Background/Purpose: Clinical outcomes in Rheumatoid arthritis (RA) have improved with the introduction of biological and targeted synthetic disease modifying anti-rheumatic drugs (b & tsDMARDs). Abatacept (CTLA4-Ig), modulates T cell co-stimulation by interacting with CD80/86 expressed on antigen-presenting cells (APC) and has the potential to interfere both with proinflammatory amplification pathways and autoimmunity. In the Phase IV Inhibition of co-stimulation in RA (ICosRA) trial, we aimed to determine the impact of Abatacept on the peripheral frequencies and phenotypes of citrulline specific T cells in seropositive and shared epitope HLA-DR*04 positive RA patients.

Methods: HLA-DRB1*04:01 or *04:04 $ACPA^+$ RA patients were recruited into a 24-week open label study (n= 25). Peripheral blood mononuclear cells were harvested at baseline, 12 weeks, and 24 weeks after abatacept treatment. A panel of 18 markers expressed on various T-cell subsets and 12 known citrullinated epitope specific HLA class II tetramers was employed to investigate citrulline specific and broad T-cell responses, using spectral flow-cytometry. One-way Anova or Friedman test, with post-hoc tests were used for testing statistical significance.

Results: Evaluation of the global $CD4^+$ T cell compartment revealed that abatacept treatment significantly decreased $CD4^+CD69^+$ recently activated T cells ($p = 0.03$), $CD4^+HLA\text{-}DR^+$ T cells ($p = 0.005$) and $CXCR3^-CCR6^+CD4^+$ Th17 cells ($p = 0.05$). Abatacept treatment also significantly decreased $CD4^+CD25^+CD127^-$ regulatory T cells ($p= 0.03$). This was accompanied by a significant decrease in expression of HLA-DR ($p = 0.0004$), CD137 ($p = 0.003$), CD95 ($p = 0.0004$) and

CD38 (p = 0.03), but not PD1. Characterization of the citrulline specific T cell compartment, demonstrated that citrullinated Tenascin C specific T cells dominated the autoreactive TCR fine-specificities (p< 0.05). Moreover, the frequencies of citrulline specific T cells decreased significantly over time (p= 0.003). Patients responding to therapy showed significantly higher baseline number of citrulline specific T cells than non-responders (p= 0.05). TCR sequencing of *in-vitro* expanded cit-Tenascin C specific T cells from 4 patients at baseline and subsequent follow up, revealed persistence of autoreactive TCR clones.

Conclusion: Abatacept decreases both global and citrulline specific T cell populations. Notably, prior to treatment there were higher numbers of autoreactive T cells in those patients that respond; suggesting that not only do these individuals potentially have a stronger autoimmune disease component but are also more receptive to therapeutic intervention targeting inhibition of co-stimulation. Finally, the persistence of citrulline specific T cell clones underscores the notion that abatacept does not fully abrogate the T cell compartment's propensity to drive autoimmunity.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a critical complication of rheumatoid arthritis (RA). Abatacept and rituximab are the preferred disease-modifying antirheumatic drugs (DMARDs) for RA-ILD. However, progression of ILD despite its use is not uncommon. A subgroup analysis of the INBUILD trial has shown a slower decline in forced vital capacity (FVC) in patients with progressive fibrosing autoimmune disease-related ILD with nintedanib (NINTE) [*Arthritis Rheumatol* 2022;74(6):1039-47]. However, data on antifibrotics use for RA-ILD in clinical practice (CP) are scarce. Our aim was: **a)** To assess the efficacy of antifibrotic drugs, NINTE and pirfenidone (PIRFE), in Spanish RA-ILD patients with a progressive phenotype in CP; **b)** To compare the profile of CP RA-ILD patients with those included in the INBUILD trial.

Methods: National multicenter study of RA-ILD patients to whom NINTE or PIRFE were added due to progressive fibrosing ILD. Demographic and clinical variables were collected from all patients. These features were compared with those of RA-ILD patients included in the INBUILD trial (n=89, 42 NINTE and 47 placebo). Forced vital capacity (FVC) evolution was the primary endpoint. Results are expressed as percentage, mean±SD or median [IQR].

Table 1. Baseline characteristics of RA-ILD patients treated with NINTE in clinical practice and RA-ILD patients included in the INBUILD trial.

	Clinical practice (n=66)	INBUILD trial (n=89, 42 NINTE vs 47 PCB)
Age, years mean±SD	68.7±8.8	66.9±9.6
Women, n (%)	29 (43.9)	35 (39.3)
Smoker ever, n (%)	47 (71)	57 (64)
Time since ILD diagnosis, years, mean±SD	4.8±4.1	3.6±3.2
RF, n (%)	60 (91)	-
ACPA, n (%)	55 (83)	-
FVC (% of the predicted), mean±SD	71.4±22.6	71.5±16.2
DLCO (% of the predicted), mean±SD	49.1±13.9	47.7±15.6
Dyspnea Score (mMRC), median [IQR]	2 [2-3]	-
UIP-like fibrotic pattern on HRCT, n (%)	42 (63.6)	77 (86.5)

Biologic DMARD	43 (65.1)	19 (21.3)
JAKi	4 (6.1)	-

ACPA, anti-citrullinated protein antibodies; DLCO, diffusing capacity of the lung for carbon monoxide; DMARD, disease-modifying antirheumatic drug; FVC, forced vital capacity; HRCT, high-resolution computed tomography; ILD, interstitial lung disease; IQR, interquartile range; JAKi, JAK inhibitor; mMRC: modified Medical Research Council scale; NINTE, nintedanib; PCB, placebo; RA, rheumatoid arthritis; RF, rheumatoid factor; SD, standard deviation; UIP, usual interstitial pneumonia.

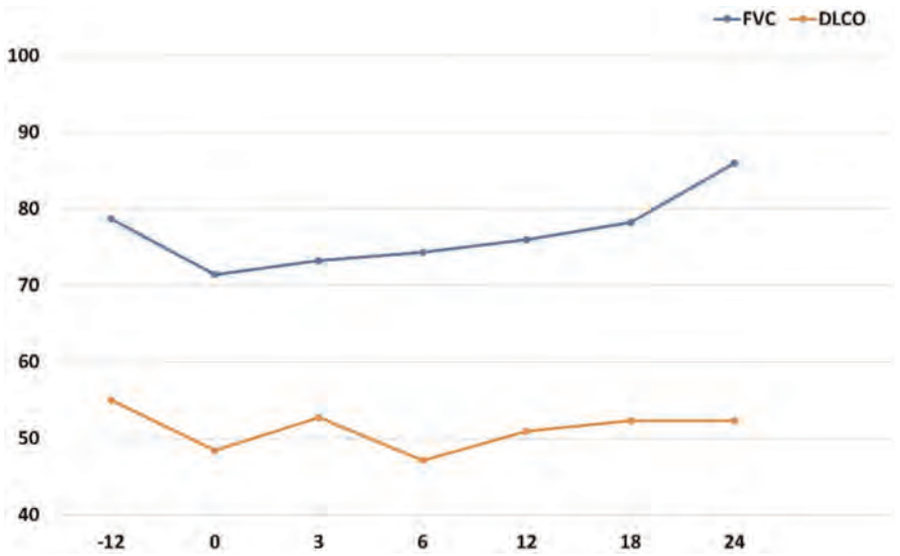

Figure 1. Evolution of FVC and DLCO in 66 patients with RA-ILD treated with nintedanib in clinical practice since the previous year of initiation.

Results: A total of 73 patients (24 women/49 men) from CP were collected, mean age of 69±9 years. The median [IQR] ILD duration up to antifibrotic initiation was of 56.5 [21.5-83] months. NINTE was the most widely used antifibrotic (n=66), combined with immunosuppressive treatment in all cases: corticosteroids in 44, cDMARD in 20 (mycophenolate mofetil=8, leflunomide=6, methotrexate=3, hydroxychloroquine=2, azathioprine=1), bDMARD in 43 (abatacept=31, rituximab=10, anti-IL6R=2) and/or JAKi in 4 (baricitinib=2, tofacitinib=1, filgotinib=1). Mean FVC one year before NINTE start was 80±21 (% pred.), whilst mean baseline FVC was 71±23 (% pred.). **Table 1** shows the comparison of baseline characteristics of RA-ILD patients treated with NINTE in CP and in the INBUILD trial. The evolution of FVC and diffusing capacity of the lungs for carbon monoxide (DLCO) in our patients with NINTE from the previous year of antifibrotic initiation is shown in **Figure 1**. After a median follow-up of 15.5 [3.5-23.5] months, no significant decline in mean FVC or DLCO values was observed. In addition, 86% of the patients presented stabilization or improvement of dyspnea. NINTE was withdrawn in 14 patients due to: gastrointestinal adverse events (11), death (1), hemorrhage risk (1), and stabilization (1). PIRFE was administered to 7 patients (4 men), combined with abatacept in 3 patients, leflunomide in 1, and methotrexate in 1. Mean baseline FVC and DLCO were 69±22 and 49±14 (% pred.), respectively. As with NINTE, a stability in the evolution of lung function was observed. PIRFE was withdrawn in 4 patients due to: gastrointestinal adverse events (2), inefficacy (1), and stabilization (1).

Conclusion: Antifibrotics, especially NINTE, seem to slow ILD progression in patients with RA-ILD. In CP, our patients are treated belatedly in the evolution of the disease, but results are satisfactory. Combination of antifibrotics and DMARDs is feasible and safe.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Helper T cells (Th) are key players in rheumatoid arthritis (RA). Th17 and Th17.1 have a prominent function in the early phase of inflammation, while Th1 characterize a well-established disease (Kotake S, 2017). Th22, characterized by synthesis of IL-22 (and IL-13 and TNF-α) but not IL-17A or IFN-γ, are still. In RA animal model, IL-22 hampered Th1 plasticity, favoring Th17 maintenance and survival (Justa S, 2014). Th9 are involved in RA synovitis, IL-9 being an enhancer of Th17 cells differentiation in the synovium (Chowdhury, 2018). Innate lymphoid cells (ILC) were recently described as critical in the perpetuation of immune responses during the autoimmune processes, being resident in the tissues and activating without the presence of antigen-specific cell receptors. The three major groups in the ILC family (1, 2, 3) mirror the canonical T helper subsets Th1, Th2, and Th17 (Wu X, 2020). Considering the crucial role played by the CD28 co-stimulation in the process of Th priming and its effect on inflammatory environment, we hypothesized that its

blocker abatacept (ABA) might modulate the circulating levels of Th and ILC cells and their involvement in B-cell maturation and antigen-driven differentiation.

Methods: Sixteen bDMARDs-naïve RA patients [female/male=10/6; median (IQR) age=64 (54.3-67.6) years; disease duration=51 (30-108) months; 13/16 (81.3%) seropositive; C Reactive Protein (CRP)=6 (2.4-11.5) mg/L (normal value < 5 mg/L), CRP-28-joint Disease Activity Score (CRP-DAS28)=4 (3.3-4.4)] were enrolled before starting ABA. Peripheral blood mononuclear cells, obtained from the patients before the start of ABA therapy (T0) and after 12 months (T12), were extracellular stained and evaluated by flow cytometry (FACSCantoII, Beckton Dickinson). EULAR criteria were used to evaluate the treatment response [good and moderate responders (R), n=11 and non-responders (NR), n=5].

Results: Baseline CRP-DAS28 was differently correlated with various T helper cell subsets, but not with ILC (Table 1A). In the whole cohort, Th and ILC subpopulation levels did not significantly change between T0 and T12, except for Th22 levels (expressed as % of CD3+CD4+CCR6+CCR4+) which decreased [20.1 (17.93-23.53) vs 16 (14.1-19.4); p:0.016] (Table 1B), mainly in the R group [19 (17.75-20.5) vs 15.85 (13-17.45); p:0.004]. The same level of circulating subsets was found when comparing NR vs R patients at T0 and T12.

Conclusion: All the circulating Th cells expressing CCR6, which is the main chemokine receptor of Th17 and Th17-related cells, were positively correlated with the disease activity at baseline, except for Th22, a distinct Th lineage that can display plasticity towards Th1 and Th2 lineages under special circumstances, showing regulatory properties and participating to the early RA pathogenesis. The decrease of Th22 after CD28 blockade may suggest the potential role of ABA in targeting one of the earliest phases of the disease pathophysiology.

Effect of Subcutaneous Local Anaesthesia Prior to Intra-Articular Injection: An Open Label, Paired-group, Randomized Controlled Trial

Alan Shaji[1], **Varun Dhir**[2], Chandra Bhushan Prasad[3], Shankar Naidu[1], Aman Sharma[4], Shefali Sharma[5], Babita Ghai[1] and Sanjay Jain[1], [1]PGIMER, Chandigarh, India, [2]PGIMER, CHD, INDIA, Chandigarh, India, [3]Healthway Hospital, Goa, Zuarinagar, India, [4]PGIMER, Chandigarh, India, Chandigarh, India, [5]PGIMER< Chandigarh, Chandigarh, India

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Intraarticular injections are commonly used both for diagnostic and therapeutic injections of glucocorticoids in patients with inflammatory arthritis. The procedural pain felt by patients may be an important factor for patients to consider future injections. Subcutaneous local anaesthesia given a few minutes prior may reduce the pain felt by the patient, however, has the disadvantage of pricking the patient twice. Once problem of studies comparing pain is that individual perception of pain varies, thus, we planned this study which included patients with two same (paired) joints swollen who were undergoing therapeutic joint injections.

Methods: This was an open-label (patients blinded) randomized controlled trial that included patients with rheumatoid arthritis or spondyloarthritis who had both (paired) medium-large joints swollen - either both knees or ankles or writs or elbows, and planned for therapeutic joint injections. The study design was that patients underwent intra-articular into left joint followed by right joint after a gap of 10-minutes. Whether the left or the right joint got local anesthesia was decided by using randomization (online software, serial permuted blocks). (Figure 1) Local anesthesia consisted of 5 ml lignocaine infiltrated in the skin and subcutaneous tissue using a 23-G needle. Intraarticular injections were given using a 10 ml syringe with a 21 G needle. Primary outcome was immediate procedural pain felt by the patient and secondary endpoints were 1-hour

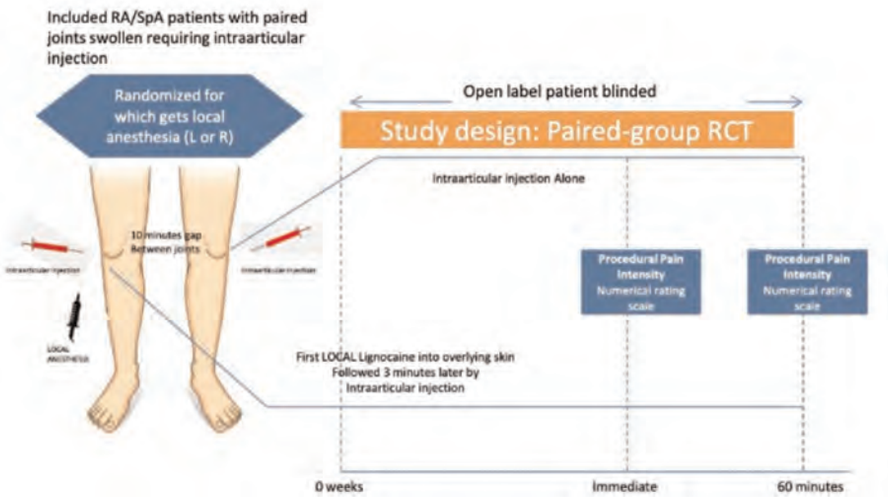

Figure 1: Study design

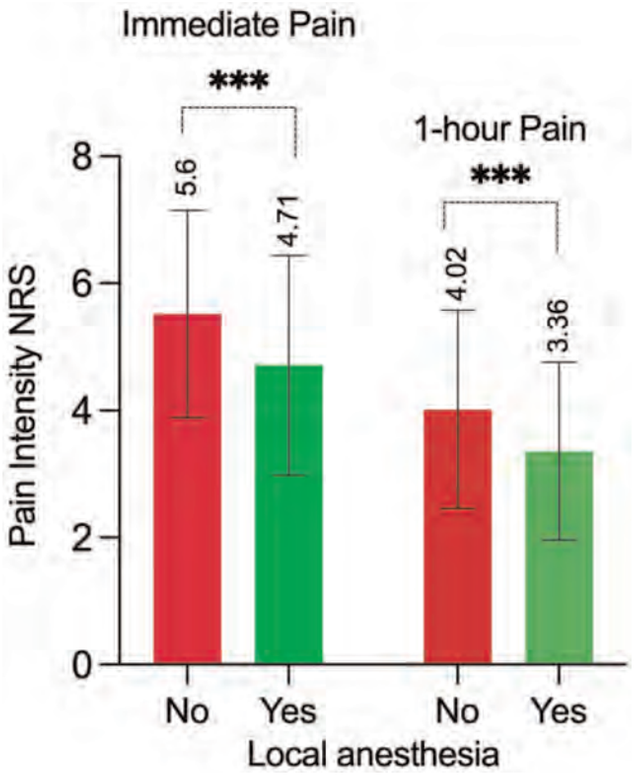

Figure 2: Immediate and 1-hour pain in the joint given prior local anesthesias versus the one not given local

pain assessment, patient preference for future injections (after telling them which joint received LA) and complications. Pain was assessed using numerical rating scale. Paired t-test and Wilcoxon Signed Rank test was used to compare the intensity of pain. Trial registration number CTRI/2021/07/034777

Results: This study included 42 patients undergoing paired joint injections (84 joints). A majority of patients had rheumatoid arthritis (37, 88%), mean age (±SD) was 44.6 ± 14 years and 71% were females. The joints injected were knees (21 patients), wrists (14 patients), ankles (5 patients) and elbows (2 patients). There was a significantly lower immediate pain in the joint given local anaesthesia compared to that not given (difference -0.8, 95 CI -0.6 to -1.0) as well as significantly lower pain at 1-hour (difference -0.7, 95 CI -0.4 to -0.9). (Figure 2) A majority of patients (78.6%) preferred the procedure with local anaesthesia for future injections in their joints. There was no difference in complications of hypopigmentation or purpura nor in residual pain prick-site at 1-month. No significant differences were noted in pain by gender or age, nor by joint injected.

Conclusion: In this study with a unique paired design to obviate individual differences in pain, local anaesthesia of the overlying skin led to a definite but modest reduction (approximately 15%) in pain felt by the patient during intraarticular injection.

Efzofitimod, a First-in Class NRP2-targeting Immunomodulator, Ameliorates Rheumatoid Arthritis and Associated Lung Fibrosis in Preclinical Models

Christoph Burkart, Clara Polizzi, Lisa Eide, Max Pastenes, David Siefker and Leslie Nangle, aTyr Pharma, San Diego, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Efzofitimod, a novel immunomodulator, has shown clinical proof-of-concept in a Phase 1b/2a clinical trial in patients with pulmonary sarcoidosis and is currently enrolling a global Phase 3 clinical trial. By selectively binding to its target neuropilin-2 (NRP2), a membrane protein that is strongly upregulated on myeloid cells during inflammation, efzofitimod reduces inflammation and fibrosis in a range of animal models of interstitial lung disease (ILD). NRP2 appears to also play a role in other inflammatory diseases such as arthritis [1]. In this work, we confirm that connection utilizing a genetic NRP2 knock-out (KO) mouse model. Based on efzofitimod's anti-inflammatory effects and NRP2's role in the pathology of arthritis, we tested its therapeutic potential in experimental models of rheumatoid arthritis.

Methods: The collagen-induced arthritis (CIA) model was performed in NRP2 WT and KO animals utilizing the Hooke Kit™ for CIA induction. Efzofitimod was dosed at 1 mg/kg weekly intravenously upon emergence of clinical signs. Study animals were scored every other day until termination. Terminal serum samples were analyzed for pro-inflammatory cytokines. To test the effect of efzofitimod in rheumatoid arthritis-associated ILD (RA-ILD), we utilized the SKG mouse model of RA-ILD. The disease was induced via IP injection of 5 mg of zymosan. Efzofitimod was dosed at 3 mg/kg weekly intravenously starting one day prior to disease induction. At termination, lung single cell suspensions were immunophenotyped and lung sections were analyzed for fibrosis.

Results: NRP2 KO animals exhibited heightened sensitivity to disease induction in the CIA model, resulting in excessive mortality. Analysis of serum samples from these animals demonstrated elevated levels of pro-inflammatory cytokines, indicating a deficiency in the negative regulation of the immune response. Based on the impaired immune regulation observed in NRP2 KO animals, we hypothesized that efzofitimod may produce therapeutic benefit in the CIA model via modulation of NRP2. Encouragingly, we observed improved clinical scores in 37.5% of the study animals treated with efzofitimod, compared to only 12.5% in the control group. Additionally, efzofitimod displayed activity in the SKG model of RA-ILD. Treatment with efzofitimod led to a reduction in the number of immune cell populations in the lungs and exhibited a noteworthy reduction in RA-induced lung fibrosis.

Conclusion: The data presented here indicate a critical role for NRP2 in modulating immune responses in autoimmune diseases, such as rheumatoid arthritis and RA-ILD. By targeting NRP2 with efzofitimod, we observed improved disease outcomes, reduced inflammation, and mitigated lung fibrosis, suggesting the potential of efzofitimod as a therapeutic intervention for rheumatoid arthritis and potentially other immune mediated diseases.

Abstract Number: 1323

Distinct Treatment Responses in Patients with Rheumatoid Arthritis Receiving Filgotinib 200 Mg over 12 Months: A *Post Hoc* Analysis of FINCH 1

Peter C. Taylor[1], Yoshiya Tanaka[2], Emily Aiello[3], Thomas P.A. Debray[4], Chris Watson[5], Kristina Harris[6] and Gerd Burmester[7], [1]Nuffield Department of Orthopedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]University of Occupational and Environmental Health, Kitakyushu, Japan, [3]Real-world Analytics, Cytel, Toronto, ON, Canada, [4]Biostatistics, Galapagos NV, Mechelen, Belgium, [5]Medical Affairs, Galapagos Biotech Ltd., Cambridge, United Kingdom, [6]Medical Safety, Galapagos NV, Mechelen, Belgium, [7]Charité – Universitätsmedizin Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: FINCH 1 (NCT02889796) was a Phase 3 randomized controlled trial evaluating filgotinib (FIL) in patients with rheumatoid arthritis and an inadequate response to methotrexate (MTX).[1] Patients received background MTX and were randomized 3:3:2:3 to FIL 200 mg (FIL200), FIL 100 mg, adalimumab or placebo. This analysis aimed to identify patterns of response trajectory over 12 months in patients from FINCH 1 receiving FIL200.

Methods: Group-based trajectory modeling is a statistical method which groups individuals based on similar patterns of change in an outcome over time.[2] A group-based trajectory modeling approach was applied to identify five distinct phenotypic groups in terms of observed clinical disease activity index (CDAI) outcomes (and components) over a 12-month period (**Figure**). Responders were recorded as either low disease activity (LDA) or remission, defined as CDAI between ≥ 2.9 and ≤ 10, or ≤ 2.8, respectively, at 6 months.

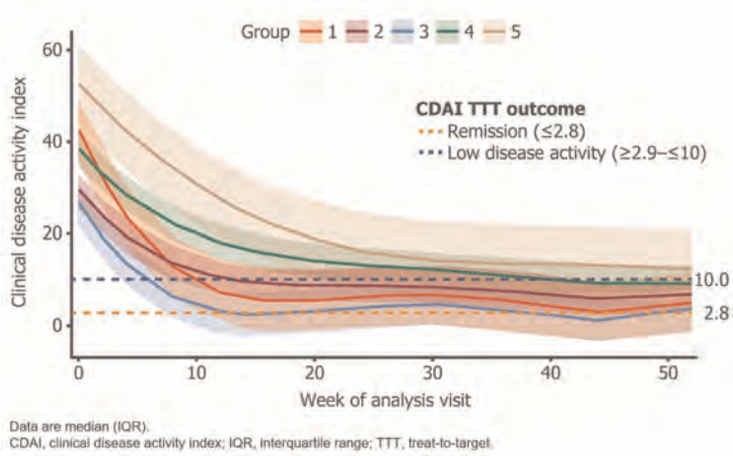

Figure. CDAI trajectory in patients from FINCH 1 receiving FIL200

Table. Efficacy outcomes from baseline to Month 12 in phenotypic patient groups receiving FIL200: CDAI components

	Group 1 N=94	Group 2 N=103	Group 3 N=131	Group 4 N=67	Group 5 N=80

12-month value	0 (0, 2)	1 (0, 2)	0 (0, 0)	3 (1, 5)	5 (2, 9)
CDAI responders (LDA and remission), n (%)					
6-months	79 (92)	66 (78)	122 (99)	11 (21)	14 (23)
12-months	75 (91)	75 (90)	119 (99)	27 (52)	20 (34)

Data are median (IQR) unless otherwise stated.
abs, absolute; CDAI, Clinical Disease Activity Index; IQR, interquartile range; LDA, low disease activity; PhGADA, Physician's Global Assessment of Disease Activity; PtGADA, Patient's Global Assessment of Disease Activity; SJC28, swollen joint count in 28 joints; TJC28, tender joint count in 28 joints.

Results: Mean age, the proportion of females and disease duration were similar across all groups. Improvements in efficacy outcome measures were seen for all groups. Baseline (median interquartile range [IQR]) CDAI was highest (worst) in Group 5 (52 [48, 60]), followed by Group 1 (48 [44, 55]). Groups 1 and 3 showed a rapid reduction in CDAI in the first 6 months and sustained response over 12 months. Groups 2, 4 and 5 demonstrated slower response trajectories, with continued improvements in the proportion of CDAI responders between 6 and 12 months; of note, Group 5 constituted 16.8% (80/475) of the total analysis population. **Table** shows that despite substantial and comparable improvements in CDAI components across all 5 groups over 12 months, Group 5 demonstrated some residual disease activity.

Conclusion: A group-based multivariate trajectory model identified five distinct CDAI disease activity trajectories in patients from FINCH 1 receiving FIL200. Patients in all groups demonstrated either fast and sustained response or slower and continued improvements, with no or low numbers of swollen or tender joints at Month 12. The current analysis suggests that patients who do not achieve CDAI LDA within 6-months may still benefit from treatment continuation and informs a range of expectations for times to clinical response. Future work will assess biomarker profiles that may be used to predict the observed clinical response patterns.

Abstract Number: 1324

Previous History of Serious Infection Is Associated with the Use of IL-6 Inhibitors in Rheumatoid Arthritis in Wales, UK

Roxanne Cooksey[1] and **Ernest Choy**[2], [1]Cardiff University, Cardiff, United Kingdom, [2]Section of Rheumatology, Cardiff University, Cardiff, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic therapy has revolutionised the treatment of rheumatoid arthritis (RA). Randomised control trials have shown that IL-6 inhibitors are superior to adalimumab, a TNF inhibitor, when used as monotherapy in RA. However more information is required to assess the real-life burden and to predict infection risk in RA patients using biologics and IL-6 receptor antibodies. Here, we describe the characteristics and comorbidities of RA patients treatment with either IL-6 inhibitors, (tocilizumab or sarilumab) versus non-IL-6 (anti-TNF, B-or T-cell therapies) biologic disease modifying anti-rheumatic drugs (bDMARDs).

Methods: A retrospective cohort study of patients with the diagnosis of RA in the Secure Anonymised Information Linkage (SAIL) databank, which includes primary care, secondary care and specialist rheumatology clinic records of over 90% of the population in Wales, UK. Patients treated with IL-6 inhibitors or biologics are compared in a descriptive study and include both biologic/il6-inhibitor naïve and non-naïve patients. Funding and acknowledgement: This study was funded a grant from Sanofi (20190412).

Results: Of 4,922 patients identified with RA in their primary care records, 95.7% (4,691/4,922) received csDMARD treatment. Over a third of patients (36.2%) were treated with bDMARDs (1,784/4,922).Of these biologic-naïve patients, 116 (6.5%) were treated with IL-6 inhibitors. Treatment with IL-6 bDMARDs was associated with previous history of infection (difference: 8.8%, 95% CI 1.1 to 17.8) and kidney disease (14.3% 95% CI 8.0 to 22.5). The rate of treatment failure was significantly higher in the non-IL-6 bDMARDs-treated patients (23.1%) compared to the IL-6 inhibitor treated individuals (18.1%) (difference: 9.4%, 95% CI: 1.1 to 15.7). Orthopaedic surgery pre-treatment and steroid use was associated with non-IL-6 bDMARDs treatment failure (HR: 1.64, 95% CI: 1.00 to 2.68; HR: 1.62, 95% CI: 1.26 to 2.08, respectively). Post-treatment infection rate was higher with non-IL-6 bDMARDs (difference: 10.5%, 95% CI: 3.7 to 19.0) than IL-6 bDMARDs. Orthopaedic surgery was also more common in non-IL-6 bDMARDs (difference: 9.9%, 95% CI: 4.1 to 13.3). No factor was found to be associated with treatment failure in the IL-6 inhibitor treated patients which may be due to fewer number of patients. 385 patients (23%) and 21 patients (18%) switched to alternative bDMARD from the non-IL-6 and IL-6 groups respectively. Of the 385 switchers from the non-IL6 bDMARD group, 298 patients (77.4%) received a second non-IL-6 bDMARDs and 87 patients received IL-6 bDMARDs (22.5%). Treatment failure in biologic-experienced patients was significantly higher in the IL-6 bDMARD treated group (difference: 28.3%, 95% CI: 17.6 to 39.3). The patient characteristics were not significantly different between the two groups.

Conclusion: Comorbidities, previous history of infection and previous history of kidney disease, were associated with choosing IL-6 bDMARDs in biologic naïve RA patients in Wales. IL-6 treated biologic-naïve patients were more likely to continue treatment than non-IL-6 biologic treated patients. The reverse is the case in biologic-experience patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is an oral Janus kinase 1 preferential inhibitor, approved for the treatment of moderate to severe active rheumatoid arthritis (RA). In previous analyses, comparable incidence of selected adverse events (AEs) occurred in FIL 200 mg (FIL200) and 100 mg (FIL100) dose groups, except for herpes zoster.[1] This analysis aimed to provide an update on FIL selected AEs up to a median (max) exposure of 3.8 (8.3) years.

Methods: Integrated FIL RA data from 7 clinical trials are reported: Phase 2 (NCT01888874, NCT01894516), Phase 3 (NCT02889796, NCT02873936, NCT02886728), and the long-term extension studies DARWIN 3 Phase 2 (NCT02065700) and FINCH 4 Phase 3 (NCT03025308). Exposure-adjusted incidence rates (EAIRs)/100 patient-years of exposure (PYE), censored at time of first event, were determined for major adverse cardiovascular event (MACE), venous thromboembolism (VTE), arterial systemic thromboembolism, nonmelanoma skin cancer (NMSC), malignancies excluding NMSC, herpes zoster, serious infections and deaths. Data were as of May 2, 2022 (DARWIN 3) and May 6, 2022 (FINCH 4). MACE and VTE only include positively adjudicated events with a data cutoff of April 3, 2022.

Table. Frequencies and EAIRs of selected AEs in parent and ongoing long-term extension RA clinical trials

	FIL100 (PYE= 4532.4) (n=1647)	FIL200 (PYE= 8008.6) (n=2267)
	n (%), EAIR per 100 PYE (95% CI)	
MACE*	22 (1.3), 0.49 (0.3, 0.7)	27 (1.2), 0.34 (0.2, 0.5)
VTE*	9 (0.5), 0.20 (0.1, 0.4)	15 (0.7), 0.19 (0.1, 0.3)
ASTE	1 (<0.1), 0.02 (0.0, 0.1)	1 (<0.1), 0.01 (0.0, 0.1)
NMSC	9 (0.5), 0.20 (0.1, 0.4)	27 (1.2), 0.34 (0.2, 0.5)
Malignancies (excluding NMSC)	30 (1.8), 0.66 (0.4, 0.9)	57 (2.5), 0.71 (0.5, 0.9)
Herpes zoster	49 (3.0), 1.10 (0.8, 1.5)	114 (5.0), 1.48 (1.2, 1.8)
Serious infections	97 (5.9), 2.18 (1.8, 2.2)	149 (6.6), 1.88 (1.6, 2.2)
All-cause mortality	26 (1.6), 0.57 (0.4, 0.8)	57 (2.5), 0.71 (0.5, 0.9)

*Positively adjudicated MACE/VTE.
AE, adverse event; ASTE, arterial systemic thromboembolism; CI, confidence interval; EAIR, exposure-adjusted incidence rate; FIL100/200, filgotinib 100/200 mg; MACE, major adverse cardiovascular event; NMSC, nonmelanoma skin cancer; PYE, patient-years of exposure; RA, rheumatoid arthritis; VTE, venous thromboembolism.

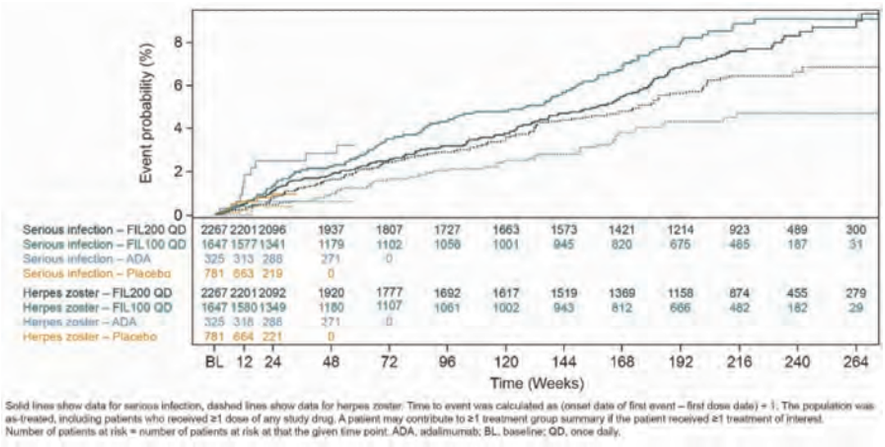

Figure. Event probability of serious infection and herpes zoster

Results: The as-treated population included 3691 patients with 12,541 PYE. Median (max) exposure was 3.8 (8.3) in the pooled FIL group; 3.8 (8.3) years for FIL200 and 3.3 (7.8) years for FIL100. Baseline demographics and disease characteristics were balanced between groups.[2] Small numerical differences were observed between FIL doses for EAIRs of selected AEs. Numerically higher incidences of NMSC, herpes zoster and all-cause mortality were reported with FIL200 vs FIL100; incidences of MACE and serious infections were numerically lower with FIL200 vs FIL100, with overlapping confidence intervals (**Table**). Over 240 weeks, the risks of MACE and VTE were comparable for FIL100 vs FIL200; low event numbers make interpretation difficult. The risk of herpes zoster was higher with FIL200 vs FIL100, and generally similar for serious infection or all-cause mortality (**Figure**).

Conclusion: Over a maximum of 8.3 years, FIL200 and FIL100 continued to show small numerical differences in EAIRs of selected AEs between dose groups in the overall RA population. Slightly higher incidence rates for NMSC, herpes zoster and all-cause mortality were reported in the FIL200 than FIL100 group, with a higher incidence of MACE and serious infections with the lower dose; confidence intervals overlapped between the dose groups.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

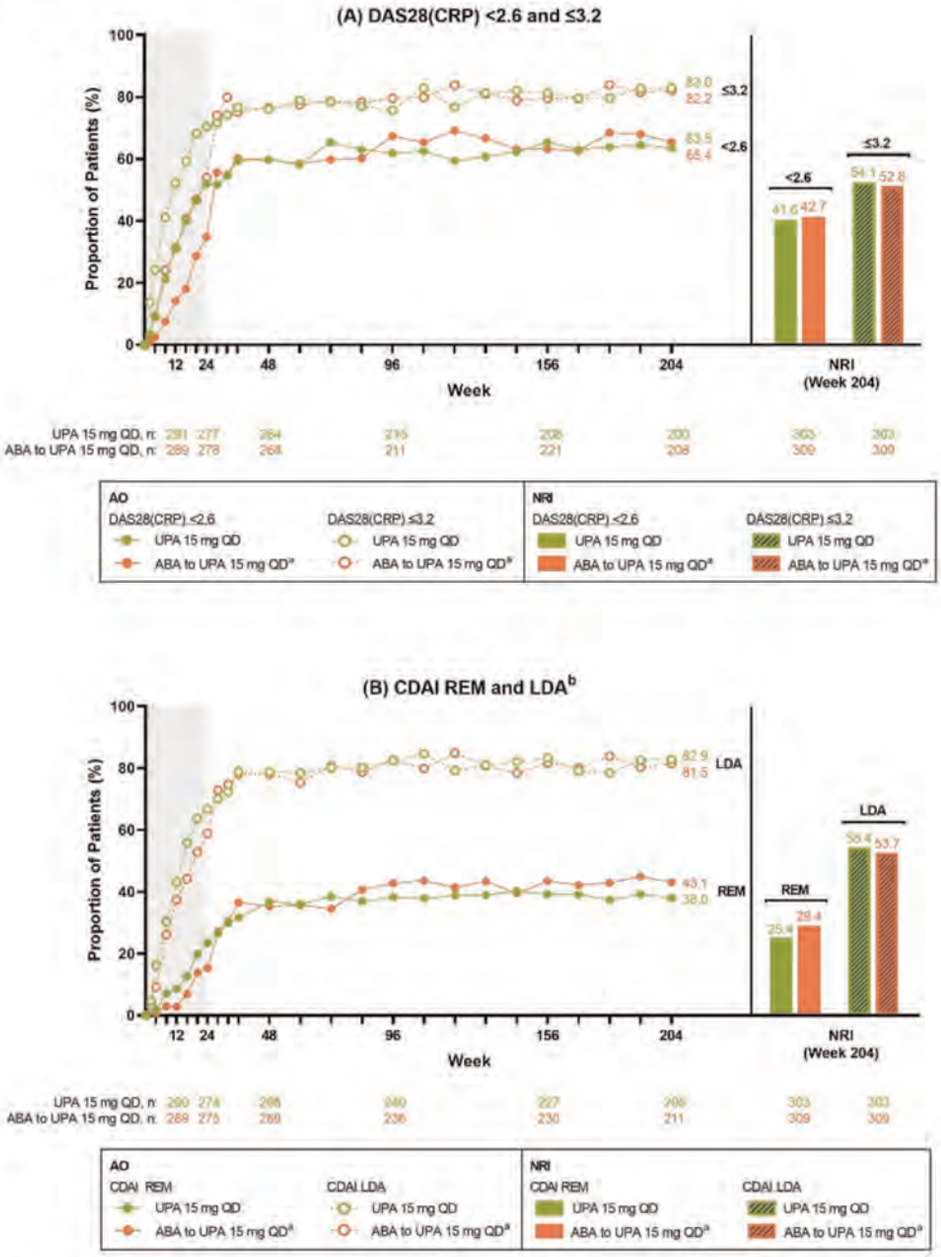
Background/Purpose: To evaluate the long-term safety and efficacy of upadacitinib (UPA), an oral JAK inhibitor, through week 204 in patients with RA from the long-term extension (LTE) of the SELECT-CHOICE study.

Methods: In SELECT-CHOICE (period 1: 24-week, phase 3, double-blind), RA patients refractory to biologic DMARDs were randomized to either upadacitinib 15 mg (UPA15) once daily or intravenous abatacept (ABA).[1] In period 2, open-label LTE patients initially randomized to ABA were switched to UPA15 at week 24, while patients initially randomized to UPA15 continued to receive UPA15 for up to 4 years. Efficacy endpoints, including patient-reported outcomes (PROs) through week 204, were analyzed using as observed (AO) and NRI for binary endpoints or descriptive statistics based on AO and mixed-effect model repeated measures (MMRM) for continuous endpoints. Treatment-emergent adverse events (TEAEs) are summarized through week 204.

Results: In total, 304 patients were randomized to UPA15; 278 (91.4%) patients completed week 24 and 277 (91.1%) continued to the LTE. Of the 309 patients randomized to ABA, 277 (89.6%) patients completed week 24 and entered the LTE. Of the patients who entered the LTE on UPA15 (n=547), 151 (27.6%) patients discontinued UPA15 treatment, with the most common reasons being adverse event (9.1%), withdrawal of consent (5.9%), and other reason(s) (7.3%). Of patients on continuous UPA15, a high proportion achieved DAS28(CRP) < 2.6 or ≤3.2, which was maintained or further improved through week 204 (< 2.6: 63.5%; ≤3.2: 83.0%) (AO) (**Figure 1A**). Greater than one-third of patients achieved CDAI remission (38.0%) and over 80% achieved LDA (82.9%) at week 204 (AO) (**Figure 1B**); similarly, 36.5% of patients achieved SDAI remission and 82.2% achieved LDA (AO) (**Table 1**). At week 204, 90%/75%/58% of patients achieved ACR20/50/70 responses (AO). Boolean remission was achieved at week 204 by 26.7% (95% CI: 20.7, 32.7) of patients (AO); more conservative estimates using NRI showed similar results (19.1% [14.7, 23.6]). Mean change from baseline in HAQ-DI was -0.84 and the patient's assessment of pain was -44.7 at week 204 (AO). Across all efficacy endpoints, similar results were observed in patients who switched from ABA to UPA15, compared to those who continued UPA15. Patients with an inadequate response to ≥1 prior anti-TNF (UPA15: n=263; ABA to UPA15: n=273) showed similar responses to the overall population (data not shown). No new safety risks were identified with long-term exposure to UPA15 in patients with RA through week 204 (**Table 2**). A total of 24 deaths occurred; 18 deaths were treatment-emergent, of which 9 were related to COVID-19.

Conclusion: Efficacy responses with UPA15 were maintained over time, including DAS28(CRP) < 2.6 and ≤3.2, CDAI and SDAI remission and LDA, ACR20/50/70 responses, and PRO outcomes.[1] The safety profile of UPA through week 204 is consistent with previous findings[1] and the broader RA clinical program. These data further support the long-term safety and efficacy of UPA for the treatment of patients with RA.

Figure 1. Proportion of Patients Achieving **(A)** DAS28(CRP) <2.6 or ≤3.2 and **(B)** CDAI REM or LDA Through Week 204 (AO, NRI)



ABA, abatacept; AO, as observed; LDA, low disease activity; QD, once daily; REM, remission; UPA, upadacitinib.
[a]Patients randomized to ABA were switched to UPA 15 mg QD at week 24; shading indicates treatment with ABA.
[b]CDAI REM defined as ≤2.8; CDAI LDA defined as ≤10.

Table 1. Efficacy Endpoints at Week 204 With UPA15 or ABA Switched to UPA15 (AO, NRI or MMRM)

Endpoint	UPA 15 mg QD		ABA to UPA 15 mg QD[a]	
Proportion of patients, % (95% CI)	AO	NRI	AO	NRI

ABA, abatacept; AO, as observed; CI, confidence interval; LDA, low disease activity; MMRM, mixed effect model repeated measurement; QD, once daily; UPA, upadacitinib.
[a]Patients randomized to ABA were switched to UPA 15 mg QD at week 24.

Table 2. TEAEs in Patients Treated With UPA15 Through Week 204[a]

E/100 PY (95% CI)	UPA 15 mg QD[b] n=579; PY=1833.3
Overall TEAEs	
Any AE	226.1 (219.3, 233.1)
Any serious AE	12.8 (11.2, 14.5)
Any AE leading to discontinuation of study drug	4.2 (3.3, 5.2)
All deaths[c]	1.3 (0.8, 1.9)
≤30 days after last dose of study drug	1.0 (0.6, 1.6)
>30 days after last dose of study drug	0.3 (0.1, 0.7)
TEAEs and AEs of Special Interest	
Any infection	72.7 (68.9, 76.7)
Serious infection	3.5 (2.7, 4.5)
Opportunistic infection[d]	0.2 (0.0, 0.5)
Herpes zoster	4.0 (3.2, 5.1)
COVID-19	8.8 (7.5, 10.3)
COVID-19 related AE	9.7 (8.3, 11.2)
GI perforation (adjudicated)	<0.1 (0.0, 0.3)
CPK elevation	4.3 (3.4, 5.4)
Malignancies (excluding NMSC)	0.8 (0.5, 1.3)
NMSC	0.4 (0.2, 0.8)
MACE (adjudicated)[e]	0.3 (0.1, 0.6)
VTE (adjudicated)[f]	0.4 (0.2, 0.8)

ABA, abatacept; AE, adverse event; CI, confidence interval; CPK, creatine phosphokinase; E, event; GI, gastrointestinal; LTE, long-term extension; NMSC, nonmelanoma skin cancer; PY, patient-year; QD, once daily; TEAE, treatment-emergent adverse event; UPA, upadacitinib.
[a]TEAEs are defined as any AE with onset on or after the first dose of study drug and ≤30 days after the last dose of study drug.
[b]Includes patients who started on UPA 15 mg and patients who switched from ABA to UPA 15 mg at week 24; one patient was randomized to UPA 15 mg but was never treated and one patient randomized to ABA entered the LTE but was never treated with UPA 15 mg.
[c]Includes non-treatment emergent deaths; a total of 24 deaths occurred (18 were treatment-emergent, of which 9 were COVID-19 related; 6 were non-treatment emergent, of which 1 was COVID-19 related).
[d]Excludes tuberculous and herpes zoster infections; no cases of tuberculosis were reported.
[e]MACE defined as non-fatal myocardial infarction, non-fatal stroke, and cardiovascular death.
[f]VTE includes deep vein thrombosis (DVT) and pulmonary embolism (PE).

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: High-dose glucocorticoids (GCs) can cause weight gain and hypertension. It is unclear whether GCs at ≤7.5mg/day prednisone equivalent ("low dose"), administered for rheumatoid arthritis (RA), do as well. Prior studies could not definitively answer this research question: Observational studies are confounded by indication, and individual randomized trials are usually underpowered for small safety signals. The objective was to assess the effects of long-term treatment with low dose GCs in RA on body weight and blood pressure by pooling individual patient data from randomized trials.

Methods: Data from five randomised controlled trials with two-year interventions were pooled.[1-5] Intervention groups received GCs at a dose of ≤7.5mg/day prednisone equivalent. Co-primary outcomes were the difference in change from baseline in a) body weight (kg) and b) mean arterial blood pressure (MAP; mmHg). A secondary outcome was difference in the change of number of administered antihypertensive drugs. Several sensitivity and subgroup analyses were conducted. All analyses were based on analyses of covariance, trial ID was included as a random effects factor to account for clustering of patients within trials. Multiple imputation was used to account for missing data under the Intention-To-Treat approach. No imputations were performed for trials with no data collected or available for the given outcome. A detailed prespecified protocol (dx.doi.org/10.17504/protocols.io.x54v9y4d1g3e/v1) with a gatekeeping procedure for statistical testing was followed. All trials originated in Europe (twelve countries), and all allowed concomitant treatment with disease-modifying antirheumatic drugs.

Results: 1,112 participants were included (mean ± SD age 61 ± 15 years; 68% female). A mean DAS28 of 4.87 ± 1.16 indicates moderate disease activity at baseline. Disability was moderate to severe with a median (interquartile range) health assessment questionnaire score of 1.38 (0.80; 2.25). 64% and 67% of patients with available data were ACPA and

Table. Changes in weight and mean arterial blood pressure in GC and control groups over two years.

Table. Bone mineral density and trabecular bone score in PPI users and non-users.

	PPI use	No PPI use	Contrast	P-value
Crude (unadjusted)				
Left femoral neck T-score	-1.24 (-1.36 to -1.13)	-1.01 (-1.12 to -0.89)	-0.24 (-0.11 to -0.37)	<0.001
Lumbar spine T-score	-0.87 (-1.06 to -0.69)	-0.64 (-0.79 to -0.48)	-0.23 (-0.05 to 0.42)	0.01
Trabecular bone score	1.28 (1.24 to 1.31)	1.30 (1.26 to 1.33)	-0.02 (-0.06 to 0.02)	0.35
Adjusted				
Left femoral neck T-score	-1.24 (-1.36 to -1.13)	-1.08 (-1.27 to -0.88)	-0.17 (-0.35 to 0.01)	0.07
Lumbar spine T-score	-0.87 (-1.06 to -0.69)	-0.62 (-0.83 to -0.41)	-0.25 (-0.47 to -0.04)	0.02
Trabecular bone score	1.28 (1.24 to 1.31)	1.27 (1.24 to 1.31)	0.00 (-0.04 to 0.04)	0.97

Numbers are estimated marginal means and 95% confidence intervals.

rheumatoid factor positive, respectively, and the median (interquartile range) disease duration was 1 year (0.42; 7). Most patients (44%) were never smokers. Baseline values for weight and MAP were 73kg ± 14 and 98mmHg ± 12; median number of antihypertensive drugs was 0 (interquartile range 0; 1). After two years, patients on GCs gained mean 1.1kg (95%CI 0.5 to 1.8; $p < 0.001$; **Table**) more weight than patients in the control groups. Both groups increased MAP by 2-3mmHg, without difference between the groups (–0.4; 95% CI –3.0 to 2.2 mm Hg; $p = 0.19$; **Table**). The change in number of antihypertensive drugs was low and similar in both groups. Results were consistent across sensitivity and subgroup analyses focusing on overweight or hypertensive patients, and when comparing GCs at 5mg/d with 7.5mg/d (data not shown).

Conclusion: We present robust evidence that low dose GCs, taken over two years for the treatment of RA, lead to about one additional kg of weight gain but do not cause changes in blood pressure.

Switching Biologics or Janus Kinase Inhibitors Is Effective in Difficult-to-treat Rheumatoid Arthritis, Regardless of Inflammation

Katsuaki Onishi[1], Yutaro Yamada[2], Tadashi Okano[2], Kenji Mamoto[2], Shohei Anno[3], Tatsuya Koike[4] and Hiroaki Nakamura[2], [1]Baba Memorial Hospital, Osaka, Japan, [2]Osaka Metropolitan University, Osaka, Japan, [3]Yodogawa Christian Hospital, Osaka, Japan, [4]Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Shirahama, Japan

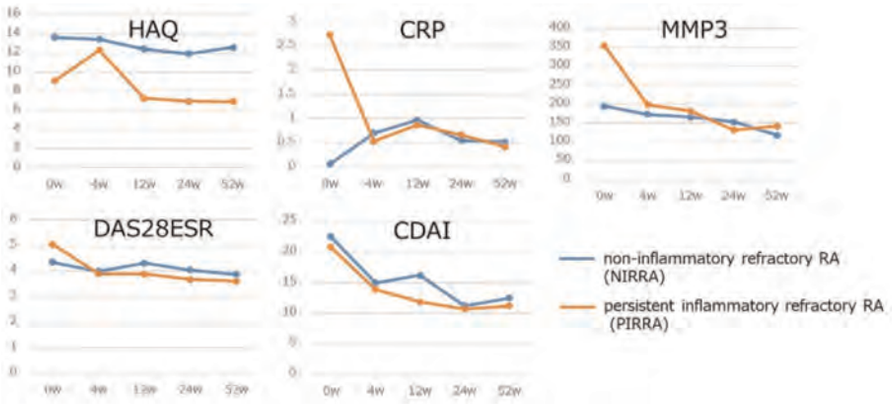
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Although biologics (BIO) or Janus kinase inhibitors (JAKi) have improved treatment for rheumatoid arthritis (RA), there are patients with difficult disease activity control even after using several BIO/JAKi, that is difficult-to-treat rheumatoid arthritis (D2TRA). D2TRA can be divided to two groups by mechanism: persistent inflammatory refractory RA (PIRRA) and non-inflammatory refractory RA with only persistent pain (NIRRA). We investigated these two different types of D2TRA.

Methods: Total of 147 patients switched to another BIO/JAKi because of inadequate response to previous BIO/JAKi and considered as D2TRA in our institution as of 2021. Patients with negative CRP and tender joint count > swollen joint count was defined as NIRRA, otherwise was defined as PIRRA. We investigated clinical characteristics and efficacy of following BIO/JAKi in both types of D2TRA for 52 weeks.

Results: Compared to NIRRA (n=33), PIRRA (n=114) showed significantly low hemoglobin (12.9 vs 12.0, p=0.02) and high DAS28ESR (4.43 vs 5.25, p=0.003) at the time of switching (baseline). There was no significant difference in MMP3 and CDAI. Retention rate at 52w also showed no difference (51.5% vs 45.6%, p=0.48). MMP3 and CDAI significantly improved during 52w in NIRRA, whereas CRP, MMP3, DAS28ESR, CDAI, and HAQ significantly improved in PIRRA. Switched BIO/JAKi consisted of IL6 inhibitors (n=7) and JAKi (n=15) in NIRRA, IL6 inhibitors (n=24) and JAKi (n=70) in PIRRA. Efficacy of switched BIO/JAKi showed no difference regardless of mechanism in both NIRRA and PIRRA.

Conclusion: MMP3 and CDAI improved after switching both in NIRRA and PIRRA. This tendency was similar whichever following BIO/JAKi was IL6 inhibitors and JAKi. Switching BIO/JAKi was effective in both types of D2TRA.



The clinical characteristics and efficacy of BIO/JAKi after switching in two types of D2TRA

R851, a Potent Second Generation IRAK1 and IRAK4 Inhibitor Suppresses IL-6 in Vitro and in Vivo for the Treatment of Rheumatoid Arthritis

Yan Chen[1], Sothy Yi[1], Vadim Markovtsov[1], Bhushan Samant[1], Andrew Chow[1], Esteban Masuda[1] and **Simon Shaw**[2], [1]Rigel Pharmaceuticals, Inc, South San Francisco, CA, [2]Rigel Pharmaceuticals, Inc., South San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The Toll-Like Receptor family (except TLR3) signal through IRAK4 and IRAK1 to produce an array of cytokines (including IL-6, IL-23 and TNFα in response to pathogen and damage associated molecular patterns (PAMPs and DAMPs).The IRAK proteins are also involved in the signaling cascade of the IL-1 receptor family; therefore, they play a critical role in innate immune response controlling chronic inflammation. As a result, inhibition of IRAK4 has been investigated as a means of attenuating a range of autoimmune diseases including rheumatoid arthritis, with zimlovisertib demonstrating encouraging results in a Phase 2 rheumatoid arthritis study. We identified R835, which has shown proof of mechanism in an LPS challenge study in healthy human volunteers. In this study we report an improved molecule R851 which has been modeled to require five-fold lower dosing for similar efficacy making it suitable for chronic indications such as rheumatoid arthritis.

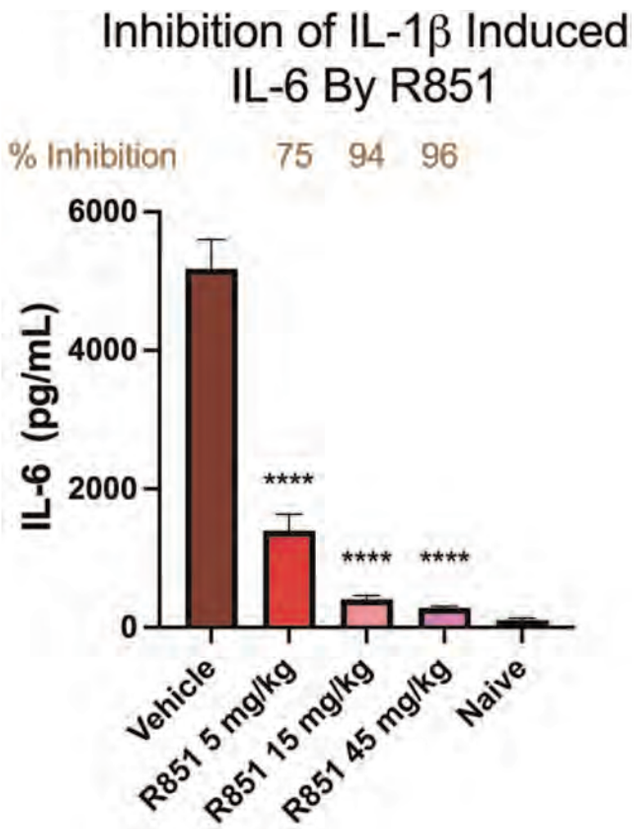

Fig A. The effect of R851 on inhibition of IL-6 production after stimulation with IL-1 in Balb/c mice.

Methods: Prioritizing inhibition of TLR signaling in a cell-based assay in conjunction with IRAK4 biochemical inhibition, we identified a series of potent and selective dual IRAK1 and IRAK4 inhibitors. The results suggested that dual IRAK1/4 inhibition results in a more effective inhibition of TLR signaling than IRAK4 alone. Having identified R835, we undertook a retrospective analysis of our IRAK1/4 inhibitor portfolio to identify R851.

Results: Our first molecule R835, currently being developed for low-risk myelodysplastic syndrome, demonstrated robust efficacy in a number of animal models including a collagen induced arthritis model.R835 not only inhibited disease when dosed prophylactically but also reversed symptoms when dosing was initiated after onset of disease. In the clinic, R835 showed dose-dependent, linear PK and proof of mechanism in humans. While R835 is a promising IRAK1/4 inhibitor with clinical potential, we hoped to identify an alternative molecule with favorable pharmacokinetic characteristics and increased potency for chronic autoimmune indications such as rheumatoid arthritis. A retrospective analysis of the data from the IRAK1/4 inhibitors generated over the program led to R851, a molecule from the R835 scaffold that showed improved potency in both cellular and biochemical assays. Further, R851 demonstrated 7-10 fold improvement in potency in our whole blood assays, driven by reduced plasma protein binding. Building on our understanding of the scaffold we expect R851 to require 5-fold less exposure for a similar effect to R835.The compound has been taken through PK studies across species demonstrating a dose-dependent, linear and predictable PK profile in multiple day dosing. In vivo, R851 shows a robust inhibition of IL-6 after IL-1β stimulation (**Fig. A**) which is expected to translate into efficacy in chronic models.

Conclusion: Using the knowledge gained in the development of R835, we have identified R851 as a second generation dual IRAK1 and IRAK4 inhibitor. The increased potency in whole blood assays is believed to be driven by a reduction in protein binding. We predict that R851 will require a significantly lower exposures for efficacy in humans which should position this molecule for a chronic condition like rheumatoid arthritis.

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The optimal first-line treatment of patients with early rheumatoid arthritis (eRA) is not established.

Methods: In this investigator-initiated, randomized, open-label study (NCT01491815), patients with treatment-naïve eRA with DAS28 >3.2 and RF+/ACPA+/CRP >10mg/L, were randomized 1:1:1:1 to methotrexate (MTX) combined with: 1) oral prednisolone (tapered quickly; discontinued at w36); or: sulphasalazine, hydroxychloroquine and mandatory intra-articular (IA) glucocorticoid injections in swollen joints (ACT); 2) certolizumab-pegol (CZP); 3) abatacept (ABA) or 4) tocilizumab (TCZ). IA glucocorticoid was allowed in all arms except during w20-24 and w44-48. The primary outcome Clinical Disease Activity Index (CDAI) remission and key secondary outcomes at 24 weeks have previously been published (Hetland ML et al, BMJ 2020;371:m4328). Differences between ACT and each of the 3 biological therapies for PRO (pain, patient´s global assessment, HAQ-DI, fatigue (VAS and FACIT) at 48 weeks were tested and descriptive data presented with 95% CI. Longitudinal data points were analyzed using a linear mixed model analysis. The continuous and dichotomous PRO data were adjusted for country, sex and anti-citrullinated protein antibody status. For continuous data, additional adjustment included baseline values of PRO endpoint and treatment arm and time as well as their interaction as categorical covariates.

Table 1. Baseline characteristics for clinical data and 48-week values for selected PROs.

Demographics/baseline characteristics		ACT (n=200)	CZP+MTX (n=203)	ABA+MTX (n=204)	TCZ+MTX (n=188)[§]

	48 weeks	19.9 (17.1, 22.7)	16.0 (13.2, 18.7)	15.6 (12.9, 18.2)	16.2 (13.3, 19.1)
HAQ-DI	0 weeks	1.04 (0.99, 1.09)	1.04 (0.99, 1.09)	1.04 (0.99, 1.09)	1.03 (0.98, 1.08)
	48 weeks	0.30 (0.25, 0.35)	0.27 (0.22, 0.32)	0.27 (0.22, 0.32)	0.23 (0.17, 0.28)
Fatigue (VAS, mm)	0 weeks	51.6 (48.6, 54.6)	51.6 (48.6, 54.6)	51.5 (48.6, 54.5)	51.0 (47.9, 54.2)
	48 weeks	25.8 (22.5, 29.0)	20.4 (17.2, 23.5)	20.7 (17.6, 23.8)	19.8 (16.4, 23.2)
Fatigue, FACIT score	0 weeks	18.3 (17.5, 19.1)	18.3 (17.6, 19.1)	18.3 (17.6, 19.1)	18.3 (17.5, 19.1)
	48 weeks	12.2 (11.3, 13.0)	11.5 (10.6, 12.3)	11.2 (10.4, 12.1)	11.3 (10.4, 12.2)

[#]Values are mean (95% CI), if not otherwise indicated, adjusted for country, sex, anti-citrullinated protein antibody status and baseline values of respective PRO endpoint. Bold values show non-overlapping 95% CI vs ACT. ITT: Intention-to-treat population.

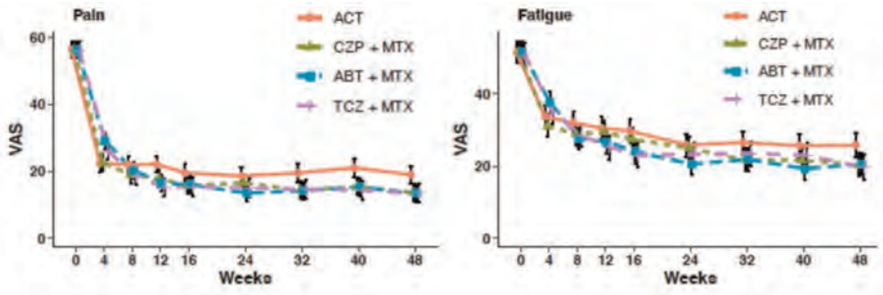

Figure 1. Longitudinal values of pain and fatigue stratified by treatment arms. The values are mean (95% CI)

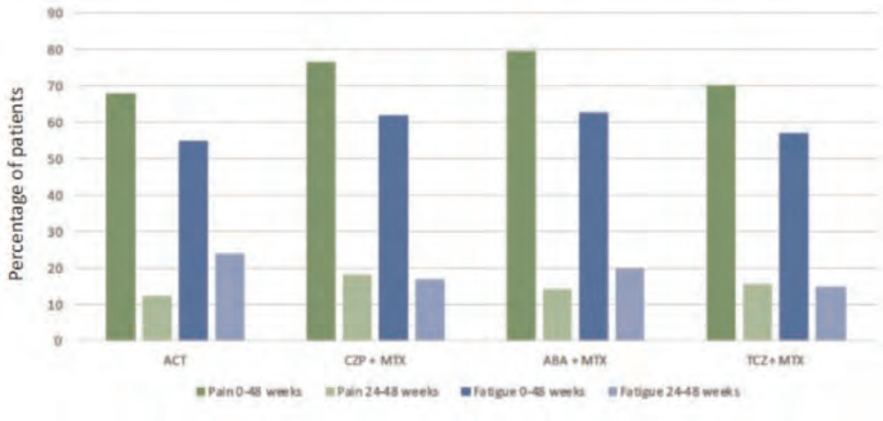

Figure 2. Patients reporting improvement ≥ Minimal Clinical Important Difference for pain and fatigue

MCID for pain and fatigue were defined as: ≥ 10-point decrease for VAS pain (Strand V et al; J Rheumatol 2011;38;1720-7) and ≥10-point decrease for VAS Fatigue (Wells et al, J Rheumatol 2007:34(2);280-9), respectively.

Results: 812 patients were randomized. Baseline characteristics and adjusted baseline and 48-week PRO data are shown in table 1. In the longitudinal analysis there was a trend for greater improvement of pain and fatigue in biological groups compared to ACT (figure 1). Adjusted for baseline values, pain levels and physician global assessment were numerically lower in all biological groups compared to ACT at week 48. The percentage of patients reporting improvements above MCID for pain and fatigue (from baseline until 48 weeks) were numerically higher in biological arms compared to ACT (% and 95% CI), as follows: MCID for pain: ACT 68% (61, 74); CZP+MTX 77% (71, 82); ABA+MTX 80% (74, 85); TCZ+MTX 70% (64, 77); and for fatigue: ACT 55% (48, 62); CZP+MTX 62% (55, 69); ABA+MTX 63% (56, 69); TCZ+MTX 57% (59, 64) (figure 2).

Conclusion: All four different modes of action lead to marked improvements of PROs after 48 weeks. Compared with csDMARD+glucocorticoid treatment pain levels were lower in all biological arms at week 48. Likewise, the percentages of patients with clinically important improvements for pain and fatigue were numerically higher in the treatment arms with biological vs. conventional treatment.

Abstract Number: 1331

Long-term Effectiveness of a Lifestyle Program for Rheumatoid Arthritis: One-year Follow-up of the "Plants for Joints" Randomized Clinical Trial

Carlijn Wagenaar[1], Wendy Walrabenstein[1], Marike Van der Leeden[2], Franktien Turkstra[2], Jos W.R. Twisk[1], Maarten Boers[1], Henriët van Middendorp[3], Peter Weijs[4] and Dirkjan van Schaardenburg[5], [1]Amsterdam University Medical Centers, Amsterdam, Netherlands, [2]Reade Rheumatology Center, Amsterdam, Netherlands, [3]Leiden University, Leiden, Netherlands, [4]Amsterdam University of Applied Sciences, Amsterdam, Netherlands, [5]Reade, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The 16-week Plants for Joints (PFJ) multidisciplinary lifestyle program, based on a whole-food plant-based diet, physical activity, and stress management, significantly reduced 28-joint Disease Activity Score (DAS28) compared to usual care in people with rheumatoid arthritis (RA).[1,2] The objective was to determine the long-term effectiveness of the PFJ lifestyle program on disease activity in people with RA.

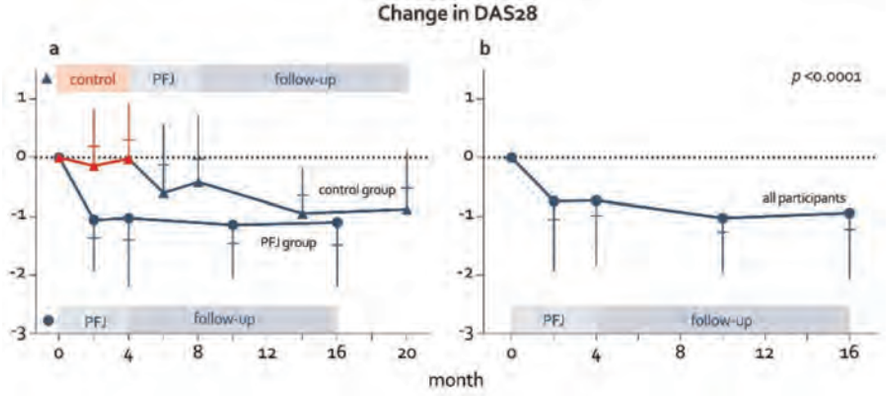

Figure 1. Mean change in DAS28 (a) during the randomized controlled trial phase and one-year follow-up period per trial arm and (b) for the whole cohort before and after completing the lifestyle intervention and one year follow-up.

Table 1. Plants for Joints cohort at start and end of the 16-week intervention period as well as during the one year extension study (6 and 12 months after completing the intervention). Continuous variables reported as mean (SD) when normally distributed or as median [IQR] when skewed. Within-group difference shown between start of the lifestyle intervention and end of the 12-month follow-up determined using the linear-mixed model when model assumptions were met. For variables in which model assumptions were not met (†) a linear-mixed model was performed after log transformation and within group differences were reported as median difference of complete paired values determined using a Wilcoxon test (p-values from the linear mixed model are shown, all were similar to the Wilcoxon test). ESR = Erythrocyte sedimentation rate.

	Intervention			Extension study		Within group	
	Start	Halfway	End	6 months	12 months	difference (95% CI)	*p-value*

Diastolic blood pressure (mmhg)	86	85	84	85	86	−0.4 (−3.1 to 2.2)	0.8

Methods: In the PFJ assessor-blind randomized clinical trial, people with RA (DAS28 ≥ 2.6 and ≤ 5.1) were randomized to receive the PFJ program in addition to usual care, or the control group which received usual care. After this 16-week period the control group also received the program. After completion of the program all participants were followed-up for one year with biannual visits and six adherence-promoting webinars. Participants with a DAS28 < 2.6 were instructed to taper antirheumatic medication following a pre-specified protocol. Medication changes were assessed at one year as an "increase," "stable," or "decrease" compared to baseline by an independent committee. Secondary outcomes included anthropometric and metabolic markers. An intention-to-treat analysis with a linear mixed model was used to analyze within-group differences.

Results: 65 (84%) of the 77 participants, who completed the initial 16-week clinical trial, completed the one-year follow-up. 92% of participants were female with a mean (SD) age of 55 (12) and body mass index of 26 (4) kg/m^2. In the year after the PFJ program the DAS28 continued to improve slightly whereby a within-group difference of –0.9 points was observed after one year compared to baseline ($p < 0.0001$) (Figure 1). All components of the DAS28 improved significantly compared to baseline (Table 1). Of the 56 participants who completed the follow-up and used disease modifying anti-rheumatic medication, 27 (48%) decreased or stopped, 16 had stable, and 13 had increased medication. 45 participants (58%) improved DAS28 scores (20 with DAS28 < 2.6) with stable or less medication compared to baseline. After the 1-year follow-up period waist circumference, LDL cholesterol, and CRP remained significantly lower than baseline values, although there was no longer a significant difference in weight or HbA1c.

Conclusion: The PFJ lifestyle program significantly decreased disease activity in people with RA and its effects were sustained till one year after program completion with on average slightly less antirheumatic medication. Metabolic benefits found after the lifestyle intervention were only partially sustained, possibly indicating attenuated adherence to the program in the follow-up.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The efficacy of filgotinib (FIL) for treating RA has been demonstrated in clinical trials. Real-world data are valuable to assess patient-reported outcomes such as pain, fatigue and work productivity, which are negatively impacted by RA.

Methods: FILOSOPHY (NCT04871919) is an ongoing Phase 4, prospective, observational, European study that will enroll ~1500 patients aged ≥18 years with moderate to severe active RA, prescribed FIL for the first time and in accordance with the product label in general practice. At Week 1, 2 and 3 and Month 1, 3, 6, 9 and 12, we assessed the proportion of patients with clinically meaningful change from baseline in pain (reduction of ≥ 10 on a visual analog scale [VAS]) and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue score (increase of ≥ 4) in advanced therapy (AT)-naïve and -experienced patients. AT-naïve patients had received no prior biologic (b) or targeted synthetic (ts) disease modifying anti-rheumatic drugs (DMARDs) for RA; AT-experienced patients had received ≥ 1 prior bDMARD or tsDMARD for RA. Work productivity was also assessed at these timepoints using the Work Productivity and Activity Impairment Questionnaire. DAS28-CRP was assessed at baseline and Month 1, 3, 6 and 12. Adverse events (AEs) were recorded.

Results: As of Jan 31, 2023, 798 patients had been treated; baseline characteristics are presented in the **Table**. 53.6% of patients received FIL monotherapy and 37.3% FIL + MTX. 38.2% were AT naïve; 61.8% were AT experienced.

Pain and fatigue improved as early as Week 1. At Week 1, 40.0% of AT-naïve and 48.5% of AT-experienced patients had a clinically meaningful change in VAS pain score (**Figure 1A**); 44.0% of AT-naïve and 42.9% of AT-experienced patients had a clinically meaningful change from baseline in FACIT-Fatigue (**Figure 1B**). Clinically meaningful changes in pain and FACIT-Fatigue were maintained until Month 12. Improvements in pain and fatigue were accompanied by changes in work productivity and time spent on daily activities, which increased from as early as Week 1, with further improvements observed until Month 12. Mean (SD) absenteeism decreased between baseline (23.5 [34.1]) and Month 1 (17.0 [30.3]) (**Figure 2**).

Median DAS28-CRP decreased after 1 month, and decreases were maintained through Month 12. Least squares mean change (SE) from baseline in DAS28-CRP was –1.4 (0.1) to Month 1 and –1.9 (0.1) to Month 12. 43 patients (5.4%) discontinued treatment due to AEs. AEs were mainly infections, including COVID-19 (11.0%), herpes zoster (1.0%), active

*Data for RF or ACPA status are missing for 364 participants (45.6%); †Data are missing for 203 participants (25.4%); ‡Data are missing for 17 patients (2.1%).
ACPA, anticitrullinated protein antibody; (b/cs/ts)DMARD, (biologic/conventional synthetic/targeted synthetic) disease-modifying antirheumatic drug; CDAI, Clinical Disease Activity Index; CNS, central nervous system; DAS28-CRP, Disease Activity Score in 28 joints using C-reactive protein; FIL, filgotinib; RA, rheumatoid arthritis; RF, rheumatoid factor; SD, standard deviation; SJC28, swollen joint count based on 28 joints; TJC28, tender joint count based on 28 joints; VAS, visual analog scale.

tuberculosis (0.1%) and opportunistic infections (0.1%). The reported cardiovascular events included stroke (0.5%), transient ischemic attack (0.5%) and unstable angina (0.3%). Neoplasms (excluding NMSC) were reported in 0.8% and fractures in 0.9% of patients. There were 2 deaths.

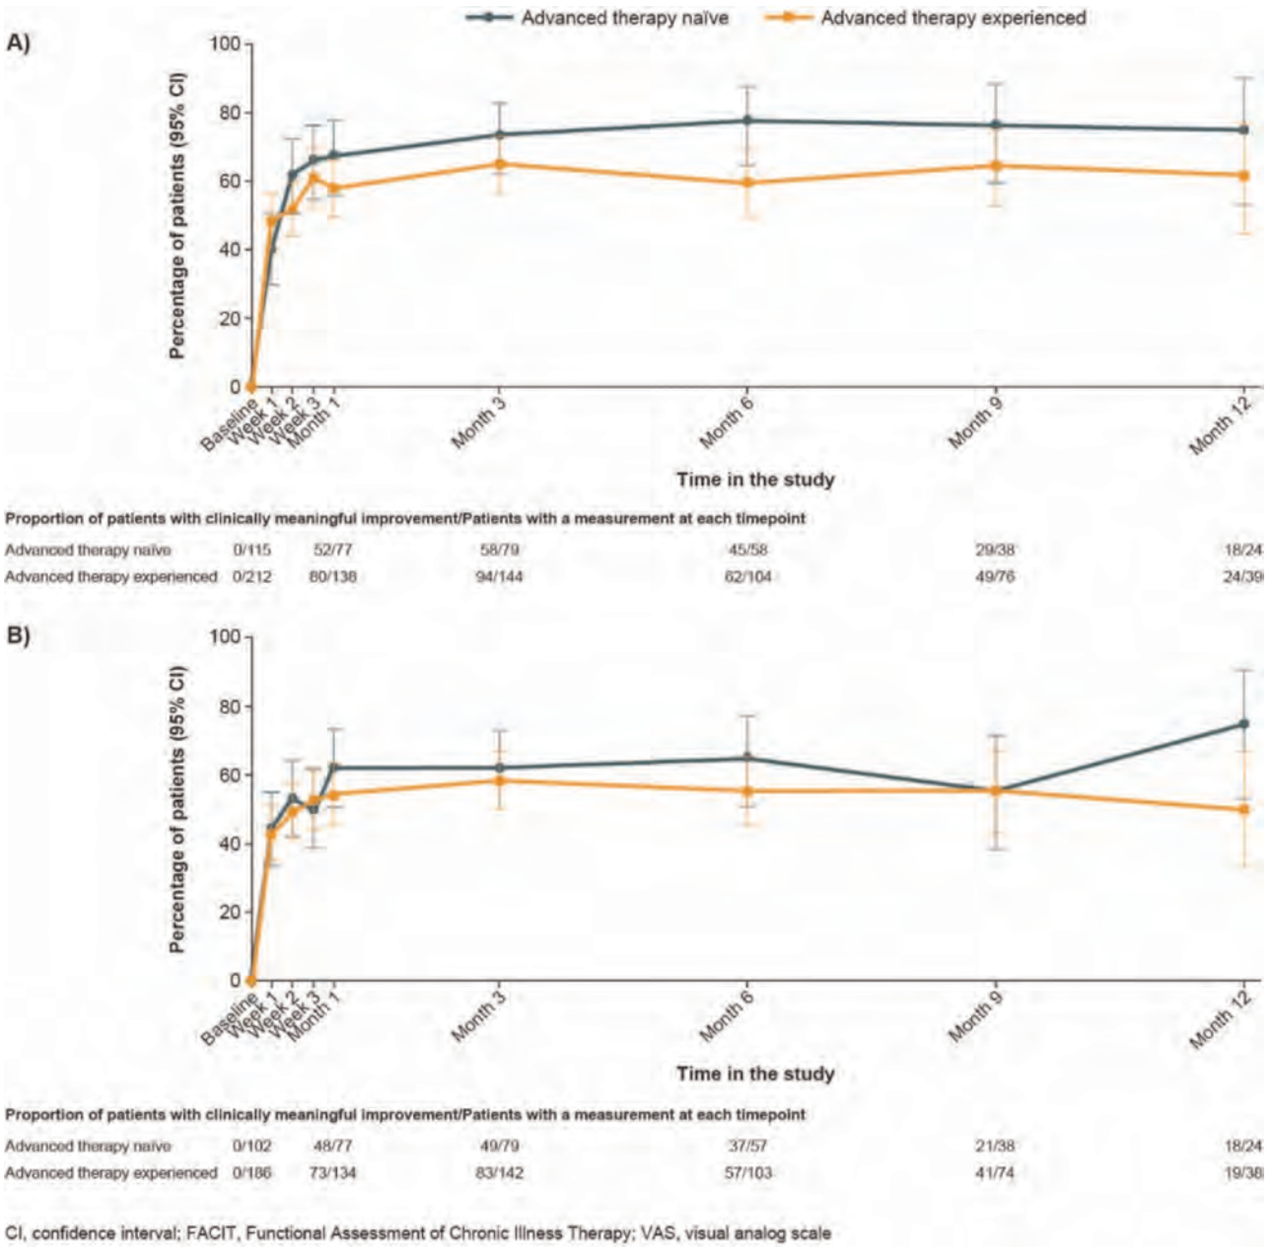

Figure 1. Proportion of patients with a clinically meaningful improvement from baseline in (A) VAS pain score and (B) FACIT-Fatigue score

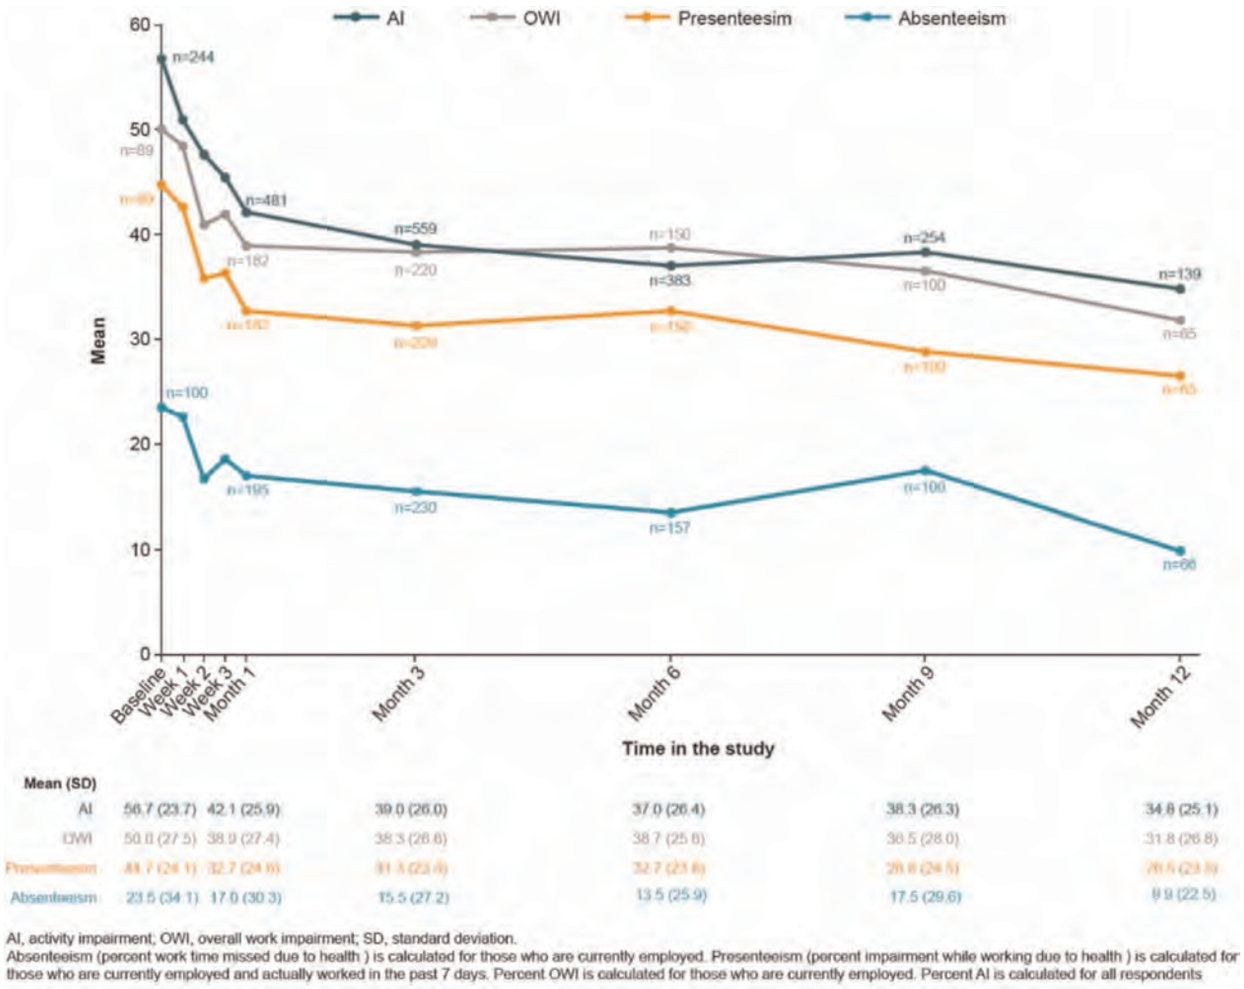
Conclusion: Interim data from patients treated with FIL show pain, fatigue and work productivity improved as early as Week 1 and DAS28-CRP as early as Month 1, the first timepoint at which DAS28-CRP was assessed; improvements were maintained up to Month 12. No new safety findings were observed up to 12 months. Long-term follow-up is needed to further evaluate effectiveness and safety.



Mean (SD)						
AI	56.7 (23.7)	42.1 (25.9)	39.0 (26.0)	37.0 (26.4)	38.3 (26.3)	34.8 (25.1)

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The largest multi-center collaborative study on lymphoproliferative disorders (LPD) in rheumatoid arthritis (RA) (RA-LPD) in Japan was conducted to characterize its clinical outcomes and identify suitable treatments.

Methods: Patients with RA who developed LPD between January 1999 and March 2021 were retrospectively analyzed in a multicenter collaborative study across 48 hospitals in Japan. Significant differences were evaluated using Fisher's exact test, the Mann-Whitney U-test, the Log-rank test, and a multivariate analysis with the Cox proportional hazard model. Significance was set at $p < 0.05$.

Results: Clinical outcomes of RA-LPD A total of 752 RA-LPD patients were enrolled. Their clinicopathological characteristics were presented at the ACR Convergence 2022. As shown in Figure 1, among 438 patients, 81.4% spontaneously regressed after the withdrawal of immunosuppressive agents, while 32.0% showed regrowth after a median of 12 months (range: 1-92). Among the 439 patients treated with first-line therapy, 365 (77.8%) achieved a complete or partial response to first-line therapy. The 5-year overall survival (OS) rate was 86.3%. The multivariate analysis identified an advanced clinical stage, Hodgkin lymphoma as independent regrowth after spontaneous regression, an older age (>70 years), the T cell phenotype, and a sIL-2R level >1300 U/mL as independent unfavorable prognostic factors. Necessity for re-biopsy in patients with regrowth or relapse Eight patients with RA-LPD developed different histological subtypes after the regression or

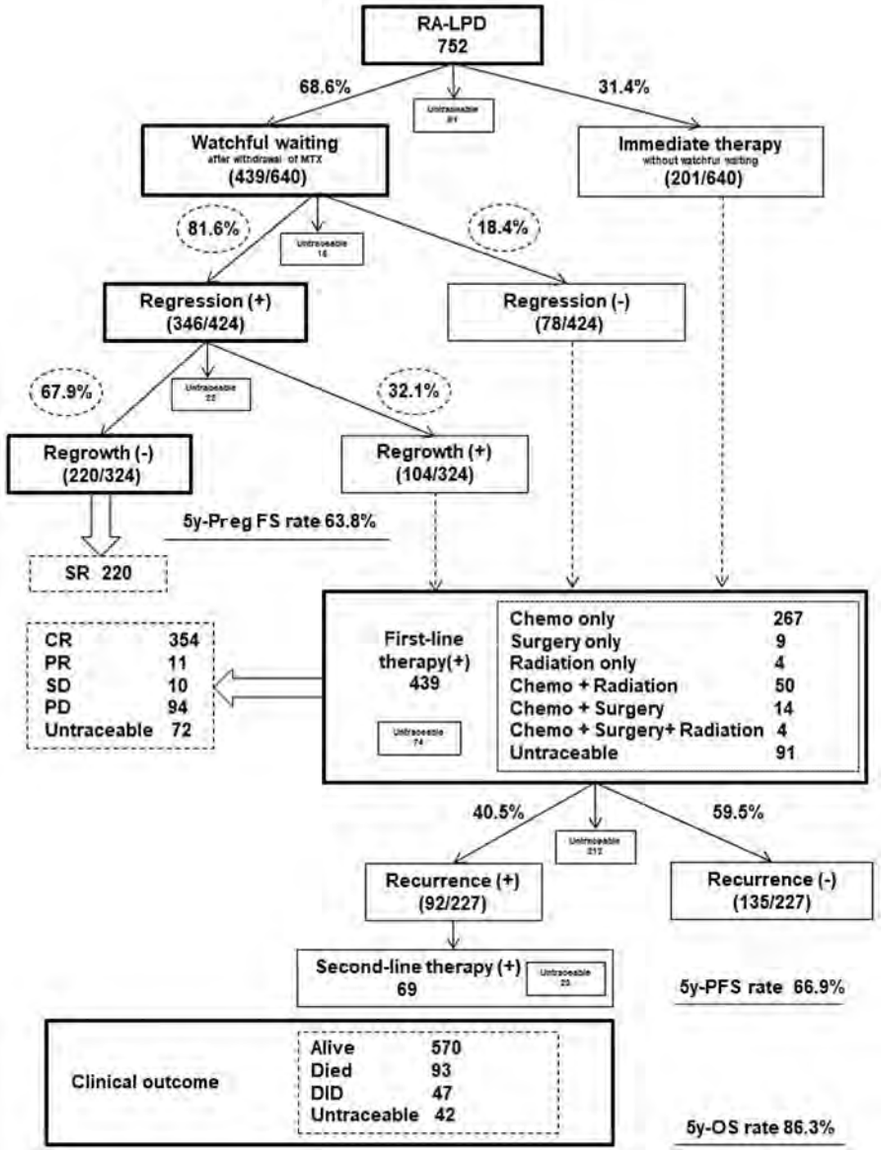

Figure 1. The clinical course of RA-LPD. Among 752 patients with RA-LPD, 68.5% spontaneously regressed after the withdrawal of immunosuppressive agents. Among them, 81.4% showed tumor regression, while 32.0% showed regrowth with a median of 12 months (range: 1-92).

Figure 2. The clinical course after LPD onset

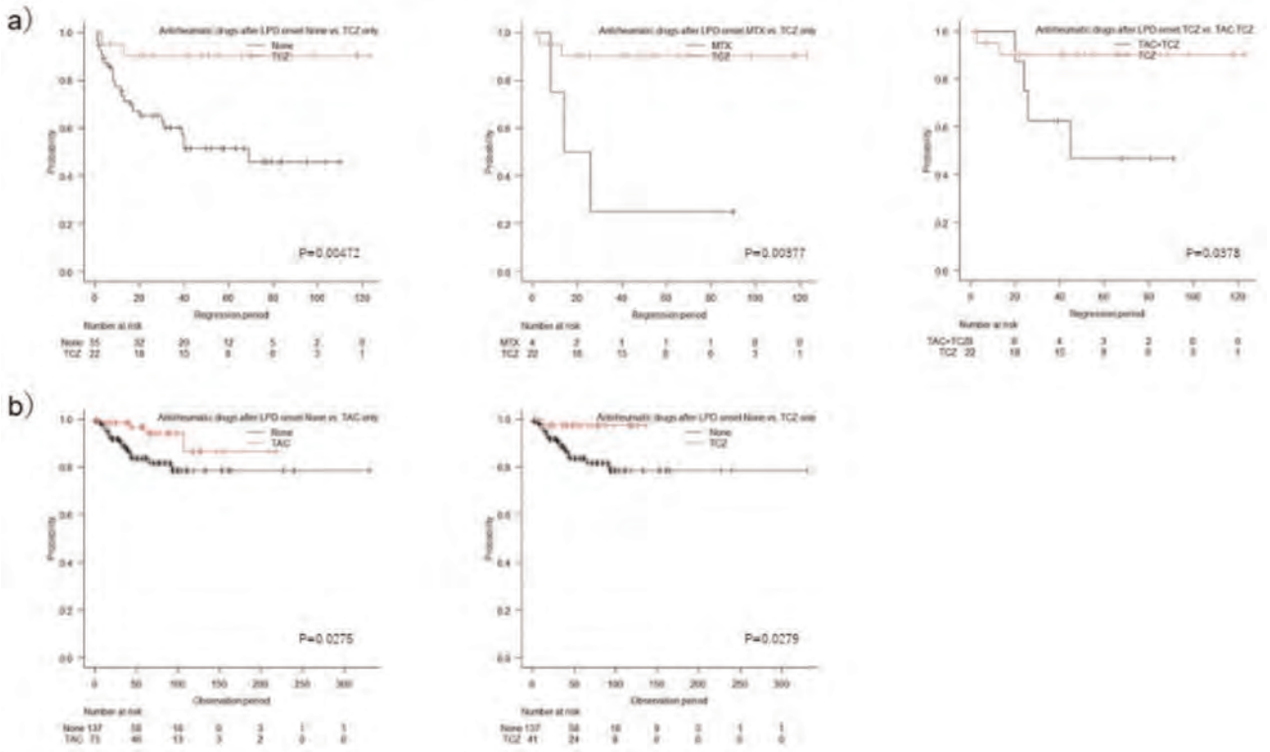

Figure 2. Kaplan-Meier curves of RA-LPD according to antirheumatic drugs administrated after the onset of LPD. a). PSRFS curve of RA-LPD. The rate of spontaneous regression was significantly higher in the TCZ only group than in the none, MTX only, and TCZ plus TAC groups. b) OS curve of RA-LPD. The prognosis of patients after the onset of LPD was better in the TAC only and TCZ only groups than in the none group.

Table 1. Summary of eight patients who developed different histological subtypes after the regression or remission of RA-LPD.

No.	Sex	Age at first LPD onset (y)	Therapy for RA after first LPD onset	Periods from primary LPD to secondary LPD (m)	First LPD		Secondary LPD	First LPD		Secondary LPD	First LPD		Secondary LPD	First LPD		Secondary LPD	Follow-up periods (m)	Outcome

RA-LPD: Rheumatoid arthritis-associated lymphoproliferative disorders; y: Year; m: Month; EBER-1: Epstein-Barr virus-encoded small RNA-1; F: Female; M: Male; MTX: Methotrexate; SASP: Salazosulfapyridine; TAC: Tacrolimus; EBVMCU: Epstein-Barr virus-positive mucocutaneous ulcer; AITL: Angioimmunoblastic T-cell lymphoma; HL-like lesion: Hodgkin lymphoma-like lesion; FL: Follicular lymphoma; P-LPD: Polymorphic lymphoproliferative disorders; HL: Hodgkin's lymphoma; DLBCL: Diffuse large B-cell lymphoma; TRBCL: T-cell rich B-cell lymphoma; MALToma: Mucosa-associated lymphoid tissue lymphoma; LN: Lymph node; CHOP: (C: Cyclophosphamide; H: Doxorubicin Hydrochloride; O: Oncovin; P: Prednisolone); R: Rituximab; A-AVD: ADCetris (brentuximab vedotin)-Adriamycin (doxorubicin) Vinblastine Dacarbazine; ABVD: Adriamycin Bleomycin Vinblastine Dacarbazine; R-GDP:Rituximab + GEM + Dexamethasone + CDDP; RT: radiotherapy; Hyper-CVAD: (C: Cyclophosphamide; V: Vincristine sulfate; A: Adriamy hydroxydaunorubicin Hydrochloride; D: Dexamethasone); MA: MTX+Ara-c; HP: Helicobacter Pylori.

remission of RA-LPD. Among them, 6 patients (5.7%) showed regrowth after temporary tumor regression following the withdrawal of methotrexate (MTX), and 2 (2.2%) relapsed during temporary remission after chemotherapy. The tumor-related death rate was significantly higher in these patients (62.5%) than in those who developed LPD with the same histology (24.6%) (p=0.030) (Table 1). Therefore, re-biopsy is required for patients with regrowth or relapse. Recommended antirheumatic drug regimens after LPD onset The effects of antirheumatic drugs administered after the onset of LPD on the clinical outcomes of RA-LPD were examined in 393 patients with the relevant information available. The trastuzumab (TCZ) only group maintained a significantly higher rate of spontaneous regression than the none, MTX only, and TCZ plus tacrolimus (TAC) groups (Figure 2a). The prognosis of patients after the onset of LPD was better in the TAC only and TCZ only groups than in the none group, which included patients who had never been treated with MTX, TAC, TCZ, tumor necrosis factor inhibitors, abatacept, or a Janus-activating kinase inhibitor (Figure 2b).

Conclusion: The present study showed the clinical outcomes of RA-LPD and identified independent factors associated with post-spontaneous regression (SR)-free survival (PSRFS) and overall survival. Based on the results obtained, TCZ only regimens are recommended after the onset of LPD and re-biopsy is required for patients with regrowth or relapse.

Comparison of Malignancies and Serious Infections Between Etanercept Biosimilar and Bio-Originator Initiators: Population-Based Analyses

Marina Birck[1], Luck Lukusa[2], Michal Abrahamowicz[3], Gilles Boire[4], Denis Choquette[5], **Walter P. Maksymowych**[6] and Sasha Bernatsky[1], [1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [2]RI-MUHC, Montreal, QC, Canada, [3]McGill University, Verdun, QC, Canada, [4]Université de Sherbrooke, Sherbrooke, QC, Canada, [5]Centre hospitalier de l'Université de Montréal (CHUM), Université de Montréal, Montréal, QC, Canada, [6]University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment safety, particularly malignancy and infections, is an important issue for biologics; hence, surveillance and analyses comparing biosimilar versus bio-originator use in the real world are needed. We aimed to compare malignancy and serious infections among initiators of etanercept originator (ETA-O) versus biosimilar (ETA-B), all users and rheumatoid arthritis (RA) specific.

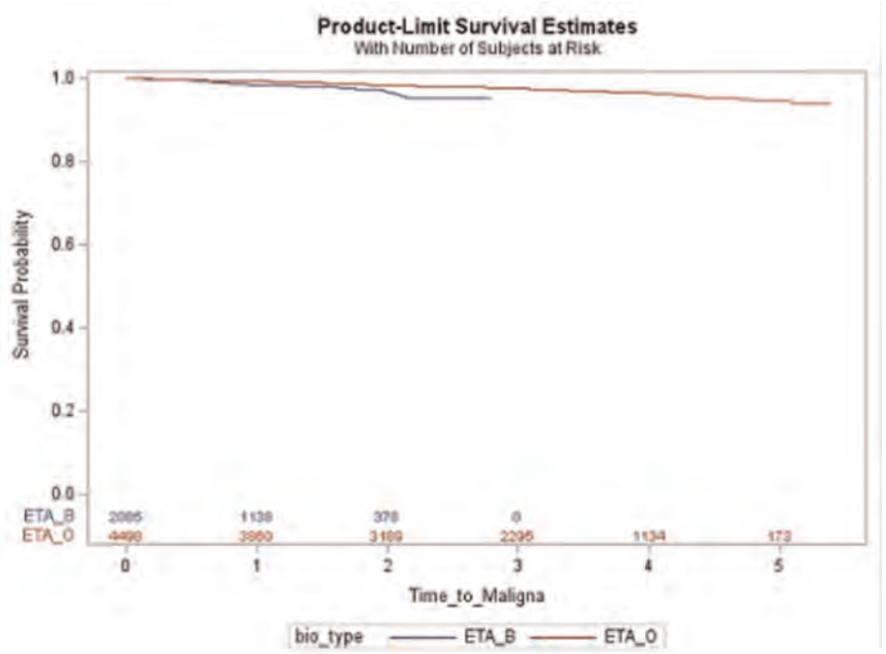

Figure 1. Time to first malignancy event for etanercept biosimilar and originator (all users)

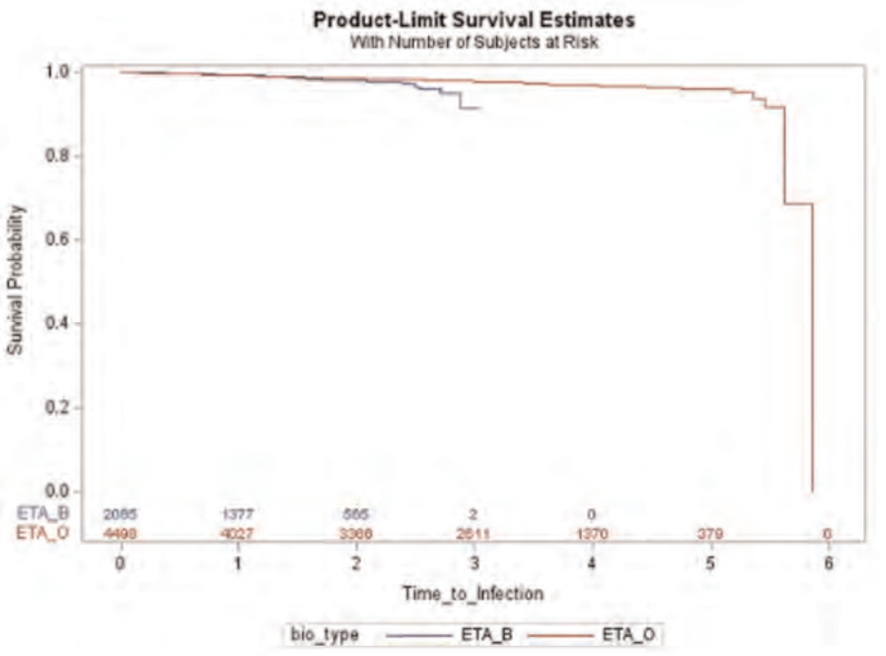

Figure 2. Time to first serious infection for etanercept biosimilar and originator (all users)

Table 1. Unadjusted and adjusted hazard ratio (HR) for serious infection and malignancy, comparing etanercept biosimilar and originator in patients with RA.

Variables	HR (95% CI)	
	Unadjusted	Adjusted*
1. First malignant event (ETA-B vs ETA-O)		
Biosimilar	0.83 (0.31, 2.18)	0.51 (0.14, 1.78)
Female (biological sex)	0.49 (0.22, 1.11)	0.48 (0.21, 1.09)
Age at ETA initiation ≥ 65 years	**1.04 (1.00, 1.08)**	**1.04 (1.01, 1.08)**
Corticosteroids prior to initiation	1.17 (0.50, 2.77)	1.13 (0.47, 2.70)
Biologic prior to initiation	1.04 (0.31, 3.50)	1.09 (0.31, 3.90)
Ontario province	1.49 (0.64, 3.46)	1.38 (0.58, 3.27)
Calendar year ≥2018	1.26 (0.49, 3.27)	1.79 (0.53, 6.06)
2. First serious infection (ETA-B vs ETA-O)		
Biosimilar	1.13 (0.54, 2.34)	1.69 (0.64, 4.49)
Female (biological sex)	0.91 (0.45, 1.82)	0.89 (0.44, 1.78)
Age at ETA initiation ≥ 65 years	1.00 (0.98, 1.02)	1.00 (0.97, 1.02)
Corticosteroids prior to initiation	**2.23 (1.02, 4.88)**	**2.17 (1.00, 4.79)**
Biologic prior to initiation	1.38 (0.57, 3.33)	1.39 (0.55, 3.49)
Ontario province	1.92 (0.96, 3.85)	**2.09 (1.03, 4.24)**
Calendar year ≥2018	0.74 (0.34, 1.60)	0.43 (0.16, 1.22)

Methods: CAN-AIM is a team funded to do high-priority research projects for Health Canada and other stakeholders. We used data from the National Prescription Drug Utilization Information System (NPDUIS), which contains pan-Canadian (except Quebec) claims-level data on prescriptions dispensations paid from public drug programs, linked to the hospital Discharge Abstract Database (DAD) and the National Ambulatory Care Reporting System (NACRS). We studied adults (≥18 years), initiating ETA between January 2015 and December 2019, further restricted to RA (ICD-10 M05, M06, M45, M70, M71, M72, M73andL40). Those with ICD diagnostic codes indicating malignancy, HIV or organ transplant one year before ETA/INF initiation (baseline) were excluded. For infection, follow-up began at treatment initiation and ended at end of data or 90 days after discontinuation or end of study; and for malignancy, 365 days after treatment initiation up to 365 days after discontinuation. Serious infections were defined as the first hospitalization with ICD-10 indicating infectious disease, observed from treatment initiation up to end of data or 90 days after treatment discontinuation. Malignancy was defined by the first record of neoplasm except non-melanoma skin cancer, from 365 days after treatment start up to 365 days after discontinuation. We compared originator and biosimilar using Cox regression models. We presented the adjusted hazard ratio (aHR) - potential confounders or effect modifiers included sex at birth, age at ETA initiation, prior corticosteroids or other biologics, region (Ontario vs other), and calendar year. Kaplan-Meier curves were plotted to compare time to first event between both treatment groups.

Results: The cohort (6,583 users, 695 RA, 31.7% on ETA-B) was mostly female (65%), with a median age (interquartile range, IQR) of 62 (50-69) at treatment initiation. Overall, malignancy incidence was 10.3 (95%CI 8.8-12.1), and infection rate was 8.9 (95%CI 7.5-10.4) per 1,000 person-year. Time to first event between ETA-B and ETA-O is presented in Figures 1-2. The aHR for ETA-B versus ETA-O (reference) was 1.14 (95%CI 0.68-1.91) for malignancy and 1.33 (95%CI 0.77-2.30) for infection. Non-significant results were also found when restricted to RA (Table 1).

Conclusion: In this real-world dataset, we were unable to identify clear differences in serious infections and malignancy comparing biosimilar and originator of etanercept, all users and RA-specific. Limitations include inability to control for residual confounders (e.g., disease severity), potential outcome misclassification and selection bias and short follow-up or treatment exposure to detect malignancy.

Abstract Number: 1335

Effectiveness of Longstanding Exercise Therapy versus Usual Care in People with Rheumatoid Arthritis and Severe Functional Limitations: A Randomized Controlled Trial (L-EXTRA)

Max Teuwen[1], Salima van Weely[1], Thea Vliet Vlieland[2], Manja van Wissen[1], Wilfred Peter[1], Alfons den Broeder[3], Dirkjan van Schaardenburg[4], Wilbert van den Hout[1], Cornelia van den Ende[3] and Maaike gademan[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leids University Medical Center, Leiden, Netherlands, [3]Sint Maartenskliniek, Nijmegen, Netherlands, [4]Reade, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Supervised exercise therapy is an effective and safe treatment option for people with rheumatoid arthritis (RA). However, most studies involve interventions of relatively short duration (≤12 weeks) or in patients with stable disease and a favorable health status. Patients with persistent disease activity, irreversible joint damage, multiple joint replacements and/or severe comorbidities are underrepresented in research, although in particular patients in this subgroup might be in need of exercise therapy, most likely longstanding. However, studies on longstanding exercise interventions in this subgroup are lacking. Therefore, this study aimed to evaluate the effectiveness of longstanding personalized, supervised exercise therapy compared with usual care in people with RA and severe functional limitations.

Table 1: Registration, Acknowledgements and Funding of the L-EXTRA study

Registration number Netherlands Trial Register NL8235, included in the International Clinical Trial Registry Platform (ICTRP) (https://trialsearch.who.int/Trial2.aspx?TrialID=NL8235).

Acknowledgements: This research would not have been possible without the cooperation of many people. We would like to acknowledge the work of:

- All physical and exercise therapist who participated in the training and treatment of patients and/or have made their practice available for the assessments.
- All rheumatologists, nurse specialists, physician assistants and other clinicians that informed patients about the study and/or were involved in active recruitment strategies and/or provided information on participants' characteristics.
- All medical students who voluntarily supported the research team with the enormous amount of administrative tasks
- Mrs. I. Hoeve for her continuous support in the administration of the reimbursement for the therapists involved

Funding: This project is financially supported by the Netherlands Organization for Health Research and Development (ZonMw; 852004018), Ministry of Health, Welfare and Sport (Ministerie van Volksgezondheid, Welzijn en Sport), the Royal Dutch Society for Physical Therapy (KNGF) and the Dutch Arthritis Society (ReumaNederland).

Methods: Adults with RA and severe limitations in basic activities of daily living were randomized 1:1 to longstanding (>52 weeks) personalized, supervised exercise therapy or usual care. The intervention consisted of exercise therapy tailored to individual goals, combined with self-management support to increase physical activity and fitness levels, and was delivered by specifically trained, primary care physical/exercise therapists. The primary endpoint was the change in the Patient-Specific Complaint (PSC (0-10)) at 52 weeks. Secondary endpoints included the Health Assessment Questionnaire-Disability Index (HAQ-DI), Rheumatoid Arthritis Quality of Life questionnaire Patient (RAQoL), 6-minute walk test (6MWT), Patient Reported Outcome Measurement Information System-Physical Function-10 (PROMIS-PF-10) and the Short Form-36 (SF-36). Results are reported from the 52-week rater-blind treatment period using analysis of covariance, expressed as mean difference between change scores with the 95% confidence interval.

Results: 215 people (90% female, age 58.8 (SD; 12.9) years) with RA and severe functional limitations were randomized. At 52 weeks n=104 (intervention) and n=98 (usual care) participants were included in the intention-to-treat analyses. The improvement in the primary outcome (PCS) was statistically significantly greater in the intervention group vs usual care difference in change score between groups (mean [95% CI] -1.7 [-2.4 – 1.0]) at week 52. Except for the PROMIS-PF-10 and SF-36, all secondary outcomes showed statistically significantly greater improvements in the intervention group vs usual care group at week 52 (HAQ-DI 0.17 [0.05 – 0.29], RAQoL 1.97 [0.62 – 3.32], 6MWT 56 meter [38 – 75]) indicating consistent improvements across domains, with between-group effect sizes ranging from 0.4 to 0.9. No intervention-related (serious) adverse events were reported.

Conclusion: Longstanding, personalized, supervised exercise therapy was more effective than usual care after 52 weeks of treatment in people with RA and severe functional limitations. Improvements were consistently observed across domains.

Abstract Number: 1336

Adalimumab and Etanercept Serum Levels in Rheumatoid Arthritis Patients with and Without a Disease Flare During Tapering

Zohra Layegh[1], Femke Hooijberg[2], Floris loeff[3], lisanne Dijk[3], Gaelle vaz[3], Theo Rispens[3], radboud J.e.m. Dolhain[4], Gertjan Wolbink[5] and Pascal de Jong[1], [1]Erasmus medical center, Rotterdam, Netherlands, [2]Amsterdam Rheumatology and Immunology Center, Location Reade, Department of Rheumatology, Dr. Jan van Breemenstraat 2, 1056 AB, Amsterdam, Netherlands, [3]Sanquin Diagnostic Service, Biologics Laboratory, Amsterdam, Netherlands, [4]Rheumatology, Erasmus MC, Rotterdam, Netherlands, [5]Reade, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Due to the improved management strategies and availability of biologic disease-modifying antirheumatic drugs (bDMARDs), ~60% of the rheumatoid arthritis (RA) patients will achieve sustained remission. To ensure optimal rheumatic care, effective use of bDMARDs is required, which includes tapering for RA patients with stable low disease activity. However, previous tapering trials for TNF inhibitors (TNFi) in RA reported that 51-77% of patients experience a disease flare during tapering and stopping. For personalized tapering approach therapeutic drug monitoring (TDM) might be of added value. TDM is based on pharmacokinetics that uses measurements of circulating drug level to adjust the dose

individually. Unfortunately, current knowledge on pharmacokinetics of TNFi during tapering is incomplete, e.g. what is the minimal drug level that should be aimed for to prevent disease flares. We aimed to assess the serum level of etanercept (ETN) and adalimumab (ADL) in well-controlled RA patients with and without a disease flare during tapering.

Methods: All RA patients who participated in the TApering strategies in Rheumatoid Arthritis (TARA) trial and followed the tapering protocol and had serum samples from ≥3 visits (n=111) were selected. The TARA trial was a multicenter, single-blinded randomized trial that included established RA patients with a well-controlled disease, defined as a disease activity score (DAS) ≤2.4 and a swollen joint count ≤1. Eligible patients were randomized into gradual tapering csDMARD (mainly methotrexate) followed by the TNFi (ETN or ADL), or vice versa. Tapering of the TNFi was done every three months by doubling the dosing interval, then cutting the dosage into half, and finally stopping. TNFi serum levels were measured at each 3-monthly visit, if serum samples were available, by a drug tolerant enzyme-linked immunosorbent assay.

Results: Of the 111 included RA patients 54 tapered their TNFi first, while 57 patients tapered the csDMARD first. The 54 patients who tapered TNFi first had an average symptom duration of 7,2 years and were predominantly female (58%) with an average age of 58 years. At baseline, the DAS (standard deviation) was 1,0 (0,5).Respectively 40% and 60% of the RA patients used ADL and ETN as TNFi. The baseline mean serum concentration for ADL was 7.2 ug/ml (range 0.023-13.4 ug/ml) and 2.7 ug/ml (range 0.5-4.38 ug/ml) for ETN. ADL and ETN serum levels decreased during tapering, but ADL remained longer in the blood circulation after stopping compared to ETN, 6 versus < 3 months respectively (figure 1A and C). Approximately 43% of the patients who tapered the TNFi first flared. At the time of a flare, mean serum level for ADL was 0.6 ug/ml and 0.5 ug/ml for ETN (figure 1B and D).

Conclusion: For both ADL and ETN, the critical serum level below which flares occur seems to be 1 ug/ml. TDM might prevent disease flares during tapering by allowing personalized TNFi dosing targeting levels above this critical threshold. In line with the longer half-live ADL remains longer in the blood circulation after stopping compared to ETN. One should, therefore, be aware that it can take up to 6 months after cessation before the TNFi drops to undetectable levels in blood.

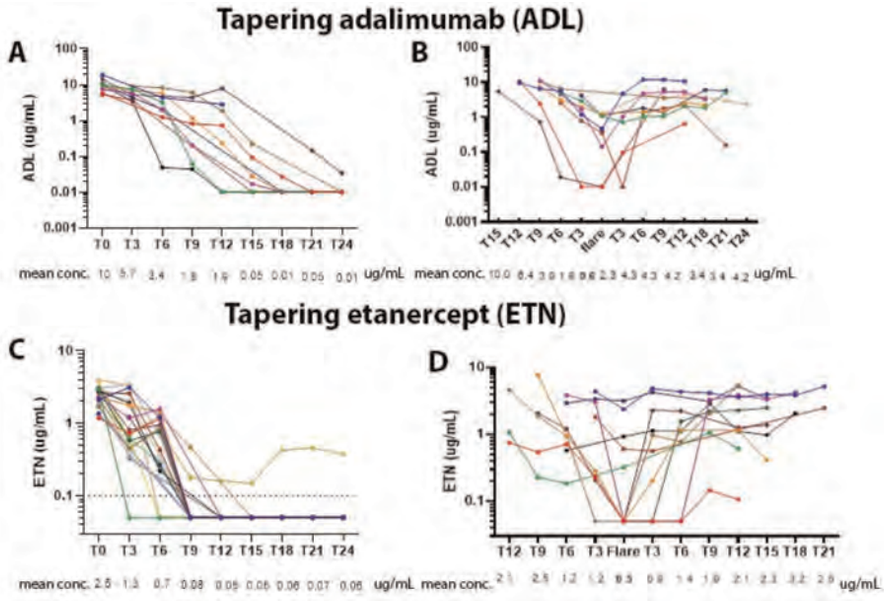

Figure 1: Drug levels of Rheumatoid Arthritis patients with and without a disease flare during tapering of a TNF inhibitor. Each dot represents a drug level measurement per individual RA patient on ADL without (1A) or with a disease flare (1B) or ETN without (1C) or with (1D) a disease flare during tapering. Measurements within each individual patient are connected by a coloured line. Abbreviations: ADL, adalimumab; conc., concentration; ETN, etanercept

Effect of Tofacitinib Therapy on Angiotensin Converting Enzyme Activity in Rheumatoid Arthritis

Dorottya Kacsándi, Miklós Fagyas, Ágnes Horváth, Edit Végh, Anita Pusztai, Monika Czókolyová, Boglárka Soós, Attila Ádám Szabó, Attila Hamar, Zsófia Pethő, Nóra Bodnár, György Kerekes, Katalin Hodosi, Szilvia Szamosi, Gabriella Szücs, Zoltán Papp and **Zoltán Szekanecz**, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The Renin-Angiotensin-Aldosterone system (RAAS) has been implicated in the regulation of the cardiovascular system and linked to rheumatoid arthritis (RA). Little information has become available on the effects of Janus kinase (JAK) inhibition on RAAS. here we studied the effects of 12-month tofacitinib treatment on angiotensin converting enzyme (ACE), ACE2 production and ACE/ACE2 ratios in RA along with numerous other biomarkers.

Methods: Thirty RA patients were treated with tofacitinib in this prospective study. Serum ACE concentrations were assessed by ELISA. ACE2 activity was determined by a specific quenched fluorescent substrate. ACE/ACE2 ratios were calculated. We also determined common carotid intima-media thickness (ccIMT), brachial artery flow-mediated vasodilation (FMD) and carotid-femoral pulse-wave velocity (cfPWV) by ultrasound. C-reactive protein (CRP), rheumatoid factor (RF) and anti-citrullinated protein autoantibodies (ACPA) were also determined. All measurements were performed at baseline, as well as after 6 and 12 months of tofacitinib treatment.

Results: After the dropout of 4 patients, 26 completed the study. Tofacitinib treatment increased ACE levels after 6 and 12 months, while ACE2 activity only transiently increased at 6 months. The ACE/ACE2 ratio increased after one year of therapy ($p < 0.05$). Logistic regression analyses identified correlations between ACE, ACE2 or ACE/ACE2 ratios and RF at various time points. Baseline disease duration also correlated with erythrocyte sedimentation rate (ESR) ($p < 0.05$). One-year changes of ACE or ACE2 were determined by tofacitinib treatment plus ACPA or RF, respectively ($p < 0.05$).

Conclusion: JAK inhibition increases serum ACE and ACE/ACE2 ratio in RA. Baseline inflammation (ESR), disease duration and ACPA, as well as RF levels at various time points can be coupled to the regulation of ACE/ACE2 ratio. The effect of tofacitinib on RAAS provides a plausible explanation for the cardiovascular effects of JAK inhibition in RA.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: RA – Treatments Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Since 2018, all patients with new-onset rheumatoid arthritis (RA) at the Department of Rheumatology, Skåne University Hospital, Lund, Sweden, are invited to participate in a ”tight control” and ”treat-to-target” (TC+T2T) follow-up strategy. This strategy includes follow-up visits to a rheumatologist (at diagnosis and 3, 6, 12, 18, 24 months) plus physical/telephone consultations with a rheumatology nurse between physician visits – both with disease activity assessments and, if needed, adjustment of anti-rheumatic treatment, aiming for remission. The aim of the current study was to explore the possible advantages of implementing this TC+T2T strategy over routine care in reaching remission (DAS28 < 2.6, DAS28CRP < 2.4 or CDAI≤2.8) in clinical practice of new-onset RA patients.

Methods: RA patients with symptom duration < 24 months at diagnosis were eligible. Data on disease and treatment characteristics, as well as outcome measures during follow-up, were retrieved from the Swedish Rheumatology Quality register (SRQ). In total, 336 patients entered one of the follow-up strategies between January 1, 2018, and October 31, 2022. Of these, 193 were followed according to the TC+T2T strategy and 143 according to routine care. Percentage females/mean age/mean symptom duration at inclusion were 75%/56 years/4.5 months (TC+T2T) and 71%/62 years/7.6 months (routine

	TC+T2T group (n=193)	Controls (n=143)
Swollen 28 joint count	6.1 (4)	5.8 (5)
Tender 28 join count	8.4 (6)	7.3 (6)
ESR	46.8 (29)	41.3 (28)
CRP	21.7 (30)	20.6 (32)
DAS28	5.4 (1)	4.9 (1)
DAS28CRP	4.7 (1)	4.4 (1)
CDAI	23.5 (11)	21.6 (12)
HAQ	1.0 (0.6)	1.1 (0.7)
Fatigue (VAS)	32.3 (28)	38.1 (30)
Pain (VAS)	28.8 (25)	34.1 (27)
Smoking (ever) (%)	42%	30%
Methotrexate started at diagnosis (%)	75%	66%
Prednisolone started at diagnosis (%)	68%	42%

Mean and standard deviation (SD) if not otherwise stated.

Disease and treatment characteristics at diagnosis

care). Achievement of remission was compared between the two strategies using logistic regression, adjusted for sex, age, symptom duration, and DAS28/DAS28CRP/CDAI at diagnosis. In addition, changes in patient-reported outcomes (fatigue and pain) were assessed for the respective strategies.

Results: Disease and treatment characteristics at diagnosis are summarized in Table1.

Percentages of patients reaching DAS28, DAS28CRP and CDAI remission criteria increased in both groups over time, but this was more pronounced in the TC+T2T group (Figure). A similar pattern was seen in the dynamics of fatigue and pain (Figure). Follow-up according to the TC+T2T was associated with a numerical higher odds ratio of achieving remission at all follow-up times regardless the remission criteria used and a significantly higher odds ratio of CDAI remission at 6 months (after adjustment for sex, age, symptom duration and CDAI at diagnosis) (Table 2).

	B	p-value	Odds ratio	95% CI
T2T+TC (vs. routine care)*	**1.5**	**0.032**	**4.32**	**1.1-16.4**
CDAI at inclusion	-0.04	0.083	0.97	0.9-1.01
Female (vs. male)	-0.09	0.854	0.91	0.3-2.6
Age (years)	0.01	0.398	1.01	1.0–1.04
Disease duration (months)	0.00	0.998	1.00	0.9-1.1

*T2T+TC= treat to target and tight control

Achievement of remission between "treat -to-target" strategy and routine rheumatology care (logistic regression analysis)

Conclusion: Compared to routine rheumatology care, the implementation of a ”tight control” and ”treat-to-target” strategy resulted in numerically larger proportions of patients reaching remission at majority of follow-up visits over two years. Similarly, both strategies showed an early and sustained numerical improvement in patient-reported outcomes. Our results suggest that this type of strategy should be integrated into daily clinical practice of new-onset RA.

Neutrophil Activation and Formation of Neutrophil Extracellular Traps Are Associated with Response to Abatacept in Patients with Moderate to Severe Rheumatoid Arthritis

Ting Wang[1], Natalia V. Giltiay[2], Christian Lood[2] and Bobby Kwanghoon Han[2], [1]University of Washington, Seattle, WA, [2]Division of Rheumatology, University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophil activation and formation of neutrophil extracellular traps (NETs) have been implicated in the pathogenesis of rheumatoid arthritis (RA). Calprotectin, a neutrophil activation marker, correlates with RA disease activity and is a novel biomarker that can be used to distinguish RA patients in remission and active disease and to predict disease progression. Abatacept is a CTLA-4-Ig fusion protein, which is widely used as a treatment for RA. However, the response rates to abatacept are variable in heterogeneous RA patients. We conducted this study to determine the effect of abatacept on neutrophil-related markers and to explore whether these markers could predict the therapeutic efficacy of abatacept in RA patients.

Methods: A total of 23 RA patients, who had an inadequate response to methotrexate and other conventional DMARDs, were enrolled in this study. All participants fulfilled the 1987 ACR criteria or 2010 ACR/EULAR criteria, with clinical disease activity index (CDAI) ≥16. Plasma samples were collected at baseline, week 6, week 14, and week 24. Levels of calprotectin, myeloperoxidase (MPO)-DNA, and neutrophil elastase (NE)-DNA complexes were determined by ELISA. Responders (n=10) were defined as subjects who achieved ACR50 Response at week 24. Changes in these markers were compared before and after treatment using the Wilcoxon matched-pairs signed rank test. Baseline levels of these markers were compared between the responder and non-responder groups by the Mann-Whitney test.

Results: Plasma levels of calprotectin and MPO-DNA complexes were significantly decreased at week 6 (p=0.0011 and p=0.0025, respectively), week 14 (p=0.0003 and p=0.0002, respectively), and week 24 (p=0.0121 and p=0.0037, respectively) with the treatment of abatacept when compared to baseline. Abatacept reduced the levels of NE-DNA only at week 14 (p=0.0085). Compared to the non-responders, the responders had a numerically higher percentage of anti-CCP antibodies (90% vs 62%, p=0.1790) and RF (90% vs 54%, p=0.0886). Baseline levels of calprotectin (3190 ng/mL vs 2167 ng/mL, p=0.0493) and NE-DNA complexes (6708 pM vs 0 pM, p=0.0305) were significantly higher in responders when compared to non-responders (Figure 1).

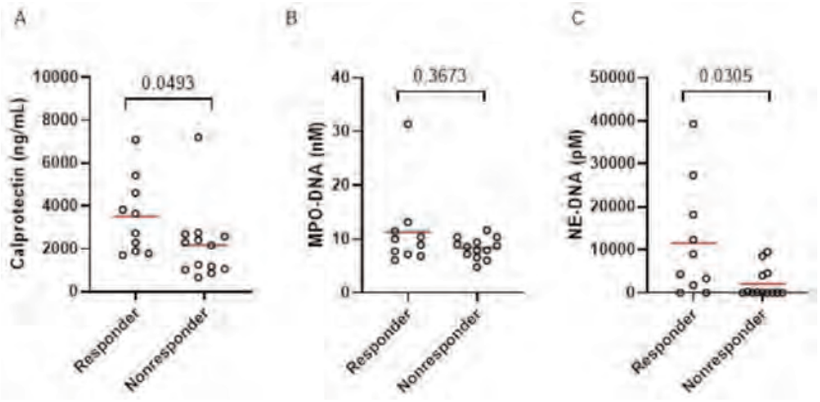

Figure 1. Comparison in baseline plasma levels of neutrophil-related markers between responders and non-responders. Comparison of plasma levels of calprotectin (A), MPO-DNA (B), and NE-DNA in circulation at baseline in patients treated with abatacept. Differences between groups were determined by the Mann-Whitney test.

Conclusion: Abatacept significantly decreased neutrophil activation in RA patients. Calprotectin and NE-DNA complexes may serve as useful markers in predicting the therapeutic efficacy of abatacept in moderate to severe RA patients.

Recent Trends in Treatment Patterns for Rheumatoid Arthritis in Response to Emerging Data

Stephanie Song[1], Michael George[2], Ted R Mikuls[3], Bryant England[4], Brian Sauer[5], Grant Cannon[6] and Joshua Baker[2], [1]Hospital of the University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE, [4]University of Nebraska Medical Center, Omaha, NE, [5]Salt Lake City VA/University of Utah, Salt Lake City, UT, [6]University of Utah and Salt Lake City VA, Salt Lake City, UT

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Janus kinase inhibitors (JAKi) have demonstrated substantial efficacy in decreasing symptoms and in reducing progressive joint damage in patients with rheumatoid arthritis (RA). In light of the ORAL Surveillance trial, which was published in January 2021, all JAKi (tofacitinib, baricitinib, upadacitinib) now carry black box warnings concerning risks of serious cardiac events, thromboembolism, cancer, and death associated with these agents. The purpose of this study was to determine whether prescribing practices for Janus kinase inhibitors (JAKi), TNF inhibitors (TNFi), and non-TNFi biologic agents changed after the results of the ORAL Surveillance trial were released in January 2021.

Methods: This is a retrospective study in adult patients with RA receiving advanced therapies within the Veterans Affairs (VA) Health System from January 2012 through September 2022. Eligible patients were required to have at least one diagnosis code for RA and to have received a biologic DMARD or JAKi. Treatment courses were defined

from pharmacy dispensing data and the proportion of new courses of each advanced therapy was quantified over time. We assessed changes in the use of each therapy before and after the release of safety data (January 2021).

Results: A total of 88,253 individual drug courses (in 34,656 unique patients) were included. The overall number of new drug courses decreased for most of the 11 advanced therapies in 2020, corresponding to the start of the COVID-19 pandemic, before resuming similar levels in 2021. From January 2021 through December 2020, there were consistent increases in the number and proportion of new courses of JAKi, which was followed by a significant net decrease in the proportion of JAKi use through September 2022 (**Figure 1A**). There were proportionally fewer initiations of tofacitinib after the release of safety data, with a significant difference in the slope of change with time (**Figure 1B**). In contrast, while use of TNFi declined leading up to 2021, TNFi use significantly increased after January 2021 (**Figures 1A and 2A**). The number and proportion of prescribed non-TNFi biologics were more variable over these years, with fluctuations in prescribing patterns observed as a class (**Figure 2B**).

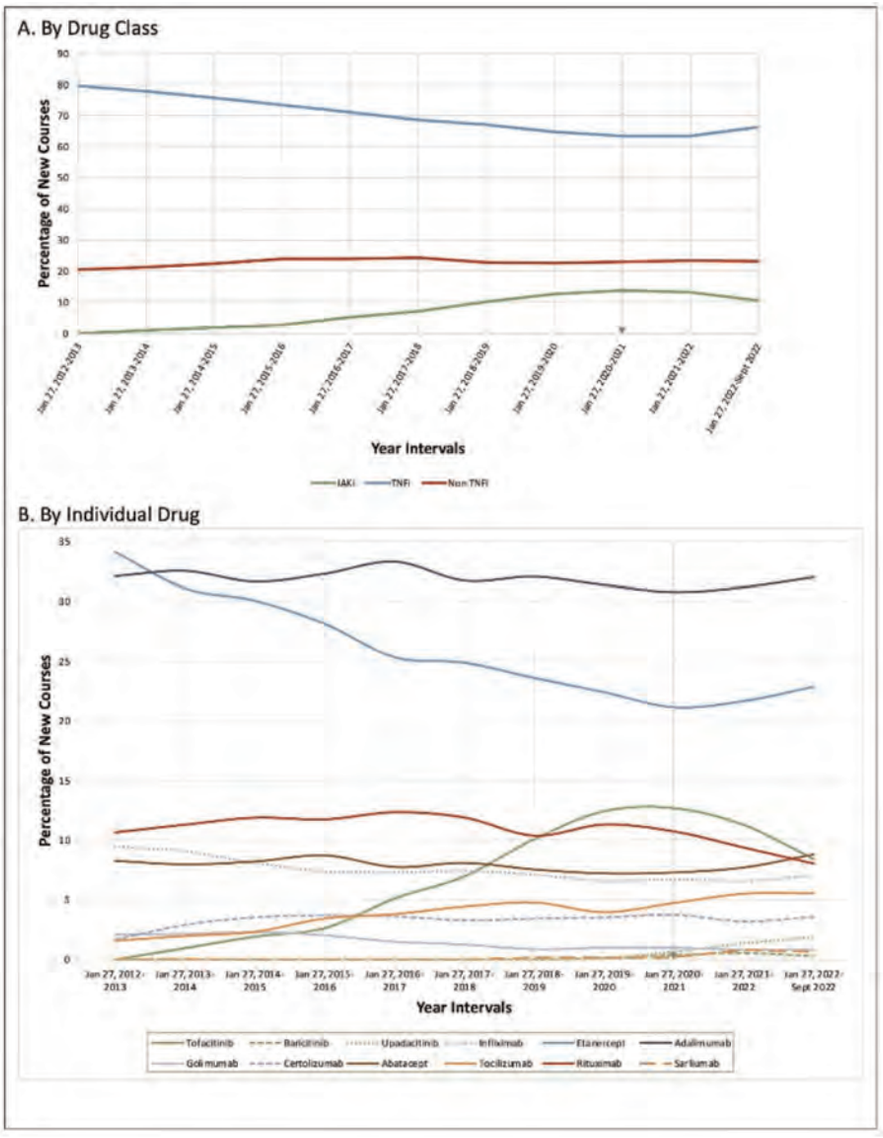

Figure 1. Percentage of Incident Drug Courses from January 2012 through September 2022

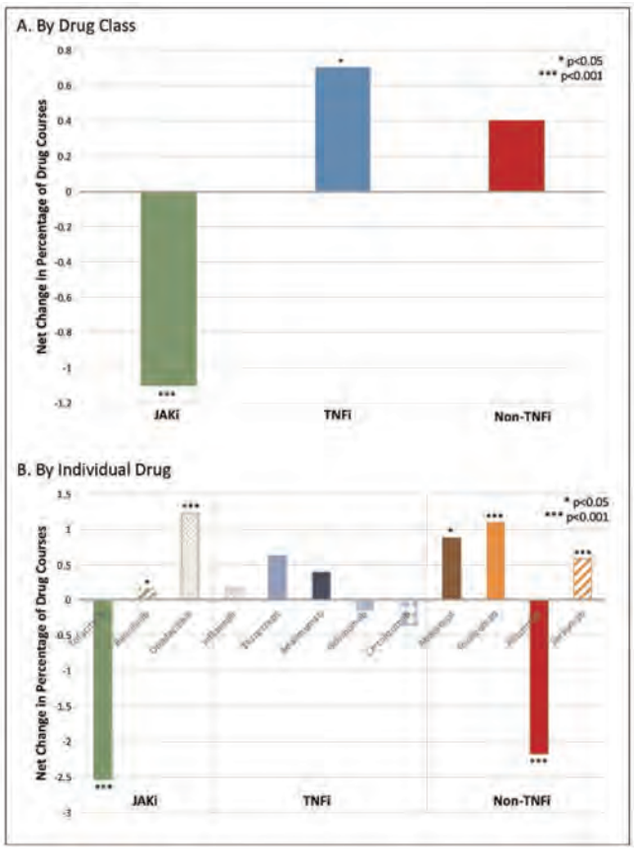

Figure 2. Net Change in Incident Courses of Biologic Agents 664 Days Before vs. After January 2021

Conclusion: The results of this study suggest that the release of safety data in January 2021 regarding adverse effects of JAKi influenced providers' prescribing practices for patients with RA. Changes in prescribing in response to new evidence emphasize the impact that safety trials have on prescribing practices. Ongoing study in this area, with attention to specific patient characteristics and risk profiles, will help characterize these changes in practice.

Abstract Number: 1341

Impact of Ultrasound on Physician Assessments of Patients with RA with Elevated Clinical Disease Activity Scores

Stephanie Song[1], Odette Kolenky[1], Antje Greenfield[2], Dana Direnzo[3], Joshua Baker[4] and Michael George[4], [1]Hospital of the University of Pennsylvania, Philadelphia, PA, [2]University of Pennsylvania Health System, Philadelphia, PA, [3]University of Pennsylvania, Bala Cynwyd, PA, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target is recommended in RA, but physicians often do not escalate therapy despite elevated disease activity measures due to uncertainty regarding the true degree of joint inflammation. This study evaluated the utility of ultrasound (U/S) in assessing disease activity in patients with RA with moderate disease activity measures but few swollen joints. We aimed to determine the frequency of active synovitis on U/S and compare physician treatment recommendations before and after U/S.

PROMIS Pain interference T-Score (std)	63.6 (6.9)	65.3 (6.7)

std: standard deviation; IQR: inter-quartile range

Methods: This single-center, prospective study enrolled adults who met 2010 ACR classification criteria for RA, had a clinical disease activity index (CDAI) >10 (moderate or high disease activity) but a swollen joint count (SJC) ≤2, and were receiving a DMARD. Patients completed surveys and underwent standardized U/S performed in the musculoskeletal (MSK) ultrasound department by a certified MSK U/S technologist using a high-resolution GE Logiq E10 system. Exams were interpreted by a single MSK U/S radiologist using the validated OMERACT scoring system, grading synovial hypertrophy by grayscale (GS) and hyperemia by power doppler (PD) in each of the bilateral MCPs, PIPs, and wrists as absent (0), minimal (1), moderate (2), or severe (3). Treating rheumatologists were surveyed pre-U/S and again after U/S to capture their impression of disease activity, confidence in their assessment (100-point scale), and treatment recommendations.

Results: We recruited 18 patients with RA: 15 (83%) females, mean age 62 years, and mean RA duration 14 years. U/S revealed moderate or severe synovial hypertrophy (GS grade 2 or 3) of at least one joint in 17/18 (94%) patients. In contrast, moderate or severe hyperemia of at least one joint (PD grade 2 or 3) was found in 7/18 (39%). Patients with active PD signal tended to be older, have longer disease duration, more frequent glucocorticoid use, higher body mass index, and more frequent seropositivity and erosions on radiographs; patient and physician global scores and PROMIS measures were similar (**Table 1**). Although CDAI scores indicated at least moderate disease activity pre-U/S, physician impression was that disease activity was low in 8/18 (44%) of patients pre-U/S. Physician-rated disease activity assessment changed after U/S in 6/18 (33%) patients: 3 to a higher level of disease activity and 3 to a lower level (**Figure 1**). Similarly, treatment decisions changed after U/S in 6/18 (33%) patients: 3 from no change to escalation of therapy and 3 from escalation to no change (**Figure 1**). Mean physician confidence in disease activity assessment increased from 54 pre-U/S to 72 post-U/S ($p< 0.01$).

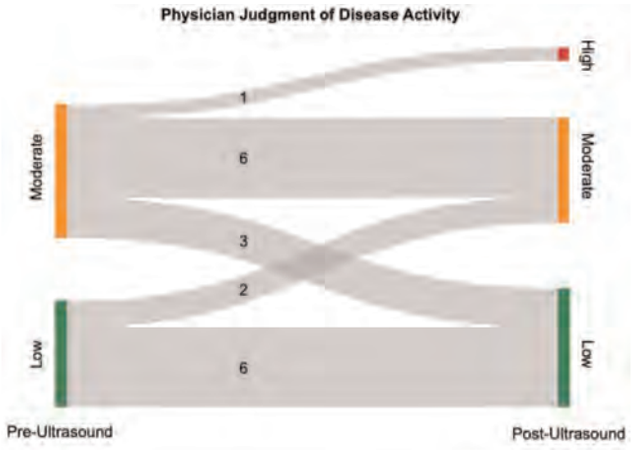

Figure 1. Pre- and Post-Ultrasound Physician Disease Activity Assessments

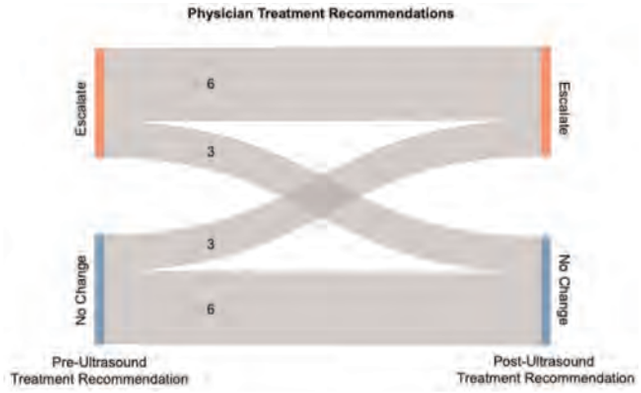

Figure 2. Pre- and Post-Ultrasound Physician Treatment Recommendations

Conclusion: In patients with longstanding RA, U/S demonstrating a moderate to high degree of synovial hypertrophy in at least one joint was nearly universal, but the presence of active PD signal was less common. Musculoskeletal U/S increased physician confidence in the assessment of disease activity and frequently led to a change in assessment and treatment recommendation. Future research should evaluate whether use of U/S to refine assessments of disease activity in patients with RA with high disease activity scores but few swollen joints can improve patient outcomes.

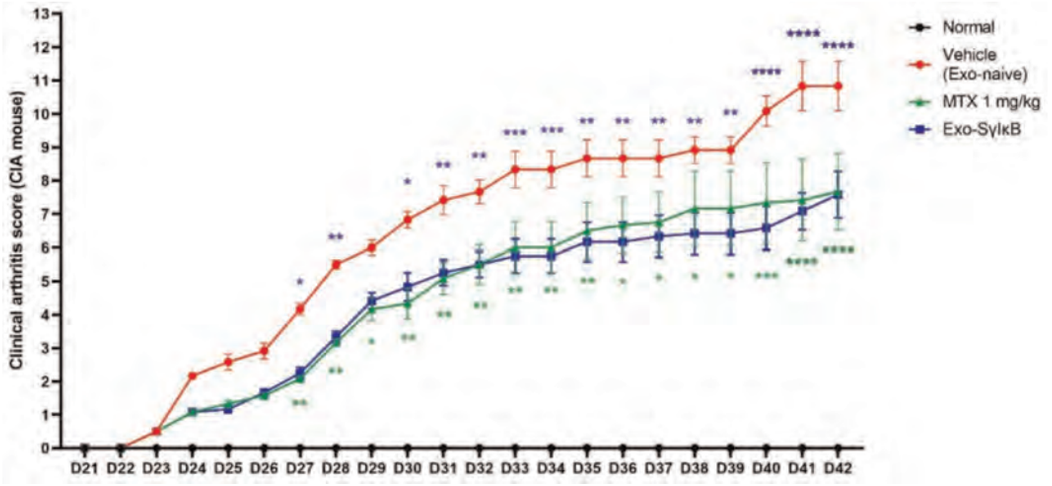
The Delivery of the Super-repressor IκBα by Exosomes Has the Potential to Alleviate Inflammation Associated with Rheumatoid Arthritis

Ki-Jeong Park[1], Ji-Hyoun Kang[1], Hae-In Lee[2], Yu Jeong Lee[1], Moon-Ju Kim[1], So-Hee Ahn[3], Jae-Kwang Yoo[3], Chulhee Choi[3] and Tae-jong Kim[4], [1]Chonnam National University Hospital, Gwangju, South Korea, [2]Chonnam National University, Gwangju, South Korea, [3]ILIAS Biologics, Daejeon, South Korea, [4]Department of Rheumatology, Chonnam National University Medical School and Hospital, Gwang-Ju, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a persistent inflammatory disease primarily affecting the diarthrodial joints. Nuclear factor-κB (NF-κB) is a family of inducible transcription factors responsible for regulating numerous genes involved in various aspects of immune and inflammatory diseases, including RA. This study aims to evaluate the potential anti-inflammatory properties of suppressor IκB (srIκB), an inhibitor of NF-κB when delivered by exosomes in the context of RA.



Exo-SrIκB treatment resulted in a reduction of clinical symptoms in mice with collagen-induced arthritis (CIA). The severity of arthritis in each group was assessed and scored based on clinical manifestations following treatment with either MTX, Exo-Naïve, or Exo-SrIκB.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from both healthy controls (HCs) and rheumatoid arthritis (RA) patients, and additional synovial fluid mononuclear cells (SFMCs) were collected from RA patients. Collected PBMCs and SFMCs were pretreated with Exo-srIκB or vehicle (Exo-Naïve) and then evaluated for cell viability. The subset of cells producing inflammatory cytokines, including IFN-γ, IL-17, and GM-CSF, was examined by flow cytometry and quantified by enzyme-linked immunosorbent assay (ELISA). To evaluate the therapeutic potential of Exo-srIκB in vivo, collagen-induced arthritis (CIA) mouse model was used. Mice were treated with Exo-srIκB or vehicle, and arthritis scores were calculated for monitoring disease progression. Histological observations of ankle joints were performed using hematoxylin and eosin (H&E) staining, and radiation damage scores were measured using micro-computed tomography micro-CT) imaging.

Results: Administration of Exo-SrIκB for 7, 24, and 48 hours had no significant effect on cell viability. However, treatment with Exo-SrIκB showed a significant reduction in the frequency of IL-17A- and GM-CSF-producing cells in PBMCs from rheumatoid arthritis patients. Exo-SrIκB treatment also reduced the frequency of GM-CSF-producing cells in SFMCs from RA patients. In the mouse experiment, Exo-SrIκB administration delayed the onset of arthritis and significantly reduced the severity of arthritis compared to the control group **(Figure 1)**. In addition, radiographic arthritis scores were significantly lower in Exo-SrIκB treated mice than in Exo-Naïve treated mice.

Conclusion: Exo-srIκB, which contains IκB as an inhibitor, demonstrates the ability to inhibit inflammatory cytokines in vitro and exhibits inhibitory effects in animal models. These findings suggest that regulation of NF-κB signaling by Exo-srIκB may be a promising therapeutic target for the treatment of RA.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is a Janus kinase (JAK) 1 preferential inhibitor for the treatment of RA. Data from the ORAL Surveillance post-marketing study (NCT02092467) suggest that in patients with active RA aged ≥50 years with ≥ 1 CV risk factor, the risks of cancer and major adverse cardiovascular events (MACE) are higher

Table. Baseline characteristics

	FIL200		FIL100	
	<65 y (n=1860)	≥65 y (n=407)	<65 y (n=1321)	≥65 y (n=326)

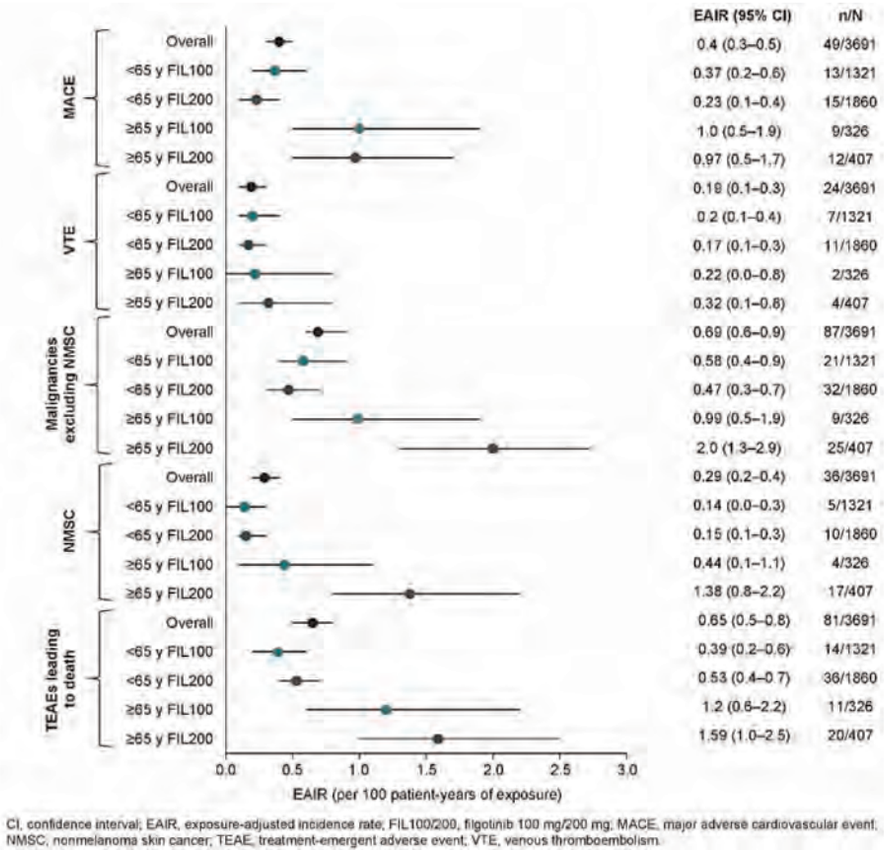
*FIL200 <65 y: n=1436, ≥65 y: n=340; FIL100 <65 y: n=1081, ≥65 y: n=289.
†FIL200 <65 y: n=1434, ≥65 y: n=339; FIL100 <65 y: n=1081, ≥65 y: n=289.
BMI, body mass index; CRP, C-reactive protein; CV, cardiovascular; FIL100/200, filgotinib 100 mg/200 mg; SD, standard deviation.

with the pan-JAK inhibitor tofacitinib vs tumor necrosis factor inhibitors, with higher rates in those aged ≥ 65 vs < 65 years.[1]



CI, confidence interval; EAIR, exposure-adjusted incidence rate; FIL100/200, filgotinib 100 mg/200 mg; MACE, major adverse cardiovascular event; NMSC, nonmelanoma skin cancer; TEAE, treatment-emergent adverse event; VTE, venous thromboembolism.

Figure. EAIRs for treatment-emergent MACE, VTE, malignancies excluding NMSC, and NMSC overall, and by filgotinib dose and patient age (safety analysis set, as treated)

The objective of this analysis was to assess the incidence of malignancies excluding nonmelanoma skin cancer (NMSC), NMSC, MACE and venous thromboembolism (VTE) in patients treated with FIL 200 mg (FIL200) and FIL 100 mg (FIL100) in RA clinical trials.

Methods: Data were pooled from patients treated with FIL200 or FIL100 from DARWIN 1–3 (NCT01888874, NCT01894516, NCT02065700) and FINCH 1–4 (NCT02889796, NCT02873936, NCT02886728, NCT03025308). Data cuts used for the ongoing DARWIN 3 and FINCH 4 studies were May 2, 2022, and May 6, 2022, respectively. Exposure-adjusted incidence rates (EAIRs) per 100 patient-years of exposure (PYE) were calculated for MACE, VTEs, malignancies excluding NMSC, NMSC and treatment-emergent adverse events (TEAEs) leading to death, according to FIL dose (200 vs 100 mg) and age (< 65 vs ≥ 65 years); no statistical testing was performed, so all differences are numerical. MACE and VTE were adjudicated by an independent committee; the cutoff for adjudication was April 3, 2022.

Results: Overall, 3691 patients were treated with FIL for a total of 12,541 PYEs. Median (max) PYE was 3.8 (8.3) years for FIL200 and 3.3 (7.8) years for FIL100. Baseline characteristics are shown in the **Table**. A greater proportion of those aged ≥ 65 years vs < 65 years had a CV medical history in both the FIL200 (75.7% vs 36.1) and FIL100 (71.8% vs 40.9%) groups. Overall EAIRs (95% confidence interval [CI]) were 0.40 (0.3, 0.5) for MACE, 0.19 (0.1, 0.3) for VTEs, 0.69 (0.6, 0.9) for malignancy excluding NMSC, 0.29 (0.2, 0.4) for NMSC and 0.65 (0.5, 0.8) for TEAEs leading to death. EAIRs of MACE and VTE were higher in patients aged ≥ 65 vs < 65 years but were generally similar for FIL200 and FIL100 within each age group (**Figure**). EAIRs of malignancies, NMSC and TEAEs leading to death were also higher in the ≥ 65- vs < 65-year group. Within the ≥ 65-year group, EAIRs (95% CI) of these events were numerically higher in the FIL200 vs FIL100 group: 2.0 (1.3, 2.9) vs 0.99 (0.5, 1.9) for malignancies, 1.38 (0.8, 2.2) vs 0.44 (0.1, 1.1) for NMSC, and 1.59 (1.0, 2.5) vs 1.20 (0.6, 2.2) for TEAEs leading to death, respectively.

Conclusion: Rates of MACE and VTE in FIL-treated patients were low and similar for FIL200 and FIL100. There was a higher proportion of patients aged ≥ 65 years vs < 65 years with a CV medical history. In patients aged ≥ 65 years, EAIRs of malignancies, NMSC and TEAEs leading to death were higher with FIL200 vs FIL100, although CIs overlapped.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: RA – Treatments Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Use of JAK inhibitors (JAKi) may be challenged in difficult to treat rheumatoid arthritis (D2TRA) by the multiplicity of previous treatment lines and the presence of comorbidities that may trigger the occurrence of potentially severe side effects. Our objective was to assess the efficacy and safety profile of JAKi in patients with D2TRA in clinical practice

Methods: Retrospective routine care study carried out between 2018 and 2022 our department. We selected from our electronic medical report database RA patients initiating a JAKi between 2018 and 2022. D2TRA was defined by failure to at least two targeted biological therapies of different mechanisms of action and at least one of the following: active disease, defined by a DAS28 >3.2, signs and/or symptoms suggestive of active disease or inability to taper glucocorticoid treatment below 7.5mg/day (1). D2TRA patients were compared to JAKi-treated patients not fulfilling this D2TRA definition (non-D2TRA). Efficacy was assessed at the first visit (FV) (3 to 6 months following the JAKi initiation) and at the last available visit (LV) up to December 2022 on the basis of the DAS28 and DAS28-CRP composite index and its components. The number of side effects and causes of treatment discontinuations were collected during the exposition period

Results: We included 83 RA patients initiating a JAKi, with a mean age of 58±14 years and a mean disease duration of 16 ±13 years. Among them, we identified 45 D2TRA and 38 non-D2TRA patients (**Table 1**). Patients with D2TRA had longer disease duration and active disease and previous targeted therapies. DAS28 was reduced between baseline and FV in both groups, with a significantly higher extent in non-D2TRA patients, and then remain stable in both groups between FV and the LV, which occurred 15±10 months after the baseline (**Table 2**). These results were similar for other parameters assessing disease activity (**Table 2**). Higher proportion of patients reached remission or low disease activity (LDA, DAS28< 3.2) in the non-D2TRA subgroup (FV: 82% vs. 53%, p=0.012; LV: 71% vs. 33%, p=0.006) compared to D2TRA. A total of 35 patients discontinued the JAKi during a mean observation period of 20±10 months. Mean time to discontinuation was 10±8 months. Frequency of discontinuation was not different for D2TRA and non-D2TRA patients (21/45, 47% vs 14/38, 37%, p=0.36). Discontinuations related to inefficacy and side effects occurred in 20/83 patients (24%) and 11/83 patients (13%), respectively, and were evenly distributed between patients with D2TRA and non-D2TRA. Frequency of infections (n=31), herpes zoster (n=3) myocardial infractions (n=3) and venous thromboembolism (n=3) was similar between groups. These events were more likely to occur in the subgroup of patients aged ≥65 years and/or with at least one CV risk factor (30/39, 77%)

Table 1: Patients' characteristics at inclusion

TNF inhibitors, n (%)	16 (4)	44 (98)	<0.001
Rituximab, n (%)	5 (13)	17 (38)	0.011
IL6 receptor inhibitors, n (%)	3 (8)	21 (47)	<0.001
abatacept, n (%)	3 (8)	23 (51)	<0.001

VAS: Visual Analogic Scale, PGA: patient Global Assessment, ESR: Erythrocyte Sedimentation Rate, CRP: C-reactive Protein; DAS: Disease Activity Score, SD: Standard Deviation; BMI: Body Ma Index, CV: cardiovascular, DMARD: Disease-Modifying Anti-Rheumatic Drug, MTX: Methotrexate, TNF: Tumor Necrosis Factor

Conclusion: JAKi reduced disease activity parameters of patients with D2TRA. However, disease activity level of these patients remained high, with a proportion of LDA or remission significantly lower compared to non-D2TRA, highlighting the need of improved therapeutic strategies in D2TRA. Tolerance profile of JAKi was not different between patients with D2TRA and non-D2TRA and largely depended on the presence of risk factors

Abstract Number: 1345

Maternal and Infant Outcomes Following Abatacept Exposure During Pregnancy

Michelle Ann Caesar, Diana Johnson, Kenneth Lyons Jones and **Christina Chambers**, University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept is approved for the treatment of moderate to severe rheumatoid arthritis (RA) and psoriatic arthritis. However, there are limited data on the safety of abatacept when used in pregnancy. The purpose of this study was to estimate the incidence/birth prevalence of selected maternal and infant outcomes in pregnancies exposed to abatacept.

Methods: Pregnant women exposed to any dose of abatacept from the first day of the last menstrual period to the end of the first trimester (with or without continued use in pregnancy) and who resided in the U.S. or Canada were enrolled in the Organization of Teratology Information Specialists (OTIS) Abatacept Pregnancy Exposure Registry between 2007 and 2019. Data on maternal characteristics, pregnancy and infant outcomes including major and minor birth defects were collected throughout pregnancy and the first-year post-partum through maternal interviews, medical records abstraction, and dysmorphology examinations.

Results: The study sample was comprised of 30 abatacept-exposed pregnancies (Table 1). Of these, 16 were treated for RA and were enrolled in a prospective cohort, and 14 who did not meet the cohort criteria were enrolled in a "registry group".Reasons that pregnancies did not meet the cohort criteria included retrospective enrollment, co-exposure to an exclusionary medication, or abatacept used for an indication other than RA. In the prospective cohort, 13/16 pregnancies (81.3%) resulted in at least one live birth, 2/16 pregnancies (12.5%) ended in spontaneous abortion, 2/13 pregnancies (15.4%) were delivered preterm (< 37 weeks' gestation) and 1/16 (6.3%) was lost-to-follow-up. One pregnancy of 13 ending in a livebirth (8.3%) involved a child with a major birth defect, congenital chordee (Table 2). In the registry group 14/14 pregnancies (100.0%) resulted in at least one livebirth and 6/14 (42.9%) were delivered preterm. Three of 14 pregnancies (21.4%) ended with a liveborn infant with a major birth defect (pyloric stenosis, cleft lip and palate, and patent foramen ovale).An additional two pregnancies in the registry group (14.3%) ended with an infant with major birth defects in association with a genetic or chromosomal alteration (Table 2). A dysmorphology examination for minor birth defects was completed for 6 infants in the prospective cohort and 7 in the registry group. No patterns of either major or minor birth defects were identified. The number of liveborn infants who were small for gestational age (SGA) ($\leq 10^{th}$ centile for sex and gestational age at birth) or smaller ($\leq 10^{th}$ centile) at about one year of age on weight, length or head circumference was unremarkable.

Conclusion: Although there was no internal comparison group and the sample size was small, no specific risks were identified in the prospective cohort for any of the outcomes examined. In the registry group, selected adverse outcomes were more frequent, likely due to the biases that led to exclusion of these pregnancies from the prospective cohort. However, no patterns of major or minor birth defects were identified in either group. Future studies with a larger sample size are needed.

*One pregnancy involved twins ending in one live birth and one spontaneous abortion; counted only in the outcome of livebirth

Table 1. Outcomes in Pregnancies Exposed to Abatacept (n=30)

	Abatacept-Exposed (N = 16)	Abatacept-Registry (N = 14)
Major Birth Defects in Pregnancies Ending with Live-born Infants	1/13* (7.7)	5/14 (35.7)
Major Birth Defects in All Pregnancies Excluding Lost-to-Follow-up	1/15 (6.7)	5/14 (35.7)
Pattern of Minor Birth Defects in Infants Who Received the Physical Examination	0/6 (0.0)	0/7 (0.0)

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA) are commonly diagnosed in young males in their reproductive years. However, only a few studies have investigated male fertility in patients with spondyloarthritis (SpA). Our objective was to evaluate the sperm quality in male patients with PsA and AxSpA compared to healthy controls (HC) and to investigate the effects of disease activity and anti-rheumatic drugs on sperm quality.

Methods: Consecutive PsA and AxSpA patients (age range 18-50 years), who fulfilled the classification criteria for PsA (CASPAR) and AxSpA (ASAS) were recruited prospectively. HC were recruited from candidate sperm donors at the male fertility clinic. Each patient was evaluated by a comprehensive clinical assessment that included measurement of disease activity scores (MDA/DAPSA/CPDAI/PASDAS for PsA and ASDAS for AxSpA). Treatments ranged from no treatment to conventional and biologic DMARDs. Sperm collection and analysis were performed on the day of clinical assessment. Sperm analysis was performed according to the World Health Organization 2010 guidelines. In addition, sperm DNA-fragmentation test was performed.

Continuous variables were compared using a t-test or Anova for normally distributed data, otherwise, a non-parametric test was applied. Fisher's exact test was used to compare categorical variables.

Results: 70 patients (40 PsA and 30 AxSpA) and 50 HC were included. Demographics and clinical characteristics are presented in Table 1. Most semen parameters, including concentration, and vitality of PsA and AxSpA patients were similar to those of HC ($p > 0.05$).The proportion of normal morphology in patients was significantly lower compared to HC (3.01 (± 1.39) vs 4.64 (±2.00), $p < 0.0001$). The motility in patients vs. controls was lower (56.89 (± 11.50) vs. 59.54 (± 14.31), $p=0.04$). Nevertheless, values for both groups were within the normal range (>40%) and the total motile count was normal and similar between the groups (Table 2).

Table 1 - Demographic and clinical characteristics of patients with PsA, AxSpA and healthy controls

	PsA n=40	AxSpA n=30	Healthy controls n=50

Total DNA fragments, mean (± s.d)	<30%	11.75 (±4.80)	8.67 (±0.58)	14.75 (±6.70)	11.69 (±4.60)	0.37

*CsDMARDs= conventional synthetic DMARDs: Methotrexate, Leflunomide
**Biologic therapy= TNFi (Infliximab+Etanercept+Adalimumab+Golimumab), Anti-IL17 (Secukinumab+Ixekizumab), Anti-IL23 (Guselkumab), Anti-IL12/23 (Ustekinumab)

In addition, no differences were observed in semen analysis in the different disease activity states (remission/low and moderate/high disease activity) for PsA and for AxSpA ($p > 0.05$). Finally, a comparison of the different treatment options (no treatment, conventional and biologic DMARDs) showed overall no differences, while motility was slightly lower in patients treated with biologic therapy (62.57 (±7.99), 62.33 (±7.02), 58.75 (±4.99) and 51.66 (±12.44) for no treatment, conventional synthetic DMARDs, conventional synthetic DMARDs+biologic therapy, and biologic monotherapy respectively, $p=0.003$). However, values for all groups were within the normal range (>40%) and the total motile count was normal and similar between the groups (Table 3).

Conclusion: In this relatively large study evaluating semen analysis in spondyloarthropathies, the semen quality of PsA and AxSpA patients was comparable to HC in most parameters. In addition, neither disease activity nor antirheumatic drugs substantially affected sperm quality. Our results do not support cryopreservation of semen before treatment initiation nor a drug free interval prior to conception. Further longitudinal large studies are needed.

Continuing Biologic DMARDs During Pregnancy in Women with Rheumatic Disease Was Not Associated with Increased Unfavorable Pregnancy Outcomes, Serious Infections, and Adverse Effects of Vaccination

Hiromi Shimada[1], Risa Wakiya[2], Shusaku Nakashima[2], Taichi Miyagi[3], Yusuke Ushio[4], Koichi Sugihara[5], Rina Mino[6], Mao Mizusaki[2], Kanako Chujo[7], Ryoko Kagawa[4], Hayamasa Yamaguchi[4], Tomohiro Kameda[2] and Hiroaki Dobashi[2], [1]Kagawa University, Kagawa, Japan, [2]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan, [3]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Kidagun, Japan, [4]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Miki-cho, Kita-gun, Japan, [5]Kagawa University, Miki-cho, Kita-gun, Japan, [6]Kagawa University, Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa, Japan, [7]Kagawa University, Miki, Kita District, Kagawa, Japan

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: It is important to control disease activity during pregnancy in women with rheumatic diseases because its exacerbation is associated with increased adverse pregnancy outcomes. Some of biologic disease-modifying anti-rheumatic drugs (bDMRARDs), especially in TNF inhibitors, are safe to continue during pregnancy, and become key drugs for controlling disease activity during pregnancy. However, there is little evidence whether continuing these drugs really does not affect unfavorable pregnancy outcomes, serious infections for mothers and infants, and adverse events of vaccination. Therefore, we investigated the effects of bDMARDs continuation on them.

Methods: We used the data of patients with rheumatic diseases who had been treated before pregnancy and gave birth in our institution. We extracted cases who were treated with bDMARDs at the time of conception, and divided them into two groups that discontinued bDMARDs at the time of pregnancy confirmed (discontinued group), and continued bDMARDs after pregnancy confirmed (continued group). We retrospectively examined pregnancy outcomes, serious infections requiring hospitalization for mothers and infants, live vaccination for infants in these two groups

Results: Of 238 cases with rheumatic diseases who gave birth in our institution, 32 cases were treated with bDMARDs at the time of conception. Of these, 27 cases were rheumatoid arthritis, 3 cases were Behcet disease, 1 case was juvenile idiopathic arthritis, and 1 case was Takayasu aortitis, which were divided into 17 cases of the continued group, and 15 cases of discontinued group. Table 1 showed patients' characteristics and treatment during pregnancy. In the continued group, certolizumab pegol was administered in 10 cases, etanercept was 3 cases, adalimumab was 3 cases, and tocilizumab was one case. All cases continued into second or third trimester with mean discontinued weeks of 28.5±5.1 weeks. In discontinued group, the mean dose of glucocorticoid was significantly higher compared to continued group (7.7±3.7 vs. 3.6 ±1.6, P=0.03). Table 2 showed pregnancy outcomes. The gestational weeks at delivery and birth weight in continued group were similar with discontinued group, and there was no significant difference of adverse pregnancy outcomes between these two groups. No serious infections requiring hospitalization were observed in either mother and infant in both groups.

Table 1. patients' characteristics and treatment during pregnancy. Values are presented as the mean ± standard deviation or number (%). #Wilcoxon rank sum test; ##Fisher's exact test. *P < 0.05.

	Continued group (n=17)	Discontinued group (n=15)	P value
Mean age at delivery, years old#	33.5 ± 3.8	33.3 ± 4.3	0.66
Mean disease duration, years#	7.2 ± 4.5	5.1 ± 3.3	0.19
Primiparity, n(%)##	8 (47.1)	8 (53.3)	1.00
Treatment during pregnancy			
Glucocorticoid, n(%)##	9 (52.9)	6 (40.0)	0.50
Mean dose of glucocorticoid, mg/day#	3.6 ± 1.6	7.7 ± 3.7	0.03*
Increasing dose of glucocorticoid, n(%)##	3 (17.7)	5 (33.3)	0.42
bDMARDs			
Certolizumab pegol, n(%)	10 (58.8)		
Etanercept, n(%)	3 (17.7)		
Adalimumab, n (%)	3 (17.7)		
Tocilizumab, n(%)	1 (5.9)		

Table 2. Pregnancy outcomes, serious infection, and adverse events of vaccination. Values are presented as the mean ± standard deviation or number (%). #Wilcoxon rank sum test; ##Fisher's exact test. *P < 0.05.

	Continued group (n=17)	Discontinued group (n=15)	P value
Caesarean section, n(%)##	8 (47.1)	3 (20.0)	0.15
Gestational age at delivery, week#	38.5 ± 1.3	38.6 ± 1.5	0.73
Birth weight, gram#	2891.2 ± 372.9	2887.5 ± 469.7	0.92
Adverse pregnancy outcomes, n(%)##	3 (17.7)	2 (13.3)	1.00
preterm birth, n(%)##	1 (5.9)	1 (6.7)	1.00
Low birth weight, n(%)##	2 (11.8)	2 (13.3)	1.00
Small for gestational age, n(%)##	0 (0)	1 (6.7)	0.47
Hypertensive disorder, n(%)##	0 (0)	1 (6.7)	0.47
Congenital malformation, n(%)##	1 (5.9)	0 (0)	1.00
Serious infections for mothers and infants, n(%)	0 (0)	0 (0)	
Adverse evets of vaccination for infants, n(%)	0 (0)	0 (0)	

In addition, the infants received rotavirus vaccine from 2 months after birth, and BCG vaccine after 6 months according to the Japanese vaccine schedule, however, none of the infants had any adverse events due to vaccination.

Conclusion: In patients with rheumatic diseases, continuing bDMARDs had no association with the increase of unfavorable pregnancy outcomes, serious infections, and adverse events of vaccination. It was suggested that the continuation of bDMARDs may be an effective treatment option for rheumatic diseases during pregnancy. Larger number of examinations are needed as to how long to continue bDMARDs during pregnancy.

Reproductive Outcomes for Women with Vasculitis

Catherine Sims[1], Christine Yeung[2], Heather Tam[3], Joyce Kullman[4], Amanda Eudy[5], Renee Borchin[6], Cristina Burroughs[6], Megan Clowse[7] and Peter Merkel[2], [1]Duke University School of Medicine, Durham, NC, [2]University of Pennsylvania, Philadelphia, PA, [3]Vasculitis Patient Powered Research Network, Stanford, CA, [4]Vasculitis Foundation, Kansas City, MO, [5]Duke University, Raleigh, NC, [6]University of South Florida, Tampa, FL, [7]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There are limited data on the reproductive health of women with vasculitis. This study utilized a large, prospective, international vasculitis pregnancy registry to survey women during and after pregnancy to improve characterization of reproductive outcomes.

Methods: The Vasculitis Pregnancy Registry (VPREG) is imbedded within the online Vasculitis Patient-Powered Research Network (VPPRN). Any pregnant woman with a diagnosis of vasculitis can self-enroll. After enrollment, women are invited to complete online surveys at study entry, once each trimester, and post-partum. Survey questions are organized into three categories: pregnancy outcomes and complications, vasculitis medications, and disease activity. VPREG surveys are currently available in five languages.

Results: Since 2015, 147 women with 149 pregnancies have enrolled in VPREG from 16 countries. Seventy-one pregnancies were excluded as nine women have ongoing pregnancies and 62 women were lost to follow-up. Seventy-eight pregnancies have known pregnancy outcomes (live or non-live birth) and were included in this analysis. Of these 78 pregnancies, ANCA-associated vasculitis was the most frequently reported diagnosis (n=35, 45%) followed by Takayasu's arteritis (n=15, 19%), Behcet's (n=7, 9%), and other forms (n=21, 27%). During pregnancy, women experienced low pain related to vasculitis (scale 0-10, mean 3.1 ± 3.0) and preserved feelings of wellness (scale 0-10, mean 3.4 ± 3.1). Nineteen women reported experiencing a flare of vasculitis during pregnancy. Of the 15 women requiring hospitalization during pregnancy outside of delivery, four cited vasculitis activity as the indication for inpatient care. Most women (54/73, 74%) were prescribed medications for vasculitis during pregnancy with glucocorticoids (n=36) and azathioprine (n=18) being the most frequently prescribed. Four women were prescribed rituximab. Nineteen (26%) women took no medications to treat vasculitis during pregnancy. Seventy-six (97%) pregnancies resulted in live births. Of these live births, 63% delivered vaginally and 21% experienced a preterm delivery. The median gestational age at delivery was 38 weeks.

Conclusion: These results demonstrate that most women with vasculitis can have successful pregnancies. During pregnancy, a minority of women reported vasculitis flares or the need for hospitalization due to vasculitis. Medications to treat vasculitis are prescribed in most patients for disease control during pregnancy. These data can be used by rheumatologists to inform and facilitate discussions about reproductive health with women with vasculitis.

Abstract Number: 1349

Paternal Effects of Anti-TNFs in Inflammatory Arthritis

Zeynep Toker Dincer, Bahaddin Ates, Ayten Dag, Ilayda Turkoglu, Ali Yagiz Ayla and Serdal Ugurlu, Istanbul University-Cerrahpasa, Istanbul, Turkey

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory arthritis is a group of rheumatic diseases characterized by the inflammation of joints with systemic manifestations: psoriatic arthritis (PsA), rheumatoid arthritis (RA), and spondyloarthritis (SpA) are included in this group. The use of anti-TNFs in arthritis has become very frequent, especially after the 2000s with established efficacy.

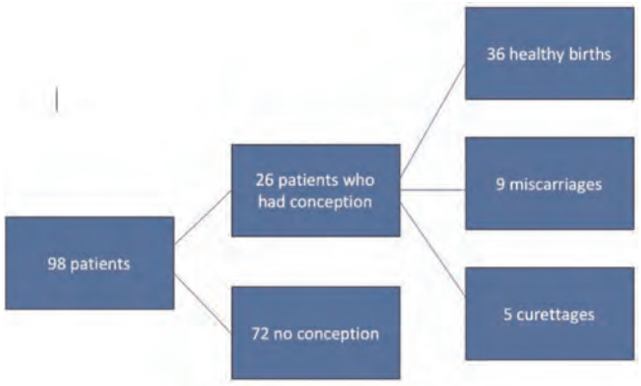

Figure 1.Flow chart of the patients according to conception

However, their effects on fertility in men remain mostly unknown. In this study, we aimed to determine the effect of anti-TNFs on the fertility of men.

Methods: We performed a questionnaire on married male patients who were diagnosed between 1987-2020. The following questions were asked: Did your wife get pregnant while you were using an anti-TNF agent? How many times did she get pregnant? Which drug were you using when your wife got pregnant? Was there any problem during the pregnancy? Were you using any contraception? Have you ever been evaluated for infertility? What drug were you using during the time your wife could not get pregnant? Did you have any children when you were not taking anti-TNF treatments? After this questionnaire, we reevaluated the patient group who had pregnancy under anti-TNF treatment. We recorded any data regarding pregnancy complications and pregnancy-associated situations.

Results: 98 patients were involved in our study. The mean age of the patients was 54. 82 (80.39%) patients had AS, 12 (11.76%) patients had PsA, and 8 patients had RA. 72 patients did not experience pregnancy and 67 of them were using contraception (Figure 1). The number of patients taking anti-TNF treatments (infliximab, etanercept, golimumab, and adalimumab) who could not get pregnant despite trying to conceive was 5.Among those 5 patients, 4 were screened for infertility, revealing unknown etiology for 3, and the remaining 1 was of female origin. 2 of these 5 patients had already conceived and given birth before anti-TNF treatment. The patient who was not screened for infertility had been trying to conceive for the previous 2 months. The total number of conceptions was 50. There were 9 miscarriages under anti-TNF treatment and 5 curettages under anti-TNF treatment (four of them were voluntary and one of them was a medical requirement). There were 36 healthy births (Figure 1). The patients who had miscarriages were using the following medications: certolizumab pegol (2 patients), golimumab (1 patient), etanercept (1 patient), adalimumab (1 patient), etanercept (3 patients), and infliximab (1 patient). The patient who had a curettage due to a medical requirement was using golimumab.

Conclusion: Among the male patients taking anti-TNF treatment, infertility due to paternal origin does not seem to be a major issue according to our limited data. Anti-TNF treatment thus seems to be safe with regards to fertility in male patients.

Identification of ACR Guidelines for SLE Pregnancy Care in the Electronic Health Record

Noah Forrest[1], Joshua Waytz[2], April Barnado[3], Megan Clowse[4], Theresa Walunas[1] and Rosalind Ramsey-Goldman[5], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern Medicine, Chicago, IL, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Duke University, Chapel Hill, NC, [5]Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is an autoimmune disease with an increased risk for poor outcomes in pregnancy. In 2020, ACR specified several recommendations to assist clinicians in preparing patients with SLE and other rheumatic diseases for pregnancy management, with the intention of risk reduction for both the mother and developing fetus (1). Two recommendations that are of particular importance in managing SLE pregnancies are to initiate low dose aspirin (LDA) and continuation of hydroxychloroquine (HCQ) therapy. We investigated whether the rate of adherence to these guidelines increased after their release at a single healthcare site.

Methods: We identified all patients at Northwestern Medicine (NM) with 4 or more encounters billed for SLE, with at least one SLE encounter billed by a rheumatologist. Using diagnosis and procedure codes, we ascertained the approximate start and end dates of pregnancies that occurred following the first SLE diagnosis among these patients from 2012 to 2022. Next, we identified the presence of LDA if a medication order for low dose or baby aspirin occurred from 6 months prior to the beginning of pregnancy up to the end of the first trimester. The presence of HCQ therapy was determined by medication orders for HCQ occurring either 6 months before or during the pregnancy. The presence of antiphospholipid (APL) antibodies was determined if anti-cardiolipin, anti-beta-2-glycoprotein, or lupus anticoagulant were positive on two separate occasions 12 or more weeks apart. Finally, the number of pregnancies during which patients received specific ACR guidelines over the study period were summarized over time, before and after the start of 2020, and further delineated by patient APL status at the time of pregnancy.

Results: We identified 529 pregnancies among people with SLE that occurred over the study period from 3,312 total female patients meeting our SLE identification algorithm. Overall, there was a general upward trend in the rates of patients receiving HCQ, LDA, or both over the study period (Figure 1). The rates of pregnancies during which both LDA and HCQ were administered were 34% and 39% ($p = 0.30$) before 2020 and following the start of 2020, respectively (Table 2). A larger, although non-significant, increase was also observed among patients with two different positive APLs, where the rate increased from 37% to 50% ($p = 0.55$).

Conclusion: Our results suggest that there was only a modest, non-significant increase in implementing ACR guidelines for SLE in pregnancy in our health system following their release. Limitations include the single-center nature of the study, use of only structured and semi-structured data in detecting medication orders, and short follow-up period after implementation of the guidelines. It is anticipated that the recommended care will continue to increase as the guidelines are disseminated more widely. To obtain a sample with adequate size to study changes in prescribing patterns for pregnancy among patients with SLE in a broader context, future work will focus on implementation of our SLE and pregnancy identification strategies in a larger data network derived from multiple healthcare sites and development of more sophisticated tools to detect physician recommended LDA.

Session Date: Monday, November 13, 2023

Session Title: Reproductive Issues in Rheumatic Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Adolescent and young adults (AYAs) with rheumatic disease (RD) may face disproportionate risk of HPV and associated cancers due to immune dysregulation, immunosuppression and gaps in preventive health care delivery. As vaccination is a safe and effective means of prevention, we aimed to evaluate whether having an RD is associated with decreased HPV vaccine uptake in AYAs seen by a rheumatologist.

Table 1. Demographic, Clinical, and Immunization Information About Patients Aged 16-22 Seen in an Academic Rheumatology Clinic with and without Rheumatic Disease (RD)

Variable	RD (N=321)	No RD (N=213)	p-value

HPV vaccinated	160 (49.8)	75 (35.2)	*<0.001*
Influenza vaccination (ever)	252 (78.5)	131 (61.5)	*<0.001*
COVID-19 vaccination			*<0.001*
• 0 doses	70 (21.8)	92 (43.2)	
• 1-2 doses	104 (32.4)	60 (28.2)	
• ≥3 doses	147 (45.8)	61 (28.6)	

Values are reported as N (%) unless otherwise indicated. A p-value <0.05 was considered statistically significant; missing values were excluded from analysis.

Methods: This retrospective study included individuals aged 16-22 seen in our academic rheumatology center ≥2 times (2020-2022) with New York State (NYS) residence. We used chart review to ascertain demographics, vaccine information (automatically pulled from the NYS Immunization Information System), reason for evaluation by a rheumatologist, and medication information. We descriptively compared demographic and clinical variables between patients with and without an RD diagnosis. We performed a multivariable logistic regression to assess whether having an RD diagnosis was associated with having received 2-3 HPV vaccine doses after adjusting for relevant demographic characteristics and receipt of other elective vaccines.

Results: There were 534 patients aged 16-22 seen by a rheumatologist at our center ≥2 times during the study period with NYS residence (mean age ± 2.1 years, 74.7% female, and 61% White). Compared to those without RD (n=213), patients with RD (n=321) were older (mean age 19.6 vs. 18.4 years, p< 0.001), more frequently Hispanic/Latino (23.4% vs. 10.8%, p< 0.001), more had Medicaid and/or Medicare (21.8% vs. 11.3%, p=0.003), more were employed (10.3% vs. 4.7%) and students (60.1% vs. 46.5; p=0.002) [**Table 1**].

Table 2. Clinical Characteristics of Patients Aged 16-22 with a Rheumatic Disease (RD) Seen in an Academic Rheumatology Center

RD Diagnosis	N (%)
• Inflammatory arthritis[1]	185 (57.6)
• Connective tissue disease[2]	94 (29.3)
• Other[3]	42 (13.1)
Age at RD Diagnosis	
• <11	60 (18.7)
• 11-16	137 (42.7)
• 17-22	124 (38.6)
Immunosuppression (at most recent visit)?	202 (62.9)

Values are reported as N (%) unless otherwise indicated.
1. RA, PsA, SpA, JIA
2. SLE, APS, Sjögren's, Myositis, UCTD, MCTD
3. Chronic recurrent multifocal osteomyelitis, vasculitis, scleroderma, autoinflammatory disease, other inflammatory disease

Table 3. Logistic Regression Model Evaluating the Association Between Rheumatic Disease (RD) Status and HPV Vaccination in Patients Aged 16-22 Seen in an Academic Rheumatology Center

Variable	Odds Ratio	95% Confidence Interval	p-value
RD Status			
• No RD	*Referent*		
• RD	0.74	0.45 – 1.22	0.23
Age (at most recent visit)	1.10	0.98 – 1.22	0.10
Sex			
• Male	*Referent*		
• Female	1.09	0.65 – 1.81	0.75
Race			
• White	*Referent*		
• Asian	2.35	0.86 – 6.47	0.10
• Black	3.09	1.27 – 7.55	*0.01*
• Other	1.76	0.86 – 3.54	0.12
Ethnicity			
• Hispanic/Latino	*Referent*		
• Not Hispanic/Latino	0.94	0.50 – 1.78	0.84
Insurance			
• Private	*Referent*		
• Medicaid and/or Medicare	1.22	0.64 – 2.31	0.55
Influenza vaccination (ever)			
• No	*Referent*		
• Yes	12.68	6.35 – 25.33	*<0.001*
COVID-19 vaccination			
• 0 doses	*Referent*		
• 1-2 doses	3.71	2.00 – 6.87	*<0.001*
• ≥3 doses	4.56	2.52 – 8.26	*<0.001*

A p-value <0.05 was considered statistically significant.

Overall, 235 (44%) patients were HPV vaccinated (49.8% with RD vs. 35.2% without RD, p< 0.001). Compared to non-RD patients, those with RD were more likely to have ever received the influenza vaccine (78.5% vs. 61.5%, p< 0.001) and ≥3 doses of the COVID-19 vaccine (45.8% vs. 28.6%, p< 0.001) [**Table 1**]. Of 321 patients with RD, 86.9% were diagnosed with inflammatory arthritis or CTD; 61.4% were diagnosed with RD before age 17 [**Table 2**].

In adjusted models, RD status was not associated with HPV vaccination (OR 0.74, 95% CI 0.45-1.22, p=0.23). Black vs. White race was associated with HPV vaccination (OR 3.09, 95% CI 1.27-7.55, p=0.01). Influenza vaccination (ever) (OR 12.68, 95% CI 6.35-25.33, p< 0.001) and COVID-19 vaccination (OR 3.71 for 1-2 vs. 0 doses, 95% CI 2.00-6.87, p< 0.001; OR 4.56 for ≥3 vs. 0 doses, 95% CI 2.52-8.26, p< 0.001) were associated with HPV vaccination [**Table 3**].

Conclusion: Among AYAs seen in an academic rheumatology center, less than half were HPV vaccinated, and having an RD was not associated with HPV vaccination in adjusted models. Receipt of HPV and other elective vaccines was more common for patients diagnosed with an RD compared to those who were not. Influenza vaccination (ever) was associated with 13-fold increased likelihood of HPV vaccination, and COVID-19 vaccination (≥3 doses) with 5-fold increased likelihood of HPV vaccination, after adjusting for relevant factors. Interventions are needed to improve HPV vaccine uptake in AYAs, including those with RD at increased risk of vaccine-preventable illnesses; targeting elective vaccine uptake in general may be a fruitful approach.

Similar Delivery Outcomes in Pregnant Patients with and Without Takayasu Arteritis - A Nationwide Inpatient Database Study

Yanint Raksadawan[1], Aravind Polam[1], Nattanicha Chaisrimaneepan[2] and Sabahat Usmani[1], [1]Weiss Memorial Hospital, Chicago, IL, [2]Texas Tech University Health Sciences, Lubbock, TX

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu's arteritis (TA) is a large vessel vasculitis which affects women of reproductive age. There is limited information about the effect of TA on pregnancy. We ran an analysis in pregnant women with an already established diagnosis of TA in an effort to determine the effect of TA on delivery outcomes.

Methods: We queried the National Inpatient Sample database in the period between 2016 - 2019. Patients who were admitted for delivery were identified and stratified based on the presence of diagnosis of TA. The adjusted odds ratios (aOR) of in-hospital outcomes and resource utilization were calculated using chi-square statistics in software STATA v.17.

Results: Of 1.44e+07 hospitalizations for pregnancy between 2016-2019; 120 pregnant patients had TA. The mean age of TA patients was older (31 vs. 29, p-value 0.04). Patients with TA had significantly higher rates of gestational hypertension (15.83% vs 6.4%, p-value 0.03), thyroid disorders (12.5% vs 4.14%, p-value 0.04), genitourinary infections (8.3% vs

Session Title: Reproductive Issues in Rheumatic Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Due to its multisystemic involvement, systemic lupus erythematosus (SLE) can have a significant impact on patients' quality of life (QoL). Sexual (dis)function is a key component of QoL but is often underappreciated. Little is known about sexual disfunction in SLE patients, a condition that primarily affects women during their fertile age.

We aimed at determining the prevalence of sexual dysfunction among women with SLE and predictors thereof.

Methods: We performed a cross-sectional multicenter study in which women (18-70 years-old) with a clinical diagnosis of SLE (according to their treating rheumatologist) were included. An anonymous online questionnaire was perfomed where data on demographics (e.g., age), symptoms of depression and anxiety [Hospital Anxiety and Depression Scale (HADS)), health-related QoL (Short Form Health

	Total (n=194)	No sexual dysfunction (n=66; 34%)	Sexual dysfunction (n=128, 66%)	p-value

Multivariable analysis. * Not selected in the univariable model (p>0.25); † Not selected in the multivariable model (p>0.05); Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA) – systemic lupus erythematosus disease activity index (SLEDAI); CCI, Charlson Comorbidity Index; bDMARDs, biologic disease-modifying anti-rheumatic drugs; cDMARDs, classic disease-modifying anti-rheumatic drugs

Survey Index 36 Item (SF36)]) and sexual function [Female Sexual Function Index (FSFI) - a 19-item patient-report outcome that assesses female sexual function]) were collected. Data on clinical features [disease activity according to the Safety of Estrogens in Lupus National Assessment-SLE Disease Activity Index (SELENA-SLEDAI), organ involvement and evaluation of comorbidity (Charlson Comorbidity Index)] and on treatment status were collected from medical records. The main outcome was sexual dysfunction, defined as FSFI< 26.5 (validated cut-off). A multivariable logistic regression was perfomed to test the association of clinical and demographic characteristics with sexual dysfunction (present vs absent).

Results: In total, 194 female patients with SLE were included (mean age 44 years-old [standard deviation (SD) 11]). The mean SELENA-SLEDAI score was 1.7 (SD: 2.2), corresponding to low disease activity, and 94% of patients were on classical disease-modifying antirheumatic drugs. The mean value of HADS was 9 (0-21), for both depression and anxiety scores. Regarding SF36, the mental component had a mean value of 61 (0-100) and the physical one of 70 (0-100). Sexual disfunction was present in 128 (66%) patients.

In the multivariable analysis (Table 1), older age (OR: 1.04; 95%CI: 1.01; 1.07), higher SELENA-SLEDAI (OR: 1.18; 95%CI: 1.01; 1.40), higher HADS depression score (OR: 1.20; 95%CI: 1.01; 1.43), as well as a lower (that is, worse) SF36 mental component score (OR: 0.97; 95%CI: 0.95; 0.98) were independently associated with sexual dysfunction.

Conclusion: Sexual disfunction is common in women with SLE and is influenced by both physical and mental health components. Clinicians should consider both for the optimal management of their patients in order to improve their sexual QoL.

Session Date: Monday, November 13, 2023

Session Title: Reproductive Issues in Rheumatic Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Mental health conditions are the leading cause of maternal mortality across most of the United States. Among individuals with SLE, pregnancy intention has been noted as a risk factor for adverse pregnancy outcomes and infant complications. However, the impact of pregnancy intention on maternal mental health and quality of life in this population is poorly understood.

Methods: We conducted a prospective cohort study using data from a university-based pregnancy registry that enrolls pregnant women with rheumatic disease. Patient reported outcomes including the London Measure of Unplanned Pregnancy (LMUP) and Edinburgh Postnatal Depression Scale (EPDS) were collected at first rheumatology visit of pregnancy. The EPDS is validated in pregnancy. Data for patient measures and physician assessed SLE activity were obtained at each subsequent visit. Pregnancy intention was stratified into two categories: (1) Planned versus unplanned based on LMUP≥10 and (2) Medically optimized versus not optimized. Medically optimized for pregnancy was defined as < 1g of proteinuria, no rheumatic teratogens at conception, and continuing pregnancy compatible SLE medications after conception. We conducted primary and secondary analyses using Fisher's exact test to estimate the association of pregnancy intention with maternal depression, maternal mental health/quality of life, and maternal SLE activity. Multivariable logistic regression models were used to estimate the association of pregnancy intention with each outcome of interest.

Results:

Depression: Individuals with unplanned pregnancy were 2-3 times as likely to have maternal depression as those with planned pregnancy. On the other hand, individuals who were not medically optimized for pregnancy did not have a significant increase in depression (Table 1).

SLEPDAI ≥6	12 (32%)	5 (6%)	0.0005	0.14 (0.05, 0.45)	0.19 (0.06, 0.64)
PGA ≥1.0	14 (38%)	5 (6%)	<0.0001	0.11 (0.04, 0.35)	0.16 (0.05, 0.51)
Renal PGA ≥1.0	7 (19%)	0 (0%)	0.0002		

[1]SLEPDAI: SLE Pregnancy Disease Activity Index: 0=none, ≥6 moderate to severe SLE.
[2]PGA: Physician's Global Assessment: 0=none, ≥1.0 moderate, 3=severe
[3]Renal PGA: Physician's Global Assessment for renal disease, recorded within the LFA-REAL: 0=none, ≥1.0 moderate, 3=severe

Patient-reported SLE activity: Higher patient-reported lupus activity was seen in unplanned pregnancy than in planned pregnancy, with three-times as many reporting a moderate or severe flare. However, patient-reported lupus activity was not associated with whether or not pregnancy was medically optimized (Table 2).

Physician-reported SLE activity: When adjusted for marital status, household income, and Medicaid/Medicare insurance, unplanned pregnancies did not have higher SLE activity, despite higher patient-reported symptoms (Table 3).On the other hand, pregnancies that were not medically optimized had significantly higher rates of active SLE, SLEPDAI, and active nephritis, even though the women did not report higher SLE activity.

Conclusion: Early in pregnancy, maternal depression and patient-reported SLE symptoms were associated with unplanned pregnancy, but not whether SLE activity or medications were optimized in pregnancy. On the other hand, physician-reported SLE activity, which is an important predictor of pregnancy outcomes, was not increased in unplanned pregnancies, but was higher in pregnancies not medically optimized. These results suggest that addressing unplanned pregnancy may improve maternal mental health, and increasing medical optimization prior to conception may have more impact on pregnancy outcomes.

Delivering Care for Pregnant Women with Rheumatic and Musculoskeletal Diseases in Ireland: Current Challenges and Practices

Rebecca O'Farrell[1], Sinead Maguire[2], Louise Moore[3], Kieran Murray[4], Áine Gorman[5], Elisabeth Ball[6], Claire Riddell[6], Madeline O'Neill[7], Natasha Jordan[8], Barry O'Shea[9], Douglas Veale[10], Suzanne Donnelly[11], Grainne Murphy[12] and Gillian Fitzgerald[13], [1]Department of Rheumatology, Galway, Dublin, Ireland, [2]Toronto Western Hospital, Toronto, ON, Canada, [3]Our Lady's Hospice and Care Services, Harold's Cross, Dublin 6W, Harold's Cross, Ireland, [4]University Hospital Limerick, Limerick, Ireland, [5]Royal United Hospital, Bath, United Kingdom, [6]Belfast Health and Social Care Trust, Belfast, United Kingdom, [7]Our Lady's Hospice, Harold's Cross, Dublin, Ireland, [8]Addenbrooke's Hospital, Cambridge, United Kingdom, [9]St James's Hospital, Dublin, Ireland, [10]St.Vincent's University Hosp, Dublin, Ireland, [11]Mater Misericordiae University Hospital, Dublin, Ireland, [12]Cork University Hospital, Cork, Ireland, [13]University Hospital Galway, Galway, Ireland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic disease frequently affects women of childbearing age. Women with pre-existing rheumatic disease who are planning a pregnancy or develop these conditions during pregnancy often require specialist input from maternal-foetal medicine and Rheumatology. The aim of this study is to establish current practices regarding the management and monitoring of women with RMD (Rheumatic and Musculoskeletal disease) in Ireland and to identify current challenges.

Methods: In March 2023, a 17-question anonymised online survey was distributed using a well-recognised electronic survey tool. Rheumatology consultants, Registrars, Clinical Nurse Specialists (CNS), advanced nurse practitioners (ANP) and Allied health professionals currently working in a rheumatology unit in Ireland were invited to participate. The survey collected

demographics and data focusing on current delivery of care in place for pregnant women with RMD in Irish rheumatology units. SPSS was used for statistical analysis.

Results: The response rate was 69 %: 82% (n=54) female, 29% (n=19) Consultant Rheumatologists, 18% (n=12) Registrars, 27% (n=18) CNS, 20% (n=13) ANPs. Significant variability exists across clinical sites for pregnancy care delivery in RMD, with combined rheumatology/obstetric clinics occurring in only 18% of units (Figure 1). Preconception counselling is conducted in the General Rheumatology Clinic setting in 61% (n=40) of hospitals. In 41 % (n=27) of centres, women with RMD are reviewed once per trimester and 27 % (n=18) of centres reported no change to pre-pregnancy care. Less than 5 % (n=3) of clinical centres arranged monthly reviews during pregnancy. In 56% (n=37) of hospitals, there is no named Obstetrician for managing complex RMD patients during pregnancy.

The majority 49% (n=32) of respondents wished to review patients between 6 weeks and 3 months post-delivery and 46% (n=30) of centres reported offering clinical reviews in this period at present (Figure2). In 12 % (n=8) centres, clinicians offered no change to pre-pregnancy care. Professional healthcare role had no association with time to review post-delivery ($p > 0.05$). Challenges identified in delivering desired care included suboptimal communication between Rheumatologists and Obstetricians (23 %, n=15), complex care needs of patients (17 %, n=11), suboptimal infrastructure (17 %, n=11) (Figure 3). Common barriers to implementing a dedicated clinic included lack of clinical space (62 %, n=41), insufficient staffing (46 %, n=30) and maternity hospital not co-located with main hospital (50%, n=33).

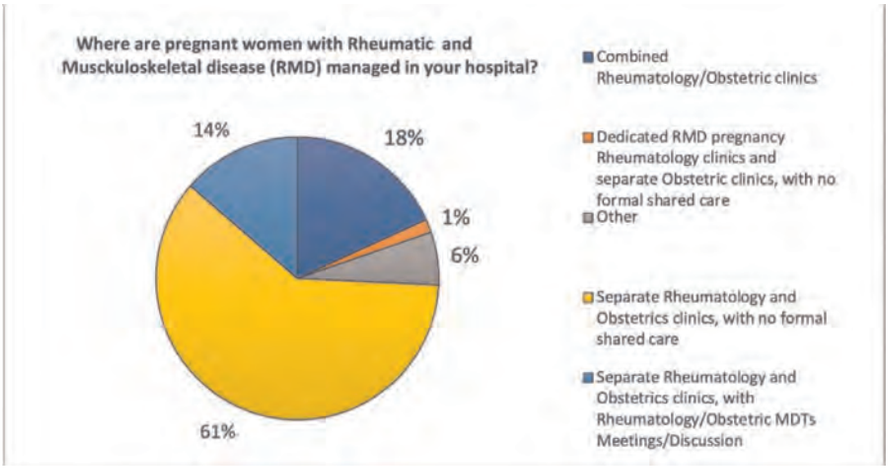

Figure 1.

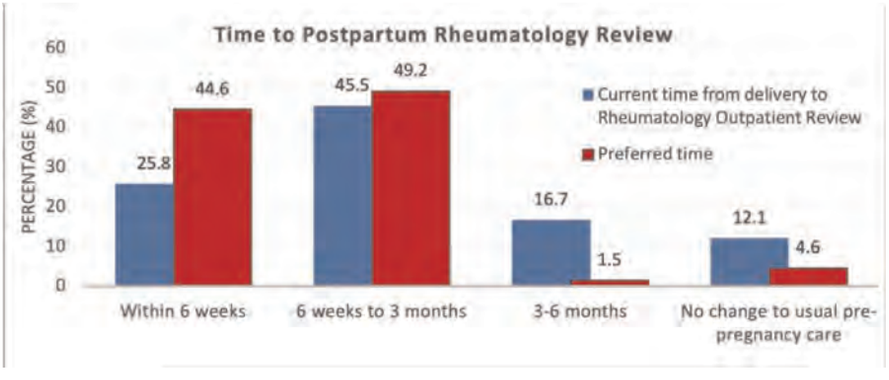

Figure. 2

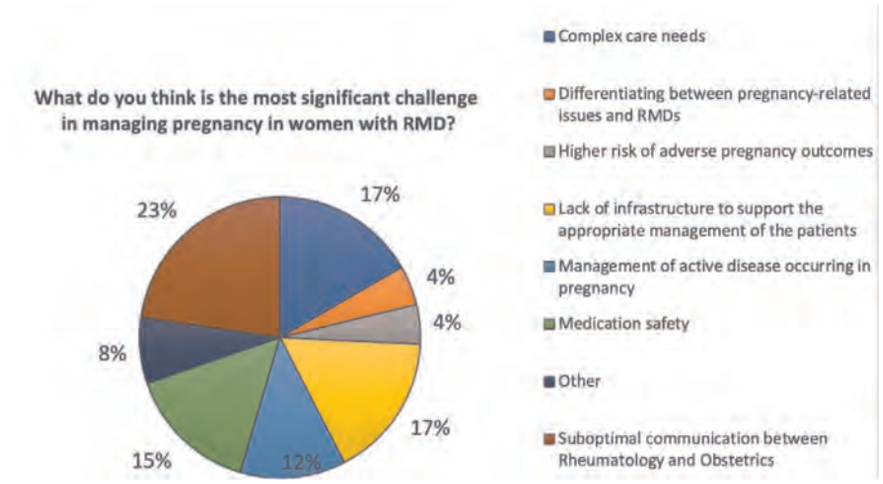

Figure 3.

Conclusion: Significant variation in the delivery of care for pregnant women with RMD is identified in this survey. The delivery of care to patients with RMD may be limited by deficiencies in our current healthcare setting. The development of a national framework for management and monitoring of women with RMD during their pregnancy would unify care, promoting optimisation of maternal health, control of disease and neonatal outcomes.

Reproductive History and HPV Vaccination Awareness Among Women with Systemic Lupus Erythematosus and Rheumatoid Arthritis

Amaya Smole[1], Lucy Masto[1], Caroline Siegel[1], Sarah Lieber[2], Sanjana Adurty[3], Jonah Levine[1], Bessie Stamm[1], Lisa Mandl[2], Michael Lockshin[2], Lisa Sammaritano[2] and Medha Barbhaiya[2], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [3]Weill Cornell Medical College, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with systemic rheumatic diseases (SRDs), particularly those with SLE, may be more vulnerable to HPV infection and HPV-related cervical cancer. However, HPV testing and vaccination rates are low in patients with SLE (Dhar et al. *J. Clin Rheumatol. 2019*). We aimed to assess and compare HPV vaccination status and awareness in female rheumatology patients with systemic lupus erythematosus (SLE) vs. rheumatoid arthritis (RA).

Methods: Women aged 18-65 years seen by a Hospital for Special Surgery rheumatologist ≥2 times between 2020-2022 were recruited to the Rheumatology Women's Reproductive Health and Wellness Cohort; cohort enrollment is ongoing. This interim analysis included cohort members self-reporting rheumatologist-diagnosed SLE or RA (excluding those reporting

both) who responded to questions on rheumatology history, reproductive history, and HPV vaccination awareness. We compared reproductive history and HPV vaccination status and awareness in women with SLE vs. RA.

Results: Of the 812 cohort participants, 711 (87.6%) completed the relevant questionnaires. This analysis included 295 participants: 111 with SLE and 184 with RA. Demographics were similar between the two groups, except those with SLE were younger (45.6 vs. 49.0 years, p=0.02). Women with SLE and RA were similarly likely to be sexually active, report a prior Pap smear, and report similar time since their most recent Pap smear (Table 1). While the two groups had numerically but not statistically different rates of abnormal Pap smears (42.9% vs. 32.8%, p=0.09), women with SLE were more likely to have persistent abnormal smears on follow up (13.3% vs. 1.7%, p=0.04). Gynecologic diagnoses were similar between groups, except two women with SLE and none with RA reported cervical cancer diagnoses (Table 1). Although more women with SLE discussed cervical cancer screening with their rheumatologist (33.3% vs. 11.4%, p< 0.01), women with SLE and RA were similarly due/overdue for cervical cancer screening. HPV vaccination uptake was similar between the groups, with 37% of previously/currently eligible women having completed the vaccine series. Of the 50% of previously/currently eligible women never beginning vaccination, 90% reported it not being offered. Both groups responded similarly to HPV vaccination awareness questions (Table 2).

Conclusion: Compared to women with RA, women with SLE at our tertiary musculoskeletal center reported a higher frequency of persistent abnormal Pap smears and were more likely to have discussed cervical cancer screening with their rheumatologists. Among women previously/currently eligible for HPV vaccination, 37% completed the vaccine series with no

Table 1. Demographic characteristics and reproductive history among women with systemic lupus erythematosus and rheumatoid arthritis

Reason for not starting HPV series (N = 72) - I was not offered the vaccine - Other**	 26 (86.7) 8 (26.7)	 39 (92.9) 5 (11.9)	 0.44 0.11

†Correct responses denoted in parentheses.
‡†Analysis conducted among respondents 49 years or younger given extended eligibility approved in 2019 for ages ≤45 years if clinically appropriate.
*These subjects reported the following reasons for not completing HPV series: I thought the first vaccine dose triggered a flare of my rheumatic disease (4 subjects), I forgot (3 subjects), other reason (2 subjects).
**Subjects reported the following *other* reasons for not beginning HPV vaccination (not mutually exclusive): did not know it was important for me (3 subjects), was concerned about vaccine side effects (3 subjects), other reason (8 subjects).

difference in vaccination rate or awareness between women with SLE and RA. Among the 50% of previously/currently eligible women who did not begin HPV vaccination, 90% reported never having been offered the vaccine although vaccination may have been warranted for those >26 years in certain instances (e.g. immunosuppressive medication use) based on expanded eligibility criteria. Our results suggest the importance of increasing both HPV vaccination and cervical cancer screening discussion in women with SLE and RA.

Systemic Lupus Erythematosus and Assisted Reproductive Technology: A Case Series and Systematic Literature Review

Erinn Coe[1], Emily Petrinec[1] and Omer Pamuk[2], [1]Case Western Reserve University/University Hospitals Cleveland Medical Center, Cleveland, OH, [2]Division of Rheumatology, Case Western Reserve University/University Hospitals, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is one of the most common autoimmune diseases in women of childbearing age and female sex hormones are known to play a role in the pathophysiology of SLE. Multiple studies have suggested impaired ovarian reserve in patients with even mild SLE. Women with SLE may also be advised to defer pregnancy until disease remission; however, the likelihood of conception decreases with advancing age and the use of potentially gonadotoxic immunomodulatory agents. For these reasons, assisted reproductive technology (ART) is an important consideration for women with SLE who desire pregnancy. Patients with SLE utilizing ART are theoretically at increased risk of hormone-associated disease flare or thrombosis. In this study, we aim to evaluate outcomes in women with SLE who have utilized ART in our center. We also performed a systematic literature review regarding safety and efficacy of ART in women with SLE.

Methods: A retrospective chart review was performed at a large tertiary care center. Patients with a diagnosis of SLE whose records included mention of in-vitro fertilization (IVF) or ART between 2010-2023 were reviewed. All included patients had a diagnosis of SLE based on the modified 1997 ACR criteria. In addition, a literature search was performed using electronic databases including PubMed, Web of Science, and Cochrane Library. Studies that reported data for patients with SLE who utilized ART were included. Case reports were excluded. Data collected for both the case series and literature review included type of ART utilized and number of cycles performed, demographic data, obstetric history, autoantibody positivity, etiology of infertility, delivery mode, maternal outcomes including SLE disease activity, and fetal outcomes.

Results: Nine patients were included in the case series and 6 studies in the literature review. Amongst patients included in the case series, ART was performed in 7 patients with SLE and SLE developed after the use of ART in 2 patients. - **Table 1** summarizes the main clinical features of patients. A total of 25 ART stimulation attempts resulted in 10 intrauterine (IU) pregnancies (40%). Of these, 8 resulted in live births. Two patients had SLE flare while receiving hormonal therapy. Our literature review revealed 256 relevant articles. The full text of 25 articles was reviewed resulting in 6 eligible studies. Between these studies and our case series, 283 SLE patients were reviewed. A total of 610 ART cycles were analyzed. These ART cycles resulted in 148 IU pregnancies and clinical pregnancy rate was 24.3%. Live birth occurred in 133 cases (89.9%). **Table 2** summarizes clinical features and major outcomes in the literature.

Conclusion: The rate of SLE flare in patients utilizing ART appears to be like that of SLE patients not receiving hormonal therapy. The success rate of ART in women with SLE is similar to that of the general population. This case series and review of the current literature supports the use of ART in patients with SLE who desire pregnancy.

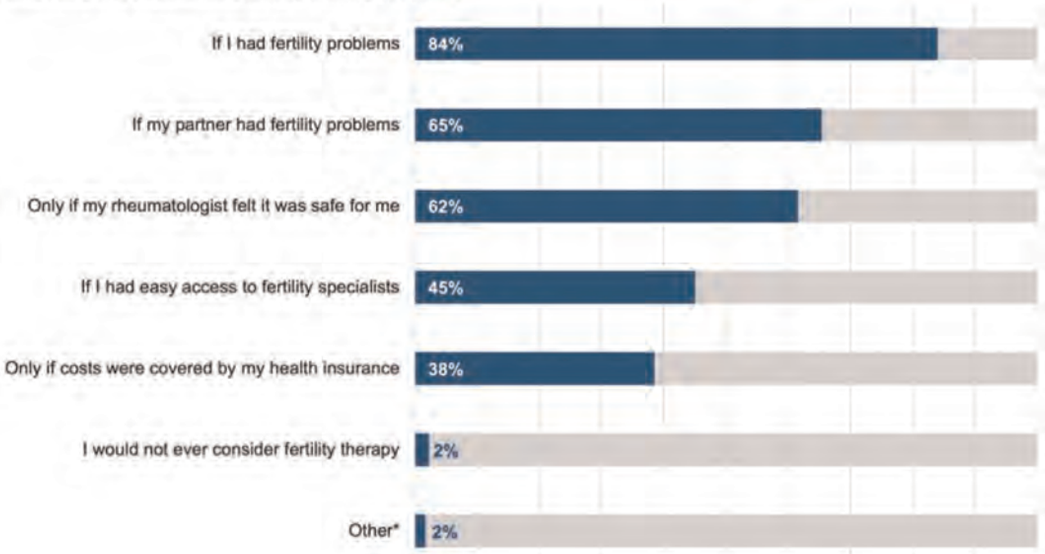
Experiences and Attitudes Related to Assisted Reproductive Technologies Among Women with Systemic Rheumatic Disease

Sanjana Adurty[1], Lucy Masto[2], Amaya Smole[2], Caroline Siegel[2], Sarah Lieber[3], Jonah Levine[2], Bessie Stamm[2], Lisa Mandl[3], Michael Lockshin[3], Medha Barbhaiya[3] and Lisa Sammaritano[3], [1]Weill Cornell Medical College, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic rheumatic disease (SRD) may be associated with decreased fertility. Advances in the safety and efficacy of oocyte cryopreservation (OOC) and other assisted reproductive technologies (ART) make these therapies increasingly appealing. However, few studies have assessed ART utilization among women with SRD. Here, we evaluate how sociodemographic factors and medical history influence OOC experiences and attitudes towards ART among women with SRD.

Figure 1. Relative importance of factors when considering whether to pursue fertility therapies among individuals who have not experienced fertility-related problems†



† The 228 (86%) participants who responded that they had never used other fertility therapies were asked why not, to which 121 (53%) had not previously tried to get pregnant and 61 (27%) had not had fertility problems. These 182 participants were subsequently asked to select the circumstances under which they consider receiving fertility therapies if they had fertility problems. They could select all responses that applied to them.
* The 3 participants who selected 'Other' were able to describe their thoughts in more detail through a free text box. Their responses are as follows:
- "I am egg freezing soon"
- "I would be concerned about egg /embryo freeze for religious and ethical reasons, so would only consider therapies that didn't result in extra eggs/embryos being harvested"
- "If the moment came that I'm prepared for a pregnancy and find difficulties conceiving"

Methods: We enrolled women ages 18-65 seen ≥2 times by a Hospital for Special Surgery rheumatologist from 2020-2022 in the Rheumatology Women's Reproductive Health and Wellness Cohort; cohort enrollment is ongoing. We included women aged 18-45 years with a self-reported SRD in this interim analysis. Using descriptive statistics, we assessed how sociodemographic factors, reproductive history, SRD, and rheumatology medications influence attitudes towards OOC. We also detailed the experiences of women who have undergone OOC, and we explored the relative importance of factors affecting decisions to use ART among women without previous fertility issues.

Results: Out of 815 cohort participants, 641 (79%) provided information on fertility; 265 were reproductive-aged with SRD. Of these, 21 (7.9%) had done OOC, and an additional 102 (38.5%) had contemplated OOC (Table 1). Openness to OOC was associated with no previous pregnancy ($p< 0.01$), greater infertility concern ($p< 0.01$), age< 30 ($p=0.01$), lack of a spouse/partner ($p< 0.01$), bachelor's degree or higher ($p=0.01$), and use of antimalarials ($p=0.04$) or DMARDs/immunosuppressives ($p=0.03$). Previous use of other ART and age ≥40 were associated with either completing OOC or never having considered OOC (both $p< 0.01$). Of participants who had undergone OOC, most (81%) did so before 35 years of age (Table 2). Three women had complications related to OOC, all reporting SRD flares. For those who did not have fertility issues, 112 (64%) reported that, if necessary, they would consider ART only if their rheumatologist felt it was safe (Figure 1). This was the third most important factor influencing consideration of ART, preceded only by the participant or partner experiencing fertility problems.

Conclusion: Almost half of women with SRD in our cohort have either undergone or considered OOC for fertility preservation. Attitudes towards OOC were associated with pregnancy history, fertility concern, experience with other ART, age, marital status, education, and rheumatologic medications. Among women who have completed OOC, most initiated their cycles before age 35. Receiving their rheumatologists' approval regarding the safety of ART is an important factor for many women who have not pursued ART. This analysis provides one of the first reports of OOC use in SRD. Our results highlight the significant role of SRD-related factors on attitudes towards and experiences with ART in women with SRD.

Table 1. Characteristics of reproductive-aged women with SRD who have completed OC compared to those who had not completed OC

Variable[1]	Completed OOC (N=21)	Considered OOC (N=102)	Never Considered OOC (N=140)	p-value[2]

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Whether the timing of menstruation impacts disease activity or severity among women with SLE or RA is poorly understood. We evaluated systemic rheumatic disease (SRD) flares related to the timing of menses, along with demographic, medical, and lifestyle characteristics among pre-menopausal women with self-reported diagnoses of SLE or RA.

Methods: We enrolled women ages 18-65 evaluated by a Hospital for Special Surgery rheumatologist ≥2 times from 2020-2022 in the Rheumatology Women's Reproductive Health and Wellness Cohort. This analysis includes participants who self-reported SLE or RA diagnoses and provided information on SRD flares and menstrual cycles. We conducted descriptive analyses to compare self-reported demographics, lifestyle factors, medication use, and SRD flare activity overall and related to timing of menstrual cycles, between women with self-reported RA and SLE. We excluded women self-reporting overlapping SLE and RA diagnoses, though participants may have additional SRD diagnoses.

Results: Out of 812 cohort participants,307 (37.8%) pre-menopausal women responded to our questions on menstruation. The current analysis includes 122 of the respondents (40%) who self-reported an SRD diagnosis of SLE (N=49) or RA (N=73). 85 (71.4%) participants were White, 16 (13.2%) were Hispanic or Latina/Latinx, and mean age was 37.6 years. Of those who reported medication use, women with RA were more likely to use biologics, DMARDS/immunosuppressives, or Janus kinase inhibitors within the last year (83.8% RA vs. 67.3% SLE, $p< 0.01$), while those with SLE more commonly used antimalarials (79.6% SLE vs. 43.8% RA $p< 0.01$). Fewer women with SLE used prescription birth control (20.8% vs. 39.7%, $p=0.03$). RA patients were also more likely to report a recent SRD flare within the last 3 months (64.4% vs. 42.9% $p=0.02$); however, SRD flares were most common in this time frame for both groups with comparable flare severity (mild, moderate, severe) between groups (Table). Of those answering our question on timing of SRD flare in their menstrual cycle, 39.1% reported any association of menstrual cycle timing with an SRD flare. Variation in the duration and schedule of menstrual cycles and the impact of participants menstrual cycles on SRD flares was consistent between SLE and RA groups. While the majority of participants in each group reported not experiencing SRD flares related to their menses, those who did typically experienced flares within one week before/during their menses (Table).

Conclusion: Our findings suggest that over a third of women with SLE or RA experience disease flares related to timing of menstruation, with most occurring before/during their menses. Our results highlight an important trend reported by many patients that may inform physician counseling and encourage closer monitoring during vulnerable phases of the menstrual cycle, allowing for timely intervention and better disease control. As cohort recruitment is ongoing, planned multivariable analyses adjusting for demographic, lifestyle, and medical conditions will investigate factors influencing this potential association.

Table. Demographic, Lifestyle, Medical, and Menstrual Cycle Characteristics in Women with SLE versus RA			
	SLE (N=49)	RA (N=73)	p-value
Demographics			
• Age (years), mean (SD)	37.17 (± 7.9)	38.0 (± 8.0)	0.58
Race (N=119)			
• White Only	30 (62.5)	55 (77.4)	0.08

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Reproductive Issues in Rheumatic Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancies in women with chronic diseases are often accompanied by concerns about potential complications [1]. This analysis explored medication-related concerns among women with inflammatory rheumatic disease (IRD) and identified influencing factors.

[1] PMID: 26039501

Methods: The German registry Rhekiss is a nationwide, multicentre, web-based cohort study to investigate pregnancies in women with various IRD. Women can participate if they are either planning a pregnancy (cohort 1) or are already pregnant (up to 20 weeks of gestation; cohort 2). Rheumatologist- and patient-reported data are captured at regular, pre-defined follow-up visits.

We analysed data of women who had responded to a question about concerns regarding pregnancy and child's health in relation to medication. Categorical answers and patient characteristics were analysed descriptively. The impact of factors associated with patients' anxieties was estimated by multivariable ordinal logistic regression using the proportional odds model and combining the two cohorts. Missing values were replaced by single imputation.

Table: Characteristics of patients stratified by level of concern.

	Cohort 1 (n=455)				Cohort 2 (n=784)			
Level of concern	Not at all	Not really	A little	A lot	Not at all	Not really	A little	A lot
Number of patients	29 (6.4)	79 (17.4)	193 (42.4)	154 (33.8)	124 (15.8)	159 (20.3)	302 (38.5)	199 (25.4)
Age in years (mean ± SD)	32.3 (4.0)	32.0 (3.8)	32.0 (4.4)	31.9 (4.4)	32.7 (4.2)	32.9 (3.9)	32.7 (4.3)	32.4 (4.3)
Disease duration in years (mean ± SD)	10.6 (9.3)	7.1 (7.0)	8.9 (8.0)	7.1 (7.4)	7.5 (7.0)	7.8 (6.2)	8.2 (7.3)	8.3 (6.9)
Moderate-severe disease	10 (50.0)	33 (49.3)	96 (61.5)	76 (65.5)	33 (31.4)	61 (47.3)	145 (58.7)	110 (65.5)
RAID score* (mean ± SD)	1.3 (1.3)	1.7 (1.6)	2.2 (1.9)	3.0 (2.2)	1.7 (1.7)	1.7 (1.7)	2.2 (1.8)	3.3 (2.3)
Current flare	3 (15.8)	4 (6.7)	15 (10.5)	42 (43.3)	4 (4.3)	4 (3.3)	19 (8.6)	29 (18.7)
Treatment changes**	9 (31.0)	31 (39.2)	112 (58.0)	96 (62.3)	29 (27.4)	47 (36.2)	125 (48.3)	85 (51.2)
Nulligravidae	15 (62.5)	52 (73.2)	111 (66.9)	88 (67.7)	55 (51.9)	65 (53.3)	141 (56.2)	95 (55.9)
Number of comorbidities (mean ± SD)	0.8 (0.9)	0.6 (0.8)	0.7 (1.0)	0.9 (1.0)	0.7 (0.8)	0.8 (0.9)	0.8 (1.0)	0.8 (1.0)

Values are given as number (percentage) unless otherwise indicated.
**RAID score: Patient-reported seven-item composite index originally developed for rheumatoid arthritis and now used for all IRD ranging from 0-10.*
***Treatment change either due to the intention to become pregnant or the ongoing pregnancy.*

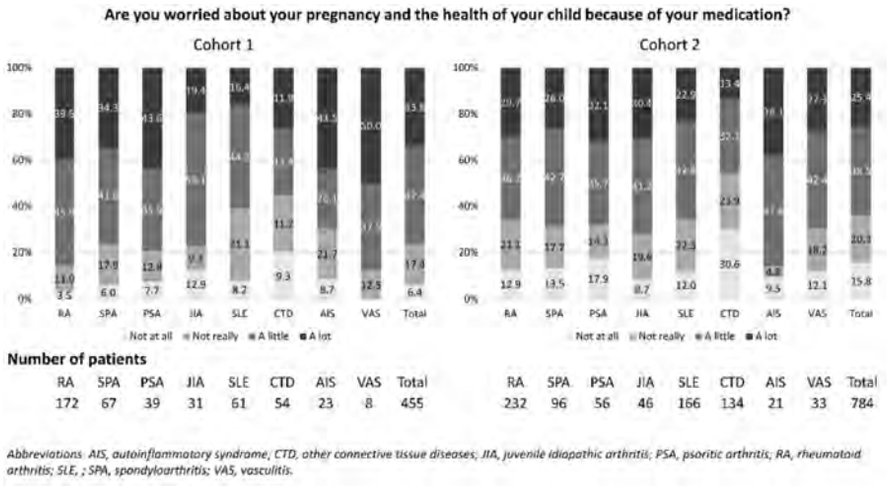

Figure: Level of concerns stratified by cohort and by IRD diagnosis.

Results: Between 09/2015 and 10/2022, a total of 2,240 patients were enrolled (cohort 1: 708, cohort 2: 1,532). Out of those, n=455 and n=784, respectively, were eligible for the analysis.On average, women were 32-33 years old and disease duration was 7-11 years (table).A total of 34% in cohort 1 and 25% in cohort 2 stated that they are concerned "a lot" (figure). Responses varied across different IRD diagnoses.

Treatment changes had the greatest impact on higher levels of worries, (odds ratio 1.72 [95% confidence interval 1.38; 2.14]). Furthermore, a significant association was found for moderate-severe IRD (1.34 [1.17; 1.53]) and a higher disease impact, measured by patient-reported RAID score (per 1-point-increase: 1.31 [1.24; 1.38]). Patients who were already pregnant at enrolment were less worried than patients planning a pregnancy (0.63 [0.51; 0.79]). No significant relationship was found for maternal age, number of prior pregnancies and comorbidities.

