential to further broaden teaching prospects in medical schools going forward.

Methods: In this study we assessed and compared the learning success of medical students in MSUS, achieved through a conventional and a teledidactic course. During the theoretical teaching sessions, an ultrasound-certified course instructor (DEGUM/EFSUM level III-highest level) introduced the most important standard sections in a video-based approach using the validated course concept of the MUDE study [1] . Following that, both groups received practice time and individualized feedback during hands-on sessions. Throughout the course, all students were equipped with an 8th generation Apple iPad and a ButterflyIQ+® portable ultrasound system. To assess student learning objectively, an Objective Clinical Structured Examination (OSCE) was conducted before the course commenced and upon its completion.

Results: A total of thirty medical students in clinical semesters were randomly assigned to either a conventional on-campus cohort or a teledidactic teaching cohort, receiving virtual teaching exclusively. Prior to the course, students achieved an average score of 20.68% (SD ± 6.67) in the OSCE, whereas the average score following the course completion was 96.83% (SD ± 6.71). There were no statistically significant differences in OSCE scores between the two teaching cohorts (p=0.479), indicating that neither course was inferior to the other.

Conclusion: The teledidactic teaching concept utilizing portable ultrasound devices resulted in a significant increase in MSUS knowledge among medical students, demonstrating a comparable learning outcome to the conventional course. This worldwide pilot study extends MSUS training opportunities for medical students through innovative teaching methods, contributing to the development of future rheumatologists by emphasizing ultrasound as a crucial imaging tool in rheumatology.

Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Journal clubs are an essential part of lifelong learning for physicians. After fellowship, access to journal club discussions may be limited. TheMednet is a physician-only online platform that allows for dissemination of expert knowledge in a searchable, private, and moderated question and answer (Q&A) format. A clinically focused online journal

Trial	Questions	Total Views	Total Users Reached	Total Institutions
ADVOCATE	How long do you recommend using avacopan as maintenance therapy in AAV? How should the results of the ADVOCATE trial be applied in AAV patients who receive rituximab induction and maintenance therapy? Are there particular subsets of AAV patients in which avacopan is more effective? Should the use of avacopan be limited to those patients at increased risk of steroid toxicity given the anticipated high cost of this medication?	727	240	117
SEAM-RA	What was the rationale for abrupt discontinuation of etanercept rather than gradual tapering in the SEAM-RA trial? Were the patients enrolled in the SEAM-RA trial prior methotrexate monotherapy non-responders? Are the results of the SEAM-RA trial generalizable to other TNF inhibitors given the differences in immunogenicity? Was the methotrexate dose reduced over time in the combination therapy or methotrexate monotherapy groups in the SEAM-RA trial?	721	236	127
ORAL	How do you approach CV risk assessment in RA patients when RA itself is associated with some degree of increased CV risk at baseline? What role do you see for JAK inhibitors in RA treatment strategies given the data we now have regarding CV and cancer outcomes? Would you recommend that a patient with stable coronary artery disease and well-controlled RA on a JAK inhibitor continue on their current therapy? How do you counsel patients regarding the cardiovascular and cancer risks associated with tofacitinib? Do you still plan to offer tofacitinib to RA patients over 65 if they have one or more additional C	1777	450	115
DISCOVER 2	Where in the sequence of biologics would you consider guselkumab for patients with active psoriatic arthritis despite standard DMARD therapy? How do you interpret treatment response in the DISCOVER-2 Trial when patients were allowed to remain on up to 10mg of prednisone equivalent for disease control while on guselkumab? How long would you recommend that a patient continues guselkumab prior to deciding that the therapy is not effective?	1050	287	168
Racial Disparities in Pediatric Lupus Nephritis	Are there any major differences in clinical manifestations or autoantibody profiles in children with SLE based on ethnicity? What are some explanations for the persistent renal outcome disparity gaps affecting certain minority groups of patients with pediatric SLE despite improvement in overall renal outcomes? How can ethnic representation in clinical research studies in childhood and adult SLE be improved?	465	179	87

club was designed and hosted on theMednet to engage rheumatologists and rheumatology fellows. Here we describe our experience in establishing a rheumatology journal club on theMednet.

Methods: TheMednet launched in Rheumatology in July 2020 and the first online journal club was implemented in March 2021. A physician editorial team reviewed major rheumatology publications and identified journal articles with significant clinical impact. An academic partnership with the journals allowed for sharing of the article with theMednet community. The article was distributed via email to registered rheumatologists with a call for questions. Study authors and content experts were recruited by the editorial team to answer questions submitted by the rheumatology community. The Q&A was distributed over 3-4 weeks in email newsletters.

Results: Five journal clubs were conducted between March 2021 and January 2023. Journal club articles and questions are listed in Table 1. The articles were downloaded 936 times. On average, 278 users at 122 unique institutions, including academic and community were reached during each journal club. A total of 19 questions were included among the five programs and comprised 36 individual answers from 6 authors and 3 non-author content experts. Q&A were viewed 4,740 times. In all five journal clubs, at least one author of the chosen manuscript participated in the online discussion and in three of the five journal clubs, non-author content experts participated. Eleven polls created by the editorial team resulted in 430 individual poll voters participating and a total of 447 votes. The most engaging journal club was ORAL Surveillance with 1,777 question views and least engaging was Racial Disparities in Pediatric Lupus Nephritis with 465 question views. As of May 2023, theMednet rheumatology community included 1,760 practicing rheumatologists across the United States.

Conclusion: TheMednet Journal Club feature is an effective way to connect academic and community rheumatologists around high impact publications in the field of rheumatology. Journal club engages physician users to submit Q&A and participate in interactive polls. Physicians are able to share insights on clinical practice and to exchange viewpoints on translation of data into clinical practice.

Harnessing the Power of Social Media for Good: Using Instagram as a Formative Assessment Tool

Anna Thompson[1], Jessica Nguyen[2], Amanda Braddock[1], Shelley Kumar[1] and Miriah Gillispie-Taylor[3], [1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine, Manvel, TX, [3]Baylor College of Medicine, Texas Children's Hospital, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood rheumatologic and musculoskeletal diseases (RMDs) have an estimated prevalence of 1:300,000 in the general population and are associated with morbidity and mortality in children. Approximately 30% of acute pediatric visits are for musculoskeletal (MSK) complaints, often the initial presenting symptom of RMDs, while only 2% of pediatric board examinations cover rheumatologic topics. Additionally, there is a variable amount of graduate medical education (GME) pediatric rheumatology training due to a paucity of pediatric rheumatologists nationwide, with 33% of medical schools and 40% of pediatric residency programs having no affiliated pediatric rheumatologist. This discrepancy highlights

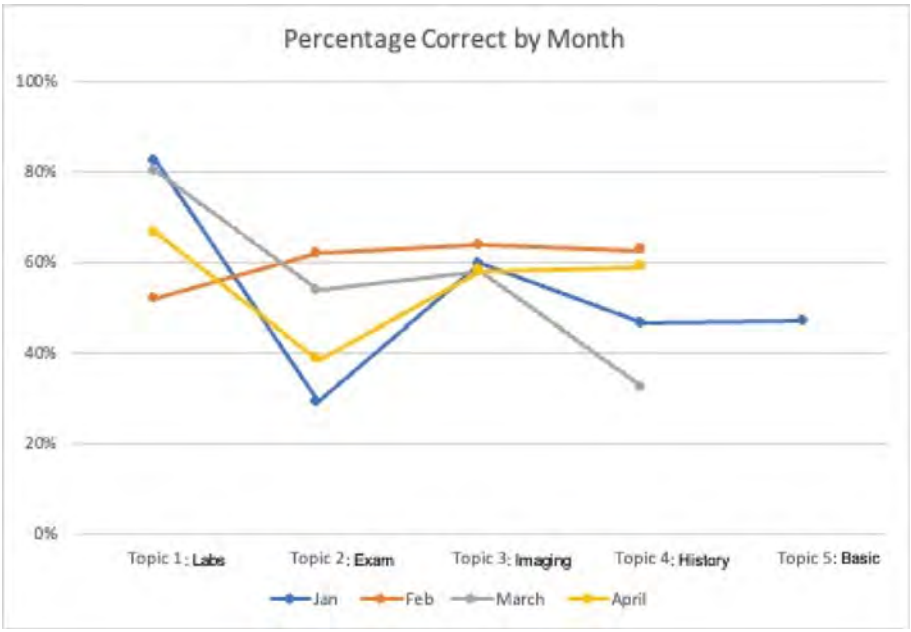

Figure 1. Percent of correct answers separated by month. Questions released during the first week of the month always cover laboratory studies in RMD, week two covers physical exam findings, week 3 covers imaging, week 4 covers history and clinical criteria, and when there is a 5th week, it is dedicated to basic science. Users most consistently correctly responded to questions covering imaging in RMD, ~60% of respondents answered correctly. Of all items, 12% were noted to be "easy," 6% were "difficult," and the remaining 82% were in the "average" difficulty index.

the need to improve the education of pediatric providers to evaluate and appropriately triage presentations concerning for RMDs.

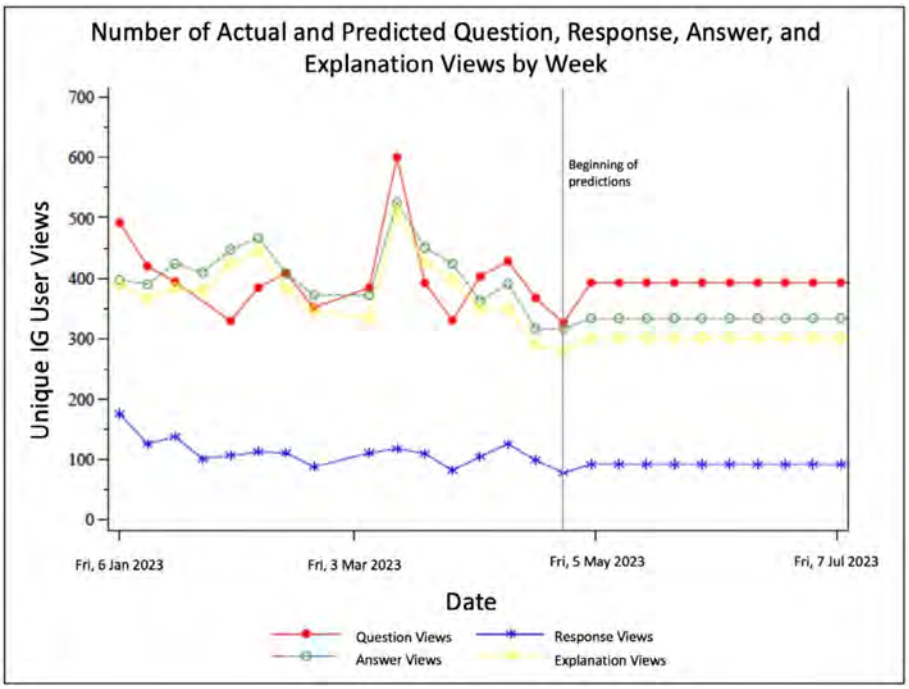

Figure 2. Number of actual and predicted unique users engaging with IG content by week. For the first 17 weeks, there were 395 question views, 110 responses, 403 answer views, and 376 explanation views. The total number of question views was not recorded for week 4, so this week was not used to forecast. Of note, there was also a notable jump in views on week 11, which coincided with resident match day. Predictions were made for the next three months using the SAS ESM procedure, which generates forecasts using exponential models with optimized smoothing weights for time series models.

Within GME, learner engagement, motivation, and enjoyment pose a significant challenge. Previous studies have shown gamification to be an effective strategy in addressing these issues by promoting risk-free decision-making, providing quick feedback, and demonstrating improvement in student knowledge and achievement. In this vein, we developed a gamified rheumatology review intervention using, Instagram (IG), a social media platform to determine effects on learner engagement and information retention.

Methods: Board-style questions covering RMDs were written to target GME learners. A Question of the Week (QOTW) is posted weekly to the Baylor College of Medicine (BCM) Pediatric Residency business IG page (with approximately 1600 followers) for 24 hours. The correct response is revealed immediately, and the following day an explanation is posted for 24 hours. Available data from IG was collected, including number of viewers per question and response, and response breakdown. The following week, the usernames associated with the first five correct answers are posted, incorporating gamification and friendly competition. Additionally, surveys collected information on enjoyment of QOTW, perceived knowledge acquisition, and preferred question difficulty.

Results: Engagement with QOTW has been tracked for 4 months and was higher than expected. Figure 1 depicts the percent correct broken down by month and weekly topic, showing the highest average of correct answers regarding imaging. Figure 2 illustrates user engagement derived from unique username. Additional IG surveys showed 94% of users enjoyed QOTW, 100% learned from it, and 56% of respondents would prefer more challenging questions.

Conclusion: This data indicates that the QOTW educational intervention utilizing IG as a delivery method unites gamification and formative assessment in the social media space. Given the frequent interaction with social media by young learners, we are successfully able to utilize this platform to reach and engage many more learners than traditional teaching methods. Ultimately, we believe this method is an effective way to educate our target audience - pediatricians, residents, and medical students - which will improve recognition, work up, and timely, appropriate referral for those patients with concerns for RMDs.

Abstract Number: 2082

Delivery of Rheumatology Education to Internal Medicine Residents in Rwanda: Evaluation of a New Virtual Rheumatology Course Supplemented by On-site Clinical Teaching

Carol Hitchon[1], Becky Abdissa Adugna[2], Richard Akintayo[3], Paul Caldron[4], Ines Colmegna[5], Ida Dey[6], Paul McGill[7], Andres Ponce[8], Rosie Scuccimarri[9], Mohammed Tikly[10], Girish Mody[11] and Michele Meltzer[12], [1]University of Manitoba, Winnipeg, MB, Canada, [2]Addis Ababa University, Addis Ababa, Ethiopia, [3]Dumfries and Galloway Royal Infirmary, Edinburgh, United Kingdom, [4]Arizona Arthritis & Rheumatology Associates, P.C. - Emeritus (no longer in patient care role), Depoe Bay, OR, [5]The Research Institute of the McGill University Health Centre, Montréal, QC, Canada, [6]University of Ghana Medical School, Accra, Ghana, [7]Department of Rheumatology Stobhill Hospital, Glasgow, United Kingdom, [8]Jefferson, Philadelphia, PA, [9]McGill University/Montreal Children's Hospital, Montréal, QC, Canada, [10]Wits University, Johannesburg, South Africa, [11]University of KwaZulu-Natal, Durban, South Africa, [12]Thomas Jefferson University/ Rheumatology for All,Inc., Philadelphia, PA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Professional Education Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: There exists a critical lack of rheumatology resources in many parts of the world including sub-Saharan African countries. As a result, in these countries, rheumatology education is limited and often provided by specialists with variable rheumatology expertise. As an initial step to improving rheumatology capacity in Africa, our organization "Rheumatology For All" (RFA) has developed a rheumatology program for Internal Medicine (IM) Residents that can be delivered in person or virtually. Here we describe the evolution, implementation and acceptance of the virtual educational program in Rwanda.

Methods: We delivered a virtual rheumatology curriculum course for second year IM residents (approximately 30/year) in the University of Rwanda, Rwanda in 2021,2022 and 2023.Weekly lectures and tutorials were delivered (in English) over 16 weeks by rheumatology faculty from Ghana, Ethiopia, South Africa, United Kingdom, United States and Canada. In 2021, prerecorded lectures were uploaded to a central course website for students to review in preparation for weekly interactive online tutorials. In 2022 and 2023, there were no prerecorded lectures only the interactive lectures and tutorials. Additional teaching material including customized videos demonstrating musculoskeletal exam techniques and reading material was uploaded to a central website. In 2023, the virtual lecture series was followed by a week-long program delivered in Kigali by 4 faculty (CH, IC, MM, RS) consisting of supplementary lectures, case-based tutorials and clinical skill teaching. We evaluated virtual course experiences from 29 responding students (13 in 2021; 12 in 2022; 4 in 2023) and evaluated on-site teaching experiences from 10 students.

Results: Feedback from 2021 was incorporated into the 2022 and 2023 courses when feasible. Only 8/29 (27%) were able to attend all virtual lectures. All students found lectures and tutorials beneficial, especially physical exam videos. Half (52%) wanted more interaction with faculty (2021 vs 2022 p=NS).Some students reported difficulty accessing online content, though this improved in 2022 after switching to a university-based platform. Case-based discussions were considered important and culturally relevant images were appreciated. Students requested more clinical cases, including student-led case presentations even if this extended course/tutorial duration. While appreciative of the online course, many students requested on-site training to allow more face-to face discussion, bedside teaching, and hands-on demonstration of rheumatology skills. Student comment: "*… we hope this will continue for the coming years and probably not only virtually but also [face-to-face] … It would be good if we share cases … (though we don't have all investigations) …*" At the end of the courses, students' confidence level with rheumatology cases was good with a median rating of 7/10 (range 5-9) for the virtual course and 7.5 (range 5-8) for the in-person course.

Conclusion: The RFA virtual rheumatology course is a feasible means to provide rheumatology education to African medical students but does not replace the need for in person teaching. This program will continue to evolve in response to regional needs.

Abstract Number: 2083

Compiled Verbal Feedback as a Novel Mechanism for Faculty Feedback from Rheumatology Fellows-in-Training

Guy Katz[1], Eli Miloslavsky[2], Ana Fernandes[1] and Marcy Bolster[3], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Newton, MA, [3]Massachusetts General Hospital, Concord, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Feedback from fellows-in-training (FITs) is important for faculty professional development and to enrich clinical teaching in rheumatology fellowship training programs. Most fellowship training programs use online evaluations completed annually by FITs to provide feedback on clinical teaching by faculty. The quality of feedback provided through this mechanism may be limited by time burden on trainees and concerns for confidentiality. We sought to evaluate the effectiveness of online evaluations vs. a novel feedback mechanism of compiled verbal feedback.

Methods: We developed a novel feedback system in which FITs provided verbal feedback on all faculty to a facilitator who then compiled the feedback and shared it in a de-identified manner with individual faculty members. Based on the FITs' preferences, this was done with all FITs together as a group and facilitated by the fellowship training program director. FITs also completed standard annual anonymous online evaluations for all faculty with whom they worked. All FITs and faculty in our institution's Rheumatology Division were invited to participate voluntarily in the study; study investigators (one FIT, two faculty) were excluded. Participating FITs and faculty completed surveys assessing the perceived effectiveness of feedback and confidentiality of both forms of evaluation. Surveys used Likert scales (1="Strongly Disagree"; 5="Strongly Agree"). Responses were converted into two categorical variables: "Favorable," representing responses 4-5 or 1-2 depending on question phrasing; and "Neutral/Unfavorable," representing all other answer choices. Comparisons of paired responses between the two feedback mechanisms were performed using McNemar tests.

Results: Thirteen of 15 eligible faculty and 4/4 eligible FITs completed both surveys. Faculty responses in both surveys are summarized in **Table 1**. Favorable responses were numerically higher in all questions for the compiled verbal feedback system and statistically significantly higher in questions on the feedback's effectiveness in explaining strengths, specificity, actionability, and consistency with faculty self-assessment of strengths. FIT responses are summarized in **Table 2**. FITs responses were largely neutral/unfavorable in most questions regarding online evaluations; no FITs responded favorably to the two questions on confidentiality of online evaluations. In contrast, all FITs responded favorably to every question in the survey on compiled verbal feedback with one exception: concerns about confidentiality. Although only one FIT responded favorably to this question, all FITs responded favorably regarding concerns about future interactions with evaluated faculty.

Table 1. Faculty responses regarding online evaluation and compiled verbal feedback formats. All values reported as N (%).

	Online Evaluations		Compiled Verbal Feedback		P-Value
	Favorable	Unfavorable/Neutral	Favorable	Unfavorable/Neutral	
Quality of Feedback					
Explains strengths	7 (54)	6 (46)	13 (100)	0 (0)	**0.041**
Explains areas for improvement	4 (31)	9 (69)	9 (69)	4 (31)	0.131
Improves teaching skills	2 (15)	11 (85)	7 (54)	6 (46)	0.131
Specific	0 (0)	13 (100)	7 (54)	6 (46)	**0.023**
Actionable	2 (15)	11 (85)	8 (62)	5 (38)	**0.041**
Prompts reflection	6 (46)	7 (54)	10 (77)	3 (23)	0.221
Consistency with self-assessment					
Strengths	5 (38)	8 (62)	12 (92)	1 (8)	**0.023**
Areas for improvement	3 (23)	10 (77)	7 (54)	6 (46)	0.289
Confidentiality					
Unable to identify evaluator	8 (62)	5 (38)	11 (85)	2 (15)	0.450

Table 2. FIT responses regarding online evaluation and compiled verbal feedback systems. All values reported as N (%).

	Online Evaluations		Compiled Verbal Feedback		P-value
	Favorable	Unfavorable/Neutral	Favorable	Unfavorable/Neutral	
Quality of feedback					
Specific	3 (75)	1 (1)	4 (100)	0 (0)	1
Provides positive feedback	4 (100)	0 (0)	4 (100)	0 (0)	N/A
Provides feedback on areas for improvement	2 (50)	2 (50)	4 (100)	0 (0)	0.480
Reflective and meaningful	1 (25)	3 (75)	4 (100)	0 (0)	0.248
Improves faculty teaching	1 (25)	3 (75)	4 (100)	0 (0)	0.248
Confidentiality					
Concerns about confidentiality	0 (0)	4 (100)	1 (25)	3 (75)	1.000
Concerns about future faculty interactions	0 (0)	4 (100)	4 (100)	0 (0)	0.134

Conclusion: Compiled verbal feedback by FITs produced more actionable and effective feedback with no concerns for future interactions with faculty when compared with standard online evaluations, as perceived by both FITs and faculty. Other fellowship training programs may consider incorporating compiled verbal feedback to enrich the quality of feedback provided to faculty on clinical teaching. Further study of this method across different program sizes and institutions is warranted.

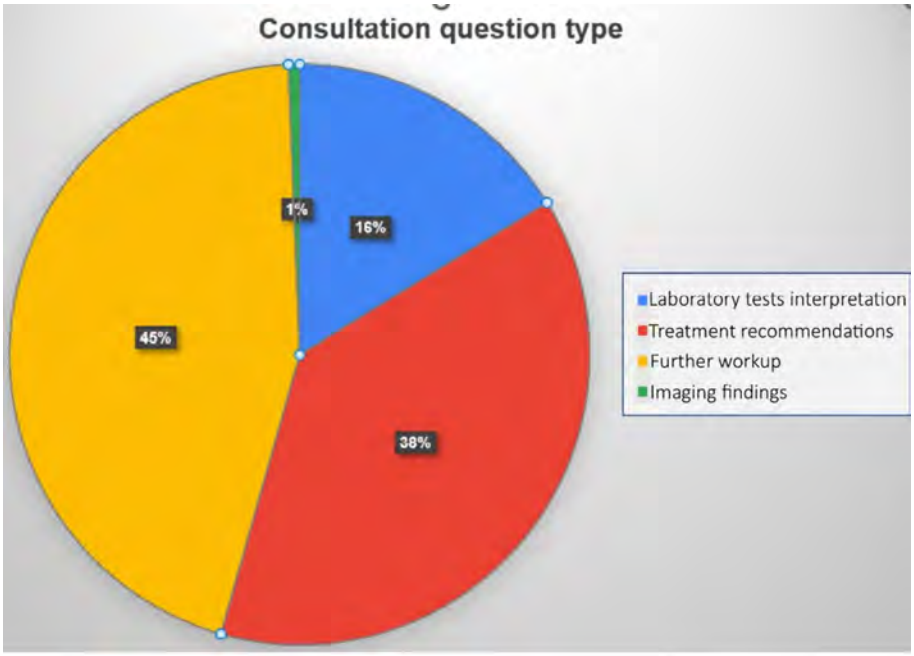
Abstract Number: 2084

Enhancing Internal Medicine Curriculum: Key Rheumatology Themes in Inpatient Setting

Jose Ferraz Neto[1], Dina Ismail[1], Stepan Esagian[1] and Milena Vukelic[2], [1]Albert Einstein College of Medicine/Jacobi Medical Center, New York, NY, [2]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite rheumatology being a critical component of internal medicine (IM) residency training, internists are often inadequately trained to identify and manage rheumatologic disorders. In order to evaluate teaching gaps in the core inpatient curriculum, we surveyed inpatient rheumatology consults placed by IM residents over 6 months period. To help inform curriculum revisions, we compared the extracted data to the current curriculum objectives and identified areas of improvement for the inpatient setting.



Methods: Using Epic SlicerDicer we performed a qualitative analysis of inpatient consult encounters from June 2022-January 2023. Extracted data was exported into an excel sheet for analysis. Each consult question was attributed to one theme category: 1) laboratory test interpretation;2) imaging findings;3) workup for complex presentations; 4) management of rheumatic disease. Rheumatologic diagnosis was extracted in the sheet if mentioned in the consult question. Of note, some consult questions contained more than one diagnosis and theme.

Results: 160 consultations were assessed. The purpose of the consultations was recommendation regarding further workup in 72 (45%), treatment recommendation in 61 (38%), laboratory tests interpretation 26 (16%), imaging findings in one (1%). A broad range of rheumatic diseases was covered in the consult questions. Most common was arthralgia/ RA33%, gout 19%, SLE 15%, ILD 10%, vasculitis 5%, myopathy 5%, scleroderma 4%, GCA 4%, APLS 3%, rashes 2% and 1.6% for Sjogren's syndrome, dermatomyositis, MCTD, SJS/TEN, IgG4-RD.The most concise questions were about gout or lupus flare. When our rheumatology curriculum was examined, we found that 40% of consultation topics were not included.

Conclusion: Our analysis of consult questions revealed gaps in internists' training related to rheumatologic disorders. Most common consults were regarding gout and unspecified joint pain which can be commonly managed by the IM team. The variety of rheumatic diseases covered in the consult questions underscores the importance of comprehensive training in this field. By addressing these gaps and expanding the trainees' knowledge base, we can improve the overall academic and clinical training in rheumatology for internal medicine residents.

Abstract Number: 2085

A Survey on Giant Cell Arteritis-Related Knowledge Among Internal Medicine Residents

Helina Maharjan[1], Muhammad Abdullah[2], Summia Matin Afridi[3], Alsayed Osman[4], Aleena Sammar[5] and Ahmad Raja[6], [1]Bassett Medical Center, Cooperstown, NY, [2]Islamic International Medical College, Rawalpindi, Pakistan, [3]Albany Medical Center, Albany, NY, [4]AdventHealth Florida, Orlando, FL, [5]Parkview Medical Center, Pueblo, CO, [6]Mary Imogene Bassett Hospital, Evanston, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) poses challenges in clinical practice, necessitating a deep understanding. Internal medicine residents play a crucial role in patient care and management. This study evaluates their comprehension of GCA diagnosis and management, aiming to identify knowledge gaps and develop tailored educational programs. GCA, a medical emergency with risks of blindness and cerebrovascular complications, relies on diagnostic tools such as imaging and biopsies alongside clinical judgment. Glucocorticoids form the foundation of treatment, while future strategy involve targeted biologics. Enhancing training and addressing knowledge gaps empower residents to effectively identify and manage GCA, ensuring optimal patient outcomes.

Methods: An 18-item questionnaire was developed following the latest guidelines from the ACR and EULAR. A cross-sectional survey was conducted among residents from three different programs located in New York, Colorado, and Florida. The questionnaire encompassed 11 questions related to the presentation, diagnosis, and management of GCA. The

remaining questions were focused on assessing the residents' comfort level in diagnosing and managing GCA patients, as well as evaluating their educational training in this area.

Results: Out of 107 participants, 48 (approximately 44%) completed the survey, yielding significant insights. The response rates varied across different levels of training, with 27% of PGY1, 33.33% of PGY2, and 37% of PGY3 participants providing their feedback. While 40% of respondents expressed satisfaction with their instruction, around 41% admitted to not attending teaching sessions, and 47% had no experience in caring for GCA patients. Surprisingly, although 56% felt confident in diagnosing GCA, only 31% were comfortable managing such patients. Furthermore, only 37% demonstrated familiarity with FDA-approved GCA medications. While 90% correctly identified prednisone as the initial drug of choice, only 50% knew the recommended dosage. Awareness of alternative diagnostic methods and appropriate ocular symptom management was limited among the participants. However, 89% acknowledged the importance of annual DEXA scans for monitoring bone health. These findings highlight the specific areas that require further education and training in the field of GCA.

Conclusion: The findings of this study reveal significant limitations in the understanding of GCA recognition and treatment among internal medicine residents. Although some residents expressed confidence in diagnosing GCA, there was a notable lack of familiarity with FDA-approved medications and discomfort in managing patients. Challenges were identified in comprehending initial dosages, utilizing alternative diagnostic techniques, and addressing ocular symptoms. These findings emphasize the critical need for targeted educational initiatives aimed at bridging these gaps and improving GCA care and management. By enhancing residents' understanding, we can strive for better patient outcomes and advance the management of GCA.

Abstract Number: 2086

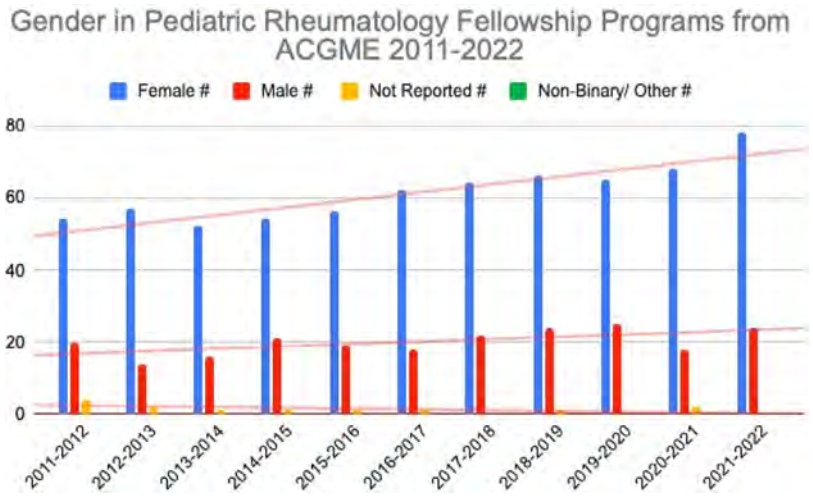
From Fellow to Fellowship Director: Gender Equity in Pediatric Rheumatology Pipeline

Bessie Roca loor[1], Maya Pandit[2], **Tracey Wright**[3] and Mill Etienne[4], [1]New York Medical College, Yonkers, NY, [2]Columbia University, New York, NY, [3]UT Southwestern, Dallas, TX, [4]New York Medical College, Valhalla, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: As the demand for pediatric rheumatologists rise across the United States with a projected demand of almost 100% more pediatric rheumatologists needed by 2030 (1), it is essential to create a more balanced healthcare workforce, in hopes of achieving gender equity. We investigated the proportions of male-to-female fellows in pediatric rheumatology from 2011 to 2022 and compared this data to the gender diversity of the current pediatric rheumatology fellowship directors across the country.

Methods: This is a retrospective analysis of data extracted from the Accreditation Council of Graduate Medical Education (ACGME) Data Resource Books from 2011 to 2022. The data collection and trend analysis were conducted on Microsoft Excel. Gender was categorized as male, female and unreported. However, in the last two academic years, non-binary was added as a gender category. Additionally, to identify each pediatric rheumatology fellowship program director, the American Medical Association's Fellowship and Residency Electronic Interactive Database Access System (FREIDA) was utilized. The



pronouns each director used were extrapolated from their publicly available biographies to classify their gender. This data was publicly available therefore, IRB approval was not required.

Results: From 2011 to 2022, the reported data indicate female representation in pediatric rheumatology fellowship programs increased from 69% to 76.50% while the proportion of male fellows decreased from 26% to 23.5%. The representation of female fellows is approximately 40 to 50% higher than their male counterparts for each academic year in the period reported. Moreover, of the 38 pediatric rheumatology fellowship programs, 78.9% of the program directors were female.

Conclusion: More than three-fourths of pediatric rheumatology fellows as well as fellowship program directors are women. These findings are consistent with the 2015 American College of Rheumatology Workforce Study's overall prediction that women will constitute the majority of the rheumatology workforce by 2025. These results are also consistent with trends within the field of pediatrics with more females in training and pediatric practice (2). Pediatric rheumatology leadership mirrors the pediatric rheumatology pipeline, which is not consistent seen in fields that are predominantly women. Pediatric rheumatology's leadership pipeline can serve as a model for other fields that are predominantly women. To achieve gender equity in this subspeciality, future studies must examine the underlying causes of this gender shift and explore strategies to ensure broad exposure and recruitment of males into pediatric rheumatology.

Racial and Ethnic Diversity in Pediatric Fellowships: Fortifying the Pipeline

Bessie Roca Loor[1], Maya Pandit[2], **Tracey Wright**[3] and Mill Etienne[4], [1]New York Medical College, Yonkers, NY, [2]Columbia University, New York, NY, [3]UT Southwestern, Dallas, TX, [4]New York Medical College, Valhalla, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2015 American College of Rheumatology Workforce study estimated the pediatric rheumatology full-time equivalent workforce to be 300 providers while the estimated excess demand was 95 providers (33%), with an estimated demand increase to almost 100% by 2030 (1). Nine states do not have a pediatric rheumatologist and the shortage is especially severe in Black, Hispanic, and Native American communities. This further emphasizes the need for physicians from demographics underrepresented in medicine (URiM), who are more likely to work in underserved communities, to care for children with rheumatic disease, while contributing to diverse perspectives in medical practice. This study explores trends of racial and ethnic diversity among US pediatric rheumatology fellows and consider consequences of these results on healthcare access, quality, and outcomes.

Methods: This is a quantitative analysis of the Accreditation Council for Graduate Medical Education (ACGME) Data Resource Book from 2011 to 2022. Demographics, including race and ethnicity of pediatric rheumatology fellows, were extracted, and analyzed in Microsoft Excel. A Chi-square analysis was utilized, and expected values were calculated using the 2020 census data (2011 to 2019) and the 2020 US census data for 2020 onwards. The primary outcome was trend in URiM representation (as defined by Licensing Committee on Medical Education) in pediatric rheumatology fellowship programs. The data was publicly available therefore IRB approval was not required.

Results: There were 910 pediatric rheumatology fellows between 2011-2022. Chi-square analysis demonstrated significant underrepresentation of Black, Hispanic, and Native Americans ($p < 0.0001$) in US pediatric rheumatology fellowship training programs. As seen in Figure 1, there were 3.4% Black (31/910), 8.4% Hispanic (76/910), and 0% Native Americans (0/910) fellows. The number of the fellows with these respective race and ethnicities was consistent throughout the 11 years analyzed. This data indicates that the percentage of URiM fellows in pediatric rheumatology fellowship programs is falling behind compared to the demographic shift in the US.

Conclusion: This data underscores the need to attract URiM physicians to pediatric rheumatology to practice in underserved communities and help address health equity gaps. The ACGME has prioritized the expansion and support of a diverse physician workforce, representative of the population it serves. Medical institutions throughout the US should be intentional in recruiting, cultivating, and retaining URiM fellows to create a culturally informed and inclusive clinical environment that will better serve our growingly diverse population. This call to action will improve health outcomes in underserved groups by training more physicians who are aware of these disparities and fostering patients' trust in the healthcare system.

Abstract Number: 2088

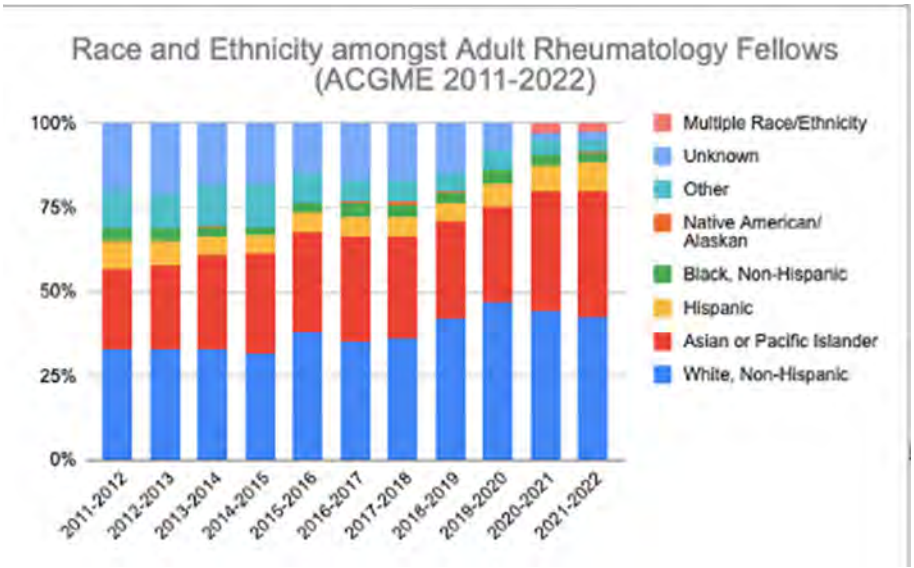
Room for Racial and Ethnic Diversity in Adult Rheumatology Fellowship Pipeline

Bessie Roca Loor[1], Maya Pandit[2], **Tracey Wright**[3] and Mill Etienne[4], [1]New York Medical College, Yonkers, NY, [2]Columbia University, New York, NY, [3]UT Southwestern, Dallas, TX, [4]New York Medical College, Valhalla, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Professional Education Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2015 American College of Rheumatology Workforce study showed 8 of 1011 adult rheumatologists identified as Black, 85 Hispanic and 3 American Indian or Alaska Native (1). Recent studies show persistent disparities in disease activity and clinical outcomes for minoritized patients versus their White counterparts, including in minoritized patients with Systemic Lupus Erythematosus (2). Diversifying the physician workforce is a necessary strategy to address equity in patient care as URiM (Underrepresented in Medicine) physicians are more likely to work in underserved communities, while also providing diverse perspectives. We investigated the trends of URiM representation, as defined by the Licensing Committee on Medical Education (LCME), among adult rheumatology fellows.

Methods: This is a quantitative analysis of the Accreditation Council for Graduate Medical Education (ACGME) Data Resource Book from 2011 to 2022. This data was publicly available therefore no IRB approval was required. Demographic data including race, ethnicity, and gender of US adult rheumatology fellows were extracted and analyzed in Microsoft Excel.



Additionally, a multiracial category was introduced as an option in 2020. Chi-Square test was utilized and expected values were calculated using the 2010 census data (2011) to (2019) and the 2020 US census data for 2020 onwards.

Results: There were 5151 adult rheumatology fellows between 2011-2022. Chi-square analysis demonstrated significant underrepresentation of Black, Hispanic and Native Americans ($p < 0.0001$) in US adult rheumatology fellowship programs. As seen in figure 1, Three percent of fellows were Black (171/5151), 7% were Hispanic (337/5151), and 0.2% were Native American (11/5151). Although, trend analysis demonstrated a gradual increase in percentage of Hispanic and Black fellows over time, the proportion of URiM adult rheumatology fellows still lags behind the proportion of minority racial/ethnic groups in the US population.

Conclusion: Despite recent increased attention to the importance of diversity in healthcare, the pipeline of adult rheumatology fellows has not shown a significant increase in URiM representation. Actionable and attainable strategies for diversification amongst US adult rheumatology fellows are urgently needed for the workforce to better reflect the rheumatic disease patient population where a greater disease burden is prevalent in minoritized groups. Engaging URiM students in grade school, college and those entering medical school is essential to ensure early and sustained exposure to rheumatology via career awareness, mentorship, and access to research opportunities.

Social Listening Analysis of IgG4-Related Disease Social Media Discussions

Esteban Rivera[1], Kelly Gavigan[2], Daniel Hernandez[3], Maria Picone[4], Angeni Cordova[4], Lauren Dougherty[4], Kristina Davidson[5], Brian LaMoreaux[6], Anthony Amatucci[7] and W. Benjamin Nowell[8], [1]Global Healthy Living Foundation, Long Island City, NY, [2]Global Healthy Living Foundation, Upper Nyack, NY, [3]Global Healthy Living Foundation, St. Johns, FL, [4]TREND Community, Philadelphia, PA, [5]Horizon Therapeutics, Dublin, Ireland, [6]Horizon Therapeutics, Deerfield, IL, [7]Horizon Therapeutics, Cambridge, MA, [8]Global Healthy Living Foundation, Nyack, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Education/Community Service – Interprofessional Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunogobulin G4-Related Disease (IgG4-RD) is a rare chronic immune-mediated fibroinflammatory disorder that often manifests with tumor-like masses and/or enlargement of multiple organs. In order to guide future communications for people living with IgG4-RD, our objective was to examine the emotions expressed in social media discussions regarding IgG4-RD.

Table 1: Text Analysis Results of Aggregated YouTube Comments (N=314 words)

Table 1: Text Analysis of Aggregated YouTube Video Comments, n (%) (N=314 words)

Sentiment		
Positive*	165 (52.5%)	
Negative**	149 (47.5%)	
Emotion		**Associated Words**
Trust	116 (36.9%)	Advice, aspiring, intelligent
Sadness	84 (26.8%)	Pain, suffering
Anticipation	79 (25.2%)	Finally, hopeful
Fear	79 (25.2%)	Infection, diagnosis
Joy	64 (20.4%)	Hope, advance, progress
Anger	56 (17.8%)	Dying, anxiety, cancer
Disgust	50 (15.9%)	Suffering, insane
Surprise	37 (11.8%)	Chance, hope

*Positive: Trust, Joy, Surprise, Anticipation

**Negative: Sadness, Fear, Anger, Disgust

Methods: Data from YouTube and Reddit conversations from January 2017 to March 2023 were accessed using R packages*tuber*, for YouTube, and *RedditExtractoR*, for Reddit. The top viewed YouTube videos and their comments were searched using the terms "IgG4-RD" or "IgG4-Related Disease". Resulting words from the video comments were used for sentiment analysis. Because IgG4-RD does not have its own subreddit,the subreddit r/Autoimmune was used for the Reddit analysis. We applied the same search terms to the top eight most commented subreddit threads for the analysis because these were the only IgG4-RD-related posts with comments. Data were separated into two groups: posts and comments on posts. Text was analyzed by classifying words within the *Emotional Dynamic Classification System* (EmoLex). Each word was assigned a positive or negative sentiment; each sentiment has four exclusive possible emotions associated with them. Depending on the sentiment, the word was assigned one to four negative or positive emotions. Only words with strong associations according to the EmoLex's Association Score were included.

Results: Comments from seven YouTube videos, all created by or featuring physicians, were included in the analysis, with a total of 314 words analyzed. Fifty-three (165/314) words from comments had a positive sentiment (Table 1). Trust (37%) was the emotion most frequently associated with the text, followed by sadness (27%), anticipation (25%), fear (25%) and joy (20%). Advice and intelligence were words used evoking trust in the comments. Pain and hopeful evoked the emotions sadness and anticipation in the comments, respectively (Table 1). For Reddit, eight posts and their comments were included in the analysis. Posts had a total of 753 words and comments had 585 words. Posters to the subreddit were either recently

Table 2a: Text Analysis Results of Aggregated Reddit Posts (N=753 words)

Table 2a: Text Analysis of Aggregated Reddit Posts, n (%) (N=753 words)

Sentiment		
Negative**	532 (70.7%)	
Positive*	221 (29.3%)	
Emotion		**Associated Words**
Sadness	319 (42.4%)	Discomfort, irritation
Fear	252 (33.5%)	Alarming, anxiety, worsening
Trust	162 (21.5%)	Experienced, strength
Disgust	154 (20.5%)	Constipation, bleeding
Anticipation	144 (19.1%)	Progression
Anger	140 (18.6%)	Broken, depressed, hurt
Surprise	91 (12.1%)	Safe, shot
Joy	90 (12.0%)	Kind

*Positive: Trust, Joy, Surprise, Anticipation

**Negative: Sadness, Fear, Anger, Disgust

Table 2b: Text Analysis Results of Aggregated Reddit Comments (N=585 words)

Table 2b: Text Analysis of Aggregated Reddit Comments, n (%) (N=585 words)

Sentiment		
Positive*	301 (51.5%)	
Negative**	284 (48.5%)	
Emotion		**Associated Words**
Trust	246 (42.1%)	Specialist, objective, understanding
Anticipation	182 (31.1%)	Hope, finally
Sadness	162 (27.7%)	Impossible, worried,
Fear	158 (27.0%)	Biopsy, diagnosis
Anger	101 (17.3%)	Anxiety, bias
Joy	94 (16.1%)	Completion, approval
Disgust	88 (15.0%)	Abnormal, coldness, bloated
Surprise	68 (11.6%)	Finally

*Positive: Trust, Joy, Surprise, Anticipation

**Negative: Sadness, Fear, Anger, Disgust

diagnosed with IgG4-RD or seeking information on getting a diagnosis. Seventy-one percent (532/753) of words in these posts expressed negative sentiment (Table 2a). The top negative emotions for posts were sadness (42%), fear (34%), and disgust (21%) based on words like discomfort and anxiety (Table 2a). Trust was the only positive emotion associated with more than a fifth of the words (22%). Aggregated comment emotions were similar to those of YouTube comments, with trust as the most frequently associated emotion (42%), followed by anticipation (31%), sadness (28%), and fear (27%) (Table 2b).

Conclusion: Social media discussions of IgG4-RD provide insight into the patient experience. People living with IgG4-RD may benefit from patient-centered educational and supportive resources that focus on trust of health care providers and address negative emotions associated with the disease journey.

Adaptation of the Making it Work^{TM} for People with Systemic Sclerosis

Janet Poole[1], Kristine Carandang[2], Mary Thelander Hill[1], Anna Koch[3], Pamela Rogers[4] and Diane Lacaille[5], [1]University of New Mexico, Albuquerque, NM, [2]University of Wisconsin, San Diego, CA, [3]New Mexico Highlands University, Rio Rancho, NM, [4]Arthritis Research Canada, Richmond, BC, Canada, [5]Arthritis Research Canada, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Patient Education/Community Service – Interprofessional Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) limits participation in paid employment, threatening well-being. Few resources exist to help people with SSc remain in the work force despite the high prevalence of work disability[1]. The programs that do exist were developed for other rheumatic conditions such as arthritis.[2] The objective is to engage workers with

SSc to adapt the Making it Work™ (MiW) program, an evidence-based program developed to prevent work loss and maintain productivity for Canadians with arthritis.

Methods: Participants were adults ≥18 years of age who were currently employed in the United States (U.S.), English-speaking, and self-reported SSc diagnosis affecting work. Participants were recruited through the National Scleroderma Foundation and word of mouth. This session provides results from the first steps of the ADAPT-ITT model of implementation science.[3] Fourteen people with SSc engaged in 3 focus groups to help the researchers understand the unique needs of workers with SSc in the U.S. Nine people with SSc reviewed at least one online module from the MiW program with researchers, and described their perceptions using the think-aloud technique. Participants completed a survey rating the relevance of the content to SSc. Interviews were recorded and transcribed.

Results: Focus group participants generated a list of over 50 unique workplace challenges. While some challenges overlapped with those identified in the original MiW program, notable differences included an emphasis on hand function, sensitivity to temperature, and the systemic nature of SSc affecting all body systems. Think-aloud interview participants confirmed that the adapted MiW program should include accommodations and strategies for pulmonary, cardiac, and systemic affects for people with SSc. Also echoing focus groups, interview participants emphasized that oftentimes, people with SSc "don't even know any of [the MiW resources] exists" and therefore cannot ask for them. While many had already worked through their own employment issues, they stated that had it been available, the MiW program would have efficiently guided their work plans. Participants reacted positively to plans to add a fillable workbook to increase interaction and implementation of the content, promote goal setting and follow through, and act as a resource during discussions with their employers and healthcare professionals.

Conclusion: Workers with SSc have unique needs that remain unaddressed in existing programs tailored to other rheumatic conditions. Our next step is to continue working with patients and other topic experts to make the necessary adaptations to the MiW program for SSc and pilot test its effectiveness.

Abstract Number: 2091

Reach and Representativeness of Participants in an Evidence-Based, Community-Delivered Physical Activity Intervention in Adults with Arthritis

Dina Jones[1] and Jennifer Hootman[2], [1]West Virginia University, Morgantown, WV, [2]Centers for Disease Control and Prevention, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Education/Community Service – Interprofessional Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: It is imperative that adults with arthritis and other chronic conditions are active enough to maintain health. Enhance®Fitness (EF) is an evidence-based physical activity intervention for older adults. Although EF has been nationally disseminated, its impact specifically in adults with arthritis, across the adult age spectrum, has not been evaluated. We conducted a community-based, non-randomized, wait-list controlled effectiveness trial of 12 weeks of EF in 4 urban and 5 rural West Virginia (WV) counties. This study determined if EF reached those in need, and how representative participants were of other adults with arthritis. We expected to reach at least 82% of eligible respondents.

Methods: Eligible participants were sedentary/low-active adults, aged 18 years or older, with self-reported physician-diagnosed arthritis. We documented the number of people who were screened for eligibility, deemed eligible, and enrolled. Reach was the number of enrolled participants divided by the number of eligible participants, multiplied by 100. Baseline data on sociodemographics, chronic conditions, obesity, arthritis-attributable activity and work limitations, disability (1. activities limited by physical, mental, or emotional problems; 2. needed special equipment), and falls in the past 3 months were used to determine representativeness. Descriptive statistics were calculated and compared with WV and US general population data, and data from other EF studies.

Results: We screened 672 people of which 437 (65%) were eligible. Of 437 eligible participants, 323 (74%) enrolled and 114 (26%) declined. Reach was 74% (323 enrolled of 437 eligible). Non-enrollees were significantly younger than enrollees ($p < 0.01$) and more likely to be from rural versus urban areas ($p < 0.01$). Participants had a mean ± SD age of 68.3 ± 10.6 years (range 27-95) and were primarily white (94.6%), non-Hispanic (99%), and women (86.1%). Participants had high rates of diabetes (24.2%), hypertension (63.1%), obesity (56.2%), arthritis-attributable activity (75.7%) and work (50.0%) limitations, disability (1. activities limited 38.2%, 2. needed special equipment 19.7%), and recent falls (21.4%). Participants were representative of WV and US adults with arthritis on age. Participants were mostly non-Hispanic whites and representative of WV but not of the US or other EF studies. Participants had higher rates of diabetes, obesity, and arthritis-attributable activity limitations than other WV or US populations with arthritis. Compared with other EF studies, participants had a higher prevalence of diabetes, hypertension, disability, and falls.

Conclusion: Although the study reach was good, it was lower than expected. Perhaps, offering evening and weekend classes could have improved reach into the younger adult population. Overall, participants were less diverse, with a higher prevalence of chronic conditions, arthritis-attributable activity limitations, disability, and falls than other arthritis populations and EF study participants. Thus, this study reached adults with arthritis in need of a physical activity intervention in the state with the highest US prevalence of arthritis.

Feasibility and Efficacy of Culturally Appropriate Spanish Language-First Patient Education for Rheumatoid Arthritis

Daniel Hernandez[1], Julio Bravo[2], Juan Maya Villamizar[3], Oscar Soto[4], Angel Tapia[5], Guillermo Valenzuela[6], W. Benjamin Nowell[7] and Shilpa Venkatachalam[8], [1]Global Healthy Living Foundation, St. Johns, FL, [2]Novant, Winston-Salem, NC, [3]Rheumatology Center of Palm Beach, PLLC, Boca Raton, FL, [4]Mindful Rheumatix and Medical Research Group, San

Juan, PR, [5]Global Healthy Living Foundation, Upper Nyack, NY, [6]Integral Rheumatology & Immunology Specialists, Plantation, FL, [7]Global Healthy Living Foundation, Nyack, NY, [8]Global Healthy Living Foundation, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Education/Community Service – Interprofessional Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Spanish-speaking patients with rheumatic arthritis (RA) need RA education that is medically accurate, conversational, and engaging. Our study examined the feasibility and efficacy of creating and disseminating such education online.

Methods: Members of our research team who are fluent in Spanish collaborated with Hispanic/Latin(a/o/x) rheumatologists and RA patients to create culturally appropriate, medically accurate, Spanish-language, patient education on RA. Educational topics, identified as needs by Hispanic/Latin(a/o/x) RA patients, included RA causes, disease-modifying antirheumatic drugs (DMARDs), remission, treating to target, and lifestyle modification. Each topic was created as a distinct module that included a pre-education question to answer before viewing the module. The same question was repeated at the end of the module and had to be answered before progressing to the next. After posting modules to the CreakyJoints Español website (Fig 1), the education was promoted through national bilingual radio and television and in Spanish on social media sites (e.g., YouTube patient story videos, TikTok music videos, Instagram campaigns, and WhatsApp direct messaging). All responses were collected with SurveyMonkey with internet protocol (IP) addresses and timestamps. We calculated the number and percentage of correct and incorrect answers and the number and proportion of people who answered both

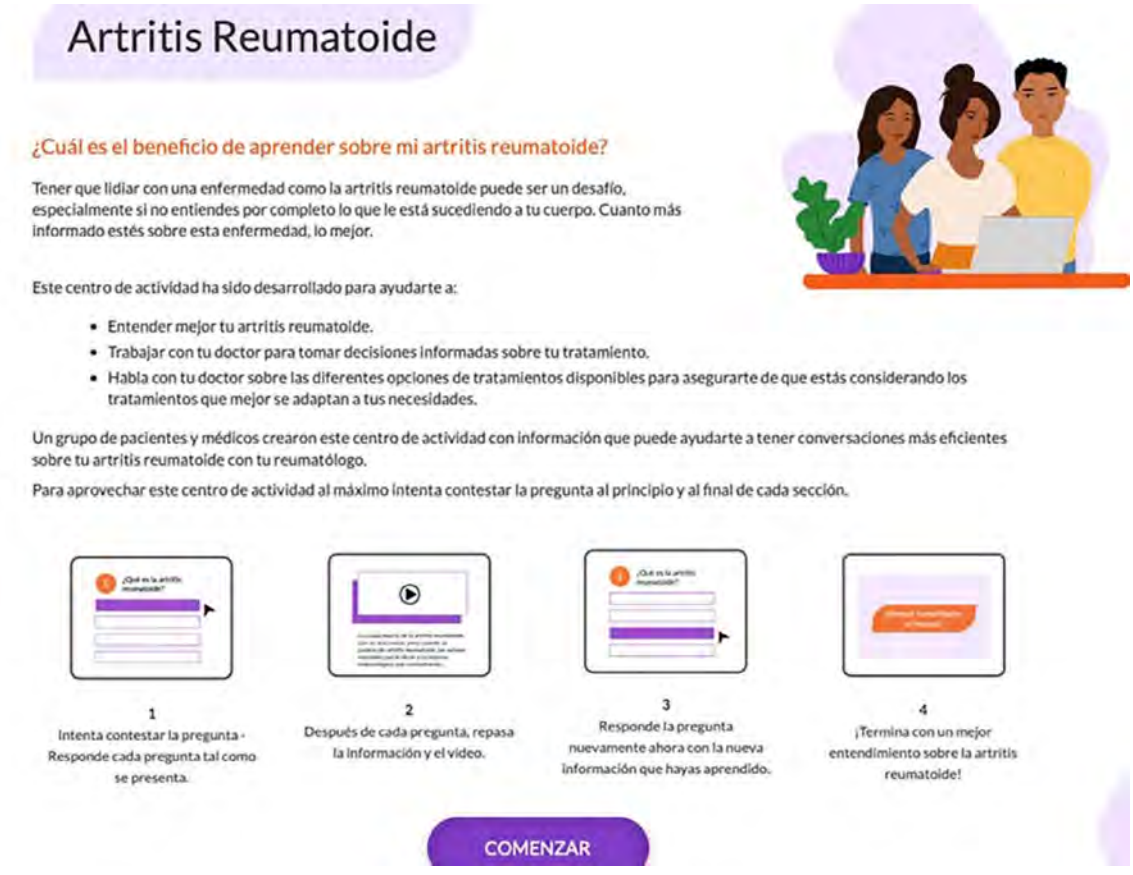

Figure 1. A screenshot of the landing page where the educational modules were hosted.

Table 1. Participants Pre- and Post-Education Test Results by Module

	Module 1	Module 2	Module 3	Module 4	Module 5
Answered pre-test question (n,% of intention to educate cohort)	1048 (100%)	653 (62%)	517 (49%)	412 (39%)	346 (33%)
Answered post education question (n, % of intention to educate cohort)	737 (70%)	527 (50%)	444 (42%)	344 (33%)	306 (29%)
Mean time on module (min, SD)	3.73 (18.54)	3.36 (6.02)	3.32 (6.32)	2.38 (3.22)	2.54 (3.24)
Correct pre-test answers, (% of n who answered pre-test question)	535 (51%)	310 (47%)	252 (49%)	247 (60%)	185 (53%)
Correct post-test answers, (% of n who answered post-test question)	538 (73%)	347 (66%)	342 (77%)	271 (79%)	250 (82%)

Table 2. Changes in Answers After Viewing Educational Content

	Module 1	Module 2	Module 3	Module 4	Module 5
			n (%)		
Pre-test and post-test incorrect	99 (13%)	113 (21%)	78 (18%)	23 (7%)	40 (13%)
Pre-test and post-test correct	432 (59%)	233 (44%)	229 (52%)	254 (73%)	177 (58%)
Pre-test incorrect, post-test correct	106 (14%)	112 (21%)	112 (25%)	47 (14%)	77 (25%)
Pre-test correct, post-test incorrect	100 (14%)	69 (13%)	25 (6%)	20 (6%)	12 (4%)
P-value for observed changes	.46	.08	<.001	.12	<.001

pre- and post-education questions correctly or incorrectly or changed their answer from incorrect to correct and vice-versa. Changes in knowledge for those who completed each module and for those who completed all five modules were evaluated with the two-tailed Student's paired t-test.

Results: Over six months, 1,048 users started the first module, and 70% completed it. Of those who completed the first module, 306 (33%) completed all five modules (Table 1). Responders spent a mean 3.59 minutes (SD, 11.25 minutes) on each module. Correct answers increased from pre- to post-education for all modules, as did the proportion of correct answers for all modules. Knowledge improvements (Table 2) were statistically significant for two modules at a 95% confidence interval (CI) ($P< .001$) and for one at a 90% CI ($P< .08$). One module without significant knowledge gains had similar numbers of answers changed from correct to incorrect and vice versa. The other without significant knowledge gains had a high proportion (74%) of correct answers on the pre-test. For the 306 people who completed all five modules (29%), the sum of post-education vs the sum of pre-education scores showed a statistically significant 12.5% improvement in knowledge ($P=.001$) with a medium effect size (Cohen's d=.52).

Conclusion: Over 1,000 people accessed culturally appropriate, online, Spanish-language patient education. Among those who viewed all modules, knowledge increased. Three of five modules led to significant knowledge gains. For modules without significant gains, it appears one was ineffective, and another used a pre-test question that could not measure knowledge increases. Together, these data suggest it is feasible to deliver medically accurate, Spanish, RA patient education online to effectively improve health literacy.

Meeting the Educational and Language Needs of the Lupus Community: A Snapshot of 2022 Lupus Inquiries

Leticia Ocana[1], Ashley Holden[1], Joy Buie[2] and Melicent Miller[1], [1]Lupus Foundation of America, Washington, DC, [2]Lupus Foundation of America, York, SC

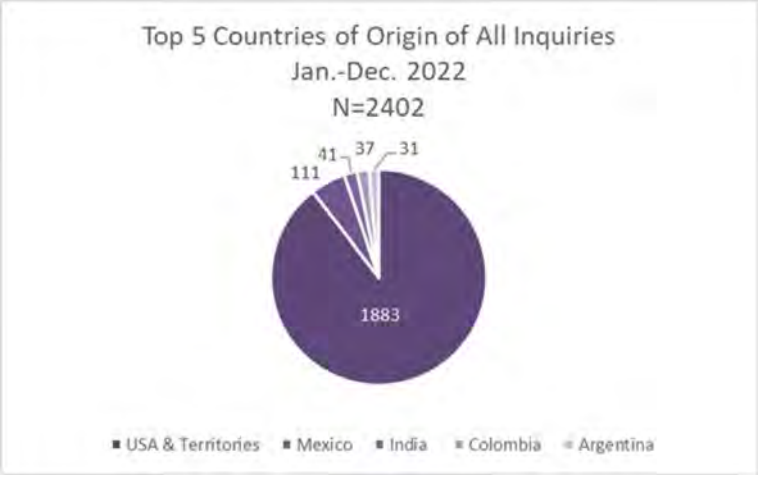
SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Patient Education/Community Service – Interprofessional Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Each year, the Lupus Foundation of America's (LFA) Health Education Specialists (HES) respond to thousands of national and international inquiries from people affected by lupus providing free and tailored non-medical support, disease education, and helpful resources. The vast majority of inquiries are submitted in English and Spanish languages. A team of four HES including two bilingual-bicultural HES respond to the inquiries by email, phone or mail. A review of the inquiry database was conducted to analyze the topics by language and country origin.

Methods: Demographic and inquiry information are collected using Salesforce, a cloud-based Customer Relationship Management (CRM) platform. HES tag each inquiry with topic(s) as applicable. Reports are generated from the database. Topics from the US inquiries by language and the non-US Spanish inquiries were compared.

Results: In 2022, the Lupus Foundation of America responded to a total of 2,402 inquiries from the US and 67 other countries. Eighty percent (n=1,907) of the inquiries were in English and 20% (n=495) were in Spanish. Data demonstrates that the majority of inquiries originated in the US and US Territories (78%), followed by Mexico (5%), India (2%), Colombia (2%) and Argentina (2%) (Graph 1). Graph 2 shows that while 37% of the Spanish-language inquiries originated from the US (n=181), a significant number also come from Mexico (n=98), Colombia (n=37), Argentina (n=29), and Peru (n=27), among other countries. Analysis of the topics show that there is little variation among the English- and Spanish- language inquiries and whether they are US or non-US inquiries. Chart 3 shows the ranking of the top five topics of inquiries by language and country of origin. Data shows that regardless of the language or origination of the inquiry, the top two topics are 1. resources and 2. living and coping. Topics for English-language inquiries from the US include diagnosis, support groups and physician



Top 5 Countries of Origin of All Inquiries

	English-language inquiries form US & Territories	Spanish-language inquiries from US & Territories	Spanish-language inquiries from outside the US
RANK			
#1	Resources (406)	Resources (50)	Living and Coping (99)
#2	Living and Coping (254)	Living and Coping (40)	Resources (93)
#3	Diagnosis (207)	Support groups (25)	Treatment (50)
#4	Support Groups (221)	Treatment (20)	Diagnosis (35)
#5	Physician Referral (198)	Diagnosis (14) & Physician Referral (14) (tied)	Understanding Lupus (29)

Top 5 Countries of Origin of Spanish-Language Inquiries

	English-language inquiries form US & Territories	Spanish-language inquiries from US & Territories	Spanish-language inquiries from outside the US
RANK			
#1	Resources (406)	Resources (50)	Living and Coping (99)
#2	Living and Coping (254)	Living and Coping (40)	Resources (93)
#3	Diagnosis (207)	Support groups (25)	Treatment (50)
#4	Support Groups (221)	Treatment (20)	Diagnosis (35)
#5	Physician Referral (198)	Diagnosis (14) & Physician Referral (14) (tied)	Understanding Lupus (29)

Top 5 Topics of Inquiries

referrals. Spanish-language inquiries (US and non-US) include support groups, treatment, diagnosis, physician referral and understanding lupus. There is a need for not only more lupus information but financial resources as evidenced by resources being a top topic across all languages.

Conclusion: The LFA HES fill an important knowledge gap by providing lupus non-medical support and resources in both English and Spanish to people in the US and around the world. English and Spanish language inquiries from within and outside the US show that the top topics discussed in the inquiries are similar and differ only in ranking, highlighting the similarities in the needs of people affected by lupus. These findings further support the organization's goals of increasing language capabilities that meet the universal needs of people affected by lupus.

Abstract Number: 2094

Increasing Collaboration, Education, and Awareness of Scleroderma Through an Interprofessional Education Program: Emphasizing the Importance of a Multidisciplinary Team and the Patient as the Primary Educator

Corey Fellon[1], Hannah Bowen[2] and Lee Shapiro[3], [1]Albany Medical College, Albany, NY, [2]Steffens Scleroderma Foundation, Batavia, NY, [3]Albany Medical College, Stillwater, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Patient Education/Community Service – Interprofessional Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleroderma is a condition that can affect almost every organ system and thus requires an interprofessional team to optimally manage symptoms and improve patient quality of life. The Steffens Scleroderma Foundation and participating colleges developed an Interprofessional Education (IPE) Program to promote awareness of this disease among health professional students and emphasize the importance of interprofessional collaboration. Held annually since 2018, the program's unique feature is its utilization of the patient as the educator.

Methods: Each year, the program connects 25 or more individuals with scleroderma with students of 9 distinct health-related disciplines including medicine, pharmacy, physical therapy, occupational therapy, nutrition, dentistry, nursing, psychology, and public health. These students are assigned to small groups to interview a patient with scleroderma, asking about the individual's experience with the disease and critical aspects of care. After an interlude in which student questions are answered by a panel of experts from various disciplines, each group of students is assigned a new patient with a unique perspective of their disease. Afterwards, all attendees are asked to complete an anonymous survey regarding the event.

Results: The IPE program demonstrated an over five-fold increase in awareness of scleroderma in participating students, from 16.5% aware/very aware pre-event to 93.67% post-event. After the event, 55.7% of students felt confident/very confident they could recognize the condition in a clinical setting and 62.5% commented in an open response that the most important knowledge they gained regarded the diagnosis, symptoms, and treatment of scleroderma. Importantly, 95% of students said the patient educator was their favorite aspect of the IPE program, and 92.21% believed having the patient as the educator was important/very important for a condition such as scleroderma. In terms of multidisciplinary teams, 94.67% of students felt a collaborative team approach for the care of a multifaceted disease like scleroderma was very important/important.

The patient survey results reaffirmed the students: 89.47% of patients believed the IPE program was effective/very effective at increasing scleroderma awareness in students, and 84.21% were confident/very confident in the students' abilities to be successful in a collaborative healthcare team. The patients also emphasized the importance of an interprofessional team

management approach in a multi-system disease, with 94.74% saying it was very important and the remaining 5.26% saying it was important.

Conclusion: The IPE program provides an opportunity to connect graduate students from several disciplines and promote interprofessional collaboration for scleroderma. It highlights the importance of awareness and education for early diagnosis and uniquely places the patient at the center of the education model. Our goal is to replicate this IPE program on a National level at other scleroderma centers and universities. Expanding this pilot model nationally can promote the collaboration necessary among future healthcare professionals to assure the best quality of care for those living with scleroderma.

Integrated Analysis of Gene Expression and Methylation Identifies Biomarkers Associated with Mode of Action of Upadacitinib Treatment in Rheumatoid Arthritis

Preeti Lal[1], Yilin Xu[1], Thierry Sornasse[1], Rhiya Sharma[1], Laleh Jafarpour[1], Heidi Camp[1] and **Iain McInnes**[2], [1]AbbVie, Inc., North Chicago, IL, [2]University of Glasgow, Glasgow, United Kingdom

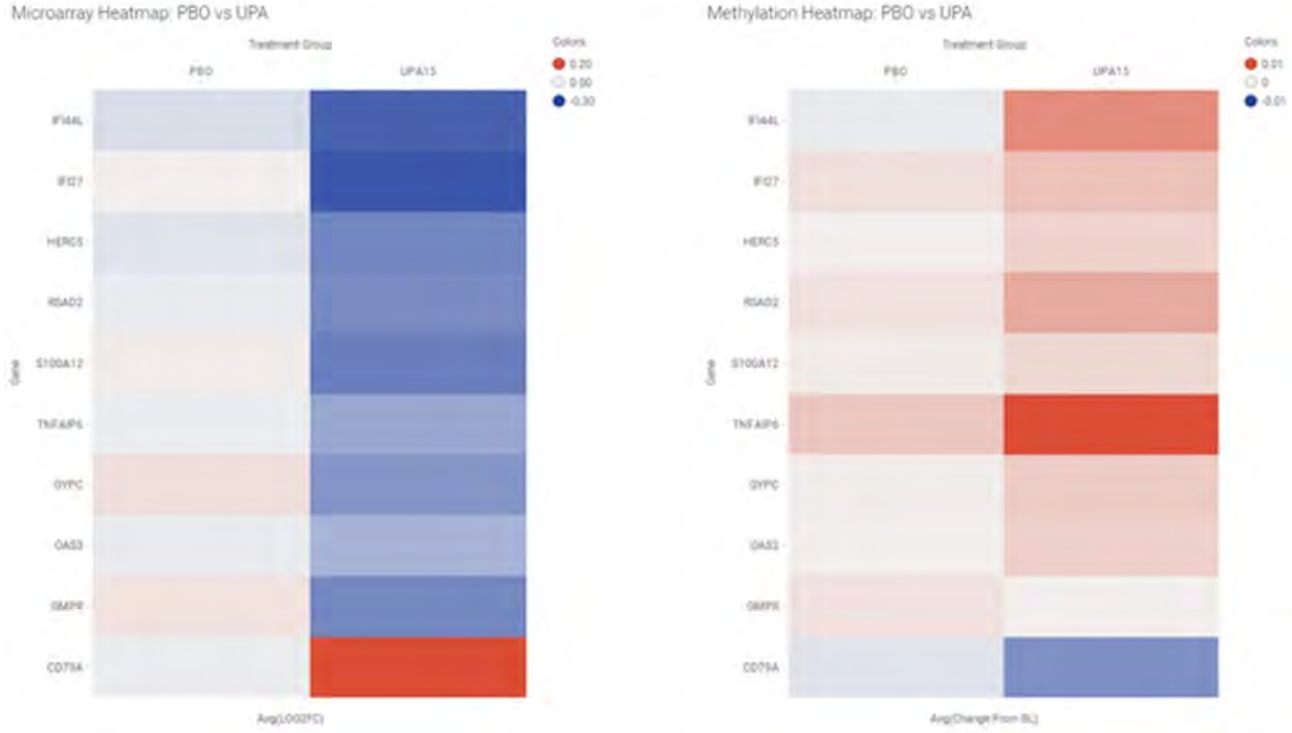
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral Janus kinase (JAK) inhibitor, significantly improves the signs and symptoms of RA patients[1-3]. The present study aims to elucidate the mechanism of action of UPA by integrating changes in a genome-wide analysis of methylome data and the blood transcriptome over time from patients enrolled in three phase-3 studies of UPA.

Methods: Longitudinal (baseline [BL], week [W] 2 and W12]) peripheral whole blood samples were randomly selected for analysis (SELECT-NEXT [1]; placebo [PBO], n = 62; UPA 15 mg once daily [QD], n = 61), SELECT-BEYOND [2] (PBO, n = 53; UPA 15 mg QD, n = 55) and SELECT-COMPARE [3] (PBO, n = 181; UPA 15 mg QD, n = 101). This analysis assessed the impact of UPA treatment on all subjects regardless of change in the disease activity. The biospecimen were used to analyze gene expression with a transcriptome-wide gene-level expression profiling tool and methylation profiling with a genome-wide methylation screening tool array. Transcriptome data from the 3 studies were combined following single channel array normalization. Linear models for microarray and RNA-Seq data model (LIMMA package) were used to evaluate transcriptome and methylation changes at W2 and W12 compared to BL. The threshold of significance was defined by false discovery rate < 0.05 and $\log_2$ fold-change above the levels observed in the PBO samples. Canonical and Upstream Regulators Pathway analyses were performed with ingenuity pathway analysis (IPA).

Results: The transcripts for 294 genes were differentially expressed (DE) at W2, of which 114 remained DE at W12. An additional 98 genes were DE at W12 vs baseline. Pathway analysis of DE genes shows early modulation of key pathways like IFN, IL10 and S100 signaling. Furthermore, pathway analysis predicted that UPA downregulates pathways related to IL1B, TNF, types 1 and 2 IFN, IL17A, and IL6 biology. The methylation data covered 282 genes out of the 294 identified above. Of the

Figure 1. Top 10 differentially expressed genes and their corresponding methylation pattern.



282, 34% (n=97) of the genes were significantly differentially methylated and consistent with the RNA expression data. Pathway analysis based on these 97 genes predicted the upstream downregulation of inflammatory regulators such as TNF, IFNα, TGF-β, IL1B, and IL17.

Conclusion: The present study reveals the effect of treatment with UPA on the transcription machinery of leukocytes from RA patients at the RNA and DNA methylation levels. While UPA may directly affect the methylation state and expression of target genes, we cannot exclude that some of the observed changes reflect a change in blood cell composition. This integrated analysis confirms that UPA normalizes key pathological pathways associated with RA, expanding our understanding of its mode of action in RA and creates a framework for multi-omic biomarker discovery for response to JAK inhibitors.

Association of Left Ventricular Mass with Interleukin-17 in Rheumatoid Arthritis Patients Without Clinical Heart Failure

Elizabeth Park[1], Kazato Ito[2], Christopher Depender[1], Jon Giles[3] and Joan Bathon[3], [1]Columbia University Irving Medical Center, New York, NY, [2]Columbia University Medical Center, New York, NY, [3]Columbia University, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated left ventricular (LV) mass (LVM) is an important precursor to clinical heart failure (HF) in the general population. In fact, rheumatoid arthritis (RA) patients without HF demonstrate higher LVM than non-RA patients without HF. However, few studies have established direct associations between LVM and inflammatory cytokines in RA patients without clinical HF. Interleukin-17 (IL-17) is an important contributor to LV structural abnormalities in RA, given its dual pathologic roles in myocardial fibrosis and articular cartilage breakdown. Here we present previously unreported associations between IL-17, obtained from a large inflammatory cytokine panel, and LVM in a RA cohort without clinical HF.

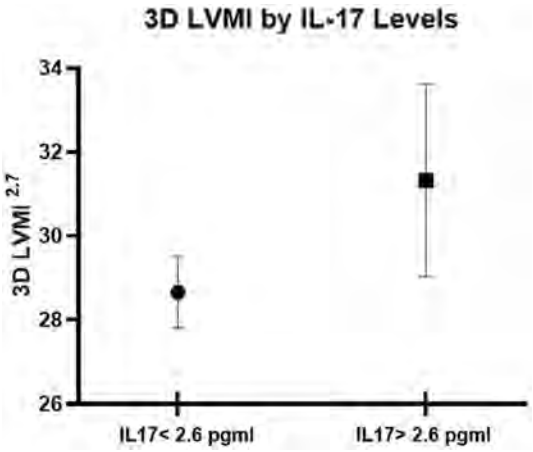

Figure 1. 3D LVMI by IL-17 levels, adjusted for RA and CV covariates

Methods: RA patients (n=158) without clinical HF underwent RA and cardiovascular (CV) clinical assessment, including myocardial inflammation and myocardial flow reserve (MFR) measured on 18F-Fluorodeoxyglucosecardiac positron emission tomography–computed tomography (FDG-PET/CT), as well as transthoracic echocardiography (TTE) at baseline. A subset (n=60) returned for follow-up TTE 3-6 years later. Real-time 3-dimensional (3D) TTE was utilized to calculate LVM (indexed to height ($m^{2.7}$); LVMI). Baseline plasma from all RA patients was assayed using the Rule Based Medicine (RBM)/ Inflammation MAP v 1.1, a 54-marker Discovery Panel, assaying a broad group of inflammatory proteins. Multivariable (MV) regression models with LVMI as the outcome were constructed, adjusting for biologically plausible confounders identified from univariable regressions.

Results: The baseline cohort was predominantly middle aged, female, with moderate RA disease activity, and multiple CV risk factors. LVMI did not change significantly from baseline to follow-up. Up to 14% of the baseline cohort had IL-17 levels >2.6 pg/ml (lower limit of quantitation). In a MV model adjusted for demographics including BMI, RA disease activity, seropositivity, TNF inhibitor use, blood pressure, smoking, troponin levels, myocardial inflammation and MFR, baseline IL-17 levels >2.6 were associated with a higher baseline LVMI (*Table 1*; MV model). *Figure 1* demonstrates adjusted LVMI stratified by IL-17 levels (based on aforementioned MV regression model). IL-17 levels were not significantly associated in univariable and MV models with myocardial measures such as MFR and myocardial inflammation (mean standardized uptake value; SUV), as well as baseline and follow-up diastolic dysfunction, and baseline/annual rate of change in ejection fraction (-*Tables not shown*).

Conclusion: In an RA cohort without clinical HF, higher IL-17 levels were associated with higher LVMI, while adjusting for important RA and CV covariates. Whether anti IL-17 therapy could ameliorate these LV mass abnormalities, needs to be explored in future clinical studies.

Comparing the World Health Organization and the American College of Cardiology/American Heart Association Algorithms for Detection of Carotid Plaque

Natalia Guajardo-Jauregui[1], Iris Colunga[2], José Ramón Azpiri-López[2], Dionicio A. Galarza-Delgado[2], Rosa Arvizu-Rivera[3] and Jesus Alberto Cardenas-De la Garza[4], [1]Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico, [2]Hospital Universitario UANL, Monterrey, Mexico, [3]Hospital Universitario \"Dr. José Eleuterio Gonzalez\", Escobedo, Mexico, [4]Hospital Universitario "Dr. José Eleuterio González", San Nicolas, Mexico

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease is the major cause of death in rheumatoid arthritis (RA) patients. Cardiovascular risk algorithms are employed to assess the likelihood of experiencing a major cardiovascular event within 10 years based on the presence of conventional cardiovascular risk factors, however, no algorithm existed for the Hispanic population until the World Health Organization (WHO) published the cardiovascular disease risk charts for 21 regions, including Mexico. This study aimed to compare the effectiveness of the 2019 WHO algorithm and the 2013 ACC/AHA algorithm in detecting the presence of carotid plaque (CP) in patients with RA.

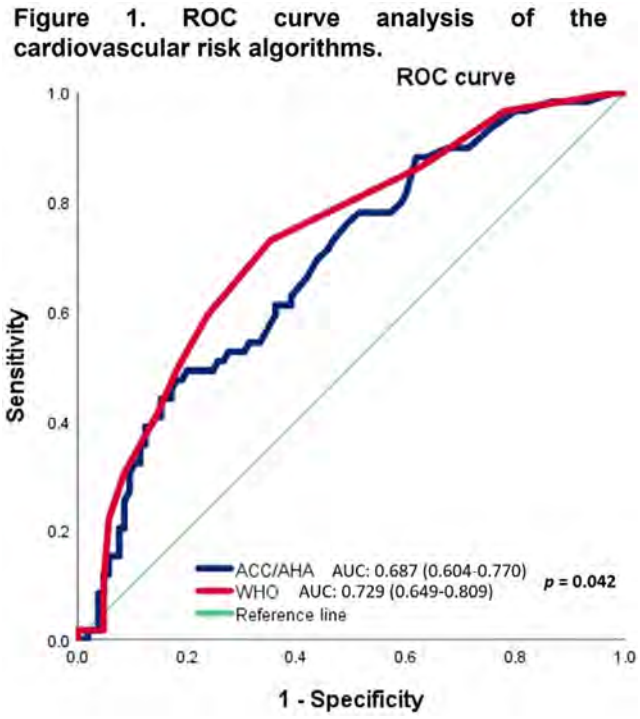
Methods: This was a cross-sectional study. We recruited a total of 164 patients with RA diagnosis, according to the 2010 ACR/EULAR classification criteria, aged 40-75 years. Patients with a previous cardiovascular event were excluded. Cardiovascular risk was evaluated with the 2019 WHO algorithm for the Mexican population and the 2013 ACC/AHA cardiovascular algorithm. The results were multiplicated by 1.5, according to current guidelines. A carotid ultrasound was performed to all study subjects by a certified radiologist blinded to clinical information. Distribution was evaluated with the Kolmogorov-Smirnov test. Correlations were performed with the Spearman-rho coefficient (rho). A ROC-curve analysis was performed for both algorithms. The areas under the curve (AUC) of the algorithms were compared using the method of DeLong. A p-value < 0.05 was considered statistically significant.

Table 1. Demographic characteristics of RA patients.

Characteristics	RA patients (n=164)
Age, years, mean ± SD	55.82 ± 8.94
Women, n (%)	157 (95.73)
T2DM, n (%)	27 (16.46)
Hypertension, n (%)	53 (32.32)
Dyslipidemia, n (%)	58 (35.36)
Obesity, n (%)	56 (34.15)
Active smoking, n (%)	15 (9.15)
WHO algorithm, median (IQR)	4.5 (3.0-9.0)
ACC/AHA algorithm, median (IQR)	3.75 (1.80-9.26)
Carotid plaque, n (%)	59 (36.0)

RA, rheumatoid arthritis; T2DM, type 2 diabetes mellitus; WHO, world health organization; ACC/AHA, American College of Cardiology/American Heart Association.

RA, rheumatoid arthritis; T2DM, type 2 diabetes mellitus; WHO, world health organization; ACC/AHA, American College of Cardiology/American Heart Association.



Results: The presence of CP was detected in 59 (36.0%) patients. Demographic characteristics are shown in Table 1. There was a large positive correlation between the WHO and the ACC/AHA algorithms (rho = 0.880, $p = < 0.001$). Both algorithms showed significant discrimination for the presence of CP in RA patients, the WHO algorithm had an AUC 0.729 (95% CI 0.649-0.809, $p = < 0.001$) and the ACC/AHA algorithm had an AUC 0.687 (95% CI 0.604-0.770, $p = < 0.001$). However, there was a difference when comparing the AUC for both algorithms, with the WHO algorithm demonstrating a higher AUC value ($p = 0.042$) (Figure 1).

Conclusion: Our findings indicate that both algorithms exhibited significant discrimination for the presence of CP. However, in the Hispanic RA population, the 2019 WHO algorithm displayed superior capacity for detecting CP compared to the 2013 ACC/AHA algorithm. The WHO algorithm is more suitable for the Hispanic RA population due to its tailored design specifically for their demographic characteristics. Consequently, it outperforms the ACC/AHA algorithm in accurately detecting and assessing cardiovascular risk factors in this population.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: RA-associated interstitial lung disease (ILD) and idiopathic pulmonary fibrosis (IPF) share genetic risk factors such as *MUC5B* rs35705950. The exact role of telomere related genes (TRG) in the RA-ILD genetic background is unclear. A previous work found an excess of TRG rare deleterious variants in RA-ILD compared to healthy controls but did not allow to conclude without a control population of patients with RA without ILD. Our aim was to test for association TRG rare deleterious exonic variants with ILD in patients with RA.

Methods: This genetic case-control association study was composed of a derivation (France) and a replication (US) population. Cases with RA-ILD and controls with RA without ILD (RA-noILD) that had whole exome sequencing (WES) data were included. ILD status and pattern (usual interstitial pattern, UIP or non-UIP) was determined by review of clinically-indicated high-resolution computed tomography (HRCT) chest imaging. Rare deleterious exonic variants from 14 candidate TRG previously associated with pulmonary fibrosis (*TERT, TERC, PARN, RTEL1, CTC1, TINF2, ACD, POT1, NAF1, ZCCHC8, NHP2, NOP10, WRAP53,* and *DKC1*) were selected using 1) a reported frequency in gnomAD database < 0.1%, 2) a deleterious impact predicted by SIFT, POLYPHEN-2, and 3) a CADD score > 15. Proportions of variants carriers in RA-ILD and RA-noILD were compared using a classical burden test adjusted for sex, age at RA, RA duration, *MUC5B* rs3570590 genotype and a principal component analysis using ancestry informative markers. Results were combined in a meta-analysis.

Table 1. Characteristics of the included patients ACPA: anti-citrullinated peptides antibodies; HRCT: high resolution computed tomography; ILD: interstitial lung disease; MAF: minor allele frequency; RF: rheumatoid factor; UIP: usual interstitial pneumonia.

	French derivation set		US replication set	
	RA-ILD cases (n=157)	RA-noILD controls (n=231)	RA-ILD cases (n=85)	RA-noILD controls (n=305)
Female sex	85/157 (54.1)	188/231 (81.4)	61/85 (71.8)	229/305 (75.1)

nonUIP RA-ILD *vs* RA-noILD	5/56 (8.9%)	19/305 (6.2%)	1.60 [0.50 – 4.34]	0.38
RA-UIP *vs* nonUIP RA-ILD	4/29 (13.8%)	5/56 (8.9%)	1.01 [0.17 – 5.61]	0.99
META-ANALYSIS				
RA-ILD *vs* RA-noILD	23/242 (9.5%)	27/536 (5.0%)	2.16 [1.09 – 4.26]	0.03
RA-UIP *vs* RA-noILD	12/105 (11.4%)	27/536 (5.0%)	3.28 [1.30 – 8.27]	0.01
nonUIP RA-ILD *vs* RA-noILD	11/137 (8.0%)	27/536 (5.0%)	1.77 [0.79 – 3.96]	0.16
RA-UIP *vs* nonUIP RA-ILD	12/105 (11.4%)	11/137 (8.0%)	1.57 [0.55 – 4.50]	0.40

Results: The French derivation dataset included 388 patients, 157 cases (40.5%), mean age at ILD or last normal HRTC 60.1 years, 273 female (70.4%); **Table 1**. 22 rare deleterious variants were identified in 13/157 cases (8.3%) and 8/231 controls (3.5%). The burden test suggested an excess of TRG rare variants in RA-ILD (OR 2.83, 95% CI 0.96-8.58; p=0.06); (**-Table 2, Figure 1)**. A significant association was observed for usual interstitial pneumonia (UIP) HRCT pattern (OR 4.66, 95% CI 1.27-16.86; p=0.02) whereas no association was detected for patients with RA-ILD and a non-UIP HRCT patterns (OR 2.14, 95% CI 0.48-8.26; p=0.29). The US replication dataset included 390 patients, 85 cases (21.8%), mean age at ILD or last normal HRCT was 61.4 years and 74.4% were female. Similar trend for an excess of TRG rare variants was observed with 28 variants identified in 9/85 cases and 19/305 controls (10.5% vs 6.2%, OR 1.83, 95% CI 0.72-4.33; p=0.18); (**-Table 2**, **Figure 1)**. Like in the derivation population, the excess of rare variants was more pronounced for RA-UIP: 13.8% vs 6.2% (OR 2.26, 95% CI 0.48-8.53; p=0.26) The meta-analysis provide evidence for a significant contribution of TRGs rare

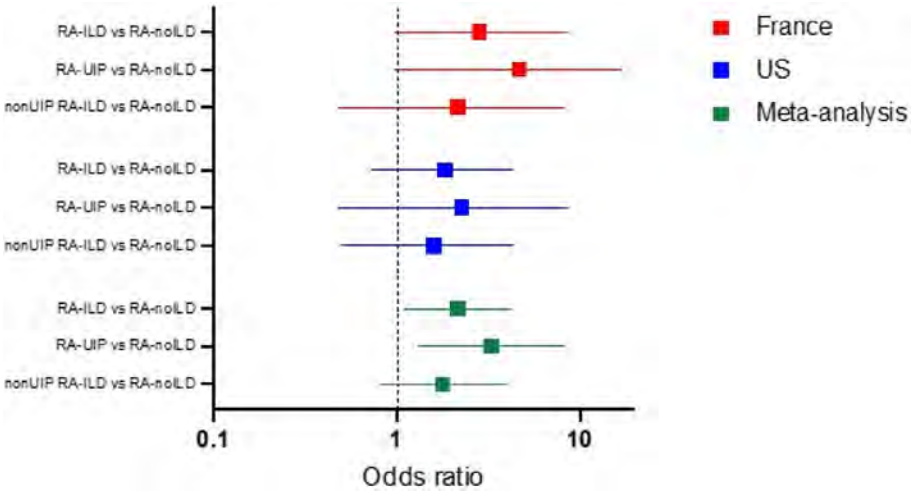

Figure 1. Results from the Burden test assessing TRG rare deleterious variants contribution in RA-ILD. Forest plot of odds ratios (OR) and 95% confidence intervals (CI). The boxes indicate OR, and the horizontal lines indicate 95% CI for the burden test comparing frequency of telomere related genes (TRG) rare deleterious exonic variants carriers in cases vs controls.

variants to RA-ILD (OR 2.16, 95% CI 1.09-4.26; p=0.03), more specifically for the UIP pattern (OR 3.28, 95% CI 1.30-8.27; p=0.01). No significant association was found for non-UIP patterns in the meta-analysis (OR 1.77, 95% CI 0.79-3.96; p=0.16).

Conclusion: TRG rare deleterious exonic variants contribute to the risk of ILD in patients with RA, more specifically in RA-UIP. These results confirmed the shared genetic architecture between RA-ILD and IPF.

Lesser Impact of Lower-Small Joint Involvement on Pain Than Upper-Small Joint in Rheumatoid Arthritis: Analysis Based on a Large Rheumatoid Arthritis Database in Japan

Tetsuji Sawada[1], Susumu Nishiyama[2], Shigemoto Igari[1], Toshihiro Matsui[3] and Shigeto Tohma[4], [1]Tokyo Medical University Hospital, Shinjuku Tokyo, Japan, [2]Kurashiki Medical Center, Kurashiki, Japan, [3]NHO Sagamihara National Hospital, Kanagawa, Japan, [4]NHO Tokyo National Hospital, Dallas, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have highlighted the influence of pain, functional impairment, and affected joint distribution on the discordance in the global assessment of disease activity between patients with rheumatoid arthritis (RA) and their physicians. This study aimed to analyze the effect of affected joint distribution on pain in patients with RA, based on a nationwide RA database in Japan (*NinJa*).

Methods: The affected joints were divided into four regions: upper-large (shoulder, sternoclavicular, elbow, and wrist), upper-small (proximal interphalangeal and metacarpophalangeal), lower-large (hip, knee, ankle, and tarsometatarsal), and lower-small (metatarsophalangeal) joints. The modified joint index (JI) was calculated using the following formula: number

of tender joint counts (instead of the sum of tender and swollen joint counts in the original JI [Rheumatol Int 32:2569, 2012]) divided by the number of evaluable joints within each region. Multiple regression analysis was performed using the pain visual analog scale (VAS) as an objective variable and modified Health Assessment Questionnaire (mHAQ), CRP, and affected joint variables, including JIs and tender joint counts, as explanatory variables.

Results: Multiple regression analysis involving 13,653 RA patients revealed that mHAQ, upper-large joints, lower-large joints, CRP, and upper-small joints significantly contributed to pain VAS in the order of standardized partial regression coefficients (SPRCs), although the contribution of lower-small joints was insignificant (Figure 1). Further analysis using tender joint counts showed the impact of each affected joint on pain VAS in the following order of SPRCs: wrists, knees, ankles, shoulders, proximal interphalangeal (PIP) joints, elbows, metacarpophalangeal (MCP) joints, distal interphalangeal (DIP) joints, and hips (Figure 2). Notably, the effects of metatarsophalangeal (MTP) and toe interphalangeal (IP) joints, which were excluded from the disease activity score-28 (DAS28), were not statistically significant.

Conclusion: The effect of lower-small joint involvement on pain in RA is smaller than that of upper-small joint involvement. Thus, patients with RA are relatively less aware of MTP and toe IP joint pain as compared to PIP and MCP joints, and may not complain to their physicians, which could lead to forefoot joint deformities. Therefore, it is necessary to consider lower-small joint involvement, which is not included in DAS28 evaluation, and pay attention to its potential impact on management in RA patients.

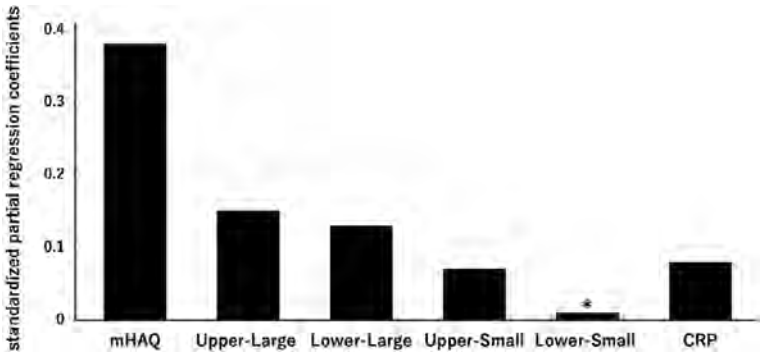

Figure 1 Impact of affected joint distribution on pain visual analog scale in patients with rheumatoid arthritis. *Lower-small joint involvement is not statistically significant. mHAQ: modified Health Assessment Questionnaire; CRP: C-reactive protein.

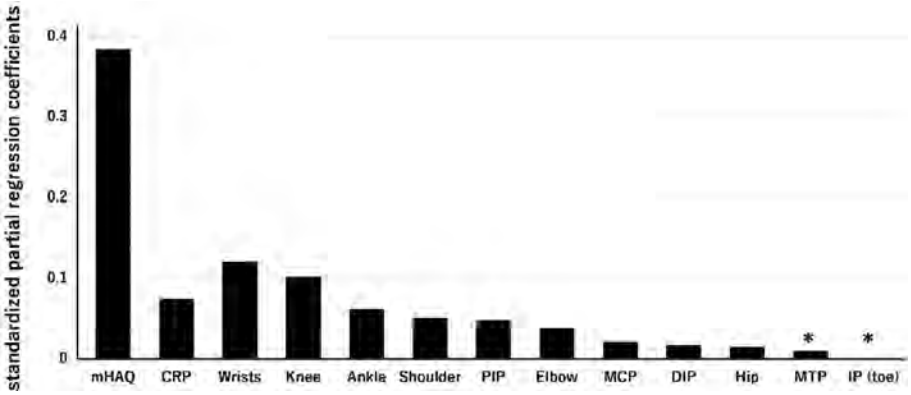

Figure 2 Impact of affected joint on pain visual analog scale in patients with rheumatoid arthritis. *Lower-small joint involvement is not statistically significant. mHAQ: modified Health Assessment Questionnaire; CRP: C-reactive protein.

Paradoxical Antagonistic Association of Visceral and Subcutaneous Adipose Tissue with Circulating C-Reactive Protein in Rheumatoid Arthritis

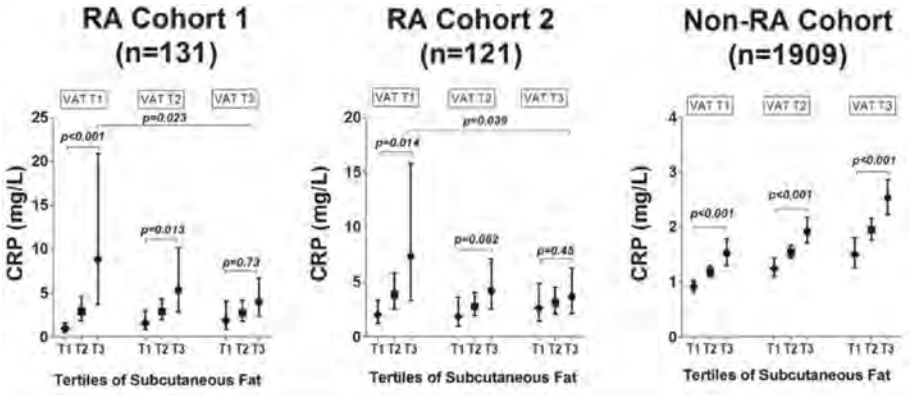
Jon Giles and Joan Bathon, Columbia University, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: C-reactive protein (CRP) is used as an indicator of disease activity in people with RA.However, adipose tissue also expresses inflammatory cytokines that induce hepatic CRP production.Both visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT) express inflammatory cytokines, with effects on CRP that are additive.However, whether this is also true for RA has not been explored.

Methods: RA patients were from two independent cohorts exploring subclinical cardiovascular disease.Non-RA controls were from a large multi-center cohort study, also studying subclinical cardiovascular disease.Known cardiovascular disease was an exclusion criterion for all 3 cohorts.In all 3 cohorts, participants underwent abdominal CT scanning with quantification



Adjusted means and 95% CIs are depicted. T1, T2, T3=tertile groups. RA Cohort 1 adjusted for sex, smoking, HDL-C, RA duration, rheumatoid factor, swollen joint count, tender joint count, methotrexate use, and TNF inhibitor use. p-value for interaction=0.004. RA Cohort 2 adjusted for sex, smoking, RA duration, swollen joint count, tender joint count, and TNF inhibitor use. p-value for interaction=0.054. Non-RA cohort adjusted for age, sex, race/ethnicity, smoking, hypertension, diabetes, LDL-C, HDL-C, triglycerides.

of the areas of VAT and SAT at the L4/L5 disc interspace.VAT and SAT were interpreted by the same reader for both RA cohort 1 and the non-RA cohort.Readers were unaware of patient characteristics.For each cohort, stored serum samples were assayed for CRP via a central lab in single batches.Generalized linear models were constructed to explore the interaction of VAT and SAT with CRP.

Results: There were 131 RA patients in RA cohort 1 and 121 RA patients in RA cohort 2 (total n=252).The mean age of the combined RA cohorts was 57 years.The RA patients were mostly women (71%) of non-Hispanic White race (63%) with a median RA duration of 8.1years, 80% seropositive for RF or anti-CCP and a median DAS28 of 3.7.Non-biologics, biologics, and prednisone were used in 81%, 39, and 35%, respectively.In the non-RA cohort, higher SAT was associated with significantly higher CRP levels within each tertile of VAT, with progressively higher CRP with both higher SAT and VAT (Fig).In contrast, in both RA cohorts, there was a strong and significant association of higher SAT with CRP among those in the lowest tertile of VAT.However, the association of SAT with CRP among those in the highest tertile of VAT was weaker and not statistically significant in both RA cohorts (Fig).For those in the highest tertile of SAT, CRP was significantly lower among those in the highest vs lowest tertile of VAT, despite those in the highest tertile of VAT having a higher BMI (35.6 vs 32.6 kg/m2 for the combined RA cohorts) and similar DAS28, swollen, and tender joints counts.Use of biologic and non-biologic DMARDs and prednisone was not different between the groups. Adjusting for demographics and BMI did not reduce the significance of the antagonistic interaction.

Conclusion: We observed a similar paradoxical association of VAT and SAT on circulating CRP level in two independent cohorts of RA patients.These findings have implications on how elevated CRP levels are interpreted in RA patients and warrant additional study into the mechanism of how higher VAT may suppresses SAT-associated inflammation in RA.

Diagnosis of Mental Disorder Complicated by Rheumatoid Arthritis: A Study of the Validity of a Psychiatrist's Diagnosis and Questionnaire Method

Yusuke Miwa[1], Yuko Miwa-mitamura[2], Hiroi Tomioka[3] and Michio Hosaka[4], [1]Division of Rheumatology, Department of Medicine, School of Medicine, Showa University, Tokyo, Japan, [2]Department of Nursing, Showa University School of Nursing and Rehabilitation Sciences, Tokyo, Japan, [3]Department of Psychiatry, School of Medicine, Showa University, Yokohama, Japan, [4]Department of psychosomatic medicine, Katsuyama Clinic, Fujikawaguchiko, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been reported that about 15% of patients with rheumatoid arthritis (RA) have depression, and most of these studies have used questionnaire methods. For example, the Patient Health Questionnaire-9 (PHQ-9) and Center for Epidemiologic Studies Depression Scale (CES-D) questionnaires were used; a score of 10 or more on the PHQ-9 and 16 or more on the CES-D was considered a cutoff. Most of the studies have used questionnaires for depression. Because the depression questionnaire includes questions about physical symptoms, it is necessary to interpret the results carefully when there is an underlying disease. In addition, there are no studies on other mental disorders. In this study, we examined the validity of the questionnaire method for diagnosing RA complicated by psychiatric disorders and searching for optimal cutoff values in patients with rheumatoid arthritis.

Methods: One hundred twenty-three outpatients with RA who agreed to participate in this study were included. Age, gender, type of Disease-modifying anti-rheumatic drugs, prednisolone use, presence of diabetes, hypertension, dyslipidemia, and CRP were investigated. The PHQ-9 and CES-D questionnaires were used. The psychiatrist was blinded to the questionnaire results and conducted a structured interview in a separate room. The psychiatrist's diagnosis was defined as the Gold Standard and was compared with the PHQ-9 and CES-D.

Results: Twenty-three patients were excluded. Seven patients disagreed and withdrew their consent, and 16 could not adjust their schedules. The psychiatrist's diagnosis was abnormal in 15 patients. This included one patient with major depression, two patients with moderate depression, five patients with minor depression, two patients with adjustment disorder, two patients with neurosis, one with anxiety, one with insomnia, and one with mental retardation. The Receiver Operating Characteristic curve produced the following cutoff values. A score of 3 or more on the PHQ-9 and 17 or more on the CES-D was considered a cutoff. The PHQ-9 had a specificity of 62.4%, a sensitivity of 93.3%, and the area under the curve (AUC) was 0.792 (95%CI 0.674-0.91). The CES-D had a specificity of 89.4%, a sensitivity of 73.3%, and an AUC was 0.881 (95%CI 0.808-0.955).

Conclusion: The PHQ-9 and CES-D may be helpful in screening for psychiatric disorders, including those associated with RA. However, a different cutoff value should be used than the standard cutoff value.

Is This Prosthetic Joint Infected or Flaring?

Susan Goodman, Insa Mannstadt, Kathleen Tam, Alejandro Kochen, Lorien Shakib, Peter Sculco, Mark Figgie, Alberto Carli, Andy Miller, Linda Russell, Allina Nocon and Laura Donlin, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Diagnosis of a periprosthetic joint infection (PJI) in a patient with inflammatory arthritis (IA) is challenging, as features of IA flares can mimic an infection. We aimed to identify the optimal tests to diagnose a PJI accurately and efficiently in patients with IA.

Methods: We included participants in three patient groups: 1) IA patients with a flaring native joint, 2) IA patients with a prosthetic joint undergoing aseptic revision, and 3) patients with PJI regardless of IA. Demographic characteristics were compared across the three groups. Blood and synovial fluid markers were compared across groups to assess the sensitivity and specificity in diagnosing PJI versus IA flares.

Results: This study included 52 participants, mostly female (60%), and 40% had rheumatoid arthritis. Among the three groups, the confirmed PJI patients were older (p=0.03), while no significant statistical differences were observed in the remaining demographic variables. Synovial fluid and blood markers were significantly different between groups. PJI cases had the highest average C-Reactive Protein (CRP) and there was a significant difference between the groups (PJI: 82 mg/dl, IA flares: 29 mg/dl, aseptic revisions:10 mg/dl, $p< 0.05$) (Table 2). Similarly, the percent of synovial fluid polymorphonuclear neutrophils (PMNs) was highest in PJI cases and significantly differed between groups (PJI: 88.9%, IA flares: 54%, aseptic

revisions: 17%, p< 0.01). Among PJI cases, alpha-defensin was positive in 93%. However, positive alpha-defensin was also observed in 20% of flares and 6% of aseptic revisions, with a significant difference (p< 0.01). There was no significant difference in procalcitonin and IL-6 levels across groups. Synovial white blood cells (WBC) exceeding 3,000 cells/μL, positive alpha-defensin, CRP levels exceeding 3 mg/dl, and PMNs exceeding 80% were highly sensitivity but less specific in diagnosing PJI (Table 3). Synovial WBC counts exceeding 3,000 cells/μL, alpha-defensin positivity, CRP level exceeding 3 mg/dl, and PMNs exceeding 80% were highly sensitive yet less specific for PJI diagnosis. For example, while synovial WBC counts exceeding 3,000 cells/μL and positive alpha-defensin had 100% sensitivity for identifying PJI, their specificity was poor with 50% of IA native joint flares and 79% of aseptic revisions scoring positive for an infection, respectively. The relatively poor specificity of synovial WBC and alpha-defensin indicate that that there is a higher likelihood of these tests incorrectly detecting PJI in cases where it is not present. Positive tests for alpha-defensin or synovial fluid PMNs exceeding 80% increased the likelihood of diagnosing PJI by 5 and 6 times, respectively. However, in cases without PJI, a negative result for PMNs exceeding 80% only marginally increased the likelihood of accurately ruling out diagnosis by 1 time. IL-6, procalcitonin, and D-Dimer demonstrated high sensitivity and specificity, while ESR and CRP had 80% sensitivity but had significantly lower specificity.

Table 1: Demographic and clinical characteristics of study patients*

	Overall (n=52)	PJI revision (n=15)	IA prosthetic joint revision (n=17)	IA native joint flare (n=20)	p-value**

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: High-density lipoprotein (HDL) eliminates cholesterol from atherosclerotic lesions, a function known as cholesterol efflux capacity (CEC). ATP-binding-cassette A1 (ABCA1) membrane transporter initiates cholesterol transfer from plaque macrophages to pre-b HDL particles. Methotrexate and biologic disease modifying drugs (bDMARDs) are atheroprotective whereas corticosteroids are proatherogenic. We here evaluated the influence of inflammation and these treatments on ABCA1-CEC and its relationship with coronary atherosclerosis burden, progression and cardiovascular risk in patients with rheumatoid arthritis (RA).

Methods: Coronary atherosclerosis (noncalcified, partially or fully calcified plaque) was evaluated with computed tomography angiography in 140 patients without cardiovascular disease and reassessed in 99 after 6.9±0.4 years. Incident cardiovascular events were recorded. ABCA1-CEC was measured in J774 macrophages. Multivariable negative binomial and

Figure 1 Impact of inflammation and disease-specific therapies on the relationship between ABCA1-CEC and baseline plaque burden in RA

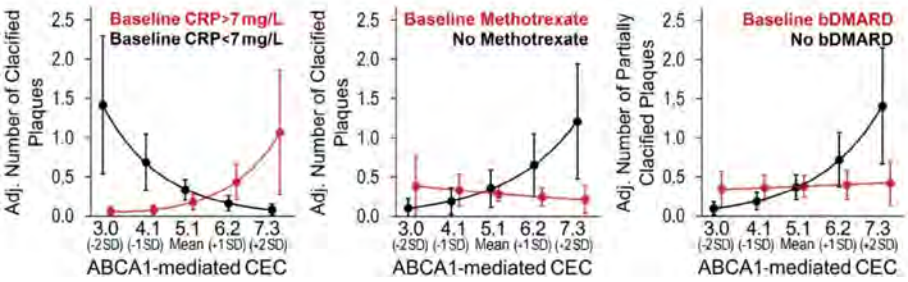

Figure 2 Impact of inflammation and disease-specific therapies on the relationship between ABCA1-CEC and baseline plaque burden in RA

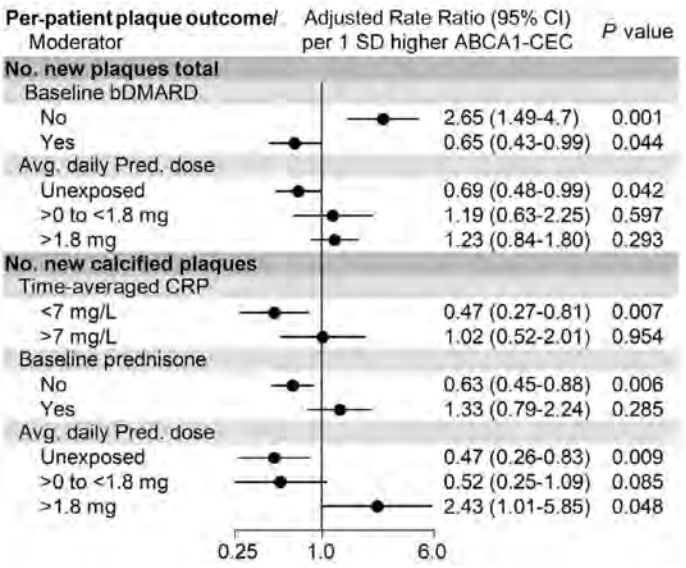

robust logistic regression evaluated associations of ABCA1-CEC with baseline plaque numbers and their progression at follow-up respectively. The moderating role of baseline inflammation, prednisone, methotrexate and bDMARD use on the relationship between ABCA1-CEC and cardiovascular risk was examined in multivariable Cox models including the respective moderators and their interaction term with ABCA1-CEC.

Results: ABCA1-CEC had no main effect on baseline atherosclerosis; prednisone use did not influence this relationship. Higher ABCA1-CEC (per standard deviation increment) associated with (i) more calcified plaques at baseline only in patients with CRP > 7mg/L (median) (p for interaction = 0.001), more calcified plaques only in methotrexate nonusers (p for interaction = 0.037), and more partially-calcified plaques only in bDMARD nonusers (p for interaction = 0.029, Figure 1); (ii) fewer new calcified plaques in patients with time-averaged CRP < 7mg/L (median) (p for interaction = 0.028, Figure 2); (iii) fewer new calcified plaques in baseline prednisone nonusers but not users (p for interaction = 0.021); (iv) fewer new total plaques in prednisone unexposed but not those exposed to prednisone during follow-up (p for interaction = 0.034), and fewer new calcified plaques in prednisone unexposed and more in those with high time-weighted average dose (p for interaction = 0.004); (v) more new plaques in baseline bDMARD nonusers and fewer in bDMARD users (p for interaction≤0.001); (vi) greater cardiovascular risk in baseline prednisone users but not nonusers (p for interaction = 0.027).

Conclusion: ABCA1-CEC attenuated coronary atherosclerosis burden and progression in patients with low baseline and cumulative inflammation and baseline methotrexate and bDMARD use. In contrast, ABCA1-CEC associated with plaque increase in corticosteroid users, methotrexate and bDMARD nonusers. While in well-treated, controlled disease ABCA1-CEC is atheroprotective, in uncontrolled RA its action may be masked or fails to counteract the proatherogenic state promoted by inflammation.

Relationship Between Frailty and Large Joint Symptoms in Rheumatoid Arthritis Patients

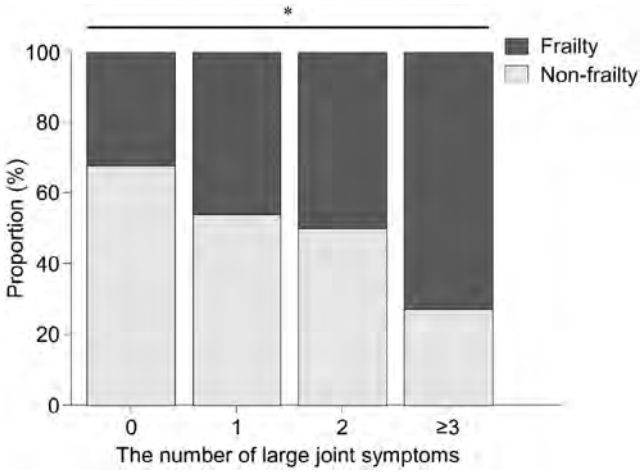
Yasumori Sobue[1], Mochihito Suzuki[2], yoshifumi Ohashi[2], Shuji Asai[2] and Shiro Imagama[2], [1]Japanese Red Cross Nagoya Daiichi Hospital, Nagoya, Japan, [2]Nagoya University Graduate School of Medicine, Nagoya, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a causative factor in frailty. Large joint symptoms in RA patients may be more strongly associated with physical disability than small joint symptoms. The aim of this study was to investigate the relationship between large joint symptoms and frailty in RA patients.

Methods: The T-FLAG (Tsurumai - Frailty and Locomotive syndrome of rheumatoid Arthritis for Globalization) Study included 630 RA patients who consecutively visited our hospitals between June and August 2021, of which 591 had background information available, including Clinical Disease Activity Index (CDAI) and the Kihon Checklist (KCL). Frailty was defined as a KCL score of 8 points or more. Large joint symptoms were defined as tenderness or swelling in any of the following joints: shoulders, elbows, hips, knees, and feet. The cut-off value for the number of large joint symptoms (tender joint count + swollen joint count) associated with frailty was calculated using Receiver Operating Characteristic (ROC) analysis. Furthermore, the odds ratios of large joint symptoms associated with frailty (by site) were determined by a multivariable logistic regression analysis, which was adjusted for age, sex, disease duration, and CDAI.

Results: Out of the 591 patients analyzed, 71.7% were female, with an age of 67.4 ± 13.9 years (mean ± standard deviation), disease duration of 11.8 ± 9.8 years, CDAI of 6.5 ± 7.5, KCL score of 7.2 ± 4.8 points. The proportions of patients with large joint symptoms (shoulders, elbows, hips, knees, and feet) were 13.2%, 10.5%, 7.5%, 20.0%, and 14.2%, respectively. The specificity of large joint symptoms for frailty (proportions of patients without large joint symptoms among those without frailty) was 92.2%, 93.9%, 95.9%, 88.1%, and 92.2%, respectively. The proportion of frailty significantly increased as the



The proportions of frailty by the number of large joint symptoms (tender joint count + swollen joint count of large joints). The Kihon Checklist <8 points, non-frailty; ≥8 points, Frailty. (*) P<0.001 by Cochran Armitage trend test.

number of large joint symptoms increased (p< 0.001, Cochran Armitage trend test). The cut-off value for the number of large joint symptoms associated with frailty was 1 site (specificity 74.4%; sensitivity 51.0%; Area under curve 0.647). Knee joint (odds ratio 1.72, 95% confidence interval 1.02-2.91) and ankle joint (odds ratio 1.81, 95% confidence interval 1.02-3.20) symptoms were significantly associated with frailty.

Conclusion: This study suggests that even one site of large joint symptom in RA patients indicates a high possibility of frailty. Among large joint symptoms, lower extremity disability (specifically, knee and ankle joints) was found to have a significant effect on frailty. Therefore, it may be prudent to adopt a more aggressive intervention of RA treatment for RA patients with large joint symptoms (e.g., elderly-onset RA) to prevent frailty. Additionally, if RA patients have large joint destruction and frailty, total joint replacement surgery may be an effective means of improving frailty. Focusing on large joint symptoms is crucial for the prevention of frailty.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune rheumatic diseases (AIRDs) are systemic but heterogeneous diseases characterized by orchestration of disrupted self-tolerance of immune systems. We face a challenge in characterizing clinical immune features and selecting best treatment strategy of the AIRD patients. Deconvolution of immunological and clinical heterogeneity within and across AIRDs is an essential step towards implementation of personalized medicine. Immuno-phenotypes, immune-related cell types in peripheral blood mononuclear cells quantified by flow-cytometry analysis, can less invasively describe immune profiles of individuals and is considered as a promising technique.

Methods: We conducted large-scale and cohort-wide immuno-phenotyping of 46 peripheral immune cells using the Human Immunology Protocol of comprehensive 8-color flow cytometric analysis. The dataset consisted of >1,000 Japanese patients of 11 AIRDs and controls with deep clinical information registered at the FLOW study, including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE),systemic sclerosis (SSc), ANCA related vasculitis (AAV), idiopathic inflammatory myopathy (IIM), psoriasis, IgG4 related disease (IgG4RD), mixed connective tissue disease (MCTD), ankylosing spondylitis (AS), Sjogren's syndrome (SjS), and giant cell aortitis (GCA). In depth and longitudinal clinical analysis was

conducted for the identified RA patient clusters registered at the FIRST registry. Inborn human genetics represented by genome-wide polygenic risk score (PRS) were estimated for the RA patients.

Results: Multimodal clustering of immuno-phenotypes deciphered underlying disease-cell type network, providing immune cell type specificity shared or distinct across AIRDs (**Figure 1**), such as close immunological network of MCTD with SLE rather than with SSc. Individual patient-level clustering deconvoluted the AIRD patients into several clusters with different immunological features (**Figure 2**). Of these, RA- or SLE-like clusters were exclusively dominant, showing immunological polarization between RA and SLE across AIRDs (the patient clusters 4-6 and 1-3 for RA and SLE, respectively). In depth and longitudinal clinical analysis of RA revealed that such patient clusters differentially defined clinical heterogeneity in disease activity and treatment responses, which were supported by immune cell-type specificity (e.g., decreased regulatory T cells associated with treatment resistance in the RA patients with SLE-like immuno-phenotypes). PRS based on RA case-control genome-wide association study (GWAS) and within-case stratified RA GWAS were associated with patient characteristics, disease activity, and immuno-phenotypes of the RA patients, such as dendritic cells for RA-interstitial lung disease (**Figure 3**).

Conclusion: Our study demonstrated a value of cohort-wide and cross-disease immuno-phenotyping to elucidate clinically heterogenous patient subtypes existing within the single disease in an immune cell type-specific manner.

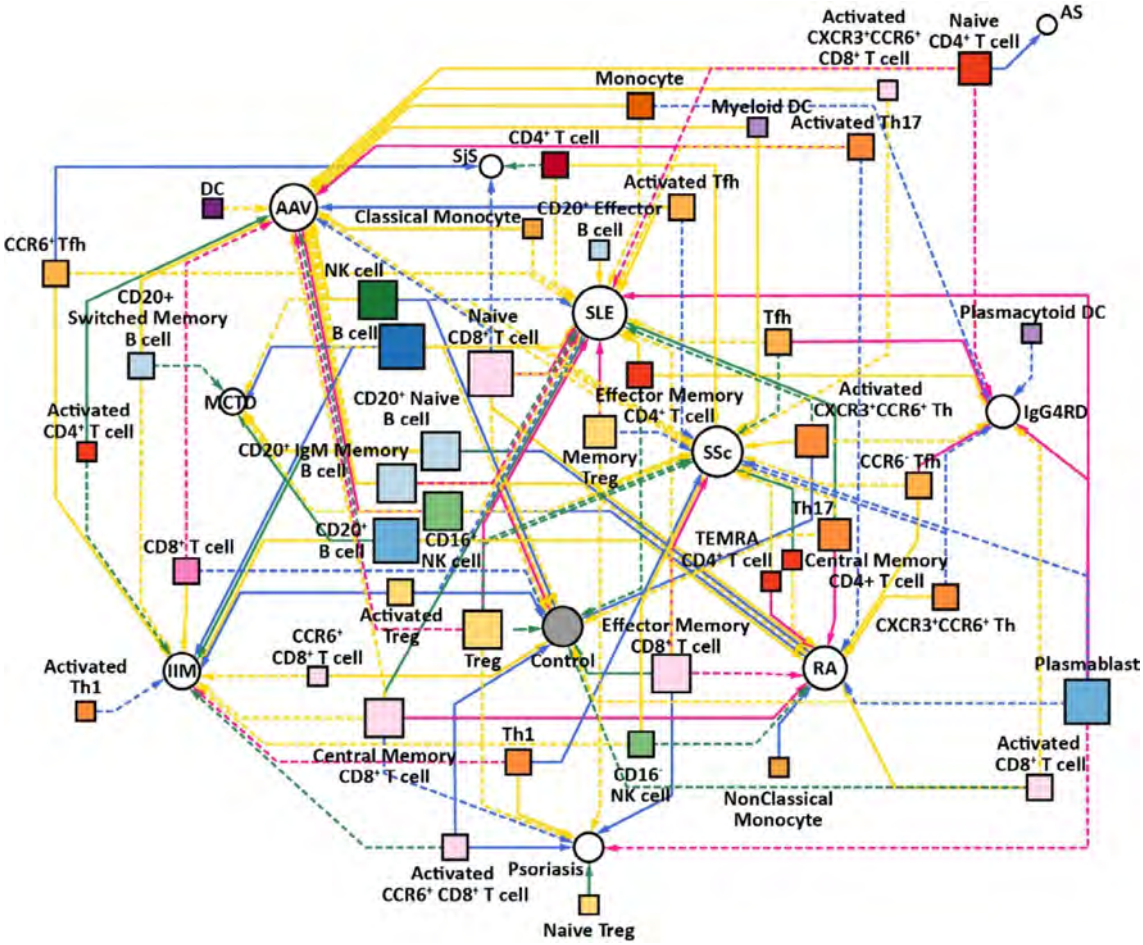

Figure 1 Immune-phenotype network across AIRDs and immune cell types. AIRD-immune cell type associations based on backward-forward stepwise logistic regression adjusted by sex were visualized as a network plot.

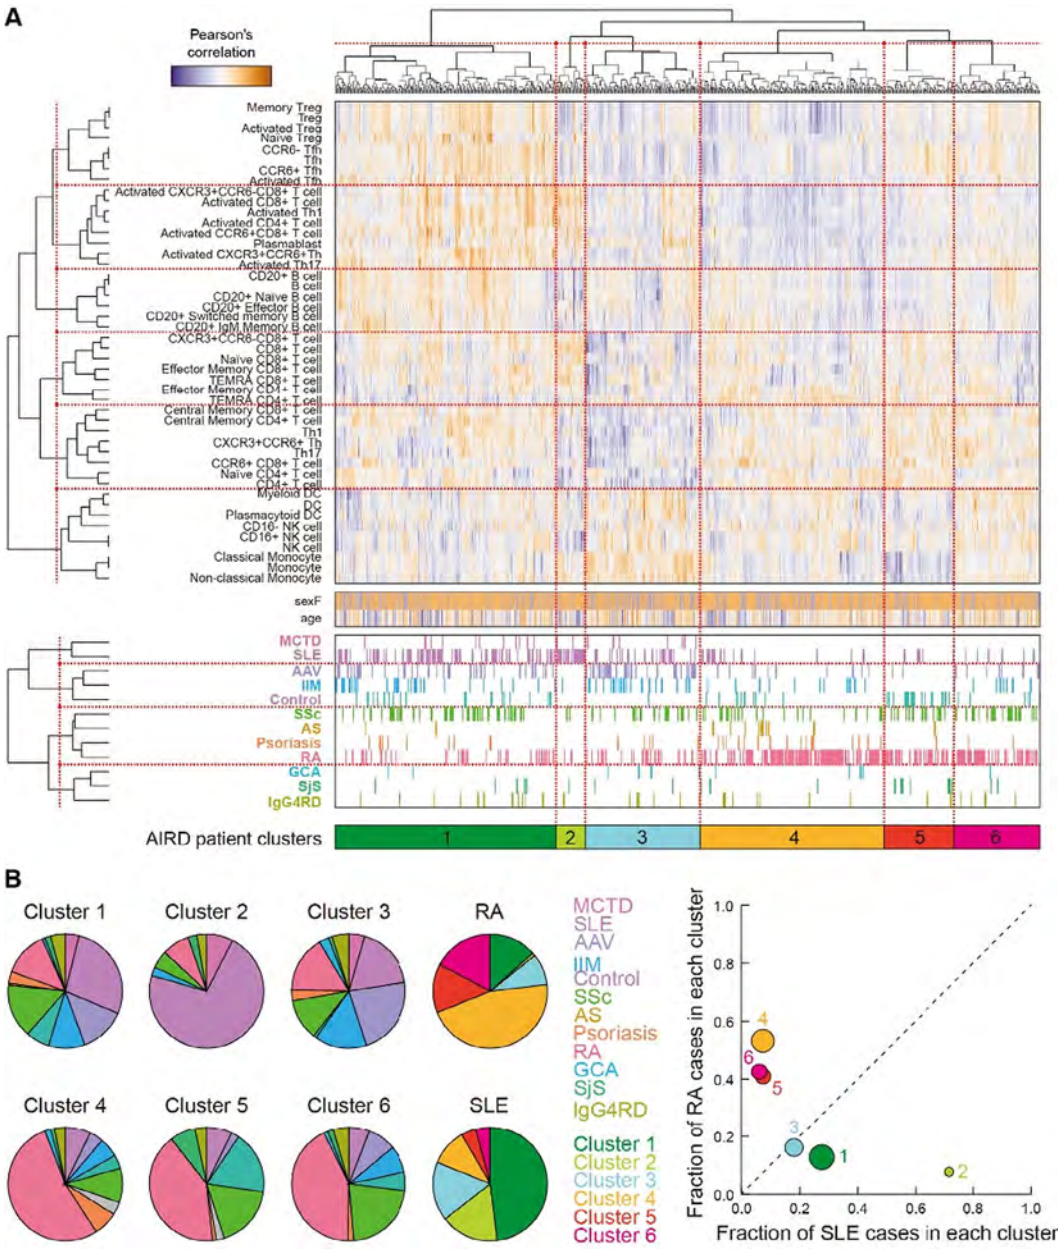

Figure 2. Patient-level clustering of the 11 AIRDs based on the cohort-wide immuno-phenotypes. (A) Unsupervised clustering of individual AIRD patients according to the immuno-phenotypes of the 46 peripheral immune cells. (B) Pie charts showing proportions of the AIRDs within each cluster, and those of the clusters within RA and SLE (left). A co-plot of the fractions of the RA and SLE patients within each cluster (right).

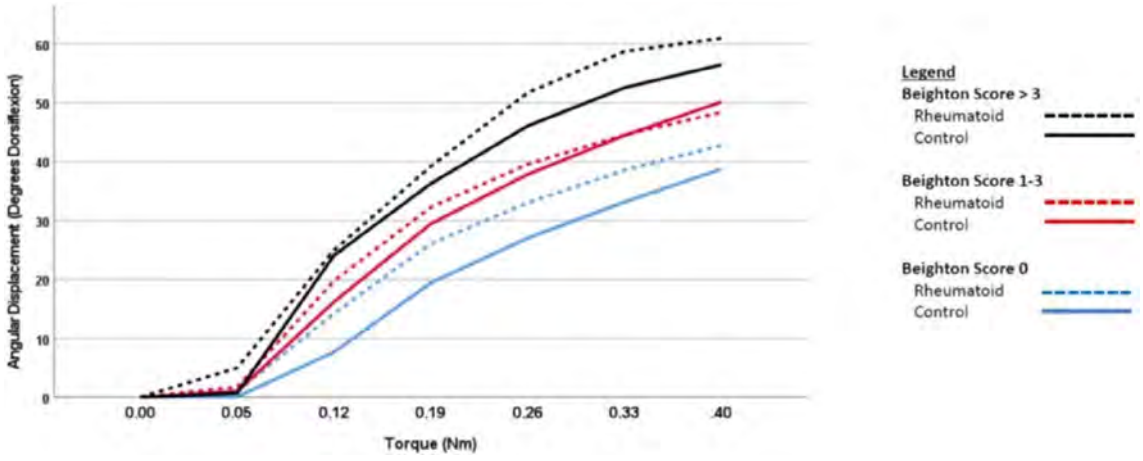
Evaluation of the Construct of Constitutional Stiffness (CS) in Anti-CCP-Antibody-Positive Rheumatoid Arthritis (ACPA+RA) and Controls

Stephen Oakley[1], Samantha Stott[1], Kerri Gill[1], Chan Virgil[1], Lyanne Weston[2] and Theo de Malmanche[1], [1]John Hunter Hospital, New Lambton, Australia, [2]Australian Red Cross Blood Service, Alexandria, Australia

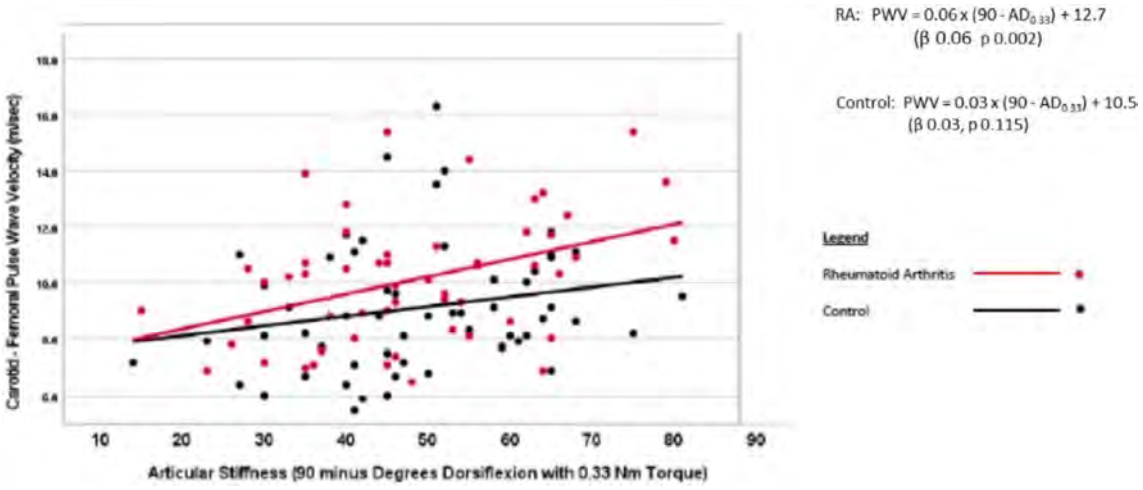
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of developing ACPA+RA, predictors of severity and causes of excess cardiovascular disease (CVD) are incompletely understood. We have observed that RA patients with concurrent benign joint hypermobility have less severe arthritis and lower arterial stiffness. We hypothesise that biomechanical characteristics are similar in different connective tissues within individuals and that Constitutional Stiffness (CS) is a common determinant of RA severity and risk of CVD.

The aimof this study was to evaluate the validity of biomechanical assessments of a single joint (right 5th metacarpophalageal joint R-MCPJ5) as a measure of total body articular stiffness and to compare these assessments with measurements of skin and arterial stiffness in RA and Control.



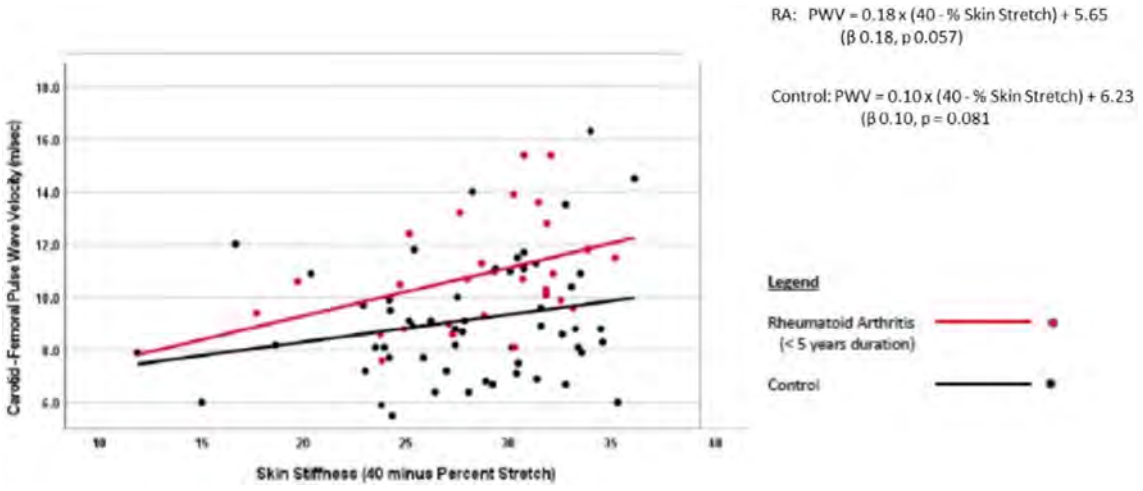
Right 5th MCPJ Stress-Strain responses for Rheumatoid Arthritis (dashed lines) and Control (solid lines) subjects. For both groups there is correlation between Right 5th MCPJ Stiffness (Strain responses measured as dorsal angular displacement) and Overall Total Body Articular Stiffness (Beighton Score).



Arterial Stiffness (Carotid-Femoral Pulse Wave Velocity) versus Articular Stiffness in RA (red) and Control (black) Groups. Scatterplots with univariate linear regression lines of best fit. Note that Articular stiffness has been expressed as (90 minus Angular Displacement degrees dorsiflexion) so that greater values indicate greater stiffness.

Methods: Fifty-eight ACPA+RA and 57 controls (47 Healthy Volunteers and 10 Benign Joint Hypermobility) were recruited. R-MCPJ5 stiffness was measured as angular displacement (AD) degrees passive extension in response to a range of torque moments. Stress-strain responses were evaluated. Responses to 0.33Nm torque ($AD_{0.33}$) were examined in detail. Beighton Scores (BS) used clinically to assess hypermobility were categorised as Low (BS 0), moderate (BS 1-3) and High (BS >3). Skin Stretch (SKST) was measured as percentage increase in distance between 2 dots dorsal right hand upon manual traction (Vernier calipers 0.1 mm resolution). Scores were dichotomised as High Stiffness ≤ 9.7% or Low Stiffness > 9.7%. Arterial stiffness was measured as Carotid-Femoral Pulse Wave Velocity (PWV metres/sec). Scores were dichotomised as High Stiffness ≥ 9.3 m/sec or Low Stiffness < 9.3 m/sec.

Results: Reproducibility (ICC/Kappa): $AD_{0.33}$ 0.94, BS 0.67, SKST 0.27 and PWV 0.99. Stress-Strain responses curves found that R-MCPJ5 assessments correlate with BS. BS correlated with $AD_{0.33}$ in ACPA+RA (BS_0:37, $BS_{1\text{-}3}$:45, $BS_{>3}$:54, p0.000) and Control (BS_0:33, $BS_{1\text{-}3}$:45, $BS_{1\text{-}3}$:53, p0.000). High PWV (>9.3 m/sec) was associated with lower $AD_{0.33}$ in ACPA+RA (38 vs 47, p0.011) and Controls (38 vs 43, p0.206). Linear regression found negative correlation with $AD_{0.33}$ in



Arterial Stiffness (Carotid-Femoral Pulse Wave Velocity) versus Skin Stiffness in RA <5 years duration (red) and Controls (black). Scatterplots with univariate linear regression lines of best fit. Note that skin stretch is expressed as 40 - Percent stretch so that higher values represent greater stiffness.

ACPA+RA (β -0.06, p 0.002) and Controls (β -0.03, p 0.115). PWV correlated negatively with BS in ACPA+RA (BS_0:10.5, BS_{1-3}:9.4, $BS_{>3}$:9.4, p0.207) and Controls (BS_0:9.4, BS_{1-3}:9.8, $BS_{>3}$:7.1, p0.004). SKST correlated with lower $AD_{0.33}$ significantly in RA ≤5 years duration (31 vs 44, p0.027) with similar trends for BS in ACPA+RA (BS_0:11%, BS_{1-3}:12% $BS_{>3}$:13%, p0.746) and in Controls for $AD_{0.33}$ (39 vs 43, p0.2638) and BS (BS_0:10%, BS_{1-3}:12%, $BS_{>3}$:15%, p0.008). Skin stiffness correlated with PWV in Control (OR 1.91, p0.242) and ACPA+RA (Odds Ratio 2.2, p0.157). In RA ≤5 years duration no subjects with High PWV had Low skin stiffness (OR infinite, p0.000). Linear regression PWV correlated negatively with SKST in ACPA+RA of less than 5 years duration (β -0.18, p 0.057) and Controls (β -0.10, p 0.081).

Conclusion: R-MCPJ5 assessments are representative of total body articular biomechanical properties. There is correlation between articular, arterial and skin biomechanical characteristics supporting the construct of CS. CS is a plausible common determinant of articular and arterial disease.