Conclusion: At least one in four women with IRD is "very concerned" about pregnancy and infant health due to medications. Treatment changes, moderate-severe disease and higher RAID score were associated with higher levels of concern. Therefore, worries should be an essential part of individual counselling for patients who either wish to become pregnant or are already pregnant.

Session Date: Monday, November 13, 2023

Session Title: Reproductive Issues in Rheumatic Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Achieving remission is one of the treatment targets in the lupus care and it is also important in preventing the prevalence of adverse pregnancy outcomes (APO).

Table 1: achievement of Zen/Doria remission and its relationship with adverse pregnancy outcome

Although there are reports on relationship with LLDAS/DORIS remission and APOs, little is known on the relationship with Zen/Doria remission and APO, so we conducted this study. In addition, we aimed to investigate optimal cutoff glucocorticoid dosage to predict APO prevalence.

Methods: Pregnant with SLE who was followed up at two Japanese tertiary referral centers were included in our study. We divided the patients into two groups according to the achievement of Zen/Doria remission at conception and analyzed the APO prevalence. Furthermore, we investigated the optimal glucocorticoid dosage to minimize APO.

Results: Of the 124 pregnancies, 59 achieved Zen/Doria remission at conception. Baseline characteristics except for glucocorticoid dosage and hydroxychloroquine usage at conception did not differ according to the achievement of Zen/Doria remission. (remission vs not on remission; prednisolone (PSL): 4.0 [0.0, 5.0] mg/day vs 10.0 [8.0, 11.0] mg/day, p< 0.01, hydroxychloroquine: 54.2% vs 37.8%, p=0.14)

table 2: glucocorticoid dosage and its relationship with adverse pregnanyc outcome

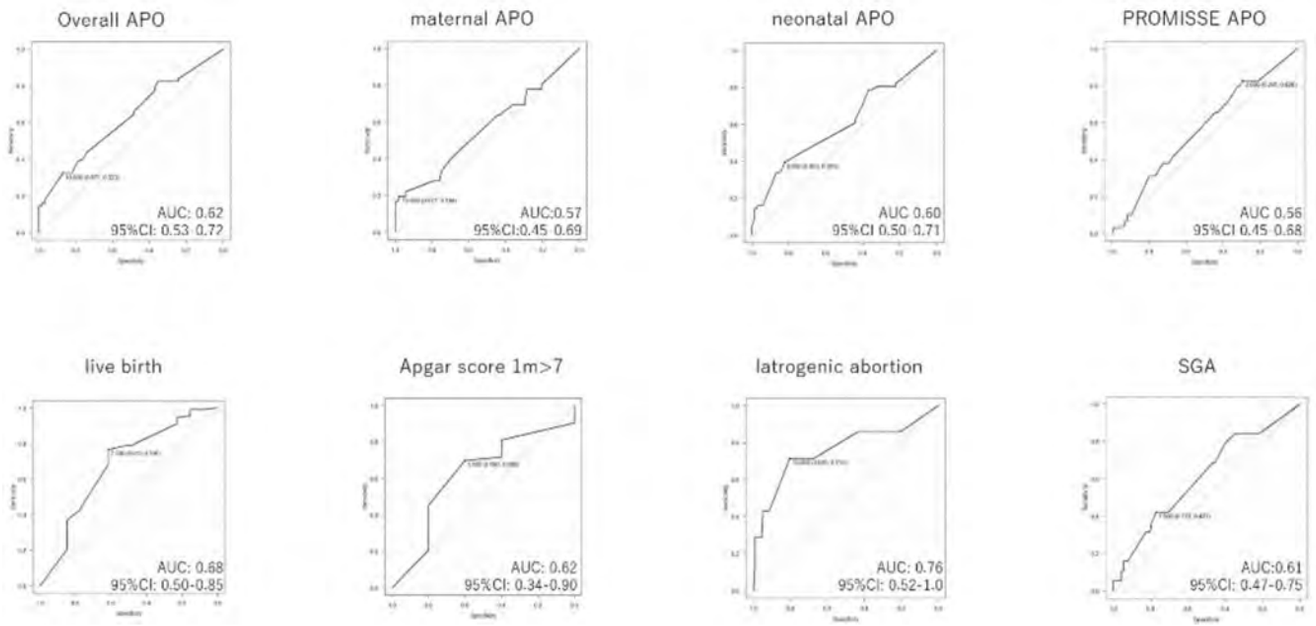

Figure 1 Receiver operating characteristic (ROC) curve for glucocorticoid dosage at first trimester to predict each adverse pregnancy outcomes

Pregnant on Zen/Doria remission showed significant decrease in the APO ratio compared with those without. (overall APO: OR 0.27, 95%CI 0.11-0.65, p< 0.01, maternal APO: OR 0.34, 95%CI 0.13-0.85, p=0.02, neonatal APO: OR 0.36, 95%CI 0.16-0.85, p=0.02, PROMISSE APO: OR 0.69, 95%CI 0.26-1.8, p=0.45)

On the other hand, glucocorticoid dose of prednisolone equivalent≥7.5mg/day at conception was associated with the increase in APO prevalence. (overall APO: OR 2.36, 95%CI 1.07-5.28, p=0.03, maternal APO: OR1.51, 95%CI 0.66-3.44, p=0.33, neonatal APO: OR 2.69, 95%CI 1.22-5.94, p=0.01, PROMISSE APO: OR 1.62, 95%CI0.68-3.89, p=0.28)

ROC curve also showed that prednisolone dosage >7.5mg/day was related to the decrease in live birth rate (AUC 0.68, 95% CI 0.50-0.85, sensitivity 0.77, specificity 0.62)

Conclusion: Achieving Zen/Doria remission can be a clinical target to reduce APOs in patients who wants to be conceived. In addition, if clinically feasible, reducing glucocorticoid dosage to less than 7.5mg/day before conception can be another treatment target.

Improving Reproductive Health Counseling for Pediatric Adolescent Females Prescribed Teratogenic DMARDs

Rina Ferguson[1], Itay Marmor[2] and Maleewan Kitcharoensakkul[1], [1]Washington University/B-JH/SLCH Consortium, St. Louis, MO, [2]Dana-Dwek Children's Hospital, Hod Hasharon, Israel

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Several rheumatologic medications routinely prescribed to adolescent females are teratogenic. However, there is no standard method to educate our patients and their families about this risk. This is a significant problem because U.S. teenage females with chronic illnesses engage in sex without contraception, and there are now strict abortion bans in some states prohibiting abortions for fetal anomalies. We performed a quality improvement (QI) project to increase the proportion of reproductive-age females receiving documented reproductive health counseling (RHC) at outpatient clinics in our single-center tertiary care practice. We specifically sought to educate patients about the teratogenicity of their medications and the need for contraception.

Methods: We included female patients aged 13 or older who were being seen as an outpatient and were taking methotrexate, mycophenolate, cyclophosphamide, or leflunomide. Two plan-do-study-act (PDSA) cycles were completed to test the following interventions: (cycle 1) physician and nurse educational seminar and creation of a smart phrase, which is a short template in our electronic health record system that users can pull into their notes on demand, (cycle 2) personal appeal to clinicians via email and development of an electronic health record note template, which automatically populates a note unlike a smart phrase. Chart review was performed at three time periods (baseline and after each round with n=80 each time period) to assess for documentation of "full RHC" (discussed risk of pregnancy AND the need for contraception), "partial

RHC" (discussed risk of pregnancy OR the need for contraception), or "no RHC." Chi-squared test was used for statistical analysis.

Results: In the anonymous pre-intervention questionnaire administered to patients (n=30), 46.7% said a rheumatologist had already discussed the need for contraception and 53.3% of patients knew that their medications may cause birth defects. However, chart review at baseline found that 60 of 80 (75.0%) patients received no documented RHC. After the first PDSA cycle, 26 of 80 (32.5%) patients received documented RHC, which was not a statistically significant improvement from baseline, p=0.5765. After the second PDSA cycle, 39 of 80 (48.8%) patients received documented RHC, which was a statistically significant improvement from the first PDSA cycle, p=0.0002. We found that patients prescribed methotrexate were more likely to receive RHC than those prescribed mycophenolate or leflunomide.

Conclusion: Overall, we learned that the most effective intervention for our group was creating a note template in Epic and sending a division-wide email. This project shows that it can be simple to improve reproductive health counseling because both interventions required no specialized skills or significant investment of resources. The next step in our PDSA cycle is to include RHC on printed after visit summaries (AVS) that are given to patients at the end of each visit.

Table 1: Patient demographic information

		Baseline 1/1/20 - 12/31/20	Post-intervention #1 8/1/21 - 12/31/21	Post-intervention #2 8/1/22 - 2/1/23

Plasma Neutrophil Extracellular Trap Remnant Levels Are Lower in Premenopausal Healthy Women Using Oral Contraceptive Pills

SESSION INFORMATION

Session Date: **Monday, November 13, 2023**
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Women develop RA 3 times more often than men, and several risk factors for RA are female specific. Prior studies demonstrate an association between oral contraceptive pill (OCP) use and a reduced risk of developing RA. However, the etiology of this protective effect remains unexplained. Anti-citrullinated protein antibodies (ACPA) develop prior to arthritis in RA, and their presence is associated with an increased risk of developing RA in the future. Exaggerated

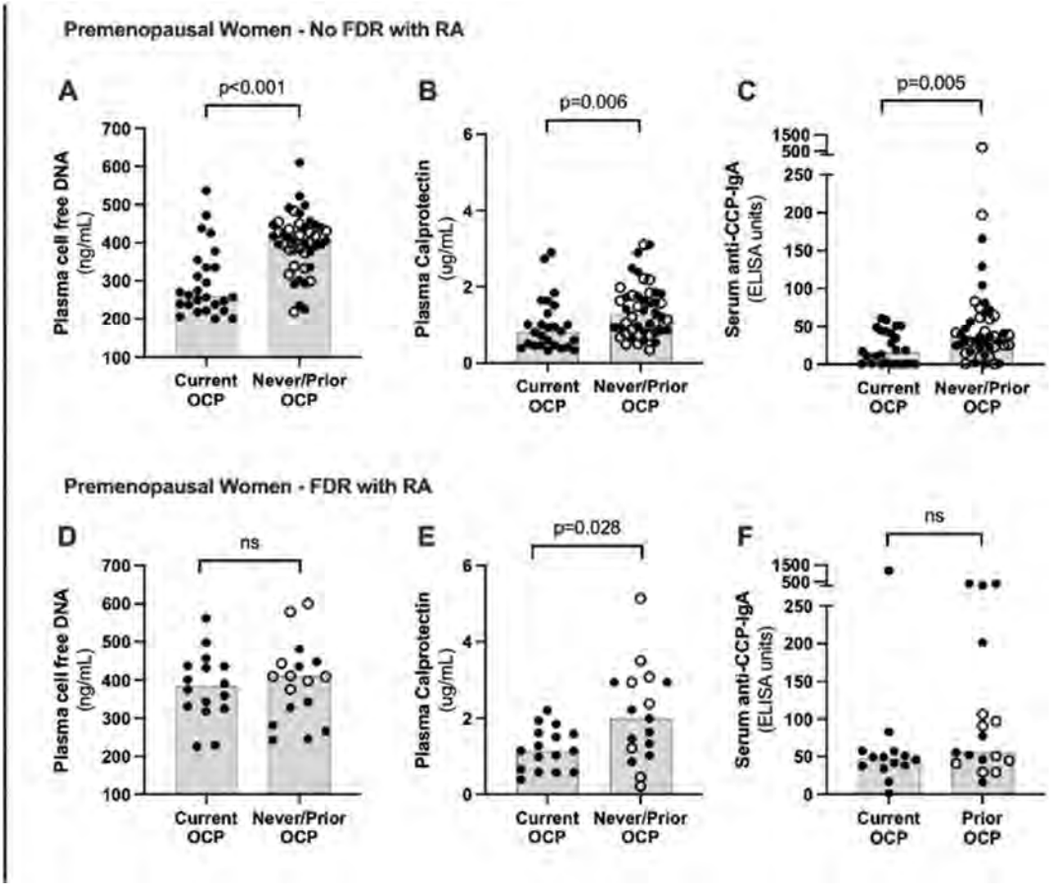

Figure 1. The figure depicts the levels of plasma cell free DNA (Panels A and D), calprotectin (Panels B and E) and serum anti-CCP-IgA (Panels C and F) in premenopausal healthy women (Panels A-C) and premenopausal women with a first degree relative (FDR) with RA (Panels D-F). Closed circles = current or prior OCP users; Open circles = never OCP users. P=values compare levels between groups using Wilcoxon rank sum test. OCP use could include combined OCPs (estrogen and progesterone) or progestin-only OCPs. There was no difference in cfDNA, calprotectin or anti-CCP-IgA levels between prior and never users in non-FDR or FDR groups (p>0.05 for all).

neutrophil extracellular trap (NET) formation has been implicated in RA pathogenesis, in part via externalization of citrullinated proteins targeted by ACPA. Moreover, neutrophils from pre-menopausal women are more prone to undergo NET formation (Blazkova 2017). Therefore, we investigated the relationship between OCPs, NETs and ACPA in pre-menopausal women without RA.

Methods: From the Denver site of the Studies of the Etiologies of RA cohort, we included all premenopausal women without RA and without pre-RA (i.e. serum anti-CCP-IgG positive) who had stored blood and were: 1) 'current OCP' users without prior use of other hormonal contraception, or 2) 'never/prior OCP' users without current/prior use of other hormonal contraception. Thirty-three had a first degree relative (FDR) with RA and 72 had no FDR with RA. Plasma was tested for NET remnants using immunofluorescence for cell free DNA (cfDNA, Quanti-iT PicoGreen dsDNA) and ELISA for calprotectin (Werfen). Serum was tested by ELISA for anti-CCP-IgA (research modification of CCP3.1, Werfen) as a measure of mucosal-based ACPA.

Results: Overall, FDRs were older, more likely smokers and had higher anti-CCP-IgA levels (Table 1). In women without an FDR with RA, cfDNA, calprotectin and anti-CCP-IgA levels were significantly lower in current OCP users compared to never/prior OCP users (Figure 1A-C). In adjusted analyses, cfDNA levels remained significantly inversely associated with current OCP use, while lower calprotectin maintained a trend toward an inverse association with current OCP use (Table 2). In FDRs, current OCP users had lower calprotectin levels but not lower cfDNA or lower anti-CCP-IgA levels (Figure 1D-F). The relationships between cfDNA, calprotectin, and OCP use in non-FDRs and FDRs was maintained in adjusted analyses (Table 2). In current OCP users, there was no correlation between cfDNA, calprotectin or anti-CCP-IgA level and duration of OCP use ($p > 0.05$), although overall median OCP duration was 7 years.

Conclusion: We found lower levels of plasma NET remnants and anti-CCP-IgA levels in current OCP users who were healthy premenopausal women without an FDR with RA. Calprotectin was similarly lower in FDRs currently using OCPs, although cfDNA and anti-CCP-IgA levels in FDRs did not differ by OCP status. Differences between FDRs and non-FDRs did not appear related to age or smoking, based on adjusted analyses, and may instead be related to underlying genetic

Table 1. Clinical characteristics, plasma NET remnants and serum anti-CCP-IgA levels by group

	Non-FDRs (N=72)	FDRs (N=33)	p-value
Age	30 (24 – 38)	36 (27 - 46)	0.03
Ever smoker	3 (4%)	10 (31%)	<0.01
Ever pregnant	28 (39%)	17 (52%)	0.23
Current OCP use	26 (36%)	16 (49%)	0.23
OCP duration	6 (3 - 10)	11 (4 - 24)	0.08
≥1 Shared epitope allele*	22 (43%)	12 (44%)	0.91
cfDNA	383 (271 - 430)	398 (327 - 440)	0.25
Calprotectin	1.0 (0.7 - 1.6)	1.5 (0.9 - 2.2)	0.07
Anti-CCP-IgA	30 (11 - 51)	51 (38 - 91)	<0.01

Results are reported in median (IQR) or N (%)
*Shared epitope testing available in 51/72 non-FDRs and 27/33 FDRs

Table 2. Results of multivariable linear regression for plasma NET remnant levels and current OCP use

	Non-FDRs (N=72)			FDRs (N=33)		
	Adjusted*			Adjusted*		
	Beta	95% CI	p-value	Beta	95% CI	p-value
cfDNA	-0.5	-142, -50	<0.01	-0.1	-95, 41	0.43
Calprotectin	-0.2	-0.7, 0.1	0.09	-0.5	-1.7, -0.3	<0.01

*Linear regression model adjusted for age, history of pregnancy and ever smoking

or environmental predisposition to increased NET formation. These findings support further studies to better understand whether modulation of NETs could explain the previously established relationship between OCP use and reduced RA risk.

Both Low and High 25(OH)-Vitamin D Levels Increase Adverse Pregnancy Outcomes in Systemic Lupus Erythematosus

Nima Madanchi[1], Andrea Fava[2], Daniel Goldman[3], Larry Magder[4], Rebecca Jacobson[1] and Michelle Petri[3], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [4]University of Maryland, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Reproductive Issues in Rheumatic Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: We evaluated the role of maternal 25(OH)-vitamin D in adverse pregnancy outcomes in systemic lupus erythematosus (SLE).

Methods: We used a longitudinal cohort that included visits of pregnant patients with assessment of 25(OH)-vitamin D at each visit. Pregnancies were excluded if there was no vitamin D level during pregnancy, if the outcomes of pregnancies were missing (such as data on due date, birth date, gestational age, and complications of pregnancies), or if the pregnancy was terminated. 270 pregnancies were available for the statistical analysis.

Results: We found a U-shape association between the maternal serum 25(OH)-vitamin D level and the combined adverse pregnancy outcomes (P=0.0022), miscarriage (P=0.0048), and preterm delivery (P=0.0003). We also found the same U-shape curve with the low birth weight; but it did not reach statistical significance due to the smaller number of cases. The lowest prevalence of adverse pregnancy outcomes was with 25(OH)-vitamin D in the range of 40-59 ng/dL (Figure 1). The multivariate analysis confirmed the same U-shape association controlling for age, race, and antiphospholipid antibodies (Table 1, Figure 2). The results were similar when we examined the subset in which pre-pregnancy or first trimester BMI were available.

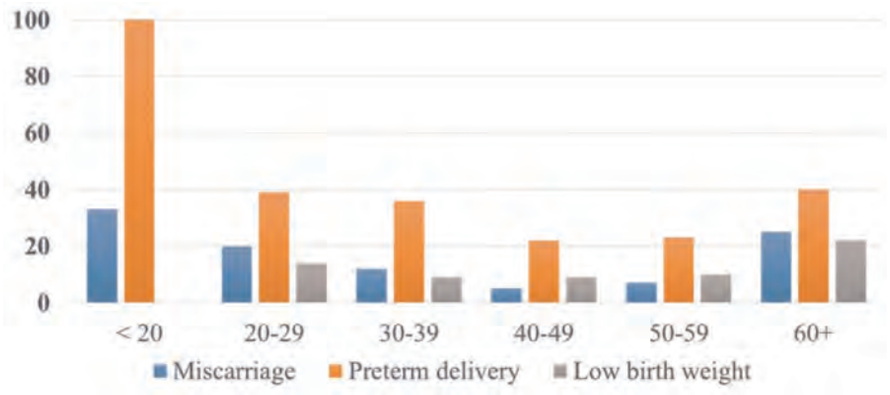

Figure 1. Adverse pregnancy outcomes occurrence (%) by mean 25(OH)-vitamin D (ng/dL) during pregnancy.

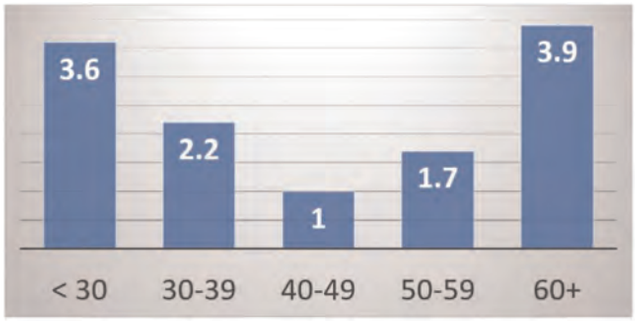

Figure 2. Odds ratios of combined adverse pregnancy outcomes with different mean 25(OH)-vitamin D levels controlling for age, race, and antiphospholipid antibodies.

Table 1. Odds ratios of adverse pregnancy outcomes with different mean maternal 25(OH)-vitamin D levels controlling for age, race, and antiphospholipid antibodies.

Mean 25(OH)-vitamin D during pregnancy (ng/dL)	Odds Ratio (95% Confidence Interval)	P-value
<30	3.6 (1.6-8.0)	0.0014
30-39	2.2 (1.1-4.4)	0.029
40-49	1.00 (reference group)	--
50-59	1.7 (0.7-3.8)	0.21
60+	3.9 (1.3-12.2)	0.018

Conclusion: Our study design cannot prove a cause-and-effect relationship. Most of our patients were prescribed vitamin D supplementation (but obviously many did not take it). We recommend monitoring 25(OH)-vitamin D levels during SLE pregnancies. The ideal 25(OH)-vitamin D range was 40-59 ng/dL.

Extraglandular Involvement and Autoantibody Status as Risk Factors for Cardiovascular Disease in Primary Sjogren's Syndrome (pSS): A 20 Year-follow up Study

Cristiana Sieiro Santos[1], Rúben Rego Salgueiro[2], Clara Moriano Morales[3], Carolina Álvarez Castro[3] and Elvira Díez Álvarez[3], [1]Complejo Asistencial Universitario de León, León, Spain, [2]ULS Guarda, Guarda, Portugal, [3]CAULE, León, Spain

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune disorder characterized by chronic multisystem inflammation with shared pathophysiology with SLE and RA. Cardiovascular events have emerged as major causes of morbidity and mortality in patients with autoimmune diseases however, the clinical significance of cardiovascular disease in patients with pSS remains unclear. We aim to study the association between cardiovascular disease and primary Sjögren's syndrome (pSS) and analyze the risk of cardiovascular disease accordingly to glandular/extraglandular involvement and anti-Ro/SSA and/or Anti-La/SSB autoantibody status.

Methods: pSS patients fulfilling the 2016 ACR/EULAR classification criteria for pSS were consecutively evaluated and followed in our department between 2000 and 2022. We evaluated the prevalence and clinical significance of cardiovascular risk factors with primary Sjögren's syndrome (SS), focusing on the possible association with clinical and immunological features, the therapies administered, and the impact on cardiovascular disease. A two-tailed value of $p< 0.05$ was taken to indicate statistical significance. Potential risk factors associated with cardiovascular involvement were determined by multivariate regression analyses.

Results: A total of 102 pSS patients were included. 90% were female, with a mean age of 65±24 years and a disease duration of 9.9 ±7 years. Patients with extraglandular involvement had a higher prevalence of cardiovascular risk factors, including arterial hypertension (OR 2.28 95% CI (1.01-5.09), p 0.04), dyslipidemia (OR 4.4 95% CI (1.67-11.6), p 0.003), higher LDL mean values (116±48 vs 99±44, p 0.038), uric acid (6.58±1.7 vs 4.3±1.03, p 0.04) and higher risk for myocardial ischemia (OR 4.09 95% CI (1.46-11.4), p 0.01) after adjustment for age, sex, disease duration, and the significant variables in the univariate analysis. Patients positive for both Ro/SSA and La/SSB autoantibodies had a substantially higher risk of arrythmia (OR 3.4 95% CI (1.01-10.6), p 0.04), arterial and venous thromboembolism (OR 5.5 95% (1.18-25.7), p 0.03) and stroke (OR 3 95% (1.02-8.8), p 0.04). In the multivariate logistic regression analysis, extraglandular organ involvement (p=0.008), beta2microglobulin levels (p=0.001), hypocomplementemia of C3 (p=0.01), the use of glucorticoids (p=0.02), hypergammaglobulinemia (p=0.02), ESR levels (p=0.007), treatment with HCQ (p=0.03) and an ESSDAI (Sjögren's syndrome disease activity index) >13 (p=0.02) were found to be factors associated with increased or decreased odds ratio forcardiovascular events in pSS patients. Anti-Ro/SSA and anti-La/SSB were significant predictors in univariate but not in multivariate analysis.

Conclusion: pSS patients are more vulnerable to cardiovascular diseases (CVDs). In addition to traditional CVD risk factors, we identified risk factors independently associated with cardiovascular involvement in pSS patients, which suggests the need for early detection and prevention measures to improve the prognosis in those patients.

	OR 95% IC	P value
Extraglandular involvement	16.5 (4.51-28.5)	0.008
Beta2microglobulin (mg/dL)	7.83 (3.16-12.5)	0.001
C3 (mg/dl)	0.92 (0.24-0.98)	0.01
Corticoids	7.2 (2.34-15.7)	0.02
Hypergammaglobulinemia	10.2 (4.5-21.2)	0.02
ESSDAI >13	1.8 (1.13-4.52)	0.02
ESR (mm/h)	1.4 (1.10-3.45)	0.007
HCQ	0.82 (0.26-0.92)	0.03

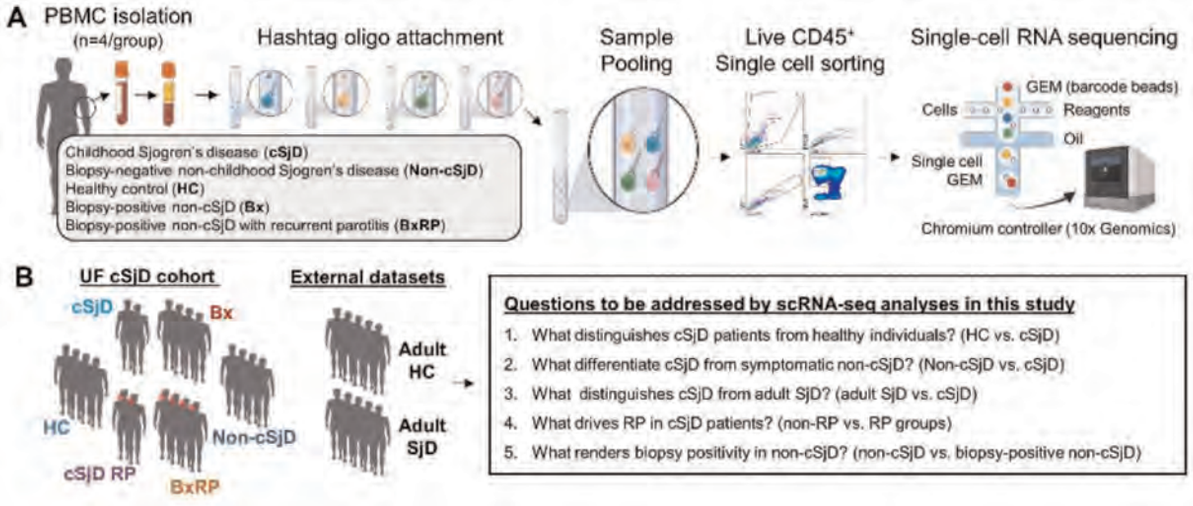
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: This study was performed to characterize key immune cell subsets and their interactions in patients with childhood Sjögren's disease (cSjD) for the first time in the field. Unlike Sjögren's disease (SjD), diagnostic criteria, treatment protocols, and natural history are unavailable in cSjD. In the current study, we aimed to address the following questions: 1) What distinguishes cSjD patients from healthy individuals?, 2) What distinguishes cSjD from symptomatic non-cSjD?, 3) Is cSjD a distinct disease entity from adult SjD?, 4) What involves biopsy positivity in non-cSjD?, and 5) Most importantly, what are the transcriptome and interactome profiles contributing to recurrent parotitis (RP), a chief complaint that prompts the most clinical visits from young children with cSjD?

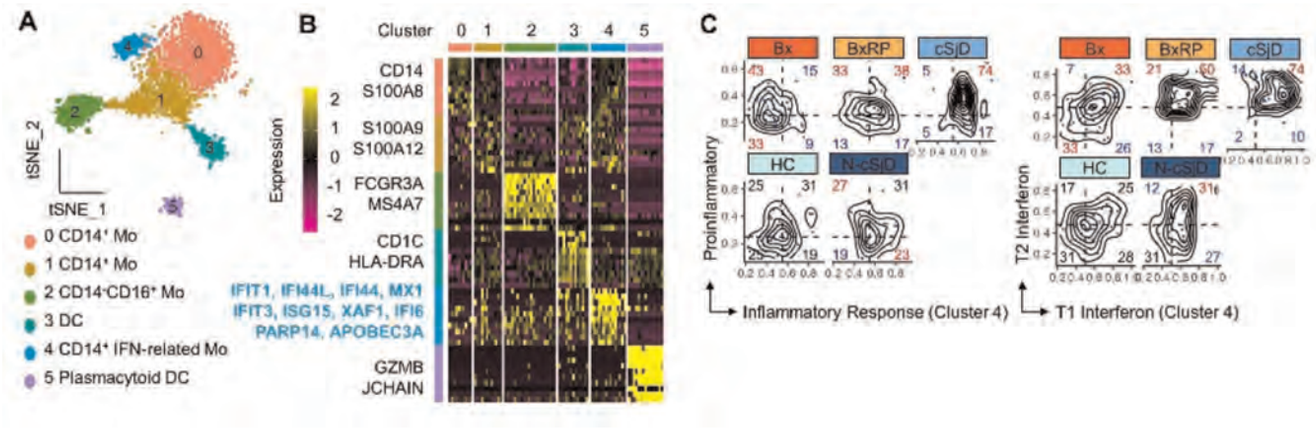
Methods: Five groups of four PBMC samples from the University of Florida (UF) pediatric cohort were profiled by single-cell RNA-seq (scRNA-seq). The groups include: cSjD, non-cSjD, biopsy-positive non-cSjD (Bx), biopsy-positive non-cSjD with RP (BxRP), and healthy controls (HC) (Figure 1). cSjD patients were diagnosed based on the 2016 ACR/EULAR criteria for



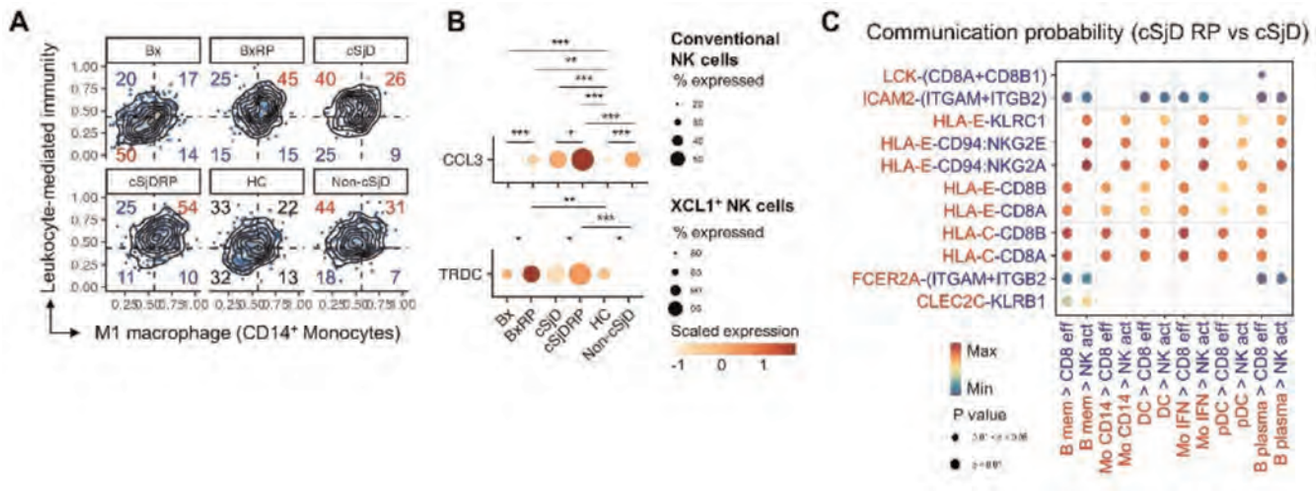
Overall study scheme. (A) Single cell RNA sequencing applied to peripheral blood mononuclear cells from 5 groups of interest is present. (B) Study design, groups, and analyses that will be covered by this study.

primary SjD. The CellChat R package identified cell-to-cell interaction strength and frequency. Flow cytometry for immune subsets and regulatory T cell (Treg) functional assays for Treg suppression were also performed.

Results: Prominent effector memory $CD4^+$ T cells (Tem) noted in cSjD were characterized by genes involving inflammation and cytolysis. A unique cluster of proinflammatory $CD14^+$ monocytes enriched with type I and type II IFN-related genes was highly specific to cSjD compared with the published scRNA-seq dataset from adult SjD (Figure 2). Surprisingly, *in vitro* Treg function in cSjD was intact and distinct from reduced Treg functionality in SjD. The X-C-motif-chemokine-ligand-1 $(XCL1)^+$ NK subset was expanded significantly, exhibiting functional enhancement in NK-mediated cytotoxicity and transmigration. Subjects with RP



Identification and characterization of proinflammatory myeloid subpopulations by scRNA-seq. (A) Six myeloid subsets are presented on the tSNE plot. (B) Among the top 20 DEGs defining each subset, representative genes are presented on the heatmap with Cluster 4 characteristically distinguished from others by the distinct upregulation of IFN-related genes. (C) Hex density enrichment plot reveals enrichment pattern of proinflammatory and inflammatory responses and type I and II IFN signatures in Cluster 4 of each group. Red and blue numbers on each quadrant illustrate upward and downward trends, respectively, compared to HC.



Molecular and interactome characterization of immune subsets involved in recurrent parotitis. (A) Hex density enrichment plot revealing enrichment pattern of "M1 macrophage" and "leukocyte-mediated immunity" in the classic monocyte subsets across the groups. RP exhibits a more inflammatory phenotype than those without, as evidenced by the RP-preferential shift toward the inflammatory signatures. The numbers in red and blue on each quadrant illustrate upward and downward trends, respectively, compared to HC. (B) Dot plot presenting RP-related upregulation of CCL3 and TRDC genes in NK subsets. Statistical significance was obtained by comparing two groups of interest with a non-parametric Wilcoxon rank-sum t-test. * $p < 0.05$, ** $p < 0.01$, and *** $p < 0.001$. (C) Identification of significant ligand and receptor pairs between immune subsets of interest, including effector CD8+ T and XCL1+ NK subsets. These subsets have shown increased communication probability with B and myeloid subsets via MHC class I-related genes in cSjD RP, compared to the groups without RP.

had more M1-like CD14$^+$ monocytes, Tem, and XCL1$^+$ NK cells. Importantly, effector CD8$^+$ T and XCL1$^+$ NK cells were analyzed to be activated by dendritic cells or memory B cells, based on our interactome analyses (Figure 3). Significant upregulation of CCL3 was noted in NK cells from patients in the RP group, compared to those not in the RP group.

Conclusion: Our study, based on scRNA-seq analysis of PBMC from our UF cohort, revealed that: 1) Enhanced immune cell interactions and inflammatory monocyte clusters enriched with IFN-related genes are the key features in cSjD. 2) M2-polarized monocytes distinguish non-cSjD from cSjD. 3) Tregs in cSjD are functionally competent, whereas the regulatory function of Tregs in adult SjD are suppressed. 4) Biopsy-positive non-cSjD contains proinflammatory M1-polarized monocytes. 5) Patients with RP present inflammatory immune subsets and enhanced interactions similar to cSjD. A subset of more activated NK cell subset might also contribute to RP through preferential recruitment of effector types of T cells, including MAIT-like CD8$^+$ T cells, by CCL3-producing NK cells.

Novel Autoantibodies Might Circumvent the Need for Labial Biopsy in a Subset of Seronegative Sjögren's Disease Patients

Maxwell Parker[1], Zihao Zheng[2], Michael Lasarev[3], Roxana Alexandridis[3], Michael Newton[3], Miriam Shelef[3] and **Sara McCoy**[4], [1]University of Wisconsin-Madison, Madison, WI, [2]Google, Sunnyvale, CA, [3]University of Wisconsin, Madison, WI, [4]University of Wisconsin School of Medicine and Public Health, Middleton, WI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's disease (SjD) is typically diagnosed by the presence of an anti-SSA antibody or focal lymphocytic sialadenitis in salivary gland tissue. Among SjD patients who are anti-SSA antibody negative (SSA-), a salivary gland biopsy is required for diagnosis. Our objective was to identify novel autoantibodies to non-invasively diagnose SSA- SjD.

Methods: IgG binding to a high density whole human peptidome array was quantified using sera from SSA- SjD (n=8) cases and age- and sex-matched healthy controls (n=8). The highest bound peptides from the array were confirmed by ELISA. Fifteen peptides were selected for external validation by ELISA using an independent cohort of subjects that were age-, sex-, and race-matched from the SICCA biorepository: SSA- SjD subjects (met 2016 ACR/EULAR criteria for SjD; n=76), sicca controls (sicca with negative ANA, rheumatoid factor, SSA, and focus score < 1; n=75), and autoimmune controls (positive ANA [≥1:320], rheumatoid factor, or SSA, but failed to meet 2016 ACR/EULAR criteria for SjD; n=41). Among all subjects, 85/192 (44.3%) had a positive focus score (FS ≥1). Peptide abundance was compared between groups using area under the ROC curve (*c*-index; AUC). Binary decision trees using R trees package were used to generate models predictive of SjD vs. controls. Adaptive Lasso was used for variable selection for binary logistic regression models.

Results: IgG against a peptide from DTD2 (D-aminoacyl-tRNA deacylase 2) and RESF1 (retroelement silencing factor 1) was bound more in SSA- SjD than in sicca controls (p=.004; p=0.045; Fig 1a) and more in SSA- SjD than in combined controls (sicca and autoimmune) (p=0.003, p=0.03; Fig 1b). The top performing classification tree model discriminating SjD vs. sicca

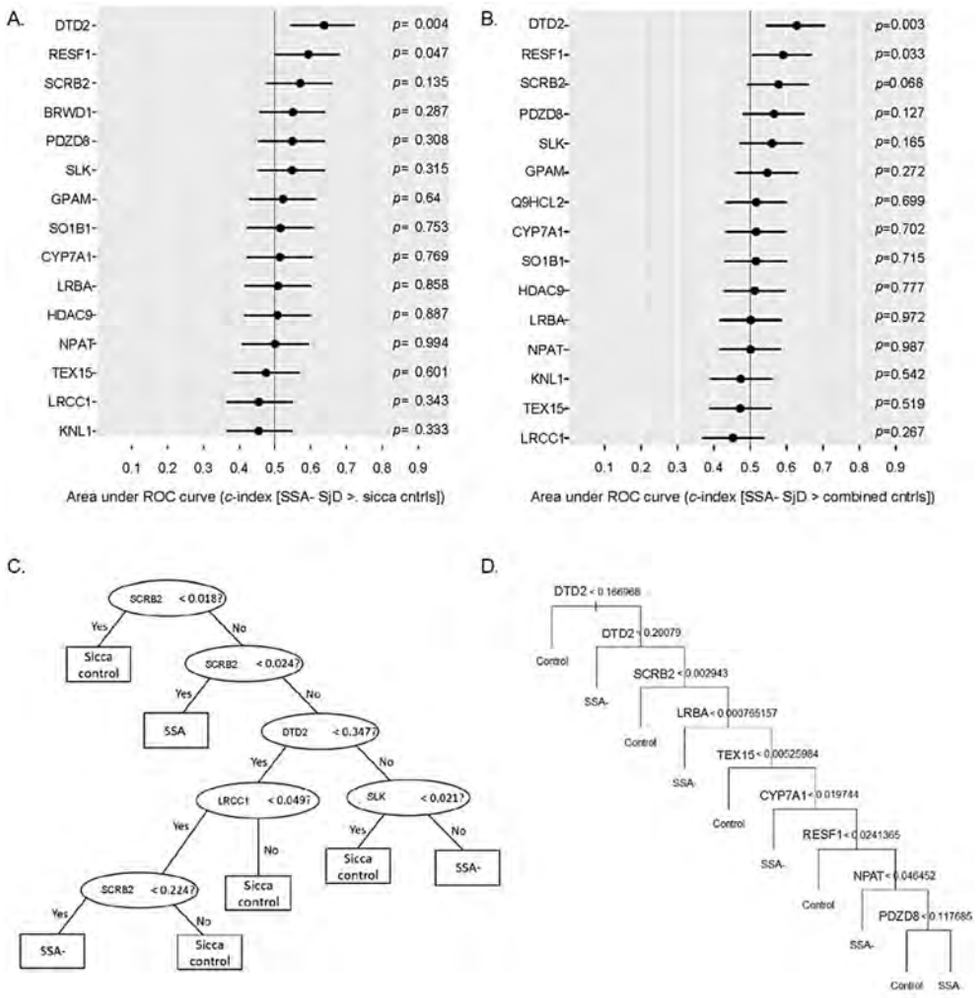

Figure 1. SSA- SjD subjects bind peptides from DTD2 and RESF1 more than controls. A) Area under the ROC curve (AUC) of the adjusted optical density of peptide groups between SSA- SjD (n=76) and sicca controls (n=75); B) AUC of the adjusted optical density of peptide groups between SSA- SjD (n=76) and a combined control comprising sicca and autoimmune controls (n=116); C) Best performing tree discriminating SSA- SjD vs. sicca controls; D) Best performing tree discriminating SSA- SjD vs. combined controls.

control included peptides from proteins SCRB2, DTD2, LRCC1, and SLK (65% accurate on validation set; Fig 1c). The top performing tree (55% accuracy upon validation) to discriminate between SjD and sicca controls involved peptides from proteins DTD2, SCRB2, CYP7A1, LRCC1, and KNL1. The top performing (62% accuracy upon validation) to discriminate between SjD and combined controls included peptides from proteins DTD2, RESF1, SCRB2, LRBA, TEX15, CYP7A1, NPAT, and PDZD8 (Fig 1d). Next, we defined if we could predict a positive FS. IgG against peptides from proteins RESF1, DTD2, and SCRB2 were bound more in patients with FS positive vs. negative (p=.010; p=0.012; p=0.027; Figure 2a). We incorporated peptide binding into a regression model with clinical variables including platelet count, SSB, ANA≥1:320, rheumatoid factor, and unstimulated whole salivary flow. Our dependent variable was FS (positive vs. negative). The final model showed good discrimination between FS positive vs. negative (Fig 2b-c). The AUC for this model is 71.6% (95% CI 63.9-78.2%) and allows flexibility to optimize for specificity, sensitivity, and positive and negative predictive value (Fig 2d-g).

Conclusion: We present novel autoantibodies inSSA- SjD compared to autoimmune- and sicca-controls that can be used to predict an abnormal FS on labial salivary gland biopsy with good predictive value.

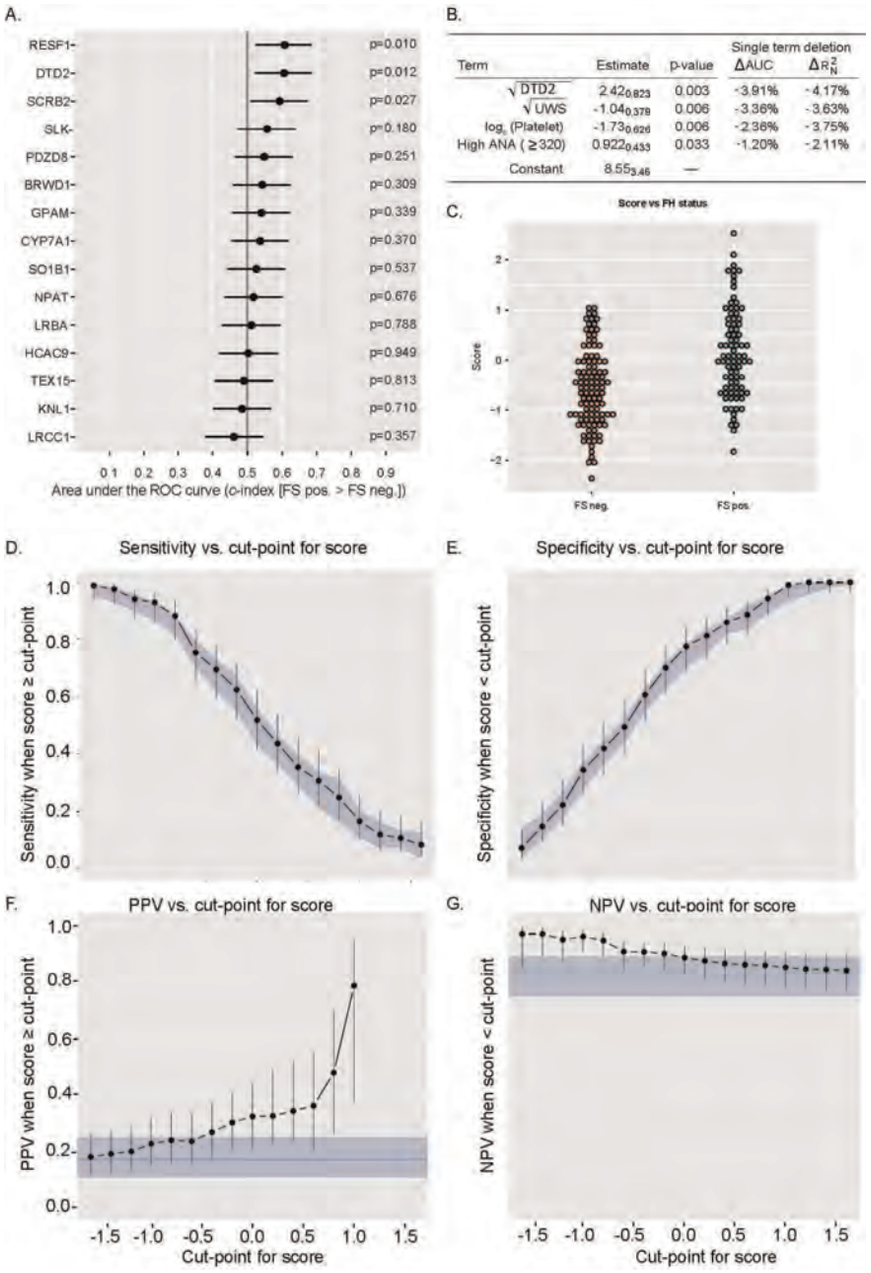

Figure 2. Models that incorporate binding to a peptide from DTD2 yield clinically relevant sensitivity, specificity, and positive and negative predictive value among SSA- patients. A) AUC comparing distributions of adjusted optical density of peptide groups comparing between focus score positive vs. negative (n=85 focus score positive and n=107 focus score negative). The forest plot shows the degree of IgG binding to the peptide of interest differed between focus score positive and focus score negative comparisons; B) Adaptive Lasso reduced variables from 33 to 5 (anti-SSB antibodies, RF, high ANA titer, IgG level, and platelet count) for separate binary logistic regression models. The model incorporated four predictors (binding a peptide form DTD2, unstimulated salivary flow, platelet count, and high ANA) with an AUC of 71.6% (95% CI 63.9-78.2%). The table shows estimated model coefficients and their standard errors in subscript; C) dot plot showing the separation between positive and negative focus score groups; D-E) Specificity and sensitivity graphed separately for cut-points of the score ranging from -1.6 to 1.6. Optimism-corrected values as dotted lines and differ from original values by at most 2.6 or 1.8% for sensitivity and specificity, respectively; F-G) Positive and negative predictive value graphed separately.

Development of the Sjögren's-related Quality of Life (SRQoL) to Assess Health-related Quality of Life (HRQoL) in Sjögren's

Benjamin A Fisher[1], Linda Stone[2], **Jessica Marvel**[3], Pushpendra Goswami[4], Monia Steenackers[4], Gayle Kenney[4], Chiara Perella[5], Wolfgang Hueber[4], Chloe Howse[6], Elizabeth Gargon[6], Aishwarya Chohan[6], Megan Mayhew[6] and Nicola Williamson[6], [1]University of Birmingham, Birmingham, United Kingdom, [2]The British Sjogren's Syndrome Association, Birmingham, United Kingdom, [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharma AG, Riehen, Switzerland, [6]Adelphi Values Patient-Centered Outcomes, Bollington, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

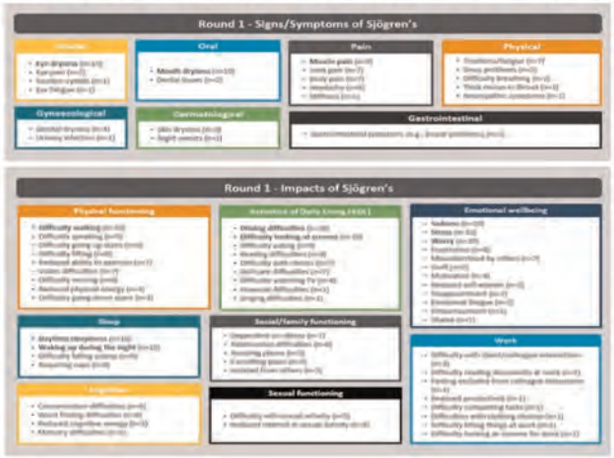
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's is a heterogenous chronic auto-immune disease, characterized by excessive dryness of the eyes and mouth, as well as systemic complications which can significantly impact patients' health-related quality of life (HRQoL). Existing patient-reported outcome (PRO) measures focus on the frequency/severity of symptoms but do not capture the impacts that Sjögren's has on patients' HRQoL. To address this gap, the Sjögren's-Related Quality of Life (SRQoL), was developed in line with Food and Drug Administration's Clinical Outcome Assessment (COA) guidance documents.[1-4] Qualitative interviews were conducted to evaluate the content validity and appropriateness of the SRQoL.

Methods: Patient advisory boards, social media listening, previous patient interviews, and findings from a prior literature review were reviewed to gain insights into the patient experience and HRQoL impact of Sjögren's to develop the SRQoL. Global impression of severity (PGI-S) and change (PGI-C) items were developed to inform further validation of the SRQoL. SRQoL and PGI-S/C development involved a patient advocate and physician as research partners. Combined qualitative concept elicitation (CE) and cognitive debriefing (CD) interviews are being conducted with adult (≥18 years) patients with primary Sjögren's from the US and UK, over two rounds. Round-one has been completed (n=10; 70% female; mean age = 52 years).

Figure 1: Conceptual model of signs/symptoms and impacts elicited from CE interviews during development of Sjögren's Related Quality of Life (SRQoL) in patients with Sjögren's



Results: From the review, an initial 36-item draft PRO measure was developed to assess HRQoL across seven hypothesized domains including physical functioning, activities of daily living, cognition, sleep, emotional wellbeing, social/family functioning, and work. Round-one CE results were consistent with Sjögren's related symptoms and HRQoL impacts elicited from the review (difficulty walking, driving difficulties, low mood/sadness, and daytime sleepiness). Concepts from the participant interviews (round one) were organized into a preliminary conceptual model in Figure 1. SRQoL and PGI-S/C items were well understood and relevant to most participants during round-one CD. Participants endorsed the 7-day recall period and frequency and severity response scales.

Conclusion: Initial findings support the content validity and suitability of the draft SRQoL, with round-two interviews currently underway. Following further testing and psychometric evaluation, the SRQoL is intended to provide greater understanding of patient burden and treatment benefit of Sjögren's in randomized clinical trials and may be used in clinical practice to monitor patients' HRQoL and improve patient-physician communication.

Treatment Patterns and Drivers of Biologic Prescriptions in Patients with Primary Sjögren's Disease: Results from a Multinational, Real-World Survey

Sara McCoy[1], Alan Baer[2], **Ann Xi**[3], Giorgio Castellano[4], Victoria Barton[4], Anthony Amatucci[5], Ilias Alevizos[6] and Haridarshan Patel[7], [1]University of Wisconsin School of Medicine and Public Health, Middleton, WI, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Horizon Therapeutics, Indianapolis, IN, [4]Adelphi Real World, Bollington, United Kingdom, [5]Horizon Therapeutics, Cambridge, MA, [6]Horizon Therapeutics, Rockville, MD, [7]Horizon Therapeutics, Deerfield, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Currently, no systemic therapies have been approved for Sjögren's disease (SjD) due to limited evidence regarding efficacy. However, biologics are often used in patients with active systemic involvement. Real-world data on treatment patterns and off-label use of biologics in SjD are lacking. We aimed to describe treatment patterns and identify potential drivers of biologic prescription in patients with primary SjD in real-world clinical settings.

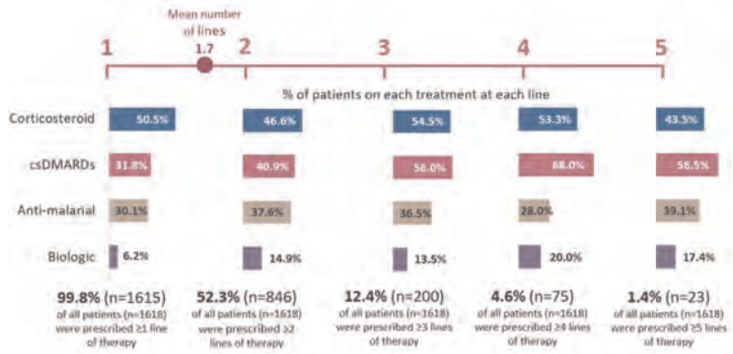

Figure 1. Lines of therapy in patients with primary Sjögren's disease. Progression in line of therapy defined as change in treatment regimen (including addition or removal of any other class of therapy from a regimen). Overall, 1618 patients had complete treatment pattern data. At each line of therapy, the % of patients prescribed each treatment class does not sum to 100% due to concomitant treatment class prescription. csDMARDs (conventional synthetic disease-modifying anti-rheumatic drugs) include azathioprine, methotrexate, cyclosporine, cyclophosphamide, mycophenolate mofetil and other csDMARD. Anti-malarial includes hydroxychloroquine and other anti-malarials.

Table 1. Variables identified from LASSO regression as factors associated with biologic prescription in patients with primary Sjögren's disease. Note that base size differs from main sample due to data completeness for all variables.

Characteristics associated with biologic prescription (N=1187)	Directionality of association with biologic prescription
United States of America (reference), N=320 (27%)	
Germany, N=213 (18%)	Negatively associated
Spain, N=209 (18%)	Positively associated
Patient aged 18-49 and 65+ (reference), N=674 (57%)	
Patients aged 50-64, N=513 (43%)	Positively associated
Physician-reported severity prior to treatment: mild (reference), N=168 (14%)	
Severe, N=230 (19%)	Positively associated
Physician-reported lines of therapy: 1 line (reference), N=585 (49%)	
2 lines, N=476 (40%)	Positively associated
3+ lines, N=126 (11%)	Positively associated
Physician-reported number of organs involved: 1 organ (reference), N=497 (42%)	
4+ organs involved, N=186 (16%)	Positively associated
Physician-reported organ involvement at diagnosis: not experiencing symptom (reference)	
Ulcers, N=18 (2%)	Positively associated
Lachrymal swelling, N=103 (9%)	Positively associated
Thrombocytopenia, N=40 (3%)	Positively associated
Lymphadenopathy, N=115 (10%)	Positively associated
Physician-reported concomitant conditions before diagnosis: not experiencing the concomitant condition (reference)	
Myocardial infarction, N=13 (1%)	Positively associated

Methods: Data were drawn from the Adelphi SjD Disease Specific Programme™, a cross-sectional survey of rheumatologists and their consulting patients with SjD in France, Germany, Italy, Spain, and the United States of America from 2018. Rheumatologists completed patient record forms for their next six SjD patients, reporting on demographics, clinical characteristics, physician-perceived disease severity (mild, moderate, severe), treatment history and reasons for treatment selection. A least absolute shrinkage and selection operator (LASSO) regression model was applied to identify drivers associated with biologic prescription. All other data were analyzed descriptively.

Results: 316 rheumatologists reported data for 1879 patients with SjD; 89% of patients were female, the mean (SD) age was 53 (12.18) years, 89% of patients were white and 67% of patients had moderate SjD as perceived by rheumatologists prior to SjD treatment. Of 1618 patients with complete data on treatment patterns, 99.8% (N=1615) of patients received ≥1 line of therapy (LoT), 52% (N=846) of patients received ≥2 LoTs and 12% (N=200) of patients received ≥3 LoTs. Corticosteroids were prescribed in 44-55% of patients with SjD, while biologics were least prescribed (6-20%) and were typically initiated at LoT 2 or later (**Figure 1**). LASSO regression (N=1187) revealed a higher likelihood of biologic prescription at 2 or later LoT. Patients with physician-perceived severe disease were also more likely to be prescribed a biologic than those with mild disease, as were patients with ≥4 organs involved at diagnosis (**Table 1**).

Rheumatologists' top five reasons for biologic prescription (N=223) included efficacy in treating organ manifestations (55%), reducing pain (51%), intent to slow disease progression (51%), and maintaining quality of life (50%). A further 49% also reported wanting to reduce steroid burden, even though around 50% of patients with biologic prescriptions had concomitant steroid use.

Conclusion: From this international survey, we found that patients with more LoTs, physician-perceived severe primary SjD, and greater organ involvement were more likely to be prescribed biologics. Across all LOTs, biologic use was low reflecting the lack of approved or effective drugs in SjD. Overall corticosteroid use was common, suggesting that available biologics may not be efficacious enough to reduce steroid use in SjD. There remains an unmet need among patients with primary SjD and further research is warranted to fully understand the impact of biologics on corticosteroid use among patients with SjD.

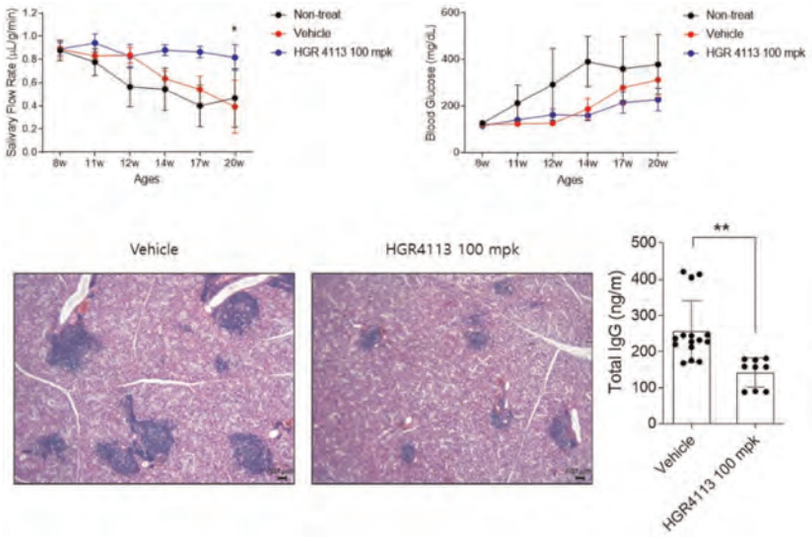
Synthetic Glabridin Derivatives Improves Sjogren's Syndrome by Inducing Salivary Secretion and Salivary Gland Regeneration

Eui-Jong Kwon[1], Jin-Sil Park[2], Ha Yeon Jeong[3], Hye Yeon Kang[4], JeongWon Choi[3], Mi-La Cho[3] and Sung-Hwan Park[5], [1]Division of Rheumatology, Department of Internal Medicine, The Catholic University of Korea Seoul St. Mary's Hospital, Seocho-gu, South Korea, [2]The Rheumatism Research Center, Catholic Research Institute of Medical Science, College of Medicine, The Catholic University of Korea, Seocho-gu, South Korea, [3]Rheumatism Research Center, Catholic Research Institute of Medical Science, College of Medicine, The Catholic University of Korea, Seoul, South Korea, [4]Rheumatism Research Center, Catholic Research Institute of Medical Science, College of Medicine, The Catholic University of Korea, Seocho-gu, South Korea, [5]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, South Korea

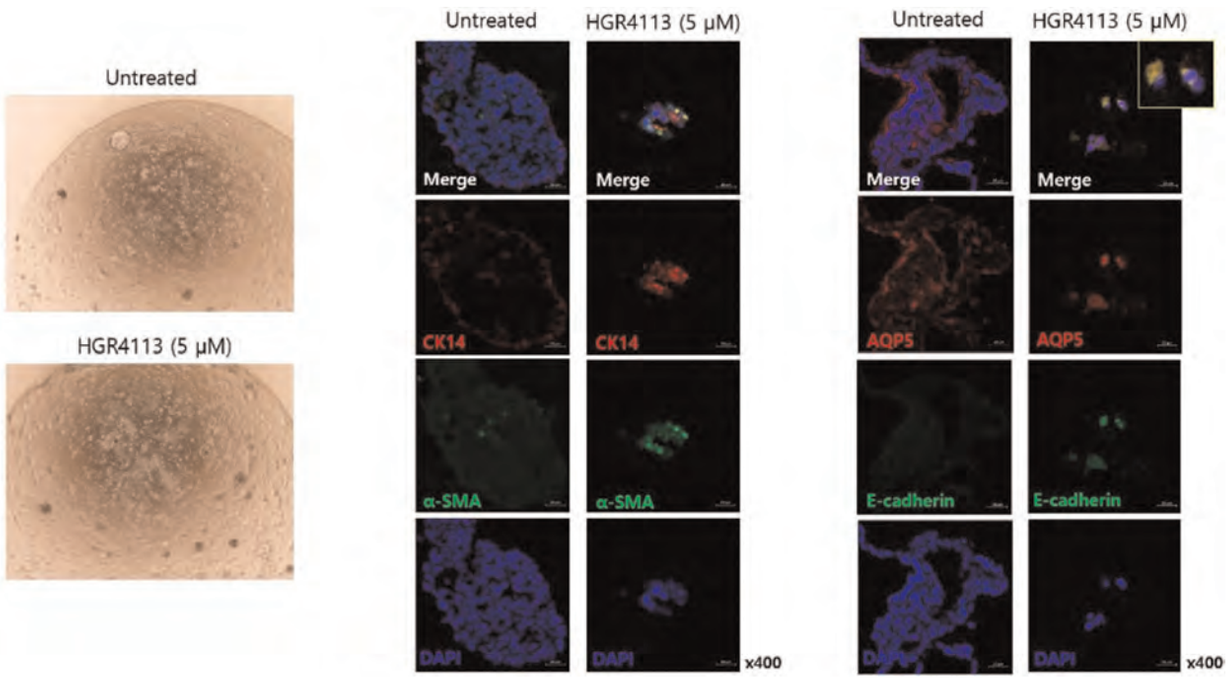
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjogren's syndrome (SS) is a systemic autoimmune disease characterized by infiltration of lymphocytes into the exocrine gland resulting in progressive lacrimal and salivary estruction and dysfunctional glandular secretion. Metabolic abnormalities of immune cells infiltrated into the salivary gland of patients with SS induce abnormal cell death



HGR4113 attenuates the severity of SS in NOD/ShiLtJ mice

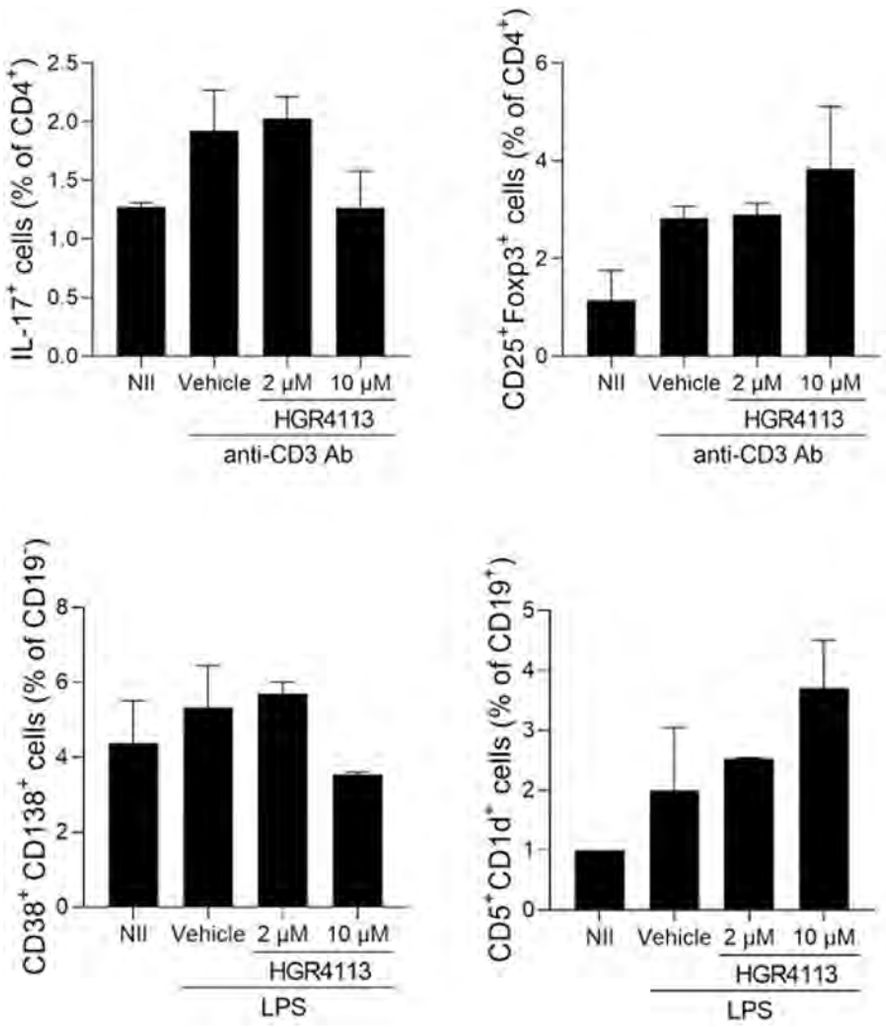


Treatment with HGR4113 promotes the generation of salivary gland organoids in vitro

and hyperactivity, which is involved in the exacerbation of SS. In this study, we investigated the effects of HGR4113, a structural analogue of glabridin under clinical trial for obesity, that promotes mitochondrial function, on the development of Sjogren's syndrome in non-obese diabetic NOD/ShiLtJ (NOD) mice.

Methods: NOD mice were orally administered 100 mg/kg of HGR4113 daily, and body weight, salivary flow rate, and blood glucose levels were measured every 3 weeks. Infiltration of inflammatory cells and levels of inflammation-related factors in salivary gland were histologically analyzed, and the development of salivary gland tissue organoids was investigated. The populations of various T– and B–cell subtypes in the spleen were assessed by flow cytometry. In vitro formation of salivary gland organoids was investigated by treatment with HGR4113.

Results: Oral administration of HGR4113 improved salivary flow rate and the infiltration of lymphocytes and the level of inflammatory cytokines in salivary gland of NOD mice. HGR4113 lowered the frequencies of splenic IL-17-producing T and B cells, germinal center B cells and plasma cells ex vivo in NOD mice. In addition, organoid formation from salivary gland stem cells of NOD mice administered with HGR4113 increased, and the levels of E-cadherin-14, Aquaporin-5, α-SMA, and Cytokeratin-14 increased. Treatment with HGR4113 also promoted the formation of salivary gland organoids in vitro.



Treatment with HGR4113 regulates the frequency of inflammatory cells in humans

Conclusion: These results show that HGR4113 can improve salivary gland hypofunction by inhibiting lymphocyte infiltration and inflammation in the salivary gland and restoring the damaged salivary gland in SS-Like NOD mice.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Salivary gland ultrasonography (SGUS) is commonly used in primary Sjögren Disease (pSD) as a diagnostic tool. It could also be used to monitor disease activity, but severity of SGUS parenchymal abnormalities in relation to disease duration is not well characterized. The objective was to assess transversally the severity of ultrasound salivary parenchymal abnormalities in relation to pSD duration.

Methods: In this prospective cross-sectional international multicentric study, patients with pSD according to 2002 or 2016 ACR/EULAR classification criteria were included. Parenchymal abnormalities assessed by ultrasound within both parotid and sub-mandibular glands were reported on a standardized form and classified according to the semi-quantitative score of the OMERACT. Reliability between experts was measured after online training. Patients were separated into 4 groups according to disease duration from the first buccal dryness symptoms (group A : < 5 years, group B : between 5 and 9 years, group C : between 10 and 20 years, group D : > 20 years of evolution).The association between disease duration groups and SGUS parenchymal abnormalities was quantified in terms of odds ratio and its 95% confidence interval.

Results: 247 patients were consecutively included between May 2019 and February 2022 in 11 international centers. They were 47, 69, 78 and 53 in groups A, B, C and D, respectively. Women represented 94.7% of patients, with a median age of 58 [range 19-89] years old. Oraldryness was reported by 99.6% of patients with an abnormal salivary flow in 75% of patients. The focus score was ≥1/4mm2 in 89% of patients. 85% of patients had positive anti-SSA. The median ESSDAI score was 3 [0-48]. Considering for each patient the most severe gland, there was a global significant association between disease duration and OMERACT score (OR for 5 years duration : 1.23 [IC95% 1.04 ; 1.47], p=0.02). Considering each US parameter, there was not any statistical difference between the 4 groups, notably in relation to the proportion of an/hypoechoic areas in the gland. The only statistical difference between groups was found regarding the proportion of hyperechoic bands (p = 0.002). Proportion of hyperechoic bands was not associated with age (p=0,90) but was associated with visual analogic scale for dryness (p=0,002).

Conclusion: This large international cross-sectional study in patients with pSD found a positive association between the OMERACT score and disease duration, with a significant difference only observed in the proportion of hyperechoic bands, when considering separately each US parameter. This may suggest a progressive fibro-adipous evolution of the gland across disease duration related to pSD itself and not related to older age, while surface of hypoechoic areas could be more linked to inflammation, and could be more usefull in clinical trials to assess SGUS modifications after treatment.

Obinutuzumab Efficacy and Tolerance in Patients with Auto-Immune Diseases Immunized Against Rituximab

Mathilde Pezot[1], Gaetane Nocturne[2], Rakiba Belkhir[1], Julien Henry[1], Stephan Pavy[1], Raphaele Seror[3], Xavier Mariette[4] and Samuel Bitoun[5], [1]Rheumatology Department, Université Paris-Saclay, INSERM U1184, Hôpital Bicêtre, APHP, FHU CARE, Le Kremlin-Bicêtre, France, [2]APHP, Le Kremlin-Bicêtre, France, [3]University Hospital Paris Saclay, Le Kremlin-Bicêtre, France, [4]Université Paris-Saclay, Le Kremlin-Bicêtre, France, [5]CHU Bicêtre APHP, Le Kremlin-Bicêtre, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Among patients with auto-immune diseases (AID) treated with Rituximab (RTX), anti-drug antibodies (ADAb) leading to inefficacy and infusion reactions (Wincup and al., Ann Rheum Dis, 2019) is a frequent complication. We previously showed that it was more common in systemic AID than in RA (Combier and al, Rheumatology, 2020) In these conditions, targeting B cells with another anti-CD20 molecule is the only option. Obinutuzumab (OBZ) is an anti-CD20 humanized antibody frequently used in hematological malignancies. However, only few studies reported its efficacy and

safety on a limited number of patients with autoimmune diseases, and never in the context of immunization against RTX. (Kvacskay and al., Ann Rheum Dis, 2022 ; Furie and al. Ann Rheum Dis, 2022). The presence of ADAb allows to hypothesize that targeting CD20 can still be efficacious with another molecule to which ADAb against RTX are not cross-reactive.

Methods: This study aims to describe efficacy and tolerance of consecutive patients with confirmed ADAb against rituximab and treated with OBZ between 2019 and 2023 in our tertiary department. Clinical and biological variables were collected before OBZ and 3 months after the first infusion. Response to OBZ was determined by the physician.

Results: Thirteen out of 15 were females (87%), with a median age of 53 years; 13/15 (87%) had Sjogren's syndrome (SS). Among Sjögren patients 3/13 also had systemic lupus erythematosus (SLE), and 2/13 also had anti-synthetases syndrome. The remaining 2 patients did not have Sjogren's and had eosinophilic granulomatosis with polyangiitis and mixed connective tissue disease.Thirteen out of 15 (87%) patients had been tested positively for anti-RTX antibodies. The most frequent symptoms leading to OBZ infusions were polyarthritis for 6/15 (40%) of them, cryoglobulinaemia for 3/15 (20%). The median duration from onset of the disease to first OBZ infusion was 9 years. The median number of cycles of RTX before OBZ was 2. Two patients had also received ofatumumab, another anti-CD20 therapeutic antibody. (Table 1). OBZ was well-tolerated in all patients without any infusion reaction even in patients with previous infusions reactions to RTX. Seven out of 15 (46%) patient presented with non-serious infections (Grade 1-2) mainly respiratory. Eight out of 15 patients (53%) had a clinical response to OBZ at 3 months. Comparing OBZ responders and non-responders at 3 months showed that responders trended to have longer disease duration (11 years vs 6, p=0.08). Number of treatment lines, co-treatments with corticosteroids or methotrexate were not different between groups.

Conclusion: In conclusion, obinutuzumab can be a good therapeutic option for AID patients who are immunized against RTX without symptomatic cross immunogenicity, with good tolerance and with clinical response in half of the patients. Further studies are required to determine which type of patients could respond to this treatment.

Abstract Number: 1373

Deltex1 May Involve the Function of T Regulatory Cells and Regulate the Disease Activity of Sjögren's Syndrome

Ming-Han Chen, Division of Allergy, Immunology & Rheumatology, Department of Medicine, Taipei Veterans General Hospital, Taipei, Taiwan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Deltex1 is a transcription target of nuclear factor of activated T cells in mice and promotes T cell anergy. We have previously reported that silencing of Deltex1 expression enhanced IFN-γ secretion by human T cells after stimulation with anti-CD3 and anti-CD28 antibodies. In this study, we aimed to investigate the role of Deltex1 in patients with Sjögren's syndrome (SjS).

Methods: Peripheral T cells were collected from SjS patients and healthy controls for analysis of Deltex1 gene expression by RT-QPCR. The expression of T regulatory cells (Tregs)-associated molecules, including PD-1, CTLA-4, LAG-3, TIGIT, TIM-3, and cytokines were measured by flow cytometry.

Results: We found that Deltex1 expression in T cells was significantly lower in the primary Sjogren's syndrome patients than inhealthy controls ($p < 0.001$). Interestingly, Deltex1 expression in T cells was negatively correlated with the v*isual analogue scale* (*VAS*) for dryness, VAS for fatigue, European League Against Rheumatism (EULAR) SjS outcome measures, the patient reported index (ESSPRI), and the disease activity index (ESSDAI) ($p < 0.001$, $p = 0.003$, $p = 0.017$, and $p = 0.003$, respectively), but not with VAS for pain ($p = 0.495$). Importantly, we found that Treg-associated molecules expression, including PD-1, CTLA-4, and TIM-3, andanti-inflammatory cytokine interleukin-10 on $CD4^+FoxP3^+$ Tregs was significantly higher in low Deltex1 expression group than high Deltex1 expression group (all $p < 0.05$).

Conclusion: These results suggested that Deltex1 may involve the function of Tregs and regulate the disease activity of SjS.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) has been reported to be present in 10-15% of patients with primary Sjögren's syndrome (pSS). Knowledge on risk factors predicting the development of ILD in pSS and its impact on long-term outcome is limited and no standardized disease management exists, including screening and monitoring. The aim of this project was to evaluate the presence of ILD in pSS, assess risk factors for the development of ILD and its impact on mortality.

Methods: This is an international multicenter study including patients with pSS with and without ILD from expert centers. All patients fulfilled the 2016 ACR-EULAR classification criteria for pSS. ILD was diagnosed on high resolution computed tomography (HRCT) assessed by expert radiologists in each center. Comprehensive clinical characteristics, lung function tests including forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO) were available. Vital status was assessed at last available observation. We applied multivariable Cox regression to assess risk factors predicting ILD and mortality, presented as hazard ratio (HR) with 95% confidential interval (CI). Survival was assessed using Kaplan-Meier estimates.

Table: Disease characteristics of all patients and patients with ILD

	All pSS (n=843)	pSS-ILD (n=74)
Male sex, n (%)	73 (8.7)	15 (19.7)
Age, yrs (SD)	50.5 (14.7)	52.7 (14.9)
Time from pSS to ILD diagnosis, yrs (SD)	n.a.	6.9 (8.9)
ILD diagnosed after pSS, n (%)	n.a.	48 (65.8)
Anti-Ro-SSA, n (%)	456 (72.6)	58 (90.6)
Anti-Ro-SSA and La-SSB, n (%)	227 (34.6)	34 (50)
CRP, mg/l (SD)	5.2 (13.6)	6.4 (11.2)
ESR, (SD)	23.8 (20.2)	30 (19.4)
Extraglandular manifestation		
Polyneuropathy, n (%)	64 (8.9)	13 (18.6)
Dermal affection, (%)	48 (6.7)	11 (15.5)
Nephritis, n (%)	18 (2.5)	3 (4.1)
Lymphadenopathy, n (%)	62 (8.6)	16 (21.9)
Lymphoma, n (%)	24 (3.3)	7 (9.7)
Death, n (%)	140 (16.6)	13 (17.1)

Results: The study cohort included a total of 843 patients with pSS; 9% were male, age at time of pSS diagnosis was 51.5 (SD 15.1) years, 72.6% were positive for anti-Ro-SSA and 34.6% for both anti-Ro-SSA and anti-La-SSB (Table).

In total, 498 (59%) patients were assessed by HRCT. Of these, 76 (15%) were diagnosed with ILD (Table). Of all pSS-ILD patients, 21 (33%) were diagnosed with ILD at time point of or prior to the diagnosis of pSS, while 48 (67%) were diagnosed in a mean follow-up of 11 (SD 8.2) years after diagnosis of pSS.

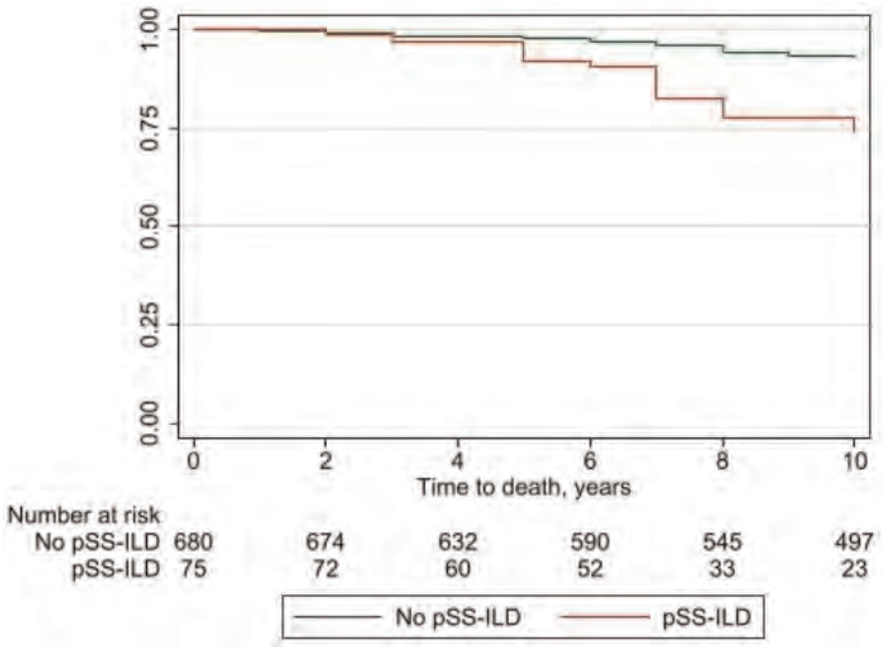

Figure 1: Time to death in pSS patients with (red line) and without ILD (green)

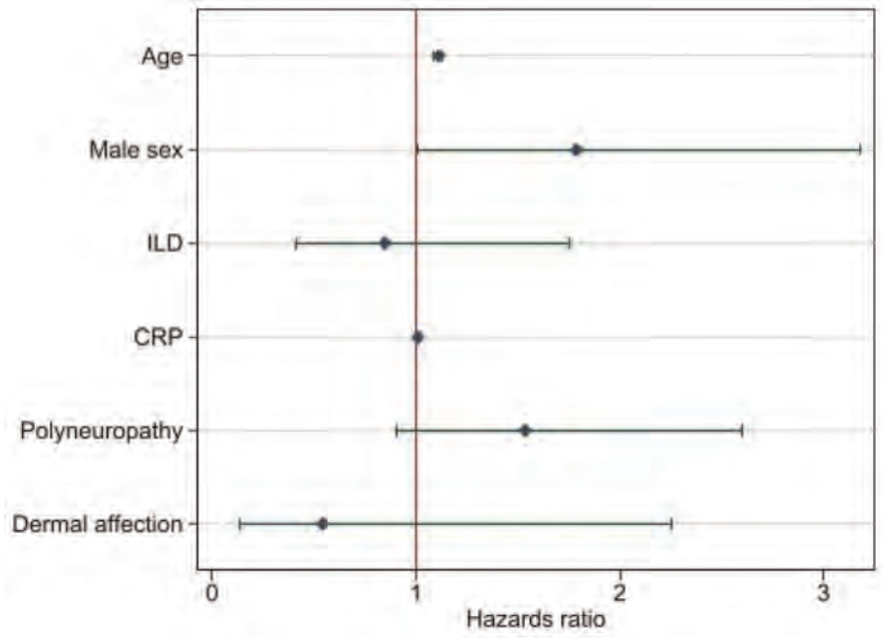

Figure 2: Risk factors predicting mortality in pSS in multivariable Cox regression

In these 48 patients, we assessed risk factors for the development of pSS-ILD and found that male sex, increased inflammatory markers, reduced complement factor C3, presence of interstitial nephritis and absence of arthritis were predicting development of ILD in univariable Cox regression. In multivariable Cox regression, only older age predicted ILD development.

Over mean 15.9 (SD 8.9) years follow up, 140 (16%) pSS patients died. ILD was associated with impaired survival with a reduced 10-year survival from 93% to 74% in patients without and with ILD (p=0.001) (Figure 1). In multivariable Cox regression, male sex, older age and increased inflammatory markers were associated with mortality (Figure 2).

Conclusion: Based on the relatively high prevalence of ILD in pSS and its significant impact on long-term survival, we suggest that screening strategies should be developed and that at least patients at risk of ILD development should be screened on a regular basis. As pSS-ILD patients have a reduced long-term outcome, regular monitoring is of outmost importance.

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the prevalence of anti-thyroid autoantibodies, abnormal thyroid function, and their clinical impacts in Korean patients with primary Sjögren's syndrome (pSS).

Methods: One hundred ninety-six pSS patients (190 females; median age 58.6 [IQR, 46.5-67.3]), satisfying the 2016 ACR/EULAR criteria, were consecutively enrolled. Those with a history of overt thyroid disease (n=22) or thyroid cancer (n=4) were excluded. Clinical variables including EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) and Patient Reported Index (ESSPRI) were collected. For the relative contribution of fatigue to ESSPRI, the fraction of fatigue ($F_{fatigue}$)

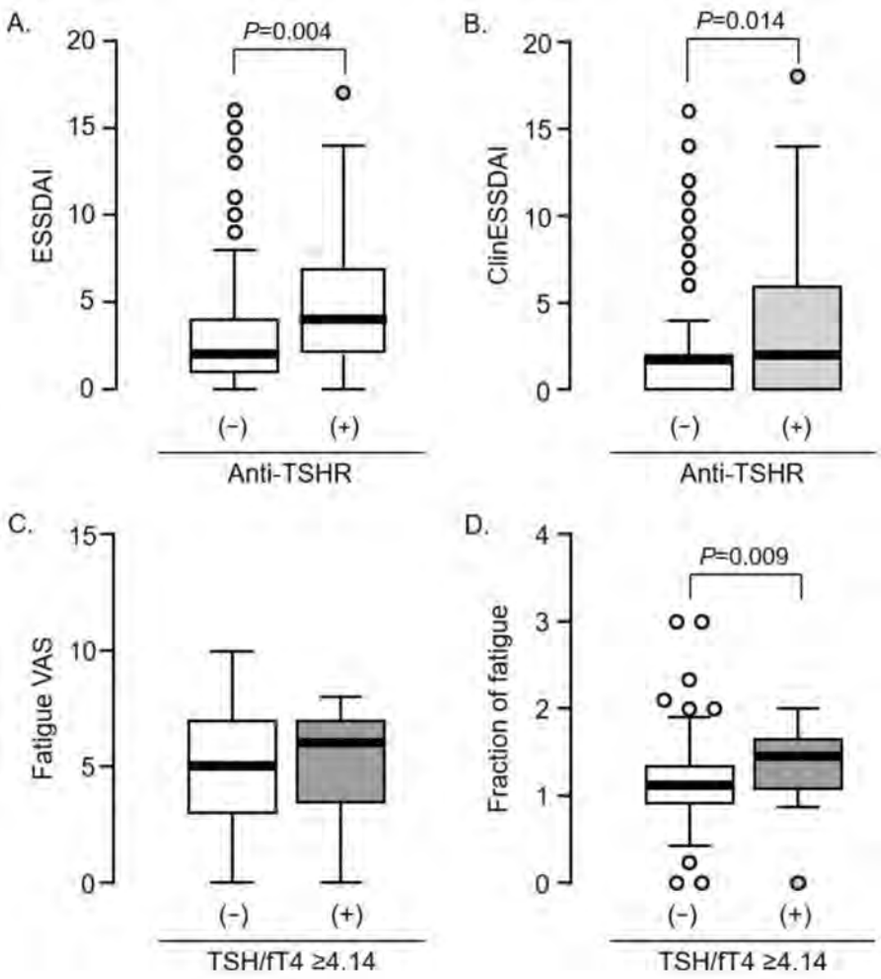

Figure 1. ESSDAI (A) and clinical ESSDAI (ClinESSDAI, B) levels were significantly different according to anti-TSH receptor (TSHR) positivity. Fatigue VAS levels were compatible (C) but fractions of fatigue in ESSPRI were significantly higher in patient with TSH/fT4 ≥4.14 (D) than those with TSH/fT4 <4.14. P values were calculated by the Mann-Whitney test.

Table 1. Logistic regression analysis results for the highest quartile of the fraction of fatigue in ESSPRI. Variables with p <0.1 in univariate analyses were incorporated into the multivariate analysis.

	Univariate		Multivariate			
			Model 1		Model 2

ALC = absolute lymphocyte counts; OR = odds ratio; CI = confidence intervals.

was calculated using ESSPRI fatigue score/ESSPRI score. Laboratory data including the complete blood count, ESR, and levels of thyroid-stimulating hormone (TSH; uIU/mL), free T4 (ng/dL), IgG, β2-microglobulin, cryoglobulin, and complement C3 and C4 were assessed. TSH/fT4 ratio was calculated. Anti-thyroglobulin (TG), anti-thyroperoxidase (TPO), TSH-binding inhibiting immunoglobulin (TBII), and anti-TSH receptor antibody (TSHR) were measured. Subclinical hypothyroidism (ST) was defined as TSH > 4.0 and the presence of hypothyroidism-related autoantibodies. The Mann-Whitney test, Chi-squared or Fischer's exact test, and logistic regression analysis were performed.

Results: Of 196 patients, 71 (36.2%) had one of the anti-thyroid autoantibodies and 53 (27%) had one of the hypothyroidism-related autoantibodies. The prevalence of anti-TG, anti-TPO, TBII, and anti-TSHR was 31 (15.8%), 28 (14.3%), 8 (4.1%), and 28 (14.3%), respectively. Twenty-four (12.2%) had TSH > 4.0 and 3 (1.5%) had TSH < 0.3. No patients had TSH > 10.0. ST was observed in 7 (3.6%) and was significantly associated with anti-TPO ($p < 0.001$) and TBII ($p < 0.05$). Patients with anti-TSHR had significantly higher levels of ESSDAI or clinical ESSDAI (both $p < 0.05$) and those with TSH/fT4 ≥ 4.14 had significantly higher $F_{fatigue}$ levels ($p < 0.01$; Fig. 1). In multivariate logistic regression analyses, subclinical hypothyroidism (OR=5.61 [95% CI 1.07-29.50]) or TFI ≥ 4.14 (OR=9.01 [2.35-34.56]) was associated with the top quantile of $F_{fatigue}$. Additionally, TSH/fT4 ≥ 4.14 was an independent predictor for the highest quantile of $F_{fatigue}$ (OR=8.00 [2.05-31.26]; Table 1).

Conclusion: Despite a high positive rate of thyroid-related autoantibodies, subclinical hypothyroidism was uncommonly observed in Korean pSS patients. The high TSH/fT4 ratio was significantly associated with "fatigue-dominance" in ESSPRI, and it may be related to the neuroendocrine aspects of fatigue in pSS.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Describe the evolution of patients with Sjögren's syndrome (SS) in relation to the appearance of new systemic manifestations and disease activity, as well as factors associated with an unfavorable outcome.

Methods: SJÖGRENSER PROS (SS-PROS) is an observational, longitudinal, and multicenter study of patients with SS who met 2002 classification criteria under active follow-up in rheumatology clinics of 31 Spanish hospitals that participated in the cross-sectional phase of the study (SJÖGRENSER TRANS; SS-TRANS). For the prospective phase, an 8 years follow-up visit was performed (2021-2022) comparing the results with baseline visit (SS-TRANS 2013-2014, 437 patients). Medical history was reviewed and a medical interview was performed. Epidemiological, clinical and serological variables as well as causes of death were recorded. Continuous and categorical variables were analyzed using means, medians, and frequencies, with their respective deviations and interquartile ranges (Q1-Q3). Student's T test was used to establish statistical associations, considering $p< 0.05$ significant.

Results: Up to January 2023, 180 patients have been included, 96% women, mean age 68 years (SD 11.2) and mean evolution time from diagnosis to inclusion of 18 years (SD 7.27). Newly developed systemic involvement was: joint in 47% of patients (arthritis in 17%), hematological (cytopenia) in 44%, lung involvement in 14%, renal in 13%, digestive in 17%. %, hepatic 6%, central and peripheral nervous system (NS) 4% and 3% respectively, and cardiac 2.7%; parotid inflammation was described in 13%. In the last 8 years, 3 new lymphomas have appeared (3/180, 1.6%).

Mean of the ESSDAI in SS-PROS was lower than in SS-TRANS: 2.78 (SD 4.3; 1-4) vs. 3.66 (SD 5.15; 2-4), respectively. By domains, the greatest variations were observed in the articular, hematological and biological domains; while in the rest of the domains, stability was evidenced in ≥94% of the cases (Figure 1). By organs, the most affected organ during follow-up was the lung, with 8 patients who increased the mean value of this domain.

ESSPRI mean improved: 5.24 (SD 2.35; 3.67-7) vs. 4.47 (SD 2.14; 2.67-6), respectively; being greater in the VAS of pain, 5.16 (SD 3.02; 3- 8) vs. 3.98 (SD 2.95; 1- 7), respectively (Figure 2).

Twenty-seven patients out of 180 have died since their inclusion in SS-TRANS (15%), 89% women, with a mean age of 75 years (SD 11.5; 65-84.5).

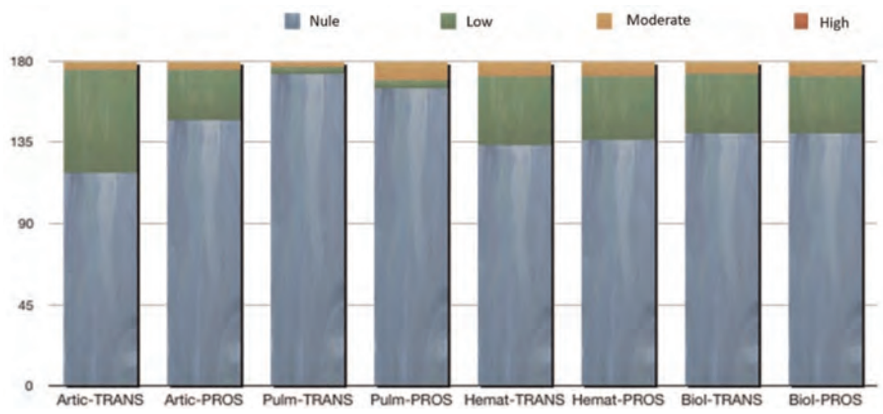

Figure 1: ESSDAI analysis by domains comparing SjögrenSER TRANS vs. SjögrenSER PROS

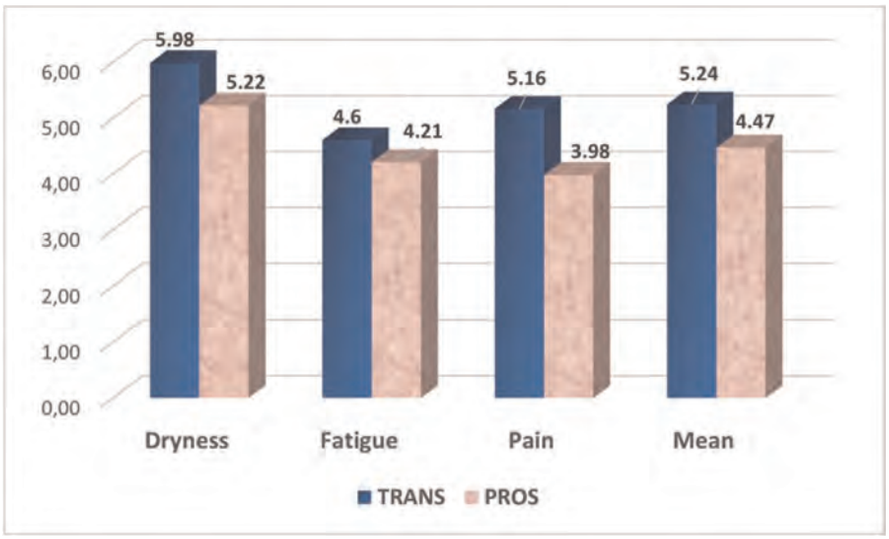

Figure 2: Mean ESSPRI in SjögrenSER TRANS compare with SjögrenSER PROS

Comparing baseline data visit (SS-TRANS) from the group of deceased (during SS-PROS) and of non-deceased (remaining under follow-up in SS-PROS), we observed that age (70 years; SD 11; 59-77), disease evolution time (11.5 years; SD 8; 4-17) and ESSDAI (5.22; SD 6.35; 0-8), were higher in the deceased vs. non-deceased (age 59 years, SD 12, p< 0.001; evolution time 9 years, SD7, p=0.078; ESSDAI 3.38, SD 4.88, 0-4, p0.087). There were no differences in ESSPRI.

Conclusion: Patients with SS develop new systemic manifestations over the years, despite maintaining or improving ESSDAI, suggesting the need of a close follow-up. The ESSPRI varies little over time, which represents a great challenge for the scientific community. Mortality in this cohort is 15%. Greater age, time of evolution and baseline ESSDAI were associated with a worse outcome.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren disease (Sjo) is a systemic immune-related disease with pulmonary manifestations occurring in up to 16% of patients [1], including interstitial lung disease (SS-ILD) and airway disease (SS-AD). Our objective was to assess the associated factors with SS-ILD and SS-AD and to describe these manifestations.

Methods: We performed a retrospective multicentric study, involving 9 French centers. We included Sjo patients fulfilling the ACR/EULAR 2016 criteria with a pulmonary disease evidenced by at least one clinician and one computed tomography (CT) report. We collected clinical and biological data at the visit giving access to the most exhaustive collection, pulmonary function test (PFT) and CT scans, that were all reviewed by a radiologist specialist in thoracic diseases. SS-ILD were considered progressive when associating a CT scan worsening and at least a 10% decrease of the forced vital capacity (FVC) between 2 consecutive measurements during follow-up. SS-ILD and SS-AD were compared to Sjo controls with no history of pulmonary involvement, matched on age and disease duration with a 2/1 ratio.

Results: We included 35 SS-ILD, 31 SS-AD and 132 Sjo controls. SS-ILD and SS-AD had significantly higher disease activity (ESSDAI) than control, even when excluding the pulmonary criteria of the score (**Table 1**). Thus, SS-ILD was also associated with anti-RNP antibodies and B cell biological markers at visit time. SS-ILD were mostly nonspecific interstitial pneumonia (NSIP, 26%), with fibrosis features and restrictive lung disease occurring in 46% of cases at baseline. 41% of SS-ILD were considered progressive, independently of Sjo characteristics and CT pattern. On the other hand, SS-AD were mostly diffuse,

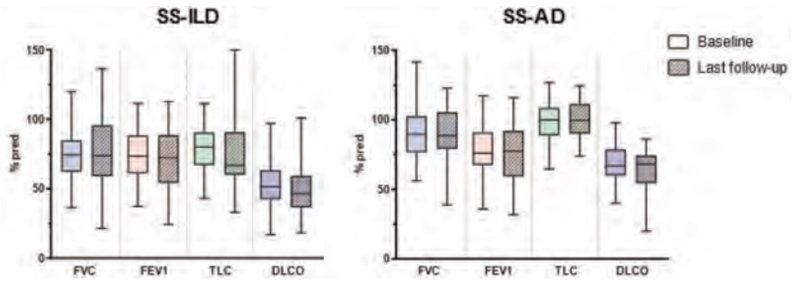

Figure 1: PFT evolution in SS-ILD and SS-AD

associating bronchiolitis and bronchiectasis in 60% of cases, with CT scan worsening observed in 41% of cases. Finally, both were poorly progressive in terms of PFT with respectively five and nine years of follow-up for SS-ILD and SS-AD (**Figure 1**).

Conclusion: SS-ILD are usually fibrosing and progressive manifestations of Sjo, associated with the disease activity and B cell biological markers. SS-AD readily associate proximal and distal airways and associate with the disease activity. Both slowly progress functionally. **Bibliography** 1. Ramos-Casals et al., Rheumatology. 54(12):2230-8.

Abstract Number: 1378

The UCSD Shortness of Breath Questionnaire Is a Useful Tool for the Assessment of Dyspnea in Primary Sjögren's Syndrome Patients with Interstitial Lung Disease: A Monocentric Cross-Sectional Study

Gaetano La Rocca[1], Francesco Ferro[2], Elena Elefante[3], Silvia Fonzetti[4], Giovanni Fulvio[5], Inmaculada Conception Navarro Garcia[3], Chiara Romei[6], Marta Mosca[3] and Chiara Baldini[5], [1]University of Pisa, Rheumatology Unit, Pisa, Italy, [2]Clinical and Experimental Medicine Department, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy, [3]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, Pisa, Italy, [4]AOUP, Pisa, Italy, [5]University of Pisa, Pisa, Italy, [6]Department of Diagnostic Imaging, Diagnostic Radiology 2, Pisa University Hospital, Pisa, Italy

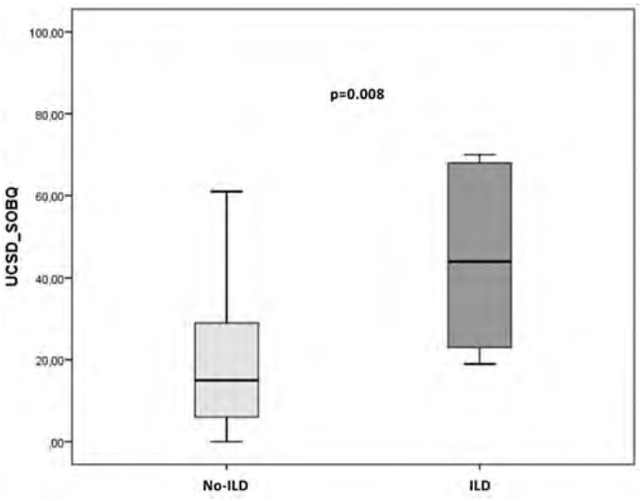
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

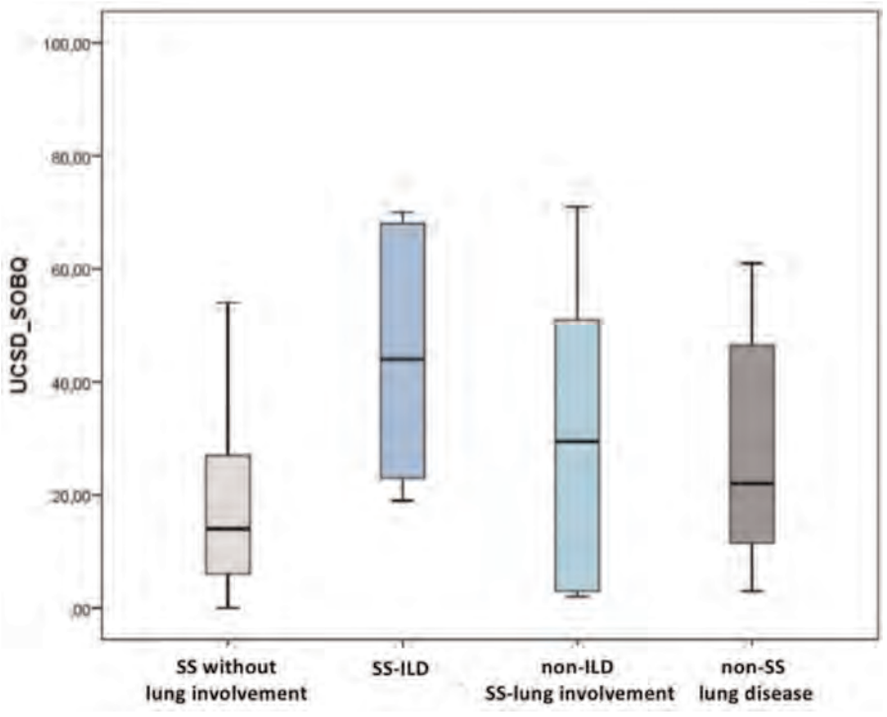
Background/Purpose: In clinical trials investigating new drugs for the management of Interstitial Lung Disease (ILD) patient reported outcomes (PRO) are increasingly employed as outcome measures in addition to objective pulmonary function tests (PFT). The UCSD Shortness of Breath Questionnaire (UCSDSOBQ) is a domain-specific PRO for the evaluation of dyspnea.

It has been recently validated in a large cohort of patients with fibrotic ILD of various etiologies. However, assessing dyspnea in Sjögren's Syndrome (SS) patients is especially challenging since it can be caused by both ILD and airway disease, ranging from xero-trachea to small airway involvement.

Aims: 1) to assess the impact of dyspnea in SS patients by using the UCSDSOBQ; 2) to investigate the correlation of the UCSDSOBQ score with underlying lung involvement and other PRO commonly employed for the multidimensional assessment of SS.



Comparison of UCSDSOBQ total score between SS-ILD patients and non-ILD SS patients



Comparison of UCSDSOBQ total score between SS patients subgroups

Methods: This was an observational cross-sectional study involving consecutive Primary SS patients (2016 ACR/EULAR classification criteria) evaluated in our outpatient clinic from November 2022 to May 2023. Clinical, biological, and imaging data were registered, as well as detailed information regarding smoking and pulmonary history.

Patients were asked to compile the UCSDSOBQ, a 24-item questionnaire assessing the impact of dyspnea on common daily activities with a score from 0 ("not at all") to 5 ("unable to do because of breathlessness") for each question.

PRO including ESSPRI, FACIT and HADS (hospital anxiety and depression scale) were also collected.

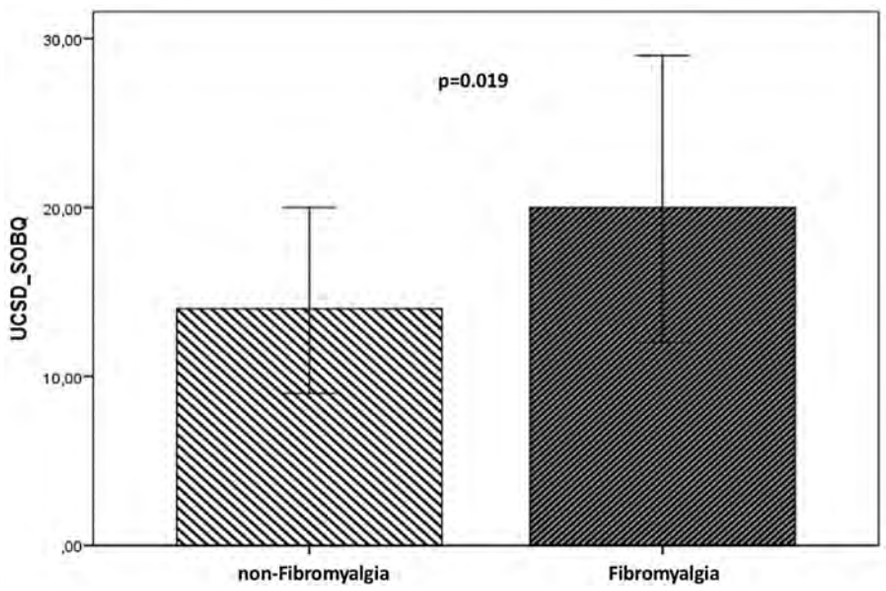
Based on clinical history, PFT and high-resolution computed tomography, we classified patients in the following subgroups: a) absence of lung involvement; b) SS-ILD; c) non-ILD SS-related lung involvement; d) non-SS-related lung disease.

Results: 137 SS patients were enrolled, with a median age of 64 (IQ 57-72) yrs, disease duration of 7 (IQ 5-14) yrs, F:M=133:4, anti-SSA positivity in 97/137 (70.8%). 39/137 (31.7%) patients were current or past smokers. Out of 137 patients 110 (80.3%) were classified as SS without lung involvement, 6 (4.4%) as SS-ILD, 10 (7.3%) as non-ILD SS-related lung involvement and 11 (8%) as non-SS related lung disease, including bronchial asthma and COPD.

The UCSDSOBQ total score was significantly higher in SS-ILD compared to non-ILD SS patients with a median score of 44 (IQR 22-68,5) vs 15 (5,75-29,75) respectively (p=.008).

We observed a trend towards a higher median UCSDSOBQ total score in SS-ILD patients compared to those with non-ILD SS-related lung involvement. However, this difference was not statistically significant. The UCSDSOBQ total score showed a moderate correlation with ESSPRI (r=.449; p< .001), FACIT (r=.564; p< .001) and HADS (r=.417; p< .001). Finally, SS patients with comorbid fibromyalgia exhibited a higher median UCSDSOBQ total score (p= .019) compared to the remaining SS patients.

Conclusion: Dyspnea assessment in SS-ILD patient is challenging due to potential airway involvement and comorbid conditions such as chronic fatigue, anxiety and depression that may alter its perception. Despite these difficulties the UCSDSOBQ seems a promising tool both for screening of lung involvement and as an outcome measure in future clinical trials.



Comparison of UCSDSOBQ total score between SS patients with comorbid fibromyalgia and the remaining SS patients

Population Pharmacokinetic/Pharmacodynamic Modeling of Dazodalibep, a CD40L Antagonist, in Healthy Volunteers and Patients with Rheumatoid Arthritis and Sjogren's Syndrome

Kenneth Der[1], Ryan Crass[2], Brendan Smith[3], Wonkyung Byon[4], Yan Xin[5] and Jiayin Huang[6], [1]Horizon Therapeutics, Danville, CA, [2]Apellis Pharmaceuticals, Michigan, [3]A2-Ai, Michigan, [4]Amador Bioscience, Michigan, [5]Horizon Therapeutics, South San Francisco, CA, [6]Horizon Therapeutics, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's (SjS) is a chronic, systemic autoimmune disease caused by aberrant activation and infiltration of lymphocytes. Dazodalibep (DAZ), a novel non-antibody biologic antagonist of CD40 ligand (CD40L), inhibits the costimulatory signals between immune cells. The concentration of DAZ and immune biomarker data from existing clinical trials were analyzed using a population pharmacokinetic (PK)/pharmacodynamic (PD) model to inform dose selection for future studies.

Methods: PK and PD data from 4 clinical trials in healthy volunteers (HV) and subjects with rheumatoid arthritis (RA) and SjS were pooled and analyzed to characterize the PK of DAZ, including the effects of demographic covariates, and evaluate the PK/PD relationship on immune biomarkers (Ki67+ B cells, rheumatoid factor [RF], and CXCL13).

Results: Population PK modeling demonstrated that the PK of DAZ was adequately described by a two-compartment model with first-order elimination pathway from the central compartment. Following intravenous administration (IV), estimated clearance (CL; 0.347 L/day), distributional clearance (Q; 0.242 L/day), central volume of distribution (Vc; 3.4 L), and peripheral volume of distribution (Vp; 1.39 L) were consistent with typical biologics. Age, sex, race, ADA (anti-drug antibody) and renal function had no clinically relevant impact on DAZ CL. Body weight and patient population (HV or RA vs SjS) were identified as statistically significant covariates of DAZ PK. DAZ CL and VC increased less than linearly with increasing body weight. Healthy volunteers and RA patients had increase clearance relative to SjS patients. DAZ reduced circulating immune biomarkers which was well described with an indirect response model with DAZ effect applied as an inhibitory maximal effect (Imax) on the zero order production (Kin) for RF and CXCL13 and a direct effect model with DAZ effect applied as a proportional inhibitory maximal effect reduction from baseline for Ki67+ B cells. The proposed phase 3 doses are supported by the PK/PD modeling results and are expected to achieve sustained average drug concentration above the IC50 of Ki67+ B cells and RF within the dose interval.

Conclusion: The PK and PK/PD of DAZ were successfully described by population modeling. The modeling results supported the selection of dose to be further evaluated in upcoming phase 3 studies.

Synergistic Dose Effects of Extra X Chromosome in Development of Sjogren's Syndrome in Klinefelter and Triple X Syndromes

Anna-Kay Palmer[1] and Irene Tan[2], [1]Albert Einstein Medical Center, Philadelphia, PA, [2]Einstein Medical Center Philadelphia, Bala Cynwyd, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune-related genes located on the X chromosome are known to be important in the regulation of sex hormones and immune tolerance. It has been postulated that a dose relationship exists between the X chromosome and certain female predominant autoimmune diseases most notable for an increase of SLE in patients with triple X syndrome compared to females with XX karyotype. We investigate the proportion of individuals with Klinefelter syndrome (KS) karyotype 47, XXY and triple X syndrome karyotype 47, XXX who developed Sjogren's syndrome (SjS) compared with the general population.

Methods: This is a retrospective, multicenter, observational study using the TrinetX global research database. Using ICD-10 codes, we identified patients with the karyotype 47, XXY (KS) and 47, XXX (Triple X syndrome) from 6/1/2000 to 6/1/2023 who developed Sjogren's syndrome at any time. This was compared with the prevalence of SjS in the general population within the same time frame.

Table 1. Proportion of Sjogren's syndrome patients in general population, Klinefelter syndrome karyotype 47, XXY and in triple X syndrome karyotype 47, XXX.

Disorders	Affected patients	Total patients	Affected/Total patients	%	# Affected in 100,000	proportion
Sjogren in general population	221,860	121,080,766	0.0018	0.183	183	-
Sjogren in female	188,581	121,080,766	0.00156	0.156	156	5.7
Sjogren in male	33,279	121,080,766	0.00027	0.027	27	1 (reference)
Klinefelter in gen pop	1,634	121,080,766	0.0000135	0.00135	1.35	-
Sjogren in KS	10	1,634	0.0061	0.612	612	22.6
Triple X syndrome in gen pop	2,800	121,080,766	0.000023	0.0023	2.3	-
Sjogren in triple X	13	2,800	0.0046	0.464	464	3

Results: A total of 120,908,054 patients were queried on 6/1/2023 on the Global Collaborative Network. A total of 221,821 patients with Sjogren's syndrome (188,581 or 85% females; 33,279 or 15% males) were found in general population.A total of 1,637 patients have KS identified by 47, XXY karyotype and 2,467 patients have triple X syndrome identified by karyotype 47,XXX. A total of 10 patients with KS were found to have SjS and 13 patients with triple X syndrome have SjS. Prevalence of SjS in general population is 0.18% (0.16% in females; 0.027% in males). There is a 22.6-fold increase in SjS in KS when compared with male patients in the general populations; and a 3-fold increase in SjS in patients with Triple X syndrome compared to females in the general population.

Conclusion: In this real-world, real-time study, extra X chromosome in Klinefelter syndrome and triple X syndrome have a non-proportional, synergistic dose effect on the risk of developing Sjogren's syndrome when compared with males and females in the general population, respectively.

Fatigue and Associated Factors in Patients with Primary Sjogren's Syndrome Compared to Secondary Sjogren's Syndrome

Hyeji Jeon, Hyun-Sook Kim and Kyung-Ann Lee, Soonchunhyang University Seoul Hospital, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is one of the dominant symptoms of patients with Primary Sjogren's syndrome (pSS). However, whether fatigue is specific to pSS compared to secondary SS (sSS) has not been investigated to date. The severity and risk factors that can affect fatigue may differ in groups between pSS and sSS. In this study, we aimed to evaluate the differences in subjective manifestations including fatigue, dryness, and pain between patients with pSS and sSS, and to determine the risk factors associated with fatigue.

Methods: This single-center, prospective study enrolled patients with pSS and sSS who met the 2016 American College of Rheumatology/European League Against Rheumatism (ACR/ EULAR) classification criteria and were aged ≥19 years. Patients were evaluated using questionnaire with Functional Assessment of Chronic Illness Therapy- Fatigue (FACIT-Fatigue) scale (Version 4), having thirteen items associated with fatigue evaluation with numeric scale of 0 to 4. Additionally, EULAR Sjogren Syndrome Patients Reported Index (ESSPRI), which have numerical scale from 0 to 10 for measurement of musculoskeletal pain, fatigue and dryness, were assessed. The following data were collected from all patients: disease duration, smoking history, autoantibodies, laboratory data, Schirmer's test, whole unstimulated salivary flow rate, focus score, salivary gland ultrasound, organ involvement, medication, and other comorbidities including fibromyalgia and hypothyroidism. A linear regression analysis was performed to determine the factors associated with fatigue.

Results: A total of 72 patients with pSS and 78 sSS patients were included in this study. Patients with pSS had significantly higher scores of FACIT-fatigue scales (7.95 vs 5.88, $p< 0.01$) and ESSPRI (5.56 vs 4.49, $p< 0.01$) compared to those with sSS. Among the thirteen questions of FACIT-fatigue scales, nine questions were proved to be significantly higher in patients with pSS while four (questionnaire number 5-8 related to physical activity) were not. Each score of ESSPRI was also higher in

pSS than sSS: fatigue (6.08 vs 5.10), pain (4.35 vs 3.32), dryness (6.24 vs 5.05) (all $p< 0.05$). In univariate regression analysis, only presence of arthritis (β=2.36, $p< 0.05$) was associated with the FACIT-Fatigue scale. Age, other clinical findings, laboratory findings, severity of glandular involvement, organ involvement, and medication were not associated with fatigue.

Conclusion: Our study confirmed patients with pSS manifest higher subjective discomfort with fatigue, pain, and dryness than those with sSS. Arthritis was an only risk factor associated fatigue in pSS patients, suggesting management of arthritis could improve fatigue.

Efficacy of Tofacitinib Immunotherapy Suppresses Tfh and Tph Cells in Patients with Primary Sjögren's Syndrome

Qinghong Liu[1] and Jing He[2], [1]Peking University People's Hospital, Beijing, China, [2]Peking University People's Hospital, Beijing, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is an autoimmune disease characterized by systemic involvement and lacks effective treatment options. The Janus kinase (JAK) pathway plays a pivotal role in cytokine signaling pathways that contribute to the pathogenesis of SS. This study aims to investigate the underlying mechanisms and therapeutic efficacy of the JAK inhibitor, tofacitinib, in primary Sjögren's syndrome.

Methods: We enrolled 10 patients with active pSS and administered oral tofacitinib, assessing disease activity scores, laboratory parameters, and immune cell subsets. Additionally, NOD mice were treated with either tofacitinib or vehicle, and we evaluate saliva flow rates, immune cell subsets, and submandibular gland (SMG) pathology.

Results: Following tofacitinib treatment, a significant decrease in ESSDAI scores was observed at the 6th compared to baseline (9(6, 11.25) vs 4(1, 6), (p=0.002)).Additionally, at 6 months, 80% of patients achieved MCII of ESSPRI, which was defined as an improvement of ESSPRI at least one point or 15%.Notably, arthritis exhibited significant improvement at the 6th month compared to baseline (p=0.020). No serious adverse events were observed. In tofacitinib-treated mice, the results demonstrated a significant increase in saliva production compared to the control group from weeks 8 to 14 (4.20(3.29, 4.41)mg/min vs 5.74(4.44,6.15)mg/min, p=0.033), and SMGs exhibited fewer lymphocytic infiltrations and foci under a photomicroscope. Finally, immunological analysis revealed that both NOD mice and pSS patients exhibited a decrease in effector follicular helper T (Tfh) cells and peripheral helper T cells (Tph cells), which correlated positively with the level of pSTAT-3 in CD4+ T cells and disease activity scores.

Conclusion: Our findings demonstrate that the dosage of 5 mg tofacitinib twice a day proven to be effective and safe for the management of pSS. Tofacitinib inhibits the progression of pSS in both murine models and patients, potentially through the regulation of T cell differentiation.

Long-term Association Between Physical Activity and Global Functioning in Patients with axSpA: Results of a 2 Year Prospective Study

Kwi Young Kang[1] and Hyoun-Ah Kim[2], [1]Catholic University of Korea, Seoul, South Korea, [2]Ajou University School of Medicine, Suwon, South Korea

SESSION INFORMATION

Session Date: Monday, November 13, 2023

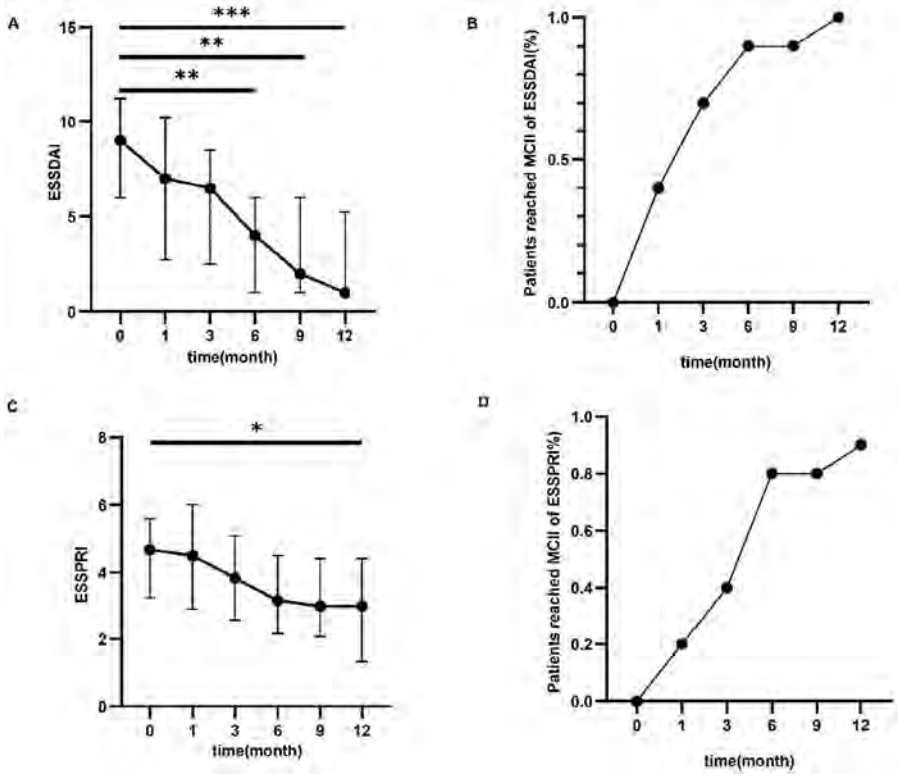
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

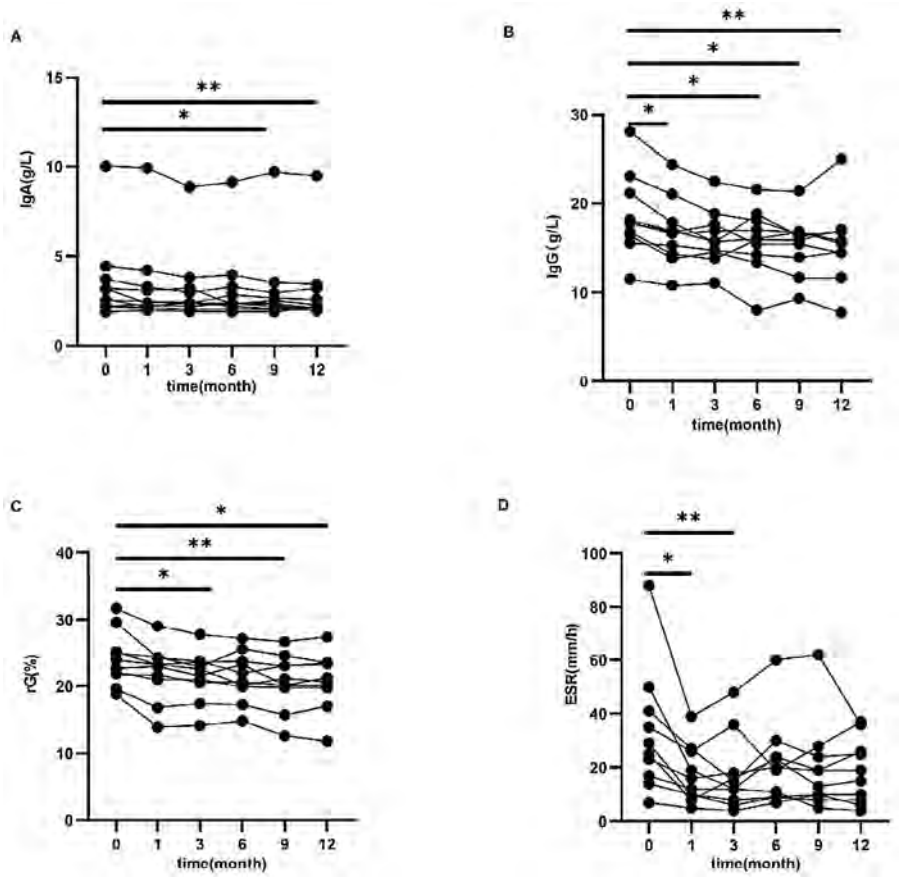
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess the longitudinal association between physical activity and global functioning in patients with axial spondyloarthritis (axSpA) and to identify the subtype of physical activity that is longitudinally related to global functioning.

Methods: Data from 160 patients enrolled in the Incheon Saint Mary's axSpA prospective observational cohort were evaluated. Physical activity was measured using the Global Physical Activity Questionnaire. Global functioning was assessed using the ASAS health index (HI). The amount and subtype of physical activity, disease activity, and ASAS HI were assessed at baseline, and at the 1 year and 2 year follow-ups. Levels of physical activity were categorized as low, moderate, or high. The longitudinal association between physical activity and ASAS HI scores was analyzed using a generalized estimating equation.



Clinical response to tofacitinib treatment. Changes of ESSDAI (A) , ESSPRI (C) score of pSS patients after the treatment of tofacitinib. After 6 months of treatment, 90% patients achieved MCII of ESSDAI (B) and 80% patients achieved MCII of ESSPRI (D). ESSPRI, EULAR primary SS Patient Reported IndESSDAex; ESSDAI, EULAR primary SS Disease Activity Index. (*P<0.05; **p<0.01; ***p<0.001.)



Longitudinal follow-up of laboratory values during the trial. (A) A decrease in the IgA level was observed at the 9th and 12th month compared with that at baseline (p=0.028 and p=0.004, respectively); (B) A decrease in the IgG level was observed at the 1st, 6th, 9th and 12th month compared with that at baseline (p=0.011, p=0.015, p=0.023 and p=0.008, respectively). (C) A decrease in γG level was observed at the 3rd, 9th and 12th month compared with that at baseline (p=0.018,p=0.008 and p=0.013, respectively). (D) A decrease in the ESR level was observed at the 1st, 3rd month compared with that at baseline (p=0.004, p=0.004); (*P<0.05; **p<0.01; ***p<0.001.)

Results: Univariate analysis identified physical activity exceeding moderate levels, disease activity status, and syndesmophyte number as being longitudinally associated with ASAS HI over 2 years. Multivariate analysis identified physical activity exceeding moderate levels as being longitudinal association with ASAS HI (β (95% confidence interval) = -0.244 (-0.423 – -0.065)). Physical activity above moderate levels was associated independently with good global functioning (ASAS HI ≤5). Subgroup analysis revealed a positive association between physical activity and global functioning, which was consistent for both radiographic axSpA and nonradiographic axSpA. Only recreational activity, but not work- and transport-related activity, showed an independent longitudinal relationship with the ASAS HI score.

Conclusion: Physical activity exceeding moderate levels was associated independently with global functioning in axSpA; thus, patients should maintain physical activity above moderate levels to preserve global function.

Functional Status by Sex and Socioeconomic Status in Axial Spondyloarthritis

Rachael Stovall[1], Jing Li[1], zara izadi[1], Lianne Gensler[2], Gabriela Schmajuk[3] and Jinoos Yazdany[4], [1]University of California San Francisco, San Francisco, CA, [2]University of California San Francisco, Department of Medicine, Division of Rheumatology, San Francisco, CA, [3]UCSF / SFVA, San Francisco, CA, [4]University of California, General Department of Medicine, Division of Rheumatology, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Women with axial spondyloarthritis (axSpA) tend to have worse patient reported outcomes compared to men. Non-U.S. studies have evaluated functional status (FS) by sex in axSpA, but data are inconsistent. Studies in other rheumatic diseases suggest that lower socioeconomic status (SES) is correlated with worse FS. Yet little is known about the effect of SES in axSpA. We evaluated FS by sex and SES in the U.S. using the Rheumatology Informatics System for Effectiveness (RISE) registry.

Methods: Data were derived from RISE, a large, national electronic health record-based registry from 2016-2022. Patients ages 18+ with ≥2 visits for axSpA or ankylosing spondylitis (AS) with a rheumatologist, ≥ 30 days apart and ≥1 FS measure (Multi-Dimensional Health Assessment Questionnaire or MDHAQ) were included. RAPID3 (of which MDHAQ is a

Table 1. Baseline characteristics and the primary outcome for the cross-sectional analysis: GEE models clustered by rheumatology practice for functional status as measured by the MDHAQ among individuals with axial spondyloarthritis in the RISE Registry.

	N = 5,658 (%)	Coefficients (95% CI)*
Age Mean (SD)	53.8 (15.2)	0.04 (0.001-0.08) per 10 years

component) has been validated in AS. Patients with HIV or cancer were excluded. Area deprivation index (ADI), a zip code-based measure for neighborhood poverty, was used as a proxy for SES. We performed cross-sectional and longitudinal analyses using GEE models in which patients were clustered within rheumatology practices, and adjusting for age, sex, race, ethnicity, ADI quintile, smoking status (ever/never), and targeted synthetic or biologic DMARD (ts/bDMARD) use (yes/no during the study period). In the cross-sectional analysis, the outcome was the most recent MDHAQ score (0-10 scale) during 2019-2022. We tested for a linear trend across ADI quintiles for MDHAQ, with and without interaction for sex. In the longitudinal analysis, the outcome was functional decline (yes/no) defined as a >1.2 point difference in MDHAQ at 2 time points (most recent MDHAQ minus the next most recent MDHAQ ≥12 months prior), adjusted for baseline MDHAQ. We reported predictive margins in both analyses.

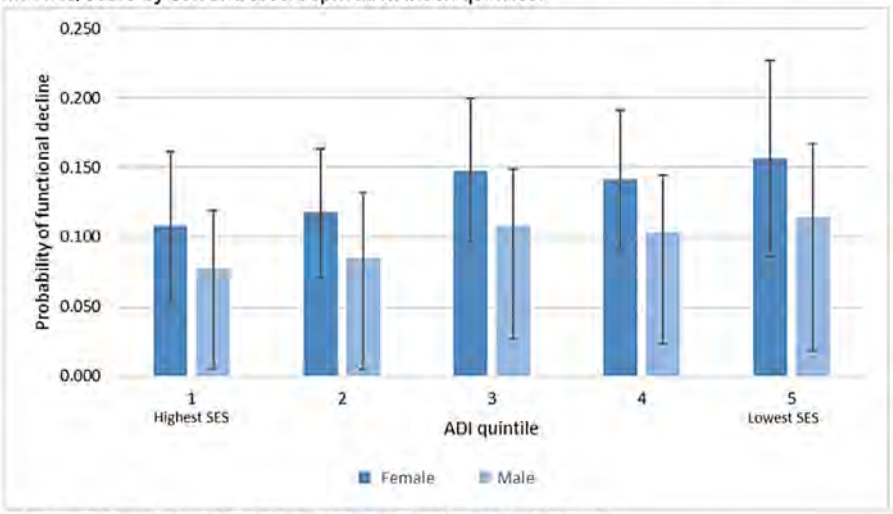
Results: We identified 5,658 adults with axSpA for the cross-sectional analysis and 2,357 were included in the longitudinal cohort. The mean (SD) age was 53.8 years (15.2), 55.8% were female, and 71.4% were non-Hispanic White (**Table 1**). The mean (SD) MDHAQ score for women and men were 2.1 (2.2) and 1.6 (2.0), respectively. There was no evidence of an

Table 2. Predictive margins on ADI quintiles by most recent MDHAQ (cross-sectional) and change in MDHAQ (longitudinal) during the study period.

	Cross-sectional analysis, N = 5,658		Longitudinal analysis, N = 2,357	
	Un-adjusted	Adjusted GEE model*	Un-adjusted	Adjusted GEE model**
ADI quintile	Mean MDHAQ score (95% CI)	Predicted Mean (95% CI)	Proportion of patients with declines in MDHAQ score (95% CI)	Predicted Proportion (95% CI)
1st ADI quintile (highest SES)	1.5 (1.4-1.6)	1.7 (1.4-2.1)	10.2 (7.7-13.2)	10.2 (6.0-14.3)
2nd ADI quintile	1.8 (1.7-2.0)	2.0 (1.6-2.4)	11.7 (9.0-14.8)	11.6 (6.4-16.8)
3rd ADI quintile	1.7 (1.5-1.8)	2.0 (1.6-2.4)	12.8 (9.8-16.3)	13.9 (8.8-19.1)
4th ADI quintile	2.1 (2.0-2.2)	2.2 (1.8-2.6)	14.8 (11.7-18.3)	14.0 (8.4-19.6)
5th ADI quintile (lowest SES)	2.2 (2.0-2.3)	2.3 (1.9-2.7)	15.3 (12.1-19.0)	15.5 (8.8-22.2)

ADI: area deprivation index; MDHAQ: Multi-Dimensional Health Assessment Questionnaire; SES: socioeconomic status.
* Adjusted for age, sex, race, ethnicity, smoking status, and targeted synthetic or biologic DMARD use.
**Longitudinal model additionally adjusted for baseline MDHAQ score.

Figure. Primary outcome for the longitudinal analysis: predicted proportion of decline in MDHAQ score by sex and area deprivation index quintiles.



MDHAQ: Multi-Dimensional Health Assessment Questionnaire; ADI: area deprivation index.

Disclaimer: Data collection was supported by the ACR's RISE Registry. The views expressed represent those of the authors, not necessarily those of ACR.

interaction between sex and SES on FS; instead, women had consistently lower FS than men across all ADI quintiles (**Figure**). In the cross-sectional analysis, the predicted mean MDHAQ score was 2.3 (95% CI 1.9-2.7) for the 5th ADI quintile (lowest SES) compared to 1.7 (95% CI 1.4-2.1) for the 1st ADI quintile (highest SES; **Table 2**). In the longitudinal analysis, the predicted proportion of patients with FS decline were 15.5 (95% CI 8.8-22.2) in the 5th ADI quintile compared to 10.2 (95% CI 6.0-14.3) in the 1st ADI quintile. In the longitudinal analysis, women had 1.65 (95% CI 1.3-2.14) times higher odds of functional decline compared to men.

Conclusion: In this large U.S. sample of adults with axSpA, women had worse FS than men, at baseline and over time, and FS was worse in both sexes with lower SES. Women and individuals with low SES should be prioritized for interventions to reduce FS decline and disability in AS. Future work should assess the mechanisms of SES and sex-based FS differences.

Where Are We with Implementing Axial Spondyloarthritis Treatment Recommendations and Disease Activity Monitoring in Clinical Practice - Results of an Online Survey Amongst Rheumatology Care Providers

Joerg Ermann[1], **Stephanie Sinnappan**[2] and Alexandra Forte[3], [1]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Memorial Sloan Kettering Cancer Center, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Several sets of treatment recommendations for axial spondyloarthritis and ankylosing spondylitis (axSpA/AS) have been published. Clinical practice guidelines are not followed consistently by health care providers. Five groups of factors are thought to contribute to poor adherence: guideline, practice setting, patient, health professional and societal factors. To better understand potential barriers to the implementation of treatment guidelines in axSpA/AS, we performed an online survey amongst rheumatology care providers.

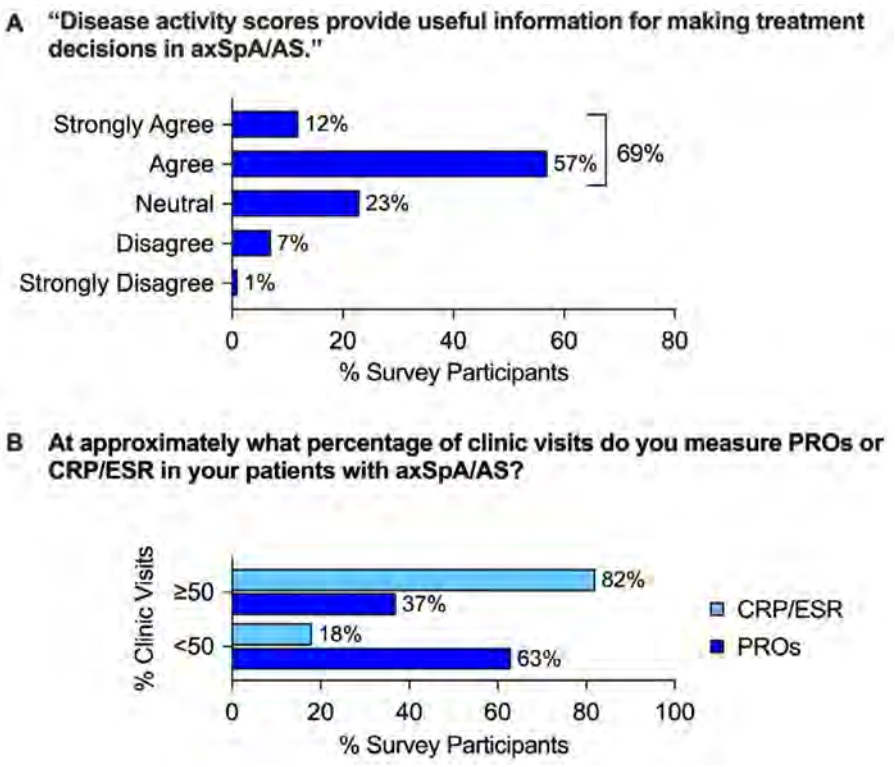
Methods: Based on the results of a focus group, a survey was developed with 20 questions and an estimated completion time of 5-7 minutes. The survey was distributed via email to 441 rheumatology care providers in the New England States (CT, MA, ME, NH, RI, VT) in January 2023. Anonymized data were collected in REDCap.

Results: 104/441 (24%) health professionals participated including 80/104 (77%) board-certified rheumatologist and 20/104 (19%) fellows. 73/104 (70%) participants work in academic medical centers while 27/104 (26%) work in either hospital-based, group or solo practices.

Table 1. Characteristics of respondents (N=104).

Demographics	**n (%)**
Male	50 (48)
Training Level	
Board-certified Rheumatologist	80 (77)
Rheumatology Fellow	20 (19)
Physician Assistant or Nurse Practitioner	3 (3)
Other	1 (1)
Practice Setting	
Academic Medical Center	73 (70)
Hospital-based practice	14 (13)
Group practice	11 (11)
Retired	3 (3)
Solo practice	2 (2)
Other	1 (1)
Number of axSpA/AS patients seen per week	
< 5	65 (63)
5 to 10	33 (32)
> 10	6 (6)
Years Since Rheumatology Board Certification N=80	
1-10 years	34 (43)
11-30 years	23 (29)
31 or more years	23 (29)

Characteristics of survey respondents (N=104).

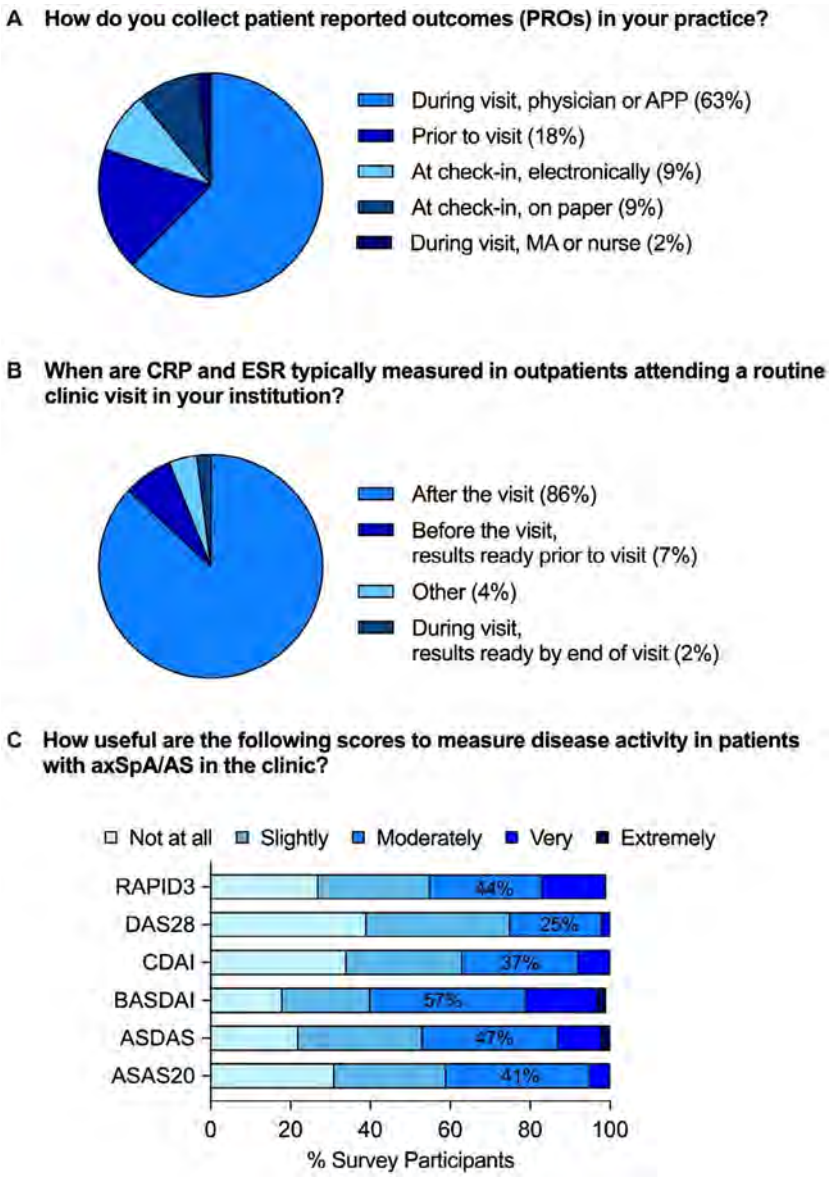


Discrepancy between agreement with the utility of using axSpA/AS disease activity scores and clinical practice.

Survey participants identified UptoDate (85%), treatment guidelines (74%) and colleagues (54%) as relevant sources of knowledge for managing axSpA/AS patients. 64% and 53% of participants considered themselves to be at least moderately familiar with the ACR/SAA/SPARTAN and the ASAS/EULAR recommendations, respectively.

The ACR/SAA/SPARTAN guidelines recommend regular-interval use and monitoring of a validated AS disease activity measure and monitoring of CRP/ESR. While 69% of survey participants agreed or strongly agreed that "disease activity scores provide useful information for making treatment decisions in axSpA/AS", only 38% measure patient-reported outcomes (PROs) frequently (in 50% of clinic visits or more) while 82% measure CRP/ESR frequently. PROs are typically recorded during clinic encounters (63%) while CRP/ESR are obtained after the clinic encounter (86%).

When asked about the utility of specific scores to measure disease activity in patients with axSpA/AS, BASDAI and ASDAS were considered to be at least moderately useful by 57% and 47% of participants, respectively, while 41% thought the same about the ASAS20. BASDAI and ASDAS were considered to very or extremely useful by 20% and 13%, respectively.



Potential barriers to measuring axSpA/AS disease activity in clinical practice.

Conclusion: Treatment guidelines are an important source of knowledge for rheumatologists when managing patients with axSpA/AS. Although there is general agreement that disease activity monitoring is important, implementation of the respective guideline recommendations is lacking. Potential reasons may include lack of familiarity and an underdeveloped infrastructure to efficiently collect PROs prior to clinic visits. Guideline uptake and implementation should be considered in future updates of axSpA/AS treatment recommendations.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Although current axial spondyloarthritis (axSpA) management guidelines do not address opioid use for chronic pain, available data show that opioid use is common among this population despite widespread uptake of effective biologic therapies, including TNF inhibitors and IL-17 inhibitors. We examined temporal trends in opioid prescription for individuals with ankylosing spondylitis (AS) in the United Kingdom (UK) before and after effective immunomodulatory agents have become available in the mid-2000s.

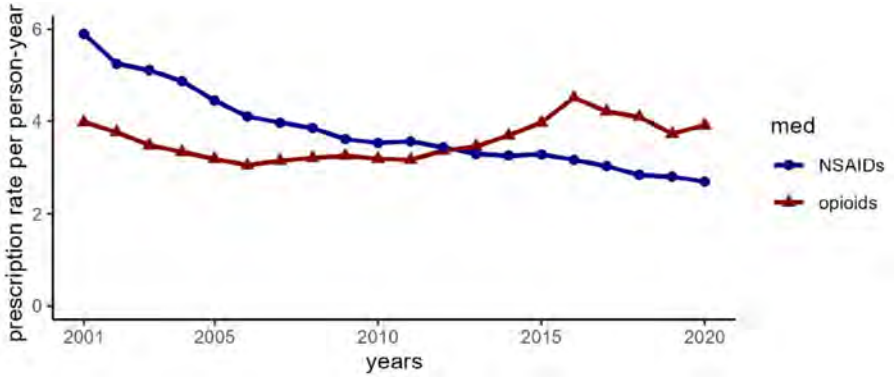

FIGURE Annual prescription rates of opioids and NSAIDs among people with ankylosing spondylitis in the IQVIA Medical Research Database 2001-2020

Methods: We used the IQVIA Medical Research Database (IMRD), incorporating data from THIN, a Cegedim database, an electronic health record database collected by general practitioners throughout the UK. We included adults aged 18-89 from 2000-2020 with AS, defined by ≥2 diagnostic Read codes (coded thesaurus of clinical terms used in the National Health Service since 1985) ≥7 days apart, and ≥1 year data prior to AS diagnosis. Baseline was defined as the date of the second AS diagnosis code. We excluded individuals with ≥2 rheumatoid arthritis Read codes prior to baseline. Individuals were followed until censoring at the date of codes for hospice or palliative care services, death, or end of the study (12/2020). Clinical characteristics included age, gender, baseline treatments for AS (defined within 1 year prior to the index date), and the presence of specific comorbidities (defined using Read codes any time prior to the index date). We calculated annual prescription rates from 2001-2020 for opioids and NSAIDs (comparator drug), as the number of prescriptions in a calendar year divided by person-time contributed by enrolled subjects meeting inclusion criteria for the year. Biologic prescription rates were not adequately captured in this general practitioner-entered database and thus not reported.

Results: We identified 2094 individuals with incident AS (mean age 47 years, 74.6% male, median follow-up time of 6.2 years with interquartile range 2.8-10.6 years). Of these, 395 (18.9%) had history of hypertension, 128 (6.1%) had history of cardiovascular disease, 72 (3.4%) had chronic kidney disease, and 70 (3.3%) had history of cancer. Baseline conventional synthetic DMARD use was present in 10.9% and glucocorticoid use in 10.4%. Opioid prescription rates were relatively unchanged over time with a range of 3.04-4.51 prescriptions per person-year (PY) from 2001-2020 whereas NSAID rates declined over time from 5.90 prescriptions per PY in 2001 to 2.69 per PY in 2020 (**Figure**).

Conclusion: In this UK-based AS cohort, opioid prescription rates remained relatively stable between 2001-2020 whereas NSAID use decreased over time consonant with the uptake of effective biologic therapies. Further, the rates of opioid prescriptions were similar in range to that of NSAID prescriptions. These findings may indicate inadequate pain control in AS despite the introduction and uptake of effective biologic agents.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is an immune-mediated disease associated with skin psoriasis that, if untreated, can lead to joint destruction. Up to 30% of patients with psoriasis progress to PsA and, in most cases, psoriasis precedes synovio-entheseal inflammation, providing a unique opportunity for early and potentially preventive intervention in a susceptible and readily identifiable population. The ongoing Preventing Arthritis in a Multicenter Psoriasis At Risk cohort (PAMPA) study (NCT05004727) aims to evaluate the efficacy of the fully human IL-23p19-subunit inhibitor guselkumab in preventing PsA and reducing musculoskeletal ultrasound (US) abnormalities in a population of patients with psoriasis at increased risk of PsA progression (Figure 1). Interim findings from screening US evaluations to date are reported.

Methods: Patients were screened across 5 sites in the US and Canada. PAMPA inclusion required ≥ 3% body surface area (BSA) affected by psoriasis, no current systemic immunosuppressant therapy at time of screening or prior exposure to biologic/JAK inhibitor, and evidence of musculoskeletal abnormalities on US. The US scanned a set of 36 joints and 34 periarticular structures (including tendons and entheses), each scored by 2 independent central readers using the Rochester Modified (RM)-PsASon scoring system (range 0-614). Participants required a mean score of ≥ 3.36 to enroll (the maximized Youden's index based on previous analysis of scores in healthy controls and patients with psoriasis).

Results: Among the 49 participants screened to date, 42 met US criteria. The screened population was mostly male (57.1%), white (83.7%), with an average age of 49.2 (SD 14.3) and a body mass index (BMI) of 30.6 (SD 8.6). Participants had mostly plaque psoriasis (95.1%) at the time of enrollment with a mean BSA of 10.4% (SD 11.9). The mean total US score was 13.55 (SD 10.5, range 1-50), composed of inflammatory and structural subscores (Figure 2A-B). The intraclass correlation coefficient (ICC) assessing reader agreement was 0.89 (95% CI 0.80-0.94) and ICCs on joints, tendons, and entheses were all greater than 0.75 indicating excellent reliability (Figure 2C-F). US scores correlated with increasing age ($r = 0.55$, $p = < 0.001$), but did not correlate with BMI, BSA, FACIT-Fatigue score, patient reported pain intensity, or sex (Figure 3).

Conclusion: In a biologic-naïve cohort of patients with psoriasis at increased risk for PsA progression, 85.7% of those with US evaluation exceeded a score of 3.36, a previously identified threshold to distinguish those with psoriasis from healthy controls. The interrater reliability of the US scoring was excellent. US scores were moderately correlated with increasing age, but not with other demographic or disease activity measures, and the biological meaning of this finding is unclear. While

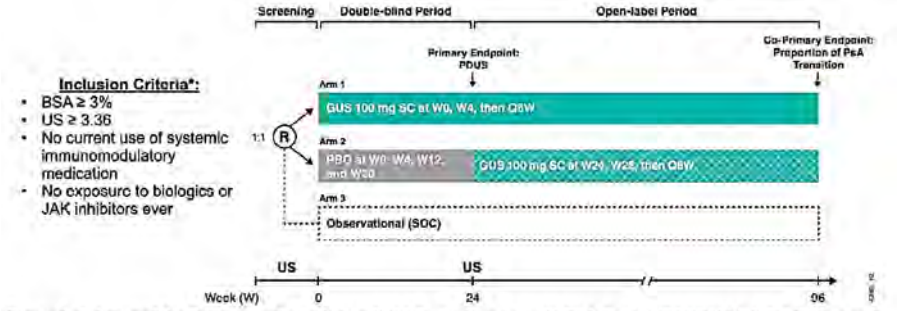

Figure 1. Schema of the Preventing Arthritis in a Multi-Center Psoriasis At-Risk Cohort (PAMPA) trial. PAMPA is a multicenter, randomized, double-blind, placebo-controlled, wait-list, interventional, preventive trial of guselkumab in high-risk psoriasis patients compared to non-biologic standard of care. Participants are eligible if they have a percent body surface area covered by psoriasis (BSA) of at least 3% and a targeted musculoskeletal ultrasound (US) score of at least 3.36. For participants opting for intervention (Arms 1+2), they are randomized (1:1) into drug or placebo for 24 weeks. At 24 weeks, they undergo repeat US and all participants receive active drug for the remainder of the study. For participants who do not want to be on systemic therapy but meet all inclusion criteria, they are enrolled into the observational arm (Arm 3) and are followed every 6 months, also undergoing repeat US at month 6. The primary endpoints are: (1) change in US score at 6 months (Arm 1 vs. Arm 2+3) and (2) proportion of participants transitioning to PsA at 96 weeks (Arm 1+2 vs. Arm 3). *Figure presented previously at CCR-West 2022, San Diego, Ca.*

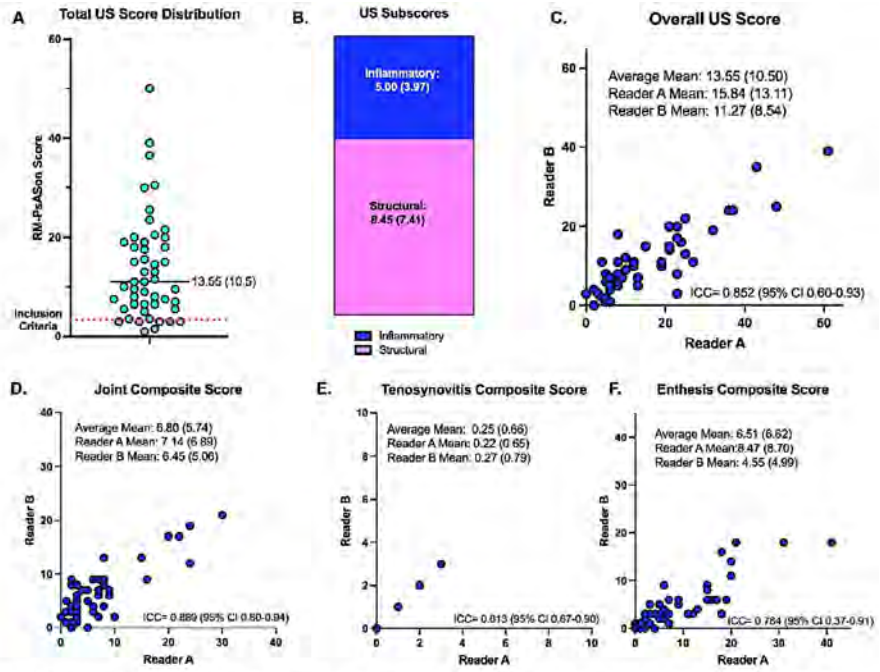

Figure 2. Musculoskeletal Ultrasound (US) Scores. (A) Distribution of the total US scores (an average of the 2 readers, n=49). Pink dashed line indicates the study inclusion threshold of 3.36. Solid black line represents the mean. (B) Total score broken down into inflammatory and structural subscores. Inflammatory subscore includes: joint synovial hypertrophy, joint intra-articular power Doppler, tenosynovitis (gray scale), tenosynovitis (power Doppler), enthesis power doppler, enthesis bursitis, enthesis structure/hypoechogenicity, enthesis thickness, and peritendonitis (gray scale and power Doppler). Structural includes: joint erosions, joint osteophytes, enthesis erosions, and enthesis calcifications. (C) Intraclass correlation coefficient (ICC) between Reader A and Reader B for total US score. Total RM-PsASon score ranges from 0-614. (D-F) ICC between readers for joint composite score, tenosynovitis composite score, and enthesis composite score. Peritendonitis composite score not shown as all scores were 0.

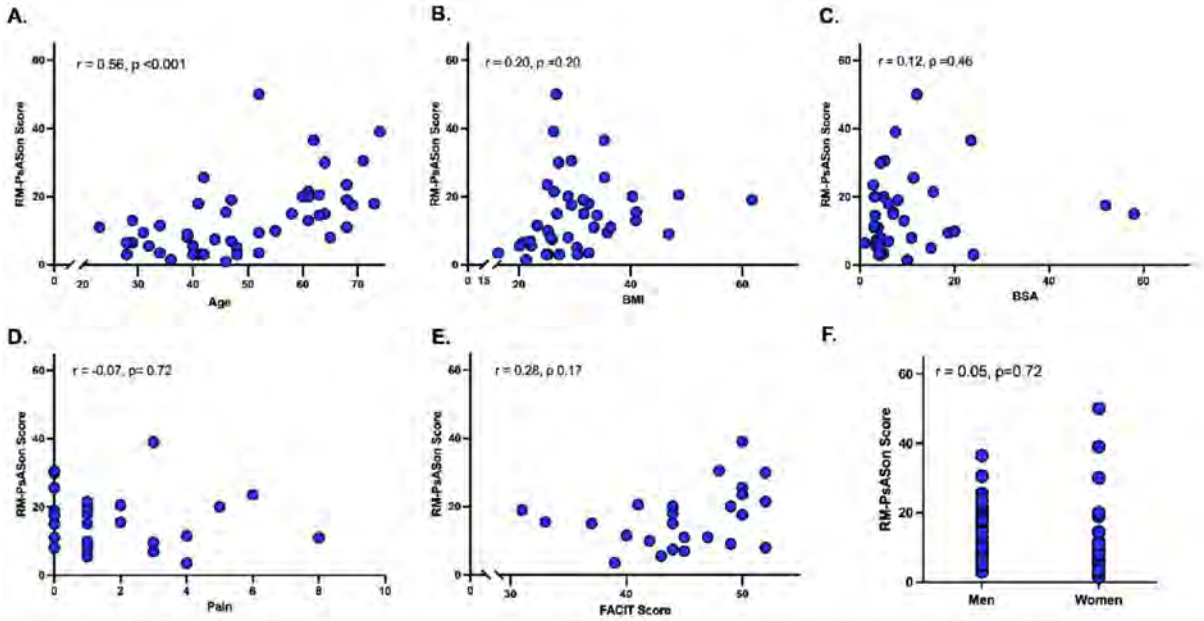

Figure 3. Correlation between total ultrasound score and age (A), body mass index (BMI, B), percent body surface area affected by psoriasis (BSA, C), pain numeric rating scale (D), FACIT Score (measuring fatigue, E) and sex (F). Pain score of 0 indicating no pain and 10 worst pain imaginable. Higher FACIT score indicated higher levels of fatigue. All continuous correlations calculated using Pearson's coefficient. Sex correlation calculated using point biserial correlation.

the ongoing PAMPA study is actively recruiting for a planned enrollment of 350 participants, these preliminary findings suggest that appropriate patients are being enrolled. These data also underscore the need to better characterize clinical and imaging phenotypes of high-risk patients with psoriasis for subclinical soft tissue/structural changes that may foreshadow transition to PsA.

Pain Mechanisms in Psoriatic Arthritis: Differentiating Inflammation Related Pain in Enthesitis Using Ultrasound, in Comparison to Functional MRI

Ummugulsum Gazel[1], Kristen Noges[2], Burak Ayan[2], Gizem Ayan[3], Olivier Brown[1], Andra Smith[1] and sibel aydin[4], [1]University of Ottawa, Ottawa, ON, Canada, [2]University of Ottawa, Rheumatology, Ottawa, ON, Canada, [3]Hacettepe University Faculty of Medicine Division of Rheumatology, Ankara, Turkey, [4]University of Ottawa - Ottawa, Ottawa, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 50% of PsA patients have persistent pain despite a well-controlled inflammatory state, which has been attributed to non-nociceptive pain and central sensitization. Enthesitis is a key domain in PsA. Unfortunately, physical examination of the entheses is challenging and lacks sensitivity and specificity. Ultrasound (US) is used to differentiate inflammatory enthesitis from widespread or non-specific pain syndromes, however whether "inflammatory enthesitis on US" corresponds to a different underlying pathogenic mechanism is yet to be tested. In this proof-of-concept study, we aimed to compare functional MRI (fMRI) features in response to entheseal pain stimuli in PsA, within patients with or without entheseal inflammation on US.

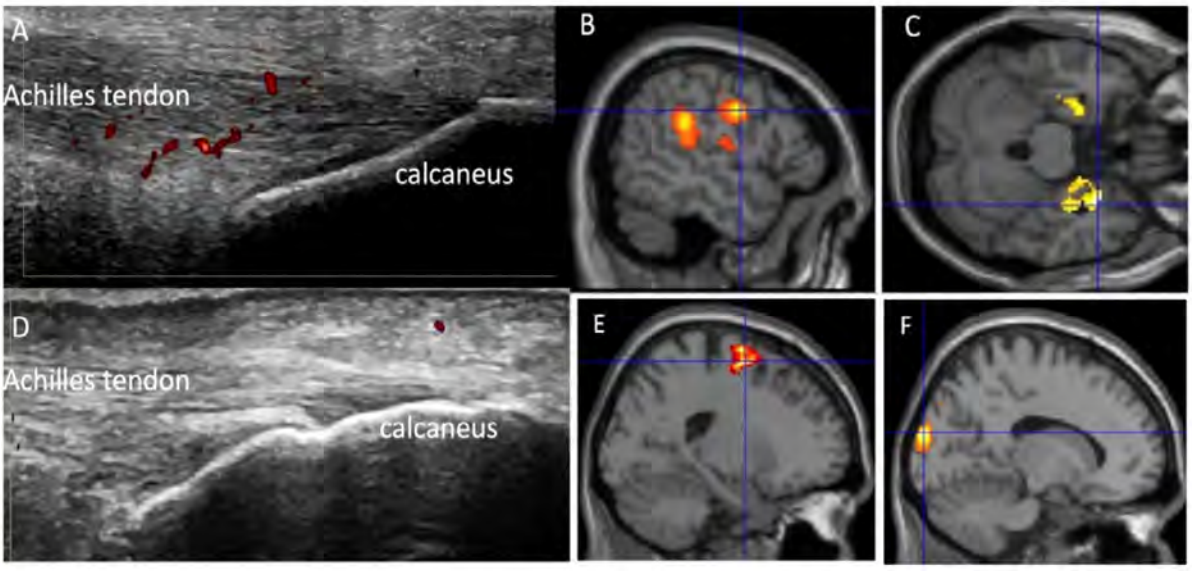

Figure: fMRI and Ultrasound Images in PsA patients with Achilles enthesitis
A-C: Patient with pain on the Achilles enthesis and Doppler positive on US (A). Functional MRI activity with induction of pain on the Achilles entheses: B) in left precentral and supramarginal brain regions C): Functional MRI activity in Amygdala, hippocampus and para hippocampus brain regions.
D-F: Patient with pain on the Achilles enthesis and Doppler negative on US (D). Functional MRI activity with induction of pain on the Achilles entheses : E) and F)

Methods: This study was conducted at the Arthritis Center at The Ottawa Hospital and the Brain Imaging Centre of the Royal Ottawa Mental Health Centre. We recruited two PsA groups; *Group-1:* With Achilles enthesitis on exam and positive US (hypoechogenicity and Doppler signals), *Group-2:* With or without Achilles tenderness on exam, but negative US. Patients had a fMRI with rest and after induction of pain by applying pressure on the Achilles with a blood pressure cuff. Whole brain, between group investigations included a two-sample t-test analysis (second level analyses) conducted at a set threshold of p= 0.05 corrected, with a cluster-wise correction at $p_{FWE} = 0.05$.

Results: Among 12 patients included to the study, five patients were in Group-1 and seven in Group-2. Nine patients were female and mean age was 50.6 (25.2). The mean (SD) TJC and SJC were lower in group-1 (TCJ: 1.80 (2.68), SJC: 1 (2.23)) then group-2 (TJC: 6.86 (8.15); 3 (4.9)). The SPARCC enthesitis score was also numerically lower in group-1 than group-2 (1.40 vs 2.14) Patients who were US (+) had more neural activity when processing pain than US (-) patients. With induction of pain, US (+) patients had significantly more activity in the orbitofrontal gyrus, anterior cingulate, left precentral gyrus, supramarginal gyrus, superior temporal gyrus, and left paracentral lobule than the US (-) group. These regions are related to movement, body representation, and pain. The US (+) patients did not show less activity than US (-) patients in any brain regions.

Conclusion: According to our preliminary results, patients who have pain and inflammatory enthesitis on US, process pain differently than the US negative patients, despite the induction of pain or discomfort on all groups. This pilot study confirms that the US can differentiate different pain mechanisms.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is characterized by progressive structural damage on the sacroiliac joints and/or the spine. Conventional radiology allows to assess radiology through available scales such as the mSASSS (modified Stoke Ankylosing Spondylitis Spinal Score) in the spine. However, scarce is the data on long-term radiographic

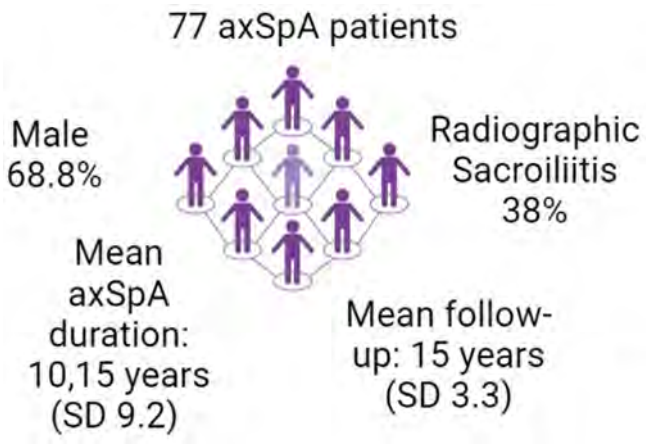

Figure 1. Baseline Characteristics.

Figure 2. Two readers radiographic lecture

progression and factors associated with such progression. The aim of this study was to evaluate the radiographic progression in the spine in patients with axSpA after a mean of 15 years of follow-up as well as the factors associated with such progression.

Methods: Patients with axSpA pertaining to the Reina Sofia University Hospital and included in the multicentre Spanish registry REGISPONSER between 2006-2007 were re-evaluated in 2021-2022. Spine (cervical and lumbar) radiographs were obtained with the aim to be compared with those obtained in 2007. Two trained blinded readers scored the mSASSS in radiographs from both visits (baseline and current). First, intraclass correlation coefficients (ICC) were obtained to evaluate the agreement between both readers in mSASSS. Mean mSASSS of both readers in both timepoints were calculated and the absolute progression (ΔmSASSS) was evaluated. In addition, it was evaluated the mean and median progression per year dividing the ΔmSASSS by the years of follow-up in each patient. Then, the median progression per year was used to divide patients in "low progressors" and "high progressors". Baseline characteristics between these two groups were compared using univariate analysis.

Results: A total of 77 axSpA patients with both baseline and current radiographs were included. A total of 53 (68.8%) were male and the mean disease duration was 10.15 (SD 9.2) years. All of them were naïve to bDMARD at baseline and 38% had radiographic sacroiliitis. The mean years of follow-up (i.e, mean time separating the radiographs) was 15 years (SD 3.3) (Figure 1). ICC between the two readers was moderate for mSASSS at baseline (0.73, 95%CI 0.26-0.88) and at the 15 years visit (0.65, 95%CI 0.11-0.84) (Figure 2). After a mean of 15y of follow-up, the mean progression was 0.54 (SD 0.55) points in mSASSS per year and the median progression was 0.38 points per year. A total of 37 (48%) patients were considered "low progressors" (i.e., median progression < 0.38 points per year) and 40 (52%) were considered as "high progressors"

Table 1. Baseline population characteristics observed by two readers

Baseline Variables		15 year progression according to mSASSS/year		
		Low progressors 37 (48%) (<0,38 points mSASSS/year)	High progressors 40 (52%) (≥0,38 points mSASSS/year)	P-value
Sex	Male	25 (67.6)	28 (70.0)	1.000
	Female	12 (32,4)	12 (30.0)	
Age at diagnosis (mean, SD)		31.1 (9.5)	34.7 (8.1)	0.08
Smoking		1 (2.7)	3 (7.5)	1.000
HLAB27 +		32 (86.5)	34 (85.0)	0.670
Inflamatory low back pain		18 (48.6)	33 (82.5)	**0.003**
Entesitis now or preview		10 (27.0)	8 (20.0)	0.600
Dactilitis now or preview		0 (0.0)	4 (10.0)	0.120
BASDAI median (SD)		4.38 (2.3)	4.3 (2.3)	0.890
BASFI median (SD)		3.8 (2.6)	3.6 (2.4)	0.630
High PCR (mg/L)		18 (48.6)	21 (52.5)	0.450
High VSG (mm/h)		8 (21.6)	14 (35.0)	0.330
NSAID now or preview		34 (91.9)	36 (90.0)	1.000

(i.e., median progression ≥0.38 points per year). The only significant variable associated with "high progression" was low back pain before the diagnosis (82.5% vs. 48.6%, p-value 0.003). Neither sex, smoking, disease duration, HLAB27 or c-reactive protein were associated with the "high progression" group (Table 1).

Conclusion: In this stablished axSpA population, the mean and median progression were 0.54 and 0.38 points in mSASSS per year respectively, which is lower than what has been reported in similar cohorts (i.e., change in 2 points per two years in mSASSS). Only low back pain was found as predictor of spinal radiographic progression.

Abstract Number: 1390

Prediction of Low Disease Activity in Patients with Ankylosing Spondylitis Treated with Secukinumab in Real World – Data from a German Observational Study

Asmir Vodencarevic[1], Jan Brandt-Juergens[2], Daniel Peterlik[1], Benjamin Gmeiner[1] and **Uta Kiltz**[3], [1]Novartis Pharma GmbH, Nürnberg, Germany, [2]rheumatologische Schwerpunktpraxis, Berlin, Germany, [3]Rheumazentrum Ruhrgebiet, Herne, Germany

SESSION INFORMATION

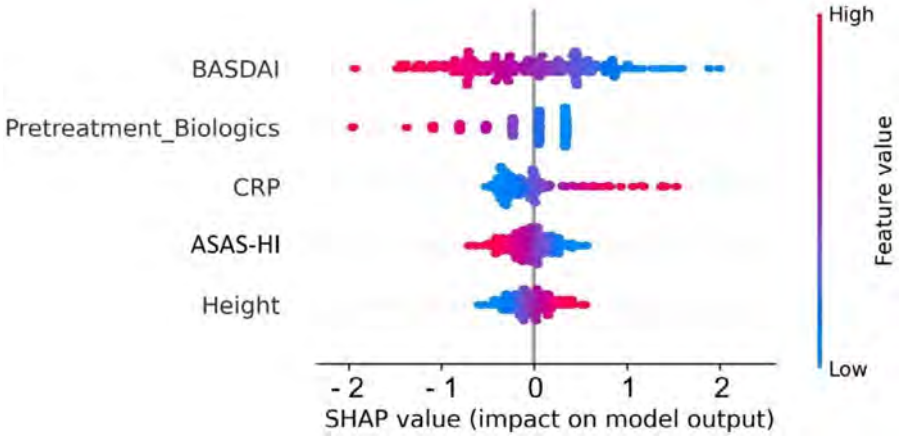
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab (SEC) proved to be an effective treatment for patients suffering from ankylosing spondylitis (AS) in randomized clinical trials [1]. There is only limited knowledge on prediction of low disease activity (LDA) and treatment strategy in AS patients under SEC treatment in routine clinical care.

Using real-world data from the German non-interventional study AQUILA [2], the main objectives were (1) to predict LDA in individual AS patients treated with SEC through machine learning methods and (2) to identify the most important predictors and their influence on the prediction using explainable artificial intelligence (XAI).

Methods: Data of 580 AS patients from the AQUILA study were used. Thirty-two demographic, clinical and treatment parameters at baseline (BL) served as input data to develop prediction models. LDA was defined as Bath ankylosing spondylitis disease activity index (BASDAI) ≤ 2.0 at week (w) 16 (+/- 6 w). Samples were divided into training (70%) and validation (30%) cohorts. Ten different prediction models were applied and compared. Model performance was measured using area under the receiver operating characteristic curve (AUROC) which represents the probability that a randomly selected patient with LDA will have higher prediction to achieve LDA than a patient with moderate/high disease activity. Additionally, sensitivity and specificity of the prediction model were computed and express the proportion of correctly identified patients who reach or don't reach LDA at w16, respectively. Shapley XAI estimated importance and impact of each predictor based on how it affected the change in individual prediction [3].

Results: The most influencing predictor was BASDAI at BL, followed by the number of pretreatments with biologics, C-reactive protein (CRP), assessment of spondyloarthritis international society health index (ASAS-HI) and patient height (**-Figure 1 A**). AUROC of the best performing prediction model was 0.84. Sensitivity and specificity were 0.87 and 0.67, respectively. Applied XAI approach showed that the lower the BL values of BASDAI, ASAS-HI and number of pretreatments with biologics were, the higher the probability of reaching LDA at w16 was. The opposite was the case for BL values of CRP and body height (**Figure 1 A**). The approach also provided visual explanations of patient-individual predictions: Variables with values shown in green color increased probability of reaching LDA at w16, whereas red ones showed the opposite effect (**Figure 1 B)**.



A: Main predictors at baseline and their direction of influence based on Shapley values [3]

B: Explanation of patient-individual prediction of 88% using baseline data

Conclusion: A promising prediction model accuracy of LDA in AS patients treated with SEC could be reached and validated. Identified main predictors at BL, such as BASDAI and number of pretreatments with biologics, and their direction of influence on the prediction of LDA mostly match the existing clinical knowledge [4]. The analysis showed that XAI can provide useful clinical insights into patient-individual predictions, potentially guiding AS treatment decisions in future.

Rates of Remission in Patients with Axial Spondyloarthritis Treated in Tertiary Care

Franziska Neinert[1], Imke Redeker[2], Styliani Tsiami[1], David Kiefer[1], Barbara Guminski[1], Xenofon Baraliakos[3], Juergen Braun[1] and **Uta Kiltz**[4], [1]Ruhr-Universität Bochum and Rheumazentrum Ruhrgebiet, Herne, Germany, [2]Ruhr Universität Bochum, Bochum, Germany, [3]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany, [4]Rheumazentrum Ruhrgebiet, Herne, Germany

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Achieving remission is the treatment target for patients (pts.) with axial spondyloarthritis (axSpA). Remission rates over longer periods in a real-life setting have not been studied so far. To evaluate the remission rates in a cohort of axSpA pts. treated in a tertiary care center using retrospective and prospective data.

Methods: Adult pts. with a diagnosis of axSpA were eligible for inclusion when ≥ 2 consecutive ASDAS assessments were documented in the hospital information system in the past. At the next clinical visit, patients and disease characteristics as well as standard assessments using validated outcome parameters for disease activity (ASDAS, BASDAI) and physical function (BASFI) were then prospectively documented. Values of BASDAI, ASDAS and BASFI were taken retrospectively from the hospital information system. ASDAS was calculated either by ASDAS-CRP or alternative-ASDAS the latter one, when patient global assessment was unavailable.1Remission was defined as an ASDAS < 1.3 and sustained remission was defined by ASDAS < 1.3 for at least 6 consecutive months. Multivariable logistic regression was used to estimate ORs, 95% CIs and p-values of achieving remission.

Table 1: Patients demographics and disease characteristics at clinical visit *values are mean (SD) **all of these pts. suffered from severe psoriasis vulgaris, which could not be successfully treated by other bDMARDs

Characteristics*	axSpA patients (n=200)
Age, in years	46.3 (13.3)
Gender female, n (%)	71 (35.5)
Smoker, n (%)	63 (31.5)
Education, university level, n (%)	24 (12.0)
Employment, n (%)	143 (71.5)
Time since symptom onset, years	19.8 (12.9)
Early axSpA status, n (%)	85 (42.5)
HLA-B27 n (%), missings=8	154 (80.2)
At least one syndesmophyte , n (%)	69 (39.0)
NSAR on-demand, n (%)	105 (52.5)
Patients on bDMARD or tsDMARD, n (%)	156 (78)
TNFi, n (%)	130 (65.0)
IL17, n (%)	18 (9.0)
IL12/23**, n (%)	3 (1.5)
JAKi, n (%)	5 (2.5)
No. of previous b- or tsDMARD	0.8 (1.4)
Pain (NRS 0-10)	3.9 (2.6)
Patient Global (NRS 0-10)	3.7 (2.5)
Physician Global (NRS 0-10)	1.4 (1.5)
ASDAS	2.0 (1.0)
ASDAS, n (%)	
Remission	52 (26.0)
Low Disease Activity	59 (29.5)
High Disease Activity	71 (35.5)
Very High Disease Activity	18 (9.0)
BASFI	3.3 (2.5)
physiotherapy, n (%)	96 (48.0)

Results: A total of 200 pts. were consecutively examined at their clinical visit between March and September 2022. Retrospective chart data were available over a period of 82.6 (58.6) months. Mean ASDAS at the clinical visit was 2.0 (1.0) and 52 pts. (26.0%) were in ASDAS remission. 74 (37.0%) pts. showed limitations in physical functioning (BASFI >4) (table 1). 117 pts. (58.5%) achieved ASDAS remission at least once. On average, remission was reached 37.7 (44.5) months after the index visit. 44 pts. achieved remission within the first year (37.6%), 20 in the second (17.1%), 13 in the third (11.1%)

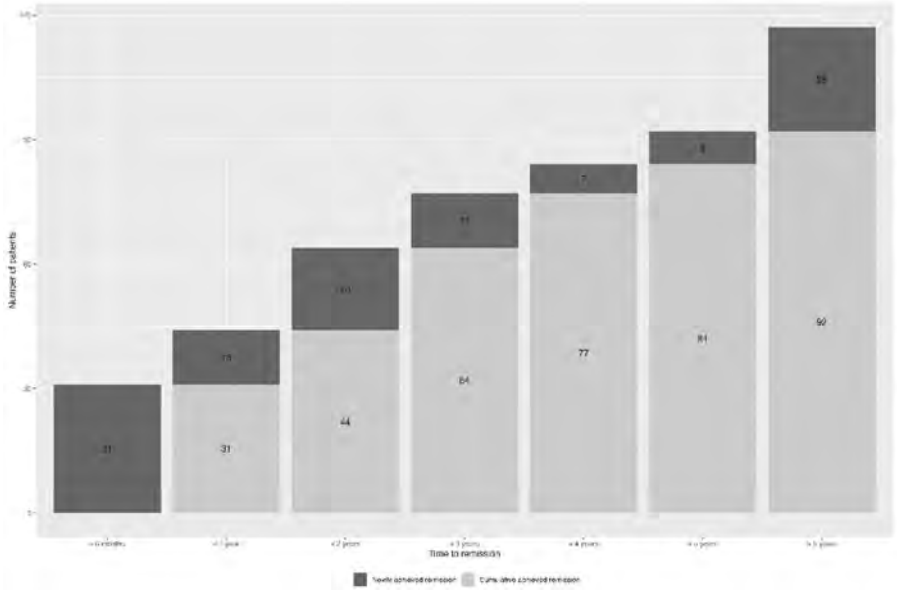

Figure 1: Time to remission

Table 2: Baseline predictors of achieving remission at least once over study period

		Univariable			Multivariable		
Characteristic	N	OR[1]	95% CI[1]	p-value	OR[1]	95% CI[1]	p-value
Sex,	200						
female		0.87	0.48, 1.57	0.65	1.08	0.46, 2.57	0.9
Age, at clinical visit	200	1.00	0.97, 1.02	0.66	1.02	0.99, 1.05	0.2
Symptom duration, clinical visit	200	1.00	0.98, 1.03	0.88			
early axSpA, duration between first symptoms and diagnosis <2 years	200	1.02	0.58, 1.81	0.94	0.89	0.38, 2.05	0.8
HLA-B27	192						
positive		1.79	0.88, 3.68	0.11	2.08	0.79, 5.70	0.14
Smoker, clinical visit	200						
never		—	—		—	—	
former		0.74	0.37, 1.48	0.39	0.49	0.17, 1.41	0.2
current		0.49	0.24, 0.99	**0.048**	0.80	0.30, 2.17	0.7
ASDAS, index visit	135	0.69	0.46, 1.01	0.064			
CRP, index visit	153	1.21	1.04, 1.45	**0.028**	1.35	1.10, 1.73	**0.009**
BASDAI, index visit	165	0.65	0.52, 0.80	**<0.001**	0.72	0.53, 0.97	**0.036**
BASFI, index visit	150	0.80	0.69, 0.93	**0.004**	0.82	0.65, 1.02	0.074
Charlson Comorbidity Index >0, clinical visit	200	0.62	0.33, 1.15	0.13	0.58	0.21, 1.57	0.3

and 40 patients (34.2%) after 3 years (figure 1). 9 (7.7%) pts. achieved their first ASDAS remission at the clinical visit. During the observation period pts. achieved remission for 9.9 (16.8) months or 21.6% (29.9%) of the time, while 51 pts. (43.6%) achieved sustained remission for at least 6 consecutive months, 31 pts. (26.5%) achieved sustained remission for at least 12 consecutive months. 83 pts. (41.5%) never achieved ASDAS remission. In a multivariable model, high CRP (OR=1.35, 95% CI 1.10 to 1.73) and low BASDAI (OR=0.72, 95% CI 0.53 to 0.97) at index visit were associated with higher odds of achieving remission at least once (both $p< 0.05$). Pts. with low BASFI at index visit also tended to have higher odds of achieving remission, however this was not significant (OR=0.82, 95% CI 0.65 to 1.02, p=0.074). Age nor gender was significantly associated with achieving remission (OR=1.02, 95% CI 0.99 to 1.05, p=0.2), (OR=1.08, 95% CI0.46 to 2.57, p=0.9, respectively).

Conclusion: Achievement of remission is an attainable goal for patients with axSpA. High CRP and low BASDAI at index visit were shown to be predictors of ASDAS remission. The majority of patients achieved remission within the first two years after the initial visit. However, also after the fifth year of follow up a quarter of patients achieved ASDAS remission for the first time.

Improving the Diagnostic Accuracy in Axial Spondyloarthritis: Interim Results of a Nationwide Telemedicine Project

Denis Poddubnyy[1], Marc Kämmerer[2], Marcus Kremers[3], Berit Schoppen[3], Charlotte Arens[3], Annette Wiedon[4], Imke Redeker[5] and Xenofon Baraliakos[6], [1]Department of Gastroenterology, Infectious Diseases and Rheumatology, Charité – Universitätsmedizin Berlin, Berlin, Germany, [2]VISUS Health IT GmbH, Bochum, Germany, [3]MedEcon Telemedizin GmbH / MedEcon Ruhr GmbH, Bochum, Germany, [4]Novartis Pharma GmbH, Nürnberg, Germany, [5]Ruhr Universität Bochum, Bochum, Germany, [6]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is often diagnosed late, while there is also a problem of over- and misdiagnosis in patients with chronic back pain. Imaging, especially magnetic resonance imaging (MRI), is important for diagnosis and differential diagnosis, but interpreting imaging findings in sacroiliac joints requires specific expertise.

The Improve-axSpA project was aimed to assess the effectiveness of telemedicine support in enhancing the diagnostic accuracy of patients suspected of having axSpA.

Methods: We established a central telemedicine platform that allowed the collection of clinical and imaging information from patients who presented to rheumatologists and orthopaedists with suspicion of axSpA. Participating centres were encouraged to recruit appropriate patients consecutively. Collected information included the suspected diagnosis and imaging findings, demographic and laboratory data, information on potential mechanical stress factors, characteristics of back pain

Table 1. Agreement and discrepancies between the local and central assessment of 277 patients with suspicion of axSpA.

		Central diagnosis (N=277)		
		axSpA (n=68)	No axSpA (n=179)	Unclear (n=30)
Local diagnosis (N=277)	axSpA (n=90)	45 50 %	32 35.6 %	13 14.4 %
	No axSpA (n=82)	7 8.5 %	70 85.4 %	5 6.1 %
	Unclear (n=105)	16 15.2 %	77 73.3 %	12 11.4 %

and SpA features as assessed by the local physician. The central expert evaluation included detailed assessment of the submitted data including imaging and the final conclusion on the presence or absence of axSpA.

Results: A total of 25 study centres submitted 277 cases for the central evaluation until March 2023. The distribution of the diagnoses according to the local and central assessment is presented in table 1. A total of 90/277 patients (33%) were locally diagnosed with axSpA. Only in 45 (50%) of those cases axSpA could be confirmed after central evaluation, while in 32 patients (36%) an alternative reason of back pain (in the majority of cases – degenerative / mechanical disorders, non-specific back pain) were found to be more likely. In contrast, among 82 patients with no axSpA according to local assessment, in 70 (85%) of those patients axSpA could be excluded based on central evaluation. In 105 cases with inconclusive local diagnosis, axSpA was more frequently excluded than confirmed (73% vs. 15%). In a total of 30 patients, the diagnosis could not be finally determined after central assessment, this being related in most cases to insufficient imaging. Several important differences could be found between patients with centrally confirmed vs. excluded axSpA: patients without SpA were older, more often females (and more often with a history of pregnancies and 2 and more deliveries), had lower CRP, higher BMI and were less frequently HLA-B27-positive. At the same time, other SpA-characteristics including inflammatory back pain, as well as imaging characteristics as reported by the local rheumatologist were not discriminative between the groups. However, the presence or absence of SpA-compatible active inflammatory and structural changes on MRI of sacroiliac joints according to the central assessment were highly discriminative between the groups with confirmed and excluded SpA.

Conclusion: The Improve-axSpA interim analysis suggests a high risk of overdiagnosis of SpA in daily clinical practice. Telemedicine tools with central evaluation of clinical and imaging information may be helpful in the diagnostic process for patients with suspected axSpA.

Fully Automated Detection of Active Sacroiliitis in Patients with Axial Spondyloarthritis: A Machine Learning-Based Analysis Magnetic Resonance Image

Go-Eun Lee[1], Sang-Il Choi[1], Jungchan Cho[2], Seon Ho Kim[3], Geun Young Lee[4] and **Sang Tae Choi**[5], [1]Department of Computer Engineering, Dankook University, Seongnam, South Korea, [2]School of Computing, Gachon University, Seongnam, South Korea, [3]Integrated Media Systems Center, Viterbi School of Engineering, University of Southern California, Los Angeles, CA, [4]Department of Radiology, Chung-Ang University College of Medicine, Seoul, South Korea, [5]Division of Rheumatology, Department of Internal Medicine, Chung-Ang University College of Medicine, Seoul, South Korea

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic Resonance Imaging (MRI) is a crucial modality for early diagnosis of active inflammation in the sacroiliac joint in patients with axial spondyloarthritis (axSpA). This study focused on developing a fully automated classification model that leverages machine learning to detect sacroiliac joints and determine the presence of bone marrow edema in MRI.

Methods: We collected 815 MRI slices of sacroiliac joints (SIJs) from 60 axSpA patients and 19 healthy subjects. Active sacroiliiitis was identified by bone marrow edema observed in gadolinium-enhanced fat-suppressed T1-weighted oblique coronal images. First, a region of interest (ROI) was manually set, and the ResNet18 model was applied to detect bone marrow edema automatically. The prediction models were evaluated using 5-fold cross-validation sets. In the second phase, we introduced a text-guided cross-position attention module (CPAMTG) that integrates cross-attention into the position attention module (PAM) to localize the ROI automatically. The effectiveness of attention in extracting feature maps was assessed by comparison with backbone networks (U-Net) and PAM.

Results: The semi-automated model demonstrated commendable performance in detecting bone marrow edema, with 77.48% accuracy, 92.15% recall, 73.43% precision, 74.24% specificity, and an F1 score of 81.74% at the image level. At the patient level, active sacroiliiitis was diagnosed with 96.06% accuracy, 100% recall, 94.84% precision, 86.43% specificity, and an F1 score of 97.32%. Remarkably, the fully automated ROI patch exhibited higher accuracy (84.73% vs. 77.48%, $p < 0.001$) and specificity (85.03% vs. 74.24%, $p = 0.004$) and maintained or improved performance in comparison to the semi-automated model, with 92.17% recall, 82.81% precision, and an F1 score of 87.24%.

Conclusion: We presented a fully automated classification model for detecting active sacroiliiitis in MRI, which showed excellent performance. These findings suggest that MRI analysis with machine learning can offer valuable assistance to clinicians, enabling rapid and objective diagnosis of active inflammation in patients with axSpA.

Comorbidities, Not Long-Term Use of Nonsteroidal Anti-Inflammatory Drugs, May Be Associated with Chronic Kidney Disease in Patients with Ankylosing Spondylitis: A Nationwide Population-Based Study

Bon San Koo[1], Subin Hwang[1], Ye-Jee Kim[2], Soo Min Ahn[2] and Wook Jang Seo[3], [1]Inje University Seoul Paik Hospital, Seoul, South Korea, [2]Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea, [3]Department of Rheumatology, Veteran Health Service Medical Center, Seoul, South Korea

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Nonsteroidal anti-inflammatory drugs (NSAIDs) are commonly prescribed as first-line treatment for symptom relief and inflammation reduction in patients with ankylosing spondylitis (AS). However, long-term NSAID use has been linked to an increased risk of developing chronic kidney disease (CKD). This study aimed to identify the risk factors, including cumulative NSAID dosage, associated with CKD in AS patients using data from the National Health Insurance.

NSAID Index Score 0< <33.3	1.11	(0.61	-2.03)	0.725	1.22	(0.67	-2.22)	0.528
NSAID Index Score 33.3≤ <66.6	0.51	(0.28	-0.93)	0.028	0.80	(0.44	-1.48)	0.483
NSAID Index Score ≥66.6	1.29	(0.63	-2.67)	0.484	2.02	(0.97	-4.03)	0.060

Methods: The incidence of CKD was determined in AS patients diagnosed between May 1, 2016, and December 31, 2019, using Korean national health insurance data. The cumulative NSAID dosage was assessed using the ASAS NSAID Intake Score. The ASAS NSAID Intake Score was categorized into four groups based on the score at 3 months, 6 months, and 1-year intervals: = 0, >0 and ≤33.3, >33.3 and ≤66.6, and >66.6. The hazard ratio was used to evaluate the risk of CKD based on baseline characteristics. A nested case-control analysis was performed to investigate the correlation between the ASAS NSAID Intake Score during 3 months, 6 months, and 1 year before CKD diagnosis and the development of CKD.

Results: Out of the initial 12,000 AS patients, 120 were identified with CKD. The incidence rate of CKD was 4.64 per 10,000 patient-years. Factors significantly associated with CKD included age ≥60 (Ref. age< 30, HR 3.27, 95% CI 1.49 – 7.17), Charlson comorbidity index 1–2 (HR 1.65, 95% CI 1.049 – 2.612) and 3–4 (HR 2.27, 95% CI 1.27 – 4.08), hypertension (HR 2.408, 95% CI 1.595 – 3.634), diabetes mellitus (HR 1.538, 95% CI 1.016 – 2.329), and sulfasalazine (HR 0.682.76, 95% CI 0.47 – 0.99) (Table 1). However, the odds ratios adjusted for comorbidity and medication did not show a correlation between the 3-month, 6-month, and 1-year ASAS NSAID Intake Scores and CKD. A 1-year ASAS NSAID Intake Score > 66.6 was associated with a reduced risk of CKD (OR 0.46, 95% CI 0.22–0.94) (Table 2).

NSAID Index Score 33.3<= <66.6	1.334	0.639	2.785	0.4436	0.435**	0.178	1.064	0.068
NSAID Index Score >=66.6+	1.905	1.066	3.403	0.0295	0.448**	0.21	0.957	0.0381

* adjusted for CCI, dyslipidemia, hypertension, diabetes mellitus, ischemic heart disease, use of corticosteriods, TNF inhibitor use

** adjusted for CCI, dyslipidemia, hypertension, diabetes mellitus, ischemic heart disease, use of corticosteriods, sulfasalazine, TNF inhibitor use

Conclusion: The risk of CKD in AS patients was associated with comorbidities. However, long-term NSAID use may not be associated with an increased risk of CKD.

Aerobic Capacity and Its Relation to Disease Characteristics and Lifestyle Habits in Patients with Axial Spondyloarthritis

Elisabet Lindqvist[1], Johan Karlsson Wallman[1], Jonas Sagard[2], Tor Olofsson[1] and Elisabeth Mogard[1], [1]Lund University and Skåne University Hospital, Lund, Sweden, [2]Skåne University Hospital, Lund, Sweden

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Physical activity is part of the treatment of axial spondyloarthritis (axSpA), but despite this almost half of the patients do not meet the required level of physical activity to promote health. (1)Low aerobic capacity (cardiorespiratory fitness) is an important risk factor for cardiovascular disease, morbidity, and mortality. (2) The aim of this study was to

evaluate aerobic capacity in patients with axSpA, and to examine differences between patients with low versus high aerobic capacity.

Methods: Patients with clinical axSpA from a defined area of southern Sweden were cross-sectionally examined and classified as non-radiographic axSpA (nr-axSpA; ASAS criteria; n=74) or radiographic axSpA (r-axSpA; modified NY or ASAS criteria; n=112). Aerobic capacity was measured by a submaximal bicycle ergometer test (Åstrand). A value of >28 mL O_2 x kg^{-1} x min^{-1} (mL O_2) is associated with a reduced risk of all-cause mortality, and ≥35 mL O_2 is estimated to be an acceptable level for health in the short term. For health in the long term, a value of 35.1 - 48 mL O_2depending on age, is desirable. (4) Other assessments included spinal mobility, chest expansion, vital capacity (VC), pain sensitivity (by computerized cuff pressure algometry (3)), radiographic assessments (sacroiliac joints [SI-joints]/modified Stoke Ankylosing Spondylitis Spinal

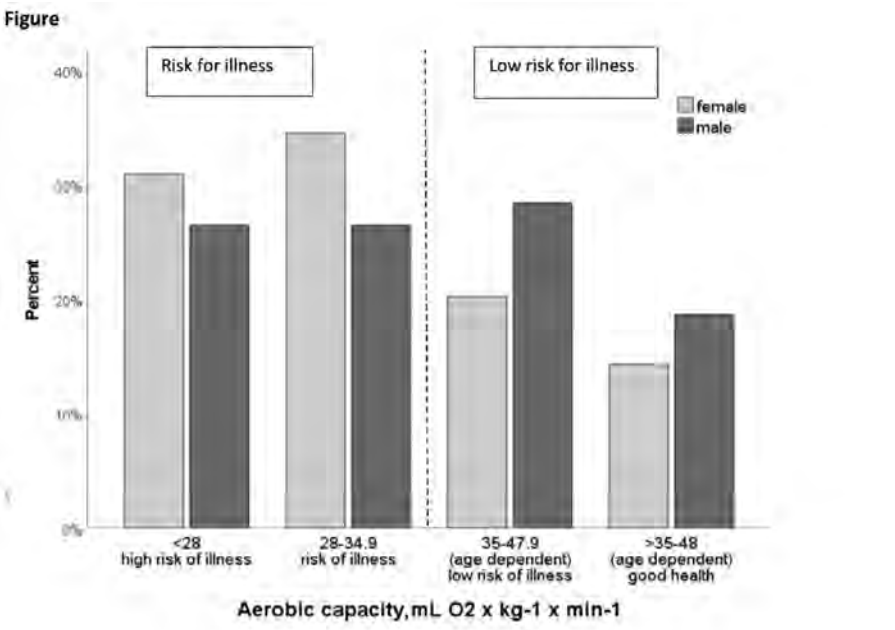
[i] Healthy dietary habits equals ≤4/12 points on a dietary questionnaire from the National board of Health and Welfare, Sweden, [j] Non-smoking = never smoked or stopped smoking >6 months ago, smoker = present smoker or stopped <6 months ago. [k] non-hazardous alcohol consumption equals not drinking more than 9 glass per week and/or more than 4 glasses at the same occasion for women and 14 glasses per week and/or more than 5 glass at the same time for men. [l] Healthy physical activity level equals performing ≥150 minutes of moderate physical activity/week or ≥ 75 min/week of vigorous physical activity or a combination of the two.

Figure



Aerobic capacity in mL O_2 x kg^{-1} x min^{-1} for women and men split into 4 groups according to impact on health. We have compared patients with risk for morbidities to patients with low risk for morbidities stratified on aerobic capacity </≥35 mL O_2 x kg^{-1} x min^{-1}, (dotted line)

Score [mSASSS]), lifestyle habits, health-related quality of life, and standard axSpA outcome measures. Comparisons between patents with aerobic capacity ≥/< 35 mL O_2 were performed by Student's t-test/Chi-square test, Mann-Whitney U-test, as appropriate.

Results: Mean aerobic capacity was 33.9 mL O_2, with no differences between nr-axSpA and r-axSpA or men and women (Figure). Only 17% displayed the desirable level of aerobic capacity for health in the long term, and 28% had an aerobic capacity of < 28 mL O_2, indicating a high risk of illness. Patient characteristics, stratified on aerobic capacity ≥/< 35 mL O_2 are presented in the Table. Patients with aerobic capacity ≥35 mL O_2 were younger, had lower disease activity, better physical function, and spinal mobility. Aerobic capacity ≥35 mL O_2 was further associated with better VC and chest expansion, and more healthy body mass index (BMI) and dietary habits, while mSASSS showed borderline significance (p=0.067). No associations were found between aerobic capacity (≥/<35 mL O_2) and grade of radiographic changes in the SI-joints, global health, pain, fatigue, or health-related quality of life. Patients with aerobic capacity ≥35 mL O_2 had higher pain tolerance, while chronic pain was equally common in both groups.

Conclusion: The majority of patients with established axSpA displayed an aerobic capacity indicating a high risk of morbidity. Better chest mobility and vital capacity, as well as healthy BMI and dietary habits were associated with higher aerobic capacity. These findings emphasize the importance of supporting patients with axSpA to a healthy lifestyle and improved aerobic capacity by physical exercise. **References** *1 Mogard*. Comprehensive Evaluation of the Digital Annular Pulleys: From Ultrasonographical to Anatomical and Histological Evaluation with Special Focus on the Entheses

Luis Coronel[1], Peter Mandl[2], María Isabel Miguel[3], Joan Blasi[4], Maria Lopez-Lasanta[1], Sara Marsal[1], Maria-Antonietta D'Agostino[5] and Ingrid Moller[6], [1]Hospital Universitari Vall d'Hebron, Rheumatology, Barcelona, Spain, [2]Department of Rheumatology, Medical University of Vienna, Vienna, Austria, [3]Universitat de Barcelona - Campus Bellvitge, Unitat d'anatomía i embriología humana, L'Hospitalet de Llobregat, Barcelona, Spain, [4]Universitat de Barcelona - Campus Bellvitge, Histologia, L'Hospitalet de Llobregat, Barcelona, Spain, [5]Universita Cattolica del Sacro Cuore Rome, Courbevoie, France, [6]Instituto Poal de Reumatología, Barcelona, Spain

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The digital annular pulleys (DAP) are anatomical structures of soft connective tissue organized as transverse fibers of variable width, thickness, and configuration that overlay the synovial sheath of the flexor tendons. These structures prevent the flexor tendons from bowing and maintain them in constant relationship with the joint axis of motion. The thickening of DAP has been described as one of the elementary lesions involved in dactylitis in psoriatic arthritis (PsA) patients highlighting the importance of functional pulleys in the pathophysiological manifestations of PsA, as a form of functional enthesis. The present study assesses the ultrasonographic, anatomical and histological characteristics of the DAP anatomical entheses.

Methods: DAP from 20 formalin-embalmed cadaveric hands were assessed with grey-scale ultrasound (US).The US evaluations, performed by 2 expert sonographers, included identification, width, and characterization of insertion sites of the annular pulleys with a newly proposed dynamic maneuver that grants a better exposure of DAP entheses (Figure 1). Then, dissection was performed from the midcarpal area to the distal end of each finger, second to fifth (Figure 2). Measurements of the thickness of the DAP were obtained with a digital caliper. Intra and inter-reader reliability was evaluated using Cohen´s Kappa for all the evaluations. For the histological study, the samples were decalcified using EDTA, sectioned by microtome, and fixed in buffered formalin for two days and, stained with hematoxylin-eosin. The slides were observed and measured with a Leica DMD 108 microscope. Quantitative demographic variables were summarized in means and standard deviations (SD) and qualitative variables in frequencies and percentages (n [%]). Quantitative and qualitative demographic variables

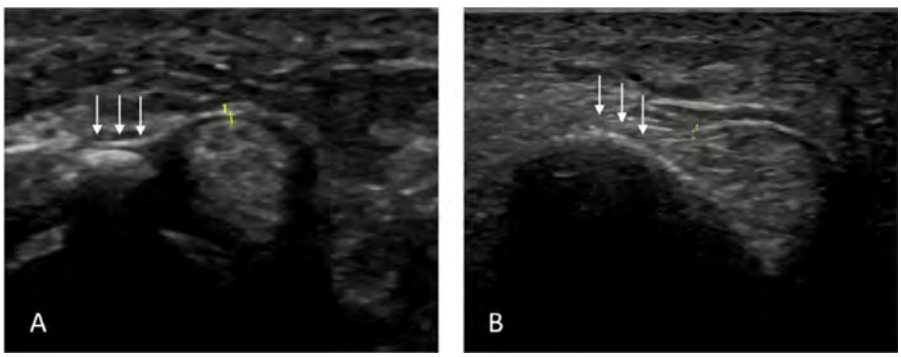

Figure 1. Ultrasound longitudinal scans of the annular pulleys entheses. A) A1 enthesis at the sesamoid bone. B) A2 enthesis in the proximal phalanx. White arrows: Annular pulley entheses. Yellow stars: Dorsal and volar limits of the pulley.

Figure 2. Anatomical dissection of the fingers exposing DAP from A1 to A5.

were compared across groups using Student's t-test and chi-square and Fisher test, respectively.All tests were two-sided and p-values < 0.05 were considered statistically significant. Statistical analyses were performed using R studio (program version RStudio 2022.12.0+353).

Results: The mean age of donors and HC was 81±9 years; range 58–96 years and 11 were females (55%). The mean values of DAP thickness detected by US were analyzed for each finger. Detailed results are presented in Table 1. The intra-reader (mean 0.85, Standard Deviation 0.11) and inter-reader reliability (mean: 0.82, 95% confidence interval: 0.81-0.82) was high. A high correlation between ultrasonographic and anatomical measurements was found (r=0.96). The histological

Table 1. Mean values of pulleys thickness for all annular pulleys (A1-A5) in fingers II-V.

	II	III	IV	V
A1, mean (SD), mm	0.353 (0.066)	0.395 (0.083)	0.378 (0.073)	0.295 (0.09)
A2, mean (SD), mm	0.413 (0.072)	0.455 (0.084)	0.408 (0.086)	0.328 (0.075)
A3, mean (SD), mm	0.135 (0.043)	0.135 (0.056)	0.145 (0.051)	0.128 (0.044)
A4, mean (SD), mm	0.373 (0.072)	0.383 (0.075)	0.358 (0.075)	0.313 (0.086)
A5, mean (SD), mm	0.106 (0.024)	0.113 (0.034)	0.113 (0.033)	0.103 (0.013)

description of the DAP shows a well-vascularized outer surface and a fibrocartilaginous component in the inner surface. The insertion points at the sesamoid or the phalangeal bones demonstrate a diverse nature of the enthesis with fibrocartilaginous and fibrous areas.

Conclusion: These preliminary results show that DAP have a mixed fibrous and fibrocartilaginous enthesis and US is a valuable tool for identifying DAPs' width and anatomical structures, with good correlation with the histological study.

Sustainability of Clinical Response at Week 52 to Upadacitinib Among Patients with Axial SpA: Data from the SELECT-AXIS 1 and SELECT-AXIS 2 Trials

Victoria Navarro-Compán[1], Lianne Gensler[2], Martin Rudwaleit[3], Fabiana Ganz[4], Shirley Chen[4], Jayne Stigler[4], Anna Schmagel[4] and Xenofon Baraliakos[5], [1]Department of Rheumatology, La Paz University Hospital, IdiPaz, Madrid, Spain, [2]University of California San Francisco, Department of Medicine, Division of Rheumatology, San Francisco, CA, [3]University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany, [4]AbbVie, Inc., North Chicago, IL, [5]Rheumazentrum Ruhrgebiet Herne, Ruhr University Bochum, Bochum, Germany

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib 15 mg (UPA), an oral Janus kinase inhibitor, has shown efficacy and tolerability through 14 weeks in patients (pts) with active radiographic axial SpA (also known as AS), including biological DMARD (bDMARD)-naive pts and pts with intolerance or inadequate response [IR] to bDMARDs, and in pts with non-radiographic axial SpA (nr-axSpA).[1-3] Sustained clinical response is a crucial treatment target. We evaluated the 52-week sustainability of clinical responses in pts with active AS and nr-axSpA from the SELECT-AXIS 1 (NCT03178487) and SELECT-AXIS 2 (NCT04169373) trials who achieved week 14 treatment responses.

Methods: This post hoc analysis included adult pts enrolled in SELECT-AXIS 1 (bDMARD-naive AS) or SELECT-AXIS 2 (comprises 2 studies conducted under a master protocol: 1 in pts with bDMARD-IR AS and 1 in pts with nr-axSpA). Efficacy measures included Assessment of SpA international Society 40 (ASAS40) response, ASAS partial remission (ASAS-PR), AS Disease Activity Score (ASDAS) status (inactive disease [ID] and low disease activity [LDA]) and improvement (clinically important or major improvement), achievement of ≤2.0 score on numerical rating scale (NRS) and minimal clinically important difference (MCID) in total and nocturnal back pain,[4] and achievement of ≤1.5 score and MCID in BASFI.[5,6] Durability of response was assessed at week 52 in pts who achieved a response in each efficacy endpoint at week 14 with UPA. No imputation of missing data was performed. The 95% CIs for durability of response were based on Wald limits without continuity correction.

Results: This analysis included 460 pts (bDMARD-naive AS, n=93; bDMARD-IR AS, n=211; nr-axSpA, n=156). In pts who achieved ASAS40 response at week 14 (**Table**), most sustained this response at week 52 (bDMARD-naive AS, 86.7%; bDMARD-IR AS, 94.4%; nr-axSpA, 93.9%; **Fig 1**). Similar results occurred in other disease activity measures with pts

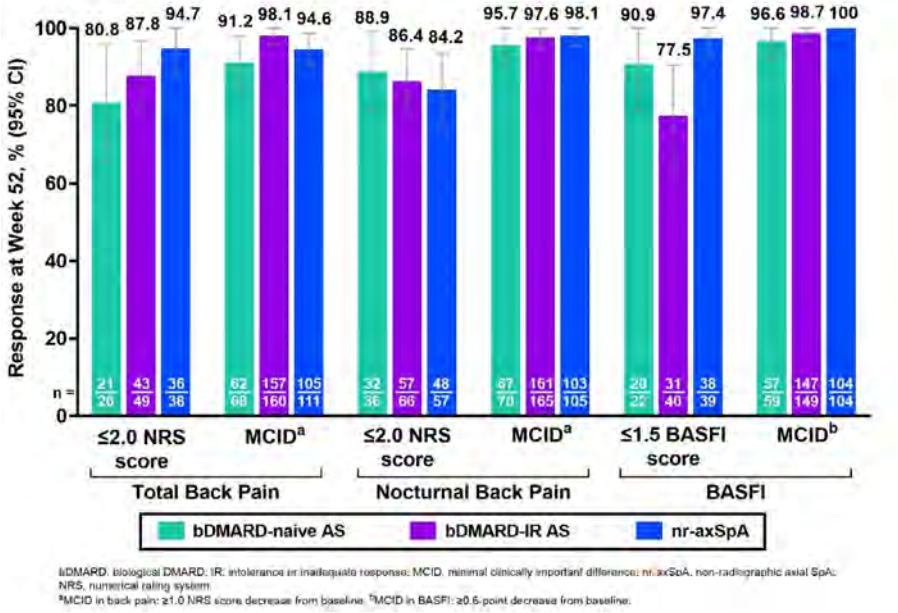
Figure 2. Sustainability of Clinical Response at Week 52 in Patients Who Achieved Significant Improvement in Back Pain or Physical Function at Week 14



bDMARD, biological DMARD; IR, intolerance or inadequate response; MCID, minimal clinically important difference; nr-axSpA, non-radiographic axial SpA; NRS, numerical rating system.
[a]MCID in back pain: ≥1.0 NRS score decrease from baseline. [b]MCID in BASFI: ≥0.6-point decrease from baseline.

sustaining effects at week 52: ASAS PR (77.1%–92.9% across pt groups), ASDAS-LDA (88.1%–95.2%), ASDAS-ID (58.3%–100%), ASDAS-CII (93.2%–94.7%), and ASDAS-MI (87.7%–90.9%). At week 52, sustained treatment effects were also observed on back pain (≤2.0 NRS score: total [80.8%–94.7%], nocturnal [84.2%–88.9%]; MCID: total [91.2%–98.1%]; nocturnal [95.7%–98.1%]) and on BASFI (score ≤1.5: 77.5%–97.4%; MCID: 96.6%–100%; **Fig 2**). In the bDMARD-IR AS group, sustainability of more stringent outcomes (ASAS PR, ASDAS-LDA, ASDAS-ID, and BASFI score ≤1.5) were numerically lower vs other pt groups (**Fig 1–2**).

Conclusion: UPA-treated pts with a clinical response at week 14 experienced a sustained response in improvements in disease activity, back pain, and physical function at week 52, supporting the long-term efficacy of UPA across the entire axSpA spectrum.

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Deep learning has achieved wide applications in different areas of medical imaging analysis. Limited studies have explored the use of deep learning for imaging interpretation in axial spondyloarthritis (SpA). This study aims to develop a deep learning algorithm for the detection of active spinal inflammation in short tau inversion recovery (STIR) sequence magnetic resonance imaging (MRI) in patients with axial SpA.

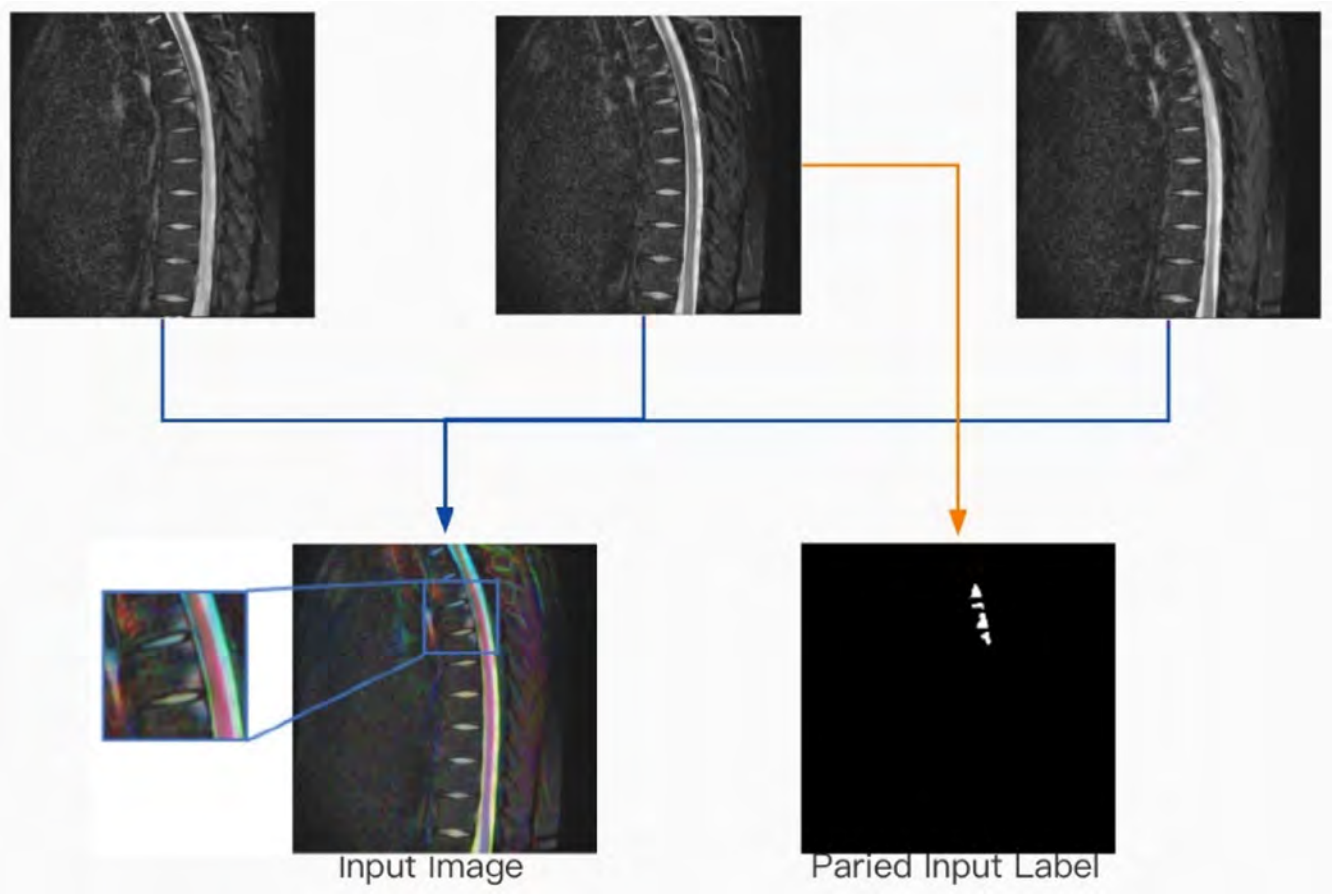

Figure 1: The process of the generation of a 'fake-color' input image and the paired input label. The Blue arrow points to the 'fake-color' image. The orange arrow points to the original image. The blue box shows the zoom-in view.

Methods: A total 330 patients with axial spondyloarthritis (SpA) were recruited. STIR MRI of the whole spine and clinical data were obtained. Spinal inflammation was defined by the presence of an active inflammatory lesion on the STIR sequence. Regions of interests (ROIs) were drawn outlining the active inflammatory lesion. 'Fake-color' images were constructed to mimic adjacent MRI slices (figure 1). Images from 270 patients and 60 patients were separated into the training/validation and testing sets, respectively (table 1). Deep learning algorithms were developed using attention-Unet. The performance of the neural network was compared to the image interpretation by a general radiologist blinded to the ground truth.

Table 1: Baseline characteristics of the training and validation cohort.

Table 1: Baseline characteristics of the training and validation cohort

	Training cohort (N=270)	Validation cohort (N=60)	p-value
Age	44.6±17.8	45.6±14.0	0.323
Male sex	**174/270 (64.4%)**	**27/60 (45.0%)**	**0.005**
Chinese	264/270 (97.8%)	60/60 (100%)	0.244
Age of onset	31.6±12.9	33.3±14.4	0.202
Back pain duration	14.0±14.6	12.4±11.3	0.210
Smoker	88/267 (33.0%)	13/59 (22.0%)	0.101
Drinker	30/261 (11.5%)	6/56 (10.7%)	0.924
HLA-B27	195/252 (77.4%)	34/62 (65.4%)	0.068
CRP	0.89±1.90	1.42±3.62	0.140
ESR	31.6±23.8	34.9±27.0	0.198
BASDAI	4.7±2.2	4.7±2.2	0.398
BASFI	3.0±2.4	3.0±2.4	0.278
Sulphasalazine	62/263 (23.6%)	13/59 (22.0%)	0.800
Other csDMARDs	32/265 (12.1%)	9/60 (15.0%)	0.538

CRP= C-reactive protein; ESR = erythrocyte sedimentation rate; BASDAI = Bath Ankylosing Spondylitis Disease Activity Index (BASDA); BASFI = Bath Ankylosing Spondylitis Functional Index (BASFI); csDMARDs = conventional synthetic disease-modifying anti-rheumatic drugs.

Table 2: Sensitivity and specificity of deep neural network and radiologist in image level and individual spinal vertebral part.

Table 2. Sensitivity and specificity of deep neural network and radiologist in image level and of individual spinal vertebral part

	Radiologist	
	Sensitivity	Specificity
Level of image	0.82	0.87
Level of individual spinal vertebral part	0.87	0.70
	Deep neural network	
	Sensitivity	Specificity
Level of image	0.80+/-0.03	0.88+/-0.02
Level of individual spinal vertebral part	0.85+/-0.04	0.73+/-0.03
	Deep neural network in individual spinal segment	
	Sensitivity	Specificity
Cervical vertebra	0.75+/-0.02	0.81+/-0.02
Thoracic vertebra	0.91+/-0.04	0.62+/-0.04
Lumbar vertebra	0.82+/-0.03	0.74+/-0.02

Results: Active inflammatory lesions were identified in 2891 MR images and were absent in 14590 MR images. The sensitivity and specificity of the derived deep neural network were 0.80±0.03 and 0.88±0.02, respectively. The Dice coefficient of the truth-positive lesions was 0.55±0.02. The area under the curve of the receiver operating characteristic (AUC-ROC) curve of the algorithm was 0.87±0.02. The performance of the developed deep neural network was comparable to the interpretation of a general radiologist with similar sensitivity and specificity (table 2).

Conclusion: A deep neural network was developed to detect spinal inflammation in axial SpA with performance comparable to a general radiologist.

Trends in Proportionate Cardiovascular Mortality in Patients with Ankylosing Spondylitis in the Era of Biologic Therapies: Analysis of US Death Certificate Data

Ansaam Daoud[1], Sadeer Al-Kindi[2] and **Marina Nighat Magrey**[3], [1]University Hospitals, Case Western Reserve University, Akron, OH, [2]Case Western Reserve University/University Hospitals, Cleveland, OH, [3]Case Western Reserve University, University Hospitals, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing Spondylitis (AS) is associated with an increased risk of cardiovascular disease, partly due to systemic inflammation, and an increased risk of vascular mortality. Since the late 1990s, biologic and targeted therapies have improved outcomes in immune-mediated inflammatory diseases. We sought to investigate cardiovascular mortality trends in AS in the USA in the era of biologic therapies.

Methods: This retrospective cohort study used the Multiple Cause of Death files maintained by the National Center for Health Statistics. The data set contains death certificates for US residents, in which the underlying cause of death is ascertained by the treating physician in the section on the cause of death on the certificate. Each certificate identifies demographic information, a single underlying cause of death, and up to 20 additional contributory causes of death. We investigated temporal trends of proportionate cardiovascular mortality, defined as the number of cardiovascular deaths (the underlying cause of death: International Classification of Diseases, version 10 [ICD10]: I00-I99), divided by the number of all-cause mortality, in patients with AS (defined in multiple causes of death: ICD10 code M45) between 1999 and 2020. Spearman's correlation test was used for trend analysis, and the Chi-square test was used for comparisons.

Results: 4,405 deaths in subjects with AS occurred during the study period, with an age-adjusted mortality rate of 7 per 10 million people. Overall, 984 (22%) died of cardiovascular causes. The mean age of cardiovascular mortality was 73 years. The proportionate cardiovascular mortality decreased from 34% in 1999 to 21% in 2020 (trend P< 0.001), Figure 1. Proportionate cardiovascular mortality was similar in men and women (23% vs. 20%, P=0.08) and in Black and White individuals

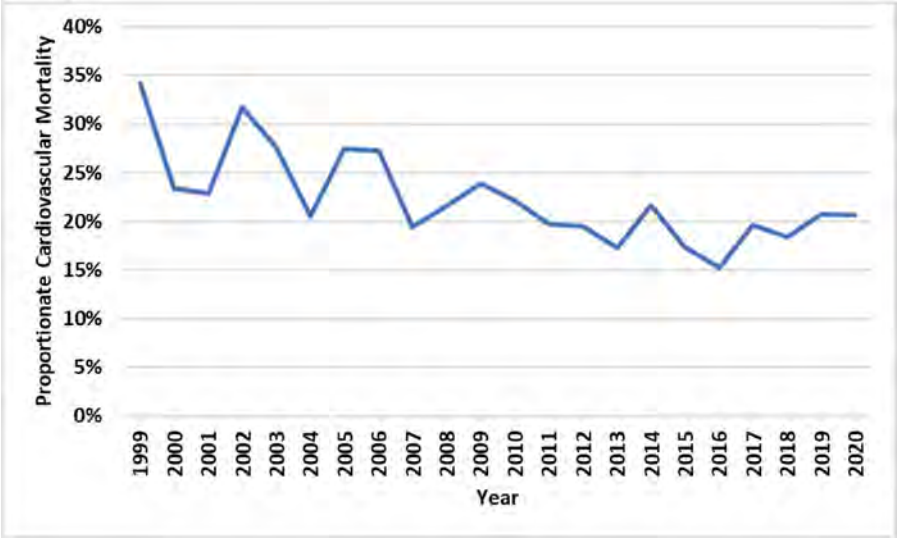

Figure 1. Proportionate Cardiovascular Mortality in Ankylosing Spondylitis from 1999 to 2020

(25% vs. 22%, P=0.47). The most common cardiovascular causes were ischemic heart disease (51%), hypertension and its sequelae (12%), heart failure (7%), stroke (5%), arrhythmia (4%), aortic valve disease (3%), and others (16%).

Conclusion: This national study of death certificate data showed a significant reduction in proportionate cardiovascular mortality in AS in the USA in the era of biologic and targeted therapies. Mechanistic prospective cohort studies are needed to understand the impact of biological therapies on cardiovascular risk in AS.

Achieving ASDAS Inactive Disease Status in Axial Spondyloarthritis: A Systematic Review and Meta-analysis

Sarah Abi Doumeth[1], Omer Pamuk[2] and Marina Nighat Magrey[3], [1]Case Western Reserve University/University Hospitals Cleveland Medical Center, Cleveland, OH, [2]Division of Rheumatology, Case Western Reserve University/University Hospitals, Cleveland, OH, [3]Case Western Reserve University, University Hospitals, Cleveland, OH

SESSION INFORMATION

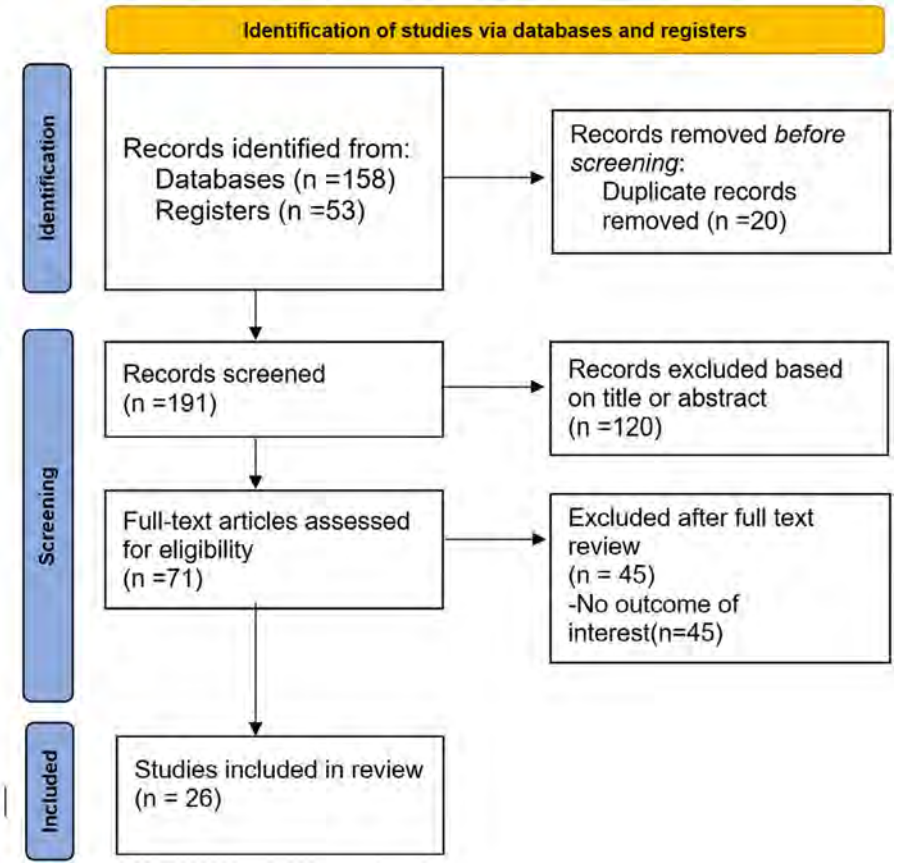
Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: ASDAS-CRP is a composite score that measures disease activity in axial spondyloarthritis (axSpA) and is based on patient-reported outcomes and objective measures of inflammation. An ASDAS-CRP score of < 1.3 indicates inactive disease in axSpA clinical trials and is considered equivalent to clinical remission. We hypothesized that achieving ASDAS-CRP< 1.3 is not feasible in clinical practice. We aimed to evaluate the proportion of patients achieving inactive disease compared to low disease activity (ASDAS< 2.1) with axSpA.



PRISMA Flow chart

Methods: Our PICO question was what proportion of patients with axSpA could reach inactive disease status compared to low disease activity in the treatment group in clinical trials with Biologics and targeted disease-modifying agents. A comprehensive literature search was conducted using electronic databases, including PubMed, Embase, and Cochrane Library, and screening the EU clinical trial registry to identify relevant studies published until May 2023. Clinical trials reporting inactive disease and low disease activity were included. The studies included patients with both radiographic and non-radiographic axSpA treated with different biologic therapies (TNF-i, IL-17-i, JAK-i). The risk of bias was assessed using the Cochrane risk of bias tool. Two independent reviewers screened the articles, and the senior author did conflict resolution. Data were extracted and analyzed using forest plot to compare odds ratios (95% CI). Study heterogeneity was assessed using I^2. All analyses were performed using R Statistical Software meta package (v4.2.1; R Core Team 2022).

Results: Twenty-six clinic trials (randomized and open-label extensions) were identified (PRISMA flow chart attached) with 5024 patients included in the meta-analysis. The proportion of patients reaching inactive disease status in the treatment group at 12-24 weeks was 18% (95% CI:0.16-0.19), and at 52-104 was 24% (95% CI: 0.23-0.26). (Figures 1A and 1B). The odds of achieving inactive disease was 0.28 compared to low disease activity in the treatment group (95% CI 0.22-0.34) (Figure 2A)

Conclusion: The proportion of patients with axSpA achieving inactive disease status was low, suggesting that achieving inactive disease status may be an overarching goal. Hence the definition of clinical remission may need to be revisited with a more feasible outcome.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: A feasible, widely accepted, comprehensive disease activity measure is needed for daily use in psoriatic arthritis (PsA). Current measures are either complex (Psoriatic Arthritis Disease Activity Score (PASDAS) and strict (Minimal Disease Activity ((MDA)) for use in daily practice or only joint-oriented (DAPSA). To address this, the 3-item VAS (3VAS) and 4-item VAS (4VAS) were developed. This study investigates the association between 3VAS/4VAS and radiographic progression in early PsA patients. Our aim is to evaluate 3VAS/4VAS having association in terms of radiographic progression over 3 years in early PsA.

Methods: Data were from the DEPAR study which consists of newly diagnosed PsA patients. Radiographic changes were graded with the modified Total Sharp Score (mTSS) for PsA chronologically by two independent assessors. The radiographic progression was defined as a change in mTSS >0.7 (SDC) at any time in 3 years of follow-up. The 3VAS consists of a physician's global VAS, the patient global VAS, and the patient skin VAS. The 4VAS has comprised of a physician global VAS, patient pain VAS, patient joint VAS, and patient skin VAS. Reaching low disease activity (LDA) at 6 months was

Table 1: Baseline Characteristics of Groups

	Non-Progressive Group (n:405)	Progressive Group (n:71)	p-value
BASELINE CHARACTERISTICS			
Age (mean (S.D))	49 (13)	59 (12)	**0.000**
Gender (Female)(%)	51%	52%	0.907
Symptom duration (median(IQR))	9 (4-28)	10 (4-32)	0.190
Body mass index (mean (S.D))	28 (5)	28 (5)	0.247
DISEASE ACTIVITY SCORES			
Baseline 3VAS (mean (S.D))	3.58 (1.85)	3.48 (1.70)	0.449
Baseline 4VAS (mean (S.D))	4.01 (1.84)	3.72 (1.52)	0.151
Baseline DAPSA (mean (S.D))	19.08 (11.5)	19.87 (10.1)	0.488
RADIOGRAPHIC ASSESSMENT			
Baseline mTSS (median(IQR))	0 (0-0)	16 (1-36)	**0.000**
Baseline JSN (median(IQR))	0 (0-0)	7 (1-19)	**0.000**
Baseline Erosion score (median(IQR))	0 (0-0)	5 (0-25)	**0.000**

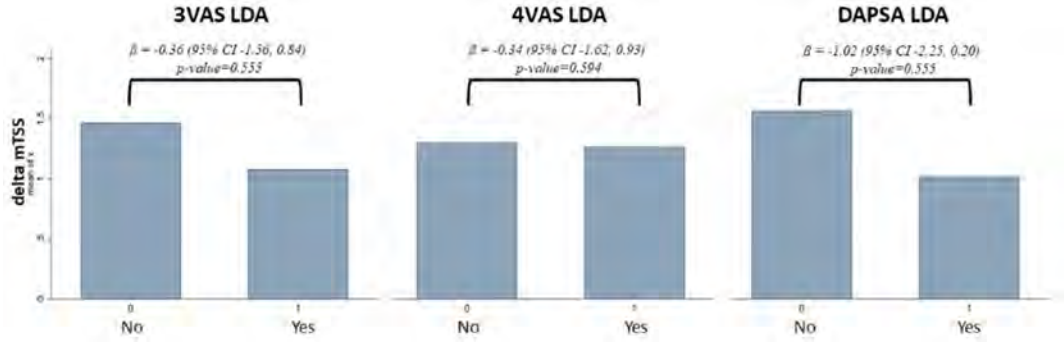

Figure 1. Predicted change in mTSS values over 3 years according to the achievement of LDA at 6 months with GLM results.

determined as 3VAS(< 2.4), 4VAS(< 2.8), and DAPSA (≤14). Comparisons between groups were made by Student's t-test, chi-squared test, or ANOVA. The generalized linear model (GLM) and the Generalized Linear Mix Model (GLMM with a sub-type of negative binomial regression analysis) were adjusted for baseline determinants(age, gender, time (visit time), mTSS, CRP, and biological use at any time point).

Results: In comparing the two groups, a total of 476 patients were included, with 71 patients in the progressive group and 405 patients in the non-progressive group (Table 1). During the first 2-year period, the non-progressive and progressive groups showed similar patterns in terms of disease activity scores. However, in the 2nd year, there was a notable change: the progressive group surpassed the non-progressive group in terms of 3VAS, 4VAS, and DAPSA levels (at 3rd year non-prog. vs prog. (mean(S.D.)); 3VAS: 1.75(1.62) vs 2.17(1.64), 4VAS: 2.03(1.76) vs 2.40(2.00), DAPSA: 7.58(5.88) vs 10.4 (9.30)) (Figure 2).

Even though patients who achieved LDA according to 3VAS, 4VAS, and DAPSA at 6 months had fewer radiographic changes in 3 years, there were no found significant differences (Figure 1).

For longitudinal analysis, 1.758 mTS scores were included from 4 different time points. The generalized linear mixed-effects model showed that there was no significant association between 3VAS/4VAS or DAPSA levels and radiographic changes over time (Figure 2).

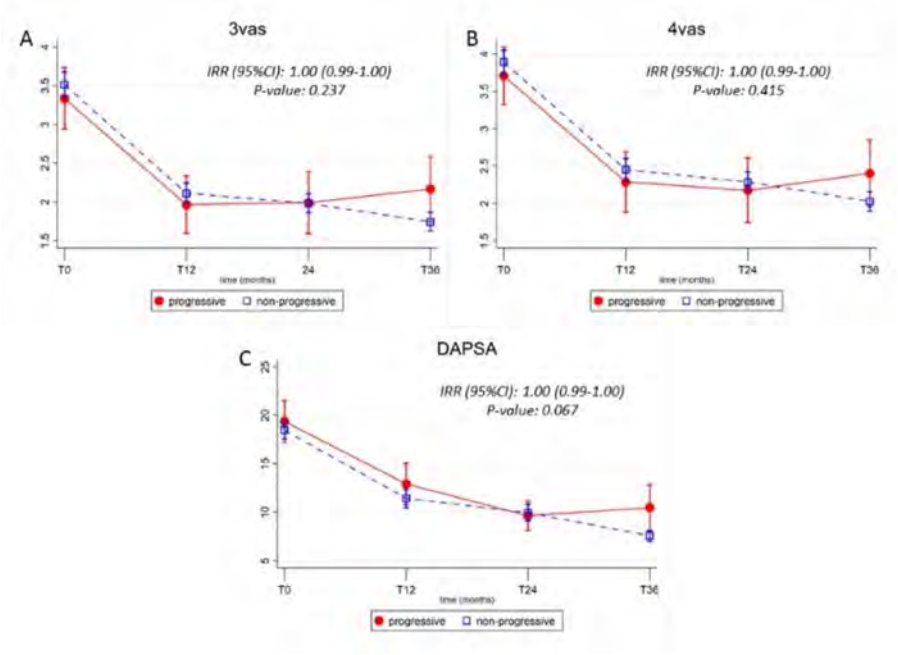

Figure 2. Observed means of A.3VAS, B.4VAS, and C.DAPSA over 3 years according to radiographic progression with GLMM results.

Conclusion: No significant association was observed between the 3VAS and 4VAS measures and radiographic damage in our longitudinal real-world cohort of early PsA patients. This lack of association is likely attributed to the relatively low radiographic progression observed in this cohort rather than being solely influenced by the measures themselves. Furthermore, the articular-oriented measure DAPSA also exhibited no significant association with radiographic damage in early PsA patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The Canadian 24-Hour Movement Guidelines were recently published in 2022 and integrate evidence-based targets for physical activity, sleep and sedentary behaviours, with recommendations regarding duration, intensity and quality of each activity to achieve health outcomes in adults aged 18-64 years. The purpose of this study was to determine if patients diagnosed with axial spondyloarthritis (axSpA) are meeting these guidelines. The specific objectives were to: 1) profile moderate-vigorous physical activity (MVPA); 2) profile sedentary behaviours and sleep patterns and 3) evaluate discrepancy between objective and subjective measures of activity and sleep.

Methods: Participants with axSpA (meeting ASAS criteria) attending an urban academic rheumatology clinic were provided a wrist-mounted accelerometer, worn for 24 hours over a consecutive 7-day period. The average data validated for a 75% wear-time was used for analysis and included time spent in MVPA per week; time spent in sedentary activity per 24 hours, and sleep/wake duration per 24 hours. Participants completed the International Physical Activity Questionnaire to measure subjective physical activity engagement and a 7-day sleep log to subjectively evaluate sleep quality. Univariate statistics were used to create profiles aligned with the guideline's core recommendations.

Results: Out of 41 people with axSpA who participated in the study, 37 (90%) had validated accelerometer data.Most participants were male (56.7%); mean age of 46.0 years (SD 12.6); mean disease duration 23.9 years (SD 11.4); mean Bath Ankylosing Spondylitis Disease Activity Index was 3.2 (SD.1); mean Bath Ankylosing Spondylitis Functional Index was 2.6 (SD 2.2). 35.1% had a history of peripheral joint involvement; 56.7% were receiving biologic treatment; 51.3% were receiving non-steroidal anti-inflammatories.All of the cohort met the MVPA targets of a minimum of 150 minutes of MVPA per week (mean 978.5 minutes, SD 387.9) and sedentary behaviour limits of no more than 8 hours daily (mean 5.0 hours, SD 0.9).Only 37.8% of participants met the sleep target of 7 to 9 hours of sleep (mean 6.4 hours, SD 2.0), with multiple disruptions per sleep period (mean 17.7, SD 7.1), indicating poor sleep quality. Participants tended to underestimate their subjective engagement in physical activity and overestimate sleep quality.

Conclusion: The results of this study suggest people with axSpA are highly engaged in physical activity and demonstrate minimal sedentary behaviour, both which exceed recommended activity guidelines. These results are considerably higher when compared to the literature. There is discrepancy between subjective and objective measures of activity and sleep.-Sleep quantity and quality are of significant concern, with few people with axSpA meeting recommended targets.Further study that examines sleep-wake patterns, understanding of sleep physiology in this patient population and potential management strategies are recommended to address sleep deficiency in people with axSpA.

MRI-defined Sacroiliitis in First Degree Relatives of Ankylosing Spondylitis Patients

Kristyna Bubova[1], Lenka Hasikova[2], Katerina Mintalova[2], Monika Gregova[2], Sarka Forejtova[2], Ladislav Senolt[3] and Karel Pavelka[4], [1]Institute of Rheumatology, Prague, Czech Republic, [2]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Prague, Czech Republic, [3]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Praha, Czech Republic, [4]Institut of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Praha, Czech Republic

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sacroiliitis is a main radiographic finding in axial spondyloarthritis (axSpA) - the inflammatory rheumatic disease with a strong genetic background. The aim of this study was to evaluate the presence of sacroiliitis in first-degree relatives of patients with ankylosing spondylitis (AS) and to determine fulfilment of Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axial and/or peripheral spondyloarthritis (SpA), and the clinical diagnosis of SpA.

Methods: One hundred subjects without a previous rheumatological diagnosis with a first-degree relative treated for AS were included in the study. Clinical data were collected and rheumatological examinations were performed by trained rheumatologists. Magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) was read by a trained rheumatologist who was blinded to all patient data. Subjects were further divided into both SpA (according to ASAS classification criteria and clinician opinion) and non-SpA subgroups.

BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, Body mass index; BP, back pain; CRP, C-reactive protein; HLA, human leukocyte antigen; IBP, inflammatory back pain, * P value < 0.05

Patient characteristics and subsets differences

Results: We detected active sacroiliitis defined by MRI in 13 subjects who were further diagnosed with axSpA, 7 (54%) of whom already had advanced radiographic changes on conventional radiographs of the sacroiliac joints. In addition, active sacroiliitis was also present in 4 individuals who did not have back pain. The data are shown in Figure 1. A total of 26 subjects met ASAS classification criteria for SpA, of which the diagnosis of SpA was confirmed in 14 subjects (13 subjects met ASAS classification criteria for axial and 1 subject for peripheral SpA). In addition, 12 individuals met the clinical arm of the ASAS classification criteria for axSpA, but were not diagnosed with axSpA in the clinicians' opinion. Analysis of clinical characteristics showed a significant difference in CRP and BASDAI between the SpA vs. non-SpA subgroups (8.8 (±10.5) vs. 2.3 (±4.1) mg/l, p=0.0048, and 3.1 (±1.8) vs. 1.76 (±1.78), respectively). Individuals diagnosed with SpA were more likely to be HLA-B27 positive and had inflammatory back pain compared to the non-SpA subgroup (87% vs. 43%, p=0.0069 and 57% vs. 9%, p=0.0002, respectively). Individuals who were not diagnosed with SpA but met the clinical arm of the ASAS classification criteria for axSpA were excluded from the analysis. Other clinical characteristics and differences between subgroups are shown in Table 1.

Conclusion: In this cross-sectional study, 17% of first degree relatives of patients with AS had MRI- defined sacroiliitis, however not all of them were diagnosed with SpA due to the absence of back pain. A quarter of the subjects with first-degree AS relative met the classification criteria for SpA, and 14% were diagnosed with SpA based on physician opinion.

Factor H-related protein-5 Exacerbates Pathological Bone Formation of Ankylosing Spondylitis

Chang-Nam Son[1], Ji-Hyun Lee[1], Sungsin Jo[2] and Tae-Hwan Kim[3], [1]Uijeongbu Eulji Medical Center, Eulji University School of Medicine, UIJEONGBU, South Korea, [2]Hanyang University Institute for Rheumatology Research, Seoul, South Korea, [3]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The complement factor H-related protein-5 (FHR-5), a member of the human factor H protein family, enhances complement activation. The influence of complement activation on bone and joint was recognized in bone fracture healing, arthritis, and osteomyelitis. Recently, FHR-5 has been linked to eye, kidney, infection, cancer and autoimmune diseases. FHR-5 was also significantly up-regulated in proteomic analysis of serum and synovial fluid for ankylosing spondylitis (AS). Hence, we aimed to evaluate whether FHR-5 exacerbates bone inflammation and ectopic formation of AS.

Methods: The study included 65 patients with AS and 25 healthy controls (HC). Collected sera were divided into three groups according to HC, two AS groups (low CRP and high CRP) based on the CRP 0.8. Human TNF, IL6, IL-17, IL-23, and FHR-5 in three groups were measured with ELISA and human FHR-5 levels were compared to TNF, IL-6, IL-17, and IL-23 levels. In addition, soluble FHR-5 proteins were administered with Curdlan-injected SKG mice 2 time for a week and monitored for 5 weeks *In vivo* model. Foot and ankle were evaluated by micro-CT, Hematoxylin and Eosin for histological observation, and Safranin O for cartilages. Moreover, these finding were further assessed in the AS-osteoprogenitor In vitro model.

Results: In consistent with human data, proinflammatory cytokines (TNF, IL-6, IL-17A, and IL-23) and FHR-5 were elevated in AS group compared to HC group. FHR-5 levels were not significantly correlated with proinflammatory cytokines, whereas FHR-5 levels in AS were only positively correlated with the high CRP group. Notably, treatment with soluble FHR-5 has no effect on clinical arthritis scores and thickness at hindpaw in Curdlan-injected SKG, but significantly increased the ectopic bone formation at the calcaneus and tibia bones of ankle as revealed by micro-CT image and quantification. Basal FHR-5 expression was upregulated in AS-osteoprogenitors compared to control cells. Also, treatment with FHR-5 remarkedly induced bone mineralization status of AS-osteoprogenitors during osteogenic differentiation accompanied by MMP13 expression.

Conclusion: We provide the first evidence demonstrating that FHR-5 can exacerbate pathological bone formation of AS. Therapeutic modulation of FHR-5 could be promising for future treatment of AS.

Diagnostic Delay of Axial Spondyloarthritis in African American Patients

John Byun[1], Hans Vitzthum von Eckstaedt[1], Kichul Ko[2] and Reem Jan[1], [1]University of Chicago, Chicago, IL, [2]The University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The identification of axial spondyloarthritis (axSpA) remains challenging. The initial presentation is not always immediately apparent as an inflammatory disease, potentially leading to years of delay in diagnosis. Our hypothesis is that the delay is worse in African American (AA) patients who have a lower disease prevalence of axSpA and lower

frequency of HLA-B27 positivity compared to other racial groups. This retrospective study assessed whether AA patients experience a longer delay in diagnosis from symptom onset to diagnosis of axSpA compared to other ethnic cohorts, and whether they exhibit any significant differences in disease characteristics.

Methods: All adult rheumatology patients evaluated between 2012-2022 with a diagnosis code for ankylosing spondylitis, sacroiliitis, undifferentiated spondyloarthritis, or inflammatory back pain were enrolled. Variables collected include age at diagnosis (years, yrs), time to diagnosis (months, m), ethnicity, sex, HLA-B27 status, CRP at diagnosis (mg/L), history of IBD, psoriasis, uveitis, and family history of axSpA. All enrolled subjects had to have radiographic and/or MRI evidence of sacroiliitis. Fisher's exact test and Mann-Whitney test were performed to compare categorical variables and non-parametric continuous variables respectively, and a multivariate logistic regression analysis was performed to identify independently associated variables with studied outcomes.

Results: 29 AA and 100 sex-matched non-AA subjects were enrolled. The median time to diagnosis from symptom onset was similar at 36 m for both groups. The AA group was older at diagnosis (median 38 yrs [interquartile range {IQR} 26 – 48 yrs] vs 29 years [IQR 23 – 37 yrs], p = 0.03) with higher CRP (15 mg/L [IQR 6 – 32 mg/L] vs 4 mg/L [IQR 2 – 10.5 mg/L], p = 0.001), and lower HLA-B27 positivity rate (36.8% vs 70.5%, p = 0.008). Due to the difference in age at diagnosis, subjects diagnosed at 45 years of age or older were compared to those diagnosed at a younger age. Those diagnosed at an older age had higher proportions of AA subjects (42.3% vs 17.5%, p = 0.015) and HLA-B27 positivity (70.4% vs 31.2%, p = 0.004). A multivariate logistic regression analysis showed that older age at diagnosis (≥45 yrs) was associated with negative HLA-B27 (Odds Ratio [OR] 5.94, 95% Confidence Interval [CI] 0.52 – 7.61) but not with ethnicity. It was also linked to time to diagnosis but the effect was minimal (OR 1.01, CI 1.004 – 1.017).

Conclusion: The time to diagnosis was similar between AA and non-AA groups. However, AA subjects were statistically older at diagnosis; whether this implies a delay in diagnosis or a different disease phenotype is not clear. In addition, AA subjects had a statistically higher degree of CRP elevation and lower HLA-B27 positivity rates. Through a multivariate analysis, older age at diagnosis was associated with negative HLA-B27, and this effect negated the relationship between race and age of diagnosis. Further research is needed to understand the interplay between CRP levels, HLA-B27 positivity and race in terms of disease characteristics vs delay in diagnosis.

Temporal Trends in Cardiovascular Events in Axial Spondyloarthritis Patients with Medicare Insurance versus Commercial Insurance: An Analysis Using Claims Data

Rouhin Sen[1], Justin Leach[1], Maria I. (\"Maio\") Danila[2], Fenglong Xie[1], Jasvinder Singh[1], Liron Caplan[3], Iris Navarro-Millán[4] and Jeffrey Curtis[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham (UAB), Birmingham VA Medical Center, Birmingham, AL, [3]Rocky Mountain Regional VAMC, Aurora, CO, [4]Weill Cornell Medicine, Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: AS is an inflammatory disorder of the axial skeleton and can cause complications including disabling joint damage. Nearly 20% of people with AS are on Medicare disability insurance[1]. Major adverse cardiovascular events (MACE) are the leading cause of death in AS[2]. Despite the high prevalence of disability in AS, these patients are understudied[1] and may be different than similarly aged commercially insured patients. We sought to compare MACE incidence temporal trends in AS patients who are beneficiaries of Medicare disability insurance against those with commercial insurance in order to understand the excess risk for CVD events in disabled patients.

Methods: We conducted a retrospective longitudinal analysis from 2007-2019 using the Medicare Fee-for-Service and MarketScan claims databases. Subjects were identified by having ≥ 2 AS International Classification of Diseases (ICD)-9/10 diagnosis codes in outpatient visits with age between 18 and 64 years. MACE was defined as an incident hospitalized myocardial infarction or ischemic stroke and identified by validated ICD 9/10 diagnosis codes. Patients with prior MACE were excluded[3]. We reported demographics, cumulative raw incidence/1000 person and determined incidence rate ratios for disabled Medicare enrollees versus commercially insured AS patients. We displayed incidence trends and calculated yearly annual percentage change (APC) based off end-of-year cutpoints; significance was determined using the Monte Carlo Permutations method. SAS v9.4 and Joinpoint Trend Analysis v5.0 software were used for analyses; $p < 0.05$ determined statistical significance.

Results: The total number of AS patients eligible for analysis was 1,097,297 from Medicare and 2,258,212 from MarketScan. Incident MACE was identified in 10,494 subjects in Medicare and 8,860 individuals in MarketScan. The mean age in years at which MACE occurred was 54.8 and 53.3 in patients with Medicare and MarketScan, respectively. Most patients

Table 1. Demographic information of AS patients < 65 years of age with incident MACE enrolled in Medicare and MarketScan (commercial/private insurance).

		Disabled Medicare	Commercially insured
Age in years (mean, SD)	at incident MACE	54.78 (6.96)	53.18 (8.23)

AS: axial spondyloarthritis; MACE: major adverse cardiovascular events; pts: patients

with MACE were female and White (Table 1). In the disabled Medicare cohort, the incidence of MACE ranged from 7.7-11.5/1000 patients. This cohort showed a significant decrease in incidence from 2007-2014 (-4.1 APC), then a significant increase from 2014-2017 (14.0 APC), then no significant difference from 2017-2019 (Figure 2b). In the MarketScan cohort, the incidence of MACE was between 3.2-4.7/1000 patients and there was a non-significant upward trend (3.4 APC) in the MACE incidence rate (Figure 1c). The incidence rate ratio compared disabled Medicare enrollees with AS to commercially insured AS patients ranged from 2.2-3 (Table 2).

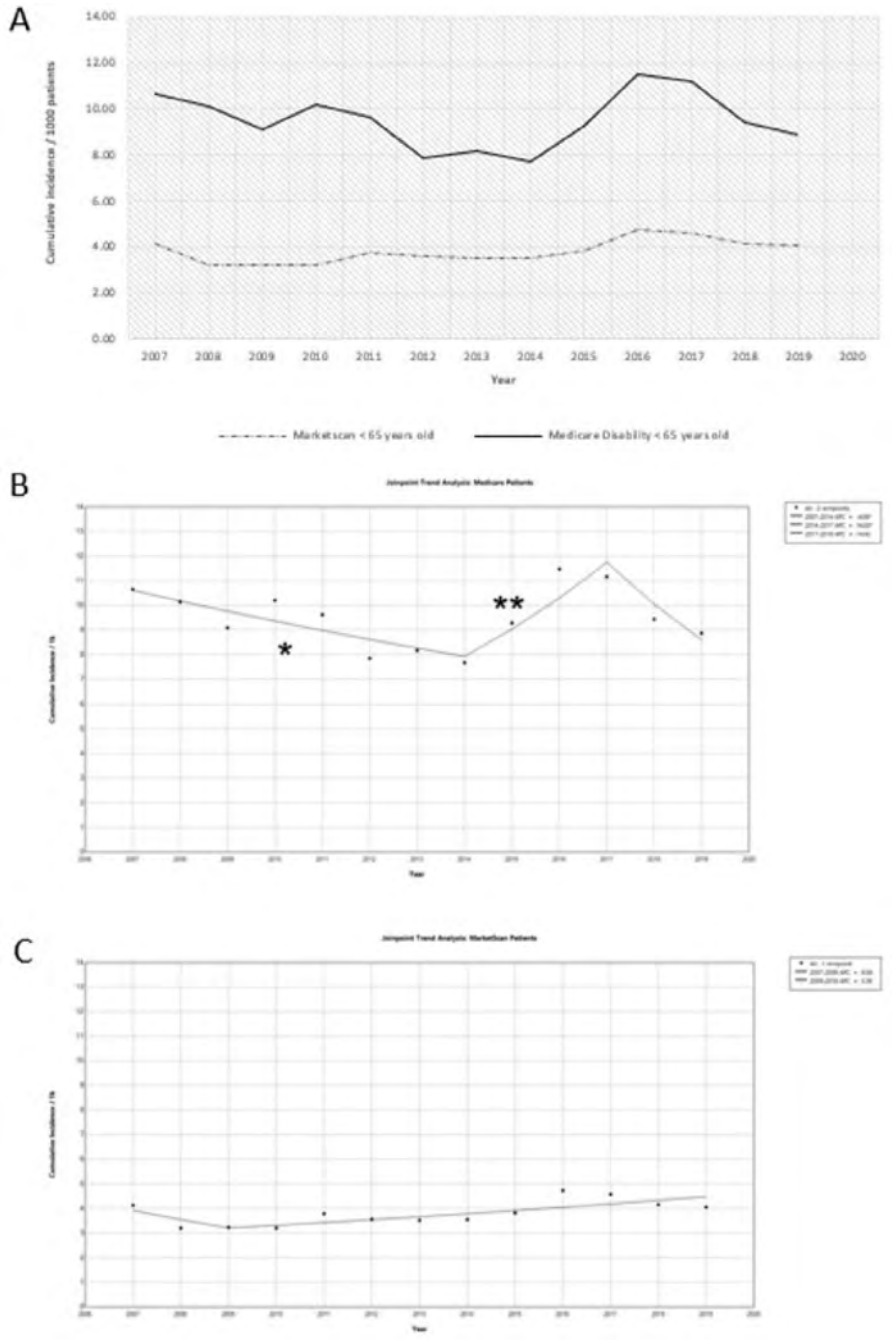

Figure 1. Incidence rate trend of Myocardial infarction and ischemic stroke in AS patients. Panel A: Raw incidence/1000 patients enrolled in Medicare (dark, solid line) versus MarketScan insurance (dashed line). Panel B: JoinPoint analysis of the raw incidence trend for Medicare patients. The single asterisk (*) displayed under the trend line shows a significant decrease in incidence (-4.09 APC) from 2007-2014 while the double asterisk (**) depicts a statistically significant increase in incidence (14.00 APC) from 2017-2019. Panel C JoinPoint analysis of the raw incidence trend for commercially or privately insured MarketScan patients. There was no statistically significant difference in the incidence trend.

Conclusion: Disabled AS patients younger than age 65 years with Medicare experienced a 2-3-fold higher incidence of MACE compared to younger commercially insured patients; unexpectedly, the group of AS patients experiencing MACE events was made up of a high percentage of women. Incidence trend for MACE differed for both groups and did show signs of increase, though not significant. Our future research is to understand why there is a difference between the groups, including differences in the prevalence comorbidities, socioeconomic status, treatment patterns, and healthcare access.

Abstract Number: 1407

Defining Thresholds of Presenteeism Measures for Unacceptable Work Participation in axSpA

Dafne Capelusnik[1], Sofia Ramiro[2], Elena Nikiphorou[3], Walter P. Maksymowych[4], Marina Nighat Magrey[5], Helena Marzo-Ortega[6] and Annelies Boonen[7], [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands, [3]King's College London, London, United Kingdom, [4]University of Alberta, Edmonton, AB, Canada, [5]Case Western Reserve University, University Hospitals, Cleveland, OH, [6]NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [7]Care and Public Health Research Institute (Caphri), Maastricht University, Maastricht, Netherlands

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Presenteeism is associated with lower work satisfaction and future sick leave in axial spondyloarthritis (axSpA). It is generally assessed as a continuous variable; however, despite a lower precision, categorical variables are more meaningful in routine practice.

Table. Optimal thresholds for presenteeism measures and patients correctly classified for unacceptable work status and adverse work outcome at 12 months.

	Optimal threshold (SE/SP)	Correctly classified for unacceptable work status n (%)	Correctly classified for AWO at 12 months n (%)
WPAI presenteeism (0-100)	≥40 (70/86)	283 (83)	215 (76)
QQ method (0-10)	<7 (81/62)	218 (65)	160 (57)
WALS (0-3)	≥0.75 (86/75)	255 (76)	193 (68)
WLQ 25	≥29 (77/80)	266 (79)	201 (71)
BASDAI (0-10)	≥4.7 (81/71)	245 (73)	290 (67)
BASFI (0-10)	≥3.5 (81/67)	232 (69)	185 (66)

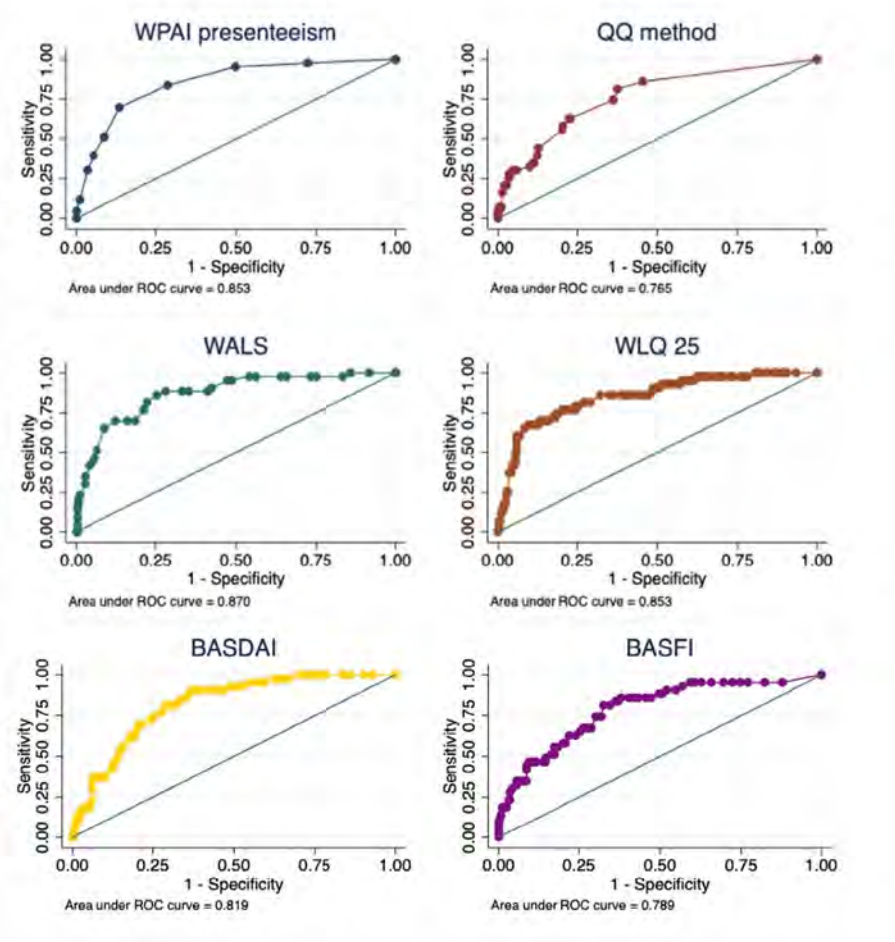
SE, Sensibility; SP, Specificity; AWO, adverse work outcomes.

Our objectives were: 1) To identify thresholds of presenteeism instruments that reflect unacceptable work status in patients with axSpA and whether those thresholds could predict future adverse work outcomes, 2) to compare the performance of these thresholds with thresholds from traditional outcomes for axSpA and 3) to understand whether thresholds are stable across contextual factors.

Methods: We used data from the 1-year multinational prospective study on Patient-Reported Outcomes in Employment Study in Ankylosing Spondylitis (AS-PROSE). Thresholds to determine when patients consider themselves in 'unacceptable work status' were calculated at baseline for 4 presenteeism instruments (Work Productivity and Activity Impairment questionnaire -WPAI-, Quality and Quantity method -QQ-, Workplace Activity Limitations Scale -WALS- and Work Limitations Questionnaire -WLQ 25-); and for BASDAI and BASFI.

We performed receiver operating characteristic (ROC) analysis using as external criteria the Patient Acceptable Work State (PAWS) question 1, addressing ability to perform your current job satisfactorily. We used different approaches (75th percentile, Youden index, Liu method, nearest to 0.1) to determine the optimal cut-off, while balancing over-under diagnosis. Temporal validation was assessed by applying the thresholds in different timepoints. Influence of context (age, gender, nature of work, symptom duration) was explored in subgroup analyses.

Figure. ROC curves for excessive presenteeism and health state from different measurement instruments according to unacceptable work stat



Finally, accuracy of thresholds to predict "future adverse work outcome" throughout 12 months (defined as sick leave or long-term disability) was assessed.

Results: A total of 366 patients were included: 72% males, mean age 43 (SD 10), with a mean symptom duration of 18.2 (11) years. 15% of the patients considered themselves in an unacceptable work status, and 6% had at least one adverse work outcome during the 12 months.

The optimal thresholds of the presenteeism instruments that reflect an unacceptable work status are expressed in the table. BASDAI and BASFI performed similarly to the presenteeism instruments (Figure). Across numerous contextual factors the thresholds were stable, expect for some underdiagnoses among women and persons with a physical loading job by WPAI-, QQ- , BASDAI- and BASFI-thresholds.

The threshold accuracy to predict adverse work outcome over 12 months was similar across all the presenteeism instruments (68-76% of correctly classified patients), except for the QQ (< 60%). BASDAI and BASFI also performed slightly worse (66-67%).

Conclusion: Thresholds for presenteeism and health status representing unacceptable work status have been established, showing stability across contextual factors. Threshold for QQ were insufficiently accurate and for BASDAI and BASFI were slightly worse although acceptable. The capacity of these thresholds to predict future adverse work outcome was somehow lower for all instruments.

Impact of Disease Activity on Functional Impairment in Patients with Spondyloarthritis Is Different According to the Degree of Radiographic Progression: Result from SNUH-AS Cohort

Ji In Jung[1], Ju Yeon Kim[2], Jin Kyun Park[3], Eun Young Lee[3], Eun Bong Lee[2] and Jun Won Park[2], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea, [2]Seoul National University Hospital, Seoul, South Korea, [3]Seoul National University College of Medicine, Seoul, South Korea

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Although previous studies suggested that physical functioning is largely driven by disease activity in patients with spondyloarthritis (SpA), its relationship to radiographic progression has not been thoroughly investigated. The aim of this study was to investigate whether the effect of disease activity on physical function varies according to the radiographic progression in SpA patients.

Methods: This cross-sectional study used baseline data from the patients in a single-center, prospective cohort of SpA. Disease activity was assessed through Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS). Physical function was measured using Bath Ankylosing Spondylitis Functional Index (BASFI) and functional impairment of the patients was defined as BASFI ≥4. Radiographic progression of SpA was assessed using modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Clinical factors related to functional impairment of the patient were investigated using logistic regression analysis.

Results: A total of 221 patients were analyzed. Mean (SD) age at baseline was 43.4 (14.1) yeas and 176 (79.6%) were male. Mean (SD) disease duration of the included patients was 7.5 (9.5) years. Remission or low disease activity (LDA, ASDAS-CRP < 2.1) was achieved in 149 (67.4%) patients. Mean (SD) mSASSS was 19.5 (20.6) and 96 (43.4%) patients had at least one syndesmophyte on baseline spinal radiographs.

At the baseline, functional impairment was present in 41 (18.6%) patients. Univariable analysis showed that older age at diagnosis, shorter disease duration based on two years, and higher ASDAS-CRP were associated with functional impairment. Although the effect of ASDAS-CRP on the outcome was consistent in the multivariable analysis (adjusted OR 2.46 [95% CI 1.70-3.58]), it was significantly different according to the severity of radiographic progression (*P* value for interaction = 0.001). In the absence of bridging syndesmophyte, increase in ASDAS-CRP was associated with more frequent functional impairment (adjusted OR 5.12 [2.61-10.05]). By contrast, in the subgroup of patients with bridging syndesmophyte, ASDAS-CRP did not increase the likelihood for functional impairment (adjusted OR 1.14 [0.70-1.86]). In fact, in the subgroup without bridging syndesmophyte, no patient with LDA showed a functional impairment. However, in advanced patients with bridging syndesmophyte, the rate of functional impairment was 23.8% despite achieving LDA. (Figure 1)

Conclusion: In the presence of advanced radiographic progression, low disease activity was not significantly associated with less functional impairment in patients with SpA, which suggests that early diagnosis and optimal treatment are critical for better physical function.

Analysis of Soluble Biomarkers in Axial Spondyloarthritis

Caroline Bauchiero[1], Stephanie Sinnappan[2] and Joerg Ermann[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Columbia University, New York, NY, [3]Division of Rheumatology, Inflammation and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Distinguishing patients with axial spondyloarthritis (axSpA) from patients with other causes of chronic back pain remains a challenge. The lack of reliable biomarkers contributes to the diagnostic delay in axSpA. Recently, macrophage migration inhibitory factor (MIF) has been proposed as a candidate diagnostic and prognostic biomarker. MIF is a proinflammatory cytokine that was shown to be upregulated in several autoimmune/inflammatory diseases including axSpA. The putative role of CD8+ T cells in axSpA pathogenesis suggests further that serum markers of cytotoxicity might have value as biomarkers in axSpA. The goal of this study was to compare serum levels of MIF and other candidate serum proteins in patients with axSpA and controls.

Methods: Study subjects were recruited from our hospital's Orthopedic and Arthritis Center. Four cohorts were compared: healthy controls (HC), patients with chronic low back pain without axSpA (cLBP), axSpA patients not on a biologic (axSpA/-), and axSpA patients treated with a TNF inhibitor (axSpA/TNFi). Study subjects were matched for age, sex and genotyped for HLA-B27 (Table 1). All axSpA patients fulfilled modified New York criteria for ankylosing spondylitis or the 2009 ASAS criteria for axSpA. Serum was evaluated using the LEGENDplex Human CD8/NK panel (BioLegend) for thirteen markers including IL-17A, IL-6, TNF, granzyme B, and perforin. CRP and MIF were evaluated by DuoSet ELISA (R&D Systems).

Results: The severity of back pain in the cLBP controls and axSpA/- patients was comparable (BASDAI Q2 mean 5.0±1.9 vs. 5.0± 3.0). axSpA/- patients had higher back pain, BASDAI and ASDAS scores than axSpA/TNFi patients consistent with higher disease activity in the biologic naïve group. Serum CRP values were significantly higher in axSpA/- patients compared

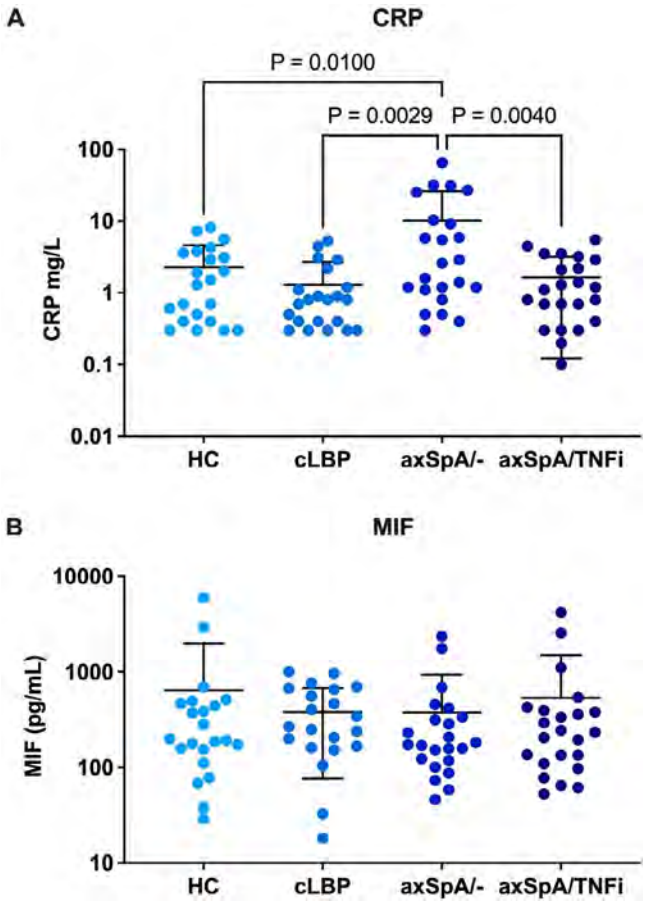
* $P = 0.9058$, # $P = 0.0556$, & $P = 0.0149$

Study subject characteristics.



Serum levels of (A) CRP (mg/L) and (B) MIF (pg/mL) in healthy controls (HC), chronic low back pain (cLBP) controls, axSpA patients not on a biologic (axSpA/-) and axSpA patients on a TNF inhibitor (axSpA/TNFi). Error bars represent mean ± SD, P values by ANOVA with post hoc Tukey's.

with HC, cLBP controls, and axSpA/TNFi patients (P= 0.01, P=0.0029, P=0.004 respectively) (Figure 1A). Serum MIF levels were not statistically different across all four groups (P= 0.8069) (Figure 1B). Additionally, there were no statistically significant differences between the groups for any of the markers included in the LEGENDplex Human CD8/NK panel.

Conclusion: The strength of this study is the comparison of well-characterized groups of axSpA patients with/without biologic therapy and controls including patients with cLBP. In contrast to a previous study, we did not find differences in serum MIF levels between axSpA patients and controls. Of the evaluated serum biomarkers, only CRP values correlated with active axSpA. Our results underscore the need for more research into diagnostic biomarkers in axSpA.

Abstract Number: 1410

The Use of the ASAS Referral Criteria Together with Increased Education and Training of Its Use Improves Delay to Diagnosis of Axial Spondyloarthritis

Antoni Chan, Kathryn Rigler and Arran McDougall, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of axial spondyloarthritis (AxSpA) remains a challenge in the management of this condition worldwide. Over the last decade, there remains a significant delay in the diagnosis of the condition. The delay is 8-10 years from symptom onset in Europe. This is contributed by the lack of awareness of the condition, unstructured referral pathways and limited access to diagnostic tests such as MRI. The delayed diagnosis leads to increased complications from AxSpA, delays in treatment and poorer long-term outcomes. Multiple referral strategies are available with the aim of improving the time to diagnosis of AxSpA.

Methods: We reviewed the time from symptom onset to diagnosis of the axial spondyloarthritis over a 12-year period from 2010 to 2023. During this time, we evaluated the effectiveness of the referral strategies we had put in place for use by general practitioners (GPs) to reduce the time to diagnosis. A baseline audit was carried out between January to August 2013 to help understand existing delivery levels against the key National Institute of Clinical Excellence (NICE) recommendations. From 2017, the ASAS referral criteria for suspected AxSpA was implemented in primary care1. This was available as an electronic referral from GPs to the AxSpA clinic. Educational and training events were held to improve the use of the ASAS referral criteria. Follow-up audits were carried out between February to July 2017, January to May 2019 and January to March 2023 to assess the impact of the implementation of the referral strategy with the local AxSpA best practice pathway. Data on length of time of symptoms before seeing the GP, time to referral and diagnosis were captured.

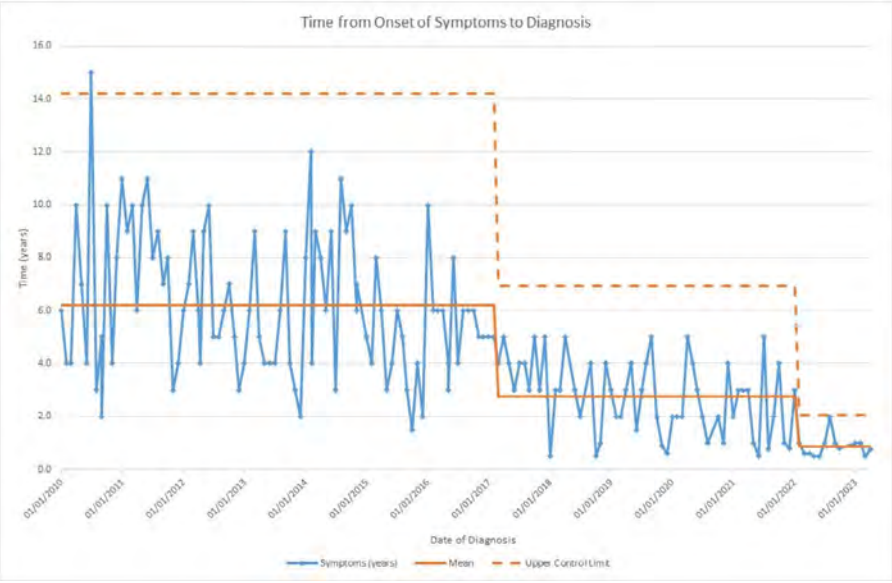

Figure 1. Time to diagnosis from symptom onset over study period

Results: We studied 160 axSpA patients, 87 (54.5%) were male and 73 (45.5%) female. The mean (range) age was 37 (18-52) years. All patients met the ASAS classification criteria for axSpA. Radiographic axSpA (Ankylosing spondylitis) fulfilled the modified New York criteria. There were more patients with radiographic axSpA in the earlier years of diagnosis (100% in 2010) and more of non-radiographic axSpA in the later years (85% in 2022). HLA-B*27 positivity was found in 118 (73.8%) of patients. The majority of referrals were from general practitioners 96 (60.2%), physiotherapists 32 (20.3%), orthopaedics 18 (15.5%) and other specialties 6 (4%). There was no significant difference in the mean (years) delay to diagnosis from the source of the clinic referral. The mean and median delay for time to diagnosis in years were in 2011 (8, 8.5), 2014 (7.8, 8), 2017 (4.2, 4), 2020 (2.5, 2), 2022 (1.1, 0.9) (Figure 1). The majority of the patients were diagnosed between 31-40 years (41%), 22% between 18-30 years, 31% between 41-50 years and 4% after the age of 50 years. We have managed to reduce mean time to diagnosis from a mean of 8 years (2011) to 1.1 years (2022).

Conclusion: The use of the ASAS referral criteria for suspected AxSpA together with increased educational and awareness campaign of its use in primary care and musculoskeletal triage has led to the earlier recognition and referral for suspected AxSpA.

Prevalence of Early Axial Spondyloarthritis in the Be-GIANT Cohort Based on the ASAS Consensus Definition of Early Axial Spondyloarthritis

Gaelle Varkas[1], Ann-Sophie De Craemer[2], Zuzanna Lukasik[1], Thomas Renson[3], Liselotte Deroo[4], Philippe Carron[5], Dirk Elewaut[6] and Filip Van den Bosch[7], [1]Dept. of Rheumatology, Ghent University Hospital, Ghent, Belgium, [2]Ghent University Hospital, Gent, Belgium, [3]Dept. of Pediatrics, Ghent University Hospital, Ghent, Belgium, [4]Ghent University, Gent, Belgium, [5]UZ Gent, Gent, Belgium, [6]Ghent University and VIB Center for Inflammation Research, Ghent, Belgium, [7]Department of Internal Medicine and Pediatrics, Ghent University and VIB Center for Inflammation Research, Ghent, Belgium

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes Poster II: Imaging & AS
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently, the Assessment of SpondyloArthritis international Society (ASAS) community, led by the ASAS-SPEAR (SPondyloarthritis EARly definition) working group, endorsed a uniform definition for early axial spondyloarthritis (axSpA). Therefore, in a research setting "early axSpA" should be defined as ≤2 years duration of axial symptoms. The objective was to explore the prevalence of early axSpA as defined by the ASAS community in the prospective Be-GIANT cohort. Additionally, differences in the baseline characteristics of early and late axSpA were analyzed.

Methods: An explorative analysis of all axSpA patients from the prospective Be-GIANT cohort consisting of newly diagnosed adult SpA patients fulfilling the ASAS criteria for axial or peripheral SpA, was performed. Patients were divided in 'early' and 'late' axSpA based on the proposed ASAS definition. Differences in baseline characteristics between these

Table 1. Comparison of baseline characteristics between early axSpA (≤2 years symptom duration) and late axSpA (>2 years symptom duration).

	≤2 years symptom duration (n=162)	>2 years symptom duration (n=204)	p-value
Age, mean (±SD)	29.7 (±7.7)	34.5 (±9.5)	p<0.001
Male, % (n)	51.9 (84)	50.7 (103)	NS
HLAB27 status, % (n)	76.4 (123)	73.0 (146)	NS
Smoking, % (n)	23.4 (37)	20.8 (42)	NS
BASDAI, mean (SD)	4.2 (± 2.0)	4.3 (±1.9)	NS
ASDAS, mean (SD)	2.6 (±1.0)	2.5 (±0.9)	NS
BASFI, median [Q1;Q3]	2.2 [0.9;4.0]	2.7 [1.2;4.6]	NS (p=0.059)
Patient global, mean (SD)	4.9 (±2.8)	4.5 (±2.8)	NS
Physician global, mean (SD)	4.2 (±2.5)	3.7 (±2.4)	p=0.041
Sacroiliitis CR* (ModNY), % (n)	17.3 (27)	32.3 (62)	p=0.001
Sacroiliitis MRI* (ASAS), % (n)	91.1 (143)	84.4 (162)	NS (p=0.06)

Statistically significant test result ($p \leq 0.05$). SD: standard deviation. CR: conventional radiographs; MRI: magnetic resonance imaging.

groups were explored by using the (non) parametric independent- samples T test for continuous variables, and the Chi-square test for categorical variables.

Results: Collected patient data from the Be-GIANT cohort between November 2010 to November 2022 were considered, of which 366 patients with a clinical diagnosis of axial spondyloarthritis and data on symptom duration of axial disease were selected. Overall, 51.2% of patients were male, with mean age of 32.4 ± 9.1 years (mean ± SD). Median axial symptom duration was 30.0 months [10.0; 85.0] (median [Q1;Q3]). HLA-B27 status was positive in 74.5%, with elevated CRP in 41.7% of patients. At baseline, patients exhibited high active disease as indicated by ASDAS 2.5 ± 0.9 (mean ± SD). Strikingly, the definition of early axSpA was met by 44.3% of patients. Regarding imaging, 87,4% fulfilled the ASAS definition of a positive MRI of the sacroiliac joints, whereas 25.6% fulfilled the modified New York criteria for sacroiliitis. When comparing baseline characteristics (Table 1), no significant differences were seen between 'early' and 'late' axSpA regarding BASDAI, ASDAS, patient global or baseline CRP. Likewise, a similar proportion of family history, good response to NSAIDs or previous infection was seen. As expected, patients in the early axSpA group were significantly younger ($p< 0.001$), with significantly less radiographic sacroiliitis ($p=0.001$). Also, physician global was higher in early axSpA as compared to late axSpA ($p=0.041$). No differences were seen in distribution of sex, HLAB-27 status, nor inflammatory back pain features. A trend was seen in favour of insidious onset of back pain ($p=0.051$), lower BASFI ($p= 0.059$) and higher MRI positivity ($p=0.06$) in the early axSpA group.

Conclusion: In the prospective Be-GIANT cohort, almost half of patients met the definition of 'early axSpA'. These patients did not differ in baseline characteristics, except for younger age and lower frequency of radiographic sacroiliitis. Although the disease activity scores at baseline were similar, physicians consider the early disease to be more severe.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS) has demonstrated significant efficacy across disease domains in controlled clinical trials of patients (pts) with active PsA.[1,2] Recent CorEvitas PsA/SpA Registry analyses confirmed real-world GUS effectiveness, showing that pts with persistent on-label GUS use at 6 months had significant mean improvements from baseline (BL) in peripheral joint and skin symptoms and pt-reported pain.[3] Here we report secondary findings from the CorEvitas PsA/SpA Registry further assessing changes in pt-reported outcomes (PROs) among pts with persistent GUS use from BL through the 6-month visit (On-Label GUS Persisters).

Methods: This analysis includes registry pts who initiated on-label GUS after FDA approval for active PsA (7/13/2020; 100 mg SC at Weeks 0 & 4 then Q8W) and were On-Label Persisters. Demographics, PsA disease activity, PROs, and medication history at GUS initiation (BL visit) were summarized descriptively. Among On-Label GUS Persisters not meeting response criteria at BL, response rates at 6 months were determined for established outcomes related to improvements or achievement of low levels of disease activity in pt-reported pain (0-100 mm visual analog scale [VAS]), pt global assessment of arthritis + psoriasis (PtGA; 0-100 mm VAS), and HAQ-DI (0-3). Unadjusted, nominal p-values were calculated using a single-proportion, one-sided test to determine if response at the 6-month visit differed from 0% at BL. Mean (95% CI) change from BL to 6 months was determined for fatigue (0-100 mm VAS); nominal p-value calculated using a paired t-test at α=0.05.

Results: Among 114 on-label GUS initiators with a 6-month follow-up visit, 90 (79%) had persistent on-label GUS use. On average, pts had longstanding, treatment-resistant, active PsA (**Table 1**). BL pt-reported pain, HAQ-DI, and fatigue scores were 57.0, 0.9, and 56.5, respectively. Substantial proportions of On-Label GUS Persisters experienced clinically meaningful improvements in pain (38% with ≥30% reduction and 40% with ≥15-mm reduction), overall joint and skin disease (47% with ≥15-mm reduction in PtGA), and physical function (30% with HAQ-DI improvement ≥0.35; all nominal p< 0.001; **Figure 1**). Further, up to one quarter of pts achieved the more stringent thresholds of response, generally representing a major response or minimal disease activity, including 22% with ≥50% reduction in pain, 18% with pain score ≤15 mm, 26% with PtGA score ≤20 mm, and 10% with HAQ-DI ≤0.5 (all nominal p< 0.001; **Figure 2**). Mean change (95% CI) in fatigue from BL at 6 months was -8.8 (-14.9, -2.7; nominal p=0.005).

Table 1. BL characteristics of pts with persistent on-label GUS use at 6 months (N=90)	
	Mean (SD)[a]
Demographics at BL visit	
Age, y	55.2 (12.5)

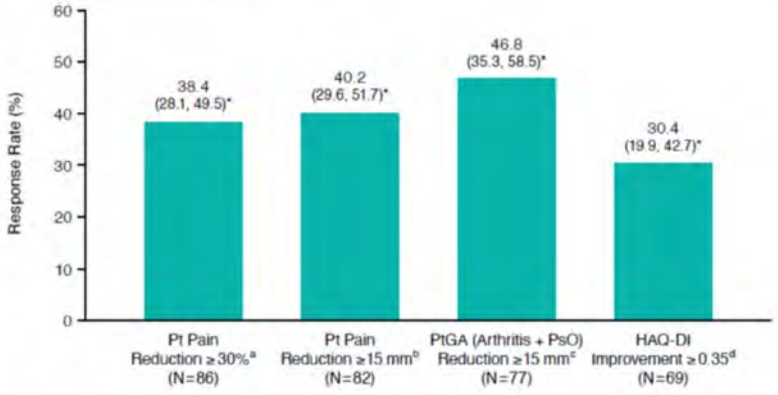
Efficacy	3 (3.3%)
Other (not specified)	1 (1.1%)
Number of prior csDMARDs, n, (%)	
0	34 (37.8%)
1	35 (38.9%)
≥2	21 (23.3%)
Number of prior b/tsDMARDs, n (%)	
0	7 (7.8%)
1	17 (18.9%)
≥2	66 (73.3%)

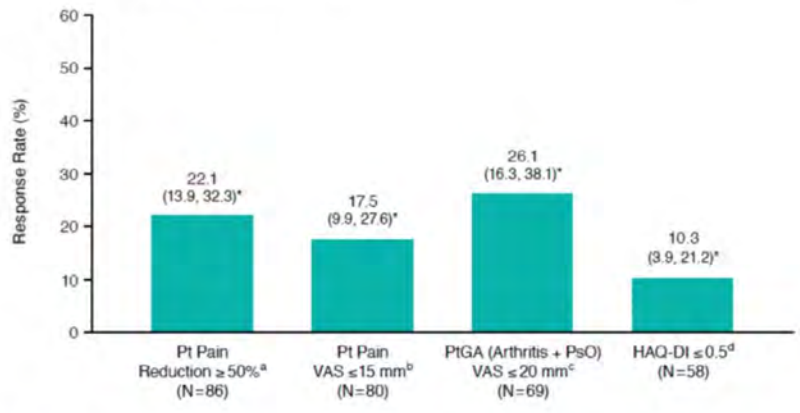
bDMARD, biologic disease-modifying antirheumatic drug; BMI, body mass index; BSA, body surface area; cDAPSA, clinical Disease Activity Index for PsA; csDMARD, conventional systemic DMARD; tsDMARD, targeted synthetic DMARD.
[a]Unless specified otherwise.
[b]In pts with BSA >0 at BL.
[c]cDAPSA score ≤4 indicates remission; score >27 indicates high disease activity.
[d]Based on Question 1 of the BASDAI.

Figure 1. Response rates (95% CI) at the 6-month visit for clinically meaningful improvements in PROs among On-Label GUS Persisters.



* Nominal p<0.001; derived from a one-sided, single-proportion test conducted to determine if the 6-month response rate differed from the BL rate of 0%.
[a] In pts with pt-reported pain (Pt Pain) VAS >0 at BL.
[b] In pts with Pt Pain VAS ≥15 mm at BL.
[c] In pts with a history of PsO with PtGA of arthritis + PsO ≥15 mm at BL.
[d] In pts with HAQ-DI ≥0.35 at BL.

Figure 2. Response rates (95% CI) at the 6-month visit for more stringent thresholds of response among On-Label GUS Persisters.



* Nominal p<0.001; derived from a one-sided, single-proportion test conducted to determine if the 6-month response rate differed from the BL rate of 0%.
[a] In pts with Pt Pain VAS >0 at BL.
[b] In pts with Pt Pain VAS >15 mm at BL.
[c] In pts with a history of PsO with PtGA of arthritis + PsO >20 mm at BL.
[d] In pts with HAQ-DI >0.5 at BL.

Conclusion: In this real-world population of pts with treatment-resistant active PsA and persistent on-label GUS use, consistent with prior results for physician-reported endpoints of joint and skin disease, pts reported meaningful improvements in pain, physical function, and fatigue. These represent difficult-to-treat domains that are important contributors to pts' health-related quality of life.

Effect of Apremilast Treatment on the Domains of MDA-Joints in Patients with Early Oligoarticular Psoriatic Arthritis: 16-Week Results from FOREMOST

Philip J. Mease[1], Alexis R Ogdie[2], Kristina Callis Duffin[3], Jyotsna Reddy[4], Rebecca Wang[4], Shauna Jardon[4] and Laura Coates[5], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Utah, Salt Lake City, UT, [4]Amgen, Inc., Thousand Oaks, CA, [5]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The modified minimal disease activity (MDA-Joints) is a novel composite endpoint to assess disease activity and treatment effect in PsA based on a criteria set of mandated tender and swollen joints, and 3/5 items of skin involvement, patient assessments, functionality, and enthesitis.[1] FOREMOST evaluated apremilast 30 mg BID (APR) treatment by MDA-Joints in patients (pts) with early oligoarticular (oligo) PsA.

Methods: FOREMOST (NCT03747939) is a phase 4, multicenter, randomized, double-blind, placebo (PBO)-controlled, parallel-group study. Eligible pts had early disease (PsA duration ≤5 years) and oligo PsA (>1 but ≤4 tender and >1 but ≤4 swollen joint count [TJC and SJC]) despite prior treatment with either nonsteroidal anti-inflammatory drugs and/or ≤2 conventional systemic disease-modifying antirheumatic drugs. Pts were randomized 2:1 to APR or PBO (stratified by concomitant medication use) for 24 weeks, with an early escape at Week 16. The primary endpoint was the proportion of pts at Week 16 who achieved MDA-Joints, a composite of TJC ≤1 and SJC ≤1 plus achieving 3 of the following: psoriasis body surface area (BSA) ≤3%, pt assessment of pain visual analog scale (0–100-mm) ≤15, Pt Global Assessment of Disease Activity (PtGA; 0–100-mm) ≤20, health assessment questionnaire disability index (HAQ-DI) ≤0.5, and enthesitis count ≤1 based on the Leeds Enthesitis Index (LEI). This analysis assesses achievement of each domain in the overall population and only among those with baseline (BL) disease activity. All *P*-values are nominal.

Results: BL values for the overall population and all MDA-Joints domains were comparable between APR and PBO groups (**Table 1**). Improvements were observed across all domains for the entire cohort. In the overall population, more pts achieved TJC ≤1 (66.2% vs 44.4%), SJC ≤1 (74.0% vs 69.0%), BSA ≤3% (70.8% vs 60.5%), pt assessment of pain ≤15 (29.4% vs 13.1%), PtGA ≤20 (30.4% vs 19.1%), HAQ-DI ≤0.5 (47.5% vs 34.2%), and LEI ≤1 (76.0% vs 71.3%) at Week 16 with APR vs PBO. Of pts with BSA >3% at BL, significantly more achieved BSA ≤3% with APR vs PBO at Week 16 (52.2% vs 25.1%; *P*=0.0043) (**Figure 1**). Of pts with a pt assessment of pain score >15 at BL, pt assessment of pain ≤15 was reached by significantly more patients with APR vs PBO at Week 16 (27.1% vs 9.9%; *P*=0.0012) (**Figure 1**). Of pts with PtGA >20 at BL, significantly more achieved PtGA ≤20 at Week 16 with APR vs PBO (28.5% vs 13.0%; *P*=0.0044) (**Figure 1**). Of pts with HAQ-DI >0.5 at BL, 32.4% and 19.0% achieved HAQ-DI ≤0.5 at Week 16 with APR and PBO, respectively (*P*=0.0302) (**Figure 1**). Of pts with LEI >1 at BL, numerically greater proportions achieved LEI ≤1 at Week 16 with APR vs PBO, although this was not significant (53.1% vs 41.0%; *P*=0.3815) (**Figure 1**).

APR, apremilast; BSA, body surface area; HAQ-DI, health assessment questionnaire disability index; LEI, Leeds enthesitis index; PBO, placebo; PtGA, Patient's Global Assessment of Disease Activity; SD, standard deviation; VAS, visual analog scale.

Figure 1. Achievement of Individual MDA-Joints Domains at Week 16 in Patients With Baseline Disease Activity

	TJC ≤1	SJC ≤1	BSA ≤3%	Patient's Assessment of Pain ≤15	PtGA ≤20	HAQ-DI ≤0.5	LEI ≤1
n, PBO	105	105	42	97	93	77	27
n, APR	203	203	78	184	179	145	41
Adjusted difference, %	22.1	5.1	28.0	17.3	15.9	14.0	11.3

In patients with baseline activity for each respective parameter. Patients who discontinued the study prior to the given week due to an adverse event or lack of efficacy were imputed as non-responders. The remaining missing values at the given week were imputed by multiple imputation.
APR, apremilast; BSA, body surface area; HAQ-DI, health assessment questionnaire disability index; LEI, Leeds enthesitis index; PBO, placebo; PtGA, Patient's Global Assessment of Disease Activity; SJC, swollen joint count; TJC, tender joint count.

Conclusion: Improvements were seen in all MDA-Joints domains with APR vs PBO at Week 16 in pts with early oligo PsA who did not meet any of the thresholds at BL. Improvements were significantly greater for TJC, BSA, pt assessment of pain, PtGA, and HAQ-DI domains and numerically greater for the SJC and LEI domains with APR treatment compared with PBO, possibly related to the small sample size.

Effects of Apremilast on Changes in Cardiometabolic Parameters by Diabetes and Obesity Status in Patients with Psoriatic Arthritis

Philip J. Mease[1], Dafna Gladman[2], Iain McInnes[3], Sue Cheng[4], Stephen Colgan[5], Yuri Klyachkin[6], Lichen Teng[7] and Nehal Mehta[8], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA, [2]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Department of Medicine, University of Toronto, Toronto, ON, Canada, [3]University of Glasgow, Glasgow, United Kingdom, [4]Amgen, Inc., Bradenton, FL, [5]Amgen, Inc., Halton Hills, ON, Canada, [6]Amgen, Inc., Lexington, KY, [7]Amgen, Inc., Thousand Oaks, CA, [8]George Washington University School of Medicine, Washington, DC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of cardiometabolic diseases including obesity and diabetes is higher in patients with psoriatic arthritis (PsA) than those without PsA. Apremilast (APR) is associated with weight loss and a reduction in glycated hemoglobin (HbA1c). The objective of this analysis was to evaluate the effects of APR on cardiometabolic parameters over 52 weeks in patients with active PsA.

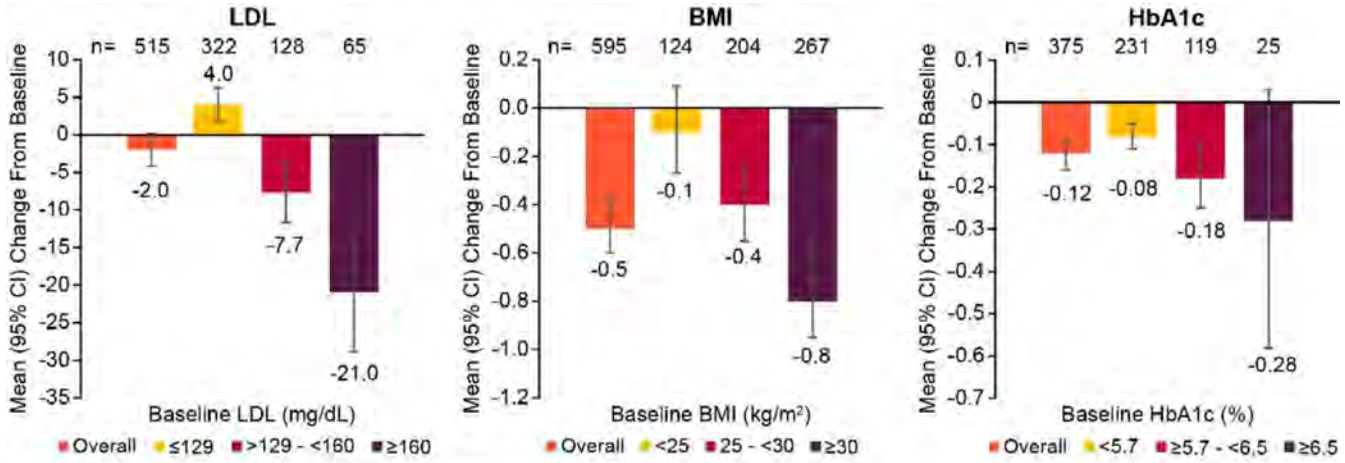
Methods: Data from 5 randomized, placebo-controlled, phase 3 studies (PALACE 1–4 and ACTIVE) in patients with active PsA receiving APR 30 mg twice daily were pooled. Included in this analysis were patients who were treated with APR for 52 weeks. Changes from baseline to Week 52 in low- and high-density lipoprotein (LDL, HDL), body mass index (BMI), and HbA1c were assessed and stratified by baseline level of these parameters and Week 52 disease activity (Clinical Disease Activity Index for Psoriatic Arthritis [cDAPSA] remission/low disease activity [REM/LDA] vs moderate/high disease activity [ModDA/HDA]).

Results: Data from 781 patients with PsA who received APR were pooled (mean age: 50 years, 55% female). Mean LDL was 119.6 mg/dL in the overall population at baseline and decreased by 2.0 mg/dL on average at Week 52 (**Figure**). The greatest decreases in LDL were seen in patients with the highest LDL levels at baseline (**Figure**). Similar favorable changes in HDL were

observed. A total of 34/65 (52.3%) moved from the high LDL category (≥160 mg/dL) at baseline to borderline (>129 – < 160 mg/dL) or normal (≤129 mg/dL) at Week 52 and 49/128 (38.3%) changed from borderline high to normal LDL levels (**Table**).

Mean BMI was 30.3 kg/m^2 in the overall population at baseline and decreased by 0.5 kg/m^2 at Week 52 (**Figure**). A trend was again seen where patients with higher BMI at baseline saw greater decreases in BMI at Week 52 (**Figure**). Additionally, 24/267 (9.0%) patients changed from the obese category (≥30 kg/m^2) to the overweight category (25 – < 30 kg/m^2), and 25/204 (12.3%) patients changed from the overweight category to the normal category (< 25 kg/m^2) (**Table**).

Mean HbA1c was 5.6% in the overall population at baseline and decreased by 0.1% at Week 52 (**Figure**). Greater changes in HbA1c were seen in patients who were pre-diabetic (HbA1c 5.7% – < 6.5%) and diabetic (HbA1c ≥6.5%) at baseline vs those who had normal HbA1c (HbA1c < 5.7%) (**Figure**). Furthermore, 60/119 (50.4%) patients who had pre-diabetes changed to normal HbA1c levels, and 10/25 (40.0%) moved from diabetes to pre-diabetes (**Table**).



Includes patients who were treated with APR for 52 weeks and had both baseline and Week 52 values.
APR, apremilast; BMI, body mass index; HbA1c, glycated hemoglobin; LDL, low-density lipoprotein.

Changes in Cardiometabolic Parameters from Baseline to Week 52 by Baseline Subgroup

	Week 52 LDL (mg/dL), n/N (%)		
Baseline LDL (mg/dL)	Normal (≤129)	Borderline (>129 – <160)	High (≥160)
Normal (≤129)	274/322 (85.1)	41/322 (12.7)	7/322 (2.2)
Borderline (>129 – <160)	49/128 (38.3)	63/128 (49.2)	16/128 (12.5)
High (≥160)	13/65 (20.0)	21/65 (32.3)	31/65 (47.7)
	Week 52 BMI (kg/m^2), n/N (%)		
Baseline BMI (kg/m^2)	Normal (<25)	Overweight (25 – <30)	Obese (≥30)
Normal (<25)	111/124 (89.5)	13/124 (10.5)	0/124 (0.0)
Overweight (25 – <30)	25/204 (12.3)	163/204 (79.9)	16/204 (7.8)
Obese (≥30)	0/267 (0.0)	24/267 (9.0)	243/267 (91.0)
	Week 52 HbA1c (%), n/N (%)		
Baseline HbA1c (%)	Normal (<5.7)	Pre-diabetes (5.7 – <6.5)	Diabetes (≥6.5)
Normal (<5.7)	224/231 (97.0)	6/231 (2.6)	1/231 (0.4)
Pre-diabetes (5.7 – <6.5)	60/119 (50.4)	53/119 (44.5)	6/119 (5.0)
Diabetes (≥6.5)	1/25 (4.0)	10/25 (40.0)	14/25 (56.0)

Includes patients who were treated with APR for 52 weeks.
APR, apremilast; BMI, body mass index; HbA1c, glycated hemoglobin; LDL, low-density lipoprotein.

LDL, BMI, and HbA1c Shift from Baseline to Week 52

Results were consistent across Week 52 cDAPSA psoriatic disease activity subgroups; greater changes in cardiometabolic parameters were seen in patients with higher baseline LDL, BMI, HbA1c, or lower baseline HDL regardless of whether REM/LDA was achieved at Week 52.

Conclusion: APR treatment was associated with improvement in cardiometabolic parameters observed across psoriatic disease activity groups. The most favorable changes were seen in patients with high LDL, low HDL, obesity, or diabetes at baseline. These findings suggest that those with a high burden of comorbid cardiometabolic diseases and active PsA treatment may gain benefit beyond joint disease with APR. However, these findings require larger, prospective studies.

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: PsA impacts the physical health and functional ability of patients (pts),which can contribute to reduced work productivity.[1] Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, and has demonstrated efficacy and tolerability in pts with PsA to 16 weeks (wks), vs placebo (PBO), sustained to 52 wks.[2–5]Here, we report the impact of BKZ treatment on work productivity up to 1 year using data from two phase 3 studies.

Methods: BE OPTIMAL (NCT03895203; biologic DMARD [bDMARD]-naïve pts) and BE COMPLETE (NCT03896581; inadequate response or intolerance to TNF-α inhibitors [TNFi-IR] pts) were PBO-controlled phase 3 studies assessing BKZ in pts with active PsA.[2,3] Pts in BE OPTIMAL were randomized 3:2:1 to subcutaneous (sc) BKZ 160 mg every 4 wks (Q4W), PBO,

Table. Baseline employment status and WPAI-SHP dimension scores for bDMARD-naïve patients (BE OPTIMAL) and TNFi-IR patients (BE COMPLETE) (OC)

	BE OPTIMAL (bDMARD-naïve)		BE COMPLETE (TNFi-IR)	
	PBO/BKZ 160 mg Q4W n=281	BKZ 160 mg Q4W n=431	PBO/BKZ 160 mg Q4W n=133	BKZ 160 mg Q4W n=267
Employment Status, n (%)				
Employed at study start	197 (70.1) (n=281)	280 (65.1) (n=430)	78 (58.6) (n=133)	171 (64.0) (n=267)
WPAI-SHP dimension score,[a] mean % (SD)				
Overall work impairment	34.2 (26.3) (n=181)	37.0 (27.2) (n=262)	40.3 (28.1) (n=73)	40.7 (27.9) (n=158)
Activity impairment[b]	43.2 (24.5) (n=281)	43.2 (24.4) (n=430)	47.1 (26.0) (n=133)	46.5 (25.6) (n=267)
Absenteeism[c]	8.5 (22.1) (n=189)	7.7 (21.4) (n=270)	7.1 (19.7) (n=75)	9.7 (20.4) (n=162)
Presenteeism[d]	32.3 (24.7) (n=181)	34.8 (25.7) (n=262)	38.6 (26.6) (n=73)	38.0 (26.3) (n=158)

Randomized set. [a] Dimensions were assessed only in patients employed at baseline, with the exception of the activity impairment dimension which was assessed for the entire cohort; [b] Ability to undertake regular, non-work-related activities (e.g., childcare); [c] Work time missed due to PsA; [d] Impairment while working due to PsA. bDMARD: biologic DMARD; BKZ: bimekizumab; OC: observed case; PBO: placebo; Q4W: every 4 weeks; SD: standard deviation; TNFi-IR: inadequate response or intolerance to TNF-α inhibitors; WPAI-SHP: Work Productivity and Activity Impairment Questionnaire – Specific Health Problem v2.0.

or reference (sc adalimumab 40 mg Q2W; not reported here); the study was active treatment-blind to Wk 52, after which pts could enter the ongoing open-label extension BE VITAL (NCT04009499). Pts in BE COMPLETE were randomized 2:1 to sc BKZ 160 mg Q4W or PBO; pts who completed Wk 16 were eligible for BE VITAL. BE COMPLETE plus BE VITAL is referred to as 'BE COMPLETE' hereafter. In both BE OPTIMAL and BE COMPLETE, PBO-randomized pts switched to BKZ 160 mg Q4W at Wk 16 (PBO/BKZ). Pt work productivity is derived from the Work Productivity and Activity Impairment Questionnaire – Specific Health Problem v2.0 (WPAI-SHP), adapted for PsA;[6] collected to Wk 52 in BE OPTIMAL and Wk 40 in BE COMPLETE. Percentage change from baseline in WPAI-SHP scores are reported for four dimensions: overall work impairment, activity impairment, work time missed (absenteeism), and impairment while working (presenteeism).

Results: Baseline WPAI-SHP scores suggest work productivity was impaired in pts: mean overall work impairment was 34.2%–40.7% across studies, with similar rates of activity impairment and presenteeism between treatment arms (**Table**). At Wk 16, BKZ-treated pts in both studies showed numerically greater mean percentage reduction from baseline in overall work impairment compared with PBO-treated pts; bDMARD-naïve: 16.7% BKZ, 3.0% PBO and TNFi-IR: 15.6% BKZ, 3.6% PBO. Work productivity continued to improve up to 1 year; PBO/BKZ pts demonstrated similar reductions in overall work impairment to BKZ-randomized pts at Wk 52 for the bDMARD-naïve population (21.3% BKZ, 14.9% PBO/BKZ) and at Wk 40 for the TNFi-IR population (21.5% BKZ, 21.6% PBO/BKZ). Trends were generally comparable for all dimensions in both studies (**Figure**).

Conclusion: BKZ demonstrated improvements vs PBO in all WPAI-SHP dimensions to Wk 16 which were clinically meaningful,[6] with greatest improvements observed in activity impairment and presenteeism. Work productivity continued to improve with BKZ to 1 year; pts who switched to BKZ at Wk 16 experienced similar levels of improvement to BKZ-randomized pts. Improvements in work productivity were similar in bDMARD-naïve and TNFi-IR pts, demonstrating consistent response.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: In many countries, methotrexate (MTX) monotherapy is the first-line disease-modifying anti-rheumatic drug (DMARD) therapy for psoriatic arthritis (PsA), despite that its efficacy in PsA (in contrast to rheumatoid arthritis [RA]) has not been clearly shown in placebo-controlled trials. In light of this paucity of evidence, data on the effect of MTX on work absenteeism in PsA –relevant to both individual and society – is of interest. Thus, we aimed to investigate absenteeism development in relation to MTX start in newly-diagnosed PsA, and to contrast this to the situation in RA and among general population (GP) comparator-subjects.

Table 1.

Table 1. Characteristics at start of methotrexate monotherapy

	Psoriatic arthritis n=2525	Rheumatoid arthritis n=2525	General population comparator-subjects n=12028

N (%) if not otherwise stated. [1] Based on a registered diagnosis within 5 years prior to MTX start. [2] Based on a diagnosis within 5 years or a prescription within 1 year prior to MTX start. [3] Based on a prescription within 1 year prior to MTX start. Missing data (PsA/RA/GP): Education (0.2/0.5/1%); Patient pain (70/46%); Patient global (70/45%); Tender joints (68/41%); Swollen joints (68/41%); CRP (67/40%). GP, general population; MTX, methotrexate; NA, not applicable; PsA, psoriatic arthritis; RA, rheumatoid arthritis.

Methods: Patients aged 18-62 years (y) with newly-diagnosed PsA in Sweden (≤2y since first main PsA ICD-code from rheumatology/internal medicine), starting MTX monotherapy as their first DMARD 2011-2019, were identified from nationwide registers (with a diagnostic validity of >85% for both PsA and RA). Each PsA case was matched to a corresponding patient with newly-diagnosed RA, starting MTX monotherapy, and to 5 GP comparator-subjects (matching for age, sex, county, and [for RA] MTX start-year). The number of absenteeism days (sick leave or disability pension, due to any reason) per quarter of a year (90 days) was retrieved from the Social Insurance Agency and evaluated from 1y before until 2y after MTX start. In order to assess absenteeism development specifically in relation to MTX monotherapy, in case of switch to/addition of other DMARDs or if stopping MTX, last observation carried forward (LOCF) of the number of absenteeism days in the month when this change occurred, was applied in our main analysis. An alternative analysis without LOCF was, however, also performed, thus reporting the absenteeism development as observed, regardless of further DMARD changes. Within-group changes in absenteeism were analyzed by Wilcoxon´s matched-pair rank-sign test, and comparisons between PsA and RA by bootstrapped ANCOVA, crude and adjusted for relevant confounders (see **Table 2**).

Results: At MTX start, patient-reported outcomes in PsA and RA were similar, while CRP and swollen joints were numerically higher, and time from diagnosis shorter, in RA (**Table 1**). Already 1y prior to MTX start, the PsA cases (but not RA) displayed higher absenteeism levels compared to the GP (**Figure, panel A**). In PsA and RA, absenteeism thereafter increased, peaking in the first quarter after MTX start, but then decreased significantly over the 2y follow-up in the main (**Figure, panel A**) as well as the alternative analysis (**Figure, panel B**), although numerically more in RA. While significant improvements were seen with MTX monotherapy (**Figure, panel A**), the superior outcomes in the as observed analysis (**Figure, panel B**)

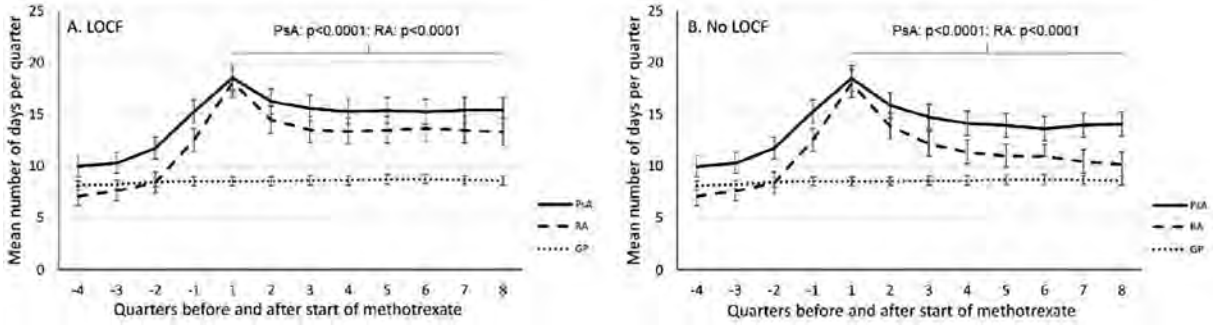

Figure. Mean number of absenteeism days (due to sick leave or disability pension) per quarter of a year (90 days) before and after start of methotrexate. **A.** Main analysis, applying LOCF in case of switch to/addition of other DMARDs or if stopping MTX. **B.** Alternative analysis without LOCF (i.e. as observed, regardless of subsequent DMARD changes). Both analyses censored at death, migration or if receiving the other diagnosis (e.g. a patient with PsA receiving a RA diagnosis). Within-group changes in absenteeism from the 1st to the 8th quarter of a year after MTX start assessed by Wilcoxon's matched-pair rank-sign test. DMARD, disease-modifying anti-rheumatic drug; GP, general population comparator-subjects; LOCF, last observation carried forward; MTX, methotrexate; PsA, psoriatic arthritis; RA, rheumatoid arthritis.

Table 2.

Table 2. Mean differences in absenteeism days (due to sick leave or disability pension) between PsA and RA

Main analysis with LOCF. 2525 PsA/RA cases			
Quarter	**Crude**	**Model 1**	**Model 2**
Q-4	**2.9 (1.5 to 4.3)**	1.6 (-0.1 to 3.4)	NA
Q+1	0.4 (-1.5 to 2.3)	-0.8 (-3.3 to 1.6)	-1.3 (-3.6 to 0.8)
Q+8	**2.2 (0.2 to 4.1)**	0.2 (-2.2 to 2.6)	-0.7 (-2.8 to 1.3)
Alternative analysis without LOCF. 2525 PsA/RA cases			
Q-4	**2.9 (1.5 to 4.3)**	1.6 (-0.1 to 3.4)	NA
Q+1	0.5 (-1.5 to 2.3)	-0.7 (-3.2 to 1.7)	-1.2 (-3.5 to 0.9)
Q+8	**3.9 (2.2 to 5.6)**	1.3 (-0.8 to 3.5)	0.4 (-1.4 to 2.3)

Model 1 adjusted for sex, age, county, MTX start-year, level of education, comorbidities (reported in Table 1), any unemployment in the calendar year prior to MTX start and number of days from first PsA/RA-diagnosis to MTX start. Model 2 additionally adjusted for number of absenteeism days in the first quarter of the year preceding the MTX start (i.e. quarter -4) LOCF, last observation carried forward; MTX, methotrexate; NA, not applicable; PsA, psoriatic arthritis, Q, quarter; RA, rheumatoid arthritis.

suggest an added benefit of subsequent DMARD changes. In the adjusted comparisons, absenteeism levels did not differ significantly between PsA and RA at any timepoint (regardless of analysis; **Table 2**).

Conclusion: Our results suggest a significant improvement of work absenteeism, following MTX start in PsA. Considering that work ability is a both prioritized and objectively assessed outcome, this offers additional support for MTX use in PsA, for which trial-based evidence is limited.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient reported outcomes (PROs) are important in the treatment evaluation of patients with spondyloarthritis, including axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA). For secukinumab, limited real world data on PROs is available – and no comparison between axSpA and PsA patients has been performed. In European patients with axSpA and PsA who initiated secukinumab, we aimed to determine: 1) the proportion of patients achieving 6-, 12- and 24-month pain, fatigue, patient global assessment (PGA) and health assessment questionnaire (HAQ) remission, and 2) the 24-month secukinumab retention rate.

Methods: The study was conducted within the European Spondyloarthritis Research Collaboration Network (EuroSpA)(1). From 16 European registries, patients with axSpA or PsA who initiated secukinumab between 2015 and 2021 were included. Based on the ASAS working group definition of partial remission in axSpA(2), we applied the following definitions of PRO remission: pain≤20, PGA≤20, fatigue≤20 (all on visual analogue scales 0-100 mm) and HAQ≤0.5 for both axSpA and PsA patients, to make comparisons feasible.PRO remission rates were calculated as crude and adjusted for secukinumab adherence (LUNDEX). Comparisons of remission rates were performed with univariable and multivariable (baseline covariates: age, gender, registry, and number of previous b/tsDMARDs)logistic regression analyses. Kaplan-Meier with log-rank test and Cox regression analyses were performed to assess and compare the 24-month secukinumab retention rate between axSpA and PsA patients.

Results: We included 3062 axSpA patients and 3217 PsA patients initiating secukinumab in routine care. At secukinumab treatment start (baseline), axSpA patients had a mean (SD) age of 46.8 (12.0) years, with 52.7% being male. PsA patients had a mean age (SD) of 51.9 (11.9) years and were predominantly female (56.9%). No clinically relevant differences in

*Adjustment with age, gender, registries, and number of previous b/tsDMARDS (0/1/≥2). PRO, patient reported outcomes; CI, Confidence Interval; PGA, patient global assessment; HAQ, Health assessment questionnaire; pain, fatigue, PGA, were scored on a 0–100 mm visual analogue scale (VAS); HAQ was scored on a scale ranging from 0–3; PRO remission criteria were defined as following: pain remission ≤ 20mm, PGA ≤ 20mm, fatigue ≤ 20mm, HAQ ≤ 0.5; Significant values are indicated by bold type.

	Retention rates		24-month Hazard ratios [95%CI] PsA *vs.* axSpA		
	axSpA	PsA	Unadjusted	Adjusted Age+gender	Adjusted: All*
24 months	61.2%	62.8%	0.93 [0.85-1.02]	0.92 [0.84-1.01]	0.92 [0.84-1.02]

*Values adjusted for age, gender, registries, and number of previous b/tsDMARDS. (0/1/≥2). CI, Confidence Interval.

Figure 1. Secukinumab retention rates in axSpA and PsA patients, with unadjusted and adjusted hazard ratios

axSpA than for PsA patients at all timepoints, LUNDEX-adjusted remission rates were similar (Table 2). After correction for multiple confounders no difference was found between the groups, except for a higher remission rate for fatigue in PsA at 24 months (OR= 1.8 [95% CI 1.1-3.0]) (Table 2). The 24-month retention rates were similar in axSpA and PsA (61.2% *vs*. 62.8%, HR= 0.92 [95% CI 0.84-1.02], p=0.14 in fully adjusted analyses) (Figure 1).

Conclusion: Our study supports the real-world effectiveness of secukinumab in both axSpA and PsA, as measured by PROs, and suggests that PROs (including pain, PGA and HAQ) and 24-month retention rate after secukinumab initiation are similar in axSpA and PsA patients. Further analyses, aiming to evaluate long-term effectiveness of axSpA and PsA are needed.

Abstract Number: 1418

Efficacy of the Oral, Selective, Allosteric Tyrosine Kinase 2 Inhibitor, Deucravacitinib, on Psoriasis in Patients with Active PsA: Results from a Phase 2 Trial

Alice B. Gottlieb[1], April W. Armstrong[2], Joseph Merola[3], Andrew Napoli[4], Miroslawa Nowak[4], Subhashis Banerjee[4], Thomas Lehman[5] and Philip J. Mease[6], [1]Icahn School of Medicine at Mount Sinai, New York, NY, [2]Keck School of Medicine of University of Southern California, Los Angeles, CA, [3]Harvard Medical School, Brigham and Women's Hospital, Newton, MA, [4]Bristol Myers Squibb, Princeton, NJ, [5]Bristol Myers Squibb, Philadelphia, PA, [6]Swedish Medical Center/Providence St. Joseph Health and University of Washington School of Medicine, Seattle, WA

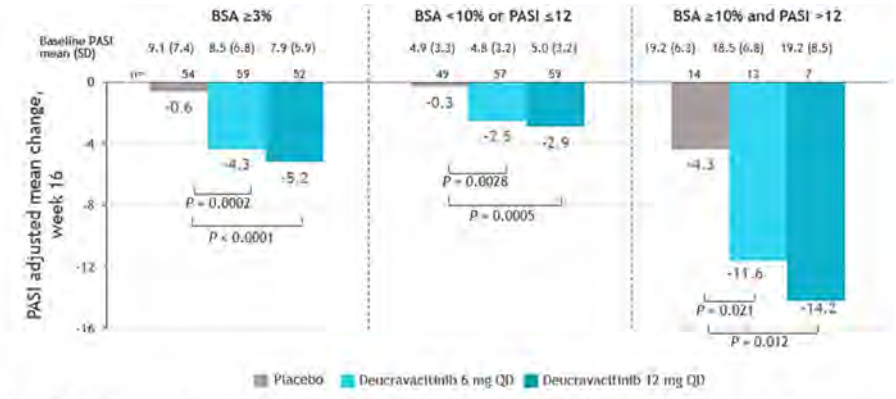
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Tyrosine kinase 2 (TYK2) mediates signaling of key cytokines involved in plaque psoriasis (PsO) and PsA pathophysiology. Deucravacitinib is a first-in-class, oral, selective, allosteric TYK2 inhibitor approved in multiple countries for the treatment of adults with moderate to severe PsO, based on superiority of deucravacitinib over apremilast and placebo (PBO) in various outcome measures in 4 phase 3 trials, including in China and Japan (NCT03611751, NCT03624127, NCT04167462, NCT03924427) in patients with moderate to severe PsO.[1,2] DEUC also improved multiple measures of disease activity, including in arthritis and PsO, vs PBO in a phase 2 trial (NCT03881059) in patients with active PsA.[3] This analysis further evaluated the efficacy ofdeucravacitinib on PsO in patients with concomitant PsA in the phase 2 trial.

Methods: The phase 2 double-blind trial in PsA randomized patients (N=203) 1:1:1 to PBO, deucravacitinib 6 mg once daily (QD), or deucravacitinib 12 mg QD. After wk 16 (part A), patients could optionally enroll in a double-blind period until wk 52 (part B), where deucravacitinib-treated patients with minimal disease activity at wk 16 continued deucravacitinib treatment to wk 52. PsO disease activity measures, including mean body surface area (BSA), mean Psoriasis Area and Severity Index (PASI) score, and achievement of different treat-to-target PASI and BSA thresholds, were assessed at week 16 in part A.

Results: At baseline (BL), PsO characteristics were generally similar across treatment groups, with most evaluable patients (≥ 74%) having a PASI< 12 or BSA< 10 (**Table**). At wk 16, mean PASI scores significantly decreased from BL and the improvements were significantly greater with deucravacitinib in PBO in patients treated with deucravacitinib vs PBO, even in those with very low BL PASI scores (**Figure**). Deucravacitinib treatment significantly decreased PASI scores from BL in patients with 6 mg QD and 12 mg QD vs PBO, respectively inpatients on background conventional synthetic (cs) DMARD (–4.0 and –4.9 vs –2.3; $P < 0.05$ for both) as well as those without csDMARD use (–3.7 and –4.0 vs +2.5; $P < 0.001$, for both) vs PBO. At wk 16, a greater proportion of patients treated with deucravacitinib at either dose vs PBO achieved PASI ≤ 1 in patients with mild to moderate or moderate to severe PsO. Decreases in mean PASI score at wk 16 were maintained



Modified baseline observation carried forward method was used to handle missing data. Adjusted means and nominal *P* values were derived from an analysis of covariance model with factors for body weight and TNFi use and the baseline value as a covariate.

BSA, body surface area; PASI, Psoriasis Area and Severity Index; PsO, plaque psoriasis; QD, once daily; SD, standard deviation; TNFi, tumor necrosis factor inhibitor.

Figure. PASI mean change from baseline at week 16 by psoriasis severity at baseline

Table. Baseline psoriasis characteristics

Table. Baseline psoriasis characteristics

		Placebo (n = 66)	Deucravacitinib 6 mg QD (n = 70)	Deucravacitinib 12 mg QD (n = 67)
BSA severity	BSA < 3%, n (%)	9 (14)	11 (16)	14 (21)
	BSA ≥ 3% to < 10%, n (%)	32 (49)	37 (53)	29 (43)
	BSA ≥ 10%, n (%)	22 (33)	22 (31)	23 (34)
PASI severity	PASI ≤ 5, n (%)	30 (46)	33 (47)	29 (43)
	PASI > 5 to ≤ 12, n (%)	18 (27)	23 (33)	30 (45)
	PASI > 12, n (%)	15 (23)	14 (20)	7 (10)
	NR, n (%)	3 (5)	0	1 (2)
BSA ≥ 3% (*mild to severe*)	n (%)	54 (82)	59 (84)	52 (78)
BSA < 10%, PASI ≤ 12 (*mild to moderate*)	n (%)	49 (74)	57 (81)	59 (88)
BSA ≥ 10%, PASI > 12 (*moderate to severe*)	n (%)	14 (21)	13 (19)	7 (10)

BSA, body surface area; NR, not reported; PASI, Psoriasis Area and Severity Index; QD, once daily.

through wk 52 in patients who achieved MDA and continued treatment with deucravacitinib 6 mg or 12 mg QD in part B of the study.

Conclusion: Treatment with deucravacitinib significantly improved PsO in patients with PsA, regardless of BL PsO severity and background csDMARD use. Of note, improvement in the moderate to severe PsO patient subgroup was comparable with that observed in the phase 3 POETYK PSO-1 trial in patients with moderate to severe PsO.[1]

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain in PsA has multifaceted origins (e.g., peripheral joint inflammation, axial involvement [axPsA], skin lesions, dactylitis, enthesitis, underlying conditions) and can be difficult to treat. Guselkumab (GUS), a fully human IL-23p19 subunit inhibitor, is effective in treating multiple PsA domains and elicited durable improvement in patient-reported pain (PtP) in the DISCOVER-1&2 trials[1,2]. Here, we assessed association between improvement in key PsA manifestations and PtP using 1-year DISCOVER-1&2 data.

Methods: DISCOVER-1&2 enrolled adults with active PsA despite standard therapies[3,4]. Patients were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo with crossover to GUS 100 mg Q4W at W24. Treatment groups were pooled (N=1120). Longitudinal associations of improvement in swollen joint count (SJC,0-66), tender joint count (TJC, 0-68), Leeds enthesitis index (LEI), dactylitis severity score, Psoriasis Area and Severity Index (PASI), axPsA (N=312), and improvement in overall PtP (0-100 mm) and spinal pain (BASDAI question 2 in patients with axPsA) were assessed. Longitudinal associations of improvement in these PsA manifestations with ≥30%/50%/70% improvements in PtP (PtP-30/50/70) were assessed.

Table. Adjusted[1] Associations Between Improvements in Key PsA Manifestations and Pain Improvement Through W52

Pt Population	Predictor (Δ)	Δ PtP (β)[2]	Odds Ratio (OR)[3]			Δ Spinal Pain (β)[2,4]
			PtP-30	PtP-50	PtP-70	
All (N=1120)	PASI	0.41‡	1.05‡	1.04‡	1.04	0.03
	SJC	0.28‡	1.03*	1.03	1.06	0.03
	TJC	0.55‡	1.05‡	1.08‡	1.12‡	0.06‡
BL Enthesitis (N=728)	LEI	1.62‡	1.19‡	1.25‡	1.32‡	0.18*
	PASI	0.47‡	1.06‡	1.06‡	1.06*	0.02
	SJC	0.28‡	1.03*	1.03	1.03	0.03
	TJC	0.39‡	1.04‡	1.05‡	1.08‡	0.05‡
BL Dactylitis (N=473)	DSS	-0.04	0.97*	1.01	1.07	0.01
	PASI	0.31‡	1.04*	1.05*	1.05	0.02
	SJC	0.19	1.03	1.03	1.02	0.05*
	TJC	0.60‡	1.05‡	1.06‡	1.11‡	0.05‡

*p<0.05; †p<0.01; ‡p≤0.0001.

[1]Adjusted for BL values, age, gender, BMI, SF-36 Mental Component Summary score, presence of TJC – SJC ≥7 (central pain sensitization proxy), FACIT-Fatigue score, and treatment group;

[2]β correspond to the incremental increase in pain improvement;

[3]ORs correspond to the incremental increase in the odds of achieving pain endpoints, for every increase in improvement in key PsA manifestations or in the presence (vs absence) of axPsA. Higher β = greater impact on pain improvement;

[4]N=312.

AxPsA, axial involvement of psoriatic arthritis; BL, baseline; BMI, body mass index; DSS, dactylitis severity score; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; LEI, Leeds enthesitis index; OR, odds ratio; PASI, psoriasis area and severity index; PsA, psoriatic arthritis; PtP, patient-reported pain; SJC, swollen joint count; TJC, tender joint count; W, week.

Results: Mean (SD) baseline PtP of 61.2 (19.8) indicated substantial burden. Upon adjusting for potential confounders, greater improvement in PASI, SJC, and TJC (mutually adjusted) were each associated with significantly greater improvement in PtP and higher odds of achieving PtP-30 through W52 **(Table)**. PASI reduction was also associated with greater odds of PtP-50, as was TJC improvement for PtP-50/70. In patients with baseline enthesitis, improvements in LEI, PASI, and TJC were each associated with greater PtP improvement and attaining PtP-30/50/70; SJC reduction was only associated with PtP-30. In patients with baseline dactylitis, PASI and TJC reductions were significantly associated with PtP improvement. Overall, axPsA presence did not impact the extent of PtP improvement (data not shown). In patients with axPsA, significant associations were observed between spinal pain improvement and TJC and LEI improvement.

Conclusion: Improvements in key PsA manifestations were significantly associated with pain reduction, although to varying extents. TJC reduction had the greatest impact on PtP improvement, likely due to overlap of the construct measured. Psoriasis improvement had a greater impact on pain relief than SJC improvement, highlighting the sensory burden of skin lesions, while enthesitis improvement showed a significant association with both overall and spinal pain relief. These findings underscore the importance of utilizing treatments effective across manifestations to address recalcitrant PsA symptoms.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: In the phase 3 DISCOVER-2 study of biologic-naïve patients (pts) with active psoriatic arthritis (PsA), guselkumab (GUS), a fully human, selective interleukin (IL)-23p19 subunit inhibitor significantly reduced the signs and symptoms of disease and radiographic progression vs placebo (PBO), with durable response across multiple disease domains through 2 years. GUS also significantly decreased serum levels of collagen turnover markers, which are elevated in PsA pts vs healthy controls. Furthermore, changes in these and other serum cytokine levels through Week 24 (W24) of GUS treatment are associated with clinical response through 2 years. Here, we further assessed effects of GUS on serum cytokine and collagen turnover biomarkers from W24 through W100 (2 years) and explored associations between biomarker levels and longer-term clinical response (W100).

Methods: In DISCOVER-2, biologic-naïve adults with active PsA (swollen joint count ≥5, tender joint count ≥5, CRP ≥0.6 mg/dL) were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4 and then Q8W; or PBO with crossover to GUS Q4W at W24. Blood samples from consenting GUS-treated pts (Q4W and Q8W pooled) were assessed

for serum cytokine levels (N=100), including Th17-related effector molecules (IL-17A, IL-17F, IL-22), β-defensin 2 (BD-2), acute phase proteins (CRP, serum amyloid A [SAA], IL-6), and serum collagen turnover biomarkers (N=174; C1M, C3M, C4M, C6M). Using Spearman linear regression and general linear models, pooled changes from baseline (BL) in biomarkers during GUS treatment, correlations between changes in biomarker levels and reductions from BL at three time points (W24, W52, W100) in disease activity (measured by changes in Disease Activity in Psoriatic Arthritis [DAPSA] score, Psoriatic Arthritis Disease Activity Score [PASDAS], Psoriasis Area and Severity Index [PASI] score) were assessed. Associations between biomarker changes and achievement of American College of Rheumatology (ACR)50 response at W100 were also assessed.

Results: Continued treatment with GUS led to significant and sustained reductions in serum cytokines from W24 through W100. Reductions in CRP and IL-6 were associated with changes in DAPSA score, with a similar trend observed for PASDAS. Reductions in BD-2, IL-17A, IL-17F and IL-22 from BL correlated with improvements in the PASI score, and

Table. Correlation of Change in Serum Biomarker Levels With Change in PsA Disease Activity From BL Through 24, 52 or 100 Weeks of GUS Treatment

	DAPSA	PASDAS	PASI

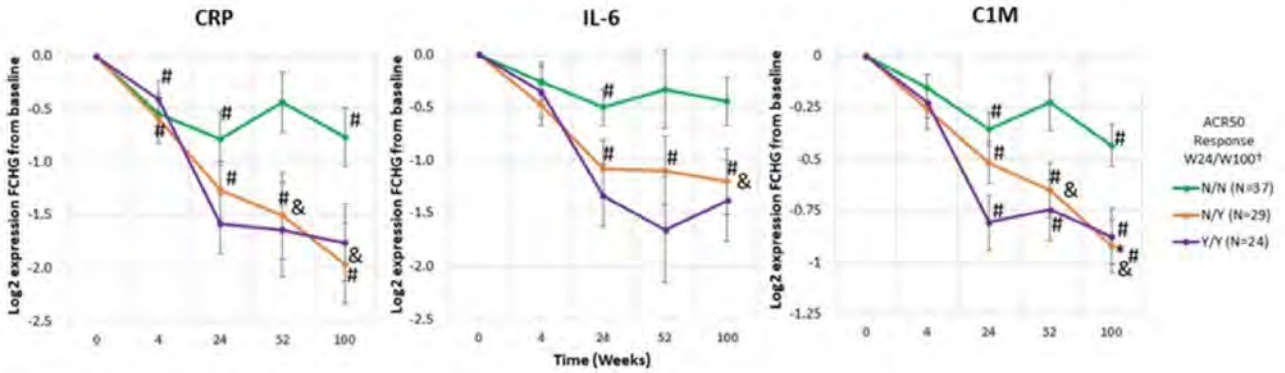
[a]Significant correlation between biomarker expression and disease activity; $r>0.25$ and $P<0.05$.

Figure. Reduction in serum cytokine levels and collagen biomarkers in patients who achieved ACR50 response at W24 and through W100.



Statistics based on general linear model. No apparent differential expression was observed across groups at baseline.
*Indicates statistical significance compared to W24 by $P<0.05$ and |fold difference| ≥1.25.
#Indicates statistical significance compared with baseline by $P<0.05$ and |fold difference| ≥1.4.
&Indicates statistical significance of W24 nonresponder→W100 responder compared with W24 nonresponder→W100 nonresponder by $P<0.05$ and |fold difference| ≥1.4.
†Y/N group was not included in this analysis due to a limited number of subjects.

reductions in collagen turnover biomarkers correlated with changes in the PASDAS (Table). Continued disease improvement with long-term GUS treatment, assessed clinically using ACR50 response, was supported by the further reductions in CRP, SAA, IL-6 and collagen turnover biomarkers in ACR50 responders at W100 who were ACR50 nonresponders at W24 (Figure). Among ACR50 responders at W24, mean reductions in CRP, SAA and IL-6 were sustained through W100.

Conclusion: These results provide molecular evidence that sustained reductions in serum acute phase proteins and collagen turnover biomarkers may contribute to the continuous, durable improvements in joint symptoms and that reductions in Th17-related effector molecules contribute to improvements in skin symptoms seen in PsA pts receiving GUS.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sustained minimal disease activity (MDA) is achieved by a minority of patients (pts) receiving biologics for psoriatic arthritis (PsA). Pt-reported MDA domains are less frequently achieved than physician-reported domains. Here, we assessed MDA achievement in pts with PsA and inadequate response to 1–2 TNF inhibitors (TNFi-IR) to identify PsA disease domains and factors contributing to the lack of MDA achievement at Week (W)48 for TNFi-IR PsA pts treated with guselkumab (GUS) using data from the Phase 3b COSMOS trial.

Methods: In COSMOS, adults with active PsA (swollen/tender joint counts [SJC/TJC] each ≥3) and TNFi-IR were randomized 2:1 to subcutaneous GUS 100 mg or placebo (PBO) at W0, W4, then every 8 weeks. PBO pts crossed over to GUS at W16 (early escape) or W24 (planned). MDA was defined as fulfilment of ≥5/7 domains: tender entheses (Leeds enthesitis

index [LEI]; 0–6) ≤1; Health Assessment Questionnaire-Disability Index (HAQ-DI; 0–3) ≤0.5; pt pain (0–100) ≤15; Psoriasis Area and Severity Index (PASI; 0–72) ≤1; Pt Global Assessment (PtGA; 0–100) ≤20; SJC (0–66) ≤1; and TJC (0–68) ≤1. Primary fibromyalgia (pFM) was defined at baseline (BL) using TJC minus SJC ≥7 as a proxy. A longitudinal trajectory of achieving each MDA domain through W48 was derived (non-responder imputation). Time to achieving each domain was assessed with Kaplan–Meier analyses; to account for differences in scales and domain strictness, scores were also normalized to the SJC (0–66) scale. Response predictors (for pts not meeting each MDA domain criteria at BL) were identified using multivariate regression for time to achievement (Cox proportional hazards) and W48 achievement (logistic) of MDA.

Results: GUS pts (n=189) showed improvement from BL in all MDA domains, with overall W24/48 response rates (%) of: LEI (74.5/79.8), HAQ-DI (26.1/37.0), pt pain (14.7/30.6), PASI (66.8/81.5), PtGA (24.5/39.9), SJC (46.2/63.0), and TJC (14.7/28.3), respectively. Times to achievement of minimal scores for LEI, SJC, and PASI were faster than for PtGA, HAQ-DI, pt pain, and TJC for native-scale scores; when normalized, PtGA, HAQ-DI, and pt pain showed a slower response (Figure 1). Higher BL HAQ-DI and worse fatigue (lower functional assessment of chronic illness therapy [FACIT]-fatigue score) were significantly associated with longer time to HAQ-DI ≤0.5; these factors plus older age predicted W48 non-achievement of HAQ-DI ≤0.5 (Table 1). Worse BL pt pain and fatigue were significant predictors of longer time to pt pain ≤15; these factors plus pFM predicted W48 non-achievement of pt pain ≤15. Worse BL fatigue was also significantly associated with longer time to PtGA ≤20 and W48 non-achievement of PtGA ≤20. Higher TJC, methotrexate (MTX) use, and no

	TJC				0.9 (0.9–1.0)‡

BL, baseline; CI, confidence interval; FACIT, Functional Assessment of Chronic Illness Therapy; pFM, primary fibromyalgia; GUS, guselkumab, HAQ-DI: Health Assessment Questionnaire-Disability Index; HR, hazard ratio; MDA, minimal disease activity; MTX, methotrexate; OR, odds ratio; pt, patient; PtGA, Patient Global Assessment; TJC, tender joint count; W, week
*$P<0.05$; †$P<0.01$; ‡$P<0.001$

pFM at BL were significantly associated with longer time to TJC ≤1; higher BL TJC, MTX use, and older age predicted W48 non-achievement of TJC ≤1.

Conclusion: GUS provided sustainable improvement in all MDA domains through W48. Physician-reported domains (LEI, PASI and SJC) were achieved faster than pt-driven domains (PtGA, HAQ-DI, pt pain, and TJC). BL domain scores, worse fatigue and MTX use (for TJC only) were inversely correlated with MDA in the refractory domains.

Long-Term Safety of Risankizumab in Patients with Psoriatic Disease: Integrated Analysis of Psoriasis and Psoriatic Arthritis Clinical Trial Data

Kenneth Gordon[1], Andrew Blauvelt[2], Herve Bachelez[3], **Laura Coates**[4], Blair Kaplan[5], Willem Koetse[5], Leonidas Drogaris[5], Ranjeeta Sinvhal[5] and Kim A Papp[6], [1]Medical College of Wisconsin, Milwaukee, WI, [2]Oregon Medical Research Center, Portland, OR, [3]APHP Hopital Saint-Louis, Universite de Paris, Paris, France, [4]University of Oxford, Oxford, United Kingdom, [5]AbbVie, Inc., North Chicago, IL, [6]Alliance Clinical Research and Probity Medical Research, Waterloo, and University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Risankizumab, an interleukin-23 inhibitor, was efficacious and well tolerated in plaque psoriasis (PsO) and psoriatic arthritis (PsA) clinical trials.The objective of this integrated data analysis of multiple PsO and PsA clinical trials was to report long-term safety of risankizumab in patients with psoriatic disease.

Methods: Integrated risankizumab safety data sets (data cutoff March 25, 2023) were compiled from 20 phase 1–4 clinical trials in PsO and 4 phase 2–3 trials in PsA. Treatment-emergent adverse events (AEs) and AEs of safety interest were reported for patients receiving ≥1 dose of risankizumab. Exposure adjusted event rates are presented as events per 100 patient years (E/100 PY).

Results: Among 3658 patients with PsO (13,329.3 PY exposure), median (range) of treatment duration was 4.1 years (81 days–8.8 years); among 1542 patients with PsA (3803.0 PY exposure), median (range) treatment duration was 2.8 years (84 days–4.0 years). Rates of treatment-emergent AEs (145.5 events [E]/100PY), serious AEs (7.4 E/100PY), and AEs leading to discontinuation (1.9 E/100PY) in patients with PsO were similar to those in patients with PsA (142.6 E/100PY, 8.6 E/100PY, and 1.8 E/100PY, respectively; **Table**). Similar rates of infections (46.2 and 41.3 E/100 PY) and serious infections (1.2 and 2.0 E/100PY) were reported among PsO and PsA groups, respectively. Nasopharyngitis (12.1

Table. Treatment-Emergent AEs in Patients with Psoriasis and Psoriatic Arthritis

	PsO (n=3658, 13,329.3 PY) E (E/100PY) [95% CI]	PsA (n=1542, 3803.0 PY) E (E/100PY) [95% CI]
AEs	19,390 (145.5) [143.4–147.5]	5423 (142.6) [138.8–146.
Serious AEs	986 (7.4) [6.9–7.9]	327 (8.6) [7.7–9.6]
AEs leading to discontinuation	250 (1.9) [1.7–2.1]	68 (1.8) [1.4–2.3]
Infections	6157 (46.2)	1570 (41.3)

COVID-19	426 (3.2)	306 (8.0)
Herpes zoster	70 (0.5) [0.4–0.7]	12 (0.3) [0.2–0.6]
Serious infections	165 (1.2) [1.1–1.4]	75 (2.0) [1.6–2.5]
Sepsis	15 (0.1)	3 (<0.1)
COVID-19[a]	13 (<0.1)	8 (0.2)
Pneumonia	13 (<0.1)	7 (0.2)
COVID-19 pneumonia	7 (<0.1)	12 (0.3)
Opportunistic infection[b]	11 (<0.1) [0.0–0.2]	3 (<0.1) [0.0–0.2]
Active tuberculosis	1 (<0.1) [0.0–0.04]	0
Fungal infections	319 (2.4) [2.1–2.7]	61 (1.6) [1.2–2.1]
Tinea infections	186 (1.4)	11 (0.3)
Candida	69 (0.5) [0.4–0.7]	17 (0.4) [0.3–0.7]
Malignant tumors	161 (1.2) [1.0–1.4]	39 (1.0) [0.7–1.4]
NMSC	76 (0.6) [0.5–0.7]	19 (0.5) [0.3–0.8]
Malignant tumors excluding NMSC	85 (0.6) [0.5–0.8]	20 (0.5) [0.3–0.8]
Gastrointestinal cancers[c]	23 (0.2) [0.1–0.3]	2 (<0.1) [0.0–0.2]
Breast cancer	13 (<0.1) [0.1–0.2]	3 (<0.1) [0.0–0.2]
Prostate cancer	12 (<0.1) [0.1–0.2]	5 (0.1) [0.0–0.3]
Melanoma	8 (<0.1) [0.0–0.1]	2 (<0.1) [0.0–0.2]
Serious hypersensitivity[d]	10 (<0.1) [0.0–0.1]	3 (<0.1) [0.0–0.2]
Injection site reaction	373 (2.8) [2.5–3.1]	35 (0.9) [0.6–1.3]

AE, adverse event; E, event; NMSC, non-melanoma skin cancer; PsA, psoriatic arthritis; PsO, psoriasis; PY patient-years; TEAEs, treatment-emergent adverse events; URTI, upper respiratory tract infection.
[a]Clinical trial data for patients with psoriasis mostly pre-dated the onset of the COVID-19 pandemic.
[b]Excluding tuberculosis and herpes zoster.
[c]Events for PsO: pancreatic carcinoma (n=5), adenocarcinoma of colon (n=3), colorectal adenocarcinoma (n=2), colorectal cancer (n=2), gastric cancer (n=2), rectal cancer (n=2), anal cancer (n=1), colon cancer metastatic (n=1), colon cancer stage 0 (n=1), intestinal adenocarcinoma (n=1), esophageal carcinoma (n=1), pancreatic carcinoma stage IV (n=1), and rectal adenocarcinoma (n=1); events for PsA: adenocarcinoma of colon (n=1) and colorectal cancer (n=1).
[d]Events for PsO: eczema (n=2), Steven-Johnson syndrome (n=2), urticaria (n=2), angioedema (n=1), drug hypersensitivity (n=1), erythema multiforme (n=1), and hypersensitivity (n=1); events for PsA: anaphylactic reaction (n=1), hypersensitivity (n=1), and immune thrombocytopenia (n=1).

E/100PY), upper respiratory infection (6.4 E/100PY) and COVID-19 (3.2 E/100PY) were the most common infections in PsO and COVID-19 (8.0 E/100PY), nasopharyngitis (5.7 E/100PY) and upper respiratory infection (4.1 E/100PY) were the most common infections in PsA. The most common serious infections were sepsis, COVID-19, and pneumonia in PsO (0.1, < 0.1, and < 0.1 E/100PY, respectively) and COVID-19 pneumonia, COVID-19, and pneumonia in PsA (0.3, 0.2 and 0.2 E/100PY, respectively). Rates of opportunistic infections excluding tuberculosis (both < 0.1 E/100PY) and herpes zoster (0.5 and 0.3 E/100 PY, respectively) were comparable in PsO and PsA. Rates of non-melanoma skin cancer (NMSC) were 0.6 and 0.5 E/100PY and malignant tumors excluding NMSC were 0.6 and 0.5 E/100PY in PsO and PsA, respectively.

Conclusion: Rates of AEs, AEs of safety interest, and AEs leading to discontinuation remained low in this largest and longest safety reporting for risankizumab in patients with psoriatic disease to date. Rates of AEs of safety interest were within reported benchmarks for both PsO and PsA. Rates of COVID-19 infection were as expected. Overall, these results support the safety profile of risankizumab for the long-term treatment of patients with psoriatic disease.

Impact of Upadacitinib on Enthesitis and Dactylitis by Location in Patients with Psoriatic Arthritis and an Inadequate Response to Biologic DMARDs from the SELECT-PsA 2 Trial

Laura Coates[1], Catherine Bakewell[2], Majed Khraishi[3], Shirley Chen[4], Tianming Gao[4], Arathi Setty[4], Heather Jones[5], Sandra Ciecinski[4] and Eduardo Mysler[6], [1]University of Oxford, Oxford, United Kingdom, [2]Intermountain Healthcare Medical Group, Salt Lake City, UT, [3]Memorial University of Newfoundland, St. John's, NL, Canada, [4]AbbVie, Inc., North Chicago, IL, [5]AbbVie, Inc., Mettawa, IL, [6]Organización Medica de Investigación, Buenos Aires, Argentina

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis and dactylitis are associated with reduced quality of life and greater impairment in daily activities. In the SELECT-PsA 2 phase 3 trial, the JAK inhibitor upadacitinib (UPA) demonstrated greater resolution of enthesitis and dactylitis compared to placebo (PBO) in patients with PsA. However, while the sites of enthesitis and dactylitis involvement are highly variable, relatively limited data are available regarding location-specific resolution of these disease manifestations in PsA. In this post hoc analysis, we evaluated site-specific responses of enthesitis and dactylitis to treatment with UPA over 56 weeks in patients with PsA from SELECT-PsA 2.

Methods: In SELECT-PsA 2, patients with an inadequate response or intolerance to ≥1 biologic DMARD (bDMARD-IR) were randomized to receive once daily UPA 15 mg or PBO.[1] Patients initially randomized to PBO were switched to UPA at week 24. Baseline characteristics were evaluated for patients with enthesitis (defined as Leeds Enthesitis Index [LEI] or

SPARCC Enthesitis Index >0) or dactylitis (defined as Leeds Dactylitis Index [LDI] >0). Among patients with baseline involvement, the presence of enthesitis (shoulders, elbows, hips, knees, and heels) and dactylitis (hands, feet, both hands and feet, and either hands or feet) was assessed at baseline, week 24, and week 56 in patients randomized to UPA 15 mg and in those who switched from PBO to UPA 15 mg at week 24.

Results: Of the 423 patients receiving UPA 15 mg (n=211) or PBO (n=212) in SELECT-PsA 2, 344 (81%) had baseline enthesitis or dactylitis. More patients had baseline enthesitis involvement (n=257) than dactylitis (n=87), although subgroups were non-exclusive, and patients could present with both. The mean LEI and LDI scores at baseline were ~3.1 and ~113.2 for patient subgroups with enthesitis and dactylitis, respectively, indicating a relatively high disease burden (**Table 1**). Across all examined locations, treatment with UPA resulted in greater decreases in the proportions of patients with enthesitis or dactylitis compared to PBO at week 24 (**Figure 1**). Notably, all sites of enthesitis or dactylitis involvement demonstrated improvement with UPA, ranging from a 30-percentage point reduction from baseline for heel enthesitis to a 7-percentage point reduction for hip enthesitis, as well as a 51-percentage point reduction in dactylitis of the hands or feet. The proportions of UPA-treated patients with enthesitis or dactylitis continued to decrease from week 24 to week 56. Additionally,

Table 1. Baseline Demographics and Disease Characteristics of Patients With Enthesitis and Dactylitis in SELECT-PsA 2

	Enthesitis[b]		Dactylitis	
Characteristic[a]	PBO to UPA 15 mg QD[c] (n = 84)	UPA 15 mg QD (n = 173)	PBO to UPA 15 mg QD[c] (n = 32)	UPA 15 mg QD (n = 55)

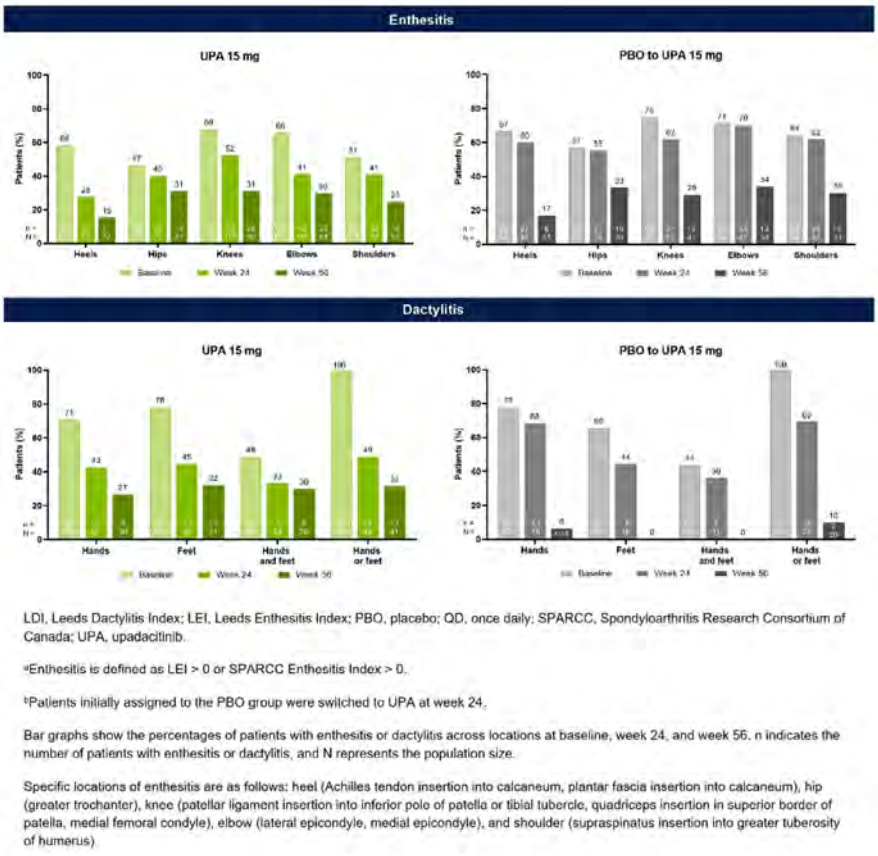
bDMARD, biologic DMARD; BL, baseline; HAQ-DI, Health Assessment Questionnaire-Disability Index; hsCRP, high-sensitivity C-reactive protein; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; NRS, numeric rating scale; PBO, placebo; QD, once daily; SPARCC, Spondyloarthritis Research Consortium of Canada; UPA, upadacitinib.

[a]Baseline characteristics are reported as mean ± SD unless otherwise noted.

[b]Enthesitis is defined as LEI > 0 or SPARCC Enthesitis Index > 0.

[c]Patients initially assigned to the PBO group were switched to UPA at week 24.



LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; PBO, placebo; QD, once daily; SPARCC, Spondyloarthritis Research Consortium of Canada; UPA, upadacitinib.

[a]Enthesitis is defined as LEI > 0 or SPARCC Enthesitis Index > 0.

[b]Patients initially assigned to the PBO group were switched to UPA at week 24.

Bar graphs show the percentages of patients with enthesitis or dactylitis across locations at baseline, week 24, and week 56. n indicates the number of patients with enthesitis or dactylitis, and N represents the population size.

Specific locations of enthesitis are as follows: heel (Achilles tendon insertion into calcaneum, plantar fascia insertion into calcaneum), hip (greater trochanter), knee (patellar ligament insertion into inferior pole of patella or tibial tubercle, quadriceps insertion in superior border of patella, medial femoral condyle), elbow (lateral epicondyle, medial epicondyle), and shoulder (supraspinatus insertion into greater tuberosity of humerus)

Figure 1. Proportions of PsA Patients With Enthesitis or Dactylitis By Site Over Time in SELECT-PsA 2 (As Observed)

patients who switched from PBO to UPA 15 mg at week 24 were able to achieve similar responses as the continuous UPA group by week 56.

Conclusion: UPA treatment was effective in controlling enthesitis and dactylitis at all evaluated locations in bDMARD-IR PsA patients at week 24, including locations where the disease burden may significantly impact quality of life, with continued improvements evident at week 56. However, results should be interpreted with caution given the small sample size for some subgroups, particularly dactylitis.

Session Date: Monday, November 13, 2023

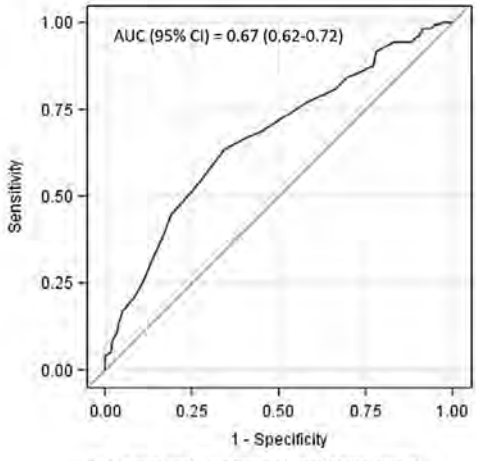
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is commonly reported by PsA patients (pts) and contributes to disease burden. The fully human IL-23p19-subunit inhibitor guselkumab (GUS) induces clinically meaningful and sustained fatigue improvements through 1y, with GUS exhibiting a substantial direct effect on fatigue, independent of its impact on other clinical outcomes[1,2]. We previously showed that early fatigue response predicted clinically meaningful improvement (CMI) in fatigue at 2y[3]. In a sub-population of PsA pts with substantial fatigue at baseline (BL), relationships between early fatigue improvement and disease control at 1y were assessed.

Figure 1. ROC Analysis for Discriminatory Power of FACIT-F Score at W8 Using PASDAS at 1 Year as External Criterion (Representative Example) – 448 Pts Randomized to GUS Q4W & GUS Q8W with BL FACIT-F score ≤43

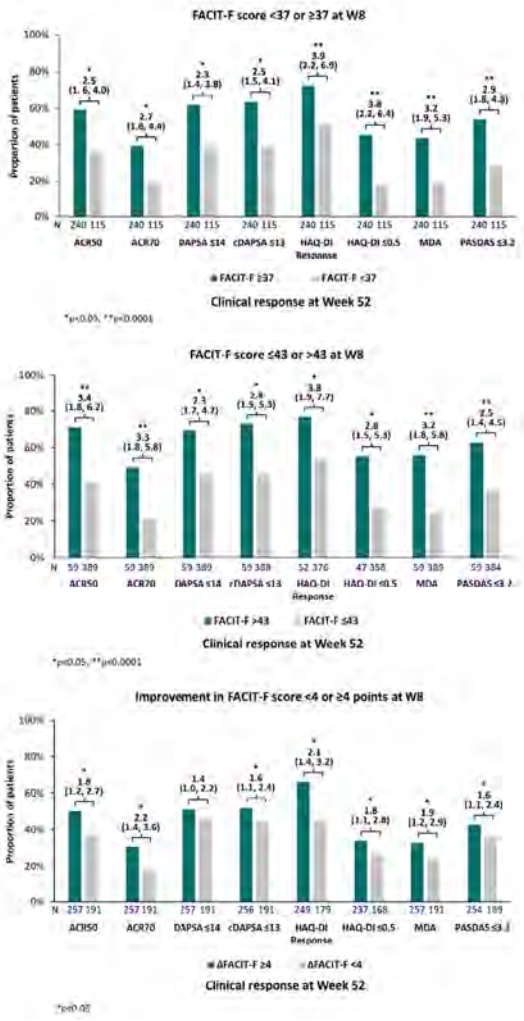


AUC = area under the curve; CI: confidence interval.

Methods: DISCOVER-2 enrolled bionaïve adults with active PsA (≥5 swollen & ≥5 tender joints, CRP ≥0.6 mg/dl). Pts were randomized (1:1:1) to GUS 100mg every 4 weeks (Q4W); GUS 100mg at W0, W4, Q8W; or placebo (PBO). Pts with BL fatigue below normative levels (Functional Assessment of Chronic Illness Therapy – Fatigue [FACIT-F] score ≤43)[3] were included in the analysis. Receiver operating characteristic (ROC) analyses pooling GUS Q4W and Q8W utilized Youden's index to determine optimal FACIT-F cutoffs at W8 (1st post-BL timepoint assessed) for predicting 1y achievement of ACR50/70, Disease Activity (DA) Index for PsA (DAPSA) ≤14 (in pts with BL DAPSA >14), clinical (c) DAPSA ≤13 (in pts with BL cDAPSA >13), PsA DA Score (PASDAS) ≤3.2 (in pts with BL PASDAS >3.2), HAQ-Disability Index (HAQ-DI) response (improvement ≥0.35 in pts with BL HAQ-DI ≥0.35), HAQ-DI ≤0.5 (in pts with BL HAQ-DI >0.5), and MDA. The association of identified and established FACIT-F cutoffs (≥4-point improvement & score >43) with 1y response was assessed via BL-adjusted logistic regression.

Results: In this sub-population of 448/493 GUS-randomized bionaïve PsA pts with BL FACIT-F score ≤43, the mean (SD) BL FACIT-F level of 28.4 (8.7) indicated severe fatigue. ROC analysis **(Figure 1)** identified optimal FACIT-F cutoffs at W8 for predicting 1y disease control with GUS ranging from ≥36 (ACR50, DAPSA≤14, cDAPSA≤13, HAQ-DI≤0.5, PASDAS≤3.2) to ≥41 (HAQ-DI response); intermediary cutoffs were identified for remaining endpoints. The FACIT-F ≥37 cutoff was selected for further analyses as the lowest score (highest fatigue) with a significantly higher probability of achievement with GUS vs PBO (32% vs 24%; p=0.0445).

Figure 2. Early (W8) Achievement of Fatigue (FACIT-F) Targets and 1-Year Clinical Outcomes – 448 Pts Randomized to GUS Q4W & GUS Q8W with BL FACIT-F score ≤43



In pts with BL FACIT-F < 37, W8 FACIT-F ≥37 achievement with GUS associated with significantly higher odds of clinical response at 1y (nominal p< 0.05; odds ratio range: 2.3-3.9) **(Figure 2)**. W8 achievement of normative FACIT-F levels or FACIT-F CMI also associated with significantly greater clinical response rates at 1y.

Conclusion: In this sub-population of bionaïve pts with active PsA enriched for high fatigue levels, early achievement of FACIT-F endpoints with GUS associated with higher rates of clinical response and improved/normalized physical function at 1y. Results of this post hoc analysis further underscore the importance of early improvement in patient-reported outcomes such as fatigue on the trajectory of long-term pt outcome.

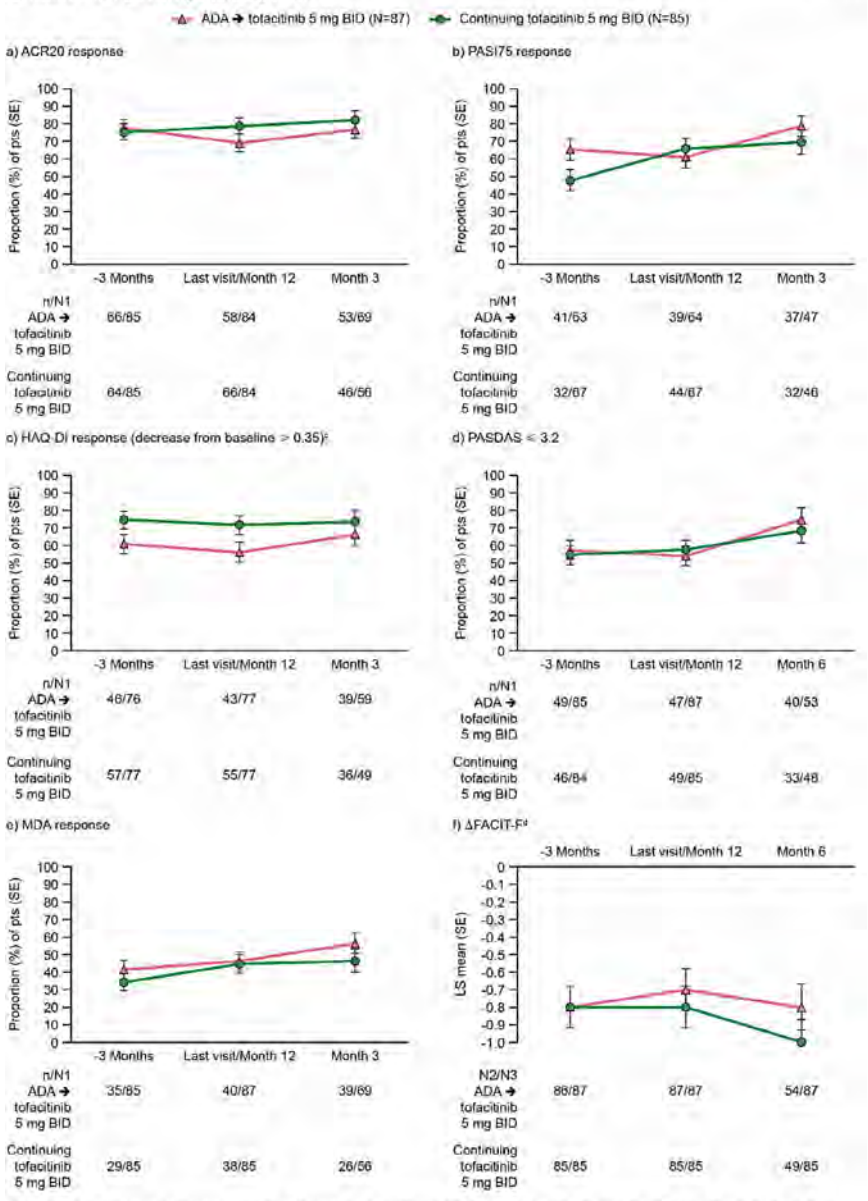
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with PsA and an inadequate response (IR) to conventional synthetic DMARDs are routinely treated with TNF inhibitors (TNFi).[1,2] Intolerance/IR to TNFi may require switching treatments.[1,2] Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. Data on whether treatment can be safely and effectively switched from TNFi



-3 months: 3 months prior to the last visit in the P3 study. Last visit/Month 12: the last visit or Month 12 in the P3 study. Month 3: Month 3 in the LTE study. Month 6: Month 6 in the LTE study

Baseline refers to the baseline visit of the P3 study

The LTE SAS includes pts from the P3 study who had at least one dose of treatment in the LTE study with the 14-day gap rule. The 14-day gap rule was defined as the number of days between a pt's last visit in the P3 study and their first dose of tofacitinib 5 mg BID in the LTE study. Pts who met the 14-day gap rule were excluded

[a]LTE study: NCT01976364 (OPAL Balance)

[b]P3 study: NCT01877668 (OPAL Broaden)

[c]In pts with baseline HAQ-DI ≥ 0.35 (N=77)

[d]Results are based on a repeated measures model with the fixed effects of treatment, visit, treatment by visit interaction, geographic location, and baseline value – an unstructured covariance matrix was used

Total follow-up time calculated up to the day of the first event, subject to a risk period of 28 days beyond the last dose or to the data cut-off date. Gaps in dosing between treatment switches or between the P3 and LTE studies are included up to 28 days or to the data cut-off date

[a]MedDRA (v22.0) coding dictionary applied

[b]P3 study: NCT01877668 (OPAL Broaden)

[c]LTE study: NCT01976364 (OPAL Balance)

ADA, adalimumab; BID, twice daily; CI, confidence interval; IR, incidence rate (pts with events/100 pt-years); LTE, long-term extension; M, Month; MedDRA, Medical Dictionary for Regulatory Activities; N, number of evaluable pts; n, number of pts with events; P, Phase; pt, patient; Q2W, once every 2 weeks; TEAE, treatment-emergent adverse event

to tofacitinib are limited. This post hoc analysis assessed tofacitinib efficacy and safety in pts with PsA in a long-term extension (LTE) study who had received either adalimumab (ADA) or tofacitinib in a Phase (P)3 study.

Methods: Data were analyzed frompts with active PsA who received tofacitinib 5 mg twice daily (BID) or ADA 40 mg once every 2 weeks in aP3 randomized, double-blind, placebo-controlled 12-month study (NCT01877668; OPAL Broaden) and then continued or switched to tofacitinib 5 mg BID and maintained this dose in an open-label LTE study (NCT01976364; OPAL Balance). Efficacy outcomes were assessed 3 months before the last visit and at the last visit/Month (M)12 in the P3 study, and at M3 (or M6 for select outcomes) in the LTE study and included: proportions of pts achieving ACR20, Psoriasis Area and Severity Index 75 (PASI75), HAQ-Disability Index (DI) response (decrease from baseline ≥ 0.35 for pts with baseline HAQ-DI ≥ 0.35), Psoriatic Arthritis Disease Activity Score (PASDAS) ≤ 3.2, minimal disease activity (MDA); and least squares mean change from baseline (Δ) in Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F). Safety outcomes were assessed at 3-month intervals to M12 in both studies and included proportions and incidence rates (pts with events/100 pt-years) for: treatment-emergent adverse events (TEAEs), serious AEs, and serious infections. Data reported as observed.

Results: In this post hoc analysis, 180 pts from the P3 study received tofacitinib 5 mg BID in the LTE study (ADAàtofacitinib 5 mg BID: n=91, 50.6%; continuing tofacitinib 5 mg BID: n=89, 49.4%). Baseline characteristics were generally similar across groups. Approximately half of pts were female (50.6%), with a mean (standard deviation [SD]) age of 47.5 (11.3) years and mean (SD) PsA disease duration of 5.9 (6.2) years. Efficacy was similar between groups 3 months before the last visit and at the last visit in the P3 study and was maintained to M3 (or M6 for PASDAS ≤ 3.2 and ΔFACIT-F) in the LTE study (Fig a–f). TEAEs, serious AEs, and serious infections were similar in the P3 and LTE studies, and between groups within each study (Table 1). The most common TEAEs across both studies were nasopharyngitis and upper respiratory tract infection (Table 2).

Conclusion: Tofacitinib efficacy and safety were similar in pts with PsA who continued or switched to tofacitinib 5 mg BID in the LTE study after receiving tofacitinib 5 mg BID or ADA in the P3 study, respectively. These data suggest that treatment can be directly switched from ADA to tofacitinib 5 mg BID. Limitations include the post hoc nature, small sample size and short time frame analyzed.

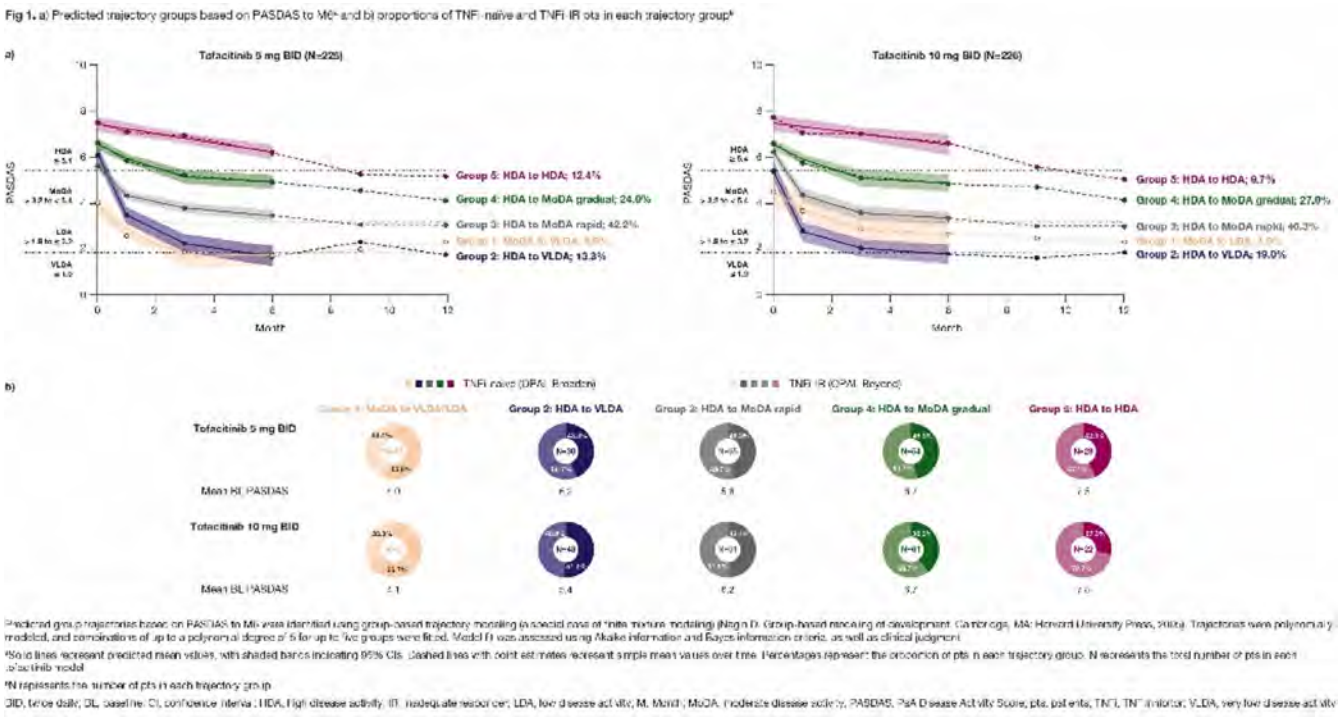
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: PsA is a heterogeneous disease, and identifying clinical phenotypes may assist clinical decision making. Patients (pts) treated with advanced therapies demonstrate varying treatment responses. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. In this post hoc analysis, we aimed to capture these variations by identifying pt groups with distinct disease activity trajectories; comparisons of associated baseline (BL) variables across groups were used to describe clinical phenotypes in pts with PsA treated with tofacitinib.

Methods: Data were pooled from two Phase 3 randomized controlled trials (RCTs) in pts with PsA who were conventional synthetic DMARD-inadequate responders (IR)/TNF inhibitor (TNFi)-naïve (OPAL Broaden; 12 months (M); NCT01877668) or TNFi-IR (OPAL Beyond; 6M; NCT01882439); pts randomized to tofacitinib 5/10 mg twice daily (BID) were included and analyzed separately. PsA Disease Activity Score (PASDAS) to M6 was used in group-based trajectory modeling (a special case of finite mixture modeling) to identify distinct trajectory groups for each tofacitinib dose. Groups were compared by



Predicted group trajectories based on PASDAS to M6 were identified using group-based trajectory modeling (a special case of finite mixture modeling) (Nagin D. Group-based modeling of development. Cambridge, MA: Harvard University Press, 2005). Trajectories were polynomially modeled, and combinations of up to a polynomial degree of 5 for up to five groups were fitted. Model fit was assessed using Akaike information and Bayes information criteria, as well as clinical judgment.

[a]Solid lines represent predicted mean values, with shaded bands indicating 95% CIs. Dashed lines with point estimates represent simple mean values over time. Percentages represent the proportion of pts in each trajectory group. N represents the total number of pts in each tofacitinib model.

[b]N represents the number of pts in each trajectory group.

BID, twice daily; BL, baseline; CI, confidence interval; HDA, high disease activity; IR, inadequate responder; LDA, low disease activity; M, Month; MoDA, moderate disease activity; PASDAS, PsA Disease Activity Score; pts, patients; TNFi, TNF inhibitor; VLDA, very low disease activity

BL characteristics using t-tests (2-sided) or chi-squared tests, applying a Bonferroni correction for pairwise comparisons for each variable. Safety to M6 across groups was assessed descriptively.

Results: From 225/226 pts with PsA who received tofacitinib 5/10 mg BID, respectively, five disease trajectory groups were identified by PASDAS from BL to M6 for each dose separately; resulting models for either dose were of similar shape with the same polynomial degree and clinical interpretation. Groups progressed from moderate disease activity (MoDA) to very low disease activity (VLDA)/LDA (Group 1), high disease activity (HDA) to VLDA (Group 2), HDA to MoDA rapidly/gradually (Groups 3/4), or remained in HDA (Group 5; Fig 1a). In the tofacitinib 10 mg BID model, proportions of TNFi-naïve and TNFi-IR pts were numerically higher in Groups 1 and 4/5, respectively, vs other groups (Fig 1b). Groups 4/5 vs 1/2/3 had

AE, adverse event; BID, twice daily; HDA, high disease activity; LDA, low disease activity; M, Month; MoDA, moderate disease activity; N, number of pts in each trajectory group; n, number of pts with events; PASDAS, PsA Disease Activity Score; pts, patients; SOC, System Organ Class; VLDA, very low disease activity

generally significantly higher BL PsA clinical domain scores, but no significant differences in psoriasis/nail disease scores were seen across groups (Table). In Groups 4 vs 2, which had HDA at BL but distinct responses to M6, significant BL characteristic differences included higher enthesitis scores and tender joint counts (TJC; Table). Across groups, adverse event (AE) rates were generally comparable; most common AEs were infections/infestations (Fig 2).

Conclusion: In pts with PsA treated with tofacitinib, PASDAS response analysis by group-based trajectory modeling identified distinct clinical phenotypes at BL. As expected, higher BL disease burden was associated with poorer responses and differences in BL enthesitis and TJC may impact response to tofacitinib; phenotypes affecting treatment responses were consistent across doses. Trajectory groups showed comparable safety. Limitations included small pt numbers and restricted extrapolation of used RCT data to routine care. Identification of clinical phenotypes may be used to develop personalized treatment algorithms.

Abstract Number: 1427

Efficacy of Upadacitinib in Patients with Psoriatic Arthritis Stratified by Involvement of Weight-bearing Joint Regions: A Post Hoc Subgroup Analysis of the Phase 3, Randomized, SELECT-PsA 1 and SELECT-PsA 2 Trials

Kristi Mizelle[1], William R Tillett[2], Mira Ali[3], Thomas Iyile[3], Tianming Gao[3], Arathi Setty[3], Jessica A Walsh[4] and Laura Coates[5], [1]Tidewater Physicians Multispecialty Group, Newport News, VA, [2]Department of Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [3]AbbVie, Inc., North Chicago, IL, [4]Salt Lake City Veterans Affairs Health and University of Utah Health, Division of Rheumatology, Salt Lake City, UT, [5]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

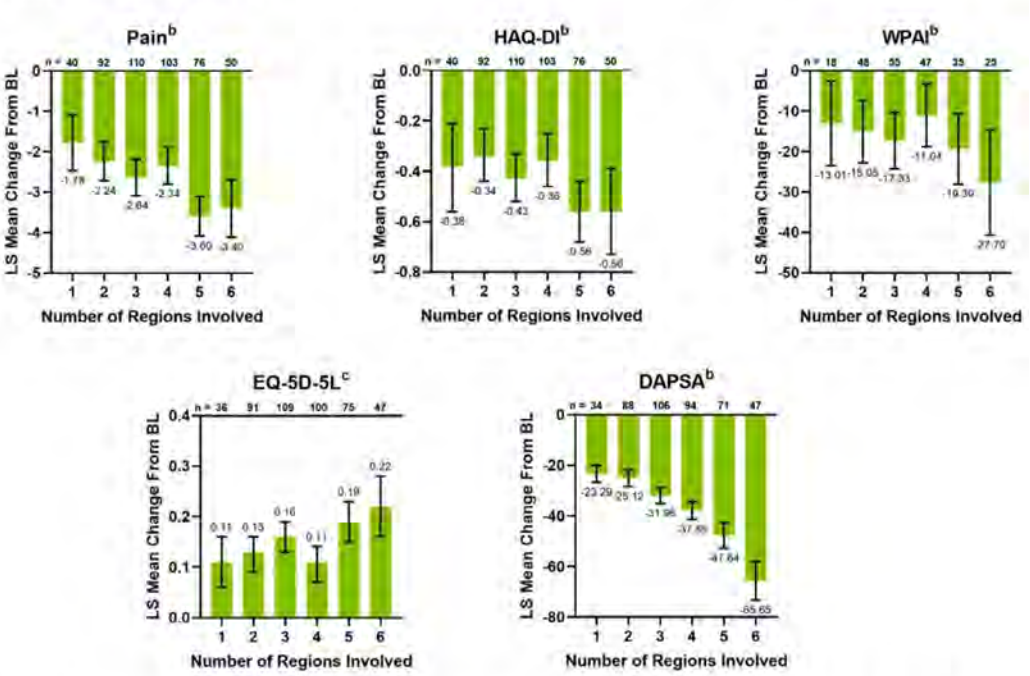
Session Time: 9:00AM–11:00AM

Background/Purpose: Involvement of weight-bearing joints in patients with PsA can be associated with reduced activities of daily living and quality of life. Upadacitinib (UPA) is an oral JAK inhibitor approved for the treatment of active PsA in adults. In the SELECT-PsA 1 and SELECT-PsA 2 trials, treatment with once daily UPA 15 mg (UPA15) or 30 mg (UPA30) resulted in greater improvements in the number of swollen and tender joints as well as other patient- and physician-reported outcomes when compared with placebo.[1–3] The objective of this post hoc analysis was to evaluate the long-term efficacy of UPA in patients with PsA and involvement in 1 or more regions of weight-bearing joints.

Methods: The SELECT-PsA 1 and SELECT-PsA 2 phase 3, randomized, controlled trials enrolled patients ≥ 18 years old with active PsA and intolerance or inadequate response to ≥ 1 nonbiologic disease modifying anti-rheumatic drug (DMARD; SELECT-PsA 1) or biologic DMARD (SELECT-PsA 2). This post hoc analysis of the 2 phase 3 trials stratified patients with involvement in 1 to 6 regions of weight-bearing joints (hips, knees, ankles, midfoot, metatarsophalangeal [MTP], or proximal interphalangeal [PIP]) who were randomized at baseline to receive either UPA15, placebo (PBO), or adalimumab (ADA; only in SELECT-PsA 1); at week 24, PBO-treated patients switched to UPA15 (PBO/UPA15). This analysis did not include patients who received UPA30 or PBO/UPA30. A mixed-effects model with repeated measures was used to analyze the change from baseline to week 104 in 4 patient-reported outcome measures (pain, Health Assessment Questionnaire-Disability Index [HAQ-DI], Work Productivity and Activity Impairment [WPAI] questionnaire, and EuroQol 5 Dimension 5 Level [EQ-5D-5L]) and 1 composite outcome measure (Disease Activity in Psoriatic Arthritis [DAPSA]). UPA safety results in patients with PsA have been previously reported.[1–3]

Results: A total of 1069 patients from the SELECT-PsA 1 trial and 317 patients from the SELECT-PsA 2 trial were included in the pooled analysis. Of all patients with any involvement in regions of weight-bearing joints, > 91% of patients had involvement in ≥ 2 regions. The most common weight-bearing joints with involvement were the PIP (SELECT-PsA 1, 79.8%; SELECT-PsA 2, 84.5%), MTP (71.1%; 73.8%), and knee (62.3%; 64.9%) joints. Improvements from baseline to week 104 were observed with UPA15 treatment in patient-reported outcomes of pain, HAQ-DI, WPAI, EQ-5D-5L, and the DAPSA score across all subgroups of patients with involvement in 1 to 6 regions of weight-bearing joints (**Figure**). In general, the magnitude of improvement in outcome scores with UPA15 was greater in patients with involvement in a higher number of regions. Similar improvements from baseline to week 104 in outcome scores were observed in patients who received PBO/UPA15 or ADA to week 104.

Figure. Mean Change at Week 104 in Outcome Scores Among Subgroups of Patients With Psoriatic Arthritis and Involvement in 1 to 6 Regions of Weight-bearing Joints[a] Treated With UPA 15 mg



[a]Weight-bearing joints include hips, knees, ankles, midfoot, metatarsophalangeal (MTP), or proximal interphalangeal (PIP).
[b]Decrease in score indicates improvement.
[c]Increase in score indicates improvement.
BL, baseline; DAPSA, Disease Activity in Psoriatic Arthritis; EQ-5D-5L, EuroQol 5 Dimension 5 Level; HAQ-DI, Health Assessment Questionnaire-Disability Index; LS, least squares; UPA, upadacitinib; WPAI, Work Productivity and Activity Impairment questionnaire.

Conclusion: UPA15 treatment was associated with long-term improvements in pain, disability, work productivity, disease activity, and quality of life in patients with PsA and involvement in 1 or more regions of weight-bearing joints.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

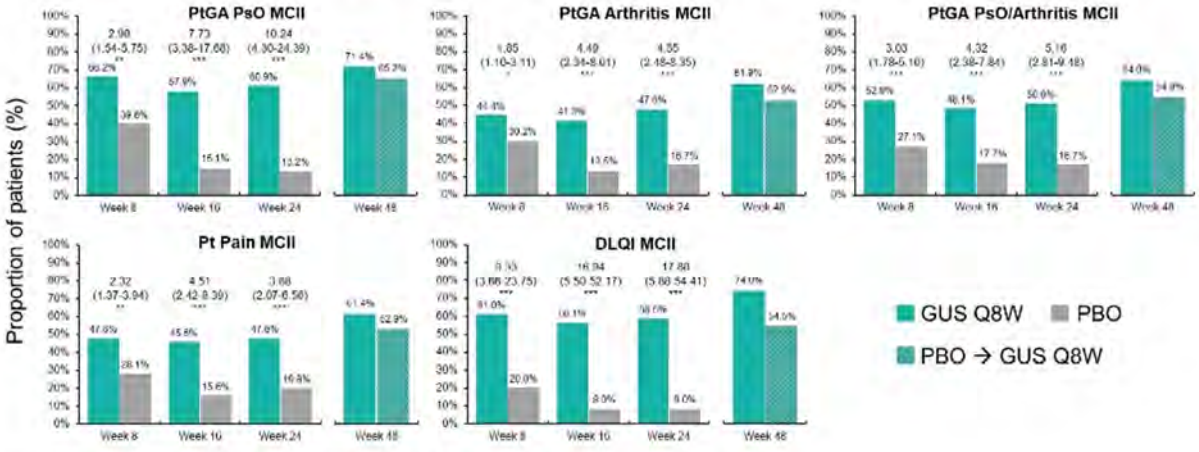
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: In the Phase 3b COSMOS trial, guselkumab (GUS), a fully human IL-23p19 inhibitor (i), was associated with significantly greater improvements vs placebo (PBO) in joint and skin disease at week (W) 24 in patients (pts) with active PsA with inadequate response (IR) to TNFi[1]. Here, we report GUS effect on achievement of clinically important improvements (CII) in patient-reported outcomes (PROs) through W48 of COSMOS.

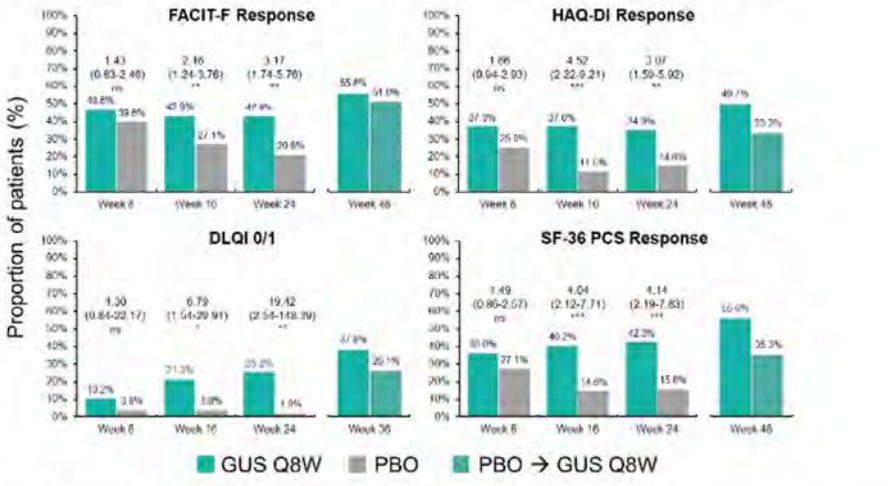
Methods: COSMOS pts had active PsA (≥3 swollen and ≥3 tender joints; SJC/TJC) after discontinuing 1-2 TNFi due to lack of efficacy or intolerance. Pts were randomised (2:1) to GUS 100 mg or PBO at W0, W4, then Q8W through W44. PBO pts crossed over to GUS at W16 (early escape if < 5% improvement in SJC/TJC) or W24. Early response to GUS was assessed

Figure 1. Effect† of GUS Q8W vs. PBO on PRO MCII Achievement (NRI) Through W48‡



ns = p≥0.05; * = p<0.05; ** = p≤0.01; *** = p≤0.0001 vs. PBO.
†Upon adjustment for BL levels, number of prior TNFi, and and concomitant use of conventional synthetic DMARDs.
‡Results for the PBO → GUS group at week 48 are reported for pts without early exit that crossed over to GUS at week 24.
Note: PtGA PsO MCII in pts with BSA ≥3% and IGA ≥2 at BL; DLQI MCII in pts with DLQI score ≥5, BSA ≥3% and IGA ≥2 at BL.
NRI: non-responder imputation.

Figure 2. Effect† of GUS Q8W vs. PBO on PRO Response Achievement (NRI) Through W48‡



ns = p≥0.05; * = p<0.05; ** = p≤0.01; *** = p≤0.0001 vs. PBO.
†Upon adjustment for BL levels, number of prior TNFi, and and concomitant use of conventional synthetic DMARDs.
‡Results for the PBO → GUS group at week 48 are reported for pts without early exit that crossed over to GUS at week 24.
Note: DLQI 0/1 in pts with DLQI score >1, BSA ≥3% and IGA ≥2 at BL.
NRI: non-responder imputation.

with achievement of minimal CII (MCII; 15-point improvements on 0-100 VAS) in Pt Pain, pt global assessment of psoriasis (PtGA PsO), PtGA Arthritis, and PtGA PsO/Arthritis, and Dermatology Life Quality Index (DLQI) MCII (≥5-point-improvement in pts with DLQI ≥5, PsO BSA ≥3% & IGA ≥2 at BL). More rigorous response criteria were used for longer-term pt outcomes: Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F; ≥4-point improvement), Health Assessment Questionnaire Disability Index (HAQ-DI; ≥0.35-point improvement), DLQI 0/1 (in pts with DLQI >1, PsO BSA ≥3%, and IGA ≥2 at BL), and 36-item Short-Form Health Survey physical component summary score (SF-36 PCS; ≥5-point improvement). GUS vs PBO were compared with logistic regression adjusting for BL levels, number of prior TNFi, and concomitant use of conventional synthetic DMARDs. Non-responder imputation (NRI) was used for missing data and pts meeting treatment failure criteria.

Results: The post hoc analysis included 285 randomized pts (GUS Q8W: n=189; PBO: n=96). Mean (SD) BL DLQI (13.1 [7.0]), PtGA PsO (60.9 [23.9]), PtGA Arthritis (64.2 [17.5]), PtGA PsO/Arthritis (66.6 [17.9], Pt Pain (63.2 [18.6]), FACIT-F (29.2 [11.0]), and SF-36 PCS (33.3 [7.3]) scores indicated active disease and impaired health-related quality of life (QoL). GUS treatment was associated with higher rates of PRO endpoint achievement compared with PBO at W8, W16, and W24, as evidenced by significantly greater odds of achieving MCII in PtGA PsO (odds ratio range across timepoints [ORs]: 3.0-10.2), PtGA Arthritis (ORs: 1.8-4.5), PtGA PsO/Arthritis (ORs: 3.0-5.2), Pt Pain (ORs: 2.3-4.5), and DLQI (ORs: 10.4-15.5) as of W8 (**Figure 1**), as well as responses in FACIT-F (ORs: 1.7-3.0), HAQ-DI (ORs: 2.2-2.8), DLQI 0/1 (ORs: 10.6-24.7), and SF-36 PCS (ORs: 1.3-2.9) through W24 (**Figure 2**). Further increases in response rates (NRI) were seen through W48 of GUS, with consistent patterns following crossover from PBO to GUS.

Conclusion: In PsA pts with TNFi-IR, GUS was associated with rapid effect for achievement of MCIIs and sustained achievement of more rigorous response criteria across PROs, including patient-reported skin and joint symptoms, pain, fatigue, functional status, and skin-specific and physical function-related QoL, with increasing response rates from W24 to W48.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: PsA-5Ts is a simple multidimensional composite measure, assessing pain, fatigue, physical function, skin problems, and depression, recently developed to measure overall health in PsA patients (pts) and correlate with established composite measures[1]. We assessed the longitudinal construct validity of the PsA-5Ts domains (PsA-5T-Ds) using data from three Phase 3 trials of the fully human IL-23p19-subunit inhibitor guselkumab (GUS), and evaluated the GUS effect on PsA-5T-Ds through week (W)24.

Methods: Pts in DISCOVER 1&2 (D1/D2; n=1120 ~90% bionaive) and COSMOS (n=285; inadequate response to 1 or 2 TNFi) had active PsA and were randomized to GUS 100 mg every 4 W (Q4W; D1/D2 only); GUS 100 mg at W0, W4, Q8W; or placebo (PBO). A PsA-5T-Ds score (range 0-100) was calculated[1] based on the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F) scale, Health Assessment Questionnaire Disability Index (HAQ-DI), and question 28 ('*Have you felt downhearted and depressed*') of the 36-Item Short Form Survey (SF-36) to assess fatigue, physical function, and

Figure 1. Correlation of Changes from BL in PsA-5T-Ds Score and PASDAS Through W24 of DISCOVER-1, DISCOVER-2, and COSMOS (N=1405 Pts)

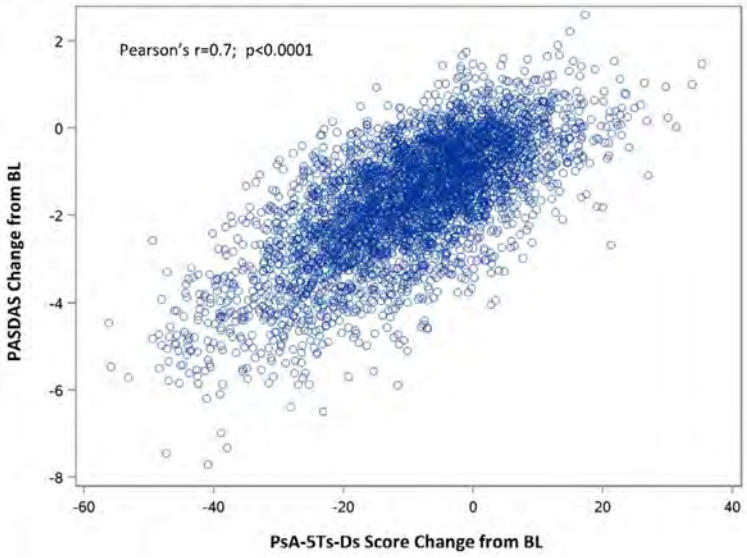

Figure 2. Effect† of GUS vs. PBO on PsA-5T-Ds Score Through W24 of DISCOVER-1, DISCOVER-2, and COSMOS

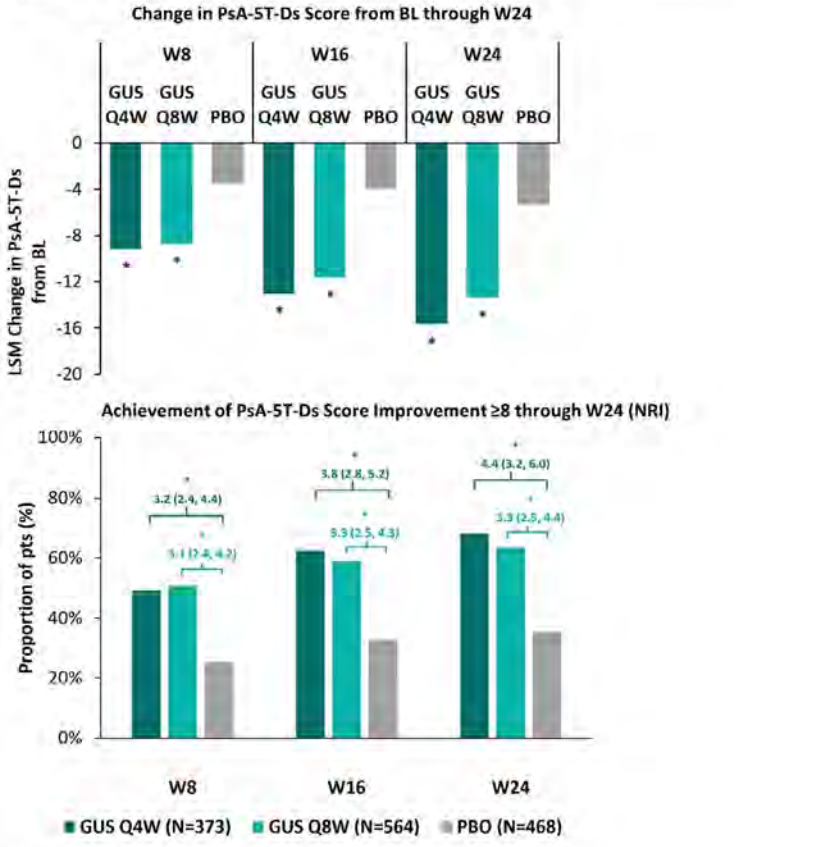

*p<0.0001 vs. PBO. LSM=least squares mean.

†Upon adjustment for BL PsA-5T-Ds score, age, sex, BL body mass index, prior TNFi use, and concomitant use of conventional synthetic DMARDs at BL.

NRI: non-responder imputation.

depression, respectively, after 0-10 transformation; pt pain and skin disease activity were assessed with native 0-10 visual analogue scales. Correlation of change in PsA-5T-Ds score with changes in PsA disease activity (DA) Score (PASDAS), DA Index for PsA (DAPSA), clinical (c) DAPSA, and SF-36 physical component summary score (PCS) was assessed with Pearson's coefficient. Known-groups validity was assessed with mixed models for repeated measures (MMRM) using change in PsA-5T-Ds score as dependent variable; clinically meaningful improvements (CMI) in PASDAS ($\Delta \leq -0.8$), DAPSA ($\Delta \leq -7.25$), cDAPSA ($\Delta \leq -5.7$), and SF-36 PCS ($\Delta \geq 5$) as independent variables; and age, sex, treatment, and BL PsA-5T-Ds score as covariates. GUS' effect on PsA-5T-Ds score change and CMI achievement was assessed with multivariate MMRM and logistic regression, respectively.

Results: Changes in PsA-5T-Ds score through W24 correlated strongly with variations in PASDAS ($r=0.7$; $p< 0.0001$) **(Figure 1)** and moderately with variations in DAPSA, cDAPSA, and SF-36 PCS ($r=0.5$; all $p< 0.0001$). CMI achievement in PASDAS, DAPSA, cDAPSA, and SF-36 PCS through W24 associated with significantly greater improvements in PsA-5T-Ds score vs non-achievement; corresponding time-weighted least square means (95% CI) differences of -7.9 (-8.5 to -7.3), -7.3 (-7.9 to -6.6), -7.2 (-7.9 to -6.6), and -5.9 (-6.5 to -5.4), respectively, suggested a cutoff of ≥8 points for CMI in PsA-5T-Ds score. Upon adjusting for potential confounders, treatment with GUS Q4W or Q8W associated with significantly greater PsA-5T-Ds improvements through W24 and higher odds of achieving PsA-5T-Ds CMI vs PBO, starting at the first timepoint assessed **(Figure 2)**.

Conclusion: In our first assessment of the PsA-5T-Ds longitudinal construct validity, we observed a strong correlation with PASDAS, which encompasses most core PsA domains, and good ability to discriminate between pts with and without CMI. GUS treatment was associated with greater improvements and higher rates of CMI achievement than PBO, supporting the established GUS efficacy across key PsA domains.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory cytokines can alter the way the central nervous system processes pain as shown in patients with rheumatoid arthritis. However, the relationship between TNFα inhibition and pain processing in individuals with psoriatic arthritis (PsA) has not been investigated.

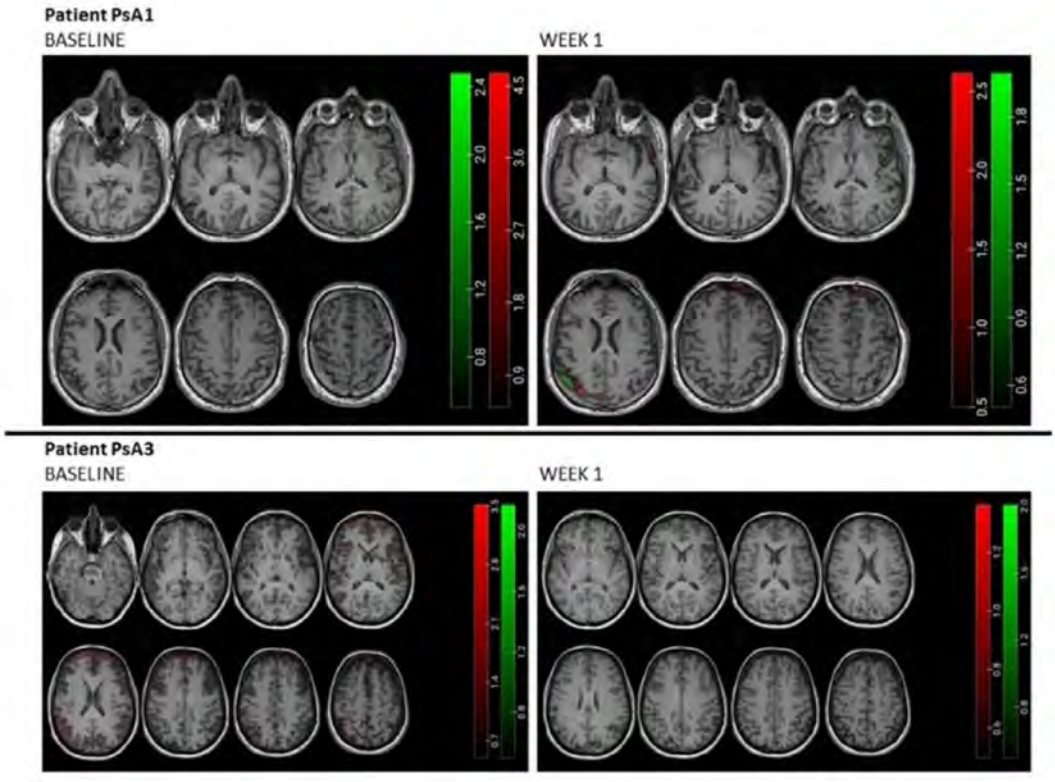

Figure 1. Brain fMRI response to pressure of the non-affected joint (green) and the affected joint (red) overlaid on top of the structural image. Upper panel corresponds to a patient with clinical improvement (PsA1) and lower panel to a patient that did not respond (PsA3) at baseline (left column) and week 1 (right column). Differences are observed in the sensorimotor cortex activation between patients: there is an increase in the activation after week 1 in PsA1 while PsA3 showed activation at baseline but not in week 1.

Table 1. All subject's demographic characteristics ans PsA patients' clinical response

VASp change (Δmm)					-14	-21	-5	0	-51	-7

HS: healthy subject; PsA: psoriatic arthritis patient; F: female; M: male; BMI: body mass index; TJC: tender joint count; SJC: swollen joint count; CRP: C-reactive protein; TNFi: TNF inhibitor; DAPSA: Disease Activity in Psoriatic Arthritis; VASp: visual analogue scale pain

The purpose of this study is to assess the feasibility of functional magnetic resonance imaging (fMRI) paradigm to estimate the respone to pain and the effect of treatment in PsA patients.

Methods: 6 patients with active PsA eligible to start a TNF inhibitor (TNFi) were included: 3 were naïve to biological disease modifying anti-rheumatic drugs and 3 were experienced. Four healthy subjects (HS) were also included. The physician selected a swollen and tender joint (affected joint) and a control joint in the contralateral hand (non-affected joint). Subjects were scanned in a 3.0T scanner at baseline (BL) and week 1 (W1) after starting treatment. First, the brain pain response was investigated pressing the non-affected joint followed by the affected joint. Each acquisition included 2 fMRI runs. The fMRI effect of pressure was represented for each subject individually, for each time point ($p< 0.0001$ uncorrected level, minimum extension 10 voxels). We provided a descriptive analysis of the differences in PsA patients brain response between BL and W1 and the clinical response evaluated by the percentage of improvement of Disease Activity in Psoriatic Arthritis (DAPSA) score and visual analogue scale pain (VASp) change.

Results: All subject's demographic characteristics and PsA patients' clinical response are shown in Table 1. Brain response to pressure in HS produced activation in the sensory motor cortex, with more or less involvement of additional areas in the prefrontal, parietal and temporal cortex. In PsA patients with a higher treatment response (PsA 1, 2, 5), the brain response to pressure did not show any activation at BL whilst sensory motor cortex activation was seen at W1, with amygdala and insula activation in patients PsA 2 and 5 and prefrontal and frontal activity in patients PsA 1 and 2. In those with less response (PsA 3, 4, 6), the sensory motor cortex was activated at BL with little changes when evaluated at W1 (Fig. 1). No evident differences in brain response activation were observed between naïve and TNFi experienced patients.

Conclusion: The proposed fMRI paradigm seems to be a promising candidate to predict response to treatment with TNFi in PsA patients. Studies with more patients are needed to confirm our preliminary results.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Izokibep is a novel small protein IL-17A inhibitor, unique for its high IL-17A binding affinity, a small size at 18.6 kD and albumin binding site enabling access in inflamed tissues and two-week half-life. IL-17A is key in psoriatic arthritis (PsA) pathogenesis and its inhibition is known to improve quality of life. Here, we report results of izokibep treatment to week 46 on patient-reported outcomes (PROs), following a 16-week placebo-controlled period[1]. PRO endpoints include PsAID-9, HAQ-DI, TSQM-9, and patient reported pain, itch, and global disease activity.

Methods: Izokibep doses of 80 mg Q2W or 40 mg Q2W were evaluated to 46 weeks or study termination. The original placebo arm continued to 16 weeks, then switched to 80 mg Q2W in a multicenter trial (NCT04713072). This study was terminated once 16-week results were available to continue to explore the effective dose range in a next P2b/3 trial. The results include as observed analysis evaluating change from baseline to weeks 16, 32 and 46. Patients met CASPAR criteria and had ≥3 swollen (SJC) and ≥3 tender joints (TJC) on a 66/68 joint count and inadequate response to previous NSAIDs, csDMARDs, or TNF inhibitor therapy.

Results: 135 patients were randomized 1:1:1 to izokibep 40 mg, 80 mg or placebo to week 16 when placebo transitioned to 80 mg Q2W. Patients had a mean age of 49 (SD 12) years, a mean BMI of 29 (5) kg/m^2, a mean PsA disease duration of 7 (8) years, a mean SJC of 10 (7) and TJC of 17 (10). At week 32, 96 of 102 eligible patients had evaluable data and at week 46, 59 of 62 eligible patients had evaluable data with similar distribution across groups. Clinically important improvements were evident for pain, patient global disease activity, itch, PsAID-9, treatment satisfaction on the TSQM-9 for those starting on 80 mg at baseline as well as those switching to 80 mg at week 16. The 80 mg dose showed improvements from week 16 to 46, whereas the 40 mg dose was largely stable (Figure 1). Consistent improvements across all PsAID-9 subdomains were evident for the 80 mg doses at week 32 and week 46 (Figure 2). Pain responders, defined as achieving patient reported pain < 30/100, improved from weeks 16 to 32 and 46 for those starting with 80 mg and those switching to 80 mg at week 16 while the 40 mg dose remained largely stable (Figure 3). From week 16 to week 46, the most frequently reported adverse events were injection site reactions, injection site erythema and nasopharyngitis which were distributed similarly across groups. One patient dropped out for ISR over this interval. There were no dose-related infection risks.

Conclusion: Izokibep led to continuing improvements across all PROs from baseline to weeks 16, 32 and 46 with greater improvements in the 80 mg dose groups. The GRAPPA validated PsAID-9 showed clinically important improvements in patient reported quality of life across all subdomains over weeks 16, 32 and 46. More than 70% of patients achieved marked pain control. Izokibep was generally well tolerated with no new safety issues to week 46.

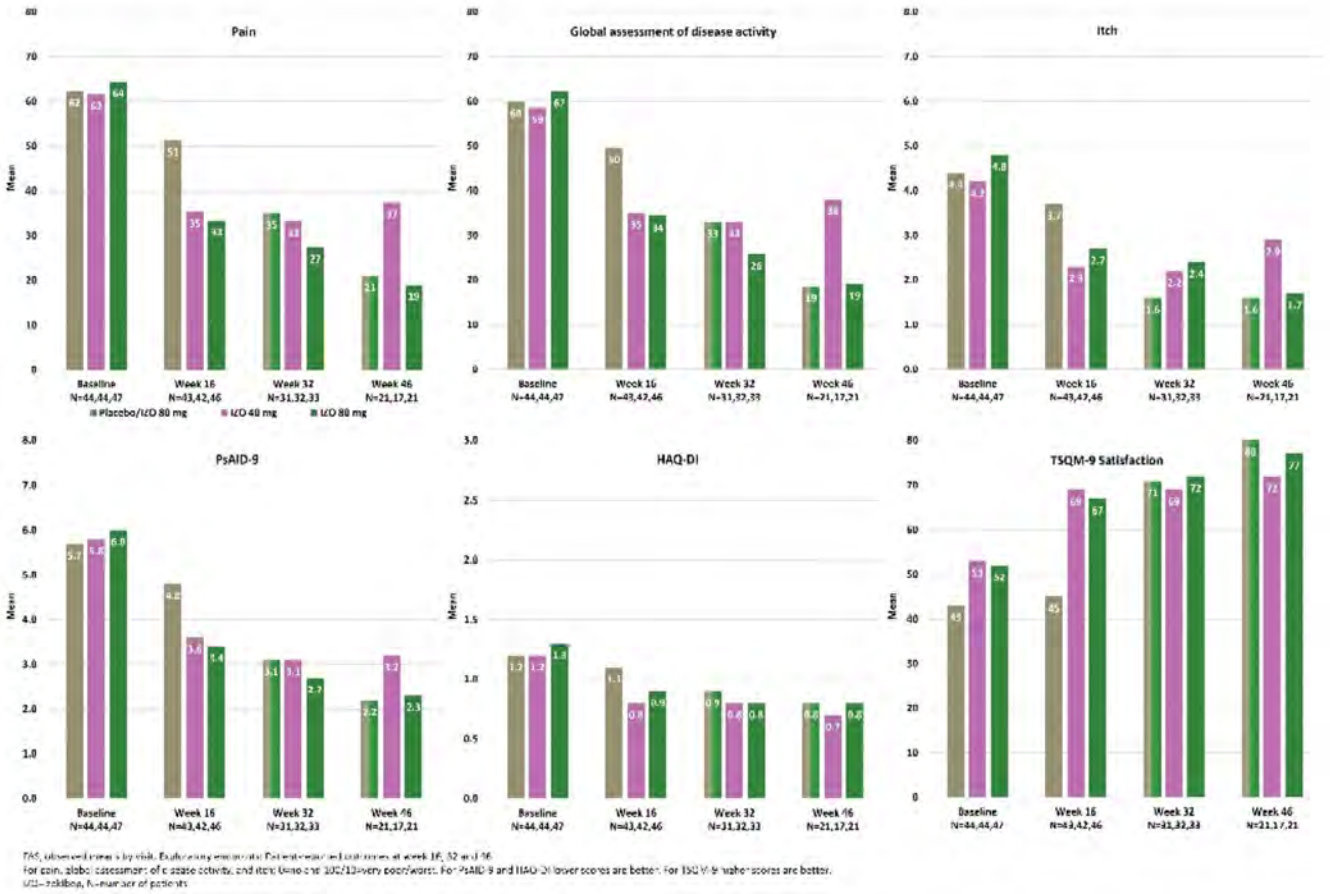

Figure 1. Continued Improvements in Multiple Patient-Reported Outcomes from Baseline to Weeks 16, 32 and 46

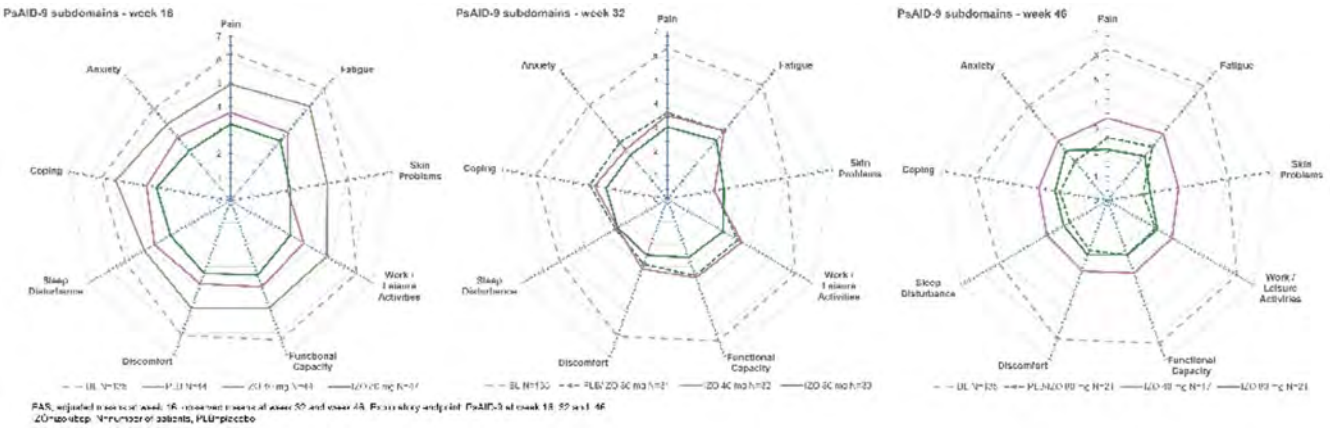

Figure 2. Continued Improvement in the GRAPPA Validated PsAID Quality of Life Index over Weeks 16, 32, 46

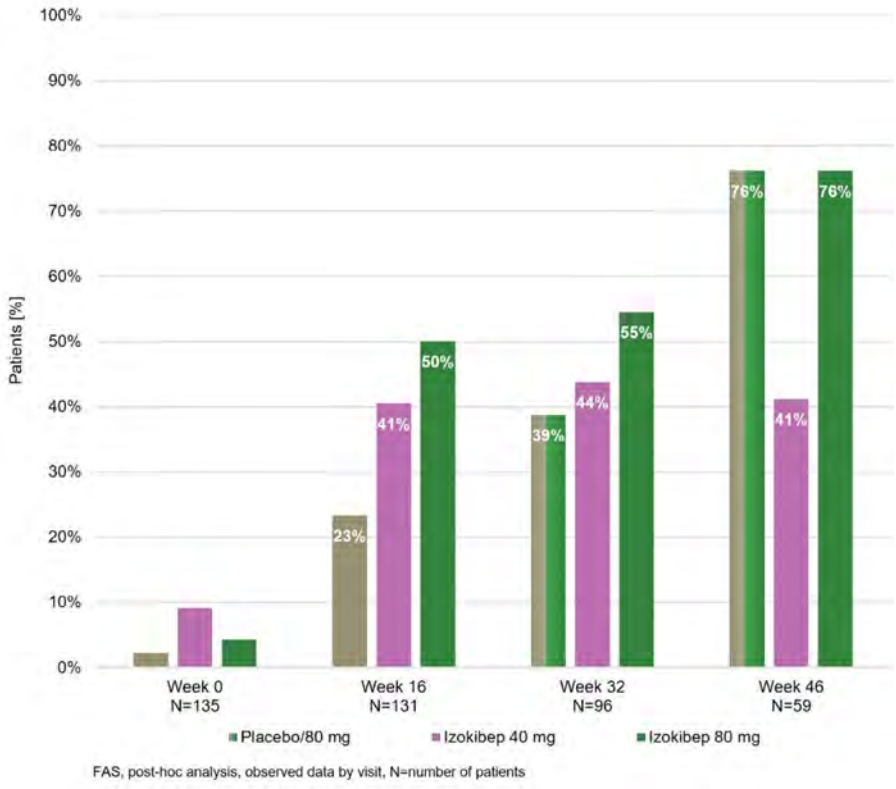

Figure 3. Patient Reported Pain Responders with Pain <30/100 at Weeks 16, 32 and 46

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Dietary Interventions in psoriatic arthritis (DIPSA) is a randomized controlled trial (RCT) assessing the efficacy of dietary modifications in patients with psoriatic arthritis (PsA). Ideally, the design of an adjunct therapy trial and the intervention itself should engage patients in a positive experience. We aimed to describe patients' experience participating in a dietary RCT in a rheumatology setting.

Methods: DIPSA (NCT04180904) compares the efficacy of the Mediterranean diet and DASH-low caloric diet as adjunct therapy to the standard of care in PsA. Patients with moderately active PsA (DAPSA > 10) who were overweight or obese (BMI 25-40) were enrolled into the trial for 24 weeks. The trial design is shown in **Figure 1**. At the end of the trial, participants underwent a semi-structured interview regarding their participation including challenges faced, positive aspects of the trial, and recommendations for a future intervention and/or trial. Interviews lasted 20-30 min and were carried out by trained research coordinators. The interviews of first 50 participants who completed the trial (out of intended 90) were analyzed using modified grounded theory by two research coordinators with input from the two PIs.

Results: The mean age of the participants was 54.8 years (SD 12.3 years) and 66% were females. Key themes identified included the benefit of increased wellness from healthy diet, structured intervention, support from dietitian and other staff, self-awareness, barriers to dietary changes, and other lifestyle changes (Figure 2). The themes, subthemes and a few representative quotes are included in **Table 1**. Patients found advice regarding healthy eating habits, setting personal goals, incorporating or avoiding particular food items in the diet to be beneficial for their overall health and well-being. However, most wished for a well-organized and structured diet in the form of recipes, menus, or a booklet. Support from the staff, phone calls from a dietitian and daily text messages motivated participants to adhere to the diet. Participants became more cognizant of the effect of diet on their pain and arthritis which led to higher confidence in controlling pain through dietary modification. Our study identified some important barriers to dietary change in PsA. Psychological barriers included reluctance to change the diet because of taste and habit, and difficulty adhering during times of stress and fatigue. Social issues arose when eating out, traveling or dining with others. Other barriers to healthy eating were related to time constraints and affordability. Finally, participants expressed a desire to continue beneficial dietary changes as well as to commit to other healthy lifestyle choices, e.g., increased physical activity, mindfulness and meditation.

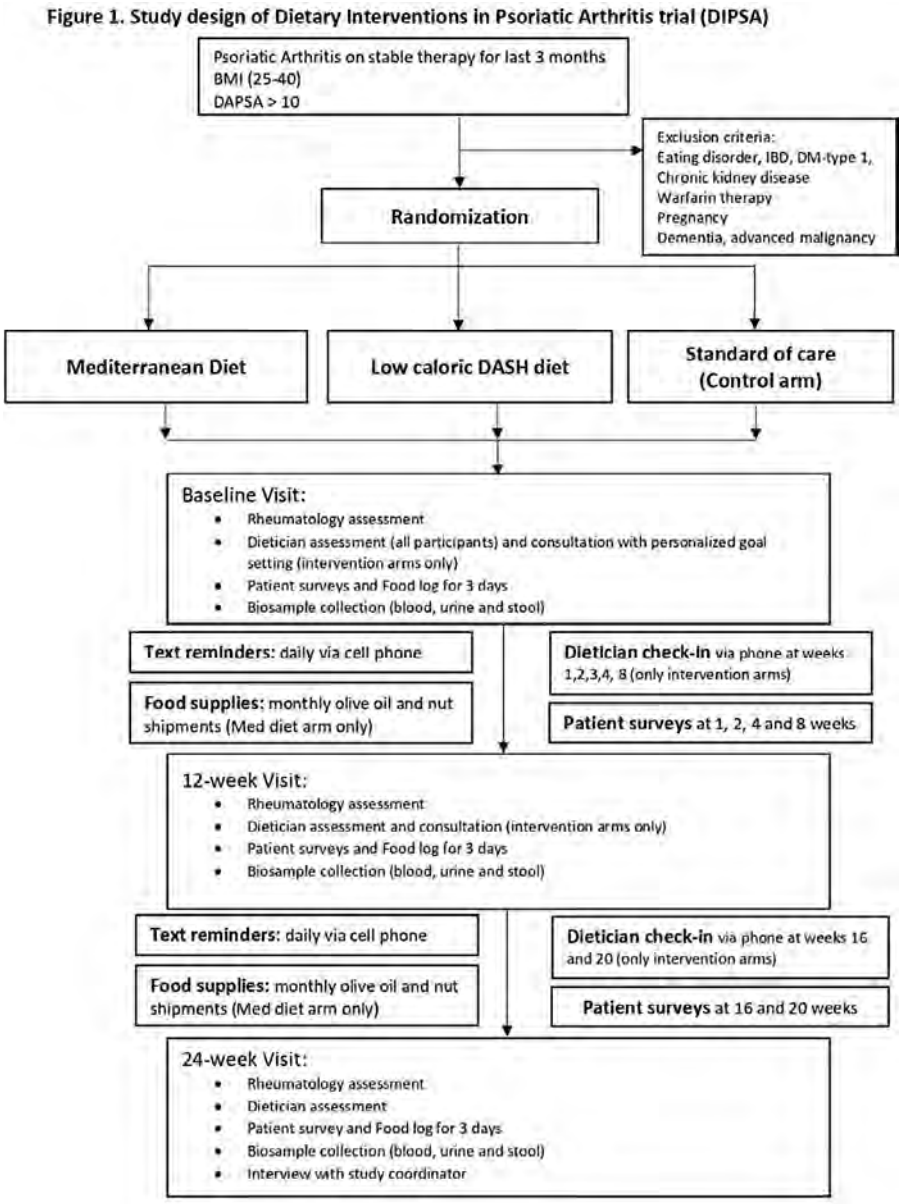

Figure 1: DIPSA study design and procedures

Conclusion: Patients with PsA found the DIPSA interventions to be feasible and valuable. Support from a multidisciplinary team, especially dietitian advice, was deemed crucial. Psychosocial barriers, cost and time constraints prevent patients from implementing healthy dietary changes. Finally, focusing on dietary change had carryover, helping patients to make healthy choices in other aspects of life.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The Group for Research and Assessment of Psoriasis and PsA (GRAPPA) domain-based treatment recommendations for PsA focus on six key domains: peripheral arthritis, axial disease, enthesitis, dactylitis, skin psoriasis, and nail psoriasis, and PsA-related conditions: uveitis and IBD.[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has demonstrated superior clinical efficacy vs placebo (PBO) to Week (Wk) 16 in phase 3 clinical trials of patients (pts) with PsA.[2,3] In pts with psoriasis, superior skin domain efficacy has been demonstrated versus secukinumab (IL-17A inhibitor), ustekinumab (IL-12/23 inhibitor), and adalimumab (TNF-α inhibitor [TNFi]).[4–6] The objective of this analysis is to show BKZ efficacy across GRAPPA core domains to Wk 52 from two phase 3 trials in PsA, with axial domain outcomes from two phase 3 trials in axial spondyloarthritis (axSpA).

Methods: Included pts were randomized to receive subcutaneous BKZ 160 mg or PBO every 4 wks (Q4W) in BE OPTIMAL (NCT03895203; biologic DMARD-naïve pts with PsA), BE COMPLETE (NCT03896581; pts with PsA who were TNFi-inadequate responders [TNFi-IR]), BE MOBILE 1 (NCT03928704; non-radiographic axSpA) and BE MOBILE 2 (NCT03928743; radiographic axSpA, i.e. ankylosing spondylitis). BE OPTIMAL included a reference arm (adalimumab 40 mg Q2W) to Wk 52; data not shown.[2,3,7] From Wk 16, all PBO-randomized pts received BKZ 160 mg Q4W to Wk 52 (PBO/BKZ). Wk 16 completers from BE COMPLETE were eligible to enter BE VITAL (NCT04009499; open-label extension). Outcomes are reported by GRAPPA domain (**Table 1**). Missing data are imputed using non-responder and multiple imputation (NRI; MI) for binary and continuous outcomes, or reported using observed case (OC).

Results: Wk 52 completion was high (BE OPTIMAL: 770/852 [90.4%], BE COMPLETE: 347/400 [86.8%], BE MOBILE 1: 220/254 [86.6%], BE MOBILE 2: 298/332 [89.8%]). Baseline demographics and disease characteristics were previously reported.[2,3,7] Across all GRAPPA domains, improvements from Wk 16 were sustained at Wk 52 in BKZ-treated pts across

Figure. GRAPPA individual domain response and change from baseline at Week 52 from BE OPTIMAL (bDMARD-naïve), BE COMPLETE (TNFi-IR), BE MOBILE 1 (nr-axSpA) and BE MOBILE 2 (r-axSpA) [NRI, MI]

all studies (**Table 2**). Individual domain responses were generally consistent between bDMARD-naïve and TNFi-IR pts (**Figure**). Results from BE MOBILE 1 and 2 demonstrated BKZ efficacy in pts with axSpA (**Table 2**, **Figure**) and were suggestive of efficacy for axial disease in PsA.[1] Responses were generally consistent between BKZ and PBO/BKZ pts at Wk 52 (**Figure**). To Wk 52, there were no instances of uveitis (BE OPTIMAL; BE COMPLETE). 2 (0.2%) pts in BE OPTIMAL had definite adjudicated IBD; no pts had adjudicated IBD in BE COMPLETE.

Conclusion: Treatment with BKZ resulted in robust and sustained improvements across GRAPPA domains with low rates of IBD and no uveitis to Wk 52 for both bDMARD-naïve and TNFi-IR pts with PsA; results from pts with axSpA support efficacy in the axial domain.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: PsA is a chronic systemic inflammatory disease that affects 30% of patients diagnosed with psoriasis, with a clinical burden that includes dactylitis, enthesitis, cutaneous manifestations, chronic pain, progressive joint damage, and disability. Risankizumab (RZB), an antibody that targets the p19 subunit of interleukin-23 with high affinity and specificity, is approved for the treatment of adult patients with active PsA. RZB has been previously reported to show efficacy across several disease domains up to week 100.[1] Here, we report the efficacy and safety results through week 148.

Table 1. Efficacy Results for KEEPsAKE 2 at Week 52, Week 100 and Week 148

Resolution of dactylitis, % (n/N)[a,e]	67.5 (27/40)	70.9 (40/57)	77.5 (31/40)	68.4 (39/57)	82.5 (33/40)	61.4 (35/57)

All changes are least square mean changes from baseline.

[a]Results for binary endpoints are based on as-observed (AO) data with missing data imputed as non-responder imputation incorporating multiple imputation (NRI-MI) if there are missing data due to COVID-19.

[b]Results for continuous endpoints are reported by mixed-effect model repeated measurement (MMRM).

[c]Reported for patients with ≥ 3% of body surface area (BSA) affected by psoriasis at baseline (RZB, N=123; PBO/RZB, N=119).

[d]Defined as Leeds Enthesitis Index (LEI)=0 and reported among patients with LEI >0 at baseline (RZB, N=147; PBO/RZB, N=158).

[e]Defined as Leeds Dactylitis Index (LDI)=0 and reported among patients with LDI>0 at baseline (RZB, N=40; PBO/RZB, N=57).

[i]Number of unique patients contributing to MMRM model estimates: patients with at least one available change from baseline value and no missing data for the factors and covariates in the model. The MMRM N is not visit-specific and is displayed for model estimates for all visits. For change in HAQ-DI (RZB, N=224; PBO/RZB, N=215); for change in FACIT-Fatigue score and change in SF-36 PCS score (RZB, N=223; PBO/RZB, N=213).

ACR20/50/70, ≥20/50/70% improvement in American College of Rheumatology score; BSA, body surface area; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue Questionnaire; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; LS, least square; MDA, minimal disease activity; PASI 90, ≥90% reduction in Psoriasis Area and Severity Index; PBO, placebo; RZB, risankizumab; SF-36 PCS, 36-Item Short Form Health Survey Physical Component Summary.

Methods: KEEPsAKE 2 is an ongoing phase 3 global, multicenter clinical trial evaluating the efficacy and safety of RZB versus placebo (PBO) in patients with active PsA,defined as ≥5 tender joints and ≥5 swollen joints, meeting the Classification Criteria for Psoriatic Arthritis (CASPAR), with symptom onset of ≥6 months before screening, and active plaque psoriasis or nail changes consistent with psoriasis at screening. Eligible patients were 18 years or older and had previous inadequate response or intolerance to 1 or 2 biological therapies (Bio-IR) and/or ≥1 conventional synthetic DMARD (csDMARD-IR). Patients were randomized in a 1:1 ratio to receive double-blinded treatment with subcutaneous RZB 150 mg or matched placebo for 24 weeks, administered at weeks 0, 4 and 16. Starting at week 24, all patients in the ongoing trial receive open-label RZB 150 mg every 12 weeks through week 316. Efficacy and safety analyses were conducted in all randomized patients who received one or more doses of the study drug. Statistical reporting and imputation methods for efficacy assessments are defined in the figures. Safety assessments were based on monitoring of treatment emergent adverse events (TEAEs) and are summarized using exposure-adjusted event rates (EAERs, events/100 patient-years [PYs]).

Results: Patients in KEEPsAKE 2 (RZB N=224; PBO/RZB N=219) maintained similar efficacy results at week 148 to those reported at week 52 and week 100 (**Table 1**). 33.9% of RZB and 28.8% of PBO/RZB patients achieved ACR50 response at week 148 (**Figure 1**). 65.9% of RZB and 58.8% of PBO/RZB patients achieved PASI 90 response at week 148. A consistent change from baseline in HAQ-DI (RZB -0.24, PBO/RZB -0.27), SF-36 PCS (RZB 6.09, PBO/RZB 5.60) and FACIT-

Any TEAE	286 (274.2)	292 (288.3)	1874 (177.0)
Serious TEAE	14 (13.4)	15 (14.8)	99 (9.3)
TEAE leading to discontinuation of study drug	2 (1.9)	6 (5.9)	12 (1.1)
COVID-19 related TEAE	1 (1.0)	0	124 (11.7)
Any MACE	1 (1.0)	0	4 (0.4)
Cardiovascular death due to acute myocardial infarction	0	0	1 (<0.1)
Non-fatal myocardial infarction	0	0	2 (0.2)
Non-fatal stroke	1 (1.0)	0	1 (<0.1)
Any serious infection	3 (2.9)	5 (4.9)	18 (1.7)
Any serious hypersensitivity	0	0	1 (<0.1)[b]
Opportunistic infections excluding TB and herpes zoster	0	0	2 (0.2)
Active TB	0	0	0
Herpes zoster	0	1 (1.0)	5 (0.5)
Malignant tumors	1 (1.0)	3 (3.0)	17 (1.6)
Including NMSC	1 (1.0)	3 (3.0)	15 (1.4)
Excluding NMSC	0	0	2 (0.2)
Any adjudicated anaphylactic reaction	0	0	0
All Deaths	0	0	1 (0.1)[c]

Treatment-emergent adverse events (TEAE) were defined as any AE with an onset date that was on or after the first dose of risankizumab and up to 140 days after the last dose of risankizumab if the patient discontinued the study drug prematurely.

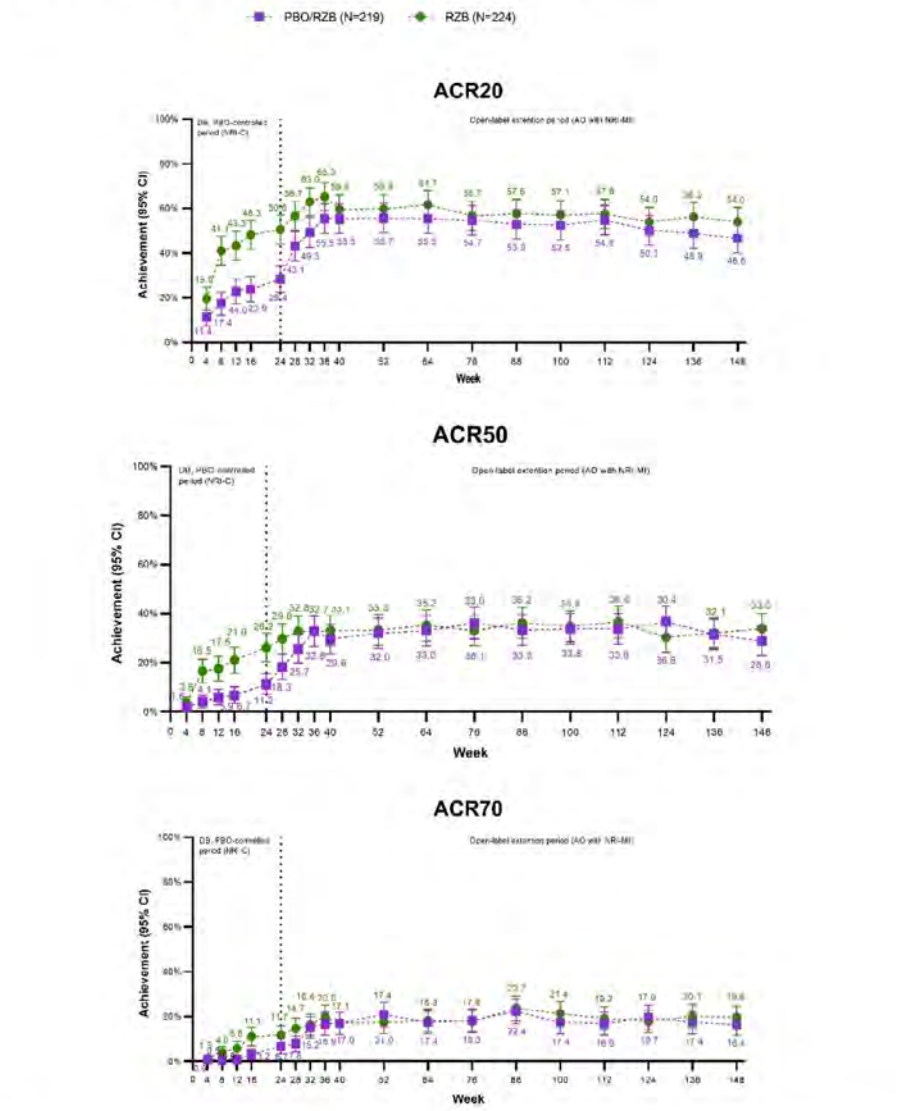
[a]24 week data from KEEPsAKE 2 was previously published in Östör A, et. al. Ann Rheum Dis. 2022;81:351-358.

[b]Event of idiopathic thrombocytopenic purpura assessed as NRP per investigator. Patient remained on study drug.

[c]One death was caused by coronary artery plaque rupture in a patient who had multiple risk factors, including obesity, a long history of smoking, hypertension, hypercholesterolemia, and a family history of cardiovascular disease.

MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer; PYs, patient-years; RZB, risankizumab; TB, tuberculosis; TEAE, treatment-emergent adverse events.

Figure 1. ACR20, 50, and 70 Achievement Over 148 Weeks



DB, double-blind; NRI-C, non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19; AO with NRI-MI, as-observed (AO) data with missing data imputed as non-responder imputation incorporating multiple imputation (NRI-MI) if there are missing data due to COVID-19; PBO, placebo; RZB, risankizumab.

Fatigue (RZB 6.0, PBO/RZB 5.1) was observed at 148 weeks. 33.0% of RZB patients and 28.3% of PBO/RZB patients achieved MDA at week 148, consistent with results reported at week 52 and week 100. For those patients with enthesitis at baseline, resolution was observed in 53.1% of RZB and 47.5% of PBO/RZB patients at week 148. For patients with dactylitis at baseline, resolution was observed in 82.5% of RZB and 61.4% of RZB/PBO patients at week 148. The overall rates of TEAEs, serious TEAEs and AEs leading to discontinuation of study drug remained stable and was consistent with the rates reported for the placebo-controlled period (**Table 2**).

Conclusion: Long-term treatment with RZB 150mg shows durable efficacy in patients with PsA through 148 weeks, with no new safety findings.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Risankizumab (RZB), a humanized immunoglobulin G1 monoclonal antibody that inhibits interleukin-23 by targeting its p19 subunit with high affinity and specificity, is approved for the treatment of adult patients (pts) with active PsA. Pts in the KEEPsAKE 1 trial who received RZB 150 mg achieved the primary efficacy endpoint at week

24. The long-term efficacy, safety and tolerability of RZB has been previously reported through 100 weeks of treatment. Here, we report the efficacy and safety results through week 148.

Methods: KEEPsAKE 1 is an ongoing, global, phase 3, multicenter clinical trial to evaluate the efficacy and safety of RZB versus placebo (PBO) in patients with active PsA. Eligible patients were≥18 years old and demonstrated an inadequate response, intolerance or contraindication to ≥1 conventional syntheticDMARD (csDMARD-IR). Following a 24-week double-blind, PBO-controlled, parallel-group treatment period (period 1), the trial is ongoing with an open-label extension treatment period from week 24 through week 316 (period 2). In period 1, pts were randomized 1:1 to receive subcutaneous RZB 150 mg or PBO at weeks 0, 4 and 16. At week 24, pts who were randomized to RZB received blinded PBO and pts who were randomized to PBO received the first dose of blinded RZB. Starting at week 28, all pts continue to receive open-label RZB 150 mg every 12 weeks until week 316. Beginning at week 36, pts who were classified as non-responders (defined as < 20% improvement in tender or swollen joint count on two consecutive visits vs baseline) were discontinued from the study drug. Efficacy and safety analyses were conducted in all randomized pts who received one or more doses of the study drug. Safety assessments were based on monitoring of treatment-emergent adverse events (TEAEs).

Results: Overall efficacy results were maintained at week 148 of the KEEPsAKE 1 trial, as compared to week 52 and 100 (**-Table 1**). At week 148, 41.1% of RZB and 41.5% of PBO/RZB pts achieved ACR50 and 38.1% of RZB and 35.5% of PBO/RZB pts achieved MDA (**Figure 1**). 69.3% of RZB and 67.1% of PBO/RZB pts achieved PASI90 at week 148. mNAPSI and PGA-F scores improved from baseline by 15.01 and 1.5 points, respectively, for RZB pts and by 13.99 and 1.4 points for PBO/RZB pts. For pts with enthesitis at baseline, resolution was seen in 62.6% of RZB and 62.4% of PBO/RZB pts. For pts with dactylitis at baseline, resolution was seen in 77.5% of RZB and 74.8% of PBO/RZB pts. At week 148, the mean PSA-mTSS score increased by 0.55 from baseline for RZB and by 0.94 for PBO/RZB pts. 88.5% of RZB and 84.4% of

All changes are least square mean changes from baseline.

[a]Results for binary endpoints are based on as-observed (AO) data with missing data imputed as non-responder imputation incorporating multiple imputation (NRI-MI) if there are missing data due to COVID-19 or geo-political conflict in Ukraine and Russia.

[b]Results for continuous endpoints are reported by mixed-effect model repeated measurement (MMRM). Number of unique patients contributing to MMRM model estimates: patients with at least one available change from baseline value and no missing data for the factors and covariates in the model. The MMRM N is not visit-specific and is displayed for model estimates for all visits.

[c]Reported for patients with ≥ 3% of body surface area (BSA) affected by psoriasis at baseline (RZB, n=273; PBO/RZB, n=272).

[d]Reported for patients with nail psoriasis at baseline.

[e]Defined as Leeds Enthesitis Index (LEI)=0 and reported among patients with LEI >0 at baseline (RZB, n=297; PBO/RZB, n=290).

[f]Defined as Leeds Dactylitis Index (LDI)=0 and reported among patients with LDI>0 at baseline (RZB, n=148; PBO/RZB, n=147).

[g]Results for PsA-mTSS were recorded from reading session 4 and reported as observed.

[h]For HAQ-DI, lower scores indicate lower difficulty.

[i]For NAPSI, lower scores indicate lower severity of nail psoriasis.

[j]For PGA-F, lower scores reflect lower severity of finger-nail psoriasis.

[k]For SF-36, higher scores reflect better health-related quality of life.

[l]For FACIT-Fatigue, higher scores reflect lower levels of fatigue.

ACR20/50/70, ≥20/50/70% improvement in American College of Rheumatology score; BSA, body surface area; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue Questionnaire; HAQ-DI, Health Assessment Questionnaire-Disability Index; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; LS, least square; MDA, minimal disease activity; PASI 90, ≥90% reduction in Psoriasis Area and Severity Index; PBO, placebo; PGA-F, Physician Global Assessment of Fingernail Psoriasis; PsA-mTSS, psoriatic arthritis modified Total Sharp Score; RZB, risankizumab; SF-36 PCS, 36-Item Short Form Health Survey Physical Component Summary.

PBO/RZB pts showed no radiographic progression (PSA-mTSS ≤0 from baseline). At week 148, HAQ-DI (RZB -0.41, PBO/RZB -0.35), SF-36 PCS (RZB 8.61, PBO/RZB 7.78) and FACIT-Fatigue (RZB 7.4, PBO/RZB 6.4) scores showed consistent increase from baseline. The overall rates of TEAEs, serious TEAEs and AEs leading to discontinuation of study drug have remained stable and comparable to those reported in period 1 (**Table 2**).

Conclusion: The 148-week results of the ongoing KEEPsAKE 1 trial demonstrate the durable efficacy of RZB 150 mg in treating the clinical manifestations and improving health-related quality of life in csDMARD-IR pts with PsA. RZB was well-tolerated, with no new safety signals.

Table 2. Safety Summary for KEEPsAKE 1 through Week 148

Any TEAE	398 (177.6)	387 (173.2)	3005 (124.6)
Serious TEAE	15 (6.7)	22 (9.8)	185 (7.7)
TEAE leading to discontinuation of study drug	6 (2.7)	4 (1.8)	45 (1.9)
COVID-19 related TEAE	1 (0.4)	2 (0.9)	215 (8.9)
Any MACE	0	0	5 (0.2)
Cardiovascular death - sudden cardiac death	0	0	2 (<0.1)
Non-fatal myocardial infarction	0	0	2 (<0.1)
Non-fatal stroke	0	0	1 (<0.1)
Any serious infection	6 (2.7)	8 (3.6)	47 (1.9)
Any serious hypersensitivity	0	0	1 (<0.1)
Opportunistic infections excluding TB and herpes zoste	0	0	1 (<0.1)
Active TB	0	0	0
Herpes zoster	2 (0.9)	1 (0.4)	6 (0.2)
Malignant tumors	0	2 (0.9)	18 (0.7)
Including NMSC	0	0	3 (0.1)
Excluding NMSC	0	2 (0.9)	15 (0.6)
Any adjudicated anaphylactic reaction	0	0	0
All Deaths	1 (0.4)	0	9 (0.4)[b]

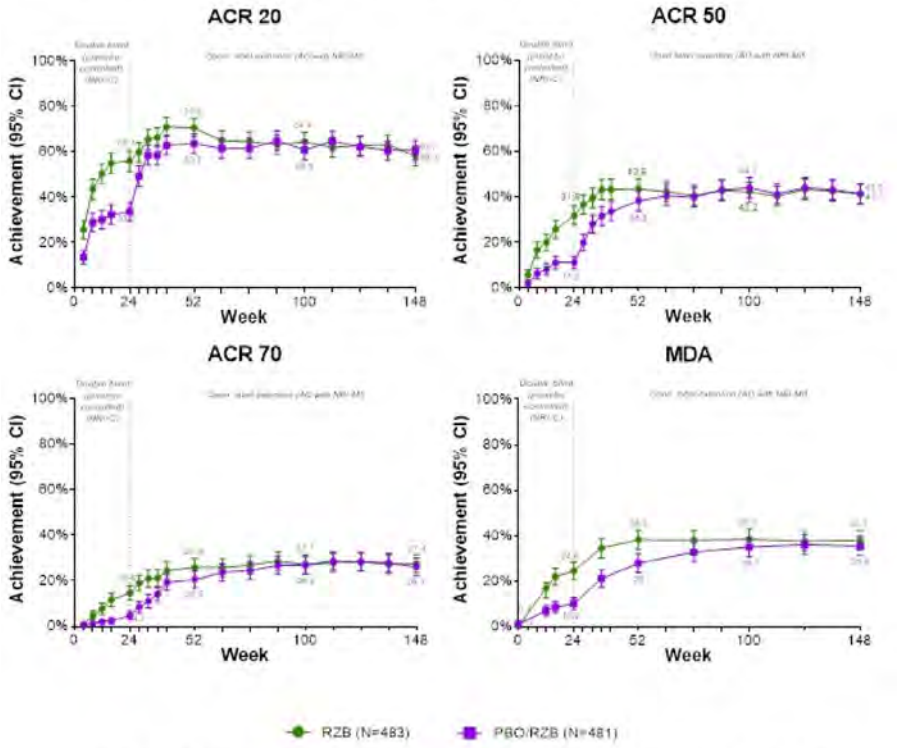
Treatment-emergent adverse events (TEAE) were defined as any AE with an onset date that was on or after the first dose of risankizumab and up to 140 days after the last dose of risankizumab if the patient discontinued the study drug prematurely.