Social Determinants of Health and Clinical Outcomes in Rheumatoid Arthritis: A Single Center Study

Nicholas Wiemer[1], Yue Yin[2] and Tarun Sharma[1], [1]Allegheny Health Network, Pittsburgh, PA, [2]Allegheny Health Network Singer Research Institute, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic and potentially debilitating disease.Social determinants, including smoking and depression, have been shown to be linked to worse clinical outcomes in RA.In this study, we aim to determine the prevalence of eleven social determinants of health (SDOH) in the RA cohort at our health system.

Table 1: Comparison of SDoH Between CDAI Groups

Variable	CDAI < 10 (n=32)	CDAI ≥ 10 (n=18)
Smoking	10 (31.25%)	10 (55.56%)
Alcohol use	11 (34.38%)	6 (33.33%)
Food insecurity	19 (59.38%)	8 (44.44%)
Housing stability	0	2 (11.11%)
Safety environment	1 (3.13%)	1 (5.56%)
Financial strain	1 (3.13)	1 (5.56%)
Transportation	0	2 (11.11%)
Depression	2 (6.25%)	3 (16.67%)
PHQ9	0.88	18
Stress	15 (46.88%)	7 (38.89%)
Health literacy	1 (3.13%)	2 (11.11%)
Social connection	15 (46.88%)	9 (50%)

SDoH: social determinants of health, CDAI: clinical disease activity index, PHQ: patient health questionnaire

Table 2: Logistic Regression for Univariate and Multivariate Analyses				
Variable	Univariate		Multivariable	
	OR[95% CI]	P value	OR[95% CI]	P value
Smoking	2.32[1.08, 5.02]	.0321	2.25[1.03, 4.89]	.0413
Alcohol use	1.09[0.54, 2.18]	.8135	-	-
Food insecurity	0.78[0.43, 1.41]	.4109	-	-
Housing stability	3.39[0.28, 41.23]	.3384	-	-
Safety environment	1.31[0.30, 5.65]	.7179	-	-
Financial strain	1.30[0.31, 5.50]	.7180	-	-
Transportation	2.92[0.43, 19.70]	.2712	-	-
Depression	3.00[0.45, 19.92]	.2556	-	-
PHQ9	1.11[0.97, 1.28]	.1324	1.06[0.90, 1.24]	.5072
Health literacy	1.79[0.43, 7.53]	.4271	-	-
Social connection	1.29[0.64, 2.62]	.4742	-	-

PHQ: patient health questionnaire

Methods: A retrospective review of patients seen as part of the RA Care Pathway, a well-defined cohort of adult patients with RA at AHN Rheumatology, was performed.Demographics, serologies, medications, and SDOH metrics were captured and validated via chart review. Patients were included if they had a RA Clinical Disease Activity Index (CDAI) and at least 3 social determinants completed within 6 months of each other. Patients were then examined in two groups, CDAI ≥10 (moderate-severe RA) and CDAI < 10 (remission and low disease activity) to assess any differential impact of SDOH.

Results: A total of 137 patients were reviewed, of which 50 met inclusion criteria. Average age was 65.5 years, 74% were female, and 66% were Caucasian. Mean CDAI was 9.64 with 36% patients in the moderate-severe CDAI group. Several SDOH metrics were unfavorably distributed in the CDAI ≥10 compared to < 10 group, including smoking (55.56% vs 31.25%), housing instability (11.11% vs 0%), depression (16.67% vs 6.25% with mean PHQ9 scores 18 vs 0.88, respectively), and low health literacy (11.11% vs 46.88%).Smoking patients were more likely to have high disease activity (OR 2.25, 95% CI [1.03, 4.89], p=0.04).

Conclusion: Our data reveals that RA patients with moderate-high disease activity are more likely to have high risk social determinants of health including high likelihood of smoking, housing instability, and depression. A team-based care approach has been implemented at AHN Rheumatology. Our next steps are to better capture SDOH and determine the impact of SDOH interventions on clinical outcomes in RA.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Symptom clusters are stable groups of 2+ symptoms that are related to each other and frequently co-occur. Identifying symptom clusters in early RA may point to underlying mechanisms and RA subtypes, help predict disease trajectories and personalize symptom management to improve outcomes. We used scores from PROMIS-29 to identify symptom clusters at diagnosis in MTX-naïve patients starting MTX therapy. We evaluated the stability of these clusters and likelihood of transitioning between clusters over the first 6 months of treatment.

Methods: Data were from new onset RA patients (sx < 1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) who started MTX and had clinical and PROM measures available at 0, 3, and 6-months. Based on empirical and qualitative data, we used latent class analyses to identify symptom clusters from PROMIS-29 physical (pain, fatigue, sleep) and emotional (depression, anxiety) scales (levels: minimal, mild, moderate, severe). Models were compared using AIC, BIC, G-square and log-likelihoods. We estimated transitioning between clusters at 3- and 6-months using latent transition analyses.

Results: Of 310 adults with new RA, followed for 6 months and starting MTX, 67% were women and 78%White. Participants had a mean age of 56 yrs, CDAI 29.3, and RA symptom durationof 5 months. Optimal clusters included pain, fatigue, anxiety and depression and three intensity levels. We identified 4 discrete symptom clusters at diagnosis:**MINIMAL** (12%); **Moderate-Severe Physical** (**M-S P**: 40%); **Mild Physical + Emotional** (**MILD P+E:** 11%); **Moderate-Severe Physical + Emotional** (**M-S P+E** 37%). Clusters had similar sociodemographics except the **MINIMAL**class were slightly older and fewer were women; **M-S P+E** had a greater likelihood of depression history (Table). SJC and TJC were similar among classes; worse symptoms were associated with higher CDAI. Classes with emotional sx had significantly worse mood and sleep, and the **M-S P** class were more likely to report a history of depression. More patients with moderate-severe symptoms were on parenteral steroids. Most transitions occurred over the first 3 months. The best prognosis was for the

RA patient characteristics by symptom clusters identified at diagnosis.

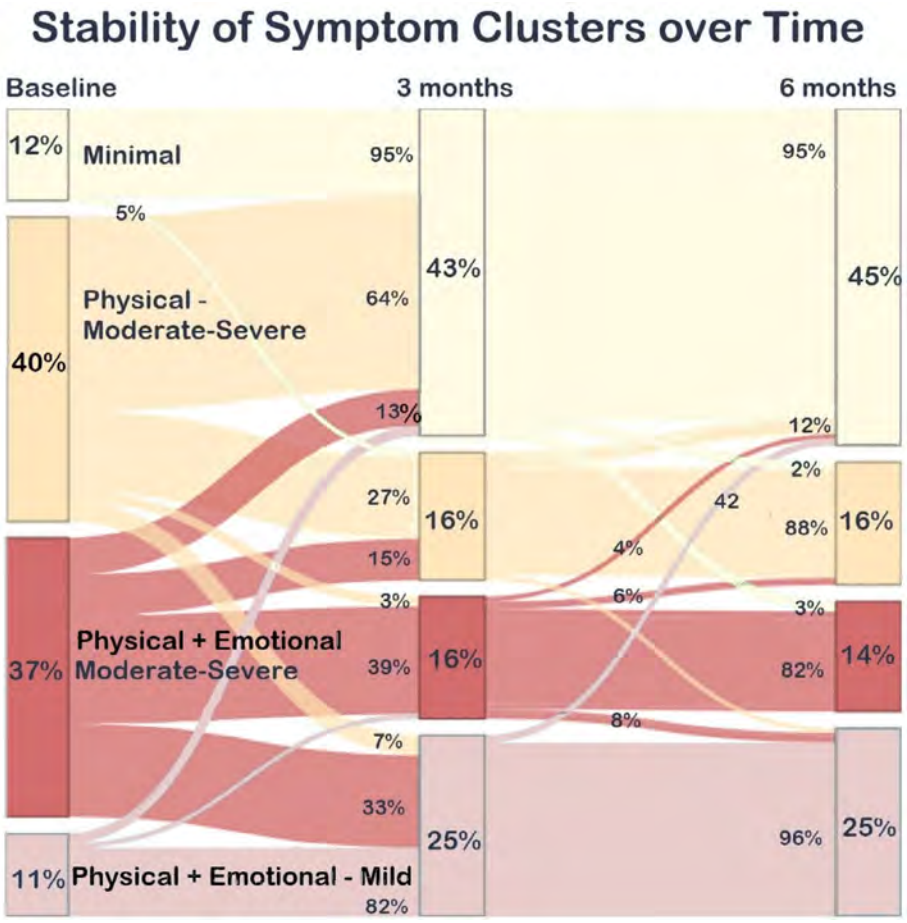
CDAI, mean (SD)	**25.5 (11.4)**	**29.2 (12.7)**	**24.8 (12.6)**	**32.0 (14.0)**	**0.0103**



MINIMAL class; 95% were classified similarly at 3 and 6 months. Among those with **MILD P+E ,** almost all were classified similarly at 3 (82%) and 6 (96%) months. Participants with **M-S P** at diagnosis were also likely to transition to **MINIMAL** (64%) or **MILD P+E** (7%). The worse prognosis was among those with **M-S P+E**; at 3 months, a minority transitioned to **MINIMAL** (13%) or **MILD P+E** (33%) classes. Patients with either mild or moderate-severe emotional symptoms were the least likely to transition to milder symptom classes.

Conclusion: We identified 4 ERA patient subsets with varying physical (pain, fatigue) and emotional (depression, anxiety) symptoms and evaluated transitions over 6-months of initial MTX treatment. At baseline, most participants had moderate-severe Physical +/- Emotional symptoms. Patient subsets with emotional symptoms at RA-diagnosis were less likely to transition to better controlled symptom classes. Our results suggest that co-occurring emotional symptoms at diagnosis may reflect important subsets and signal a more guarded RA prognosis over the first 6 months.

Real-world Positivity of 14-3-3η Protein in Rheumatoid Arthritis

Roshan Subedi[1], Massiel Jimenez Artiles[2], Adnan Al Najada[2], Afrah Misbah[2], Qi Wang[3], Alexander Kusnik[2], Zhiting Tang[2], Syed Mohammed Faizaan Zabiullah[2] and Anthony Ocon[4], [1]Rochester Regional Health/Unity Hospital, Greece, NY, [2]Rochester Regional Health, Rochester, NY, [3]Rochester Regional Health/Unity Hospital, Rochester, NY, [4]Rochester Regional Health, Fairport, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: 14-3-3η protein may be elevated in the blood of inflammatory arthritis patients. It is a commercially available novel biomarker used to aid in the diagnosis of rheumatoid arthritis (RA), in addition to rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP), especially in seronegative patients. 14-3-3η is not routinely checked in all patients with arthritis. We aim to see the positivity rate of the 14-3-3η in real-world patients with rheumatoid arthritis compared to other arthritis.

Methods: A retrospective study was conducted via review of electronic medical records after approval by the institutional review board. All patients with a result for the lab test of 14-3-3η in the last five years (March 2018 – February 2023) were included. The data, including demographics, arthritis diagnosis, and relevant lab components, were compared.

Results: Three hundred and twenty-eight patients were tested for 14-3-3η, with 26 (8%) positive results. The mean age was 55 ± 15 years, with 72% female and 84% white. The characteristics of the patients with positive and negative 14-3-3η results are summarized in Table 1. Eighty patients (24%) with positive results were diagnosed with RA, with 39 patients being seropositive. The positivity rate of 14-3-3η was significantly higher in RA patients than other arthritis (14% vs. 6%, p=0.048). Other diagnoses with positive values included undifferentiated arthritis (n=14) and reactive arthritis (n=1). No patients with

Table 1: Distribution of the positive and negative 14-3-3η result

Characteristics	Mean positive 14-3-3η ± SD (ng/ml)	14-3-3η result (positive vs negative)		
		Positive N (%)	Negative N (%)	p-value
Mean age (years)	-	56.3	54.7	0.555
Sex				0.896
Female	3.6 ± 6.3	18 (8)	219 (92)	
Male	2.9 ± 3.7	8 (9)	83 (91)	
Arthritis type				**0.048**
Rheumatoid arthritis (RA)	6.2 ± 7.6	11 (14)	69 (86)	
Other*	1.3 ± 2.1	15 (6)	233 (94)	
Rheumatoid arthritis type				0.343
Seropositive	8.1 ± 8.8	7 (18)	32 (82)	
Seronegative	1.3 ± 1.5	4 (10)	37 (90)	
Rheumatoid factor in RA				0.330
Positive	6.2 ± 7.8	6 (17)	29 (83)	
Negative	4.8 ± 2.4	4 (9)	39 (91)	
Anti-cyclic citrullinated peptide in RA				0.399
Positive	6.8 ± 11.4	3 (20)	12 (80)	
Negative	2.7 ± 4.7	7 (11)	55 (89)	

*Other: Undifferentiated arthritis (including reactive arthritis, osteoarthritis, non-RA and non-psoriatic inflammatory arthritis) (n=195), psoriatic arthritis (n=30), ankylosing spondylitis (n=3)

psoriatic arthritis had positive values. The mean value for 14-3-3η in RA patients was 6.2 ± 7.6 compared to 1.3 ± 2.1 in non-RA patients (p=0.06; reference range 0.2 ng/ml - >20 ng/ml). In the patients with RA, RF was positive in 44%, anti-CCP positive in 19%, and both were positive in 14%, and antinuclear antibody was positive in 25%. The positivity rate of 14-3-3η was numerically higher in seropositive RA compared to those with seronegative RA (18% vs. 10%, p=0.343). The mean value for 14-3-3η in seropositive RA was 8.1 ± 8.8 compared to 1.3 ± 1.5 in seronegative (p=0.09). Logistic regression showed no association between 14-3-3η positivity with age, sex, erythrocyte sedimentation rate, C-reactive protein, RF, or anti-CCP in patients with RA.

Conclusion: 14-3-3η protein is positive more often in patients with RA than in other causes of arthritis but is not exclusive to RA. Although 14-3-3η has been thought to increase the sensitivity of diagnosis of seronegative patients, the positivity rate was only 10% in our study. Further studies are needed to better understand its importance in seronegative patients.

Doyle[1], Gregory Kinney[3], Danielle Sansone-Poe[3], Kendra Young[3], Paul Dellaripa[4], Zachary Wallace[5], Elizabeth Regan[6], Gary Hunninghake[1], Edwin Silverman[1], Samuel Ash[1], Raul San Jose Estepar[1], George Washko[1] and Jeffrey Sparks[7], [1]Brigham and Women's Hospital, Boston, MA, [2]Division of Rheumatology, Inflammation, and Immunity Brigham & Women's Hospital, Boston, MA, [3]University of Colorado Denver, Denver, CO, [4]Brigham and Women's Hospital, Boston, MA, [5]Massachusetts General Hospital, Newton, MA, [6]National Jewish Health, Denver, CO, [7]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) has known extra-articular manifestations that can result in restrictive and obstructive patterns on pulmonary function measures, especially in smokers. However, investigations comparing RA and non-RA for pulmonary function change have not been performed. In this study, we compared longitudinal spirometry measures between smokers with and without RA.

Methods: We analyzed longitudinal data from COPDGene, a multicenter prospective cohort of smokers with at least 10 pack-years. We investigated longitudinal pulmonary function measures in people with RA compared to non-RA comparators and healthy non-smokers. Spirometry was conducted at baseline (2007-2011) and at a second visit 5 years later. RA cases were identified by self-reported RA and DMARD use (PPV 88%); non-RA comparators reported no RA and no DMARD use. The outcomes were the annual change in postbronchodilator percent predicted forced expiratory volume in one second (%FEV_1), percent predicted forced vital capacity (%FVC), and FEV_1/FVC ratio. We compared these outcomes between RA cases and non-RA comparators using linear regression, adjusted for age, sex, BMI, smoking status (current/past), pack-years, baseline spirometry results, and inhaled/systemic medication use for obstructive lung diseases. An

Table 1. Baseline characteristics of RA cases, non-RA comparators and healthy non-smokers (n=5220)

Table 1. Baseline characteristics of RA cases, non-RA comparators and healthy non-smokers (n=5220)

	RA smoker cases (n=45)	Non-RA smoker comparators (n=5175)
Demographic		
Age at enrollment (years, mean, SD)	63.4 (8.0)	59.7 (8.7)
Female (n, %)	30 (67%)	2549 (49%)
White Race (n, %)	33 (73%)	3665 (71%)
Black Race (n, %)	12 (27%)	1510 (29%)
Lifestyle		
Current smoker (n, %)	16 (36%)	2497 (48%)
Former smoker (n, %)	29 (64%)	2678 (52%)
Pack-years (mean, SD)	42.4 (18.6)	42.1 (23.3)
BMI (kg/m^2, mean, SD)	30.8 (8.6)	29.0 (6.0)
Pulmonary features		
Spirometry pattern (n, %)		
Restrictive: %FVC <80% & FEV_1/FVC ≥70%	8 (18%)	662 (13%)
Obstructive: FEV_1/FVC <70%	14 (31%)	2083 (40%)
Normal: none of the above	23 (51%)	2430 (47%)
Inhaled/systemic medication use for obstructive lung disease (n, %)	24 (53%)	1706 (33%)

additional analysis used inverse probability of censoring weighting (IPCW) to account for possible differential censoring, defined by drop-out or death before the follow-up visit was due. We also stratified the analysis by the presence of obstructive pattern (FEV_1/FVC< 0.7) at baseline.

Results: We analyzed 45 RA smoker cases and 5175 non-RA smoker comparators with available follow-up spirometry data (**Table 1**). The mean %FEV_1 at baseline was 77% in RA cases and 80% in non-RA comparators. The mean change in %FEV_1 from baseline to the 5-year follow-up was +1.8% in RA cases and -2.3% in non-RA comparators. Proportions of each group with improved, stable, and declined %FEV_1 are shown in **Figure 1**. In the multivariable linear regression models, both %FEV_1 and FEV_1/FVC showed significantly less decline in RA cases compared to non-RA comparators (%FEV_1: β 0.68, p=0.026; FEV_1/FVC: β 0.52, p=0.002; **Table 2**). This result was more prominent in participants with obstructive pattern at baseline (RA vs. non-RA: %FEV_1: β 1.17, p=0.0025; FEV_1/FVC: β 1.73, p< 0.001). There was no significant difference in the annual change in %FVC between the two groups. Results were similar after accounting for possible differential loss to follow-up or death.

Figure 1. Proportions of each group with improved, stable, and declined %FEV_1 among RA smoker cases (n=45) and non-RA smoker comparators (n=5175).

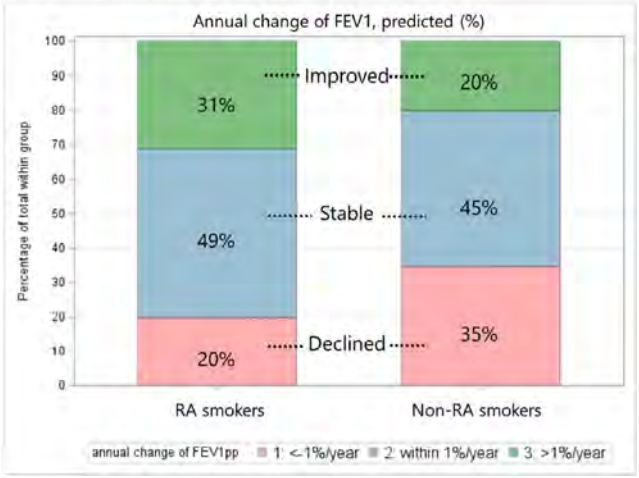

Figure 1. Proportions of each group with improved, stable, and declined %FEV1 among RA smoker cases (n=45) and non-RA smoker comparators (n=5175).

Table 2. Results from the linear regression of annual change of measures in pulmonary function test (PFT), comparing RA smoker cases vs. non-RA smoker comparators.

%FVC	0.33 (0.33)	0.311	0.21 (0.33)	0.517	0.08 (0.32)	0.813
Obstructive pattern ($FEV_1/FVC<70\%$) at baseline: RA cases: n=14, non-RA comparators: n=2083						
%FEV	**1.37 (0.54)**	**0.012**	**1.17 (0.52)**	**0.025**	**1.05 (0.53)**	**0.048**
$FEV_1/FVC_{(*100)}$	**1.81 (0.38)**	**<0.001**	**1.73 (0.37)**	**<0.001**	**1.62 (0.37)**	**<0.001**
No obstructive pattern ($FEV_1/FVC\geq70\%$) at baseline: RA cases: n=31, non-RA comparators: n=3093						
%FEV	0.38 (0.35)	0.274	0.21 (0.33)	0.529	0.17 (0.34)	0.611
$FEV_1/FVC_{(*100)}$	-0.12 (0.17)	0.497	-0.07 (0.17)	0.666	-0.06 (0.18)	0.712

Annual change of spirometric measure = (PFT at baseline – PFT at 2nd visit)/(years from baseline to 2nd visit)
Adjusted for age, sex, smoking status (current/past), pack-years, body mass index, spirometric measure (%FEV_1, FEV_1/FVC, or %FVC) at baseline, and medication use for obstructive lung diseases
Inverse probability of censoring weighting (IPCW) was calculated using baseline characteristics (RA/non-RA status, age, sex, race, smoking status, pack-years, body weight, body mass index, limit of walking, cancer, cardiovascular disease, diabetes, hypertension, hyperlipidemia, and spirometric measure at baseline).

Conclusion: In this first comparative study among smokers to examine longitudinal pulmonary function in RA, RA cases were less likely to have %FEV_1 and FEV_1/FVC declines than non-RA comparators. Results were strongest among RA cases with baseline obstructive defect and not explained by differences in smoking, suggesting that RA with obstruction may be a unique phenotype. Further studies are needed to replicate with larger sample size and to examine mechanisms and potential for reversibility related to systemic inflammation, autoimmunity, and RA treatment.

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) adherence is suboptimal and is associated with disease flare, DAS-28 response, radiographic damage and healthcare costs. Adherence can be measured using self-reported questionnaires such as the validated Medication Adherence Report Scale (MARS-5). Often the prescriber is blinded to patient non-adherence and self-reported adherence may be an underestimate. Our group has previously developed a sensitive biochemical assay for the detection of MTX adherence, The Methotrexate use Improvement in Rheumatoid Arthritis using Biomarker Feedback (MIRA) is a feasibility trial designed to assess the feasibility of a randomised controlled trial of MTX biochemical adherence biofeedback. Here we investigate the agreement between self-reported and biochemical adherence.

Baseline biochemical non-adherence	4 (17)	4 (15)

Table 2. Biochemical and self-reported adherence at baseline and follow-up

Biochemical Adherence n(%)	Self-reported MARS-5 Adherence		
Baseline	Non-adherent	Adherent	Missing
Adherent	3 (6)	35 (71)	3 (6)
Non-adherent	5 (10)	3 (6)	0 (0)
Follow-up	Non-adherent	Adherent	Missing
Adherent	6 (12)	32 (65)	2 (4)
Non-adherent	3 (6)	5 (10)	1 (2)

Methods: MIRA is a prospective multi-centre randomised controlled trial investigating the feasibility of a fully powered randomised controlled trial to examine if a biochemical adherence guided intervention is superior to standard clinical care in RA patients. All analyses are exploratory in nature. RA patients prescribed oral MTX for ≥ two years were randomised 1:1 to receive biochemical adherence biofeedback or control (figure 1). Clinico-demographics, biochemical MTX adherence, MARS-5 and DAS-28 were measured at baseline and three months. Self-reported MARS-5 adherence was dichotomised and agreement with biochemical adherence analysed using Cohen's Kappa.

Results: 57 participants were recruited, withdrawal rate was 14% and reasons given were intercurrent illness, lost contact, withdrawn consent and one patient died during follow-up leaving full outcome data available for 49 participants. Baseline clinico-demographics were similar in control and intervention cohorts (Table 1).

Biochemical adherence worsened in the control cohort and improved in the intervention cohort (83 to 70%, 85 to 92% respectively) whilst change in DAS(CRP)-28 worsened in the control cohort and improved in the intervention cohort (-0.04 STD 1.26 and 0.38 STD 0.78 respectively). Self-reported and biochemical adherence demonstrated fair agreement (κ=0.24) at baseline but poor (κ=0.09) at follow-up (Table 2).

Conclusion: The MIRA trial has shown early evidence of biofeedback improving MTX biochemical adherence and DAS-28 compared to control. Poor agreement between self-reported and biochemical adherence suggests biochemical adherence may be a more clinically useful measure of adherence.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Physical activity has numerous benefits for Rheumatoid Arthritis (RA) patients such as reducing symptoms like fatigue and pain and improving physical function. The International *Physical Activity Questionnaire - Short Form* (IPAQ-SF) is a widely used self-administered questionnaire consisting of seven items that measures physical activity levels in minutes and metabolic equivalents (METs) over the previous week. The aim of this study was to evaluate physical activity levels in RA patients and explore potential associations with patient characteristics, disease activity, functional capacity, quality of life, anxiety, depression, and treatment.

Methods: Multicenter, analytical, observational, cross-sectional study. Patients ≥ 18 years old with a diagnosis of RA (ACR-EULAR 2010) were included. Sociodemographic data, habits, comorbidities, body mass index (BMI), RA characteristics, Clinimetrics measures and treatment were collected. In addition, participant's physical activity levels were assessed using the IPAQ-SF. **Statistical analysis:**Descriptive statistics. The results of IPAQ-SF were compared according to patient characteristics, disease activity, functional capacity, quality of life, anxiety, depressionand treatment by means of an appropriate test: Student T-test, Wilcoxon, Pearson, ANOVA, or Spearman. Significance level was set at 0.05.

Results: A total of 101 patients from five centers were included. Patient characteristics are shown in **Table 1**. Results of clinical measurements can be observed in **Table 2** and RA treatment in the **Figure**.A total of 31% practiced sports, with a mean of 24 months (SD 8.5). The IPAQ-SF reported a median total physical activity of 1386 METs (IQR 594-3066), with an average frequency of 7 days (IQR 3-7) and 119 minutes (SD 94.9) per week: 42% had low activity, 31% moderate, and 28% high. Median sitting time was 4.4 hours per day (IQR 2-7). Total METs median was associated with higher education (p=0.008) and sports practice (p< 0.0001). Correlation was negative with BMI (p=0.01), functional class (FC, p=0.002), P-VAS (p=0.008), PtGA-VAS (p=0.01), fatigue VAS (p=0.02), DAS28 (p=0.009) and HAQ-A (p< 0.0001). Mean total MET was higher in patients who didn't required assistance in daily activities (p=0.0005). In addition, weekly physical activity minutes showed a negative

Figure. Treatment of RA (N=101)

association with PtGA-VAS (p=0.02). A higher minute mean was observed in those who practiced sports (p=0.0001), had no comorbidities (p=0.04) and didn't need assistance (p=0.01). Physical activity day mean was higher in non-smokers (p=0.02), sports players (p=0.002), those with no erosive disease (p=0.002) and those with no need for assistance (p=0.001). High physical activity was linked to no comorbidities (p=0.02), sport practice (p< 0.001) and no assistance need (p=0.004). Patients without corticosteroids (p=0.012) and no erosive disease (p=0.012) showed more moderate/high physical activity.

Conclusion: Fifty-eight percent of the patients had moderate/high physical activity, positively associated with sports, lower RA activity and better function. Fewer comorbidities and glucocorticoid treatment were observed in this RA cohort.

Impact of Sociodemographic Factors on Efficacy and Safety of Tofacitinib in Patients with Rheumatoid Arthritis: A Post Hoc Analysis of Phase 2/3/3b/4 Studies

Grace Wright[1], Eduardo Mysler[2], Kevin Roberts[3], Lindsay Sweet[4] and Ahmed Shelbaya[5], [1]Grace C Wright MD PC, New York, NY, [2]Organizacion Medica de Investigacion, Buenos Aires, Argentina, [3]Pfizer Inc., Cambridge, MA, [4]Pfizer Inc., Collegeville, PA, [5]Pfizer Inc., New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sociodemographic factors can impact treatment response and safety outcomes in patients (pts) with RA. Here, we explore the impact of sociodemographic index (SDI) on the efficacy and safety of tofacitinib and adalimumab in pts with RA.

Table 1. Demographics and BL disease characteristics for all pts,[a] stratified by SDI tertiles[b]

	Low SDI (N=1,969)	Medium SDI (N=1,538)	High SDI (N=3,071)

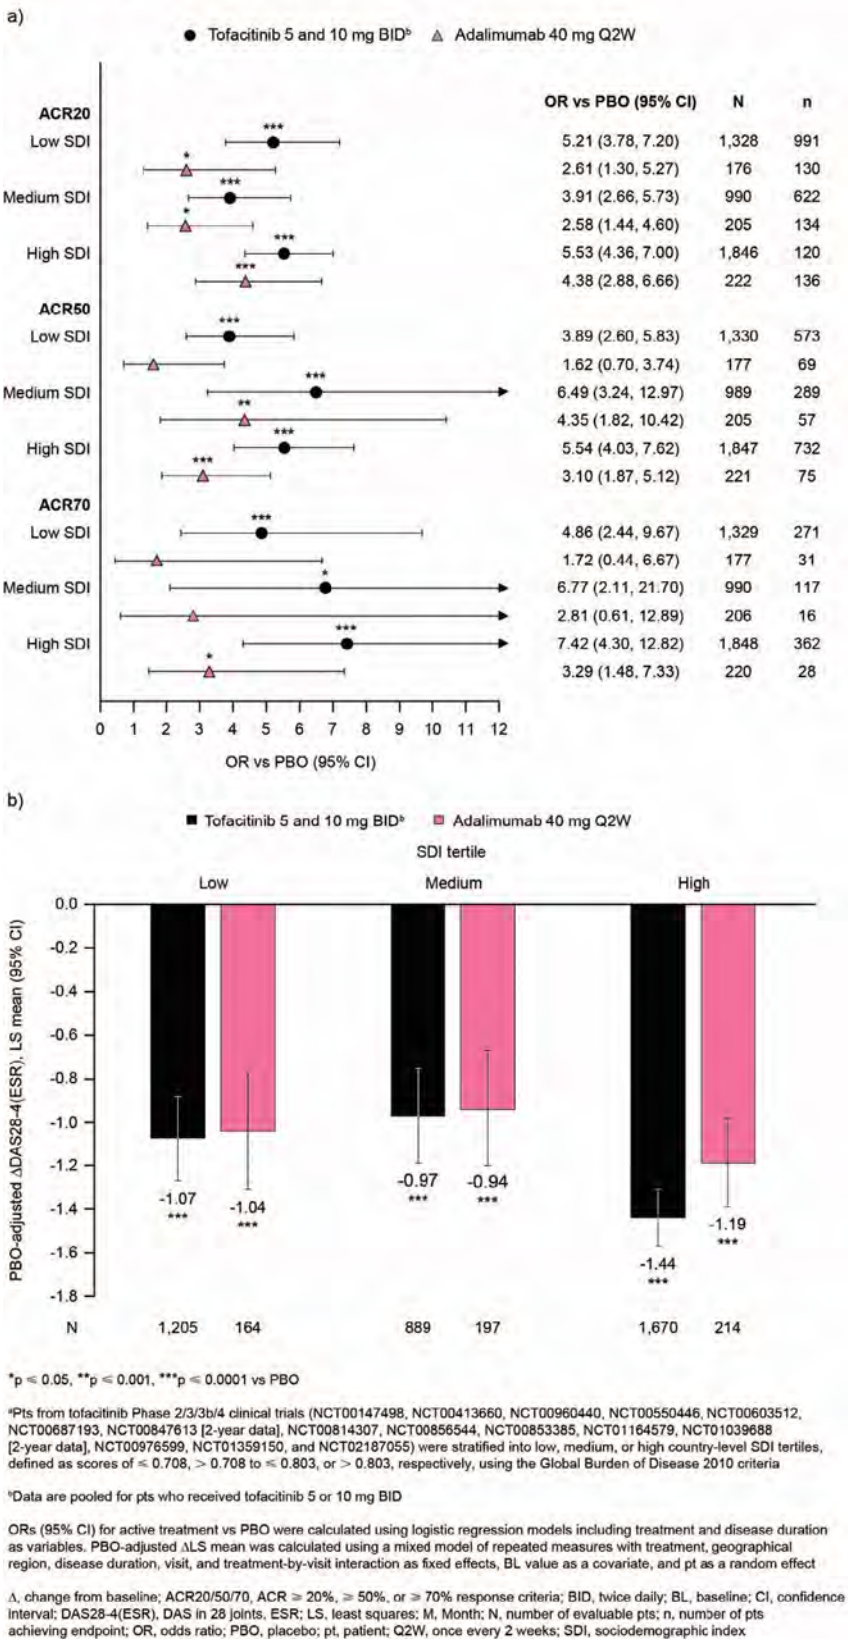
Hypertension at BL (yes), n (%)	501 (25.4)	606 (39.4)	1,165 (37.9)

[a]Includes pts enrolled in tofacitinib Phase 2/3/3b/4 clinical trials (NCT00147498, NCT00413660, NCT00960440, NCT00550446, NCT00603512, NCT00687193, NCT00847613 [2-year data], NCT00814307, NCT00856544, NCT00853385, NCT01164579, NCT01039688 [2-year data], NCT00976599, NCT01359150, and NCT02187055), receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, placebo, adalimumab, or methotrexate

[b]Pts were stratified into low, medium, or high country-level SDI tertiles, defined as scores of ≤ 0.708, > 0.708 to ≤ 0.803, or > 0.803, respectively, using the Global Burden of Disease 2010 criteria

bDMARD, biologic DMARD; BID, twice daily; BL, baseline; N, number of evaluable pts; n, number of pts with characteristic; pt, patient; SD, standard deviation; SDI, sociodemographic index; TNFi, TNF inhibitor; US, United States

Fig 1. a) ORs (95% CI) for ACR20/50/70 responses and b) ΔDAS28-4(ESR), at M3, stratified by treatment group and SDI tertile[a]



*p ⩽ 0.05, **p ⩽ 0.001, ***p ⩽ 0.0001 vs PBO

[a]Pts from tofacitinib Phase 2/3/3b/4 clinical trials (NCT00147498, NCT00413660, NCT00960440, NCT00550446, NCT00603512, NCT00687193, NCT00847613 [2-year data], NCT00814307, NCT00856544, NCT00853385, NCT01164579, NCT01039688 [2-year data], NCT00976599, NCT01359150, and NCT02187055) were stratified into low, medium, or high country-level SDI tertiles, defined as scores of ⩽ 0.708, > 0.708 to ⩽ 0.803, or > 0.803, respectively, using the Global Burden of Disease 2010 criteria

[b]Data are pooled for pts who received tofacitinib 5 or 10 mg BID

ORs (95% CI) for active treatment vs PBO were calculated using logistic regression models including treatment and disease duration as variables. PBO-adjusted ΔLS mean was calculated using a mixed model of repeated measures with treatment, geographical region, disease duration, visit, and treatment-by-visit interaction as fixed effects, BL value as a covariate, and pt as a random effect

Δ, change from baseline; ACR20/50/70, ACR ⩾ 20%, ⩾ 50%, or ⩾ 70% response criteria; BID, twice daily; BL, baseline; CI, confidence interval; DAS28-4(ESR), DAS in 28 joints, ESR; LS, least squares; M, Month; N, number of evaluable pts; n, number of pts achieving endpoint; OR, odds ratio; PBO, placebo; pt, patient; Q2W, once every 2 weeks; SDI, sociodemographic index

Methods: This post hoc analysis used pooled data from Phase 2/3/3b/4 studies of pts with RA receiving tofacitinib 5 or 10 mg twice daily (BID), adalimumab 40 mg every 2 weeks, or placebo (PBO). At a country level, pts were stratified into low, medium, or high SDI tertiles, defined as scores of ≤ 0.708, > 0.708 to ≤ 0.803, or > 0.803, respectively, using the Global Burden of Disease 2010 criteria. Efficacy outcomes assessed at Month (M)3 included ACR20/50/70 responses (odds ratios for active treatment vs PBO calculated via logistic regression models, by SDI tertile) and change from baseline (Δ) for DAS in 28 joints, ESR (DAS28-4[ESR]; PBO-adjusted, assessed for active treatments via a mixed model of repeated measures, by SDI tertile). Incidence rates (IRs; pts with first events/100 pt-years) for safety outcomes to M24 were calculated for each treatment group, by SDI tertile.

Results: Of pts included (low SDI, N=1,969; medium SDI, N=1,538; high SDI, N=3,071), there was a higher percentage aged > 50 years, located in North America, of ever smokers and prior biologic DMARD users, and RA duration was longer, in the high vs low/medium SDI tertiles (Table 1). Across SDI tertiles, efficacy at M3 was generally greater with tofacitinib and adalimumab vs PBO (Fig 1). Odds ratios vs PBO showed that ACR20/50/70 responses at M3 for tofacitinib and adalimumab were generally numerically greatest in the high SDI tertile, but 95% confidence intervals (CIs) overlapped between tertiles (Fig 1a). PBO-adjusted ΔDAS28-4(ESR) at M3 was numerically greater in the high vs medium/low SDI tertile with tofacitinib and adalimumab (Fig 1b). In the PBO group at M3, fewer pts in the high vs low SDI tertile achieved ACR20/50/70 (ACR20: 25.3% [113/447] vs 35.1% [71/202]); similarly, mean ΔDAS28-4(ESR) was smaller in pts with high vs low SDI (-0.58 [N=406] vs -1.17 [N=173]). Across treatments,IRs for safety outcomes were generally numerically greatest in the high SDI tertile, but 95% CIs overlapped between tertiles (Table 2).

Conclusion: Pts with RA responded better to active treatment vs PBO at M3, regardless of SDI. Across efficacy outcomes, PBO-adjusted treatment responses were generally numerically greatest in the high SDI tertile; PBO responses were lowest in this tertile. IRs of adverse events were generally numerically highest in the high SDI tertile, in all treatment groups. 95% CIs overlapped for numerical differences between tertiles. Results were confounded by differences in baseline smoking status, prior biologic DMARD use, concomitant medications, and RA duration between SDI tertiles. Data represent SDI at country level, which does not account for within-country variation.

Table 2. IRs (95% CI) for safety outcomes up to M24, stratified by treatment group and SDI category[a]

	IR (95% CI)

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic kidney disease (CKD) is a common comorbidity of rheumatoid arthritis (RA) affecting 10-20% of patients. However, the influence of the longitudinal RA disease activity on the long-term prognosis of kidney function has not been thoroughly evaluated.

Methods: We conducted a longitudinal study using the prospective CorEvitas RA registry and included patients with eGFR ≧60 mL/min/1.73 m^2 at baseline for whom kidney function was recorded at least twice from 2001 to 2022. The primary outcome was eGFR change from the baseline visit; secondary outcome was development of CKD G3b or worse (eGFR < 45 mL/min/1.73 m^2 for more than 3 months). The category of time-averaged Clinical Disease Activity Index (CDAI) until each visit was an exposure of interest. We used all visit data in primary analyses, and data only from patient visits where time-averaged CDAI was stable in one category from the baseline were used in secondary analyses. Multivariable mixed-effect random intercept and slope model with the interaction term of time and time-averaged CDAI was used to evaluate the association between CDAI categories and changes in the slope of eGFR. We adjusted for baseline variables including age, sex, race, eGFR, RF/CCP, and secondary Sjogren's syndrome. Body mass index, smoking status, modified Health Assessment Questionnaire, C-reactive protein, comorbidities, and the use of medications (non-steroidal anti-inflammatory drugs, glucocorticoids, and each of disease-modifying antirheumatic drugs) were included as time-varying covariates. Kaplan-Meier curves and multivariable Cox proportional hazard models were used to evaluate the hazard ratio (HR) of time-averaged CDAI categories for the development of CKD G3b or worse renal function. We adjusted for baseline covariates in the survival analyses.

Results: We included 31,129 patients with 234,973 visits in the analyses. The mean (standard deviation) age was 57.3 (12.9) years, and 23,758 (76.3%) were female with a median follow-up of 3.5 years. The mean baseline eGFR was 90.2 ml/min/1.73 m^2 (Table 1). The mixed-effect model showed that the annual eGFR decline was -0.855 mL/min/1.73 m^2 in

Table 1. Baseline characteristics of patients with rheumatoid arthritis by the disease activity

	Remission N=6,647	Low disease activity N=10,028	Moderate disease activity N=8,548	High disease activity N=5,906

Biological DMARDs	47.0%	46.5%	48.2%	51.1%
JAK inhibitors	1.6%	2.2%	2.9%	2.9%

Note:
DMARDS: disease-modifying antirheumatic drugs.
Categorical variables were presented as percentages. Continuous variables are presented as mean (standard deviation) or median (interquartile range) based on their distribution.

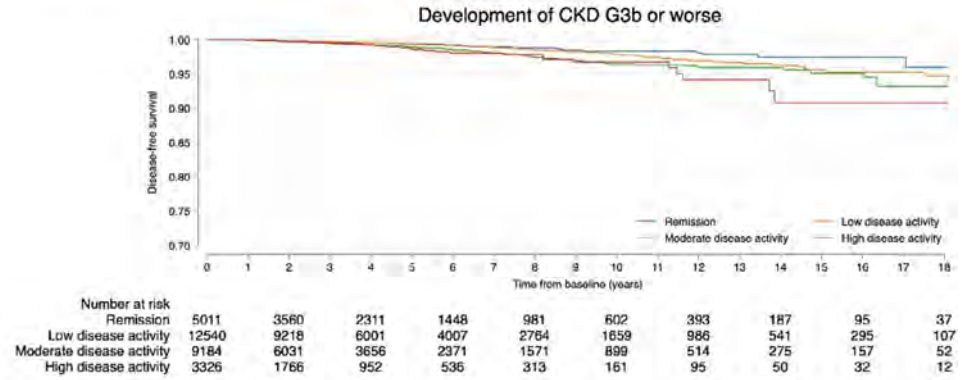
RA remission. Patients with low, moderate, and high disease activity had additional -0.070, -0.150, and -0.168 ml/min/1.73 m^2 declines annually vs. patients in remission. Secondary analyses revealed larger differences in the eGFR slopes between time-averaged CDAI categories (Table 2). Kaplan-Meier curve showed RA patients with higher disease activity developed more CKD G3b (Figure 1). Adjusted HRs (95%CI) were 1.12 (0.77-1.63) in low, 1.47 (1.00-2.20) in moderate, and 1.84 (1.11-3.05) in high disease activity patients for CKDG3b.

Table 2. Disease activity of rheumatoid arthritis and annual eGFR slope changes

	Primary analyses				Secondary analyses			
	Coefficient	95%CI		p value	Coefficient	95%CI		p value
Annual eGFR change (mL/min/1.73 m2)	-0.855	-0.912	-0.799	< 0.001	-0.819	-0.926	-0.711	< 0.001
Differences in the eGFR slope (mL/min/1.73 m2)								
Remission	Ref				Ref			
Low Disease Activity	-0.070	-0.130	-0.010	0.021	-0.108	-0.247	0.031	0.128
Moderate Disease Activity	-0.150	-0.221	-0.079	< 0.001	-0.403	-0.562	-0.243	< 0.001
High Disease Activity	-0.168	-0.270	-0.066	0.001	-0.456	-0.645	-0.267	< 0.001

Note:
CI: confidence intervals, eGFR: estimated Glomerular Filtration Rate.
We used all visit data in primary analyses. In secondary analyses, data only from patient visits where ta-CDAI was stable in one category from baseline were used.
We adjusted for age, sex, race, eGFR, RF/ACPA, and secondary Sjogren's syndrome at baseline. Body mass index, smoking status, modified Health Assessment Questionnaire, C-reactive protein, comorbidities, and the use of medications were included as time-varying covariates.

Figure 1. Development of CKDG3b or worse by disease activity of rheumatoid arthritis



Number at risk										
Remission	5011	3560	2311	1448	981	602	393	187	95	37
Low disease activity	12540	9218	6001	4007	2764	1659	986	541	295	107
Moderate disease activity	9184	6031	3656	2371	1571	899	514	275	157	52
High disease activity	3326	1766	952	536	313	161	95	50	32	12

Note:
CKD: chronic kidney disease. CKD G3b was defined as eGFR < 45 mL/min/1.73 m^2 for more than 3 months.
We adjusted for baseline variables including age, sex, race, body mass index, smoking status, eGFR, comorbidities, secondary Sjogren's syndrome, RF/ACPA, modified Health Assessment Questionnaire, C-reactive protein, and medications

Conclusion: After adjusting for potential confounders, RA patients with higher disease activity had a larger decline in eGFR and developed clinically significant CKD more frequently. This study suggests that controlling the disease activity of RA may potentially improve renal prognosis.

Genetic Risk Load as a Predictor of Radiographic Damage and Mortality in Female Patients with Rheumatoid Arthritis

Jihye Kim[1], Yeon-Kyung Lee[2], Youngho Park[3], Ayeong Kwon[4], Young-Chang Kwon[1], Young Bin Joo[2], Hye-Soon Lee[5], Kwangwoo Kim[4], Sang-Cheol Bae[6] and **So-Young Bang**[2], [1]Hanyang University Institute for Rheumatology Research, Seoul, South Korea, [2]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [3]Department of Business Statistics, Hannam University, Daejeon, South Korea, [4]Department of Biology, Kyung Hee University, Seoul, South Korea, [5]Hanyang University, Guri, South Korea, [6]Hanyang University Hospital for Rheumatic Diseases and Hanyang University Institute for Rheumatology Research, Department of Rheumatology, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by an unpredictable prognosis and increased mortality risk. Although the role of genetics in RA mortality remains undefined, this study aimed to investigate the clinical and genetic contributions to radiographic damage and mortality in female RA patients.

Methods: The Korean patients with RA were recruited from a prospective BAE RA cohort at Hanyang University Hospital for Rheumatic Diseases since 2001. Baseline demographics, clinical features, autoantibodies profiles, and radiologic damage were collected. All patients were genotyped using four-digit HLA–DRB1 typing and genome-wide association study (GWAS). Weighted genetic risk score (wGRS) was calculated from 100 well-validated non-HLA SNPs and HLA–DRB1 haplotypes in amino acid positions 11, 13, 71, and 74. Individual wGRS was tested for associations with clinical features, and radiologic damage by using multivariable regression. Cox proportional hazards models were used to examine the associations with wGRS and mortality.

Results: A total of 1,788 female patients were genotyped and included in the analysis. Mortality data were obtained from registered death records provided by Statistics Korea for the period between 2001 and 2018, with 175 deaths reported during this observation period. Multivariable linear regression analysis was employed to assess the independent effects of genetic risk load on radiographic damage and mortality, irrespective of age and disease duration. The analysis revealed a significant association between ever-smokers and high wGRS with increased radiographic damage. Moreover, patients with erosive RA exhibited a higher incidence risk of all-cause mortality, even after adjusting for age, smoking status, and disease duration.

Conclusion: The findings of this study demonstrate that genetic risk load, which implicates pathogenesis, could serve as a predictor of a poor clinical course in female patients with RA. These results emphasize the importance of considering genetic factors in assessing the prognosis and mortality risk in RA patients.

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are known to have an increased risk of tuberculosis, particularly in association with the use of biologic disease-modifying anti-rheumatic drugs (bDMARD) including tumor necrosis factor-α (TNF-α) inhibitors. Korea is a country with a intermediate risk of tuberculosis, and large-scale studies on the risk of tuberculosis in patients with RA in Korea are still lacking. Our study aimed to identify the risk of tuberculosis in patients with RA compared to the general population in a large population-based cohort, and to identify factors associated with the risk of tuberculosis in patients with RA.

Methods: Among patients diagnosed with RA between 2010 and 2017, patients who had undergone a national health examination within two years prior to RA diagnosis were included in the study (n = 59,577). Control group included age- and sex-matched non-RA controls who received a health check-up at the same time as RA patients (n = 297,885). The primary outcome of the study was incident tuberculosis, which was defined by an ICD-10 code and enrollment in the rare intractable disease program. Kaplan-Meier curves and Cox proportional hazards regression analysis were used for the analysis

Results: During a mean follow-up period of 4.5 ± 2.2 years, 979 subjects in the control group and 619 patients in the RA group developed tuberculosis. Patients with RA had a 3-fold higher risk of tuberculosis than age- and sex-matched non-RA controls (adjusted hazard ratio [aHR] 3.02, 95% confidence interval [CI] 2.73–3.35). The association between RA and tuberculosis was more prominent in young adults aged 20-39 years. Using the control group as the reference, the aHR of tuberculosis in bDMARD-naïve patients with RA was 2.87 (95% CI 2.58–3.19), and the aHR of tuberculosis in bDMARD-exposed patients with RA was 4.97 (95% CI 3.92–6.29). In patients with RA, male sex, advanced age, underweight, diabetes, hypertension, airway disease, and bDMARD exposure were associated with an increased risk of tuberculosis.

Conclusion: In a nationwide population-based cohort in Korea with a intermediate risk of tuberculosis, patients with RA had a three-fold higher risk of tuberculosis than age- and sex-matched controls, and even bDMARD-naïve patients had a higher risk of tuberculosis than the general population. Even in patients who do not use bDMARDs, if suspicious symptoms occur, the possibility of tuberculosis should be considered.

Frailty Is Associated with Mortality in Veterans with Rheumatoid Arthritis

Sayuli Bhide[1], Punyasha Roul[2], Namrata Singh[3], Grant Cannon[4], Gary Kunkel[5], Ted R Mikuls[6], Bryant England[2], Dolores Shoback[7], Patti Katz[8], Jose Garcia[9], Ariela Orkaby[10], Joshua Baker[11] and K Wysham[12], [1]University of Washington, Seattle, WA, [2]University of Nebraska Medical Center, Omaha, NE, [3]University of Washington, Bellevue, WA, [4]University of Utah and Salt Lake City VA, Salt Lake City, UT, [5]University of Utah, Salt Lake City, UT, [6]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE, [7]San Francisco VA Medical Center, San Francisco, CA, [8]University of California San Francisco, San Rafael, CA, [9]VA Puget Sound Healthcare System, Seattle, WA, [10]Veterans Affairs Boston Healthcare System & Brigham and Women's Hospital, Harvard Medical School, Boston, MA; VA Geriatric Research Education and Clinical Center, Boston, MA, [11]University of Pennsylvania, Philadelphia, PA, [12]VA Puget Sound/ University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty is established as an important predictor of mortality in the general population.1Rheumatoid arthritis (RA) is associated with higher rates of frailty than the general population,[2] yet how frailty impacts important outcomes in RA, such as mortality, is less well understood. We sought to evaluate the relationship between frailty and mortality in a cohort of Veterans with RA.

Methods: Data were obtained from the Veterans Affairs Rheumatoid Arthritis (VARA) Registry from 1/2003 through 12/2021. The VA Frailty Index(VA-FI) is a validated deficit accumulation index based on 31 health deficits mapped from >6000 diagnostic codes found in administrative claims and electronic health records of Veterans. The VA-FI was calculated

for each participant at baseline using diagnostic codes with a 3-year look-back period. The VA-FI scores were categorized as robust, pre-frail and frail based on established cutoffs. Death data were obtained from the VA Corporate Data Warehouse vital statistics records. Cox proportional hazard regression models were used to evaluate the relationship between baseline frailty and mortality controlling for baseline age, sex, race, body mass index, anti-cyclic citrullinated peptide (CCP) status, RA disease duration, smoking status, rheumatic disease comorbidity index, use of prednisone, conventional synthetic disease modifying anti-rheumatic drugs (DMARDs) and biologic DMARDs.

Results: 3,007 Veterans were studied with a mean age of 64.4±11.1 years and 85% were male (Table 1). Over 16,515 person-years of follow-up, 43% (N=1,293) Veterans died. Those who died were older (68.9 vs. 61.0 years), more likely to be male (95% vs. 82%) and had higher rates of high disease activity (21% vs 12%, respectively). Those who died also had

-Variables with <5% missing data were not included in this table.
*CCP antibody status variable is missing N = 550 (18%). Data above for CCP antibody status are % of non-missing.

Table 2: Unadjusted and adjusted Cox proportional hazard models showing the risk of mortality by baseline frailty status.			
	Hazard Ratio (HR)	[95% confidence interval]	p-value
Unadjusted*			
Robust	Ref	--	--
Pre-Frail	1.69	1.46 – 1.95	<0.0001
Frail	1.89	1.63 – 2.20	<0.0001
Adjusted**			
Robust	Ref	--	--
Pre-Frail	1.43	1.22 – 1.69	<0.0001
Frail	1.90	1.56 – 2.30	<0.0001
*Unadjusted model: Number of subjects = 3,008 subjects. Number of deaths = 1,291. **Adjusted model: Number of subjects = 2,373 subjects. Number of deaths = 1,187. Model adjusted for age, sex, race, body mass index, anti-CCP status, disease duration, smoking status, rheumatic disease comorbidity index, prednisone use, csDMARD use and bDMARD use.			

higher prevalence of baseline pre-frailty and frailty compared to those who did not die (40% vs. 34% and 38 vs. 30%, respectively). In multivariable models, pre-frailty and frailty were independently associated with a higher risk of death(HR 1.43 [95%CI 1.22-1.69] and 1.90 [95%CI 1.56-2.30], respectively) (Table 2).

Conclusion: Higher baseline frailty is independently associated with an increased risk of death in Veterans with RA. The VA-FI may serve as a tool to aid in early recognition of frailty in people with RA. Further research is necessary regarding the applicability of these findings in informing prognostication and RA disease interventions in vulnerable adults.

New Onset Disability in Rheumatoid Arthritis Is an Underrecognized Cardiovascular Risk Factor: A Retrospective Cohort Study Using the CorEvitas Registry

Robert Spandorfer[1], Kevin Kane[2], George Reed[2], Dimitrios Pappas[2], Joel Kremer[2], Jeffrey Curtis[3] and Iris Navarro-Millán[4], [1]Hospital for Special Surgery, Brooklyn, NY, [2]CorEvitas, LLC, Waltham, MA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Weill Cornell Medicine, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease (CVD) is the most common cause of death among patients with RA. Prior research found a higher rate of CVD events associated with disability among patients with RA. There is insufficient data however on disease activity and duration in this population, and the impact of new-onset disability is unknown. We need to understand these factors to develop sufficient preventive measures for patients with RA and disability. We hypothesize that

Table 1. Baseline characteristics of patients with rheumatoid arthritis younger than age 65, overall and by disability status*.

*Disabled and working groups were coarse-matched by age in 10-year intervals and matched by sex 4:1.

among patients with RA younger than 65 years of age, new-onset disability is associated with a higher risk for CVD, and the primary contributing factors include traditional risk factors, disease characteristics, and medications.

Methods: This retrospective cohort study using the CorEvitas RA registry included patients age < 65 years who were working as of registry enrollment and had no history of CVD (MI, CAD, CVA, TIA, or PAD). The exposure was new-onset disability defined as a change from working to disabled while < 65 years or to retired while < 60 years. The comparator group was patients consistently working who were age- and sex-matched in a 4:1 ratio to the newly disabled. Demographics, comorbidities, RA-specific variables, and medications at baseline (time of onset of disability or enrollment for matched controls) were analyzed using descriptive statistics. Incidence rates of CVD for each group were calculated using Poisson regression. We built sequential Cox proportional hazards models with age as the time axis to identify the factors that best explained the excess CVD risk associated with disability among patients with RA. We selected covariates based on the association with CV risk or new-onset disability in the univariate analysis.One set of models used all factors at baseline; a second set allowed for time-varying covariates.

Results: 8370 patients were included (1674 in the disabled group and 6696 in the working group) with an overall mean age of 53 years and 80.7% female (Table 1). Mean follow-up was 10 years. Almost half (46%) of the disabled group reported depression compared to 9.14% in the working group ($p < 0.001$). The age and sex-adjusted incidence rate of CV events was 5.40 (95% CI 3.88, 7.52) events per 1000 person-years in the disabled group and 2.17 (95% CI 1.68, 2.80) in the non-disabled group ($p < 0.001$). The hazard ratio (HR) for CVD associated with disability was 2.32 (95% CI 1.52, 3.53) in the age- and sex-adjusted model, 1.78 (95% CI 1.09, 2.91) in the fixed covariate model, and 1.86 (95% CI 1.12, 3.08) in the time-varying model (Table 2). No model fully explained the excess risk for CVD in the disabled population as a significant association persisted despite multivariate adjustment.

Table 2. Hazard ratio (HR) for cardiovascular disease event among RA patients with and without disability. Univariate and multivariable-adjusted Cox proportional hazards models with fixed and time-varying covariates shown.

Table 2. Hazard ratio (HR) for cardiovascular disease event among RA patients with and without disability. Univariate and multivariable-adjusted Cox proportional hazards models with fixed and time-varying covariates shown.

Education (college vs. no college education)	0.61 (0.40, 0.93)	0.020	0.68 (0.44, 1.05)	0.083	0.62 (0.39, 0.99)	0.045

CVD = cardiovascular disease
mHAQ = modified Health Assessment Questionnaire.
Notes: All models adjusted by age and sex as the disabled and working groups were matched by age and sex.
*CVD risk factor present means the presence of at least one of the following: hypertension, diabetes, hyperlipidemia.
[a]Time varying covariates included CVD risk factors, mHAQ, Smoking status, Opioid use, and Prednisone dose> 5mg.

Conclusion: Patients younger than 65 with RA who experience new-onset disability are at significantly higher risk for CVD compared to age- and sex-matched non-disabled patients with RA. This excess risk is partially explained by traditional risk factors, reduced physical function, and medications, but much of the risk remains unexplained. This is likely due to unmeasured variables, such as social determinants of health and related health behaviors. We thus need to examine how a holistic approach in patient care may mitigate this excess CVD risk in RA patients with disability.

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Alarmins are endogenous cytokines released following cellular damage and physiologic stress to promote homeostasis through tissue inflammation, remodeling, and fibrosis. Alarmins may facilitate maladaptive responses that play a role in the development of chronic inflammatory diseases, including RA (*Ebina-Shibuya R, Nat Rev Immunol*

Table 1. Association of serum alarmins with prevalent cardiovascular disease

Table 1. Association of serum alarmins with prevalent cardiovascular disease (N=2,528)

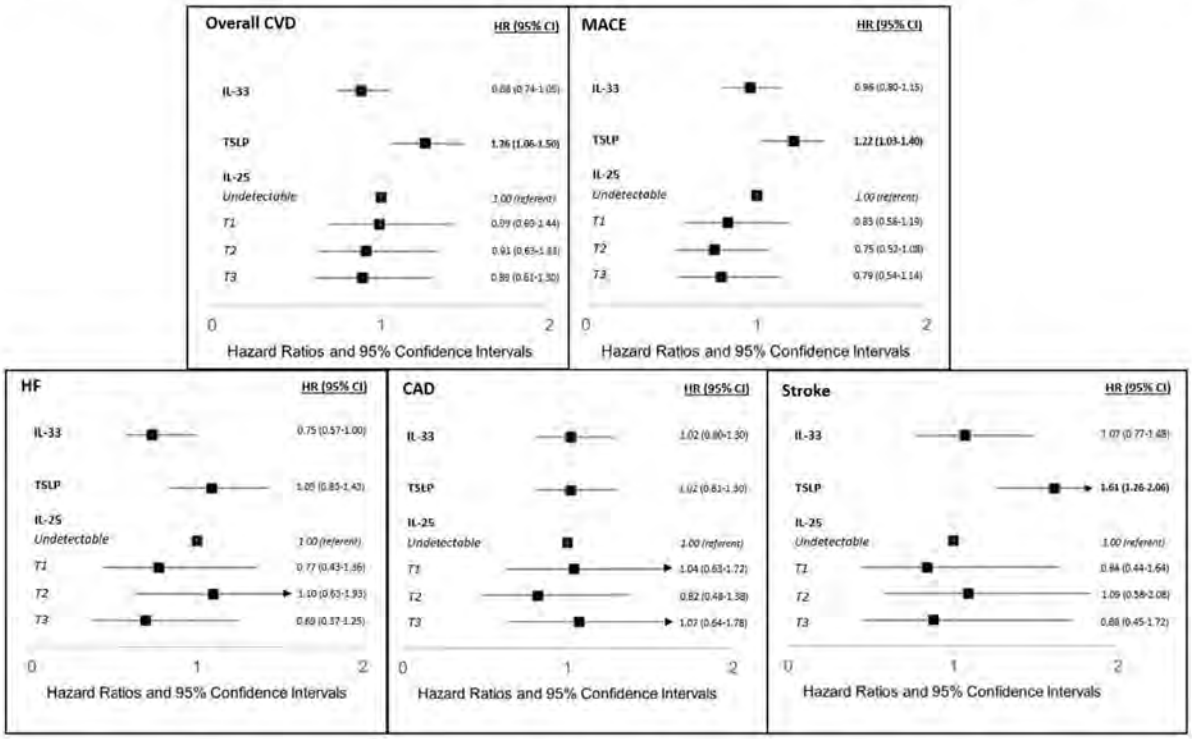
2023). Whereas studies have implicated alarmins in cardiovascular disease (CVD) pathogenesis, it is unknown whether they may serve as a marker of CVD risk in RA. We examined associations of serum alarmin concentrations with CVD in a prospective RA cohort.

Methods: In a multicenter, prospective cohort of US Veterans with RA, we identified MACE (myocardial infarction, coronary revascularization, stroke, or CVD-related death) and heart failure (HF) hospitalizations before and after registry enrollment using validated administrative algorithms in linked VA, Medicare, and National Death Index data. From banked serum at registry enrollment, we measured the alarmins IL-25, IL-33, and thymic stromal lymphopoietin (TSLP) using U-PLEX immunoassay (Meso Scale Discovery). Given their distributions, IL-33 and TSLP concentrations were log-transformed and standardized (per 1 SD).Detectable IL-25 was categorized into tertiles (undetectable values as referent). Cross-sectional associations of alarmin concentrations with prevalent CVD were examined in multivariable logistic regression models. We then followed participants without prevalent CVD from registry enrollment to incident MACE, HF hospitalization, death, or end of study (12/2020). Associations of circulating alarmin concentrations with incident CVD events were tested in multivariable Cox regression models, adjusting for age, sex, race/ethnicity, smoking status, body mass index, DAS28, hypertension, diabetes, lung disease, LDL cholesterol, statin use, NSAID use, and aspirin use.

Results: Among 2,528 patients (mean age 64 years, 88% male, mean DAS28 3.6), 505 (20.0%) patients had prevalent MACE or HF. We observed CVD outcomes in 414 (20.5%) of the remaining 2,023 patients over a mean follow up of 7.3 years. After multivariable adjustment, IL-33, but not TSLP or IL-25, concentrations were associated with an increased odds of prevalent CVD (**Table 1**; aOR 1.29 [1.04-1.60] per 1 SD increase) and MACE (aOR 1.32 [1.04-1.68]). For incident

Figure 1. Multivariable associations of serum alarmin concentrations with incident cardiovascular disease events in patients with rheumatoid arthritis



Adjusted hazard ratios (95% confidence intervals) for analytes estimated in separate Cox regression models adjusted for age, sex, race/ethnicity, BMI, smoking status, RA disease activity, hypertension, diabetes, lung disease, LDL cholesterol, statin use, NSAID use, and aspirin use. Bold indicates p<0.05.

Abbreviations: CAD, coronary artery disease; CVD, cardiovascular disease; HF, heart failure; MACE, major adverse cardiovascular event; T1/2/3, tertile 1/2/3; TSLP, thymic stromal lymphopoietin

Figure 1. Association of serum alarmins with incident cardiovascular disease

disease, TSLP concentrations were most strongly associated with CVD risk (**Figure 1**; aHR 1.26, [1.06-1.50]), which was driven by its association with stroke (aHR 1.61 [1.26-2.06]) and MACE (aHR 1.22 [1.03-1.20]). A trend toward an inverse association between IL-33 and HF was observed, otherwise no associations were seen between IL-33 or IL-25 with incident CVD in fully adjusted models.

Conclusion: In this large, multicenter, prospective RA cohort, serum IL-33 concentration was independently associated with prevalent CVD, whereas TSLP concentration was associated with incident CVD, particularly stroke and MACE. These findings suggest that alterations in endogenous alarmins occurring in RA may contribute to RA-associated CVD risk. Further study is warranted to determine whether serum alarmins can improve CVD risk stratification in RA.

Abstract Number: 2120

Independent and Combined Impact of Interstitial Lung Disease and Airway Disease on Rheumatoid Arthritis Disease Activity and Infections

Misaki Yoshida[1], takeshi Zoshima[2], Ichiro Mizushima[2] and Mitsuhiro Kawano[2], [1]Kanazawa University, Fukui, Japan, [2]Kanazawa University, Kanazawa, Japan

SESSION INFORMATION

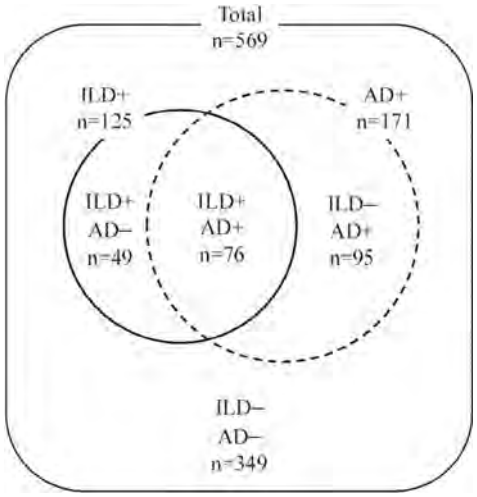
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: How interstitial lung disease (ILD) and airway disease (AD) independently affect the clinical course of rheumatoid arthritis (RA) is unclear since previous studies conflated ILD and AD. We aimed to clarify the effects of ILD, AD, and their combination on RA disease activity and infections.

Methods: RA patients at our facilities during 2011 and 2021 that had chest computed tomography (CT) scans were investigated retrospectively. Baseline was defined as 'time of first CT scan', and final observation as 'last visit'. Two experienced radiologists evaluated CT findings. We excluded patients with incomplete evaluation of ILD/AD in CT scans. The study primary outcome was development of infection requiring hospitalization, while the secondary was RA disease activity at final observation. We compared patients with and without ILD, and with and without AD. To identify factors associated with RA disease activity or infections, multivariate analyses were performed.

Results: We enrolled 569 patients (75.7% female, mean: age 60.9 yrs, observation period 73.9 mo.), including 125 (22.0%) with ILD, 171 (30.1%) AD, and 76 (13.4%) both (Figure 1).

At baseline, ILD+ and AD+ patients were older significantly than ILD– and AD– patients. ILD+ patients received significantly less methotrexate (MTX) than ILD– patients, while treatments for AD+ and AD– patients were comparable. RA disease activity was similar among groups.

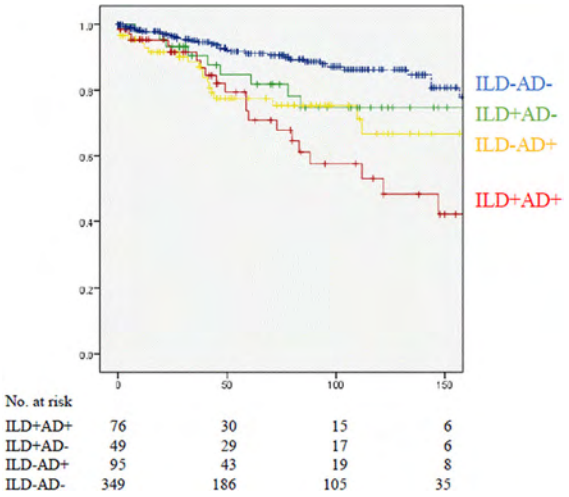


Schematic representation of the cohort

At final observation, ILD+ and AD+ patients had significantly higher Disease Activity Score 28 based on C-reactive protein (DAS28-CRP) (mean 2.4 vs. 2.1 and 2.3 vs. 2.1) and Simplified Disease Activity Index (SDAI) (mean 7.6 vs. 5.8 and 7.4 vs. 5.6) than ILD– and AD– patients. ILD+ patients received significantly less MTX but more glucocorticoids than ILD– patients. ILD+AD+ patients had higher RA activity than the other groups.

Analysis of covariance revealed significant association between DAS28-CRP and ILD [F(1,155) = 7.248], but not AD or their interaction. Similar results were found for SDAI. Kaplan-Meier analysis with log-rank tests revealed significantly lower infection-free rate in ILD+ and AD+ than ILD– and AD– patients. In ILD+ patients, the rate decreased prominently after 50 months. The infection-free rate was lower in ILD+AD+ patients than the other groups (Figure 2).

Cox regression analysis revealed significant association between infections and AD (hazard ratio [HR] 1.970, 95% confidence interval [CI] 1.065-3.646), but not ILD or their interaction. Cox regression analysis with time-dependent covariates, categorizing ILD into >50 and ≤50 months, showed significant association between infections and ILD >50 months (HR 3.702, 95% CI 1.637-8.372) and AD (HR 1.744, 95% CI 1.054-2.885), but not ILD ≤50 months.



Cumulative rate of total infectious events

Conclusion: Disease activity of RA was independently associated with ILD but not AD, suggesting an impact of reduced MTX in ILD. Risks of developing infections included ILD after 50 months and AD, both independently. The ILD+AD+ group showed higher RA activity and a greater susceptibility to infection than the other groups. Careful detection of ILD and AD, along with implementation of safe and effective alternative treatments, is necessary.

Clinical Significance of Negative Seroconversion of Anti-CCP and Anti-Mutated Citrullinated Vimentin Antibodies in Patients with Rheumatoid Arthritis

Takao Fujii, Katsunori Tanaka, Ryo Matsumiya, Kayoko Tabata and Shigeru Iwata, Department of Rheumatology and Clinical Immunology, Wakayama Medical University, Wakayama, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-cyclic citrullinated peptide antibody (anti-CCP Ab) positivity is closely associated with bone destruction in rheumatoid arthritis (RA) patients, but the correlation between the Ab titer and disease activity is poor. On the other hand, anti-mutated citrullinated vimentin (MCV) Ab, a subset of anti-citrullinated protein/peptide Abs (ACPA), have been suggested to be pathogenic in animal model (Harre U, et al, J Clin Invest, 2012) and an association between negative conversion of this Ab and radiographic remission has been reported in RA patients (Kastbom A, et al. Ann Rheum Dis, 2016). In this study, we aimed to determine the association of negative seroconversion of anti-CCP and MCV Abs with clinical and functional remission of RA.

Methods: Four-hundred and thirty-nine RA patients (female 74.9%, mean age 62.1 years old, and disease duration 8.1 years) who are followed up in our hospital and had anti-CCP and MCV Abs measured sequentially for more than 2 years were enrolled. Both Ab titers were measured using ELISA and the association of negative conversions of these Abs with clinical disease activity was investigated.

Results: 1) There were 12 cases (2.8%) with anti-CCP Ab (cut off 4.5 U/mL) and 57 cases (13.0%) with anti-MCV Abs (cut off 20 IU/mL) those had negative conversion at least once during the course. Whereas negative conversion of anti-CCP Abs was not observed in patients with titers >36.2 U/mL (approximately 8 times of the upper limit of normal) at the first determination, anti-MCV Abs with high titers >35 times of the upper limit of normal decreased to negative. There were cases in which high anti-MCV Ab titer (=719.6 IU/mL) turned to negative in 1 year. In the anti-MCV Ab negative conversion cases, 24.6% of cases with high anti-CCP Ab titers (≧100 U/mL) were also included. 2) In anti-MCV Ab negative conversion cases, disease activity score-ESR (DAS28-ESR) (3.21 vs. 2.44, P< 0.001), simplified disease activity index (7.89 vs.4.29, P< 0.001), and health assessment questionnaire score (0.62 vs.0.49, P< 0.001) were significantly decreased after negative conversion. However, similar changes were not observed in anti-CCP Ab negative conversion cases. 3) Clinical remission using DAS28-ESR was more frequently achieved after negative conversion of anti-MCV Ab than of anti-CCP Ab (67.9 vs. 33.3%, P=0.046). In cases with low disease activity or higher, clinical remission rate was also significantly higher in anti-MCV Ab negative conversion than in anti-CCP Ab negative conversion cases (58.9 vs. 14.3%, P=0.045).

Conclusion: Unlike anti-CCP Ab, negative conversion of anti-MCV Ab was associated with clinical remission. "Immunological remission" with anti-MCV Abs may have clinical implications in RA patients.

Coronary Calcium and Carotid Artery Stiffness as Predictors of Cardiovascular Events and Mortality in Patients with Rheumatoid Arthritis: A 10-year Prospective Follow-up Study

Cristina Corrales Selaya[1], Nuria Vegas Revenga[2], Jose Antonio Parra[3], Virginia Portilla[4], Ricardo Blanco[5], Miguel A Gonzalez-Gay[6], Ivan Ferraz Amaro[7] and Alfonso Corrales[4], [1]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [2]Hospital Galdakao- Usansolo, Galdakao, Spain, [3]Hospital Universitario Marques de Valdecilla, Santander, Spain, [4]Rheumatology Department, Immunopathology Group, Hospital Universitario Marqués de Valdecilla-IDIVAL, Santander, Spain, [5]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain, [6]IDIVAL and School of Medicine, UC, Santander; Department of Rheumatology, IIS-Fundación Jiménez Díaz, Madrid, Santander, Spain, [7]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of mortality is increased in patients with RA compared to the general population. Different non-invasive surrogate markers of atherosclerosis have been implemented to identify RA patients who are at high risk of cardiovascular (CV) disease.

In the present study, we aimed to establish the predictive capacity of the following surrogate markers: Coronary calcium (CAC) and carotid pulse wave velocity (PWV) to predict CV events and all-cause mortality in a cohort of RA patients prospectively followed.

Methods: We conducted a prospective longitudinal study that included 126 patients with RA. The patients were recruited in 2011 and followed-up for 10 years. All patients had undergone baseline CAC score, and carotid PWV by US. Multivariate Cox regression analysis was performed to identify the predictive ability of these surrogate markers for CV events and all-cause mortality.

Results: A total of 126 patients were included, 92 women (73%), with a mean age of 59±10 years. The main baseline characteristics, CV risk factors, disease activity data and treatments are detailed in **Table 1**, as well as the baseline parameters that showed statistically significant association with mortality and CV events. After a follow-up of 14,479 person-months, there were 15 deaths and 24 cardiovascular events in 18 patients. The main causes of mortality were infections (n=7, 46.7%) and neoplasms (n=5, 33.3%). In univariate analysis, CAC values above 400 Agatston units were associated with a statistically significant increased risk of overall mortality (HR 5.13 (1.03-25.41 95% CI), p=0.045) **(Table 2).** However, in multivariate analysis adjusted for classical CV risk factors, the results obtained were not statistically significant. Increasing CAC value as a continuous variable was significantly associated with an increased risk of cardiovascular event in both univariate

Table 1. Baseline characteristics of a cohort of 126 arthritis patients without previous cardiovascular events.

(HR 1.002 (1.0008-1.003 95% CI), p=0.001) and multivariate (HR 1.002 (1.0004- 1.003), p=0.011) analyses. The increase in carotid arterial stiffness value measured by PWV was statistically significantly related to overall mortality in the univariate analysis. The same was observed when categorizing this variable, as values higher than 10 m/s in the univariate analysis were statistically associated with overall mortality. However, this relationship did not maintain in the multivariate analysis, nor could it be demonstrated for CV events.

Dose Trabecular Bone Score (TBS) Add Predictive Value to Fracture Risk Assessment (FRAX) in Rheumatoid Arthritis?

Jia-Feng Chen[1], Tien-Tsai Cheng[2] and Hong-Yo Kang[3], [1]Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan, [2]Department of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University, College of Medicine, Kaohsiung, Taiwan, [3]Graduate Institute of Clinical Medical Sciences, Chang Gung University, College of Medicine, Kaohsiung, Taiwan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

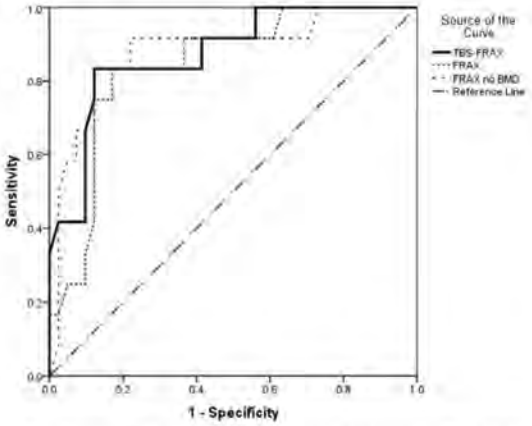
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Trabecular bone score (TBS) of lumbar spine is a dual X-ray densitometry (DXA)-based tool to evaluate bone microarchitecture, providing information on bone quality in metabolic bone diseases. The aim of this study is to assess whether TBS provides additional benefit to Fracture Risk Assessment (FRAX) tool to predict fractures in rheumatoid arthritis (RA) patients.

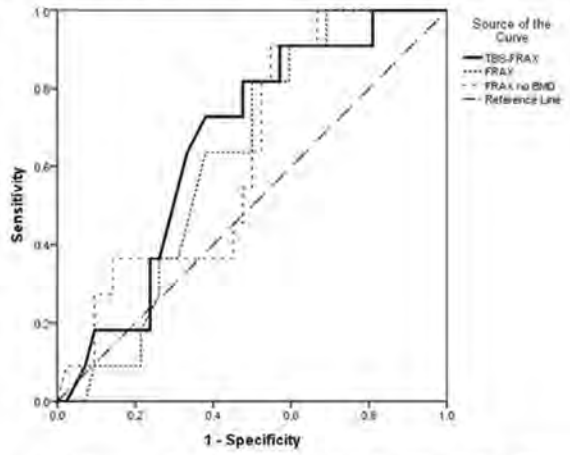
Image 1. ROC curve analysis for prevalent vertebral fracture by different FRAX models



Model	The area under the curve	Standard error	95% confidence interval	p-value
TBS-FRAX	0.874	0.057	0.760-0.988	<0.001
FRAX	0.842	0.061	0.720-0.965	<0.001
FRAX-no BMD	0.881	0.062	0.757-1.000	<0.001

Comparison between ROC curves: TBS-FRAX vs. FRAX, p=0.42; TBS-FRAX vs. FRAX-no BMD, p=0.86; FRAX vs. FRAX-no BMD, p=0.24. Abbreviations: Receiver operating characteristic (ROC); Fracture Risk Assessment (FRAX); Trabecular bone score (TBS); bone mineral density (BMD).

Image 2. ROC curve for new fractures within three years by different FRAX models



Model	Area under the curve	Standard error	95% confidence interval	p-value
TBS-FRAX	0.662	0.082	0.498-0.826	0.052
FRAX	0.626	0.078	0.470-0.781	0.114
FRAX-no BMD	0.633	0.085	0.462-0.804	0.127

Comparison between ROC curves: TBS-FRAX vs. FRAX, p=0.26; TBS-FRAX vs. FRAX-no BMD, p=0.64; FRAX vs. FRAX-no BMD, p=0.88. Abbreviations: Receiver operating characteristic (ROC); Fracture Risk Assessment (FRAX); Trabecular bone score (TBS); bone mineral density (BMD).

Methods: This is a retrospective study enrolling RA patients who fulfilled ACR/EULAR 2010 criteria from September 2014 to April 2021. We recruited participants aged between 40-90 and excluded those with malignancy. At enrollment, we measured bone mineral density (BMD) by Dual X-ray densitometry (DXA) at hip and lumbar spine, and assessed TBS at the lumbar spine. The 10-year risk of major osteoporotic fractures and TBS-adjusted risks were calculated on the FRAX website (https://frax.shef.ac.uk/tbs/index.aspx), and the FRAX scores were adjusted by glucocorticoid dose. In current studies, three FRAX models were evaluated, including conventional FRAX score, FRAX adjusted by TBS (TBS-FRAX) and FRAX without input of BMD (FRAX-noBMD). All patients were followed for at least three years to monitor fractures. We defined prevalent vertebral fracture by the morphometric change of vertebral bodies on the X-rays at baselines, according to Genant's semiquantitative assessment. New fracture was defined by any clinical fragility fractures by medical records or vertebral body morphometrical changes after comparing baseline and final X-ray images by independent radiologists. Receiver operating characteristic (ROC) curves were illustrated to compare prediction models.

Results: Fifty-three RA participants were enrolled in current study, with a mean age of 55.8± 9.6 years and female predominant (83.0%). Among them, 14 (26.4%) had prevalent vertebral fractures at baseline, while 11 (20.8%) developed new fractures during follow-up. For prevalent vertebral fracture, the area under ROC curves (AUCs) of TBS-FRAX, FRAX, FRAX-noBMD were 0.874, 0.842, and 0.881(all p-value < 0.001), respectively, and there was no statistical significance between different models (Image 1). Regarding new fracture, the AUCs were 0.662, 0.626, and 0.633, and the p-values were 0.052, 0.114, and 0.127, respectively. Also, no statistical significance was displayed between models (Image 2).

Conclusion: FRAX alone demonstrates good prediction ability for prevalent vertebral fractures, so TBS-adjusted FRAX does not add much value to the outcome. The performance of test models is not optimal for new fractures, and adding TBS might improve prediction ability with a borderline of statistical significance.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Seropositive RA is preceded by an at-risk stage characterized by elevated circulating autoantibodies (AAb), including ACPA, in otherwise healthy individuals without clinically-apparent inflammatory arthritis. Rising autoantibody levels prior to clinical diagnosis suggest changing immune activity but what additional immune dysregulation may be occurring in this period is incompletely understood. The purpose of this study was to profile the immune state that accompanies elevated AAb to identify novel immune features present in individuals at-risk (ARI) to develop clinical RA.

Methods: We profiled 1463 plasma proteins, 69 peripheral blood mononuclear cell (PBMC) phenotypes, and 1,973,362 PBMCs by single-cell RNA sequencing (scRNA-seq) for a cross-sectional analysis of ARI with high levels of ACPA (anti-CCP3 IgG > 40 units) compared to healthy control individuals (HCI) (Table 1). Linear regression models were used to identify differentially expressed proteins (ARI/HCI), and to identify lineage-defining gene programs in scRNA-seq. PBMC phenotypes were selected and analyzed based on their identification in the clinical RA literature to evaluate features of clinical disease present in ARI. Wilcoxon rank sum was used to evaluate the association of B cells to AAb levels. Finally, NicheNet was used to identify putative relationships between plasma proteins and gene expression in the target cells.

Results: 314 proteins exhibited significant differential expression between ARI and HCI, including CCN1, CXCL6, CCL18, OSM, CCL5, and SERPINE1, all of which were not previously reported in ARI, as well as proteins related to B cell biology, including CXCL13, SEMA4D, LIGHT, and BAFF (Fig 1A). In addition, we found evidence for features of classifiable RA, including increased IL-1B, IL-6, TNF, CCL3, and CXCL8 plasma proteins and elevated PBMC phenotypes. Among PBMC, atypical (IgD- CD27-) B cells and Tph-like (CXCR5- PD1+) CD4T cells (Fig 1B) were significantly increased. Transcriptomic

Table 1. Characteristics of participants in this study

Variable	At-risk individuals	Controls	P value
Age at sample collection, median	62	57	0.01
Sex at birth, %	36 (78%)	41 (79%)	1.000
Race, %			
African-American	8.70	0.00	0.05
Asian	2.17	7.69	0.37
Caucasian	82.61	88.46	0.57
Other	6.52	3.85	0.66
Ethnicity, Hispanic or Latino, %	4.35	3.85	1.00
Ever smoked tobacco, n (%)	17 (37%)	8 (15%)	0.036
Autoantibodies, units (%)			
Serum CCP3+, median (IQR)	60 (42.5, 183)	0 (0,2)	< 1e-6
Serum RFIgM+, median (IQR)	0.57 (0.25, 22.23)	0 (0,4.3)	2.5e-4

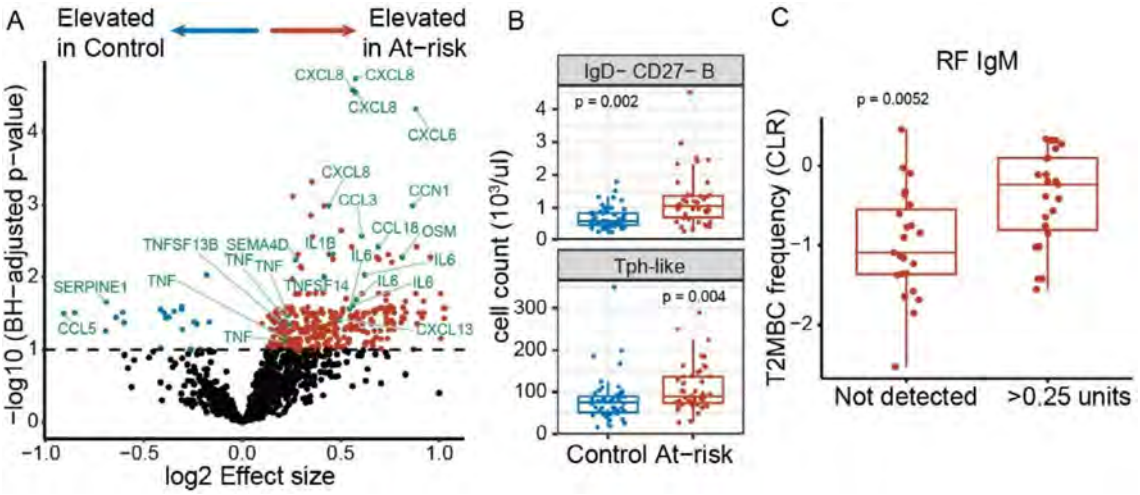

Figure 1. (A) Volcano plot of differential plasma protein expression between at-risk (red) and control (blue) individuals. Effect sizes and P values were determined using a linear regression model. Replicate annotations of the same protein result from repeated plate assays as part of Olink's standard protocol. (B) PBMCs from at-risk (red) and control (blue) individuals were compared for IgD- CD27- B cells (top) and CXCR5- PD1+ CD4 T cells (Tph-like; bottom) and were tested using Wilcoxon Rank Sum with Benjamini/Yekutieli correction. Each dot represents a participant. (C) At-risk individuals were categorized by RF-IgM levels as Not detected (≤ 0.25 units) or > 0.25 units and the frequency of type 2-polarized memory B cells (T2MBC) in PMBCs was tested using Wilcoxon Rank Sum.

analysis (scRNA-seq) of atypical B cells, enriched in ARI, demonstrated a gene program indicative of type 2-polarized memory B cells (T2MBC), including IL4R, IL13RA1, FCER2, IGHG4, IGHE, and MEF2C (Fig 2). T2MBC abundance was correlated to RF-IgM levels (Fig 1C). NicheNet analysis identified differentially-regulated proteins CCL3 (Pearson correlation coefficient (r) = 0.093), TNFSF13B (BAFF) (r = 0.077), TNFSF14 (LIGHT) (r = 0.048), and TNF (r = 0.047), as potential regulators of the T2MBC gene program.

Conclusion: We find that otherwise healthy at-risk individuals have immune dysregulation characterized by plasma protein and PBMC phenotype changes, including some that are similar to published findings in clinical RA. In particular, the number of T2MBC B cells were elevated in ARI and we recognized a relationship to RF-IgM AAb levels. Based on NicheNet analysis,

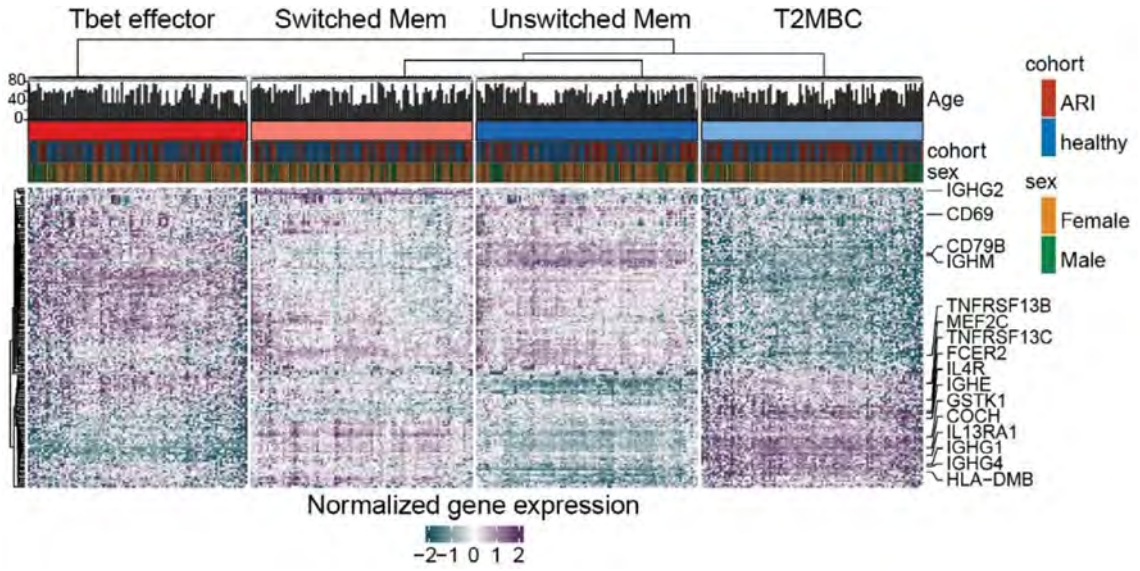

Figure 2. Gene expression heatmap indicating the DEGs (AUC > 0.55 or AUC < 0.45 and absolute log2 fold change > 0.1) between T2MBC and switch/unswitched memory B cells. Tbet effector are shown for comparison. Scaled normalized transcripts of pseudobulk samples are displayed.

we hypothesize that circulating plasma proteins in ARI reflect the maintenance or generation of T2MBC. These data deepen our understanding of this critical at-risk state and further emphasize the tight link between the dysregulation within the B cell compartment and autoimmune disease, which could be exploited for preventative therapeutic intervention.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic condition characterized by persistent joint inflammation, functional impairment, and disability. Adhering to a Western diet has been associated with an overproduction of pro-inflammatory mediators and a reduced release of anti-inflammatory mediators. The gut microbiota plays a crucial role in determining the metabolic response to specific nutrients and can influence the levels of circulating pro- and anti-inflammatory mediators. The objective of this study is to compare the response of RA patients following either the anti-inflammatory ITIS diet or the Mediterranean diet (MD), assessing their respective improvements in various outcomes and examining the microbiome variations associated with each dietary approach.

Methods: We evaluated the effect of either ITIS diet or the MD for a period of 3 months in an evaluator blinded randomized clinical trial. In an ongoing trial, RA patients with active disease are being recruited. Physical examination is performed at each visit, along with the collection of clinical data, data on dietary adherence, and fecal samples for microbiome analysis. 16S rRNA gene amplicon profiling of the stools was performed. A generalized linear model was employed to assess the relationship between time and diet. Microbiome analysis was conducted using RStudio to describe variations in the abundance of microbial taxa associated with different diet groups and responses, defined as patients with a 50% pain improvement.

Results: A total of 44 patients (95.45% women, age average: 52.82, standard deviation (SD): 9.42), clinical disease activity index (CDAI) average 34.55 (17.44)) diagnosed with RA were recruited for this study. The study findings revealed significant improvements in health indicators among patients following the ITIS diet and MD. Specifically, patients on the ITIS diet

Table 1. Table with changes of outcomes through visits in each diet, ITIS and Mediterranean diet. Significant p-values are seen in bold font. Outcomes showed here are pain measured with visual analog scale (VAS), fatigue measured with VAS, clinical disease activity index (CDAI), VAS from overall health from physician's evaluation and VAS overall health from patient

	ITIS					Mediterranean Diet

experienced significant reductions in pain (p=0.03), fatigue (p=0.02),CDAI (p=0.02) and visual analog scale (VAS) from physician (p=0.004) at 3 months. Patients following MD had a significant decrease of CDAI (p=0.01) and VAS from physician (p=0.004) at 3 months (**Table 1**). Remission was achieved by 11.11% of patients on the ITIS diet, while no patients following the MD reached remission. In microbiome analysis, the differential abundance between responders (R) and non-responders

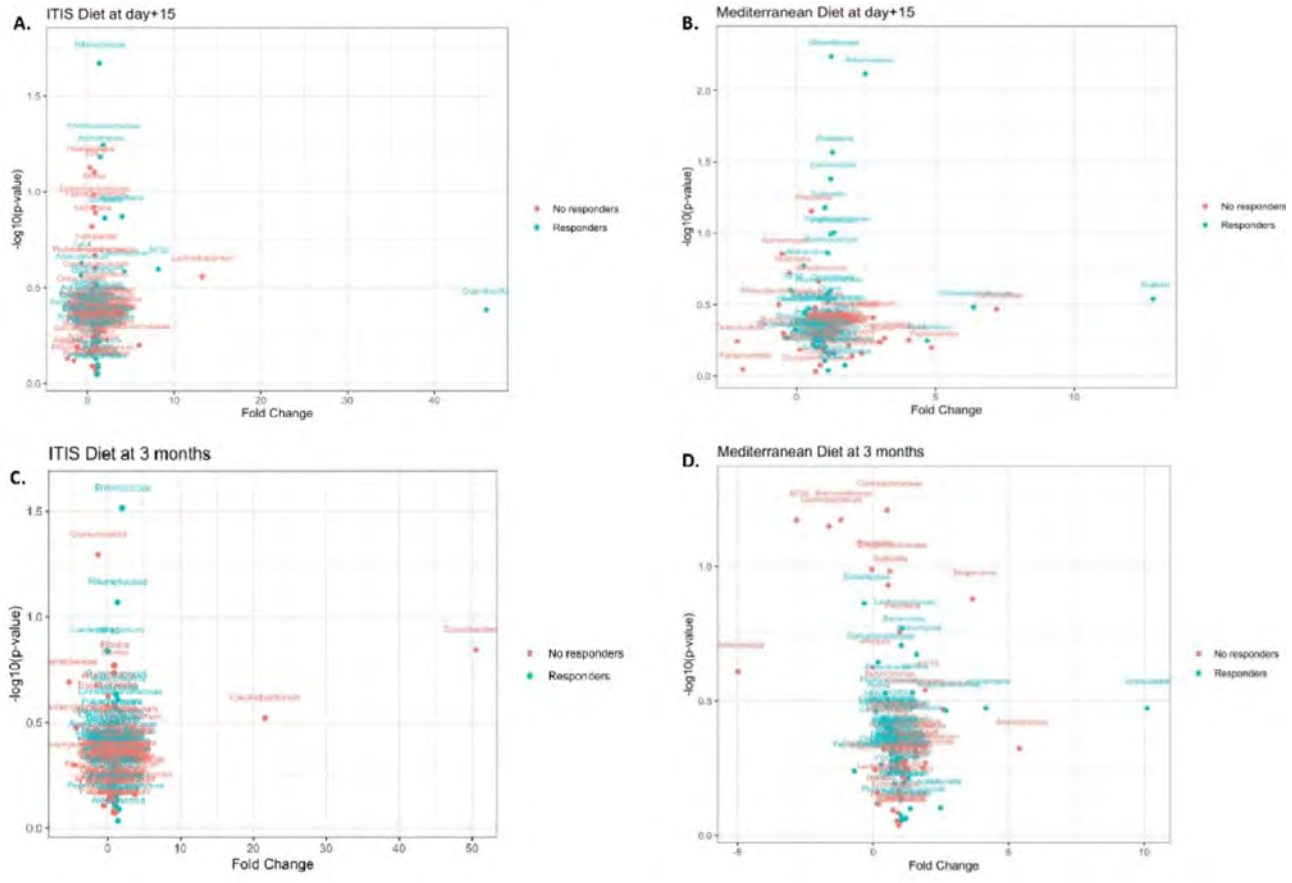

Figure 2. Volcano plots representing the distribution of the relative abundance of the microbiome at baseline. A) Distribution of the response at day +15 of ITIS diet patients. Blue color means that responders have higher relative abundance compared to non-responders. Red color means that non-responders have higher relative abundance compared to responders. B) Distribution of the response at day +15 of Mediterranean diet patients. C) Distribution of the response at the end of the trial of ITIS patients. D) Distribution of the response at the end of the trial of Mediterranean diet patients.

(NR) for each diet was calculated. **Figure 1** shows the volcano plots representing the distribution of the relative abundance of the microbiome at baseline within R and NR of each diet after 15 days and 3 months of diet intervention.

Conclusion: Preliminary results of our randomized clinical trial show improvements in clinical outcomes for both the ITIS diet and the MD. We also observed baseline differences in the microbiome between R and NR. More patients are being recruited to further investigate the differences in clinical and microbiome outcomes between the two diets.

Performance of the Rheumatoid Arthritis Impact of Disease (RAID) Score in Relation to Flares in Disease Activity

Karen Holten, Nina Paulshus Sundlisæter, Joseph Sexton, Lena Bugge Nordberg, Till Uhlig, Tore Kvien, Espen Haavardsholm, Siri Lillegraven and Anna-Birgitte Aga, Center for Treatment of Rheumatic and Musculoskeletal Diseases (REMEDY), Diakonhjemmet Hospital, Oslo, Norway

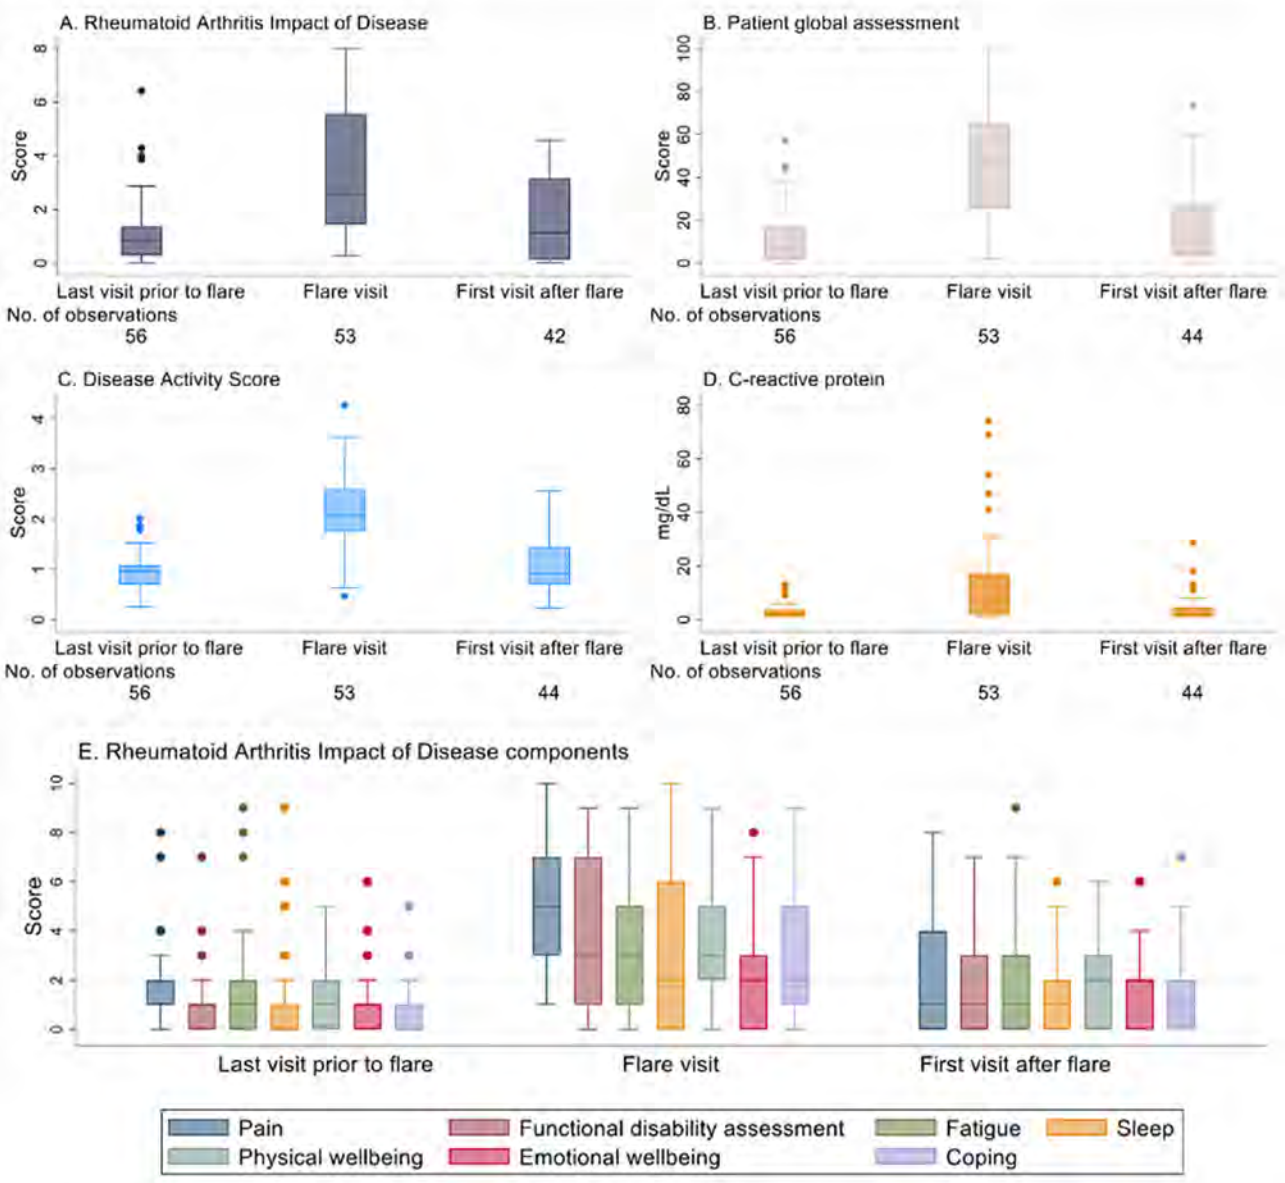
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The Rheumatoid Arthritis Impact of Disease (RAID) is a patient-reported outcome measure (PROM) originating from a EULAR initiative. It might support patient-centred care and shared decision-making between patient and health care provider. RAID could be a useful tool in regular clinical settings and remote monitoring, and its association with disease activity is thus of interest. RAIDs performance with regard to flare is not known, and our aim was to explore its responsiveness and discriminative abilities with regard to flares in disease activity.

Methods: We used pooled data from the first 12 months of the two ARCTIC REWIND trials assessing tapering of TNFi and csDMARDs (ClinicalTrials.gov: NCT01881308) (Lillegraven et al, JAMA, 2021). Eligible participants had RA according to the ACR/EULAR 2010 criteria, were in sustained remission for ≥12 months on stable DMARDs with Disease Activity Score (DAS) remission combined with no swollen joints at inclusion. Patients were randomized to continued stable treatment or tapered treatment. Study visits were conducted every four months, if a flare was suspected between visits the patient was seen within a week. Flare was defined as a combination of DAS >1.6, a ≥0.6 units increase and minimum 2 swollen joints, or a flare could be recorded in consensus between patient and rheumatologist. We evaluated the median RAID (total score and components) at the last visit before flare, at the flare visit and first visit after flare in relation to the suggested ≤2 RAID threshold for patient acceptable symptom state (PASS), and assessed the changes between those visits using Wilcoxon signed-rank test. The discriminative accuracies of RAID (total score and components) with respect to flares were assessed using area under the ROC curve (AUC) analyses based on logistic regression models. For comparison, similar analyses were performed for patient global assessment (PGA), DAS and C-reactive protein (CRP).

Results: Of the 248 patients included, 159 (64%) were female. Mean (SD) age and disease duration were 56.1 (11.8) and 6.3 (5.7) years. For patients who experienced a flare the median (IQR) RAID score was 0.9 (0.3, 1.4) at last visit prior to flare with 86% of scores below the PASS threshold (**Figure**). At the flare visit median RAID was 2.6 (1.4, 5.6) with 70% of scores above the PASS. Similar changes were observed in DAS, PGA and CRP (**Figure, Table**). All seven RAID domains increased significantly at the flare visit (p-values < 0.001), with the largest increase in pain. AUC (95% CI) values were0.88 (0.83, 0.93) for RAID, 0.92 (0.87, 0.97) for PGA, 0.94 (0.90, 0.98) for DAS and 0.76 (0.69, 0.84) for CRP. The RAID components with highest and lowest discriminative accuracies were pain (0.91 (0.86 to 0.95)) and sleep (0.69 (0.59 to 0.79)).

*Figure. Outcome measures at last visit before flare, at flare visit and first visit after flare. A: Rheumatoid Arthritis Impact of Disease[1] B: Patient global assessment VAS[2] C: Disease Activity Score[3] D: C-reactive Protein[4] E: Rheumatoid Arthritis Impact of Disease components**



*[1]RAID (NRS 0-10). [2]Patient global assessment (PGA) of the disease activity from 0-100 mm on a visual analogue scale. [3]Disease Activity Score (0-10) includes a swollen joint count of 44 joints, assessment of tender joints by Ritchie Articular Index, erythrocyte sedimentation rate (ESR) and PGA. [4]C-reactive protein (mg/dL). *Higher values indicate poorer outcome.*

PGA	34.9 (26.0)	6.1 <0.0001	51/53 (96)	31.1 (32.1)	-4.7 <0.0001	35/44 (80)
DAS	1.2 (0.7)	6.3 <0.0001	51/53 (96)	1.0 (0.9)	-5.2 <0.0001	40/44 (91)
C-reactive protein	9.4 (16.0)	4.8 <0.0001	33/53 (62)	9.9 (17.0)	-4.0 <0.0001	27/44 (61)

RAID, Rheumatoid Arthritis Impact of Disease, Numeric Rating Scale (0-10). PGA, patient global assessment, of the disease activity from 0-100 mm on a visual analogue scale. DAS, Disease Activity Score (0-10) includes a swollen joint count of 44 joints, assessment of tender joints by Ritchie Articular Index, erythrocyte sedimentation rate (ESR) and PGA.

Conclusion: Disease activity flares were associated with a significant increase in median RAID, supporting RAIDs ability to respond to flare. RAID and PGA discriminated well between flare and non-flare, hence both PROMs might contribute to identification of flare in a regular clinical setting as well as in remote monitoring of disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of developing certain cancers, including bladder cancer (*Beydon et al*. 2023[1]). However, few studies have examined the outcomes following a bladder cancer diagnosis in patients with RA. RA is also associated with an increased risk of frailty. Bladder cancer is the second most common urologic cancer with a mean age of diagnosis of 73 years and a high burden of frailty and comorbidity. Importantly, among patients with bladder cancer, frailty is associated with an increased risk of mortality. We sought to evaluate associations between RA and all-cause and cancer-specific mortality in older adults with bladder cancer, adjusted for frailty.

Methods: In this retrospective cohort study, using the Surveillance Epidemiology and End Results cancer registry and linked Medicare claims data (SEER-Medicare), we included patients ^{3}65 years old with incident bladder cancer diagnosed between 2004 and 2017. Patients with a pre-existing diagnosis of RA were identified based on the presence of ^{3}2 ICD-10 codes ≥ 30 days and < 365 days apart. A validated claims-based Frailty Index (*Kim et al*. 2017[2]) and National Cancer Institute (NCI) Comorbidity Index were derived from claims in the 12 months prior to bladder cancer diagnosis. Patients with a frailty score > 0.2 were categorized as frail. Separate Cox proportional hazards regression models evaluated the association between RA and frailty and 1) overall mortality and 2) bladder cancer-specific mortality, after adjusting for demographics, socioeconomic status, comorbidities, cancer stage, and receipt of guideline-directed bladder cancer treatment per stage. We evaluated the interaction between RA and frailty and performed stratified analyses by frailty status.

Table 2: Cox regression model for mortality among older adults with bladder cancer stratified by frailty status.

Table 2: Cox regression model for mortality among older adults with bladder cancer stratified by frailty status.

	Hazards Ratio* *Rheumatoid arthritis vs. no rheumatoid arthritis*	95% Confidence Interval
Overall mortality	1.11**	1.04 – 1.16
Stratified for frailty score <0.2	1.18	1.08 – 1.29
Stratified for frailty score ≥0.2	0.97	0.90 – 1.04
Bladder cancer-specific mortality	1.07	0.98 – 1.18
Stratified for frailty score <0.2	1.23	1.07 – 1.41
Stratified for frailty score ≥0.2	0.93	0.82 – 1.05

** Model is adjusted for sex, age, race, marital status, cancer stage, Yost ACS Quintile, NCI Comorbidity Index, and bladder cancer treatment*

***Interaction term of RA*frailty for overall mortality is p = 0.0006*

Results: We identified 99,418 patients with bladder cancer of whom 1751 (1.8%) had pre-existing RA (Table 1). Among patients with RA, 923 (52.7%) were frail while 33,518 (34.3%) of patients without RA were frail (p< 0.0001). Median follow-up for survivors overall was 5.3 years (interquartile range, IQR, 2.8-8.8) during which time 61,499 patients died. The 5-year overall survival was 73.0% versus 71.9% for patients with and without RA respectively (p< 0.0001) and was 73.0% versus 68.6% for patients with and without frailty (p=0.0001). Among non-frail patients, RA was associated with an increased risk of cancer-specific (aHR 1.22, 95% CI 1.07 – 1.41) and overall mortality (aHR 1.18, 95% CI 1.08-1.29) (Table 2). However, among frail patients, RA was not associated with an increased risk of cancer-specific (aHR 0.92, 95% CI 0.82 – 1.05) or overall mortality (aHR 0.97, 95% CI 0.90-1.04).

Conclusion: RA was associated with a higher risk of bladder cancer-specific and overall mortality in non-frail pts with bladder cancer. Limitations of our study include retrospective nature, potential selection bias, and unmeasured confounding. Our hypothesis-generating results support further evaluation of the association between RA, frailty, and survival in older adults with bladder cancer.

Higher Vitamin D Levels Before Methotrexate Start Are Associated with Lower Subsequent Mortality in Rheumatoid Arthritis

Shahdi Malakooti[1], Hinnah Siddiqui[2], Brigid Wilson[2], Taissa Bej[2], Megan O'Mara[2], Nora Singer[3], Grace McComsey[4], Lenche Kostadinova[5], Maya Mattar[6], David Zidar[5] and Donald Anthony[7], [1]Case Western Reserve University, Cleveland, OH, [2]Louis Stokes Cleveland VA Medical Center, Cleveland, OH, [3]The MetroHealth System at Case Western Reserve University School of Medicine, Cleveland, OH, [4]University Hospitals Health System at Case Western Reserve University, Cleveland, OH, [5]Louis Stokes Cleveland VA Medical Center, Case Western Reserve University, Cleveland, OH, [6]Louis Stokes VA Medical Center, Cleveland, OH, [7]Case Western Reserve University, Cleveland VA Medical Center, The MetroHealth System, Cleveland, OH

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Vitamin D is an immune-modulating hormone. Low Vitamin D levels have been associated with development of autoimmune disease and higher disease activity in early Rheumatoid Arthritis (RA). Furthermore, Vitamin D supplementation may reduce incidence of autoimmune disease. Finally, low Vitamin D levels have been associated with subsequent mortality in non-autoimmune disease populations. Here in the setting of RA we investigated the relationship between serum 25-hydroxyvitamin D (25(OH)D) levels before starting methotrexate (MTX) therapy and subsequent all-cause mortality in national and local Cleveland Veterans Affairs (VA) cohorts.

Methods: This is a retrospective cohort study of patients with an ICD-9/10 diagnosis of RA seen in Rheumatology clinic visits. The data collected was time oriented around initial prescribing of MTX, a MTX medication possession ratio > 75%, and a clinical 25(OH)D level before starting MTX in the national (n=15,109) and local Cleveland (n=197) VA cohorts. Chart adjudication to verify RA diagnosis and Vitamin D supplementation was performed for the Cleveland cohort (n=197). We examined survival in groups of RA patients with adequate serum 25(OH)D (> 20 ng/mL) and deficient 25(OH)D (< 20 ng/mL) levels using Cox Proportional-Hazards Model. The model was adjusted for traditional cardiovascular risk factors, including age, sex, race and ethnicity, smoking status, body mass index (BMI), statin use, and the Charlson comorbidity index. We used a signed rank test to evaluate changes among patients with 25(OH)D levels measured before and after supplementation.

Results: Patients with 25(OH)D levels > 20 ng/mL before starting MTX had a 28% reduced risk of mortality when compared to patients with 25(OH)D levels < 20 ng/mL (HR 0.72; CI 0.64, 0.80; $p < 0.001$) in the national VA cohort. Age, gender, smoking status, Charlson comorbidity index, and BMI were also independently associated with mortality. We observed higher 25(OH)D levels after Vitamin D supplementation compared to before ($p=0.008$) in the Cleveland chart-reviewed cohort in which supplementation status was obtained.

Conclusion: RA patients with adequate Vitamin D levels (> 20 ng/mL) have lower subsequent mortality when compared to those with Vitamin D deficiency (< 20 ng/mL) in a large national RA cohort receiving standard of care MTX. The relationship between Vitamin D level and mortality held after adjusting for Charlson comorbidity score and traditional cardiovascular disease risk factors. The data from Cleveland demonstrate the feasibility of normalizing serum Vitamin D levels with Vitamin D supplementation in this patient population. The extent to which correction of serum Vitamin D levels in patients who were initially found to be Vitamin D deficient impacts upon all-cause mortality in RA is yet to be determined.

SCORE and SCORE2 Comparison in Cardiovascular Risk Estimation in Rheumatoid Arthritis Patients: A Cross-sectional Study Including Carotid Ultrasound

Cristina Campos Fernández[1], Pablo Martínez Calabuig[2], Jorge Juan Fragío Gil[1], Roxana González Mazarío[1] and Jose Andres Roman Ivorra[3], [1]Escuela de Doctorado, Universidad Católica de Valencia San Vicente Mártir, Valencia, Spain, [2]Hospital General Universitario Valencia, Valencia, Spain, [3]Hospital Universitari i Politècnic la Fe, Valencia, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by joint inflammation and cartilage destruction. RA has been recognized as a systemic disease associated with an increased risk of cardiovascular disease. Current CV risk screening and management strategies underestimate the actual CV risk in RA.Thus, an adequate CV risk stratification has special relevance in RA to identify patients at risk of CV disease.

To evaluate the cardiovascular risk profile in patients with RA by assessing both traditional CVD risk factors, carotid ultrasound finding and risk estimation using SCORE and SCORE2.

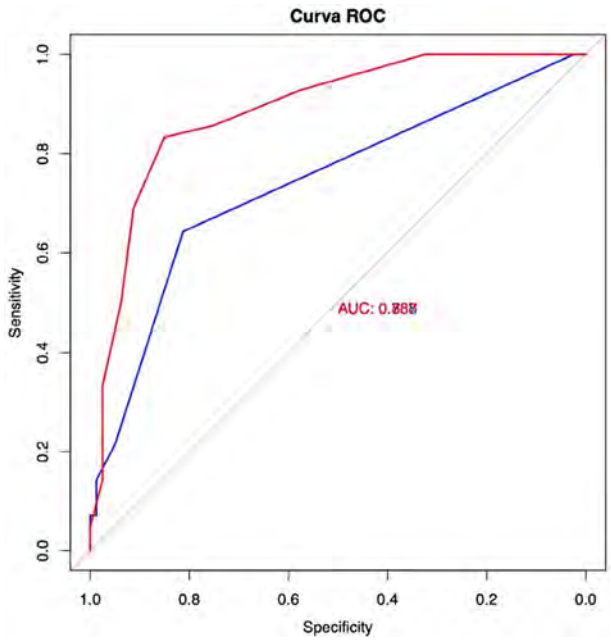
Methods: A cross-sectional study was performed including adult moderate to severe RA patients who had initiated treatment with JAK inhibitors or anti TNF. Traditional risk factors were evaluated. The Systematic Coronary Risk Evaluation (SCORE) and its updated version, SCORE2, were employed to estimate the global cardiovascular risk in this population. Furthermore, carotid ultrasound examinations were conducted to investigate subclinical atherosclerosis in RA patients. Measurements of carotid intima-media thickness (IMT) were obtained as a surrogate marker of early vascular damage. Additionally, the presence of atherosclerotic plaques, a hallmark of advanced vascular disease, was documented. This study was performed from September-2022 to April-2023 and was approved by the Ethics Committee. Statistical analysis was performed using R.

Results: A total of 123 patients were included in the study. Demographical and clinical variables are shown in table 1. Among the RA patients, a high prevalence of CVD risk factors was observed. The mean values of SCORE and SCORE2 indicated a moderate to high estimated 10-year risk of fatal CVD events in this population (mean SCORE: 2.77%, mean SCORE2: 4.07%). Carotid ultrasound measurements revealed an increased mean IMT in RA patients (mean right carotid cIMT: 0.64 [0.12]; mean left carotid cIMT 0.69 [0.11]). Furthermore, a substantial proportion of patients (34.1%) displayed the presence of atherosclerotic plaques. The concordance correlation coefficient between SCORE and SCORE2 demonstrated a significant moderate positive relationship (estimate 0.32 [0.19-0.43] IC 95%). ROC curves were calculated for SCORE and SCORE2 regarding their predictive capacity for plaques, showing a significant difference between them ($p< 0.001$) indicating a superior predictive capacity of SCORE2. A linear regression model, adjusted for confounding factors, was used to assess the relationship between SCORE and SCORE2 with IMT. Both SCORE (estimate 1.41 $p=0.02$, $R2=0.045$) and SCORE2 (estimate 1.55 $p< 0.01$, $R2=0.015$) were positively associated with IMT.

Table 1

Table 1: Demographic, clinical characteristics and Ultrasound Results

Characteristic	All RA patients n=123
Age - years	56.01 (10.84)
Female sex – number (%)	104 (84.5%)
BMI – value (ds)	27.6 (4.5)
Smoking habit (%)	
Never Smoked	87 (70.7%)
Ex-smoker	4 (3.3%)
Active smoker	32 (26%)
Race – number (%)	
Caucasian	119 (96.7%)
Comorbidities – number (%)	
High blood pressure	62 (50.4)
Dyslipemia	80 (65)
Diabetes Mellitus	21 (17.1)
Ultrasound findings	
Right carotid cIMT	0.64 (0.12)
Left carotid cIMT	0.69 (0.11)
Plaques	42 (34.1%)
Bilateral	16 (13%)
Right carotid	12 (9.8%)
Left carotid	14 (11.4%)



ROC

Conclusion: The relationship between SCORE and SCORE2 was found to be satisfactory, indicating their adequacy for prediction plaque development. However, the predictive capacity of both scores may be further enhanced by incorporating multiplication factors. Additionally, both SCORE and SCORE2 were positively associated with IMT, but SCORE2 demonstrated a greater predictive capacity in this regard. Furthermore, the SCORE2 explained a higher proportion of the IMT variation compared with SCORE.

Prevalence and Risk Factors of *Pneumocystis Jirovecii* Colonization in Patients with Rheumatoid Arthritis Treated with Tumor Necrosis Factor Inhibitors and Tocilizumab

Yi-Min Huang[1], Chieh-An Chuang[2], Jui-Hung Kao[2], Yen-Chun Lin[2], Jen-Hao Chen[3], Chiao-Feng Cheng[4], Cheng-Hsun Lu[4], Yu-Min Kuo[4], Chieh-Yu Shen[4], Chin-Hsiu Liu[5], Ko-Jen Li[4], Song-Chou Hsieh[4], Jung-Yien Chien[4] and Po-Ren Hsueh[4], [1]National Taiwan University Cancer Center, Taipei City, Taiwan, [2]National Taiwan University Hospital Yunlin Branch, Yunlin, Taiwan, [3]National Taiwan University Cancer Center, Taipei, Taiwan, [4]National Taiwan University Hospital, Taipei, Taiwan, [5]National Taiwan University Hospital, Taipei, Taiwan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are susceptible to *Pneumocystis jirovecii* colonization and prone to develop life-threatening *Pneumocystis* pneumonia (PCP). An increased risk of *P. jirovecii* colonization and PCP was found in RA patients treated with tumor necrosis factor (TNF) inhibitors. However, the impact of other biologics on *P. jirovecii* colonization remains unrecognized. This study aims to investigate the prevalence and risk factors of *P. jirovecii* colonization in patients with rheumatoid arthritis treated with TNF inhibitors and tocilizumab.

Methods: We enrolled the patients with RA, who were treated with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), TNF inhibitors, and tocilizumab between March 2022 to February 2023. The patients with acute respiratory symptoms were excluded. *P. jirovecii* polymerase chain reaction (PCR) assays of induced sputum, nasal swab, and oral wash were performed. Factors associated with *P. jirovecii* colonization were evaluated.

Results: A total of 94 patients with RA were included, and none of these patients received chemoprophylaxis for PCP. *P. jirovecii* colonization was found in 8 (8.5%) patients, and positive *P. jirovecii* PCR was detected in 3 (3.2%) specimens of induced sputum, 4 (4.2%) in nasal swabs, and 2 (2.1%) in oral washes. One patient exhibited positive *P*. jirovecii PCR in both induced sputum and oral wash samples. The mean (standard deviation, SD) age was 63.1 (11.6) years, and 73 (77.7%) patients were female. There were 39 (41.5%) patients treated with TNF inhibitors, 25 (26.6%) with tocilizumab, and 30 (31.9%) with csDMARDs only. In the TNF inhibitors group, 21 (53.8%) patients were treated with etanercept, 11 (28.2%) with adalimumab, 6 (15.4%) with golimumab, and 1 (2.6%) with certolizumab. One (2.6%) patient in the TNF inhibitors group had *P. jirovecii* colonization, 5 (20.0%) patients in the tocilizumab group, and 2 (6.7%) patients in the csDMARDs group. The chi-square test revealed a significant difference among TNF inhibitors, tocilizumab, and csDMARDs groups (chi-square = 6.141; *P*= 0.046). Patients with *P. jirovecii* colonization had a higher rate of tocilizumab use (62.5%

ESR, mm/hr	7	3	1	2	1	11	41	2

Anti-CCP antibody = anti-cyclic citrullinated peptide antibody; bDMARD = biologic disease-modifying antirheumatic drug; CRP = C-reactive protein; ESR = erythrocyte sedimentation rate; ETN = etanercept; HCQ = hydroxychloroquine; LEF = leflunomide; MTX = methotrexate; NA = not applicable; RA = rheumatoid arthritis; SSZ = sulfasalazine; TCZ = tocilizumab

vs. 23.3%, *P*= 0.029), a numerically higher rate of prednisolone use (75.0% vs. 23.3%, *P*= 0.154), and a numerically lower lymphocyte count (1252 vs. 1685 cell/mm^3; *P*= 0.053) than patients without *P. jirovecii* colonization (Table 1). In the backward multivariable logistic regression analysis, tocilizumab (OR 11.658; 95% CI 2.037-66.718; *P*= 0.006) and prednisolone (OR 8.255; 95% CI 1.238-55.059; *P*= 0.029) were independent risk factors of *P. jirovecii* colonization (Table 2). The detailed characteristics of the 8 patients with *P. jirovecii* colonization were outlined in Table 3, and no PCP was observed during the study period.

Conclusion: We demonstrated the prevalence of *P. jirovecii* colonization in RA by the combined sampling of the induced sputum, nasal swab, and oral wash. Tocilizumab and prednisolone might be associated witha higher risk of*P. jirovecii* colonization in patients with RA.

Patient characteristic of COVID-19 in RA

Background/Purpose: We analyzed trends in the incidence and severity of novel coronavirus disease (COVID-19) from the first wave to early 2023 in patients with rheumatoid arthritis (RA).

Methods: Cases who were diagnosed according to ACR/EULAR 2010 classification criteria were recruited to SHin-yokohama Arthritis REgister (SHARE) between 2020 and 2023. We conducted a retrospective cohort study investigating COVID-19 outcomes in clinic-confirmed rheumatoid arthritis patients from March 1, 2020 to February 28, 2023. We aggregated the total number of COVID-19 cases and the number of critically ill cases (hospitalized or died) and calculated the number of severe cases of COVID-19 by calendar period. compared the proportions. We estimated the clinical features of severe COVID-19 in each period. Rheumatic Disease Comorbidity Index (RDCI) were analyzed to detect the clinical features of severe COVID-19 in RA patients.

Results: 2,481 RA patients were enrolled. 316 cases were diagnosed as COVID-19 (12.8%, average age 57.8-+/-12.8 years, female 84.5%). There were 7 cases of severe COVID-19 (2.2%). The proportion of serious outcomes due to COVID-19 decreased over calendar time ($p < 0.0001$). 16% of cases were severe in the early stage of COVID-19

RDCI:Rheumatic disease comorbidities score

The clinical features of severe COVID-19 in the after omicron stage (December 1, 2021-February 28, 2023)

(March 1, 2020-November 30, 2021), compared with after omicron stages (December 1, 2021-February 28, 2023) was 1.0%.

In the early stage of COVID-19, elderly age (p=0.0054), hypertension (p=0.0021), diabetes (p=0.0291) and RDCI (1.5+/-1.3 vs. 0.4+/-0.7, p=0.0388) were associated with critical ill cases. After omicron stages of COVID-19, elderly age (p=0.0292), hypertension (p=0.0006), RA-ILD (p< 0.0001) and RDCI (4.0+/-2.6 vs. 0.4+/-0.8, p=0.0002) were associated with critical ill cases.

Conclusion: CONCLUSIONS Although the proportion of severe COVID-19 RA cases has decreased in after omicron stages compared to early stages of COVID-19, the clinical features of severe COVID-19 were very similar between two groups.

Systematic Screening for Multimorbidities Leads to an Increased Use of Comorbidity-preventing Medications and Lower Hospitalization Rates

Claire Daien[1], Vera Georgescu[2], Guillaume Decarriere[3], Gael Mouterde[3], Cedric Lukas[4], Gregoire Mercier[2] and JACQUES MOREL[5], [1]University Hospital, Montpellier, France, [2]Department of Medical Information, Montpellier, France, [3]Rheumatology, Montpellier, France, [4]CHU Montpellier, Montpellier, France, [5]Protocole thérapeutique immuno-rhumatologie, Montpellier, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systematic screening for multimorbidities has been carried out since 2014 at Montpellier University Hospital in patients with chronic inflammatory rheumatism (IRD). The aim of this work was to evaluate the impact of this screening on patient management and hospitalization rates during a 3-year follow-up.

Methods: IRD patients benefiting from the screening program (index date) were identified in the French national health database SNDS and matched to 3 controls on age, sex, IRD and disease duration. The primary endpoint was a composite score assessing the dispensing of comorbidity-preventing drugs (vaccines, anti-platelet treatments, lipid-lowering drugs, anti-osteoporotic drugs) in the year following the index date. Secondary endpoints were cardiologist/pneumologist consultation, all-cause hospitalization rate, hospitalization for fractures, cardiovascular events or infections. Odds ratios (IC95%) were calculated, with multivariate logistic regression adjusted for medical history (hypertension, diabetes, heart failure, CV disease, lung disease, osteoporotic fractures) and medications related to IRD or included in the primary endpoint in the previous year.

Results: 441 patients who had participated in the screening program (exposed) were identified in the national database and matched with 1323 unscreened patients (controls). Of these, 73.9% suffered from rheumatoid arthritis, 18.1% from ankylosing spondylitis and 7.9% from psoriatic arthritis. Exposed patients had significantly less diabetes than controls (4.5 vs. 7.6%) and received significantly less glucocorticoids (36.5 vs. 42.1%), more csDMARDs (56.9 vs. 42.8%) and more bDMARDs (57.4 vs. 32.6%) than controls. The use of drugs evaluated in the primary criteria was more frequent in the year prior to inclusion in the exposed group than in controls (58.4 vs. 45.3%). Exposed patients met the primary endpoint almost twice as often as controls (OR=1.9 [1.5-2.4]). The initiation of preventive medication for comorbidity remained significantly more frequent after adjustment for medical history and previous medication (OR=1.5 [1.1-2.1]). After adjustment for baseline comorbidities, exposed patients consulted significantly more cardiologists or pulmonologists in the year following screening than controls (OR=1.6 [1.2-2.1]). Controls had a three-fold higher risk of all-cause hospitalization (3.1 [2.1-4.6]) at one-year follow-up, which remained significant after adjustment (2.4 [1.5-4.0]). Controls had a significantly higher risk of hospitalization for cardiovascular events (2.1 vs. 0.3%), infections (6.8 vs. 3.6%) and emergency room admissions (20.3 vs. 10.6%) than controls at 2-year follow-up.

Conclusion: The recommendations given during the comorbidity screening program were applied, with an increase in the use of preventive medication for comorbidities and more consultations with specialists. After adjusting for comorbidities and medications at baseline, we observed a decrease in the risk of hospitalization rates, which may reflect the positive impact of carrying out systematic screening for multi-morbidities in IRD patients.

Cardiovascular Risk Factors Are Associated with Discontinuation of Advanced Therapies Due to Treatment Failure in Rheumatoid Arthritis: Results from the OBRI

Samar Aboulenain[1], Xiuying Li[2], Mohammad Movahedi[3], Claire Bombardier[1] and Bindee Kuriya[1], [1]University of Toronto, Toronto, ON, Canada, [2]Toronto General Hospital, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

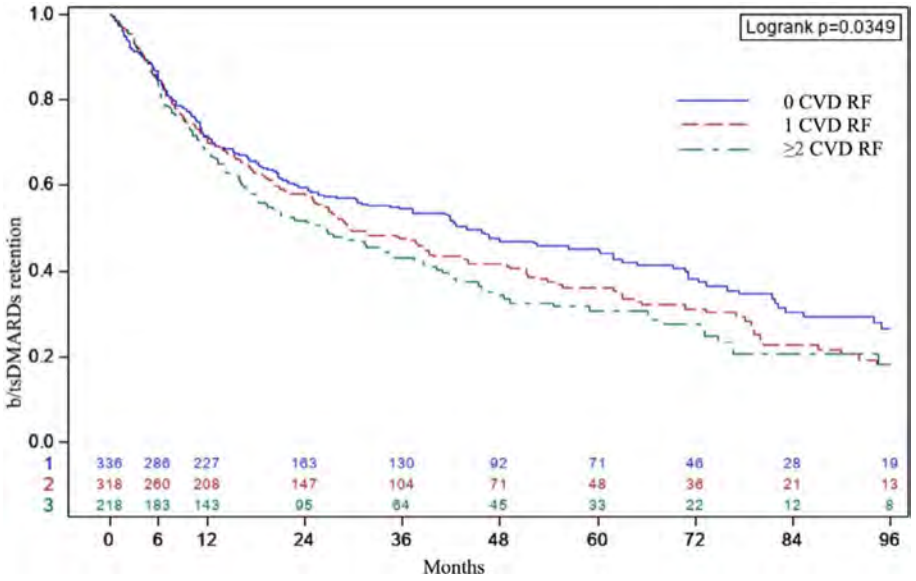

Figure. Kaplan Meier survival analysis of b/tsDMARDs, stratified by the number of cardiovascular risk factors

Background/Purpose: Cardiovascular (CVD) comorbidity can impact overall RA care. We demonstrated that CVD risk factors were associated with higher disease activity and disability. Here, we investigated whether CVD risk factors reduce treatment response by influencing retention of a first biologic disease-modifying antirheumatic drug (bDMARD) or targeted synthetic DMARD (tsDMARDs).

Methods: Participants enrolled in the Ontario Best Practices Initiative (OBRI) RA registry were included if they initiated their first bDMARD or tsDMARD. They were grouped by the number of baseline CVD risk factors (0, 1 or ≥2) including hypertension, dyslipidemia, diabetes, obesity and current smoking. The primary outcome was time-to-discontinuation of therapy for any reason. Secondary outcomes included discontinuation for primary failure, secondary failure or due to adverse events. Multivariable Cox proportional hazards model, adjusted for clinically important confounders, estimated the association between CVD risk factors and drug retention.

Results: A total of 872 patients were included, of which 62% had at least one CVD risk factor. The baseline characteristics are described in Table 1. Fifty-eight percent (N=508) of the study population discontinued their initial b/tsDMARD after a median of 13 (interquartile range [IQR], 6 to 29) months. The most common causes for treatment discontinuation were primary failure (N=72), secondary failure (N=126), and adverse events (N=133). Patients with no CVD risk factors experienced

Table. Multivariate analysis of reasons for discontinuation of the initial bDMARD or tsDMARD based on CVD risk factor status.

Reason for discontinuation	One CVD risk factor		Two or more CVD risk factor	
	SHR (95% CI)	p-value[a]	SHR (95% CI)	p-value[a]
Primary failure	1.71 (0.90, 3.25)	0.10	1.21 (0.60, 2.44)	0.60
Secondary failure	1.34 (0.80, 2.22)	0.26	1.79 (1.04, 3.08)	0.03
All treatment failure (primary and secondary)	1.53 (1.03, 2.28)	0.03	1.54 (1.01, 2.35)	0.04
Adverse events	1.15 (0.74, 1.77)	0.54	1.16 (0.71, 1.89)	0.56
All treatment failure and adverse events	1.36 (1.02, 1.83)	0.04	1.39 (1.01, 1.92)	0.04

Abbreviations: CVD, cardiovascular disease; SHR, Subdistribution hazard ratio; CI, confidence interval

[a]Adjusted hazard ratios by age (categorized into two groups as <65 and ≥65), gender, CDAI score, disease duration, HAQ disability index score, number of non-CVD comorbidities, concurrent conventional DMARD use or oral glucocorticoid use

longer drug survival, with a median (IQR) duration of 44 months (30 to 62). In contrast, patients with 1 or ≥2 CVD risk factors had significantly shorter drug survival, averaging 29 (IQR 25 to 39) and 26 (IQR 18-34), respectively (p= 0.03). Compared to patients with no CVD risk factors, only patients with ≥2 CVD risk factors had a significant increase in all-cause discontinuation: HR 1.32 (95% CI 1.07, 1.65, p= 0.01). In multivariate-adjusted analysis, no significant association was found between all-cause discontinuation and CVD risk factor status. However, there was a significant association between the presence of >1 CVD risk factor and drug discontinuation, notably for secondary failure (Table 2).

Conclusion: The presence of multiple CVD risk factors increases the risk of treatment failure, primarily secondary failure, among biologic naïve patients starting their first advanced therapy. Future research is needed to explore the effect of interventions aiming at reducing these modifiable risk factors on the response to targeted therapies.