[a]24 week data from KEEPsAKE 1 was previously published in Kristensen, et. al. Ann Rheum Dis. 2022;81(2):225-231.

[b]There were 8 patients reported with fatal TEAEs. 2 deaths were related to COVID 19; 1 was due to complications related to acute leukemia; 1 patient with anemia from diverticulosis died due to multiorgan failure from septicemia as a complication from anastomosis surgery (left hemicolectomy surgery); 1 patient, who was 81 years old with dementia, was hospitalized for pneumonia, developed urosepsis and died from related complications; 1 patient was hospitalized for anxiety and depression, developed septicemia, nausea, vomiting, fever and loss of appetite a week after discharge, and died from unknown causes a week later; 2 patients died of unknown causes (one had a 40 year history of smoking and died after COPD exacerbation). Additionally, 1 patient died on day 363 (166 days after last dose; non treatment emergent) from cardiorespiratory arrest.

MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer; PBO, placebo; PYs, patient-years; RZB, risankizumab; TB, tuberculosis; TEAE, treatment-emergent adverse events.

Figure 1. Achievement of ACR 20, 50, 70 and MDA Over 148 Weeks in KEEPsAKE 1



DB, double-blind; NRI-C, non-responder imputation incorporating multiple imputation to handle missing data due to COVID-19; AO with NRI-MI, as-observed (AO) data with missing data imputed as non-responder imputation incorporating multiple imputation (NRI-MI) if there are missing data due to COVID-19; PBO, placebo; RZB, risankizumab

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Pooled safety data have been reported for secukinumab administration in patients with psoriasis (PsO), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA).[1,2] The aim of this study is to describe the safety profile of secukinumab after extensive patient exposure in clinical trials. We report safety analysis from a larger pool of patients and more studies than previously published.[3]

Methods: The pooled safety analysis included 48 Phase II/III/IV clinical trials with patients who had received subcutaneous (s.c.) secukinumab 150 mg and / or 300 mg for at least 16 weeks in PsO (31 trials), PsA (9 trials), and axSpA (8 trials), with a cut-off date of June 2022. AxSpA includes data from patients with either radiographic axSpA or non-radiographic axSpA. Adverse events (AEs) were reported as exposure-adjusted incidence rates (EAIRs) per 100 patient-years. Analysis included all patients who received ≥1 dose of secukinumab.

Results: A total of 17,008 patients with PsO (10,150), PsA (4,401) and axSpA (2,457) were included in this analysis. The most frequent AEs reported across all indications were nasopharyngitis (EAIR [95% CI]; PsO, 19.44 [18.66, 20.24]; PsA, 11.36 [10.54, 12.23]; axSpA, 12.88 [11.73, 14.11]) and upper respiratory tract infection (EAIR [95% CI]; PsO, 6.14 [5.75, 6.56]; PsA, 8.1 [7.42, 8.82]; axSpA, 8.28 [7.41,9.22]). EAIRs per 100 patient-years for inflammatory bowel disease (IBD), malignancies and major adverse cardiovascular events (MACE) remained low across all indications. The EAIRs per 100 patient-years for adverse events (AEs) of special interest are reported in **Table 1**.

Conclusion: This pooled safety data analysis of 48 Phase II/III/IV clinical trials demonstrates that secukinumab is well tolerated in patients with PsO, PsA and axSpA, and shows no new signals with longer-term follow-up beyond those already identified in shorter studies.[1,2]

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

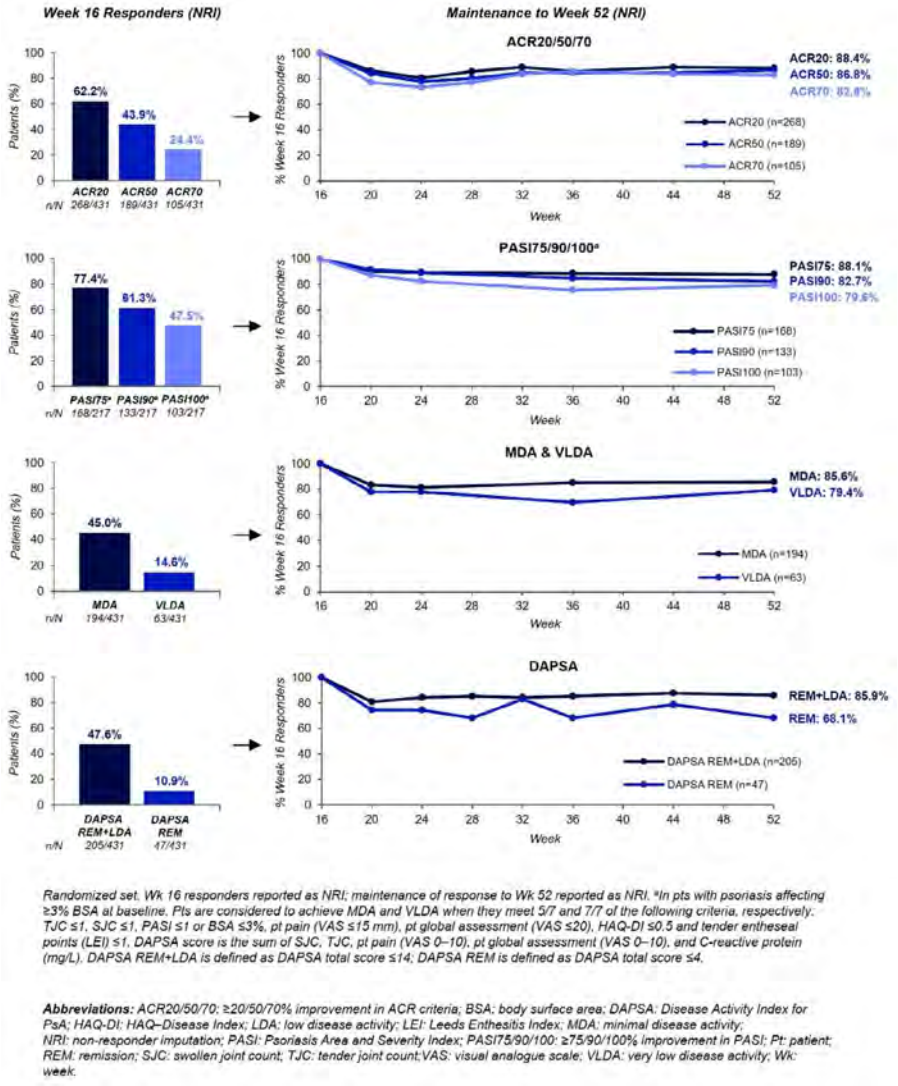
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Given the chronic nature of PsA, sustaining high levels of disease control with treatment is important. Assessing maintenance of response in patients (pts) that achieve treatment targets is of interest as pts can experience loss of response with long-term therapy.[1] Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits IL-17F in addition to IL-17A, has demonstrated rapid, clinically meaningful joint and skin efficacy responses at Week (Wk) 16 versus placebo (PBO) in pts with PsA.[2,3] Responses were sustained to Wk 52.[4] We report maintenance of response in joint and skin efficacy outcomes to Wk 52 in BKZ-treated pts with PsA who responded at Wk 16.

Methods: BE OPTIMAL (NCT03895203), which included a 16-wk double-blind, PBO-controlled period and a 36-wk active treatment-blind period, assessed BKZ in patients with active PsA who were biologic DMARD (bDMARD)-naïve. Pts were randomized 3:2:1 to subcutaneous BKZ 160 mg every 4 wks (Q4W), PBO, or reference (adalimumab 40 mg Q2W). At Wk 16, PBO pts switched to BKZ 160 mg Q4W. Maintenance of response is reported as the percentage of BKZ-treated pts who achieved response at Wk 16 and maintained response at Wk 52. Data are reported for pts randomized to BKZ 160 mg Q4W at baseline (BL). Endpoints include ACR20/50/70, Psoriasis Area and Severity Index (PASI)75/90/100, minimal and very low disease activity (MDA, VLDA), and Disease Activity Index for PsA (DAPSA) remission or low disease activity (REM+LDA; ≤14) and remission (REM; ≤4) responses. Wk 16 responders are reported using non-responder imputation (NRI); maintenance of response to Wk 52 is reported using NRI and observed case (OC). Treatment-emergent adverse events (TEAEs) to Wk 52 are reported for pts who received ≥1 dose of BKZ, including pts randomized to PBO at BL.

Results: At BL, 431 pts were randomized to BKZ 160 mg Q4W; 217/431 (50.3%) had psoriasis affecting ≥3% of body surface area (BSA). 414/431 (96.1%) completed Wk 16; 388 (90.0%) completed Wk 52. Most pts who achieved response at Wk 16 maintained response at Wk 52, across a range of outcomes (**Figure**). At Wk 16, ACR20/50/70 was achieved by 268 (62.2%)/189 (43.9%)/105 (24.4%) pts; responses were maintained at Wk 52 by 88.4%/86.8%/82.9% (NRI); 92.9%/91.1%/87.9% (OC). Of 217 pts with psoriasis affecting ≥3% of BSA at BL, 133 (61.3%)/103 (47.5%) achieved PASI90/100 at Wk 16. Most pts maintained response at Wk 52: 82.7%, 79.6% (NRI); 94.0%, 89.1% (OC). The same pattern was observed for the composite measures of efficacy. 194 (45.0%) pts achieved MDA at Wk 16; 85.6% (NRI) and 90.7% (OC) maintained response at Wk 52. A high proportion of Wk 16 responders maintained their response at Wk 52 for VLDA,



Randomized set. Wk 16 responders reported as NRI; maintenance of response to Wk 52 reported as NRI. ªIn pts with psoriasis affecting ≥3% BSA at baseline. Pts are considered to achieve MDA and VLDA when they meet 5/7 and 7/7 of the following criteria, respectively: TJC ≤1, SJC ≤1, PASI ≤1 or BSA ≤3%, pt pain (VAS ≤15 mm), pt global assessment (VAS ≤20), HAQ-DI ≤0.5 and tender entheseal points (LEI) ≤1, DAPSA score is the sum of SJC, TJC, pt pain (VAS 0–10), pt global assessment (VAS 0–10), and C-reactive protein (mg/L). DAPSA REM+LDA is defined as DAPSA total score ≤14; DAPSA REM is defined as DAPSA total score ≤4.

***Abbreviations:** ACR20/50/70: ≥20/50/70% improvement in ACR criteria; BSA: body surface area; DAPSA: Disease Activity Index for PsA; HAQ-DI: HAQ–Disease Index; LDA: low disease activity; LEI: Leeds Enthesitis Index; MDA: minimal disease activity; NRI: non-responder imputation; PASI: Psoriasis Area and Severity Index; PASI75/90/100: ≥75/90/100% improvement in PASI; Pt: patient; REM: remission; SJC: swollen joint count; TJC: tender joint count;VAS: visual analogue scale; VLDA: very low disease activity; Wk: week.*

Figure. Maintenance efficacy responses to Week 52 in Week 16 responders (NRI)

DAPSA REM+LDA, and DAPSA REM (**Figure**). To Wk 52, 555/702 (79.1%) BKZ-treated pts reported ≥1 TEAE; 46 (6.6%) reported serious TEAEs.

Conclusion: With BKZ treatment, Wk 16 responders maintained robust efficacy responses to Wk 52 across joint, skin, and composite efficacy outcomes. The safety profile of BKZ was consistent with previous reports.[2,3]

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Late-onset PsA may be associated with elevated acute phase reactants, higher joint count, and erosive disease at diagnosis[1,2]. Given potential phenotype differences and increasing prevalence with aging populations, it is important to establish the efficacy of current treatments in late-onset PsA. Previous analyses of DISCOVER-1&2 (D1&2) have shown the fully human IL-23p19-subunit inhibitor guselkumab (GUS) to be associated with robust and sustained improvement in PsA signs/symptoms over 52 weeks (W) in subgroups of patients (pts) across a variety of baseline (BL) characteristics[3]. These post hoc analyses contrasted early- vs. late-onset PsA pts and evaluated GUS efficacy through W52 in both cohorts.

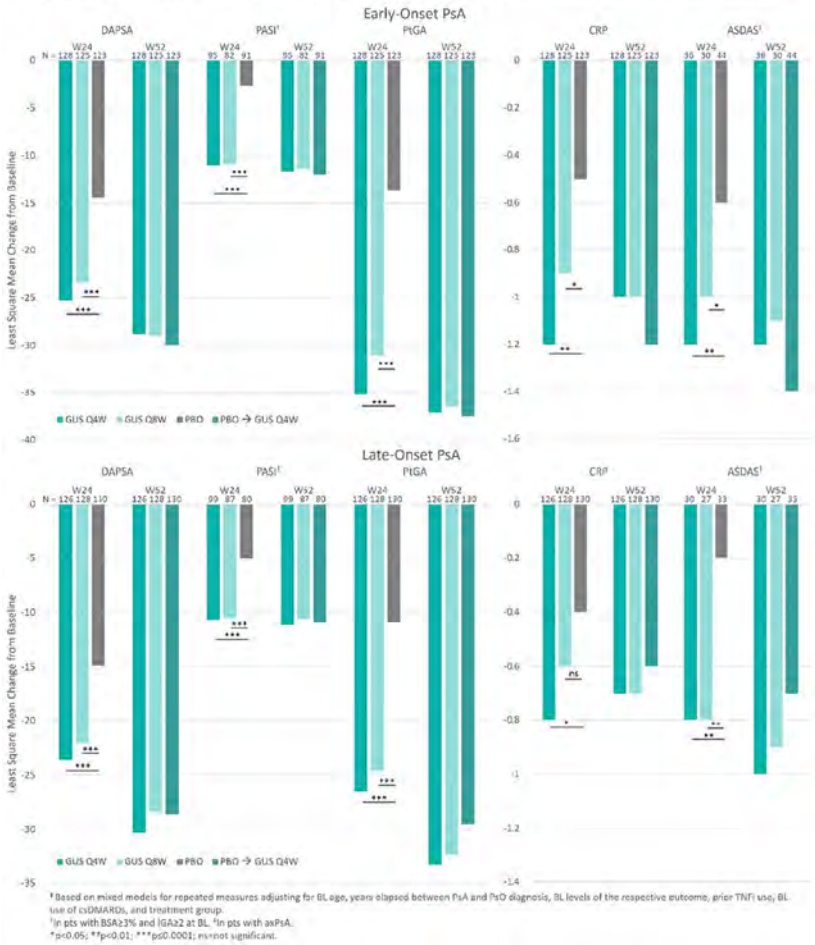
Methods: Adults in D1&2 (90% bionaive) with active PsA despite standard therapies were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo (PBO) with crossover to GUS 100 mg Q4W at W24. The tertile (T) distribution of age at PsA diagnosis in the pooled D1&D2 population informed the definition of early- (T1 < 36y) and late- (T3 ≥47y) onset. W24/52 efficacy assessments included least-square mean changes in Disease Activity Index for PsA (DAPSA), swollen/tender joint counts (SJC/TJC), Psoriasis Area Severity Index (PASI; in pts with BSA≥3% and IGA≥2 at BL), CRP, pt-reported pain (Pt-Pain), pt global assessment of arthritis and psoriasis (PtGA), Short Form 36-item

Table. Baseline Characteristics of Patients with Early-Onset vs. Late-Onset PsA

	Early-Onset PsA (N=376)	Late-Onset PsA (N=384)	Nominal P-value
Age at study BL (years)	35.5 (8.9)	58.1 (6.1)	**<0.001**
Male sex, n (%)	198 (52.7)	181 (47.1)	0.128
Body mass index (kg/m²)	27.4 (6.4)	30.3 (5.3)	**<0.001**
PsA disease duration (years), median (IQR)	5.1 (2.0-11.0)	3.0 (1.2-6.4)	**<0.001**
Years between PsO and PsA diagnosis, median (IQR)	4.0 (0.2-10.3)	8.2 (1.2-22.9)	**<0.001**
DAPSA	46.1 (20.2)	45.4 (20.5)	0.629
SJC (0-66)	11.2 (7.5)	11.1 (6.8)	0.991
TJC (0-68)	20.0 (12.6)	20.5 (13.7)	0.630
% BSA affected by PsO	17.0 (20.4)	14.9 (18.1)	0.145
PASI score (0-72)	9.9 (11.1)	8.6 (9.1)	0.092
CRP (mg/dL)	2.2 (2.6)	1.5 (2.0)	**<0.001**
Pain (VAS, 0-100 mm)	62.4 (19.7)	59.9 (20.8)	0.089
PtGA (VAS, 0-10)	67.7 (19.5)	64.5 (20.9)	**0.032**
Presence of enthesitis, n (%)	247 (65.7)	244 (63.5)	0.600
LEI score (1-6)	2.8 (1.6)	2.9 (1.7)	0.336
Presence of Dactylitis, n (%)	175 (46.5)	135 (35.2)	**0.002**
Dactylitis severity score (1-60)	8.8 (10.8)	8.4 (8.7)	0.772
Axial involvement (axPsA), n (%)	110 (29.3)	90 (23.4)	0.069
BASDAI (0-10) in pts with axPsA	6.7 (1.7)	6.2 (1.7)	**0.031**
ASDAS in pts with axPsA	3.1 (0.7)	2.7 (0.7)	**<0.001**
SF36-PCS (US norm=50; lower=more impairment)	33.3 (8.1)	33.8 (7.5)	0.409

Data are presented as mean (SD) unless stated otherwise.
BSA: body surface area; IQR: interquartile range; LEI: Leeds enthesitis index; PsO: psoriasis.

Figure 1. Least Square Mean Changes[‡] in Key Outcomes Through W52 in Patients with Early-Onset and Late-Onset PsA



[‡] Based on mixed models for repeated measures adjusting for BL age, years elapsed between PsA and PsO diagnosis, BL levels of the respective outcome, prior TNFi use, BL use of csDMARDs, and treatment group.
[†] In pts with BSA≥3% and IGA≥2 at BL. [§] In pts with axPsA.
* p<0.05; ** p<0.01; *** p<0.001; ns=not significant.

Figure 2. Achievement (Using NRI) of ACR Responses and MDA Through W52 in Patients with Early-Onset and Late-Onset PsA

†Odds ratios with corresponding 95% confidence intervals and p-values based on logistic regression adjusting for BL age, years elapsed between PsA and PsO diagnosis, BL levels of the respective outcome, prior TNFi use, BL use of csDMARDs, and treatment group.
*p<0.05; **p<0.01; ***p≤0.0001.

physical component summary score (SF-36 PCS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI; in pts with axial involvement [axPsA]), and Ankylosing Spondylitis Disease Activity Score (ASDAS; in pts with axPsA), as well as ACR and Minimal Disease Activity (MDA) response rates (employing non-responder imputation [NRI] for missing data).

Results: Relative to pts with late-onset (n=384), those with early-onset (n=376) PsA were significantly younger at BL but had longer PsA duration and a shorter interval between psoriasis and PsA diagnoses **(Table 1)**. The two cohorts had generally comparable joint and skin disease severity at BL, although those with early-onset PsA were more likely to have axPsA and dactylitis, and exhibited higher CRP levels, PtGA, BASDAI and ASDAS.

Irrespective of PsA onset age, GUS Q4W or Q8W was associated with significantly (nominal p< 0.001) greater improvements in DAPSA, PASI, PtGA, CRP, ASDAS **(Figure 1)**, SJC, TJC, Pt-Pain, BASDAI, and SF-36 PCS (data not shown), and higher ACR20/50/70 and MDA response rates vs. PBO at W24 **(Figure 2)**. Further improvements/increased response rates were generally seen through W52 of GUS across early- and late-onset subgroups **(Figure 1, 2)**.

Conclusion: Results of post hoc analyses, conducted in a large cohort of mainly bio-naïve pts with active PsA from D1&2, suggest early-onset PsA may be associated with more aggressive presentation several years post-diagnosis. Irrespective of age of PsA onset and differences in baseline profile, however, GUS was associated with significant and clinically meaningful improvements across key PsA domains, with further enhancements generally seen through W52.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To compare drug survival, effectiveness and safety of anti-IL17A with anti-TNF drugs as first line biologic therapy in patients (pts) with PsA using real life data from the Czech biologics registry ATTRA. ATTRA is a prospective observational cohort study that captures more than 90% of PSA patients treated with b/tsDMARDs in the Czech Republic (CZ). Anti-IL17A bDMARDs have been reimbursed in CZ since Jan 2016 with the same label and restrictions as anti-TNFs.

Methods: PsA pts who initiated their first bDMARD in Jan 2016–Mar 2022 with at least one year of follow-up were included. By the type of first bDMARD exposure patients were dichotomized to anti-IL17A and anti-TNF cohorts. Effectiveness was assessed every 3-6 months by DAS28-ESR and DAPSA, physician global assessment of psoriasis (PGApso) on numerical rating scale (1-5), and by EQ-5D utility. Incidence of reported AEs and SAEs per 1000 patient-years (p-yrs) was calculated. Propensity score (PS) matching was used to account for differences in baseline characteristics. Drug survival was visualized using Kaplan-Meier curves, and Cox proportional hazards models were used to calculate adjusted Hazard Ratios (HRs) with 95% confidence intervals (CIs) for risk of discontinuing therapy.

Table 1. Baseline characteristics after PS matching

Characteristics	anti-IL17A (n=177)		anti-TNF (n=577)	p-value
Female	85 (48.0%)		289 (50.1%)	0.631
Age at diagnosis, yrs	41.0 (33.0–52.0)		43.0 (34.0–51.0)	0.377
Age at start of 1st line, yrs	49.0 (42.0–57.0)		51.0 (42.0–58.0)	0.697
BMI	28.7 (25.3–33.1)		28.3 (25.3–32.5)	0.741
Tender joint count (66 joints)	12.0 (8.0–20.0)		12.0 (7.0–19.0)	0.439
Swollen joint count (68 joints)	7.0 (3.0–12.0)		8.0 (4.0–12.0)	0.329
ESR (mm/h)	24.0 (11.0–38.0)		26.0 (12.0–40.0)	0.206

	Medium	50 (29.2%)	164 (28.9%)	
	Severe	10 (5.8%)	26 (4.6%)	
Enthesitis	23 (13.0%)		67 (11.6%)	0.620
DAS28-ESR	5.3 (4.6–5.9)		5.4 (4.5–6.1)	0.380
DAPSA	35.0 (26.8–47.6)		36.0 (27.3–45.4)	0.900
Data are median (IQR) or n (percentage).				

Results: 994 PsA pts started first-line anti-IL-17A (n=192) or anti-TNF (n= 802) therapy within period Jan 2016–Mar 2022, and 178 and 719 resp. had non-missing values for the outcomes of interest. Important baseline characteristics were similar between anti-IL17A and anti-TNF cohorts save for swollen joint counts (SJC), and after PS matching (using logistic model with 1 covariate: 68 SJC, matching ratio 1:4, caliper 0.1) 177 pts on anti-IL17A and 577 on anti-TNF were PS-matched and further analyzed. Baseline characteristics of PS-matched cohorts are in table 1. Drug retention on anti-IL7A was significantly better than on anti-TNF drugs with HR (95% CI) 0.57 (0.41; 0.78), see fig. 1. More pts on anti-IL7A discontinued therapy because of primary failure (31% vs 16%), but less of them because of adverse events (9% vs 17%) or other unspecified reasons (13% vs 21%). In pts remaining on first line therapy, mean levels of DAS28-ESR and DAPSA were significantly lower and of utility EQ-5D significantly higher at each time point since month(M)3 until M18 after start of anti-TNF compared with anti-IL-17A therapy (Fig. 2). Skin involvement assessed by PGApso was significantly better in anti-IL17A treated pts at M3 and M12. Incidence of AEs and SAEs was lower in anti-17A than in anti-TNF treated group (93 vs 168/1000 p-yrs, $p< 0.001$; and 7 vs 18 /1000 p-yrs, $p=0.079$, resp.).

Conclusion: We have observed better drug retention on anti-IL17A compared to anti-TNF therapy despite its inferior effect on composite joint indexes and quality of life in pts with PsA. This discrepancy may be explained either by superior safety, tolerability, and effectiveness of anti-IL17A on skin involvement, limited possibility to switch between anti-L17A drugs, or lower confidence of physicians to switch from anti-IL17A to anti-TNF than vice versa.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is often used as first-line DMARD therapy in active psoriatic arthritis (PsA). The value of MTX in combination with different bDMARDs is still unclear. We designed an investigator-initiated, randomized, placebo-controlled trial (IIT) in active PsA to examine if outcomes of treatment with ustekinumab (UST) in combination with MTX (either newly initiated or ongoing) were different from UST only (+Placebo; PBO). It was allowed to include patients with stable MTX treatment. Here, we analyze the data stratified to MTX pretreatment, focusing on early treatment response within the first 16 weeks.

Methods: A total of 186 patients with active PsA (defined as TJC≥4, SJC≥4 [68/66 joint count], and DAS28≥3.2) were screened for eligibility. 173 patients were randomized to UST+MTX (new or ongoing) or UST+PBO. Patients were stratified regarding their previous MTX therapy (blinded continuation of MTX or replacement of MTX with PBO [MTX-pre-treated] or blinded newly initiated MTX or PBO [MTX-naïve]). Demographic data and disease activity status on peripheral arthritis (response rates for LDA and remission for DAS28-CRP, DAPSA) were compared between treatment groups regarding MTX pretreatment. Early response behavior was investigated by identification of DAS28-CRP and DAPSA low disease activity (LDA) and remission rates at weeks 4, 16, and 24.

Figure 1: LDA and Remission rates for DAS28-CRP and DAPSA response at weeks 4, 16, and 24 in the cohort of PsA patients with MTX pretreatment and either discontinuation at the start of UST treatment or continuation of both MTX and UST

Results: BL data were well-balanced between treatment groups (UST+MTX, n=87; UST+PBO, n=79), including gender (42.5% vs. 40.5% female) and mean values for age (49.2 vs. 47.2 years), BMI (29.4 vs. 28.9 kg/m^2), SJC (8 vs. 8), TJC (12 v.s 12), DAS28-CRP (4.6 v.s 4.4), DAPSA (36.7 v.s 34.9), PASI (2.8 .vs 2.4), enthesitis (LEI >0: 50.57% .vs 50.63%), and other domains. BL differences were seen in dactylitis (24.1% .vs 19.0%), BSA (2.9%. vs. 1.0%), and DLQI (8.6. vs 6.9). The patient cohort stratified according to MTX pretreatment was taken out (n=80) for analysis. The proportion of patients who reached LDA and remission rates in DAS28-CRP was slightly lower in the group who discontinued MTX treatment at the study start compared to those who continued MTX (DAS28-CRP 21.62% vs. 25.59%, respectively). This was more prominent in analyzing the achievement of LDA/remission rates in DAPSA at week 4 (10.81% for those discontinuing MTX vs. 25.59 % for those who continued MTX (Figure 1)). At weeks 16 and 24, both treatment groups reached the same levels for LDA/remission rates in DAS28-CRP and DAPSA.

Conclusion: We have previously shown that MTX+UST vs. UST+PBO is non-inferior for efficacy assessments in active PsA. Here we present the data from the analysis focusing on early response behavior to answer whether the overlapping treatment with MTX is of clinical value after the decision to initiate a biological therapy with ustekinumab is made. With a focus on DAS28-CRP and DAPSA response rates (LDA+remission), we can show that an overlapping treatment by the continuation of MTX within the first 12-16 weeks is of clinical value to increase response rates in the early treatment phase of UST treatment. MTX can be stopped at week 12 when UST efficacy increases, independent of MTX use.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster II: SpA
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical improvements through Week (Wk)96, with no unexpected safety findings, have previously been reported with bimekizumab (BKZ) in the BE RADIANT phase 3b trial in patients with moderate to severe plaque psoriasis.[1,2] Here, we evaluate the efficacy of BKZ, as measured by complete or near complete skin clearance using the Psoriasis Area and Severity Index (PASI), over 144 weeks, and assess long-term safety of BKZ treatment.

Methods: Patients with moderate to severe plaque psoriasis received BKZ (320mg every 4 wks [Q4W] through Wk16, then Q4W or Q8W) or secukinumab (SEC; 300mg weekly to Wk4, then Q4W) through Wk48, then BKZ (Q4W or Q8W; all received Q8W from Wk64/next scheduled visit). Wks48–144 (open-label extension [OLE]) overlapped with the COVID-19 pandemic. Wk48–144 efficacy data are reported for patients treated with BKZ or SEC to Wk48 who entered the OLE, receiving BKZ Q4W or Q8W. Patients discontinuing due to lack of efficacy/treatment-related adverse events (AEs) were considered non-responders; multiple imputation was used for other missing data (modified non-responder imputation [mNRI]). Wk48–144 safety data (incidence/100 patient-years [PY]) are grouped for patients receiving ≥1 BKZ dose in this period.

Results: 336/373 BKZ-randomized and 318/370 SEC-randomized patients entered the OLE. Among these, 74.9% BKZ vs 52.8% SEC (Wk48) and 68.8% BKZ/BKZ vs 69.1% SEC/BKZ (Wk144) achieved PASI100 (100% improvement from baseline in PASI); 94.3% vs 83.9% (Wk48) and 89.8% vs 87.0% (Wk144) achieved PASI≤2. Wk48–144 serious AE rate with BKZ was low (5.4/100PY).Four deaths (two from coronavirus infection [unvaccinated patients]) occurred; none treatment-related. The most common AEs were: nasopharyngitis (8.4/100PY); oral candidiasis (7.1/100PY); coronavirus infection (5.1/100PY). Most (98.3%) oral candidiasis events were mild/moderate; three led to discontinuation.

Conclusion: Clinical improvements with BKZ were maintained through Wk144; outcomes improved for SEC-treated patients after switching to BKZ (Wk48–144). AEs were consistent with BKZ's safety profile.[1–3]

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Awareness of comorbidity in patients with SLE is increasing. Most studies to date have described comorbidity burden in prevalent SLE. We estimated the incidence of vascular events, - by age and sex, - in a large inception cohort of patients with SLE compared with matched general population controls.

Methods: We assembled a cohort of adult patients registered with a first-time diagnosis of SLE (ICD codes) from January 1996 to July 2018 in the Danish National Patient Register (DNPR). SLE patients were age, - and sex-matched to population controls randomly selected from the Danish Civil Registration System. We used ICD codes from the DNPR to determine the presence of cardiovascular disease (Myocardial Infarction (MI)), cerebrovascular disease (CVD), and peripheral vascular disease (PVD) during outpatient and inpatient care. Individuals with prevalent MI, CVD, and PVD at baseline (SLE diagnosis) were excluded from the analyses of incident events. We estimated incidence rates (IRs), incidence rate ratios (IRRs), and incidence rate differences (IRDs) per 1,000 person-years of MI, CVD, and PVD by sex and age (< 50 years vs ≥ 50 years at baseline) during up to 10 years of follow-up. Analyses were done separately for each disease category, e.g., individuals with incident MI were retained for analyses of CVD and PVD. IRRs and IRDs were adjusted for age and sex using Poisson regression and presented with 95% CIs.

Results: We identified 3,178 patients with incident SLE and 60,090 age- and sex-matched general population comparators. 84% of SLE patients and non-SLE controls were female; the mean age at baseline was 47 years. At baseline, the prevalence of MI (2.9% vs 1.40%), CVD (7.0% vs 2.7%), and PVD (5.5% vs 1.4%) was higher in SLE patients compared with the general population controls.

During follow-up, patients with SLE had substantially increased IRs of the above vascular events, with IRRs ranging from 1.7 to 7.6 across sex and age groups (Table 1). Although the absolute rates (IRs) were higher in SLE patients vs controls in the older age group, the IRRs were consistently higher for those aged < 50 at baseline, both females and males. In this age group, female SLE patients had a 5-fold increased risk of CVD and PVD and a 3-fold increased risk of MI. Male SLE patients had an 8-fold increased risk of PVD and a 6-fold increased risk of CVD and MI.

Table 1. Measures of occurrence and association (per 1,000 person-years, with 95% CI) of incident vascular events in patients with incident SLE (n=3,178) compared with matched population controls (n=60,090) during up to 10 years of follow-up after SLE diagnosis, stratified by sex and age group

Females <50	1.0 (0.6-1.7)	0.3 (0.2-0.4)	3.4 (1.8-6.2)	0.7 (0.1-1.3)
≥50 years	4.5 (3.1-6.4)	2.6 (2.3-2.9)	1.7 (1.2-2.5)	1.9 (0.3-3.6)
Males <50	5.8 (2.6-11.3)	1.0 (0.7-1.4)	5.8 (2.5-13.3)	4.8 (0.5-9.1)
≥50 years	13.5 (8.7-20.3)	5.7 (5.0-6.6)	2.4 (1.5-3.7)	7.8 (2.0-13.7)
Cerebrovascular disease				
N of eligible persons	N=2949		N=58459	
Females <50	6.1 (4.7-7.7)	1.2 (1.1-1.3)	5.1 (3.9-6.7)	4.9 (3.4-6.3)
≥50 years	15.5 (12.5-18.9)	7.6 (7.1-8.1)	2.0 (1.6-2.5)	7.9 (4.6-11.1)
Males <50	9.6 (5.1-16.6)	1.7 (1.2-2.2)	5.6 (3.0-11.1)	7.9 (2.2-13.6)
≥50 years	18.2 (12.2-26.2)	12.6 (11.4-13.8)	1.4 (1.0-2.1)	5.6 (1.5-12.7)
Peripheral vascular disease				
N of eligible persons	N=2989		N=59233	
Females <50	2.8 (2.0-4.0)	0.5 (0.5-0.6)	5.2 (3.5-7.6)	2.3 (1.3-3.3)
≥50 years	8.7 (6.6-11.3)	3.4 (3.1-3.8)	2.5 (1.9-3.4)	5.3 (2.9-7.6)
Males <50	5.8 (2.6-11.4)	0.8 (0.5-1.2)	7.6 (3.2-17.9)	5.1 (0.7-9.4)
≥50 years	18.0 (12.2-25.8)	6.6 (5.8-7.4)	2.7 (1.8-4.1)	11.4 (4.6-18.3)

CI: confidence interval; SLE: systemic lupus erythematosus; IR: incidence rate; IRR: incidence rate ratio; IRD: incidence rate difference.

The IRDs ranged from 0.7 (MI in females aged < 50) and 11.4 (PVD in males aged ≥ 50) (Table 1). Interestingly, IRDs were higher in males vs females in both age groups for MI and PVD, and in the younger age group for CVD.

Conclusion: In this nationwide study utilizing prospectively collected registry data, incident patients with SLE were more likely to develop vascular disease than general population controls during up to 10 years of follow-up after SLE diagnosis. This was seen for women and men aged less or more than 50 years at the time of diagnosis but with the highest IRRs of MI, CVD, and PVD in the younger group of SLE patients. Male subjects had a higher incidence of vascular disease, reflected in male SLE patients having the highest IRDs for MI and PVD. Our findings highlight the need for a thorough assessment of vascular comorbidities in SLE patients, at the time of SLE diagnosis and during follow-up, irrespective of sex and age.

Abstract Number: 1443

Vasculitis Associations Among Patients with Systemic Lupus Erythematous

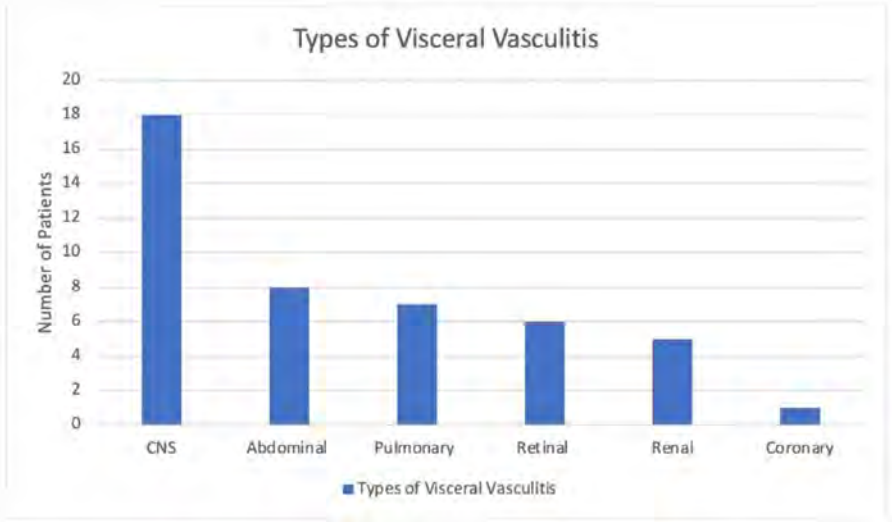
Emily Cosentino[1], Mia Blanchard[2], Diane L. Kamen[1] and Jim Oates[1], [1]Medical University of South Carolina, Charleston, SC, [2]Claremont Graduate University, Claremont, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Vasculitis is rare manifestation of systemic lupus erythematous (SLE) that often leads to increased morbidity and mortality. Vasculitis prevalence in SLE patients have ranged from 11-36% and can be mild to life-threatening. While there have been limited studies focusing on cutaneous small vessel vasculitis, there are not many studies focusing on risk factors of patients that develop vasculitis within a large longitudinal SLE cohort. The purpose of our study is to identify SLE clinical characteristics associated with vasculitis, testing the hypothesis that certain organ involvement with SLE will be associated with a higher risk of vasculitis.

Characteristics	All patients with SLE N=804	SLE patients with vasculitis n=76	SLE patients without vasculitis n=728	P-value
Male sex (%)	9.5%	10.5%	9.3%	0.737
Black race (%)	74.0%	82.9%	73.1%	0.063
Hispanic Ethnicity (%)	3.1%	4.0%	3.0%	0.723
No High School Diploma (%)	11.2%	14.5%	10.9%	0.228
Uninsured (%)	4.2%	2.6%	4.4%	0.453
History of smoking (%)	24.6%	22.4%	24.9%	0.941
Presence of overlapping autoimmune disorders (%)	**25.9%**	**30.3%**	**25.4%**	**0.028**
Presence of arthritis (%)	**66.2%**	**54.0%**	**67.5%**	**0.043**
Presence of Serositis (%)	28.0%	35.5%	27.2%	0.072
Presence of renal disorder (%)	**47.0%**	**64.5%**	**45.2%**	**<0.01**
Presence of Neurologic disorder (%)	**12.1%**	**23.7%**	**10.9%**	**<0.01**
Presence of heme disorder	51.1%	57.9%	50.4%	0.084
Presence of low complement (%)	**44.7%**	**51.3%**	**44.0%**	**0.026**

Comparison of demographics and disease characteristics between patients with SLE and vasculitis to those without vasculitis.



Prevalence of visceral vasculitis organ involvement among patients with SLE.

Methods: We collected data from consented patients within our institutional longitudinal SLE Database. Data included sex, race, ethnicity, age at lupus onset, SLE classification criteria, medical history, and complications in patients' disease course, including history of vasculitis. If history of vasculitis was present, notes from the database visits and electronic medical record encounters were reviewed to determine what type of vasculitis was present and which organ systems were involved. Once form of vasculitis and organ involvement was confirmed, Stata v15 was utilized to perform descriptive statistics, Chi-squared, Fisher's exact, and t-tests, as appropriate.

Results: Of the 804 patients with SLE included our study, 728 (90.5%) were female, 595 (74%) were Black, and 76 (9.5%) had a history of vasculitis (**Table 1**). 44.7% had visceral vasculitis, 43.4% had cutaneous vasculitis, 7.9% had both cutaneous and visceral vasculitis. Out of the 40 patients that had visceral vasculitis, the breakdown of specific organ involvement was noted (**Figure 1**). Overall, most of patients with vasculitis had CNS, abdominal, or pulmonary involvement. The mean age of SLE onset in patients with vasculitis was 27.3 ± 13.0, compared to 31.5 ± 14.0 in patients without vasculitis. We analyzed the correlation between vasculitis and many factors, including race, ethnicity, symptoms such as arthritis and serositis, smoking history, and others (**Table 1**). We found that presence of other autoimmune disorders, history of renal disorder, and history of neurologic disorder, and low complement was associated with the development of vasculitis. Although mortality rates were higher among patients with vasculitis (21.1% vs 14.0%, p=0.099), the difference was not statistically significant.

Conclusion: Among patients with SLE from a unique population-based cohort, vasculitis was a less common (9.5%) manifestation, yet with important implications for SLE severity and organ involvement. Given the low prevalence of vasculitis, we were limited in ability to identify rare associations, however the strong negative association with arthritis adds to what was previously described in the literature. Based on our findings, presence of low complement, renal, and/or neurologic disorder among patients with SLE could be important clues to the identification of early vasculitis, prompting recognition and treatment which is crucial to improve outcomes.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) can result in impaired daily physical function through various mechanisms including active disease, chronic damage, and mental health symptoms that are common in the disease. However, the key drivers of reduced physical function are poorly understood, and no large-scale global studies investigating this have been conducted to date. Our objective is to investigate key factors that contribute to impaired physical function in SLE globally.

Methods: SLE patients were identified from the COVAD 2 database, a global register of more than 20,000 respondents. Healthy controls (HC) were included to compare differences in physical function using the Patient Reported Outcome Measurement Information System (PROMIS) questionnaire. Demographics, medication, comorbidities, disease activity, Global Physical Health (GPH) and Global Mental Health (GMH) were collected. Multivariable regression analysis was used to identify contributing factors to favourable or poor physical function (measured by PROMIS Physical Function shortform PF-10a score).

Results: 979 SLE patients and 3358 HCs were included in analysis. Patients with SLE had significantly lower PF-10a score as compared to HCs (median 42, IQR 36-47 vs median 49, IQR 45-50, p< 0.0001), as shown in Figure 1. Determinants of physical function status in patients with SLE are summarised in Table 1. Briefly, factors associated with poor physical function included increasing age (-0.042, 95% CI -0.069 to -0.015, p=0.002) and methotrexate use (-0.928, 95% CI -1.844 to -0.012, p=0.047). Diabetes (-1.862, 95% CI -3.481 to -0.243, p=0.024) and interstitial lung disease (ILD) (-2.441, 95% CI

-4.366 to -0.517, p=0.013), but not asthma or COPD, also contributed to lower PF-10a score. From a mental health perspective, anxiety (-0.970, 95% CI -1.853 to -0.087, p=0.031) but not depression contributed to a lower physical function score. Higher Pain Visual Analogue Scales (VAS) (-2.889, 95% CI -3.107 to -2.671, p< 0.001) and Fatigue VAS (-1.459, 95% CI -1.974 to -0.945, p< 0.001) also contributed to lower PF-10 scores. Hydroxychloroquine use (0.844, 95% CI 0.190 to 1.498, p=0.012) and higher GPH score (2.287, 95% CI 2.079 to 2.494, p< 0.001) were associated with favourable physical function.

Conclusion: Patients with SLE show significantly reduced physical function compared with HCs. Key contributors to poor physical function include intercurrent diabetes and ILD. Screening for, and aggressive early treatment of these conditions may confer improved long-term function. As expected, higher levels of pain and fatigue were associated with poor physical function. Methotrexate use was also identified as a contributing factor to reduced function, which could represent its use in articular manifestations that limit physical function. Importantly, use of hydroxychloroquine was associated with favourable physical function, which might be due to its protective effect in preventing damage, adding to the well-recognised benefits of this drug in SLE.

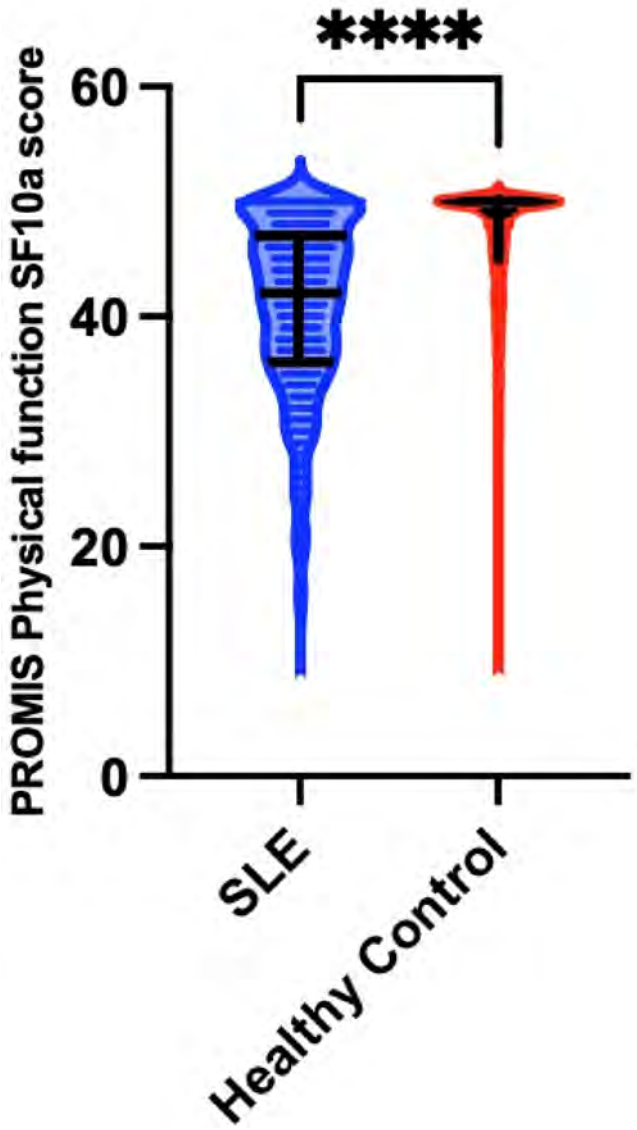

Figure 1: This figure demonstrates that patients with SLE had significantly lower PROMIS Physical Function SF10a scores as compared to healthy controls (median 42, IQR 36-47 vs median 49, IQR 45-50, P<0.0001)

Table 1: This table summarises the determinants of physical function status in patients with SLE

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk of serious infections that varies with the severity of the disease, use of immunosuppressives, including glucocorticoids (GC), and damage, among others. Estimating the infection risk in these patients is important to balance the immunosuppression but there is no evidence-based and suitable tool available to make a prediction of severe infection in these patients.

The SLESIS score had been previously developed for the prediction of severe infections in SLE and was initially validated in an external cohort[1]. This score had 7 predictors, including the Katz index (SKI), a severity score for SLE with a limited degree of validation and difficult to implement in daily practice. Moreover, its performance was only moderate, with an AUC of 0.63 (95% CI: 0.56 - 0.70).

The objective of our study was to improve the SLESIS score in terms of prediction accuracy and feasibility.

Methods: We used the prospective phase of RELESSER (RELESSER-P), the SLE register of the Spanish Society of Rheumatology, a register that includes patients with SLE or incomplete SLE (91%≥4 ACR 1997 criteria) from 45 centers. The outcome variable was any serious infection identified over the first year of follow up, with serious infection being defined as one leading to hospitalization or death.

The sample was randomly divided into development and validation cohorts. A multivariable logistic model was populated with those variables already forming the SLESIS score, including clinical characteristics, demographic features, hospitalization by SLE comorbidities and treatments [2] plus all other potential predictors identified by literature review and available in the first visit of RELESSER-P.

The most parsimonious model with the least information criteria (AIC and BIC) were chosen as the final model. The performance of the final model was analyzed with C-statistics and AUC. Internal validation was tested using bootstrap techniques.

Table 1. Univariate analysis. Variables associated with serious infection.

Potential predictors	OR (95%CI)	p-value
Aged	**1.04 (1.01 - 1.07)**	**0.006**
Female	1.22 (0.28 - 5.23)	0.789
Latin American	0.90 (0.12 - 6.77)	0.918
Active smoking	1.45 (0.56 - 3.78)	0.446
Charlson's Index	**1.34 (1.15 - 1.56)**	**<0.0001**
Diabetes	0.33 (0.53 - 6.44)	0.333
Malignancy	1.28 (0.21 - 7.67)	0.788
Chronic kidney disease	**3.82 (1.54 - 9.44)**	**0.004**
Disease activity (SELENA-SLEDAI)	1.03 (0.94 - 1.13)	0.559
Damage (SDI)	**1.29 (1.13 - 1.48)**	**<0.0001**
Severity Katz Index (SKI)	**1.33 (1.12 - 1.58)**	**0.001**
SLE-related hospitalization	**15.50 (5.26 - 45.69)**	**<0.0001**
Previous serious infection	**14.78 (6.41 - 34.1)**	**<0.0001**
Creatinine	1.02 (0.88 - 1.19)	0.756
Lymphopenia any time	1.45 (0.57 - 3.68)	0.439
Hypocomplementemia	1.00 (0.43 - 2.30)	1.000
Maximal GC dose over the period (prednisone)	-	-
≤ 5 mg	1	NA
> 5 mg and <10	2.31 (0.68 - 7.81)	0.177
≥ 10 mg and <30	2.00 (0.52 - 7.68)	0.311
≥ 30 mg	**7.47 (1.87 - 29.82)**	**0.004**

SLE: Systemic lupus erythematosus; SDI: SLICC/ACR DAMAGE INDEX; GC: glucocorticoids

Table 2. Adjusted final multivariate predictive model.

Predictor	OR (95%CI)	p-value
Age	1.03 (1.00-1.06)	0.040
Previous SLE-related hospitalization	3.81 (1.33-10.97)	0.013
Previous serious infection	3.72 (1.58-8.77)	0.003
Having received a GC dose ≥30 mg	4.45 (1.34-14.76)	0.015

SLE: Systemic lupus erythematosus; GC: glucocorticoids

Results: A total of 1459 patients who had completed visit 2 (one year of follow up),or had information on infections or death in the period, were included in the development cohort (mean age of 49 ± 13, 90% females). Twenty-five (1.7%) had experienced at least one serious infection.

The results of univariate analysis are shown in Table 1.According our final, adjusted multivariate model, serious infection in SLE could be predicted from 4 variables (Table 2) and the SKI could be excluded from the model. The model correctly classified 97% of the infections with C-statistic = 0.82 (0.67 - 0.92) and a Hosmer-Lemeshow p=0.997. The AUC was 0.88 (0.80 – 0.96).

Conclusion: The revised SLESIS score (SLESIS-R) is a fairly accurate and feasible instrument to predict infections in SLE patients in the daily clinical practice that could help making informed decisions on the use of immunosuppressive or biological therapy in SLE patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of depression and associated factors in systemic lupus erythematosus (SLE) are not well known and there are no longitudinal studies addressing this relevant subject in SLE.We aimed to evaluate the prevalence of self-perceived depression in patients with SLE and associated factors in a large, multicenter cohort (RELESSER-PROS).

Methods: Prospective longitudinal study. Patients with SLE (1997 ACR criteria) answering positively to the depression question of the Lupus Impact Tracker (LIT) questionary (LITQ7), over 4 years of follow-up (5 annual visits, V1 to V5). Self-perceived depression was addressed as "depression any time" or "depression most of time", according to the kind of answer to the LITQ7 (answers 1,2,3 or 4 and answers 3 or 4 respectively). Only patients with no missing values in the covariates, were included in the multivariable analysis. The following covariates were considered: SLEDAI, age, duration of the disease, SLICC/AR DI (SDI), fibromyalgia, Charlson index, smoking, BMI, menopause, sedentary lifestyle, marital status,

Table 1: best multivariable GEE model

	OR	Lower limit	Upper limit
(Intercept)	0,121	0,028	0,529
SLEDAI	1,066	0,991	1,147
SLICC/ACR DI	1,138	0,962	1,346
Age	1,022	0,994	1,051
Fibromyalgia	2,898	1,576	5,328
BMI	1,485	0,685	3,219
Unemployment	1,86	0,972	3,56
Low incomes	1,726	0,89	3,347
Glucocorticoids use	1,853	1,173	2,928
Single marital status	1,292	0,766	2,179
QICC: 1006.75			
SLICC/ACR DI: SLICC/ACR damage index; BMI: body mass index			

unemployment and glucocorticoid (GC) use. Friedman test was used to test if the change in repeated measures. Generalized estimating equation (GEE) models with binomial response, were built exploring the associations of individual longitudinal determinants with longitudinal assessment of depression. The best model was selected using quasi-likelihood under the independence model information criterion

Results: A total of 1463 were included. Mean age: 55 (DS±13) years, 90% were female. Mean duration of the disease: 14 (±8.59) years. Fibromyalgia was present in 5.7% (76/1343). Corticosteroids use ranged from 49.4% to 57%, depending on the visit. Median SLEDAI ranged from 0 to 2 and SDI ranged from 1 to 2.

Prevalence of "depression any time" was 89.9% (1104/1228) and 34.6% (200/578) were in depression "most of time". Up to 26.5% (153/578) answered to LITQ7 "depression most of time" in the five visits; 89.7% of the patients which perceived themselves as depressed at least in 2 out of 5 visits. Only 6.9% of the patients with previous diagnosis of depression answered "0" to the Q7 of LIT ("none of the time").

Patients with "depression any time" develop more damage at V5 than patients without depression (answer to LITQ7=0) ($p = 0.00931$, T-test). In the GEE binomial analysis considering all the predefined covariates, that included only patients with no missing values for any of them (namely, 155 patients), fibromyalgia (OR 2.79; 95%CI: 1.28-6.05), unemployment (OR 1.95; 95%CI 1.02 -3.73), and GC use (OR 1.88; 95%CI 1.18-2.99) were significant associated with "depression any time".

The best model (according QIC) displayed a statistically significant association only with fibromyalgia (OR 2.90; 95%CI: 1.58-5.33) and GC (OR 1.85; 95%CI 1.17-2.93). (Table 1). Without entering glucocorticoids, SLEDAI turns significant in the model, suggesting collinearity.

Conclusion: The prevalence of self-perceived depression is high in SLE. Longitudinal data analysis suggests a causal relationship between glucocorticoids use, fibromyalgia and self-perceived depression.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) and lupus nephritis (LN) are at increased risk of cardiovascular (CV) morbidity and mortality, compared to those without LN due to the additional burden of kidney involvement, inflammation, and potential renal impairment contributing to cardiovascular complications. This elevated risk may be associated to the higher values of left ventricular (LV) mass observed in SLE patients, particularly when compared to age and sex-matched controls. Echocardiographic evaluation is not included in current guidelines for managing CV risk in

Figure 1. Comparison of demographic characteristics between SLE patients with and without LN.

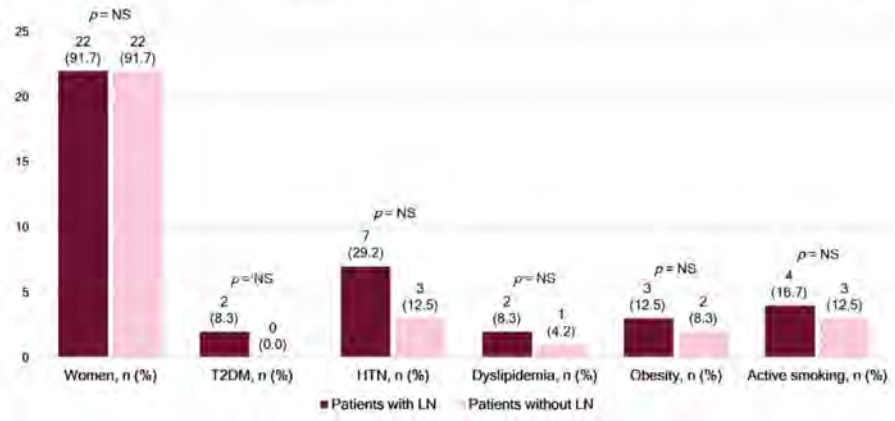

Table 1. Comparison of echocardiographic findings of SLE patients with and without LN.

Variables	Patients with LN (n=24)	Patients without LN (n=24)	*p*-value
LV mass index, g/m^2, mean ± SD	66.9 ± 21.8	54.8 ± 16.1	**0.035**
RWT, mean ± SD	0.37 ± 0.08	0.34 ± 0.10	0.265
LV geometry abnormality, n (%)	7 (29.2)	4 (16.7)	0.303
LAESVI, ml/m^2, mean ± SD	29.72 ± 10.80	26.04 ± 8.76	0.208
LVEF, %, mean ± SD	58.16 ± 7.42	58.04 ± 7.04	0.953
LVESV, ml, median (IQR)	39.0 (26.0-54.5)	32.5 (23.7-39.7)	0.185
LVEDV, ml, mean ± SD	92.10 ± 25.09	81.57 ± 27.80	0.211

SLE, systemic lupus erythematosus; LN, lupus nephritis; LV, left ventricular; RWT, relative wall thickness; LAESVI, left atrial end-systolic volume index; LVEF, left ventricular ejection fraction; LVESV, left ventricular end-systolic volume; LVEDV, left ventricular end-diastolic volume.

SLE, systemic lupus erythematosus; LN, lupus nephritis; LV, left ventricular; RWT, relative wall thickness; LAESVI, left atrial end-systolic volume index; LVEF, left ventricular ejection fraction; LVESV, left ventricular end-systolic volume; LVEDV, left ventricular end-diastolic volume.

patients with rheumatic diseases. This study aimed to compare LV mass and other echocardiographic parameters between SLE-patients with and without LN.

Methods: We performed a nested case-control study among the SLE-cohort from our center. This cohort includes patients older than 18 years who fulfill the 2019 EULAR/ACR Classification Criteria for SLE. Patients with LN were matched with patients without LN by age and gender. A transthoracic echocardiogram was performed by two certified echocardiographers blinded to clinical information. Comparisons were done with Chi-square or Fisher's exact test for qualitative variables, and Student's T-test or Mann-Whitney's U-test for quantitative variables. A p-value < 0.05 was considered significant.

Results: A total of 48 SLE patients, 24 with LN and 24 without LN, were included. Both groups were similar regarding age (36.9 vs 36.5, $p = 0.873$) and prevalence of traditional CV risk factors including type 2 diabetes mellitus, hypertension, dyslipidemia, obesity, and smoking (Figure 1). LV mass index was significantly higher in SLE patients with LN (66.9 g/m^2 vs 54.8 g/m^2, $p = 0.035$) in comparison to those without it. There was no difference regarding other echocardiographic parameters (Table 1).

Conclusion: LV mass measurements were higher in patients with SLE and LN in comparison to patients without LN, regardless of traditional CV risk factors. The consequences of increased LV mass can include an elevated risk of CV events such as heart failure, cardiac arrhythmias, and CV mortality. Further studies are necessary to establish the potential role of echocardiography in the CV assessment of patients with SLE, especially those with LN.

Association of Disease Activity and Anti-Double Stranded DNA Antibodies Titers with Echocardiographic Parameters in Systemic Lupus Erythematosus Patients

Natalia Guajardo-Jauregui[1], Iris Colunga[2], José Ramón Azpiri-López[2], Dionicio A. Galarza-Delgado[2], Jesus Alberto Cardenas-De la Garza[3] and Rosa Arvizu-Rivera[4], [1]Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico, [2]Hospital Universitario UANL, Monterrey, Mexico, [3]Hospital Universitario "Dr. José Eleuterio González", San Nicolas, Mexico, [4]Hospital Universitario \"Dr. José Eleuterio Gonzalez\", Escobedo, Mexico

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease that involves the deposition of immunocomplexes on vital organs, including the heart. Cardiovascular disease is the leading cause of long-term mortality in SLE patients, and their increased risk of cardiovascular events is attributed to disease characteristics, such as the systemic inflammatory state associated with the disease. In this study we aimed to evaluate the association of disease characteristics, such as the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and anti-double stranded DNA antibodies (anti-dsDNA) titers, with echocardiographic parameters in patients with SLE.

Methods: This was a cross-sectional study. We recruited 75 SLE patients aged ≥ 18 years who fulfill the 2019 EULAR/ACR Classification Criteria for SLE. Patients with a previous cardiovascular event, another connective tissue disease or pregnancy were excluded. A transthoracic echocardiogram was performed by two certified echocardiographers blinded to clinical information. A blood sample was drawn to measure anti-dsDNA antibody titers and disease activity was evaluated with SLEDAI. Correlations were assessed with Spearman's correlation coefficient (rs). A p-value < 0.05 was considered statistically significant.

Results: Median age of SLE patients was 37 (25-44) years with a median SLEDAI of 8.0 (4.0-12.0). The rest of demographic and clinical characteristics are shown in Table 1. We found a positive correlation between SLEDAI and left ventricular mass index (rs=0.243, p=0.036), between SLEDAI and the ratio between early mitral inflow velocity and mitral annular early

Table 1. Demographic and clinical characteristics.

Variable	SLE patients (n=75)
Women, n (%)	67 (89.3)
Age, median (IQR)	37 (25-44)
T2DM, n (%)	3 (4.0)
Hypertension, n (%)	17 (22.7)
Dyslipidemia, n (%)	8 (10.7)
Obesity, n (%)	12 (16.0)
Active smoking, n (%)	10 (13.3)
Disease duration months, median (IQR)	72 (18-132)
SLEDAI, median (IQR)	8 (4-12)
Anti-dsDNA antibody titers, median (IQR)	0 (0-160)
LV mass index, median (IQR)	63.5 (50.9-79.6)
E/e', median (IQR)	7.1 (5.9-8.7)
LAVI, median (IQR)	25.9 (20.8-31.1)
LVEF, median (IQR)	59.2 (7.9)

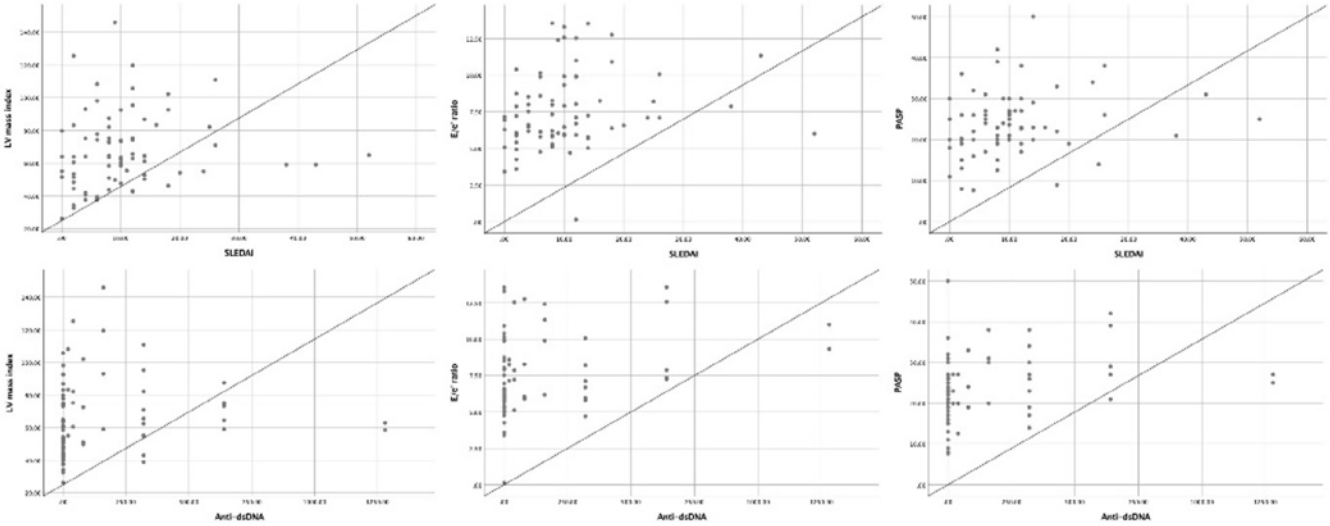
PASP, median (IQR)	23.0 (20.0-27.0)

SLE systemic lupus erythematosus; *T2DM* type 2 diabetes mellitus; *SLEDAI* Systemic Lupus Erythematosus Disease Activity Index; *dsDNA* double stranded DNA; *LV* left ventricular; *E/e'* the ratio between early mitral inflow velocity and mitral annular early diastolic velocity; *LAVI* left atrial volume index; *LVEF* LV ejection fraction; *TAPSE* tricuspid annular plane systolic excursion; *PASP* pulmonary arterial systolic pressure.

SLE systemic lupus erythematosus; T2DM type 2 diabetes mellitus; SLEDAI Systemic Lupus Erythematosus Disease Activity Index; dsDNA double stranded DNA; LV left ventricular; E/e' the ratio between early mitral inflow velocity and mitral annular early diastolic velocity; LAVI left atrial volume index; LVEF LV ejection fraction; TAPSE tricuspid annular plane systolic excursion; PASP pulmonary arterial systolic pressure.

Figure 1. Scatter plots of correlations between SLEDAI, anti-dsDNA and echocardiographic parameters.



diastolic velocity (E/e') (rs=0.277, p=0.016) and between SLEDAI and pulmonary arterial systolic pressure (PASP) (rs=0.271, p=0.019). We also found a positive correlation between anti-dsDNA and left ventricular mass index (rs=0.264, p=0.022), between anti-dsDNA and E/e' (rs=0.295, p=0.010), and between anti-dsDNA and PASP (rs=0.292, p=0.011) (Figure 1).

Conclusion: Our study demonstrated significant associations between higher SLEDAI and anti-dsDNA with increased left ventricular mass index, E/e' and PASP, which could lead to the progression of ventricular hypertrophy, diastolic dysfunction, and pulmonary hypertension respectively, suggesting a potential role of disease activity and anti-dsDNA in the development of adverse cardiac remodeling and function in SLE patients. A transthoracic echocardiogram may be helpful to detect early cardiovascular abnormalities, especially in patients with high disease activity and anti-dsDNA titers, and therefore, should be considered as part of the cardiovascular evaluation of SLE patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the development of a systemic autoimmune rheumatic disease (SARD) in undifferentiated and asymptomatic individuals with antinuclear antibodies (ANA). We evaluated fulfillment of classification criteria and comparatively evaluated manifestations between those who did and did not develop a SARD.

Methods: We conducted a retrospective cohort study of undifferentiated (UCTD) and asymptomatic patients with ANA who were assessed at baseline and annually for developing signs, symptoms, and serology of a SARD. The primary outcome was a physician-based diagnosis of SARD over two years. We assessed fulfillment of classification criteria and used risk ratios (RR) to evaluate differences in manifestations in those who did and did not progress to a SARD.

Results: We evaluated 207 asymptomatic ANA^+ or UCTD subjects, of whom 20 (9.7%) progressed to a SARD while 187 (90.3%) did not progress. Progressors developed systemic lupus erythematosus (SLE) (n=11 (55%)), Sjogren's disease (n=5 (25%)), systemic sclerosis (n=3 (15%)) and rheumatoid arthritis (n=1 (5%)). Fever occurred less frequently in those who progressed to a SARD (RR 0.90, 95%CI 0.86, 0.94). Among SLE patients, 100% fulfilled the EULAR/ACR SLE criteria (sensitivity 91.7%, specificity 100%), whereas 73% fulfilled the 1997 ACR SLE criteria (sensitivity 81.8%, specificity 98.9%). Progressors to SLE had arthritis (91%), hypocomplementemia (45%), alopecia (36%), oral ulcers (27%), acute cutaneous lupus (18%), subacute cutaneous lupus (18%), and pericarditis (18%); while none developed delirium, psychosis, seizures, or lupus nephritis.

Conclusion: Most undifferentiated/asymptomatic individuals with ANA do not progress to a SARD over two years. The EULAR/ACR SLE criteria have improved the ability to identify those who develop SLE. SLE progressors appear to have mild disease in the short term.

Clinical Manifestations and Outcomes in Systemic Lupus Erythematosus Patients Who Received Antiviral Therapy During the COVID-19 Omicron Variant Wave: Results from a Single Center Cohort of Puerto Rico

Lilliana Serrano-Arroyo[1], Rafael Ríos-Rivera[2], Ariana González-Meléndez[2] and Luis M. Vilá[2], [1]Centro Medico Episcopal San Lucas, San Juan, PR, [2]University of Puerto Rico Medical Sciences Campus, San Juan, PR

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The impact of COVID-19 in patients with systemic lupus erythematosus (SLE) has been a subject of great concern. Antiviral therapy has emerged as a key approach in the treatment of COVID-19 in the general population, but their efficacy in SLE patients in terms of reducing the risk of hospitalizations, lupus flares, and death remains unclear. Thus, we sought to compare the clinical manifestations and outcomes in SLE patients with COVID-19 that received antiviral therapy to those who did not.

Methods: A cohort of adults (≥21 years) with SLE (per the revised 1997 American College of Rheumatology classification criteria) from a single center in Puerto Rico who had COVID-19 during the Omicron period (December 2021 to December 2022) were studied. SARS CoV-2 infection was confirmed by polymerase chain reaction or antigen tests. Antiviral therapy (nirmatrelvir/ritonavir or molnupiravir) was prescribed to those who presented with mild-to-moderate infection. Demographic parameters, cumulative SLE manifestations, disease activity, damage accrual, lupus treatments, comorbidities, COVID-19 symptoms, emergency room (ER) visits, hospitalizations, SLE flares, and mortality were compared between patients that received antiviral therapy and those who did not using bivariate and multivariate analyses adjusted for age.

Results: Out of 347 SLE patients, 147 (42.4%) had COVID-19 during the Omicron wave. Among these patients, 35 (23.8%) received antiviral therapy as they presented with mild-to-moderate symptoms. The rest of the cohort had mild symptoms. Older age, pleuritis, diabetes mellitus, some COVID-19 symptoms (dyspnea, vomiting, and diarrhea), and ER visits were significantly more common in patients that received antiviral therapy compared to those who did not (Table 1). All these

Table 1. Demographic characteristics, clinical features, and outcomes of SLE patients with COVID-19 who received antiviral therapy versus those who did not.

Table 1. Demographic characteristics, clinical features, and outcomes of SLE patients with COVID-19 who received antiviral therapy versus those who did not.

Characteristics	All patients (n=147)	Antiviral therapy (n=35)	No antiviral therapy (n=112)	p-value

Diarrhea	2.75 (1.13-6.69)	2.54 (1.02-6.37)
Emergency room visit	4.58 (1.68-12.46)	5.31 (1.83-15.38)

*No antiviral use is the reference group. Model adjusted for age. OR: Odds ratio; CI: Confidence interval

variables retained significance in the multivariate analysis (Table 2). No significant differences were observed for sex, disease duration, disease activity, disease damage, SLE treatments, hospitalizations, SLE flares, and mortality.

Conclusion: In this cohort of Puerto Ricans with SLE who had COVID-19 during the Omicron period, patients who required antiviral therapy were older and more likely to have pleuritis, diabetes mellitus, and more COVID-19 symptoms than those who did not receive antiviral treatment. Despite having these clinical manifestations and risk factors for severe outcomes, those who were treated with antiviral drugs had a favorable outcome in terms of hospitalizations, SLE flares, and mortality.

Evaluation of Changes in SLE Patients' Phenotype at Disease Onset, and Assessment of Disease Activity, Damage and Therapy at Diagnosis and During Follow up in the Last Forty Years: Preliminary Data of a Single Center Experience

Micaela Fredi[1], Silvia Ebe Lucia Della Pina[1], Claudia Barison[1], Chiara Orlandi[1], Marzia Tedeschi[2], Mai Chiara[2], Cecilia Nalli[1] and Franco Franceschini[1], [1]Rheumatology and Clinical Immunology, ASST Spedali Civili of Brescia, Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy, [2]University of Brescia, Brescia, Italy

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease associated with a high degree of variability at onset, which may make SLE diagnosis challenging, with an estimated time between onset of symptoms and diagnosis of 24 months[1]. Moreover, in SLE early diagnosis and therapeutic advances have led to better improve outcomes, and achievement of persistent low disease activity and/or remission have been associated with reduced long-term organ damage. The aim of this study was to evaluate the changes in the onset pattern of SLE in demographic and clinical terms, and for changes in assessment and therapy at diagnosis and during the f-up.

Methods: Medical records of 125 patients diagnosed between 1970 to 2019 and regularly followed up were reviewed. Patients were divided into 4 groups based on the year of diagnosis: 1970-'89, 1990-'99, 2000-'09, 2010-'19. Disease activity, cumulative organ damage and remission were recorded according to validated indices (SLEDAI-2K, SLEDAS, SLICC Damage Index, LLDAS and DORIS) at the time of diagnosis (T0) and at 1 (T1), 5 (T2) and 10 (T3) years after. GCs (both in absolute terms and daily dosage), hydroxychloroquine (HCQ) and DMARDS use were also evaluated at the same time

Categorical variables were reported as proportion and/or percentage, continuous variables were expressed as mean (±standard deviation) values. Qualitative variables were compared with Chi-Squared or Fisher's exact test, quantitative variables with one-way Anova or Mann-Whitney test.

points. Qualitative variables were compared with Chi-Squared or Fisher's exact test, quantitative variables with one-way Anova or Mann-Whitney test

Results: Our cohort consisted of 119 females and 6 males; the mean age of onset was 30,62 years and the mean age of diagnosis was 31,95. Mean age of onset, and consequently mean age of diagnosis, has significantly increased in different groups (p=0,0011) (Figure 1). We observed a decreasing trend in the mean diagnostic delay from 28,25 months to 11,6 although without statistical significance (p=0,5015). Concerning the clinical presentation at onset, the most frequent symptoms observed were musculoskeletal (78,23%) and mucocutaneous (70,97%).

Evaluating patients at the time of diagnosis through the different decades (Figure 2), no significant changes were found in disease activity or damage, nor in the treatment except in the early use of HCQ: from less than 50% before 1999, to more than 70% of patients (p=0.0069). As for disease activity, a significant variation in the different decades appears at T2, with a reduction in SLEDAI (p=0.0120) and a higher number of patients reaching LLDAS and DORIS (both p< 0.0001); similar results were confirmed at T3 for both indexes. As for the use of GCs, no difference was observed in number of patients treated, although a significant reduction in GCs daily dose was observed at T2 and T3 (p< 0.0001 and p=0.0092 respectively). Finally, in patients with a more recent diagnosis, an increased use of HCQ (p< 0.0001 for T2 and p=0.0022 for T3) and DMARDS (p=0.0127 at T3) was observed during f-up

Conclusion: Our preliminary data demonstrated a progressive increase in the mean age at the onset of SLE over the years. However, this increase does not deviate from the mean age range defined in the literature [2].Moreover, our data reflect the therapeutic improvements of the past decades characterized by use of lower doses of GCs, increased use of HCQ and DMARDS and faster achievement of LLDAS and DORIS.

Inflammatory Markers and Left Ventricular Dysfunction in Systemic Lupus Erythematosus (SLE)

Audrey Hagiwara, Moumita Bose, Marianne Bernardo, Michael Nelson, Mariko Ishimori, Daniel Berman, C. Noel Bairey Merz, janet wei and Caroline Jefferies, Cedars-Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with SLE have an elevated risk of cardiovascular disease. Many women with SLE frequently report chest pain in the absence of obstructive coronary artery disease (CAD) due to coronary microvascular dysfunction (CMD), a form of ischemia with no obstructive CAD (Manchanda et al, 2022). Echocardiographic studies have shown that SLE patients have reduced left ventricular (LV) function, which may also correlate with higher SLE disease activity scores

Table 1: Baseline Characteristics of Female SLE Participants. There was no group difference in clinical and laboratory values in the SLE participants with and without CMD. Complement 3 (C3); Complement 4 (C4); Erythrocyte Sedimentation Rate (ESR); C-Reactive Protein (CRP); Antinuclear antibody (ANA); Ribonucleoprotein (RNP); Smith (Sm); Anti-topoisomerase I antibody (Scl-70).

T1	1263 ± 35	1259 ± 56 (n=11)	NS
ECV	29 ± 3	29.3 ± 2.3 (n=11)	NS

(Gegenava et al, 2020). As such, we used cardiac magnetic resonance imaging (cMRI) to investigate the relationship between SLE, related inflammatory biomarkers, and cardiac function in female SLE patients.

Methods: We performed stress cMRI in women with SLE and chest pain with no obstructive CAD (n=13, all met ACR 1997 criteria, **Table 1**) and reference controls (n=22) using our published protocol (Aldiwani et al, 2022). We evaluated LV function, tissue characterization (T1 mapping, ECV), and delayed enhancement, using CV142 software (Circle Cardiovascular Imaging Inc, Calgary, AB, Canada). Myocardial perfusion reserve index (MPRI) was calculated using our published protocol (Thomson et al, 2015). SLEDAI and SLICC Damage Index (DI) were calculated per validated criteria (Bombardier et al, 1992, Gladman et al, 1997). Serum samples were analyzed for inflammatory markers and autoantibodies (**Table 1**). Independent two-tailed t test was performed on clinical values with CMD and no CMD SLE subjects, and on cMRI values with all SLE subjects and controls. Correlation analysis was done on clinical values, and cMRI values on all SLE subjects.

Results: Overall, 40% of SLE subjects had MPRI values < 1.84, consistent with CMD. Compared to controls, SLE subjects had significantly lower LVEF, and higher LVESVi and LVMi (**Table 2**). Corresponding to this, radial, longitudinal, and circumferential strain were significantly lower in the SLE subjects. In correlation analysis of serum inflammatory biomarkers to cMRI values in the SLE subjects, SLICC DI was related to worse cardiac function (lower radial, circumferential and longitudinal strain) and higher T1 time (**Table 3**). Additionally, fasting insulin and ESR were negatively correlated with LVMi. Fasting insulin also negatively correlated with ECV. CRP had a positive association with LVESV index and CI and a negative association with longitudinal strain.

Table 3: Correlation analysis of cardiac function versus clinical values from SLE participants in the study. The Spearman r coefficient (r) and p value (p) is shown. Ejection Fraction (EF); Cardiac Output (CO); Left Ventricular (LV) Systolic Volume (LVSV); LV mass (LVM); Body Surface Area (BSA); Extracellular Volume (ECV); Systemic Lupus International Collaborating Clinics (SLICC) Damage Index; C-reactive Protein (CRP); Erythrocyte Sedimentation Rate (ESR).

		SLICC	CRP	Fasting Insulin	ESR
EF (%)	*r*	-0.54			
	p	*0.06*			
CO (L/min)	*r*		0.57		
	p		*0.04*		
LVSV/BSA (mL/m^2)	*r*		0.53		
	p		*0.07*		
CO/BSA (L/min/m^2)	*r*		0.57		
	p		*0.05*		
LVMASS/BSA (g/m^2)	*r*			-0.66	-0.60
	p			*0.03*	*0.03*
Radial Strain	*r*	-0.74			
	p	*0.00*			
Circumferential Strain	*r*	0.67			
	p	*0.01*			
Long strain	*r*	0.50	-0.53		
	p	*0.08*	*0.07*		
native T1	*r*	0.62			
	p	*0.03*			
ECV	*r*			-0.66	
	p			*0.03*	

Conclusion: Among women with SLE with chest pain and no obstructive CAD, 40% have CMD. While evaluations of known inflammatory markers (such as ESR and CRP) predictably correlated with decreased cardiac function (Lertratanakul et al, 2014), our study found that decreased fasting insulin levels is a novel marker associated with diminished LV function. In addition, although studies have used SLEDAI as a marker of disease activity when assessing cardiac dysfunction, we are the first to demonstrate that SLICC DI, an assessment of SLE damage, is also correlated with cardiac dysfunction in SLE. This indicates that SLE patients with higher SLICC DI and increased SLE-related damage could potentially have silent involvement in their cardiac tissue, and as such, SLICC DI is another tool that can be used to evaluate the association between SLE and LV dysfunction.

Musculoskeletal Involvement in Systemic Lupus Erythematosus: Insights from a Survey of Lupus Experts

Rashmi Dhital[1], Maria Dall'Era[2] and Kenneth Kalunian[3], [1]UC San Diego, San Diego, CA, [2]University of California San Francisco, San Francisco, CA, [3]University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal manifestations of systemic lupus erythematosus (SLE) are common, consisting ofarthralgia and arthritis (95%), myalgia/myositis (17%), tenosynovitis, and bursitis (12%). Joint involvement is a common reason for inclusion in SLE clinical trials. Involvement of ≥2 joints with pain and signs of inflammation satisfies 4 points required to meet trial entry criteria [SLE Disease Activity Index 2000 (SLEDAI-2K) ≥6 points and "Clinical" SLEDAI-2K ≥4 points). Likewise, the SRI-4 response which includes ≥4-point reduction in SLEDAI-2K score can be achieved through joint improvement alone and may allow patients with lower 'initial' joint counts to meet the response threshold of involvement of < 2 joints at the trial end with greater ease compared to those with higher entry joint counts. Additionally, not all joint symptoms in SLE patients are directly attributable to lupus, as comorbid osteonecrosis, osteoarthritis, and fibromyalgia can contribute to joint pain, and may not respond to SLE-directed therapy, thus influencing end-outcome attainment. To gain further perspectives into SLE joint involvement, a survey was conducted among lupus experts within the Lupus Clinical Investigators Network (LuCIN) network, a North American consortium of investigators from 54 academic sites who are actively involved in clinical trials.

Methods: The survey was created in Google Forms with questions focused on the most frequent reasons for therapy change in lupus, the frequency of specific joint involvements that prompted therapy change and enrollment into clinical trials, and the number of active joints necessitating a change in patient care (**Table 1**). The survey was disseminated via email to LuCIN investigators.

Results: Out of 54 LuCIN members, 26 responded to the survey. Joint involvement was identified as the most frequent reason for therapy change in non-renal SLE by 30.8% of respondents, and the 2nd and 3rd top reasons by 46.2% and 15.4% of respondents (**Figure 1**). The combination of joint and mucocutaneous manifestations was cited as the top reason for

Table 1. The survey questionnaire disseminated to the Lupus Clinical Investigators Network (LuCIN) Principal Investigators (PIs)

1. What are the top 3 reasons that have prompted you to change therapy in patients with SLE with non-renal disease?
a. Mucocutaneous manifestations (e.g., inflammatory-type rash, alopecia, oral or nasal mucosal ulcers) b. Musculoskeletal manifestations (tender and swollen joints) c. Combination of mucocutaneous and musculoskeletal manifestations d. Constitutional symptoms (fever, malaise, fatigue, loss of appetite, loss of weight) e. Others (please specify)
2. On a scale of 1 to 10, how frequently have the pain, tenderness and swelling of the following joints prompted you to consider changing the patient's care or enrolling them in a clinical trial?
a. Hand PIPs b. Hand MCPs c. Wrists d. Elbows e. Shoulders f. Feet joints (PIPs, MCPs) g. Ankles h. Knees i. Others
3. In your practice, how many of these active joints would require a change in patient's care when encountering such a situation?
a. Hand PIPs (0-10) b. Hand MCPs (0-10)
4. (Optional) If you have any additional comments regarding the topic of musculoskeletal manifestations in lupus, please share them here.

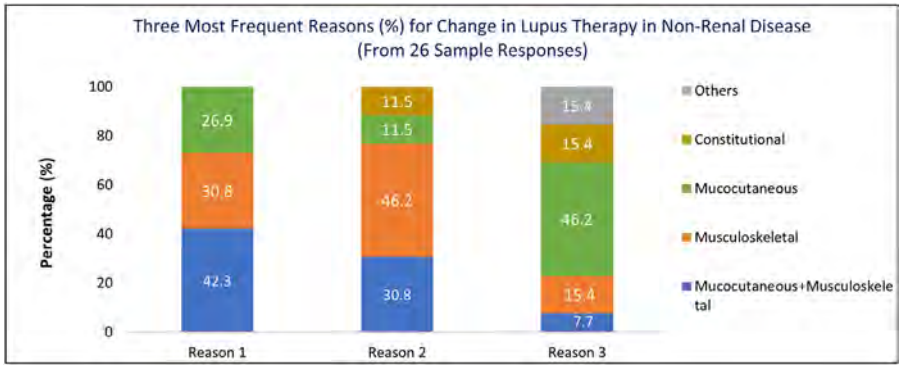

Figure 1. Top Reasons for Therapy Change in Non-Renal Lupus Patients in Clinical Care

therapy change by 42.3% (11/26). MCPs, hand PIPs, wrists, and knees were the joints most frequently associated with therapy change or enrollment in clinical trials (**Figure 2**). The respondents indicated that approximately 3- 4 active MCPs or hand PIPs would prompt a change in therapy.

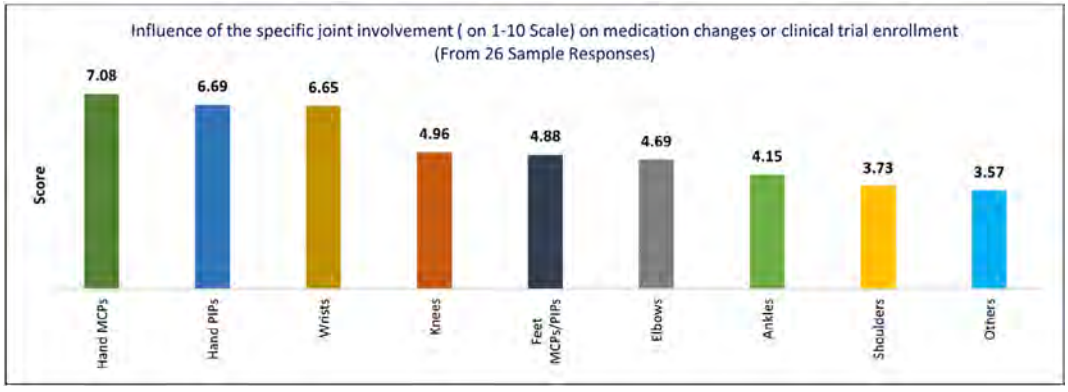

Figure 2. Influence of Specific Joint Involvement (on a 1-10 Scale) on Medication Changes or Clinical Trial Enrollment in Lupus

Conclusion: Joints and the combination of joint and mucocutaneous manifestations were identified as the most common reasons for therapy change in non-renal SLE. MCPs, hand PIPs, wrists, and knees were identified as joints most frequently associated with the decision to change therapy or enroll in a clinical trial. Future Directions: Understanding the pattern and extent of joint involvement over time using data from completed prospective clinical trials may contribute to a more comprehensive understanding of SLE joint manifestations and their influence on trial outcomes. Refined clinical assessment of joints using advanced imaging techniques may improve the characterization of joints and the assessment of interventions in both clinical practice and clinical trials.

Neuropsychiatric Systemic Lupus Erythematosus in Children: A Scoping Review

Alexandra Theisen[1], Ekemini Ogbu[2], Emily Beil[3], Onengiya Harry[4], Simone Appenzeller[5], Ryan Kammeyer[6], Hanne Van der Heijen[7], Andrea Knight[8], Hannah Craven[9] and Martha Rodriguez[10], [1]Saint Louis University School of Medicine, SSM Health Cardinal Glennon Children's Hospital, St. Louis, MO, [2]Cincinnati Children's Hospital Medical Center, University of Cincinnati School of Medicine, Johns Hopkins University, Cincinnati, OH, [3]Baylor College of Medicine / Texas Children's Hospital, Houston, TX, [4]Brenner Children's Hospital - Wake Forest Baptist Health, Winston-Salem, NC, [5]UNICAMP, Campinas, Brazil, [6]University of Colorado School of Medicine, Children's Hospital Colorado, Denver, CO, [7]Boston Children's Hospital, Harvard Medical School, Boston, MA, [8]The Hospital for Sick Children, Toronto, ON, Canada, [9]Ruth Lilly Medical Library, Indiana University School of Medicine, Indianapolis, IN, [10]Indiana University School of Medicine, Riley Hospital for Children, Indianapolis, IN

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Neuropsychiatric systemic lupus erythematosus (NPSLE) remains a challenging entity to diagnose and treat. The clinical heterogeneity of NPSLE coupled with the difficulty with attribution of neuropsychiatric symptoms to SLE contribute to the challenges in diagnosis. Furthermore, recommendations for diagnosis and treatment may be limited in their applicability to childhood-onset SLE (cSLE), as there are limited diagnostic tools and treatments and current evidence is largely extrapolated from adult studies. The objective of this scoping review is to review the current literature on NPSLE in cSLE (cNPSLE), grade the level of evidence and identify knowledge gaps in the scope of clinical manifestations, diagnosis, predictors, treatment, and outcomes of cNPSLE.

Methods: An exhaustive search was performed in MEDLINE, Embase, Cochrane, and PsycINFO. Articles were screened in Covidence. We included articles of systematic reviews, cohort, case-control and cross-sectional studies published between 2000 and 2022, studies involving children aged 18 years or younger diagnosed with NPSLE, and only original manuscripts available in English. Five reviewers performed abstract and full-text screening. Eight reviewers performed data extraction. Full text extraction was performed by two reviewers and any conflicts were resolved by a third reviewer. Thirty-four articles met our study eligibility criteria (Figure 1). The certainty of the evidence was assessed using the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) methodology.

Results: Article characteristics are shown in Figure 2. The prevalence of cNPSLE ranged from 17% to 95%. The mean age in years was 13.7 +/- 4.6. The most common clinical manifestations were cognitive dysfunction (8-100%), headaches (13-85%), and seizures (19-84%). However, some studies did not classify mood disorders or headaches as NPSLE manifestations. Predictive factors of cNPSLE are shown in Table 1. Cerebral and cerebellar volume loss and white matter hyperintensities were the most common findings on MRI, though many patients with active cNPSLE had a normal MRI. PedANAM was the only validated screening tool to assess neurocognitive dysfunction in cNPSLE. Only one study focused primarily on treatment for cNPSLE; this was retrospective and focused on psychosis. Complete recovery of NSPLE ranged from 40-86%, and mortality from 5-45%. Causes of death included status epilepticus, cerebrovascular accident, infection, and brainstem encephalitis.

Conclusion: This scoping review addresses significant knowledge gaps about cNPSLE. Most studies were retrospective, single center studies, with low quality of evidence. The wide range in the prevalence and frequency of cNPSLE manifestations is likely due to the lack of consensus in methods for definition and evaluation of cNPSLE. The evidence of treatment

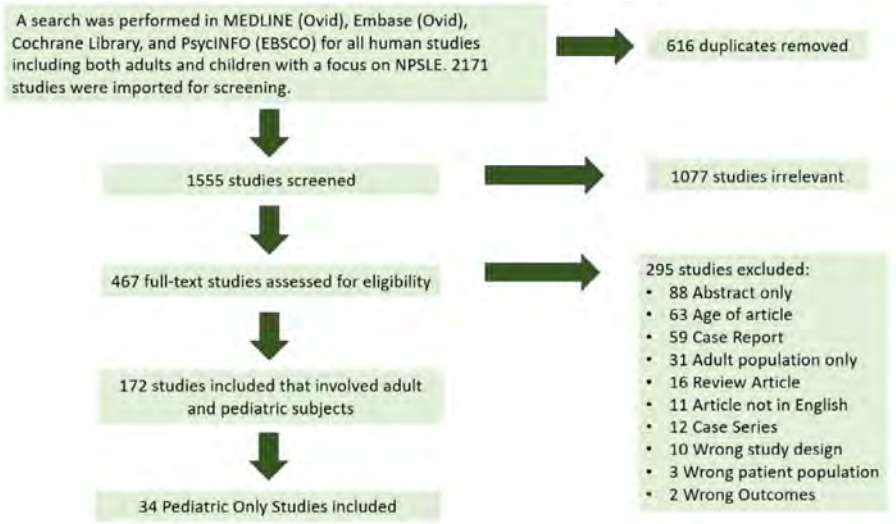

Figure 1: PRISMA Flow Diagram for Scoping Review

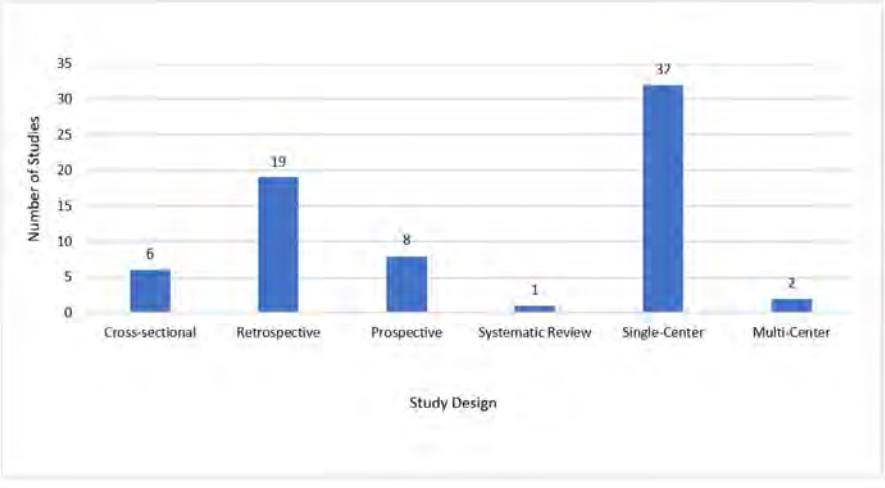

Figure 2: Characteristics of Studies focused on Neuropsychiatric Lupus in Children

Table 1: Articles focused on Predictive Factors for childhood-onset NPSLE

Author and Year	Predictive/Risk Factors	Results	Quality of Evidence
Avcin 2008	anti-B2GP1, LAC	The prevalence of anti-B2GP1 AB was higher in NPSLE compared to those without (p=0.02). There was a significant association between positive LAC and chorea (p=0.02).	Low
Brunner 2014	Serum AP-AB, S100A8/9, ANR2-AB, AGP1-AB, NGAL	aP-AB was more commonly present in SLE with neurocognitive dysfunction than without (p=0.05). There were negative associations between aP-AB, S100A8/9, aNR2-AB, aGP1-AB, and LAC and accuracy rates on Ped-ANAM subtests (p<0.05).	Low
Descloux 2009	Age	The frequency of NPSLE increased when age at disease onset decreased (p=0.037).	Low
Gomes 2016	Age	No differences of NPSLE in three age groups with rates of NPSLE 36%, 25%, and 24% (p=0.236).	Low
Khajezadeh 2018	DsDNA, Platelet count	Higher frequency of dsDNA elevation (p=0.03) and thrombocytopenia (p=0.02) in NPSLE. No difference between NPSLE and SLE as far as sex, age, mortality, or ANA titer (p>0.05).	Low
Knight 2015	Race	Non-White race and longer disease duration were independent risk factors for depression (OR = 3.7, 95% CI 1.5-9.3, P= .005; OR = 1.1, 95% CI 1.01-1.19, P= .02) and suicidal ideation (OR = 7.4, 95% CI 2.3-25.0, P= .001; OR = 1.1, 95% CI1.03-1.27, P= .006). Depression symptoms were associated with increased SLEDAI (OR = 1.1, 95% CI 1.1-1.2, P< .001).	Low
Lisa 2004	RANTES-28G allele	The RANTES −28G allele was more frequent in patients with SLE (23.9% vs 11%; p = 0.006, OR 2.37, 95% CI 1.25–4.28). Patients with −28 C/G RANTES gene had a higher rate of central nervous system SLE (p value not provided).	Low
Mondal 2010	Biologic Sex	The incidence of NPSLE in boys was more than that of girls (66.7% vs. 15.15%; p=0.005).	Very Low
Morsad 2010	HLA-Class II DRB1	Increased HLA-DRB1*15 allele in SLE compared to controls (p=0.004). No association between most frequent HLA-DRB1 alleles and clinical manifestations (including NPSLE) (p=0.41).	Very Low
Mostafa 2009	Antineuronal AB, EEG abnormalities, P300	Antineuronal AB was higher in SLE patients (60%) than controls (3.3%), (p<0.001). Antineuronal AB and abnormalities in EEG and P300 were higher in patients with NPSLE (p < 0.001).	Low
Mostafa 2010	Serum Anti-ganglioside M1 IgG AB, anti-ribosomal P	Patients with and without NPSLE had similar values of anti-ganglioside M1 IgG AB (P= 0.1). Clinical NPSLE had higher anti-ribosomal P AB than patients without clinical NPSLE (p<0.001).	Low
Nowling 2021	Serum Anti-NMDAR AB, Anti-Ribosomal P	Anti-NMDAR AB was higher in SLE patients compared to JIA (p=0.026) but were not associated with any measures of cognitive function in SLE compared with JIA (p>0.05).	Very Low
Singh 2009	Biologic Sex APLA	Male:Female ratio was higher in patients with NPSLE (1:1.125) compared to patients without (1:12), (P<0.0001). No difference in occurrence of APLA in patients with NP events compared to those without (p not provided).	Low
Ulloa 2022	GWAS PRS for Schizophrenia	An increase in GWAS PRS for schizophrenia was not associated with increased odds of having any NPSLE feature vs no features (OR 1.04, 95% CI 0.87–1.26, P = 0.62).	Moderate
Vyas, 2002	Presence of LN+NPSLE	Children with LN and NPSLE had a 5x higher progression rate to ESRD compared to children with LN alone (OR=5.7, P=0.007). There was a higher risk of death in patients with LN + NPSLE than LN alone (p<0.016).	Very Low
Yu, 2007	Lymphopenia, C3 level, DsDNA	Lymphopenia was independently associated with increased risk for NPSLE (OR 7.41, 95% CI 1.99–27.0, P < 0.003). C3 decrease and anti-dsDNA elevation was protective from NPSLE (OR 0.14, 95% CI 0.02-0.87, p=0.035 and OR 0.29, 95% CI 0.1-0.85, p=0.021)	Very Low
Zhu, 2018	SNP-eNOS GT	The genotype GT was higher in NPSLE than in the control group (p=0.028) and the genotype GT rs1808593 was related to pSLE with CNS damage (OR=6.24, 95% CI 1.17-33.15).	Low
Zuniga Zambrano 2014	LAC, APLS	APLS was a risk factor for NPSLE (p=0.03). There were differences regarding the presence of LAC and NPSLE (OR 3.66, 95% CI 1.33-10.03, p=0.01).	Low

AB – antibody; ANA – anti-nuclear antibody; APLA – antiphospholipid antibody; APLS – antiphospholipid syndrome; anti-B2GP1 – anti-beta-2-glycoprotein antibody; CI – confidence interval; CNS – central nervous system; dsDNA – double-stranded DNA; EEG – electroencephalogram; ESRD – end-stage renal disease; GWAS – genome-wide association study; JIA – juvenile idiopathic arthritis; LAC – lupus anticoagulant; LN – lupus nephritis; NMDAR – anti-N-methyl-d-aspartate receptor; NPSLE – neuropsychiatric systemic lupus erythematosus; NP – neuropsychiatric; OR – odd's ratio; SLE – systemic lupus erythematosus; SNP-eNOS – single nucleotide polymorphism of endothelial nitric oxide synthase

for cNPSLE is also sparse. We highlight the need for further prospective, multicenter studies, and consensus regarding approaches to cNPSLE investigation and management. The results of this work also provide the literature background (first phase) in a project to develop a multi-disciplinary, patient-centered prioritized research agenda for cNPSLE.

Risk Factors of Cytomegalovirus Reactivation and Disease in Patients with Systemic Lupus Erythematosus

Miyu Wakatsuki[1], Hiroyuki Yamashita[1], Yuuya Akiyama[1], Setsuko Oyama[1], Shintarou Aozaki[1], Ryo Kuwata[2], Misa Yamaji[1], Takuya Harada[1], Kyouko Motomura[1], Yuusuke Nakamichi[1] and Hiroshi Kaneko[3], [1]National Center for Global Health and Medicine, Tokyo, Japan, [2]Department of Rheumatology, National Center for Global Health and Medicine, Tokyo, Japan, [3]Division of Rheumatic Disease, National Center for Global Health and Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Cytomegalovirus (CMV) infection is classified as an opportunistic infection that occurs in autoimmune diseases. Systemic lupus erythematosus (SLE) is one of the most frequently reported autoimmune diseases that cause CMV reactivation, but no studies have examined the risk factors in patients with SLE. This study aimed to identify the risk factors of CMV reactivation and disease in patients with SLE undergoing remission induction therapy.

Methods: This study reviewed patients with SLE who received remission induction therapy at our institution from May 2010 to October 2022 and enrolled patients whose CMV pp65 antigen levels were measured within 3 months of admission. Patients with CMV reactivation were divided into two groups, namely, CMV disease (presence of symptoms or end-organ disease) and asymptomatic CMV reactivation. We examined the risk factors associated with CMV reactivation and disease.

Results: CMV reactivation was observed in 64 out of 130 patients. Univariate analysis revealed the association between CMV reactivation and old age (46.5 vs. 39.5; P = 0.02), lower serum albumin levels at admission (2.9 vs. 3.3; P< 0.001), higher Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) (17 vs. 10; P = 0.001) at admission, and increased steroid pulse therapy (64.1% vs. 45.5%; P = 0.04) and immunosuppressive drug use (70.3% vs. 50.0%; P = 0.02) (Table 1). Log-rank tests on the above factors revealed significant differences for all except for steroid pulse therapy. Moreover, the Cox proportional hazards regression analysis on the four factors revealed the association of old age (hazard ratio [HR]: 2.03, 95% confidence interval [CI]: 1.09–3.78, P = 0.026), lower albumin (HR: 2.35, 95% CI: 1.09–5.07, P = 0.029),

Table 1. Risk factors of CMV reactivation

	CMV reactivation		
	(+) n=64	(-) n=66	P-value
Age (years)	46.5 (35.8-62.3)	39.5 (31.0-55.8)	0.02
Female, n, (%)	51.0 (77.2%)	49.0 (76.6%)	1.00
BMI (kg/m^2)	20.7 (18.7-23.2)	20.4 (18.9-22.8)	0.69
New-onset SLE, n, (%)	33.0 (51.6%)	27.0 (40.9%)	0.29
SLEDAI	17.0 (9.75-21.0)	10.0 (7.25-15.8)	0.001
Serum albumin (g/dL)	2.90 (2.38-3.30)	3.30 (2.93-3.80)	<0.001
Anti-dsDNA antibodies (IU/mL)	15.3 (3.90-70.8)	20.0 (1.80-84.6)	0.52
Prednisolone dose at admission (mg/kg/day)	0.00 (0.00-0.21)	0.07 (0.00-0.27)	0.38
Use of pulsed methylprednisolone, n (%)	41.0 (64.1%)	30.0 (45.5%)	0.04
Use of immunosuppressant, n, (%)	45.0 (70.3%)	33.0 (50.0%)	0.02
Platelet ($\times 10^4$/μL)	16.4 (9.50-20.6)	15.8 (10.6-20.7)	0.90
Lymphocyte (/μL)	565 (285-919)	590 (317-881)	0.41
Hb (g/dL)	10.6 (8.80-12.0)	11.1 (9.53-12.5)	0.17
CRP (mg/dL)	0.75 (0.18-1.67)	0.44 (0.08-1.89)	0.28
IgG (mg/dL)	1846 (1341-2468)	1617 (1211-2111)	0.13
C3 (mg/dL)	54.0 (35.3-76.8)	58.0 (49.0-78.0)	0.40
C4 (mg/dL)	9.90 (4.50-18.4)	10.1 (6.20-17.8)	0.74

higher SLEDAI (HR: 1.73, 95% CI: 1.00–2.98, P = 0.048), and immunosuppressive drug use (HR: 1.94, 95% CI: 1.12–3.35, P = 0.018) with CMV reactivation. Receiver operating characteristic (ROC) curve analysis using the above four factors revealed that the sensitivity and specificity were 82.8% and 60.6%, respectively (area under the curve = 0.748, 95% CI: 0.664–0.831) for CMV reactivation when all four factors were present. The log-rank test revealed that CMV reactivation developed more frequently when two or more risk factors were present (Figure 1). Among the 64 cases with CMV reactivation, an increased number of CMV pp65 antigen-positive cells was found in the 25 cases with CMV disease than the 39 cases without the disease (6 vs. 2; P = 0.02) (Table 2). ROC curve analysis revealed that the cutoff value for organ damage development was 12 cells out of 2 slides (sensitivity: 36.0% and specificity: 94.9%).

Conclusion: Old age, low albumin levels, high disease activity, and the use of immunosuppressive drugs are possible risk factors of CMV reactivation in patients with SLE. CMV pp65 antigen-positive cells of 12 per 2 slides were determined for the diagnosis of CMV disease.

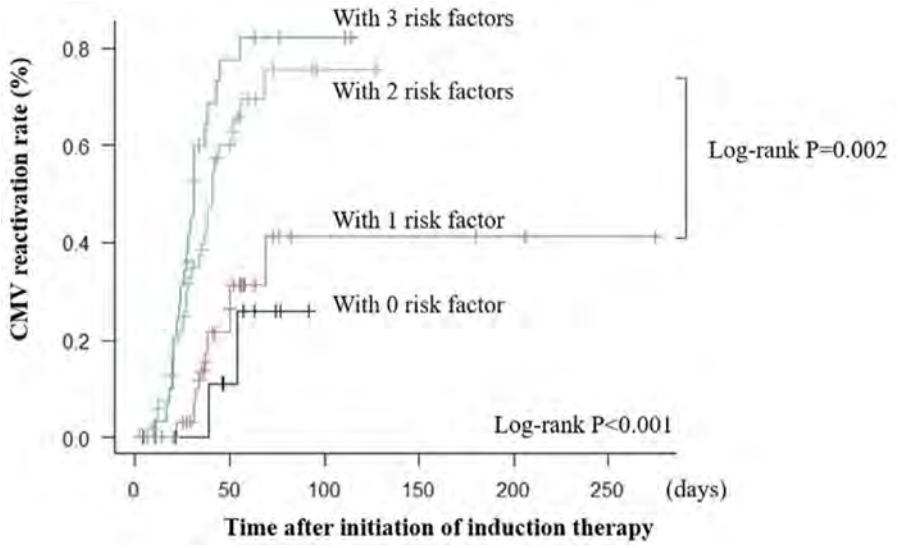

Figure 1. Cumulative probability of CMV reactivation depending on the number of risk factors

Table 2. Comparison of patients with and without CMV disease

	CMV reactivation with disease n=25	CMV reactivation without disease n=39	P-value
Age (years)	48.0 (40.0-62.0)	45.0 (34.0-62.0)	0.60
Female, n, (%)	20.0 (80.0%)	29.0 (74.4%)	0.77

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive dysfunction (CD) is highly prevalent in systemic lupus erythematosus (SLE), and advanced structural magnetic resonance imaging (MRI) has revealed brain abnormalities in patients with SLE. We conducted a systematic review of advanced neuroimaging studies to investigate the relationship between structural neuroimaging metrics and CD in SLE.

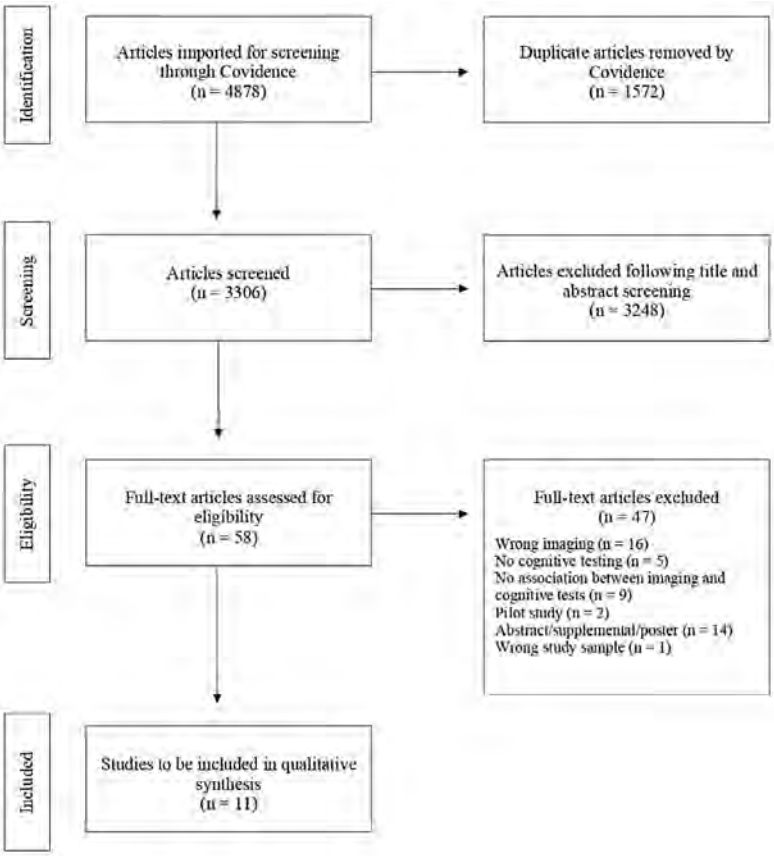

Figure 1: PRISMA flow diagram of the assessed studies.

Methods: A literature search was conducted in accordance with Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The search was performed in PUBMED, MEDLINE, EMBASE, Web of Science, and COCHRANE, between January 2000 and April 2022. Both free-text and expanded medical subject headings were used. The search strategy was developed by the research team with the aid of an experienced librarian and included the following terms: systemic lupus erythematosus (SLE), neuropsychiatric lupus (NPSLE), CNS lupus, magnetic resonance imaging (MRI, sMRI), DRI/dMRI, diffusion tensor imaging (DTI), diffusion-weighted imaging (DWI), brain volume, voxel-based morphometry (VBM), cortical thickness, surface area, tractography, fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity (RD). We included observational, case series, cohort, cross-sectional, longitudinal, retrospective, and prospective studies, and selected for neuroimaging studies using MRI and DTI investigating structural brain correlates of cognitive function in SLE.

Results: We identified 11 articles meeting search criteria (Figure 1); including two longitudinal studies and only one study in childhood-onset SLE (cSLE). Sample sizes ranged from 22 to 119 (SLE samples, n=11 to 75), and 8 studies included non-SLE controls. Neuroimaging techniques and neurocognitive assessments differed across studies. Structural MRI analysis (n=4 studies) showed cognitive impairment in patients with SLE was associated with overall gray and white matter atrophy, as well as regional atrophy (Table 1). DTI and DWI analyses (n=7 studies) showed associations between cognitive impairment and white matter microstructural changes consistent with tissue disorganization/damage of several regions, in SLE patients with and without NPSLE (Table 1).One longitudinal study found progressive regional atrophy over an average 19-month interval, and the other found stable white matter microstructure over an average 15-month interval.

Table 1: Associations between cognitive impairment and regional brain structural metrics in SLE.

Impaired Cognitive Domains	Structural MRI - Regional Atrophy	Diffusion Tensor/Diffusion-weighted Imaging - White Matter Microstructure Findings*
General Cognition	Bilateral hippocampi, left amygdala (2) Overall gray and white matter (3)	- ↑ mean diffusivity (1), and ↓ density, strength, global efficiency, and clustering coefficient (5) of overall white matter - ↓ fractional anisotropy (FA) in right external capsule (8) - NPSLE (neuropsychiatric SLE): ↓ FA in thalamic radiation, corpus callosum, longitudinal fasciculus, forceps major, corona radiata (8)
Executive Function		- NPSLE: ↓ FA in thalamic radiation and longitudinal fasciculus (8) - NPSLE: ↑ FA in the superior white matter pathways (10)
Memory	Left supramarginal superior temporal gyri; right superior frontal, caudal, and rostral middle frontal and precentral gyri (episodic memory) (11)	- NPSLE: ↓ FA in longitudinal fasciculus (verbal memory) and fronto-occipital fasciculus/forceps minor/longitudinal fasciculus (visual memory) (8) - ↓ FA in bilateral parahippocampal area (spatial memory) (9)
Attention		- ↑ free water in callosal regions, fronto-parietal pathway, fronto-temporal pathway, fronto-occipital pathway, cingulum (7) - NPSLE: ↓ FA in corpus callosum, longitudinal fasciculus, major forceps (8)
Visuo-constructual ability		- childhood-onset SLE (cSLE): ↑ blood flow in posterior precuneus (6)
Psychomotor Speed	Left cerebellum (4)	- cSLE: ↑ parenchymal diffusion of water and higher blood flow in posterior precuneus (6)
Processing Speed		- NPSLE: ↓ FA in thalamic radiation, corpus callosum, longitudinal fasciculus, forceps major, corona radiata (8)

*Metrics for white matter microstructure: higher mean diffusivity, lower fractional anisotropy, and increased free water indicate loss of directionality of diffusion due to tissue disorganization/damage.

Included Articles:

5. Wiseman et al. *Lupus*. 2018;27(8):1329-1337.
6. DiFrancesco et al. *Arthritis Res Ther*. 2020;22(1):135.
7. Qian et al. *Rheumatology (Oxford)*. 2022;61(3):1166-1174.
8. Jung et al. *PLoS One*. 2012;7(1):e28373.
9. MacKay et al. *JCI Insight*. 2019;4(1):e124002.
10. Cesar et al. *AJNR Am J Neuroradiol*. 2015;36(10):1874-1883.
11. Bizzo et al. *J Neuroimaging*. 2017;27(1):122-127.

Conclusion: Studies identified in this systematic review showed abnormalities in brain structure in SLE associated with CD. Limitations included small cross-sectional samples, difficulty in comparing findings across studies due to lack of uniformity in neuroimaging techniques and neurocognitive assessments, and the paucity of pediatric data. Larger, longitudinal studies utilizing standardized measures in both adults and children are needed to better understand the impact of SLE on the brain structure and function across the age spectrum.

Obesity Is an Independent Poor Prognostic Factor in Lupus Nephritis

Francy Milena Cuervo Gutiérrez[1], Antoine Enfrein[2], Frederic Houssiau[3] and Farah Tamirou[4], [1]Fundacion Santa Fe de Bogota, Bogotá, Colombia, [2]CHU de Nantes, Nantes, France, [3]CUSL - UCLouvain, Brussels, Belgium, [4]UCLouvain - Cliniques universitaires Saint-Luc, Brussels, Belgium

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 50% of patients suffering from systemic lupus erythematosus (SLE) develop lupus nephritis (LN) within the first 10 years of diagnosis and 5 to 20% of them progress to end-stage kidney disease (ESKD) (1,2). Several poor prognostic factors have been identified, such as the presence of tubulointerstitial and/or vascular lesions, a high chronicity index (3), African American descent (4), hypertension (5), absence of renal remission (3),(5) and renal flare(s) (6). Obesity, *per se*, is a risk factor for chronic kidney disease (CKD).Thus, obesity-related glomerulopathy in patients with a body mass index (BMI) ≥30kg/m^2(7)progresses to CKD in up to 50% of the cases (8). In addition, obesity is a risk factor for progression of primary glomerular diseases, such as IgA nephropathy (IgAN) (9). Whether obesity contributes to CKD risk in LN has never been investigated, to the best of our knowledge. We took advantage of the Louvain LN Inception cohort to test this hypothesis.

Table 1. Time-dependent proportional hazards (Cox) regression analysis

	Univariate analysis			Multivariate analysis

V	0.98	0.23-4.14	0.981	-	-	-
Absence of remission	0.11	0.05-0.25	**<0.001**	0.03	0.01-0.09	**<0.001**
Relapse	1.62	0.80-3.29	0.184	-	-	-

Methods: We retrospectively studied 132 patients with biopsy-proven class III, IV or V incident LN followed for a median period of 140 months (min. 25). Remission was defined as a urine protein to creatinine (uP:C) ratio < 0.5 g/g and a serum creatinine value < 120% of baseline. Renal relapse was defined as the reappearance of a uP:C >1 g/g, leading to a repeat kidney biopsy and treatment change. Poor long-term renal outcome was defined as the presence of CKD. Unpaired

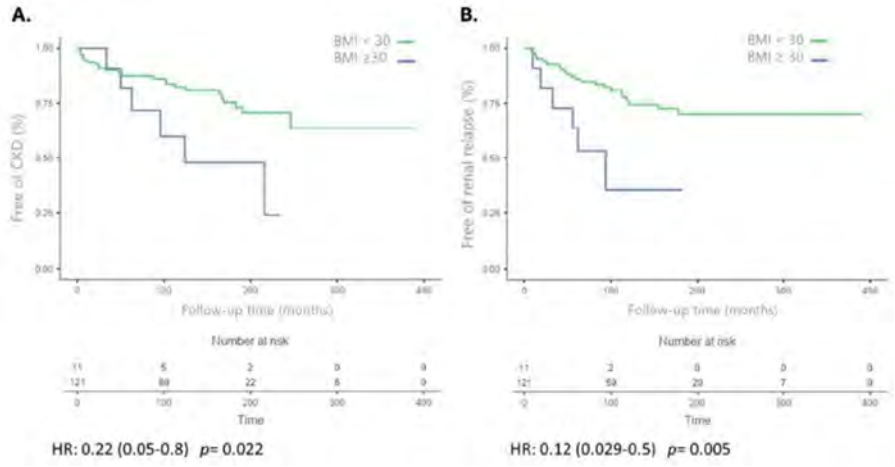

Figure 1. Kaplan-Meier analysis of the probability of survival without CKD (A) and relapse (B) in obese patients compared with non-obese patients. Survival curves were compared with the log-rank test. Hazard ratio (HR) (95% Confidence interval (CI)). Numbers shown on the abscissa are the numbers of patients at risk in each group at each time point.

t-tests, Wilcoxon's signed rank tests, chi-square tests, Fisher's exact tests, log-rank test and Cox regression were used as appropriate.

Results: The majority of patients were women (89%) and Caucasian (70.5%). Thirty-two patients (24%) developed CKD. Their baseline characteristics did not differ from those without CKD. Nine patients (6.8%) developed ESKD. Eleven patients (8.3%) suffered from obesity, defined by a body mass index (BMI) ≥30kg/m^2. Of note, "dry" weight was considered for patients presenting with oedema related to nephrotic syndrome. None of the obese patients was pregnant at disease onset. Renal remission was achieved in 90% of the cases, but 54% relapsed. Only one obese patient died from lupus-related macrophage activation syndrome. Obesity significantly increased long-term CKD risk [OR= 4.23 (IC95% 1.32-13.59), p = 0.015]. As shown in Table 1, obesity was an independent risk factor of CKD, as were African descent and absence of remission. Time-to-CKD and time-to-renal relapse were shorter in obese patients compared to non-obese patients (Fig 1). By Cox regression, factors independently associated with CKD were African descent, hypertension, absence of remission and obesity, as shown in **Table 1**.

Conclusion: A BMI ≥30 kg/m^2 is an independent poor prognostic factor for CKD in LN and is associated with shorter time to renal relapse. More attention should therefore be paid to weight control in LN patients.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is one of the most severe manifestations of systemic lupus erythematosus (SLE), which is characterized by abnormal B-cell activation and their subsequent differentiation into autoreactive plasma blasts/cells. The heterogeneity of autoreactive B cell subsets and their contribution to the pathogenesis of LN are not well elucidated.

Methods: Thirty-five SLE patients, including twenty-eight with positive anti-dsDNA antibodies (80%), and fifteen healthy controls were recruited in this study. Data are represented as median and interquartile range (IQR). To identify DNA-reactive B cells, a surrogate peptide (DWEYSVWLSN) that serves as dsDNA mimotope was used, as previously shown (*Jacobi, Annett M et al. 2009* and *Wangriatisak, Kittikorn et al. 2021*). The phenotype of peripheral B cell subsets (SLE, n = 37 from 35 patients and HCs, n = 15) and DNA-reactive B cells (SLE, n = 10 and HCs, n = 6) was analyzed by spectral flow cytometry. Correlations between different B-cell subsets and Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) score, clinical manifestations, and laboratory parameters were assessed.

Results: In SLE patients, the median SLEDAI-2K score was 9 (4-17), median age and disease duration were 34 (28-46) and 9 (1.5-13.0), respectively. Twenty-one patients presented with lupus nephritis (LN), with proliferative (class III, n = 3 and class IV, n = 4), membranous (class V, n = 7) and mixed histological patterns (class III & V, n = 5 and class IV & V, n = 2). Phenotypic analyses showed an expansion of circulating activated naïve (aNAV: $CD11c^{+}CD21^{-}CD27^{-}IgD^{+}$, $p < 0.01$), double negative 2 B cells (DN2: $CD11c^{+}CD21^{-}CD27^{-}IgD^{-}$, $p < 0.05$) and plasmablasts (PB: $CD27^{hi}CD38^{hi}$, $p < 0.05$) in LN patients, especially in class V, compared to non-LN and age-matched HCs. Intriguingly, an upregulation of CD71, as well as a downregulation of CD95, was observed on both DN2 and PB from patients with LN. Further analysis showed that expansion of DNA-reactive B cells was observed in LN patients (median (IQR): 0.13% (0.095-0.160)) compared with non-LN patients (median (IQR): 0.056% (0.042-0.070), $p < 0.05$). Surprisingly, the majority of these autoreactive cells were mostly represented by an activated naïve phenotype ($CD11c^{+}CXCD5^{-}CD21^{-}$), which was more frequent in patients with LN. The percentage of aNAV B cells were positively associated with DN2 ($r = 0.567$, $p = 0.0003$) and PB ($r = 0.498$, $p = 0.002$), especially in patients with LN. These expanded aNAV, DN2 and PB showed a significant positive correlation with the SLEDAI-2K index, and were inversely correlated with C3 and C4 levels in LN patients. Furthermore, DN2 and aNAV B cells were expanded in anti-dsDNA positive patients, while a lower frequency of such cells was found in anti-Smith positive patients.

Conclusion: Our data show that aNAV B cells display autoreactivity to dsDNA. The cooperation between these cells and DN2 and PB might be involved in the generation of anti-dsDNA antibody in LN which proceed of these B cell responses might via the extrafollicular pathway.

Abstract Number: 1459

Unveiling the Impact of Neuropsychiatric Involvement in Systemic Lupus Erythematosus on Damage Accrual

Dionysis Nikolopoulos[1], Nursen Cetrez[2], Julius Lindblom[2] and Ioannis Parodis[2], [1]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The link between neuropsychiatric involvement in systemic lupus erythematosus (NPSLE) and heightened morbidity, mortality, and organ damage, as well as detrimental impacts on health-related quality of life has been well-documented. However, the direct association between NPSLE and specific SLICC/ACR damage index (SDI) items, especially non-neuropsychiatric items, remains unclear. Herein, we sought to investigate the impact of NPSLE on organ damage accrual in a large lupus cohort.

Methods: We conducted an analysis of baseline data derived from five phase III trials (BLISS-52, BLISS-76, BLISS-SC, BLISS-NEA, EMBRACE), encompassing a total of 3645 SLE participants. NPSLE involvement was defined as NP BILAG A/B/C/D or scores on any of the NP SLEDAI-2K domains (n=372); the non-NPSLE group comprised patients with NP BILAG E and no neuropsychiatric involvement based on the NP SLEDAI-2K domains (n=3273). We employed univariable logistic regression analysis in case of < 30 events, or multivariable analysis to adjust for age, disease duration, sex, and ethnic origin in all other cases.

Results: The median; mean (IQR; SD) SDI score and SLE disease duration were 0.0; 0.6 (0.0–1.0; 1.1) and 4.5; 6.4 (1.6–9.3; 6.3) years, respectively. Compared with the non-NPSLE group, SLE patients with neuropsychiatric involvement had greater SDI scores (adjusted (a)OR: 2.7; 95% CI: 2.1–3.4; p< 0.001). This held true also after suppression of the NPSLE SDI items from the total SDI score (aOR: 1.5; 1.2–1.9; p< 0.001). As expected, neuropsychiatric involvement was associated with damage in the neuropsychiatric domain (aOR: 8.7; 6.6–11.4; p< 0.001). More importantly, neuropsychiatric involvement was associated with damage in the cardiovascular (aOR: 2.4; 1.6–3.7; p< 0.001), musculoskeletal (aOR: 1.8; 1.3–2.4; p< 0.001), and skin (aOR: 1.5; 1.0–2.1; p=0.050) domains. Dissecting the non-neuropsychiatric SDI domains into specific items, neuropsychiatric involvement was associated with established damage in terms of coronary artery disease (aOR: 2.8; 1.3–6.2; p=0.007), myocardial infraction (aOR: 2.9; 1.4–6.0; p=0.004), valvular disease (OR: 4.9; 1.7–14.8; p=0.004), muscle atrophy (aOR: 3.2; 2.1–4.9; p< 0.001), bowel infarction (aOR: 1.8; 1.1–3.0; p=0.018), and scarring alopecia (aOR: 1.7; 1.1–2.6; p=0.013). Lastly, SLE patients with neuropsychiatric involvement were more likely to have developed premature gonadal failure (aOR: 2.0; 1.1–3.7; p=0.032) compared with SLE patients with no history of neuropsychiatric events.

Conclusion: The intricate association between neuropsychiatric involvement in SLE and damage accrual extends beyond the realm of the nervous system, impacting the musculoskeletal, skin, and cardiovascular organ systems. Prospective research, especially survey in non-selected real-world SLE cohorts, would be required to determine the causal relationship between NPSLE and the various components of the SDI. Clarifying this association would contribute to a more comprehensive understanding of the disease and facilitate more targeted management strategies for individuals affected by NPSLE.

Impact of Neuropsychiatric Involvement on Health-related Quality of Life in Patients with Systemic Lupus Erythematosus

Dionysis Nikolopoulos[1], Nursen Cetrez[2], Julius Lindblom[2] and Ioannis Parodis[2], [1]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Substantial proportions of systemic lupus erythematosus (SLE) patients report severe fatigue and adverse Health-related Quality of Life (HRQoL). Particularly neuropsychiatric manifestations have been associated with reduced HRQoL. Our objective was to investigate patient-reported outcomes in patients with neuropsychiatric SLE (NPSLE) in comparison to SLE patients without neuropsychiatric involvement.

Methods: We analysed baseline data from four phase III trials (BLISS-52, BLISS-76, BLISS-SC, EMBRACE; N=2968). The NPSLE group comprised individuals with NP BILAG scores A/B/C/D (N=350). The active NPSLE group was defined as individuals with NP BILAG scores A/B or active neuropsychiatric involvement based on NP SLEDAI-2K domains (n=71). The non-NPSLE group consisted of patients with NP BILAG score E (N=2621). HRQoL was assessed utilising the generic instruments Medical Outcomes Study Questionnaire Short Form 36 (SF-36) health survey, the three-level version of EQ-5D (EQ-5D-3L), and the Functional Assessment of Chronic Illness Therapy (FACIT) Fatigue (FACIT-F) scale. Full health state (FHS) was defined as an experience of "no problems" in all five EQ-5D dimensions. Impaired HRQoL by EQ-5D was defined as level 2 or 3 responses in the different dimension.

Results: We observed clinically momentous reduced HRQoL in SLE patients with neuropsychiatric manifestations. NPSLE patients had significantly lower scores of SF-36 physical component summary (PCS) and mental component summary (MCS) compared to the non-NPSLE population [mean (s.d.): 35.7 (9.1) vs. 39.6 (9.6); $p< 0.001$ and 37.3 (12.1) vs. 41.4 (11.0); $p< 0.001$, respectively]. NPSLE patients also exhibited impaired HRQoL in all five EQ-5D dimensions compared to non-NPSLE patients ($p< 0.05$ for all). A substantially lower proportion among NPSLE patients experienced FHS in comparison to the non-NPSLE group (3.3% vs. 14.5%; $p< 0.001$). Neuropsychiatric involvement in SLE was associated with more severe fatigue as measured by FACIT-F [23.8 (12.2) vs. 31.5 (11.6); $p< 0.001$]. Similar associations were detected between active NPSLE patients and the non-NPSLE group with regards to SF-36 PCS/MSC domains, FHS, and FACIT-F scores. However, our findings revealed no discernible distinctions between NPSLE and active NPSLE patients, indicating that impaired HRQoL in patients with NPSLE persists regardless of the disease activity state in the neuropsychiatric domain.

Conclusion: Neuropsychiatric involvement in patients with SLE has a detrimental effect on HRQoL experience and is associated with more severe fatigue. Impaired HRQoL scores remain steady in NPSLE patients regardless of the degree of neuropsychiatric activity. Early intervention strategies are warranted in this specific group of SLE patients to enhance long-term patient-reported outcomes.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive impairment (CI) is highly prevalent in patients with SLE [prevalence of 38% (range: 20%-80%)]. The exact mechanisms underlying CI is complex and multifactorial. Understanding the relationship between SLE CI phenotypes and analytes may be crucial for improving patient care and developing targeted interventions. We have previously defined two SLE CI subtypes (A and B) where subtype A performed worst on objective cognitive function compared with subtype B. Subtype A also, had greater levels of disease burden/damage, worse performance on subjective cognitive function, worse HRQoL and psychiatric measures compared with subtype B. We aimed to explore the associations between SLE CI phenotypes and serum analytes levels.

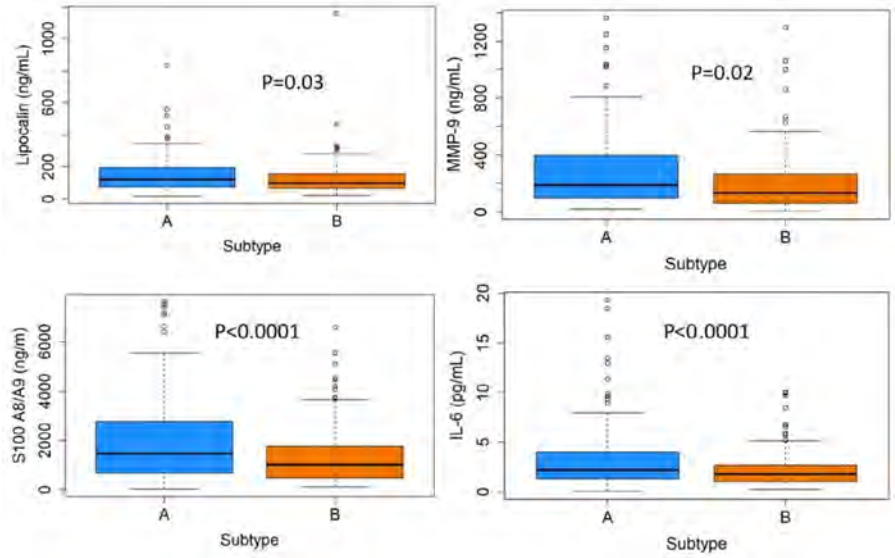

Figure 1 Subtype A (blue) performed worst on objective cognitive function compared with subtype B. Subtype A also, had greater levels of disease burden/damage, worse performance on subjective cognitive function, worse HRQoL and psychiatric measures compared with subtype B (orange).

Methods: SLE patients aged 18-65 years attending a single lupus centre (January 2016 – October 2019) completed the ACR Neuropsychological Battery (ACR-NB) cognitive assessment. Age and gender matched normative data were used to obtain z-scores on all 19 tests of ACR-NB. The ACR-NB tests were reduced using principal component analysis (PCA). Similarity network fusion (SNF) was used to identify patient subtypes on the ACR-NB data, demographic and clinical variables, disease burden/activity, health related quality of life (HRQoL: SF-36, LupusQoL), the PDQ-20 (perceived cognitive deficits), Beck Depression Inventory-II, Beck Anxiety Inventory, and the fatigue severity scale (FSS) in addition to the serum levels of nine analytes (IL-6, IL-10, IFN-ɣ, MMP-9, NGAL/lipocalin, S100A8/A9, S100B, TNF-α, and TWEAK [determined by ELISA]). Differences between the SNF identified subtypes were evaluated using Kruskal-Wallis tests and chi-square tests.

Results: Of the 296 patients, 87% were female, mean age 41.5 ± 18.4 and mean disease duration 13.8 ± 10.1 years at study visit.The level of S100A8/A9, MMP-9, NGAL/lipocalin, and IL-6 were statistically significantly higher in the more severe SLE CI subtype A compared to B (Figure 1). No difference in the levels of IL-10, IFN-ɣ, S100B, TNF-α, and TWEAK were identified between SLE CI subtypes A and B.

Conclusion: This study demonstrated a higher level of serum analytes in association with the SLE CI subtypes identified with machine learning analysis. S100A8/A9, MMP-9, NGAL, and IL-6 levels were higher in the more severe subtype A where patients experience worse objective and and subjective cognitive function with a higher disease burden and damage compared with subtype B. The results of this study will further in deciphering the mechanisms of cognitive impairment in patients with SLE and the identification of targeted therapy.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) survival has improved during recent decades, so other outcomes like damage accrual become more relevant. Damage represents that clinical feature that is irreversible and occurs after SLE diagnosis, being present fot at least 6 months. Our approach is to assess damage accrual, with emphasis on the cardiovascular domain over the different stages of the disease in a large SLE cohort.

Table 1. Comparison of patient characteristics with and without damage in the RELESSER-TRANS Cohort

PATIENT CHARACTERISTICS	WITH SOME DAMAGE (n = 2116)	WITHOUT DAMAGE (n = 2103)	p-value
Age at diagnosis, mean (± S.D.), years	37.9 (16.7)	33.9 (12.9)	0.96
Sex, %			
Male	12.4%	8.3%	≈0
Female	87.6%	91.7%	
Race/Ethnicity, n (%)			
Caucasian	94.2%	89.8%	
Afro-Caribbean	0.2%	0.4%	
Latin American	4.8%	5.8%	≈0
Asian	0.3%	1.1%	
Others	0.4%	2.9%	
Disease duration, mean (± S.D.), months	159.7 (109.9)	105.9 (93.1)	0.49
SDI Score, mean (± S.D.)	2.3 (1.8)	0 (0)	≈0
Number of SDI domains affected, mean (± S.D.)	1.8 (1.1)	0 (0)	≈0
Death, n (%)	203 (9.6%)	25 (1.2%)	≈0

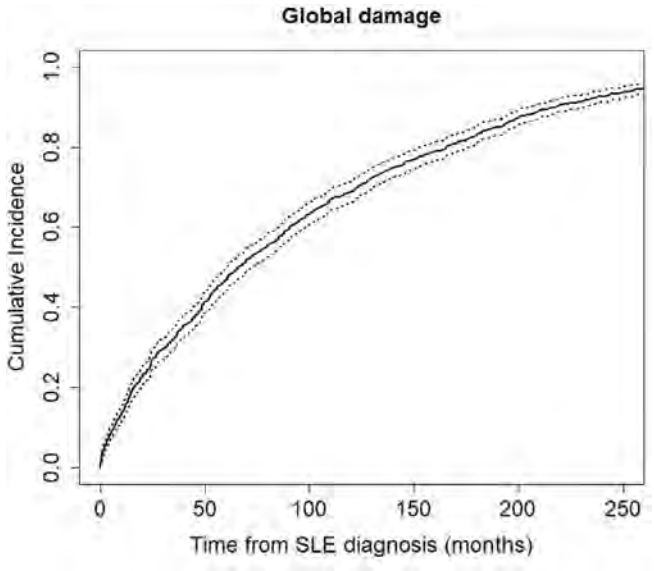

Figure 1.Gobal damage over time

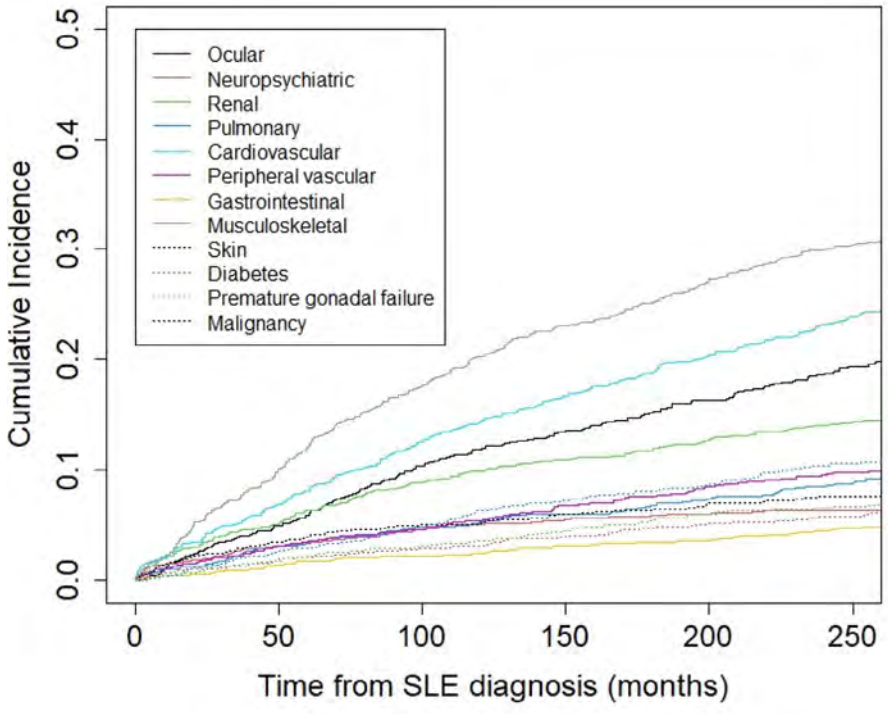

Figure 2. Damage over time by SDI domain

Methods: Multicentre, cross-sectional study of a cohort of 4,219 SLE patients enrolled in the Spanish Society of Rheumatology Lupus Registry (RELESSER) with an average age at diagnosis (±SD) of 35.9 (±15.1) years, 89,6% of women, 92% caucasian and the average duration (±SD) of SLE 133.2 months. Organ damage was ascertained using the SDI (SLICC/ACR Damage Index). For the chronological analysis we considered, globally and for every SDI domain, only those 1,299 patients whose dates of damage events had been recorded.

Results: After 133 months of follow-up, 2,116 (50.1%) of 4,219 patients manifested some damage. Table 1 shows the comparison between patients with and without damage in the RELESSER Cohort . The damage accrual rate was higher during early stages of the disease, with 22.0% and 38.1% of those patients accumulating damage during the first and third year after SLE diagnosis, respectively. Figure 1 graphically represents the cumulative incidence of global damage over the course of the disease.

Analyzing the different domains, musculoskeletal and neuropsychiatric systems were the ones accumulating more damage at those time points. The musculoskeletal system was the one contributing more to damage during late stages.Including "cerebrovascular accident" and "claudication for 6 months" as cardiovascular items, the cardiovascular system became the second one that contributed the most to damage accrual in the early stages of SLE, with 7.0% and 11,1% of the patients who presented damage doing so in this system at year 1 and 3 after diagnosis, respectively. Figure 2 shows the cumulative incidence of damage (per SDI domain) over the course of the disease from the time of SLE diagnosis.

Conclusion: The higher rate of damage accrual occurs during the first year after SLE diagnosis. The cardiovascular system is the second leading cause of damage accrual within the first years. Strategies to prevent cardiovascular damage should be implemented early on starting from the initial SLE diagnosis.

Abstract Number: 1463

Predictors of Cognitive Impairment in Individuals with Systemic Lupus Erythematosus

Alexandra Lee[1], Sharon Phillips[2] and Leslie Crofford[3], [1]Meharry Medical College, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Vanderbilt University Medical Center, Melbourne, AR

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this study was to investigate factors associated with objective cognitive impairment in patients diagnosed with Systemic Lupus Erythematous (SLE). Subjective complaints of changes in cognition are common, being reported by up to 50% of patients with SLE.Previous studies have showed objective declines in immediate memory and total memory.

Methods: This study was conducted using baseline data from ClearMEMory (Clearing Lupus Fog with Memantine), an ongoing clinical trial. Seventy-nine participants who reported neuropsychiatric symptoms on pre-screen and came for in-person screening were included. The dependent variable was the Repeatable Battery for the Assessment of

Variable	N	Value
Sex Female	79	 96% (76)
Ethnicity Not Hispanic or Latino	79	 94% (74)
Age (Median, IQR)	79	51(b)
Race White	79	 70% (55)
ESR	76	19
Anti-dsDNA	63	12.0
PSD Total WPI SSS	77	13.0 5.0 8.0
HADS-Anxiety	78	8
HADS-Anxiety Normal (0-7) Borderline abnormal (8-10) Abnormal (11-21)	78	 44% (34) 29% (23) 27% (21)
HADS-Depression	78	5
HADS-Depression Normal (0-7) Borderline abnormal (8-10) Abnormal (11-21)	78	 72% (56) 15% (12) 13% (10)
RBANS Total Scale	79	86
RBANS Immediate Memory Scale	79	97

IQR = Interquartile range, a b c represent the lower quartile a, the median b, and the upper quartile c for continuous variables. ESR = Erythrocyte sedimentation rate, PSD = Polysymptomatic Distress, WPI = Widespread pain index, SSS = Somatic symptom score, HADS = Hospital Anxiety and Depression Scales, RBANS = Repeatable Battery for the Assessment of Neuropsychological Status. For the RBANS, a score of 100 is the age-adjusted mean.

Factor	Effects	Lower 95% Limit	Upper 95% Limit	p-value
HADS-D (6,12)	-3.9541	-7.8828	-0.0253	0.0486
PSD Total (12,16)	-2.3539	-4.1684	-0.5394	0.0117
Race Non-White:White	-7.7678	-13.0171	-2.5185	0.0043

Overall model P = 0.0004. HADS-D = Hospital Anxiety and Depression Scales – Depression, PSD = Polysymptomatic Distress

Neuropsychological Status (RBANS), a brief, age-normalized, individually administered battery to measure cognitive decline or improvement. Potential predictive variables were sex, race, ethnicity, ESR, anti-dsDNA antibodies, the polysymptomatic distress scale (PSD) and the hospital anxiety and depression scales (HADS-A, HADS-D). Regression models were run to determine covariates that effect the RBANS total and the RBANS immediate memory. The models examined HADS-D scores between 6-12 to determine if there was a statistically significant difference when the scores went from normal to depressed. The models used PSD values 12-16 which are values that cross the threshold for diagnosis of fibromyalgia.

Results: Participant's median age was 51 years, and they were predominantly female (96%), non-Hispanic (94%) and White (70%) (**Table 1**). We used linear regression to model the RBANS total score. A model including HADS-D, PSD, and race was the most significant (p = 0.0004) (**Table 2**). As the HADS-D score increased from 6 to 12, the RBANS total decreased by 3.95 points and as the PSD total increased from 12 to 16, the RBANS total decreased by 2.35 points on average. Non-Whites, when compared to Whites had a decrease in the RBANS total by 7.77 points. The most significant model for RBANS immediate memory included the same factors (p = 0.0004, **Table 3**).

Factor	Effects	Lower 95% Limit	Upper 95% Limit	p-value
HADS-D (6,12)	-4.2360	-9.2266	0.7546	0.0950
PSD total (12,16)	-2.9600	-5.2649	-0.6551	0.0126
Race Non-White:White	-11.3691	-18.0371	-4.7010	0.0011

Overall model P = 0.0004. HADS-D = Hospital Anxiety and Depression Scales – Depression, PSD = Polysymptomatic Distress

Conclusion: Results support race, depression, and polysymptomatic distress as significant contributors to the risk of cognitive impairment in patients with SLE. Disease activity did not appreciably affect cognition in this participant sample. As participant scores crossed thresholds for depression or fibromyalgia diagnosis, measurable declines in cognition, particularly immediate memory, were observed. Further studies with different measures of cognition and larger sample size are necessary to understand the impact of race in these models.

Lupus Flares More Common in Patients on Dialysis Compared to After Renal Transplant: A Systematic Review and Meta-analysis

Omer Pamuk[1], Ansaam Daoud[2], Loai Dweik[3], Niraj Desai[4] and sarfaraz Hasni[5], [1]University Hospitals Cleveland Medical Center, Cleveland, OH, [2]University Hospitals, Case Western Reserve University, Akron, OH, [3]Cleveland Clinic Akron General, Akron, OH, [4]Case Western Reserve University / University Hospitals Cleveland Medical Center, Cleveland, OH, [5]Lupus Clinical Trials Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: End-stage renal disease (ESRD) may develop in up to 20% of patients with lupus nephritis (LN). The SLE disease activity generally declines after the development of ESRD and renal transplantation (RT). However, several studies reported SLE flares could occur after ESRD or RT. In this study, we performed a systematic literature review and meta-analysis to assess the frequency of SLE flares, in patients with ESRD or after RT.

Methods: We used PubMed, Web of Science, and Cochrane Library to search the literature from 1973 to 2023. PRISMA 2020 guidelines and checklist were used to conduct the meta-analysis. Studies investigating frequency of lupus flare in patients after renal replacement therapy (RRT) were included in the analysis. If the information was available, SLE flares were recorded separately for different RRT modalities such as hemodialysis (HD), peritoneal dialysis (PD), and RT. ACR 1997 revised classification criteria was utilized to ascertain SLE diagnosis. We excluded studies that did not mention lupus flares after the development of ESRD or RT. Two authors (O.N.P., A.D.) independently reviewed all articles and evaluated the data for consistency between the abstracts and tables to avoid bias. A forest plot was used to compare odds ratios (95% CI) of SLE flares after ESRD or RT. Study heterogeneity was assessed using I^2. All analyses were performed using the R Statistical Software meta package (v4.2.1; R Core Team 2022).

Results: Our literature review revealed 583 relevant articles, 487 were deemed unsuitable by title or abstract. We reviewed the full text of remaining 96 articles and 69 fulfilled study entry criteria. Twenty-eight studies (862 SLE patients) evaluated clinical SLE disease flares after RRT (HD and PD). Overall 30% of patients with ESRD had at least one flare after RRT (Figure 1). Seven studies (307 SLE patients) compared SLE disease flares after PD or HD initiation. The frequency of SLE flares was similar in both PD (25.6%) and HD (25.3%) (OR: 1.05, 95% CI: 0.57-1.94, p=0.88). Clinical SLE disease flares were evaluated in 5 studies after RT (91 patients). 14.3% of patients had at least one clinical SLE flare (95%CI: 8.5-23.1%). Four studies (204 SLE patients) compared lupus flares in SLE patients with PD/HD or RT. Flare risk was significantly higher in PD/HD

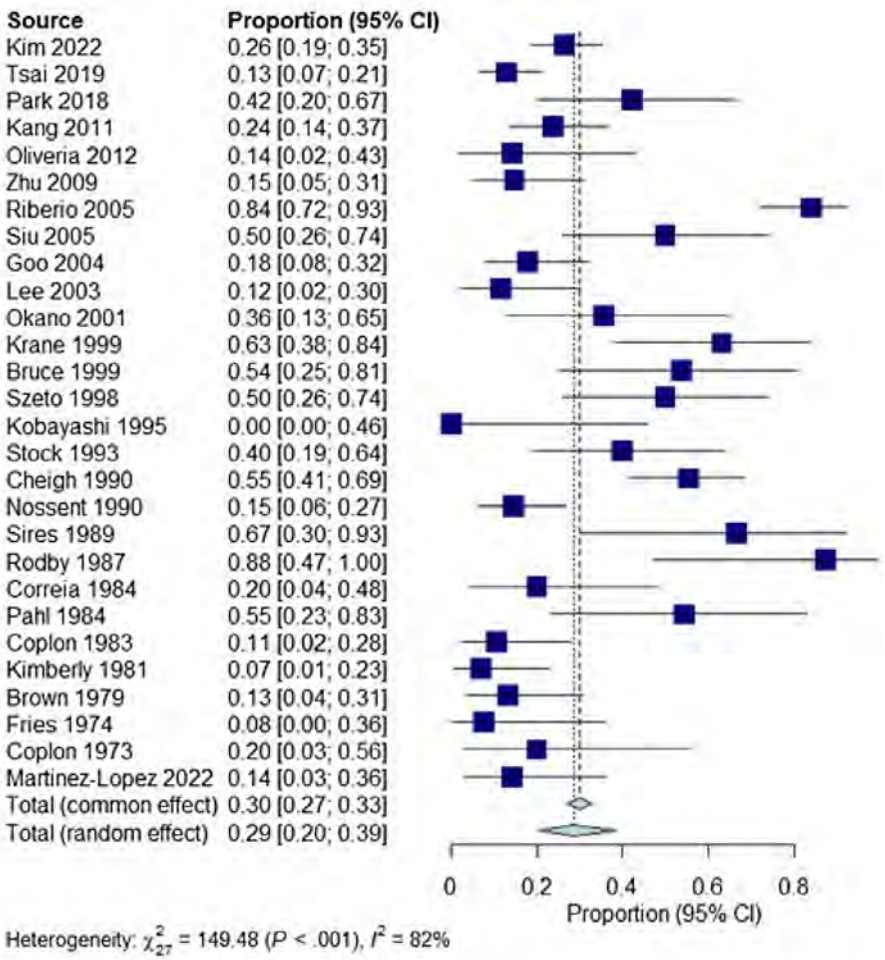

Figure 1. The frequency of SLE flares after renal replacement therapy.

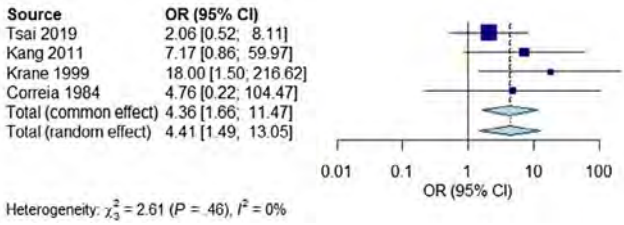

The comparison of lupus disease flares in kidney transplantation and peritoneal dialysis (PD)/hemodialysis (HD) groups

group when compared to RT (OR: 4.36, 95%CI: 1.66-11.47, p=0.0028) (Figure 2). Twenty-nine studies (7890 SLE patients with RT) analyzed the recurrence of the LN after RT. LN had been diagnosed in 3.4% of patients (95%CI: 3-3.8%) (Figure 3).

Conclusion: Our meta-analysis showed lupus flares can still occur in up to 30%of patients with ESRD on RRT. The risk of flare is increased in patients on dialysis as compared to after RT. The flare risk is similar in patients on either HD or PD. A small percentage of SLE patients get recurrence of LN even after transplant.

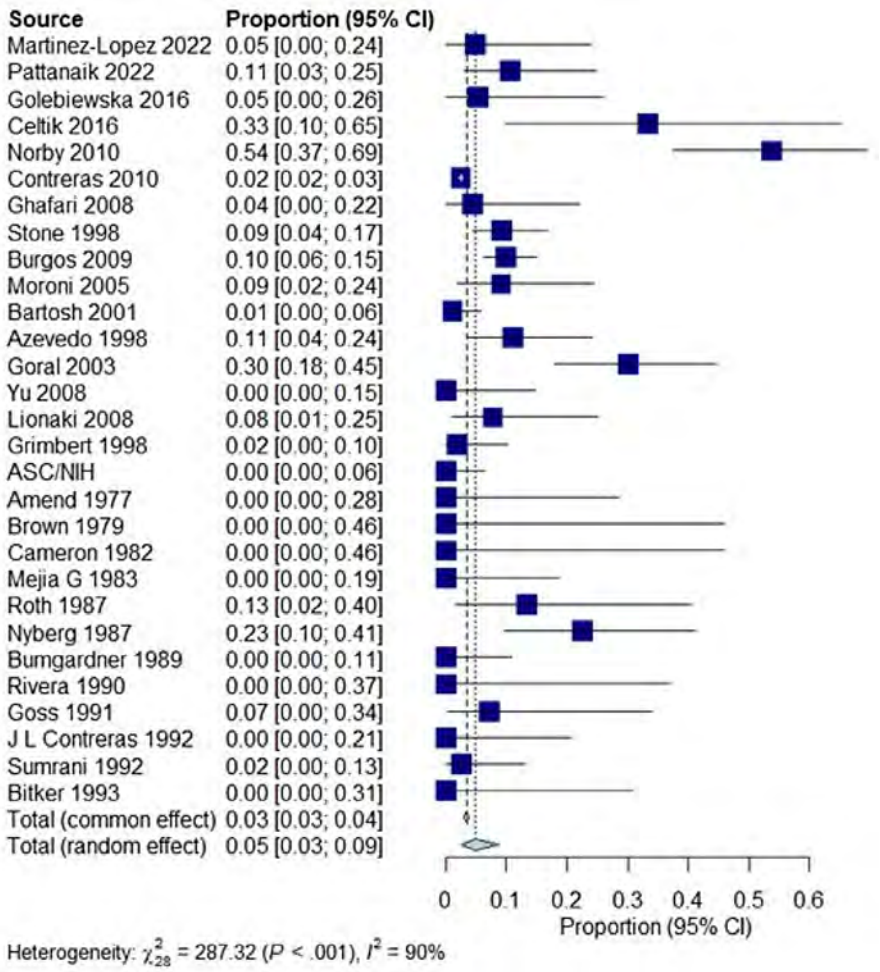

Figure 3. The frequency of lupus nephritis flares after the Renal Transplant.

Blood-dominant Disease in Older-onset Lupus: A Systematic Review and Meta-analysis

Sarah Abi Doumeth[1], Marina Nighat Magrey[2] and Omer Pamuk[3], [1]Case Western Reserve University/University Hospitals Cleveland Medical Center, Cleveland, OH, [2]Case Western Reserve University, University Hospitals, Cleveland, OH, [3]University Hospitals Cleveland Medical Center, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have shown that the clinical manifestations of systemic lupus erythematosus (SLE) differ based on age of onset. Late onset SLE has been shown to be milder, with lower frequency of lupus nephritis, cutaneous and neuropsychiatric presentations however with more prevalent pulmonary manifestations. There have been multiple

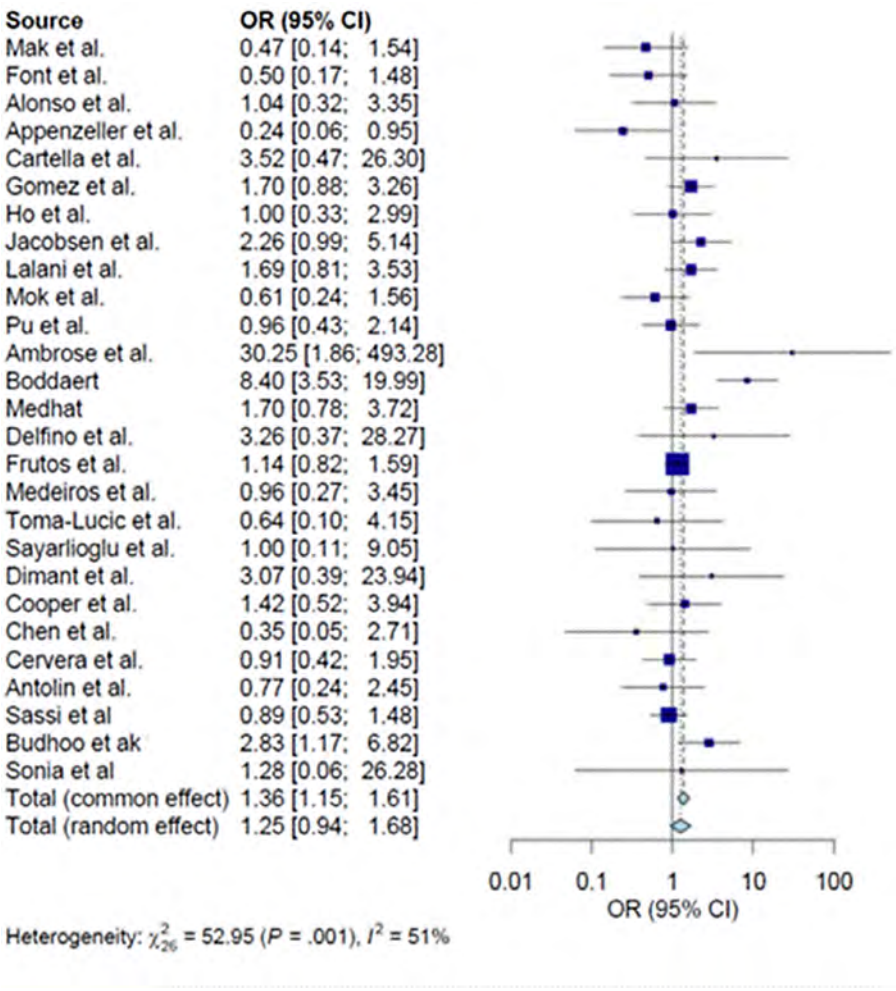

Figure 1. Odd ratios for AIHA in early and late onset SLE patients

retrospective or prospective studies comparing hematological manifestations in early-onset SLE patients (age< 50) with older onset SLE patients (age >50) with varying results. We performed a systematic review and meta-analysis to evaluate the differences in hematologic manifestations (autoimmune hemolytic anemia(AIHA),thrombocytopenia(TP), lymphopenia, leukopenia, lymphadenopathy and thrombosis) in late-onset SLE patients (ltSLE) compared to adult-onset SLE patients (aSLE).

Methods: Literature search was performed using PubMed, Web of Science and Cochrane Library. PRISMA 2020 guidelines and checklist were used. Studies were included if they investigated the frequency of hematological manifestations in ltSLE patients and excluded if they did not include aSLE as control group. The diagnosis of SLE was performed with ACR 1997 revised classification criteria for SLE**.** We included cohort, case-control, and population-based studies. Two authors independently reviewed all articles and evaluated the data for consistency between the abstracts, tables, and text to avoid a bias. Forest plot was used to compare odds ratios (95% CI) of hematological manifestations by age groups. Study heterogeneity was assessed using I^2.All analyses were performed using R Statistical Software meta package (v4.2.1; R Core Team 2022).

Results: 44 eligible studies comprising 20,508 SLE patients (17421 aSLE and 3087 ltSLE) were included in analysis. Among these studies, 27 reported the occurrence of AIHA which was found to be more frequent in the aSLE group compared to ltSLE (OR: 1.36, 95% CI: 1.15-1.61, p=0.0003) (Figure 1). Further analysis of 40 studies revealed a higher frequency of TP in the aSLE group (OR: 1.16, 95% CI: 1.05-1.28, p=0.0045) (Figure 2). 19 studies provided data on lymphopenia which was found to be more frequent in aSLE (OR: 1.16, 95%CI: 1.04-1.30, p=0.0082) (Figure 3). 31 studies included data for

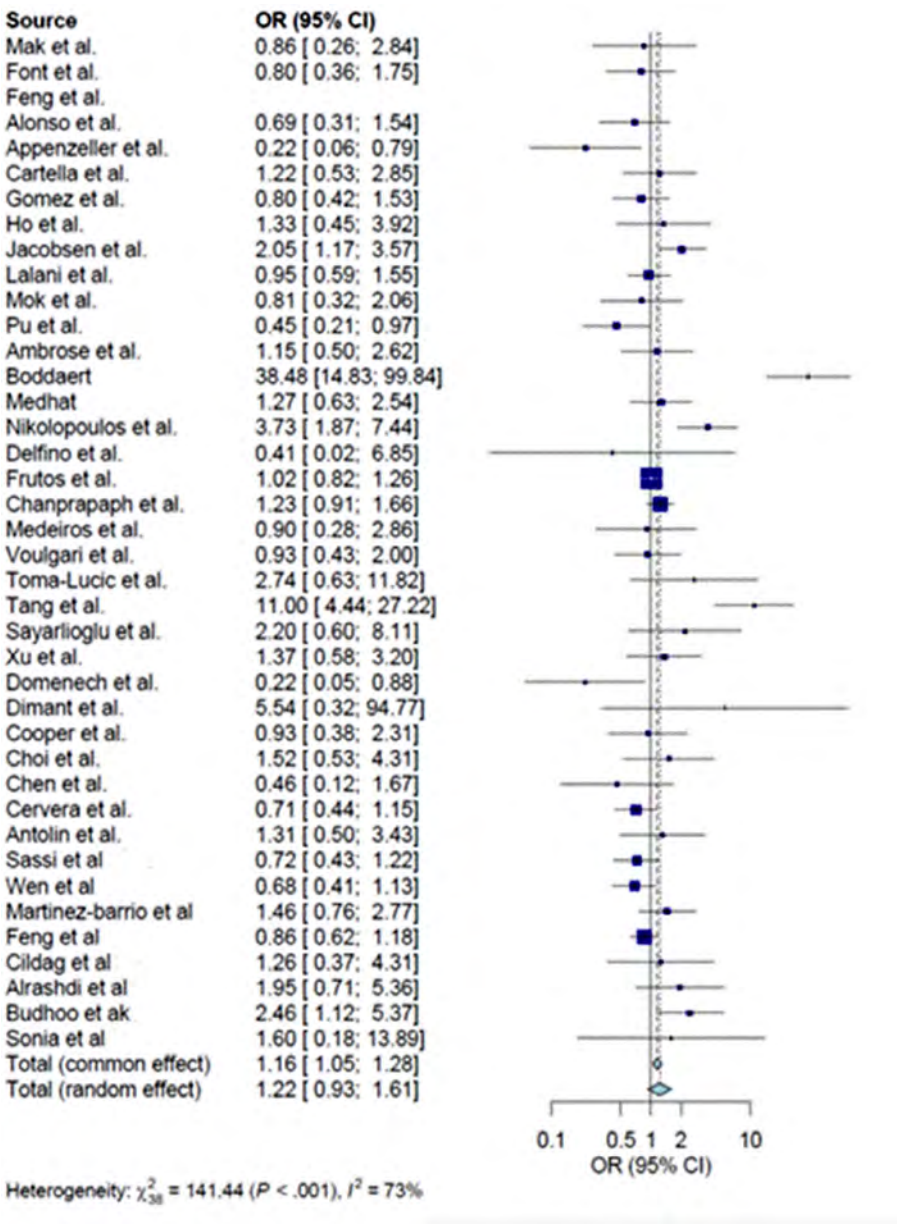

Figure 2. ORs for TP in early and late onset lupus groups.

leukopenia and the frequency was higher in the aSLE (OR: 1.28, 95% CI: 1.17-1.41). Additionally, lymphadenopathy was more commonly seen in aSLE group (OR: 2.18, 95%CI: 1.47-3.24, p=0.0001). However, no significant difference was observed in the frequency of thrombosis between the two groups.

Conclusion: Attributing hematological findings to SLE may be challenging in older onset patients due to comorbidities and polypharmacy. In this study, the overall frequencies of AIHA, TP, lymphopenia, leukopenia and lymphadenopathy were more common in aSLE patients compared to ltSLE.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients are prone to hospitalizations and readmissions compared to general population. Depression is highly prevalent among patients with SLE and is an important inpatient comorbidity. Studies have established that depression is an independent risk factor for CVD and premature CVDs are a major cause of mortality in SLE. The additive effect of depression on CVD in SLE remains unknown. Hence, we aimed to investigate the impact of co-morbid depression on SLE hospitalizations in terms of mortality or CVD outcomes and readmissions.

Methods: We performed a retrospective analysis using the 2020 National readmission database (NRD) and identified patients over 18 years of age hospitalized with a principal diagnosis of SLE (ICD 10 code: M32). NRD is a nationally representative database that has discharge data from 31 states and weighted, estimates over 32 million discharges in a year. Depression was identified using ICD 10 codes (F32, F33, F34.1) and SLE patients were divided into two subgroups based on presence or absence of co-morbid depression. Baseline characteristics including demographics, hospital level variables and co-morbidities (table 1) were identified for the two groups. Nearest propensity matching (PSM) was performed using a 1:1 ratio for all baseline characteristics. The primary outcome of interest was mortality. Secondary outcomes include ischemic stroke, acute myocardial infarction, acute heart failure, vasopressor use, acute kidney injury, 30- and 90-day readmissions. T-test and chi-square tests were performed to compare outcomes and p value < 0.05 was considered statistically significant. STATA 18 was used to perform the analysis.

Results: Among 167,825 SLE hospitalizations, 32,619 (19.4%) had co-morbid depression. Baseline characteristics are shown in Table 1. After matching, SLE patients with depression have low all-cause mortality rates (2.05% vs 2.98%, p < 0.001). No significant impact seen on 30- and 90- day readmission rates (8.26% vs 8.09%, p 0.581, and 7.03% vs 6.73%, p 0.267 respectively), and incidence of ischemic stroke (2.00 vs 2.26%, p < 0.100). However, depression reduced acute MI (5.14% vs 6.34%, p< 0.001), acute HF (7.16 vs 7.88%, p 0.012), vasopressor use (0.68% vs 0.93%, p 0.009), and AKI (19.71% vs 21.27%, p < 0.001) (Table 2).

Impact of depression on cardiovascular outcomes in patient with SLE
Table 1

	SLE

Drug abuse n (%)	9,265.7 (6.85%)	3,229.8 (9.9%)
Fluid electrolyte imbalances n (%)	56,378.8 (41.7%)	14,146.1 (43.37%)
Chronic heart failure n (%)	12,336.2 (9.12%)	3,463.7 (10.62%)
Obesity n (%)	28,320.6 (20.95%)	8,762.3 (26.86%)
Anemia n (%)	48,996.6 (36.24%)	11,892.1 (36.46%)

Impact of depression on cardiovascular outcomes in patient with SLE
Table 2

	SLE		
Outcomes, n (%)	Without depression (n=17,109)	With depression (n=17,109)	p-value
Mortality	510 (2.98%)	350 (2.05)	<0.001
Ischemic stroke	387 (2.26%)	343 (2.00%)	<0.100
90-day readmissions	1,385 (8.09%)	1,413 (8.26%)	0.581
30-day readmissions	1,151 (6.73%)	1,203 (7.03%)	0.267
Acute MI	1,085 (6.34%)	879 (5.14%)	<0.001
Acute HF	1,349 (7.88%)	1,226 (7.16%)	0.012
Vasopressor use	159 (0.93%)	116 (0.68%)	0.009
Acute kidney injury	3,640 (21.27%)	3,372 (19.71%)	<0.001

Conclusion: Depression was highly prevalent among hospitalized SLE patients and traditional CVD risk factors such as DM, HTN, and obesity were noted to be higher in the SLE + depression group. However, co-morbid depression did not impact readmissions, or adverse cardiovascular events. Interestingly, a significant reduction in all- cause mortality was seen. Further studies are warranted to analyze the reasons for hospitalizations and readmission in this subgroup which may help providers predict morbidity and mortality and provide tailored medical care.

Antiphospholipid Antibodies and the Risk of Diffuse Alveolar Hemorrhage in Patients with Systemic Lupus Erythematosus: A Systematic Review and Meta-Analysis

Mariana Gonzalez-Trevino[1], Jeffrey Yang[2], Larry J. Prokop[3], Gabriel Figueroa-Parra[1] and Ali Duarte-Garcia[4], [1]Division of Rheumatology, Mayo Clinic, Rochester, MN, [2]Department of Internal Medicine, Mayo Clinic, Rochester, MN, [3]Mayo Clinic Libraries, Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Diffuse alveolar hemorrhage (DAH) is one of the most devastating complications of SLE. The exact pathogenesis leading to DAH in SLE is not well understood. Nonetheless, about a third of the patients with SLE have positive aPL, which are associated with non-thrombotic manifestations, including DAH. We aimed to assess the risk of DAH in patients with SLE based on their aPL profile by performing a systematic review (SR) and meta-analysis (MA).

Methods: MEDLINE, EMBASE, CENTRAL, and Scopus were systematically searched from inception to February 2023. Studies were eligible if they included SLE patients (population) with a description of the association of the aPL status (exposure) and DAH (outcome). SLE and DAH were defined as stated by the authors of primary studies. Studies were excluded if they reported findings only for patients with SLE with specific organ involvement. Two reviewers independently screened the studies and extracted data from the reports. The main analysis explored the association between any aPL (overall) and DAH; when multiple aPL subtypes were available in the same study, we prioritized their inclusion in the main analysis in the

Table 1. Characteristics of the included studies.

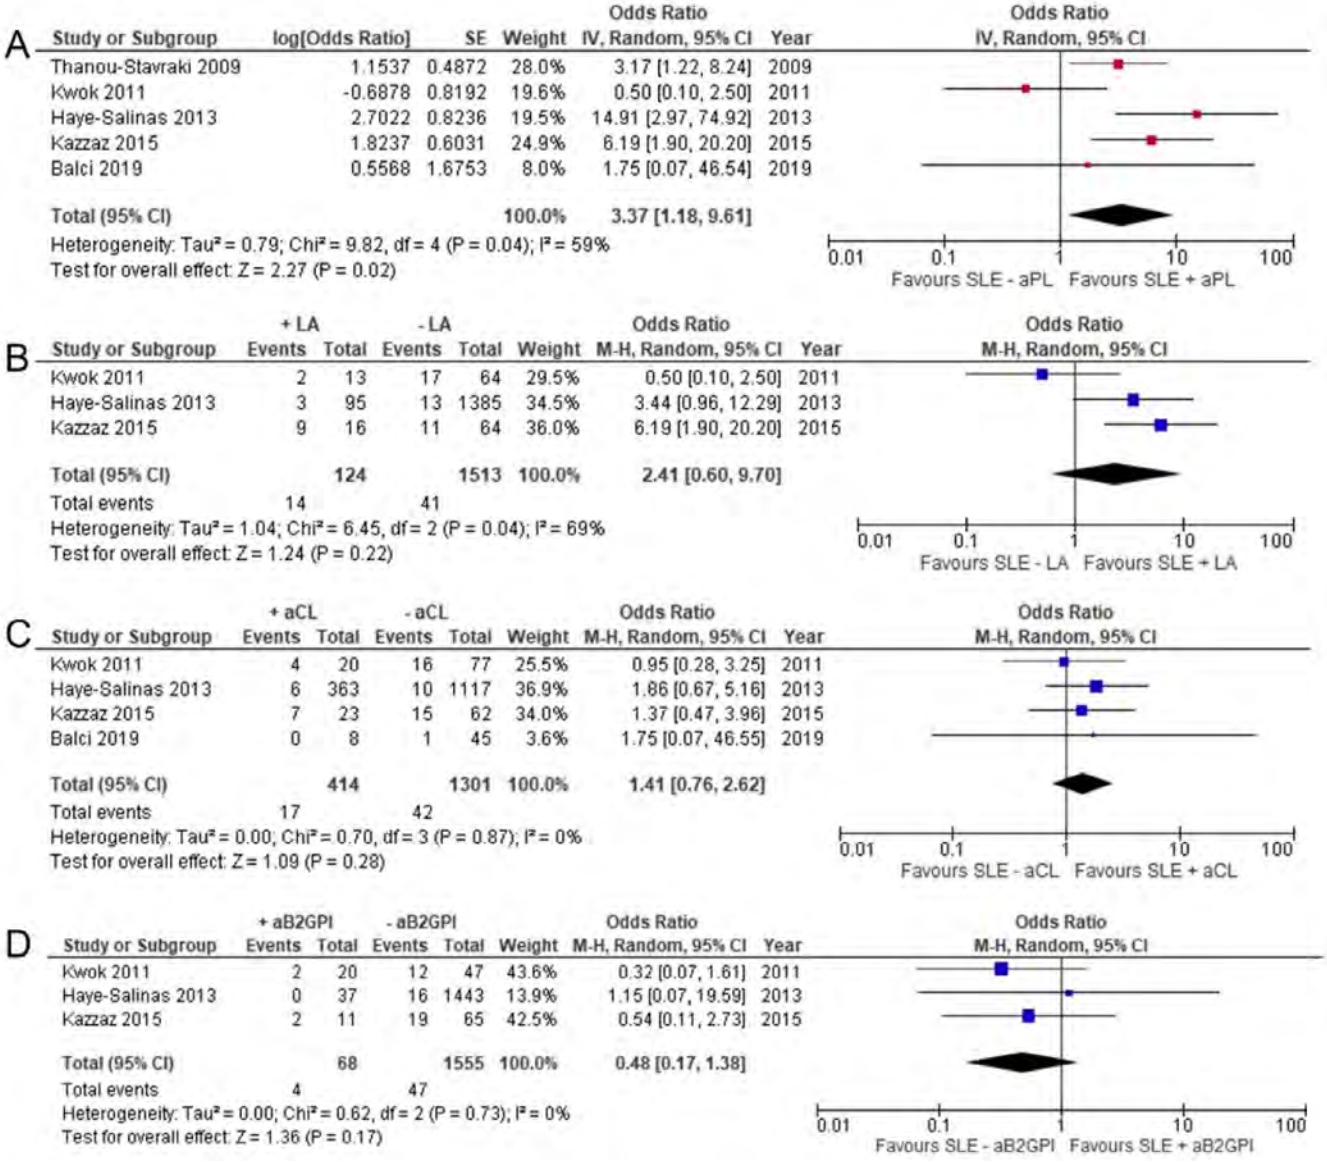
•Included in main analysis

Figure 1. Forest plots for the risk of diffuse alveolar hemorrhage in patients with systemic lupus erythematosus (SLE) according to A) overall antiphospholipid antibodies (aPL), B) lupus anticoagulant (LA), C) anticardiolipin antibodies (aCL), and D) anti-β2 glycoprotein I antibodies (aβ2GPI) positivity.



following order: 1) LA, 2) aCL, and 3) anti-β2 glycoprotein I (aβ2GPI). Subgroup analyses were performed by each aPL subtype. Sensitivity analyses assessed the effect of excluding studies where the population included only a subset of patients with SLE. Estimates were pooled using random-effects models, and the risk of bias was assessed using the Newcastle-Ottawa Scale. We followed the PRISMA guidelines for all stages of the SR and MA.

Results: A total of 399 studies were screened. Only five met inclusion criteria (three case-control and two cohort studies), adding up to 1790 patients with SLE and 73 events of DAH (**Table 1**). Patients with SLE and positive aPL (any) were three times more likely to have DAH than aPL-negative patients with SLE (OR 3.37, 95% CI 1.18-9.61; I^2=59%; 1745 patients; 5 studies). Subgroup analyses based on aPL subtype showed that patients with SLE and positive LA (OR=2.41, 95% CI 0.60-9.70; I^2=69%; 1637 patients, 3 studies), aCL (OR=1.41, 95% CI 0.76-2.62; I^2=0%; 1715 patients; 4 studies), and aβ2GPI (OR=0.48, 95% CI 0.17-1.38; I^2=0%; 1623 patients; 3 studies) had no significant difference in the risk of DAH compared to negative patients (**Figure 1**). Risk of bias assessment showed concerns in the definition and selection of the non-exposed participants and comparability between groups. Sensitivity analysis excluding studies with hospitalized SLE controls showed that patients with SLE and positive LA were four times more likely to present with DAH than negative patients (OR=4.72, 95% CI 1.98-11.22; I^2=0%; 1560 patients; 2 studies).

Conclusion: In patients with SLE, aPL positivity might increase the risk of DAH compared with negative-aPL subjects. The certainty of our findings is limited by the paucity of available evidence exploring the aPL-DAH relationship, decreasing the precision of the risk assessment by aPL subtype.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have higher risks of developing cardiovascular disease (CVD). Traditional risk factors do not adequately capture the risk of CVD in patients with SLE, and although SLE-specific prediction risk tools have been developed, none has achieved an adequate combination of high sensitivity and specificity. Recently, machine learning techniques, such as random survival forests (RSF), were shown to be effective approaches for the prediction of cardiovascular outcomes in the general population. The purpose of this study was to evaluate the use of RSF in the prediction of CVD events in SLE patients.

Table 1: Descriptive Statistics Data presented as mean ± standard deviation for continuous variables, and N (percentage) for categorical variables. Corticosteroid therapy	33.6 ± 12.9	41.9 ± 14.1	34.5 ± 13.3	<0.001

Methods: A retrospective analysis was conducted on patients at a single Lupus centre between 1970 and 2018. For each patient, baseline demographic, clinical and laboratory variables were collected using a standard protocol. Multiple imputation by chained equations was used to impute missing variables. Patients were followed for up to 25 years, and CVD event was defined as the development of angina, myocardial infarction, congestive heart failure, stroke, transient ischemic attack, pacemaker insertion or peripheral vascular disease related to atherosclerosis. Patients who had CVD event at baseline, had no follow-up visits after initial visit, or had CVD death and no visits within 10 years prior to death were excluded. To evaluate the risks of developing CVD events, univariate and multivariate survival analyses were conducted using Cox proportional hazard models. In addition, RSF was constructed, and its performance was compared against the multivariate Cox model by calculating the integrated Brier score with bootstrap cross-validation.

Results: Out of the 1791 patients included in the final analyses, 211 (11.8%) developed CVD events over a mean follow-up period of 9.6 years. Patients who developed CVD tended to be older, had higher body mass index (BMI), LDL, homocysteine levels and disease activity, and were more likely to be male, Caucasian, smokers, on corticosteroid treatment, and have hypertension, renal impairment, elevated inflammatory markers, and positive antiphospholipid antibodies (**Table 1**). In ***multivariate Cox regression***, age (HR=1.05, P< 0.001), BMI (HR 1.05, P< 0.000), LDL (HR 1.14, P=0.019), abnormal C-reactive protein (HR=1.36, P=0.040), abnormal erythrocyte sedimentation rate (HR 1.3, P= 0.072), elevated creatinine (HR=1.00, P< 0.001), SLEDAI-2K score (HR=1.04, P < 0.001), and corticosteroid treatment (HR=1.52, P=0.007) were

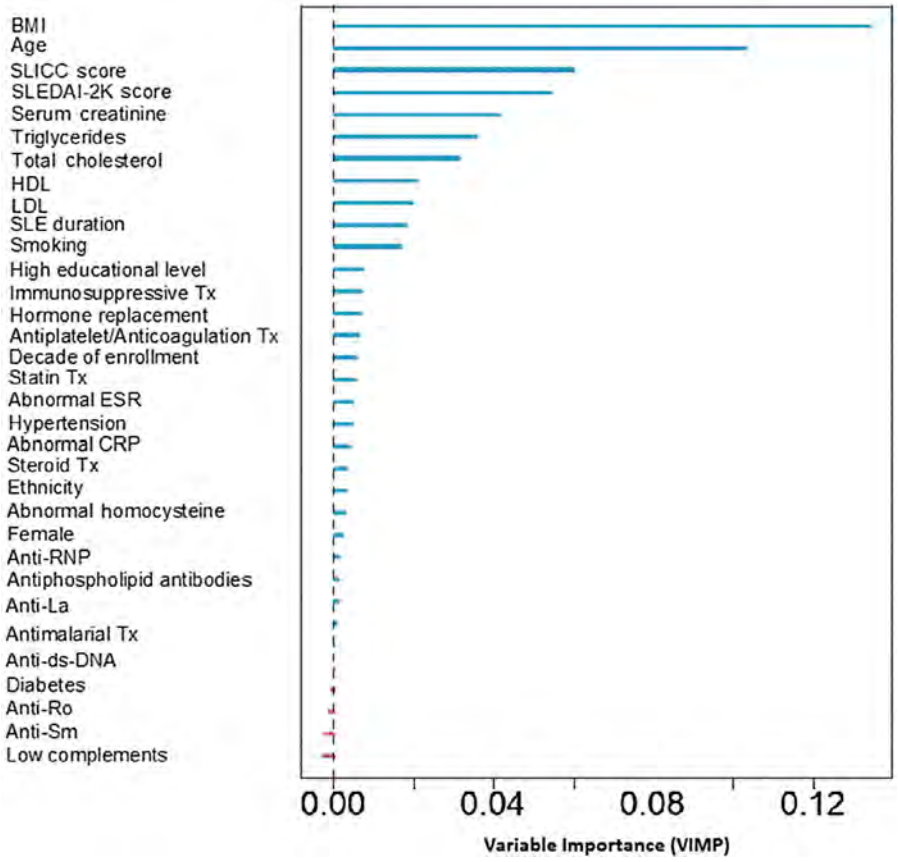

Figure 1: Graph of Variable Importance (VIMP) The greater the VIMP, the more impact a variable has on the prediction accuracy of a model. A value of 0 means that the variable has no impact on the model. A negative VIMP means that the variable decreases prediction accuracy. Tx: Treatment.

associated with increased CVD risk. In the ***RSF model***, the variables with the highest predictive values were: BMI, age, SDI, SLEDAI-2K score and serum creatinine (**Figure 1**). The integrated Brier score was 0.094 for the random survival forest model, compared to 0.100 for the Cox model, suggesting that the RSF yielded lower prediction errors (**Figure 2**).

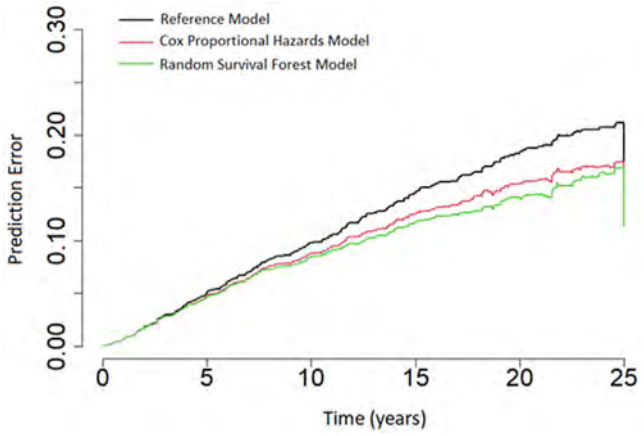

Figure 2: Prediction Error Over Time for Different Models The reference model refers to the marginal Kaplan-Meier prediction model, where no variables were used for stratification. The integrated Brier score (IBS) is calculated based on the integration of the average squared differences between predicted and observed survival, and a lower score is suggestive of overall lower prediction error. The IBS was 0.094 for the random survival forest model, compared to 0.100 for the Cox model.

Conclusion: RSF is a machine learning tool that could help improve the accuracy of CVD event prediction in SLE patients, and could lend insight into important predictors for CVD risk. The random survival forest yielded lower prediction errors compared to the multivariate Cox model.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with SLE are at increased risk for cardiovascular disease (CVD). Population estimates of CVD in SLE remains limited for non-White racial/ethnic populations in the United States. The Manhattan Lupus Surveillance Program (MLSP), a population-based retrospective registry of SLE patients, was used to investigate the prevalence of CVD among SLE patients in 2007.

Methods: MLSP patients were identified from rheumatologists, hospitals and population databases using ICD-9 codes. We included prevalent SLE patients aged ≥20 residing in Manhattan in 2007 who met one of the SLE classification criteria: 1997 ACR, SLICC or EULAR/ACR. CVD was captured if documentation existed confirming a myocardial infarction (MI) or cerebrovascular accident (CVA). Crude risk ratios were calculated for sex, age group, and race/ethnicity, and adjusted risk ratios (ARR) controlled for sex, age group, race/ethnicity and number of years since diagnosis. We used data from the National Health and Nutrition Examination Survey (NHANES 2009–2010) and the NYC Health and Nutrition Examination Survey (NYC HANES 2013–2014) to determine the prevalence of MI or CVA nationally and in NYC, respectively. Estimates for those identified as non-Hispanic Asian and non-Hispanic other race/ethnicity were not included, as they were either not available (NHANES) or estimates were unreliable (NYC HANES). We calculated the expected prevalence of MI or CVA by multiplying NHANES and NYC HANES prevalence estimates by strata-specific counts of MLSP SLE patients. We calculated crude prevalence ratios using both national and NYC estimates and age standardized prevalence ratios (ASPR) with three age groups using national estimates. We were unable to calculate age standardized prevalence ratios using the NYC estimates, as prevalence estimates broken down by demographic group and age group were unreliable.

TABLE 1. Demographics of SLE patients with evidence of cardiovascular outcomes - Manhattan Lupus Surveillance Project, 2007

	Any CVD outcome	SLE patients	Percent	Crude risk ratio	Adjusted risk ratio* (95% CI)
Total	179	1,285	13.9		
Male	23	108	21.3	(ref)	(ref)

Non- Hispanic Other	5	54	9.3	0.7	2.2 (0.7-6.5)

CVD = cardiovascular disease. Outcomes include myocardial infarction and cerebrovascular disease Patients include residents of Manhattan in 2007 with a new or existing diagnosis of SLE by ACR, EULAR, or SLICC criteria who are aged 20 or older. *Adjusted risk ratios were calculated from a Poisson model which incorporated sex, age group, race/ethnicity, and years since SLE diagnosis. 41 patients were excluded due to missing race/ethnicity information.

Results: Overall 1285 patients met SLE classification criteria (92% female, 30% non-Hispanic White, 26% non-Hispanic Black, 29% Hispanic, 11% non-Hispanic Asian.) CVD occurred in 179 (13.9%), occurred less frequently among women (ARR 0.6, 95% CI 0.4-0.8), and risk increased with age, Table 1. Compared with non-Hispanic White patients, risk of CVD was elevated among non-Hispanic Black (ARR: 1.8, 95%CI 1.3-2.6) and Hispanic SLE patients (ARR: 1.6 ,95%CI

TABLE 2. Crude and age standardized prevalence ratios for SLE patients, overall and by sex and race/ethnicity - Manhattan Lupus Surveillance Project, 2007

	Number of SLE patients	Observed patients	NYC HANES		NHANES			
			Unadjusted		Unadjusted		Adjusted	
			Expected patients	Ratio	Expected patients	Ratio	Expected patients	Ratio (95% CI)

Sex								
Male	108	23	4.2	5.4	6.9	3.4	6.1	3.8 (3.6-3.9)
Female	1,177	156	36.2	4.3	43.0	3.6	40.2	3.9 (3.8-3.9)
Race/Ethnicity								
Non-Hispanic White	388	48	13.2	3.6	18.7	2.6	21.6	2.2 (2.2-2.3)
Non-Hispanic Black	331	58	17.0	3.4	21.6	2.7	17.9	3.2 (3.2-3.3)
Hispanic	374	62	11.4	5.5	16.0	3.9	14.5	4.3 (4.2-4.4)
Non-Hispanic Asian	138	6						
Non-Hispanic Other	54	5						

Outcomes include myocardial infarction and cerebrovascular disease. Patients include residents of Manhattan in 2007 with a new or existing diagnosis of SLE by ACR, EULAR, or SLICC criteria who are aged 20 or older.

1.1-2.3), Table 1. CVD prevalence was approximately 3 times higher among MLSP patients than national estimates (ASPR: 3.1,9 5%CI 3.0-3.1) and ASPRs did not differ by sex, Table 2. Compared with the national population, the ASPR among SLE patients was most elevated among Hispanics (4.3, 95% CI 4.2-4.4) followed by non-Hispanic Blacks (3.2, 95% CI 3.2-3.3) and non-Hispanic Whites (2.2, 95% CI 2.2-2.3), Table 2. Unadjusted prevalence ratios of CVD were also elevated in comparison with NYC residents (4.0), particularly among men (5.4) and Hispanics (5.5).

Conclusion: These findings provide population-based estimates of CVD amongst a multi-racial/ethnic SLE registry These data can help providers ensure SLE patients are appropriately screened for CVD disease.

SARS-CoV-2 Antibody Formation After COVID-19 Vaccination in SLE Patients Treated with Belimumab: Single-Center Prospective Observational Study

Eun song Kang[1] and Yong-Gil Kim[2], [1]Korea University Ansan Hospital, Seoul, South Korea, [2]Department of Rheumatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) should be more proactive with the administration of the COVID-19 vaccine, as their systemic conditions are prone to developing severe outcomes. However, there are concerns that immunosuppressive agents used in SLE patients could reduce the immune response. Previous data demonstrates that total B-cell depletion impairs the humoral response in patients treated with Rituximab, but there is very limited information about Belimumab. Thus, we aimed to assess the immunogenicity and safety of COVID-19 vaccine in SLE patients treated with Belimumab.

Methods: Between December 14, 2021, and June 17, 2022, patients diagnosed with SLE who were receiving B-cell targeted therapy with Belimumab were recruited. We examined the patients' inoculation history, and antibody titer was measured in patients who had completed the third dose of COVID-19 vaccine. SARS-CoV-2 antibody titers were determined through semiquantitative anti-SARS-CoV-2 S enzyme immunoassay.

Results: As a result of surveying 21 SLE patients receiving Belimumab, only 10 patients completed up to the 3 doses of COVID-19 vaccine. The mean duration between the last (3rd) vaccination date and the date of sample acquisition was 22.5 weeks, and there was no patient with side effect other than mild myalgia. The antibody titer was positive in all

Table 1. Baseline characteristics of 10 SLE patients with Belimumab

Characteristics	Total patients (n=10)
Belimumab & Antibody	
Belimumab duration, month, median (IQR)	7 (2.5)
mRNA 3rd vaccination, n (%)	10 (100)
Vaccine date to serum date (week), median (IQR)	22.5 (2.5)
Side effect (moderate to severe), n (%)	0
COVID infection, n (%)	2 (20)
Antibody positivity (>0.8U/mL), n (%)	10 (100)
High antibody titer (>250U/mL), n (%)	8 (80)
Clinical features	
Age, years, median (IQR)	35.5 (13.28)
Female, n (%)	9 (90)
Duration of SLE, years, median (IQR)	4 (0–8)
SLEDAI, median (IQR)	11 (4.5)
Combined Medication	
Hydroxychloroquine, n (%)	8 (80)
Corticosteroid / Prednisone, n (%)	4 (40)
MMF, n (%)	5 (50)
Azathioprine, n (%)	1 (10)
Tacrolimus, n (%)	3 (30)
History of Rituximab, n (%)	2 (20)
SLE-related manifestations	
Lupus nephritis, n (%)	6 (60)
Cytopenia, n (%)	5 (50)
Pleuritis, n (%)	2 (20)
Anti-phospholipid syndrome, n (%)	2 (20)
Laboratory data	
WBC, mg/dL, median (IQR)	4720 (2645.24)
Hb, mg/dL, median (IQR)	11.67 (2.19)
Platelet, IU/mL, median (IQR)	154.1 (89.01)
C3, mg/dL, median (IQR)	55.02 (22.89)
C4, mg/dL, median (IQR)	10.98 (8.86)
Anti-dsDNA Ab, IU/mL, median (IQR)	242.32 (166.39)
ESR, median (IQR)	26.2 (22.8)
CRP, median (IQR)	0.28 (0.11)

Values are median (interquartile range) or n (%)
SLE, systemic lupus erythematosus, SLEDAI, systemic lupus erythematosus disease activity index; WBC, white blood cell; Hb, hemoglobin; C3/C4, complement 3/4; anti-dsDNA, anti-double strand DNA; ESR, erythrocyte sedimentation rate; CRP, c-reactive protein; IQR, interquartile range

10 patients, and among them, 8 patients showed a high antibody titer of 250 U/mL or more, and the remaining two patients showed a relatively low antibody titer of 117 U/mL and 112 U/mL, respectively. One patient had been treated with Rituximab within one year and the other was using hydroxychloroquine.

Conclusion: Our findings suggest that Belimumab does not compromise the antibody production from the vaccination. SLE patients with Belimumab need not be reluctant to get the COVID-19 vaccines because of worrying about the humoral response impairment.

A Comparative Study of Lupus Nephritis Class II and IgA Nephropathy: Renal Disease Other Than Lupus Nephritis in Systemic Lupus Erythematosus Patients

Eun song Kang[1] and Seokchan Hong[2], [1]Korea University Ansan Hospital, Seoul, South Korea, [2]Department of Rheumatology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is one of major organ involvement of SLE and renal biopsy is commonly performed in SLE patients suspected of having LN to assess the severity of renal damage and guide treatment decisions. However, there have been cases where renal biopsies performed in SLE patients resulted in the diagnosis of other renal diseases, such as IgA nephropathy. The prevalence and similarities between IgA nephropathy and LN in SLE patients have not been extensively studied. This study aims to investigate the characteristics of SLE patients diagnosed with renal disease other than LN, with a focus on IgA nephropathy and its similarities and differences with class II LN.

Methods: A retrospective analysis was conducted on SLE patients who underwent renal biopsies between April 1997 and October 2022 at a single tertiary care academic center. Patients diagnosed with renal diseases other than LN were identified, with a particular focus on IgA nephropathy. Baseline characteristics, laboratory findings, and renal biopsy pathologic findings were collected and statistical analyses were performed.

Results: Among 483 SLE patients who underwent renal biopsies, 25 (5%) were diagnosed with renal diseases other than LN. The most common non-LN pathology was IgA nephropathy, accounting for 28% of cases. A comparison between patients with IgA nephropathy and class II LN showed no significant differences in age, sex, SLEDAI, eGFR or UPCR. In

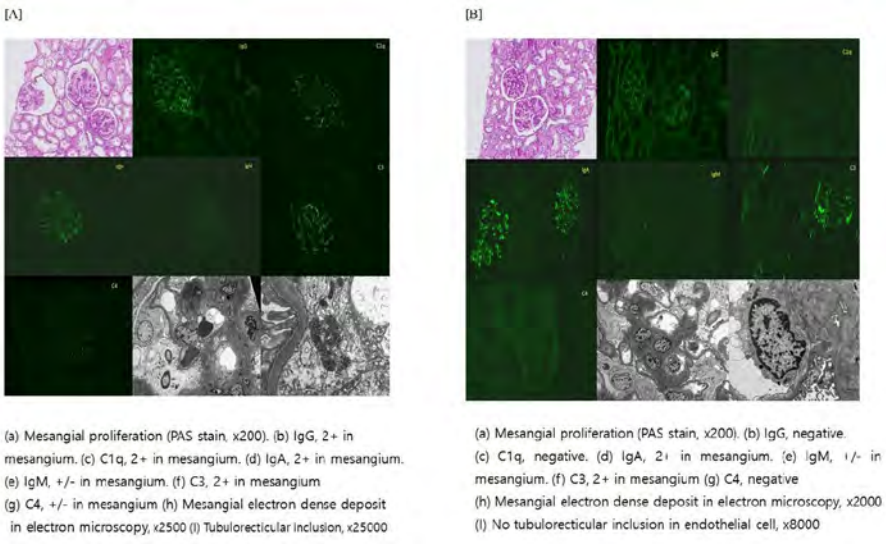

Figure 1. Comparison of Renal outcome of patients with IgA nephropathy and class II Lupus nephritis in SLE patients

Table 1. Kidney biopsy proflie of non-LN in patients with SLE

Total	25
IgA nephropathy	7 (28%)
DM nephropathy	2 (8%)
ANCA-associated GN	2 (8%)
Acute interstitial nephritis	2 (8%)
MPGN	4 (16%)
FSGS	3 (12%)
MGN	2 (8%)
TMA	2 (8%)
MCD	1 (4%)

Abbreviation: LN, lupus nephritis; DM, diabetes mellitus; ANCA-associated GN, anti-neutrophil cytoplasmic antibody-associated glomerulonephritis, MPGN, membranoproliferative glomerulonephritis; FSGS, focal segmental glomerulosclerosis; MGN, membranous nephropathy; TMA, thrombotic microangiopathy; MCD, minimal change disease.

pathologic finding, IgA nephropathy exhibited predominant IgA staining with higher intensity, while class II LN demonstrated "Full house" pattern. Long-term renal outcomes did not significantly differ between the two groups.

Conclusion: SLE patients can have renal diseases other than LN and IgA nephropathy was the most observed non-LN pathology in SLE patients. Comparison between IgA nephropathy and class II LN revealed similarities in clinical and pathological characteristics, although there were differences in immunofluorescence findings. The long-term renal outcomes

Prevalence of Hepatic Injury in Patients with Systemic Lupus Erythematosus: A 28-Year Single Center Experience

Asif Hitawala[1], Zerai Manna[2], Yenealem Temesgen-Oyelakin[3], Elaine Poncio[3], Christopher Koh[4], **sarfaraz Hasni**[2] and Theo Heller[4], [1]NIDDK/NIH, Bethesda, MD, [2]Lupus Clinical Trials Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, [4]NIDDK/Liver disease branch, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are known to have hepatic injury (HI), however large-scale longitudinal studies are lacking.We report our experience of HI in SLE patients.

Methods: A retrospective longitudinal single center study was conducted from 1994-2022 to identify patients enrolled in natural history protocol for SLE. Inclusion: 1) Age ≥ 18 years; 2) Diagnosis of SLE based on 1997 American College of Rheumatology revised criteria. Exclusion: Patients with either < 3 visits or < 6 months of follow-up. Demographic, laboratory, medication and liver histology data (when available) were obtained from the electronic medical records. Patients were divided into two categories- with and without HI. HI was divided into 5 categories- persistent hepatocellular injury, transient hepatocellular injury, persistent cholestatic injury, transient cholestatic injury and mixed. Patients were allowed to be in more than one category. Chi-square test and Kruskal-Wallis tests were used for comparing categorical and numerical variables, respectively. P-value < 0.05 was considered statistically significant and R software was used for all statistical analyses.

Results: Out of 1106 patients, 636 patients were included in the final cohort, with median duration of follow-up of 9.7 yrs (IQR 4.15-16.96). Mean age was 53.85 yrs (±15.31) and majority were females (555, 87.26%). A large proportion of patients (303, 47.64%) developed HI- persistent hepatocellular injury, transient hepatocellular injury, persistent cholestatic injury, transient cholestatic injury and mixed injury were present in 91, 174, 55, 78 and 67 patients, respectively. Patients with HI were older, more likely to be male, Asian, Caucasian or Hispanic and less likely to be African American (Table 1). Patients with HI also had longer follow-up. In majority of patients (230, 75.91%), the cause of HI could not be identified. Of the remaining 73 patients, non-alcoholic fatty liver disease was the most common, followed by drug-induced liver injury, SLE flare and non-alcoholic steatohepatitis (Table 2). On univariable analysis, apart from liver enzymes, age, gender, race, date of SLE diagnosis, duration of follow-up, iron, ferritin, ESR, and ANA were significantly associated with HI (Table 3). However, on multivariable analysis, only alkaline phosphatase, alanine transaminase and duration of follow-up remained associated with higher odds of HI, while older age was associated with lower odds, suggesting patients tend to develop HI at a younger age. All-cause mortality was higher in patients with HI.

Conclusion: A large number of SLE patients develop HI during the course of the disease, with transient hepatocellular injury the most common type of HI. While males and Asians, Caucasians and Hispanics seem to be at a higher risk, African-Americans seem to be at lower risk of HI, although in a majority of patients the cause remains unclear. Fatty liver disease

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic autoimmune disease and affects many organ systems. Juvenile onset disease, male sex, renal involvement, and central nervous system involvement are poor prognostic factors in SLE. ACR defined some neuropsychiatric symptoms in SLE. However, their attribution to SLE is challenging due to confounding factors, especially in

older populations. Atherosclerotic complications, including cardiovascular and cerebrovascular diseases, are important causes of mortality in patients with SLE. Until now, no study has evaluated nervous system mortality causes in SLE patients. This study investigated nervous system-related mortality in SLE in the past two decades in the USA.

Methods: This retrospective cohort study used the Multiple Cause of Death files maintained by the National Center for Health Statistics to investigate the direction of proportionate nervous system-related mortality in SLE, defined as the number of deaths from diseases of the nervous system (the underlying cause of death: International Classification of Diseases, version 10 [ICD10]: G00-G98), divided by the number of all-cause mortality in patients with SLE (defined in multiple causes of death: ICD10 code M32) from 1999-2020. The data set utilizes death certificate data for US residents. To analyze changes in mortality trends, we separated the study period into two decades, the first decade (1999-2009) and the last decade (2010-2020). Spearman's correlation test was used for trend analysis, and the Chi-square test was used for comparisons.

Results: 47,337 deaths in SLE occurred during the study period. 814 (1.72%) died of nervous system causes. The mean age for nervous system-related mortality was 69.3 years. Proportionate nervous system-related mortality in SLE was higher in women than men (1.79% vs. 1.34%, p=0.0087), significantly lower in African-American SLE patients than in other races (1.27% vs. 1.93%, p< 0.00001), and lower in Hispanic SLE patients than non-Hispanic patients (1.24% vs. 1.79%, p=0.0034). Proportionate mortality from nervous system disease increased from 1.33% in the first decade (1999-2009) to 2.11% in the second decade (p< 0.00001) (Figure 1). The most common nervous system cause of death in SLE was Alzheimer's Disease (27%). Table 1 shows other nervous system causes for mortality (Table 1).

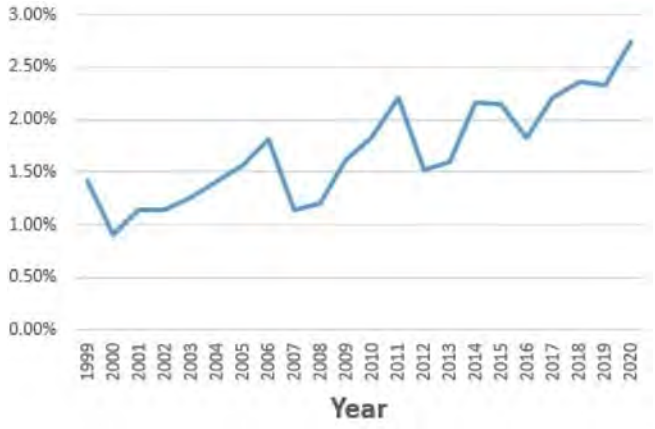

Figure 1. Proportionate Nervous System Disease Mortality in SLE Patients Over the Past Two Decades

Table 1. Mortality in SLE Patients from Diseases of the Nervous System

Mortality cause	N (%)
Alzheimer disease	220 (27)
Others (not listed)	168 (21)
Meningitis/Encephalitis	83 (10)
Epilepsy/status epilepticus	70 (9)
Parkinson disease	60 (7)
Multiple sclerosis	54 (7)
Anoxic brain damage	48 (6)
Senile degeneration of the brain	23 (3)
Acute transverse myelitis	20 (2)
Unspecified Encephalopathy	18 (2)
Guillan-Barre syndrome	14 (2)
Myasthenia gravis	14 (2)
Motor neuron disease	13 (2)
Sequelae of inflammatory diseases of CNS	10 (1)

Conclusion: This national data showed a significant increase in proportionate mortality from nervous system diseases in SLE. SLE patients in ethnic or racial minority groups seem protected from nervous system-related mortality. Prospective cohort studies are required to understand these trends.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Among the cutaneous manifestations of SLE, critical peripheral ischemia (CPI) including digital infarcts and gangrene are considered rare, gangrene occurring only in about 0.2% as initial presentation and in 1.2% in the longest longitudinal cohort with a follow up of 44 years[1]. Whether vasculitis or thrombosis or both contribute to these remains debated. We report the incidence, associations and outcome of digital infarcts and gangrene in the Indian Systemic Lupus Erythematosus(SLE) Cohort.

Methods: From the ongoing prospective INdian SLE inception cohort For Research (INSPIRE), baseline data on CPI was accessed with key terms: 'Digital Infarct' and 'Digital gangrene' in May 2023. Association with other clinical domains and autoantibodies including antiphospholipid antibodies were analysed between cases and controls (all others without digital infarcts or gangrene). Adjusted odds ratios were reported using multivariable logistic regression analysis to identify the factors associated with gangrene and or digital infarcts

Results: Of 2503 patients in the INSPIRE cohort, 79 (3.2%) patients had CPI at initial presentation. Their mean age was 28.7 ±9.5 years including 9 (11.3%) children and 76(96.2%) women. There were 92 events (gangrene 47, digital infarcts 45 and with both gangrene and infarcts in 13). The duration of CPI symptoms was 7.0 ±11.9 days. None of the CPI patients were smokers.

The presence of coexistent thrombosis AOR[10.2(3.91,24.5)]($p< 0.001$), Raynaud's phenomenon AOR[6.41(1.83,17.4)] ($p< 0.006$) and longer disease duration prior to diagnosis AOR[1.01(1.00,1.02)] ($p< 0.007$) were significantly associated with the presence of CPI in SLE patients. The presence of anti Scl-70 antibody AOR[5.34(1.78,13) ($p< 0.008$) and the

Abbreviations: ACL- Anticardiolipin Antibody , B2GP1- Beta 2 glycoprotein 1, SLEDAI- SLE disease activity index

antiphospholipid antibodies including lupus anticoagulant {AOR for triple positivity [3.75(1.10,9.70)](p< 0.05)} were significantly associated with higher odds of CPI positivity.(Table 1) None of Scl-70 positive patients had features of scleroderma. The disease activity as measured by SLEDAI and the proportion of early mortality were similar in those with and without CPI.

Conclusion: Critical peripheral ischemia occurred in a higher proportion (3.2%) of SLE patients in the INSPIRE cohort as compared to earlier reports. Both prothrombotic state and vasculopathy contribute to its occurrence.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by autoantibodies and systemic inflammation, affecting multiple organs especially kidney. Environmental factors, genetic predisposition, and hormone contribute to lupus pathogenesis. One of the environmental factors, obesity is now considered as a state of chronic low-grade inflammation, but the role of obesity in SLE remains controversial. Studies have shown that adipose tissue contributes to systemic inflammatory status in obese individuals by secreting adipokines, complement components, and other pro-inflammatory mediators. Our recent published studies showed that a high-fat diet exacerbated lupus development and autoimmunity in MRL/lpr lupus-prone mice. Here we compared the clinical features, lab parameters, and autoimmunity in obese and non-obese lupus patients.

Methods: For data abstraction, the AI software Deep6 was used for query building in patients diagnosed with SLE (ICD-10 code: M32.9). Using Slicer Dicer (via EPIC) and Microsoft Excel, data organization resulted in 1126 SLE patients in 2022, with 133 being obese (BMI >30) and 913 being non-obese control (BMI< 25). In a representative sample of patients with SLE in 2022, BMI levels, SLE disease activity (SLEDAI), lupus nephritis involvement, creatinine level, levels of autoantibodies including antinuclear antibody (ANA) and anti-dsDNA antibody, levels of C-reactive protein (CRP) and complement (C3 and C4), levels of triglyceride and cholesterol in patients' serum were extracted from EPIC to REDCap and exported as Excel file. Unpaired Student's *t-test* and multi-variable ANOVA were used for statistical significance analysis among the groups. Two-tailed $p< 0.05$ was considered significant.

Results: Ninety-nine lupus patients were included in this study; 49% were obese (BMI ≥ 30 kg/m^2) with a significantly higher ratio of total cholesterol/HDL and higher triglyceride level, in comparing to the 21% were non-obese (BMI< ![if !msEquation] > < ![endif] >25kg/m^2) patients. A significantly higher frequency of lymphocytes was observed in the blood of obese lupus patients compared to non-obese lupus patients (p< 0.01). There is no difference in SLEDAI, CRP, and ANA levels between obese and non-obese lupus patients. However, anti-dsDNA titer (p< 0.05) and C3 level (p< 0.005) were significantly increased in the obese lupus patients comparing to non-obese patients. Additionally, significant higher level of creatinine (p< 0.005) and significantly increased incidence of lupus nephritis (p< 0.05) and were found in obese patients compared to non-obese lupus patients.

Conclusion: Our results showed that obese lupus patients had a dysfunctional clinical and immunological phenotype with worse outcomes, indicating that obesity may directly influence SLE pathogenesis and autoimmunity. Further study in cellular and molecular levels in obese lupus patients may help us understand the complex mechanism underlying the relationship between SLE and obesity, providing better preventive and treatment strategies for obese lupus patients.

Discriminating Disease Flare from Infection in Febrile Patients with Systemic Lupus Erythematosus Admitted to a Safety-Net Hospital System: A Retrospective, Multicenter Study

Abhimanyu Amarnani[1], Flora Liu[2], Melissa Lee Wilson[2], Nathan Lim[2], William Stohl[3] and Leanna Wise[4], [1]NYU Langone Medical Center, New York, NY, [2]Keck School of Medicine and LAC+USC Medical Center, Los Angeles, CA, [3]University of Southern California Keck School of Medicine, Division of Rheumatology, Los Angeles, CA, [4]LAC+USC/Keck Medicine of USC, Pasadena, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Fever in systemic lupus erythematosus (SLE) patients presents a diagnostic challenge as the differential diagnosis includes disease flare and infection. Identifying laboratory parameters to distinguish between the two is important for clinical care improvement. This study evaluates clinical laboratory parameters in febrile SLE patients admitted to three safety-net hospitals in Los Angeles for their ability to discriminate flare from infection.

Methods: Patients aged over 18 years admitted between August 1, 2016, and July 31, 2019, with a diagnosis of SLE and fever (≥38C) were reviewed for infection versus flare based on viral panels, microbial cultures, antibiotic use, discharge diagnosis, and SLEDAI-2K scores. Laboratory parameters collected within 48 hours of admission (CBC with differential, liver function panel, ESR, CRP, C3, C4, lactate, procalcitonin, and ferritin) were analyzed.

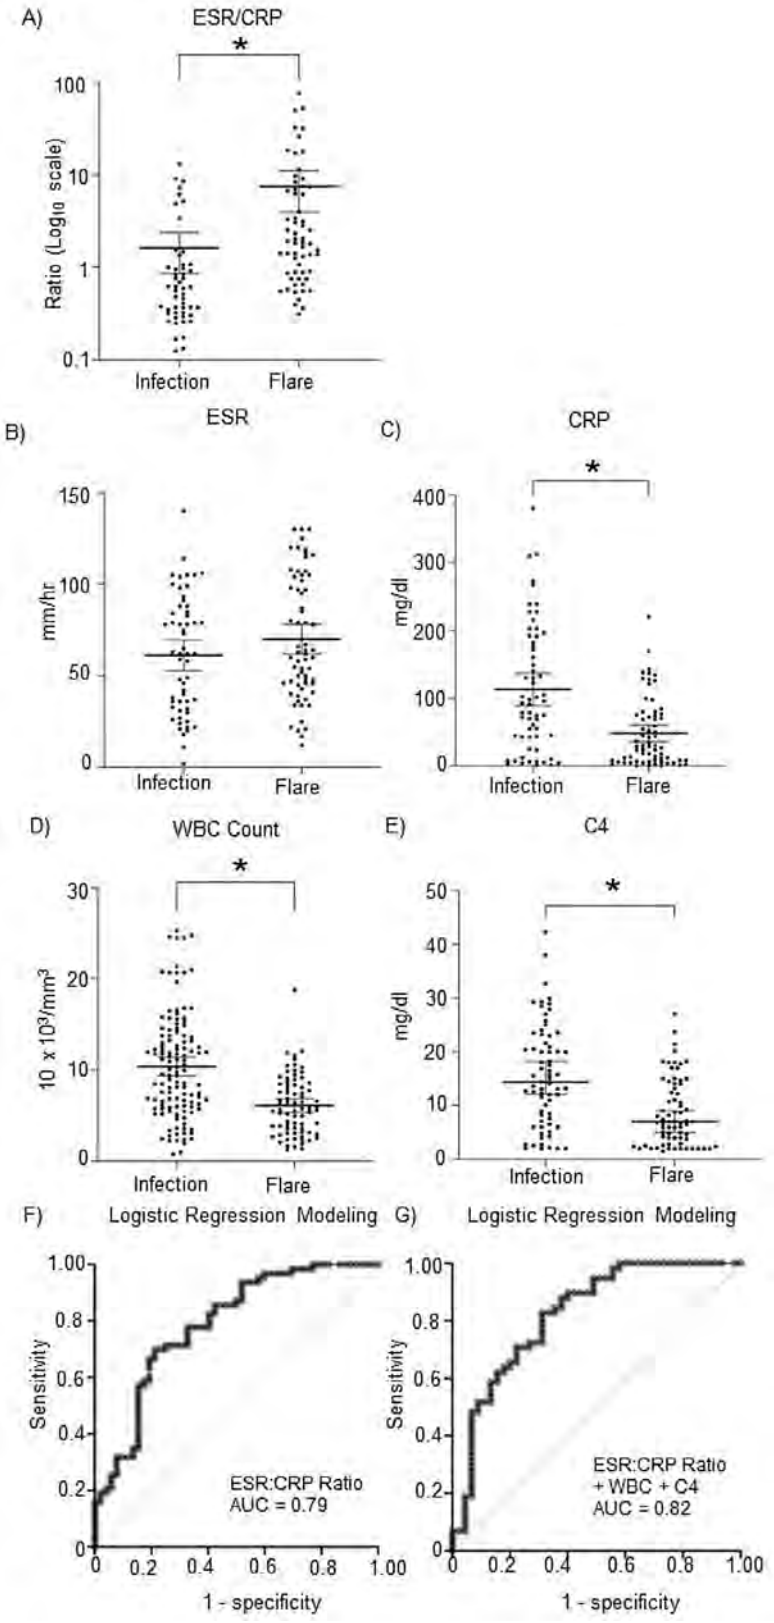

Figure 1. Scatterplots and ROC for variables included in ESR:CRP ratio + WBC count + C4 model. Scatter plots for ESR (A), CRP (B), and variables used in the model (C-E). *p<0.01, independent t-tests, Data are presented as individual points and mean ± 95% confidence interval. The ROC curves for the ESR:CRP ratio alone as well as the ESR:CRP ratio + WBC count + C4 used for logistics regression (F) as well as ESR:CRP ratio + WBC count + C4 vs. CRP + WBC count + C4.

Table 1. Demographics (sex, race/ethnicity, age, hospital site of admission), immunomodulatory medications and prednisone equivalents at time of admission, and proportion of patients discharged with increased steroid use and/or antimicrobials. All numbers represent the first case if the same patient had multiple presentations. All statistics Chi-square, except age which was a independent, t-test shown as mean +/- SD. UCLA = University of California, Los Angeles; LAC = Los Angeles County; USC = University of Southern California; DMARD = disease-modifying antirheumatic drugs; GC = glucocorticoids; mg = milligrams

Results: The study population included 200 admissions (123 infection and 77 lupus flare cases), representing 180 unique patients (Table 1). Thirteen percent of patients identified as Black and 72% as Hispanic. Febrile SLE patients with disease flare were younger than those with infection (mean age 37 versus 43, $p < 0.01$). Patients with an SLE flare were more likely using immunomodulatory medications on admission (25% versus 13%, $p < 0.05$) and were more likely to be discharged with an increased steroid regimen (84.3% versus 16.5%, $p < 0.001$) (Table 1). WBC count, hemoglobin, platelet count, neutrophil count, monocyte count, CRP, C3, C4, lactate, neutrophil/lymphocyte ratio, monocyte/lymphocyte ratio, and ESR:CRP ratio were significantly different in febrile SLE patients ultimately diagnosed with an infection from those diagnosed with an SLE flare (Table 2). Multivariable mixed effects logistic regression indicated that optimized differentiation of infection from SLE flare using a single metric is best when considering the ESR:CRP ratio, yielding a receiving operator characteristic (ROC) area under the curve (AUC) of 0.79. Combining the ESR:CRP ratio, C4 level, and WBC count improved the AUC to 0.82 (Figure 1). We defined ideal predictive cut-off point values for ESR:CRP ratio, WBC count, and C4 within the model. The thresholds for predicting flare over infection for each variable are ESR:CRP ratio ≥ 3.4 (Odds Ratio [OR] 1.39, Sensitivity [SE]=0.85, Specificity [SP]=0.35), WBC count ≤ 9.4 10^3/mm3 (OR 2.33, SE=0.52, SP=0.84), and for C4 ≤ 10.9 mg/dl (OR 1.67, SE=0.69, SP=0.69).

Table 2. Laboratory parameters as stratified by diagnosis of infection or flare. All values used are results from the first 48hours of admission. Hypothesis testing was conducted using independent t-tests. Data are presented as mean ± standard deviation. WBC = white blood cells; RDW = red cell distribution width; ESR = erythrocyte sedimentation rate; CRP = c-reactive protein; globulin gap = total protein – albumin

Clinical and Economic Burden of Herpes Zoster in Patients with Systemic Lupus Erythematosus: A Retrospective Cohort Study

Nikita Stempniewicz[1], Andrea Steffens[2], Kimvi Kim[1], Christopher Bell[3], Mary DuCharme[2], Helen Trenz[2] and David Singer[1], [1]GlaxoSmithKline, Philadelphia, PA, [2]Optum, Eden Prairie, MN, [3]GlaxoSmithKline, US Value Evidence and Outcomes, Durham, NC

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Herpes zoster (HZ) is characterized by a painful dermatomal rash and is associated with increased healthcare costs and reduced quality of life. Systemic lupus erythematosus (SLE) is associated with an increased risk of HZ. Data on the clinical and economic impact of HZ among people with SLE in the United States (US) is limited. This study aimed to estimate healthcare resource utilization (HRU) and costs in patients with SLE and HZ in comparison to patients with SLE only.

Methods: This retrospective cohort study used US administrative claims data (Optum Research Database) between October 2015 and March 2022 to identify adults (aged ≥18 years) with SLE, based on ≥1 inpatient or ≥2 outpatient claims ≥30 days apart with an International Classification of Diseases, 10th Revision, Clinical Modification (ICD-10-CM) diagnosis code for SLE (M32.xx, excluding M32.0). Patients with SLE were either assigned to an SLE+HZ or SLE-only cohort based on ≥1 HZ diagnosis code (ICD-10-CM: B02.xx, excluding B02.2x). Index date was the first observed HZ diagnosis between October 2016 and March 2022 for the SLE+HZ cohort and was assigned for the SLE-only cohort based on the distribution of index dates in the SLE+HZ cohort. All patients were required to have 12 months of continuous enrollment (CE) pre-index (baseline) and ≥1 month of CE post-index (follow-up). Patients with a baseline HZ diagnosis or a HZ vaccine in the up to 5 years pre-index (depending on data availability for patients) were excluded. Clinical and demographic characteristics were measured during baseline. Patients with SLE+HZ were propensity score matched 1:4 to patients with SLE-only with at least as much post-index follow-up time. Propensity scores were calculated using logistic regression with cohort as the outcome and baseline characteristics as predictors. Outcomes included all-cause HRU and costs in the 1-month period post-index and for matched sets with sufficient follow-up time, also in the 3-month period post-index. Outcomes were described overall, and stratified by ambulatory, emergency room, inpatient, and pharmacy HRU and costs.

Results: After matching, 2,126 and 8,504 patients were included in the SLE+HZ and SLE-only cohorts, respectively. No significant differences were observed in demographic and clinical characteristics between the matched cohorts, with similar mean (standard deviation [SD]) age (59 [14]), percent female (91-92%), and baseline HRU and costs (table 1). In the 1-month post-index, mean (SD) HRU was higher in the SLE+HZ vs. SLE-only cohort for ambulatory (SLE+HZ: 4.5 [4.3]; SLE-only: 3.1 [4.1]) emergency (SLE+HZ: 0.41 [0.99]; SLE-only: 0.17 [0.71]), inpatient (SLE+HZ: 0.09 [0.32]; SLE-only: 0.04 [0.20]), and pharmacy HRU (SLE+HZ: 6.23 [4.75]; SLE-only: 4.44 [4.45]). Mean (SD) costs 1-month post-index were

*Standardized differences are the difference in means divided by a pooled standard deviation. Standardized differences <10% were considered balanced (Austin PC. Balance diagnostics for comparing the distribution of baseline covariates between treatment groups in propensity-score matched samples. Stat Med. 2009).

#Costs computed as the combined health plan and patient paid amounts, and presented in 2021 USD

[1] Quan H, Li B, Couris CM, Fushimi K, Graham P, Hider P, Januel JM, Sundararajan V. Updating and validating the Charlson comorbidity index and score for risk adjustment in hospital discharge abstracts using data from 6 countries. Am J Epidemiology. 2011

also higher in the SLE+HZ cohort ($4,383 [$13,737]) vs. SLE-only cohort ($3,033 [$11,337]). Among matched sets with ≥ 3 months of follow-up (93% of overall cohorts), higher HRU and costs in the SLE+HZ vs. SLE-only cohort were also observed in the 3-months post-index (Table 2).

Conclusion: Patients with SLE and HZ had higher HRU and costs than those without HZ, and HZ prevention may be important to consider in this population.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To describe the clinical characteristics, therapies, and outcomes of patients with SLE and Posterior reversible encephalopathy syndrome (PRES).

Methods: We performed a multicenter cohort study in the United States from August 1999 - March 2021. We included patients with SLE who met the 2019 EULAR/ACR criteria and had incident PRES events. A case of incident PRES was defined as 1) the first acute neurological episode attributable to PRES, and 2) confirmation of vasogenic edema with MRI/CT and other causes excluded. A systematic literature review (SLR) was performed according to the PRISMA guidelines. We did a comprehensive search in multiple databases from their inception to October 20, 2021, in any language. Two reviewers independently screened and reviewed the articles and extracted information. We included case reports/case series

Table 1. Demographics and comorbidities of patients with systemic lupus erythematosus (SLE) and posterior reversible encephalopathy syndrome (PRES).

Demographics and comorbidities	n/N (%)
Age at PRES onset, mean (SD)	27.6 (12.28)
Female	276 (91%)
Male	27 (9%)
Comorbidities (history of)	
Hypertension	71/168 (42%)
Dyslipidemia	14/93 (15%)
Diabetes	9/93 (10%)
Ischemic heart disease	3/94 (3%)
Characteristics of SLE	
Duration of SLE, months, median (IQR)	36 (2 – 69)
Disease activity, SLEDAI score at onset (n=77), mean (SD)	17.8 (10.66)
SLE manifestations (history or at onset)	
Lupus nephritis (Biopsy proven)	225/254 (83%)
Available biopsy description (n=132)	
Class IV	85/132 (64%)
Class III	22/132 (17%)
Class IV+V	12/132 (9%)
Class III+V	6/132(5%)
Other (Class I/II or V)	7/132 (5%)
Hematological activity *	112/190 (59%)
Mucocutaneous	86/179 (48%)
Musculoskeletal	83/178 (47%)
Serositis	43/177 (24%)
Secondary antiphospholipid syndrome	25/186 (13%)
Thrombotic microangiopathy	30/206 (17%)
Diffuse alveolar hemorrhage	12/187 (6%)
Immunologic profile (history of)	
Anti-dsDNA antibodies	147/183 (80%)
Anti-Sm antibodies	29/71 (41%)
Antiphospholipid antibodies	57/151 (38%)
Exposure to immunosuppressants (≤ 3 months to PRES onset)	
Any immunosuppressant	219/250 (88%)
Glucocorticoids	199/219 (91%)
Cyclophosphamide	78/219 (36%)
Mycophenolate Mofetil	47/219 (21%)
Antimalarials	38/219 (17%)
Calcineurin inhibitors	20/219 (9%)

Abbreviatures: SD, standard deviation; IQR, Interquartile range; SLEDAI, Systemic Lupus Erythematosus Disease Activity Index.
*Hemolysis, leukopenia, or thrombocytopenia.

reporting cases that met the inclusion criteria used for the cohort. We abstracted demographics, clinical and imaging features, treatment, and disease activity (SLEDAI). We summarized the days to recovery and length of stay (LOS). Neurological symptoms were classified as transient (≤3 days), persistent (≥14 days), or sequelae if permanent. The first available imaging was used to assess the distribution of vasogenic edema and other findings: restricted diffusion, hemorrhages, contrast enhancement, and angiography (MRI/CT). At least two consecutive imaging studies were required to determine the reversibility of edema. Patients were observed until death or last follow-up. The main outcomes after discharge were PRES relapses and all-cause mortality at 90 days. Cases in the cohort were combined with data from the SLR. Descriptive statistics were used to summarize pooled results.

Results: A total of 303 cases were included, 50 (17%) from the cohort, and 253 (83%) from the SLR. The mean age at PRES onset was 27.6 years (SD 12.3), and 91% were women. Comorbidities included hypertension in 42%, dyslipidemia in 15%, and diabetes in 10%. The median (IQR) time between SLE and PRES was 36 months (2-92), and the median follow-up was one month (0.3-12). At onset, SLEDAI was 17.8 (SD 10.7), lupus nephritis was present in 83%, and the autoantibody profile consisted of Anti-dsDNA (80%), Anti-Sm (41%), and aPL (38%) (Table 1). Clinically, 90% had associated high blood pressure (BP) (>140/90 mm Hg), and neurological manifestations were seizures in 78%, headache in 55%, visual disturbance in 45%, altered mental status in 38%, and focal deficits in 9% (Table 2). 97% of the patients survived and recovered after a median of 4 days (2-8), and LOS of 11 days (6-21). Among survivors, symptoms were transient in 45%, persistent in

Table 2. Clinical features of incident posterior reversible encephalopathy syndrome (PRES) in patients with systemic lupus erythematosus (SLE).

Clinical features of PRES at the onset	n/N (%)
PRES as part of initial SLE manifestations.	21/289 (7%)
Neurological symptoms	
Seizures	229/294 (78%)
Headache	163/294 (55%)
Visual disturbance	133/294 (55%)
Altered mental status	112/294 (38%)
Focal deficits	25/294 (9%)
Status epilepticus	15/294 (5%)
Other clinical manifestations at onset	
High blood pressure, >140/90 mm Hg	258/287 (90%)
Systolic blood pressure, mm Hg, mean (SD)	177.8 (30.53)
Diastolic blood pressure, mm Hg, mean (SD)	106.9 (19.32)

Abbreviatures: SD, standard deviation.

Table 3. Imaging features of incident posterior reversible encephalopathy syndrome (PRES) in patients with systemic lupus erythematosus (SLE).

Radiographic features of PRES at the onset	n/N (%)
Distribution of vasogenic brain edema	
Parieto-occipital	275/294 (94%)
Frontal lesions	94/294 (32%)
Temporal lobe	73/294 (25%)
Cerebellum	52/294 (18%)
Basal Ganglia	32/294 (11%)
Brainstem	27/294 (9%)
Asymmetric edema	60 /279 (22%)
Other imaging findings	
Diffuse or focal vasoconstriction on angiography (CT/MRI)	22/64 (34%)
Hemorrhages	27/264 (10%)
Restricted diffusion in DWI, or ADC	21/225 (9%)
Contrast enhancement	11/190 (6%)
Second radiographic assessment	
Improvement or reversible edema	178/183 (97%)
The time between imaging studies (n=159), days, median (IQR)	15 (7 – 49)

Abbreviatures: CT: computed tomography; MRI, magnetic resonance imaging, IQR, Interquartile range; DWI, Diffusion-weighted imaging; ADC, apparent diffusion coefficient.

19%, and 8% had sequelae. In the first imaging study, most had posterior and symmetric vasogenic edema. Among the 183 (60%) with follow-up imaging, brain edema improved in 97% after 15 days (7-49) (Table 3). Treatment strategies for PRES included BP control in 86%, antiepileptics in 64%, and new immunosuppressant therapy in 37%. After discharge, 12% relapsed after a median of 283 days (21-749). The 90-day mortality was 4%.

Conclusion: PRES in SLE develops predominantly in patients who have lupus nephritis. While most cases are reversible, sequelae are possible, and relapses are not uncommon.

Risk Factors for Human Papillomavirus Cervical Infection and Clearance in Patients with Systemic Lupus Erythematosus: The PAPILUP Study

Tiphaine Goulenok[1], Valentine Marie Ferre[2], Celine Mendes[1], Lea Dayan[3], Margot Bucau[1], Fatima Farhi[1], Thomas Papo[2] and Karim Sacre[2], [1]Assistance Publique Hopitaux de Paris, Paris, France, [2]Université Paris Cité, Paris, France, [3]Maison de Sante les Epinettes, Paris, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: An impaired clearance of cervical human papillomavirus (HPV) related to inadequate immune responses may result in persistent infection and increase the risk to develop cervical dysplasia in patients with systemic lupus erythematosus (SLE). We aim to identify risk factors for HPV infection and clearance in patients with SLE.

Methods: All SLE patients have been included in the *ongoing*PAPILUP study (National center for rare immune-mediated inflammatory diseases, Internal Medicine Department, Bichat Hospital, Paris, France) that aimed to improve HPV-related cervical cancer screening (CCS) in SLE patients. All SLE patients aged 30 to 65 who had HPV-related CCS between September 2021 and July 2022 were screened. The frequency of High-Risk (HR)-HPV was assessed in SLE patients in comparison to healthy and HIV-positive controls screened during the same period. The risk factors for persistent infection and clearance of HR-HPV in SLE patients were analyzed.

Results: Overall, 65 of the 107 SLE patients involved in the PAPILUP study were analyzed. The median age at CCS was 45 [39-51]. CCS was up to date in only 36 (55.4%) patients and only one patient (1.5%) had received HPV vaccine. The median SLE disease duration was 12 years [6-21] with a median SLEDAI score of 2 [0-4] at study time. Thirty-one (47.7%) patients had an history of lupus nephritis. Thirty-four (52.3%), 62 (95.4%) and 21 (32.3%) were currently receiving glucocorticoids, hydroxychloroquine and immunosuppressive drugs, respectively. HR-HPV were detected in 19 (29.2%) SLE patients. The frequency of HR-HPV did not differ between SLE patients and healthy controls (119 subjects, median age 43 [37-50], 21.8% of HR-HPV infection, p= 0.291). However the frequencies of multiple HR-HPV (at least 2 coexisting types)and abnormal cervical cytology (ACC, i.e cervical cytology samples enriched with atypical squamous cells, low-grade or high-grade squamous intraepithelial lesions) tended to be higher in SLE patients as compared to healthy controls (15.4% of multiple HR-HPV in SLE vs 6.7 % in healthy p=0.059; 16.9% of ACC in SLE vs 9.2% in healthy, p=0.125). Of note, the

frequency of multiple HR-HPV (15.4% vs 11.5%, p=0.407) and ACC (16.9% vs 11.5%, p=0.255) in SLE patients were in the same range as those in HIV-positive patients (n=192, median age 46 [41-53]). Using multivariable logistic regression model, the only significant risk factor for HR-HPV identified in SLE patients was the duration of the lupus disease (OR 16.1 [1.7-156], p=0.017) . A second HPV screening was performed 12.9 [10.2-14.1] months after the first one in 14 (73.7%) of the 19 HPV +SLE patients. A persistent HR-HPV infection was observed in 11 cases (78.6%). Of note, HR-HPV cleared in 2 of 4 (50%) patients who had never received steroids and immunosuppressive (IS) drugs but in only 1 of 10 (10%, p=0.099) who received long term steroids (median exposure length 9 [5.5-17.7] years) and IS drugs (median exposure length 6 [3.6-10] years).

Conclusion: Multiple HR-HPV and abnormal cervical cytology are frequent in SLE patients comparable to that of HIV-positive patients. The duration of SLE disease increases the risk for HR-HPV regardless of age. Long lasting immunosuppression induced by treatment might impede HPV clearance.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Data from limited studies of LN in the Gulf region suggest that LN manifests more severely in this region than in Caucasian populations, yet there are no treatment recommendations specific to the Gulf region.[1] This study aims to characterize patients with LN in the Gulf region to better understand disease burden and inform treatment recommendations to improve patient outcomes.

Methods: In this prospective, multicenter study (GSK Study 216989), adults with an established diagnosis of LN (biopsy proven or clinician diagnosis) were enrolled from sites in Kuwait, Oman, Qatar, and the UAE. At enrollment, the site physician extracted patient demographics and clinical characteristics retrospectively from medical charts for the previous < 12 months, and patients completed the 36-Item Short Form Health Survey (SF-36). Prospective medical chart follow-up continued for up to 12 months after enrollment. This analysis reports only data collected retrospectively at enrollment.

Results: This analysis comprised 193 patients with LN, the majority of whom were female (83.9%), of Arab ethnicity (85.0%), and with a mean (standard deviation [SD]) age of 37.2 (10.4) years (**Table**). Patients had a mean (SD) age of 27.4 (10.6) years at the time of SLE diagnosis, 30.5 (10.8) at LN diagnosis, and 35.3 (9.9) at ESKD diagnosis (n=11). Comorbidities were reported for 69.4% (n=134) of patients, most commonly endocrine and metabolic disorders (32.1%; n=62). One-third of patients had no kidney biopsy in the year preceding enrollment (35.6%; n=68), and LN class was not available for 26.9% (n=52) of patients, suggesting a potential lack of routine biopsy for some patients. Among available data, the proportions of LN Class III, IV, and V were similar (22.0–25.5%; n=31–36). Renal remission was achieved any time after LN diagnosis in 57.7% (n=101) of patients with available data. The mean (SD) number of prior treatment failures/relapses was 1.4 (3.6)

Table. Summary of demographics and characteristics among patients with LN in the Gulf region. *Those reported for >10% of patients are shown; †for 11 of the 12 patients with ESKD; ‡percentage among those with available data (n=191); §percentage among those with classification (n=141) ||percentage among those with available data (n=175); ¶data missing for 42 patients (n=151). Figure. Mean (SD) SF-36 subscale scores (N=193).

in those with available data. Mean (SD) overall SF-36 score was 66.3 (19.1); scores across domains were generally similar, with energy/fatigue having the lowest score (57.7 [21.2]), and social functioning the highest (72.6 [26.5]; **Figure**).

Conclusion: These retrospective data suggest that approximately one-quarter of patients with LN in the Gulf region did not have sufficient histological classification to guide therapy, and these inconsistencies in histological data make it difficult to compare Gulf patient characteristics to published data from international cohorts. However, age at SLE diagnosis was young, and patients appeared to be similarly impacted across all SF-36 quality of life subscales, whereas a large international inception cohort reported relatively greater impacts in role of physical functioning than other domains.[2] Prospective data generated from this cohort may aid understanding of differences in care and may have the potential to inform LN treatment guideline development in the Gulf region.

Racial Disparities in Lupus Nephritis: A Nationwide Analysis

Faria Sami[1], Shahzad Ahmed Sami[2], Augustine Manadan[3] and Shilpa Arora[1], [1]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, [2]Trinity Health Oakland Hospital, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a significant predictor of morbidity and mortality in Systemic Lupus Erythematosus (SLE). Racial disparities are known to exist in SLE in terms of the prevalence of LN, healthcare access, and outcomes. We aimed to study racial disparities in LN and predictors of in-hospital death.

Methods: Data was obtained from the National Inpatient Sample (NIS) between 2016-2019 using ICD-10 codes. All adult hospitalizations with a primary or secondary diagnosis of LN were included and divided into African American (AA) and Hispanic race vs others. Demographics, socio-economic variables, several complications, health care burden, and mortality were compared between the two groups. Univariate and multivariate logistic regression analyses were conducted for predictors of in-hospital death in LN. Variables with a P value ≤0.2 in the univariate analysis were included in the multivariate model and a P value of ≤0.05 was considered to be significant in the final model.

Results: We identified 104, 865 adult LN hospitalizations, of which 66.3% were African Americans or Hispanics (table 1). This group had more females (85.5% vs 79.9%, p< 0.001), were younger (38.4 vs 45.6 years, p< 0.001),were more likely to be from the low-income group (45.8% vs 23.6%, p< 0.001) and more often had Medicaid (30.6% vs 19.4% p< 0.001) in comparison to other races. In-patient mortality was low overall with lower odds of death in the AA-Hispanic group (1.7% vs 2.6%, OR 0.67, p< 0.001) (table 2).AA/ Hispanic LN patients had higher odds of renal failure (82.5% vs 79.1%, OR 1.25, p< 0.001) and end-stage renal disease (ESRD) (44.6% vs 33.9%,OR 1.6, p< 0.001) but were less likely to receive a renal transplant (4.3% vs 5.2%, OR 0.8, p=0.005). They were more likely to leave against medical advice (3.0% vs 1.7%, OR 1.8, p< 0.001,)and less likely to be transferred to a skilled nursing facility (8.7% vs 13.3%,OR 0.6, p< 0.001). Multivariable analysis for predictors of in-hospital death in LN showed following significant variables: Age (OR 1.0, p< 0.001), CCI (OR 1.2, p< 0.001), Medicaid (OR 0.7, p=0.014), small bed size (OR 0.6, p=0.003), sepsis (OR8.54, p< 0.001), PE/DVT (OR 2.8, p< 0.001), and kidney failure (OR4.1, p< 0.001) (table 3).

Conclusion: In the national inpatient sample, almost two-thirds of LN patients were AA or Hispanic. This group had a higher proportion of females, was younger, belonged more often to the lower income quartile, and was more likely to have Medicaid insurance. They had higher odds of renal failure and ESRD in comparison to other races and were less likely to receive renal transplants. The in-hospital mortality was lower in the AA/Hispanic-LN group, but race was not found to be an independent predictor of death in LN. Sepsis, kidney failure, PE/DVT, Charlson comorbidity index, and age were associated with higher odds of in-hospital death in LN.

Hospitalization Characteristics	Adult AA/Hispanic LN N = 69510 (66.29%)	Adult non-AA/Hispanic LN N = 35355 (33.71%)	P-Value Odds ratio (OR)

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Over the past several decades, the treatment of lupus has seen significant advancements, with the approval of belimumab in 2017, and anifrolumab in 2021. Yet, the impact of changes in the standard of care on systemic lupus erythematosus (SLE) mortality and the prevalence of lupus nephritis remains understudied. This study was conducted to fill this knowledge gap.

Methods: We analyzed data from patients with SLE who received follow-up care at St. Luke's International Hospital between April 2006 and February 2023, excluding those with missing diagnosis date information. Patients were stratified based on the timing and their age at the onset of their disease. We utilized Gray's test to examine differences in mortality rates and the prevalence of lupus nephritis among the groups.

Results: We included a total of 501 SLE patients in the study. The median age at diagnosis was 31.0 years [21.0, 43.0], with approximately 90% of the patients being Japanese. Biopsy-proven lupus nephritis and class III lupus nephritis were observed in 24% and 16.4% of the patients, respectively. chronic kidney disease (CKD) stage 4 or 5 was noted in 2.5% of the patients, while 2.7% died during the follow-up period. When patients were segregated according to the calendar year of diagnosis, lower cumulative incidence of biopsy-proven lupus nephritis, class III/IV lupus nephritis, and mortality was noted in those diagnosed in the 2010s and 2020s, as compared to those diagnosed in the 2000s and prior. Additionally,

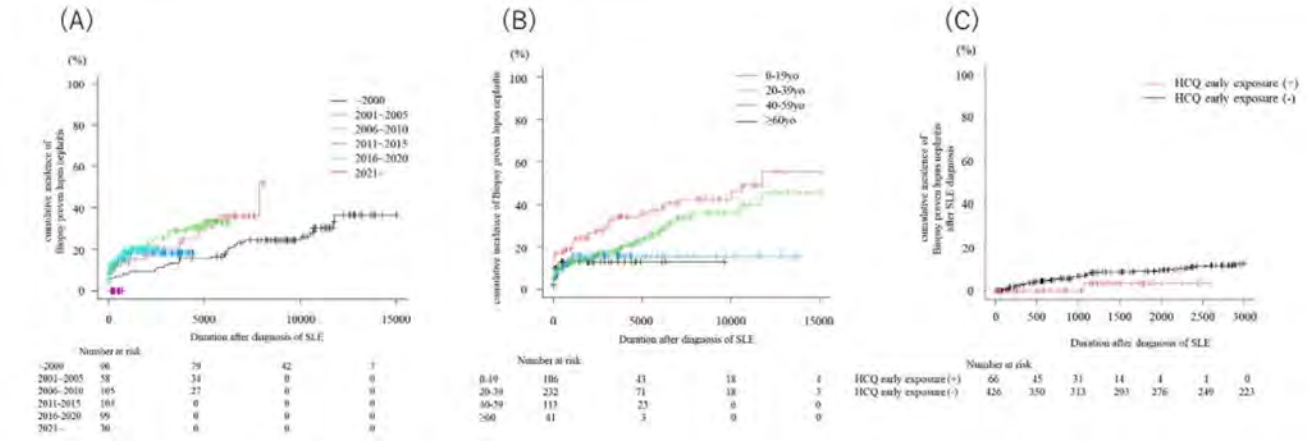

Figure 1: cumulative incidence of biopsy proven lupus nephritis A) Change in the cumulative incidence of lupus nephritis according to the year of diagnosis B) Change in the cumulative incidence of lupus nephritis according to the age of diagnosis C) Change in the cumulative incidence of lupus nephritis after the diagnosis of SLE according to the early exposure (<3m of onset) to hydroxychloroquine

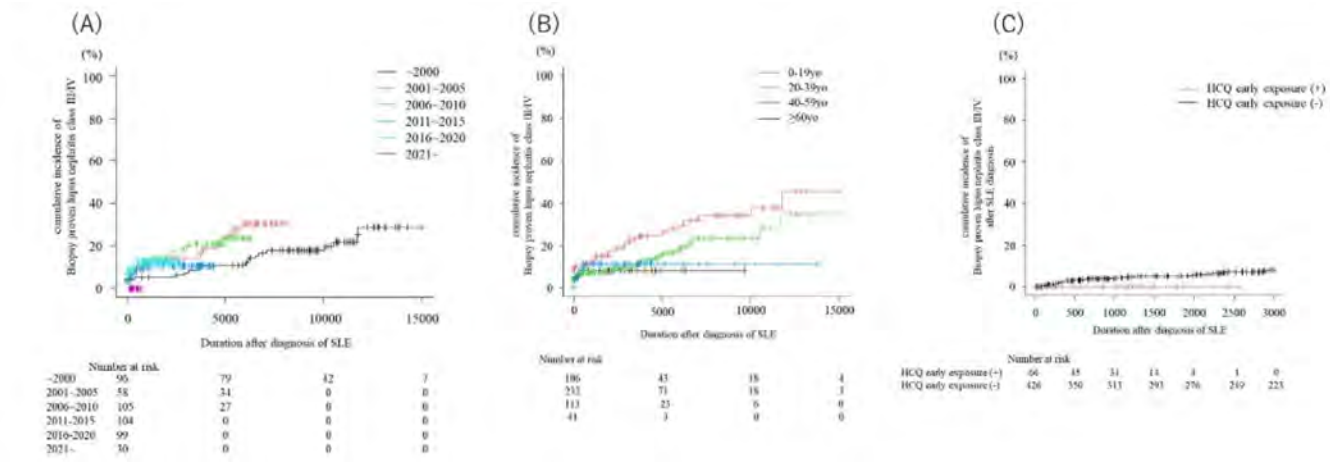

Figure 2: cumulative incidence of biopsy proven lupus nephritis class III/IV A) Change in the cumulative incidence of lupus nephritis class III/IV according to the year of diagnosis B) Change in the cumulative incidence of lupus nephritis class III/IV according to the age of diagnosis C) Change in the cumulative incidence of lupus nephritis class III/IV after the diagnosis of SLE according to the early exposure (<3m of onset) to hydroxychloroquine

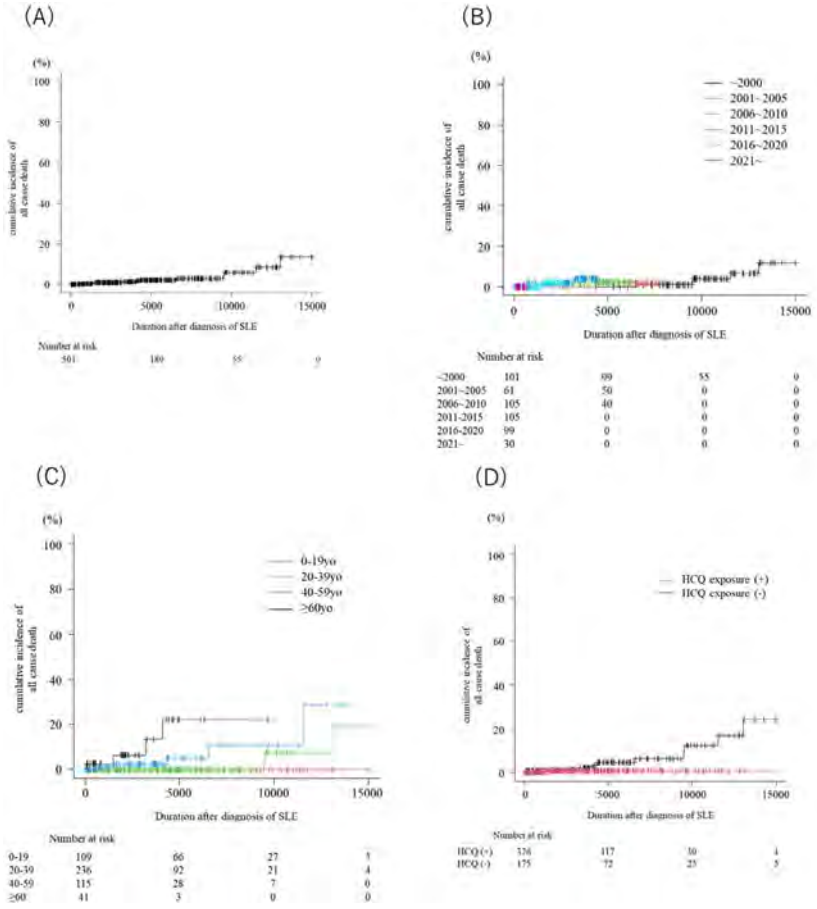

Figure 3: cumulative incidence of all cause death A) Change in the cumulative incidence of all cause death B) Change in the cumulative incidence of all cause death according to the year of diagnosis C) Change in the cumulative incidence of all cause death according to the age of diagnosis D) Change in the cumulative incidence of all cause death after the diagnosis of SLE according to the exposure to hydroxychloroquine

the incidence of new lupus nephritis and class III/IV lupus nephritis was lower among patients who initiated HCQ at diagnosis. HCQ was demonstrated to be a protective factor against the development of CKD stage 4 or 5 and all-cause mortality (CKD stage 4 or 5: Hazard Ratio [HR] 0.22, 95% Confidence Interval [CI] 0.06-0.83, p=0.03; all-cause death: HR 0.124, 95% CI 0.03-0.56, p< 0.01). Furthermore, the prevalence of lupus nephritis and class III/IV lupus nephritis was higher among patients diagnosed with SLE before the age of 40, compared to those diagnosed at or after 40. However, even among this group, the mortality rate was lower.

Conclusion: Advancements in lupus treatment have considerably improved SLE mortality and the prevalence of lupus nephritis. Moreover, initiating treatment with hydroxychloroquine was found to be a significant factor in improving lupus outcomes.

High Chronicity Index of the Modified NIH (National Institute of Health) Scoring System of Lupus Nephritis Is Associated with Increased Risk of End-stage Kidney Disease: A Retrospective Single-center Study

Shiori Nakagawa, Yasunori Iwata, Takahiro Yuasa, Keisuke Sako, Keisuke Horikoshi, Taichiro Minami, Megumi Oshima, Tadashi Toyama, Shinji Kitajima, Akinori Hara, Norihiko Sakai, Miho Shimizu and Takashi Wada, Department of Nephrology, Kanazawa University Hospital, Kanazawa, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a major manifestation which develops in more than 50% of patients with systemic lupus erythematosus (SLE), and is also a primary risk factor for morbidity and mortality in these patients. The revision of International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification guidelines for lupus nephritis (LN) was suggested by a working group, who recommended a modified National Institute of Health (NIH) activity and chronicity scoring system to evaluate active and chronic LN lesions. However, whether this approach was useful for estimating long-term prognosis for LN patients is unclear.

Methods: We conducted a retrospective cohort study in Japanese subjects with biopsy-proven LN, between 1977 and 2022. Pathologic lesions were evaluated based on ISN/RPS 2003 classifications and the modified NIH scoring system. Patients were grouped by activity index (low, 0–5; moderate, 6–11; high, 12–24), and chronicity index (low, 0–2; moderate, 3–5; high, 6–12). The primary outcome was a composite of end-stage kidney disease (ESKD) or all-cause death, and the secondary outcome was ESKD alone.

Results: Seventy subjects with a median age of 31 years were included. Median follow-up period was 11.3 years. For the activity index, Kaplan–Meier analysis showed that the survival rate of the primary outcome decreased with a higher activity index (log-rank trend p = 0.026) . Multivariable analysis, adjusted by age and serum creatinine, did not show any significant relationship to the activity index. For the chronicity index, Kaplan–Meier analysis showed that the survival rate of the primary outcome decreased with a higher chronicity index (log-rank trend p< 0.001). Multivariable analysis, adjusted by age and serum creatinine, revealed that moderate (HR 6.18, 95% CI 1.15 to 33.3; p = 0.034) and high chronicity indices (HR 20.33, 95% CI 1.14 to 360.50; p = 0.04) were significant risk factors for the primary outcome. Consistent results with the primary outcome were determined by Kaplan–Meier and univariable analysis.

Conclusion: Moderate and high chronicity indices were associated with an increased ESKD risk for LN. This modified NIH activity and chronicity scoring system may help physicians predict long-term prognosis for patients with LN.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE). Current investigations implicate microbiome changes in disease pathogenesis, particularly pathobiont expansions of *Ruminococcus gnavus* (RG) ranging from minor dysbiosis to extreme blooms. Transient spikes in RG communities in human and mouse models have been associated with disease activity.

Methods: A methodical search of MEDLINE, Science Direct, and EMBASE was conducted to evaluate the understanding of *Ruminococcus* involvement in LN up to May 28, 2023. Two reviewers independently assessed the literature for the inclusion and exclusion criteria methodically by title, abstract, and full text resulting in a cumulative 83 articles. Once screened for duplicates and open-access content on relevant primary literature, 13 remaining articles were identified.

Results: The 13 included articles commonly recognized RG population blooms in active SLE including LN, outnumbering other members of the genus. These blooms correlated with the presence of anti-native DNA autoantibodies. LN patients were found to have elevated fecal RG based on 16S rRNA amplicon analysis with serum IgG anti-RG Ab in concordance with anti-dsDNA. Furthermore, anti-RG Ab targeted to bacterial cell-wall lipoglycans correlated with SLE disease activity index indicating a disease model in which specific strains of gut commensal contribute to the immunopathogenesis of LN. Distorted tryptophan metabolism toward the kynurenine pathway is reported in SLE; differential microbial catabolism

has been implicated since tryptophan and the metabolite tryptamine increase pro-inflammatory T cell metabolism and mTOR activation thus promoting damage to renal tubular epithelial cells. RG expresses tryptophan decarboxylase necessary to synthesize tryptamine from tryptophan, contributing to elevated tryptamine levels in LN pathogenesis. The experimental administration of *Lactobacillus casei Zhang* shows evidence of delayed kidney disease in mice. Short-chain fatty acids and nicotinamide in these studies reduced renal inflammation, suggesting the commensal metabolic impact can mitigate or progress renal decline in mice models. Despite SLE disease heterogeneity, pathobiont blooms may impair gut barriers and fuel systemic inflammation. In another study, SLE mouse models given acidic pH water developed nephritis slower compared to those given neutral pH water. A higher level of circulating auto-Ab against plasma cells and nuclear antigen were found in the latter with notable variations in 16S rRNA gene-targeted sequencing of the gut microbiome and immune responses shifted to TH17 and Th9-associated factors. This suggests that dietary changes can influence SLE flares through the regulation of the microbiome.

Conclusion: The microbiomes of SLE patients show a decrease in species diversity; disease activity, including LN development, is associated with RG pathobiont blooms. Given the demonstrated association between the microbiome and immunomodulation, RG populations may be a novel therapeutic target in the treatment of patients with LN.

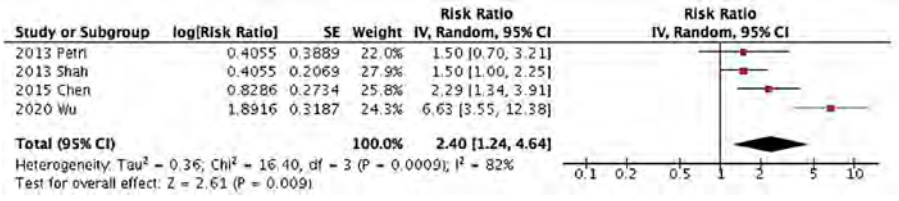
Risk of Diabetes Mellitus in Systemic Lupus Erythematosus: Systematic Review and Meta-analysis

CLAUDIA MENDOZA PINTO[1], Pamela Munguía-Realpozo[1], Ivet Etchegaray-Morales[2], Mario García-Carrasco[2] and Socorro Méndez Martínez[1], [1]Instituto Mexicano del Seguro Socia, Puebla, Mexico, [2]Medicine School, Benemérita Universidad Autónoma de Puebla, Puebla, Mexico

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that increases the risk of severe clinical outcomes and mortality. However, the association between SLE and the risk of diabetes mellitus (DM) is unclear. Our study aimed to investigate the risk of DM and to evaluate the impact of SLE therapies on the risk of developing DM in patients with SLE.



Forest plot of DM risk in SLE patients treated with glucocorticoids

Methods: Electronic database searches of PubMed, Embase, Cochrane Library, and Web of Science, together with hand search, were performed from inception to February 2023. Studies analyzing the relationships between risk factors for DM in SLE patients in cohort or case-control were included. Data were pooled utilizing fixed- or random-effects metanalysis to estimate pooled relative risk (RR) and 95% confidence intervals (CIs). The study was registered with PROSPERO, CRD42023402774.

Results: A total of 36 studies (23 case-control and 13 cohort studies) involving 265,822 patients with SLE were included. In the pooled analysis from case-control studies, we found a greater risk (OR = 1.05, 95% CI 0.87-1.27; P = 0.63) of diabetes in patients with SLE compared with non-SLE controls. However, the pooled risk estimate of cohort studies did not show a significant risk of DM (RR= 1.32, 95% CI 0.93-1.87; P = 0.12). In a subgroup analysis, reduced risk of diabetes was reported with antimalarials (RR= 0.56, 95% CI 0.42-0.75; P < 0.001), while glucocorticoids use was associated with an increased risk of developing diabetes (RR= 1.45, 95% CI 1.20-1.76; P = 0.0002). Age, sex, hypertension, and immunosuppressants were not associated with DM in SLE patients.

Conclusion: Although there was not an increased risk of DM in overall SLE patients compared to controls, antimalarials users or adherents had a decreased risk, while GCT users had an increased risk.

Clinical Outcomes in Patients Admitted for ST-Elevation Myocardial Infarction with vs Without Systemic Lupus Erythematosus: An Analysis from National Inpatient Sample Database (2015-2018)

Hamza Liaqat[1], Muhammad Qureshi[2], Awais Farooq[3], **Mashal Awais**[2], Amar Patel[4] and Aisha Barlas[5], [1]Wah Medical College, Wah Cantt, Pakistan, [2]Southeast Health Internal Medicine Residency Prog., Dothan, AL, [3]University of Illinois Chicago, Chicago, IL, [4]Texas Tech University Health Sciences Center, El paso, TX, [5]Mercy Health, Rockford, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Impact of systemic lupus erythematosus (SLE) on the clinical outcomes of patients admitted for ST-elevation myocardial infarction (STEMI).

Methods: Patient data was collected for years 2015-2018 from National Inpatient Sample using the International Classification Of Disease Revision Codes (ICD-10). We selected patients who were admitted with the diagnosis of STEMI. We then divided our patient population into two groups, those without SLE (STEMI group) and patients with an underlying diagnosis of SLE (STEMI/SLE group). Multivariate Logistic Regression and Mann-Whitney U testing were employed for this purpose.

Results: Our study included 1,009,407 patients with a primary diagnosis of STEMI. Of these patients, 4150 (0.41%) had an underlying diagnosis of SLE. The mean age of patients in the STEMI group was 67 years, compared to 61 years in the STEMI/SLE group. 61.8% were males in STEMI patients and female predominance was noted in STEMI/SLE group,

81.3%. The predominant race involved in both groups was noted to be Caucasian, 70.5% in the STEMI group vs 58.53% in STEMI/SLE group. In regards to mortality, we found that the underlying diagnosis of SLE in STEMI patients was associated with an increased risk of mortality, adjusted odds ratio of 1.278 (95% CI 1.09-1.48, p< 0.05). The length of stay in STEMI patients was 4.5 days, vs 4.7 days in the STEMI/SLE group. Hospitalization charges were noted to be $84522 and $82783 in STEMI and STEMI/SLE groups respectively.

Conclusion: This nationwide study showed that concomitant SLE in patients admitted with STEMI was associated with a statistically significant increase in inpatient mortality and length of stay. However, reduced cost of hospitalization was noted among STEMI/SLE patients.

Prevalence of Objectively Measured Sleep Disturbance in Systemic Lupus Erythematosus (SLE)

Patti Katz[1], Jinoos Yazdany[2] and Maria Dall'Era[3], [1]University of California San Francisco, San Rafael, CA, [2]University of California, General Department of Medicine, Division of Rheumatology, San Francisco, CA, [3]University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Self-reported poor sleep is common in SLE, but few studies have objectively measured sleep have been conducted. In general population studies, sleep disorders are associated with poor health outcomes relevant to SLE, including lower pain thresholds and higher rates of depression, cognitive impairment, systemic inflammation, and cardiovascular events. We report on the prevalence of objectively-measured sleep disturbances in an SLE cohort, examine whether patient-reported measures of sleep correspond with objective measures, and analyze the association of sleep disturbances with patient-reported outcomes.

Methods: All participants were drawn from the California Lupus Epidemiology Study (CLUES). A subset of CLUES participants (n = 61) who received their SLE care at our institution participated in a sleep study and underwent 7 nights of home sleep monitoring via actigraphy (GT9X, Actigraph Corp., Pensacola, FL), as well as concurrent interviews in which patient-reported outcome measures (PROMs) of sleep (PROMIS Sleep Disturbance and Sleep Impairment) and symptoms (pain rating 0-10, PROMIS Fatigue, and depressive symptoms [Patient Health Questionnaire, PHQ-8]) were collected. Actigraphs yielded estimates of time in bed, time asleep, and sleep efficiency (time asleep/time in bed).We examined 2 indicators of sleep disturbance: poor sleep efficiency and short sleep. Poor sleep efficiency was defined as < 85% (the standard criterion) and < 80%.Short sleep time was defined as < 7 hours (based on CDC guidance) and < 6 hours. Analyses examined differences in PROMs by each sleep disturbance indicator.

Results: Participant characteristics are shown in Table 1.Mean sleep efficiency was 79.4% ± 8.7%, 74% had sleep efficiency < 85%, and 39% had sleep efficiency < 80% (Table 2). Mean sleep time was 6.6 ± 1.0 hours, 66% had sleep time < 7 hours, and 23% had sleep time < 6 hours. Sleep PROM scores were generally within 0.5 SD of the population mean,

not reflecting the high prevalence of objective sleep disturbance in the sample. There were no significant differences in the sleep or symptom PROMs by any of the sleep disturbance indicators (Table 3).

Conclusion: Overall, objective sleep disturbances measured by actigraphy were common in this cohort. However, these results were discordant with self-reported sleep PROMs, which were similar to the general population. The lack of differences in sleep or symptom PROMs by sleep disturbance may be due to our relatively small sample. It is also possible that if sleep disturbances are of long duration, individuals' perceptions of the effects sleep disturbances may have normalized. If findings are replicated, research will be needed to identify more sensitive methods of measuring sleep disturbances in SLE by patient report.

Association of Glucocorticoid Use with Patient-Reported Outcomes Among Persons with Systemic Lupus Erythematosus

Patti Katz[1], Sofia Pedro[2], Jiyoon Choi[3] and Kaleb Michaud[4], [1]University of California San Francisco, San Rafael, CA, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]Bristol Myers Squibb, Lawrenceville, NJ, [4]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GCs) have long been a mainstay of treatment for SLE. While GCs do provide benefit, there are potential side effects that increase with dose and duration and that have potential to affect quality of life negatively. In these analyses, we examine the association of GC use and patient-reported outcomes (PROs).

Methods: Data are from the FORWARD Databank questionnaires collected from participants with physician-diagnosed SLE at 6-month intervals from July 2015 – July 2020.Respondents provide comprehensive health information including GC use and dosage during the prior 6 months and complete PROs, including PROMIS Physical Function, Fatigue, Pain Interference, Sleep Disturbance, and Satisfaction with Social Roles; Systemic Lupus Activity Questionnaire (SLAQ); PHQ-8 (depressive symptoms); and a numeric rating scale of pain (0–10).Analyses examined PROs at baseline according to GC use/non-use. For GC users, baseline data were drawn from the questionnaire in which GCs were first reported during the analysis period. For non-users, baseline data were drawn from the first questionnaire completed during the observation period. Longitudinal logistic regression analyses used generalized estimating equation (GEE) models to estimate the likelihood of worsening in PROs from prior to current observation (by ≥0.5 standard deviation) based on increases in GC dose, addition of other medications, or both during the same period. Models controlled for age, sex, race, BMI, comorbidities, education level, smoking, SLE duration, self-reported lupus disease activity, and SLE organ damage measured by BILD (Brief Index of Lupus Damage).

Results: 512 participants qualified for the analysis; 46.3% reported GC use in at least one 6-month period (Table 1).GC users were less likely to be male or white, had more comorbidities, had longer SLE duration, were more likely to also be taking immunosuppressive medications, and reported more active SLE and greater disease damage. GC users had worse scores on all PROs at baseline (**Table 1**).Non-GC users rarely had medication changes (97% of observations, 89% of GC non-users; **Table 2**). The majority of GC users also had no medication changes (83% of observations, 53% of GC users).

Table 1. Participant characteristics and PROs at baseline

Variable	No GC use 53.7% (275)	GC use 46.3% (237)	p-value
Dose of GC		9.1 (12.2)	
0 – <5 mg)		9.5 (46)	
5 – <10 mg)		24.3 (118)	
≥ 10 mg		13.4 (65)	
Male sex	8.0 (22)	3.4 (8)	0.028
White, non-Hispanic ethnicity	88.4 (243)	78.1 (185)	0.002

† Higher scores indicate worse status

Table 2. Observation time and frequency of medication changes

			Medication changes, % (n)			
	Observation time (years)		No change	Increase GC	Add other medications	Both
GC non-users	3.0 ± 2.3	N observations	97.2 (1803)	---	2.8 (51)	---
		N people	88.7 (293)	---	11.3 (37)	---
GC users	3.4 ± 2.2	N observations	83.0 (1342)	11.1 (180)	4.4 (71)	1.4 (23)
		N people	53.1 (126)	27.8 (66)	14.2 (34)	4.9 (12)

Table 3. Likelihood of worsening in PROs by medication changes

			Medication changes		
Patient-reported outcomes	N observations	N people	Increase GC	Add other medications	Both
PROMIS Physical Function	1984	355	0.8 (0.4, 1.6)	0.9 (0.4, 1.6)	2.3 (0.6, 7.9)
PROMIS Fatigue †	1988	355	0.9 (0.5, 1.5)	1.3 (0.8, 2.2)	1.6 (0.5, 5.8)
PROMIS Pain Interference †	1758	358	1.2 (0.7, 2.1)	0.9 (0.4, 1.8)	1.0 (0.2, 4.3)
PROMIS Sleep Disturbance †	1963	354	0.8 (0.4, 1.3)	1.3 (0.8, 2.1)	1.2 (0.3, 4.5)
PROMIS Satisfaction Social Roles	1973	357	1.3 (0.8, 2.1)	1.4 (0.7, 2.6)	2.0 (0.6, 7.0)
SLAQ †	2321	359	0.9 (0.6, 1.3)	1.0 (0.6, 1.7)	2.1 (0.6, 6.7)
PHQ-8 †	2576	400	1.4 (0.9, 2.1)	1.1 (0.6, 1.9)	**2.6 (1.2, 5.7)**
Pain rating †	2958	424	1.0 (0.6, 1.4)	1.0 (0.6, 1.7)	1.3 (0.4, 3.9)

However, increases in GC dose were noted in 11.1% of observations, other medications added in 4.4%, and both GC increases and medication additions in 1.4%.Increases in GC dose, addition of other medications, or the combination were not associated with PRO worsening (**Table 3**).The exception was PHQ, for which there was a significant likelihood of higher scores in the group with increase in GC plus addition of another medication.

Conclusion: GC use was associated worse with PROs at the baseline for these analyses. In this non-inception cohort with relatively long disease duration, however, PROs generally did not worsen over time with changes in GC dosage or other medications; i.e., the differences between GC users and non-users appeared to be static over time. Results suggest that despite potential side effects, patients tend to remain on relatively stable GC doses over time. Patients may be willing to risk negative side effects of GCs to avoid further worsening of symptoms such as pain and fatigue.

Treatment with Upadacitinib in Patients with Systemic Lupus Erythematosus Results in the Inhibition of B-Cell–related Biomarkers: Analysis of the M19-130 (SLEek) Phase 2 Study

Marie-Claude Gaudreau[1], James Fann[1], Alan Friedman[1], Thierry Sornasse[1] and Joan Merrill[2], [1]AbbVie, Inc., North Chicago, IL, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: B-cell hyperactivity (1) is a hallmark of the disordered immunity of SLE, arising in the context of a complex array of innate and adaptive mediators. A phase 2 study (NCT03978520) in SLE of upadacitinib (UPA, Janus kinase inhibitor) administered alone or in combination (ABBV-599) with elsubrutinib (a Bruton's tyrosine kinase inhibitor). found significant improvement in disease activity, as measured by SLE Responder Index-4 (SRI-4) and BILAG-Based Combined Lupus Assessment, (BICLA) at weeks 24 and 48.

This analysis evaluates response to UPA and ABBV-599 of immunologic pathways associated with SLE pathogenesis.

Methods: Patients with SLE (n = 205) were randomized to placebo (PBO; n = 75), UPA 30 mg once daily (n = 62), or ABBV-599 (n = 68). At screening, patients were stratified by immunosuppressant use (Yes/No), corticosteroid dose (> 10-mg prednisone or not), IFN score (High/Low), and SLE Disease Activity Index 2000 score. Changes in biomarkers between treatment vs PBO were evaluated with a repeated mixed-linear model, with the Benjamini–Hochberg method used to correct for multiple testing. Total IgG and IgM and anti-dsDNA IgG were measured from serum using a commercially available immunoturbidimetric assay and enzyme linked immunosorbent assay. B-cell subsets and immune cell counts were identified using flow cytometry. Plasma samples were collected for proteomic analyses and assessed with a proximity-extension immunoassay.

Results: Flow cytometry analyses revealed an increase in absolute number of B cells in the peripheral blood of patients treated with UPA or ABBV-599, while the percentage of plasmablasts and plasma cells were reduced, corresponding to a decrease in total IgG and anti-dsDNA antibodies. Reduction in B-cell activation proteins in plasma such as CD72, CD22 and CD79b suggests a direct impact of UPA and ABBV-599 on B cells (**Figure 1**). The observed increase in total peripheral

Figure 1. B cell-related proteins. **$P < .01$; ***$P < .001$.

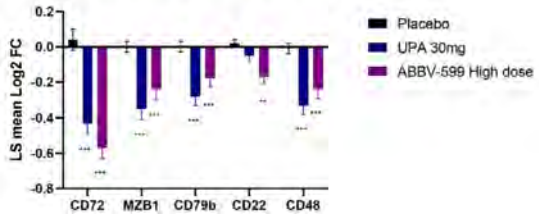

Figure 2. Chemokines. **$P < .01$; ***$P < .001$.

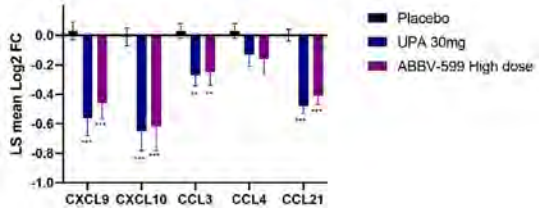

B cells could be explained by the marked reduction in chemokines induced by UPA or ABBV-599 including CXCL9, CXCL10, CCL3 and CCL21 (**Figure 2**). These effects were similar with UPA and ABBV-599, suggesting that the main impact on B cell and plasma cell activating pathways was due to activity of UPA.

Conclusion: These results suggest an association between clinical benefit seen with UPA and an impact on pathogenic B cells involved in SLE, with biomarker effects of both UPA and ABBV-599 apparently driven by UPA. These findings are consistent with our previous analysis in this population that showed treatment with UPA or ABBV-599 significantly reduced the IFN gene scores compared with PBO at weeks 4 and 24. Early Experience with SGLT2i in Systemic Lupus Erythematosus

Michelle Petri[1], Daniel Goldman[1], Andrea Fava[2] and Larry Magder[3], [1]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University of Maryland, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) occurs in over 50% of the systemic lupus erythematosus (SLE) patients. It remains an independent risk factor for mortality, with deaths from LN increasing from 2015-2020. Progression to chronic kidney disease occurs from both lupus specific and non-specific factors, that are due to general mechanisms that occur in many types of chronic kidney disease. In patients with type 2 diabetes and albuminuric kidney disease the risk of kidney failure and cardiovascular events was lower with SGLT2 inhibitors (SGLT2i) than placebo after 2.6 years median follow up. We examined changes in trajectories of eGFR and proteinuria after starting SGLT2i among patients with SLE.

Methods: 45 SLE patients who started taking SGLT2i were included:87% female; 35.5% Caucasian, 55.5% African-American, 9% East Asian; mean age when started on SGLT2i was 47.2 ± 13.4 yrs (mean ± SD). SGLT2i was started for standard of care (diabetes mellitus, chronic kidney disease, or both). eGFR was calculated using the 2021 CKD-EPI creatinine equation. eGFR and Urine protein/creatine ratio were measured at every quarterly visit.The analysis was based on clinical visits up to three years prior to starting SGLT2i and all clinical visits after starting SGLT2i. The mean follow-up time prior to starting SGLT2i was 1.9 years with 5 patients contributing no pre-SGLT2i follow-up. The mean follow-up time after starting SGLT2i was 1.1 years with 2 patients contributing no post SGLT2i follow-up. For each outcome (GFR and urine protein), we estimated each person's trajectory before and after starting SGLT2i using a mixed effects longitudinal regression model with random person-specific slopes and intercepts.

Results: Prior to starting SGLT2i, the average annual change in eGFR was a decline of 3.1 (P=0.0014, Table 1). After starting SGLT2i, the average annual change in eGFR was estimated to be a decline of 0.9. The difference between these two degrees of decline did not reach statistical significance (p=0.27). Prior to starting SGLT2i, the average annual change in urine protein-creatinine ratio was estimated to be an increase of 0.40 (p=0.16, Table 2). However, after starting SGLT2i, the average annual change was estimated to be a decline of 0.37. Again, the difference between these two slopes was not statistically significant (p=0.18).

Conclusion: SLE patients were excluded from the canagliflozin CREDENCE trial (Perkovic V et al. NEJM 380:2295, 2019). Thus, there is a crucial need for data on SGLT2i use in SLE. Like the CREDENCE trial, we observed a reduction in decline in eGFR after starting SGLT2i, however, this reduction was not statistically significant. Similarly, like the CREDENCE trial, we observed an improvement in urine protein/creatinine ratio after starting SGLT2i, but again, our observed difference did not achieve statistical significance. In the CREDENCE trial, reduction in proteinuria was observed by 6 months, and then plateaued. Thus, early experience suggested marginal benefit of SGLT2i in SLE. Additional patients and longer follow-up are needed for a more definite conclusion regarding the value of SGLT2i in SLE.

Table1: Estimated impact of SGLT2i on trajectories of eGFR before and after starting SGLT2

Effect	Estimated average slope	95% CI	Estimated range of 95% of patient-specific slopes	P-value
Average annual slope in eGFR prior to starting SGLT2i	-3.1	-5.0, -1.2	-11.7, 5.53	0.0014
Average annual slope in eGFR after starting SGLT2i	-0.9	-3.6, 1.8	-7.7, 5.9	0.52
Difference between the two slopes	2.2	-1.7, 6.1	-11.6, 16.0	0.27

Table2: Estimated impact of SGLT2i on trend based in mean urine protein/creatinine ratio

Effect	Estimated average slope	95% CI	Estimated range of 95% of patient-specific slopes	P-value
Average annual slope in urine protein/creatinine ratio prior to starting SGLT2i	0.40	(-0.16, 0.97)	(-3.20, 4.0)	0.16
Average annual slope in urine protein/creatinine ratio after starting SGLT2i	-0.37	(-0.94, -0.20)	(-3.83, 3.09)	0.21
Difference between the two slopes	-0.77	(-1.90, 0.35)	-0.77 (-7.83, 6.29)	0.18

Abstract Number: 1491

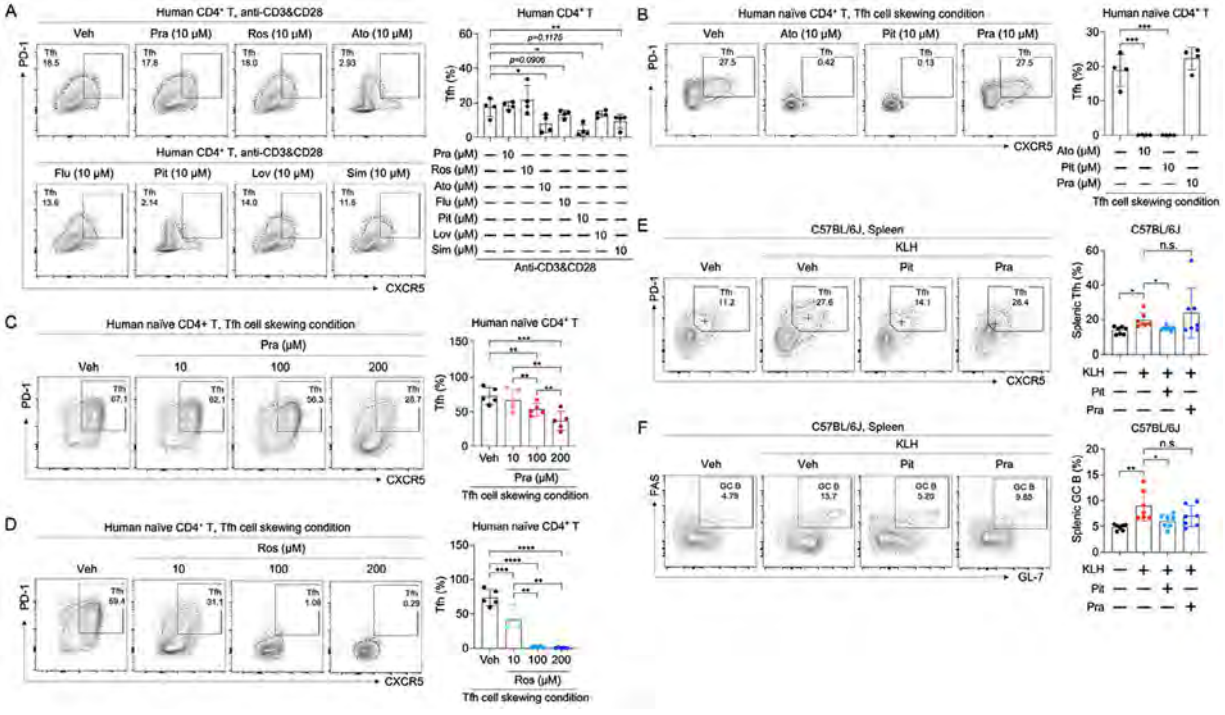
Targeting the Mevalonate Pathway-dependent Protein Geranylgeranylation to Restrict Follicular Helper T Cell Differentiation for the Treatment of Systemic Lupus Erythematosus

Lai Wang, Institute of Dermatology, Chinese Academy of Medical Sciences and Peking Union Medical College, Nanjing, China

SESSION INFORMATION

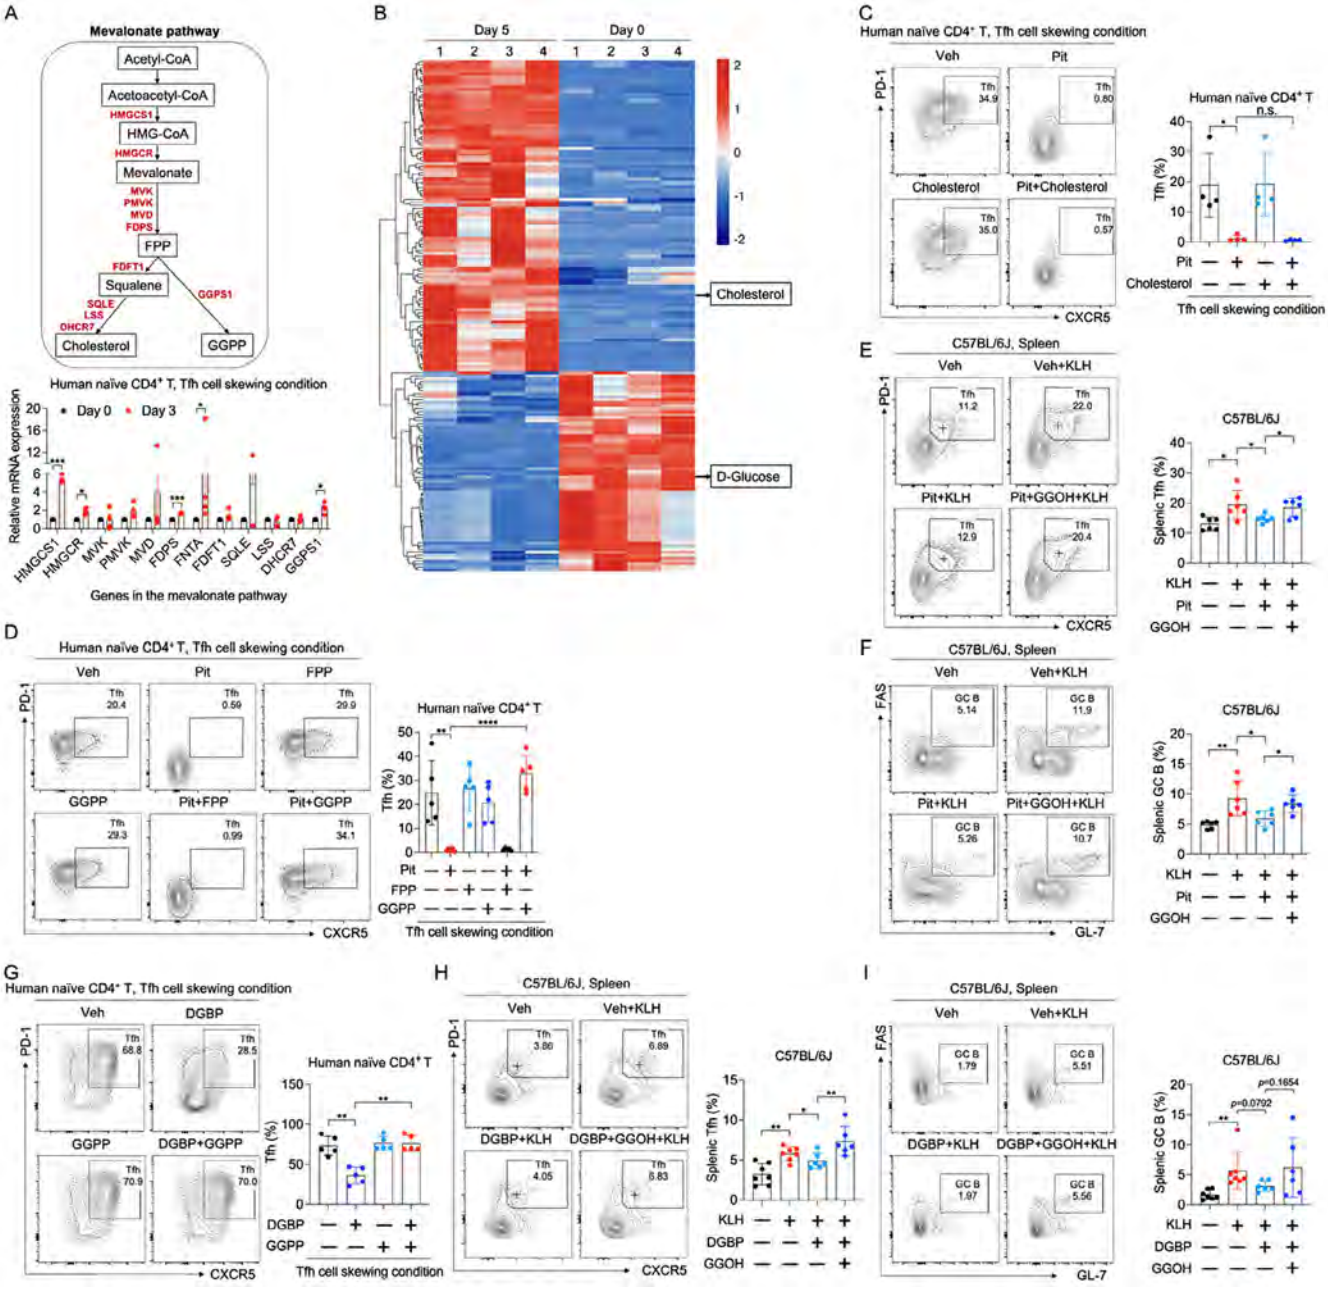
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent research focusing on follicular helper T (Tfh) cells emphasizes its importance in autoimmune diseases, such as systemic lupus erythematosus (SLE). However, the mechanisms underlying Tfh cell differentiation remain largely unknown, and therapeutic strategies targeting Tfh cells for SLE are urgently needed.



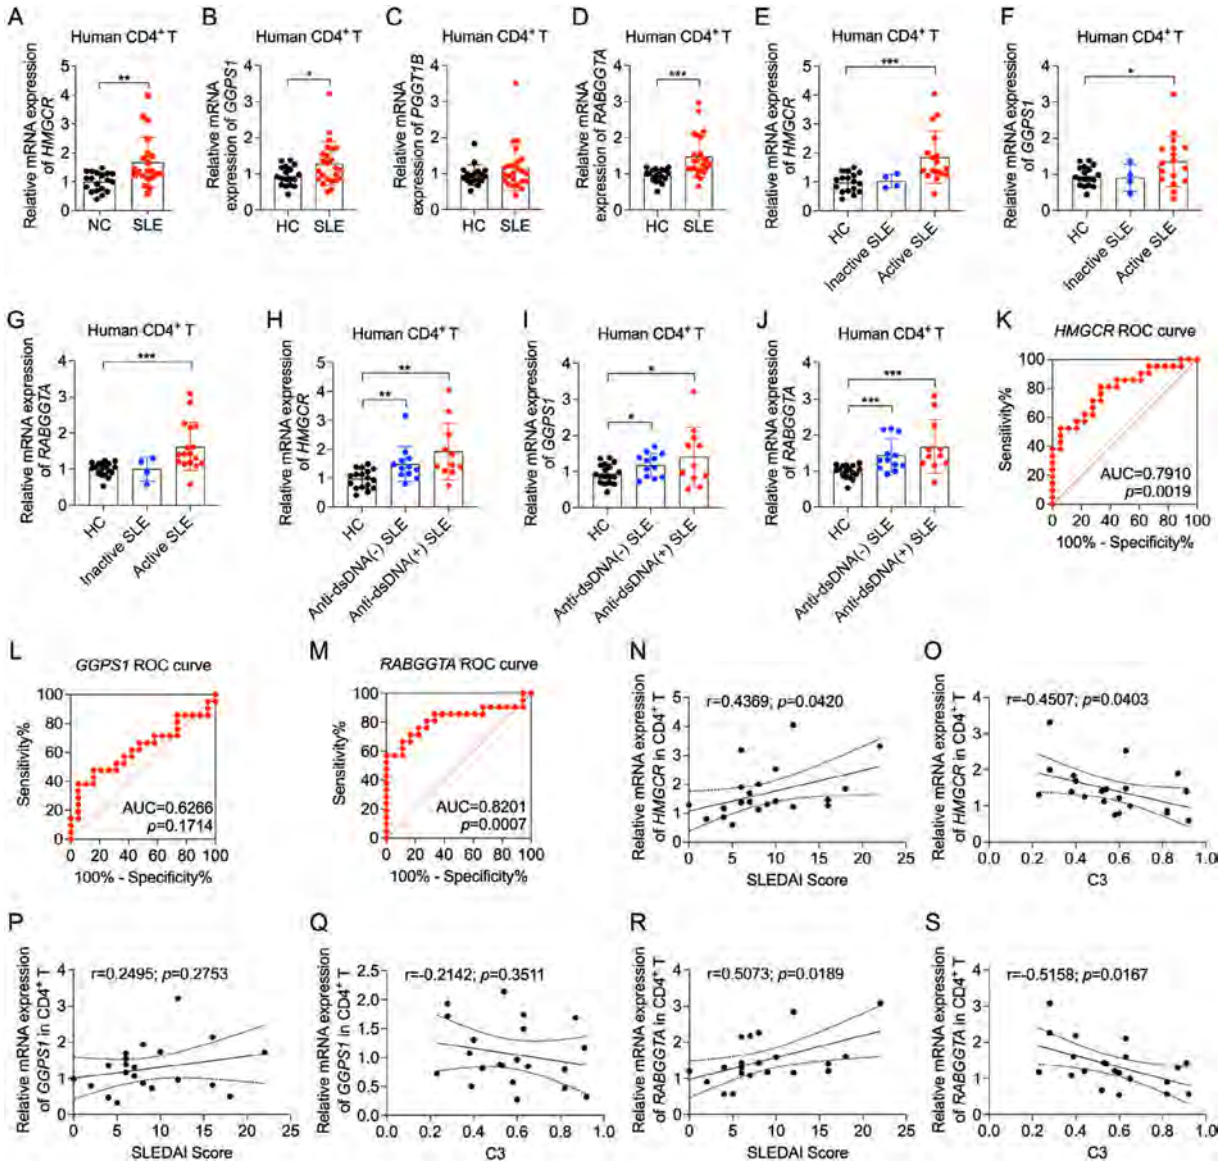
Lipophilic statins inhibited Tfh cell differentiation in vitro and in vivo.

Methods: The effects of seven clinically used statins on human CD4$^+$ T cell subsets were investigated and compared. Chemical and genetic approches were employed to investigate the role of the mevalonate pathway in Tfh cell differentiation and germinal center (GC) reactions *in vitro* and *in vivo*. Chemical and genetic approches were subsequently employed to investigate the role of GGPS1 and GTase II in Tfh cell differentiation and GC reactions *in vitro* and *in vivo*. Expression of the genes in the mevalonate pathway and the genes for protein geranylgeranylation in SLE CD4$^+$ T cells was detected by RT-qPCR and flow cytometry. The role of key genes in the mevalonate pathway and GGTase II in CD4$^+$ T cells in SLE pathogenesis was investigated in pristane-induced lupus-like mice. The effects of pitavastatin on SLE were evaluated in lupu prone MRL/lpr mice.



GGPP derived from the mevalonate pathway is essential for Tfh cell differentiation and GC reactions.

Results: Pharmacological and genetic inhibition of the mevalonate pathway leads to suppressed Tfh cell differentiation and impaired germinal center (GC) reactions. We identify geranylgeranyl pyrophosphate (GGPP) as the key intermediate metabolite derived from the mevalonate pathway driving Tfh cell differentiation. Further studies emphasize that geranylgeranyl transferase II (GGTase II) facilitates the membrane localization of CXCR5 by regulating the geranylgeranylation of RAB proteins, which transfers the effect of GGPP on Tfh cell differentiation. Conditional ablation of the specific subunit of GGTase II, *RABGGTA,* in $CD4^+$ T cells, leads to impaired Tfh cell differentiation and GC reactions. Moreover, the expression of key genes in the mevalonate pathway and *RABGGTA* is increased in SLE $CD4^+$ T cells and is positively correlated with SLE disease activity. Genetic ablation of key genes in the mevalonate pathway and *RABGGTA* postpones the pathological progression in pristane-induced lupus-like mice. Additionally, RAB35 is identified as the key RAB protein that upregulated in SLE $CD4^+$ T cells, and whose expression is positively correlated with SLE disease activity. Point mutation of the Cys sites for geranylgeranylation at the carboxyl terminus of RAB35 impedes the membrane localization of CXCR5 and restricts Tfh cell differentiation both *in vitro* and *in vivo*. Finally, lipophilic pitavastatin is effective in ameliorating SLE disease activity.



The mevalonate pathway was dysregulated in SLE CD4+ T cells and was positively associated with SLE disease activity.

Conclusion: In summary, our current study highlights the importance of geranylgeranylation of RAB proteins regulated by the mevalonate pathway in Tfh cell differentiation and SLE pathogenesis, and proposes pitvastatin as an adjuvant therapy for SLE.

Pre-treatment Differentially Expressed Metagenes Characterize Systemic Lupus Patients Who Subsequently Achieve Clinical Response to Belimumab

Miles Smith[1], Kevin Thomas[1], Nicolas Dominguez[1], Susan Macwana[1], Wade DeJager[1], Stan Kamp[1], Carla Guthridge[1], Bridget Parrish[1], Cristina Arriens[2], Judith James[1], Joan Merrill[1] and Joel Guthridge[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Department of Arthritis & Clinical Immunology, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab, which targets the B Cell activator and survival factor BLyS, is an approved treatment for systemic lupus (SLE) and has demonstrated efficacy in multiple clinical trials around the world. Nevertheless, like other SLE treatments, belimumab can have disappointing results in a significant proportion of this heterogenous population, a problem further complicated by the unpredictable impact of various combination treatments used with belimumab in trials and clinical practice. Using gene expression variables, we aim to identify SLE patients prior to treatment who will respond favorably to belimumab treatment.

Methods: A prospective open-label study of belimumab was conducted in 24 SLE patients with active but non-organ threatening disease, who were required to withdraw other immune suppressants (only antimalarials or low dose steroids allowed). At baseline, after blood samples obtained, patients were given optional steroid injections for temporary relief, then

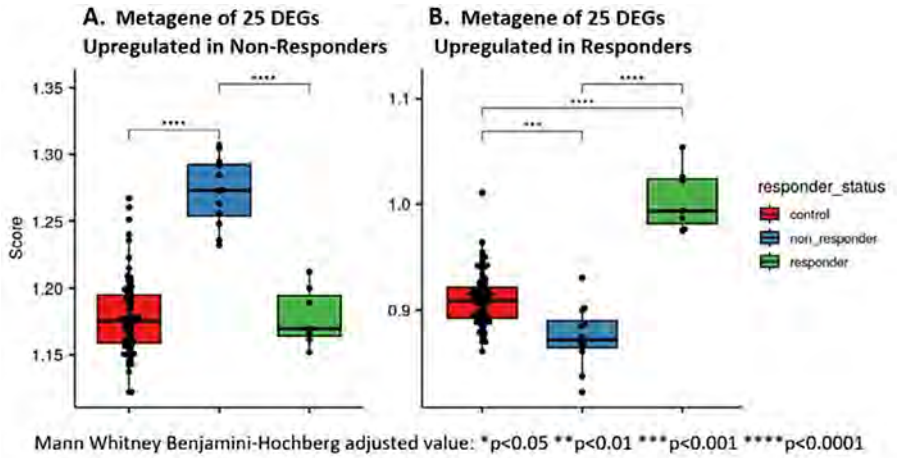

Figure: No overlap between pre-treatment metagene module scores In SLE patients who do vs do not respond to belimumab

followed for six months on intravenous belimumab (10 mg/kg). The primary endpoint was time to treatment failure (flare, treatment change or study withdrawal) compared to historical controls from the BOLD study[1] (same protocol but without treatment after initial steroids). Response was also evaluated at six months by the SLE Responder Index (SRI-4) or the BILAG-based Combined Lupus Assessment (BICLA). Before and during treatment, PAX gene tubes were collected, and RNA sequenced, using the same methods for healthy control samples. To maximally discriminate clinical responders from non-responders by baseline gene expression patterns in a small, heterogenous population, principal component analysis was conducted with modules (metagenes) comprised of differentially expressed genes (DEGs).

Results: Of 24 patients entering the study, 20 completed 6 months of treatment. The mean survival time without treatment failure was 18.4 weeks (CI 15.3-21.5) compared to the 41 BOLD participants with mean survival 9.829 weeks (CI 0.999-7.871) ($p< 0.001$ by log rank test). At 6 months, 14 patients who received belimumab (58%) and 1 from the BOLD study (2.4%) remained free of flare. The SRI-4 was met by 7 patients in this study (29.2%), the BICLA by 9 (37.5%). SRI-4 response was used as the basis for modeling two metagenes comprised of baseline expression of the 25 most upregulated genes in non-responders and the 25 most upregulated genes in responders with no overlap between metagene scores of responders vs non-responders (figure). After 3 months of treatment with belimumab the metagene scores corrected towards levels in healthy controls. The most discriminatory DEGs included protein transcription factors and long non-coding RNA (some being known transcription regulators).

Conclusion: When background immune suppressants are excluded, belimumab still achieves SRI 4 or BICLA response for a subset of patients, and most do not flare for at least six months. Preliminary identification of a composite metagene model as a potential predictor of belimumab response provides an intriguing model which will require testing in prospective confirmation studies. Novel BCMA-CD19 Compound CAR-T (cCAR) Targets B Cells and Plasma Cells Achieving Immune Reset and Eliminates All Autoantibodies in Systemic Lupus Erythematosus (SLE) and Lupus Nephritis (LN) Patients Resulting in Long-Term, Medication-Free Remission

Yong Yuan[1], Shanzhi He[1], Wenli Zhang[2], Hongyu Zhang[2], Vincent DeStefano[3], Masayuki Wada[3], Kevin Pinz[3], **Greg Deener**[3], Yu Ma[4], Min Wang[1], Fugui Li[1], Ming Hong[1], Chanjuan Zou[1], Mingxia Wang[1], Ling Ding[1], Yingwen Liang[1], Yupo Ma[3] and Weijia Wang[1], [1]Zhongshan People's Hospital, Zhongshan, China, [2]Peking University Shenzhen Hospital, Shenzhen, China, [3]iCell Gene Therapeutics Inc., Stony Brook, NY, [4]iCAR Bio Therapeutics Ltd, Zhongshan, China

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Evaluate cCAR safety in SLE, LN and autoimmune conditions. Determine whether a single dose eliminates autoantibodies with well tolerated long-term, medication-free remission in open label proof of concept.

Methods: BCMA-CD19 cCAR approved by Zhongshan People's Hospital and Peking University Shenzhen Hospital IRBs for autoimmune patients. Initially compassionate use in 2 lymphoma patients with 20-year history of SLE (Patient 1 Sept 2019). After initial SLE patients safely in remission, IRB approved cCAR for use in LN (11 LN patients June 22 to April 23). 18 patients in safety dataset (includes NMOSD, donor specific antibodies in transplant).

Lupus patients: After apheresis, prior to cyc/fludarabine conditioning all lupus medications discontinued. Patients dosed 1.5-3x10^6 cCAR cells/kg (LN target 3x10^6/kg) and then monitored, IVIG given PRN. LN: required to fail multiple lines of therapy, be refractory and active disease on kidney biopsy (class III to V). All LN, SLE patients met ACR criteria.

Baseline Characteristics: Lupus age range: 17-58. 10 of 13 female. SLEDAI-2K baseline mean = 10. All LN patients at screening treated with HCQ, glucocorticoids, immunosuppressant (MMF, CYC); majority with belimumab. At screening, mean 24-hour urine microprotein 1.7g and urine/creatine ratio 1.0. Patients avg 3.9 elevated autoantibodies (2.5 >3X ULN, many >20X ULN). Majority had low C3.

Results: Safety: cCAR well tolerated; no CRES/iCANs, no CRS >Grade 1, no fever >40^o C. All LN patients received target dose and only infection other than Covid was a Grade 1 UTI.8 patients tested positive for Covid (at time >80% local population tested positive), 3 hospitalized as precaution, none in ICU. No other URIs reported. No GI infections or diarrhea AEs suggesting no concerning IgA related AEs.

B cells/Ig: B cells eliminated in 1-10 days; IgM, IgA, IgG eliminated in 1-2 months. WBC normal in 7-21 days. B cells returned to normal in all patients (mean 90 days, range 40 to 150). All patients treated >150 days normal IgM. Flow cytometry, BCR sequences confirm immune reset achieved. Given B cells, IgM normal within 150 days, expect all patients to fully regain humoral immunity.

Efficacy: All elevated autoantibodies eliminated, including those derived from long-lived plasma cells, most in first month. All C3, C4 normal within 21 days. All patients had significant medication-free symptom improvement (11 of 13 in first month). All 3 patients at >1 year (up to 44 months) in medication-free remission (no symptoms). Renal function significantly improved in LN patients within first 6 months.

Conclusion: Proof of concept achieved. cCAR safely eliminated all autoantibodies, reset B cell and humoral immune system, and delivered long-term, medication-free remission in a single dose. Monitoring patients to ensure humoral immunity fully recovers. Will update with full dataset, further research is needed.

Acknowledgements: Patients and their families.

The Effect of Belimumab on Steroid Use in Patients with SLE: Results from a Retrospective Observational Study of Real-World Data from a US Rheumatology Provider Network

Karen Worley[1], Scott Milligan[2] and Bernard Rubin[3], [1]GlaxoSmithKline, US Value Evidence and Outcomes, Cincinnati, OH, [2]Trio Health, Analytics, Louisville, CO, [3]GlaxoSmithKline, US Medical Affairs and Immuno-inflammation, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: While oral CS (OCS) are the mainstay of SLE therapy, prolonged use is associated with organ damage and early mortality.[1,2] Minimizing OCS use is among SLE treatment goals.[1] The beneficial effect of belimumab (BEL) on OCS reduction was shown in two pooled analyses of five randomized clinical trials,[3] and six retrospective observational real-world studies.[4]

This study used real-world data from a large rheumatology provider network to compare OCS use in patients (pts) with SLE in the US before and after BEL initiation.

Methods: This retrospective cohort study (GSK Study 214140) utilized data from the Patient-Important Outcomes Data Repository (PIONEER)-Rheumatology database.[5] Eligible adults with SLE initiated BEL between Jan 1, 2012, and Jun 30, 2021, and had available data for ≥180 days before and ≥360 days post BEL initiation. The index was the date of BEL initiation. Primary objectives: proportion of pts receiving any OCS; mean total OCS dose per pt; mean total number of OCS days supplied per pt; mean daily OCS dose for days supplied per pt (in pts with ≥1 OCS prescription); proportion of pts with daily OCS dose of ≤5 mg and ≤7.5 mg for days supplied. A secondary objective was to describe pt clinical

Table 1. Change from P1 to P2 and P3 in OCS use among pts adherent to BEL treatment at 180 days (P1 vs P2) and 360 days (P1 vs P3) who were receiving OCS in P1. Note: Percentages for differences are shown after rounding to the nearest whole number. Distributions of differences between periods were assessed by Kolmogorov–Smirnov and Shapiro–Wilk tests and none of the measures were found to be normally distributed. Wilcoxon Signed Ranks test was used to generate p values. OCS dose=prednisone equivalent.

	P1 (N=342)	P2 (N=342)	P1 vs P2 difference, %	P1 vs P2 p value	P1 (N=268)	P3 (N=268)	P1 vs P3 difference, %	P1 vs P3 p value
Proportion of pts receiving OCS, n (%)	342 (100.0)	268 (78.4)	-22	<0.001	268 (100.0)	174 (64.9)	-35	<0.001
Mean total OCS dose per pt, mg	718.8	572.8	-20	<0.001	695.1	426.6	-39	<0.001
Mean total OCS days supplied per pt	64.1	59.6	-7	0.064	62.7	51.9	-17	<0.001
Mean OCS daily dose for days supplied, mg	12.3	10.4	-15	<0.001	11.7	9.4	-20	<0.001
Proportion of pts with OCS dose of ≤5 mg/day for days supplied, n (%)	85 (24.9)	163 (47.7)	92	<0.001	68 (25.4)	161 (60.1)	137	<0.001
Proportion of pts with OCS dose of ≤7.5 mg/day for days supplied, n (%)	121 (35.4)	196 (57.3)	62	<0.001	100 (37.3)	183 (68.3)	83	<0.001

characteristics during follow-up. Changes in OCS use were assessed between Period (P) 1 (180 days pre-index [–180 to –1 days]), P2 (first 6 months post index [0 to 180 days]), and P3 (second 6 months post index [180 to 360 days]) in ptswith OCS use in P1 who were adherent to BEL at each assessed period.

Results: Of the 14,439 pts with SLE in the database, 608 received BEL for >180 days (full analysis set, FAS; 92.8% female, 70.4% with moderate SLE) and were included; 492 pts adhered to 360 days of BEL. In P1, 56.3% of FAS pts and 54.5% of pts who adhered to 360 days of BEL were receiving OCS.

Improvements in OCS use were more pronounced in pts with OCS use in P1 (**Table 1**), compared with the FAS, which included pts with no OCS use in P1 (**Table 2**).

Table 2. Change from P1 to P2 and P3 in OCS use among pts adherent to BEL treatment at 180 days (P1 vs P2) and 360 days (P1 vs P3). Note: Percentages for differences are shown after rounding to the nearest whole number. Distributions of differences between periods were assessed by Kolmogorov–Smirnov and Shapiro–Wilk tests and none of the measures were found to be normally distributed. Wilcoxon Signed Ranks test was used to generate p values. OCS dose=prednisone equivalent.

	P1 (N=608)	P2 (N=608)	P1 vs P2 difference, %	P1 vs P2 p value	P1 (N=492)	P3 (N=492)	P1 vs P3 difference, %	P1 vs P3 p value
Proportion of pts receiving OCS, n (%)	342 (56.3)	335 (55.1)	−2	0.613	268 (54.5)	236 (48.0)	−12	0.013
Mean total OCS dose per pt, mg	404.3	377.1	−7	0.260	378.7	292.2	−23	0.004
Mean total OCS days supplied per pt	36.0	38.6	7	0.220	34.1	34.2	0	0.775
Mean OCS daily dose for days supplied, mg	12.3	11.0	−11	<0.001	11.7	10.4	−11	<0.001
Proportion of pts with OCS dose of ≤5 mg/day for days supplied, n (%)	351 (57.7)	377 (62.0)	7	0.048	292 (59.3)	337 (68.5)	15	0.001
Proportion of pts with OCS dose of ≤7.5 mg/day for days supplied, n (%)	387 (63.7)	417 (68.6)	8	0.022	324 (65.9)	368 (74.8)	14	0.001

Table 3. Changes from P1 to P2 and P3 in pt clinical characteristics among pts adherent to BEL treatment at 180 days (P1 vs P2) and 360 days (P1 vs P3). *Among pts with data available for the given period; data may not be for the same pts assessed in each period. IQR, interquartile range; SD, standard deviation.

	P1 (N=608)	P2 (N=608)	P1 (N=492)	P3 (N=492)
C3* (mg/dL)				
N	326	323	259	255
Mean (SD)	113.9 (34.7)	120.6 (33.3)	113.1 (34.8)	120.7 (33.3)
Median (IQR)	113.0 (86.0, 136.0)	119.0 (99.0, 145.0)	112.0 (85.0, 136.0)	117.0 (97.0, 146.0)
C4* (mg/dL)				
N	240	260	189	211
Mean (SD)	25.7 (8.9)	26.9 (9.4)	25.7 (8.9)	27.3 (9.9)
Median (IQR)	24.0 (19.0, 31.2)	25.0 (20.0, 31.9)	24.0 (19.0, 31.3)	25.6 (20.0, 31.5)
SLEDAI*				
N	34	30	28	23
Mean (SD)	12.5 (6.3)	9.6 (6.4)	12.7 (5.7)	11.6 (9.4)
Median (IQR)	11.5 (8.0, 16.0)	8.5 (6.0, 16.0)	12.0 (8.0, 16.5)	8.0 (4.0, 17.0)

Among pts receiving OCS in P1, significantly fewer received OCS in P2 and P3 versus P1 (**Table 1**). Significant reductions from P1 were observed in P2 and P3 for mean total OCS dose per pt, mean OCS daily dose for days supplied, and mean total OCS days supplied per pt in P3 only; significantly more pts received daily OCS dose of ≤5 mg and ≤7.5 mg in P2 and P3 versus P1 (**Table 1**).

Slight increases from P1 in C3 and C4 levels were observed in P2 and P3; mean SLEDAI scores (for pts with available data for the specified period) decreased from 12.5 in P1 to 9.6 in P2 in FAS pts and from 12.7 in P1 to 11.6 in P3 in pts who adhered to 360 days of BEL (**Table 3**).

Conclusion: This analysis of data from a large rheumatology database showed OCS dose and use reductions with BEL in pts receiving OCS before BEL initiation, providing more real-world evidence for the steroid-sparing effect of BEL in pts with SLE and baseline OCS use. The beneficial effect was more pronounced with longer duration of BEL treatment.

Deep Serological Profiling of SLE Patients Treated with anti-CD19 CAR T Cells

Samik Basu[1], Daniel Nunez[1], Darshil Patel[1], Jenell Volkov[1], Zachary Vorndran[1], Steven Wong[1], Andreas Mackensen[2] and Georg Schett[3], [1]Cabaletta Bio, Philadelphia, PA, [2]Department of Internal Medicine 5, Hematology and Oncology, Universitätsklinikum Erlangen and Friedrich-Alexander-Universität Erlangen Nürnberg, Erlangen, Germany, [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-CD19 chimeric antigen receptor (CAR) T cell therapy is a ground-breaking emerging treatment modality for severe refractory systemic lupus erythematosus (SLE) and has shown early promise in other diseases.Initial clinical data demonstrate that adoptive transfer of anti-CD19 CAR T cells induce a durable long-term remission in SLE paitents. However, the mechanisms underlying remission are unclear. Our aim was to elucidate the serological factors that are associated with responses in SLE patients following treatment with anti-CD19 CAR T cells.

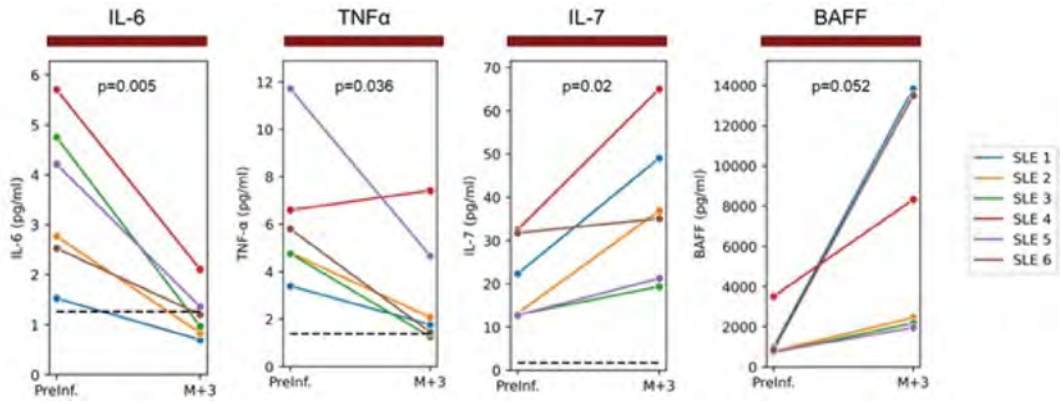

Figure 1. Changes in serum cytokines following CD19 CAR T cell infusion across 6 patients

Methods: Sera were collected from six severe refractory SLE patients prior to and 3 months following anti-CD19 CAR T cell therapy.All patients were in remission off-therapy at 3 months following adoptive T cell transfer. Sera were evaluated for 25 cytokines by electro-chemiluminescence immunoassay (MSD). Sera were also evaluated for 17 SLE-associated and 14 infectious disease-associated antibodies using a custom developed Luminex-based immunoassay.

Results: Serum levels of the inflammatory cytokines IL-6 and TNFα were decreased in SLE patients 3 months post-anti-CD19 CAR T cell infusion relative to pre-infusion (Figure 1).Over the same period, the B cell memory and homeostatic cytokines IL-7 and BAFF increased (Figure 1).SLE associated antibodies decreased dramatically in 5 out of 6 patients following anti-CD19 CAR T cell infusion.In 1 out of 6 patients, SLE associated antibodies either remained stable or increased mildly despite resolution of clinical disease. Infectious disease associated antibodies typically remained stable or changed minimally following anti-CD19 CAR T cell infusion. Lastly, circulating $CD19^+$ B cells were detected in all patients 3 months following anti-CD19 CAR T cell infusion.

Conclusion: We report on 6 SLE patients following anti-CD19 CAR T therapy showing sustained remission off-therapy. Serum cytokine data suggest that systemic inflammation is consistently decreased at three months post infusion. An expanded panel of SLE-associated antibodies shows a profound drop in SLE-associated antibodies observed in most patients supports the idea of an immune reset following CAR T therapy. These studies support the continued exploration of anti-CD19 CAR T cell therapy in SLE.

Clinical Safety and Efficacy Results from EQUALISE Type B: A Phase 1b Open-label Clinical Study of Itolizumab, a Novel anti-CD6 Therapy, in Subjects with Active Proliferative Lupus Nephritis

Kenneth Kalunian[1], Robert Levin[2], Sreejith Parameswaran[3], nelson kopyt[4], Stephen Connelly[5], Eugene Sun[5], Katie Kim[5], maple fung[5] and Manish Rathi[6], [1]University of California San Diego, La Jolla, CA, [2]South Florida University, Tampa, FL, [3]JIPMER, New Delhi, India, [4]LeHigh University, LeHigh, PA, [5]Equillium, La Jolla, CA, [6]Postgraduate Institute of Medical education and Research, Chandigarh, India

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Itolizumab is a first-in-class, non-depleting, monoclonal antibody against the co-stimulatory receptor CD6 that blocks its interaction with ALCAM, to inhibit T_{eff} cell activity and trafficking. It is being evaluated to treat immunoinflammatory diseases where T cells play a central role, including active proliferative lupus nephritis (apLN). Here we present results from EQUALISE (Type B; NCT04128579), a Phase 1b study of itolizumab in subjects with apLN.

Methods: 17 adult subjects with apLN (ISN/RPS class III or IV with or without class V) were enrolled. All were treated with open-label itolizumab subcutaneously at 1.6 mg/kg Q2W for up to 13 doses in combination with mycophenolate mofetil (2-3 g/day) and systemic corticosteroids (methylprednisolone with rapid taper to prednisone < 10 mg/day by W10). Subjects were followed for 12 weeks after their last dose. Safety and efficacy measures were assessed.

Results: The median age of subjects was 34 years; 94% were female with 82% Asian; most subjects had ISN/RPS class IV +V disease (47%). Mean duration of LN was 5.4 years with Baseline mean 24 hour urine protein of 4.9 g and eGFR of 104 ml/min/1.73m2. Treatment was completed in 11 subjects with 4 discontinuing early (3 due to AEs and 1 due to physician decision) and 2 are still dosing.

88% of subjects experienced at least 1 adverse event (AE), most common were peripheral edema and lymphopenia. At least 1 low lymphocyte count was reported by 7 subjects (41%). Serious AEs occurred in 2 subjects (12%), including dehydration and COVID-19 infection, with none deemed related to study treatment.

Based on the 14 subjects that completed/terminated the study and had a post-baseline measure, there was a median 72% reduction in spot urine protein creatinine ratio (UPCR), resulting in high partial and complete response (PR and CR) rates (FIGURE). At Week 12, the overall response rate was 57% (n=14), and at Week 36 (n=12) was 83%. 2 subjects are still dosing, and 2 are in the follow up period. These responses occurred as early as Week 4 on study with steroids tapered to a median of prednisone 5 mg by Week 12.

Conclusion: EQUALISE Type B demonstrates that subjects with proteinuric apLN had high CR and PR rates with rapid and deep reduction in UPCR when itolizumab was added to mycophenolate mofetil and corticosteroids. Further controlled studies are warranted in this population at high risk of disease progression and end stage kidney disease.

EQUALISE Type B: % response at Week 12/EOS and Week 36/EOS

Eltrombopag in SLE-Associated Thrombocytopenia: Treatment Response and Thrombotic Complications

Asmaa Beltagy[1], Abeer Abdelati[1], Fatma Fayed[2], **Nouran Eshak**[3], Ashraf Elghandour[1] and Mohamed Halaby[4], [1]Faculty of Medicine, Alexandria University, Alexandria, Egypt, [2]Alexandria University Student Hospital, Alexandria, Egypt, [3]Mayo Clinic Arizona, Lubbock, TX, [4]Faculty of Medicine, Alexandria University, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: This study aimed to assess the efficacy of Eltrombopag, a medication used to treat thrombocytopenia, in patients with systemic lupus erythematosus (SLE)-associated thrombocytopenia. Additionally, we investigated the occurrence of thrombotic complications in these patients.

Methods: Nineteen SLE patients with thrombocytopenia were followed for two years or until Eltrombopag discontinuation. Data included medical history, examinations, labs, antiphospholipid serology, response rates, and complications

Results: All patients (12 females, mean age 33±12 years) fulfilled the SLICC criteria for SLE and presented with mucocutaneous bleeding. Antiphospholipid serology was positive in 11 patients, with two patients meeting the criteria for antiphospholipid syndrome due to a history of deep vein thrombosis. Six patients had a history of lupus nephritis. Eltrombopag was initiated after the failure of prior therapies. At the start of treatment, the mean platelet count was 12±13 x 109. A daily dose of 50mg of Eltrombopag was used, with one patient requiring 75mg. Twelve patients demonstrated a sustained response, and four patients were able to taper off corticosteroids. However, one patient did not respond to Eltrombopag. Six patients developed thrombotic complications, including deep vein thrombosis, pulmonary embolism, myocardial infarction, cavernous sinus thrombosis, stroke, and catastrophic antiphospholipid syndrome. The median time to thrombotic events was 5.5 months (range: 0.3-8) with a median platelet count of 170 x 10^9 (range: 68-330). These complications necessitated the discontinuation of Eltrombopag. Four out of the six patients with thrombotic events had positive antiphospholipid antibodies, and two had a history of lupus nephritis.

Conclusion: Our study demonstrates that Eltrombopag is effective in treating SLE-associated thrombocytopenia, with favorable treatment responses observed in the majority of patients, including steroid tapering. However, caution should be exercised regarding the development of thrombotic complications, especially in patients with positive antiphospholipid antibodies. Further research is warranted to identify risk factors and strategies for preventing these complications in this patient population.

Session Title: SLE – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Toll-like receptor (TLR)7 is a pattern recognition receptor, whose ligands include nucleic acids and whose activation is part of the pathogenesis of systemic lupus erythematosus (SLE).In mice, TLR7 overexpression worsens lupus models, while TLR7 deficiency ameliorates them.In humans, TLR7 gain-of-function mutations confer susceptibility to SLE.DS-7011a is an anti-TLR7 monoclonal antibody (mAb), which prevents TLR7 from signaling.DS-7011a inhibits in vitro production of cytokines stimulated by TLR7.A surrogate anti-TLR7 mAb effectively treats mouse lupus models, improving survival and decreasing autoantibody production.The aim of this first-in-human, single ascending intravenous (IV) and

Baseline characteristics	Results
Total number of patients	19
Gender (female)	12 (63.2%)
Mean age (years)	33 ± 12 (range: 16-55)
SLICC criteria for SLE	All patients fulfilled the criteria
Presenting symptom	Mucocutaneous bleeding
Patients with positive serology for APS	11 (57.9%)
Patients fulfilling APS criteria	2 (10.5%)
Patients with a history of lupus nephritis	6 (31.6%)
Treatment and response	
Platelet count at time of Eltrombopag initiation (mean)	12 ± 13 x 10^3/L
Eltrombopag dosage	50 mg daily (one patient required 75 mg)
Sustained response to Eltrombopag	12 (63.2%)
Patients weaned off steroids	4 (21.1%)
No response	1 (5.3%)
Treatment discontinuation due to side effects (thrombosis)	6 (31.6%)
Complications n=6	
Patients with positive APS serology and complications	4/6 (66.6%)
Patients with lupus nephritis and complications	2/6 (33.3%)
Median time to thrombosis	5.5 months (range: 0.3-8)
Platelet count at the time of thrombosis	170 x 10^3/L (range: 68-330)
Thrombotic complications	Deep vein thrombosis, Pulmonary embolism, Myocardial infarction, Cavernous sinus thrombosis, Stroke, Catastrophic APS.

subcutaneous (SC) dose study was to evaluate the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of DS-7011a in human volunteers (HV), including HV of Japanese descent [NCT05203692].

Methods: This study was a double-blind, randomized, and placebo-controlled trial. Eighty HV were enrolled in 3 stages and assigned to receive DS-7011a or placebo 6:2 in 10 cohorts of 8 each.Non-Japanese HV were enrolled in Stage 1 in 6 ascending IV dose (0.1, 0.3, 1, 3, 10, and 20 mg/kg) cohorts and in Stage 2 in 3 ascending SC dose (100, 300, and 600 mg) cohorts; Japanese HV were enrolled in Stage 3 in 1 IV dose (3 mg/kg) cohort.HV received a single DS-7011a dose on Day 1 and were followed for 8 weeks until Day 57 for safety, PK, and PD assessments. PK exposure was evaluated by measuring DS-7011a in plasma by ligand-binding assay.PD response was evaluated ex vivo in blood using TruCulture® tubes containing gardiquimod, which is a TLR7-specific stimulant, and measuring interleukin (IL)-6 by ligand-binding assay.

Results: DS-7011a was generally safe and well tolerated across all cohorts given by either IV (up to the dose of 20 mg/kg) or SC (up to the dose of 600 mg) administration to either non-Japanese or Japanese HV. The treatment emergent adverse events (TEAE) observed during the study were mostly mild in severity and not drug-related (one TEAE of hospitalization for bone fractures was considered severe and reported as serious but not drug-related).DS-7011a exposure (AUClast and Clast) generally increased with dose increment.PK linearity started at 3 mg/kg following IV administration and at 300 mg following SC, while the elimination of lower doses was noticeably accelerated probably by target-mediated disposition. Mean terminal half-life was about 17 days (within dose range of PK linearity) and mean Tmax upon SC administration was about 5 days. PK exposure in non-Japanese HV was slightly higher than Japanese, reflecting difference in body weight.DS-7011a showed ex vivo inhibition of TLR7-stimulated IL-6 production that was of large extent, early onset, and lasting duration.

Conclusion: DS-7011a, a mAb that specifically antagonizes TLR7, was generally safe and well tolerated and showed appealing PK and PD properties that support its development for the treatment of SLE.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab (BEL) is an approved treatment for active SLE and LN, in addition to standard therapy (ST). Despite BEL clinical studies demonstrating a favorable benefit–risk profile, varying incidence rates of mortality and adverse events of special interest, including malignancies, require further evaluation. This study aimed to assess the long-term safety of BEL therapy in patients with SLE.

Methods: This was a Year-5 post-treatment follow-up of the Phase 4, double-blind, placebo (PBO)-controlled Belimumab Assessment of Safety in SLE (BASE) study (GSK Study BEL115467; NCT01705977).[1] Overall, 4003 adults with active, autoantibody-positive SLE received BEL (10 mg/kg intravenously [IV]) or PBO, plus ST, for 48 weeks. Patients then entered a Year 2–5 follow-up period in which they received physician-directed ST. All patients were contacted annually by telephone, including patients who discontinued treatment in Year 1. Mortality and new primary malignancies (including nonmelanoma skin cancer) were the endpoints collected, and rates summarized. We present the final Year-5 follow-up data by treatment received during Year 1.

Results: Out of the Year-1 population, 77.0% (N=3081) were followed up through to Year 5 with a similar proportion of patients in each Year-1 treatment group. Baseline characteristics for the Year-5 follow-up population were similar to the Year-1 study population (N=4003). By the Year-5 follow-up, cumulatively 13.4% and 11.4% of patients in the BEL and PBO Year-1 treatment groups had received BEL as part of physician-directed care, respectively. Cumulative follow-up adjusted mortality rates were lower in the BEL vs PBO Year-1 treatment group by Years 2 to 5 (Year 5 BEL 0.61 vs PBO 0.96 per 100 patient-years; **Table**). Post hoc analyses of the Year 2–5 follow-up period showed that 96 patients (2.85%) died and the highest incidence of deaths by system organ class was infections and infestations (total 0.83%: BEL 0.83% and PBO 0.84%) and cardiac disorders (total 0.51%: BEL 0.29% and PBO 0.72%). Cumulative follow-up adjusted new

Table. Year 1 plus Years 2–5 post-treatment* follow-up mortality and new primary malignancy† rates by Year-1 study treatment. *Patients in the post-treatment follow-up period were no longer receiving study treatment; †includes nonmelanoma skin cancer.

	Patients with events per year, n (%)			Cumulative patient incidence rate per 100 patient-years, (%)		
	BEL	PBO	Total	BEL	PBO	Total
Year-1 (as-treated) population	**N=2002**	**N=2001**	**N=4003**	**N=2002**	**N=2001**	**N=4003**
Deaths	13 (0.65)	22 (1.10)	35 (0.87)	0.66 (0.65)	1.11 (1.10)	(0.87)

Deaths	9 (0.54)	17 (1.04)	26 (0.79)	0.58 (1.55)	1.14 (3.00)	0.86 (2.27)
New primary malignancies	8 (0.48)	9 (0.55)	17 (0.52)	0.38 (1.00)	0.49 (1.25)	0.44 (1.12)
Year-4 (as-treated in Year-1) population	**N=1619**	**N=1583**	**N=3202**	**N=2002**	**N=2001**	**N=4003**
Deaths	14 (0.86)	13 (0.82)	27 (0.84)	0.65 (2.25)	1.07 (3.65)	0.86 (2.95)
New primary malignancies	10 (0.62)	5 (0.32)	15 (0.47)	0.44 (1.50)	0.44 (1.45)	0.44 (1.47)
Year-5 (as-treated in Year-1) population	**N=1555**	**N=1526**	**N=3081**	**N=2002**	**N=2001**	**N=4003**
Deaths	6 (0.39)	7 (0.46)	13 (0.42)	0.61 (2.55)	0.96 (4.00)	0.78 (3.27)
New primary malignancies	3 (0.19)	2 (0.13)	5 (0.16)	0.40 (1.65)	0.38 (1.55)	0.39 (1.60)

primary malignancy patient incidence rates were lower in the BEL vs PBO Year-1 treatment group by Years 2 and 3, but similar by Years 4 and 5 (Year 5 BEL 0.40 vs PBO 0.38 per 100 patient-years; **Table**). Post hoc analyses of the Year 2–5 follow-up period showed that 46 patients (1.37%) developed new primary malignancies (BEL 1.42% and PBO 1.32%). The area most affected by neoplasm was the breast (total 0.36%: BEL 0.35% and PBO 0.36%).

Conclusion: The Year-5 follow-up results of BASE, the largest double-blind, placebo-controlled clinical trial in patients with SLE to date, support the safety of BEL therapy with no new BEL safety concerns identified in this analysis.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with SLE have a high risk of infections, which remains a common cause of mortality in this population.[1] This infection risk can result from the pathophysiology of SLE itself, with corticosteroids and immunosuppressive therapy contributing to further infection risks.[1] Belimumab is an approved treatment for active SLE and LN, in addition to standard therapy.[2] To evaluate the incidence of infections onbelimumab treatment, we summarized 52-week infection data from placebo-controlled belimumab SLE studies.

Methods: Infection data were sourced from the Phase 4 Belimumab Assessment of Safety in SLE (BASE) study (GSK Study BEL115467)[3] and GSK Study BEL116559, a pooled post hoc analysis of 52-week safety data from six studies (BEL110751,[4] BEL110752,[5] BEL112341,[6] BEL113750,[7] BEL115471,[8] and LBSL02[9]). In BASE, 4003 adults with active, autoantibody-positive SLE (no criteria based on disease activity level) received belimumab (10 mg/kg/month intravenously [IV]) or placebo, plus standard therapy (ST), for 48 weeks. Only data for patients receiving marketed doses of belimumab (10 mg/kg/month IV or 200 mg/week subcutaneously) or placebo, plus ST are reported from BEL116559 integrated randomized controlled trials (RCTs) included in this analysis, with criteria to exclude patients with low disease activity at baseline. The number of serious infections and infections of special interest (opportunistic infections, active tuberculosis, herpes zoster, sepsis) through 52 weeks were summarized for belimumab and placebo treatment groups.

Results: The age and sex profile of patients in the BASE and integrated BEL116559 studies were similar; however, in BASE more patients were white, the median disease duration was longer, and disease activity and average doses of corticosteroids were lower than in BEL116559 (**Table 1**). Over 52 weeks, serious adverse events (SAEs) of infection and infestation occurred slightly more frequently with placebo than belimumab in both BASE and BEL116559 (**Table 2**). Infections of special interest were of a similar or higher incidence (such as with opportunistic infections and herpes zoster) in BEL116559 versus BASE and occurred more frequently with placebo than belimumab in both datasets (**Table 2**).

Table 1. Baseline patient characteristics for the BASE and BEL116559 datasets. *Baseline patient characteristics are presented for the intention-to-treat population; †patient characteristics for integrated randomized-controlled trials include patients on all doses of belimumab; this cohort is not limited to patients receiving marketed doses (10 mg/kg intravenous or 200 mg subcutaneous) of belimumab. IQR, interquartile range; SD, standard deviation; SELENA, Safety of Estrogens in Lupus Erythematosus National Assessment.

	BASE*		BEL116559 integrated RCTs*

Table 2. Incidence of infection and infestation SAEs, and infections of special interest through Week 52 for the BASE and BEL116559 integrated RCT datasets. *BASE and BEL116559 safety data are shown for the on-treatment population, patient numbers vary between baseline data and Week 52 follow-up data, since patients could withdraw from study agent during Year 1 and continue on study, or could withdraw from Year 1 study visits and reconsent to a Week 52 follow-up; †this cohort is limited to patients receiving marketed doses (10 mg/kg intravenous or 200 mg subcutaneous) of belimumab; ‡data for the 4 most common individual SAEs for the BASE and BEL116559 datasets are shown, calculated as the total incidence across both treatment arms; §only treatment-emergent SAEs for the on-treatment period are summarized from patients who received ≥1 dose of belimumab or placebo; ||all infections of special interest are limited to opportunistic infections, active tuberculosis, herpes zoster, and sepsis; ¶per sponsor adjudication.

	BASE*		BEL116559 integrated RCTs*	
	Placebo (N=2001)	Belimumab (N=2002)	Placebo (N=1355)	Belimumab (N=2031)†
Infection and infestation SAEs,‡ n (%)	82 (4.1)§	75 (3.7)§	80 (5.9)	96 (4.7)
Pneumonia	21 (1.0)	17 (0.8)	18 (1.3)	14 (0.7)
Herpes zoster	5 (0.2)	0	4 (0.3)	9 (0.4)
Urinary tract infection	8 (0.4)	16 (0.8)	8 (0.6)	5 (0.2)
Cellulitis	6 (0.3)	6 (0.3)	5 (0.4)	6 (0.3)
Infections of special interest,‖ n (%)	50 (2.5)	36 (1.8)	97 (7.2)	122 (6.0)
Serious infections of special interest	17 (0.8)	17 (0.8)	17 (1.3)	29 (1.4)
Opportunistic infections¶	15 (0.7)	11 (0.5)	92 (6.8)	112 (5.5)
Active tuberculosis	4 (0.2)	4 (0.2)	5 (0.4)	4 (0.2)
Herpes zoster	36 (1.8)	18 (0.9)	59 (4.4)	77 (3.8)
Sepsis	7 (0.3)	10 (0.5)	10 (0.7)	14 (0.7)

Conclusion: Over 52 weeks, serious infections and infections of special interest occurred at a similar or higher incidence with placebo versus belimumab in the Phase 4 BASE safety study and the BEL116559 pooled analysis of safety RCT data. These data further support the favorable safety profile of belimumab for SLE treatment.

Lupus Low Disease Activity State (LLDAS) Achievement with Deucravacitinib, an Oral, Selective, Allosteric Tyrosine Kinase 2 Inhibitor, in a Phase 2 Trial in SLE

Eric Morand[1], Coburn Hobar[2], Samantha Pomponi[3], Ravi Koti[4], Thomas Wegman[5] and Ronald van Vollenhoven[6], [1]Monash University, Centre for Inflammatory Diseases, Melbourne, Australia, [2]Bristol Myers Squibb, Bradenton, FL, [3]Bristol Myers Squibb, Princeton, NJ, [4]Syneos Health, Morrisville, NC, [5]Bristol Myers Squibb, Beaver Falls, PA, [6]Amsterdam University Medical Centers, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: SLE – Treatment Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis. A 48-week, double-blind, phase 2 trial (NCT03252587) in patients with SLE showed that deucravacitinib demonstrated efficacy across multiple endpoints compared with placebo, including the primary endpoint of Systemic Lupus Erythematosus Responder Index 4 (SRI[4]) at week 32 and the secondary endpoint of LLDAS at week 48.[1] Achievement and maintenance of LLDAS is associated with reduced risk of SLE-associated organ damage and mortality.[2] Here, we further investigate LLDAS outcomes with deucravacitinib through post hoc analyses assessing time to first LLDAS response and cumulative time in LLDAS.

Methods: Patients with active SLE (N=363) were randomized 1:1:1:1 to placebo or deucravacitinib 3 mg twice daily (BID), 6 mg BID, or 12 mg once daily (QD). Exploratory outcomes included median time to first LLDAS response and the percentage of patients who achieved LLDAS for ≥ 3 or ≥ 5 consecutive visits and the percentage of patients who achieved LLDAS for ≥ 20% or ≥ 50% of the time through week 48, via logistic regression. Odds ratios and nominal *P* values for each treatment group compared with the placebo group were provided.

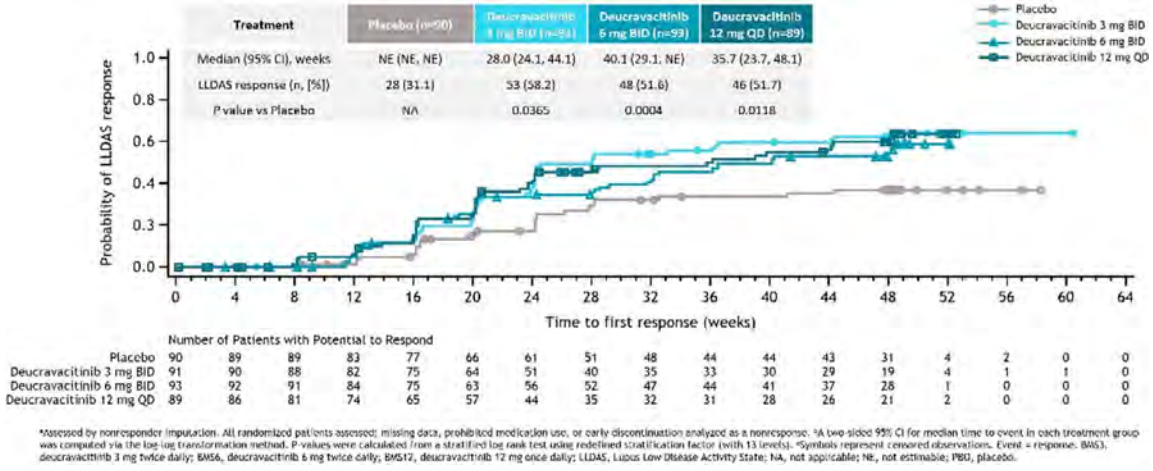

Figure 1. Time to first LLDAS response (a, b, c)

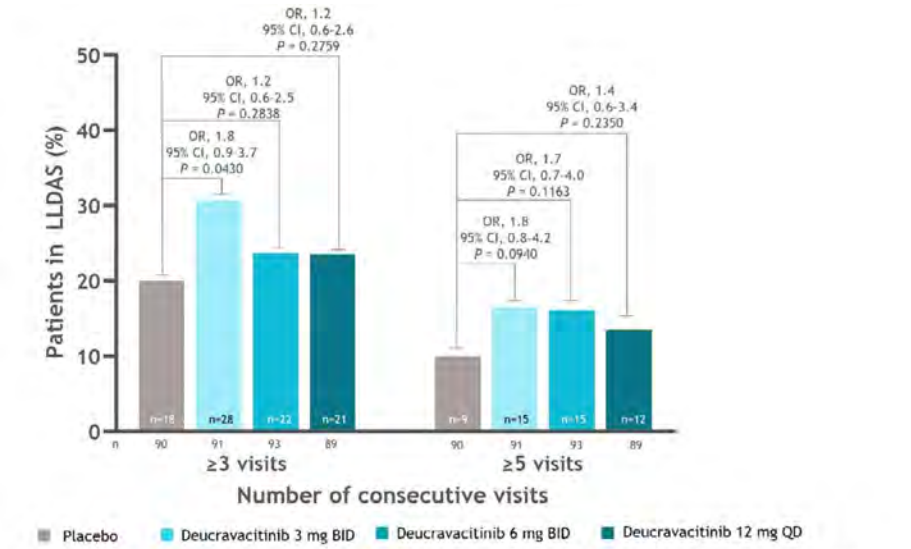
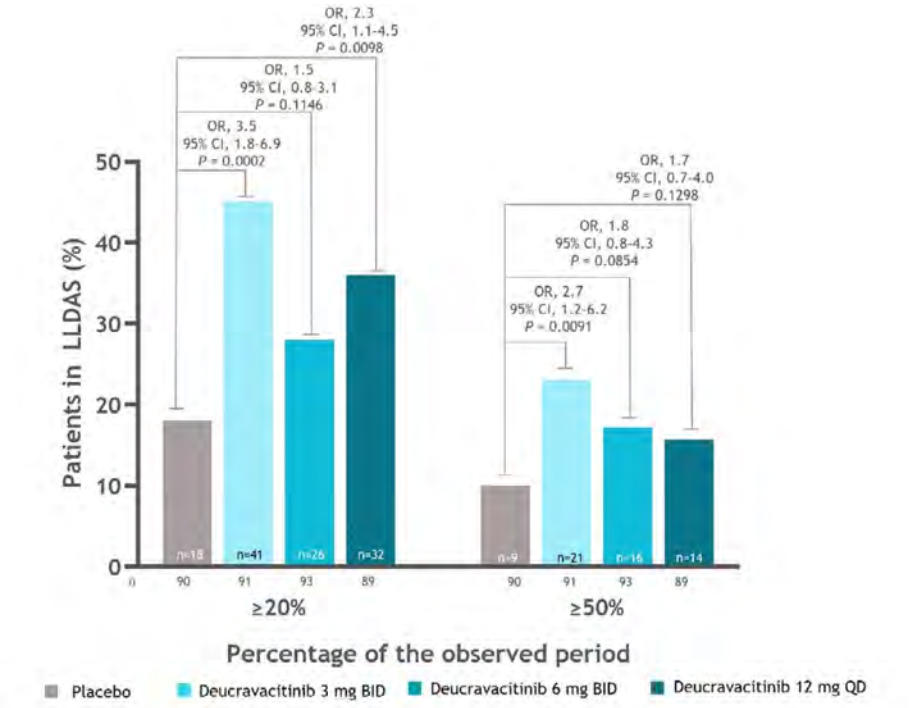


[a]Assessed by nonresponder imputation. All randomized patients assessed; missing data, prohibited medication use, or early discontinuation analyzed as a nonresponse. [b] Logistic regression with treatment group and redefined stratification factor as fixed factors; redefined stratification factor has 13 levels based on the combination of 3 factors: CS dose (≥10 mg QD or <10 mg QD), SLEDAI-2K score (≥10 or <10), and Region (North America, Latin America, Japan, and rest of world). CS dose and SLEDAI-2K score are not applied for stratification in Japan, therefore Japan is considered a separate stratum. In case the logistic regression model fit is not stable, the region stratification factor may be removed from the model (resulting in 5 stratification factors). One sided p-value was used for comparison vs placebo.
BID, twice daily; LLDAS, Lupus Low Disease Activity State; NA, not applicable; OR, odds ratio; QD, once daily.

Figure 2. Percentages of patients attaining LLDAS for ≥ 3 or ≥ 5 consecutive visits (a, b)



[a]Assessed by nonresponder imputation. All randomized patients assessed; missing data, prohibited medication use, or early discontinuation analyzed as a nonresponse. [b] Logistic regression with treatment group and redefined stratification factor as fixed factors; redefined stratification factor has 13 levels based on the combination of 3 factors: CS dose (≥10 mg QD or <10 mg QD), SLEDAI-2K score (≥10 or <10), and Region (North America, Latin America, Japan, and rest of world). CS dose and SLEDAI-2K score are not applied for stratification in Japan, therefore Japan is considered a separate stratum. In case the logistic regression model fit is not stable, the region stratification factor may be removed from the model (resulting in 5 stratification factors). One sided p-value was used for comparison vs placebo.
BID, twice daily; LLDAS, Lupus Low Disease Activity State; NA, not applicable; OR, odds ratio; QD, once daily.

Figure 3. Percentages of patients attaining LLDAS for ≥ 20% or ≥ 50% of observed time (a, b)

Results: Median time to first LLDAS response was significantly shorter in all deucravacitinib groups compared with the placebo group (3 mg BID, 28.0 weeks: P = 0.0365 vs placebo; 6 mg BID, 40.1 weeks: P = 0.0004 vs placebo; 12 mg QD, 35.7 weeks: P = 0.0118 vs placebo). Median time to first LLDAS response was not estimable in the placebo group because 50% of the patients had not yet achieved an LLDAS response **(Figure 1)**. The deucravacitinib 3 mg BID group had a significantly higher percentage of patients who achieved LLDAS for ≥ 3 visits compared with the placebo group (OR, 1.8; 95% CI, 0.9–3.7, P = 0.0430). A higher percentage of patients treated with any dose of deucravacitinib attained LLDAS for ≥ 3 or ≥ 5 visits compared with patients receiving placebo **(Figure 2)**. A higher percentage of patients treated with deucravacitinib attained LLDAS for ≥ 20% and ≥ 50% of cumulative observed time compared with patients receiving placebo **(Figure 3)**. The deucravacitinib 3 mg BID and 12 mg QD groups had significantly higher percentages of patients who achieved LLDAS for ≥ 20% of cumulative time compared with placebo (3 mg BID: OR, 3.5; 95% CI, 1.8–6.9; P = 0.0002; 12 mg QD: OR, 2.3; 95% CI, 1.1–4.5; P = 0.0098), and the 3 mg BID group also had a significantly higher percentage of patients who achieved LLDAS for ≥ 50% of cumulative time (3 mg BID: OR, 2.7; 95% CI, 1.2–6.2; P = 0.0091).

Conclusion: Patients treated with deucravacitinib achieved LLDAS response earlier and demonstrated more sustained and cumulative LLDAS responses compared with patients receiving placebo. Taken together, these data suggest that deucravacitinib may contribute to better long-term prospects for patients with SLE.

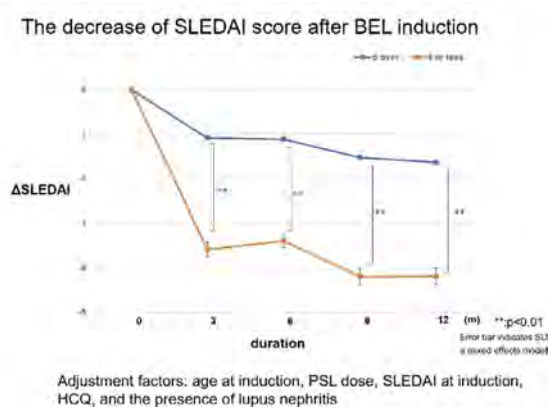
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Figure 1.



The decrease of SLEDAI score after BEL induction

Background/Purpose: Belimumab (BEL), B cell-targeted biologic agent for systemic lupus erythematosus (SLE), is cumulating evidence such as reducing glucocorticoids and preventing the progressionof organ damage. The BLISS-LN study evaluated the effect of BEL on lupus nephritis (LN) and found that BEL administered early in the course of LN improved proteinuria. There is ongoing debate regarding the optimal timing of administering BEL in the treatment of SLE in real-world settings. BAFF receptor expression decreases along with B cell differentiation, and the number of memory B cells is higher in SLE patients with longer disease duration. In addition, the shorter disease duration correlated with the higher blood BAFF concentration in SLE patients. Based on these reports, we hypothesized that BEL, which targeted BAFF, would be more effective in patients with shorter disease duration. In this study, we investigated whether the duration of SLE at the time of BEL introduction contributes to its treatment responsiveness.

Methods: Ninety-eight patients diagnosed with SLE according to the 1997 ACR Diagnostic Revision Criteria or 2012 SLICC Classification Criteria at Nagasaki University Hospital and its affiliated hospitals in Nagasaki Prefecture and who started BEL between December 2017 and August 2021 were included in the analysis. The primary objective of the study is to compare the decrease in SLEDAI scores after the introduction of BEL at different time points (3, 6, 9, and 12 months) between two groups categorized based on disease duration at BEL introduction (≤5 years and >5 years). The analysis will be adjusted using a mixed-effects model. Adjustment factors include age at induction, prednisolone (PSL) dose, SLEDAI at induction and hydroxychloroquine (HCQ), and the presence of lupus nephritis.

Results: In the overall patient population, the mean age at BEL introduction was 41 years, the mean SLEDAI score was 7, the mean dose of PSL was 9 mg/day, and HCQ was used in 50 patients (51%). The number of ≤5 years group was 20 patients and the number of >5 years was 78 patients. Both groups (≤5 years and >5 years) showed improvement in SLEDAI scores 3 months after the BEL introduction. In addition, the group receiving BEL at 5 years or less showed significantly greater improvement in SLEDAI than the group receiving BEL at more than 5 years at each evaluation time point after BEL introduction.

Conclusion: Our investigating headlights and earlier introduction of BEL in SLE patients may contribute to a more remarkable improvement in disease activity. This finding could potentially impact the clinical decision-making process regarding the implementation of a treat-to-target strategy for patients with SLE.

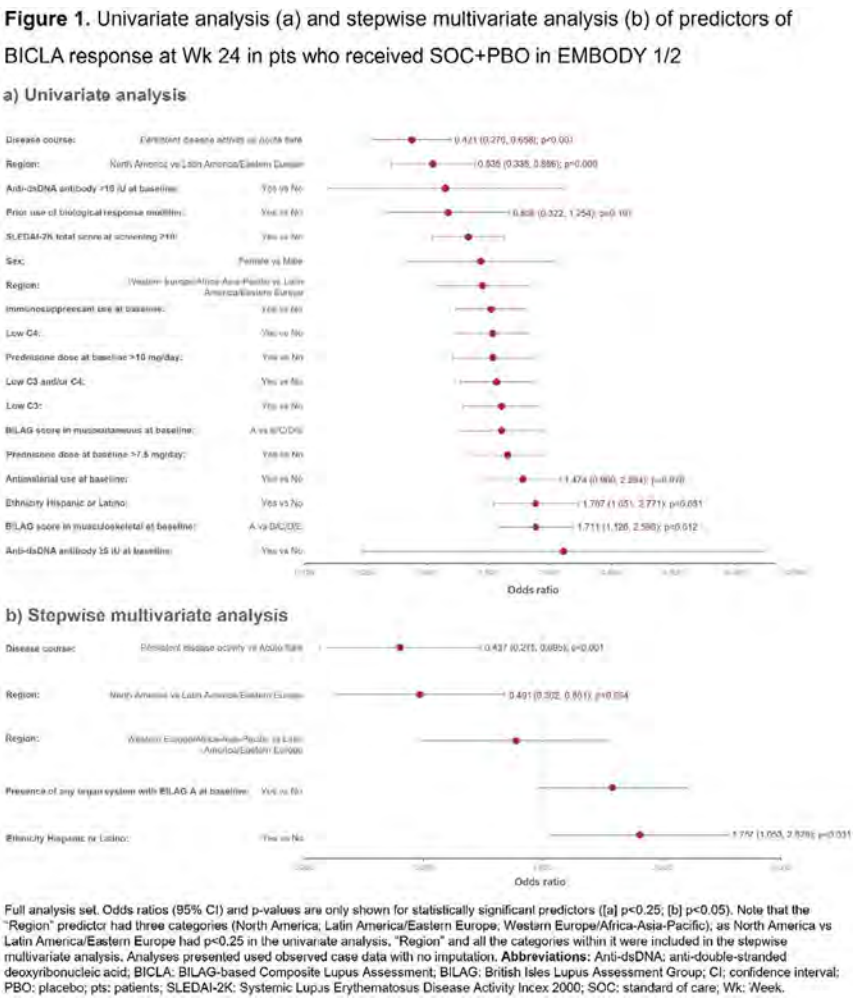
Disease Course and Complement as Predictors of Response to Standard of Care Plus Placebo in Patients with SLE: A Post Hoc Analysis of Dapirolizumab Pegol and Epratuzumab Clinical Trial Data

Christian Stach[1], Caroline Gordon[2], Vanessa Taieb[3], George Stojan[4] and **Joan Merrill**[5], [1]UCB Pharma, Monheim am Rheim, Germany, [2]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom, [3]UCB Pharma, Colombes, France, [4]UCB, Baltimore, MD, [5]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

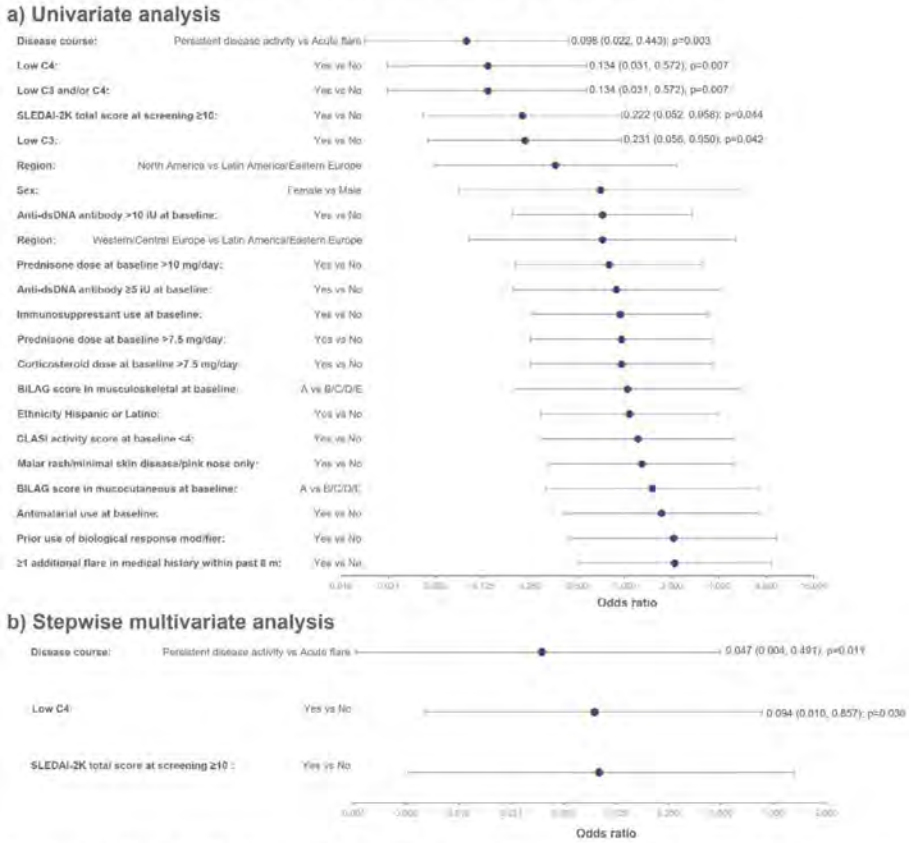
Background/Purpose: High placebo responses pose challenges to systemic lupus erythematosus (SLE) clinical trials.[1]This analysis aims to identify predictors of standard of care plus placebo (SOC+PBO) response using data from epratuzumab (Emab; a humanized anti-CD22 monoclonal antibody) and dapirolizumab pegol (DZP; a polyethylene glycol-conjugated antigen-binding fragment lacking a functional Fc domain that inhibits CD40L) trials.[2,3]

Figure 1. Univariate analysis (a) and stepwise multivariate analysis (b) of predictors of BICLA response at Wk 24 in pts who received SOC+PBO in EMBODY 1/2



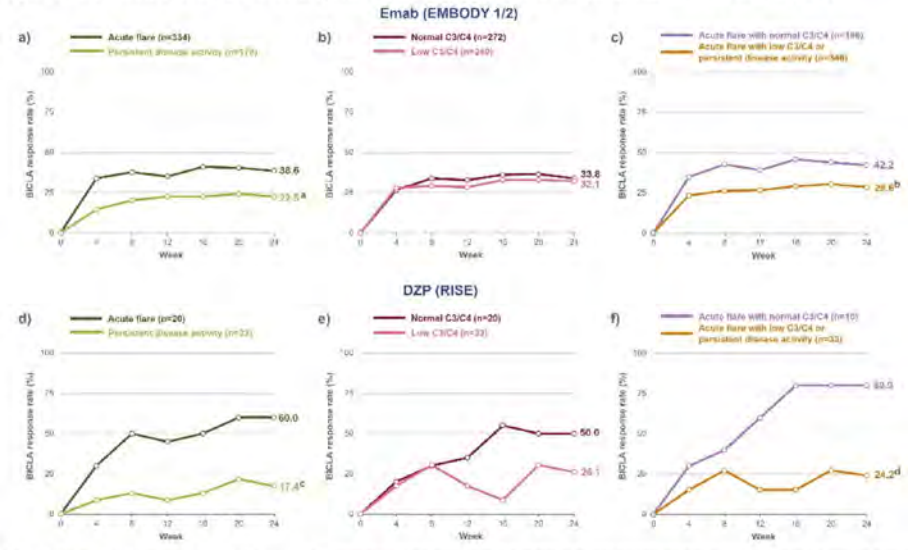
Full analysis set. Odds ratios (95% CI) and p-values are only shown for statistically significant predictors ([a] p<0.25; [b] p<0.05). Note that the "Region" predictor had three categories (North America; Latin America/Eastern Europe; Western Europe/Africa-Asia-Pacific), as North America vs Latin America/Eastern Europe had p<0.25 in the univariate analysis. "Region" and all the categories within it were included in the stepwise multivariate analysis. Analyses presented used observed case data with no imputation. **Abbreviations:** Anti-dsDNA: anti-double-stranded deoxyribonucleic acid; BICLA: BILAG-based Composite Lupus Assessment; BILAG: British Isles Lupus Assessment Group; CI: confidence interval; PBO: placebo; pts: patients; SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index 2000; SOC: standard of care; Wk: Week.

Figure 2. Univariate analysis (a) and stepwise multivariate analysis (b) of predictors of BICLA response at Wk 24 in pts who received SOC+PBO in RISE



Full analysis set. Odds ratios (95% CI) and p-values are only shown for statistically significant predictors ([a] p<0.25; [b] p<0.05). Analyses presented used observed case data with no imputation. **Abbreviations:** Anti-dsDNA: anti-double-stranded deoxyribonucleic acid; BICLA: BILAG-based Composite Lupus Assessment; BILAG: British Isles Lupus Assessment Group; CI: confidence interval; CLASI: Cutaneous Lupus Erythematosus Disease Area and Severity Index; m: months; PBO: placebo; pts: patients; SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index 2000; SOC: standard of care; Wk: Week.

Figure 3. BICLA response to Wk 24 by subgroups of pts receiving SOC+PBO in (a–c) EMBODY 1/2, and (d–f) RISE



Full analysis set. [a]p=0.0002 for the odds ratio (95% CI) of persistent disease activity vs acute flare (0.5 [0.3, 0.7]). [b]p=0.0023 for the odds ratio (95% CI) of acute flare with low C3/C4 or persistent disease activity vs acute flare with normal C3/C4 (1.8 [1.2, 2.7]). [c]p=0.0064 for the odds ratio (95% CI) of persistent disease activity vs acute flare (0.1 [0.0, 0.6]). [d]p=0.0050 for the odds ratio (95% CI) of acute flare with low C3/C4 or persistent disease activity vs acute flare with normal C3/C4 (0.1 [0.0, 0.5]). Only significant p values at Wk 24 are presented. Missing data were imputed using modified non-responder imputation. Low C3/C4 was defined as below the lower limit of normal (C3: <0.9 g/L; C4: <180 mg/L). **Abbreviations:** BICLA: British Isles Lupus Assessment Group-based Composite Lupus Assessment; CI: confidence interval; DZP: dapirolizumab pegol; Emab: opratuzumab; PBO: placebo; pts: patients; SOC: standard of care; Wk: Week.

Methods: Analyses were performed on the full analysis sets of the SOC+PBO arms of two phase 3 trials of Emab (EMBODY 1 [NCT01262365]; n=249, and EMBODY 2 [NCT01261793]; n=263) and the phase 2b trial of DZP (RISE [NCT02804763]; n=43) in SLE.[2,3] Response was assessed by British Isles Lupus Assessment Group (BILAG)-based Composite Lupus Assessment (BICLA) response at Week (Wk) 24.[4] Univariate/multivariate analyses were performed, with 18 and 22 potential predictors of SOC+PBO response evaluated in EMBODY 1/2 and RISE, respectively. Stepwise multivariate analysis included univariate predictors with $p< 0.25$, using $p\leq 0.1$ as entry/stay criteria. In subgroup analyses, disease course at screening was defined using BILAG 2004 item level scores as acute flare (worsening/new symptoms) or persistent disease (symptoms rated as the same) based on the past 4 wks compared with the 4 wks prior to those; low C3/C4 was defined as below the lower limit of normal at screening.

Results: Univariate and subsequent stepwise multivariate analysis found the following significant ($p < 0.05$) predictors of BICLA response at Wk 24 in EMBODY 1/2: acute flare (vs persistent disease activity; $p< 0.001$), Latin America/Eastern European (vs North America; p=0.004), and Hispanic or Latino (vs not; p=0.031; **Figure 1**). Significant ($p < 0.05$) predictors of BICLA response at Wk 24 in RISE following stepwise multivariate analysis were: acute flare (vs persistent disease activity; p=0.011) and normal C4 (vs low C4; p=0.036; **Figure 2**).

Focusing on disease characteristics, recent acute flares and normal complement were identified as predictors of SOC+PBO response. In all trials, a significantly higher proportion of patients (pts) with acute flare (vs persistent disease activity) achieved BICLA response (**Figure 3a& 3d**). In RISE, a significantly higher proportion of pts with normal C3/C4 (vs low C3/C4) achieved BICLA response (**Figure 3e**); this pattern was not observed in EMBODY 1/2 (**Figure 3b**). In all trials, when the subgroups were combined, a significantly higher proportion of pts with acute flare and normal C3/C4 (vs acute flare with low C3/C4 or persistent disease activity) achieved BICLA response (**Figure 3c & 3f**).

Conclusion: In both EMBODY 1/2 and RISE, acute flare predicted SOC+PBO response. In RISE, normal complement levels also predicted SOC+PBO response; low complement has been described as a predictor of increased treatment effect in previous studies.[5] Recent medical history of pts may have to be considered when defining SLE study populations.

Characteristics and Prior Treatment Journey of Systemic Lupus Erythematosus (SLE) Patients Who Were Prescribed Anifrolumab -- Observations from the American Rheumatology Network (ARN) in the U.S

Vasileios Kyttaris[1], Gelareh Atefi[2], Daniel Persons[3], Christopher S. Ambrose[4], Scott Milligan[5] and Sandra Wu[6], [1]BIDMC, Boston, MA, [2]BioPharmaceuticals Medical, AstraZeneca, Wilmington, DE, [3]Trio Health, Denver, CO, [4]AstraZeneca, Wilmington, DE, [5]Trio Health, Analytics, Louisville, CO, [6]AstraZeneca, Hockessin, DE

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: FDA-approved for moderate-severe SLE in August 2021, anifrolumab is a type I interferon (IFN) receptor antagonist that has been shown to decrease lupus flares and reduce corticosteroid use. Here we provide real world data describing its use in daily rheumatology practice, focusing on the clinical/laboratory characteristics and previous treatments of SLE patients who were prescribed anifrolumab for the first time.

Methods: Data were collected from patients under the care of ARN providers using PIONEER Rheumatology, an enhanced database combining fielded EMR data with extracted information from open text (office visits, infusion logs, and provider-patient communications). The study population consisted of adult (18+ years old) patients with documented diagnosis of SLE at least twice who were prescribed anifrolumab between August 1, 2021, to March 30, 2023. The index date for each patient was defined as the initial prescription date and baseline measures were those occurring within 365 days prior to the index date. Reasons for prior therapy discontinuation were extracted from office visit notes by clinically-trained scribes and categorized as lack/loss of efficacy, clinical reasons, or non-clinical reasons.

Results: 203 patients met study criteria [TABLE 1]; they were predominantly female (93%), commercially insured (51%), and in the Southern region of the U.S. (74%). At baseline, mean±SD SLEDAI was 10.7±5.9. Treatment history prior to anifrolumab prescription included oral corticosteroids (80%), hydroxychloroquine (87%), belimumab (55%), mycophenolate (37%), and methotrexate (35%). Patients' treatment regimen immediately prior to anifrolumab included belimumab (31%), antimalarials (76%), and immunosuppressants (52%) [TABLE 2]. 30% of patients who initiated anifrolumab were biologic-naïve. In 69/203 patients, anifrolumab substituted another medication in the treatment regimen, most notably belimumab. Therefore, we analyzed reasons behind discontinuation of belimumab prior to anifrolumab. Among the 57 patients who discontinued belimumab within 90 days of anifrolumab prescription, 49 (86%) indicated lack or loss of efficacy, 33 (58%) indicated a clinical reason, and 4 (7%) indicated a non-clinical reason [TABLE 3]. The top reasons for discontinuation from belimumab among the 57 patients included joint pain (47%), rash/pruritus/urticaria (46%), and fatigue (26%).

TABLE 3: Reasons* for discontinuation of the last regimen that a) contained belimumab and b) was stopped within 90d of anifrolumab prescription (n=57)

*Patients may have more than 1 reason for discontinuation.

Conclusion: This is one of the first studies to characterize real-world utilization of anifrolumab in management of SLE patients in the US. The majority of patients receiving anifrolumab within ARN were DMARD-experienced. Lack or loss of efficacy of belimumab, most frequently associated with joint pain, skin rashes, or fatigue, was a common reason for switching to anifrolumab. These findings highlight a need to understand which patients will benefit from anifrolumab as an early-line biologic therapy.

Abstract Number: 1505

Long-term Safety and Efficacy of Voclosporin in Black Patients with Lupus Nephritis: Results from the AURORA 1 and AURORA 2 Studies

Gabriel Contreras[1], Matt Baker[2], Lucy Hodge[2] and Ernie Yap[2], [1]University of Miami Health System, Miami, FL, [2]Aurinia Pharmaceuticals Inc., Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Black patients with lupus nephritis (LN) are reported to have more severe disease, are often refractory to treatment, and have worse long-term outcomes. Voclosporin in conjunction with low-dose glucocorticoids and mycophenolate mofetil (MMF) has shown significant benefit across ancestries and classes of LN. Here we report outcomes from up to three years of follow-up in patients identifying as Black and treated with voclosporin during the global Phase 3 AURORA studies.

Methods: Key inclusion criteria for the parent AURORA 1 study included biopsy-proven LN, urine protein creatinine ratio (UPCR) ≥1.5 g/g (≥2 g/g for Class V) and estimated glomerular filtration rate (eGFR) >45 mL/min/1.73 m^2. Patients completing AURORA 1 were eligible to enter the AURORA 2 continuation study on the same blinded therapy of voclosporin or placebo in combination with MMF and glucocorticoids for an additional two years. Programmed complete renal response (CRR; UPCR ≤0.5 g/g, stable eGFR, low-dose steroids, and no rescue medication), partial renal response (PRR; reduction in UPCR of ≥50% from baseline) and safety were assessed in patients self-identifying as Black or mixed Black.

Results: Twenty-six of 179 (14.5%) and 19 of 178 (10.6%) patients identified as Black or mixed Black in the voclosporin and control arms of AURORA 1. Baseline characteristics were similar between arms. Complete renal response rates at one year numerically favored voclosporin (46.2% vs 15.8%, Odds Ratio [OR] 3.92 [CI 0.95, >9.99] p=0.0597) as did PRR rates (69.2% vs 47.4%, OR 2.62 [CI 0.72, 9.45] p=0.1422).

Eighteen voclosporin-treated patients and seven control-treated patients in the Black subgroup continued into AURORA 2. Response rates at three years continued to numerically favor voclosporin (CRR, 44.4% vs. 14.3%, OR 4.17 [CI 0.41, >9.99] p=0.2276; PRR, 66.7% vs. 42.9%; OR 1.67 [CI 0.23, >9.99] p=0.6094). Greater reductions in mean UPCR were observed over the three-year period in the voclosporin arm (change from baseline -3.4 vs -1.5 g/g, p=0.0349). Mean eGFR levels remained stable and in the normal range over three years of treatment.

Conclusion: Black patients treated with a voclosporin-based regimen achieved higher rates of renal response than patients treated with MMF and glucocorticoids alone. For patients entering the continuation study, the response was largely durable for up to 3 years.

Prescribing Patterns in Lupus Nephritis: Analyzing Time from Proteinuria to Prescription of ACE/ARB

JM JANSZ[1], WL GALLANTER[1], EM Adams[2], Nadera Sweiss[3] and Huan Chang[4], [1]University of Illinois at Chicago, Chicago, IL, [2]Jesse Brown VA Medical Center, Chicago, IL, [3]University of Illinois, Chicago, IL, [4]University of Illinois at Chicago; Jesse Brown VA Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Black patients with lupus nephritis have worse renal outcomes compared with their White counterparts. Currently, there is a paucity of data evaluating the use of angiotensin-converting enzyme inhibitors (ACE) and angiotensin receptor blockers (ARB) in lupus patients with proteinuria despite their well-established benefits. The objective of this study was to examine the prescribing patterns of ACE/ARB in lupus patients with laboratory evidence of proteinuria, focusing on demographic factors such as race/ethnicity, gender and age.

Methods: The study population comprised patients seen in an urban academic medical center from January 1, 2000 through September 12, 2020 with at least one ambulatory encounter and a diagnosis code associated with either lupus or lupus nephritis. Proteinuria was defined according to the American College of Rheumatology (ACR) definition of renal disease, which includes a urine protein 3+ or above (300 mg/dL or greater), a urine protein creatinine ratio > 0.5, a 24-hour urine protein excretion greater than 0.5g, or a urine microalbumin/creatinine ratio greater than 50. The time interval from the first laboratory result indicating proteinuria in patients naive to an ACE/ARB to the day of ACE/ARB prescription was measured in days.

Results: Data show 39% of lupus patients with laboratory evidence of proteinuria were prescribed an ACE/ARB during the study time frame. For those who received a prescription, the median time from the detection of proteinuria to the prescription of an ACE/ARB was 382 days. Non-White patients (Black, Hispanic, and Other) were more frequently prescribed an ACE or

Table 1. Cohort and Treatment Cohort Demographics

	Cohort Demographics (N=682)		Demographics of Proportion Given ACE/ARB (N=264)	
	No. of Patients	Percentage of Patients	Patients Given ACE/ARB	Percent Given ACE/ARB
Sex				
Female	427	62.6%	177	41.5%
Male	255	37.4%	87	34.1%*
Age				
18-40	269	44.0%	108	40.1%
40-65	343	56.0%	136	39.7%
>65	70	11.4%	20	28.6%**
Race				
Hispanic	197	28.9%	73	37.1%
Black	356	52.2%	156	43.8%
White	78	11.4%	18	23.1%***
Other	51	7.5%	17	33.3%
*p=0.06, **p=0.07, ***p=0.003				

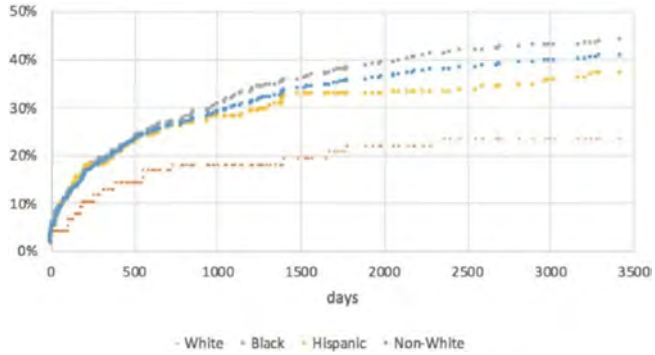

Figure 1. Percentage of Patients with Proteinuria Prescribed an ACE/ARB Over Time in Days

an ARB compared with White patients (p=0.005). There was also a trend indicating higher prescription rates for female patients compared with male patients (p=0.06). There was a non-statistically significant reduction in prescription of ACE/ARB in patients greater than 65 years old.

Conclusion: Our study reveals a pattern of incomplete and delayed treatment of proteinuria with an ACE/ARB in lupus patients with evidence of proteinuria. Less than half of lupus patients with proteinuria received an ACE/ARB during the study timeframe, with Non-White patients significantly more likely to receive an ACE/ARB than White patients. The median time to ACE/ARB initiation was greater than a year. We intend to conduct further analysis to investigate hypertension as a potential confounding factor in the earlier initiation of an ACE/ARB among Non-White patients. Additionally, we plan to examine the time elapsed from proteinuria diagnosis to the prescription of immunosuppressive medications. These additional analyses will provide insight into optimizing timely evidence-based management of lupus nephritis patients.

Pharmacodynamic Changes in SLE Relevant Gene Expression Induced by Deucravacitinib in Patients Enrolled in the Phase 2 PAISLEY Trial

Chun Wu[1], Cristina Arriens[2], J. Michelle Kahlenberg[3], **Yanhua Hu**[1], Coburn Hobar[1], Adrian Coles[4] and Ian M. Catlett[5], [1]Bristol Myers Squibb, Princeton, NJ, [2]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Department of Arthritis & Clinical Immunology, Oklahoma City, OK, [3]University of Michigan, Ann Arbor, MI, [4]Bristol Myers Squibb, Lawrenceville, NJ, [5]Bristol Myers Squibb, Pennington, NJ

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Deucravacitinib (DEUC) is a first-in-class, oral, selective, allosteric inhibitor of TYK2. TYK2 is required for signal transduction downstream of cytokines implicated in SLE pathophysiology, including type I and III interferons (IFN), IL-12 and IL-23. In a phase 2 trial (NCT03252587), DEUC was effective vs placebo (PBO) in patients with SLE receiving standard background therapy. Lupus is a disease with activation of innate and adaptive arms of the immune system, including pathways driven by IFN and B cell activity. Inhibition of TYK2 is expected to reduce the activity of SLE (ie,

IFN-activation), however, the role of additional TYK2-regulated cytokines in SLE is not clear. We performed global transcriptomic analysis of patients treated with DEUC to further explore the mechanism of action (MOA) and effects of DEUC in SLE.

Methods: Blood samples (Paxgene RNA) were collected at baseline and multiple timepoints throughout the study following patient randomization (N=363). In a sub-study, samples (n=80) were collected 22-114 hours after the first dose. Global gene expression was assessed by RNA-sequencing and specific genes of interest were measured by endpoint PCR (Dxterity). Following quality control, 16,725 protein-coding genes were analyzed from 3,334 samples from patients with SLE. A set of demographically matched (sex and age) healthy control samples were collected to compare with study groups. Statistical analysis was conducted using Dream package in R. Differentially expressed genes from disease association and pharmacodynamic analyses were further characterized by pathway enrichment using standard databases.

Figure 1. 527 genes were significantly differentially expressed in patients with active SLE compared to healthy volunteers

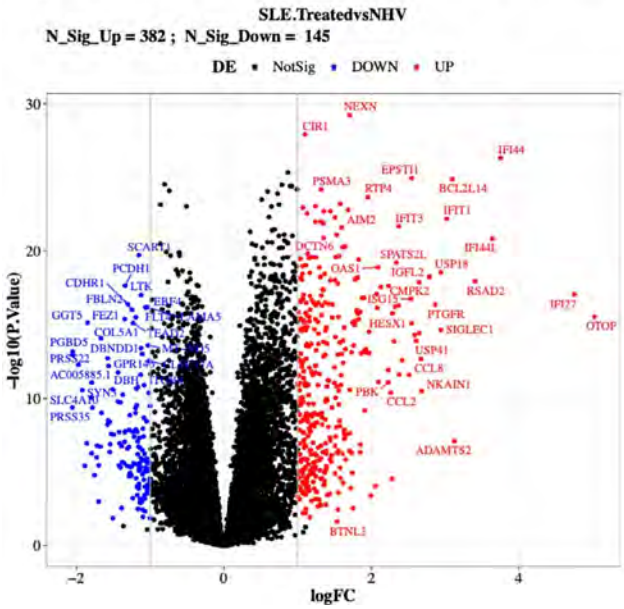

Figure 2. Deucravacitinib normalized the 527-gene SLE signature as early as 22-114 hours after the first dose

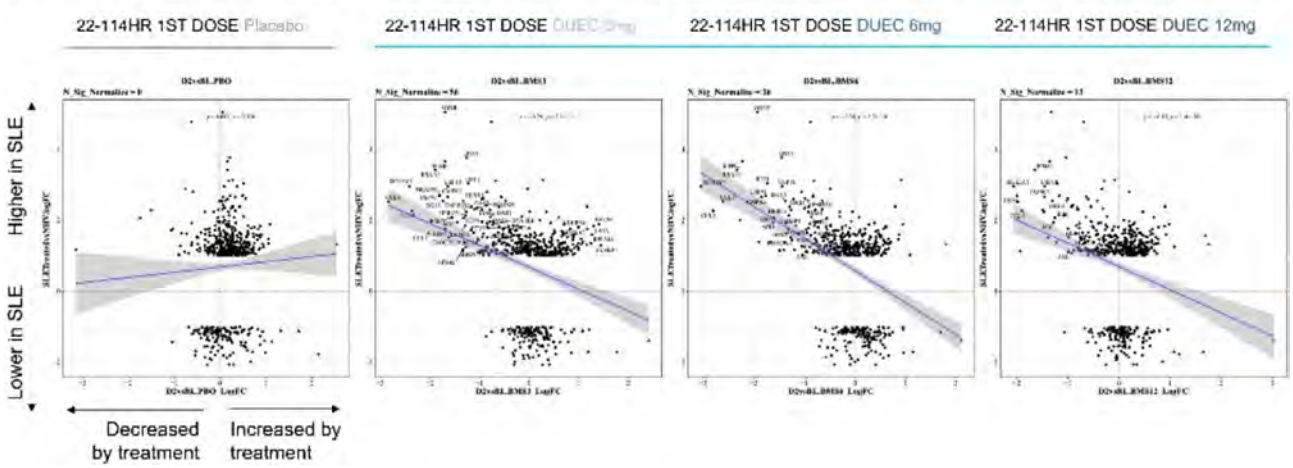

Results: 527 genes were significantly differentially expressed in subjects with active SLE compared to healthy volunteers with logFC >1 and adjusted P< 0.05 (Figure 1). The 527-gene signature was significantly enriched in 6 KEGG pathways, including "hsa05322-Systemic lupus erythematosus". IFN-regulated genes were overexpressed as expected for patients with SLE. No gene expression changes were observed in PBO patients, however, treatment with DEUC significantly normalized the 527-gene set of differentially regulated genes. In the sub-study, gene expression was normalized in DEUC treated patients as early as 22-114 hours after the first dose (Figure 2). At the primary clinical endpoint of week 32, patients treated with DEUC exhibited significantly modulated gene expression of 461, 833 and 2529 genes, in the 3 mg BID, 6 mg BID, and 12 mg QD groups respectively.

Conclusion: Moderate to severe SLE is characterized by significant elevation of IFN regulated gene expression and B cell autoimmunity gene expression pathways. DEUC treatment significantly reduced IFN-regulated gene expression. These findings are consistent with the expected MOA, which inhibits signaling at the type I and type III IFN receptors. These results support the anticipated MOA and novel inhibition of B cell autoreactivity pathways, increasing evidence of this therapeutic strategy in the treatment of SLE. Additional analyses will focus on additional SLE-specific pathways by deucravacitinib and whether data will support a wider array of indications.

Predicting in Virtual Patients the Efficacy of an Anti IFNa Mab in Cutaneous Lupus Erythematosus

Vincent Hurez[1], Krishnakant Dasika Dasika[1], Perrine Soret[2], Renee Myers[3], Katherine Kudrycki[1], Robert Sheehan[1], Christina Friedrich1[1], Sandra Hubert[2], Mike Reed[1], Emiko Desvaux[2], Audrey Aussy[2], Laurence Laigle[2], Loubna Chadli[2], Florian Chassereau[2], Sylvain Fouliard[2], Glenn Gauderat[2] and **Philippe Moingeon**[2], [1]Rosa and Co, San Carlos, CA, [2]Les Laboratoires Servier SAS, Suresnes, France, [3]Les Laboratoires Servier SAS, San Carlos, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a heterogeneous autoimmune disease that requires more specific treatments to target patient subsets. To support precision medicine approaches, we report herein on a molecular profiling approach to stratify SLE patients, as well as the creation of a cohort of virtual patients to predict the efficacy of an anti-interferon (IFN)-α monoclonal antibody in Cutaneous Lupus Erythematosus (CLE) across patient heterogeneity. Systemic Lupus Erythematosus (SLE) is a heterogeneous autoimmune disease that requires more specific treatments to target patient subsets. To support precision medicine approaches, we report herein on a molecular profiling approach to stratify SLE patients, as well as the creation of a cohort of virtual patients to predict the efficacy of an anti-interferon (IFN)-α monoclonal antibody in Cutaneous Lupus Erythematosus (CLE) across patient heterogeneity.

Methods: Multiomics profiling data from whole blood samples of 300 SLE patients and 330 matched healthy controls from the PRECISESADs cohort were used to stratify patients through hierarchical and k-means clustering. A quantitative systems pharmacology (QSP) mechanistic model recapitulating skin manifestations of CLE was developed using proprietary and public literature data, and qualified using the Rosa model qualification method [1]. This model was used to assess the efficacy of the pan-neutralizing anti-IFN-α S95021 monoclonal antibody .

Results: The integrated analysis of multiomics profiling data led to the identification of four clusters of SLE patients. Gene enrichment analyses confirmed the upregulation of the type I IFN pathway in a majority of SLE patients, while further revealing distinct patterns of immune dysregulation involving B lymphocytes and autoantibodies, as well as T and polymorphonuclear cells. The QSP model of CLE relates various cellular and soluble proinflammatory mediators in the blood, lymph nodes and skin to subcomponents of the cutaneous severity score (CLASI). The time-course of CLASI score responses simulated in the model matched published clinical trial data with the anti-type I IFN receptor anifrolumab. Additionally, it predicted the efficacy of the S95021 antibody at various doses in CLE. By varying the contribution of the different cell types and mediators to skin damage and inflammation in the model, a cohort of ∼700 virtual patients was generated, reflecting the heterogeneity observed across the various clusters of real patients from PRECISESADs. The analysis of predicted responders vs non responders using machine learning yielded biomarkers that could be used for the stratification of patients in subsequent clinical studies.

Table 1: CLASI score subcomponents and their mapping to QSP model species

CLASI score component	QSP model species
Erythema	Pro-inflammatory mediators Activated vasculature
Ulceration	Correlated with disease activity
Alopecia	Hair follicle damage Effector T cells Pro-inflammatory mediators
Scarring	Fixed value (no change with therapy)

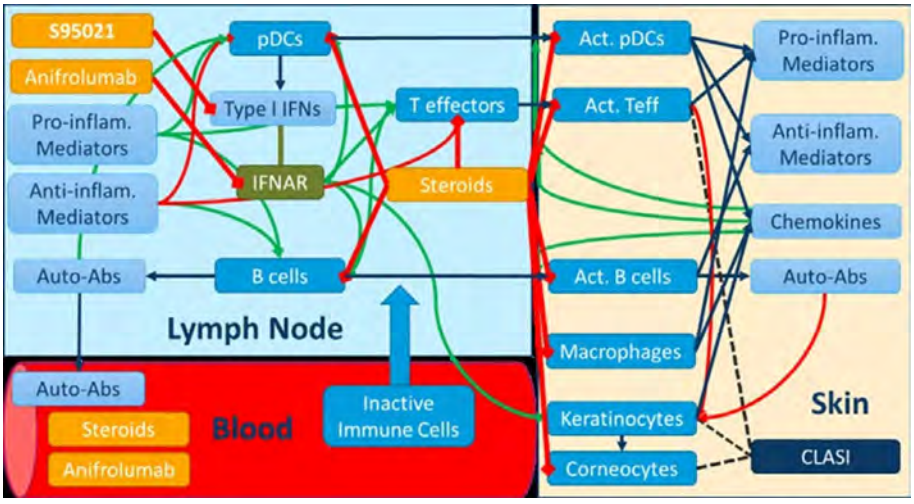

Figure 1: Overview of the mechanistic QSP model of Cutaneous Lupus

Conclusion: Combining molecular profiling of large cohorts of actual patients with QSP simulation encompassing hundreds of virtual patients is a powerful approach to document patient heterogeneity in a complex autoimmune disease. It also supports precision medicine strategies by enabling the creation of predictive models of drug response at an individual patient level. 1. Friedrich, C.M. et al, A model qualification method for mechanistic physiological QSP models. CPT Pharmacometrics Syst Pharmacol, 2016. 5: 43-53

Calcineurin Inhibitors for Treatment of Lupus Nephritis: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

Gabriel Figueroa-Parra[1], Maria Cuellar-Gutierrez[1], Mariana Gonzalez-Trevino[1], Larry J. Prokop[2], M. Hassan Murad[3] and Ali Duarte-Garcia[4], [1]Division of Rheumatology, Mayo Clinic, Rochester, MN, [2]Mayo Clinic Libraries, Mayo Clinic, Rochester, MN, [3]Evidence-based Practice Center, Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Rochester, MN

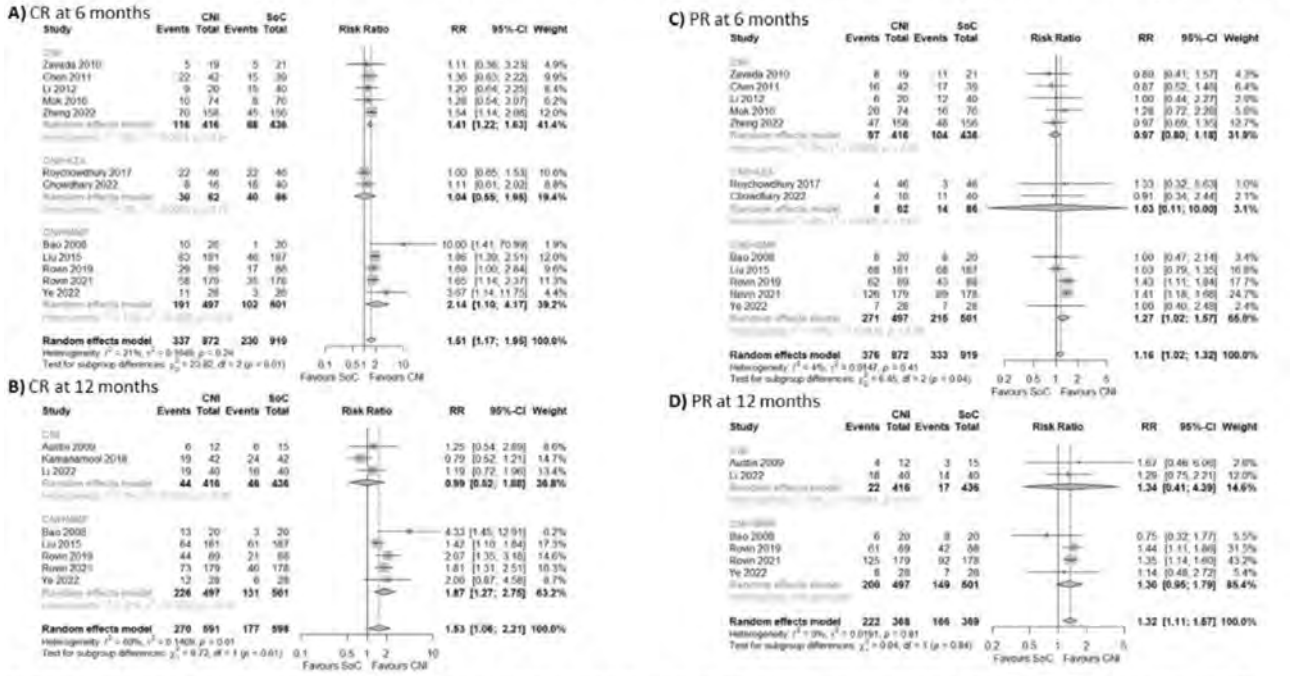
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The current recommendations for the treatment of LN consider as the standard of care (SoC) the use of MMF or CYC. Considering the expanding evidence for the use of calcineurin inhibitors (CNI) in patients with LN, we aimed to summarize and assess the efficacy and safety of CNI compared to the current SoC for the treatment of patients with LN.

Methods: We comprehensively searched MEDLINE, EMBASE, CENTRAL, and Scopus from each database's inception to January 19, 2023. Studies were eligible if they included (P) patients with biopsy-proven LN, (I) compared CNI (voclosporin, tacrolimus, and CSA) alone or in combination with other immunosuppressors against (C) the SoC (MMF or CYC), (O) for efficacy (complete and partial renal response [CR and PR, respectively]) and safety (death, infections, gastrointestinal adverse effects [GIAE], cytopenias). Exclusion criteria were patients with SLE without biopsy-proven LN, non-pharmacological interventions, observational studies, and non-RCTs. We used the revised Cochrane risk of bias tool for randomized trials 2. We expressed the results as relative risk (RR) with 95% confidence intervals (CI). We used random-effect models and assessed heterogeneity by visual inspection and by using the I^2 and Chi^2 tests. We performed subgroup analyses to test for interactions based on CNI and SoC.

Results: We included 1998 patients with LN (16 RCTs), 975 patients who received CNI, and 1023 patients who received SoC (433 MMF and 590 CYC). The overall risk of bias was low in nine studies, five studies showed some concerns, and two had a high risk of bias (**Table 1**). Patients with LN treated with CNI for induction of remission may be more likely to achieve CR at 6 (RR 1.51, 95% CI 1.17-1.95; I^2 = 21%; 12 RCTs; 1791 patients; **Figure 1A**) and 12 months (RR 1.53, 95% CI 1.06-2.21; I^2 = 60%; 8 RCTs; 1189 patients; **Figure 1B**) than those treated with the SoC. CNI alone (RR 1.41, 95% CI 1.22-1.63; I^2 = 0%; 5 RCTs; 852 patients) and CNI+MMF (RR 2.14, 95% CI 1.10-4.17; I^2 = 15%; 5 RCTs; 998 patients) were more likely to achieved CR at 6 months against the SoC. Only CNI+MMF was better than SoC at

Figure 1. Forest plots for efficacy of calcineurin inhibitors (CNI) versus the standard of care (SoC) at 6 and 12 months. Complete (CR) and partial (PR) renal response.



CR: Defined as a <0.5g/d and inactive urinary sediment; PR: Defined as a fall to <3.0g/d (if baseline ≥3.0g/d) or ≥50% reduction of urinary protein excretion from baseline and stabilization of serum creatinine ±25%.

12 months (RR 1.87, 95% CI 1.27-2.21; I^2 = 31%; 5 RCTs; 998 patients). CNI also showed a higher probability of achieving PR at 6 and 12 months compared with the SoC (**Figure 1C and 1D**). We did not find a difference in the risk of death between patients treated with CNI or SoC (RR 0.96, 95% CI 0.50-1.85; I^2 = 0%; 14 RCTs; 1826 patients; **Figure 2A**). Patients with LN treated with CNI showed a similar infection risk to those patients treated with the SoC (RR 0.86, 95% CI 0.66-1.22; I^2

Figure 2. Forest plots for safety outcomes of calcineurin inhibitors (CNI) versus standard of care (SoC).

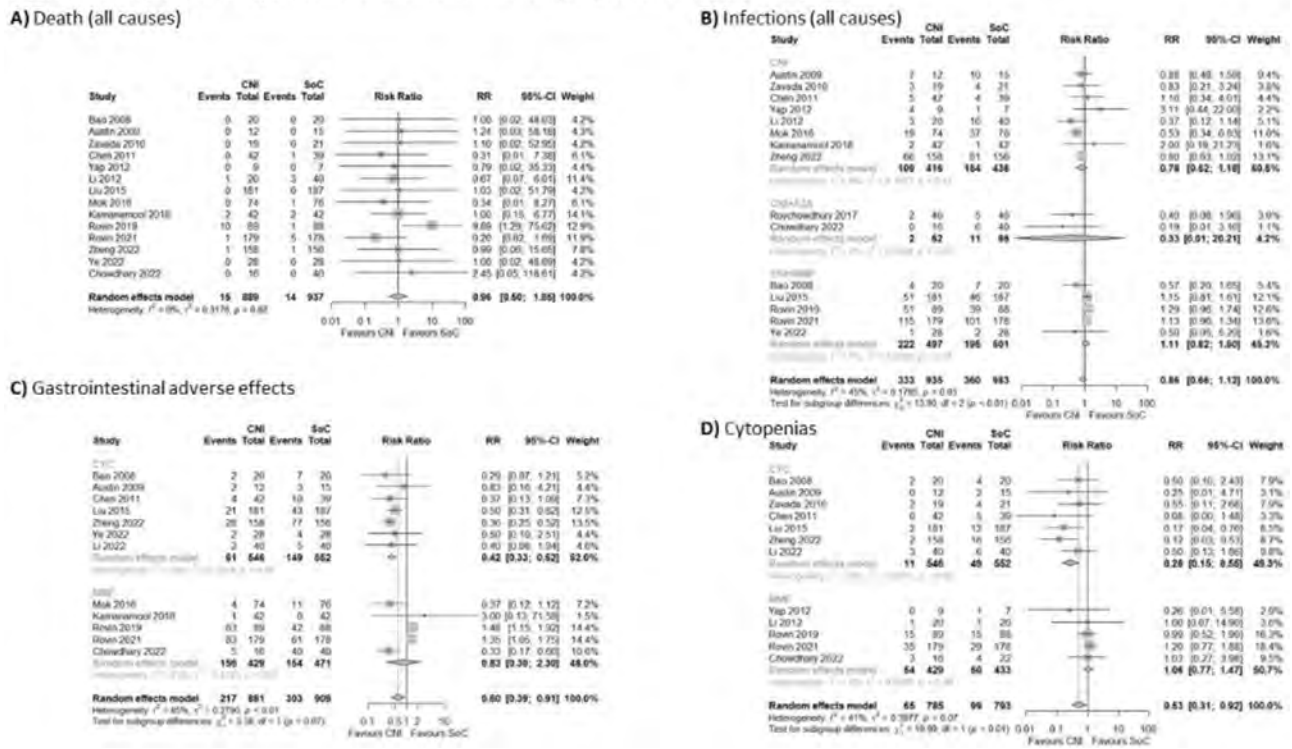


Table 1. Risk of bias assessment of included studies

Study	Randomization process	Deviations from interventions	Missing outcome data	Measurement of outcome	Selection of reported results	Overall risk of bias
Bao 2008	Low	Low	Low	Low	Low	Low risk
Austin 2009	Some concerns	Low	Low	Low	Low	Some concerns
Zavada 2010	Low	Low	Low	Low	Low	Low risk
Chen 2011	Low	Low	Low	Low	Low	Low risk
Yap 2012	Some concerns	Low	Low	Low	Low	Some concerns
Li 2012	Low	Low	Low	Low	Low	Low risk
Liu 2015	Low	Low	Low	Low	Low	Low risk
Mok 2016	Low	Low	Low	Low	Low	Low risk
Roychowdhury 2017	Some concerns	High	High	Some concerns	Some concerns	High risk
Kamanamool 2018	Low	Low	Low	Low	Low	Low risk
Rovin 2019	Low	Low	Low	Low	Low	Low risk
Rovin 2021	Low	Low	Low	Low	Low	Low risk
Zheng 2022	Low	Some concerns	Low	Low	Low	Some concerns
Ye 2022	Some concerns	Low	Low	Low	Low	Some concerns
Li 2022	Some concerns	High	Low	Low	Some concerns	High risk
Chowdhary 2022	Some concerns	Some concerns	Low	Low	Some concerns	Some concerns

= 45%; 15 RCTs, 1918 patients; **Figure 2B**). There was a difference given by the subgroups of CNI ($p< 0.01$), but not according to the SoC (p=0.99). We found a lower risk of GIAE (RR 0.6, 95% CI 0.39-0.91; I^2 = 85%; 12 RCTs; 1790 patients; **Figure 1C**) and cytopenias (RR 0.52, 95% CI 0.31-0.87; I^2 = 41%; 12 RCTs; 1616 patients; **Figure 1D**) among patients treated with CNI than those treated with the SoC.

Conclusion: Patients with LN treated with CNI for the induction of remission may have better response compared with MMF or CYC. CNI might be considered as equally safe in mortality and infections as the SoC. Possibly CNI might have less GIAE and cytopenias than the SoC, particularly compared with CYC.

Efficacy of Gonadotropin-releasing Hormone Agonist (GnRHa) in Ovarian Preservation in Women with Systemic Lupus Erythematosus (SLE) Receiving Cyclophosphamide (CYC)

Jun Chu[1], Dania Abid[2], Zerai Manna[1], Subrata Paul[3], Isabel Ochoa[3], Yalan Wu[3], Sonia Goyal[4], Syed Ali Abbas Naqvi[5], Lubna Hooda[3] and Sarfaraz Hasni[3], [1]Lupus Clinical Trials Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD, [2]Idaho College of Osteopathic Medicine, Meridian, ID, [3]National Institutes of Health, Bethesda, MD, [4]George Washington University, Washington, DC, [5]Jewish Hospital of Cincinnati, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients with life-threatening lupus manifestations are often treated with cyclophosphamide (CYC), which has known cytotoxic effects on ovarian reserve. Co-administration of Gonadotropin-releasing hormone agonist (GnRHa) is suggested to protect ovaries from the cytotoxic effects of CYC but there is lack of data to support its use. We administered a questionnaire evaluating ovarian function of a cohort of SLE patients who either received CYC alone or GnRHa+CYC.

Methods: The study was approved by the National Institutes of Health, Institutional Review Board. Female SLE patients < 40 years old at the time of IV CYC treatment were included in this study. Review of medical records resulted in: CYC only (n=20) =group 1, GnRHa+CYC (n=30) =group 2. These patients were age/gender matched with SLE patients not treated

with CYC (n=50) =group 3. Data about demographics, disease activity, damage accrual, and cumulative CYC dose were collected. Data from questionnaires assessed regularity, duration of menstrual cycles, and pregnancies, before and after CYC. Premature ovarian insufficiency (POI)was defined as menopause prior to 40 years. Fisher's exact test and one-way ANOVA were performed in R (version 4.2.2) for categorial and continuous variables, respectively.

Results: There were no significant differences in age, disease activity, damage accrual, mean cumulative CYC dose, and duration of follow-up (Table 1).However, age at diagnosis and consequently age at time of CYC infusion was higher in group 1 compared to group 2. There were more Hispanic patients in group 2 and 3. 88/100 patients completed the questionnaire (Group 1=20, Group 2=23, Group 3=43).Post-CYC, 40% of group 1 patients reported POI compared to 20% of group 2 and 16% group 3, calculated as total of all POI defined (Table 2). Length of menses was decreased by 1.4 days (p=0.083) in group 1 compared to 0.7 days (p=0.122) in group 2 (Figure 1). There was no statistical significance seen between regularity of menses between group 1 and 2 pre and post CYC treatment. Similar numbers of pregnancies and live birth were reported by all groups. Data concerning adverse events related to GnRHa were not collected.

Table 1. Baseline Demographics

Table 1. Baseline Demographics

Characteristic	Group1 (Only CYC[2]) N = 20[1]	Group2(GnRHa[3]+CYC) N = 23[1]	Group3(No CYC), N = 43[1]
Age at diagnosis (years)	27.00 (7.68)	23.32 (5.89)	24.79 (8.97)
Duration of SLE (years)	6.56 (6.64)	6.40 (4.24)	5.43 (4.32)
Race:			
African American	8	4	11
Asian	1	4	6
Caucasian	5	1	7
Hispanic	6	17	19
Age when IV CYC started (years)	32.22 (7.17)	29.18 (5.96)	N/A
Age at the time of self-reported questionnaire (years)	46.50 (6.95)	40.43 (6.56)	42.28 (7.51)
Cumulative CYC dose in mgs[4]	14,241.54 (9,421.69)	15,331.77 (7,785.67)	NA (NA)
SELENA-SLEDAI[5] score at the start of CYC treatment	6.8 (4.7)	8.7 (6.7)	6.2(5.7)
SLICC/ACRDI[6] score at the start of CYC treatment	1.6(2.3)	1.4(1.4)	1.2(1.4)

[1] Mean (SD). [2] CYC – Cytoxan. [3] GnRHa – gonadotropin-releasing hormone agonist.
[4] mgs= Milligrams. [5] SELENA-SLEDAI= Safety of Estrogens in Lupus Erythematosus National Assessment–SLE Disease Activity Index. [6] SLICC/ACRDI – Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index

Table 2. Premature Ovarian Insufficiency (POI)

Table 2. Premature Ovarian Insufficiency (POI)

Group	No	Yes	NA*	Percent
Group1(CYC Only)	9	6	5	40
Group2 (GnRha+CYC)	12	3	8	20
Group3 (SLE Controls)	21	4	18	16

*NA= Not applicable when POI is not definable if a patient is younger than 40 and was not diagnosed with menopause

Figure 1: Changes in menstrual cycle length before and after cyclophosphamide treatment

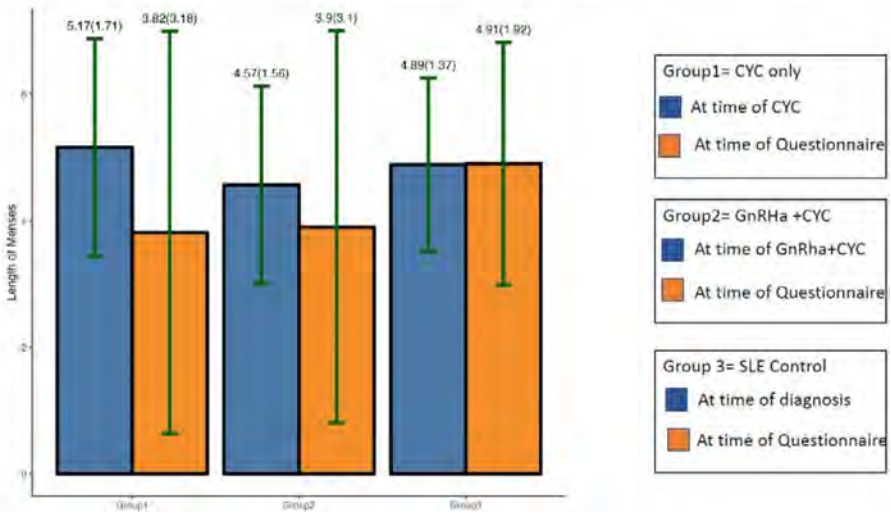

Figure 1: Changes in menstrual cycle length before and after cyclophosphamide treatment

Conclusion: Our study suggests that co-administration of GnRHa with CYC protects the ovary from its cytotoxic effects. Incidence of POI, and other markers of ovarian dysfunction such as length of menstrual cycle were significantly higher when CYC was administered alone. Larger, prospective studies are needed to establish role of GnRHa in preserving ovarian function in patients with SLE.

SESSION INFORMATION

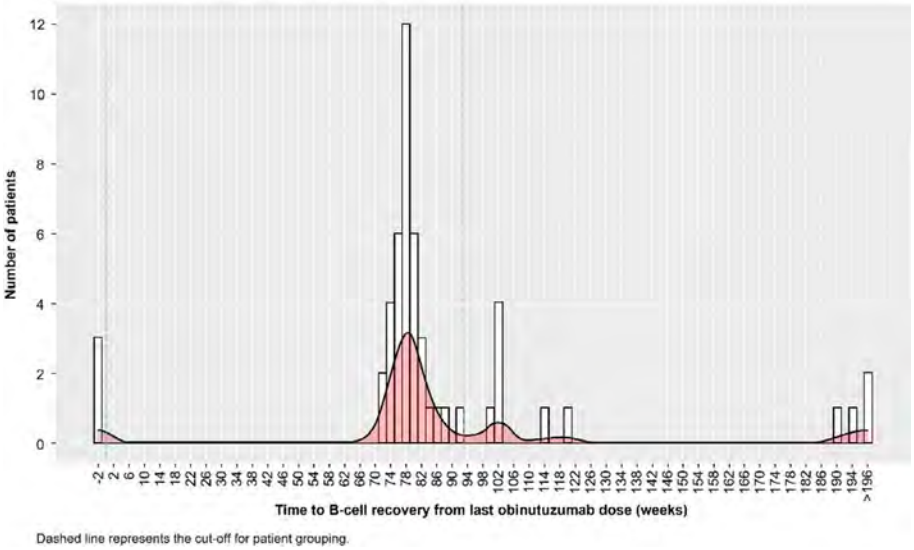
Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with LN who received obinutuzumab, a humanized type II anti-CD20 monoclonal antibody, with standard-of-care (MMF) immunosuppression (Phase II NOBILITY; NCT02550652; PMID 34615636) showed improved clinical responses through Week 104 versus those who received MMF alone. Sustained depletion up to Week 52 was associated with a better initial clinical response.[1] This analysis aims to characterize subsequent B-cell recovery after the last dose of obinutuzumab in NOBILITY and its impact on later response and safety.

Methods: 125 patients with active Class III/IV LN receiving MMF and corticosteroids were randomized and received either obinutuzumab 1000 mg (n=63) or placebo (n=62) on Day 1 and Weeks 2, 24 and 26, and followed through Week 104 or to B-cell recovery, whichever was longer. Blood B cells were measured using both a TBNK cell assay with a LLoQ of 10 $CD19^+$ cells/μL and a high-sensitivity minimal residual B-cell 1.1 assay with an LLoQ of 0.4 cells/μL. B-cell depletion was defined as ≤0.4 cells/μL, and recovery was defined as ≥20 cells/μL or the patient's predose baseline, whichever was lower. Time to peripheral B-cell recovery after the last dose of obinutuzumab, the relationship between time to recovery and efficacy at Week 104, and safety throughout the main study and follow-up period were evaluated (SAE and infectious SAE rates, adjusted for patient-years [PY] at risk).

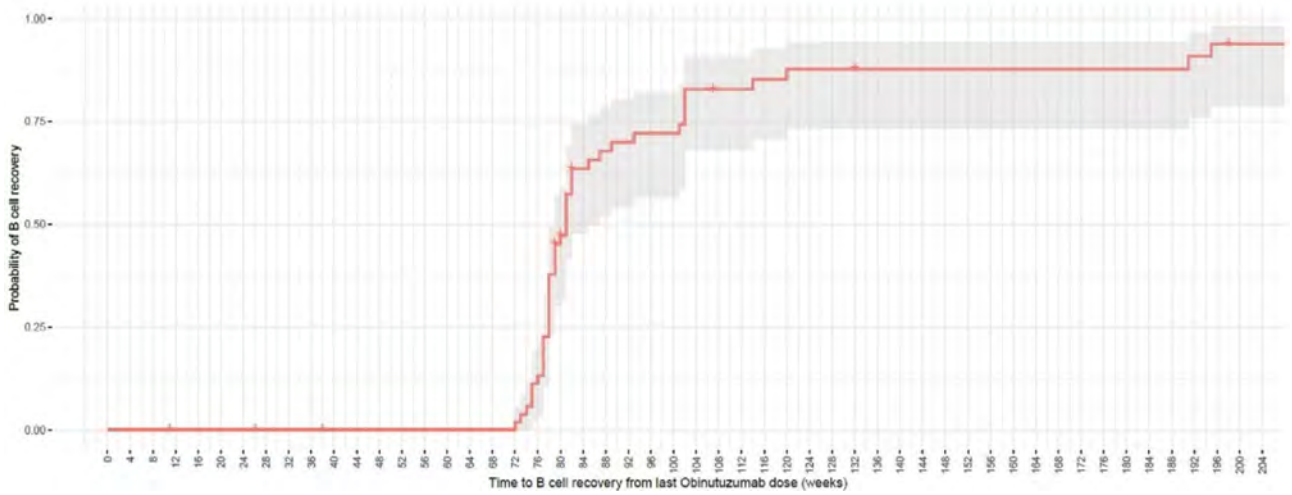
Results: Of 63 patients who received obinutuzumab, 4 did not achieve full B-cell depletion during the study. By Week 24, 59 patients (93.7%) achieved B-cell depletion (before obinutuzumab redosing); of those, 4 discontinued prior to B-cell recovery, and 4 completed the study at or after Week 104 but before achieving B-cell recovery. The remaining 51 patients comprised the analysis population, which was grouped based on the time to B-cell recovery distribution (**Figures 1 and 2**). Of the 51 patients, 3 (5.9%) recovered B cells before redosing at Week 26; 1/3 achieved CRR at Week 104. 37 patients (72.5%) attained B-cell recovery ≤93 weeks of their last dose of obinutuzumab (median, 78.1 weeks). 18/ 37 (48.6%) and 23/37 (62.2%) achieved CRR and overall renal response (ORR), respectively, at Week 104. In these 37 patients, SAE and infectious SAE rates per 100 PY were 13 and 8. 11 patients (21.6%) did not recover B cells by Week 93 after their last dose of obinutuzumab. 9/11 patients achieved B-cell recovery at a median of 102 weeks, and 2/11 had not yet achieved B-cell

Figure 1. Distribution of Time to B-Cell Recovery



Dashed line represents the cut-off for patient grouping.

Figure 2. Time to B-Cell Recovery From the Last Obinutuzumab Infusion (in Weeks)



recovery at the time of writing. 5/11 patients (45.5%) achieved CRR, and 8/ 11 (72.7%) achieved ORR at Week 104. In these 11 patients, SAE and infectious SAE rates per 100 PY were 10 and 0, respectively.

Conclusion: Most patients recovered peripheral B cells ≤93 weeks after the last obinutuzumab dose. Renal response rates at Week 104 were similar among patients who recovered B cells within 2 years of their final obinutuzumab infusion and those who recovered later or were still depleted, suggesting a greater clinical effect of early sustained depletion vs duration of depletion on clinical response.[1] Within the limitation of small sample size, the SAE and infectious SAE rates appeared similar regardless of the duration of B-cell depletion. 1. Vital E, et al. *Arthritis Rheumatol*. 2020;72 (suppl 10).

Abstract Number: 1512

Rituximab Objective Outcome Measures Trial in SLE (ROOTS): Randomised and Rescue Therapy Outcomes from a Randomised Controlled Trial

Khaled Mahmoud, Michelle Wilson, Md Yuzaiful Md Yusof, Sarah Brown, Elizabeth Hensor and **Ed Vital**, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: SLE – Treatment Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: New medicines in SLE have not met endpoints in placebo-controlled RCTs when other evidence indicates they are effective. Reasons suggested are inclusion of patients with inactive disease, inaccurate or subjective outcome measures that seek to address diverse manifestations, comparator arms that include excessive glucocorticoid dose and retention of patients.

Objectives: (i) To evaluate the feasibility of a novel trial design focusing on musculoskeletal SLE with objective eligibility criteria and endpoints and low-dose glucocorticoids (ii) To provide additional validation of LAMDA and ultrasound outcome measures (iii) To provide preliminary evidence for efficacy of rituximab

Methods: Adults with SLE were enrolled if they had clinical synovitis and/or ultrasound (US) tenosynovitis and/or positive power Doppler (PD) in >=1 joint despite stable background therapies including a maximum 10mg prednisolone. Patients were randomized to 1000mg rituximab (Rixathon, RTX) or placebo, on days 1 and 15. Blinded infusions were preceded by 100mg methylprednisolone. Outcome measures, including BILAG-2004, SLEDAI-2K, The Lupus Arthritis and Musculoskeletal Disease Activity Score (LAMDA), tender and swollen joint counts, physician global, patient MSK pain and global VAS, patient reported outcome measures, BICLA, SRI-4 were evaluated monthly. US of both hands and wrists was performed at 0 and 16 weeks. The primary endpoint was overall feasibility. The key efficacy timepoint was 16 weeks. After 16 weeks placebo patients with active disease were eligible for rescue rituximab with repeat follow up timepoints. US and LAMDA were validated against BILAG-MSK improvement at 16 weeks using regression models adjusted for baseline.

Results: 24/27 (89%) patients were female, 17/27 (63%) were white, 7/27 (26%) were South Asian. Mean (SD) age was 49.7 (12.7) and disease duration 6.7 (9.0). BILAG MSK domain at baseline was scored A in 7/27 (26%), B in 16/27 (59%) and C in 2/27 (7.4%). At 16 weeks, BILAG-MSK response was significantly associated with improvement in LAMDA (OR 0.48, 95% CI 0.18, 0.84); US joints grey-scale (OR 0.56, 95% CI 0.28, 0.85) and US tendons PD (OR 0.33, 95% CI 0.04, 1.01). No substantive difference between arms in efficacy variables was found at week 16. Unexpectedly, results suggested greater improvement in some outcomes in patients who received methylprednisolone and placebo compared to methylprednisolone and rituximab. These measures then converged by 16 weeks (Figure 1) Pooling all rituximab cycles administered (as initial therapy or as rescue) showed improvement in LAMDA (coefficient(95% CI) -2.68 (--4.02, -0.09)), number of joints with US-PD >0 (-0.59(-1.16, -0.02)), and number of joints with GS >1 (-2.68(-4.74, -0.62).

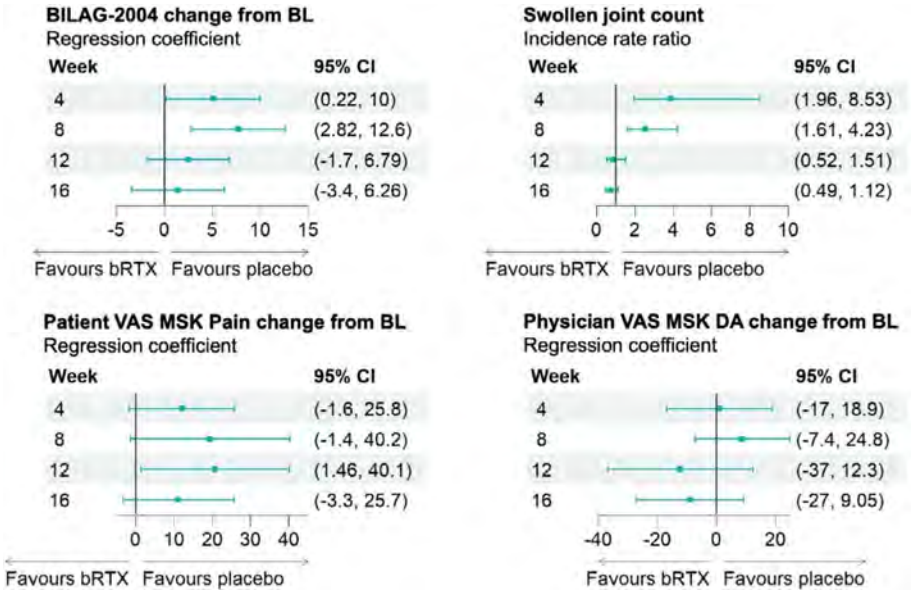

Figure 1

Conclusion: Clinical trials focused on a single feature of SLE (arthritis) are feasible and offer a homogenous trial population, control of standard of care and opportunities for objective imaging. The LAMDA is responsive and associates with validated outcome measures. ROOTS was not powered to measure efficacy but these data suggest potential worsening before benefit from rituximab. Detecting such signals may be enhanced by the greater sensitivity of this trial design.

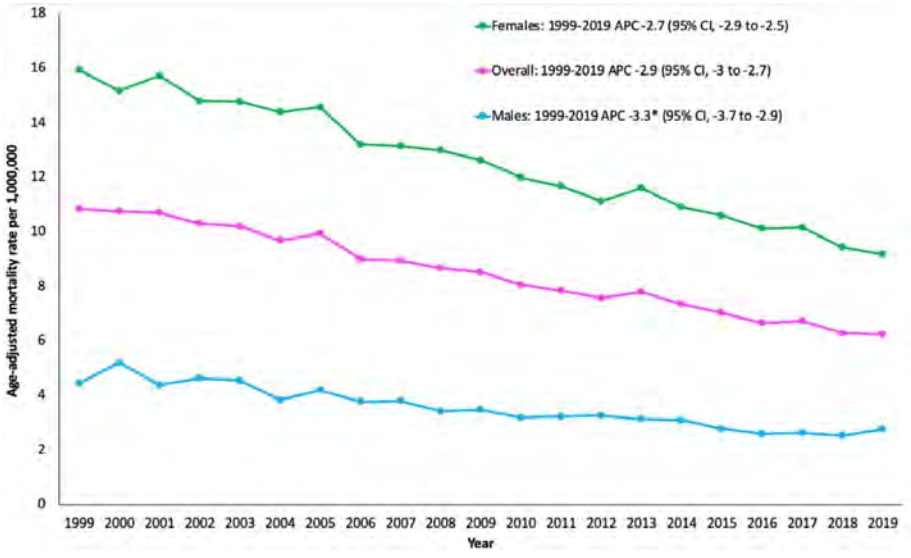
Trends in Systemic Sclerosis- related Mortality by Age, Sex and Race in the United States, 1999-2019

Anum Akhlaq[1], **Emily He**[2] and Risha Fayyaz[3], [1]University of Mississippi Medical Center, Jackson, MS, [2]Loma Linda University Health, Loma Linda, CA, [3]University of Mississippi Medical Center, Flowood, MS

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a rare chronic disease characterized by widespread vascular damage and tissue fibrosis of the skin and various internal organs, which is associated with high morbidity and mortality. National disparities in SSc- related deaths based on age, sex, and race have not been extensively studied. We examined the trends in SSc-related deaths in the United States from 1999-2019 stratified by age, sex, and race/ethnicity.

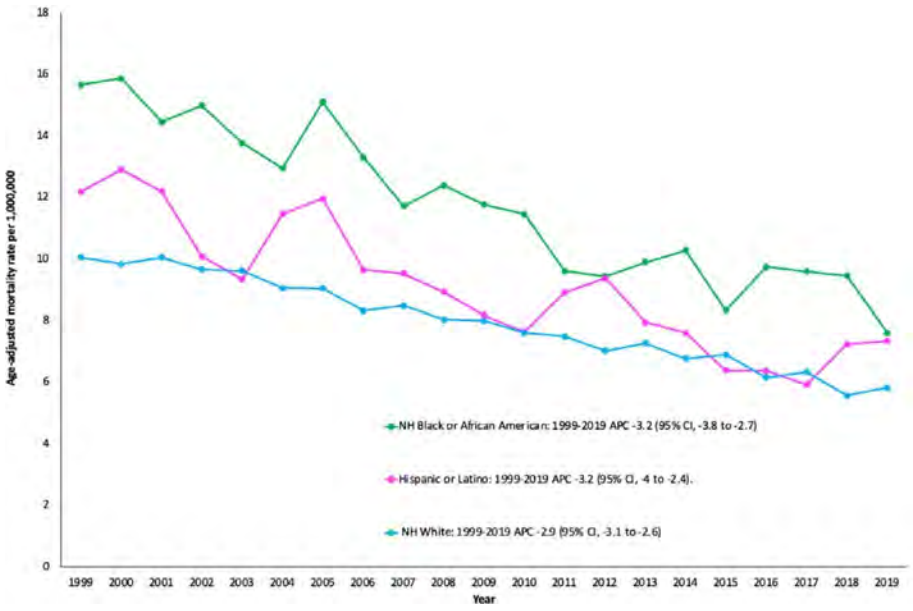
Methods: We used the Centers for Disease Control and Prevention Wide-Ranging OnLine Data for Epidemiologic Research (CDC WONDER) to access National Vital Statistics System data from 1999 to 2019. SSc-related deaths, age >/= 25 years were identified using the International Classification of Diseases, Tenth Revision, codes M34 from multiple causes of death



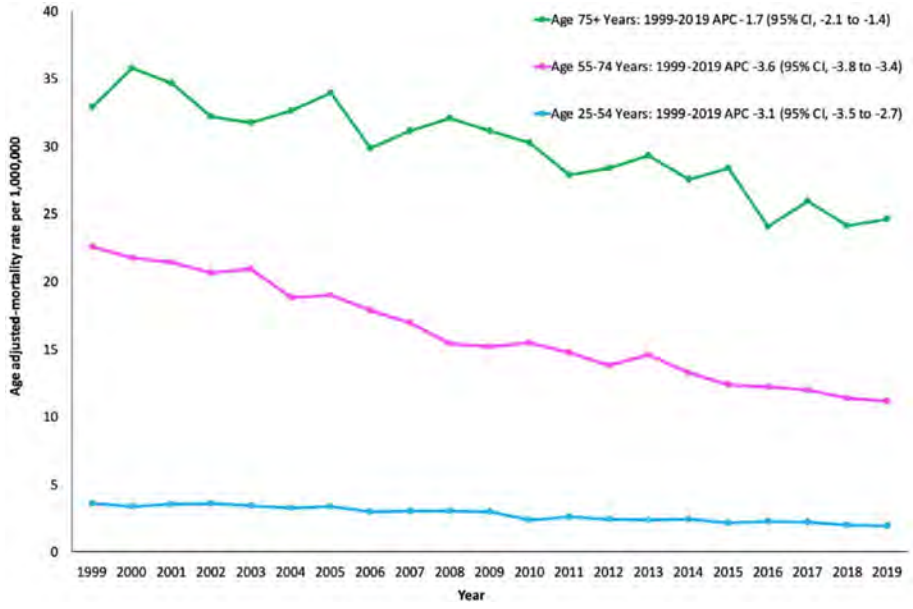
Trends in SSc related-mortality overall and stratified by sex

and were represented as age-adjusted mortality rates (AAMR) per 1,000,000 population. Joinpoint regression was used to examine changes in trend using annual percentage change (APC) in SSc-related deaths overall and stratified by age groups (25-54 years [young], 55-74 years [midlife], and >/=75 years [old]), sex, racial/ethnic groups (non-Hispanic whites (NHWs), non-Hispanic blacks or African Americans (NHB/AAs), and Hispanic or Latinos).

Results: There were a total of 37,594 SSc-related deaths during the study period. AAMR related to SSc decreased from 10.84 (95% CI, 10.35 to 11.32) in 1999 to 6.24 (95% CI, 5.93 to 6.55) in 2019 (APC -2.9 [95% CI, –3.0 to –2.7]). AAMR was higher in women (12.37) than men (3.49). Among the racial/ethnic groups, AAMR was highest in NHB/AAs (11.47) followed by Hispanic or Latinos (8.58), and lastly NHWs (7.86). AAMR was highest in old (29.76) followed by midlife (15.64) and young (2.83). From 1999-2019 APC in AAMR decreased in men (-3.3 [95% CI, -3.7 to -2.9]), women (-2.7 [95% CI, -2.9 to -2.5]), NHWs (-2.9 [95% CI, -3.1 to -2.6]), NHB/AAs -3.2 (95% [CI, -3.8 to -2.7]), Hispanic or Latinos (-3.2 [95% CI, -4 to



Trends in SSc related-mortality stratified by race/ethnicity



Trends in SSc related-mortality stratified by age

-2.4]), young (-3.1 (95% [CI, -3.5 to -2.7]) midlife (-3.6 [95% CI, -3.8 to -3.4] and old -1.7 [95% CI, -2.1 to -1.4]). AAMR related to SSc in 2020 was 6.28.

Conclusion: Our study showed a progressive decrease in SSc-related mortality throughout the study period regardless of gender, race, and age group. This could be due to early screening and management of life-threatening complications. Mortality was higher among females, NHBs, and older people. This could be due to higher SSc prevalence among these groups. Further research is required to understand the reasons for these disparities.

Phase I Study to Evaluate the Safety of Allogeneic Bone Marrow Derived Mesenchymal Stem Cells for Interstitial Lung Disease in Patients with Connective Tissue Disorders

Andy Abril[1], Isabel Mira-Avendano[2], Nisha Durand[1], Hassan Baig[1], augustine Lee[1], Meghan Baer[1] and Abba Zubair[1], [1]Mayo Clinic, Jacksonville, FL, [2]University of Texas, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of morbidity and mortality in connective tissue disorders (CTD) including rheumatoid arthritis, scleroderma and inflammatory myopathies. Conventional immunosuppressive therapies for CTDs are not always successful at preventing and treating pulmonary interstitial. Mesenchymal Stem Cells (MSC) have immunomodulating properties by blocking T cell proliferation, NK-Cell function and cytokine production. MSC have ability to induce tissue repair. Pulmonary fibrosis maybe the result of failed epithelial repair on stromal cells. Phase 1 trials in patients with post-transplant bronchiolitis obliterans, and idiopathic pulmonary fibrosis have shown MSCs are safe and patients showed stability. These characteristics suggest MSC may be an attractive therapeutic alternative in ILD associated with CTD. In this study, we assessed the safety of the adding allogeneic bone marrow derived mesenchymal stem cells to conventional pharmacological treatment in CTD patients who developed ILD.

Methods: Subjects with CTD who have developed ILD within the previous 2 years, were recruited from the clinical practice of the Pulmonary and Rheumatology clinics in Mayo Clinic Florida. Allogeneic MSC were manufactured at the Mayo Clinic Florida. 0.5 - 1 million MSC per Kg were infused IV. There were no adverse reactions reported during the infusions. Basic CBC and chemistries were obtained pre and post infusion, and on day1, 7, 30, 91 and 182. B, NK and T cell enumerations including T-reg cells, pro-inflammatory cytokines (TH1) and tolerogenic cytokines (TH2) levels as well as pro-angiogenic factors such as VEGF and iNOS were obtained prior to infusion. We assesed. Chest CT without contrast were obtained 1 to 7 days pre-infusion and day 182 post-infusion approximately. Spirometry was obtained at day 1, 7 and 30. Pulmonary function tests were obtained before the infusion, and at day 90 and 182

Results: Age ranged from 39-76 years, 7 patients were female and 3 were male.3 patient's had scleroderma, 3 rheumatoid arthritis, 2 anti synthetase syndrome, 1 polymyositis and 1 patient had interstitial pneumonia with autoimmune features (IPAF). 6 patients had a fibrotic NSIP (Nonspecific Interstitial Pneumonia) pattern, three patients UIP (Usual Interstitial

Diffusion Capacity

Pneumonia) and 1 patient had fibrotic organizing pneumonia. There were no adverse events related to the MSC infusions. CT scans stable 6 months post-infusion, and in 1 patient the CT worsened. Pulmonary function tests were stable in 4 patients, 4 patients improved and 1 worsened at 6 months post infusion. The 6-minute walk testing showed improved oxygenation in 3 patients, stable numbers in 5 patients and worsening in 2 patients, overall there was a decline on the a distance walked at 6 months. There was a general trend towards improvement of the median diffusion capacity.

Conclusion: The results of our study suggest that MSCs are safe in patients with ILD associated with autoimmune rheumatologic disorders. There were no adverse events related to the infusion. Most patients achieved clinical stability regarding pulmonary function test and CT scan however future Phase II trials would be necessary to determine efficacy in this group of patients.

Performance of the Revised CRISS in a Phase 3 Trial of Early Systemic Sclerosis

Dinesh Khanna[1], Christopher Denton[2], Masataka Kuwana[3], Daniel Furst[4], Suiyuan Huang[1], Barbara White[5] and Robert Spiera[6], [1]University of Michigan, Ann Arbor, MI, [2]University College London, London, United Kingdom, [3]Nippon Medical School Graduate School of Medicine, Tokyo, Japan, [4]University of California Los Angeles, Los Angeles, CA, [5]SFJ Pharmaceuticals, Towson, MD, [6]Hosptial for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Revised CRISS has been proposed an approvable outcome measure in early diffuse cutaneous SSc (dcSSc)[1]. The index is undergoing the FDA review as part of the Drug Development Tool Clinical Outcomes Assessments Qualification Program. The Revised CRISS is a two-step process wherein trial patients are determined to have improved (responder) or not improved (non-responder). The first step of the Revised CRISS accounts for worsening or incident cases of any internal organ involvement. If the patient meets any of the Step 1 criteria, their percentage change is 0%, and they are considered a non-responder in a trial. Step 2 includes 5 core set measures. The FVC% is evaluated to see if the change is at least 5% The other 4 core set measures (mRSS, HAQ-DI, Patient (PGA) and Clinician global assessments (CGA)) are evaluated for change of at least 25% from baseline. A responder is a patient who has relative improvement on at least 2 of the 5 core set measures without worsening on more than 1 core set measure. The improvement or worsening must be at least 25% relative change from the baseline for 4 core set measures (or ≥5% for FVC%). Our objective was to assess the performance of Revised CRISS in a phase 3 clinical trial of lenabasum in early dcSSc at week 52[2].

Methods: The Phase 3 trial was not able to discriminate the active medication vs. placebo and the data was pooled together. Percentages of revised CRISS and corresponding group differences (95% CI) were reported for each factor we explored. Multiple imputation was used for missing data. The imputation model includes five core set measures and three non-missing variables: 1) treatment; 2) indicator of meeting the ACR CRISS step 1; 3) visit weeks. All Results were pooled from each imputed dataset using the Rubin's rule.

	% of patients achieving Revised CRISS	Group Differences (95% CI)
Revised CRISS, Overall, Completers only N=294 At least 2 improvements (25%/ 5% in FVC) and no more than 1 worsening	62.2	NA
Revised CRISS, Overall, Imputation only N=363 At least 2 improvements (25%/ 5% in FVC) and no more than 1 worsening	62.1	NA
Age, Median <52 years, N=178	58.5	-7.2 (-17.7, 3.3)
Age, Median ≥52 years, N=185	65.7	
Disease duration, Median <30 mths, N=181	62.5	0.8 (-9.8, 11.4)
Disease duration, Median ≥30 mths, N-182	61.8	
Female, N=275	62.4	0.9 (-11.3, 13.0)
Male, N= 88	61.5	
White, N=252	63.5	White - Asian 9.3 (-4.1, 22.7), White- Others -5.7 (-22.8, 11.4)
Asians, N=74	54.2	**Asians- Others -15.0 (-34.5, 4.5)**
Others, N=37	69.2	
ILD Present, N=249	63.2	3.4 (-8.0, 14.8)
ILD Absent, N= 114	59.8	
Anti-SCL-70, N =144	56.5	SCL-70- RNA Pol3 -7.5 (-19.7, 4.8) **SCL-70- Others -11.7 (-25.0, 1.6)**
Anti-RNA Pol 3, N=119	63.9	RNA Pol3- Others, -4.3 (-18.4, 9.9)
Others, N=100	68.2	
MMF, N=185	67.0	MMF- Other Immuno 8.3 (-3.2, 19.8) **MMF- No 13.3 (-1.4, 28.0)**
Other Immunosuppressives §, N=119	58.7	Others Immuno - No 5.0 (-10.7, 20.7)
No Immunosuppressives, N=59	53.7	
North America, N= 140**	68.5	**NA- Asia 15.2 (0.2, 30.2)**; NA- Others 8.4 (-3.1, 19.9)
Asia*+, N= 64	53.3	Asia- Others -6.8 (-21.9, 8.3)
Others, N= 159	60.1	

Results: Of 363 patients, 294 (81.0%) are completers, among which 9 (3.1%) met Step 1 (internal organ involvement). The overall response in the Revised CRISS was 62.1% in the imputed dataset. The different baseline factors influenced the response in the Revised CRISS (Table). Using a cutoff of 10% difference between the baseline factors (Table), the variables associated with lower Revised CRISS responses were being an Asian/ living in Asia, anti-SCL-70 antibody, and no background immunosuppressive therapy. Patients who lived in Asia had both lower prevalence of RNA pol3 + (23.4% in Asia vs. 47.9% in North America and 23.3% in Europe), and lower utilization of MMF (23.4% in Asia vs. 74.3% in North America and 41.5% in Europe).

The heatmap (Figure) visualizes the performance of the individual 5 core set measures and the Revised CRISS. There were large improvements in the mRSS followed by CGA that drove a high response in the RCT.

Conclusion: We propose a new preliminary definition of the Revised CRISS that is undergoing the FDA Qualification. The mRSS and CGA drove the Revised CRISS in this RCT, and the future trials should enrich for more severe skin involvement (progressive skin phenotype and less regressive disease) to limit improvement in mRSS (as part of the natural history). In addition, stratification by autoantibodies and background immunosuppressives may balance the Revised CRISS response.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Gastrointestinal tract symptoms are common in systemic sclerosis (SSc). The Scleroderma Clinical Trials Consortium University of California Los Angeles Gastrointestinal Tract Questionnaire (GIT 2.0) is a validated, patient-reported outcome measure to assess gastrointestinal tract symptom severity in SSc. Intravital microscopy of the sublingual microcirculation can be used in SSc patient assessment for measurement of microvascular function and the glycocalyx, which is an indicator of endothelial dysfunction. In this study, biomarkers of endothelial dysfunction were examined in SSc patients by categorical GIT symptom severity.

Methods: SSc patients were enrolled at Vanderbilt University Medical Center and Tennessee Valley Healthcare System (IRB # 1618579).Enrolled patients who completed the GIT 2.0 and had same day sublingual microscopy measurement of glycocalyx penetrability by perfused boundary region [PBR]) in microvessel segments, and serum samples available for analysis were included. The PBR is scored as healthy (0-1.5), abnormal (1.6-3.5), or significantly elevated (3.6 and greater; indicative

Age (years), Mean (SD)	42 (11)
Sex: Female	23 (85%)

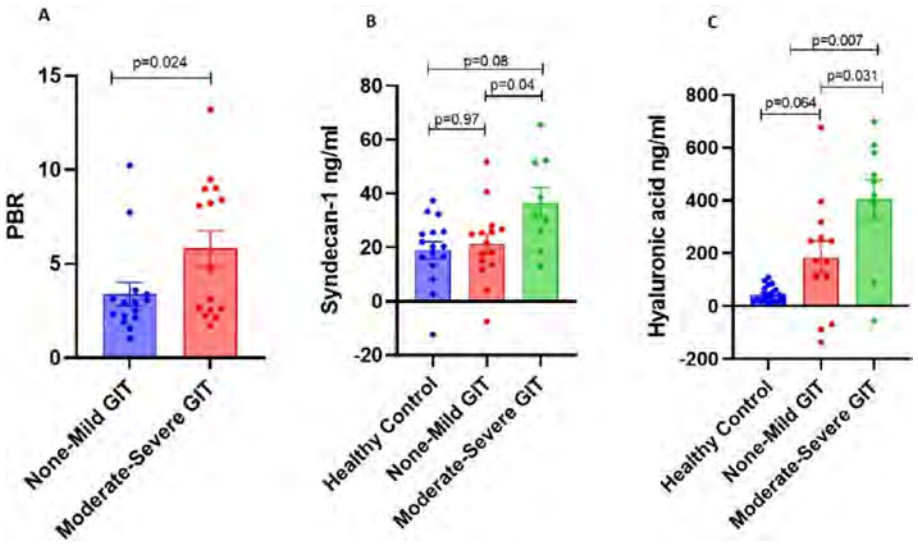
Clinical Features of SSc Patients (n=28)



Endothelial Biomarkers of Gastrointestinal Tract Symptoms in Systemic Sclerosis: A) Perfused Barrier Region (PBR), B) Syndecan-1, C) Hyaluronic Acid (HA)

of glycocalyx dysfunction). The plasma measurements of serum glycocalyx turnover (hyaluronic acid [HA] and syndecan-1) were determined by ELISA and compared to age- and sex- matched healthy controls. The endothelial biomarkers (PBR, HA, and syndecan-1) were analyzed by total GIT 2.0 severity: none-to-mild (0.49) and moderate-to-severe (0.5-3.00).

Results: The clinical features of 28 SSc patients that had same day acquisition of complete datasets are shown in Table 1. There were 15 SSc patients with mild GIT 2.0 and 13 SSc patients with moderate-to-severe GIT 2.0 symptoms, which were compared to 24 healthy control samples. The endothelial function biomarkers by GIT score category is shown in Figure 1. Only one patient had a healthy PBR measurement, 14 had an abnormal level, and 11 had an elevated PBR, which was significantly higher in patients with moderate-severe SSc-GIT symptoms (p=0.024). The syndecan -1 levels were significantly higher in SSc patients with moderate-severe GIT symptoms compared to patients with mild GIT symptoms (p=0.04), but not healthy controls. The HA levels were significantly higher in patients with moderate-severe SSc-GIT symptoms compared to both SSc mild GIT symptoms (p=0.031) and healthy controls (p=0.007).

Conclusion: This study supports that GIT symptoms in SSc may be due to endothelial dysfunction. The glycocalyx is a multifunctional and dynamic structure that participates in many vascular processes, including but not limited to vascular permeability, inflammation, thrombosis, mechano-transduction, and cytokine signaling. Sublingual estimates of endothelial glycocalyx health and serum measures of HA and syndecan-1 support the potential use of these biomarkers for objectively quantifying the role of vasculopathy in symptomatic SSc-GIT disease.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: We previously published a proof-of-principle study demonstrating the potential utility of computer vision (Deep Neural Network/DNN) methods applied to stained skin biopsy sections from patients with systemic sclerosis (SSc) as a novel skin outcome. The present study compared the 'DNN-Fibrosis Score' with histopathologic and modified Rodnan Skin Score (mRSS) changes for participants enrolled in a clinical trial.

a.

Stain	Visual Analog Scale
CD34 Alpha Smooth Muscle Actin	0= Normal Changes consistent with SSc 1= Mild 2= Moderate 3= Maximum
Hematoxylin & Eosin	1= Normal Changes consistent with SSc 2= Slight 3= Mild 4= Moderate 5= Marked 6= Maximum
Trichrome	1= Normal Changes consistent with SSc 2= Slight 3= Mild 4= Moderate 5= Maximum

b.

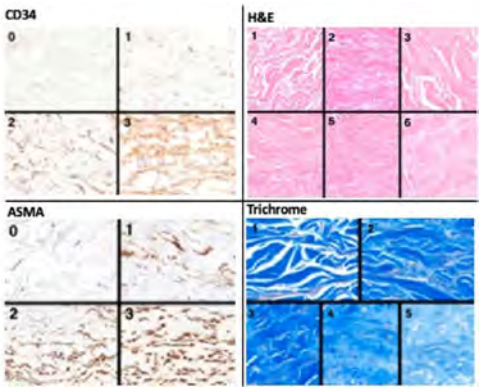

Figure 1. Histopathology assessment. a. Visual Analog Scale keys. b. Composite visual analog scales (from normal to maximum).

Methods: Ten adults with early (≤ 6 y) diffuse cutaneous SSc (15 ≤ mRSS ≤ 35) in an open-label belumosudil (ROCK2 inhibitor, 200 mg PO BID) trial had mRSS and two, 4mm, dorsal arm skin biopsies performed at weeks 0, 24, and 52. Biopsies were stained with CD34, CD3, CD8, alpha smooth muscle actin (ASMA), H&E, and trichrome. Two blinded dermatopathologists assessed biopsies for 16 histopathological parameters important in SSc (Van Praet JT et al., 2011). CD3+, CD8+ were counted, and visual analogue scales (VAS) were used to score CD34, ASMA, and relative SSc severity on H&E and

Figure 3. Belumosudil open-label trial results. a. Subject's mRSS W0 to last follow-up. b. Scatter plot of DNN Fibrosis Score and mRSS (p = 0.125). c. Ordinal logistic regression (95% CI) comparing DNN Fibrosis Score to 16 scored histologic parameters.

trichrome (**Fig. 1**). A previously developed DNN algorithm (AlexNet) was applied to trichrome-stained images to generate a 'DNN-Fibrosis Score' as previously reported. 'DNN-Fibrosis Scores' were compared to mRSS using a linear regression model and Spearman correlation. Histopathologic parameters were compared to mRSS or DNN Fibrosis-Scores using logistic regression models. A $p \leq 0.05$ was considered significant.