Abstract Number: 2134

Autoantibodies to Joint-related Proteins Predict Remission with High Specificity in New Onset RA

Monica Leu Agelii[1], Outi Sareila[2], Erik Lönnblom[2], Kristina Forslind[3], Maria Andersson[3], Alf Kastbom[4], Christopher Sjöwall[5], Lennart Jacobsson[6], Jan Kihlberg[7], Rikard Holmdahl[2], Ingiäld Hafström[2] and **Inger Gjertsson**[8], [1]Gothenburg University, Goteborg, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]FoU Spenshult, Halmstad, Sweden, [4]Linköping University, Linköping, Sweden, [5]Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection/Rheumatology, Linköping University, Linköping, Sweden, [6]University of Gothenburg, Malmö, Sweden, [7]Uppsala University, Uppsala, Sweden, [8]Department of Rheumatology and Inflammation research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

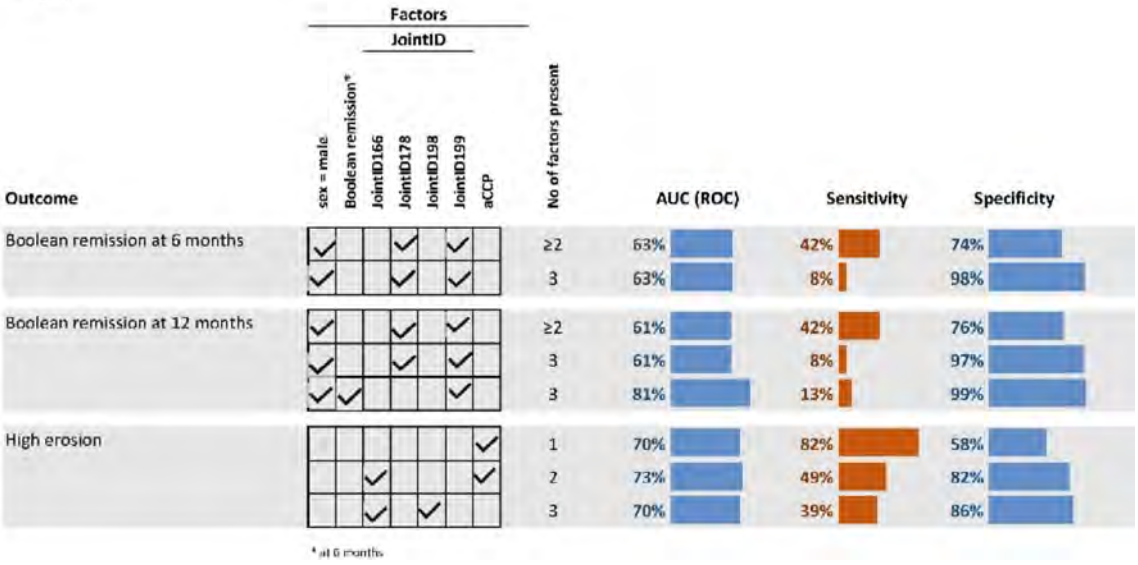
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: One of the major challenges in the management of rheumatoid arthritis (RA) is to determine individual treatment and predict the prognosis. On a group level, high disease activity and antibodies specific for citrulline (ACPA) and immunoglobulins (RF) are factors associated with poor prognosis. New alternative biomarkers, which could provide more specific information, are antibodies to disease-related targets in the joints.

The purpose of this study is to identify circulating autoantibodies to joint-related proteins (hereafter named JointIDs) that predict disease outcome in patients with new onset RA

Methods: Sera at diagnosis from BARFOT and TIRA-2 cohorts (n=1986) with new onset RA patients were screened with a bead-based multiplex flow immunoassay to detect IgG autoantibodies against 47 peptides derived from joint proteins (JointIDs). Disease outcomes included Boolean remission at 6 and 12 months, swollen joint count (SJC) and radiological progression at 12 months (>8% affected feet joints and >3% affected hand joints) in patients who were without joint damage at inclusion. Multivariate logistic regression and zero-inflated negative binomial models adjusted for clinical factors (age, gender, ACPA, RF, changes in medication at 3 and 6 months) were used to identify JointIDs with the strongest potential to predict prognosis

Table 1



Results: Six JointIDs were identified as predictors for these disease outcomes in multivariate analyses. Presence of JointID178 predicted an average decrease in SJC at 6 months with 41% and with 33% at 12 months. Presence of at least 2 of the following factors: JointID178 positive and JointID199 negative at inclusion in combination with male sex identified approx. 40% of the patients in Boolean remission at 6 months with approx. 75% specificity (Table 1). A similar test performance was obtained even for Disease Activity Score 28 remission. The sensitivity and specificity for being in Boolean remission at 12 months if the patients were male, negative for JointID199 and in Boolean remission at 6 months was 13% (CI 9%;16%) and 99% (CI 99%;100%), respectively. RF and ACPA did not predict remission but were the strongest predictors of joint destruction at 12 months although with low specificity (58%). Addition of JointID166 significantly increased the specificity at the expense of sensitivity.

Conclusion: Autoantibodies to joint-related proteins at RA diagnosis can predict remission with a high specificity at 6 and 12 months. This knowledge is of clinical importance as patients positive or negative for these JointIDs in combination with clinical factors may potentially guide future treatment choices.

Synovial Fluid High-density Lipoprotein (HDL)-miR-1246 Is Enriched in Patients with Inflammatory Arthritis Compared to Osteoarthritis and Increases Synovial Fibroblast IL-6 Expression

Olivia Posey[1], Qiong Wu[1], Anastasiia Phothisane[1], Christine Pham[2], Deborah Parks[2], Antonina Akk[3], Danielle Michell[1], Kasey Vickers[1] and Michelle Ormseth[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Washington University, St. Louis, MO, [3]Washington University in St. Louis, St. Louis, MO

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: High-density lipoprotein (HDL), known for its anti-atherogenic reverse cholesterol transport function, also transports miRNAs between cells, altering cellular function. We found that compared to control subjects, patients with rheumatoid arthritis (RA) - a type of inflammatory arthritis (IA) – have increased plasma HDL-bound miR-1246, which increased macrophage IL-6 expression. Previous reports indicate that HDL is enriched in the synovial fluid of patients with RA versus osteoarthritis (OA). We hypothesize that in IA the higher concentration of synovial HDL promotes joint inflammation by delivering a higher cargo load of miR-1246 to synovial fibroblasts and enhancing the release of inflammatory cytokines. The purpose of this study is to determine if HDL and HDL-miR-1246 is enriched in IA versus OA synovial fluid and increases synovial fibroblast proinflammatory cytokine expression.

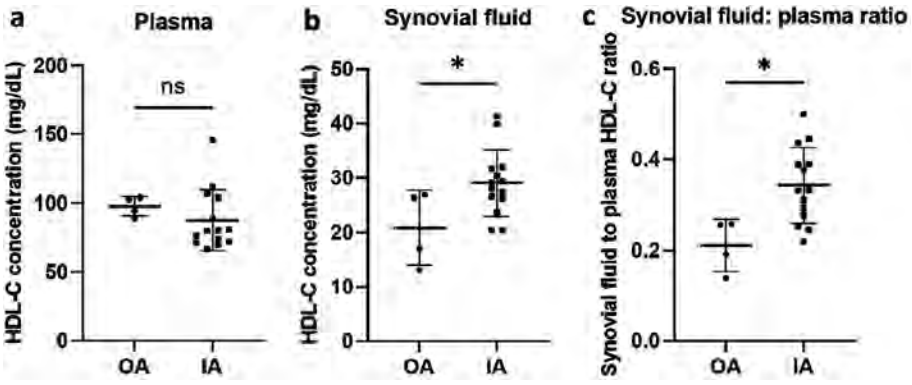

Figure 1. NMR-based HDL-C concentration (mg/dL) in plasma (a), synovial fluid (b), and ratio of synovial fluid to plasma (c) in patients with osteoarthritis (OA) versus inflammatory arthritis (IA). Plasma HDL is similar compared IA and OA (P=0.19) (a). Synovial fluid HDL is significantly enriched 1.4-fold in IA versus OA (b). The ratio of synovial fluid to plasma HDL-C was 1.6-fold enriched in IA versus OA (c). HDL-C = high-density lipoprotein – cholesterol. IA = inflammatory arthritis. OA = osteoarthritis. ns= not significant. *P<0.05. Bars = mean, whiskers = standard deviation. Mann-Whitney U test.

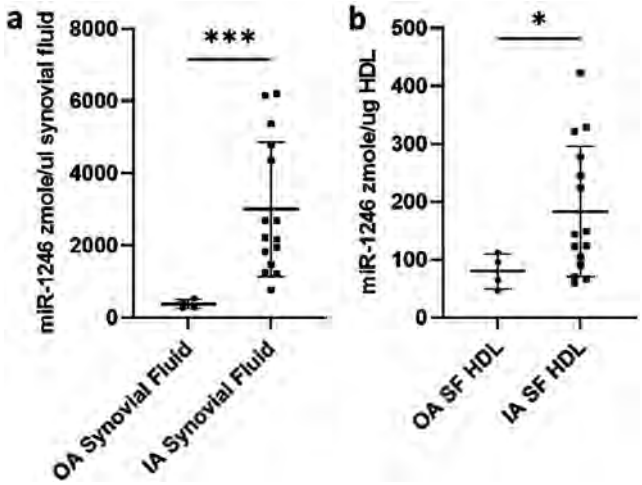

Figure 2. Concentration of miR-1246 in synovial fluid (a) and purified synovial fluid HDL (b) from patients with osteoarthritis (OA) versus inflammatory arthritis (IA). miR-1246 in synovial fluid is 7.9-fold enriched in IA versus OA (a). miR-1246 in purified synovial fluid HDL is 2.3-fold enriched in IA versus OA (b). SF= synovial fluid. *P<0.05, ***P< 0.001. Bars=mean, whiskers= standard deviation. Mann-Whitney U test.

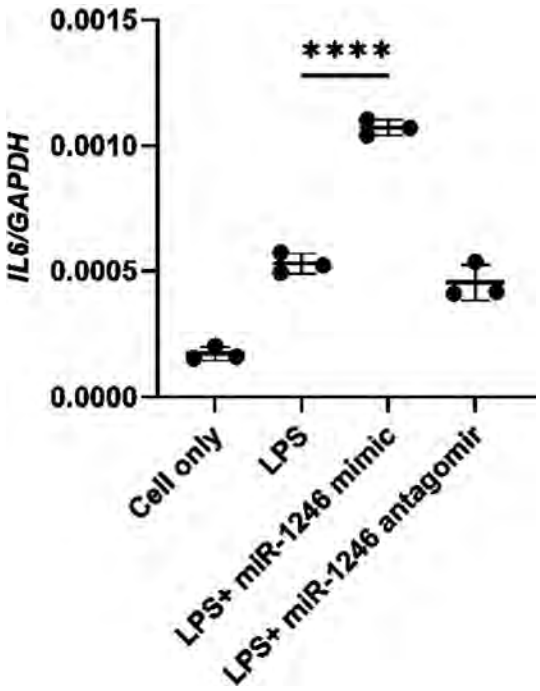

Figure 3. Synovial fibroblasts treated with LPS then miR-1246 expressed 2.0-fold more IL-6 versus LPS alone. Treatment with LPS then an antagomir to block endogenous miR-1246 production did not significantly alter IL-6 expression. IL-6 = interleukin 6. GAPDH = glyceraldehyde-3-phosphate dehydrogenase. LPS = lipopolysaccharide. ****P < 0.0001. Bars = mean, whiskers = standard deviation. T-test.

Methods: Synovial fluid and plasma were collected consecutively from 15 IA (10 RA and 5 with immune-checkpoint inhibitor-induced IA) and 4 OA patients who underwent arthrocentesis for routine care. Nuclear magnetic resonance was used to measure the synovial fluid and plasma lipoproteins. Synovial fluid HDL was isolated by fast protein liquid chromatography. Synovial fluid miR-1246 and synovial fluid HDL-miR-1246 were measured by qPCR and normalized to a spike-in miRNA and DNA mimic standard to determine miRNA concentration. RA synovial fibroblasts were activated with LPS for 24-hours then washed and treated with a miR-1246 mimic or antagomir for 24-hours. Cellular *IL-6* expression was measured by qPCR.

Results: HDL-cholesterol (HDL-C) concentration was similar in IA versus OA plasma (P=0.19). However, synovial fluid HDL was enriched 1.4-fold in IA (29 mg/dl ± 6.1 mg/dl) versus OA (21mg/dl ± 6.9mg/dl) (P=0.04). Similarly, the ratio of synovial fluid to plasma HDL-C was 1.6-fold enriched in IA versus OA patients (P=0.02) (Figure 1). Synovial fluid miR-1246 concentrations were increased 7.9-fold in IA (3000 zmol/uL ± 1860 zmol/uL) versus OA patients (379 zmol/uL ± 126 zmol/uL, P=0.0005). Synovial fluid HDL miR-1246 concentrations were also increased 2.3-fold in IA (183 zmol/ug HDL ± 113 zmol/ug HDL) versus OA patients (80 zmol/ug HDL ± 30 zmol/ug HDL, P=0.049) (Figure 2). Treatment of activated synovial fibroblasts with miR-1246 increased *IL-6* expression 2.0-fold (P< 0.0001, Figure 3).

Conclusion: HDL is concentrated in synovial fluid and enriched in miR-1246 in patients with IA versus OA. miR-1246 is proinflammatory to synovial fibroblasts. These data suggest that the HDL may enhance IA synovial inflammation by transport of proinflammatory miRNAs. Future studies will be dedicated to examining HDL-mediated transfer of miR-1246 to synovial fibroblasts and its effect *in vivo*.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: T cells play an important role in the genesis of rheumatoid arthritis (RA). HLA class II genes, such as HLA-DRB1*0401 (HLA-DR4), confer the strongest genetic risk and suggest involvement of $CD4^+$ T cells. However, the exact pathogenesis of RA is still elusive. Existing mouse models mimic specific aspects of the disease but do not fully recapitulate the human immune system. Thereby current research is limited and would profit from a humanized mouse model. We aimed to identify arthritogenic cells by transferring HLA-$DR4^+$ peripheral blood mononuclear cells (PBMC) of RA patients into NSG-DR4 mice. Thereby generating a novel mouse model with inflammatory joint disease, only triggered by the transfer of human immune cells.

Methods: Humanized NSG-DR4 mice (NSG-AB^0 Tg(HLA-DR4)) were generated by injecting PBMC of HLA-DR4 positive patients or controls. Engraftment within peripheral blood, bone marrow, skin, liver, and spleen was assessed comprehensively using multicolor flow cytometry. Development of RA was monitored by examination of the joints, followed by micro computed tomography analysis and histology. Joints were analyzed regarding pannus formation, bone erosions, cartilage damage, and human cell infiltration.

Results: Here, we show that $DR4^+$ T cells of the peripheral blood of RA patients are capable of inducing an RA-like disease in NSG-DR4 mice. These mice recapitulate different hallmarks of the disease including immune cell infiltration, pannus formation, increased osteoclastogenesis, cartilage damage, and bone erosions. Compared to healthy controls, cells of RA patients are more likely to develop inflammatory joint disease in these mice (RA donor 70% vs. healthy control 20%, p=0.00196). T-helper 1 (Th1) cells, dominated the human immune cell composition in humice, while regulatory T cells (Tregs) were diminished compared to donor PBMC composition. Transfer of *in vitro* Th1 polarized T cells increased arthritis incidence.

Conclusion: Arthritogenic cells found in the peripheral blood of RA patients are capable of inducing an RA-like disease in NSG-DR4 mice. This novel mouse model will allow to identify these cells on a patient-personalized level.

Line of Therapy of Biologics and JAK Inhibitors in RA, PsA and AxSpA: Implications for Design and Uptake of New Drugs and Diagnostics

Jeffrey Curtis[1], Fenglong Xie[1], Yuji Su[2], Patrick Stewart[3] and Amy S. Mudano[1], [1]Illumination Health, Hoover, AL, [2]University of Alabama at Birmingham and Illumination Health, Birmingham, AL, [3]Illumination Health, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (AxSpA) have an increasing array of treatment options available, and new blood-based diagnostic tests to predict future treatment response are commercially available or are in development. Moreover, certain medications are restricted to patients who are already biologic experienced. We examined the point prevalence of the line of therapy (LoT) by type of arthritis to assess the size of the eligible patient population.

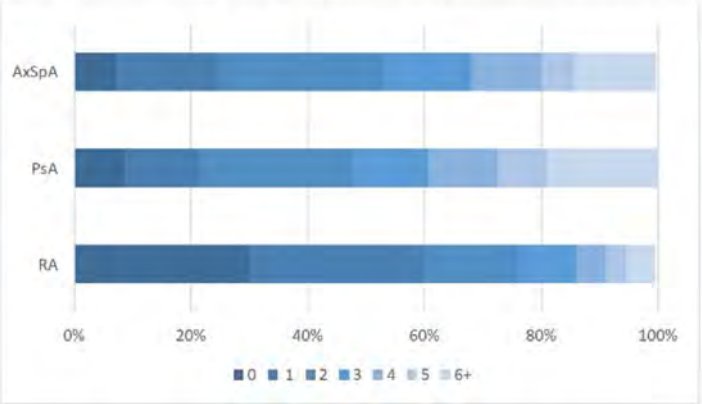
Methods: We queried the data warehouse of the Excellence Network in Rheumatology (ENRGY), a national practice-based research network (PBRN), to identify patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (AxSpA). Data from the electronic health record (EHR) was linked to a custom in-office tablet app that captures patients' lifetime treatment history, disease duration and other disease features. We used both linked data sources to identify current users of conventional, biologic, or targeted synthetic DMARDS (cs/b/tsDMARDs) and classify them as to their prior treatment history over their lifetime. Results were reported by disease and by medication class

Table: Characteristics of RA, PsA and AxSpA patients eligible for analysis requiring EHR data linked to in-office tablet data

	RA	PsA	AxSpA
N	6,740	1,901	471
Age	64 (55, 72)	60 (50, 69)	54 (44, 64)
Female	5,294 (79%)	1,155 (61%)	234 (50%)
Disease duration, years	6 (4, 11)	5 (3, 11)	5 (3, 11)
Current therapy, %			
MTX, with or without other csDMARDs	1,806 (27%)	251 (13%)	24 (5.1%)
csDMARD(s) without MTX	1,368 (20%)	94 (4.9%)	38 (8.1%)
Apremilast (without biologics/JAKi)	0 (0%)	196 (10%)	1 (0.2%)
TNFi	1,967 (29%)	722 (38%)	312 (66%)
IL-6Ri	238 (3.5%)	0 (0%)	0 (0%)
Abatacept	394 (5.8%)	28 (1.5%)	1 (0.2%)
Rituximab	223 (3.3%)	0 (0%)	0 (0%)
JAKi	744 (11%)	80 (4.2%)	15 (3.2%)
IL-12/23	0 (0%)	46 (2.4%)	2 (0.4%)
IL-17	0 (0%)	338 (18%)	74 (16%)
IL-23	0 (0%)	146 (7.7%)	4 (0.8%)
Glucocorticoids, %	4,040 (60%)	947 (50%)	235 (50%)
Opioids, %	993 (15%)	239 (13%)	72 (15%)
Area deprivation index >=80% (i.e. deprived), %	831 (12%)	161 (8.5%)	55 (12%)

Data shown as median (IQR) or n(%)

Figure 1: Number of Prior Biologics or JAKi in AxSpA, PsA, and RA patients (n=9,112)



Results: As of Q4 2022, we identified 6,740 RA, 1,901 PsA, and 471 AxSpA patients who had linked EHR and self-reported lifetime treatment history data available who were current users of any cs/b/tsDMARDs (Table). The point prevalence of the number of prior biologics and JAKi is shown in the Figure. The proportion of patients who were biologic and JAKi naïve was 30% in RA, 9% in PsA, and 7% in AxSpA (Figure, left-most dark blue panel). The proportion of patients who were biologic naïve or treatment experienced with only 1 current or past biologic or JAKi was 25% in AxSpA, 22% in PsA, and 60% in RA.

Conclusion: Stakeholders interested in developing or marketing new therapies and diagnostic tests that target RA, PsA or AxSpA patients who are biologic naïve or minimally treatment experienced will be advantaged by these estimates as they estimate the potential opportunity and size of the eligible patient population. These proportions are being extrapolated to the U.S. to provide an estimate of the number of patients who might be eligible to receive various treatments or diagnostics that might be positioned or marketed according to line of therapy

Background/Purpose: Frailty occurs prematurely in RA. Levels of frailty are higher in Veteran populations than civilians[1]. Frailty has been shown to predict osteoporotic fractures in a single Canadian RA cohort, however the frailty instrument lacked external validation[2]. The aim of this study was to evaluate whether frailty predicted incident osteoporotic fractures in Veterans with RA using an externally validated frailty index.

Methods: We used data from the national Veterans Affairs Rheumatoid Arthritis (VARA) Registry 1/2003-12/31/2021. Baseline frailty was calculated using the VA Frailty Index (VAFI)[1]. The VAFI is based on diagnostic and CPT codes which are categorized into 31 deficits including morbidity, function, mood, cognition and geriatric syndromes. Osteoporotic fractures were identified by searching fracture-related diagnostic and procedure codes and subsequently validated by chart review. High-trauma, periprosthetic and pathologic fractures related to cancer were excluded. Missing data at baseline were imputed using multiple imputation with chained equations with 10 iterations and for further time points using the last observation carried forward. Age-adjusted fracture incidence rates were calculated. Multivariable Cox regression evaluating the relationship between baseline frailty and incident osteoporotic fracture was performed adjusting for baseline age, sex, race, smoking status, anti-cyclic citrullinated peptide (CCP) positivity and prior osteoporotic fracture; and time-varying body mass index (BMI), DAS28ESR, prednisone use, conventional synthetic disease modifying antirheumatic drug (DMARD) use, and biologic DMARD use. Participants were followed from enrollment and censored at osteoporotic fracture, death or end of study period.

Results: 2,930 Veterans were included, mean age 64±11 years. Compared to those without incident osteoporotic fracture, those with fracture were more frequently female (19% vs 11%), less frequently Black (10% vs 17%) and had more pre-enrollment fractures (35% vs 28%) (Table 1). Age, anti-cyclic citrullinated peptide (CCP) positivity, BMI, disease activity and medication use at baseline were similar between those who did and did not fracture. There were higher rates of baseline

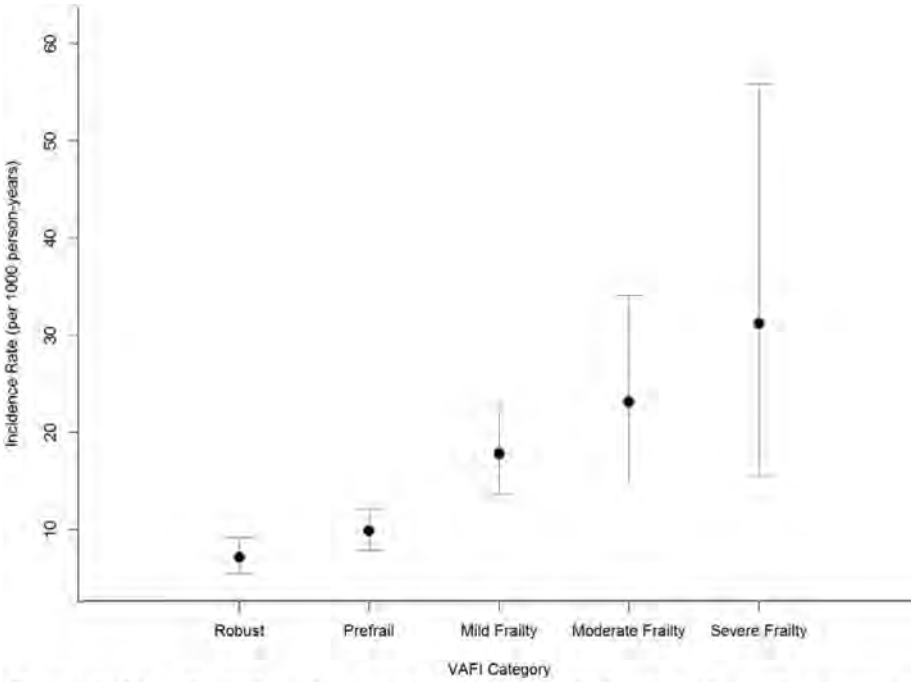

Figure 1. Age-adjusted incidence rates of osteoporotic fractures by frailty category.

Table 2. Unadjusted and adjusted cox models evaluating relationship between frailty and incident osteoporotic fracture.

Frailty Category	HR	95% CI	p-value	aHR*	95% CI	p-value
Robust	ref	--	--	ref	--	--
Pre-Frail	1.54	1.10-2.16	0.0134	1.38	0.97-1.95	0.0748
Mild Frailty	2.85	1.96-4.13	<0.0001	2.16	1.45-3.22	0.0002
Moderate Frailty	3.88	2.41-6.25	<0.0001	3.04	1.83-5.03	<0.0001
Severe Frailty	5.32	2.77-10.21	<0.0001	4.54	2.28-9.03	<0.0001

*Model was adjusted for baseline age, sex, race, smoking status, anti-cyclic citrullinated peptide (CCP) positivity and prior osteoporotic fracture; and time-varying body mass index (BMI), DAS28ESR, prednisone use, conventional synthetic disease modifying antirheumatic drug (DMARD) use and biologic (DMARD) use.

frailty in the fracture group (25% vs 17% mild frailty, 10% vs 7% moderate frailty, and 5% vs 2% severe frailty). Over the 21,800 person-years of observation, 240 incident osteoporotic fractures occurred (79 extremity, 58 rib, 47 spine, 43 hip and 13 pelvis). Age-adjusted incidence rates of osteoporotic fractures increased by frailty category (Figure 1). In the multivariable Cox model, mild, moderate and severe frailty each had significantly increased risk of incident osteoporotic fracture compared to those who were robust (Table 2; aHR 2.16 [95% CI 1.45-3.22], 3.04 [95%CI 1.83-5.03] and 4.54 [95%CI 2.28-9.03]; all $p < 0.001$, respectively).

Conclusion: Baseline frailty is associated with incident osteoporotic fractures in Veterans with RA. Frailty measurement in RA using the VAFI, a validated, automated tool, may prove to be useful in identifying Veterans at high risk for osteoporosis and fractures. SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: A prior study suggested a higher risk of cancer mortality in patients with rheumatoid arthritis (RA) with higher levels of circulating leptin, an adipocytokine [1]. Leptin and leptin receptor signaling pathway have been implicated in various key processes in cancer progression, such as cell proliferation, metastasis, and angiogenesis [2]. We examined the associations between circulating adipocytokines with incident cancer in Veterans with RA.

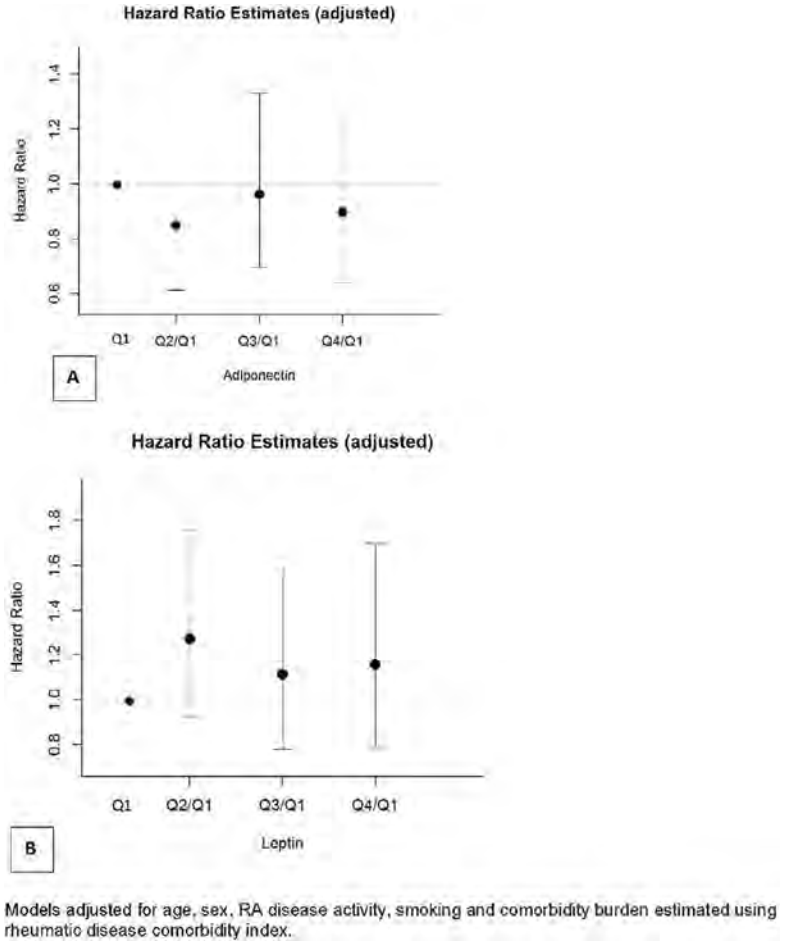

Figure 1. Multivariable model of adipocytokine quartiles and incident overall cancer with reference to quartile 1.

Methods: Veterans enrolled in Veterans Affairs RA (VARA) registry, a multicenter prospective RA cohort, without a prior history of cancer were eligible for this study. Adipocytokines (adiponectin and leptin) were measured as part of a multi-analyte panel on banked serum at VARA enrollment. Records were linked to VA central cancer registry to identify incident cancers. Participants were followed from enrollment to the first of incident cancer, death, or end of study period (2/1/23). Associations between adipocytokine levels (divided into quartiles) and incident overall cancers were assessed in Cox regression models accounting for covariates (measured at baseline) including age, sex, RA disease activity, smoking status, and comorbidity burden estimated using rheumatic disease comorbidity index (RDCI). In a sub-analysis, we also assessed associations between adipocytokine levels and incident lung cancer, the most frequent malignancy in this cohort.

Results: 2391 Veterans met eligibility criteria of whom 87.7% were male. Higher adiponectin levels were associated with older age, lower BMI, former smoking status. Higher leptin levels were associated with higher BMI and higher comorbidity scores. Over a median (interquartile range) 6.2 (6.9) years of follow-up, there were 322 incident cancers. The most common cancers observed were: lung (n= 75), prostate (n= 61), gastrointestinal cancers (n=42), and hematological (n=40). In multivariable Cox Proportional hazard models, we did not observe a significant association between levels of adiponectin

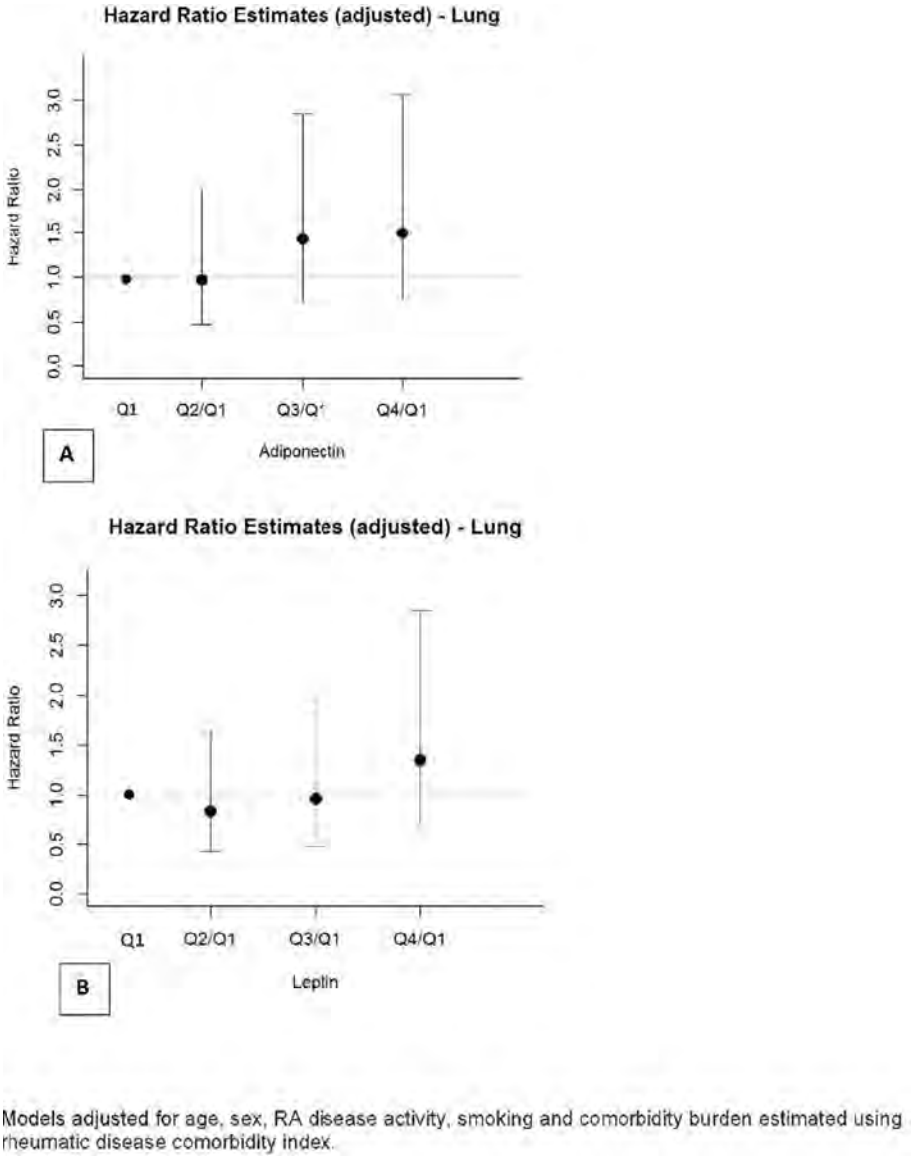

Figure 2. Multivariable model of adipocytokine quartiles and incident lung cancer with reference to quartile 1.

(HR 0.90, 95% confidence interval, CI, 0.64-1.26 for quartile 4 versus quartile 1) (**Figure 1, panel A**) or leptin (HR for quartile 4 versus first quartile 1.16, 95% CI 0.79-1.70) with incident cancer (**Figure 1, panel B**). Those with the highest adiponectin or leptin levels tended to have higher incidence of lung cancer although the associations were not statistically significant (**Figure 2**).

Conclusion: In this study, we did not observe an association between levels of adipocytokines and incident overall cancer risk and specifically lung cancer risk in Veterans with RA. Further studies will explore the association between adipocytokines and incidence of specific cancers, especially obesity-related cancers.

Serum Alarmins and the Risk of Interstitial Lung Disease in Patients with Rheumatoid Arthritis

Ted R Mikuls[1], Bryant England[2], Harlan Sayles[2], Tate Johnson[2], Michael Duryee[2], Carlos Hunter[2], Joshua Baker[3], Gail Kerr[4], Gary Kunkel[5], Grant Cannon[6], Brian Sauer[7], K Wysham[8], Amy Joseph[9], Beth Wallace[10], Geoffrey Thiele[2] and Jill Poole[2], [1]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]University of Pennsylvania, Philadelphia, PA, [4]Washington DC VAMC/ Georgetown and Howard Universities, Washington, DC, [5]University of Utah, Salt Lake City, UT, [6]University of Utah and Salt Lake City VA, Salt Lake City, UT, [7]Salt Lake City VA/University of Utah, Salt Lake City, UT, [8]VA Puget Sound/University of Washington, Seattle, WA, [9]Washington University / St. Louis VA, St. Louis, MO, [10]Ann Arbor VA, Ann Arbor, MI

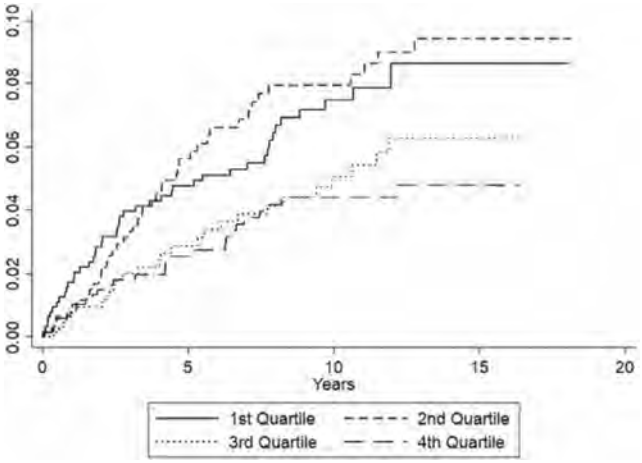
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Diagnosis, Manifestations, and Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Alarmins are proteins found in the nuclei of epithelial, endothelial, and immune cells that are released following cell damage and act as stress signals. Facilitating tissue homeostasis and repair, alarmins have also been implicated in the pathogenesis of both rheumatoid arthritis (RA) and tissue fibrosis in other conditions including idiopathic pulmonary fibrosis (Lee JU et al. BMC Pulm Med 2017). The objective of the current study was to quantify associations of serum alarmins with risk of rheumatoid arthritis-associated interstitial lung disease (RA-ILD).

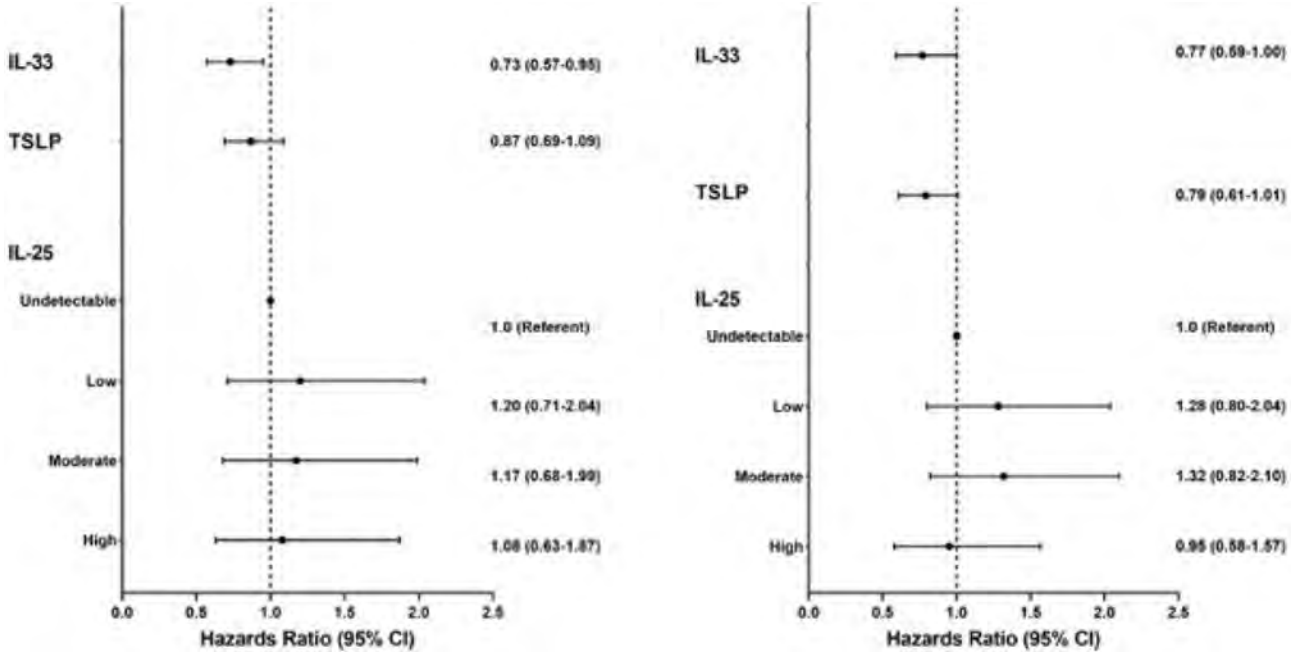
Methods: Three alarmins (IL-33, thymic stromal lymphopoietin [TSLP], and IL-25) were measured using serum collected at enrollment from the multicenter prospective Veterans Affairs RA registry. RA-ILD was classified using systematic medical record review and based on a provider diagnosis of ILD, plus either consistent findings from chest CT or histopathological abnormalities. Given their distributions, IL-33 and TSLP concentrations were log-transformed and standardized (per 1 SD), while detectable IL-25 was categorized into tertiles (undetectable as referent). Cross-sectional associations of alarmin values with RA-ILD at enrollment (prevalent RA-ILD) were examined using separate logistic regression models. Associations

of alarmins with incident RA-ILD were examined using Cox proportional hazards regression. Covariates in multivariate models included age, sex, race, smoking status, RA disease activity score, and anti-CCP antibody positivity. For analytes associated with incident RA-ILD, the cumulative incidence of ILD was summarized graphically by alarmin quartile.

Results: Of 2,835 study participants (88% male, mean age 65 ± 11 years, 77% White, 76% current or former smoker), 115 participants (4.1%) had prevalent RA-ILD at baseline. An additional 146 (5.1%) developed incident ILD over a median follow-up of 3.0 years (IQR 1.2-6.3 years). There were no associations between serum alarmins and prevalent ILD in unadjusted or adjusted logistic regression models (not shown). Likewise, no significant associations of TSLP or IL-25 with incident ILD were observed. The cumulative incidence of RA-ILD development by IL-33 quartile among those without ILD at enrollment is shown in **Figure 1.** After 10 years of follow-up, approximately 8% of uncensored patients with RA in the lower



Cumulative incidence of developing incident RA-ILD based on baseline IL-33 quartile.



Univariate (left) and multivariable (right) associations of alarmin concentrations with the development of incident RA-ILD. Models for each analyte examined separately; multivariable models adjusted for age, sex, race, smoking status, DAS28, and anti-CCP status; univariate p-values for IL-33 = 0.018; TSLP = 0.222; IL-25 (trend test) = 0.930; multivariable p-values for IL-33 = 0.047; TSLP = 0.056; IL-25 (trend test) = 0.912; IL-33 and TLSP log-transformed, HR reported per log-fold increase.

two IL-33 quartiles had developed ILD compared to approximately 4% in the upper two quartiles. There was a significant inverse association between IL-33 concentration and risk of developing incident RA-ILD in unadjusted (HR 0.73 per log-fold increase; 95% CI 0.57-0.95; p=0.018) and adjusted (HR 0.77; 95% CI 0.59-1.00, p=0.047) models (**Figure 2**).

Conclusion: In contrast to our a priori hypothesis, we observed a significant inverse association between serum IL-33 concentration and the risk of developing incident RA-ILD. These results suggest that by promoting tissue homeostasis and repair, circulating IL-33 could play a protective role in the 'pre-clinical' stages of RA-ILD and its measurement could improve risk stratification efforts in addition to informing future strategies of treatment and prevention.

Session Date: Tuesday, November 14, 2023

Session Title: RA – Treatments Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an elevated risk for developing atherosclerotic cardiovascular disease (CVD). Proprotein convertase subtilisin/kexin type 9 (PCSK9) is a key regulator of low-density lipoprotein (LDL) metabolism as it gives an increased breakdown of LDL-receptors on the liver resulting in enhanced LDL-cholesterol levels. We aimed to investigate i) the influence of glucocorticoids and biologic treatments on PCSK9 levels and ii) whether the presence of autoantibodies associates with the changes in the PCSK9 levels in DMARD-naïve early RA patients after treatment.

Table 1. Baseline characteristics and the medication of interest at baseline and at 24 weeks of patients with early rheumatoid arthritis.

	Group 1: glucocorticoids plus methotrexate (n=75)	Group 2: certolizumab-pegol plus methotrexate (n=84)	Group 3: abatacept plus methotrexate (n=89)	Group 4: tocilizumab plus methotrexate (n=82)	Total (n=330)
Baseline characteristics					
Female	49/75 (65%)	57/84 (68%)	60/89 (67%)	56/82 (68%)	222/330 (67%)
Age (years)	57.5 (14.7)	54.3 (16.2)	55.5 (15.2)	54.0 (12.8)	55.3 (14.8)
Body-mass index, kg/m^2	26.4 (5.0)	25.2 (4.4)	26.1 (4.4)	26.4 (5.0)	26.0 (4.7)
Anti-citrullinated peptide antibody positive	62/75 (83%)	66/84 (79%)	73/89 (82%)	71/82 (87%)	272/330 (82%)
Rheumatoid factor positive	55/75 (73%)	66/84 (79%)	71/89 (80%)	67/82 (82%)	259/330 (79%)
Antinuclear antibody positive	24/69 (35%)	30/78 (39%)	34/87 (39%)	21/80 (26%)	109/314 (35%)
Medication of interest					
Statin use at baseline	8/75 (11%)	6/84 (7%)	9/89 (10%)	5/82 (6%)	28/330 (9%)
Statin use at 24 weeks	11/75 (15%)	6/84 (7%)	8/89 (9%)	7/82 (9%)	32/330 (10%)
Oral glucocorticoids dose at 24 weeks (mg)	4.9 (1.3)	0.1 (0.8)	0.2 (1.0)	0.4 (1.5)	1.3 (2.3)
Cumulative glucocorticoids dose (mg)	1500.3 (170.4)	29.8 (136.4)	42.7 (207.5)	96.4 (298.0)	384.0 (642.5)

Data are n/N (%) or mean (SD). PCSK9= Proprotein convertase subtilisin/kexin type 9.

Methods: In this post-hoc analysis of the phase 4 NORD-STAR randomized controlled trial, PCSK9 levels were assessed in 330 Swedish patients who were randomised (1:1:1:1) to receive methotrexate (MTX) in combination with glucocorticoids (GC), certolizumab-pegol (CZP), abatacept (ABA), or tocilizumab (TCZ). PCSK9 levels were determined by commercial ELISA kit (R&D Systems, UK) at baseline and 24 weeks after the initiation of randomised RA treatment. The assay range of ELISA was 125.0–8000 pg/mL. Linear regression models were used to analyse the difference between the treatment groups on PCSK9 levels at 24 weeks. Analyses were adjusted for the baseline level of PCSK9, sex, age, BMI, DAS28-CRP, anti-citrullinated protein antibody (ACPA) status, rheumatoid factor (RF) status, and statin use at 24 weeks. In a second analysis, the interaction between the treatment groups and RF, ACPA and antinuclear antibody (ANA) were added to the model.

Results: Baseline characteristics and the medications of interest are shown in Table 1. The mean PCSK9 levels at baseline were similar across treatment groups. At 24 weeks, highest PCSK9 levels were observed in the MTX+GC treatment group (see table 2). The mean PCSK9 levels at 24 weeks were as follows: MTX+GC (1934 pg/mL [SD 888]); CZP+MTX (1679 [759]); ABA+MTX (1693 [634]); and TCZ+MTX (1784 [761]). Because the effect of the three biological treatment groups on PCSK9 levels at week 24 were more or less the same, for the analyses with the interactions with RF, ACPA and ANA, we

Table 2. Mean levels of PCSK9 at baseline and 24 weeks after the initiation of randomised RA treatment.

PCSK9 (pg/mL)	Baseline	At 24 weeks
Glucocorticoids plus methotrexate	1656 (895)	1934 (888)
Certolizumab-pegol plus methotrexate	1655 (865)	1679 (759)
Abatacept plus methotrexate	1669 (689)	1693 (634)
Tocilizumab plus methotrexate	1772 (965)	1784 (761)

Data are mean (SD). PCSK9=Proprotein convertase subtilisin/kexin type 9.

Table 3. Results of interaction analysis estimating the influence of autoantibody status on PCSK9 levels between glucocorticoid treatment and pooled biologic treatment at 24 weeks.

	Glucocorticoid treatment plus methotrexate (n=75)	Biologic treatment plus methotrexate (n=255)	P interaction
PCSK9 (pg/mL) levels at 24 weeks	**Ref**	-194.9 (-374.1 to -15.8); **p=0.03**	-
Interaction analyses			
Rheumatoid factor status			
positive	**Ref**	-311.8 (-517.5 to -106.1); **p=0.003**	**0.03**
negative	**Ref**	154.7 (-201.2 to 510.6); p=0.39	
Anti-citrullinated peptide antibody status			
positive	**Ref**	-278.2 (-474.0 to -82.4); **p=0.005**	**0.04**
negative	**Ref**	207.7 (-222.5 to 637.8); p=0.34	
Antinuclear antibody status			
positive	**Ref**	-440.2 (-763.8 to -116.5); **p=0.008**	**0.09**
negative	**Ref**	-98.5 (-328.9 to 131.9); p=0.40	

PCSK9=Proprotein convertase subtilisin/kexin type 9. Biologic treatment refers to a treatment with either certolizumab-pegol, abatacept, or tocilizumab. Analyses were adjusted for the baseline PCSK9 level, sex, age, BMI, DAS28-CRP, ACPA status, RF status, and statin use at 24 weeks.

combined the three biological treatment groups into one group in order to increase power. At 24 weeks, PCSK9 levels were significantly lower in the pooled biologic treatment group compared with the GC+MTX treatment group(β coefficient -194.9; 95% CI -374.1 to -15.8). Interaction analyses demonstrated that the differences between MTX+GC and biological treatments was most pronounced for RF, ACPA and ANA positive patients (See table 3).

Conclusion: Glucocorticoid treatment was associated with increased PCSK9 levels at 24 weeks. These increases were observed primarily in RF, ACPA, ANA positive patients. Our data provide a potential mechanistic link between glucocorticoid treatment and cardiovascular disease.

Adherence Patterns in Rheumatoid Arthritis Patients Receiving a Janus Kinase (JAK) Inhibitor or a Tumor Necrosis Factor α Inhibitor (TNFi) After the Addition of a Black Box Warning to JAK Inhibitors

W. Cliff Rutter, Kunal Patel, **Samantha Delgado**, Guy Cozzi, Elisea Avalos-Reyes, Will Cavers, Chen Liu, Rashmi Grover, Lucia Feczko and Kjel Johnson, CVS Health, Woonsocket, RI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2021, the FDA concluded that there is an increased risk of serious heart-related events with the Janus Kinase (JAK) inhibitor tofacitinib, which is currently indicated for rheumatoid arthritis (RA), psoriatic arthritis (PsA), ulcerative colitis (UC), ankylosing spondylitis (AS) and polyarticular course juvenile idiopathic arthritis (pcJIA). Accordingly, a black box warning was applied to the JAK class for drugs that are indicated for the treatment of arthritis and other inflammatory conditions. Tumor necrosis factor α inhibitors (TNFi) do not carry a black box warning for these adverse events. It is unknown if prescribing patterns or patient behavior was impacted in response to the new black box warning.

Methods: This is a retrospective cohort study of RA patients receiving a JAK inhibitor or TNFi. Patients were included if they received at least 3 fills for a JAK inhibitor or TNFi between 4/1/2021 and 8/31/2022 and maintained coverage until 8/31/2022. Three periods were assessed: pre-black box warning (4/1/2021 – 8/31/2021), washout (9/1/2021-12/1/2021), and post-black box warning period (12/2/2021-8/31/2022). Propensity score matching was conducted utilizing the patient's demographic profile, including age, gender, socioeconomic status (SES), location, and comorbid conditions. Adherence was measured using proportion of days covered (PDC) and was evaluated overall and during each period. Discontinuation was determined if the last fill occurred greater than 30 days from the end of the study. Discontinuation rates were calculated for each period; p-values < 0.05 were significant.

Results: A total of 815 patients were included in the unmatched analysis, with 215 (26.4%) receiving JAK inhibitors. Differences in age and gender were found between JAK inhibitor and TNFi patients (mean age (SD): 54.8 [8.9] vs 52.4 [11.4] years in JAK inhibitor vs TNFi, $p = 0.002$; 36 (16.7%) vs 149 (24.8%) males in JAK inhibitor vs TNFi, $p=0.02$). No differences in SES or comorbidity were found. Patients prescribed JAK inhibitors had higher median PDC (5.6%; $p=0.022$) during the study compared to TNFi patients and higher median PDC (7.1%; $p = 0.014$) during the post-black box warning period. No difference in discontinuation rates were found overall and stratified by study period. After matching, 408 patients were evaluated with 50% receiving JAK inhibitors; no differences in underlying demographics or comorbidities were found. Adherence metrics were similar between matched cohorts. There were no significant differences in median PDC (1.8%; $p=0.235$) or discontinuation rates (28.9% vs 27.9%), in JAK inhibitor and TNFi groups, respectively, $p = 0.529$.

Conclusion: Adherence and persistence to JAK inhibitors were not significantly impacted by the addition of the black box warning.

Session Title: RA – Treatments Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In the treatment of RA, JAK inhibitors are a valuable option to meet remission or low disease activity (LDA) treatment targets following an inadequate response (IR) or intolerance to ≥ 1 conventional synthetic disease-modifying antirheumatic drug (DMARD). Filgotinib (FIL) is a JAK1 preferential inhibitor available in two doses for the treatment of moderate to severe RA. The objective of this analysis was to evaluate long-term efficacy of two doses of FIL in clinically relevant pt populations. Response rates for Boolean remission 2.0 were reported as an exploratory objective.

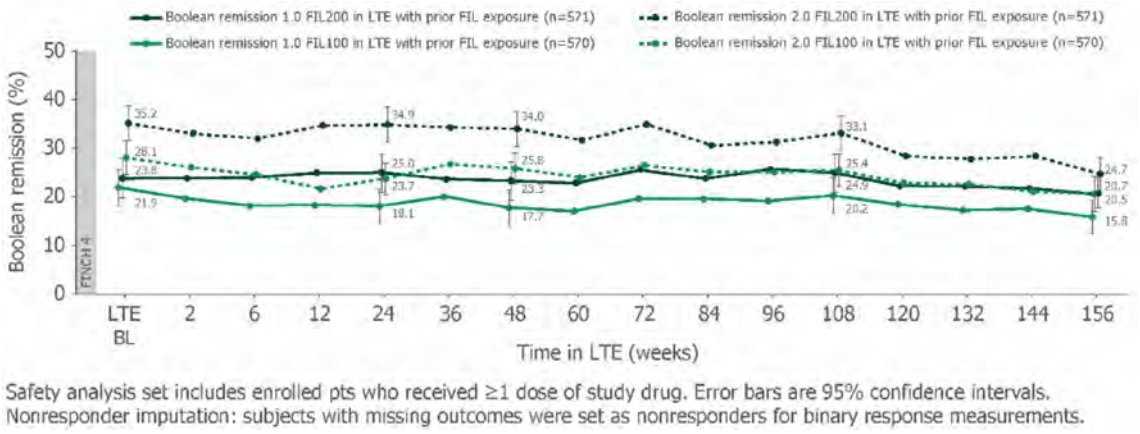

Figure. Boolean remission 1.0 and 2.0 for MTX-IR pts in FINCH 4 LTE through W156 (safety analysis set, nonresponder imputation)

Table. Efficacy in MTX-IR and bDMARD-IR pts through W156 in FINCH 4 (safety analysis set; nonresponder imputation)

*Pain and HAQ-DI: MTX-IR LTE BL FIL200/200 (n=569); LTE W156 FIL200/200 (n=414), FIL100/100 (n=405), ADA/FIL200 (n=87), ADA/FIL100 (n=83). bDMARD-IR LTE BL FIL100/100 (n=123); LTE W156 FIL200/200 (n=80), FIL100/100 (n=74), PBO/FIL200 (n=38), PBO/FIL100 (n=38).
ADA, adalimumab; PBO, placebo; SD, standard deviation.

Methods: In this interim analysis, efficacy (nonresponder imputation) of FIL 200 mg (FIL200) and 100 mg (FIL100) was assessed from long-term extension (LTE) baseline (BL) to Week (W) 156 in patients (pts) with an IR to methotrexate (MTX-IR) and biologics (bDMARD-IR), enrolled from FINCH 1 (NCT02889796) and 2 (NCT02873936) parent studies, respectively, receiving ≥ 1 FIL dose in FINCH 4 (NCT03025308).

Results: Study design, BL characteristics and W48 outcomes for MTX-IR[1] and bDMARD-IR[2] pts were reported previously. For MTX-IR and bDMARD-IR pts who received FIL200 or FIL100 in the parent study, W156 remission rates using Boolean 1.0 criteria were 20.5% and 15.8%, and 18.2% and 8.9%, respectively. Adopting the Boolean 2.0 criteria slightly increased remission rates for FIL200 and FIL100 at W156: +4.2% and +4.9% for MTX-IR pts, and +1.5% and +2.4% for bDMARD-IR pts, respectively. For pts rerandomized to FIL on entering the LTE, Boolean 2.0 criteria also increased remission rates vs Boolean 1.0. Both MTX-IR (**Figure**) and bDMARD-IR pts maintained long-term Boolean remission through W156 with FIL200 and FIL100, irrespective of prior FIL. Results for Disease Activity Score in 28 joints using C-reactive protein (DAS28-CRP) < 2.6, Clinical Disease Activity Index (CDAI) ≤ 2.8 and Simplified Disease Activity Index (SDAI) ≤ 3.3, and mean change from parent study BL in Health Assessment Questionnaire–Disability Index (HAQ-DI) and pain are shown (**Table**). Similar trends in efficacy were seen for LDA and ACR response criteria.

Conclusion: In FINCH 4, both FIL200 and FIL100 showed sustained efficacy up to W156 in clinically relevant pt populations. Boolean 2.0 criteria classified more pts in remission, in line with the range reported in the validation study.[3]

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Nipocalimab is a fully human, immunoglobulin G (IgG) 1 monoclonal antibody that blocks the neonatal crystallizable fragment receptor (FcRn), thereby lowering IgG levels. RA is a chronic inflammatory autoimmune disease with a multitude of pathogenic mechanisms. Anti-citrullinated protein autoantibody (ACPA) is one of the hallmark autoantibodies that may contribute to the pathogenesis and active inflammation in RA. In a phase 2a proof-of-concept study (IRIS-RA; NCT04991753), nipocalimab demonstrated numerically greater improvements in clinical endpoints (reported separately). Here, we report the initial pharmacodynamics of nipocalimab and associated disease biomarkers in the IRIS-RA study.

Methods: IRIS-RA was a phase 2a, multicenter, randomized, double-blind, placebo-controlled study. Eligible adult patients had active, seropositive RA with prior inadequate response or intolerance to≥1 tumor necrosis factor inhibitors. Nipocalimab or placebo was given intravenous every 2 weeks from Weeks 0-10. Blood samples were collected from consenting patients for the measurement of serum immunoglobulin levels, including total IgG and IgG subclasses. Levels of serum ACPA IgG were measured by an anti-cyclic citrullinated peptide 2 (CCP2) assay. Circulating immune complexes (CICs), complement activation markers, and serum inflammatory markers, including cytokines and C-reactive protein (CRP), were also measured. Associations between changes in biomarker levels and clinical responses at Week 12 were assessed.

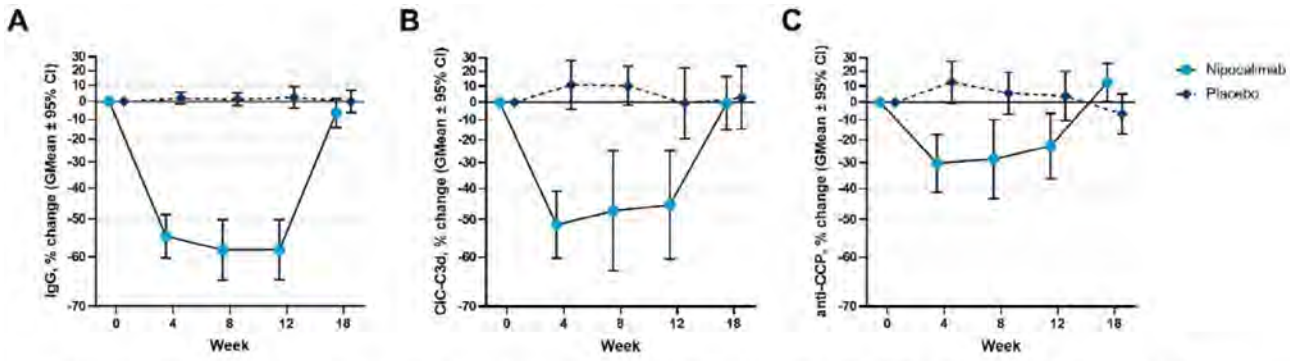

Figure 1. Changes in pharmacodynamic biomarkers: (A) total IgG, (B) CIC, and (C) ACPA IgG (anti-CCP). Values after treatment failure reported as missing; for change in anti-CCP analyses, patients with baseline anti-CCP below lower limit of quantitation excluded. GMean and 95% CI based on ratio of value at visit over baseline value, with y-axes transformed to corresponding % change value (= 100% × [ratio – 1]).

ACPA, anti-citrullinated protein autoantibodies; CI, confidence interval; GMean, geometric mean; IgG, immunoglobulin G; anti-CCP, anti-cyclic citrullinated peptide antibody; CIC, circulating immune complex.

Results: A total of 53 patients (nipocalimab, n=33; placebo, n=20) were enrolled in the study. Baseline biomarker levels were generally comparable between groups. Serum total IgG levels were reduced by nipocalimab from Weeks 4 through 12 and returned to baseline levels at Week 18. At Week 12, there was a 58% reduction (geometric mean) in the total IgG level observed in the nipocalimab group compared to a 2.4% increase in the placebo group (**Figure 1**). Decreases from baseline in all IgG subclasses were consistent with those observed for total IgG levels. Significant reductions of total CIC and ACPA IgG levels were also observed in the nipocalimab group versus the placebo group (**Figure 1**), with a trajectory similar to total IgG reduction. Relative to the baseline, no changes in complement activation markers or serum inflammatory markers were observed in either group. In nipocalimab group, those who achieved remission in the Disease Activity Score 28-CRP at Week 12 had numerically greater reduction in ACPA compared to non-responders.

Conclusion: Nipocalimab significantly and reversibly reduced IgG, ACPA, and CICs, consistent with the expected mechanism of action, but did not impact complement activation markers or serum inflammatory markers. Reduction in ACPA by nipocalimab was associated with clinical remission. These findings support the observed clinical response and suggest that combination of nipocalimab and a therapy with an orthogonal mechanism may provide clinical benefits for patients with refractory RA.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Based mainly on results from a randomized clinical trial (RCT) in rheumatoid arthritis (RA) patients (ORAL Surveillance), major regulatory agencies have concluded that JAK inhibitors, including Upadacitinib (UPA), a selective and reversible JAK1 inhibitor, may be associated with an increased risk of serious cardiovascular events and cancer compared with tumor necrosis factor inhibitors (TNFi). In this context, evidence on safety, effectiveness and risk minimization measures in patients treated with UPA in routine clinical practice are of particular interest.

Methods: Observational, retrospective, and multicenter study including patients diagnosed with RA, and spondylarthritis (SpA) (psoriatic arthritis, and axial-SpA), who received UPA for at least 3 months between January 1, 2021, and March 31, 2023. For a comparison of baseline cardiovascular risk (CVR), RA and SpA patients who initiated TNFi treatment during this same period were also analyzed. Baseline demographic and disease characteristics, changes over time in DAS28 or BASDAI, baseline CVR by Systemic Coronary Risk Estimation (SCORE)2 or SCORE2_OP (patients >70 years), concomitant medications, line and persistence of UPA treatment, and adverse events data were collected. Cox regression and Kaplan-Meier curves were used to analyze the UPA persistence, and a general mixed linear model to study the variation of disease activity over time. Chi-squared, t-Student, and U-Mann-Whitney tests were used to compare groups.

Results: A total of 104 patients treated with UPA, 80 RA (77%) and 24 (23%) SpA, were included. The mean follow-up time was 12.8±6.7 (SD) months. Table 1 shows baseline demographic and disease characteristics, disease activity, and CVR factors, including baseline SCORE2 of patients treated with UPA and TNFi. UPA showed significant effectiveness in controlling RA disease activity by DAS28 during follow-up ($p< 0.001$). UPA persistence in both RA and SpA patients is shown in Figure 1, with a tendency to a better persistence in SpA (log rank: 2.9, $p=0.08$). According to the COX regression analysis, the only factor associated with lower UPA persistence was its use in 2nd or higher line (HR 7.1 $_{95\%}$CI 0.98-52.08, $p= 0.052$). The main reason for discontinuation of UPA was adverse events (n=11, 44%), followed by ineffectiveness (n=8, 32%) and loss to follow-up (n=6, 24%). To examine changes over time in CVR minimization in UPA-treated patients, 109 patients who initiated TNFi during the same period with similar demographic characteristics and clinical activity (Table 1) were analyzed as a comparator. SCORE2, both as a percentage ($p=0.47$) and categorized ($p=0.21$), were similar between patients treated with UPA or TNFi (Table 1). However, when SCORE2 was categorized and analyzed by trimester, a significant reduction ($p=0.03$) was observed in moderate-high risk patients who initiated UPA versus TNFi since April 2022 (Table 2).

Table 1. Basal demographics, disease characteristics, treatments and cardiovascular risk of patients included.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The appearance of JAK inhibitors (JAKi) in the last few years has proved a great clinical application in rheumatic pathology and it has become an innovative and widely-used therapeutic line. In fact, JAKi has been recently included in the management algorithms of psoriatic arthritis, axial spondyloarthritis or rheumatoid arthritis. Nevertheless, the evidence of therapeutic alternatives in real life after the failure of a JAK inhibitor is limited: another JAKi or the change in therapeutic target.

The purpose of the study is to analyze the treatment alternatives after JAKi failure in real life conditions and in multiple diseases.

Methods: Retrospective longitudinal observational study of patients that started JAKi treatment and was discontinued from 2013 to 2022. Demographic and clinical variables were collected from the electronic medical record. "Switching" and "cycling" were analyzed depending on the prescribed medicine after the JAKi, classifying them in the following targets: anti-TNF, anti-IL6, anti-CTLA4, anti-IL12/23, anti-IL17, anti-IL23, another JAKi or other situations like anti-CD20. We studied the retention rate at 9 months after the start of the new treatment.

Results: In our series, the most prescribed JAKi was Tofactinib (n=119), followed by Baricitinib (n=76), Upadacitinib (n=66) and Filgotinib (n=4). The most recurrent indications for JAKi treatment were rheumatoid arthritis (n=71) and psoriatic arthritis (n=12).

Out of 265 JAKi prescriptions, 95 failures to JAKi treatment were included in this study. The JAKi with higher failure rate was tofacitinib (n=61) followed by baricitinib (n=22) and upadacitinib (n=12). We do not have data from filgotinib due to its recent incorporation to the Spanish national market. The main cause of end of treatment was adverse reaction (34.74%), followed by secondary failure (28.42%).

After all the JAKi failures, "switching" to other families like anti-TNF or anti-IL6 was the main therapeutical choice (n=57), followed by "cycling" to another JAKi (n=25). 8 patients did not start a new treatment after JAKI failure.

The retention rate at 9 moths after the treatment showed that the 83,33% of the "cycling" to another JAKi and the 73,5% of the "switching" to another therapeutic target maintained the treatment (see image). The retention rate was not studied in 17 patients because the treatment period was less than 9 months.

Table 1. Total of "switching" and "cycling"

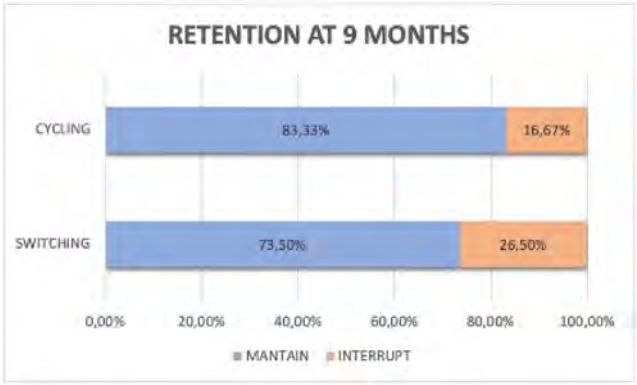

Image 1. Retention rate at 9 months

Conclusion: After a JAKi failure, "switching" is the most recurrent alternative in our series, used most frequently in patients with side events or primary failure. "Cycling" was the most common alternative used with patients who stopped receiving treatment due to secondary failure and in patients with a major proportion of failure to bDMARD.

The retention rate after 9 months was 83,33% for "cycling" and 73,50% for "switching" groups.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic inflammatory disease. Strategies for addressing treatment failure with TNF inhibitors according to the recent EULAR recommendations include switching to an alternate TNF inhibitor (known as "switching" or "cycling") or moving to a different class of targeted agents with an alternative mechanism of action ("swapping"). Although efficacy data on switching from one TNFi after failure to another TNFi are available,

Table 1. Patient characteristics of total cohort, patients exposed to selective JAKi and patients with switches from non-selective JAKi to selective JAKi.

	Total Cohort	Exposure to Selective JAKi (Upa)	Switch Among JAKis (Tofa and/or Bari to Upa)
n	186	55	27

Table 3. CDAI, DAS-ESR and CRP at baseline and after 6 months from switching to Upa.

	Baseline prior switching from Tofa or Bari to Upa (Mean±SD)	6 months after switching from Tofa or Bari to Upa (Mean±SD)	p value
CDAI	29.4±9.7	6.7±5.3	<0.0001
DAS28-ESR	5.5±1.1	2.9±0.6	<0.0001
DAS28-CRP	4.6±0.9	2.5±1.0	<0.0001

information on switching from one JAK inhibitor (JAKi) to another JAKi is lacking and it is unclear whether cycling or swapping is preferable between JAKis. We evaluated the overall safety of JAKis in the Middle Eastern population, as well as the clinical efficacy of cycling from Tofacitinib (Tofa) or Baricitinib (Bari) to Upadacitinib (Upa).

Methods: Between May 2015 and May 2023, 186 patients with RA received Tofa, Bari, or Upa in any order in clinical practice at 3 centers (UAE, Saudi Arabia and Jordan). The drug retention rate, the drug's safety, and the reason for switching due to ineffectiveness or an adverse event were all obtained. We compared the efficacy of switching from a non-selective JAKi to a more selective JAKi in terms of CDAI, DAS28 ESR and CRP evolution over the course of 6 months after starting the second treatment. Unpaired t test was used for comparison of disease activity. The level of significance was $p < 0.05$.

Results: 186 patients were exposed to Tofa, Bari and Upa (67%, 25% and 30% respectively). The mean age at the time of RA diagnosis was 40±16 (Mean±SD) years, with a BMI of 31±7 kg/m^2, and a disease duration of 10±7 years. At baseline, the most common comorbidities were hypertension, dyslipidemia, and diabetes (30%, 33% and 26% respectively). Prior to starting any JAKi, there was a history of cardiovascular disease (10%) and cancer (6%). 3% had a previous history of varicella zoster (VZV) infection. All patients had previously received csDMARD, however 56% received bDMARD and 59% received oral prednisolone. Mean drug retention for Tofa (27.7±21.9), Bari (17.3±14.4) and Upa (11.7±6.6) months. Of the 186 patients, 55 patients (30%) were exposed to Upa. 6% had a previous history of VZV infection. Over the course of the 51.2 months of JAKi drug exposure, two patients developed VZV reactivation, one patient developed a DVT with no MACE. 27 patients out of the 55 exposed to Upa had prior use of Tofa or Bari. There were 31 instances of cycling among JAKis: 3 (Tofa to Bari), 18 (Tofa to Upa) and 9 (Bari to Upa). Over the course of the 51 months of JAKi drug exposure, 1 patient developed VZV reactivation (Tofa to Upa) with no reported DVT or MACE. Over a 6-month period, the switch to Upa was well tolerated and patients maintained a low disease activity response. Prior to switching from Tofa or Bari to Upa, the baseline CDAI, DAS-ESR, and CRP were (29.4±9.7, 5.5±1.1 and 4.6±0.9 respectively) and after 6 months were (6.7±5.3, 2.9±0.6 and 2.5±1.0 respectively; p value < 0.0001).

Conclusion: Our findings show that switching from non-selective JAKi to selective JAKi is feasible and safe, and that it may improve disease activity outcomes in patients who have failed to achieve low disease activity or remission with a previous JAKi.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Treatments Poster III

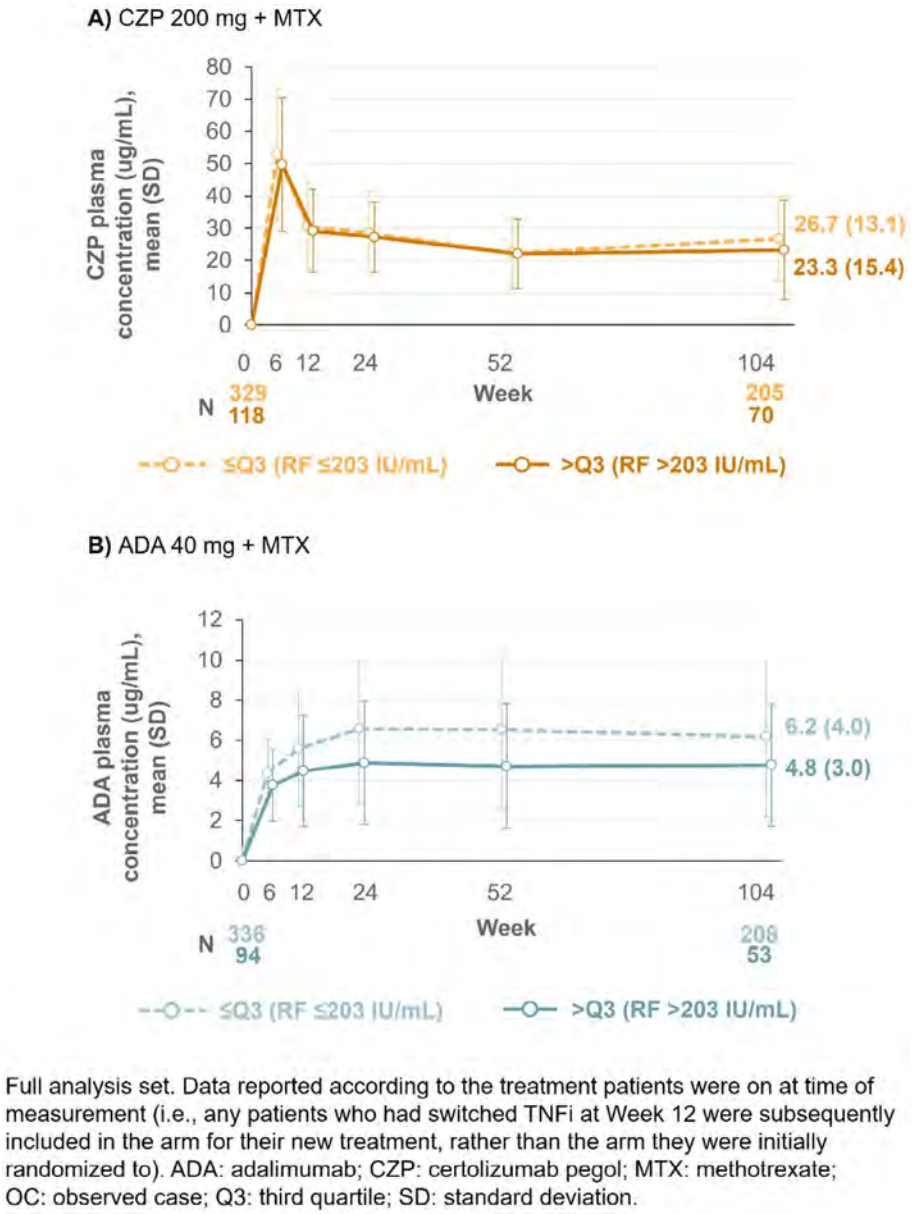
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with RA, high RF titers are considered a poor prognostic factor and are associated with higher disease activity, risk of radiographic progression, and decreased response to TNF inhibitors (TNFis).[1–3] Recent data suggest that patients with RA and high RF titer may achieve and maintain greater clinical improvement with TNFis without a crystallizable fragment (Fc) compared to TNFis with an Fc.[4] In this post hoc analysis of the EXXELERATE trial, we assessed efficacy outcomes of certolizumab pegol (CZP), a PEGylated Fc-free TNFi, versus adalimumab (ADA; Fc-containing TNFi) in patients with RA and high RF titers.

Methods: The phase 4 EXXELERATE trial (NCT01500278) compared the efficacy and safety of CZP to ADA in a head-to-head comparison; full study design and primary outcomes have been reported previously.[5] Patients were randomized 1:1 to CZP 200 mg every 2 weeks (Q2W) plus methotrexate (MTX), or ADA 40 mg Q2W plus MTX. At Week (Wk) 12, patients were classified as responders or non-responders; non-responders were switched to the other TNFi with possible follow-up to Wk 104. Both Wk 12 responders and non-responders were included in this analysis. Here, we report drug plasma concentrations, mean disease activity score (DAS)28-CRP score, and proportion of patients achieving low disease activity (LDA; threshold: DAS28-CRP ≤2.7) to Wk 104. Results are stratified by RF titer quartile (≤Q3: ≤203 IU/mL; >Q3: >203 IU/mL; measured by Roche Tina-quant®) and reported as observed data.

Results: Baseline (BL) data by RF quartile were available for 453 CZP-randomized patients (≤Q3: n=334; >Q3: n=119) and 454 ADA-randomized patients (≤Q3: n=347; >Q3 n=107). BL characteristics were similar between CZP- and ADA-randomized patients across the RF titer quartiles. At Wk 12, 66 CZP-treated patients switched to ADA and 59 ADA-treated patients switched to CZP. At Wk 104, mean ADA plasma concentrations were 22.9% lower in patients with RF >203 IU/mL vs those with RF ≤203 IU/mL; in CZP-treated patients, this difference was smaller (13.0%; **Figure 1**). For patients in RF ≤Q3, mean DAS28-CRP scores were similar between CZP- and ADA-treated patients through Wks 0–104 (mean [SD] DAS28 at Wk 104: 2.48 [1.18] CZP vs 2.49 [1.14] ADA). However, for patients in RF >Q3, mean DAS28-CRP scores were nominally lower in CZP- vs ADA-treated patients (Wk 104: 2.50 [1.18] CZP vs 2.93 [1.22] ADA; **Figure 2**). A similar pattern was observed for the proportion of patients achieving LDA at Wk 104 (≤Q3: 64.8% CZP vs 65.1% ADA; >Q3: 65.7% CZP vs 48.3% ADA).



Full analysis set. Data reported according to the treatment patients were on at time of measurement (i.e., any patients who had switched TNFi at Week 12 were subsequently included in the arm for their new treatment, rather than the arm they were initially randomized to). ADA: adalimumab; CZP: certolizumab pegol; MTX: methotrexate; OC: observed case; Q3: third quartile; SD: standard deviation.

Figure 1. Mean drug plasma concentrations of (A) CZP and (B) ADA to Week 104, stratified by RF titer quartiles [OC]

Conclusion: CZP-treated patients with RA and high titer RF had similar drug concentrations and clinical responses to patients with RA and low titer RF, a pattern not observed in ADA-treated patients. These data, together with previous reports where CZP showed consistent efficacy irrespective of BL RF titer,[6,7] suggest CZP may be a suitable therapy for patients with RA and high RF titer. **References:1.** Vastesaeger N. Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: IRL201805 is a novel biologic derived from Binding Immunoglobulin Protein (BiP) that has been developed for the treatment of Rheumatoid arthritis (RA) (P Eggleton, et al, J Cell Mol Med, 2023;27:322-339). A phase I/IIa clinical trial with a single IRL201805 intravenous infusion has demonstrated improvement in Disease Activity Score 28 (DAS28) (B Kirkham, et al, Rheumatology, 2016;55:1993-2000). Moreover, IRL201805 directly interacts with

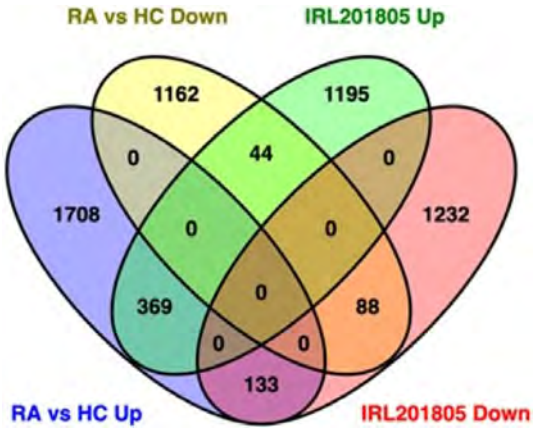

Fig 1. Venn Diagram of the transcriptional changes in RA monocytes vs HC monocytes (RA Up and RA Down) compared to the transcriptional changes in RA monocytes treated with IRL201805 (RA IRL201805 Up and RA IRL201805 Down). In RA monocytes, 44 of the downregulated genes are upregulated with IRL201805 treatment, while upregulated 133 genes were downregulated by IRL201805 treatment.

Monocytes, which play a key role in initiation of inflammation and bone erosion in RA. Thus, there is a need to identify the inflammatory pathways that drive the involvement of the myeloid compartment in RA and to how IRL201805 modulates these pathways. Herein, we performed a comprehensive RNA-seq analysis on monocytes from RA patients compared with healthy donors in the presence or absence of IRL201805 to investigate the impact on transcriptional profiles.

Methods: $CD14^{+}CD16^{-}$ monocytes were isolated from peripheral blood mononuclear cells (RA patients with active disease and healthy controls (HC)), and cultured overnight with macrophage-colony stimulating factor (M-CSF). RNAseq was performed on the monocytes collected with or without 24h IRL201805 stimulation.

Results: Evaluation of the transcription profiles changes in monocytes from active RA patients and age-gender matched HC in the presence or absence of IRL201805 revealed that untreated monocytes from RA patients had 2210 upregulated differentially expressed genes (DEGs) and 1294 downregulated DEGs when compared to HC cells (adjusted $p < 0.05$ & absolute log2fold > 0.58). Furthermore, exposure to IRL201805 resulted in the upregulation of 1608 transcripts and downregulated of 1453 in RA monocytes whilst only altering the expression of < 20 genes in cells derived from HC. In RA samples, the upregulated transcripts were associated with cell adhesion and chemotaxis whilst the downregulated transcripts were associated with metabolic processes. To further investigate the effect of IRL201805 upon monocytes, we compared the DEGs in IRL201805 treated RA monocytes (vs untreated RA macrophages) to the DEGs in circulating RA monocytes (vs HC monocytes). This revealed that 133 upregulated DEGs in RA were decreased and 44 downregulated DEGs in RA were increased with IRL201805 treatment. Notably, a larger proportion of DEGs in RA circulating monocytes were altered in the same direction with IRL201805 treatment.

Conclusion: Our data suggests that IRL201805 selectively target transcriptional changes in RA and not healthy monocytes. Notably, IRL201805 downregulates transcripts that are upregulated in RA whilst simultaneously upregulating transcripts that are downregulated in RA. Combined this suggests that IRL201805 has the capacity to 'reset' a number of cell-cell and metabolic linked inflammatory pathways in disease-state cells.

Novel Biologic IRL201805 Inhibits Osteoclastogenesis in Monocytic Cells from RA Patients

Yuriko Yamamura[1], Valerie Corrigall[2], Lara Ravanetti[3], Jorge De Alba[3], Roly Foulkes[4], Paul Eggleton[5] and Carl Goodyear[6], [1]School of Infection & Immunity, University of Glasgow, Glasgow, United Kingdom, [2]Revolo Biotherapeutics, Tadworth, United Kingdom, [3]Revolo Biotherapeutics, London, United Kingdom, [4]Revolo Biotherapeutics, Slough, United Kingdom, [5]Revolo Biotherapeutics, Exeter, United Kingdom, [6]University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

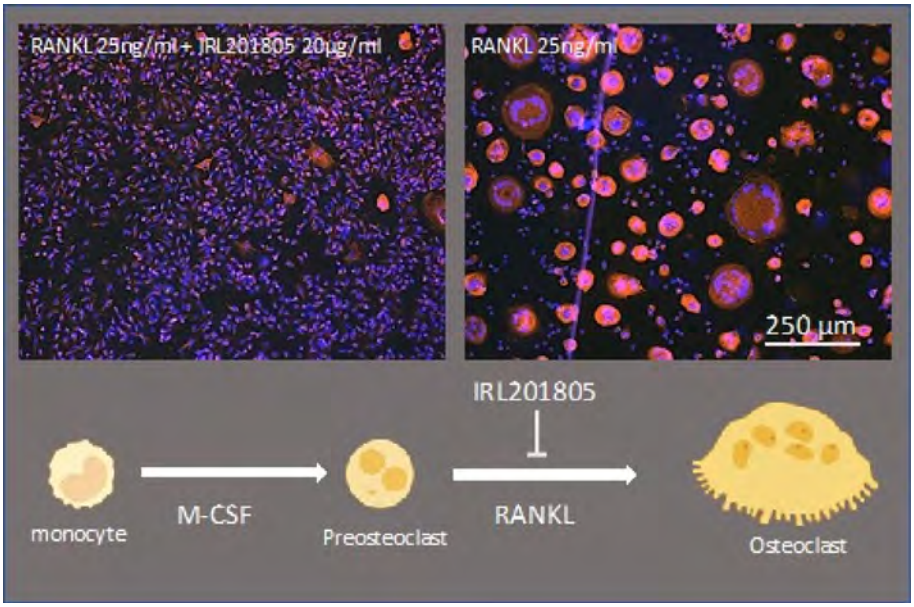

Figure 1. Osteoclast differentiation is inhibited by IRL201805 treatment, which involves down regulation of several osteoclast and metabolic genes.

Background/Purpose: In Rheumatoid arthritis (RA), osteoclasts derived from $CD14^+$ Monocytes are associated with a risk of progressive bone and joint destruction, which fundamentally impacts quality-of-life. Current RA treatments such as immunosuppressants, steroids, and biologics can in part ameliorate joint destruction and decrease the need for subsequent orthopaedic surgery. However, such treatments are far from perfect and knowledge of their mode-of-action in preventing osteoclast induced bone destruction is limited. IRL201805 is a novel biologic derived from Binding Immunoglobulin Protein (BiP) that has been developed for the treatment of RA (P Eggleton, et al, J Cell Mol Med, 2023;27:322-339). In a Phase I/IIa clinical trial, a single IRL201805 intravenous infusion was demonstrated to improve Disease Activity Score 28 (DAS28) (B Kirkham, et al, Rheumatology, 2016;55:1993-2000). Moreover, IRL201805 was also shown to inhibit osteoclast function (V M Corrigall, et al, Immunology, 2009;128: 218-226). In this study, we have further investigated the capacity and mode-of-action of IRL201805 on receptor activator of nuclear factor-kB ligand (RANKL)-induced osteoclastogenesis in the context of RA patient derived $CD14^+$ monocytes.

Methods: Pre- and mature osteoclasts were derived from $CD14^+CD16^-$ monocytes, isolated from peripheral blood mononuclear cells of RA patients and healthy individuals, in *in vitro* cultures supplemented with macrophage-colony stimulating factor (M-CSF) and RANKL. Changes in gene transcript levels in preosteoclasts was examined by RNAseq, 24h after drug treatment.

Results: IRL201805 reduced the numbers of osteoclasts generated from preosteoclasts derived from both RA patients (vehicle: 777±587 vs IRL201805: 102±12; n=5) and healthy controls (vehicle: 812±569 vs IRL201805: 148±179; n=5), as visualized by immunofluorescent TRAP staining(**Figure 1**). Notably, IRL201805 also inhibited actin ring formation. Transcriptional evaluation of pre-osteoclast exposure to IRL201805 revealed that several genes implicated in osteoclast differentiation were significantly downregulated (e.g. *TNFSF11A* ($p< 0.002$)) or upregulated (e.g. *NFKBIZ* ($p< 0.01$)). Moreover, several vacuolar ATPases (i.e. *ATP6V0E2* ($p< 0.001$) and *ATP6V1C1* ($p< 0.01$)), which play a role in acidification of osteoclasts and bone resorption, were strongly downregulated.

Conclusion: Our finding suggest that IRL201805 inhibits osteoclast differentiation via modulation of RANK/RANKL signaling. Notably, there is an impact on metabolic pathways such as V-ATPases, which are critical for bone resorption. This is particulary revelant, as antiresorptive drugs that inhibit V-ATPase activity in osteoclasts have become an area of development. Taken together, these findings underpin the need for further investigations in RA patients and upcoming clinical phase IIb RA trials.

Effects of Methotrexate on Blood Pressure in Rheumatoid Arthritis: A Randomized Controlled Trial

Sara Tommasi[1], Richard Woodman[1], Michael Wiese[2], **Michael Shanahan**[1] and Arduino Mangoni[1], [1]Flinders University, Adelaide, Australia, [2]University of South Australia, Adelaide, Australia

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment with methotrexate (MTX) has been shown to be associated with lower cardiovascular risk and lower blood pressure (BP) compared with other disease modifying anti-rheumatic drugs (DMARDs) in cross-sectional and epidemiological studies in patients with rheumatoid arthritis (RA). However, the evidence in longitudinal, randomized trials is lacking. We sought to address this issue by performing a randomized trial comparing the effect of MTX on BP against a control group on sulfasalazine.

Methods: Adult treatment-naïve patients, recently diagnosed with RA according to the 2010 ACR/EULAR criteria, were randomized to clinically guided doses of subcutaneous MTX (Group 1, n=31, age 57±15 years, 65% females) or the DMARD sulfasalazine (SSZ, Group 2, n=31, age 54±17 years, 58% females). Clinic systolic (SBP, primary study endpoint), diastolic

Table 1. Baseline clinical and demographic characteristics of the MTX (group 1) and the SSZ (group 2) groups.

Variables	Group 1 (n = 31)	Group 2 (n = 31)	p value
Age	57 ± 15	54 ± 17	ns
Gender (% of female)	65	58	ns
BMI (Kg/m^2)	30 ± 6	31 ± 8	ns
DAS28 - CRP	4.73 ± 1.20	5.00 ± 0. 83	ns
DAS28 - ESR	5.29 ± 1.44	5.31 ± 1.22	ns

DAS28, disease activity score 28; BMI, body mass index; CRP, C-reactive protein, ESR, erythrocyte sedimentation rate; MTX, methotrexate; SSZ, sulfasalazine.

Table 2. Differences between MTX-group (Group 1) and SSZ group (Group 2) after 1 month and 6 months of treatment

	Differences (mean ± SD) between Group 1 and Group 2 after 1 month	*p* value	Differences (mean ± SD) between Group 1 and Group 2 after 6 months	*p* value
Clinical peripheral SBP (mmHg)	-2.6 ± 10.6	.09	-4.0 ± 10.8	.038*
Clinical peripheral DBP (mmHg)	-1.8 ± 6.7	.053	-0.7 ± 6.8	.053*
Clinical peripheral PP (mmHg)	-.8 ± 7.2	ns	-4.8 ± 11.3	ns
Clinical peripheral MAP (mmHg)	-2.1 ± 7.5	.049	-4.3 ± 17.9	.023*
AIx (%)	-1.1 ± 1.6	ns	-0.5 ± 1.6	ns

*Not corrected for ties

MTX, methotrexate; SSZ, sulfasalazine; SD, standard deviation; SBP, systolic blood pressure; DBP, diastolic blood pressure; PP, pulse pressure; MAP, mean arterial pressure.

(DBP), and mean arterial pressure (MAP), and the augmentation index (AIx), (a marker of arterial wave reflection) were measured at baseline (before treatment), and after 1 and 6 months (ClinicalTrials.gov: NCT03254589).

Results: At baseline, the two groups were matched for age, gender, body mass index, and 28-joint disease activity score (p>0.05 for all comparisons). After 1 month of treatment, group 1 had a trend towards a significant reduction in SBP (mean difference -2.6±10.6 mmHg, p=0.09) and DBP (mean difference -1.8±6.7 mmHg, p = 0.053) and a significant reduction in MAP (mean difference -2.1±7.5 mmHg, p=0.049) compared to Group 2. After 6 months of treatment, group 1 had a significant reduction in SBP (mean difference -4.0±10.8 mmHg, p=0.038) and MAP (mean difference -4.3±17.9 mmHg, p=0.023) and a trend towards a significant reduction in DBP (mean difference -0.7±6.82 mmHg, p=0.053). There were no significant between-group differences in AIx over time.

Conclusion: The results of this study provide the first evidence that MTX treatment causes a significant reduction in SBP (primary endpoint) at 6 months in RA patients in intervention studies. The effects of MTX on BP are not mediated by changes in arterial wave reflections. Further research is warranted to identify the mechanisms involved in the MTX-induced BP lowering effects and whether such effects account for the protective effects of MTX against cardiovascular disease observed in RA.

Survival Benefits of Knee and Hip Arthroplasty in Patients with Rheumatoid Arthritis: A General Population-based Cohort Study

Xinjia Deng[1], Yuqing Zhang[2], Yilun Wang[1], Na Lu[3], Dongxing Xie[4], Houchen Lyu[5], Jie Wei[6], Chao Zeng[1], Guanghua Lei[1] and **Hui Li**[1], [1]Department of Orthopaedics, Xiangya Hospital, Central South University, Changsha, China, [2]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [3]Arthritis Research Canada, Vancouver, BC, Canada, [4]Xiangya Hospital, Central South University, Changsha, China, [5]Chinese PLA General Hospital, Department of Orthopedics, Beijing, China, [6]Health Management Center, Xiangya Hospital Central South University, Changsha, China

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Treatments Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with increased risk of cardiovascular disease (CVD), venous thromboembolism (VTE), and mortality. Many patients with RA underwent knee and hip replacement surgeries, i.e., knee arthroplasty and hip arthroplasty. The primary role of knee arthroplasty and hip arthroplasty is to remove the structural abnormality, leading to significant improvements in pain and function. However, the aforementioned improvements may not translate into a lower risk of all-cause mortality, one of the most important indicators for the net risk-benefit effect of any clinical treatment regimen, among patients with RA. Considering physical inactivity and use of non-steroidal anti-inflammatory drugs (NSAIDs) are major risk factors for CVD, one would anticipate that there is a potential cardioprotective advantage coupled with knee arthroplasty and hip arthroplasty as they enhance the capacity for physical activity and reduced usage of analgesics (e.g., NSAIDs). Nevertheless, the impact of these surgeries on CVD risk among patients with RA also needs to be yet confirmed. We aimed to examine the relation of knee or hip arthroplasty to the risk of all-cause mortality, CVD and VTE among patients with RA.

Methods: We included patients with RA (ages≥20 years) from the IQVIA Medical Research Data primary care database in the United Kingdom. The primary outcome was all-cause mortality. The secondary outcomes included CVD and VTE. We conducted propensity score-matched cohort studies to compare the risks of each outcome between subjects with knee arthroplasty (n=2,387) and hip arthroplasty (n=1,681), and those without knee arthroplasty (n=2,387) or hip arthroplasty (n=1,681), respectively.

Results: Subjects with knee arthroplasty had 23% lower risk of mortality than those without knee arthroplasty (HR: 0.77, 95%CI: 0.65-0.90) (Figure 1A). Similarly, a lower, albeit non-statistically significant, mortality rate was observed among subjects with hip arthroplasty than those without arthroplasty (HR: 0.87, 95%CI: 0.73-1.04) (Figure 1B). Compared with those without arthroplasty, subjects with knee or hip arthroplasty had a lower, albeit non-statistically significant, risk of CVD. The corresponding HRs were 0.86 (95%CI: 0.73-1.01) and 0.84 (95%CI: 0.69-1.02), respectively (Figure 2). Both subjects with knee or hip arthroplasty showed a higher risk of VTE than their counterparts (HR for knee arthroplasty: 1.63 (95%CI: 1.23-2.17); HR for hip arthroplasty: 2.19 (95%CI: 1.54-3.11) (Figure 3). The associations of knee and hip arthroplasty with the risks of mortality, CVD and VTE were generally consistent across strata of age and sex.

Conclusion: Our population-based cohort study provides the first evidence that knee and hip arthroplasty were associated with lower risks of mortality and CVD but increased risk of VTE among patients with RA.

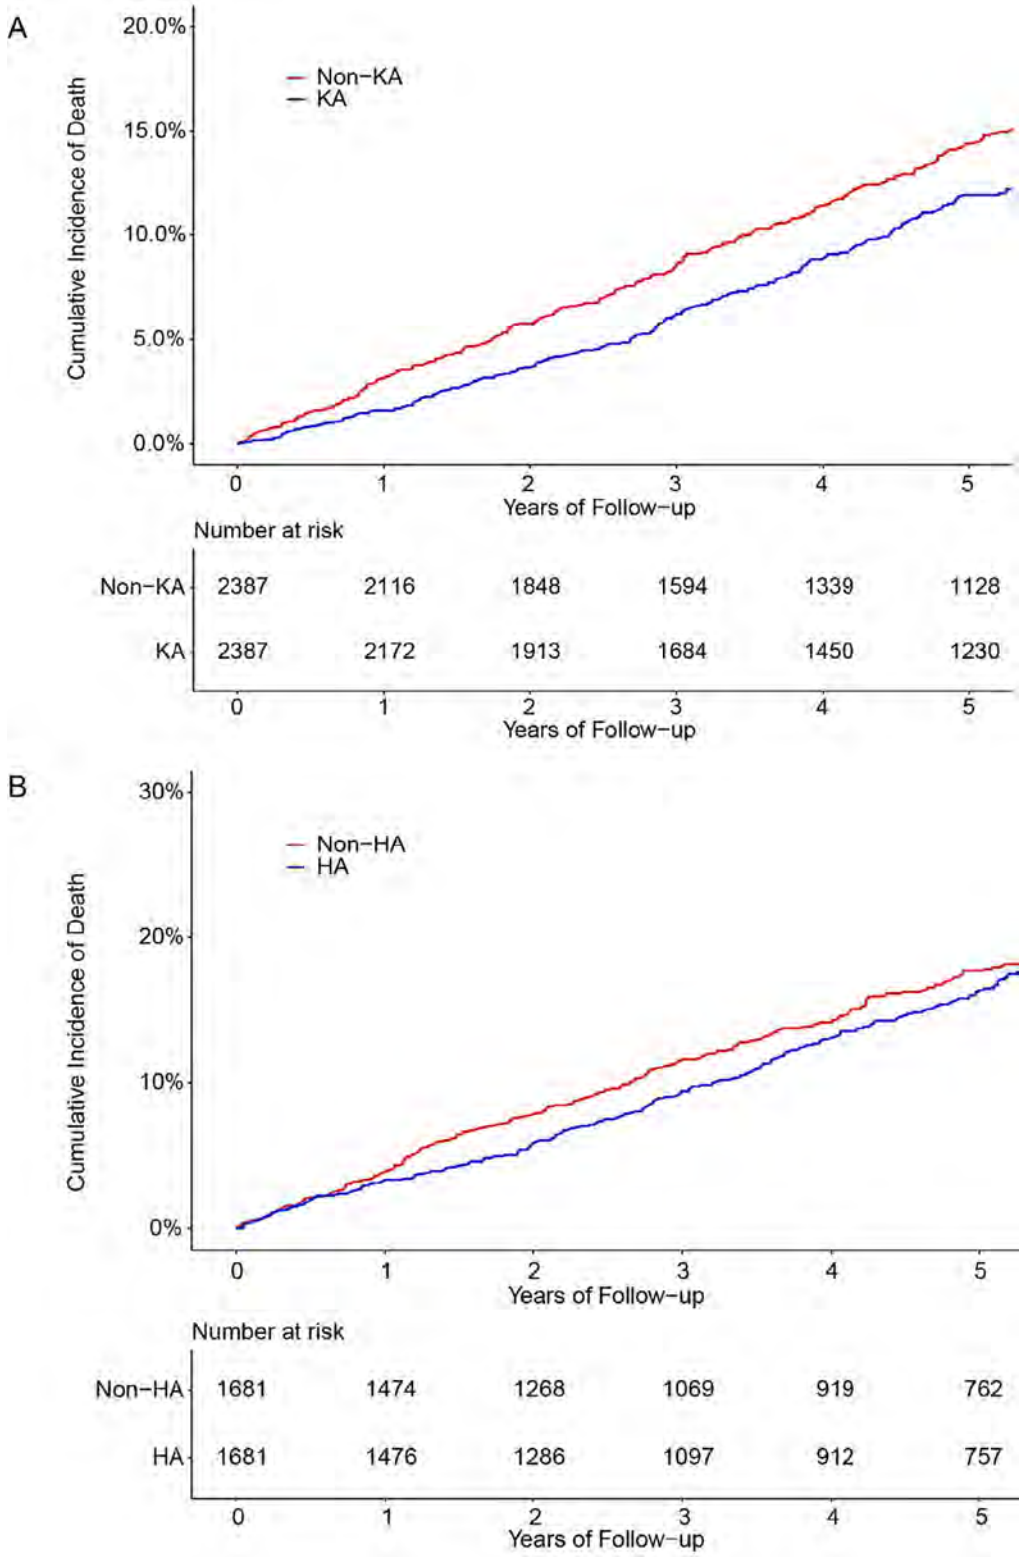

Figure 1. Cumulative incidence of death among subjects with knee or hip arthroplasty compared subjects without knee or hip arthroplasty. A, subjects with knee arthroplasty compared subjects without knee arthroplasty; B, subjects with hip arthroplasty compared subjects without hip arthroplasty. Effects of One-year Tofacitinib Therapy on Angiogenic Biomarkers in Rheumatoid Arthritis

György Kerekes[1], Monika Czókolyová[1], Attila Hamar[1], Anita Pusztai[1], Gábor Tajti[1], Mónika Katkó[1], Edit Végh[1], Zsófia Pethő[1], Nóra Bodnár[1], Ágnes Horváth[1], Boglárka Soós[1], Szilvia Szamosi[1], Zsolt Hascsi[1], Mariann Harangi[1], Katalin Hodosi[1], György Panyi[1], Tamas Seres[2], Gabriella Szücs[1] and **Zoltán Szekanecz**[1], [1]University of Debrecen, Faculty of Medicine, Debrecen, Hungary, [2]University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular (CV) morbidity, mortality and perpetuated synovial angiogenesis have been associated with rheumatoid arthritis (RA). In our study we evaluated angiogenic factors in relation to vascular inflammation and function and clinical markers in RA patients undergoing one-year tofacitinib therapy.

Methods: Thirty RA patients treated with either 5 mg or 10 mg bid tofacitinib were included in a 12-month follow-up study. Eventually 26 patients completed the study and included in data analysis. Levels of various angiogenic cytokines (TNF-α, IL-6), growth factors (VEGF, bFGF, EGF, PlGF), cathepsin K (CathK), CXCL8, galectin-3 (Gal-3) and NT-proBNP were determined at baseline, 6 and 12 months after initiating tofacitinib treatment. In order to assess flow-mediated vasodilation (FMD), common carotid intima-media thickness (ccIMT) and carotid-femoral pulse-wave velocity (cfPWV) ultrasonography was performed. Synovial and aortic inflammation was also assessed by ^{13}F-FDG-PET-CT.

Results: One-year tofacitinib therapy significantly decreased IL-6, VEGF, bFGF, EGF, PlGF and CathK, while increased Gal-3 production ($p < 0.05$). Basic FGF, PlGF and NT-proBNP levels were higher, while PECAM-1 levels were lower in RF seropositive patients ($p < 0.05$). TNF-α, bFGF and PlGF correlated with post-treatment synovial inflammation, while aortic inflammation was rather dependent on IL-6 and PECAM-1 as determined by PET/CT ($p < 0.05$). In the correlation analyses, NT-proBNP, CXCL8 and Cath variable correlated with ccIMT ($p < 0.05$).

Conclusion: Decreasing production of bFGF, PlGF or IL-6 by one-year tofacitinib therapy potentially inhibits synovial and aortic inflammation, respectively. Although NT-proBNP, CXCL8 and CathK were associated with ccIMT, their role in RA-associated atherosclerosis needs to be further evaluated.

Two-Year Persistence of First-Line Biological or JAK Inhibitor Treatment in Patients with Long-Standing Rheumatoid Arthritis and Failure of Triple Therapy with Synthetic DMARDs

Sebastian Ibanez Vodnizza[1], María Paz Poblete[2], María Francisca Valenzuela[3], María Magdalena Canals[2], Dominga García[2] and Carla Jaque[3], [1]Clinica Alemana de Santiago / Facultad de Medicina Universidad del Desarrollo-CAS, Santiago, Chile, [2]Hospital Padre Hurtado / Facultad de Medicina Universidad del Desarrollo-CAS, Santiago, Chile, [3]Hospital Padre Hurtado, Santiago, Chile

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Treatments Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In Chile, patients with rheumatoid arthritis (RA) can apply to receive state-funded biological or JAK inhibitor treatment if they have failed (defined as a DAS28-ESR persistently greater than 5.1) to the combination of three synthetic DMARDs (including methotrexate, leflunomide, sulfasalazine, and/or hydroxychloroquine) used for at least 6 months. Our objective was to evaluate the two-year persistence of the first biologic or JAK inhibitor used in this group of patients.

Methods: We conducted a retrospective evaluation of patients benefiting from state-funded biological or JAK inhibitor treatments at two healthcare centers. Demographic variables were recorded, including gender, age, comorbidities (Charlson Comorbidity Index), years since RA diagnosis, synthetic DMARDs used at the time of starting biological or JAK inhibitor treatment, use of corticosteroids and NSAIDs, the specific biological or JAK inhibitor used, persistence with the medication after two years, and, for those who discontinued treatment, the cause of discontinuation and duration of persistence. The relationship between persistence and different demographic and baseline variables was evaluated using logistic binary regression.

Table 1. Baseline use of synthetic DMARDs, corticosteroids, and NSAIDs.

Drug	Number of patients (% of total)
Methotrexate	41 (68.3)
Leflunomide	35 (58.3)
Sulfasalazine	24 (40)
Hydroxychloroquine	32 (53.3)
Corticosteroids	47 (78.3)
NSAIDs	41 (68.3)

Table 2. Two-year persistence of the first biologic or JAK inhibitor.

Biologic or JAK inhibitor	Two-year persistence	
	Yes	No
Abatacept	10	19
Etanercept	11	5
Adalimumab	1	8
Tocilizumab	1	1
Golimumab	2	0
Rituximab	1	0
Tofacitinib	1	0
Total	27	33

Results: We included 60 patients, of whom 52 were women (86.7%). The mean age was 58 years (standard deviation 12.5), and the Charlson Comorbidity Index was 3 or higher in 40% of patients. The median baseline DAS28-ESR was 5.8 (interquartile range 5.4-6.7), and the median years since diagnosis was 10.5 (IQR 5.7-16.5). Table 1 provides the distribution of synthetic DMARDs, corticosteroids, and NSAIDs used at the start of biologic or JAK inhibitor treatment. Table 2 presents the first-line biologic or JAK inhibitor used and its persistence. At the two-year mark, 27 patients (45%) persisted with the first-line biologic or JAK inhibitor. Among the 33 patients who discontinued treatment, the mean duration of persistence was 323 days (SD 176). The univariate analysis revealed significant associations between persistence and the use of baseline sulfasalazine (62.5% of users persisted at 2 years, compared to 33.3% of non-users), as well as with the specific first biologic or JAK inhibitor used (see Table 2). The primary cause of treatment discontinuation was loss of efficacy (60.6%), followed by adverse effects (24.2%).

Conclusion: The two-year persistence rate of the first biologic or JAK inhibitor in this group of patients with long-standing rheumatoid arthritis, high comorbidity index, and failure of synthetic DMARDs triple therapy was low, at only 45%. Loss of efficacy was the main reason for treatment discontinuation. A trend towards lower persistence with the use of adalimumab was observed, but this finding should be interpreted with caution as adalimumab was the only biologic that underwent exchanges between biosimilars and the original molecule. The association between greater persistence and the initial use of sulfasalazine should be explored in future studies. Notably, the utilization of JAK inhibitors as first-line advanced therapy was very low.

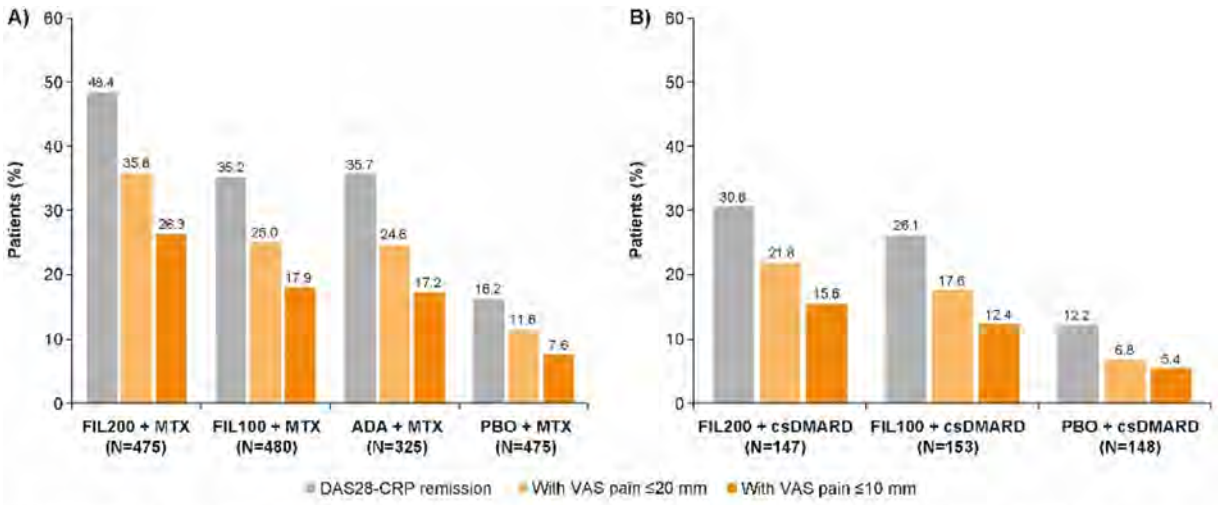
*Placebo-treated patients were re-randomized to FIL at Week 24.
ADA, adalimumab; csDMARD, conventional synthetic disease-modifying antirheumatic drug; FIL(100/200), filgotinib 100/200 mg; MTX, methotrexate; PBO, placebo; SD, standard deviation; VAS, visual analog scale.

Methods: FINCH 1–3 (NCT02889796, NCT02873936, NCT02886728) were Phase 3, randomized, double-blind trials of FIL 100 mg and 200 mg (FIL100/200). In FINCH 1, pts with an inadequate response (IR) to methotrexate (MTX) received FIL, adalimumab (ADA) or placebo (PBO) + MTX for 52 weeks. In FINCH 2, pts with an IR to bDMARDs received FIL or PBO + csDMARDs for 24 weeks. In FINCH 3, MTX-naïve pts received FIL ± MTX or MTX for 52 weeks. For each treatment group, pts reported pain on a 100-mm visual analog scale (VAS). VAS pain ≤ 20 mm indicated health status was not negatively affected by pain; ≤ 10 mm reflected limited to no pain.[1] Time to first VAS pain ≤ 10 mm was assessed. The duration of



ADA, adalimumab; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DAS28-CRP, Disease Activity Score in 28 joints using C-reactive protein; FIL(100/200), filgotinib (100/200 mg); MTX, methotrexate; PBO, placebo; VAS, visual analog scale.

Figure 1. DAS28-CRP remission and improvement in VAS pain score (up to Week 24) in (A) FINCH 1 and (B) FINCH 2

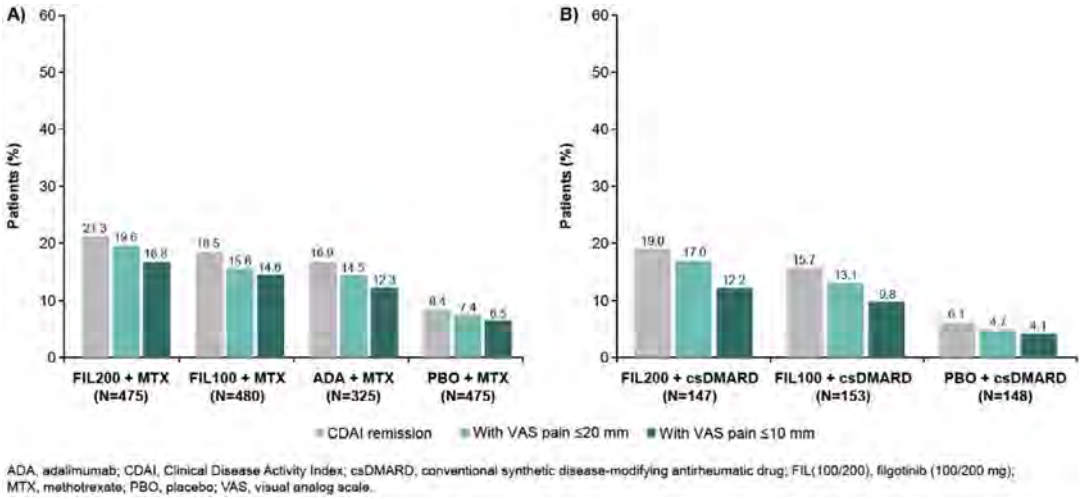


Figure 2. CDAI remission and improvement in VAS pain score (up to Week 24) in (A) FINCH 1 and (B) FINCH 2

the study period during which VAS pain was ≤ 20 mm or ≤ 10 mm and the proportion of pts who achieved remission (DAS28-CRP < 2.6 or CDAI ≤ 2.8) at Week 24 was evaluated. Of pts who achieved DAS28-CRP or CDAI remission, the proportion who also reported VAS pain ≤ 20 mm or ≤ 10 mm was determined.

Results: In FINCH 1, there was a higher probability of achieving VAS pain ≤ 10 mm with FIL200, vs ADA + MTX or PBO + MTX; responses were better or comparable with FIL100 vs other treatments. Similar findings were seen in FINCH 2 and 3. In FINCH 1, the time during which VAS pain score was ≤ 20 mm or ≤ 10 mm was greatest in the FIL200 group, and comparable between the FIL100 and ADA groups (**Table**). The duration of time under each pain threshold was greater in each FIL group vs PBO in FINCH 2 (**Table**) and in each FIL group vs MTX in FINCH 3. In FINCH 1, the proportion of pts achieving DAS28-CRP remission was greater with FIL200 + MTX (48.4%) and comparable for FIL100 + MTX (35.2%) vs ADA + MTX (35.7%; **Figure 1A**). The proportion of pts who achieved VAS pain ≤ 20 mm and ≤ 10 mm in addition to DAS28-CRP remission was 35.8% and 26.3%, respectively, in the FIL200 + MTX group, vs 24.6% and 17.2% in the ADA + MTX group (**-Figure 1A**). In FINCH 2, a greater proportion of pts in the FIL groups achieved DAS28-CRP remission and pain responses in addition to DAS28-CRP remission vs the PBO group (**Figure 1B**). Findings were similar when CDAI remission was assessed for FINCH 1 and 2 (**Figure 2A and B**). In FINCH 3, the proportion of pts to achieve remission and pain responses in addition to remission was greater in the FIL vs MTX groups; e.g. DAS28-CRP remission and VAS pain ≤ 10 mm was achieved by 23.3% of pts on FIL200, 33.2% on FIL200 + MTX, 27.5% on FIL100 + MTX and 14.9% on MTX.

Conclusion: Across the studies, duration of threshold pain responses achieved over the observation periods was greater with FIL vs comparators. In FINCH 1, FIL200 had a particularly favorable impact when pain response and remission were assessed together; results were comparable between FIL100 and ADA. Similar findings were seen with FIL vs PBO and MTX in FINCH 2 and 3, respectively. These findings suggest that JAK1 inhibition may offer potential added value with respect to patient-reported pain as well as treat-to-target goals.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interleukin-6 (IL) plays an important role in the pathogenesis of comorbid rheumatoid arthritis (RA) depression, and IL-6 inhibitors used to treat RA patients may have antidepressant effects. The **objective** was to evaluate the efficacy of IL-6 inhibitor olokizumab (OKZ) in reducing the symptoms of depression in patients with moderate/high RA disease activity.

Methods: To date, 76 RA patients have been included, of which 65 (85.5%) are women, with an average age of 48.2 ±11.5 years; with predominantly high RA disease activity according to DAS28 (CRP) (89.2%), SDAI (83.8%) and CDAI (79.7%) indices and inefficacy of stable 12-week csDMARD therapy. In all patients, a psychiatrist diagnosed chronic or recurrent depression of varying severity (in accordance with ICD-10) during a semi-structured interview. At week 0, all patients were randomized by the method of sequential numbers in a ratio of 1:1:1 to one of the 3 study groups: group 1 – csDMARDs+OKZ 64 mg subcutaneously once every 4 weeks (n=27); group 2 – csDMARDs+OKZ 64 mg subcutaneously once every 4 weeks + psychopharmacotherapy (PPT) (n=39); group 3 – csDMARDs+PPT (n=10). The duration of the study is 24 weeks. The dynamics of depression severity were assessed by the Patient's Health Questionnaire – 9 (PHQ-9), Montgomery – Asberg Depression Rating Scale(MADRS); anxiety – Hamilton Anxiety Rating Scale (HAM-A); experimental psychological projective tests were also used.

Results: There were no differences between the three groups in the duration of RA, severity of pain, TJC, SJC, nor patient or physician global assessments, physical function limitations according to the HAQ DI and health related quality of life according to EQ-5D-3L. After 12 and 24 weeks of therapy, there was a significant decrease in the severity of depression and anxiety in all groups of patients. However, the difference between the final and initial values of all scales was statistically significantly greater ($p < 0.05$) in the groups of patients receiving PPT: csDMARDs+PPT (ΔPHQ-9 24–0=–15.5±3.53; ΔMADRS 24–0=–25.0±1.41; ΔHAM-A 24-0=–18.5±3.53) and csDMARDs+OKZ+PPT (ΔPHQ-9 24–0=–5.73±4.31; ΔMADRS 24–0=–22.3±4.44; ΔHAM-A 24-0=–12.5±4.22), compared with the csDMARDs+OKZ group (ΔPHQ-9 24–0=–

Table 1. 3.08±3.67; ΔMADRS 24-0=–5.25±7.33; ΔHAM-A 24–0=–5.75±7.74) (Table 1). According to a semi-structured psychiatric interview and experimental psychological tests, the proportion of patients without depression after 24 weeks of therapy was significantly higher in the groups of patients receiving PPT: 100% in the group of csDMARDs+PPT and 83% - csDMARDs +OKZ+PPT, as opposed to 22% in the group of csDMARDs+OKZ. OKZ therapy contributed to the normalization of night sleep but did not lead to a decrease in the frequency and severity of cognitive impairments (CI).

Conclusion: OKZ has an antidepressant effect, leads to a decrease in the frequency of sleep disorders, but a complete regression of depression was also found in 22% of patients who received OKZ without PPT, mainly in patients with mild depression. The combination of OKZ and PPT was optimal for the complete regression of depression, anxiety and a decrease in the frequency and severity of CI.

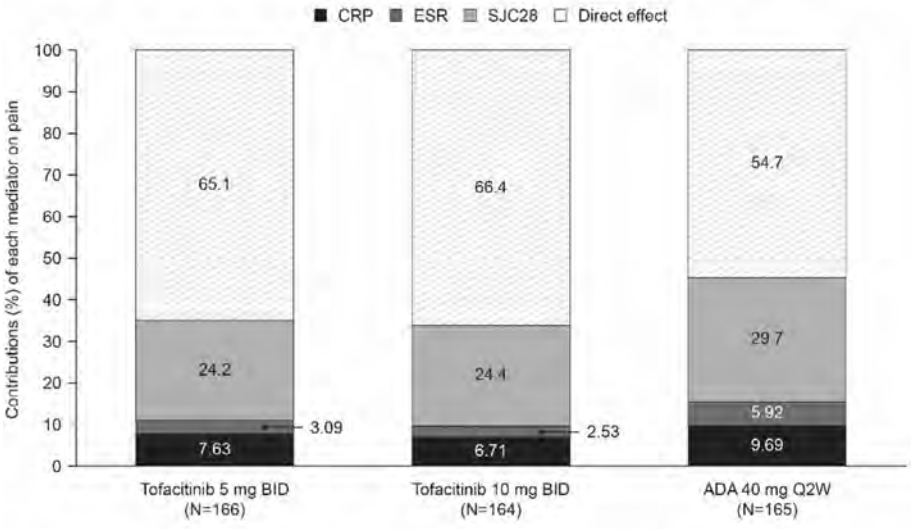
Exploratory Analysis of the Mechanisms of Action of the Potential Analgesic Effect of Tofacitinib and Adalimumab over Placebo in Patients with Rheumatoid Arthritis: Results of a Mediation Modeling Analysis

Maxime Dougados[1], Peter C. Taylor[2], David Gruben[3] and Meriem Kessouri[4], [1]Rheumatology Department, Cochin Hospital; INSERM (U1153): Clinical Epidemiology and Biostatistics, University of Paris, Paris, France, [2]Nuffield Department of Orthopedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [3]Pfizer Inc., Groton, CT, [4]Pfizer Inc., Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is the most common symptom reported by patients (pts) with rheumatic disorders, such as RA.[1] Improvement in pain with antirheumatic drugs is generally believed to be mediated by anti-inflammatory effects; however, a possible direct effect on pain of new antirheumatic drugs, such as Janus kinase inhibitors, is being debated.[2] Here, we used mediation modeling to explore the mechanisms of action of the effects of tofacitinib on pain in pts with RA.

Fig. Mediation effects: percentage contribution of indirect effects (via CRP, ESR, and SJC28) and direct effects on pain over PBO at M3 in pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, and ADA in ORAL Standard



Pain was assessed using Pt's Assessment of Arthritis Pain (Visual Analog Scale; 0–100 mm) scores at M3. Parameter estimates of the mediation model were linearly combined to calculate the direct and indirect effects. The software package PROC CALIS (SAS version 9.4) was used

ADA, adalimumab; BID, twice daily; M, Month; N, number of pts in each treatment group; PBO, placebo; pts, patients; Q2W, once every 2 weeks; SJC28, swollen joint count in 28 joints

Methods: This post hoc analysis used data at Month (M)3 from pts with active RA enrolled in the 12-month, Phase 3, randomized, placebo (PBO)-controlled ORAL Standard (NCT00853385) trial.[3] Pts received tofacitinib 5 or 10 mg twice daily (BID), adalimumab (ADA) 40 mg once every 2 weeks, or PBO (advancing to tofacitinib 5 or 10mg BID at M3), with stable doses of background methotrexate.[3] A mediation, or path, analysis was performed, with pain (Visual Analog Scale; 0–100mm) scores at M3 the dependent variable, treatment (tofacitinib 5 or 10 mg BID or ADA) the independent variable, and inflammation (measured by inflammatory markers CRP, ESR, and swollen joint count in 28 joints [SJC28]) a mediator. An indirect effect was defined as the treatment effect on pain over PBO mediated by CRP, ESR, and SJC28. A direct effect (over PBO) was defined as the treatment effect on pain not attributable to CRP, ESR, and SJC28. M3 data were used without imputations.

Results: Data for 580 pts were included: 166, 164, 165, and 85 pts received tofacitinib 5mg BID, tofacitinib 10 mg BID, ADA, and PBO, respectively. At M3, the percentage contribution of the indirect effect on pain (ie, attributable to CRP, ESR, or SJC28) over PBO was significant for all treatment arms (all $p < 0.001$) with the mediation effect being greater for SJC28 vs CRP and ESR (Fig). The percentage contribution of the indirect effect was numerically lower with tofacitinib 5 mg BID (34.9% [95% confidence intervals: 18.1, 51.7]) and 10 mg BID (33.6% [17.1, 50.1]) compared with ADA (45.3% [19.6, 70.9]) (Fig). The percentage contribution of the direct effect on pain over PBO (ie, not attributable to CRP, ESR, or SJC28) was numerically higher with tofacitinib 5 mg BID (65.1% [48.3, 81.9]) and 10 mg BID (66.4% [49.9,82.9]) compared with ADA (54.7% [29.1, 80.4]) (Fig), and significant for all treatment arms (allp < 0.000).

Conclusion: Inflammation, particularly measured by SJC28, was a significant mediator of the effect of tofacitinib 5 and 10 mg BID and ADA on pain. However, the majority of the treatment effects on pain were not attributable to inflammatory changes; this was particularly the case for tofacitinib 5 and 10 mg BID (> 65%). Therefore, more work is needed to assess whether additional mediators of pain can be found. Limitation: this analysis could only assess variables that were collected in the ORAL Standard study as mediators.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In the INBUILD trial in patients with progressive pulmonary fibrosis, nintedanib reduced the rate of decline in forced vital capacity (FVC) compared with placebo, with a safety profile characterized predominantly by gastrointestinal events. The open-label extension of the INBUILD trial, INBUILD-ON, collected data on adverse events and FVC decline over longer-term treatment with nintedanib. We analyzed data from patients with progressive pulmonary fibrosis related to autoimmune disease in INBUILD-ON.

Methods: Patients in the INBUILD trial had diffuse fibrosing interstitial lung disease (ILD) (reticular abnormality with traction bronchiectasis, with or without honeycombing) of >10% extent on HRCT and met criteria for progression of ILD within the prior 24 months, despite management deemed appropriate in clinical practice. Patients who completed the INBUILD trial on treatment were eligible to enter INBUILD-ON. Patients who received nintedanib in INBUILD and continued to take it in INBUILD-ON comprised the "continued nintedanib" group. Patients who received placebo in INBUILD and initiated nintedanib in INBUILD-ON comprised the "initiated nintedanib" group. In descriptive analyses, we analyzed adverse events and changes in FVC in patients with autoimmune disease-related ILDs. Median exposure to nintedanib in INBUILD-ON in these patients was 21.8 months.

Results: Of the 434 patients treated in INBUILD-ON, 113 had autoimmune diseases (52 rheumatoid arthritis, 29 systemic sclerosis, 13 mixed connective tissue disease, 19 other diseases). Of these patients, 66.4% received ≥1 disease-modifying anti-rheumatic drug or high-dose glucocorticoid (>20 mg/day prednisone or equivalent) at baseline or during the trial. Diarrhea was the most frequently reported adverse event (Table). Serious adverse events were reported in 27 (51.9%) patients in the continued nintedanib group and 37 (60.7%) patients in the initiated nintedanib group. In the continued and initiated nintedanib groups, respectively, 10 (19.2%) and 31 (50.8%) patients had ≥1 dose reduction and 15 (28.8%) and 28 (45.9%) patients had ≥1 treatment interruption. Adverse events led to discontinuation of nintedanib in 17 (32.7%) patients in the

Table. Most frequent adverse events in patients with autoimmune disease-related progressive pulmonary fibrosis in INBUILD-ON.

	Continued nintedanib (n=52)	Initiated nintedanib (n=61)

Bronchitis	2 (3.8)	8 (13.1)
Gamma-glutamyltransferase increased	1 (1.9)	8 (13.1)

Data are n (%) of patients with ≥1 such adverse event with onset date between first nintedanib intake and last intake plus 28 days. Adverse events reported in >12% of patients in either group are shown. Adverse events were coded according to preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA). *Based on MedDRA preferred term "interstitial lung disease"

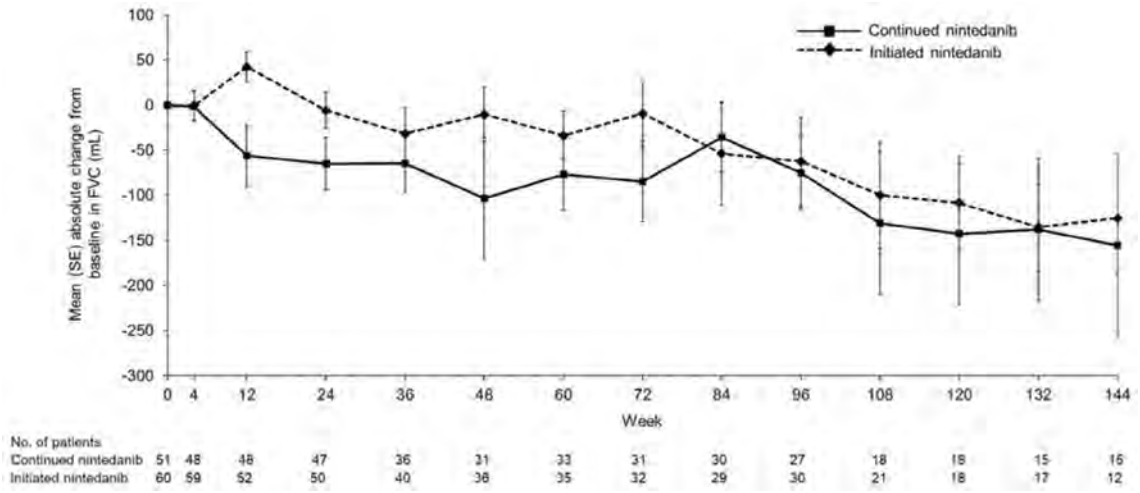

Figure. Changes in FVC (mL) over 144 weeks in patients with autoimmune disease-related progressive pulmonary fibrosis in INBUILD-ON.

continued nintedanib group and 28 (45.9%) patients in the initiated nintedanib group. Mean (SE) changes in FVC from baseline to week 144 of INBUILD-ON were –155.3 (101.8) mL in the continued nintedanib group and –125.2 (61.6) mL in the initiated nintedanib group (Figure).

Conclusion: The adverse event profile of nintedanib in patients with progressive pulmonary fibrosis due to autoimmune disease in INBUILD-ON was consistent with that observed in patients with autoimmune diseases in the INBUILD trial. Permanent discontinuations of nintedanib were less frequent in patients who continued nintedanib in INBUILD-ON than in those who initiated nintedanib in INBUILD-ON. These data should be interpreted with caution given the small number of patients who provided data, particularly at the later time-points.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic has significantly changed the understanding of the safety profile of therapies for immunoinflammatory rheumatic diseases. This is primarily due to the negative impact of a number of DMARDs and biological DMARDs on the course and outcomes of a new coronavirus infection. A number of studies have shown that anti-B-cell therapy (rituximab) was associated with statistically significant increase in the risk of severe COVID-19 and an increase in mortality. At the same time, the analysis of real clinical practice data dictated the need to establish a number of restrictions on the use of certain classes of biological DMARDs and to search for alternative therapeutic approached to maintain control over disease activity.

We evaluate the efficacy and safety of olokizumab, solution for subcutaneous injection, 160mg/ml - 0.4ml for the treatment of patients with RA in real clinical practice after switchingfrom rituximab during the COVID-19 pandemic.

Methods: The study included 19 patients with a confirmed diagnosis of RAwho were previously on rituximab therapy at a dose of 1000 (500) mg twice with an interval of 2 weeks not less than 6 months,and received at least one course of therapy with this drug. As RA worsened, patients switched to olokizumab and continued to receive standard DMARDs. At weeks 0, 4, 8, 12, 16, 20 and 24 after the switch, the following parameters were assessed: the severity of pain(VAS scale), the number of tender and swollen joints (TJC28 and TSC28), the level of acute phase markers of inflammation, the disease activity

Table 1. Main Efficacy Results Dynamic. Footnotes: *p<0.05 compared to baseline; Me [Q1;Q3]. median [1st; 3nd quartile]

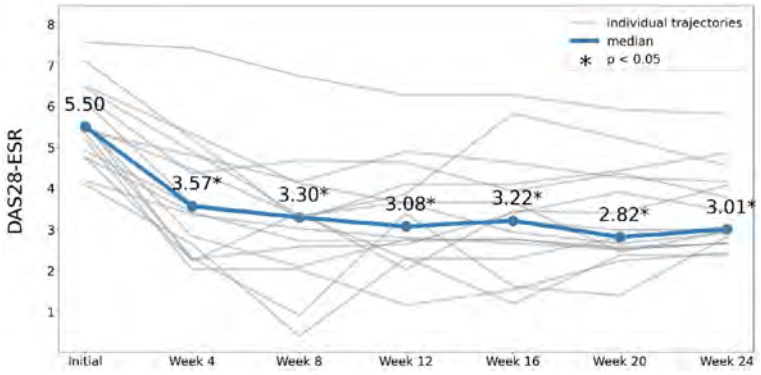

Figure 1. DAS28-ESR Dynamic

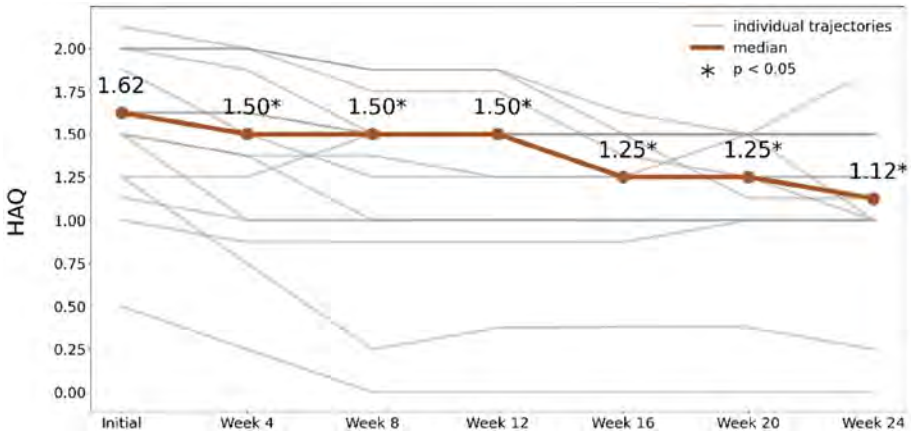

Figure 2. HAQ Dynamic

index (DAS28) calculated using ESR and CRP, and the CDAI (clinical disease activity index), functional state index HAQ, as well as the safety profile of therapy.

Results: Data analysis was performed using median values (Me). TJC28 and SJC28 decreased 4 weeks after the injection of olokizumab in comparison to baseline values (Table 1). Laboratory markers of inflammation analysis showed a decrease in CRP and ESR levels after 4 weeks of treatment with positive trend in place at weeks 8, 12, 16, 20 and 24. The level of CRP by the week 4 became within the normal range, regardless of the baseline values (Table 1). All activity indices improved from the week 4 in each evaluation period compared to baseline (Table 1, for DAS28-ESR see Figure 1). All patients showed a reduction in pain (VAS scale) improved starting from week 4. There was a significant improvement in the functional status of patients by study week 4 according to the HAQ index (Figure 2).

Conclusion: The study found that non-medical switching from rituximab to olokizumab was effective and safe during the COVID-19 pandemic.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously reported on difficult to treat Rheumatoid Arthritis (RA) in nearly 1600 patients treated with biologic (b) or target synthetic (ts) DMARDs including failure or were intolerant to all classes, i.e. what we termed poly-refractory RA (1).Here, we sought to characterise this further, by exploring whether there is an underlying inflammatory drive underpinning this response, by utilizing ultrasound.

Table 1. PIRRA and NIRRA subgroups within Poly-Refractory RA pool

	Poly refractory RA valid with US scan (N= 34)		
	NIRRA(N=11)	PIRRA (N=23)	Significance
Demographics			
Age, median (IQR)	59 (46-69)	64 (57-73)	No
Female, N (%)	6 (55%)	19 (83%)	No
BMI, median (IQR)	30 (26-33)	27 (23-31)	No
Osteoarthritis	9 (82%)	16 (70%)	No
Fibromyalgia	1 (9%)	0 (0%)	No
Depression	0 (0%)	1 (4%)	No
Chronic widespread pain	1 (9%)	2 (9%)	No
Osteoporosis, N (%)	4 (36%)	4 (17%)	No
Osteoporotic fractures, median	0 (0-0)	0 (0-0)	No
Joint replacements, median	1 (0-3)	0.5 (0-1)	No
Disease characteristics			
Age at onset	45 (31-51)	45 (34-49)	No
Disease duration in years, median (IQR)	18 (14-19)	18 (15-20)	No
Time since 1st bDMARDs, median (IQR)	11 (9-18)	13 (11-16)	No
Time from diagnosis to start 1st b/tsDMARDs (years), median (IQR)	2 (0-7)	2 (2-4)	No
TJC28, median (IQR)	15 (7-21)	11 (9-15)	No
SJC28, median (IQR)	1 (0-2)	7 (5-9)	**<0.001**
Main joint involvement, N (%)			
Small	8 (72%)	17 (74%)	No
Large	1 (9%)	0 (0%)	No
Both	2 (18%)	6 (26%)	No
VAS in mm, median (IQR)	60 (50-70)	70 (60-80)	0.095
DAS28, mean ±SD	4.75 (4.1-5.6)	5.42 (4.9-6.1)	**0.05**
Current use of steroids, N (%)	3 (27%)	17 (74%)	**0.023**
Current use of oral glucocorticoid therapy, N (%)	1 (9%)	14 (61%)	**0.008**
Patients with extra-articular manifestations, N (%)			
Vasculitis	1 (9%)	0 (0%)	No
Glomerulonephritis	0 (0%)	0 (0%)	CNC
Scleritis	0 (0%)	3 (13%)	No
Pericarditis	1 (9%)	0 (0%)	No
CRP, median (IQR)	5 (5-16)	15 (5-29)	0.067
CRP elevated >10, N (%)	3 (27%)	13 (57%)	No
Erosions by US	9 (82%)	18 (86%)	No
RF positive, N (%)	9 (82%)	17 (74%)	No
Anti-CCP positive, N (%)	11 (100%)	18 (78%)	No

Methods: We reviewed electronic medical records of all D2TRA and identified 40 patients with poly-refractory RA. In addition to clinical assessment, we performed musculoskeletal ultrasonography (US) of clinically swollen joints. Patients were divided into two groups according to the presence or absence of US synovitis, respectively Persistent Inflammatory Refractory RA (PIRRA) and Non-inflammatory Refractory RA (NIRRA). US synovitis was considered as the presence of both grey-scale and power Doppler grades of at least 1. Univariate analyses were performed to differentiate the two groups' characteristics.

Results: Only 40 out of 1591 patients with poly-refractory RA representing only 2.5% of cases. Of these, 34 (85%) had a recent US. 3/34 died and 3/34 were lost to follow-up from our clinic. 23/34 (67.6%) had US synovitis and therefore had PIRRA, while 11/34 (32.4%) with no US synovitis were classified as NIRRA, with baseline characteristics of both grops described in Table 1. When compared to NIRRA, PIRRA poly-refractory patients had significantly higher SJC (7 vs 1, $p < 0.001$) and, as expected, DAS-28-CRP scores (5.42 vs 4.75, $p = 0.05$), as well as higher need for corticosteroids to control their symptoms (61% vs 9%, $p = 0.008$). CRP levels were numerically but not significantly higher in the PIRRA group (median 15 vs 5mg/L, $p = 0.067$). The NIRRA group had a higher BMI, that may have impacted on CRP levels, and contained more fibromyalgia patients.

Conclusion: Poly-Refractory RA represented only 2.5% of RA cases under b/tsDMARDs and at least one-third of those patients had no signs of active inflammation on US. Patients that had exhausted all available b/tsDMARD options, the NIRRA group, with objective evidence of inflammation comprised only 1.5% of RA.

Abstract Number: 2161

Pharmacokinetic and Safety Similarity of High- and Low-Concentration Formulations of Adalimumab Biosimilar ABP 501

Vincent Chow, Muhan Zhou, Daniel Mytych, Alexander Colbert, Mieke Jill Miller, Iwona Wala and **Waldemar Radziszewski**, Amgen, Inc., Thousand Oaks, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ABP 501 has been developed as a biosimilar for Humira® (adalimumab), a fully human monoclonal antibody targeting tumor necrosis factor alpha (TNFα). ABP 501 is the first adalimumab biosimilar approved in the United States (AMJEVITA™) and European Union (AMGEVITA®) as a 50 mg/mL formulation for treating certain immune-mediated inflammatory diseases. An ABP 501 100 mg/mL formulation is being developed as a high-concentration formulation and requires half the injection volume to deliver the same subcutaneous (SC) dose. This study evaluates the similarity

Table 1. Summary of Statistical Assessment of PK Parameters

Treatment and Comparison	AUC_{inf} (hr*µg/mL) LS Geometric Mean [n]	C_{max} (µg/mL) LS Geometric Mean [n]
ABP 501-HCF	2177 [154]	3.75 [180]
ABP 501-LCF	2086 [153]	3.52 [184]
Ratio of LS Geometric Means (90% CI)		
ABP 501-HCF vs ABP 501-LCF	1.04 (0.9634, 1.1297)	1.06 (0.9960, 1.1380)

ANCOVA = analysis of covariance; AUC = area under the concentration-time curve; AUC_{inf} = AUC from time 0 extrapolated to infinity; CI = confidence interval; C_{max} = maximum observed concentration; HCF = high-concentration formulation; LCF = low-concentration formulation; LS = least squares; PK = pharmacokinetics.
Note: Primary analysis of mean geometric LS, ratio of geometric LS means, and 90% CI were estimated based on the ANCOVA model with a fixed effect for treatment and adjusting for baseline weight.

between single-dose pharmacokinetics (PK), safety, and immunogenicity of the low-concentration (ABP 501-LCF) and high-concentration (ABP 501-HCF) formulations of ABP 501 in healthy adult subjects.

Methods: In this randomized, single-blind, single-dose, 2-arm, parallel-group study in healthy adults, approximately 350 subjects were planned for dosing. Eligible subjects were randomized in a 1:1 ratio to receive a single 40 mg SC injection of either ABP 501-HCF (n = 175) or ABP 501-LCF (n = 175). The primary objective was to determine PK similarity of ABP 501-HCF with ABP 501-LCF, as assessed by area under the concentration time curve from time 0 extrapolated to infinity (AUC_{inf}) and maximum observed concentration (C_{max}). Pre-specified similarity criterion for the primary PK analysis was the standard 90% confidence interval (CI) for the ratio of least square (LS) geometric means (GM) to be within 0.80 to 1.25. Secondary endpoints included other PK parameters, safety, tolerability, and immunogenicity.

Results: A total of 370 of 372 randomized subjects received study drug (ABP 501-HCF, n = 183 of 185; ABP 501-LCF, n = 187 of 187). Demographic and baseline characteristics were comparable between the two treatment groups. Ratios of LS GM (90% CIs) between ABP 501-HCF and ABP 501-LCF for AUC_{inf} and C_{max} were 1.04 (0.9634, 1.1297) and 1.06 (0.9960, 1.138); the 90% CIs (for the ratio of LS GM between ABP 501-HCF and ABP 501-LCF for AUC_{inf} and C_{max}) were fully contained within the prespecified PK similarity margin (0.8 – 1.25) (Table 1). Both the high- and low-concentration formulations were well tolerated; the frequency, type, and severity of adverse events (AEs) were comparable between ABP 501-HCF and ABP 501-LCF and were consistent with the safety profile of adalimumab (Table 2). Headache was the most commonly reported AE in both treatment groups (ABP 501-HCF, n = 8; ABP 501-LCF, n = 9). Subjects in both groups tested positive for pre-existing binding anti-drug antibodies (ADAs) and neutralizing ADAs at baseline; 182 subjects in the

Table 2. Overall Summary of Adverse Events

	ABP 501-HCF (N = 183) n (%)	ABP 501-LCF (N = 187) n (%)
Any adverse event	49 (26.8)	51 (27.3)
Any grade ≥ 3 adverse event	0 (0.0)	0 (0.0)
Any fatal adverse event	0 (0.0)	0 (0.0)
Any serious adverse event	0 (0.0)	0 (0.0)
Any adverse event leading to discontinuation of study	1 (0.5)	1 (0.5)
Any adverse event of interest	12 (6.6)	11 (5.9)
Any COVID-19-related adverse event	5 (2.7)	3 (1.6)

HCF = high-concentration formulation; LCF = low-concentration formulation.
Note: Only treatment-emergent adverse events were summarized by actual treatment received. For each category, subjects were included only once, even if they experienced multiple adverse events in that category.

Table 3. Antidrug Antibody Results

Variable	ABP 501-HCF (N = 183) n (%)	ABP 501-LCF (N = 187) n (%)
Subjects with an on-study result[a]	**183**	**187**
Total antibody incidence, n (%)		
Binding antibody positive anytime	172 (94.0)	179 (95.7)
Neutralizing antibody positive anytime	32 (17.5)	29 (15.5)
Subjects with a result at baseline	**183**	**187**
Pre-existing antibody incidence, n (%)		
Binding antibody positive at or before baseline	7 (3.8)	8 (4.3)
Neutralizing antibody positive at or before baseline	1 (0.5)	0 (0.0)
Subjects with a post-baseline result through EOS	**182**	**185**
Treatment boosted antibody incidence, n (%)		
Binding antibody positive at baseline with a ≥ 4x increase in magnitude post-baseline	4 (2.2)	6 (3.2)
Developing antibody incidence, n (%)		
Binding antibody positive post-baseline with a negative or no result at baseline	165 (90.7)	171 (92.4)
Transient[b]	4 (2.2)	3 (1.6)
Neutralizing antibody positive post-baseline with a negative or no result at baseline	31 (17.0)	29 (15.7)
Transient[b]	1 (0.5)	0 (0.0)

EOS = end-of-study; HCF = high-concentration formulation; LCF = low-concentration formulation.
Note: Baseline was defined as the last non-missing assessment taken prior to the first dose of study investigational product. Percentages were calculated using the corresponding category count as the denominator.
[a] Subjects were considered on-study after signing informed consent.
[b] Negative result at the subject's last time point tested within the study period

ABP 501-HCF group and 185 in the ABP 501-LCF group had post-baseline results through end of study (Table 3). In the ABP 501-HCF group, 165 (90.7%) subjects developed binding ADAs and 31 (17%) developed neutralizing ADAs. In the ABP 501-LCF group, 171 (92.4%) subjects developed binding ADAs and 29 (15.7%) developed neutralizing ADAs.

Conclusion: Results of this study demonstrate PK similarity between ABP 501-HCF (100 mg/mL) and ABP 501-LCF (50 mg/mL) following a single SC injection in healthy adult subjects. Immunogenicity and safety of ABP 501-HCF and ABP 501-LCF were also found to be similar.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: DARWIN 3 (NCT02065700) is a long-term extension (LTE) study assessing the safety and efficacy of filgotinib (FIL) in patients with rheumatoid arthritis (RA) and an inadequate response to methotrexate (MTX).[1] In the DARWIN 1 (NCT01888874) and DARWIN 2 (NCT01894516) parent studies, patients received FIL in combination with MTX or FIL monotherapy, respectively. This analysis aimed to provide an update on the safety and efficacy of FIL 200 mg (FIL200) in patients with RA, with or without MTX, with a maximum of 8.2 years of exposure.

Methods: Patients completing the DARWIN 1 (FIL + MTX) and DARWIN 2 (FIL monotherapy) Phase 2 studies could enter DARWIN 3, receiving FIL200. The proportion of patients experiencing treatment-emergent adverse events (TEAEs) were reported using the safety analysis set, comprising data from both the parent and LTE studies. Efficacy was assessed from LTE baseline using the American College of Rheumatology (ACR) 20/50/70 improvement criteria and Disease Activity Score in 28 joints using C-reactive protein (DAS28-CRP), up to 264 weeks. Low disease activity and remission were defined as DAS28-CRP $\leq$ 3.2 and $<$ 2.6, respectively.

Results: In total, 739 patients were enrolled in DARWIN 3. Mean (standard deviation; SD) FIL exposure was 4.89 (2.72) years in the FIL + MTX group and 4.78 (2.79) years in the FIL monotherapy group. In the FIL + MTX vs FIL monotherapy groups, TEAEs were reported for 90.9% and 92.1% of patients, respectively (**Table**). The most common TEAE was infection. In both treatment groups, 8 patients had a TEAE leading to death (1.6% and 3.3%, respectively). Exposure-adjusted incidence rates, censored at time of first event for major adverse cardiovascular event, venous thromboembolism, herpes zoster, infections, serious infections, nonmelanoma skin cancer (NMSC), malignancies excluding NMSC, gastrointestinal perforations and TEAEs leading to death, will be reported. Through 5 years, ACR20/50/70 responses were maintained in 86.3%/66.7%/50.7% of the FIL + MTX group and 90.8%/74.8%/51.4% of the FIL monotherapy group, respectively (observed data). DAS28-CRP low disease activity and remission rates (nonresponder imputation) at DARWIN 3 baseline were 46.1%/40.1% (FIL + MTX) and 29.6%/24.8% (FIL monotherapy) (**Figure**). At Week 264, the proportion of patients achieving low disease activity and remission were 34.0%/34.3% (FIL + MTX) and 27.0%/24.8% (FIL monotherapy).

Table. TEAEs of interest

	FIL + MTX N=497	FIL monotherapy N=242
Any TEAE	452 (90.9)	223 (92.1)
MACE	4 (0.8)	3 (1.2)
VTE	3 (0.6)	0
Herpes zoster	30 (6.0)	14 (5.8)
Infections	317 (63.8)	140 (57.9)
Serious infections	28 (5.6)	19 (7.9)
NMSC	6 (1.2)	2 (0.8)
Malignancies excluding NMSC	12 (2.4)	8 (3.3)
GI perforations	1 (0.2)	0
TEAEs leading to death	8 (1.6)	8 (3.3)

Data are n (%).
FIL, filgotinib; GI, gastrointestinal; MACE, major adverse cardiovascular event; MTX, methotrexate; NMSC, nonmelanoma skin cancer; TEAE, treatment-emergent adverse event; VTE, venous thromboembolism.

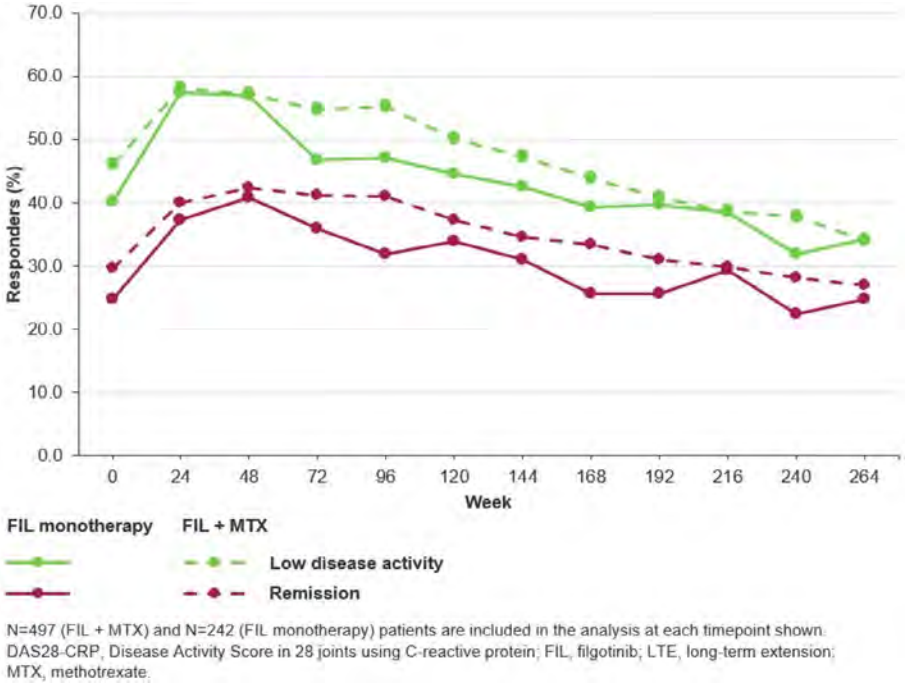

Figure. Proportion of patients achieving DAS28-CRP low disease activity and remission, from LTE baseline to Week 264 (nonresponder imputation analysis)

Conclusion: With a maximum of 8.2 years of exposure in patients with RA, the FIL safety profile is similar between the background MTX and monotherapy treatment arms. Both arms show sustained efficacy over time.

Omnipresent Poor Prognostic Factors in Early Rheumatoid Arthritis in the IMPROVED Trial; Is Earlier bDMARD Treatment Escalation for All Necessary?

Joy van der Pol[1], Sytske Anne Bergstra[2], Thomas Huizinga[2] and CF Allaart[2], [1]Leiden University Medical Center, Utrecht, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The EULAR recommendations for the treatment of RA state, by expert opinion, that if a treatment target is not achieved with the first csDMARD strategy, addition of a bDMARD or a tsDMARD should be considered if at least 1 poor prognostic factor (PPF) is present. PPF are defined as: moderate to high disease activity after csDMARDs, high acute phase reactant levels, high swollen joint counts presence of RF and/or ACPA (especially in high levels), combinations of aforementioned PPFs and presence of early erosions. We investigated the presence of PPF in early RA patients, aiming to compare the clinical response on either csDMARD combination or bDMARD therapy in relation to presence or absence of PPF, in the IMPROVED trial.

Methods: In the IMPROVED trial, 479 patients with rheumatoid arthritis (2010-criteria) started treatment with MTX and a 4-month tapered high dose of prednisone bridging scheme. Patients not in early remission (DAS ≥1.6) after 4 months of the initial treatment were randomized to either 4 months MTX + HCQ + SSZ + continued low dose prednisone (arm 1) or to 4 months MTX + adalimumab (arm 2). A maximum of 5 PPFs could be present in any patient. High acute phase reactants were defined as CRP ≥0.8 mg/dl or ESR levels >20 mm/hour in women and >15 mm/hour in men. For swollen joint counts (SJC), we defined a high SJC as >10 in our main analysis and performed a sensitivity analysis with a definition of high SJC when the SJC was >4.

Results: Almost all RA patients had at least one PPF as mentioned in the EULAR recommendations. Presence of each PPF is displayed in figure 1. High inflammatory parameters and presence of antibodies at baseline were the most frequent PPFs (present in 366 and 390 patients, respectively). Presence of PPFs was evenly distributed between the randomization arms (figure 1b). Only 5 patients (1%) had no PPFs in the main analysis and only 10 (2%) in the sensitivity analysis. Of these, 2/5 and 2/10 patients did not achieve early remission and were randomized to the two treatment arms. Due to these small numbers, no further comparison in treatment response was done. In total, 65 patients with PPFs were evenly randomized to each study arm. Mean (SD) DAS change in arm 1 was -0.47 (-0.79) and in arm 2 -0.57 (-0.74), p = 0.48. Changes in HAQ were similar, median (IQR) HAQ change was -0.13 (-0.13 ; 0.13) in arm 1 and -0.13 (-0.25 ; 0.25) in arm 2, p=0.13. In the 5 and 6 patients that showed progression of radiographic damage, median (IQR) progression was 1 (0.5 ; 2) in arm 1 and 0.5 (0.5 ; 1) in arm 2, p =0.48.

Conclusion: Empirically identified PPFs were present in up to 99% of patients with early RA. High prevalence of PPFs is probably due to a large overlap between these PPFs and the 2010 RA classification criteria. According to current EULAR recommendations, it is recommended to start a b/tsDMARD in patients with PPF after failing first therapy with MTX and GC bridging. After failure to achieve the treatment target on this first treatment, we found no significantly better response in these patients on bDMARDs compared to csDMARDs. No comparison could be made with non-PPF patients.

Figure 1a: presence of poor prognostic factors in all RA patients

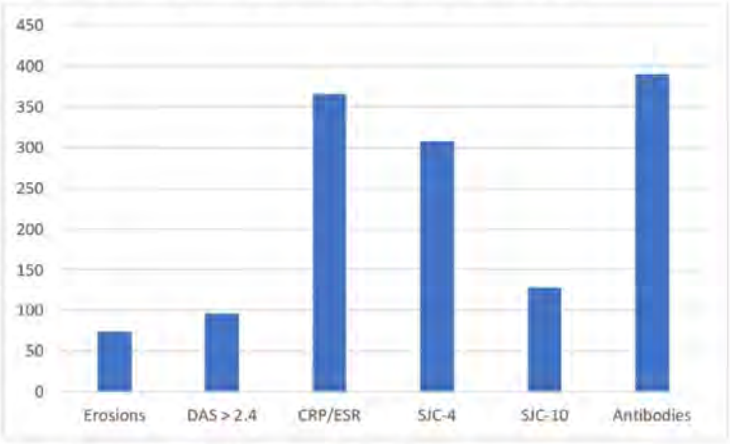

Figure 1b: presence of PPFs per randomization arm

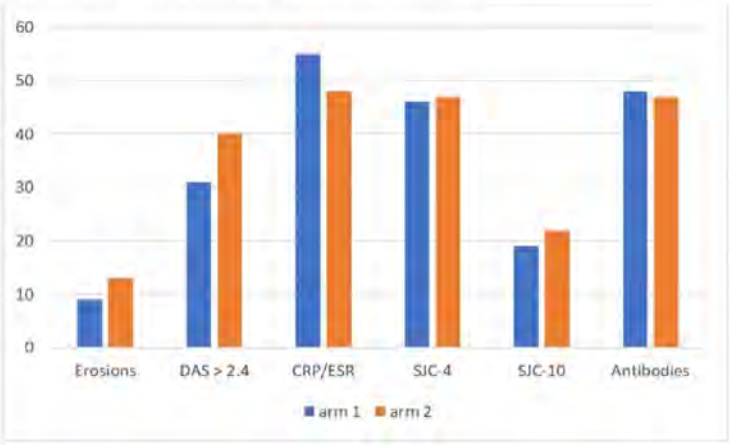

Erosions: presence of baseline erosions, DAS > 2.4: moderate/high DAS after 4 months of treatment with MTX + prednisone bridging, CRP/ESR: high c-reactive protein or erythrocyte sedimentation rate at baseline, SJC-4: presence of >4 swollen joints at baseline, SJC-10: presence of >10 swollen joints at baseline, antibodies: presence of ACPA or RF at baseline. Patients can be present in multiple categories; numbers don't add up to 479 RA patients in figure 1a.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical practice guidelines, based on information from clinical trials, provide different recommendations for the use of combination therapies for the treatment of rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA). Few studies have evaluated the persistence of different treatment strategies (combination *vs*. monotherapy) as a primary endpoint based on data from real-world settings. The aim of this study was to evaluate the persistence of the initial strategy with or without conventional synthetic (cs) disease-modifying antirheumatic drugs (DMARDs) (combination and monotherapy strategies, respectively) of targeted therapy in patients with RA, AS and PsA under real-life conditions. Factors associated with maintenance of the initial strategy were also analyzed.

Methods: Nested cohort study within BIOBADASER III, a prospective Spanish registry of patients with rheumatic diseases treated with targeted therapy, including biologic(b) and targeted synthetic(ts) DMARDs. Bivariate comparisons and multivariate Cox proportional hazards models were used for the analyses.

Results: A total of 2,521 patients were included in the study. Baseline demographics and disease characteristics, disease activity, type of targeted therapy, and concomitant medications are shown in Table 1. In the multivariate model, the initial strategy of combination therapy was associated with shorter persistence in patients with RA (hazard ratio [HR] 1.58;95% confidence interval [CI] 1.00 to 2.50; p=0.049), PsA (HR 2.48; 95%CI 1.65 to 3.72) and AS (HR 16.77; 95%CI 7.37 to 38.16; p < 0.001). 48; 95%CI 1.65 to 3.72; p < 0.001) and AS (HR 16.77; 95%CI 7.37 to 38.16; p < 0.001), regardless of age, sex, time of disease progression, baseline disease activity or type of b/tsDMARD. Figure 1 shows the analyses of persistence by disease using Kaplan-Meier curves. Overall, the combination strategy was associated with an increased incidence of adverse events (incidence rate ratio [IRR] 1.13; 95%CI 1.05-1.21).

Figure 1. Persistence of biologic disease-modifying antirheumatic drug treatment strategy (Kaplan-Meier plots).

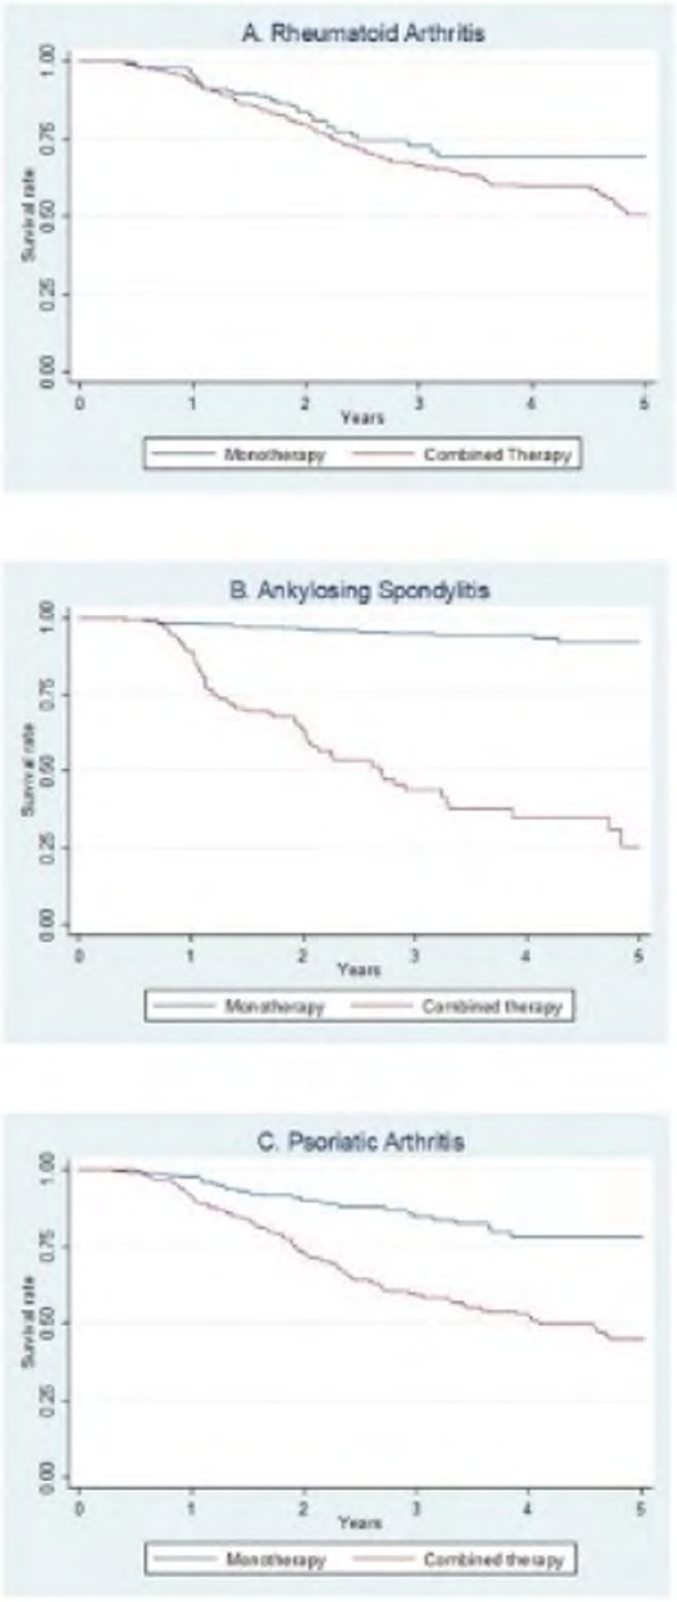

Figure 1. Persistence of biologic disease-modifying antirheumatic drug treatment strategy (Kaplan-Meier plots).

Conclusion: Analysis of a large database collected under real-world conditions shows that initiation of targeted therapy in monotherapy has a significantly better persistence and safety profile than in combination with csDMARD(s) in patients with PsA and AS. In patients with RA, the results also suggest that monotherapy should be considered as a therapeutic option as it offers a higher chance of persistence.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Usual interstitial pneumonia (UIP) is the most frequent, and severe ILD pattern in RA. Abatacept (ABA) has demonstrated effectiveness in RA-ILD during a 12-month period of treatment [*Rheumatology (Oxford)* 2020;59(12):3906-16, *Rheumatology (Oxford)* 2021;61(1):299-308]. However, little is known about the specific effect of ABA in the UIP pattern. Therefore, the aim of this study was to assess the effectiveness and safety of ABA in RA-ILD patients with radiological pattern of UIP during a long-term follow-up.

Methods: From a large observational multicenter study of 509 RA-ILD patients treated with ABA, we selected those with UIP. The following outcomes were assessed from baseline to final follow-up: **a)** pulmonary function tests (PFTs) -forced vital capacity (FVC) and diffusing capacity of the lungs for carbon monoxide (DLCO)-, **c)** chest high resolution computed tomography (HRCT), **d)**dyspnea (evaluated with the modified Medical Research Council scale), and **e)** arthritis activity (measured with DAS28-ESR).

Results: We included a total of 233 patients with UIP (118 women/115 men; mean age of 67.5±9.9 years). **Table 1** shows baseline demographic and clinical characteristics. The median ILD duration up to ABA initiation was relatively short, with a median [IQR] of 9.5 [2-36] months. Mean baseline values of FVC and DLCO were >80% and >60%, respectively. During a median of 22 [6-43] months of ABA therapy, 73.8% and 59.4% of patients showed an improvement/ stabilization of FVC

Table 1. Main general clinical features at baseline.

	RA-ILD patients with UIP (n=233)
Age, years mean±SD	68±10
Women, n (%)	118 (51)
Smoker ever, n (%)	123 (53)
ILD duration up to ABA, months, median [IQR]	9.5 [2-36]
RF // ACPA, n (%)	216 (93) // 205 (88)
DAS28-ESR, mean±SD	4.4±1.6
FVC (% of the predicted), mean±SD	85±22
DLCO (% of the predicted), mean±SD	64±20
ABA monotherapy, n (%)	102 (44)
ABA combined + MTX /other cDMARD, n (%)	131 (56)
Prednisone at baseline, mg/day, median [IQR]	5 [5-10]
Previous immunosuppressive therapy, n (%)	
MTX	167 (72)
Leflunomide	107 (46)
Sulfasalazine	27 (12)

Anti-TNF drugs	90 (39)
Rituximab	28 (12)
Tocilizumab	19 (8)
JAK inhibitors	7 (3)

ABA, abatacept; ACPA, anti-citrullinated protein antibodies; cDMARD, conventional disease-modifying antirheumatic drug; DAS28, disease activity score on 28 joints; DLCO, diffusing capacity of the lung for carbon monoxide; ESR, erythrocyte sedimentation rate; FVC, forced vital capacity; ILD, interstitial lung disease; IQR, interquartile range; MTX, methotrexate; RA, rheumatoid arthritis; RF, rheumatoid factor; SD, standard deviation; TNF, tumor necrosis factor; UIP, usual interstitial pneumonia.

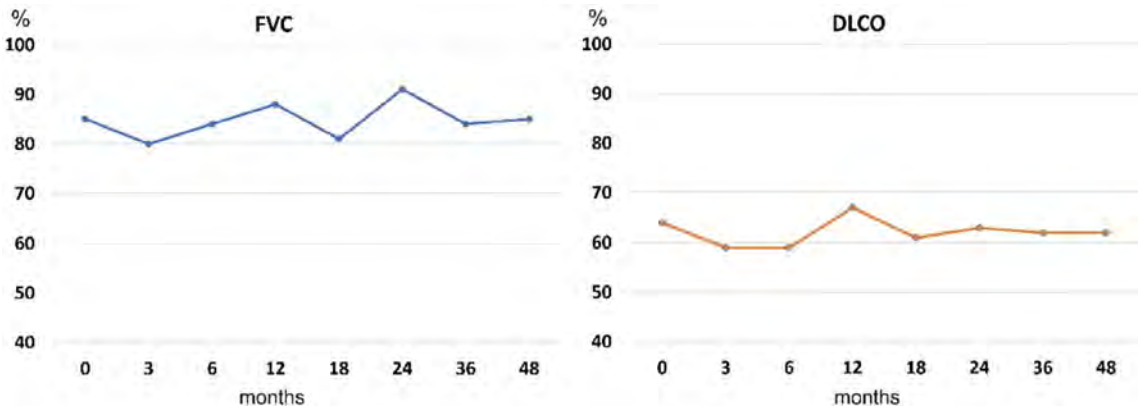

Figure 1. Evolution of pulmonary function tests (mean % of the predicted FVC and DLCO) in RA-ILD patients with UIP pattern at baseline and 48 months of follow-up.

and DLCO, respectively. **Figure 1** displays the evolution of PFTs along 48 months. Available chest HRCT images improved/stabilized in 67.1% of patients. Stabilization or improvement of dyspnea was found in 79.5% of patients. The majority of patients showed articular remission or low activity (mean DAS28-ESR of 4.4±1.6 at baseline and 2.6±1.3 at 48 months). ABA was withdrawn in 50 (21.5%) patients due to ILD worsening (n=20), articular inefficacy (n=15), serious infections (n=7), and other causes (n=8, development of malignancy in 3, neutrophilic dermatosis in 1, diagnosis of giant cell arteritis and change to tocilizumab in 1, patient's decision in 1, and 2 deceases).

Conclusion: ABA demonstrates a long-term efficacy and safety in patients with RA-associated UIP, the most severe pattern of ILD in RA patients.

Long-Term Effects of Abatacept on Arthritis and Atherosclerosis in Older vs Younger Patients with Rheumatoid Arthritis: 3-year Results of a Prospective, Multicenter, Observational Study

Zento Yamada[1], Sei Muraoka[1], Mai Kawazoe[2], Wataru Hirose[3], Hajime Kono[4], Shinsuke Yasuda[5], Takahiko Sugihara[6] and Toshihiro Nanki[2], [1]Division of Rheumatology, Department of Internal Medicine, Toho University School of Medicine, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Toho University School of Medicine, Ota-ku, Japan, [3]Hirose Clinic of Rheumatology, Saitama, Japan, [4]Teikyo University School of Medicine, Tokyo, Japan, [5]Department of Rheumatology, Graduate School of Medical and Dental Science, Tokyo Medical and Dental University (TMDU), Tokyo, Japan, [6]Toho University, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at an increased risk of cardiovascular disease secondary to atherosclerosis. Although it has been reported that TNF inhibitor improved carotid intima-media thickness (IMT) progression, the effect of abatacept (ABT) is unknown. We reported that 24-week ABT treatment was efficacious and safe in both older vs younger patients with RA who were refractory to csDMARDs. Presently, we report the long-term results of ABT on disease activity and safety for 3 years (156 weeks) in the same population while focusing on the effectiveness of ABT on atherosclerosis progression.

Methods: This was a prospective observational study. Patients were stratified by age and treatment into four groups: younger (20-64 years old) and older (≥65 years) patients taking ABT (AY and AO) and csDMARD (CY and CO). Patients could either initiate ABT (ABT group), and those in the csDMARD group could add a csDMARD to their prescribed regimen, or switch to a new csDMARD. Change from baseline in mean IMT of the common carotid artery, IMT max (bulbus, bifurcation,

Table 1. Changes in intima-media thickness, plaque score and pulse wave velocity at weeks 156.

Table 2. Factors affecting the extent of changes in plaque score using a linear mixed model.

Figure 1. Proportions of patients with rheumatoid arthritis who had the indicated EULAR responses at Weeks 52, 104 and 156.

internal and common carotid artery), plaque score, pulse wave velocity (PWV), and EULAR response in the ABT vs csDMARD groups in younger vs older patients were analyzed up to week 156.

Results: By age and treatment, 216 patients were evaluated (AY, n=52; AO, n=73; CY, n=41; CO, n=50). Change of mean IMT of the common carotid artery and max IMT in the ABT group tended to be small compared with the csDMARD group at week 156 (Table 1). Change of plaque score in the ABT group also tended to be small compared with the csDMARD group at week 156, which was statistically significant in the older patients (p=0.0302). Overall, there was no consistent trend in PWV. Furthermore, multivariate analysis, which also considered disease activity, showed that change in plaque score was significantly smaller in ABT group (AY+AO) compared with csDMARD group (CY+CO) (p=0.0303) (Table 2). In AY vs CY groups, the patient proportions with good or good/moderate EULAR response were higher in the ABT vs csDMARDs group at all time points (Figure 1). In AO vs CO groups, proportions of patients with good or good/moderate EULAR response were also higher in the ABT group. Decrease in DAS28-ESR, simple disease activity index, clinical disease activity index, or HAQ was significantly greater in the ABT vs csDMARDs group in both younger vs older patients. No significant differences in good or good/moderate EULAR response, DAS28-ESR, simple disease activity index, clinical disease activity index, or HAQ were observed between younger vs older patients in ABT-treated groups (AY vs AO). ABT retention rates were not significantly different between younger vs older patients. Adverse events tended to be more frequent in the ABT group, but no significant differences were found.

Conclusion: ABT may be effective in slowing atherosclerosis. ABT efficacy on disease activity was maintained for 3 years without differences in older vs younger patients. No new safety signals were detected.

Session Title: RA – Treatments Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA) was approved in 2020 in Japan for the treatment of "Rheumatoid arthritis (RA) patients with inadequate response to conventional therapy, including inhibition of structural damage progression". All-case post-marketing Surveillance (PMS) in Japan was started at the same time of the market launch and is currently collecting data up to 3-years (24-week data for solicited events). In Japanese label, UPA15 mg should be orally administered once daily for adult RA patients. UPA 7.5 mg may be acceptable for some patients according to their condition.

Table 1. Patient baseline characteristics

Variable		Patients included in safety analysis set, N=2,106	Patients included in efficacy analysis set, N=1,482
Sex	Male	416 (19.8)	298 (20.1)
	Female	1,690 (80.2)	1184 (79.9)
Age	Years, Mean (SD)	65.3 (13.7)	65.1 (13.6)
	<65	873 (41.5)	624 (42.1)
	≥65	1,233 (58.5)	858 (57.9)
Body weight	kg, Mean (SD)	55.74 (12.00), N=1,938	55.76 (11.68), N=1,390
	<50	618 (29.4)	437 (29.5)
	≥50 and <70	1,083 (51.4)	783 (52.8)
	≥70 and <90	210 (10.0)	152 (10.3)
	≥90	27 (1.3)	18 (1.2)
	Unknown/Unlisted	168 (8.0)	92 (6.2)
Disease duration	Years, Mean (SD)	11.99 (10.80), N=1,928	12.13 (10.99), N=1,396
	<2	325 (15.4)	251 (16.9)
	≥2 and <5	308 (14.6)	212 (14.3)
	≥5 and <10	352 (16.7)	245 (16.5)
	≥10	943 (44.8)	688 (46.4)
	Unknown/Unlisted	178 (8.5)	86 (5.8)
RA treatment history	Yes	2,091 (99.3)	1,471 (99.3)
	MTX	1,852 (87.9)	1,314 (88.7)
	MTX > 8mg/w continued for at least 3 months	1,299 (61.7)	920 (62.1)
	csDMARD (immunosuppressant excl. MTX)	572 (27.2)	426 (28.7)
	csDMARD (immunomodulator excl. MTX)	1,178 (55.9)	843 (56.9)
	JAK inhibitor	1,011 (48.0)	722 (48.7)
	bDMARDs (TNF inhibitor)	1,260 (59.8)	904 (61.0)
	bDMARDs (IL-6 inhibitor)	897 (42.6)	658 (44.4)
	bDMARDs (CTLA-4-Ig)	558 (26.5)	385 (26.0)
	Corticosteroid	1,374 (65.2)	979 (66.1)
	No	13 (0.6)	11 (0.7)
	Unknown/Unlisted	2 (0.1)	0 (0.0)

Numerical values refer to the number of patients (%) unless otherwise stated; SD: standard deviation; csDMARD: conventional synthetic disease-modifying antirheumatic drug; CTLA4-Ig: T-cell-selective co-stimulation modulator; IL-6: interleukin 6; JAK: Janus kinase; MTX: methotrexate; RA: rheumatoid arthritis; TNF: tumor necrosis factor

Table 2. Incidences of adverse events / drug reactions up to Week 24

Variable	Patients included in safety analysis set N=2,106 Number of patients (%)	Patients with MTX at least 8mg per week, for more than 3 months N = 1,299 Number of patients (%)	Patients without MTX at least 8mg per week, for more than 3 months N = 806 Number of patients (%)
Adverse events	464 (22.0)	268 (20.6)	196 (24.3)
Serious adverse events	99 (4.7)	47 (3.6)	52 (6.5)
Adverse drug reactions	329 (15.6)	184 (14.2)	145 (18.0)
Clinically significant adverse drug reactions	50 (2.4)	22 (1.7)	28 (3.5)

1 subject was unknown or undescribed for MTX dose and duration regarding guideline for the proper use of Upadacitinib in post-marketing surveillance.
"Adverse drug reactions" are defined as adverse events considered to be related to upadacitinib by the treating physician.

Japan College of Rheumatology guideline for the proper use of Upadacitinib in post-marketing surveillance, revised October 23, 2022, defines eligible patients as below. "Patients with an inadequate response to MTX > 8mg per week continued for at least 3 months are eligible. From a safety perspective, patients who cannot receive MTX e.g., patients with high risk of infection, renal dysfunction, or interstitial pneumonia, principally should not be eligible[1]."

Methods: This ongoing PMS includes all patients with RA prescribed with UPA since April 2020. An interim analysis of PMS was performed to evaluate the safety and the effectiveness (disease activity) of UPA for 24 weeks.

Results: As of August 15, 2022, 2878 patients were enrolled, with 2,106 and 1,482 patients included in the safety (mean age=65.3 years old; >65 years old=58.5%; female=80.2%; mean RA duration=12.0 years) and efficacy analysis set, respectively (Table 1). In the safety analysis set, 1,694 (80.4%) continued UPA treatment for 24 weeks. UPA doses at onset were 7.5mg/day in 540 (25.6%), 15mg/day in 1,549 (73.6%) of patients in the safety analysis set, respectively. At baseline, 44.4% and 41.0% of patients in the safety analysis set received methotrexate (MTX) and glucocorticoid, respectively, and 22.4% had mild or greater renal failure. Most common comorbidities were osteoporosis, hypertension, and gastroesophageal reflux disease. AEs and serious AEs (SAEs) occurred in 464 (22.0%) and 99 (4.7%) patients, respectively. In the 1,299 patients receiving MTX >8 mg/week for ≥3 months,[2] AEs occurred in 268 (20.6%) and SAEs in 47 (3.6%). In the 806 patients not receiving MTX > 8mg/week for ≥3 months, AEs occurred in 196 (24.3%) and SAEs in 52 (6.5%) (Table 2). Ten deaths were reported, with causes including lung tumor, subarachnoid hemorrhage, organizing pneumonia, bacterial pneumonia, pneumocystis jirovecii, COVID-19 and unknown. Serious infections were reported in 37 (1.8%) patients. Herpes zoster in 69 (3.3%), impaired liver function in 59 (2.8%), serious cytopenia in 3 (0.1%), renal impairment in

Table 3. Adverse event of special interest up to Week 24

	Number of patients (%)	Number of events	Dose at onset 15 mg/day n = 1,549	7.5 mg/day n = 540	Other n = 16
Adverse event of special interest	190 (9.0)				
Serious infection	37 (1.8)	42	33	9	0
Herpes zoster	69 (3.3)	75	53	20	2[a]
Malignancy	10 (0.5)	12	11	1	0
Cardiovascular event	8 (0.4)	8	5	3	0
Venous thromboembolism	1 (0.0)	2	2	0	0
Impaired liver function	59 (2.8)	62	45	17	0
Renal impairment	11 (0.5)	11	9	2	0
Interstitial pneumonia	5 (0.2)	5	5	0	0
Serious cytopenia	3 (0.1)	3	1	2	0
Gastrointestinal perforation	3 (0.1)	3	3	0	0
Hepatitis B reactivation	1 (0.0)	1	1	0	0
Event leading to death	10 (0.5)	10	9	1	0

"Solicited adverse events" in this study are as follows: events leading to death, serious infection, hepatitis B virus reactivation, interstitial pneumonia, malignancy, cardiovascular event, venous thromboembolism, gastrointestinal perforation, herpes zoster, Impaired liver function, renal impairment, rhabdomyolysis/myopathy, and serious cytopenia (neutropenia, lymphopenia, hemoglobin level decreased). Rhabdomyolysis or myopathy is not listed because these events did not occur. Numbers of 15 mg / day, 7.5 mg / day, and other indicate patient number of each group by starting dose, respectively.

[a]One patient who occurred while on doses other than 7.5 mg/day or 15 mg/day was included. One patient withdrew at the first onset of herpes zoster and 16 days after withdrawal, a second herpes zoster event was developed which was included.

11 (0.5%), malignancy in 10 (0.5%), cardiovascular event in 8 (0.4%), interstitial pneumonia in 5 (0.2%), and venous thromboembolism (VTE) in 1 (0.0%) were reported, respectively (Table 3). 6 of 10 patients with malignancies were diagnosed within 2 months of UPA initiation. 621 patients were assessed in DAS28-CRP, of which 488 (78.6%) achieved LDA or CR and 382 (61.5%) achieved CR.

Conclusion: The 24-week interim analysis of all-case PMS in Japan showed that more than half of the patients receiving UPA are over aged 65 years or older. Although the mean age is higher than that of patients in clinical studies, the safety profile was consistent with clinical trials, and no new safety signals were identified.[3,4] The safety and efficacy data from this real-world setting will continue to be collected to assess for RA patients treated with UPA in Japan.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

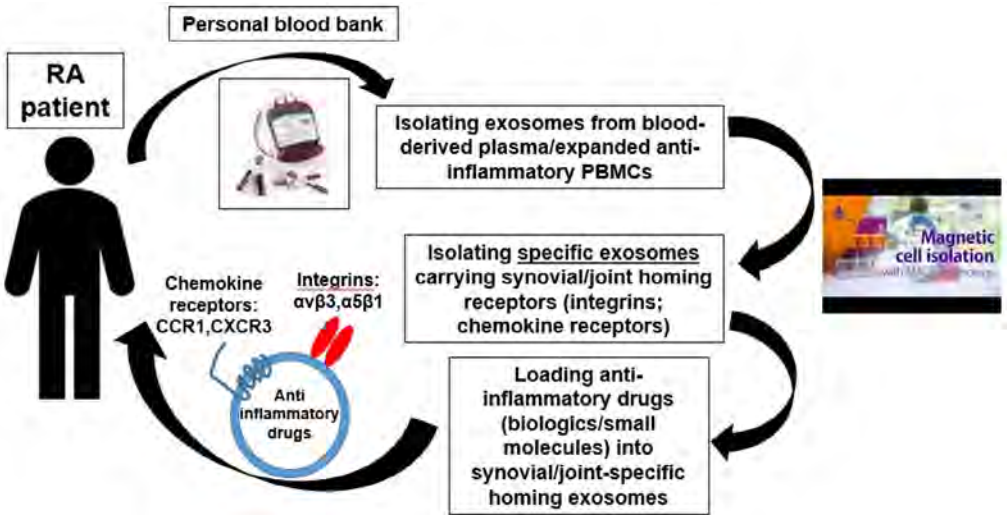

Figure 1: Our proposed strategy: Enrichment of autologous patient-derived 'joint-specific' homing exosomes for the treatment of RA patients.

Background/Purpose: The use of biological treatment in patients with rheumatoid arthritis (RA) can induce non-specific immune suppression, which might result in higher rates of infections. Therefore, there are still unmet needs to develop more specific and safe therapies in the management of RA patients. Accumulating evidence suggests that extracellular vesicles (EVs) may play a role in the modulation and maintenance of autoimmune processes. In the current study, we aimed to prove that isolation of circulating autologous 'tissue-specific' homing EVs from RA patients - may improve the delivery of current FDA-approved anti-inflammatory drugs, which will be encapsulated into these EVs. We assume that the drug-loaded EVs will find their way specifically to the inflamed tissue, following their administration to the same patient (Figure 1).

Methods: Plasma/serum-derived EVs had been isolated from arthritic mice (collagen-induced arthritis [CIA] model) and RA patients using: ultrafiltration, commercial exosome purification kit (NORGEN BIOTEK CORP) and size exclusion chromatography techniques. Characterization of these EVs have been conducted using nanoparticle tracking analysis, transition electron microscopy and western blot analysis. The expression of 'tissue-specific homing receptors' such as integrins, on plasma/serum-derived EVs isolated from arthritic mice (CIA model) or RA patients, had been examined, using WB analysis. EVs were labelled using DiR fluorescent dye and their potential *in-vivo* migration towards inflamed synovia, had been explored in collagen antibody-induced arthritis (CAIA) model, using In Vivo Imaging System (IVIS). Cellular uptake of RA patients-derived labelled EVs have been conducted using SW982, a human synovial cells.

Results: We found that autologous labeled EVs, derived from blood of arthritic mice with CAIA, can migrate towards inflamed synovia. Moreover, we show that these EVs strongly expresses glucose transporter 1 (mGLUT1) which in turn, improve their therapeutic potential to be loaded with anti-inflammatory drugs using glucose-coated gold nanoparticles (GNPs). Finally, we show that EVs derived from plasma of RA patients expresses the joint/synovia-specific homing receptor αVβ3 integrin and can be taken up by LPS/TNFα-induced activated human synovial cell line *in vitro*.

Conclusion: Overall, we show the potential of autologous circulating EVs of RA patients to serves as natural nano-carrier for current FDA-approved drugs. We believe that this strategy will increase the specificity and efficiency of current treatment, possibly reducing side effects and will improve the quality of life of RA patients and potentially other autoimmune disease patients.

Abstract Number: 2169

Cost-utility of a Progressive Spacing of Tocilizumab or Abatacept in Patients with Rheumatoid Arthritis in Sustained Remission: A Medico-economic Analysis of the Towards the Lowest Efficacious Dose Trial

Joanna Kedra[1], Benjamin Granger[2], Lina El Houari[3], Florence Tubach[4] and **Bruno Fautrel**[5], [1]Sorbonne Université, IPLESP, and Pitié-Salpêtrière Hospital, Paris, France, [2]Sorbonne Université, INSERM, and Pitié Salpêtrière Hospital, Paris, France, [3]Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France, [4]Centre de pharmaco-épidémiologie de l'APHP, Paris, France, [5]Sorbonne Université APHP, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic Disease Modifying Anti-Rheumatic Drugs (bDMARDs) progressive tapering is a real opportunity in people living with rheumatoid arthritis (RA) having achieved remission both from the patient (reduction in the disease and drug-related burden) and the Society (cost alleviation) perspectives. The ToLEDo (Towards the Lowest Efficacious Dose) trial aimed to assess a disease activity-driven progressive tapering strategy of tocilizumab (TCZ) or abatacept (ABA) compared to their maintenance at full dose in RA patients in sustained remission. Non-inferiority (NI) was not demonstrated in terms of disease activity nor relapses, major relapses, radiographic progression. The aim of this secondary analysis was to assess the cost-utility of the spacing strategy (S-arm) in the ToLEDo trial compared to full dose maintenance (M-arm).

Methods: ToLEDo is a multicenter 2-year NI randomized open-label controlled trial, which enrolled 228 patients (113 in the S-arm and 115 in the M-arm). A cost-utility analysis was conducted on the per protocol population. In each arm, health benefits were estimated every 6 months by Short Form Health Survey (SF-6D) and EuroQoL (EQ-5D)-derived utility measurements. Cost elicitation integrated health resource use including bDMARD costs (direct cost) as well as productivity loss

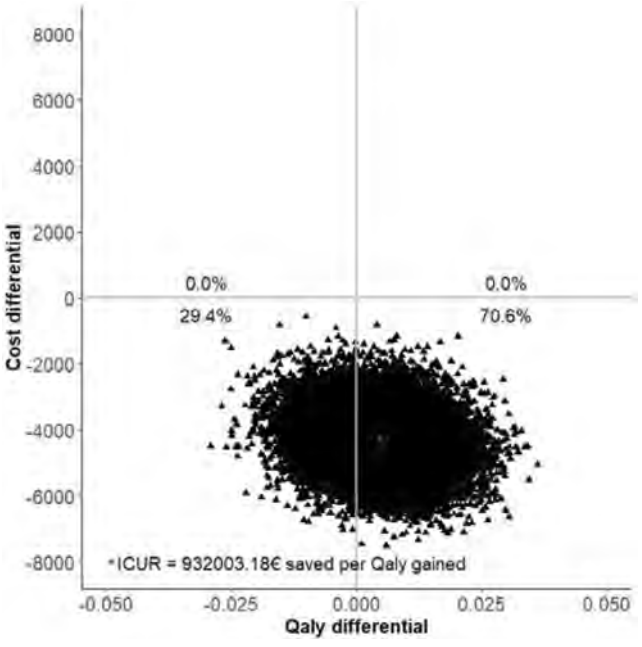

Figure 1: cost-utility plane (spacing versus maintenance), with utilities derived from PP SF-6D

Table 1: ICUR in ABA subgroup, TCZ subgroup, using EQ-5D-derived utilities, and stochastic sensitivity analysis

	ABA subgroup (PP SF-6D)	TCZ subgroup (PP SF-6D)	PP EQ-5D	Stochastic sensitivity analysis (PP SF-6D)
ICUR, €/QALY gained	-420,076.22 (95%CI -1,044,462 ; 1,461,037)	-1,008,225 (95%CI -2,436,237; 1,898,967)	-52,005 (95%CI -458,934; 369,967)	-481,029.28 (95%CI -1,300,747; 1,867,263)

(indirect cost).The incremental cost-utility ratios (ICUR) were calculated by dividing the difference of costs between S-arm and M-arm by the difference of utilities between the 2 arms. 95% confidence interval (95%CI) were calculated by bootstrap (20,000 iterations). The incremental net benefit (INB) was calculated for willingness to pay (WTP) values ranging from 0 to 150,000€. The analyses were replicated using SF-6D (primary analysis) or EQ-5D, and in ABA and TCZ subgroups. Acceptability analyses as well as stochastic sensitivity analyses (simulating costs and utilities using MCMC algorithms) were also performed.

Results: Overall, 178 patients were included (82 in S-arm, 96 in M-arm) in the per protocol analysis. At the end of the follow-up in the S-arm, 15.0% of patients discontinued their biologic, 48.7% spaced the injections, and 36.3% remained at the standard dose. The difference in terms of two-years utility gains between S-arm and M-arm was 0.004 (95%CI -0.012, 0.021) with SF-6D. The difference of total costs between S-arm and M-arm was -4,275 € (95%CI -5,955 to -2,542). The estimated ICUR of the spacing strategy over the maintenance at full dose was €932,003 saved per QALY (95% CI -7,534,788 to 6,720,372) with SF-6D. The INB was 4,734.6€ for a WTP of 100,000€. With a willingness to accept of 0 €/QALY lost, the probability to be cost-effective for the spacing strategy was 70.6% (***Figure 1***). The results were consistent when using EQ-5D-derived utilities, in ABA and TCZ subgroups, as well as in the stochastic sensitivity analyses (***Table 1***).

Conclusion: Although the ToLEDo trial did not demonstrate non-inferiority, the tested disease activity-driven tapering strategy was not associated with health loss in terms of utilities and incurred for substantial cost savings, making this strategy potentially dominant.

Systemic Glucocorticoids Are Associated with a Time and Dose-dependent Risk of Major Adverse Cardiovascular Event in Patients with Rheumatoid Arthritis: A Population-based Study

Ho SO[1], Tommy LAM[2], Huan MENG[3], Steven LAM[3] and Lai-Shan Tam[4], [1]The Chinese University of Hong Kong, Hong Kong, China, [2]Medicine and Therapeutics, Prince of Wales Hospital, Hong Kong, Hong Kong, [3]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [4]The Chinese University of Hong Kong, New Territories, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) and systemic glucocorticoid (GC) use are associated with increased risk of cardiovascular disease. The latest RA management recommendations from the American College of Rheumatology (ACR, updated in 2021) and European Alliance of Associations for Rheumatology (EULAR, updated in 2022) are divergent in terms of GC use. Whether there exists a CV-safe dose or duration of GC in the treatment of RA is still debatable and of great clinical interest.

Methods: This was a population-based retrospective cohort study. RA patients without major MACE at baseline were recruited from a Hong Kong citywide database from 2006 to 2015, and followed till the end of 2018. The primary outcome was the first occurrence of a major adverse cardiovascular events (MACE). Cox regression analysis with time-varying covariates was used to evaluate the association of GC and MACE, adjusting for demographics, traditional CV risk factors, inflammatory markers and the usage of anti-rheumatic drugs.

Results: Among 12,233 RA patients with 105,826 patient-years of follow-up with a mean follow-up duration of 8.7 years, 860 (7.0%) developed MACE. The crude incidence rate was 8.13 per 1,000 person-years. The baseline characteristics of the subjects are summarized in Table 1. In the time-varying analyses after controlling for confounding factors, a daily prednisolone dose of ≥ 5mg significantly increased the risk of MACE (erythrocyte sedimentation rate [ESR] model: HR 2.02, 95%CI 1.72-2.37; C-reactive protein [CRP] model: HR 1.87, 95%CI 1.60-2.18), while a daily dose below 5mg was not associated with MACE risk, compared to no GC use. The adjusted hazard ratios (HRs) of all candidate covariates are summarized in the forest plots (Figure 1). The MACE-free Kaplan-Meier survival curves of the groups receiving different GC doses are shown in Figure 2. In patients receiving daily prednisolone ≥5mg, both intermediate- (up to 180 days) and long-term (longer than 180 days) use of prednisolone ≥5mg daily were significantly associated with increased risk of MACE, with an adjusted HR of 1.07 (p-value < 0.001) per month of GC use.

Conclusion: In this population-based real-world database, after controlling for multiple confounding factors, the use of GC was associated with up to two-fold increased risk of incident MACE on long term follow-up. No safe duration of use was found in patients receiving daily prednisolone ≥5mg.Very low dose prednisolone (< 5mg daily) did not appear to increase CV risk.

Common IL-6 Signaling Is Inhibited by IL-6 Inhibitors and JAK Inhibitors, but Which Is Better at Preventing Bone Destruction in RA?

Yoshinobu Koyama[1], Yoshiharu Sato[2], Moe Tokunaga(Sakamoto)[3] and Yu Nakai[3], [1]Japanese Red Cross Okayama Hospital, Okayama, Japan, [2]DNA Chip Research Inc, Tokyo, Japan, [3]Rheumatology, Center for Autoimmune diseases, Japanese Red Cross Okayama Hospital, Okayama, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To date, there are no head-to-head clinical trials directly comparing the effects between IL-6i and JAKi on bone destruction in RA. In recent years, a series of JAK inhibitors (JAKi) have been introduced, all of which have JAK1 inhibitory activity, and inhibition of IL-6 signaling plays an important role in their pharmacological actions. IL-6 inhibitors

(IL-6i)have also been commonly used for rheumatoid arthritis (RA), and several anti-receptor antibodies are in clinical application. Recent studies have revealed the molecular basis of the immune cell-fibroblast-bone triad interactions in RA bone destruction. Therefore, to examine changes in peripheral blood gene expression after IL-6i or JAKi treatment, which inhibit a common pathway, and to estimate their respective effects on the bone immune system.

Methods: Peripheral blood gene expression changes in 38 RA patients (Tocilizumab(TCZ)=13, Tofacitinib(TOF)=15, Baricitinib (BAR)=10) were analyzed before and 3 months after the initiation of treatment using next generation sequencing. Changes in gene expression of molecules involved in bone immunity were analyzed before and after each treatment.

Results: Comparison of L-6i and JAKi showed that JAKi treatment significantly suppressed RANKL expression in peripheral blood. At the same time, significant suppression of RANK, ETS1, and IL-34 gene expression was also observed with JAKi treatment. Comparison of TOF and BAR treatment showed significant suppression of IL-4 expression in TOF and significant suppression of MMP-2 and IL-12 expression in BAR.

Conclusion: JAKi suppressed RANKL expression significantly compared to IL-6i, suggesting that JAKi is more potent than IL-6i in suppressing bone destruction. Furthermore, assuming that the promoter regions of RANK in synovial osteoclasts and ETS1 in fibroblasts are similar to those in peripheral blood, the following prediction emerges. JAKi suppresses RANK and ETS1 expression more than IL-6i, suggesting that JAKi may be favorable for preventing bone destruction in terms of (1) suppressing osteoclast differentiation and (2) suppressing tissue-destructive fibroblasts. The effect on gene expression of molecules involved in bone immunity was found to vary among each JAK inhibitor.

Session Date: Tuesday, November 14, 2023

Session Title: RA – Treatments Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept (ABA) has demonstrated efficacy in RA-ILD**.** Clinical trials have shown equivalence in subcutaneous (SC) and intravenous (IV) administration of ABA for articular manifestations**.** However, it has not been studied in RA-ILD. Our objective was tocompare the effectiveness of ABA in RA-ILD patients according to the route of administration (IV-ABA vs SC-ABA).

Methods: National multicenter study of RA-ILD patients on treatment with ABA. They were divided into 2 groups according to the route of administration: a) IV, and b) SC. We analyzed from baseline the following outcomes in both groups: **a)** forced vital capacity (FVC), **b)** diffusing capacity of the lungs for carbon monoxide (DLCO), **c)** chest high resolution computed tomography (HRCT), **d)** dyspnea (assessed with the modified Medical Research Council scale), **e)** arthritis activity (assessed with DAS28-ESR or described in clinical records), and **f)** sparing corticosteroids effect.

Table 1. Main general features at baseline of RA-ILD patients with subcutaneous vs intravenous ABA.

	All ABA (n=509)	ABA IV (n=100)	ABA SC (n=360)	p
Age, years mean±SD	66 ± 10	66 ± 10	66 ± 10	0.97
Women, n (%)	286 (56)	61 (61)	201 (56)	0.47
Smoker ever, n (%)	286 (56)	52 (52)	199 (55)	0.48
ILD duration up to ABA, months, median [IQR]	9 (11-45)	10 (3-48)	10 (2-36)	0.52
RF, n (%)	442 (87)	85 (85)	317 (88)	0.65
ACPA, n (%)	425 (85)	83 (83)	310 (87)	0.79
DAS28-ESR	4.37 ± 1.59	4.33±1.55	4.47±1.52	0.46
ILD pattern, n (%)				
NIU	233 (47)	51 (51)	165 (46)	
NINE	145 (29)	20 (22)	111 (31)	0.26
Other	98 (25)	29 (29)	83 (23)	
FVC (% of the predicted), mean±SD	87 ± 22	87 ± 23	87 ± 21	0.92
DLCO (% of the predicted), mean±SD	66 ± 20	67 ± 20	66 ± 20	0.66
Prednisone at baseline, mg/day, median [IQR]	5 (5-10)	7.5 (5-10)	5 (5-10)	0.37

ABA: Abatacept; ACPA, anti-citrullinated protein antibodies; DLCO, diffusing capacity of the lung for carbon monoxide; DMARD, disease-modifying antirheumatic drug; FVC, forced vital capacity; HRCT, high-resolution computed tomography; ILD, interstitial lung disease; JAKi, JAK inhibitor; RA, rheumatoid arthritis; RF, rheumatoid factor; UIP, usual interstitial pneumonia.

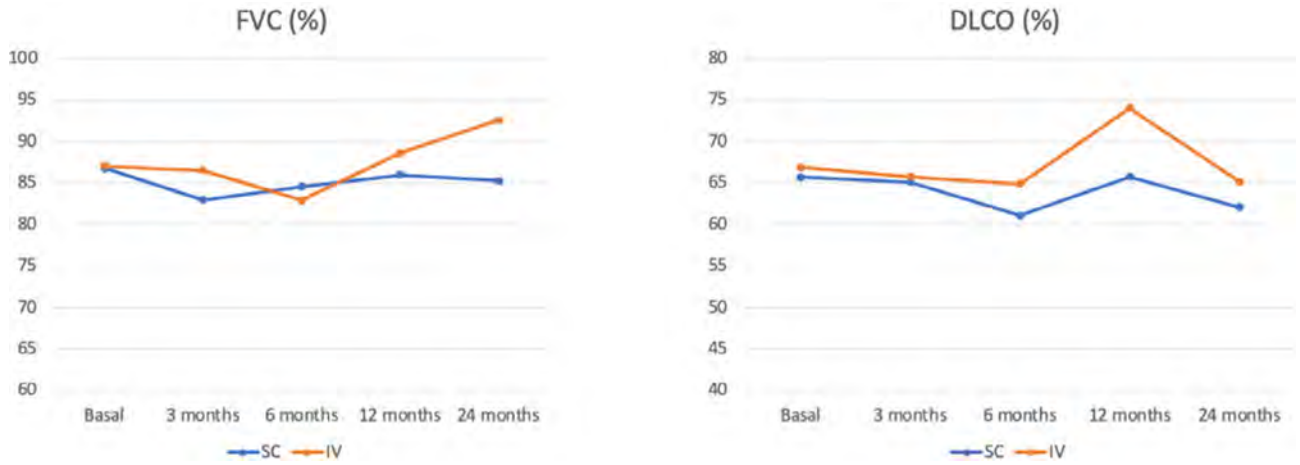

Figure 1. Evolution of pulmonary function tests (mean % of the predicted FVC and DLCO) in RA-ILD patients with SC-ABA vs IV-ABA therapy at baseline and 24 months.

Results: We studied a total of 509 [SC-ABA/IV-AB; 360/100 (available data)] patients. Baseline demographic and clinical characteristics are shown in **Table 1.**Patients were followed-up for a median [IQR] of 24 [7-48] months.FVC and DLCO remain stable during the first 24 months in both SC-ABA and IV-ABA **[Figure 1].** Dyspnea stabilized or improved in 84% of patients (89% of IV-ABA; 82% of SC-ABA). ABA was withdrawn in 106 patients: 81(34%) in SC-ABA group and 25 (40%) in IV-ABA group. ILD worsening and articular inefficacy were the most common reasons of ABA discontinuation.

Conclusion: In RA-ILD, ABA seems equally effective and safe regardless of the route of administration IV or SC.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a severe complication of rheumatoid arthritis (RA). Abatacept (ABA) has demonstrated efficacy in the treatment of RA-ILD, especially if it is initiated early during the ILD. Our objective was to compare the efficacy of ABA in RA-ILD patients according to ILD duration.

Methods: National multicenter study of 509RA-ILD patients treated with ABA. Patients with ABA initiation early in the disease (during the first 6 months since ILD diagnosis) were compared to those in whom ABA was started after 2 years of ILD diagnosis ("early" vs. "late" group, respectively). We analyzed in the 2 groups the following outcomes: **a)** forced vital capacity (FVC), **b)** diffusing capacity of the lungs for carbon monoxide (DLCO), **c)** chest high resolution computed tomography (HRCT), **d)**dyspnea (modified Medical Research Council scale), and **e)** arthritis activity (DAS28-ESR or clinical records).

Results: A total of 216 patients were included in the "early" group and 165 patients in the "late" group. Baseline demographic and clinical characteristics are shown in **Table 1**. Mean baseline values of FVC were significantly higher in the "early" group. The evolution of FVC and DLCO for 48 months is shown in **Figure 1.** Both parameters remained stable during 48 months of ABA therapy, with statistically significant differences found in case of FVC (although lower stable values of

Table 1. Main general features at baseline of RA-ILD patients with "early" vs. "late" initiation of ABA in ILD course.

	All RA-ILD patients (n=509)	"Early" RA-ILD (n=216)	"Late" RA-ILD (n=165)	"Early" vs "Late" p
Age years mean±SD	66 ± 10	66 ± 9	66 ± 10	0.79
Women n (%)	286 (56)	98 (45)	91 (55)	0.91
Smoker ever, n (%)	269 (52)	117 (54)	85 (52)	0.61
ILD duration up to ABA, months, median [IQR]	9 (11-45)	2 (1-4)	52 (36-90)	**<0.001**
RF n (%); ACPA n (%)	442 (87); 425 (85)	187 (87); 185 (86)	146 (88); 140 (86)	0.58; 0.96
DAS28-ESR	4.37 ± 1.59	4.14 ± 1.55	4.43 ± 1.64	0.13
ILD pattern n (%)				
NIU	233 (47)	100 (47)	71 (44)	0.73
NINE	145 (29)	63 (30)	49 (30)	
FVC (% of the predicted) mean±SD	87 ± 22	88 ± 23	81 ± 19	**0.003**
DLCO (% of the predicted) mean±SD	66 ± 20	65 ± 19	64 ± 21	0.66
ABA monotherapy n (%)	226 (45)	101 (47)	73 (45)	0.56
ABA combined n (%)	276 (55)	112 (53)	90 (55)	
Prednisone at baseline, mg/day, median [IQR]	5 (5-10)	7.5 (5-10)	5 (5-10)	0.32
Previous immunosuppressive therapy n (%)				
MTX	379 (75)	172 (80)	118 (72)	0.05
Leflunomide	233 (46)	93 (43)	77 (47)	0.48
Sulfasalazine	68 (13)	27 (13)	23 (14)	0.66
Hydroxychloroquine	161 (32)	70 (33)	52 (32)	0.83
Anti-TNF drugs (IFX; ADA; ETA)	42 (8); 69 (14); 73 (14)	14 (6); 37 (17); 31 (14)	13 (8); 18 (11); 25 (15)	0.59; 0.08; 0.83
Rituximab	61 (12)	21 (10)	23 (14)	0.20
Tocilizumab	56 (11)	26 (12)	18 (11)	0.73

*IFX: Infliximab; ADA: Adalimumab; ETA: Etanercept.

FVC in the "late" group). Available chest HRCT images improved/ stabilized in 76% and 54% of patients in the "early" and "late" group, respectively. Stabilization or improvement of dyspnea was found in most patients of both groups.

Conclusion: Our study suggests a window of opportunity for the treatment of RA-ILD patients with ABA. However, treatment with ABA at any time of the course in the ILD seems to prevent interstitial lung progression.

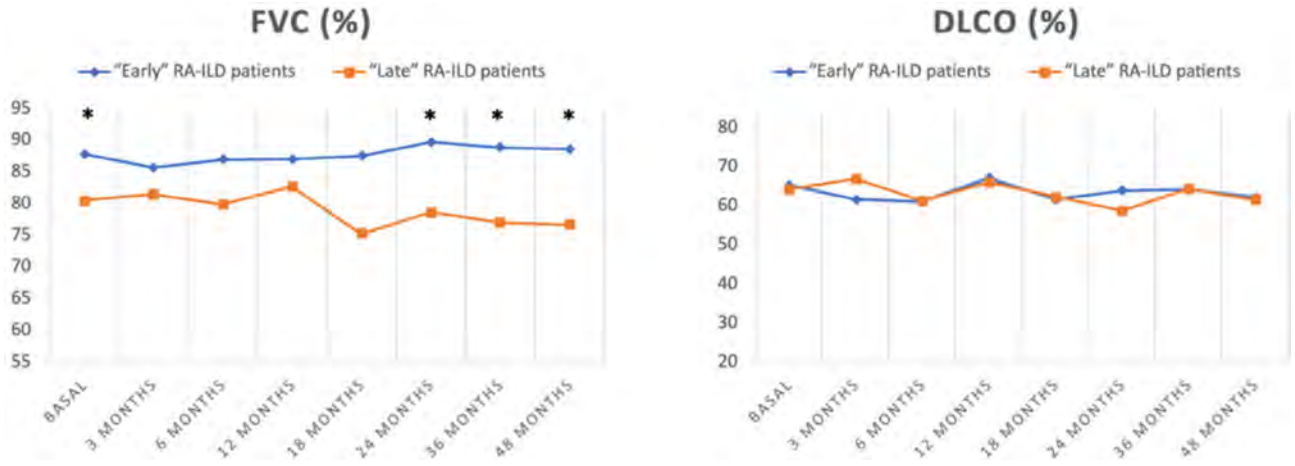

Figure 1. Evolution of pulmonary function tests in RA-ILD patients with "early" and "late" initiation of ABA in ILD course. FVC and DLCO are expressed as mean (95%CI) and compared between the 2 groups. (*) P value is statistically significant in FVC at baseline, 24, 36 and 48 months of follow up.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: RA – Treatments Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a severe extra-articular manifestation of rheumatoid arthritis (RA). Abatacept and Rituximab are the recommended drugs**.** JAK inhibitors (JAKi) have demonstrated efficacy in RA. However, in clinical trials patients with active ILD were usually excluded. Moreover, a warning on ILD toxicity is included in SmPC (Summary of Product Characteristics) with tofacitinib (TOFA). Nonetheless, evidence on efficacy of JAKi in RA-ILD is growing. The objective of the study was to assess **a)** the effectiveness and **b)** the safety of JAKi in AR-ILD patients.

Methods: National multicenter study of 73 RA-ILD patients on treatment with JAKi. We analyzed from baseline the following outcomes: **a)** forced vital capacity (FVC), **b)** diffusing capacity of the lungs for carbon monoxide (DLCO), **c)** chest high resolution computed tomography (HRCT), **d)**dyspnea (modified Medical Research Council scale), **e)** arthritis activity (DAS28-ESR or clinical records), and **f)** sparing corticosteroids effect.

Results: We studied 73 patients (50 women/ 23 men; mean age 66 ± 10 years) from clinical practice on treatment with JAKi [Baricitinib (BARI)= 55 (74%), TOFA= 8 (11%), Upadacitinib (UPA)= 8 (11%), Filgotinib (FILGO)= 2 (3%)]. Baseline demographic and clinical characteristics are shown in **Table 1**. All patients had received disease-modifying antirheumatic drugs (DMARDs) before JAKi [Methotrexate (63; 86%), Leflunomide (46; 63%), Sulfasalazine (19; 26%), Hydroxychloroquine (16; 22%), Abatacept (47; 64%), Tocilizumab (26; 36%) and Rituximab (16; 22%)]. Since most patients were on BARI we focused on this group (n=55). Median [IQR] ILD duration up to BARI initiation was of 29 [15-64] months. Mean baseline values of FVC and DLCO (% predicted) were 88±27 and 69±20, respectively. Patients were followed-up for a mean of 36 ± 23 months. The evolution of FVC and DLCO remained stable during the first 12 months **(Figure 1).** At the end of the follow-up, available chest HRCT images improved/ stabilized in 76% of patients. Stabilization or improvement of dyspnea was found in 95% of patients. Most patients showed articular remission or low activity. BARI was withdrawn in 22 (42%) patients due to articular inefficacy (n=15), lung inefficacy (n=4), development of hypersensitivity pneumonitis (n=1), and appearance of brain cancer (n=1).

Table 1. Baseline characteristics of RA-ILD patients treated with JAKi.

	RA-ILD with JAKi (n=73)
Age, years mean±SD	66 ± 10
Women, n (%)	50 (69)
Smoker ever, n (%)	47 (64)
Time since ILD diagnosis, months, median [IQR]	35 [16-64]
RF // ACPA, n (%)	69 (95) // 69 (95)
FVC (% of the predicted), mean±SD	90 ±26
DLCO (% of the predicted), mean±SD	81 ± 16
UIP-like fibrotic pattern on HRCT, n (%)	36 (51)
Joint activity n (%)	40 (56)
Type of JAKi, n (%)	
Baricitinib (BARI)	55 (74)
Tofacitinib (TOFA)	8 (11)
Upadacitinib (UPA)	8 (11)
Filgotinib (FILGO)	2 (3)
Previous immunosuppressive therapy, n (%)	
Conventional / biologic DMARD	73 (100) / 62 (85)
Concomitant immunosuppresive therapy, n (%)	32 (44)
Concomitant antifibrotic therapy, n (%)	6 (8)

ACPA, anti-citrullinated protein antibodies; DLCO, diffusing capacity of the lung for carbon monoxide; DMARD, disease-modifying antirheumatic drug; FVC, forced vital capacity; HRCT, high-resolution computed tomography; ILD, interstitial lung disease; JAKi, JAK inhibitor; RA, rheumatoid arthritis; RF, rheumatoid factor; UIP, usual interstitial pneumonia.

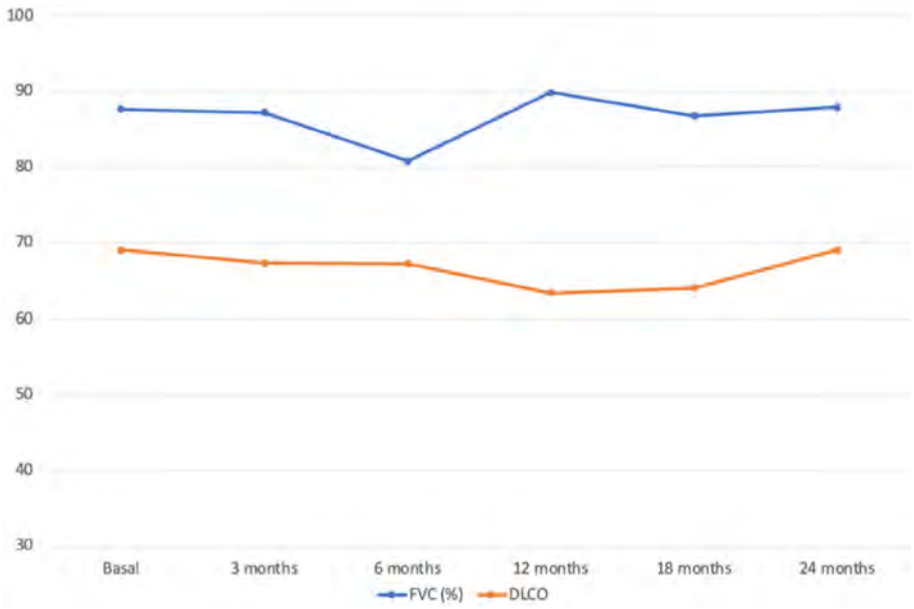

Figure 1. Evolution of pulmonary function tests (mean % of the predicted FVC and DLCO) in RA-ILD patients with BARI therapy at baseline and 24 months.

Conclusion: JAKi, especially BARI, may be useful and safe in controlling the course of both pulmonary and joint disease in RA-ILD patients, even in refractory cases.

Abstract Number: 2175

Real-World Drug Persistence of GP2015, an Etanercept Biosimilar, in Patients with Rheumatoid Arthritis: Results from the Multi-Country COMPACT Study

Marc Schmalzing[1], Charlotte Both[2], Ines Brueckmann[2], Javier de Toro Santos[3], Tom Sheeran[4], Herbert Kellner[5] and Ayman Askari[6], [1]University Hospital, Rheumatology/Clinical Immunology, Department of Internal Medicine II, Würzburg, Germany, [2]Sandoz Hexal AG, Rheumatology, Holzkirchen, Germany, [3]University Hospital Coruña, Rheumatology, A Coruña, Spain, [4]University of Wolverhampton, New Cross Hospital, Wolverhampton, United Kingdom, [5]Hospital Neuwittelsbach, Center for Rheumatology and Gastroenterology, Munich, Germany, [6]Robert Jones and Agnes Hunt Orthopaedic Hospital NHS Foundation Trust, Rheumatology, Shropshire, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: COMPACT is a multi-country, non-interventional study that evaluated the drug persistence, effectiveness, safety and patient-reported outcomes in patients with rheumatoid arthritis (RA), axial spondyloarthritis and psoriatic arthritis treated with GP2015 (an etanercept biosimilar) in real-world conditions. Here, we report the drug persistence of GP2015 in patients with RA after 12 months.

Methods: RA patients aged ≥18 years on GP2015 treatment prior to study were enrolled. Patients were categorized based on prior treatment status: patients in clinical remission or low disease activity under treatment with reference etanercept (ETN) or other biosimilar ETN (initial ETN: [iETN]) and switched to GP2015 (Group A) or patients who received non-ETN targeted therapies and switched to GP2015 (Group B) or biologic-naïve patients who started GP2015 as the first biologic treatment after conventional therapy failure (Group C) or DMARD-naïve patients with recent diagnosis of RA considered suitable for treatment initiation with a biologic and started on treatment with GP2015 (Group D). Patients' drug persistence from GP2015 treatment start was assessed and is presented here. Median drug persistence was calculated using the median time estimate from Kaplan-Meier curve.

Results: Of 1466 patients enrolled, 844 (57.6%) patients had RA reported as the primary indication. Of the 844 patients with RA, 295 patients were switched from iETN (Group A), 88 were switched from other targeted therapies (Group B), 451 were biologic-naïve (Group C), and 10 were DMARD-naïve (Group D).[1] Drug persistence from start of GP2015 treatment in RA patients is presented in **Figure 1**. In the overall RA population, the discontinuation rate was 18.0% at Month 12 after initiation of GP2015 treatment. At Month 12, patients in Group A reported the lowest rate of discontinuation of 10.2%, while patients in Group B and C reported discontinuation rates of 23.9%, and 21.8%, respectively. Due to limited patient numbers in Group D (n=10) the drug persistence rate was difficult to interpret.

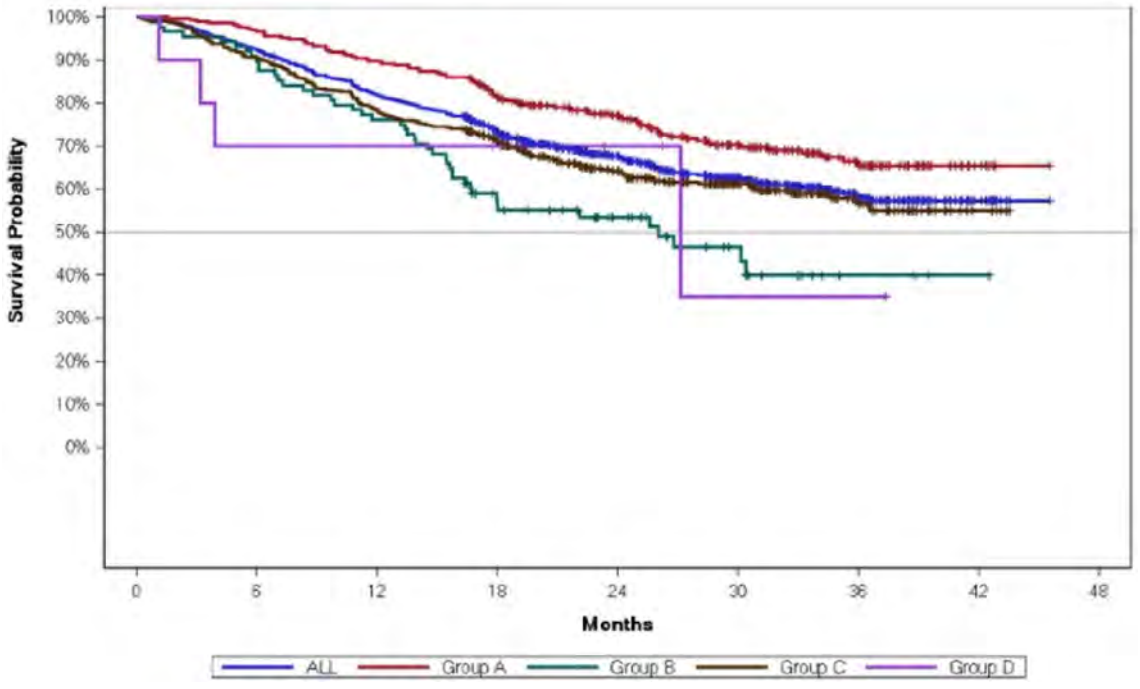

Figure 1. Drug persistence from GP2015 treatment start in patients with rheumatoid arthritis

Conclusion: The results of the study show high treatment persistence under GP2015 treatment in RA patients under real-world conditions. The results are in line with the reported persistence rates in the overall study population. Patients who were on previous iETN treatment and who had stable disease presented the highest drug survival rates after switch to GP2015.

Cellular and Proteomic Changes Following Administration of Peresolimab, in a Phase 2a Trial in Rheumatoid Arthritis

Robert J. Benschop[1], Jay Tuttle[1], Paul Emery[2], Christoph Preuss[1], Mark Daniels[1], Veavi Ching-Yun Chan[1], Pia Yachi[1] and Ajay Nirula[1], [1]Eli Lilly and Company, Indianapolis, IN, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, and NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: RA – Treatments Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Peresolimab is a humanized immunoglobulin G1 monoclonal antibody that stimulates human programmed cell death protein 1 (PD-1). Peresolimab demonstrated superiority to placebo in Disease Activity Score-28 with CRP (DAS28-CRP) improvements from baseline at Week 12 in a Phase 2a placebo-controlled, double-blind, randomized clinical trial (NCT04634253) in adult patients with moderate to severe Rheumatoid Arthritis (RA).[1] We report here, changes in exploratory biomarkers from this study.

Methods: Ninety-eight adult patients with moderate-to-severe RA (defined per American College of Rheumatology [ACR] criteria) were randomized 2:1:1 to peresolimab 700mg, 300mg, or placebo for 12 weeks. Whole blood, serum, and plasma were collected at baseline through Week 14 (end of the placebo control period). Cells were stained for CD3, CD4, CD8, CD19, CD16/56, and PD-1, processed and analyzed using standard flow cytometry methods. Serum samples were analyzed using the Olink Explore3072 panel which includes proteins that were detected in at least 25% of patients. Thirty age- and sex-matched healthy control samples were included for comparison. A gene set enrichment analysis approach was used to analyze proteomic results, and analyses were performed on comparing the combined peresolimab dose groups versus placebo.

Results: Peresolimab treatment reduced the number of peripheral CD4+ PD-1 high and PD-1 intermediate T cells by 53.6-57.7% and 33.8-38.5%, respectively, relative to baseline from weeks 2 through 12. No meaningful differences were observed for PD-1 low cells; Figure 1. There were no meaningful changes with major circulating cell types (ie, CD3+, CD4+, CD8+ T cells, B or NK cells) following treatment with peresolimab. Analysis of the proteomic data identified multiple pathways that showed differences between peresolimab-treated patients and placebo controls starting at week 8. This included treatment-induced down-modulation of cytokines and chemokines in interleukin signaling pathways, including

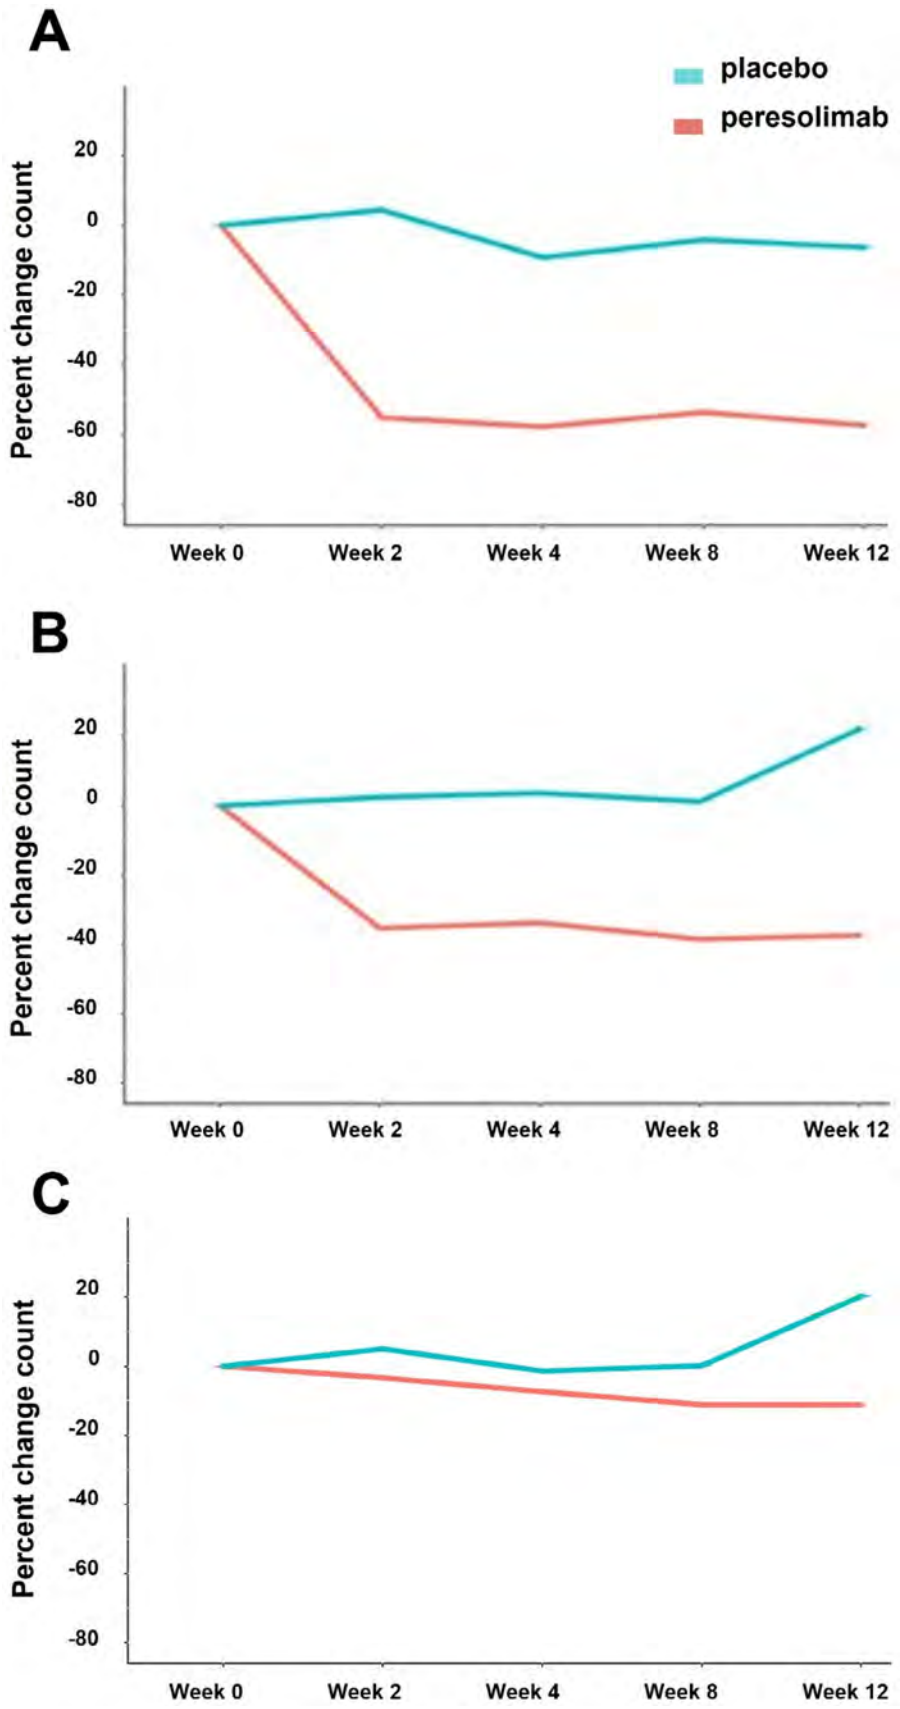

Figure 1. Peresolimab reduced peripheral CD4+ A) PD-1 high, B) PD-1 intermediate, and C) PD-1 low CD4+ T cells through 12 weeks of treatment in samples from patients with RA.

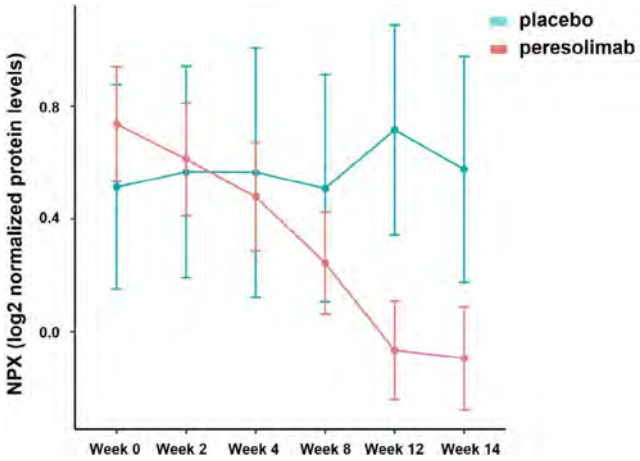

Figure 2. Peresolimab treatment decreases IL-6 protein levels (mean ± SEM) in serum samples from patients with moderate to severe RA through 14 weeks of treatment.

IL-6, Figure 2. Similar patterns of change were observed for several other immune-related pathways. Overall, pathway analysis suggests that protein levels of peresolimab-treated patients trend toward what was observed in age- and sex-matched healthy controls.

Conclusion: We report here changes in several exploratory biomarkers from patients enrolled in the Phase 2a study of peresolimab in RA patients. A rapid reduction was observed in circulating PD-1 high CD4+ T cells lasting through week 12, but no changes in any of the major lymphocyte subsets were detected with peresolimab treatment. Several molecular pathways that are altered in RA patients, trended towards patterns in healthy subjects with peresolimab treatment as early as week 8, which corresponds to the timing of DAS28-CRP improvements. These results provide insights into the timing and impact of PD-1 inhibition with peresolimab in the treatment of patients with moderate to severe RA.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To describe the taxonomic composition of the microbiota in the crevicular fluid of patients with primary Sjögren's syndrome (PSS), and to assess their association with parotid gland enlargement, periodontal disease, oral quality of life, and anti-Ro/SSA and anti-La/SSB antibodies.

Methods: We included 48 PSS patients according to the ACR/EULAR criteria. We excluded patients with concomitant connective tissue disease, diabetes mellitus, active neoplasia, antibiotic use in the two weeks before the study, or with current active infection. A single rheumatologist registered the following variables: demographics, disease duration, oral/ocular sicca symptoms, parotid enlargement and serology. We evaluated the non-stimulated whole salivary flow (NSWSF). Patients rated the ESSPRI and the Xerostomia-related Quality of Life Scale (XeQoLS). Two experienced periodontists systematically examined six sites per tooth of each patient, to determine the presence of periodontal disease. Crevicular fluid was collected from 6 teeth with the greatest periodontal pocket depth using filter paper (sterile paper points). Samples were immediately frozen at -86 °C until processing. We also included 17 control subjects from the same hospital's Dentistry department matched by

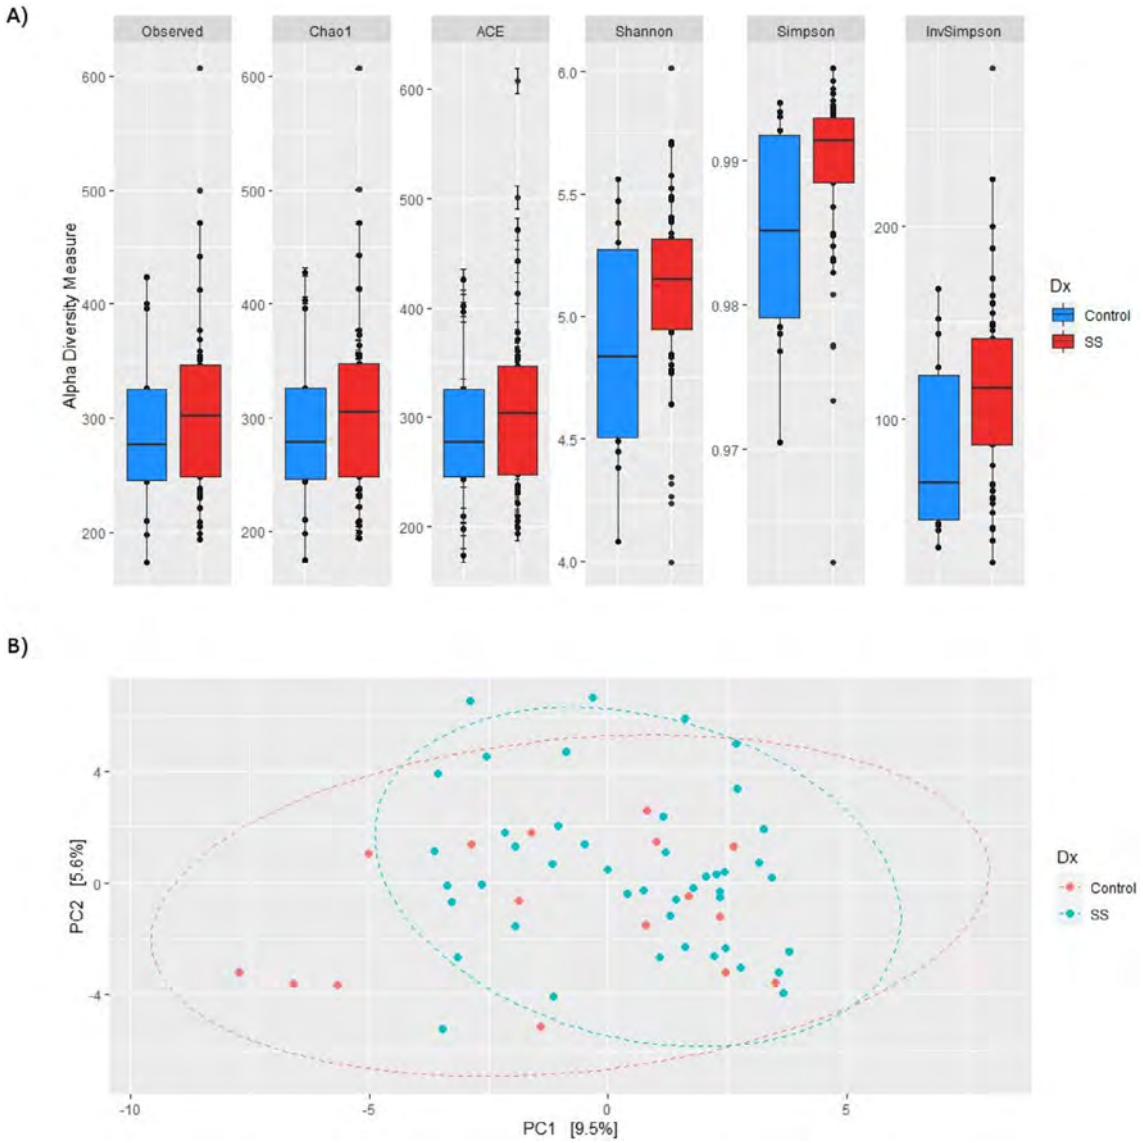

Figure 1 . Alfa diversity indexes stratified by the presence of (A) anti-Ro/SSA, (B) anti-La/SSB, and (C) parotid enlargement; and beta diversity compared between the presence of (D) anti-Ro/SSA , (E) anti-La/SSB, and (F) parotid enlargement.

gender and age (±5 years). Bacterial DNA was extracted from the crevicular fluid sample using a commercial kit. 16SrRNA V3-V4 region was sequenced using reversible adaptor technology. Sequences were pre-processed and analyzed with QIIME2 and phyloseq software programs. Functionality profiles were predicted using the Tax4Fun2 package.

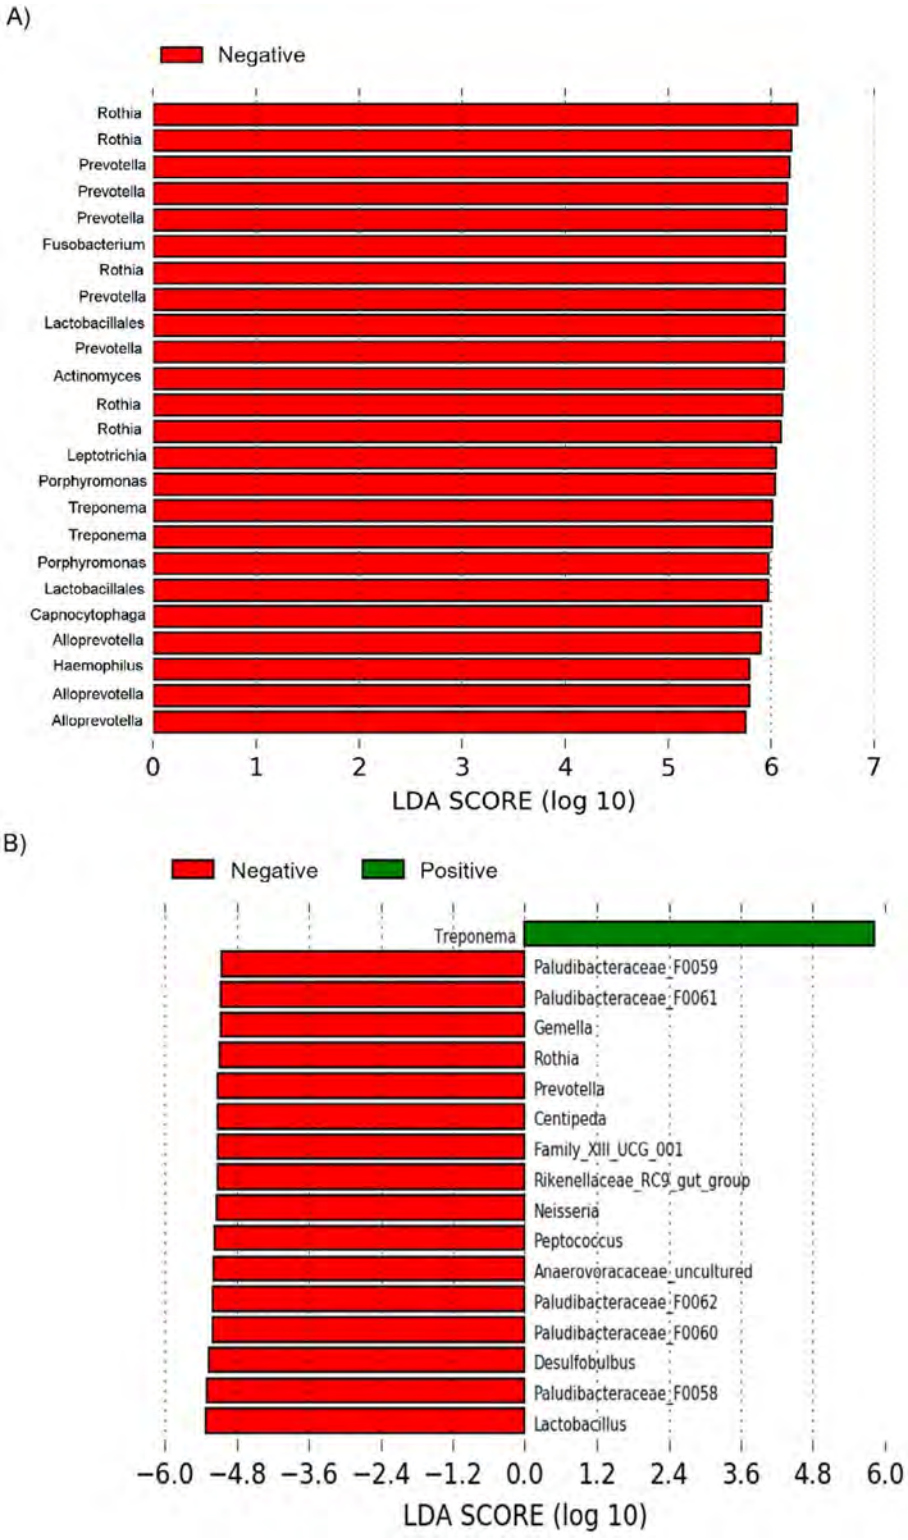

Figure 2 ASVs that best describe the crevicular fluid microbiota of SS patients and healthy controls (A) SS patients negative to anti-Ro/SSA or anti-La/SSB and (B) SS patients with and without parotid enlargement

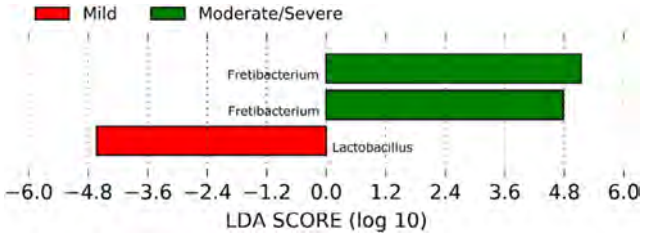

Figure 3 Bacteria genus ASVs whose relative abundance best describe the crevicular fluid microbiota of SS patients with mild and moderate or severe periodontal disease.

Results: Most patients were women, the mean age was 52.4 years and the median disease duration was 9.3 years. We found that the microbiota of PSS patients contained more bacteria of the genera *Prevotella, Streptococcus, Veillonella, Fusobacterium*, and *Leptotrichia* genera and fewer bacteria of the genus *Selenomonas* than that of healthy subjects. We also found significant differences in microbiota taxonomy between patients with anti-Ro or anti-La positive antibodies, parotid gland enlargement (Figure 1) , and periodontal disease severity (Figure 2) . We found no correlation between microbiota and NSWSF, and oral quality of life. The predicted functional profile showed that the microbiota of PSS patients contained more genes encoding for accessory secretory proteins than healthy controls.

Conclusion: The composition of the crevicular fluid microbiota of PSS patients and healthy subjects differed significantly. Differences were found among patients with parotid gland enlargement as well as anti-Ro and anti-La antibody positivity, suggesting that autoimmunity per se may play an important role in the composition of the oral microbiota in PSS.

Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmunity and systemic inflammation may play a role in early-stage dementia. Few studies have investigated whether primary Sjogren's syndrome (pSS) increases the risk of dementia. As hydroxychloroquine (HCQ) has recently been shown to inactivate STAT3 in microglia, neurons, and astrocytes, we also evaluated the association of HCQ use with the development of dementia in patients with pSS.

Methods: This cohort study used data from the Health Insurance Review and Assessment Service, a representative national healthcare database in Korea. From the database, we established a cohort of patients with pSS without a history of dementia between January 2008 and December 2020. The control group consisted of sex- and age-matched individuals with neither a history of autoimmune disease nor dementia. We assessed the incidence of newly diagnosed dementia in patients

Table 2. Risk of Newly Diagnosed dementia in the pSS Group Compared with the Control Group

Variable	pSS	Control	P-value
Total no. of subjects	20,160	100,800	
Newly diagnosed dementia	980 (4.9%)	4243 (4.2%)	<0.001
Incidence rate, /100 person-yr	0.68 (0.64-0.72)	0.58(0.56-0.60)	
Crude HR	1.17 (1.09-1.25)	reference	<0.001
adjust HR(age group, sex, comorbidity)	1.20 (1.10-1.31)	reference	<0.001
adjust HR(age group, sex, comorbidity)		reference	
Use of HCQ	1.12 (1.00-1.24)		0.043
Non-use of HCQ	1.24 (1.13-1.36)		<0.001
adjust HR(age group, sex, comorbidity)			
Use of HCQ	0.38 (0.73-0.95)		
Non-use of HCQ	Reference		

pSS: primary Sjogren's syndrome, HR, hazard ratio, HCQ: hydroxychloroquine

with pSS and the matched cohort. A Cox proportional hazard analysis was performed to identify the association of pSS with the development of dementia.

Results: We identified 20,160 patients with pSS and 10,800 matched controls. The incidence of dementia was 0.68 (95% confidence interval [CI], 0.64-0.72) cases per 100 person-years in pSS, and it was 0.58 (95% CI: 0.56-0.60) in matched controls. In multivariate analysis adjusted for age, sex, and comorbidities, the adjusted hazard ratio (aHR) of developing dementia was 1.20 (95% CI 1.10–1.31) times greater in the pSS group than in the matched controls. When stratified by the use of HCQ, HCQ users had 1.12 (95% CI 1.00-1.24) times the risk, and HCQ non-users had 1.24 (1.13-1.36) times the risk of developing dementia compared to the matched controls. Indeed, multivariate analysis showed that the use of HCQ lowered the development of dementia in patients with pSS (aHR 0.83, 95% CI 0.73-0.95).

Conclusion: pSS is independently associated with the development of dementia. HCQ may have a preventive role in dementia for patients with pSS.

Disease Burden of Patients with Primary Sjögren's Disease: Results from a Multinational Real-World Survey

Sara McCoy[1], Alan Baer[2], **Ann Xi**[3], Corey Moorhead[4], Giorgio Castellano[4], Anthony Amatucci[5], Ilias Alevizos[6] and Haridarshan Patel[7], [1]University of Wisconsin School of Medicine and Public Health, Middleton, WI, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Horizon Therapeutics, Indianapolis, IN, [4]Adelphi Real World, Bollington, United Kingdom, [5]Horizon Therapeutics, Cambridge, MA, [6]Horizon Therapeutics, Rockville, MD, [7]Horizon Therapeutics, Deerfield, IL

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's disease (SjD) is a debilitating disease that has been shown to impact patients' quality of life (QoL). Though oral and ocular dryness are well-recognized causes of reduced QoL, there is limited evidence on impact of dental decay and vaginal dryness on QoL. Our study aims to describe the disease burden of patients with SjD, as measured by clinical testing and patient-reported outcome (PRO) measures in real-world clinical settings.

Table 1. Physician-reported symptoms in patients with Sjögren's disease at the time of data collection.

	Patients with Sjögren's disease and completed patient record forms from rheumatologists N=1879
Symptoms reported in >20% patients, n (%)	
Dry eyes	1711 (91.1)
Physical fatigue	1452 (77.3)
Xerostomia	1326 (70.6)
Diffuse pain	716 (38.1)
Mental fatigue	667 (35.5)
Muscle pain	662 (35.2)
Limb pain	621 (33.0)
Disturbed sleep	592 (31.5)
Vaginal dryness	503 (30.0) [N=1677 female patients]
Blurred vision or light sensitivity	558 (29.7)
Xeroderma	533 (28.4)
Glandular swelling	497 (26.5)
Anxiety	435 (23.2)
Dental decay	405 (21.6)

Table 2. Patient reported outcome (PRO) scores for all patients with Sjögren's disease (SjD), SjD patients with dental decay and SjD patients with vaginal dryness. Note that base size fluctuates due to data completeness for all variables. The EQ-5D-3L Utility score is measured on a scale of 0-1 where 1 indicates full health and 0 death. The EQ-VAS is measured on a 0-100 scale with 100 indicating full health. The FACIT-Fatigue is measured on a scale of 0-52 where lower scores indicate more severe fatigue. EQ-5D-3L Utility and EQ-VAS population norms are taken from Janssen, MF et al., 2019 (https://doi.org/10.1007/s10198-018-0955-5), and the FACIT-Fatigue population norm from Montan et al., 2018 (https://doi.org/10.1016/j.jval.2018.03.013). WPAI is measured using a series of questions asked to patients about how their disease affects their work and normal activities. Absenteeism refers to work time missed due to disease. Presenteeism refers to impairment whilst working due to disease. FACIT: Functional assessment of chronic illness therapy; SD: standard deviation; US: United States; VAS: visual analogue scale

	All patients with Sjögren's disease and complete form	Patients with dental decay	Patients with vaginal dryness	Patients with vaginal dryness			Population normative values
				Mild	Moderate	Severe

% Activity impairment due to Sjögren's disease, Mean [SD]	**(N=841)** 37.8 [21.65]	**(N=170)** 44.9 [21.24]	**(N=209)** 42.7 [19.25]	**(N=101)** 40.2 [18.92]	**(N=101)** 44.3 [19.56]	**(N=7)** 55.7 [12.72]	-

Methods: Data were drawn from the 2018 Adelphi Primary Sjögren's Disease Specific Programme™, a cross-sectional survey with retrospective data collection of rheumatologists and their consulting patients with SjD in France, Germany, Italy, Spain and the United States. Rheumatologists completed patient record forms for their next 6 primary SjD patients with systemic disease activity and reported on patient demographics, clinical characteristics, and patient assessments. Patients were invited to complete a form capturing PROs, including EQ-5D-3L, the Work Productivity and Activity Impairment Questionnaire (WPAI), and Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F). QoL, work productivity, and fatigue were evaluated and all data were analyzed descriptively.

Results: 316 rheumatologists provided data for 1,879 patients: mean [SD] age 53 [12] years, 89% female, 89% White. Patients had a mean [SD] of 13 [7] tests leading up to diagnosis and 7 [12] consultations in the past 12 months. Patients are most commonly co-managed by PCP/GPs (48%) and ophthalmologists (47%), with other health care professional types co-managing < 20% of patients. Rheumatologists recorded dry eyes, physical fatigue, and dry mouth as the most common symptoms in 91%, 77%, and 71% of patients respectively. Of note, 22% of patients reported dental decay and nearly 1 in 3 female patients experienced vaginal dryness (**Table 1**). EQ-5D-3L utility, EQ-5D-3L VAS, and FACIT-F scores were 0.741, 63.5 and 31.3 across all SjD patients respectively, compared to the population norms of 0.867, 79.3 and 43.5. Patients with SjD experiencing dental decay or vaginal dryness reported lower PRO scores than the overall SjD population (**Table 2**).

Conclusion: Analyses from this multinational survey revealed that patients with SjD are burdened with multiple diagnostic tests and physician consultations to manage their symptoms following diagnosis. There is a substantial impact of SjD on patients' general QoL, fatigue, and work productivity, which is worsened in patients with dental decay or vaginal dryness, which highlights the systemic nature of dryness and downstream consequences of oral dryness. These findings suggest an unmet need among patients with SjD, who may require additional management by dentists or sexual health professionals who currently have limited involvement in patient care.

Salivary and Plasma Mitochondrial Double-strand RNAs as a Diagnostic Biomarker for Sjögren Syndrome

SE RIM CHOI[1], Jee-in Lee[2], Yong Seok Choi[3], You-Jung Ha[3], Eun Ha Kang[3] and Yun Jong Lee[4], [1]Seoul National University Bundang Hospital, Seoul, South Korea, [2]Seoul National University of Bundang Hospital, Seongnam, South Korea, [3]Seoul National University Bundang Hospital, Seongnam, South Korea, [4]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam-si, South Korea

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Since mitochondrial double-stranded RNAs (mt-dsRNAs), an endogenous activator of interferon signaling, are elevated in primary Sjögren's syndrome (pSS), we evaluated their association with the expression levels of interferon-inducible genes (IFIGs) and their diagnostic performance.

Table 1. Results of multivariate logistic regressions. UWS = unstimulated whole saliva; OR = odds ratio; CI = confidence interval; PBMC = peripheral blood mononuclear cell

Samples	Transcripts	coefficient β	OR [95% CI]	*p* value
UWS	ND1	2.159	8.665 [3.639-20.633]	1.07×10^{-6}
	ND6	−1.867	0.155 [0.052-0.459]	0.001
Plasma	ND1	−1.090	0.336 [0.189-0.599]	2.19×10^{-4}
	ND4	0.714	2.093 [1.507-2.906]	1.05×10^{-5}
PBMC	IFIT1	0.796	2.216 [1.172-4.192]	0.014
	IFIT3	0.828	2.289 [1.156-4.534]	0.018
	IFT44L	0.755	2.128 [1.014-4.464]	0.046
	OAS1	−1.250	0.286 [0.132-0.623]	0.002

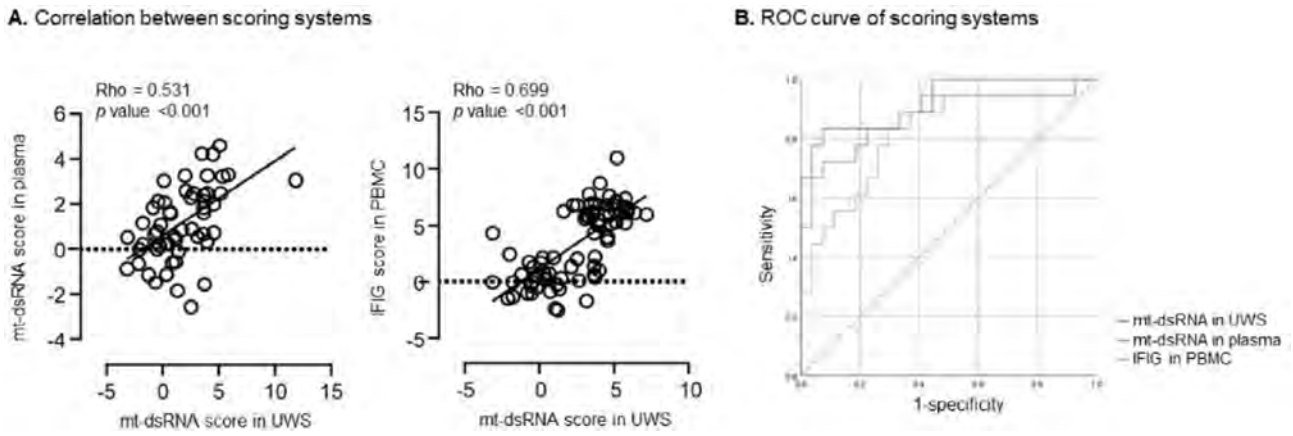

Figure 1. Correlation between mt-dsRNA scores and IFIG scores (A) and ROC curves of mt-dsRNA and IFIG scores for in primary Sjögren's syndrome. IFIG = interferon inducible genes; mt-dsRNA = mitochondrial double strand RNA; PBMC = peripheral blood mononuclear cell; SS = Sjögren's syndrome; UWS = unstimulated whole saliva

Methods: One hundred four pSS patients satisfying the 2016 ACR/EULAR criteria, 14 non-SS sicca patients, and 25 healthy controls were included. Seven mt-dsRNAs levels (CYTB, ND1, CO1, ND4, CO2, ND5, and ND6) in unstimulated whole saliva (UWS) and plasma samples and 8 IFIGs (IFIT1, IFIT3, IFI44, IFI44L, LY6E, OAS1, MX1, and ISG15) levels in peripheral blood mononuclear cells (PBMCs) were measured using RT-PCR. Z-score-based standardized mt-dsRNAs and IFIGs scoring systems were constructed using multivariate logistic regressions. The area under the ROC curve (AUC), sensitivity and specificity, andYouden's index were calculated.

Results: mt-dsRNAs ND1 and ND6 in UWS and ND1 and ND4 in plasma and IFIT1, IFIT3, IFI44L, and OAS1 in PMBCs remained to be significantly associated with pSS. The mt-dsRNA score was defined as (2.16′ND1)–(1.87′ND6) in UWS and (–1.09′ND1)+(0.74′ND6) in plasma. The IFIG score in PBMC was calculated using (0.80′IFIT1)+(0.83′IFIT3)+(0.76′IFI44L) –(1.25′OAS1). Despite that they were derived from different samples, all three scores were significantly correlated mutually. The AUC of UWS (0.924) and plasma (0.874) mt-dsRNA scores were larger than that of PMBC IFIG score (0.817). With the optimal cut-off of 1.71, the sensitivity and specificity of UWS mt-dsRNA score were 97.4% and 89.7%, respectively.

Table 2. Diagnostic performance of mt-dsRNA and IFIG scores in Sjögren's syndrome AUC = area under the curve; CI = confidence interval; IFIG = interferon inducible genes; mt-dsRNA = mitochondrial double strand RNA; PBMC = peripheral blood mononuclear cell; SS = Sjögren's syndrome; UWS = unstimulated whole saliva

	AUC [95% CI]	At the optimal cut-offs for each score		
		Sensitivity	Specificity	Youdens index
mt-dsRNA in UWS	0.924 [0.844-1.000]	97.4	89.7	0.810
mt-dsRNA in plasma	0.874 [0.758-0.991]	87.5	66.7	0.542
IFIG in PBMC	0.817 [0.686-0.948]	76.8	89.2	0.660

Conclusion: Increased transcript levels of some mt-dsRNA in UWS and plasma were significantly associated with pSS. A novel mt-dsRNA scoring system could be a potential diagnostic marker for pSS diagnosis.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In primary Sjögren's syndrome (pSS), salivary epithelial cells show an active role in the initiation and reiteration of the immunomediated damage. Epithelial saliva production is regulated by autonomic stimuli, intracellular calcium and cAMP concentration. The latter controls the action of cystic fibrosis transmembrane conductance regulator (CFTR), whose malfunction is postulated in sicca syndrome and pSS pathogenesis. (1) Forskolin is an activator of CFTR used in organoid swelling test in human salivary-gland derived organoid culture systems. Interestingly, also PDE4 is involved in intracellular cAMP deregulation: PDE4 inhibition might thus stimulate salivary function in pSS. (2-3) To the best of our knowledge, no data on the application of human salivary gland organoids specifically for testing drugs effective on xerostomia in pSS are found in literature. The objectives of this study are: to culture vital salivary gland organoids obtained through labial or parotid biopsy of pSS patients; to evaluate the morphological structure and functional capacity of organoids in basal condition and after stimulation with forskolin and PDE4 inhibitor apremilast.

Methods: Salivary gland tissues were harvested from 5 pSS patients through labial or parotid biopsy. After tissue processation and vital organoids obtainment, swelling essay and cell proliferation tests were performed after forskolin and apremilast application, compared to DMSO-treated controls. Immunohistochemistry evaluation on original salivary gland tissue and corresponding organoids was performed, by testing: alpha-amylase and AQP5 for acinar differentiation; EMA for ductal differentiation; calponin for myoepithelial differentiation and CK5 for basal differentiation; CK14, cKit and CD34 as markers of progenitor/stem cells.

Results: After application of forskolin or apremilast, we observed organoid swelling after 30 minutes, compatible with positive functional status and enhancement of saliva production. DMSO-treated controls were instead unaffected. In 3 cases apremilast induced proliferation of the organoids (Fig.1). All the cases were positive for CK14, most of the cases for CK5. All the cases were positive for amylase; its secretion, and thus functional status of organoids, was confirmed by its high concentration in the culture medium. A focal ductal differentiation was found in some cases, highlighted by EMA positivity. The more differentiated EMA positive areas were negative for the staminal marker CK14, showing a sort of "complementary staining" (Fig.2).

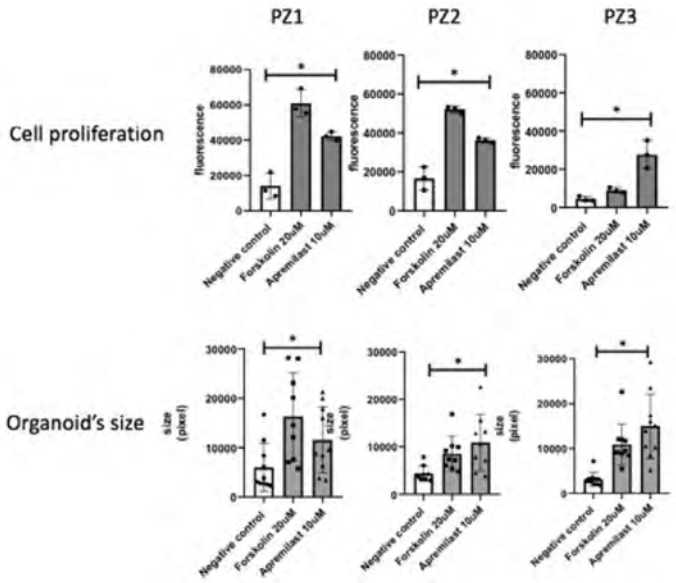

Figure 1. *The swelling of salivary organoids was induced by the activation of cystic fibrosis transmembrane conductance regulator (CFTR) using forskolin and Apremilast. It was observed organoid swelling after 30 minutes, whereas DMSO-treated control organoids were unaffected. Of note, Apremilast increased organoid growth rate compared to control group.*

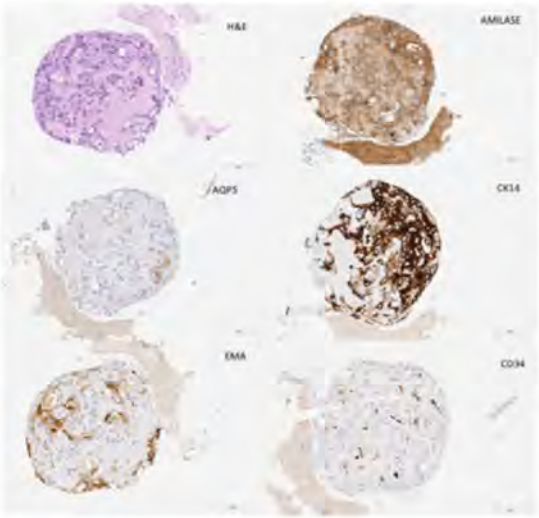

Figure 2. *Hematoxylin and eosin-stained section of a representative organoid (Hematoxylin and eosin stain, original magnification 20X) and pictures showing immunohistochemical expression of some markers on the same cells; in particular amylase, aquaporin5, CK14, EMA and CD34. Note that the EMA positive cells are negative for CK14 and vice versa, showing a sort of complementary positivity, related to a different level of differentiation.*

Conclusion: Our data confirm that, from pSS epithelium, differentiated cells that escape senescence and vital and functional organoids that recapitulate the development of original salivary glands can be obtained from different target tissues of pSS. The direct stimulating effect of PDE4 inhibitor apremilast on pSS human salivary gland organoids is reported, opening new perspectives on targeting oral dryness with drugs that combine secretagogue and immunomodulatory effects.

Mitochondrial Alterations in Primary Sjögren´s Syndrome

Pavlina Javorova[1], Johannes Fessler[1], Melanie Zeiler[1], Angelika Lackner[1], Josef Hermann[2], Sabine Zenz[3], Jens Thiel[4] and Martin Stradner[1], [1]Medical University of Graz, Graz, Austria, [2]Division of Rheumatology and Immunology, Department of Internal Medicine, Medical University Graz, Graz, Austria, [3]Medical University Graz, Graz, Austria, [4]University Hospital Freiburg, Freiburg, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's Syndrome (pSS) is a systemic autoimmune disorder characterized by lymphocytic infiltrations in exocrine glands. T-cells are considered major players in the pathogenesis of pSS. Previously, we reported naïve CD4+ T-cells exhibited signs of immune cell aging including shortened telomeres, increased senescence-associated -β-galactosidase activity, a reduction in IL-7R expression and reduced level of T-cell receptor excision circles. Homeostatic proliferation of naïve CD4+ T-cells was impared both ex vivo and after stimulation in vitro. Senescencence and impaired homeostasis of pSS naïve CD4+ T-cells lead to peripheral lymphopenia, a frequent finding in pSS patients. As mitochondrial fitness has been linked to cellular aging and AI conditions, we assessed mitochondrial parameters in T cells of pSS patients.

Methods: Peripheral blood mononuclear cells (PBMC) were isolated from venous blood of pSS patients fulfilling 2016 ACR/EULAR classification criteria and sex- and age-matched healthy control subjects (HC). Flow cytometric analysis was performed to identify and further characterise CD4+ T-cell subsets (Naïve, Central memory, Effector memory and Terminally differentiated effector memory) at single-cell level: staining with mitochondrion-selective fluorescent dyes MitoTracker® Green (MTG), MitoTracker® Deep Red (MTDR), MitoSox Red was performed to assess mitochondrial mass, membrane potential (MtMP) and superoxide production, respectively. Mitochondrial fitness was assessed by combined staining method with MTG and MTDR.Uptake of glucose analogue 2-NBDG was used to monitor glucose uptake ability of the CD4+ T-cell subsets.

Results: Staining with MTG and MTDR showed decreased mitochondrial mass and mitochondrial membrane potential in all CD4+ T-cell subsets of pSS patients. Despite having reduced mitochondrial mass and MtMP, we observed that pSS T-cells produced higher amount of mitochondrial superoxides compared to HC. Percentage of dysfunctional mitochondria (MTG

high, MTDR low) was significantly increased in pSS, probably due to accumulation of mitochondrial superoxides. On the other hand, glucose uptake was increased in all pSS CD4+ T-cells, which can indicate enhanced glycolysis.

Conclusion: We found that T-cells premature aging in pSS patients is linked with mitochondrial dysfunction associated with accumulation of mitochondrial superoxides and enhanced glucose uptake ex vivo. The underlying mechanisms of mitochondrial dysfunction of T-cells in primary Sjögren's Syndrome should be investigated in further studies.

Evolution of Lymphoma Predictors in Primary Sjogren's Syndrome by Data Driven Analysis in Harmonized Patients

Andreas Goules[1], Loukas Chatzis[2], Vasileios pezoulas[3], Francesco Ferro[4], Valeria Manfrè[5], Dimitrios Fotiadis[3], Luca Quartuccio Quartuccio[6], Chiara Baldini[7], Salvatore De Vita[5] and Athanasios Tzioufas[1], [1]Dept. of Pathophysiology, School of Medicine, University of Athens, Athens, Greece, [2]Dept. of Pathophysiology, School of Medicine, University of Athens, Cholargos Athens, Greece, [3]Unit of Medical Technology and Intelligent Information Systems, Dept. of Materials Science and Engineering, University of Ioannina, Ioannina, Greece, [4]Clinical and Experimental Medicine Department, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy, [5]Clinic of Rheumatology, Dept. of Medical and Biological Sciences, Udine University, Udine, Italy, [6]Rheumatology Division, Department of Medicine, University of Udine, Udine, Italy, [7]University of Pisa, Pisa, Italy

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lymphoma is the most serious complication of primary Sjogren's syndrome (pSS), occurring as a late sequel during disease course. So far, lymphoma predictors have been identified only at the time of pSS diagnosis in single center cohorts using classical logistic regression models. The current work aims to study the evolution of lymphoma predictors towards lymphoproliferation by employing data driven analysis on totally harmonized pSS patients.

Methods: Two curated and harmonized datasets with pSS patients from3 centers (Athens, Piza, Udine) were constructed to be analyzed for lymphoma predictors at two different time points before lymphoma diagnosis. Each dataset incorporated the same set of 30 clinically useful features covering the major aspects of the disease (Table 1, 2). The first dataset included 80 lymphoma patients and non-lymphoma controls (1:1 ratio), representing the time point of pSS diagnosis and the second dataset 68 lymphoma and non-lymphoma controls (1:1 ratio) representing the time point of 3-4 years before lymphoma diagnosis. All included patients fulfilled the 2016 ACR/EULAR criteria and non-lymphoma controls were matched according to age, gender, disease duration from pSS diagnosis to last follow up and treatment modalities. Systemic manifestations were defined as described in the ESSDAI domains and for those not included in the ESSDAI system, either by tissue biopsy or by applying international consensus criteria. A Fast-Correlation based feature selection (FCBF)/logistic regression (LR) model with lymphoma as an outcome, was applied on both datasets as described previously (1).

Results: Regarding the time point of pSS diagnosis, 5 prominent features in terms of magnitude of order were identified by the FCBF algorithm as potential predictors including rheumatoid Factor (RF), cryoglobulinemia, ACA pattern, ESSDAI≥5 and lacrimal gland enlargement of which only RF was finally proven an independent lymphoma predictor (Table 1). For the

Table 1. FCBF-based multivariable logistic regression analysis for lymphoma predictors at pSS diagnosis*

** < 0.05 (95% confidence interval)

FCBF-based multivariable logistic regression analysis for lymphoma predictors at 3-4 years before lymphoma diagnosis

second time point of 3-4 years before lymphoma diagnosis, a similar set of prominent features was found by the FCBF algorithm with the exception of lacrimal gland enlargement and cryoglobulinemia while RF and ESSDAI≥5 were identified as independent lymphoma risk factors (Table 2). Both FCBF/LR models had good overall performance after 10-fold cross validation strategy (pSS diagnosis: accuracy=63%, sensitivity=63%, specificity=63%, AUC=76% and for the second time point of 3-4 years before lymphoma diagnosis: accuracy=65%, sensitivity=65%, specificity=71%, AUC=75%).

Conclusion: Rheumatoid factor is the earliest and more persistent pSS associated lymphoma predictor while high ESSDAI≥5 in combination with RF connote an advanced stage across the lymphomagenesis process, predicting the occurrence of lymphoma in approximately 4 years before.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren disease (Sjo) is an autoimmune disease characterized by the infiltration of exocrine glands by immune cells, especially salivary glands (SG). SG epithelial cells (SGEC) are involved in Sjo pathogenesis, mostly through their crosstalk with immune cells. The primary 2D culture of SGEC derived from Sjo patients has been very useful to better understand Sjo pathogenesis but does not recapitulate the complexity of the SG and lacks epithelial readout, highlighting the necessity to develop new relevant models. Our objective was to develop and characterize differentiated organoids of SGEC derived from minor salivary gland (MSG) of Sjo patients and controls.

Methods: We included Sjo patients fulfilling the ACR/EULAR 2016 criteria and controls with sicca syndrome. MSG were firstly dissociated enzymatically, then encapsulated in Matrigel© and cultured in Growth Expansion Medium (GEM) containing growth factors, until organoids formation. Organoids were passaged every 7-11 days for self-renewal and cultured in a Differentiation Medium (DM) inhibiting the NOTCH pathway, to develop mature organoids. Proliferation was assessed by cell counting and SGEC markers were investigated by RT-qPCR and immunofluorescence.

Results: Ten patients were included: 8 controls and 2 Sjo patients. Organoids with an average size of 100-200 μm were forming and differentiating in both patients and controls (**Figure 1A**). The mean culture duration was 2.7 ± 1.7 months and was continued for up to 6 months. The self-renewal capacity of organoids in expansion condition was comparable between the two groups, as evidenced by comparable growth curves for the 2 groups (**Figure 1B**) and the high expression of the Ki67 marker in the periphery of organoids, arguing an active cell proliferation (**Figure 1C**). We then differentiated the organoids. Mature organoids highly expressed the ductal markers CK7/CK18 and, to a lesser degree, the acinar markers AQP5 and α-amylase, in both Sjo patients and controls (**Figure 1D**). We confirmed these results in RNA expression, showing an enhanced expression of acinar and ductal markers with DM compared to GEM (**Figure 1E**). Last, we have performed one preliminary experiment in which we have been able to develop immune-organoids by adding PBMC in the organoids (**-Figure 1F**). Work is still in progress to assess the impact of immune cell infiltrate on organoid characteristics.

Conclusion: We established a culture system of SG organoids from MSG in Sjo patients and controls with long term expansion and maturation markers expression. Additional investigations are ongoing to assess the functionality of the organoids and to develop immune-organoids for assessing the impact of adding immune cells in the system. **Bibliography**

35 Years Follow-up of Primary Sjögren's Disease: A Single Center Study

Lorena Montano-Tapia[1], Resit Yildrim[2], Ana Mafalda Abrantes[3] and David Isenberg[4], [1]Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Spain, [2]Eskişehir Osmangazi University I, Eskişehir, Turkey, [3]Centro Hospitalar Universitario Lisboa Norte, Lisbon, Portugal, [4]University College London, London, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune rheumatic disease characterized by lymphocytic infiltration of exocrine glands. Its clinical manifestations are heterogeneous. Currently, the evidence regarding the outcomes of the disease during a long term of follow-up is poor.

We studied a cohort of Sjogren's syndrome patients followed for up to over 35 years to analyze their outcomes during the course of the disease.

Methods: A cohort of 232 patients who were diagnosed with pSS and under care in a single center (University College London Hospital) between 1984 and December 2022 were retrospectively screened. The authors reviewed case notes, computer records, and primary healthcare databases on an audit basis. Demographic features and clinical features were assessed, as well as the outcome, death, and cause of death. Statistical analysis using frequencies, univariant analysis ($\chi 2$ and Fisher's tests), multivariant analysis, logistic regression, and bivariant analysis were performed.