Results: Five patients had paired biopsies (**Fig. 2**). The median (interquartile range/IQR) mRSS change between 0 - 52W was -2.5 (-11 to 7.5) while the median (IQR) DNN-Fibrosis Score change (W0 - last follow-up) was -6 (-10.5 to 6.5) (**Fig. 3**). Of the histopathological scores, subcutaneous (SC) fat loss ($p = 0.012$), eccrine entrapment ($p = 0.008$), % CD8+ among CD3+ cells ($p = 0.006$) changed most during treatment. The correlation between mRSS and DNN-Fibrosis Score for the 5 paired biopsies was 0.18 [at higher mRSS, *i.e*. 25-51, the correlation was weaker] (**Fig. 3b**). Per 1-unit mRSS increase, the histopathological parameter odds ratios (OR); p-values were: telangiectasia =2.01; 0.001, perivascular CD3+ =1.03; 0.015, and % of CD8+ among CD3+ =1.08; 0.031 (**Fig. 3c**). Likewise, per 1-unit DNN Fibrosis-Score increase, OR; p-values for histopathological parameters were: hyalinized collagen =1.1; 0.00033, SC fat loss =1.47; 0.00033, intima wall =1.21; 0.005, and eccrine entrapment =1.14; 0.046 (**Fig. 3c**).

Conclusion: In this novel exploratory analysis, the DNN-Fibrosis Score exhibited sensitivity to histopathologic changes. The weak correlation between mRSS and DNN-Fibrosis Score contrasted with our previous findings. We note that predicted DNN-Fibrosis Scores tended to be lower for participants with higher mRSS (>25). We attribute this divergence to batch effects from staining protocols between our published and our current analysis which may be overcome with analyses of larger cohorts. However, despite the weak correlation with mRSS, the DNN-Fibrosis Score significantly correlated with a set of histopathological variables that were distinct from those correlated with mRSS, including hyalinized collagen, SC fat loss, intima wall thickness, and eccrine entrapment.

Efficacy and Safety of Prostaglandins Analogues in Systemic Sclerosis-associated Raynaud's Phenomenon. a Systematic Review and Meta-Analysis

Hana Alahmari[1], Hila Jazayeri[2] and Sindhu Johnson[3], [1]Toronto Scleroderma Program, Mount Sinai Hospital, Toronto Western Hospital, Division of Rheumatology, Department of Medicine, University of Toronto, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Institute of Health Policy, Management, and Evaluation, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Raynaud's phenomenon (RP) is a vasculopathic manifestation of Systemic Sclerosis (SSc) that can lead to digital ulceration, gangrene, autoamputation, and hand disability. Prostaglandin analogs are prostacyclin-derived medications with potent vasodilatory properties. We conducted a systematic review and meta-analysis evaluating the efficacy and tolerability of prostaglandin analogs in controlling RP among SSc patients.

Methods: We conducted a systematic review and meta-analysis of randomized controlled trials (RCTs) of adults with SSc-associated RP with or without digital ulcers. The exposure was any prostaglandin compared to placebo or active control. The primary outcome was the effect on RP frequency. Secondary outcomes included RP severity, duration of RP attacks, healing of digital ulcers, development of new digital ulcers, change of capillary blood flow, impact on the patient's health-reported outcome, and tolerability. The time points were divided into short-term-follow (< 16 weeks) and long-term follow-up (≥ 16 weeks). The statistical analysis used RevMan software. Data were reported as pooled weighted mean difference (WMD) or odds ratio (OR) with 95% confidence intervals (95%CI). The study was compliant with PRISMA-S 2020 guidelines.

Results: Our search yielded 11 RCTs, of which ten were parallel, and 1 was crossover design. The studies were published between 1981 and 2017 and included five PGs (iloprost n=6, PGE1 n=2, baroprost n=1, trepinostil n=1, and selexipag n=1), often against a placebo. Most of the studies were conducted during winter to eliminate seasonal variability as a confounder. We performed meta-analyses using -effects models. PG significantly reduced RP severity in the short-term WMD -0.63 (95%CI -0.99, -0.27)]. In addition, there were trends for PG to reduce the frequency of RP attacks WMD -0.32 (95%CI -0.76, 1.13), and duration of attacks WMD -4.78 (95%CI -14.69, 5.14) but were not statistically significant. Withdrawal from trials due to adverse events was considered an indirect measure of drug intolerability. PGs increase the odds of withdrawal by 88%, OR 1.88 [95% CI 1.00, 3.55]. The most common adverse effects were postural hypotension, flushing, and headache. The quality of evidence ranged from moderate to low.

Conclusion: PGs can be beneficial in the short term to reduce the severity of SSc-associated RP. Therefore, PG may be considered a therapeutic option in people with SSc-associated RP.

Abstract Number: 1519

Renal Complications Following Autologous Stem Cell Transplantation for Systemic Sclerosis

Malcolm MacKenzie[1], Harry Atkins[2] and Nancy Maltez[1], [1]The Ottawa Hospital, Ottawa, ON, Canada, [2]Ottawa Hospital Research Institute, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rapidly progressive diffuse systemic sclerosis (SSc) is a devastating autoimmune disease with high morbidity and mortality. Autologous hematopoietic stem cell transplantation (AHSCT) is recognized as an effective treatment option with randomized controlled trials demonstrating long-term improvement in skin fibrosis, pulmonary function, and overall survival. Although the risk of renal complications following AHSCT for hemato-oncologic conditions has been well established, the risk in SSc remains unclear. In addition to acute kidney injury (AKI), this subset of patients with rapidly

progressive, severe SSc is particularly vulnerable to developing scleroderma renal crisis (SRC), a life-threatening complication of SSc characterized by malignant hypertension and AKI.

Methods: We conducted a retrospective review of all patients with SSc treated with AHSCT between 2001 and 2023 at The Ottawa Hospital. All patients satisfied the ACR classification criteria for SSc. Data was sought for baseline patient characteristics and the development of AKI and SRC as defined by the KDIGO 2012 definition or the International Scleroderma Renal Crisis Survey Criteria respectively, during the first 120 days following AHSCT.

Table 1. Demographic and clinical characteristics

	Total	Any renal* complication	No renal complication	SRC total

HTN, hypertension; CKD, chronic kidney disease; AHSCT, autologous hematopoietic stem cell transplantation; AKI, acute kidney injury; BP, blood pressure; Cr, creatinine, LDH, lactate dehydrogenase; ICU, intensive care unit; RRT, renal replacement therapy; SSA, anti-Sjögren's-syndrome-related antigen A autoantibodies; ANA, antinuclear antibody; GFR, glomerular filtration rate; CTX, cyclophosphamide; rATG, rabbit anti-thymocyte globulin; eATG, equine anti-thymocyte immunoglobulin; TBI, total body irradiation; SLED, sustained low-efficiency dialysis; N/A, not applicable

Results: 34 patients underwent AHSCT, the mean age was 49.6 years (21-65), 53% were female, 10 received cyclophosphamide (CTX), equine anti-thymocyte globulin (ATG), total body irradiation (TBI) conditioning and 26 received CTX, rabbit ATG conditioning. The mean modified Rodnan skin score (mRSS) was 25 (2-43), the mean FVC was 79% (37-119) and the mean DLCO was 61% (32-119) before AHSCT. The median follow-up time was 29.9 months (0-72). 50% (n=17) experienced renal complications following AHSCT with 29% (n=10) experiencing AKI alone, 20% (n=7) with SRC alone and 3% (n=1) having SRC without AKI. AKI occurred earlier with a mean of 18 days (-3 to 92) following AHSCT compared to SRC with a mean of 44 days (-1 to 109). 4 of the 7 patients with SRC required admission to the intensive care unit (ICU) and 2 required permanent hemodialysis. Of those with AKI only, 8 out of 10 were diagnosed with pre-renal AKIs and 2 had cardiorenal AKIs. Transient hemodialysis was required in 2 AKI patients. Among those with SRC, 5 patients were receiving steroids at the time of diagnosis. There was no statistically significant difference in overall survival associated with the development of renal complications post-AHSCT.

Conclusion: Although renal complications were common following AHSCT for SSc, affecting half of our cohort, there was no significant impact on survival observed with renal injury in our series. Nonetheless, given the frequency and often the severity of renal morbidity, close monitoring both before and after transplant is warranted as early intervention could be effective. Ideally, with much-needed prospective studies, high-risk patients may be identified prior to AHSCT and provided with pre-emptive supportive interventions to mitigate renal morbidity.

Abstract Number: 1520

Identifying Core Domains for Clinical Trials in Systemic Sclerosis-Associated Raynaud's Phenomenon and Digital Ulcers Using the Delphi Consensus Method

Susanna Proudman[1], Michael Hughes[2], Nancy Maltez[3], Edith Brown[4], Virginia Hickey[5], shawna grosskleg[6], B Shea[6], Ariane Herrick[7], John Pauling[8] and Peter Merkel[9], [1]Royal Adelaide Hospital and University of Adelaide, Adelaide, Australia, [2]Northern Care Alliance NHS Foundation Trust, Salford Care Organisation, Salford, United Kingdom, [3]Department of Medicine, Division of Rheumatology, The Ottawa Hospital, Ottawa, ON, Canada, [4]OMERACT, Manchester, United Kingdom, [5]OMERACT, Adelaide, Australia, [6]OMERACT, Ottawa, ON, Canada, [7]University of Manchester, Salford, United Kingdom, [8]North Bristol NHS Trust, Bristol, United Kingdom, [9]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The OMERACT Scleroderma Vascular Disease Working Group sought to identify essential core outcome domains for inclusion in clinical trials focusing on Raynaud's phenomenon (RP) and digital ulcers (DUs) caused by systemic sclerosis (SSc). This effort aimed to gather insights from patients and other stakeholders, ensuring their perspectives are reflected in the development of a Core Outcome Set.

Methods: Candidate items identified from previous qualitative work and systematic literature reviews were included in separate Delphi surveys for RP and DUs. The surveys were in English and conducted in parallel. Participants were invited by email: patients through international patient advocacy groups, and other stakeholders, including physicians and others with experience

in treating patients with SSc-related RP and DUs and/or conducting clinical trials in these disorders. Patients completed the surveys for RP and DUs only if they had lived experience of RP and DUs, respectively. Core domains were defined as those reaching group consensus (≥70% ratings of 'critical' in both patient and other stakeholder groups) in the third/final Delphi exercise.

Results: The 3-round Delphi surveys were completed by 62 patients and 132 others from 39 countries for RP, and by 20 patients and 105 others from 36 countries for DUs.

For RP, group consensus for core domains was met for i) *pathophysiological manifestations core area*: severity and frequency of RP attacks; and ii) *life impact core area:* items grouped under the target domain of function, adaptation required to manage life with RP, and impact on health-related quality of life (HRQoL). Pain, duration of RP attacks, patient global assessment (PtGA), and need for hospitalization (*resource usecore area*) were considered critical by other stakeholders but not by patients. Conversely, patients but not other stakeholders considered coldness to be critical. Assessment of perfusion and temperature (*biomarkers* category) did not meet the threshold for inclusion by either group but assessment of microvasculature was raised for further consideration by the Working Group.

For DUs, group consensus for core domains was met for i) *pathophysiological manifestations core area*: pain, number, global burden, healing of DUs, and physician global assessment; and ii) *life impact core area:* items grouped under the target domain of function, adaptation required to manage life with DUs, and impact on HRQoL; and iii) *resource use core area:* items grouped under hospitalization or urgent intervention. Digital sensitivity, impact on emotional well-being, and assessment of microvasculature were considered critical by patients but not by other stakeholders. PtGA was considered critical by others but not patients.

Conclusion: Patients with SSc and clinicians identified core domains for use in clinical trials in SSc-associated RP and DUs, with several domains common to both manifestations of disease. These results will inform development of a final Core Domain Set for use in clinical trials.

Microvascular Remodeling After Autologous Stem Cell Transplant for Systemic Sclerosis

Lisa Balistreri[1], Megan Sullivan[1], Florentina Berianu[1], Ernesto Ayala[2] and Andy Abril[2], [1]Mayo Clinic Florida, Jacksonville, FL, [2]Mayo Clinic, Jacksonville, FL

SESSION INFORMATION

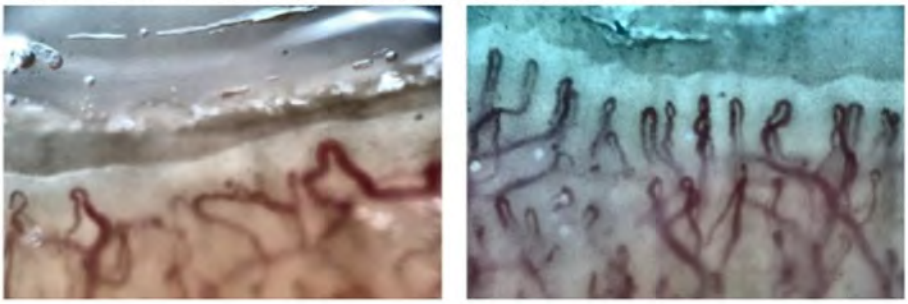
Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Figure 1: Nailfold video capillaroscopy images prior to HSCT and after HSCT



A B

A. NVC performed prior to HSCT shows low capillary density with disorganization of the normal capillary array B. NVC performed after HSCT shows increased capillary density to normal, hairpin-shaped capillaries, and absence of enlarged capillaries

Background/Purpose: Autologous hematopoietic stem cell therapy (HSCT) is an effective therapy for patients with rapidly progressive systemic sclerosis (SSc) refractory to standard therapies. The disease is characterized by microvascular damage and dysfunction which can be observed using nailfold video capillaroscopy (NVC). NVC can be useful to examine the severity, activity, and stage of microvascular damage. At this time, there are few reported cases of NVC improvement after HSCT. Other therapies for SSc have not been found to provide reversal of the capillary abnormalities. Our objective was to evaluate the effect of HSCT on nailfold capillary changes in SSc.

Methods: Prospective study in patients diagnosed with SSc followed at our institution who underwent treatment with HSCT and had NVC images available pre- and post- treatment. All patients met the ACR 2013 classification criteria for SSc. Demographics, clinical features, serologies, date of diagnosis, laboratory data, last follow-up, response to treatment, NVC, and outcome were recorded. NVC was performed on all eight nailbeds using the 2nd-5th digits of both hands. Capillary morphology, density, organization, microhemorrhages, and ramifications of each nailbed were compared to determine the degree of vascular remodeling pre and post HSCT.

Results: A total of 5 patients diagnosed with SSc underwent HSCT. Mean age was 43.75 years with 4 women (80%) and 1 man (20%). Post-treatment images were collected at a median of 2 months (range 1-3 months) after HSCT. From baseline to follow-up, 80% of HSCT patients showed significant improvement in parameters including density, architecture, and microhemorrhages. The change in capillary density and disorganization to the resemblance of a normal capillary was seen in most patients. The most notable improvement was seen in one patient with scleroderma overlap syndrome with normal capillary density noted as early as one month post transplant in most of the fingers corresponding with significant clinical improvement in the modified Rodnan skin score. NVC findings showed overall positive changes with increased capillary density, reduced capillary loss, and improved capillary morphology.

Conclusion: Our findings support reversibility of the NVC changes in patients with SSc in a short time interval post HSCT. Further research is warranted to determine if microvascular improvements post HSCT contribute to the improved mortality and quality of life previously reported in the literature.

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment options for pulmonary arterial hypertension (PAH) have expanded in the last two decades. However, evidence for the treatment of connective tissue disease-associated PAH (CTD-PAH) mostly depends on subgroup analysis of randomized controlled trials (RCTs). Thus, we performed a meta-analysis of the RCTs reporting outcomes for CTD-PAH.

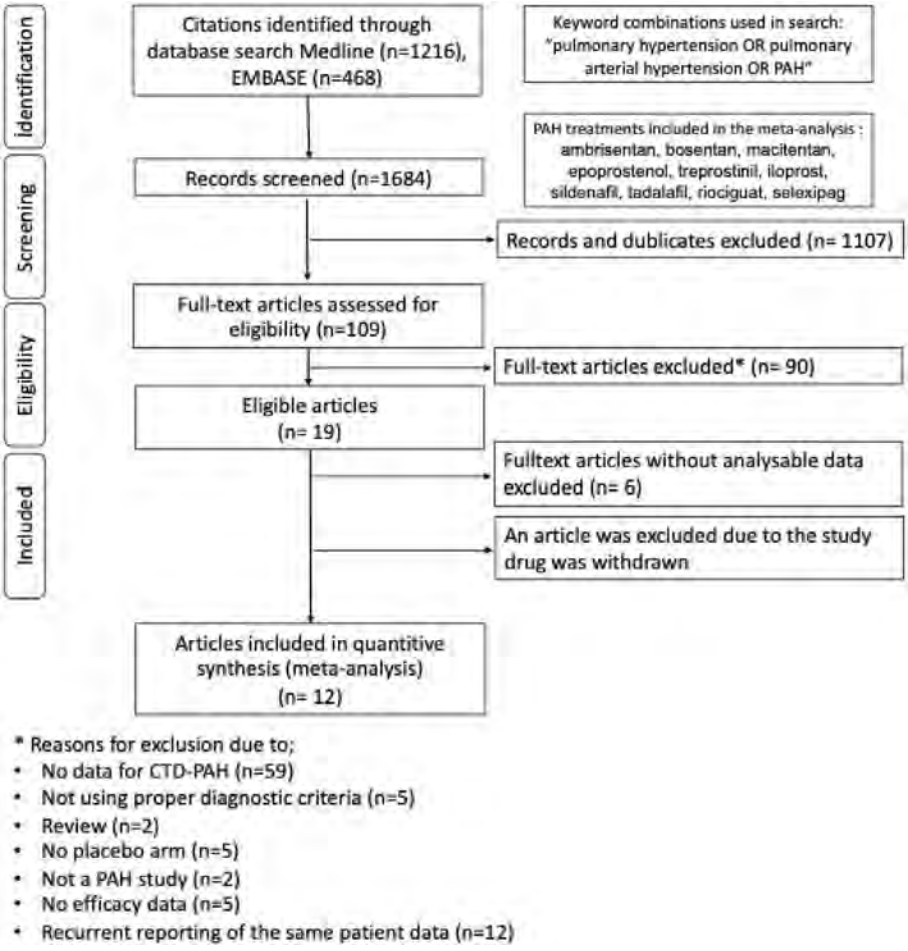

Figure 1. Flow chart of the study inclusion process

Methods: The search strategy was summarized in Figure 1. The outcomes selected for meta-analysis were functional class (FC) change, survival rates, six-minute walk distance (6-MWD), clinical worsening (CW), N-terminal prohormone BNP (NT-proBNP), pulmonary vascular resistance (PVR), mean pulmonary arterial pressure (mPAP), right atrial pressure (RAP), and cardiac index (CI). The systematic review and meta-analysis protocol was registered in PROSPERO (CRD42020153560).

Results: PubMed and Embase searches revealed 1216 and 468 articles, respectively. After excluding the irrelevant articles and studies without available data for meta-analysis, 12 RCTs, including 1837 patients, were selected (Figure 1). The diagnoses were SSc in 59%, SLE in 20%, and other CTDs in 21%. The follow-up duration of selected trials ranged between 12 weeks to 192 weeks. The pharmacological interventions were prostacyclin analogs in 3 studies (epoprostenol in 1 study and treprostinil in 2 studies), PDE-5 inhibitors in 2 studies (sildenafil and tadalafil in one study each), ERA in 4 studies (bosentan in 2 studies, macitentan and, ambrisentan in 1 study each), riociguat in 1 study, selexipag in 1 study and, ambrisentan and tadalafil combination in 1 study. There was a significant difference between the groups in FC, 6MWD, CW, PVR, RAP, and CI, favoring the intervention arms (Figure 2.) Our analysis showed a 30% reduction in the risk of CW with PAH treatment. The reduction was higher (46%) with combination therapies. However, short-term (24-26 weeks) survival and mean serum NT-proBNP level changes were similar between groups. The RoB of the studies were summarized in Figure 3.

Conclusion: Although treatment for CTD-PAH had favorable effects on many of the clinical and hemodynamic outcomes, the effect on survival and NT-proBNP levels were not significant. This is the first meta-analysis on CTD-PAH that reported the pooled analysis of change in functional class, hemodynamic measurements (RAP, PVR, CI), and NT-proBNP, some of which have important prognostic value for PAH. Improvement in exercise capacity and reduction in risk of CW in CTD-PAH patients were less pronounced compared to idiopathic PAH (IPAH). However, changes in hemodynamic parameters in patients with CTD-PAH in our meta-analysis were similar to those in patients with IPAH in the published RCTs.

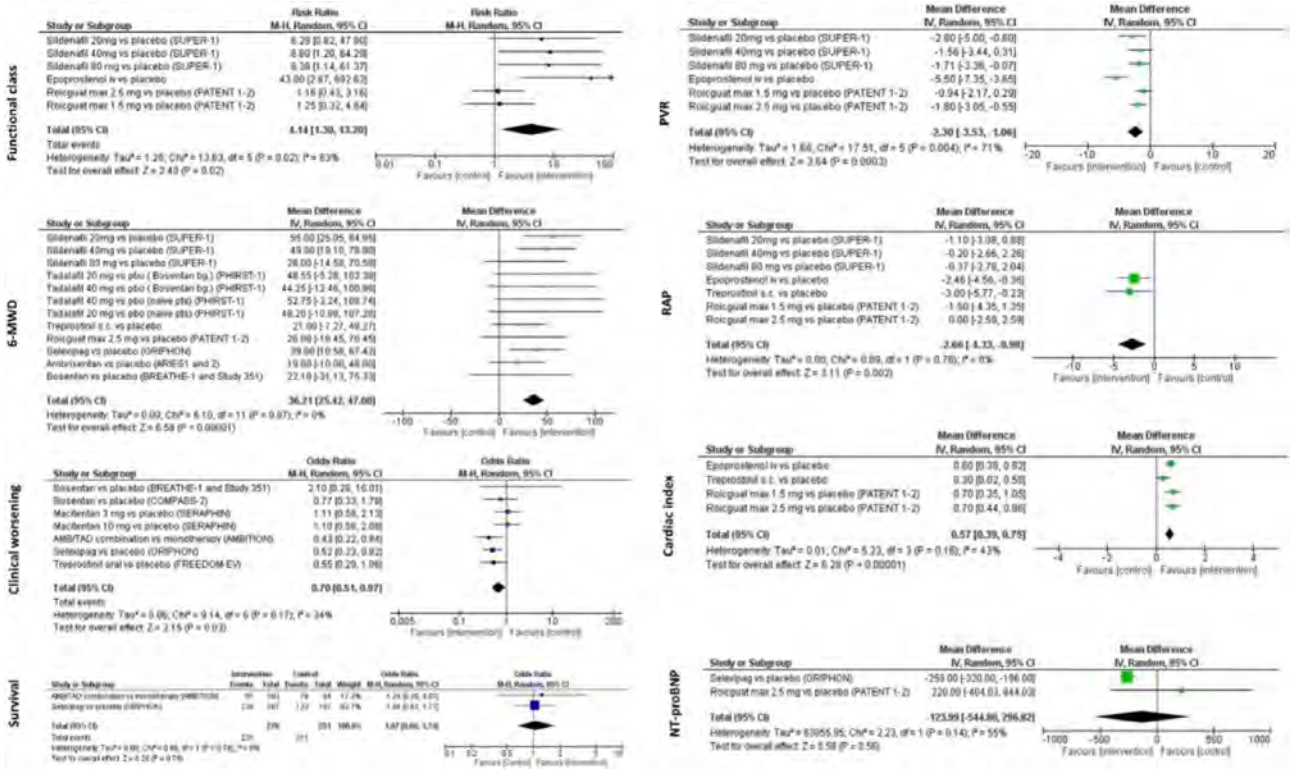

Figure 2. The results of the meta-analyses

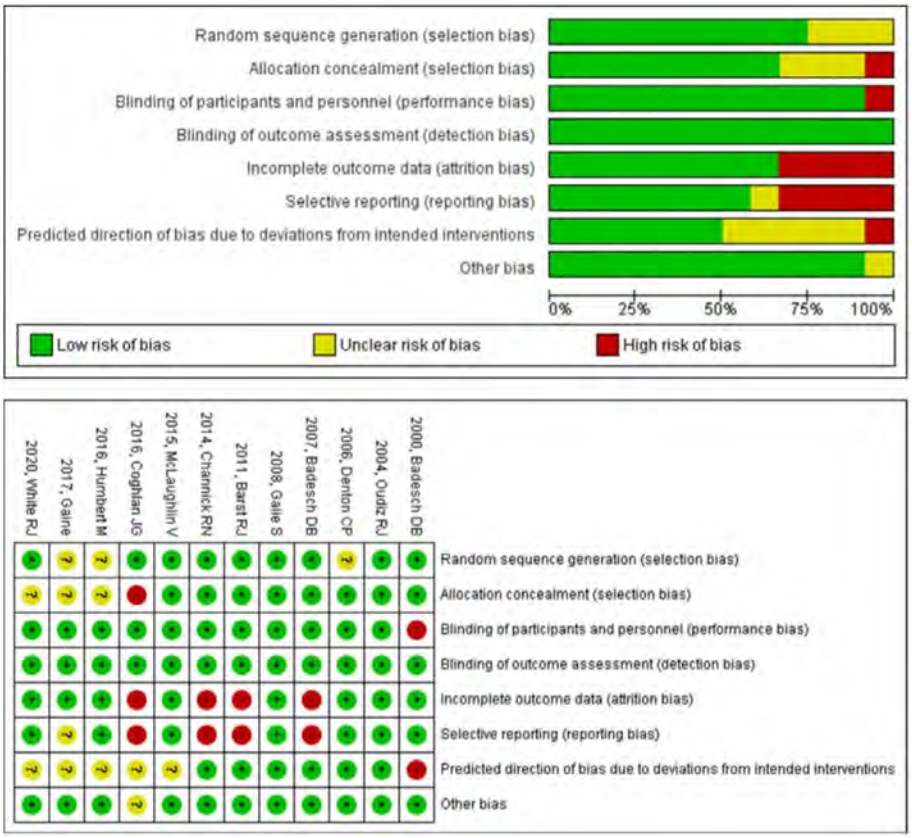

Figure 3. Risk of bias graph and summary: review authors' judgments about each risk of bias item for each included study

The Risk of Scleroderma Renal Crisis from Intraarticular Corticosteroid Injection in Systemic Sclerosis

Muruganandam Maheswari, **Eyerusalem Akpan**, Matthew Mcelwee, Meredith Keller, Angie Ariza - Hutchinson, Rosemina Patel, Wilmer Sibbitt, Frank O'Sullivan, Sharon nunez, N. Suzanne Emil and Roderick Fields, University of New Mexico, Albuquerque, NM

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

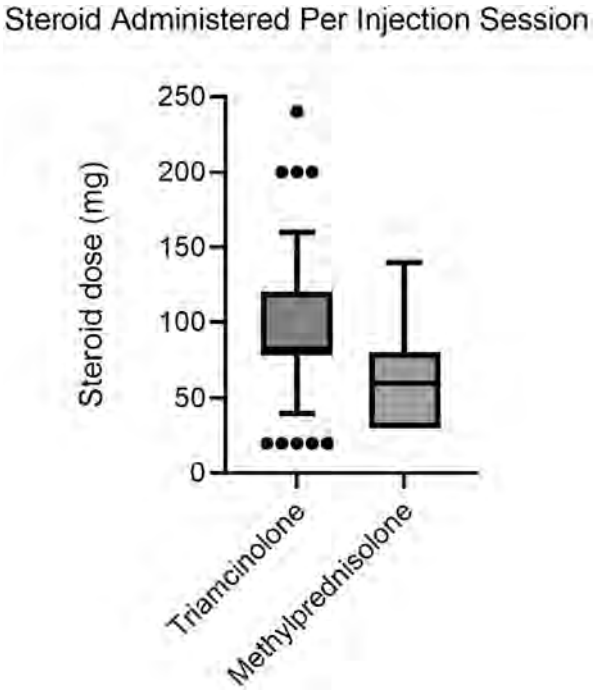
Session Time: 9:00AM–11:00AM

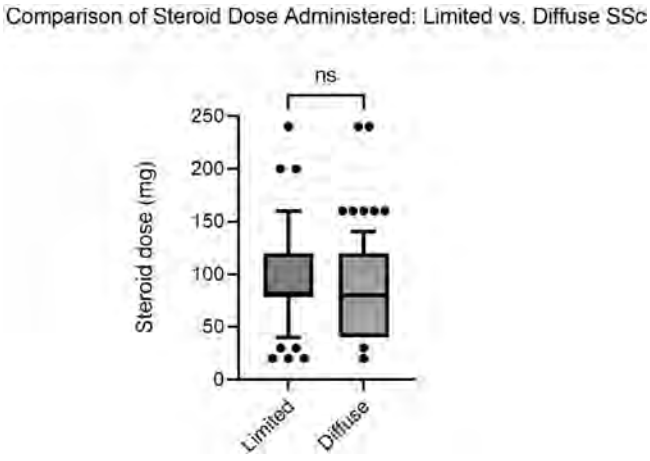
Background/Purpose: Scleroderma renal crisis (SRC) is a rare but a life-threatening complication of systemic sclerosis (SSc), affecting 2-15% of patients with SSc. SRC has been tied to the use of oral and intravenous corticosteroids in SSc. Due to this association, SSc patients with musculoskeletal complaints are often denied intraarticular (IA) corticosteroids when these therapies might otherwise benefit them. Although dose-dependent risk of oral corticosteroids in inducing SRC is well understood, the risk of IA corticosteroids for inducing scleroderma renal crisis has not been well studied. We

investigated the prevalence of SRC and other complications in patients with SSc following the injection of commonly used dosages of IA corticosteroids used to treat musculoskeletal complaints.

Methods: Under an IRB approved protocol, 136 patients with SSc followed in single university-based rheumatology clinic were retrospectively reviewed for receiving and complications subsequent to IA corticosteroid injections including: SRC, infection, hypertension, hyperglycemia, infection, tendon rupture and mortality. 46 of 136 SSc patients received IA steroids with a total 191 injection sessions (4.15± 4.04 injection sessions/subject). The mean steroid dose was 95.2± 44.2 mg/session. (Figure 1). Blood pressure, serum creatinine, and serum glucose were determined before and after the injection session (mean 5.9±4.8 weeks). Incidence of SRC, local infection, hypertension, hyperglycemia, infection, tendon rupture and mortality were assessed 12 months after the last injection session.

Results: The IA injection and control SSc subjects were similar in age (IA: 58.9±12.1 vs. 55.5±14.9 years), female gender (IA: 100% vs.89.9%, odds ratio (OR)=NA, p=0.02), antinuclear antibody (IA: 71.7% vs.81.1% OR=0.59, CI: 0.25-1.36, p=0.08), anti-centromere antibody (ACA) (IA: 47.8% vs.37.8%, OR=1.51, CI: 0.74-3.1, p=0.08), anti-topoisomerase





antibody (ATA) (IA: 26.1% vs. 26.7%, OR=0.97, CI: 0.43-2.18, p=0.16), antibody negative (negative for ACA/ATA or positive for RNA-polymerase III) (IA: 32.6% vs. 35.6%, OR=0.79, p=0.13). Additionally, there was not a difference in steroid dosing between limited and diffuse SSc patients(Figure 2). Outcome characteristics were very similar before and after the injections: systolic BP (before IA: 127±22 vs. after 127±21 mm Hg, p=1), diastolic BP (before IA: 71±13 vs. after 71±11 mm Hg, p=1), creatinine (before IA: 0.78±0.56 vs. after 0.76±0.20 mg/dL, p = 0.54), and blood glucose (before IA: 100±21 vs. after 99±24 mg/dL, p=0.57).One episode of SRC occurred in the control group. No episodes of SRC, serious local or systemic infection, tendon rupture, or death occurred in the IA injection group during the 12-month period after the 330 injections.

Conclusion: IA corticosteroid injections in patients with SSc does not appear to increase risk of SRC or other negative outcomes. These findings indicate that IA injections should not be denied to patients with systemic sclerosis if they are otherwise indicated.

Abstract Number: 1524

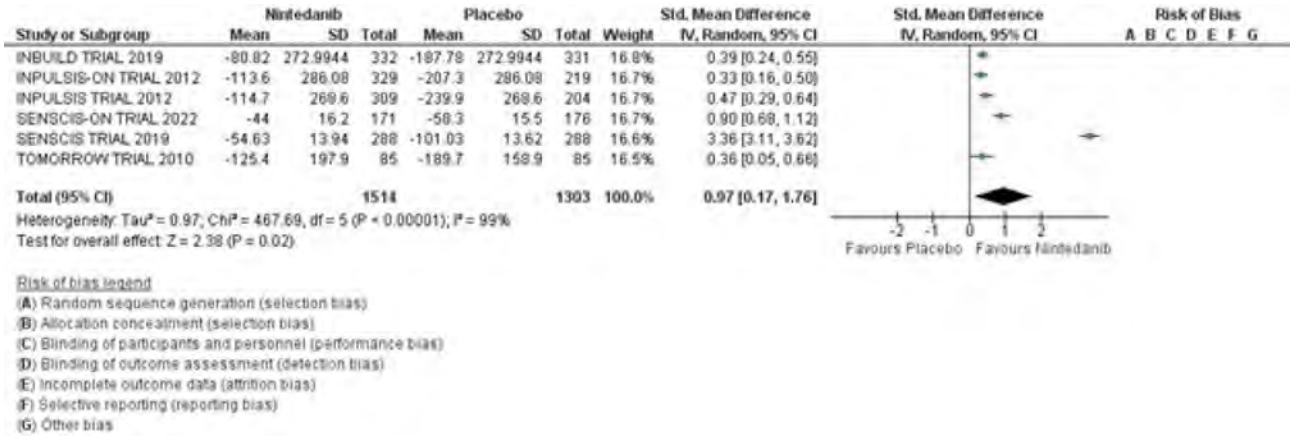
The Effectiveness of Nintedanib in Treating Fibrosing Interstitial Lung Disease in Both Scleroderma and Non-scleroderma Patients: A Systematic Review and Meta-analysis

Yasmin Khader, Fatima Rawish, Aya Abughrbyeh, Samantha Davis, Sabeen Sidiki, Pejma Safavi and Nezam Altorok, University of Toledo, Toledo, OH

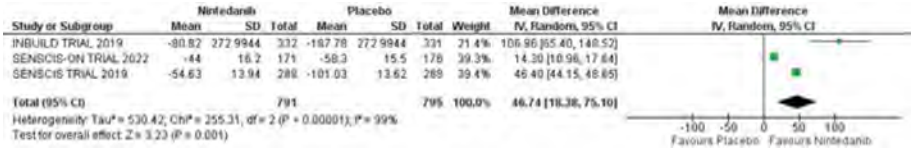
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Nintedanib, an intracellular inhibitor of tyrosine kinases, has shown promise in clinical trials by inhibiting key processes associated with the advancement of lung fibrosis. Its effectiveness has been demonstrated in treating idiopathic pulmonary fibrosis (IPF) as well as Systemic Sclerosis associated Interstitial Lung Disease (SSc-ILD). In this meta-analysis, we assessed the effectiveness of nintedanib in treating fibrosing interstitial lung diseases in both scleroderma and non-scleroderma patients.

Methods: We conducted a systematic review and meta-analysis of studies that investigated the effect of nintedanib on the annual decline of Forced Vital Capacity (FVC) in patients with fibrosing interstitial lung disease. We performed a comprehensive search in the databases of PubMed/MEDLINE, Embase, and the Cochrane Central Register of Controlled Trials from inception through May 2023. We included all randomized controlled trials. We excluded observational studies, abstracts, animal studies, case reports, reviews, editorials, and letters to editors. From each study, we collected the rate of annual reduction of FVC in both treatment and control groups. The treatment group included patients with fibrosing lung disease treated with nintedanib. The primary outcome was the rate of annual reduction in FVC measured in millimeters per year assessed after 52 weeks of follow-up. The random-effects model was used to calculate the mean differences (MD), and confidence intervals (CI). A p value < 0.05 was considered statistically significant. Heterogeneity was assessed using the Higgins I^2 index.



Annual reduction rate in FVC (ml/year) in patients with fibrosing interstitial lung disease treated with nintedanib compared to placebo group



Annual reduction rate in FVC (ml/year) in patients with SSc-ILD treated with nintedanib compared to placebo group

Results: Five randomized controlled trials involving 2817 patients were included in the meta-analysis. Patients were randomized to treatment and placebo groups in almost 1:1 ratio. The rate of annual decline in FVC was significantly lower in all patients with fibrosing lung disease treated with nintedanib (MD 0.97, 95% CI 0.17-1.76, $p < 0.02$. $I^2 = 99\%$). Three of the five randomized trials included 1586 patients with known scleroderma associated interstitial lung disease. The annual reduction in the FVC was also significantly lower in scleroderma patients treated with nintedanib (MD 46.74, 95% CI 18.38-75.10, $p < 0.001$, $I^2 = 99\%$).

Conclusion: Our meta-analysis revealed that patients treated with nintedanib experienced a decelerated rate of interstitial lung disease progression compared to those who received a placebo, regardless of the underlying cause of the fibrosing interstitial lung disease.

Abstract Number: 1525

Chelation Therapy in the Management of Calcinosis Associated with Systemic Sclerosis

Alison Fernandes, Ashraf El-Meanawy and ME Csuka, Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis is a common complication of systemic sclerosis (SSc), though effective treatment options are limited. Of the several medical therapies that have been employed over the years, chelation with intravenous ethylenediaminetetraacetic acid (EDTA) has shown subjective and objective improvement, but its use has been limited by side effects, such as tetany, hypocalcemia, and kidney dysfunction. Using a slower rate of intravenous (IV) administration, toxicity was less frequently demonstrated in animal models. The objective of this project was to evaluate the safety and efficacy of EDTA in a case series of patients with SSc associated calcinosis.

Methods: Out of 34 identified patients with SSc associated calcinosis as defined by the 2013 ACR/EULAR classification criteria, three accepted the invitation to receive EDTA. These patients had clinical and radiographic evidence of one or more calcinotic deposits in either the trunk or the upper or lower extremities. Patients received EDTA chelation infusion (1.5gm EDTA in 500ml total volume IV) once weekly for total of 12 weeks. Radiographs of calcinotic burden were monitored prior to treatment and at 12 weeks. The primary endpoint was the percentage of patients without radiographic progression of calcinosis at 12 weeks. Key secondary endpoints included the completion of an unvalidated Mawdsley Calcinosis Questionnaire (MCQ) per permission of Dr. Saketkoo (1), and important safety signals, which included monitoring of renal function, and serum calcium.

Results: Three female patients with SSc were included, two limited cutaneous SSc and one diffuse cutaneous SSc. The median age was 63 years old. Two patients completed all 12 infusions and 1 patient discontinued therapy after 7 infusions due to financial constraints. No patient experienced clinical or radiographic progression while on therapy. The MCQ survey supported moderate disease burden. One patient reported subjective improvement which was reflected in the MCQ survey results at week 12. Increased 24hr urine calcium excretion was observed in one patient. Due to expected excretion of EDTA in the urine, the urinary calcium post infusion will be an under-estimate. A limitation of the study is that urinary calcium estimate using atomic emission was not done, which would avoid EDTA interference in assessing accurate total urinary calcium excretion. Other secondary endpoints revealed no adverse events occurred.

Conclusion: Low dose EDTA infused at a slow rate was well tolerated. No patients progressed on therapy, one patient reported subjective improvement, and measures of calcium excretion suggested successful chelation in one patient. Larger studies using higher dose of EDTA, are needed to determine the possible benefit of using EDTA to reduce the burden of calcinosis.

Evusheld Efficacy and Safety in Autoimmune Rheumatic Diseases (AIRD) Treated by B Cell Depeting Therapy or Autologous Stem Cell Transplantation: A Prospective Observational Study

Lisa Kaly[1], mark Volevich[1], shiri keret[2], Abid Awisat[3], Aniela Shouval[1], Itzhak Rosner[4], Michel Rozenbaum[1], Nina Boulman[1] and Doron Rimar[1], [1]Bnai Zion Medical Center, Haifa, Israel, [2]Bnai Zion, Atlit, Israel, [3]Bney-Zion Medical Center, Baqa Elgharbiya, Israel, [4]Bnai Zion Medical Center/Technion, Haifa, Israel

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: B cell depleting therapy (rituximab) and Autologous Hematopoietic Stem Cell transplantation (AHSCT) result in impaired ability to mount a humoral immune response.

Evusheld (tixagevimab co-packaged with cilgavimab) is a passive vaccine against SARS-CoV-2.

The aim of our study was to evaluate prospectively the efficacy and safety of evusheld vaccine for preventing SARS-COV2 infection in patients with autoimmune rheumatic diseases (AIRD) treated with rituximab or AHSCT.

Methods: We compared rheumatoid arthritis and systemic sclerosis patients treated with rituximab or AHSCT, who agreed to receive evusheld, to patients who refused. The primary outcome was the risk of severe COVID19 infection (omicron variant) defined as pneumonia, hospitalization, or death. A secondary outcome was safety.

Table 1 - Clinical and epidemiological characteristics

		Evusheld injection		
Characteristic	N	No, N = 26[1]	Yes, N = 45[1]	p-value[2]
Gender(female)	71	20 (77%)	40 (89%)	0.2
Age	62	55 (15)	59 (12)	0.5
Autoimmun disease	70			0.5
RA		10 (38%)	18 (41%)	
SSC		9 (35%)	18 (41%)	
ANCA VASCULITIS		5 (19%)	3 (6.8%)

>3		2 (18%)	9 (32%)	

[1] n (%); Mean (SD)

[2] Fisher's exact test; Wilcoxon rank sum test; Pearson's Chi-squared test

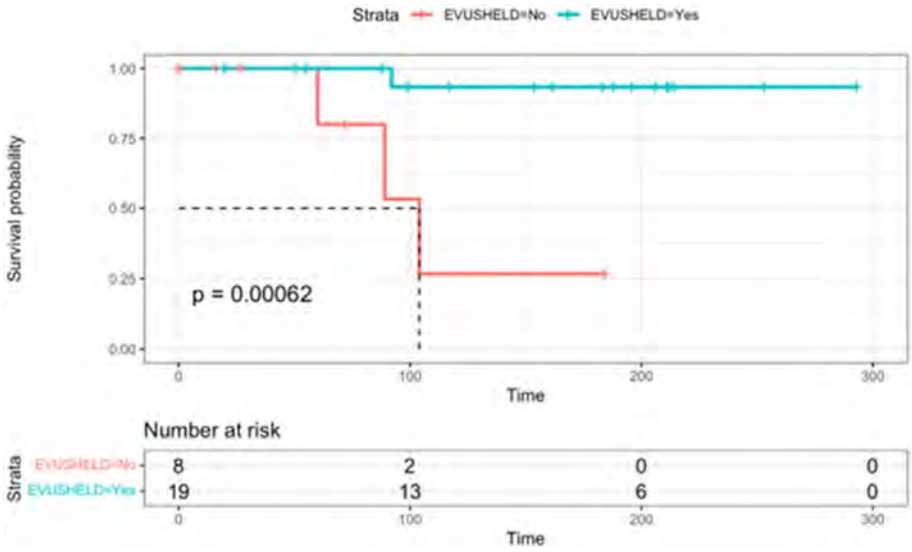

Figure 1 - The risk for severe COVID-19 infection - Kaplan-Meir Survival curve

Results: A total of 45 AIRD patients (41 treated by rituximab and 4 systemic sclerosis patients who underwent AHSCT) in the intervention group and 26 in the control group, were recruited. There was no difference between the groups with regard to sex, age, years of rituximab treatment, previous mRNA vaccination and serum immunoglobulins level (table1). No difference in the infection rate was found between intervention group and control group (21 (49%) versus 12 (48%) respectively). Four patients had a severe infection, 3 in the control group and 1 in the intervention group. Evusheld reduced the risk for severe infection by 94% (HR 0.06, 95% CI 0.01-0.76, p-value 0.017) (figure 1). There were no adverse events related to evusheld injection.

Conclusion: Evusheld decreased the risk for severe COVID19 infection in patients with AIRD treated with B-cell depleting therapy or after AHSCT in a period in which Omicron BA.5, BQ1 and BQ.1.1 variants were prevalent in Israel, with a favorable safety profile.

Acute Effects of Intravenous Iloprost on Finger Power Doppler Ultrasound in Scleroderma Patients

Sofia Testoni[1], **Luca Magnani**[2], Caterina Tomassini[3], Alessia Laneri[3], Carlo Salvarani[4] and PIERLUIGI MACCHIONI[2], [1]Università degli Studi di Modena e Reggio Emilia, San Giovanni in Persiceto, Italy, [2]Azienda USL -IRCCS di Reggio Emilia, Reggio Emilia, Italy, [3]Università degli Studi di Modena e Reggio Emilia, Modena, Italy, [4]Azienda USL -IRCCS di Reggio Emilia and Università di Modena e Reggio Emilia, Reggio Emilia, Italy

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: So far few studies explored ultrasound (US) as a tool to assess vascular subcutaneous involvement in patients affected by systemic sclerosis (SSc). We aim to evaluate the acute vascular effects of intravenous iloprost (ILO) infusion by power Doppler US (PDUS) examination at periungual (PU) and finger pulp (FP) subcutaneous areas in a consecutive series of SSc patients.

Table 1. Demographic, clinical and laboratory characteristics of the 38 patients. SD: standard deviation; ILD: interstitial lung disease; HAP: pulmonary arterial hypertension; ERA: endothelin receptors antagonists; CCB: calcium channel blockers; PDE5i: Phosphodiesterase type 5 inhibitors; ENA: extractable nuclear antigen; ACA: Anti-centromere antibody.

	number (%)	Mean ± SD	Median (range)
Disease Duration (years)		13.3±10.5	10 (1-40)
Age (years)		55.9±13.1	54.5 (31-78)
Female/male	35/3 (92/8%)		
Iloprost therapy duration (years)		6.4±5.9	4.0 (0.2-25.0)
Disease features

Diffuse	19 (50%)		
Limited	16 (42.1%)		
Other	3 (7.9%)		

Table 2. Values of Total PD score of the 77 observations before and after iloprost infusion. SRM = Standardized Response Mean (< 0.20 = trivial, 0.20-0.40 = small, 0.40-0.80 = moderate; > 0.80 = good).

	PD score T0	PD score T1	SRM*	p
Total PD score (TotS)	9.43±6.34	16.1±6.6	0.88	<0.001
Total Periungueal PD score (TotPU)	5.21±3.37	9.17±3.7	0.85	<0.001
Total Finger Pulp PD score (TotFP)	4.22±3.75	6.9±4.22	0.68	<0.001

Methods: Seventy-seven consecutive observations were done in 38 SSc patients (ACR/EULAR criteria). FP and PU vascularization of the 1st, 2nd, and 3rd finger of the dominant hand were evaluated before and after ILO infusion (dosage 0.5-2.0 ng/kg/min for 4-6 hours) using an Esaote MylabClassC, (Genoa, Italy) machine equipped with a 22-8 Mhz multifrequency linear probe. The image with the highest presence of PD signal at PU and FP for each finger was scored according to a semiquantitative 0-5 scale (0 = no signal, 5 = signal of healthy controls) and summed up to obtain a total patient PD score (TotS). Single finger PU PD scores were summed to obtain total PU PD score (TotPU). Single finger FP PD scores were summed to obtain total FP PD score (TotFP). Values before and after ILO treatment were compared by T-test for paired samples. No improvement in TotS was defined as a difference between T1 and T0 observation ≤ 0; improvement if the difference between T1 and T0 was 1. Clinical demographic and US data entered in a multivariate logistic regression analysis to evaluate factors predictive of TotS improvement.

Results: Clinical and laboratory features of the enrolled patients are reported in Table 1. The effects of ILO infusion on total PD scores are reported in Table 2. TotS was 9.43±6.34 at T0 and increased to 16.1±6.6 after treatment (**p= < 0.001**). TotS improved in 60 observations, while in 17 there was no variation or worsening. TotPU was 5.21±3.37 at T0 and increased to 9.17±3.7 after treatment (**p= < 0.001**). TotFP was 4.22±3.75 at T0 and increased to 6.9±4.22 at T1 (**p= < 0.001**). At multivariate logistic regression analysis concomitant therapy with calcium channel blockers (CCB) was predictive of PD total score improvement > 0 (**OR 4.53**; 95% CI 1.14-18.1 **p=0.032**) and concomitant pulmonary arterial hypertension (HAP) was associated to lack of response (**OR 0.27**; 95% CI 0.08-0.94 **p=0.04**).

Conclusion: PDUS examination of the PU and FP area can demonstrate an ILO acute vascular effect in SSc patients. Therapy with CCB and presence of HAP impact on PD score improvement.

Intravenous or Subcutaneous Immunoglobulins as Potential Treatment for Gastrointestinal, Cutaneous and Vascular Involvement in Systemic Sclerosis: Data from an Italian Cohort of 65 Patients

Francesco Bonomi[1], Arianna Damiani[1], Carmela Coccia[1], Juela Levani[1], elisa Fiorentini[2], silvia peretti[1], Gemma Lepri[1], martina orlandi[1], francesca bartoli[1], marco Matucci Cerinic[3], silvia bellando randone[1] and serena guiducci[1], [1]Department of Experimental and Clinical medicine, Division of Rheumatology, Azienda Ospedaliero Universitaria Careggi, University of Florence, Florence, Italy, [2]Department of Experimental and Clinical medicine, Division of Rheumatology, Azienda Ospedaliero Universitaria Careggi, University of Florence, Firenze, Italy, [3]Unit of Immunology, Rheumatology, Allergy and Rare diseases, IRCCS San Raffaele Hospital, Milan, Milan, Italy

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of systemic sclerosis (SSc) is challenging, and in the last 2 decades there has been an increasing interest for immunoglobulin (Igs) treatment as it exhibits both immunomodulatory and antifibrotic properties. Currently, its efficacy on gastrointestinal (GI), skin and muscle involvement has been described only in case series with limited numbers of patients. With this study we wanted to evaluate the efficacy of Ig therapy on GI, cutaneous, and vascular involvement of SSc.

Table 1. Variation trend and significancy of clinical items from BL to T12

	BL	T6	P value (BL-T6)	T12	P value (T6-T12)
GER, n (%)	59 (90.8)	31 (49.2)	**p<0.0001**	15 (25.9)	**p<0.001**
Diarrhea, n (%)	31 (49.2)	12 (19.4)	**p<0.0001**	4 (6.9)	0.0771
mRSS, median (min-max)	10 (0-50)	6 (0-34)	**p<0.0001**	3 (0-23)	**p<0.0001**
Digital edema, n (%)	50 (76.9)	28 (44.4)	**p<0.0001**	17 (30.9)	0.131
Digital ulcers, n (%)	25 (38.5)	9 (14.1)	**0.0022**	3 (5.3)	0.0736
VCP, n - Normal, n (%) - Early, n (%) - Active, n (%) - Late, n (%)	64 - 2 (3.1) - 14 (21.9) - 29 (45.3) - 19 (29.7)	45 - 7 (15.6) - 7 (15.6) - 16 (35.6) - 15 (33.3)	**0.00448**	42 - 8 (19.0) - 10 (23.8) - 12 (28.6) - 12 (28.6)	0.00596

Methods: A retrospective observational study was conducted enrolling patients with diagnosis of SSc (ACR/EULAR 2013) and that were treated with Ig (intravenously or subcutaneously) at a 2 gr/kg/month dosage for at least 6 months. Demographical data, antibodies positivity, associated therapies (vasoactive and immunosuppressants) and disease duration were

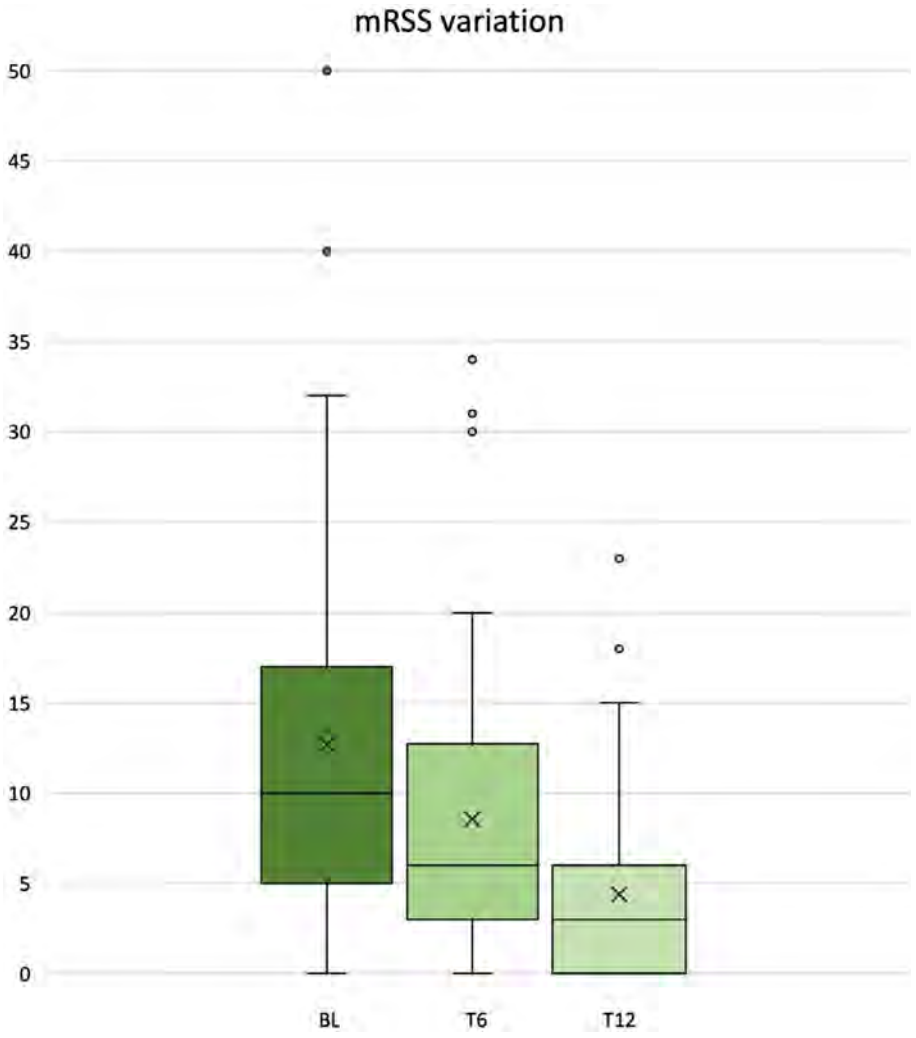

Figure 1. Variation of mRSS from BL to T12

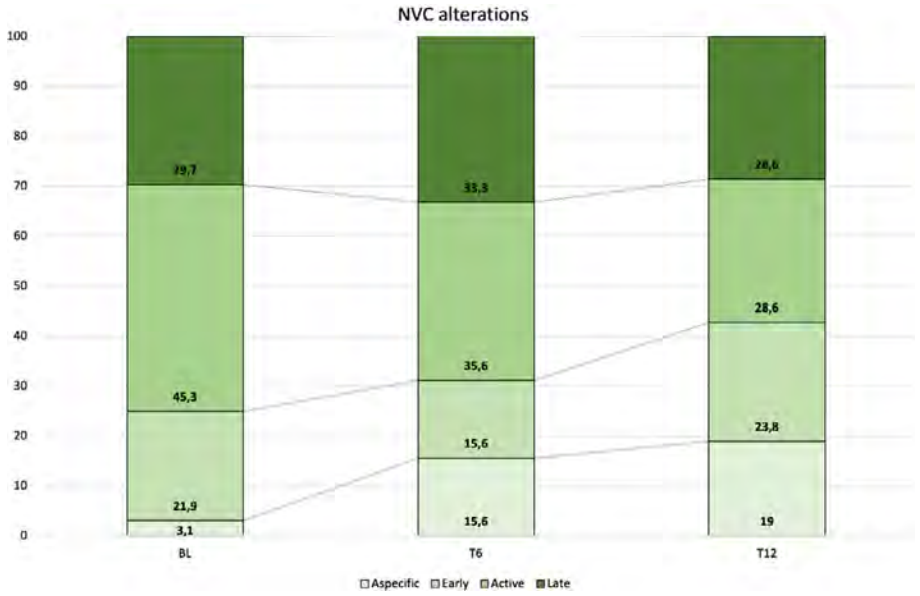

Figure 2. Variation of NVP from BL to T12

collected from clinical records. Moreover, the presence of diarrhea, gastroesophageal reflux (GER), digital edema, digital ulcers (DUs), as well as the modified Rodnan Skin Score (mRSS) and videocapillaroscopic pattern (VCP; normal, early, active, late) were assessed at baseline (BL) and after 6 (T6) and 12 (T12) months of Ig therapy. Variation of these items from BL to T6 and T12 was tested by Paired T Test, Mc Nemar test, Wilcoxon's signed rank test as appropriate. Regression analysis were than performed to assess influence of possible confounders variables (vasoactive and immunosuppressants drugs) on outcome variables (VCP, digital edema, DUs)

Results: Sixty-five patients were enrolled, and their clinical data were analyzed. Mean age was 56.18 (± 12.32) and median disease duration was 10.00 years (min-max 1.00-38.00). Sixty-three patients (96.9%) were ANA positive, with positivity for anti-centromeric antibodies in 23 (35.4%), Scl-70 in 27 (41.5%) and RNA polymerase III in 8 (12.3%) patients. Fifty-five patients received the treatment intravenously, the remaining subcutaneously. Table 1 summarizes the trend and significancy of clinical items from BL to T12. At BL, 49.2% of patients complained diarrhea, 90.8% GER, 76.9% digital edema; 38.5% DUs. VCP was normal in 3.1% of patients, early in 21.9%, active in 45.3%, and late in 29.7%. Also, median mRSS was 10 (min-max 0-50). At T6, median mRSS significantly improved [6 (min-max 0-34), $p< 0.0001$] together with VCP (normal in 15.6%, early in 15.6%, active in 35.6%, and late in 33.3%, $p=0.00448$). Moreover, a significant reduction of the prevalence of GER (49.2%, $p< 0.0001$), diarrhea (19.4%, $p< 0.0001$), digital edema (44.4%, $p< 0.0001$), DUs (14.1%, $p=0.0022$) was found. At T12, median mRSS improved even more [3 (min-max 0-23), $p< 0.0001$] along with VCP (normal in 19.0%, early in 23.8%, active in 28.6%, and late in 28.6%, $p=0.00596$). Also, the prevalence of GER was lower (25.9%, $p< 0.001$). Regression analysis did not evidence any influence of other treatments on the tested outcome variables.

Conclusion: Our data confirm the efficacy of Ig on GER and diarrhea and skin involvement and, for the first time, also a possible positive effect on VCP. Further studies on larger samples are required to confirm these findings.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

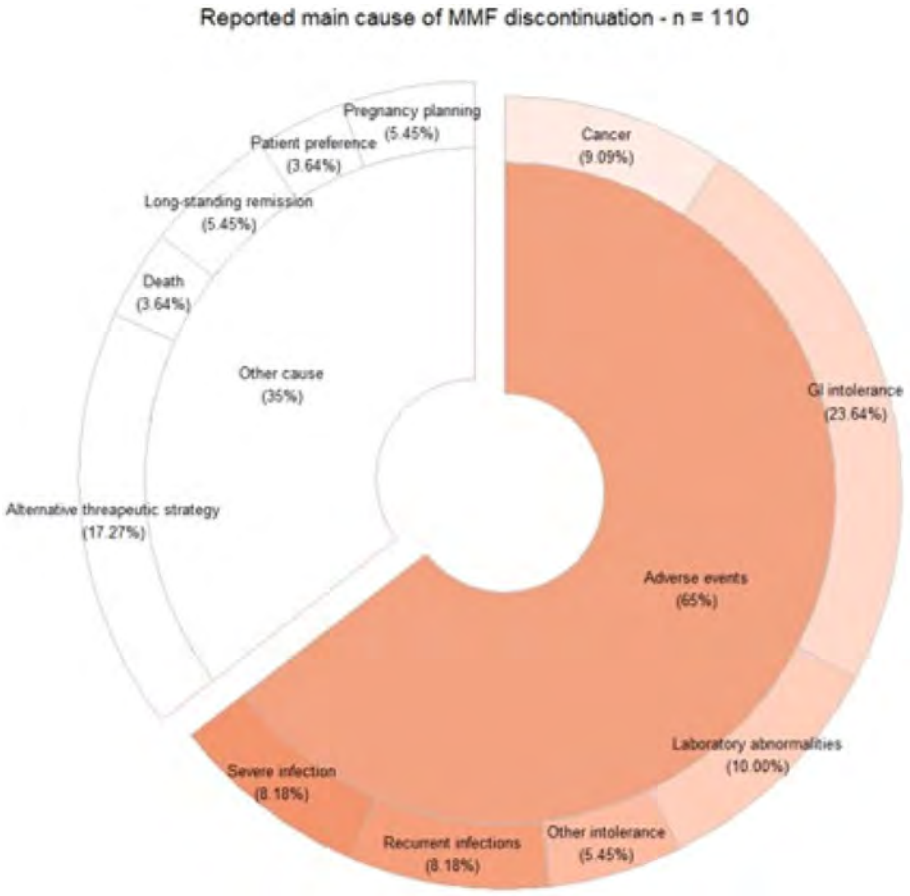
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Mycophenolate mofetil (MMF) is a first-line immunosuppressant treatment for systemic sclerosis (SSc), particularly for patients with interstitial lung disease (ILD) and diffuse skin involvement. MMF persistence reflects its efficacy, the risk or occurrence of adverse events (AEs), the risk of relapse after discontinuation, and the availability of therapeutic alternatives. Real-life evidence about early and long-term adverse events (AEs) associated with the use of MMF in SSc is lacking, and predictors of drug discontinuation are not identified yet. We aimed to investigate a) the incidence and causes of MMF discontinuation due to AEs in SSc patients and b) the incidence and association of severe infections, lower airway infections, and unbearable gastrointestinal symptoms leading to MMF discontinuation.

Methods: Medical records of SSc patients treated with MMF from January 2012 to December 2021 and followed up in 9 tertiary centers were retrospectively collected and evaluated. Clinical and demographic data included AEs (i.e., infections, gastrointestinal (GI) intolerance, laboratory abnormalities, new cancer diagnosis) and reasons for dosage reduction or discontinuation. Infection severity was ranked according to the GREFIG study classification system. A competing risk analysis was performed to explore the association of AE-related MMF discontinuations with alternative causes of MMF discontinuation as a competing risk.

Results: Data from 545 SSc patients observed for 3.1 years (IQR 1.4-4.9) were analyzed. Combination therapy with steroids was recorded in 37.0% of patients, while in 14.7% of cases, MMF was associated with additional immunosuppressants. Almost 25% of patients did not tolerate the prescribed dose of MMF because of drug-related AEs. MMF discontinuation rate was 6.6/1000 patients-year (95% IC 5.3-8.0) with a 70.3% 5-year retention rate (95% IC 0.65-0.76). Gastrointestinal intolerance and infections (GREFIG grades 2-3) were the most common AEs leading to discontinuation with



different time patterns. Infection severity tended to increase over time. Respiratory infections were the most commonly reported infections. The risk of major infections (grades 2-3) was associated with male gender (HR 1.9, 95% IC 1.3-2.9), anti-centromere antibody (HR 1.7, 1.1-2,6), pulmonary hypertension (HR 2.0, 95% IC 1.3-3.0), late capillaroscopy pattern (HR 1.5, 95% IC 1.0-2.3), and concomitant COPD (HR 3.0, 95% IC 1.4-6.4) at univariate analysis.

Conclusion: One in four SSc patients had to reduce or discontinue MMF due to adverse events, primarily gastrointestinal intolerance and infections. Factors linked with microvascular impairment served as a risk factor for severe infections during MMF treatment.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Lung transplantation (LT) is gaining ground in managing advanced ILD in SSc patients. However, concerns remain among surgeons due to SSc's complexity, multiorgan involvement (including oesophagus), and heightened risk of post-transplant complications. To date, outcomes focused on survival rates, lacking a comprehensive evaluation of how LT and immunosuppressive therapy affect SSc disease activity and progression. The aim of the study was to evaluate in a cohort of SSc patients, survival, complications, and post-LT outcomes regarding extra-pulmonary involvement, disease activity according to the EUSTAR activity index, and progression of lung scleroderma function

Methods: A retrospective analysis was conducted on SSc patients post-lung transplantation. Outcome variables (mRss, FVC, ulcers, EUSTAR activity, NVC) were evaluated at baseline, 6 months, 1 year, and 2 years. The study aimed to assess cutaneous involvement, lung function, ulcers, and disease activity in these patients

Results: We evaluated 11 patients, 9 with dcSSc and 2 lcSSc. M/F=8/3. Median disease duration: 10.33 yrs (IQR 9,42). Main reason for LT was ILD-related end-stage lung disease (11/11); 6/11 patients had concomitant PAH. NSIP pattern at HRTC scan was the most common one (9/11). Bilateral LT was performed in all patients but 1, who underwent unilateral procedure. Maintenance therapy with tacrolimus was the standard of care after LT and the mean dosage decreased from 4.31 mg at 6 months to 1.22 at 2 years. Perioperative complications included 4 acute rejects, with only 1 *exitus*. The survival at 1 and 2 years was of 100%, and 81,8% respectively. Mean value of FVC significantly increased from 42±10% at baseline, to 63.6±18% at 6 months, 69.8±22% at 1 year, and 76.6±6% at 2 years ($p< 0.001$ for all). Mean mRSS at baseline was 6.8 decreasing at 6 months (4.6), 1 yr (4.2) and 2yr (1.5) ($p< 0.0001$). 7 patients with active ulcers before transplantation experienced their resolutions after 6 months, with just one patient relapsing after 1 year, and another one after 2 years. In the same patients, the NVC features improved from late to active pattern. The EUSTAR activity index decreased progressively over time from 3.23 ±1.5 at baseline to 0,7 ±0.6 after 2 years ($p< 0.0001$)

Conclusion: To our knowledge this is the first study evaluating clinical outcomes and disease activity in SSc patients following LT. Previous studies have primarily focused on survival and post-transplant complications. The survival rate was 82% with no unexpected complications. Despite the underlying disease, we observed improvements in FVC, and disease activity scores consistently decreased after LT. These results were sustained throughout the follow-up period. Our findings confirm

that LT is a viable therapeutic option for progressive, end-stage lung disease in SSc. Prolonged immunosuppressive therapy and improved tissue perfusion may contribute to the persistent reduction in disease activity.

A Retrospective Analysis of the Efficacy of Nintedanib in Connective Tissue Disease-Associated Interstitial Lung Disease (CTD-ILD): A TriNetX Database Study

Jasmeen Uppal[1], Kavya Keerthi Vadlamudi[1], Sulman Hasan[2], Ayeesha Kattubadi[1], Meenakshi Mishra[3], Sarwat Umer[1], Samina Hayat[2] and Kinza Muzaffar[2], [1]LSU Health Science Center, Shreveport, LA, [2]Louisiana State University, Shreveport, LA, [3]Oschner, Shreveport, LA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

<**Background/Purpose:** Connective tissue diseases such as scleroderma are frequently associated with interstitial lung disease (ILD). Detection of autoantibodies is crucial in characterizing disease phenotypes, but there remains a lack of substantial data on the association of some autoantibodies present in scleroderma patients with specific ILD patterns. We sought to investigate possible association, describe the phenotypes of scleroderma seen in our study cohort, and review findings from other studies.

Methods: The cohort included adults with scleroderma and ILD who were treated at Mayo Clinic between January 2011 and December 2021. Baseline demographic, serologic, and imaging data were extracted from the electronic medical record. Continuous variables were summarized with median and range, and categorical variables were summarized with frequency and percentage (%). The Kruskal-Wallis Rank Sum test was used for continuous measures and the Chi-square test was used for categorical measures. All tests were two-sided and p-values less than 0.95 were considered to be statistically significant. Analysis programming was performed by R-studio with R version 4.1.2.

Results: A total of 454 patients with both scleroderma and ILD were included in the study. The study cohort had a mean age of 62 years, and 103 patients (22.7%) were males. ILD patterns analyzed included NSIP (83.3%), UIP (11%), probable UIP (2.9%), indefinite UIP (2.9%), OP (1.5%) and LIP (2%). The antibody and symptoms were determined for patients with and without each of these ILD patterns. NSIP patients were more likely to have anti-Scl70 antibodies compared to patients without NSIP (p=0.01). OP patients were more likely to have anti-PM/Scl antibodies compared to patients without OP (p=0.006), and LIP patients were more likely to have anti-U1 snRNP antibodies compared to patients without LIP (p=0.002). LIP patients were significantly less likely to have antiScl70 antibodies than patients without LIP (p=0.025). Additionally, UIP patients were also less likely to have anti-Scl70 antibodies than patients without UIP (p=0.017). There were no

clinically significant findings of anti-centromere antibodies or anti-RNA Pol III antibodies in any of the ILD patterns. No symptoms had a clinically significant association with the ILD pattern groups.

Conclusion: Our study examined associations between serologic data and ILD patterns and demonstrated a statistically significant association of anti-Scl70 antibodies with NSIP and antiPM/Scl antibodies with OP. There also appears to be an association between anti-U1 snRNP antibodies and LIP, which has not been demonstrated in the literature thus far aside from another observational study. LIP and UIP patterns were significantly less likely to have association with anti-Scl70 antibodies. We did not find any statistically significant association between anticentromere antibodies and specific ILD patterns. Finally, our study suggests that antibodies may develop in scleroderma but are not necessarily associated with development of ILD. Autoantibodies offer an invaluable tool in predicting disease outcomes and further studies are needed to elucidate this, especially with regards to scleroderma-associated ILD.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The progressive endothelial damage is one of the hallmarks of systemic sclerosis (SSc), an autoimmune connective tissue disease characterized by organ fibrotic involvement. Aminaphtone is a synthetic moleculeregistered for clinical use to treat microvascular disorders that interferes with the expression of vasoactive mediators released by activated endothelial cells [1,2].Nailfold videocapillaroscopy (NVC) is a reliable and non-invasive tool to assess microvascular damage and is considered a morphological biomarker for detection of disease progression in SSc [3].The aim of this retrospective study was to evaluate the safety data and the possible beneficial effects on microcirculation induced by aminaphtone when added to standard therapy (ST) in SSc patients during a four-year follow-up.

Methods: Seventy-five Caucasian SSc patients (7 males and 68 females, mean age 68±15 years; mean disease duration 13 ±7 years) (according to 2013 EULAR/ACR criteria) with secondary Raynaud's phenomenon (RP) started aminaphtone treatment (75 mg BID) in addition to ST. NVC was performed at baseline, after 1 year and 4 years of treatment, adopting the SSc-pattern classification (‘‘Early’’, ‘‘Active’’, ‘‘Late’’ NVC SSc-patterns) [4]. The timing of transition between capillaroscopic

patterns in SSc treated with aminaphtone and ST was compared to SSc patients only treated with ST [5]. The study was conducted in accordance with the principles of the Declaration of Helsinki and Good Clinical Practice, and all patients provided written informed consent.

Results: No life-threatening side effects were reported in the SSc cohort during 4 years of treatment. However, 10% of patients discontinued aminaphtone treatment due to mild intolerance due to well-known adverse events (headache 2.7%, itching 1.3%, others 6%). NVC SSc-patterns in SSc patients treated with aminaphtone remained stable during the observational time frame in 72% of cases, in 8 of the patients (14.7%) was observed a dynamic transition from "Early" to "Active" or from "Active" to "Late" pattern (2.7% and 10.7%, respectively). Of note, SSc patients treated with aminaphtone showed a slower timing of transition between NVC patterns compared to the control group with ST alone (from "Early" to "Active" 57.6 ± 37.4 months vs 28 ± 20 months; P= 0.12 and from "Active" to "Late" 48± 1.0 months vs 36 ± 29 months; P =0.42), even if this difference was not statistically significant.

Conclusion: Aminaphtone seems to be a safe and well tolerated drug in SSc patients with secondary RP during long term treatment. NVC scleroderma-pattern stability over time suggests a possible additional therapeutical effect as a concomitant treatment to ST in SSc patients with RP, but the suggestion deserves further investigations.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II: Clinical Trial, Treatment & Intervention
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab(RTX) has been used for the management of systemic sclerosis(SSc). Its efficacy has been recently confirmed in a phase III clinical trial with extension observation up to 48 weeks, but long term data are limited. We analyzed the real life long-term use of RTX in SSc Italian patients.

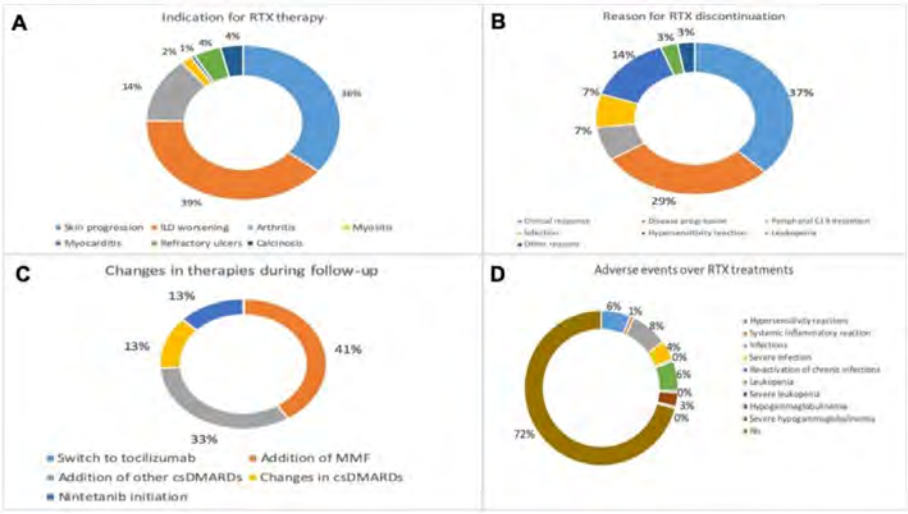
Methods: SSc patients treated with RTX and with a follow-up ^{3}36 months were included. Disease features at baseline, 6, 12, 24 months and latest available follow-up were analyzed. Persistence of RTX, reasons for RTX introduction and suspension, immunosuppressive therapy (ISTs) modifications, and RTX-related adverse events (AEs) were recorded.

Results: the main characteristics of SSc patients are presented in on Table 1 (median follow-up was 72(52-96) months). RTX was primarily started for lung (38.8%), skin (36.2%), or arthritis (13.8%) worsening (Figure 1A). Patients were treated with RTX for a median of 42.5(26.0-69.7) months: 138 patients(90.8%) were treated with ^{3}1 RTX course. In the entire cohort, mRSS significantly improved both at 6 months and at final follow- (mRSS: 11.9±8.0 and 8.3±7.4 vs 16.5±9.6) and in dcSSc patients with progressive skin involvement (mRSS: 15.6±9.6 and 9.2±7.9 vs 21.0±10.8)($p< 0.001$ for all). Mean predicted (%) FVC and DLCO remained stable at 6 months and at final follow-up, both in the entire cohort (FVC: 105.1±84.2 and 87.0±23.5 vs 91.1±49.3; DLCO: 69.4±23.2 and 63.0±26.5 vs 62.1±19.7) and in patients with ILD (FVC: 88.7±38.2 and 82.9±22.5 vs 89.0±54.8; DLCO: 63.8±18.0 and 56.9±18.8 vs 58.7±19.9)(p= ns for all). in 41 patients(27.0%) ILD worsened, defined as a decline in pFVC ≥5% or in pDLCO ≥10% at 12±3 months. During follow-up, in 26 patients (17.1%)

Table 1. Demographic and clinical characteristics

	Patients n=152
Age (years), mean ± SD	54.7 ± 12.3
Females, n (%)	121 (79.6)
Disease duration (months), mean ± SD	146.9 ± 79.2
Diffuse cutaneous disease, n (%)	118 (77.6)
Anti-topoisomerase I, n (%)	96 (63.2)
Anti-centromere, n (%)	25 (16.4)
Interstitial lung disease, n (%)	115 (75.7)
Gastrointestinal involvement, n (%)	96 (63.2)
History of digital ulcers, n (%)	91 (59.9)
Musculoskeletal involvement, n (%)	63 (41.4)
Myositis, n (%)	21 (13.8)
Calcinosis, n (%)	26 (17.1)
Pulmonary arterial hypertension, n (%)	21 (13.8)
Primary heart involvement, n (%)	18 (11.9)
Renal involvement, n (%)	2 (1.4)
Previous and concomitant therapies	
Previous csDMARDs therapy, n (%)	141 (92.8)
Concomitant csDMARDs, n (%)	107 (70.4)
Rituximab treatment*	
Rituximab started for multiple clinical indications, n (%)	41 (27.0)
Rituximab routinely planned every 6 months, n (%)*	78 (51.3)
Rituximab re-treatment based on clinical status, n (%)*	74 (48.7)
Rituximab discontinuation, n (%)	70 (46.0)

SD= standard deviasion; n= number; csDMARDs=conventional synthetic disease modifying anti-rheumatic drug. *RTX administered at 1 gr repeated after 15 days in 98.7% of cases.



RTX= rituximab; ILD=interstitial lung disease; MMF=mycophenolate mofetil; csDMARDs= conventional synthetic disease modifying anti-rheumatic drugs.

RTX was stopped for complete clinical response, especially in dSSc ($p< 0.001$); median time to discontinuation was 30.0 [24.0-48.0] months. RTX was stopped due to disease progression in 20 patients (13.2%) and due to infections in 5 (3.3%) (Figure 1B-C). AEs were recorded in 42 patients (27.6%)(Figure 1D). Discontinuation for both clinical remission or AEs was not influenced by indication for RTX, disease features or therapeutic scheme (p=ns).

Conclusion: our study shows that in Italian SSc patients, RTX is used as a long-term immunosuppressive drug due to its clinical effectiveness and satisfactory safety profile. The most common reason for RTX suspension was indeed clinical remission, whereas infectious concerns were only marginal.

ANCA-associated Vasculitis Incidence in a Norther Spanish Health Region

Salma Al Fazazi[1], Fabricio Benavides[2], Alba Herrero-Morant[3], Vanesa Calvo Río[4], monica renuncio garcia[2], clara escagedo Cagigas[2], maria rodriguez Vidriales[2] and Ricardo Blanco[5], [1]Hospital Universitario Puerta Del Mar, Cádiz, Spain, [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [3]Hospital Universitario Marqués de Valdecilla, Ontinyent, Spain, [4]Valdecilla Hospital, Santander, Spain, [5]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) includes granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) or microscopic polyarteritis (MPA). Precise estimation of the incidence of AAV has been difficult due to the absence of reliable diagnostic criteria.

To estimate the incidence in a Northern Spanish population-based cohort.

Methods: Population-based study of 132 patients diagnosed with small vessel vasculitis between 1994 and 2022 in a tertiary hospital. Finally, 98 patients were included as AAV according to ACR/EULAR 2022 criteria (1). Incidence was estimated by gender, age, and year of diagnosis.

Results: AAV was diagnosed in 98 (49 women/ 49 men) patients: GPA (n=47, 48%) MPA (n=37,37.8%) and EGPA (n=14, 14.3%). Annual incidences were estimated in AAV (**Figure**). GPA annual incidence in our population area in the 1994-2022 period was 2.81 per 1,000,000 people, 95% CI: 3.77-1.85 (2.82 [4.35-1.29] in males and 2.80 [4.50-1.09] in females). An upward trend in annual incidence over time was observed with rates ranging from 1.88 in 1994 to 6.84 in 2022 (weak correlation; r^2=0.2729). On the other hand, MPA annual incidence was 2.23 per 1,000,000 people (1.92 [3.55-0.27] in males and 2.46 [4.07-0.85] in females). Rates ranged from 1.88 in 1994 to 1.71 in 2022 with an upward trend over time (very weak correlation; r^2=0.0746). In the case of GEPA, annual incidence was 0.83 per 1,000,000 people, 95% CI: 1.72-0.06 (1.22 [2.74-0.30] in males and 0.46 [2.29-1.37] in females). As in the other types of AAV, there was an upward trend over time with variations of from 1.88 in 1999 to 3.42 in 2022 (weak correlation; r^2=0.3335). A comparison between different geographical areas is summarized in **Table**. Wide variations in annual incidence per million were observed in all AAV (GPA 2.1-34; MPA 2.23-10.4; EGPA 0.64-2.7). The highest annual incidence of all AAV was observed in nordic countries and central Europe while the lowest in Southern Europe.

Conclusion: There seems to be a progressive increase in incidence of AAV over the years in the studied population. Annual incidence in our population was similar to that of other southern European countries.

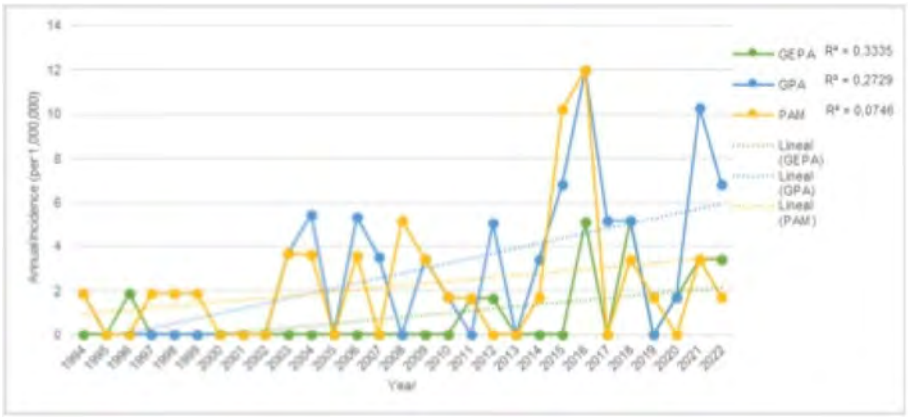

Figure . Annual incidence of AAV in 1994-2022.

Epidemiology and Treatment Outcome of ANCA-associated Vasculitis in South Korea: A Nationwide, Population-based Cohort Study

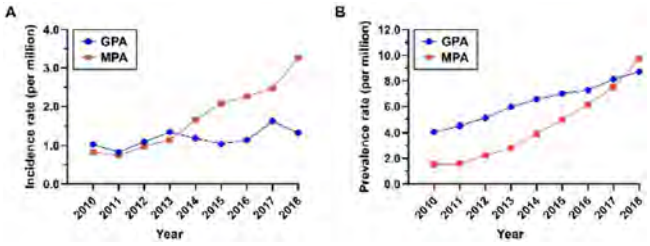
Ji In Jung[1], Jun Won Park[2], Song Jihun[3], Seulggie Choi[2], Sun Jae Park[3], Sang Min Park[2] and Eun Young Lee[4], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea, [2]Seoul National University Hospital, Seoul, South Korea, [3]Seoul National University Graduate School, Seoul, South Korea, [4]Seoul National University College of Medicine, Seoul, South Korea

SESSION INFORMATION

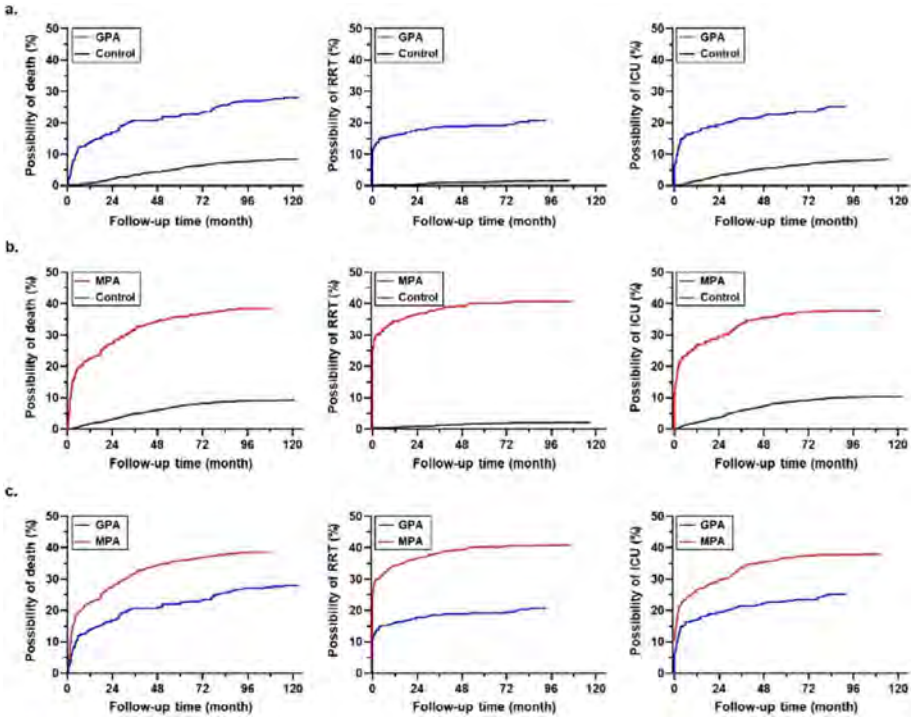
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies on AAV have shown that the epidemiology and clinical features of GPA and MPA differ among countries. Considering their high mortality and morbidity, establishing a national epidemiology for GPA and MPA is necessary for physicians and healthcare systems to estimate the impact and burden of AAV. In this study, we investigated the epidemiological features of granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) in South Korea.

Methods: We identified index cases of GPA and MPA using the 2010-2018 Korean National Health Insurance Service database and Rare Intractable Disease registry for the entire Korean population. Each disease's incidence and prevalence rates and trends over time were analysed. To assess the impact of disease on morbidity and mortality, a comparator group



Annual incidence (A) and prevalence (B) rates (per million) of GPA and MPA over time.



Kaplan-Meier curves indicating cumulative incidence of all-cause mortality, renal replacement therapy (RRT), and admission to intensive care unit (ICU) compared to the comparator group in patients with GPA (A) and MPA (B). Direct comparison of the incidence of these outcomes showed that all-cause mortality, RRT, and ICU care were more common in patients with MPA (C).

indicating the general population was established using nearest neighbourhood matching by age, sex, income, and comorbidity index, at a 5:1 ratio. Morbidity outcomes included the initiation of renal replacement therapy and admission to the intensive care unit (ICU).

Results: A total of 546 and 795 patients with GPA and MPA, respectively, were identified. The incidence rates of both diseases increased with age, and the peak incidence rate was observed in patients aged > 70 years. GPA and MPA showed different trends in incidence rates over time. In 2010, the annual incidence rates (per million) of GPA and MPA were 1.03 and 0.83, respectively. The incidence of MPA has continuously increased over time and increased to 3.26 in 2018. In contrast, the annual incidence of GPA did not significantly change during the observation period and was 1.33 in 2018 (Figure 1).

During the observation period, 90 (28.3%) and 187 (38.6%) patients in the GPA and MPA groups, respectively, died. Although all-cause mortality rates in the GPA and MPA group were significantly higher compared to that in each comparator group (adjusted HR 5.15 [3.21 to 8.38] and 8.62 [6.52 to 11.4], respectively), it was even higher in patients with MPA (adjusted HR 1.69 [1.31 to 2.18]). Patients in the GPA and MPA groups also showed a significantly higher risk of renal replacement therapy and ICU admission than those in the comparator population. In both groups, mortality and morbidity outcomes occurred mainly within the first year from the diagnosis of underlying vasculitis (Figure 2).

Conclusion: In South Korea, the incidence of MPA has increased over time. Although both GPA and MPA had high rates of mortality and morbidity, MPA has a poorer prognosis than GPA.

Abstract Number: 1536

The Impact of COVID-19 Vaccination on ANCA Vasculitis Hospitalisations: A Perspective from Sydney Australia

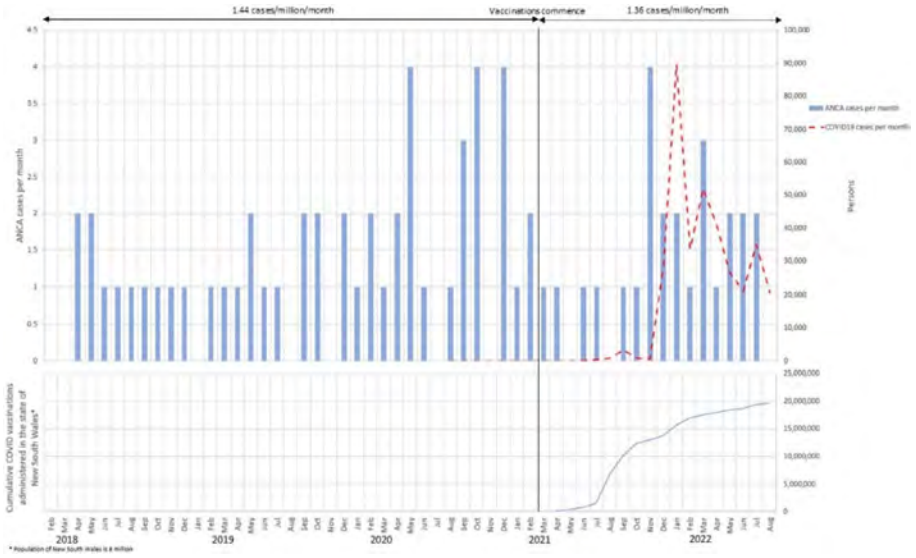
Dane Turner[1], Grant Luxton[1], Kenneth Yong[1] and **Anthony Sammel**[2], [1]South East Sydney Local Health District, Sydney, Australia, [2]Prince of Wales Hospital, Randwick, Australia

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose:

COVID-19 vaccination can trigger a range of inflammatory and auto-immune phenomena, potentially including AAV. There are several international case reports of de novo and relapsed AAV following primary and booster vaccines, though few reports from Australia. Our study assessed the rate of new-onset and relapses of ANCA-associated vasculitis following COVID-19 vaccination, within our Sydney Local Health District of approximately 1 million people.

Methods: All patients admitted between February 2018 and July 2022, with the diagnosis of AAV (Granulomatosis with Polyangiitis or Microscopic Polyangiitis) were included. Patients were classified as de novo if they fulfilled the 2022 American College of Rheumatology classification criteria. Patients were classified as relapsed if they presented with symptoms included in the Birmingham Vasculitis Activity Score (BVAS) and their dose of corticosteroids was increased. The pre-



AAV and COVID-19 cases between 2018 and 2022 within the South East Sydney Local Health District (SESLHD)

vaccination period was defined as February 2018 to February 2021 (37 months), the post-vaccination period was defined as March 2021 to August 2022 (18 months). The rate of AAV cases was calculated using the Poisson count method and adjusted for exposure time.

Results: There were 75 cases of AAV between February 2018 and August 2022, with 51 during the pre-vaccine period and 24 during the post-vaccine period. The case rate of AAV in the pre-vaccination period was 1.44 cases/million/month, and 1.36 cases/million/month in the post-vaccination period. The rate ratio was 0.95 (95% CI 0.56 to 1.57, p = 0.93). There was no significant difference between the characteristics of patients who presented with AAV within 4 weeks of vaccination.

Conclusion: There was no significant increase in the rate of AAV presentations following vaccination within our Sydney Local Health District.

Long-term Observational Study of Interstitial Lung Disease in ANCA-associated Vasculitis

aglaia chalkia[1], Dr Rachel Jones[2], Pasupathy Sivasothy[3] and **David Jayne**[4], [1]Department of Medicine, University of Cambridge, Cambridge, United Kingdom, [2]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom, [3]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom, [4]University of Cambridge, Cambridge, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: There is limited data on the epidemiology and long-term outcome of patients with Interstitial Lung Disease (ILD) in ANCA-associated Vasculitis (AAV) with conflicting results regarding the effectiveness of the immunosuppressive treatment.

Methods: We retrospectively reviewed 1,002 patients with AAV or ANCA associated ILD followed at a single academic medical centre. ILD patients were those with chest CTs showing UIP, NSIP, organising pneumonia or chronic hypersensitivity pneumonia. We compared the occurrence of ILD with the presence and histology of nephritis, focusing on fibrotic phenotypes and assessed the impact of immunosuppressive therapy on the rate of evolution of FVC% and TLCOc% between treatment initiation (T0) and 12(±3) months (T12).

Results: 54 had microscopic polyangiitis (MPA; AAV-ILD), 15 had granulomatosis with polyangiitis (GPA; AAV-ILD) and 20 had ANCA positive ILD without vasculitis (ANCA-ILD). The total prevalence of ILD was 8.9% (n=89) with mean age 69.2±10.8 years and MPO positivity in 82%. In MPO cohort the prevalence of ILD was 19.6% and these patients presented

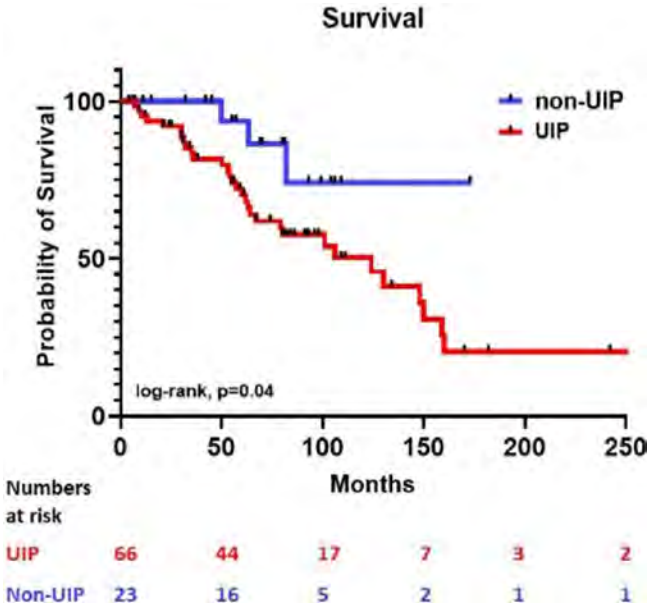

Figure 1. Kaplan Meir survival curve according to UIP and non-UIP ILD groups.

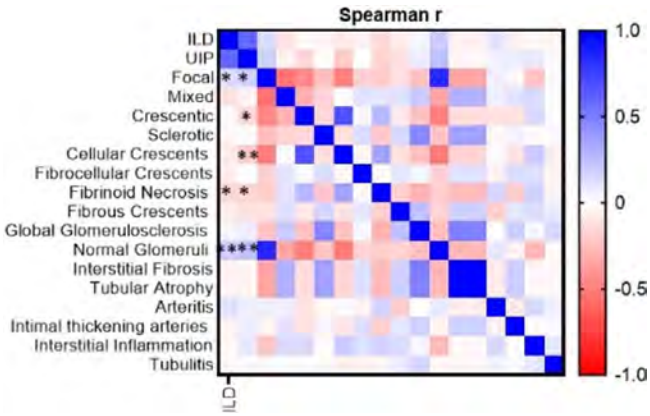

Figure 2. Correlative analysis among renal histopathological parameters shown by heatmap reflecting mean values of Spearman's r, asterisks indicate * $p < 0.05$, ** $p<0.01$.

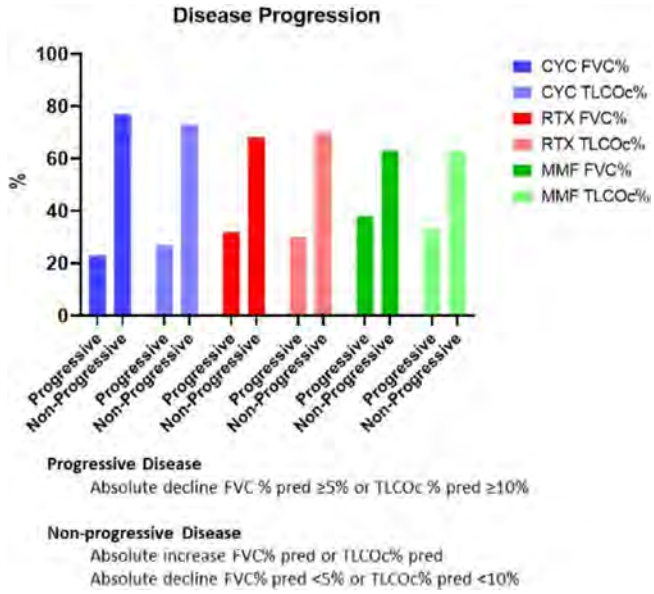

Figure 3. Column chart indicated the percentage of patients with progressive and non-progressive disease over 12 months, according to CYC, RTX and MMF-treated groups.

higher ANCA levels [81.5±50.8 (ILD) vs 59.9±51 (non-ILD), p=0.002]. The median survival was 10 years; the survival with UIP (n=66) was worse compared to non-UIP (n=23) (log-rank, p=0.04, figure 1). No difference in survival between AAV and ANCA-ILD was found. Patients with AAV-ILD and renal involvement (n=47) had better kidney function and lower proteinuria at diagnosis compared to those with nephritis without ILD (n=186) (mean eGFR 41.87 vs 29.6 ml/min/1.73m^2, p=0.007). The presence of ILD was also correlated with lower kidney histological activity (normal glomeruli r=0.193, cellular crescents r=-0.200, fibrinoid necrosis r=-0.151, all p< 0.05, figure 2), while the mixed class in ILD patients characterized with more interstitial fibrosis compared to mixed class in non-ILD (r=0.289, p=0.04) [total cohort 10y ESRD-free survival 91.3 (ILD) vs 82% (non-ILD)]. Median respiratory failure free-survival was 10 years and FVC% at baseline was an independent risk factor for respiratory failure (oxygen requirement) [HR 0.94 CI 95% (0.892-0.994), p=0.030]. When evaluating the impact of immunosuppression on lung progression over 12 months (cyclophosphamide, CYC, n=30; rituximab, RTX, n=25; mycophenolate, MMF, n=8) (figure 3), higher increase of FVC% and lower decline of TLOCc% were reported in the CYC compared to the RTX groups [mean difference: FVC%= -2.49, 95% CI (-10.06 to 5.07), TLCOc=-11.25, 95% CI (-33.08 to 10.58)].

Conclusion: We have reported the prevalence and long-term outcomes of AAV and ANCA associated ILD. Respiratory failure rates were similar between AAV-ILD and ANCA-ILD groups and dominated over ESKD in AAV-ILD. Kidney involvement in ILD presented with less glomerular abnormalities while the mixed class with more fibrotic features compared to patients without ILD. Within the limitations of this study, immunosuppressive treatment appeared to retard progression of lung disease in the short term.

Large Vessel Involvement in Antineutrophil Cytoplasmic Antibody-Associated Vasculitis: A Single Center Experience over Two Decades

Mahmut Kaymakci[1], Mohanad Elfishawi[1], Hannah Langenfeld[2], Andrew Hanson[2], Cynthia Crowson[1], Melanie Bois[1], Umar Ghaffar[1], Ulrich Specks[1], Matthew Koster[1] and Kenneth Warrington[1], [1]Mayo Clinic, Rochester, MN, [2]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) is currently categorized under the small vessel vasculitides and includes granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA). There is limited knowledge about large vessel involvement in AAV (L-AAV), which is mainly described in case reports and small series. L-AAV can involve temporal arteries (TA-AAV), aorta (A-AAV), and periaortic soft tissue (PA-AAV). The objective of this study was to investigate the characteristics of L-AAV.

Methods: Patients older than 18 years at diagnosis of TA-AAV, A-AAV and PA-AAV seen at a single institution between January 1, 2000, and December 31, 2021, were identified through a proprietary medical text search algorithm. Patients were included if diagnosed with L-AAV by the treating physician, fulfilled 2022 American College of Rheumatology/ European Alliance of Associations for Rheumatology classification criteria for GPA, MPA or EGPA, had positive ANCA, and had more than one outpatient or inpatient visit. Arteritis of the temporal artery was based on histopathology whereas the diagnosis of aortitis and periaortitis could be either based on radiology or histopathology. Descriptive statistics were used to summarize patient characteristics and clinical manifestations. Survival rates were estimated using Kaplan-Meier methods. Overall observed survival was compared with lifetable rates from the US population. The standardized mortality ratio was estimated as the ratio of the observed and expected number of deaths.

Results: The study cohort consists of 36 patients with L-AAV. Of those, 23 had p-ANCA/ MPO-ANCA and 13 had c-ANCA/ PR3- ANCA. Mean (SD) age at AAV diagnosis was 63.4 (12.79); 20 (56%) were male. Seventeen patients had TA-AAV, 10 had A-AAV and 9 had PA-AAV (Table 1). Most of the patients (n=25, 69%) were diagnosed with large vessel involvement and AAV within a one-year timespan (Figure 1). Inflammatory markers were elevated at the time of diagnosis of large vessel involvement. Twenty-five (69%) patients had histopathologic confirmation of AAV diagnosis. There was no overlap between TA-AAV, A-AAV and PA-AAV groups. Of the 17 patients with TA-AAV, 6 had inflammation of a temporal artery branch vessel. The most frequent site of involvement in the A-AAV group was the ascending thoracic aorta, whereas in the PA-AAV group, the abdominal aorta was most frequently involved. Glucocorticoids (36/36), rituximab (19/36), and methotrexate (18/36) were the most frequent treatments. During the study period 8 patients died (4 in TA-AAV, 3 in A-AAV, and 1 in PAAAV). There was no difference in mortality between this cohort of L-AAV patients and the general population (standardized mortality ratio: 0.99; 95% CI, 0.43- 1.95) (Figure 2).

Conclusion: This is the largest single-center cohort of patients with L-AAV to date. Clinicians should consider L-AAV in the differential diagnosis of vasculitides especially in the context of positive ANCA and atypical organ manifestations.

Table 1. Features of the study cohort.

Characteristics	Arteritis of Temporal Artery (N=17)	Aortitis (N=10)	Periaortitis (N=9)	Total (N=36)

Digital Ischemia, a Rare Manifestation in Anti-neutrophil Cytoplasmic Antibody (ANCA) Associated Vasculitis (AAV)

Adil Vural[1], Chao Zhang[2] and Kinanah Yaseen[1], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Digital ischemia is a rare, yet severe manifestation observed in AAV. Despite gangrene being a major criterion in the Birmingham Vasculitis Activity Score, this clinical entity is not well described in the literature. We aimed to investigate digital ischemia in AAV.

Methods: This retrospective case series analyzed adult patients with a confirmed diagnosis of AAV and digital ischemia/gangrene, as determined by vasculitis specialists at Cleveland Clinic. Patients without digital ischemia, those diagnosed with a vasculitis other than AAV, and those with digital ischemia related to other causes were excluded from the study. Data collection spanned from January 2002 to January 2023 obtained by chart review.

Table 1. Baseline characteristics.

Table 1. Baseline characteristics

Variable	n=12
Diagnosis Age*	52.6 (18.2)
Gender	
Male	9 (75.0%)
Female	3 (25.0%)
Race	
White	12 (100%)
Active Smoker	4 (33.3%)
Anticoagulation therapy prior to diagnosis (Yes/No)	1 (8.3%)
Warfarin	1 (100%)
Antiplatelet therapy prior to diagnosis (Yes/No)	
No	12 (100%)
History of cardiovascular disease	
Hypertension	7 (58.3%)
Coronary artery disease	2 (16.7%)
Cerebrovascular accident	1 (8.3%)
Prior history of venous thromboembolism	1 (8.3%)
AAV-Disease Type

Cutaneous	7 (58.3%)
Mucous membrane/Eyes	2 (16.7%)
Cardiovascular	1 (8.33%)
Gastrointestinal	2 (16.7%)

Results: Twelve patients met the inclusion criteria. The mean age at diagnosis was 52.6 years (SD=18.2), with a male-to-female ratio of 3:1. 33.3% of the patients were active smokers. All patients were diagnosed with granulomatosis with polyangiitis (GPA) and the majority (75%) tested positive for c-ANCA antibodies and PR3 antigen. Other organ involvements at the time of digital ischemia presentation were pulmonary (75%), followed by upper respiratory tract (66.7%), and renal (66.7%) **(Table 1)**.

In terms of digital ischemia, 5 patients (41.6%) had isolated upper extremity involvement, 2 patients (16.6%) had isolated lower extremity involvement, and 5 patients (41.6%) had in both upper and lower extremities. The mean count of involved digits was 4.5 (SD=2.97). Doppler US was the most frequently employed vascular diagnostic modality (83.3%). The most frequently involved vessels were the digital arteries (33.3%). 75% of patients presented with digital ischemia leading to a new diagnosis of GPA, while 3 patients (25%) developed digital ischemia during a disease flare **(Table 2)**.

Table 2. Summary of digital ischemia features.

Table 2. Summary of digital ischemia features

Location	**n=12**
Upper extremity only	5 (41.6%)

*Digit count presented as Mean (SD) other variables presented as N (column %).

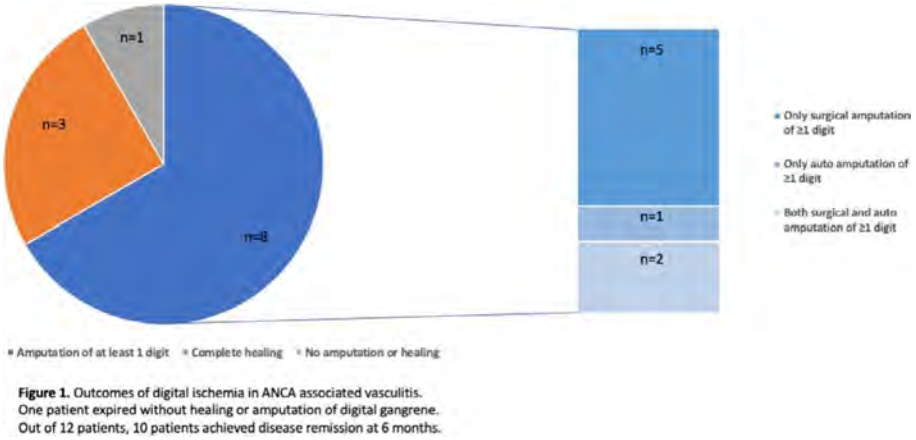

Figure 1. Outcomes of digital ischemia in ANCA associated vasculitis.
One patient expired without healing or amputation of digital gangrene.
Out of 12 patients, 10 patients achieved disease remission at 6 months.

Figure 1. Outcomes of digital ischemia in ANCA associated vasculitis.

Treatment strategies for induction therapy were cyclophosphamide CYC in 33.3%, and rituximab (RTX) in 50.0% of patients respectively in addition to glucocorticoids. Maintenance therapy predominantly consisted of RTX (41.7%). Following diagnosis, 66.7% of patients received anticoagulation therapy, primarily with warfarin (62.5%), and 41.7% received anti-platelet therapy **(Table 1)**.

At 6 months, remission was achieved in 10 patients **(Figure 1)**. Surgical amputation was required in 58.3% of patients, 25% experienced autoamputation, while only 25% of patients had complete healing of all digital gangrene. Among the 3 patients who had complete healing; 2 patients were on anticoagulation after developing digital ischemia for a treatment of deep venous thrombosis.

Conclusion: This study provides insights into AAV-associated digital ischemia which is a rare manifestation of this disease. When present, digital ischemia can be the initial presenting feature leading to GPA diagnosis and generally it occurs in conjunction with other organ involvement. Therefore, GPA should be on the differential diagnosis for patients presenting with digital ischemia. Despite most patients achieving remission, a high degree of morbidity occurred with surgical and/or autoamputation of single or multiple digits. Further research is needed to evaluate the role of adjunct treatments such as anticoagulation and anti-platelet for this rare manifestation.

Evaluation of the Validity of the 2022 American College of Rheumatology/European Alliance of Associations for Rheumatology Classification Criteria for Antineutrophil Cytoplasmic Antibody-associated Vasculitis for an Asian Population on the Basis of the Patterns of Organ Involvement

Ryo Kuwata[1], Yuko Shirota[2], Tsuyoshi Shirai[3], Hiroyuki Yamashita[1], HIroko Sato[3], Yumiko Oka[2], Takao Kodera[2], Kyoko Motomura[1], Hiroshi Kaneko[4], Junichi Kameoka[2], Hiroshi Fujii[3] and Tomonori Ishii[5], [1]Department of Rheumatology, National Center for Global Health and Medicine, Tokyo, Japan, [2]Department of Hematology and Rheumatology, Tohoku Medical and Pharmaceutical University, Sendai, Japan, [3]Department of Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, [4]Division of Rheumatic Disease, National Center for Global Health and Medicine, Tokyo, Japan, [5]Clinical Research, Innovation and Education Center, Tohoku University Hospital, Sendai, Japan

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The European Medicines Agency (EMA) algorithm has been widely accepted as a conventional and reliable method to diagnose ANCA-associated vasculitis (AAV). In 2022 the ACR/EULAR endorsed new classification criteria for three clinicopathological subtypes of AAV. Epidemiological studies revealed that MPO-ANCA-positive GPA patients are more common in Asia than in northern Europe and the United States. However, the new criteria assign greater importance to ANCA serology than histology and surrogate markers compared with the conventional method.

This study aimed to evaluate the reliability and validity of the new criteria when targeting AAV patients from an Asian background. The performance of the new criteria was assessed with a focus on the phenotypes of organ involvement, including histology and surrogate markers.

Methods: This study included a total of 432 patients diagnosed with MPA, GPA, and EGPA (147, 141, and 144, respectively) by the conventional method at three medical institutions in Japan between 2000 and 2023 (Table). Only Asians accounted for the whole population. Firstly, the distribution of each AAV subtype was examined before and after reclassification according to the new criteria. Secondly, the difference in the proportion of each AAV subtype per phenotype of organ involvement before and after reclassification.

Table. Clinical characteristics of patients diagnosed with MPA, GPA, and EGPA, according to the 2022 ACR/EULAR classification criteria for AAV.

		Total	The EMA algorithm-based diagnosis		
			MPA	GPA	EGPA
Total number of patients, n (%)		432 (100)	147 (100)	141 (100)	144 (100)
Female, n (%)		173 (40)	60 (41)	54 (38)	59 (41)
Age at diagnosis, mean (SD), years		64.3 (16.1)	71.1 (13.7)	65.9 (15.3)	55.8 (15.4)
Items related to the 2022 ACR/EULAR classification criteria for AAV

	Alveolar hemorrhage	14 (3)	13 (9)	0 (0)	1 (1)
	Endobronchial disease	13 (3)	2 (1)	9 (6)	2 (1)
	Pleural effusion	21 (5)	6 (4)	4 (3)	11 (8)
Renal, n (%)		207 (48)	114 (78)	65 (46)	28 (19)
	Pauci-immune glomerulonephritis on biopsy	126 (29)	77 (52)	40 (28)	8 (6)
	Hematuria	207 (48)	113 (77)	64 (45)	29 (20)
Cardiovascular, n (%)		27 (6)	4 (3)	8 (6)	15 (10)
Cutaneous, n (%)		97 (22)	26 (18)	13 (9)	58 (40)
	Purpura/ulcers	93 (22)	24 (16)	12 (9)	57 (40)
	Nodules	2 (0)	0 (0)	1 (1)	1 (1)
Gastrointestinal, n (%)		24 (6)	5 (3)	0 (0)	19 (13)

Results: The patients diagnosed with MPA and EGPA by the conventional method were significantly more likely to be reclassified as the same AAV subtype (146 out of 147 and 142 out of 144 patients [99 % and 98 %], respectively) (Figure 1). On the other hand, the patients diagnosed with GPA by the conventional method were less likely to be reclassified as the same AAV subtype (97 out of 141 patients [69%]). Figure 2 shows the proportion of each AAV subtype per phenotype of organ involvement before and after reclassification. (A and B, respectively). In the conventionally-diagnosed GPA population, those who presented with pulmonary nodules and sinusitis were partially reclassified as MPA, and most of them were MPO-ANCA-positive. Also, those who presented with chronic otitis media and interstitial lung disease were partially reclassified as MPA. However, those who presented with orbital and intracranial nodules were all reclassified as GPA as ever. In the conventionally-diagnosed MPA population, those who presented with alveolar hemorrhage and pauci-immune glomerulonephritis were mostly reclassified as MPA as ever, and most of them were MPO-ANCA-positive. In the conventionally-diagnosed EGPA population, there were almost no significant changes except for two PR3-ANCA-positive patients who were excluded from the diagnosis of EGPA after reclassification.

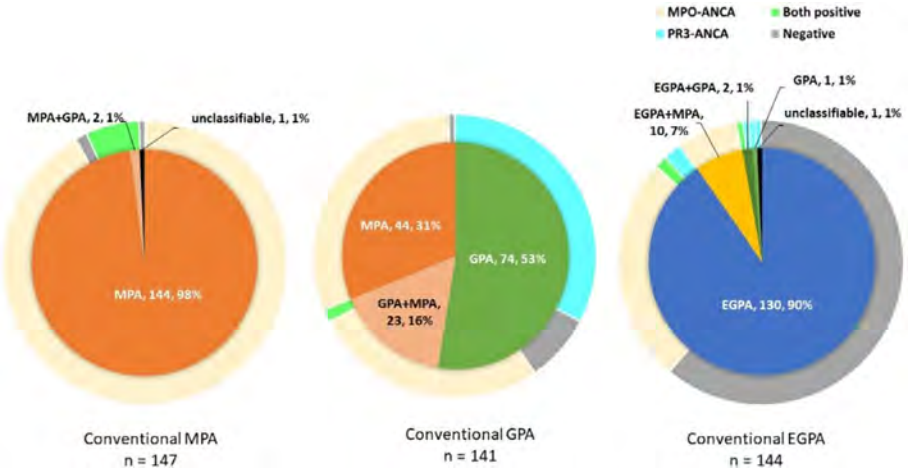

Figure 1. Reclassification of the patients diagnosed with MPA, GPA, and EGPA by the conventional method according to the 2022 ACR/EULAR classification criteria for AAV, including the distribution of ANCA serotypes.

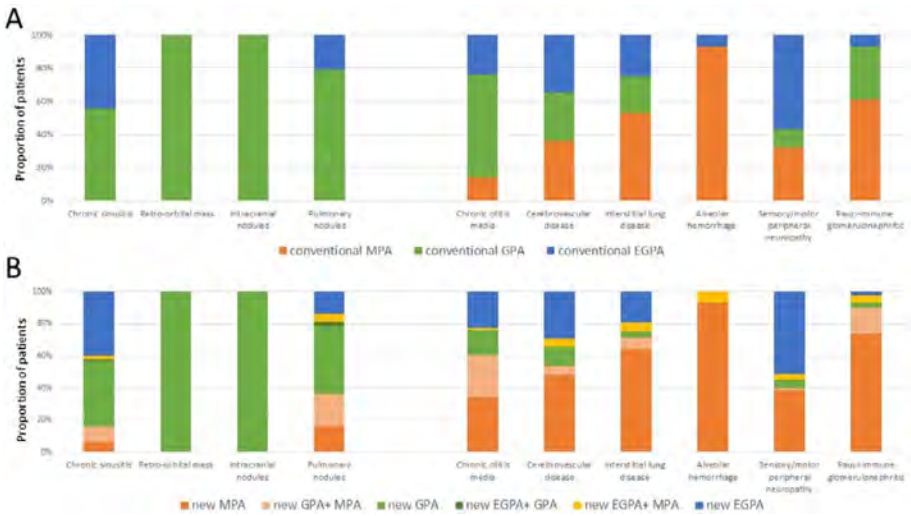

Figure 2.The proportion of patients with each AAV subtype before and after reclassification. (A) conventional criteria and (B) 2022 ACR/EULAR criteria.

Conclusion: The 2022 ACR/EULAR criteria were more likely to reclassify MPO-ANCA-positive patients diagnosed with GPA according to the EMA algorithm as MPA even in the presence of findings suggesting granulomatous inflammation, which led to a diagnostic contradiction. However, PR3-ANCA-positive patients diagnosed with GPA by the conventional method were likely to present with recurrent or severe organ involvement, including orbital and intracranial nodules, and the new criteria also reclassified these patients as GPA.

Neurologic Involvement Does Not Affect Cumulative Survival Rates in Patients with ANCA-associated Vasculitis and Is Less Commonly Associated with Rapidly Progressive Glomerulonephritis in Patients with GPA

Gatr-alnada Gheriani[1] and Petar Lenert[2], [1]University of Iowa Hospital and Clinics, Tiffin, IA, [2]University of Iowa Hospitals and Clinics, Iowa City, IA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to analyze the incidence of nervous system manifestations in a cohort of patients with Microscopic Polyangiitis (MPA) and Granulomatosis with Polyangiitis (GPA), and to identify if neurological manifestations influence the overall survival rates in these patients. We also evaluated how other clinical characteristics of AAV patients correlated with the neurologic involvement.

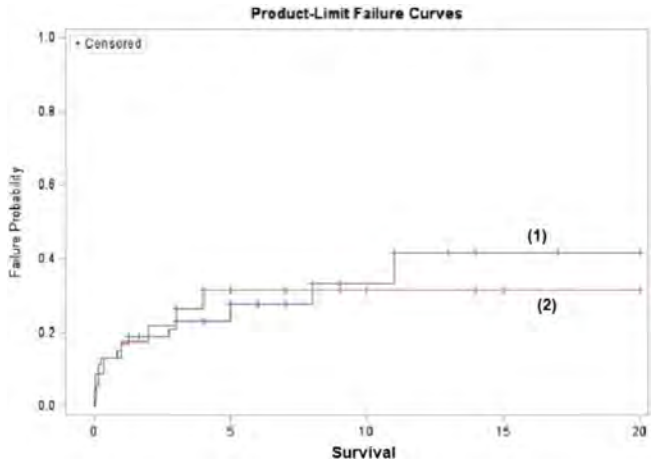

Fig. 1 : Microscopic Polyangiitis (MPA) Kaplan-Meyer's survival curves. (1) Represents those without neurologic involvement (2) Represents those with neurologic involvement

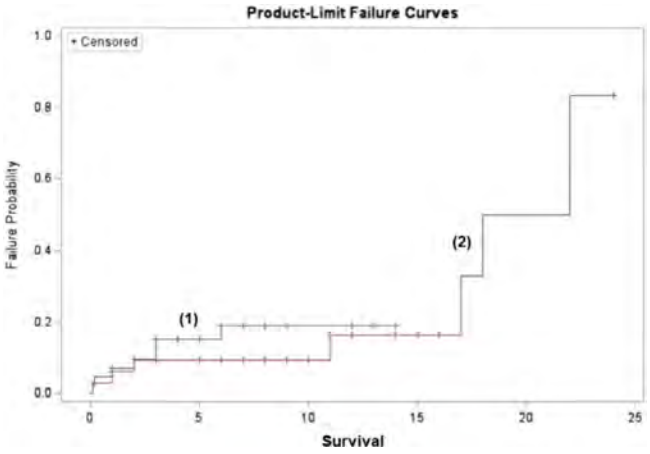

Fig. 2 : Granulomatosis with Polyangiitis (GPA) Kaplan-Meyer's survival curves. (1) Represents those without neurologic involvement (2) Represents those with neurologic involvement

Methods: This is a retrospective single-center cohort study of AAV patients. Medical records of all patients with ANCA-positive serology from 08/2/2014 to 8/7/2021 were analyzed. One hundred and fifty one patients met the 2022 ACR/EULAR classification criteria for either MPA or GPA. An additional 19 patients with limited GPA were diagnosed but not included in this analysis. Data were collected from medical records and analyzed for organ involvement, neurologic manifestations, laboratory findings, electrophysiology and imaging.

Results: One hundred and seventy patients with ANCA associated systemic vasculitis were identified. Of this number, 75 patients were diagnosed with MPA and 76 patients were diagnosed with GPA. The median duration of follow-up was 6.3 years. The majority of the MPA patients were female (60.5%) with a mean age of 58.0 years. GPA patients were mostly male (58.7%) with a mean age of 54.2 years. Each ANCA vasculitis group was analyzed separately as well as cumulative analysis was also completed. A total of 30.3% of MPA- and 44.0% of GPA-patients had neurological involvement. Peripheral neuropathy was the most common neurologic manifestation noted in 60.9% of those with evidence of neurologic involvement in the MPA group. On the contrary, the central nervous involvement was more common in the GPA group with 54.4% involvement. In the GPA cohort, the estimated cumulative survival at 1 year point in patients with neurological involvement was 82.6% in comparison to those without neurologic involvement (83.0%). In the MPA cohort, survival rate was 93.9% in those with neurologic involvement in comparison to those without neurologic involvement (92.9%). The 5-year survival in the MPA group was comparable between those with neurologic involvement (73.6%) and those without neurologic involvement (69.6%). Interestingly, patients with GPA showed a trend towards reduced overall 5-year survival rates in those without neurologic involvement (85.7%) to those that had neurologic involvement (90.9%). Analysis of secondary outcomes showed that the patients with peripheral neurologic involvement were statistically less likely to develop rapidly progressive renal disease, 29.4% vs 63.8% in the GPA group (p value=0.02) while this difference didn't reach statistical significance in the MPA group (50.0% vs 69.4%, p value=0.22).

Conclusion: Neurologic manifestations commonly accompany systemic vasculitis such as ANCA-associated vasculitis. Nervous system involvement causes increased morbidity and reduces the quality of life in patients with either MPA or GPA but does not affect the overall survival rate at either 1 year or 5-year point in these patients. Interestingly, GPA patients with peripheral nervous system involvement were less likely to develop rapidly progressive glomerulonephritis.

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: With improvements in the risks of relapse and mortality in ANCA-associated vasculitis (AAV), a better understanding of disease- and treatment-related complications is necessary to optimize outcomes and personalize care. Multimorbidity (MM) is a patient-centered approach to measuring complications and is associated with risk of death and quality of life in other conditions. It is defined as having multiple chronic conditions but remains poorly understood in AAV. We sought to determine the burden of multimorbidity in AAV.

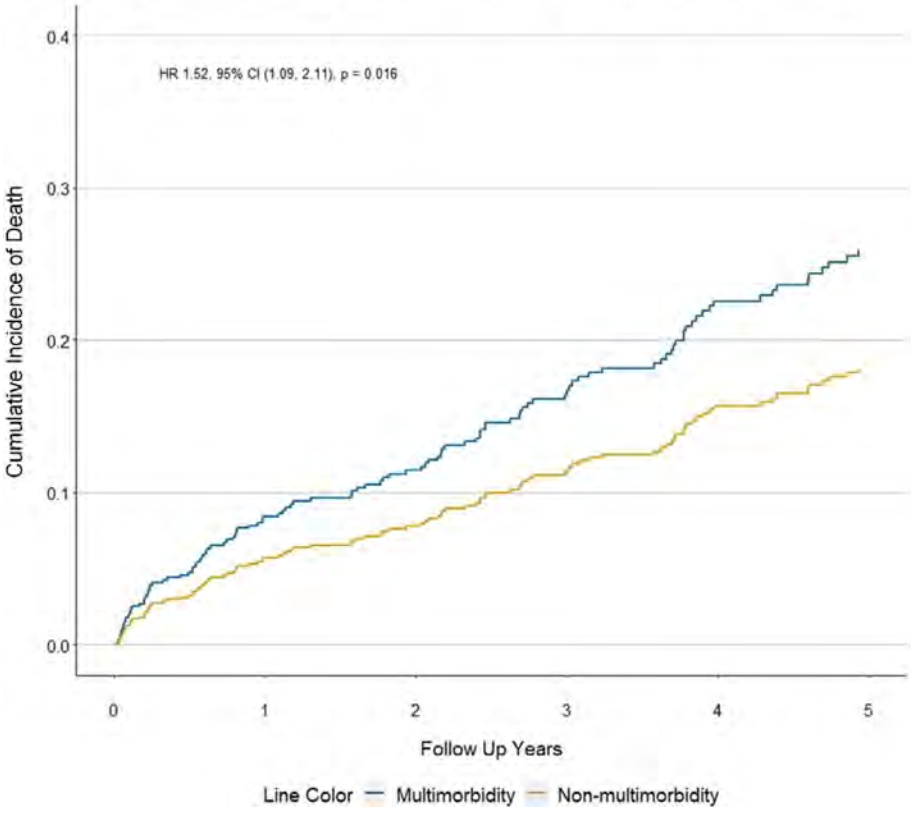
Methods: We used the 2002-2019 Mass General Brigham (MGB) AAV cohort: an inception cohort of consecutive MPO- or PR3-ANCA+ incident AAV cases at a multi-center healthcare system. Up to 10 comparators without systemic rheumatic disease were identified from MGB and matched to each case by encounter date, age, sex, and race. We adapted a definition of MM as the presence of ≥ 2 of 37 chronic conditions, identified by use of ICD-9/10 codes. Manifestations of AAV (e.g., kidney disease) were excluded from this definition. Pre-existing comorbidities were excluded. We determined the proportion of cases and comparators with MM using the Aalen-Johansen method, accounting for the competing risks of death and loss to follow up. We used Cox proportional hazard models to estimate the risk of MM in cases vs comparators and restricted mean survival time to estimate days free of MM. Among patients with AAV, we used latent class analysis to characterize clusters of morbidity among people with MM and time-varying multivariable-adjusted Cox proportional hazards models to assess the association of MM with mortality risk.

Table 1: Baseline Demographic Features	**AAV Cases**	**Comparators**
N	547	5259
Age (mean, SD)	59 (17)	59 (17)
Female (%)	39%	39%
Race		
White	88%	92%
Black/African American	2%	2%
Asian	1%	1%
Other	2%	2%
Unknown	3%	1%
BMI (mean, SD)	28.3 (6.9)	28.5 (7.3)
BVAS/WG (median, IQR)	4 [4, 6]	--
Renal Manifestation (n, %)	351 (64)	--
MPO-ANCA+	372 (68)	--
Initial Treatment		
Rituximab-Based	241 (44)	--
Cyclophosphamide-Based	227 (42)	--

Table 2: The Burden of Multimorbidity	**AAV Cases**	**Comparators**	**Difference in Days Free from Multimorbidity**
Primary Analysis: Proportion with Multimorbidity (>= 2 comorbid conditions)			
Year 1	32.9%	2.3%	
Year 2	44.7%	3.6%	
Year 3	47.6%	4.9%	
Year 4	53.2%	6.5%	
Year 5	57.4%	8.6%	
Primary Analysis: Days Free from Multimorbidity*			
Year 1	282	353	-71 (-81, -61)
Year 2	489	696	-207 (-230, -184)
Year 3	666	1028	-362 (-400, -324)
Year 4	823	1353	-530 (-582, -478)
Year 5	963	1671	-707 (-773, -641)
Sensitivity Analysis: Multimorbidity defined as >= 5 comorbid conditions			
Year 1	7.2%	0.03%	
Year 2	9.0%	0.03%	
Year 3	10.3%	0.03%	
Year 4	11.3%	0.04%	
Year 5	11.6%	0.04%	
Sensitivity Analysis: Annual proportion with multimorbidity, as assessed at each year of follow-up among those surviving and with >= 1 visit in previous 12 months**			
Year 1	27.6%	2.9%	
Year 2	14.6%	2.2%	
Year 3	10.6%	1.5%	
Year 4	14.2%	1.4%	
Year 5	13.1%	1.8%	

Multimorbidity is defined by the presence of at least 2 morbidities identified by ICD9/10 codes used at least twice at least 30 days apart; *Adjusted for age, sex, race, **Cases alive at each year of follow-up were matched to comparators who were alive and, to be eligible for inclusion, both cases and comparators had to have at least 1 visit in the preceding 12 months

Figure: The cumulative incidence of death among those with vs without multimorbidity



Results: There were 547 cases matched to 5,259 comparators (**Table 1**). AAV cases had nearly an 8-fold higher risk of MM vs comparators (**Table 2**, aHR 7.6, 95% CI 6.6-8.7). Over 5 years, each case had an average of 707 fewer days with MM than comparators (963.4 vs 1670.5 days, p< 0.001). At 1 year, two clusters of MM in AAV were identified: Clusters 1A (76%) and 1B (24%). Hypertension and hyperlipidemia were common in Cluster 1A; Cluster 1B was characterized by painful conditions (e.g., headache, back pain, GERD). At 2 years, two clusters were identified: Clusters 2A (82%) and 2B (18%). Cluster 2B was distinguished from 2A by a high burden of cardiovascular (CV) and pulmonary disease. At 5 years, three clusters were identified: Cluster 5A (81%), 5B (11%), and 5C (8%). Morbidities most common in Cluster 5A were hypertension and hyperlipidemia. Cluster 5B was distinguished by a high burden of CV and pulmonary disease; 5C had a high burden of glucocorticoid toxicities (e.g., osteoporosis, obesity, hypertension). Among AAV patients, developing MM is associated with a 52% higher risk of death than not having MM (**Figure**, age-, sex-, race-, and creatinine-adjusted HR 1.52, 95% CI 1.09-2.11).

Conclusion: AAV is associated with a high burden of MM and greater risk of MM than the general population. MM in AAV is characterized by clusters defined by morbidity burdens that vary over disease course and reflect a high impact of disease and its treatment. MM in AAV is associated with mortality risk. The development of interventions to prevent MM and minimize its impacts are needed.

The Association of Frailty with Outcomes in Patients with Vasculitis

Sebastian Sattui[1], John Stadler[2], Renee Borchin[3], Cristina Burroughs[3], Christine Yeung[4], Peter Merkel[4] and Robert Spiera[5], [1]University of Pittsburgh, Pittsburgh, PA, [2]Vasculitis Foundation, Kansas City, MO, [3]University of South Florida, Tampa, FL, [4]University of Pennsylvania, Philadelphia, PA, [5]Hosptial for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty is associated with poor health outcomes including increased risk of hospitalizations, infections, and fractures. In the baseline survey of the VascStrong study, we reported a high prevalence of frailty and pre-frailty in participants with multiple forms of vasculitis. The 1-year follow-up survey collected data on adverse health outcomes, patient-reported outcomes (PRO), and a reassessment of self-reported frailty.

Methods: VascStrong was a longitudinal study using the Vasculitis Patient-Powered Research Network (VPPRN), an internet-based prospective longitudinal cohort. All participants of the baseline survey were invited to participate in the 1-year follow-up survey.

Data elements collected included type of vasculitis, demographic, medications, and PROs that included a patient global assessment (PGA) and several domains of the Patient-Reported Outcomes Measurement Information System (PROMIS). Frailty was measured by the FRAIL scale, a self-reported tool, and patients were classified as robust, pre-frail, and frail based on meeting 0, 1-2, or ≥ 3 criteria, respectively.

Participants reported the occurrence over the prior year of hospitalizations, infections, fractures, and disease flares. Data were analyzed by frailty classification (baseline and follow-up).

Results: Between October 28, 2022 and January 26 2023, 272/328 participants (82.9%) responded to the follow-up survey. Most participants were female (71.0%) and non-Hispanic white, and the most common diagnosis was granulomatosis with polyangiitis (39.0%), followed by eosinophilic granulomatosis with polyangiitis (14.3%), and microscopic polyangiitis (12.9%). Mean age of participants was 62.5 years.

Prevalence of robustness, pre-frailty, and frailty was 47.1%, 33.8%, and 19.1%, respectively. PROs at follow-up showed similar associations to baseline with pre-frail and frail patients reporting worse pain (intensity and interference), fatigue, depression, and physical function (**Table 1**). The majority of participants were classified similarly to their baseline assessment (75%, 50.9%, and 66.1% for robust, pre-frailty, and frailty, respectively). However, transitions in frailty classification between consecutive states were observed from robust to pre-frail (21.2%), pre-frail to robust (38.9%), pre-frail to frail (10.2%), and frail to pre-frail (25%) (**Figure 1**). Transitions from frail to non-frail (8.9%) or non-frail to frail (3.7%) were rare.

Table 1. Patient-reported outcomes among patients with vasculitis by frailty classification Data presented as median (interquartile range). *Raw score, scale 0-10.

Table 1. Patient-reported outcomes among patients with vasculitis by frailty classification

	Robust (N = 128)	Pre-frail (N = 92)	Frail (N = 52)	p-value
Patient Global Assessment	2.0 (0.0, 5.0)	4.5 (1.0, 6.0)	6.0 (5.0, 8.0)	<0.0001
PROMIS-29 Pain intensity*	1.0 (0, 2.5)	3.0 (1.0, 5.0)	5.5 (4.0, 7.0)	<0.0001
PROMIS T-scores				
Anxiety	77.9 (71.2, 81.6)	73.3 (65.3, 81.6)	68.3 (63.4, 71.2)	<0.0001
Fatigue	48.6 (46.0, 53.1)	58.8 (51.0, 66.7)	64.6 (60.7, 69.0)	<0.0001
Depression	49.0 (41.0, 53.9)	52.9 (45.0, 58.9)	57.3 (49.0, 62.2)	<0.0001
Pain Interference	41.6 (41.6, 53.9)	55.6 (41.6, 61.2)	63.8 (58.5, 66.6)	<0.0001
Physical functioning	56.9 (45.3, 56.9)	41.8 (36.7, 48.0)	34.4 (32.1, 36.7)	<0.0001

Data presented as median (interquartile range). *Raw score, scale 0-10.

Table 2. Adverse health outcomes of patients with vasculitis at one-year follow-up based on baseline frailty classification *Severe infections were defined as infections requiring hospitalization. **Flares of disease that required changes in immunosuppressive treatment.

Table 2. Adverse health outcomes of patients with vasculitis at one-year follow-up based on baseline frailty classification

	Total	Non-frail	Pre-frail	Frail	p-value
Hospitalizations	51 (18.8%)	13 (12.0%)	20 (18.5%)	18 (32.1%)	0.0075
Infections	138 (50.7%)	48 (44.4%)	55 (50.9%)	35 (62.5%)	0.0134
Severe infections*	19 (13.8%)	7 (14.6%)	6 (10.9%)	6 (17.1%)	0.7045
Fractures	21 (17.7%)	6 (5.6%)	9 (8.3%)	6 (10.7%)	0.4911
Flares	66 (24.3%)	17 (15.7%)	26 (24.1%)	23 (41.1%)	0.0005
Flares requiring treatment**	45 (68.2%)	9 (52.9%)	20 (76.9%)	16 (69.6%)	0. 3698

*Severe infections were defined as infections requiring hospitalization.
**Flares of disease that required changes in immunosuppressive treatment.

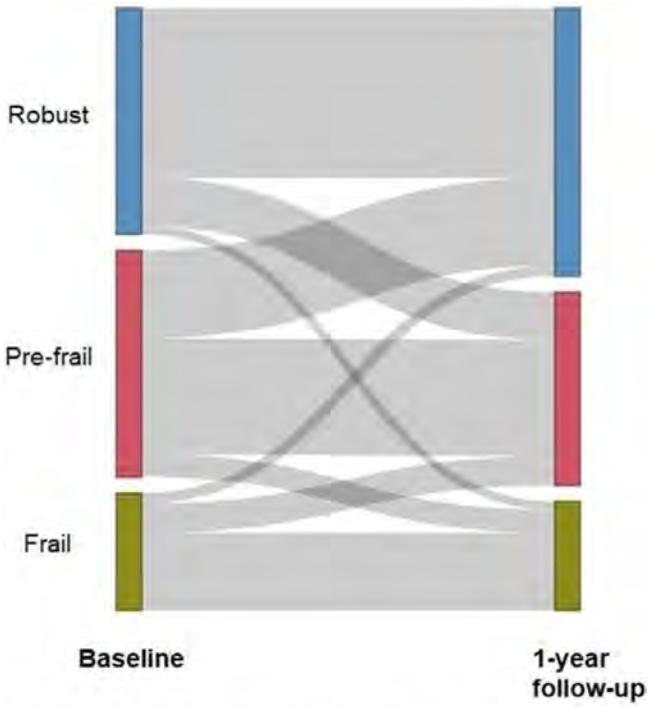

Figure 1. Changes in frailty status among patients with vasculitis at one-year follow-up

Figure 1. Changes in frailty status among patients with vasculitis at one-year follow-up

Hospitalizations, infections, and flares were most frequent in participants classified as frail at baseline (**Table 2**). Similar observations were made using follow-up frailty classification. No difference was observed in severe infections and fractures, that were overall uncommon in the cohort.

Conclusion: At 1-year follow-up, pre-frailty and frailty remained prevalent among patients with vasculitis and were associated with worse PROs. Transitions in frailty status were observed among participants, showing that amelioration of frailty is achievable in a subset of patients with vasculitis. Among patients with vasculitis, pre-frailty and frailty are associated with a substantial 1-year risk of hospitalizations, infections, and flares of disease.

Increased Risk of Severe Infection in Patients with Antineutrophil Cytoplasmic Antibody-associated Vasculitides: A Population-based Trend Analysis

Kai Zhao[1], J. Antonio Avina-Zubieta[2], Hui Xie[3], Natasha Dehghan[4] and John Esdaile[2], [1]Arthritis Research Canada, Coquitlam, BC, Canada, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]Simon Fraser University, Richmond, BC, Canada, [4]University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

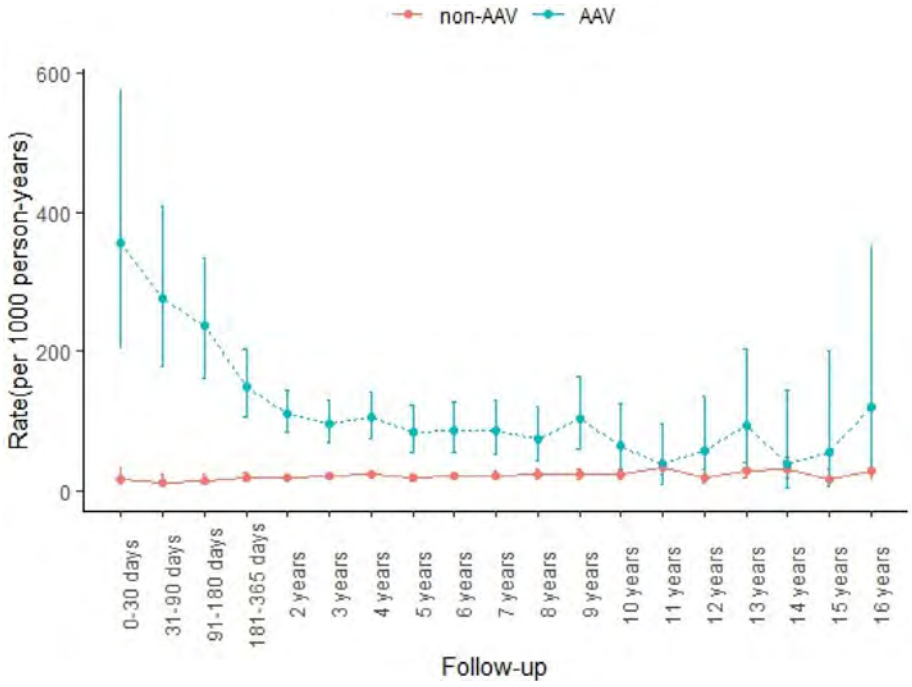
Session Date: Monday, November 13, 2023

Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAVs) are a group of multisystem inflammatory diseases. One of the most serious and common side-effects of GC and immunosuppressant drug use is infection. No studies have explained the change in risk over time. What's more, findings from previous studies may not accurately represent the risk of infection due to AAV as many studies are based on hospitalized patients, small sample sizes, prevalent cohorts, different approaches to defining AAV, and/or limited adjustment of potential confounders. To address these research gaps, we conducted a large population-based study of all patients with incident AAV. We aimed to answer three questions: a) what is the independent risk of first severe infection due to AAV, b) the trajectory of the risk for severe infection in AAV compared to the matched controls , and c) the trajectory of the rate of repeated severe infections in AAV compared to the matched controls.



Comparing secular trends in the rate of severe infections in AAV and non-AAV.

Cohorts	Mixed Logistic Part (No infection vs infection)			Mixed Poisson Part (Infection count)		
	OR	95% CI	P-value	RR	95% CI	P-value
	AAV onset					
AAV	0.00	0.003-0.37	0.01	0.00	0-0.001	<0.001
non-AAV	0.00	0-0.005	<0.001	0.00	0-0.001	<0.001
AAV vs non-AAV	77.01	11.66-508.51	<0.001	2.55	1.36-4.78	<0.001
	Before the 2nd year of AAV onset					
Secular trend in AAV	0.32	0.16-0.62	<0.001	0.97	0.79-1.20	0.79
Secular trend in non-AAV	1.08	0.76-1.53	0.66	1.08	0.89-1.31	0.46
Secular trend in AAV vs non-AAV	0.29	0.13-0.64	0.00	0.90	0.66-1.23	0.52
	After the 2nd year of AAV onset					
Secular trend in AAV	0.85	0.76-0.96	0.01	1.11	1.04-1.17	0.00
Secular trend in non-AAV	1.05	0.93-1.18	0.43	1.04	0.97-1.11	0.23
Secular trend in AAV vs non-AAV	0.81	0.68-0.97	0.02	1.06	0.96-1.18	0.23

Secular trend of infection count in AAV relative to the general population using ZIPMM spline model. Abbreviations: AAV, Antineutrophil cytoplasmic antibody-associated Vasculitis; OR = odds ratio. RR = Rate ratio; 95% CI = 95% confidence interval. RRs and 95% CI are individual-specific (or conditional) estimates.

Methods: We conducted an age- and sex-matched cohort study of all patients with incident AAV using administrative health data from British Columbia, Canada. The primary outcome was the first severe infection after AAV onset necessitating hospitalization or occurring during hospitalization. We used multivariate Cox proportional hazard models to compare time to the onset of infection and estimate hazard ratios. The secondary outcome was the longitudinal counts of severe infection. We used two-part zero-inflated Poisson mixed model (ZIPMM) with splines to assess the secular trend in the infection count.

Results: One in three patients with newly diagnosed AAV developed severe infection (3.8-fold when compared to non-AAV). AAV patients had the highest risk of severe infection during the first 30 days of diagnosis, which dropped at different rates before and after the second year. However, among those at risk for severe infections, the rate of repeated severe infections stayed the same over time within the first two years of AAV diagnosis and even increased over time afterward.

Conclusion: In summary, this is the first large comprehensive population-based study evaluating the risk of infection with incident AAV. Our study demonstrates that one in three AAV patients developed severe infections, demonstrating that the diagnosis of AAV is an independent risk factor for severe infection. ZIPMM spline model suggests that an AAV patient who has experienced infection should be treated differently and properly from one who experiences no infection. Having a more precise understanding of which individuals are likely to experience infection and develop repeated infections could help to ensure a more efficient use of healthcare dollars and perhaps a more accurate attribution of intervention effects. This research is a further step towards a deeper understanding of the prevention, screening and treatment of infection over time. We recommend a closer surveillance for severe infections in AAV patients and routine risk checks for severe infections for AAV patients after diagnosis. Further studies are also warranted to further clarify the relative contribution of inflammation and medication, and to identify modifiable risk factors for infections in AAV.

Abstract Number: 1545

Validation of the 2022 American College of Rheumatology/European Alliance of Associations for Rheumatology Classification Criteria in Patients with ANCA-associated Vasculitis

Liubov Petelytska, Vladyslav Kravchenko and Oleg Iaremenko, Bogomolets National Medical University, Kyiv, Ukraine

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The early diagnosis of ANCA-associated vasculitis (AAV) and treatment initiation may prevent progression to end organ damage, particularly renal disease. Based on the Vasculitis Patient-Powered Research Network study, the delay with diagnosis of AAV draws up to 7 months and 73% of patients are misdiagnosed initially. Recently the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) have proposed the new classification criteria for AAV, but they have not yet validated in a different external cohort. We aimed to validate the 2022 ACR/EULAR classification criteria in a Ukrainian patients with AAV.

Methods: The retrospective study included patients diagnosed between 2010 and 2022 with Granulomatosis with Polyangiitis (GPA), Eosinophilic Granulomatosis with Polyangiitis (EGPA) and Microscopic Polyangiitis (MPA) and undifferentiated vasculitis (UV) in two expert rheumatology centers. All patients have serology confirmation (positivity of antibodies against proteinase-3 and/or myeloperoxidase performed using the ELISA test) and surrogate clinical markers of vasculitis. The 1990 ACR criteria, the 2007 European Medicine Agency (EMA) algorithm and the new ACR/EULAR 2022 criteria were applied for all patients. The level of agreement was evaluated by Cohen's kappa coefficient with determination of sensitivity and specificity.

Results: A total of 42 patients (female: male ratio 1:0.6) diagnosed AAV with mean age at the time of diagnosis of 47.19 ±11.55 years were included. The distribution of AAV patients classified according to various classification criteria is shown in Fig 1. The established diagnosis simultaneously corresponded to the diagnosis according to the previous and new criteria

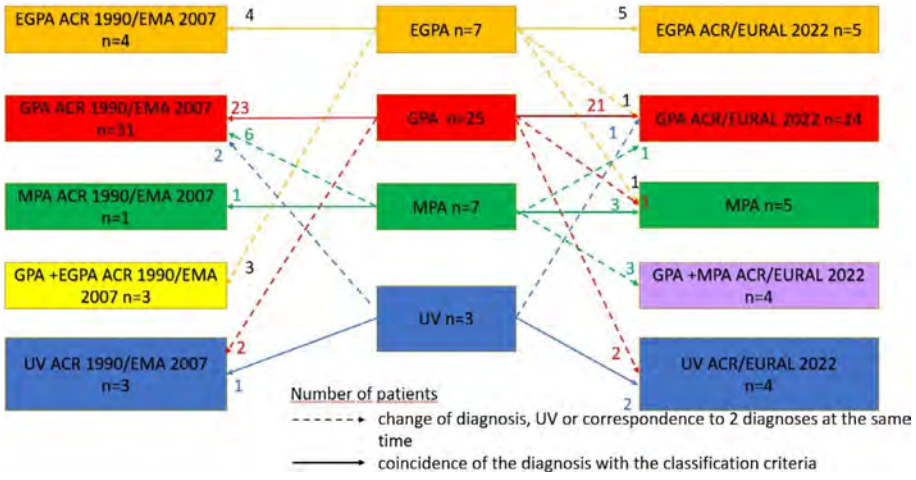

Figure 1. Distribution of patients with AAV according to various classification criteria

in 28 patients, only to the ACR/EULAR 2022 criteria in 8 patients (6 MPA, 1GPA, 1 UV), to the classification criteria of ACR 1990 and the EMA algorithm in 5 patients (3 EGPA, 1 UV, 1 GPA), and one patient has not met any criteria. The ACR/EULAR 2022 classification criteria compared to the previous ones demonstrated better agreement with the established diagnosis of GPA (k 0.6 vs 0.3, sensitivity 88.0% vs 92.0%, specificity 70.6% vs 35.3 %) and MPA (k 0.5 vs 0.2, sensitivity 71.4% vs 14.3%, specificity 88.6% vs 100%) but worse agreement with the diagnosis of EGPA (k 0.8 vs 1.0, sensitivity 71.4% vs 100%, specificity 100% vs 100%).

Conclusion: The ACR/EULAR 2022 classification criteria for AAV demonstrate a good accuracy in the Ukrainian patient population (for GPA, sensitivity - 88%, specificity - 71%, for MPA - 71% and 89%, respectively, and for EGPA - 71% and 100%, respectively) and an advantage compared to the previous classification criteria for GPA and MPA. However, about 10% of the patients are still unclassified and the same amount are matched two diagnoses with the ACR/EULAR 2022 criteria.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic Granulomatosis with Polyangiitis (EGPA) is a rare ANCA-associated vasculitis, characterized histologically by eosinophilic tissue infiltration, necrotizing vasculitis, and eosinophil-rich granulomatous inflammation.

The diagnosis of EGPA is often challenging due to its rarity, heterogeneous and multiorgan clinical presentation, and the overlapping with other vasculitis or eosinophilic disorders. The identification of suspicion signals of EGPA addresses a fundamental practical barrier in achieving timely diagnosis for patients with this rare but potentially devastating disease.

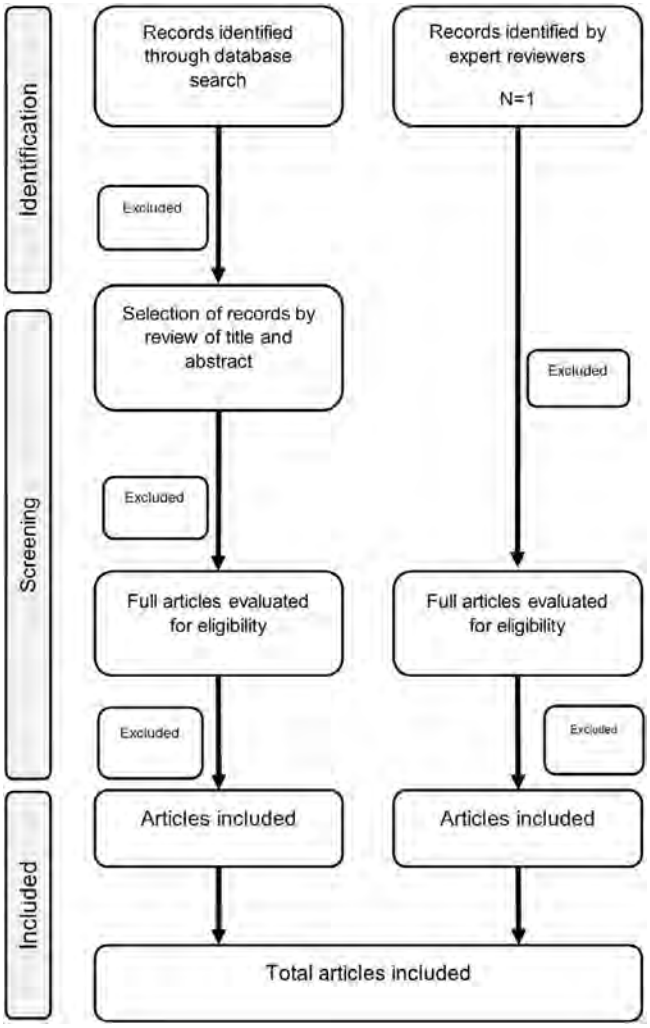

Figure 1. PRISMA flowchart for the systematic literature review.

Our purpose was to identify a comprehensive and evidence-based checklist of signs, symptoms and laboratory parameters reported to precede the diagnosis of EGPA that can be used as red flags, raising the suspicion and prompt the performance of appropriate confirmatory tests.

Methods: A systematic literature search strategy was developed to identify signs, symptoms and laboratory abnormalities that should raise the suspicion of a possible EGPA patient. GRADE (Grading of Recommendations, Assessment, Development and Evaluations) methodology was used to assess the quality of the scientific evidence supporting each criterion.

A multidisciplinary nominal group consensus approach (including rheumatologists, internal medicine specialists, pulmonologists, and allergists) was established for the development of the expert consensus.

Red flags identified as suspicion signals for EGPA were categorized by organ system, manifestation, and laboratory test to facilitate rational, evidence-based clinical review of patients presenting with eosinophilia.

Results: A total of 382 records were identified and reviewed, and 85 studies were included in the literature review (Figure 1). From these 85 publications a total of 214 items were assessed and 40 red flags were identified as relevant to raise a suspicion of EGPA. As the publications were derived from observational studies the GRADE level of evidence was low.

Blood eosinophil count. - levels of > 1000 cells /µL (>1 x 109/L) with no pharmacological treatment that could explain an alteration of this value - levels of > 500 cells /µL with a treatment that could decrease this value (such as glucocorticoids)			
	Red flag		**Red flag**
Respiratory		ENT	
	Asthma		Nasal polyps
	Lung infiltrates / nodules / alveolitis		Chronic media otitis
	Eosinophilic pleural effusion	Dermatological	
	Alveolar haemorrhage / haemoptysis		Palpable purpura
	Chronic cough over 8 weeks / wheezing (not explained by another cause)		Skin lesions such as ulcers, urticaria, nodules and papules (cannot be explained by another cause)
Histopathological		Neurological	
	Vasculitis on biopsy		Mononeuritis multiplex/polyneuropathy
	Biopsy with inflammatory infiltrate predominantly eosinophilic		Paraesthesia
Analytical marker-related			Cerebrovascular disease, other pathologies ruled out
	ANCA positive	Renal	
	Elevated creatinine (together with sediment alteration)		Glomerulonephritis
	Proteinuria (>500 mg)		Glomerular extra-capillary proliferation in renal biopsy
	Elevated troponin (cannot be explained by another cause)		Renal infarction
	High BNP (without any other apparent cause)	Gastrointestinal	
	Positive rheumatoid factor		Ischaemic injuries including intestinal ischaemia and perforation (gastric, oesophageal, and small intestine, unexplained by any other cause)
	High IgE		Recurrent abdominal pain ischemic in nature (cannot be explained by another cause)
Cardiac			Chronic diarrhoea, melena (not explained by another cause)
	Pericardial effusion / pericarditis	Musculoskeletal	
	Cardiomyopathy		Polyarthritis (no alternative explanation)
	Ischaemic heart disease /arterial occlusion / infarction in a patient under 45 years of age		Myositis / myopathy
	Cardiomegaly	Ophthalmological	
Vascular			Retinal vasculitis
	Digital ischaemia		Episclentis / scleritis
	Venous thrombosis (without any other factors)		Orbital inflammatory disease/ orbital pseudotumour
			Red eye (including conjunctivitis and keratitis)
Constitutional syndrome and/or fever (not attributable to any other cause)			
If a patient has the indicated levels of eosinophilia, the detection of any of the listed factors, with no other apparent cause, should alert to the possibility of EGPA. The presence of more than one factor will reinforce the suspicion of EGPA.			

TABLE 1. EGPA suspicion red flags

Using these 40 red flags, an evidence-based clinical checklist tool was developed for use in routine practice to raise EGPA suspicion in patients with eosinophilia (peripheral blood eosinophil count >1 x 10^9/L, with no treatment that could explain an alteration of this value) (Table 1).

Conclusion: Systematic literature review, multidisciplinary expert consensus rating and GRADE methodology has enabled, for the first time, the identification of a comprehensive set of red flags that could be used to raise a suspicion for EGPA, providing clinicians with an evidence-based checklist tool that can be integrated into their routine practice.

Disease Burden of Eosinophilic Granulomatosis with Polyangiitis (EGPA): A Retrospective Analysis of US Health Insurance Claims Data

Paul Dolin[1], Danuta Kielar[1], Anat Shavit[1], **Karina Keogh**[2], Jennifer Rowell[1], Chris Edmonds[3], Juliana Meyers[4], Elizabeth Esterberg[4], Tram Nham[4] and Stephanie Chen[5], [1]AstraZeneca, Cambridge, United Kingdom, [2]Mayo Clinic, Rochester, MN, [3]AstraZeneca, Gaithersburg, MD, [4]RTI Health Solutions, Research Triangle Park, NC, [5]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare necrotizing small-to-medium vessel vasculitis with a relapsing-remitting course involving prodromal (various allergic reactions), eosinophilic (infiltration into organs), and vasculitic (widespread inflammation of small and medium blood vessels) phases, with symptoms depending on the affected organ. Using a retrospective analysis of US administrative health insurance claims data (Merative™ MarketScan® databases), we assessed the clinical burden of EGPA.

Methods: Patients with newly diagnosed EGPA from 2017 to 2021 with ≥12 months of continuous pre-diagnosis health plan enrollment and ≥1 inpatient or ≥2 outpatient EGPA-related diagnoses (≥90 days apart, ICD-10-CM code M30.1) were included. Follow-up was from date of first observed EGPA diagnosis (index date; ID) until health plan disenrollment or database end. Major and non-major coexisting conditions and symptoms were analyzed in patients with EGPA and in a general population cohort matched on demographic characteristics.

Results: In total, 236 patients with EGPA were identified ('EGPA cohort'); 88% had commercial insurance. At ID, mean (standard deviation [SD]) age was 50.4 (14.5) years, 88% were < 65 years, and 58% were female. Mean (SD) duration of follow-up from ID was 21.7 (14.6) months; 26% had ≥30 months' follow-up. Of these, 213 patients with EGPA ('matched EGPA cohort') were matched to a general population cohort ('matched general population cohort'; N=779; mean [SD] age 50.6 [13.7] years, 90% were < 65 years, 59% were female). The most common coexisting conditions at ID in the EGPA cohort were asthma (74% of patients), allergic rhinitis (57%), throat and chest pain (46%), and dyslipidemia (42%) (**Table 1**). After the ID, 79.2% of patients in the EGPA cohort reported ≥1 new EGPA symptom, with 31.4% experiencing a major symptom, of which the most common was hematuria (8.1%). At ID, in the matched EGPA cohort, 44% of patients had major symptoms, the most common of which were respiratory failure (19%), hematuria (9%), hemoptysis/alveolar hemorrhage (6%), and cardiomyopathy (6%). More patients in the matched EGPA cohort had a major symptom compared with the matched general population cohort at ID (prevalence ratio 8.0 [95% confidence interval (CI) 5.8–11.1]; p< 0.001) as well as new symptoms after ID (prevalence ratio 3.0 [95% CI 2.2–4.0]; p< 0.001) (**Table 2**). The symptoms with the three highest prevalence ratios in the matched EGPA cohort versus the matched general population cohort at ID were respiratory failure (73.1 [17.8–300.2]; p< 0.001), hemoptysis or alveolar hemorrhage (23.8 [5.4–104.5]; p< 0.001), and congestive heart failure (21.9 [4.9–97.3]; p< 0.001).

Table 1. History of coexisting conditions in the EGPA cohort at the index date

Coexisting condition*	EGPA cohort (n=236)
Asthma	174 (73.7%)
Severe persistent asthma	152 (64.4%)
Severe uncontrolled asthma	105 (44.5%)
Other eosinophilic conditions	
Atopic dermatitis/eczema	44 (18.6%)
Pulmonary eosinophilia	39 (16.5%)
Eosinophilic esophagitis	8 (3.4%)
Hypereosinophilic syndrome	5 (2.1%)
All malignancies	24 (10.2%)
Primary (essential) thrombocythemia	9 (3.8%)
Allergic rhinitis	134 (56.8%)
Throat and chest pain	109 (46.2%)
Dyslipidemia	98 (41.5%)
Gastro-esophageal reflux disease	90 (38.1%)
Back pain (dorsalgia)	77 (32.6%)
Nasal polyposis	66 (28.0%)
Vitamin D deficiency	60 (25.4%)
Obesity	59 (25.0%)
Anxiety	58 (24.6%)
Sleep disorder/Obstructive sleep apnea	46 (19.5%)
Arrhythmia	46 (19.5%)
Depression	45 (19.1%)
Ischemic heart disease	45 (19.1%)
Interstitial pulmonary disease	33 (14.0%)
Deep vein thromboembolism	11 (4.7%)
Hyperthyroidism	9 (3.8%)
Irritable bowel syndrome	8 (3.4%)
Arterial thrombosis	3 (1.3%)

*Before or at the index date.

CI, confidence interval; CKD, chronic kidney disease; EGPA, eosinophilic granulomatosis with polyangiitis; ENT, ear, nose, and throat; GI, gastrointestinal.

Rate ratios and their corresponding confidence intervals and p-values were obtained using Zeger modified Poisson regression (Zou, G. Am J Epidemiol 2004;159:702–9).

Conclusion: At ID, over 40% of patients with EGPA had major symptoms. New major symptoms continued to occur after ID, with many occurring significantly more frequently than in a matched population without EGPA. These data highlight the substantial burden of EGPA, with a large portion of symptoms within the respiratory system. Greater awareness of EGPA symptoms is needed to ensure proper disease management between different specialties and multidisciplinary teams.

Diagnosis Pathways in Patients with Eosinophilic Granulomatosis with Polyangiitis (EGPA): A Retrospective Analysis of US Health Insurance Claims Data

Paul Dolin[1], Danuta Kielar[1], Anat Shavit[1], **Karina Keogh**[2], Jennifer Rowell[1], Chris Edmonds[3], Juliana Meyers[4], Elizabeth Esterberg[4], Tram Nham[4] and Stephanie Chen[5], [1]AstraZeneca, Cambridge, United Kingdom, [2]Mayo Clinic, Rochester, MN, [3]AstraZeneca, Gaithersburg, MD, [4]RTI Health Solutions, Research Triangle Park, NC, [5]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD

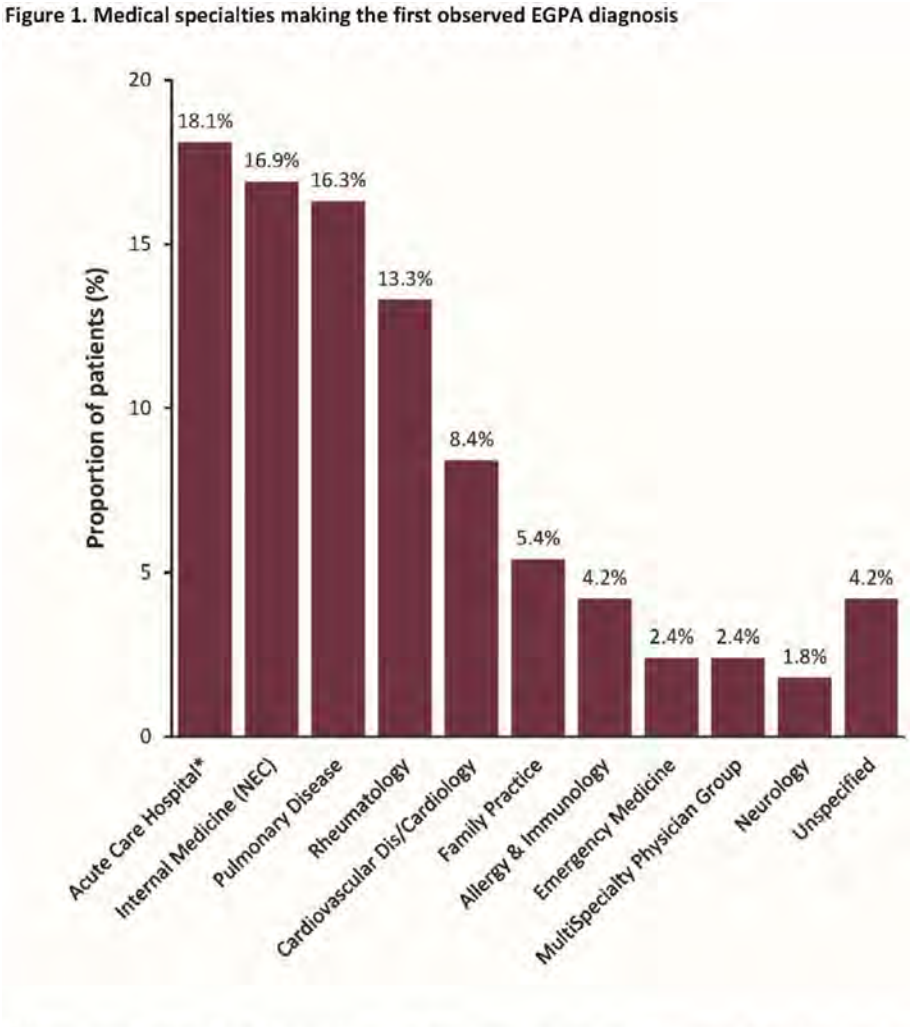
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Raising awareness of eosinophilic granulomatosis with polyangiitis (EGPA), a rare necrotizing small-to-medium vessel vasculitis, amongst clinicians is important to ensure timely diagnosis and treatment. EGPA is associated with substantial disease burden and impact on health-related quality of life, with patients often facing a long and complex pathway from symptom onset to diagnosis. We aimed to characterize the diagnostic journey of patients with EGPA using a retrospective analysis of US administrative health insurance claims (Merative™ MarketScan® databases).

Methods: Patients with newly diagnosed EGPA from 2017 to 2021 with ≥12 months of continuous pre-diagnosis health plan enrollment and ≥1 inpatient or ≥2 outpatient EGPA-related diagnoses (≥90 days apart, ICD-10-CM code M30.1) were included. Follow-up was from date of first observed EGPA diagnosis (index date; ID) until health plan disenrollment or database end. Drug therapies and outpatient visits prior to ID, specialties making incident EGPA diagnosis, time from first observed symptom to ID, and persistent vasculitic damage were analyzed.

Results: In total, 236 patients with incident EGPA were identified; 88% had commercial insurance. At ID, mean (standard deviation [SD]) age was 50.4 (14.5) years, 88% were < 65 years, and 58% were female. In the year before ID, 80% of patients were receiving systemic glucocorticoids, most commonly oral glucocorticoids (OGCs; 77%), 13.6% were receiving immunosuppressants, and 12.7% biologics. Among the 164 patients receiving prednisone, the mean (SD) daily dose was 28 (17) mg, for a mean (SD) of 3.2 (3.5) months. In the year before ID, 96% of patients had at least one outpatient visit; most frequently family practice (50%) and internal medicine (45%). The most frequent (mean [SD]) outpatient visits were to allergy and immunology (6.2 [8.0]), family practice (4.7 [4.2]), internal medicine (4.3 [3.6]), otolaryngology (3.7 [3.0]), and pulmonary

Figure 1. Medical specialties making the first observed EGPA diagnosis



*Most claims (93.6%) came from Outpatient Hospital - On Campus. Other places of service include Inpatient Hospital, Office, Emergency Room - Hospital, and Other/Unknown.
EGPA, eosinophilic granulomatosis with polyanglitis

disease (3.3 [4.4]). Overall, 31% and 70% of patients had their first observed EGPA diagnosis in an inpatient and/or outpatient setting, respectively, which were most commonly made by acute care hospital specialists, followed by internal medicine, and pulmonary disease specialists (**Figure 1**). The mean (SD) time from first observed EGPA symptom or organ damage in the claims record to first observed EGPA diagnosis was 25.0 (15.0) months, with >99% of patients experiencing symptoms or organ damage prior to their first observed diagnosis. At ID, 95% of patients had persistent damage to at least one organ. Most patients had pulmonary damage, followed by ear, nose, and throat, and cardiovascular damage (**Table 1**).

Conclusion: Prior to their first observed diagnosis, most patients with EGPA were prescribed OGCs and made frequent health care provider (HCP) visits. At the time of their first observed diagnosis, the vast majority of patients had already experienced an EGPA event/organ damage for >2 years.These data highlight that greater awareness of EGPA is needed amongst HCPs to facilitate more rapid diagnosis, minimize organ damage, reduce exposure to therapies with harmful side effects, and better enable a multidisciplinary approach.

Table 1. Cumulative incidence of persistent organ damage

Characteristic	n (%)
Persistent damage in ≥1 organ	224 (94.9)
Pulmonary	194 (82.2)
Ear, nose, and throat	120 (50.8)
Cardiovascular	101 (42.8)
Ocular	40 (16.9)
Endocrine	25 (10.6)
Peripheral vascular disease	13 (5.5)
Renal	12 (5.1)
Musculoskeletal	9 (3.8)
Neuropsychiatric	4 (1.7)
Skin	3 (1.3)
Bone marrow	3 (1.3)
Gastrointestinal	1 (0.4)

Treatment Patterns for Eosinophilic Granulomatosis with Polyangiitis (EGPA): A Retrospective Analysis of US Health Insurance Claims Data

Paul Dolin[1], Danuta Kielar[1], Anat Shavit[1], Karina Keogh[2], Jennifer Rowell[1], Chris Edmonds[3], Juliana Meyers[4], Elizabeth Esterberg[4], Tram Nham[4] and **Stephanie Chen**[5], [1]AstraZeneca, Cambridge, United Kingdom, [2]Mayo Clinic, Rochester, MN, [3]AstraZeneca, Gaithersburg, MD, [4]RTI Health Solutions, Research Triangle Park, NC, [5]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare, immune-inflammatory disorder characterized by asthma, eosinophilia, eosinophil-rich granulomatous inflammation, and chronic necrotizing vasculitis of small-to-medium-sized blood vessels. Systemic glucocorticoids (SGCs) and immunosuppressants remain the cornerstone of treatment, even though chronic SGC use increases the risk of side effects. This retrospective analysis of US administrative health insurance claims data (Merative™ MarketScan® databases) evaluated treatment patterns for patients with EGPA.

Methods: Patients with newly diagnosed EGPA from 2017 to 2021 with ≥12 months of continuous pre-diagnosis health plan enrolment and ≥1 inpatient or ≥2 outpatient EGPA-related diagnoses (≥90 days apart, ICD-10-CM code M30.1) were included. Follow-up was from date of first observed EGPA diagnosis (index date; ID) until health plan disenrollment or database end. Use of SGCs, immunosuppressants, and biologics was analyzed, including duration and dosages (for oral medications). Duration of drug therapy was the period of continuous use including the estimated duration of last fill/refill.

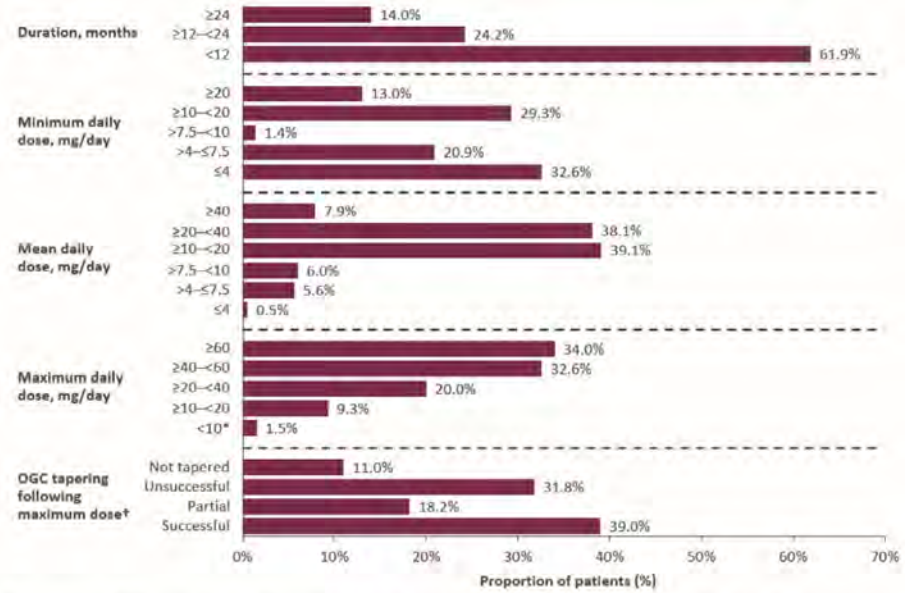
Results: 236 patients were included; 57.6% were female and mean (standard deviation [SD]) age at ID was 50.4 (14.5) years. Mean (SD) follow-up duration was 21.7 (14.6) months and 26.3% of patients had ≥30 months of follow up. In the 12 months before ID and at any time after ID, 92.4% of patients were prescribed a SGC (**Table**). Prednisone was used by 86.0% of patients, with a mean (SD) daily dose of 22.2 (12.7) mg and mean (SD) duration of 11.8 (11.5) months. Of the 236 patients, 91.1% received oral glucocorticoids (OGCs) either before or after ID, 14.0% had continuous use for ≥24 months, the mean (SD) average dose was 22.4 (13.7) mg/day, and 34.0% had a maximum dose ≥60 mg/day for a mean (SD) duration of 1.6 (1.6) months (**Figure**). Mean (SD) cumulative OGC dose was 6.3 (6.3) g with 25.6% of patients receiving ≥8 g. Among the 154 patients with at least one OGC dose >4 mg/day, OGC dose was tapered to ≤4 mg/day within 60 days of maximum dose and remained ≤4 mg/day for ≥60 days for 39.0% of patients, and OGC was tapered to >4 mg/day with ≥50% reduction in OGC dose and no subsequent increase in dose for ≥60 days for 18.2%; 11.0% did not attempt to taper their dose. Immunosuppressants were used by 40.3% of patients, most commonly azathioprine (18.2%), methotrexate (17.8%), and mycophenolate mofetil (8.1%). Mean (SD) daily dose and treatment duration were 112.4 (39.6) mg and 10.2 (11.2) months for azathioprine, 3.4 (5.5) mg and 15.5 (14.9) months for methotrexate, and 1,644.4 (749.1)

Table. Treatment patterns before and after the index date

	Patients, n (%) (N=236)		Daily dose (mg*), mean (SD)		Total duration of use (months†), mean (SD)	
	Post-index	Pre- and/or post-index	Post-index	Pre- and/or post-index	Post-index	Pre- and/or post-index
Any systemic glucocorticoids	188 (79.7)	218 (92.4)				
Oral glucocorticoids						
Any	197 (83.5)	215 (91.1)				
Prednisone	188 (79.7)	203 (86.0)	21.1 (12.5)	22.2 (12.7)	9.9 (10.0)	11.8 (11.5)
Methylprednisolone	44 (18.6)	93 (39.4)	13.9 (2.4)	13.8 (2.3)	1.3 (3.2)	1.0 (2.9)
IV glucocorticoids	65 (27.5)	95 (40.3)	N/A	N/A	3.7 (3.2)	3.5 (3.5)
Traditional immunosuppressants						
Any	90 (38.1)	95 (40.3)				
Methotrexate	39 (16.5)	42 (17.8)	3.6 (5.8)	3.4 (5.5)	14.2 (13.8)	15.5 (14.9)
Azathioprine	37 (15.7)	43 (18.2)	116.8 (38.7)	112.4 (39.6)	10.3 (10.8)	10.2 (11.2)
Mycophenolate mofetil	18 (7.6)	19 (8.1)	1,696.1 (734.8)	1,644.4 (749.1)	10.4 (10.0)	11.7 (11.5)
Cyclophosphamide (IV)	10 (4.2)	10 (4.2)	N/A	N/A	3.8 (1.6)	4.2 (1.8)
Cyclophosphamide (oral)	7 (3.0)	7 (3.0)	114.5 (50.0)	114.5 (50.0)	4.3 (2.7)	4.3 (2.7)
Cyclosporin	3 (1.3)	3 (1.3)	111.8 (10.6)	120.1 (23.1)	10.6 (4.3)	16.0 (1.1)
Biologic agents						
Any	88 (37.3)	91 (38.6)				
B-cell targeting						
Rituximab	36 (15.3)	37 (15.7)	N/A	N/A	13.3 (11.3)	14.1 (10.7)
Eosinophil/type 2 inflammation targeting						
Mepolizumab	42 (17.8)	44 (18.6)	N/A	N/A	11.4 (9.4)	11.7 (9.5)
Benralizumab	10 (4.2)	10 (4.2)	N/A	N/A	7.9 (4.3)	9.1 (4.9)
Omalizumab	8 (3.4)	13 (5.5)	N/A	N/A	9.1 (10.3)	9.9 (10.3)

The index date is the date of the first claim with a diagnosis of eosinophilic granulomatosis with polyangiitis between 2017 and 2021. The pre-index period is the 12 months prior to the index date.
*Calculated for oral tablet medications only. Methylprednisolone dose is reported as prednisone equivalent. †Total duration of drug therapy was calculated as the period of continuous use, including the estimated duration of the last fill or refill, and excluding any gaps due to discontinuation.
IV, intravenous; N/A, not applicable; SD, standard deviation.

Figure. Proportion of patients with eosinophilic granulomatosis with polyangiitis using oral glucocorticoids (N=215)



Data relate to OGC use during the 12 months before the index date, or at any time after the index date. Doses are prednisolone equivalent doses.
*Percentages for subcategories of maximum OGC were: 0.5% for ≤4 mg/day, 0.5% for >4.1–≤7.5 mg/day, and 0.5% for >7.5–<10 mg/day.
†Tapering data are for patients with ≥1 OGC dose >4 mg/day. Successfully tapered: within 60 days of the maximum dose, the OGC dose was tapered to ≤4 mg/day and remained ≤4 mg/day for ≥60 days. Partially tapered: within 60 days of the maximum dose, the OGC dose was tapered to >4 mg/day with ≥50% reduction in the OGC dose and subsequently no increase in dose for ≥60 days.
OGC, oral glucocorticoid.

mg and 11.7 (11.5) months for mycophenolate mofetil. Biologics were used by 38.6% of patients, with 15.7% using a B-cell targeting therapy (rituximab).

Conclusion: Despite the use of traditional immunosuppressants and biologics by more than one-third of patients with EGPA, the vast majority were prescribed glucocorticoids, with many receiving OGCs for long, continuous periods, and many with a maximum dose ≥60 mg/day. Most patients were unable to maintain reduced OGC doses during the follow-up period suggesting there is a need for better OGC-sparing therapies.

Importance of Shared Decision-Making for Patients with ANCA-Associated Vasculitis

Jo Robson[1], Montserrat Díaz Encarnación[2], Peter Verhoeven[3], Raquel Olivenza[4], Monica Balcells[4], **Sara Monti**[5] and Andreas Kronbichler[6], [1]University of the West of England, Bristol, United Kingdom, [2]Autonoma de Barcelona University, Barcelona, Spain, [3]Vasculitis Stichting, Silvolde, Netherlands, [4]CSL Vifor, Glattbrugg, Switzerland, [5]Division of Rheumatology, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy; Department of Internal Medicine and Therapeutics, Università di Pavia, Pavia, Italy, [6]Department of Internal Medicine IV (Nephrology and Hypertension), Innsbruck, Austria

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a rare autoimmune disease associated with significant morbidity. It can present at any age and treatment needs change over time. Multimorbidity is common, leading to polypharmacy and increased treatment burden. Management is a complex balance of achieving effective disease control to prevent progressive organ damage and minimizing treatment-emergent toxicities with long-term health consequences. Revised EULAR recommendations in 2022 for the management of AAV recommend shared decision-making (SDM) between patient and specialist, acknowledging that involving patients in decision-making enables better understanding of patient needs and priorities and potential to improve treatment decisions. (1) As significant opportunity exists to enhance multidisciplinary care of AAV, this expert review aims to identify opportunities to support SDM across the care pathway.

Methods: Embase, Medline, and Cochrane Library were searched for relevant publications using terms and strategies including variations of ANCA-associated vasculitis plus shared decision-making in titles or abstracts. Extracted data are described without synthesis of quantitative data.

Results: Beyond the EULAR guidelines, few publications highlight the practice of, implementation of, or outcomes associated with SDM in AAV. Barriers to implementation include lack of sufficient knowledge and communication about the disease (owing to its rarity and few experts), uncertain prioritization of management goals, absence of proven initiatives in healthcare settings, lack of dedicated healthcare spaces, and poor patient health status. Central to SDM is discussion between patients and specialists on the benefits and harms of therapeutic options, leading to collaborative management decisions based on the best available evidence. Potential approaches to meet the challenges of practical implementation include sharing information on AAV management to help close knowledge gaps by broadening understanding of disease impact, key warning symptoms, and treatment-related toxicities. Support mechanisms for SDM in AAV include use of decision aids such as the three-talk model based on choice, option and decision talk stages to provide balanced information. Increasing use of patient-reported outcome measures may help evaluate the impact of symptoms and interventions on patient health-related quality of life (HRQoL), and should support the choice of treatment.

Conclusion: The implementation of SDM in AAV has the potential to increase knowledge about the disease and risks, give patients an active role allowing for a collaborative approach and enhance the responsiveness and confidence of patients and caregivers, supporting enhanced outcomes and improved patient HRQoL.

Measurement of Sinonasal Disease Activity in Granulomatosis with Polyangiitis

Roger Yang[1], Ellen Romich[2], Shubhasree Banerjee[3], Naomi Amudala[3], Peter Merkel[3], Joshua Baker[3] and **Rennie Rhee**[3], [1]University of Pennsylvania, Montréal, QC, Canada, [2]Hospital of the University of Pennsylvania, Media, PA, [3]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In granulomatosis with polyangiitis (GPA), sinonasal inflammation can be severe and significantly impact quality of life. Little is known about the most effective local and systemic therapies for sinonasal disease in GPA, in part due to outcome measures which lack sensitivity to change. The Sino-Nasal Outcome Test-22 (SNOT22) is a patient-reported outcome measure validated in chronic rhinosinusitis but it has not been well-studied in GPA. This study measured sinonasal disease activity using the SNOT22 and the more widely-used Birmingham Vasculitis Activity Score for Wegener's Granulomatosis (BVAS/WG) in patients treated for active GPA.

Methods: This prospective, longitudinal cohort study included patients who met the 1990 ACR classification criteria for GPA. Patients with active disease during enrollment and at least one follow-up visit 3 or more months later were included. The following therapy initiations were examined: I) saline nasal rinses; II) topical nasal glucocorticoids; III) topical nasal antibiotics; and IV) rituximab (within the prior 6 months); patients could be in more than one group. Outcome measures included: (a) percent of patients achieving the minimal clinically important difference (MCID) for SNOT22 of 8 as determined for chronic rhinosinusitis; (b) percent change in SNOT22; and (c) percent of patients achieving BVAS/WG=0 for sinonasal items. For analysis of MCID, regression models adjusted for baseline SNOT22 score and predicted values were plotted. In secondary analyses models also adjusted for potential confounders, including prednisone, other concurrent treatments, and active sinus disease at relapse visit.

Results: The study included 52 flares in 42 patients with GPA. 35 (83%) patients had a prior history of sinonasal involvement, 28 (67%) were PR3-ANCA positive, and mean disease duration was 2 (0-5) years. At the active visit, 37 (70%) visits had active sinonasal involvement, and mean SNOT-22 score was 27 (IQR 4,15). New medications prescribed included: 30 (58%) saline nasal rinse, 9 (18%) topical nasal glucocorticoids, 4 (8%) topical nasal antibiotics, and 8 (15%) rituximab. For topical nasal glucocorticoids, new initiation vs. no initiation was associated with a greater probability of achieving an MCID for SNOT22 (OR 8.5 [95% CI 1.3, 55.6], P-value 0.026) **(Figure 1**). For saline nasal rinse, new initiation vs no initiation was associated with a greater percent change in SNOT22 (coefficient -0.60, [95% CI -1.17, -0.04], P= 0.037) (**Figure 2**). Results remain statistically significant even after adjusting for confounders. No significant changes were seen between any treatment groups when using the sinonasal items on BVAS/WG (**Figure 3**).

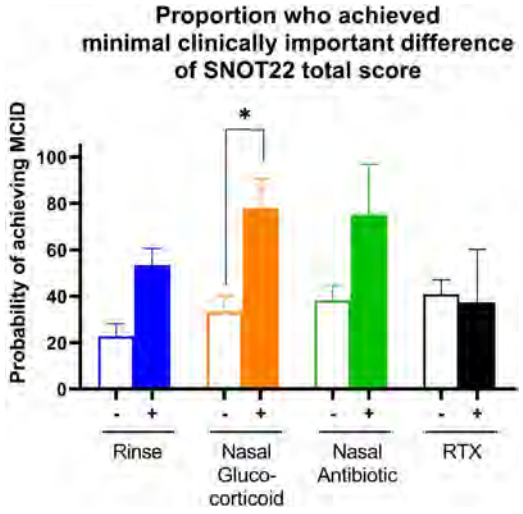

Figure 1: Proportion of patients with active GPA who achieved MCID of SNOT22 after new initiation of treatment. Bar graphs show mean (95% CI) of probability of achieving the minimal clinically important difference (MCID) of the Sino-Nasal Outcome Test 22 (SNOT22) score. Four treatments were analyzed separately so each patient contributed to each analysis and were categorized based on no initiation of treatment (-) vs initiation of treatment (+). Four medications were evaluated: saline nasal rinse (blue), topical nasal glucocorticoids (orange), topical nasal antibiotic (green), and rituximab within the prior 6 months (RTX; black). Logistic regression models adjusted for baseline SNOT22 score at time of active disease. * $P < 0.05$.

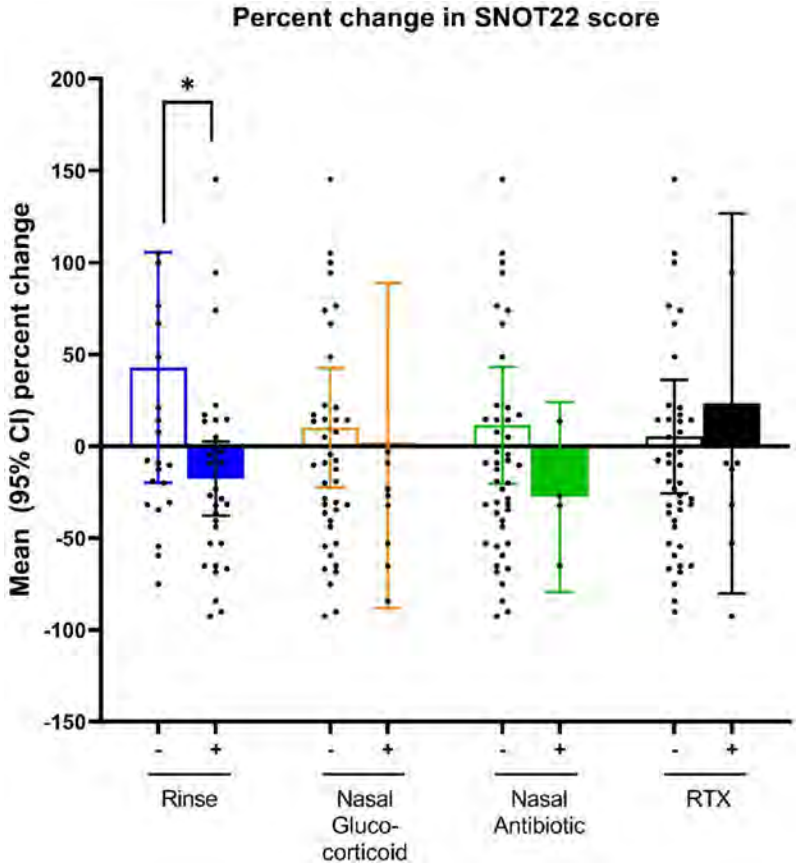

Figure 2: Percent change in SNOT22 score after initiation of new treatment for active granulomatosis with polyangiitis. Bar graphs show mean (95% CI) percent change in Sino-Nasal Outcome Test 22 (SNOT22) score between active and follow-up visits. Four different treatments were analyzed separately so each patient contributed to each analysis and were categorized based on no initiation of treatment (-) vs initiation of treatment (+). Four medications were evaluated: saline nasal rinse (blue), topical nasal glucocorticoids (orange), topical nasal antibiotic (green), and rituximab within past 6 months (RTX; black). * $P < 0.05$.

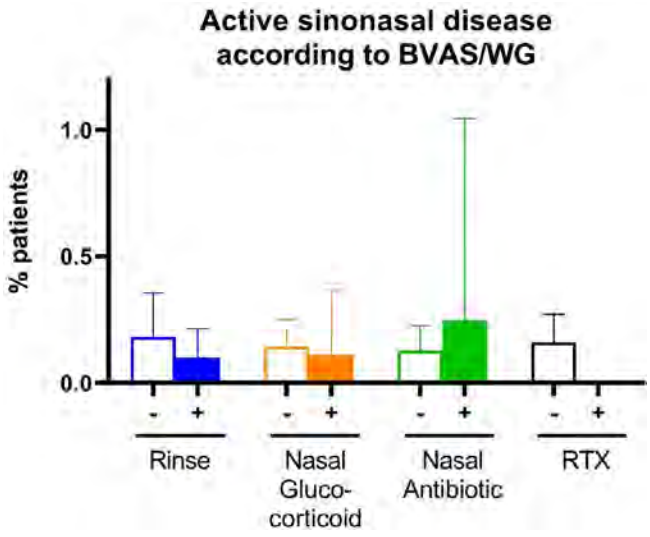

Figure 3: Proportion of patients with sinonasal disease activity according to BVAS/WG after initiation of new treatment for active granulomatosis with polyangiitis. Bar graphs show percentage (95% CI) of patients who had new/worsening or persistent sinonasal activity according to the BVAS/WG. Four different treatments were analyzed separately so each patient contributed to each analysis and were categorized based on no initiation of treatment (-) vs initiation of treatment (+).. Four medications were evaluated: saline nasal rinse (blue), topical nasal glucocorticoids (orange), topical nasal antibiotic (green), and rituximab within the prior 6 months (RTX; black). No statistically significant differences were found among the four treatment comparisons.

Conclusion: In GPA use of a patient-reported outcome measure of sinonasal symptoms (SNOT22) enabled detection of response to topical nasal therapies. Specifically, use of saline nasal rinse and topical nasal glucocorticoids were associated with improvement in sinonasal symptoms. In contrast, treatment response was not detected when using the BVAS/WG, suggesting that SNOT22 may have more responsiveness and convergent validity when assessing sinonasal disease in GPA.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA, formerly Churg-Strauss) belongs to the group of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV). There are no recent data on the epidemiology and outcome of EGPA in France.

Methods: Patients with EGPA were identified from 2013 to 2019 for the epidemiological objective and from 2012 to 2016 for the longitudinal analysis in the French National Health System database, which covers 98% of the French population. To be included, patients had to be affiliated to the general health insurance system and either have full coverage for EGPA (ICD-10 code M30 Polyarteritis nodosa and related conditions or M301 Periarteritis with pulmonary involvement [Churg-Strauss]) or have been hospitalised for EGPA (ICD-10 code M301 only). A sensitivity analysis was also performed on a population restricted to patients who had at least 3 courses of oral glucocorticoids in the year after diagnosis.

Results: There were 7,238 subjects in the main analysis and 3,328 subjects in the sensitivity analysis, corresponding to a prevalence of 85.3 cases/million and 38.4 cases/million, respectively. There were 1,650 and 1,035 new cases/year in the main and the sensitivity analysis, corresponding to an incidence of 3.5 and 2.1 cases/million/year, respectively. In the incident case population (main analysis), the mean age was 61.7 ± 17.4 years, with 57.1% of females; the mean duration of follow-up was 60.1 ± 22.3 months.

The mean duration of oral glucocorticoids was 45.6 months and 53.1 months in the main and sensitivity analyses, respectively. The mean monthly dose of glucocorticoids during the first 6 months was 449.5 mg (i.e. 15 mg/d) in the main analysis and 693.9 mg (i.e. 23.1 mg/d) in the sensitivity analysis, while it gradually decreased to reach a plateau from the 3rd year and until the 8th year of follow-up, with a mean monthly dose of glucocorticoids during these years of approximately 135 mg (or 4.5 mg/d) in the main analysis and 190 mg (or 6.3 mg/d) in the sensitivity analysis.

During follow-up, 62.6% of patients in the main analysis and 69.1% of patients in the sensitivity analysis had at least one complication or new comorbidity, the most common being osteoporosis (21.6% and 31.4%, respectively), followed by arterial hypertension (20.7% and 21.7%), arrhythmia (14.6% and 15.2%) and diabetes (10.9% and 12.2%).

The age- and sex-standardized mortality rate of EGPA was 11.3/1000 patients (main analysis) and 9.7/1000 (sensitivity analysis), compared with 9.2/1000 patients in the general population. At 5 years, the rate of hospitalization for asthma exacerbation was 10.2% (8.7-11.8), and the rate of EGPA relapse was 69.3% (66.9-71.6).

Conclusion: The incidence of EGPA estimated in a large population is consistent with previous estimates but prevalence seems to be higher. This comprehensive study of treatments and complications highlights the extensive and prolonged use of oral corticosteroid therapy. Complications are common and include osteoporosis, hypertension, cardiac arrhythmias, and diabetes. Overall survival of EGPA is excellent but relapses are still frequent, suggesting that the burden of disease remains high.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – ANCA-Associated Poster II: Epidemiology, Outcomes, & Classification

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Central nervous system (CNS) involvement is rare in ANCA associated vasculitis (AAV). On the other hand, AAV patients may develop complications or other conditions that mimic CNS involvement. We aimed to present the clinical, laboratory and imaging features of our AAV patients with CNS involvement and conditions other than CNS involvement that caused neurologic symptoms.

Methods: We surveyed the charts of 430 AAV patients in order to identify patients who were evaluated for neurologic symptoms suggesting CNS involvement. We extracted data on their demographics, types of AAV, neurologic symptoms, final diagnoses after neurologic work-up and their outcome.

Results: Of 430 AAV patients, 61 patients (14%) (41 GPA, 11 MPA, 9 EGPA; 27 women, 34 men; mean age: 51.6±15.4) with neurologic symptoms were identified. Among these, the cause of neurologic symptoms was CNS involvement of AAV in 7 patients (data summarized in Table 1), other AAV manifestations in 30, and secondary complications mimicking CNS involvement in 15 patients, whereas neurologic work-up did not lead to an underlying condition in 9 (Table 2). Among the 61 AAV patients with neurologic symptoms, the most common neurologic symptom suggesting CNS involvement was headache (n=20), followed by muscle weakness (n=17), numbness (n=17), and visual impairment (n=16). At the time of the occurrence of neurologic symptoms, all patients had active disease [median (IQR) BVAS=11.9 (7-15)]. 14 patients (22.9%) had accompanying peripheral nervous system (PNS) involvement. Regarding the outcomes, 6 of the 7 patients with CNS involvement of AAV recovered with sequelae, whereas one patient completely recovered. Among the 30 patients with other AAV manifestations causing neurologic symptoms, 21 recovered without sequela while the remaining 9 recovered with sequela despite treatment. Finally, among the 15 patients with conditions mimicking CNS involvement of AAV, one patient with spondylodiscitiscomplicated with aortic pseudoaneurysm, one with septic emboli and one with diabetic ketoacidosis complicated with pneumosepsis had died, one patient withskull base osteomyelitis recovered with a sequela of blindness, and the remaining patients recovered without sequela.

Conclusion: CNS involvement was uncommon, observed in only 1.6% of our 430 AAV patients. AAV manifestations other than CNS involvement such as ocular, orbital and nasopharyngeal involvement, as well as complications like infections and cardiovascular disease, may mimic CNS involvement in patients with AAV. These non-CNS entities account for almost 75% of the causes for any neurological symptom among AAV patients.

Table 1. Demographic features of the patients and causes for neurologic sign or symptoms

Variable, n (%)	61 AAV patients
Male	34 (55.7)
Mean age, years	51.6±15.4
Type of AAV	
GPA	41 (67.2)
MPA	11 (18)
EGPA	9 (14.7)
CNS involvement of AAV	7 (11.4)
Meningeal involvement	3 (4.9)
Dural involvement and secondary parenchymal infarct	1 (1.6)
Meningeal, parenchymal involvement and syringomyelia	1 (1.6)
Dural involvement	1 (1.6)
Vascular involvement	2 (3.2)
Ischemic CVA	1 (1.6)
Ischemic CVA with hemorrhagic transformation	1 (1.6)
Intracranial hypertension	1 (1.6)
Cerebral venous sinus thrombosis	1 (1.6)
AAV manifestations other than CNS involvement	30 (49.1)
PNS involvement	8 (13.1)
Sinonasal involvement	4 (6.5)
Nasal involvement	2 (3.2)
Associated with disease activation	2 (3.2)
Orbital and paranasal involvement, seconder CNS paralysis and PNS	2 (3.2)
Orbital involvement	1 (1.6)
Ocular involvement	1 (1.6)
Facial paralysis due to facial nerve involvement	1 (1.6)
Facial paralysis due to orbital involvement	1 (1.6)
Facial paralysis due to parotid gland involvement	1 (1.6)
Associated with disease activation and PNS involvement	1 (1.6)
Associated with disease activation and cervical hernia	1 (1.6)
Retinal vasculitis	1 (1.6)
Nasopharyngeal mass and PNS involvement	1 (1.6)
Parotid gland involvement	1 (1.6)
Cardioembolic CVA associated with cardiac mass	1 (1.6)
Cardiac thrombus	1 (1.6)
Secondary complications	15 (24.5)
Atherosclerotic CVA	5 (8.1)
Drug side effect	2 (3.2)
Cardioembolic CVA associated with atrial fibrillation and PNS inv.	1 (1.6)
PRES	1 (1.6)
Hemorrhagic CVA secondary to hypertension	1 (1.6)
Spondylodiscitis complicated with aortic pseudoaneurysm	1 (1.6)
Heart failure	1 (1.6)
Skull base osteomyelitis	1 (1.6)
Septic cranial embolism	1 (1.6)
Ketoacidosis and sepsis	1 (1.6)

Table 2. Management and outcome of 7 AAV patients with CNS involvement

Type of CNS involvement	Type of AAV	Treatment	Outcome
Ischemic CVA with hemorrhagic transformation	EGPA	CYC, GC, anti-epileptic	Recovered without sequela
Intracranial hypertension	GPA	CYC, RTX, GC	Recovered with sequela
Ischemic CVA	GPA	CYC, GC	Recovered with sequela
Meningeal, parenchymal involvement and syringomyelia	GPA	RTX, AZA, GC	Recovered with sequela
Dural involvement and secondary parenchymal infarct	GPA	RTX, GC, anti-epileptic	Recovered with sequela
Dural involvement	GPA	IVIG	Recovered with sequela
Cerebral venous sinus thrombosis	MPA	RTX, AZA, GC	Recovered

CNS, Central Nervous System; GC, glucocorticoids; CYC, Cyclophosphamide; RTX, Rituximab; CVA, cerebrovascular accident; AZA, Azathioprine; IVIG, intravenous immunoglobulin

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The management of severe ocular involvement in Behçet's disease (BD) is an important issue with major functional implications due to the risk of blindness. In patients with severe ocular involvement, *TNF*-alpha blockers have been shown to be a rapid and effective therapeutic option for controlling the disease. Once complete remission of ocular involvement has been achieved, there is a risk of relapse and potential blindness. We aimed to describe the therapeutic strategies used and to identify factors associated with ocular relapse.

Methods: This French, multicenter, retrospective study was conducted using a standardized data collection form over a 2-year period and included adults with Behçet's disease presenting with severe ocular involvement (posterior uveitis, retinal vasculitis, macular involvement). Patients' systemic and ocular characteristics were compared using Student's t-tests, Chi-2 tests and Fischer tests, as appropriate. Variables associated with the risk of relapse were assessed using Cox proportional hazards models and adjusted for potential confounders.

Results: A total of 119 patients were included in this study (male/female ratio of 2.1, median age 34 (28-43) years). Severe ocular involvement was the first manifestation of BD in 101 (88%) patients. Fifty percent of patients were active smokers at the time of ocular involvement.

Severe ocular involvement consisted of posterior uveitis in 108 (91%) patients, retinal vasculitis in 86 (72%) cases, and macular involvement was found in 32 patients (34%).

Oral glucocorticoids therapy was initiated in 114 (97%) patients at a median dose of 60 mg per day (IQR 50-70), preceded by pulses of methylprednisolone in 54/110 (49%). In combination with systemic and/or topical corticosteroid therapy, 91 patients (76%) received at least one immunosuppressive and/or immunomodulatory treatment: azathioprine (n=62), *TNF*-alpha blockers (n=36), cyclophosphamide (n=13), mycophenolate mofetil (n=6), interferon-alpha (n=6) or methotrexate (n=5). Colchicine was prescribed in 85 patients (71%).

Characteristics and therapeutic management according to whether the presence or absence of macular involvement or the presence or absence of retinal vasculitis did not show any difference.

At the end of the first line of treatment, 99/119 patients (87%) achieved remission, and 52 of them (53%) relapsed during follow-up.

Remission and relapse rates were similar between patients with and without macular involvement and with and without retinal vasculitis. After achieving remission, the risk of relapse was significantly associated with active smoking (adjusted HR 1.92 (1.02-3.61)) and was lower in those who received prolonged glucocorticoids (adjusted HR 0.3 (0.16-0.55)), colchicine (adjusted HR 0.43 (0.22-0.83)), and anti-TNF-alpha (adjusted HR 0.5 (0.25-0.99)).

Conclusion: Among patients with Behçet's disease and severe ocular involvement, the risk of ocular relapse was reduced by prolonged glucocorticoid therapy, systematic use of colchicine, and TNF-alpha blockers. Active smoking was associated with an increased risk of relapse, supporting the need for tobacco cessation in patients with Behçet's disease and severe ocular involvement.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Controlled studies have shown that radiographic sacroiliitis was not increased in Behçet syndrome (BS), compared to other inflammatory diseases. However, gastrointestinal involvement of Behçet syndrome (GIBS) shares common features with inflammatory bowel disease which, in turn, can be associated with spondyloarthritis (SpA). We wanted to see whether GIBS patients have an increased frequency of radiographic sacroiliitis or non-radiographic axial spondyloarthropathy (nr-AxSpA) compared to BS patients with only mucocutaneous and/or joint involvement with no major organ involvement.

Table. Demographics and clinical characteristics

	GIBS (n=71)	BS with only mucocutaneous and/or joint involvement (n=76)
Male	38 (53.5%)	23 (30%)
Mean (SD) age, years	45 ±12	42 ± 13
AxSpA according to ASAS criteria	5 (7%)	4 (5%)
Clinical arm	2	2
Imaging arm	3	2
Chronic back pain	30 (42%)	25 (33%)
Inflammatory back pain	17 (24%)	13 (17%)
SpA features among patients with chronic back pain		
Inflammatory back pain	17 (57%)	13 (52%)
HLA-B27	2 (7%)	3 (12%)
Arthritis	14 (47%)	11 (44%)
Enthesitis	11 (37%)	7 (28%)
Dactylitis	2	0
Psoriasis	1	1
Good response to NSAID	21 (70%)	16 (64%)
Family history for SpA	10 (33%)	6 (24%)
Elevated CRP	7 (23%)	3 (12%)

Methods: We included 71 GIBS patients and 76 consecutive BS patients without major organ involvement. Patients were screened for axial spondyloarthritis (axSpA) using the Assessment of Spondyloarthritis International Society (ASAS) criteria. First they were questioned for chronic back pain, defined by ASAS as the presence of chronic back pain for more than 3 months and an age at onset of < 45 years. Patients with chronic back pain were questioned for other spondyloarthritis features and tested for HLA-B27 status, CRP levels and X-ray and magnetic resonance imaging of the sacroiliac joints. All radiologic images were evaluated independently and blind bytwo radiologists.

Results: Chronic back pain was reported by 30 (42%) GIBS patients and 25 (33%) BS patients with only mucocutaneous and/or joint involvement (p=0.24). Five (7%) GIBS patients and 4 (5%) controls met ASAS criteria for axSpA (p=0.74). Only 1 GIBS patient had radiographic axSpA (also termed ankylosing spondylitis), whereas 4 GIBS patients and 4 patients among the controls had nr-AxSpA. HLA B27 was positive in 3 (4%) of the GIBS patients and in 5 (7%) of the controls (p=0.72). There were no significant differences between the groups regarding other SpA features of the ASAS criteria (Table).

Conclusion: The frequency of axSpA in GIBS patients was not found to be higher than that in BS patients who have only mucocutaneous and/or joint involvement. This finding further suggests that, despite certain clinical similarities between GIBS and Crohn's disease, different disease mechanisms may be involved.

Abdominal Surgical Interventions Among Patients with Gastrointestinal Involvement of Behçet Syndrome

Sinem Nihal Esatoglu[1], Sabriye Guner[1], Sevim Guler[2], Gulen Hatemi[1], Nuray Kepil[3], Yusuf Ziya Erzin[4], Aykut Ferhat Celik[4] and Ibrahim Hatemi[4], [1]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Istanbul, Turkey, [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Pathology, Istanbul, Turkey, [4]Istanbul University-Cerrahpasa, Cerrahpasa Medical School, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gastrointestinal involvement of Behçet's syndrome (GIBS) may require surgery in up to one third of the patients. We aimed to investigate the clinical characteristics, treatments, and long-term prognosis of GIBS patients who underwent abdominal surgical interventions.

Methods: We conducted a retrospective chart review of all Behçet syndrome (BS) patients recorded between 1978 and 2022 to identify those with GIBS who had undergone abdominal surgery for GIBS. Data were collected regarding demographics, type of interventions, treatment, recurrences, and outcomes. Relapse was defined as the presence of endoscopic or clinical activity with a positive fecal calprotectin test following bowel resection.

Table. Demographic and characteristics of the patients

Variable	GIBS patients who underwent abdominal surgery (n=29)
Male, n (%)	19
Mean (SD) current age, years	49 ± 11
Juvenile onset, n (%)	4 (13%)
Mean (SD) age at BS diagnosis, years	28 ± 10
Mean (SD) age at GIBS diagnosis, years	34 ± 11
Patients fulfilling ISG criteria, n (%)	23 (79%)
Major organ involvement, n (%)	15 (51%)
Uveitis	11
Vascular	5
Central nervous system	2
Pathergy positivity , n/N (%)	13/27 (48%)
HLAB51 positivity, n/N (%)	12/18 (66%)
Reasons for surgery	
Perforation	18 (62%)
Massive hematochezia	6 (21%)
Ileus	2
Suspicion of acute abdomen	2
Refractory disease	1
Patients who were receiving immunosuppressive treatment at the time of surgery	3 (10%)

Results: Among our 11,200 BS patients, 119 (1%) had GIBS, and 27 (24%) of these GIBS patients (19 male, mean age: 49 ± 11 years) had undergone abdominal surgery (Table). BS was already diagnosed at the time of gastrointestinal involvement in 19 (65%) patients while 10 were diagnosed with BS with the development of gastrointestinal involvement. All except 1 patient who underwent ileocecal resection due to refractory disease, were diagnosed with GIBS following abdominal surgery. Perforation (n=18, 62%) and massive hematochezia (n=6, 21%) were the main reasons for surgery. The type of surgery

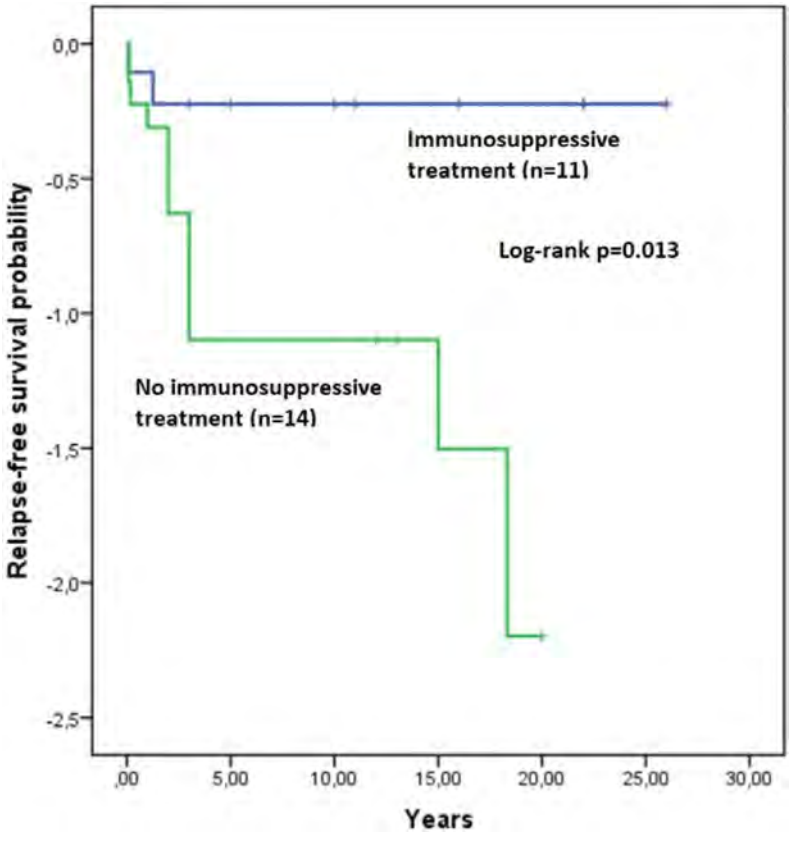

Figure. Relapse-free survival of patients who used postoperative immunosuppressive vs who did not

was bowel resection in 25 patients, primary closure in 2 and diagnostic laparotomy in 2 patients. Two patients with refractory GIBS had died due to extensive vascular involvement (n=1) and secondary amyloidosis (n=1). Among the 25 patients who underwent bowel resection, 14 (56%) experienced a relapse during a median follow-up of 24 (IQR: 1.75-36) months. Of these 14 patients, 12 had only one relapse. At the time of relapse, 4 (29%) patients required a reoperation. The remaining 11 patients did not experience any relapses during a median follow-up of 13 (IQR: 10-22) months. Postoperative azathioprine treatment was initiated in 11 patients, with 3 of them also receiving a TNF inhibitor. Three of these 11 patients experienced a relapse while among the 14 patients who did not receive postoperative immunosuppressive treatment, 11 had a relapse (27% vs 79%; p=0.01). The use of postoperative immunosuppressive treatment was associated with a reduced risk of relapse (OR: 0.10; 95% CI: 0.016-0.644). Moreover, time to relapse was significantly longer in patients who received postoperative immunosuppressive treatment compared to those who did not (p=0.013, log-rank test, Figure)

Conclusion: GIBS may presently acutely with perforation or severe bleeding requiring surgery, as the first manifestation. In this cohort 24% of GIBS patients required abdominal surgery and all except one were diagnosed with GIBS following the surgical procedure. Approximately 50% of the patients experienced a relapse, with most relapses occurring within 3 years. Among the patients who relapsed, 30% required reoperation. The use of immunosuppressive treatment after surgery showed a significant protective effect, reducing the risk of relapse by 90%.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Monoclonal antibody tumor necrosis factor alpha inhibitors, particularly infliximab and adalimumab, are the most commonly used biological agents in the treatment of Behçet's syndrome (BS). Treatment response may show variability across organ manifestations of BS. We aimed to determine the frequency of de novo manifestations during adalimumab (ADA) treatment.

Methods: We conducted a chart review of 285 BS patients who received ADA in our Behçet Disease Research Center. Demographic data, reasons for initiating ADA, concurrent medications, previous treatments, and treatment outcomes were recorded. We defined de novo manifestations as new BS manifestations that had not manifested prior to the initiation of ADA treatment. For patients with vascular involvement, a new vascular event at another vessel was also considered as a de novo manifestation.

Age at ADA initiation, gender	BS manifestations	Main involvement requiring ADA	Previous drugs	Concomitant drugs	Time to de novo (months)	De novo manifestation	Treatment for de novo manifestation

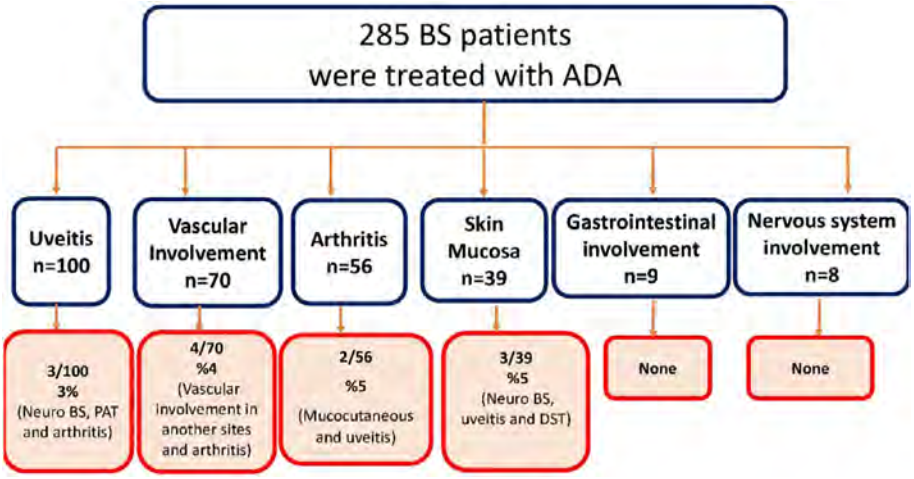
Demographics, characteristics, de novo manifestations and treatment of de novo manifestations of 12 patients



Results: The main reasons for ADA use among our 285 patients were uveitis in 100 patients (35%), vascular involvement in 70 (%25), arthritis in 56 (%20), mucocutaneous involvement in 39 (%14), parenchymal central nervous system involvement in 8 (%3), and gastrointestinal involvement in 9 (%3). Among these patients, 12 (4%) developed a de novo manifestation. De novo manifestations that occurred in 12 patients were vascular involvement in 5 patients, arthritis in 3, anterior uveitis in 2, and parenchymal central nervous system involvement in 2. The primary reasons for ADA treatment were vascular involvement in 3, arthritis in 3, uveitis in 3, and mucocutaneous involvement in 2 of these 12 patients. Among these 12 patients, 8 (61%) were using concomitant conventional immunosuppressive treatment at the time of occurrence of de novo manifestations.

Treatment with ADA was intensified in 3 patients by shortening the intervals to 1 week, along with the addition of high dose glucocorticoids in one patient. In the 3 patients, ADA was switched to another agent (infliximab in 2 patients, certolizumab in 1 patient). Only glucocorticoids were added in two patients, azathioprine along with high dose corticosteroids in one patient and colchicine in one patient. Two patients who had developed anterior uveitis were initiated topical treatment (Table).

Conclusion: De novo manifestations occurred in 4% of BS patients treated with adalimumab. Majority of these (75%) were major organ involvement, mainly vascular involement. None of the patients developed posterior uveitis, the 2 patients with uveitis developing during ADA had anterior uveitis that was controlled with topical agents.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A considerable number of patients with Behçet's syndrome (BS) have vitreous cells (VC) on slit lamp examination at the time of diagnosis. However, the prognostic importance of VC and their association with the development of posterior uveitis (PU) requiring immunosuppressive treatment is unknown. We aimed to determine the prognostic importance of VC in BS patients.

Methods: The charts of 572 consecutive BS patients fulfilling ISG criteria who were registered between 2010 and 2012 were reviewed. At baseline visit 164 patients had VC in one or both eyes. Among the remaining patients, 229 had no eye involvement, 116 patients had bilateral pan or posterior uveitis, 14 had unilateral pan or posterior uveitis and no eye involvement in the other eye, 20 had isolated anterior uveitis, and 29 had insufficient data in their medical records. Among the 164 patients with VC, 110 patients with a follow-up of ≥2 years were included in this study (Figure).

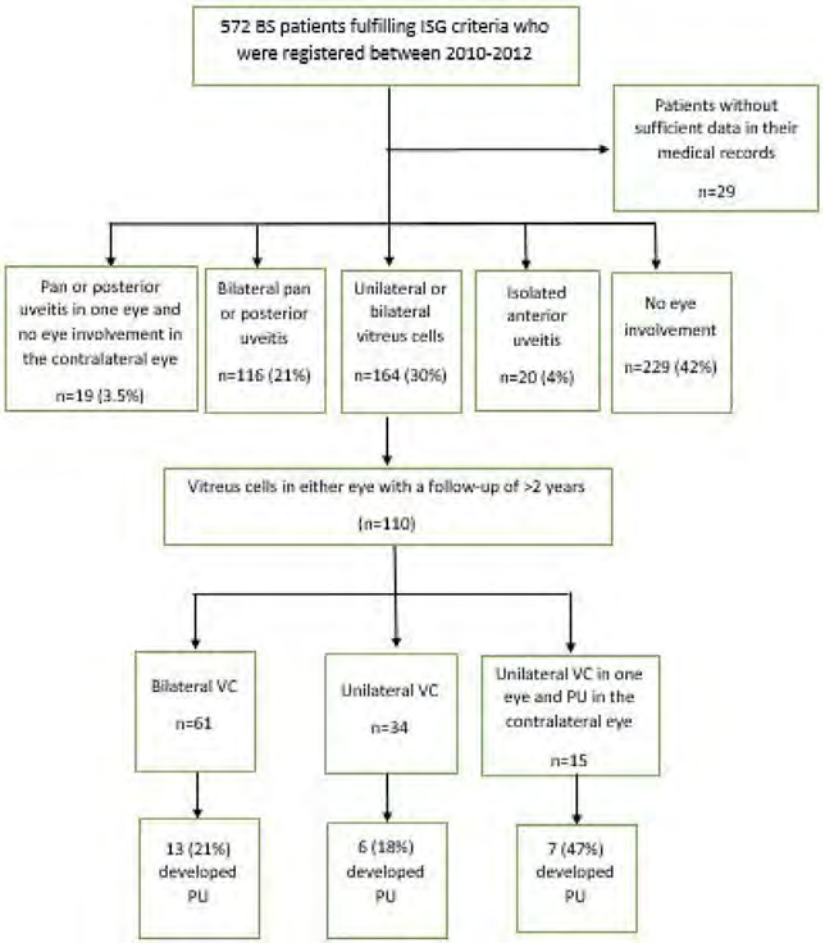

Figure. Flowchart of the patients

Results: At baseline, among the 110 included patients (68 men, mean ± SD age: 31±9 years), 61 had VC in both eyes, 34 had VC in only one eye, and 15 had VC in one eye and PU in the other eye. There was anterior uveitis (AU) in addition to VC in the same eye in 13 patients at baseline.

New PU developed in 26 (24%) patients during a mean follow-up of 1.9±1.1 years. Seven patients that developed PU in the eye with VC had had PU in the contralateral eye at baseline. This means 7 of 15 patients with VC in one eye and PU in the contralateral eye developed bilateral PU despite treatment. Two of these 7 patients had developed AU before they developed PU. Additionally, 6 patients that developed PU in the eye with VC had anterior uveitis in the same eye at baseline (Figure).

Multivariate logistic regression analysis showed that the presence of both VH and AU in the same eye at baseline (OR, 3.75, 95% CI; 1.07-13.18) and the presence of VH in one eye and PU in the other eye at baseline (OR, 3.86, 95% CI; 1.19-12.60) were the independent risk factors for the development of PU in patients with VH. Age at diagnosis, sex, and the use of immunosuppressive medications during the first 3 years of follow-up were not associated with the development of PU.

Conclusion: Careful follow-up is required for patients with VC since one quarter developed PU within 2 years. The presence of PU in the contralateral eye and AU in the same eye are risk factors for the development of PU in patients with VC.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Cystoid macular edema (CME) is the leading cause of blindness in non-infectious uveitis. One of the most frequently associated conditions is Behçet's disease (BD) (1-3). The objective is to compare efficacy and safety of Adalimumab (ADA), Infliximab (IFX) and Certolizumab (CZP) in CME refractory due to BD.

Methods: Multicenter study of patients with CME secondary to BD refractory to glucocorticoids (GC) and at least 1 conventional immunosuppressant. All patients had CME (OCT >300μ) at baseline. From baseline up to 2 years of follow-up, the evolution of macular thickness (μm), visual acuity (BCVA), anterior chamber (AC) cells, vitritis and GC-sparing effect was analyzed to assess the efficacy of ADA, IFX and CZP. Statistical analysis was performed with IBM SPSS Statistics v.23.

Results: Fifty patients (78 eyes) were evaluated. Twenty-five patients were treated with ADA, 15 with IFX and 10 patients received CZP. No significant differences in demographic parameters were identified in all groups. However, patients in the CZP group had a significantly longer time from diagnosis to drug initiation (75 [36-120] vs 30 [12-82] vs 15 [8-60] months; p=0.04) and had received a greater median [IQR] number of biological treatments (2 [0.75-3] vs 0 [0-0] vs 0 [0-0]) than the ADA and IFX groups. In CZP group, ADA and IFX were used previously in 7 patients. ADA was used in combined therapy in 64%, IFX in 66.7% and CZP in 70% of patients (p=0.94) (**TABLE**).

TABLE. Main general features of CME patients due to BD receiving adalimumab (ADA), infliximab (IFX) or Certolizumab Pegol (CZP).

	ADA *group* **(n=25)**	**IFX** *group* **(n=15)**	**CZP** *group* **(n=10)**	**P**

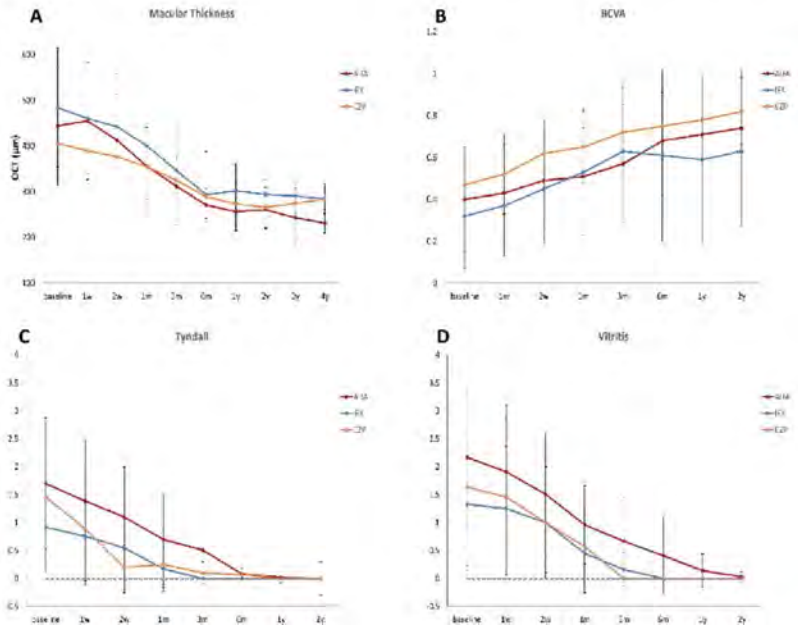
FIGURE. Rapid and maintained improvement following the onset of ADA, IFX and CZP. **A.** Macular thickness (OCT); **B.** Best-corrected visual acuity (BCVA); **C.** Anterior Chamber (AC) cells – Tyndall; **D.** Vitritis.



Concerning efficacy outcomes, a rapid and maintained improvement in macular thickness was observed after 2 years of follow-up in three groups with no statistically significant differences between them (**FIGURE**). Improvement in BCVA, AC cells, vitritis and a GC-sparing effect was also noted. No serious adverse events were observed in IFX and CZP group. One case of pyelonephritis was reported in the ADA group.

Conclusion: ADA, IFX and CZP are effective and safe in refractory CME due to BD. CZP appears effective even in patients with inadequate response to ADA and/or IFX.

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Behcet's syndrome (BS) is an autoimmune disease characterized by recurrent mucocutaneous ulcerations, vascular and nervous system involvement. While there have been a lot of researches proving that immune cells play a vital role in rheumatic disease, opinions on the effect of different immune cell subsets on BS is inconsistent. Therefore, we performed this real-world study to investigate the changes in the levels of several immune cell subsets in BS, and the correlation between the levels of different immune cell subsets and clinical features in patients with BS.

Methods: This is a retrospective, single-center study conducted in Beijing. We enrolled a total of 136 patients diagnosed with BS in rheumatology and immunology department of Peking University People's Hospital from 2018 to 2021 and 114 healthy controls (HCs) in this study. All patients met the International Criteria for Behcet's Disease (ICBD). The levels of peripheral immune cells, including CD4$^+$ T lymphocytes, CD8$^+$ T lymphocytes, B lymphocytes, NK lymphocytes, several subsets of CD4$^+$ T lymphocytes and several subsets of Treg cells were analyzed by flow cytometry. Wilcoxon rank test, student's t-test and Logistic regression analysis were used and a P-value < 0.05 was considered statistically significant.

Results: Compared with HCs, the absolutely numbers of CD4$^+$ T lymphocytes, B lymphocytes and NK lymphocytes were decreased in BS patients. Among CD4$^+$ T lymphocytes, the proportion of IFN-g, IL-2 and IL-4 producing lymphocytes, follicular helper T cells and Foxp3$^+$ Tregs were significantly elevated, while TNF-a producing lymphocytes, Naïve Th cells and T

Naïve Th (%)	-0.083	0.031	7.165	0.007	0.920	(0.866, 0.978)
CD161+Treg (%)	0.147	0.056	6.950	0.008	1.158	(1.038, 1.292)
CLA+Treg (%)	0.102	0.037	7.518	0.006	1.107	(1.029, 1.190)

Multivariate Logistic regression analysis of Neurological subtype Behcet's syndrome patients

patients without that manifestation. Multivariate Logistic regression analysis showed that decreased level proportion of CLA^+ Treg among Tregs was a protective factor of nervous system involvement in BS patients (b=0.102, SE=0.037, *Wald*=7.518, P=0.006, OR=1.107, 95%IC: [1.029, 1.190]). The proportion of CLA^+ Treg among Tregs in 11 BS patients of 14 was elevated after treatment of corticosteroids and immune suppressor.

Conclusion: BS patients have a decreased level of CLA^+ Treg than HCs. Decreased CLA^+ Treg may be a protective factor of nervous system involvement in BS patients. BS patients' level of CLA^+ Treg can be elevated after treatment.

Clinical Features and Quality of Life of Japanese Bechet's Disease Patients with Arthritis: A Japanese Monocentric Study

Koichi Sugihara[1], Risa Wakiya[2], Yusuke Ushio[3], Shusaku Nakashima[2], Hiromi Shimada[2], Taichi Miyagi[4], Kanako Chujo[5], Ryoko Kagawa[3], Hayamasa Yamaguchi[3], Tomohiro Kameda[2] and Hiroaki Dobashi[6], [1]Kagawa University, Miki-cho, Kita-gun, Japan, [2]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Kagawa, Japan, [3]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Miki-cho, Kita-gun, Japan, [4]Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine, Kagawa University, Kidagun, Japan, [5]Kagawa University, Miki, Kita District, Kagawa, Japan, [6]Kagawa University, Kagawa, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis is positioned as one of the main symptoms in Behcet's disease (BD), and it is a relatively frequent symptom that is observed in about 57% of patients in Japan. Arthritis associated with BD is considered to be important domain affecting the patient's QOL same as oral ulcers. However, few reports have compared the clinical symptoms and QOL of BD patients with and without arthritis. This study aims to clarify the correlation between arthritis and other clinical manifestations of BD, which affect the patient's QOL in Japanese patients with BD.

Methods: Sixty-six BD patients treated at Kagawa University Hospital for more than 6 months and who visited the hospital from January to October 2022 were included in this retrospective study. We divided these patients into with (arthritis group) or without arthritis (non-arthritis group), and evaluated clinical symptoms, disease activity, and patient quality of life. Patient's global assessment(PGA), Evaluator's global assessment (EGA) and Behcet's disease current activity form (BDCAF) were used as indices of disease activity. Behcet's disease quality of life scale (BDQOL) was used to assess patient QOL. Statistical analysis was performed using JMP® Pro 16.1.0 software (SAS Institute, Cary, NC, USA).

Results: Arthritis was observed in 48.5% of patients. No significant difference in patient characteristics was observed between two groups. Activity of arthritis in arthritis group evaluated by SDAI, CDAI and DAS-28CRP was low to moderate (Table 1). The frequency of oral ulcers were significantly higher in arthritis group than in non-arthritis group. Although skin lesions tended to be detected in arthritis group more than non-arthritis group, there was no significant difference between two groups. Among the skin domain, papulopustular lesion tended to be observed more frequently in arthritis group (Table 2). EGA and BDCAF were significantly higher in arthritis group. Although PGA and BDQOL were higher in arthritis group, the difference was not significant between two groups (Figure 1).

CDAI, median(IQR)	-	9.7 [6.6-12]	-
DAS28-CRP, median(IQR)	-	2.8 [2.3-3.5]	-

P values were determined by the Mann–Whitney U test.
*Data were considered significant at P < 0.05.

Table.2 Association between arthritis and major lesions of Behcet's disease

	Without arthritis n=34	With arthritis n=32	P-value
Oral ulcer	17 (50.0%)	25 (78.1%)	0.0176*
Genital ulcer	6 (17.7%)	8 (25.0%)	0.4652
Skin lesion	6 (17.7%)	10 (31.3%)	0.1975
Erythema nodosum	3 (8.8%)	4 (12.5%)	0.6278
Thrombophlebitis	0 (0%)	0 (0%)	-
Papulopustular skin lesions	4 (11.8%)	7 (21.9%)	0.2707
Eye involvement	0 (0%)	1 (3.1%)	0.299
Epididymitis	1 (2.9%)	0 (0%)	0.3283
Gastrointestinal involvement	1 (2.9%)	0 (0%)	0.3283
Nervous system involvement	0 (0%)	0 (0%)	-
Vascular involvement	0 (0%)	0 (0%)	-

P values were determined by the Mann–Whitney U test.
*Data were considered significant at P < 0.05.

Conclusion: Japanese BD patients with arthritis tended to be complicated with mucocutaneous lesions. In addition, arthritis may affect overall disease activity and QOL in patients with BD, even if its activity is low to moderate. Because this study was a small, single-center, observational study, further research is needed to clarify the relationship between clinical feature and QOL in BD patients.

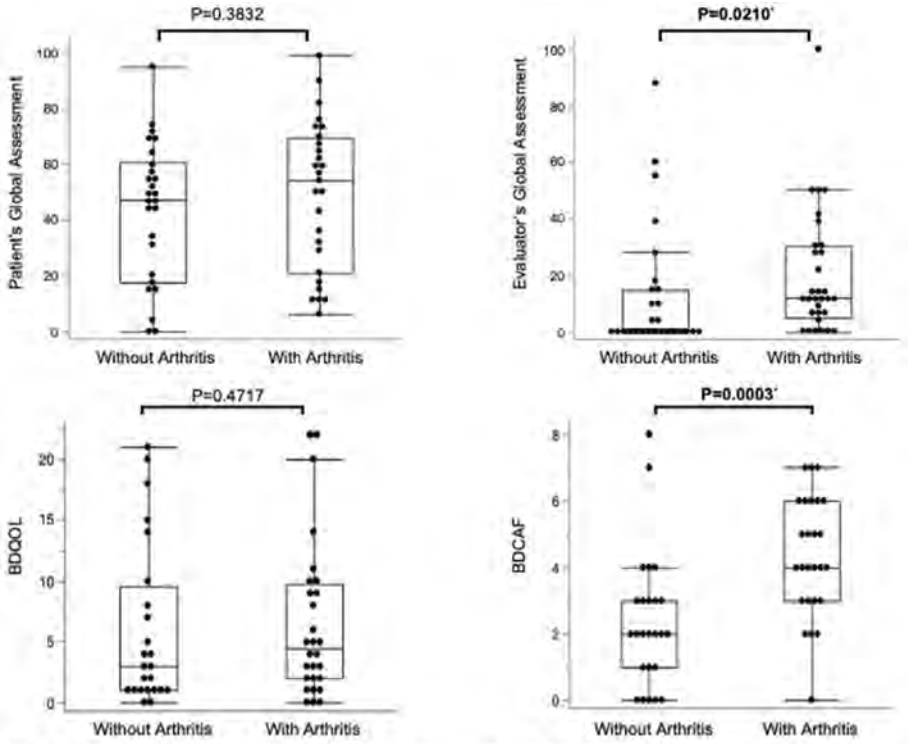

Figure 1. Comparison of disease activity and QOL of patients with Behcet's disease with and without arthritis. BDQOL = Behcet's disease quality of life scale; BDCAF = Behcet's disease current activity form. *Data were considered significant at P < 0.05.

Behcet's Disease Coagulopathy in a Racially Diverse Patient Population

Sundus Mian[1], Talia Meisel[2], Hussain Md[1], Xianhong Xie[3], Tamara Tanner[1], Anand Kumthekar[4] and Bibi Ayesha[4], [1]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [2]Montefiore Medical Center, Bronx, NY, [3]Albert Einstein College of Medicine, Bronx, NY, [4]Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Behcet's disease (BD) is a vasculitis with both thrombotic and bleeding complications which can make management challenging. Thrombosis is due to direct vascular inflammation, and thus guidelines emphasize immunosuppression (IS) as the mainstay of treatment [1] rather than anticoagulation (AC). BD is most prevalent in the Mediterranean region and East Asia [2]. Countries may vary in management of BD coagulopathy, possibly due to differences in prevalence of BD [1]. Our study objective is to explore management of BD coagulopathy in a racially diverse population, and we compared clinical features of BD patients on anticoagulation to those not on anticoagulation.

Methods: After institutional review board (IRB) approval, we queried Montefiore Medical Center electronic medical record and the clinical looking glass databases to identify patients with a diagnosis of BD aged 16 years and older who met International Criteria for Behcet's Disease (ICBD). We performed a retrospective chart review and analyzed the results using two sample t-tests for continuous variables and Fisher's exact tests for categorical variables.

Results: We identified 26 patients with BD. Among them, 46% were Hispanic, 39% were Black, 8% were Asian, and 8% were Middle Eastern. A total of 10 patients had vascular manifestations of BD [Figure 1], out of which 8 had thrombosis. Of those patients with thrombosis, 7 were both on IS and AC, and 1 was on IS alone. Of the 7 patients who were on AC, 3 were on AC for less than 1 year, 4 were on AC for more than 1 year. Two patients suffered from both bleeding and thrombotic complications of BD. No patients were identified to have pulmonary artery aneurysm. Out of the 8 patients with thrombosis, 2 patients were noted to have hypercoagulable diseases– one had protein C and protein S deficiency, and another had protein S deficiency.

Table 1: Comparison of clinical features Behcet's disease patients on anticoagulation versus not on anticoagulation

Characteristic	Behcet's disease patient on anticoagulation (n=7)	Behcet's disease patient not on anticoagulation (n=19)	p-value
Age at diagnosis, mean (SD)	23 (6.35)	24 (9.61)	0.72

Both clotting and bleeding event	2 (28.6%)	0 (0%)	0.06

Table 2 - Management of Behcet's disease patients with thrombosis

Patient	Type of Thrombosis	On anticoagulation	On immuno-suppression	Bleeding complication	Gastrointestinal ulcer	Pulmonary Artery Aneurysm	Recurrence of thrombosis	Other hypercoagulable state
1	DVT	Yes (<1 year)	Yes	Yes (hemorrhagic stroke)	No	No	Yes	No
2	DVT	Yes (>1 year)	Yes	No	No	Not checked	Yes	Protein S deficiency
3	DVT	Yes (>1 year)	Yes	Yes (gastrointestinal bleed)	Yes	No	Yes	Protein C/S deficiency
4	DVT	No	Yes	No	No	No	No	No
5	DVT, IVC filter thrombosis	Yes (>1 year)	Yes	No	No	Not checked	Yes	No
6	Extensive DVT	Yes (>1 year)	Yes	No	No	Not checked	No	No
7	Tricuspid valve thrombus	Yes (<1 year)	Yes	No	No	No	No	No
8	Sinus vein thrombosis	Yes (<1 year)	Yes	No	No	No	No	No

* DVT = deep venous thrombosis

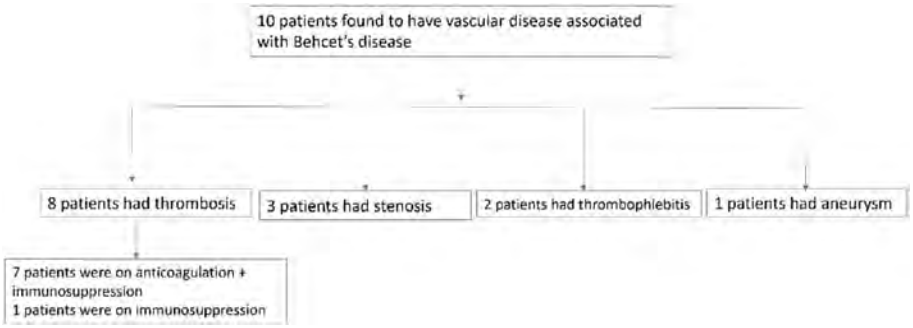

Figure 1: Vascular manifestations of Behcet's disease

Conclusion: We compared the clinical features of BD patients on anticoagulation to those not on anticoagulation, and we found that unless there was a thrombotic event, patients were not initiated on AC [p< 0.0001]. Among our patients, 31% experienced thrombosis, and 25% of these patients experienced a bleeding event related to BD. The majority of our patients with thrombosis were treated with both IS and AC, though one patient with thrombosis was given IS alone. We found decisions on AC use considered presence of other hypercoagulable disorders, severity and location of clot, clot recurrence, pulmonary artery aneurysm screening, and history of major bleed. Our study suggests that while the mainstay of treatment for BD coagulopathy remains IS, each individual's clotting and bleeding risk should be evaluated when considering AC. If patients have recurrent clotting despite IS, they should also be screened for hypercoagulable disorders and pulmonary artery aneurysms if AC is considered to avoid untoward outcomes.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD) is characterized by great clinical heterogeneity. The therapeutic strategy for BD could be tailored to the specific needs of the patient, based on clinical phenotypes, as we often find refractory cases with overlapping of different clinical manifestations. Eular recommendations on the management of BD were updated in 2018 and did not include methotrexate (MTX) as a therapeutic strategy, despite being a widely used drug in Rheumatology. OBJECTIVES: To describe the efficacy and safety of MTX treatment in patients diagnosed with BD.

Methods: We performed a multicentre retrospective observational study that included 68 BD patients (ICBD 2013) on MTX treatment. The indication of MTX was based on the criteria of the treating physician with the informed consent of the patient. Statistical analysis was performed by T-test and Fisher's exact test to compare quantitative and qualitative variables. Values of $p < 0.05$ were considered statistically significant.

Results: 68 patients diagnosed with BD and treated with MTX was evaluated, 53% women, 94% caucasians, with a median age of 39.7 (33.7-42.8) years and 3.6 (1.5-15.7) years of disease progression at MTX onset. Table I summarises the main general and clinical features at baseline. Previously to MTX, patients had received colchicine (95.6%), oral glucocorticoids (80.9%, maximum median dose of 20 [10-30] mg/day), hydroxychloroquine (17.7%) and csDMARDs (35.8%). In addition, 6 patients had received apremilast and 13 had received bDMARDs. MTX was started due to joint phenotype (54.4%), refractory oral and/or genital aphthosis (35.3%) and ocular involvement (8.8%). The mean dose of MTX was 12.6±3.6 mg/week. Survival at 3, 6 and 12 months was 94% (61/68), 84% (57/68) and 68% (42/68). The median duration of MTX was 26.8 (8-71.3) months, and treatment was discontinued in 43 patients (63.2%) (Table II).

To assess efficacy, patients who presented early intolerance or adverse effects (< 6 months) were eliminated (7/68).46% of patients (28/61) received MTX for joint involvement and 54% of patients (33/61) for other reasons. Those who received treatment for arthritis had a higher response rate (24/28) compared to those who received MTX for other clinical manifestations (19/33) (p=0.016). There were no significant differences between these two groups in terms of maximum dose of methotrexate or the use of concomitant biologic therapy.

Conclusion: Despite not being included as a therapeutic strategy in the latest Eular 2018 recommendations, methotrexate appears to be an effective treatment in patients with BD, especially against the articular phenotype, with a good safety profile.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The diagnosis of Behçet's disease (BD) is mainly based on multi-systemic clinical manifestations after ruling out other potential causes. There is no specific diagnostic feature for BD. Therefore, the diagnosis may be a challenge in patients especially those presenting with only major organ involvement. The development of other disease manifestations to make a definite diagnosis can sometimes take months and even years and disease can remain clinically limited lifelong in some patients. In this group of patients, the term incomplete or suspected BD was used especially in Japanese Criteria, also possible BD was defined in recent ICBD Classification Criteria. Diagnosis is made by 'expert opinion' according to the presence of specific clinical manifestations of BD. We recently published the first controlled Doppler US study showing increased venous wall thickness (VWT) of lower extremity veins in male BD patients, and suggested that the cut-off value

Table 1: Baseline characteristics of patients with suspected Behçet's Disease and healthy controls

	Suspected Behçet's Disease (n=51)	Healthy Controls (n=41)	p value

SD, standard deviation

of≥0.5 mm for common femoral vein (CFV) thickness had a high specificity and sensitivity for the diagnosis of BD (>80%). We later assessed the diagnostic performance of CFV thickness measurement in BD compared to multiple disease control groups. We found that CFV thickness is a distinctive feature of BD, rarely present in other inflammatory or vascular diseases. Most recently, increased VWT was observed in childhood BD with and without vascular involvement, and suggested as a new criterion for the diagnosis in both definite and incomplete pediatric BD patients. In this study, we aimed to assess the diagnostic performance of CFV thickness measurement in patients with 'suspected' BD and compared it with healthy controls.

Table 2: Subgroup analysis of suspected Behçet's patients (BD) and healthy controls

	R-CFV, mean (SD),mm	L-CFV, mean (SD), mm
Suspected BD patients, all group	0.71 (0.16)	0.71 (0.15)

Suspected BD patients with major organ involvement	0.72 (0.17)	0.71 (0.16)
Suspected BD patients with vascular involvement	0.72 (0.15)	0.73 (0.14)
Suspected BD patients only with ocular involvement	0.68 (0.12)	0.64 (0.14)
Suspected BD patients only with neurological involvement	0.75 (0.28)	0.73 (0.23)
Suspected BD patients non-vascular involvement	0.70 (0.17)	0.68 (0.19)

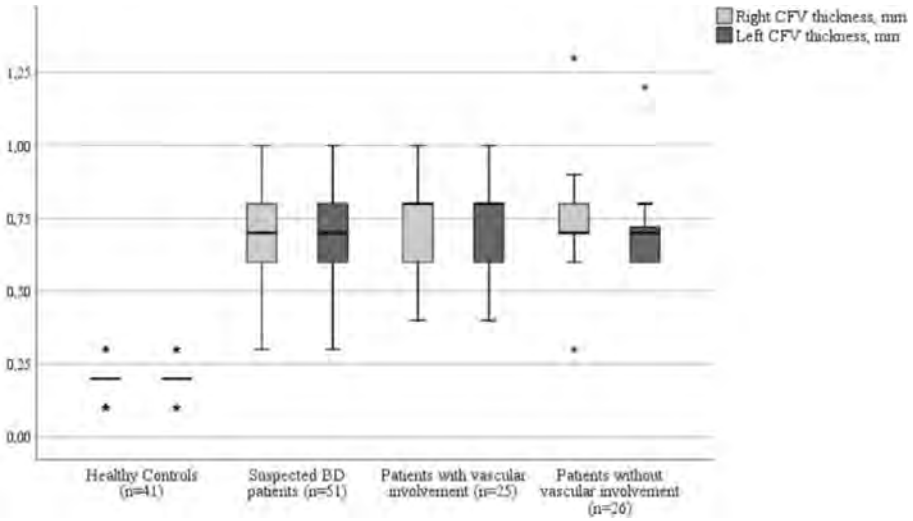

Figure 1: Distribution of common femoral vein (CFV) wall thicknesses in healthy controls and suspected Behçet's Disease (BD) according to organ involvements (The asterisk (*) symbols represent the extreme values)

Methods: Suspected BD was defined as limited manifestations not meeting ISG and Japan Research Committee Criteria, but diagnosed as BD by expert opinion. 51 patients were recruited from Behçet's Clinic of Marmara University. Bilateral CFV wall thickness was measured in the prone position from the posterior wall by an experienced radiologist blinded to the clinical data.

Results: The mean age of suspected BD patients was 39 years (SD: 10.9), and the mean disease duration was 60.3 (SD: 51.7) months *(Table 1)*. 42 (82.4%)had major organ involvement (20 vascular, 8 ocular, 8 neurological involvement). The mean right CFV (R-CFV) wall thickness was 0.71 (SD: 0.16) mm, the left CFV (L-CFV) wall thickness was 0.71 (SD: 0.15) mm in the study group. Bilateral CFV thickness was significantly higher than age-sex-matched healthy controls ($p< 0.001$ for both). There was no difference between patients with and without vascular involvement (*Table 2, Figure 1)*. 48 (94.1%) patients had CFV wall thickness above the cut-off value of ≥ 0.5 mm.

Conclusion: Our study shows that CFV thickness measurement can be helpful in daily practice for the differential diagnosis of BD in patients presenting with limited disease manifestations. Early diagnosis of BD is important, especially in cases presenting with venous thrombosis due to major treatment differences between thrombosis associated with BD and non-inflammatory thrombosis. Our results suggest that CFV thickness measurement is a noninvasive, and widely accessible diagnostic tool in suspected BD.

Abstract Number: 1565

Baseline Vascular Ultrasound of Polymyalgia Rheumatica Patients at Time of Diagnosis Predicts Clinical Outcomes at 3 Months

Sharon Cowley[1], Colm Kirby[2], Patricia Harkins[3], Richard Conway[4] and David Kane[5], [1]Tallaght University Hospital, Dublin, Dublin, Ireland, [2]Tallaght University Hospital, Dublin, Ireland, [3]St James's Hospital, Dublin, Ireland, [4]Trinity College Dublin, Dublin, Ireland, [5]Tallaght University Hospital & Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been reported that up to a quarter of patients with polymyalgia rheumatica (PMR) have subclinical giant cell arteritis (GCA). It is currently uncertain if the presence of this finding may predict clinical outcomes in PMR.

Methods: 65 newly diagnosed PMR patients who met a clinical diagnosis for PMR were examined with ultrasound of their temporal and axillary arteries at time of diagnosis. US of all 6 branches of the superficial temporal arteries and both axillary arteries was performed using a GE P9 device. Sonographic abnormalities considered indicative of vasculitis in the temporal arteries included the halo sign and non-compressible arteries with a thickened intima-media complex. An intima-media thickness of 0.42mm for the common superficial temporal branch, 0.34mm for the frontal branch, and 0.29mm for the parietal branch was considered positive. In the axillary arteries, a halo sign, and an intima-media thickness of >1.0mm was considered positive. Halo scores were calculated for positive cases. Clinical, ultrasound and laboratory characteristics were recorded at baseline, 1 month and 3 months. Ultrasound findings were compared to a cohort of 48 GCA patients.

Baseline Characteristics	PMR (54)	PMR with subclinical GCA (11)	GCA (48)
Age (mean and range)	71.2 (51-89)	68.2 (53-78)	72.8 (56-92)
Female	32	3	17
Male	22	8	33
Mean baseline ESR (mm/hr)	41	51	57
Mean baseline CRP (mg/l)	38	36	53
Mean initial steroid dose (mg)	17.2	20.4	45.5
3 month outcomes			
Mean cumulative steroid at 3 months (mg) + SD	1336.8 ± 404.3	2051.5 ± 840.7	2411.3 ± 424.6
% of patients with relapse at 3 months	14.8%	36.6%	6%

Baseline Characteristics And Three-Month Outcomes:

Results: 65 patients with a clinical diagnosis of PMR and 48 patients with a diagnosis of GCA were included in the study. 58 (89%) of the PMR patients met the 2012 ACR/EULAR PMR classification criteria (those who did not meet this classification were primarily due to prior corticosteroid use in primary care resulting in normal ESR/CRP). All 48 GCA patients met the 2022 ACR/EULAR GCA classification criteria. 20.3% of patients with PMR had evidence of subclinical GCA on ultrasound of their temporal and axillary vessels. The mean initial prednisolone dose initiated for PMR was 17.2mg, while those with subclinical GCA in PMR were started on a mean of 20.4mg prednisolone and those with GCA were on average started on 45.5mg of prednisolone. The mean cumulative corticosteroid dose at 3 months was 1336.8mg ± 404.3mg for PMR, 2051.5mg ± 840.7mg for subclinical GCA in PMR and 2411.3 ± 424.6 in GCA. PMR with subclinical GCA had significantly more cumulative corticosteroid than those with pure PMR (p=0.0069). Patients with subclinical GCA in PMR were more likely than either those with PMR or GCA patients to experience a relapse, with 36.6% of patients having a minor relapse, compared to 14.8% of the PMR group and 6% of the GCA group having a minor relapse in the first three months of treatment.

Conclusion: The presence of subclinical GCA in PMR at baseline predicts increased cumulative steroid dose at three months compared with PMR alone. Patients with subclinical GCA in PMR are also more likely to have a clinical relapse in the first three months of treatment than those with either PMR or GCA.

Exposure-Response Analysis of Sarilumab in Patients with Polymyalgia Rheumatica

Christine Xu[1], Ying Liu[1], Jennifer Sloane[2], Remco Diab[3], **Hubert van Hoogstraten**[1], Hisham Abdallah[4], Sreeraj Macha[1] and Bhaskar Dasgupta[5], [1]Sanofi, Bridgewater, NJ, [2]Sanofi, Cambridge, MA, [3]Sanofi, Rotkreuz, Switzerland, [4]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [5]Anglia Ruskin University, East Anglia, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarilumab blocks interleukin-6 (IL-6) from binding to the membrane-bound and soluble IL-6 receptor-α subunit (IL-6Rα). Sarilumab is now approved for both rheumatoid arthritis (RA) and polymyalgia rheumatica (PMR) in adult patients. The objectives of the exposure-response (E-R) analyses presented here are to characterize the pharmacokinetic-pharmacodynamic (PK-PD) relationships of sarilumab exposure with key efficacy, and safety endpoints in patients with PMR.

Methods: The SAPHYR study (NCT03600818) assessed the efficacy and safety of sarilumab in patients with steroid resistant active PMR. Patients were randomized (1:1) to 52 weeks of treatment with sarilumab 200 mg every 2 weeks (q2w) + 14 weeks glucocorticoid (GC) tapering regimen or placebo q2w + 52 weeks GC tapering regimen. In the E-R analyses, the efficacy endpoints included the primary endpoint of the proportion of patients achieving sustained remission at Week 52 and the cumulative proportion (%) of patients who had rescue GC therapy during the 52-week treatment period; the safety endpoints included treatment-emergent adverse events (TEAEs), serious adverse events, adverse events of special interest, and absolute neutrophil count (ANC). PK-PD relationships were assessed using descriptive E-R analyses for the efficacy and safety endpoints and were explored graphically for biomarkers (IL-6, total soluble [s] IL-6Rα and C-reactive protein [CRP]) using the observed steady state trough concentrations (C_{trough}) of sarilumab at Week 24. Descriptive E-R analyses were conducted by tertiles of sarilumab steady-state C_{trough}. Results were compared with results in patients with RA when appropriate.

Results: Greater sarilumab C_{trough} in patients with PMR was associated with an increase in total sIL-6Rα and a decrease in CRP levels and was similar in patients with PMR and RA.

There was a slight increase in the proportion of patients achieving sustained remission from the low to the medium tertile. The treatment effect approached a plateau with increasing $C_{trough.}$ However, higher C_{trough} was not associated with decreased need for rescue therapy. No clear E-R relationships were observed between increasing sarilumab C_{trough} and a higher incidence of TEAEs. There was a greater ANC reduction with an increase in sarilumab C_{trough}; however, the effect appeared to reach a plateau at ~20 mg/L. In contrast, no higher proportion of patients with ANC < 1.0 Giga/L in patients with increasing sarilumab C_{trough} was observed. These results in patients with PMR were consistent with those observed in patients with RA.

Conclusion: The PK-PD relationship between sarilumab exposure and efficacy, and safety endpoints demonstrated that the pharmacodynamic effect of sarilumab appeared to reach a plateau at C_{trough} levels of 20 to 25 mg/L for target saturation, supporting a sarilumab dose of 200 mg q2w for the treatment of patients with PMR.

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Damage is the irreversible consequence of disease or its treatment**.** This study aimed to evaluate the accrual of damage in Takayasu's arteritis (TAK) using 2 currently-available indices of damage.

Methods: Patients with TAK enrolled in a multicenter, prospective, observational cohort from North America, and, a single-center in Turkey were included. Damage was assessed using the Vasculitis Damage Index (VDI) and the Large-Vessel Vasculitis Index of Damage (LVVID) at baseline and last visit.

Results: The study included 350 patients with TAK, mean±SD age 40.3 (13.4) years, 91% female, median (25^{th}, 75^{th} percentile) disease duration 69 (1.6, 274) weeks. 39% were enrolled ≤180 days from diagnosis. 313 (89%) had at least 1 follow-up visit, median (25^{th}, 75^{th}) duration 4.5 (2.1, 8.0) years. Damage was present at first visit in 83% on VDI, 89% on LVVID with median VDI (range) 3 (0, 10) and median (range) number of damage items on LVVID 3 (0, 13). Most items of damage at baseline visit were captured in the peripheral vascular (83% VDI, 89% LVVID) and cardiac (42% VDI, 44% LVVID) categories. At last follow-up, damage items were noted in 95% on VDI and 95% on LVVID mainly in the peripheral vascular (97% VDI, 89% LVVID) and cardiac (60% VDI, 59% LVVID) categories (**Table 1**). *New* damage was captured in 52% patients on VDI and 53% on LVVID. In patients with *new items,* median (range) number of *new* items was 1 (range 1, 13) on VDI and 2 (1, 17) on LVVID (**Table 1**). The majority of *new* items of damage were disease-related and were in the peripheral vascular (18% VDI), and cardiac (18% VDI) categories on VDI and cardiovascular category (37% total, 26% peripheral vascular, 20% cardiac) and "Other" (22%) categories on LVVID (**Table 1**). The most frequent items of damage at last visit in the most frequently affected categories, and, *new* items of damage at last visit are in **Table 2**. Damage captured on VDI but not LVVID included major vessel stenosis (83%), pulse loss (98%), elevated diastolic blood pressure (40%), second pulse loss (12%); items of damage captured on LVVID but not VDI included hypertension (40%), arterial thrombosis (41%), renal artery stenosis (28%), damage requiring vascular intervention (8% angioplasty alone, 20% angioplasty with stent), bypass surgery (22%), aortic aneurysms (14%). 12 of 64 items (19%) on VDI and 20 of 87 items (23%) on LVVID were never applicable to

N = number, % = percentage, VDI=Vasculitis Damage Index, LVVID=Large-Vessel Vasculitis Index of Damage, ---=Not applicable (i.e. item not queried on index), [a]Cardiovascular category on LVVID

any patient with TAK but 13 of the 20 (65%) items not used on LVVID were in the ocular category with manifestations that can occur in giant cell arteritis.

Conclusion: Damage is present in >80% of patients with TAK at first visit. During follow-up, new damage items, mostly disease related, are observed in 50% including new cardiovascular damage in nearly 40%. LVVID captures *new* damage items in the cardiovascular category more comprehensively than VDI but many damage items were captured in the "Other" category on both measures. Based on these results, LVVID can be modified and streamlined to more efficiently measure damage in TAK and perhaps be focused on disease-related damage. Disease-associated damage accrues in TAK despite treatment and assessment of damage should be included in therapeutic trials.

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Conventional disease-modifying anti-rheumatic drugs (cDMARDs) are recommended in addition to glucocorticoids (GC) for all active Takayasu's arteritis (TAK) patients as the first-line therapy. However, there is limited data comparing cDMARDs as the first-line immunosuppressive (IS) treatment. In this study, we aimed to compare the outcomes of methotrexate (MTX) and azathioprine (AZA), which were used most frequently as the first-line cDMARDs, in TAK patients.

Methods: TAK patients who received cDMARDs in addition to GCs as the initial therapy were included in this multicenter retrospective cohort study. Clinical, laboratory and imaging data of the patients were assessed. In addition, a match analysis (cc match) using variables 'age', 'gender' and 'diffuse aortic involvement' was performed between patients who received MTX or AZA as first-line cDMARD treatment.

Results: We included 301 (F/M: 260/41, mean age: 42.2±13.3) patients from 10 centres in the study. As the first-line cDMARD, 204 (67.8%) patients received MTX and 77 (25.6%) patients received AZA. First cDMARD was cyclophosphamide in 17 (5.6%), leflunomide in 2 (0.5%) and mycophenolate mofetil in one patient. The remission, relapse and radiographic progression rates were similar between patients who received MTX and AZA as first-line cDMARDs. Vascular surgery rate was higher in the AZA (23% vs. 9%, p=0.001), whereas the frequency of patients receiving ≤5 mg/day GCs at the end of the follow-up was higher in the MTX group (76 vs 62%, p=0.034). Similarly, the rate of vascular surgery was higher and the GC dose reduction rate (≤5 mg) was lower in AZA group in match analysis. Drug survival was similar between

PGA: Physician global assessment

MTX and AZA groups (median 48 months, MTX vs AZA: 32% vs 42%, p=0.34). IS therapy was discontinued in 18 (11 MTX, 7 AZA) patients during the follow-up period due to remission. In the IS discontinuation group 2 patients had a relapse at 2 and 6 months, while 16 patients were still on remission at the end of mean 69.4 (±50.9) months of follow-up.

Conclusion: Remission, relapse, radiographic progression and drug survival rates of azathioprine and methotrexate were similar in Takayasu's arteritis patients having the first-line of therapy. The rate of vascular surgery was higher and the rate of steroid dose reduction was lower with azathioprine compared to methotrexate at the end of the follow-up.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To compare the efficacy and safety of tofacitinib and tocilizumab in patients with Takayasu arteritis (TAK) in real world situation.

Methods: A post-hoc analysis was conducted in 84 patients with TAK registered in the Chinese Registry of Systemic Vasculitis (CRSV) cohort [median age 26 years (interquartile range 22-32), 76 (90%) females] were included (Figure 1). Patients who were treated with either tofacitinib (*n*=42) or tocilizumab (*n*=42) were followed up regularly according to the pre-set protocol. Complete response was defined as both clinically and imagine remission with the dosage of prednisone ≤ 10mg daily

Table 1 Baseline characteristics of patients with Takayasu's arteritis in tofacitinib and tocilizumab treatment groups

Characteristics	Total (N=84)	Tofacitinib (N=42)	Tocilizumab (N=42)	*P*-value

Note: IQR: interquartile range; NIH: National Institute of Health; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein; IL-6: interleukin-6; TNF-a: tumor necrosis factor-a. * Combinations of immunosuppressive agents: MTX+MMF(7), MTX+AZA(2), MMF+HCQ(2), LEF+HCQ(2), MTX +TAC(1), MTX+LEF(1), MTX+HCQ(1), MTX+CTX(1), MTX+CsA(1), MTX+HCQ+CsA(1), MTX+HCQ+AZA(1), CTX+TAC(1), AZA+TAC(1), AZA +LEF(1), AZA+HCQ(1), AZA+CTX(1). # Number of patients who ever received cyclophosphamide.

and normal acute-phase reactant, while partial response were the same with complete response except that ESR was less than 40mm/h or hs-CRP (hypersensitive C reactive Protein) higher than 16mg/L or the acute-phase reactant decreased by more than 50% compared to the baseline.

Results: The baseline clinical features and demographic date were similar in these two groups (Table 1). Complete response at 6 months was found in 18/27 (67%) patients treated with tofacitinib and 22/32 (69%) with tocilizumab, and rates of overall response in intention-to-treat (ITT) populations were 43% and 52% respectively (P>0.05). At 12, 18 and 24 months, the rates of overall response in ITT population (41%, 24% and 14% *vs*. 41%, 36% and 29%) and in per-protocol (PP) population (77%, 71% and 75% *vs*.65%, 83% and 80%) were similar in patients treated with tofacitinib to those with tocilizumab (Table 2). There were no significant difference found in the changes of ESR, CRP, TNFa, dose of glucocorticoid, mural thickness and lumen diameters of common carotid and subclavian arteries in these two groups. And the cumulative incidences of relapse, treatment failure, and drug retention were similar, too (Figure 1). The drug retention rates at 6, 12, 18 and 24 months in patients treated with tofacitinib and tocilizumab were 64%, 52%, 33% and 19% *vs*. 76%, 60%, 43% and 36%, respectively.

Six (14%) adverse events occurred in the tofacitinib treatment group (including 3 patients with herpes zoster infection, 1 with pulmonary infection, 1 with headache and 1 with abdominal pain) and 6 (14%) occurred in the tocilizumab treatment group (including 2 patients with back pain, 1 with acute pancreatitis, 1 with pulmonary infection, 1 with vomiting and 1 with hepatic dysfunction).

Conclusion: Tofacitinib and tocilizumab are both effective for refractory TAK with similar response rates, cumulative incidences of relapse, treatment failure, and drug retention. Both medications may be effective alternatives for patients who failed to respond to traditional immunosuppressive agents.

Table 2 Response to treatment at 6, 12, 18 and 24 months by intention-to-treat analysis and per-protocol analysis among patients with Takayasu's arteritis in tofacitinib and tocilizumab treatment groups

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The 2022 ACR/EULAR classification criteria for Takayasu arteritis (TAK) rely on a point-based clinical and imaging scoring system (from 0 to 22). The aim of this study is to investigate whether the baseline cumulative score and the fulfillment of each item included in the score correlate with the long-term prognosis of TAK patients.

Methods: Data of TAK patients from 4 centres (2 from Italy; 2 from India) were retrospectively reviewed. For each patient, the score provided by the 2022 classification criteria was calculated and the following outcomes were evaluated: glucocorticoid (GC) suspension, need of conventional and biologic DMARDs (cs- and bDMARDs) introduction, need of vascular procedures. Data on bDMARDs were retrieved only from the Italian cohorts. Correlation of these outcomes with the cumulative baseline score and with single item fulfillment was assessed. Additionally, the correlation between baseline ACR/EULAR 2022 score and disease activity indexes (i.e., DEI.Tak, ITAS2010) was evaluated. Univariate and multivariate logistic analyses and Spearman correlation analyses were performed as appropriate.

Table 1 legend. Univariate and multivariate logistic analyses evaluating the association of each item with different outcomes

Abd. aorta + renal/mesenteric involvement	0.479	0.293-0.782	**0.002**	0.577	0.341-0.976	**0.040**	0.790	0.472-1.329	0.358				1.233	0.592-2.569	0.576				1.074	0.670-1.699	0.761			

Results: We included 407 patients (163 from Italy; 244 from India) with a median follow-up of 80 (IQR, 37-143) months. Mean baseline score was 10.1 ± 3.5 and 378 (92.9%) patients were classified as TAK according to the 2022 ACR/EULAR criteria. GCs were started in 348 patients (85.5%) and suspended in 110 (31.6%) after a median of 43 (IQR, 23-87) months. csDMARDs were started in 331 patients (81.3%) after a median of 1 (IQR, 0-5) month. bDMARDs were started in 108 patients (66.3%) after a median of 16 (IQR 8.8-39) months. Vascular procedures were performed in 101 patients (24.8%). Mean baseline DEI.Tak and ITAS2010 scores were 8.8 ± 5.5 and 10.4 ± 6.6, respectively. A higher baseline cumulative score was negatively associated with GC suspension (OR 0.901 [95%CI 0.844-0.962], p=0.002) and positively associated with csDMARD introduction (OR 1.102 [95%CI 1.027-1.184] p=0.007). No correlation with bDMARD start and vascular procedures was found. **Table 1** shows the association of each item with different outcomes. At multivariate analysis, difference in blood pressure ≥20 mmHg and abdominal aorta + renal/mesenteric involvement were negative predictors of GC suspension; limb claudication and carotid abnormalities were predictors of csDMARD introduction. Angina/ischemic cardiac pain was predictor of need for vascular procedure, conversely to carotid abnormalities. Finally, a higher score strongly correlated with both baseline DEI.Tak (rho=0.549, p< 0.001) and ITAS2010 (rho=0.575, p< 0.001).

Conclusion: A higher baseline score obtained from the ACR/EULAR 2022 TAK classification criteria was associated with a more aggressive disease course. No specific item was associated with disease prognosis. At baseline, the ACR/EULAR 2022 score might be a surrogate of disease activity scores.

Abstract Number: 1571

Tocilizumab in Pregnant Takayasu Arteritis - The Use of Tocilizumab at Conception and Throughout Pregnancy in Those with Takayasu Arteritis

Nurul Aulia Zakaria[1], Andrew Porter[2], Robert Maughan[2], Charis Pericleous[2], Japna Satara[3], Matthew Colquhoun[4], Priyanka Agrawal[3], jan Nouza[3], Harold Wilson-Morkeh[3], Taryn Youngstein[2] and Justin Mason[2], [1]National Heart & Lung Institute, Imperial College London, Kuantan, Malaysia, [2]National Heart & Lung Institute, Imperial College London, London, United Kingdom, [3]Rheumatology, Hammersmith Hospital, London, United Kingdom, [4]Department of Rheumatology, Imperial College Healthcare Trust, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TA) is a large vessel vasculitis predominantly affecting female of reproductive age. Tocilizumab (TCZ) is frequently used in synthetic DMARD refractory cases. Preclinical animal studies and small case reports suggest potential teratogenicity of TCZ in pregnancy. The current ACR guidance is to continue TCZ at conception but to cease upon confirmation of pregnancy. Herein we describe the use of tocilizumab throughout pregnancy in those with TA.

Methods: A total of 160 cases of TA were identified from a single center in the United Kingdom from 2016-2023. Cases limited to female who received TCZ during pregnancy were screened. Data regarding disease, medications, and pregnancy outcomes; live birth, miscarriage, fetal abnormalities, and fetal anomalies were extracted from the database.

LBW -Low birth weight

Pregnancy Outcomes

Results: Out of 160 TA patients, 45 were on TCZ between 2016-2022. Six patients were identified to have concomitant use of TCZ during pregnancy, all received Tocilizumab 162mg subcutaneously per week. The baseline characteristic and pregnancy outcomes of each case are shown in Table 1 and 2 respectively. The age at delivery range between 28 to 33 years old with the mean duration of illness of 7.5 years. In 5/6 cases the risk of flare off tocilizumab was considered higher than the potential teratogenicity. Patients and obstetric physicians were involved in the decision making. In 2 of 6 cases TCZ was stopped prior to the active transport of the monoclonal antibody across the placenta from week 30 of gestation. In 3 cases risk of flare was considered so high that TCZ was continued throughout gestation. Live vaccination of the newborn was avoided in all cases. No teratogenicity was reported following TCZ usage in TA pregnancy. However, a high proportion (50%) of pre-term deliveries and low birth weight were observed.

Conclusion: The use of TCZ in TA is well established. TA is a disease predominantly in female of childbearing age. Often TCZ cannot be stop during pregnancy. We describe six successful pregnancies exposed to tocilizumab with good maternal and neonatal outcomes

Abstract Number: 1572

Long-term Efficacy and Retention Rate of Molecular Targeted Drugs in Takayasu Arteritis

Tsuyoshi Shirai[1], Hiroko Sato[1], Tomonori Ishii[2] and Hiroshi Fujii[1], [1]Tohoku University, Sendai, Japan, [2]Clinical Research, Innovation and Education Center, Tohoku University Hospital, Sendai, Japan

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TAK) is a type of large-vessel vasculitis that predominantly affects young females. The relapse is frequent, accounting for 60% of cases, and molecular targeted drugs including tocilizumab (TCZ) and tumor necrosis factor inhibitor (TNFi) are used. Although the steroid-sparing effect of molecular targeted drugs has been reported in short period, information about the long-term efficacy and retention rate is scarce. The aim of this study is to investigate the long-term efficacy and retention rate of molecular targeted drugs in TAK.

Methods: 117 patients with TAK who satisfied the JCS or ACR classification criteria and visited Tohoku University Hospital during 2018 to 2022 were enrolled to this study. The use of molecular targeted drugs, clinical background, long-term efficacy and retention rate of the drugs were retrospectively evaluated.

Results: 45 of 117 patients (38.5 %) received molecular targeted drugs, and all were applied for the relapse of TAK. The clinical characteristics of patients required molecular targeted drugs included young age at onset and the presence of extra-arterial comorbidities. Eight and four patients required more than two and three molecular targeted drugs, respectively. The numbers of molecular targeted drugs used were as follows, TCZ, 35; TNFi, 12; JAK inhibitors, 2; abatacept, 1; rituximab, 1. During 45 months of median-follow up period after the initiation of molecular targeted drugs, the retention rate

was as follows; TCZ, 77.1 %, TNFi, 91.6 %. TCZ was discontinued in following cases; infection, 3; major relapse, 2; exacerbation of extra-arterial manifestation, 2; infusion reaction, 1. In four patients who discontinued TCZ, TNFi was used as the 2nd molecular targeted drug. Although the retention rate of TCZ was high, TCZ was not discontinued in following seven cases; worsening of vascular legion, 2; major relapse without vascular change, 2; minor relapse, 2; severe infection, 1. This was because there existed little evidences for the effectiveness of other molecular targeted drugs. The discontinuation of TCZ was frequent in patients receiving vascular surgery or complicating with extra-arterial comorbidities. Of note, severe colitis was observed in 8.8% of patients receiving TCZ, and infective endocarditis was also documented. The mean dose of prednisolone (PSL) was significantly reduced in patients receiving molecular targeted drugs, irrespective of drugs, as follows; before initiation, 10.1±3.9 mg/day; upon initiation 25.1±11.6mg/day; the most recent, 5.6±3.7 mg/day. PSL was discontinued in seven cases treated with TCZ, and six cases remained relapse-free.

Conclusion: The retention rate of molecular targeted drugs was high, and molecular targeted drugs were useful for the maintenance of remission and reducing the dose of corticosteroid in relapsed cases. Nevertheless, there existed patients who were not able to change TCZ due to insufficient evidences of other molecular targeted drugs in TAK.

Abstract Number: 1573

Inpatient Prevalence and Comorbidity of Takayasu's Arteritis: Nationwide Inpatient Sample 2016-2020

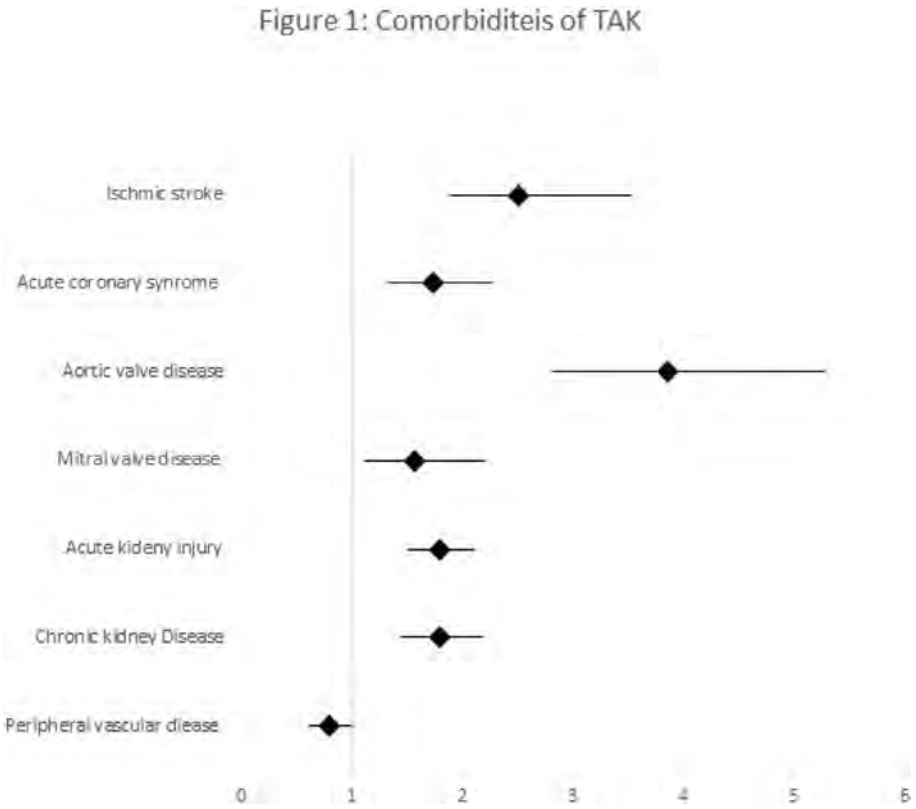
Husam el Sharu[1], Sukhvir Singh[1], Omar Alwahadneh[2], Mohammad Alqaisieh[3] and Laksmi Subramanian[1], [1]East Carolina University, Greenville, NC, [2]Carle Foundation Hospital, Urbana, IL, [3]Hamilton Medical Center, Dalton, GA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu's Arteritis (TAK) is a granulomatous large-vessel vasculitis that affects the aorta and its branches, and it is more commonly observed in women. We aimed to describe the prevalence, comorbidities, and burden of admitted TAK patients in the United States

Methods: The 2016-2020 National Inpatient Sample database (NIS) was analyzed to identify adult hospitalizations with TAK, using International Classification of Diseases – 10 Clinical Modification (ICD-10-CM) codes. The studied primary outcome was to assess TAK inpatient comorbidities. A multivariate logistic regression, and linear regression analyses were used to adjust for possible confounders.

Results: 5439 hospitalizations of TAK were analyzed. Of these, 4389 (80.69%) were females. The mean age was 52.2. Logistic regression analysis showed that patients had a higher risk of ischemic stroke (adjusted Odds Ratio [aOR] of 2.5, 95% Confidence Interval [CI] 1.89-3.53), acute coronary syndrome (aOR: 1.73, CI: 1.32-2.28), aortic valve disease (aOR: 3.86, CI: 2.81-5.28), mitral valve disease (aOR: 1.57, CI: 1.12-2.21), acute kidney injury (aOR: 1.79, CI: 1.51-2.11), and chronic kidney disease (aOR: 1.79, CI: 1.45-2.19). There was no statically significant difference in peripheral vascular disease (aOR: 0.79, CI: 0.62-1.02). Patients with TAK required the use of more expensive imaging modalities (aOR: 2.84, CI: 1.40-5.74). Figure 1 shows the Forrest plot for multivariate analysis of in hospital morbidities when adjusted for patient demographics, comorbidities, and hospital characteristics.



Comorbidities of TAK

Conclusion: Analysis of patients with TAK showed a higher risk of comorbidities including ischemic stroke, acute coronary syndrome, aortic valve disease, mitral valve disease, acute kidney injury, and chronic kidney disease.

The Role of ^{18}F-FDG PET/CT Scans in Takayasu Arteritis

Sahil Jain[1], Abdulrahman Khormi[2], Marcela Munoz-Urbano[3], Shirish Sangle[1] and David D'Cruz[4], [1]Louise Coote Lupus Unit, Guy's and St Thomas' Hospital NHS Foundation Trust, London, United Kingdom, [2]Prince Sattam University Medical College, Al-Kharj, Saudi Arabia, [3]Clínica Imbanaco, Cali, Colombia, [4]Guy's Hospital, Louise Coote Lupus Unit, London, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TA) is a large-vessel vasculitis which primarily affects the aorta and its main branches. Accurate assessment of disease activity has always been challenging and inadequate treatment may result in irreversible damage. The Indian Takayasu Clinical Arteritis Scores (ITAS 2010, ITAS.A) are validated and reliable measures of

disease activity. Positron-emission tomography (PET) and ^{18}F-FDG PET with computed tomography (PET/CT) are non-invasive metabolic imaging modalities that have been proposed as important tools to assess disease activity.

Methods: We retrospectively studied 26 TA patients between January 2008 – March 2023. The diagnosis was confirmed on clinical, laboratory and imaging criteria. Disease activity as assessed by the ITAS 2010, clinical, laboratory and imaging techniques (including magnetic resonance imaging, Doppler ultrasound and/or digital subtraction angiography) was compared with the results of the PET/CT scans.

Results: Median age at TA diagnosis was 33 years (13-57). There were 22 females (84.6%), 4 males and Caucasians (61.5%), Asians (30.8%) and Afro-Caribbean (7.7%). Median follow up was 156 months (20 – 444). Thirteen of 26 patients (50%) had positive antiphospholipid antibodies (aPL). Two of the patients were diagnosed with obstetric anti-phospholipid syndrome (APS) and 1 with both thrombotic and obstetric APS.

Of 26 patients, there were 43 PET/CT scans performed in 22 patients. Ten patients had a single scan and 12 patients had 2 or more scans (maximum 4 scans). Nine scans were done for diagnosis and 34 during follow up. Of the 9 diagnostic scans, all 9 had clinically active disease (ITAS score ≥ 2), 8 (88.9%) had raised inflammatory markers (median ESR 57 (20 -115), median CRP 46 (1-126)) and 7 (77.8%) had a positive PET scan (suggestive of active vasculitis). Of the 34 follow up scans, 27 scans (in 17 patients) had clinically active disease (ITAS score ≥ 2) and 7 scans (in 6 patients) were in remission (ITAS score 0). Of the 27 scans with clinically active disease, 12 scans were positive (44.4%). In the remaining 15 scans,

Table 1: Role of PET scan in Takayasu Arteritis (TA)

Groups	No. of scans (n)	Median ESR (range)	Median CRP (range)	ITAS ≥ 2 (n)	PET +ve (n)	%
1. Patients with active disease (symptomatic ± raised ESR/CRP)						
• For diagnosis	9	57 (20-115)	46 (1-126)	9	7	77.8%
• For flares	10	47 (11-118)	35 (8-48)	10	6	60%
2. Asymptomatic patients with raised ESR, CRP	2	65 (15-115)	18 (6-30)	0	0	-
3. Asymptomatic patients with radiological progression	7	15 (8-53)	9 (1-34)	7	2	28.6%
4. Symptomatic patients with normal ESR, CRP	10	5 (2-17)	1 (0-3)	10	4	40%
5. Patients in remission (normal ESR/CRP, asymptomatic)	5	6 (2-20)	2 (0-2)	0	0	-
Total	43					

11 (73.3%) were done while on steroids and/or immunosuppression (median prednisolone dose 5mg (2.5 - 10mg)). The 7 follow up scans in clinical remission and had no FDG uptake.

Conclusion: ^{18}F-FDG PET/CT scanning is helpful as a diagnostic and monitoring tool to assess disease activity in TA. PET scan imaging correlates with ITAS activity. Corticosteroid therapy may negatively impact the PET scan result and results should be correlated carefully with clinical, laboratory and other radiological assessments. It remains unclear whether presence of aPL/APS is a clinically important association.

Takayasu Arteritis Is Associated with Worse Fatigue Than Healthy Controls Which Persists over Time - A Longitudinal Cohort Study

Darpan Radheshyam Thakare, Upendra Rathore, Kritika Singh, Vikas Agarwal and Durga P Misra, Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Lucknow, India

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Few studies have assessed patient-reported outcome measures in Takayasu arteritis (TAK), a rare large vessel vasculitis. We prospectively analysed fatigue and fibromyalgia in TAK and its relationship with disease activity in a large cohort of TAK from India.

Methods: Patients with TAK satisfying ACR 1990 criteria or 2012 Chapel Hill consensus conference definition for TAK and age- and gender-similar healthy controls (HC) were enrolled after written informed consent. Disease activity scores (using DEI.TAK, ITAS2010 and NIH disease activity scores), fatigue [using Multidimensional Fatigue Inventory (MFI), FACIT Fatigue Scale (Version 4)] and fibromyalgia (using 2019 American College of Rheumatology diagnostic criteria for fibromyalgia) were assessed at baseline and 6 months.

TAK were compared with healthy controls using unpaired student's t-test or Chi squared test. Comparisons between TAK at baseline and at 6 months follow-up were performed using paired student's t-test or Chi squared test. Pearson's correlation coefficient was computed for the association of fatigue and fibromyalgia scores with disease activity scores. p values < 0.05 were considered as statistically significant.

Results: One hundred and two TAK patients (Females-73.5%, mean age-35.5 years, mean disease duration-94.4 months) and fifty healthy controls (Females-68%, mean age-31.4 years) were enrolled. Hata's Type V was the most common angiographic subtype (63.7%) and 17.6% had active disease as per physician global assessment. TAK had greater severity of fatigue than HC [MFI (p= 0.045), FACIT (p =< 0.001), *lower FACIT scores indicate greater fatigue*]. The prevalence of fibromyalgia was similar between TAK and HC (p=0.286) (Table 1). Active TAK had higher fatigue scores [MFI (p= 0.002), FACIT (p=0.033)] than inactive TAK (Table 2). At baseline, MFI had weak positive correlation (r=0.231, p=0.019) & FACIT score had weak negative correlation (r=-0.226, p =0.022) with NIH disease activity score but not with ITAS 2010 or DEI TAK. The

ACR- American College of Rheumatology, CRP – C-reactive protein, , DEI.TAK- Disease Extent Index for Takayasu Arteritis, ESR – Erythrocyte sedimentation rate, FACIT- The Functional Assessment of Chronic Illness Therapy, ITAS2010- Indian Takayasu Clinical Activity Score 2010, , ITAS-A-CRP – ITAS2010 adjusted for CRP, ITAS-A-ESR – ITAS2010 adjusted for ESR, MFI- Multidimensional Fatigue Inventory, NIH- National Institute of Health, SD- standard deviation, TAK- Takayasu arteritis,

number of items on the 2019 ACR diagnostic criteria for fibromyalgia showed a weak positive correlation with ITAS 2010 (r=0.230, p=0.020), DEI TAK (r=0.227, p=0.022), and NIH disease activity score (r=0.285, p=0.004). No difference was observed in fatigue or fibromyalgia scores at six months of follow-up (Table 3).

Conclusion: Fatigue was more prevalent in TAK than in healthy controls, and correlated with TAK disease activity. Fibromyalgia did not differ between TAK and controls. Fatigue and fibromyalgia remained similar in TAK over time.

ACR: the American College of Rheumatology; EULAR: the European Alliance of Associations for Rheumatology; TAK: Takayasu arteritis; CT: computed tomography, FDG-PET: fluorodeoxyglucose-positron emission tomography, MR: magnetic resonance.

Background/Purpose: Recently, a joint group of the American College of Rheumatology (ACR) and the European Alliance of Associations for Rheumatology (EULAR) proposed new criteria for Takayasu arteritis (TAK) (the 2022 ACR/EULAR criteria). This study applied the 2022 ACR/EULAR criteria to patients with previously diagnosed TAK based on the 1990 ACR criteria and investigated the concordance rate between the two criteria according to the four imaging modalities.

Table 2. Comparison of the results of the application of the 2022 ACR/EULAR criteria to patients with previously diagnosed TAK (CT angiography and FDG-PET performed simultaneously) (N=61)

Table 2. Comparison of the results of the application of the 2022 ACR/EULAR criteria to patients with previously diagnosed TAK (CT angiography and FDG-PET performed simultaneously) (N=61)

Among patients undergoing at least one of the four imaging modalities		153/156 (98.1)	22/23 (95.7)	0.426

Values are expressed as number (percentage) or median (quartile).
ACR: the American College of Rheumatology; EULAR: the European Alliance of Associations for Rheumatology; TAK: Takayasu arteritis.

Methods: This study reviewed the medical records of 179 patients who met the 1990 ACR criteria for TAK. The imaging modalities included conventional angiography, computed tomography (CT) angiography, fluorodeoxyglucose-positron emission tomography (FDG-PET), and magnetic resonance (MR) angiography.

Results: Regardless of the imaging modalities, the concordance rate between the two criteria was 85.5% when including all patients, whereas, it increased to 98.1% when only patients aged ≤60 years were included. Among the four imaging modalities, CT angiography exhibited the highest concordance rate between the two criteria (85.6%). The concordance rate among patients aged >60 years was 95.7%. Only one patient aged 50—60 years was reclassified as having both TAK and giant cell arteritis (GCA).

Conclusion: The concordance rate was 85.5% regardless of the imaging modalities, and increased to 86.9% on simultaneous CT angiography and FDG-PET imaging. We suggest that the upward readjustment of the age requirement should be reconsidered not to miss patients with TAK over the age of 60.

Analysis of Takayasu's Arteritis as Risk Factor for Acute Coronary Syndrome

Maria Romero Noboa[1], Shilpa Arora[1] and Augustine Manadan[2], [1]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu's arteritis (TAK) is an autoimmune disease that primarily affects the aorta and its major branches. It has an incidence of 1-3 per million people in the USA and Europe and is primarily seen in females between the ages of 10 – 40 years. Coronary artery involvement has been reported in TAK. This study aims to analyze TAK as a risk factor for acute coronary syndrome (ACS) in a US inpatient population.

Methods: We conducted a retrospective review of 2016-2020 National Inpatient Sample (NIS) database. All adult hospitalizations were selected as our study population and were subdivided into those with and without ACS (ICD-10 codes I20 and I21). For ACS risk factors, the following ICD-10 codes were used: diabetes (DM) code E08-E13, hypertension (HTN) code I10, hyperlipidemia (HLD) code E78, and obesity code E66. A univariable analysis was used to calculate unadjusted odds ratios (ORs) for ACS. All variables with p values ≤ 0.2 were included in a multivariable logistic regression model with p values < 0.05 considered to be significant.

Results: There were 148,767,786 adult hospitalizations in the 2016 to 2020 NIS database. Of those, 3,282,749 of those had a primary diagnosis of ACS. Compared to non-ACS hospitalizations (Table 1), the ACS group was older (median age 67 vs 61 years; p< 0.001), had less females (37.8% vs 57.8%; p< 0.001), more Whites (70.7% vs 65.8%; p< 0.001), less

Household Income (%)			
Q1	22.2%	30.3%	0.293
Q2	30.6%	27.1%	0.643
Q3	30.6%	22.9%	0.277
Q4	13.9%	17.9%	0.531
LOS, median (IQR)	2 (1 - 4.5)	3 (2 - 5)	0.716
Total charges median (IQR)	$70,319 (32,179 – 135,036)	$66,803 (36,697 – 116,752)	0.617
In-Hospital Mortality (n, %)	15 (8.3%)	150,130 (4.6%)	0.281

Abbreviations: ACS= Acute Coronary Syndrome; IQR=interquartile range, n=number, CCI= Charlson Comorbidity Index, LOS=Length of Stay; *=Not reported as below permitted reporting threshold; PI=Pacific Islander,

African Americans (11.2% vs 14.9%; p< 0.001), less Hispanics (8.6% vs 11%; < 0.001), same Asian/Pacific Islander (2.7% vs 2.7%; p=0.641), less Native Americans (0.5% vs 0.6%; p< 0.001), higher CCI (3 vs 1; < 0.001), lower household income, higher median total hospital charges ($66,803 vs $32,167; p< 0.001) and higher in-hospital mortality (4.6% vs 2.4%; p< 0.001). LOS was similar between the ACS and non-ACS hospitalizations. Univariable analysis for the outcome of ACS showed that age, white race, lowest income quartile, DM, HTN, HLD, obesity, nicotine dependence/tobacco use and TAK were associated with higher odds of ACS (Table 2). Female, African American race, Hispanic race, Native American race and upper two income quartiles were associated with a lower odds of ACS. Multivariable analysis showed that age (OR 1.02; 95% C.I. 1.0168 – 1.0173), lowest income quartile (OR 1.03; 95% C.I. 1.0093 – 1.0607), DM (OR 1.19; 95% C.I. 1.1786 – 1.1944), HTN (OR 1.06; 95% C.I. 1.0558 – 1.0715), HLD (OR 2.94; 95% C.I. 2.9090 – 2.9666), obesity (OR 1.21; 95% C.I. 1.1981 – 1.2210), nicotine dependence/tobacco use (OR 1.96; 95% C.I. 1.9430 – 19717) and TAK (OR 1.78; 95% C.I. 1.2702 – 2.4976) were associated with higher odds of ACS (Table 2). In comparison to ACS without TAK, ACS with TAK group comprised of more females (86.1% vs 37.8%; p< 0.001) and showed a trend towards being younger (Table 3).

Conclusion: We performed an analysis of the 2016-2020 NIS database to better understand TAK as a risk factor for ACS. After controlling for traditional ACS risk factors, TAK was found to increase the odds of ACS by 1.78 times. Other significant ACS risk factors from the multivariable analysis included age, low income, DM, HTN, HLH, obesity, and nicotine dependence. This study emphasizes the importance of recognizing TAK as a risk factor for ACS especially in women and in the younger population.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TAK) is a chronic, granulomatous large-vessel vasculitis. As TAK has a chronic course, higher frequency rates of anxiety and depression are reported in these patients [Misra DP, et al. Rheumatol Ther. 2021 Sep;8(3):1073-93]. Fibromyalgia (FM) incidence in active TAK patients is higher [Alibaz-Oner F, et al. Intern Med. 2013;52(24):2739-42]. Data regarding the impact of anxiety, depression, and FM in adherence to treatment on TAK have not been previously reported. This study aimed to explore the impact of mental illness and fibromyalgia on adherence to treatment of TAK patients.

Methods: A cross-sectional study was designed for including patients who satisfy the 2022 ACR/ EULAR classification criteria for TAK. FM screening was made with the 2016FM criteria published by Wolfe. Patient Health Questionnaire-9 (PHQ-9) and General Anxiety Disorder-7 (GAD-7) were used to measure depression and anxiety severity. Impact on quality of life was measured by EuroQol-5D (EQ-5D) questionnaire. Patients completed the Morisky-Green Test (MGT) for treatment adherence. Disease activity was assessed by the National Institutes of Health (NIH) scale and the Indian Takayasu Clinical Activity Score (ITAS2010).

Data were described as percentages, mean ± standard deviation or median and interquartile range (IQR) according to its distribution. The assessment of normality was done by the Kolmogorov-Smirnov test. The Chi-square, Fisher test, Student's t-test, or Mann-Whitney U test were used for comparisons as required. The correlation between MGT values and PHQ-9 or GAD-7 was evaluated by Spearman's method. A value of $p < 0.05$ was considered statistically significant.

Results: Fifty-five TAK patients were invited. Two patients denied answering questionnaires, and one was excluded because of a lack of medical data therefore 52 patients were analyzed. Fifty (96%) female patients were included, and the mean age was 39±18. Remission was found in 28 (54%) patients, according to the rheumatology care provider. Activity according to NIH score was found in 16 (30%) patients and by ITAS2010 in 20 (38%) patients. Anxiety was found in 23 (44%) and depression in 30 (58%) patients. 16 (31%) patients have poor treatment adherence, 20 (38%) moderate, and 16 (31%) have high adherence rates. EQ-5D median score was 80 (67-90). 5 patients fulfilled FM 2016 criteria and all of them have depression or anxiety. There was a tendency for lesser MGT scores in mental illness-affected TAK patients [6 (5 -7) vs 7 (6.7-8), p=0.060]. Interestingly, a weak negative correlation between MGT and GAD7 score was found (Rho=-0.314, p=0.023). Higher treatment adherence has a positive significant correlation with better EQ-5D (Rho=0.357, p=0.009) and a negative correlation with the patient global assessment of disease activity (Rho= 0.311, p=0.025). Paresthesias are higher in patients with mental illness (46.9% vs 15%, p=0.018).

Conclusion: Higher treatment adherence scores were associated with a better quality of life and a better patient global assessment of disease activity. Despite anxiety and depression have a high prevalence, there was no great impact on the medication adherence rates. More studies regarding treatment adherence are needed.

Abstract Number: 1579

Sodium-Glucose Co-transporter-2 Inhibitors and the Risk of Cardiac and Renal Outcomes in Systemic Lupus Erythematosus

April Jorge[1], Baijun Zhou[1], Natalie McCormick[1], Chio Yokose[1], Yuqing Zhang[2] and Hyon K. Choi[3], [1]Massachusetts General Hospital, Boston, MA, [2]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Plenary II
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Sodium-glucose cotransporter-2 inhibitors (SGLT2) have benefits on kidney and cardiovascular (CV) outcomes that are largely independent of glycemic control. These benefits have been demonstrated in patients with type 2 diabetes, heart failure, and other causes of proteinuric kidney disease, but it is unknown whether SGLT2 have similar benefits in patients with SLE and lupus nephritis (LN).

Methods: We designed and emulated a pragmatic target trial to determine the impact of SGLT2 versus a comparator oral hypoglycemic agent, dipeptidyl peptidase 4 inhibitors (DPP4), on kidney and CV outcomes among patients with SLE and LN. Using a large US multi-center electronic health record-based SLE cohort (N=96,511), we identified all patients with incident prescriptions for SGLT2 or DPP4 after diagnosis with SLE from 3/2013 to 8/2021. We used propensity score overlap weighting to balance baseline covariates including demographics, geographic region, LN, comorbidities (e.g., CKD, diabetes, heart failure), tobacco use, diabetic complications, HbA1c, medication use including other hypoglycemic agents, angiotensin converting enzyme inhibitors (ACEi)/angiotensin receptor blockers (ARBs), glucocorticoids, hydroxychloroquine, and immunosuppressants, SLE severity index, and healthcare utilization. We assessed the outcomes of renal progression, defined by a decrease in eGFR by ≥30% or new onset end-stage renal disease, and major adverse cardiac events (MACE), defined by CV death or hospitalization for ischemic stroke, myocardial infarction, heart failure, or venous

Table 1. Baseline Characteristics of Patients Initiating SGLT2 Inhibitor Versus DPP4 Inhibitor Therapy

Characteristics	Before Propensity Score Overlap Weighting			After Propensity Score Overlap Weighting

thrombosis. We also assessed the safety outcome of genital infection and the control outcome of traumatic injury. We used Cox regression to assess the risk of each outcome, using an intention-to-treat analysis and a per-protocol analysis with censoring from deviation from treatment assignment.

Results: There were 426 and 865 incident users of SGLT2 and DPP4 with SLE. This included 154 and 270 patients with LN, respectively. After propensity score overlap weighting, all baseline covariates were balanced (**Table 1**). The mean age was 57 years; 89% were female. 36% were Black and 8% were Hispanic. 35% had CKD and 24% had heart failure. ACEi/ARBs were used by 45%. SGLT2 use was associated with a lower risk of MACE (HR 0.69 [95% CI 0.48-0.99]) and renal progression (HR 0.71 [95% CI 0.51-0.98]) than DPP4 use (**Table 2**). Among the subgroup with LN, the risk of MACE was also lower with SGLT2 use (HR 0.58 [95% CI 0.34-0.99]); there were numerical differences in renal progression but it did not reach statistical significance. SGLT2 us was associated with a higher risk of genital infections (**Table 3**). There was no difference in the risk of traumatic injury (HR 1.02 [0.80-1.29]) as expected.

Conclusion: In this cohort of patients with SLE who initiated SGLT2 or DPP4, we found a lower risk of MACE and renal progression associated with SLGT2i use, suggestive of cardiac and renal benefits as have been observed in other disease populations. Limitations include the small sample size and that patients in this study used SGLT2 for non-SLE indications. However, the findings indicate a potential role for SGLT2 for patients with SLE/LN and warrants further investigation in these populations.

Table 2. Cardiovascular and Renal Outcomes Associated with SGLT2 Inhibitors versus DPP4 Inhibitors Among People with Systemic Lupus Erythematosus and Lupus Nephritis

Outcomes	Events, n		Follow-up Time, years		Incidence Rate (per 100 PY)		Hazard Ratio (95% CI)
	SGLT2	DPP4	SGLT2	DPP4	SGLT2	DPP4	
All SLE							
Intention-to-treat							
MACE	36	61	1.7	2.4	7.6	9.4	0.74 (0.55-1.00)
Renal outcome	39	75	1.6	2.3	8.7	12.3	0.65 (0.49-0.87)
Per Protocol							
MACE	24	41	1.0	1.2	9.2	12.6	0.68 (0.48-0.98)
Renal outcome	30	51	0.9	1.2	11.9	16.3	0.71 (0.51-0.98)
Lupus Nephritis

CXCL13^{+} T Cell Differentiation in Systemic Lupus Erythematosus Is Controlled by Opposing Effects of Aryl Hydrocarbon Receptor and Type I Interferon

Calvin Law[1], Vanessa Wacleche[2], Ye Cao[3], Arundhati Pillai[1], Alice Horisberger[4], Sabrina Bracero[3], Viktoriya Skidanova[3], Zhihan Li[3], Ifeoluwakiisi Adejoorin[2], Isaac Benque[3], Diana Pena Nunez[3], Daimon Simmons[2], Joshua Keegan[4], Lin Chen[3], John Sowerby[3], Accelerating Medicines Partnership (AMP): RA/SLE[2], Elena Massarotti[2], Karen Costenbader[4], Michael Brenner[4], James Lederer[4], Judd Hultquist[1], Jaehyuk Choi[1] and Deepak Rao[2], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

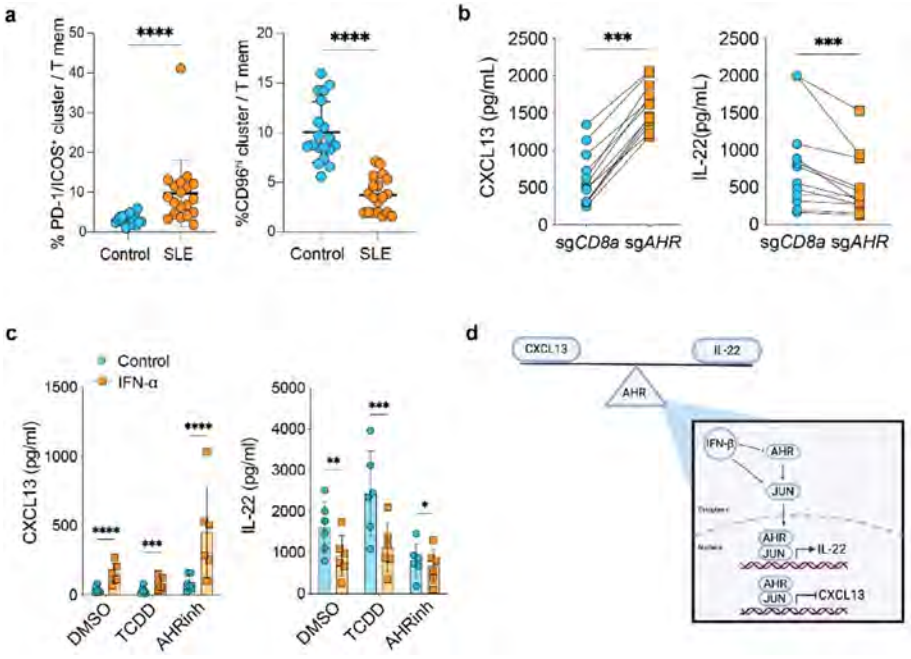
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Plenary II
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Expansion of B cell-helper T cells including T follicular helper (Tfh) and T peripheral helper (Tph) cells is a prominent feature of systemic lupus erythematosus (SLE). Tfh and Tph cells are marked by high production of the B cell chemoattractant CXCL13; however, regulation of T cell CXCL13 production and the relationship between a CXCL13^{+} state and other differentiated T cell states remain largely undefined.

Methods: We used mass cytometry to characterize CD4 T cell phenotypes of SLE patients (n=19) and controls (n=19). We used CRISPR screens of primary human CD4 T cells to identify transcription factors that drive core Tph phenotypes. We used transcriptomics (bulk RNA-Seq), epigenetics (ATAC-Seq and CUT&RUN), and functional studies (pharmacological modulators, lentiviral overexpression, reporter cell lines) to characterize mechanisms and pathways that influence CXCL13 production in disease relevant T cells.

Results: Mass cytometry immunophenotyping demonstrated a dramatic imbalance in CD4 T cell phenotypes in SLE patients, with expansion of PD-1^{+}/ICOS^{+} CXCL13^{+} T cells and reduction of CD96^{hi} IL-22^{+} T cells. An arrayed CRISPR screen targeting 80 transcription factors or signaling molecules revealed that deletion of the aryl hydrocarbon receptor (AHR) significantly increased T cell CXCL13 production. Validation experiments confirmed that AHR deletion or pharmacologic inhibition strongly induced T cell CXCL13 production and T cell acquisition of a transcriptomic and epigenetic signature of ex vivo Tph cells. Conversely, AHR activation inhibited a CXCL13 production and a Tph signature while promoting an IL-22^{+} Th22 cell signature. Luciferase reporter assay using AHR reporter cells show decreased luciferase activity from cells cultured with SLE serum in the presence of AHR agonist. Time coursed transcriptomic analyses of AHR-activated cells combined with unbiased analysis for transcription factor binding sites in AHR CUT&RUN peaks indicated AP-1 transcription factors and AHR co-regulate gene expression. A second CRISPR screen targeting AP-1 family members identified JUN as a potent negative regulator of CXCL13 production and a Tph signature. Further CUT&RUN analyses placed both JUN and AHR at the CXCL13 locus, suggesting direct inhibition of CXCL13 expression. Finally, type I interferon (IFN), a pathogenic driver of SLE, promoted T cell CXCL13 production and a Tph-associated epigenetic signature in part by inhibiting AHR activation and reducing JUN protein expression, while overexpression of JUN inhibited the ability of IFN to induce T cell CXCL13 production.

Conclusion: Our results identify AHR and JUN as potent inhibitors of a Tph cell fate and implicate type I IFN as a key signal in SLE that inhibits AHR and JUN to induce Tph cells.



a, Quantification of indicated clusters in SLE patients (n=19) and controls (n=19), P=6.32e-6 for PD-1/ICOS+, P=2.9e-9 for CD96hi. b, ELISA data for indicated cytokines in supernatants of memory CD4+ T cells nucleofected with sgAHR or sgCD8 control. Microbiome Transplantation Prevents Osteoarthritis in Mice and Is Associated with Immunophenotype Changes

Gabby Dyson[1], Montana Barrett[2], Meeshal Khan[3], Cindy Miranda[1], Nicholas Hanebutt[1], Christopher Dunn[3] and **Matlock Jeffries**[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma State University, Guthrie, OK, [3]University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Plenary II

Session Type: Plenary Session

Session Time: 11:00AM–12:30PM

Background/Purpose: MRL/MpJ mice are protected from developing post-traumatic osteoarthritis (OA). We have previously shown transplantation prior to OA induction prevents OA development. We now extend this work to include measures of synovitis and osteophytes, transplantation after OA induction, transplantation breeding experiments, and peripheral blood immunoprofiling.

Methods: Adult male B6 and MRL mice were inoculated by oral gavage with diluted cecal contents from the opposite mouse strain or vehicle control. Adult male germ-free (GF) mice were inoculated with B6 or MRL cecal contents. A subset of male MRL-transplanted-B6 mice were bred to transplanted female mice and F1 and F2 generation mice were evaluated. Destabilization of the medial meniscus (DMM) surgery was then performed unilaterally to induce OA. Eight weeks after DMM, mice were sacrificed, knee joints fixed, paraffin-embedded, stained with Safranin-O and histologically graded for OARSI

Figure 1: OA outcomes in mice under various transplant conditions

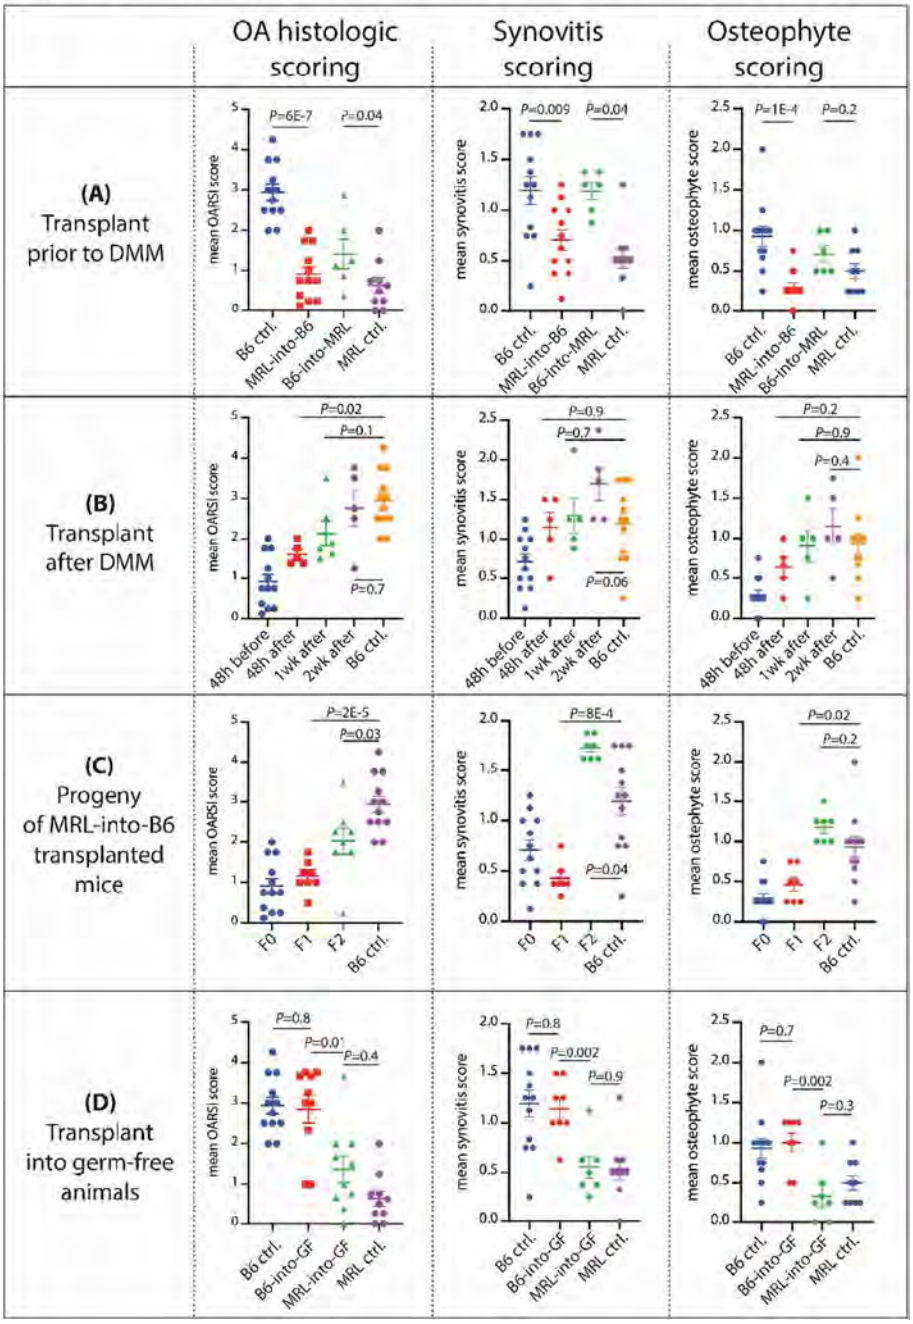

Figure 2: Peripheral blood immune cell subset analysis under various transplant conditions

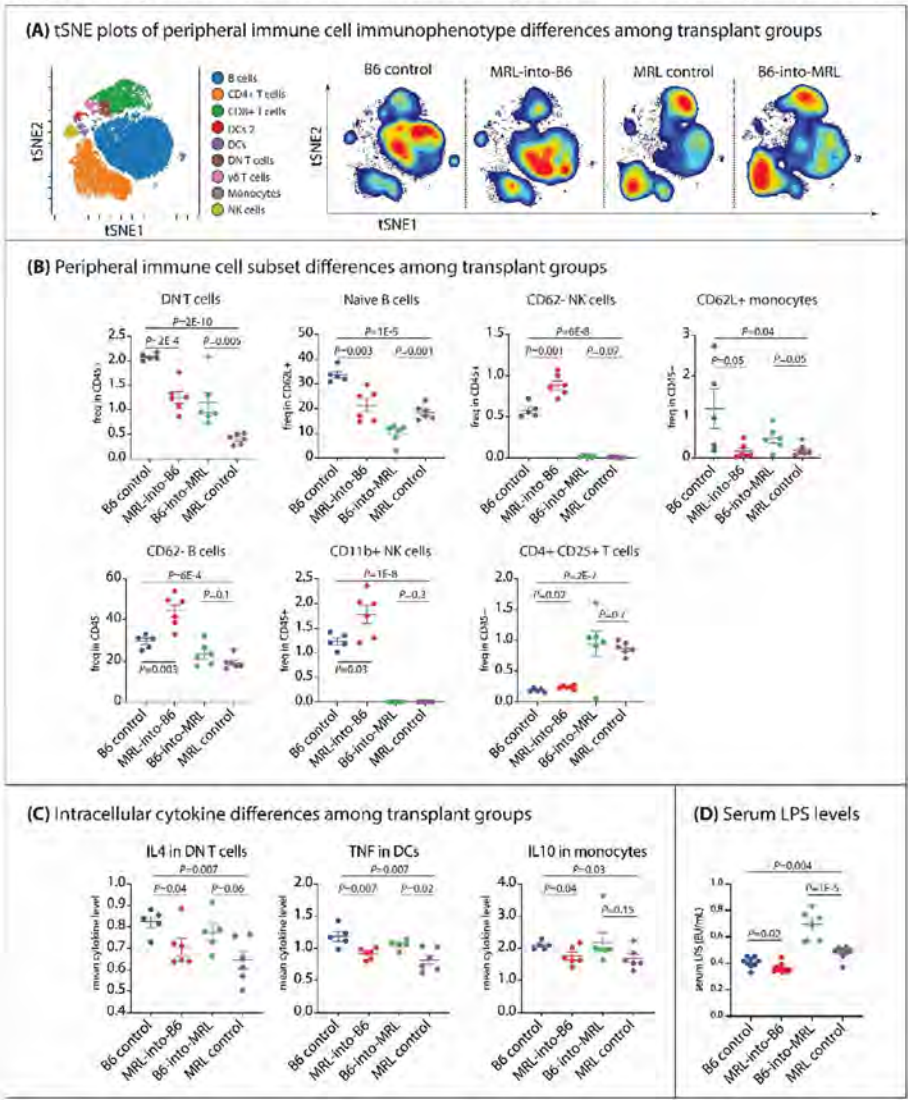

score, synovitis, and osteophytes. Immunophenotyping of splenocytes was performed by mass cytometry (CyTOF). Seurm LPS was determined by chromogenic assay.

Results: Adult male MRL and MRL-transplanted B6 (48h prior to DMM) were protected from OA (Figure 1,OARSI: *P*=6.7E-7, 6.3E-7 respectively, synovitis: *P*=0.002, *P*=0.009; osteophytes: *P*=0.02, *P*=0.0001). Transplant 48h after DMM (*P*=0.002) but 1 week (*P*=0.1) and 2 weeks (*P*=0.7) after DMM were not effective. Synovitis and osteophytes were not improved by transplant after DMM. B6-into-MRL transplant worsened OA (OARSI: *P*=0.04, synovitis: *P*=0.04). F1 and F2 progeny of MRL-into-B6 mice were protected from OA (OARSI: *P*=2E-5, *P*=0.003 respectively). B6-into-GF mice developed OA similar to B6 controls (OARSI: *P*=0.8), whereas MRL-into-GF mice were protected from OA similar to MRL controls (OARSI: *P*=0.4). Five cecal microbiome clades were strongly correlated with OA outcome (*Lactobacillus* R=-0.32, *Akkermansia* R=-0.31, *Oscillospira* R=-.28, *Anaerostipes* R=0.35, *Christensenellaceae* R=0.37, *Rikenellaceae* R=0.43). Immunophenotyping revealed reduced DN T-cells, reduced naïve B cells, reduced CD26+ monocytes, and increased CD4+CD25+ regulatory T cells with transplantation and in MRL mice vs. B6 controls. LPS levels were reduced in MRL-into-B6 vs. B6 controls.

Conclusion: Gut microbiome transplantation from OA-protected MRL mice to OA-susceptible B6 mice 48h before or 48h after DMM prevents OA development. Specific microbiome clades associated with OA protection, and are associated with changes in circulating immunophenotypes.

Non-TNFi b/tsDMARDs vs. TNFi in Rheumatoid Arthritis-Interstitial Lung Disease: An Active-Comparator, New-User, Propensity Score Matched Study Using National Veterans Affairs Data

Bryant England[1], Joshua Baker[2], Michael George[2], Tate Johnson[1], Yangyuna Yang[1], Punyasha Roul[1], Harlan Sayles[1], Fang Yu[1], Jorge Rojas Jr[3], Brian Sauer[4], Grant Cannon[5], Jeffrey R Curtis[6] and Ted R Mikuls[7], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pennsylvania, Philadelphia, PA, [3]Puget Sound VA and University of Utah, Seattle, WA, [4]Salt Lake City VA/University of Utah, Salt Lake City, UT, [5]University of Utah and Salt Lake City VA, Salt Lake City, UT, [6]Division of Clinical Immunology and Rheumatology, University of Alabama, Birmingham, AL, [7]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

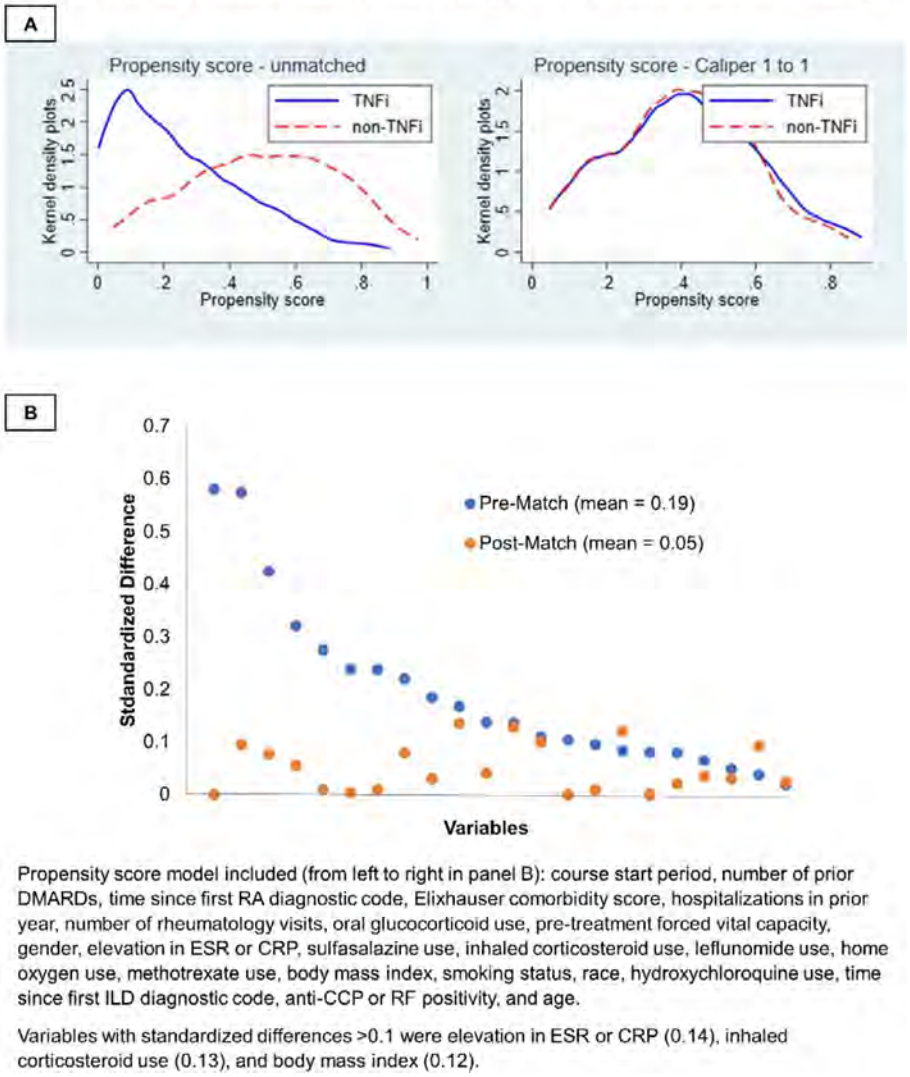
SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Plenary II
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: There is a paucity of data to guide biologic and JAKi DMARD selection in rheumatoid arthritis-interstitial lung disease (RA-ILD), with some reports of higher mortality with TNFi use in this population (Druce et al. *RMD Open*, 2017). We performed a real-world pharmacoepidemiologic study of non-TNFi/JAKi vs. TNFi in RA-ILD using the Target Trial Emulation framework (Hernan et al. *JAMA*, 2022).

Methods: We performed an active-comparator, new-user study of patients with RA-ILD initiating TNFi or non-TNFi biologic/JAKi in the Veterans Health Administration (VA) between 2006 and 2018. Receipt of ILD-focused therapies (e.g., mycophenolate, antifibrotics) was an exclusion. RA-ILD was identified using validated administrative algorithms requiring multiple RA and ILD diagnostic codes (PPV >70%). TNFi and non-TNFi/JAKi initiators were 1:1 propensity score (PS) caliper-matched using calendar time-specific PS models (2006-2010, 2011-2015, 2016-2018) that included demographics, healthcare utilization, comorbidities, and several RA- and ILD-related factors (including pre-treatment forced vital capacity [FVC]) obtained from EHR and administrative data (**Figure 1**). The primary outcome was a composite of time to respiratory-related hospitalization (by VA and Medicare data linkage) or death (by National Death Index linkage) using Cox regression models following an intention-to-treat analysis approach. Secondary outcomes were respiratory hospitalization and death (all-cause, respiratory). Outcomes were assessed over 3-year (primary) and 1-year (secondary) follow-up periods. Sensitivity analyses were performed among modified cohorts requiring: 1) prior biologic/JAKi treatment, 2) non-missing pre-treatment FVC values, or 3) additional ILD classification criteria.

Results: Among 1,046 RA-ILD patients fulfilling eligibility criteria (n=704 TNFi), 237 TNFi initiators were matched to 237 non-TNFi/JAKi initiators in the primary analyses (mean age 68 years, 92% male). Mean standardized differences of variables in the PS model improved from 0.19 to 0.05 after matching, though few variables remained modestly imbalanced (**Figure 1**). Adalimumab (51%) and etanercept (37%) were the most frequent TNFi while rituximab (53%) and abatacept (28%) were

Figure 1. Distribution of propensity scores (A) and standardized differences for variables (B) among RA-ILD patients initiating a non-TNFi/JAKi or TNFi before and after matching.



Propensity score model included (from left to right in panel B): course start period, number of prior DMARDs, time since first RA diagnostic code, Elixhauser comorbidity score, hospitalizations in prior year, number of rheumatology visits, oral glucocorticoid use, pre-treatment forced vital capacity, gender, elevation in ESR or CRP, sulfasalazine use, inhaled corticosteroid use, leflunomide use, home oxygen use, methotrexate use, body mass index, smoking status, race, hydroxychloroquine use, time since first ILD diagnostic code, anti-CCP or RF positivity, and age.

Variables with standardized differences >0.1 were elevation in ESR or CRP (0.14), inhaled corticosteroid use (0.13), and body mass index (0.12).

Figure 1. Distribution of propensity scores (A) and standardized differences for variables (B) among RA-ILD patients initiating a non-TNFi/JAKi or TNFi before and after matching.

the most frequent non-TNFi/JAKi. There was no significant difference in the primary outcome between non-TNFi/JAKi vs. TNFi (HR 1.19 [0.91, 1.56]; aHR 1.22 [0.92, 1.60]; **Table 1**). There were also no significant differences in respiratory hospitalization, all-cause mortality, or respiratory-related death (**Table 1**). In sensitivity analyses with modified cohort eligibility requirements, no significant differences in outcomes were observed between non-TNFi/JAKi and TNFi (**Figure 2**).

Conclusion: In this national VA, PS-matched study using the Target Trial Emulation framework, we did not observe significant differences in the risk of respiratory hospitalization or death between RA-ILD patients initiating non-TNFi/JAKi vs. TNFi. Our findings do not support systematic avoidance of TNFi in RA-ILD. Comparative data from clinical trials are needed to further guide these routine clinical decisions.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Plenary II
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Methotrexate (MTX), the anchor drug for rheumatoid arthritis (RA), has limited bioavailability above an oral dose of 15 mg. Split-dose oral MTX (morning, evening same day) has been shown to lead to higher blood levels compared to single-dose, however, its effect on clinical efficacy is unknown. Thus, we planned to compare the efficacy, safety and tolerability of oral split-dose to single-dose MTX once a week in RA.

Methods: This multicenter (six centers), open-label (assessor blinded) RCT recruited patients with Rheumatoid arthritis (2010 ACR/EULAR), 18-60 years of age, seropositive (RF or ACPA), disease duration < 5 years, not on DMARDs (except hydroxychloroquine and/or low-dose prednisolone) but with active disease (TJC28 ≥4 and SJC28 ≥2). Patients were randomized 1:1 (online generator) and allocated (concealed using SNOOSE) into either single dose (25 mg) or split-dose (10 mg morning, 15 mg evening, same day) once weekly MTX for 24 weeks. Disease activity was assessed by DAS28 (ESR) at 16 and 24 weeks. At 16 weeks, either leflunomide or sulfasalazine could be added if DASS28≥3.2. (Figure 1) Primary outcome was EULAR good response at 24 weeks, and secondary outcomes were EULAR response at 16 weeks, DAS28, ACR20, 50, 70 and HAQ at 16 and 24 weeks. Safety outcomes included laboratory abnormalities. Intolerance to methotrexate was assessed using MISA score. Analysis was by intention-to-treat and missing data was accounted by last-observation-carried-forward (locf), and non-response was imputed for categorical variables.

Trial registration CTRI/2021/02/03136

Results: 253 patients (females 83%), with age and disease duration (mean ± SD) of 42.2±10.4 and 2.1±1.5 years, were randomized to split-dose (n=128) and single-dose (n=125) group. Baseline DAS28 was comparable, 6.5±1.0 and 6.6±1.0 (p=0.554), but after 16 weeks of MTX monotherapy, DAS28 was significantly lower in split-dose (4.4±1.4) than single-dose (5.1±1.5, p< 0.001) group. At 16 weeks, there was significantly higher EULAR good response (difference 12.3%, CI 12.4 to 66); ACR20 (difference 24.6%, CI 13.1 to 36), ACR50 (difference 19.5%, CI 7.5 to 31.5%) and ACR70 (difference 12.2%, CI 2.5 to 28.9) in split versus single-dose group. Fewer patients in the split-dose (35%) compared to single-dose (54.5%,

Table 1: Efficacy measures

Table 1: Efficacy measures between the two groups at 16 and 24 weeks (intention-to-treat).

Parameters	Split Dose (n=128)	Single Dose (n=125)	p-value
16 weeks (MTX monotherapy phase)

16 weeks	0	1	0.310
24 weeks	0	2	0.152
Any intolerance[3]			
8 weeks	54 (44.6)	41 (36)	0.176
16 weeks	57 (49.1)	49 (44.1)	0.451
24 weeks	59 (53.1)	50 (45)	0.227
Ever	82 (67.8)	67 (58.8)	0.152

[1] Either ALT or AST above 40 IU/L

[2] Persistent implies on atleast two visits out of 4, 8, 16 and 24 weeks

[3] Methotrexate intolerance score in adults score >=1, consists of nausea, vomiting, stomach discomfort, fever, diarrhea, fatigue, anticipatory nausea, oral ulcers (Ref Int J Rheum Dis 2021;24:1294-1301)

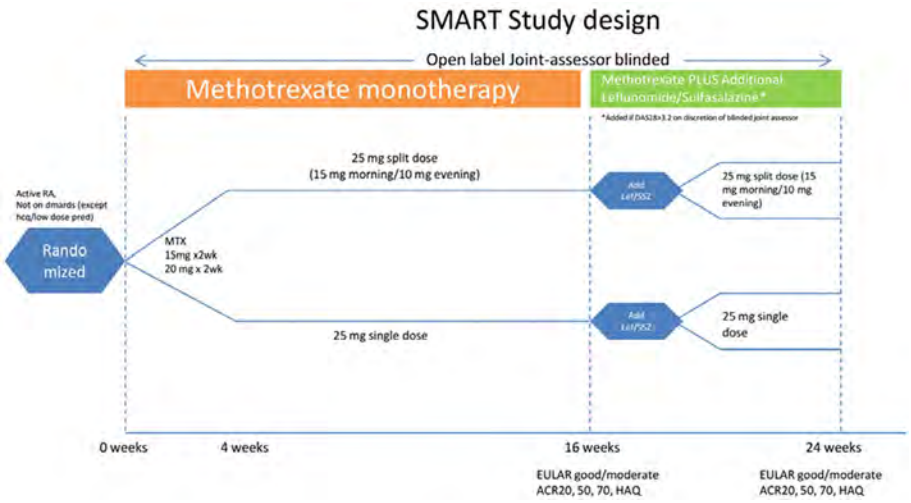

Figure 1: Study design

p=0.005) group were started on additional DMARD at 16 weeks; leflunomide was started in 34 (30%) and 54 (49%), and sulfasalazine in 6 each. At 24 weeks, there was significantly lower DAS28 in split-dose (4.1±1.5) compared to single-dose (4.5 ±1.5, p=0.03) group, however, no difference in other efficacy measures (Table 1). There was no difference in HAQ scores at 16 or 24 weeks. There was no major AE, but significantly higher frequency of transaminitis at 16 weeks and persistent transaminitis in split-dose group. Frequency of leucopenia was higher in single-dose group at 24 weeks (Table 2). No significant difference in symptoms of intolerance between groups. (Table 2)

Conclusion: Oral split-dose MTX given once weekly in RA patients had significantly higher efficacy and reduced the need for additional DMARDs, compared to single-dose MTX given once a week. There was no major AE, but slight increase in frequency of persistent transaminitis in split-dose group.

Abstract Number: 1584

Effect of Trimethoprim Sulfamethoxazole Prophylaxis on Infections During Treatment of Granulomatosis with Polyangiitis with Rituximab: A Population-Based Study

Arielle Mendel[1], Hassan Behlouli[2], Evelyne Vinet[1], Jeffrey Curtis[3] and Sasha Bernatsky[2], [1]McGill University Health Centre, Montréal, QC, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [3]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Plenary II
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Infections during treatment of ANCA-associated vasculitis (AAV) lead to excess mortality. Trimethoprim sulfamethoxazole (TMP-SMX), recommended for pneumocystis jirovecii pneumonia (PJP) prophylaxis, has broad antimicrobial activity. We assessed associations between TMP-SMX prophylaxis and subsequent infections within a United States population sample of granulomatosis with polyangiitis (GPA) treated with rituximab (RTX).

Methods: We included adults with GPA within the Merative™ Marketscan® Research Databases who had a minimum 6 months of insurance enrolment prior to a first (index) RTX treatment (2011-2020). Baseline TMP-SMX prophylaxis was defined as a >=28-day prescription dispensed within 30 days (before/after) RTX initiation. We defined serious infections as an inpatient ICD-9 or -10 primary diagnostic code for infection following the index date (excluding viral and mycobacterial codes). Secondary outcomes were outpatient infections (for the same codes), and PJP. Subjects were followed until end of insurance enrolment or Dec 31, 2020. Multivariable Cox proportional hazards regression assessed the association of baseline and time-dependent TMP-SMX with serious infection. Models were adjusted for age, sex, prednisone (>=20 mg/day dispensed < 30 days prior to index RTX), hospitalization and/or serious infection in the 6 months prior to index RTX, and having any of of the following: interstitial or obstructive lung disease, diabetes, chronic kidney disease, or dialysis. As a sensitivity analysis, we assessed the association between TMP-SMX prophylaxis and a "control" infection, herpes

Table 1 Baseline cohort characteristics, overall and according to trimethoprim sulfamethoxazole (TMP-SMX) use

Characteristic at time of first rituximab treatment	Overall cohort (N=919)	Baseline TMP-SMX (n=281)	No baseline TMP-SMX (n=638)
Age, mean (SD)	52.1 (16.1)	**49.8 (15.5)**	**53.1 (16.2)**

[b] at least one prescription dispensed in the month prior to rituximab
[c] at least one prescription in the 6 months prior to rituximab

Table 2. Cox proportional hazards regression of factors associated with time to serious infection, considering baseline and time-dependent (TD) TMP-SMX exposure (n=917, 104 events)

Covariate	Univariable	Multivariable	Multivariable (TD)
	HR (95% CI)	HR (95% CI)	HR (95% CI)
TMP-SMX use	**0.58 (0.34-0.92)**	**0.49 (0.30-0.79)**	**0.49 (0.28-0.87)**
Age (years)	1.02 (1.01-1.03)	1.01 (0.99-1.02)	1.01 (0.99-1.02)
Female sex (vs male)	**0.67 (0.45-0.98)**	0.69 (0.46-1.02)	0.73 (0.49-1.08)
Prednisone ≥20 mg/day	1.12 (0.76-1.64)	0.94 (0.63-1.40)	0.92 (0.62-1.38)
Induction RTX	0.67 (0.45-1.02)	-	-
Other immunosuppressant in the prior 6 months	0.87 (0.51-1.49)	-	-
Hospitalization prior 6 months	**2.42 (1.59-3.71)**	**1.93 (1.19-3.11)**	**1.79 (1.11-2.88)**
Serious infection prior 6 months	**3.01 (1.96-4.63)**	**2.35 (1.47-3.77)**	**2.36 (1.47-3.78)**
Chronic obstructive pulmonary disease	1.48 (0.99-2.22)	-	-
Interstitial lung disease	1.78 (0.90-3.54)	-	-
Diabetes	1.55 (0.99-2.42)	-	-
Chronic kidney disease	**1.98 (1.34-2.92)**	-	-
Dialysis	**2.72 (1.69-4.36)**	-	-
≥1 of above comorbidities	**2.50 (1.6-3.90)**	**2.20 (1.38-3.51)**	**2.33 (1.46-3.69)**

zoster (HZ). Finally, we determined rates of adverse events potentially attributable to TMP-SMX during person-time exposed and unexposed to TMP-SMX.

Results: The cohort included 919 RTX-treated individuals with GPA, of which 53% were female, mean age 52 years (SD 16). TMP-SMX was dispensed to 281 (31%) at the time of index RTX (and to 40% on prednisone >=20 mg/day). Over a median (IQR) follow-up of 496 (138, 979) days, the rates of serious infection, outpatient infection, and PJP per 100-person years were 6.1 (95% confidence interval, CI 5-7), 28.7 (95% CI 26-32), and 0.7 (0.4-1.2), respectively. Serious infections were primarily pulmonary (36%) or general sepsis (45%). In multivariable analyses, TMP-SMX was negatively associated with serious infections, considering baseline (adjusted HR 0.5; 95% CI 0.3-0.8) and time-varying TMP-SMX exposure (aHR 0.5; 95% CI 0.3-0.9). Prophylaxis was also negatively associated with outpatient infections (aHR 0.7; 95% CI 0.5-0.9). Thirteen PJP infections occurred, all in TMP-SMX unexposed subjects. TMP-SMX was not associated with reduced HZ (aHR; 1.6, 95% CI 0.6-3.2). Rates for adverse events potentially attributable to TMP-SMX per 100 person-years were 29.6 (95% CI, 22-39) during periods of TMP-SMX exposure and 13.4 (95% CI, 11-16) during periods without TMP-SMX exposure.

Conclusion: TMP-SMX prophylaxis was associated with subsequent reduced serious and overall infections in RTX-treated GPA. Further study is needed to determine how to balance potential benefits and harms from prophylaxis in individual patients, and determine optimal prophylaxis duration.

Abstract Number: 1585

Defining Neutrophil-Mediated Renal Damage Triggered by Ultraviolet (UV) Skin Exposure

Angelique Cortez[1], Lindsay Mendyka[2], Fred Kolling[3], Michael Whitfield[1] and Sladjana Skopelja-Gardner[4], [1]Dartmouth College, Hanover, NH, [2]Dartmouth Hitchcock, Lebanon, NH, [3]Geisel School of Medicine at Dartmouth, Hanover, NH, [4]Dartmouth-Hitchcock, Lebanon, NH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Innate Immunity
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Lupus (SLE) is one of the leading causes of death in young women in the United States. Roughly ~80% of SLE patients experience sensitivity to ultraviolet light (UV), which leads to local and systemic inflammation and can trigger nephritis flares. While we previously showed skin exposure to UV leads to neutrophil-mediated kidney damage, the exact mechanisms are unknown. We use scRNA-Seq to characterize kidney injury pathways resulting from skin UV exposure.

Methods: B6 female mice (3-mo) were exposed to UVB (1x500mJ/cm^2). On day 2 (D2) or No UV, cardiac perfusion was performed with Dynabeads for glomerular magnetic isolation. Glomeruli were digested (Col IV, Pronase I, DNase I) following Col. I kidney digest and scRNA-seq performed by 10X Genomics. Glomeruli from anti-GCSF and IgG D2 UV-exposed mice were digested and sent for 10X Genomics scRNA-seq. Neutrophils were enriched from digested skin, lungs, and kidney by Ly6G magnetic beads and sorted for >90% purity. Single Cell clustering and differential gene expression (DGE) analyses were performed using Seurat 4.1.1 R package. Gene ontology pathway analysis was performed using clusterProfiler. Ligand-receptor analysis was performed using CellChat. Injury scores created using DGE from D2-UV renal structural cells.

Results: ScRNAseq analysis of kidney structural cells revealed endothelial, stromal, podocyte and distal tubular cell (DTC) injury on D2 after skin UV exposure. Pathway analysis showed downregulation of actin filament organization in podocytes and ion transport in DTCs (Fig 1B-C). Type I interferon pathway was upregulated in stromal cells, while angiogenic and cell

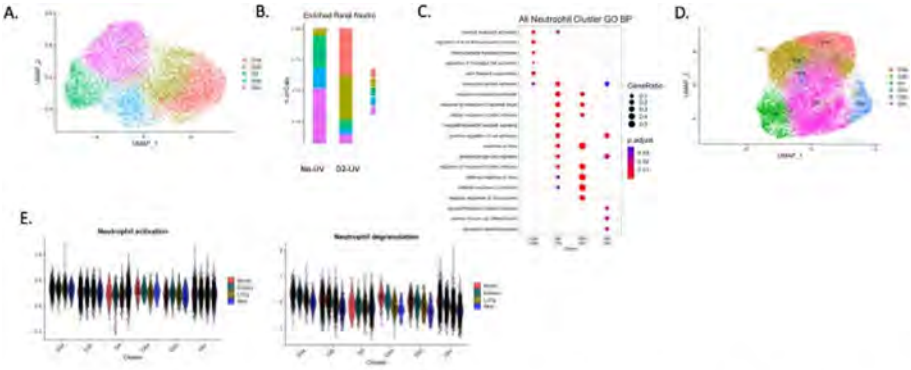

Figure 2. UV skin exposure triggers neutrophil heterogeneity. (A) UMAP of enriched neutrophils from D2-UV and No-UV exposed mice. (B) Stacked bar plot of enriched neutrophils separated by D2-UV and No-UV . (C) UV-exposed Injury (D) UMAP of enriched neutrophils from lung, skin, blood & kidney. (E) Neutrophil activation and Neutrophil degranulation scores on different clusters from lung, skin, blood & kidney.

Figure 3. UV skin exposure triggers neutrophil heterogeneity.

stress pathways were increased in renal endothelial cells (Fig 1D-E). Kidney-infiltrating neutrophils showed an increased number and strength of interactions with stromal, endothelial, and DT cells (Fig 2A). Preventing neutrophil recruitment by anti-GCSF IgG abolished endothelial injury pathways (Fig 2B) and decreased injury scores in podocytes and DTCs (Fig2C-D). Five distinct neutrophil clusters (G3a, G3b, G4, G5b, & G5c) were identified in the kidney, though activated immature G3a and G3b neutrophil clusters were only present after UV (Fig3A-B). Pathway analysis showed G3a was enriched for myeloid leukocyte activation and actin regulation pathways (Fig3C). ScRNA-Seq analysis revealed neutrophil heterogeneity at the local site of injury (skin) vs. the distal organs (kidney, lung, & blood) (Fig3D). Kidney infiltrating neutrophils had increased degranulation and activation scores in the kidney vs. the lung or skin (Fig3E).

Conclusion: We identified that neutrophils primarily cause endothelial renal injury but also contribute to podocyte and DTC damage after skin UV exposure. The increased number and strength of podocyte and stromal interactions indicates UV skin exposure triggers injury to the glomerular filtration barrier, supporting our previous findings of UV triggered proteinuria. Altered neutrophil heterogeneity at the local site of injury and distal organs demonstrates tissue specificity in the skin-kidney pathogenic axis.

Keratinocyte VISTA Suppresses Skin IFN-I Production by Regulating DNA Damage Repair and Cytosolic DNA Sensing

Zachary Peters[1], Lindsay Mendyka[2], Sicong Shan[1], William Rigby[3], Christopher Burns[4], Randolph Noelle[5] and Sladjana Skopelja-Gardner[4], [1]Dartmouth College, Hanover, NH, [2]Dartmouth Hitchcock, Lebanon, NH, [3]Dartmouth-Hitchcock, Norwich, VT, [4]Dartmouth Hitchcock Medical Center, Lebanon, NH, [5]Geisel School of Medicine at Dartmouth, Hanover, NH

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Innate Immunity

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Persistent production of type I interferons (IFN-Is) is one of the hallmarks of lupus skin disease that is exacerbated by ultraviolet (UV) light. We previously showed IFN-I induction by UV occurs in a cGAS-STING-dependent manner, but the IFN-I signature returns to baseline levels in healthy skin, unlike in lupus. Here, we propose that the immune checkpoint VISTA is a regulator of skin IFN-I production in keratinocytes of therapeutic relevance to lupus.

Methods: Skin biopsies from B6, B6.*Vsir*-/- (VISTA-deficient), B6.*Vsir-/-Sting-/-*, KRT14^{cre}*Vsir*$^{fl/fl}$ (*Vsir*-/- in keratinocytes), and cre-*Vsir*$^{fl/fl}$ female mice (3 mo) were collected prior to, 3 and 24h after UVB (500mJ/cm^2). Gene expression was quantified by RNA-seq (Rosalind). Skin infiltrating cells were quantified by flow cytometry. Human keratinocytes were isolated from healthy skin and *cultured in vitro*. Cells were treated with agonistic anti-VISTA (803) or isotype IgG2a (20ug/ml) prior to UVB (50mJ/cm^2), in the presence or absence of IFNa (100U). Expression of IFN-Is and IFN-I stimulated genes (ISGs) were quantified by qPCR (4hr after UV) and IFN-I score derived.

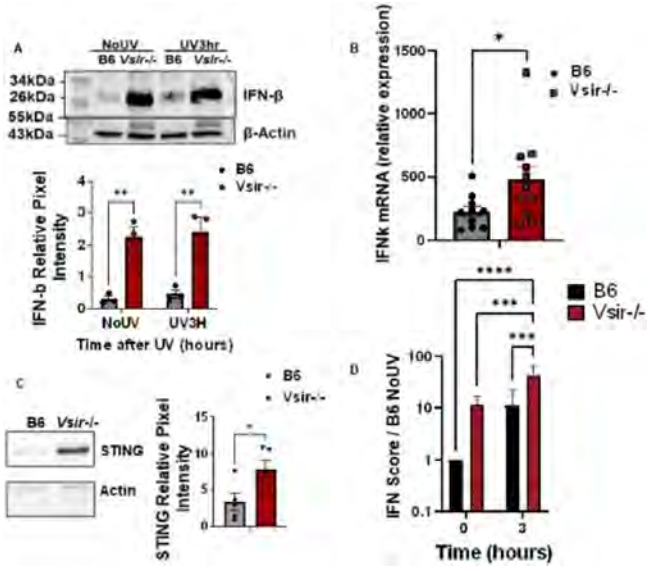

Figure 1. Elevated skin IFN-I production in the absence of VISTA. A. IFN-β immunoblot of B6 and B6.Vsir-/- skin lysates; levels normalized to β-actin (ImageJ). B. IFN-k gene expression in B6 and Vsir-/- whole skin measured by qPCR. C. STING immunoblot of B6 and B6.vsir-/- skin lysates. D. Skin IFN score in B6 and Vsir-/- mice, before and after UVB exposure (1x500mJ/cm2). Differences in gene expression determined relative to baseline B6 and all statistical significance determined by two-way ANOVA (A,D) or Student's T test(B,C) (n=5, *p<0.05, **p<0.01, ***p<0.005, ****p<0.00001). IFN-I score calculated as sum normalized expression of 6 ISGs relative to baseline B6 (ISGs: IRF7, IFIT1, IFIT3, ISG15, IFI27La, Mx1) and normalized to 18s.

Results: At baseline, B6.*Vsir-/-* skin had increased IFN-k mRNA, IFN-b protein, as well as total STING protein levels (Fig. 1A-C). RNA-seq revealed increased expression of *Sting* and upstream cytosolic DNA sensors in VISTA-deficient mouse skin before and after UV. B6.*Vsir-/-* mice exhibited a 5-fold higher skin IFN-I score after UV compared to B6 mice (Fig.1D). Higher baseline and UV-induced IFN-I response in VISTA-deficient skin was suppressed in the absence of STING (*Vsir-/-Sting-/-* mice). Moreover, fewer skin-infiltrating neutrophils and inflammatory monocytes were recruited to *Vsir-/-Sting-/-* vs. STING-sufficient *Vsir-/-* skin post UV. RNAseq also revealed decreased expression of DNA repair genes like *Ogg1, Xpd and Pole* in *B6.Vsir-/-* skin, which are essential for repair of UV-induced DNA damage. VISTA deficient mouse keratinocytes produced 2-fold higher IFN-k at baseline *ex vivo* and accumulated higher levels of oxidized DNA (8-OHdG) compared

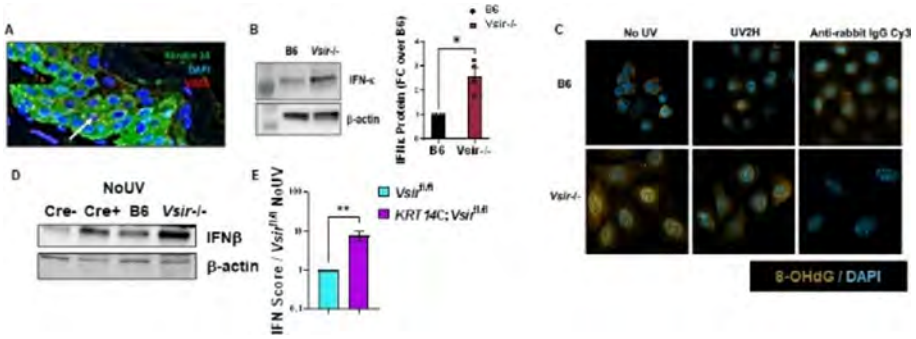

Figure 2. VISTA regulates IFN-I production in keratinocytes. A. Mouse epidermis stained for VISTA (red), Keratin-14 (green), and DAPI (blue). B. Baseline IFN-κ protein in B6 and Vsir-/- keratinocyte lysates after 6 days in culture, quantified relative to B-actin. C. Mouse keratinocytes stained for 8-hydroxyguanosine (yellow) and DAPI (blue). D. IFN-b immunoblot of skin lysates from B6, B6.Vsir-/-, Vsirfl/fl and KRT14Cre:Vsirfl/fl mice. E. Baseline skin IFN-I score of Vsirfl/fl and KRT14Cre:Vsirfl/fl mice. Significance determined by two-way ANOVA (A). (n=3, * p<0.05, p<0.01). Differences in gene expression relative to Vsirfl/fl control and statistical significance determined by T test (n=4).

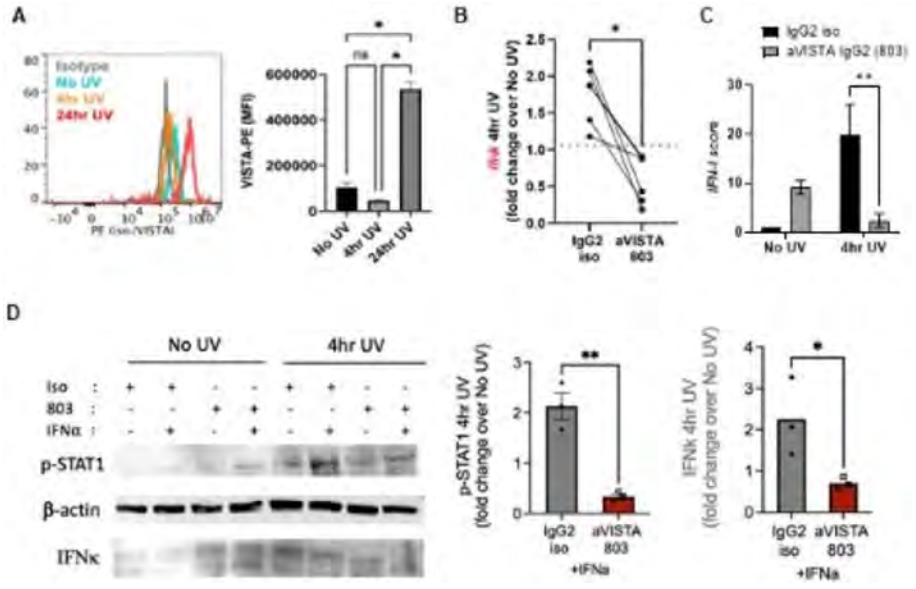

Figure 3. Anti-VISTA agonistic IgG suppresses UV-induced IFN-I signature in human keratinocytes. A. VISTA surface expression on primary human keratinocytes measured by flow cytometry, without UV, 4 and 24hr after UVB (50mJ/cm2). B. IFN-k gene expression in human keratinocytes pre-treated with either anti-VISTA INX803 IgG2 or isotype control IgG2 antibody. C. IFN-I scores of human keratinocytes pre-treated with 803 or isotype control IgG2 before and after UV exposure were derived as the sum of normalized expression levels of 9 interferon-stimulated genes (CXCL10, BST2, ifitm3, ifi27, isg15, ifit1, mx1, Ly6E, irf7). D. Immunoblot of phosphorylated STAT1 and IFN-k in human keratinocyte lysates from cells before and after UVB exposure, in the absence or presence of IFNα (100U, 24hr prior to UV exposure) and pre-treated with anti-VISTA 803 or isotype control IgG2 antibody. Pixel intensity calculated relative to b-actin (ImageJ) and fold change of P-STAT1 and IFN-k in the presence of IFNa calculated relative to baseline NoUV. Statistical significance was determined by two-way ANOVA(A,C) and Student's t-test (B,D); *p<0.05, **p<0.01, ns= not significant.

with B6 cells (Fig. 2B-C).Mice with a conditional VISTA deletion only in keratinocytes exhibited a 10-fold higher baseline IFN-I signature and increased IFN-b protein levels compared to controls (Fig. 2D-E). Expression of VISTA on human keratinocytes decreased 4 hr after UV, but increased 5-fold 24 hr after UV(Fig. 3A).Pre-treatment of human keratinocytes with an agonistic anti-VISTA antibody (803) suppressed UV-induced IFN-k, Stat1 phosphorylation and IFN-I score, even in keratinocytes with a pre-existing IFN-I signature (Fig. 3C-D).

Conclusion: These studies identify VISTA as a suppressor of IFN-I production in keratinocytes and demonstrate STING-dependent IFN-I production in the absence of VISTA. As oxidized DNA is resistant to degradation in the cytosol where it can serve as a potent trigger of cGAS-STING, VISTA promotion of DNA repair may indirectly suppress STING signals. Antibody-mediated activation of VISTA in keratinocytes demonstrates its potential as a target to suppress IFN-I production in the context of photosensitivity and lupus.

Abstract Number: 1587

Mitochondrial Z-DNA and ZBP1 Drive Autoimmune Photosensitivity

Benjamin Klein, Mack Reynolds, Bin Xu, Mehrnaz Gharaee-Kermani, Amanda Victory, Shannon Loftus, Mary O'Riordan and J. Michelle Kahlenberg, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Innate Immunity
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Autoimmune photosensitivity is observed in type I Interferon (IFN) mediated diseases such as systemic and cutaneous lupus erythematosus (SLE/CLE) and dermatomyositis. Type I IFN has been described as an activator of UV-induced immune responses, but how a chronic IFN-high environment drives photosensitivity is not understood. Mitochondrial DNA has been identified as a source of IFN responses via activation of cGAS-STING in diverse cells of SLE. Here, we investigated how UV light and type I IFN exposure impact mitochondrial stress and Z-DNA formation, a left-handed dsDNA primarily localized in mitochondria which leads to type I IFN production through activation of cGAS.

Methods: Confocal microscopy of primary keratinocytes (KCs) from healthy controls and SLE patients and N/TERT immortalized KCs was performed to assess mitochondrial dynamics and cytosolic Z-DNA formation after UV exposure and IFN-α treatment. qPCR and single cell RNA sequencing was used to assess gene expression. Tissue immunofluorescence was used for protein expression of ZBP1. shRNA-mediated knockdown of ZBP1 was performed in NTERTs.

Results: After UV light exposure, NTERTs showed significantly upregulated gene expression of *IFNB, IFNK, IFNL, MX1* and *OASL*. This upregulation was significantly inhibited by preincubation with the mitochondrially-targeted antioxidant mito-TEMPO (MT), indicating mitochondrial reactive oxygen species-dependent IFN responses. Additionally, mitochondria showed significant fragmentation after UV light that was associated with cytosolic Z-DNA accumulation. Strikingly, this accumulation was enhanced with IFN incubation leading to large Z-DNA puncta within the cytosol. Primary SLE KCs exhibit cytosolic Z-DNA at baseline and showed strong cytosolic Z-DNA accumulation after UV exposure. Cytosolic Z-DNA accumulation and UV-induced ISG expression was prevented by MT in SLE KCs. Importantly, ZBP1, the cytosolic sensor of Z-DNA, is induced by IFN-α and upregulated in nonlesional and lesional SLE and dermatomyositis skin biopsies but is

not detectable in healthy control biopsies. Confocal analysis showed colocalization of Z-DNA with ZBP1 and cGAS after IFN +UVB exposure. Knockdown of ZBP1 in NTERTs attenuated ISG expression after UVB in an IFN-high environment.

Conclusion: Our data indicate that type I IFN priming, coupled with UV light exposure, results in mitochondrial stress that leads to increased mitochondrial Z-DNA formation and cytoplasmic release. Cytosolic Z-DNA interacts with ZBP1 and cGAS to activate IFN upregulation. Collectively, we describe a new pathway of mitochondrial Z-DNA sensing by ZBP1 that drives and sustains IFN responses in KCs, giving further insight into autoimmune photosensitivity.

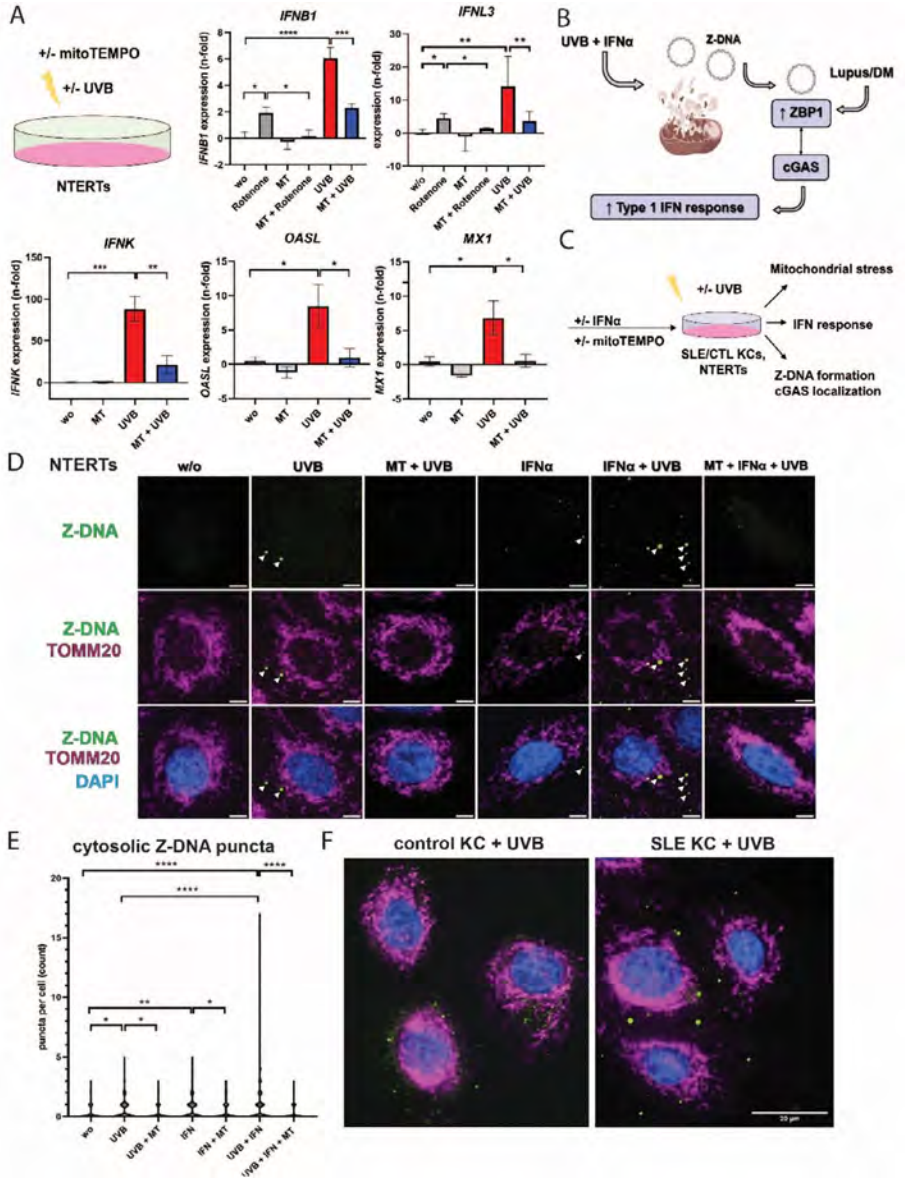

Figure 1. UVB leads to mitochondrial ROS-dependent IFN upregulation and cytoplasmic release of Z-DNA in keratinocytes (KCs). A) Expression of interferon genes in NTERTs +/- UVB exposure and +/- preincubation with mitochondrial targeted antioxidant mitoTEMPO (n=4). B) Schematic of Z-DNA release: Upon mitochondrial damage by UVB and IFN-α, Z-DNA is released into the cytosol and bound by ZBP1 which is overexpressed in the epidermis of lupus and dermatomyositis patients. ZBP1 can interact with cGAS to sustain IFN responses in KCs. C) Methodology to assess mitochondrial stress and Z-DNA formation in KCs. D) Immunofluorescence (IF) staining of NTERTs identifies mitochondrial-derived cytoplasmic Z-DNA release upon UVB exposure resulting in large Z-DNA puncta after IFN-α treatment (n=4). E) Quantification of cytoplasmic Z-DNA by automatic image analysis using CellProfiler software. F) IF of control KCs (n=3) and SLE KCs (n=2) for Z-DNA after UVB exposure identifies large Z-DNA puncta in SLE KCs.

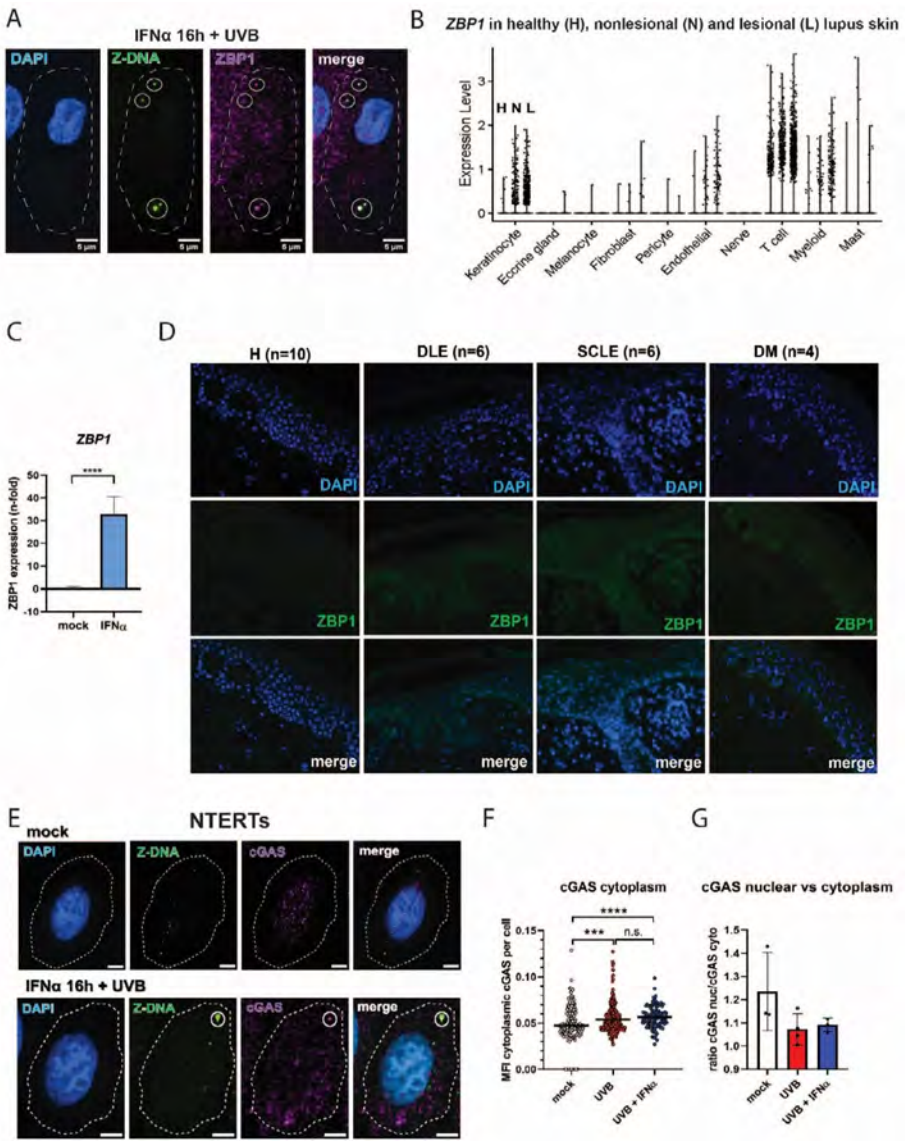

Figure 2. ZBP1 interacts with Z-DNA and is upregulated in autoimmune photosensitivity disorders. A) IF staining of Z-DNA and ZBP1 in NTERTs reveals colocalization of large cytoplasmic Z-DNA puncta with ZBP1. B) Violin plots showing expression levels of ZBP1 in different cell types of healthy control (HC, n=14), nonlesional (n=7) and lesional (n=7) lupus skin. C) ZBP1 is induced by IFN-α incubation in NTERTs (n=4). D) IF staining of HC, discoid lupus (DLE), subacute cutaneous lupus (SCLE), and dermatomyositis (DM) identifies increased epidermal ZBP1 expression in autoimmune photosensitive disorders compared to HC. E) IF staining of cGAS in NTERTs reveals colocalization of cGAS with large Z-DNA puncta after UVB exposure and IFN-α treatment (n=3). F) Quantification of cGAS staining shows cytoplasmic shift of cGAS after UVB exposure. G) Ratio of nuclear and cytoplasmic cGAS after UVB and IFN-α treatment.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Innate Immunity

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Anti-melanoma differentiation-associated gene 5-positive dermatomyositis (anti-MDA5+ DM) is a rare inflammatory autoimmune disease with impressively life-threatening rapid progressive interstitial lung disease (RP-ILD). The mechanism that leads to immune dysfunction and lung injury remains elusive.

Methods: We applied single-cell RNA sequencing to the peripheral blood mononuclear cells (PBMCs) from three anti-MDA5+ DM patients and cells in paired broncho-alveolar lavage fluid (BALF). The datasets of healthy controls are from GSE158055 (PBMC) and GSE14592 (BALF). Flow cytometry and Luminex assay were further applied to validate the results.

Results: A high-quality scRNA-seq dataset composed of 64,565 cells were generated from three anti-MDA5+ DM patients, revealing profound aberrations of various immune compartments and distinct immune responses both in peripheral blood and lungs. We found increased monocytes resembling myeloid-derived suppressor cells (MDSCs), which correlated with inflammatory markers in the blood ofanti-MDA5+ DM patients. While those MDSC-like monocytes showed enhanced activation of type I interferon signaling pathway, they were immune-paralyzed, with downregulation of cytokines and inflammatory gene expressions. In contrast, the lung microenvironmentofanti-MDA5+ DM exhibited overactivation of immune responses, with monocyte-macrophages in BALFs producing massive amounts of cytokines and chemokines. To be more specific, monocyte-derived alveolar macrophages (Mo-AMs) might be the major source triggering the cytokine storm in the lung, with cell ratios and inflammatory expression both significantly elevated inanti-MDA5+ DM patients. The prominent expression of chemokines of Mo-AMs suggested a feed forward loop of immune cell recruitment and inflammatory cascade. Besides, pseudo-time trajectory analysis revealed that recruited Mo-AMs adopt a fibrosis-associated phenotype during the process of differentiation.

Conclusion: Our study comprehensively depicts the dysregulated peripheral and lung immune landscape inanti-MDA5+ DM, and highlights the proinflammatory and profibrotic role of Mo-AMs in the pathogenesis and progression ofanti-MDA5+ DM with RP-ILD, implying that targeting Mo-AMs or blockade of monocyte influx to lung may present an effective strategy.

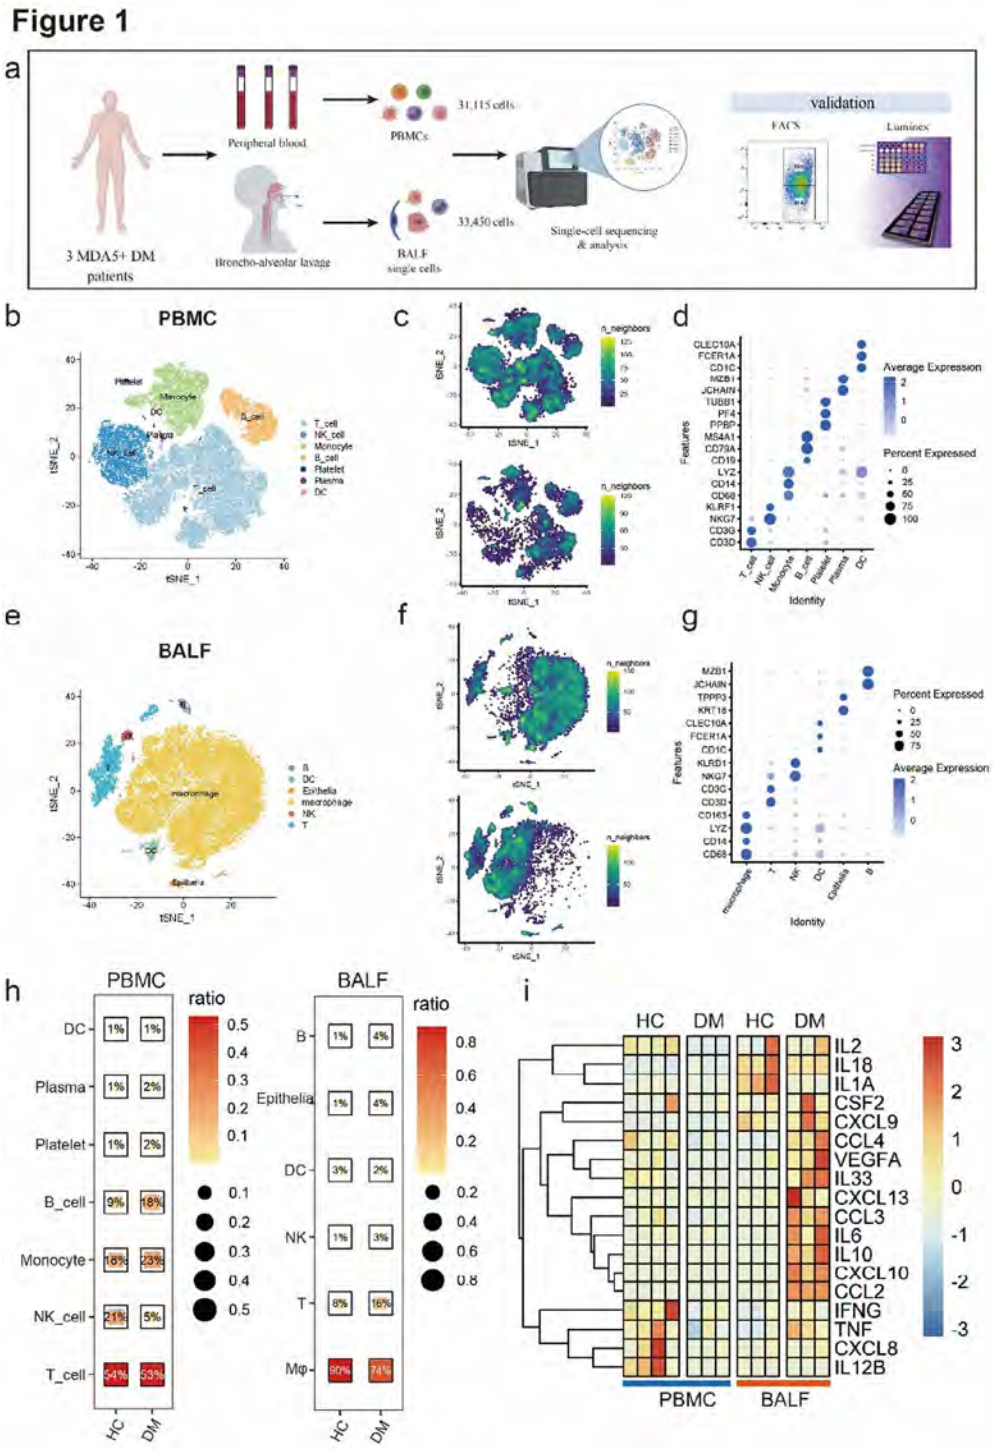

Figure 1. (a) Flowchart depicting the overall experimental design of this study. (b&e) t-SNE plot showing the overview of cell clusters in the integrated single-cell transcriptomes of PBMCs and BALFs from anti-MDA5+ DM patients and healthy controls (HCs). (c&f) t-SNE plots showing the single-cell transcriptomes of PBMCs and BALFs from HCs (top) and anti-MDA5+ DM patients (bottom) respectively. (d&g)The specific markers for identifying each immune cell types in b&e are indicated. (h)The ratios of each cell cluster in PBMCs and BALFs from anti-MDA5+ DM patients and HCs. (i) Heatmap showing the expressions of key cytokines and chemokines involved in cytokine strom of PBMCs and BALFs from HCs and patients.

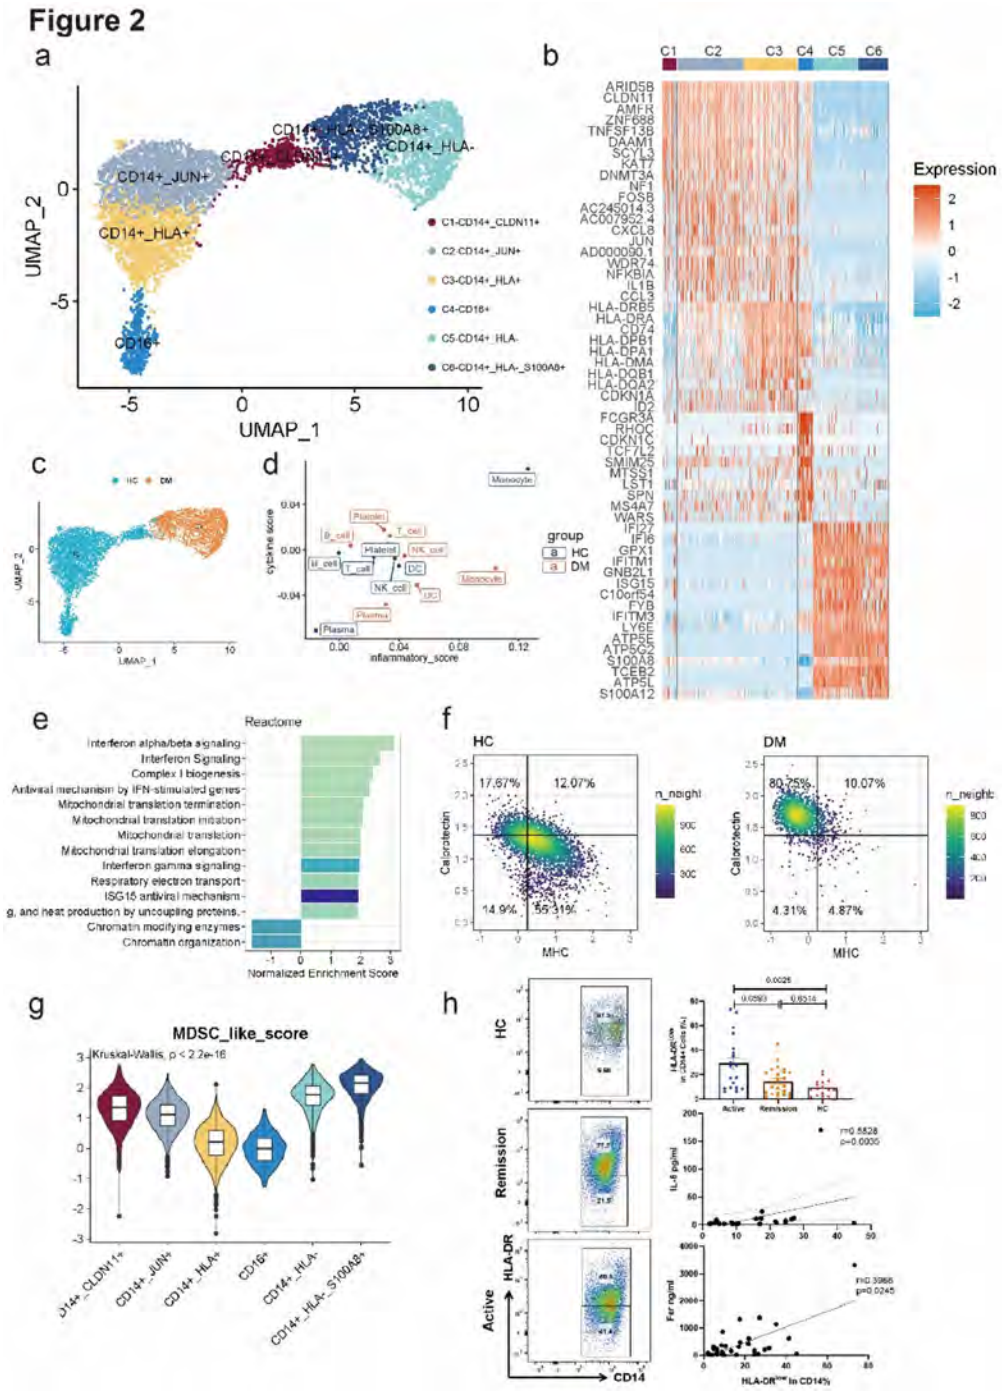

Figure 2. (a) UMAP plot of six cell clusters of monocytes in PBMCs. (b) Heatmap showing top 10 marker genes for each cluster. (c) UMAP plot showing monocytes across HCs and patients. (d) Inflammatory scores and cytokine scores of PBMC cell clusters. (e) Bar plot showing the pathways enriched in the anti-MDA5+ DM group across monocytes. (f) Density plots show the composite MHC II signature scores and calprotectin signature scores of peripheral CD14+ monocytes in 2D maps. The horizontal and vertical lines separating the four quadrants represent the median scores of all CD14+ monocytes. The percentages of cells in each quadrant are indicated. (g) Violin plot showing the MDSC-like score of each monocyte cluster. (h) Left panel shows the representative flow cytometric data of HLA-DR expression on CD14+ PBMCs. Right top plot shows the percentage of HLA-DRLow cells in CD14+ PBMCs among anti-MDA5+ DM-active group, anti-MDA5+ DM-remission group and HC group. The middle and bottom plot on the right shows the Spearman correlation of HLA-DRLow% and IL-6, and ferritin levels.

Epigenetic Regulation of DNMT3A by TFEB and DOT1L Through AMPK Signalling Orchestrates the Lysosomal Response of Macrophages During Gout and Clonal Hematopoiesis

Isidoro Cobo[1], Jessica Murillo-Saich[2], Mohnish Alishala[1], Stephen Calderon[1], Roxana Coras[3], Nathanael Spann[1], Anyan Cheng[4], Thomas Prohaska[1], Babak Razani[5], Robert Terkeltaub[1], Benjamin Ebert[6], Ru Liu Bryan[7], Monica Guma[8] and Christopher glass[1], [1]University of California San Diego, San Diego, CA, [2]Department of Medicine, University of California San Diego, La Jolla, CA, [3]Cedars-Sinai Medical Center, Los Angeles, CA, [4]University of California San Diego, San Francisco, CA, [5]Universit of Pittsburgh, Pittsburgh, PA, [6]Dana-Farber Cancer Institute, Boston, MA, [7]UCSD and VASDHS, San Diego, CA, [8]San Diego VA Healthcare Service, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Innate Immunity
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Gout is the most common form of inflammatory arthritis worldwide, which is characterised by the deposition of monosodium urate crystals (MSUc) in the joints that leads to lysosomal damage and triggers the activation of the inflammasome leading to acute episodes of inflammation. **Clonal hematopoiesis** of indeterminate potential (CHIP) is defined as a common, age-related disorder marked by the expansion of blood-cell clones by somatic mutations, mainly in *DNMT3A* or *TET2*. Interestingly, individuals with CHIP have a higher risk of developing gout. In line with this, activating similar inflammatory programs raises the question of what epigenetic molecular mechanisms underlying the association between gout and CHIP are.

Methods: We performed ATAC-Seq, ChIP-Seq, RNA-Seq, Western Blot, RT-qPCR, ChIP-qPCR, LysoTracker staining, in murine bone marrow-derived macrophages and human monocyte-derived macrophages stimulated with MSUc for 5h. Tfeb KO, Dnmt3a KO and Tfeb overexpressing macrophages (Tfeb-Tg) were used. AMPK activators Metformin or A766992 and DOT1L inhibitor SGC0946 (DOT1Li) were used.

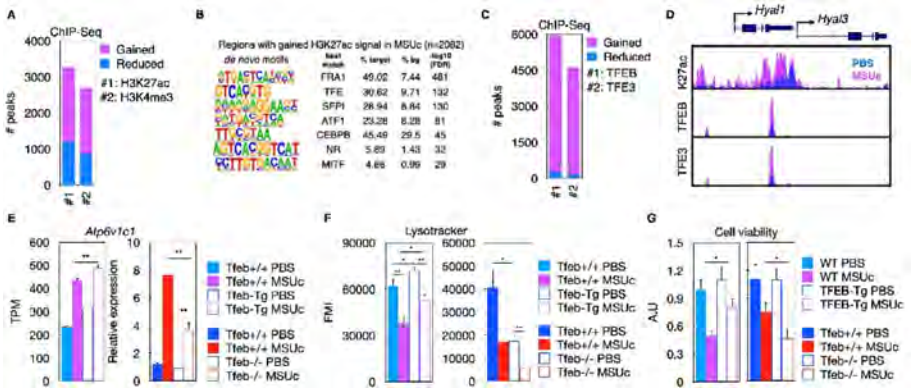

Figure 1. MSUc leads to an altered histone landscape with increased TFEB, which is required to activate the lysosomal program during gouty inflammation. (A) ChIP-Seq of H3K27ac and H3K4me3 in macrophages by MSUc. (B) Motif analysis of regions with gained H3K27ac signal. (C) ChIP-Seq of TFEB and TFE3 after stimulation with MSUc. (D) UCSC Browser composite of H3K27ac (K27ac), TFEB and TFE3 ChIP-Seq. (E-G) Analysis of Atp6v1c1 expression (E), LysoTracker staining (F) or cell viability (G) of macrophages over-expressing Tfeb (Tfeb-Tg) or Tfeb KO. TPM=transcripts per million reads. FMI=fluorescence mean intensity. N>3/experiment. Except for RNA-Seq experiments, Student T-test was used to calculate statistical significance.

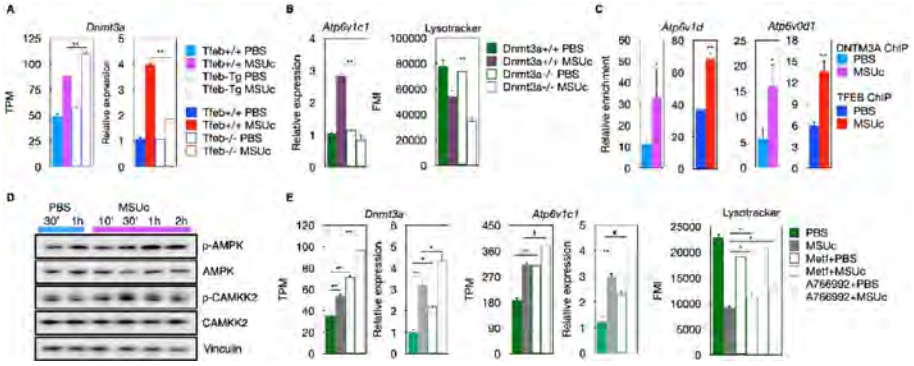

Figure 2. Upregulation of DNMT3A by TFEB through AMPK signaling is required to activate the lysosomal gene expression program by MSUc. (A) Expression analysis of Dnmt3a of macrophages over-expressing Tfeb (Tfeb-Tg) or Tfeb. (B) Expression of Atp6v1c1 (left) or LysoTracker staining (right) of wild type or Dnmt3a KO macrophages stimulated with MSUc. (C) Chromatin Immunoprecipitation of TFEB and DNTM3A over the promoter of Atp6v1d and Atp6v0d1. (D) Protein analysis by Western blot of AMPK signaling components. (E) Expression analysis of Dnmt3a (left), Atp6v1c1 (center) or LysoTracker staining (right) of macrophages incubated with Metformin (Metf) or A766992 prior to stimulation with MSUc. TPM=transcripts per million reads. FMI=fluorescence mean intensity. N>3/experiment. Except for RNA-Seq experiments, Student T-test was used to calculate statistical significance.

Results: We found over 2000 genomic regions with increased H3K27ac or H3K4me3 signal **(Figure 1A)**. These genomic regions are enriched in binding sequences for MITF/TFE transcription factors **(Figure 1B)** which are master regulators of lysosomal biogenesis. Interestingly, we found that stimulation by MSUc leads to an increased binding of TFEB and TFE3 over 4000 genomic regions **(Figure 1C)** associated with the promoter of lysosomal genes *Hyal1* and *Hyal3* **(Figure 1D)**. Moreover, whereas genetic overexpression of *Tfeb* (Tfeb-Tg) leads to increased expression of lysosomal genes including *Atp6v1c1*, higher LysoTracker staining and improved cell viability **(Figure 1E-G, left panel)**, the opposite is observed for Tfeb knock-out macrophages **(Figure 1E-G, right panel)**. In addition, we found that TFEB regulates *Dnmt3a* upregulation

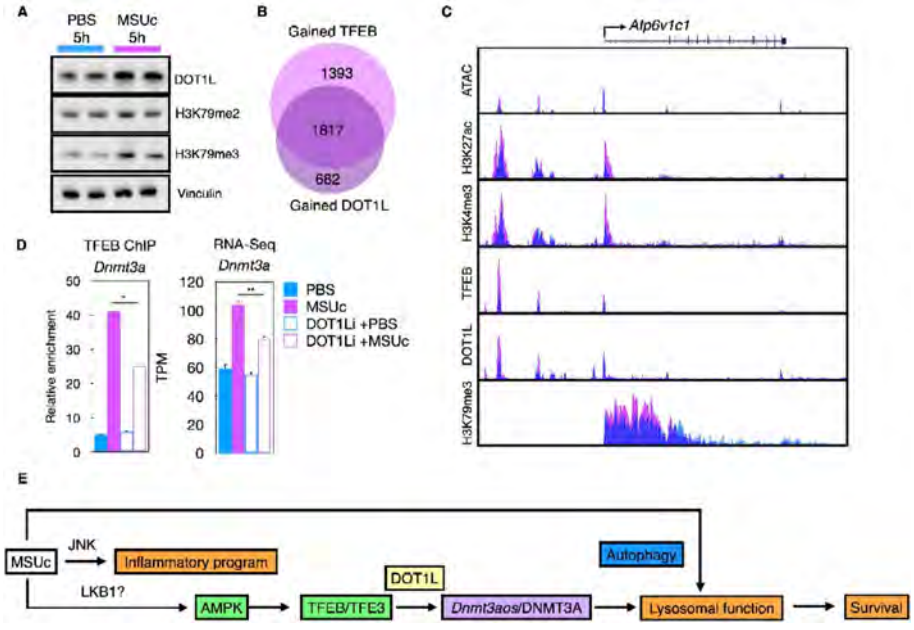

Figure 3. DOT1L is a TFEB binding partners that regulate Dnmt3a and lysosomal gene expression during gouty inflammation. (A) Protein analysis by Western blot for DOT1L and its downstream modified histone products. (B) Overlap between genes associated to increased TFEB and increased DOT1L signal by MSUc. (C) UCSC browser composite. (D) Chromatin immunoprecipitation of TFEB over the promoter of Dnmt3a (left) or Dnmt3a expression analysis (right) of macrophages incubated with DOT1L inhibitors prior to stimulation with MSUc. (E) Schematic summary of the response of macrophages to MSUc . TPM=transcripts per million reads. FMI=fluorescence mean intensity. N>3/experiment. Except for RNA-Seq experiments, Student T-test was used to calculate statistical significance.

by MSUc **(Figure 2A)** and that *Dnmt3a* deletion leads to downregulation of lysosomal gene expression and LysoTracker staining **(Figure 2B)**.

Moreover, we found that DNMT3A co-binds with TFEB over the promoter of *Atp6v1d*, and *Atp6v0d1* **(Figure 2C)**, indicating that TFEB and DNMT3A are part of the same genomic network. We also found that MSUc leads to activation of AMPK signaling **(Figure 2D)** and that treatment with AMPK activators Metformin or A766992 induces *Dnmt3a* and lysosomal gene expression and increases the LysoTracker staining by MSUc **(Figure 2E)**. Furthermore, we found that the histone-methyl transferase DOT1L is upregulated by MSUc **(Figure 3A)** and co-bind with TFEB **(Figure 3B)** and DNMT3A over the promoter of lysosomal genes such as *Atp6v1c1***(Figure 3C)**. Treatment with DOT1L inhibitor reduces the recruitment of TFEB to the promoter of *Dnmt3a*, thereby, downregulating *Dnmt3a* expression **(Figure 3D)**.

Conclusion: Our data indicate that DNMT3A cooperates with TFEB and DOT1L for the required regulation of lysosomal gene expression during gout flares by MSUc and provides a mechanistic explanation as to why patients with clonal hematopoiesis by *DNMT3A* mutations are at higher risk of developing more severe gout **(Figure 3E)**. Our data opens novel therapeutic possibilities for patients with clonal hematopoiesis and gout.

Autoimmune Pathway Blockade by a Potent Orally Bioavailable STING Antagonist

Min Yang[1], Hailong Li[1], yangyang liu[1], lili yao[1], Jing Lin[1], Zhi xie[2] and Wenge zhong[1], [1]Regor Therapeutics, Shanghai, China, [2]Regor Pharmaceuticals, Inc., San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Innate Immunity
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The cyclic GMP-AMP synthase (cGAS)-stimulator of interferon genes (STING) pathway has emerged as a key innate immune mediator of autoimmune and inflammatory diseases. However, the development of a drug-like STING antagonist remains challenging. Here, we report the discovery and characterization of RGT-118, a highly potent, selective and orally bioavailable small molecule STING antagonist for autoimmune disorders in preclinical models.

Methods: By leveraging the Computer Accelerated Rational Design (rCARD^{TM}) platform, we designed and synthesized a small molecule STING antagonist RGT-118. Cellular potency was measured in cGAMP stimulated THP-1 cells with IFN-b secretion as a readout. The absorption (MDCK based permeability assay and kinetic solubility), distribution (free fraction in plasma), and metabolism (liver microsomes, hepatocytes, plasma and blood stability) were characterized in *in vitro* assays. The pharmacokinetic (PK) study was performed in preclinical species to evaluate the exposure and bioavailability. Proof-of-mechanism (POM) studies were also performed using a mouse model in which the inhibition of RGT-118 on the

production of IFN-a, IFN-b, IL-6 and TNF-a was measured after being challenged with cGAMP. Trex1$^{-/-}$ mouse model was used to investigate the mechanistic activity of RGT-118. In addition, imiquimod-induced psoriasis model was used to evaluate the efficacy of RGT-118 in inhibiting disease development. Furthermore, to explore the therapeutic window of RGT-118, rat and dog 14-day dose-range finding (DRF) exploratory toxicity studies were performed.

Results: RGT-118 covalently binds to cysteine residue 91 in transmembrane domain, which blocks the activation induced palmitoylation of STING. The downstream pathways (i.e. type I IFN and NF-kB) mediated by cGAS-STING were attenuated by RGT-118 in a dose-dependent manner in both cellular assay and *in vivo* POM study. RGT-118 demonstrated good permeability and solubility *in vitro*. Furthermore, it showed good oral bioavailability and drug exposure *in vivo* in rat and dog. In Trex1$^{-/-}$ mice, treatment of RGT-118 significantly increased body weight and decreased ISGs and NF-kB related cytokines. Additionally, it showed comparable therapeutic effect in IMQ-induced psoriasis model with head-to-head comparison of PDE4i and anti-IL-17 treatment. Moreover, no severe toxicological signs were observed in both rat and dog 14-day dose-range finding studies and the no-observed-adverse-effect-level (NOAEL) of this compound was determined to be 200 mg/kg/day.

Conclusion: RGT-118 is a highly potent, selective and orally bioavailable small molecule STING antagonist with demonstrated efficacy in several preclinical animal models. With a favorable therapeutic window, RGT-118 provides therapeutic opportunities in multiple autoimmune and inflammatory diseases.

Complement Factor D/Adipsin Knockout Mice Demonstrate Disparate Pain and Structural Damage Phenotypes in Obesity-induced Post Traumatic Osteoarthritis

Kelsey Collins[1], Kristin Lenz[2], Arin Oestreich[2], Luke Springer[2], Antonina Akk[2], Huimin Yan[2], Xiaobo Wu[2], John Atkinson[3], Christine Pham[4] and Farshid Guilak[4], [1]University of California San Francisco, San Francisco, CA, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine, St. Louis, MO, [4]Washington University, St. Louis, MO

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Osteoarthritis (OA) is the leading cause of musculoskeletal pain, which is a primary driver of care-seeking behavior. There is lack of mechanistic information detailing the interface between OA pain and structural damage. Understanding pain signals independent of structural damage has been difficult using existing pre-clinical models. We have identified a mouse model that displays discordant knee pain and structural damage, which provides a unique opportunity to explore pain independently of structural changes. Mice that lack fat-derived adipsin (also known as complement factor D, FD) are protected from cartilage damage induced by the destabilization of the medial meniscus (DMM) but demonstrate increased sensitivity to pressure-pain hyperalgesia. The goal of this study is to determine the mechanism by which FD modulates pain in OA.

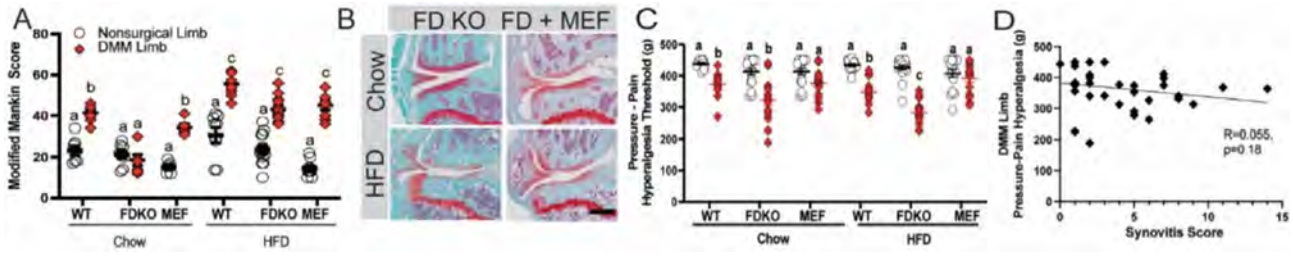

Figure 1. Modified Mankin Score (A), red diamonds indicate limbs challenged with destabilization of the medial meniscus (DMM), circles contralateral limbs, Mouse Embryonic Fibroblast (MEF) indicates FD KO + MEF; (B) Medial tibial plateau Safranin-O/Fast Green histology sections of DMM limbs (black bar indicates 100μm); (C) pressure-pain hyperalgesia measured by SMALGO on DMM (red diamonds) and nonsurgical (circles) limbs; (D) relationship between synovitis score and DMM-limb pressure-pain hyperalgesia is not significant (p=0.18), indicating that the hyperalgesia phenotype is not explained by synovitis. Different letters indicate $p<0.05$ by ANOVA, data are shown as mean ± standard error.

Methods: FD KO mice and WT controls (7-12/group) were fed chow (10% kcal fat) or high-fat diet (HFD, 60% kcal fat). To restore circulating FD, FD KO mice were transplanted with mouse embryonic fibroblast (MEF)-derived fat implants. At 16-weeks, mice underwent destabilization of the medial meniscus (DMM) unilaterally to induce OA. At 26-weeks, forelimb grip strength, knee hyperalgesia (via small animal algometer) and tactile allodynia (Electronic von Frey) were assessed. Knee joints were evaluated using a Modified Mankin Score and immunohistochemistry for C3 and C5-9. Bulk RNA sequencing was performed on L3-L5 dorsal root ganglia (DRG). Data were analyzed by repeated measures of ANOVA (genotype, limb, diet) and post hoc testing.

Results: Chow-fed FD KO mice were protected from DMM-induced structural OA (Fig. 1a,b) but not from increased synovitis, osteophyte formation, or pain in the DMM limb (Fig. 1c). Specifically, chow-fed FD KO mice demonstrated reduced pressure-pain thresholds and increased tactile allodynia when compared to WT DMM limb. Protection against DMM-induced cartilage damage was reversed in HFD FD KO mice (Fig.1a). There was no evidence of an alternative pathway (AP) bypass mechanism to explain this reversal in phenotype suggesting that complement is dispensable for structural damage under HFD conditions. However, HFD FD KO mice demonstrated lower pressure-pain threshold, or increased hyperalgesia at the knee (Fig. 1c), despite having a similar Modified Mankin Score to HFD WT DMM limbs (Fig. 1a,b). Restoration of AP activity using MEF transplantation in both diet groups induced a reversal of pain thresholds in FD KO to corresponding WT DMM limb levels, suggesting a role for FD in joint pain (Fig. 1c). Gene ontology (GO) analysis of DRG from FD KO mice revealed differentially expressed genes associated with neutrophil infiltration and histone modifications. Lastly, no significant relationship was found between pain and synovitis (Fig. 1d).

Conclusion: We observed paradoxically heightened pain phenotype in the FD KO mice post DMM suggesting that this model can be used to dissect the clinical discordance between subjective pain and objective joint structural damage. Understanding the mechanism by which FD modulates the DRG neuroimmune profile in regulating OA pain may inform whether therapeutic targeting of complement activity will be beneficial in OA treatment.

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Memantine is an FDA proved drug utilized for the treatment of dementia and exerts its function by blocking the NMDA (N-methyl-D-aspartate) receptor, a calcium permeable ion channel that reduces cytotoxic calcium overload. Chondrocyte senescence is a crucial cellular event that contributes to articular cartilage degeneration during osteoarthritis (OA) development. However, little information has been reported regarding the effects of memantine and its downstream NMDA receptor on chondrocyte senescence and OA.

Methods: The protein levels of the NMDA receptor and its agonistic ligand, glutamate, were compared in OA and normal chondrocytes. The amount of intracellular calcium ions and mitochondrial damage were evaluated using specific fluorescent probes and transmission electron microscopy (TEM). Senescence-associated β-galactosidase (SA-β-gal) staining and $p16^{INK4a}$ were analyzed to assess chondrocyte senescence. The function of the NMDA receptor in chondrocyte senescence and OA were tested through agonists activation and gene knockout experiments. The therapeutic effects of memantine on OA were tested both in vitro and in vivo. Additionally, to verify the findings from animal samples, a propensity score matched human cohort study using the IQVIA Medical Research Data primary care database in the UK was conducted to compare the risk of OA associated joint replacement (the clinically relevant endpoint of OA) in memantine initiators with initiators of active comparator, i.e., acetylcholinesterase (AchE), among patients with dementia.

Results: The protein expression of the NMDA receptor and the secretion of glutamate were both significantly higher in OA chondrocytes. Activation of the NMDA receptor stimulated chondrocyte calcium overload, which resulted in mitochondrial fragmentation and chondrocyte senescence. Inhibiting the NMDA receptor by memantine and knockout NR1, the gene encoding NMDA receptor, resulted in reduced calcium influx, mitochondrial fragmentation as well as cellular senescence in OA chondrocyte. In addition, intra-articular injection of memantine in OA mice model exhibited protective effects on cartilage degeneration. What's more, in the 1:5 propensity-score matched cohort study consisted of 6,218 patients (n=1,435 in memantine cohort; n=4,783 in AchE cohort), memantine initiators was associated with a lower risk of OA-associated joint replacement compared with AchE initiators (hazard ratio=0.57, 95% confidence interval: 0.34 to 0.99).

Conclusion: As a clinically licensed drug used for dementia, memantine shows promising therapeutic effects on OA. Mechanistically, it blocks NMDA receptor-mediated chondrocyte senescence. The protective effects of memantine on OA were verified not only through in vitro and in vivo experiments but also via a propensity-score matched human cohort study. These findings present robust evidence for repurposing memantine for the treatment of OA.

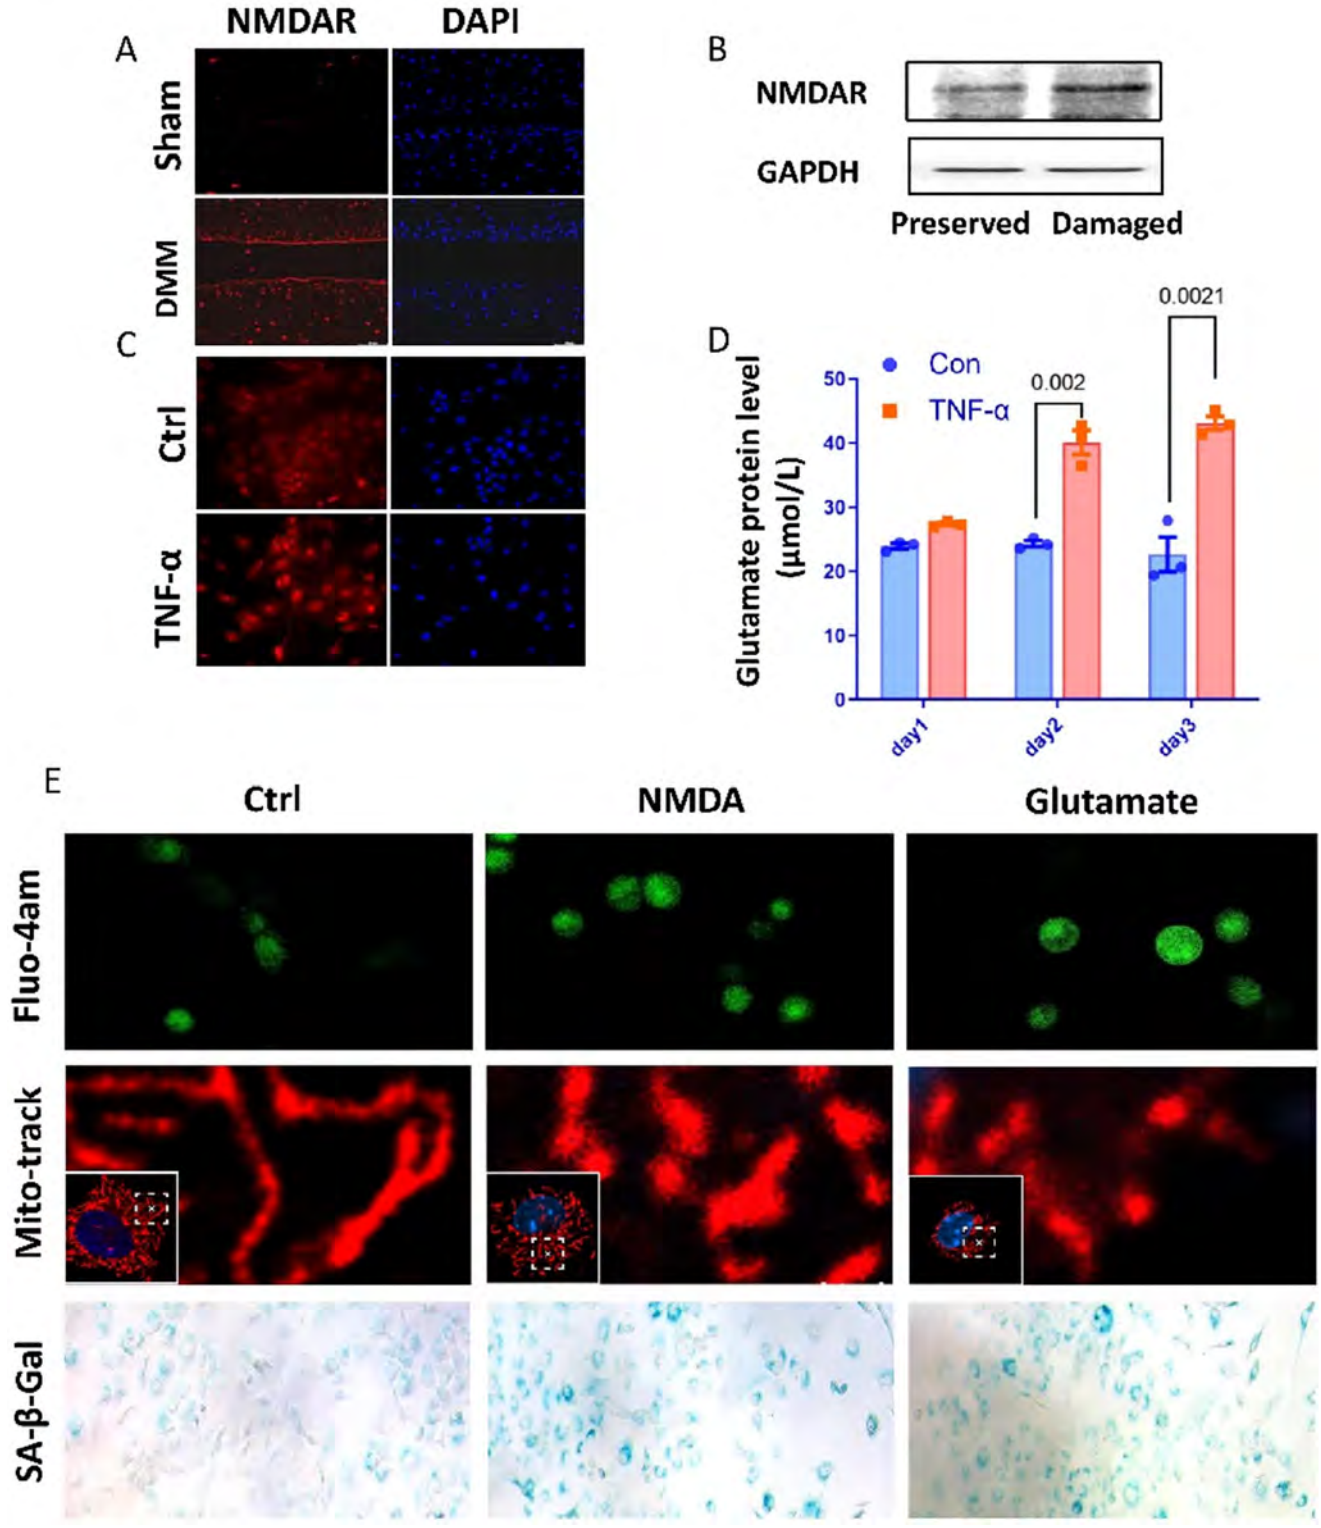

Figure 1. OA progression accompanied by highly expressed and activated levels of NMDA receptor that led to mitochondrial fragmentation and chondrocyte senescence. Immunostaining was used to analyze the level of NMDA receptor in the destabilization of the medial meniscus (DMM) surgery-induced OA mice knee joint (A), as well as the inflammatory-induced OA chondrocyte (C). The protein level of NMDA receptor in preserved and damaged cartilage from OA patients (B). The secretion of glutamate from OA chondrocytes in cell culture medium (D). The calcium probe Fluo-4am, the mitochondrial probe mito-tracker, and the SA-β-gal staining were used for chondrocytes stimulated with NMDA or glutamate (E).

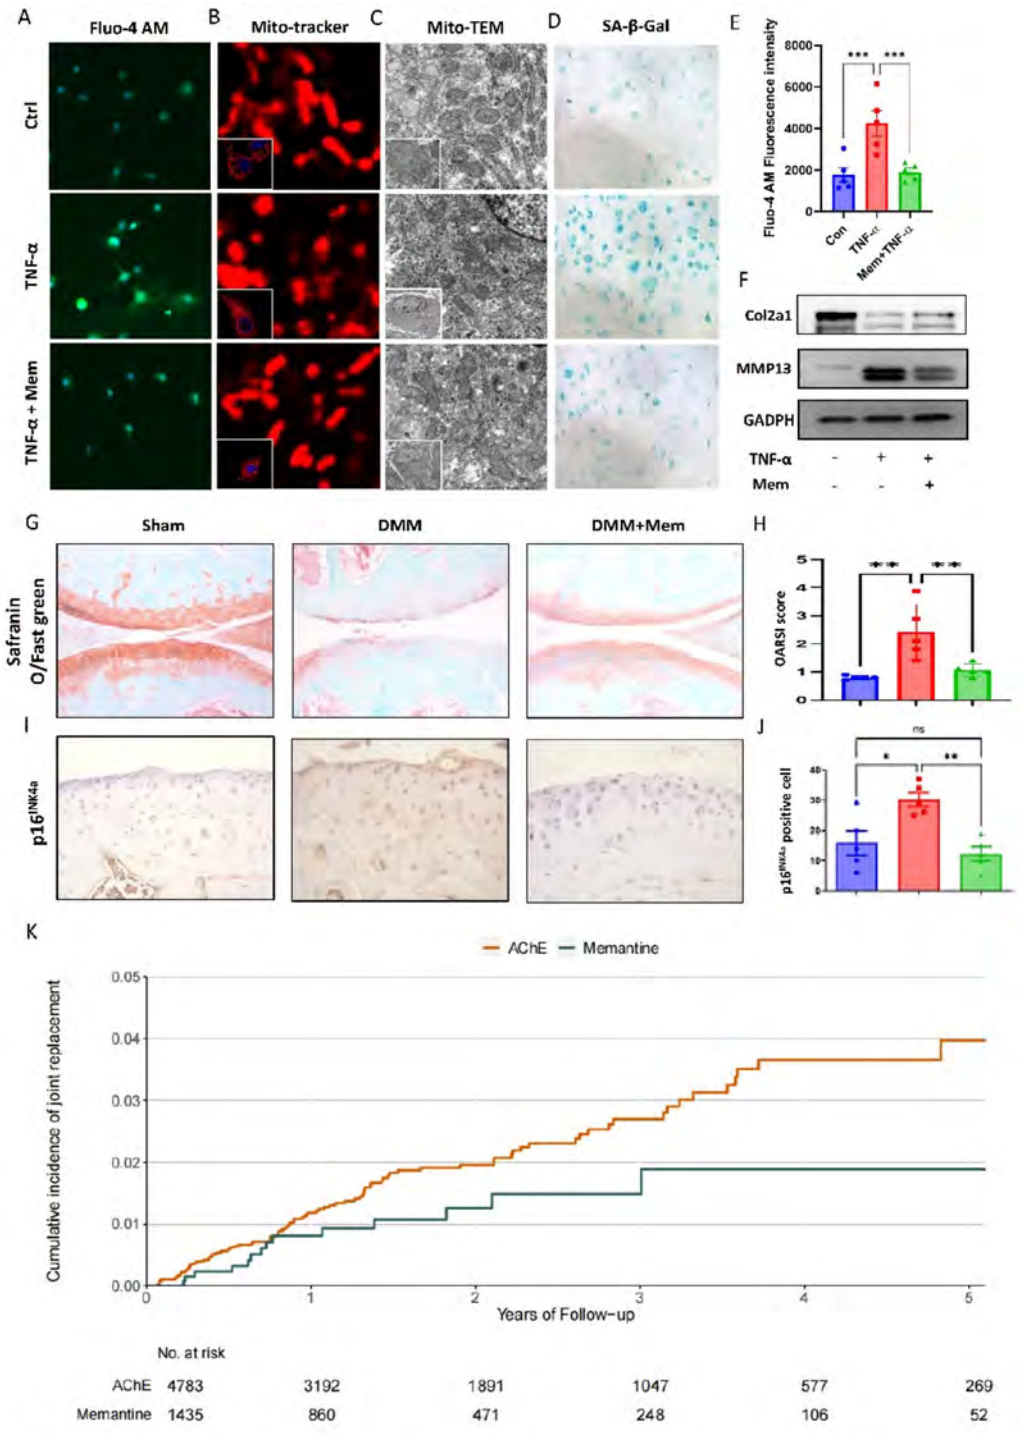

Figure 2. Memantine protects against OA and is associated with reduced risk of knee or hip OA-associated joint replacement among patients with dementia. The Fluo-4am (A), mito-tracker (B), TEM (C), and SA-β-gal staining (D) were used for OA chondrocytes stimulated with Memantine or not. Semi-quantification of calcium overload based on the staining (E). Protein levels of Col2a1 and MMP13 were detected (F). Safranin O/Fast green staining (G) and OARSI score (H), p16INK4a immunohistochemistry staining (I), and semi-quantification (J) for DMM-induced OA model. Cumulative incidence of knee or hip osteoarthritis-associated joint replacement in 1,435 memantine users and 4,783 AchE users (K), matched by propensity score.

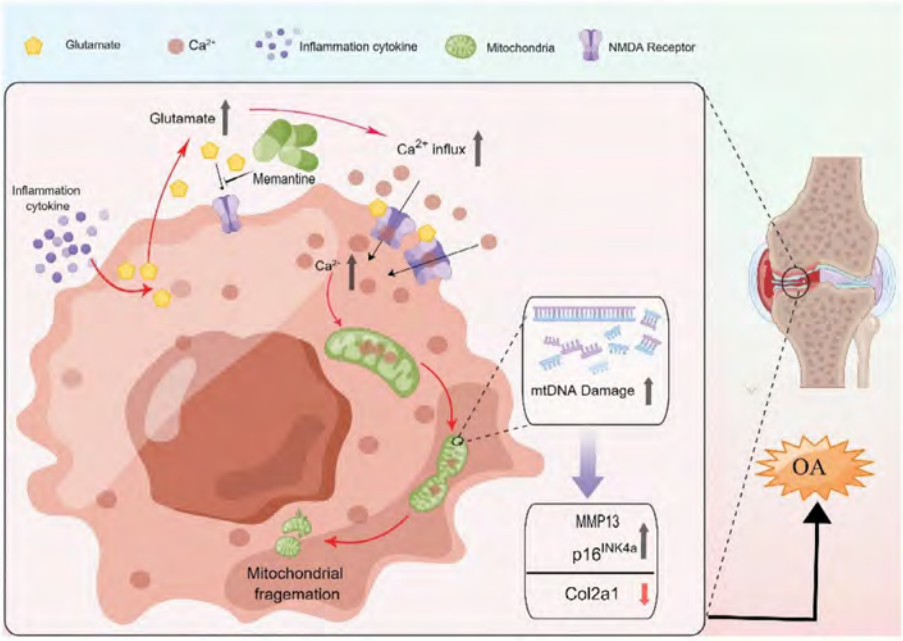

Figure 3. The mechanistic diagram of memantine as a potential chondroprotective drug for OA.

Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Hand osteoarthritis (OA) is a common heterogeneous joint disorder with differences in etiology and pathophysiology from the large weight-bearing knee or hip OA. Its pathophysiological mechanism remains largely unexplored, partially because of limited access to clinical sample tissues and lack of animal models. To date, there is no known cure for hand OA, indicating an urgent need for better understanding of the underlying mechanisms to develop appropriate treatment strategies. Here, we aimed to identify hand joint chondrocyte subpopulations and investigate the molecular

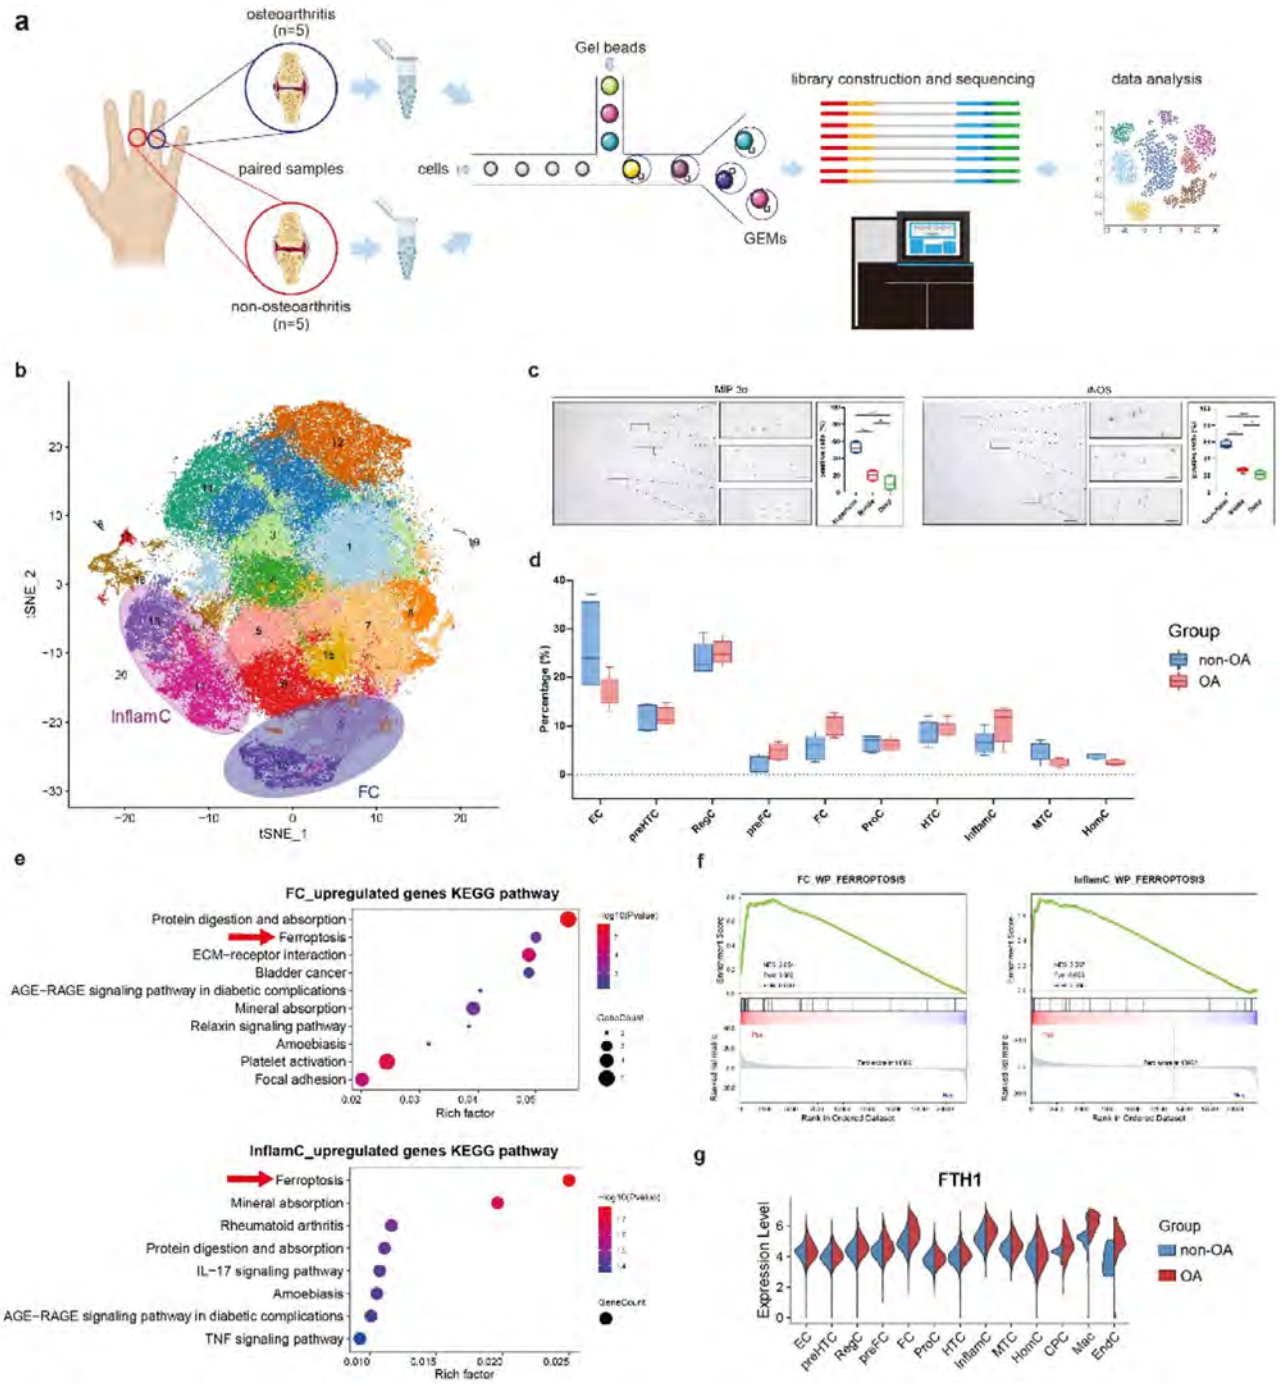

Figure 1. ScRNA-seq analysis of human hand OA and non-OA articular cartilage (a) Schematic workflow of single-cell RNA sequencing. (b) t-SNE embedding plot for 105,142 cells, derived from paired articular cartilage samples of five donors. (c) Representative immunohistochemistry (IHC) staining for MIP-3α and iNOS in hand articular cartilage tissues (n=4). Scale bar, left, 100 μm; right, 20 μm. ***P<0.001, ****P<0.0001. (d) Differential analysis of subpopulation abundance between osteoarthritic and non-osteoarthritic cartilage. Wilcoxon matched-pairs signed rank test was used for analysis. (e) KEGG enrichment analysis of the upregulated genes of FC and InflamC in hand OA. Arrows indicate ferroptosis enriched in the upregulated genes in osteoarthritic FC and InflamC. mechanism of hand OA by performing single-cell RNA sequencing (scRNA-seq) analysis, and verify the findings in two large independent population-based studies.

Table 1. Association between serum ferritin levels and prevalence of hand OA

	Quintiles of serum ferritin, μg/L					*P*-for-trend
	Q1	Q2	Q3	Q4	Q5	
Hand (n)*	495	496	491	494	487	
Median of serum ferritin levels, μg/L	75.0	138.5	213.0	308.0	564.0	
Number of hand OA (%)	99 (20.0)	105 (21.2)	104 (21.2)	119 (24.1)	136 (27.9)	
Crude OR (95% CI)	1.00 (Ref)	1.07 (0.74-1.56)	1.07 (0.74-1.56)	1.27 (0.88-1.84)	1.55 (1.08-2.22)	0.037
Age-sex-BMI adjusted OR (95% CI)	1.00 (Ref)	1.31 (0.89-1.93)	1.23 (0.83-1.83)	1.46 (0.97-2.22)	1.69 (1.13-2.52)	0.005

OA, osteoarthritis; Q, quantile; n, number; OR, odds ratio; CI, confidence interval; BMI, body mass index; Ref, reference.
*The association between serum ferritin levels and hand osteoarthritis was evaluated by logistic regression model using generalised estimating equations (hand specific analysis).

Methods: We obtained hand interphalangeal joints from five donors who had destructive forearm injury. Using scRNA-seq analysis, we analyzed the cellular composition and subpopulation-specific gene expression of hand articular cartilage, and then compared these features between cartilages from joints with macroscopically confirmed OA (n=5) and those without OA (n=5). We further conducted: (1) a Mendelian randomization study using data from the UK Biobank to investigate the causal association between the key differentially expressed gene and hand OA; and (2) a cross-sectional study using data collected from a community-based observational study, i.e., the Xiangya OA (XO) Study, to examine the association between a serum biomarker (encoded by the key gene) and hand OA.

Results: Of 105,142 cells we identified 13 subpopulations, including a novel inflammatory chondrocyte subpopulation that specifically expressed genes related to inflammatory and immune response. Fibrocartilage chondrocytes represented a major source of OA-related proteases and exhibited an extensive alteration of gene expression patterns in OA cartilage compared with non-OA cartilage. Both inflammatory chondrocytes and fibrocartilage chondrocytes showed a trend towards increased numbers in hand OA cartilage. In these two subpopulations from OA cartilage, the ferroptosis pathway was enriched, in which the expression of iron overload-related genes, e.g., *FTH1*, was elevated. These findings are further validated by two independent population-based studies. Among participants (n=332,668) in the UK Biobank, genetic predisposition to higher expression of *FTH1* mRNA significantly increased the risk of hand OA (OR=1.07, 95%CI:1.02-1.11). Among participants (n=1,241) from the XO Study, high levels of serum ferritin (encoded by *FTH1*), a biomarker of body iron overload, were significantly associated with a high prevalence of hand OA (*P*-for-trend=0.037).

Conclusion: Our datasets will be valuable as a rich resource and open new possibilities for the research of molecular mechanism, drug development and precise treatment for hand OA. Inflammatory and fibrocartilage chondrocytes are key subpopulations and ferroptosis may be a key pathway in hand OA. Markers of these chondrocyte subpopulations, as well as ferroptosis inhibitors or iron chelators, could be focus of attention in future studies.

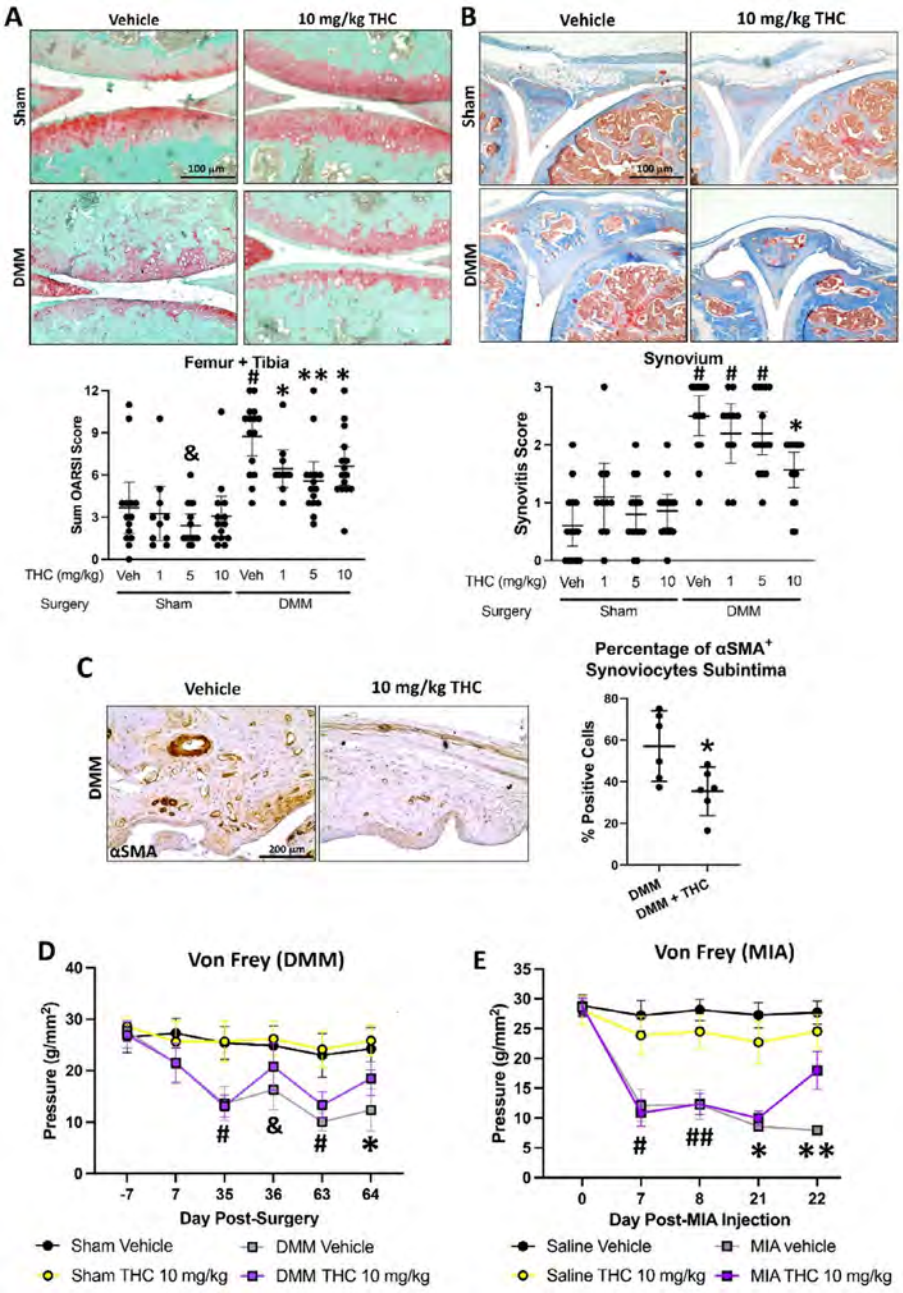

Fig 1. Oral administration of THC attenuates modifies disease progression and pain in OA-induced mice. Sham or DMM mice received treatment by oral gavage 5 days/week with vehicle [veh; medium chain triglyceride (MCT)] or THC (1, 5, 10 mg/kg) for 9 weeks. Knee joints were collected at 10 weeks post-surgery and stained with (A) Safranin O for OARSI scoring of cartilage degeneration and (B) Masson's Trichrome for synovitis, respectively (n=10-15/group). Data was analyzed by Kruskal-Wallis tests followed by Mann-Whitney post-hoc tests corrected for multiple comparisons using the method of Benjamini, Kreiger and Yekutieli using R v 3.5.03 with coin package v 1.3-24 to account for ties.*, &, or #, $q < 0.05$ compared to all other comparison groups with different or no symbols. (C) Representative images and quantification of synovial subintima IHC staining for αSMA in knee joint synovium collected from DMM mice given MCT or 10mg/kg THC treatment by oral gavage for 9 weeks (n=6/group). Data was log transformed prior to analysis by Student's two-tailed t-tests with Welch's correction. *, $p < 0.05$. (D) Sham and DMM-surgical mice (n=10-15/group) or (E) saline and MIA-injected mice (n=10-25/group) were administered vehicle (MCT) or 10 mg/kg THC by oral gavage and were evaluated for mechanical allodynia using the von Frey test. (D & E) Data was log-transformed prior to analysis by repeated measures two-way ANOVA followed by multiple comparison's tests using the method of Benjamini, Kreiger and Yekutieli to correct for false-discovery rate. (D) #, $q < 0.0001$ in DMM groups vs Sham groups. &, $q < 0.01$ for DMM + vehicle compared to Sham + vehicle or Sham + THC groups. *, $p < 0.05$ for all comparisons except between sham groups. (E)#, $p < 0.05$ for all comparisons except for MIA + saline vs. MIA + THC. ##, $p < 0.01$ for all comparisons except for MIA + saline vs. MIA + THC. *, $p < 0.05$ for all comparisons. **, $q < 0.05$ for all comparison and $q < 0.0001$ between MIA + vehicle and MIA + THC.

Background/Purpose: Osteoarthritis (OA) results in joint pain, cartilage degeneration, and synovitis. Recent studies suggest that some OA patients are self-medicating with cannabis. Δ^9-tetrahydrocannabinol (THC) is a prominent psychoactive phytocannabinoid in cannabis that can signal in joint cells, including chondrocytes and fibroblast-like synoviocytes (FLS). Currently, no studies link THC to disease modification in OA. We investigated effects and mechanisms of action of THC on pain and disease modification in pre-clinical models of knee OA.

Methods: OA was induced in male C57BL/6 mice by destabilization of the medial meniscus (DMM) or monosodium iodoacetate (MIA; 0.5 mg) and mice were administered THC (0, 1, 5 or 10 mg/kg) orally 5 days/week for 9 or 3 weeks, respectively. Von Frey tests were used to evaluate mechanical allodynia (pain) and open field tests were used to evaluate locomotion and anxiety. DMM knee joints were evaluated for cartilage degeneration/synovitis (OARSI scoring) and Ki67, αSMA, and collagen degradation (C2C) expression (immunohistochemistry). Human FLS and chondrocytes were cultured with 1 mM THC for 48h. RNA was sequenced to determine differentially expressed genes (DEGs; FDR-adjusted $p< 0.05$; absolute FC≥1.5) and DEG-enriched pathways. Pathway and transcription factor enrichment analyses were used to determine putative cellular mechanisms and transcriptional regulators modified by THC.

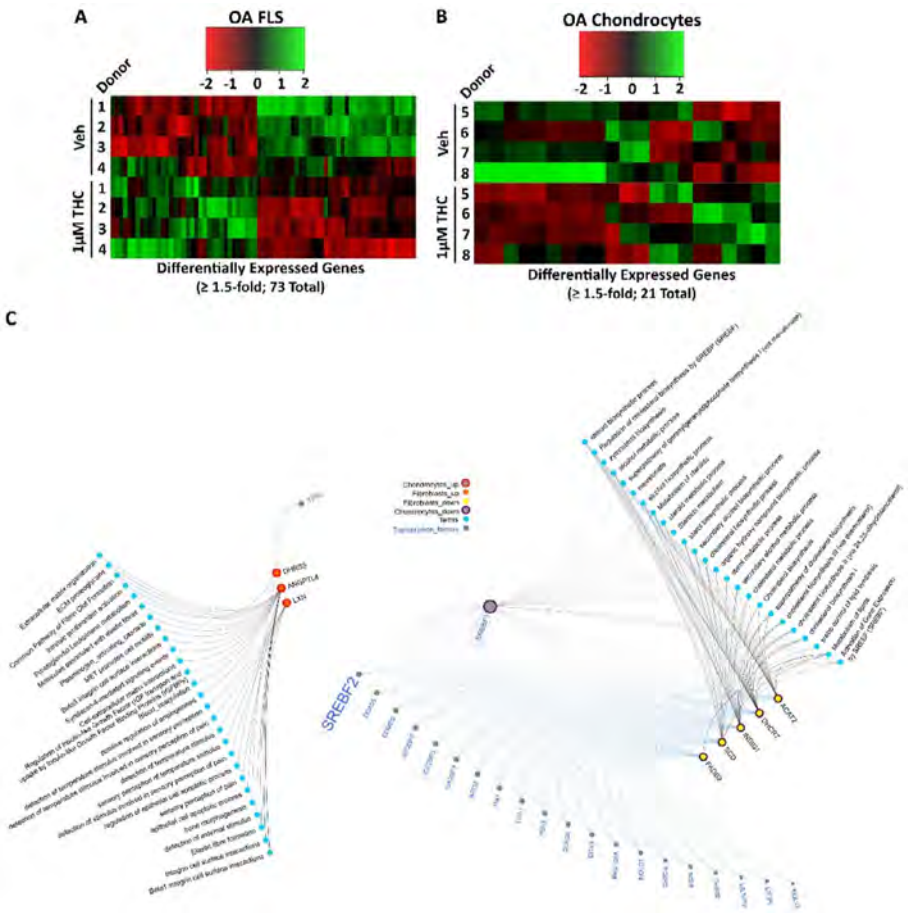

Fig 2. RNA Sequencing of THC-treated human OA fibroblast-like synoviocytes (FLS) or chondrocytes identifies differentially expressed genes (DEGs) associated with ECM and lipid metabolism pathways. Human OA FLS and chondrocytes were treated with 1 μM THC and was isolated after 48h and subjected to RNA sequencing. (A) Heat map shows the 73 DEGs from human OA FLS and (B) 21 DEGs from human OA chondrocytes stimulated with 1μM THC compared to vehicle-treated controls (veh; 0.5% DMSO) (n=4/group). (C) Network analysis shows combined transcription factors [determined by analysis through Catrin (http://ophid.utoronto.ca/Catrin/index.jsp] and protein-protein interactions (PPIs) with the overlapping DEGs and linked pathways [identified through analysis using pathdip (http://ophid.utoronto.ca/pathDIP/) and Gene Ontology Annotation analysis] in FLS and chondrocytes after THC treatment compared to vehicle-treated cells. Red nodes with red outlines represent upregulated genes and yellow nodes with purple outlines represent the downregulated genes in both FLS and chondrocytes after THC treatment. Grey lines connect genes to interacting pathways (blue nodes) and blue lines connect genes to predicted upstream TFs (grey nodes). Note SREBF2 is a putitive upstream regulator of common genes downregulated in both OA FLS and chondrocytes.

Results: In DMM mice, all THC doses reduced cartilage degeneration. 10 mg/kg THC also reduced synovitis (n=14-15/group) and synovial αSMA expression, but not Ki67 or C2C expression (n=6/group). Administration of 5 or 10 mg/kg THC in DMM (n=14-15/group) or MIA (n=10 25/group) mice reduced pain, particularly with 10 mg/kg administration (Fig. 1). Locomotion or anxiety were not modified longitudinally by THC administration. In cultured OA FLS (n=4), RNA sequencing identified 73 DEGs (35 up, 38 down) after treatment with 1 mM THC for 48h compared to vehicle. In cultured OA chondrocytes (n=4), 21 DEGs (9 up, 12 down) were identified after treatment with 1 mM THC compared to vehicle. Computational biology analyses found extracellular matrix (ECM)-related pathways were enriched in the upregulated DEGs in both fibroblasts and chondrocytes, while lipid/steroid/cholesterol-related pathways were enriched in the downregulated DEGs in both cell types. Three genes were commonly upregulated while 5 genes were commonly downregulated in FLS and chondrocytes by THC treatment. From FLS and chondrocyte downregulated DEGs, 22 common putative transcription factors were identified as potential regulators, with SREBF2 as a candidate of interest (Fig. 2).

Conclusion: Oral administration of 10 mg/kg THC reduced cartilage degeneration synovitis and synovial αSMA expression in DMM mouse knee joints, and modified pain in both DMM and MIA OA models. THC treatment of human OA FLS or chondrocytes modified expression of genes associated with ECM and lipid-based pathways, with common genes and putative regulatory transcription factors identified, including SREBF2. We are currently investigating contributions of SREBF2 to effects of THC on joint cells in vitro and mechanisms of pain in vivo.

Pharmacological Modulation of Krüppel-like Factor 4 Reduces the Severity of Experimental Osteoarthritis via Tissue Protection and Regeneration

Manabu Kawata[1], Merissa Olmer[2], Kristen Johnson[3] and Martin K Lotz[2], [1]Scripps Research Institute, San Diego, CA, [2]Scripps Research Institute, La Jolla, CA, [3]CALIBR, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Krüppel-like factors (KLFs) are members of the zinc finger family of transcription factors, which includes 17 members in mammals. We found that expression of KLF4 is dysregulated with progression of osteoarthritis (OA) in human and mouse knee cartilage. Further, we identified KLF4 as a new central transcription factor that regulates protective and regenerative functions in joint tissue cells. We hypothesized that molecules that increase KLF4 expression would be novel therapeutic candidates for OA.

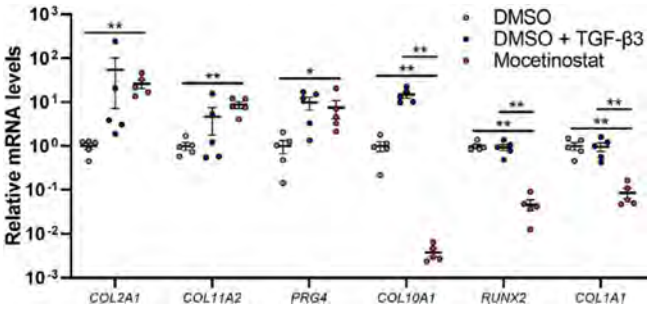

Figure 1. Regulation of chondrogenic and hypertrophic genes by mocetinostat in human BMSC pellets. Human BSMCs were cultured in pellets, and were treated with mocetinostat, or DMSO + TGF-b3. RNA was collected one week after pellet culture. mRA levels are expressed as means +SE, relative to DMSO (n=5 donors). *P<0.05, **P<0.01, Dunnett's test versus mocetinostat.

Methods: We performed high throughput drug screening (HTS) using the Repurposing, Focused Rescue, and Accelerated Medchem (ReFRAME) library with 11,948 clinical-stage molecules. Hit compounds were tested in joint tissue cells The lead compound was tested in the surgical destabilization of the medial meniscus (DMM) model of OA. As mechanistic studies included transcriptomic and proteomic profiling.