Results: The mean age at diagnosis was 50.5 years (SD=14.78 years). The mean years of follow-up since diagnosis was 12.1 years (SD= 8.65); 48 patients (20.7%) were lost to follow-up at some point during the study period and 37 patients (20.1%) died during this period. Lymphoma developed in 20 patients. When compared with the rest of the patients, the incidence of glandular manifestations was significantly higher in the lymphoma group (11 [55%] vs 59 [37.8%]; p=0.005). In an independent multivariate regression analysis, parotid swelling at the time of diagnosis was found to be the most important predictive factor ($p< 0.001$). The majority of lymphomas developed < 15 years post-diagnosis. Death occurred in 37 patients (20%), with a mean age of 80.20 years old (SD=8.547). Infection was the commonest cause of death, followed by malignancy related.

Conclusion: In our very long-term follow-up of Sjogren's patients, the main complication associated with the disease was related to lymphoma development, which invariably occurred during the first years after diagnosis. In contrast, in our cohort among the patients who died, the majority were over 70 years old, confirming that the disease is clearly compatible with a long-life expectancy. Infection was the commonest cause of death.

Table 1: General characteristics of primary SS patients

Abstract Number: 2186

Neurological Complications in Sjögren's: Occurrence & Impact on Patient Quality of Life

Matt Makara, Janet Church and Katherine Hammitt, Sjögren's Foundation, Reston, VA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's is a serious and systemic autoimmune disease that affects the entire body, including the nervous system. This study aimed to better understand the occurrence of neurological symptoms and comorbidities as well as their impact on quality of life (QoL) in Sjögren's patients.

Methods: An online survey was administered between October and November 2021 to U.S.-based Sjögren's patients aged ≥18 years. The survey was reviewed by the Western Clinical Group IRB and determined to be exempt under 45 CFR § 46.104(d)(2).

Results: Of the total respondents (n=3,622), 83% reported having been diagnosed with ≥1 nervous system-related condition. The most common diagnoses were anxiety/depression (50%), brain fog (47%), and neuropathy (45%). Notable differences in QoL were found between those reporting a comorbid neurological-related diagnosis and those who did not. Those with ≥1 neurological condition were more likely to experience a greater negative impact on their ability to exercise, participate in social activities, be independent, their overall mood, and when performing activities of daily living (OR Ranges: 1 neurological condition, 1.96-2.35; ≥5 conditions, 11.46-17.78). Additionally, respondents with neurological conditions were more likely to state that they did not feel they were living a fulfilling life (1, OR 1.67; ≥5, 6.88). An analysis of neurological symptoms found that more than half of the respondents reported experiencing the following during the prior 12 months: brain fog (80%), trouble sleeping (73%), anxiety (66%), forgetfulness (64%), neuropathy (64%), and headache (56%). When askedhowimpactful each of these symptoms was on their lives, the majority of respondents noted that they experienced a major-to-moderate impact(range: 58%-88%). When looking at neurological symptoms collectively,respondents, on average, stated they experienced nearly 6 neurological symptoms during the prior 12 months and 97.8% of respondents experienced ≥1. Furthermore, 92.0% of respondents stated they experienced ≥1 neurological symptom either daily or weekly and 89.5% of respondents noted experiencing ≥1 neurological symptom to a moderate or

severe degree during the past 12 months. When respondents were asked to identify a single symptom that has the greatest negative impact on their life, 5 of the top 10 symptoms were related to the nervous system. Respondents also expressed a critical need for new therapies to address a range of neurological-related issues, including sleep problems (77%), brain fog/forgetfulness (77%), and neuropathy (68%).

Conclusion: Neurologicalsymptoms and comorbid diagnoses frequently occur in Sjögren's patients and are associated with worsening QoL. Greater awareness and further study into these connections is needed to inform optimal approaches to recognition, diagnosis and care. Due to a lack of currently available or effective treatments, Sjögren's patients feel strongly that more and improved therapies are needed to address neurological disease manifestations.Because of its multifactorial nature, fatigue was not included in this analysis, though it remains one of the biggest issues for Sjögren's patients.

Association Between Illness Perception, Anxiety and Depression State, Disease Activity and Glucocorticoid Therapy in Patients with Sjögren's Syndrome

Chiara Baldini[1], Elena Elefante[2], Inmaculada Conception Navarro Garcia[2], Francesco Ferro[3], Gaetano La Rocca[4], Giovanni Fulvio[1], Silvia Fonzetti[5], Michele Moretti[6] and Marta Mosca[2], [1]University of Pisa, Pisa, Italy, [2]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, Pisa, Italy, [3]Clinical and Experimental Medicine Department, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy, [4]University of Pisa, Rheumatology Unit, Pisa, Italy, [5]AOUP, Pisa, Italy, [6]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's syndrome (SS) may affect several aspects of patients' daily lives, leading to impairment of quality of life and patient functioning. Aims of this study were: a) to investigate the relationship between disease activity, illness perception and psychopathological state in patients with SS; b) to specifically explore the impact of glucocorticoid (GC) therapy on patient-reported outcome measures (PROMs).

Methods: This is an observational cross-sectional study including consecutive SS patients (ACR/EULAR 2016) from November 2022 to May 2023. We collected demographic and clinical data including disease duration, ESSDAI, systemic manifestations and pharmacotherapy (GC therapy dose, antimalarial agents, psychotropic and DMARDs). We also assessed the following PROMs: ESSPRI, Visual analogue scale (VAS) for dry mouth, VAS for dry eyes, FACIT-Fatigue, Hospital Anxiety and Depression Scale (HADS). Patients were subdivided into two groups: no GC-treatment vs GC-treatment of ≥1 year. ANOVA, t-tests, Mann Whitney and $\chi 2$ tests were used to assess differences between the two groups. Spearman's correlation was used to measure the correlations between continuous variables. Logistic regression analysis was used to assess independent variables associated with GC therapy.

Results: We included 204 patients (197 F:7M), mean age (DS): 62.6(12.4) yrs; mean follow-up (DS): 9.9 (8-4) yrs. A fifth of the patients showed an ESSDAI≥5, 109/204 (53.4%) presented an ESSPRI≥5 and an ESSDAI< 5 and 55/204 (27%) had both an ESSPRI< 5 and an ESSDAI< 5. The ESSDAI did not correlate either with the ESSPRI nor with other PROMs.

However, Cryo positive patients and subjects with moderate-to-high activity in the glandular domain of the ESSDAI presented significantly higher scores in the VAS questionnaire for dry mouth (8.7 (2.3) vs (6.2 (2.9), p=0.02 and 8.0 (2.1) vs 6.2 (2.9), p=0.02, respectively). By contrast, the ESSPRI scores were significantly lower in patients with low-to-moderate disease activity in the biological domain of the ESSDAI (5.2 (2.8) vs 6.3 (2.4), p =0.01). ESSPRI, HADS, VAS for dry mouth, VAS for dry eyes, and FACIT-Fatigue were statistically significantly correlated with each other (p< 0.001, Table 2). At the inclusion, 40/204 patients (19.6%) were assuming low-dose GC (i.e., ≤7.5 mg of prednisone or equivalent per day). Table 1 summarizes the demographic, disease characteristics and PROMs of the study population comparing patients treated with GC versus no-GC treated patients. The former had a longer disease duration, higher scores in ESSDAI, ESSPRI and HADS depression questionnaire and lower FACIT-Fatigue scores. GC therapy was independently associated with the ESSDAI (OR 1.073 (1.005-1.145), p=0.035) and with the HADS depression questionnaire (OR 1.134 (1.038-1.204), p=0.005)(Fig 1).

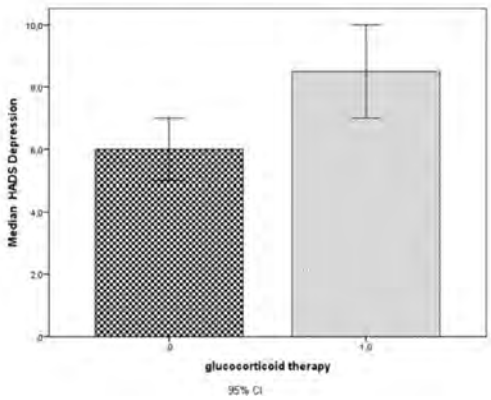
HADS_D	0.461**	0.078	-0.710**	0.527**			
VAS dry mouth	0.634**	0.024	-0.459**	0.349**	0.442**		
VAS dry eyes	0.630**	-0.015	-0.349**	0.202**	0.277**	0.581**	1

Fig 1: Median HADS_ Depression in patients treated with GC versus no-GC treated patients.



Conclusion: We confirmed a limited correlation between disease activity and PROMs in real life. GC therapy, even at the low dosage, contributes to patients' perception of a poorer control of SS with a negative impact on self-reported depression scores.

Lung Cysts in Primary SS: New Findings on an Allegedly Innocuous liagnosis

Regis Sewa Marques, Maria Fernanda Zacarin, Pamela Bellini, Raissa Dudienas D Pereira, Aloma Guinami Scabora, Zoraida Sachetto, Manoel Bertolo and ALISSON PUGLIESI, Universidade Estadual de Campinas, Campinas, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lung cysts are a frequent finding in patients with SS, with previous data indicating a prevalence of approximately 30% on chest CT scans. In SS, it is postulated that, among others, its genesis may be due to bronchiolar obstruction by the lymphoid tissue. Retrospective and small-sample data showed that the disease was not associated with radiological progression, suggesting an innocuous disease. However, prospective data are scarce.

Methods: Between 2015 and 2019, patients classified as having primary SS (pSS) according to the 2002 American-European Consensus or the 2016 ACR/EULAR classification criteria and respiratory asymptomatics were systematically evaluated using high-resolution chest CT. Cysts were defined as an air space delimited by a thin (< 2 mm) layer of thin layer.Other findings were classified according to the standard descriptive guidelines. Patients with findings of pulmonary cysts on examination were subsequently evaluated with a new CT scan within at least 1 year, using the same CT machine, and analyzed by the same thoracic radiologist. The cysts were characterized comparatively by their largest diameters and numerically. Patients who increased in size by at least 0.5 cm and the total number of cysts were considered to have radiological progression.

Table 1: Main radiological characteristics of prospectively evaluated patients with pulmonary cysts

Patient (year of birth and sex)	Smoking history	Size of the largest cyst in the first image	Size of the largest cyst in comparative image	Ground Glass Opacities on CT	Cyst progression in size and number
Patient 1 (1970, F)	no	1.2cm	1.2cm	no	no
Patient 2 (1962, F)	yes	0.6cm	0.6cm	no	no
Patient 3 (1957, F)	yes	2.5cm	3.3cm	yes	yes
Patient 4 (1985, F)	no	2.0cm	3.1cm	yes	yes
Patient 5 (1970, F)	no	6.8cm	7.3cm	no	yes
Patient 6 (1954, F)	no	1.7cm	2.3cm	yes	yes

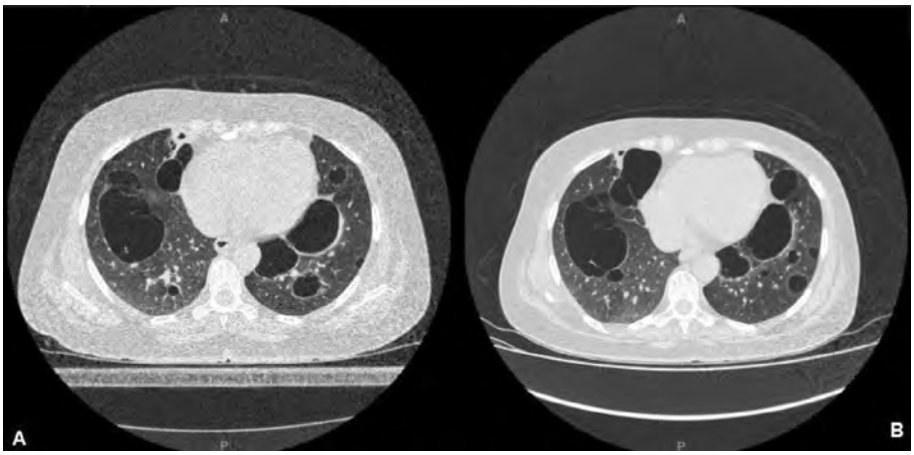

Figure 1 – Thoracic imaging of a 52-year-old woman with cystic lung disease. (A) CT scan done in 2015 showing multiple lung cysts. (B) Progression of cysts in number and size on CT scan taken in 2018

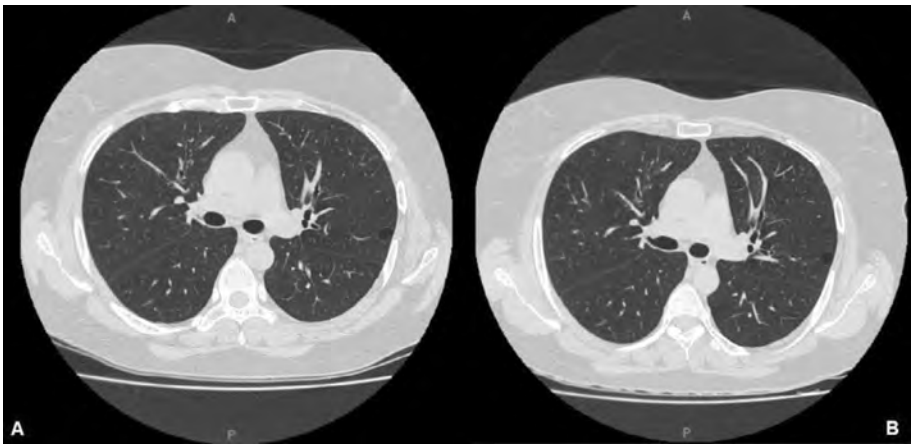

Figure 2 – Thoracic imaging of a 52-year-old woman with cystic lung disease. (A) CT scan done in 2018 with a lung cyst in left lung lobe. (B) New CT scan done in 2019 with no progression of the cyst.

Results: Thirty-five patients with pSS without respiratory symptoms were evaluated using high-resolution chest CT. Of these, 11 (31.4%) had at least one lung cyst, and in six, a prospective evaluation was performed (the remaining patients were not evaluated because of difficulties caused by the Covid-19 pandemic). Among them, four patients showed an increase in both the size and quantity of the cysts, especially those with cysts larger than 2 cm in diameter and with ground-glass opacities on CT. Two patients who had fewer than five cysts each, all smaller than 1.3 cm, had no radiological evolution. In figure 1, we summarize the main radiological characteristics of the evaluated patients, and in figures 2 and 3, we illustrate two patients with lung cysts but with different evolutions.

Conclusion: We found a high prevalence (31.4%) of lung cysts in asymptomatic respiratory patients with pSS who underwent chest CT scans, with most showing radiological progression. In our small sample, patients with cysts > 2 cm or those with ground-glass opacity showed radiological progression. Our findings do not support the hypothesis that lung cysts in patients with pSS do not progress, and point to the need for further larger studies to better evaluate this common lung manifestation of pSS.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjogren's disease (SjD) is characterized by a moderate prevalence of cytopenia, mainly neutropenia and lymphocytopenia with a typical fluctuating pattern. The associations between clinical manifestations and cumulative hematological involvement are well described. However, the prognostic value of white blood cell counts over time is still not fully understood. Our aim was to determine the prevalence of neutropenia and lymphopenia in patients with SjD, their variations over time and the corresponding clinical associations.

Methods: This is a multicentric study conducted at the University of Pisa and Lisbon Academic Medical Centre. Data of SjD patients (ACR/EULAR 2016 criteria) with hematological involvement were retrospectively collected. Patients were divided into groups accordingly to the presence of lymphopenia and neutropenia throughout their disease course: no cytopenia, cytopenia only present at baseline, cytopenia only present at the last follow up and persistent cytopenia. Demographic and cumulative clinical features, such as serological markers, organ involvement (assessed by ESSDAI), and salivary gland biopsy findings were analyzed. Univariate and multivariate logistic regression analysis was performed.

Results: We included 143 patients, 92.3 % were female and the mean follow up was 8,46±0,76 (Table 1). During the disease course, lymphopenia and neutropenia were present in 61/136 pts (44.9%) and32/133 (26.31%), respectively. Lymphopenia was associated with a longer disease duration, serological features (SSB positivity, RF positivity and cryoglobulinemia), higher focus score, higher disease activity as assessed by ESSDAI, more common involvement of the peripheral nervous system, articular and muscular systems, and a higher risk of lymphoma development. Neutropenia was associated with a younger age at diagnosis and lower C3 levels at baseline. A trend was observed for sex (0/35 vs 11/98, p=0.07), as male patients did not have neutropenia (Table 2). In multivariate analysis, lymphopenia was independently associated with focus score (OR 1,312 C.I. 1.02-1.68, p-value 0,034), whereas neutropenia remained associated with both age and C3 (OR 0.95, C.I 0.92-0.99, p-value 0,014; OR 0.95, C.I. 0,92-0.99, respectively). Patients presented different features depending on variations of blood cell levels: persistent lymphopenia tended to be associated with higher focus score, whereas the onset of lymphopenia during the disease course was associated with peripheral nervous involvement (p=0.003) Variations in neutropenia were not associated with any specific SjD clinical manifestations (Fig.1).

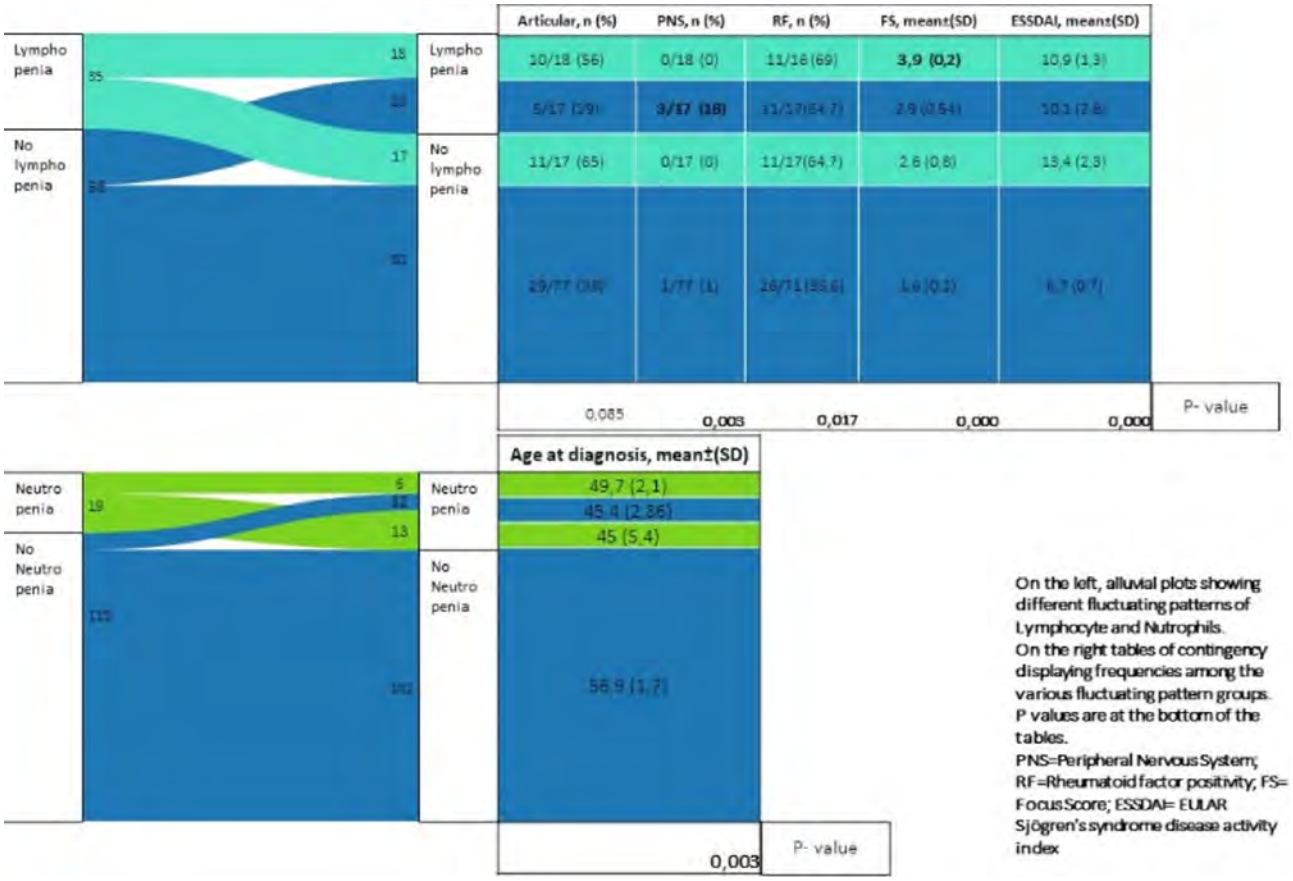
Table1
In the upper part of the tabel cumulative manifestations of Sjogren's Syndrome, in the lower part laboratory test collected at baseline. PNS= peripheral nervous system; CNS=central nervous system;ESSDAI= EULAR Sjögren's syndrome disease activity index



Conclusion: Our study highlights the associations of lymphopenia with key histological, serological and clinical features of SjD. Interestingly, lymphocytopenia may show different pattern of variations, ultimately associated with higher disease activity and tissue infiltration. This is consistent with the hypothesis of glandular tissue homing of circulating lymphocytes in the pathogenesis of SjD and should be further explored.

Saliclick: A Novel Technology for Minimal Invasive Salivary Gland Biopsy in Suspected Sjögren's Syndrome

Thomas Hügle[1], Diana Dan[2] and Alexandre Dumusc[3], [1]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University of Lausanne, Lausanne, Switzerland, [2]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University Lausanne, Lausanne, Switzerland, [3]Dept. of Rheumatology, University Hospital Lausanne (CHUV) and University Lausanne, Switzerland, Lausanne, Switzerland

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Labial minor salivary gland (MSG) biopsy is a major element in the diagnosis of Sjögren´s Syndrome and the exclusion of other pathologies, respectively. Transient local paraesthesia as a complication of MSG biopsy has been described in up to 11%. We recently developed a device in the form of a lip clamp exerting transcutaneous pressure on the salivary glands thus allowing a more superficial incision and less invasive procedure. In this study we report four years experience of MSG using this device in our rheumatology department.

Methods: Retrospective study of 114 MSG biopsies performed with the use of Saliclick (Curmed, Switzerland). For each MSG biopsy we recorded complications, salivary gland surface, intervention time, need of assistance and focus score.

Results: In 106 (95%) out of114 MSG biopsies, representative salivary gland material was obtained. No numbness was recorded. No stitches were needed. In 6 (5.2%) patients, moderate haemorrhage occurred which was controllable by intraoral pressure using a swab. 4 (3.5%) patients suffered from a vaso-vagal reaction. The mean (SD) duration of the intervention was 10.4 (3.5) min. 85% of the interventions could be performed by a rheumatologist without the technical assistance of another person. The mean glandular surface area was 5.9 mm2. A focal lymphocytic sialadenitis was reported in 21 patients (20%), with a focus score >1 for 62% of them.

Conclusion: MSG biopsy using Saliclick is a safe and rapid procedure for the diagnosis in Sjögren's Syndrome without observed numbness occurring in this study. The lack of technical assistance safed resources and the procedure was integrated more quickly into the clinical workflow.

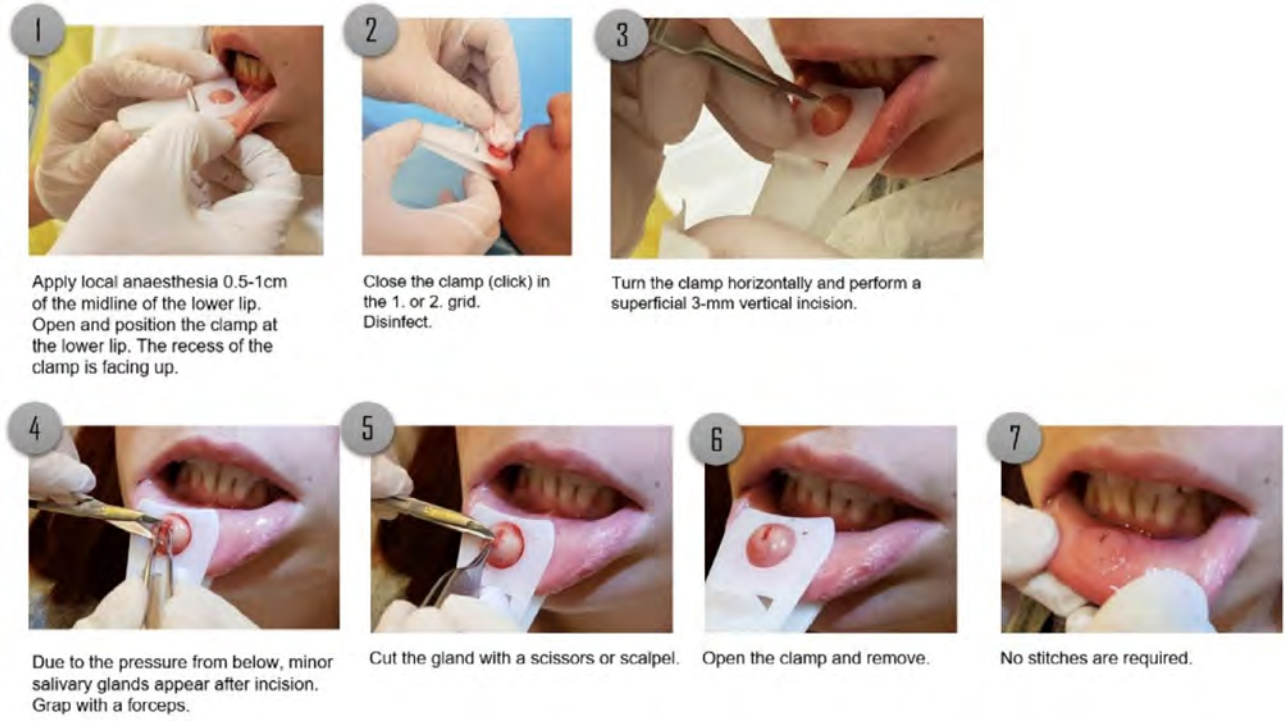

Figure 1. Step-by-step description of the lLabial minor salivary gland biopsy using the novel device 'Saliclick'.

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's disease (Sjo) is a systemic autoimmune disease. In 80% of the patients, Sjo is responsible for dryness, fatigue, and joint pain. In 10% of the patients, severe and potentially life-threatening systemic disease occur. B cell-targeted therapies have shown efficacy in some of these systemic manifestations, but some patients remain refractory to anti-CD20 therapy. Plasmablasts and plasma cells have been identified as key drivers of disease activity in Sjo, suggesting them as a potential therapeutic target. Daratumumab, a monoclonal antibody targeting CD38 and approved for multiple myeloma, depletes plasmablasts and plasma cells. Here, we present the two first cases of patients with severe Sjo complications refractory to rituximab (RTX) successfully treated with daratumumab.

Methods: Patient 1 is, an 18-year-old woman with a diagnosis of Sjo at age of 13 years old. She had positive anti-SSA and SSB antibodies, positive rheumatoid factor, hypergammaglobulinemia at 18 g/l and severe hypertriglyceridemia at 52 g/l due to an autoimmune hyperchylomicronemia with positive anti GPIHBP1 complicating Sjo. RTX treatment had no effect on triglyceride levels, leading to the decision to treat the patient with daratumumab at a dose of 16 mg per kilogram of body weight once a week for 4 weeks. Patient 2, a 68-year-old woman with Sjo, presented with positive anti-SSA and SSB antibodies, type II cryoglobulinemia-associated vaculitis, polyneuropathy, and glomerulonephritis. Despite multiple lines of treatment-included cyclophosphamide and the association rituximab/belimumab, vasculitis relapsed. Daratumumab treatment was initiated following the protocol used for Patient 1.

Results: The follow-up after daratumumab was 8 months for the 2 patients. After daratumumab treatment, Patient 1 showed normalized triglyceride levels (0.67 g/L), decreased gammaglobulin levels from 18 g/l to 9 g/l, and a dramatic decrease in anti-GPIHBP1 antibodies from 6121 U/ml to 234 U/ml(Figure 1). Patient 2 experienced no more purpura flare, negative proteinuria, normalization of complement level, negativation of cryoglobulinemia, and a very important decrease in rheumatoid factor titer from 339 to 48 UI/ml (Figure 2). For the 2 patients, no severe adverse events occurred during follow-up, and no hospitalization was required for the management of Sjo, infections or comorbidities.

Conclusion: Daratumumab may be an effective therapeutic strategy in severe and refractory Sjo patients, particularly when systemic manifestations are driven by pathogenic autoantibodies. Further studies are needed to assess the long-term efficacy and impact of daratumumab on autoreactive B cell repertoire and the room of daratumumab in the therapeutic arsenal of the disease.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a chronic rheumatic disease characterized by lymphocytic infiltration of exocrine glands, resulting in sicca syndrome with extra-glandular autoimmune features. The etiopathogeny is unknown, involving environmental and hormonal factors on a predisposing genetic background. For fundamental research, several inbred

mice strains predisposed to SS exist but backcrossing them with transgenic mice from another genetic background is tedious and time consuming. The aim of this work is to describe an inducible model of pSS that is easy to implement and compatible with CreLox transgenic mice on a C57Bl/6 background, using NFAT5 conditional knockout (KO) mice as a proof of concept.

Methods: Female C57Bl/6 UbC-Cre-NFAT5flx/flx or UbC-Cre+NFAT5flx/flx mice were injected subcutaneously at weeks 12 and 15 with either 25mg/kg 5,6-dimethylxanthenone-4-acetic acid (DMXAA) or vehicule, then at week 17 with two consecutive intraperitoneal injections (at 24h interval) of either 100µl of corn oil or 20mg/ml tamoxifen (TAM). Saliva and lacrymal flow were measured under pilocarpine stimulation at week 18. Mice were sacrified at week 19. Orbit content, submandibular and lacrymal glands were evaluated by histology. Anti-Ro/SSA, anti-Ro/SSB and rheumatoid factor (RF) antibodies were detected by ELISA. FACS analysis of lymphocytic populations was performed on submandibular glands. RNA-sequencing was performed to generate a comprehensive global gene expression profile of submandibular glands from DMXAA-treated groups compared to controls.

Results: Compared to controls, DMXAA/oil- and DMXAA/TAM-treated Cre- mice display a significant decrease in salivary flow (p=0.0009) and Schirmer's test (p=0.03). Histologically, treated groups show low-grade focal sialadenitis within the submandibular glands, increased corneal epithelium thickness but no reproducible dacryoadenitis within the external lacrimal glands. FACS analysis on submandibular glands confirms the presence of predominantly CD8+ and CD4+ T-cells infiltrate. Treated groups also show higher serum reactivity for Ro/SSA (p=0.011), anti-Ro/SSA and RF positivity (both 0% vs 12.5% vs 31.2%, p=0.0232). Only 1 out of 21 mice in the DMXAA/TAM-treated Cre- group showed double anti-Ro/SSA and anti-La/SSB positivity. Comparative analysis of the transcriptomes revealed distinct gene expression patterns in DMXAA-treated groups compared to control mice. Notably, there was in both DMXAA-treated group a significant enrichment of interferon (IFN)-related genes. Compared to DMXAA/TAM-treated Cre- mice, induction of NFAT5 KO in DMXAA/TAM-treated Cre+ mice results in reduced focus-score (p=0.0238), anti-Ro/SSA reactivity (p=0.0127), but does not restore salivary (p=0.77) or lacrimal flow (p=0.9355).

Conclusion: DMXAA-based inducible mouse model of pSS – demonstrating key phenotypic features of human pSS – is an attractive alternative to spontaneous inbred models, allowing the use of any C57Bl/6 mice in pSS experiments.In this study, induction of NFAT5 KO at week 17 reduced focal sialadenitis and anti-Ro/SSA levels but did not rescue salivary and lacrimal flow at week 19.

Table 1 - Clinical features of patients with Sjögren's syndrome

Parameter (0)	ACPA positive, N = 57	ACPA negative, N = 119	P value
Female	54 (94.7%)	114 (95.8%)	0.752
Age at diagnosis (years)	52.7±13.4 (19-78)	50.6±14.6 (17-80)	0.928
Smoking status			0.814
- Never smoker	25 (73.5%)	65 (67.7%)	
- Active Smoker	3 (8.8%)	11 (11.5%)	
- Former smoker	6 (17.7%)	20 (20.8%)	
SS duration (years)	8.9±8.1 (0-39)	10.7±8.5 (1-47)	0.069
Disease assessment at diagnosis			
- ESSDAI	4.0±4.0	3.8±6.1	0.107
- ESSPRI	5.8±2.3	6.0±2.3	0.523
- ESS	5.7±2.6	5.9±2.6	0.891
- PROFAD-SSI	24.7±16.1	27.1±9.2	0.426
Disease assessment at last visit			
- ESSDAI	4.5±7.8	2.0±3.0	0.194
- ESSPRI	4.3±1.8	5.9±1.9	0.373
- ESS	4.3±2.9	5.5±1.9	0.189
Salivary and lacrimal gland assessment			
- Xerostomia	46/54 (85.2%)	40/44 (90.9%)	0.297
- Unstimulated salivary flow (ml/15min)	4.7±5.6	4.1±5.2	0.309
- Clinical oral dryness score	3.7±1.5	3.6±1.8	0.325
- Focus score	2.2±2.7	1.6±1.7	0.983
- Salivary gland swelling	8/36 (22.2%)	23/107 (21.5%)	0.371
- Xerophthalmia	43/46 (93.5%)	41/45 (91.1%)	0.488
- Schimer's test	3.5±2.2	3.2±2.7	0.487
- van Bijsterveld ocular score	2.4±2.4	1.8±1.8	0.108
- Tear break-up time	7.7±4.6	7.7±4.4	0.776
Autoantibodies, n (%)			
- ANA	48 (84.2%)	106 (89.1%)	0.147
- Anti-Ro52	30 (52.6%)	84 (70.6%)	**<0.001**
- Anti-Ro60	29 (50.9%)	75 (63.0%)	**0.009**
- Anti-SSB	17 (29.8%)	69 (58.0%)	**<0.001**
- Rheumatoid Factor	41 (71.9%)	97 (81.5%)	0.107
Biological markers of disease activity			
- ESR elevation	14/50 (28%)	24/77 (31.2%)	0.430
- CRP elevation	15/53 (28.3%)	17/73 (23.3%)	0.332

- Vasculopathy (2)	5/56 (8.9%)	10/119 (8.4%)	0.557
- Hematological neoplasms	2/57 (3.5%)	0/119 (0%)	0.104
- Solid neoplasms	1/57 (1.8%)	4/119 (3.4%)	0.478

Abbreviations: ACPA - Anticyclic-citrullinated protein antibody; CRP - C-reactive Protein; ESR - Erythrocyte sedimentation rate; ESSPRI - Eular Sjögren's Syndrome Patient Reported Index; ESSDAI - EULAR Sjögren's syndrome disease activity index; ESS - EULAR sicca score; MGUS - monoclonal gammopathy of undetermined significance; PROFAD-SSI - Profile of Fatigue and Discomfort Sicca Symptoms Inventory; pSS - Sjögren's syndrome; SD - Standard Deviation.

(0) Continuous variables presented as mean ± sd (range); categorical variables presented as n (%) or n/N (%).
(1) Pulmonary - Nonspecific interstitial pneumonia, ground-glass pattern, pulmonary amyloid tumour, pulmonary micronodules and bronchiectasis.
(2) Vasculopathy - Raynaud's Phenomenon.

Background/Purpose: Extraglandular manifestations may occur in up to 40-50% of patients with SS, including inflammatory arthralgia and chronic polyarthritis (1-3). ACPA are prototypical markers of RA, but have also been described in 4-10% of patients with SS (3,4). Although ACPA have been associated with articular and lung involvement, their clinical relevance remains to be fully clarified (3,4).

Objective: To evaluate the prevalence of ACPA in SS patients and assess their associations with clinical, laboratorial and radiographic features.

Methods: We screened patients from the Observational Lisbon Sjögren's Syndrome Prospective (OLISSIPO) and University of Pisa (UNIPI) cohorts, included until May 2023, for the presence of ACPA. For each ACPA-positive, two ACPA-negative patients matched for age and sex were selected. We collected demographic, clinical and laboratorial variables. t-student or Mann-Whitney tests were used, as appropriate, for continuous variables and chi-square or Fisher tests for categorical variables.

Results: From 438 patients tested for ACPA, 176 patients (95.5% women) were selected (Table 1), 57 of them ACPA-positive (94.7% female), corresponding to a prevalence of 13.0%. Age at pSS diagnosis and disease duration were similar between groups. There were no differences in systemic disease activity, as assessed by the EULAR Sjögren's Syndrome disease activity index (ESSDAI), nor in dryness, pain and fatigue assessed by the EULAR Patient Reported Index (ESSPRI), EULAR sicca score (ESS), and Profile of Fatigue and Discomfort Sicca Symptoms Inventory (PROFAD-SSI). Similarly, xerostomia, xerophthalmia, salivary gland swelling and objective measures of reduced glandular function or inflammation (focus score) were also comparable between ACPA-positive and ACPA-negative patients. However, ACPA-positivity was associated with a significantly lower frequency of anti-Ro52 (52.6% vs 70.6%, $p< 0.001$), anti-Ro60 (50.9% vs 63.0%, $p=0.009$), and anti-SSB (29.8% vs 58.0%, $p< 0.001$) antibodies, but no differences in RF positivity (71.9% vs 81.5%, $p=0.107$). In accordance, markers of B cell hyperactivation such as C3 consumption (14.0% vs 35.7%, $p=0.024$), hypergammaglobulinemia (30.9% vs 54.8%, $p=0.026$) and IgG elevation (21.2% vs 74.2%, $p< 0.001$) were also less commonly associated with the presence of ACPA. Of note, articular involvement or erosive disease was not more frequent in ACPA-positive patients. Nonetheless, a higher number of ACPA-positive patients met the ACR/EULAR 2010 classification criteria for RA (40.0% vs 3.4%, $p< 0.001$). Finally, lung disease was significantly more common in the ACPA-positive group (23.5% vs 8.6%, $p=0.028$), whereas involvement of additional organs was not.

Conclusion: In patients with SS, ACPA is not associated with joint involvement, but, surprisingly, seems to define a subgroup of patients with lower markers of B cell activation (such as circulating anti-SSA/B, complement consumption and raised immunoglobulins). Furthermore, ACPA was associated with lung involvement, despite a similar distribution of known markers of pulmonary disease in SS such as RF. These findings deserve further confirmation in larger cohorts.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Salivary gland hypofunction, manifested as xerostomia in Sjögren's syndrome (SS), causes dental, language, and nutritional problems, leading to a detriment in oral health. The Geriatric/General Oral Health Assessment Index Spanish Version (GOHAI-SP) is a useful tool that has been used to assess the self-perception of oral status in SS patients (1). This study aims to associate and correlate the subjective EULAR SS Patient Reported Index (ESSPRI) and GOHAI-SP results with objective data from unstimulated salivary flow in 15 minutes (USF/15min).

Methods: A cross-sectional and observational study was conducted from October to December 2022 in the rheumatology service at Hospital Universitario "Dr. José Eleuterio González", Mexico. Patients meeting ACR/EULAR criteria for pSS and sSS were included and assessed with ESSPRI and GOHAI-SP during their follow-up appointment or reached by telephone. The latter index consists of 12 questions on a 1 to 5 Likert-type scale. The lowest obtainable score is 12 and the maximum is 60. Scores ≤ 44 were classified as poor oral health, moderate from 45 to 50, and good ≥ 51. Questions 1-4 assess oral functionality, 6, 7, 9-11 psychosocial status; 8 and 12 for pain. Data of USF/15min was obtained from patients' charts.

Results: A total of 41 patients were included: 31 (75.6%) with pSS and 10 (24.4%) with sSS most of whom were women (n=40, 97.6%) with a mean age of 53.41 (SD: 12.58). The median score of GOHAI-SP was 50 [IQR 43.5-52], medians for dryness, fatigue, and pain reported in ESSPRI domains were: 3 [0-7], 2 [0- 6.5] and 1 [0-5]; for USF/15min 1.5 [0.5-2.25]. The self-perceived health status was classified as good in 19 (46.3%), moderate and poor both in 11 (26.8%). We found that the worse the self-perceived oral condition, the higher ESSPRI medians for dryness ($p < 0.001$), fatigue (p 0.003), and pain (p 0.002) were reported. No significant differences were found when compared to USF/15min. Results of Spearman's correlation model are shown in Table 1. No significant differences were found between pSS and sSS groups.

Conclusion: The greater the severity of dryness, fatigue, and muscular or joint pain, the greater the functional impairment of mouth and oral pain; as well as the worse the psychosocial aspect manifested as concern, nervousness, discomfort, and limitation of interaction with people due to the dental appearance.

Table 1. Correlation between GOHAI-SP, ESSPRI and USF/15min.

		GOHAI-SP domains							
	Media n, [IQR]	Oral functionality 4 [3.5-4.37]		Psychosocial 4.2 [4-4.5]		Pain 4 [3-4.75]		Total 50 [43.5-52]

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

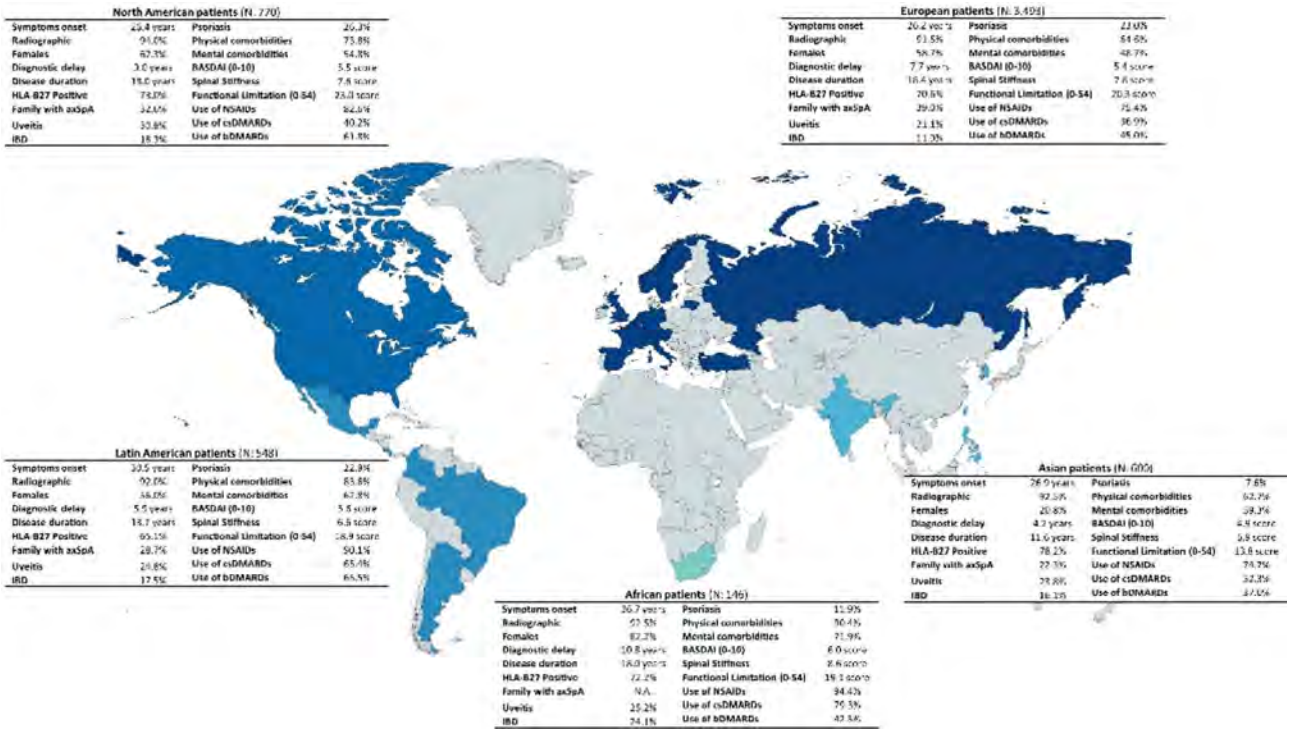
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have suggested there could be regional differences in clinical phenotype of axial spondyloarthritis (axSpA). This analysis aims to explore differences in axSpA clinical phenotype around the world in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS).

Methods: IMAS was a cross-sectional online survey (2017-2022) of 5,557 unselected axSpA patients from 27 countries. We analysed across 5 geographic regions the age at onset of symptoms, classification as radiographic or non-radiographic, gender, HLA-B27, axSpA family history, extra-musculoskeletal manifestations (uveitis, inflammatory bowel disease and psoriasis), presence of comorbidities, disease activity (BASDAI), level of spinal stiffness, and treatment (NSAIDs, csDMARDs and bDMARDs). Kruskal-Wallis and chi-square test were used to compare axSpA characteristics across the regions.

Results: 5,557 patients participated in IMAS survey of which 3,493 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Results showed statistically significant differences between regions, except for the classification status (radiographic or non-radiographic). Age at onset of symptoms ranged between 25-30 years, and was higher in Latin America as compared to other regions. Diagnostic delay was longest in South Africa and lowest in Asia. The lowest frequency of HLA-B27 positivity was observed in Latin America and the highest in Asia. Family history of SpA was most often recorded in Europeand less often in Asia. All extra-musculoskeletal manifestations included were lowest in Europe compared with other regions. Physical and mental comorbidities were frequent in African patients and less common in Europe and Asia. Mean disease activity (BASDAI) was 5.4, with highest values in South Africa and lowest in Asia. Spinal stiffness was highest in South Africa and lowest in Latin America. Functional limitation was higher in North America and Europe and lower in Asia. Most of the patients had used NSAIDs for their condition and less than half had ever



Map 1. Regional Differences in Clinical Phenotype of Axial Spondyloarthritis

taken csDMARDS; both were more frequent in Latin America and South Africa. Almost half of the patients had ever taken bDMARDs, more frequent being in the Americas (Map 1).

Conclusion: There is great heterogeneity of axSpA clinical phenotype presentation around the world. Further understanding of these differences is needed to achieve early diagnosis and initiation of disease treatment in axSpA.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: There is increasing evidence of differences between males and females in axial spondyloarthritis (axSpA), but the source is restricted to specific geographic locations or populations. This analysis aims to assess gender differences in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS) study from around the globe.

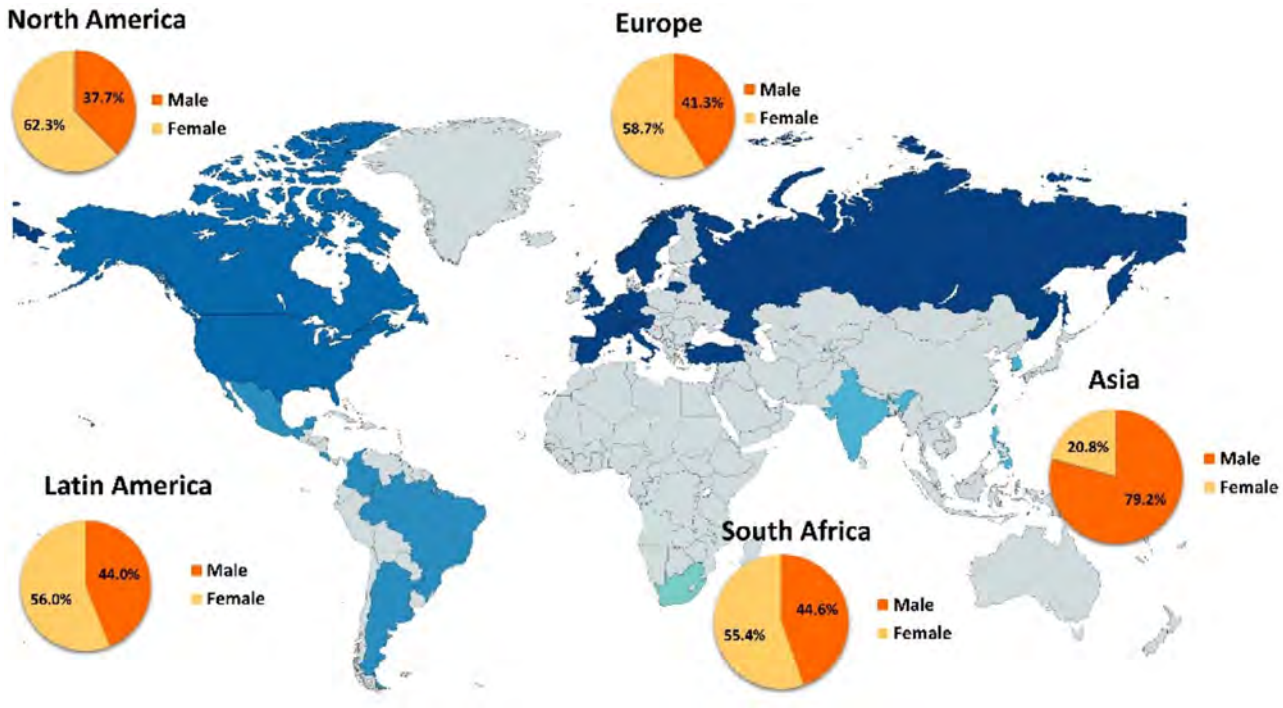

Figure 1. Gender proportion by region (N= 5,555)

Table 1. Patient and disease characteristics in males and females with axSpA (N= 5,555)

	Mean ± SD or n (%)		P-value
	Male 2,475 (44.6%)	Female 3,080 (55.4%)	
Sociodemographic			
Age	44.9 ± 13.6	43.2 ± 12.1	**<0.001**
Patient organization membership	1113 (45.0)	1293 (42.0)	**0.025**
Lifestyle			
Smoking	548 (23.3)	580 (19.7)	**0.002**
Alcohol consumption	823 (33.8)	808 (26.7)	**<0.001**
Disease characteristics			
Diagnostic delay	6.1 ± 7.8	8.5 ± 9.7	**<0.001**
HLA-B27 Positive	1115 (78.9)	1348 (65.8)	**<0.001**
Family history of axSpA	459 (31.4)	752 (39.8)	**<0.001**
Uveitis	564 (25.3)	607 (21.5)	**0.002**
Psoriasis	172 (17.3)	289 (22.7)	**0.002**
Patient-reported outcomes			
Disease activity (0-10)	5.0 ± 2.2	5.7 ± 2.0	**<0.001**
Functional limitation (0-54)	18.1 ± 15.2	21.2 ± 15.3	**<0.001**
Mental health (0-12)	4.2 ± 4.0	5.1 ± 4.1	**<0.001**
Mental comorbidities			
Anxiety	623 (27.0)	1149 (39.2)	**<0.001**
Depression	620 (26.8)	1007 (34.4)	**<0.001**
Sleep disorders	696 (30.3)	1206 (41.4)	**<0.001**
Treatment			
NSAIDs	1729 (75.5)	2190 (81.2)	**<0.001**
csDMARDs	933 (41.3)	1206 (45.5)	**0.003**
bDMARDs	1093 (47.1)	1362 (50.2)	**0.030**

Methods: IMAS is a cross-sectional online survey (2017-2022) of 5,557 unselected axSpA patients from 27 countries. The current analysis looked at the differences in a variety of patient and disease characteristics/assessments between males and females. The factors evaluated were: sociodemographic (age, educational level, marital status, employment status, and patient organization membership), health behaviours (smoking, alcohol consumption, and physical activity), disease characteristics (age at symptom onset, diagnostic delay, HLA-B27, family history of axSpA, uveitis, inflammatory bowel disease), patient-reported outcomes (disease activity [0-10] on the BASDAI scale, spinal stiffness [3-12], functional limitation [0-54], and mental health [0-12] using GHQ-12 scale), mental comorbidities (anxiety, depression, and sleep disorders), and treatments (NSAIDs, csDMARDs and bDMARDs).

Results: Data from 5,555 patients reporting gender were analyzed: 3,492 from Europe, 769 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Globally, 55.4% were females, with higher proportions in South Africa (82.2%) and lower in Asia (20.8%; Figure 1). Compared to males, females were of a younger age, more frequently university educated, more often divorced, more commonly on permanent sick leave, and less often members of patient organizations. With respect to health behaviours, male participants smoked and drank more than females.Compared to males, diagnostic delay was significantly longer (by 2.4 years) while the rate of HLA-B27 positivity and family history with axSpA were lower in females. With respect to patient-reported outcomes, females presented with higher disease activity, greater functional limitation, and poorer mental health. The use of axSpA drug treatment was more common in females with a higher proportion having ever taken NSAIDs, csDMARDs and bDMARDS (Table 1).

Conclusion: Globally, females with axSpA practiced better health behaviors and reported lower frequency of HLA-B27 positivity but had longer diagnostic delay. Despite more frequently receiving medication, females presented with higher disease activity, greater functional limitation, and worse mental health. Reducing the disease burden and diagnostic delay in females is crucial to improving axSpA care around the world.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite efforts for early detection, delayed diagnosis in axial spondyloarthritis (axSpA) remains an unresolved challenge. This analysis aimed to assess diagnostic delay and its associated factors around the world in a large sample of patients included in the International Map of Axial Spondyloarthritis (IMAS).

Methods: IMAS is a cross-sectional online survey (2017-2022) including 5,557 unselected axSpA patients from 27 countries. Diagnostic delay was calculated as the difference between age at diagnosis and age at symptom onset reported by patients. The independent factors evaluated were: age at symptom onset, disease duration, gender, education level, diagnosed by rheumatologist, number of HCPs seen before diagnosis, HLA-B27, uveitis, and inflammatory bowel disease. The factor world region was introduced as a dummy variable taking Europe as the reference region due to its larger sample size and diagnostic delay close to the overall mean. The Mann-Whitney, Kruskal-Wallis test and Pearson correlation were used to evaluate the differences in diagnostic delay and independent variables. Associations between diagnostic delay and regions, sociodemographic characteristics, as well as disease-related factors were explored through univariable and multivariable linear regression analysis.

Results: Data from 5,327 patients who reported data to calculate diagnostic delay in IMAS survey were analyzed: 3,231 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. Overall, patients reported a diagnostic delay of 7.4 years (median: 4.0) since symptom onset, with substantial variation across regions, being the highest in South Africa and the lowest in Asia (Figure 1). Furthermore, mean disease duration was 17.1 ± 13.3. Patients with longer diagnostic delay were more frequently female, younger at symptom onset, with more years with the condition, more commonly diagnosed by the rheumatologist, with a higher number of HCPs seen before diagnosis, had experienced uveitis, and inflammatory bowel disease. The variables independently associated with longer diagnostic delay in the final multivariable regression model were: younger age at symptom onset (b=-0.100), more disease duration (b=0.363), female gender (b=2.274), being diagnosed by rheumatologist (b=1.163), higher number of healthcare professionals (HCPs) seen before diagnosis (b=1.033), and presence of uveitis (b=1.286; Table 1).

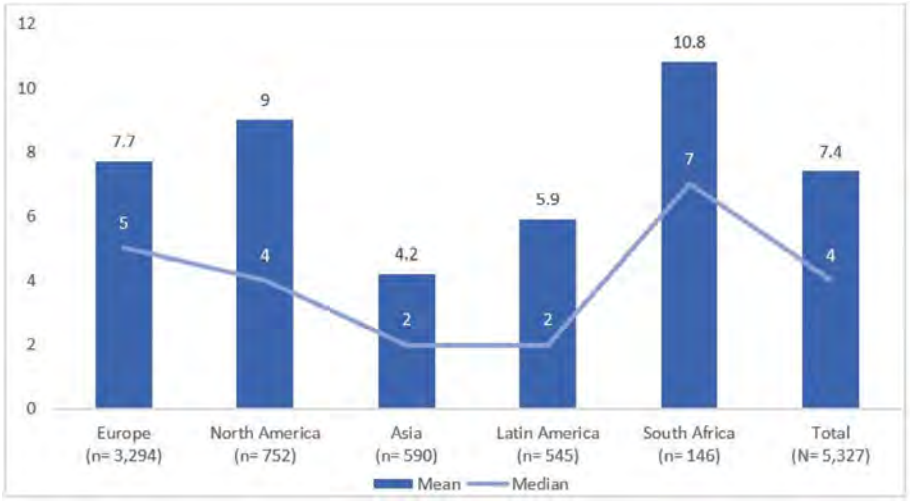

Figure 1. Mean and median diagnostic delays by region (N= 5,327)

Table 1. Univariable and multivariable linear regression analysis of the association between diagnostic delay and independent variables in patients with axial spondyloarthritis (N= 4,595)

Variables	Ref.	Univariable analysis		Multivariable analysis	
		B	95% CI	B	95% CI
Age at symptom onset, years	-	**-0.306**	**-0.326, -0.287**	**-0.100**	**-0.120, -0.080**
Disease duration	-	**0.401**	**0.386, 0.416**	**0.363**	**0.346, 0.380**
Female gender	Male	**2.324**	**1.843, 2.804**	**2.274**	**1.860, 2.687**
Diagnosed by rheumatologist, yes	No	**2.410**	**1.868, 2.952**	**1.163**	**0.710, 1.615**
No. of HCPs seen before diagnosis	-	**1.696**	**1.520, 1.873**	**1.033**	**0.877, 1.189**
Uveitis	No	**1.580**	**0.996, 2.165**	**1.286**	**0.808, 1.764**
Inflammatory bowel disease	No	**0.834**	**0.117, 1.550**	-0.043	-0.610, 0.525
Region, Asia	Europe	**-3.511**	**-4.241, -2.781**	**1.003**	**0.334, 1.673**
Region, North America		**1.228**	**0.499, 1.958**	**1.470**	**0.902, 2.039**
Region, Latin America		**-1.792**	**-2.583, -1.000**	0.626	-0.045, 1.297
Region, South Africa		**3.015**	**1.549, 4.481**	**3.356**	**2.170, 4.541**

Conclusion: In this global sample of axSpA patients, the mean diagnostic delay was 7.4 years, and had significant differences across regions. Younger age at symptom onset, longer disease duration, female gender, diagnosed by rheumatologist, higher number of HCPs seen before diagnosis, and the presence of uveitis were the parameters associated with a longer diagnostic delay in axSpA patients.

Abstract Number: 2198

Which Factors Are Associated with Clinically High Disease Activity in Axial Spondyloarthritis? Results from the International Map of Axial Spondyloarthritis (IMAS)

Marco Garrido-Cumbrera[1], Victoria Navarro-Compán[2], Fernando Sommerfleck[3], Christine Bundy[4], Souzi Makri[5], Jose Correa Fernandez[6], Shashank Murlidhar Akerkar[7], Jo Davies[8], Elie Karam[9], Asif Siddiqui[10] and Denis Poddubnyy[11], [1]University of Seville, Sevilla, Spain, [2]Department of Rheumatology, La Paz University Hospital, IdiPaz, Madrid, Spain, [3]Sanatorio Julio Mendez, Buenos Aires, Argentina, [4]Cardiff University, Cardiff, United Kingdom, [5]Cyprus League for People with Rheumatism (CYLPER), Nicosia, Cyprus, [6]Universidad de Sevilla, Health & Territory Research (HTR), Sevilla, Spain, [7]Mumbai Arthritis Clinic, Mumbai, India, [8]Axial Spondyloarthritis International Federation (ASIF), London, United Kingdom, [9]Canadian Spondylitis Association (CSA), Toronto, ON, Canada, [10]Novartis Pharma AG, Basel, Switzerland, [11]Department of Gastroenterology, Infectious Diseases and Rheumatology, Charité – Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Active axial spondyloarthritis (axSpA) is associated with poorer physical and mental health outcomes. This study aims to assess the prevalence of clinically active disease in axSpA and its associated factors in a large sample of patients from the International Map of Axial Spondyloarthritis (IMAS) study from around the globe.

Methods: IMAS is a cross-sectional online survey (2017-2022) including 5,557 unselected axSpA patients. Patients were divided between those with active disease (BASDAI < 4) and those without active disease (BASDAI ≥ 4). The factors evaluated were: age, gender, physical activity engagement, work-related issues, work choice and difficulty finding a job due to axSpA, number of self-reported symptomatic body regions, diagnostic delay, HLA-B27, extra-musculoskeletal manifestations, spinal stiffness (3-12), functional limitation (0-54), mental health using GHQ-12 scale (0-12), and treatments

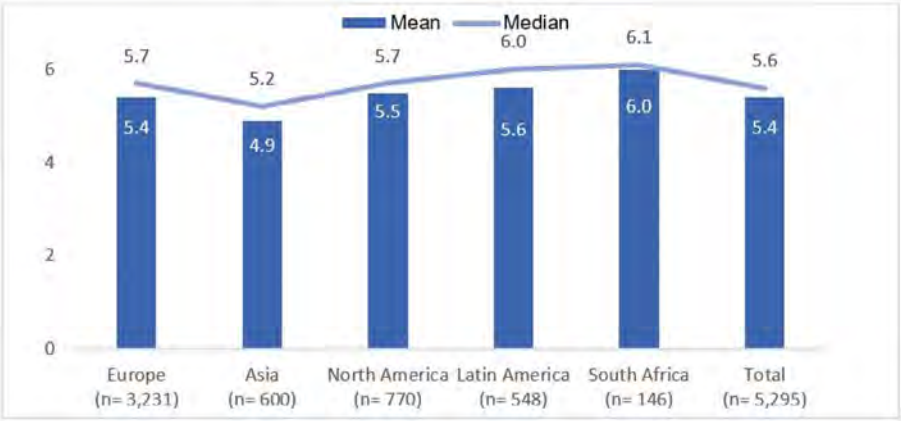

Figure 1. Mean and median of disease activity by region (N= 5,295)

(NSAIDs, csDMARDs and bDMARDs). Mann-Whitney, chi-square test and logistic regression analysis were used to evaluate the possible association of the investigated factors with active disease in axSpA patients.

Results: 5,295 patients who had responded to the BASDAI scale in IMAS survey were included in the present study: 3,231 were from Europe, 770 from North America, 600 from Asia, 548 from Latin America, and 146 from Africa. The mean age was 43.8±12.9 years and 55.4% were females. Patient reported a mean BASDAI of 5.4 (median 5.6; Figure 1) with 75% having active disease (BASDAI≥4). In South Africa, 87.0% of patients reported having active disease, compared to 68.5% in Asia. Compared to patients with non-active disease, patients with active disease were more likely to be older, female, physically inactive, experience work-related issues, have greater difficulty finding a job and faced limited work choice due to axSpA, had higher number of self-reported symptomatic body regions, longer diagnostic delay, higher proportion of HLA-B27 negative, presence of inflammatory bowel disease, greater spinal stiffness, higher functional limitation, worse mental health, and greater use of csDMARDs. In the multivariable logistic regression, the factors associated with active disease were the presence of work-related issues due to axSpA, difficulty finding a job due to axSpA, higher number of self-reported symptomatic

Table 1. Logistic regression analysis to determine factors associated with active disease (N= 2,630)

	Univariable logistic regression		Multivariable logistic regression	
	OR	CI 95%	OR	CI 95%

Difficulty finding a job due to axSpA, Yes	5.08	**4.38, 5.90**	1.92	**1.38, 2.68**
Work-related issues due to axSpA, Yes	3.16	**2.70, 3.69**	1.73	**1.22, 2.44**
Work choice due to axSpA, Yes	2.10	**1.84, 2.41**	1.03	0.75, 1.41
Mental health GHQ-12 scores (0-12)	1.27	**1.24, 1.29**	1.20	**1.14, 1.26**
Use of csDMARDs	1.18	**1.03, 1.35**	1.11	0.82, 1.49

body regions, greater spinal stiffness, higher functional limitation, longer diagnostic delay, HLA-B27 negative, and worse mental health (Table 1).

Conclusion: Globally, three in four patients with axSpA reported clinically active disease, with higher proportion of patients with active disease in South Africa and lower in Asia. The causal relationship between the identified factors and clinical disease activity is complex and may vary from patient to patient. Our results underline the complexity of the clinical disease activity concept in axSpA and underline the need of a holistic approach in the patient management.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) are part of the spondylarthritis spectrum that can be treated with secukinumab, a fully human IgG1 monoclonal antibody targeting interleukin-17A. Real-word data on long-term secukinumab effectiveness in these two diseases are limited. In separate cohorts of axSpA and PsA patients treated with secukinumab in routine care, we aimed to assess a) 24-, and 48-month retention rates; and b) proportions of patients achieving 24-, and 48-month composite scores of remission and response.

	Number of previous b/tsDMARDS	Retention rates	Fully adjusted* HR ref. b/tsDMARD naïve
24 months	b/tsDMARD naïve	79.0%	
	1 prior b/tsDMARD	55.5%	**2.59 [1.69-3.96], p<0.001**
	≥2 prior b/tsDMARDs	56.1%	**2.38 [1.58-3.59], p< 0.001**
48 months	b/tsDMARD naïve	66.0%	
	1 prior b/tsDMARD	44.8%	**2.13 [1.47-3.08], p<0.001**
	≥2 prior b/tsDMARDs	46.0%	**1.92 [1.35-2.73], p<0.001**

* Values adjusted for age, gender, register, time since diagnosis and baseline ASDAS-CRP. Values in bold indicate statistically significant results.

Figure 1: The 48-month retention rate for secukinumab in axSpA patients, stratified according to the number of previous b/tsDMARDs

Methods: Patients with axSpA and PsA who initiated secukinumab were included from 13 registriesparticipating in the European Spondyloarthritis (EuroSpA) Research Collaboration Network [1]. Kaplan-Meier plots with log-rank tests and Cox regression analyses were performed to assess 24-, and 48-month secukinumab retention rates overall, and compared by prior b/tsDMARD status (0/1/≥2). Comparisons of remission and response rates according to b/tsDMARDs status, were performed by logistic regression adjusted for age, gender, register, time since diagnosis and disease activity at treatment start (baseline). Missing baseline data were imputed by multivariate imputation by chained equations.

	Number of previous b/tsDMARDS	Retention rates	Fully adjusted* HR ref. b/tsDMARD naïve
24 months	b/tsDMARD naïve	70.9%	
	1 prior b/tsDMARD	67.2%	0.81 [0.46-1.44], p=0.47
	≥2 prior b/tsDMARDs	58.9%	1.32 [0.83-2.10], p=0.25
48 months	b/tsDMARD naïve	53.2%	
	1 prior b/tsDMARD	53.6%	0.94 [0.58-1.52], p=0.79
	≥2 prior b/tsDMARDs	44.9%	1.23 [0.81-1.86], p=0.33

** Values adjusted for age, gender, register, time since diagnosis and baseline DAPSA28.

Values in bold indicate statistically significant results. N, number.

Results: A total of 767 axSpA and 975 PsA patients from 13 and 12 countries, respectively, were included. At baseline, axSpA patients had a median (IQR) age of 47 (38-55) years, were predominantly male (60%), and had high disease activity (median (IQR)Ankylosing Spondylitis Disease Activity Score (ASDAS)-CRP 3.6 (2.9-4.2)). PsA patients had a median (IQR) age of 52 (44-59) years, were predominantly female (56%), and had moderate disease activity (median (IQR) Disease Activity index for PSoriatic Arthritis in 28 joints (DAPSA28) 25.1 (16.7-37.3)). The overall 24-/48-month secukinumab retention rates were 61%/51% in axSpA, and 63%/49% in PsA patients, respectively. The 24-/48-month secukinumab retention rates in axSpA were significantly higher in bio-naïve patients than in patients treated with 1 or ≥2 prior b/tsDMARDs (Figure 1). In PsA patients, both 24-/48-month secukinumab retention rates were similar between bio-naïve patients and patients who previously received 1 prior b/tsDMARD, and numerically lower in patients having received ≥2 b/tsDMARDs (Figure 2). In axSpA patients, ASDAS-CRP low disease activity (LDA) and ASDAS-CRP clinically important improvement (CII) crude rates were numerically higher in the bio-naïve group at 24 and 48 months. After confounder adjustment, bio-naïve patients had higher rates of ASDAS-CRP LDA than patients who had previously received one or more b/tsDMARDs (Table 1). Similarly, the crude proportions of PsA patients achieving DAPSA28 LDA or moderate response were numerically (but not statistically significantly) higher in the bio-naïve group (Table 1).

Conclusion: This large real-life study showed that secukinumab retention rates after four years wereapproximately 50% in patients with axSpA and PsA. Bio-naïve patients had higher retention, remission and response rates than patients with prior b/tsDMARD exposure, particularly in axSpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The change over time of the structural damage of axial spondyloarthritis (axSpA) is important to consider since it may reflect the severity of the disease. In axSpA this structural damage can be evaluated either at the sacroiliac joints (SIJ) or spine level, and also either on conventional radiographs or Magnetic Resonance Imaging (MRI). The

Table. Sensitivity of change of the structural lesions.

	Imaging outcome	Standardized RoC per year	Relative standardized RoC	Relative standardized RoC per anatomic site
SIJ radiographs	mNY dichotomous	0.043	1 (reference)	1 (reference)
	mNY 1-grade change	0.045	1.047	1.047
	mNY 1-grade change and value >=2	0.048	1.116	1.116
	mNY continuous grade (range 0-8)	0.107	2.488	2.488
SIJ MRI	≥5 fatty lesions and/or erosions	0.165*	3.837	3.837
	≥3 erosions	0.030	0.670	0.670
	≥3 fatty lesions	0.227*	5.279	5.279
	No. of erosions (range 0-40)	0.038	0.884	0.884
	No. of fatty lesions (range 0-40)	0.192	4.465	4.465
	Total structural lesions (range 0-144)	0.099	2.302	2.302
Spine radiographs	≥1 syndesmophyte	0.076	1.767	1 (reference)
	mSASSS score (range 0-72)	0.134	3.116	1.763
Spine MRI	≥5 fatty lesions	-0.068*	1.581	0.089
	Total structural lesions (range 0-322)	0.059*	1.372	0.776
	No. of fatty lesions (range 0-92)	0.064*	1.488	0.842
	No. of corner erosions (range 0-92)	0.020*	0.465	0.263
	No. of corner bone spurs (range 0-92)	0.057	1.326	0.750

*Quadratic distribution

objective of this study was to evaluate the sensitivity to change of different structural imaging outcomes over 10 years of follow-up in patients with early axSpA.

Methods: Patients from the DESIR inception cohort (≤3 years of symptoms) axSpA (according to the treating rheumatologist) from the DESIR cohort were included. Radiographs and MRI of the SIJ and spine were obtained at baseline, 1, 2, 5 and 10 years. Images were scored in four separate reading waves by 3 trained central readers (wave 1 only 2 readers with one adjudicator) unaware of chronology. The yearly rate of change (RoC) of each outcome was analyzed using generalized estimation equations (GEEs) including all patients with ≥1 score from ≥1 reader from ≥1 wave and using time (years) as explanatory variable and adjusting for reader and wave. All outcomes (Table) were standardized (difference between the individual's value and the population mean divided by the population SD). In addition, the relative standardized RoC (i.e., the standardized yearly RoC of an outcome divided by the corresponding rate of a reference imaging outcome) was calculated, with a value >1 reflecting larger sensitivity, and < 1 lower sensitivity compared to the reference. Finally, the relative standardized ROC per anatomic site was calculated.

Results: A total of 704 patients (46% males and mean age 33.7 years) were included. Among all locations and modalities, the change in ≥3 fatty lesions was the outcome with the highest sensitivity to change (standardized RoC 0.227 per year). The two most sensitive to change outcomes in SIJ (both MRI and radiographs) were ≥3 fatty lesions, with a standardized RoC per year of 5.279, which is 5.3 times higher than the RoC of the definitive damage on pelvic radiographs according to the modified New York criteria (mNY) criteria (reference), followed by the absolute number of fatty lesions also 4.5 times more sensitive than the reference. Similarly, the most sensitive to change lesion in the spine (both MRI and radiographs) was the mSASSS score, which was 1.8 times more sensitive than the reference, i.e. ≥1 syndesmophyte.

Conclusion: MRI structural outcomes in the SIJ, in particular fatty lesions, are more sensitive to change than radiographic outcomes. On the other hand, mSASSS remains the most sensitive method, even if compared to MRI of the spine.

When Usual Care Is Not so Usual: Facing the Challenges of Protocol Violations and Generalisability When Running a Strategy Trial. the Example of the Cluster-Randomized TICOSPA Trial

Clementina López Medina[1], Filip Van den Bosch[2], Désirée van der Heijde[3], Maxime Dougados[4] and Anna Molto[5], [1]Rheumatology Department, Cochin Hospital; INSERM (U1153): Clinical Epidemiology and Biostatistics, University of Paris; Rheumatology Department, Reina Sofia Hospital, Cordoba / IMIBIC / University of Cordoba, Cordoba, Spain, [2]Department of Internal Medicine and Pediatrics, Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [3]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [4]Rheumatology Department, Cochin Hospital; INSERM (U1153): Clinical Epidemiology and Biostatistics, University of Paris, Paris, France, [5]HOPITAL COCHIN AP-HP, Service de Rhumatologie, Paris, France

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the ASAS-HI (primary outcome) did not reach statistical significance in the TICOSPA trial, other secondary outcomes were numerically higher in the treat-to-target (T2T) strategy in comparison to Usual Care (UC). Three hypotheses have been considered to explain this: a lack of power, the risk of protocol violations in the T2T arm and the potential optimal care in the UC arm. *Objectives:* a) to evaluate the proportion of patients (pts) who violated the protocol in the T2T arm during the 48 weeks (48W) of follow up as well as the impact and predictive factors of such violation; b) to compare the proportion of pts treated according to the ASAS/EULAR 2016 management recommendations for axSpA over the first 12W of follow-up period in both arms.

Methods: *Study design:* pragmatic, prospective, cluster-randomized controlled, 48W trial (NCT03043846). *Inclusion criteria*: Pts with a diagnosis of axSpA and fulfilling ASAS criteria, non-optimally treated with NSAIDs, bDMARD-naïve and ASDAS >2.1. *Study treatment regimens:*SpA expert centers were randomly allocated (1:1) to the treatment arm: a) T2T: pre-specified management strategy (Q4W visits), with a target of ASDAS< 2.1; b) UC: treatment decisions at the rheumatologist's discretion (Q12W). *Outcome:* Protocol violations in the T2T arm were evaluated at every visit by a specific question. *Statistical analysis*: Factors associated with at least one protocol violation over the study were evaluated using multivariate logistic regression. Outcomes at 48W were compared between T2T violators (T2T-V) vs. T2T non-violators (T2T-NV) vs. UC using GEE models adjusted by country and sex; b) *optimal care in UC:* proportion of pts treated according to the 2016 ASAS/EULAR recommendations over the first 12W in both arms were compared.

Table. Impact of protocol violation on the efficacy outcomes at week 48.

	T2T-NV N = 39	T2T-V N = 41	UC* N = 80	T2T-NV vs. T2T-V P-value	T2T-NV vs. UC P-value	T2T-V vs. UC P-value
ASAS-HI improvement W48	14 (35.9%)	16 (39.0%)	21 (26.6%)	0.773	0.299	0.160
ASAS20 W48	33 (84.6%)	33 (80.5%)	61 (77.2%)	0.640	0.340	0.650
ASAS40 W48	14 (35.9%)	16 (39.0%)	19 (24.1%)	0.773	0.180	0.089
BASDAI50 W48	24 (61.5%)	21 (51.2%)	25 (31.6%)	0.314	**0.002**	**0.037**
ASDAS-CII W48	22 (56.4%)	16 (39.0%)	26 (32.9%)	0.149	**0.022**	0.500
ASDAS-MI W48	6 (15.4%)	8 (19.5%)	9 (11.4%)	0.442	0.709	0.190
ASDAS-LDA W48	24 (61.5%)	19 (46.3%)	32 (40.5%)	0.377	0.081	0.451
ASDAS-ID W48	11 (28.2%)	8 (19.5%)	10 (12.7%)	0.730	0.130	0.299

*79 patients as denominator in the UC group. Generalized Estimating Equation (GEE) models using the group as dependent variable and the disease activity outcome as covariate. All comparisons have been adjusted by country and sex.

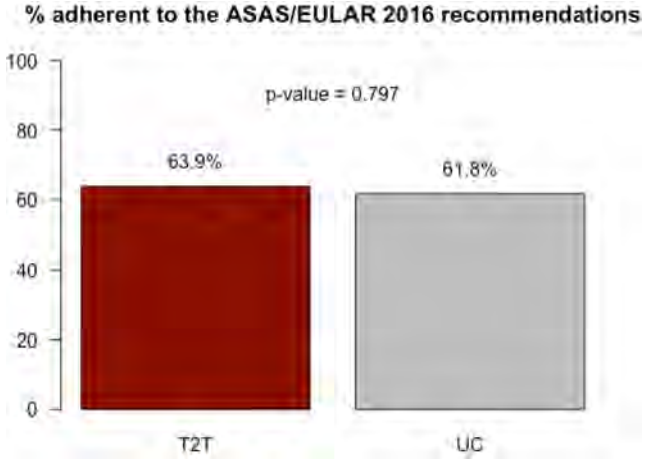

Figure. Proportion of patients treated according to the ASAS/EULAR 2016 management recommendations for axSpA in both groups during the first 12 weeks of follow-up.

Results: 160 pts initiated the trial (T2T:80 and UC:80). *a) Protocol violations:* In the T2T arm, 41/80 (51.2%) pts violated the protocol during at least one visit, with a total of 119 violations (27.7% represented by an intensification of bDMARD and 62.2% by a maintenance or reduction of the treatment against protocol). Baseline predictive factors independently associated with the protocol violation were the country (France vs. others; OR 3.8 (95%CI 1.1-15.0)), female sex (OR 4.4 (1.5-15.1)), diagnosis delay ≤7 years (OR 3.4 (1.1-11.9)), HLA-B27 negative (OR 6.4 (1.6-32.2)) and CRP≥6mg/L (OR 4.2 (1.3-15.9)). After 48W of follow-up, T2T-NV vs. T2T-V showed similar ratios of ASAS-HI improvement. ASDAS-LDA, ASDAS-ID and ASDAS-CII outcomes were more prevalent in T2T-NV vs. T2T-V, although they did not reach statistical significance (Table). b) *Optimal care in UC*: the proportion of pts managed according to the 2016 ASAS/EULAR recommendations during the first 12W of follow-up was similar in both arms (63.9% in T2T vs. 61.8% in UC, p=0.490) (Figure).

Conclusion: These results confirm that protocol violations in the T2T arm in the TICOSPA trial were frequent, although they did not have an impact on the rate of the primary outcome. The proportion of patients managed according to the 2016 ASAS/EULAR recommendations in the UC arm was very high, suggesting that the UC group was optimally treated and explaining the non-achievement of the primary objective in the TICOSPA trial.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Deucravacitinib, a first-in-class, oral, selective, allosteric tyrosine kinase 2 inhibitor, is approved in multiple countries for the treatment of adults with plaque psoriasis; it is currently being investigated in several immune-mediated diseases and has shown efficacy in phase 2 trials for SLE and PsA (NCT03252587 and NCT03881059, respectively). Deucravacitinib was superior to placebo and apremilast in the global, 52-week, phase 3 POETYK PSO-1 (NCT03624127) and PSO-2 (NCT03611751) trials in moderate to severe plaque psoriasis. Patients who completed

PSO-1 and PSO-2 could enroll in the ongoing POETYK long-term extension (LTE) trial (NCT04036435). Patients treated with continuous deucravacitinib in PSO-1 maintained long-term efficacy responses through week 112. In the present analysis, we assessed the efficacy of deucravacitinib for up to 112 weeks among patients from PSO-1 who crossed over from placebo to deucravacitinib at week 16.

Methods: Patients in PSO-1 were randomized 1:2:1 to oral placebo, deucravacitinib 6 mg once daily (QD), or apremilast 30 mg twice daily. Patients randomized to placebo at baseline crossed over to deucravacitinib at week 16. At week 52, patients who completed the parent trial were able to enroll in the LTE trial and receive open-label deucravacitinib 6 mg QD. Efficacy outcomes included ≥ 75%/≥ 90% reductions from baseline in Psoriasis Area and Severity Index (PASI 75/90) and static Physician's Global Assessment (sPGA) score of

0 (clear) or 1 (almost clear) with a ≥ 2-point improvement from baseline. Efficacy is reported using modified nonresponder imputation; patients who had not reached the week 112 assessment or had not discontinued as of October 1, 2021, were excluded. As-observed data and results by treatment failure rule imputation were also analyzed.

Results: At week 16, PASI 75, PASI 90, and sPGA 0/1 response rates in patients treated with placebo were 12.7%, 4.2%, and 7.2%, respectively. A total of 126 patients randomized to placebo at baseline crossed over to deucravacitinib at week 16 and received open-label deucravacitinib in the LTE through week 112. At week 112, PASI 75 and PASI 90 response rates were 81.4% and 50.6%, respectively, and the sPGA 0/1 response rate was 58.2%. These results were similar to those at week 112 in patients who were treated with deucravacitinib from day 1.

Conclusion: Deucravacitinib treatment is associated with long-term efficacy in patients who originally received placebo and crossed over to deucravacitinib after 16 weeks in PSO-1, with results replicating those with continuous deucravacitinib treatment from day 1. These findings further indicate that the once-daily, oral treatment of deucravacitinib is an effective long-term therapy for moderate to severe plaque psoriasis.

Self-Reported and Physician's Assessment of Inflammatory Back Pain According to ASAS Criteria: Is It the Same?

Diego Benavent[1], Mar Tapia[2], Daniel Bernabeu[2], Victor muley[2], Chamaida Plasencia-Rodríguez[3], Alejandro Balsa[3] and Victoria Navarro-Compán[4], [1]Hospital la Paz, Madrid, Spain, [2]Radiology Department, Hospital La Paz, Madrid, Spain, [3]Hospital Universitario La Paz, Madrid, Spain, [4]Department of Rheumatology, La Paz University Hospital, IdiPaz, Madrid, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory back pain (IBP) is the core symptom in patients with axial spondyloarthritis (axSpA). For its assessment, experts recommend using the Assessment of SpondyloArthritis International Society (ASAS) criteria. Advances in telemedicine and online screening strategies require to evaluate whether self-reported perform equally to

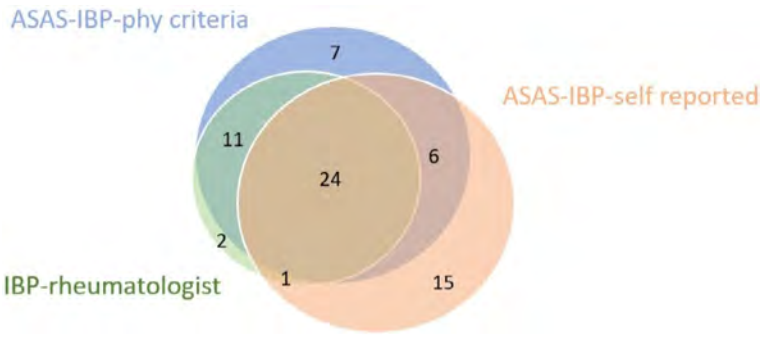

Figure. Number of patients showing IBP by each method of assessment

Table. Utility measures for each IBP assessment method to capture IBP according to rheumatologist judgement

	ASAS-IBP-phy criteria	ASAS-IBP-self reported
Accuracy	0.89	0.78
Sensitivity	0.89	0.81
Specificity	0.92	0.66
Negative Predictive Value	0.73	0.54
Positive Predictive Value	0.97	0.87

physicians' assessment.The objective of this study is to assess the agreement and correlation between self-reported and physician´s assessments of ASAS IBP criteria and evaluate their performance compared with rheumatologist´s judgement for IBP.

Methods: The "Strategy for a Hospital Early Referral in Patients with Axial Spondyloarthritis" (SHERPAS) is a prospective ongoing study recruiting young patients (18 to 40 years) with chronic back pain asked to undergo an MRI of the spine by other specialists different than rheumatologists in a tertiary hospital, starting in September 2021. After inclusion, an additional MRI of the sacroiliac joints (SIJ), followed by a rheumatology visit and eligible blood tests were performed. IBP was assessed in 3 different independent ways: i) ASAS criteria asked verbatim by the rheumatologist (ASAS-IBP-phy criteria), ii) ASAS criteria embedded in a self-reported questionnaire (ASAS-IBP-self reported), and iii) according to rheumatologist judgement in the interview (IBP-rheumatologist). Dataset for this interim analysis was locked in October 2022. Kappa statistic (κ) and tetrachoric correlation coefficient (rt) were calculated to assess the agreement and correlation between ASAS-IBP-phy criteria and ASAS-IBP-self reported. Overall accuracy, sensitivity, specificity, positive and negative predictive values for each IBP assessment method were calculated, using IBP-rheumatologist as gold standard.

Results: Among 152 recruited patients, 85 (55.9%) were female; mean (SD) age was 34.2 (5.3) years. 66/152 (43.4%) patients reported IBP by at least one of the three assessments, and 24 (15.8%) patients presented back pain as assessed by the three methods altogether. Venn diagrams representing the overlap between the different IBP assessments are shown in Figure. A moderate agreement (κ =0.48) and strong correlation (rt=0.7) were found between ASAS-IBP-self reported and ASAS-IBP-phy criteria. While ASAS-IBP-phy criteria showed a strong level of agreement and very strong correlation with IBP- rheumatologist (κ = 0.74, rt= 0.94), ASAS-IBP-self reported showed a moderate agreement and moderate correlation with this outcome (κ = 0.44, rt=0.67). ASAS-IBP-phy criteria showed better performance than ASAS-IBP-self reported for capturing IBP- rheumatologist [accuracy of 0.89 (95%CI 0.83- 0.94) vs 0.77 (95%CI 0.70- 0.84)] (Table).

Conclusion: ASAS criteria to define IBP show higher level of agreement and correlation with IBP rheumatologist overall judgement when assessed by physician as compared to a self-reported assessment. These results call for caution when extrapolating use of experts IBP criteria from clinical to online setting and suggest that clinicians should prioritize physician assessment over self-report to define this.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with axial spondyloarthritis (axSpA), treatment goals consist of achieving remission or low disease activity (LDA) to alleviate symptoms, improve function, decrease disease complications, and forestall skeletal damage. Notably, it has been shown that failure to achieve Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) < 3 leaves significant disease activity for patients. No studies have yet used patient information from multiple Canadian rheumatology registries to better understand outcomes and unmet needs in patients with axSpA. The objective of this study was to describe residual disease activity in Canadians with axSpA treated with currently available therapies.

Methods: This is a multi-registry, observational, retrospective analysis of data extracted from the Rhumadata™ (Quebec), SPARCC (East/Atlantic and West regions, and Ontario), and FORCAST (Alberta) registries. Data were extracted for up to 12 months of the latest axSpA therapy initiation in adult patients between January 2010 and December 2020. The primary endpoint was the proportion of patients who failed to achieve sustained LDA at 12 months; LDA was defined as a BASDAI score < 3, and sustained LDA defined as achieving LDA at both 6 and 12 months. A secondary endpoint further described the proportion of patients who failed to achieve sustained LDA with a definition of BASDAI score < 4. Analyses included outcomes by treatment class (NSAIDs, TNFi, or IL-17i) and number of prior advanced therapies. Data from each registry and region were analyzed separately using a standard set of inclusion/exclusion criteria and statistical analysis plan.

Results: A total of 980 patients (Rhumadata™, N=488; SPARCC, N=239; FORCAST, N=253) were included. The mean age of patients ranged from 40.9 to 44.2 years, with a majority of male and HLA-B27 positive patients overall (Table 1). Mean time since diagnosis ranged from 5.1 to 10.6 years. In all 3 registries, most patients had failed NSAIDs and were receiving their first advanced therapy. The most common current advanced therapy class used was TNFi (Table 1) with less than 10% of patients receiving IL-17i.Nearly half of all patients from Rhumadata™ and FORCAST and 66% of those from SPARCC failed to achieve LDA (BASDAI < 3) at 6 months. At 12 months, failure to achieve sustained LDA ranged from 62.0% in Rhumadata to 81.0% in SPARCC (Table 1). This trend persisted even when using a less stringent definition to measure sustained LDA (BASDAI < 4). Small sample sizes from the West (n=12) and East/Atlantic (n=6) in SPARCC prevented reliable assessments in these regions.

Conclusion: This analysis demonstrated that most Canadians with axSpA failed to achieve sustained LDA after 12 months of initiating therapy. The variations seen in this analysis may reflect distinct regional patient profiles, differing prior biologic treatments at study entry, different provincial reimbursement criteria, or lack of standardized measurements. There is significant residual disease activity and a high unmet need for improved therapeutic approaches and patient outcomes for Canadians living with axSpA.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease affecting global functioning and health (GH). GH, a concept linked to health-related quality of life, is multifactorial in axSpA. On top of the disease itself, chronic widespread pain, comorbidities, and patient-related factors seem to play a role in GH [1]. Our objective was to assess the relative importance of factors associated with GH in axSpA.

Methods: This was a post-hoc cross-sectional analysis of 4 databases, for patients fulfilling ASAS criteria for axSpA, and with available GH scores: COMOSPA (N= 2756 patients analysed) and PERSPA (N= 2651) international cross-sectional studies; DESIR at 7 years (N= 284), a French inception cohort, and COMEDSPA (N= 373) at baseline, a French randomized

Table 1: Multivariable logistic models of factors associated to GH in axSpA.

Dataset	COMOSPA	PERSPA	COMEDSPA	DESIR
N patients	2756	2651	373	284
ASDAS	4.48 [3.80; 5.32]	2.60 [2.25; 3.01]	3.42 [1.96; 6.30]	3.90 [1.51; 11.39]
Widespread pain construct	2.19 [1.39; 3.56]	4.39 [3.35; 5.76]	4.11 [1.96; 8.78]	8.39 [2.07; 38.08]
Currently unemployed	1.67 [1.33; 2.13]	1.69 [1.33; 2.17]	4.76 [2.22; 10.00]	NS
Depression construct	1.93 [1.28; 2.92]	6.04 [3.83; 9.77]	NS	NS
b/ts DMARD intake	1.56 [1.22; 1.99]	NS	4.37 [1.59; 14.43]	NS
Current enthesitis	1.44 [1.03; 2.00]	1.34 [1.06; 1.70]	NS	NS
Current arthritis	2.25 [1.65; 3.07]	NS	NS	NS
Comorbidities RDCI	1.43 [1.22; 1.67]	NA	NS	NS
Obesity (BMI≥ 30kg/m²)	NS	NS	2.61 [1.13; 6.01]	NS
Age, years	1.01 [1.00; 1.03]	NS	NS	NS
CRP (per 10 mg/L increase)	0.54 [0.48; 0.61]	0.92 [0.88; 0.96]	NS	0.05 [0.00; 0.57]

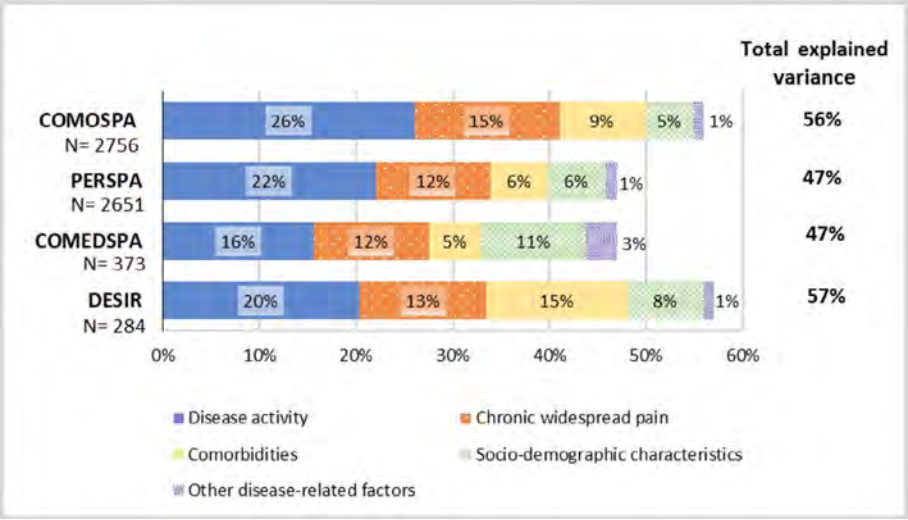

Figure 1: Relative variance of GH explained by each group of variables in the 4 datasets. RDCI was not available in PERSPA, diagnostic delay was not available in COMEDSPA and bamboo spine was not included in DESIR. Percentages are the proportion of the partial variance explained by each group of variables, relative to the total explained variance.

control trial. GH was assessed through the ASAS Health Index (ASAS-HI), range 0-17; in COMOSPA we used the EuroQoL-5D-3L (EQ-5D) since ASAS-HI was not available. Altered GH was defined by ASAS-HI ≥ 10 according to its graphical distribution and quartiles distribution in the datasets; a ROC curve of EQ-5D corresponding to this cut-off was obtained, and the Youden index that maximizes sensitivity and specificity was computed: thus, altered GH was defined by EQ-5D< 0.597. Disease-related factors included (a) disease activity: ASDAS, CRP, current psoriasis, current arthritis, current enthesitis; (b) other disease-related factors: disease duration, diagnostic delay, structural damage (bamboo spine), and bDMARD use. Non-disease-related factors included (a) sociodemographic data (sex, age, employment status and educational level), (b) comorbidities (Rheumatic Disease Comorbidity Index RDCI, obesity and depression) and (c) the construct of chronic widespread pain. Bivariate and multivariate logistic and linear regression were performed in each dataset. Partial R^2 explored the proportion of variance explained by groups of variables, relative to the total explained variance, in each dataset.

Results: In 6064 patients, mean age ranged from 38.9 to 45.8 years, 51.1%- 67.7% were male, 42.0%- 66.1% were in high disease activity, and 14.2%- 24.2% were screened positively for chronic widespread pain. GH was generally moderate to good: median ASAS-HI ranged from 5.0 to 7.0. In all, 47.0%, 29.1%, 23.1% and 16.5% patients had altered GH in COMOSPA, PERSPA, COMEDSPA and DESIR respectively. Altered GH was explained in all databases (multivariable logistic regression) by: ASDAS (odds ratio, OR, ranging 2.60-4.48) and chronic widespread pain (OR 2.19-8.39) **(Table1)**, and 47%-57% of GH was explained by the models (total variance of GH, linear regression). Disease activity (partial $R^{2,}$ 16%-26%) and chronic widespread pain (partial R^2 12%- 15%) were the key variables explaining GH (**Figure 1**).

Conclusion: Overall, 16 to 47% axSpA patients reported altered GH in this large population. Two elements were consistently associated to altered GH and together were the key variables explaining GH: higher ASDAS and chronic widespread pain. Our results allow to attribute a relative role to groups of variables to explain GH in axSpA. These results may be helpful for patient-physician communication and shared decision-making. Abstract Number: 2206

Increased Frequency of Activated MAIT Cells Expressing the Gut Homing Receptor CCR9 in Patients with Radiographic Axial Spondyloarthritis

Eric Toussirot[1], Caroline Laheurte[2], Eléonore Gravelin[2], Charline Vauchy[3], Marc Puyraveau[3] and Philippe Saas[4], [1]University Hospital of Besancon, Besançon, France, [2]INSERM UMR1098, plateforme de biomonitoring, EFS Bourgogne-Franche-Comté, Besançon, France, [3]INSERM CIC-1431, Besançon, France, [4]INSERM UMR1098, EFS Bourgogne-Franche-Comté, Besançon, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: MAIT (mucosal associated invariant T) cells are involved in mucosa defense against bacteria. This cellular subset is characterized by a semi-invariant αβ TCR and the expression of CD161. In patients with axial spondyloarthritis (ax SpA), previous works reported a decreased frequency of circulating MAIT cells compared to normal subjects. IL-17A is a relevant cytokine involved in SpA pathophysiology. MAIT cells are a cellular source of IL-17 and IL-17$^+$ MAIT cells were found increased in ax SpA. We have previously reported an increased frequency of IFNγ$^+$/IL-17$^+$ MAIT cells as well as IL-22$^+$ MAIT cells in ax SpA.

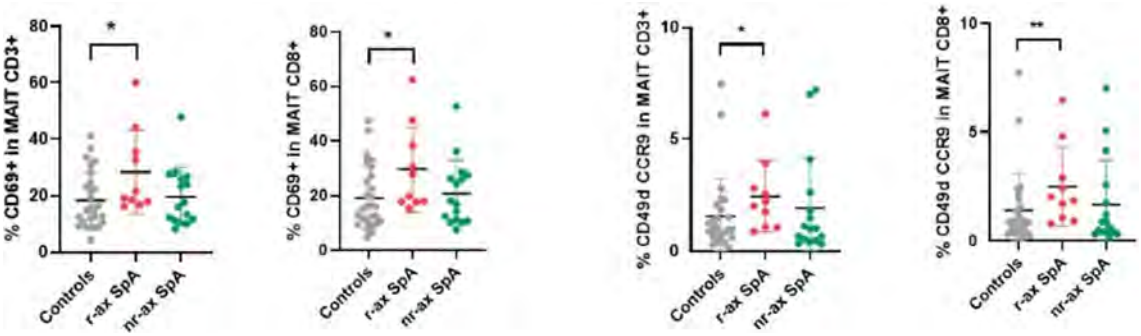
In this study, we aimed to complete our previous results by evaluating activation markers and chemokine receptor/integrin expression, especially those for gut homing, in MAIT cells.

Methods: patients exhibited ax SpA (ASAS criteria) with a radiographic (r-ax SpA) or non-radiographic (nr-ax SpA) form. They all were under NSAIDs and biologic naïve. Healthy subjects were recruited as controls (HC). Circulating CD4$^+$and CD8$^+$T cells and MAIT cells were determined on blood samples by single platform flow cytometry (Cytoflex, Beckman Coulter). MAIT cells were identified by the co-expression of CD3, CD161 and TCRα7.2. In each subpopulation, we examined the expression of CD26, CD69, CCR9 and CD49d integrin.

Results: 26 patients were included (11 r-ax SpA: 9 males [M]; mean age 54.1 ± 19.6 years; disease duration: 16.2 years; ASDAS score: 4.1; and 15 nr-ax SpA: 7 M; age: 36.4 ± 1.3; ASDAS: 5.6) and 27 HC (16 M; age: 43 ± 12.7). In patients with r-ax SpA, we observed an increased frequency of activated CD3$^+$ CD69$^+$ MAIT cells and CD3$^+$ MAIT cells expressing the gut

Table

	Healthy Controls	r-ax SpA	nr-ax SpA
% CD69$^+$ MAIT CD3$^+$	18.4 ± 9.9	**28.3** ± 14.7 *	19.7 ± 10.3
% CD69$^+$ MAIT CD8$^+$	19.1 ± 11.4	**29.5** ± 15.6 *	20.8 ± 12.0
% CD49d$^+$CCR9$^+$ MAIT CD3$^+$	1.6 ± 1.7	**2.5** ± 1.6 *	1.9 ± 2.3
% CD49d$^+$CCR9$^+$ MAIT CD8$^+$	1.4 ± 1.7	**2.5** ± 1.8**	1.7 ± 2



homing markers CCR9 and CD49d, as compared to HC ($p < 0.05$). These higher frequencies were not observed in patients with nr-ax SpA. In addition, when examining the $CD8^+$ MAIT population, similar higher frequencies of cells positive for CD69, CCR9 and CD49d were observed in patients with r-ax SpA compared to HC and patients with nr-ax SpA ($p< 0.01$ and $p< 0.05$, respectively).These modifications were specific for MAIT cells and were not observed in conventional $CD4^+$ or $CD8^+$ T lymphocytes.

Conclusion: patients with r-ax SpA are characterized by an increased frequency of activated MAIT cells that expressed homing receptors (chemokine and integrin) for the gut. These results suggest an involvement of this cellular population in the gut-joint axis that is well described in the pathophysiology of SpA.

these results confirm that MAIT cells are altered in ax SpA and highlight the relationships between ax SpA and gut inflammation, especially for the radiographic form.

Knowledge, Awareness, and Attitudes Regarding Inflammatory Back Pain Among Non-Rheumatology Physicians in the United States

William Odell[1], Swetha Ann Alexander[2], Nicolas Page[3], Narinder Maheshwari[4] and Abhijeet Danve[5], [1]Yale University, Wethersfield, CT, [2]University of Utah Health, Salt Lake City, UT, [3]Yale University, New Haven, CT, [4]UCONN Health, Farmington, CT, [5]Yale University School of Medicine, Glastonbury, CT

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory back pain (IBP) is the defining feature of axial spondyloarthritis (axSpA). However, it may be difficult for non-rheumatology physicians (non-rheums) to distinguish between mechanical and inflammatory back pain (IBP) thus contributing to delayed and missed diagnosis. This study aims to systematically survey non-rheums in the US to gain insights into their knowledge, awareness, and attitudes towards IBP. The objective is to identify barriers for timely referral and opportunities for intervention.

Methods: An online survey questionnaire was developed and refined using input from previous smaller regional studies, methodologies, and pilot testing. The survey included demographic information, practice patterns, and questions about the knowledge and approach toward IBP and axSpA. The survey was distributed to non-rheums taking care of chronic back pain (CBP) patients, namely Family/Internal Medicine, Spine Surgery/Orthopedics, Pain Medicine, and Physical Medicine/ Physiatry/Rehabilitation across the US using third-party vendors. The survey was also sent to rheumatologists (rheums), who served as the comparator group. Descriptive statistics was used to summarize the results.

Results: Of 3136 physicians who received the survey, 750 completed it (response rate 24%). **Table 1** presents information regarding physician specialty, demographics, and practice details. Physicians with variable years of practice experience were included (40% < 5-15 years, 40% 15-30 years, and 10% > 30 years). Respondents reported CBP as a common symptom among the patients; 72% of physicians reported CBP in 15% of their patients and 44% in 30% of patients. Seventy percent of non-rheums reported that 15 to 50% of their CBP patients have onset before age 50 years. About 75% of non-rheums are either moderately or very familiar with the term IBP; an additional 15% are somewhat familiar. Only 21% of non-rheums could identify all 8 IBP items, but 87% could recognize more than 4 of 8 IBP items (**Figure 1**). Among rheums, 69 % could recognize all eight features, and 27% could recognize 7 of 8 features. About 60% of non-rheums do not routinely

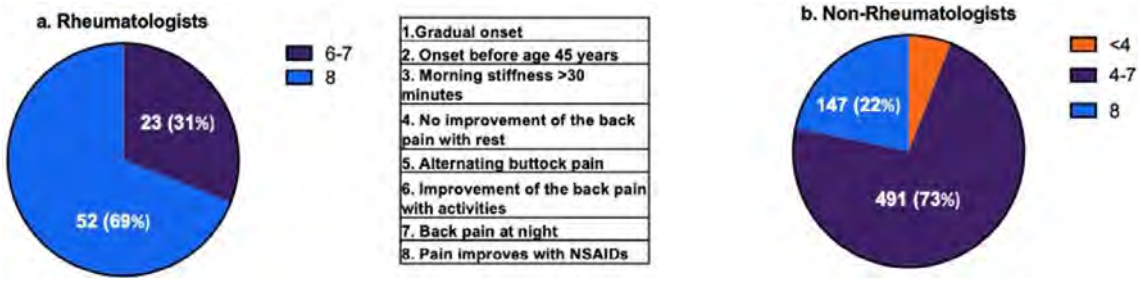

Figure 1: Percentages of rheumatology (a) and non-rheumatology (b) respondents who selected correct answer choices (shown in Figure) describing inflammatory back pain out of 16 choices, with 8 being highest score possible.

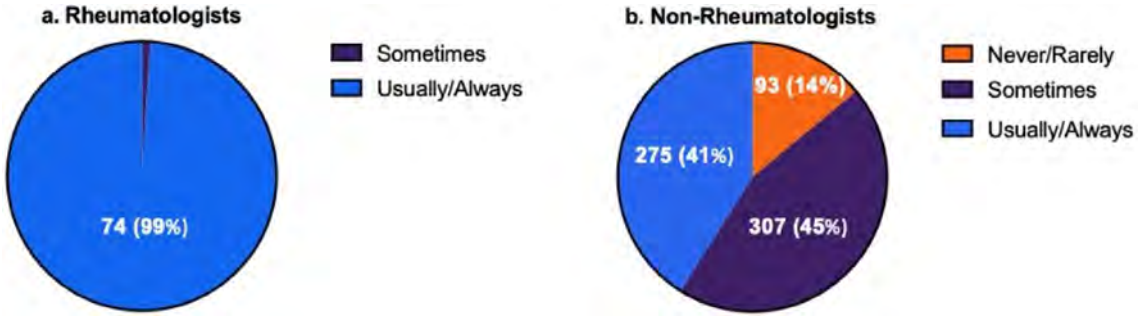

Figure 2: Percentages of rheumatology (a) and non-rheumatology (b) respondents who consider or assess for inflammatory back pain in practice for patients with chronic back pain

assess CBP patients for IBP; 14% rarely/ never assess, and 45% assess for IBP sometimes (**Figure 2**). In contrast, 99% of rheums are routinely assessed for IBP. Data about the IBP and response rates remained consistent across the non-rheums surveyed.

Conclusion: In this large nationwide survey study involving physicians from different specialties who manage CBP, we found that non-rheums are familiar with the term IBP, and the majority may have optimal knowledge about the IBP items, but fewer actually assess the CBP patients for the presence of IBP in routine practice. The use of computerized Clinical Decision Support Systems (CDSS) and improved education regarding the true prevalence of axSpA may help to wind down this barrier.

as comparator group. Descriptive statistics was used, and Pearson's chi-squared test was used to compare categorical variables

Results: Of 3136 physicians who received the survey, 750 completed it (response rate 24%). **Table 1** shows baseline information of respondents. Physicians were in various practice settings (42 % single specialty, 29% multi-specialty, 20% academics) and varying post-training experience (40% < 5-15 years, 40% 15-30 years, and 10% > 30years). CBP was

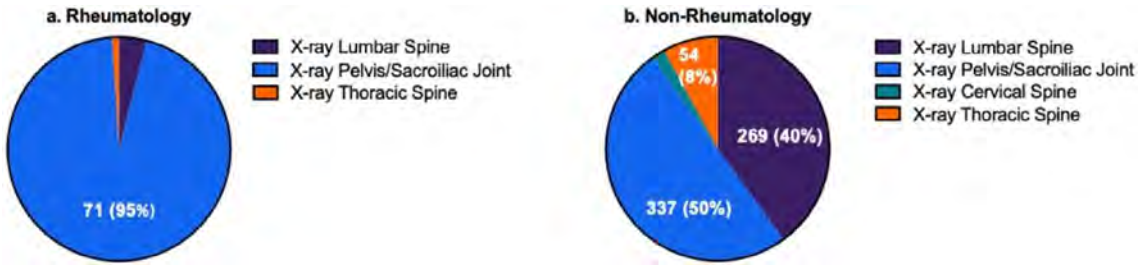

Figure 1: Rheumatology (a) and non-rheumatology (b) responses to question "Select the most appropriate initial imaging test that you would order in a patient with suspected ankylosing spondylitis/axial spondyloarthritis presenting to you with chronic back pain?"

commonly reported; 72% physicians reported CBP in >15% of their patients and 44% in >30% patients. While majority (75%) of non-rheums were familiar with IBP and 87% recognized >4 of 8 IBP items, only 40% routinely assess for IBP in clinical practice. Non-rheums screen CBP patients for inflammatory arthritis, IBD and family history of SpA for only 50% of the times and even less often for heel enthesitis, uveitis and psoriasis (see Table 2) as compared to rheums. Non-rheums also order the CRP and HLA-B27 significantly less often in CBP patients compared to rheums. Non-rheums usually/always order ANA and RF in 47% and 52% IBP patients; rheums order these in 27% and 35% patients respectively. Only 50% of non-rheums correctly answered x-ray SI/pelvis as initial imaging test of choice in suspected axSpA. MRI pelvis was selected as next imaging test by only 37% non-rheums. Non-familiarity with term axSpA and nr-axSpA was reported by 11% and 35% non-rheums respectively. Non-rheums less often (p value < 0.0001) consider axSpA/AS as a possible diagnosis in CBP patients; 20% never or rarely do it and 49% do it sometimes. Formal referral guidelines for axSpA patients were felt important or very important by 81% non-rheums and 97% rheums.

Conclusion: In this large nationwide survey study involving different specialists caring for CBP patients, we found that there is lack of knowledge and awareness about nomenclature, lab testing, and proper imaging in suspected axSpA patients. Unnecessary lab tests are commonly ordered in CBP patients by non-rheumatologists and also to an extent by rheumatologists. Formal referral guidelines and improved education may help in reducing the diagnostic delay of axSpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) typically starts before the fourth decade of life. Consistent with that, the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA should be applied only in patients with chronic back pain starting before 45 years of age. It has, however, been suggested that axSpA can sometimes start later in life with a distinctive phenotype, the so-called 'late onset axSpA' (lo-axSpA). There is, nevertheless, only limited data in support of the existence of such phenotype. We aimed to evaluate the occurrence of lo-axSpA and if these patients differ from those with early onset axSpA (eo-axSpA).

	All patients (N=2165)	**Late onset axSpA** age at symptom onset ≥ 45 years **(N=273)**	**Early onset axSpA** age at symptom onset <45 years **(N=1892)**	**p-value***

Comparison of patient and disease characteristics between patients with late and early onset axSpA.

Methods: We performed a cross-sectional, multicentre, nationwide study using data from Reuma.pt, the Portuguese registry of patients with rheumatic diseases. Adult patients with the clinical diagnosis of axSpA, according to their treating rheumatologist, and with available information on the age of symptom onset were included. Lo-axSpA was defined as axSpA with a symptom onset ≥ 45 years of age. Demographic characteristics (e.g., age, gender, smoking status, and employment), SpA features [12 features (see Table) recorded as ever present, i.e., any time in the past or at the current study visit], measures of disease activity (ASDAS and BASDAI), disability (BASFI) and treatment with NSAIDs, csDMARDs and bDMARDs were compared between patients with lo-axSpA and eo-axSpA at the last available visit at the time of data extraction (13/12/2022).

Results: In total, 2165 patients with axSpA were included. The mean (standard deviation; SD) age at symptom onset was 32 (10) years and the mean (SD) symptom duration was 17 (12) years. The majority of the patients were male (56%), most had definite damage on pelvic radiographs according to the modified New York criteria (85%) and were treated with bDMARDs (77%). Out of the total 2165 patients, 273 (13%) had symptom onset ≥ 45 years and were therefore labelled as lo-axSpA. There were no differences in disease activity, disability or treatment between patients with lo-axSpA and eo-axSpA (Table). There were, however, some notable differences between the two groups. Patients with lo-axSpA were less often positive for HLA-B27 (51% vs 65%), less likely to have family history of SpA (8% vs 14%), acute anterior uveitis (13% vs 20%) and inflammatory back pain (81% vs 88%) than patients with eo-axSpA. On the contrary, patients with lo-axSpA had more peripheral arthritis (36% vs 28%) than patients with eo-axSpA.

Conclusion: This study shows that axSpA indeed starts before 45 years of age in the vast majority of the patients. Even though recall bias cannot be entirely ruled out, clinicians should however be aware that late-onset disease, though infrequent, may in some cases exist. This minority phenotype has a weaker association with HLA-B27, a lower probability of family history, inflammatory back pain or uveitis but more peripheral involvement.

Antibodies to Four Novel Peptides in New Onset Axial Spondyloarthritis

Pieter Ruytinx[1], Elien Luyten[1], Ann-Sophie De Craemer[2], Filip Van den Bosch[3], Dirk Elewaut[4] and Veerle Somers[1], [1]Biomedical Research Institute, Hasselt University, Department of Immunology and Infection, Diepenbeek, Belgium, [2]Ghent University Hospital, Gent, Belgium, [3]Department of Internal Medicine and Pediatrics, Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [4]Ghent University and VIB Center for Inflammation Research, Ghent, Belgium

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Diagnosis of axial spondyloarthritis (axSpA) is challenging and a specific laboratory diagnostic test is lacking. Previously, an axSpA cDNA phage display library, constructed from axSpA hip synovium, was screened to identify novel antibodies in early axSpA patients. This resulted in the identification of novel immunoglobulin G (IgG) and IgA

antibodies to 4 Hasselt University (UH)-axSpA peptides (UH-axSpA-IgG 4, 8 and UH-axSpA-IgA 1,10), corresponding to non-physiological peptides and to a novel axSpA autoantigen, Double homeobox protein 4 (DUX4). Validation of antibody reactivity in plasma samples of early axSpA patients (disease duration < 5 years) from 2 independent cohorts revealed antibody reactivity against at least one of these 4 peptide targets in 21.1% of early axSpA patients (30/142). Here we aim to validate the diagnostic potential of these 4 antibodies in a third independent cohort of new onset axSpA patients and controls.

Methods: Using ELISA, presence of antibodies to the 4 peptides was determined in 187 serum samples of the Belgian Inflammatory Arthritis and Spondylitis (Be-Giant) cohort and 74 controls with chronic low back pain (CLBP) and 101 age and gender-matched healthy controls (HC) from the UH cohort.

Results: The presence of antibodies against the 4 UH-axSpA peptides was confirmed in the Be-Giant cohort. Antibody reactivity against this panel of 4 antigens was present in 13.4% of newly diagnosed axSpA patients (25/187) compared to 6.2% (4/65, *p=0.1740*) in CLBP. The positive likelihood ratio (LR+) for confirming axSpA using antibodies to these 4 peptides was 2.2, which is comparable to the currently used laboratory marker C-reactive protein (CRP) with a LR+ of 2.5. So far, no correlation between these antibodies and clinical disease characteristics could be identified.

Conclusion: The presence of antibodies to 4 UH-axSpA peptides was confirmed in the Be-Giant of newly diagnosed axSpA patients and could be of added value for axSpA diagnosis.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of axial spondyloarthritis (axSpA) has been shown to improve symptoms of the disease such as back pain (BP) and morning stiffness (MS). As a result, early referral of patients suspected of having axSpA is strongly recommended. However, little data is available on the disease course of early axSpA in clinical practice, and particularly in comparison to referred patients who have chronic BP (CBP) but not axSpA. We set out to compare spinal symptoms at baseline and after 2 years (2y) in early axSpA and non-axSpA CBP patients in clinical practice.

Table 1. Baseline and two-years back pain and morning stiffness in early axSpA and non-axSpA chronic back pain patients.

	AxSpA			Non-axSpA		
	Baseline	2-years	p-value (overtime)	Baseline	2-years	p-value (overtime)
Back pain at any time, N		249			94	
mean (SD)	4.0 (2.4)	2.6 (2.3)	**p<0.001***	5.5 (2.2)	3.9 (2.6)	**p<0.001***
Change overtime, mean (SD)		-1.4 (2.5)			-1.6 (2.4)	
Present (score >2), n (%)	168 (67%)	107 (43%)		85 (90%)	63 (67%)	
Back pain at night, N		247			94	
mean (SD)	3.6 (2.9)	2.2 (2.5)	**p<0.001***	4.6 (2.7)	3.6 (2.8)	**p=0.001***
Change overtime, mean (SD)		-1.4 (2.9)			-1.0 (2.7)	
Present (score >2), n (%)	147 (60%)	82 (33%)		71 (76%)	56 (60%)	
Morning stiffness severity, N		261			106	
mean (SD)	4.7 (2.9)	3.1 (2.6)	**p<0.001***	6.0 (2.8)	4.0 (3.0)	**p<0.001***
Change overtime, mean (SD)		-1.6 (3.2)			-1.9 (2.9)	
Present (score >2), n (%)	186 (71%)	126 (48%)		89 (84%)	66 (62%)	
Morning stiffness duration#, N		260			107	
mean (SD)	3.6 (2.8)	2.3 (2.4)	**p<0.001***	4.6 (2.9)	3.1 (2.9)	**p<0.001***
Change overtime, mean (SD)		-1.2 (3.0)			-1.5 (3.1)	
Present (score >2), n (%)	159 (61%)	97 (37%)		82 (77%)	51 (48%)	

* Statistical significance (p-value <0.05). # Morning stiffness duration was assessed using a numeric rating scale (NRS) ranging from 0 (0 hours) to 10 (≥2 hours); for the other outcomes, a NRS ranging from 0 (no symptom) to 10 (unbearable symptom) was used.

Methods: The population consisted of adults (≥16 years) with CBP of unknown origin lasting more than 3 months and less than 2y, starting before 45 years, included in the SPondyloArthritis Caught Early (SPACE) cohort. Patients had a diagnosis of axSpA or non-axSpA at 2y with a high level of confidence by the treating rheumatologist (Marques ML, *Ann Rheum Dis* 2023;82:3-4). Patients reported the severity of BP (total and at night) and MS in the previous week on a numeric rating scale (NRS) ranging from 0 (no symptom) to 10 (unbearable symptom), both at baseline and 2y. For MS duration, a NRS ranging from 0 (0 hours) to 10 (≥2 hours) was used. For the assessment of each outcome, only patients with data at both timepoints were included. Wilcoxon signed-rank tests (for not normally distributed data) were used to compare baseline and 2y results within groups. For the comparison between groups, linear regression models were built, adjusting for the baseline value of the respective outcome, gender, age and use of NSAID.

Results: A total of 434 patients (303 axSpA; 131 non-axSpA) had undergone baseline and 2y visits. Data was available for both timepoints on at least one of the four questions related to BP and MS in 266 (88%) axSpA and 110 (84%) non-axSpA patients. Compared to non-axSpA, axSpA patients were more frequently male (52% vs 25%) and had more SpA features (mean (SD): 5 (2) *vs* 3 (1)), including HLA-B27 positivity (73% *vs* 29%). Age (mean (SD): 29 (8) *vs* 31 (8) years) and symptom duration (mean (SD): 13 (7) *vs* 13 (7) months) were similar between groups.

Overall, lower levels of BP and MS were observed in axSpA (*vs* non-axSpA) patients at baseline and 2y (Table 1). After 2y, BP (total and at night) and MS severity and duration significantly improved in both groups (all p≤0.001), even though symptoms persisted in a considerable number of patients (mainly in the non-axSpA group). A mean improvement ranging from 1.4 to

Table 2. Comparison of two-year outcomes of axSpA (vs non-axSpA) chronic back pain patients.

Outcome	Adjusted Coefficient (95% CI)#	p-value
Back pain at any time	-0.5 (-1.1; 0.1)	p=0.088
Back pain at night	**-0.8 (-1.5; -0.2)**	**p=0.012***
Morning stiffness severity	-0.5 (-1.2; 0.1)	p=0.082
Morning stiffness duration	-0.5 (-1.1; 0.1)	p=0.114

* Statistical significance (p-value <0.05). # Linear regression models, adjusted for the baseline value of the respective outcome, gender, age and use of NSAID.

1.6 points for axSpA patients and 1.0 to 1.9 points for non-axSpA patients was reported for each outcome. In adjusted multivariate analysis, axSpA (*vs* non-axSpA) was an independent predictor of a lower BP at night at 2y (Table 2, adjusted coefficient = -0.8, 95% CI (-1.5; -0.2); p=0.012), with no significant differences found for total BP or MS severity and duration.

Conclusion: Over 2y, BP and MS significantly improve in early axSpA. Although a similar improvement is seen in non-axSpA patients, at 2y most patients have persisting symptoms. AxSpA (*vs* non-axSpA) is an independent predictor of larger improvement in BP at night but not of the observed improvements in total BP and MS.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In axial spondyloarthritis (axSpA), assessment of disease activity and physical function in clinical studies relies on patient-reported outcomes (PRO) such as patient's global, BASDAI, ASDAS and BASFI. However, it still remains unclear how response criteria adequately reflects the patients' opinion on disease status in daily practice. We aimed to investigate whether the results of PROs used in clinical studies with axSpA are indeed related to patient's opinion on disease status as reported in daily clinical routine.

Methods: Data were retrieved from the very first and from the last five visits within a timeframe of 5 years. Patient´s clinical characteristics, physician's global assessment and PROs (ASDAS, BASDAI, BASFI) were assessed at each visit. Status and change of all assessed information during follow-up were compared with patient´s opinion on symptoms related to axSpA, categorized into absent, mild, severe or very severe.

Results: 3,120 visits with median follow-up (IQR) 4.7 (4.3) years from 557 axSpA patients were analyzed. Mild symptoms were stated in 98.7% and 90.0% of visits with inactive or low ASDAS disease status, while 67.9% and 39.3% of visits showing association to high or very high ASDAS disease activity status, respectively (Fig.). In comparison, BASDAI < 4 was found in 90.8% of visits with mild symptoms, while BASDAI≥4 showed severe symptoms in 76.4% of visits (Fig.).

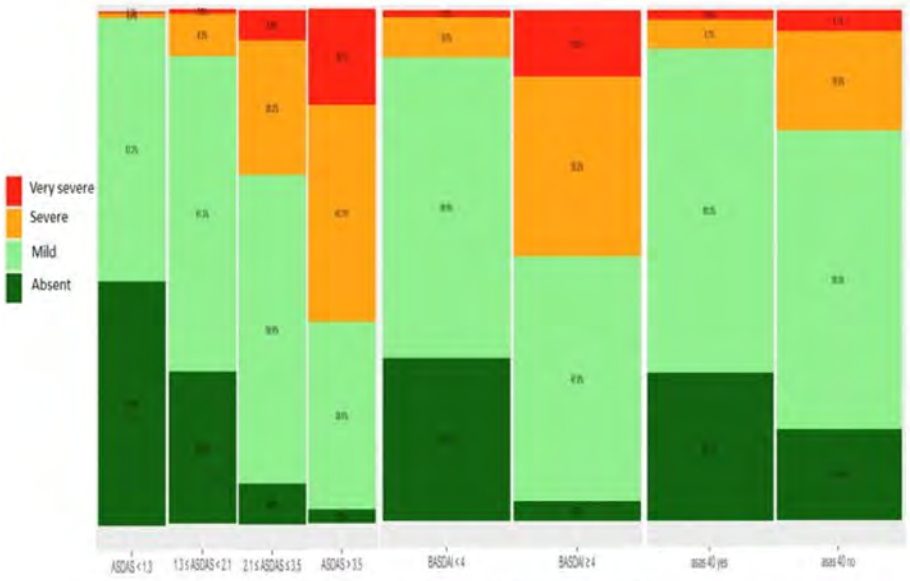

Figure: Percentages of visits with patients' subjective assessment of their symptoms sorted by disease activity

Achievement of ASAS40 was associated with 92.4% visits reporting absent/mild symptoms, while this was the case in 76.4% visits despite not reaching ASAS40. Similar data were observed for ASAS20. Severe symptoms were reported in 0.6% patients achieving vs. 30.1% patients not achieving ASAS partial remission (PR). BASFI correlated with patients' opinion regarding symptoms at each visit.

Conclusion: Low disease activity as assessed by ASDAS or BASDAI were associated with mild symptoms in the majority of visits over a period of up to 5 years. Interestingly, a large proportion of visits showed low disease activity even when not achieving ASAS20 or ASAS40 responses or ASAS-PR.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In axial spondyloarthritis (axSpA), early diagnosis plays a key role in preventing disease progression. However, a validated diagnostic algorithm does not exist, while classification criteria are frequently misused diagnostically.

This study aimed at identifying which decision model is being used for diagnosing patients with axSpA based on evaluations made in daily practice.

Table 1. Patient characteristics

	no axSpA, N = 216[1]	**axSpA**, N = 183[1]
Male	105 (49%)	111 (61%)
Age	35 (28, 43)	36 (27, 47)
Symptom duration	1.5 (0.5, 5.0)	2.0 (1.0, 5.0)
Insidious onset of back pain	94 (44%)	177 (97%)
Improvement with exercise of back pain	119 (55%)	140 (77%)
Morning stiffness of back pain	61 (28%)	103 (56%)
Awakening at second half of night due to back pain	87 (40%)	24 (13%)
Arthritis	24 (11%)	52 (28%)
Uveitis	4 (1.9%)	33 (18%)
Dactylitis	15 (6.9%)	9 (4.9%)
Psoriasis	18 (8.3%)	21 (11%)
Inflammatory bowel disease	6 (2.8%)	11 (6.0%)
Good NSAID response	100 (46%)	151 (83%)
Elevated CRP	36 (17%)	108 (59%)
HLA-B27 positivity	35 (16%)	125 (68%)
Bone marrow edema on SIJ MRI	76 (35%)	140 (77%)
Erosion on SIJ MRI	4 (1.9%)	88 (48%)
Sclerosis on SIJ MRI	71 (33%)	110 (60%)
Fat metaplasia on SIJ MRI	17 (7.9%)	81 (44%)
Ankylosis on conventional radiograph	1 (0.5%)	28 (15%)
Family history for axSpA	18 (8.3%)	59 (32%)

[1] n (%); Median (IQR). axSpA: axial spondyloarthritis; MRI: magnetic-resonance-imaging; NSAID: non-steroidal anti-inflammatory drug; SIJ: sacroiliac-joints

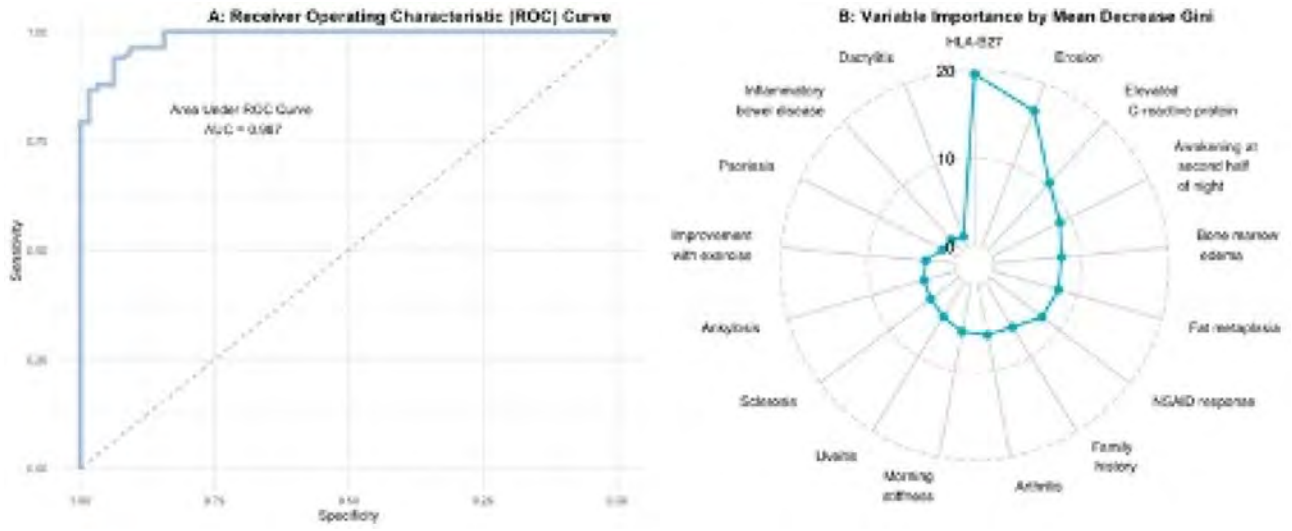

Figure 1

Methods: Complete clinical data of 399 patients who presented with chronic back pain in a specialized university clinic were retrospectively evaluated. All patients received complete rheumatologic examination. The total dataset was randomly split into training and test datasets at a 7/3 ratio. A model was built to classify patients into axSpA and non-axSpA based on the random forest algorithm, an ensemble machine learning technique which allows computing the importance of each variable in the statistical modelling process. The Mean Decrease Gini measure was used for the variable importance. The overall accuracy, sensitivity, specificity, and the area under the receiver operating characteristic (ROC) curve (AUC) in the test dataset were calculated.

Results: In total, 183 patients were diagnosed with axSpA and 216 with non-SpA (Table 1). In the test dataset, the model reached an accuracy of 0.9315, a sensitivity of 0.9634, a specificity of 0.8906, and an AUC of 0.9868 (Fig. 1A). HLA-B27 positivity, erosion on SIJ MRI, and elevated CRP played the most important role in the statistical modelling process followed by awakening at second half of night due to back pain and bone marrow edema and fat metaplasia on SIJ MRI (Fig. 1B).

Conclusion: Machine learning-based random forest classifier revealed a high performance in diagnosing patients with chronic back pain with axSpA and excluding patients with non-SpA using clinical, laboratory and imaging characteristics as evaluated in a daily practice scenario of a SpA-specialized clinic. External validation of the model is needed to investigate its clinical utility as a diagnostic decision support tool.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Lack of timely referral of suspected axSpA patients to rheumatologists contributes to misdiagnosis, delayed treatment, and poor outcomes. Currently there are no formal guidelines in the United States (US) to guide which chronic back pain (CBP) patients should be referred to rheumatology for evaluation of axSpA. To synthesize the evidence for the Spondyloarthritis Research and Treatment Network (SPARTAN) 2023 referral recommendations, we performed a systematic literature review (SLR) and meta-analysis to calculate predictive values of spondyloarthritis (SpA) features.

Methods: We generated Population, Intervention, Control and Outcome (PICO) questions using the framework "Are patients with CBP with SpA feature XYZ more likely to be diagnosed (or classified) as axSpA compared to those without SpA feature XYZ?" The list of SpA features was developed with input from research team members as well as stakeholders including patient partners. Databases including Cochrane Library, Google Scholar, Ovid Embase, Ovid Medline, PubMed, Scopus, and Web of Science Core Collection were searched from inception to April 2022 using relevant keywords to find observational studies in which CBP patients were referred to rheumatologists with suspicion of axSpA and which included information about SpA features in those diagnosed with axSpA and comparators. We followed PRISMA guidelines to report the SLR findings. Two reviewers from a team of 13 reviewers screened abstracts and full-length articles and abstracted the data from eligible studies. Conflicts were resolved by a senior author. Risk of bias was assessed using the QUADAS2 tool. A meta-analysis was performed to calculate and pool sensitivity, specificity, positive likelihood ratios (LR+), and positive predictive values for each SpA feature.

Results: We screened the title and abstracts of 8526 articles and 295 full-length articles were selected for full text review. Thirty-eight full text publications were included for data abstraction and evidence synthesis **(Figure 1)**. **Table 1** shows the test characteristics of 28 individual SpA features. LR+ ranged from 0.5 to 10. Objective SpA features including imaging evidence of sacroiliitis (6.4), elevated CRP (3.77) and positive HLA B27 (4.20) had higher LR+ followed by uveitis (3.25) and family history of spondyloarthritis (2.32). Except for good response to NSAIDs (2.32), individual items of inflammatory back pain as well as peripheral inflammatory arthritis, psoriasis, enthesitis had LR+ less than 2.

1. Reveille et al The Epidemiology of Back Pain, Axial Spondyloarthritis and HLA-B27 in the United States Am J Med Sci. 2013 Jun 431–436.

IBP= Inflammatory Back Pain FH= Family History, IBD = inflammatory bowel disease, ESR = erythrocyte sedimentation rate, CRP = C-reactive protein, axSpA: Axial Spondyloarthritis LR positive= Positive Likelihood Ratio

Conclusion: Our SLR and meta-analysis reveal important information about predictive values of individual SpA features and provide a foundation for formulating evidence-based referral recommendations in a data-driven process –first such effort in North America. The ultimate goal of this endeavor is to facilitate early and appropriate referral of patients with suspected axSpA to rheumatologists. Low LR+ for individual SpA features may necessitate using combinations of SpA features in the referral strategy.

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Unacceptable diagnostic delay in axial Spondyloarthritis (axSpA) remains an issue. In 2008, the longitudinal SPondyloArthritis Caught Early (SPACE)-cohort started to assess the prevalence of axSpA and the reliability of an early diagnosis in patients with chronic back (CBP) of unknown origin. Here we present the primary outcomes of SPACE. We aimed to assess the two-year (2y) prevalence of an axSpA diagnosis in patients with recent onset CBP referred to the rheumatologist; the sustainability of a baseline (BL) diagnosis of axSpA when reviewed after 2y; and to explore BL patient differences of those with and without an axSpA diagnosis at 2y.

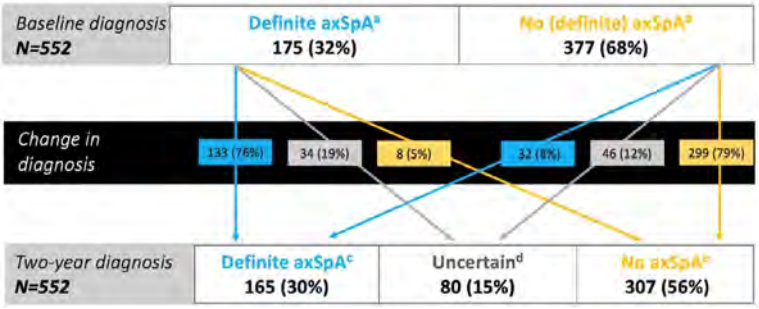

Figure 1. Diagnosis course from baseline (BL) to the two-year (2y) anchor visit. a. patients diagnosed at BL with axSpA with a Level of Confidence (LoC) ≥7; b. patients diagnosed at BL with axSpA (LoC <7) or with no axSpA (any LoC); c. patients diagnosed with axSpA with LoC ≥7 at 2y (if complete follow-up) or at the last two available visits (if missing the 2y visit); d. patients diagnosed with axSpA with LoC <7 at 2y (or LoC ≥7, if only baseline observation available), and patients with axSpA with LoC <7 at the last available observation and no consistent diagnosis at the last two observations nor alternative no axSpA diagnosis given at the last observation; e. patients with no axSpA at the last observation over 2y with LoC ≥7 (or if <7, plus an alternative no axSpA diagnosis reported, e.g. fibromyalgia or aspecific back pain). axSpA: axial Spondyloarthritis.

Methods: We analysed the 2y data from SPACE, a European inception cohort of patients (< 45y) with CBP of recent onset (≥3 months, ≤2y) and unknown origin. The full diagnostic work-up included clinical SpA features, acute phase reactants, HLA-B27, radiographs and MRI of the sacroiliac joints (SI-CR and SI-MRI) and spine (data not shown). Patients with an increased likelihood of having axSpA (≥1 major or ≥2 minor prespecified SpA features) were eligible for follow-up. The clinical diagnosis at 2y was the main outcome of this study. At each visit, the treating rheumatologist judged on the presence or absence of axSpA (axSpA or no-axSpA) with a level of confidence (LoC) on a numeric rating scale (0: *not confident at all* to 10: *very confident)*. The main outcome was the presence of 'definite axSpA' at 2y, defined by a clinical diagnosis of axSpA with LoC ≥7 at 2y (complete follow-up) or at the two last available visits (missing at 2y). 'No axSpA' was defined as not having axSpA at 2y (LoC ≥7; or if LoC < 7, plus an alternative diagnosis for CBP reported). All other patients were considered to have 'uncertain' diagnosis (***Figure 1***). ASAS classification criteria were computed using sacroiliitis local reading in *definite axSpA* patients. We assessed the prevalence of *definite axSpA* at 2y as well as changes in diagnosis over time, and descriptively summarised BL characteristics.

Table 1. Baseline characteristics by two-year (2y) diagnosis of patients with chronic back pain duration of ≥3 months but ≤2y, < 45y of age. # Currently present or past presence (if confirmed/reported by a physician). § Local data. axSpA: axial Spondyloarthritis; MRI: magnetic resonance imaging.

	Definite axSpA N=165	*Uncertain* N=80	*No axSpA* N=307
Age at inclusion, years	29.8 (7.6)	30.9 (8.7)	31.0 (8.4)
Male	52%	38%	26%
Symptom duration, months	12.8 (7.0)	13.4 (7.2)	13.4 (7.2)
HLA-B27 +	81%	60%	15%
Family history of SpA	48%	61%	39%
Inflammatory back pain[§]	76%	63%	55%
Good response to NSAIDs	43%	40%	24%
Peripheral arthritis[#]	16%	16%	7%
Dactylitis[#]	7%	9%	3%
Heel pain[#]	19%	15%	8%
Anterior uveitis[#]	13%	13%	3%
Inflammatory bowel disease[#]	7%	6%	7%
Psoriasis[#]	11%	9%	8%
Increased acute phase reactants[§]	37%	20%	19%
Sacroiliitis on radiographs[§]	23%	9%	0%
Sacroiliitis on MRI[§]	67%	26%	6%

Results: We included 552 CBP patients (Leiden n=383, Oslo n=94, Amsterdam n=48, and Gouda n=27).A diagnosis of definite axSpA was given to 175 (32%) patients at BL and 165 (30%) at 2y (***Figure 1***). The mean (SD) LoC were 8.1 (2.0) and 8.7 (1.0), with 155/175 (89%) and 145/165 (87%) fulfilling ASAS classification criteria, respectively. BL diagnostic judgments were relatively unequivocal and remained rather stable: At 2y, 5% of the BL diagnoses of definite axSpA were refuted; and -*vice versa*: 8% of those who did not obtain a BL diagnosis of axSpA 'gained' one at 2y. Diagnostic uncertainty remained in 15% of CBP-patients. Expectedly, BL SpA features were more prevalent in the 2y definite axSpA group (***Table 1***). HLA-B27 status and (presence or absence of) imaging-detected sacroiliitis at BL appeared the best discriminator(s) between *definite axSpA* and *no axSpA* at 2y.

Conclusion: One third of patients with CBP of recent onset referred to the rheumatologist has definite axSpA. Most patients can be unequivocally and reliably diagnosed at first assessment, though residual diagnostic uncertainty persisted after 2y. None of the many SpA features suffices alone, but HLA-B27 positivity andsacroiliitis on imaging best discriminate the 2y diagnostic groups.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Spondyloarthritis (SpA) is a disease of the working-age individual, with diverse economic and societal implications, including decreased employment rates. Our aim was to investigate the hierarchy of determinants contributing to work impairment in SpA.

Methods: Data was retrieved from the Assessment of SpondyloArthritis international Society (ASAS)-Health Index (HI) international validation study, a cross-sectional international observational study with a longitudinal component for reliability and responsiveness. Patients >60y reporting to be retired were excluded from the analyses (according to usual retirement ages across the 23 participating countries: www.oecd-ilibrary.org). The Work Productivity and Activity Impairment (WPAI) questionnaire was used to assess work productivity loss outcomes: absenteeism, presenteeism, overall work impairment, overall activity impairment. Initial univariable analyses using generalised estimated equations (GEE) explored the association between work-related outcomes (dependent variables) and sociodemographic and clinical variables (independent variables). A manual forward stepwise variable selection procedure was used for the selection of best-fit multivariable models. To avoid collinearity, separate models were built using ASDAS and BASDAI+CRP as independent variables. Lastly, a decision tree was built using Chi-square Automatic Interaction Detector (CHAID), a method of unbiased hierarchical multivariable analysis.

Results: From the original 1548 patients, a total of 1450 patients were included in the analysis, 345 of which had a follow-up reliability/responsiveness visit. Most patients were male (65%), mean age was 40 (±12) years and mean disease duration was 13 (±10) years. Most patients had axial SpA (84%) and a minority had peripheral SpA (16%). Medication use was: NSAIDs 64%, csDMARDs 26% and bDMARDs 38%. Most patients worked full-time (57.1%). Levels of absenteeism were 16% (±32%), presenteeism 29% (±26%), overall work impairment 39% (±34%), and overall activity impairment 41% (±29%). Worse physical function (measured by BASFI) and higher disease activity (measured by ASDAS or by BASDAI +CRP) were independently and consistently associated with all work productivity loss outcomes (Tables). Other variables less consistently associated with work productivity loss outcomes were bDMARD and NSAID use, history of uveitis and peripheral arthritis, disease duration, presence of radiographic sacroiliitis, and level of education (Tables). In the CHAID analysis (Figure), BASFI was the variable with higher discriminative power in predicting overall work impairment; ASDAS was the second-level discriminative variable. University education, disease duration, sex, radiographic sacroiliitis and history of arthritis were the third-level parameters. Similar results were observed for other work productivity loss outcomes (data not shown).

Conclusion: Loss of physical function and higher disease activity are major contributors to work productivity loss and are hierarchically superior to the contribution provided by other demographic and clinical variables.

Table 1. Best-fit multivariable model (adjusted B and 95%CI, p-values) for work productivity loss outcomes (GEE analysis), using ASDAS as independent variable. p-values in bold reflect significant associations. Variables tested in the univariable analyses and considered for multivariable models included: sex, age, symptom duration, disease duration, university education, history of arthritis, history of dactylitis, history of enthesitis, history of uveitis, history of psoriasis, history of inflammatory bowel disease, HLA-B27 status, CRP, NSAID use, cDMARD use, bDMARD use, number of comorbidities, radiographic sacroiliitis (modified New York criteria), anterior syndesmophytes (radiography), ASDAS-CRP, BASDAI and BASFI. Abbreviations: ASDAS, axial spondyloarthritis disease activity score-C-reactive protein; BASDAI, Bath ankylosing spondylitis disease activity index; BASFI, Bath ankylosing spondylitis function activity score; bDMARD, biological disease-modifying antirheumatic drug; GEE, generalised estimated equations.

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The assessment of disease activity in axial spondyloarthritis (axSpA) heavily relies on patient-reported outcomes. It is well-established that gender can influence these outcomes. Accordingly, our study aimed to investigate gender-based differences in disease activity scores before and after treatment with biologic disease-modifying antirheumatic drugs (bDMARDs).

Methods: We conducted a retrospective analysis utilizing data from the Korean College of Rheumatology Biologics therapy (KOBIO) registry, encompassing axSpA patients treated between December 2012 and August 2021. We compared the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) at the initial visit after commencing bDMARDs between male and female patients. Generalized linear model analyses were performed to assess the relationship between changes in disease activity scores and gender with the correction of other clinical variables.

Results: A total of 1,753 patients (1,343 males and 410 females) were included in the analyses. Baseline characteristics revealed that male patients were younger, exhibited longer disease duration, and had a higher proportion of HLA-B27 positive and radiographic disease cases. Additionally, male patients presented lower BASDAI scores and higher C-reactive protein (CRP) levels. At the first follow-up visit (after an average duration of 11.2 months from the initial visit), a significantly

BASDAI, Bath ankylosing spondylitis disease activity index; *ASDAS*, ankylosing spondylitis disease activity score; *SE*, standard error

The results of the multivariate generalized linear model of the relationship between the change in disease activity scores and clinical variables, including gender.

greater proportion of male patients achieved a BASDAI score < 4 compared to female patients (79.57% vs. 71.54%, p < 0.0010). However, there were no significant differences between genders in the proportion of patients achieving low disease activity (ASDAS < 2.1) or inactive disease (ASDAS < 1.3) in terms of ASDAS disease activity score (71.14% vs. 71.5%, p = 0.8892; 38.82% vs. 39.44%, p = 0.8265, respectively). After adjusting for baseline clinical information, a statistically significant association was observed between gender and the difference in BASDAI scores between the first follow-up visit and baseline (p = 0.0033, Table 1). Conversely, no significant relationship was found between gender and the difference in ASDAS scores (p = 0.1303, Table 1).

Conclusion: Our findings highlight the potential impact of gender on the interpretation of treatment response to bDMARDs in axSpA, emphasizing the need to consider diverse methods of calculating disease activity when assessing therapeutic outcomes in male and female patients.

Exploring Metabolite Markers Associated with Treatment Response of Biologic Disease Modifying Antirheumatic Drugs in Psoriatic Arthritis Patients

John Koussiouris[1], Nikita Looby[1], Max Kotlyar[2], Vathany Kulasingam[3], Igor Jurisica[4], Ashish J Mathew[5], Proton Rahman[6] and **Vinod Chandran**[7], [1]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network, Toronto, ON, Canada, [2]Osteoarthritis Research Program, Division of Orthopaedic Surgery, Schroeder Arthritis Institute and Data Science Discovery Centre for Chronic diseases, Krembil Research Institute, Toronto, ON, Canada, [3]Department of Laboratory Medicine and Pathobiology, University of Toronto and Division of Clinical Biochemistry, Laboratory Medicine Program, University Health Network, Toronto, ON, Canada, [4]Schroeder Arthritis Institute, Krembil Research Institute and Departments of Medical Biophysics and Computer Science and Faculty of Dentistry, University of Toronto and Institute of Neuroimmunology, Slovak Academy of Sciences, Bratislava, Slovakia, [5]Christian Medical College, Vellore, India, [6]Craig Dobbin Research Institute, Memorial University, St. John's, NL, Canada, [7]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network and Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of biologic disease-modifying anti-rheumatic drugs (bDMARDS) is the current standard of care for severe diseases like psoriatic arthritis (PsA) which affects approximately 25% of psoriasis patients. However, randomized controlled trials demonstrate a difference in the ACR20 response rate of only 20-30% in patients receiving treatment vs placebo. Thus, choosing the appropriate type of bDMARDS to administer targeted therapy of PsA remains challenging. Predictive biomarkers may help facilitate precision medicine. The objective of this study was to apply a global metabolomics approach to identify small molecules associated with treatment efficacy in PsA patients treated with either tumour necrosis factor inhibitors (TNFi) or Interleukin 17A inhibitors (IL-17Ai).

Methods: Serum samples were obtained from PsA patients satisfying the CASPAR criteria. Patients were treated with either TNFi (n = 20; infliximab, adalimumab, etanercept, certolizumab or golimumab) or IL-17Ai (n = 20; secukinumab or ixekizumab). Patients were evaluated at baseline and 3 months post-therapy and determined as responders or non-responders

Table 1: Demographic and disease characteristics of patients at baseline.

	IL-17i	TNFi
# of patients	20	20
Gender (% female)	55%	75%
Age (Years) (Mean)	55.95	56.85
Age (SD)	9.46	12.63
Disease Duration (Years) (Mean)	10.45	7.35
Disease Duration (SD)	6.91	7.89
Response status (% responder)	35%	65%

based on the Disease Activity Index for PsA (DAPSA) wherein responders had DAPSA < 14. Solid phase microextraction (SPME), a novel high throughput technique was used to prepare all samples simultaneously followed by liquid chromatography – high-resolution mass spectrometry (LC-HRMS) analysis. Data processing and feature identification was performed using 2 platforms – Metaboanalyst R and Compound Discoverer 3.3 respectively. Various Machine Learning (ML) algorithms including Naïve-Bayes (NB), logit boost, adaptive boosting, linear regression, support vector machine (SVM), linear discriminant analysis (LDA), and random forest (RF), was used for predictive feature analysis. Only features in models with an area under the curve of 0.7 or greater were considered as candidate metabolite markers.

Results: Table 1 provides the demographic and disease characteristics of the patients at baseline. 7/20 (35%) of patients treated with TNFi and 13/20 (65%) of patients treated with IL17Ai were responders. As little as 5 features from an SVM model produced an AUROC value of 0.732, while as many as 20 features using NB produced a value of 0.812 between responders and non-responders for both treatments combined at baseline. When considering a single treatment option (TNFi or IL-17Ai only), less than 5 features were required to produce AUROC scores of > 0.9 in both positive and negative mode data. Several exposome-related metabolites were identified via MS level 2 spectral matching including cotinine, adipic acid, toluic acid, monobutylphthalate and tridecylic acid. Glycochenodeoxycholic acid, an endogenous metabolite was also identified.

Conclusion: The identification of cotinine – a metabolite found in tobacco, could indicate that a risk behaviour such as smoking, or an exposure to second hand smoke as well as glycochenodeoxycholic acid – a metabolite that stimulates the mitochondrial pathway to cell death, may indicate that multiple mechanisms of action affects response to treatment. Validation of these results is required.

Comparing the Construct Validity Among Measures of Pain and Stiffness in Patients with Axial Spondyloarthritis

Dafne Capelusnik[1], Elena Nikiphorou[2], Annelies Boonen[3], Désirée van der Heijde[4], Robert BM Landewé[5], Astrid van Tubergen[6] and Sofia Ramiro[4], [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]King's College London, London, United Kingdom, [3]Care and Public Health Research Institute (Caphri), Maastricht University, Maastricht, Netherlands, [4]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [5]Amsterdam Rheumatology & Clinical Immunology Center, Amsterdam and Zuyderland MC, Herleen, Netherlands, [6]Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In the context of the recent update of the ASAS core outcomes set (COS), the preferred comparative validity of the measurement instruments to assess the domains 'Pain' and 'Stiffness' has been questioned as for each domain responsiveness of instruments was comparable. Group discrimination across various external constructs can help provide useful insights and represents unmet need.

Our objective was to compare the group discriminatory capacity, as part of the construct validity, of three instruments to assess pain and three questions of morning stiffness.

Methods: Data from the 8-year visit of patients with axSpA from the multinational OASIS cohort was assessed. The available instruments for pain assessment were: i) total spinal pain, ii) spinal pain at night, iii) spinal pain from BASDAI Q2 (addressing neck, back or hip pain); and for morning stiffness: i) severity of morning stiffness (BASDAI Q5), ii) duration of morning stiffness (BASDAI Q6), iii) the combined score between severity and duration of morning stiffness (average BASDAI Q5/6). Data from 8 year-visit were used as the first time-point where all the instruments were obtained on a 0–10 numeric rating scale (as currently used). The discriminatory capacity was assessed through the standardised mean difference (SMD) that is calculated as the difference of the group means divided by the pooled SD of the group means, with a higher value reflecting a higher discriminatory capacity. The external constructs used to compare the ability to discriminate between subgroups of patients were: ASDAS, BASDAI (dichotomized into inactive/active disease), PGA, PhGA, fatigue, BASFI, BASMI and mSASSS (dichotomized by the median).

Results: 98 patients were included: 71% males, mean age 54 (SD 11), with a mean symptom duration of 31 (11) years. The mean scores for pain were 3.7 (2.3), 2.9 (2.3) and 4.6 (2.6) for spinal pain, spinal pain at night and BASDAI Q2, respectively. The mean scores of morning stiffness were 3.7 (2.6), 3.3 (3.1) and 3.5 (2.7) for BASDAI Q5, Q6 and Q5/6, respectively. Spinal pain by BASDAI Q2 and total spinal pain had higher SMDs compared to spinal night pain across all group comparisons, with spinal pain BASDAI Q2 performing mostly slightly better (Table). Regarding morning stiffness, the severity question (BASDAI Q5) had consistently higher SMDs across all the clinical external constructs, while duration of morning stiffness (BASDAI Q6) performed worse.

Conclusion: Spinal pain from BASDAI Q2 and severity of morning stiffness (BASDAI Q5) are, respectively, the pain and morning stiffness instruments that best discriminate subgroups of patients classified according to disease activity, functional ability, fatigue or spinal mobility. The recommended ASAS COS pain instrument spinal pain BASDAI Q2, was confirmed to discriminate best. In the case of stiffness, the ASAS COS stiffness measure (BASDAI Q5/6) performed well although slightly less than the severity of morning stiffness (BASDAI Q5).

Table. Discrimination between subgroups of patients

Assessment measure	ASDAS <2.1 vs ≥2.1 SMD	BASDAI <4 vs ≥4 SMD	Fatigue <5 vs ≥5 SMD	BASFI <4 vs ≥4 SMD	BASMI <4 vs ≥4 SMD	mSASSS <15 vs ≥15 SMD
Total spinal pain	1.57	1.92	1.62	0.92	0.27	-0.32
Spinal night pain	1.07	1.39	1.27	0.78	0.07	-0.20
Spinal pain BASDAI Q2	1.88	2.37	1.65	0.89	0.31	-0.29
Morning stiffness severity BASDAI Q5	1.52	2.14	1.58	0.99	0.26	-0.11
Morning stiffness duration BASDAI Q6	1.18	1.80	1.09	0.83	0.09	-0.14
Morning stiffness average BASDAI Q5/6	1.40	2.14	1.38	0.95	0.17	-0.13

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Depending on leading manifestation, Spondyloarthritis (SpA) is classified as axial (axSpA) or peripheral SpA (pSpA). Achieving of remission/inactive disease is key goal in treatment of SpA, including pSpA. Results from recent worldwide ASAS PerSpA study showed that nearly 10% of SpA patients were identified as having pSpA (as opposed to other forms of SpA) by rheumatologist, but there are still no long-term observational studies focusing on outcomes including

Figure. Multivariable GEE analyses show associations between parameters and outcomes A) DAPSA, B) ASDAS, and C) Clinical remission

disease activity/remission in pSpA. The aim of this study is to investigate factors associated with disease activity and achievement of remission over a period of up to 10 years of clinical observation in early pSpA patients.

Methods: Data from patients diagnosed with pSpA in GESPIC (with predominant peripheral manifestations, symptom duration of up to 5 years and not classified as axSpA) according to rheumatologist were used for this study. Visits were scheduled every 6 months for 2 years, then annually up to year 10. Clinical characteristics, examination (arthritis, enthesitis), and activity (questionnaires and laboratory) were collected at visits. Association between parameters and disease activity/remission [defined by Disease Activity in Psoriatic Arthritis (DAPSA), Axial SpA Disease Activity Score (ASDAS), and clinical remission (complete absence of arthritis or enthesitis)], was analysed by generalized estimating equations (GEE).

Results: The mean age of 115 pSpA patients (51.3% male) was 37.3 ± 12.2 years, and 71 (61.7%) patients were HLA-B27 positive. Baseline DAPSA and ASDAS were 13.3 ± 8.1 and 2.4 ± 0.9. During follow up 48 (41.7%), 46 (41.7%), and 94 (81.9%) patients reached at least once DAPSA remission (DAPSA < 4), ASDAS-Inactive disease (ASDAS< 1.3), and clinical remission, respectively. In univariable analyses, female sex, older age, HLA-B27 negativity, current and history of psoriasis, steroid, csDMARDs and higher NSAID intake were associated with higher DAPSA and lower odds of remission. Similar results were observed regarding ASDAS and clinical remission (Table). Multivariable analyses showed that history of psoriasis, HLA-B27 negativity, steroid intake, and higher NSAID intake were associated with higher DAPSA and ASDAS scores (Fig A,B), while longer symptom duration, psoriasis history, steroid, TNFi and higher NSAID intake, and higher CRP were associated with lower odds of remission (Fig C).

Conclusion: Several parameters associated with higher disease activity and absence of remission were identified. Psoriasis and higher CRP were associated with lower odds of achieving clinical remission, while an association with drug usage is likely a consequence of high disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic inflammation is closely associated with an increased risk of cardiovascular diseases (CVD) through the activation of the immune system and the release of inflammatory molecules like C-reactive protein (CRP). In Spondyloarthritis (SpA), prolonged inflammation can harm the vascular system, further raising the likelihood of developing CVD. Currently, there is a lack of tools available to identify patients who had persistent inflammation and its connection to CVD. The aim of this study was to analyze the clinical and molecular characteristics associated with persistent inflammation and to identify potential plasma protein biomarkers for an easy identification of patients with prolonged inflammation over the years in SpA patients

Methods: A study involving 136 patients diagnosed with SpA was conducted. Clinical and laboratory parameters, as well as CVD risk factors were recorded. To assess the presence of persistent inflammation, levels of CRP were retrospectively collected for a period of 5 years. A patient was classified as having persistent inflammation if increased CRP levels were detected in at 100% of the measurements taken during the preceding 5-year timeframe. Radiographs of the cervical spine, lumbar spine, and sacroiliac joints were obtained. Lateral views of the cervical and lumbar spine were scored according to the mSASSS index. Sacroiliitis was scored from right side and left side pelvic radiographs using the modified New York criteria. The plasma levels of 92 proteins related to CVD were analyzed using proximity extension assay (PEA) technology (Olink Target 96 CVD III panel, Cobiomic Biosciences).

Results: 36% of SpA patients had persistence of inflammation. Clinically, these patients showed higher levels of disease activity (ASDAS), peripheral forms, structural damage (mSASSS), acute phase reactants, altered metabolic profile, activation of complement component and higher rates of cardiometabolic comorbidities compared to non-persistent SpA patients. At molecular level, 16 CVD-related plasma proteins were significantly associated with presence of persistence of inflammation: MMP-9, RETN, PGLYRP-1, UPAR, PRTN-3, TR, RARRES-2, AZU-1, GP-6, TNF-R1, MPO, GDF-15, CCL-16, IL-2RA, PI3 and PDGF. The most contributing proteins to differentiate groups of SpA patients with persistent and non-persistent inflammation were MMP-9, RETN, PGLYRP-1 and UPAR. The combination of these proteins could predict the presence of constant persistent inflammation with an AUC=0.865. These proteins exhibit specific biological functions such as neutrophil degranulation, immune response, leukocyte migration and apoptosis.

Conclusion: 1) persistent inflammation over five years was associated with peripheral forms, increased disease activity and radiographical damage in SpA patients. 2) SpA patients with persistent inflammation display a pronounced alteration in their plasma CVD protein profile, indicating a connection between subclinical CVD risk and chronic inflammation. 3) we identified novel biomarkers that have the potential to differentiate SpA patients with persistent inflammation, offering valuable insights for therapeutic approaches.

Association Spondyloarthritis and Inflammatory Bowel Disease, More Severe Diseases on Both Sides

Juliane Michel[1], Clément Prati[2], Lucine Vuitton[3], Eric Toussirot[4], Charline Vauchy[5], Daniel Wendling[6] and frank Verhoeven[2], [1]Rheumatology, CHU Besancon, Besançon, France, [2]Service de rhumatologie, CHU de Besançon, Besançon, France, [3]Gastroenterology, CHU Besancon, Besançon, France, [4]University Hospital of Besancon, Besançon, France, [5]INSERM CIC-1431, Besançon, France, [6]Besançon University Hospital, Besançon, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a pathophysiological link between spondyloarthritis (SpA) and Inflammatory Bowel Disease (IBD), so that 10% of IBD is estimated to have SpA and 10% of SpA is estimated to have IBD. Recently, Luchetti *et al* demonstrated an increased level of bacterial translocation in cases of co-diagnosis of SpA and IBD compared to patients with IBD alone. These data suggest that coexistence of IBD with SpA is associated with more inflammation and therefore more active diseases. The aim of this study is to describe and to evaluate the characteristics of this population in comparison with SpA and IBD alone.

Methods: A single-centre retrospective observational study was conducted. We included all consecutive patients followed between 2019 and 2022 for spondyloarthritis (SpA) meeting the ASAS 2009 criteria and IBD histologically proven. For each patient, we collected demographics, smoking, extrarticular manifestations, imaging data and the number of bDMARDs used. We compare these patients with single diagnosis patients from the MISTIC cohort. The MISTIC cohort, a monocentric cohort, included 2000 patients aged 18–80 years who had SpA, rheumatoid arthritis or IBD and who were regularly followed-up. The MISTIC cohort was approved by the appropriate ethics committee and was conducted according to good clinical practice guidelines. Fischer's exact test was used for comparison between categorical variables and Student's t test for quantitative variables.

Results: A total of 62 patients with SpA/IBD, 51% male and 67% HLA B27+, were included (table). In 61% of the cases, IBD was diagnosed first, mainly Crohn's disease (68%), with a mean age at diagnosis of 31.1 (±15.6) years. Concerning SpA, it was mostly axial (95%), with radiographic sacroiliitis (55%) and with a mean age at diagnosis of 36.8 (±13.4) years. Patients

Table : patients characteritics

	SpA/IBD (n=62)	SpA (n=100)	IBD (n=100)	P value
Gender (% male)	51%	58%	54%	0.5
Age at diagnosis of IBD	**35.7 (±12.9)**		**31.1 (±15.6)**	**0.05**
Age at diagnosis of SpA	**36.8 (±13.4)**	**32.4 (±10.8)**		**0.02**
Disease duration IBD (years)	17.1 (±10.5)		14.5(±10.6)	0.13
Disease duration SpA (years)	14.0 (±9.84)	15.2 (±11.7)		0.17
HLA B27+	**63%**	**80%**		**0,002**
axSpA	95%			1
Number of bDMARDs	**2.8 (±1.7)**	**2 (±1.15)**	**1.65 (±0.8)**	**0.01**
Association bDMARDs	9.5 %			
Psoriaisis	**27%**	**17%**	**20%**	**0.04**
uveitis	**27%**	**18%**	**1%**	**0.087**
Sacroiliitis (Rx)	**55%**	**70%**		**0.24**
Syndesmophytes (Rx)	27%	27%		1
Crohn disease	68%		68%	1
Smoking	66%	44.9%	51.5%	0.01
Physical work	20%			
HBI score at diagnosis	**8.2 (±5.7)**		**2.6 (±3.1)**	**0.0006**
HBI score at last cinsultation	**4.2 (±3.4)**		**2.4 (±2.5)**	**0.0074**

had used an average of 3 bDMARDs and 10% were treated with a combination of bDMARDs. When comparing patients with SpA/IBD to those with a single diagnosis of SpA patients were older at diagnosis (36.8 (±13.4) VS 32.4 (±10.8) years old; p= 0.02), had more uveitis (27% VS 18%, p= 0.08) and psoriasis (27% VS 17%, p= 0.04), were more smoker (66% VS 44.9%; p= 0.01) but less HLA B27 positive (63% VS 80%, p= 0.002). They used more bDMARDs for the same disease duration (2.8 (±1.7) VS 2 (±1.15); p= 0.01). When comparing patients with a co-diagnosis to those with a single diagnosis of IBD, patients were older at diagnosis (35.7 (±12.9) VS 31.1 (±15.6) years old; p=0.05), had more uveitis (27% VS 1%, p= 0.08) and psoriasis (27% VS 20%, p= 0.04), were more smoker (66% VS 44.9%; p= 0.01). They used more bDMARDs for the same disease duration (2.8 (±1.7) VS 1.65 (±0.8); p= 0.01). Interstingly, patients with a codiagnosis have a higher endoscopic severity score (HBI) at diagnosis (8.2 (±5.7) VS 2.6 (±3.1) p= 0.0006) and at last follow-up (4.2 (±3.4) VS 2.4 (±2.5); p= 0.0074).

Conclusion: The population of patients with a co-diagnosis of SpA and IBD is a more severe both on the rheumatological and intestinal side. This population showed more frequent extraarticular manifestations and represent a cluster more difficult to treat.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Sleep problems are prevalent in 30-70% of patients with axial Spondyloarthritis (SpA), negatively impacting their quality of life. Poor sleep quality in these patients has been associated with reduced exercise tolerance, worsened pain and fatigue, decreased functional status, and compromised response to therapy. While previous studies have

Correlation coefficients between the PSQI and demographic, clinical variables and PROs and index of disease activity, functionality, and Metric indices

explored the determinants of sleep problems in axial SpA patients, our study is the first in India to assess sleep quality and its components, as well as the influence of various factors on sleep in this population.

Methods: This prospective, cross-sectional study was conducted from March 2021 to September 2022 at the Department of Rheumatology, Indraprastha Apollo Hospital, Delhi. A total of 119 axial SpA patients participated, and sleep quality was measured using the PSQI questionnaire. Bivariate correlations were performed to examine the relationships between sleep quality (PSQI score) and various factors, including age, gender, disease duration, inflammatory markers, quality of life, disease activity, functionality, spinal mobility, anxiety, depression, fatigue, pain, socioeconomic status, and biological usage. Significant variables were included in a multiple linear regression model. Additionally, univariate analysis compared baseline variables and disease activity between patients with good sleep quality (PSQI < 5) and poor sleep quality (PSQI ≥ 5).

Results: Among the participants, 53% experienced poor sleep quality, with a mean global PSQI score of 5.54±4.03. As many as, 73% were not receiving treatment for insomnia. Patients with poor sleep quality had significantly higher scores across all seven dimensions of the PSQI. Sleep latency and subjective sleep quality were the most affected components, while the use of sleep medication was the least affected. Factors associated with poor sleep quality included older age, longer disease duration, smoking, radiographic evidence of sacroiliitis, hip disease, elevated inflammatory markers, low back pain, fatigue, high disease activity, poor functional status, increased spinal mobility limitation, anxiety, and depression (table 1). Gender, socioeconomic status, use of conventional DMARDs and biological therapy, enthesitis, and daytime sleepiness did not significantly influence sleep quality. Multivariate analysis revealed that limitations in spinal and hip mobility (OR: 3.76 [1.53-9.24]), fatigue (OR: 1.99 [1.27-3.11]), and depression (OR: 1.63 [1.10-2.41]) were independent risk factors for poor sleep quality.

Conclusion: Our study highlights the high prevalence of poor sleep quality in patients with axial SpA, despite limited utilization of insomnia treatments. Emotional factors such as fatigue and depression, as well as limitations in spinal and hip mobility, were identified as contributors to sleep problems in these patients. The complex relationship between sleep quality, emotional disorders, and disease activity underscores the importance of a multidisciplinary approach to managing axial SpA.

Difficult to Treat Axial Spondyloarthritis. Predictors of Poor Outcomes

FERNANDO MONTERO[1], Laura Berbel Arcobé[2], Karen Carpio Astudillo[1], Jose Maria Bellón[3] and Xavier Juanola Roura[4], [1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]H.U. Bellvitge, Barcelona, Spain, [3]Gregorio Marañón Health Research Institute, Madrid, Spain, [4]Hospital Universitari de Bellvitge, Barcelona, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The term "Difficult-to-Treat" (D2T) defines those patients who remain active despite having undergone various treatments within the established recommendations. This concept is defined by EULAR for rheumatoid arthritis (RA)[1], and is yet to be presented in axial spondyloarthritis (ax-SpA) by the ASAS group, although it is proposed by some studies as those who require three or more biological drugs[2].

Table 1. Proposal of an extrapolated definition of D2T ax-SpA.	
To be classified as D2T the patient must meet one of the following:	
1. Treatment as recommended and failure of ≥ 4 b/tsDMARD or;	
2. Treatment as recommended and failure of ≥ 3 b/tsDMARD regardless of the MoA and evidence of disease activity.	
3. Treatment as recommended and failure of ≥ 2 b/tsDMARDs with different mechanisms of action and evidence of disease activity.	
Evidence of disease activity defined as:	ASDAS-CRP ≥ 2.1
	BASDAI ≥ 4/10
b/tsDMARD: Biologic and targeted synthetic disease-modifying antirheumatic drugs. D2T ax-SpA: Difficult-to-treat axial spondyloarthritis. MoA: Mode of Action.	

Our objectives are to determine the prevalence of D2T-ax-SpA in our Spondyloarthritis hospital registry cohort and to determine predictive factors prior to first b/ts DMARD in D2T-ax-SpA patients.

Methods: Single-center, retrospective study using a longitudinal cohort of patients with ax-SpA from a third level hospital registry in Cataluña who met the criteria for axial spondyloarthritis according to ASAS, from January 2000 to September 2022 and had a follow-up of more than 6 months with valid baseline information.

Sociodemographic, clinical, radiographic and treatment variables were collected. Patients in our study were classified as D2T according to a series of variables to achieve the most specific definition (Table 1). The comparator group included patients with axial spondyloarthritis with use of at least one b/tsDMARDs and who did not meet our D2T criteria.

For the bivariate analysis, the categorical variables were analyzed using the chi-square test and Fisher's test, the quantitative variables through the student's t test and U Mann Whitney.

For the multivariate analysis, we used logistic regression using imputations of missing values through a multiple imputation by chained equations.

Results: Five hundred and ten patients met the ASAS criteria for the diagnosis of AxSpA, 161 of whom had received treatment with at least one ts/bDMARD. Thirty-four (21.12%) met our definition of D2T, of which 55.9% were men, mean age 59.82 years (+/- 10.13).

No significant differences were found in the presence of comorbidities such as arterial hypertension, hyperlipidemia, diabetes mellitus, ischemic heart disease, and cerebrovascular disease. Nor in disease activity index or clinical manifestations such as uveitis, inflammatory bowel disease, enthesitis, arthritis, dactylitis. These results are summarized in Table 2.

Female sex (p= 0.0083), presence of psoriasis (p= 0.0007), onset as psoriatic axial spondyloarthritis (p= 0.0096) were found as risk factors for D2T AxSpA (Table 2). These findings were confirmed in the multivariate analysis (Table 3).

We also found a tendency to greater cervical involvement (SASSSmCC p= 0.025; BASRI CC p= 0.069; FLECHE p= 0.061), and being an active smoker in these patients, although this could not be demonstrated in the multivariate analysis.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The cross-sectional REGISPONSER study was conducted in 2004 in 31 centers from Spain, including a total of 2367 patients who met the European Spondyloarthropathy Study Group (ESSG) criteria for Spondyloarthritis (SpA). To date, the evolution/progression of SpA is not clearly defined due to the significant heterogeneity in the clinical profiles of patients and the challenges of conducting long-term prospective studies. Therefore, in this REGISPON-3 study, patients who participated in REGISPONSER from 8 out the 31 centers were reevaluated in a single visit 17 years after their initial assessment in REGISPONSER. The objective of this study is to describe, 17 years later, the confirmation or not of the initial diagnosis, clinical and radiographic evolution/progression, treatments used, and disease burden of these patients.

Methods: This is a longitudinal and multicenter study in which the REGISPONSER dataset has been combined with the REGISPON-3 data. In a single face-to-face visit, the following is carried out: a) interview with the patient; b) physical examination; c) plain X-ray of the spine, sacroiliac and hip; d) blood sample. Firstly, a descriptive analysis has been carried out to evaluate the change in the diagnosis of the patients 17 years later. The different treatments used in REGISPONSER and subsequently in REGISPON-3 have been described. Among the deceased patients, the different causes of death and diagnoses have been analysed. Finally, the average age of death has been calculated. The study was carried out in accordance with the Good Clinical Practice guidelines and after approval of the Ethics Committee in each center.

Results: From the total patients evaluated in REGISPONSER in the 8 participating centers (n=1151), we were able to recruit 437 patients (37.9%), of whom 339 were alive and 83 deceased. Table 1 shows the description of the REGISPONSER diagnoses and how they have changed 17 years later. Interestingly, among the 59 patients with undifferentiated SpA,

Rituximab	0/355 (0)	3/306 (0.9)
Vedolizumab	0/355 (0)	2/306 (0.6)

37 developed r-axSpA, 9 nr-axSpA and 4 finally did not have SpA. Table 2 shows the treatments used in REGISPONSER and later in REGISPON-3. In general, the use of biologics increased after 17 years in the REGISPON-3 study. Among the 83 patients who died, the most frequent causes were infection (29.3%), cardiovascular (CV) events (24%), and cancer (22.7%). The mean age of death was 72.6 (10.1) years. The most frequent diagnoses of deceased patients were axial SpA (AxSpA) (69.1%), psoriatic arthritis (PsA) (19.8%) and axial PsA (AxPsA) (4.9%).

Conclusion: This study shows the preliminary results of the REGISPON-3 project. It has been observed that over the years some diagnoses changed and there are even patients whose diagnosis is not confirmed. The treatments have also evolved with a greater use and a greater variety of biological treatments, which has allowed to improve the prognosis of the disease. Finally, the causes of death in SpA have been studied, being infection, CV events and cancer the most frequent causes.

Funding: This work was supported by grants from the Spanish Institute of Health Carlos III (PMP21/00119 and RICOR-RD21/0002/0033).

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster III: SpA
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The definition for early spondyloarthritis (SpA) implies the correct identification of the initial symptom of SpA. There is currently no consensus on whether only musculoskeletal manifestations (MM) or also extra-MM (EMM) should be considered as the onset of SpA.

Objectives: a) To describe the initial symptom (either MM or EMM) in the different SpA subtypes; b) to describe the initial symptom stratified by the clinical diagnosis and by the presence of HLA-B27; c) to analyze the clinical factors associated with different forms of initiation.

Methods: Observational, cross-sectional and multicenter study, including patients with a diagnosis of SpA (Ankylosing Spondylitis (AS), AS associated with Psoriasis (AS-Pso), AS associated with Inflammatory Bowel Disease (AS-IBD), Psoriatic Arthritis (PsA), Reactive Arthritis (ReA), Juvenile Spa (Juv-SpA), Arthritis associated with IBD (A-IBD) and undifferentiated SpA (u-SpA)) from REGISPONSER and RESPONDIA registries. Investigators responses to the question "Indicate the first sign or symptom attributable to the disease" have been recorded. The date of appearance of each MM and EMM feature was collected, allowing to determine the first symptom(s) in each patient. Differences in the first symptom across diagnosis and between HLA-B27 carriers were compared using the chi-square test. Finally, factors associated with the most prevalent initial symptom were evaluated.

Results: A total of 4411 patients were included. AS (54.9%), PsA (18.7%) and uSpA (11.1%) were the most prevalent diagnosis. In the overall population, low back pain (60.3%) was the most prevalent initial symptom followed by buttock pain (35.3%) and lower limbs arthritis (39.9%). The percentage of patients who started the disease with each symptom according to the diagnosis is represented in Figure 1.

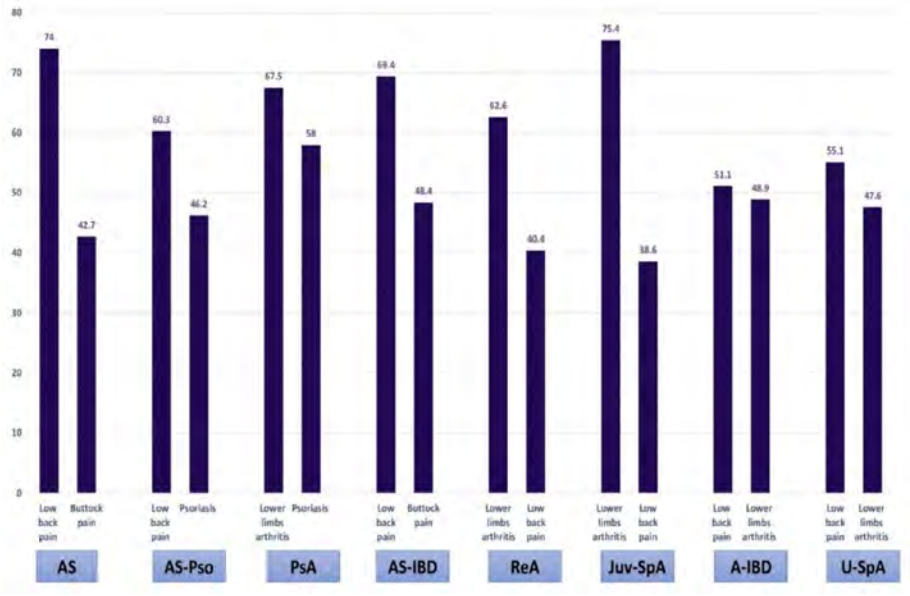

Figure 1: Description of the first symptoms according to the SpA diagnosis.

In AS patients, the absence of HLA-B27 lead to an increment in the probability of initiating the disease with cervical pain (25.6% vs. 15.5%), enthesitis (18.8% vs. 12.4%) and coxitis (15.7% vs. 8.4%) in comparison with HLA-B27 positives. In PsA, the initiation with upper limb arthritis (61% vs. 38.4%) and psoriasis (62.1% vs. 37%) was more prevalent in HLA-B27 negatives, while the initiation with low back pain (22.1% vs. 38.4%) and buttock pain 13.6% vs. 28.8%) was more prevalent in HLA-B27 positives. In AS-Pso, the absence of HLA-B27 was more frequently associated with peripheral features and psoriasis as first symptom.

In the whole population, factors associated with cervical pain vs. low back pain as first symptom were cutaneous psoriasis, negative HLA-B27 and peripheral involvement (arthritis, enthesitis and dactylitis). On the other hand, factors associated with upper limbs arthritis vs. lower limbs arthritis as first symptom were female gender, cutaneous psoriasis, HLA-B27 negative and absence of axial symptoms.

Conclusion: In this SpA population, the most prevalent initial symptoms were musculoskeletal, with differences across diagnosis and depending on the presence of HLA-B27 antigen. In AS patients the absence of the HLA-B27 seems to be associated with cervicalgia and peripheral involvement as first symptom, while in PsA it was associated with upper limbs involvement as initial symptom.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Smoking has been associated with higher disease activity, poorer treatment response, and drug retention rate among psoriatic arthritis (PsA) patients treated with Tumor Necrosis Factor inhibitors. However, few studies have investigated the impact of smoking on secukinumab (an IL17A inhibitor) treatment outcomes. In this study, we therefore aimed to investigate the association between smoking status and 12-month secukinumab retention rate in patients with PsA treated in routine care.

Methods: Patients with PsA, initiating secukinumab between January 1st, 2015 and December 31st, 2020, with available smoking data were identified in 10 European registries participating in the European Spondyloarthritis Research Collaboration Network (EuroSpA RCN). Patients were stratified according to their smoking status (never/former/current) at treatment start (baseline). Kaplan-Meier estimation with log-rank tests and Cox regression with hazard ratios (HR) were performed to assess and compare 12-month secukinumab retention rates. Three regression models were assessed: Model A) unadjusted analyses, Model B) adjusted for baseline age and gender and Model C) further adjusted for registry, time since

Table 1 Baseline characteristics of never, former, and current smokers.

	Never smoked N = 778	Former smoker N = 535	Current smoker N = 371	Data availability n(%)
Patient age, years	53 (44-60)	52 (45-60)	50 (41-57)	1683 (100)

Number of previous b/tsDMARDs: 0/1/≥2	30%/25%/45%	26%/22%/52%	25%/27%/48%	1684 (100)

Data are as observed, median (IQR) or percentage. Pooled data from 11 registries participating in the EuroSpA Research Collaboration Network. b/tsDMARD, biologic/targeted Disease-Modifying Antirheumatic Drug; BMI, Body Mass Index; CRP, C-reactive protein; DAS28, Disease Activity Score in 28 joints; DAPSA Disease Activity index for PSoriatic Arthritis; DAPSA28, Disease Activity index for PSoriatic Arthritis in 28 joints; HAQ, Health Assessment Questionnaire; IQR, Interquartile Range; N, number of patients in cohort; n, total number of patients with available data; PGA, Patient Global Assessment; PhGA, Physician Global Assessment

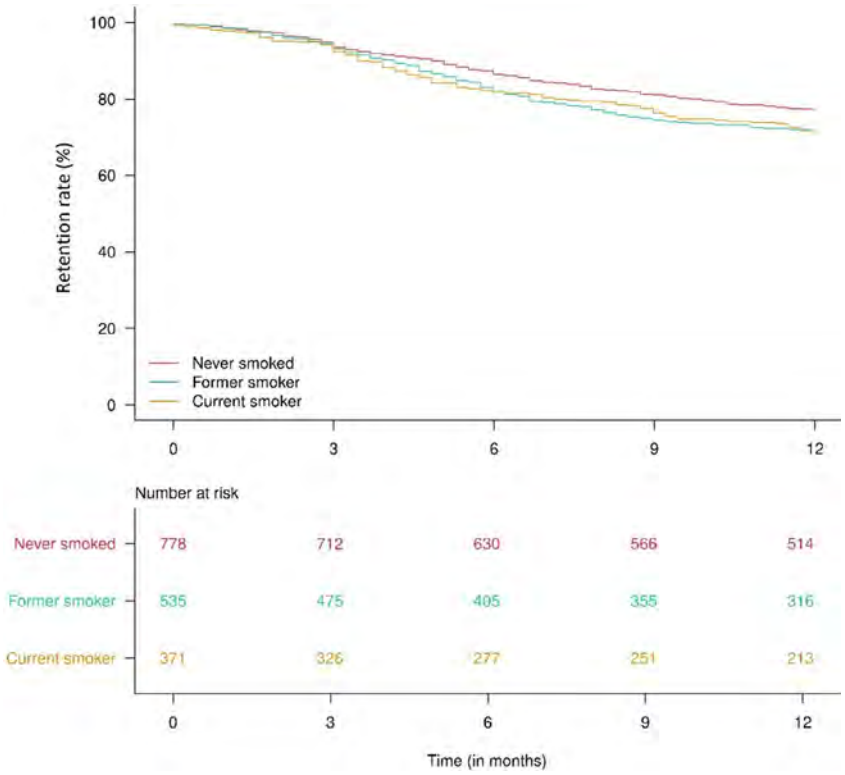

Figure 1 Kaplan-Meier curves of 12-months secukinumab retention rates in PsA patients according to smoking status (Log-rank test, p=0.039).

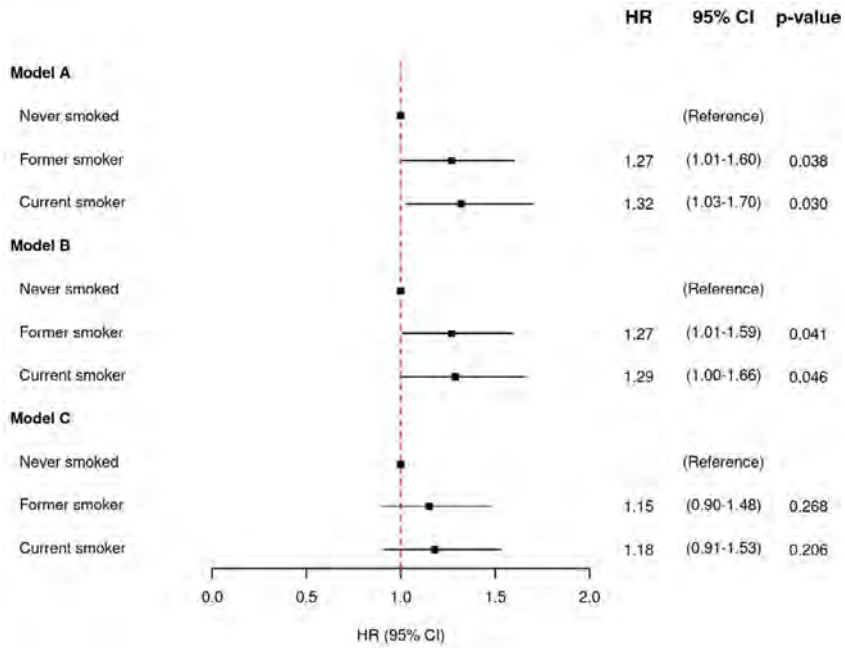

Figure 2 Secukinumab retention rates at 12-months according to smoking status. Forest plots of Cox regression analyses.

diagnosis, and line of treatment with biologic/targeted disease-modifying antirheumatic drugs(b/tsDMARD). Missing baseline covariates were imputed using multiple imputation with chained equations.

Results: Of 2,325 patients starting secukinumab treatment, 1,684 had available data on smoking status and were included. At baseline, never smokers compared to former and current smokers were older and scored higher in Disease Activity index for PSoriatic Arthritis in 28 joints (DAPSA28), C-reactive protein (CRP), and Physician Global Assessment, table 1. The 12-month retention rates were 77%, 72% and 71% among never, former, and current smokers, respectively, figure 1. For both former and current smokers, the hazard rates of withdrawal were significantly higher compared to never smokers in unadjusted, and in age and gender-adjusted analyses, figure 2. A similar trend was found in the fully adjusted Model C (HR 1.15 (95% confidence interval 0.90-1.48) and HR 1.18 (0.91-1.53), respectively), figure 2.

Conclusion: In PsA, current and former smokers, who initiate secukinumab treatment appear at increased risk of withdrawing therapy within 12 months as compared to never smokers. Studies of effectiveness should include smoking status, and further studies are needed to investigate if smoking cessation improves treatment outcomes.

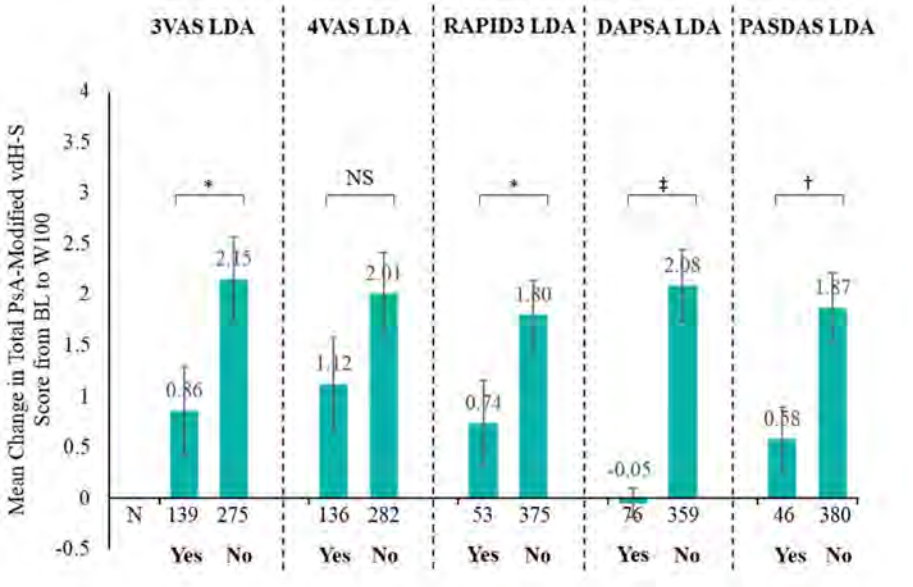
SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), a fully human IL-23p19 subunit inhibitor, was shown to reduce mean changes in radiographic progression vs placebo (PBO) by week (W)24 and to be associated with low rates of radiographic progression through W100 among GUS-treated patients (pts) with PsA, irrespective of dosing regimen (every [Q] 4W or Q8W). Furthermore, earlier clinical response predicted improved long-term radiographic outcome in GUS-treated pts with active PsA. The recently developed 3 Visual Analogue Scale (3VAS) and 4VAS scores are the first short multidimensional composite measures specifically for use in PsA routine clinical care. Here we determined whether early improvement in 3VAS/4VAS predicts radiographic change through W100.

Methods: DISCOVER-2 included bio-naive pts with active PsA (≥5 swollen and ≥5 tender joint counts [SJC/TJC]; CRP ≥0.6 mg/dL) randomized (1:1:1) to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W at W24. In the current analysis, only pts randomized to GUS (Q4W and Q8W) were included (N=493). Response at W8 was defined as achievement of low disease activity (LDA) in 3VAS (≤3.4), 4VAS (≤3.5), routine assessment of pt index data 3 (RAPID3; ≤6), Disease Activity in PsA (DAPSA; ≤14), and PsA Disease Activity Score (PASDAS; ≤3.2). Association of W8 response with change from baseline (BL) to W100 in total PsA-modified van der Heijde-Sharp (vdH-S) score was assessed with the independent samples t-test and generalized linear models adjusting for known BL determinants of radiographic progression (vdH-S score, age, gender, and CRP). Pairwise correlations and agreement in LDA classification between the endpoints were assessed with Pearson's correlation coefficient and the kappa statistic, respectively.



*p<0.05; †p<0.01; ‡p<0.001.
BL, baseline; DAPSA, disease activity in psoriatic arthritis; LDA, low disease activity; NS, not significant; PASDAS, psoriatic arthritis disease activity score; PsA, psoriatic arthritis; RAPID3, routine assessment of patient index data 3; VAS, visual analogue scale; vdH-S, van der Heijde-Sharp; W, week.

Mean Change in Total PsA-Modified vdH-S Score from BL to W100 by Achievement of LDA in Outcomes of Interest

Results: Among GUS-treated pts not meeting the respective endpoints at BL, 32.9%, 31.6%, 12.4%, 17.8%, and 10.8% achieved LDA in 3VAS, 4VAS, RAPID3, DAPSA, and PASDAS, respectively, at W8. LDA achievement in 3VAS (0.86 vs 2.15, p=0.03), RAPID3 LDA (0.74 vs 1.80, p=0.049), DAPSA LDA (-0.05 vs 2.08, p< 0.001), and PASDAS LDA (0.58 vs 1.87, p=0.006) at W8 were associated with significantly less radiographic progression through W100 **(Figure)**. For 4VAS, achievement of remission (≤2.1; 0.71 vs 1.84, p=0.045), but not LDA (1.12 vs 2.01, p=0.142), was also associated with improved radiographic outcome. In multivariate analyses, improved response to GUS treatment at W8 in all endpoints assessed was associated with numerically less radiographic progression through W100. At W8, 3VAS and 4VAS showed strong correlations with RAPID3 (r_{3VAS}=0.787; r_{4VAS}=0.877) and PASDAS (r_{3VAS}=0.795; r_{4VAS}=0.790) and moderate correlations with DAPSA (r_{3VAS}=0.466; r_{4VAS}=0.524), whereas fair to moderate agreement (kappa range: 0.325-0.545) in LDA classification was noted.

Conclusion: Approximately one-third of GUS-treated pts achieved early response (W8 LDA) in 3VAS/4VAS, which was associated with reduced rates of radiographic change, as was early response in the other outcomes assessed. These results suggest that, in addition to their usefulness in assessing disease activity in routine clinical care, 3VAS and 4VAS, the former being more sensitive, may predict long-term radiographic changes.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with mono/oligoarticular psoriatic arthritis (PsA), swelling or tenderness of specific joints can be associated with poorer patient-reported outcomes (PROs) and physician global assessment[1]. We hypothesize that location of affected entheseal points may also have differential impact on PROs or time to enthesitis resolution with guselkumab (GUS). The objectives of this post-hoc analysis were: (1) to describe the distribution of affected entheseal points in patients with active polyarticular PsA; (2) to evaluate the impact of anatomical location of enthesitis and Leeds enthesitis index (LEI) score on patient-reported pain (PtP), patient global assessment (PtGA), and functional status; and (3) to compare the time to resolution of each entheseal point following treatment with GUS.

Methods: This post-hoc analysis used pooled data from adults with active PsA, despite standard therapies, from the DISCOVER-1 and DISCOVER-2 studies who were randomized to GUS 100 mg every 4 weeks (Q4W) or at W0, W4, then Q8W. Only patients with baseline enthesitis were included (N=473). Proportions of patients with enthesitis were determined for each entheseal point assessed by LEI score. Longitudinal impact of LEI score and location of individual entheseal points on PtP, PtGA, and health assessment questionnaire disability index (HAQ-DI), upon adjusting for potential confounders (age, sex, body mass index, prior use of tumor necrosis factor inhibitors, baseline PsA duration, swollen joint count, tender joint count), was assessed with mixed models for repeated measures through W52. Time to resolution of enthesitis at each anatomical location was assessed with Kaplan-Meier survival analysis.

Results: Approximately half (49.5%) of GUS-randomized patients with baseline enthesitis had an LEI score of 1 or 2. The most commonly affected entheseal point was Achilles tendon insertion among both patients with baseline enthesitis and patients with an LEI score of 1 or 2. Through W52, higher baseline LEI score was associated with increased PtP, PtGA, and HAQ-DI scores (**Table**). Of the individual entheseal points assessed, enthesitis of Achilles tendon insertion had the

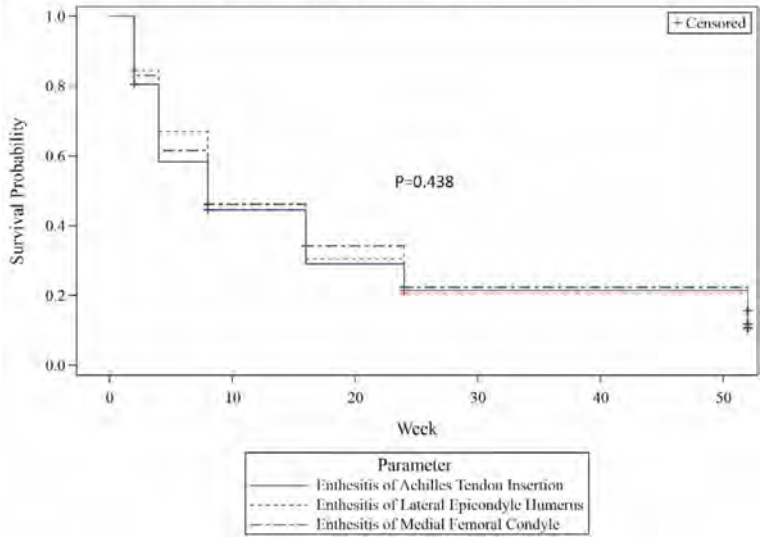
	2 vs. 0[¥]	0.3 (-1.4, 1.9)	2.0 (-0.2, 4.1)	0.02 (-0.01, 0.06)
	1 vs. 0[¥]	0.1 (-1.5, 1.8)	1.6 (-0.5, 3.7)	-0.02 (-0.05, 0.01)

[§]Parameter estimates correspond to the incremental increase in each PRO for 'Yes vs No', '2 vs 0', and '1 vs 0' or for every increase in LEI score by one unit.
[¥]Categories 'No' and '0' correspond to pts with BL enthesitis who do not have enthesitis of the individual entheseal point.
[*]p <0.05; [†]p <0.01; [‡]p ≤0.0001. Bold text=statistical significance.
BL, baseline; HAQ-DI, health assessment questionnaire disability index; LEI, Leeds enthesitis index; PRO, patient-reported outcome; PtGA, patient global assessment; PtP, patient-reported pain.

Figure. Time to Resolution of Enthesitis by Anatomical Location



greatest impact on all PROs and enthesitis of medial femoral condyle the least. Following GUS treatment, median time to enthesitis resolution was W8 for each of the three anatomical locations assessed by the LEI (**Figure**).

Conclusion: In this population of patients with active polyarticular PsA, Achilles tendon insertion was the most commonly affected entheseal point and more highly associated with worse PtP, PtGA, and functional status. GUS treatment was associated with rapid enthesitis resolution, including resolution of Achilles enthesitis.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has shown superior efficacy to 16 weeks (wks) vs placebo (PBO) and tolerability in patients (pts) with active PsA in the phase 3 BE OPTIMAL and BE COMPLETE studies.1,2 Efficacy of BKZ to 52 wks has also been demonstrated in the

Table. BKZ efficacy at Weeks 16 and 52 [NRI and MI]

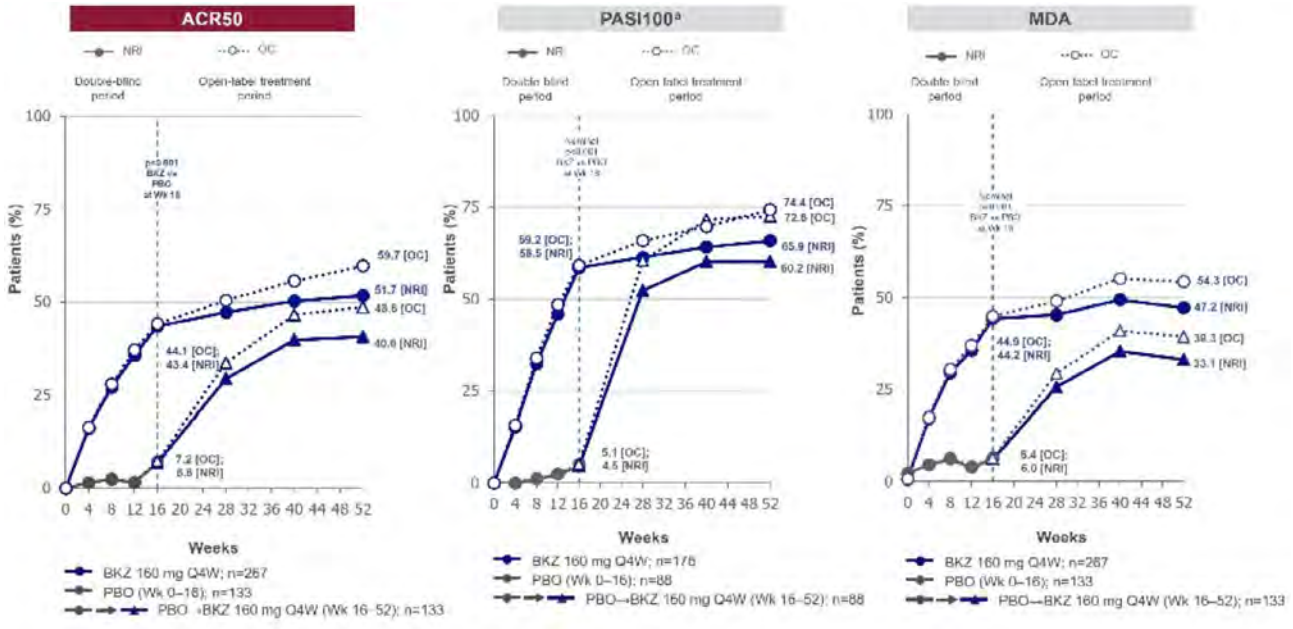
	Week 16		Week 52	
	PBO n=133	BKZ 160 mg Q4W n=267	PBO/BKZ 160 mg Q4W n=133	BKZ 160 mg Q4W n=267
ACR20 [NRI]	21 (15.8)	179 (67.0)	80 (60.2)	182 (68.2)
ACR70 [NRI]	1 (0.8)	71 (26.6)	34 (25.6)	95 (35.6)
PASI75[a] [NRI]	9 (10.2)	145 (82.4)	71 (80.7)	148 (84.1)
PASI90[a] [NRI]	6 (6.8)	121 (68.8)	65 (73.9)	131 (74.4)
MDA responder rate [NRI]	8 (6.0)	118 (44.2)	44 (33.1)	126 (47.2)
HAQ-DI CfB [MI], mean (SE)	−0.07 (0.04)	−0.38 (0.03)	−0.35 (0.05)	−0.39 (0.03)
mNAPSI resolution[b] [NRI]	12 (14.5)	73 (45.9)	51 (61.4)	107 (67.3)
Enthesitis resolution[c] [NRI]	8 (22.2)	52 (49.1)	21 (58.3)	60 (56.6)
Dactylitis resolution[d] [NRI]	6 (42.9)	24 (70.6)	12 (85.7)	29 (85.3)

Randomized set. n (%) unless otherwise specified. [a] In patients with psoriasis affecting ≥3% of body surface area at BL. [b] In patients with mNAPSI >0 at BL, PBO n=83, BKZ n=159; [c] In patients with LEI >0 at BL, PBO n=36, BKZ n=106; [d] In patients with LDI >0 at BL, PBO n=14, BKZ n=34. ACR20/70: ≥20/70% improvement in ACR criteria; BKZ: bimekizumab; HAQ-DI: HAQ – Disability Index; MDA: minimal disease activity; LDI: Leeds Dactylitis Index; LEI: Leeds Enthesitis Index; MI: multiple imputation; mNAPSI: modified Nail Psoriasis Severity Index; NRI: non-responder imputation; PASI: Psoriasis Area and Severity Index; PASI75/90: 75/90% improvement in PASI; PBO: placebo; Q4W: every four weeks; SE: standard error.

BE OPTIMAL study in biologic-naïve pts with PsA.3 Here, the efficacy and safety of BKZ treatment in pts with active PsA and prior inadequate response or intolerance to TNF inhibitors (TNFi-IR) are reported up to Wk 52 in the BE COMPLETE study.

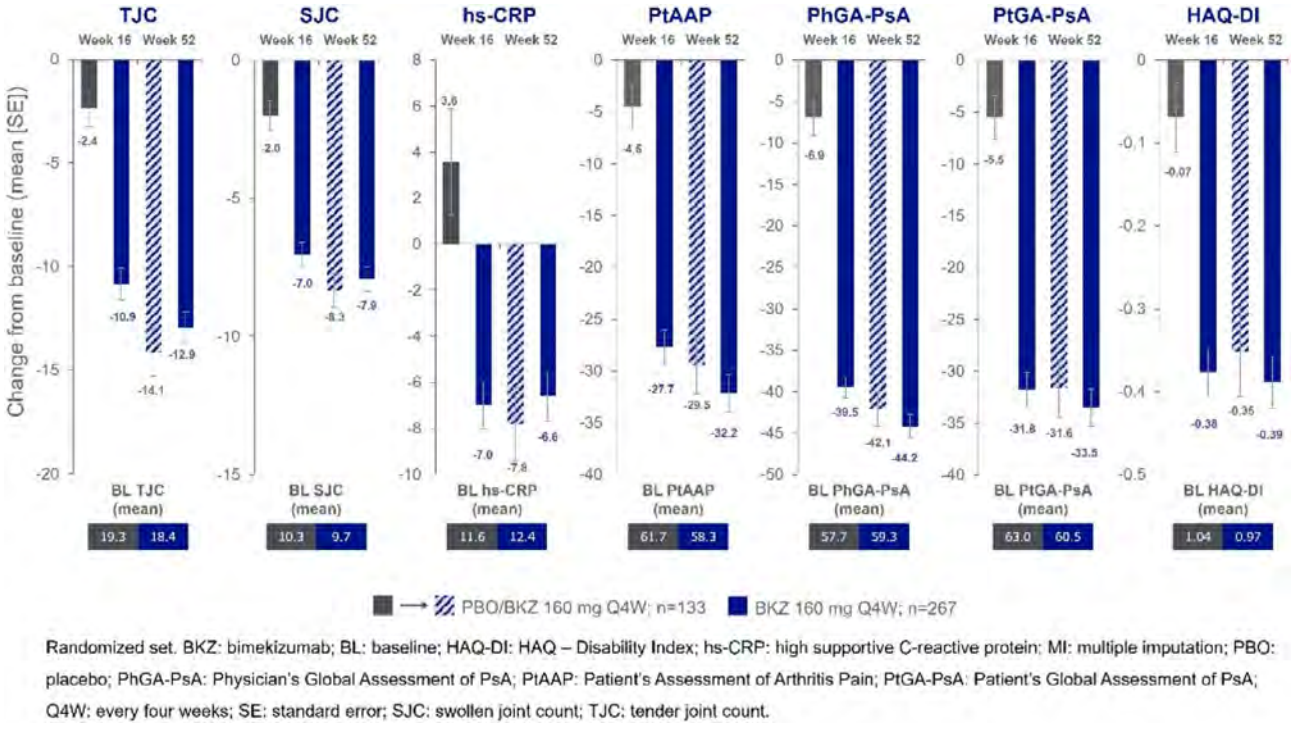
Methods: BE COMPLETE (NCT03896581) included a 16-wk double-blind, PBO-controlled period. Wk 16 completers were eligible for entry into BE VITAL (NCT04009499; open-label extension). Pts were randomized 2:1 to subcutaneous BKZ 160 mg every 4 wks or PBO. At Wk 16, PBO pts switched to BKZ (PBO/BKZ; received 36 wks of BKZ treatment up to Wk 52). BE VITAL included pts from BE OPTIMAL and BE COMPLETE; data here are for pts randomized at baseline (BL [Wk 0]) of BE COMPLETE only, up to 52 wks. Efficacy data are reported as observed case (OC) or using non-responder imputation (NRI; binary) or multiple imputation (MI; continuous). The number of treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ.

Results: 388/400 (97.0%) pts completed Wk 16; 377 (94.3%) entered BE VITAL and 347 (86.8%) completed Wk 52. Improved joint and skin efficacy responses with BKZ treatment were sustained from Wk 16 to Wk 52 (Table). At Wk 52, 138/267 (51.7%) of BKZ and 54/133 (40.6%) of PBO/BKZ pts achieved ACR50 (Figure 1). Improvements from BL in all ACR components were seen at Wk 16 and sustained to Wk 52 in BKZ-treated pts (Figure 2). In pts with BL psoriasis (≥3% body surface area), 116/176 (65.9%) of BKZ and 53/88 (60.2%) of PBO/BKZ pts achieved complete skin clearance (Psoriasis Area Severity Index [PASI]100) at Wk 52. At Wk 52, 126/267 (47.2%) of BKZ and 44/133 (33.1%) of PBO/BKZ pts achieved minimal disease activity (MDA; Figure 1). To Wk 52, 243/388 (62.6%) pts had ≥1 TEAE whilst receiving BKZ (exposure-adjusted incidence rate per 100 pt-years [EAIR/100 PY]: 126.0); 23 (5.9%) pts reported a serious TEAE (7.0/100 PY). Malignancies (excluding nonmelanoma skin cancers) were reported by 2 (0.7%) pts receiving BKZ (0.77/100 PY). Candida infections were reported by 25 (6.4%) pts receiving BKZ (7.7/100 PY); all were reported as mild or moderate by investigators and none were systemic. Two cases of oral candidiasis led to study discontinuation. There was one death (sudden death; pt with history of cardiac events), two adjudicated major adverse cardiac events and no definite or probable adjudicated inflammatory bowel disease.



Randomized set. [a] In pts with psoriasis affecting ≥3% of body surface area at BL. For binary variables, p values were obtained from logistic regression with treatment, prior TNFi exposure, and region as factors. Nominal p values are not powered or adjusted for multiplicity and should not be used to assess statistical significance. ACR50 responders using OC (n/Nsub) at Wk 16: BKZ 116/263, PBO 9/125; at Wk 52: BKZ 138/231, PBO/BKZ 54/111. PASI100 responders (OC: n/Nsub) at Wk 16: BKZ 103/174, PBO 4/79; at Wk 52: BKZ 116/156, Wk 52 PBO →BKZ 53/73. ACR50: ≥50% improvement in ACR criteria; BKZ: bimekizumab; MDA: minimal disease activity; NRI: non-responder imputation; OC: observed case; PASI: Psoriasis Area and Severity Index; PASI100: 100% improvement in PASI; PBO: placebo; Q4W: every four weeks; Wk: Week.

Figure 1. ACR50, PASI100 and MDA responses over time up to Week 52 [NRI and OC]



Randomized set. BKZ: bimekizumab; BL: baseline; HAQ-DI: HAQ – Disability Index; hs-CRP: high supportive C-reactive protein; MI: multiple imputation; PBO: placebo; PhGA-PsA: Physician's Global Assessment of PsA; PtAAP: Patient's Assessment of Arthritis Pain; PtGA-PsA: Patient's Global Assessment of PsA; Q4W: every four weeks; SE: standard error; SJC: swollen joint count; TJC: tender joint count.

Figure 2. Change from BL in the ACR components to 52 weeks [MI]

Conclusion: In pts with PsA and TNFi-IR, BKZ demonstrated sustained clinical efficacy from Wk 16 up to Wk 52. The safety profile was consistent with previous reports.1–3

Ixekizumab Significantly Improves Nail Disease and Adjacent Joint Tenderness and Swelling in Psoriatic Arthritis

Dennis McGonagle[1], Arthur Kavanaugh[2], Iain McInnes[3], Lars Erik[4], Joseph Merola[5], Bruce Strober[6], Rebecca Bolce[7], Jeffrey Lisse[7], Jennifer Pustizzi[7], Christophe Sapin[7] and Christopher T Ritchlin[8], [1]Leeds Teaching Hospitals NHS Trust, Academic Unit for the Musculoskeletal Diseases, Leeds, United Kingdom, [2]Division of Rheumatology, Allergy, and Immunology, University of California San Diego, La Jolla, CA, [3]University of Glasgow, Glasgow, United Kingdom, [4]Bispebjerg-Frederiksberg Hospital, Vedbæk, Denmark, [5]Harvard Medical School, Brigham and Women's Hospital, Newton, MA, [6]Yale University, New Haven, CT, [7]Eli Lilly and Company, Indianapolis, IN, [8]University of Rochester Medical School, Allergy, Immunology & Rheumatology Division, Canandaigua, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Nail psoriasis (PsO) is a strong predictor for the development of psoriatic arthritis (PsA) and has been reported in 63–83% of patients with PsA[1]. Psoriatic nails are linked to arthritis in the adjacent distal interphalangeal joint (DIP) of fingers or interphalangeal joint of thumbs[2], and both can lead to severe functional impairment. In the SPIRIT-H2H study of adults with PsA, 354 of 566 participants had nail PsO and adjacent joint disease in at least one digit at baseline[3-4]. At the group level, SPIRIT-H2H patients treated with ixekizumab (IXE) achieved significantly greater improvements in nail PsO compared to those treated with adalimumab (ADA)[5]. This analysis aimed to assess the treatment effects of IXE and ADA at the individual digit level among patients with PsA, nail PsO, and adjacent joint disease.

Methods: This post hoc analysis included 354 patients from SPIRIT-H2H (NCT03151551) treated with either IXE (N=186) or ADA (N=168) who had nail PsO (Nail Psoriasis Severity Index (NAPSI) total score >0) and adjacent joint disease (tenderness and/or swelling) in at least one digit at baseline. Treatment effects were assessed for each individual finger unit displaying nail PsO and adjacent joint disease; here, finger unit defines the nail and adjacent joint of an individual digit; adjacent joint refers to the DIP of fingers or the interphalangeal joint of thumbs. Nail PsO was measured using NAPSI in the fingers only. Joint involvement was measured by tender/swollen joint count scores (TJC68/SJC66). Patients were evaluated for both nail and joint involvement at baseline and Weeks 12, 16, 24, 32, 40, and 52. Proportions of finger units with resolution of nail PsO, and proportions of finger units with resolution of adjacent joint disease were analyzed using Chi-square tests. Non-responder imputation was used to handle missing data.

Table 1.
Baseline demographics and disease characteristics of patients treated with either IXE or ADA who had psoriatic arthritis with nail psoriasis and adjacent joint disease at baseline.

	IXE	ADA
Number of patients	186	168
Affected finger units (n)	639	670
Age, years	47.4 (11.8)	48.7 (12.5)
Male, n (%)	115 (61.8)	96 (57.1)
Duration of symptoms since PsA diagnosis, years	7.4 (7.8)	6.4 (6.7)
TJC68	20.5 (13.2)	22.6 (15.5)
SJC66	10.9 (7.6)	11.3 (8.9)
NAPSI, fingers only	19.5 (18.2)	19.3 (16.5)
PASI	8.6 (8.7)	8.9 (8.2)

Data are mean (standard deviation) unless stated otherwise.
Abbreviations: ADA=adalimumab; IXE=ixekizumab; NAPSI=Nail Psoriasis Severity Index; PASI=Psoriasis Area and Severity Index; PsA=psoriatic arthritis; SJC66=Swollen Joint Count, 66 joints; TJC68=Tender Joint Count, 68 joints.

Results: There were 1309 (IXE=639, ADA=670) finger units affected by nail and adjacent joint disease at baseline (Table 1). Resolution of psoriatic nail disease (Figure 1A) and resolution of adjacent tenderness and/or swelling (Figure 1B) of the finger unit was significantly higher with IXE vs ADA at all post-baseline assessments over 52 weeks. Joint tenderness was resolved in a significantly larger proportion of IXE-treated finger units vs ADA at all post-baseline assessments over 52 weeks (Figure 2A). Joint swelling was resolved in a larger proportion of IXE-treated finger units vs ADA, and these differences reached statistical significance at all visits except Week 16 and Week 40 (Figure 2B). The tenderness and/or swelling of the finger unit resolved more rapidly than the adjacent nail disease (Figure 1).

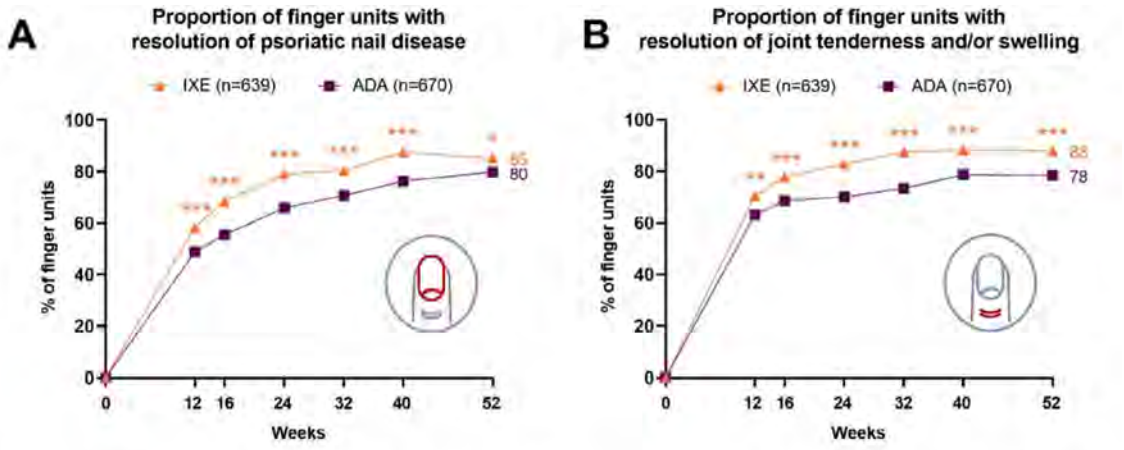

Figure 1. Proportion (%) of finger units with (A) resolution of psoriatic nail disease, and (B) resolution of joint tenderness and/or swelling, among patients treated with IXE or ADA who had psoriatic arthritis with nail psoriasis and adjacent joint disease at baseline.
Finger unit defines the nail and adjacent joint of an individual digit; adjacent joint refers to the DIP of fingers or the interphalangeal joint of thumbs. Data are nonresponder imputation mean. Significant difference between IXE vs ADA treatment denoted by *($p < 0.05$), **($p < 0.01$), and ***($p < 0.001$).
Abbreviations: ADA=adalimumab; IXE=ixekizumab.

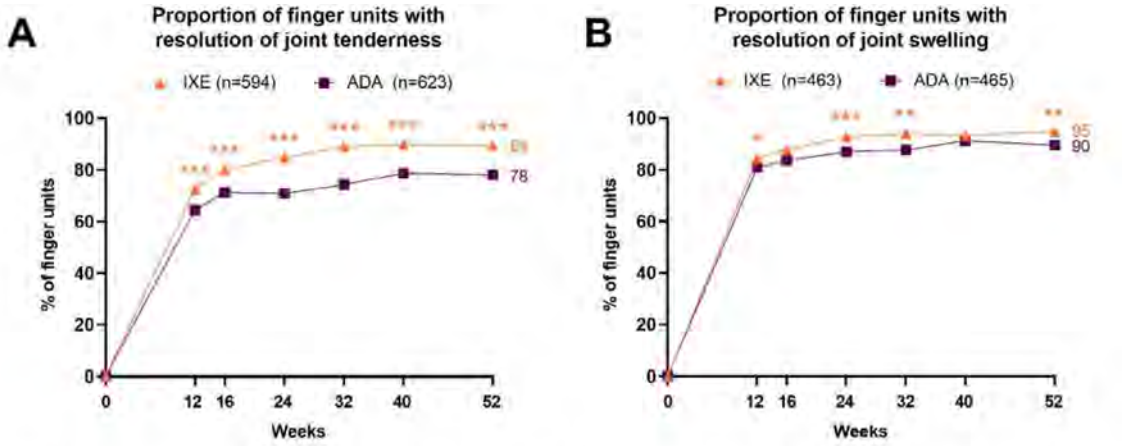

Figure 2. Proportion (%) of finger units with (A) resolution of joint tenderness, and (B) resolution of joint swelling, among patients treated with IXE or ADA who had psoriatic arthritis with nail psoriasis and adjacent joint disease at baseline.
Finger unit defines the nail and adjacent joint of an individual digit; adjacent joint refers to the DIP of fingers or the interphalangeal joint of thumbs. Data are nonresponder imputation mean. Significant difference between IXE vs ADA treatment denoted by *(p <0.05), **(p <0.01), and ***(p <0.001).
Abbreviations: ADA=adalimumab; IXE=ixekizumab.

Conclusion: IXE treatment showed a significant advantage over ADA in resolving nail PsO, joint tenderness, and joint swelling among the finger units with nail and adjacent joint disease of patients with PsA.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Monoclonal antibodies (mAbs) targeting the interleukin (IL)-23p19 subunit are effective in treating psoriatic disease; however, their molecular attributes may translate to differences in clinical efficacy. Guselkumab (GUS) is a fully human anti-IL-23p19 subunit IgG1 mAb with a native Fc region, whereas risankizumab (RZB) is a humanized anti-IL-23p19 subunit IgG1 mAb with a mutated Fc region. Binding of mAbs to Fcγ receptors (FcγRs) is of particular interest, because FcγRI (CD64)$^+$ IL-23–producing myeloid cells are increased within inflamed tissue of patients with psoriatic disease. Furthermore, in psoriatic arthritis, joint disease activity is positively correlated with the frequency of peripheral CD64$^+$ monocytes. Here, *in vitro* functional characteristics of the antigen-binding and Fc regions of GUS and RZB, as well as implications of CD64 binding for mAb function and IL-23 neutralization, were explored.

Methods: IL-23 binding affinity of GUS and RZB was evaluated using a kinetic exclusion assay. Cellular potency was measured by mAb impact on IL-23–induced STAT3 phosphorylation in human peripheral blood mononuclear cells. Binding of GUS and RZB to FcγRs was assessed in cells transfected with individual FcγRs. Primary human monocytes differentiated into an inflammatory state were utilized in flow cytometry assays to assess GUS and RZB binding to CD64 and capture of locally produced endogenous IL-23. Cellular activation following mAb binding to CD64 on inflammatory monocytes was assessed using a 41-plex cytokine bead assay. Internalization of IL-23, GUS, and RZB within CD64$^+$ macrophages was assessed using live cell confocal imaging.

Results: GUS and RZB displayed comparable picomolar binding affinity for IL-23 and similar high potency for inhibiting IL-23–induced STAT3 phosphorylation. GUS showed the strongest binding to CD64 versus other FcγRs; RZB had negligible binding to any FcγR. GUS, but not RZB, showed dose-dependent Fc-mediated binding to CD64 on inflammatory monocytes, and CD64-bound GUS was able to capture endogenous IL-23 secreted from the same cells. GUS binding to CD64

on inflammatory monocytes did not induce or enhance cytokine production. GUS, but not RZB, bound to the cell surface of $CD64^+$ macrophages and mediated internalization of IL-23 to low pH intracellular compartments.

Conclusion: Compared with RZB, GUS has unique attributes that allow it to simultaneously bind $CD64^+$ myeloid cells via its native Fc region and neutralize IL-23 with high affinity and potency. These data suggest a potential mechanistic benefit through enrichment of GUS within inflamed tissue of patients with psoriatic disease, where $CD64^+$ IL-23–producing myeloid cells are increased, enabling potent neutralization of IL-23 at its source and removal of IL-23 from inflamed tissue via internalization.

Session Date: Tuesday, November 14, 2023

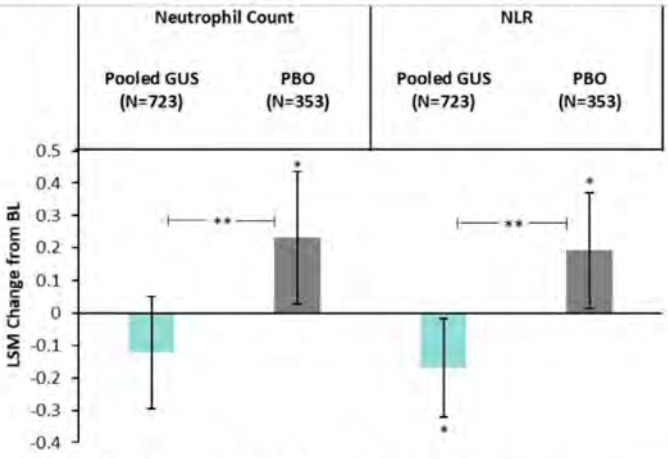
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophils have potential pathogenic roles in chronic inflammatory diseases (e.g., neutrophilic cutaneous microabscesses in psoriasis, and neutrophils in the synovial fluid/tissue in PsA and early sacroiliac joint biopsies in ankylosing spondylitis [AS]).[1] An amplification mechanism involving neutrophilic IL-23 production, as part of the T-cell-neutrophil axis, has been theorized to associate with rapid-onset action of IL-23 pathway inhibition seen in some pts.[2]In these post hoc analyses of the Phase 3 DISCOVER-1&2 studies, we explored relationships between blood neutrophils and clinical outcomes during treatment with the fully human IL-23p19-subunit inhibitor guselkumab (GUS).

Figure 1. Effect† of GUS vs. PBO on Change from BL to W4 in Neutrophil Levels



*p<0.05 vs. BL; **p<0.0001 for GUS vs. PBO. LSM: least squares mean.

†Upon adjustment for age; sex; obesity; smoking; prior TNFi use; and BL use of conventional synthetic DMARDs, corticosteroids, and NSAIDs.

Table. Association of W4 Changes in Neutrophil Levels with Achievement of Clinical Outcomes at W24 in GUS-Treated Pts

Achievement at W24	$\Delta_{BL \rightarrow W4}$Neutrophil Count OR† (95% CI)	$\Delta_{BL \rightarrow W4}$NLR OR† (95% CI)
BASDAI20 (in 194 pts with axPsA)	1.15 (0.93, 1.41)	1.34 (1.03, 1.73)**
ACR50	1.11 (1.00, 1.24)**	1.14 (1.02, 1.28)**
PASDAS LDA/VLDA (in 740 pts with BL PASDAS>3.2)	1.12 (1.00, 1.25)*	1.07 (0.95, 1.21)
Dactylitis resolution (in 319 pts with BL dactylitis)	1.22 (1.02, 1.46)**	1.18 (0.98, 1.43)*
Enthesitis resolution (in 473 pts with BL enthesitis)	1.08 (0.95, 1.23)	0.97 (0.85, 1.10)

†ORs>1 indicate an association between greater reductions in neutrophil levels and higher likelihood of achieving clinical outcomes at W24. Adjusted for BL levels, GUS regimen, prior TNFi use, and BL use of conventional synthetic DMARDs. *p<0.1, **p<0.05.

Methods: Adults in DISCOVER-1&2 (90% bio-naive) with active PsA were randomized 1:1:1 to GUS 100 mg every 4weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo (PBO). GUS effect (vs PBO) on early (W4) neutrophil (assessed as absolute count and neutrophil-to-lymphocyte ratio [NLR]) reduction was assessed using mixed models adjusting for potential confounders. In GUS patients (pts), associations between early (W4) neutrophil reduction and W24 achievement of 20% improvement in Bath AS Disease Activity Index (BASDAI20), ACR50, PsA Disease Activity Score (PASDAS) low/very low disease activity (LDA/VLDA), and enthesitis or dactylitis resolution were assessed with multivariate logistic regression. Associations between BL neutrophils and early clinical improvements (1st timepoint assessed) in swollen/tender joint counts (SJC/TJC at W4); skin visual analogue scale (VAS at W8); Leeds enthesitis index (LEI at W4); dactylitis severity score (DSS at W4); and spinal pain, BASDAI, and ASDAS in pts with axial involvement (axPsA; all at W8) were assessed in GUS pts using multivariate mixed models.

Results: GUS significantly reduced neutrophils (absolute count and NLR) vs PBO as early as W4 **(Figure 1)**. Early (W4) reductions in neutrophils with GUS were associated with significantly higher odds of achieving BASDAI20; ACR50; PASDAS LDA/VLDA; and dactylitis, but not enthesitis, resolution at W24 **(Table)**.However, no associations were observed between BL neutrophils in GUS-treated pts and early improvements in SJC, TJC, skin VAS, LEI, or DSS **(Figure 2A)**; lower BL neutrophil levels, conversely, were associated with a significantly greater improvement in spinal pain, and numerically greater improvements in BASDAI and ASDAS, at W8 in axPsA pts **(Figure 2B)**.

Conclusion: GUS rapidly (W4) reduced neutrophil levels, which in turn associated with greater likelihood of W24 achievement of important measures of disease control across PsA domains, e.g., ACR50, PASDAS LDA/VLDA, and dactylitis. The association between lower BL neutrophil levels and greater W8 improvement in spinal pain, but not with peripheral PsA domains, with GUS may signal a potential role of neutrophil reduction in mediating rapid improvements in axial symptoms and suggests a more impactful role for neutrophils in driving axial over peripheral symptoms. Such relationships thus require further study.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The PsA core domain set developed by the Outcome Measures in Rheumatology working group includes musculoskeletal disease, fatigue, physical function, and structural damage, of which arthritis activity, pain, and fatigue were identified as essential by both patients (Pts) and physicians (Phs).[1-2] Assessing agreement between Pt and Ph global assessments (GA) may provide valuable insight into differential importance of specific PsA manifestations to Pts vs Phs. Although previous studies have assessed Pt/Ph disagreement, they have not evaluated potential variation over time.[3] This study assessed the agreement of PtGA and PhGA through week (W) 24 and identified factors driving disagreement between PtGA and PhGA using pooled data (N=1120) from the phase 3 DISCOVER (D)1 & 2 studies of the fully human IL-23p19 subunit inhibitor, guselkumab (GUS).

Table. Factors Associated with PhGA>PtGA and PtGA>PhGA Through W24

Visit	Predictors of Interest[¥]	Odds Ratio (95% CI)	
		PhGA>PtGA	PtGA>PhGA

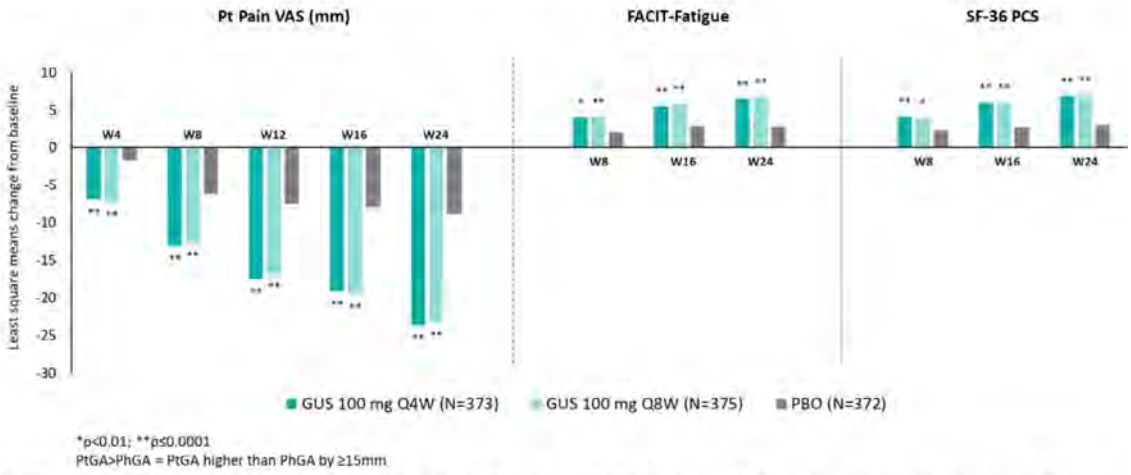
*p <0.05, †p <0.01, ‡p ≤0.0001

¥Variables retained after backward selection; prior TNFi use was significant for W8/W24 but not shown. Other variables considered were age, sex, obesity, BL PsA duration, axial involvement, enthesitis, dactylitis, psoriasis, physical function, SF-36 MCS.

BL, baseline; CI, confidence interval; CRP, C-reactive protein; FACIT, Functional Assessment of Chronic Illness Therapy; MCS, mental component summary; PCS, physical component summary; PhGA, physician global assessment; PsA, psoriatic arthritis; Pt, patient; PtGA, patient global assessment; SF-36, 36-item Short-Form; SJC, swollen joint count; TJC, tender joint count; TNFi, tumor necrosis factor inhibitor; VAS, visual analogue scale; W, week

Figure. Effect of GUS on Disease Parameters Associated with PtGA>PhGA



FACIT, Functional Assessment of Chronic Illness Therapy; GUS, guselkumab; PBO, placebo; PCS, physical component summary; PhGA, physician global assessment; Pt, patient; PtGA, patient global assessment; Q4W, every 4 weeks; Q8W, every 8 weeks; SF-36, 36-item Short-Form; VAS, visual analogue scale; W, week

Methods: Pts with active PsA despite standard therapies (D1: ≥3 swollen/tender joint counts [SJC/TJC], CRP ≥0.3 mg/dL, ~30% with prior TNF inhibitors [TNFi]; D2: ≥5 SJC/TJC, CRP ≥0.6 mg/dL, biologic-naïve) were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo. Pt/Ph agreement was defined as a difference of -15< PhGA-PtGA< 15. Determinants of PhGA exceeding PtGA by ≥15 (PhGA >PtGA) and PtGA exceeding PhGA by ≥15 (PtGA >PhGA) among Pts with PtGA/PhGA disagreement were assessed with the same logistic regression model considering Pt demographics, disease characteristics, and Pt-reported outcomes (PROs). The effect of GUS on disease parameters identified as determinants of PtGA vs PhGA disagreement was assessed with repeated measures mixed models adjusting for treatment group, baseline (BL) levels, prior TNFi use, and BL DMARD use.

Results: At BL, mean (SD) SJC=11.5 (7.4), TJC=20.6 (13.3), Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score=29.9 (10.0), PtGA=66.9 (19.9), and PhGA=64.8 (15.9) were consistent with moderate to high disease activity. Agreement between PtGA and PhGA was seen in most instances (61.2%); 23.2% of cases were characterized by PtGA >PhGA and 15.7% by PhGA >PtGA. The proportion of Pts with PtGA >PhGA increased to 39.1% at W24, while that with PhGA >PtGA decreased to 11.2%. The main determinant of PtGA >PhGA was higher Pt Pain (all time points); additional factors included worse physical health-related quality of life at BL and worse fatigue at W24 (**Table**). Conversely, Phs emphasized objective disease measures, namely higher SJC (all time points) and TJC (W8 to W24), and elevated CRP (BL to W16). GUS treatment was associated with prompt and sustained significant improvements in all identified determinants, including those driving PtGA >PhGA (**Figure**).

Conclusion: PtGA and PhGA were aligned in most encounters. PtGA >PhGA disagreement was driven by pain, fatigue, and physical health being weighed more by Pts than Phs. These findings have important implications in shared decision making and highlight the need to prioritize treatments addressing the full spectrum of PsA symptoms, including PROs.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 30 to 40% of patients are primary non-responders, and the response rate declines after each successive biological therapy. The primary aim is to determine if cell type-specific transcriptomic data obtained at baseline can predict response to biologics at three months.

Methods: Ethics approval was obtained, and all patients consented to participate. Consecutive patients initiating TNFi or IL-17Ai therapy were assessed using a standardized protocol before initiation of biologic therapy and three months after treatment initiation. Responders were defined as patients with low DAPSA disease activity (≤14). CD8+ T cells were super paramagnetically isolated from PBMCs with Dynabeads (TM) CD8 kit (Cat#11147D). Total RNA was extracted from the CD8+ cells using Lexogen's Split RNA Kit (Cat#008.48). Libraries were pooled and sequenced on the NovaSeq 6000 for 2 x 150bp reads. STAR (v 2.6) package was used to align raw FASTQ reads and Cufflinks tool (v 2.2.1) was used to quantify the gene expression and then normalized within-sample to transcripts per million (TPM) reads. Differentially expressed genes (DEGs) were detected using limma (v 3.38.3) package. To identify biological pathways that related with drug treatment, the differential expressed genes were ranked by fold change and then to perform Gene Set Enrichment Analysis (GSEA) using MSigDB HALLMARK 2020.

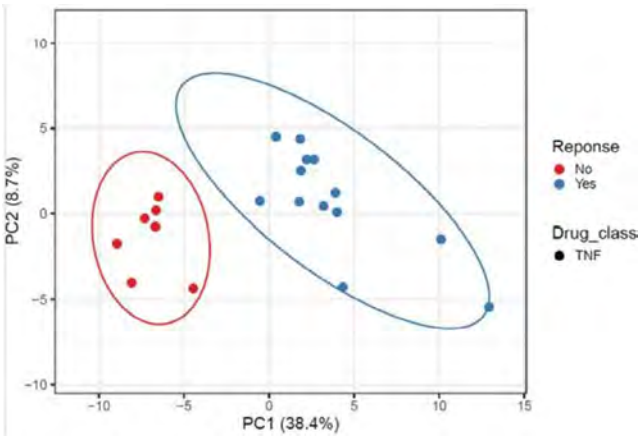

Figure 1: PCA plot of TNFi responder vs non responders of PsA patients at baseline

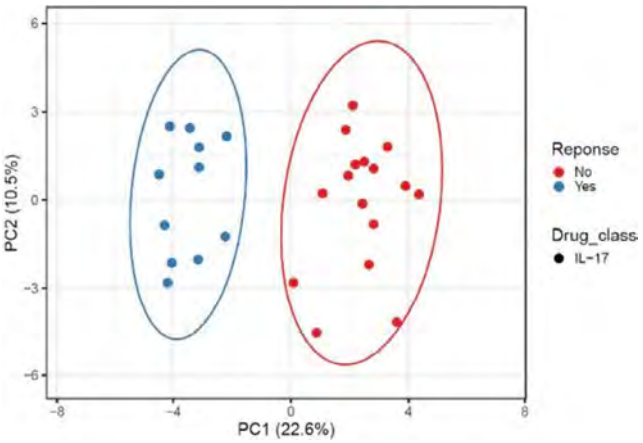

Figure 2: PCA plot of IL-17Ai among responders vs non responders of PsA patients at baseline

Results: We interrogated 49 PsA patients initiating either TNFi or interleukin-17A inhibitors. Of the 21 TNFi patients the mean age was 56, 14 were females (67%), and 13 (61%) were TNFi responders. For IL-17Ai, there were 28 PsA patients with a mean age of 56, 18 females (64%) and 11 (40%) were responders. PCA analysis discriminated responders vs. non-responder for both TNFi and IL-17Ai. The top five differentially expressed genes for TNFi response were *PM20D1, CLIC6, OR1L8, KLHL12, GPALPP1* and for IL-17Ai response were *C19orf81, NMI, RPIA, ALG1L, TUBA3E*. Using these DEGs, GSEA with the Hallmark gene sets identified MITOTIC_SPINDLE, E2F, G2M as the top down-regulated pathway after IL-17 treatment response, whereas INFLAMMATORY_RESPONSE, INTERFERON_GAMMA_RESPONSE and IL6_JAK_-STAT3_SIGNALING remained the top up-regulated pathways before TNFi treatment.

Conclusion: Genomic heterogeneity among PsA patients and cytokine led to differences in expressed genes in different biologic classes. Integration of cell-type-specific DEGs with protein-protein interactions and further comprehensive pathway enrichment analysis is pending.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS) has demonstrated robust efficacy across key PsA domains at Week (W) 24, with effects sustained or further enhanced through 2 years. Timing of clinically meaningful improvement in disease activity (DA), functional status, and health-related quality of life is of interest to PsA patients (pts) and providers. Here we 1) evaluated effect of GUS on time to minimal clinically important improvements (MCII) in pt reported outcomes and composite measures of DA; 2) assessed association between W4/W8 MCII achievement and later disease control (W24/W52).

Methods: This post hoc analysis evaluated 1120 adults with active PsA despite standard therapies from DISCOVER-1 (D1) (swollen & tender joint counts [SJC/TJC] ≥3 each, CRP ≥0.3 mg/dL, 1-2 prior TNF inhibitors [TNFi] in 31% of pts) and D2 (SJC/TJC ≥5 each, CRP ≥0.6 mg/dL, biologic-naïve). Pts were randomized 1:1:1 to GUS 100 mg every

Endpoint with MCII	Week	GUS Q4W	GUS Q8W	PBO
cDAPSA	4[¥]	58.5%[†]	57.9%[†]	46.8%
	8	73.9%[‡]	72.1%[‡]	56.8%
Joint VAS	4[¥]	31.9%[†]	34.1%[‡]	21.1%
	8	45.3%[‡]	45.7%[‡]	30.7%
Pt Pain	4[¥]	27.8%[†]	29.4%[†]	18.9%
	8	44.7%[‡]	44.1%[‡]	28.1%
HAQ-DI	4[¥]	33.9%[†]	30.5%[*]	22.7%
	8	41.7%[‡]	42.6%[‡]	27.6%
PASDAS	8[¥]	68.4%[‡]	64.9%[‡]	44.0%
PtGA	8[¥]	53.4%[‡]	53.7%[‡]	32.9%
Skin VAS	8[¥]	64.0%[‡]	62.1%[‡]	35.2%
FACIT-F	8[¥]	51.1%[*]	53.1%[†]	43.4%
SF-36 PCS	8[¥]	43.2%[†]	41.6%	35.8%

[*]nominal p<0.05; [†]p<0.01; [‡]p≤0.0001 vs PBO. [¥]First time point assessed.
cDAPSA, clinical disease activity index for psoriatic arthritis; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; GUS, guselkumab; HAQ-DI, Health Assessment Questionnaire-Disability Index; MCII, minimal clinically important improvements; PASDAS, Psoriatic Arthritis Disease Activity Score; PBO, placebo; PCS, physical component summary; PtGA, Patient Global Assessment; Pts, patients; Q4W, every 4 weeks; Q8W, every 8 weeks; SF, Short Form; VAS, Visual Analogue Scale.

4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO)®GUS 100 mg Q4W at W24. Time to MCII in outcomes of interest, i.e., improvement in clinical DA Index for PsA (cDAPSA) ≥5.7, Joint Visual Analogue Scale (VAS) ≥15mm, Pt Pain ≥15mm, HAQ-DI ≥0.35, PsA DA Score (PASDAS) ≥0.8, Pt Global Assessment (PtGA) ≥15mm, Skin VAS ≥15mm, Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F) ≥4, Short Form (SF)-36 physical component summary (PCS) ≥5, was compared between GUS vs PBO with Cox regression adjusting for baseline (BL) levels of respective outcome, treatment group, prior TNFi use, and BL DMARD use. MCII achievement was determined using non-responder imputation and compared between GUS and PBO using logistic regression adjusting for the above covariates. The association between MCII achievement at W4/W8 and stringent clinical response at W24/W52 amongst GUS-treated pts was assessed with logistic regression adjusting for prior TNFi use and BL DMARD use.

Results: Time to achieve MCII in all studied outcomes was significantly shorter (hazard ratio range: 1.3-2.5; all p< 0.01) for both GUS Q4W and Q8W vs PBO, including cDAPSA as a representative example (**Figure**), with curve separation occurring at the first timepoint assessed. MCII rates also were significantly higher with GUS vs PBO at the first timepoint assessed, i.e., W4 for cDAPSA, Joint VAS, Pt Pain, and HAQ-DI and W8 for PASDAS, PtGA, Skin VAS, FACIT-F, and SF-36 PCS (**Table**). W4 achievement of MCII in cDAPSA, Joint VAS, Pt Pain, and HAQ-DI was associated with greater odds of achieving future disease control, defined as ACR50, ACR70, cDAPSA ≤13, PASDAS ≤3.2, and minimal DA (MDA), at W24 (odds ratio [OR]: 1.5-3.6) and W52 (OR: 1.2-2.4). W8 achievement of MCII in all studied outcomes was also associated with greater odds of achieving disease control at W24 (OR: 1.4-17.2) and W52 (OR: 1.2-5.4).

Conclusion: In pts with active PsA, treatment with GUS was associated with more rapid MCII in both clinical and pt reported outcomes compared with PBO. As early as W4, achievement of MCII vs non-achievement in each studied outcome, particularly PASDAS and cDAPSA, was associated with greater odds of longer-term stringent DA control. Findings highlight the impact of these rapid improvements with GUS (as early as W4) on the trajectory of long-term pt outcomes.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The EMA authorized Upadacitinib (UPA) in PsA in January 2021. UPA has shown efficacy in PsA refractory to anti-TNF in a clinical trial (RCT). Our objectives are: **a)** to study the effectiveness and safety of UPA in the 1st clinical practice (RWE) cases in Spain and **b)** to compare RWE patients with those of RCT.

TABLE 1. Baseline characteristics

	CLINICAL PRACTICE n=134	CLINICAL TRIAL n=211	p
Baseline demographic characteristics			
Age, years (mean ± SD)	51.82± 11.22	53.0 ± 12.0	0.362
Sex, n (%) women	97(72.4)	113 (53.6)	**< 0.001**
Disease Characteristics			
Duration of PsA, years (mean ± SD)	9.94 ± 7.72	9.5 ± 8.4	0.625

Swollen joints, mean ± SD	4.33 ± 5.01	11.3 ± 8.2	**< 0.001**
Painful joints, mean ± SD	6.10 ± 5.6	24.9±17.3	**< 0.001**
Enthesitis, n (%)	29 (21.6) (MASES)	172 (81.5) (SPARCC)	**< 0.001**
Dactylitis, n (%)	14 (10.5)	55(26.1)	**< 0.001**
PASI score, mean ± SD	0.95 ±1.65	10.1± 9.2	**< 0.001**
PCR (mg/L), mean ± SD	8.36 ± 14.47	11.2±18.5	0.133
Oral glucocorticoid, n (%)	58 (43.28)	22 (10.4)	**< 0.001**
Previous b-DMARDs			
Previous use of b-DMARD, n (%)	123 (91.8)	195 (92.4)	0.833
Number of previous b-DMARDs, n (%)			
0	11 (8.2)	18 (8.5) *	0.916
1	22 (16.4)	135 (63.7)	**< 0.001**
2	21 (15.7)	35 (16.5)	0.822
≥3	80 (59.7)	24 (11.3)	**< 0.001**
UPA at the beginning			
Monotherapy, n (%)	70 (52.24)	113 (53.6)	0.811
Combined with conventional DMARDs, n (%)	64 (47.76)	98 (46.4)	0.811

TABLE 1. Baseline characteristics

Methods: Multicenter study of 134 patients with PsA treated with UPA in Spain. The diagnosis of PsA was made using CASPAR criteria. Patients with refractory PsA from 29 Rheumatology Services (January 2021-January 2023) who had received ≥1 dose of UPA (15 mg/d) with at least 1 follow-up visit were included. Refractory PsA was defined if low clinical activity or remission had not been achieved with biological (b) and/or targeted synthetic (ts) DMARDs.

Table 2. Evolution

	Baseline (n=134)	1 month (n=89)	3 months (n=84)	6 months (n=55)	12 months (n=25)
Prednisone, n (%)	58 (43.28)	32 (35.95)	33 (39.28)	16 (29.09)	6 (24)

TABLE 2. Evolution

The outcomes were the effectiveness, safety and saving of corticosteroids (CS). A comparative study was carried out between this RWE cohort and those of the SELECT-PsA 2 RCT.

Results are expressed as percentages, mean±SD or median [IQR] depending on the distribution of the variable.

Results: 134 patients (97 women) were studied, mean age 51.8±11.2 years **(Table 1)**. The joint pattern was: peripheral (61.9%), mixed (30.6%) and axial (7.5%). During the evolution, they had also presented enthesitis (35.3%), dactylitis (25.4%), skin involvement (73.9%) and onychopathy (24.4%).

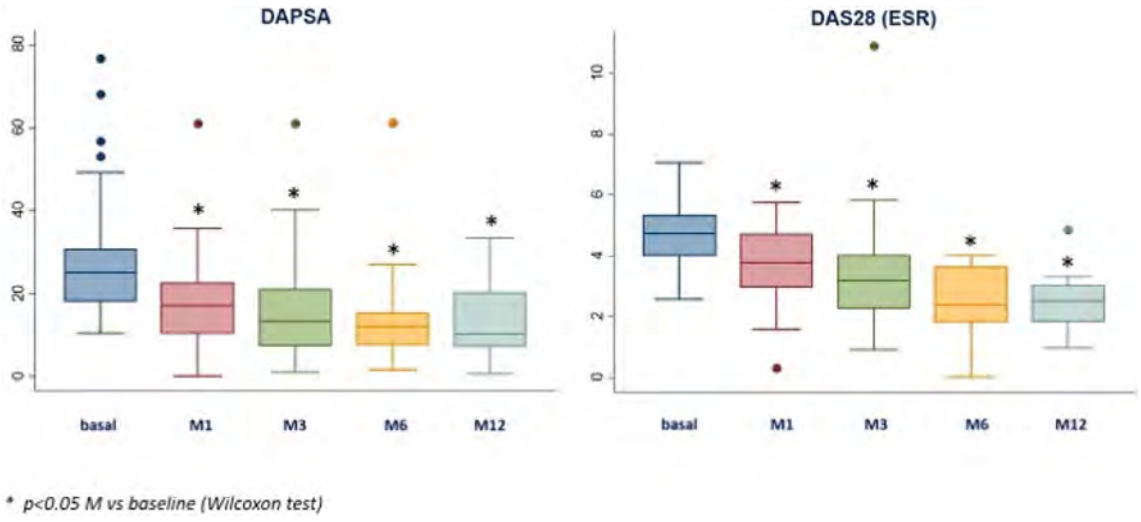
Prior to the UPA, they had received oral CS (68.7%) (mean maximum dose of prednisone 13.4±9.3) and a mean per patient of csDMARDs (1.8±1.0) and b-DMARD (3.3±2.2). The b-DMARDs were: Adalimumab (n=101), Secukinumab (66), Etanercept (53), Ixekizumab (44), Ustekinumab (44), Certolizumab (37), Infliximab (30), Golimumab (26), Guselkumab (2), Abatacept (2), Brodalumab (1). In addition, they received the following ts-DMARDs: Tofacitinib (n=29), Apremilast (27), Filgotinib (1).

UPA at baseline was associated with: **a)** prednisone (43.3%; mean dose 8.3±5.6 mg/d). **b)** csDMARDs (n=64; 47.8%): MTX (n=39), LEF (19), SSZ (10). At the start of the UPA they presented peripheral arthritis (78.4%), axial activity (29.1%), skin involvement (25.4%), onychopathy (11.3%), enthesitis (21.6%) and dactylitis (10.5%). After a mean follow-up of 5.9 ±5.1 months, a rapid and sustained improvement was observed in the activity indices **(table 2, figure)** and in the laboratory tests **(table 2)**.

At the 6th month, an improvement in axial involvement (35.7%) and extra-articular manifestations was observed: dactylitis (80%), enthesitis (53.8%) and skin involvement (69.2%), as well as a CS-sparing effect (p=0.031) **(table 2)**.

The RWE patients compared to the RCT were mostly women, refractory to a greater number of previous b-DMARDs and received more concomitant CS **(Table 1)**.

No serious adverse effects (AE) were observed. Minor AE were reported in 23 (17.2%) patients. UPA was discontinued in 44 (32.8%) (28 ineffectiveness, 4 patient decision, 4 infection, 2 de novo anterior uveitis episodes, 1 thrombosis, 1 surgery, 1 pregnancy, 1 urticaria and 1 diarrhea).



Figure

Conclusion: In this study, the first patients treated with UPA in PsA in RWE in Spain received more CS simultaneously and were refractory to a greater number of b-DMARDs than those in the RCT. As in the RCT, UPA was effective, fast, and relatively safe in refractory APs in RWE.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) has been associated with an increased risk of cardiovascular (CV) disease, likely due to accelerated atherosclerosis secondary to chronic inflammation.[1] As such, patients (pts) and their health care providers have high interest in modification of CV risk. Neutrophil-to-lymphocyte ratio (NLR) and high-sensitivity (hs) CRP are biomarkers of systemic inflammation that can be followed over time and may serve as markers of CV risk. Guselkumab (GUS), a fully human IL-23p19-subunit inhibitor, has demonstrated efficacy in treating multiple PsA domains and a favorable safety profile.[2,3] This analysis assessed the impact of GUS on NLR and hsCRP as markers of CV risk in subsets of pts with active PsA and high systemic inflammatory burden.

Methods: DISCOVER-2 enrolled bionaïve adults with active PsA (≥5 swollen and ≥5 tender joints, and hsCRP ≥0.6 mg/dL) despite standard therapies; pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo (PBO) with crossover to GUS 100 mg Q4W at W24 (PBO àGUS). The cohorts of DISCOVER-2 pts included in this analysis had baseline (BL) NLR values >2.5 (High NLR)[4] or BL hsCRP levels >10 mg/L (High hsCRP).[5] Changes from BL through W24 in NLR and hsCRP were assessed with mixed models for repeated measures adjusting for BL values of NLR and hsCRP, respectively, and BL use of conventional synthetic DMARDs, corticosteroids, and NSAIDs. Systolic (SBP) and diastolic (DBP) blood pressure as well as body mass index (BMI) through W100 were assessed descriptively.

Results: The High NLR and High hsCRP cohorts comprised 445 and 393 patients, respectively, with approximately 60% of pts in each cohort also meeting the criteria for the other; BL characteristics (other than NLR/hsCRP) were generally consistent both between cohorts and across randomized treatment groups **(Table)**. Upon adjusting for BL values and concomitant PsA medications, GUS-treated pts exhibited significantly greater reductions compared with PBO in both NLR **(Figure 1)** and hsCRP **(Figure 2)** as of the first timepoint assessed (W4) and through W24, with PBOà GUS quickly (W28) converging following crossover to GUS. Reduced NLR and hsCRP levels ($p< 0.0001$ vs BL) were sustained through 2 years of GUS treatment. In both cohorts, mean BMI, SBP, and DBP remained stable through up to 2 years of GUS treatment, irrespective of GUS dosing regimen (data not shown).

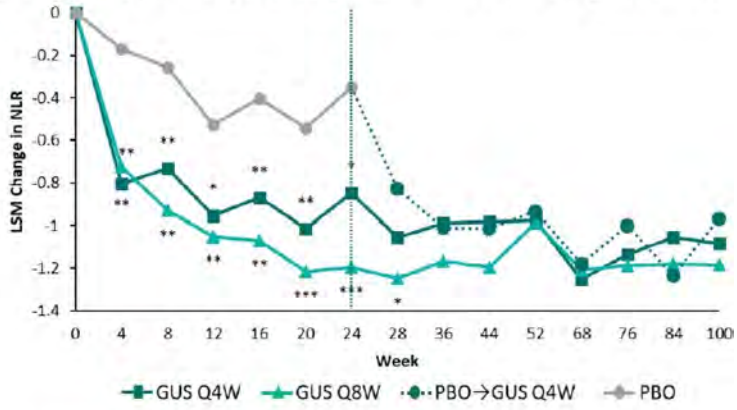
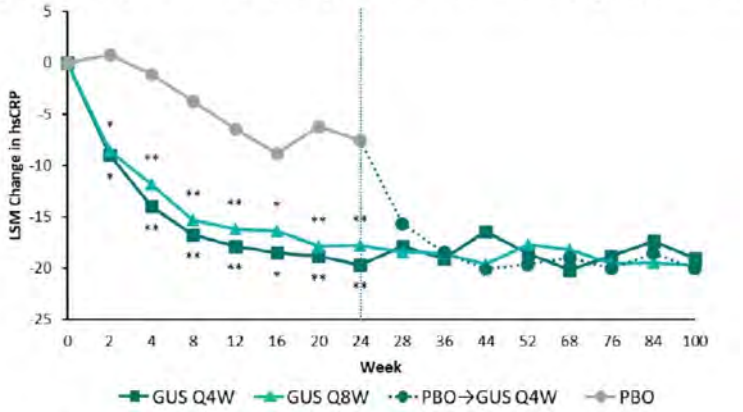
Data are presented as mean (SD) unless stated otherwise.
BMI: body mass index; BSA: body surface area; csDMARD: conventional synthetic disease-modifying antirheumatic drugs; DAPSA: Disease Activity in PSoriatic Arthritis; DBP: diastolic blood pressure; Def: by definition; DSS: dactylitis severity score; HAQ-DI: health assessment questionnaire-disability index; hsCRP: high-sensitivity C-reactive protein; LEI: Leeds enthesitis index; NLR: neutrophil-to-lymphocyte ratio; NSAID: non-steroidal anti-inflammatory drug; PASI: Psoriasis Area Severity Index; PhGA: physician global assessment; PsO: psoriasis; PtGA: patient global assessment (joint and skin); SBP: systolic blood pressure; SJC: swollen joint count; TJC: tender joint count.

Figure 1. Least Square Mean (LSM) Changes from BL to W24 in NLR (High NLR Cohort)



*p<0.05, **p<0.01, ***p<0.0001 for GUS Q4W/Q8W vs. PBO

Figure 2. Least Square Mean (LSM) Changes from BL to W24 in hsCRP (High hsCRP Cohort)



*p<0.001, **p<0.0001 for GUS Q4W/Q8W vs. PBO

Conclusion: In these two subgroups of bionaïve PsA pts with high levels of biomarkers of inflammation and CV risk, GUS led to rapid and sustained reductions in NLR and hs-CRP. In addition, traditional CV risk factors remained stable for 2 years. These findings highlight the potential utility of GUS to ameliorate systemic inflammation associated with elevated CV risk and support a consistent guselkumab safety profile in patients with PsA and high systemic inflammatory burden.

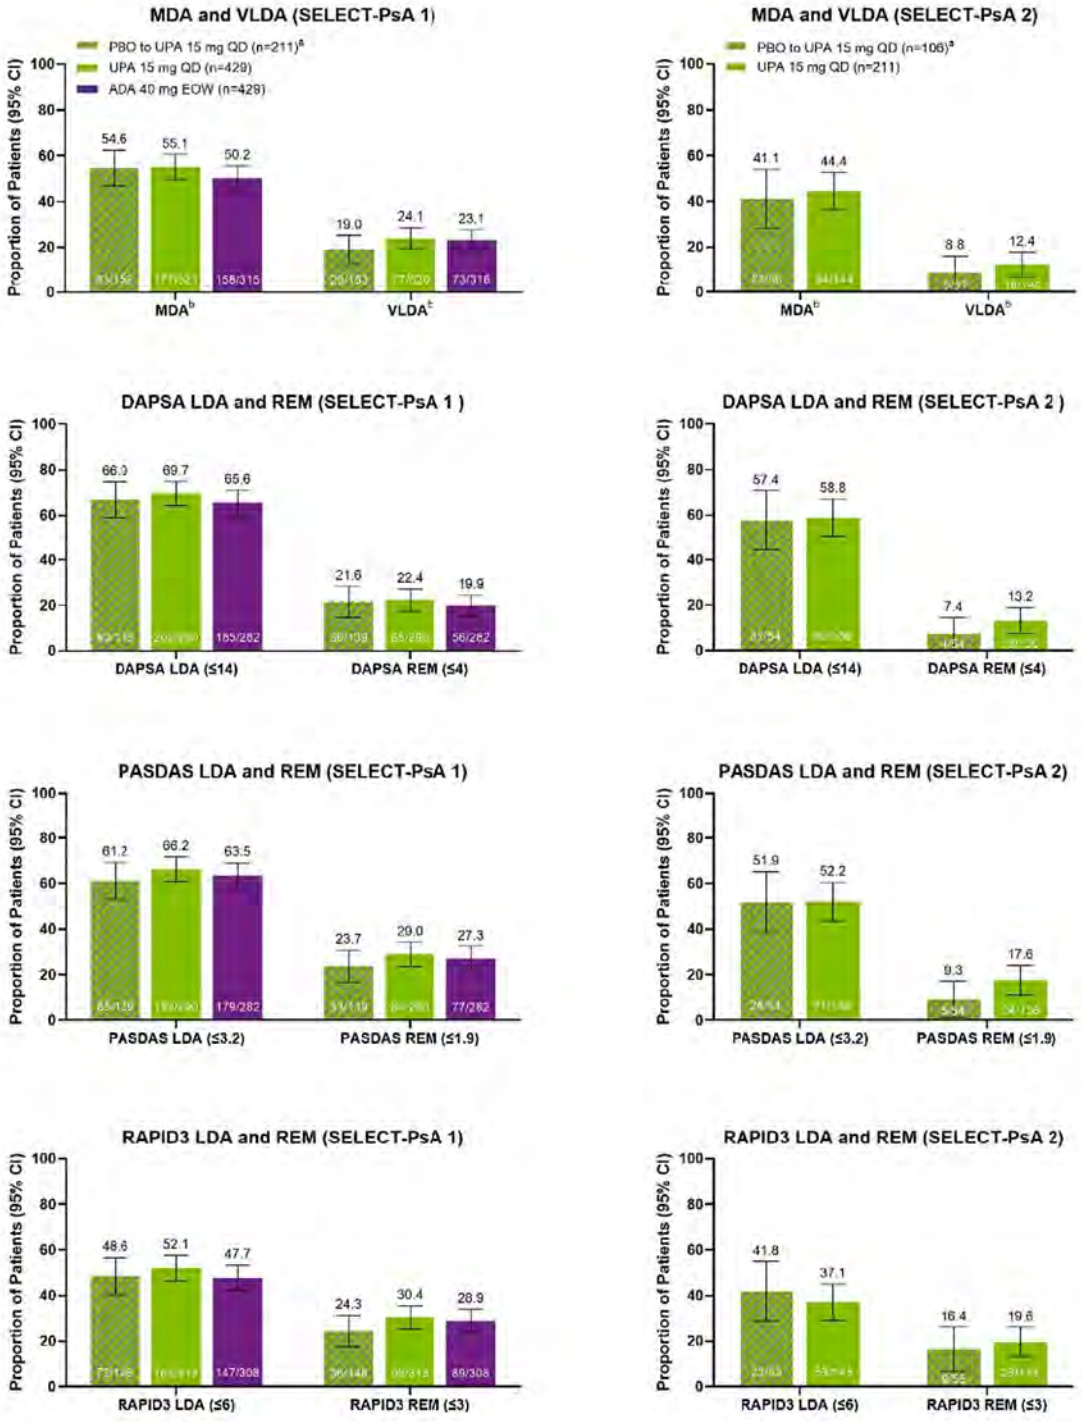
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A main goal of therapy for patients (pts) with PsA is to achieve and maintain the lowest possible level of disease activity across domains.[1] Composite measures used to assess disease activity include Minimal Disease Activity (MDA)/Very Low Disease Activity (VLDA), as well as achievement of low disease activity (LDA) or remission (REM) using the Disease Activity index for PsA (DAPSA), PsA Disease Activity Score (PASDAS), and/or Routine Assessment of Patient Index Data 3 (RAPID3). Here, we assess the achievement of goals according to these measures in pts with PsA following long-term treatment with upadacitinib (UPA), an oral JAK inhibitor, at week (wk) 152 from two phase 3 trials.

Methods: Post hoc analysis of pts from the SELECT-PsA 1 (N=1704; inadequate response to non-biologic DMARDs [non-bDMARD-IR]) and SELECT-PsA 2 (N=641; bDMARD-IR) studies was performed.[2,3] Pts randomized to once daily UPA 15 mg (UPA15), placebo (switched to UPA15 at wk 24), or every other wk adalimumab (ADA; SELECT-PsA 1 study only) were evaluated. Proportions of pts achieving MDA (≥5/7 criteria)/VLDA (7/7 criteria), DAPSA LDA (≤14)/REM (≤4), PASDAS LDA (≤3.2)/REM (≤1.9), or RAPID3 LDA (≤6)/REM (≤3) at wk 152 were assessed. Additionally, proportions of pts achieving individual MDA components among those who did (responder) or did not (non-responder) achieve MDA at wk 152 are shown. As observed (AO) data are presented.

Results: At 3 years, ~50-70% of pts remained in the studies. In SELECT-PsA 1, similar proportions of pts treated with UPA15, PBO switched to UPA15, or ADA achieved MDA (range: 50-55%) or VLDA (range: 19-24%) at wk 152 (**Figure 1**). In SELECT-PsA 2, similar response rates were observed for MDA (range: 41-44%) and VLDA (range: 9-12%) amongst pts receiving UPA15 or PBO switched to UPA15. The proportions of pts achieving LDA or REM for DAPSA, PASDAS, and RAPID3 were similar between UPA15, PBO switched to UPA15, and ADA. As expected, pts identified as responders had higher response rates for all individual MDA components compared to non-responders across both studies (**Figure 2**). High proportions of responders and non-responders treated with UPA15 achieved SJC66 ≤1, PASI ≤1 or Body Surface Area-Psoriasis (BSA-Ps) ≤3%, and Leeds Enthesitis Index (LEI) ≤1; similar rates were observed with PBO switched to UPA15

Figure 1. Proportion of Patients Achieving LDA and REM at Week 152 (AO)

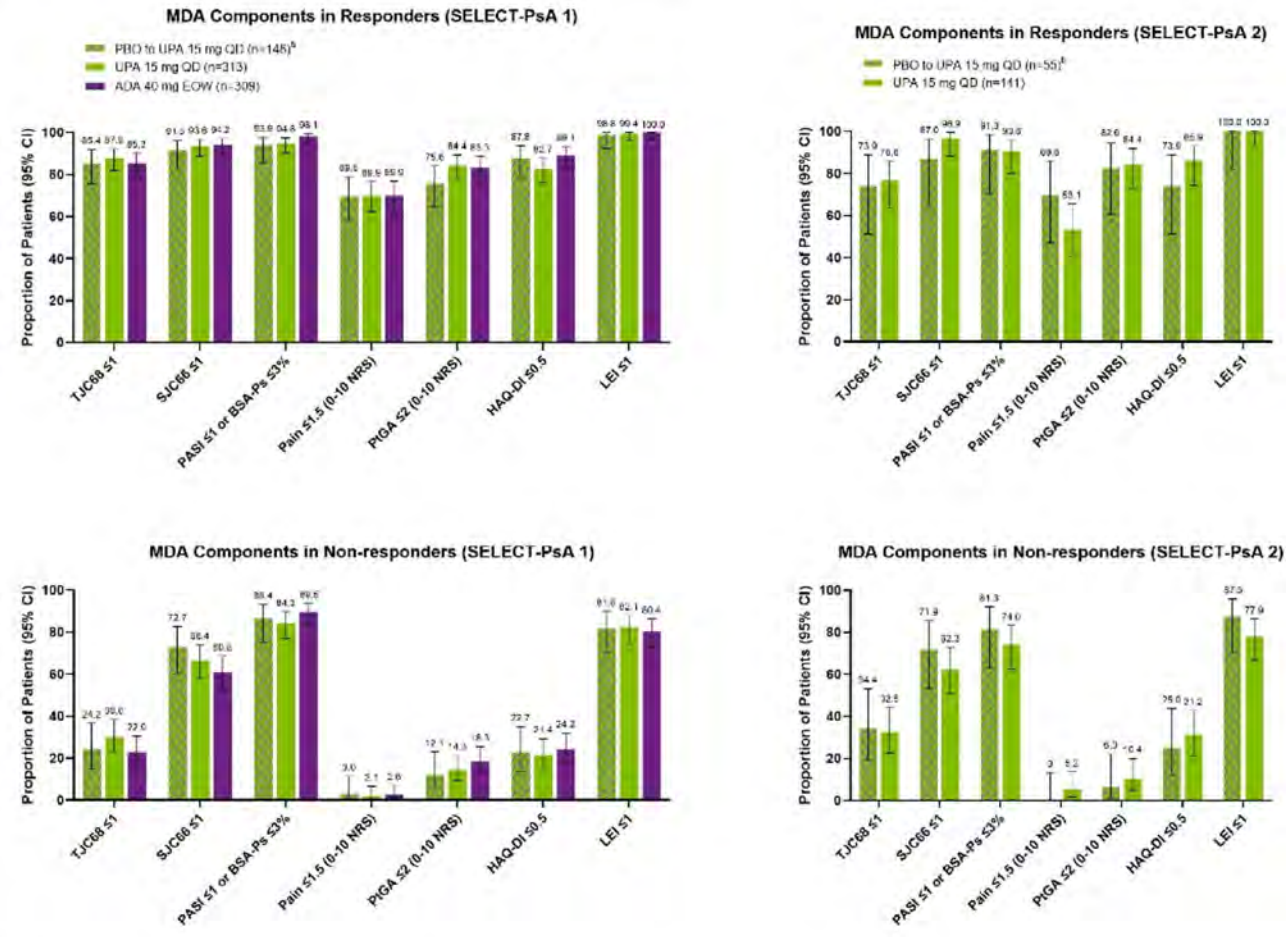


ADA, adalimumab; AO, as observed; BSA-Ps, body surface area with psoriasis; CI, confidence interval; DAPSA, Disease Activity index for PsA; EOW, every other week; LDA, low disease activity; LEI, Leeds Enthesitis Index; MDA, minimal disease activity; NRS, numeric rating scale; PASDAS, PsA Disease Activity Score; PBO, placebo; PtGA, patient global assessment of disease activity; QD, once daily; RAPID3, Routine Assessment of Patient Index Data 3; REM, remission; UPA, upadacitinib; VLDA, very low disease activity.

[a]Patients randomized to PBO were switched to UPA 15 mg QD at week 24.

[b]MDA (≥5/7 criteria) or VLDA (7/7 criteria): SJC66 ≤1, TJC68 ≤1, PASI ≤1 or BSA-Ps ≤3%, pain ≤1.5 (0-10 NRS), PtGA ≤2 (0-10 NRS), HAQ-DI ≤0.5, and LEI ≤1.

Figure 2. Proportion of Patients Achieving MDA Components at Week 152 (AO)[a]



ADA, adalimumab; AO, as observed; BSA-Ps, body surface area with psoriasis; EOW, every other week; LEI, Leeds Enthesitis Index; MDA, minimal disease activity; NRS, numeric rating scale; PBO, placebo; PtGA, patient global assessment of disease activity; QD, once daily; UPA, upadacitinib.
[a]Results exclude patients with at least one missing component of MDA.
[b]Patients randomized to PBO were switched to UPA 15 mg QD at week 24.

and ADA. In contrast, TJC68 ≤1, pts assessment of pain ≤1.5, pts global assessment of disease activity ≤2, and HAQ-DI ≤0.5 appeared to be more difficult to achieve across all treatments.

Conclusion: Among pts who remained in the studies with data at wk 152, high rates of LDA and REM were reported in pts treated with UPA15, which were similar to PBO switched to UPA15 and ADA, across several measures of disease activity irrespective of prior DMARD exposure. Across measures of LDA and REM, response rates were numerically lower in SELECT-PsA 2, likely due to the treatment refractory population, compared to SELECT-PsA 1. Even in pts who did not achieve MDA at wk 152, treatment with UPA15 led to a high proportion of pts achieving SJC66 ≤1, PASI ≤1 or BSA-Ps ≤3%, and LEI ≤1 in both studies.

Persistence to Therapy Among Patients with Psoriatic Arthritis Treated with IL-17A or TNFα Inhibitors (IL-17Ai or TNFi)

Aisha Vadhariya[1], **Sarah Ross**[1], Brenna Brady[2], Helen Varker[2], Anh Thu Tran[2] and Jessica A Walsh[3], [1]Eli Lilly and Company, Indianapolis, IN, [2]Merative, Cambridge, MA, [3]Salt Lake City Veterans Affairs Health and University of Utah Health, Division of Rheumatology, Salt Lake City, UT

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment paradigm for psoriatic arthritis (PsA) has changed over the last two decades, with increasing numbers of therapy options that target a variety of inflammatory pathways. This analysis sought to examine treatment patterns among patients with PsA initiating either IL-17Ai or TNFi in order to understand patterns of persistence across biologics that utilize different mechanisms of action to treat PsA.

Methods: Adult patients newly initiating an IL-17Ai (ixekizumab or secukinumab) or TNFi biologic (adalimumab, certolizumab pegol, etanercept, golimumab, or infliximab) between April 1, 2016 and June 30, 2021 were identified in the MarketScan Commercial and Medicare Database. The first biologic claim served as the index date and patients were required to have continuous eligibility for 6 months prior and 12 months following index. Patients also had ≥1 PsA diagnosis claim in the pre-period or on index and could not have claims for other indicated conditions, except psoriasis. Biologic treatment patterns, including persistence and switching, were examined over the 12-month follow-up within the IL-17Ai and TNFi cohorts.

Results: A total of 4,338 IL-17Ai and 7,753 TNFi treated patients were eligible for the analyses. The majority of patients in both cohorts were female and aged 45-64 at index; mean±SD Charlson Comorbidity Index was 0.5±1.0 in the TNFi cohort and 0.7±1.2 in the IL-17Ai cohort (Table 1). Prior biologic use was observed in the baseline period for 29.0% of TNFi patients and 61.8% of IL-17Ai patients, while baseline conventional disease-modifying antirheumatic drug (cDMARD) use was observed for 43.3% and 37.6% of the respective cohorts (Figure 1; Table 1). TNFi or IL-17Ai treatment was initiated as combination therapy with cDMARDs in 22.6% of the TNFi cohort and 17.3% of the IL-17Ai cohort. Over the post-period, IL-17Ai patients remained on an IL-17Ai for a mean persistence of 261±126 days; TNFi patients remained on drug for 243 ±127 days (Figure 2). Rates of biologic switching over the post-period were 25.3% in the IL-17Ai cohort and 29.3% in the TNFi cohort.

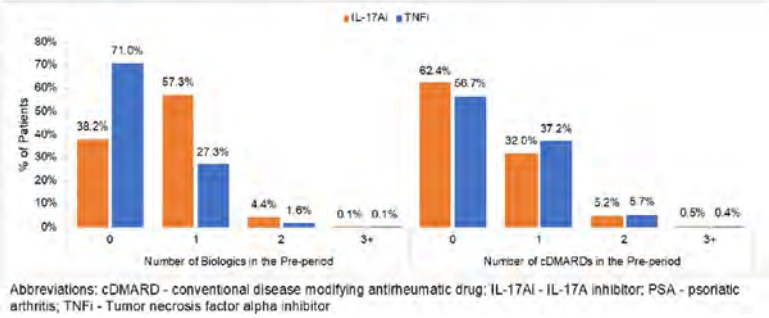
[1] Obesity diagnoses are known to be under-reported in administrative claims.