Results: Fifty-one hit compounds were identified in the HTS, and 18 compounds were confirmed in a secondary screen. We validated the 18 hits using SW1353 cells and human chondrocytes, and found that mocetinostat, a class I histone deacetylase (HDAC) inhibitor, had the best profile of biological activities. While mocetinostat upregulated KLF4, KLF2, FOXO1 and cartilage signature genes such as COL2A1, COL11A2, SOX9 and PRG4 in human chondrocytes, meniscal cells and pellet-cultured BMSCs, it down-regulated hypertrophic and catabolic genes, including COL10A1, RUNX2, ADAMTS5 and IL6 (Figure 1 for pellet-cultured BMSCs). Mocetinostat enhanced protective functions in human chondrocytes and synoviocytes through down-regulation of inflammatory and catabolic genes. Intraperitoneal administration of mocetinostat into mice after surgical OA induction significantly improved pain behaviors and reduced the severity of OA histopathological changes

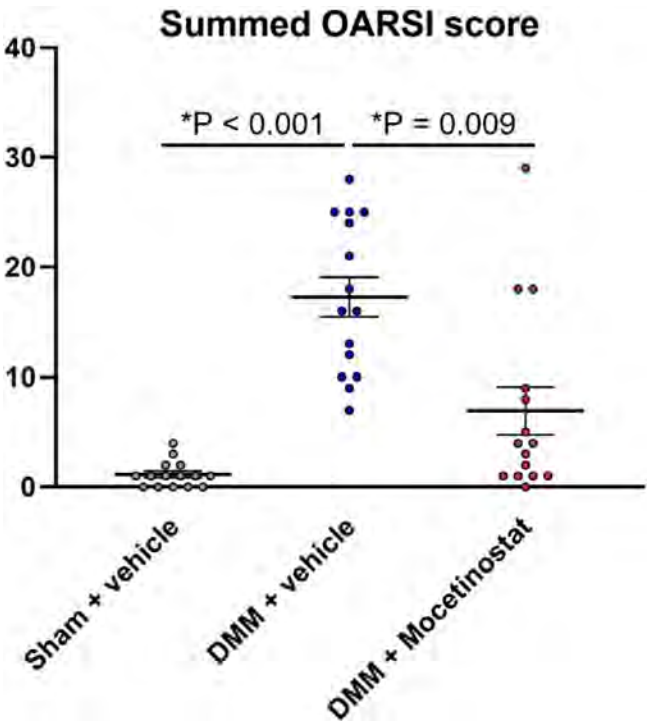

Figure 2. Therapeutic effects of OA by mocetinostat. Summed OARSI scores for the medial femoral condyle and the tibial plateau are expressed as means +SE (n=15 for each group). *P<0.05 versus DMM + vehicle, Dunn's test.

in cartilage, meniscus, and synovium (Figure 2 for the summed OARSI scores). We performed RNA-seq and TMT mass spectrometry analysis using mocetinostat-treated TC28a2 cells. While the significantly upregulated genes and proteins showed enrichment of Rap1 signaling pathway and ECM-receptor interaction previously shown to be modulated by KLF4, several unique pathways and terms were also enriched such as PPAR signaling pathway, suggesting novel regulatory mechanisms of HDAC inhibitors.

Conclusion: The class I HDAC inhibitor mocetinostat was identified through the HTS of compounds activating endogenous expression of KLF4. Mocetinostat increased protective and regenerative functions in joint tissue cells and reduced the severity of experimental OA in mice, qualifying it as a novel potential therapeutic candidate for OA.

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Knee osteoarthritis (KOA) is the most common form of arthritis that affects multiple knee joint tissues. The infrapatellar fat pad is the largest fat pad in the knee; however, its cell composition, including associated transcriptomic profiles, during KOA are not well described. Defining these cellular and transcriptomic profiles is crucial to defining the role of the infrapatellar fat pad in KOA pathogenesis. In this study, we subjected infrapatellar fat pad from KOA patients to high throughput single nuclei RNA sequencing (snRNAseq) and advanced bioinformatics to identify and define the cellular and transcriptomic atlas of KOA fat pad. Furthermore, we investigated transcriptomic differences in cell subsets identified in the fat pad of obese BMI patients compared to normal BMI patients with KOA.

Methods: Infrapatellar fat pad was obtained from late-stage KOA patients [KL grades III/IV; n=15; 53% females, 47% obese, BMI 30-40 and 53% non-obese, BMI 18.5-25] undergoing total knee arthroplasty and subjected to snRNAseq. Nuclei were sequenced on an Illumina NextSeq 550 using the 150bp high output sequencing kit. Cluster analysis, advanced bioinformatics and pathway analyses were employed to identify key cell types, cell subsets, cell transcriptomic profiles and biological pathways.

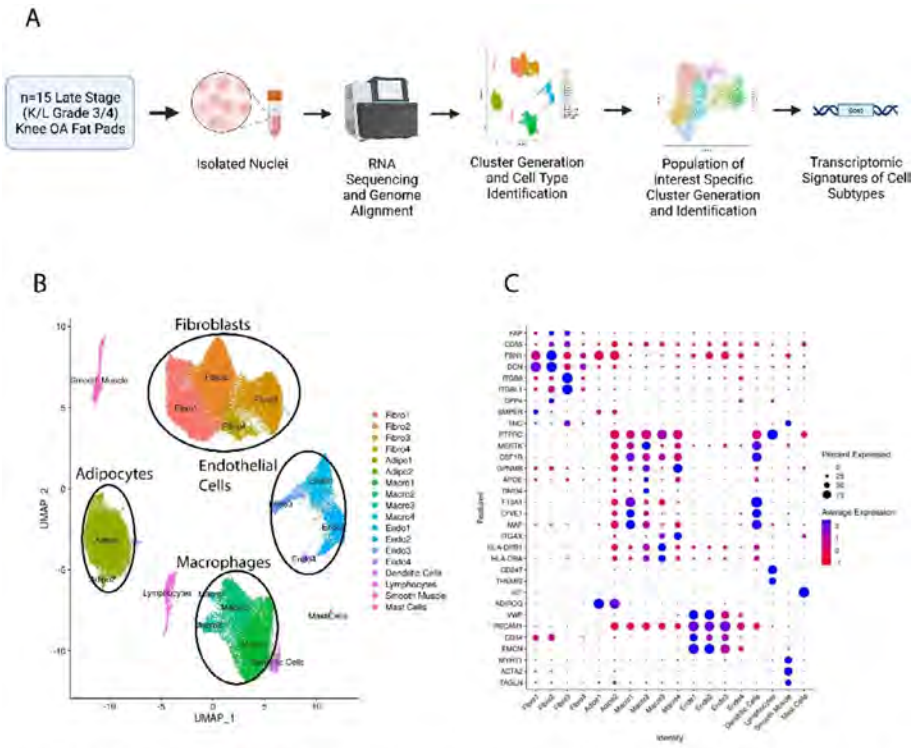

Figure 1: Infrapatellar Fat Pad Cell Populations A) Schematic workflow to identify cell subtypes and their functions within a fat pad. B) Uniform manifold approximation and projection (UMAP) of snRNA seq data of eight normal BMI (18.5 – 25) and seven obese BMI (30 – 40) fat pad samples with late-stage knee OA. C) Dot plot with the average expression of canonical cell surface markers for each cell population.

Results: Clustering analysis of snRNAseq data identified multiple cell populations based on canonical cell surface markers (Fig 1). The major cell types observed within the fat pad include fibroblasts (43.3%), macrophages (20.8%), adipocytes (18.5%), and endothelial cells (11.6%) (Fig 1). Interestingly, each major cell population identified had multiple cell subsets with unique transcriptomic profiles. Specifically, we identified nine distinct fibroblast cell subsets, four macrophage subsets, two adipocyte subsets and six endothelial subsets, each with unique transcriptomic profiles of highly expressed genes (Fig 2). We did not identify any differences in the proportions of fibroblast subsets when comparing normal BMI and obese BMI fat pads; however, we did identify a distinct transcriptomic signature with uniquely upregulated and downregulated genes in fibroblasts of the fat pad from obese BMI KOA patients compared to normal BMI KOA patients (Fig 3). We are now employing computational analyses of identified transcriptomic signatures and functional assays using primary fat pad fibroblasts of KOA patients to elucidate the mechanisms associated with the transcriptomic differences in obese BMI versus normal BMI KOA patients.

Conclusion: Using snRNAseq, we have generated a KOA fat pad transcriptomic and cell atlas. We have identified distinct cell subsets and transcriptomic profiles of fibroblasts, adipocytes, macrophages, and endothelial cells in the fat pad of patients with KOA. We also uncovered differences in transcriptomic profiles within fat pad fibroblasts of obese BMI KOA patients compared to normal BMI KOA patients. Further investigations regarding the contributions of these transcriptomic profiles and their function within the OA fat pad are currently underway.

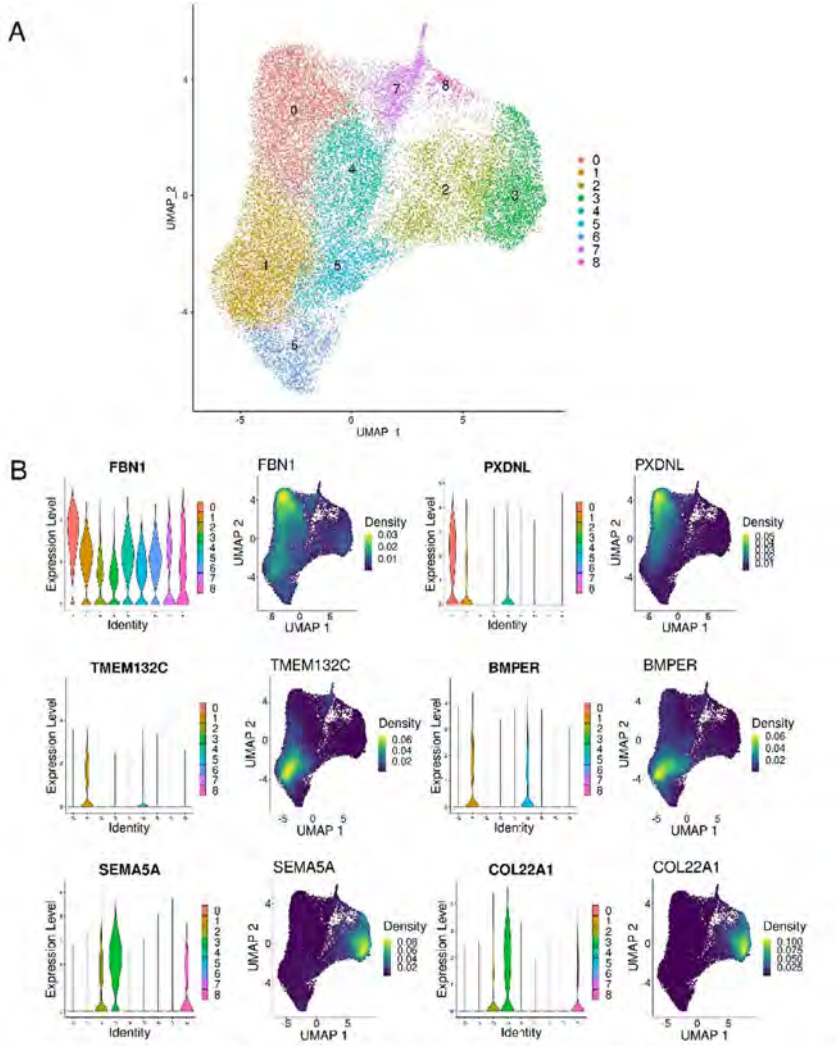

Figure 2: Fibroblast Subsets Present within Infrapatellar Fat Pad A) Projection of fibroblast subsets only from snRNA seq data of the 15 sequenced fat pad samples with late-stage knee OA. B) Violin plots and nebulosa plots displaying the expression of the top two significantly differentially expressed genes within the major fibroblast subsets 0, 1 and 3. Nebulosa plots display expression density from dark purple (low) to yellow (high).

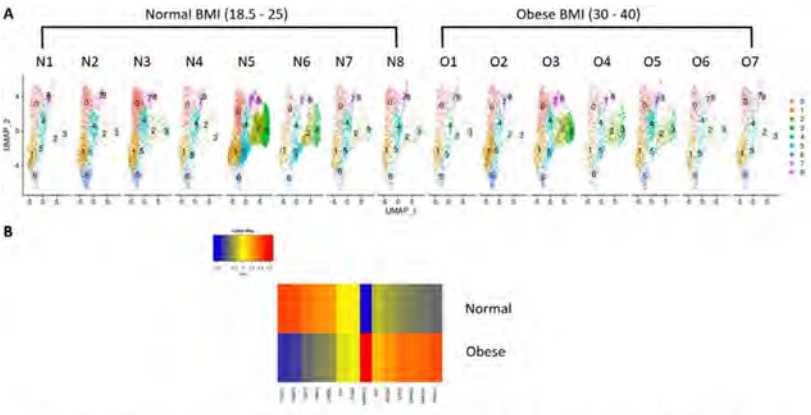

Figure 5: Transcriptomic Differences in Fibroblast Subsets Based on BMI A) Cell projections showing the contribution of fibroblast subsets within each sample from snRNA seq data. The left seven samples have a normal BMI (18.5 – 25) while the right eight samples have an obese BMI (30 – 40). B) Heat map showing the level of expression of significant differentially expressed genes within obese BMI fat pad compared to normal BMI fat pad with KOA. Expression levels range from blue (highly downregulated) to red (highly upregulated).

Staphylococcus Aureus Peptidoglycan Induces Pathogenic Autoantibody Production via Autoreactive B Cell Receptor Clonal Selection, Implications in Systemic Lupus Erythematosus

Wangbin Ning, Gary Gilkeson and **Wei Jiang**, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: There is an intricate interplay between the microbiome and the immune response impacting the development of normal immunity and autoimmunity. However, we do not fully understand how the microbiome affects the production of natural-like and pathogenic autoantibodies. Peptidoglycan (PGN) is a component of the bacterial cell wall that is highly antigenic. PGNs from different bacteria can differ in their immune regulatory activities.

Methods: Female C57BL/6 and MRL/lpr mice were intraperitoneally injected (i.p.) with PBS, *Staphylococcus aureus* PGN, or *Bacillus subtilis* PGN (100 μg/time). C57BL/6 mice (6-week-old) were treated with PGNs and PBS twice per week for 8 weeks; then the treatment was stopped for another 8 weeks. MRL/lpr lupus-prone mice (6-week-old) were treated with PBS and PGNs twice per week for 12 weeks. Spleen anti-double-stranded DNA (dsDNA) IgG+ B cells were sorted for B-cell receptor sequencing. Serum autoantibody levels and kidney damage were analyzed.

In a human study, we recruited unrelated controls (n = 25) or lupus patients (n = 32) as defined by the updated American College of Rheumatology classification criteria. All participants were premenopausal females (age ≥18 years). Pregnant or breastfeeding, recent severe illness, contraindications for blood withdrawals, or received antibiotics within the past 90 days were excluded. The method for determining plasma S. aureus DNA levels was evaluated by qPCR usingprimersfor *S. aureus* were forward:5′-TTCGCTACTAGTTGCTTA-3′ and reverse: 5′-GCACTATATACTGTTGGATC-3′.

We applied non-parametric Mann-Whitney U tests to compare differences between two groups, and Spearman's correlation tests to evaluate associations. All tests were two-sided, and $P \leq 0.05$ was considered significant.

Results: Administration of B. subtilis PGN-induced natural-like anti-dsDNA autoantibodies (e.g., IgM, short-lived IgG response, and no tissue damage), whereas S. aureus PGN-induced pathogenic anti-dsDNA autoantibodies (e.g., prolonged IgG production, low IgM, autoantibody-mediated kidney damage) in C57BL/6 and/or MRL/lpr mice (Figures 1-2, $P < 0.05$, non-parametric MannWhitney U tests). However, serum total IgG did not differ ($P > 0.05$, Figure 1B). S. aureus PGN drives specific clonal expansion, somatic hypermutation of IGHV3-74, and TLR2-dependent Class switch recombination in splenic anti-dsDNA autoreactive B cells ($P < 0.05$, Figure 2). In women with SLE, plasma S. aureus DNA levels were increased compared to control women ($P < 0.05$, Figure 3) and plasma S. aureus DNA levels were correlated with levels of lupus-related autoantibodies and renal involvement ($P < 0.05$, Spearman Correlation tests, Figure 3).

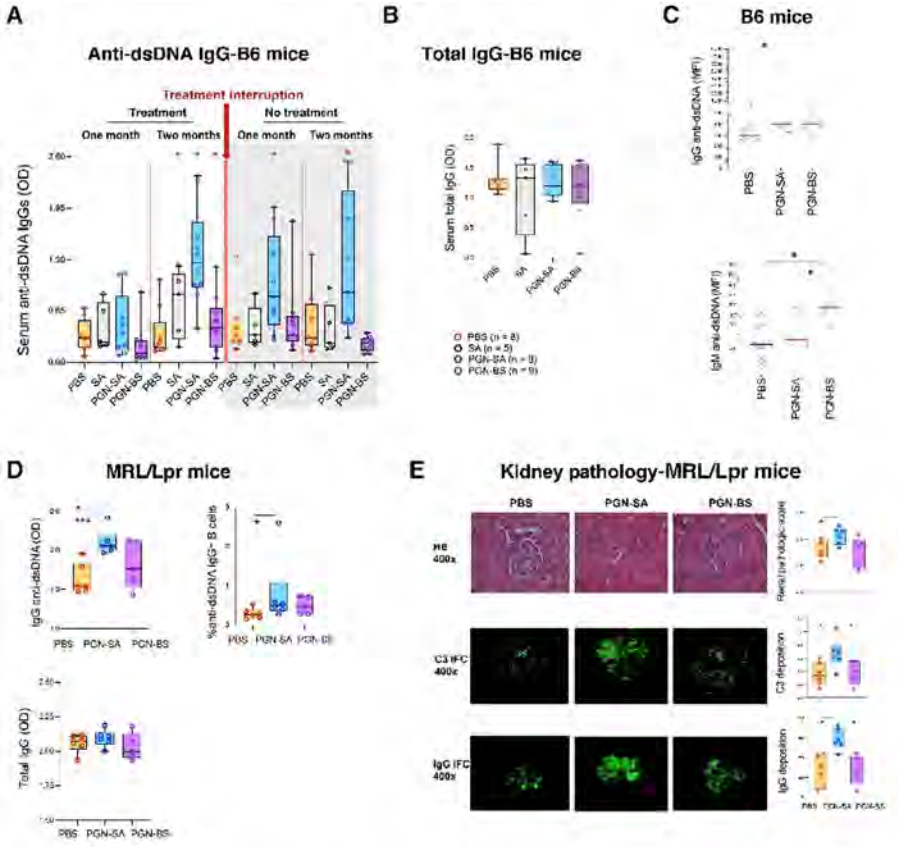

Figure 1. Administration of *B. subtilis* PGN induced natural-like anti-dsDNA autoantibodies (e.g., IgM, short lived IgG response, and no tissue damage), whereas *S. aureus* PGN induced pathogenic anti-dsDNA autoantibodies (e.g., prolonged IgG production, low IgM, autoantibody-mediated kidney damage) in C57BL/6 and/or MRL/lpr mice. (A-C) C57/B6 mice were treated with PBS (0.2 mL), *S. aureus* or *B. subtilis PGN* (100 µg/mouse/injection), or whole inactivated *S. aureus* ($5x10^7$ CFU/mouse/injection) via i.p. injection twice per week for 8 weeks. Then treatment was stopped for 8 weeks. (A) Serum levels of IgG anti-dsDNA and (B) endpoint serum levels of total IgG. Median ± Interquartile range. $^*P < 0.05$ compared to the PBS group. (C) Heatmaps show the relative levels of IgG or IgM autoantibodies in mouse serum after 8 weeks of treatment with PGNs or PBS (red color represents higher level and green color represents lower level). Mean fluorescent intensity (MFI) of IgG or IgM anti-dsDNA. (D-E) MRL/Lpr mice were treated with PBS, *S. aureus* PGN, or B. subtili PGN (100 µg/mouse/injection) via i.p. injection twice per week for 12 weeks. (D) Serum levels of IgG anti-dsDNA, percent of anti-dsDNA IgG+ B cells in spleen (gating on B cells), and serum levels of total IgG at the end of the study. (E) Representative kidney H&E imaging and collective glomerular lesion index. Representative kidney C3 and total IgG staining and collective quantification of C3 and IgG deposition. Statistical analysis involved non-parametric Mann-Whitney U tests.

Figure 1. Administration of B. subtilis PGN induced natural-like anti-dsDNA autoantibodies (e.g., IgM, short lived IgG response, and no tissue damage), whereas S. aureus PGN induced pathogenic anti-dsDNA autoantibodies (e.g., prolonged IgG production, low IgM, autoantibody-mediated kidney damage) in C57BL/6 and MRL/lpr mice.

Conclusion: *S. aureus* PGN induces pathogenic autoantibody production, whereas *B. subtilis* PGN drives the production of natural nonpathogenic autoantibodies. The higher plasma S. aureus DNA in patients, we postulate, is one factor that induces autoantibody production and disease development in susceptible individuals. Therapeutics aimed at blocking TLR2 or *Staphylococcus* colonization may have a role in treating lupus.

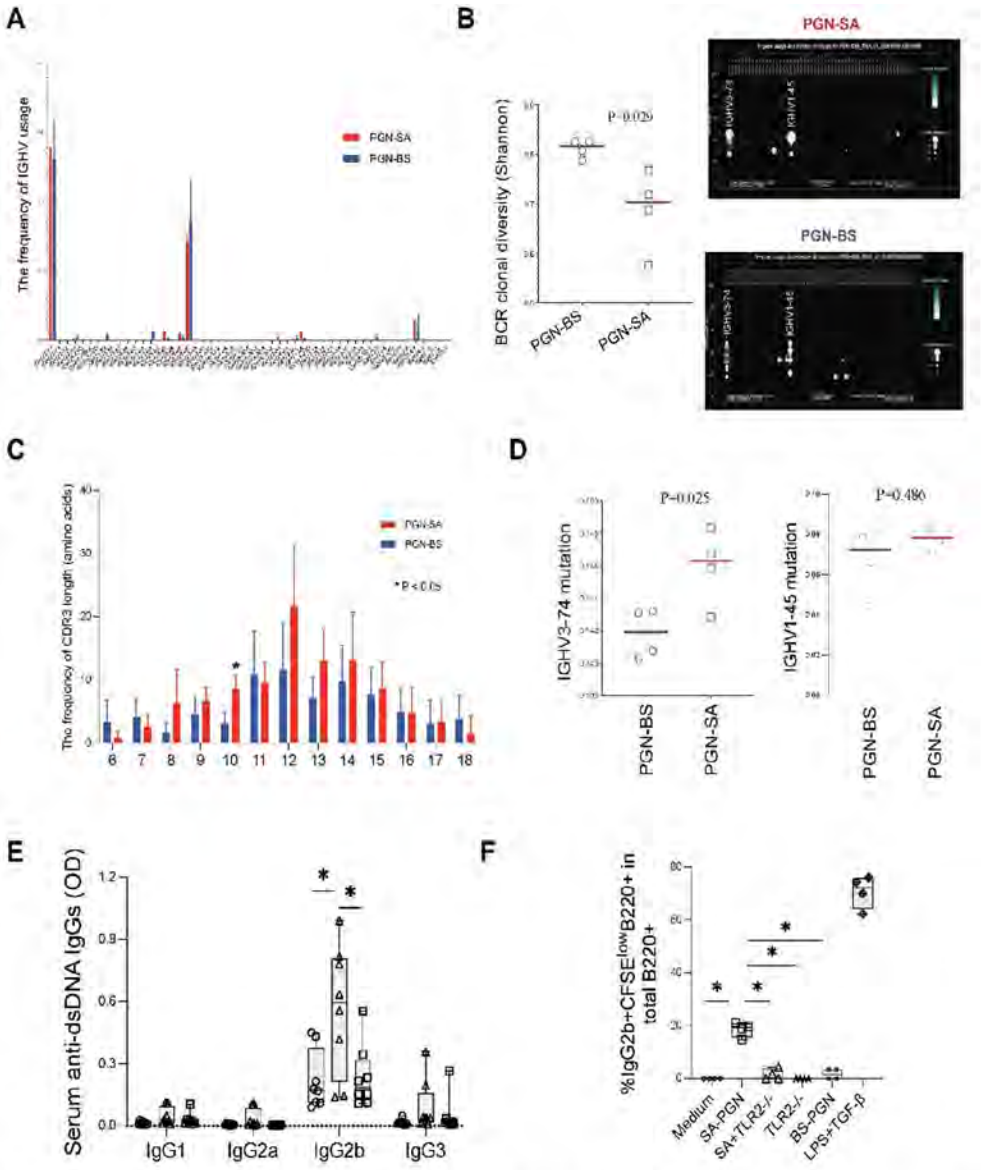

Figure 2. Characteristics of BCR repertoire from anti-dsDNA IgG+ B cells from spleen; Class switch recombination in response to *S. aureus* PGN. C57/B6 mice were treated with *S. aureus* or *B. subtilis* PGNs via i.p. injection twice per week for 8 weeks. At the end of study, B cells were isolated from spleen and anti-dsDNA IgG+ B cells were sorted using flow cytometry. RNA was extracted, and BCR sequencing was conducted. BCR clonality was analyzed in C57/B6 mice treated with *S. aureus (SA) and* B. subtilis (BS) PGN (n = 4 per group). (A) The frequency of IGHV usage. (B) BCR clonal diversity. (C) The frequency of CDR3 length. (D) Somatic mutation of IGHV3-74 and IGHV1-45. (E) Subclasses of serum anti-dsDNA IgG at the end of the study in vivo. (F) B cells were isolated from spleen of untreated C57/B6 mice, cultured with basal medium (control), LPS plus TGF-β1 (a positive control), *S. aureus* (SA) or *B. subtilis* (BS) PGN for 72 hours in vitro. The percentages of proliferating IgG2b+ B cells (%$CFSE^{low}$IgG2b+ in B220+ cells) were calculated. Statistical analysis used non-parametric Mann-Whitney U tests.

Figure 2. Characteristics of BCR repertoire from anti-dsDNA IgG+ B cells from spleen and class switch recombination in response to S. aureus PGN in B6 mice.

Single-cell Spatial Proteomics Identifies Intraglomerular Myeloid Cells in Membranous Lupus Nephritis

Chen-Yu Lee[1], Caleb Marlin[2], Xiaoping Yang[1], Tayte Stephens[2], Alessandra Ida Celia[3], Jeff Hodgin[4], Peter Izmirly[5], H Michael Belmont[6], Jill Buyon[7], Chaim Putterman[8], Judith James[2], the Accelerating Medicines Partnership in RA/SLE[9], Michelle Petri[10], Joel Guthridge[2], Avi Rosenberg[11] and **Andrea Fava**[1], [1]Johns Hopkins University, Baltimore, MD, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]John Hopkins University of Medicine, Rome, Italy, [4]University of Michigan, Ann Arbor, MI, [5]New York University School of Medicine, New York, NY, [6]NYU School of Medicine, New York, NY, [7]NYU Grossman School of Medicine, New York, NY, [8]Albert Einstein College of Medicine, Bronx, NY, [9]Multiple, Multiple, [10]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [11]Department of Pathology, The Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Lupus nephritis (LN) leads to end-stage kidney disease (ESKD) in more than 20% of patients despite optimal treatment. Up to 30% of LN patients have membranous LN which is characterized by subepithelial immune deposits without immune infiltration in the glomeruli. Despite its association with ESKD, membranous LN is considered a milder type of LN with no consensus on the optimal use of immunosuppression. To develop mechanistic hypotheses of disease, we analyzed kidney samples from patients with LN using a whole slide spatially resolved proteomic approach as part of the Accelerating Medicines Partnership in RA/SLE. We report here the initial analysis.

Methods: We developed a serial immunohistochemistry (sIHC) staining workflow to stain for 18 antibodies, DNA, and PAS to be visualized on a single section via a cycle of staining, imaging, and destaining. This included incubation of FFPE slides with primary antibody, secondary HRP reagents, AEC-Red Chromogen, and Hematoxylin. Image processing was performed using HALO (Indica Labs) and included deconvolution of single-color channels, registration, fusion, cell segmentation, and automated tissue classification (glomeruli, tubulointerstitium, connective tissue, vasculature, background, and biopsy edges). To minimize batch effect, the analytical pipeline included within sample CLR-normalization and scaling, followed by harmonization (Harmony).

Results: In this initial analysis, we included 29 clinically indicated kidney biopsies classified as LN (13 pure proliferative, 10 pure membranous, 5 mixed, and 1 ISN class II). Patients were 79% female, 34% White, 31% Black, 10% Asian, and 24% identified with Other race/ethnicity. We detected 182,783 CD45+ cells out of 1,913,845 cell objects. Our analysis identified 10 immune cell clusters at low resolution (**Figure 1A**). **Figure 1B** displays the tissue distribution of each cell subset. B and T lymphocytes dominated the tubulointerstitium. The CD68+ myeloid subsets were the predominant cell type in the glomeruli (**Figure 2**). More than half of CD68+ cells expressed Ki67 indicating active proliferation. Surprisingly, we identified intraglomerular CD68+ cells (including endocapillary) also in patients with pure membranous LN, but at a lower tissue density than proliferative LN (**Figure 2**). **Figure 3** demonstrates intraglomerular CD68+ cells in a biopsy classified as pure membranous LN by two experienced renal pathologists.

Conclusion: sIHC can be successfully employed to perform multiplexed whole slide analysis harnessing both the subcellular resolution (brightfield) and the reliability of IHC. Our analysis revealed intraglomerular CD68+ myeloid cells in pure membranous LN. By traditional clinical pathology, intraglomerular / endocapillary immune cells characterize proliferative LN and are

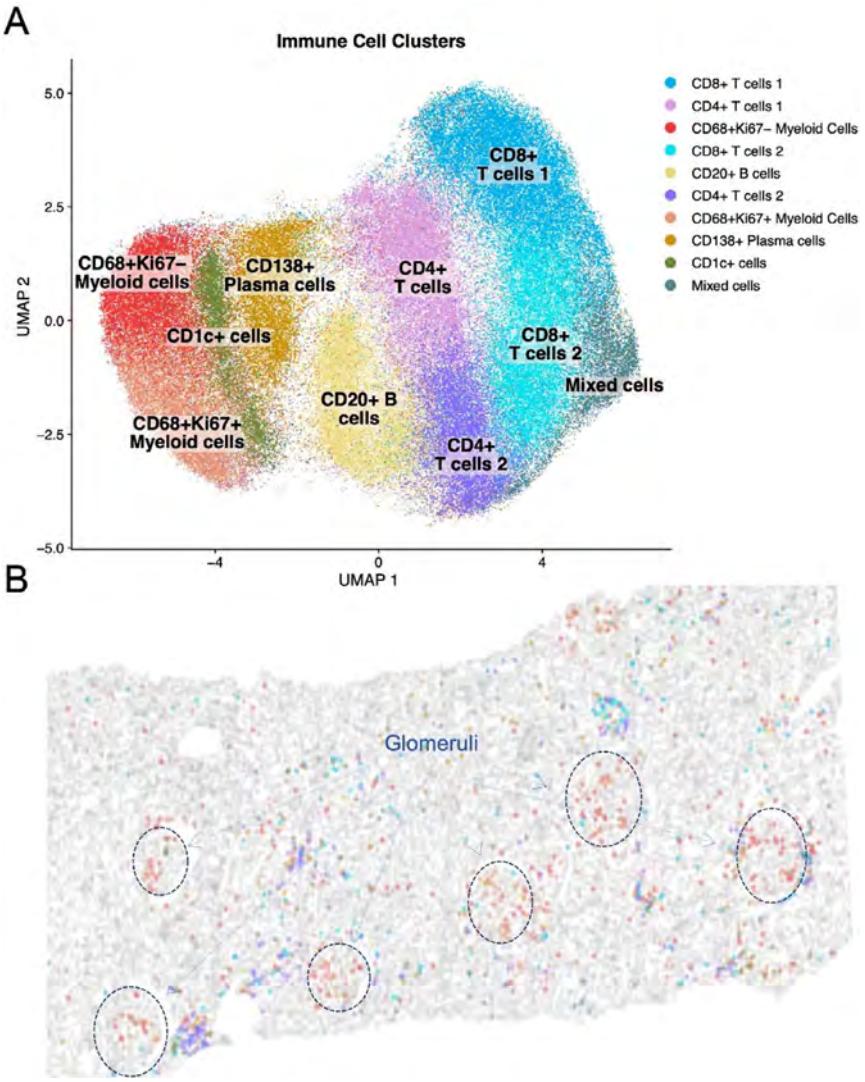

Figure 1. Phenotype and spatial distribution of intrarenal immune cells. (A) UMAP of CD45+ cells (n=182,783, 29 patients) indicating the low-resolution cluster annotation. (B) Digital reproduction of a representative biopsy displaying the distribution of the cells clusters (colors matching panel A). The biopsy in panel B was classified as ISN class III, NIH Activity Index 6, NIH Chronicity Index 3.

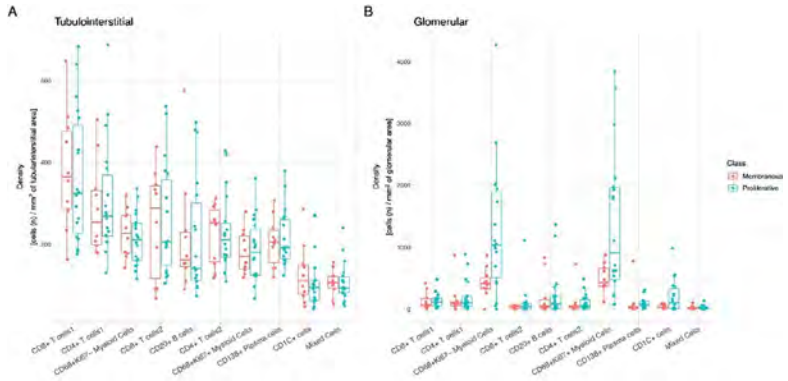

Figure 2. Myeloid cells dominate intraglomerular inflammation, including membranous LN. Box plots displaying the density (cells / area) of the immune cell clusters in the tubulointerstitium (A) and glomeruli (B) according to ISN class group. Both CD68+ myeloid cell clusters showed a statistically significant higher intraglomerular density compared to all other clusters in both proliferative and membranous LN ($p<0.05$, Wilcoxon test). Proliferative LN includes ISN class III and IV +/- V (n=18); membranous LN indicate pure ISN class V (n=10).

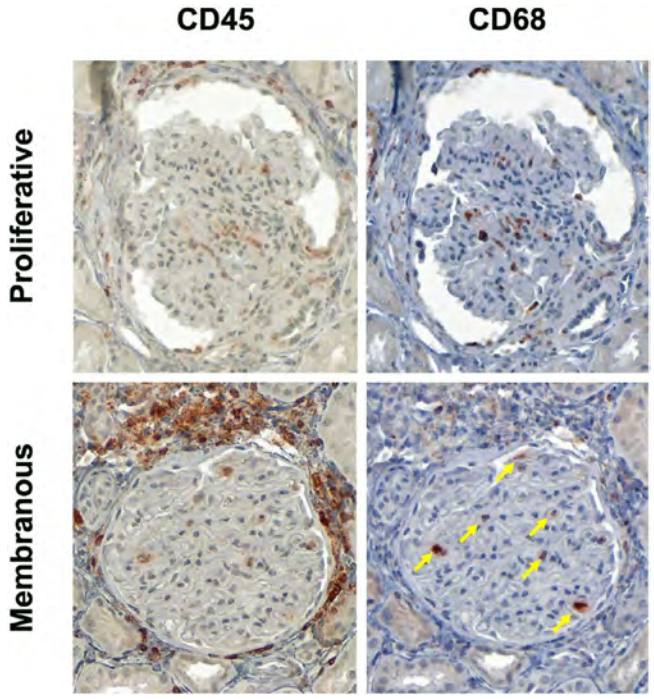

Figure 3. Intraglomerular CD68+ monocyte/macrophages in proliferative and membranous LN. Immunohistochemistry images displaying the expression of CD45 and CD68 in a representative glomerulus from a patient with proliferative LN (upper panels) and a patient with pure membranous LN (lower panels). The yellow arrows indicate intraglomerular CD68+ cells in membranous LN.

not consistent with pure membranous LN. These findings implicate macrophages/monocytes in the glomerular disease in membranous LN with therapeutic implications. The analysis of 90 additional biopsies and a myeloid-focused panel is underway to validate and extend these findings.

Single-Cell RNA Sequencing Reveals Cellular Drivers of UV-mediated Skin Injury in Cutaneous Lupus

Mitra Maz[1], Feiyang Ma[2], Mehrnaz Gharaee-Kermani[2], Amanda Victory[2], Amy Hurst[2], Johann E. Gudjonsson[2] and J. Michelle Kahlenberg[2], [1]University of Michigan Medical School, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Ultraviolet light (UV) is a known trigger of cutaneous lupus erythematosus (CLE) flares in systemic lupus erythematosus (SLE) patients, yet cell populations and mechanisms driving UV-induced skin inflammation are poorly understood. In this study, we use single-cell RNA sequencing of skin from healthy control (HC) and SLE patients with a history CLE to identify differences in SLE UV responses that serve as novel mediators of UV injury.

Methods: Seven HC and eight SLE patients were recruited. Biopsies were taken from the upper thigh 24 hours after treatment with 1x minimal erythema dose or from unexposed skin. Cells were processed via 10x pipelines, RNA was sequenced with an average of 10,000 reads per cell, and DEGs were analyzed and compared between HC and SLE patients.

Results: Globally, an increase in type I IFN regulated gene expression was seen in SLE >HC across all cell populations after UV exposure. In the epidermis, UV exposure led to differential gene expression in basal keratinocytes (KCs) where stress responses such as S100 proteins were noted in HC, while chemokines and IFN responses were noted in SLE KC, particularly in spinous and basal inflammatory KCs. Subclustering of fibroblast (FB) populations revealed two subpopulations that increase in proportion following UV exposure in both SLE and HC, identified as IFN-FBs and IL6+ FBs. CellphoneDB analysis revealed significant crosstalk between basal and spinous inflammatory KCs and IFN- and IL6+- FBs in SLE skin, suggesting that basal and spinous inflammatory KCs represent critical mediators of UV signal between the epidermis and dermis in lupus. Analysis of the myeloid compartment did not support an influx of pDCs into the skin at our selected timepoint. However, recruitment of myeloid dendritic cells (moDCs) was robust in both SLE and HC skin. Compared with HC skin, moDCs from SLE patients engaged in greater crosstalk with IL-6- and IFN-fibroblasts through CXCL12, a myeloid chemoattractant. Additionally, lupus moDCs engaged in crosstalk with TREM2+ macrophages, a lupus-specific skin resident population, through chemoattractant proteins.

Conclusion: We thus propose that in SLE skin, UV light induces unique inflammatory keratinocyte responses that educate fibroblasts and resident myeloid cells to recruit inflammatory myeloid dendritic cells, which may contribute to inflammatory cytokine production and downstream adaptive immune cell activation in SLE. Targeting of these pathways may be beneficial for prevention of photosensitive responses.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Lupus Nephritis (LN) significantly reduces the survival and life expectancy of patients with SLE. Given this, considerable effort has gone into characterizing the histologic classes that confer the highest standardized mortality ratios. Although Class II LN is considered a milder form of disease which often requires less aggressive treatment, a growing body of clinical evidence suggests that these patients can progress to more advanced LN classes. Accordingly, this

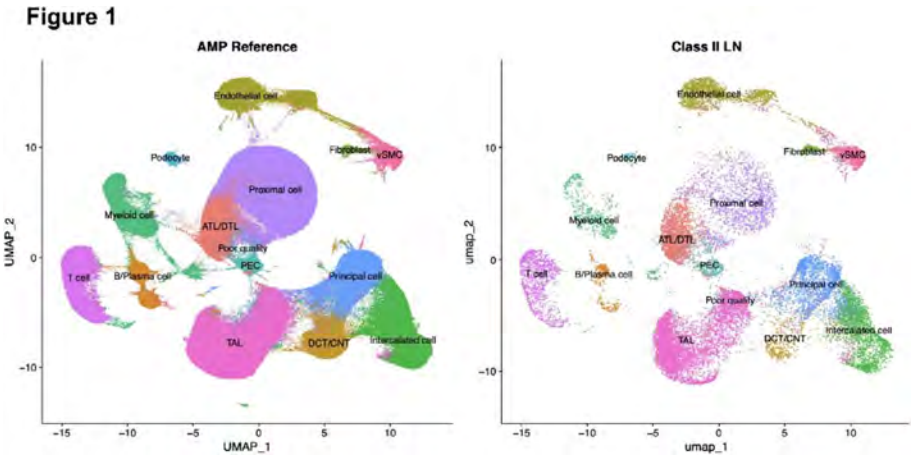

Figure 1: UMAP representation of all cells in AMP dataset from control and membranous, proliferative, and mixed LN biopsies (left); UMAP representation generated by Symphony reference mapping of all cells from Class II LN biopsies (right).

study leveraged the multi-center LN Accelerating Medicine Partnership (AMP) Network to focus on the transcriptome of Class II kidney biopsies with comparison to other histologic classes to provide insights into the molecular underpinnings of early disease and potential drivers of progression.

Methods: LN patients were enrolled in AMP at the time of a clinically indicated kidney biopsy and followed for one year. scRNA-seq was performed using the 10x genomics sequencing platform and quality control was performed to retain high-quality cells. Using the AMP consortium dataset which includes patients with membranous, mixed and proliferative LN, a reference-based mapping approach was employed to identify shared cell states and insights into Class II pathogenesis and outcomes.

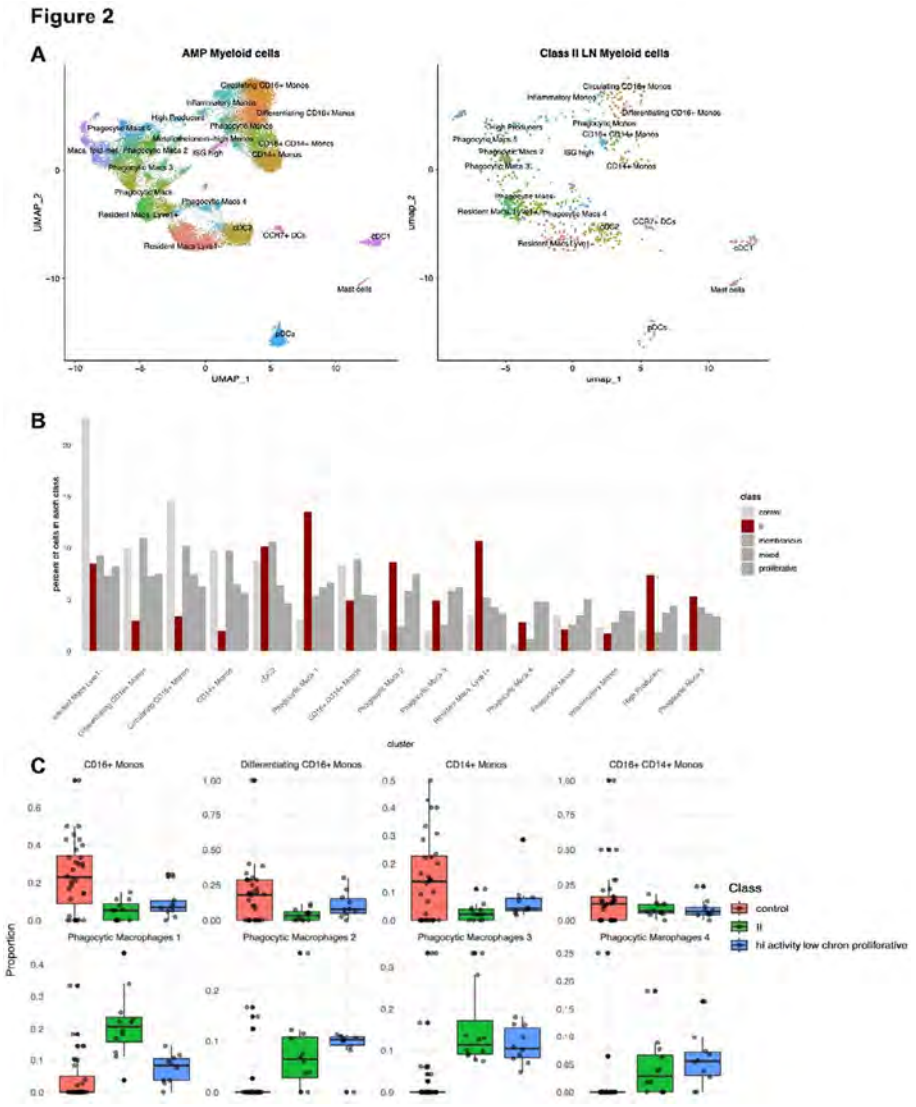

Figure 2: (A) UMAP representation of myeloid cells in AMP (left); UMAP representation generated by Symphony reference mapping of Class II myeloid cells (right). (B) Per disease condition proportion of cells in each myeloid subcluster (control = light gray; proliferative, membranous or mixed LN = dark gray; Class II LN = red) (C) Per sample proportion of cells in various monocyte (top) and macrophage (bottom) subclusters. All comparisons of the median proportion of cells in Class II LN versus control were significant ($p<0.05$) using Mann-U Whitney test. When comparing Class II LN with high activity low chronicity proliferative LN, only the porportion of differentiating CD16+ Monocytes and Phagocytic macrophages were found to be significant ($p = 0.033$, 0.003 respectively). Control = red; Class II LN = green; High activity low chronicity proliferative LN = blue.

Results: scRNA-Seq from 12 patients with Class II LN biopsies yielded 25,483 high-quality cells comprised of 11 parenchymal and three immune cell types (Fig 1). Reference mapping identified B, T and myeloid cells which are infrequently found in Class II LN by conventional microscopy (Fig 2A). In the myeloid compartment, cell type proportion analysis revealed a distinct signature with fewer monocytes and a greater number of differentiated and phagocytic macrophages in Class II compared to control and other LN classes (Fig 2B). This distinct myeloid signature was also identified in proliferative LN samples with high activity and low chronicity (activity index >= 4, chronicity index = 0). In both Class II and proliferative LN with high activity, monocytes and phagocytic macrophage subtypes were contracted and expanded relative to biopsies from healthy donors, respectively (Fig. 2C). The stromal compartment of Class II unexpectedly had a higher proportion of fibroblasts and myofibroblasts compared to all other classes (3A-B). These myofibroblasts were characterized by high expression of canonical markers, such as ACTA2 as well as markers of immune activation such as CTGF, CCL19, and CCL21 (3C). The proportion

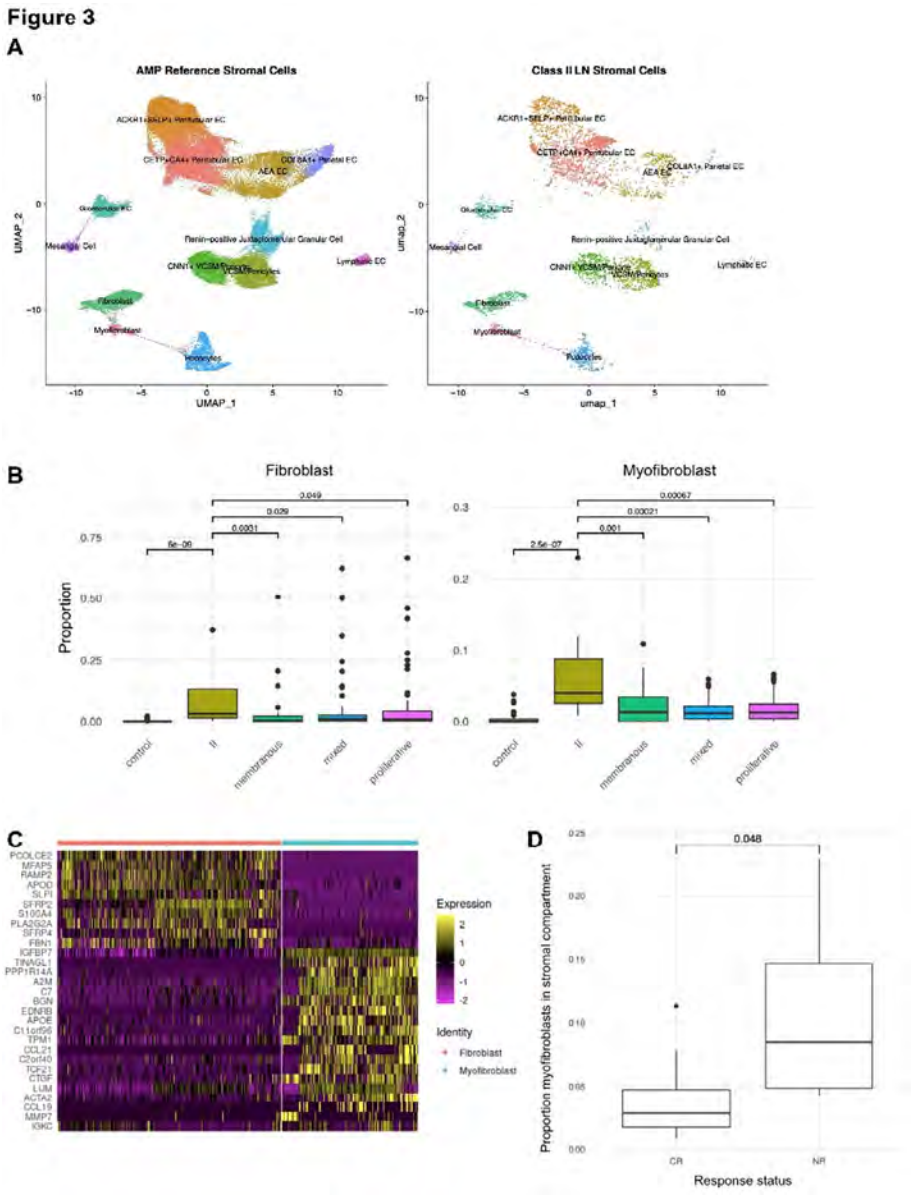

Figure 3: (A) UMAP representation of stromal cells in AMP dataset (left); UMAP representation generated by Symphony reference mapping of Class II stromal cells (right). (B) Proportion of fibroblast and myofibroblast cells in each disease class. P-values calculated using Mann-U Whitney test. (C) Heatmap of markers in Class II fibroblasts (red) and myofibroblasts (blue). (D) Proportion of myofibroblasts in Class II LN patients that were complete responders to treatment (CR) and non-responders to treatment (NR). P-value comparing median myofibroblast proportion using Mann-U Whitney test.

of myofibroblasts was higher in Class II patients whose UPCR fell below 0.5 and creatinine remained normal or did not exceed 125% of baseline compared to Class II patients considered non-responders at 52 weeks (3D, p = 0.048).

Conclusion: These data support that histology provides an incomplete picture of the molecular and cellular landscape in Class II LN. Increased phagocytic macrophage activity and immune-induced myofibroblast differentiation were associated with higher disease activity, highlighting these cellular composition changes as potential drivers of non-responsiveness and progression.

Interleukin-6 Disrupts Blood-cerebrospinal Fluid Barrier Permeability in Murine Neuropsychiatric Lupus

Joshua Reynolds[1], Lola Torz[2], Natalia Petersen[2], Ayal Ben-Zvi[3] and **Chaim Putterman**[1], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Novo Nordic, Global Obesity Research, Malov, Denmark, [3]Hebrew University of Jerusalem, Jerusalem, Israel

Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: In exploring the pathogenic mechanisms underlying neuropsychiatric lupus (NPSLE), it was discovered that cerebrospinal fluid (CSF) from lupus patients often contains neurotoxic antibodies, cytokines, and metabolites. Disruption of the blood-CSF barrier (B-CSFB), formed by choroid plexus (CP) epithelia, could explain these abnormalities. In

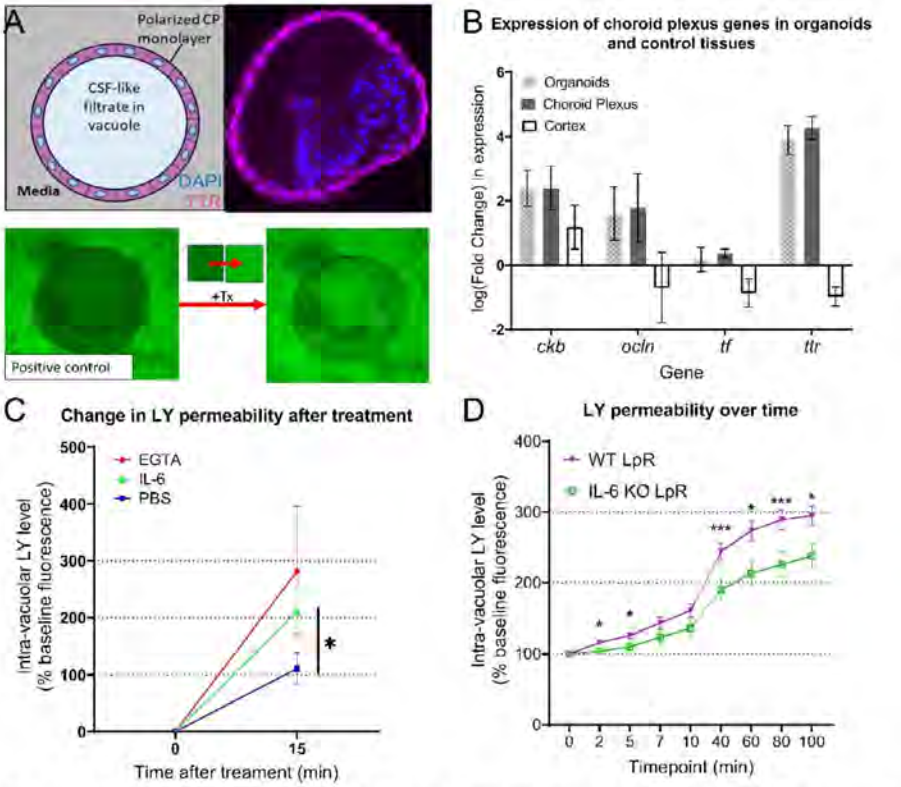

Figure 1. Choroid plexus organoids faithfully replicate in-vivo characteristics of CP tissue and demonstrate IL-6's impact on permeability. To directly assess lupus-related changes in blood-cerebrospinal fluid barrier (B-CSFB) permeability, spherical organoids were grown from 16+ week-old, female MRL/lpr lupus mouse choroid plexus (CP), the tissue forming the B-CSFB. In all groups, CP explants from 2 to 5 mice were pooled, mechanically digested, plated in an extracellular matrix, and cultured in epithelia-specific media for 2 weeks before experiments. A) Top: Schematic of a single CP explant organoid (left) and a representative immunofluorescent image of an actual organoid (right). TTR = transthyretin, a canonical CP marker; DAPI = 4',6-diamidino-2-phenylindole, a nuclear stain. Bottom: A representative permeability experiment wherein fluorescence intensity within the organoid's central vacuole ("intra-vacuolar") rapidly increases following administration of a permeabilizing agent. This exemplar color change reflects increasing permeability to a tracer. B) Real-time qPCR measurement of key CP gene expression in organoids, control CP tissue, and cortex tissue (all from MRL/lpr mice). C) Change in permeability to lucifer yellow (LY) tracer over 15 minutes following organoid treatment with positive control EGTA (egtazic acid; tight-junction disruption; n=20), 10 ng/mL IL-6 (n=39), or PBS (n=40). The IL-6 group had higher LY permeability at the 15-minute time point (p=0.0141). D) To determine if IL-6 is necessary for increased permeability, organoids were generated from either IL-6 knockout (KO) MRL/lpr mice or wildtype (WT) MRL/lpr as described. Permeability to LY was significantly lower in IL-6 KO organoids (n= 31) compared to WT ones (n= 27) at almost all timepoints. * $p < 0.05$, *** $p < 0.01$.

both NPSLE patients and lupus mouse models, immune cells infiltrate the CP and can alter normal epithelial functions through extensive cytokine signaling. Interleukin-6 (IL-6) is elevated in the serum and CSF of both NPSLE patients and lupus mice. ATP-binding cassette (ABC) transporter function in the CP, including P-gp, MRP1, and BCRP, is fundamental to the

clearance of neurotoxic substrates from the CSF. In this study, we assessed the effects of IL-6 on lupus mouse derived CP organoids to investigate the integrity of the B-CSFB in NPSLE.

Methods: CP tissue from 2-5 female MRL/lpr (WT) or IL-6 knockout (KO) mice of at least 16 weeks of age were pooled and cultured for two weeks to generate CP organoids for each experiment, as described (Petersen et al, 2020). Organoid morphology was confirmed using whole-mount immunostaining and electron microscopy. Gene expression was measured by

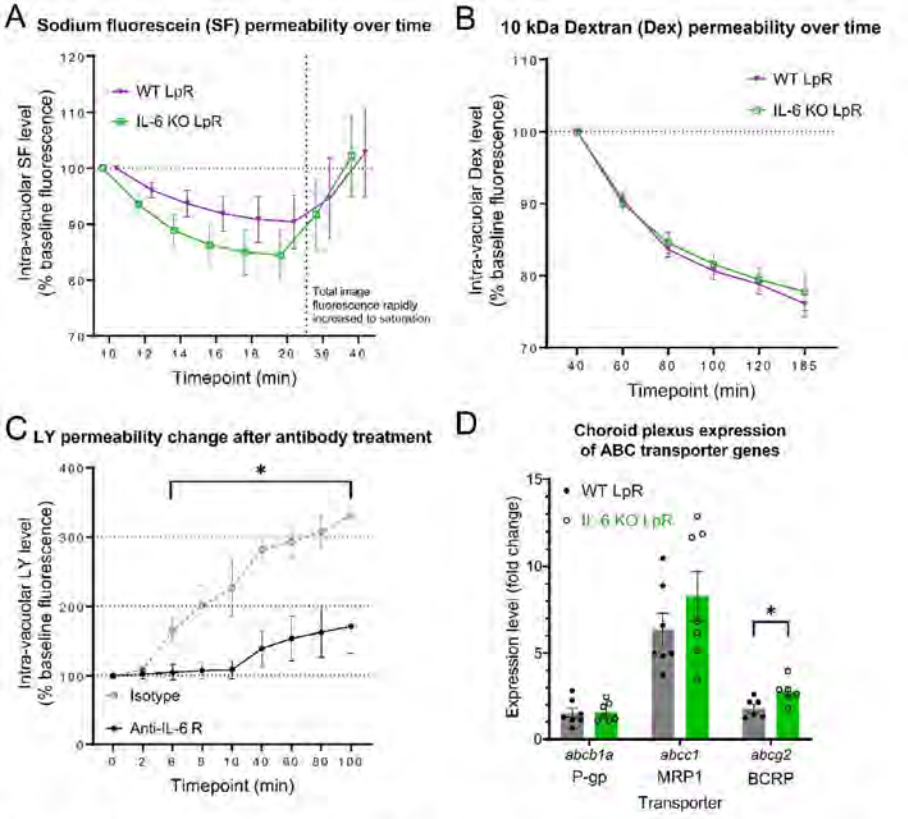

Figure 2. IL-6 signaling selectively alters LY permeability and alters BCRP transporter expression. Given the observed increased LY permeability with IL-6 supplementation and decreased LY permeability when IL-6 is knocked out, we assessed this IL-6 effect on other tracer molecules. A) Permeability to sodium fluorescein (SF), a small molecule like LY but which is not affected by ATP-binding cassette transporters, was measured over 40 minutes in IL-6 KO and WT MRL/lpr organoids but no differences were apparent. The parabolic shape of each curve is due to shifting pH over the observation window increasing fluorescence to saturation. B) Permeability to 10 kDa Dextran, a large molecule tracer, was measured over three hours to assess possible transcytotic differences (which were not observed). C) To determine if IL-6 signaling is responsible for the observed knockout effect on LY permeability, organoids were treated with anti-IL-6 receptor blocking (n= 8) or isotype control antibodies (n= 3). All timepoints after 2 minutes showed reduced permeability in the anti-IL-6 receptor antibody treated group. D) Real-time qPCR measurement of ABC transporter gene expression within the CP of IL-6 KO or WT MRL/lpr mice to elucidate possible mediators of the IL-6 effect on LY permeability. BCRP expression was significantly increased in IL-6 KO mice (p=0.0259) * $p < 0.05$.

Figure 2. IL-6 signaling selectively alters LY permeability and alters BCRP transporter expression. Given the observed increased LY permeability with IL-6 supplementation and decreased LY permeability when IL-6 is knocked out, we assessed this IL-6 effect on other tracer molecules. A) Permeability to sodium fluorescein (SF), a small molecule like LY but which is not affected by ATP-binding cassette transporters, was measured over 40 minutes in IL-6 KO and WT MRL/lpr organoids but no differences were apparent. The parabolic shape of each curve is due to shifting pH over the observation window increasing fluorescence to saturation. All timepoints after 2 minutes showed reduced permeability in the anti-IL-6 receptor antibody treated group. D) Real-time qPCR measurement of ABC transporter gene expression within the CP of IL-6 KO or WT MRL/lpr mice to elucidate possible mediators of the IL-6 effect on LY permeability. BCRP expression was significantly increased in IL-6 KO mice (p=0.0259) * $p < 0.05$.

real-time qPCR. A standard time-lapse permeability assay which quantified tracer fluorescence within each organoid's central vacuole was performed under various conditions. We assessed organoid permeability to tracer in the presence of supplemental IL-6 (10 ng/mL) or anti-IL-6 receptor antibodies (1 ug/mL). We also assessed inherent tracer permeability differences between IL-6 competent WT and IL-6 KO MRL/lpr-derived organoids. The fluorescent tracers used included two small dyes, lucifer yellow (LY) and sodium fluorescein (SF), and a larger 10 kDa dextran molecule (Dex). Importantly, LY but not SF is transported by ABC transporters. Two-tail Mann-Whitney u tests compared differences between groups.

Results: MRL/lpr-derived organoids replicated the *in-vivo* morphology and gene expression of the CP (Fig 1A-B). IL-6 rapidly increased MRL/lpr organoid permeability to LY (IL-6: n=39, 174.4+/- 37.91; PBS: n=40, 76.1+/-27.1; p=0.014; Fig 1C). IL-6 KO organoids demonstrated consistently reduced permeability to LY compared to WT (KO: n=31; WT: n=27; p<< 0.05; Fig 1D). No permeability differences between IL-6 KO (n=19) and WT (n=19) organoids were seen for SF (Fig 2A) or Dex (Fig 2B). Incubation with an anti-IL-6 receptor antibody (n=8) significantly decreased LY permeability relative to an isotype control (n=3; Fig 2C). *In-vivo* expression of *abcg2*, a constituent of BCRP, was increased in IL-6 KO MRL/lpr mice (KO: n=6, 8.83+/-0.84; WT: n=4.17+/-0.61; p=0.026; Fig 2D).

Conclusion: In the first application of a novel CP organoid model to study lupus, we found that IL-6 signaling appears sufficient and necessary to increase permeability to LY, but not other tracers studied. Changes in BCRP, which effluxes only LY, could explain this accumulation of LY within organoids. Therefore, the high IL-6 environment of SLE could interfere with BCRP function and hinder the CP's ability to clear potentially neurotoxic metabolites, and thus contribute to the pathogenesis of NPSLE.

NADPH Oxidase Exerts a B Cell-intrinsic Contribution to Lupus Risk by Modulating Endosomal Toll-like Receptor (TLR) Signals

Shuozhi Liu[1], Natali Shumlak[1], Andrea Largent[1], Sebastien Lewis[1], Mridu Acharya[1] and **Shaun Jackson**[2], [1]Seattle Children's Research Institute, Seattle, WA, [2]Seattle Children's Research Institute / University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Genome-wide association studies in systemic lupus erythematosus (SLE) have linked loss-of-function mutations in phagocytic NADPH oxidase complex (NOX2) genes, including *NCF1* and *NCF2*, to disease pathogenesis. The prevailing model holds that reduced NOX2 activity promotes SLE via defective efferocytosis, the immunologically silent clearance of apoptotic cells. However, we previously showed that B cell-intrinsic Toll-like receptor (TLR) signaling is modulated by endolysosomal trafficking, such that dysregulated endosomal flux can drive breaks in B cell tolerance. Since NCF1/NCF2 are known regulators of endosomal trafficking in myeloid lineages, we hypothesized that a parallel B cell-intrinsic mechanism contributes to lupus risk.

Methods: We tested the impact of NOX2 family gene deletion on B cell TLR signaling using in vivo animal models, primary murine B cells, NCF1-null human B cell lymphoma lines, and CRISPR-edited primary human B cells

Results: We show that NOX2-deficient mice exhibited increased humoral responses to nucleic acid-containing antigens, findings which correlate with enhanced B cell signals downstream of endosomal TLRs. In keeping with important roles for B cell TLRs in lupus pathogenesis, B cell-intrinsic NADPH oxidase deletion promoted murine humoral autoimmunity

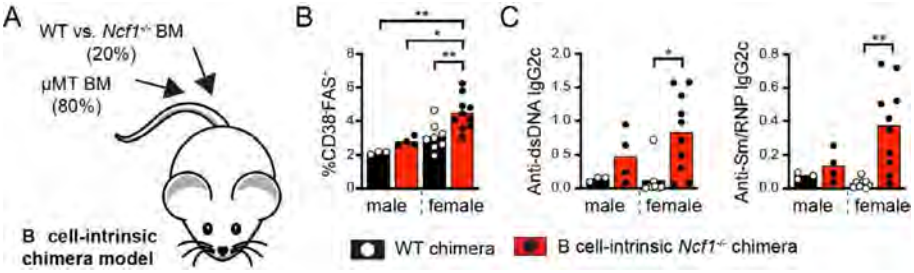

Figure 1: (A) Bone marrow chimeras with B cell-intrinsic Ncf1-/- deletion exhibit spontaneous germinal centers (B) and class-switched auto-antibodies (C).

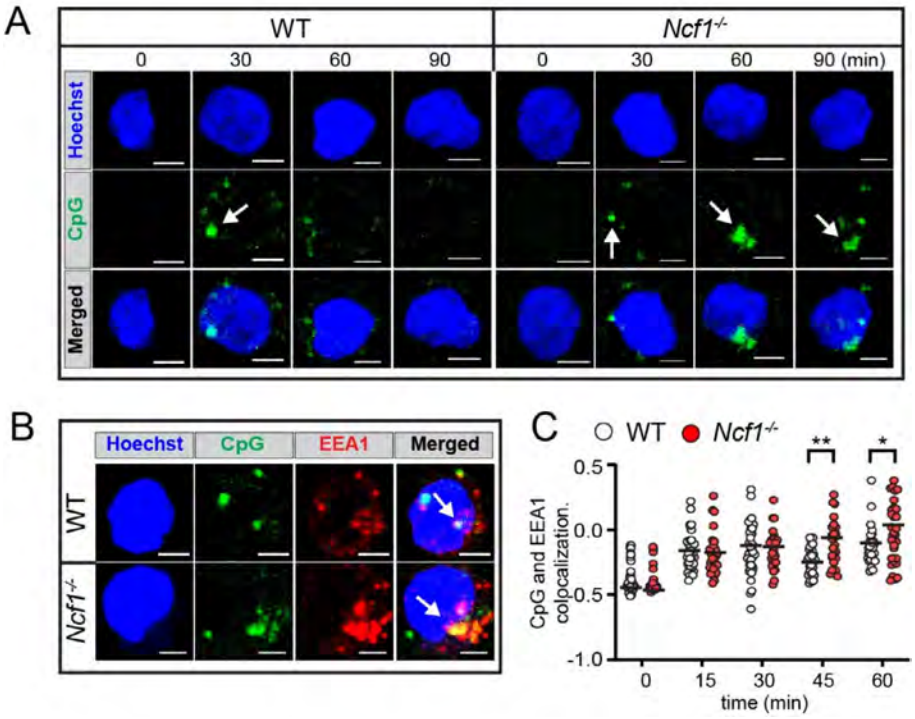

Figure 2: Delayed endolysosomal trafficking of CpG in NCF1-/- B cells. (A) NCF1-/- B cells exhibit prolonged retention of fluorescent CpG in EEA1 early endosomes (B, C).

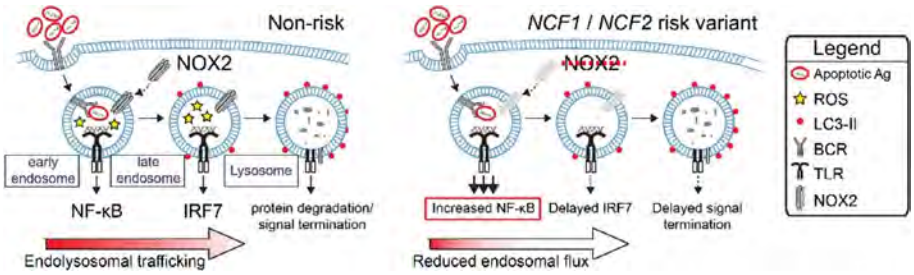

Figure 3: Disease model showing impact of NOX2 loss-of-function on B cell-intrinsic Toll-like receptor signaling. NOX2 deletion promotes dysregulated endolysosomal trafficking, resulting in delayed signal termination and increased TLR signaling thresholds.

(Figure 1). To understand the underlying mechanisms, we quantified TLR-induced intracellular trafficking in B cells using live cell microscopy. Following CpG stimulation, NADPH oxidase activation facilitated trafficking of TLR-containing endosomes to lysosomes, resulting in TLR signal termination. Whereas initial uptake and aggregation of fluorescent CpG in early endosomes was preserved in NCF1-null B cell, loss of NADPH oxidase activity limited signal degradation resulting in enhanced downstream NFkB activation (Figure 2). Finally, CRISPR-mediated disruption of NCF1 in primary human B cells confirmed a direct role for NOX2 in regulating endosomal TLR signaling in B cells. In response to in vitro TLR9 activation, NCF1-deficient human B cells exhibited increased differentiation into IgM- and IgG-producing plasma cells, supporting a mechanistic link between B cell NADPH oxidase activity and human lupus pathogenesis.

Conclusion: Together, these data highlight a new B cell-specific mechanism contributing to autoimmune risk in *NCF1* and *NCF2*variant carriers. We show that loss of NADPH oxidase results in disruption of B cell endolysosomal trafficking, thereby lowering endosomal TLR signaling thresholds and promoting B cell-intrinsic breaks in tolerance (disease model shown in Figure 3).

Infection-Associated Antiphospholipid Antibodies and Their Potential Role in Sepsis Outcomes

Katarina Kmetova, Emily Chong, NaveenKumar K. Somanathapura, Sherwin Navaz, Lyndsay Kluge, Srilakshmi Yalavarthi, Jason Knight, Michael Maile and Yu Zuo, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Antiphospholipid Syndrome
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Antiphospholipid syndrome (**APS**) is an acquired autoimmune thrombophilia characterized by circulating antiphospholipid antibodies (**aPL**). While the association between aPL and infection has long been recognized, the factors that trigger the production of aPL during infection are largely unknown, and the clinical significance of those infection-associated aPL continues to be debated. Here, we endeavored to comprehensively evaluate the presence of aPL in a large cohort of critically ill sepsis patients and non-sepsis intensive care unit controls. We further investigated whether purified IgG fraction from APS patients with high anti-phosphatidylserine/prothrombin (**aPS/PT**) IgG can modulate neutrophil activation and neutrophil extracellular traps (**NETs**) formation in the mouse sepsis model.

Methods: Plasma from 231 critically ill sepsis and 94 non-sepsis patients were evaluated for eight different types of aPL: anticardiolipin (**aCL**) IgG/IgM/IgA, anti-beta-2 glycoprotein I (**aβ2GPI**) IgG/IgM/IgA, aPS/PT IgG/IgM with ELISA kits (Werfen), Human E-Selectin/CD62E and BAFF/BLyS/TNFSF13B DuoSet ELISA (R&D Systems). An intranasal *Klebsiella pneumonia*-induced mouse sepsis model was used to evaluate the potential role of patient-derived aPL in sepsis outcomes.

Results: We found that 23% of critically ill sepsis patients had at least 1 positive aPL, as compared with 9.6% of non-sepsis patients. The most prevalent aPL found among sepsis patients was aPS/PT IgM (16%), followed by aCL IgM (8.2%), and aβ2GPI IgM (3.5%). When considering only aPL at moderate-to-high titer, 16% of critically ill sepsis patients had at least 1 positive aPL compared to 5.3% of non-sepsis patients (**Table 1**). High aPL levels, such as aPS/PT IgM demonstrated a

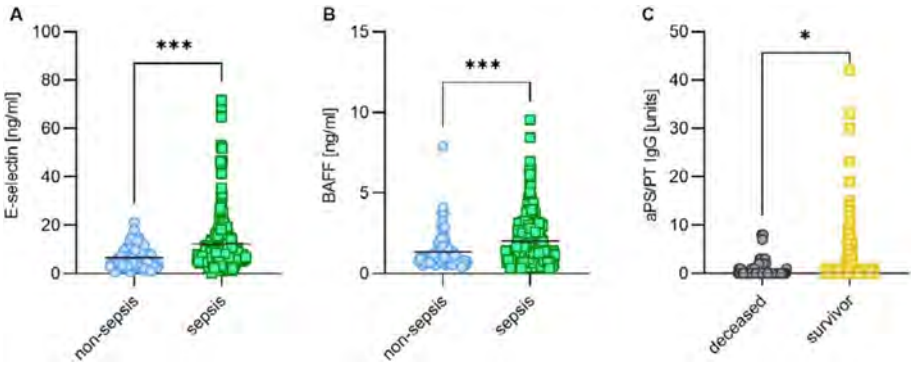

Figure 1: A, Circulating levels of E-selectin were compared between critically ill sepsis patients and non-sepsis patients. B, Circulating levels of BAFF were compared between critically ill sepsis patients and non-sepsis patients. C, Levels of aPS/PT IgG were compared between sepsis survivors and those who died. For statistical analyses, the Mann-Whitney test was used. * - $p<0.05$; *** - $p<0.00$; aPS/PT – anti-phosphatidylserine/prothrombin

positive correlation with soluble E-selectin ($r=0.21$, $p=0.039$), a marker of endothelial cell activation. Higher levels of E-selectin were found in critically ill sepsis patients compared to non-sepsis patients (**Fig 1A**). To evaluate a potential trigger of infection-associated aPL, we measured BAFF, a B cell-activating factor that promotes the differentiation of autoantibody-secreting cells. We found markedly elevated BAFF among critically ill sepsis patients (**Fig 1B**). Interestingly, patients who survived sepsis were more likely to have elevated aPS/PT IgG as compared to those who did not (**Fig 1C**). To evaluate the extent to which aPL may improve sepsis outcomes, we set up an intranasal *Klebsiella pneumoniae* mouse sepsis model (**Fig 2A**). Our data suggest that the administration of IgG purified from patients with high-titer anti-PS/PT antibodies to septic mice led to a strong trend toward improved survival while ameliorating infection-associated weight loss and sepsis severity (**Fig 2B-D**). Interestingly, aPL treatment also attenuated in situ neutrophil activation and NET formation, which are well-known orchestrators of sepsis hyper-inflammation (**Fig 2E-G**).

Conclusion: Our study suggests that many critically ill sepsis patients can develop aPL, potentially driven by heightened B-cell stimulating signals. While further mechanistic studies are warranted, some aPL may contribute to improved sepsis survival.

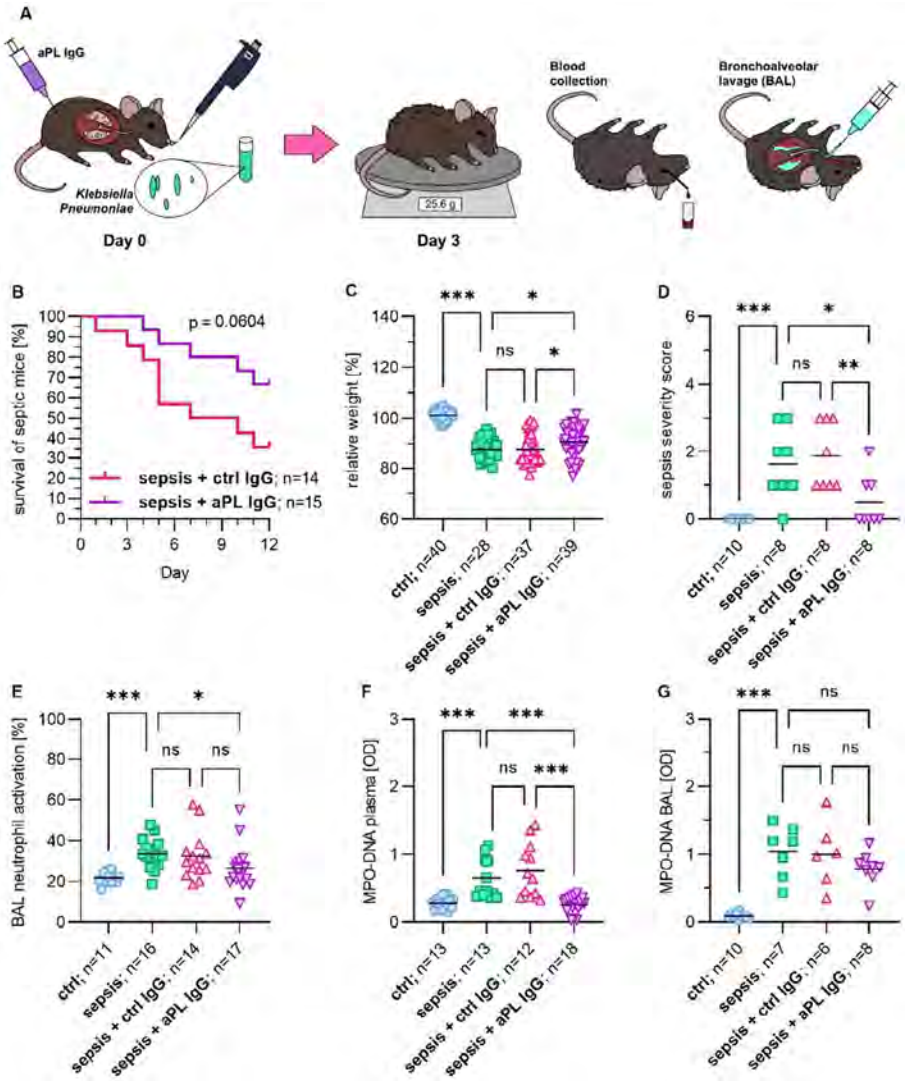

Figure 2: A, Schematic of Klebsiella pneumoniae sepsis mouse model. Mice were infected intranasally with Klebsiella pneumoniae. After 3 days, mice were sacrificed, and plasma and bronchoalveolar lavage fluid (BAL) were collected. B, Survival curves were compared between aPL and control (ctrl) IgG-treated mice by the Gehan-Breslow-Wilcoxon test. C, % weight change relative to day 0 was determined and compared between groups. D, Sepsis severity score was assessed based on observation of mice's piloerection, hunching, and movement and compared between groups. E, Activation of BAL neutrophils determined by flow cytometry based on CD63 positivity. F, circulating MPO-DNA complexes were measured in mouse plasma and compared between groups. G, MPO-DNA complexes were measured in BAL and compared between groups. We used the Kruskal-Wallis test with Dunn's correction to determine differences between groups. * - p<0.05; ** - p<0.01; *** - p<0.001; aPL – antiphospholipid antibodies MPO – myeloperoxidase; OD – optical density

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Antiphospholipid Syndrome

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: The APS ACTION Registry was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with or without other systemic autoimmune diseases (SAID). The primary objective of this study was to update the incident first and recurrent thrombosis risk in registry-enrolled patients, previously reported in 2021 as 1.02 and 2.09 per 100 pt-y, respectively (*Arthritis Rheumatol*.2021;73[suppl 9]).

Methods: A web-based data capturing system is used to store patient demographics, history, and medications. The inclusion criteria are positive aPL according to the Updated Sapporo Classification Criteria, tested within one year prior to enrollment. Follow-up occurs every 12±3m with clinical data and blood collection. In this prospective analysis, based on patients who completed 1- to 10-year follow-up visits, we report the incident thrombosis risk in persistently aPL-positive patients with and without a history of thrombosis. Secondarily, we compare baseline clinical and laboratory characteristics of patients with vs without new thrombosis.

Results: As of April 2023, 1,166 patients were enrolled; 22 patients with a prior history of transient ischemic attack and no prior imaging-confirmed thrombosis were excluded. Five other patients were excluded due to incomplete data. Of the remaining 1,139 patients; a) 606 had aPL/APS without SAID, including aPL without APS classification (n=125), thrombotic

Table 1: Frequencies and Types of New Thrombotic Events Since the Inception of APS ACTION Registry

Table 1: Frequencies and Types of New Thrombotic Events Since the Inception of APS ACTION Registry

	First Events (n = 14)	Recurrent Events (n = 88 in 65 patients)
Venous Thrombosis	6 (43%)	39 (44%)
Arterial Thrombosis	7 (50%)	44 (50%)
Catastrophic APS	0 (0%)	1 (1%)
Microthrombosis*	1 (7%)	4 (5%)

*Includes diffuse alveolar hemorrhage (3), aPL-nephropathy (2), cutaneous ulceration (1), and adrenal infarction with hemorrhage (1). Lung, kidney, and skin involvement occurred concurrently in one patient and were thus counted as a single small vessel event.

APS (TAPS, n=357), obstetric APS (OAPS, n=57), and TAPS+OAPS (n=67); and b) 533 patients had aPL/APS associated with SAID, including aPL without APS (n=164), TAPS (n=269), OAPS (n=35), and TAPS+OAPS (n=65). Mean follow-up (enrollment to first new thrombosis or most recent follow-up) was 3.67 years (1401 pt-y) and 4.03 years (3053 pt-y) for those

Hyperlipidemia on Medication	3 (21%)	21 (32%)
Obesity	2 (14%)	28 (43%)
Renal Failure	0 (0%)	12 (18%)

*Among APS patients with multiple recurrent events during follow-up, characteristics from the time of the first recurrent event were analyzed; **Vitamin K antagonist; ***Low molecular weight heparin; ****CVD risk factors include hypertension, hyperlipidemia, diabetes mellitus, renal failure (GFR < 60), obesity (BMI > 30), history of smoking, family history of early cardiovascular disease (myocardial infarction in a first-degree relative before age 55 in men or age 65 in women).

without and with a history of thrombosis, respectively. Based on *14 first events in 14 patients,* and *88 recurrent events in 65 patients* (Table 1), the incident thrombosis risk was 1.00 and 2.13 per 100 pt-y in patients without and with a history of thrombosis, respectively. Baseline characteristics were similar between aPL-positive patients with (n=14) or without (n=368) first thrombosis, and between APS patients with (n=65) or without (n=692) recurrent thrombosis, except: a) obesity, renal failure, and direct oral anticoagulant use were more common in APS patients with recurrent thrombosis than in those without (p=0.02, 0.01, and 0.005, respectively); and b) smoking history was more common in patients with first thrombosis than in those without (p=0.05) (Table 2). Table 3 describes patient characteristics at the time of new events.

Conclusion: Based on 4,454 pt-y of follow-up, the incident thrombosis risk in persistently aPL-positive patients remains relatively low. Secondary analysis revealed possible differences in medications and cardiovascular risk factors at enrollment between patients with and without thrombosis during follow-up, but these results should be interpreted with caution given the large number of covariates analyzed (multiplicity). Future Cox proportional hazards analysis will help better define the risk and protective factors for thrombosis in persistently aPL-positive patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Antiphospholipid Syndrome

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Recent studies implicate complement activation in the pathophysiology of antiphospholipid syndrome (APS), especially in patients with severe manifestations, such as catastrophic APS (CAPS). This study aimed to prospectively evaluate whether complement activation biomarkers are associated with new (first or recurrent) thrombosis in antiphospholipid antibody (aPL)-positive patients.

Methods: APS ACTION registry inclusion criteria are positive aPL based on the updated Sapporo APS Classification Criteria, tested at least twice within one year prior to enrollment. Patients are prospectively followed every 12±3m with clinical data and blood collection. We identified patients with new thrombosis during follow-up, and controls without new

Table 1: Baseline Characteristics of Antiphospholipid Antibody (aPL)-positive Patients with or without New Thrombosis During the Follow-up

Characteristics	Total (n=52)	New Thrombosis (n=27)	No New Thrombosis (n=25)	p-value

- Data are expressed as number (percentage of the total), mean (±standard deviation), or median (±interquartile range). Comparisons between groups were performed using T-test or Mann Whitney U test for continuous variables and Chi-square or Fisher's exact test for categorical variables. Statistical significance $p<0.05$.
- APS= antiphospholipid syndrome, SAID= systemic autoimmune disease, SLE= systemic lupus erythematosus, LA= lupus anticoagulant, aCL= anticardiolipin antibody, aβ_2GPI= anti-β_2-glycoprotein-I antibody

thrombosis, matched (1:1) for gender, age (±5 years), history of thrombosis, and associated autoimmune disease. Complement activation was evaluated by plasma levels of soluble C5b-9 (sC5b-9), C4d, and Bb fragment (commercial ELISA), and the modified HAM (mHAM) assay that measures complement-dependent cell killing. For each patient, two annual follow-up samples were evaluated (first available and most recent prior to event; or first two available in those without new thrombosis). If available, a third "acute" sample within three months of the new thrombosis was also studied.

Results: As of May 2022, 365 aPL-positive patients from North American centers were included in the registry; 27 (7%) patients had a new thrombosis during the prospective follow-up and were matched with 25 patients without new thrombosis. Baseline characteristics were similar, except those with new thrombosis were more likely to have a history of both arterial and venous thromboses ($p=0.02$), a higher body mass index ($p=0.03$), and a trend towards triple aPL positivity ($p=0.09$) (Table 1). After a median follow-up of 4.6 years (±IQR, 5.6), 13 patients had new arterial thrombosis, 12 venous, and two microvascular. In patients with new thrombosis, compared to those with no new thrombosis: a) C4d level was significantly elevated (median level 4.22 (±IQR, 3.39) μg/ml versus 3.33 (±IQR, 2.56) μg/ml; $p=0.041$); b) the number of patients with positive mHAM test was significantly higher (8 [30%)]versus 1 [4%]; $p=0.026$); and c) there was no significant difference in

Table 2: Complement Activation Biomarkers in Antiphospholipid Antibody-positive Patients with or without New Thrombosis During the Follow-up

Complement Biomarkers	Total (n=52)	New Thrombosis (n=27)	No New Thrombosis (n=25)	p-value
Elevated sC5b-9 (# patients (%))	44/50 (88)	23/26 (89)	21/24 (88)	1.00
sC5b-9 level, ng/ml (median (±IQR))	412 (±307)	491 (±367)	346 (±308)	0.20
sC5b-9 in acute* samples, ng/ml		482 (±295)		
Elevated C4d	NA	NA	NA	NA
C4d levels, µg/ml (median (±IQR))	3.63 (±3.18)	4.21 (±3.39)	2.87 (±2.56)	**0.041**
C4d in acute* samples, µg/ml		4.27 (3.7)		
Elevated Bb (# patients (%))	15/50 (30)	10/26 (39)	5/24 (21)	0.17
Bb level, µg/ml (median (±IQR))	1.06 (±0.59)	1.03 (±0.77)	1.16 (±0.53)	0.71
Bb in acute* samples, µg/ml		1.41 (±1.54)		
Positive mHAM (# of patients)	9/51 (18)	8/27 (30)	1/24 (4)	**0.026**

- Data are expressed as number (percentage of the total), or median (±interquartile range). Comparisons between groups were performed using Mann Whitney U test for continuous variables and Chi-square or Fisher's exact test for categorical variables. Statistical significance $p<0.05$
- Elevated levels were defined based on manufacturer 's normal range values, which were available for soluble C5b-9 (sC5b-9) (normal: (≤219 ng/ml) and Bb (normal: ≤1.42 µg/ml), but not for C4d. Positive modified HAM (mHAM) test was based on >20% cell non-viability.
- sC5b-9, C4d, and Bb values were expressed as the mean of the two values obtained from samples before the new thrombosis (no significant changes in results if analyzed based on the first or second sample – data not shown). * within three months of acute thrombosis.

sC5b-9 and Bb levels despite a trend toward a higher number of elevated Bb in patients with new thrombosis (Table 2). In nine patients with "acute" samples obtained within three months of new thrombosis, sC5b-9 was elevated in all, Bb fragment in four (44%), and mHAM test was positive in three (33%).

Conclusion: Based on the analysis of our multi-center prospective cohort of persistently aPL-positive patients, our preliminary findings suggest that markers of complement activation, specifically elevated C4d levels and positive mHAM test, are associated with a higher risk of thrombosis, which might be a useful tool to aid risk-stratification.

Session Title: Abstracts: Antiphospholipid Syndrome
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: In first responding cells such as neutrophils and platelets, extracellular ATP released from activated or dying cells engages cell-surface receptors to launch proinflammatory and prothrombotic signals. As a counterpoint to this thromboinflammatory purinergic signaling, the surface ectonucleotidases CD39 (ATP to AMP) and CD73 (AMP to adenosine) convert ATP into homeostatic adenosine. Adenosine then activates G protein-coupled receptors to increase

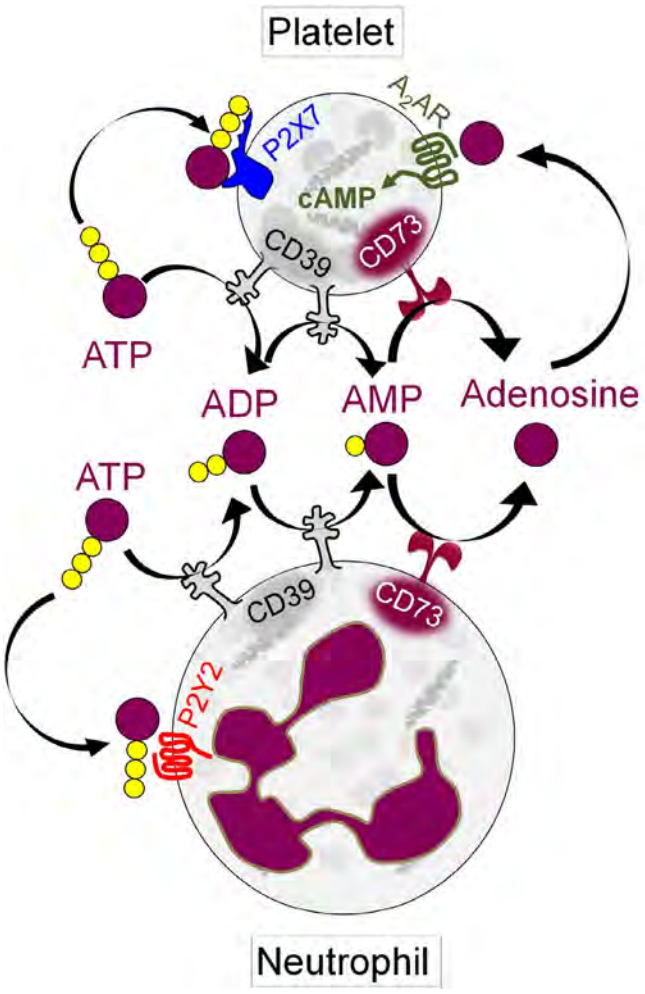

Figure 1: Schematic representation of purinergic signaling in platelets and neutrophils.

intracellular cyclic AMP (**cAMP**), thereby blunting inflammation and thrombosis. Here, we aimed to understand the potential relationship between the CD39/CD73 axis, neutrophils, and platelets in antiphospholipid syndrome (**APS**).

Methods: Neutrophil-platelet aggregates (**NPAs**) and platelet P-selectin (CD62P) were assessed in the blood of patients with primary APS by flow cytometry. In parallel, CD39 and CD73 activities on both neutrophils and platelets were measured by a standard malachite green assay. Levels of adenosine generation and intracellular cAMP were estimated using standard kits. In some experiments, healthy neutrophils and platelets were treated with APS IgG, specific CD39/CD73 activity inhibitors (ARL 67156, PSB 12379), or inhibitors of various surface receptors.

Results: As compared with healthy controls (n=48), patients with primary APS (n=55) showed at least a 50% reduction in median activities of neutrophil CD39 ($p< 0.0001$), neutrophil CD73 ($p< 0.0001$), platelet CD39 ($p< 0.0001$), and platelet CD73 ($p< 0.0004$). These changes were negatively correlated with significant increases in both NPAs (up to 80%, $p< 0.0001$) and platelet activation as defined by CD62P expression ($p< 0.002$). The levels of NPAs were higher in patients with APS who had a history of thrombosis than those without. When healthy neutrophils and platelets were cultured with either APS IgG or a CD39 inhibitor, there was a dose-dependent increase in NPA formation (from baseline 15% to 70%), and this phenotype was substantially blocked by inhibition of either the neutrophil P2Y2 receptor or the platelet P2X7 receptor. Focusing further on APS platelets, we found a significant decrease in their ability to generate adenosine ($p< 0.01$), as well as in their accumulation of intracellular cAMP ($p< 0.001$). Notably, CD62P expression was inversely correlated with platelet cAMP levels in patients ($r=-0.52$, $p=0.007$). Exposure of healthy platelets to APS IgG induced AKT phosphorylation (ser473) followed by downstream activation of GSK3β (ser9). This pro-activation signaling was efficiently blunted by agents that either activated adenosine receptors or directly boosted intracellular cAMP.

Conclusion: In primary APS, deficiency of CD39 and CD73 on both neutrophils and platelets potentiates pro-thrombotic platelet activation and NPA formation. By interrogating the downstream mechanisms, we identified several potential therapeutic targets including neutrophil P2Y2 and platelet P2X7 (**Figure 1**). Adenosine receptor agonists might be a strategy for restoring platelet homeostasis in APS. Overall, we speculate that a subset of patients with APS would benefit from therapies that modulate extracellular purinergic signaling.

Autoantibodies to Transcription Factor a Mitochondria Link Mitochondrial Damage and Thrombosis in Systemic Lupus Erythematosus

Eduardo Gomez-Banuelos[1], Alessandra Ida Celia[2], Maria Isabel Trejo Zambrano[3], Merlin Paz[3], Erika Darrah[3], Daniel Goldman[4], Michelle Petri[4] and Felipe Andrade[3], [1]The Johns Hopkins University, Baltimore, MD, [2]John Hopkins University of Medicine, Rome, Italy, [3]Johns Hopkins University, Baltimore, MD, [4]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Antiphospholipid Syndrome

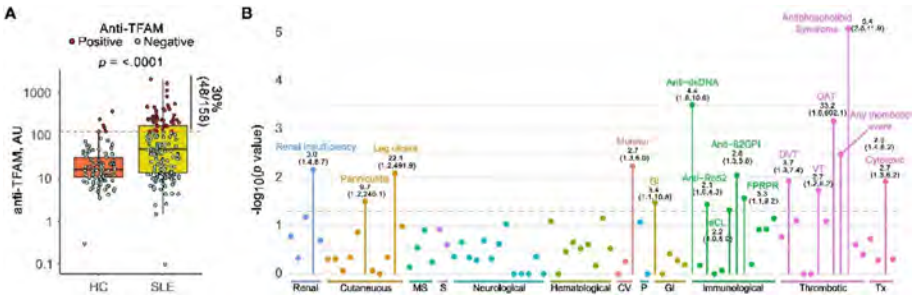
Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

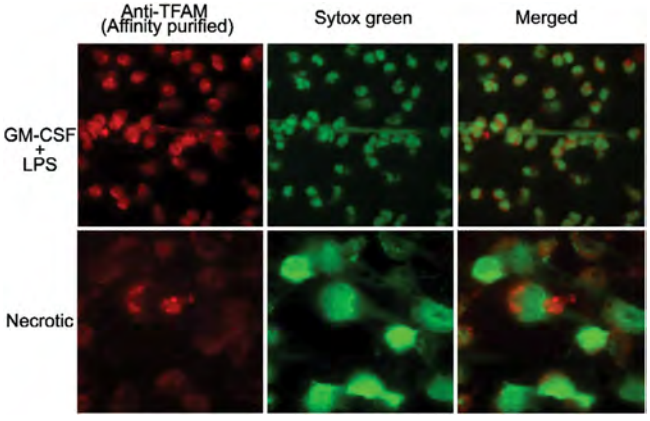
Background/Purpose: Upon activation with interferon (IFN) and RNP-immune complexes, defective mitophagy in neutrophils results in the release of mtDNA in complex with transcription factor A mitochondria (TFAM), leading to immune activation in SLE. TFAM is a member of the high-mobility group (HMG) family of DNA-binding proteins, which is essential for mtDNA transcription and for packaging mtDNA into nucleoids. Extracellular TFAM released from necrotic cells is also a DAMP. While characterizing novel autoantigens expressed by neutrophils, we identified TFAM as a target of antibodies in SLE. The purpose of this study was to investigate the relationship between anti-TFAM antibodies and clinical and transcriptional markers of disease activity in SLE

Methods: Anti-neutrophil antibodies in SLE sera were detected by indirect immunofluorescence (IIF). Anti-TFAM antibodies were screened by ELISA in sera from 98 healthy controls and 158 SLE patients from the "Study of biological Pathways, Disease Activity and Response markers in patients with Systemic Lupus Erythematosus" (SPARE). SPARE is a 2-year prospective cohort of adult patients for which extensive clinical, serologic, and whole blood transcriptional data is available. Binding of anti-TFAM antibodies to activated (GM-CSF + LPS) and necrotic neutrophils was determined by IIF.

Results: A subset of antibodies in SLE serum co-localizes with TFAM in neutrophils. The existence of anti-TFAM antibodies in SLE was confirmed by ELISA and immunoblotting. Thirty percent (48/158) of SLE patients were positive for anti-TFAM antibodies (Fig. 1A). Anti-TFAM antibodies were significantly associated with antibodies to dsDNA, cardiolipin (aCL), and β2-glycoprotein I (β2GPI) (Fig 1B). Anti-TFAM antibodies were strongly associated with history of thrombotic events, OR (95% CI) 2.9 (1.4,6.2), and secondary antiphospholipid syndrome (APS), OR (95% CI) 5.4 (2.5,11.9), independently of



Anti-TFAM antibodies are associated with thrombosis and APS in SLE. (A) Serum levels of anti-TFAM antibodies in patients with SLE (n=158) and Healthy controls (HC, n-98). Dots in red represent subjects positive for anti-TFAM. (B) Clinical and serological associations of anti-TFAM antibodies in SLE. Each dot represents the p value for the indicated SLE feature. Only features with a p value < 0.05 are labeled. P values were obtained with Fisher's exact test. Odds ratios and 95% CI, OR (95%CI), are indicated below each label.



Anti-TFAM antibodies recognize extracellular TFAM from GM-CSF + LPS activated (upper row) and necrotic neutrophils (lower row). Anti-TFAM antibodies (red) were purified by affinity chromatography, using recombinant TFAM, from a pool (n=3) of anti-TFAM positive SLE sera. DNA was stained using Sytox Green (Green channel).

aCL and anti- β2GPI (Fig. 1B). Unlike antibodies to dsDNA and RNPs, anti-TFAM antibodies were not associated with blood transcriptional markers of SLE disease activity, including the IFN signature, supporting a primary role of anti-TFAM antibodies in thrombosis rather than disease flaring. Anti-TFAM antibodies bind to TFAM-decorated DNA released from activated and necrotic neutrophils (Fig. 2), which is a mechanism that may contribute to thrombosis.

Conclusion: TFAM is novel autoantigen in SLE, which is associated with thrombosis and APS independently of aCL in SLE. These data support a link between mitochondrial damage and thrombosis in SLE.

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: Antiphospholipid Syndrome
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Antiphospholipid syndrome (APS) is an autoimmune disease with thrombotic and obstetric complications arising via a model of immunothrombosis. Patients may present with a spectrum of phenotypes, including thrombotic (tAPS), obstetric (oAPS), or catastrophic/microvascular APS (C/MAPS), while others may have antiphospholipid antibodies (aPL) without disease manifestations. Mechanisms underlying the development of these diverse phenotypes remain uncertain. Proteomic profiling was used in other thrombotic and microvascular disorders to highlight potential mechanisms of disease pathogenesis and may have a role in understanding the pathophysiology of APS.

We performed multiplex plasma proteomic profiling in aPL-positive patients with different clinical phenotypes to gain a greater understanding of potential immunothrombotic mechanisms in the pathogenesis of APS.

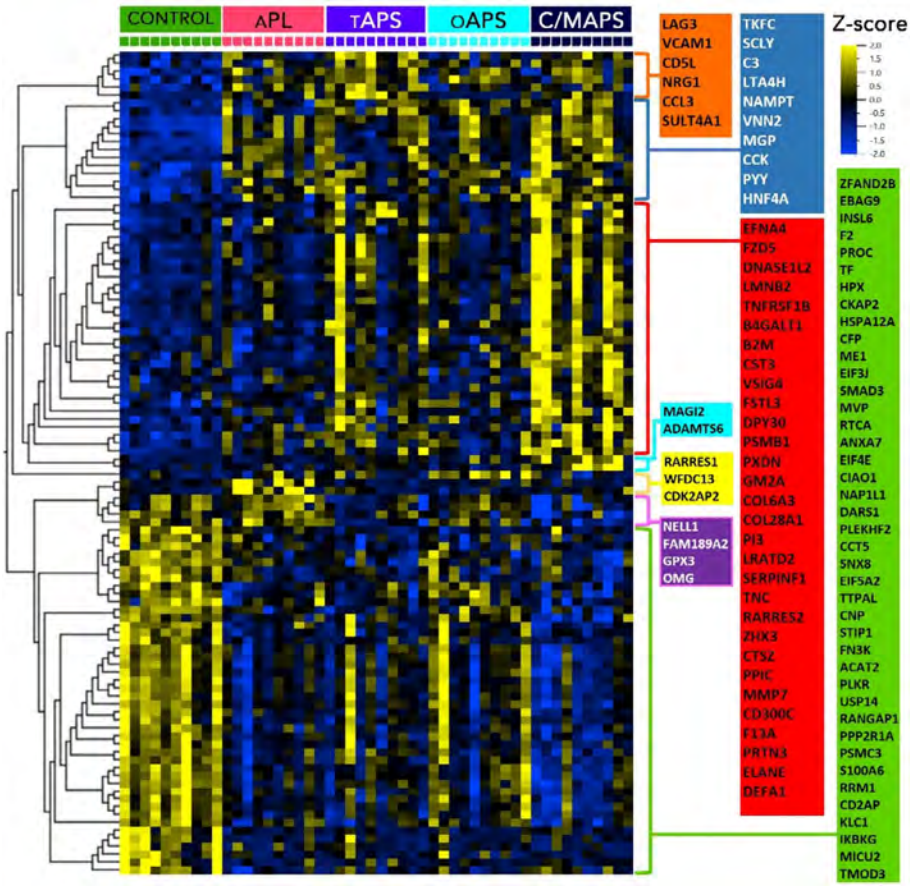

Figure A. Differentially abundant proteins by APS types and control subjects; APL, non-thrombotic APS (antibodies only); TAPS, thrombotic APS; OAPS, obstetric APS; CAPS/MV, catastrophic /microvascular APS. ANOVA on log-normalized data ($p<0.0007$, FDR $q<0.05$). FDR, false discovery rate.

Methods: A web-based data capturing system was used to store patient demographics, history, and medications. The inclusion criteria were positive aPL per Updated Sapporo Classification Criteria tested within 1 year prior to enrollment. Multiplex proteomic profiling measuring approximately 7,000 unique proteins (SomaLogic; Boulder, CO, USA) was performed

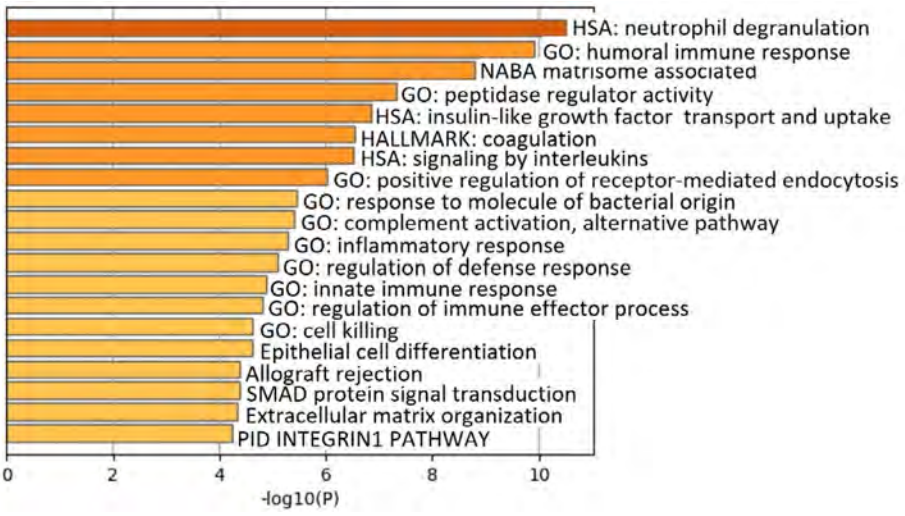

Figure B. Pathways enrichment analysis of proteins from Figure A.

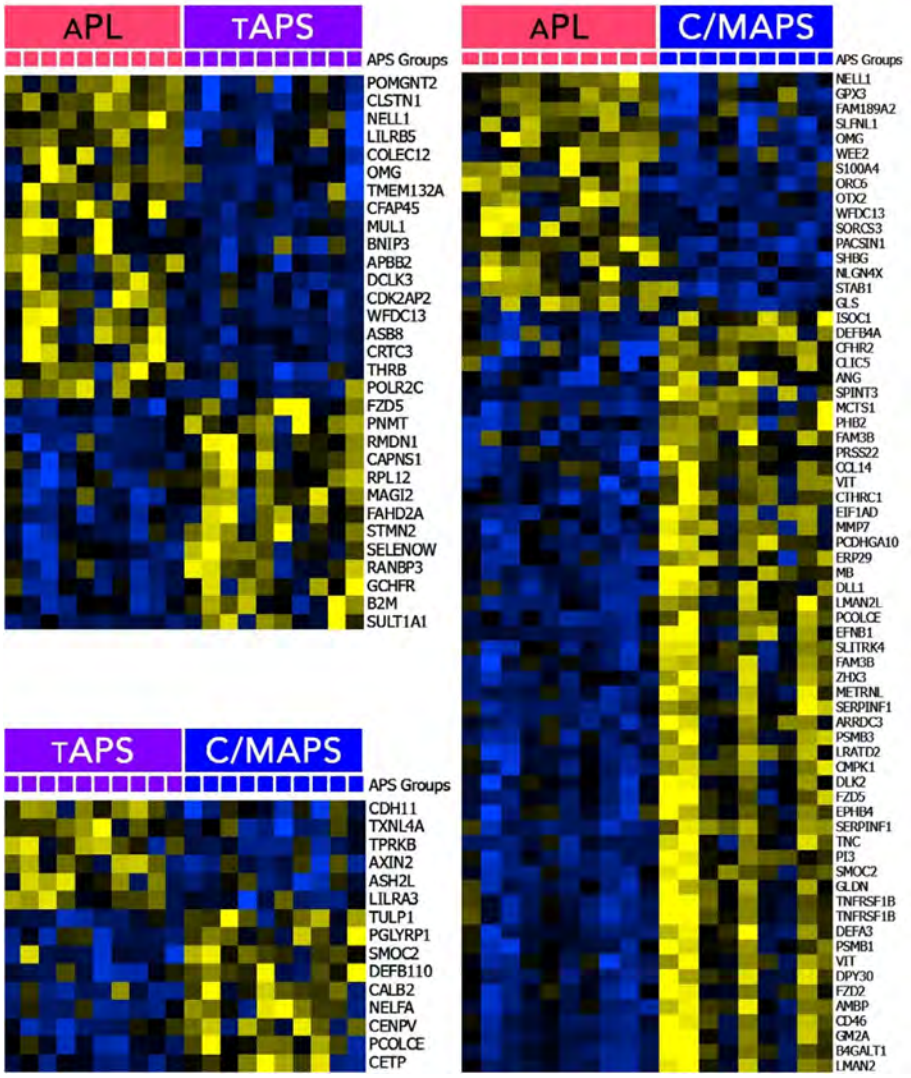

Figure C. Differentially abundant proteins by APS in pairwise comparisons between APS types; APL (non-thrombotic APS, antibodies only), p<0.01; TAPS (thrombotic APS), p<0.01; CAPS/MV (catastrophic /microvascular APS), p<0.005. T-tests on log-normalized data.

on 40 primary aPL-positive patient plasma samples from APS ACTION Registry (10 each of tAPS with/without oAPS, oAPS only, C/MAPS, and positive aPL without APS classification), and 10 of healthy controls. Differentially abundant proteins among all phenotypic groups and in pairwise comparisons were determined by applying ANOVA and t-tests to log-normalized data, respectively, with $p < 0.05$ considered statistically significant. Tests were adjusted for false discovery to minimize the likelihood of false positives.

Results: The median age of patients was 48 years; 30% were men, 70% had triple aPL-positivity, and no one had a concurrent diagnosis of lupus. A set of concordant and differentially abundant proteins clustered patients with 4 APS clinical phenotypes and controls (Figure A) with a high statistical significance ($p < 0.0007$) and a high false discovery confidence ($q < 0.05$). Pathway enrichment analysis of proteins in the identified set revealed involvement of several pathways such as neutrophil degranulation ($p < 10^{-10}$), humoral immune response ($p < 10^{-9}$), coagulation ($p < 10^{-6}$), alternative complement ($p < 10^{-5}$) and others (Figure B). Pairwise analyses of APS subtypes revealed increasing abnormalities in these pathways with worsening APS severity, but distinctly in cellular processes such as endocytosis/vesicle-mediated transport, receptor signaling, signal transduction and cellular differentiation (Figure C). This was particularly striking in C/MAPS subtype, with members of negative regulation of inflammatory response and cellular differentiation processes being the only distinction between tAPS and C/MAPS.

Conclusion: Plasma proteome of several APS subtypes is characterized by alteration in peripheral blood cellular processes, particularly receptor signaling, signal transduction and regulation of cellular differentiation, in addition to significant neutrophil, complement, coagulation and cytokine activation notable in all aPL-positive patients.

Associations Between SARS-Cov-2 Infection and Neuropathic Pain in Fibromyalgia Patients: A Cohort Study

Danilo Perretta[1], Daniele Mauro[1], flavia riccio[1], valentina marino[1], emma scoppetta[2], Francesco ciccia[1] and rosella tirri[1], [1]University of Campania - Luigi Vanvitelli, Naples, Italy, [2]University of Salerno, Salerno, Italy

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: SARS-CoV-2 infection has been increasingly recognized for its potential neurological manifestations. Fibromyalgia (FM) patients, who already experience neuropathic pain, may be particularly vulnerable to the impact of COVID-19 on their symptoms.

This study aims to investigate the specific influence of SARS-CoV-2 infection on the neuropathic component of pain in Fibromyalgia patients, shedding light on potential interactions between COVID-19 and FM.

Methods: We conducted a prospective cohort study enrolling FM patients who met the ACR 2016. The cohort was divided into two groups: patients who tested positive for SARS-CoV-2 infection and a matched cohort of uninfected FM patients. Neuropathic pain was assessed using the PainDetect Questionnaire (PDQ) at baseline (t0) and after six months (t1). Prevalence, incidence, and worsening of neuropathic pain were evaluated in both groups. Patients were considered to have neuropathic pain if the PDQ score was > 20, and data were analyzed by Chi-Square and paired T student test as appropriate

Results: We conducted a cohort study involving 58 FM patients (median age: 47 years; 2 males, 56 females). All patients were receiving treatment with SNRI antidepressants and Pregabalin, except for one patient who solely underwent physical therapy. At baseline, there were no significant differences in clinical or demographic characteristics between the infected and uninfected groups (table 1).

Baseline characteristics	COVID-19 Group	Uninfected Group	*p value*
Sex n (% of Female)	29 (96.5%)	29 (96.5%)	
Age Median years (SD)	52,07 (11.53)	55,72 (8.73)	*0,179*
BMI Kg/m2 (SD)	26,59 (9.45)	26,38 (5.41)	*0,2781*

As assessed by PDQ, the prevalence of neuropathic pain did not differ significantly between the two groups at baseline (36.21% vs 27.59%, p=0.17). However, patients who experienced SARS-CoV-2 infection had a significantly higher incidence of neuropathic pain at the six-month follow-up compared to the uninfected controls (46.55% vs. 31.03%, p=0.004, Relative Risk 5.5, 95% CI [1.5;21.1]).

When analyzing the sequential changes in PDQ scores, we found no statistically significant alteration in neuropathic pain severity over the six-month observation period among the uninfected group (t0 PDQ mean 20,1 (SD 6.7) vs. t1 20.72 (SD 7.4), p =0.37). Conversely, the infected group demonstrated a significant worsening of neuropathic pain at six months post-infection, as indicated by higher mean PDQ scores (t0 21.1 (SD 5.8) vs. t1 26.9 (SD 5.3) $p < 0.0005$).

Conclusion: This study indicates a potential link between infections and chronic pain in FM patients, as evidenced by the associations observed between SARS-CoV-2 infection and increased incidence and worsening of neuropathic pain. Further research is required to confirm these findings and explore potential interventions for FM patients.

Session Title: Abstracts: Fibromyalgia & Other Clinical Pain Syndromes

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Acceptance and Commitment Therapy (ACT), a form of guideline-recommended Cognitive Behavioral Therapy (CBT), has been empirically validated as a non-drug treatment for fibromyalgia (FM). However, clinical adoption of the therapy has been limited partly due to availability of qualified providers as a major barrier.

A smartphone-based, prescription digital application (FM-ACT) that has been recently cleared by the FDA helps address the access barrier by delivering self-guided ACT for treatment of FM symptoms. Its preliminary clinical benefits have been demonstrated in a pilot RCT.[1] This report presents the results from PROSPER-FM (NCT05243511), a pivotal, prospective, multicenter, randomized controlled trial (RCT).

Methods: Individuals meeting 2016 FM diagnostic criteria were randomized to receive 12 weeks of FM-ACT or a digital symptom tracker control (ST) while remaining stable on any ongoing FM treatment(s). The FM-ACT intervention consists of 42 daily structured ACT lessons, mindfulness practices, and activities to encourage paced exercise and behavior change. The ST program offers daily symptom tracking and access to FM education materials. Participants were informed they would receive one of two potentially beneficial treatments that were being evaluated for clinical effectiveness.

The primary endpoint was Patient Global Impression of Change (PGIC). Secondary endpoints included the Revised Fibromyalgia Impact Questionnaire (FIQ-R), pain intensity, pain interference, and sleep interference. Endpoints were collected weekly through electronic patient-reported outcomes (ePROs).

Results: A total of 275 participants were randomized (Fig 1, Table 1). Analysis results are summarized in Table 2. At week 12, 70.6% of the FM-ACT participants reported an improvement on PGIC, which was significantly greater than that reported by ST participants (22.2%) ($p < 0.001$). The FM-ACT arm exhibited a significantly greater post-treatment reduction on the

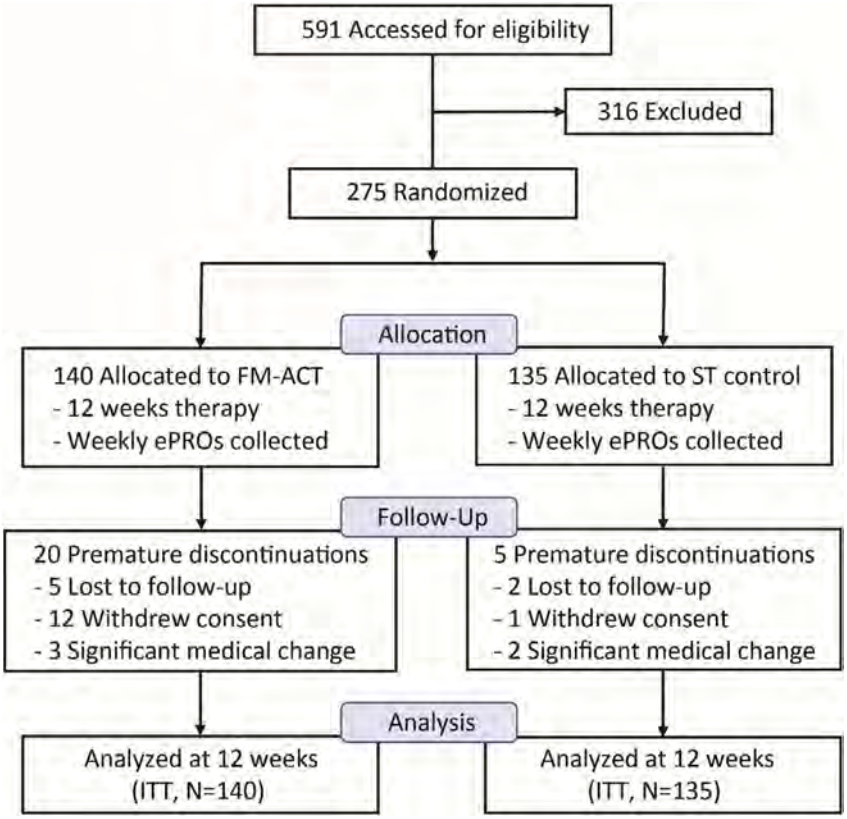

Figure 1. Consolidated Standard of Reporting Trials (CONSORT) diagram. Screening and enrollment were conducted between February 2022 and February 2023. ePROs, electronic patient reported outcomes; ITT, intention to treat.

FIQ-R total score as compared to the ST arm ($p < 0.001$, Effect Size = 0.65). FM-ACT was statistically superior to the control treatment on virtually all measures, including FIQ-R (total and domain-level scores), PGIC, pain intensity and interference, PROMIS Fatigue and Sleep Disturbance, Beck Depression Inventory II (BDI II), Psychological Inflexibility in Pain Scale (PIPS), and committed action (CAQ-8). No treatment related adverse events were observed.

BDI II: Beck Depression Inventory II; CAQ-8: Committed Action Questionnaire; CFB: Change from baseline; CI: confidence interval; FIQ-R: Revised Fibromyalgia Impact Questionnaire; LS mean: least-square mean; NRS: numerical rating scale; PGIC: Patient Global Impression of Change; PIPS: Psychological Inflexibility in Pain Scale; PROMIS: Patient-Reported Outcomes Measurement Information System; SE: standard error. The NRS scores range from 0 (worst outcome) to 10 (best outcome).

Conclusion: Analysis of the PROSPER-FM pivotal trial supports the clinical benefits of FM-ACT in managing FM. This smartphone based digital therapeutic demonstrated statistical superiority over the control on patients' wellbeing, FM symptoms, impact, and function, as well as common disorders associated with FM.

Validated digital ACT therapy provided by FM-ACT, combined with the low-risk safety profile of this device-based intervention, offers an important step forward in reaching and benefiting the broader FM population with a non-drug therapy.

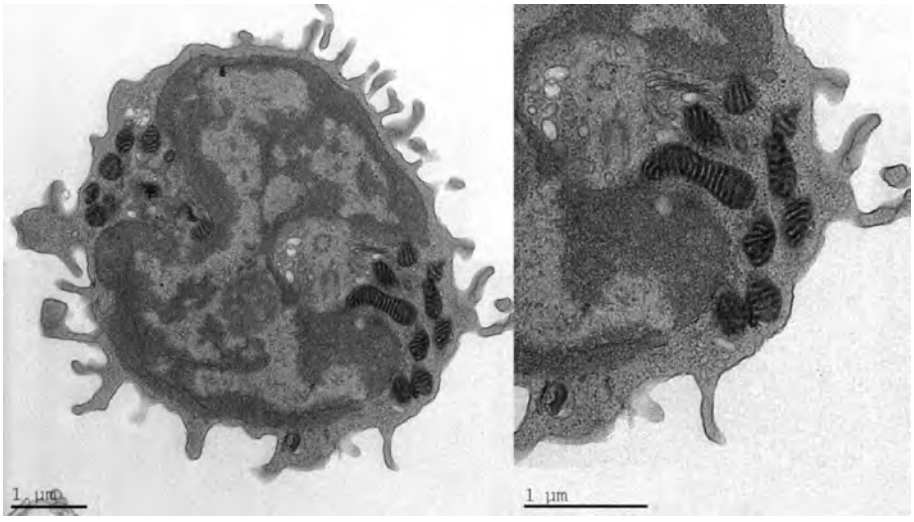
Mitochondrial Structural Alterations in Fibromyalgia - A Pilot Electron Microscopy Study

Linoy Israel[1], Victoria Furer[2], Atan Gross[1] and **Jacob Ablin**[2], [1]Weizmann Institute of Science, Rehovot, Israel, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel

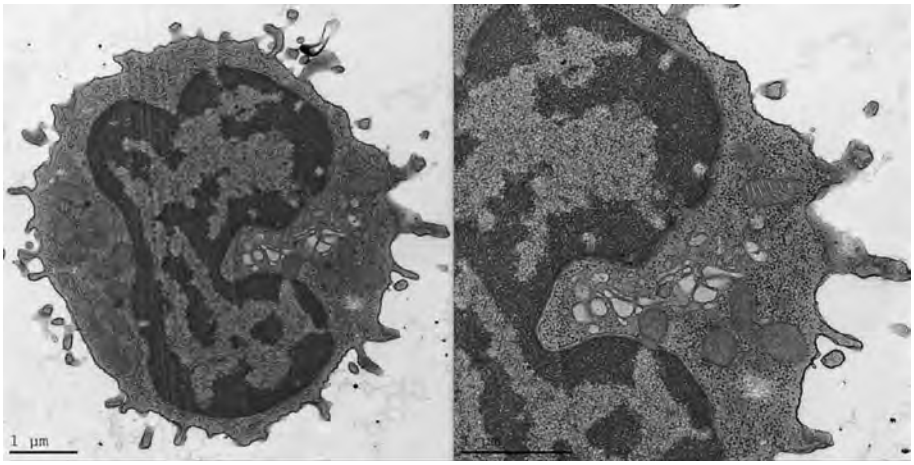
SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Fibromyalgia (FM) is among the most common chronic pain conditions, clinically characterized by widespread pain and fatigue. FM pathogenesis remains unknown, leading to challenges in diagnosis and treatment. Mitochondria are the headquarters of cellular energy metabolism and their malfunction has been proposed to contribute to both

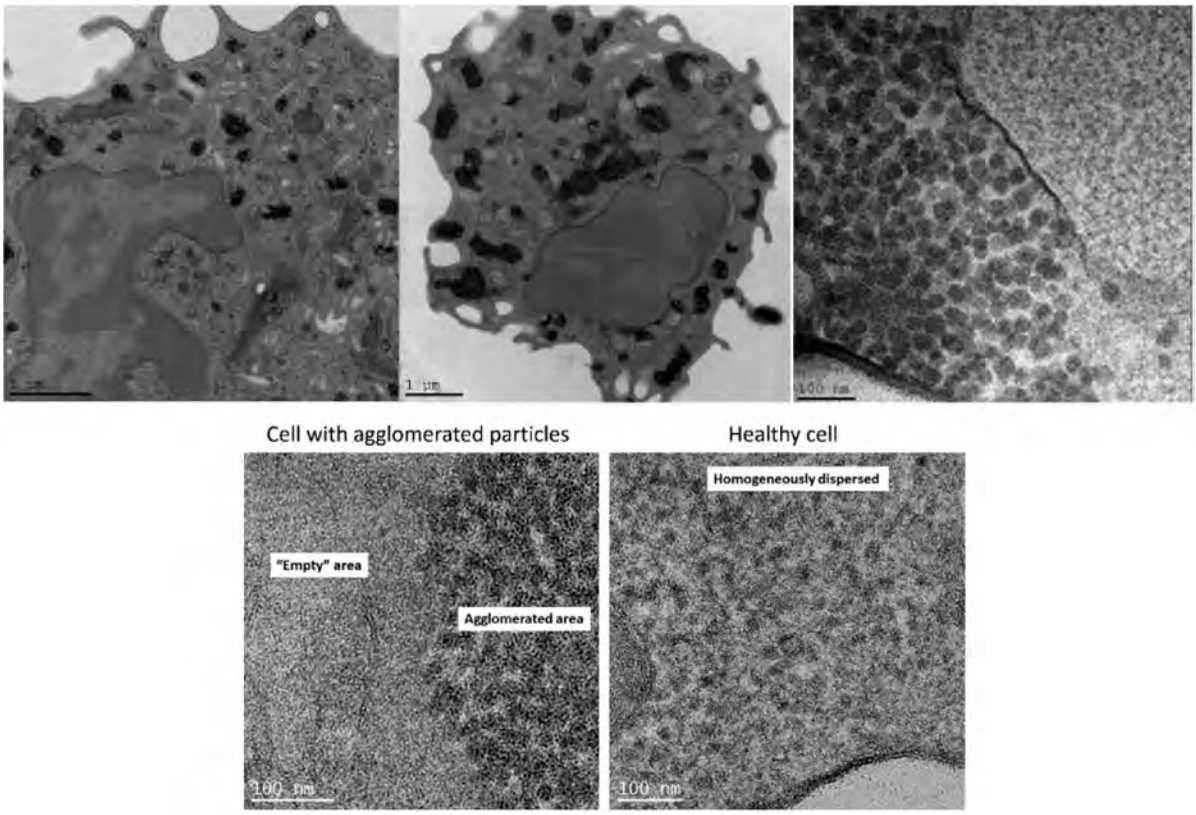


TEM of PBMCs, Healthy controls, showing normal mitochondrial crista (A) vs. FM with partial or complete loss of crista (B).



fibromyalgia and chronic fatigue. Thus, the aim of the current study was to detect structural changes in mitochondria of peripheral blood mononuclear cells (PBMCs) of FM patients, using transmission electron microscopy (TEM).

Methods: To detect mitochondrial structural alterations in FM patients, we analyzed PBMCs from seven FM patients and seven healthy controls using TEM. Patients were recruited from a specialized fibromyalgia clinic at a tertiary hospital. After providing informed consent, patients responded to questionnaires, including the Widespraede Pain Index (WPI) and the symptom severity Scale (SSS), to verify a diagnosis of FM according to ACR criteria. Subsequently, blood samples were drawn and PBMCs were collected for EM analysis.



TEM from FM patient PBMCs, showing stages of accumulation of "black particles (Size bars = 1 m). Right: high magnification of the particles (100 m).

Results: TEM analysis of PBMCs showed several distinct mitochondrial patterns, including total loss of normal crista in FM patients (Fig. 1). The number of mitochondria with intact crista morphology was reduced in FM patients and the percentage of mitochondria that completely lacked crista was significantly increased. These results correlated with WPI severity. Moreover, in FM patient samples we observed a high percentage of cells containing "black-particles" (Fig. 2), which may represent ribosomal aggregates. Crista loss and possible ribosome aggregation were intercorrelated, and thus may represent reactions to a shared cellular stress condition. These changes may indicate an adaptive hypometabolic "hibernation-like" state to a stressful event, similar to hibernation in some mammalian species. The changes in mitochondria morphology suggest that mitochondrial dysfunction, resulting in inefficient respiration, Reactive Oxygen Species generation, etc., may play a pathogenetic role in FM.

Conclusion: We here describe novel morphological changes in mitochondria of FM patients, including loss of mitochondrial crista. While these observations cannot determine whether the changes are pathogenetically primary, or represent an epiphenomenon, they highlight the possibility that mitochondrial malfunction may play a causative role in the cascade of events leading to chronic pain and fatigue in FM. Moreover, the results offer the possibility of utilizing changes in mitochondrial morphology as an objective biomarker in FM. Further understanding the connection between FM and mitochondria morphology, function, and turnover (biogenesis/mitophagy), may assist in developing both novel diagnostic tools as well as specific treatments for FM.

Design and Validation of a Comparator for Randomized Controlled Trials of a Digital Cognitive Behavioral Therapy

Michael Gendreau[1], Yifei Dai[2], Michael Rosenbluth[3], David Williams[4] and Daniel Clauw[5], [1]Gendreau Consulting, LLC, Poway, CA, [2]Swing Therapeutics, Gainesville, FL, [3]Swing Therapeutics, San Francisco, CA, [4]Chronic Pain and Fatigue Research Center, Department of Anesthesiology, University of Michigan, Ann Arbor, MI, [5]Department of Anesthesiology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The use of a control arm (comparator) in randomized controlled trials (RCTs) is considered the gold standard for trial conduct and interpretation. Choosing an appropriate control for RCTs evaluating Cognitive Behavioral Therapy (CBT) interventions is particularly challenging, as it is not feasible to develop a blinded sham behavioral treatment. Pilot and pivotal RCTs were performed to evaluate the efficacy of a smartphone based digital therapeutic app (FM-ACT), which delivers self-guided Acceptance and Commitment Therapy (ACT) for treatment of fibromyalgia symptoms. For the control arm of these RCTs, a digital comparator app was developed. The comparator app was designed to offer similar participant engagement and usability to control for potential study biases. This report presents the approach and validation of the novel comparator design.

Methods: In both RCTs, participants meeting 2016 diagnostic criteria for fibromyalgia were randomized to receive 12 weeks of FM-ACT or the digital symptom tracker (ST) comparator. The FM-ACT intervention consists of 42 daily sessions of structured ACT lessons, mindfulness practices, and activities to encourage paced exercise and behavior change. The ST

app was developed as an alternative intervention consisting of two common pain management components: 1) patient education on FM and general health; and 2) daily symptom and function tracking with progress reports available to the participant. During consent, participants were informed that they would be evaluating one of two potentially effective digital treatments. Participant engagement (number of sessions completed during the study) and usability factors were assessed to compare the performance of this novel control strategy.

Results: The pilot RCT data demonstrated a similar number of completed sessions between the FM-ACT and ST comparator arms, which was further supported by the results from the pivotal RCT (Fig. 1). Usability assessment from the pivotal trial showed more participants reported "good" to "excellent" usability comparing the ST arm to FM-ACT (Fig. 2).

Participants from both arms reported high rates of satisfaction with their app experience (proportion of satisfied participants: FM-ACT 80%, ST: 85%). Similar proportion of participants from both arms reported that they would use the app again (FM-ACT 80%, ST 79%).

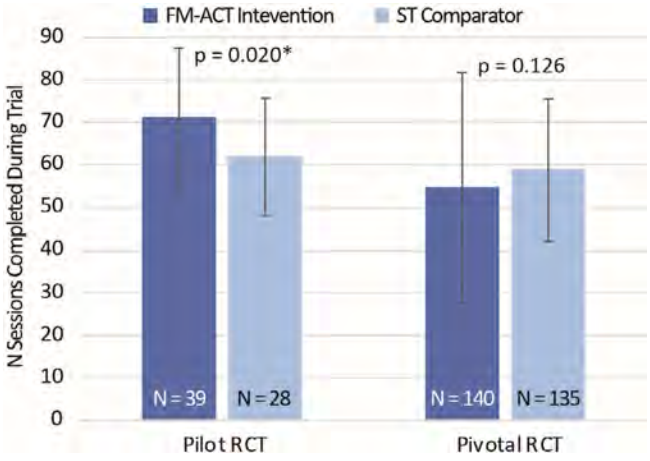

Figure 1. Comparison of participant app engagement between the FM-ACT intervention and the ST comparator arms from the pilot and pivotal RCTs. *Although statistical significance was found in the pilot RCT, both arms exhibited high app engagement with 97.3% and 92.6% of the participants completed ≥ 42 sessions (corresponding to the core therapy content) in the FM-ACT and ST arm, respectively.

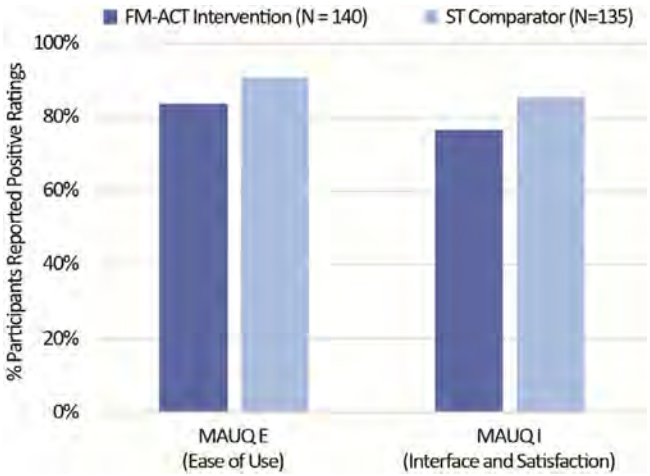

Figure 2. Participants reported "Good" to "Excellent" app experience from the pivotal RCT, measured by the mHealth App Usability Questionnaire (MAUQ), Domains: E – "Ease of Use" and I – "Interface and Satisfaction".

Conclusion: Participants randomized to the ST comparator arm engaged with the app at rates equal to or exceeding FM-ACT engagement rates and had similar usability ratings. The evidence suggests that the ST design may minimize participant bias towards a perceived inferior therapy. This approach may provide a basis for comparator strategies for RCTs of behavioral health interventions.

Tetrodotoxin Sensitive $Na_v1.7$ Sodium Channel SCN9A Gene Polymorphism rs6754031(T >G) Is Associated with Fibromyalgia

Koshy Nithin Thomas, Shivika Guleria, Amita Aggarwal and Able Lawrence, Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Lucknow, India

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: SCN9A gene encodes a tetrodotoxin sensitive $Na_v1.7$ Sodium channel expressed in dorsal root ganglia, peripheral nerves, olfactory nerves and inner ear. Rare Mutations in SCN9A are associated with a spectrum of pain disorders from erythromelalgia (gain of function) to congenital insensitivity to pain. We planned a case control study to explore the association of intronic SNPs rs6754031(T >G) and rs6746030 (G >A) of which rs6754031 minor allele (GG) was previously associated with Fibromyalgia.

Methods: Patients diagnosed as Fibromyalgia using ACR1990 and/or ACR2016 criteria and consenting to genetic study were included. Healthy controls with no widespread pain or connective tissue disease or medical comorbidity were included. Although a sample size of 250 each was targeted, study was terminated due to slow recruitment during covid pandemic. DNA was extracted by phenol-chloroform method. Genotyping was done by real time PCR. All continuous variables among baseline characteristics are expressed in mean (SD) and comparison by one way ANOVA while Fisher's exact test was used for frequency tables. Odds Ratios and confidence intervals were estimated using Logistic Regression using a recessive minor allele (G) model using STATA14.

Results: A total of 118 FMS patients (88% female) of mean age of onset 35 (±9.6) years and 118 healthy controls (78% female) of age 34.7 (±10.9) years were included. Clinical features and comorbidities of patients are given in Table 1. SCN9A polymorphism rs6754031 was in Hardy Weinberg equilibrium among controls (P=0.83) while SNP rs6746030 was not (P=0.002). The two SNPs were independent of each other consistent with genomic distance and lack of linkage. Genotyping results are given in Table 2. Of the 118 patients, 74 were classified Fibromyalgia by both ACR2016 and ACR1990 criteria while 33 and 11 subjects were classified by ACR2016 and ACR1990 alone respectively. Minor allele of rs6754031 (GG versus TT/TG) was associated with Fibromyalgia **OR=2.62 (1.15-6.00)** and diagnosis of Fibromyalgia by ACR2016

Table 1. Clinical features of FMS cohort

Table 3. SCN9A gene polymorphism rs6754031 association in recessive (G) model

Table 3. SCN9A gene polymorphism rs6754031 association in recessive (G) model			
	rs6754031 (TT/TG)	**rs6754031 (GG)**	
Fibromyalgia (N=118)	**97**	**21**	**P=0.03 OR=2.62 (1.15-6.00)**
Controls (N=118)	**109**	**9**	
	N=206	N=30	
Fibromyalgia by ACR2016 (N=107)	86	21	**P=0.005 OR=3.26 (1.42-7.46)**
No Fibromyalgia by ACR2016 (N=129)	120	9	
	N=206	N=30	
Fibromyalgia by ACR1990 (N=85)	73	12	P=0.685 OR=1.21 (0.55-2.66)
No Fibromyalgia by ACR1990 (N=151)	133	18	
	N=206	N=30	
Multivariate Analysis with ACR2016 (OR 5.05 CI 1.90-13.45 P<0.001) and ACR1990 (OR 0.47 CI 0.18-1.20 P=0.113)			

OR=3.26 (1.42-7.46) but not with ACR1990 OR=1.21 (0.55-2.66) using a recessive model (Table 3). On multivariate analysis, association of rs6754031 GG with ACR2016 (**OR 5.05 CI 1.90-13.45 P< 0.001**) strengthened while ACR1990 (OR 0.47 CI 0.18-1.20 P=0.113) showed a negative trend. Among core Fibromyalgia features, rs6754031(GG) was associated with non-restorative sleep (waking unrefreshed) **OR=1.61(1.00-2.57) P=0.048**.

Conclusion: Our study supports previously reported association of rs6754031 GG with Fibromyalgia with a differential association between ACR2016 and ACR1990 underscoring the heterogeneity of Fibromyalgia.

Abstract Number: 1614

Therapy Combining Millimeter Wave-based Neuromodulation with Coaching for the Improvement in Quality of Life of Patients with Fibromyalgia: A Prospective, Multicenter, Randomized, Controlled Trial

Caroline Maindet[1], Anne Dumolard[2], Mélanie Veloso[2], Mario Barmaki[3], Rodrigue Deleens[4], Raphaël Gonon-Demoulian[5], Alberta Lorenzi-Pernot[6], Mireille Michel-Cherqui[7], Alain Serrie[8], Stanislas Velliet[9] and Jean-Luc Bosson[2], [1]University Hospital Grenoble Alpes, Grenoble, France, [2]Grenoble Alpes University Hospital, Grenoble, France, [3]Médipôle Lyon Villeurbanne, Lyon, France, [4]Rouen University Hospital, Rouen, France, [5]Montpellier University Hospital, Montpellier, France, [6]Neurology private practice, Mornant, France, [7]Foch hospital, Suresnes, France, [8]Paris University Hospital, Paris, Guinea, [9]Valenciennes hospital, Valenciennes, France

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Fibromyalgia is a chronic syndrome with symptoms of moderate to severe intensity, including diffuse pain, fatigue, sleep disturbance, and cognitive impairment. While first-line recommendation for this pathology is non-drug therapies (Macfarlane et al., 2017), namely physical therapy, symptoms often prevent patients from exercising. Therapies that rely on the body's endogenous opioid system thus present an interesting non-pharmacological method of helping patients. The objective of this trial was to assess the efficacy of an intervention combining a millimeter-wave emitting wristband (MMW) and a coaching program. Exposure of the peripheral nervous system to MMW has been shown to provide a neuromodulating effect, mediated by the release of various neurotransmitters, including endorphins. Endorphins have pain relief and parasympathetic modulation properties that can alleviate the symptoms of fibromyalgia patients. Coaching aims to improve treatment adherence and efficacy.

Methods: In a multicenter, randomized, controlled trial (ClinicalTrials.gov NCT05058092), 170 fibromyalgia patients (ACR 2016 criteria, Wolfe et al., 2016)) with moderate or severe Fibromyalgia Impact Questionnaire score (FIQ, Bennett et al., 2009, score ≥ 39/100) were divided into 2 groups of immediate (IG) or delayed (DG) intervention. The IG (N=84) received the intervention immediately after groups were assigned, in addition to their usual care (UC). The DG (N=86) received the intervention with a delay of 3 months, intervention starting after assessment of the primary endpoint (M3). In both groups, patients first received MMW wristband treatment and coaching for 3 months, then wristband treatment alone for 3 months. The intervention consisted of using the wristband for three 30-minute sessions a day and receiving 4 coaching sessions including educational content on the intervention and training in the use of the device (D0), a usability assessment (D7) and a benefit assessment (M1 and M2). In the event of low benefit at M1 or M2, the wristband's stimulation mode (power &

duration) could be adapted. Efficacy of intervention was assessed by comparing the number of patients in both groups whose quality of life measurement on the FIQ significantly improved between inclusion and M3. A decrease in FIQ score of ≥14% is considered clinically significant (Bennett et al., 2009). FIQ scores of the 2 groups were also measured at 6 months (M6).

Results: At M3, 55.1% patients of IG improved their quality of life beyond 14%, compared with 35.9% in the DG, and this difference between the groups was statistically significant (p=0.021). On average, patients in the IG improved their FIQ score by 21.7%, versus 7.2% in the DG. Benefits observed in the IG were preserved at M6, patients in this group having used their device autonomously between M3 & M6.

Conclusion: The combination of MMW and coaching led to improvements in the quality of life of fibromyalgia patients superior to those obtained with UC after M3. This improvement was maintained at M6, while patients were using their wristband autonomously. This non-pharmaceutical therapy offers patients a therapy they can use independently and on an outpatient basis.

Therapeutic Hydroxychloroquine Blood Levels Are Cost Effective and May Reduce Health Disparities by Reducing Lupus Hospitalizations

Shivani Garg[1], Giancarlo Valiente[2], Lexie Kolton[3], Callie Saric[3], Betty Chewning[4] and Christie M. Bartels[2], [1]Department of Medicine, University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]University of Wisconsin, School of Medicine and Public Health, Madison, WI, [3]University of Wisconsin, Madison, WI, [4]University of Wisconsin, School of Pharmacy, Madison, WI

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Health Services Research II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Studies show factors including daily hydroxychloroquine (HCQ) dosing or nonadherence affect blood concentrations risking 6-fold higher lupus (or SLE) flares requiring hospitalization. Given disparities in nonadherence resulting in more hospitalizations, measuring HCQ levels in blood could guide clinicians to tailor HCQ dosing to maximize efficacy and improve adherence at the individual patient level. Yet, HCQ blood level monitoring is *not* routinely done due to cost, coverage, and unclear clinical standardization. Thus, we aimed to examine the cost effectiveness of HCQ blood level monitoring by measuring: 1) risk of lupus-related acute care utilization (Hospital or Emergency Room (ER) visits) by HCQ blood levels overall and in patients of Black race or Hispanic ethnicity; 2) the cost of lupus-related acute care visits vs. HCQ blood level monitoring.

Methods: We measured HCQ blood levels during 167 consecutive visits of unique patients using liquid chromatography mass spectrometry. HCQ blood levels were categorized as: a) subtherapeutic (< 750 ng/ml), b) therapeutic (750-1100 ng/ml), or c) supratherapeutic (>1100 ng/ml) per our prior findings. All lupus-related acute care (hospital/ER) visits from the clinic visit until next follow-up visit were manually abstracted. Covariates included socio-demographics, SLE disease

activity score, SLE damage index, kidney function (eGFR), steroid and HCQ doses. Using Cox hazard models, we examined associations between HCQ blood levels and time to first acute care visit after the index clinic visit. We compared published data (Kan, 2013) on the cost of lupus-related acute care visits to HCQ blood level monitoring in our cohort.

Results: Table 1 shows characteristics of 167 patients included in this study by: subtherapeutic (n=74), therapeutic (n=50), supratherapeutic (n=43) HCQ blood levels. A total of 31 lupus-related acute care visits were observed during the study period. Patients of Black race or Hispanic ethnicity and those with public insurance had 3-fold higher acute care utilization risk (Adjusted HR 3.3 & HR 3.6; Fig. 1 & Table 2A). A 71% lower acute care utilization risk was seen in patients with therapeutic HCQ blood levels, 750-1100 ng/ml, compared to those with subtherapeutic levels, < 750 ng/ml (Fig. 1 & Table 2A; p=0.029).

In a subgroup analysis among patients of Black race or Hispanic ethnicity (n=51), we noted that public insurance predicted 5-fold higher acute care utilization risk (Table 2B). Therapeutic HCQ blood levels were associated with 94% lower acute care utilization (Table 2B).

Using published costs of $562 per SLE ER visit and $11,716 per SLE hospitalization, 28 ER visits and 3 hospitalizations cost approximately $50,584 in our study. At a cost of $50 per HCQ blood level measurement, monitoring HCQ blood levels for 167 draws costs $8,350. Thereby, preventing one ER visit could cover the cost of up to 11 HCQ blood level draws per year.

Geographic and Demographic Representation in Industry-sponsored, US-based Clinical Trials of Systemic Lupus Erythematosus Therapies

Joshua Skydel[1], Reshma Ramachandran[2], Sakinah Suttiratana[2], Joseph Ross[2], Joshua Wallach[3] and Christopher Burns[4], [1]Dartmouth-Hitchcock Medical Center, Lebanon, NH, [2]Yale University, New Haven, CT, [3]Emory University, Atlanta, GA, [4]Dartmouth Hitchcock Medical Center, Lebanon, NH

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Health Services Research II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Clinical trials of systemic lupus erythematosus (SLE) therapies have increased over the last decade, driven by evolving knowledge of targetable pathways. However, these trials are often small, leading to evidentiary gaps over which patients benefit from new therapies. Racially minoritized populations, which disproportionately experience severe disease, are underrepresented in published SLE trials, but little is known specifically about trials supporting drug development, including where enrollment sites are located and whether enrollment is representative of the US population with SLE. Our objective was to assess geographic and demographic enrollment patterns for registered SLE clinical trials.

Methods: Industry-sponsored clinical trials investigating small molecules and biologics for use in SLE or lupus nephritis with at least 1 US site were identified from ClinicalTrials.gov; cutaneous lupus trials were excluded. Study characteristics were abstracted from trial registrations. US sites were characterized at the county level using the National Center for Health

Abbreviations: SLE, systemic lupus erythematosus; LN, lupus nephritis; PPR, participation-to-prevalence ratio; IQR, interquartile range.
[a] Categorizations are based on United States Census Bureau categories for race reporting.
[b] Excludes 7 clinical trials for which "Hispanic" was reported as a race rather than an ethnicity.
[c] Enrollment differences across study characteristics were evaluated using Kruskal-Wallis tests. Statistical tests are two-sided, with significance defined as $P < 0.0025$.

Statistics Urban-Rural Classification Scheme and Health Resources and Services Administration Medically Underserved Area designation. For completed and terminated trials with results, participation-to-prevalence ratios (PPRs) were calculated by dividing proportions of participants by sex, ethnicity, and race by US population proportions across Centers for Disease Control and Prevention SLE registries; PPRs from 0.80 to 1.20 indicated adequate representation. Enrollment differences across study characteristics were evaluated using Kruskal-Wallis tests.

Results: Among 144 industry-sponsored SLE clinical trials, 3454 US sites were reported, including 2565 (74%) in large metropolitan counties and 237 (7%) in small- or non-metropolitan counties (**Table 1**). Only 164 sites (5%) were in medically underserved counties. Female participants were adequately represented relative to the US population with SLE (median PPR 1.03, IQR 0.99-1.05) in 81 trials reporting enrollment by sex (**Table 2**). Among 72 trials reporting enrollment for at least 1 race, representation was inadequate for Black (median PPR 0.38, IQR 0.25-0.62) and American Indian/Alaska Native participants (median PPR 0.22, IQR 0-1.14), and adequate for White participants (median PPR 1.04, IQR 0.76-1.18). Asian participants were overrepresented in trials overall (median PPR 2.08, IQR 0.59-3.74), but underrepresented in trials with US sites only. Among 47 trials reporting ethnicity data, Hispanic participants were adequately represented (median PPR 1.01, IQR 0.84-1.73).

Conclusion: Among registered industry-sponsored clinical trials of SLE therapies, US enrollment sites were concentrated in metropolitan areas; only 5% were in medically underserved counties. Female, White, Asian, and Hispanic participants were adequately represented in trials overall, but Black and American Indian/Alaska Native participants were underrepresented relative to the US population with SLE. Future analyses are needed to further characterize regional enrollment, and to assess the alignment of research practices with the needs of clinicians seeking new therapies for SLE.

Abstract Number: 1617

Comparing Uptake of Biosimilar Infliximab Among Patients with Medicare, Medicaid and Private Insurance in U.S. Rheumatology Practices 2016-2022

Eric Roberts[1], Jing Li[1], Nick Bansback[2], Chien-Wen Tseng[3], Steve Shiboski[1], Gabriela Schmajuk[4] and Jinoos Yazdany[1], [1]University of California San Francisco, San Francisco, CA, [2]University of British Columbia, Vancouver, BC, Canada, [3]University of Hawai'i John A. Burns School of Medicine, Honolulu, HI, [4]UCSF / SFVA, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Health Services Research II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The first infliximab biosimilar (infliximab-dybb) entered the U.S. market in 2016, and two additional products have subsequently been introduced (infliximab-axxq (2017) and infliximab-abda (2020)). Biosimilars have significant potential to slow drug spending; however, uptake in the U.S. has lagged behind other countries. We compared rates of biosimilar uptake for Medicare, Medicaid, and private insurance after each infliximab biosimilar approval from 2016 to 2022.

Methods: Data from RISE, a national registry with electronic health records from one-third of U.S. rheumatology practices, was used. We examined all bio-originator or biosimilar infliximab administrations for users ≥ 18 years from the release of -dybb (biosimilar #1) in November 2016 through March 2022 regardless of diagnosis among participants with Medicare, Medicaid or private insurance. Dual Medicare-Medicaid patients were assigned to Medicaid. We modeled the log odds of receiving a biosimilar as a function of a three-way interaction between time (month), time-window (windows between

Table 1. Demographic characteristics of infliximab bio-originator or biosimilar recipients in RISE registry between April 2016 and March 2022.

	Overall (n= 422388)	
	n	%
Biosimilar	40401	9.56
Age group		
18-30	8034	1.90
31-50	63502	15.03
51-64	113856	26.96
65+	236996	56.11
Sex		
Women	285571	67.61
Men	136811	32.39
Race-ethnicity		
White	318426	75.39
Black	27869	6.60
Hispanic	15214	3.60
Asian	5072	1.20
Other/mixed	2271	0.54
Insurance		
Medicare	232722	55.10
Medicaid	16502	3.91
Private	173164	41.00

*Numbers may sum to less than 422388 due to missing values.

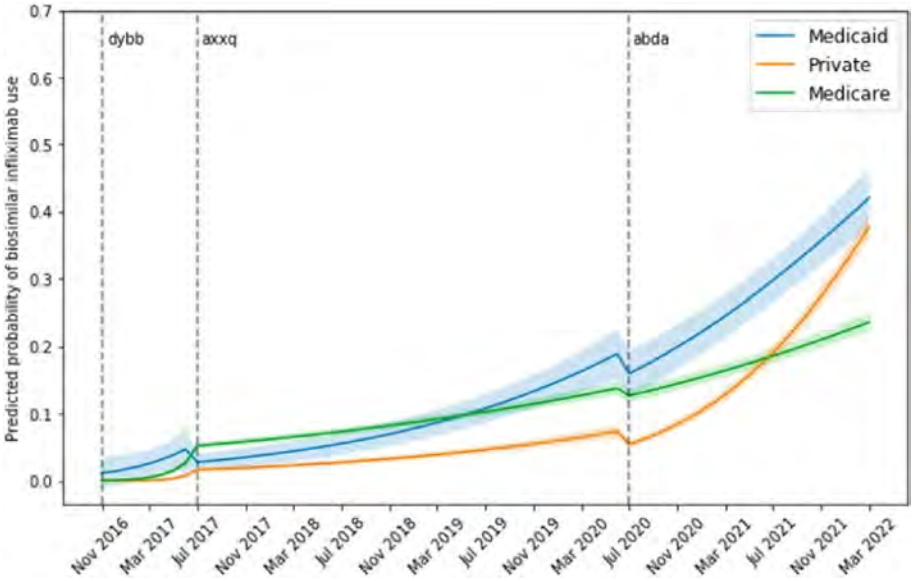

Figure 1. Predicted probability and 95% confidence interval of receiving biosimilar infliximab over time by insurance type

biosimilar market introductions), and insurance (Medicare, Medicaid, Private) adjusting for age, sex, race or ethnicity, and socioeconomic status (as measured by Area Deprivation Index (ADI)). We used cluster robust standard errors to account for repeated measures on patients. We reported patient demographics, and adjusted predicted probabilities of receiving a biosimilar by insurance type over time.

Results: Among 33,751 distinct patients, there were 422,388 administrations of infliximab products in RISE between November 2016 and March 2022, 40,401 (9.6%) of which were for a biosimilar. Overall, 56.1% of patients were ≥65 years; 67.6% were women; 75.4% white; 55.1% had Medicare, 3.9% had Medicaid, and 41% had private insurance (Table 1). Figure 1 depicts the predicted probability of receiving biosimilar infliximab over time by time-window and insurance. After -dyyb (biosimilar #1) came out, uptake for all insurances remained low at less than 10%. With -axxq (biosimilar #2) release, Medicaid was the only insurance to show rapid increase in uptake reaching 19% over 3 years (4 times increase) versus 14% and 7% for Medicare and private insurance. However, after -adba (biosimilar #3) release, both Medicaid and private insurance uptake skyrocketed, reaching similar rates around 40%. Meanwhile, Medicare uptake continued to remain modest at 24%.

Conclusion: Adoption of biosimilar infliximab was quickest for Medicaid, with private insurance catching up after the release of a third biosimilar. Medicare uptake lagged significantly. To reduce drug spending, efforts are needed to understand poor Medicare uptake of biosimilars such as manufacturer rebates for biologics, and lack of financial incentives to switch to biosimilars.

Abstract Number: 1618

Intervention to Improve Medication Adherence Among Patients with SLE

Kai Sun[1], Nneka Molokwu[1], Emily Hanlen[1], Amy Corneli[2], Kathryn Pollak[1], Jennifer Rogers[1], Rebecca Sadun[1], Lisa Criscione-Schreiber[2], Jayanth Doss[1], Hayden Bosworth[1] and Megan Clowse[3], [1]Duke University, Durham, NC, [2]Duke University School of Medicine, Durham, NC, [3]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Health Services Research II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Medication nonadherence is common and is associated with increased disease activity, morbidity, and mortality in SLE. To optimize medication adherence and SLE outcomes, we developed a simple clinician-led adherence intervention that involves clinicians reviewing real-time pharmacy refill data during the encounter and using effective communication techniques with patients to collaboratively overcome adherence barriers (Figure 1). Prior pilot testing demonstrated intervention feasibility, acceptability, and preliminary effect on adherence. In this study, we aimed to examine how the intervention is performed in practice and identify areas for improvement to inform future implementation.

Methods: We audio recorded clinic encounters between clinicians and patients seen at an academic lupus clinic. Patients were included if they had 90-day medication possession ratio (MPR) < 80% for SLE-specific medications. We coded which intervention components clinicians performed, quality of patient-clinician communication, and time spent discussing adherence. Following the intervention encounter, we also conducted audio-recorded semi-structured interviews with patients and

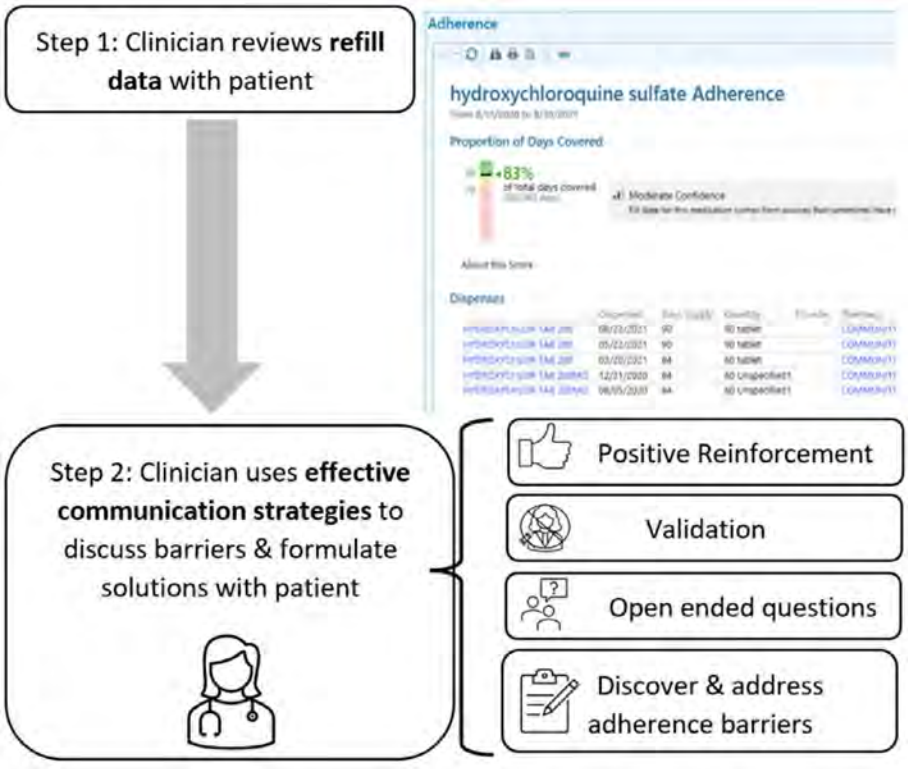

Figure 1. Adherence intervention steps.

Table 1. Intervention components performed during 25 recordings of the adherence intervention.

Intervention components	Definition	N=25 (% yes)
Reviewed refills	Clinician reviewed pharmacy refill data with patient during the visit	88%
Positive Reinforcement	Clinician praised patient for good behavior observed related to adherence, e.g., refilling regularly, being honest about nonadherence	88%
Validation	Clinician made statement to normalize missing doses and difficulties patients face in taking medications consistently	84%
Open-ended questions	Clinician asked a question about adherence that cannot be answered with yes or no or a finite number of answers	52%
Identified barriers	Clinician and patients discussed reasons for missing refills	76%
Addressed barriers	Clinician made suggestions about how to improve adherence	68%

clinicians about their experiences with the intervention and analyzed the data using applied thematic analysis. Lastly, we assessed change in 90-day MPR after the intervention visit and considered a 20% increase as major improvement.

Results: We recorded and analyzed 25 patient encounters (median age 39, 100% female, 72% Black) among 6 clinicians. Clinicians performed the majority of intervention components in most of encounters, suggesting fidelity (Table 1). Global communication scores and rates of active patient participation were high, suggesting excellent communication. Adherence discussions took on average 3.8 minutes.

Nineteen patients and 5 clinicians completed in-depth interviews. Nearly all participants felt the time spent discussing adherence was just right and necessary. Almost all patients felt the intervention was useful. Many patients described feeling heard and valued, being more honest about nonadherence, and being more knowledgeable and motivated to take SLE medications. Clinicians described less judgmental adherence discussions as a result of the intervention. To improve the intervention, patients emphasized better patient-clinician communication and wanted help problem solving financial and logistical barriers. Clinicians suggested additional resources and training to improve adherence conversations and utilizing peer support and other staff in the intervention.

Table 2. Quality of patient-clinician communication during the adherence intervention.

Global score category	Definition	Median score
Attentive	How engaged was the clinician	4.0/5.0
Concerns	How well did clinician address and anticipate patient concerns	5.0/5.0
Flow	Ease of flow of the conversation between clinician and patient	4.5/5.0
Respect	How much respect clinician conveyed to patient	5.0/5.0
Warmth	Warmth of the clinician	5.0/5.0
Active patient participatory behavior		**% of encounters, n/visit**
Asking questions	Seeking information and clarification related to medical encounter	88%, 3/visit
Assertive responses	Offering opinions, making requests, introducing new topics, stating preferences, making recommendations, disagreeing, clarifying, or interruption	88%, 2/visit

Following the intervention visit, almost half (48%) of patients had a major improvement (>20% increase) in MPR.

Conclusion: Our findings suggest that this intervention can be performed with high fidelity in a short amount of time. It encouraged high quality communication and improved adherence. Both patients and clinicians described positive experiences with the intervention. Future work will focus on optimizing clinician training, exploring ways to increase the intervention's efficiency and effectiveness, and testing the intervention in a larger controlled setting.

Receipt of Antimicrobial Prophylaxis in U.S. Medicare Beneficiaries Initiating Immunosuppressive Medications for ANCA Vasculitis

Carolyn Thorpe, Ryan Hickson, Sherrie Aspinall, Vimal Derebail, Xinhua Zhao, Joshua Thorpe, Binxin Cao, Alexa Ehlert, Ronald Falk and Susan Hogan, University of North Carolina, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Health Services Research II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Infections are the leading cause of hospitalization and mortality in patients with ANCA vasculitis (AV). Multiple AV treatment guidelines recommend antimicrobial prophylaxis during treatment with rituximab or cyclophosphamide, with agents that target prevention of *Pneumocystis jirovecii*pneumonia (PJP), but vary in recommendations for AV patients on other immunosuppressant (IS) medications. Providers may also initiate prophylaxis with other antimicrobials to prevent non-PJP infections. To address a gap in knowledge regarding real-world patterns of prophylaxis in AV, we characterized receipt, type, and duration of antimicrobial prophylaxis in U.S. Medicare beneficiaries initiating IS medication over 2016-18.

Methods: Using Medicare fee-for-service claims and a 90-day washout, we identified a national, retrospective cohort of new IS treatment episodes in 2016-18, including rituximab (RTX), cyclophosphamide (CYC), methotrexate, azathioprine, mycophenolate, leflunomide, mepolizumab, reslizumab, benralizumab, dupilumab, and/or corticosteroids (CS) at >10 mg/day prednisone equivalents. Episodes were restricted to adults with ≥1 diagnosis code for granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), or eosinophilic granulomatosis with polyangiitis (EGPA) in the prior year. IS regimens were classified as having either a strong indication for prophylaxis (regimens containing RTX, CYC, or CS of >20 mg/day in combination with another IS) or weaker indication (all other regimens). Prophylaxis was defined as ≥14 days' supply of a qualifying antimicrobial overlapping the first 30 days of IS treatment. Antimicrobials included PJP prevention (trimethoprim-sulfamethoxazole, pentamidine, dapsone, atovaquone), other antibacterials (azithromycin, doxycycline, fluoroquinolones), and antifungals (azole or mold-active). We calculated descriptive statistics overall and by IS regimen. We estimated Aalen-Johansen cumulative incidence of prophylaxis discontinuation over one year of follow-up, with death as a competing risk.

Results: Among 14,798 new AV IS treatment episodes (Table 1), 35% involved regimens with a stronger indication for prophylaxis. Overall, 21% received prophylaxis in the 30 days following IS initiation (Table 2). PJP prophylaxis was most frequent (16%), followed by other antibacterials (7%) and antifungals (2%). IS regimens with a stronger vs. weaker indication

Table 1. Characteristics of fee-for-service Medicare enrollees initiating a new course of immunosuppressive medication for ANCA vasculitis (AV) over 2016-2018 (n=14,798 treatment episodes; 8,446 unique patients)

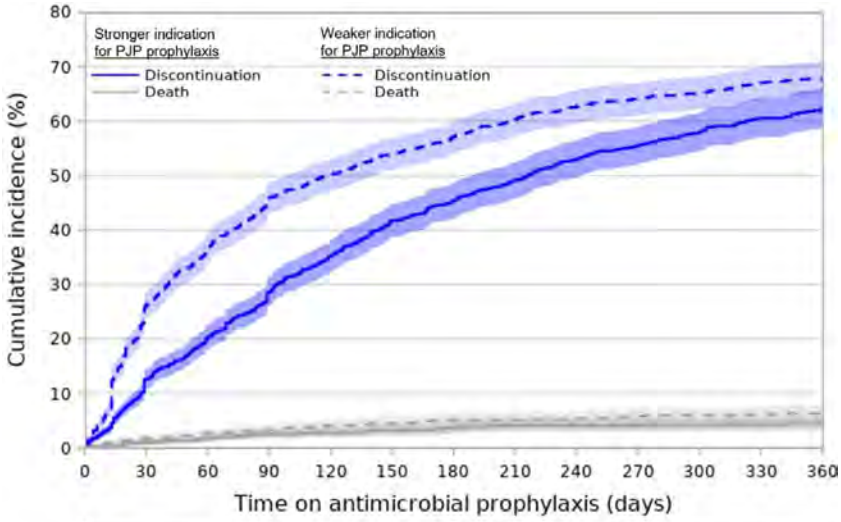
	%
Age Group (as of immunosuppressant episode start date)	
<65	21.2%
65 to <70	20.6%
70 to <75	23.2%
75 to <80	17.8%
>=80	17.2%
Female	62.9%
Race/Ethnicity	
Non-Hispanic White	82.8%
Black	5.3%
Hispanic	6.9%
Asian	1.9%
Native American	0.9%
Other/unknown	2.2%
Type of ANCA vasculitis (most recent AV code on/before index date)	
Granulomatosis with polyangiitis (M31.30 or M31.31 or 446.4)	72.9%
Microscopic polyangiitis (M31.7)	16.1%
Eosinophilic granulomatosis with polyangiitis (M30.1)	10.0%
Multiple types	1.0%
Immunosuppressive medication regimen	
RTX and/or CYC with any dose of corticosteroids[1]	26.0%
RTX and/or CYC without any corticosteroids[1]	7.8%
Other IS[3] plus corticosteroid dose of >20 mg prednisone equivalents[1]	1.6%
Other IS[3] alone or with corticosteroid dose of <=20 mg prednisone equivalents[2]	10.7%
Corticosteroids alone at >10 mg/day prednisone equivalents[2]	54.0%

[1]Regimen with Stronger Indication for PJP Prophylaxis; [2]Regimen with Weaker Indication for PJP Prophylaxis. [3]Other IS=methotrexate, azathioprine, mycophenolate, leflunomide, mepolizumab, reslizumab, benralizumab, or dupilumab. RTX=rituximab; CYC= cyclophosphamide.

for prophylaxis more often involved any prophylaxis (29% vs. 16%) and PJP prophylaxis (26% vs. 11%), but less often involved other antibacterials (5.5% vs. 7.4%). The cumulative incidence of antimicrobial discontinuation was 51.3% (95% CI=49.1, 53.7) at 180 days after IS initiation and 65.1% (95% CI=62.6-67.5) at 360 days, and was higher for regimens with a weaker indication for prophylaxis (360-day RD=5.6%, 95% CI=0.9-9.9; Figure 1).

Table 2. Use of antimicrobial prophylaxis in the 30 days following the start of a new immunosuppressant treatment episode.

	Full Sample (n=14,798)	Regimen with Stronger Indication for PJP Prophylaxis (n=5,228)	Regimen with Weaker Indication for PJP Prophylaxis (n=9,570)
	%	%	%
Receipt of any type of prophylaxis	20.7%	29.0%	16.1%
Type of Prophylaxis Received			
PJP Prevention	16.3%	26.4%	10.8%
Trimethoprim-sulfamethoxazole (TMP/SMX)	14.3%	22.7%	9.8%
Atovaquone, dapsone, or inhaled pentamidine	2.2%	4.1%	1.1%
Other Antibacterials	6.7%	5.5%	7.4%
Fluoroquinolones	3.5%	2.5%	4.0%
Azithromycin	2.3%	1.8%	2.5%
Doxycycline	2.1%	1.6%	2.3%
Antifungal	1.5%	1.1%	1.7%
Number of Antimicrobial Classes Used			
1 classes	16.4%	25.0%	11.7%
2 or more classes	4.3%	4.0%	4.4%



Follow-up time	IS Regimen: Indication for PJP Prophylaxis	Discontinuation: Risk % (95% CI)	Risk Difference % (95% CI)
180 days	Stronger	45.4 (42.2, 48.7)	–
	Weaker	57.2 (54.2, 60.1)	11.8 (7.7, 15.7)
360 days	Stronger	62.3 (58.9, 66.1)	–
	Weaker	67.9 (64.9, 70.9)	5.6% (0.9, 9.9)

Conclusion: Despite high infection risk, most AV patients initiating IS did not receive antimicrobials for prevention of PJP or other infections and a majority discontinued within 6 months. This discordance with AV treatment guidelines highlights the need to further investigate barriers and outcomes associated with prophylaxis in this population.

Cardiovascular Risk and Fracture Risk Among Women Initiating Treatment with Romosozumab or Denosumab

Ye Liu[1], Tarun Arora[2], S. Bobo Tanner[3] and **Jeffrey Curtis**[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Foundation for Advancing Science, Technology, Education, and Research, Birmingham, AL, [3]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: Health Services Research II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Romosozumab (romo) and denosumab (dmab) are recommended for postmenopausal women with osteoporosis (OP) at high risk of fracture. The U.S. prescribing information includes a boxed warning that romo should not be initiated in patients with prior myocardial infarction or stroke in the prior year. Forall other patients without recent MI or

Figure 1. Scatter plots with 95% prediction ellipse between ACC/AHA CV risk and fracture risk for romosozumab or denosumab new users (n=1072).

A: Hip fracture

B: Major osteoporotic fracture (clinical spine, forearm, hip or shoulder fracture)

*: p<0.05 between romo and dmab users

	CV risk (%, mean±SD)*	Fracture risk (%, mean±SD)
Romo	34.4±24.4	12.0±10.0
Dmab	28.2±20.9	10.8±8.5
	Low fracture risk	**High fracture risk**
High CV risk	143 (53.4%)	125 (46.6%)
Low CV risk	666 (82.2%)	138 (17.2%)

	CV risk (%, mean±SD)*	Fracture risk (%, mean±SD)*
Romo	34.4±24.4	25.5±12.1
Dmab	28.2±20.9	23.1±10.9
	Low fracture risk	**High fracture risk**
High CV risk	153 (57.1%)	115 (42.9%)
Low CV risk	673 (83.7%)	131 (16.3%)

stroke, the warning recommends to consider whether the benefits of romo outweigh its risks. This study evaluated CV and fracture risks among patients who initiated romo referent to dmab users.

Methods: We used Medicare data from 1/1/2017 to 9/30/2021 to identify women age ≥55 newly initiating romo or dmab after 4/1/2019.Claims data was linked to electronic medical record (EMR) data from multiple PCORNet Clinical Research Networks. Comorbidities and medical history were identified from claims while biometric data and lipid test results were obtained from the EMR. The ACC/AHA pooled cohort risk equation was used to calculate the 10-year CV risk. The FRAX algorithm was used to calculate 10-year risk of hip and major fracture (clinical spine, forearm, hip, or shoulder). We set the 75 percentile of each risk score as the cut-off for high CV and fracture risk. A scatter plot with 95% prediction ellipse was used to illustrate the relationship between CV risk versus the risk of fractures (Figure 1) at a patient level and to compare the cohort of romo vs. dmab patients. Multivariable logistic regression was used to evaluate the relationship between high CV or fracture risk and medication initiation.

Results: A total of 197,515 new users of romo(n=14,596)or dmab (n=182,919) were eligible for analysis and 1072 were linked to PCORNet data. Figure 1 showed romo users had lower CV risk but comparable or higher risk for hip or major fracture compared with dmab users. Romo was more likely to be prescribed to patients with higher fracture risk but lower CV risk, compared with dmab. The odds ratios (95% CI) for initiating romo vs. dmab for high CV risk, hip fracture risk, and major fracture risk were 0.46 (0.26, 0.80), 0.97 (0.47, 2.01), and 1.83 (0.89, 3.75), respectively.

Conclusion: In this cohort of older women with claims data linked to EHR data, patients with high CV risk were less likely to be given romo compared with dmab. These data suggest that the boxed warning regarding CV risk for romo appropriately influences clinical decision making of physicians when prescribing anabolic medications for osteoporosis patients.

Maxillofacial MRI Augments Detection of Non-CNS Abnormalities in Pediatric Craniofacial Scleroderma

Daniel Glaser[1], Amy Metry[2], Elena DeRosas[2], Subramanian Subramanian[2] and Kathryn Torok[3], [1]Yale University School of Medicine, New Haven, CT, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh, University of Pittsburgh Medical Center, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical II: Connective Tissue Disease

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Craniofacial scleroderma is a rare subtype of linear scleroderma affecting the head and neck. Up to 40% of patients experience extracutaneous manifestations (ECMs), but radiographic characterization of non-CNS involvement is not well described. Existing clinical assessment rubrics prioritize cutaneous changes, likely underestimating the extent of disease-related manifestations. We sought to categorize and quantify the incidence of non-CNS ECMs detected

on maxillofacial MRI in a prospective cohort of patients with craniofacial scleroderma. We hypothesize that maxillofacial MRI would identify facial involvement beyond standard clinical examination.

Methods: We performed retrospective review of 120 patients with Craniofacial Scleroderma enrolled in the prospective National Registry of Childhood Onset Scleroderma (IRB #19080297). Inclusion criteria included baseline maxillofacial MRI with concurrent clinical 3D image.

Laterality of visible facial involvement (left, right, midline) and superior to inferior facial lesion distribution (top, middle, bottom thirds) were recorded from review of 3-dimensional digital facial images. Top third was defined as the area between horizontal lines drawn through trichion and glabella, middle third between glabella and subnasale, and bottom third between subnasale and mention. Evaluation of bone, soft tissue, fat, glands, and muscles were categorized as atrophy, edema, or abnormal enhancement.

	Right		**Left**		**Bilateral**	
Clinical Sidedness	14	38%	22	59%	1	3%
Radiographic Sidedness	14	38%	14	38%	9	24%

Results: Thirty-seven patients met imaging criteria for inclusion, (age range 4-20 years, median age 10.5 years) (Table 1). Overall, structural abnormalities were frequently detected on maxillofacial MRI (bone=49%, soft tissue=73%, adipose=57%, gland=57% and muscle=74%) (Table 2). Atrophy was the most common finding, particularly in the skin/subcutis (75%) and adipose tissues (57%). Enhancement was frequently observed in glandular tissues (parotid 36%, lacrimal 29%) as well as in the muscles of facial expression. MRI demonstrated increased frequency of bilateral involvement compared to clinical assessment (24% vs 3%). Radiographic changes were more frequently seen compared to clinical abnormalities in the upper-third (84% vs 76%) and lower-third (78% vs 65%) (Table 3). Frequencies of radiographic abnormalities differed across facial thirds, with soft tissue changes most frequent in the upper third (70%), muscle changes in the middle third (49%), and glandular changes in the lower third (51%).

Conclusion: Our study demonstrated an overall high incidence of facial bone, soft tissue, glandular, and muscle involvement in craniofacial scleroderma. Clinical examination and radiographic review frequently demonstrated discordant results. Therefore, we recommended baseline maxillofacial MRI in addition to brain MRI to better delineate the full extent of disease involvement in craniofacial scleroderma patients. Future work should assess evolution of these findings over time, response to immunomodulatory treatment, and development of multi-modal assessment rubrics.

Myositis-associated Autoantibodies in Juvenile Myositis Are Associated with Severe Disease Features and Mortality

Matthew Sherman[1], Payam Noroozi Farhad[2], Katherine Pak[3], Iago Pinal-Fernandez[3], Kakali Sarkar[2], Megan Neely[4], Ira Targoff[5], Frederick Miller[6], Andrew Mammen[7] and Lisa Rider[8], [1]NIAMS/NIH, Washington, DC, [2]Environmental Autoimmunity Group, National Institute of Environmental Health Sciences, National Institutes of Health, Bethesda, MD, [3]National Institutes of Health, Bethesda, MD, [4]Department of Biostatistics and Bioinformatics, Duke University, Durham, NC, [5]Veterans Affairs Medical Center, University of Oklahoma Health Sciences Center, and Oklahoma Medical Research Foundation, Oklahoma City, OK, [6]NIH, NIEHS, Chapel Hill, NC, [7]NIH, Bethesda, MD, [8]NIEHS, NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical II: Connective Tissue Disease

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Myositis-associated autoantibodies (MAAs), such as anti-Ro52 autoantibodies (Abs), have been found to be associated with interstitial lung disease (ILD) and worse prognosis in the idiopathic inflammatory myopathies. MAAs remain largely uncharacterized in juvenile-onset myositis. Moreover, MAAs often co-exist and it is unknown whether the number of MAA specificities may be associated with increased disease severity.

Methods: Patients with juvenile myositis enrolled in cross-sectional NIH myositis natural history studies who underwent testing for myositis Abs were included. Demographics, clinical manifestations, treatments, and outcomes of those with and without MAAs were compared using Chi-squared, Fisher's exact test, or Wilcoxon rank-sum test. Multivariable logistic regression with adjustment for year of diagnosis and myositis autoantibodies was performed for statistically significant variables from the univariable analyses. Multivariable logistic regression was also used to determine whether the number of MAA specificities is predictive of severe disease features. A two-sided $p< 0.05$ was considered significant.

Results: MAAs were present in 36% of this North American cohort of 551 juvenile myositis patients and were found across serologic subgroups (**Figure 1**). Among patients with any MAA, there was a higher frequency of juvenile connective tissue myositis (JCTM) (18% vs 5.9%, $p< 0.001$) and lower frequency of juvenile dermatomyositis (JDM) (74% vs 88%, $p< 0.001$) (**Table 1**). Anti-synthetase Abs (9.1% vs 1.7%, $p< 0.001$) were more frequent and anti-NXP2 Abs (18% vs

TABLE 1: Demographics and clinicoserologic subgroups among juvenile myositis patients with and without myositis-associated autoantibodies. Abbreviations: JCTM, juvenile connective tissue myositis; JDM, juvenile dermatomyositis; JPM, juvenile polymyositis; MAA, myositis-associated autoantibody; MSA, myositis-specific autoantibody; SjS, Sjogren's syndrome; SLE, systemic lupus erythematosus; SSc, systemic sclerosis.

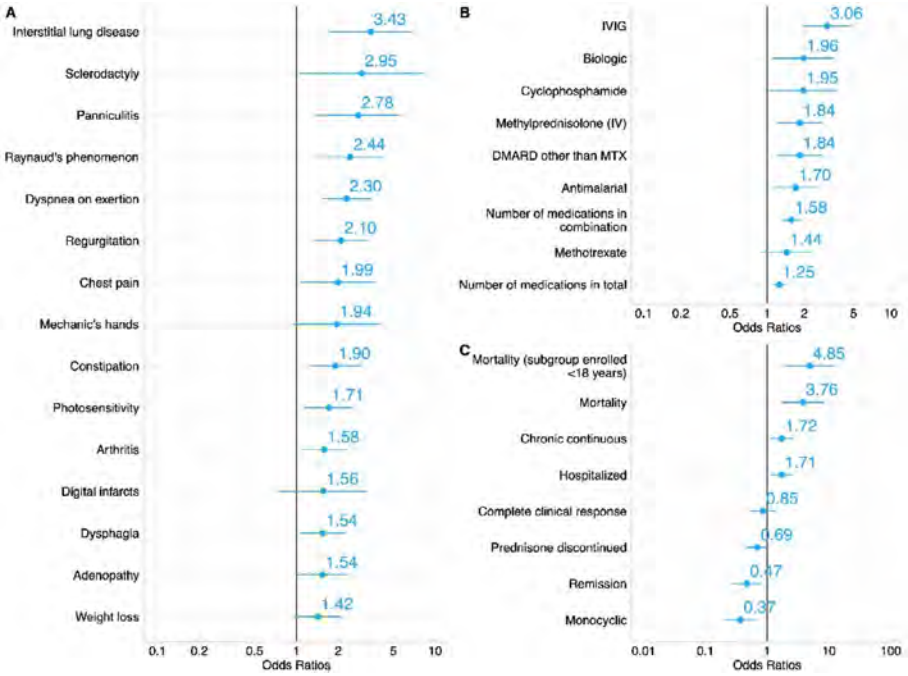

FIGURE 2: Disease features (A), medications received (B), and outcomes (C) among juvenile myositis patients with and without myositis-associated autoantibodies. Abbreviations: DMARD, disease-modifying antirheumatic drug; IV, intravenous; IVIG, intravenous immunoglobulin; MTX, methotrexate.

34%, p< 0.001) less frequent among those with an MAA. The presence of an MAA was associated with certain clinical manifestations, such as ILD (OR 3.43; 95% CI 1.75-6.96), Raynaud's phenomenon (OR 2.44; 95% CI 1.41-4.28), and arthritis (OR 1.58; 95% CI 1.07-2.34) (**Figure 2**). The presence of any MAA was associated with increased treatment burden, including a greater odds of receiving IVIG (OR 3.06; 95% CI 1.98-4.76), IV methylprednisolone (OR 1.84; 95% CI 1.21-2.83), and a greater number of major medications in combination (OR 1.58; 95% CI 1.33-1.88). Positivity for any MAA was also associated with worse outcomes, including higher odds of mortality (OR 3.76; 95% CI 1.72-8.43) and a chronic continuous disease course (OR 1.72; 95% CI 1.10-2.72) and lower odds of a monocyclic disease course (OR 0.37; 95% CI 0.19-0.67) and achievement of remission (OR 0.47; 95% CI 0.26-0.82). Moreover, the number of MAA specificities was predictive of mortality (OR 1.83; 95% CI 1.16-2.86).

Conclusion: MAAs were prevalent in this large cohort of patients with juvenile myositis and were associated with severe disease features, more refractory disease, and mortality. Future prospective studies are needed to determine whether early detection of MAAs may improve outcomes for patients with juvenile myositis.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical II: Connective Tissue Disease

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is an orphan disease with a prevalence of 3 in 1,000,000 children. In adult patients there are significant differences between clinical presentation of cutaneous diffuse (djSSc) and cutaneous limited phenotypes(ljSSc).

Methods: We reviewed the baseline clinical characteristics of the patients, who were recruited to the jSScC prior to April 2023. jSScC is a prospective cohort of jSSc patients, who developed the first non-Raynaud´s symptom before the age of 16 years and were under the age of 18 years at the time of inclusion.

Results: The jSScC included 238 patients, 69% (n=164) had cutaneous diffuse subtype. The median age at onset of Raynaud's phenomenon was 10.4 years (7.3-12.9) and the median age at the first non-Raynaud's symptom was 10.9 years (7.3-13.0). Median disease duration was 2.5 years (1.0-4.7). The female/male ratio was not significantly lower in the djSSc subtype (3.3:1 versus 4.7:1, p=0.611). Antibody profile was similar, with the exception of a significantly higher number of anticentromere positive patients in the ljSSc (10% versus 2%, p=0.019). Patients with djSSc had significantly higher modified Rodnan Skin Score (17 versus 4, p=0.011), more frequently sclerodactyly (85% versus 56%, p< 0.001), Gottron

Table 1. Characteristics of patients with diffuse and limited subtype

Comparison diff/lim at time of inclusion in the cohort	Whole Group N=238	Diffuse Subtype N=164	Limited Subtype N=74	P value
Female to Male Ratio	3.7:1 (187/51)	3.3:1 (122/37)	4.7:1 (61/13)	0.611
Cutaneous subtype				
Diffuse subtype	69% (164)	164	0	
Limited subtype	31% (74)	0	74	
Median Disease duration (years), IQR	2.5 (1 – 4.7)	2.6 (1.3 – 4.7)	2.0 (0.6 – 4.5)	0.831
Median age at onset of Raynaud's (years), IQR	10.4 (7.3 – 13.0)	10.1 (7.5 – 12.5)	11.8 (7 – 13.7)	0.617
Median age at onset of non-Raynaud's (years), IQR	10.9 (7.4 – 13.4)	10.5 (7.4 – 12.5)	12.0 (7.3 – 14.4)	0.397
Autoantibody positivity:				
ANA	92% (209/227)	92% (144/156)	93% (64/69)	0.907
Anti-scl 70	33% (74/225)	37% (57/155)	26% (17/66)	0.112
Anti-centromere	5% (8/164)	2% (2/110)	10% (5/50)	0.019
Anti-PMScl	18% (18/101)	14% (9/63)	24% (9/37)	0.207
Cutaneous:				
MRSS, median (IQR)	10 (4 – 20)	17 (8 - 27)	4 (0 – 8)	0.011
Gottron Papules	26% (61/234)	31% (50/160)	15% (11/74)	0.008
Sclerodactylie	76% (170/225)	85% (131/155)	56% (39/70)	<0.001
Vascular:				
Telangiectasia	37% (80/215)	45% (65/146)	22% (15/69)	0.001
History of ulceration	51% (121/235)	61% (100/163)	29% (21/72)	<0.001
Active ulceration	17% (39/235)	20% (33/163)	8% (6/72)	0.024
Cardiac Involvement:				
Only Cardiac Involvement	5% (12/238)	2% (4/164)	11% (8/74)	0.006
Gastrointestinal Involvement:				
BMI ≤ - 2 z score	15% (33/220)	19% (29/151)	6% (4/69)	0.010
Musculoskeletal:				
Presence of joints with decreased range	59% (139/237)	64% (104/163)	47% (35/74)	0.017
Patient Reported Outcomes				
Patient global disease activity	40 (20 – 50) n=184	40 (20 – 50) n=134	30 (15 – 54) n=50	0.041
Patient global disease damage	30 (13 – 55) n=183	40 (20 – 60) n=133	25 (6 – 54) n=50	0.001
Patient Raynaud activity	30 (10 – 60) n=208	30 (10 – 60) n=150	18 (0 – 54) n=58	0.025
Physician Reported outcomes				
Physician global disease activity	30 (20 – 45) n=202	35 (20– 50) n=143	20 (10 – 30) n=59	0.034
Physician global disease damage	28 (15 – 40) n=200	30 (20 – 45) n=143	20 (5 – 30) n=57	0.011

papules (31% versus 15%, p=0.008), a history of digital ulceration (61% versus 29%, p< 0.001), active ulceration (20% versus 8%, p=0.024),telangiectasia (45% versus 22%, p=0.001), a decreased Body Mass Index (BMI) z score ≤ -2 (19% versus 6%, p=0.010) and decreased joint range of motion (64% versus 47%, p=0.017). Patients with ljSSc had significantly higher rate of cardiac involvement (11% versus 2%, p=0.006). There was no difference between the groups regarding sicca symptoms, pulmonary involvement assessed by FVC, DLCO and high resolution lung CT; renal involvement; gastrointestinal involvement beside decreased BMI < -2 z score; and muscle weakness.

Regarding patient related outcomes assessed by visual analogue scales (VAS0 to 100), djSSc patients had more severe disease related to patient reported global disease activity (40 versus 30, p=0.041), patient reported global disease damage (40 versus 25, p=0.001), and patient reported Raynaud activity by(30 versus 18, p=0.025). Additionally, physician related outcomes assessed by visual analogue scales (VAS), the physician reported global disease activity (35 versus 20, p=0.034), and physician reported global disease damage (30 versus 20, p=0.011), were significantly higher in djSSc patients.

Conclusion: In the largest jSSc cohort in the world, djSSc patients have significantly more severe disease according to patient and physician related outcomes than ljSSc patients. Patients with djSSc also had more cutaneous, vascular, and musculoskeletal involvements and patients with ljSSc had more cardiac involvement. Interestingly, we found no significant differences regarding interstitial lung disease, pulmonary hypertension or gastrointestinal involvement, although the number of patients with decreased BMI ≤-2 z score was significantly higher in the djSSc patients.

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical II: Connective Tissue Disease

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Social determinants of health (SDoH) contribute to disparate outcomes in both adult and pediatric systemic lupus erythematosus (pSLE), including length of hospitalization, mortality, and risk of severe sequelae, such as renal damage. Differential disease control may drive racial and ethnic disparities in disease damage and mortality. Therefore, we sought to determine how race associates with achievement of low lupus disease activity state (LLDAS), a clinically relevant disease activity target associated with higher health-related quality of life and less disease damage. We hypothesized that minoritized race would associate with lower rates of achieving LLDAS in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry cohort of children with pSLE.

Table 1: Demographic and clinical characteristics of children with pSLE in the CARRA Registry (between March 2017-December 2021)

[1] Area Deprivation Index (ADI) is a national measure of neighborhood socioeconomic disadvantage at the level of census block group, developed by U.S. Census data including American Community Survey (ACS) data. Higher scores suggest more disadvantaged areas.
[2] Adjunctive DMARDs include azathioprine, methotrexate, mycophenolate mofetil, leflunomide, and tacrolimus.
[3] Conventional DMARDs include antimalarials, azathioprine, methotrexate, mycophenolate mofetil, leflunomide, and tacrolimus.
[4] Cyclophosphamide (CYC).
[5] Total 2048 encounters where LLDAS was assessed across all subjects. See Table 2 for more.

‡ All univariate models include time.
* Adjusted for age at enrollment, sex, major organ involvement, medication type, disease duration at enrollment, and presence of any secondary rheumatologic disease

Methods: This was a cohort study of children with pSLE enrolled in the CARRA Registry between March 2017-December 2021 with baseline and at least one follow-up visit and a valid U.S. zip code. The primary exposure was self-identified race or ethnicity. SDoH of interest were insurance status and area deprivation index (ADI). The primary outcomes were 1) LLDAS and 2) occurrence of prednisone restarts or dose escalation between visits. Associations between race and/or ethnicity and the outcomes were examined using univariate and multivariable logistic regression models, adjusted for covariates (insurance status, ADI, age at enrollment, sex, major organ involvement, medication use, disease duration at enrollment, and secondary rheumatologic disease). Random effect was included in the LLDAS model to account for repeated measures.

Results: A racially diverse cohort of 540 children with pSLE self-identified as 27% Black, 23% Latino/a, 25% White, 11% Asian, 5% Other, and 9% more than one race. 87% were female with a median age of 14.2 years at diagnosis (IQR 3.2-19.0). 48% were privately insured and 46% publicly insured. Black participants were more likely to be publicly insured, live in areas with higher social deprivation (ADI), and have renal disease (Table 1). In both unadjusted and adjusted analyses, Black race and more than one race were significantly associated with lower odds of achieving LLDAS (Table 2: adjusted OR 0.56, 95% CI: 0.38-0.82; OR 0.51, 95% CI: 0.31-0.86, respectively). In unadjusted analyses, Black race also associated with higher odds of prednisone dose increases or restarts. The adjusted estimate was similar, though not statistically significant at the 0.05 level (Table 3: OR: 1.7, 95% CI: 0.99-3.1, p=0.055).

Conclusion: Children with pSLE in the CARRA Registry identifying as Black or more than one race had significantly lower odds of achieving LLDAS. Black participants were more likely to be publicly insured and live in areas of higher social deprivation. Black race remained strongly associated with lower achievement of LLDAS despite adjustment for SDoH and disease characteristics. This suggests there are unmeasured factors driving the disparities, which may include other influences of structural racism, such as the experience of racial discrimination. Strategies to address these root causes will be important components of treat-to-target interventions designed to mitigate racial disparities in achievement of LLDAS.

Identifying Potential Neuroimaging Biomarkers of Neuropsychiatric Lupus in Children Using Deep Learning

santiago arciniegas[1], Matthias W. Wagner[2], Logi Vidarsson[2], Birgit Ertl-Wagner[2], Tala El Tal[3], Asha Jeyanathan[2], Lawrence Ng[2], Linda Hiraki[2], Deborah Levy[2], George M. Ibrahim[2] and Andrea Knight[2], [1]University of Toronto, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada, [3]Children's Hospital of Eastern Ontario (CHEO), Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: Pediatric Rheumatology – Clinical II: Connective Tissue Disease
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, multisystem, autoimmune disease. Childhood-onset SLE (cSLE) is characterised by a higher frequency of nervous system involvement, known as neuropsychiatric SLE (NPSLE). Biomarkers for NPSLE are lacking, posing challenges for clinical diagnosis and management. The existence of neuropsychiatric manifestations in patients without a definite NPSLE diagnosis, as well as normal conventional magnetic

resonance imaging (MRI) findings in patients with NPSLE, allude to suboptimal diagnostic protocols. To identify potential biomarkers of NPSLE, we aimed to develop a deep learning model capable of identifying structural brain image features of patients with cSLE.

Methods: This retrospective study involved a binary classification task between cSLE and non-cSLE patients. Searching all clinically-obtained brain MRIs for cSLE patients from 2000-2021, we retrieved 233 T1-weighted images of sufficient quality for analysis. We then matched these images by age and sex to an existing set of T1-weighted images (n=233) from non-cSLE patients with clinical MRIs (primarily for indication of headache; normal conventional read), obtained from 2000-2020. A chart review was conducted to extract clinical data for cSLE patients, including history of NPSLE diagnosis and SLEDAI scores. Deep learning models consisted of a 3D image feature extractor and a linear prediction layer. The data was split into 70% for training, 15% for validation, and 15% for testing. Learning was performed on the training set. We used classification performance, measured via the ROC AUC score, on the validation set to find the best model configuration.

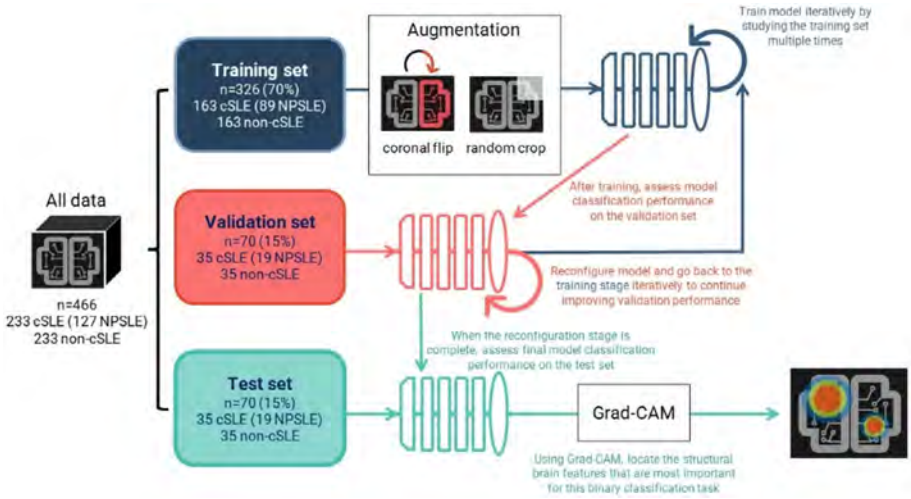

Figure 1. Methods summary for model training, configuration, evaluation, and interpretation. Grad-CAM stands for Gradient-weighted Class Activation Maps, a technique commonly used to interpret computer vision models.

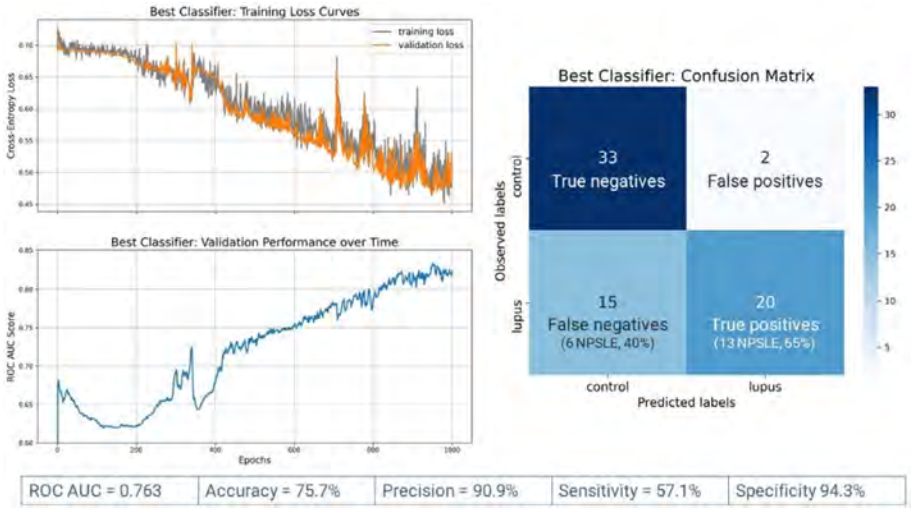

Figure 2. Learning behaviour and final classification performance of the best model. The left panel illustrates normal learning behaviour through decreasing loss curves and increasing performance over time. The right panel contains a confusion matrix illustrating the classification performance of the model on a held-out test set at an optimal classification threshold of 0.60. The bottom table summarises final model performance through 5 different classification metrics.

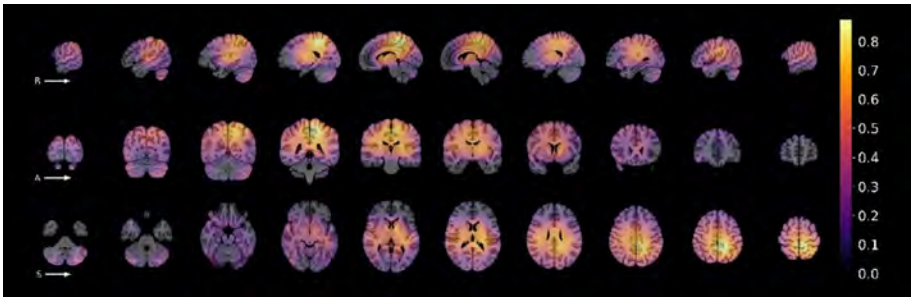

Figure 3. A standard MNI brain overlaid with the average class activation map for the correctly classified cSLE test samples (n=20). Yellow and orange colours highlight image features of the brain that were consistently used to correctly classify samples as cSLE. The top row shows sagittal slices (left -> right); middle row shows coronal slices (anterior -> posterior), and bottom row shows axial slices (inferior -> superior).

Using the test set and the best model configuration, we assessed final model performance (Fig. 1). Interpretability analyses allowed for the identification of brain image features that were most informative for this binary classification task.

Results: Of all 233 cSLE images (133 patients), 127 (55%) were obtained from 57 patients with NPSLE. Most cSLE patients had mild/moderate disease activity at the time of scan (SLEDAI < = 10, n=153, 69.96%). When distinguishing cSLE vs non-cSLE, we achieved acceptable final classification performance with ROC AUC score = 0.763. From the 70 test samples (35 cSLE, 35 control), 20/35 of cSLE were correctly classified (true positives) (Fig. 2). The proportion of NPSLE samples in the true positives was 65%, and that in the false negatives, 40%. The difference between these proportions was not significant (z-score=1.47, p=0.07). The most important brain image features for this classification task were found in intra-ventricular, peri-ventricular, and left medial parietal regions.

Conclusion: The resulting model was effective in capturing structural brain MRI features distinguishing cSLE, with and without NPSLE, from non-cSLE patients. Our findings suggest the presence of regional brain abnormalities in cSLE patients without an NPSLE diagnosis. This model may serve as a novel diagnostic tool prototype, and as a hypothesis generating tool in future NPSLE biomarker research. Further study is needed to characterise brain image features for each type of NP manifestation observed in cSLE.

Session Title: Abstracts: Pediatric Rheumatology – Clinical II: Connective Tissue Disease

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Childhood polyarteritis nodosa (PAN) is a systemic vasculitis with necrotizing inflammation that typically affects small and medium-sized arteries. The clinical presentation is variable; it can either be cutaneous or systemic and can present with mild predominantly skin disease versus severe disease with multi-organ involvement. Since it is rare in children, the data are limited. The aims of this study are to characterize the clinical presentation, disease course and outcomes in childhood polyarthritis nodosa in an international cohort.

Table 1. Presenting clinical features in the 55 patients with PAN

Presenting features	No. (%) of patients (n= 55)
Mucocutaneous involvement	47 (85)
Livedo Reticularis	21 (38)
Polymorphous exanthema	7 (13)
Panniculitis	10 (18)
Purpura	23 (42)
Skin nodules	32 (58)
Nail edge lesion	0 (0)
Splinter hemorrhage	6 (11)
Skin ulcers	3 (5.5)
Gangrene	2 (3.6)
Skin vasculitis	0 (0)
Mouth ulcers/ granulomata	7 (13)
Genital ulcers	0 (0)
Constitutional	39 (71)
Arthralgia	34 (62)
Fever	22 (40)
Weight loss > 5% of body weight	21 (38)
Myalgia	19 (35)
Renal involvement	16 (29)
Proteinuria (>0.3 g/24h)	4 (7.3)
>20mg/mmol Creatinine	6 (11)
Haematuria >= 2+ or 5 RBC/HPF or Red cells casts	8 (15)
GFR 50-80ml/min/1.73 m2	3 (5.5)
GFR 15-49 ml/min/1.73 m2	0 (0)
GFR < 15 ml/min/1.73m2	1 (1.8)
Rise in creatinine > 10% or Creatinine Clearance (GFR) fall > 25%	1 (1.8)
Neurological involvement	15 (27.3)
Headache	9 (16)
Meningitis/ encephalitis	0 (0)
Organic confusion/cognitive dysfunction	0 (0)
Seizures	1 (1.8)
Stroke	4 (7.3)
Cord lesion	0 (0)
Cranial nerve palsy	1 (1.8)
Sensory peripheral neuropathy	2 (3.6)
Motor mononeuritis multiplex	3 (5.5)
Gastrointestinal involvement	15 (27.3)
Abdominal pain	18 (33)
Peritonitis	0 (0)
Bloody diarrhea or blood in stools	0 (0)
Bowel ischemia	4 (73)
ENT involvement	5 (9)
Cardiac involvement	3 (5.5)
Pulmonary involvement	1 (1.8)

Methods: A multicenter ambispective study was conducted of children diagnosed with polyarteritis nodosa (PAN) using data collected in PedVas. PedVas is a multi-center, international study that is currently collecting clinical and biological data from children with chronic vasculitis. Eligible patients had an MD diagnosis of PAN and were < 18 years of age at time of diagnosis (TOD). Both systemic and cutaneous PAN subtypes were included. The primary outcome was the rate of inactive disease (Pediatric Vasculitis Activity Score [PVAS] of < =1) at 12 months. Secondary outcomes included rates of inactive disease at post induction (4–6 months after diagnosis), improvement rate in the PVAS at post induction (defined as a 50% reduction in PVAS), presence of damage at 12 months (measured by the Pediatric Vasculitis Damage Index [PVDI]) and relapse rates post induction.

Results: 55 children with PAN were included in the study; 19 were male, and the median age was 11 years (IQR 7-14.5). 25 of these patients were diagnosed as cutaneous PAN. 18 (33%) were Caucasian, 11 (20%) were East Asian, and 8 (14.5%) were South Asian. The most common presenting features were: mucocutaneous disease (85%), constitutional symptoms (71%), renal involvement (29%), gastrointestinal involvement (27.3%) and neurological involvement (27.3%). See Table 1. Corticosteroids were used in (80%) and cyclophosphamide in (26%). Other less frequently used agents included IVIG, methotrexate, azathioprine, other DMARDs, and biologic agents. An improvement in the PVAS score of more than 50% from TOD to post induction was seen in 79% of systemic PAN patients, and in 72% of cutaneous PAN. Rates of inactive disease at post induction and at 12 months in cutaneous PAN were 72%, and 74% respectively, and in systemic PAN were 63% and 67%, respectively. Relapses occurred in 2 (5%) of 39 patients after inactive disease had been achieved post-induction. 40 patients had completed PVDI scores at 12-months. The median PVDI score at 12 months was 0 in both cutaneous and systemic subgroups. 26 out of 40 patients (65%) had a PVDI score of 0, 14 (35%) had a PVDI score of 1 or more. There were no deaths.

Conclusion: This study describes the clinical course and outcomes of one of the largest cohorts of childhood PAN to date. The results show that the majority of patients have a reduction in disease activity by post-induction, and at least two-thirds of patients achieved inactive disease by 12-months. Disease relapse was rare in our cohort; however, one-third of patients have evidence of damage at 12-months. Further studies to evaluate predictors of treatment response and damage will help inform prognosis and guide treatment.

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Comorbidities
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) experience higher cardiovascular risk compared to non-inflammatory disease controls. Methotrexate (MTX) may decrease cardiovascular risk in patients with RA. It is, however, unclear whether sex differentially impacts cardiovascular risk in MTX users and non-users and whether men and women derive equal benefit from methotrexate use. We here explored the influence of sex on cardiovascular risk in MTX nonusers and users. We further evaluated the effect of MTX treatment on cardiovascular risk in males and females with RA.

Methods: We evaluated 4362 patients and no cardiovascular disease prospectively included in an observational cohort [*A*n I*nternationa*l *C*ardiovascular *C*onsortium for people with *RA* (ATACC-RA)]. Outcomes were (a) major adverse cardiovascular events (MACE) defined as cardiovascular death, non-fatal myocardial infarction or stroke and (b) any ischemic cardiovascular events (CVE) including MACE, stable angina, coronary revascularization, transient ischemic attack and peripheral arterial disease with or without revascularization. Missing data were imputed using multiple imputation with 10 repetitions. Multivariable Cox models stratified by center evaluated the impact of sex, baseline MTX use and their interaction on event risk after adjusting for age, hypertension, diabetes, family history, smoking, total cholesterol to high-density lipoprotein cholesterol ratio, disease duration, and activity score (DAS28 ESR). Two sensitivity analyses were conducted; The first used inverse probability of treatment weights to balance differences in MTX treated and untreated patients. The second included patients enrolled in the cohort on or after January 1, 2000, when MTX use became more prevalent.

Figure 1 Impact of sex in methotrexate nonusers and users and effect of methotrexate treatment for females and males

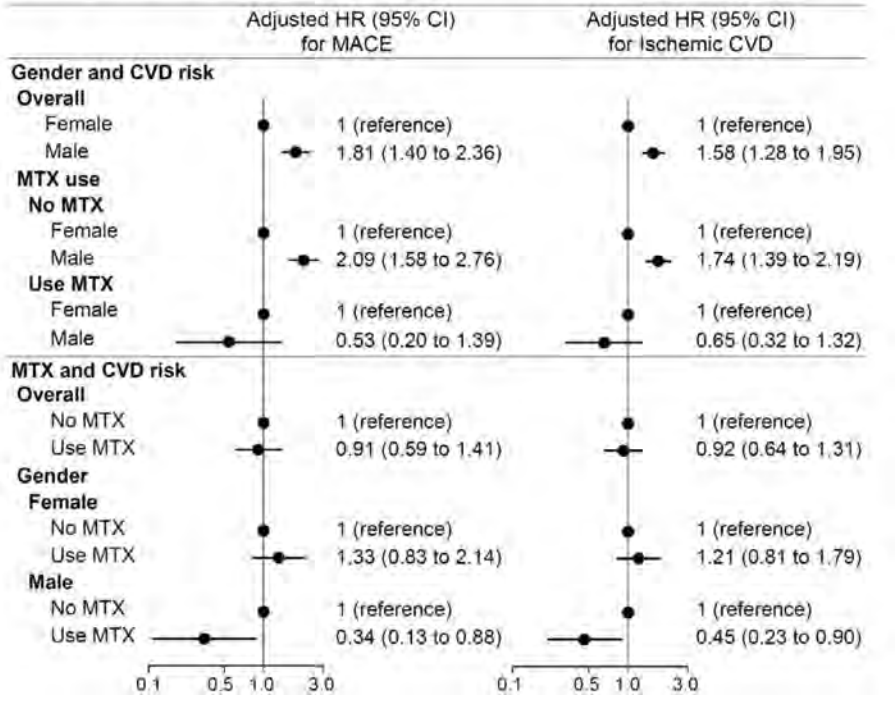

Figure 2 Risk of (A) MACE or (B) any ischemic cardiovascular event in males and females who use or do not use methotrexate

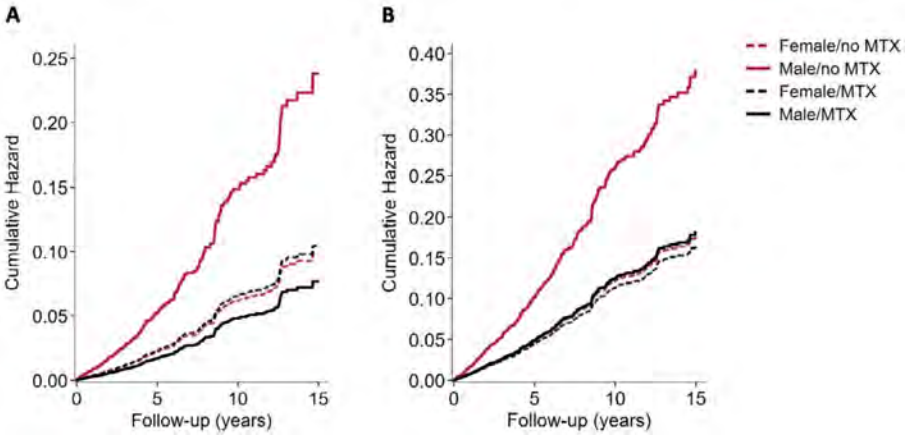

Results: There were 237 first MACE and 358 total ischemic CVE during follow-up. Male sex associated with an 81% and 58% greater risk of MACE and any ischemic CVE respectively (Figure 1). Among MTX nonusers, incidence of MACE and any ischemic CVE was higher in males [17.6 (95% CI 14.4-21.3) and 24.5 (20.7-28.9) events/1000PY] compared to females [6.9 (5.7-8.4) and 11.4 (9.8-13.3) events/1000PY, all p for difference < 0.001]. In adjusted Cox models, male nonusers had a 2.09-fold and 74% higher risk of MACE and any ischemic CVE compared to female nonusers (both p< 0.001, Figures 1 and 2). In contrast, among users, incidence of MACE and any ischemic CVE was not different in males [4.2 (1.7-10.0) and 7.6 (4.0-14.6) events/1000PY] versus females [6.4 (4.4-9.2) and 9.4 (6.9-12.8) events/1000PY] and sex was not associated with event risk in MTX users. Among males, MTX use associated with a 66% and 55% lower risk of MACE and any ischemic CVE (p=0.026 and 0.024). In contrast, MTX use was not associated with MACE or any ischemic CVE in females [adjusted HR 1.33 (0.83-2.14) and 1.21 (0.81-1.79)]. Both sensitivity analyses yielded similar results.

Conclusion: RA males not using MTX exhibit higher risk of MACE and any ischemic CVE compared to female nonusers, while no differences were observed between male and female users. Baseline MTX use associated with lower risk of MACE and all ischemic CVE in males but not females.

Abstract Number: 1628

The Impact of Cardiovascular and Cerebrovascular Disease on the Risk of Dementia in Rheumatoid Arthritis. a Mediation Analysis

Edward Lovering[1], Chanakya Kodishala[2], Rakesh Kumar[1], Cynthia Crowson[1], Ryan Lennon[1], John Davis[1] and Elena Myasoedova[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester Minnesota, Rochester, MN

SESSION INFORMATION

Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Comorbidities
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Alzheimer's disease and related dementias have an immense disease burden, with predicted continuous increase in incidence and prevalence. Systemic inflammation plays a major role in dementia, as well as in cardiovascular and cerebrovascular disease (CVD). Both RA and CVD have been reported to independently increase the risk of dementia, but little is known on the interplay between them on cognitive decline.

Methods: In this retrospective population-based study, patients with incident RA after age 50 who met 1987 classification criteria between 1980-2014, with no previous diagnosis of dementia prior to index date were included. RA cases were matched 1:1 with non-RA controls on age, sex and calendar year of index.

Data on CVD risk factors (i.e., hypertension, diabetes mellitus, hyperlipidemia, body mass index [BMI]) and CVD were abstracted from the medical records at baseline and throughout the follow-up. CVD was defined as coronary heart disease (including angina pectoris, coronary artery disease, myocardial infarction, coronary revascularization procedures), heart failure, cerebrovascular accident or transient ischemic attack. Dementia was defined as two relevant ICD-9/ICD-10 codes at least 30 days apart. Mediation analysis was carried out with RA as the exposure, CVD as a mediator, and dementia as the outcome. Models for both baseline mediation and time-dependent mediation were constructed.

Cox proportional-hazards models were used to estimate the adjusted hazard ratio (aHR) between RA and CVD along with the direct association between RA and dementia, with age, sex, education, hypertension, hyperlipidemia, and diabetes as covariates.

Results: 1,754 patients were included (877 RA cases and 877 non-RA controls). Mean age at index date was 64.7 years, with 65% females in both groups. At baseline, hypertension, hyperlipidemia, and diabetes were more prevalent in the RA cohort, with mean BMI similar in both cohorts. Prevalence of any CVD at baseline was not significantly different between the two groups (20.3% in RA vs 21.4% in non-RA, p=0.56). Mediation analysis with CVD at baseline as the mediator showed no significant mediated effect between the two cohorts.

During follow-up, 139 patients with RA and 125 individuals without RA developed dementia and 444 and 375, respectively, had any CVD. There was a significant association between RA and dementia both without (aHR 1.35, 95% CI 1.05-1.75) and with (aHR 1.33, 95% CI 1.04-1.72) CVD as a time-dependent mediator. There was a significant association between CVD on follow-up (aHR 2.02, 95% CI 1.53-2.67) with dementia risk. Yet, the mediation effect of any CVD on dementia was non-significant (p=0.69). There was a significant interaction between RA and CVD during the follow-up on dementia (aHR 1.89, 95% CI 1.12, 3.21; p=0.017).

Conclusion: Patients with RA are at a 35% increased risk of dementia, rising to 89% for patients who have both RA and CVD. We found no significant evidence that CVD acts as a mediator for the risk of dementia in RA. Yet, there is a significant synergistic effect of RA and CVD on dementia risk. This re-enforces the need for robust CVD prevention and dementia screening, along with optimization of disease activity in individuals with RA.

Persons with Rheumatoid Arthritis and Long COVID Had Worse Pre-COVID RA Symptoms and Worse Non-RA Symptoms, as Well as Higher Rates of Fibromyalgia Compared with COVID Infected Long COVID Negative

Kaleb Michaud[1], Sofia Pedro[2], Shreena Kamlesh Gandhi[3] and Frederick Wolfe[2], [1]University of Nebraska Medical Center, Omaha, NE, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]Kansas University School of Medicine, Wichita, KS

SESSION INFORMATION
Session Date: Monday, November 13, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Comorbidities
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Long COVID, also known as Post COVID syndrome or postacute sequelae of SARS-CoV-2 infection, refers to the development of persistent or new symptoms lasting for weeks or longer in individuals who have recovered from SARS-CoV-2 infection. Symptoms include breathlessness, cough, chest tightness, palpitations, fatigue, myalgia, and difficulty concentrating. Estimates of 30% who contracted COVID-19 may experience Long COVID and 10% remain positive after 6 months post infection. Recent studies showed increased odds of Long COVID in RA though uncertainty remains on whether this was due to a direct response to infection or the natural RA symptom course. We set out to examine if characteristics and symptoms of those receiving Long COVID diagnosis appeared before COVID infection.

Methods: Data are from the FORWARD, The National Databank for Rheumatic Diseases, through comprehensive questionnaires collected from participants with physician-diagnosed RA and self-reported COVID infections at 6-month intervals through April 2023. Study inclusion required a response to the following Long COVID item: "Have you EVER been told by a healthcare provider that you have Long COVID?" first available July 2022. Baseline was defined as the survey closest to and before initial COVID infection or initial Long COVID if no prior COVID infection was reported. Respondents provided health information including socioeconomic status, treatments, symptoms, hospitalizations, and several PROs including HAQ, Fatigue, Pain, Sleep Problem, Health Satisfaction, PHQ-8 (depressive symptoms), GAD2 (anxiety symptoms), WPI, SSS, and fibromyalgia 2016 criteria. Descriptive analyses examined PROs at baseline according to future Long COVID status. A Lasso approach was used for variable selection in a multivariate logistic model with Long COVID as the outcome (presented using OR 95%CI).

Results: There were 667 participants with RA, COVID infection, and who responded to the Long COVID item with 15% Long COVID positive. Those with Long COVID were older, less likely to be white, lower socioeconomic status, had more comorbidities, had worse RA PROs, more depression, more likely to meet fibromyalgia 2016 criteria, yet had no differences in DMARD use (Table 1). Fibromyalgia was ~3 times more common among those who would report Long COVID (13 vs 41%). Long COVID+ had more severe COVID infections with greater use of IV antibiotics (23% vs 9%) and hospitalizations for COVID (18 vs 5%). Multivariable logistic model had ten items after Lasso selection with several overlapping patient reported outcomes around pain and symptoms (Table 2).

Conclusion: Persons with RA who reported Long COVID in the past year had many symptoms of Long COVID prior to the development of a COVID infection. They had increases in many variables associated with RA severity and psychosocial distress. A Long COVID diagnosis may reflect preexisting illness, which may not be possible to separate. Our observations are limited by self-report and by not having official criteria for Long COVID diagnosis for healthcare providers. Future work will

Table 1

Table 1. RA participant characteristics and PROs at baseline, the observation before COVID infection, by future Long COVID status.

Variable	Long COVID– 85.5% (n=570)	Long COVID+ 14.5% (n=97)	p-value

Patient-Reported Fatigue Associated with Joint Histopathology in Rheumatoid Arthritis

Diyu Fisher[1], Dana Orange[2], Melanie Smith[3], Bella Mehta[4], Edoardo Spolaore[5], Edward DiCarlo[3], Dongmei Sun[3], Laura Donlin[3] and Susan Goodman[3], [1]Stony Brook Medicine, Port Jefferson Station, NY, [2]The Rockefeller University, New York, NY, [3]Hospital for Special Surgery, New York, NY, [4]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [5]HSS, New York, NY

SESSION INFORMATION

Session Date: Monday, November 13, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Comorbidities

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Fatigue or tiredness is an important symptom for patients with rheumatoid arthritis (RA), yet the factors associated with fatigue are poorly understood and may differ between patients with low vs. high disease activity. We sought to explore whether patient-reported fatigue is associated with histologic changes in the synovium in both low and high disease activity patients.

Table 1. Demographics and disease characteristics stratified by fatigue.

	Total (N=152)	Mild (N=43)	Moderate (N=60)	Severe (N=49)	p-value
Age[1]	62.70 (11.39)	65.80 [56.40, 71.50]	61.70 [53.60, 73.47]	63.50 [55.80, 68.00]	0.60