Abbreviations: NAFL/NAFLD - nonalcoholic fatty liver/nonalcoholic steatohepatitis; cDMARD - conventional disease modifying antirheumatic drug; IL-17Ai - IL-17A inhibitor; SD - standard deviation; TNFi - tumor necrosis factor alpha inhibitor

Figure 1. PsA Medication Use Over the 6-Month Pre-period



Abbreviations: cDMARD - conventional disease modifying antirheumatic drug; IL-17Ai - IL-17A inhibitor; PSA - psoriatic arthritis; TNFi - Tumor necrosis factor alpha inhibitor

Figure 1. PsA Medication Use Over the 6-Month Pre-period

Figure 2. Persistence to Index Biologic Over the 12-Month Post-period

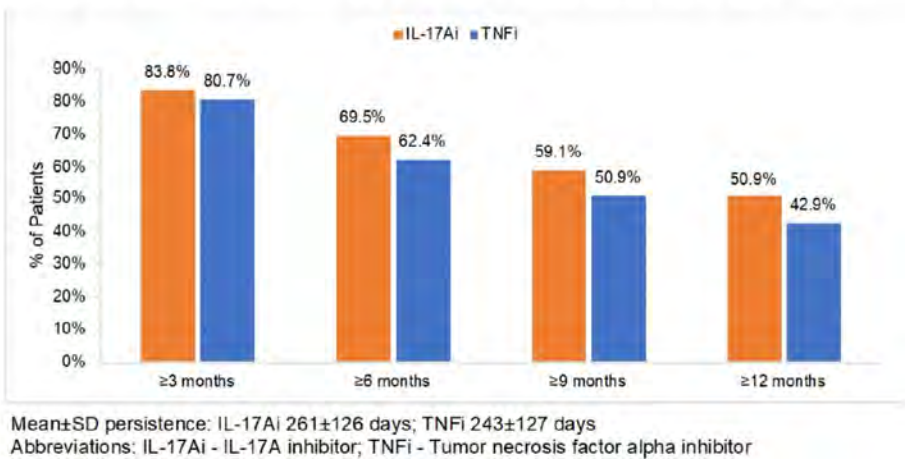


Figure 2. Persistence to Index Biologic Over the 12-Month Post-period

Conclusion: Persistence to therapy can be especially important in chronic, progressive diseases like PsA where patients will likely have to change treatment regimens over the course of disease. Results from this study indicate that IL-17Ai biologics can represent a viable, long-lived treatment choice even among patients with prior biologic experience and high comorbidity burden.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with psoriasis (PsO) or PsA are at increased risk for developing gout; and hyperuricemia (HU) prevalence is higher in PsO/PsA pts than the general population[1,2]. A previous analysis showed that the profile of pts with vs without HU was distinct and that the efficacy of secukinumab (SEC) was comparable in hyper- and normo-

uricemic pts except for PsO Area Severity Index response (PASI90), which was lower with SEC 150mg in HU pts[3]. These post hoc analyses sought to contrast PsA pts with vs without HU and evaluate the efficacy of guselkumab (GUS) through 1y in both cohorts.

Methods: Adults in DISCOVER 1&2 (90% bionaive) with active PsA despite standard therapies were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo. HU was defined as baseline (BL) serum urate levels of ≥360 μmol/L. Pts without HU (no HU) but with history of gout or uric-lowering therapies were excluded. Among GUS-randomized pts, the effect of HU vs no HU on changes from BL through W52 in Disease Activity (DA) Index for PsA (DAPSA), PsA DA Score (PASDAS), PASI, Health Assessment Questionnaire Disability Index (HAQ-DI), Short Form 36-item physical component summary (SF-36 PCS) score, and BASDAI (in pts with axial involvement) was assessed with mixed models for repeated measures adjusting for BL outcome levels, GUS regimen, prior TNFi use, and BL conventional synthetic DMARD use. The effect of HU vs no HU on achievement of ACR50, DAPSA low disease activity (LDA; ≤14), PASDAS LDA (≤3.2), PASI90, Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) response (Δ≥4), and enthesitis/dactylitis resolution in pts not in response/with condition at BL (all non-responder imputation for missing data) was assessed with logistic regression adjusting for the same covariates.

Table. Baseline Characteristics of Patients With vs. Without HU (≥360 μmol/L)

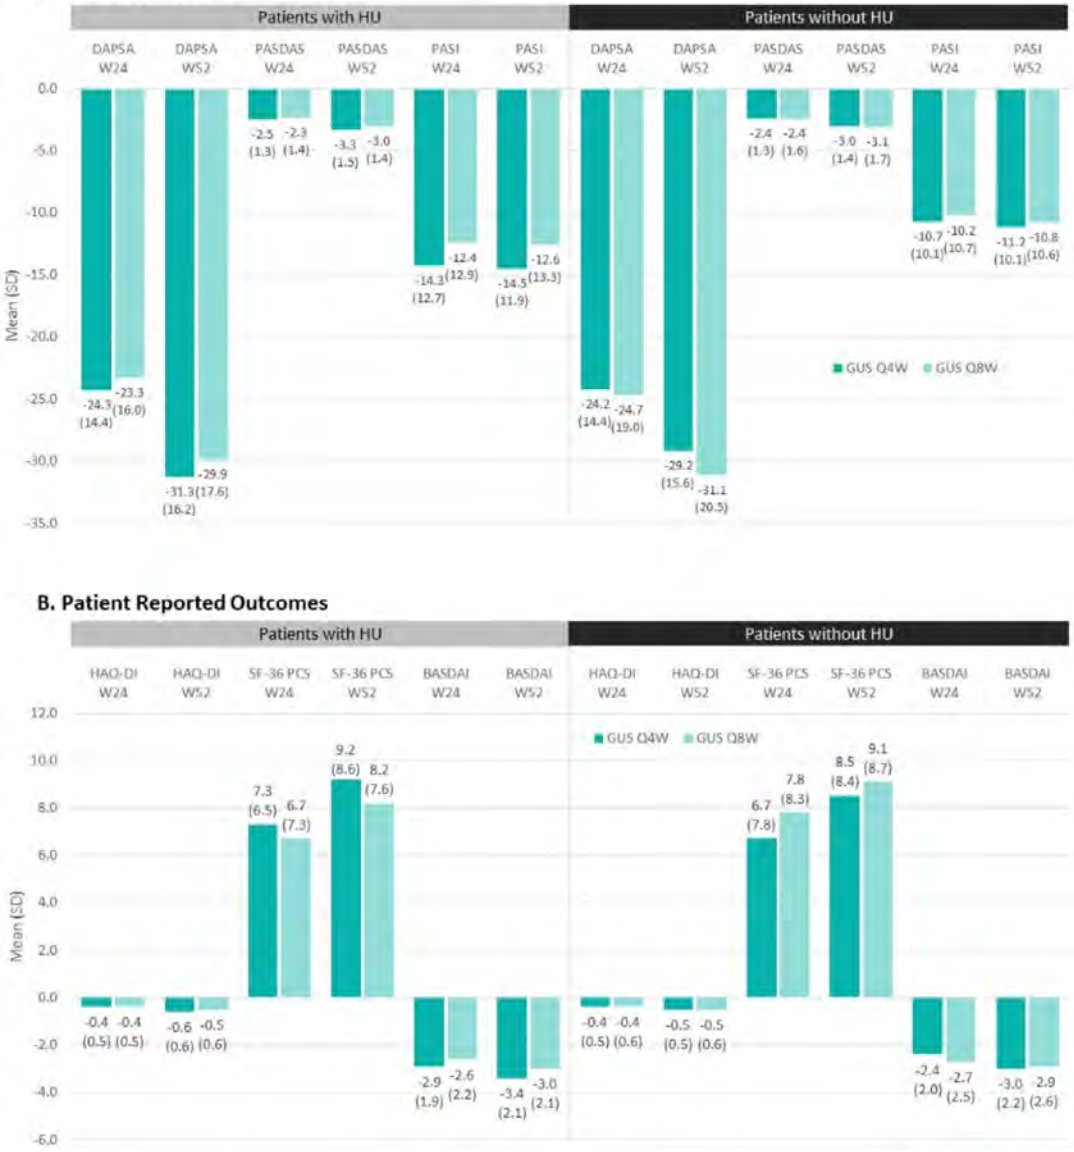
	HU (≥360 μmol/L) (N=425)	No HU (N=689)	Nominal P-value
Age at study BL (yrs)	47.8 (11.9)	45.8 (11.4)	**0.005**
Male sex, n (%)	312 (73.4)	269 (39.0)	**<0.001**
PsA disease duration (yrs)	5.9 (6.3)	5.8 (5.9)	0.819
Age at PsA diagnosis (yrs)	42.4 (12.1)	40.5 (11.6)	**0.009**
Prior TNFi use, n (%)	52 (12.2)	65 (9.4)	0.139
Concomitant csDMARD(s), n (%)	264 (62.1)	491 (71.3)	**0.002**
# of cardiovascular risk factors	1.8 (1.5)	1.4 (1.6)	**<0.001**
Hypertension, n (%)	199 (46.8)	215 (31.2)	**<0.001**
Diabetes, n (%)	45 (10.6)	57 (8.3)	0.193
Hyperlipidemia, n (%)	80 (18.8)	87 (12.6)	**0.005**
BMI≥30 kg/m², n (%)	217 (51.1)	226 (32.8)	**<0.001**
Current tobacco use	77 (18.1)	131 (19.0)	0.710
DAPSA	45.3 (19.7)	46.9 (21.0)	0.220
PASDAS	6.4 (1.1)	6.5 (1.1)	0.467
SJC (0-66)	11.2 (6.8)	11.6 (7.7)	0.416
TJC (0-68)	20.1 (13.1)	20.9 (13.4)	0.339
% BSA with psoriasis*, n (%)			**<0.001**
<3%	69 (16.2)	164 (23.8)	
≥3% to <10%	123 (28.9)	235 (34.1)	
≥10% to <20%	84 (19.8)	138 (20.0)	
≥20%	147 (34.6)	150 (21.8)	
PASI score (0-72)	11.3 (12.0)	8.4 (9.6)	**<0.001**
Presence of enthesitis, n (%)	266 (62.6)	457 (66.3)	0.210
LEI score (1-6)	2.8 (1.6)	2.8 (1.6)	0.572
Presence of Dactylitis, n (%)	175 (41.2)	296 (43.0)	0.566
Dactylitis Severity Score (1-60)	9.5 (11.0)	7.5 (8.7)	**0.041**
Pain VAS	60.3 (19.7)	61.8 (19.9)	0.214
Axial involvement (axPsA), n (%)	113 (26.6)	198 (28.7)	0.437
BASDAI (0-10) in pts with axPsA	6.4 (1.6)	6.5 (1.7)	0.527
HAQ-DI (0-3)	1.2 (0.6)	1.3 (0.6)	0.273
CRP (mg/dL)	1.7 (2.2)	1.8 (2.3)	0.349

Data are presented as mean (SD) unlessstated otherwise.

*Two pts in each group had missing information.

BSA: body surface area; csDMARDs: conventional synthetic DMARDs; LEI: Leeds enthesitis index; SJC: swollen joint count; TJC: tender joint count; VAS: visual analogue scale.

Figure 1. Changes from BL in Outcomes By Treatment Group and Presence of HU Through W52



Results: Relative to no HU pts (n=689), those with HU (n=425) were older at study BL and PsA diagnosis, and more likely to be male and have hypertension, hyperlipidemia, BMI ≥30 kg/m2 and more severe PsO and dactylitis (in pts with dactylitis) (**Table 1**). The two cohorts had generally comparable severity of joint disease, enthesitis and axial symptoms. In multivariate analysis (not shown), male sex, hypertension, high BMI, and PsO severity were associated with HU. Clinically meaningful and comparable improvements in all studied continuous outcomes were observed at W24 across HU cohorts and GUS regimens (**Figure 1**); further improvements were generally seen through W52 regardless of HU. Endpoint achievement was also comparable between HU cohorts and GUS regimens (**Figure 2**).

Conclusion: In this pooled analysis of mainly bio-naïve pts with active PsA, HU pts were more likely to be male and have high BMI, hypertension, and more severe PsO and dactylitis. The observed differential clinical profile and comorbidities, confirmed in previous studies[3], underscore the value of assessing serum urate levels in PsA pts. GUS was associated with clinically meaningful improvements across key PsA domains, with further enhancements generally seen through W52, irrespective of HU presence or GUS regimen.

Figure 2. Proportion of Patients Achieving Efficacy Endpoints By Treatment Group and Presence of HU Through W52

Elaine Husni[1], Vinod Chandran[2], Jeffrey Lisse[3], Rebecca Bolce[3], Carlos Diaz[3], Baojin Zhu[3], Elaine Lui[4] and Laura Coates[5], [1]Cleveland Clinic / Department of Rheumatic and Immunologic Diseases, Cleveland, OH, [2]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network and Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, ON, Canada, [3]Eli Lilly and Company, Indianapolis, IN, [4]Brightech International, An Everest Clinical Research Company, Somerset, NJ, [5]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic and progressive disease characterized by high rates of early joint erosions, which have been associated with impaired quality of life and increased mortality rates[1,2]. However, the relationship between the number of erosions at baseline (BL) and response to biological disease-modifying antirheumatic drugs (bDMARD) therapy has not been thoroughly investigated. In this post-hoc analysis, we assessed the efficacy of placebo (PBO), ixekizumab (IXE) or adalimumab (ADA) on patients (pts) with erosions visible on hand radiographs at BL.

Methods: Biologic-naïve pts with PsA (SPIRIT-P1, NCT01695239) were randomly assigned to PBO, IXE 80-mg every 2 weeks (Q2W) or 4 weeks (Q4W) after a 160-mg starting dose, or ADA 40-mg Q2W. Pts were stratified into two groups based on the number of BL erosions (erosion component of the modified total sharp scores ≤4 and >4). At week 24, outcomes analyzed for different baseline erosion score (BES) groups included American College of Rheumatology (ACR) 20%, 50%, 70%, Disease Activity index for PSoriatic Arthritis-Low Disease Activity (DAPSA-LDA), Health Assessment Questionnaire-Disability Index (HAQ-DI) and Minimal Disease Activity-Psoriasis Area Severity Index (MDA-PASI). Missing data were imputed using non-responder imputation (NRI) for categorical, and modified baseline observation carried forward (mBOCF) for continuous outcome variables. Comparisons between PBO and treatment within each BES group used logistic models for categorical, and ANCOVA for continuous outcome variables, adjusting for BL values, disease duration, geographic region, and prior conventional DMARD (cDMARD) experience.

Results: 183 pts with BES≤4 and 205 pts with BES >4 at BL were included. At week 24, pts with BES >4 on PBO had worse outcomes across all parameters compared to those with BES≤4. There was significant improvement in DAPSA-LDA response rates in pts treated with IXE regardless of BES, whereas significant response rates were seen in ADA treated pts with BES >4 (**Figure 1a**). MDA-PASI response rates were significant in patients treated with IXEQ2W and IXEQ4W who had BES≤4, whereas pts with BES >4 demonstrated a significant response rate with IXEQ2W and ADA (**Figure 1b**). Change from baseline in HAQ-DI was significant for all pts treated with bDMARDS, regardless of BES (**Figure 1c**). Similarly, regardless of BES, significant differences in ACR50 and ACR70 response rates versus PBO were seen for pts treated with bMDARDS (**Figure 2b and 2c**).

Conclusion: Pts with higher BES in the PBO group experienced worse outcomes. Higher response rates (e.g., ACR50/70) were also harder to achieve in pts with higher BES. Irrespective of BES, IXE treated pts showed greater improvement compared to PBO in the achievement of LDA and functional outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is a key clinical and imaging hallmark in psoriatic arthritis (PsA). ULTIMATE (NCT02662985) demonstrated responsiveness of ultrasound (US) detected synovitis and enthesitis in PsA and confirmed rapid and long-lasting benefits of secukinumab (SEC) through 52 weeks.[1,2] Little is known about the relationship between US-detected enthesitis vs clinical enthesitis over time. We evaluated the responsiveness of US enthesitis to SEC over 52 weeks and the correlation with clinical response of enthesitis.

Methods: This was a 52-week study with a 12-week double-blind, placebo-controlled treatment period, a 12-week open-label (OL) treatment period and a 6-month extension period. Patients with ≥1 clinical enthesitis site, defined by the Spondyloarthritis Research Consortium of Canada (SPARCC) index,were randomized to weekly SEC (300 or 150 mg according to severity of skin psoriasis) or placebo. Placebo patients switched to OL SEC at Week 12 ('placebo-SEC'). Enthesitis was assessed by Power Doppler (PD) performed bilaterally across 6 sites (enthesitis-level), and at patient level with the novel global Outcome Measures in Rheumatology (OMERACT) enthesitis score, which included 2 definitions of activity: definition 1 combinedB-mode morphological abnormalities (0–1) and PD vascularization abnormalities (0–3); definition 2 focused on PD signal alone (0–3). Clinical response was assessed by SPARCC enthesitis index (0–16). We report observed data on the distribution of US and clinical enthesitis, enthesitis resolution over 52 weeks, and the correlation between US and clinical enthesitis from baseline (BL) to Week 12.

Table 1. Distribution of clinical and ultrasound assessed enthesitis by site over time from Baseline to Week 52

Enthesitis site*	SEC			Placebo-SEC		
	Distribution of ultrasound detected enthesitis		Distribution of clinical (SPARCC) enthesitis	Distribution of ultrasound detected enthesitis		Distribution of clinical (SPARCC) enthesitis
	Definition 1	Definition 2		Definition 1	Definition 2	
Lateral epicondyle, n (%)

24	19 (23)	0 (0)	2 (2)	19 (23)	1 (1)	6 (7)
52	13 (16)	0 (0)	3 (4)	11 (13)	1 (1)	2 (2)

*n (%), number (percentage) of patients with enthesitis at the corresponding site, irrespective of left or right side

Composite OMERACT ultrasound enthesitis score at site level:
definition 1: range 0–4; sum of Power Doppler (0–3) and B mode (0–1) scores
definition 2: range 0–3; Power Doppler only

OMERACT, Outcome Measures in Rheumatoid Arthritis Clinical Trials; PDUS, power Doppler ultrasonography; SEC, secukinumab; SPARCC, Spondyloarthritis Research Consortium of Canada enthesitis index

Results: Overall, 166 patients were randomized; 90% (75/83) in the SEC group and 83% (69/83) in the placebo-SEC group completed 52 weeks. The mean number of clinical enthesitis sites at BL was 4 in both the SEC and placebo groups. Mean (SD) global OMERACT enthesitis scores were 6 (4.7) and 5 (3.2) (definition 1) and 3 (3.4) and 3 (1.6) (definition 2), for SEC and placebo-SEC, respectively. The proportion of patients with US-detected and clinical enthesitis decreased for most enthesitis sites in both treatment groups from BL to Week 24 and remained stable up to Week 52; definition 2 generally performed more closely to SPARCC clinical index than definition 1 **(Table 1).** According to the global OMERACT enthesitis score (definition 1 or 2), resolution of enthesitis was observed in a higher proportion of patients in the SEC vs placebo-SEC group at Week 12; the difference between SEC and placebo-SEC was similar at Week 52 **(Table 2).** No correlations were observed between the OMERACT score (definition 1 or 2) and SPARCC index regarding change from BL to Week 12 (**Table 3**).

Conclusion: A long-term stable response was observed with SEC and placebo-SEC in both US and clinical enthesitis up to Week 52. We found no correlation between US and clinically detected enthesitis, likely because the former assesses inflammation based on morphological/functional tissue changes while the SPARCC index evaluates inflammation based on tenderness of the entheseal site.

Table 2. Enthesitis resolution for SEC and placebo-SEC at Week 12 and Week 52

	Enthesitis resolution	SEC (150+300mg) n/m (%)	Placebo-SEC n/m (%)
Week 12	SPARCC resolution	39/81 (48)	22/76 (29)
	Global OMERACT enthesitis score definition 1 = 0	10/72 (14)	5/53 (9)
	Global OMERACT enthesitis score definition 2 = 0	14/34 (41)	6/19 (32)
Week 52	SPARCC resolution	36/65 (55)	37/56 (66)
	Global OMERACT enthesitis score definition 1 = 0	12/58 (21)	6/38 (16)
	Global OMERACT enthesitis score definition 2 = 0	15/28 (54)	8/16 (50)

SPARCC: range 0–16
Global OMERACT ultrasound enthesitis score:
definition 1: Sum of the 12 site level scores (6 sites bilaterally, each 0–4, see Table 1). Range 0–48
definition 2: Sum of the 12 site level scores (each 0–3). Range 0–36
m, number of patients with enthesitis assessment; n, number of patients with enthesitis resolution
Abbreviations, see Table 1

Table 3. Correlation (with 95% CI) between global OMERACT (PDUS) enthesitis score (Definition 1 or Definition 2) and SPARCC index with regards to change from Baseline to Week 12

Correlation analysis of ultrasound enthesitis vs. clinical enthesitis	SEC	Placebo-SEC
Global OMERACT PDUS enthesitis score (Definition 1) vs SPARCC index	–0.15 (–0.36 to 0.08)	0.15 (–0.10 to 0.38)
Global OMERACT PDUS enthesitis score (Definition 2) vs SPARCC index	–0.02 (–0.24 to 0.20)	0.08 (–0.16 to 0.32)
Abbreviations, see Table 1

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Biological and targeted synthetic therapies (ts/bDMARDs) have transformed the management ofP-soriatic arthritis (PsA).However, PsA might experience ts/bDMARD failure, (mainly due to inefficacy), and switching to another ts/bDMARD is the recommended strategy. In this aspect, there is a gap of knowledge regarding the correct

Table 1. Incidence rate (IR) of switching related to inefficacy by sociodemographic and clinical variables.

ts/bDMARDs: Targeted synthetic and Biologic Disease Modifying anti-rheumatic drugs; TNFi: TNF-alpha inhibitors. anti-Interlukine17 biological agent; anti-Interlukine-23 biological agent; JAKi: Janus kinase inhibitors

treatment algorithms that can be followed after ts/bDMARDfailuredue to inefficacy.**Objectives:** To assess the incidence rate of switching between ts/bDMARDs due to inefficacy, and to analyze the role of the different types of ts/bDMARDs in the risk of switching due to inefficacy. Other factors were also evaluated.

Methods: A longitudinal retrospective study (2015-2022) of PsA patients with ts/bDMARDs from an outpatient rheumatology clinic of a tertiary hospital was conducted. Main outcome: switching between ts/bDMARDs due to inefficacy.Independent variable:exposure to ts/bDMARDs during follow-up: a) anti-TNF; b) Other Biologics: abatacept; anti-IL17; anti-IL-23; c)Janus kinase inhibitors(JAKi). Covariables: Sociodemographic, clinics, and treatment.Statistical analysis:To estimate ts/bDMARDsswitchingdue to inefficacy rates, survival techniques were used, expressing the incidence rate (IR) per 100 patients*year with their confidence interval at 95% [CI 95%].Cox bivariate and multivariate regression analyses were run to assess the role of the different ts/bDMRADs in switching due to inefficacy. Results wereexpressed ashazard ratio(HR) and 95%CI.

Results: 141 PsA on ts/bDMARDs were included, with an 893.09 patients*year follow-up. 52.48% were female and the mean age was 48.06±13.21 years. 262 courses of treatment were recorded andTNFi was the ts/bDMARDsmost used, flowed byanti-IL-17. 92% were associated to a conventional DMARD, being MTX the most frequent (76.1%). Duringthe study period, 56 patients (40%) presented 121 switches between ts/bDMARDs, and 103 were related to inefficacy. The IR of switching due to inefficacy was 11.53 [9.51-13.98] and anti-TNF was the drug with the lowest incidence (Table 1). In the bivariate analysis of switching due to inefficacy, all types of ts/bDMARDs but TNFi had more risk of switching, in the comparing analysis (HR IL-17 vs TNFi: 2.26 [1.17-4.36], p=0.014; others vs TNFi: 3.21 [1.59-6.45], p=0.001); however, this statistical significance was lost in the multivariate analysis after adjustment for age, sex, year of ts/bDMARDs prescription, and comorbidity: none type of ts/bDMARD had more or less risk compared to each other (Table 2). The model also showed the effect of gender, specific clinical symptoms, prescription year, therapy courses, and the negative influence of glucocorticoids or sulfasalazine on switching due to inefficacy.

Conclusion: This study suggests that long-term control of PsA requires therapeutic switching due to inefficacy. This investigation is able to give us useful information about the comparative effectiveness of ts/bDMARDs, not finding any statistical difference in switching due to inefficacy among different ts/bDMARDs in the multivariate analysis. This studyconfirms previously identified risk factors of switching due to inefficacy and proposes new ones.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

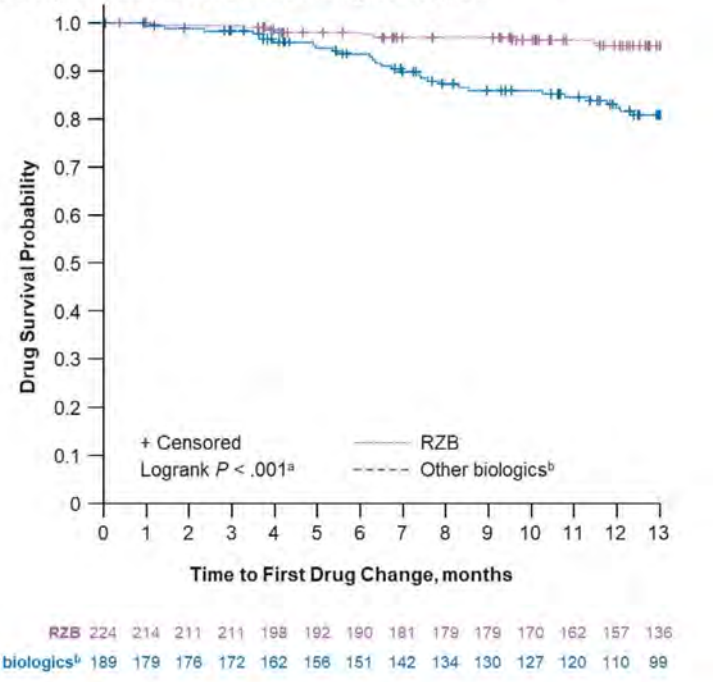
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

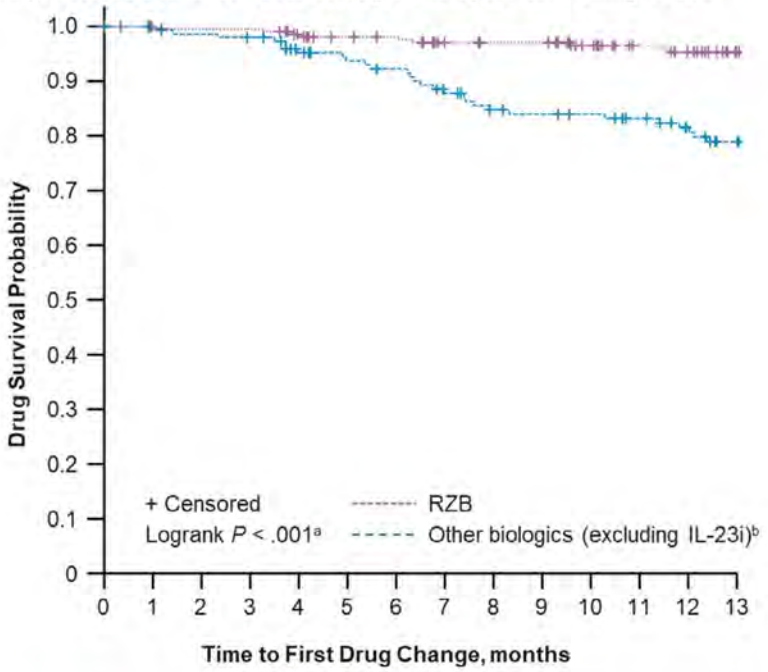
Background/Purpose: Risankizumab (RZB) is an optimized IL-23 inhibitor (IL-23i) currently approved for the treatment of plaque psoriasis (PsO), PsA, and Crohn's disease. In a post hoc analysis of data from the postmarketing VALUE study in patients with PsO who were treated with RZB or other biologic therapies, we assessed real-world drug survival for a subgroup of patients also diagnosed with PsA.

Figure 1. Kaplan-Meier estimate of drug survival among patients who were prescribed RZB or other biologic therapies.



RZB, risankizumab.
[a]Logrank *P* value based on available data through month 25.
[b]Includes secukinumab (n = 51), adalimumab (n = 38), ixekizumab (n = 37), guselkumab (n = 30), certolizumab pegol (n = 14), brodalumab (n = 7), ustekinumab (n = 6), tildrakizumab (n = 3), etanercept (n = 2), and infliximab (n = 1).

Figure 2. Kaplan-Meier estimate of drug survival among patients who were prescribed RZB or other biologic therapies excluding IL-23i.



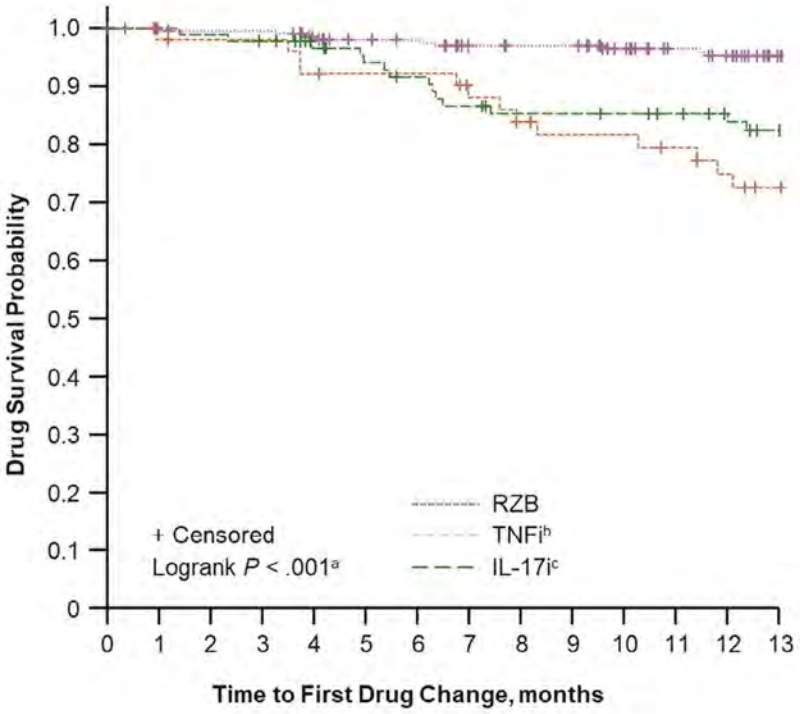
RZB	224	214	211	211	198	192	190	181	179	179	170	162	157	136
Other biologics (excluding IL-23i)[b]	156	147	145	143	133	128	125	117	110	108	106	102	94	86

IL-23i, IL-23 inhibitors; RZB, risankizumab.
[a]Logrank *P* value based on available data through month 25.
[b]Includes all other biologic therapies prescribed for psoriasis/PsA excluding the IL-23i guselkumab and tildrakizumab; secukinumab (n = 51), adalimumab (n = 38), ixekizumab (n = 37), certolizumab pegol (n = 14), brodalumab (n = 7), ustekinumab (n = 6), etanercept (n = 2), and infliximab (n = 1).

Methods: The ongoing, multicountry, prospective observational cohort VALUE study (NCT03982394) enrolled adults (aged ≥ 18 years) who were diagnosed with moderate-to-severe PsO and prescribed RZB or another biologic therapy in accordance with local labeling in a 2:1 ratio. All treatment decisions were made solely by the treating physician. This post hoc analysis included data from the subset of patients with PsO who were also diagnosed with PsA by a rheumatologist and was based on an interim database lock (data cutoff, September 26, 2022). Drug survival was compared for patients receiving RZB vs all other biologics, vs biologics excluding IL-23i, vs TNF-α inhibitors (TNFi), and vs IL-17 inhibitors (IL-17i). The probability of drug survival was estimated from Kaplan-Meier curves of time to first drug change (defined as discontinuation of the prescribed biologic treatment or changing to a different biologic treatment). Chi-squared tests were used to evaluate the proportion of patients who had drug changes by month 13. Analyses were repeated after propensity score matching (PSM) with a 1:1 ratio using greedy algorithm and exact match for biologic-naive/biologic-experienced status to account for baseline imbalances between comparison groups.

Results: A total of 244 (RZB) and 189 (other biologics) patients diagnosed with PsO and PsA were included in this analysis. Baseline demographics and characteristics were generally comparable between groups, except patients prescribed RZB vs other biologics were older (median age, 55 vs 51 years, $P = .02$) and more likely to have prior biologic therapy experience (67.4% vs 43.4%, $P < .001$). At month 13, fewer patients prescribed RZB had drug changes (5.5%) vs patients prescribed other biologics (19.0%), other biologics excluding IL-23i (20.5%), TNFi (26.7%), and IL-17i (16.4%; $P < .001$ for all comparisons). The estimated probability of drug survival [95% CI] at 13 months was higher among patients receiving RZB (95.3% [91.1%, 97.5%]) vs other biologics (80.9% [73.7%, 86.3%]; **Figure 1**); RZB vs biologics excluding IL-23i (78.9% [70.9%,

Figure 3. Kaplan-Meier estimate of drug survival among patients who were prescribed RZB, TNFi, or IL-17i.



RZB	224	214	211	211	198	192	190	181	179	179	170	162	157	136
TNFi[b]	55	51	50	50	47	46	46	42	39	37	37	35	32	28
IL-17i[c]	95	90	89	87	80	76	73	69	66	66	65	63	58	54

IL-17i, IL-17 inhibitors; RZB, risankizumab; TNFi, TNFα inhibitors.

[a]Logrank *P* value based on available data through month 25.
[b]Includes adalimumab (n = 38), certolizumab pegol (n = 14), etanercept (n = 2), and infliximab (n = 1).
[c]Includes secukinumab (n = 51), ixekizumab (n = 37), and brodalumab (n = 7).

85.0%]; **Figure 2**), or RZB vs TNFi and IL-17i (72.5% [57.3%, 83.1%] and 82.4% [72.0%, 89.2%]; **Figure 3**). Similar results were observed after PSM (estimated probability of drug survival [95% CI] at 13 months for RZB, 94.8% [88.7%, 97.6%]; other biologics, 84.8% [76.3%, 90.4%]; biologics excluding IL-23i, 82.4% [72.4%, 89.0%]; TNFi, 82.7% [63.2%, 92.4%]; and IL-17i, 82.8% [69.5%, 90.7%]).

Conclusion: Patients with PsO and PsA who were treated with RZB in the real-world setting experienced fewer drug changes and a higher probability of drug survival compared with those treated with other biologic therapies. These results can help inform clinician decision making when initiating biologic treatment in patients with PsA.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The national prevalence of PsA among patients (pts) with psoriasis (PsO) in Japan is estimated to be 14.3%. Risankizumab (RZB) was approved for the treatment of PsO and PsA in Japan in March 2019. Real-world data on treatment persistence for PsA does not fully include recently approved biologic DMARDs (bDMARDs). This analysis

Table 1. Kaplan-Meier Rates of Switching and Discontinuation of Different PsA Treatments

Drug	N	Switching		Discontinuation		Switching or Discontinuation	
		12m	24m	12m	24m	12m	24m
RZB	74	21.00%	35.00%	21.60%	31.80%	25.90%	35.70%

Cox proportional hazards models were used to estimate treatment-specific adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) for switching and discontinuation; covariates included patient demographics, treatment history, and baseline comorbidities and healthcare charges.

quantified real-world treatment switching and discontinuation rates for pts with PsA in Japan initiating bDMARDs over 24 months, accounting for recent advancements in treatment.

Methods: A retrospective database study conducted using administrative claims from the Japan Medical Data Center Payer-Based Database from January 2005 through August 2022 included pts who had ≥ 1 medical claim for PsA preceding a claim for an approved bDMARD. Pts had ≥ 6 months of continuous eligibility prior to the first claim for a bDMARD (index date) and were evaluated for all treatments for which they had a qualifying index date. Treatment switch, defined as a claim for another bDMARD approved for PsA after the index date, and treatment discontinuation, defined as a gap in treatment without refill equal to 150% of the assumed days supply of the last prescription fill, were assessed up to 24 months past treatment initiation and rates were evaluated using Kaplan-Meier time-to-event analyses censored for loss of follow-up. bDMARD-specific adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using multivariate Cox proportional hazards models. HRs were adjusted for pt demographics, treatment history, and baseline comorbidities and healthcare charges.

Results: A total of 779 unique pts met the inclusion criteria for the study, and were treated with adalimumab (ADA; n = 264), bimekizumab (BIM; n = 5), brodalumab (BRO; n = 53), certolizumab pegol (CZP; n = 108), guselkumab (GUS; n = 115), ixekizumab (IXE; n =156), risankizumab (RZB; n = 74), secukinumab (SEC; n = 188), tildrakizumab (TIL; n = 5), and ustekinumab (UST; n = 53). Owing to small sample sizes, results are not shown for BIM and TIL. At 12/24 months following treatment initiation, 37.5%/49.0% of pts had discontinued their index bDMARD, while 22.2%/31.2% of pts had switched treatment. Switch rates varied across bDMARDs from 18.9-30.3% at 12 months, and 26.3%-36.6% at 24 months (**Table 1**). Discontinuation rates at 12/24 months were lowest for RZB (21.6%/31.8%), followed by UST (24.2%/35.8%), IXE (31.2%/38.2%), GUS (37.4%/48.6%), SEC (36.1%/53.2%), BRO (48.0%/53.3%), CZP (34.7%/55.6%), and ADA (49.0%/59.1%) [**Table 1**]. Adjusting for baseline pt characteristics, HRs of switching or discontinuation over 24 months were higher among CZP, SEC, ADA, BRO, and GUS, relative to RZB ($p < 0.05$) [**Table 2**].

Conclusion: Treatment switching and discontinuation were common in the first 24 months of treatment with bDMARDs for PsA in Japan. While treatment switch rates varied across bDMARDs, discontinuation rates were lowest for RZB at each timepoint that was examined. Hazards of switching or discontinuation relative to RZB were generally higher across most bDMARDs, indicating higher treatment persistence rates for RZB.

Gender Differences in Switching Biological and Targeted Synthetic Therapies in Psoriatic Arthritis

Leticia Leon[1], Dalifer Freites[2], Maria Rodriguez Laguna[3], Cristina Martinez[4], Esther Toledano[4], Inmaculada Morado[3], Benjamin Fernandez[3] and lydia Abasolo[2], [1]Fundación Investigación Biomédica Hospital Clínico San Carlos, Madrid, Spain, [2]Hospital Clínico San Carlos, Madrid, Spain, [3]Hospital Clinico San Carlos, Madrid, Spain, [4]Hospital Clinico San Carlos, Rheumatology Deparment, Madrid, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The impact of gender on biological and targeted synthetic therapies (ts/bDMARDs) used in PsA patients has been scarce studied. Our main objective was to explore gender differences in the incidence rate and causes of switching between ts/bDMARDs.

Methods: A retrospective longitudinal observational study was performed. Subjects: All patients who visited the outpatient rheumatology clinic from January 2007 to December 2021, and followed up to June 2022, diagnosed with PsA meeting CASPAR classification and on treatment with biological and targeted therapies (ts/bDMARDs). Main outcome: Switching of the ts/bDMARDs. Covariables: sociodemographic, clinics, and treatments. Statistical analysis: descriptive analysis of the switching, stratified by gender. To estimate ts/bDMARDs switching rates, survival techniques were used, expressing the incidence rate (IR) per 100 patients*year with their respective CI at 95% [CI 95%].

Results: A total of 141 patients with a diagnosis of PsA and under treatment with ts/bDMARDs were included, with a follow-up of 893.09 patients*year. The mean age was 48.06 ± 13.22 years and a 52.48% were females. PsA females showed some baseline disease characteristics: more depression, diabetes mellitus and thyroid disease and higher BMI. Regarding treatment characteristics, PsA males required more often concomitant corticosteroids and conventional synthetic DMARDs. A total of 262 treatment courses were recorded. Throughout follow-up, TNFi were the most used DMARDs in both genders,

Table 1: Total courses of ts/bDMARDs of the PsA patients

	Total courses (n=262)	Males courses (n=98)	Females courses (n=164)
ts/bDMARDs: n (%)			
TNFi	192 (73.28)	78 (79.59)	114 (69.51)
Adalimumab	81 (30.92)	39 (39.80)	42 (25.61)
Etanercept	41(15.75)	14 (14.29)	27 (16.46)
Certolizumab	36(13.74)	11(11.22)	25 (15.24)
Golimumab	16 (6.11)	6 (6.12)	10 (6.10)
Infliximab	18 (6.87)	8 (8.16)	10 (6.10)
Anti-IL17	43 (16.41)	16 (16.33)	27 (16.46)
Secukinumab	35(13.36)	13 (13.27)	22 (13.41)
Ixekizumab	8 (3.05)	3(3.06)	5(3.05)
Anti-IL12/IL23			
Ustekinumab	7 (2.67)	1(1.02)	6 (3.66)
JAKi	14 (5.35)	2 (2.04)	12 (7.32)
Tofacinib	4 (1.53)	0	4 (2.44)
Baricitinib	5 (1.91)	0	5 (3.05)
Upacitinib	5 (1.91)	2 (2.04)	3 (1.83)

* TNFi tumor necrosis factor inhibitor; JAKi: janus kinasa inhibitor

Table 2: Incidence rate (IR) of switching by gender

	Males (460.8 patients*year)		Females (432.7 patients*year)	
	Events	IR per 100 (CI 95%)	Events	IR per 100 (CI 95%)
Global switch	31	6.72(4.73-9.56)	91	21.02 (17.12-25.82
Switch due to inefficacy	25	5.42(3.66-8.02)	78	18.02 (14.4-22.5)
Primary failure	8	1.73 (0.86-3.47)	40	9.24 (6.78-12.60)
Secondary failure	18	3.90 (2.40-6.19)	38	8.78(6.38-12.06)
Switch due to adverse events	4	0.86 (0.32-2.31)	11	2.54 (1.40-4.58)
Switch due to other reasons	1	0.21 (0.30-1.54)	2	0.46 (0.11-1.84)

* Primary failure is defined as no clinical response within the initial treatment while secondary failure is defined as loss of efficacy of the drug after initial remission.

with 192 courses (73.28%), followed by Anti-IL17, with 43 (16.41%) courses of treatment, nevertheless, females used more Anti-IL12/23 and JAKi (Table 1). Of these 262 treatment courses, 122 (46.5%) were switched, with significative differences between gender (91 for females and 31 for males, p=0.001). About provider-reported reasons for switching, the most common reasons were primary inefficacy, loss of efficacy and adverse effects. The overall ts/bDMARDs switch rate in our study was IR (95% CI): 13.65 per 100 patients*year, with a much higher rate in females (21. 02 vs 6. 72), mainly due to primary failure. Table 2 show incidence rate (IR) of switching by gender and causes.

Conclusion: PsA female patients have distinct sociodemographic and clinic features that might contribute to the differences in therapy switching. Our results suggest that female patients are likely to change more their treatments. The overall ts/bDMARDs switch rates for females were significantly higher compared to males, mainly due to lack of efficacy. Gender differences in PsA are determined by biological and psychological factors (including gestational counselling reasons), influencing in the response to treatments and trends to switching.

Primary Non-response in Psoriatic Arthritis Treated with Biologics and Targeted Synthetic Therapies in Daily Clinical Practice

Iydia Abasolo[1], Leticia Leon[2], Maria Rodriguez Laguna[3], Esther Toledano[4], Gloria Candelas[3], Cristina Martinez[4], Maria Paula Alvarez Hernandez[3], Benjamin Fernandez[3] and Dalifer Freites[1], [1]Hospital Clínico San Carlos, Madrid, Spain, [2]Fundación Investigación Biomédica Hospital Clínico San Carlos, Madrid, Spain, [3]Hospital Clinico San Carlos, Madrid, Spain, [4]Hospital Clinico San Carlos, Rheumatology Deparment, Madrid, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In Psoriatic arthritis (PsA), patients who fail to respond to biologics and targeted synthetic therapies (ts/bDMARDs), switching to another ts/bDMARD should be considered. Failure can be classified as primary non-response (without initial response probably due to therapeutic target failure), or secondary non-response (initial response achieved, but effectiveness is lost over time). Focusing in primary non-response, it seems reasonable to consider a different mode of action for the next treatment rather than switching within class, but studies addressing the best possible strategy are still lacking. Our purpose was obtain information from clinical practice regarding failures due to primary non-responsein PsA on ts/bDMARDs: 1) to assess the incidence rate of switching due to primary non-response; and 2) in those who have experienced primary non-response, to assess the risk of subsequent treatment failure by switching between classes compared to switching within class.

Methods: A longitudinal retrospective study (2015-2022) of PsA patients meeting CASPAR criteria on treatment with ts/bDMARDs from an outpatient rheumatology clinic was conducted. Main outcomes: 1) ts/bDMARD failure due to primary non-response; 2) subsequent discontinuation of ts/bDMARD due to lack of efficacy. Ourindependent variable wasswitching between classes compared to switching within class. To estimate bDMARDs switching rates, survival techniques were used, expressing the incidence rate (IR) per 100 patients*year with their CI at 95%. Cox multivariate regression analyses was run to assessthe role of switching between/within classes in the subsequent treatment failure.

Results: 141 PsA patients on treatment with ts/bDMARDs with a maximum follow-up of 16 years were included. Of these, 30 in 48 treatment courses developed primary non-response with an IR of 5.37 [4.04-7.12]. The IR was higher in women, and in those that started ts/bDMARDs after 2018. Regarding ts/bDMARDs those on TNF developed lower IR compared to the others (Table1). Focusing in those with primary non-response, there were 26 subsequent treatment failures with an IR of 22.09 [15.04-32.44]. The IR was higher in women, mainly after 2018 and in those patients who switched between classes (Table 2). In the multivariate adjusted model we found that switching within class increased the risk of subsequent failure compared switching between class (HR:3.26 [1.23-8.62], p=0.017).

Conclusion: In clinical practice, the IR of ts/bDMARDs failures due to primary non-response is 5.37% patients*year, but their subsequent failures are higher. This study provides a support to consider switching between classes a better alternative rather than switching within class after primary non-response.

Table 1: Incidence rate of switching due to primary non-response rate by covariables.

	Patients/year	N	IR	95%CI
Total	893.62	48	5.37	4.05-7.12

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

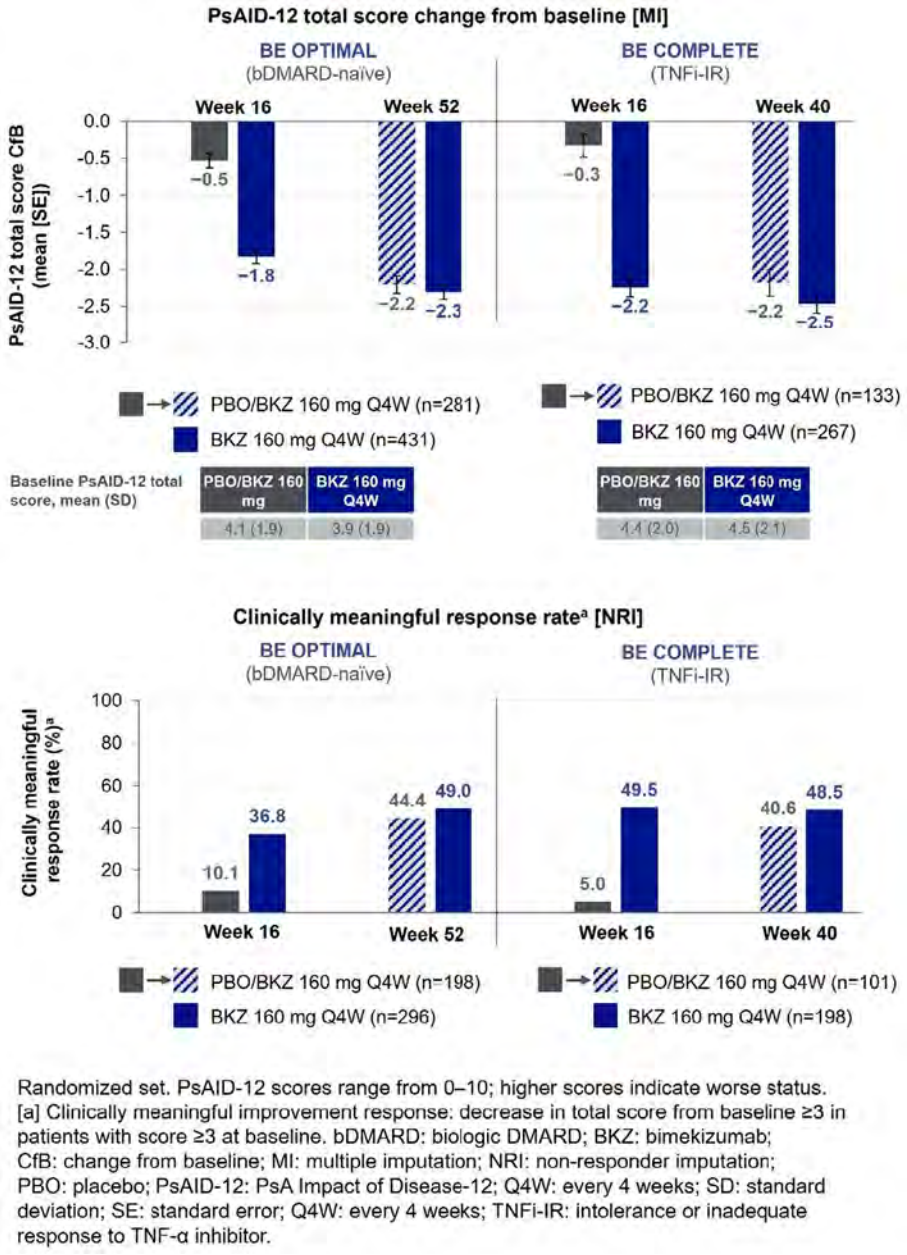
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The PsA Impact of Disease-12 (PsAID-12) questionnaire is a patient (pt)-reported outcome measure assessing the impact of PsA on 12 physical, social, and psychological domains. OMERACT provisionally endorsed PsAID-12 as a core outcome measure for health-related quality of life (HRQoL) in clinical trials.[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has demonstrated efficacy and tolerability to 52 weeks (wks) in pts with active PsA.[2,3] Here, the impact of BKZ on pt-reported symptoms and HRQoL, assessed by PsAID-12, is reported to 1 year.

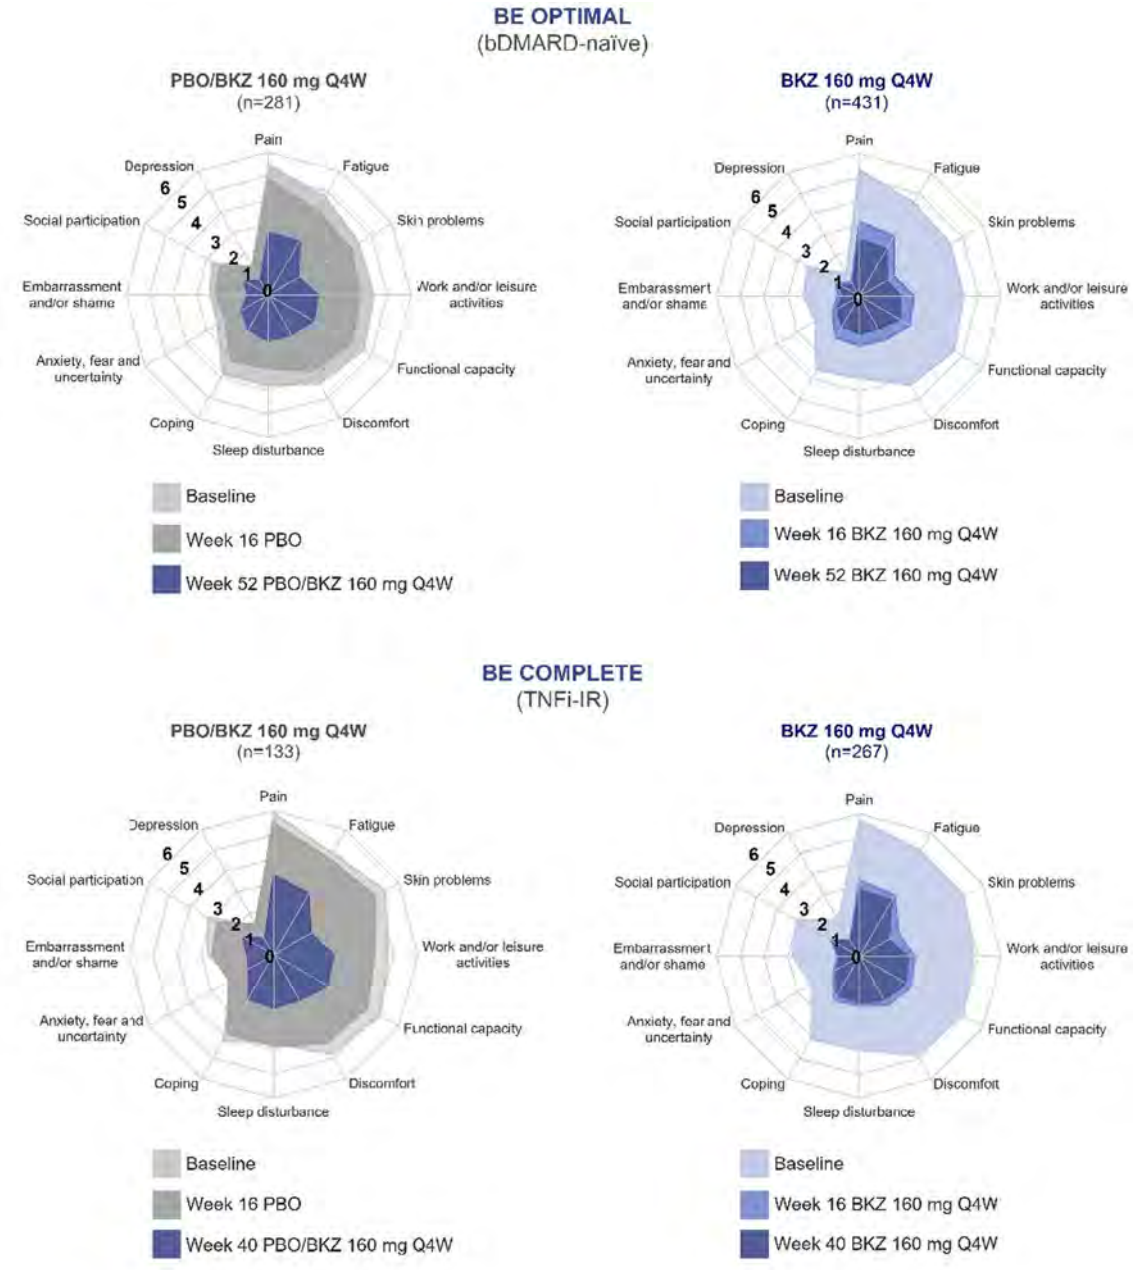
Methods: The phase 3 BE OPTIMAL (NCT03895203) and BE COMPLETE (NCT03896581) trials, both with a 16-wk double-blind, placebo (PBO)-controlled phase, assessed BKZ in pts with PsA who were biologic DMARD (bDMARD)-naïve or had intolerance or inadequate response to 1–2 TNF-α inhibitors (TNFi-IR), respectively. Pts in BE OPTIMAL were randomized 3:2:1 to subcutaneous (sc) BKZ 160 mg every 4 wks (Q4W), PBO, or reference (sc adalimumab 40 mg Q2W; data not reported here). At Wk 16, PBO pts switched to receive BKZ (PBO/BKZ). Pts in BE COMPLETE were randomized 2:1 to sc BKZ 160 mg Q4W or PBO; Wk 16 completers were eligible to enter an open-label extension, BE VITAL (NCT04009499), when PBO pts switched to BKZ (PBO/BKZ). BE COMPLETE plus BE VITAL is referred to as 'BE COMPLETE' hereafter. PsAID-12 total and single-item domain scores range from 0–10; higher scores indicate worse status.[1] Change from baseline (BL; CfB) and clinically meaningful improvement responses (decrease ≥3 from BL when respective PsAID-12 score ≥3 at BL) were collected to Wk 52 in BE OPTIMAL and Wk 40 in BE COMPLETE. Missing data imputed using multiple imputation (MI; continuous) or non-responder imputation (NRI; binary).



Randomized set. PsAID-12 scores range from 0–10; higher scores indicate worse status.
[a] Clinically meaningful improvement response: decrease in total score from baseline ≥3 in patients with score ≥3 at baseline. bDMARD: biologic DMARD; BKZ: bimekizumab; CfB: change from baseline; MI: multiple imputation; NRI: non-responder imputation; PBO: placebo; PsAID-12: PsA Impact of Disease-12; Q4W: every 4 weeks; SD: standard deviation; SE: standard error; Q4W: every 4 weeks; TNFi-IR: intolerance or inadequate response to TNF-α inhibitor.

Figure 1. PsAID-12 total score CfB [MI] and clinically meaningful improvement response rate [NRI] at Week 16 and Week 52/40

Results: 770/852 (90.4%) and 347/400 (86.8%) pts completed Wk 52 of BE OPTIMAL and BE COMPLETE, respectively. BKZ pts showed sustained improvements in PsAID-12 total score, with a mean CfB of –1.8 at Wk 16 and –2.3 at Wk 52 in BE OPTIMAL and –2.2 at Wk 16 and –2.5 at Wk 40 in BE COMPLETE. In both trials, PBO/BKZ pts achieved similar improvements to BKZ pts at Wk 52/40 (**Figure 1**). Clinically meaningful improvement response in PsAID-12 total score was achieved by 44.4% PBO/BKZ and 49.0% BKZ pts at Wk 52 in BE OPTIMAL, and 40.6% PBO/BKZ and 48.5% BKZ pts at Wk 40 in BE COMPLETE (**Figure1**). In both trials, improvements from BL in PsAID-12 individual domain mean scores were observed across all domains at Wk 16 and sustained to Wk 52/40 on BKZ (**Figure 2**). The greatest improvements were



Randomized set. PsAID-12 scores range from 0–10; higher scores indicate worse status.
bDMARD: biologic DMARD; BKZ: bimekizumab; PBO: placebo; PsAID-12: PsA Impact of Disease-12; Q4W: every 4 weeks; TNFi-IR: intolerance or inadequate response to TNF-α inhibitor.

Figure 2. PsAID-12 individual domain mean scores at baseline, Week 16, and Week 52/40 [MI]

observed in domains with the highest PsA impact at BL: pain, functional capacity, fatigue, and skin problems. Clinically meaningful improvement responses were achieved by around half of BKZ-treated patients across most individual domains, including pain, functional capacity, fatigue, and skin problems, at Wk 52/40.

Conclusion: Improvements in PsAID-12 total and most single-item domain scores at Wk 16 were sustained up to 1 year of BKZ treatment. Results were similar between the two trials, demonstrating consistent responses in bDMARD-naïve and TNFi-IR pts with active PsA.

Randomized set. bDMARD: biologic DMARD; BKZ: bimekizumab; MI: multiple imputation; PBO: placebo; Q4W: every 4 weeks; SF-36: Short-Form 36-Item Health Survey; TNFi-IR: inadequate response or intolerance to TNF-α inhibitor.

Figure 2. SF-36 single-item subscale scores at baseline, Week 16, and Week 40/52 (MI)

demonstrated clinically relevant improvements in HRQoL measures to Week (Wk) 16 vs placebo (PBO) in pts with PsA in two phase 3 trials.[3,4] In this study, the impact of BKZ treatment on HRQoL is reported up to 1 year.

Methods: The phase 3 BE OPTIMAL (NCT03895203) and BE COMPLETE (NCT03896581) trials, both with a 16-wk double-blind, PBO-controlled phase, assessed BKZ in pts with PsA who were biologic DMARD (bDMARD)-naïve or had intolerance or inadequate response to TNF-α inhibitors (TNFi-IR), respectively. BE OPTIMAL pts were randomized 3:2:1 to subcutaneous (sc) BKZ 160 mg every 4 wks (Q4W), PBO, or reference (sc adalimumab 40 mg Q2W; data not reported). At Wk 16, PBO pts switched to BKZ (PBO/BKZ). BE COMPLETE pts were randomized 2:1 to sc BKZ 160 mg Q4W or PBO. Pts completing Wk 16 were eligible to enter an open-label extension, BE VITAL (NCT04009499), when PBO pts switched to BKZ (PBO/BKZ). BE COMPLETE plus BE VITAL is referred to as 'BE COMPLETE' hereafter.

Endpoints reported for HRQoL, health status, and physical function included Short-Form 36-Item Health Survey (SF-36) Physical and Mental Component Summaries (PCS; MCS) and subscale norm-based scores; PsA Impact of Disease 12-item (PsAID-12); EuroQol-5 Dimensions-3 Level Visual Analog Scale (EQ-5D-3L VAS); PsA Quality of Life (PsAQoL); HAQ-Disability Index (HAQ-DI). BE COMPLETE outcomes were collected to Wk 40/52 as stated in the **Table**. Non-responder and multiple imputation (NRI; MI) were used for missing binary and continuous variables.

Results: Overall, 770/852 (90.4%) and 347/400 (86.8%) pts completed Wk 52 of BE OPTIMAL and BE COMPLETE. Across both trials, Wk 16 improvements in HRQoL, health status, and physical function were sustained to Wk 52 on BKZ (**Table**). PBO/BKZ pts achieved comparable improvements to BKZ-randomized pts by Wk 52/40, including PsAID-12 total score response (decrease from baseline ≥3; bDMARD-naïve/TNFi-IR BKZ: 49.0/48.5%, PBO/BKZ: 44.4/40.6%), HAQ-DI minimal clinically important difference (MCID; decrease from baseline ≥0.35; BKZ: 57.2/55.0%, PBO/BKZ: 56.6/50.0%; **Figure 1**), and reaching HAQ-DI normative state of ≤0.5 (BKZ: 57.3/53.2%, PBO/BKZ: 57.7/42.9%). SF-36 PCS improved to a greater extent at Wk 16 in BKZ vs PBO pts (**Figure 1**); responses were sustained to Wk 52 on BKZ. SF-36 physical functioning, role physical, and bodily pain subscales showed the most improvement over the other subscales (**Figure 2**). Similar improvement trends were seen in EQ-5D-3L VAS (**Table**; **Figure 1**).

Conclusion: Clinically meaningful improvements in measures of HRQoL, health status, and physical function were observed up to 1 year with BKZ treatment, irrespective of prior bDMARD use.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

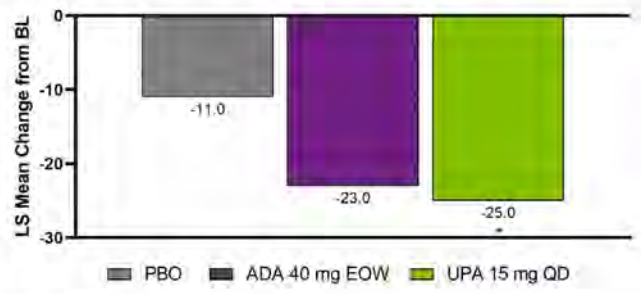
Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain, including inflammatory joint pain, may be debilitating in patients with psoriatic arthritis (PsA). Pain in PsA is multidimensional and can be influenced via reduction of inflammation and potentially by other means, such as a direct analgesic drug effect. The objective of this analysis of the SELECT-PsA 1 study was to assess the direct and indirect (ie, by changes in inflammation surrogates) effects of treatment with upadacitinib (UPA), a selective and reversible Janus kinase (JAK) inhibitor, or adalimumab (ADA), a TNF inhibitor, vs placebo (PBO) on pain in patients with PsA.

Methods: SELECT-PsA 1 was a randomized, double-blind phase 3 study in patients with PsA who had active disease at baseline. Adults (≥18 years) were randomized 1:1:1:1 to UPA 15 mg once daily, UPA 30 mg once daily, ADA 40 mg every other week, or PBO; for UPA, only UPA 15 mg data are reported here. As observed analysis was used for change from baseline to week 16 in Patient's Global Assessment (PtGA) of pain (1–100 mm) or tender joint count based on 28 joints (TJC28). Observed case multiple mediation analysis[1] for effect of UPA vs PBO and ADA vs PBO on pain (pain assessed as PtGA of pain or TJC28) was conducted. Indirect effect of treatment on pain was assessed based on inflammatory factors including itch, total enthesitis, Leeds Enthesitis Index (LEI), and CRP.

Figure 1. Change from Baseline in PtGA of Pain (mm) at Week 16



As observed analysis.
ADA, adalimumab; BL, baseline; EOW, every other week; LS, least squares; PBO, placebo; PtGA, Patient's Global Assessment; QD, once daily; UPA, upadacitinib.
*Statistically significant UPA vs PBO; $P<0.05$.

Figure 1. Change from Baseline in PtGA of Pain (mm) at Week 16

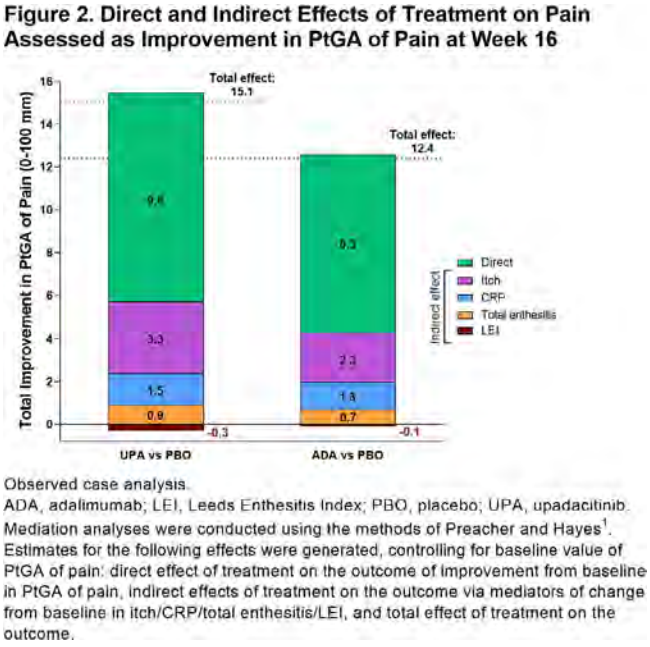


Figure 2. Direct and Indirect Effects of Treatment on Pain Assessed as Improvement in PtGA of Pain at Week 16

Results: 1281 patients were included in this analysis (UPA, n=429, ADA, n=429, PBO, n=423).PtGA of pain significantly improved with UPA vs PBO from baseline to week 16 (–25.0 [n=404] vs –11.0 [n=390]; *P*< 0.05; **Figure 1**). Improvements in pain were also observed with ADA at week 16 (–23.0 [n=408]). Total effects (15.1 and 12.4) and direct effects (9.8 and 8.3) on improvement in PtGA of pain were significantly greater with both UPA vs PBO and ADA vs PBO, respectively at week 16 (all *P*< 0.001; **Figure 2**); numerically greater reductions in total effect on pain were observed with UPA vs ADA. Direct and indirect effects on pain assessed as improvement in PtGA of pain were numerically greater with UPA vs ADA (**Figure 2)**. Improvement in elicited pain assessed asTJC28 was also significantly greater with UPA and ADA vs PBO (all *P*< 0.05;

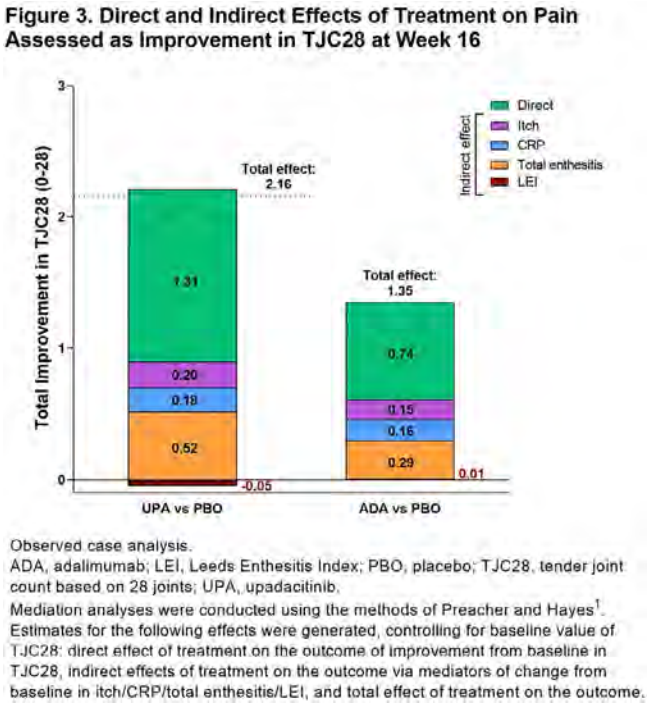

Figure 3. Direct and Indirect Effects of Treatment on Pain Assessed as Improvement in TJC28 at Week 16

Figure 3). Furthermore, UPA reduced pain assessed as TJC28 numerically more than ADA when examining the total effect explained by direct effects and the inflammatory mediators (indirect effects).

Conclusion: UPA and ADA produced relevantly higher mean improvements in pain via inflammatory or non-inflammatory mechanisms vs PBO in patients with PsA. Total effects on pain improvement were numerically greater with UPA vs ADA when assessed as PtGA of pain and TJC28.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

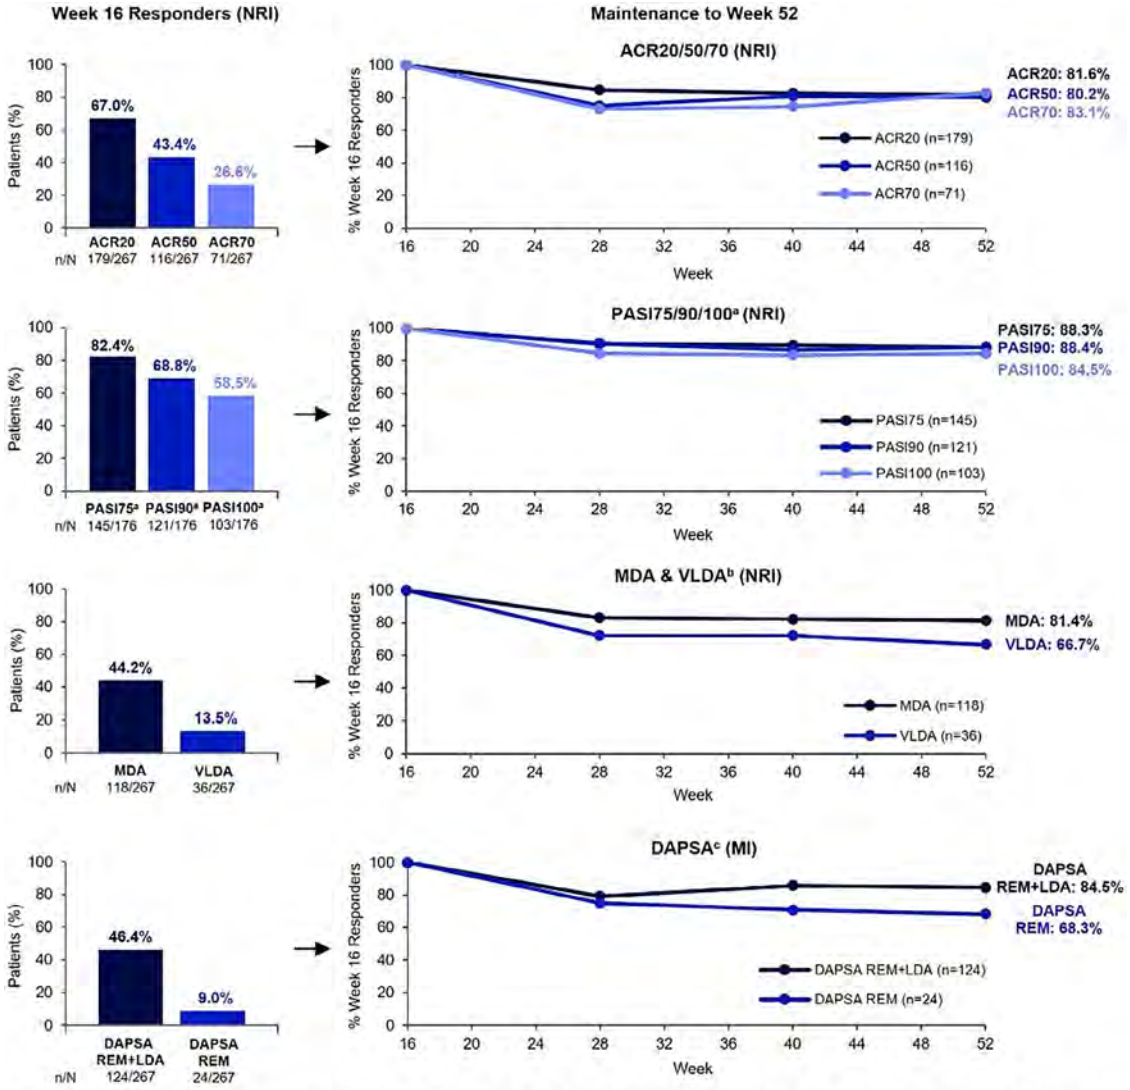
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: PsA is a chronic disease affecting multiple domains; however, patients (pts) can experience loss of response with long-term therapy.[1] Therefore, maintaining long-term treatment responses is important. Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, demonstrated rapid and clinically meaningful improvements in joint and skin efficacy outcomes to Week (Wk) 16, vs placebo (PBO), that were sustained to Wk 52.[2–4] The objective of this analysis was to report maintenance of response in joint, skin, and composite efficacy outcomes to 52 wks in BKZ-treated pts with PsA who were Wk 16 responders.

Methods: BE COMPLETE (NCT03896581), a 16-wk double-blind phase 3 study, included pts with active PsA who had inadequate response or intolerance to 1–2 TNF-α inhibitors (TNFi-IR). Pts were randomized 2:1 to subcutaneous BKZ 160 mg every 4 wks (Q4W) or PBO. Pts completing Wk 16 were eligible to enter an open-label extension, BE VITAL (NCT04009499). Maintenance of response is reported as the percentage of BKZ-treated pts who achieved a response at Wk 16 and maintained response at Wk 52. ACR20/50/70, Psoriasis Area and Severity Index (PASI)75/90/100, minimal/very low disease activity (MDA/VLDA), and Disease Activity Index for PsA (DAPSA) remission/low disease activity (REM+LDA; ≤14) and remission (REM; ≤4) responses are presented. Data are reported as observed case (OC) and using non-responder



Randomized set. All data reported as NRI, except for DAPSA maintenance reported as MI. [a] In patients with psoriasis affecting ≥3% BSA at baseline. [b] Patients are considered to achieve MDA and VLDA when they meet 5/7 and 7/7 of the following criteria, respectively: TJC ≤1, SJC ≤1, PASI ≤1 or BSA ≤3%, patient pain (VAS ≤15 mm), patient global assessment (VAS ≤20), HAQ-DI ≤0.5, and tender entheseal points (LEI) ≤1. [c] DAPSA score is the sum of SJC (range: 0–66), TJC (range: 0–68), patient pain (VAS 0–10), patient global assessment (VAS 0–10), and C-reactive protein (mg/L). DAPSA REM+LDA is defined as DAPSA total score ≤14; DAPSA REM is defined as DAPSA total score ≤4.
ACR20/50/70: ≥20/50/70% improvement in ACR criteria; BSA: body surface area; DAPSA: Disease Activity Index for PsA; HAQ-DI: HAQ–Disability Index; LDA: low disease activity; LEI: Leeds Enthesitis Index; MDA: minimal disease activity; MI: multiple imputation; NRI: non-responder imputation; PASI: Psoriasis Area and Severity Index; PASI75/90/100: ≥75/90/100% improvement in PASI; REM: remission; SJC: swollen joint count; TEAE: treatment-emergent adverse events; TJC: tender joint count; VAS: visual analogue scale; VLDA: very low disease activity.

Figure. Maintenance of efficacy responses to Week 52 in Week 16 responders (NRI, MI)

imputation (NRI) or multiple imputation (MI). Treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ, including those who entered BE VITAL (PBO/BKZ).

Results: Overall, 267 pts were randomized to BKZ 160 mg Q4W; 263 (98.5%) and 236 (88.4%) completed Wks 16 and 52, respectively. Of BKZ-treated pts who were Wk 16 responders, ≥80% maintained response across all joint and skin outcomes, as well as MDA and DAPSA REM+LDA. At Wk 16, 179 (67.0%), 116 (43.4%), and 71 (26.6%) pts achieved ACR20/50/70, respectively. Over 80% of those responders maintained an ACR20/50/70 response at Wk 52: 81.6%, 80.2%, 83.1% (NRI); 89.6%, 86.1%, 85.5% (OC) (**Figure**). Of 176 pts with psoriasis affecting ≥3% body surface area (BSA) at baseline, 145 (82.4%), 121 (68.8%), and 103 (58.5%) achieved PASI75/90/100 at Wk 16. Of those responders, 88.3%, 88.4%, 84.5% (NRI); 97.0%, 96.4%, 91.6% (OC) maintained a PASI 75/90/100 response at Wk 52 (**Figure**). Similar results were observed for composite measures; 118 (44.2%) pts achieved MDA at Wk 16 and, of those, 81.4%/87.3% (NRI/OC) maintained their response at Wk 52. A high proportion of Wk 16 responders also maintained their VLDA, DAPSA REM+LDA, and DAPSA REM response at Wk 52 (**Figure**). To Wk 52, 243/388 (62.6%) BKZ-treated pts reported ≥1 TEAE and 23 (5.9%) reported serious TEAEs.

Conclusion: BKZ demonstrated robust maintenance of response at Wk 52 in TNFi-IR pts with PsA who responded to BKZ treatment at Wk 16. The safety profile was consistent with previous reports.[2,3]

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

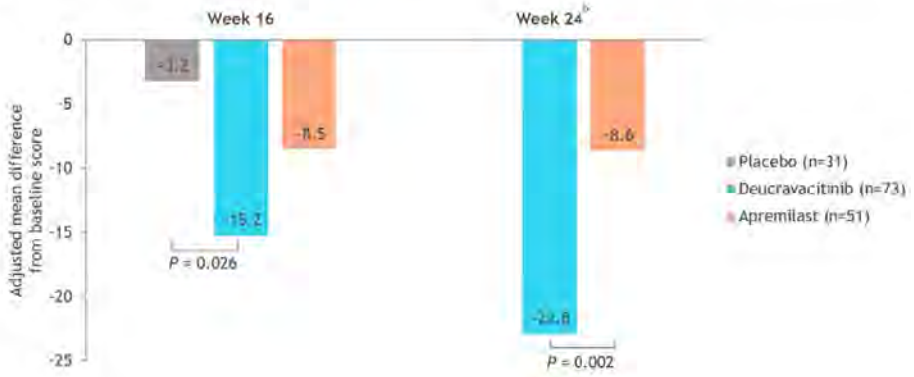
Background/Purpose: As 41% of patients with psoriasis may be undiagnosed for psoriatic arthritis, treatments must relieve both dermatologic and musculoskeletal symptoms. Deucravacitinib (DEUC), an oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor, is approved in the US, EU, and other countries for treatment of adults with moderate-to-severe plaque psoriasis who are candidates for systemic therapy. In the pivotal phase 3, randomized, controlled POETYK PSO-1 and PSO-2 trials, significantly greater proportions of patients receiving DEUC achieved 75% improvement from baseline in Psoriasis Area and Severity Index scores and static Physician Global Assessment scores of 0/1 at Week 16 vs patients receiving placebo (PBO) or apremilast (APR). The efficacy and safety of deucravacitinib in patients with active psoriatic arthritis was demonstrated in a phase 2 trial (NCT03881059), with significant improvements vs PBO observed in all key musculoskeletal, functional, and dermatologic outcomes. This analysis compared the effects of DEUC vs PBO and vs APR on peripheral joint disease, joint pain, and health-related quality of life using the 36-item Short Form (SF-36) physical component summary (PCS) score at Weeks 16 and 24 in patients from POETYK PSO-1 and PSO-2 who self-reported joint symptoms.

Methods: POETYK PSO-1 and PSO-2 randomized patients with moderate to severe psoriasis 1:2:1 to PBO, DEUC 6 mg once daily, or APR 30 mg twice daily. The self-administered Psoriatic Arthritis Screening and Evaluation (PASE) questionnaire (≥47 indicates psoriatic arthritis [PASE positive]) was completed by patients with peripheral joint complaints at baseline. Peripheral joint pain and joint disease activity were measured by a visual analog scale (VAS; range, 0–100), with changes from baseline VAS scores assessed only in patients with a baseline of ≥30 for pain and disease. All patients completed the SF-36. Higher scores indicate worse disease burden on VAS measures and better health-related quality of life on the SF-36 PCS.

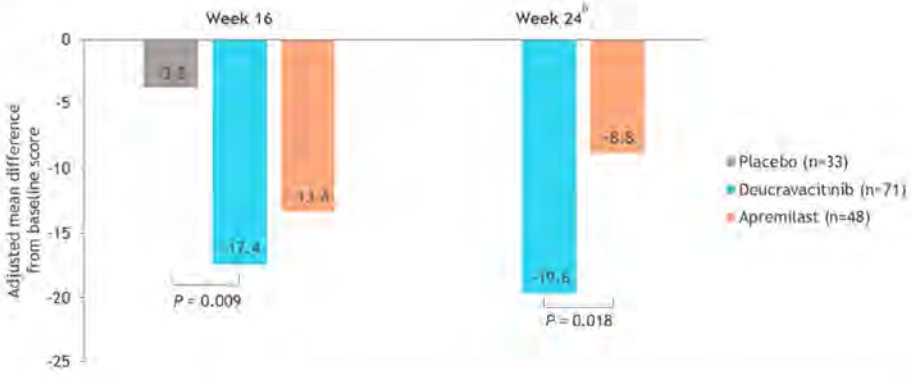
Results: This pooled analysis included 185 PASE-positive patients (11% of 1686 patients in the combined POETYK PSO-1 and PSO-2 trials). The improvement, assessed by adjusted mean change from baseline (CFB), was greater in patients treated with deucravacitinib vs placebo at Week 16 for joint pain VAS, joint disease VAS, and SF-36 PCS scores. Adjusted mean CFBs were greater in patients treated with deucravacitinib at Week 24 vs apremilast for joint pain VAS and joint disease VASscores, and were similar for SF-36 PCS scores (**Figures 1, 2**). A greater percentage of patients treated with DEUC reported 30% and 50% improvements on the joint pain VAS at Week 16 vs APR and PBO, and at Week 24 vs APR (**Figure 3**).

Figure 1. Mean change from baseline in (A) joint pain VAS scores[a] and (B) joint disease activity VAS scores[a] in the POETYK PSO-1 and PSO-2 pooled analysis

A.

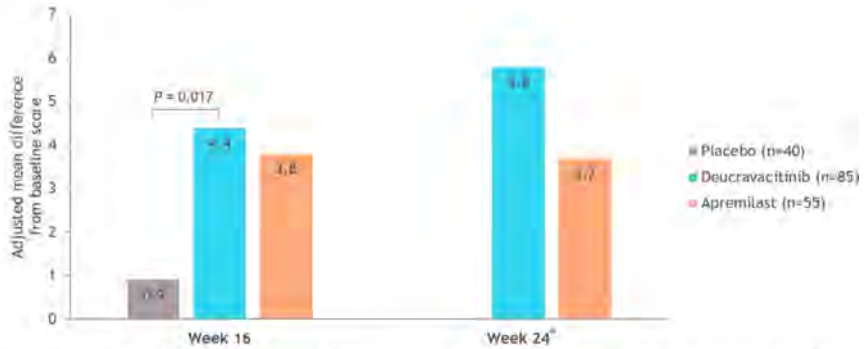


B.



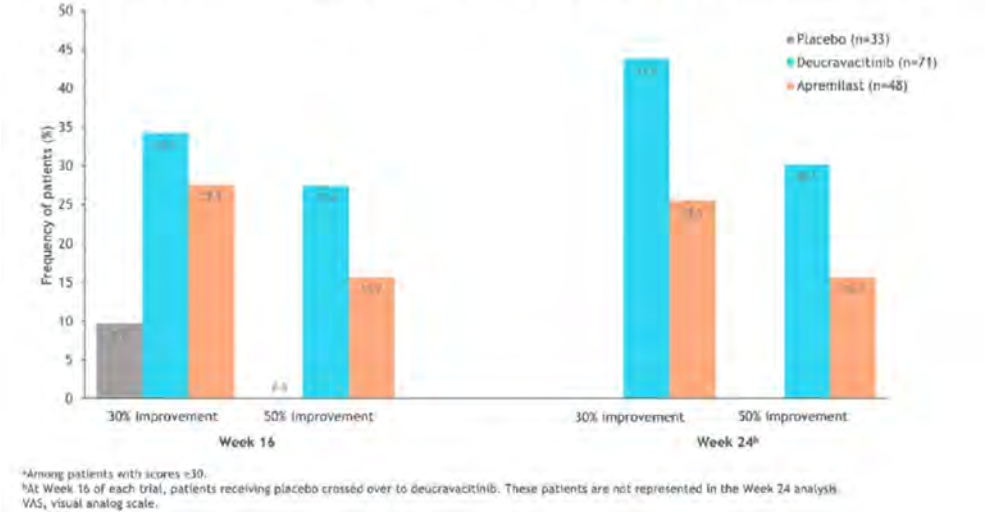
[a]Among patients with scores ≥30.
[b]At Week 16 of each trial, patients receiving placebo crossed over to deucravacitinib. These patients are not represented in the Week 24 analysis.
VAS, visual analog scale.

Figure 2. Change from baseline in SF-36 PCS score in the POETYK PSO-1 and PSO-2 pooled analysis



[a]At Week 16 of each trial, patients receiving placebo crossed over to deucravacitinib. These patients are not represented in the Week 24 analysis.
PCS, physical component summary; SF-36, 36-Item Short Form health survey.

Figure 3. Percentage of patients demonstrating 30% and 50% improvement in joint pain VAS scores[a] in the POETYK PSO-1 and PSO-2 pooled analysis



[a]Among patients with scores ≥10.
[b]At Week 16 of each trial, patients receiving placebo crossed over to deucravacitinib. These patients are not represented in the Week 24 analysis.
VAS, visual analog scale.

Conclusion: PASE-positive patients in POETYK PSO-1 and PSO-2 treated with DEUC reported greater improvements in the impact of joint disease and joint pain vs APR and PBO, and in SF-36 PCS scores vs those receiving PBO. Additionally, a greater percentage of patients treated with DEUC reported 30% and 50% improvements in joint pain vs patients receiving APR and patients receiving PBO. The magnitude of effect among DEUC-treated patients appeared to continue to improve through the 24-week active-controlled period.

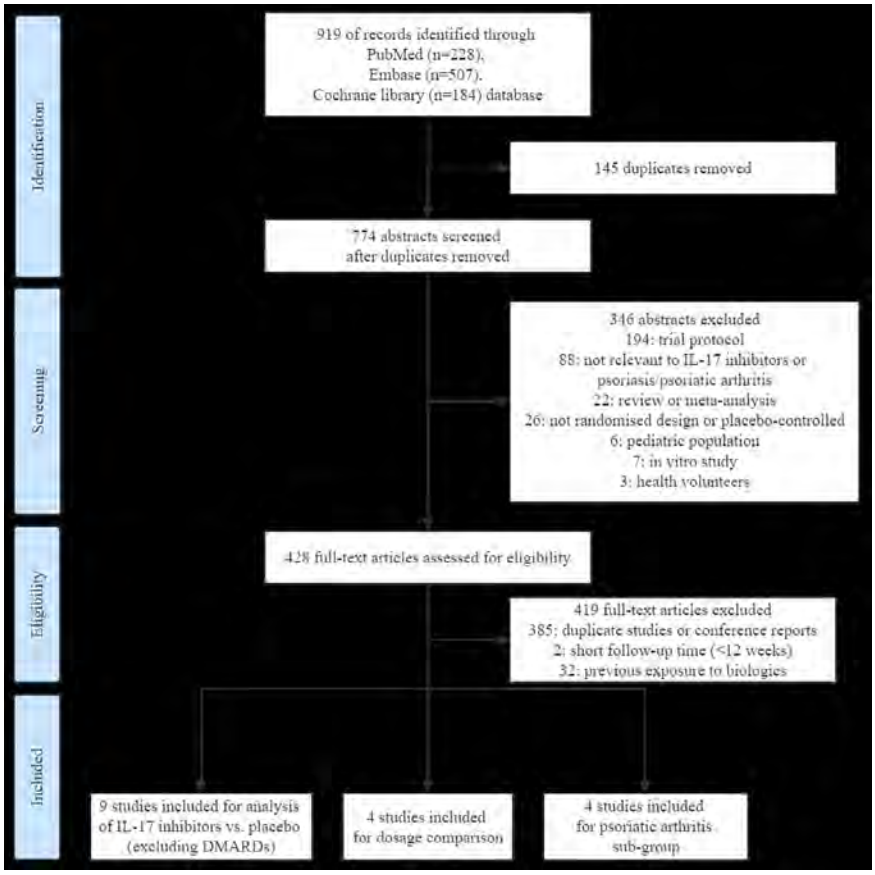
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this systematic review is to determine the effects of IL-17 inhibitors on major adverse cardiovascular events (MACEs) in patients with psoriasis (PsO) or psoriatic arthritis (PsA).

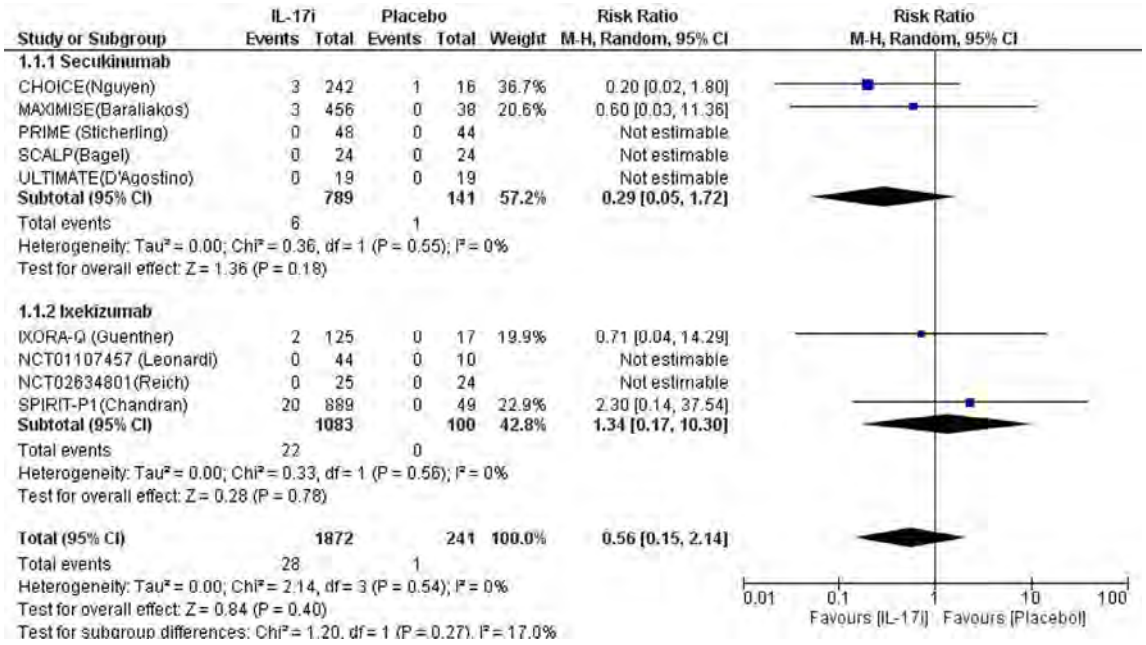
Methods: A search for randomized controlled trials of patients with PsO/PsA treated with IL-17 inhibitors that reported confirmed MACEs was conducted on December 7, 2022, in Medline, Embase, and the Cochrane Library for Randomized Controlled Trials. Two reviewers screened titles and abstracts and selected papers for full-text review. Trials that included the previous use of biologic disease modifying anti-rheumatic drugs were excluded. Risk ratios were calculated by the Mantel-Haenszel random-effect method. Heterogeneity across studies was measured by χ^2 test and I^2 statistics. Funnel plot analysis was produced to detect potential publication bias.

Results: Of the 919 references identified, 9 RCT studies were eligible for quantitative synthesis (n=2096 patients). The use of IL-17 inhibitors was not correlated with a statistically significant change in the risk of MACEs (Risk Ratio 0.56; 95% CI 0.15 to 2.14; p= 0.40). Subgroup analysis of secukinumab or ixekizumab also did not demonstrate changes in the risk for MACEs. Additionally, there was no detectable dose-dependent effect of IL-17 inhibitors on the risk of MACEs.

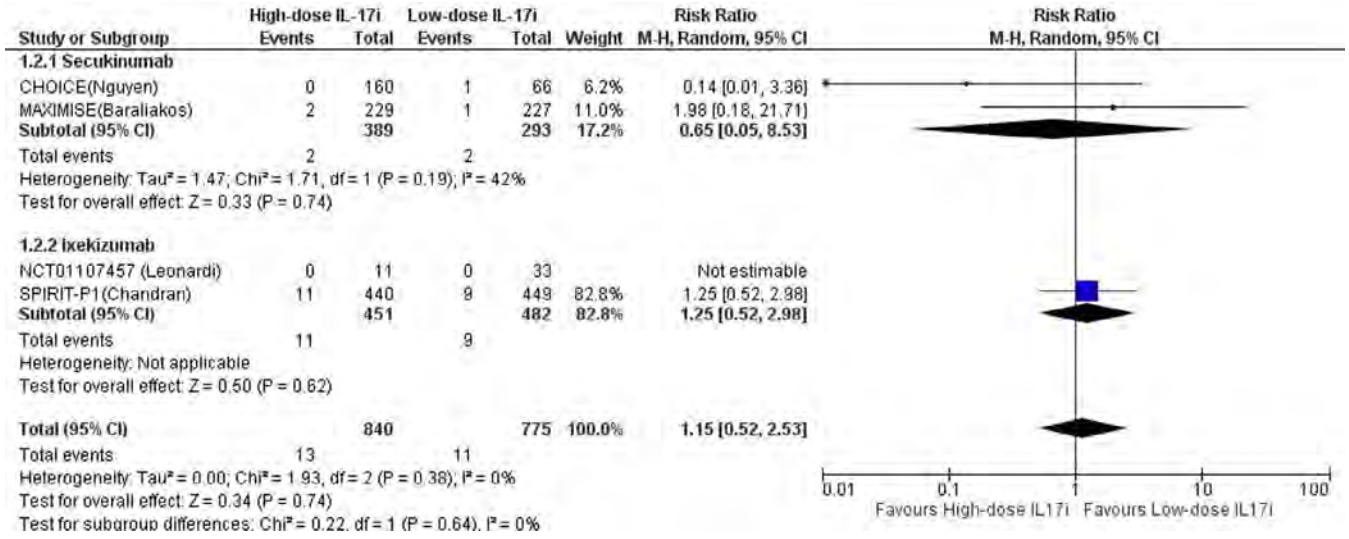
Conclusion: IL-17 inhibitor use is not correlated with a change in risk for major adverse cardiovascular in patients with PsO/PsA that have not previously received biologic disease-modifying anti-rheumatic drugs.



Flow chart of included randomized controlled trials.



Relative Risks (RRs) of all major adverse cardiovascular events (MACEs) in patients with psoriasis (PsO) and/or psoriatic arthritis (PsA) treated with interleukin 17 (IL-17) inhibitors compared with placebo or disease-modifying antirheumatic drugs (DMARDs) in randomized controlled trials (RCTs) using the Mantel-Haenszel (M-H) random-effect method. P-Y, patient-year.



RRs of all MACEs in patients with PsO/PsA treated with different dosages of IL-17 inhibitors in RCTs using the M-H random-effect method. P-Y, patient-year.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic lesions in highly visible areas, including the nails, disproportionately affect patients' health-related quality of life.[1] Here, we compare the efficacy of bimekizumab (BKZ) vs secukinumab (SEC) through 48 weeks (wks) for the treatment of nail psoriasis in patients with moderate to severe plaque psoriasis who had moderate to severe nail involvement at baseline.

Methods: In BE RADIANT, patients were randomized to BKZ 320mg every 4 wks (Q4W) or SEC 300mg weekly to Wk4 then Q4W. From Wk16, BKZ-randomized patients received BKZ Q4W or Q8W.[2] In this analysis, BKZ Q4W/Q4W and Q4W/Q8W were combined (BKZ Total). Modified Nail Psoriasis Severity Index (mNAPSI; total fingernail on a 0–130 scale) and mNAPSI sub-scores from Wks16–48 among patients with baseline mNAPSI >10 were assessed. Missing data were imputed as non-response (NRI).

Results: In total, 116 BKZ-treated and 99 SEC-treated patients had baseline mNAPSI >10; 37.1% and 40.4% achieved mNAPSI≤2 at Wk16; 75.0% and 59.6% achieved mNAPSI≤2 at Wk48. From Wks16–48, mNAPSI=0 (clear) response rates increased from 26.7% to 70.7% (BKZ), and 33.3% to 53.5% (SEC). 101 BKZ-treated and 86 SEC-treated patients had both baseline mNAPSI >10 and baseline nail pitting >0; 36.6% and 41.9% achieved nail pitting=0 (clear) at Wk16; 78.2% and 59.3% achieved nail pitting=0 at Wk48. 69 BKZ-treated and 56 SEC-treated patients had both baseline mNAPSI >10 and baseline nail plate crumbling >0; 65.2% and 69.6% achieved nail plate crumbling=0 (clear) at Wk16; 85.5% and 75.0% achieved nail plate crumbling=0 at Wk48. 59 BKZ-treated and 58 SEC-treated patients had both baseline mNAPSI >10 and baseline leukonychia >0; 69.5% and 70.7% achieved leukonychia=0 (clear) at Wk16; 79.7% and 69.0% achieved leukonychia=0 at Wk48.

Conclusion: From Wks16–48, BKZ-treated patients showed numerically greater improvements in nail psoriasis than SEC-treated patients, including complete nail clearance.

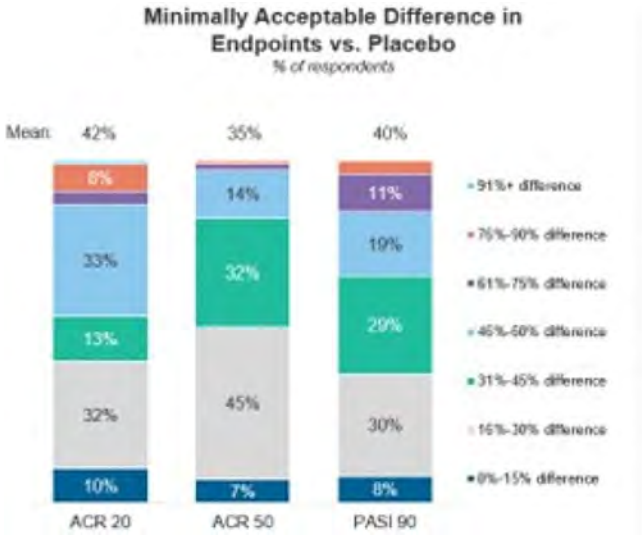
Abstract Number: 2256

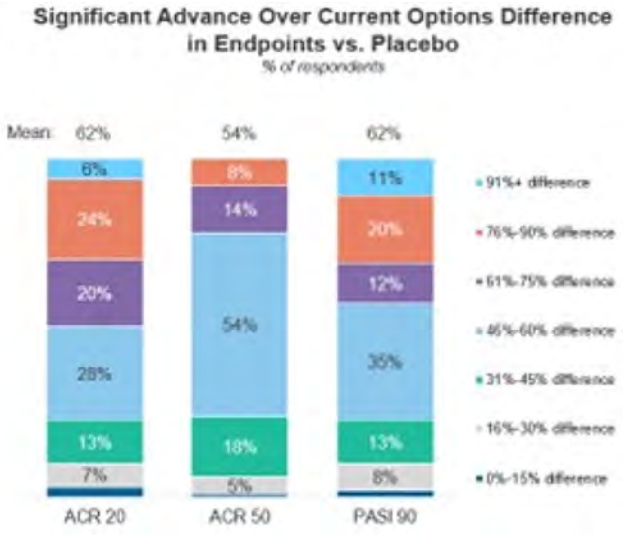
The Impact of Clinical Trial Metrics in Psoriatic Arthritis

Maxine Yarnall and **Kara Murray**, Spherix Global Insights, Exton, PA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment: SpA Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM



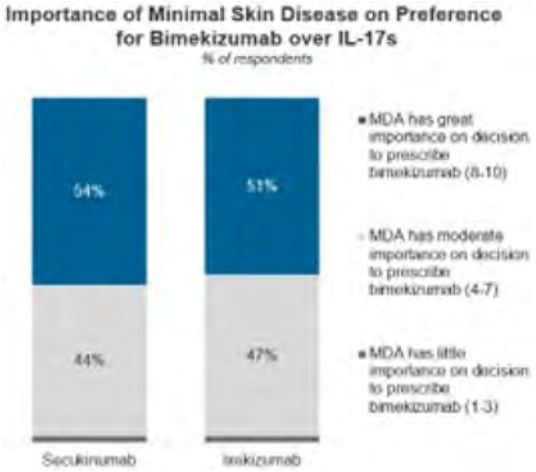


Background/Purpose: Rheumatologists have access to a plethora of advanced biologic and small molecule agents for the treatment of psoriatic arthritis (PsA). Prior to FDA approval, products undergo extensive clinical trial research vital in determining various outcome measures, such as a product's safety and efficacy. The knowledge gleaned from trial metrics empowers physicians to make informed treatment decisions for their patients. This research sought to understand brand performance, prescribing habits, and the influence of various clinical trial response criteria in treatment decisions.

Methods: An independent market analytics firm collaborated with US rheumatologists (n=101) to conduct analysis of the PsA market. Data were collected via an online survey fielded May 11 through May 23, 2023, including physician demographics, product usage, and attitudinal survey responses.

Results: Tumor necrosis factor (TNF) inhibitors continue to dominate the psoriatic arthritis market, capturing the majority of share in the first and second-line settings. Physicians reach for alternative mechanisms of action more frequently in second and later lines, led by Interleukin-17 (IL-17) inhibitors.

Two-fifths of surveyed rheumatologists indicate head-to-head studies comparing pipeline assets to adalimumab would be the most compelling as opposed to trials comparing any other pharmacologic treatment; preference for adalimumab as a comparator is unsurprising given physicians' experience, as well as the agent's long-term safety and efficacy data.



When reviewing placebo-controlled clinical trials, rheumatologists consider 42% ACR20, 35% ACR50, and 40% PASI90 responses as a minimally acceptable improvement. Although physicians do not indicate a strong preference towards one primary clinical trial endpoint, ACR50 responses and minimal disease activity (MDA) are most favorable. ACR70 responses are preferred as secondary endpoints.

With the upcoming launches of secukinumab IV and bimekizumab, physicians express the most interest in gaining access to an IV IL-17 inhibitor. Rheumatologists report having an IV formulation available will fill a number of unmet needs in PsA, most notably access for Medicare patients.

Bimekizumab's long-term data released from the BE OPTIMAL-3 study has an extremely positive impact on physician perceptions as well as their willingness to prescribe the IL-17A/F inhibitor. Half of those surveyed cite MDA as very influential in determining whether to prescribe bimekizumab over the currently available IL-17 inhibitors for the treatment of PsA.

Conclusion: Physicians express most interest in ACR50 and minimal disease activity as primary endpoints and prefer adalimumab as a comparator in head-to-head studies. The composition of clinical trials, from their primary endpoints to their outcome measurements, influence rheumatologists' prescribing habits in the PsA market.

Outcomes and Clinical Features of Acute Coronary Syndrome in Patients with SLE: A 14-Year Real-World Study (2006-2019)

Konstantinos Parperis[1] and Bikash Bhattarai[2], [1]University of Cyprus Medical School, Nicosia, Cyprus, [2]Valleywisehealth, Phoenix, AZ

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune inflammatory disease associated with an increased risk of cardiovascular complications, including acute coronary syndrome (ACS). However, there is limited real-world data available to comprehensively analyze the outcomes of ACS in patients with SLE over an extended period. This study aimed to compare the characteristics and outcomes of hospitalized patients with ACS, stratified by the presence or absence of SLE. The primary outcome was to examine the inpatient mortality, hospital length of stay, total hospital charges.

Methods: A retrospective observational analysis was conducted utilizing data from the US National Inpatient Sample (NIS) spanning the period from 2006 to 2019. Patients admitted with a diagnosis of ACS were categorized into two groups: those with International Classification of Diseases, Ninth and Tenth Revision (ICD-9 and -10) codes defining SLE and those without any SLE code. Demographics, clinical characteristics, and comorbidities were recorded. Furthermore, outcomes such as in-hospital mortality, complications, length of stay, and total hospital charges were analyzed and compared between the two groups. Associations between SLE and specific morbidity were assessed using chi-square tests, while t-tests were employed for continuous variables.

Results: A total of 17,322,365 (adjusted for sampling weight) ACS hospitalizations were identified in the NIS database, of which 70,901 (0.41%) were in patients with SLE (Table 1). Patients with SLE were more likely to be younger (mean age 61 vs 68 years; p < 0.0001), under 50 (21% vs 9%), female (82% vs 41%), and African American (25% vs 11%) compared to non-SLE patients. In addition, SLE patients were more statistically significant to have Medicaid (12% vs 7; p< 000.1) and live in the Southern region of the USA (43% vs 40%, p< 0.0001). Regarding comorbidities, SLE patients with ACS exhibited a higher prevalence of certain conditions, including antiphospholipid syndrome, chronic renal disease, ESRD and a history of thromboembolism (Table 1). Conversely, non-SLE patients with ACS had higher rates of comorbidities such as diabetes, hypertension, and dyslipidemia. Significant differences were observed in outcomes and resource utilization (Table 2). ACS in SLE patients was associated with longer length of stay (mean 6.2 vs 5.5 days; p< 0.0001) and higher cost (mean total charges $80,444 vs $74,321; p < 0.0001). No difference in the in-patient mortality was observed among the 2 groups.

Table 1: Demographics and comorbidities of SLE and non-SLE patients admitted with acute coronary syndrome from 2006 to 2019.

Variable	Non-SLE N=17,251,463	SLE N=70,901	P-value*
Age at hospitalization mean ± SD year	68.34±31.11	61.16±32.32	<.0001
Age less than 50	1678707 (9.73)	15187.8 (21.42)	<.0001
Gender			<.0001
Female	7151007 (41.46)	58246.2 (82.16)

ESRD, Maintenance dialysis	348289 (2.02)	3565 (5.03)	<.0001
History of venous thromboembolism	315022 (1.83)	3396.19 (4.79)	<.0001

*Chi-square P

Table 2. Outcomes and resource utilization of SLE and non-SLE patients admitted with acute coronary syndrome from 2006 to 2019.

Outcomes/Resource utilization			
	Non-SLE patients	SLE patients	P-value†
Length of stay, (mean ± SD)	5.51±15.74	6.29±16.74	<0.0001†
Total hospital charges, (mean ± SD)	$ 74321–228757	80444–237676	<0.0001†
Death during hospitalization(%)	1,196,400 (6.94)	4958(7)	0.5527

†t-test

Conclusion: Patients with SLE and ACS were younger, more likely to be female and African American. In addition, hospitalization of SLE patients with ACS is associated with longer hospital stay, and higher total cost compared to non-SLE. Further research is needed to optimize the prevention and management of ACS in the SLE population.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive impairment (CI) is a significant problem in SLE but there is a disconnect between objective and subjective CI. This makes it difficult to fully understand and treat CI. Functional magnetic resonance imaging (fMRI) has shown compensatory brain mechanisms may help to maintain cognitive function but potentially cause fatigue leading to subjective CI. This in part could explain the objective/subjective CI disconnect but ways to measure this are needed. We devised a new fMRI paradigm examining attention, working memory, learning and long-term associative memory. The aim was to assess this new task by examining whether attentional performance and working memory decreases over repeated trials in an SLE cohort using our preliminary data.

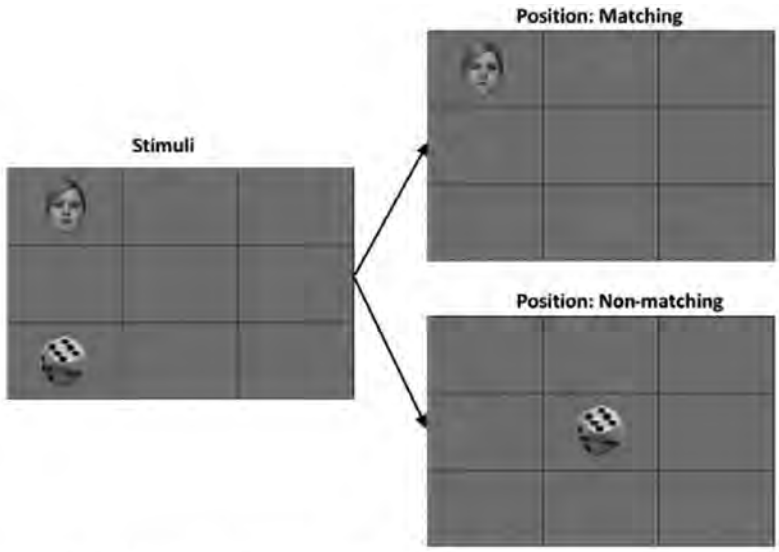

Figure 1: Stage 1 - Spatial working memory/sustained attention task
Participants saw a 3x3 matrix in which a face and an object were presented concurrently, but each in a single square. A series of face-object pairs were presented in this way in an adapted n-back design. In each trial, after a 1-sec delay participants were asked to respond if either a face or an object was presented in the same position as in the original array. In some trials the same face/object was presented in the original location (matching) or in a different one (non-matching). This provided a measure of **working memory** with a spatial emphasis. There were 3 blocks of 45 stimuli. There was a rest after the first block and fixations points within the trials. Altogether there were 135 stimuli.

Methods: Recruited adult SLE patients met EULAR/ACR criteria. Demographic, clinical and psychiatric data and patient reported outcome measures were collected. Cognitive function was assessed using a modified version of the ACR Neuropsychological Battery. MR scans included two structural scans and two functional MRI scans done during stage 1 and 2 of a cognitive task. Stage 1 (working memory and attention, Figure 1) was split into three trial blocks of equal length and performance over the trials was examined using mean number correct (maximum of 45 per trial), mean response time per trial (ms) and fMRI blood-oxygen-level-dependent (BOLD) response signal to stage 1 of the task. Differences between the trial performances were examined using repeated measures ANOVA and the fMRI data was modelled using SPM12. fMRI interference was done at a cluster extent correction threshold of family-wise error-corrected (pFWEc)< 0.05.

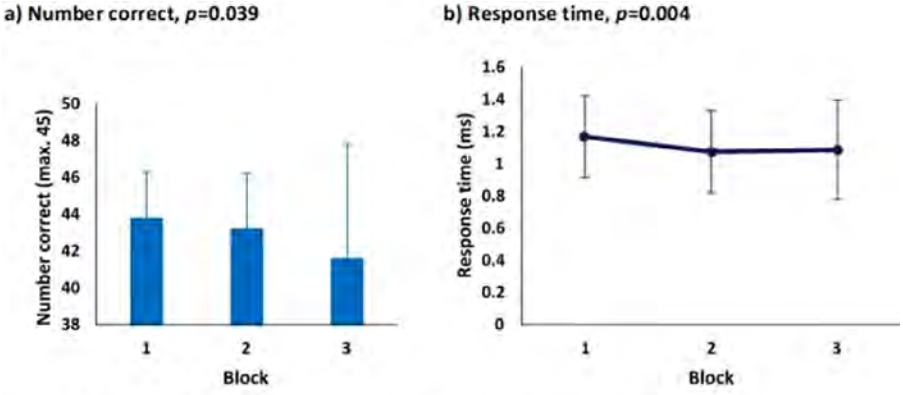

Figure 2. Stage 1 task performance across the three trial blocks, n=36

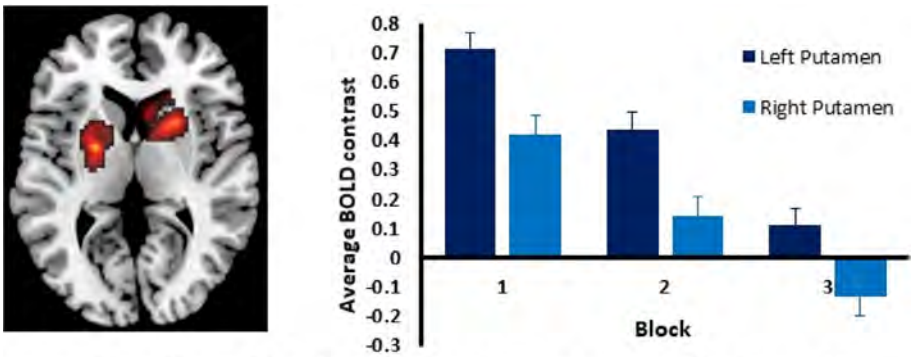

Figure 3. Significant BOLD signal response change over time for the working memory and attention task within a cluster containing the left and right putamen, n=10.

Results: Participants characteristics (n=36) were as follows; mean age 40 ±13, SLE disease duration 15 years ±10, SLEDAI-2K 4.3 ±4.8 and SDI 1 ±1.8. The majority were female (n=27, 75%), Caucasian (n=23, 63%) and educated to college level or higher (n=28, 78%). Current medication use was as follows; immunosuppressants (n=23, 64%), antimalarials (n=29, 81%), glucocorticoids (n=15, 42%) and biologics (n=6, 17%). Mean scores on the Beck Depression Inventory-II and Beck Anxiety Inventory were 14 ±12 and 33 ±11 respectively. CI was seen in 9 (35%). Participant performance on the working memory task worsened over time; response time was slowest during the first trial and quickest during the second (Figure 2). A significant cluster (900 voxels; pFWEc=0.006) containing the left and right putamen was found for the task BOLD response change over time. Within this cluster the BOLD response decreased from trial 1 to trial 3 (Figure 3).

Conclusion: Our new cognitive task is working as expected, with participants' performance worsening over time as participants become less engaged/cognitively fatigued. These results were mirrored by the fMRI results. Response time improved from trial one to two/three as the task was learnt. Final results will include data from healthy controls enabling us to determine if the decrease in performance is similar to healthy controls or if SLE patients become cognitively fatigued more quickly. We will also, examine the results from stage 2, the learning and long-term associative memory task.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive impairment (CI) in systemic lupus erythematosus (SLE) negatively impacts health-related quality of life leading to activity limitations. This qualitative study aimed to (1) explore the effect of SLE-related CI on activities of daily living and life role participation; and (2) describe factors influencing activity restriction and life role participation.

Methods: Semi-structured, in-depth interviews probing living with CI in SLE were conducted with 24 adults living with SLE. Sociodemographic and clinical data, objective cognitive function (ACR-NB), and subjective cognitive function (PDQ-20) were collected. Participants were categorized into four groups of CI to perform a qualitative thematic analysis guided by a framework analytical approach. The groupings were defined as objective and subjective CI (Group 1), objective CI (Group 2), subjective CI (Group 3), and no CI (Group 4). Themes emerged using both inductive and deductive methods of data analysis.

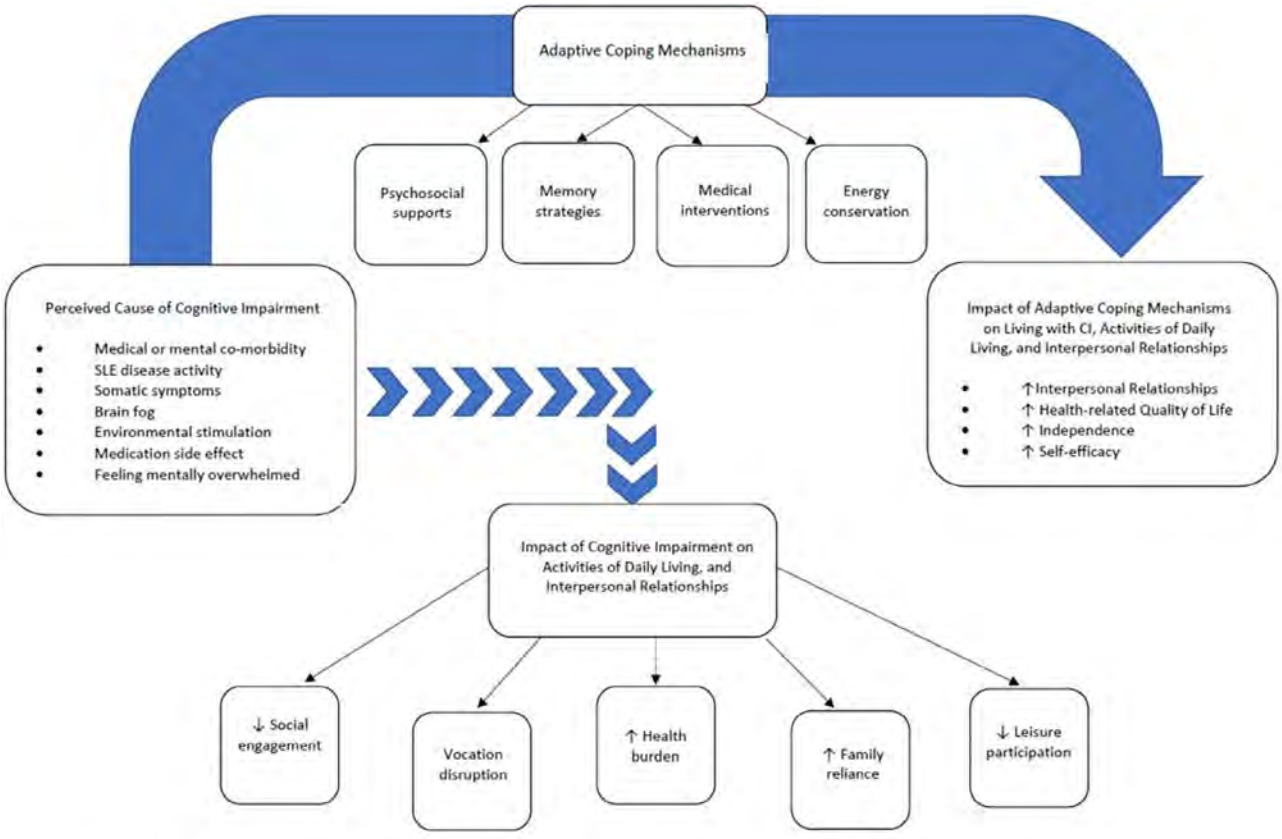

Figure 1. Relationship between SLE-related CI, activities of daily living, and life role participation.

Results: All participants met ACR classification criteria for SLE with a mean age of 42 ±13 years, SLE disease duration 13 ±10 years, SLEDAI (disease activity index) of 2.2 ±2.5, SDI (disease damage index) of 1.0±1.3, and prednisone daily dose of 3.4 mg/d ±6.0. Group sample sizes consisted of 11 participants in group 1, five in group 2, six in group 3, and 2 in group 4. Participants reported ongoing problems in multiple cognitive domains (memory, language, etc.) with multiple perceived causes. CI was felt to impact work, social, domestic and family life, health, and independence. Five overarching themes were represented in the data: (1) characterization of SLE-reported CI; (2) perceived cause of CI; (3) perceived impact of CI on activities of daily living and life role participation (4) adaptations for managing CI; (5) influence of CI adaptations on activities of daily living and life role participation. Figure 1 summarises the five identified themes and how they interact.

There were few between-group descriptive differences in the themes that emerged from the thematic and framework analyses. However, those within a subjective CI group (either group 1 or 3) characterized the involvement of mental health difficulties in perpetuating or exacerbating their self-reported experience of CI. Those within a subjective CI group also employed more frequent and diverse adaptations to manage their mental health difficulty, which had a secondary effect on their experience of CI.

Conclusion: This study provides a better understanding of the patient experience of CI in SLE, how it impacts their lives, and what coping strategies they employ. It highlights the long-term challenges those with CI in SLE undergo and provides evidence for the urgent need to implement multidisciplinary treatment options. The lack of descriptive differences between the study's CI groupings suggests that regardless of the "type" of CI defined, subjective or objective, the impact and challenges experienced by the patients remain the same.

When managing CI, it may be beneficial to evaluate and understand available psychosocial support resources to help identify and reinforce relevant adaptations to improve health-related quality of life.

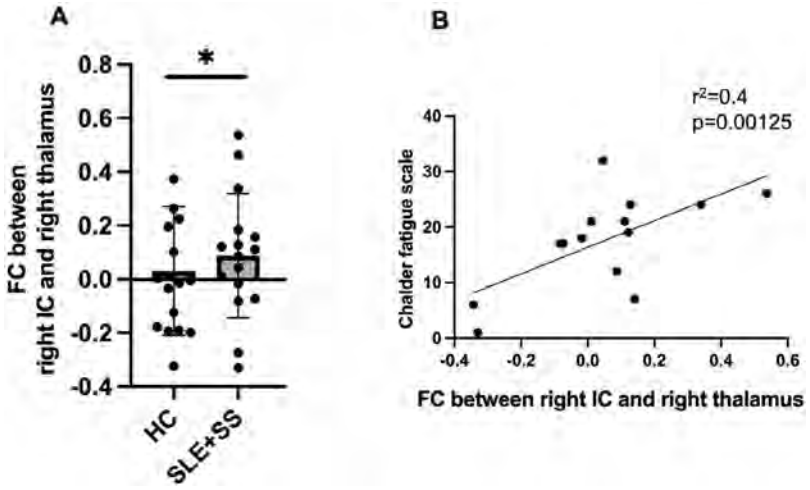
SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM



The specific functional connectivity (FC) between the right insular cortex (IC) and right thalamus in patients with systemic lupus erythematosus (SLE) and primary sjögren's syndrome (pSS). (A) FC value between right IC and right thalamus in healthy controls (HCs) and SLE/pSS. *p<0.05, ANCOVA, adjusted for age and sex. (B) Correlation analysis between the FC and Chalder fatigue scale in SLE/pSS.

Background/Purpose: Fatigue is a common symptom in patients with systemic lupus erythematosus (SLE) and primary Sjögren's syndrome (pSS). Resting-state functional magnetic resonance imaging (rs-fMRI) has emerged as a powerful tool for mapping large-scale networks in the human brain. Several studies have investigated the functional connectivity (FC) between brain regions of interests (ROIs) of fatigue using rs-fMRI. However, the evidence concerning patients with SLE and pSS remains unclear.The objective of this study is to identify the specific FC of fatigue in patients with SLE and pSS.

Methods: rs-fMRI data were acquired from SLE, pSS, and healthy controls. Demographic, clinical, and laboratory data were extracted from patients' electronic medical records. Disease activity was assessed by SLE Disease Activity Index score with the Safety of Estrogens in SLE National Assessment modification (SELENA-SLEDAI), and EULAR Sjögren's syndrome disease activity index (ESSDAI). In addition, the Chalder fatigue scale (CFS) and fatigue assessment questionnaire were collected. FCs were analyzed and compared among SLE, pSS, and HCs by ANCOVA, adjusted for age and sex. The association among SELENA-SLEDAI, ESSDAI, questionnaire scores, and FCs was evaluated by correlation analysis.

Results: A total of 9 SLE patients (90% female; median age: 44 years, IQR: 33-61), 5 SS patients (100% female; median age: 48 years, IQR: 44-49) and 16 HCs (63% female; median age: 41 years, IQR: 34-46) were enrolled. The median SELENA-SLEDAI was 4 (IQR: 0-10) and the median prednisolone dose was 4 mg/day (IQR: 0-10), the median ESSDAI was 3 (IQR: 2-4). In SLE and pSS patients with fatigue, higher FC was observed between the right insular cortex (IC) and right thalamus compared to HCs (p=0.049). There was a significant correlation between FC of the right IC and right thalamus and CFS, a fatigue evaluation index, in patients with SLE/pSS (r^2=0.4, p=0.0125). CFS did not correlate with SELENA-SLEDAI and ESSDAI either.

Conclusion: We identified a specific FC between right IC and right thalamus which may be associated with fatigue in SLE and pSS patients.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 50% of patients with SLE develop irreversible organ damage within 10 years of diagnosis, and most experience recurrent disease flares of varying severity. Both the prevalence and severity of SLE are known to be higher in patients living in the Asia Pacific region, but few data on flare and damage rates are available. We examined the prevalence of organ damage and flare and estimated the magnitude of longitudinal associations between flares and subsequent organ damage accrual using real-world data from the Asia Pacific region.

Methods: Adult patients with SLE enrolled in a multinational cohort with a minimum of 3 years of observational data, captured prospectively between 2013 and 2020, were studied. Flares were assessed at each clinic visit using the Safety of Estrogens in Lupus National Assessment-SLE Disease Activity Index (SELENA-SLEDAI). Flare Index and organ damage was assessed annually using SLICC/ACR Damage Index (SDI). Organ damage was defined as present if the SDI was greater than zero (SDI >0) while damage accrual was defined if the change in SDI was greater than zero (ΔSDI >0). Multivariable, multifailure survival analyses were carried out to quantify the association between flares and organ damage accrual.

Table. Longitudinal associations between flares and organ damage accrual (ΔSDI>0) at tn. *HRs adjusted patients age at tn-1, disease duration at tn-1, gross domestic product of patients' country, cumulative prednisolone dose at tn-1, immunosuppressant use at tn-1, time-adjusted SLEDAI score at tn-1, and for the presence of existing organ damage at tn-1.

	HR*	(95% CI)	p value
Flares at t_{n-1}			
Any (mild/moderate [M/M] or severe) flare present	1.42	(1.17, 1.72)	<0.001
Cumulative number of any flares	1.07	(1.02, 1.13)	0.011
M/M flare present	1.41	(1.14, 1.75)	0.001
Cumulative number of M/M flares	1.08	(1.01, 1.14)	0.015
Severe flare present	1.52	(1.14, 2.03)	0.004
Cumulative number of severe flares	1.05	(0.98, 1.13)	0.13

Results: Overall, 1556 patients with SLE, recruited from Australia, China, Indonesia, Japan, Korea, Malaysia, Philippines, Singapore, Taiwan and Thailand, and followed for a median (interquartile range) of 5.7 (3.9, 7.0) years were studied. The prevalence of organ damage at study enrollment (baseline) was 39% (n=614/1556) and the incidence of damage accrual during observation was ~58 per 1000 patient-years (PY) (n=496/8569.86 PY). 40% (n=247/614) of patients with baseline organ damage and 26% (n=249/942) of patients without baseline organ damage accrued damage during the study period. 74% (n=1153) of patients experienced a flare of any severity (mild/moderate or severe) at least once during the study period; 57% (n=885) experienced recurrent (≥2) flares. Flares independently increased the risk of damage accrual; after controlling for confounders, the risk of organ damage accrual at subsequent visits in patients who experienced any flare was 42% greater than in patients without flares (adjusted hazard ratio [HR] [95% confidence interval, CI]: 1.42 [1.17, 1.72]; **Table**). The risk of damage accrual was greater if patients had severe flares (HR [95% CI]: 1.52 [1.14, 2.03]). For each additional flare, the risk of damage accrual increased by 7% (HR [95% CI]: 1.07 [1.02, 1.13]).

Conclusion: The burden of organ damage and flares in SLE is substantial, and flares quantifiably increase the risk of damage accrual. Prevention of flares should be a major goal of SLE disease management to minimize permanent organ damage.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The Treatment Response Measure for Systemic Lupus Erythematosus (TRM-SLE) is a novel clinical outcome assessment (COA) for SLE randomized controlled trials (RCTs), being developed by an international clinician-industry-patient taskforce. Current COA development guidelines require that outcome measures used in RCTs should capture treatment effects relevant to how patients "feel, function or survive" to support regulatory approval (1). The aim of this study was to identify domains to be considered for inclusion in TRM-SLE from the perspective of expert SLE clinicians and patients based on this paradigm.

Methods: Candidate domains were identified via surveying a multinational panel of clinicians, patients and industry representatives. Domains were then rated in a modified Delphi study (two online survey rounds separated by a discussion meeting) in which clinicians with SLE expertise and patient advisory panellists were invited to rate the "importance" of candidate domains on a 1-9 scale (where 1 = not important and 9 = critically important). Importance was defined as domain activity having an impact on how a patient "feels, functions or survives", when assessing response to treatment in an SLE RCT. A literature review summarising associations of each candidate domain with key SLE symptoms, functional impact, damage and mortality was provided to participants to support participant ratings. The consensus threshold was prespecified as a rating of at least 7 by 70% of participants in both clinician and patient groups.

Table 1: Results of clinician and patient ratings of candidate domain importance, defined as domain activity impact on how a patient "feels, functions or survives" when assessing response to treatment in an SLE RCT.

Table 1: Results of clinician and patient ratings of candidate domain importance, defined as domain activity impact on how a patient "feels, functions or survives" when assessing response to treatment in an SLE RCT.

		% Rated Highly Important (7-9)	
Consensus on importance	**Candidate Domain**	**Clinician Group**	**Patient Group**
Consensus (≥70% participants scoring ≥7) in both clinician and patient groups	Lupus nephritis	99%	100%
	Neuropsychiatric lupus	98%	92%
	Rash	96%	73%
	Haemolytic anaemia	93%	82%
	Arthritis	90%	85%
	Thrombocytopenia	88%	91%
	Ophthalmic lupus	88%	82%
	Myositis	86%	91%
	Vasculitis	83%	75%
	Fatigue	76%	100%
	Serositis	77%	75%
	Brain fog	73%	100%
	Antiphospholipid syndrome	74%	91%
	Pulmonary lupus	71%	92%
Consensus (≥70% participants scoring ≥7) achieved in patient group only	Constitutional symptoms	69%	82%
	Mucosal ulcers	66%	82%
	Alopecia	64%	73%
	Gastrointestinal lupus	64%	73%
	Depression/anxiety	47%	82%
	Osteoporosis	35%	82%
	Fibromyalgia	35%	91%
	Hypertension	24%	82%
	Raynaud's/poor circulation	24%	82%
	Sjogren's syndrome/dryness	18%	91%
	Overlap autoimmune disease	8%	80%
Consensus not achieved in either group	Complement	27%	36%
	Anti-dsDNA antibodies	47%	0%
	Leukopenia	54%	36%
	Anaemia of chronic disease	15%	20%
	Lymphadenopathy	27%	0%
	Erythrocyte sedimentation rate	41%	36%
	Anti-Smith antibodies	7%	38%
	Costochondritis	1%	10%
	Serum iron	0%	0%

Results: The domain generation survey yielded 64 nominations, grouped into a core list of 34 candidate domains. Of 118 invitees to the modified Delphi study, 87 clinicians with a median (interquartile range; IQR) of 21 (11, 30) years' experience and 13 patients/representatives with a median (IQR) disease duration of 19 (16,33) years participated, with representation from six continents. Of the 34 candidate domains, 6 met the consensus threshold after Round 1 of voting, increasing to 14 after Round 2 (Table 1). An additional 11 domains met consensus in the patient group only. Notably, some domains meeting consensus on importance (e.g. fatigue) are not measured in current primary SLE trial endpoints, while others (e.g. anti-dsDNA, complement) included in current response measures did not reach consensus for inclusion.

Conclusion: When rated for importance, consensus was reached in both SLE clinician and patient groups on multiple candidate domains for inclusion in a novel COA for SLE trials. Discrepancies between clinician and patient perspectives were also identified. Important domains will next be rated on other characteristics relevant to inclusion in a COA (appropriateness, representation and measurability), with selected domains to proceed to definition of response measurement.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The international, multicenter SLE Prospective Observational Cohort Study (SPOCS) collected data on patients with SLE in relation to their type 1 interferon gene signature (IFNGS) status. Here, we report SLE disease activity progression over time—overall and by IFNGS category.

Table 1

Table 1. Disease activity (SLEDAI-2K total score) by baseline IFNGS status[a]

Timepoint	Overall (N = 826)	High IFNGS (N = 531)	Low IFNGS (N = 219)	*P*-value[b]
Baseline, mean (SD)	n = 591 9.8 (4.6)	n = 397 9.8 (4.3)	n = 137 9.2 (5.2)	
Score <10, n (%)	344 (58.2)	227 (57.2)	91 (66.4)	0.057
Score ≥10, n (%)	247 (41.8)	170 (42.8)	46 (33.6)	
6 months, mean (SD)	n = 440 6.4 (5.8)	n = 301 6.7 (5.9)	n = 104 5.5 (5.3)	
Score <10, n (%)	348 (79.1)	236 (78.4)	86 (82.7)	0.351
Score ≥10, n (%)	92 (20.9)	65 (21.6)	18 (17.3)	
12 months, mean (SD)	n = 333 5.7 (5.1)	n = 210 5.8 (5.1)	n = 89 5.6 (5.3)	
Score <10, n (%)	275 (82.6)	176 (83.8)	72 (80.9)	0.541
Score ≥10, n (%)	58 (17.4)	34 (16.2)	17 (19.1)	
18 months, mean (SD)	n = 313 6.0 (6.3)	n = 216 5.7 (4.9)	n = 64 6.1 (5.6)	
Score <10, n (%)	261 (83.4)	182 (84.3)	53 (82.8)	0.782
Score ≥10, n (%)	52 (16.6)	34 (15.7)	11 (17.2)	
24 months, mean (SD)	n = 266 5.4 (6.5)	n = 174 6.1 (7.5)	n = 72 4.0 (4.1)	
Score <10, n (%)	229 (86.1)	149 (85.6)	64 (88.9)	0.495
Score ≥10, n (%)	37 (13.9)	25 (14.4)	8 (11.1)	
30 months, mean (SD)	n = 278 5.2 (4.8)	n = 185 5.4 (4.8)	n = 65 4.7 (5.3)	
Score <10, n (%)	240 (86.3)	158 (85.4)	58 (89.2)	0.439
Score ≥10, n (%)	38 (13.7)	27 (14.6)	7 (10.8)	
36 months, mean (SD)	n = 245 5.7 (7.7)	n = 168 5.9 (8.4)	n = 58 5.4 (6.5)	
Score <10, n (%)	205 (83.7)	142 (84.5)	47 (81.0)	0.536
Score ≥10, n (%)	40 (16.3)	26 (15.5)	11 (19.0)	

[a]The IFNGS status was missing for 76 patients.

[b]Comparison of the total score by category (<10 or ≥10) between low and high baseline type 1 IFNGS categories using the chi-square test.

Methods: Eligible patients (aged ≥18 years) had physician-confirmed SLE (ACR or SLICC classification), ≥1 lifetime positive serology of ANA or dsDNA, a ≥6-month treatment duration with systemic SLE treatment beyond non-steroidal anti-inflammatory drugs and analgesics, and moderate-to-severe activity at enrollment. Disease activity was assessed by the modified Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), as well as by instances of flares, the Lupus Low Disease Activity State (LLDAS), and remission according to the 2021 Definition of Remission In Systemic Lupus Erythematosus (DORIS). IFNGS tests were conducted in a central laboratory; each sample was compared to pre-established cutoffs and given a qualitative diagnostic score, denoting low or high IFNGS. Comparisons between low and high IFNGS categories were performed with the chi-square test.

Results: A total of 826 patients were enrolled; 70.8% (n = 531) and 29.2% (n = 219) of patients had high and low baseline IFNGS, respectively, and the IFNGS status was missing for 76 patients. At baseline, the mean (standard deviation [SD]) SLEDAI-2K was 9.8 (4.6; n = 591); 58.2% (n = 344) of patients had a score of < 10. The mean (SD) SLEDAI-2K total scores at baseline were slightly lower in patients with a low IFNGS (9.2 [5.2]) compared with those with a high IFNGS (9.8 [4.3]; **Table 1**). Furthermore, a greater percentage of patients with a low IFNGS had SLEDAI-2K total scores of < 10 compared

Table 2

Table 2. Disease activity by incidence of flares, LLDAS, and remission status by baseline IFNGS status[a,b]

Timepoint	Overall (N = 826)	High IFNGS (N = 531)	Low IFNGS (N = 219)	*P*-value
Baseline, n (%)	n = 826	n = 531	n = 219	
≥1 flare within the last 6 months	421 (51.0)	277 (52.2)	107 (48.9)	
6 months, n (%)	n = 663	n = 427	n = 177	
≥1 flare since prior visit	120 (18.1)	81 (19.0)	29 (16.4)	
LLDAS	n = 435	n = 298	n = 104	
	31 (7.1)	20 (6.7)	7 (6.7)	0.995[c]
Remission	n = 544	n = 347	n = 148	
	13 (2.4)	6 (1.7)	6 (4.1)	0.197[d]
12 months, n (%)	n = 542	n = 327	n = 161

24 months, n (%)	n = 428	n = 276	n = 113	
≥1 flare since prior visit	60 (14.0)	36 (13.0)	15 (13.3)	
LLDAS	n = 256	n = 168	n = 69	
	19 (7.4)	12 (7.1)	5 (7.2)	1.000[d]
Remission	n = 318	n = 204	n = 83	
	19 (6.0)	14 (6.9)	2 (2.4)	0.165[d]
30 months, n (%)	n = 443	n = 276	n = 123	
≥1 flare since prior visit	61 (13.8)	37 (13.4)	16 (13.0)	
LLDAS	n = 265	n = 175	n = 63	
	15 (5.7)	10 (5.7)	4 (6.3)	1.000[d]
Remission	n = 311	n = 199	n = 81	
	16 (5.1)	14 (7.0)	2 (2.5)	0.165[d]
36 months, n (%)	n = 409	n = 257	n = 114	
≥1 flare since prior visit	60 (14.7)	34 (13.2)	21 (18.4)	
LLDAS	n = 233	n = 158	n = 56	
	23 (9.9)	18 (11.4)	5 (8.9)	0.609[c]
Remission	n = 284	n = 181	0	
	15 (5.3)	15 (8.3)	0	0.007[d]

[a]Remission status is according to the 2021 Definition of Remission In Systemic Lupus Erythematosus (DORIS).

[b]The IFNGS status was missing for 76 patients.

[c]Comparison between low and high baseline IFNGS using the chi-square test.

[d]Comparison between low and high baseline IFNGS using Fisher's exact test.

to those with a high IFNGS (66.4% [n = 91] vs 57.2% [n = 227], respectively). At baseline, 51.0% (n = 421) of patients reported having had ≥1 flare within the last 6 months; these were reported in similar percentages of patients with high and low IFNGS (52.2% [n = 277] vs 48.9% [n = 107], respectively; **Table 2**). Across the first 6 months, the percentage of patients reporting ≥1 flare since baseline was 18.1% (n = 120; high IFNGS, 19.0% [n = 81]; low IFNGS, 16.4% [n = 29]). At 6 months, the same percentage of patients with low IFNGS and high IFNGS achieved LLDAS (6.7% [n = 7] and 6.7% [n = 20], respectively), but a numerically higher percentage of patients with low IFNGS versus high IFNGS achieved remission (4.1% [n = 6] vs 1.7% [n = 6], respectively). The mean SLEDAI-2K total scores and percentages of patients reporting new flares changed little after 6 months, regardless of the baseline IFNGS status. Less than 10% of patients achieved LLDAS and less than 10% achieved remission during the entire 36 months of follow-up.

Conclusion: Although flare rates observed prospectively were lower than those reported by patients at enrollment, patients continued to have flares over the course of 36 months. There was no significant improvement in disease activity, and there were low rates of LLDAS and remission. Altogether, these indicate an unmet need for improved treatment outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In systemic lupus erythematosus (SLE), there is no definition of states of moderate and severe SLE activity. How these states may influence different disease outcomes is unknown.

To propose a definition for states of moderate and severe activity in SLE and using the largest Spanish national cohort of SLE patients, to describe the prevalence of both states of activity and to analyze the impact of this classification on flare-ups, achieving low disease activity state (LLDAS), hospital admissions, health-related quality of life (HRQoL), damage accrual and mortality.

Table 1. Criteria and proposals for the definition of states of moderate and severe activity in SLE.

Table 1. Criteria and proposals for the definition of states of moderate and severe activity in SLE.

Criteria \ Definition	**SLE Moderate activity status (at each visit):** meets at least 2 of the 3 following criteria: Definition Criteria	**SLE Severe activity status (at each visit):** meets at least 2 of the 4 following criteria:
SELENA-SLEDAI (*Safety Of Estrogens In Lupus Erythematosus National Assessment-Systemic Lupus Erythematosus Disease Activity Index*) **cSLEDAI: clinical SLEDAI,** i.e., not considering hypocomplementaemia nor the positivity of anti-dsDNA antibodies	4 < SLEDAIc ≤ 8	SLEDAIc > 8
PGA (*Physician Global Assessment*) on a 0-3 scale	1 < PGA ≤ 2	PGA >2
Glucocorticoid dose	• 7.5mg/day < prednisone < 30mg/day, or • Methylprednisolone pulses ≤125mg/day	• Prednisone ≥ 30mg/day, or • Methylprednisolone pulses >125 mg/day
Severe Non-SLEDAI manifestations: • Haemolytic anemia, autoimmune with Hb <10 g/L, • Microangiopathic haemolytic anemia and thrombotic microangiopathy (PTT), • Pure red cell aplasia, • Alveolar hemorrhage, • Lupus pneumonitis with hypoxemia, • Pulmonary hypertension, • Shrinking lung syndrome, • Gastrointestinal (vasculitis, protein-losing enteropathy), • Myocarditis, • Libman-Sacks endocarditis with valve dysfunction, • Transverse myelitis.		≥ 1 severe manifestation of non-SLEDAI SLE

Table 2. Mean number of flares (total, severe and mild-moderate) over the follow-up period (4 years) according to the activity status.

Table 2. Mean number of flares (total, severe and mild-moderate) over the follow-up period (4 years) according to the activity status.

	Moderate activity ≥ 1 time	Moderate (or severe) activity never	p	Severe activity ≥ 1 time	Severe activity never	p
Mean number (±SD) of **total flares** (V1-V5: 4 years)	3,2 (±2,5)	1,3 (±2,0)	**<0,001**	2,6 (±3,0)	1,3 (±2,0)	**<0,001**
Mean number (±SD) of **mild-moderate flares** (V1-V5: 4 years)	2,4 (±2,4)	1,0 (±1,8)	**<0,001**	1,4 (±2,3)	1,1 (±1,9)	**0,442**
Mean number (±SD) of **severe flares** (V1-V5: 4 years)	0,7 (±1,0)	0,2 (±0,6)	**<0,001**	1,2 (±1,4)	0,2 (±0,5)	**<0,001**

Methods: We propose definitions for states of moderate and severe activity in SLE (Table 1). To analyze the impact of this classification, available data from the prospective phaseof the Spanish Society of Rheumatology SLE Registry (RELESSER-PROS) were used, with 5 annual visits (V1-V5) over 4 years. Patients were required to have at least 3 consecutive visits. At each visit, the number of flares and their severity (according to the SELENA Flare Index), visits in LLDAS, hospital admissions, HRQoL according to the Lupus Impact Tracker (LIT), damage accrual (using the SLICC/ACR Damage Index [SDI]) and mortality was collected. T-test was used for group comparisons.

Results: A total of 1463 patients (90% women) were included, with a mean age (±SD) of 56 (±13.5) years. The mean disease duration of SLE (±SD) at V1 was 14 (±8.5) years. Patients had a mean (±SD) of 4.2 (±1.2) visits and a mean (±SD) follow-up of 2.5 (±0.7) years. Moderate activity was shown by 54 patients (3.7%) at V1, 20 patients (1.4%) at V2, 27 patients (1.8%) at V3, 5 patients (0.3%) at V4, and 11 patients (0.8%) at V5. On the other hand, 40 patients (2.7%) at V1, 15 patients (1.0%)

Table 3. Comparative results in LLDAS status, admissions, HRQoL, damage accrual and mortality over the follow-up period (4 years) in patients who have ever been in a situation of moderate or severe activity compared to those who have not.

Table 3. Comparative results in LLDAS status, admissions, HRQoL, damage accrual and mortality over the follow-up period (4 years) in patients who have ever been in a situation of moderate or severe activity compared to those who have not.

	Moderate activity ≥ 1 time	Moderate (or severe) activity never	p	Severe activity ≥ 1 time	Severe activity never	p
LLDAS status[a]	2,5 (±1,1)	3,7 (±1,3)	**<0,001**	2,3 (±1,3)	3,6 (±1,3)	**<0,001**
Admissions	2,4 (±3,5)	0,85 (±1,7)	**<0,001**	3,2 (±3,8)	0,86 (±1,7)	**<0,001**
Quality of life (Mean LIT[b])	40 (±21,1)	28,9 (±20,3)	**<0,001**	41,3 (±20,8)	29,1 (±20,4)	**<0,001**
Quality of life (Highest LIT[b])	54,5 (±24,6)	39,1 (±24,0)	**<0,001**	54,0 (±24,3)	39,5 (±24,1)	**<0,001**
Cumulative damage[c] (V5-V1)	0.88 (±1.19)	0.42 (±0.88)	**<0,001**	1.18 (±1.82)	0.42 (±0.83)	**<0,001**
Mortality[d]	0,029 3/105 (2,86%)	0,029 40/1358 (2,95%)	**0,959**	0,06 4/67 (5,97%)	0,028 39/1396 (2,79%)	**0,285**

Mean values ± SD.

[a] Number of visits in LLDAS.
[b] Higher LIT score means a greater deterioration in quality of life.
[c] SDI in V5 minus SDI in V1.
[d] Annual (at each visit) mortality rate. Number of deceased patients (%).

at V2, 13 patients (0.9%) at V3, 6 patients (0.4%) at V4 and 3 patients (0.2%) at V5 showed severe activity. Patients who presented both moderate and severe activity in at least 1 of the 5 visits had a significantly higher mean total number of flares over the 4-year follow-up period (V1-V5)than those who did not ($p< 0.001$). These same results occur in the case of severe flares. Regarding mild-moderate flares, patients with moderate and severe activity in at least 1 visit, had a higher mean number than patients without these activities, being statistically significant for moderate activity. More detailed information about flares can be seen in Table 2. On the other hand, patients who presented both moderate and severe activity in at least 1 of the 5 visits had significantly less number of visits in LLDAS, higher number of hospital admissions, worse HRQoL and greater damage accrual in the period V1-V5 than those who did not ($p< 0.001$ for all comparisons). Patients with severe activity in ≥1 visit had higher mortality (p=n.s.) (Table 3).

Conclusion: Patients who were in a state of moderate and/or severe activity at least on 1 occasion had worse outcomes at the end of follow-up in terms of number/severity of flares, hospital admissions, deterioration in HRQoL and damage accrual. These results emphasize the importance of setting achievable objectives in the Treat to Target (T2T) strategy for the treatment of SLE.

Lupus Damage Index Revision - Item Generation and Reduction Phase

Burak Kundakci[1], Megan Barber[2], Ann Clarke[2], Sindhu Johnson[3], Ian Bruce[4] and On behalf of the revised SLE organ damage index (SDI) collaborators[4], [1]Centre for Epidemiology Versus Arthritis, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom, [2]University of Calgary, Division of Rheumatology, Cumming School of Medicine, Calgary, AB, Canada, [3]Division of Rheumatology, Department of Medicine, Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western and Mount Sinai Hospitals; Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON, Canada, [4]University of Manchester, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The SDI is a robust instrument, but is limited by incomplete items, restricted applicability in paediatric patients, and outdated item definitions1. The SLICC, ACR and LFA have embarked on a data- and expert/patient-driven project to develop a revised SDI. Our objective was to report the item generation and reduction phases of a five-phase process for developing a revised SDI.

Methods: Item generation and reduction involved a thorough literature review, a three-round Delphi exercise, and a subsequent revision by a 14-member steering committee. A group of lupus experts conducted a literature review to identify items that reflect the construct of damage in SLE and grouped the items into organ domains. A large international group of expert lupus clinicians was established by snow-ball sampling amongst SLICC members. Patient and caregiver partners were nominated through the LFA, Lupus UK, Lupus Europe, and Lupus Canada.

Participants generated and rated candidate items based on their appropriateness for inclusion in a revised SDI using a Delphi exercise. The 14-member steering committee then reviewed the items for further refinement.

Results: We assembled a diverse group of 146 individuals (mean age 50.6, ranging from 28 to 79 years; 60.3% females; 58.9% white; clinical experience ranging from 1 to 51 years) from 35 countries, representing the lupus research and patient community extensively. There were 135 medical doctors, 2 allied health professionals and 9 patients.

Item generation resulted in a total of 220 items across 14 organ systems. The literature review identified 4 unique items (1.8%), while 103 unique items (46.8%) were derived from the Delphi exercise alone, and 113 items (51.4%) appeared in both exercises. In the second round of the Delphi exercise, participants suggested an additional 6 unique items. Overall, 226 items were subjected to re-rating for appropriateness for inclusion in the revised SDI. Completion rates for the first, second, and third Delphi rounds were 97.9%, 95.0%, and 91.7%, respectively. Thirty-six items received a median score of 4 out of 9 and these were removed. All original 1996 SDI items were retained with median appropriateness scores of 7, 8, and 9, except for upper gastrointestinal tract surgery (median appropriateness score 5) and osteomyelitis (median appropriateness score 5). The steering committee further eliminated 126 items due to redundancy, limited availability or feasibility for assessment, overlap, lack of reflection of damage construct or association with lupus disease activity, and rarity. Figure 1 shows the number of candidate items identified at different stages during revised SDI development.

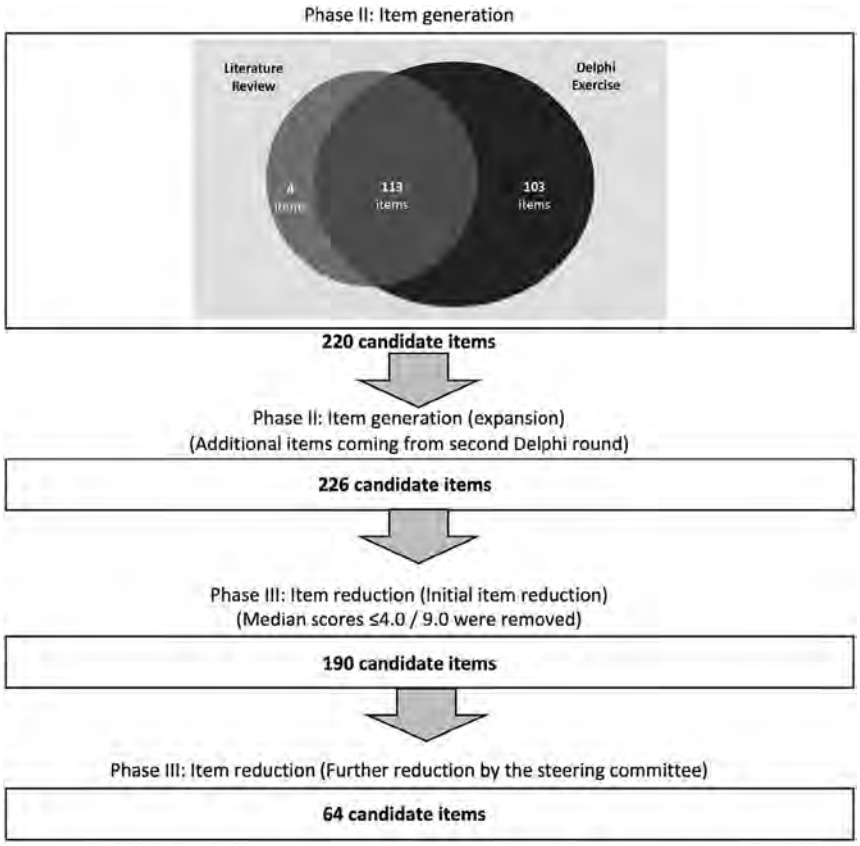

Figure 1. Number of candidate items identified at different stages of Phase II/III during revised SDI development

Conclusion: Using a combined data-driven and expert/patient-based approach, items and domains that comprise damage in SLE have been expanded. The item generation and reduction phase resulted in 64 candidate items for consideration. All original SDI items were retained in this step. Further steps are now underway to agree upon definitions for those items, including extent and duration of item presence, based on the best current evidence and internationally accepted norms.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Using machine learning, we identified 4 patient clusters based on longitudinal autoantibody profiles in an international SLE inception cohort, which were predictive of disease outcomes (*Ann Rheum Dis 2023*). We now compare direct and indirect costs between these SLE clusters to elucidate healthcare utilization patterns in SLE.

Table 1. Enrolment demographics and clinical characteristics of SLE Autoantibody Clusters in an international inception cohort (only statistically significant differences shown for clinical characteristics, indicated by bolded values[1])

	Cluster 1 N=137[2]	Cluster 2 N=376[3]	Cluster 3 N=80[4]	Cluster4 N=212[5]	FDR[1]
% Female	89.8 (30.4)	89.4 (30.9)	81.2 (39.3)	89.6 (30.6)	0.588
Mean Age of Diagnosis (SD), yrs	31.5 (10.8)	36.5 (13.9)	32.5 (13.9)	34.4 (14.1)	**0.014**
% Ethnicity					
White	32.1	61.7	68.8	42.5	**<0.001**
Asian	30.7	20.5	13.8	31.1	**0.014**

1. Comparison between cluster groups using one-way ANOVA test (null hypothesis that there is no difference between the means of the groups) and a Benjamini-Hochberg correction with false discovery rate (FDR) alpha = 0.05
2. Cluster 1 was characterized by high frequency of anti-Smith, anti-U1RNP
3. Cluster 2 was characterized by low anti-double stranded DNA (dsDNA) and ANA titres
4. Cluster 3 was characterized by high frequency of all five antiphospholipid antibodies
5. Cluster 4 had multiple autoantibody reactivity including to anti-histone, anti-dsDNA, anti-ribosomal P, anti-Sjögren syndrome antigen A or Ro60, anti-Sjögren syndrome antigen B or La, anti-Ro52/Tripartite Motif Protein 21, anti-proliferating cell nuclear antigen and anti-centromere B.
6. Cluster 1 n=106, cluster 2 n=250, cluster 3 n=63, cluster 4 n=163. Patients with less than 10-years of follow up who are still alive were excluded. Hazards of survival, adjusted for age at disease onset in a multivariable Cox regression demonstrates that patients in clusters 1 (adjusted HR 2.60 (95% CI 1.12 to 6.05), p=0.03) and 3 (adjusted HR 2.87 (95% CI 1.22 to 6.74), p=0.02) had lower survival compared with patients in cluster 2.

Methods: Patients fulfilling the 1997 Revised ACR SLE Classification Criteria from 33 centres (11 countries) were enrolled within 15 months of diagnosis and clustered by k-means using longitudinal 29 ANA immunofluorescence pattern and 20 autoantibody profiles. Data were collected annually on health care use (i.e., hospitalizations, medications, dialysis, and selected procedures, as well as SLE antibodies, organ involvement, activity [adjusted mean SLEDAI-2K] and medication use), supplemented by data on additional resource use and lost work-force/non-work-force productivity in a patient subset. Multiple imputation was used to predict all missing values for the patients in the full cohort who did not provide direct/indirect costs for all observations. Health care use was costed using 2023 Canadian prices and lost productivity using Statistics Canada age-and-sex specific wages. Average annual costs over follow up were compared between clusters using multivariable regressions, adjusting for significant predictors for direct and indirect costs.

Results: Of 1800+ patients enrolled in the SLICC cohort, 805 subjects were included in the SLE clusters and provided cost data (**Table 1**). Mean follow-up time for the entire cohort was 12.3 years (range 2.9-21.6 years) and similar across clusters. There were no clear differences in direct and indirect costs and component costs between clusters 1 (high frequency of anti-Sm/anti-U1RNP, predictive of high cumulative disease activity and immunosuppressant/biologic use), 2 (low autoantibody reactivity, predictive of low disease activity and immunosuppressant/biologic use), and 4 (multiple autoantibody reactivities, predictive of high disease activity). Thus, these 3 clusters were combined and compared with cluster 3 (highest frequency of all antiphospholipid antibodies [IgM/IgG anti-cardiolipin, -ß2GP1, -PS/PT, IgG anti-ß2GP1D1, lupus anticoagulant], predictive of seizures and mortality) using multivariable regressions. Cluster 3 had higher total direct costs than clusters 1, 2, and 4 combined ($9288 vs $7061; adj. diff. $2852 [95%CI $196, $5510]), particularly for hospitalizations ($2134 vs $1320; adj. diff. $1158 [95%CI $455, $1860]) (**Table 2**). Cluster 3 had significantly more hospitalizations for thrombotic/cardiovascular (CVD) events compared to combined clusters (2-sample test of proportions, 22.7% vs. 4.1%, diff. 18.6% [95%CI 6.0%, 31.3%]) (**Fig1**).

Table 2. Average annual complete direct and indirect health care costs (2023 Canadian Dollars)[1], n=805, comparing Cluster 3 and Combined Clusters 1, 2, and 4

	Cluster 3 N=80	Combined Clusters 1, 2, and 4 N=725	Difference (95% CI)[2]	Adjusted Difference (95% CI)[3]
Direct Costs				
Total	9288 (7338, 11238)	7061 (6572, 7551)	**2226 (219, 4233)**	**2852 (196, 5510)**
Hospital Visits[4]	2134 (1466, 2802)	1320 (1173, 1467)	**814 (131, 1497)**	**1158 (455, 1860)**
Medications	2803 (1232, 4373)	2270 (1899, 2640)	533 (-1079, 2144)	659 (-1039, 2356)
Dialysis	1265 (574, 1956)	610 (452, 767)	656 (-52, 1363)	591 (-876, 2056)
Other[5]	3086 (2575, 3597)	2862 (2643, 3081)	224 (-291, 738)	368 (-323, 1059)
Indirect Costs				
Total	30872 (24728, 37016)	30186 (25826, 34546)	686 (-6146, 7517)	-199 (-4817, 4420)

Bolded values indicate statistically significant result, p<0.05.

1. Potential predictors for imputing complete direct and indirect costs included age at diagnosis, sex, race and ethnicity, education, geographic location (i.e., residing inside vs outside North America [includes Canada, the US, and Mexico]), and the time-varying covariates: disease duration, smoking, high-risk alcohol use, and partial direct costs. Partial direct costs and geographic location remained in all models as final covariates, with the direct cost model also including age at diagnosis and education, and the indirect cost model also including disease duration. Ten sets of imputations were derived from these models, and all subsequent analyses involved pooling and averaging all estimates across imputed sets; variances were computed by applying standard combination rules.
2. The difference between Cluster 3 and others. These are the unadjusted analysis.
3. Potential predictors for adjusting cost differences included all potential predictors for the imputation models (see footnote 1) with the exception of partial costs. Direct cost differences were adjusted for disease duration and race/ethnicity, and for panel structure (multiple observations per patient); indirect cost differences were adjusted for disease duration and geographic location (residing within vs outside of North America), and multiple observations per patient.
4. Only 18.5% of the n=805 cohort had reasons for hospitalization; 12.6% for cluster 1; 19.1% for cluster 2; 25.0% for cluster 3; 19.3% for cluster 4.
5. Other costs in the complete direct cost analysis included physicians, non-physician healthcare professionals, emergency room visits, laboratory tests, radiological and other diagnostic procedures, outpatient surgeries, and help obtaining medical care over the year preceding the assessment.

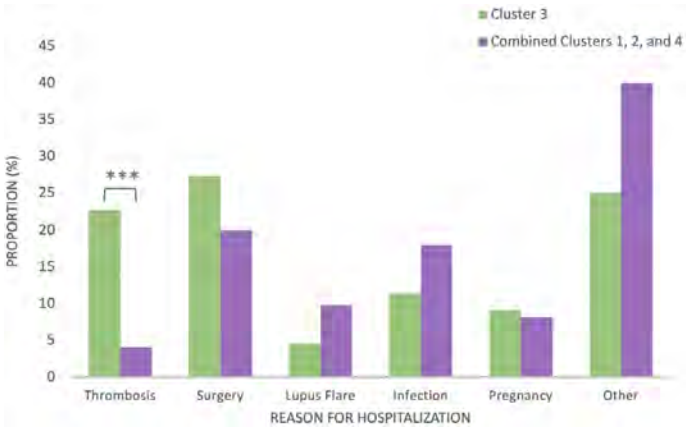

Figure 1. Reasons for Hospitalization Cluster 3 vs. Combined Clusters 1, 2, and 4. There was a higher proportion of hospitalizations for thrombotic events (e.g., myocardial infarction, stroke, pulmonary embolism) for Cluster 3 (*** $p<0.001$) compared to Combined Clusters 1, 2, and 4.

Conclusion: Machine learning based on autoantibodies alone identified a patient cluster with high antiphospholipid antibody frequency who incurred the greatest direct costs, a high proportion driven by hospitalizations due to thrombosis/CVD-related events. Even clusters with severe SLE did not incur such high cost, suggesting thrombotic and antiphospholipid-related complications are important contributors to the economic burden of SLE.

Explainable Machine Learning to Predict Hospitalized Infection in Patients with Systemic Lupus Erythematosus

Hsin-Hua Chen[1] and Wen-Nan Huang[2], [1]Taichung Veterans General Hospital, Taichung, Taiwan, [2]Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Veterans General Hospital, College of Medicine National Chung Hsing University, Department of Business Administration, Ling-Tung University, Taichung, Taiwan; School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have a 1.85-fold higher risk of all-cause mortality and a 2.74 fold higher risk of infection-related mortality compared with controls. In addition, infection is responsible for up to 45% of hospitalization and 65.8% of death. However, few studies had developed a prediction tool for hospitalized infection in patients with SLE using electronic medical records (EMR). Therefore, we aimed to develop predictive models for hospitalized infection in patients with SLE in a medical center in central Taiwan.

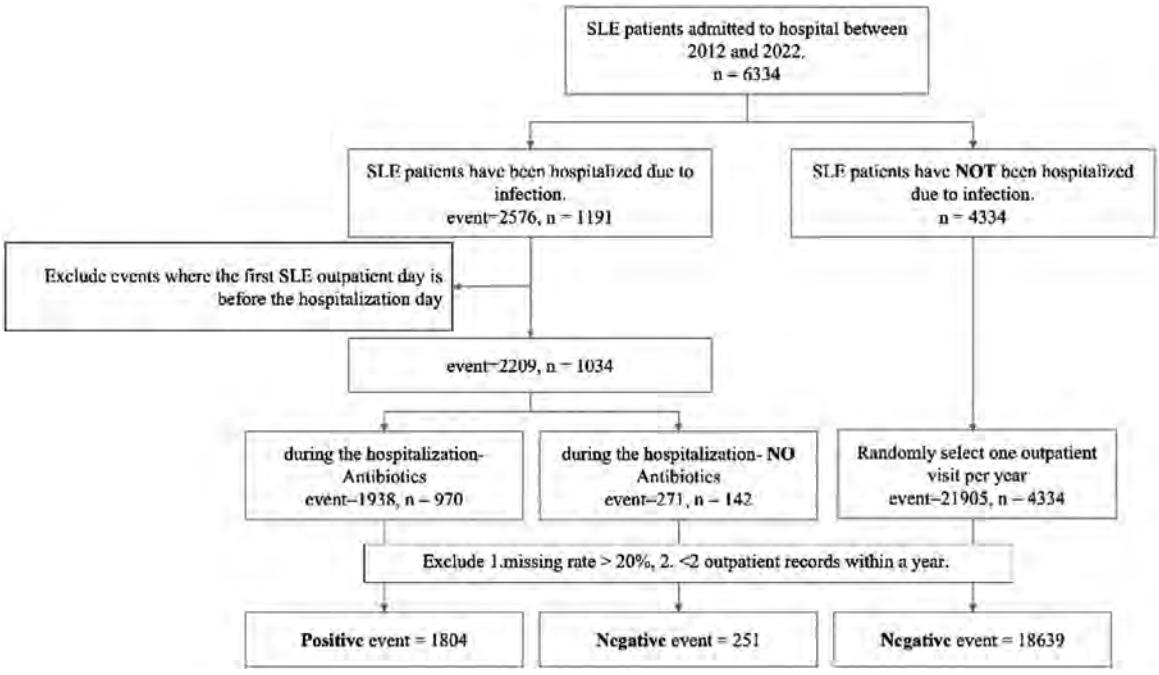

Fig 1. Flowchart of study subjects enrollment.

Methods: Using EMR data of patients with SLE from the Taichung Veterans General Hospital during the period of 2012–2022, we conducted five machine learning (ML) models, including extreme boosting (XGBoost), random forest (RF), logistic regression (LR), support vector machine (SVM) and K nearest neighbor (KNN). The ratio between training/testing was 80/20. We used the SHAP summary plot to illustrate the strength and the direction of associations between key features and 30-day risk of hospitalized infection. We performed the receiver operating characteristic (ROC) analysis, calibration curve and decision curve analysis to determine discrimination, accuracy and applicability of the predictive ML modes in the testing datasets.

Results: Figure 1 showed the flowchart of subject enrollment. A total of 5368 patients with SLE with at least two ambulatory visits were included. Table 1 summarizes characteristics of patients with and without hospitalized infection. We finally included 28 features of four domains (demographics, laboratory data within one year before the index date, comorbidities in prior one year, and cumulative dose of medications in prior 3 months [9 months for rituximab]) based on feature importance in the ML models (Fig 2A). Fig 2B showed cumulative relative feature importance of top 28 features categorized by main clinical domains in predicting 30-day hospitalized infection. As shown in Fig 2C, XGBoost showed the best performance among the five ML models with a sensitivity of 83.15%, a specificity of 94.09%, an accuracy of 93.11% and an area under curve (AUC) in ROC analysis of 95.9% in the testing datasets. Because laboratory data domain provides the largest portion of feature importance, after exclusion of 11 medication domain features, we re-conducted ML models using 15 laboratory data domain features and 2 demographic domain features and found the XGBoost model still revealed the best performance with an accuracy of 91.91% and an AUC in ROC of 93.94% (data not shown).

Conclusion: We developed explainable ML models to predict hospitalized prediction in patients with SLE using 10-year EMR data from a medical center in Taiwan.

Table 1. Characteristics of patients with SLE with and without hospitalized infection.

Mental Illness and Outcomes of COVID-19 in Patients with Systemic Lupus Erythematosus: A Global Multicenter Cohort Study

Hsin-Hua Chen, Taichung Veterans General Hospital, Taichung, Taiwan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Poor COVID-19 outcomes in patients with systemic lupus erythematosus (SLE) has been found to be associated with glucocorticoid dose, male sex, older age, mycophenolate, rituximab, cyclophosphamide, moderate or high SLE disease activity, and comorbidities including kidney disease and cardiovascular disease/hypertension. However, the influence of mental illness on COVID-19 outcomes had not been addressed.TriNetX, a global federated health research network, has been used in several studies to investigate the outcomes and clinical features. Therefore, we aimed to assess the association of mental illness and COVID-19 outcomes in patients with SLE using electronic medical records (EMR) in the TriNetX Network. The aim of the study was to assess the association of short-term outcomes of COVID-19 with mental illness in patients with SLE.

Methods: The study identified SLE patients aged 20–89 years who got COVID-19 between January 1, 2020 and April 28, 2023 with and without a history of mental illness before COVID-19 infection. The diagnoses of SLE and mental illness (mental and behavioral disorders due to psychoactive substance use, mood [affective] disorders, or anxiety, dissociative, stress-related, somatoform and other nonpsychotic mental disorders) were based on International Classification of Diseases tenth revision (ICD-10), while the diagnosis of COVID-19 was based on ICD-10, Current Procedural Terminology (CPT) Codes, or Logical Observation Identifiers Names and Codes (LOINC). Propensity score was used to match COVID-19 infected SLE patients with and without a history of mental illness for potential confounders, we conducted Cox regression analyses to examine the association between mental illness and COVID-19 outcomes shown as hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: We finally included 12,485 patients with SLE who had a history of mental illness and 12,485 matched SLE patients without a history of mental illness. The mean ± standard deviation (SD) age was 51.5 ± 15.8 years in the mental illness group and 51.6 ± 17.4 years in the non-mental illness group, respectively. The proportion of females was 89.2% in the mental illness group and 88.4% in the non-mental illness group. SLE patients with mental illness had a higher risk of hospitalization (HR, 1.26; 95% CI, 1.17–1.35), Intensive Care Unit (ICU) admission (HR, 1.47; 95% CI, 1.24–1.73), mechanical ventilation (HR, 1.50; 95% CI, 1.11–2.03), sepsis (HR, 1.24; 95% CI, 1.03–1.51) and cerebral vascular accident (CVA) (HR, 1.66; 95% CI, 1.41–1.96) than SLE patients without mental illness. However, the risk of mortality was lower in SLE patients with mental illness than in SLE patients without mental illness (HR, 0.73; 95% CI, 0.57–0.93).

Conclusion: This global multicenter matched cohort study showed that mental illness was associated with an increased risk of hospitalization, ICU admission, mechanical ventilation, sepsis and CVA, but a decreased risk of death within 30 days after the date of COVID-19 diagnosis in patients with SLE.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

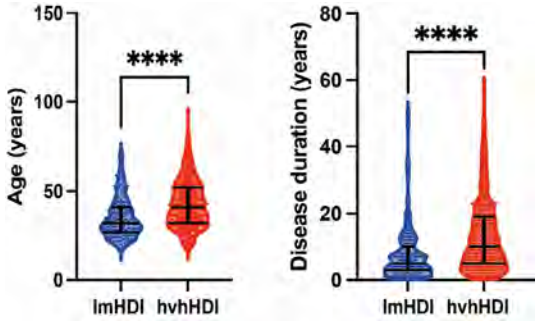

Figure 1. Patients from low/medium HDI (lmHDI) countries were significantly younger and had shorter disease duration than those from high/very high HDI (hvhHDI) countries (p<0.0001)

Background/Purpose: Regional disparities in the management of SLE are frequently described. Governance, funding, logistic barriers, and physician choice may be important determinants though data is scare from many underrepresented regions thus limiting our understanding and ability to appraise this. Steroids are a key contributor to damage and the use of steroid sparing medication has an important role in reducing these complications. In this study, we sought to evaluate global patterns in the treatment of SLE and identify the prevalence of steroid related comorbidities.

Table 1. Differences observed between patients from low/medium HDI (lmHDI) and high/very high HDI (hvhHDI) countries. Corticosteroid and anti-malarial treatment was more frequently used in the treatment of patients in low/medium HDI (lmHDI) countries, whilst biologic use was used more frequently in high/very high HDI (hvhHDI) countries.

Methods: We identified SLE patients from the COVAD 2 database, an international study of over 20,000 respondents. Data collection included, demographics, comorbidities, treatment including; corticosteroids (CS), antimalarials, immunosuppressants (IS), cyclophosphamide and biologics. Country Human Development Index (HDI) classification, a composite index formulated by the United Nations to rank countries into tiers of development, was utilised. Statistical analysis comprised of Chi square for comparison of categorical values and t-test for comparison between groups. Significance was defined as $p< 0.05$.

Results: A total of 1167 patients with SLE were included in analysis. As shown in Figure 1, patients from low/medium HDI (lmHDI) countries were significantly younger than those from high/very high HDI (hvhHDI) countries (median age 32, IQR 27-41 vs 41, IQR 32-52 years, $p< 0.0001$). In addition, disease duration was shorter in lmHDI countries (median 5, IQR 3-10 vs 10, IQR 5-19 years, $p< 0.0001$). As shown in Table 1, a higher proportion of SLE patients from lmHDI countries were on CS (73% vs 59%, p=0.0002), antimalarials (81% vs 68%, p=0.0002) and IS (66% vs 53%, p=0.0009) compared with patients from hvhHDI countries. Biologic use was more common in hvhHDI countries (7% vs 2%, p=0.0055). Comorbidity prevalence was similar between groups, however when adjusted for age, these were observed in younger patients from lmHDI countries than hvhHDI countries (with shorter disease durations), thus suggesting earlier steroid related complications. Patients with chronic kidney disease were significantly younger patients in lmHDI countries than hvhHDI countries (36.67 vs 44.64 years, p=0.015). Those with coronary artery disease (35.7 vs. 44.6 years, p=0.015) and hypertension (41.5 vs 49.8 years, p=0.003) were also younger in lmHDI countries.

Conclusion: In this large international study evaluating treatment and steroid related comorbidity incidence in SLE populations based on country HDI we identified several differences in pharmacological management globally. Whilst there was no significant difference in the incidence of comorbidities, these occurred in younger patients and earlier in the disease course in those from lmHDI countries. CS use was higher in lmHDI countries and may be a key contributor to the increased incidence in these comorbidities. Interestingly, Hydroxychloroquine, which has frequently been shown to reduce damage and cardiovascular comorbidities was more commonly used in lmHDI countries but these comorbidities persisted. Further studies are required to identify other factors contributing to this earlier development of comorbidities.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The management of SLE relies on regular assessment of disease activity. However, patient perception of disease activity can be highly variable and may be discordant with physician assessment. This problem has recently become a more important consideration due to the rise in virtual or telephone consultations, in which physicians may be guided by patient reported symptoms and perceived disease activity. In this study, we sought to evaluate factors associated with discordance between physician and patient perception of disease activity in SLE in a global cohort of patients.

Methods: Data was collected from an international collaborative research survey of more than 17,000 participants (of which 1292 had SLE). Variables such as disease duration, symptoms, comorbidities, medication and validated Patient Reported Outcome Measures (PROMs) were included. Patient perception of disease activity was self-reported. Physician defined disease activity was classified as the presence of at least one symptom of active SLE (including joint swelling, active rash, oral ulcers, alopecia, active renal disease) in addition to the need for a change or increase in lupus treatment within the last 6 months. Patients were classified into three groups; 1. Concordant active (both physician and patient in agreement of active disease); 2. Discordant (patient reported disease to be active but did not fulfil definition of physician confirmed active disease); 3. Concordant inactive (both physician and patient in agreement that the disease is inactive). Differences between groups was evaluated using Chi Square and t-test. Cramer's phi was used to assess strength on concordance between patient and physician reported disease activity. Predictors of discordance were analysed in regression models. Statistical significance was defined as $p< 0.05$.

Results: Of the 1292 patients with SLE, 5.1% were defined as Concordant Active disease, 49.46% had Concordant Inactive disease, and 45.43% were Discordant (patient perceived active with physician defined inactive disease). Cramer's phi between Physician Active and Patient Active disease was 0.16 (weak association). As summarised in Table 1, there was no difference in age, gender or disease duration between groups. In patients with inactive disease, Caucasian patients were

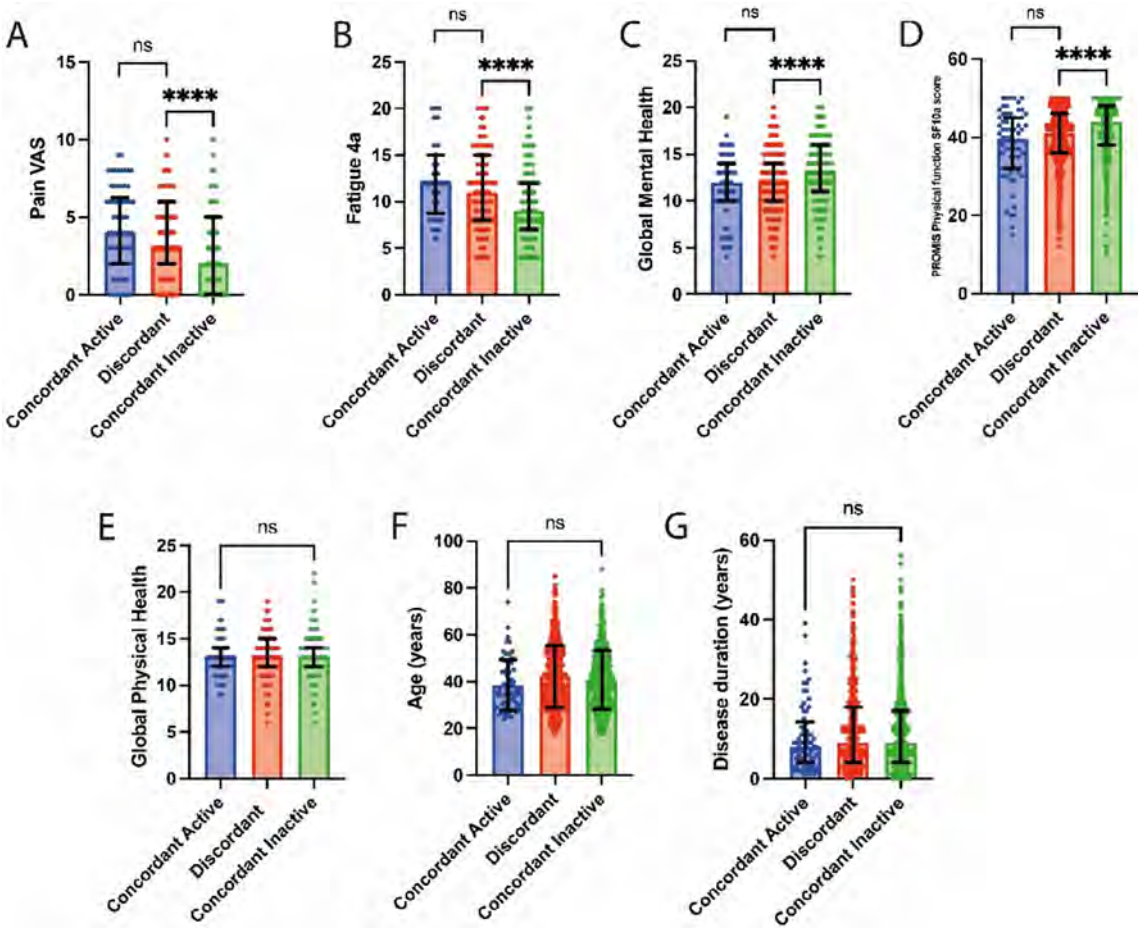

Figure 1. Patients who reported active disease (in the context of physician defined inactive disease, i.e. discordant) reported high levels of Pain (A), Fatigue (B) and had poorer mental health (C) and physical function (D) than those with concordant inactive disease (in which both patient and physician agreed the disease was not active). There was no significant difference in PROMIS Physical Health Score (E), Age (F) or Disease Duration (G) ns, not significant; **** p<0.0001

more likely to be discordant ($p < 0.0001$), with Asian, Mixed and Other ethnicities more likely to be concordant. In terms of treatment, those on steroids and immunosuppressive agents were more likely to be discordant in their assessment of disease activity, whilst those on no treatment were more likely to be in agreement with physicians that their disease was inactive. As shown in Figure 1, key symptomatic drivers of discordance included fatigue, pain and Global Mental Health scores ($p < 0.0001$). Patients were more likely to agree that their disease was inactive in the context of lower levels of pain, fatigue and better mental health scores whilst being on less treatment.

Conclusion: This study highlights that nearly half of patients perceive their disease to be active when their physicians feels it is inactive. In particular this was observed in those who reporting from high levels of fatigue, pain and poorer mental health.

Longitudinal Changes in Type 1 & Type 2 SLE Activity

Amanda Eudy[1], Jennifer Rogers[2], Daniel Wojdyla[3], Kai Sun[2], Rebecca Sadun[2], Mithu Maheswaranathan[4], Jayanth Doss[2], Lisa Criscione-Schreiber[4] and Megan Clowse[5], [1]Duke University, Raleigh, NC, [2]Duke University, Durham, NC, [3]Duke Clinical Research Institute, Durham, NC, [4]Duke University School of Medicine, Durham, NC, [5]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The Type 1 & 2 SLE Model encompass symptoms classically attributed to inflammation, including arthritis, rash, serositis and nephritis (Type 1 SLE), and symptoms of fatigue, widespread pain, mood disturbance, and cognitive dysfunction (Type 2 SLE). Our preliminary data suggest there are at least two distinct sub-types of Type 2 SLE, one that is related to active inflammation and another that exists regardless of inflammation. The objective of this study was to use longitudinal measures of Type 1 and Type 2 SLE activity to identify distinct subgroups of Type 2 SLE.

Methods: SLE patients meeting SLICC criteria with ≥2 visits at a university rheumatology clinic over a 36-month period between February 2018 and August 2022 were included. At each visit, rheumatologists scored Type 1 and 2 SLE activity separately by Physician's Global Assessments, visual analog scales of 0-3 (0=no activity, 3=severe activity). Growth mixture models derived classes of patients based on their Type 1 and Type 2 PGA trajectories. We postulated quadratic trajectories and different number of classes were assessed based on objective model criteria and interpretability of the classes. Once the number of classes was selected, posterior probabilities assigned patients to the class with the highest probability. Patients were then classified according to their classes of Type 1 and Type 2 PGA trajectories into different "groups". Differences in clinical and demographic characteristics across groups were estimated using simple statistics.

Results: We included 297 patients with 2,011 visits. The best model fit of trajectories for both the Type 1 and Type 2 PGA included three classes. When patients were grouped according to their Type 1 and Type 2 PGA classes, the majority (73%) fell into one of four groups (Figure 1): 29% had low Type 1 and Type 2 activity (Minimal); 19% had constant high Type 2 but low Type 1 activity (Type 2); 7% had constant high Type 1 but low Type 2 activity (Type 1); and 18% had constant high Type 1 and Type 2 activity (Mixed). The remaining 27% of patients had variable Type 1 and Type 2 changes over time that did not fit into a distinct group. Patients in the Type 2 SLE group were older and more likely to be on disability (Table 1). While the SLEDAI and Type 1 PGA scores were similar between the Type 1 and Mixed groups, the disease manifestations were somewhat different, with more nephritis in the Type 1 group and higher LFA-REAL Musculoskeletal PGA scores in the Mixed group. While overall Type 2 PGA scores were similar for those in the Type 2 and Mixed groups, there was more depression, pain, and symptom severity among those in the Mixed group. In a descriptive analysis to determine if Type 1 and Type 2 PGA changed concordantly, 39% of patients had Type 1 and Type 2 SLE PGAs that consistently changed together.

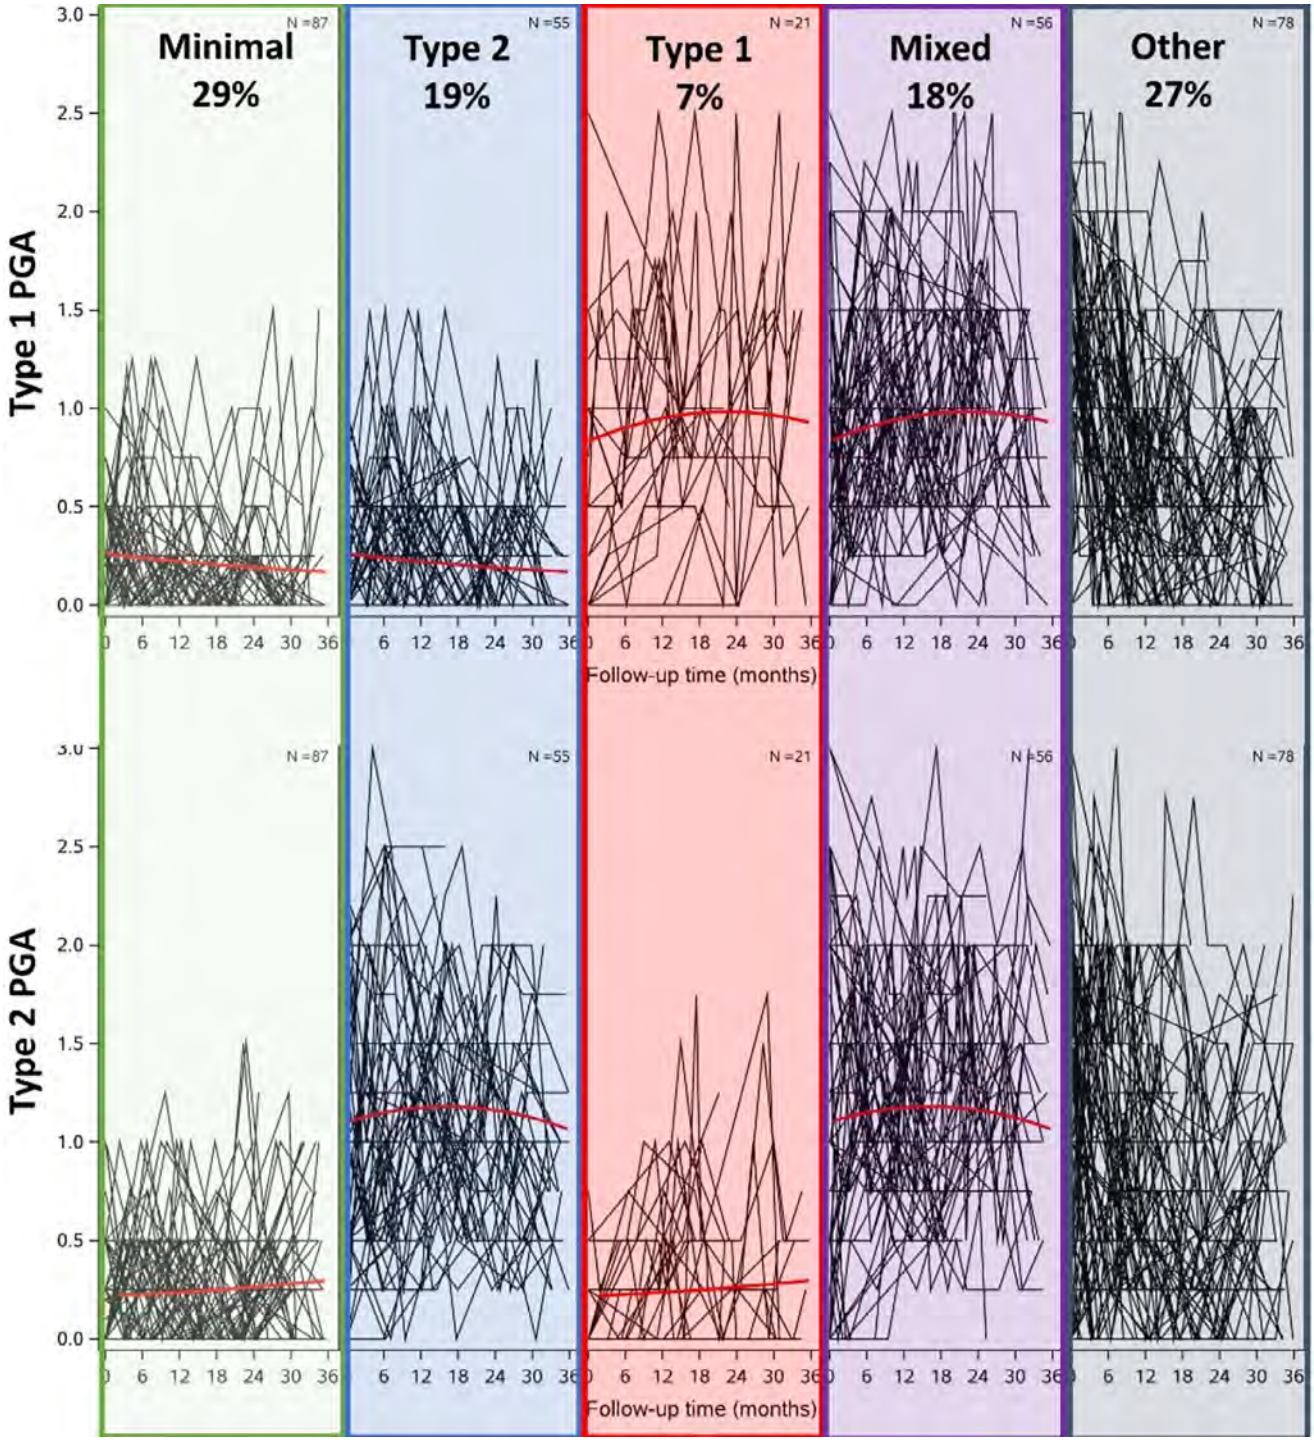

Figure 1. Spaghetti plots showing the individual trajectories of Type 1 and 2 PGAs for patients in each group.

Conclusion: We identified 4 main longitudinal subgroups of patient trajectories. Supporting our prior qualitative work, we found changes in Type 1 and Type 2 occurred together in almost 40% of patients. Future work is needed to understand the underlying etiology of each subgroup, allowing us to target these groups with appropriate medical and non-medical treatment plans.

Table 1. Cohort characteristics.

Age and Race-Based Differences in Emergency Department Utilization for Systemic Lupus Erythematosus in the United States

Rashmi Dhital[1], Ioannis Karageorgiou[2], Ashbina Pokharel[3] and Kenneth Kalunian[4], [1]UC San Diego, San Diego, CA, [2]William Beaumont University Hospital, Troy, MI, [3]William Beaumont University Hospital, Royal Oak, MI, [4]University of California San Diego, La Jolla, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) frequently visit the emergency department (ED) due to the complex disease course. Previous research highlights infection and pain as key reasons for ED use in SLE. Our previous study using the US National Emergency Department Sample (NEDS) found that SLE ED visits consisted of

more young patients, of Black race, with publicly funded insurance and a higher comorbidity burden, but Black patients were less likely to be admitted from the ED. This study aims to further investigate age and race-based variations in ED utilization.

Methods: Using NEDS (2019) discharge data for 989 hospitals, which approximates a 20% sample of US hospital-owned EDs, SLE visits were identified using ICD-10 codes (M32.xx) and categorized by age (18-30, 31-50, 51-64, and ≥ 65 years) and race (White, Black, Hispanic, Others). Demographic features, clinical comorbidities, and the top ten primary diagnoses associated with ED visits were compared across groups.

Results: We identified 414,139 ED SLE visits, 41% of which were visits by adults aged 31-50 years. Young SLE adults (18-30 years) visiting the ED were predominantly Black (47.10%), and had Medicaid (41.70%), while older adults (≥ 65 years) were mostly White (64.70%). Older adults had higher rates of chronic kidney disease (CKD), hyperlipidemia

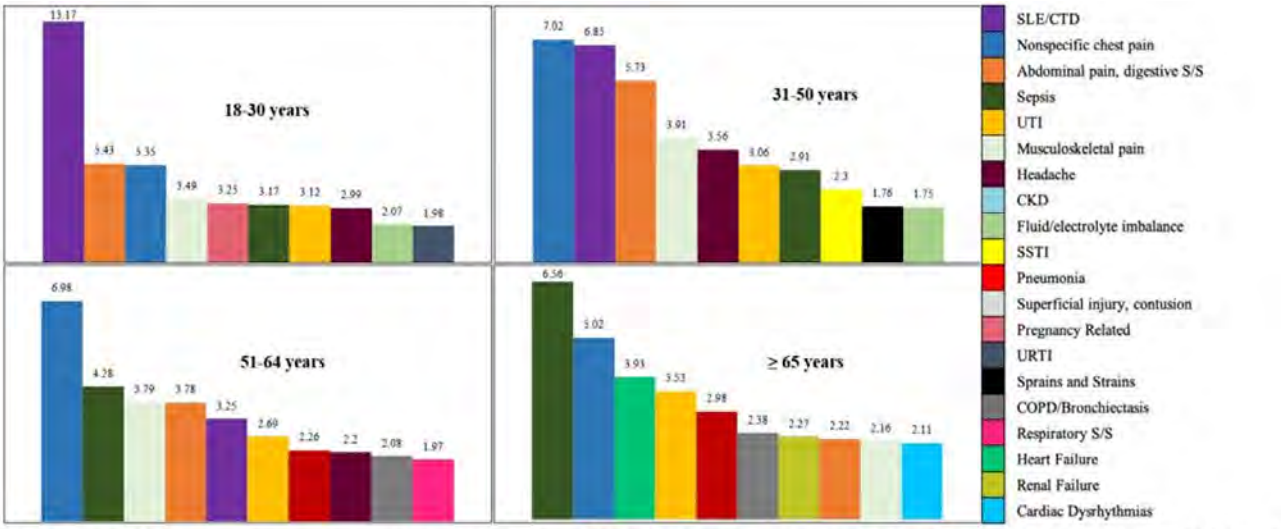

Figure 1a. Top ten primary diagnoses associated with ED visits in patients with SLE by age categories: National Emergency Department Sample (NEDS), 2019

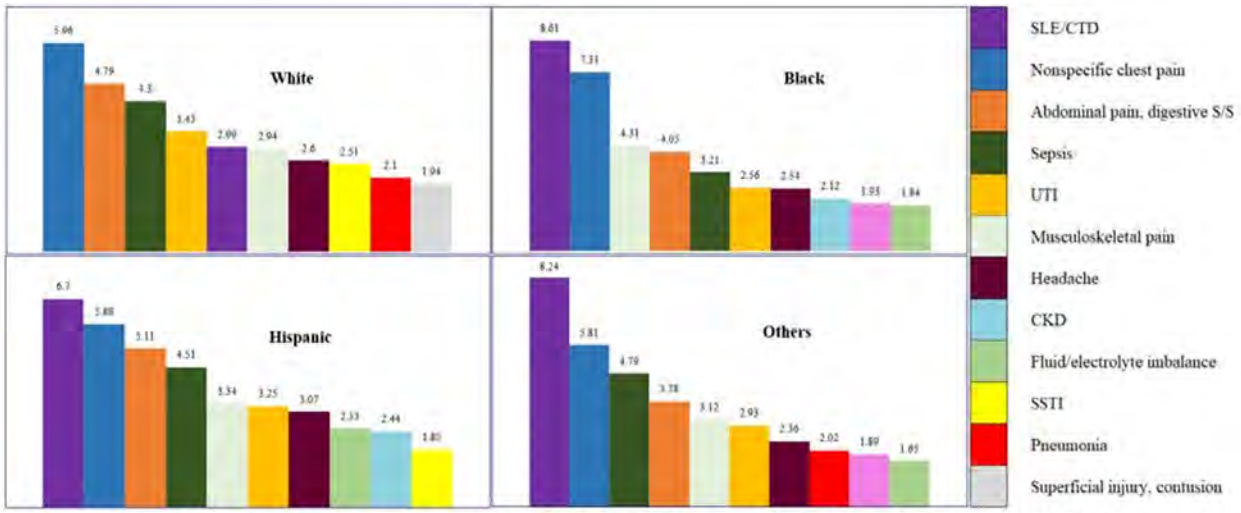

Figure 1b. Top ten primary diagnoses associated with ED visits in patients with SLE by racial/ethnic categories: National Emergency Department Sample (NEDS), 2019

Figure 1. Top ten primary diagnoses associated with ED visits in SLE by age and race categories, National Emergency Department Sample (NEDS), 2019

(HLD), hypertension (HTN), diabetes, and cardiovascular diseases (CVDs), but young SLE adults (18-30 years) also exhibited significant comorbidity burdens (CKD: 20.78%, HTN: 33.02%). Analyzing by race, more ED visits by Black and Hispanic SLE patients were in the 18-30 age group (~20%) compared to White patients (< 10%). Medicaid use was notably higher among non-White (27-32%) versus 19% in White patients. Comorbidity patterns varied, with White patients having higher HLD, ischemic heart disease (IHD), and mood disorders while Black patients had higher CKD and HTN (25% vs 13% and 61% vs 48%, respectively). The most common primary diagnosis for ED visits in young SLE adults (18-31 years) was "SLE/Connective tissue disease (CTD)", whereas sepsis was the most common diagnosis for older adults (≥ 65 years). Heart failure and arrhythmias were among the top 10 diagnoses for adults ≥ 65 years, but not in younger groups. The primary ED diagnosis of SLE/CTD was more common in Black (8.61%) and Hispanic (6.70%) than in White patients (2.99%), with no other major differences in other reasons for ED visits based on race.

Conclusion: In a previous study of general population ED visits, Black patients were less likely to be admitted from the ED, and our study suggested a similar pattern among SLE ED visits. Discriminating determinants appear to be younger age, higher Medicaid use, CKD, HTN, and heart failure amongst Black SLE patients, and higher prevalence of older age groups, and baseline CVDs among White patients. While it appears that increased age and/or more severe CVDs in the White patients may explain the disparate admission rates, further study is needed to confirm whether these discriminating factors are replicated in other datasets and whether other factors such as ED reliance as a primary source of care and insurance coverage affect the lower admission rate amongst Blacks.

Predicting SLE Disease Activity with Blood Biomarkers: A Step Towards Precision Medicine

Vasileios Kyttaris[1], Tyler O'Malley[2], Giorgio Casaburi[2], Sudha Kumar[2] and Andrew Concoff[3], [1]BIDMC, Boston, MA, [2]Exagen, Vista, CA, [3]Exagen, Los Angeles, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is the prototypical autoimmune disease with diverse clinical manifestations and variable treatment response. Conventional biomarkers of SLE activityprovide modest correlation with disease activity and suffer from several confounding factors that limit their utility as treat-to-target surrogates.The SLEDisease Activity Index 2000 (SLEDAI-2K) is often employed to monitor disease activity, but the administrative burden it requires has limited its real-world adoption.Modeling the values of serum biomarkers to predict patients'clinical SLEDAI-2Kscores (cSLEDAI-2K; which excludes its immunologic lab components, i.e., anti-dsDNA and complement), holds potential to advance the developmentof individualized treatment plans, thus advancing the field of precision medicine. Therefore, the aim of this study was to investigate the correlation of serum biomarkers with cSLEDAI-2K scores and to evaluate their potential to stratify patients in active and inactive disease states.

Table 1: Cohort demographics

	Total (N=128)
Sex	
F	116 (90.6%)

Median [Min, Max]	98.0 [6.00, 276]
C4	
Mean (SD)	19.3 (9.71)
Median [Min, Max]	17.0 [2.00, 49.0]

Methods: A total of 128 patients (90.6% female) with a mean age of 44.3 were included in the analysis. The patients sampled were raciallydiverse,as detailed in Table 1. The mean cSLEDAI-2K score was 4.35. The association of blood biomarkers, including anti-dsDNA, EC4d, PC4d, anti-C1q, C3, and C4with the cSLEDAI-2Kscore was evaluated using multiple 10-fold cross-validated regression models. The most predictive model was identified and used for further stratification of patients based on cSLEDAI-2Kscores of <4 (low activity) and >4 (high activity) groups.Significant differences in blood levels between patient groups were estimated using the Wilcoxon test.

Results: The best-performing regression model (RuleFit Regressor) had an R2 of 0.57. Despite the modest correlation, the average absolute residual between actual and predicted cSLEDAI-2Kwas only 1.3. Moreover,when the predicted scores were used to categorize patients into cSLEDAI-2K <4 or >4, the model achieved an accuracy of 84.5% in cross-validation and 72% in the unseen holdout partition (Figure 1). Biomarkers were ranked in order of predictive importance showing C3 at the top, with 100% of relative model importance, followed by the other biomarkerspresentedin relation to C3 (Figure 2,B). Finally, comparing blood levels of the ranked biomarkers confirmed a statistically significant difference between

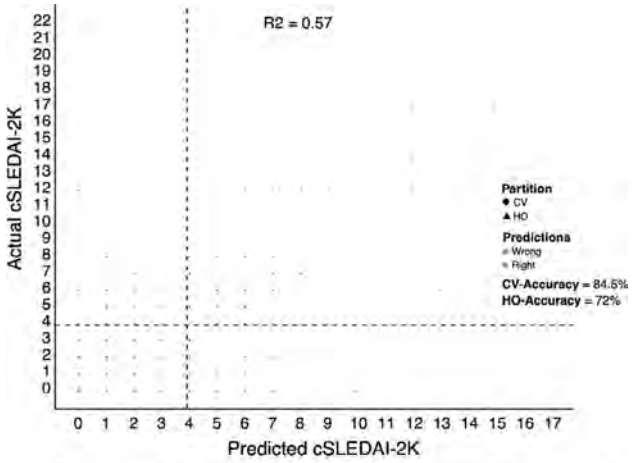

Figure 1. Scatterplot of Actual vs. Predicted stratified CSLEDAI-2k scores. The plot illustrates the top model's (RuleFit classifier) accuracy in predicting SLEDAI-2k scores derived from blood biomarkers only. Actual CSLEDAI-2k scores are reported on the Y-axis, while predicted scores are on the X-axis. The overall model R2 = 0.57 for samples included in both 10-fold cross-validation (CV) and hold out (HO) unseen partitions. After stratifying patients based on actual CSLEDAI-2k scores < 4 and those with >= 4, the model was able to correctly classify 84.5% of patients in CV and 72% of patients in the unseen HO. Red/blue dots represent wrong vs right model classification on a per sample basis.

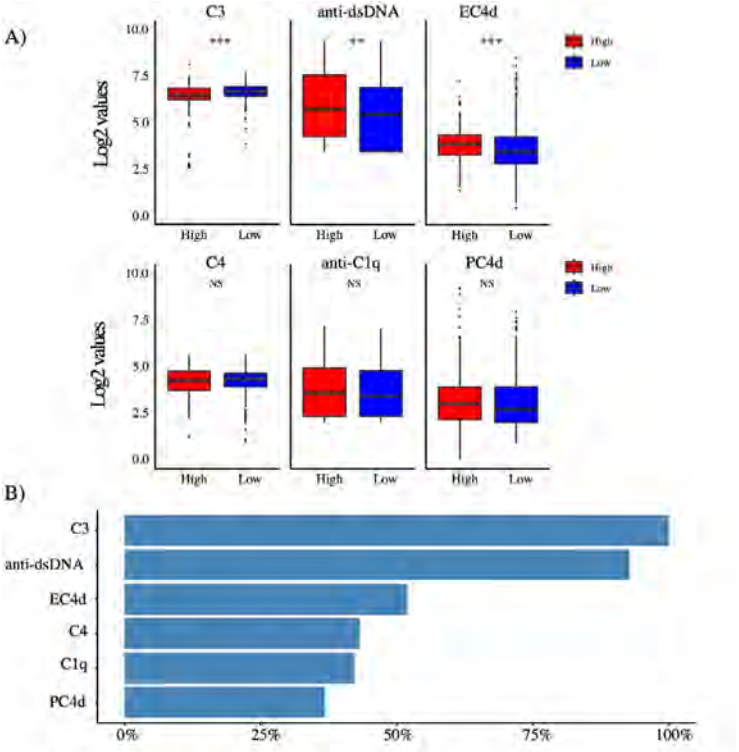

Figure 2. Blood biomarkers levels and their respective predictive power
A) Box plot showing log2 blood levels of top biomarkers required for model prediction. Whisker plots depict the interquartile range, median, minimum, and maximum for each group. Outliers, if present, are represented as individual points beyond the whiskers. A significant difference between groups is indicated by ***P< 0.0001; **P< 0.001 (Wilcoxon test). B) Biomarker importance rank score from top model. The predictive biomarkers are listed on the Y-axis, with their corresponding importance scores displayed on the X-axis. The scores are calculated in relation to the top important feature (C3; 100% importance). Higher scores indicate a greater influence on the model's predictive performance. This ranking provides insights into the relative importance of each feature in predicting cSLEDAI-2k scores, further informing our understanding of key factors contributing to disease activity in SLE.

SLE patients stratified bycSLEDAI-2K scores for C3 (P<0.001), anti-dsDNA (P= 0.005), and EC4d (P<0.001)(Figure 2, A), while differences inC4, anti-C1q, and PC4d were non-significant.

Conclusion: These results highlightthe potential of applying machine learning toselectedblood biomarkers to predict the cSLEDAI-2K score to monitor disease activity in clinical practice.EC4d emergedas anindependentpredictor,additive to the predictive power of conventional biomarkers across our top models, suggesting its potential use in a precision medicine approachto guide individualized treatment strategies in SLE. Further research is required to validate these findings and better understand their implications for individualized SLE management.

Lupus Low Disease Activity State as an Attainable Target in Lupus Nephritis Associated with Reduced Risk of Relapse

Chak Kwan Cheung[1], Chak Sing Lau[2] and **Shirley Chiu Wai Chan**[3], [1]Divison of Rheumatology and Clinical Immunology, Queen Mary Hospital, Department of Medicine, the University of Hong Kong, Hong Kong, Hong Kong, [2]University of Hong Kong, Division of Rheumatology & Clinical Immunology, Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong, [3]Divison of Rheumatology and Clinical Immunology, Department of Medicine, Queen Mary Hospital, the University of Hong Kong, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a significant comorbidity affecting approximately up to 50-60% of patients with systemic lupus erythematosus (SLE). Complete renal response (CRR) and partial renal response (PRR) have been recommended as treatment targets in LN. Lupus low disease activity state (LLDAS) is an important target associated with improved clinical outcome in SLE. Its role in patients in LN has not been fully evaluated. This study aims to investigate the attainment rate, predictors and outcomes associated with LLDAS attainment in patients with LN.

Methods: Patients with biopsy-proven LN during 2010-2020 in Queen Mary Hospital were included. Baseline demographics, blood parameters and urinalysis results were recorded. Renal response and LLDAS attainment were assessed at 12 months after LN diagnosis. CRR was defined as proteinuria ≤0.5g/day with normal estimate glomerular filtration rate (eGFR); PRR was defined as a reduction in proteinuria by ≥50% with near normal eGFR. LLDAS was attained by meeting: (1) SLE Disease Activity Index ≤4 with no major organ activity; (2) no new lupus disease; (3) physician global assessment ≤1; (4) prednisolone dose ≤7.5mg; (5) standard maintenance immunosuppressants1. Treatment response was defined as proteinuria reduction of ≥50% or to sub-nephrotic range. Relapse was defined as a biopsy-proven active LN on histology after an initial treatment response. Time-to-relapse survival analysis was performed to compare the significance of CRR/PRR and LLDAS attainment.

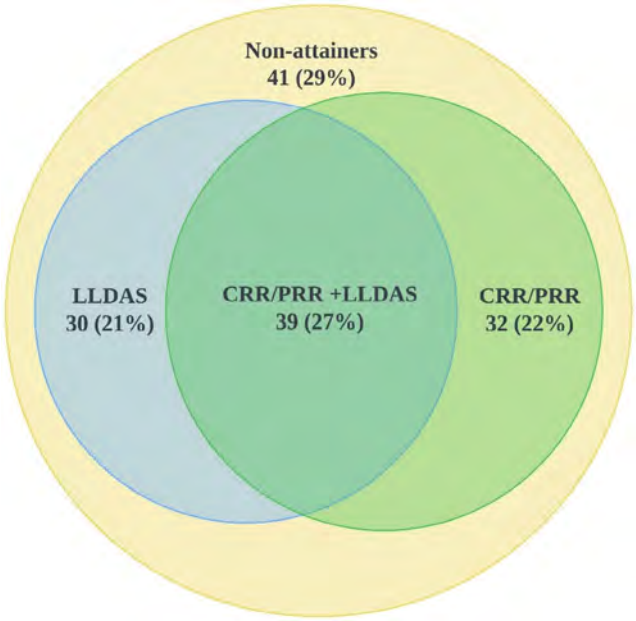

Figure 1: Attainment of CRR/PRR and/ or LLDAS at 12 months.

Results: A total of 143 LN patients were included with a median follow-up duration of 10.4 years (Table 1). At 12 months, 57 (40%), 14 (10%) and 69 (48%) patients achieved CRR, PRR and LLDAS, respectively. Although 39 (27%) patients attained both CRR/PRR and LLDAS, a significant number of 30 (21%) patients reached LLDAS without meeting CRR/PRR (Figure 1). Among 136 patients who achieved the pre-defined treatment response, 30 (22%) patients developed LN relapse after a median of 2.98 years. Patients reaching either CRR/PRR or LLDAS had a significantly lower risk of relapse (CRR/PRR: HR = 0.34, p = 0.02 ; LLDAS: HR = 0.28, p = 0.003). The attainment of both CRR/PRR and LLDAS was associated with the lowest risk of relapse (Figure 2).

Conclusion: We advocate LLDAS as a target for LN patients as LLDAS attainment lowers the risk of future relapse.

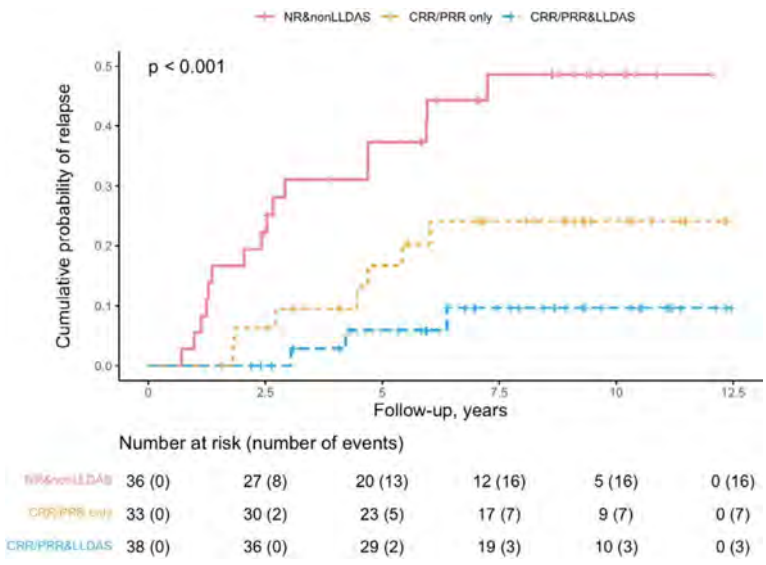

Figure 2: Risk of LN relapse.

Lupus Low Disease Activity State Ameliorates the Poor Prognosis in Lupus Nephritis Patients with anti-Sm Autoantibody

Chak Kwan Cheung[1], Chak Sing Lau[2] and **Shirley Chiu Wai Chan**[3], [1]Divison of Rheumatology and Clinical Immunology, Queen Mary Hospital, Department of Medicine, the University of Hong Kong, Hong Kong, Hong Kong, [2]University of Hong Kong, Division of Rheumatology & Clinical Immunology, Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong, [3]Divison of Rheumatology and Clinical Immunology, Department of Medicine, Queen Mary Hospital, the University of Hong Kong, Hong Kong, Hong Kong

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-Sm autoantibody has been a known specific biomarker of systemic lupus erythematosus (SLE). There have been reports about its correlation with higher disease activity, renal involvement, and lower lupus low disease activity state attainment (LLDAS) among SLE patients. However, its exact role in renal outcome among patients with known lupus nephritis (LN) has been uncertain. This study adds to the literature in the role of Anti-Sm in relation to its prognostic value among patients with lupus nephritis. We also investigate the effect of LLDAS among patients with anti-Sm.

Methods: Patients with biopsy-proven LN during 2010-2020 were included. Baseline demographics, blood parameters and urinalysis results were recorded. Immunological markers such as autoantibodies profile were also documented. Complete or partial renal response (CRR/PRR) and LLDAS was assessed at 12 months post-LN, and any future relapses were recorded. LLDAS was attained by meeting: (1) SLE Disease Activity Index ≤4 with no major organ activity; (2) no new lupus disease; (3) physician global assessment ≤1; (4) prednisolone dose ≤7.5mg; (5) standard maintenance immunosuppressants. Relapse was a biopsy-proven LN after an initial treatment response of proteinuria reduction of ≥50% to sub-nephrotic range. Predictors of LLDAS and relapse were tested by logistic regression and COX regression respectively.

Significant *p* values are in bold.

Results: A total 143 patients were included in this study. Anti-Sm positivity was present in 25 patients. Nephrotic range proteinuria and the presence of anti-Sm autoantibody were significant predictors of relapse in the univariable COX model. Only anti-Sm autoantibody was significant ($p = 0.04$) at the multivariable analysis. Anti-Sm autoantibody was the only variable found to predict LLDAS attainment ($p = 0.03$). Patients with anti-Sm had lower chance of LLDAS attainment (odds ratio = 0.34) with higher risk of subsequent relapse (hazard ratio = 2.34) compared to anti-Sm negative patients. Despite this, LLDAS attainment complementary to CRR/PRR was still found to be protective from future relapse ($p < 0.001$).

Conclusion: Patients with anti-Sm belonged to a high-risk subgroup with worse prognosis, yet LLDAS attainment could still prevent subsequent relapse among them.

Abstract Number: 2276

Patient Reported Impact of Lupus on Quality of Life

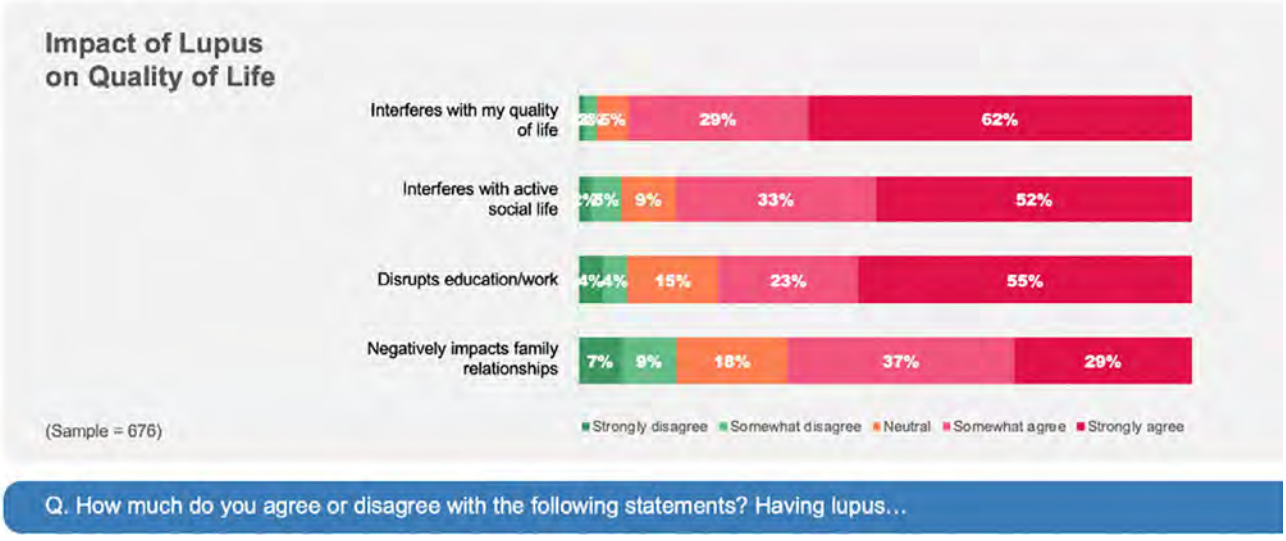
Beth Schneider, MyHealthTeam, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

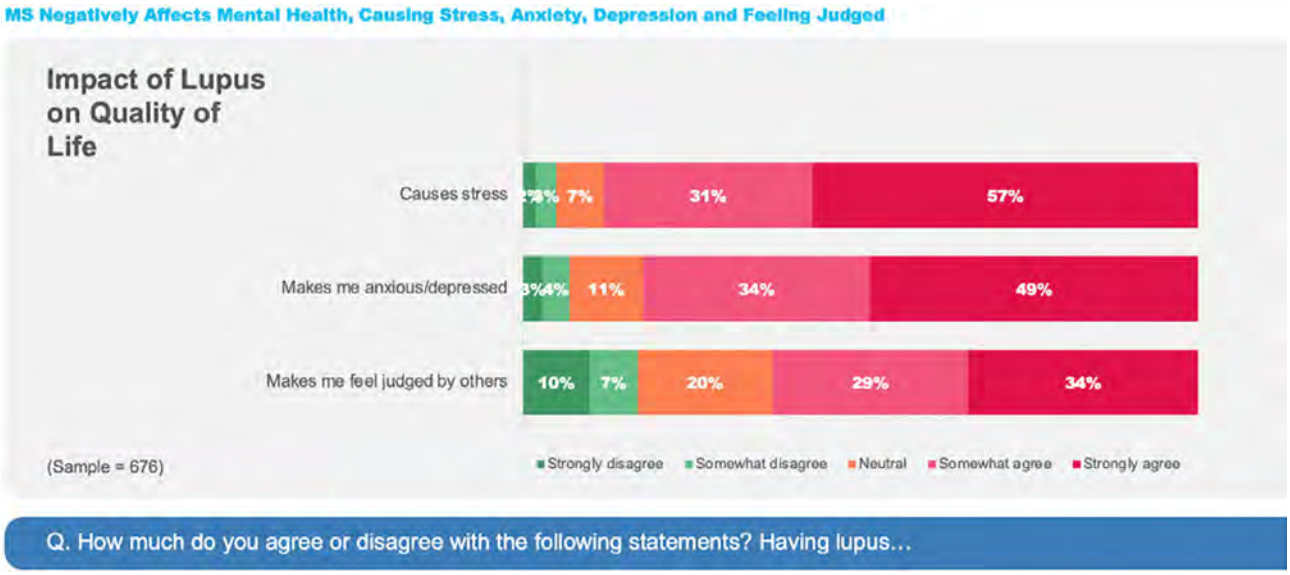
Background/Purpose: Research was undertaken to better understand how people living with lupus describe its sum total impact on their lives including work, challenges with relationships and its toll on mental health.

Methods: In August 2022, an email invitation to an online survey was sent to US members of MyLupusTeam, a social network of over 218,000 members. In total, 676 members diagnosed with *systemic lupus*erythematosus completed the 31-question survey regarding experiences with lupus and impact of the disease on everyday life.

Results: The far-reaching impact of lupus was evident in that most reported that lupus had a negative impact on overall quality of life (91%), interferes with their social life (84%), disrupts education/work (78%), and negatively impacts family relationships (66%). These lupus patients also found it hard to do everyday chores (89%) and hard to get around physically (79%). In total, only 7% felt their lupus related health was excellent or very good. "*The pain that I have means I can't do anything.*"The emotional toll of lupus manifested in feeling stressed (88%), anxious/depressed (83%) or judged by others (63%). In fact, a large number indicated depression (52%), or anxiety (55%) as diagnosed comorbidities. "*Visible symptoms appear on our faces or bodies that cause us to feel so low and embarrassed to show our faces in public.*" Despite the many obstacles, respondents were proactive in managing lupus.Most were able to stay on their prescribed medications (83%). And only 12% are not on any medication to treat lupus and its symptoms.However, 32% struggled to afford their medical expenses and these patients were much more likely be in poor health (75% versus 55% among those who could easily afford their medications).



Impact of Lupus on Quality of Life



Impact of Lupus on Mental Health

Conclusion: Understanding the physical, emotional, and quality of life impact of lupus, can help rheumatologists provide a more holistic approach to treating lupus patients. This includes listening to patient concerns and addressing the symptoms of lupus, including pain, depression, and fatigue, and not just disease progression. Importantly, by addressing the mental health aspects of lupus, rheumatologists can help create better health outcomes, including effective self-care regimens and an improved quality of life.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by multi-organ involvement, associated with substantial morbidity and mortality. A characteristic that distinguishes lupus patients is the aggressiveness of the disease, associated with worse outcomes, especially in certain ethnic groups. Patients of Afro-American ethnicity or Hispanics present more frequency of renal disease and higher damage accrual, as compared to Caucasians, and there is certain controversy regarding the factors that explain these differences and the relevance of the socio-economic status on there. **OBJETIVES:** To compare the clinical and serological features, treatments, outcomes and comorbidities of SLE patients from the cross-sectional phase of the Spanish lupus registry (RELESSER), those Latin American patients residing in Spain, who belong to the RELESSER register and patients from the Argentinian register (RELESSAR).

Methods: RELESSER and RELESSAR are large multicenter registries and share the same database, with identical definitions of the variables. Likewise, both include patients who meet the ACR /1997 classification criteria. The variables collected were: demographics, clinical, serology, comorbidities and treatments; disease activity index (SELENA-SLEDAI), damage (SLICC/ACR Damage Index (SDI). The Charlson Comorbidity Index was performed as well as Katz score. In RELESSER, Latin American patients were defined as those born in Latin American countries, whose Latin American parents have emigrated to Spain. Other ethnic groups of RELESSER were excluded from this analysis. The categorical variables were compared using Chi-square test or Fisher's test, and for the continuous variables, ANOVA or the Kruskal Wallis test were carried out. In cases where significant differences were found between the groups, and multiple comparisons were performed. The significance level < 0.05 was considered. R software was used for data analysis.

Results: A total of 5423 patients were included: 1475 in the RELESSAR group, 3627 in the Caucasian RELESSER, and 208 Latin-American from RELESSER. Table 1 shows the multiple comparisons between the groups. Latin-American patients irrespective of the country in which they live have a younger age, shorter duration of the disease with a shorter time to diagnosis, higher severity as measured by Katz Index, more frequency of nephritis, higher SLEDAI and higher use of corticosteroids treatment. However, RELESSER patients had showed higher frequency of comorbidities and hospitalizations.

Conclusion: Latin-American patients had severe disease, with higher frequency of renal involvement and use of corticosteroids, no matter the countryof residence suggesting that health resources would not be a good explanation for these differences. However, Spanish Caucasian patients have more mortality and infection, probably linked to lesser use of antimalarials and high degree of comorbidity.

Table 1. Comparison between RELESSAR patients, Latin-American RELESSER and Caucasian RELESSER.

Pregnancy in Connective Tissue Diseases: A 30 Year Follow-up Study of 465 Pregnancies from a Spanish Monocentric Registry

Cristiana Sieiro Santos[1], Paula Pérez García[2], Jose Ordas Martínez[2], Clara Moriano[2], Carolina Álvarez Castro[2] and Elvira Díez Álvarez[2], [1]Complejo Asistencial Universitario de León, León, Spain, [2]CAULE, León, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancy in patients with connective tissue diseases are known to be at high risk for the occurrence of adverse pregnancy outcomes. We aim toevaluate the pregnancy outcomes in patients with systemic autoimmune diseases, including systemic lupus erythematosus (SLE), systemic sclerosis (SSc), primary Sjögren's syndrome (pSS) and undifferentiated connective tissue disease (UCTD).

	SLE	SSc	pSS	UCTD	P value
Total of pregnancies	192	88	120	65	
Age at pregnancy	32.4±4.5	29.5±7.2	30.4±3.5	33.5±2.7	0.45
Smokers	32 (26%)	17 (34%)	25 (31%)	12 (30%)	0.27
Birth	103 (67%)	68 (77%)	90 (75%)	47 (72%)	0.28
Abortion	57 (37%)	12 (14%)	18 (15%)	10 (15%)	**0.03**
Mean abortion number	2.7±0.7	1.1±0.6	2.4±0.3	0.9±0.5	**0.03**
Preeclampsia	15 (9.8%)	3 (3%)	2 (2%)	2 (3%)	**0.04**
Ectopic pregnancy	10 (6.5%)	0	1 (1%)	1 (2%)	**0.03**
Placental abnormalities	8 (5%)	5 (5.7%)	2 (2%)	3 (5%)	0.21
Premature rupture of membranes (PROM)	5 (3.3%)	0	2 (2%)	1 (2%)	0.24
Preterm delivery	20 (13%)	0	8 (6%)	5 (8%)	**0.02**
Postpartum haemorrhage	21 (14%)	0	4 (4%)	1 (2%)	**0.01**

	Birth	Abortion	Preclampsia	Ectopic pregnancy	Placental abnormalities	PROM	Preterm delivery	Postpartum haemorrhage
non-SLE	66%	15%	2,30%	1%	4,20%	1%	4,70%	2%
SLE	67%	37%	9,80%	6,50%	5%	3,30%	13%	14%

Methods: A retrospective and descriptive study was conducted from 1990 to 2020. All data were collected from the medical records of childbearing age women with SLE, SSc, SS and UTCD enrolled in our clinic at the time of their pregnancy and childbirth. The obstetric, maternal and fetal outcomes were collected and compared regarding diagnosis and adverse outcomes.

Results: The study group included 295 patients, 125 patients (42%) with SLE, 50 patients (17%) with SSc, 80 patients (27%) with Sjogren's, 40 patients (14%) with UCTD.A total of 465 pregnancies were registered. The maternal and fetal outcomes are detailed in table 1 and figure 1. The mean age at delivery was 31.5±8.5 years and the mean duration of disease was 7.2±5.6 years. Pregnancy loss occurred in 21% of patients, live births in 66% of pregnancies, preterm delivery in 8%, postpartum haemorrhage in 6%, preeclampsia in 5%, placental abnormalities in 4%, ectopic pregnancy in 3%, premature rupture of membranes in 2%.Treatment with HCQ was received in 115 pregnancies in SLE (59%), 21 pregnancies in SSc (24%) 62 pregnancies in pSS (52%) and 32 pregnancies in UCTD (49%). Exposure to corticosteroids and biologics during pregnancy was 23 (18.4%), 6 (12%), 15 (19%) and 3 (7.5%), respectively. Patients with SLE had a higher risk of fetal morbidity, including abortion (p=0.03), mean abortion rate (p=0.03), preeclampsia (p=0.04), ectopic pregnancy (p=0.03), preterm delivery (p=0.02) and postpartum haemorrhage (p=0.01) than patients without SLE. The multivariate model adjusted for age, nulliparity, active disease activity during pregnancy, smoking and exposure to biologics, HCQ and corticosteroids found an association between unfavourable pregnancy outcomes and disease activity (OR 2.4 95% CI (1.3-7.2), p 0.003), whilst HCQ during pregnancy (OR 0.23 95% CI (0.03-0.82) had a protective effect.

Conclusion: 66% of pregnancies in patients with autoimmune diseases resulted in live births. Patients with SLE had higher rates of fetal and maternal morbidity than SSc, pSS and UCTD. Disease activity was associated with unfavourable pregnancy outcomes. Exposure to HCQ had a protective effect during pregnancy. Pregnancy planning and counselling prior to conception of patients with connective tissue diseases leads to a reduction in maternal and perinatal complications.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Self-efficacy is the belief that one can carry out a behavior necessary to reach a desired goal. A better self-efficacy has been reported as a predictor of better clinical outcomes in SLE patients such as a better HRQoL. However, predictors of a better self-efficacy in SLE patients remain to be identified. The aim of this study is to determine the predictors of a better general self-efficacy in SLE patients.

Methods: Patients from a single-center Peruvian lupus cohort were included. General self-efficacy was measured with the Patient-Reported Outcomes Measurement Information System (PROMIS) general self-efficacy instrument. For this instrument, a score of 50 is the average for a clinical population, a higher score indicates a greater self-efficacy. Potential predictors examined were gender, age at diagnosis, ethnicity, socioeconomic status, educational level, disease duration, disease activity (ascertained with the SLEDAI-2K), damage (ascertained with the SLICC/ACR damage index, SDI), Charlson comorbidity index, CS as prednisone daily dose, antimalarials and immunosuppressive drugs use, HRQoL (assessed with the LupusQoL), fatigue (ascertained with the FACIT-F) and previous general self-efficacy. Univariable and multivariable generalized estimating equations (GEEs) were performed using general self-efficacy in the subsequent visit, and the potential predictive factors in the previous visit. A multivariable model was done using a backward selection procedure with an alpha to stay in the model of 0.05.

Results: 820 visits from 274 patients were included; 256 (93.4%) were women with a mean age at diagnosis of 35.5 (13.3) years. General self-efficacy at baseline was 47.0 (10.0) and during the follow-up it was 46.6 (10.1). In the multivariable model, age at diagnosis, non-White ethnicity, lower socioeconomic status and the daily prednisone dose were negatively associated with general self-efficacy; better physical health and previous general self-efficacy were positively associated with general self-efficacy (table 1)

Conclusion: Age at diagnosis, lower socioeconomic status, non-White ethnicity and the daily prednisone dose predicted a worse self-efficacy; a better physical health and previous general self-efficacy predicted a better general self-efficacy. Further studies are needed to define the best strategies to improve general self´-efficacy in SLE patients.

Table 1: Factors associated with general self-efficacy. Univariable and multivariable models

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The Lupus Foundation of America Rapid Evaluation of Activity in Lupus (LFA-REAL) clinician-reported outcome (ClinRO) correlates well with other disease activity indices such us the SLEDAI-2K and the PGA; however, its predictive value remains to be evaluated. The aim of this study was to evaluate the predictive value of the LFA-REAL and damage accrual in SLE patients.

Methods: We evaluated SLEs patients from the Almenara Lupus Cohort, Lima, Peru. The LFA-REAL ClinRO includes nine domains: mucocutaneous, musculoskeletal, cardiorespiratory, neuropsychiatric, renal, hematological, constitutional, vasculitis and other. Mucocutaneous includes one global scale and three subdomains (rash, alopecia and mucosal ulcers), and musculoskeletal includes one global scale and two subdomains (arthralgia/arthritis and myalgia/myositis). For each manifestation, a Visual Analogue Scale (VAS) from 0 to 100 mm is used, with anchors separating mild, moderate and severe disease. Additionally, two possible summary results can be reported. The first one includes only individual manifestations and does not include the global measurement of mucocutaneous and musculoskeletal involvement; it ranges from 0 to 1400 (the sum of 14 VAS). The alternative option is to include only the global domains and not the individual manifestations; it ranges from 0 to 1100 (the sum of 11 VAS). Damage was assessed with the SLICC/ACR damage index (SDI). Generalized estimating equations were performed, using as the outcome any increase in the SDI and the LFA-REAL ClinRO in the previous visit; multivariable models were adjusted for possible confounders measured at the same visit as the self-efficacy instrument. Incidence Rate Ratio (IRR) was reported per 10 units increase in the LFA-REAL ClinRO. The main model was done using the first global LFA-REAL ClinRO; the alternative model was done using the alternative method to calculate the LFA-REAL ClinRO.

Results: A total of 456 patients and 1536 visits were included. The mean LFA-REAL ClinRO (0-1400) was 18.2 (SD 30.7); the mean alternative LFA-REAL ClinRO (0-1100) was 16.9 (SD 27.4) and the mean SLEDAI-2K was 2.5 (4.2). During the follow-up visits, 63 (13.8%) patients accrued damage once and four (0.9%) accrued damage twice. In the univariable and multivariable models, both LFA-REAL ClinRO predicted damage accrual (Table 1).

Conclusion: The LFA-REAL ClinRO is predictive of damage accrual, even after adjusting for possible confounders. Larger studies are needed to determine the relevance of this index for SLE patients

Table 1 The predictive value of LFA-REAL ClinRO on damage accrual in SLE patients

Epidemiology and Risk of Brain Abscess in Patients with Systemic Lupus Erythematosus in Taiwan: A Nationwide Population-based Study

Ke-Hung Lin[1], Tzu-Min Lin[1] and Chi-Ching Chang[2], [1]Taipei Medical University Hospital, Taipei, Taiwan, [2]Taipei Medical University, Taipei, Taiwan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune systemic disorder with high morbidity and mortality. Although CNS infections account for only 0.53–2.25% of all infections in patients with SLE, the mortality rate associated with infections of the central nervous system (CNS) such as meningitis and brain abscess (BA) has been reported to be 26.3–52.2%.However, in spite of increased understanding of SLE, many questions (such as epidemiology and risk factors of BA) remain unanswered. Up to date, no study has specifically examined the risk of BA in patients with SLE.We conducted a nationwide population-based cohort study to determine trends in the incidence, mortality and potential risk factors of brain abscess among patient with SLE in Taiwan from 2006 through 2018.

Methods: We identified systemic lupus erythematosus patients from the National Health Insurance research-oriented database, and compared the incidence rate of brain abscess with that among non-systemic lupus erythematosus controls. A Cox multivariable proportional hazards model was employed to evaluate the risk of BA the systemic lupus erythematosus cohort

Results: We included 11,457 SLE patients and 57,285 non-SLE (mean age 42.36 yr, standard deviation 16.66yr; 85.46 % were women). After a mean follow-up of more than six years, the systemic lupus erythematosus cohort had a significantly higher incidence rate of BA (28.83 vs 3.08 per 100,000 person-years, incidence rate ratio 9.36, p<0.001, Table 1) than that

1: adjust for SLE, age, sex, alcoholism, diabetes mellitus, hypertension, chronic kidney disease, heart failure, ischemia heart disease, stroke, HIV, liver disease.

of the control cohort.Kaplan–Meier analysis also revealed a significantly higher cumulative incidence of BA in the SLE patients than in the matched controls (p<0.001; Figure 1). Multivariate Cox regression analysis of the SLE and control cohorts (Table 2) revealed that SLE remained a significant risk factor even after other variables were adjusted (adjusted hazard ratio [HR] 7.33, 95% confidence interval [CI] 3.45∼15.58,p<0.001). Cox multivariate proportional hazards analysis revealed heart disease (adjusted HR 4.21, [CI] 1.23∼14.44), and receiving a mean prednisolone dose >7.5mg (adjusted HR 23.92, [CI] 2.97∼192.44) were independent risk factors for brain abscess in systemic lupus erythematosus patients.

Conclusion: A higher risk of BA was observed in systemic lupus erythematosus patients. Risk factors for BA in the systemic lupus erythematosus cohort included heart disease, and receiving a mean prednisolone dose >7.5mg

Increased Risk of Systemic Lupus Erythematosus Flare After COVID-19

Arthur Mageau[1], Christel Gerardin[2], Kankoe Sallah[2], Jean-Francois Timsit[1], Thomas Papo[1] and Karim Sacre[1], [1]Université Paris Cité, Paris, France, [2]Assistance Publique Hopitaux de Paris, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The SARS-CoV2 pandemic reopened the unresolved question of whether and how a viral infection can trigger flares of immune-mediated inflammatory diseases such as systemic lupus erythematosus (SLE). We aimed to analyze the risk of lupus flare after admission for COVID-19.

Methods: We performed a matched cohort study using the Assistance Publique - Hôpitaux de Paris Clinical Data Warehouse which collects medical, biological and administrative information from 11 million patients in Paris area. Each SLE patient hospitalized with COVID-19 between March 2020 and December 2021 was matched to one SLE control patient on age ±3years,gender,chronickidneydisease,end-stage renal disease, and lupus biology. The main outcome was a lupus flare during the 6 months follow-up. A flare was considered if a) documented by the treating physician and b) justifying a change in SLE treatment. The electronic health records were individually checked for data accuracy.

Results: Among 4,533 SLE patients retrieved from the database, 81 have been admitted for a COVID-19 between March 2020 and December 31, 2021 from whom 79 (n=79/81,97.5%) were matched to 79 unique unexposed SLE patients (Table 1). A flare occurred in 14 (17.7%) SLE patients from the COVID-19 group as compared to 5 (6.3%) in the unexposed control group, including 4 lupus nephritis in the exposed group and 1 in the control group. After adjustment for HCQ use at index date and history of lupus nephritis, the risk of flare was higher in exposed SLE patients (hazard ratio [95% confidence interval] of 3.79 [1.49-9.65]).

Table 1 Characteristics of the matched populations Q1: first quartile; Q3: third quartile; CKD: Chronic kidney disease defined as an eGFR < 60mL/min and no end-stage renal disease; ESRD: End-stage renal disease defined as chronic dialysis or renal transplantation; IS: immunosuppressive; SMD: standardized mean differences. Lupus nephritis classes refer to the ISN/RPSWG classification (25). ┼C3 levels and anti-dsDNA IgG titers measured in the serum at the latest 6 months prior the index date were considered. When performed, lupus biology was defined as either normal - when both C3 level and anti-dsDNA IgG titer were into the normal range – or abnormal – when C3 level was low and/or anti-dsDNA IgG titer was high. * Matching variables. ǂ SLE treatment modification during the six months before the index date or during COVID episode.

Anti-SARS-CoV-2 Vaccination Among Patients Living with Systemic Lupus Erythematosus in Sweden: Coverage and Clinical Effectiveness

Arthur Mageau[1], Julia Simard[2], Elisabet Svenungsson[3] and Elizabeth Arkema[4], [1]Department of Medicine Solna, Clinical Epidemiology Division, Karolinska Institutet, Stockholm, Sweden / Internal Medicine Unit, Hopital Bichat, Paris, France, [2]Department of Epidemiology & Population Health, Stanford University School of Medicine, Stanford, CA, [3]Department of Medicine Solna, Unit of Rheumatology, Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [4]Department of Medicine Solna, Clinical Epidemiology Division, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Real-world data assessing the effectiveness of the anti-SARS-CoV2 vaccination in patients living with systemic lupus erythematosus (SLE) are currently lacking. We aimed to describe the uptake of the anti-SARS-CoV2 vaccination in 2021 and to investigate its clinical effectiveness in SLE patients living in Sweden.

Methods: First, we described the cumulative incidence of first anti-SARS-CoV2 vaccination among SLE patients and matched comparators living in Sweden on January 1, 2021 using the nationwide Swedish National Patient Register (NPR) and the National Vaccination Register. To assess vaccine effectiveness, we restricted the population to SLE patients and comparators i) with no COVID-19 diagnosis code before the 2nd vaccine dose and ii) who received two doses of anti-SARS-CoV2 mRNA vaccines before January 1st, 2022. The main outcome was a first hospitalization with COVID-19 as main diagnosis in the NPR. The secondary outcome was defined as first COVID-19 diagnosis in inpatient or outpatient care, as main or secondary diagnosis. Rates of main and secondary outcomes were compared between SLE patients and comparators. Multivariable-adjusted marginal Cox models estimate hazard ratios and 95% confidence intervals (HR;95%CI) overall and stratified by immunosuppressive (IS) treatment received during the year before second vaccine dose.

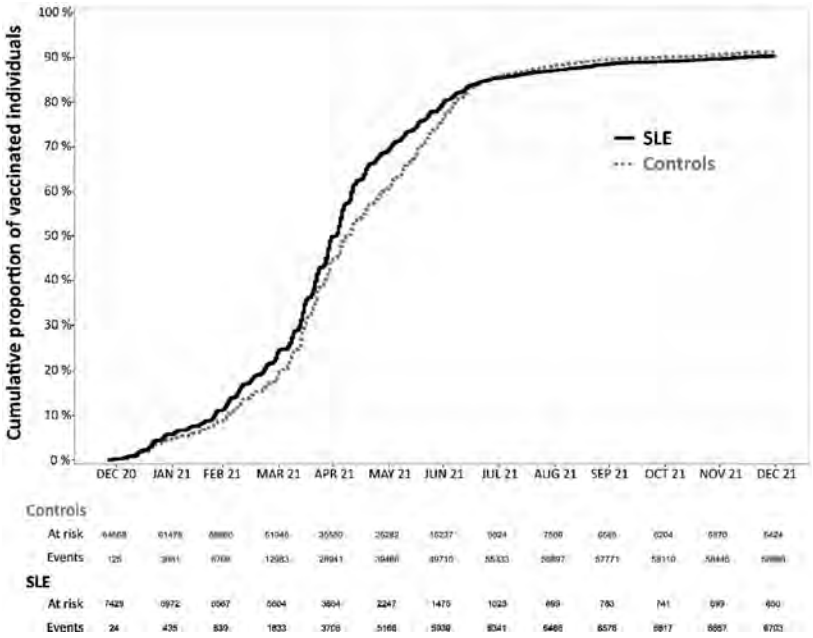

Figure 1: Uptake of the anti-SARS-CoV2 vaccine in SLE patients and matched comparators in Sweden, December 2020 to December 2021

Results: To describe the vaccine coverage, we included 7,429 SLE patients and 64,568 comparators matched on age, sex and county of residence. Vaccination uptake was similar over 2021 between SLE patients and comparators (**Figure 1**). By the end of 2021, around 10% of both SLE and comparators received no vaccine doses. Among 5,585 SLE patients and 37,102 comparators included in the effectiveness analysis, we observed 11 hospitalizations with COVID-19 listed as the primary diagnosis in the SLE group and 20 in the comparator group (**Table 1**). SLE was associated with a higher risk of COVID-19 hospitalization (HR 3.47; 95%CI 1.63-7.39). Rates of events were higher in both groups using the secondary outcome (SLE N=29, comparators N=57) but the HR was similar to the main outcome (HR 3.58; 95%CI 2.30-5.59). There were 2,802 SLE patients (50.2%) who were treated with IS during the year before second vaccine dose. The HR of COVID-19

Table 1: SLE patients and matched general population comparators who received 2 doses of mRNA anti-SARS-CoV2 vaccine in Sweden before January 1st, 2022.

Adjusted* HR [95%CI]	ref	3.47 [1.63-7.39]
First COVID-19 diagnosis in inpatient or outpatient care as main or secondary diagnosis		
Events	57	29
Patient-years	22 734	3 333
Incidence per 1000 patient-years [95%CI]	2.51 [1.93-3.25]	8.70 [6.05-12.5]
Unadjusted HR [95%CI]	ref	3.52 [2.26-5.48]
Adjusted* HR [95%CI]	ref	3.58 [2.30-5.59]

HR: hazard ratio; SLE = systemic lupus erythematosus; ref: reference; [95%CI]: 95% confidence interval.

*HRs are calculated using a marginal Cox model adjusting for age, sex, household composition and administrative health region.

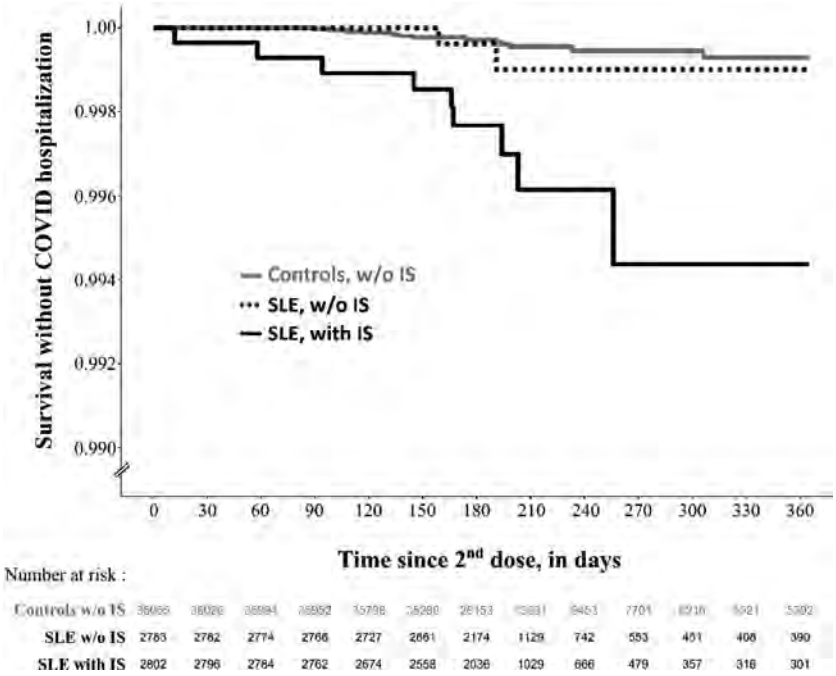

Figure 2: Survival without COVID-19 as a main diagnosis in inpatient care January 1st, 2021 among SLE patients treated with immunosuppressants, SLE patients not treated with immunosuppressants and comparators from general population who received 2 doses of mRNA anti-SARS-CoV2 vaccine in Sweden before January 1st, 2022.

hospitalization was higher for IS-treated SLE (HR 7.03; 95%CI 3.00-16.5) than for IS-untreated (HR 1.50; 95%CI 0.34-6.60; **Figure 2**) compared to the general population.

Conclusion: Anti-SARS-CoV2 vaccination coverage was similar between SLE patients and the general population in Sweden, but it could still be improved. Even though the incidence of post-vaccination COVID-19 hospitalization was very low, vaccine effectiveness was diminished in SLE patients and lowest in those treated with immunosuppressants.

Abstract Number: 2284

Effect of Air Pollutant Exposure on Disease Activity of Systemic Lupus Erythematous: A Prospective Longitudinal Study from Korea

Ji-Hyoun Kang[1], Hyemin Jeong[2], Sung-Eun Choi[2], Dong-Jin Park[2], Han Joo Baek[3], Hyo-Jin Choi[4], Jae Hyun Jung[5] and Shin-Seok Lee[2], [1]Chonnam National University Hospital, Gwangju, South Korea, [2]Chonnam National University Medical School & Hospital, Gwangju, South Korea, [3]Gil Medical Center, Gachon University College of Medicine, Inchon, South Korea, [4]Gil Medical Center, Gachon University College of Medicine, Incheon, South Korea, [5]Korea University Ansan Hospital, Ansan-si, South Korea

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Exposure to air pollutants is associated with an increased risk of pulmonary and cardiovascular disease and death. Because few studies have investigated the effects of air pollution on systemic lupus erythematosus (SLE), we investigated the association between exposure to air pollutants, including particulate matter (PM), and disease activity over 1 year in a prospective, longitudinal cohort of Korean patients with SLE.

Methods: The study enrolled 386 patients from three metropolitan regions in Korea. The daily average PM_{10}, $PM_{2.5}$, NO_2, CO, SO_2, and O_3 concentrations were measured using portable air quality monitors and data from the National Ambient Air Monitoring System. Disease activity was evaluated using the SLE Disease Activity Index 2000 (SLEDAI-2K) and Physician Global Assessment (PGA), every 3 months for 1 year. Lupus flares, a damage index, and 36-Item Short Form Health Survey (SF-36) scores were also assessed. A generalized estimating equation was used to evaluate the impact of air pollutants on clinical outcomes, including disease activity.

Results: Changes in PM_{10} and $PM_{2.5}$ were significantly associated with changes in SLEDAI-2K scores of > 8 over 1 year in SLE patients ($\beta = 0.097$, 95% confidence interval [CI]: 0.048–0.146, $p < 0.001$; $\beta = 0.100$, 95% CI: 0.054–0.146, $p < 0.001$, respectively). Changes in PM_{10} and $PM_{2.5}$ were also significantly associated with the development of lupus flares ($\beta = 1.603$, 95% CI: 1.067–2.408, $p = 0.023$; $\beta = 1.777$, 95% CI: 1.048–3.011, $p = 0.033$, respectively). However, there were no significant associations between the changes in NO_2, CO, SO_2, and O_3 and lupus activity.

Conclusion: In this study, PM_{10} and $PM_{2.5}$ exposure increased disease activity and the risk of lupus flares in SLE patients living in metropolitan regions.

Vaccine Uptake in Women with Systemic Lupus Erythematosus (SLE) - Study Update

J. Patricia Dhar[1], Hannah Forsythe[2], Louis Saravolatz[1] and Susanna Szpunar[3], [1]Ascension St. John Hospital and Wayne State University School of Medicine, Detroit, MI, [2]Michigan Department of Human and Health Services, Lansing, MI, [3]Ascension St. John Hospital, Detroit, MI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Infections are a major cause of morbidity & mortality in patients with systemic lupus erythematosus (SLE), including vaccine-preventable infections. SLE patients are considered to be immunocompromised & thus fall into the Advisory Committee on Immunization Practice's (ACIP) immunosuppressed category. Vaccines for influenza, pneumococcus, pertussis, varicella, & HPV are safe & immunogenic in patients with SLE. Despite the availability of vaccines, vaccine uptake has been generally low in this population, with one reason being that physicians fail to recommend them. We sought to assess vaccine update in SLE patients seen in our large Detroit area community hospital compared to that of the adult Michigan Care Improvement Registry (MCIR) population. MCIR is an immunization database that documents immunizations given to Michigan residents.

Table 1: Demographic characteristics of female patients with systemic lupus erythematosus (SLE) at Ascension St. John's, compared to female Michigan residents age 18-70, as of the 2020 census. NH Black women and women age 45-49 are over-represented in the SLE group.

Characteristic	SLE females		MI females (census)	
Age as of 12/31/2020				
18-24	9	2.4%	461,906	13.5%
25-29	28	7.6%	338,436	9.9%
30-34	28	7.6%	315,612	9.3%
35-39	27	7.3%	301,855	8.9%
40-44	32	8.6%	292,452	8.6%
45-49	57	15.4%	302,231	8.9%
50-54	39	10.5%	322,098	9.4%
55-59	39	10.5%	352,803	10.3%
60-64	34	9.2%	355,788	10.4%
65-70	45	12.1%	366,902	10.8%
>70	33	8.9%		
Mean (SD)	51.0 (15.0) years		43.7 years	
Race				
NH Black	161	43.4%	474,729	13.9%
NH White	124	33.4%	2,482,471	72.8%
Other	30	8.1%	453,128	13.3%
Unknown	56	15.1%	*NA*	
Total	371		3,410,328	

Methods: We performed a retrospective chart review of adult patients ages 18-70 with SLE who received care at Ascension St. John Hospital to obtain clinical information on SLE. ACR, SLICC, and 2019 ACR/EULAR criteria were used for the diagnosis of SLE. Comparison of vaccine rates of the Ascension St. John SLE cohort recorded in MCIR & the overall adult MCIR population were performed. Vaccine target goals for the SLE & adult MCIR populations were as per the CDC/AICP

Table 2: Characteristics of SLE women

Variable	Percent (n) or Mean (± sd)
Mean ACR criteria count	4.2 ± 2.1
Mean SLICC criteria count	5.6 ± 2.9
Mean 2019 EULAR/ACR score	19.7 ± 10.0
Lupus Nephritis history	29.6% (81/274)
Lupus Cerebritis history	3.0% (11/262)
Smoking history	43.7% (153/350)
Corticosteroid use	76.7% (253/330)
Hydroxychloroquine use	84.3% (284/337)
Immunosuppressives other than corticosteroids & hydroxychloroquine	49.1% (182/371)
Reproductive history	
Sexually transmitted disease	34.6% (71/205)
Gravidity	2.7 ± 2.0
Mean Parity	1.8 ± 1.5
Median No. Stillbirths (range)	0 (0,3)
Median No. Miscarriages (range)	0 (0,7)
Median No. voluntary terminations (range)	0 (0,5)
Mean years to last pap smear	6.2 ± 4.3
History of abnormal pap smear	32.2% (85/264)
History of abnormal cervical biopsy	73.5% (25/34)
+HPV test documented	30.2% (39/129)

recommended vaccine schedule for immunosuppressed and immunocompetent persons. Deceased SLE patients and males were excluded from the analysis for both groups since there were very few male SLE patients to allow for comparison.Data were analyzed using the chi-squared test.

Results: The study groups included 371 SLE women & 3,410,328 Michigan (MI) females. The mean age was slightly older for SLE (51.0 yrs.) vs. MI females (43.7 yrs.), with Black women ages 45-49 yrs. over-represented in the SLE group (Table 1).The SLE group characteristics are seen in Table 2 based on available documentation. Most were on immunomodulatory drugs, ~ 1/3 had history of lupus nephritis, almost 1/2 had history of smoking, ~1/3 had a history sexually transmitted diseases, & ~1/3 had abnormal pap smears. Target vaccine uptake in the SLE group was statistically lower than the MCIR population for HPV, Prevnar13, Pneumovax 23, Tdap, Shingrix®, the COVID primary series completion (#1&2) and booster shot (#3). Similar uptake rates were seen for both groups for Prevnar 13 after age 65, influenza (some years), Shingrix after age 50, & and the first dose of COVID vaccination. (Table 3). Vaccine uptake for SLE women was higher than the MCIR population for pneumovax 23 after age 65, influenza during some years and the bivalent COVID booster.

Conclusion: Vaccine uptake in women with SLE was subpar for most of the adult vaccines recommended for immunosuppressed persons. A gap exists with respect to vaccination for HPV, Pneumococcus (Prevnar13, Pneumovax 23), Tdap, Shingrix®, the COVID series & booster completion where uptake was lower for SLE women. HPV-related cervical disease and serious infections are preventable morbidities in these high-risk women. Increased awareness of the importance of these vaccinations for women with SLE is needed, particularly in childbearing years.

Table 3: Uptake of 7 different vaccines by female SLE patients and MI residents found in the Michigan Care Improvement Registry (MCIR). Uptake is defined as the proportion of eligible persons receiving vaccines as recommended by ACIP (age and dosing recommendations may differ for immunocompromised patients).

Vaccine	Uptake SLE females	Uptake MCIR females	p value
HPV	16/92 = **17.4%**	495,313/1,417,809 = **34.9%**	0.0004

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Work participation meaningfully influences mental wellbeing, health-related quality of life, and disease-related outcomes in individuals with systematic lupus erythematosus (SLE). Previous studies estimate that 20-50% of SLE patients experience some form of work disability (WD) yet there is limited understanding of the integrative effects of the psychosocial and workplace factors associated with WD. The objective of this study was to identify psychosocial and workplace factors associated with WD to create an SLE-related functional profile that is grounded in a WD prevention framework.

Methods: SLE patients (n=28) were purposively recruited from multiple medical centers across Canada. Guided by the WD prevention framework, semi-structured interviews were conducted with patients to explore their perspectives of factors associated with WD. The guide contained questions corresponding to the framework's proposition that disability in the workplace is not only due to the workers' characteristics but also due to environmental factors. Interview data were transcribed verbatim. Thematic analysis was utilized to analyze the data.

Results: Four themes emerged from the data: a) *modifiable workplace factors*, b) *workplace expectations and stigma with work performance*, c*) availability of workplace support and accommodations*, d) *physical limitations and feelings of safety at work* (Figure 1). Neurocognitive symptoms, fatigue, and physical limitations were frequently reported as factors associated with WD in SLE. Participants reported that participation in work increased their personal control, and reduced their physical and mental demands were more desirable and which in turn, subjectively prevented WD (Figure 2).

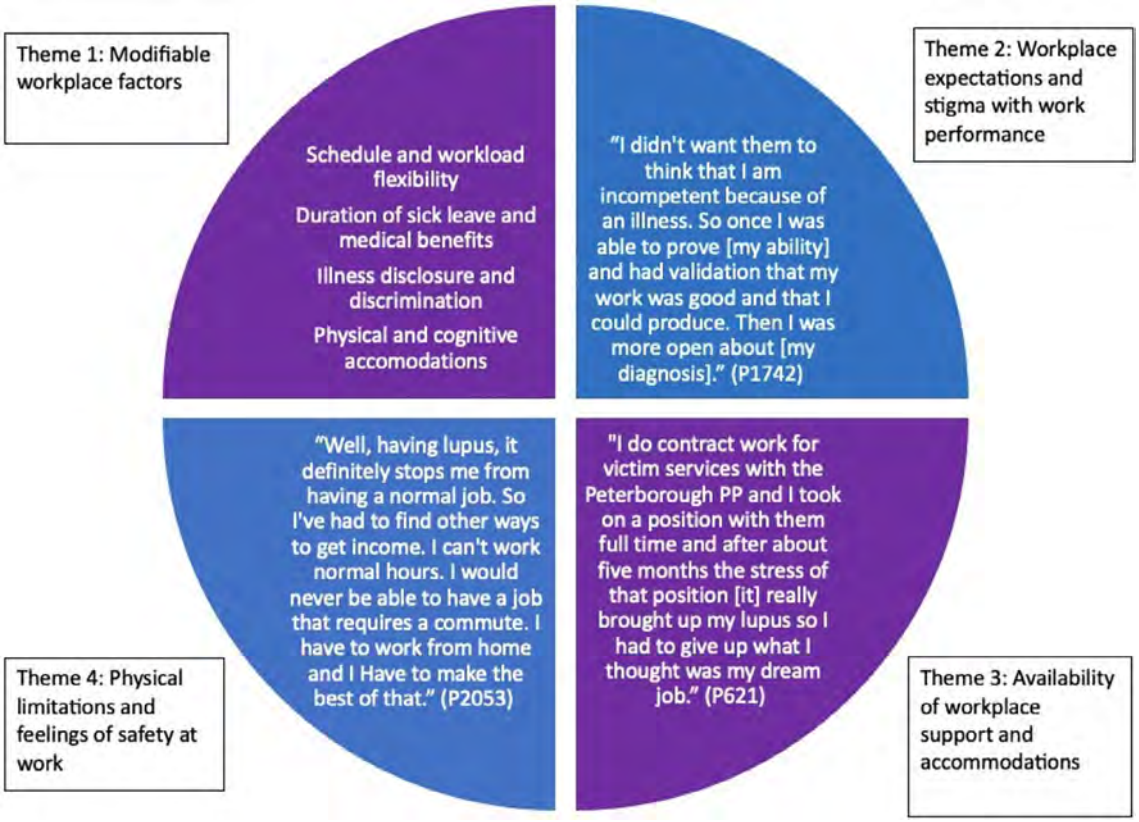

Figure 1. Thematic analysis diagram

Figure 2. Word frequency diagram

Conclusion: WD in SLE necessitates the recognition of the dynamic symptom fluctuations and multidimensionality of the disease, in the context of its relationship to work. Future studies should examine the psychosocial and workplace factors identified to establish a goal-oriented preventative framework that could improve WD outcomes in individuals with SLE.

Mental Health of Lupus Erythematosus Patients Managed in an Academic Safety-Net Clinic

Reina Gonzalez, Eleni Pilitsi, Hanni Menn, Monica Crespo-Bosque, Michael York and Christina Lam, Boston University, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus erythematosus (LE) is a complex autoimmune disease with heterogeneous manifestations ranging from life-threatening multi-organ inflammation in systemic lupus erythematosus (SLE) to limited skin disease in cutaneous LE (CLE).Comorbid mental health disorders have been extensively reported in SLE patients, and some limited data suggests a similar trend for those with CLE. A recent meta-analysis reported a depression and anxiety pooled prevalence in SLE of 35.2% and 24.2%, respectively, while a Danish nationwide cohort study found a two-fold increased risk of depression in patients with cutaneous or systemic LE compared with the general population. A study in the U.S. indicated that 34.7% of patients with CLE seen in a dermatology clinic had depressive and/or anxiety symptoms in need of psychiatric intervention. Although studies suggest a high rate of depressive and anxiety symptoms among people living with SLE, none have reported potential differences in depression and anxiety risk among those with cutaneous involvement. We aim to identify the prevalence of depression and anxiety symptoms in need of further evaluation in patients with lupus erythematosus and perform subset analysis based on cutaneous involvement.

Methods: Patients of 18 years of age and older with a diagnosis of lupus erythematosus, systemic, cutaneous or both, managed at a Multidisciplinary Lupus Clinic, were invited to participate in the study and complete the PHQ-9 and GAD-7 questionnaire. Chart review was performed to extract sociodemographic data, lupus related history, work-up and management as well as medical history. Translated versions of the questionnaires were available in Spanish, French and Portuguese. For both PHQ-9 and GAD-7, a score equal or higher to 10 was considered a positive screen prompting further intervention. For patients with a positive screen on either questionnaire, result was discussed with them and, if patient was not actively followed by a mental health provider, a referral was placed to behavioral health services. If patient responded positive to PHQ-9's item concerning suicidal ideation, same-day psychiatric evaluation was pursued. The prevalence of anxiety and depressive symptoms in patients with lupus erythematosus was analyzed. We then analyzed patients with isolated CLE vs. SLE with CLE using chi-square test.

Results: A total of 110 patients received the PHQ-9 and GAD-7 questionnaires. Of these, 29 patients (28.4%) screened positive for anxiety and 42 patients (38.2%) for depression. When comparing patients with isolated CLE vs. SLE with CLE, we found a statistically significant increase of 50% (p-value=0.0077) in depressive symptoms among patients with SLE and CLE. Anxiety symptoms did not differ among the compared groups.

Conclusion: The results are consistent with previous prevalences described for LE patients with anxiety and depressive symptoms. Subset analysis by cutaneous involvement suggests that patients with both systemic and cutaneous involvement suffer from more depressive symptoms than those with isolated cutaneous involvement. This study highlights the importance of screening for mood disorders in patients with lupus, in particular patients with systemic disease.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: We established the OMERACT SLE Working Group in 2021 which includes over 150 members representing over 25 countries and 5 continents to develop a new SLE Core Domain Set (CDS) and measurement instrument set. A CDS is essential for standardizing the measurement and reporting of domains in clinical trials and longitudinal studies in SLE. Domains in a CDS are selected from a candidate domain list through consensus voting exercises with stakeholders including patients, clinicians, researchers, pharmaceutical representatives, and others. The first CDS development

stage is generating a preliminary list of candidate domains. To inform the development of the new OMERACT SLE CDS, we have conducted a scoping literature review of systematic reviews and clinical trials of SLE, and focus groups with SLE patients about living with SLE.

Methods: ***Scoping Review***: We searched 5 databases (Medline, Embase, Cochrane, CINALH, PsycINFO) since 2010 and used Covidence for article screening. 3 reviewers performed an agreement test on the first 100 articles for title and abstract screening with a 98% agreement. Due to the large volume of studies, the 1st screening of title and abstract was conducted by a single reviewer. A 2nd agreement test on 100 articles was performed for full-text screening with the same reviewers with a 99% agreement. The 2nd screening of full-texts and data extraction of domains required 2 reviewers per article. ***Focus Groups***: We developed an interview guide of 11 open-ended questions asking about the pathophysiological manifestations and life impact of SLE. Patients were recruited by the University of Toronto from around the world representing 5 continents and 13 countries. Six focus groups were held virtually ranging from 3 to 10 participants per group. Transcripts have been developed and thematically coded using an open coding framework. ***Advisory Group***: An advisory group was established

Table 1 – Candidate Domains and Sub-Themes Generated from the Scoping Literature Review and Focus Groups

DOMAINS	SUB-THEMES
Adverse Events	Treatment side effects, glucocorticoid side effects
Anxiety	Anxiety about coping with disease uncertainty
Appearance	Body image, physical changes (weight gain), swollen body
Cognitive Function	Brain fog, cognitive impairment, Episodic memory, working Memory, attention, cognitive flexibility, prospective memory, cognition, awareness, memory
Control Over Disease	Loss of health status, controls of SLE with Covid, vulnerability
Damage	Disease-related
Depression	Depressed feelings, depressed about no longer being the same, depression about coping with disease uncertainty
Disability	
Disease Activity	Disease activity state/status/remission
Disease Severity	
Dizziness	
Economic Cost	Financial strain of illness, cost (medication, time off work, impact on employment, non-medical like lotion, alternative medicine)
Emotional Health	Emotions, mood changes, mood swings
Fatigue	Physical fatigue, emotional fatigue, lack of energy, tiredness
Flares	
Fever	
Frailty	
Health Related Quality of Life	Quality of life
Intimacy	
Isolation	Social isolation, social exclusion
Mortality	
Musculoskeletal	Swollen joints
Pain Severity	
Pain Interference	
Participation	Role participation, lifestyle impact, changes in basic needs, planning activities based on energy, understanding limitations
Physical Function	Loss of physical ability, functional ability
Pregnancy	
Satisfaction	
Self-Esteem	Guilt, self-efficacy, self-concept
Self-Management	Coping mechanisms
Sexuality	Drive, sexual dissatisfaction
Sleep	
Stiffness	
Stress	
Weakness	Muscle weakness
Work Status	Employment

with members from the OMERACT SLE Working Group Steering Committee, Patient Research Partners, and additional SLE Expert Stakeholders. This group reviewed all domains and themes and sorted them into domains.

Results: The literature search yielded 4113 articles. The 1st screening reduced the number of articles to 1421. The 2nd screening reduced the number of articles to 597. The scoping review and focus group transcripts yielded over 200 themes/domains. Duplicate and related themes/domains were grouped, and contextual factors were removed yielding a preliminary total of 36 domains (**Table 1**) which included domains such as disease activity, cognitive function, sleep, fatigue, anxiety, depression, stress, participation, pain interference, intimacy, and more.

Conclusion: Many candidate domains have been identified through the scoping literature review and focus group interviews. Further work is in process to finalize the list of the candidate domains to continue with a 4 round Delphi consensus voting exercise to achieve consensus on the new SLE CDS. The future goal for the SLE OMERACT Working Group is the instruments selection for each domain of the new CDS and appraisal of instruments measurement properties.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

b>Background/Purpose: Patients with pure membranous lupus nephritis (LN) are known to have a different disease course than those with proliferative disease. The aim of this study is to determine the differences in short and long term outcomes between patients with pure membranous LN and those with proliferative LN, in terms of achieving complete proteinuria recovery (CPR), time to CPR and a composite of poor renal outcome.

Methods: This is a retrospective analysis of patients followed prospectively at a single large Lupus cohort who had biopsy-proven Class V, Class IV+V or III+V or isolated class III or IV LN. We included only first patient-biopsy. The baseline visit corresponds to the visit with highest level of proteinuria in relation with the kidney biopsy visit. Baseline characteristics of patients (demographic data, laboratory results, clinical features and treatment protocols) were analyzed. The primary endpoint, CPR, was defined as proteinuria < 500 mg/24 h. CPR was evaluated at 1 year and 2 years for the different LN classes. The time to CPR was assessed with a Kaplan-Meier curve. Time to a composite of poor renal outcome (eGFR ≤ 15 mL/min/1.73m^2, chronic dialysis or kidney transplant) was also evaluated. These outcomes were compared between patients with pure membranous LN and those with proliferative disease (including mixed biopsies; class III+V or IV+V).

Results: 209 patients fulfilled the above criteria with at least 2 years of follow up after the baseline visit. Of these, 53 had pure membranous LN, 41 had mixed disease (class IV+V or III+V), and 115 had pure proliferative disease (class III or IV). Overall, 156 patients had proliferative disease on biopsy. Patients with pure membranous LN were slightly older at baseline than those with proliferative disease (38.89 Vs 34.53 years, p= 0.016). They also had a higher eGFR (102.69 Vs 86.16 mL/min/1.73 m^2, p= 0.008) and a lower SLEDAI-2K score (11.64 Vs 15.96, p < 0.001) at baseline. Proliferative LN patients tended to be more serologically active (p= 0.001 for anti-dsDNA and < 0.001 for low complements) and had more hematuria (p< 0.001) and urinary casts (p=0.002). There were no significant differences in the baseline proteinuria levels between the two groups. Mycophenolate was the most commonly used drug in the standard of care therapy. Less patients with pure membranous LN received corticosteroids during the first year after the baseline visit (p= 0.004) **(Table 1)**.

There were no differences in the CPR at 1 year (51% for both groups) or at 2 years (66% for membranous and 62% for proliferative disease, p= 0.660) between the 2 groups. Time to CPR was also comparable (**Figure 1**). Time to the composite of poor renal outcome showed a trend in favor of pure membranous patients, but did not meet statistical significance (**Figure 2**).

Conclusion: CPR at one and two years, and time to CPR were similar in patients with pure membranous LN and those with proliferative disease. Time to a composite of poor renal outcome was not significantly different between the two groups. These results show that pure membranous lupus nephritis may be associated with ominous long term outcomes.

Table 1. Baseline demographic, clinical, and laboratory characteristics, as well as treatment regimens in patients with pure membranous LN and those with proliferative diseases

Variables at baseline visit		Membranous LN (n= 53)	Proliferative LN (including mixed cases) (n=156)	p-value
Class V	n (%)	53 (100)	0	<0.001
Class III+V or IV+V	n (%)	0	41 (26)	
Class III or IV	n (%)	0	115 (74)	
Age in years	(mean ± SD)	38.89 ± 12.55	34.53 ± 10.79	0.016
Sex, female	n (%)	45 (85)	138 (89)	0.662
Ethnicity	Black, n (%)	23 (43)	31 (20)	0.171
	Caucasian, n (%)	19 (37)	87 (56)	
	Chinese, n (%)	7 (14)	18 (11)	
	Others, n (%)	3 (6%)	20 (13)	
SLE duration in years	(mean ± SD)	6.91 ± 8.38	5.47 ± 6.02	0.177
Hypertension	n (%)	30 (57)	108 (69)	0.094
Diabetes mellitus	n (%)	3 (6%)	14 (9%)	0.522
Creatinine, umol/L	(mean ± SD)	77.81 ± 31.88	94.60 ± 58.75	0.051
eGFR, mL/min/1.73 m2	(mean ± SD)	102.69± 38.26	86.16 ± 38.00	0.008
Serum albumin, g/L	(mean ± SD)	32.87 ±7.00	31.44 ± 7.05	0.226
SLEDAI-2K	(mean ± SD)	11.64 ±7.17	15.96 ± 6.85	<0.001
SDI	(mean ± SD)	0.62 ±1.24	0.51 ± 1.12	0.525
Low complement	n (%)	22 (42%)	114 (73%)	<0.001
Positive ant-dsDNA	n (%)	25 (48%)	112 (72%)	0.001
Proteinuria in grams/24 hour urine collection or UPCR	(mean ± SD)	2.84 ± 2.21	3.43 ± 2.60	0.140
Hematuria	n (%)	12 (23%)	94 (60%)	<0.001
Active sediment (urinary casts)	n (%)	7 (13%)	56 (36%)	0.002
Immunosuppressives at 1 year	Azathioprine, n (%)	14 (26%)	64 (41%)	0.058
	Cyclosporine, n (%)	2 (4%)	5 (3%)	0.651
	Mycophenolate Mofetil, n (%)	22 (42%)	80 (51%)	0.253
	Other (including Tacrolimus, Rituximab, or Belimumab), n (%)	2 (4%)	6 (4%)	0.981
Corticosteroids during 1st year	n (%)	48 (91%)	154 (99%)	0.004
Antimalarials during 1st year	n (%)	38 (72%)	98 (63%)	0.278
ACE-I or ARB during 1st year	n (%)	27 (51%)	87 (56%)	0.492

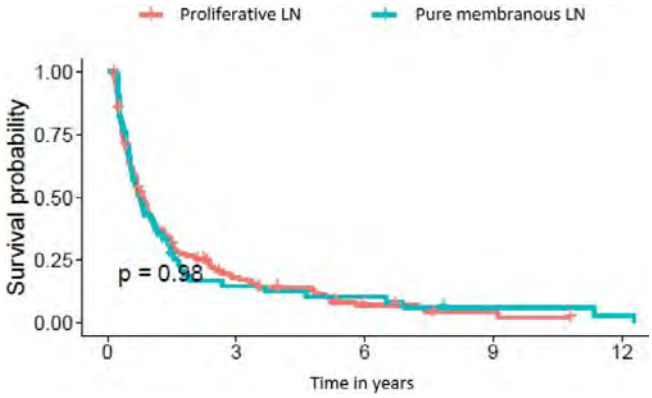

Figure 1. Time to CPR showing no difference between pure membranous and proliferative LN.
